| 2.4 Memory Model .....                                                 | 84        |
| 2.4.1 Memory Regions, Types and Attributes .....                       | 86        |
| 2.4.2 Memory System Ordering of Memory Accesses .....                  | 87        |
| 2.4.3 Behavior of Memory Accesses .....                                | 87        |
| 2.4.4 Software Ordering of Memory Accesses .....                       | 88        |
| 2.4.5 Bit-Banding .....                                                | 89        |
| 2.4.6 Data Storage .....                                               | 91        |
| 2.4.7 Synchronization Primitives .....                                 | 92        |
| 2.5 Exception Model .....                                              | 93        |
| 2.5.1 Exception States .....                                           | 94        |
| 2.5.2 Exception Types .....                                            | 94        |

|          |                                                          |            |
|----------|----------------------------------------------------------|------------|
| 2.5.3    | Exception Handlers .....                                 | 98         |
| 2.5.4    | Vector Table .....                                       | 98         |
| 2.5.5    | Exception Priorities .....                               | 99         |
| 2.5.6    | Interrupt Priority Grouping .....                        | 100        |
| 2.5.7    | Exception Entry and Return .....                         | 100        |
| 2.6      | Fault Handling .....                                     | 103        |
| 2.6.1    | Fault Types .....                                        | 104        |
| 2.6.2    | Fault Escalation and Hard Faults .....                   | 104        |
| 2.6.3    | Fault Status Registers and Fault Address Registers ..... | 105        |
| 2.6.4    | Lockup .....                                             | 105        |
| 2.7      | Power Management .....                                   | 106        |
| 2.7.1    | Entering Sleep Modes .....                               | 106        |
| 2.7.2    | Wake Up from Sleep Mode .....                            | 106        |
| 2.8      | Instruction Set Summary .....                            | 107        |
| <b>3</b> | <b>Cortex-M4 Peripherals .....</b>                       | <b>114</b> |
| 3.1      | Functional Description .....                             | 114        |
| 3.1.1    | System Timer (SysTick) .....                             | 115        |
| 3.1.2    | Nested Vectored Interrupt Controller (NVIC) .....        | 116        |
| 3.1.3    | System Control Block (SCB) .....                         | 117        |
| 3.1.4    | Memory Protection Unit (MPU) .....                       | 117        |
| 3.1.5    | Floating-Point Unit (FPU) .....                          | 122        |
| 3.2      | Register Map .....                                       | 126        |
| 3.3      | System Timer (SysTick) Register Descriptions .....       | 129        |
| 3.4      | NVIC Register Descriptions .....                         | 133        |
| 3.5      | System Control Block (SCB) Register Descriptions .....   | 148        |
| 3.6      | Memory Protection Unit (MPU) Register Descriptions ..... | 177        |
| 3.7      | Floating-Point Unit (FPU) Register Descriptions .....    | 186        |
| <b>4</b> | <b>JTAG Interface .....</b>                              | <b>192</b> |
| 4.1      | Block Diagram .....                                      | 193        |
| 4.2      | Signal Description .....                                 | 193        |
| 4.3      | Functional Description .....                             | 194        |
| 4.3.1    | JTAG Interface Pins .....                                | 194        |
| 4.3.2    | JTAG TAP Controller .....                                | 196        |
| 4.3.3    | Shift Registers .....                                    | 196        |
| 4.3.4    | Operational Considerations .....                         | 197        |

| Register 10:                | Run-Mode Clock Configuration 2 (RCC2), offset 0x070 .....                | 251 |
| Register 11:                | Main Oscillator Control (MOSCCTL), offset 0x07C .....                    | 254 |
| Register 12:                | Deep Sleep Clock Configuration (DSLPCCLKCFG), offset 0x144 .....         | 255 |
| Register 13:                | System Properties (SYSPROP), offset 0x14C .....                          | 257 |
| Register 14:                | Precision Internal Oscillator Calibration (PIOSCCAL), offset 0x150 ..... | 259 |
| Register 15:                | Precision Internal Oscillator Statistics (PIOSCCAL), offset 0x154 .....  | 261 |
| Register 16:                | PLL Frequency 0 (PLLREQ0), offset 0x160 .....                            | 262 |
| Register 17:                | PLL Frequency 1 (PLLREQ1), offset 0x164 .....                            | 263 |
| Register 18:                | PLL Status (PLLSTAT), offset 0x168 .....                                 | 264 |
| Register 19:                | Sleep Power Configuration (SLPPWRCFG), offset 0x188 .....                | 265 |
| Register 20:                | Deep-Sleep Power Configuration (DSLPPWRCFG), offset 0x18C .....          | 267 |
| Register 21:                | LDO Sleep Power Control (LDOSPCTL), offset 0x1B4 .....                   | 269 |
| Register 22:                | LDO Sleep Power Calibration (LDOSPCAL), offset 0x1B8 .....               | 271 |

|              |                                                                                                             |     |
|--------------|-------------------------------------------------------------------------------------------------------------|-----|
| Register 23: | LDO Deep-Sleep Power Control (LDODPCTL), offset 0x1BC .....                                                 | 272 |
| Register 24: | LDO Deep-Sleep Power Calibration (LDODPCAL), offset 0x1C0 .....                                             | 274 |
| Register 25: | Sleep / Deep-Sleep Power Mode Status (SDPMST), offset 0x1CC .....                                           | 275 |
| Register 26: | Watchdog Timer Peripheral Present (PPWD), offset 0x300 .....                                                | 278 |
| Register 27: | 16/32-Bit General-Purpose Timer Peripheral Present (PPTIMER), offset 0x304 .....                            | 279 |
| Register 28: | General-Purpose Input/Output Peripheral Present (PPGPIO), offset 0x308 .....                                | 281 |
| Register 29: | Micro Direct Memory Access Peripheral Present (PPDMA), offset 0x30C .....                                   | 284 |
| Register 30: | Hibernation Peripheral Present (PPHIB), offset 0x314 .....                                                  | 285 |
| Register 31: | Universal Asynchronous Receiver/Transmitter Peripheral Present (PPUART), offset<br>0x318 .....              | 286 |
| Register 32: | Synchronous Serial Interface Peripheral Present (PPSSI), offset 0x31C .....                                 | 288 |
| Register 33: | Inter-Integrated Circuit Peripheral Present (PPI2C), offset 0x320 .....                                     | 290 |
| Register 34: | Universal Serial Bus Peripheral Present (PPUSB), offset 0x328 .....                                         | 292 |
| Register 35: | Controller Area Network Peripheral Present (PPCAN), offset 0x334 .....                                      | 293 |
| Register 36: | Analog-to-Digital Converter Peripheral Present (PPADC), offset 0x338 .....                                  | 294 |
| Register 37: | Analog Comparator Peripheral Present (PPACMP), offset 0x33C .....                                           | 295 |
| Register 38: | Pulse Width Modulator Peripheral Present (PPPWM), offset 0x340 .....                                        | 296 |
| Register 39: | Quadrature Encoder Interface Peripheral Present (PPQEI), offset 0x344 .....                                 | 297 |
| Register 40: | EEPROM Peripheral Present (PPEEPROM), offset 0x358 .....                                                    | 298 |
| Register 41: | 32/64-Bit Wide General-Purpose Timer Peripheral Present (PPWTIMER), offset 0x35C .....                      | 299 |
| Register 42: | Watchdog Timer Software Reset (SRWD), offset 0x500 .....                                                    | 301 |
| Register 43: | 16/32-Bit General-Purpose Timer Software Reset (SRTIMER), offset 0x504 .....                                | 303 |
| Register 44: | General-Purpose Input/Output Software Reset (SRGPIO), offset 0x508 .....                                    | 305 |
| Register 45: | Micro Direct Memory Access Software Reset (SRDMA), offset 0x50C .....                                       | 307 |
| Register 46: | Hibernation Software Reset (SRHIB), offset 0x514 .....                                                      | 308 |
| Register 47: | Universal Asynchronous Receiver/Transmitter Software Reset (SRUART), offset 0x518 .....                     | 309 |

|               |            | <ul style="list-style-type: none"> <li>■ In Packaging Information appendix, added Packaging Materials figures.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| July 16, 2013 | 15033.2672 | <ul style="list-style-type: none"> <li>■ In the Electrical Characteristics chapter: <ul style="list-style-type: none"> <li>– Added maximum junction temperature to Maximum Ratings table. Also moved Unpowered storage temperature range parameter to this table.</li> <li>– In SSI Characteristics table, corrected values for <math>T_{RXDMS}</math>, <math>T_{RXDMH}</math>, and <math>T_{RXDSSU}</math>. Also clarified footnotes to table.</li> <li>– Corrected parameter numbers in figures "Master Mode SSI Timing for SPI Frame Format (FRF=00), with SPH=1" and "Slave Mode SSI Timing for SPI Frame Format (FRF=00), with SPH=1".</li> </ul> </li> <li>■ Additional minor data sheet clarifications and corrections.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| July 2013     | 14995.2667 | <ul style="list-style-type: none"> <li>■ In the System Control chapter, corrected resets for bits [7:4] in <b>System Properties (SYSPROP)</b> register.</li> <li>■ In the Hibernation Module chapter: <ul style="list-style-type: none"> <li>– Corrected figures "Using a Crystal as the Hibernation Clock Source with a Single Battery Source" and "Using a Dedicated Oscillator as the Hibernation Clock Source with VDD3ON Mode".</li> <li>– Clarified when the Hibernation module can generate interrupts.</li> </ul> </li> <li>■ In the Internal Memory chapter, removed the <code>INVPL</code> bit from the <b>EEPROM Done Status (EEDONE)</b> register.</li> <li>■ In the uDMA chapter, in the <math>\mu</math>DMA Channel Assignments table, corrected names of timers 6-11 to wide timers 0-5.</li> <li>■ In the Timers chapter: <ul style="list-style-type: none"> <li>– Clarified that the timer must be configured for one-shot or periodic time-out mode to produce an ADC trigger assertion and that the GPTM does not generate triggers for match, compare events or compare match events.</li> <li>– Added a step in the RTC Mode initialization and configuration: If the timer has been operating in a different mode prior to this, clear any residual set bits in the <b>GPTM Timer n Mode (GPTMTnMR)</b> register before reconfiguring.</li> </ul> </li> <li>■ In the Watchdog Timer chapter, added a note that locking the watchdog registers using the <b>WDTLOCK</b> register does not affect the <b>WDTICR</b> register and allows interrupts to always be serviced.</li> <li>■ In the SSI chapter, clarified note in Bit Rate Generation section to indicate that the System Clock or the PIOSC can be used as the source for <code>SSICLK</code>. Also corrected to indicate maximum <code>SSICLK</code> limit in SSI slave mode as well as the fact that <code>SYSCLK</code> has to be at least 12 times that of <code>SSICLK</code>.</li> <li>■ In the Electrical Characteristics chapter: <ul style="list-style-type: none"> <li>– Moved Maximum Ratings and ESD Absolute Maximum Ratings to the front of the chapter.</li> <li>– Added <math>V_{BATRMP}</math> parameter to Maximum Ratings and Hibernation Module Battery Characteristics tables.</li> <li>– Added ambient and junction temperatures to Temperature Characteristics table and clarified values in Thermal Characteristics table.</li> <li>– Added clarifying footnote to <math>V_{VDD\_POK}</math> parameter in Power-On and Brown-Out Levels table.</li> <li>– In the Flash Memory and EEPROM Characteristics tables, added a parameter for page/mass erase times for 10k cycles and corrected existing values for all page and mass erase parameters.</li> </ul> </li> </ul> |

**Table 1. Revision History (continued)**

| Date | Revision | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|      |          | <ul style="list-style-type: none"><li>- Corrected DNL max value in ADC Electrical Characteristics table.</li><li>- In the SSI Characteristics table, changed parameter names for S7-S14, provided a max number instead of a min for S7, and corrected values for S9-S14.</li><li>- Replaced figure "SSI Timing for SPI Frame Format (FRF=00), with SPH=1" with two figures, one for Master Mode and one for Slave Mode.</li><li>- Updated and added values to the table Table 22-40 on page 1200.</li><li>■ In the Package Information appendix, moved orderable devices table from addendum to appendix, clarified part markings and moved packaging diagram from addendum to appendix.</li><li>■ Additional minor data sheet clarifications and corrections.</li></ul> |

## About This Document

This data sheet provides reference information for the TM4C1233C3PM microcontroller, describing the functional blocks of the system-on-chip (SoC) device designed around the ARM® Cortex™-M4F core.

### Audience

This manual is intended for system software developers, hardware designers, and application developers.

### About This Manual

This document is organized into sections that correspond to each major feature.

**Table 2. Documentation Conventions**

| Notation                              | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>General Register Notation</b>      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>REGISTER</b>                       | APB registers are indicated in uppercase bold. For example, <b>PBORCTL</b> is the Power-On and Brown-Out Reset Control register. If a register name contains a lowercase n, it represents more than one register. For example, <b>SRCRn</b> represents any (or all) of the three Software Reset Control registers: <b>SRCR0</b> , <b>SRCR1</b> , and <b>SRCR2</b> .                                                                                            |
| bit                                   | A single bit in a register.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| bit field                             | Two or more consecutive and related bits.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| offset 0xnnn                          | A hexadecimal increment to a register's address, relative to that module's base address as specified in Table 2-4 on page 84.                                                                                                                                                                                                                                                                                                                                  |
| Register N                            | Registers are numbered consecutively throughout the document to aid in referencing them. The register number has no meaning to software.                                                                                                                                                                                                                                                                                                                       |
| reserved                              | Register bits marked <i>reserved</i> are reserved for future use. In most cases, reserved bits are set to 0; however, user software should not rely on the value of a reserved bit. To provide software compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.                                                                                                                              |
| yy:xx                                 | The range of register bits inclusive from xx to yy. For example, 31:15 means bits 15 through 31 in that register.                                                                                                                                                                                                                                                                                                                                              |
| <b>Register Bit/Field Types</b>       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| RC                                    | Software can read this field. The bit or field is cleared by hardware after reading the bit/field.                                                                                                                                                                                                                                                                                                                                                             |
| RO                                    | Software can read this field. Always write the chip reset value.                                                                                                                                                                                                                                                                                                                                                                                               |
| R/W                                   | Software can read or write this field.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| R/WC                                  | Software can read or write this field. Writing to it with any value clears the register.                                                                                                                                                                                                                                                                                                                                                                       |
| R/W1C                                 | Software can read or write this field. A write of a 0 to a W1C bit does not affect the bit value in the register. A write of a 1 clears the value of the bit in the register; the remaining bits remain unchanged. This register type is primarily used for clearing interrupt status bits where the read operation provides the interrupt status and the write of the read value clears only the interrupts being reported at the time the register was read. |
| R/W1S                                 | Software can read or write a 1 to this field. A write of a 0 to a R/W1S bit does not affect the bit value in the register.                                                                                                                                                                                                                                                                                                                                     |
| W1C                                   | Software can write this field. A write of a 0 to a W1C bit does not affect the bit value in the register. A write of a 1 clears the value of the bit in the register; the remaining bits remain unchanged. A read of the register returns no meaningful data. This register is typically used to clear the corresponding bit in an interrupt register.                                                                                                         |
| WO                                    | Only a write by software is valid; a read of the register returns no meaningful data.                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Register Bit/Field Reset Value</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 0                                     | Bit cleared to 0 on chip reset.                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Notation</b>            | <b>Meaning</b>                                                                                                                                                                                                                                                                                                                                           |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| assert a signal            | Change the value of the signal from the logically False state to the logically True state. For active High signals, the asserted signal value is 1 (High); for active Low signals, the asserted signal value is 0 (Low). The active polarity (High or Low) is defined by the signal name (see <code>SIGNAL</code> and <code><u>SIGNAL</u></code> below). |
| deassert a signal          | Change the value of the signal from the logically True state to the logically False state.                                                                                                                                                                                                                                                               |
| <code><u>SIGNAL</u></code> | Signal names are in uppercase and in the Courier font. An overbar on a signal name indicates that it is active Low. To assert <code><u>SIGNAL</u></code> is to drive it Low; to deassert <code><u>SIGNAL</u></code> is to drive it High.                                                                                                                 |
| <code>SIGNAL</code>        | Signal names are in uppercase and in the Courier font. An active High signal has no overbar. To assert <code>SIGNAL</code> is to drive it High; to deassert <code>SIGNAL</code> is to drive it Low.                                                                                                                                                      |
| <b>Numbers</b>             |                                                                                                                                                                                                                                                                                                                                                          |
| X                          | An uppercase X indicates any of several values is allowed, where X can be any legal pattern. For example, a binary value of 0X00 can be either 0100 or 0000, a hex value of 0xX is 0x0 or 0x1, and so on.                                                                                                                                                |
| 0x                         | Hexadecimal numbers have a prefix of 0x. For example, 0x00FF is the hexadecimal number FF. All other numbers within register tables are assumed to be binary. Within conceptual information, binary numbers are indicated with a b suffix, for example, 1011b, and decimal numbers are written without a prefix or suffix.                               |

# 1 Architectural Overview

Texas Instrument's Tiva™ C Series microcontrollers provide designers a high-performance ARM® Cortex™-M-based architecture with a broad set of integration capabilities and a strong ecosystem of software and development tools. Targeting performance and flexibility, the Tiva™ C Series architecture offers a 80 MHz Cortex-M with FPU, a variety of integrated memories and multiple programmable GPIO. Tiva™ C Series devices offer consumers compelling cost-effective solutions by integrating application-specific peripherals and providing a comprehensive library of software tools which minimize board costs and design-cycle time. Offering quicker time-to-market and cost savings, the Tiva™ C Series microcontrollers are the leading choice in high-performance 32-bit applications.

This chapter contains an overview of the Tiva™ C Series microcontrollers as well as details on the TM4C1233C3PM microcontroller:

- “Tiva™ C Series Overview” on page 40
- “TM4C1233C3PM Microcontroller Overview” on page 41
- “TM4C1233C3PM Microcontroller Features” on page 43
- “TM4C1233C3PM Microcontroller Hardware Details” on page 59
- “Kits” on page 60
- “Support Information” on page 60

## 1.1 Tiva™ C Series Overview

The Tiva™ C Series ARM Cortex-M4 microcontrollers provide top performance and advanced integration. The product family is positioned for cost-conscious applications requiring significant control processing and connectivity capabilities such as:

- Low power, hand-held smart devices
- Gaming equipment
- Home and commercial site monitoring and control
- Motion control
- Medical instrumentation
- Test and measurement equipment
- Factory automation
- Fire and security
- Smart Energy/Smart Grid solutions
- Intelligent lighting control
- Transportation

For applications requiring extreme conservation of power, the TM4C1233C3PM microcontroller features a battery-backed Hibernation module to efficiently power down the TM4C1233C3PM to a low-power state during extended periods of inactivity. With a power-up/power-down sequencer, a continuous time counter (RTC), multiple wake-from-hibernate options, and dedicated battery-backed memory, the Hibernation module positions the TM4C1233C3PM microcontroller perfectly for battery applications.

In addition, the TM4C1233C3PM microcontroller offers the advantages of ARM's widely available development tools, System-on-Chip (SoC) infrastructure IP applications, and a large user community. Additionally, the microcontroller uses ARM's Thumb®-compatible Thumb-2 instruction set to reduce memory requirements and, thereby, cost. Finally, much of the TM4C1233C3PM microcontroller code is compatible to the Tiva™ C Series product line, providing flexibility across designs.

Texas Instruments offers a complete solution to get to market quickly, with evaluation and development boards, white papers and application notes, an easy-to-use peripheral driver library, and a strong support, sales, and distributor network.

## 1.2 TM4C1233C3PM Microcontroller Overview

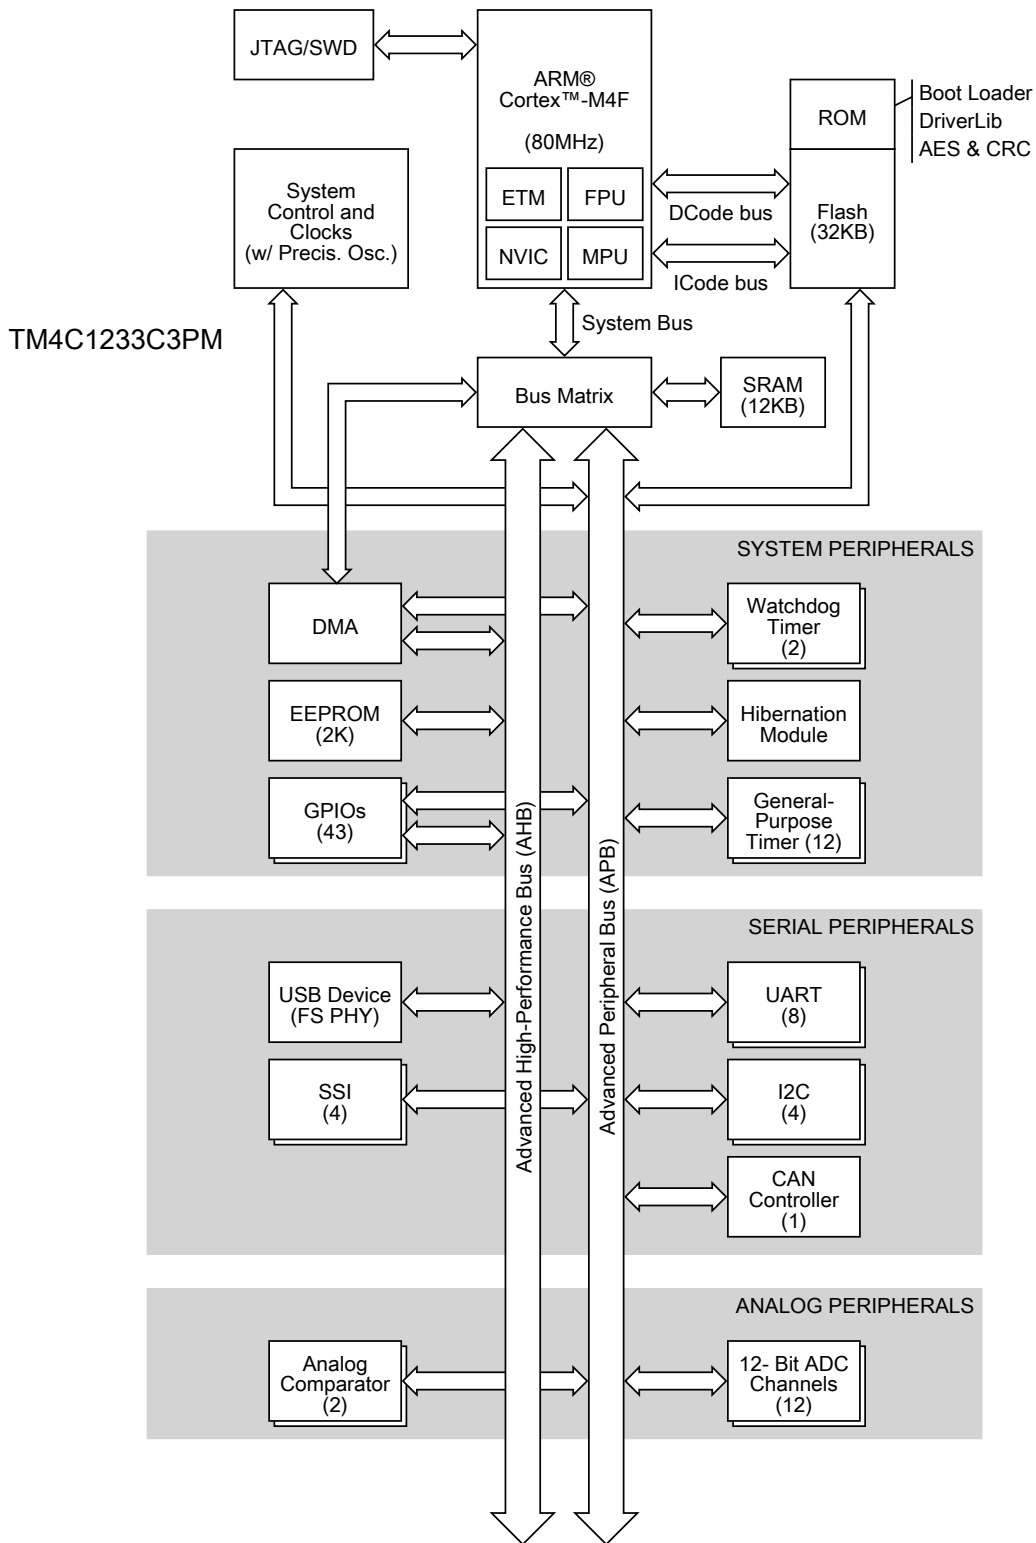

The TM4C1233C3PM microcontroller combines complex integration and high performance with the features shown in Table 1-1.

**Table 1-1. TM4C1233C3PM Microcontroller Features**

| Feature                                             | Description                                                                           |
|-----------------------------------------------------|---------------------------------------------------------------------------------------|
| <b>Performance</b>                                  |                                                                                       |
| Core                                                | ARM Cortex-M4F processor core                                                         |
| Performance                                         | 80-MHz operation; 100 DMIPS performance                                               |
| Flash                                               | 32 KB single-cycle Flash memory                                                       |
| System SRAM                                         | 12 KB single-cycle SRAM                                                               |
| EEPROM                                              | 2KB of EEPROM                                                                         |
| Internal ROM                                        | Internal ROM loaded with TivaWare™ for C Series software                              |
| <b>Security</b>                                     |                                                                                       |
| <b>Communication Interfaces</b>                     |                                                                                       |
| Universal Asynchronous Receivers/Transmitter (UART) | Eight UARTs                                                                           |
| Synchronous Serial Interface (SSI)                  | Four SSI modules                                                                      |
| Inter-Integrated Circuit (I <sup>2</sup> C)         | Four I <sup>2</sup> C modules with four transmission speeds including high-speed mode |
| Controller Area Network (CAN)                       | CAN 2.0 A/B controllers                                                               |
| Universal Serial Bus (USB)                          | USB 2.0 Device                                                                        |
| <b>System Integration</b>                           |                                                                                       |
| Micro Direct Memory Access (μDMA)                   | ARM® PrimeCell® 32-channel configurable μDMA controller                               |
| General-Purpose Timer (GPTM)                        | Six 16/32-bit GPTM blocks and six 32/64-bit Wide GPTM blocks                          |
| Watchdog Timer (WDT)                                | Two watchdog timers                                                                   |
| Hibernation Module (HIB)                            | Low-power battery-backed Hibernation module                                           |
| General-Purpose Input/Output (GPIO)                 | Six physical GPIO blocks                                                              |
| <b>Analog Support</b>                               |                                                                                       |
| Analog-to-Digital Converter (ADC)                   | Two 12-bit ADC modules, each with a maximum sample rate of one million samples/second |
| Analog Comparator Controller                        | Two independent integrated analog comparators                                         |
| Digital Comparator                                  | 16 digital comparators                                                                |
| JTAG and Serial Wire Debug (SWD)                    | One JTAG module with integrated ARM SWD                                               |
| <b>Package Information</b>                          |                                                                                       |
| Package                                             | 64-pin LQFP                                                                           |
| Operating Range (Ambient)                           | Industrial (-40°C to 85°C) temperature range                                          |

Figure 1-1 on page 42 shows the features on the TM4C1233C3PM microcontroller. Note that there are two on-chip buses that connect the core to the peripherals. The Advanced Peripheral Bus (APB) bus is the legacy bus. The Advanced High-Performance Bus (AHB) bus provides better back-to-back access performance than the APB bus.

Figure 1-1. Tiva™ TM4C1233C3PM Microcontroller High-Level Block Diagram

## 1.3 TM4C1233C3PM Microcontroller Features

The TM4C1233C3PM microcontroller component features and general function are discussed in more detail in the following section.

### 1.3.1 ARM Cortex-M4F Processor Core

All members of the Tiva™ C Series, including the TM4C1233C3PM microcontroller, are designed around an ARM Cortex-M processor core. The ARM Cortex-M processor provides the core for a high-performance, low-cost platform that meets the needs of minimal memory implementation, reduced pin count, and low power consumption, while delivering outstanding computational performance and exceptional system response to interrupts.

#### 1.3.1.1 Processor Core (see page 61)

- 32-bit ARM Cortex-M4F architecture optimized for small-footprint embedded applications
- 80-MHz operation; 100 DMIPS performance
- Outstanding processing performance combined with fast interrupt handling
- Thumb-2 mixed 16-/32-bit instruction set delivers the high performance expected of a 32-bit ARM core in a compact memory size usually associated with 8- and 16-bit devices, typically in the range of a few kilobytes of memory for microcontroller-class applications
  - Single-cycle multiply instruction and hardware divide
  - Atomic bit manipulation (bit-banding), delivering maximum memory utilization and streamlined peripheral control
  - Unaligned data access, enabling data to be efficiently packed into memory
- IEEE754-compliant single-precision Floating-Point Unit (FPU)
- 16-bit SIMD vector processing unit
- Fast code execution permits slower processor clock or increases sleep mode time
- Harvard architecture characterized by separate buses for instruction and data
- Efficient processor core, system and memories
- Hardware division and fast digital-signal-processing orientated multiply accumulate
- Saturating arithmetic for signal processing
- Deterministic, high-performance interrupt handling for time-critical applications
- Memory protection unit (MPU) to provide a privileged mode for protected operating system functionality
- Enhanced system debug with extensive breakpoint and trace capabilities
- Serial Wire Debug and Serial Wire Trace reduce the number of pins required for debugging and tracing

- Migration from the ARM7™ processor family for better performance and power efficiency
- Optimized for single-cycle Flash memory usage up to specific frequencies; see “Internal Memory” on page 498 for more information.
- Ultra-low power consumption with integrated sleep modes

#### 1.3.1.2 System Timer (SysTick) (see page 115)

ARM Cortex-M4F includes an integrated system timer, SysTick. SysTick provides a simple, 24-bit, clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism. The counter can be used in several different ways, for example:

- An RTOS tick timer that fires at a programmable rate (for example, 100 Hz) and invokes a SysTick routine
- A high-speed alarm timer using the system clock
- A variable rate alarm or signal timer—the duration is range-dependent on the reference clock used and the dynamic range of the counter
- A simple counter used to measure time to completion and time used
- An internal clock-source control based on missing/meeting durations

#### 1.3.1.3 Nested Vectored Interrupt Controller (NVIC) (see page 116)

The TM4C1233C3PM controller includes the ARM Nested Vectored Interrupt Controller (NVIC). The NVIC and Cortex-M4F prioritize and handle all exceptions in Handler Mode. The processor state is automatically stored to the stack on an exception and automatically restored from the stack at the end of the Interrupt Service Routine (ISR). The interrupt vector is fetched in parallel to the state saving, enabling efficient interrupt entry. The processor supports tail-chaining, meaning that back-to-back interrupts can be performed without the overhead of state saving and restoration. Software can set eight priority levels on 7 exceptions (system handlers) and 65 interrupts.

- Deterministic, fast interrupt processing: always 12 cycles, or just 6 cycles with tail-chaining (these values reflect no FPU stacking)
- External non-maskable interrupt signal (NMI) available for immediate execution of NMI handler for safety critical applications
- Dynamically reprioritizable interrupts
- Exceptional interrupt handling via hardware implementation of required register manipulations

#### 1.3.1.4 System Control Block (SCB) (see page 117)

The SCB provides system implementation information and system control, including configuration, control, and reporting of system exceptions.

#### 1.3.1.5 Memory Protection Unit (MPU) (see page 117)

The MPU supports the standard ARM7 Protected Memory System Architecture (PMSA) model. The MPU provides full support for protection regions, overlapping protection regions, access permissions, and exporting memory attributes to the system.

### 1.3.1.6 Floating-Point Unit (FPU) (see page 122)

The FPU fully supports single-precision add, subtract, multiply, divide, multiply and accumulate, and square root operations. It also provides conversions between fixed-point and floating-point data formats, and floating-point constant instructions.

- 32-bit instructions for single-precision (C float) data-processing operations
- Combined multiply and accumulate instructions for increased precision (Fused MAC)
- Hardware support for conversion, addition, subtraction, multiplication with optional accumulate, division, and square-root
- Hardware support for denormals and all IEEE rounding modes
- 32 dedicated 32-bit single-precision registers, also addressable as 16 double-word registers
- Decoupled three stage pipeline

### 1.3.2 On-Chip Memory

The TM4C1233C3PM microcontroller is integrated with the following set of on-chip memory and features:

- 12 KB single-cycle SRAM
- 32 KB Flash memory
- 2KB EEPROM
- Internal ROM loaded with TivaWare™ for C Series software:
  - TivaWare™ Peripheral Driver Library
  - TivaWare Boot Loader
  - Advanced Encryption Standard (AES) cryptography tables
  - Cyclic Redundancy Check (CRC) error detection functionality

#### 1.3.2.1 SRAM (see page 499)

The TM4C1233C3PM microcontroller provides 12 KB of single-cycle on-chip SRAM. The internal SRAM of the device is located at offset 0x2000.0000 of the device memory map.

Because read-modify-write (RMW) operations are very time consuming, ARM has introduced *bit-banding* technology in the Cortex-M4F processor. With a bit-band-enabled processor, certain regions in the memory map (SRAM and peripheral space) can use address aliases to access individual bits in a single, atomic operation.

Data can be transferred to and from SRAM by the following masters:

- $\mu$ DMA
- USB

#### 1.3.2.2 Flash Memory (see page 502)

The TM4C1233C3PM microcontroller provides 32 KB of single-cycle on-chip Flash memory. The Flash memory is organized as a set of 1-KB blocks that can be individually erased. Erasing a block causes the entire contents of the block to be reset to all 1s. These blocks are paired into a set of

2-KB blocks that can be individually protected. The blocks can be marked as read-only or execute-only, providing different levels of code protection. Read-only blocks cannot be erased or programmed, protecting the contents of those blocks from being modified. Execute-only blocks cannot be erased or programmed, and can only be read by the controller instruction fetch mechanism, protecting the contents of those blocks from being read by either the controller or by a debugger.

### 1.3.2.3 ROM (see page 500)

The TM4C1233C3PM ROM is preprogrammed with the following software and programs:

- TivaWare Peripheral Driver Library
- TivaWare Boot Loader
- Advanced Encryption Standard (AES) cryptography tables
- Cyclic Redundancy Check (CRC) error-detection functionality

The TivaWare Peripheral Driver Library is a royalty-free software library for controlling on-chip peripherals with a boot-loader capability. The library performs both peripheral initialization and control functions, with a choice of polled or interrupt-driven peripheral support. In addition, the library is designed to take full advantage of the stellar interrupt performance of the ARM Cortex-M4F core. No special pragmas or custom assembly code prologue/epilogue functions are required. For applications that require in-field programmability, the royalty-free TivaWare Boot Loader can act as an application loader and support in-field firmware updates.

The Advanced Encryption Standard (AES) is a publicly defined encryption standard used by the U.S. Government. AES is a strong encryption method with reasonable performance and size. In addition, it is fast in both hardware and software, is fairly easy to implement, and requires little memory. The Texas Instruments encryption package is available with full source code, and is based on Lesser General Public License (LGPL) source. An LGPL means that the code can be used within an application without any copyleft implications for the application (the code does not automatically become open source). Modifications to the package source, however, must be open source.

CRC (Cyclic Redundancy Check) is a technique to validate a span of data has the same contents as when previously checked. This technique can be used to validate correct receipt of messages (nothing lost or modified in transit), to validate data after decompression, to validate that Flash memory contents have not been changed, and for other cases where the data needs to be validated. A CRC is preferred over a simple checksum (e.g. XOR all bits) because it catches changes more readily.

### 1.3.2.4 EEPROM (see page 508)

The TM4C1233C3PM microcontroller includes an EEPROM with the following features:

- 2Kbytes of memory accessible as 512 32-bit words
- 32 blocks of 16 words (64 bytes) each
- Built-in wear leveling
- Access protection per block
- Lock protection option for the whole peripheral as well as per block using 32-bit to 96-bit unlock codes (application selectable)

- Interrupt support for write completion to avoid polling
- Endurance of 500K writes (when writing at fixed offset in every alternate page in circular fashion) to 15M operations (when cycling through two pages ) per each 2-page block.

### 1.3.3 Serial Communications Peripherals

The TM4C1233C3PM controller supports both asynchronous and synchronous serial communications with:

- CAN 2.0 A/B controller
- USB 2.0 Device
- Eight UARTs with IrDA, 9-bit and ISO 7816 support.
- Four I<sup>2</sup>C modules with four transmission speeds including high-speed mode
- Four Synchronous Serial Interface modules (SSI)

The following sections provide more detail on each of these communications functions.

#### 1.3.3.1 Controller Area Network (CAN) (see page 1015)

Controller Area Network (CAN) is a multicast shared serial-bus standard for connecting electronic control units (ECUs). CAN was specifically designed to be robust in electromagnetically noisy environments and can utilize a differential balanced line like RS-485 or twisted-pair wire. Originally created for automotive purposes, it is now used in many embedded control applications (for example, industrial or medical). Bit rates up to 1 Mbps are possible at network lengths below 40 meters. Decreased bit rates allow longer network distances (for example, 125 Kbps at 500m).

A transmitter sends a message to all CAN nodes (broadcasting). Each node decides on the basis of the identifier received whether it should process the message. The identifier also determines the priority that the message enjoys in competition for bus access. Each CAN message can transmit from 0 to 8 bytes of user information.

The TM4C1233C3PM microcontroller includes one CAN unit with the following features:

- CAN protocol version 2.0 part A/B
- Bit rates up to 1 Mbps
- 32 message objects with individual identifier masks
- Maskable interrupt
- Disable Automatic Retransmission mode for Time-Triggered CAN (TTCAN) applications
- Programmable loopback mode for self-test operation
- Programmable FIFO mode enables storage of multiple message objects
- Gluelessly attaches to an external CAN transceiver through the CAN<sub>n</sub>TX and CAN<sub>n</sub>RX signals

### 1.3.3.2 Universal Serial Bus (USB) (see page 1065)

Universal Serial Bus (USB) is a serial bus standard designed to allow peripherals to be connected and disconnected using a standardized interface without rebooting the system.

The TM4C1233C3PM microcontroller supports the USB 2.0 full-speed configuration in Device mode.

The USB module has the following features:

- Complies with USB-IF (Implementer's Forum) certification standards
- USB 2.0 full-speed (12 Mbps) operation with integrated PHY
- 4 transfer types: Control, Interrupt, Bulk, and Isochronous
- 16 endpoints
  - 1 dedicated control IN endpoint and 1 dedicated control OUT endpoint
  - 7 configurable IN endpoints and 7 configurable OUT endpoints
- 4 KB dedicated endpoint memory: one endpoint may be defined for double-buffered 1023-byte isochronous packet size
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for transmit and receive for up to three IN endpoints and three OUT endpoints
  - Channel requests asserted when FIFO contains required amount of data

### 1.3.3.3 UART (see page 861)

A Universal Asynchronous Receiver/Transmitter (UART) is an integrated circuit used for RS-232C serial communications, containing a transmitter (parallel-to-serial converter) and a receiver (serial-to-parallel converter), each clocked separately.

The TM4C1233C3PM microcontroller includes eight fully programmable 16C550-type UARTs. Although the functionality is similar to a 16C550 UART, this UART design is not register compatible. The UART can generate individually masked interrupts from the Rx, Tx, modem flow control, and error conditions. The module generates a single combined interrupt when any of the interrupts are asserted and are unmasked.

The eight UARTs have the following features:

- Programmable baud-rate generator allowing speeds up to 5 Mbps for regular speed (divide by 16) and 10 Mbps for high speed (divide by 8)
- Separate 16x8 transmit (TX) and receive (RX) FIFOs to reduce CPU interrupt service loading
- Programmable FIFO length, including 1-byte deep operation providing conventional double-buffered interface
- FIFO trigger levels of 1/8, 1/4, 1/2, 3/4, and 7/8
- Standard asynchronous communication bits for start, stop, and parity
- Line-break generation and detection

- Fully programmable serial interface characteristics
  - 5, 6, 7, or 8 data bits
  - Even, odd, stick, or no-parity bit generation/detection
  - 1 or 2 stop bit generation
- IrDA serial-IR (SIR) encoder/decoder providing
  - Programmable use of IrDA Serial Infrared (SIR) or UART input/output
  - Support of IrDA SIR encoder/decoder functions for data rates up to 115.2 Kbps half-duplex
  - Support of normal 3/16 and low-power (1.41-2.23  $\mu$ s) bit durations
  - Programmable internal clock generator enabling division of reference clock by 1 to 256 for low-power mode bit duration
- Support for communication with ISO 7816 smart cards
- Modem flow control (on UART1)
- EIA-485 9-bit support
- Standard FIFO-level and End-of-Transmission interrupts
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for transmit and receive
  - Receive single request asserted when data is in the FIFO; burst request asserted at programmed FIFO level
  - Transmit single request asserted when there is space in the FIFO; burst request asserted at programmed FIFO level

#### 1.3.3.4 I<sup>2</sup>C (see page 964)

The Inter-Integrated Circuit (I<sup>2</sup>C) bus provides bi-directional data transfer through a two-wire design (a serial data line SDA and a serial clock line SCL). The I<sup>2</sup>C bus interfaces to external I<sup>2</sup>C devices such as serial memory (RAMs and ROMs), networking devices, LCDs, tone generators, and so on. The I<sup>2</sup>C bus may also be used for system testing and diagnostic purposes in product development and manufacture.

Each device on the I<sup>2</sup>C bus can be designated as either a master or a slave. I<sup>2</sup>C module supports both sending and receiving data as either a master or a slave and can operate simultaneously as both a master and a slave. Both the I<sup>2</sup>C master and slave can generate interrupts.

The TM4C1233C3PM microcontroller includes four I<sup>2</sup>C modules with the following features:

- Devices on the I<sup>2</sup>C bus can be designated as either a master or a slave
  - Supports both transmitting and receiving data as either a master or a slave
  - Supports simultaneous master and slave operation

- Four I<sup>2</sup>C modes
  - Master transmit
  - Master receive
  - Slave transmit
  - Slave receive
- Four transmission speeds:
  - Standard (100 Kbps)
  - Fast-mode (400 Kbps)
  - Fast-mode plus (1 Mbps)
  - High-speed mode (3.33 Mbps)
- Clock low timeout interrupt
- Dual slave address capability
- Glitch suppression
- Master and slave interrupt generation
  - Master generates interrupts when a transmit or receive operation completes (or aborts due to an error)
  - Slave generates interrupts when data has been transferred or requested by a master or when a START or STOP condition is detected
- Master with arbitration and clock synchronization, multimaster support, and 7-bit addressing mode

#### 1.3.3.5 SSI (see page 920)

Synchronous Serial Interface (SSI) is a four-wire bi-directional communications interface that converts data between parallel and serial. The SSI module performs serial-to-parallel conversion on data received from a peripheral device, and parallel-to-serial conversion on data transmitted to a peripheral device. The SSI module can be configured as either a master or slave device. As a slave device, the SSI module can also be configured to disable its output, which allows a master device to be coupled with multiple slave devices. The TX and RX paths are buffered with separate internal FIFOs.

The SSI module also includes a programmable bit rate clock divider and prescaler to generate the output serial clock derived from the SSI module's input clock. Bit rates are generated based on the input clock and the maximum bit rate is determined by the connected peripheral.

The TM4C1233C3PM microcontroller includes four SSI modules with the following features:

- Programmable interface operation for Freescale SPI, MICROWIRE, or Texas Instruments synchronous serial interfaces
- Master or slave operation

- Programmable clock bit rate and prescaler
- Separate transmit and receive FIFOs, each 16 bits wide and 8 locations deep
- Programmable data frame size from 4 to 16 bits
- Internal loopback test mode for diagnostic/debug testing
- Standard FIFO-based interrupts and End-of-Transmission interrupt
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for transmit and receive
  - Receive single request asserted when data is in the FIFO; burst request asserted when FIFO contains 4 entries
  - Transmit single request asserted when there is space in the FIFO; burst request asserted when four or more entries are available to be written in the FIFO

### 1.3.4 System Integration

The TM4C1233C3PM microcontroller provides a variety of standard system functions integrated into the device, including:

- Direct Memory Access Controller (DMA)
- System control and clocks including on-chip precision 16-MHz oscillator
- Six 32-bit timers (up to twelve 16-bit)
- Six wide 64-bit timers (up to twelve 32-bit)
- Twelve 32/64-bit Capture Compare PWM (CCP) pins
- Lower-power battery-backed Hibernation module
- Real-Time Clock in Hibernation module
- Two Watchdog Timers
  - One timer runs off the main oscillator
  - One timer runs off the precision internal oscillator
- Up to 43 GPIOs, depending on configuration
  - Highly flexible pin muxing allows use as GPIO or one of several peripheral functions
  - Independently configurable to 2-, 4- or 8-mA drive capability
  - Up to 4 GPIOs can have 18-mA drive capability

The following sections provide more detail on each of these functions.

#### 1.3.4.1 Direct Memory Access (see page 557)

The TM4C1233C3PM microcontroller includes a Direct Memory Access (DMA) controller, known as micro-DMA ( $\mu$ DMA). The  $\mu$ DMA controller provides a way to offload data transfer tasks from the Cortex-M4F processor, allowing for more efficient use of the processor and the available bus bandwidth. The  $\mu$ DMA controller can perform transfers between memory and peripherals. It has

dedicated channels for each supported on-chip module and can be programmed to automatically perform transfers between peripherals and memory as the peripheral is ready to transfer more data. The  $\mu$ DMA controller provides the following features:

- ARM PrimeCell<sup>®</sup> 32-channel configurable  $\mu$ DMA controller
- Support for memory-to-memory, memory-to-peripheral, and peripheral-to-memory in multiple transfer modes
  - Basic for simple transfer scenarios
  - Ping-pong for continuous data flow
  - Scatter-gather for a programmable list of up to 256 arbitrary transfers initiated from a single request
- Highly flexible and configurable channel operation
  - Independently configured and operated channels
  - Dedicated channels for supported on-chip modules
  - Flexible channel assignments
  - One channel each for receive and transmit path for bidirectional modules
  - Dedicated channel for software-initiated transfers
  - Per-channel configurable priority scheme
  - Optional software-initiated requests for any channel
- Two levels of priority
- Design optimizations for improved bus access performance between  $\mu$ DMA controller and the processor core
  - $\mu$ DMA controller access is subordinate to core access
  - RAM striping
  - Peripheral bus segmentation
- Data sizes of 8, 16, and 32 bits
- Transfer size is programmable in binary steps from 1 to 1024
- Source and destination address increment size of byte, half-word, word, or no increment
- Maskable peripheral requests
- Interrupt on transfer completion, with a separate interrupt per channel

### 1.3.4.2 System Control and Clocks (see page 204)

System control determines the overall operation of the device. It provides information about the device, controls power-saving features, controls the clocking of the device and individual peripherals, and handles reset detection and reporting.

- Device identification information: version, part number, SRAM size, Flash memory size, and so on
- Power control
  - On-chip fixed Low Drop-Out (LDO) voltage regulator
  - Hibernation module handles the power-up/down 3.3 V sequencing and control for the core digital logic and analog circuits
  - Low-power options for microcontroller: Sleep and Deep-sleep modes with clock gating
  - Low-power options for on-chip modules: software controls shutdown of individual peripherals and memory
  - 3.3-V supply brown-out detection and reporting via interrupt or reset
- Multiple clock sources for microcontroller system clock. The following clock sources are provided to the TM4C1233C3PM microcontroller:
  - Precision Internal Oscillator (PIOSC) providing a 16-MHz frequency
    - 16 MHz  $\pm$ 3% across temperature and voltage
    - Can be recalibrated with 7-bit trim resolution to achieve better accuracy (16 MHz  $\pm$ 1%)
    - Software power down control for low power modes
  - Main Oscillator (MOSC): A frequency-accurate clock source by one of two means: an external single-ended clock source is connected to the OSC0 input pin, or an external crystal is connected across the OSC0 input and OSC1 output pins.
  - Low Frequency Internal Oscillator (LFIOOSC): On-chip resource used during power-saving modes
  - Hibernate RTC oscillator (RTCOSC) clock that can be configured to be the 32.768-kHz external oscillator source from the Hibernation (HIB) module or the HIB Low Frequency clock source (HIB LFIOOSC), which is located within the Hibernation Module.
- Flexible reset sources
  - Power-on reset (POR)
  - Reset pin assertion
  - Brown-out reset (BOR) detector alerts to system power drops
  - Software reset
  - Watchdog timer reset
  - MOSC failure

### 1.3.4.3 Programmable Timers (see page 675)

Programmable timers can be used to count or time external events that drive the Timer input pins. Each 16/32-bit GPTM block provides two 16-bit timers/counters that can be configured to operate independently as timers or event counters, or configured to operate as one 32-bit timer or one 32-bit Real-Time Clock (RTC). Each 32/64-bit Wide GPTM block provides two 32-bit timers/counters that can be configured to operate independently as timers or event counters, or configured to operate as one 64-bit timer or one 64-bit Real-Time Clock (RTC). Timers can also be used to trigger analog-to-digital (ADC) conversions and DMA transfers.

The General-Purpose Timer Module (GPTM) contains six 16/32-bit GPTM blocks and six 32/64-bit Wide GPTM blocks with the following functional options:

- 16/32-bit operating modes:
  - 16- or 32-bit programmable one-shot timer
  - 16- or 32-bit programmable periodic timer
  - 16-bit general-purpose timer with an 8-bit prescaler
  - 32-bit Real-Time Clock (RTC) when using an external 32.768-KHz clock as the input
  - 16-bit input-edge count- or time-capture modes with an 8-bit prescaler
  - 16-bit PWM mode with an 8-bit prescaler and software-programmable output inversion of the PWM signal
- 32/64-bit operating modes:
  - 32- or 64-bit programmable one-shot timer
  - 32- or 64-bit programmable periodic timer
  - 32-bit general-purpose timer with a 16-bit prescaler
  - 64-bit Real-Time Clock (RTC) when using an external 32.768-KHz clock as the input
  - 32-bit input-edge count- or time-capture modes with a 16-bit prescaler
  - 32-bit PWM mode with a 16-bit prescaler and software-programmable output inversion of the PWM signal
- Count up or down
- Twelve 16/32-bit Capture Compare PWM pins (CCP)
- Twelve 32/64-bit Capture Compare PWM pins (CCP)
- Daisy chaining of timer modules to allow a single timer to initiate multiple timing events
- Timer synchronization allows selected timers to start counting on the same clock cycle
- ADC event trigger
- User-enabled stalling when the microcontroller asserts CPU Halt flag during debug (excluding RTC mode)

- Ability to determine the elapsed time between the assertion of the timer interrupt and entry into the interrupt service routine
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Dedicated channel for each timer
  - Burst request generated on timer interrupt

#### 1.3.4.4 CCP Pins (see page 683)

Capture Compare PWM pins (CCP) can be used by the General-Purpose Timer Module to time/count external events using the CCP pin as an input. Alternatively, the GPTM can generate a simple PWM output on the CCP pin.

The TM4C1233C3PM microcontroller includes twelve 16/32-bit CCP pins that can be programmed to operate in the following modes:

- Capture: The GP Timer is incremented/decremented by programmed events on the CCP input. The GP Timer captures and stores the current timer value when a programmed event occurs.
- Compare: The GP Timer is incremented/decremented by programmed events on the CCP input. The GP Timer compares the current value with a stored value and generates an interrupt when a match occurs.
- PWM: The GP Timer is incremented/decremented by the system clock. A PWM signal is generated based on a match between the counter value and a value stored in a match register and is output on the CCP pin.

#### 1.3.4.5 Hibernation Module (HIB) (see page 467)

The Hibernation module provides logic to switch power off to the main processor and peripherals and to wake on external or time-based events. The Hibernation module includes power-sequencing logic and has the following features:

- 32-bit real-time seconds counter (RTC) with 1/32,768 second resolution and a 15-bit sub-seconds counter
  - 32-bit RTC seconds match register and a 15-bit sub seconds match for timed wake-up and interrupt generation with 1/32,768 second resolution
  - RTC predivider trim for making fine adjustments to the clock rate
- Two mechanisms for power control
  - System power control using discrete external regulator
  - On-chip power control using internal switches under register control
- Dedicated pin for waking using an external signal
- RTC operational and hibernation memory valid as long as  $V_{DD}$  or  $V_{BAT}$  is valid
- Low-battery detection, signaling, and interrupt generation, with optional wake on low battery
- GPIO pin state can be retained during hibernation

- Clock source from a 32.768-kHz external crystal or oscillator
- Sixteen 32-bit words of battery-backed memory to save state during hibernation
- Programmable interrupts for:
  - RTC match
  - External wake
  - Low battery

#### 1.3.4.6 Watchdog Timers (see page 745)

A watchdog timer is used to regain control when a system has failed due to a software error or to the failure of an external device to respond in the expected way. The TM4C1233C3PM Watchdog Timer can generate an interrupt, a non-maskable interrupt, or a reset when a time-out value is reached. In addition, the Watchdog Timer is ARM FiRM-compliant and can be configured to generate an interrupt to the microcontroller on its first time-out, and to generate a reset signal on its second timeout. Once the Watchdog Timer has been configured, the lock register can be written to prevent the timer configuration from being inadvertently altered.

The TM4C1233C3PM microcontroller has two Watchdog Timer modules: Watchdog Timer 0 uses the system clock for its timer clock; Watchdog Timer 1 uses the PIOSC as its timer clock. The Watchdog Timer module has the following features:

- 32-bit down counter with a programmable load register
- Separate watchdog clock with an enable
- Programmable interrupt generation logic with interrupt masking and optional NMI function
- Lock register protection from runaway software
- Reset generation logic with an enable/disable
- User-enabled stalling when the microcontroller asserts the CPU Halt flag during debug

#### 1.3.4.7 Programmable GPIOs (see page 621)

General-purpose input/output (GPIO) pins offer flexibility for a variety of connections. The TM4C1233C3PM GPIO module is comprised of six physical GPIO blocks, each corresponding to an individual GPIO port. The GPIO module is FiRM-compliant (compliant to the ARM Foundation IP for Real-Time Microcontrollers specification) and supports 0-43 programmable input/output pins. The number of GPIOs available depends on the peripherals being used (see “Signal Tables” on page 1138 for the signals available to each GPIO pin).

- Up to 43 GPIOs, depending on configuration
- Highly flexible pin muxing allows use as GPIO or one of several peripheral functions
- 5-V-tolerant in input configuration
- Ports A-G accessed through the Advanced Peripheral Bus (APB)
- Fast toggle capable of a change every clock cycle for ports on AHB, every two clock cycles for ports on APB

- Programmable control for GPIO interrupts
  - Interrupt generation masking
  - Edge-triggered on rising, falling, or both
  - Level-sensitive on High or Low values
- Bit masking in both read and write operations through address lines
- Can be used to initiate an ADC sample sequence or a  $\mu$ DMA transfer
- Pin state can be retained during Hibernation mode
- Pins configured as digital inputs are Schmitt-triggered
- Programmable control for GPIO pad configuration
  - Weak pull-up or pull-down resistors
  - 2-mA, 4-mA, and 8-mA pad drive for digital communication; up to four pads can sink 18-mA for high-current applications
  - Slew rate control for 8-mA pad drive
  - Open drain enables
  - Digital input enables

### 1.3.5 Analog

The TM4C1233C3PM microcontroller provides analog functions integrated into the device, including:

- Two 12-bit Analog-to-Digital Converters (ADC), with a total of 12 analog input channels and each with a sample rate of one million samples/second
- Two analog comparators
- On-chip voltage regulator

The following provides more detail on these analog functions.

#### 1.3.5.1 ADC (see page 770)

An analog-to-digital converter (ADC) is a peripheral that converts a continuous analog voltage to a discrete digital number. The TM4C1233C3PM ADC module features 12-bit conversion resolution and supports 12 input channels plus an internal temperature sensor. Four buffered sample sequencers allow rapid sampling of up to 12 analog input sources without controller intervention. Each sample sequencer provides flexible programming with fully configurable input source, trigger events, interrupt generation, and sequencer priority. Each ADC module has a digital comparator function that allows the conversion value to be diverted to a comparison unit that provides eight digital comparators.

The TM4C1233C3PM microcontroller provides two ADC modules, each with the following features:

- 12 shared analog input channels

- 12-bit precision ADC
- Single-ended and differential-input configurations
- On-chip internal temperature sensor
- Maximum sample rate of one million samples/second
- Optional phase shift in sample time programmable from 22.5° to 337.5°
- Four programmable sample conversion sequencers from one to eight entries long, with corresponding conversion result FIFOs
- Flexible trigger control
  - Controller (software)
  - Timers
  - Analog Comparators
  - GPIO
- Hardware averaging of up to 64 samples
- Eight digital comparators
- Power and ground for the analog circuitry is separate from the digital power and ground
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Dedicated channel for each sample sequencer
  - ADC module uses burst requests for DMA

### 1.3.5.2 Analog Comparators (see page 1122)

An analog comparator is a peripheral that compares two analog voltages and provides a logical output that signals the comparison result. The TM4C1233C3PM microcontroller provides two independent integrated analog comparators that can be configured to drive an output or generate an interrupt or ADC event.

The comparator can provide its output to a device pin, acting as a replacement for an analog comparator on the board, or it can be used to signal the application via interrupts or triggers to the ADC to cause it to start capturing a sample sequence. The interrupt generation and ADC triggering logic is separate. This means, for example, that an interrupt can be generated on a rising edge and the ADC triggered on a falling edge.

The TM4C1233C3PM microcontroller provides two independent integrated analog comparators with the following functions:

- Compare external pin input to external pin input or to internal programmable voltage reference
- Compare a test voltage against any one of the following voltages:
  - An individual external reference voltage

- A shared single external reference voltage
- A shared internal reference voltage

### 1.3.6 JTAG and ARM Serial Wire Debug (see page 192)

The Joint Test Action Group (JTAG) port is an IEEE standard that defines a Test Access Port and Boundary Scan Architecture for digital integrated circuits and provides a standardized serial interface for controlling the associated test logic. The TAP, Instruction Register (IR), and Data Registers (DR) can be used to test the interconnections of assembled printed circuit boards and obtain manufacturing information on the components. The JTAG Port also provides a means of accessing and controlling design-for-test features such as I/O pin observation and control, scan testing, and debugging. Texas Instruments replaces the ARM SW-DP and JTAG-DP with the ARM Serial Wire JTAG Debug Port (SWJ-DP) interface. The SWJ-DP interface combines the SWD and JTAG debug ports into one module providing all the normal JTAG debug and test functionality plus real-time access to system memory without halting the core or requiring any target resident code. The SWJ-DP interface has the following features:

- IEEE 1149.1-1990 compatible Test Access Port (TAP) controller
- Four-bit Instruction Register (IR) chain for storing JTAG instructions
- IEEE standard instructions: BYPASS, IDCODE, SAMPLE/PRELOAD, and EXTEST
- ARM additional instructions: APACC, DPACC and ABORT
- Integrated ARM Serial Wire Debug (SWD)
  - Serial Wire JTAG Debug Port (SWJ-DP)
  - Flash Patch and Breakpoint (FPB) unit for implementing breakpoints
  - Data Watchpoint and Trace (DWT) unit for implementing watchpoints, trigger resources, and system profiling
  - Instrumentation Trace Macrocell (ITM) for support of printf style debugging
  - Embedded Trace Macrocell (ETM) for instruction trace capture
  - Trace Port Interface Unit (TPIU) for bridging to a Trace Port Analyzer

### 1.3.7 Packaging and Temperature

- 64-pin RoHS-compliant LQFP package
- Industrial (-40°C to 85°C) ambient temperature range

## 1.4 TM4C1233C3PM Microcontroller Hardware Details

Details on the pins and package can be found in the following sections:

- “Pin Diagram” on page 1137
- “Signal Tables” on page 1138
- “Electrical Characteristics” on page 1160

- “Package Information” on page 1203

## 1.5 Kits

The Tiva™ C Series provides the hardware and software tools that engineers need to begin development quickly.

- Reference Design Kits accelerate product development by providing ready-to-run hardware and comprehensive documentation including hardware design files
- Evaluation Kits provide a low-cost and effective means of evaluating TM4C1233C3PM microcontrollers before purchase
- Development Kits provide you with all the tools you need to develop and prototype embedded applications right out of the box

See the Tiva series website at <http://www.ti.com/tiva-c> for the latest tools available, or ask your distributor.

## 1.6 Support Information

For support on Tiva™ C Series products, contact the [TI Worldwide Product Information Center](#) nearest you.

## 2 The Cortex-M4F Processor

The ARM® Cortex™-M4F processor provides a high-performance, low-cost platform that meets the system requirements of minimal memory implementation, reduced pin count, and low power consumption, while delivering outstanding computational performance and exceptional system response to interrupts. Features include:

- 32-bit ARM® Cortex™-M4F architecture optimized for small-footprint embedded applications
- 80-MHz operation; 100 DMIPS performance
- Outstanding processing performance combined with fast interrupt handling
- Thumb-2 mixed 16-/32-bit instruction set delivers the high performance expected of a 32-bit ARM core in a compact memory size usually associated with 8- and 16-bit devices, typically in the range of a few kilobytes of memory for microcontroller-class applications
  - Single-cycle multiply instruction and hardware divide
  - Atomic bit manipulation (bit-banding), delivering maximum memory utilization and streamlined peripheral control
  - Unaligned data access, enabling data to be efficiently packed into memory
- IEEE754-compliant single-precision Floating-Point Unit (FPU)
- 16-bit SIMD vector processing unit
- Fast code execution permits slower processor clock or increases sleep mode time
- Harvard architecture characterized by separate buses for instruction and data
- Efficient processor core, system and memories
- Hardware division and fast digital-signal-processing orientated multiply accumulate
- Saturating arithmetic for signal processing
- Deterministic, high-performance interrupt handling for time-critical applications
- Memory protection unit (MPU) to provide a privileged mode for protected operating system functionality
- Enhanced system debug with extensive breakpoint and trace capabilities
- Serial Wire Debug and Serial Wire Trace reduce the number of pins required for debugging and tracing
- Migration from the ARM7™ processor family for better performance and power efficiency
- Optimized for single-cycle Flash memory usage up to specific frequencies; see “Internal Memory” on page 498 for more information.
- Ultra-low power consumption with integrated sleep modes

The Tiva™ C Series microcontrollers builds on this core to bring high-performance 32-bit computing to

This chapter provides information on the Tiva™ C Series implementation of the Cortex-M4F processor, including the programming model, the memory model, the exception model, fault handling, and power management.

For technical details on the instruction set, see the Cortex™-M4 instruction set chapter in the *ARM® Cortex™-M4 Devices Generic User Guide* (literature number [ARM DUI 0553A](#)).

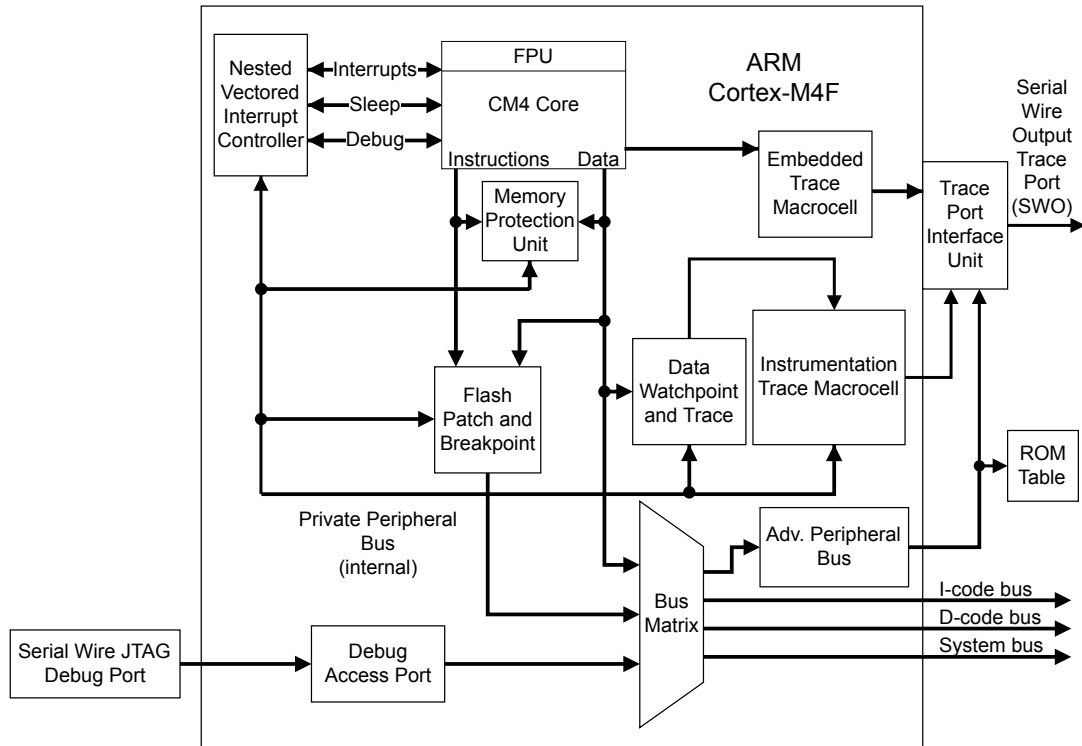

## 2.1 Block Diagram

The Cortex-M4F processor is built on a high-performance processor core, with a 3-stage pipeline Harvard architecture, making it ideal for demanding embedded applications. The processor delivers exceptional power efficiency through an efficient instruction set and extensively optimized design, providing high-end processing hardware including IEEE754-compliant single-precision floating-point computation, a range of single-cycle and SIMD multiplication and multiply-with-accumulate capabilities, saturating arithmetic and dedicated hardware division.

To facilitate the design of cost-sensitive devices, the Cortex-M4F processor implements tightly coupled system components that reduce processor area while significantly improving interrupt handling and system debug capabilities. The Cortex-M4F processor implements a version of the Thumb® instruction set based on Thumb-2 technology, ensuring high code density and reduced program memory requirements. The Cortex-M4F instruction set provides the exceptional performance expected of a modern 32-bit architecture, with the high code density of 8-bit and 16-bit microcontrollers.

The Cortex-M4F processor closely integrates a nested interrupt controller (NVIC), to deliver industry-leading interrupt performance. The TM4C1233C3PM NVIC includes a non-maskable interrupt (NMI) and provides eight interrupt priority levels. The tight integration of the processor core and NVIC provides fast execution of interrupt service routines (ISRs), dramatically reducing interrupt latency. The hardware stacking of registers and the ability to suspend load-multiple and store-multiple operations further reduce interrupt latency. Interrupt handlers do not require any assembler stubs which removes code overhead from the ISRs. Tail-chaining optimization also significantly reduces the overhead when switching from one ISR to another. To optimize low-power designs, the NVIC integrates with the sleep modes, including Deep-sleep mode, which enables the entire device to be rapidly powered down.

Figure 2-1. CPU Block Diagram

## 2.2 Overview

### 2.2.1 System-Level Interface

The Cortex-M4F processor provides multiple interfaces using AMBA® technology to provide high-speed, low-latency memory accesses. The core supports unaligned data accesses and implements atomic bit manipulation that enables faster peripheral controls, system spinlocks, and thread-safe Boolean data handling.

The Cortex-M4F processor has a memory protection unit (MPU) that provides fine-grain memory control, enabling applications to implement security privilege levels and separate code, data and stack on a task-by-task basis.

### 2.2.2 Integrated Configurable Debug

The Cortex-M4F processor implements a complete hardware debug solution, providing high system visibility of the processor and memory through either a traditional JTAG port or a 2-pin Serial Wire Debug (SWD) port that is ideal for microcontrollers and other small package devices. The Tiva™ C Series implementation replaces the ARM SW-DP and JTAG-DP with the ARM CoreSight™-compliant Serial Wire JTAG Debug Port (SWJ-DP) interface. The SWJ-DP interface combines the SWD and JTAG debug ports into one module. See the *ARM® Debug Interface V5 Architecture Specification* for details on SWJ-DP.

For system trace, the processor integrates an Instrumentation Trace Macrocell (ITM) alongside data watchpoints and a profiling unit. To enable simple and cost-effective profiling of the system trace events, a Serial Wire Viewer (SWV) can export a stream of software-generated messages, data trace, and profiling information through a single pin.

The Embedded Trace Macrocell (ETM) delivers unrivaled instruction trace capture in an area smaller than traditional trace units, enabling full instruction trace. For more details on the ARM ETM, see the *ARM® Embedded Trace Macrocell Architecture Specification*.

The Flash Patch and Breakpoint Unit (FPB) provides up to eight hardware breakpoint comparators that debuggers can use. The comparators in the FPB also provide remap functions for up to eight words of program code in the code memory region. This FPB enables applications stored in a read-only area of Flash memory to be patched in another area of on-chip SRAM or Flash memory. If a patch is required, the application programs the FPB to remap a number of addresses. When those addresses are accessed, the accesses are redirected to a remap table specified in the FPB configuration.

For more information on the Cortex-M4F debug capabilities, see the *ARM® Debug Interface V5 Architecture Specification*.

### 2.2.3 Trace Port Interface Unit (TPIU)

The TPIU acts as a bridge between the Cortex-M4F trace data from the ITM, and an off-chip Trace Port Analyzer, as shown in Figure 2-2 on page 64.

**Figure 2-2. TPIU Block Diagram**

### 2.2.4 Cortex-M4F System Component Details

The Cortex-M4F includes the following system components:

- SysTick

A 24-bit count-down timer that can be used as a Real-Time Operating System (RTOS) tick timer or as a simple counter (see “System Timer (SysTick)” on page 115).

- Nested Vectored Interrupt Controller (NVIC)

An embedded interrupt controller that supports low latency interrupt processing (see “Nested Vectored Interrupt Controller (NVIC)” on page 116).

- System Control Block (SCB)

The programming model interface to the processor. The SCB provides system implementation information and system control, including configuration, control, and reporting of system exceptions (see “System Control Block (SCB)” on page 117).

- Memory Protection Unit (MPU)

Improves system reliability by defining the memory attributes for different memory regions. The MPU provides up to eight different regions and an optional predefined background region (see “Memory Protection Unit (MPU)” on page 117).

- Floating-Point Unit (FPU)

Fully supports single-precision add, subtract, multiply, divide, multiply and accumulate, and square-root operations. It also provides conversions between fixed-point and floating-point data formats, and floating-point constant instructions (see “Floating-Point Unit (FPU)” on page 122).

## 2.3 Programming Model

This section describes the Cortex-M4F programming model. In addition to the individual core register descriptions, information about the processor modes and privilege levels for software execution and stacks is included.

### 2.3.1 Processor Mode and Privilege Levels for Software Execution

The Cortex-M4F has two modes of operation:

- Thread mode

Used to execute application software. The processor enters Thread mode when it comes out of reset.

- Handler mode

Used to handle exceptions. When the processor has finished exception processing, it returns to Thread mode.

In addition, the Cortex-M4F has two privilege levels:

- Unprivileged

In this mode, software has the following restrictions:

- Limited access to the `MSR` and `MRS` instructions and no use of the `CPS` instruction
- No access to the system timer, NVIC, or system control block
- Possibly restricted access to memory or peripherals

- Privileged

In this mode, software can use all the instructions and has access to all resources.

In Thread mode, the **CONTROL** register (see page 80) controls whether software execution is privileged or unprivileged. In Handler mode, software execution is always privileged.

Only privileged software can write to the **CONTROL** register to change the privilege level for software execution in Thread mode. Unprivileged software can use the `SVC` instruction to make a supervisor call to transfer control to privileged software.

### 2.3.2 Stacks

The processor uses a full descending stack, meaning that the stack pointer indicates the last stacked item on the memory. When the processor pushes a new item onto the stack, it decrements the stack pointer and then writes the item to the new memory location. The processor implements two stacks: the main stack and the process stack, with a pointer for each held in independent registers (see the **SP** register on page 70).

In Thread mode, the **CONTROL** register (see page 80) controls whether the processor uses the main stack or the process stack. In Handler mode, the processor always uses the main stack. The options for processor operations are shown in Table 2-1 on page 66.

**Table 2-1. Summary of Processor Mode, Privilege Level, and Stack Use**

| Processor Mode | Use                | Privilege Level                         | Stack Used                               |
|----------------|--------------------|-----------------------------------------|------------------------------------------|
| Thread         | Applications       | Privileged or unprivileged <sup>a</sup> | Main stack or process stack <sup>a</sup> |
| Handler        | Exception handlers | Always privileged                       | Main stack                               |

a. See **CONTROL** (page 80).

### 2.3.3 Register Map

Figure 2-3 on page 67 shows the Cortex-M4F register set. Table 2-2 on page 67 lists the Core registers. The core registers are not memory mapped and are accessed by register name, so the base address is n/a (not applicable) and there is no offset.

Figure 2-3. Cortex-M4F Register Set

Table 2-2. Processor Register Map

| Offset | Name | Type | Reset | Description                        | See page |
|--------|------|------|-------|------------------------------------|----------|
| -      | R0   | R/W  | -     | Cortex General-Purpose Register 0  | 69       |
| -      | R1   | R/W  | -     | Cortex General-Purpose Register 1  | 69       |
| -      | R2   | R/W  | -     | Cortex General-Purpose Register 2  | 69       |
| -      | R3   | R/W  | -     | Cortex General-Purpose Register 3  | 69       |
| -      | R4   | R/W  | -     | Cortex General-Purpose Register 4  | 69       |
| -      | R5   | R/W  | -     | Cortex General-Purpose Register 5  | 69       |
| -      | R6   | R/W  | -     | Cortex General-Purpose Register 6  | 69       |
| -      | R7   | R/W  | -     | Cortex General-Purpose Register 7  | 69       |
| -      | R8   | R/W  | -     | Cortex General-Purpose Register 8  | 69       |
| -      | R9   | R/W  | -     | Cortex General-Purpose Register 9  | 69       |
| -      | R10  | R/W  | -     | Cortex General-Purpose Register 10 | 69       |
| -      | R11  | R/W  | -     | Cortex General-Purpose Register 11 | 69       |

Table 2-2. Processor Register Map (continued)

| Offset | Name      | Type | Reset       | Description                        | See page |
|--------|-----------|------|-------------|------------------------------------|----------|
| -      | R12       | R/W  | -           | Cortex General-Purpose Register 12 | 69       |
| -      | SP        | R/W  | -           | Stack Pointer                      | 70       |
| -      | LR        | R/W  | 0xFFFF.FFFF | Link Register                      | 71       |
| -      | PC        | R/W  | -           | Program Counter                    | 72       |
| -      | PSR       | R/W  | 0x0100.0000 | Program Status Register            | 73       |
| -      | PRIMASK   | R/W  | 0x0000.0000 | Priority Mask Register             | 77       |
| -      | FAULTMASK | R/W  | 0x0000.0000 | Fault Mask Register                | 78       |
| -      | BASEPRI   | R/W  | 0x0000.0000 | Base Priority Mask Register        | 79       |
| -      | CONTROL   | R/W  | 0x0000.0000 | Control Register                   | 80       |
| -      | FPSC      | R/W  | -           | Floating-Point Status Control      | 82       |

### 2.3.4 Register Descriptions

This section lists and describes the Cortex-M4F registers, in the order shown in Figure 2-3 on page 67. The core registers are not memory mapped and are accessed by register name rather than offset.

**Note:** The register type shown in the register descriptions refers to type during program execution in Thread mode and Handler mode. Debug access can differ.

**Register 1: Cortex General-Purpose Register 0 (R0)**

**Register 2: Cortex General-Purpose Register 1 (R1)**

**Register 3: Cortex General-Purpose Register 2 (R2)**

**Register 4: Cortex General-Purpose Register 3 (R3)**

**Register 5: Cortex General-Purpose Register 4 (R4)**

**Register 6: Cortex General-Purpose Register 5 (R5)**

**Register 7: Cortex General-Purpose Register 6 (R6)**

**Register 8: Cortex General-Purpose Register 7 (R7)**

**Register 9: Cortex General-Purpose Register 8 (R8)**

**Register 10: Cortex General-Purpose Register 9 (R9)**

**Register 11: Cortex General-Purpose Register 10 (R10)**

**Register 12: Cortex General-Purpose Register 11 (R11)**

**Register 13: Cortex General-Purpose Register 12 (R12)**

The **Rn** registers are 32-bit general-purpose registers for data operations and can be accessed from either privileged or unprivileged mode.

#### Cortex General-Purpose Register 0 (R0)

Type R/W, reset -

|       | 31   | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|-------|------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
|       | DATA |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| Type  | R/W  | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset | -    | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   |
|       | 15   | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|       | DATA |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| Type  | R/W  | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset | -    | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   |

| Bit/Field | Name | Type | Reset | Description    |
|-----------|------|------|-------|----------------|
| 31:0      | DATA | R/W  | -     | Register data. |

### Register 14: Stack Pointer (SP)

The **Stack Pointer (SP)** is register R13. In Thread mode, the function of this register changes depending on the `ASP` bit in the **Control Register (CONTROL)** register. When the `ASP` bit is clear, this register is the **Main Stack Pointer (MSP)**. When the `ASP` bit is set, this register is the **Process Stack Pointer (PSP)**. On reset, the `ASP` bit is clear, and the processor loads the **MSP** with the value from address `0x0000.0000`. The **MSP** can only be accessed in privileged mode; the **PSP** can be accessed in either privileged or unprivileged mode.

#### Stack Pointer (SP)

Type R/W, reset -

| Bit/Field | Name | Type | Reset | Description                                     |
|-----------|------|------|-------|-------------------------------------------------|
| 31:0      | SP   | R/W  | -     | This field is the address of the stack pointer. |

## Register 15: Link Register (LR)

The **Link Register (LR)** is register R14, and it stores the return information for subroutines, function calls, and exceptions. The Link Register can be accessed from either privileged or unprivileged mode.

EXC\_RETURN is loaded into the **LR** on exception entry. See Table 2-10 on page 103 for the values and description.

### Link Register (LR)

Type R/W, reset 0xFFFF.FFFF

|       |      |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|-------|------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
|       | 31   | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|       | LINK |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| Type  | R/W  | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset | 1    | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   |
|       | 15   | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|       | LINK |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| Type  | R/W  | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset | 1    | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   |

| Bit/Field | Name | Type | Reset       | Description                       |
|-----------|------|------|-------------|-----------------------------------|
| 31:0      | LINK | R/W  | 0xFFFF.FFFF | This field is the return address. |

### Register 16: Program Counter (PC)

The **Program Counter (PC)** is register R15, and it contains the current program address. On reset, the processor loads the **PC** with the value of the reset vector, which is at address 0x0000.0004. Bit 0 of the reset vector is loaded into the **THUMB** bit of the **EPSR** at reset and must be 1. The **PC** register can be accessed in either privileged or unprivileged mode.

#### Program Counter (PC)

Type R/W, reset -

| Bit/Field | Name | Type | Reset | Description                                |
|-----------|------|------|-------|--------------------------------------------|
| 31:0      | PC   | R/W  | -     | This field is the current program address. |

## Register 17: Program Status Register (PSR)

**Note:** This register is also referred to as **xPSR**.

The **Program Status Register (PSR)** has three functions, and the register bits are assigned to the different functions:

- **Application Program Status Register (APSR)**, bits 31:27, bits 19:16
- **Execution Program Status Register (EPSR)**, bits 26:24, 15:10
- **Interrupt Program Status Register (IPSR)**, bits 7:0

The **PSR**, **IPSR**, and **EPSR** registers can only be accessed in privileged mode; the **APSR** register can be accessed in either privileged or unprivileged mode.

**APSR** contains the current state of the condition flags from previous instruction executions.

**EPSR** contains the Thumb state bit and the execution state bits for the If-Then (**IT**) instruction or the Interruptible-Continuable Instruction (**ICI**) field for an interrupted load multiple or store multiple instruction. Attempts to read the **EPSR** directly through application software using the **MSR** instruction always return zero. Attempts to write the **EPSR** using the **MSR** instruction in application software are always ignored. Fault handlers can examine the **EPSR** value in the stacked **PSR** to determine the operation that faulted (see “Exception Entry and Return” on page 100).

**IPSR** contains the exception type number of the current Interrupt Service Routine (**ISR**).

These registers can be accessed individually or as a combination of any two or all three registers, using the register name as an argument to the **MSR** or **MRS** instructions. For example, all of the registers can be read using **PSR** with the **MRS** instruction, or **APSR** only can be written to using **APSR** with the **MSR** instruction. page 73 shows the possible register combinations for the **PSR**. See the **MRS** and **MSR** instruction descriptions in the Cortex™-M4 instruction set chapter in the *ARM® Cortex™-M4 Devices Generic User Guide (literature number ARM DUI 0553A)* for more information about how to access the program status registers.

**Table 2-3. PSR Register Combinations**

| Register     | Type                | Combination                                 |
|--------------|---------------------|---------------------------------------------|
| <b>PSR</b>   | R/W <sup>a, b</sup> | <b>APSR</b> , <b>EPSR</b> , and <b>IPSR</b> |
| <b>IEPSR</b> | RO                  | <b>EPSR</b> and <b>IPSR</b>                 |
| <b>IAPSR</b> | R/W <sup>a</sup>    | <b>APSR</b> and <b>IPSR</b>                 |
| <b>EAPSR</b> | R/W <sup>b</sup>    | <b>APSR</b> and <b>EPSR</b>                 |

a. The processor ignores writes to the **IPSR** bits.

b. Reads of the **EPSR** bits return zero, and the processor ignores writes to these bits.

### Program Status Register (PSR)

Type R/W, reset 0x0100.0000

|       | 31       | 30  | 29  | 28  | 27       | 26       | 25    | 24       | 23     | 22 | 21 | 20 | 19  | 18  | 17  | 16  |

| 0x9A      | Interrupt Vector 138    |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |       |             |      |             |      |          |      |     |      |            |      |                         |      |           |      |             |           |          |      |         |      |                    |      |          |      |        |      |         |      |                    |      |                    |     |     |      |                      |

## Register 18: Priority Mask Register (PRIMASK)

The **PRIMASK** register prevents activation of all exceptions with programmable priority. Reset, non-maskable interrupt (NMI), and hard fault are the only exceptions with fixed priority. Exceptions should be disabled when they might impact the timing of critical tasks. This register is only accessible in privileged mode. The **MSR** and **MRS** instructions are used to access the **PRIMASK** register, and the **CPS** instruction may be used to change the value of the **PRIMASK** register. See the Cortex™-M4 instruction set chapter in the *ARM® Cortex™-M4 Devices Generic User Guide (literature number ARM DUI 0553A)* for more information on these instructions. For more information on exception priority levels, see “Exception Types” on page 94.

### Register 19: Fault Mask Register (FAULTMASK)

The **FAULTMASK** register prevents activation of all exceptions except for the Non-Maskable Interrupt (NMI). Exceptions should be disabled when they might impact the timing of critical tasks. This register is only accessible in privileged mode. The **MSR** and **MRS** instructions are used to access the **FAULTMASK** register, and the **CPS** instruction may be used to change the value of the **FAULTMASK** register. See the Cortex™-M4 instruction set chapter in the *ARM® Cortex™-M4 Devices Generic User Guide (literature number ARM DUI 0553A)* for more information on these instructions. For more information on exception priority levels, see “Exception Types” on page 94.

|-----------|-----------|------|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:1      | reserved  | RO   | 0x0000.000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 0         | FAULTMASK | R/W  | 0          | Fault Mask                                                                                                                                                                                    |

| Value | Description                                               |
|-------|-----------------------------------------------------------|
| 1     | Prevents the activation of all exceptions except for NMI. |
| 0     | No effect.                                                |

The processor clears the **FAULTMASK** bit on exit from any exception handler except the NMI handler.

## Register 20: Base Priority Mask Register (BASEPRI)

The **BASEPRI** register defines the minimum priority for exception processing. When **BASEPRI** is set to a nonzero value, it prevents the activation of all exceptions with the same or lower priority level as the **BASEPRI** value. Exceptions should be disabled when they might impact the timing of critical tasks. This register is only accessible in privileged mode. For more information on exception priority levels, see “Exception Types” on page 94.

### Register 21: Control Register (CONTROL)

The **CONTROL** register controls the stack used and the privilege level for software execution when the processor is in Thread mode, and indicates whether the FPU state is active. This register is only accessible in privileged mode.

Handler mode always uses the **MSP**, so the processor ignores explicit writes to the **ASP** bit of the **CONTROL** register when in Handler mode. The exception entry and return mechanisms automatically update the **CONTROL** register based on the **EXC\_RETURN** value (see Table 2-10 on page 103). In an OS environment, threads running in Thread mode should use the process stack and the kernel and exception handlers should use the main stack. By default, Thread mode uses the **MSP**. To switch the stack pointer used in Thread mode to the **PSP**, either use the **MSR** instruction to set the **ASP** bit, as detailed in the Cortex™-M4 instruction set chapter in the *ARM® Cortex™-M4 Devices Generic User Guide (literature number ARM DUI 0553A)*, or perform an exception return to Thread mode with the appropriate **EXC\_RETURN** value, as shown in Table 2-10 on page 103.

**Note:** When changing the stack pointer, software must use an **ISB** instruction immediately after the **MSR** instruction, ensuring that instructions after the **ISB** execute use the new stack pointer. See the Cortex™-M4 instruction set chapter in the *ARM® Cortex™-M4 Devices Generic User Guide (literature number ARM DUI 0553A)*.

The Cortex-M4F uses this bit to determine whether to preserve floating-point state when processing an exception.

**Important:** Two bits control when **FPCA** can be enabled: the **ASPEN** bit in the **Floating-Point Context Control (FPCC)** register and the **DISFPCA** bit in the **Auxiliary Control (ACTLR)** register.

### 2.3.5 Exceptions and Interrupts

The Cortex-M4F processor supports interrupts and system exceptions. The processor and the Nested Vectored Interrupt Controller (NVIC) prioritize and handle all exceptions. An exception changes the normal flow of software control. The processor uses Handler mode to handle all exceptions except for reset. See “Exception Entry and Return” on page 100 for more information.

The NVIC registers control interrupt handling. See “Nested Vectored Interrupt Controller (NVIC)” on page 116 for more information.

### 2.3.6 Data Types

The Cortex-M4F supports 32-bit words, 16-bit halfwords, and 8-bit bytes. The processor also supports 64-bit data transfer instructions. All instruction and data memory accesses are little endian. See “Memory Regions, Types and Attributes” on page 86 for more information.

## 2.4 Memory Model

This section describes the processor memory map, the behavior of memory accesses, and the bit-banding features. The processor has a fixed memory map that provides up to 4 GB of addressable memory.

The memory map for the TM4C1233C3PM controller is provided in Table 2-4 on page 84. In this manual, register addresses are given as a hexadecimal increment, relative to the module’s base address as shown in the memory map.

The regions for SRAM and peripherals include bit-band regions. Bit-banding provides atomic operations to bit data (see “Bit-Banding” on page 89).

The processor reserves regions of the Private peripheral bus (PPB) address range for core peripheral registers (see “Cortex-M4 Peripherals” on page 114).

**Note:** Within the memory map, attempts to read or write addresses in reserved spaces result in a bus fault. In addition, attempts to write addresses in the flash range also result in a bus fault.

**Table 2-4. Memory Map**

### 2.4.1 Memory Regions, Types and Attributes

The memory map and the programming of the MPU split the memory map into regions. Each region has a defined memory type, and some regions have additional memory attributes. The memory type and attributes determine the behavior of accesses to the region.

The memory types are:

- Normal: The processor can re-order transactions for efficiency and perform speculative reads.
- Device: The processor preserves transaction order relative to other transactions to Device or Strongly Ordered memory.

- Strongly Ordered: The processor preserves transaction order relative to all other transactions.

The different ordering requirements for Device and Strongly Ordered memory mean that the memory system can buffer a write to Device memory but must not buffer a write to Strongly Ordered memory.

An additional memory attribute is Execute Never (XN), which means the processor prevents instruction accesses. A fault exception is generated only on execution of an instruction executed from an XN region.

## 2.4.2 Memory System Ordering of Memory Accesses

For most memory accesses caused by explicit memory access instructions, the memory system does not guarantee that the order in which the accesses complete matches the program order of the instructions, providing the order does not affect the behavior of the instruction sequence. Normally, if correct program execution depends on two memory accesses completing in program order, software must insert a memory barrier instruction between the memory access instructions (see “Software Ordering of Memory Accesses” on page 88).

However, the memory system does guarantee ordering of accesses to Device and Strongly Ordered memory. For two memory access instructions A1 and A2, if both A1 and A2 are accesses to either Device or Strongly Ordered memory, and if A1 occurs before A2 in program order, A1 is always observed before A2.

## 2.4.3 Behavior of Memory Accesses

Table 2-5 on page 87 shows the behavior of accesses to each region in the memory map. See “Memory Regions, Types and Attributes” on page 86 for more information on memory types and the XN attribute. Tiva™ C Series devices may have reserved memory areas within the address ranges shown below (refer to Table 2-4 on page 84 for more information).

**Table 2-5. Memory Access Behavior**

| Address Range             | Memory Region          | Memory Type      | Execute Never (XN) | Description                                                                                                                                          |
|---------------------------|------------------------|------------------|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x0000.0000 - 0x1FFF.FFFF | Code                   | Normal           | -                  | This executable region is for program code. Data can also be stored here.                                                                            |
| 0x2000.0000 - 0x3FFF.FFFF | SRAM                   | Normal           | -                  | This executable region is for data. Code can also be stored here. This region includes bit band and bit band alias areas (see Table 2-6 on page 89). |
| 0x4000.0000 - 0x5FFF.FFFF | Peripheral             | Device           | XN                 | This region includes bit band and bit band alias areas (see Table 2-7 on page 89).                                                                   |
| 0x6000.0000 - 0x9FFF.FFFF | External RAM           | Normal           | -                  | This executable region is for data.                                                                                                                  |
| 0xA000.0000 - 0xDFFF.FFFF | External device        | Device           | XN                 | This region is for external device memory.                                                                                                           |
| 0xE000.0000- 0xE00F.FFFF  | Private peripheral bus | Strongly Ordered | XN                 | This region includes the NVIC, system timer, and system control block.                                                                               |
| 0xE010.0000- 0xFFFF.FFFF  | Reserved               | -                | -                  | -                                                                                                                                                    |

The Code, SRAM, and external RAM regions can hold programs. However, it is recommended that programs always use the Code region because the Cortex-M4F has separate buses that can perform instruction fetches and data accesses simultaneously.

The MPU can override the default memory access behavior described in this section. For more information, see “Memory Protection Unit (MPU)” on page 117.

The Cortex-M4F prefetches instructions ahead of execution and speculatively prefetches from branch target addresses.

#### 2.4.4 Software Ordering of Memory Accesses

The order of instructions in the program flow does not always guarantee the order of the corresponding memory transactions for the following reasons:

- The processor can reorder some memory accesses to improve efficiency, providing this does not affect the behavior of the instruction sequence.
- The processor has multiple bus interfaces.
- Memory or devices in the memory map have different wait states.
- Some memory accesses are buffered or speculative.

“Memory System Ordering of Memory Accesses” on page 87 describes the cases where the memory system guarantees the order of memory accesses. Otherwise, if the order of memory accesses is critical, software must include memory barrier instructions to force that ordering. The Cortex-M4F has the following memory barrier instructions:

- The Data Memory Barrier (DMB) instruction ensures that outstanding memory transactions complete before subsequent memory transactions.
- The Data Synchronization Barrier (DSB) instruction ensures that outstanding memory transactions complete before subsequent instructions execute.
- The Instruction Synchronization Barrier (ISB) instruction ensures that the effect of all completed memory transactions is recognizable by subsequent instructions.

Memory barrier instructions can be used in the following situations:

- MPU programming
  - If the MPU settings are changed and the change must be effective on the very next instruction, use a DSB instruction to ensure the effect of the MPU takes place immediately at the end of context switching.
  - Use an ISB instruction to ensure the new MPU setting takes effect immediately after programming the MPU region or regions, if the MPU configuration code was accessed using a branch or call. If the MPU configuration code is entered using exception mechanisms, then an ISB instruction is not required.
- Vector table

If the program changes an entry in the vector table and then enables the corresponding exception, use a DMB instruction between the operations. The DMB instruction ensures that if the exception is taken immediately after being enabled, the processor uses the new exception vector.
- Self-modifying code

If a program contains self-modifying code, use an ISB instruction immediately after the code modification in the program. The ISB instruction ensures subsequent instruction execution uses the updated program.

- Memory map switching

If the system contains a memory map switching mechanism, use a `DSB` instruction after switching the memory map in the program. The `DSB` instruction ensures subsequent instruction execution uses the updated memory map.

- Dynamic exception priority change

When an exception priority has to change when the exception is pending or active, use `DSB` instructions after the change. The change then takes effect on completion of the `DSB` instruction.

Memory accesses to Strongly Ordered memory, such as the System Control Block, do not require the use of `DMB` instructions.

For more information on the memory barrier instructions, see the Cortex™-M4 instruction set chapter in the *ARM® Cortex™-M4 Devices Generic User Guide* (literature number [ARM DUI 0553A](#)).

## 2.4.5 Bit-Banding

A bit-band region maps each word in a bit-band alias region to a single bit in the bit-band region. The bit-band regions occupy the lowest 1 MB of the SRAM and peripheral memory regions. Accesses to the 32-MB SRAM alias region map to the 1-MB SRAM bit-band region, as shown in Table 2-6 on page 89. Accesses to the 32-MB peripheral alias region map to the 1-MB peripheral bit-band region, as shown in Table 2-7 on page 89. For the specific address range of the bit-band regions, see Table 2-4 on page 84.

**Note:** A word access to the SRAM or the peripheral bit-band alias region maps to a single bit in the SRAM or peripheral bit-band region.

A word access to a bit band address results in a word access to the underlying memory, and similarly for halfword and byte accesses. This allows bit band accesses to match the access requirements of the underlying peripheral.

**Table 2-6. SRAM Memory Bit-Banding Regions**

| Address Range |             | Memory Region        | Instruction and Data Accesses                                                                                                                             |
|---------------|-------------|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Start         | End         |                      |                                                                                                                                                           |
| 0x2000.0000   | 0x2000.2FFF | SRAM bit-band region | Direct accesses to this memory range behave as SRAM memory accesses, but this region is also bit addressable through bit-band alias.                      |
| 0x2200.0000   | 0x2205.FFFF | SRAM bit-band alias  | Data accesses to this region are remapped to bit band region. A write operation is performed as read-modify-write. Instruction accesses are not remapped. |

**Table 2-7. Peripheral Memory Bit-Banding Regions**

| Address Range |             | Memory Region              | Instruction and Data Accesses                                                                                                                              |
|---------------|-------------|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Start         | End         |                            |                                                                                                                                                            |
| 0x4000.0000   | 0x400F.FFFF | Peripheral bit-band region | Direct accesses to this memory range behave as peripheral memory accesses, but this region is also bit addressable through bit-band alias.                 |
| 0x4200.0000   | 0x43FF.FFFF | Peripheral bit-band alias  | Data accesses to this region are remapped to bit band region. A write operation is performed as read-modify-write. Instruction accesses are not permitted. |

The following formula shows how the alias region maps onto the bit-band region:

$$\text{bit\_word\_offset} = (\text{byte\_offset} \times 32) + (\text{bit\_number} \times 4)$$

$$\text{bit\_word\_addr} = \text{bit\_band\_base} + \text{bit\_word\_offset}$$

where:

**bit\_word\_offset**

The position of the target bit in the bit-band memory region.

**bit\_word\_addr**

The address of the word in the alias memory region that maps to the targeted bit.

**bit\_band\_base**

The starting address of the alias region.

**byte\_offset**

The number of the byte in the bit-band region that contains the targeted bit.

**bit\_number**

The bit position, 0-7, of the targeted bit.

Figure 2-4 on page 91 shows examples of bit-band mapping between the SRAM bit-band alias region and the SRAM bit-band region:

- The alias word at 0x23FF.FFE0 maps to bit 0 of the bit-band byte at 0x200F.FFFF:

$$0x23FF.FFE0 = 0x2200.0000 + (0x000F.FFFF * 32) + (0 * 4)$$

- The alias word at 0x23FF.FFFC maps to bit 7 of the bit-band byte at 0x200F.FFFF:

$$0x23FF.FFFC = 0x2200.0000 + (0x000F.FFFF * 32) + (7 * 4)$$

- The alias word at 0x2200.0000 maps to bit 0 of the bit-band byte at 0x2000.0000:

$$0x2200.0000 = 0x2200.0000 + (0 * 32) + (0 * 4)$$

- The alias word at 0x2200.001C maps to bit 7 of the bit-band byte at 0x2000.0000:

$$0x2200.001C = 0x2200.0000 + (0 * 32) + (7 * 4)$$

Figure 2-4. Bit-Band Mapping

#### 2.4.5.1 Directly Accessing an Alias Region

Writing to a word in the alias region updates a single bit in the bit-band region.

Bit 0 of the value written to a word in the alias region determines the value written to the targeted bit in the bit-band region. Writing a value with bit 0 set writes a 1 to the bit-band bit, and writing a value with bit 0 clear writes a 0 to the bit-band bit.

Bits 31:1 of the alias word have no effect on the bit-band bit. Writing 0x01 has the same effect as writing 0xFF. Writing 0x00 has the same effect as writing 0x0E.

When reading a word in the alias region, 0x0000.0000 indicates that the targeted bit in the bit-band region is clear and 0x0000.0001 indicates that the targeted bit in the bit-band region is set.

#### 2.4.5.2 Directly Accessing a Bit-Band Region

“Behavior of Memory Accesses” on page 87 describes the behavior of direct byte, halfword, or word accesses to the bit-band regions.

#### 2.4.6 Data Storage

The processor views memory as a linear collection of bytes numbered in ascending order from zero. For example, bytes 0-3 hold the first stored word, and bytes 4-7 hold the second stored word. Data is stored in little-endian format, with the least-significant byte (lsbyte) of a word stored at the lowest-numbered byte, and the most-significant byte (msbyte) stored at the highest-numbered byte. Figure 2-5 on page 92 illustrates how data is stored.

Figure 2-5. Data Storage

## 2.4.7 Synchronization Primitives

The Cortex-M4F instruction set includes pairs of synchronization primitives which provide a non-blocking mechanism that a thread or process can use to obtain exclusive access to a memory location. Software can use these primitives to perform a guaranteed read-modify-write memory update sequence or for a semaphore mechanism.

A pair of synchronization primitives consists of:

- A Load-Exclusive instruction, which is used to read the value of a memory location and requests exclusive access to that location.
- A Store-Exclusive instruction, which is used to attempt to write to the same memory location and returns a status bit to a register. If this status bit is clear, it indicates that the thread or process gained exclusive access to the memory and the write succeeds; if this status bit is set, it indicates that the thread or process did not gain exclusive access to the memory and no write was performed.

The pairs of Load-Exclusive and Store-Exclusive instructions are:

- The word instructions `LDREX` and `STREX`
- The halfword instructions `LDREXH` and `STREXH`
- The byte instructions `LDREXB` and `STREXB`

Software must use a Load-Exclusive instruction with the corresponding Store-Exclusive instruction.

To perform an exclusive read-modify-write of a memory location, software must:

1. Use a Load-Exclusive instruction to read the value of the location.
2. Modify the value, as required.
3. Use a Store-Exclusive instruction to attempt to write the new value back to the memory location.
4. Test the returned status bit.

If the status bit is clear, the read-modify-write completed successfully. If the status bit is set, no write was performed, which indicates that the value returned at step 1 might be out of date. The software must retry the entire read-modify-write sequence.

Software can use the synchronization primitives to implement a semaphore as follows:

1. Use a Load-Exclusive instruction to read from the semaphore address to check whether the semaphore is free.
2. If the semaphore is free, use a Store-Exclusive to write the claim value to the semaphore address.
3. If the returned status bit from step 2 indicates that the Store-Exclusive succeeded, then the software has claimed the semaphore. However, if the Store-Exclusive failed, another process might have claimed the semaphore after the software performed step 1.

The Cortex-M4F includes an exclusive access monitor that tags the fact that the processor has executed a Load-Exclusive instruction. The processor removes its exclusive access tag if:

- It executes a CLREX instruction.
- It executes a Store-Exclusive instruction, regardless of whether the write succeeds.
- An exception occurs, which means the processor can resolve semaphore conflicts between different threads.

For more information about the synchronization primitive instructions, see the Cortex™-M4 instruction set chapter in the *ARM® Cortex™-M4 Devices Generic User Guide* (literature number [ARM DUI 0553A](#)).

## 2.5 Exception Model

The ARM Cortex-M4F processor and the Nested Vectored Interrupt Controller (NVIC) prioritize and handle all exceptions in Handler Mode. The processor state is automatically stored to the stack on an exception and automatically restored from the stack at the end of the Interrupt Service Routine (ISR). The vector is fetched in parallel to the state saving, enabling efficient interrupt entry. The processor supports tail-chaining, which enables back-to-back interrupts to be performed without the overhead of state saving and restoration.

Table 2-8 on page 95 lists all exception types. Software can set eight priority levels on seven of these exceptions (system handlers) as well as on 65 interrupts (listed in Table 2-9 on page 96).

Priorities on the system handlers are set with the NVIC **System Handler Priority n (SYSPRIn)** registers. Interrupts are enabled through the NVIC **Interrupt Set Enable n (ENn)** register and prioritized with the NVIC **Interrupt Priority n (PRIn)** registers. Priorities can be grouped by splitting priority levels into preemption priorities and subpriorities. All the interrupt registers are described in “Nested Vectored Interrupt Controller (NVIC)” on page 116.

Internally, the highest user-programmable priority (0) is treated as fourth priority, after a Reset, Non-Maskable Interrupt (NMI), and a Hard Fault, in that order. Note that 0 is the default priority for all the programmable priorities.

---

**Important:** After a write to clear an interrupt source, it may take several processor cycles for the NVIC to see the interrupt source deassert. Thus if the interrupt clear is done as the last action in an interrupt handler, it is possible for the interrupt handler to complete while the NVIC sees the interrupt as still asserted, causing the interrupt handler to be re-entered errantly. This situation can be avoided by either clearing the interrupt source at the beginning of the interrupt handler or by performing a read or write after the write to clear the interrupt source (and flush the write buffer).

---

See “Nested Vectored Interrupt Controller (NVIC)” on page 116 for more information on exceptions and interrupts.

## 2.5.1 Exception States

Each exception is in one of the following states:

- **Inactive.** The exception is not active and not pending.
- **Pending.** The exception is waiting to be serviced by the processor. An interrupt request from a peripheral or from software can change the state of the corresponding interrupt to pending.
- **Active.** An exception that is being serviced by the processor but has not completed.  
**Note:** An exception handler can interrupt the execution of another exception handler. In this case, both exceptions are in the active state.
- **Active and Pending.** The exception is being serviced by the processor, and there is a pending exception from the same source.

## 2.5.2 Exception Types

The exception types are:

- **Reset.** Reset is invoked on power up or a warm reset. The exception model treats reset as a special form of exception. When reset is asserted, the operation of the processor stops, potentially at any point in an instruction. When reset is deasserted, execution restarts from the address provided by the reset entry in the vector table. Execution restarts as privileged execution in Thread mode.
- **NMI.** A non-maskable Interrupt (NMI) can be signaled using the NMI signal or triggered by software using the **Interrupt Control and State (INTCTRL)** register. This exception has the highest priority other than reset. NMI is permanently enabled and has a fixed priority of -2. NMIs cannot be masked or prevented from activation by any other exception or preempted by any exception other than reset.
- **Hard Fault.** A hard fault is an exception that occurs because of an error during exception processing, or because an exception cannot be managed by any other exception mechanism. Hard faults have a fixed priority of -1, meaning they have higher priority than any exception with configurable priority.
- **Memory Management Fault.** A memory management fault is an exception that occurs because of a memory protection related fault, including access violation and no match. The MPU or the fixed memory protection constraints determine this fault, for both instruction and data memory transactions. This fault is used to abort instruction accesses to Execute Never (XN) memory regions, even if the MPU is disabled.
- **Bus Fault.** A bus fault is an exception that occurs because of a memory-related fault for an instruction or data memory transaction such as a prefetch fault or a memory access fault. This fault can be enabled or disabled.
- **Usage Fault.** A usage fault is an exception that occurs because of a fault related to instruction execution, such as:
  - An undefined instruction
  - An illegal unaligned access
  - Invalid state on instruction execution

- An error on exception return

An unaligned address on a word or halfword memory access or division by zero can cause a usage fault when the core is properly configured.

- **SVC**Call. A supervisor call (SVC) is an exception that is triggered by the SVC instruction. In an OS environment, applications can use SVC instructions to access OS kernel functions and device drivers.
- **Debug Monitor**. This exception is caused by the debug monitor (when not halting). This exception is only active when enabled. This exception does not activate if it is a lower priority than the current activation.
- **PendSV**. PendSV is a pendable, interrupt-driven request for system-level service. In an OS environment, use PendSV for context switching when no other exception is active. PendSV is triggered using the **Interrupt Control and State (INTCTRL)** register.
- **SysTick**. A SysTick exception is an exception that the system timer generates when it reaches zero when it is enabled to generate an interrupt. Software can also generate a SysTick exception using the **Interrupt Control and State (INTCTRL)** register. In an OS environment, the processor can use this exception as system tick.
- **Interrupt (IRQ)**. An interrupt, or IRQ, is an exception signaled by a peripheral or generated by a software request and fed through the NVIC (prioritized). All interrupts are asynchronous to instruction execution. In the system, peripherals use interrupts to communicate with the processor. Table 2-9 on page 96 lists the interrupts on the TM4C1233C3PM controller.

For an asynchronous exception, other than reset, the processor can execute another instruction between when the exception is triggered and when the processor enters the exception handler.

Privileged software can disable the exceptions that Table 2-8 on page 95 shows as having configurable priority (see the **SYSHNDCTRL** register on page 165 and the **DIS0** register on page 136).

For more information about hard faults, memory management faults, bus faults, and usage faults, see “Fault Handling” on page 103.

**Table 2-8. Exception Types**

| Exception Type               | Vector Number | Priority <sup>a</sup>     | Vector Address or Offset <sup>b</sup> | Activation                                                             |
|------------------------------|---------------|---------------------------|---------------------------------------|------------------------------------------------------------------------|
| -                            | 0             | -                         | 0x0000.0000                           | Stack top is loaded from the first entry of the vector table on reset. |
| Reset                        | 1             | -3 (highest)              | 0x0000.0004                           | Asynchronous                                                           |
| Non-Maskable Interrupt (NMI) | 2             | -2                        | 0x0000.0008                           | Asynchronous                                                           |
| Hard Fault                   | 3             | -1                        | 0x0000.000C                           | -                                                                      |

### 2.5.3 Exception Handlers

The processor handles exceptions using:

- **Interrupt Service Routines (ISRs).** Interrupts (IRQx) are the exceptions handled by ISRs.
- **Fault Handlers.** Hard fault, memory management fault, usage fault, and bus fault are fault exceptions handled by the fault handlers.
- **System Handlers.** NMI, PendSV, SVCcall, SysTick, and the fault exceptions are all system exceptions that are handled by system handlers.

### 2.5.4 Vector Table

The vector table contains the reset value of the stack pointer and the start addresses, also called exception vectors, for all exception handlers. The vector table is constructed using the vector address or offset shown in Table 2-8 on page 95. Figure 2-6 on page 99 shows the order of the exception vectors in the vector table. The least-significant bit of each vector must be 1, indicating that the exception handler is Thumb code

**Figure 2-6. Vector Table**

| Exception number | IRQ number | Offset | Vector                  |
|------------------|------------|--------|-------------------------|
| 154              | 138        | 0x0268 | IRQ131                  |

| 8                |            |        |                         |
| 7                |            |        |                         |
| 6                | -10        | 0x0018 | Usage fault             |
| 5                | -11        | 0x0014 | Bus fault               |
| 4                | -12        | 0x0010 | Memory management fault |
| 3                | -13        | 0x000C | Hard fault              |
| 2                | -14        | 0x0008 | NMI                     |
| 1                |            | 0x0004 | Reset                   |
|                  |            | 0x0000 | Initial SP value        |

On system reset, the vector table is fixed at address 0x0000.0000. Privileged software can write to the **Vector Table Offset (VTABLE)** register to relocate the vector table start address to a different memory location, in the range 0x0000.0400 to 0x3FFF.FC00 (see “Vector Table” on page 98). Note that when configuring the **VTABLE** register, the offset must be aligned on a 1024-byte boundary.

### 2.5.5 Exception Priorities

As Table 2-8 on page 95 shows, all exceptions have an associated priority, with a lower priority value indicating a higher priority and configurable priorities for all exceptions except Reset, Hard fault, and NMI. If software does not configure any priorities, then all exceptions with a configurable priority have a priority of 0. For information about configuring exception priorities, see page 162 and page 144.

**Note:** Configurable priority values for the Tiva™ C Series implementation are in the range 0-7. This means that the Reset, Hard fault, and NMI exceptions, with fixed negative priority values, always have higher priority than any other exception.

For example, assigning a higher priority value to IRQ[0] and a lower priority value to IRQ[1] means that IRQ[1] has higher priority than IRQ[0]. If both IRQ[1] and IRQ[0] are asserted, IRQ[1] is processed before IRQ[0].

If multiple pending exceptions have the same priority, the pending exception with the lowest exception number takes precedence. For example, if both IRQ[0] and IRQ[1] are pending and have the same priority, then IRQ[0] is processed before IRQ[1].

When the processor is executing an exception handler, the exception handler is preempted if a higher priority exception occurs. If an exception occurs with the same priority as the exception being handled, the handler is not preempted, irrespective of the exception number. However, the status of the new interrupt changes to pending.

### 2.5.6 Interrupt Priority Grouping

To increase priority control in systems with interrupts, the NVIC supports priority grouping. This grouping divides each interrupt priority register entry into two fields:

- An upper field that defines the group priority
- A lower field that defines a subpriority within the group

Only the group priority determines preemption of interrupt exceptions. When the processor is executing an interrupt exception handler, another interrupt with the same group priority as the interrupt being handled does not preempt the handler.

If multiple pending interrupts have the same group priority, the subpriority field determines the order in which they are processed. If multiple pending interrupts have the same group priority and subpriority, the interrupt with the lowest IRQ number is processed first.

For information about splitting the interrupt priority fields into group priority and subpriority, see page 156.

### 2.5.7 Exception Entry and Return

Descriptions of exception handling use the following terms:

- **Preemption.** When the processor is executing an exception handler, an exception can preempt the exception handler if its priority is higher than the priority of the exception being handled. See “Interrupt Priority Grouping” on page 100 for more information about preemption by an interrupt. When one exception preempts another, the exceptions are called nested exceptions. See “Exception Entry” on page 101 for more information.
- **Return.** Return occurs when the exception handler is completed, and there is no pending exception with sufficient priority to be serviced and the completed exception handler was not handling a late-arriving exception. The processor pops the stack and restores the processor state to the state it had before the interrupt occurred. See “Exception Return” on page 102 for more information.
- **Tail-Chaining.** This mechanism speeds up exception servicing. On completion of an exception handler, if there is a pending exception that meets the requirements for exception entry, the stack pop is skipped and control transfers to the new exception handler.
- **Late-Arriving.** This mechanism speeds up preemption. If a higher priority exception occurs during state saving for a previous exception, the processor switches to handle the higher priority exception and initiates the vector fetch for that exception. State saving is not affected by late arrival because the state saved is the same for both exceptions. Therefore, the state saving continues uninterrupted. The processor can accept a late arriving exception until the first instruction of the exception handler of the original exception enters the execute stage of the processor. On

return from the exception handler of the late-arriving exception, the normal tail-chaining rules apply.

### 2.5.7.1 Exception Entry

Exception entry occurs when there is a pending exception with sufficient priority and either the processor is in Thread mode or the new exception is of higher priority than the exception being handled, in which case the new exception preempts the original exception.

When one exception preempts another, the exceptions are nested.

Sufficient priority means the exception has more priority than any limits set by the mask registers (see **PRIMASK** on page 77, **FAULTMASK** on page 78, and **BASEPRI** on page 79). An exception with less priority than this is pending but is not handled by the processor.

When the processor takes an exception, unless the exception is a tail-chained or a late-arriving exception, the processor pushes information onto the current stack. This operation is referred to as *stacking* and the structure of eight data words is referred to as *stack frame*.

When using floating-point routines, the Cortex-M4F processor automatically stacks the architected floating-point state on exception entry. Figure 2-7 on page 102 shows the Cortex-M4F stack frame layout when floating-point state is preserved on the stack as the result of an interrupt or an exception.

**Note:** Where stack space for floating-point state is not allocated, the stack frame is the same as that of ARMv7-M implementations without an FPU. Figure 2-7 on page 102 shows this stack frame also.

Figure 2-7. Exception Stack Frame

Immediately after stacking, the stack pointer indicates the lowest address in the stack frame.

The stack frame includes the return address, which is the address of the next instruction in the interrupted program. This value is restored to the **PC** at exception return so that the interrupted program resumes.

In parallel with the stacking operation, the processor performs a vector fetch that reads the exception handler start address from the vector table. When stacking is complete, the processor starts executing the exception handler. At the same time, the processor writes an **EXC\_RETURN** value to the **LR**, indicating which stack pointer corresponds to the stack frame and what operation mode the processor was in before the entry occurred.

If no higher-priority exception occurs during exception entry, the processor starts executing the exception handler and automatically changes the status of the corresponding pending interrupt to active.

If another higher-priority exception occurs during exception entry, known as late arrival, the processor starts executing the exception handler for this exception and does not change the pending status of the earlier exception.

### 2.5.7.2 Exception Return

Exception return occurs when the processor is in Handler mode and executes one of the following instructions to load the **EXC\_RETURN** value into the **PC**:

- An `LDM` or `POP` instruction that loads the **PC**
- A `BX` instruction using any register
- An `LDR` instruction with the **PC** as the destination

`EXC_RETURN` is the value loaded into the **LR** on exception entry. The exception mechanism relies on this value to detect when the processor has completed an exception handler. The lowest five bits of this value provide information on the return stack and processor mode. Table 2-10 on page 103 shows the `EXC_RETURN` values with a description of the exception return behavior.

`EXC_RETURN` bits 31:5 are all set. When this value is loaded into the **PC**, it indicates to the processor that the exception is complete, and the processor initiates the appropriate exception return sequence.

**Table 2-10. Exception Return Behavior**

| <code>EXC_RETURN[31:0]</code> | Description                                                                                                                            |

## 2.6 Fault Handling

Faults are a subset of the exceptions (see “Exception Model” on page 93). The following conditions generate a fault:

- A bus error on an instruction fetch or vector table load or a data access.

- An internally detected error such as an undefined instruction or an attempt to change state with a BX instruction.
- Attempting to execute an instruction from a memory region marked as Non-Executable (XN).
- An MPU fault because of a privilege violation or an attempt to access an unmanaged region.

## 2.6.1 Fault Types

Table 2-11 on page 104 shows the types of fault, the handler used for the fault, the corresponding fault status register, and the register bit that indicates the fault has occurred. See page 169 for more information about the fault status registers.

**Table 2-11. Faults**

| Fault                                                                        | Handler                 | Fault Status Register                       | Bit Name          |
|------------------------------------------------------------------------------|-------------------------|---------------------------------------------|-------------------|
| Bus error on a vector read                                                   | Hard fault              | Hard Fault Status (HFAULTSTAT)              | VECT              |
| Fault escalated to a hard fault                                              | Hard fault              | Hard Fault Status (HFAULTSTAT)              | FORCED            |
| MPU or default memory mismatch on instruction access                         | Memory management fault | Memory Management Fault Status (MFAULTSTAT) | IERR <sup>a</sup> |
| MPU or default memory mismatch on data access                                | Memory management fault | Memory Management Fault Status (MFAULTSTAT) | DERR              |
| MPU or default memory mismatch on exception stacking                         | Memory management fault | Memory Management Fault Status (MFAULTSTAT) | MSTKE             |
| MPU or default memory mismatch on exception unstacking                       | Memory management fault | Memory Management Fault Status (MFAULTSTAT) | MUSTKE            |
| MPU or default memory mismatch during lazy floating-point state preservation | Memory management fault | Memory Management Fault Status (MFAULTSTAT) | MLSPERR           |
| Bus error during exception stacking                                          | Bus fault               | Bus Fault Status (BFAULTSTAT)               | BSTKE             |
| Bus error during exception unstacking                                        | Bus fault               | Bus Fault Status (BFAULTSTAT)               | BUSTKE            |
| Bus error during instruction prefetch                                        | Bus fault               | Bus Fault Status (BFAULTSTAT)               | IBUS              |
| Bus error during lazy floating-point state preservation                      | Bus fault               | Bus Fault Status (BFAULTSTAT)               | BLSPE             |
| Precise data bus error                                                       | Bus fault               | Bus Fault Status (BFAULTSTAT)               | PRECISE           |
| Imprecise data bus error                                                     | Bus fault               | Bus Fault Status (BFAULTSTAT)               | IMPRE             |
| Attempt to access a coprocessor                                              | Usage fault             | Usage Fault Status (UFAULTSTAT)             | NOCP              |
| Undefined instruction                                                        | Usage fault             | Usage Fault Status (UFAULTSTAT)             | UNDEF             |
| Attempt to enter an invalid instruction set state <sup>b</sup>               | Usage fault             | Usage Fault Status (UFAULTSTAT)             | INVSTAT           |
| Invalid EXC_RETURN value                                                     | Usage fault             | Usage Fault Status (UFAULTSTAT)             | INVPC             |
| Illegal unaligned load or store                                              | Usage fault             | Usage Fault Status (UFAULTSTAT)             | UNALIGN           |
| Divide by 0                                                                  | Usage fault             | Usage Fault Status (UFAULTSTAT)             | DIV0              |

a. Occurs on an access to an XN region even if the MPU is disabled.

b. Attempting to use an instruction set other than the Thumb instruction set, or returning to a non load-store-multiply instruction with ICI continuation.

## 2.6.2 Fault Escalation and Hard Faults

All fault exceptions except for hard fault have configurable exception priority (see **SYSPRI1** on page 162). Software can disable execution of the handlers for these faults (see **SYSHNDCTRL** on page 165).

Usually, the exception priority, together with the values of the exception mask registers, determines whether the processor enters the fault handler, and whether a fault handler can preempt another fault handler as described in “Exception Model” on page 93.

In some situations, a fault with configurable priority is treated as a hard fault. This process is called priority escalation, and the fault is described as *escalated to hard fault*. Escalation to hard fault occurs when:

- A fault handler causes the same kind of fault as the one it is servicing. This escalation to hard fault occurs because a fault handler cannot preempt itself because it must have the same priority as the current priority level.
- A fault handler causes a fault with the same or lower priority as the fault it is servicing. This situation happens because the handler for the new fault cannot preempt the currently executing fault handler.
- An exception handler causes a fault for which the priority is the same as or lower than the currently executing exception.
- A fault occurs and the handler for that fault is not enabled.

If a bus fault occurs during a stack push when entering a bus fault handler, the bus fault does not escalate to a hard fault. Thus if a corrupted stack causes a fault, the fault handler executes even though the stack push for the handler failed. The fault handler operates but the stack contents are corrupted.

**Note:** Only Reset and NMI can preempt the fixed priority hard fault. A hard fault can preempt any exception other than Reset, NMI, or another hard fault.

### 2.6.3 Fault Status Registers and Fault Address Registers

The fault status registers indicate the cause of a fault. For bus faults and memory management faults, the fault address register indicates the address accessed by the operation that caused the fault, as shown in Table 2-12 on page 105.

**Table 2-12. Fault Status and Fault Address Registers**

| Handler                 | Status Register Name                        | Address Register Name                    | Register Description |
|-------------------------|---------------------------------------------|------------------------------------------|----------------------|
| Hard fault              | Hard Fault Status (HFAULTSTAT)              | -                                        | page 175             |
| Memory management fault | Memory Management Fault Status (MFAULTSTAT) | Memory Management Fault Address (MMADDR) | page 169<br>page 176 |
| Bus fault               | Bus Fault Status (BFAULTSTAT)               | Bus Fault Address (FAULTADDR)            | page 169<br>page 177 |
| Usage fault             | Usage Fault Status (UFAULTSTAT)             | -                                        | page 169             |

### 2.6.4 Lockup

The processor enters a lockup state if a hard fault occurs when executing the NMI or hard fault handlers. When the processor is in the lockup state, it does not execute any instructions. The processor remains in lockup state until it is reset, an NMI occurs, or it is halted by a debugger.

**Note:** If the lockup state occurs from the NMI handler, a subsequent NMI does not cause the processor to leave the lockup state.

## 2.7 Power Management

The Cortex-M4F processor sleep modes reduce power consumption:

- Sleep mode stops the processor clock.
- Deep-sleep mode stops the system clock and switches off the PLL and Flash memory.

The `SLEEPDEEP` bit of the **System Control (SYSCTRL)** register selects which sleep mode is used (see page 158). For more information about the behavior of the sleep modes, see “System Control” on page 218.

This section describes the mechanisms for entering sleep mode and the conditions for waking up from sleep mode, both of which apply to Sleep mode and Deep-sleep mode.

### 2.7.1 Entering Sleep Modes

This section describes the mechanisms software can use to put the processor into one of the sleep modes.

The system can generate spurious wake-up events, for example a debug operation wakes up the processor. Therefore, software must be able to put the processor back into sleep mode after such an event. A program might have an idle loop to put the processor back to sleep mode.

#### 2.7.1.1 Wait for Interrupt

The wait for interrupt instruction, `WFI`, causes immediate entry to sleep mode unless the wake-up condition is true (see “Wake Up from WFI or Sleep-on-Exit” on page 107). When the processor executes a `WFI` instruction, it stops executing instructions and enters sleep mode. See the Cortex™-M4 instruction set chapter in the *ARM® Cortex™-M4 Devices Generic User Guide (literature number [ARM DUI 0553A](#))* for more information.

#### 2.7.1.2 Wait for Event

The wait for event instruction, `WFE`, causes entry to sleep mode conditional on the value of a one-bit event register. When the processor executes a `WFE` instruction, it checks the event register. If the register is 0, the processor stops executing instructions and enters sleep mode. If the register is 1, the processor clears the register and continues executing instructions without entering sleep mode.

If the event register is 1, the processor must not enter sleep mode on execution of a `WFE` instruction. Typically, this situation occurs if an `SEV` instruction has been executed. Software cannot access this register directly.

See the Cortex™-M4 instruction set chapter in the *ARM® Cortex™-M4 Devices Generic User Guide (literature number [ARM DUI 0553A](#))* for more information.

#### 2.7.1.3 Sleep-on-Exit

If the `SLEEPEXIT` bit of the **SYSCTRL** register is set, when the processor completes the execution of all exception handlers, it returns to Thread mode and immediately enters sleep mode. This mechanism can be used in applications that only require the processor to run when an exception occurs.

### 2.7.2 Wake Up from Sleep Mode

The conditions for the processor to wake up depend on the mechanism that caused it to enter sleep mode.

### 2.7.2.1 Wake Up from WFI or Sleep-on-Exit

Normally, the processor wakes up only when the NVIC detects an exception with sufficient priority to cause exception entry. Some embedded systems might have to execute system restore tasks after the processor wakes up and before executing an interrupt handler. Entry to the interrupt handler can be delayed by setting the `PRIMASK` bit and clearing the `FAULTMASK` bit. If an interrupt arrives that is enabled and has a higher priority than current exception priority, the processor wakes up but does not execute the interrupt handler until the processor clears `PRIMASK`. For more information about **PRIMASK** and **FAULTMASK**, see page 77 and page 78.

### 2.7.2.2 Wake Up from WFE

The processor wakes up if it detects an exception with sufficient priority to cause exception entry.

In addition, if the `SEVONPEND` bit in the **SYSCTRL** register is set, any new pending interrupt triggers an event and wakes up the processor, even if the interrupt is disabled or has insufficient priority to cause exception entry. For more information about **SYSCTRL**, see page 158.

## 2.8 Instruction Set Summary

The processor implements a version of the Thumb instruction set. Table 2-13 on page 107 lists the supported instructions.

**Note:** In Table 2-13 on page 107:

- Angle brackets, `<>`, enclose alternative forms of the operand
- Braces, `{}`, enclose optional operands
- The Operands column is not exhaustive
- `Op2` is a flexible second operand that can be either a register or a constant
- Most instructions can use an optional condition code suffix

For more information on the instructions and operands, see the instruction descriptions in the *ARM® Cortex™-M4 Technical Reference Manual*.

**Table 2-13. Cortex-M4F Instruction Summary**

| Mnemonic  | Operands             | Brief Description              | Flags      |
|-----------|----------------------|--------------------------------|------------|
| ADC, ADCS | {Rd,} Rn, Op2        | Add with carry                 | N, Z, C, V |
| ADD, ADDS | {Rd,} Rn, Op2        | Add                            | N, Z, C, V |
| ADD, ADDW | {Rd,} Rn, #imm12     | Add                            | -          |
| ADR       | Rd, label            | Load PC-relative address       | -          |
| AND, ANDS | {Rd,} Rn, Op2        | Logical AND                    | N, Z, C    |
| ASR, ASRS | Rd, Rm, <Rs #n>      | Arithmetic shift right         | N, Z, C    |
| B         | label                | Branch                         | -          |
| BFC       | Rd, #lsb, #width     | Bit field clear                | -          |
| BFI       | Rd, Rn, #lsb, #width | Bit field insert               | -          |
| BIC, BICS | {Rd,} Rn, Op2        | Bit clear                      | N, Z, C    |
| BKPT      | #imm                 | Breakpoint                     | -          |
| BL        | label                | Branch with link               | -          |
| BLX       | Rm                   | Branch indirect with link      | -          |
| BX        | Rm                   | Branch indirect                | -          |
| CBNZ      | Rn, label            | Compare and branch if non-zero | -          |

Table 2-13. Cortex-M4F Instruction Summary (continued)

| Mnemonic      | Operands               | Brief Description                              | Flags      |
|---------------|------------------------|------------------------------------------------|------------|
| CBZ           | Rn, label              | Compare and branch if zero                     | -          |
| CLREX         | -                      | Clear exclusive                                | -          |
| CLZ           | Rd, Rm                 | Count leading zeros                            | -          |
| CMN           | Rn, Op2                | Compare negative                               | N, Z, C, V |
| CMP           | Rn, Op2                | Compare                                        | N, Z, C, V |
| CPSID         | i                      | Change processor state, disable interrupts     | -          |
| CPSIE         | i                      | Change processor state, enable interrupts      | -          |
| DMB           | -                      | Data memory barrier                            | -          |
| DSB           | -                      | Data synchronization barrier                   | -          |
| EOR, EORS     | {Rd,} Rn, Op2          | Exclusive OR                                   | N, Z, C    |
| ISB           | -                      | Instruction synchronization barrier            | -          |
| IT            | -                      | If-Then condition block                        | -          |
| LDM           | Rn{!}, reglist         | Load multiple registers, increment after       | -          |
| LDMDB, LDMEA  | Rn{!}, reglist         | Load multiple registers, decrement before      | -          |
| LDMFD, LDMIA  | Rn{!}, reglist         | Load multiple registers, increment after       | -          |
| LDR           | Rt, [Rn, #offset]      | Load register with word                        | -          |
| LDRB, LDRBT   | Rt, [Rn, #offset]      | Load register with byte                        | -          |
| LDRD          | Rt, Rt2, [Rn, #offset] | Load register with two bytes                   | -          |
| LDREX         | Rt, [Rn, #offset]      | Load register exclusive                        | -          |
| LDREXB        | Rt, [Rn]               | Load register exclusive with byte              | -          |
| LDREXH        | Rt, [Rn]               | Load register exclusive with halfword          | -          |
| LDRH, LDRHT   | Rt, [Rn, #offset]      | Load register with halfword                    | -          |
| LDRSB, LDRSBT | Rt, [Rn, #offset]      | Load register with signed byte                 | -          |
| LDRSH, LDRSHT | Rt, [Rn, #offset]      | Load register with signed halfword             | -          |
| LDRT          | Rt, [Rn, #offset]      | Load register with word                        | -          |
| LSL, LSLS     | Rd, Rm, <Rs #n>        | Logical shift left                             | N, Z, C    |
| LSR, LSRS     | Rd, Rm, <Rs #n>        | Logical shift right                            | N, Z, C    |
| MLA           | Rd, Rn, Rm, Ra         | Multiply with accumulate, 32-bit result        | -          |
| MLS           | Rd, Rn, Rm, Ra         | Multiply and subtract, 32-bit result           | -          |
| MOV, MOVS     | Rd, Op2                | Move                                           | N, Z, C    |
| MOV, MOVW     | Rd, #imm16             | Move 16-bit constant                           | N, Z, C    |
| MOVT          | Rd, #imm16             | Move top                                       | -          |
| MRS           | Rd, spec_reg           | Move from special register to general register | -          |
| MSR           | spec_reg, Rm           | Move from general register to special register | N, Z, C, V |
| MUL, MULS     | {Rd,} Rn, Rm           | Multiply, 32-bit result                        | N, Z       |
| MVN, MVNS     | Rd, Op2                | Move NOT                                       | N, Z, C    |
| NOP           | -                      | No operation                                   | -          |
| ORN, ORNS     | {Rd,} Rn, Op2          | Logical OR NOT                                 | N, Z, C    |

Table 2-13. Cortex-M4F Instruction Summary (continued)

| Mnemonic     | Operands             | Brief Description                                     | Flags      |
|--------------|----------------------|-------------------------------------------------------|------------|
| ORR, ORRS    | {Rd,} Rn, Op2        | Logical OR                                            | N, Z, C    |
| PKHTB, PKHBT | {Rd,} Rn, Rm, Op2    | Pack halfword                                         | -          |
| POP          | reglist              | Pop registers from stack                              | -          |
| PUSH         | reglist              | Push registers onto stack                             | -          |
| QADD         | {Rd,} Rn, Rm         | Saturating add                                        | Q          |
| QADD16       | {Rd,} Rn, Rm         | Saturating add 16                                     | -          |
| QADD8        | {Rd,} Rn, Rm         | Saturating add 8                                      | -          |
| QASX         | {Rd,} Rn, Rm         | Saturating add and subtract with exchange             | -          |
| QDADD        | {Rd,} Rn, Rm         | Saturating double and add                             | Q          |
| QDSUB        | {Rd,} Rn, Rm         | Saturating double and subtract                        | Q          |
| QSAX         | {Rd,} Rn, Rm         | Saturating subtract and add with exchange             | -          |
| QSUB         | {Rd,} Rn, Rm         | Saturating subtract                                   | Q          |
| QSUB16       | {Rd,} Rn, Rm         | Saturating subtract 16                                | -          |
| QSUB8        | {Rd,} Rn, Rm         | Saturating subtract 8                                 | -          |
| RBIT         | Rd, Rn               | Reverse bits                                          | -          |
| REV          | Rd, Rn               | Reverse byte order in a word                          | -          |
| REV16        | Rd, Rn               | Reverse byte order in each halfword                   | -          |
| REVSH        | Rd, Rn               | Reverse byte order in bottom halfword and sign extend | -          |
| ROR, RORS    | Rd, Rm, <Rs #n>      | Rotate right                                          | N, Z, C    |
| RRX, RRXS    | Rd, Rm               | Rotate right with extend                              | N, Z, C    |
| RSB, RSBS    | {Rd,} Rn, Op2        | Reverse subtract                                      | N, Z, C, V |
| SADD16       | {Rd,} Rn, Rm         | Signed add 16                                         | GE         |
| SADD8        | {Rd,} Rn, Rm         | Signed add 8                                          | GE         |
| SASX         | {Rd,} Rn, Rm         | Signed add and subtract with exchange                 | GE         |
| SBC, SBCS    | {Rd,} Rn, Op2        | Subtract with carry                                   | N, Z, C, V |
| SBFX         | Rd, Rn, #lsb, #width | Signed bit field extract                              | -          |
| SDIV         | {Rd,} Rn, Rm         | Signed divide                                         | -          |
| SEL          | {Rd,} Rn, Rm         | Select bytes                                          | -          |
| SEV          | -                    | Send event                                            | -          |
| SHADD16      | {Rd,} Rn, Rm         | Signed halving add 16                                 | -          |
| SHADD8       | {Rd,} Rn, Rm         | Signed halving add 8                                  | -          |
| SHASX        | {Rd,} Rn, Rm         | Signed halving add and subtract with exchange         | -          |
| SHSAX        | {Rd,} Rn, Rm         | Signed halving add and subtract with exchange         | -          |
| SHSUB16      | {Rd,} Rn, Rm         | Signed halving subtract 16                            | -          |
| SHSUB8       | {Rd,} Rn, Rm         | Signed halving subtract 8                             | -          |

Table 2-13. Cortex-M4F Instruction Summary (continued)

| Mnemonic                                    | Operands               | Brief Description                                         | Flags |

## 3 Cortex-M4 Peripherals

This chapter provides information on the Tiva™ C Series implementation of the Cortex-M4 processor peripherals, including:

- SysTick (see page 115)
  - Provides a simple, 24-bit clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism.
- Nested Vectored Interrupt Controller (NVIC) (see page 116)
  - Facilitates low-latency exception and interrupt handling
  - Controls power management
  - Implements system control registers
- System Control Block (SCB) (see page 117)
  - Provides system implementation information and system control, including configuration, control, and reporting of system exceptions.
- Memory Protection Unit (MPU) (see page 117)
  - Supports the standard ARMv7 Protected Memory System Architecture (PMSA) model. The MPU provides full support for protection regions, overlapping protection regions, access permissions, and exporting memory attributes to the system.
- Floating-Point Unit (FPU) (see page 122)
  - Fully supports single-precision add, subtract, multiply, divide, multiply and accumulate, and square root operations. It also provides conversions between fixed-point and floating-point data formats, and floating-point constant instructions.

Table 3-1 on page 114 shows the address map of the Private Peripheral Bus (PPB). Some peripheral register regions are split into two address regions, as indicated by two addresses listed.

**Table 3-1. Core Peripheral Register Regions**

| Address                                            | Core Peripheral                      | Description (see page ...) |
|----------------------------------------------------|--------------------------------------|----------------------------|

### 3.1 Functional Description

This chapter provides information on the Tiva™ C Series implementation of the Cortex-M4 processor peripherals: SysTick, NVIC, SCB, MPU, FPU.

### 3.1.1 System Timer (SysTick)

Cortex-M4 includes an integrated system timer, SysTick, which provides a simple, 24-bit clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism. The counter can be used in several different ways, for example as:

- An RTOS tick timer that fires at a programmable rate (for example, 100 Hz) and invokes a SysTick routine.
- A high-speed alarm timer using the system clock.
- A variable rate alarm or signal timer—the duration is range-dependent on the reference clock used and the dynamic range of the counter.
- A simple counter used to measure time to completion and time used.
- An internal clock source control based on missing/meeting durations. The `COUNT` bit in the **STCTRL** control and status register can be used to determine if an action completed within a set duration, as part of a dynamic clock management control loop.

The timer consists of three registers:

- **SysTick Control and Status (STCTRL)**: A control and status counter to configure its clock, enable the counter, enable the SysTick interrupt, and determine counter status.
- **SysTick Reload Value (STRELOAD)**: The reload value for the counter, used to provide the counter's wrap value.
- **SysTick Current Value (STCURRENT)**: The current value of the counter.

When enabled, the timer counts down on each clock from the reload value to zero, reloads (wraps) to the value in the **STRELOAD** register on the next clock edge, then decrements on subsequent clocks. Clearing the **STRELOAD** register disables the counter on the next wrap. When the counter reaches zero, the `COUNT` status bit is set. The `COUNT` bit clears on reads.

Writing to the **STCURRENT** register clears the register and the `COUNT` status bit. The write does not trigger the SysTick exception logic. On a read, the current value is the value of the register at the time the register is accessed.

The SysTick counter runs on either the system clock or the precision internal oscillator (PIOSC) divided by 4. If this clock signal is stopped for low power mode, the SysTick counter stops. SysTick can be kept running during Deep-sleep mode by setting the `CLK_SRC` bit in the **SysTick Control and Status Register (STCTRL)** register and ensuring that the `PIOSCPD` bit in the **Deep Sleep Clock Configuration (DSLPCCLKCFG)** register is clear. Ensure software uses aligned word accesses to access the SysTick registers.

The SysTick counter reload and current value are undefined at reset; the correct initialization sequence for the SysTick counter is:

1. Program the value in the **STRELOAD** register.
2. Clear the **STCURRENT** register by writing to it with any value.
3. Configure the **STCTRL** register for the required operation.

**Note:** When the processor is halted for debugging, the counter does not decrement.

### 3.1.2 Nested Vectored Interrupt Controller (NVIC)

This section describes the Nested Vectored Interrupt Controller (NVIC) and the registers it uses. The NVIC supports:

- 65 interrupts.
- A programmable priority level of 0-7 for each interrupt. A higher level corresponds to a lower priority, so level 0 is the highest interrupt priority.
- Low-latency exception and interrupt handling.
- Level and pulse detection of interrupt signals.
- Dynamic reprioritization of interrupts.
- Grouping of priority values into group priority and subpriority fields.
- Interrupt tail-chaining.
- An external Non-maskable interrupt (NMI).

The processor automatically stacks its state on exception entry and unstacks this state on exception exit, with no instruction overhead, providing low latency exception handling.

#### 3.1.2.1 Level-Sensitive and Pulse Interrupts

The processor supports both level-sensitive and pulse interrupts. Pulse interrupts are also described as edge-triggered interrupts.

A level-sensitive interrupt is held asserted until the peripheral deasserts the interrupt signal. Typically this happens because the ISR accesses the peripheral, causing it to clear the interrupt request. A pulse interrupt is an interrupt signal sampled synchronously on the rising edge of the processor clock. To ensure the NVIC detects the interrupt, the peripheral must assert the interrupt signal for at least one clock cycle, during which the NVIC detects the pulse and latches the interrupt.

When the processor enters the ISR, it automatically removes the pending state from the interrupt (see “Hardware and Software Control of Interrupts” on page 116 for more information). For a level-sensitive interrupt, if the signal is not deasserted before the processor returns from the ISR, the interrupt becomes pending again, and the processor must execute its ISR again. As a result, the peripheral can hold the interrupt signal asserted until it no longer needs servicing.

#### 3.1.2.2 Hardware and Software Control of Interrupts

The Cortex-M4 latches all interrupts. A peripheral interrupt becomes pending for one of the following reasons:

- The NVIC detects that the interrupt signal is High and the interrupt is not active.
- The NVIC detects a rising edge on the interrupt signal.
- Software writes to the corresponding interrupt set-pending register bit, or to the **Software Trigger Interrupt (SWTRIG)** register to make a Software-Generated Interrupt pending. See the `INT` bit in the **PEND0** register on page 138 or **SWTRIG** on page 148.

A pending interrupt remains pending until one of the following:

- The processor enters the ISR for the interrupt, changing the state of the interrupt from pending to active. Then:
  - For a level-sensitive interrupt, when the processor returns from the ISR, the NVIC samples the interrupt signal. If the signal is asserted, the state of the interrupt changes to pending, which might cause the processor to immediately re-enter the ISR. Otherwise, the state of the interrupt changes to inactive.
  - For a pulse interrupt, the NVIC continues to monitor the interrupt signal, and if this is pulsed the state of the interrupt changes to pending and active. In this case, when the processor returns from the ISR the state of the interrupt changes to pending, which might cause the processor to immediately re-enter the ISR.

If the interrupt signal is not pulsed while the processor is in the ISR, when the processor returns from the ISR the state of the interrupt changes to inactive.
- Software writes to the corresponding interrupt clear-pending register bit
  - For a level-sensitive interrupt, if the interrupt signal is still asserted, the state of the interrupt does not change. Otherwise, the state of the interrupt changes to inactive.
  - For a pulse interrupt, the state of the interrupt changes to inactive, if the state was pending or to active, if the state was active and pending.

### 3.1.3 System Control Block (SCB)

The System Control Block (SCB) provides system implementation information and system control, including configuration, control, and reporting of the system exceptions.

### 3.1.4 Memory Protection Unit (MPU)

This section describes the Memory protection unit (MPU). The MPU divides the memory map into a number of regions and defines the location, size, access permissions, and memory attributes of each region. The MPU supports independent attribute settings for each region, overlapping regions, and export of memory attributes to the system.

The memory attributes affect the behavior of memory accesses to the region. The Cortex-M4 MPU defines eight separate memory regions, 0-7, and a background region.

When memory regions overlap, a memory access is affected by the attributes of the region with the highest number. For example, the attributes for region 7 take precedence over the attributes of any region that overlaps region 7.

The background region has the same memory access attributes as the default memory map, but is accessible from privileged software only.

The Cortex-M4 MPU memory map is unified, meaning that instruction accesses and data accesses have the same region settings.

If a program accesses a memory location that is prohibited by the MPU, the processor generates a memory management fault, causing a fault exception and possibly causing termination of the process in an OS environment. In an OS environment, the kernel can update the MPU region setting dynamically based on the process to be executed. Typically, an embedded OS uses the MPU for memory protection.

Configuration of MPU regions is based on memory types (see “Memory Regions, Types and Attributes” on page 86 for more information).

Table 3-2 on page 118 shows the possible MPU region attributes. See the section called “MPU Configuration for a Tiva™ C Series Microcontroller” on page 122 for guidelines for programming a microcontroller implementation.

**Table 3-2. Memory Attributes Summary**

| Memory Type      | Description                                                     |
|------------------|-----------------------------------------------------------------|
| Strongly Ordered | All accesses to Strongly Ordered memory occur in program order. |
| Device           | Memory-mapped peripherals                                       |
| Normal           | Normal memory                                                   |

To avoid unexpected behavior, disable the interrupts before updating the attributes of a region that the interrupt handlers might access.

Ensure software uses aligned accesses of the correct size to access MPU registers:

- Except for the **MPU Region Attribute and Size (MPUATTR)** register, all MPU registers must be accessed with aligned word accesses.
- The **MPUATTR** register can be accessed with byte or aligned halfword or word accesses.

The processor does not support unaligned accesses to MPU registers.

When setting up the MPU, and if the MPU has previously been programmed, disable unused regions to prevent any previous region settings from affecting the new MPU setup.

### 3.1.4.1 Updating an MPU Region

To update the attributes for an MPU region, the **MPU Region Number (MPUNUMBER)**, **MPU Region Base Address (MPUBASE)** and **MPUATTR** registers must be updated. Each register can be programmed separately or with a multiple-word write to program all of these registers. You can use the **MPUBASEx** and **MPUATTRx** aliases to program up to four regions simultaneously using an *STM* instruction.

#### **Updating an MPU Region Using Separate Words**

This example simple code configures one region:

```

; R1 = region number
; R2 = size/enable
; R3 = attributes
; R4 = address
LDR R0,=MPUNUMBER      ; 0xE000ED98, MPU region number register
STR R1, [R0, #0x0]     ; Region Number
STR R4, [R0, #0x4]     ; Region Base Address
STRH R2, [R0, #0x8]    ; Region Size and Enable
STRH R3, [R0, #0xA]    ; Region Attribute

```

Disable a region before writing new region settings to the MPU if you have previously enabled the region being changed. For example:

```

; R1 = region number
; R2 = size/enable
; R3 = attributes
; R4 = address
LDR R0,=MPUNUMBER      ; 0xE000ED98, MPU region number register

```

```

STR R1, [R0, #0x0]      ; Region Number
BIC R2, R2, #1          ; Disable
STRH R2, [R0, #0x8]    ; Region Size and Enable
STR R4, [R0, #0x4]     ; Region Base Address
STRH R3, [R0, #0xA]    ; Region Attribute
ORR R2, #1              ; Enable
STRH R2, [R0, #0x8]    ; Region Size and Enable

```

Software must use memory barrier instructions:

- Before MPU setup, if there might be outstanding memory transfers, such as buffered writes, that might be affected by the change in MPU settings.
- After MPU setup, if it includes memory transfers that must use the new MPU settings.

However, memory barrier instructions are not required if the MPU setup process starts by entering an exception handler, or is followed by an exception return, because the exception entry and exception return mechanism cause memory barrier behavior.

Software does not need any memory barrier instructions during MPU setup, because it accesses the MPU through the Private Peripheral Bus (PPB), which is a Strongly Ordered memory region.

For example, if all of the memory access behavior is intended to take effect immediately after the programming sequence, then a DSB instruction and an ISB instruction should be used. A DSB is required after changing MPU settings, such as at the end of context switch. An ISB is required if the code that programs the MPU region or regions is entered using a branch or call. If the programming sequence is entered using a return from exception, or by taking an exception, then an ISB is not required.

### **Updating an MPU Region Using Multi-Word Writes**

The MPU can be programmed directly using multi-word writes, depending how the information is divided. Consider the following reprogramming:

```

; R1 = region number
; R2 = address
; R3 = size, attributes in one
LDR R0, =MPUNUMBER ; 0xE000ED98, MPU region number register
STR R1, [R0, #0x0] ; Region Number
STR R2, [R0, #0x4] ; Region Base Address
STR R3, [R0, #0x8] ; Region Attribute, Size and Enable

```

An STM instruction can be used to optimize this:

```

; R1 = region number
; R2 = address
; R3 = size, attributes in one
LDR R0, =MPUNUMBER ; 0xE000ED98, MPU region number register
STM R0, {R1-R3}    ; Region number, address, attribute, size and enable

```

This operation can be done in two words for pre-packed information, meaning that the **MPU Region Base Address (MPUBASE)** register (see page 182) contains the required region number and has the VALID bit set. This method can be used when the data is statically packed, for example in a boot loader:

```

; R1 = address and region number in one
; R2 = size and attributes in one
LDR R0, =MPUBASE      ; 0xE000ED9C, MPU Region Base register
STR R1, [R0, #0x0]    ; Region base address and region number combined
                        ; with VALID (bit 4) set
STR R2, [R0, #0x4]    ; Region Attribute, Size and Enable

```

### Subregions

Regions of 256 bytes or more are divided into eight equal-sized subregions. Set the corresponding bit in the `SRD` field of the **MPU Region Attribute and Size (MPUATTR)** register (see page 184) to disable a subregion. The least-significant bit of the `SRD` field controls the first subregion, and the most-significant bit controls the last subregion. Disabling a subregion means another region overlapping the disabled range matches instead. If no other enabled region overlaps the disabled subregion, the MPU issues a fault.

Regions of 32, 64, and 128 bytes do not support subregions. With regions of these sizes, the `SRD` field must be configured to `0x00`, otherwise the MPU behavior is unpredictable.

### Example of SRD Use

Two regions with the same base address overlap. Region one is 128 KB, and region two is 512 KB. To ensure the attributes from region one apply to the first 128 KB region, configure the `SRD` field for region two to `0x03` to disable the first two subregions, as Figure 3-1 on page 120 shows.

**Figure 3-1. SRD Use Example**

### 3.1.4.2 MPU Access Permission Attributes

The access permission bits, `TEX`, `S`, `C`, `B`, `AP`, and `XN` of the **MPUATTR** register, control access to the corresponding memory region. If an access is made to an area of memory without the required permissions, then the MPU generates a permission fault.

Table 3-3 on page 120 shows the encodings for the `TEX`, `C`, `B`, and `S` access permission bits. All encodings are shown for completeness, however the current implementation of the Cortex-M4 does not support the concept of cacheability or shareability. Refer to the section called “MPU Configuration for a Tiva™ C Series Microcontroller” on page 122 for information on programming the MPU for TM4C1233C3PM implementations.

**Table 3-3. TEX, S, C, and B Bit Field Encoding**

| TEX  | S              | C | B | Memory Type      | Shareability | Other Attributes |
|------|----------------|---|---|------------------|--------------|------------------|
| 000b | x <sup>a</sup> | 0 | 0 | Strongly Ordered | Shareable    | -                |
| 000  | x <sup>a</sup> | 0 | 1 | Device           | Shareable    | -                |

**Table 3-3. TEX, S, C, and B Bit Field Encoding (continued)**

| TEX | S              | C | B              | Memory Type       | Shareability  | Other Attributes                                                                                            |
|-----|----------------|---|----------------|-------------------|---------------|-------------------------------------------------------------------------------------------------------------|
| 000 | 0              | 1 | 0              | Normal            | Not shareable | Outer and inner write-through. No write allocate.                                                           |
| 000 | 1              | 1 | 0              | Normal            | Shareable     |                                                                                                             |
| 000 | 0              | 1 | 1              | Normal            | Not shareable |                                                                                                             |
| 000 | 1              | 1 | 1              | Normal            | Shareable     |                                                                                                             |
| 001 | 0              | 0 | 0              | Normal            | Not shareable | Outer and inner non-cacheable.                                                                              |
| 001 | 1              | 0 | 0              | Normal            | Shareable     |                                                                                                             |
| 001 | x <sup>a</sup> | 0 | 1              | Reserved encoding | -             | -                                                                                                           |

| 010 | x <sup>a</sup> | 0 | 1              | Reserved encoding | -             | -                                                                                                           |
| 010 | x <sup>a</sup> | 1 | x <sup>a</sup> | Reserved encoding | -             | -                                                                                                           |
| 1BB | 0              | A | A              | Normal            | Not shareable | Cached memory (BB = outer policy, AA = inner policy). See Table 3-4 for the encoding of the AA and BB bits. |
| 1BB | 1              | A | A              | Normal            | Shareable     |                                                                                                             |

a. The MPU ignores the value of this bit.

Table 3-4 on page 121 shows the cache policy for memory attribute encodings with a TEX value in the range of 0x4-0x7.

**Table 3-4. Cache Policy for Memory Attribute Encoding**

| Encoding, AA or BB | Corresponding Cache Policy          |
|--------------------|-------------------------------------|
| 00                 | Non-cacheable                       |
| 01                 | Write back, write and read allocate |
| 10                 | Write through, no write allocate    |
| 11                 | Write back, no write allocate       |

Table 3-5 on page 121 shows the AP encodings in the MPUATTR register that define the access permissions for privileged and unprivileged software.

**Table 3-5. AP Bit Field Encoding**

| AP Bit Field | Privileged Permissions | Unprivileged Permissions | Description                                                  |
|--------------|------------------------|--------------------------|--------------------------------------------------------------|
| 000          | No access              | No access                | All accesses generate a permission fault.                    |
| 001          | R/W                    | No access                | Access from privileged software only.                        |
| 010          | R/W                    | RO                       | Writes by unprivileged software generate a permission fault. |
| 011          | R/W                    | R/W                      | Full access.                                                 |
| 100          | Unpredictable          | Unpredictable            | Reserved.                                                    |
| 101          | RO                     | No access                | Reads by privileged software only.                           |

**Table 3-5. AP Bit Field Encoding (continued)**

| AP Bit Field | Privileged Permissions | Unprivileged Permissions | Description                                        |
|--------------|------------------------|--------------------------|----------------------------------------------------|
| 110          | RO                     | RO                       | Read-only, by privileged or unprivileged software. |
| 111          | RO                     | RO                       | Read-only, by privileged or unprivileged software. |

**MPU Configuration for a Tiva™ C Series Microcontroller**

Tiva™ C Series microcontrollers have only a single processor and no caches. As a result, the MPU should be programmed as shown in Table 3-6 on page 122.

**Table 3-6. Memory Region Attributes for Tiva™ C Series Microcontrollers**

| Memory Region | TEX  | S | C | B | Memory Type and Attributes                           |
|---------------|------|---|---|---|------------------------------------------------------|
| Flash memory  | 000b | 0 | 1 | 0 | Normal memory, non-shareable, write-through          |
| Internal SRAM | 000b | 1 | 1 | 0 | Normal memory, shareable, write-through              |
| External SRAM | 000b | 1 | 1 | 1 | Normal memory, shareable, write-back, write-allocate |
| Peripherals   | 000b | 1 | 0 | 1 | Device memory, shareable                             |

In current Tiva™ C Series microcontroller implementations, the shareability and cache policy attributes do not affect the system behavior. However, using these settings for the MPU regions can make the application code more portable. The values given are for typical situations.

**3.1.4.3 MPU Mismatch**

When an access violates the MPU permissions, the processor generates a memory management fault (see “Exceptions and Interrupts” on page 84 for more information). The **MFAULTSTAT** register indicates the cause of the fault. See page 169 for more information.

**3.1.5 Floating-Point Unit (FPU)**

This section describes the Floating-Point Unit (FPU) and the registers it uses. The FPU provides:

- 32-bit instructions for single-precision (C float) data-processing operations
- Combined multiply and accumulate instructions for increased precision (Fused MAC)
- Hardware support for conversion, addition, subtraction, multiplication with optional accumulate, division, and square-root
- Hardware support for denormals and all IEEE rounding modes
- 32 dedicated 32-bit single-precision registers, also addressable as 16 double-word registers
- Decoupled three stage pipeline

The Cortex-M4F FPU fully supports single-precision add, subtract, multiply, divide, multiply and accumulate, and square root operations. It also provides conversions between fixed-point and floating-point data formats, and floating-point constant instructions. The FPU provides floating-point computation functionality that is compliant with the ANSI/IEEE Std 754-2008, IEEE Standard for Binary Floating-Point Arithmetic, referred to as the IEEE 754 standard. The FPU's single-precision extension registers can also be accessed as 16 doubleword registers for load, store, and move operations.

### 3.1.5.1 FPU Views of the Register Bank

The FPU provides an extension register file containing 32 single-precision registers. These can be viewed as:

- Sixteen 64-bit doubleword registers, D0-D15
- Thirty-two 32-bit single-word registers, S0-S31
- A combination of registers from the above views

**Figure 3-2. FPU Register Bank**

The mapping between the registers is as follows:

- $S_{\langle 2n \rangle}$  maps to the least significant half of  $D_{\langle n \rangle}$
- $S_{\langle 2n+1 \rangle}$  maps to the most significant half of  $D_{\langle n \rangle}$

For example, you can access the least significant half of the value in D6 by accessing S12, and the most significant half of the elements by accessing S13.

### 3.1.5.2 Modes of Operation

The FPU provides three modes of operation to accommodate a variety of applications.

**Full-Compliance mode.** In Full-Compliance mode, the FPU processes all operations according to the IEEE 754 standard in hardware.

**Flush-to-Zero mode.** Setting the **FZ** bit of the **Floating-Point Status and Control (FPSC)** register enables Flush-to-Zero mode. In this mode, the FPU treats all subnormal input operands of arithmetic CDP operations as zeros in the operation. Exceptions that result from a zero operand are signalled appropriately. VABS, VNEG, and VMOV are not considered arithmetic CDP operations and are not affected by Flush-to-Zero mode. A result that is tiny, as described in the IEEE 754 standard, where the destination precision is smaller in magnitude than the minimum normal value before rounding, is replaced with a zero. The **IDC** bit in **FPSC** indicates when an input flush occurs. The **UFC** bit in **FPSC** indicates when a result flush occurs.

**Default NaN mode.** Setting the **DN** bit in the **FPSC** register enables default NaN mode. In this mode, the result of any arithmetic data processing operation that involves an input NaN, or that generates a NaN result, returns the default NaN. Propagation of the fraction bits is maintained only by VABS,

VNEG, and VMOV operations. All other CDP operations ignore any information in the fraction bits of an input NaN.

### 3.1.5.3 Compliance with the IEEE 754 standard

When Default NaN (DN) and Flush-to-Zero (FZ) modes are disabled, FPv4 functionality is compliant with the IEEE 754 standard in hardware. No support code is required to achieve this compliance.

### 3.1.5.4 Complete Implementation of the IEEE 754 standard

The Cortex-M4F floating point instruction set does not support all operations defined in the IEEE 754-2008 standard. Unsupported operations include, but are not limited to the following:

- Remainder
- Round floating-point number to integer-valued floating-point number
- Binary-to-decimal conversions
- Decimal-to-binary conversions
- Direct comparison of single-precision and double-precision values

The Cortex-M4 FPU supports fused MAC operations as described in the IEEE standard. For complete implementation of the IEEE 754-2008 standard, floating-point functionality must be augmented with library functions.

### 3.1.5.5 IEEE 754 standard implementation choices

#### **NaN handling**

All single-precision values with the maximum exponent field value and a nonzero fraction field are valid NaNs. A most-significant fraction bit of zero indicates a Signaling NaN (SNaN). A one indicates a Quiet NaN (QNaN). Two NaN values are treated as different NaNs if they differ in any bit. The below table shows the default NaN values.

| Sign | Fraction | Fraction                                |
|------|----------|-----------------------------------------|
| 0    | 0xFF     | bit [22] = 1, bits [21:0] are all zeros |

Processing of input NaNs for ARM floating-point functionality and libraries is defined as follows:

- In full-compliance mode, NaNs are handled as described in the ARM Architecture Reference Manual. The hardware processes the NaNs directly for arithmetic CDP instructions. For data transfer operations, NaNs are transferred without raising the Invalid Operation exception. For the non-arithmetic CDP instructions, VABS, VNEG, and VMOV, NaNs are copied, with a change of sign if specified in the instructions, without causing the Invalid Operation exception.
- In default NaN mode, arithmetic CDP instructions involving NaN operands return the default NaN regardless of the fractions of any NaN operands. SNaNs in an arithmetic CDP operation set the IOC flag, FPSCR[0]. NaN handling by data transfer and non-arithmetic CDP instructions is the same as in full-compliance mode.

**Table 3-7. QNaN and SNaN Handling**

| Instruction Type   | Default NaN Mode | With QNaN Operand                                                                                                                                   | With SNaN Operand                                                                                                                       |
|--------------------|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| Arithmetic CDP     | Off              | The QNaN or one of the QNaN operands, if there is more than one, is returned according to the rules given in the ARM Architecture Reference Manual. | IOC <sup>a</sup> set. The SNaN is quieted and the result NaN is determined by the rules given in the ARM Architecture Reference Manual. |
|                    | On               | Default NaN returns.                                                                                                                                | IOC <sup>a</sup> set. Default NaN returns.                                                                                              |
| Non-arithmetic CDP | Off/On           | NaN passes to destination with sign changed as appropriate.                                                                                         |                                                                                                                                         |
| FCMP(Z)            | -                | Unordered compare.                                                                                                                                  | IOC set. Unordered compare.                                                                                                             |
| FCMPE(Z)           | -                | IOC set. Unordered compare.                                                                                                                         | IOC set. Unordered compare.                                                                                                             |
| Load/store         | Off/On           | All NaNs transferred.                                                                                                                               |                                                                                                                                         |

a. IOC is the Invalid Operation exception flag, FPSCR[0].

### Comparisons

Comparison results modify the flags in the FPSCR. You can use the MVRS APSR\_nzcv instruction (formerly FMSTAT) to transfer the current flags from the FPSCR to the APSR. See the ARM Architecture Reference Manual for mapping of IEEE 754-2008 standard predicates to ARM conditions. The flags used are chosen so that subsequent conditional execution of ARM instructions can test the predicates defined in the IEEE standard.

### Underflow

The Cortex-M4F FPU uses the before rounding form of tininess and the inexact result form of loss of accuracy as described in the IEEE 754-2008 standard to generate Underflow exceptions.

In flush-to-zero mode, results that are tiny before rounding, as described in the IEEE standard, are flushed to a zero, and the UFC flag, FPSCR[3], is set. See the ARM Architecture Reference Manual for information on flush-to-zero mode.

When the FPU is not in flush-to-zero mode, operations are performed on subnormal operands. If the operation does not produce a tiny result, it returns the computed result, and the UFC flag, FPSCR[3], is not set. The IXC flag, FPSCR[4], is set if the operation is inexact. If the operation produces a tiny result, the result is a subnormal or zero value, and the UFC flag, FPSCR[3], is set if the result was also inexact.

#### 3.1.5.6 Exceptions

The FPU sets the cumulative exception status flag in the FPSCR register as required for each instruction, in accordance with the FPv4 architecture. The FPU does not support user-mode traps. The exception enable bits in the FPSCR read-as-zero, and writes are ignored. The processor also has six output pins, FPIX, FPUFC, FPOFC, FPDZC, FPIDC, and FPIOC, that each reflect the status of one of the cumulative exception flags. For a description of these outputs, see the *ARM Cortex-M4 Integration and Implementation Manual* (ARM DII 0239, available from ARM).

The processor can reduce the exception latency by using lazy stacking. See Auxiliary Control Register, ACTLR on page 4-5. This means that the processor reserves space on the stack for the FP state, but does not save that state information to the stack. See the ARMv7-M Architecture Reference Manual (available from ARM) for more information.

#### 3.1.5.7 Enabling the FPU

The FPU is disabled from reset. You must enable it before you can use any floating-point instructions. The processor must be in privileged mode to read from and write to the **Coprocessor Access**

**Control (CPAC) register.** The below example code sequence enables the FPU in both privileged and user modes.

```
; CPACR is located at address 0xE000ED88
LDR.W R0, =0xE000ED88
; Read CPACR
LDR R1, [R0]
; Set bits 20-23 to enable CP10 and CP11 coprocessors
ORR R1, R1, #(0xF << 20)
; Write back the modified value to the CPACR
STR R1, [R0]; wait for store to complete
DSB
;reset pipeline now the FPU is enabled
ISB
```

## 3.2 Register Map

Table 3-8 on page 126 lists the Cortex-M4 Peripheral SysTick, NVIC, MPU, FPU and SCB registers. The offset listed is a hexadecimal increment to the register's address, relative to the Core Peripherals base address of 0xE000.E000.

**Note:** Register spaces that are not used are reserved for future or internal use. Software should not modify any reserved memory address.

**Table 3-8. Peripherals Register Map**

| Offset                                                       | Name      | Type | Reset       | Description                         | See page |
|--------------------------------------------------------------|-----------|------|-------------|-------------------------------------|----------|

### 3.3 System Timer (SysTick) Register Descriptions

This section lists and describes the System Timer registers, in numerical order by address offset.

**Register 1: SysTick Control and Status Register (STCTRL), offset 0x010**

**Note:** This register can only be accessed from privileged mode.

The SysTick **STCTRL** register enables the SysTick features.

## SysTick Control and Status Register (STCTRL)

Base 0xE000.E000

Offset 0x010

Type R/W, reset 0x0000.0004

|-----------|--------|------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1         | INTEN  | R/W  | 0     | Interrupt Enable<br><br>Value    Description<br>0        Interrupt generation is disabled. Software can use the <code>COUNT</code> bit to determine if the counter has ever reached 0.<br>1        An interrupt is generated to the NVIC when SysTick counts to 0.                                                                                                                                                       |
| 0         | ENABLE | R/W  | 0     | Enable<br><br>Value    Description<br>0        The counter is disabled.<br>1        Enables SysTick to operate in a multi-shot way. That is, the counter loads the <code>RELOAD</code> value and begins counting down. On reaching 0, the <code>COUNT</code> bit is set and an interrupt is generated if enabled by <code>INTEN</code> . The counter then loads the <code>RELOAD</code> value again and begins counting. |

## Register 2: SysTick Reload Value Register (STRELOAD), offset 0x014

**Note:** This register can only be accessed from privileged mode.

The **STRELOAD** register specifies the start value to load into the **SysTick Current Value (STCURRENT)** register when the counter reaches 0. The start value can be between 0x1 and 0x00FF.FFFF. A start value of 0 is possible but has no effect because the SysTick interrupt and the **COUNT** bit are activated when counting from 1 to 0.

SysTick can be configured as a multi-shot timer, repeated over and over, firing every N+1 clock pulses, where N is any value from 1 to 0x00FF.FFFF. For example, if a tick interrupt is required every 100 clock pulses, 99 must be written into the **RELOAD** field.

Note that in order to access this register correctly, the system clock must be faster than 8 MHz.

To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.                                                                                                                                            |
| 23:0      | CURRENT  | R/WC | 0x00.0000 | Current Value<br>This field contains the current value at the time the register is accessed. No read-modify-write protection is provided, so change with care.<br>This register is write-clear. Writing to it with any value clears the register. Clearing this register also clears the <b>COUNT</b> bit of the <b>STCTRL</b> register. |

## 3.4 NVIC Register Descriptions

This section lists and describes the NVIC registers, in numerical order by address offset.

The NVIC registers can only be fully accessed from privileged mode, but interrupts can be pended while in unprivileged mode by enabling the **Configuration and Control (CFGCTRL)** register. Any other unprivileged mode access causes a bus fault.

Ensure software uses correctly aligned register accesses. The processor does not support unaligned accesses to NVIC registers.

An interrupt can enter the pending state even if it is disabled.

Before programming the **VTABLE** register to relocate the vector table, ensure the vector table entries of the new vector table are set up for fault handlers, NMI, and all enabled exceptions such as interrupts. For more information, see page 155.

**Register 4: Interrupt 0-31 Set Enable (EN0), offset 0x100****Register 5: Interrupt 32-63 Set Enable (EN1), offset 0x104****Register 6: Interrupt 64-95 Set Enable (EN2), offset 0x108****Register 7: Interrupt 96-127 Set Enable (EN3), offset 0x10C**

**Note:** This register can only be accessed from privileged mode.

The **ENn** registers enable interrupts and show which interrupts are enabled. Bit 0 of **EN0** corresponds to Interrupt 0; bit 31 corresponds to Interrupt 31. Bit 0 of **EN1** corresponds to Interrupt 32; bit 31 corresponds to Interrupt 63. Bit 0 of **EN2** corresponds to Interrupt 64; bit 31 corresponds to Interrupt 95. Bit 0 of **EN3** corresponds to Interrupt 96; bit 31 corresponds to Interrupt 127. Bit 0 of **EN4** (see page 135) corresponds to Interrupt 128; bit 10 corresponds to Interrupt 138.

See Table 2-9 on page 96 for interrupt assignments.

If a pending interrupt is enabled, the NVIC activates the interrupt based on its priority. If an interrupt is not enabled, asserting its interrupt signal changes the interrupt state to pending, but the NVIC never activates the interrupt, regardless of its priority.

**Register 15: Interrupt 32-63 Set Pending (PEND1), offset 0x204**

**Register 16: Interrupt 64-95 Set Pending (PEND2), offset 0x208**

**Register 17: Interrupt 96-127 Set Pending (PEND3), offset 0x20C**

**Note:** This register can only be accessed from privileged mode.

The **PEND<sub>n</sub>** registers force interrupts into the pending state and show which interrupts are pending. Bit 0 of **PEND0** corresponds to Interrupt 0; bit 31 corresponds to Interrupt 31. Bit 0 of **PEND1** corresponds to Interrupt 32; bit 31 corresponds to Interrupt 63. Bit 0 of **PEND2** corresponds to Interrupt 64; bit 31 corresponds to Interrupt 95. Bit 0 of **PEND3** corresponds to Interrupt 96; bit 31 corresponds to Interrupt 127. Bit 0 of **PEND4** (see page 139) corresponds to Interrupt 128; bit 10 corresponds to Interrupt 138.

See Table 2-9 on page 96 for interrupt assignments.

#### Interrupt 0-31 Set Pending (PEND0)

| 10:0      | INT      | R/W  | 0x0        | Interrupt Set Pending                                                                                                                                                                         |

| Value | Description                                                                                                                              |
|-------|------------------------------------------------------------------------------------------------------------------------------------------|
| 0     | On a read, indicates that the interrupt is not pending.<br>On a write, no effect.                                                        |
| 1     | On a read, indicates that the interrupt is pending.<br>On a write, the corresponding interrupt is set to pending even if it is disabled. |

If the corresponding interrupt is already pending, setting a bit has no effect.

A bit can only be cleared by setting the corresponding `INT[n]` bit in the **UNPEND4** register.

**Register 19: Interrupt 0-31 Clear Pending (UNPEND0), offset 0x280**

**Register 20: Interrupt 32-63 Clear Pending (UNPEND1), offset 0x284**

**Register 21: Interrupt 64-95 Clear Pending (UNPEND2), offset 0x288**

**Register 22: Interrupt 96-127 Clear Pending (UNPEND3), offset 0x28C**

**Note:** This register can only be accessed from privileged mode.

The **UNPEND<sub>n</sub>** registers show which interrupts are pending and remove the pending state from interrupts. Bit 0 of **UNPEND0** corresponds to Interrupt 0; bit 31 corresponds to Interrupt 31. Bit 0 of **UNPEND1** corresponds to Interrupt 32; bit 31 corresponds to Interrupt 63. Bit 0 of **UNPEND2** corresponds to Interrupt 64; bit 31 corresponds to Interrupt 95. Bit 0 of **UNPEND3** corresponds to Interrupt 96; bit 31 corresponds to Interrupt 127. Bit 0 of **UNPEND4** (see page 141) corresponds to Interrupt 128; bit 10 corresponds to Interrupt 138.

See Table 2-9 on page 96 for interrupt assignments.

|-----------|------|------|-------------|-------------------------|
| 31:0      | INT  | R/W  | 0x0000.0000 | Interrupt Clear Pending |

#### Value Description

0 On a read, indicates that the interrupt is not pending.  
On a write, no effect.

1 On a read, indicates that the interrupt is pending.  
On a write, clears the corresponding **INT[n]** bit in the **PEND0** register, so that interrupt [n] is no longer pending.  
Setting a bit does not affect the active state of the corresponding interrupt.

**Register 23: Interrupt 128-138 Clear Pending (UNPEND4), offset 0x290**

**Note:** This register can only be accessed from privileged mode.

The **UNPEND4** register shows which interrupts are pending and removes the pending state from interrupts. Bit 0 corresponds to Interrupt 128; bit 10 corresponds to Interrupt 138. See Table 2-9 on page 96 for interrupt assignments.

## Value Description

0 On a read, indicates that the interrupt is not pending.  
On a write, no effect.

1 On a read, indicates that the interrupt is pending.  
On a write, clears the corresponding `INT[n]` bit in the **PEND4** register, so that interrupt [n] is no longer pending.  
Setting a bit does not affect the active state of the corresponding interrupt.

**Register 24: Interrupt 0-31 Active Bit (ACTIVE0), offset 0x300**

**Register 25: Interrupt 32-63 Active Bit (ACTIVE1), offset 0x304**

**Register 26: Interrupt 64-95 Active Bit (ACTIVE2), offset 0x308**

**Register 27: Interrupt 96-127 Active Bit (ACTIVE3), offset 0x30C**

**Note:** This register can only be accessed from privileged mode.

The **UNPEND<sub>n</sub>** registers indicate which interrupts are active. Bit 0 of **ACTIVE0** corresponds to Interrupt 0; bit 31 corresponds to Interrupt 31. Bit 0 of **ACTIVE1** corresponds to Interrupt 32; bit 31 corresponds to Interrupt 63. Bit 0 of **ACTIVE2** corresponds to Interrupt 64; bit 31 corresponds to Interrupt 95. Bit 0 of **ACTIVE3** corresponds to Interrupt 96; bit 31 corresponds to Interrupt 127. Bit 0 of **ACTIVE4** (see page 143) corresponds to Interrupt 128; bit 10 corresponds to Interrupt 138.

See Table 2-9 on page 96 for interrupt assignments.

**Caution – Do not manually set or clear the bits in this register.**

#### Value Description

| Value | Description                                                   |
|-------|---------------------------------------------------------------|
| 0     | The corresponding interrupt is not active.                    |
| 1     | The corresponding interrupt is active, or active and pending. |

**Register 28: Interrupt 128-138 Active Bit (ACTIVE4), offset 0x310**

**Note:** This register can only be accessed from privileged mode.

The **ACTIVE4** register indicates which interrupts are active. Bit 0 corresponds to Interrupt 128; bit 10 corresponds to Interrupt 131. See Table 2-9 on page 96 for interrupt assignments.

**Caution – Do not manually set or clear the bits in this register.**

## Interrupt 128-138 Active Bit (ACTIVE4)

|           |          |      |            | 0 The corresponding interrupt is not active.                                                                                                                                                  |
|           |          |      |            | 1 The corresponding interrupt is active, or active and pending.                                                                                                                               |

- Register 29: Interrupt 0-3 Priority (PRI0), offset 0x400**  
**Register 30: Interrupt 4-7 Priority (PRI1), offset 0x404**  
**Register 31: Interrupt 8-11 Priority (PRI2), offset 0x408**  
**Register 32: Interrupt 12-15 Priority (PRI3), offset 0x40C**  
**Register 33: Interrupt 16-19 Priority (PRI4), offset 0x410**  
**Register 34: Interrupt 20-23 Priority (PRI5), offset 0x414**  
**Register 35: Interrupt 24-27 Priority (PRI6), offset 0x418**  
**Register 36: Interrupt 28-31 Priority (PRI7), offset 0x41C**  
**Register 37: Interrupt 32-35 Priority (PRI8), offset 0x420**  
**Register 38: Interrupt 36-39 Priority (PRI9), offset 0x424**  
**Register 39: Interrupt 40-43 Priority (PRI10), offset 0x428**  
**Register 40: Interrupt 44-47 Priority (PRI11), offset 0x42C**  
**Register 41: Interrupt 48-51 Priority (PRI12), offset 0x430**  
**Register 42: Interrupt 52-55 Priority (PRI13), offset 0x434**  
**Register 43: Interrupt 56-59 Priority (PRI14), offset 0x438**  
**Register 44: Interrupt 60-63 Priority (PRI15), offset 0x43C**

**Note:** This register can only be accessed from privileged mode.

The **PRI<sub>n</sub>** registers (see also page 146) provide 3-bit priority fields for each interrupt. These registers are byte accessible. Each register holds four priority fields that are assigned to interrupts as follows:

| <b>PRI<sub>n</sub> Register Bit Field</b> | <b>Interrupt</b> |
|-------------------------------------------|------------------|
| Bits 31:29                                | Interrupt [4n+3] |
| Bits 23:21                                | Interrupt [4n+2] |
| Bits 15:13                                | Interrupt [4n+1] |
| Bits 7:5                                  | Interrupt [4n]   |

See Table 2-9 on page 96 for interrupt assignments.

Each priority level can be split into separate group priority and subpriority fields. The **PRI<sub>GROUP</sub>** field in the **Application Interrupt and Reset Control (APINT)** register (see page 156) indicates the position of the binary point that splits the priority and subpriority fields.

These registers can only be accessed from privileged mode.

| 4:0       | reserved | RO   | 0x0   | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.                                                                                                                 |

**Register 45: Interrupt 64-67 Priority (PRI16), offset 0x440**  
**Register 46: Interrupt 68-71 Priority (PRI17), offset 0x444**  
**Register 47: Interrupt 72-75 Priority (PRI18), offset 0x448**  
**Register 48: Interrupt 76-79 Priority (PRI19), offset 0x44C**  
**Register 49: Interrupt 80-83 Priority (PRI20), offset 0x450**  
**Register 50: Interrupt 84-87 Priority (PRI21), offset 0x454**  
**Register 51: Interrupt 88-91 Priority (PRI22), offset 0x458**  
**Register 52: Interrupt 92-95 Priority (PRI23), offset 0x45C**  
**Register 53: Interrupt 96-99 Priority (PRI24), offset 0x460**  
**Register 54: Interrupt 100-103 Priority (PRI25), offset 0x464**  
**Register 55: Interrupt 104-107 Priority (PRI26), offset 0x468**  
**Register 56: Interrupt 108-111 Priority (PRI27), offset 0x46C**  
**Register 57: Interrupt 112-115 Priority (PRI28), offset 0x470**  
**Register 58: Interrupt 116-119 Priority (PRI29), offset 0x474**  
**Register 59: Interrupt 120-123 Priority (PRI30), offset 0x478**  
**Register 60: Interrupt 124-127 Priority (PRI31), offset 0x47C**  
**Register 61: Interrupt 128-131 Priority (PRI32), offset 0x480**  
**Register 62: Interrupt 132-135 Priority (PRI33), offset 0x484**  
**Register 63: Interrupt 136-138 Priority (PRI34), offset 0x488**

**Note:** This register can only be accessed from privileged mode.

The **PRIn** registers (see also page 144) provide 3-bit priority fields for each interrupt. These registers are byte accessible. Each register holds four priority fields that are assigned to interrupts as follows:

| PRIn Register Bit Field | Interrupt        |
|-------------------------|------------------|
| Bits 31:29              | Interrupt [4n+3] |
| Bits 23:21              | Interrupt [4n+2] |
| Bits 15:13              | Interrupt [4n+1] |
| Bits 7:5                | Interrupt [4n]   |

See Table 2-9 on page 96 for interrupt assignments.

Each priority level can be split into separate group priority and subpriority fields. The **PRIGROUP** field in the **Application Interrupt and Reset Control (APINT)** register (see page 156) indicates the position of the binary point that splits the priority and subpriority fields .

These registers can only be accessed from privileged mode.

**Register 64: Software Trigger Interrupt (SWTRIG), offset 0xF00**

**Note:** Only privileged software can enable unprivileged access to the **SWTRIG** register.

Writing an interrupt number to the **SWTRIG** register generates a Software Generated Interrupt (SGI). See Table 2-9 on page 96 for interrupt assignments.

When the **MAINPEND** bit in the **Configuration and Control (CFGCTRL)** register (see page 160) is set, unprivileged software can access the **SWTRIG** register.

**3.5 System Control Block (SCB) Register Descriptions**

This section lists and describes the System Control Block (SCB) registers, in numerical order by address offset. The SCB registers can only be accessed from privileged mode.

All registers must be accessed with aligned word accesses except for the **FAULTSTAT** and **SYSPRI1-SYSPRI3** registers, which can be accessed with byte or aligned halfword or word accesses. The processor does not support unaligned accesses to system control block registers.

**Register 65: Auxiliary Control (ACTLR), offset 0x008**

**Note:** This register can only be accessed from privileged mode.

The **ACTLR** register provides disable bits for **IT** folding, write buffer use for accesses to the default memory map, and interruption of multi-cycle instructions. By default, this register is set to provide optimum performance from the Cortex-M4 processor and does not normally require modification.

In some situations, the processor can start executing the first instruction in an **IT** block while it is still executing the **IT** instruction. This behavior is called *IT folding*, and improves performance. However, **IT** folding can cause jitter in looping. If a task must avoid jitter, set the **DISFOLD** bit before executing the task, to disable **IT** folding.

**Register 67: Interrupt Control and State (INTCTRL), offset 0xD04**

**Note:** This register can only be accessed from privileged mode.

The **INCTRL** register provides a set-pending bit for the NMI exception, and set-pending and clear-pending bits for the PendSV and SysTick exceptions. In addition, bits in this register indicate the exception number of the exception being processed, whether there are preempted active exceptions, the exception number of the highest priority pending exception, and whether any interrupts are pending.

When writing to **INCTRL**, the effect is unpredictable when writing a 1 to both the **PENDSV** and **UNPENDSV** bits, or writing a 1 to both the **PENDSTSET** and **PENDSTCLR** bits.

**Interrupt Control and State (INTCTRL)**

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------|-------------|
|-----------|------|------|-------|-------------|

|    |         |     |   |                 |
|----|---------|-----|---|-----------------|
| 31 | NMISSET | R/W | 0 | NMI Set Pending |
|----|---------|-----|---|-----------------|

Value Description

|   |                                                                                 |
|---|---------------------------------------------------------------------------------|
| 0 | On a read, indicates an NMI exception is not pending.<br>On a write, no effect. |
|---|---------------------------------------------------------------------------------|

|   |                                                                                                              |
|---|--------------------------------------------------------------------------------------------------------------|
| 1 | On a read, indicates an NMI exception is pending.<br>On a write, changes the NMI exception state to pending. |
|---|--------------------------------------------------------------------------------------------------------------|

Because NMI is the highest-priority exception, normally the processor enters the NMI exception handler as soon as it registers the setting of this bit, and clears this bit on entering the interrupt handler. A read of this bit by the NMI exception handler returns 1 only if the **NMI** signal is reasserted while the processor is executing that handler.

|       |          |    |     |                                                                                                                                                                                               |
|-------|----------|----|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 30:29 | reserved | RO | 0x0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |

|    |        |     |   |                    |
|----|--------|-----|---|--------------------|
| 28 | PENDSV | R/W | 0 | PendSV Set Pending |
|----|--------|-----|---|--------------------|

Value Description

|   |                                                                                   |
|---|-----------------------------------------------------------------------------------|
| 0 | On a read, indicates a PendSV exception is not pending.<br>On a write, no effect. |
|---|-----------------------------------------------------------------------------------|

|   |                                                                                                                   |
|---|-------------------------------------------------------------------------------------------------------------------|
| 1 | On a read, indicates a PendSV exception is pending.<br>On a write, changes the PendSV exception state to pending. |
|---|-------------------------------------------------------------------------------------------------------------------|

Setting this bit is the only way to set the PendSV exception state to pending. This bit is cleared by writing a 1 to the **UNPENDSV** bit.

|-----------|----------|------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:10     | OFFSET   | R/W  | 0x000.00 | Vector Table Offset<br>When configuring the <code>OFFSET</code> field, the offset must be aligned to the number of exception entries in the vector table. Because there are 138 interrupts, the offset must be aligned on a 1024-byte boundary. |
| 9:0       | reserved | RO   | 0x00     | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.                                                   |

**Register 69: Application Interrupt and Reset Control (APINT), offset 0xD0C**

**Note:** This register can only be accessed from privileged mode.

The **APINT** register provides priority grouping control for the exception model, endian status for data accesses, and reset control of the system. To write to this register, 0x05FA must be written to the **VECTKEY** field, otherwise the write is ignored.

The **PRIGROUP** field indicates the position of the binary point that splits the **INTx** fields in the **Interrupt Priority (PRIx)** registers into separate group priority and subpriority fields. Table 3-9 on page 156 shows how the **PRIGROUP** value controls this split. The bit numbers in the Group Priority Field and Subpriority Field columns in the table refer to the bits in the **INTA** field. For the **INTB** field, the corresponding bits are 15:13; for **INTC**, 23:21; and for **INTD**, 31:29.

**Note:** Determining preemption of an exception uses only the group priority field.

**Table 3-9. Interrupt Priority Levels**

| PRIGROUP Bit Field | Binary Point <sup>a</sup> | Group Priority Field | Subpriority Field | Group Priorities | Subpriorities |
|--------------------|---------------------------|----------------------|-------------------|------------------|---------------|
| 0x0 - 0x4          | bxxx.                     | [7:5]                | None              | 8                | 1             |
| 0x5                | bxx.y                     | [7:6]                | [5]               | 4                | 2             |
| 0x6                | bx.yy                     | [7]                  | [6:5]             | 2                | 4             |
| 0x7                | b.yyy                     | None                 | [7:5]             | 1                | 8             |

a. **INTx** field showing the binary point. An x denotes a group priority field bit, and a y denotes a subpriority field bit.

**Register 71: Configuration and Control (CFGCTRL), offset 0xD14**

**Note:** This register can only be accessed from privileged mode.

The **CFGCTRL** register controls entry to Thread mode and enables: the handlers for NMI, hard fault and faults escalated by the **FAULTMASK** register to ignore bus faults; trapping of divide by zero and unaligned accesses; and access to the **SWTRIG** register by unprivileged software (see page 148).

**Register 75: System Handler Control and State (SYSHNDCTRL), offset 0xD24**

**Note:** This register can only be accessed from privileged mode.

The **SYSHNDCTRL** register enables the system handlers, and indicates the pending status of the usage fault, bus fault, memory management fault, and SVC exceptions as well as the active status of the system handlers.

If a system handler is disabled and the corresponding fault occurs, the processor treats the fault as a hard fault.

This register can be modified to change the pending or active status of system exceptions. An OS kernel can write to the active bits to perform a context switch that changes the current exception type.

**Caution – Software that changes the value of an active bit in this register without correct adjustment to the stacked content can cause the processor to generate a fault exception. Ensure software that writes to this register retains and subsequently restores the current active status.**

**If the value of a bit in this register must be modified after enabling the system handlers, a read-modify-write procedure must be used to ensure that only the required bit is modified.**

## Register 76: Configurable Fault Status (FAULTSTAT), offset 0xD28

**Note:** This register can only be accessed from privileged mode.

The **FAULTSTAT** register indicates the cause of a memory management fault, bus fault, or usage fault. Each of these functions is assigned to a subregister as follows:

- **Usage Fault Status (UFAULTSTAT)**, bits 31:16
- **Bus Fault Status (BFAULTSTAT)**, bits 15:8
- **Memory Management Fault Status (MFAULTSTAT)**, bits 7:0

**FAULTSTAT** is byte accessible. **FAULTSTAT** or its subregisters can be accessed as follows:

- The complete **FAULTSTAT** register, with a word access to offset 0xD28
- The **MFAULTSTAT**, with a byte access to offset 0xD28
- The **MFAULTSTAT** and **BFAULTSTAT**, with a halfword access to offset 0xD28
- The **BFAULTSTAT**, with a byte access to offset 0xD29
- The **UFAULTSTAT**, with a halfword access to offset 0xD2A

Bits are cleared by writing a 1 to them.

In a fault handler, the true faulting address can be determined by:

1. Read and save the **Memory Management Fault Address (MMADDR)** or **Bus Fault Address (FAULTADDR)** value.
2. Read the **MMARV** bit in **MFAULTSTAT**, or the **BFARV** bit in **BFAULTSTAT** to determine if the **MMADDR** or **FAULTADDR** contents are valid.

Software must follow this sequence because another higher priority exception might change the **MMADDR** or **FAULTADDR** value. For example, if a higher priority handler preempts the current fault handler, the other fault might change the **MMADDR** or **FAULTADDR** value.

### Configurable Fault Status (FAULTSTAT)

Base 0xE000.E000

Offset 0xD28

Type R/W1C, reset 0x0000.0000

**Register 77: Hard Fault Status (HFAULTSTAT), offset 0xD2C**

**Note:** This register can only be accessed from privileged mode.

The **HFAULTSTAT** register gives information about events that activate the hard fault handler.

Bits are cleared by writing a 1 to them.

**Hard Fault Status (HFAULTSTAT)**

Base 0xE000.E000

Offset 0xD2C

Type R/W1C, reset 0x0000.0000

**Register 78: Memory Management Fault Address (MMADDR), offset 0xD34**

**Note:** This register can only be accessed from privileged mode.

The **MMADDR** register contains the address of the location that generated a memory management fault. When an unaligned access faults, the address in the **MMADDR** register is the actual address that faulted. Because a single read or write instruction can be split into multiple aligned accesses, the fault address can be any address in the range of the requested access size. Bits in the **Memory Management Fault Status (MFAULTSTAT)** register indicate the cause of the fault and whether the value in the **MMADDR** register is valid (see page 169).

## Memory Management Fault Address (MMADDR)

## Register 79: Bus Fault Address (FAULTADDR), offset 0xD38

**Note:** This register can only be accessed from privileged mode.

The **FAULTADDR** register contains the address of the location that generated a bus fault. When an unaligned access faults, the address in the **FAULTADDR** register is the one requested by the instruction, even if it is not the address of the fault. Bits in the **Bus Fault Status (BFAULTSTAT)** register indicate the cause of the fault and whether the value in the **FAULTADDR** register is valid (see page 169).

## 3.6 Memory Protection Unit (MPU) Register Descriptions

This section lists and describes the Memory Protection Unit (MPU) registers, in numerical order by address offset.

The MPU registers can only be accessed from privileged mode.

**Register 80: MPU Type (MPUTYPE), offset 0xD90**

**Note:** This register can only be accessed from privileged mode.

The **MPUTYPE** register indicates whether the MPU is present, and if so, how many regions it supports.

**MPU Type (MPUTYPE)**

**Register 81: MPU Control (MPUCTRL), offset 0xD94**

**Note:** This register can only be accessed from privileged mode.

The **MPUCTRL** register enables the MPU, enables the default memory map background region, and enables use of the MPU when in the hard fault, Non-maskable Interrupt (NMI), and **Fault Mask Register (FAULTMASK)** escalated handlers.

When the **ENABLE** and **PRIVDEFEN** bits are both set:

- For privileged accesses, the default memory map is as described in “Memory Model” on page 84. Any access by privileged software that does not address an enabled memory region behaves as defined by the default memory map.
- Any access by unprivileged software that does not address an enabled memory region causes a memory management fault.

Execute Never (XN) and Strongly Ordered rules always apply to the System Control Space regardless of the value of the **ENABLE** bit.

When the **ENABLE** bit is set, at least one region of the memory map must be enabled for the system to function unless the **PRIVDEFEN** bit is set. If the **PRIVDEFEN** bit is set and no regions are enabled, then only privileged software can operate.

When the **ENABLE** bit is clear, the system uses the default memory map, which has the same memory attributes as if the MPU is not implemented (see Table 2-5 on page 87 for more information). The default memory map applies to accesses from both privileged and unprivileged software.

When the MPU is enabled, accesses to the System Control Space and vector table are always permitted. Other areas are accessible based on regions and whether **PRIVDEFEN** is set.

Unless **HFNMIENA** is set, the MPU is not enabled when the processor is executing the handler for an exception with priority –1 or –2. These priorities are only possible when handling a hard fault or NMI exception or when **FAULTMASK** is enabled. Setting the **HFNMIENA** bit enables the MPU when operating with these two priorities.

**MPU Control (MPUCTRL)**

**Register 82: MPU Region Number (MPUNUMBER), offset 0xD98**

**Note:** This register can only be accessed from privileged mode.

The **MPUNUMBER** register selects which memory region is referenced by the **MPU Region Base Address (MPUBASE)** and **MPU Region Attribute and Size (MPUATTR)** registers. Normally, the required region number should be written to this register before accessing the **MPUBASE** or the **MPUATTR** register. However, the region number can be changed by writing to the **MPUBASE** register with the **VALID** bit set (see page 182). This write updates the value of the **REGION** field.

| 2:0       | NUMBER   | R/W  | 0x0        | MPU Region to Access<br>This field indicates the MPU region referenced by the <b>MPUBASE</b> and <b>MPUATTR</b> registers. The MPU supports eight memory regions.                             |

**Register 83: MPU Region Base Address (MPUBASE), offset 0xD9C****Register 84: MPU Region Base Address Alias 1 (MPUBASE1), offset 0xDA4****Register 85: MPU Region Base Address Alias 2 (MPUBASE2), offset 0xDAC****Register 86: MPU Region Base Address Alias 3 (MPUBASE3), offset 0xDB4**

**Note:** This register can only be accessed from privileged mode.

The **MPUBASE** register defines the base address of the MPU region selected by the **MPU Region Number (MPUNUMBER)** register and can update the value of the **MPUNUMBER** register. To change the current region number and update the **MPUNUMBER** register, write the **MPUBASE** register with the **VALID** bit set.

The **ADDR** field is bits 31:*N* of the **MPUBASE** register. Bits (*N*-1):5 are reserved. The region size, as specified by the **SIZE** field in the **MPU Region Attribute and Size (MPUATTR)** register, defines the value of *N* where:

$$N = \text{Log}_2(\text{Region size in bytes})$$

If the region size is configured to 4 GB in the **MPUATTR** register, there is no valid **ADDR** field. In this case, the region occupies the complete memory map, and the base address is 0x0000.0000.

The base address is aligned to the size of the region. For example, a 64-KB region must be aligned on a multiple of 64 KB, for example, at 0x0001.0000 or 0x0002.0000.

**Register 87: MPU Region Attribute and Size (MPUATTR), offset 0xDA0**

**Register 88: MPU Region Attribute and Size Alias 1 (MPUATTR1), offset 0xDA8**

**Register 89: MPU Region Attribute and Size Alias 2 (MPUATTR2), offset 0xDB0**

**Register 90: MPU Region Attribute and Size Alias 3 (MPUATTR3), offset 0xDB8**

**Note:** This register can only be accessed from privileged mode.

The **MPUATTR** register defines the region size and memory attributes of the MPU region specified by the **MPU Region Number (MPUNUMBER)** register and enables that region and any subregions.

The **MPUATTR** register is accessible using word or halfword accesses with the most-significant halfword holding the region attributes and the least-significant halfword holds the region size and the region and subregion enable bits.

The MPU access permission attribute bits, **XN**, **AP**, **TEX**, **S**, **C**, and **B**, control access to the corresponding memory region. If an access is made to an area of memory without the required permissions, then the MPU generates a permission fault.

The **SIZE** field defines the size of the MPU memory region specified by the **MPUNUMBER** register as follows:

$$(\text{Region size in bytes}) = 2^{(\text{SIZE}+1)}$$

The smallest permitted region size is 32 bytes, corresponding to a **SIZE** value of 4. Table 3-10 on page 184 gives example **SIZE** values with the corresponding region size and value of **N** in the **MPU Region Base Address (MPUBASE)** register.

**Table 3-10. Example SIZE Field Values**

| SIZE Encoding | Region Size | Value of N <sup>a</sup>                                                              | Note                   |
|---------------|-------------|--------------------------------------------------------------------------------------|------------------------|
| 00100b (0x4)  | 32 B        | 5                                                                                    | Minimum permitted size |
| 01001b (0x9)  | 1 KB        | 10                                                                                   | -                      |
| 10011b (0x13) | 1 MB        | 20                                                                                   | -                      |
| 11101b (0x1D) | 1 GB        | 30                                                                                   | -                      |
| 11111b (0x1F) | 4 GB        | No valid ADDR field in <b>MPUBASE</b> ; the region occupies the complete memory map. | Maximum possible size  |

a. Refers to the N parameter in the **MPUBASE** register (see page 182).

## 4 JTAG Interface

The Joint Test Action Group (JTAG) port is an IEEE standard that defines a Test Access Port and Boundary Scan Architecture for digital integrated circuits and provides a standardized serial interface for controlling the associated test logic. The TAP, Instruction Register (IR), and Data Registers (DR) can be used to test the interconnections of assembled printed circuit boards and obtain manufacturing information on the components. The JTAG Port also provides a means of accessing and controlling design-for-test features such as I/O pin observation and control, scan testing, and debugging.

The JTAG port is comprised of four pins: TCK, TMS, TDI, and TDO. Data is transmitted serially into the controller on TDI and out of the controller on TDO. The interpretation of this data is dependent on the current state of the TAP controller. For detailed information on the operation of the JTAG port and TAP controller, please refer to the *IEEE Standard 1149.1-Test Access Port and Boundary-Scan Architecture*.

The TM4C1233C3PM JTAG controller works with the ARM JTAG controller built into the Cortex-M4F core by multiplexing the TDO outputs from both JTAG controllers. ARM JTAG instructions select the ARM TDO output while JTAG instructions select the TDO output. The multiplexer is controlled by the JTAG controller, which has comprehensive programming for the ARM, Tiva™ C Series microcontroller, and unimplemented JTAG instructions.

The TM4C1233C3PM JTAG module has the following features:

- IEEE 1149.1-1990 compatible Test Access Port (TAP) controller
- Four-bit Instruction Register (IR) chain for storing JTAG instructions
- IEEE standard instructions: BYPASS, IDCODE, SAMPLE/PRELOAD, and EXTEST
- ARM additional instructions: APACC, DPACC and ABORT
- Integrated ARM Serial Wire Debug (SWD)
  - Serial Wire JTAG Debug Port (SWJ-DP)
  - Flash Patch and Breakpoint (FPB) unit for implementing breakpoints
  - Data Watchpoint and Trace (DWT) unit for implementing watchpoints, trigger resources, and system profiling
  - Instrumentation Trace Macrocell (ITM) for support of printf style debugging
  - Embedded Trace Macrocell (ETM) for instruction trace capture
  - Trace Port Interface Unit (TPIU) for bridging to a Trace Port Analyzer

See the *ARM® Debug Interface V5 Architecture Specification* for more information on the ARM JTAG controller.

## 4.1 Block Diagram

Figure 4-1. JTAG Module Block Diagram

## 4.2 Signal Description

The following table lists the external signals of the JTAG/SWD controller and describes the function of each. The JTAG/SWD controller signals are alternate functions for some GPIO signals, however note that the reset state of the pins is for the JTAG/SWD function. The JTAG/SWD controller signals are under commit protection and require a special process to be configured as GPIOs, see “Commit Control” on page 628. The column in the table below titled “Pin Mux/Pin Assignment” lists the GPIO pin placement for the JTAG/SWD controller signals. The **AFSEL** bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 642) is set to choose the JTAG/SWD function. The number in parentheses is the encoding that must be programmed into the **PMC<sub>n</sub>** field in the **GPIO Port Control (GPIOPTCL)** register (page 659) to assign the JTAG/SWD controller signals to the specified GPIO port pin. For more information on configuring GPIOs, see “General-Purpose Input/Outputs (GPIOs)” on page 621.

Table 4-1. JTAG\_SWD\_SWO Signals (64LQFP)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description         |
|----------|------------|--------------------------|----------|--------------------------|---------------------|
| SWCLK    | 52         | PC0 (1)                  | I        | TTL                      | JTAG/SWD CLK.       |
| SWDIO    | 51         | PC1 (1)                  | I/O      | TTL                      | JTAG TMS and SWDIO. |
| SWO      | 49         | PC3 (1)                  | O        | TTL                      | JTAG TDO and SWO.   |
| TCK      | 52         | PC0 (1)                  | I        | TTL                      | JTAG/SWD CLK.       |
| TDI      | 50         | PC2 (1)                  | I        | TTL                      | JTAG TDI.           |
| TDO      | 49         | PC3 (1)                  | O        | TTL                      | JTAG TDO and SWO.   |

**Table 4-1. JTAG\_SWD\_SWO Signals (64LQFP) (continued)**

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description         |
|----------|------------|--------------------------|----------|--------------------------|---------------------|
| TMS      | 51         | PC1 (1)                  | I        | TTL                      | JTAG TMS and SWDIO. |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 4.3 Functional Description

A high-level conceptual drawing of the JTAG module is shown in Figure 4-1 on page 193. The JTAG module is composed of the Test Access Port (TAP) controller and serial shift chains with parallel update registers. The TAP controller is a simple state machine controlled by the TCK and TMS inputs. The current state of the TAP controller depends on the sequence of values captured on TMS at the rising edge of TCK. The TAP controller determines when the serial shift chains capture new data, shift data from TDI towards TDO, and update the parallel load registers. The current state of the TAP controller also determines whether the Instruction Register (IR) chain or one of the Data Register (DR) chains is being accessed.

The serial shift chains with parallel load registers are comprised of a single Instruction Register (IR) chain and multiple Data Register (DR) chains. The current instruction loaded in the parallel load register determines which DR chain is captured, shifted, or updated during the sequencing of the TAP controller.

Some instructions, like EXTEST, operate on data currently in a DR chain and do not capture, shift, or update any of the chains. Instructions that are not implemented decode to the BYPASS instruction to ensure that the serial path between TDI and TDO is always connected (see Table 4-3 on page 200 for a list of implemented instructions).

See “JTAG and Boundary Scan” on page 1165 for JTAG timing diagrams.

**Note:** Of all the possible reset sources, only Power-On reset (POR) and the assertion of the  $\overline{\text{RST}}$  input have any effect on the JTAG module. The pin configurations are reset by both the  $\overline{\text{RST}}$  input and POR, whereas the internal JTAG logic is only reset with POR. See “Reset Sources” on page 205 for more information on reset.

### 4.3.1 JTAG Interface Pins

The JTAG interface consists of four standard pins: TCK, TMS, TDI, and TDO. These pins and their associated state after a power-on reset or reset caused by the  $\overline{\text{RST}}$  input are given in Table 4-2. Detailed information on each pin follows.

**Note:** The following pins are configured as JTAG port pins out of reset. Refer to “General-Purpose Input/Outputs (GPIOs)” on page 621 for information on how to reprogram the configuration of these pins.

**Table 4-2. JTAG Port Pins State after Power-On Reset or  $\overline{\text{RST}}$  assertion**

| Pin Name | Data Direction | Internal Pull-Up | Internal Pull-Down | Drive Strength | Drive Value |
|----------|----------------|------------------|--------------------|----------------|-------------|
| TCK      | Input          | Enabled          | Disabled           | N/A            | N/A         |
| TMS      | Input          | Enabled          | Disabled           | N/A            | N/A         |
| TDI      | Input          | Enabled          | Disabled           | N/A            | N/A         |
| TDO      | Output         | Enabled          | Disabled           | 2-mA driver    | High-Z      |

#### 4.3.1.1 Test Clock Input (TCK)

The TCK pin is the clock for the JTAG module. This clock is provided so the test logic can operate independently of any other system clocks and to ensure that multiple JTAG TAP controllers that are daisy-chained together can synchronously communicate serial test data between components. During normal operation, TCK is driven by a free-running clock with a nominal 50% duty cycle. When necessary, TCK can be stopped at 0 or 1 for extended periods of time. While TCK is stopped at 0 or 1, the state of the TAP controller does not change and data in the JTAG Instruction and Data Registers is not lost.

By default, the internal pull-up resistor on the TCK pin is enabled after reset, assuring that no clocking occurs if the pin is not driven from an external source. The internal pull-up and pull-down resistors can be turned off to save internal power as long as the TCK pin is constantly being driven by an external source (see page 648 and page 650).

#### 4.3.1.2 Test Mode Select (TMS)

The TMS pin selects the next state of the JTAG TAP controller. TMS is sampled on the rising edge of TCK. Depending on the current TAP state and the sampled value of TMS, the next state may be entered. Because the TMS pin is sampled on the rising edge of TCK, the *IEEE Standard 1149.1* expects the value on TMS to change on the falling edge of TCK.

Holding TMS high for five consecutive TCK cycles drives the TAP controller state machine to the Test-Logic-Reset state. When the TAP controller enters the Test-Logic-Reset state, the JTAG module and associated registers are reset to their default values. This procedure should be performed to initialize the JTAG controller. The JTAG Test Access Port state machine can be seen in its entirety in Figure 4-2 on page 196.

By default, the internal pull-up resistor on the TMS pin is enabled after reset. Changes to the pull-up resistor settings on GPIO Port C should ensure that the internal pull-up resistor remains enabled on PC1/TMS; otherwise JTAG communication could be lost (see page 648).

#### 4.3.1.3 Test Data Input (TDI)

The TDI pin provides a stream of serial information to the IR chain and the DR chains. TDI is sampled on the rising edge of TCK and, depending on the current TAP state and the current instruction, may present this data to the proper shift register chain. Because the TDI pin is sampled on the rising edge of TCK, the *IEEE Standard 1149.1* expects the value on TDI to change on the falling edge of TCK.

By default, the internal pull-up resistor on the TDI pin is enabled after reset. Changes to the pull-up resistor settings on GPIO Port C should ensure that the internal pull-up resistor remains enabled on PC2/TDI; otherwise JTAG communication could be lost (see page 648).

#### 4.3.1.4 Test Data Output (TDO)

The TDO pin provides an output stream of serial information from the IR chain or the DR chains. The value of TDO depends on the current TAP state, the current instruction, and the data in the chain being accessed. In order to save power when the JTAG port is not being used, the TDO pin is placed in an inactive drive state when not actively shifting out data. Because TDO can be connected to the TDI of another controller in a daisy-chain configuration, the *IEEE Standard 1149.1* expects the value on TDO to change on the falling edge of TCK.

By default, the internal pull-up resistor on the TDO pin is enabled after reset, assuring that the pin remains at a constant logic level when the JTAG port is not being used. The internal pull-up and

pull-down resistors can be turned off to save internal power if a High-Z output value is acceptable during certain TAP controller states (see page 648 and page 650).

### 4.3.2 JTAG TAP Controller

The JTAG TAP controller state machine is shown in Figure 4-2. The TAP controller state machine is reset to the Test-Logic-Reset state on the assertion of a Power-On-Reset (POR). In order to reset the JTAG module after the microcontroller has been powered on, the TMS input must be held HIGH for five TCK clock cycles, resetting the TAP controller and all associated JTAG chains. Asserting the correct sequence on the TMS pin allows the JTAG module to shift in new instructions, shift in data, or idle during extended testing sequences. For detailed information on the function of the TAP controller and the operations that occur in each state, please refer to *IEEE Standard 1149.1*.

Figure 4-2. Test Access Port State Machine

### 4.3.3 Shift Registers

The Shift Registers consist of a serial shift register chain and a parallel load register. The serial shift register chain samples specific information during the TAP controller's CAPTURE states and allows this information to be shifted out on TDO during the TAP controller's SHIFT states. While the sampled data is being shifted out of the chain on TDO, new data is being shifted into the serial shift register on TDI. This new data is stored in the parallel load register during the TAP controller's UPDATE states. Each of the shift registers is discussed in detail in "Register Descriptions" on page 200.

### 4.3.4 Operational Considerations

Certain operational parameters must be considered when using the JTAG module. Because the JTAG pins can be programmed to be GPIOs, board configuration and reset conditions on these pins must be considered. In addition, because the JTAG module has integrated ARM Serial Wire Debug, the method for switching between these two operational modes is described below.

#### 4.3.4.1 GPIO Functionality

When the microcontroller is reset with either a POR or  $\overline{\text{RST}}$ , the JTAG/SWD port pins default to their JTAG/SWD configurations. The default configuration includes enabling digital functionality ( $\text{DEN}[3:0]$  set in the **Port C GPIO Digital Enable (GPIODEN)** register), enabling the pull-up resistors ( $\text{PUE}[3:0]$  set in the **Port C GPIO Pull-Up Select (GPIOPUR)** register), disabling the pull-down resistors ( $\text{PDE}[3:0]$  cleared in the **Port C GPIO Pull-Down Select (GPIOPDR)** register) and enabling the alternate hardware function ( $\text{AFSEL}[3:0]$  set in the **Port C GPIO Alternate Function Select (GPIOAFSEL)** register) on the JTAG/SWD pins. See page 642, page 648, page 650, and page 653.

It is possible for software to configure these pins as GPIOs after reset by clearing  $\text{AFSEL}[3:0]$  in the **Port C GPIOAFSEL** register. If the user does not require the JTAG/SWD port for debugging or board-level testing, this provides four more GPIOs for use in the design.

**Caution – It is possible to create a software sequence that prevents the debugger from connecting to the TM4C1233C3PM microcontroller. If the program code loaded into flash immediately changes the JTAG pins to their GPIO functionality, the debugger may not have enough time to connect and halt the controller before the JTAG pin functionality switches. As a result, the debugger may be locked out of the part. This issue can be avoided with a software routine that restores JTAG functionality based on an external or software trigger. In the case that the software routine is not implemented and the device is locked out of the part, this issue can be solved by using the TM4C1233C3PM Flash Programmer "Unlock" feature. Please refer to [LMFLASHPROGRAMMER](#) on the TI web for more information.**

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is provided for the GPIO pins that can be used as the four JTAG/SWD pins and the NMI pin (see "Signal Tables" on page 1138 for pin numbers). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 642), **GPIO Pull Up Select (GPIOPUR)** register (see page 648), **GPIO Pull-Down Select (GPIOPDR)** register (see page 650), and **GPIO Digital Enable (GPIODEN)** register (see page 653) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 655) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 656) have been set.

#### 4.3.4.2 Communication with JTAG/SWD

Because the debug clock and the system clock can be running at different frequencies, care must be taken to maintain reliable communication with the JTAG/SWD interface. In the Capture-DR state, the result of the previous transaction, if any, is returned, together with a 3-bit ACK response. Software should check the ACK response to see if the previous operation has completed before initiating a new transaction. Alternatively, if the system clock is at least 8 times faster than the debug clock ( $\text{TCK}$  or  $\text{SWCLK}$ ), the previous operation has enough time to complete and the ACK bits do not have to be checked.

#### 4.3.4.3 Recovering a "Locked" Microcontroller

**Note:** Performing the sequence below restores the non-volatile registers discussed in "Non-Volatile Register Programming" on page 506 to their factory default values. The mass erase of the Flash memory caused by the sequence below occurs prior to the non-volatile registers being restored.

In addition, the EEPROM is erased and its wear-leveling counters are returned to factory default values when performing the sequence below.

If software configures any of the JTAG/SWD pins as GPIO and loses the ability to communicate with the debugger, there is a debug port unlock sequence that can be used to recover the microcontroller. Performing a total of ten JTAG-to-SWD and SWD-to-JTAG switch sequences while holding the microcontroller in reset mass erases the Flash memory. The debug port unlock sequence is:

1. Assert and hold the  $\overline{\text{RST}}$  signal.
2. Apply power to the device.
3. Perform steps 1 and 2 of the JTAG-to-SWD switch sequence on the section called “JTAG-to-SWD Switching” on page 199.
4. Perform steps 1 and 2 of the SWD-to-JTAG switch sequence on the section called “SWD-to-JTAG Switching” on page 199.
5. Perform steps 1 and 2 of the JTAG-to-SWD switch sequence.
6. Perform steps 1 and 2 of the SWD-to-JTAG switch sequence.
7. Perform steps 1 and 2 of the JTAG-to-SWD switch sequence.
8. Perform steps 1 and 2 of the SWD-to-JTAG switch sequence.
9. Perform steps 1 and 2 of the JTAG-to-SWD switch sequence.
10. Perform steps 1 and 2 of the SWD-to-JTAG switch sequence.
11. Perform steps 1 and 2 of the JTAG-to-SWD switch sequence.
12. Perform steps 1 and 2 of the SWD-to-JTAG switch sequence.
13. Release the  $\overline{\text{RST}}$  signal.
14. Wait 400 ms.
15. Power-cycle the microcontroller.

#### 4.3.4.4 ARM Serial Wire Debug (SWD)

In order to seamlessly integrate the ARM Serial Wire Debug (SWD) functionality, a serial-wire debugger must be able to connect to the Cortex-M4F core without having to perform, or have any knowledge of, JTAG cycles. This integration is accomplished with a SWD preamble that is issued before the SWD session begins.

The switching preamble used to enable the SWD interface of the SWJ-DP module starts with the TAP controller in the Test-Logic-Reset state. From here, the preamble sequences the TAP controller through the following states: Run Test Idle, Select DR, Select IR, Test Logic Reset, Test Logic Reset, Run Test Idle, Run Test Idle, Select DR, Select IR, Test Logic Reset, Test Logic Reset, Run Test Idle, Run Test Idle, Select DR, Select IR, and Test Logic Reset states.

Stepping through this sequence of the TAP state machine enables the SWD interface and disables the JTAG interface. For more information on this operation and the SWD interface, see the *ARM® Debug Interface V5 Architecture Specification*.

Because this sequence is a valid series of JTAG operations that could be issued, the ARM JTAG TAP controller is not fully compliant to the *IEEE Standard 1149.1*. This instance is the only one where the ARM JTAG TAP controller does not meet full compliance with the specification. Due to the low probability of this sequence occurring during normal operation of the TAP controller, it should not affect normal performance of the JTAG interface.

### **JTAG-to-SWD Switching**

To switch the operating mode of the Debug Access Port (DAP) from JTAG to SWD mode, the external debug hardware must send the switching preamble to the microcontroller. The 16-bit TMS/SWDIO command for switching to SWD mode is defined as b1110.0111.1001.1110, transmitted LSB first. This command can also be represented as 0xE79E when transmitted LSB first. The complete switch sequence should consist of the following transactions on the TCK/SWCLK and TMS/SWDIO signals:

1. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO High to ensure that both JTAG and SWD are in their reset states.
2. Send the 16-bit JTAG-to-SWD switch command, 0xE79E, on TMS/SWDIO.
3. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO High to ensure that if SWJ-DP was already in SWD mode before sending the switch sequence, the SWD goes into the line reset state.

To verify that the Debug Access Port (DAP) has switched to the Serial Wire Debug (SWD) operating mode, perform a SWD READID operation. The ID value can be compared against the device's known ID to verify the switch.

### **SWD-to-JTAG Switching**

To switch the operating mode of the Debug Access Port (DAP) from SWD to JTAG mode, the external debug hardware must send a switch command to the microcontroller. The 16-bit TMS/SWDIO command for switching to JTAG mode is defined as b1110.0111.0011.1100, transmitted LSB first. This command can also be represented as 0xE73C when transmitted LSB first. The complete switch sequence should consist of the following transactions on the TCK/SWCLK and TMS/SWDIO signals:

1. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO High to ensure that both JTAG and SWD are in their reset states.
2. Send the 16-bit SWD-to-JTAG switch command, 0xE73C, on TMS/SWDIO.
3. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO High to ensure that if SWJ-DP was already in JTAG mode before sending the switch sequence, the JTAG goes into the Test Logic Reset state.

To verify that the Debug Access Port (DAP) has switched to the JTAG operating mode, set the JTAG Instruction Register (IR) to the IDCODE instruction and shift out the Data Register (DR). The DR value can be compared against the device's known IDCODE to verify the switch.

## **4.4 Initialization and Configuration**

After a Power-On-Reset or an external reset ( $\overline{RST}$ ), the JTAG pins are automatically configured for JTAG communication. No user-defined initialization or configuration is needed. However, if the user application changes these pins to their GPIO function, they must be configured back to their JTAG functionality before JTAG communication can be restored. To return the pins to their JTAG functions, enable the four JTAG pins (PC[3:0]) for their alternate function using the **GPIOAFSEL** register.

In addition to enabling the alternate functions, any other changes to the GPIO pad configurations on the four JTAG pins ( $PC[3:0]$ ) should be returned to their default settings.

## 4.5 Register Descriptions

The registers in the JTAG TAP Controller or Shift Register chains are not memory mapped and are not accessible through the on-chip Advanced Peripheral Bus (APB). Instead, the registers within the JTAG controller are all accessed serially through the TAP Controller. These registers include the Instruction Register and the six Data Registers.

### 4.5.1 Instruction Register (IR)

The JTAG TAP Instruction Register (IR) is a four-bit serial scan chain connected between the JTAG TDI and TDO pins with a parallel load register. When the TAP Controller is placed in the correct states, bits can be shifted into the IR. Once these bits have been shifted into the chain and updated, they are interpreted as the current instruction. The decode of the IR bits is shown in Table 4-3. A detailed explanation of each instruction, along with its associated Data Register, follows.

**Table 4-3. JTAG Instruction Register Commands**

| IR[3:0]    | Instruction      | Description                                                                                                                        |
|------------|------------------|------------------------------------------------------------------------------------------------------------------------------------|
| 0x0        | EXTEST           | Drives the values preloaded into the Boundary Scan Chain by the SAMPLE/PRELOAD instruction onto the pads.                          |
| 0x2        | SAMPLE / PRELOAD | Captures the current I/O values and shifts the sampled values out of the Boundary Scan Chain while new preload data is shifted in. |
| 0x8        | ABORT            | Shifts data into the ARM Debug Port Abort Register.                                                                                |
| 0xA        | DPACC            | Shifts data into and out of the ARM DP Access Register.                                                                            |
| 0xB        | APACC            | Shifts data into and out of the ARM AC Access Register.                                                                            |
| 0xE        | IDCODE           | Loads manufacturing information defined by the <i>IEEE Standard 1149.1</i> into the IDCODE chain and shifts it out.                |
| 0xF        | BYPASS           | Connects TDI to TDO through a single Shift Register chain.                                                                         |
| All Others | Reserved         | Defaults to the BYPASS instruction to ensure that TDI is always connected to TDO.                                                  |

#### 4.5.1.1 EXTEST Instruction

The EXTEST instruction is not associated with its own Data Register chain. Instead, the EXTEST instruction uses the data that has been preloaded into the Boundary Scan Data Register using the SAMPLE/PRELOAD instruction. When the EXTEST instruction is present in the Instruction Register, the preloaded data in the Boundary Scan Data Register associated with the outputs and output enables are used to drive the GPIO pads rather than the signals coming from the core. With tests that drive known values out of the controller, this instruction can be used to verify connectivity. While the EXTEST instruction is present in the Instruction Register, the Boundary Scan Data Register can be accessed to sample and shift out the current data and load new data into the Boundary Scan Data Register.

#### 4.5.1.2 SAMPLE/PRELOAD Instruction

The SAMPLE/PRELOAD instruction connects the Boundary Scan Data Register chain between TDI and TDO. This instruction samples the current state of the pad pins for observation and preloads new test data. Each GPIO pad has an associated input, output, and output enable signal. When the TAP controller enters the Capture DR state during this instruction, the input, output, and output-enable signals to each of the GPIO pads are captured. These samples are serially shifted out on TDO while

the TAP controller is in the Shift DR state and can be used for observation or comparison in various tests.

While these samples of the inputs, outputs, and output enables are being shifted out of the Boundary Scan Data Register, new data is being shifted into the Boundary Scan Data Register from TDI. Once the new data has been shifted into the Boundary Scan Data Register, the data is saved in the parallel load registers when the TAP controller enters the Update DR state. This update of the parallel load register preloads data into the Boundary Scan Data Register that is associated with each input, output, and output enable. This preloaded data can be used with the EXTEST instruction to drive data into or out of the controller. See “Boundary Scan Data Register” on page 202 for more information.

#### 4.5.1.3 ABORT Instruction

The ABORT instruction connects the associated ABORT Data Register chain between TDI and TDO. This instruction provides read and write access to the ABORT Register of the ARM Debug Access Port (DAP). Shifting the proper data into this Data Register clears various error bits or initiates a DAP abort of a previous request. See the “ABORT Data Register” on page 203 for more information.

#### 4.5.1.4 DPACC Instruction

The DPACC instruction connects the associated DPACC Data Register chain between TDI and TDO. This instruction provides read and write access to the DPACC Register of the ARM Debug Access Port (DAP). Shifting the proper data into this register and reading the data output from this register allows read and write access to the ARM debug and status registers. See “DPACC Data Register” on page 203 for more information.

#### 4.5.1.5 APACC Instruction

The APACC instruction connects the associated APACC Data Register chain between TDI and TDO. This instruction provides read and write access to the APACC Register of the ARM Debug Access Port (DAP). Shifting the proper data into this register and reading the data output from this register allows read and write access to internal components and buses through the Debug Port. See “APACC Data Register” on page 203 for more information.

#### 4.5.1.6 IDCODE Instruction

The IDCODE instruction connects the associated IDCODE Data Register chain between TDI and TDO. This instruction provides information on the manufacturer, part number, and version of the ARM core. This information can be used by testing equipment and debuggers to automatically configure input and output data streams. IDCODE is the default instruction loaded into the JTAG Instruction Register when a Power-On-Reset (POR) is asserted, or the Test-Logic-Reset state is entered. See “IDCODE Data Register” on page 202 for more information.

#### 4.5.1.7 BYPASS Instruction

The BYPASS instruction connects the associated BYPASS Data Register chain between TDI and TDO. This instruction is used to create a minimum length serial path between the TDI and TDO ports. The BYPASS Data Register is a single-bit shift register. This instruction improves test efficiency by allowing components that are not needed for a specific test to be bypassed in the JTAG scan chain by loading them with the BYPASS instruction. See “BYPASS Data Register” on page 202 for more information.

## 4.5.2 Data Registers

The JTAG module contains six Data Registers. These serial Data Register chains include: IDCODE, BYPASS, Boundary Scan, APACC, DPACC, and ABORT and are discussed in the following sections.

### 4.5.2.1 IDCODE Data Register

The format for the 32-bit IDCODE Data Register defined by the *IEEE Standard 1149.1* is shown in Figure 4-3. The standard requires that every JTAG-compliant microcontroller implement either the IDCODE instruction or the BYPASS instruction as the default instruction. The LSB of the IDCODE Data Register is defined to be a 1 to distinguish it from the BYPASS instruction, which has an LSB of 0. This definition allows auto-configuration test tools to determine which instruction is the default instruction.

The major uses of the JTAG port are for manufacturer testing of component assembly and program development and debug. To facilitate the use of auto-configuration debug tools, the IDCODE instruction outputs a value of 0x4BA0.0477. This value allows the debuggers to automatically configure themselves to work correctly with the Cortex-M4F during debug.

**Figure 4-3. IDCODE Register Format**

### 4.5.2.2 BYPASS Data Register

The format for the 1-bit BYPASS Data Register defined by the *IEEE Standard 1149.1* is shown in Figure 4-4. The standard requires that every JTAG-compliant microcontroller implement either the BYPASS instruction or the IDCODE instruction as the default instruction. The LSB of the BYPASS Data Register is defined to be a 0 to distinguish it from the IDCODE instruction, which has an LSB of 1. This definition allows auto-configuration test tools to determine which instruction is the default instruction.

**Figure 4-4. BYPASS Register Format**

### 4.5.2.3 Boundary Scan Data Register

The format of the Boundary Scan Data Register is shown in Figure 4-5. Each GPIO pin, starting with a GPIO pin next to the JTAG port pins, is included in the Boundary Scan Data Register. Each GPIO pin has three associated digital signals that are included in the chain. These signals are input, output, and output enable, and are arranged in that order as shown in the figure.

When the Boundary Scan Data Register is accessed with the SAMPLE/PRELOAD instruction, the input, output, and output enable from each digital pad are sampled and then shifted out of the chain to be verified. The sampling of these values occurs on the rising edge of  $TCK$  in the Capture DR state of the TAP controller. While the sampled data is being shifted out of the Boundary Scan chain in the Shift DR state of the TAP controller, new data can be preloaded into the chain for use with the EXTEST instruction. The EXTEST instruction forces data out of the controller.

**Figure 4-5. Boundary Scan Register Format**

#### 4.5.2.4 APACC Data Register

The format for the 35-bit APACC Data Register defined by ARM is described in the *ARM® Debug Interface V5 Architecture Specification*.

#### 4.5.2.5 DPACC Data Register

The format for the 35-bit DPACC Data Register defined by ARM is described in the *ARM® Debug Interface V5 Architecture Specification*.

#### 4.5.2.6 ABORT Data Register

The format for the 35-bit ABORT Data Register defined by ARM is described in the *ARM® Debug Interface V5 Architecture Specification*.

## 5 System Control

System control configures the overall operation of the device and provides information about the device. Configurable features include reset control, NMI operation, power control, clock control, and low-power modes.

### 5.1 Signal Description

The following table lists the external signals of the System Control module and describes the function of each. The **NMI** signal is the alternate function for two GPIO signals and functions as a GPIO after reset. The **NMI** pins are under commit protection and require a special process to be configured as any alternate function or to subsequently return to the GPIO function, see “Commit Control” on page 628. The column in the table below titled “Pin Mux/Pin Assignment” lists the GPIO pin placement for the **NMI** signal. The **AFSEL** bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 642) should be set to choose the NMI function. The number in parentheses is the encoding that must be programmed into the **PMC<sub>n</sub>** field in the **GPIO Port Control (GPIOPTCL)** register (page 659) to assign the **NMI** signal to the specified GPIO port pin. For more information on configuring GPIOs, see “General-Purpose Input/Outputs (GPIOs)” on page 621. The remaining signals (with the word “fixed” in the Pin Mux/Pin Assignment column) have a fixed pin assignment and function.

**Table 5-1. System Control & Clocks Signals (64LQFP)**

| Pin Name                | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                                                                               |
|-------------------------|------------|--------------------------|----------|--------------------------|-------------------------------------------------------------------------------------------|
| NMI                     | 10<br>28   | PD7 (8)<br>PF0 (8)       | I        | TTL                      | Non-maskable interrupt.                                                                   |
| OSC0                    | 40         | fixed                    | I        | Analog                   | Main oscillator crystal input or an external clock reference input.                       |
| OSC1                    | 41         | fixed                    | O        | Analog                   | Main oscillator crystal output. Leave unconnected when using a single-ended clock source. |
| $\overline{\text{RST}}$ | 38         | fixed                    | I        | TTL                      | System reset input.                                                                       |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

### 5.2 Functional Description

The System Control module provides the following capabilities:

- Device identification, see “Device Identification” on page 204
- Local control, such as reset (see “Reset Control” on page 205), power (see “Power Control” on page 210) and clock control (see “Clock Control” on page 211)
- System control (Run, Sleep, and Deep-Sleep modes), see “System Control” on page 218

#### 5.2.1 Device Identification

Several read-only registers provide software with information on the microcontroller, such as version, part number, memory sizes, and peripherals present on the device. The **Device Identification 0 (DID0)** (page 229) and **Device Identification 1 (DID1)** (page 231) registers provide details about the device's version, package, temperature range, and so on. The Peripheral Present registers starting at System Control offset 0x300, such as the **Watchdog Timer Peripheral Present (PPWD)** register, provide information on how many of each type of module are included on the device. Finally,

information about the capabilities of the on-chip peripherals are provided at offset 0xFC0 in each peripheral's register space in the Peripheral Properties registers, such as the **GPTM Peripheral Properties (GPTMPP)** register. Previous devices used the **Device Capabilities (DC0-DC9)** registers for information about the peripherals and their capabilities. These registers are present on this device for backward software capability, but provide no information about peripherals that were not available on older devices.

## 5.2.2 Reset Control

This section discusses aspects of hardware functions during reset as well as system software requirements following the reset sequence.

### 5.2.2.1 Reset Sources

The TM4C1233C3PM microcontroller has six sources of reset:

1. Power-on reset (POR) (see page 206).
2. External reset input pin ( $\overline{RST}$ ) assertion (see page 207).
3. A brown-out detection that can be caused by any of the following events: (see page 208).
  - $V_{DD}$  under BOR0. The trigger value is the highest  $V_{DD}$  voltage level for BOR0.
  - $V_{DD}$  under BOR1. The trigger value is the highest  $V_{DD}$  voltage level for BOR1.
4. Software-initiated reset (with the software reset registers) (see page 209).
5. A watchdog timer reset condition violation (see page 209).
6. MOSC failure (see page 210).

Table 5-2 provides a summary of results of the various reset operations.

**Table 5-2. Reset Sources**

| Reset Source                                                                                           | Core Reset? | JTAG Reset?     | On-Chip Peripherals Reset? |
|--------------------------------------------------------------------------------------------------------|-------------|-----------------|----------------------------|
| Power-On Reset                                                                                         | Yes         | Yes             | Yes                        |
| $\overline{RST}$                                                                                       | Yes         | Pin Config Only | Yes                        |
| Brown-Out Reset                                                                                        | Yes         | Pin Config Only | Yes                        |
| Software System Request Reset using the <code>SYSRESREQ</code> bit in the <code>APINT</code> register. | Yes         | Pin Config Only | Yes                        |
| Software System Request Reset using the <code>VECTRESET</code> bit in the <code>APINT</code> register. | Yes         | Pin Config Only | No                         |
| Software Peripheral Reset                                                                              | No          | Pin Config Only | Yes <sup>a</sup>           |
| Watchdog Reset                                                                                         | Yes         | Pin Config Only | Yes                        |
| MOSC Failure Reset                                                                                     | Yes         | Pin Config Only | Yes                        |

a. Programmable on a module-by-module basis using the Software Reset Control Registers.

After a reset, the **Reset Cause (RESC)** register is set with the reset cause. The bits in this register are sticky and maintain their state across multiple reset sequences, except when an internal POR

is the cause, in which case, all the bits in the **RESC** register are cleared except for the POR indicator. A bit in the **RESC** register can be cleared by writing a 0.

At any reset that resets the core, the user has the opportunity to direct the core to execute the ROM Boot Loader or the application in Flash memory by using any GPIO signal as configured in the **Boot Configuration (BOOTCFG)** register.

At reset, the following sequence is performed:

1. The **BOOTCFG** register is read. If the **EN** bit is clear, the ROM Boot Loader is executed.
2. In the ROM Boot Loader, the status of the specified GPIO pin is compared with the specified polarity. If the status matches the specified polarity, the ROM is mapped to address 0x0000.0000 and execution continues out of the ROM Boot Loader.
3. If then **EN** bit is set or the status doesn't match the specified polarity, the data at address 0x0000.0004 is read, and if the data at this address is 0xFFFF.FFFF, the ROM is mapped to address 0x0000.0000 and execution continues out of the ROM Boot Loader.
4. If there is data at address 0x0000.0004 that is not 0xFFFF.FFFF, the stack pointer (**SP**) is loaded from Flash memory at address 0x0000.0000 and the program counter (**PC**) is loaded from address 0x0000.0004. The user application begins executing.

**Note:** If the device fails the initialization phase, it toggles the **TDO** output pin as an indication the device is not executing. This feature is provided for debug purposes.

For example, if the **BOOTCFG** register is written and committed with the value of 0x0000.3C01, then **PB7** is examined at reset to determine if the ROM Boot Loader should be executed. If **PB7** is Low, the core unconditionally begins executing the ROM boot loader. If **PB7** is High, then the application in Flash memory is executed if the reset vector at location 0x0000.0004 is not 0xFFFF.FFFF. Otherwise, the ROM boot loader is executed.

### 5.2.2.2 Power-On Reset (POR)

**Note:** The JTAG controller can only be reset by the power-on reset.

The internal Power-On Reset (POR) circuit monitors the power supply voltage ( $V_{DD}$ ) and generates a reset signal to all of the internal logic including JTAG when the power supply ramp reaches a threshold value ( $V_{VDD\_POK}$ ). The microcontroller must be operating within the specified operating parameters when the on-chip power-on reset pulse is complete (see “Power and Brown-Out” on page 1167). For applications that require the use of an external reset signal to hold the microcontroller in reset longer than the internal POR, the  $\overline{RST}$  input may be used as discussed in “External  $\overline{RST}$  Pin” on page 207.

The Power-On Reset sequence is as follows:

1. The microcontroller waits for internal POR to go inactive.
2. The internal reset is released and the core loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

The internal POR is only active on the initial power-up of the microcontroller and when the microcontroller wakes from hibernation. The Power-On Reset timing is shown in “Power and Brown-Out” on page 1167.

### 5.2.2.3 External $\overline{\text{RST}}$ Pin

**Note:** It is recommended that the trace for the  $\overline{\text{RST}}$  signal must be kept as short as possible. Be sure to place any components connected to the  $\overline{\text{RST}}$  signal as close to the microcontroller as possible.

If the application only uses the internal POR circuit, the  $\overline{\text{RST}}$  input must be connected to the power supply ( $V_{\text{DD}}$ ) through an optional pull-up resistor (0 to 100K  $\Omega$ ) as shown in Figure 5-1 on page 207. The  $\overline{\text{RST}}$  input has filtering which requires a minimum pulse width in order for the reset pulse to be recognized, see Table 22-11 on page 1172.

**Figure 5-1. Basic  $\overline{\text{RST}}$  Configuration**

$R_{\text{PU}} = 0$  to 100 k $\Omega$

The external reset pin ( $\overline{\text{RST}}$ ) resets the microcontroller including the core and all the on-chip peripherals. The external reset sequence is as follows:

1. The external reset pin ( $\overline{\text{RST}}$ ) is asserted for the duration specified by  $T_{\text{MIN}}$  and then deasserted (see "Reset" on page 1172).
2. The internal reset is released and the core loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

To improve noise immunity and/or to delay reset at power up, the  $\overline{\text{RST}}$  input may be connected to an RC network as shown in Figure 5-2 on page 207.

**Figure 5-2. External Circuitry to Extend Power-On Reset**

$R_{\text{PU}} = 1$  k $\Omega$  to 100 k $\Omega$

$C_1 = 1$  nF to 10  $\mu\text{F}$

If the application requires the use of an external reset switch, Figure 5-3 on page 208 shows the proper circuitry to use.

**Figure 5-3. Reset Circuit Controlled by Switch**

Typical  $R_{PU} = 10\text{ k}\Omega$

Typical  $R_S = 470\ \Omega$

$C_1 = 10\text{ nF}$

The  $R_{PU}$  and  $C_1$  components define the power-on delay.

The external reset timing is shown in Figure 22-11 on page 1173.

#### 5.2.2.4 Brown-Out Reset (BOR)

The microcontroller provides a brown-out detection circuit that triggers if any of the following occur:

- $V_{DD}$  under BOR0. The external  $V_{DD}$  supply voltage is below the specified  $V_{DD}$  BOR0 value. The trigger value is the highest  $V_{DD}$  voltage level for BOR0.
- $V_{DD}$  under BOR1. The external  $V_{DD}$  supply voltage is below the specified  $V_{DD}$  BOR1 value. The trigger value is the highest  $V_{DD}$  voltage level for BOR1.

The application can identify that a BOR event caused a reset by reading the **Reset Cause (RESC)** register. When a brown-out condition is detected, the default condition is to generate a reset. The BOR events can also be programmed to generate an interrupt by clearing the BOR0 bit or BOR1 bit in the **Power-On and Brown-Out Reset Control (PBORCTL)** register.

The brown-out reset sequence is as follows:

1. When  $V_{DD}$  drops below  $V_{BORnTH}$ , an internal BOR condition is set. Please refer to “Power and Brown-Out” on page 1167 for  $V_{BORnTH}$  value.
2. If the BOR condition exists, an internal reset is asserted.
3. The internal reset is released and the microcontroller fetches and loads the initial stack pointer, the initial program counter, the first instruction designated by the program counter, and begins execution.

The result of a brown-out reset is equivalent to that of an assertion of the external  $\overline{RST}$  input, and the reset is held active until the proper  $V_{DD}$  level is restored. The **RESC** register can be examined in the reset interrupt handler to determine if a Brown-Out condition was the cause of the reset, thus allowing software to determine what actions are required to recover.

The internal Brown-Out Reset timing is shown in “Power and Brown-Out” on page 1167.

#### 5.2.2.5 Software Reset

Software can reset a specific peripheral or generate a reset to the entire microcontroller.

Peripherals can be individually reset by software via peripheral-specific reset registers available beginning at System Control offset 0x500 (for example the **Watchdog Timer Software Reset (SRWD)** register). If the bit position corresponding to a peripheral is set and subsequently cleared, the peripheral is reset.

The entire microcontroller, including the core, can be reset by software by setting the `SYSRESREQ` bit in the **Application Interrupt and Reset Control (APINT)** register. The software-initiated system reset sequence is as follows:

1. A software microcontroller reset is initiated by setting the `SYSRESREQ` bit.
2. An internal reset is asserted.
3. The internal reset is deasserted and the microcontroller loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

The core only can be reset by software by setting the `VECTRESET` bit in the **APINT** register. The software-initiated core reset sequence is as follows:

1. A core reset is initiated by setting the `VECTRESET` bit.
2. An internal reset is asserted.
3. The internal reset is deasserted and the microcontroller loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

The software-initiated system reset timing is shown in Figure 22-12 on page 1173.

#### 5.2.2.6 Watchdog Timer Reset

The Watchdog Timer module's function is to prevent system hangs. The TM4C1233C3PM microcontroller has two Watchdog Timer modules in case one watchdog clock source fails. One watchdog is run off the system clock and the other is run off the Precision Internal Oscillator (PIOSC). Each module operates in the same manner except that because the PIOSC watchdog timer module is in a different clock domain, register accesses must have a time delay between them. The watchdog timer can be configured to generate an interrupt or a non-maskable interrupt to the microcontroller on its first time-out and to generate a reset on its second time-out.

After the watchdog's first time-out event, the 32-bit watchdog counter is reloaded with the value of the **Watchdog Timer Load (WDTLOAD)** register and resumes counting down from that value. If the timer counts down to zero again before the first time-out interrupt is cleared, and the reset signal has been enabled, the watchdog timer asserts its reset signal to the microcontroller. The watchdog timer reset sequence is as follows:

1. The watchdog timer times out for the second time without being serviced.
2. An internal reset is asserted.

3. The internal reset is released and the microcontroller loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

For more information on the Watchdog Timer module, see “Watchdog Timers” on page 745.

The watchdog reset timing is shown in Figure 22-13 on page 1173.

### 5.2.3 Non-Maskable Interrupt

The microcontroller has four sources of non-maskable interrupt (NMI):

- The assertion of the `NMI` signal
- A main oscillator verification error
- The `NMISSET` bit in the **Interrupt Control and State (INTCTRL)** register in the Cortex™-M4F (see page 152).
- The Watchdog module time-out interrupt when the `INTTYPE` bit in the **Watchdog Control (WDTCTL)** register is set (see page 751).

Software must check the cause of the interrupt in order to distinguish among the sources.

#### 5.2.3.1 NMI Pin

The `NMI` signal is an alternate function for either GPIO port pin `PD7` or `PF0`. The alternate function must be enabled in the GPIO for the signal to be used as an interrupt, as described in “General-Purpose Input/Outputs (GPIOs)” on page 621. Note that enabling the NMI alternate function requires the use of the GPIO lock and commit function just like the GPIO port pins associated with JTAG/SWD functionality, see page 656. The active sense of the `NMI` signal is High; asserting the enabled `NMI` signal above  $V_{IH}$  initiates the NMI interrupt sequence.

#### 5.2.3.2 Main Oscillator Verification Failure

The TM4C1233C3PM microcontroller provides a main oscillator verification circuit that generates an error condition if the oscillator is running too fast or too slow. If the main oscillator verification circuit is enabled and a failure occurs, either a power-on reset is generated and control is transferred to the NMI handler, or an interrupt is generated. The `MOSCIM` bit in the **MOSCCTL** register determines which action occurs. In either case, the system clock source is automatically switched to the `PIOSC`. If a MOSC failure reset occurs, the NMI handler is used to address the main oscillator verification failure because the necessary code can be removed from the general reset handler, speeding up reset processing. The detection circuit is enabled by setting the `CVAL` bit in the **Main Oscillator Control (MOSCCTL)** register. The main oscillator verification error is indicated in the main oscillator fail status (`MOSCFAIL`) bit in the **Reset Cause (RESC)** register. The main oscillator verification circuit action is described in more detail in “Main Oscillator Verification Circuit” on page 218.

### 5.2.4 Power Control

The TM4C1233C3PM microcontroller provides an integrated LDO regulator that is used to provide power to the majority of the microcontroller's internal logic. Figure 5-4 shows the power architecture.

An external LDO may not be used.

**Note:** `VDDA` must be supplied with a voltage that meets the specification in Table 22-5 on page 1162, or the microcontroller does not function properly. `VDDA` is the supply for all of the analog circuitry on the device, including the clock circuitry.

Figure 5-4. Power Architecture

## 5.2.5 Clock Control

System control determines the control of clocks in this part.

### 5.2.5.1 Fundamental Clock Sources

There are multiple clock sources for use in the microcontroller:

- Precision Internal Oscillator (PIOSC).** The precision internal oscillator is an on-chip clock source that is the clock source the microcontroller uses during and following POR. It does not require the use of any external components and provides a 16-MHz clock with  $\pm 1\%$  accuracy with calibration and  $\pm 3\%$  accuracy across temperature (see “PIOSC Specifications” on page 1176). The PIOSC allows for a reduced system cost in applications that require an accurate clock source. If the main oscillator is required, software must enable the main oscillator following reset and allow the main oscillator to stabilize before changing the clock reference. If the Hibernation Module clock source is a 32.768-kHz oscillator, the precision internal oscillator can be trimmed by software based on a reference clock for increased accuracy. Regardless of whether or not the PIOSC is the source for the system clock, the PIOSC can be configured to be the source for the ADC clock as well as the baud clock for the UART and SSI, see “System Control” on page 218.
- Main Oscillator (MOSC).** The main oscillator provides a frequency-accurate clock source by one of two means: an external single-ended clock source is connected to the OSC0 input pin, or an external crystal is connected across the OSC0 input and OSC1 output pins. If the PLL is being

used, the crystal value must be one of the supported frequencies between 5 MHz to 25 MHz (inclusive). If the PLL is not being used, the crystal may be any one of the supported frequencies between 4 MHz to 25 MHz. The single-ended clock source range is as specified in Table 22-13 on page 1175. The supported crystals are listed in the `XTAL` bit field in the **RCC** register (see page 245). Note that the MOSC provides the clock source for the USB PLL and must be connected to a crystal or an oscillator.

- **Low-Frequency Internal Oscillator (LFIOSC).** The low-frequency internal oscillator is intended for use during Deep-Sleep power-saving modes. The frequency can have wide variations; refer to “Low-Frequency Internal Oscillator (LFIOSC) Specifications” on page 1176 for more details. This power-savings mode benefits from reduced internal switching and also allows the MOSC to be powered down. In addition, the PIOSC can be powered down while in Deep-Sleep mode.
- **Hibernation Module Clock Source.** The Hibernation module is clocked by a 32.768-kHz oscillator connected to the `XOSC0` pin. The 32.768-kHz oscillator can be used for the system clock, thus eliminating the need for an additional crystal or oscillator. The Hibernation module clock source is intended to provide the system with a real-time clock source and may also provide an accurate source of Deep-Sleep or Hibernate mode power savings.

The internal system clock (SysClk), is derived from any of the above sources plus two others: the output of the main internal PLL and the precision internal oscillator divided by four ( $4 \text{ MHz} \pm 1\%$ ). The frequency of the PLL clock reference must be in the range of 5 MHz to 25 MHz (inclusive). Table 5-3 on page 212 shows how the various clock sources can be used in a system.

**Table 5-3. Clock Source Options**

| Clock Source                                                          | Drive PLL? |                             | Used as SysClk? |                          |
|-----------------------------------------------------------------------|------------|-----------------------------|-----------------|--------------------------|
|                                                                       | Yes        | No                          | Yes             | No                       |
| Precision Internal Oscillator                                         | Yes        | BYPASS = 0,<br>OSCSRC = 0x1 | Yes             | BYPASS = 1, OCSRC = 0x1  |
| Precision Internal Oscillator divide by 4 ( $4 \text{ MHz} \pm 1\%$ ) | No         | -                           | Yes             | BYPASS = 1, OCSRC = 0x2  |

### 5.2.5.2 Clock Configuration

The **Run-Mode Clock Configuration (RCC)** and **Run-Mode Clock Configuration 2 (RCC2)** registers provide control for the system clock. The **RCC2** register is provided to extend fields that offer additional encodings over the **RCC** register. When used, the **RCC2** register field values are used by the logic over the corresponding field in the **RCC** register. In particular, **RCC2** provides for a larger assortment of clock configuration options. These registers control the following clock functionality:

- Source of clocks in sleep and deep-sleep modes
- System clock derived from PLL or other clock source
- Enabling/disabling of oscillators and PLL
- Clock divisors

- Crystal input selection

---

**Important:** Write the **RCC** register prior to writing the **RCC2** register.

When transitioning the system clock configuration to use the MOSC as the fundamental clock source, the `MOSCDIS` bit must be set prior to reselecting the MOSC or an undefined system clock configuration can sporadically occur.

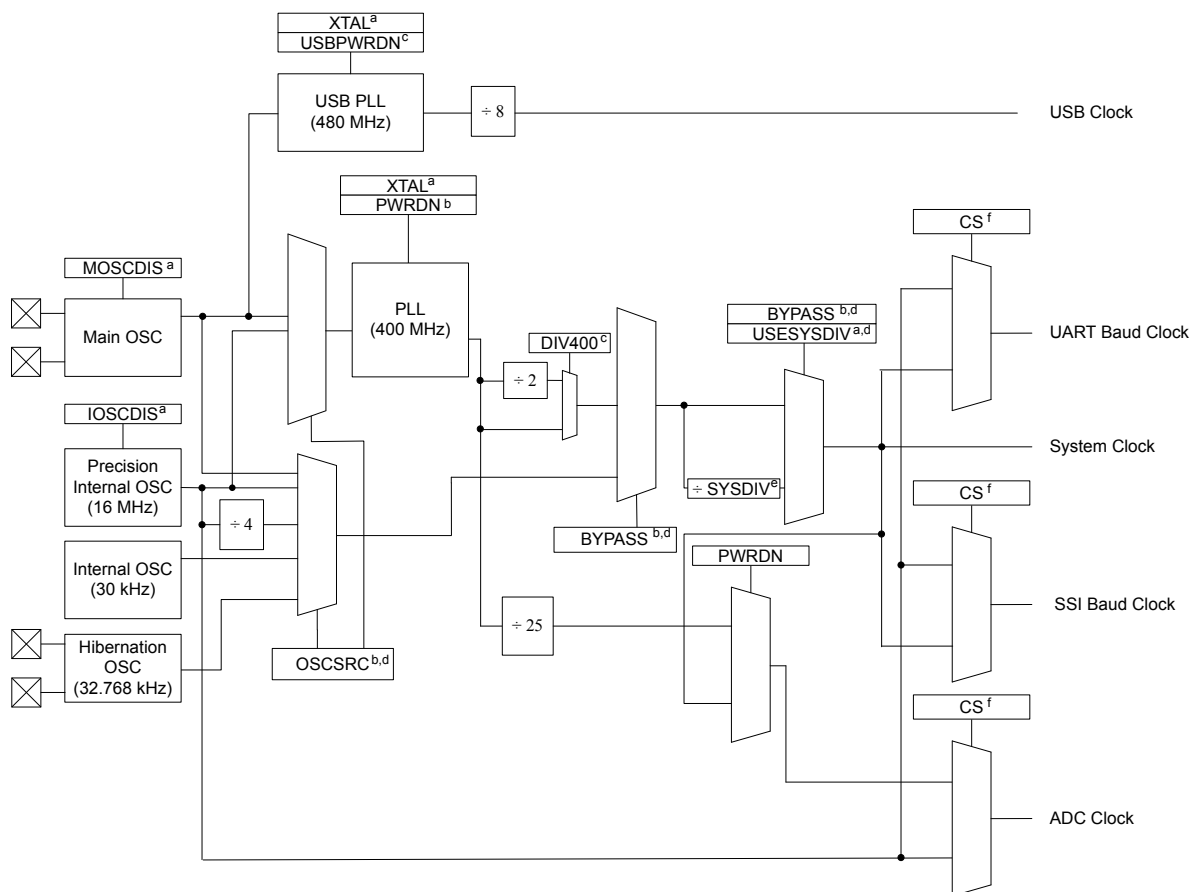

The configuration of the system clock must not be changed while an EEPROM operation is in process. Software must wait until the `WORKING` bit in the **EEPROM Done Status (EEDONE)** register is clear before making any changes to the system clock.

---

Figure 5-5 shows the logic for the main clock tree. The peripheral blocks are driven by the system clock signal and can be individually enabled/disabled. The ADC clock signal can be selected from the PIOSC, the system clock if the PLL is disabled, or the PLL output divided down to 16 MHz if the PLL is enabled.

**Note:** If the ADC module is not using the PIOSC as the clock source, the system clock must be at least 16 MHz. When the USB module is in operation, MOSC must be the clock source, either with or without using the PLL, and the system clock must be at least 20 MHz.

Figure 5-5. Main Clock Tree

- Note:**
- a. Control provided by **RCC** register bit/field.
  - b. Control provided by **RCC** register bit/field or **RCC2** register bit/field, if overridden with **RCC2** register bit USERCC2.
  - c. Control provided by **RCC2** register bit/field.
  - d. Also may be controlled by **DSLCLKCFG** when in deep sleep mode.
  - e. Control provided by **RCC** register **SYSDIV** field, **RCC2** register **SYSDIV2** field if overridden with **USERCC2** bit, or **[SYSDIV2,SYSDIV2LSB]** if both **USERCC2** and **DIV400** bits are set.
  - f. Control provided by **UARTCC**, **SSICC**, and **ADCC** register field.

### Communication Clock Sources

In addition to the main clock tree described above, the UART, and SSI modules all have a Clock Control register in the peripheral's register map at offset 0xFC8 that can be used to select the clock source for the module's baud clock. Users can choose between the system clock, which is the default source for the baud clock, and the PIOC. Note that there may be special considerations when using the PIOC as the baud clock. For more information, see the Clock Control register description in the chapter describing the operation of the module.

### Using the SYSDIV and SYSDIV2 Fields

In the **RCC** register, the **SYSDIV** field specifies which divisor is used to generate the system clock from either the PLL output or the oscillator source (depending on how the **BYPASS** bit in this register is configured). When using the PLL, the VCO frequency of 400 MHz is predivided by 2 before the divisor is applied. Table 5-4 shows how the **SYSDIV** encoding affects the system clock frequency,

depending on whether the PLL is used (BYPASS=0) or another clock source is used (BYPASS=1). The divisor is equivalent to the SYSDIV encoding plus 1. For a list of possible clock sources, see Table 5-3 on page 212.

**Table 5-4. Possible System Clock Frequencies Using the SYSDIV Field**

| SYSDIV | Divisor | Frequency (BYPASS=0) | Frequency (BYPASS=1)      | TivaWare™ Parameter <sup>a</sup> |
|--------|---------|----------------------|---------------------------|----------------------------------|
| 0x0    | /1      | reserved             | Clock source frequency/1  | SYSCCTL_SYSDIV_1                 |
| 0x1    | /2      | reserved             | Clock source frequency/2  | SYSCCTL_SYSDIV_2                 |
| 0x2    | /3      | 66.67 MHz            | Clock source frequency/3  | SYSCCTL_SYSDIV_3                 |
| 0x3    | /4      | 50 MHz               | Clock source frequency/4  | SYSCCTL_SYSDIV_4                 |
| 0x4    | /5      | 40 MHz               | Clock source frequency/5  | SYSCCTL_SYSDIV_5                 |
| 0x5    | /6      | 33.33 MHz            | Clock source frequency/6  | SYSCCTL_SYSDIV_6                 |
| 0x6    | /7      | 28.57 MHz            | Clock source frequency/7  | SYSCCTL_SYSDIV_7                 |
| 0x7    | /8      | 25 MHz               | Clock source frequency/8  | SYSCCTL_SYSDIV_8                 |
| 0x8    | /9      | 22.22 MHz            | Clock source frequency/9  | SYSCCTL_SYSDIV_9                 |
| 0x9    | /10     | 20 MHz               | Clock source frequency/10 | SYSCCTL_SYSDIV_10                |
| 0xA    | /11     | 18.18 MHz            | Clock source frequency/11 | SYSCCTL_SYSDIV_11                |
| 0xB    | /12     | 16.67 MHz            | Clock source frequency/12 | SYSCCTL_SYSDIV_12                |
| 0xC    | /13     | 15.38 MHz            | Clock source frequency/13 | SYSCCTL_SYSDIV_13                |
| 0xD    | /14     | 14.29 MHz            | Clock source frequency/14 | SYSCCTL_SYSDIV_14                |
| 0xE    | /15     | 13.33 MHz            | Clock source frequency/15 | SYSCCTL_SYSDIV_15                |
| 0xF    | /16     | 12.5 MHz (default)   | Clock source frequency/16 | SYSCCTL_SYSDIV_16                |

a. This parameter is used in functions such as SysCtlClockSet() in the TivaWare Peripheral Driver Library.

The SYSDIV2 field in the **RCC2** register is 2 bits wider than the SYSDIV field in the **RCC** register so that additional larger divisors up to /64 are possible, allowing a lower system clock frequency for improved Deep Sleep power consumption. When using the PLL, the VCO frequency of 400 MHz is predivided by 2 before the divisor is applied. The divisor is equivalent to the SYSDIV2 encoding plus 1. Table 5-5 shows how the SYSDIV2 encoding affects the system clock frequency, depending on whether the PLL is used (BYPASS2=0) or another clock source is used (BYPASS2=1). For a list of possible clock sources, see Table 5-3 on page 212.

**Table 5-5. Examples of Possible System Clock Frequencies Using the SYSDIV2 Field**

| SYSDIV2 | Divisor | Frequency (BYPASS2=0) | Frequency (BYPASS2=1)     | TivaWare Parameter <sup>a</sup> |
|---------|---------|-----------------------|---------------------------|---------------------------------|
| 0x00    | /1      | reserved              | Clock source frequency/1  | SYSCCTL_SYSDIV_1                |
| 0x01    | /2      | reserved              | Clock source frequency/2  | SYSCCTL_SYSDIV_2                |
| 0x02    | /3      | 66.67 MHz             | Clock source frequency/3  | SYSCCTL_SYSDIV_3                |
| 0x03    | /4      | 50 MHz                | Clock source frequency/4  | SYSCCTL_SYSDIV_4                |
| 0x04    | /5      | 40 MHz                | Clock source frequency/5  | SYSCCTL_SYSDIV_5                |
| ...     | ...     | ...                   | ...                       | ...                             |
| 0x09    | /10     | 20 MHz                | Clock source frequency/10 | SYSCCTL_SYSDIV_10               |
| ...     | ...     | ...                   | ...                       | ...                             |
| 0x3F    | /64     | 3.125 MHz             | Clock source frequency/64 | SYSCCTL_SYSDIV_64               |

a. This parameter is used in functions such as SysCtlClockSet() in the TivaWare Peripheral Driver Library.

To allow for additional frequency choices when using the PLL, the `DIV400` bit is provided along with the `SYSDIV2LSB` bit. When the `DIV400` bit is set, bit 22 becomes the LSB for `SYSDIV2`. In this situation, the divisor is equivalent to the (`SYSDIV2` encoding with `SYSDIV2LSB` appended) plus one. Table 5-6 shows the frequency choices when `DIV400` is set. When the `DIV400` bit is clear, `SYSDIV2LSB` is ignored, and the system clock frequency is determined as shown in Table 5-5 on page 215.

**Table 5-6. Examples of Possible System Clock Frequencies with `DIV400=1`**

| <code>SYSDIV2</code> | <code>SYSDIV2LSB</code> | Divisor | Frequency ( <code>BYPASS2=0</code> ) <sup>a</sup> | TivaWare Parameter <sup>b</sup> |
|----------------------|-------------------------|---------|---------------------------------------------------|---------------------------------|
| 0x00                 | reserved                | /2      | reserved                                          | -                               |
| 0x01                 | 0                       | /3      | reserved                                          | -                               |
|                      | 1                       | /4      | reserved                                          | -                               |
| 0x02                 | 0                       | /5      | 80 MHz                                            | <code>SYSCTL_SYSDIV_2_5</code>  |
|                      | 1                       | /6      | 66.67 MHz                                         | <code>SYSCTL_SYSDIV_3</code>    |
| 0x03                 | 0                       | /7      | reserved                                          | -                               |
|                      | 1                       | /8      | 50 MHz                                            | <code>SYSCTL_SYSDIV_4</code>    |
| 0x04                 | 0                       | /9      | 44.44 MHz                                         | <code>SYSCTL_SYSDIV_4_5</code>  |
|                      | 1                       | /10     | 40 MHz                                            | <code>SYSCTL_SYSDIV_5</code>    |
| ...                  | ...                     | ...     | ...                                               | ...                             |
| 0x3F                 | 0                       | /127    | 3.15 MHz                                          | <code>SYSCTL_SYSDIV_63_5</code> |
|                      | 1                       | /128    | 3.125 MHz                                         | <code>SYSCTL_SYSDIV_64</code>   |

a. Note that `DIV400` and `SYSDIV2LSB` are only valid when `BYPASS2=0`.

b. This parameter is used in functions such as `SysCtlClockSet()` in the TivaWare Peripheral Driver Library.

### 5.2.5.3 Precision Internal Oscillator Operation (PIOSC)

The microcontroller powers up with the PIOSC running. If another clock source is desired, the PIOSC must remain enabled as it is used for internal functions. The PIOSC can only be disabled during Deep-Sleep mode. It can be powered down by setting the `PIOSCPD` bit in the `DSLPCCLKCFG` register.

The PIOSC generates a 16-MHz clock with  $\pm 1\%$  accuracy with calibration and  $\pm 3\%$  accuracy across temperature (see “PIOSC Specifications” on page 1176). At the factory, the PIOSC is set to 16 MHz, however, the frequency can be trimmed for other voltage or temperature conditions using software in one of three ways:

- Default calibration: clear the `UTEN` bit and set the `UPDATE` bit in the **Precision Internal Oscillator Calibration (PIOSCCAL)** register.
- User-defined calibration: The user can program the `UT` value to adjust the PIOSC frequency. As the `UT` value increases, the generated period increases. To commit a new `UT` value, first set the `UTEN` bit, then program the `UT` field, and then set the `UPDATE` bit. The adjustment finishes within a few clock periods and is glitch free.
- Automatic calibration using the Hibernation module with a functioning 32.768-kHz clock source: Set the `CAL` bit in the **PIOSCCAL** register; the results of the calibration are shown in the `RESULT` field in the **Precision Internal Oscillator Statistic (PIOSCSTAT)** register. After calibration is complete, the PIOSC is trimmed using the trimmed value returned in the `CT` field.

### 5.2.5.4 Crystal Configuration for the Main Oscillator (MOSC)

The main oscillator supports the use of a select number of crystals from 4 to 25 MHz.

The `XTAL` bit in the **RCC** register (see page 245) describes the available crystal choices and default programming values.

Software configures the **RCC** register `XTAL` field with the crystal number. If the PLL is used in the design, the `XTAL` field value is internally translated to the PLL settings.

### 5.2.5.5 Main PLL Frequency Configuration

The main PLL is disabled by default during power-on reset and is enabled later by software if required. Software specifies the output divisor to set the system clock frequency and enables the main PLL to drive the output. The PLL operates at 400 MHz, but is divided by two prior to the application of the output divisor, unless the `DIV400` bit in the **RCC2** register is set.

To configure the PIOSC to be the clock source for the main PLL, program the `OSCR2` field in the **Run-Mode Clock Configuration 2 (RCC2)** register to be 0x1.

If the main oscillator provides the clock reference to the main PLL, the translation provided by hardware and used to program the PLL is available for software in the **PLL Frequency n (PLLREQn)** registers (see page 262). The internal translation provides a translation within  $\pm 1\%$  of the targeted PLL VCO frequency. Table 22-14 on page 1175 shows the actual PLL frequency and error for a given crystal choice.

The Crystal Value field (`XTAL`) in the **Run-Mode Clock Configuration (RCC)** register (see page 245) describes the available crystal choices and default programming of the **PLLREQn** registers. Any time the `XTAL` field changes, the new settings are translated and the internal PLL settings are updated.

### 5.2.5.6 USB PLL Frequency Configuration

The USB PLL is disabled by default during power-on reset and is enabled later by software. The USB PLL must be enabled and running for proper USB function. The main oscillator is the only clock reference for the USB PLL. The USB PLL is enabled by clearing the `USBPWRDN` bit of the **RCC2** register. The `XTAL` bit field (Crystal Value) of the **RCC** register describes the available crystal choices. The main oscillator must be connected to one of the following crystal values in order to correctly generate the USB clock: 5, 6, 8, 10, 12, 16, 18, 20, 24, or 25 MHz. Only these crystals provide the necessary USB PLL VCO frequency to conform with the USB timing specifications.

### 5.2.5.7 PLL Modes

Both PLLs have two modes of operation: Normal and Power-Down

- Normal: The PLL multiplies the input clock reference and drives the output.
- Power-Down: Most of the PLL internal circuitry is disabled and the PLL does not drive the output.

The modes are programmed using the **RCC/RCC2** register fields (see page 245 and page 251).

### 5.2.5.8 PLL Operation

If a PLL configuration is changed, the PLL output frequency is unstable until it reconverges (relocks) to the new setting. The time between the configuration change and relock is  $T_{\text{READY}}$  (see Table 22-13 on page 1175). During the relock time, the affected PLL is not usable as a clock reference. Software can poll the `LOCK` bit in the **PLL Status (PLLSTAT)** register to determine when the PLL has locked.

Either PLL is changed by one of the following:

- Change to the `XTAL` value in the **RCC** register—writes of the same value do not cause a relock.

- Change in the PLL from Power-Down to Normal mode.

A counter clocked by the system clock is used to measure the  $T_{\text{READY}}$  requirement. The down counter is set to 0x200 if the PLL is powering up. If the M or N values in the **PLLFREQn** registers are changed, the counter is set to 0xC0. Hardware is provided to keep the PLL from being used as a system clock until the  $T_{\text{READY}}$  condition is met after one of the two changes above. It is the user's responsibility to have a stable clock source (like the main oscillator) before the **RCC/RCC2** register is switched to use the PLL.

If the main PLL is enabled and the system clock is switched to use the PLL in one step, the system control hardware continues to clock the microcontroller from the oscillator selected by the **RCC/RCC2** register until the main PLL is stable ( $T_{\text{READY}}$  time met), after which it changes to the PLL. Software can use many methods to ensure that the system is clocked from the main PLL, including periodically polling the **PLLLRIS** bit in the **Raw Interrupt Status (RIS)** register, and enabling the PLL Lock interrupt.

The USB PLL is not protected during the lock time ( $T_{\text{READY}}$ ), and software should ensure that the USB PLL has locked before using the interface. Software can use many methods to ensure the  $T_{\text{READY}}$  period has passed, including periodically polling the **USBPLLLRIS** bit in the **Raw Interrupt Status (RIS)** register, and enabling the USB PLL Lock interrupt.

#### 5.2.5.9 Main Oscillator Verification Circuit

The clock control includes circuitry to ensure that the main oscillator is running at the appropriate frequency. The circuit monitors the main oscillator frequency and signals if the frequency is outside of the allowable band of attached crystals.

The detection circuit is enabled using the **CVAL** bit in the **Main Oscillator Control (MOSCCTL)** register. If this circuit is enabled and detects an error, and if the **MOSCIM** bit in the **MOSCCTL** register is clear, then the following sequence is performed by the hardware:

1. The **MOSCFAIL** bit in the **Reset Cause (RESC)** register is set.
2. The system clock is switched from the main oscillator to the **PIOSC**.
3. An internal power-on reset is initiated.
4. Reset is deasserted and the processor is directed to the NMI handler during the reset sequence.

if the **MOSCIM** bit in the **MOSCCTL** register is set, then the following sequence is performed by the hardware:

1. The system clock is switched from the main oscillator to the **PIOSC**.
2. The **MOFRIS** bit in the **RIS** register is set to indicate a MOSC failure.

#### 5.2.6 System Control

For power-savings purposes, the peripheral-specific **RCGCx**, **SCGCx**, and **DCGCx** registers (for example, **RCGCWD**) control the clock gating logic for that peripheral or block in the system while the microcontroller is in Run, Sleep, and Deep-Sleep mode, respectively. These registers are located in the System Control register map starting at offsets 0x600, 0x700, and 0x800, respectively. There must be a delay of 3 system clocks after a peripheral module clock is enabled in the **RCGC** register before any module registers are accessed.

---

**Important:** To support legacy software, the **RCGCn**, **SCGCn**, and **DCGCn** registers are available at offsets 0x100 - 0x128. A write to any of these legacy registers also writes the corresponding bit in the peripheral-specific **RCGCx**, **SCGCx**, and **DCGCx** registers. Software must use the peripheral-specific registers to support modules that are not present in the legacy registers. It is recommended that new software use the new registers and not rely on legacy operation.

If software uses a peripheral-specific register to write a legacy peripheral (such as TIMER0), the write causes proper operation, but the value of that bit is not reflected in the legacy register. Any bits that are changed by writing to a legacy register can be read back correctly with a read of the legacy register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

---

There are four levels of operation for the microcontroller defined as:

- Run mode
- Sleep mode
- Deep-Sleep mode
- Hibernate mode

The following sections describe the different modes in detail.

---

**Caution – If the Cortex-M4F Debug Access Port (DAP) has been enabled, and the device wakes from a low power sleep or deep-sleep mode, the core may start executing code before all clocks to peripherals have been restored to their Run mode configuration. The DAP is usually enabled by software tools accessing the JTAG or SWD interface when debugging or flash programming. If this condition occurs, a Hard Fault is triggered when software accesses a peripheral with an invalid clock.**

A software delay loop can be used at the beginning of the interrupt routine that is used to wake up a system from a WFI (Wait For Interrupt) instruction. This stalls the execution of any code that accesses a peripheral register that might cause a fault. This loop can be removed for production software as the DAP is most likely not enabled during normal execution.

Because the DAP is disabled by default (power on reset), the user can also power cycle the device. The DAP is not enabled unless it is enabled through the JTAG or SWD interface.

---

### 5.2.6.1 Run Mode

In Run mode, the microcontroller actively executes code. Run mode provides normal operation of the processor and all of the peripherals that are currently enabled by the peripheral-specific **RCGC** registers. The system clock can be any of the available clock sources including the PLL.

### 5.2.6.2 Sleep Mode

In Sleep mode, the clock frequency of the active peripherals is unchanged, but the processor and the memory subsystem are not clocked and therefore no longer execute code. Sleep mode is entered by the Cortex-M4F core executing a **WFI** (Wait for Interrupt) instruction. Any properly configured interrupt event in the system brings the processor back into Run mode. See “Power Management” on page 106 for more details.

Peripherals are clocked that are enabled in the peripheral-specific **SCGC** registers when auto-clock gating is enabled (see the **RCC** register) or the peripheral-specific **RCGC** registers when the auto-clock gating is disabled. The system clock has the same source and frequency as that during Run mode.

Additional sleep modes are available that lower the power consumption of the SRAM and Flash memory. However, the lower power consumption modes have slower sleep and wake-up times, see “Dynamic Power Management” on page 221 for more information.

---

**Important:** Before executing the **WFI** instruction, software must confirm that the EEPROM is not busy by checking to see that the **WORKING** bit in the **EEPROM Done Status (EEDONE)** register is clear.

---

### 5.2.6.3 Deep-Sleep Mode

In Deep-Sleep mode, the clock frequency of the active peripherals may change (depending on the Deep-Sleep mode clock configuration) in addition to the processor clock being stopped. An interrupt returns the microcontroller to Run mode from one of the sleep modes; the sleep modes are entered on request from the code. Deep-Sleep mode is entered by first setting the **SLEEPDEEP** bit in the **System Control (SYSCTRL)** register (see page 158) and then executing a **WFI** instruction. Any properly configured interrupt event in the system brings the processor back into Run mode. See “Power Management” on page 106 for more details.

The Cortex-M4F processor core and the memory subsystem are not clocked in Deep-Sleep mode. Peripherals are clocked that are enabled in the peripheral-specific **DCGC** registers when auto-clock gating is enabled (see the **RCC** register) or the peripheral-specific **RCGC** registers when auto-clock gating is disabled. The system clock source is specified in the **DSLPCCLKCFG** register. When the **DSLPCCLKCFG** register is used, the internal oscillator source is powered up, if necessary, and other clocks are powered down. If the PLL is running at the time of the **WFI** instruction, hardware powers the PLL down and overrides the **SYSDIV** field of the active **RCC/RCC2** register, to be determined by the **DSDIVORIDE** setting in the **DSLPCCLKCFG** register, up to /16 or /64 respectively. USB PLL is not powered down by execution of **WFI** instruction. When the Deep-Sleep exit event occurs, hardware brings the system clock back to the source and frequency it had at the onset of Deep-Sleep mode before enabling the clocks that had been stopped during the Deep-Sleep duration. If the **PIOSC** is used as the PLL reference clock source, it may continue to provide the clock during Deep-Sleep. See page 255.

---

**Important:** Before executing the **WFI** instruction, software must confirm that the EEPROM is not busy by checking to see that the **WORKING** bit in the **EEPROM Done Status (EEDONE)** register is clear.

---

To provide the lowest possible Deep-Sleep power consumption as well the ability to wake the processor from a peripheral without reconfiguring the peripheral for a change in clock, some of the communications modules have a Clock Control register at offset 0xFC8 in the module register space. The **CS** field in the Clock Control register allows the user to select the **PIOSC** as the clock source for the module's baud clock. When the microcontroller enters Deep-Sleep mode, the **PIOSC** becomes the source for the module clock as well, which allows the transmit and receive FIFOs to continue operation while the part is in Deep-Sleep. Figure 5-6 on page 221 shows how the clocks are selected.

Figure 5-6. Module Clock Selection

Additional deep-sleep modes are available that lower the power consumption of the SRAM and Flash memory. However, the lower power consumption modes have slower deep-sleep and wake-up times, see “Dynamic Power Management” on page 221 for more information.

#### 5.2.6.4 Dynamic Power Management

In addition to the Sleep and Deep-Sleep modes and the clock gating for the on-chip modules, there are several additional power mode options that allow the LDO, Flash memory, and SRAM into different levels of power savings while in Sleep or Deep-Sleep modes. Note that these features may not be available on all devices; the **System Properties (SYSPROP)** register provides information on whether a mode is supported on a given MCU. The following registers provides these capabilities:

- **LDO Sleep Power Control (LDOSPCTL)**: controls the LDO value in Sleep mode
- **LDO Deep-Sleep Power Control (LDODPCTL)**: controls the LDO value in Deep-Sleep mode
- **LDO Sleep Power Calibration (LDOSPCAL)**: provides factory recommendations for the LDO value in Sleep mode
- **LDO Deep-Sleep Power Calibration (LDODPCAL)**: provides factory recommendations for the LDO value in Deep-Sleep mode
- **Sleep Power Configuration (SLPPWRCFG)**: controls the power saving modes for Flash memory and SRAM in Sleep mode
- **Deep-Sleep Power Configuration (DSLPPWRCFG)**: controls the power saving modes for Flash memory and SRAM in Deep-sleep mode
- **Deep-Sleep Clock Configuration (DSLPCCLKCFG)**: controls the clocking in Deep-sleep mode
- **Sleep / Deep-Sleep Power Mode Status (SDPMST)**: provides status information on the various power saving events

#### **LDO Power Control**

**Note:** While the device is connected through JTAG, the LDO control settings for Sleep or Deep-Sleep are not available and will not be applied.

The user can dynamically request to raise or lower the LDO voltage level to trade-off power/performance using either the **LDOSPCTL** register (see page 269) or the **LDODPCTL** register (see page 272). When lowering the LDO level, software must configure the system clock for the lower LDO value in **RCC/RCC2** for Sleep mode and in **DSLPCCLKCFG** for Deep-Sleep mode before requesting the LDO to lower.

The LDO Power Calibration registers, **LDOSPCAL** and **LDODPCAL**, provide suggested values for the LDO in the various modes. If software requests an LDO value that is too low or too high, the value is not accepted and an error is reported in the **SDPMST** register.

The table below shows the maximum system clock frequency and PIOSC frequency with respect to the configured LDO voltage.

| Operating Voltage (LDO) | Maximum System Clock Frequency | PIOSC  |
|-------------------------|--------------------------------|--------|
| 1.2                     | 80 MHz                         | 16 MHz |
| 0.9                     | 20 MHz                         | 16 MHz |

### Flash Memory and SRAM Power Control

During Sleep or Deep-Sleep mode, Flash memory can be in either the default active mode or the low power mode; SRAM can be in the default active mode, standby mode, or low power mode. The active mode in each case provides the fastest times to sleep and wake up, but consumes more power. Low power mode provides the lowest power consumption, but takes longer to sleep and wake up.

The SRAM can be programmed to prohibit any power management by configuring the **SRAMSM** bit in the **System Properties (SYSPROP)** register. This configuration operates in the same way that legacy Stellaris<sup>®</sup> devices operate and provides the fastest sleep and wake-up times, but consumes the most power while in Sleep and Deep-Sleep mode. Other power options are retention mode, and retention mode with lower SRAM voltage. The SRAM retention mode with lower SRAM voltage provides the lowest power consumption, but has the longest sleep and wake-up times. These modes can be independently configured for Flash memory and SRAM using the **SLPPWRCFG** and **DSLPPWRCFG** registers.

The following power saving options are available in Sleep and Deep-Sleep modes:

- The clocks can be gated according to the settings in the the peripheral-specific **SCGC** or **DCGC** registers.
- In Deep-Sleep mode, the clock source can be changed and the PIOSC can be powered off (if no active peripheral requires it) using the **DSLPCCLKCFG** register. These options are not available for Sleep mode.
- The LDO voltage can be changed using the **LDOSPCTL** or **LDODPCTL** register.
- The Flash memory can be put into low power mode.
- The SRAM can be put into standby or low power mode.

The **SDPMST** register provides results on the Dynamic Power Management command issued. It also has some real time status that can be viewed by a debugger or the core if it is running. These events do not trigger an interrupt and are meant to provide information to help tune software for power management. The status register gets written at the beginning of every Dynamic Power Management event request that provides error checking. There is no mechanism to clear the bits;

they are overwritten on the next event. The real time data is real time and there is no event to register that information.

### 5.2.6.5 Hibernate Mode

In this mode, the power supplies are turned off to the main part of the microcontroller and only the Hibernation module's circuitry is active. An external wake event or RTC event is required to bring the microcontroller back to Run mode. The Cortex-M4F processor and peripherals outside of the Hibernation module see a normal "power on" sequence and the processor starts running code. Software can determine if the microcontroller has been restarted from Hibernate mode by inspecting the Hibernation module registers. For more information on the operation of Hibernate mode, see "Hibernation Module" on page 467.

## 5.3 Initialization and Configuration

The PLL is configured using direct register writes to the **RCC/RCC2** register. If the **RCC2** register is being used, the **USERCC2** bit must be set and the appropriate **RCC2** bit/field is used. The steps required to successfully change the PLL-based system clock are:

1. Bypass the PLL and system clock divider by setting the **BYPASS** bit and clearing the **USESYS** bit in the **RCC** register, thereby configuring the microcontroller to run off a "raw" clock source and allowing for the new PLL configuration to be validated before switching the system clock to the PLL.
2. Select the crystal value (**XTAL**) and oscillator source (**OSCSRC**), and clear the **PWRDN** bit in **RCC/RCC2**. Setting the **XTAL** field automatically pulls valid PLL configuration data for the appropriate crystal, and clearing the **PWRDN** bit powers and enables the PLL and its output.
3. Select the desired system divider (**SYSDIV**) in **RCC/RCC2** and set the **USESYS** bit in **RCC**. The **SYSDIV** field determines the system frequency for the microcontroller.
4. Wait for the PLL to lock by polling the **PLLLRIS** bit in the **Raw Interrupt Status (RIS)** register.
5. Enable use of the PLL by clearing the **BYPASS** bit in **RCC/RCC2**.

## 5.4 Register Map

Table 5-7 on page 223 lists the System Control registers, grouped by function. The offset listed is a hexadecimal increment to the register's address, relative to the System Control base address of 0x400F.E000.

**Note:** Spaces in the System Control register space that are not used are reserved for future or internal use. Software should not modify any reserved memory address.

Additional Flash and ROM registers defined in the System Control register space are described in the "Internal Memory" on page 498.

**Table 5-7. System Control Register Map**

| Offset                          | Name | Type | Reset       | Description             | See page |
|---------------------------------|------|------|-------------|-------------------------|----------|
| <b>System Control Registers</b> |      |      |             |                         |          |
| 0x000                           | DID0 | RO   | -           | Device Identification 0 | 229      |

## 5.5 System Control Register Descriptions

All addresses given are relative to the System Control base address of 0x400F.E000. Registers provided for legacy software support only are listed in “System Control Legacy Register Descriptions” on page 402.

## Register 1: Device Identification 0 (DID0), offset 0x000

This register identifies the version of the microcontroller. Each microcontroller is uniquely identified by the combined values of the `CLASS` field in the **DID0** register and the `PARTNO` field in the **DID1** register. The `MAJOR` and `MINOR` bit fields indicate the die revision number. Combined, the `MAJOR` and `MINOR` bit fields indicate the part revision number.

| MAJOR Bitfield Value | MINOR Bitfield Value | Die Revision | Part Revision |
|----------------------|----------------------|--------------|---------------|
| 0x0                  | 0x0                  | A0           | 1             |
| 0x0                  | 0x1                  | A1           | 2             |
| 0x0                  | 0x2                  | A2           | 3             |
| 0x0                  | 0x3                  | A3           | 4             |
| 0x1                  | 0x0                  | B0           | 5             |
| 0x1                  | 0x1                  | B1           | 6             |
| 0x1                  | 0x2                  | B2           | 7             |

### Device Identification 0 (DID0)

| 23:16     | CLASS | RO   | 0x05  | <p>Device Class</p> <p>The CLASS field value identifies the internal design from which all mask sets are generated for all microcontrollers in a particular product line. The CLASS field value is changed for new product lines, for changes in fab process (for example, a remap or shrink), or any case where the MAJOR or MINOR fields require differentiation from prior microcontrollers. The value of the CLASS field is encoded as follows (all other encodings are reserved):</p> <p>Value Description</p> <p>0x05 Tiva™ TM4C123x microcontrollers</p> |
| 15:8      | MAJOR | RO   | -     | <p>Major Die Revision</p> <p>This field specifies the major revision number of the microcontroller. The major revision reflects changes to base layers of the design. This field is encoded as follows:</p> <p>Value Description</p> <p>0x0 Revision A (initial device)</p> <p>0x1 Revision B (first base layer revision)</p> <p>0x2 Revision C (second base layer revision)</p> <p>and so on.</p>                                                                                                                                                              |
| 7:0       | MINOR | RO   | -     | <p>Minor Die Revision</p> <p>This field specifies the minor revision number of the microcontroller. The minor revision reflects changes to the metal layers of the design. The MINOR field value is reset when the MAJOR field is changed. This field is numeric and is encoded as follows:</p> <p>Value Description</p> <p>0x0 Initial device, or a major revision update.</p> <p>0x1 First metal layer change.</p> <p>0x2 Second metal layer change.</p> <p>and so on.</p>                                                                                    |

## Register 2: Device Identification 1 (DID1), offset 0x004

This register identifies the device family, part number, temperature range, pin count, and package type. Each microcontroller is uniquely identified by the combined values of the `CLASS` field in the `DID0` register and the `PARTNO` field in the `DID1` register.

### Device Identification 1 (DID1)

### Register 3: Brown-Out Reset Control (PBORCTL), offset 0x030

This register is responsible for controlling reset conditions after initial power-on reset.

**Note:** The BOR voltage values and center points are based on simulation only. These values are yet to be characterized and are subject to change.

#### Brown-Out Reset Control (PBORCTL)

Base 0x400F.E000  
 Offset 0x030  
 Type R/W, reset 0x0000.7FFF

## Register 4: Raw Interrupt Status (RIS), offset 0x050

This register indicates the status for system control raw interrupts. An interrupt is sent to the interrupt controller if the corresponding bit in the **Interrupt Mask Control (IMC)** register is set. Writing a 1 to the corresponding bit in the **Masked Interrupt Status and Clear (MISC)** register clears an interrupt status bit.

### Raw Interrupt Status (RIS)

Base 0x400F.E000

Offset 0x050

Type RO, reset 0x0000.0000

## Register 5: Interrupt Mask Control (IMC), offset 0x054

This register contains the mask bits for system control raw interrupts. A raw interrupt, indicated by a bit being set in the **Raw Interrupt Status (RIS)** register, is sent to the interrupt controller if the corresponding bit in this register is set.

### Register 6: Masked Interrupt Status and Clear (MISC), offset 0x058

On a read, this register gives the current masked status value of the corresponding interrupt in the **Raw Interrupt Status (RIS)** register. All of the bits are R/W1C, thus writing a 1 to a bit clears the corresponding raw interrupt bit in the **RIS** register (see page 235).

## Register 8: Run-Mode Clock Configuration (RCC), offset 0x060

The bits in this register configure the system clock and oscillators.

**Important:** Write the **RCC** register prior to writing the **RCC2** register.

### Run-Mode Clock Configuration (RCC)

Base 0x400F.E000

Offset 0x060

Type R/W, reset 0x0780.3AD1

The encoding for this field is provided below.</p> <p>Frequencies that may be used with the USB interface are indicated in the table. To function within the clocking requirements of the USB specification, a crystal of 5, 6, 8, 10, 12, or 16 MHz must be used.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Crystal Frequency (MHz) Not Using the PLL</th> <th>Crystal Frequency (MHz) Using the PLL</th> </tr> </thead> <tbody> <tr> <td>0x00-0x5</td> <td></td> <td>reserved</td> </tr> <tr> <td>0x06</td> <td>4 MHz</td> <td>reserved</td> </tr> <tr> <td>0x07</td> <td>4.096 MHz</td> <td>reserved</td> </tr> <tr> <td>0x08</td> <td>4.9152 MHz</td> <td>reserved</td> </tr> <tr> <td>0x09</td> <td></td> <td>5 MHz (USB)</td> </tr> <tr> <td>0x0A</td> <td></td> <td>5.12 MHz</td> </tr> <tr> <td>0x0B</td> <td></td> <td>6 MHz (USB)</td> </tr> <tr> <td>0x0C</td> <td></td> <td>6.144 MHz</td> </tr> <tr> <td>0x0D</td> <td></td> <td>7.3728 MHz</td> </tr> <tr> <td>0x0E</td> <td></td> <td>8 MHz (USB)</td> </tr> <tr> <td>0x0F</td> <td></td> <td>8.192 MHz</td> </tr> <tr> <td>0x10</td> <td></td> <td>10.0 MHz (USB)</td> </tr> <tr> <td>0x11</td> <td></td> <td>12.0 MHz (USB)</td> </tr> <tr> <td>0x12</td> <td></td> <td>12.288 MHz</td> </tr> <tr> <td>0x13</td> <td></td> <td>13.56 MHz</td> </tr> <tr> <td>0x14</td> <td></td> <td>14.31818 MHz</td> </tr> <tr> <td>0x15</td> <td></td> <td>16.0 MHz (USB)</td> </tr> <tr> <td>0x16</td> <td></td> <td>16.384 MHz</td> </tr> <tr> <td>0x17</td> <td></td> <td>18.0 MHz (USB)</td> </tr> <tr> <td>0x18</td> <td></td> <td>20.0 MHz (USB)</td> </tr> <tr> <td>0x19</td> <td></td> <td>24.0 MHz (USB)</td> </tr> <tr> <td>0x1A</td> <td></td> <td>25.0 MHz (USB)</td> </tr> </tbody> </table> | Value | Crystal Frequency (MHz) Not Using the PLL | Crystal Frequency (MHz) Using the PLL | 0x00-0x5 |  | reserved | 0x06 | 4 MHz | reserved | 0x07 | 4.096 MHz | reserved | 0x08 | 4.9152 MHz | reserved | 0x09 |  | 5 MHz (USB) | 0x0A |  | 5.12 MHz | 0x0B |  | 6 MHz (USB) | 0x0C |  | 6.144 MHz | 0x0D |  | 7.3728 MHz | 0x0E |  | 8 MHz (USB) | 0x0F |  | 8.192 MHz | 0x10 |  | 10.0 MHz (USB) | 0x11 |  | 12.0 MHz (USB) | 0x12 |  | 12.288 MHz | 0x13 |  | 13.56 MHz | 0x14 |  | 14.31818 MHz | 0x15 |  | 16.0 MHz (USB) | 0x16 |  | 16.384 MHz | 0x17 |  | 18.0 MHz (USB) | 0x18 |  | 20.0 MHz (USB) | 0x19 |  | 24.0 MHz (USB) | 0x1A |  | 25.0 MHz (USB) |

**Register 9: GPIO High-Performance Bus Control (GPIOHBCTL), offset 0x06C**

This register controls which internal bus is used to access each GPIO port. When a bit is clear, the corresponding GPIO port is accessed across the legacy Advanced Peripheral Bus (APB) bus and through the APB memory aperture. When a bit is set, the corresponding port is accessed across the Advanced High-Performance Bus (AHB) bus and through the AHB memory aperture. Each GPIO port can be individually configured to use AHB or APB, but may be accessed only through one aperture. The AHB bus provides better back-to-back access performance than the APB bus. The address aperture in the memory map changes for the ports that are enabled for AHB access (see Table 10-6 on page 631).

**Important:** Ports K-N and P-Q are only available on the AHB bus, and therefore the corresponding bits reset to 1. If one of these bits is cleared, the corresponding port is disabled. If any of these ports is in use, read-modify-write operations should be used to change the value of this register so that these ports remain enabled.

## Register 10: Run-Mode Clock Configuration 2 (RCC2), offset 0x070

This register overrides the **RCC** equivalent register fields, as shown in Table 5-8, when the `USERCC2` bit is set, allowing the extended capabilities of the **RCC2** register to be used while also providing a means to be backward-compatible to previous parts. Each **RCC2** field that supersedes an **RCC** field is located at the same LSB bit position; however, some **RCC2** fields are larger than the corresponding **RCC** field.

**Table 5-8. RCC2 Fields that Override RCC Fields**

| RCC2 Field...                      | Overrides RCC Field               |
|------------------------------------|-----------------------------------|
| <code>SYSDIV2</code> , bits[28:23] | <code>SYSDIV</code> , bits[26:23] |
| <code>PWRDN2</code> , bit[13]      | <code>PWRDN</code> , bit[13]      |
| <code>BYPASS2</code> , bit[11]     | <code>BYPASS</code> , bit[11]     |
| <code>OSCSRC2</code> , bits[6:4]   | <code>OSCSRC</code> , bits[5:4]   |

**Important:** Write the **RCC** register prior to writing the **RCC2** register.

### Register 11: Main Oscillator Control (MOSCCTL), offset 0x07C

This register provides control over the features of the main oscillator, including the ability to enable the MOSC clock verification circuit, what action to take when the MOSC fails, and whether or not a crystal is connected. When enabled, this circuit monitors the frequency of the MOSC to verify that the oscillator is operating within specified limits. If the clock goes invalid after being enabled, the microcontroller issues a power-on reset and reboots to the NMI handler or generates an interrupt.

This 6-bit field contains a system divider field that overrides the <code>SYSDIV</code> field in the <code>RCC</code> register or the <code>SYSDIV2</code> field in the <code>RCC2</code> register during Deep Sleep. This divider is applied to the source selected by the <code>DSOSCSRC</code> field.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>/1</td> </tr> <tr> <td>0x1</td> <td>/2</td> </tr> <tr> <td>0x2</td> <td>/3</td> </tr> <tr> <td>0x3</td> <td>/4</td> </tr> <tr> <td>...</td> <td>...</td> </tr> <tr> <td>0x3F</td> <td>/64</td> </tr> </tbody> </table> | Value | Description | 0x0 | /1 | 0x1 | /2 | 0x2 | /3 | 0x3 | /4 | ... | ... | 0x3F | /64 |

## Register 13: System Properties (SYSPROP), offset 0x14C

This register provides information on whether certain System Control properties are present on the microcontroller.

### System Properties (SYSPROP)

Base 0x400F.E000

Offset 0x14C

Type RO, reset 0x0000.1D31

### Register 16: PLL Frequency 0 (PLLREQ0), offset 0x160

This register always contains the current M value presented to the system PLL.

The PLL frequency can be calculated using the following equation:

$$\text{PLL frequency} = (\text{XTAL frequency} * \text{MDIV}) / ((Q + 1) * (N + 1))$$

where

$$\text{MDIV} = \text{MINT} + (\text{MFRAC} / 1024)$$

The Q and N values are shown in the **PLLREQ1** register. Table 22-14 on page 1175 shows the M, Q, and N values as well as the resulting PLL frequency for the various XTAL configurations.

**Register 21: LDO Sleep Power Control (LDOSPCTL), offset 0x1B4**

This register specifies the LDO output voltage while in Sleep mode. Writes to the VLDO bit field have no effect on the LDO output voltage, regardless of what is specified for the VADJEN bit. The LDO output voltage is fixed at the recommended factory reset value.

The table below shows the maximum system clock frequency and PIOSC frequency with respect to the configured LDO voltage.

| Operating Voltage (LDO) | Maximum System Clock Frequency | PIOSC  |
|-------------------------|--------------------------------|--------|
| 1.2                     | 80 MHz                         | 16 MHz |
| 0.9                     | 20 MHz                         | 16 MHz |

- Note:**
- The LDO will not automatically adjust in Sleep/Deepsleep mode if a debugger has been connected since the last power-on reset.
  - If the LDO voltage is adjusted, it will take an extra 4 us to wake up from Sleep or Deep-sleep mode.

The value of the field is only used for the LDO voltage when the <code>VADJEN</code> bit is set.</p> <p>For lowest power in Sleep mode, it is recommended to configure an LDO output voltage that is equal to or lower than the default value of 1.2 V.</p> <table><thead><tr><th>Value</th><th>Description</th></tr></thead><tbody><tr><td>0x12</td><td>0.90 V</td></tr><tr><td>0x13</td><td>0.95 V</td></tr><tr><td>0x14</td><td>1.00 V</td></tr><tr><td>0x15</td><td>1.05 V</td></tr><tr><td>0x16</td><td>1.10 V</td></tr><tr><td>0x17</td><td>1.15 V</td></tr><tr><td>0x18</td><td>1.20 V</td></tr><tr><td>0x19 - 0xFF</td><td>reserved</td></tr></tbody></table> | Value | Description | 0x12 | 0.90 V | 0x13 | 0.95 V | 0x14 | 1.00 V | 0x15 | 1.05 V | 0x16 | 1.10 V | 0x17 | 1.15 V | 0x18 | 1.20 V | 0x19 - 0xFF | reserved |

## Register 22: LDO Sleep Power Calibration (LDOSPCAL), offset 0x1B8

This register provides factory determined values that are recommended for the VLDO field in the LDOSPCTL register while in Sleep mode.

### LDO Sleep Power Calibration (LDOSPCAL)

Base 0x400F.E000

Offset 0x1B8

Type RO, reset 0x0000.1818

| 31:16     | reserved | RO   | 0x0   | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.                                                                  |
| 15:8      | WITHPLL  | RO   | 0x18  | <p>Sleep with PLL</p> <p>The value in this field is the suggested value for the VLDO field in the LDOSPCTL register when using the PLL. This value provides the lowest recommended LDO output voltage for use with the PLL at the maximum specified value.</p> |
| 7:0       | NOPLL    | RO   | 0x18  | <p>Sleep without PLL</p> <p>The value in this field is the suggested value for the VLDO field in the LDOSPCTL register when not using the PLL. This value provides the lowest recommended LDO output voltage for use without the PLL.</p>                      |

### Register 23: LDO Deep-Sleep Power Control (LDODPCTL), offset 0x1BC

This register specifies the LDO output voltage while in Deep-Sleep mode. Writes to the VLDO bit field have no effect on the LDO output voltage, regardless of what is specified for the VADJEN bit. The LDO output voltage is fixed at the recommended factory reset value.

The table below shows the maximum system clock frequency and PIOSC frequency with respect to the configured LDO voltage.

| Operating Voltage (LDO) | Maximum System Clock Frequency | PIOSC  |
|-------------------------|--------------------------------|--------|
| 1.2                     | 80 MHz                         | 16 MHz |
| 0.9                     | 20 MHz                         | 16 MHz |

- Note:**
- The LDO will not automatically adjust in Sleep/Deepsleep mode if a debugger has been connected since the last power-on reset.
  - If the LDO voltage is adjusted, it will take an extra 4 us to wake up from Sleep or Deep-sleep mode.

### Register 24: LDO Deep-Sleep Power Calibration (LDODPCAL), offset 0x1C0

This register provides factory determined values that are recommended for the VLDO field in the LDODPCTL register while in Deep-Sleep mode.

| 7:0       | 30KHZ    | RO   | 0x12  | Deep-Sleep with IOSC<br>The value in this field is the suggested value for the VLDO field in the LDODPCTL register when not using the PLL. This value provides the lowest recommended LDO output voltage for use with the low-frequency internal oscillator. |

**Register 25: Sleep / Deep-Sleep Power Mode Status (SDPMST), offset 0x1CC**

This register provides status information on the Sleep and Deep-Sleep power modes as well as some real time status that can be viewed by a debugger or the core if it is running. These events do not trigger an interrupt and are meant to provide information that can help tune software for power management. The status register gets written at the beginning of every Dynamic Power Management event request with the results of any error checking. There is no mechanism to clear the bits; they are overwritten on the next event. The LDOUA, FLASHLP, LOWPWR, PRACT bits provide real time data and there are no events to register that information.

## Register 26: Watchdog Timer Peripheral Present (PPWD), offset 0x300

The **PPWD** register provides software information regarding the watchdog modules.

**Important:** This register should be used to determine which watchdog timers are implemented on this microcontroller. However, to support legacy software, the **DC1** register is available. A read of the **DC1** register correctly identifies if a legacy module is present.

## Register 29: Micro Direct Memory Access Peripheral Present (PPDMA), offset 0x30C

The **PPDMA** register provides software information regarding the  $\mu$ DMA module.

**Important:** This register should be used to determine if the  $\mu$ DMA module is implemented on this microcontroller. However, to support legacy software, the **DC7** register is available. A read of the **DC7** register correctly identifies if the  $\mu$ DMA module is present.

## Register 31: Universal Asynchronous Receiver/Transmitter Peripheral Present (PPUART), offset 0x318

The **PPUART** register provides software information regarding the UART modules.

**Important:** This register should be used to determine which UART modules are implemented on this microcontroller. However, to support legacy software, the **DC2** register is available. A read of the **DC2** register correctly identifies if a legacy UART module is present. Software must use this register to determine if a module that is not supported by the **DC2** register is present.

## Register 32: Synchronous Serial Interface Peripheral Present (PPSSI), offset 0x31C

The **PPSSI** register provides software information regarding the SSI modules.

**Important:** This register should be used to determine which SSI modules are implemented on this microcontroller. However, to support legacy software, the **DC2** register is available. A read of the **DC2** register correctly identifies if a legacy SSI module is present. Software must use this register to determine if a module that is not supported by the **DC2** register is present.

**Register 37: Analog Comparator Peripheral Present (PPACMP), offset 0x33C**

The **PPACMP** register provides software information regarding the analog comparator module.

**Important:** This register should be used to determine if the analog comparator module is implemented on this microcontroller. However, to support legacy software, the **DC2** register is available. A read of the **DC2** register correctly identifies if the analog comparator module is present.

Note that the **Analog Comparator Peripheral Properties (ACMPPP)** register indicates how many analog comparator blocks are included in the module.

### Register 38: Pulse Width Modulator Peripheral Present (PPPWM), offset 0x340

The **PPPWM** register provides software information regarding the PWM modules.

**Important:** This register should be used to determine which PWM modules are implemented on this microcontroller. However, to support legacy software, the **DC1** register is available. A read of the **DC1** register correctly identifies if the legacy PWM module is present. Software must use this register to determine if a module that is not supported by the **DC1** register is present.

**Register 42: Watchdog Timer Software Reset (SRWD), offset 0x500**

The **SRWD** register provides software the capability to reset the available watchdog modules. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRWD** register. While the **SRWD** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRWD** bit.

There may be latency from the clearing of the **SRWD** bit to when the peripheral is ready for use. Software can check the corresponding **PRWD** bit to be sure.

**Important:** This register should be used to reset the watchdog modules. To support legacy software, the **SRCR0** register is available. Setting a bit in the **SRCR0** register also resets the corresponding module. Any bits that are changed by writing to the **SRCR0** register can be read back correctly when reading the **SRCR0** register. If software uses this register to reset a legacy peripheral (such as Watchdog 1), the write causes proper operation, but the value of that bit is not reflected in the **SRCR0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 43: 16/32-Bit General-Purpose Timer Software Reset (SRTIMER), offset 0x504

The **SRTIMER** register provides software the capability to reset the available 16/32-bit timer modules. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the timer modules and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRTIMER** register. While the **SRTIMER** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRTIMER** bit.

There may be latency from the clearing of the **SRTIMER** bit to when the peripheral is ready for use. Software can check the corresponding **PRTIMER** bit to be sure.

**Important:** This register should be used to reset the timer modules. To support legacy software, the **SRCR1** register is available. Setting a bit in the **SRCR1** register also resets the corresponding module. Any bits that are changed by writing to the **SRCR1** register can be read back correctly when reading the **SRCR1** register. Software must use this register to reset modules that are not present in the legacy registers. If software uses this register to reset a legacy peripheral (such as Timer 1), the write causes proper operation, but the value of that bit is not reflected in the **SRCR1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 44: General-Purpose Input/Output Software Reset (SRGPIO), offset 0x508

The **SRGPIO** register provides software the capability to reset the available GPIO modules. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the GPIO modules and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRGPIO** register. While the **SRGPIO** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRGPIO** bit.

There may be latency from the clearing of the **SRGPIO** bit to when the peripheral is ready for use. Software can check the corresponding **PRGPIO** bit to be sure.

**Important:** This register should be used to reset the GPIO modules. To support legacy software, the **SRCR2** register is available. Setting a bit in the **SRCR2** register also resets the corresponding module. Any bits that are changed by writing to the **SRCR2** register can be read back correctly when reading the **SRCR2** register. Software must use this register to reset modules that are not present in the legacy registers. If software uses this register to reset a legacy peripheral (such as GPIO A), the write causes proper operation, but the value of that bit is not reflected in the **SRCR2** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 45: Micro Direct Memory Access Software Reset (SRDMA), offset 0x50C

The **SRDMA** register provides software the capability to reset the available  $\mu$ DMA module. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the  $\mu$ DMA module and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRDMA** register. While the **SRDMA** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRDMA** bit.

There may be latency from the clearing of the **SRDMA** bit to when the peripheral is ready for use. Software can check the corresponding **PRDMA** bit to be sure.

**Important:** This register should be used to reset the  $\mu$ DMA module. To support legacy software, the **SRCR2** register is available. Setting the **UDMA** bit in the **SRCR2** register also resets the  $\mu$ DMA module. If the **UDMA** bit is set by writing to the **SRCR2** register, it can be read back correctly when reading the **SRCR2** register. If software uses this register to reset the  $\mu$ DMA module, the write causes proper operation, but the value of the **UDMA** bit is not reflected in the **SRCR2** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

### Register 46: Hibernation Software Reset (SRHIB), offset 0x514

The **SRHIB** register provides software the capability to reset the available Hibernation module. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the Hibernation module and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRHIB** register. While the **SRHIB** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRHIB** bit.

There may be latency from the clearing of the **SRHIB** bit to when the peripheral is ready for use. Software can check the corresponding **PRHIB** bit to be sure.

**Important:** This register should be used to reset the Hibernation module. To support legacy software, the **SRCR0** register is available. Setting the **HIB** bit in the **SRCR0** register also resets the Hibernation module. If the **HIB** bit is set by writing to the **SRCR0** register, it can be read back correctly when reading the **SRCR0** register. If software uses this register to reset the Hibernation module, the write causes proper operation, but the value of the **HIB** bit is not reflected in the **SRCR0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 47: Universal Asynchronous Receiver/Transmitter Software Reset (SRUART), offset 0x518

The **SRUART** register provides software the capability to reset the available UART modules. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the UART modules and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRUART** register. While the **SRUART** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRUART** bit.

There may be latency from the clearing of the **SRUART** bit to when the peripheral is ready for use. Software can check the corresponding **PRUART** bit to be sure.

**Important:** This register should be used to reset the UART modules. To support legacy software, the **SRCR1** register is available. Setting a bit in the **SRCR1** register also resets the corresponding module. Any bits that are changed by writing to the **SRCR1** register can be read back correctly when reading the **SRCR1** register. Software must use this register to reset modules that are not present in the legacy registers. If software uses this register to reset a legacy peripheral (such as UART0), the write causes proper operation, but the value of that bit is not reflected in the **SRCR1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 48: Synchronous Serial Interface Software Reset (SRSSI), offset 0x51C

The **SRSSI** register provides software the capability to reset the available SSI modules. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the SSI modules and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRSSI** register. While the **SRSSI** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRSSI** bit.

There may be latency from the clearing of the **SRSSI** bit to when the peripheral is ready for use. Software can check the corresponding **PRSSI** bit to be sure.

**Important:** This register should be used to reset the SSI modules. To support legacy software, the **SRCR1** register is available. Setting a bit in the **SRCR1** register also resets the corresponding module. Any bits that are changed by writing to the **SRCR1** register can be read back correctly when reading the **SRCR1** register. Software must use this register to reset modules that are not present in the legacy registers. If software uses this register to reset a legacy peripheral (such as SSI0), the write causes proper operation, but the value of that bit is not reflected in the **SRCR1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

**Register 49: Inter-Integrated Circuit Software Reset (SRI2C), offset 0x520**

The **SRI2C** register provides software the capability to reset the available I<sup>2</sup>C modules. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the I<sup>2</sup>C modules and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRI2C** register. While the **SRI2C** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRI2C** bit.

There may be latency from the clearing of the **SRI2C** bit to when the peripheral is ready for use. Software can check the corresponding **PRI2C** bit to be sure.

**Important:** This register should be used to reset the I<sup>2</sup>C modules. To support legacy software, the **SRCR1** register is available. Setting a bit in the **SRCR1** register also resets the corresponding module. Any bits that are changed by writing to the **SRCR1** register can be read back correctly when reading the **SRCR1** register. Software must use this register to reset modules that are not present in the legacy registers. If software uses this register to reset a legacy peripheral (such as I2C0), the write causes proper operation, but the value of that bit is not reflected in the **SRCR1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 50: Universal Serial Bus Software Reset (SRUSB), offset 0x528

The **SRUSB** register provides software the capability to reset the available USB module. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the USB module and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRUSB** register. While the **SRUSB** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRUSB** bit.

There may be latency from the clearing of the **SRUSB** bit to when the peripheral is ready for use. Software can check the corresponding **PRUSB** bit to be sure.

**Important:** This register should be used to reset the USB module. To support legacy software, the **SRCR2** register is available. Setting the **USB0** bit in the **SRCR2** register also resets the USB module. If the **USB0** bit is set by writing to the **SRCR2** register, it can be read back correctly when reading the **SRCR2** register. If software uses this register to reset the USB module, the write causes proper operation, but the value of the **USB0** bit is not reflected in the **SRCR2** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

### Register 51: Controller Area Network Software Reset (SRCAN), offset 0x534

The **SRCAN** register provides software the capability to reset the available CAN modules. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the CAN modules and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRCAN** register. While the **SRCAN** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRCAN** bit.

There may be latency from the clearing of the **SRCAN** bit to when the peripheral is ready for use. Software can check the corresponding **PRCAN** bit to be sure.

**Important:** This register should be used to reset the CAN modules. To support legacy software, the **SRCR0** register is available. Setting a bit in the **SRCR0** register also resets the corresponding module. Any bits that are changed by writing to the **SRCR0** register can be read back correctly when reading the **SRCR0** register. If software uses this register to reset a legacy peripheral (such as CAN0), the write causes proper operation, but the value of that bit is not reflected in the **SRCR0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

**Register 52: Analog-to-Digital Converter Software Reset (SRADC), offset 0x538**

The **SRADC** register provides software the capability to reset the available ADC modules. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the ADC modules and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRADC** register. While the **SRADC** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRADC** bit.

There may be latency from the clearing of the **SRADC** bit to when the peripheral is ready for use. Software can check the corresponding **PRADC** bit to be sure.

**Important:** This register should be used to reset the ADC modules. To support legacy software, the **SRCR0** register is available. Setting a bit in the **SRCR0** register also resets the corresponding module. Any bits that are changed by writing to the **SRCR0** register can be read back correctly when reading the **SRCR0** register. If software uses this register to reset a legacy peripheral (such as ADC0), the write causes proper operation, but the value of that bit is not reflected in the **SRCR0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

**Register 53: Analog Comparator Software Reset (SRACMP), offset 0x53C**

The **SRACMP** register provides software the capability to reset the available analog comparator module. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the analog comparator module and has the same bit polarity as the corresponding **SRCRn** bits.

A block is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRACMP** register. While the **SRACMP** bit is 1, the module is held in reset.
2. Software completes the reset process by clearing the **SRACMP** bit.

There may be latency from the clearing of the **SRACMP** bit to when the module is ready for use. Software can check the corresponding **PRACMP** bit to be sure.

**Important:** This register should be used to reset the analog comparator module. To support legacy software, the **SRCR1** register is available. Setting any of the **COMPn** bits in the **SRCR0** register also resets the analog comparator module. If any of the **COMPn** bits are set by writing to the **SRCR1** register, it can be read back correctly when reading the **SRCR0** register. If software uses this register to reset the analog comparator module, the write causes proper operation, but the value of **R0** is not reflected by the **COMPn** bits in the **SRCR1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

### Register 54: EEPROM Software Reset (SREEPROM), offset 0x558

The **SREEPROM** register provides software the capability to reset the available EEPROM module.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SREEPROM** register. While the **SREEPROM** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SREEPROM** bit.

There may be latency from the clearing of the **SREEPROM** bit to when the peripheral is ready for use. Software can check the corresponding **PREEEPROM** bit to be sure.

## Register 55: 32/64-Bit Wide General-Purpose Timer Software Reset (SRWTIMER), offset 0x55C

The **SRWTIMER** register provides software the capability to reset the available 32/64-bit wide timer modules.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRWTIMER** register. While the **SRWTIMER** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRWTIMER** bit.

There may be latency from the clearing of the **SRWTIMER** bit to when the peripheral is ready for use. Software can check the corresponding **PRWTIMER** bit to be sure.

## Register 56: Watchdog Timer Run Mode Clock Gating Control (RCGCWD), offset 0x600

The **RCGCWD** register provides software the capability to enable and disable watchdog modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **RCGCn** bits.

**Important:** This register should be used to control the clocking for the watchdog modules. To support legacy software, the **RCGC0** register is available. A write to the **RCGC0** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **RCGC0** register can be read back correctly with a read of the **RCGC0** register. If software uses this register to write a legacy peripheral (such as Watchdog 0), the write causes proper operation, but the value of that bit is not reflected in the **RCGC0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

### Register 57: 16/32-Bit General-Purpose Timer Run Mode Clock Gating Control (RCGCTIMER), offset 0x604

The **RCGCTIMER** register provides software the capability to enable and disable 16/32-bit timer modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the timer modules and has the same bit polarity as the corresponding **RCGCn** bits.

**Important:** This register should be used to control the clocking for the timer modules. To support legacy software, the **RCGC1** register is available. A write to the **RCGC1** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **RCGC1** register can be read back correctly with a read of the **RCGC1** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as Timer 0), the write causes proper operation, but the value of that bit is not reflected in the **RCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

### Register 58: General-Purpose Input/Output Run Mode Clock Gating Control (RCGCGPIO), offset 0x608

The **RCGCGPIO** register provides software the capability to enable and disable GPIO modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **RCGCn** bits.

**Important:** This register should be used to control the clocking for the GPIO modules. To support legacy software, the **RCGC2** register is available. A write to the **RCGC2** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **RCGC2** register can be read back correctly with a read of the **RCGC2** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as GPIO A), the write causes proper operation, but the value of that bit is not reflected in the **RCGC2** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

### Register 59: Micro Direct Memory Access Run Mode Clock Gating Control (RCGCDMA), offset 0x60C

The **RCGCDMA** register provides software the capability to enable and disable the  $\mu$ DMA module in Run mode. When enabled, the module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **RCGCn** bits.

**Important:** This register should be used to control the clocking for the  $\mu$ DMA module. To support legacy software, the **RCGC2** register is available. A write to the **UDMA** bit in the **RCGC2** register also writes the **R0** bit in this register. If the **UDMA** bit is changed by writing to the **RCGC2** register, it can be read back correctly with a read of the **RCGC2** register. If software uses this register to control the clock for the  $\mu$ DMA module, the write causes proper operation, but the **UDMA** bit in the **RCGC2** register does not reflect the value of the **R0** bit. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 60: Hibernation Run Mode Clock Gating Control (RCGCHIB), offset 0x614

The **RCGCHIB** register provides software the capability to enable and disable the Hibernation module in Run mode. When enabled, the module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **RCGCn** bits.

**Important:** This register should be used to control the clocking for the Hibernation module. To support legacy software, the **RCGC0** register is available. A write to the **HIB** bit in the **RCGC0** register also writes the **R0** bit in this register. If the **HIB** bit is changed by writing to the **RCGC0** register, it can be read back correctly with a read of the **RCGC0** register. If software uses this register to control the clock for the Hibernation module, the write causes proper operation, but the **HIB** bit in the **RCGC0** register does not reflect the value of the **R0** bit. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 61: Universal Asynchronous Receiver/Transmitter Run Mode Clock Gating Control (RCGCUART), offset 0x618

The **RCGCUART** register provides software the capability to enable and disable the UART modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **RCGCn** bits.

**Important:** This register should be used to control the clocking for the UART modules. To support legacy software, the **RCGC1** register is available. A write to the **RCGC1** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **RCGC1** register can be read back correctly with a read of the **RCGC1** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as UART0), the write causes proper operation, but the value of that bit is not reflected in the **RCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 62: Synchronous Serial Interface Run Mode Clock Gating Control (RCGCSSI), offset 0x61C

The **RCGCSSI** register provides software the capability to enable and disable the SSI modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **RCGCn** bits.

**Important:** This register should be used to control the clocking for the SSI modules. To support legacy software, the **RCGC1** register is available. A write to the **RCGC1** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **RCGC1** register can be read back correctly with a read of the **RCGC1** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as SSI0), the write causes proper operation, but the value of that bit is not reflected in the **RCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

### Register 63: Inter-Integrated Circuit Run Mode Clock Gating Control (RCGCI2C), offset 0x620

The **RCGCI2C** register provides software the capability to enable and disable the I<sup>2</sup>C modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **RCGCn** bits.

**Important:** This register should be used to control the clocking for the I<sup>2</sup>C modules. To support legacy software, the **RCGC1** register is available. A write to the **RCGC1** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **RCGC1** register can be read back correctly with a read of the **RCGC1** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as I2C0), the write causes proper operation, but the value of that bit is not reflected in the **RCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

### Register 64: Universal Serial Bus Run Mode Clock Gating Control (RCGCUSB), offset 0x628

The **RCGCUSB** register provides software the capability to enable and disable the USB module in Run mode. When enabled, the module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **RCGCn** bits.

**Important:** This register should be used to control the clocking for the USB module. To support legacy software, the **RCGC2** register is available. A write to the **USB0** bit in the **RCGC2** register also writes the **R0** bit in this register. If the **USB0** bit is changed by writing to the **RCGC2** register, it can be read back correctly with a read of the **RCGC2** register. If software uses this register to control the clock for the USB module, the write causes proper operation, but the **USB0** bit in the **RCGC2** register does not reflect the value of the **R0** bit. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 65: Controller Area Network Run Mode Clock Gating Control (RCGCCAN), offset 0x634

The **RCGCCAN** register provides software the capability to enable and disable the CAN modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **RCGCn** bits.

**Important:** This register should be used to control the clocking for the CAN modules. To support legacy software, the RCGC0 register is available. A write to the RCGC0 register also writes the corresponding bit in this register. Any bits that are changed by writing to the RCGC0 register can be read back correctly with a read of the RCGC0 register. If software uses this register to write a legacy peripheral (such as CAN0), the write causes proper operation, but the value of that bit is not reflected in the RCGC0 register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 66: Analog-to-Digital Converter Run Mode Clock Gating Control (RCGCADC), offset 0x638

The **RCGCADC** register provides software the capability to enable and disable the ADC modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **RCGCn** bits.

**Important:** This register should be used to control the clocking for the ADC modules. To support legacy software, the RCGC0 register is available. A write to the RCGC0 register also writes the corresponding bit in this register. Any bits that are changed by writing to the RCGC0 register can be read back correctly with a read of the RCGC0 register. If software uses this register to write a legacy peripheral (such as ADC0), the write causes proper operation, but the value of that bit is not reflected in the RCGC0 register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 67: Analog Comparator Run Mode Clock Gating Control (RCGCACMP), offset 0x63C

The **RCGCACMP** register provides software the capability to enable and disable the analog comparator module in Run mode. When enabled, the module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **RCGCn** bits.

**Important:** This register should be used to control the clocking for the analog comparator module. To support legacy software, the RCGC1 register is available. Setting any of the **COMP<sub>n</sub>** bits in the RCGC1 register also sets the **R0** bit in this register. If any of the **COMP<sub>n</sub>** bits are set by writing to the RCGC1 register, it can be read back correctly when reading the RCGC1 register. If software uses this register to change the clocking for the analog comparator module, the write causes proper operation, but the value **R0** is not reflected by the **COMP<sub>n</sub>** bits in the RCGC1 register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 68: EEPROM Run Mode Clock Gating Control (RCGCEEPROM), offset 0x658

The **RCGCEEPROM** register provides software the capability to enable and disable the EEPROM module in Run mode. When enabled, the module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault.

## Register 69: 32/64-Bit Wide General-Purpose Timer Run Mode Clock Gating Control (RCGCWTIMER), offset 0x65C

The **RCGCWTIMER** register provides software the capability to enable and disable 32/64-bit timer modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the timer modules and has the same bit polarity as the corresponding **RCGCn** bits.

## Register 70: Watchdog Timer Sleep Mode Clock Gating Control (SCGCWD), offset 0x700

The **SCGCWD** register provides software the capability to enable and disable watchdog modules in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SCGCn** bits.

**Important:** This register should be used to control the clocking for the watchdog modules. To support legacy software, the **SCGC0** register is available. A write to the **SCGC0** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **SCGC0** register can be read back correctly with a read of the **SCGC0** register. If software uses this register to write a legacy peripheral (such as Watchdog 0), the write causes proper operation, but the value of that bit is not reflected in the **SCGC0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 71: 16/32-Bit General-Purpose Timer Sleep Mode Clock Gating Control (SCGCTIMER), offset 0x704

The **SCGCTIMER** register provides software the capability to enable and disable 16/32-bit timer modules in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the timer modules and has the same bit polarity as the corresponding **SCGCn** bits.

**Important:** This register should be used to control the clocking for the timer modules. To support legacy software, the **SCGC1** register is available. A write to the **SCGC1** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **SCGC1** register can be read back correctly with a read of the **SCGC1** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as Timer 0), the write causes proper operation, but the value of that bit is not reflected in the **SCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 72: General-Purpose Input/Output Sleep Mode Clock Gating Control (SCGCGPIO), offset 0x708

The **SCGCGPIO** register provides software the capability to enable and disable GPIO modules in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SCGCn** bits.

**Important:** This register should be used to control the clocking for the GPIO modules. To support legacy software, the **SCGC2** register is available. A write to the **SCGC2** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **SCGC2** register can be read back correctly with a read of the **SCGC2** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as GPIO A), the write causes proper operation, but the value of that bit is not reflected in the **SCGC2** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

### Register 73: Micro Direct Memory Access Sleep Mode Clock Gating Control (SCGCDMA), offset 0x70C

The **SCGCDMA** register provides software the capability to enable and disable the  $\mu$ DMA module in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SCGCn** bits.

**Important:** This register should be used to control the clocking for the  $\mu$ DMA module. To support legacy software, the **SCGC2** register is available. A write to the **UDMA** bit in the **SCGC2** register also writes the **S0** bit in this register. If the **UDMA** bit is changed by writing to the **SCGC2** register, it can be read back correctly with a read of the **SCGC2** register. If software uses this register to control the clock for the  $\mu$ DMA module, the write causes proper operation, but the **UDMA** bit in the **SCGC2** register does not reflect the value of the **S0** bit. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 74: Hibernation Sleep Mode Clock Gating Control (SCGCHIB), offset 0x714

The **SCGCHIB** register provides software the capability to enable and disable the Hibernation module in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SCGCn** bits.

**Important:** This register should be used to control the clocking for the Hibernation module. To support legacy software, the **SCGC0** register is available. A write to the **HIB** bit in the **SCGC0** register also writes the **S0** bit in this register. If the **HIB** bit is changed by writing to the **SCGC0** register, it can be read back correctly with a read of the **SCGC0** register. If software uses this register to control the clock for the Hibernation module, the write causes proper operation, but the **HIB** bit in the **SCGC0** register does not reflect the value of the **S0** bit. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 76: Synchronous Serial Interface Sleep Mode Clock Gating Control (SCGCSSI), offset 0x71C

The **SCGCSSI** register provides software the capability to enable and disable the SSI modules in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SCGCn** bits.

**Important:** This register should be used to control the clocking for the SSI modules. To support legacy software, the **SCGC1** register is available. A write to the **SCGC1** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **SCGC1** register can be read back correctly with a read of the **SCGC1** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as SSI0), the write causes proper operation, but the value of that bit is not reflected in the **SCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

### Register 78: Universal Serial Bus Sleep Mode Clock Gating Control (SCGCUSB), offset 0x728

The **SCGCUSB** register provides software the capability to enable and disable the USB module in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SCGCn** bits.

**Important:** This register should be used to control the clocking for the USB module. To support legacy software, the **SCGC2** register is available. A write to the **USB0** bit in the **SCGC2** register also writes the **S0** bit in this register. If the **USB0** bit is changed by writing to the **SCGC2** register, it can be read back correctly with a read of the **SCGC2** register. If software uses this register to control the clock for the USB module, the write causes proper operation, but the **USB0** bit in the **SCGC2** register does not reflect the value of the **S0** bit. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 79: Controller Area Network Sleep Mode Clock Gating Control (SCGCCAN), offset 0x734

The **SCGCCAN** register provides software the capability to enable and disable the CAN modules in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SCGCn** bits.

**Important:** This register should be used to control the clocking for the CAN modules. To support legacy software, the **SCGC0** register is available. A write to the **SCGC0** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **SCGC0** register can be read back correctly with a read of the **SCGC0** register. If software uses this register to write a legacy peripheral (such as CAN0), the write causes proper operation, but the value of that bit is not reflected in the **SCGC0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

### Register 80: Analog-to-Digital Converter Sleep Mode Clock Gating Control (SCGCADC), offset 0x738

The **SCGCADC** register provides software the capability to enable and disable the ADC modules in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SCGCn** bits.

**Important:** This register should be used to control the clocking for the ADC modules. To support legacy software, the **SCGC0** register is available. A write to the **SCGC0** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **SCGC0** register can be read back correctly with a read of the **SCGC0** register. If software uses this register to write a legacy peripheral (such as ADC0), the write causes proper operation, but the value of that bit is not reflected in the **SCGC0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 81: Analog Comparator Sleep Mode Clock Gating Control (SCGCACMP), offset 0x73C

The **SCGCACMP** register provides software the capability to enable and disable the analog comparator module in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SCGCn** bits.

**Important:** This register should be used to control the clocking for the analog comparator module. To support legacy software, the **SCGC1** register is available. Setting any of the **COMP<sub>n</sub>** bits in the **SCGC1** register also sets the **S0** bit in this register. If any of the **COMP<sub>n</sub>** bits are set by writing to the **SCGC1** register, it can be read back correctly when reading the **SCGC1** register. If software uses this register to change the clocking for the analog comparator module, the write causes proper operation, but the value **S0** is not reflected by the **COMP<sub>n</sub>** bits in the **SCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 84: Watchdog Timer Deep-Sleep Mode Clock Gating Control (DCGCWD), offset 0x800

The **DCGCWD** register provides software the capability to enable and disable watchdog modules in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **DCGCn** bits.

**Important:** This register should be used to control the clocking for the watchdog modules. To support legacy software, the **DCGC0** register is available. A write to the **DCGC0** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **DCGC0** register can be read back correctly with a read of the **DCGC0** register. If software uses this register to write a legacy peripheral (such as Watchdog 0), the write causes proper operation, but the value of that bit is not reflected in the **DCGC0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

### Register 85: 16/32-Bit General-Purpose Timer Deep-Sleep Mode Clock Gating Control (DCGCTIMER), offset 0x804

The **DCGCTIMER** register provides software the capability to enable and disable 16/32-bit timer modules in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the timer modules and has the same bit polarity as the corresponding **DCGCn** bits.

**Important:** This register should be used to control the clocking for the timer modules. To support legacy software, the **DCGC1** register is available. A write to the **DCGC1** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **DCGC1** register can be read back correctly with a read of the **DCGC1** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as Timer 0), the write causes proper operation, but the value of that bit is not reflected in the **DCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

### Register 86: General-Purpose Input/Output Deep-Sleep Mode Clock Gating Control (DCGCGPIO), offset 0x808

The **DCGCGPIO** register provides software the capability to enable and disable GPIO modules in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **DCGCn** bits.

**Important:** This register should be used to control the clocking for the GPIO modules. To support legacy software, the **DCGC2** register is available. A write to the **DCGC2** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **DCGC2** register can be read back correctly with a read of the **DCGC2** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as GPIO A), the write causes proper operation, but the value of that bit is not reflected in the **DCGC2** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

### Register 87: Micro Direct Memory Access Deep-Sleep Mode Clock Gating Control (DCGCDMA), offset 0x80C

The **DCGCDMA** register provides software the capability to enable and disable the  $\mu$ DMA module in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **DCGCn** bits.

**Important:** This register should be used to control the clocking for the  $\mu$ DMA module. To support legacy software, the **DCGC2** register is available. A write to the **UDMA** bit in the **DCGC2** register also writes the **D0** bit in this register. If the **UDMA** bit is changed by writing to the **DCGC2** register, it can be read back correctly with a read of the **DCGC2** register. If software uses this register to control the clock for the  $\mu$ DMA module, the write causes proper operation, but the **UDMA** bit in the **DCGC2** register does not reflect the value of the **D0** bit. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 88: Hibernation Deep-Sleep Mode Clock Gating Control (DCGCHIB), offset 0x814

The **DCGCHIB** register provides software the capability to enable and disable the Hibernation module in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **DCGCn** bits.

**Important:** This register should be used to control the clocking for the Hibernation module. To support legacy software, the **DCGC0** register is available. A write to the **HIB** bit in the **DCGC0** register also writes the **D0** bit in this register. If the **HIB** bit is changed by writing to the **DCGC0** register, it can be read back correctly with a read of the **DCGC0** register. If software uses this register to control the clock for the Hibernation module, the write causes proper operation, but the **HIB** bit in the **DCGC0** register does not reflect the value of the **D0** bit. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

### Register 89: Universal Asynchronous Receiver/Transmitter Deep-Sleep Mode Clock Gating Control (DCGCUART), offset 0x818

The **DCGCUART** register provides software the capability to enable and disable the UART modules in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **DCGCn** bits.

**Important:** This register should be used to control the clocking for the UART modules. To support legacy software, the **DCGC1** register is available. A write to the **DCGC1** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **DCGC1** register can be read back correctly with a read of the **DCGC1** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as UART0), the write causes proper operation, but the value of that bit is not reflected in the **DCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 90: Synchronous Serial Interface Deep-Sleep Mode Clock Gating Control (DCGCSSI), offset 0x81C

The **DCGCSSI** register provides software the capability to enable and disable the SSI modules in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **DCGCn** bits.

**Important:** This register should be used to control the clocking for the SSI modules. To support legacy software, the **DCGC1** register is available. A write to the **DCGC1** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **DCGC1** register can be read back correctly with a read of the **DCGC1** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as SSI0), the write causes proper operation, but the value of that bit is not reflected in the **DCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 92: Universal Serial Bus Deep-Sleep Mode Clock Gating Control (DCGCUSB), offset 0x828

The **DCGCUSB** register provides software the capability to enable and disable the USB module in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **DCGCn** bits.

**Important:** This register should be used to control the clocking for the USB module. To support legacy software, the **DCGC2** register is available. A write to the **USB0** bit in the **DCGC2** register also writes the **D0** bit in this register. If the **USB0** bit is changed by writing to the **DCGC2** register, it can be read back correctly with a read of the **DCGC2** register. If software uses this register to control the clock for the USB module, the write causes proper operation, but the **USB0** bit in the **DCGC2** register does not reflect the value of the **D0** bit. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 93: Controller Area Network Deep-Sleep Mode Clock Gating Control (DCGCCAN), offset 0x834

The **DCGCCAN** register provides software the capability to enable and disable the CAN modules in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **DCGCn** bits.

**Important:** This register should be used to control the clocking for the CAN modules. To support legacy software, the **DCGC0** register is available. A write to the **DCGC0** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **DCGC0** register can be read back correctly with a read of the **DCGC0** register. If software uses this register to write a legacy peripheral (such as CAN0), the write causes proper operation, but the value of that bit is not reflected in the **DCGC0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

### Register 94: Analog-to-Digital Converter Deep-Sleep Mode Clock Gating Control (DCGCADC), offset 0x838

The **DCGCADC** register provides software the capability to enable and disable the ADC modules in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **DCGCn** bits.

**Important:** This register should be used to control the clocking for the ADC modules. To support legacy software, the **DCGC0** register is available. A write to the **DCGC0** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **DCGC0** register can be read back correctly with a read of the **DCGC0** register. If software uses this register to write a legacy peripheral (such as ADC0), the write causes proper operation, but the value of that bit is not reflected in the **DCGC0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 95: Analog Comparator Deep-Sleep Mode Clock Gating Control (DCGCAMP), offset 0x83C

The **DCGCAMP** register provides software the capability to enable and disable the analog comparator module in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **DCGCn** bits.

**Important:** This register should be used to control the clocking for the analog comparator module. To support legacy software, the **DCGC1** register is available. Setting any of the **COMPn** bits in the **DCGC1** register also sets the **D0** bit in this register. If any of the **COMPn** bits are set by writing to the **DCGC1** register, it can be read back correctly when reading the **DCGC1** register. If software uses this register to change the clocking for the analog comparator module, the write causes proper operation, but the value **D0** is not reflected by the **COMPn** bits in the **DCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

**Register 98: Watchdog Timer Peripheral Ready (PRWD), offset 0xA00**

The **PRWD** register indicates whether the watchdog modules are ready to be accessed by software following a change in status of power, Run mode clocking, or reset. A Run mode clocking change is initiated if the corresponding **RCGCWD** bit is changed. A reset change is initiated if the corresponding **SRWD** bit is changed from 0 to 1.

The **PRWD** bit is cleared on any of the above events and is not set again until the module is completely powered, enabled, and internally reset.

### Register 99: 16/32-Bit General-Purpose Timer Peripheral Ready (PRTIMER), offset 0xA04

The **PRTIMER** register indicates whether the timer modules are ready to be accessed by software following a change in status of power, Run mode clocking, or reset. A Run mode clocking change is initiated if the corresponding **RCGCTIMER** bit is changed. A reset change is initiated if the corresponding **SRTIMER** bit is changed from 0 to 1.

The **PRTIMER** bit is cleared on any of the above events and is not set again until the module is completely powered, enabled, and internally reset.

**Register 102: Hibernation Peripheral Ready (PRHIB), offset 0xA14**

The **PRHIB** register indicates whether the Hibernation module is ready to be accessed by software following a change in status of power, Run mode clocking, or reset. A Run mode clocking change is initiated if the corresponding **RCGCHIB** bit is changed. A reset change is initiated if the corresponding **SRHIB** bit is changed from 0 to 1.

The **PRHIB** bit is cleared on any of the above events and is not set again until the module is completely powered, enabled, and internally reset.

## Register 104: Synchronous Serial Interface Peripheral Ready (PRSSI), offset 0xA1C

The **PRSSI** register indicates whether the SSI modules are ready to be accessed by software following a change in status of power, Run mode clocking, or reset. A Run mode clocking change is initiated if the corresponding **RCGCSSI** bit is changed. A reset change is initiated if the corresponding **SRSSI** bit is changed from 0 to 1.

The **PRSSI** bit is cleared on any of the above events and is not set again until the module is completely powered, enabled, and internally reset.

### Register 106: Universal Serial Bus Peripheral Ready (PRUSB), offset 0xA28

The **PRUSB** register indicates whether the USB module is ready to be accessed by software following a change in Run mode clocking or reset. A Run mode clocking change is initiated if the corresponding **RCGCUSB** bit is changed. A reset change is initiated if the corresponding **SRUSB** bit is changed from 0 to 1.

The **PRUSB** bit is cleared on either of the above events and is not set again until the module is completely powered, enabled, and internally reset.

|-------|--------------------------------------------------------------------------------------------------------------------------|
| 1     | The EEPROM module is ready for access.                                                                                   |
| 0     | The EEPROM module is not ready for access. It is unclocked, unpowered, or in the process of completing a reset sequence. |

## Register 111: 32/64-Bit Wide General-Purpose Timer Peripheral Ready (PRWTIMER), offset 0xA5C

The **PRWTIMER** register indicates whether the timer modules are ready to be accessed by software following a change in status of power, Run mode clocking, or reset. A Run mode clocking change is initiated if the corresponding **RCGCWTIMER** bit is changed. A reset change is initiated if the corresponding **SRWTIMER** bit is changed from 0 to 1.

The **PRWTIMER** bit is cleared on any of the above events and is not set again until the module is completely powered, enabled, and internally reset.

### 32/64-Bit Wide General-Purpose Timer Peripheral Ready (PRWTIMER)

## 5.6 System Control Legacy Register Descriptions

All addresses given are relative to the System Control base address of 0x400F.E000.

---

**Important:** Register in this section are provided for legacy software support only; registers in “System Control Register Descriptions” on page 228 should be used instead.

---

**Register 112: Device Capabilities 0 (DC0), offset 0x008**

This legacy register is predefined by the part and can be used to verify features.

**Important:** This register is provided for legacy software support only.

The **Flash Size (FSIZE)** and **SRAM Size (SSIZE)** registers should be used to determine this microcontroller's memory sizes. A read of **DC0** correctly identifies legacy memory sizes but software must use **FSIZE** and **SSIZE** for memory sizes that are not listed below.

**Device Capabilities 0 (DC0)**

**Register 113: Device Capabilities 1 (DC1), offset 0x010**

This register is predefined by the part and can be used to verify features. If any bit is clear in this register, the module is not present. The corresponding bit in the **RCGC0**, **SCGC0**, **DCGC0**, and the peripheral-specific **RCGC**, **SCGC**, and **DCGC** registers cannot be set.

**Important:** This register is provided for legacy software support only.

The Peripheral Present registers should be used to determine which modules are implemented on this microcontroller. A read of **DC1** correctly identifies if a legacy module is present but software must use the Peripheral Present registers to determine if a module is present that is not supported by the **DCn** registers.

Likewise, the **ADC Peripheral Properties (ADCPP)** register should be used to determine the maximum ADC sample rate and whether the temperature sensor is present. However, to support legacy software, the **MAXADCnSPD** fields and the **TEMPSNS** bit are available. A read of **DC1** correctly identifies the maximum ADC sample rate for legacy rates and whether the temperature sensor is present.

## Register 114: Device Capabilities 2 (DC2), offset 0x014

This register is predefined by the part and can be used to verify features. If any bit is clear in this register, the module is not present. The corresponding bit in the **RCGC1**, **SCGC1**, **DCGC1**, and the peripheral-specific **RCGC**, **SCGC**, and **DCGC** registers registers cannot be set.

**Important:** This register is provided for legacy software support only.

The Peripheral Present registers should be used to determine which modules are implemented on this microcontroller. A read of **DC2** correctly identifies if a legacy module is present but software must use the Peripheral Present registers to determine if a module is present that is not supported by the **DCn** registers.

Note that the **Analog Comparator Peripheral Present (PPACMP)** register identifies whether the analog comparator module is present. The **Analog Comparator Peripheral Properties (ACMPPP)** register indicates how many analog comparator blocks are present in the module.

## Register 115: Device Capabilities 3 (DC3), offset 0x018

This register is predefined by the part and can be used to verify features. If any bit is clear in this register, the feature is not present.

**Important:** This register is provided for legacy software support only.

For some modules, the peripheral-resident Peripheral Properties registers should be used to determine which pins are available on this microcontroller. A read of **DC3** correctly identifies if a legacy pin is present but software must use the Peripheral Properties registers to determine if a pin is present that is not supported by the **DCn** registers.

### Device Capabilities 3 (DC3)

Base 0x400F.E000

Offset 0x018

Type RO, reset 0xBFFF.0FC0

## Register 116: Device Capabilities 4 (DC4), offset 0x01C

This register is predefined by the part and can be used to verify features. If any bit is clear in this register, the module is not present. The corresponding bit in the **RCGC2**, **SCGC2**, **DCGC2**, and the peripheral-specific **RCGC**, **SCGC**, and **DCGC** registers registers cannot be set.

**Important:** This register is provided for legacy software support only.

The Peripheral Present registers should be used to determine which modules are implemented on this microcontroller. A read of **DC4** correctly identifies if a legacy module is present but software must use the Peripheral Present registers to determine if a module is present that is not supported by the **DCn** registers.

The peripheral-resident Peripheral Properties registers should be used to determine which pins and features are available on this microcontroller. A read of **DC4** correctly identifies if a legacy pin or feature is present. Software must use the Peripheral Properties registers to determine if a pin or feature is present that is not supported by the **DCn** registers.

## Register 117: Device Capabilities 5 (DC5), offset 0x020

This register is predefined by the part and can be used to verify PWM features. If any bit is clear in this register, the module is not present.

**Important:** This register is provided for legacy software support only.

The **PWM Peripheral Properties (PWMPPP)** register should be used to determine what pins and features are available on PWM modules. A read of this register correctly identifies if a legacy pin or feature is present. Software must use the **PWMPPP** register to determine if a pin or feature that is not supported by the **DCn** registers is present.

## Register 118: Device Capabilities 6 (DC6), offset 0x024

This register is predefined by the part and can be used to verify features. If any bit is clear in this register, the module is not present. The corresponding bit in the **RCGC0**, **SCGC0**, and **DCGC0** registers cannot be set.

**Important:** This register is provided for legacy software support only.

The **USB Peripheral Properties (USBPP)** register should be used to determine what features are available on the USB module. A read of this register correctly identifies if a legacy feature is present. Software must use the **USBPP** register to determine if a pin or feature that is not supported by the **DCn** registers is present.

**Register 119: Device Capabilities 7 (DC7), offset 0x028**

This register is predefined by the part and can be used to verify  $\mu$ DMA channel features. A 1 indicates the channel is available on this device; a 0 that the channel is only available on other devices in the family. Channels can have multiple assignments, see “Channel Assignments” on page 559 for more information.

**Important:** This register is provided for legacy software support only. The DMACHANS bit field in the **DMA Status (DMASTAT)** register indicates the number of DMA channels.

## Register 120: Device Capabilities 8 (DC8), offset 0x02C

This register is predefined by the part and can be used to verify features.

**Important:** This register is provided for legacy software support only.

The **ADC Peripheral Properties (ADCPP)** register should be used to determine how many input channels are available on the ADC module. A read of this register correctly identifies if legacy channels are present but software must use the **ADCPP** register to determine if a channel is present that is not supported by the **DCn** registers.

## Register 121: Software Reset Control 0 (SRCR0), offset 0x040

This register allows individual modules to be reset. Writes to this register are masked by the bits in the **Device Capabilities 1 (DC1)** register.

**Important:** This register is provided for legacy software support only.

The peripheral-specific Software Reset registers (such as **SRWD**) should be used to reset specific peripherals. A write to this legacy register also writes the corresponding bit in the peripheral-specific register. Any bits that are changed by writing to this legacy register can be read back correctly with a read of this register. Software must use the peripheral-specific registers to support modules that are not present in the legacy registers. If software uses a peripheral-specific register to write a legacy peripheral (such as Watchdog 1), the write causes proper operation, but the value of that bit is not reflected in this register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 122: Software Reset Control 1 (SRCR1), offset 0x044

This register allows individual modules to be reset. Writes to this register are masked by the bits in the **Device Capabilities 2 (DC2)** register.

**Important:** This register is provided for legacy software support only.

The peripheral-specific Software Reset registers (such as **SRTIMER**) should be used to reset specific peripherals. A write to this register also writes the corresponding bit in the peripheral-specific register. Any bits that are changed by writing to this register can be read back correctly with a read of this register. Software must use the peripheral-specific registers to support modules that are not present in the legacy registers. If software uses a peripheral-specific register to write a legacy peripheral (such as **TIMER0**), the write causes proper operation, but the value of that bit is not reflected in this register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Note that the **Software Reset Analog Comparator (SRACMP)** register has only one bit to set the analog comparator module. Resetting the module resets all the blocks. If any of the **COMP<sub>n</sub>** bits are set, the entire analog comparator module is reset. It is not possible to reset the blocks individually.

## Register 123: Software Reset Control 2 (SRCR2), offset 0x048

This register allows individual modules to be reset. Writes to this register are masked by the bits in the **Device Capabilities 4 (DC4)** register.

**Important:** This register is provided for legacy software support only.

The peripheral-specific Software Reset registers (such as **SRDMA**) should be used to reset specific peripherals. A write to this legacy register also writes the corresponding bit in the peripheral-specific register. Any bits that are changed by writing to this register can be read back correctly with a read of this register. Software must use the peripheral-specific registers to support modules that are not present in the legacy registers. If software uses a peripheral-specific register to write a legacy peripheral (such as the  $\mu$ DMA), the write causes proper operation, but the value of that bit is not reflected in this register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

**Register 124: Run Mode Clock Gating Control Register 0 (RCGC0), offset 0x100**

This register controls the clock gating logic in normal Run mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled (saving power). If the module is unclocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC0** is the clock configuration register for running operation, **SCGC0** for Sleep operation, and **DCGC0** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes. Note that there must be a delay of 3 system clocks after a module clock is enabled before any registers in that module are accessed.

---

**Important:** This register is provided for legacy software support only.

The peripheral-specific Run Mode Clock Gating Control registers (such as **RCGCWD**) should be used to reset specific peripherals. A write to this legacy register also writes the corresponding bit in the peripheral-specific register. Any bits that are changed by writing to this register can be read back correctly with a read of this register. Software must use the peripheral-specific registers to support modules that are not present in the legacy registers. If software uses a peripheral-specific register to write a legacy peripheral (such as Watchdog 1), the write causes proper operation, but the value of that bit is not reflected in this register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Likewise, the **ADC Peripheral Configuration (ADCPC)** register should be used to configure the ADC sample rate. However, to support legacy software, the **MAXADCnSPD** fields are available. A write to these legacy fields also writes the corresponding field in the peripheral-specific register. If a field is changed by writing to this register, it can be read back correctly with a read of this register. Software must use the peripheral-specific registers to support rates that are not available in this register. If software uses a peripheral-specific register to set the ADC rate, the write causes proper operation, but the value of that field is not reflected in this register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 125: Run Mode Clock Gating Control Register 1 (RCGC1), offset 0x104

This register controls the clock gating logic in normal Run mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled (saving power). If the module is unclocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC1** is the clock configuration register for running operation, **SCGC1** for Sleep operation, and **DCGC1** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes. Note that there must be a delay of 3 system clocks after a module clock is enabled before any registers in that module are accessed.

**Important:** This register is provided for legacy software support only.

The peripheral-specific Run Mode Clock Gating Control registers (such as **RCGCTIMER**) should be used to reset specific peripherals. A write to this legacy register also writes the corresponding bit in the peripheral-specific register. Any bits that are changed by writing to this register can be read back correctly with a read of this register. Software must use the peripheral-specific registers to support modules that are not present in the legacy registers. If software uses a peripheral-specific register to write a legacy peripheral (such as Timer 0), the write causes proper operation, but the value of that bit is not reflected in this register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

### Run Mode Clock Gating Control Register 1 (RCGC1)

Base 0x400F.E000

Offset 0x104

## Register 126: Run Mode Clock Gating Control Register 2 (RCGC2), offset 0x108

This register controls the clock gating logic in normal Run mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled (saving power). If the module is unclocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC2** is the clock configuration register for running operation, **SCGC2** for Sleep operation, and **DCGC2** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes. Note that there must be a delay of 3 system clocks after a module clock is enabled before any registers in that module are accessed.

**Important:** This register is provided for legacy software support only.

The peripheral-specific Run Mode Clock Gating Control registers (such as **RCGCDMA**) should be used to reset specific peripherals. A write to this legacy register also writes the corresponding bit in the peripheral-specific register. Any bits that are changed by writing to this register can be read back correctly with a read of this register. Software must use the peripheral-specific registers to support modules that are not present in the legacy registers. If software uses a peripheral-specific register to write a legacy peripheral (such as the  $\mu$ DMA), the write causes proper operation, but the value of that bit is not reflected in this register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 127: Sleep Mode Clock Gating Control Register 0 (SCGC0), offset 0x110

This register controls the clock gating logic in Sleep mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled (saving power). If the module is unclocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC0** is the clock configuration register for running operation, **SCGC0** for Sleep operation, and **DCGC0** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

**Important:** This register is provided for legacy software support only.

The peripheral-specific Sleep Mode Clock Gating Control registers (such as **SCGCWD**) should be used to reset specific peripherals. A write to this legacy register also writes the corresponding bit in the peripheral-specific register. Any bits that are changed by writing to this register can be read back correctly with a read of this register. Software must use the peripheral-specific registers to support modules that are not present in the legacy registers. If software uses a peripheral-specific register to write a legacy peripheral (such as Watchdog 1), the write causes proper operation, but the value of that bit is not reflected in this register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 128: Sleep Mode Clock Gating Control Register 1 (SCGC1), offset 0x114

This register controls the clock gating logic in Sleep mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled (saving power). If the module is unclocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC1** is the clock configuration register for running operation, **SCGC1** for Sleep operation, and **DCGC1** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

**Important:** This register is provided for legacy software support only.

The peripheral-specific Sleep Mode Clock Gating Control registers (such as **SCGCTIMER**) should be used to reset specific peripherals. A write to this legacy register also writes the corresponding bit in the peripheral-specific register. Any bits that are changed by writing to this register can be read back correctly with a read of this register. Software must use the peripheral-specific registers to support modules that are not present in the legacy registers. If software uses a peripheral-specific register to write a legacy peripheral (such as Timer 0), the write causes proper operation, but the value of that bit is not reflected in this register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 129: Sleep Mode Clock Gating Control Register 2 (SCGC2), offset 0x118

This register controls the clock gating logic in Sleep mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled (saving power). If the module is unclocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC2** is the clock configuration register for running operation, **SCGC2** for Sleep operation, and **DCGC2** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

**Important:** This register is provided for legacy software support only.

The peripheral-specific Sleep Mode Clock Gating Control registers (such as **SCGCDMA**) should be used to reset specific peripherals. A write to this legacy register also writes the corresponding bit in the peripheral-specific register. Any bits that are changed by writing to this register can be read back correctly with a read of this register. Software must use the peripheral-specific registers to support modules that are not present in the legacy registers. If software uses a peripheral-specific register to write a legacy peripheral (such as the  $\mu$ DMA), the write causes proper operation, but the value of that bit is not reflected in this register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 130: Deep Sleep Mode Clock Gating Control Register 0 (DCGC0), offset 0x120

This register controls the clock gating logic in Deep-Sleep mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled (saving power). If the module is unclocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC0** is the clock configuration register for running operation, **SCGC0** for Sleep operation, and **DCGC0** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

**Important:** This register is provided for legacy software support only.

The peripheral-specific Deep Sleep Mode Clock Gating Control registers (such as **DCGCWD**) should be used to reset specific peripherals. A write to this legacy register also writes the corresponding bit in the peripheral-specific register. Any bits that are changed by writing to this register can be read back correctly with a read of this register. Software must use the peripheral-specific registers to support modules that are not present in the legacy registers. If software uses a peripheral-specific register to write a legacy peripheral (such as Watchdog 1), the write causes proper operation, but the value of that bit is not reflected in this register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 131: Deep-Sleep Mode Clock Gating Control Register 1 (DCGC1), offset 0x124

This register controls the clock gating logic in Deep-Sleep mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled (saving power). If the module is unclocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC1** is the clock configuration register for running operation, **SCGC1** for Sleep operation, and **DCGC1** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

**Important:** This register is provided for legacy software support only.

The peripheral-specific Deep Sleep Mode Clock Gating Control registers (such as **DCGCTIMER**) should be used to reset specific peripherals. A write to this legacy register also writes the corresponding bit in the peripheral-specific register. Any bits that are changed by writing to this register can be read back correctly with a read of this register. Software must use the peripheral-specific registers to support modules that are not present in the legacy registers. If software uses a peripheral-specific register to write a legacy peripheral (such as Timer 0), the write causes proper operation, but the value of that bit is not reflected in this register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 132: Deep Sleep Mode Clock Gating Control Register 2 (DCGC2), offset 0x128

This register controls the clock gating logic in Deep-Sleep mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled (saving power). If the module is unclocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC2** is the clock configuration register for running operation, **SCGC2** for Sleep operation, and **DCGC2** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

**Important:** This register is provided for legacy software support only.

The peripheral-specific Deep Sleep Mode Clock Gating Control registers (such as **DCGCDMA**) should be used to reset specific peripherals. A write to this legacy register also writes the corresponding bit in the peripheral-specific register. Any bits that are changed by writing to this register can be read back correctly with a read of this register. Software must use the peripheral-specific registers to support modules that are not present in the legacy registers. If software uses a peripheral-specific register to write a legacy peripheral (such as the  $\mu$ DMA), the write causes proper operation, but the value of that bit is not reflected in this register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

### Register 133: Device Capabilities 9 (DC9), offset 0x190

This register is predefined by the part and can be used to verify ADC digital comparator features.

**Important:** This register is provided for legacy software support only.

The **ADC Peripheral Properties (ADCPP)** register should be used to determine how many digital comparators are available on the ADC module. A read of this register correctly identifies if legacy comparators are present. Software must use the **ADCPP** register to determine if a comparator that is not supported by the **DCn** registers is present.

## Register 134: Non-Volatile Memory Information (NVMSTAT), offset 0x1A0

This register is predefined by the part and can be used to verify features.

**Important:** This register is provided for legacy software support only.

The **ROM Third-Party Software (ROMSWMAP)** register should be used to determine the presence of third-party software in the on-chip ROM on this microcontroller. A read of the **TPSW** bit in this register correctly identifies the presence of legacy third-party software. Software should use the **ROMSWMAP** register for software that is not on legacy devices.

## 6 System Exception Module

This module is an AHB peripheral that handles system-level Cortex-M4 FPU exceptions. For functions with registers mapped into this aperture, if the function is not available on a device, then all writes to the associated registers are ignored and reads return zeros.

### 6.1 Functional Description

The System Exception module provides control and status of the system-level interrupts. All the interrupt events are ORed together before being sent to the interrupt controller, so the System Exception module can only generate a single interrupt request to the controller at any given time. Software can service multiple interrupt events in a single interrupt service routine by reading the **System Exception Masked Interrupt Status (SYSEXCMIIS)** register. The interrupt events that can trigger a controller-level interrupt are defined in the **System Exception Interrupt Mask (SYSEXCIM)** register by setting the corresponding interrupt mask bits. If interrupts are not used, the raw interrupt status is always visible via the **System Exception Raw Interrupt Status (SYSEXCRIS)** register. Interrupts are always cleared (for both the **SYSEXCMIIS** and **SYSEXCRIS** registers) by writing a 1 to the corresponding bit in the **System Exception Interrupt Clear (SYSEXCIC)** register.

### 6.2 Register Map

Table 6-1 on page 459 lists the System Exception module registers. The offset listed is a hexadecimal increment to the register's address, relative to the System Exception base address of 0x400F.9000.

**Note:** Spaces in the System Exception register space that are not used are reserved for future or internal use. Software should not modify any reserved memory address.

**Table 6-1. System Exception Register Map**

| Offset | Name       | Type | Reset       | Description                              | See page |

### 6.3 Register Descriptions

All addresses given are relative to the System Exception base address of 0x400F.9000.

## Register 1: System Exception Raw Interrupt Status (SYSEXCRIS), offset 0x000

The **SYSEXCRIS** register is the raw interrupt status register. On a read, this register gives the current raw status value of the corresponding interrupt. A write has no effect.

## Register 2: System Exception Interrupt Mask (SYSEXCIM), offset 0x004

The **SYSEXCIM** register is the interrupt mask set/clear register.

On a read, this register gives the current value of the mask on the relevant interrupt. Setting a bit allows the corresponding raw interrupt signal to be routed to the interrupt controller. Clearing a bit prevents the raw interrupt signal from being sent to the interrupt controller.

### System Exception Interrupt Mask (SYSEXCIM)

### Register 4: System Exception Interrupt Clear (SYSEXCIC), offset 0x00C

The **SYSEXCIC** register is the interrupt clear register. On a write of 1, the corresponding interrupt (both raw interrupt and masked interrupt, if enabled) is cleared. A write of 0 has no effect.

## 7 Hibernation Module

The Hibernation Module manages removal and restoration of power to provide a means for reducing system power consumption. When the processor and peripherals are idle, power can be completely removed with only the Hibernation module remaining powered. Power can be restored based on an external signal or at a certain time using the built-in Real-Time Clock (RTC). The Hibernation module can be independently supplied from an external battery or an auxiliary power supply.

The Hibernation module has the following features:

- 32-bit real-time seconds counter (RTC) with 1/32,768 second resolution and a 15-bit sub-seconds counter
  - 32-bit RTC seconds match register and a 15-bit sub seconds match for timed wake-up and interrupt generation with 1/32,768 second resolution
  - RTC predivider trim for making fine adjustments to the clock rate
- Two mechanisms for power control
  - System power control using discrete external regulator
  - On-chip power control using internal switches under register control
- Dedicated pin for waking using an external signal
- RTC operational and hibernation memory valid as long as  $V_{DD}$  or  $V_{BAT}$  is valid
- Low-battery detection, signaling, and interrupt generation, with optional wake on low battery
- GPIO pin state can be retained during hibernation
- Clock source from a 32.768-kHz external crystal or oscillator
- Sixteen 32-bit words of battery-backed memory to save state during hibernation
- Programmable interrupts for:
  - RTC match
  - External wake
  - Low battery

## 7.1 Block Diagram

Figure 7-1. Hibernation Module Block Diagram

## 7.2 Signal Description

The following table lists the external signals of the Hibernation module and describes the function of each.

Table 7-1. Hibernate Signals (64LQFP)

| XOSC1    | 36         | fixed                    | O        | Analog                   | Hibernation module oscillator crystal output. Leave unconnected when using a single-ended clock source.                                                                                    |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 7.3 Functional Description

The Hibernation module provides two mechanisms for power control:

- The first mechanism uses internal switches to control power to the Cortex-M4F as well as to most analog and digital functions while retaining I/O pin power (VDD3ON mode).
- The second mechanism controls the power to the microcontroller with a control signal ( $\overline{\text{HIB}}$ ) that signals an external voltage regulator to turn on or off.

The Hibernation module power source is determined dynamically. The supply voltage of the Hibernation module is the larger of the main voltage source ( $V_{DD}$ ) or the battery/auxilliary voltage source ( $V_{BAT}$ ). The Hibernation module also has an independent clock source to maintain a real-time clock (RTC) when the system clock is powered down. Hibernate mode can be entered through one of two ways:

- The user initiates hibernation by setting the `HIBREQ` bit in the **Hibernation Control (HIBCTL)** register
- Power is arbitrarily removed from  $V_{DD}$  while a valid  $V_{BAT}$  is applied

Once in hibernation, the module signals an external voltage regulator to turn the power back on when an external pin ( $\overline{\text{WAKE}}$ ) is asserted or when the internal RTC reaches a certain value. The Hibernation module can also detect when the battery voltage is low and optionally prevent hibernation or wake from hibernation when the battery voltage falls below a certain threshold.

When waking from hibernation, the  $\overline{\text{HIB}}$  signal is deasserted. The return of  $V_{DD}$  causes a POR to be executed. The time from when the  $\overline{\text{WAKE}}$  signal is asserted to when code begins execution is equal to the wake-up time ( $t_{\text{WAKE\_TO\_HIB}}$ ) plus the power-on reset time ( $T_{\text{POR}}$ ).

### 7.3.1 Register Access Timing

Because the Hibernation module has an independent clocking domain, hibernation registers must be written only with a timing gap between accesses. The delay time is  $t_{\text{HIB\_REG\_ACCESS}}$ , therefore software must guarantee that this delay is inserted between back-to-back writes to Hibernation registers or between a write followed by a read. The `WC` interrupt in the **HIBMIS** register can be used to notify the application when the Hibernation modules registers can be accessed. Alternatively, software may make use of the `WRC` bit in the **Hibernation Control (HIBCTL)** register to ensure that the required timing gap has elapsed. This bit is cleared on a write operation and set once the write completes, indicating to software that another write or read may be started safely. Software should poll **HIBCTL** for `WRC=1` prior to accessing any hibernation register.

Back-to-back reads from Hibernation module registers have no timing restrictions. Reads are performed at the full peripheral clock rate.

### 7.3.2 Hibernation Clock Source

In systems where the Hibernation module is used, the module must be clocked by an external source that is independent from the main system clock, even if the RTC feature is not used. An external oscillator or crystal is used for this purpose. To use a crystal, a 32.768-kHz crystal is connected to the XOSC0 and XOSC1 pins. Alternatively, a 32.768-kHz oscillator can be connected to the XOSC0 pin, leaving XOSC1 unconnected. Care must be taken that the voltage amplitude of the 32.768-kHz oscillator is less than  $V_{BAT}$ , otherwise, the Hibernation module may draw power from the oscillator and not  $V_{BAT}$  during hibernation. See Figure 7-2 on page 470 and Figure 7-3 on page 471.

The Hibernation clock source is enabled by setting the CLK32EN bit of the HIBCTL register. The CLK32EN bit must be set before accessing any other Hibernation module register. If a crystal is used for the clock source, the software must leave a delay of  $t_{HIBOSC\_START}$  after writing to the CLK32EN bit and before any other accesses to the Hibernation module registers. The delay allows the crystal to power up and stabilize. If an external oscillator is used for the clock source, no delay is needed. When using an external clock source, the OSCBYP bit in the HIBCTL register should be set. When using a crystal clock source, the GNDX pin should be connected to digital ground along with the crystal load capacitors, as shown in Figure 7-2 on page 470. When using an external clock source, the GNDX pin should be connected to digital ground.

**Note:** In the figures below the parameters  $R_{BAT}$  and  $C_{BAT}$  have recommended values of  $51\Omega \pm 5\%$  and  $0.1\mu F \pm 5\%$ , respectively. See “Hibernation Module” on page 1184 for more information.

**Figure 7-2. Using a Crystal as the Hibernation Clock Source with a Single Battery Source**

**Note:** Some devices may not supply the GNDX signal. See “Signal Tables” on page 1138 for pins specific to your device.

$X_1$  = Crystal frequency is  $f_{XOSC\_XTAL}$ .

$C_{1,2}$  = Capacitor value derived from crystal vendor load capacitance specifications.

$R_{PU}$  = Pull-up resistor is 200 k $\Omega$

$R_{BAT}$  = 51 $\Omega \pm 5\%$

$C_{BAT}$  = 0.1 $\mu F \pm 20\%$

See “Hibernation Clock Source Specifications” on page 1176 for specific parameter values.

Figure 7-3. Using a Dedicated Oscillator as the Hibernation Clock Source with VDD3ON Mode

**Note:** Some devices may not supply the GNDX,  $\overline{WAKE}$  or  $\overline{HIB}$  signals. See “Signal Tables” on page 1138 for pins specific to your device.

$R_{PU}$  = Pull-up resistor is 1 M $\Omega$

$R_{BAT}$  = 51 $\Omega$   $\pm$ 5%

$C_{BAT}$  = 0.1 $\mu$ F  $\pm$ 20%

### 7.3.3 System Implementation

Several different system configurations are possible when using the Hibernation module:

- Using a single battery source, where the battery provides both  $V_{DD}$  and  $V_{BAT}$ , as shown in Figure 7-2 on page 470.
- Using the VDD3ON mode, where  $V_{DD}$  continues to be powered in hibernation, allowing the GPIO pins to retain their states, as shown in Figure 7-3 on page 471. In this mode,  $V_{DDC}$  is powered off internally. The GPIO retention will be released when power is reapplied and the GPIOs will be initialized to their default values.
- Using separate sources for  $V_{DD}$  and  $V_{BAT}$ . In this mode, additional circuitry is required for system start-up without a battery or with a depleted battery.
- Using a regulator to provide both  $V_{DD}$  and  $V_{BAT}$  with a switch enabled by  $\overline{HIB}$  to remove  $V_{DD}$  during hibernation as shown in Figure 7-4 on page 472.

Figure 7-4. Using a Regulator for Both  $V_{DD}$  and  $V_{BAT}$ 

**Note:** Some devices may not supply a  $GNDX$  signal. See “Signal Tables” on page 1138 for pins specific to your device.

Adding external capacitance to the  $V_{BAT}$  supply reduces the accuracy of the low-battery measurement and should be avoided if possible. The diagrams referenced in this section only show the connection to the Hibernation pins and not to the full system.

If the application does not require the use of the Hibernation module, refer to “Connections for Unused Signals” on page 1158. In this situation, the  $HIB$  bit in the **Run Mode Clock Gating Control Register 0 (RCGC0)** and the **Hibernation Run Mode Clock Gating Control (RCGCHIB)** registers must be cleared, disabling the system clock to the Hibernation module and Hibernation module registers are not accessible.

### 7.3.4 Battery Management

**Important:** System-level factors may affect the accuracy of the low-battery detect circuit. The designer should consider battery type, discharge characteristics, and a test load during battery voltage measurements.

The Hibernation module can be independently powered by a battery or an auxiliary power source using the  $V_{BAT}$  pin. The module can monitor the voltage level of the battery and detect when the voltage drops below  $V_{LOWBAT}$ . The voltage threshold can be between 1.9 V and 2.5 V and is configured using the  $V_{BATSEL}$  field in the **HIBCTL** register. The module can also be configured so that it does not go into Hibernate mode if the battery voltage drops below this threshold. In addition, battery voltage is monitored while in hibernation, and the microcontroller can be configured to wake from hibernation if the battery voltage goes below the threshold using the  $BATWKEN$  bit in the **HIBCTL** register.

The Hibernation module is designed to detect a low-battery condition and set the  $LOWBAT$  bit of the **Hibernation Raw Interrupt Status (HIBRIS)** register when this occurs. If the  $V_{ABORT}$  bit in the **HIBCTL** register is also set, then the module is prevented from entering Hibernate mode when a low-battery is detected. The module can also be configured to generate an interrupt for the low-battery condition (see “Interrupts and Status” on page 476).

Note that the Hibernation module draws power from whichever source ( $V_{BAT}$  or  $V_{DD}$ ) has the higher voltage. Therefore, it is important to design the circuit to ensure that  $V_{DD}$  is higher than  $V_{BAT}$  under nominal conditions or else the Hibernation module draws power from the battery even when  $V_{DD}$  is available.

### 7.3.5 Real-Time Clock

The RTC module is designed to keep wall time. The RTC can operate in seconds counter mode. A 32.768 kHz clock source along with a 15-bit pre-divider reduces the clock to 1 Hz. The 1 Hz clock is used to increment the 32-bit counter and keep track of seconds. A match register can be configured to interrupt or wake the system from hibernate. In addition, a software trim register is implemented to allow the user to compensate for oscillator inaccuracies using software.

#### 7.3.5.1 RTC Counter - Seconds/Subseconds Mode

The clock signal to the RTC is provided by either of the 32.768-kHz clock sources available to the Hibernation module. The **Hibernation RTC Counter (HIBRTCC)** register displays the seconds value. The **Hibernation RTC Sub Seconds register (HIBRTCSS)** is provided for additional time resolution of an application requiring less than one-second divisions.

The RTC is enabled by setting the `RTCEN` bit of the **HIBCTL** register. The RTC counter and sub-seconds counters begin counting immediately once `RTCEN` is set. Both counters count up. The RTC continues counting as long as the RTC is enabled and a valid  $V_{BAT}$  is present, regardless of whether  $V_{DD}$  is present or if the device is in hibernation.

The **HIBRTCC** register is set by writing the **Hibernation RTC Load (HIBRTCLD)** register. A write to the **HIBRTCLD** register clears the 15-bit sub-seconds counter field, `RTCSSC`, in the **HIBRTCSS** register. To ensure a valid read of the RTC value, the **HIBRTCC** register should be read first, followed by a read of the `RTCSSC` field in the **HIBRTCSS** register and then a re-read of the **HIBRTCC** register. If the two values for the **HIBRTCC** are equal, the read is valid. By following this procedure, errors in the application caused by the **HIBRTCC** register rolling over by a count of 1 during a read of the `RTCSSC` field are prevented. The RTC can be configured to generate an alarm by setting the `RTCAL0` bit in the **HIBIM** register. When an RTC match occurs, an interrupt is generated and displayed in the **HIBRIS** register. Refer to “RTC Match - Seconds/Subseconds Mode” on page 473 for more information.

If the RTC is enabled, only a cold POR, where both  $V_{BAT}$  and  $V_{DD}$  are removed, resets the RTC registers. If any other reset occurs while the RTC is enabled, such as an external  $\overline{RST}$  assertion or BOR reset, the RTC is not reset. The RTC registers can be reset under any type of system reset as long as the RTC and external wake pins are not enabled.

#### 7.3.5.2 RTC Match - Seconds/Subseconds Mode

The Hibernation module includes a 32-bit match register, **HIBRTCM0**, which is compared to the value of the RTC 32-bit counter, **HIBRTCC**. The match functionality also extends to the sub-seconds counter. The 15-bit field (`RTCSSM`) in the **HIBRTCSS** register is compared to the value of the 15-bit sub-seconds counter. When a match occurs, the `RTCAL0` bit is set in the **HIBRIS** register. For applications using Hibernate mode, the processor can be programmed to wake from Hibernate mode by setting the `RTCWEN` bit in the **HIBCTL** register. The processor can also be programmed to generate an interrupt to the interrupt controller by setting the `RTCAL0` bit in the **HIBIM** register.

The match interrupt generation takes priority over an interrupt clear. Therefore, writes to the `RTCAL0` bit in the **Hibernation Interrupt Clear (HIBIC)** register do not clear the `RTCAL0` bit if the **HIBRTCC** value and the **HIBRTCM0** value are equal. There are several methodologies to avoid this occurrence, such as writing a new value to the **HIBRTCLD** register prior to writing the **HIBIC** to clear the `RTCAL0`. Another example, would be to disable the RTC and re-enable the RTC by clearing and setting the `RTCEN` bit in the **HIBCTL** register.

**Note:** A Hibernate request made while a match event is valid causes the module to immediately wake up. This occurs when the `RTCWEN` bit is set and the `RTCAL0` bit in the **HIBRIS** register is set at the same time the `HIBREQ` bit in the **HIBCTL** register is written to a 1. This can be

avoided by clearing the `RTCAL0` bit in the **HIBRIS** register by writing a 1 to the corresponding bit in the **HIBIC** register before setting the `HIBREQ` bit. Another example would be to disable the RTC and re-enable the RTC by clearing and setting the `RTCEN` bit in the **HIBCTL** register.

### 7.3.5.3 RTC Trim

The RTC counting rate can be adjusted to compensate for inaccuracies in the clock source by using the predivider trim register, **HIBRTCT**. This register has a nominal value of `0x7FFF`, and is used for one second out of every 64 seconds in RTC counter mode, when bits [5:0] in the **HIBRTCC** register change from `0x00` to `0x01`, to divide the input clock. This configuration allows the software to make fine corrections to the clock rate by adjusting the predivider trim register up or down from `0x7FFF`. The predivider trim should be adjusted up from `0x7FFF` in order to slow down the RTC rate and down from `0x7FFF` in order to speed up the RTC rate.

Care must be taken when using trim values that are near to the sub seconds match value in the **HIBRTCSS** register. It is possible when using trim values above `0x7FFF` to receive two match interrupts for the same counter value. In addition, it is possible when using trim values below `0x7FFF` to miss a match interrupt.

In the case of a trim value above `0x7FFF`, when the `RTCSSC` value in the **HIBRTCSS** register reaches `0x7FFF`, the `RTCC` value increments from `0x0` to `0x1` while the `RTCSSC` value is decreased by the trim amount. The `RTCSSC` value is counted up again to `0x7FFF` before rolling over to `0x0` to begin counting up again. If the match value is within this range, the match interrupt is triggered twice. For example, as shown in Figure 7-5 on page 474, if the match interrupt was configured with `RTCM0=0x1` and `RTCSSM=0x7FFD`, two interrupts would be triggered.

**Figure 7-5. Counter Behavior with a TRIM Value of 0x8002**

In the case of a trim value below `0x7FFF`, the `RTCSSC` value is advanced from `0x7FFF` to the trim value while the `RTCC` value is incremented from `0x0` to `0x1`. If the match value is within that range, the match interrupt is not triggered. For example, as shown in Figure 7-6 on page 474, if the match interrupt was configured with `RTCM0=0x1` and `RTCSSM=0x2`, an interrupt would never be triggered.

**Figure 7-6. Counter Behavior with a TRIM Value of 0x7FFC**

### 7.3.6 Battery-Backed Memory

The Hibernation module contains 16 32-bit words of memory that are powered from the battery or an auxiliary power supply and therefore retained during hibernation. The processor software can save state information in this memory prior to hibernation and recover the state upon waking. The battery-backed memory can be accessed through the **HIBDATA** registers. If both  $V_{DD}$  and  $V_{BAT}$  are removed, the contents of the **HIBDATA** registers are not retained.

### 7.3.7 Power Control Using $\overline{HIB}$

**Important:** The Hibernation Module requires special system implementation considerations when using  $\overline{HIB}$  to control power, as it is intended to power-down all other sections of the microcontroller. All system signals and power supplies that connect to the chip must be driven to 0 V or powered down with the same regulator controlled by  $\overline{HIB}$ .

The Hibernation module controls power to the microcontroller through the use of the  $\overline{HIB}$  pin which is intended to be connected to the enable signal of the external regulator(s) providing 3.3 V to the microcontroller and other circuits. When the  $\overline{HIB}$  signal is asserted by the Hibernation module, the external regulator is turned off and no longer powers the microcontroller and any parts of the system that are powered by the regulator. The Hibernation module remains powered from the  $V_{BAT}$  supply until a Wake event. Power to the microcontroller is restored by deasserting the  $\overline{HIB}$  signal, which causes the external regulator to turn power back on to the chip.

### 7.3.8 Power Control Using VDD3ON Mode

The Hibernation module may also be configured to cut power to all internal modules during Hibernate mode. While in this state, if **VDD3ON** is set in the **HIBCTL** register, all pins are held in the state they were in prior to entering hibernation. For example, inputs remain inputs; outputs driven high remain driven high, and so on. There are important procedural and functional items to note when in VDD3ON mode:

- In the VDD3ON mode, the regulator should maintain 3.3 V power to the microcontroller during Hibernate. GPIO retention is disabled when the **RETCLR** bit is cleared in the **HIBCTL** register.

### 7.3.9 Initiating Hibernate

Hibernate mode is initiated when the **HIBREQ** bit of the **HIBCTL** register is set. If a wake-up condition has not been configured using the **PINWEN** or **RTCWEN** bits in the **HIBCTL** register, the hibernation request is ignored. If a Flash memory write operation is in progress when the **HIBREQ** bit is set, an interlock feature holds off the transition into Hibernate mode until the write has completed. In addition, if the battery voltage is below the threshold voltage defined by the **VBATSEL** field in the **HIBCTL** register, the hibernation request is ignored.

### 7.3.10 Waking from Hibernate

The Hibernation module is configured to wake from the external  $\overline{WAKE}$  pin by setting the **PINWEN** bit of the **HIBCTL** register. It is configured to wake from RTC match by setting the **RTCWEN** bit. Note that the  $\overline{WAKE}$  pin uses the Hibernation module's internal power supply as the logic 1 reference.

The Hibernation module can also be configured to wake from hibernate when the following events occur:

- RTC match wake event
- Low Battery wake event

By setting the `RTCWEN` bit in the `HIBCTL` register a wake from hibernate can occur when the value of the `HIBRTCC` register matches the value of the `HIBRTCM0` register and the value of the `RTCSS` field matches the `RTCSSM` field in the `HIBRTCSS` register.

To allow a wake from Hibernate on a low battery event, the `BATWKEN` bit in the `HIBCTL` register must be set. In this configuration, the battery voltage is checked every 512 seconds while in hibernation. If the voltage is below the level specified by the `VBATSEL` field, the `LOWBAT` interrupt is set in the `HIBRIS` register.

Upon external wake-up, external reset, or RTC match, the Hibernation module delays coming out of hibernation until  $V_{DD}$  is above the minimum specified voltage, see Table 22-5 on page 1162.

When the Hibernation module wakes, the microcontroller performs a normal power-on reset. The normal power-on reset does not reset the Hibernation module, but does reset the rest of the microcontroller. Software can detect that the power-on was due to a wake from hibernation by examining the raw interrupt status register (see “Interrupts and Status” on page 476) and by looking for state data in the battery-backed memory (see “Battery-Backed Memory” on page 475).

### 7.3.11 Arbitrary Power Removal

The microcontroller goes into hibernation if  $V_{DD}$  is arbitrarily removed when the `CLK32EN` bit is set and any of the following bits are set:

- `PINWEN` bit in the `HIBCTL` register
- `RTCEN` bit in the `HIBCTL` register

The microcontroller wakes from hibernation when power is reapplied.

If the `CLK32EN` bit is set but the `PINWEN`, and `RTCEN` bits are all clear, the microcontroller still goes into hibernation if power is removed; however, when  $V_{DD}$  is reapplied, the MCU executes a cold POR and the Hibernation module is reset. If the `CLK32EN` bit is not set and  $V_{DD}$  is arbitrarily removed, the part is simply powered off and executes a cold POR when power is reapplied.

If  $V_{DD}$  is arbitrarily removed while a Flash memory or `HIBDATA` register write operation is in progress, the write operation must be retried after  $V_{DD}$  is reapplied.

### 7.3.12 Interrupts and Status

The Hibernation module can generate interrupts when the following conditions occur:

- Assertion of `WAKE` pin
- RTC match
- Low battery detected
- Write complete/capable
- Assertion of an external `RESET` pin
- Assertion of an external wake-enabled GPIO pin (port J)

All of the interrupts are ORed together before being sent to the interrupt controller, so the Hibernate module can only generate a single interrupt request to the controller at any given time. The software interrupt handler can service multiple interrupt events by reading the **Hibernation Masked Interrupt Status (HIBMIS)** register. Software can also read the status of the Hibernation module at any time

by reading the **HIBRIS** register which shows all of the pending events. This register can be used after waking from hibernation to see if a wake condition was caused by one of the events above or by a power loss.

The events that can trigger an interrupt are configured by setting the appropriate bits in the **Hibernation Interrupt Mask (HIBIM)** register. Pending interrupts can be cleared by writing the corresponding bit in the **Hibernation Interrupt Clear (HIBIC)** register.

## 7.4 Initialization and Configuration

The Hibernation module has several different configurations. The following sections show the recommended programming sequence for various scenarios. Because the Hibernation module runs at a low frequency and is asynchronous to the rest of the microcontroller, which is run off the system clock, software must allow a delay of  $t_{\text{HIB\_REG\_ACCESS}}$  after writes to registers (see “Register Access Timing” on page 469). The  $\overline{\text{WC}}$  interrupt in the **HIBMIS** register can be used to notify the application when the Hibernation modules registers can be accessed.

### 7.4.1 Initialization

The Hibernation module comes out of reset with the system clock enabled to the module, but if the system clock to the module has been disabled, then it must be re-enabled, even if the RTC feature is not used. See page 329.

If a 32.768-kHz crystal is used as the Hibernation module clock source, perform the following steps:

1. Write 0x0000.0010 to the **HIBIM** register to enable the  $\overline{\text{WC}}$  interrupt.
2. Write 0x40 to the **HIBCTL** register at offset 0x10 to enable the oscillator input.
3. Wait until the  $\overline{\text{WC}}$  interrupt in the **HIBMIS** register has been triggered before performing any other operations with the Hibernation module.

If a 32.768-kHz single-ended oscillator is used as the Hibernation module clock source, then perform the following steps:

1. Write 0x0000.0010 to the **HIBIM** register to enable the  $\overline{\text{WC}}$  interrupt.
2. Write 0x0001.0040 to the **HIBCTL** register at offset 0x10 to enable the oscillator input and bypass the on-chip oscillator.
3. Wait until the  $\overline{\text{WC}}$  interrupt in the **HIBMIS** register has been triggered before performing any other operations with the Hibernation module.

The above steps are only necessary when the entire system is initialized for the first time. If the microcontroller has been in hibernation, then the Hibernation module has already been powered up and the above steps are not necessary. The software can detect that the Hibernation module and clock are already powered by examining the **CLK32EN** bit of the **HIBCTL** register.

Table 7-2 on page 477 illustrates how the clocks function with various bit setting both in normal operation and in hibernation.

**Table 7-2. Hibernation Module Clock Operation**

| CLK32EN | PINWEN | RTCWEN | RTCEN | Result Normal Operation       | Result Hibernation          |
|---------|--------|--------|-------|-------------------------------|-----------------------------|
| 0       | X      | X      | X     | Hibernation module disabled   | Hibernation module disabled |
| 1       | 0      | 0      | 1     | RTC match capability enabled. | No hibernation              |

Table 7-2. Hibernation Module Clock Operation (continued)

| CLK32EN | PINWEN | RTCWEN | RTCEN | Result Normal Operation | Result Hibernation                                                                       |
|---------|--------|--------|-------|-------------------------|------------------------------------------------------------------------------------------|
| 1       | 0      | 1      | 1     | Module clocked          | RTC match for wake-up event                                                              |
| 1       | 1      | 0      | 0     | Module clocked          | Clock is powered down during hibernation and powered up again on external wake-up event. |
| 1       | 1      | 0      | 1     | Module clocked          | Clock is powered up during hibernation for RTC. Wake up on external event.               |
| 1       | 1      | 1      | 1     | Module clocked          | RTC match or external wake-up event, whichever occurs first.                             |

#### 7.4.2 RTC Match Functionality (No Hibernation)

Use the following steps to implement the RTC match functionality of the Hibernation module:

1. Write 0x0000.0040 to the **HIBCTL** register at offset 0x010 to enable 32.768-kHz Hibernation oscillator.
2. Write the required RTC match value to the **HIBRTCM0** register at offset 0x004 and the **RTCSSM** field in the **HIBRTCSS** register at offset 0x028.
3. Write the required RTC load value to the **HIBRTCLD** register at offset 0x00C.
4. Set the required RTC match interrupt mask in the **RTCALTO** in the **HIBIM** register at offset 0x014.
5. Write 0x0000.0041 to the **HIBCTL** register at offset 0x010 to enable the RTC to begin counting.

#### 7.4.3 RTC Match/Wake-Up from Hibernation

Use the following steps to implement the RTC match and wake-up functionality of the Hibernation module:

1. Write 0x0000.0040 to the **HIBCTL** register at offset 0x010 to enable 32.768-kHz Hibernation oscillator.
2. Write the required RTC match value to the **HIBRTCM0** register at offset 0x004 and the **RTCSSM** field in the **HIBRTCSS** register at offset 0x028.
3. Write the required RTC load value to the **HIBRTCLD** register at offset 0x00C. This write causes the 15-bit sub seconds counter to be cleared.
4. Write any data to be retained during hibernation to the **HIBDATA** register at offsets 0x030-0x06F.
5. Set the RTC Match Wake-Up and start the hibernation sequence by writing 0x0000.004B to the **HIBCTL** register at offset 0x010.

#### 7.4.4 External Wake-Up from Hibernation

Use the following steps to implement the Hibernation module with the external  $\overline{\text{WAKE}}$  pin as the wake-up source for the microcontroller:

1. Write 0x0000.0040 to the **HIBCTL** register at offset 0x010 to enable 32.768-kHz Hibernation oscillator.
2. Write any data to be retained during hibernation to the **HIBDATA** register at offsets 0x030-0x06F.

3. Enable the external wake and start the hibernation sequence by writing 0x0000.0052 to the **HIBCTL** register at offset 0x010.

### 7.4.5 RTC or External Wake-Up from Hibernation

1. Write 0x0000.0040 to the **HIBCTL** register at offset 0x010 to enable 32.768-kHz Hibernation oscillator.
2. Write the required RTC match value to the **HIBRTCM0** register at offset 0x004 and the **RTCSSM** field in the **HIBRTCSS** register at offset 0x028.
3. Write the required RTC load value to the **HIBRTCLD** register at offset 0x00C. This write causes the 15-bit sub seconds counter to be cleared.
4. Write any data to be retained during hibernation to the **HIBDATA** register at offsets 0x030-0x06F.
5. Set the RTC Match/External Wake-Up and start the hibernation sequence by writing 0x0000.005B to the **HIBCTL** register at offset 0x010.

## 7.5 Register Map

Table 7-3 lists the Hibernation registers. All addresses given are relative to the Hibernation Module base address at 0x400F.C000. Note that the system clock to the Hibernation module must be enabled before the registers can be programmed (see page 329). There must be a delay of 3 system clocks after the Hibernation module clock is enabled before any Hibernation module registers are accessed. In addition, the **CLK32EN** bit in the **HIBCTL** register must be set before accessing any other Hibernation module register.

**Note:** The Hibernation module registers are on the Hibernation module clock domain and have special timing requirements. Software should make use of the **WRC** bit in the **HIBCTL** register to ensure that the required timing gap has elapsed. If the **WRC** bit is clear, any attempted write access is ignored. See “Register Access Timing” on page 469.

**Important:** The Hibernation module registers are reset under two conditions:

1. Any type of system reset (if the **RTCEN** and the **PINWEN** bits in the **HIBCTL** register are clear).
2. A cold POR occurs when both the  $V_{DD}$  and  $V_{BAT}$  supplies are removed.

Any other reset condition is ignored by the Hibernation module.

**Table 7-3. Hibernation Module Register Map**

| Offset | Name     | Type | Reset       | Description                | See page |
|--------|----------|------|-------------|----------------------------|----------|
| 0x000  | HIBRTCC  | RO   | 0x0000.0000 | Hibernation RTC Counter    | 481      |
| 0x004  | HIBRTCM0 | R/W  | 0xFFFF.FFFF | Hibernation RTC Match 0    | 482      |

## 7.6 Register Descriptions

The remainder of this section lists and describes the Hibernation module registers, in numerical order by address offset.

## Register 1: Hibernation RTC Counter (HIBRTCC), offset 0x000

This register is the current 32-bit value of the RTC counter.

The RTC counter consists of a 32-bit seconds counter and a 15-bit sub seconds counter. The RTC counters are reset by the Hibernation module reset. The RTC 32-bit seconds counter can be set by the user using the **HIBRTCLD** register. When the 32-bit seconds counter is set, the 15-bit sub second counter is cleared.

The RTC value can be read by first reading the **HIBRTCC** register, reading the **RTCSSC** field in the **HIBRTCSS** register, and then rereading the **HIBRTCC** register. If the two values for **HIBRTCC** are equal, the read is valid.

### Hibernation RTC Counter (HIBRTCC)

Base 0x400F.C000

Offset 0x000

Type RO, reset 0x0000.0000

|       |      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------|------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
|       | 31   | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|       | RTCC |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| Type  | RO   | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO |
| Reset | 0    | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
|       | 15   | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|       | RTCC |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| Type  | RO   | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO |
| Reset | 0    | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

| Bit/Field | Name | Type | Reset       | Description |
|-----------|------|------|-------------|-------------|
| 31:0      | RTCC | RO   | 0x0000.0000 | RTC Counter |

A read returns the 32-bit counter value, which represents the seconds elapsed since the RTC was enabled. This register is read-only. To change the value, use the **HIBRTCLD** register.

### Register 2: Hibernation RTC Match 0 (HIBRTCM0), offset 0x004

This register is the 32-bit seconds match register for the RTC counter. The 15-bit sub second match value is stored in the reading the *RTCSSC* field in the **HIBRTCSS** register and can be used in conjunction with this register for a more precise time match.

**Note:** The Hibernation module registers are on the Hibernation module clock domain and have special timing requirements. Software should make use of the *WRC* bit in the **HIBCTL** register to ensure that the required timing gap has elapsed. If the *WRC* bit is clear, any attempted write access is ignored. See “Register Access Timing” on page 469.

#### Hibernation RTC Match 0 (HIBRTCM0)

Base 0x400F.C000

Offset 0x004

Type R/W, reset 0xFFFF.FFFF

| Bit/Field | Name  | Type | Reset       | Description                                                                                                    |
|-----------|-------|------|-------------|----------------------------------------------------------------------------------------------------------------|
| 31:0      | RTCM0 | R/W  | 0xFFFF.FFFF | RTC Match 0<br>A write loads the value into the RTC match register.<br>A read returns the current match value. |

**Register 3: Hibernation RTC Load (HIBRTCLD), offset 0x00C**

This register is used to load a 32-bit value loaded into the RTC counter. The load occurs immediately upon this register being written. When this register is written, the 15-bit sub seconds counter is also cleared.

**Note:** The Hibernation module registers are on the Hibernation module clock domain and have special timing requirements. Software should make use of the `WRC` bit in the `HIBCTL` register to ensure that the required timing gap has elapsed. If the `WRC` bit is clear, any attempted write access is ignored. See “Register Access Timing” on page 469.

**Hibernation RTC Load (HIBRTCLD)**

Base 0x400F.C000

Offset 0x00C

Type R/W, reset 0x0000.0000

|       |       |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

### Register 4: Hibernation Control (HIBCTL), offset 0x010

This register is the control register for the Hibernation module. This register must be written last before a hibernate event is issued. Writes to other registers after the HIBREQ bit is set are not guaranteed to complete before hibernation is entered.

**Note:** Writes to this register have special timing requirements. Software should make use of the WRC bit in the HIBCTL register to ensure that the required synchronization has elapsed. While the WRC bit is clear, any attempts to write this register are ignored. Reads may occur at any time.

#### Hibernation Control (HIBCTL)

Base 0x400F.C000  
 Offset 0x010  
 Type R/W, reset 0x8000.2000

| Bit/Field | Name | Type | Reset | Description            |
|-----------|------|------|-------|------------------------|
| 31        | WRC  | RO   | 1     | Write Complete/Capable |

| Value | Description                                                                                                                                   |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| 0     | The interface is processing a prior write and is busy. Any write operation that is attempted while WRC is 0 results in undetermined behavior. |
| 1     | The interface is ready to accept a write.                                                                                                     |

Software must poll this bit between write requests and defer writes until WRC=1 to ensure proper operation. An interrupt can be configured to indicate the WRC has completed.

The bit name WRC means "Write Complete," which is the normal use of the bit (between write accesses). However, because the bit is set out-of-reset, the name can also mean "Write Capable" which simply indicates that the interface may be written to by software. This difference may be exploited by software at reset time to detect which method of programming is appropriate: 0 = software delay loops required; 1 = WRC paced available.

| 9         | BATWKEN  | R/W  | 0     | <p>Wake on Low Battery</p> <p>Value Description</p> <p>0 The battery voltage level is not automatically checked. Low battery voltage does not cause the microcontroller to wake from hibernation.</p> <p>1 When this bit is set, the battery voltage level is checked every 512 seconds while in hibernation. If the voltage is below the level specified by <code>VBATSEL</code> field, the microcontroller wakes from hibernation and the <code>LOWBAT</code> interrupt bit in the <code>HIBRIS</code> register is set.</p>                                                                                                                                                                                                                                                          |
| 8         | VDD3ON   | R/W  | 0     | <p>VDD Powered</p> <p>Value Description</p> <p>0 The internal switches are not used. The <code>HIB</code> signal should be used to control an external switch or regulator.</p> <p>1 The internal switches control the power to the on-chip modules (VDD3ON mode).</p> <p>Regardless of the status of the <code>VDD3ON</code> bit, the <code>HIB</code> signal is asserted during Hibernate mode. Thus, when <code>VDD3ON</code> is set, the <code>HIB</code> signal should not be connected to the 3.3V regulator, and the 3.3V power source should remain connected. When this bit is set while in hibernation, all pins are held in the state they were in prior to entering hibernation. For example, inputs remain inputs; outputs driven high remain driven high, and so on.</p> |
| 7         | VABORT   | R/W  | 0     | <p>Power Cut Abort Enable</p> <p>Value Description</p> <p>0 The microcontroller goes into hibernation regardless of the voltage level of the battery.</p> <p>1 When this bit is set, the battery voltage level is checked before entering hibernation. If <code>V<sub>BAT</sub></code> is less than the voltage specified by <code>VBATSEL</code>, the microcontroller does not go into hibernation.</p>                                                                                                                                                                                                                                                                                                                                                                               |
| 6         | CLK32EN  | R/W  | 0     | <p>Clocking Enable</p> <p>This bit must be enabled to use the Hibernation module.</p> <p>Value Description</p> <p>0 The Hibernation module clock source is disabled.</p> <p>1 The Hibernation module clock source is enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 5         | reserved | RO   | 0     | <p>Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

### Register 5: Hibernation Interrupt Mask (HIBIM), offset 0x014

This register is the interrupt mask register for the Hibernation module interrupt sources. Each bit in this register masks the corresponding bit in the **Hibernation Raw Interrupt Status (HIBRIS)** register. If a bit is unmasked, the interrupt is sent to the interrupt controller. If the bit is masked, the interrupt is not sent to the interrupt controller. The **WC** bit of the **HIBIM** register may be set before the **CLK32EN** bit of the **HIBCTL** register is set. This allows software to use the **WC** interrupt trigger to detect when the **RTCOSC** clock is stable, which may be in excess of one second. If the **WC** bit is set before the **CLK32EN** has been set, the mask value is not preserved over a hibernate cycle unless the bit is written a second time.

**Note:** The **WC** bit of this register is in the system clock domain such that a write to this bit is immediate and may be done before the **CLK32EN** bit is set in the **HIBCTL** register.

### Register 6: Hibernation Raw Interrupt Status (HIBRIS), offset 0x018

This register is the raw interrupt status for the Hibernation module interrupt sources. Each bit can be masked by clearing the corresponding bit in the **HIBIM** register. When a bit is masked, the interrupt is not sent to the interrupt controller. Bits in this register are cleared by writing a 1 to the corresponding bit in the **Hibernation Interrupt Clear (HIBIC)** register or by entering hibernation.

**Note:** The bits in this register do not reflect hibernation due to an arbitrary power loss on  $V_{DD}$ . If the **LOWBAT** bit was set prior to the loss of power, it will still be set when power is reapplied. In addition, the **EXTW** bit is self-clearing when exiting from hibernation, so if it was set prior to the power loss, the event is lost after the power is reapplied.

### Register 7: Hibernation Masked Interrupt Status (HIBMIS), offset 0x01C

This register is the masked interrupt status for the Hibernation module interrupt sources. Bits in this register are the AND of the corresponding bits in the **HIBRIS** and **HIBIM** registers. When both corresponding bits are set, the bit in this register is set, and the interrupt is sent to the interrupt controller.

### Register 8: Hibernation Interrupt Clear (HIBIC), offset 0x020

This register is the interrupt write-one-to-clear register for the Hibernation module interrupt sources. Writing a 1 to a bit clears the corresponding interrupt in the **HIBRIS** register.

| 0         | RTCALTO  | R/W1C | 0          | RTC Alert0 Masked Interrupt Clear<br>Writing a 1 to this bit clears the <b>RTCALTO</b> bit in the <b>HIBRIS</b> and <b>HIBMIS</b> registers.<br>Reads return the raw interrupt status.        |

**Note:** The timer interrupt source cannot be cleared if the RTC value and the **HIBRTCM0** register / **RTCSS** field values are equal. The match interrupt takes priority over the interrupt clear.

**Register 9: Hibernation RTC Trim (HIBRTCT), offset 0x024**

This register contains the value that is used to trim the RTC clock predivider. It represents the computed underflow value that is used during the trim cycle. It is represented as  $0x7FFF \pm N$  clock cycles, where N is the number of clock cycles to add or subtract every 64 seconds in RTC mode.

**Note:** The Hibernation module registers are on the Hibernation module clock domain and have special timing requirements. Software should make use of the `WRC` bit in the `HIBCTL` register to ensure that the required timing gap has elapsed. If the `WRC` bit is clear, any attempted write access is ignored. See “Register Access Timing” on page 469.

| 15:0      | TRIM     | R/W  | 0x7FFF | <p>RTC Trim Value</p> <p>This value is loaded into the RTC predivider every 64 seconds in RTC counter mode.</p> <p>It is used to adjust the RTC rate to account for drift and inaccuracy in the clock source. Compensation can be adjusted by software by moving the default value of 0x7FFF up or down. Moving the value up slows down the RTC and moving the value down speeds up the RTC.</p> |

### Register 10: Hibernation RTC Sub Seconds (HIBRTCSS), offset 0x028

This register contains the RTC sub seconds counter and match values. The RTC value can be read by first reading the **HIBRTCC** register, reading the **RTCSSC** field in the **HIBRTCSS** register, and then rereading the **HIBRTCC** register. If the two values for **HIBRTCC** are equal, the read is valid.

**Note:** The Hibernation module registers are on the Hibernation module clock domain and have special timing requirements. Software should make use of the **WRC** bit in the **HIBCTL** register to ensure that the required timing gap has elapsed. If the **WRC** bit is clear, any attempted write access is ignored. See “Register Access Timing” on page 469.
