**Register 11: Hibernation Data (HIBDATA), offset 0x030-0x06F**

This address space is implemented as a 16x32-bit memory (64 bytes). It can be loaded by the system processor in order to store state information and retains its state during a power cut operation as long as a battery is present.

**Note:** The Hibernation module registers are on the Hibernation module clock domain and have special timing requirements. Software should make use of the `WRC` bit in the `HIBCTL` register to ensure that the required timing gap has elapsed. If the `WRC` bit is clear, any attempted write access is ignored. See “Register Access Timing” on page 469.

**Note:** If  $V_{DD}$  is arbitrarily removed while a `HIBDATA` register write operation is in progress, the write operation must be retried after  $V_{DD}$  is reapplied.

**Hibernation Data (HIBDATA)**

## 8 Internal Memory

The TM4C1233C3PM microcontroller comes with 12 KB of bit-banded SRAM, internal ROM, 32 KB of Flash memory, and 2KB of EEPROM. The Flash memory controller provides a user-friendly interface, making Flash memory programming a simple task. Flash memory is organized in 1-KB independently erasable blocks and memory protection can be applied to the Flash memory on a 2-KB block basis. The EEPROM module provides a well-defined register interface to support accesses to the EEPROM with both a random access style of read and write as well as a rolling or sequential access scheme. A password model allows the application to lock one or more EEPROM blocks to control access on 16-word boundaries.

### 8.1 Block Diagram

Figure 8-1 on page 498 illustrates the internal SRAM, ROM, and Flash memory blocks and control logic. The dashed boxes in the figure indicate registers residing in the System Control module.

**Figure 8-1. Internal Memory Block Diagram**

Figure 8-2 on page 499 illustrates the internal EEPROM block and control logic. The EEPROM block is connected to the AHB bus.

**Figure 8-2. EEPROM Block Diagram**

## 8.2 Functional Description

This section describes the functionality of the SRAM, ROM, Flash, and EEPROM memories.

**Note:** The  $\mu$ DMA controller can transfer data to and from the on-chip SRAM. However, because the Flash memory and ROM are located on a separate internal bus, it is not possible to transfer data from the Flash memory or ROM with the  $\mu$ DMA controller.

### 8.2.1 SRAM

The internal SRAM of the TM4C1233C3PM device is located at address 0x2000.0000 of the device memory map. To reduce the number of time consuming read-modify-write (RMW) operations, ARM provides bit-banding technology in the processor. With a bit-band-enabled processor, certain regions in the memory map (SRAM and peripheral space) can use address aliases to access individual bits in a single, atomic operation. The bit-band base is located at address 0x2200.0000.

The bit-band alias is calculated by using the formula:

$$\text{bit-band alias} = \text{bit-band base} + (\text{byte offset} * 32) + (\text{bit number} * 4)$$

For example, if bit 3 at address 0x2000.1000 is to be modified, the bit-band alias is calculated as:

$$0x2200.0000 + (0x1000 * 32) + (3 * 4) = 0x2202.000C$$

With the alias address calculated, an instruction performing a read/write to address 0x2202.000C allows direct access to only bit 3 of the byte at address 0x2000.1000.

For details about bit-banding, see “Bit-Banding” on page 89.

**Note:** The SRAM is implemented using two 32-bit wide SRAM banks (separate SRAM arrays). The banks are partitioned such that one bank contains all even words (the even bank) and the other contains all odd words (the odd bank). A write access that is followed immediately by a read access to the same bank incurs a stall of a single clock cycle. However, a write to one bank followed by a read of the other bank can occur in successive clock cycles without incurring any delay.

## 8.2.2 ROM

The internal ROM of the TM4C1233C3PM device is located at address 0x0100.0000 of the device memory map. Detailed information on the ROM contents can be found in the *TM4C1233C3PM ROM User's Guide*.

The ROM contains the following components:

- TivaWare™ Boot Loader and vector table
- TivaWare Peripheral Driver Library (DriverLib) release for product-specific peripherals and interfaces
- Advanced Encryption Standard (AES) cryptography tables
- Cyclic Redundancy Check (CRC) error detection functionality

The boot loader is used as an initial program loader (when the Flash memory is empty) as well as an application-initiated firmware upgrade mechanism (by calling back to the boot loader). The Peripheral Driver Library APIs in ROM can be called by applications, reducing Flash memory requirements and freeing the Flash memory to be used for other purposes (such as additional features in the application). Advance Encryption Standard (AES) is a publicly defined encryption standard used by the U.S. Government and Cyclic Redundancy Check (CRC) is a technique to validate if a block of data has the same contents as when previously checked.

### 8.2.2.1 Boot Loader Overview

The TivaWare Boot Loader is used to download code to the Flash memory of a device without the use of a debug interface. When the core is reset, the user has the opportunity to direct the core to execute the ROM Boot Loader or the application in Flash memory by using any GPIO signal in Ports A-H as configured in the **BOOTCFG** register (see page 553).

At reset, the following sequence is performed:

1. The **BOOTCFG** register is read. If the **EN** bit is clear, the ROM Boot Loader is executed.
2. In the ROM Boot Loader, the status of the specified GPIO pin is compared with the specified polarity. If the status matches the specified polarity, the ROM is mapped to address 0x0000.0000 and execution continues out of the ROM Boot Loader.
3. If the **EN** bit is set or the status doesn't match the specified polarity, the data at address 0x0000.0004 is read, and if the data at this address is 0xFFFF.FFFF, the ROM is mapped to address 0x0000.0000 and execution continues out of the ROM Boot Loader.
4. If there is data at address 0x0000.0004 that is not 0xFFFF.FFFF, the stack pointer (**SP**) is loaded from Flash memory at address 0x0000.0000 and the program counter (**PC**) is loaded from address 0x0000.0004. The user application begins executing.

The boot loader uses a simple packet interface to provide synchronous communication with the device. The speed of the boot loader is determined by the internal oscillator (PIOSC) frequency as it does not enable the PLL. The following serial interfaces can be used:

- UART0
- SSI0
- I<sup>2</sup>C0
- USB

The data format and communication protocol are identical for the UART0, SSI0, and I2C0 interfaces.

**Note:** The Flash-memory-resident version of the boot loader also supports CAN.

See the *TivaWare™ Boot Loader for C Series User's Guide* (literature number [SPMU301](#)) for information on the boot loader software. The USB boot loader uses the standard Device Firmware Upgrade USB device class.

#### **Considerations When Using the UART Boot Loader in ROM**

U0Tx is not driven by the ROM boot loader until the auto-bauding process has completed. If U0Tx is floating during this time, the receiver it is connected to may see transitions on the signal, which could be interpreted by its UART as valid characters. To handle this situation, put a pull-up or pull-down on U0Tx, providing a defined state for the signal until the ROM boot loader begins driving U0Tx. A pull-up is preferred as it indicates that the UART is idle, rather than a pull-down, which indicates a break condition.

### **8.2.2.2 TivaWare Peripheral Driver Library**

The TivaWare Peripheral Driver Library contains a file called `driverlib/rom.h` that assists with calling the peripheral driver library functions in the ROM. The detailed description of each function is available in the *TM4C1233C3PM ROM User's Guide*. See the "Using the ROM" chapter of the *TivaWare™ Peripheral Driver Library for C Series User's Guide* (literature number [SPMU298](#)) for more details on calling the ROM functions and using `driverlib/rom.h`. The `driverlib/rom_map.h` header file is also provided to aid portability when using different Tiva™ C Series devices which might have a different subset of DriverLib functions in ROM. The `driverlib/rom_map.h` header file uses build-time labels to route function calls to the ROM if those functions are available on a given device, otherwise, it routes to Flash-resident versions of the functions.

A table at the beginning of the ROM points to the entry points for the APIs that are provided in the ROM. Accessing the API through these tables provides scalability; while the API locations may change in future versions of the ROM, the API tables will not. The tables are split into two levels; the main table contains one pointer per peripheral which points to a secondary table that contains one pointer per API that is associated with that peripheral. The main table is located at 0x0100.0010, right after the Cortex-M4F vector table in the ROM.

DriverLib functions are described in detail in the *TivaWare™ Peripheral Driver Library for C Series User's Guide* (literature number [SPMU298](#)).

Additional APIs are available for graphics and USB functions, but are not preloaded into ROM. The TivaWare Graphics Library provides a set of graphics primitives and a widget set for creating graphical user interfaces on Tiva™ C Series microcontroller-based boards that have a graphical display (for more information, see the *TivaWare™ Graphics Library for C Series User's Guide* (literature number [SPMU300](#))). The TivaWare USB Library is a set of data types and functions for creating USB Device,

Host or On-The-Go (OTG) applications on Tiva™ C Series microcontroller-based boards (for more information, see the *TivaWare™ USB Library for C Series User's Guide (literature number SPMU297)*).

### 8.2.2.3 Advanced Encryption Standard (AES) Cryptography Tables

AES is a strong encryption method with reasonable performance and size. AES is fast in both hardware and software, is fairly easy to implement, and requires little memory. AES is ideal for applications that can use pre-arranged keys, such as setup during manufacturing or configuration. Four data tables used by the XySSL AES implementation are provided in the ROM. The first is the forward S-box substitution table, the second is the reverse S-box substitution table, the third is the forward polynomial table, and the final is the reverse polynomial table. See the *TM4C1233C3PM ROM User's Guide* for more information on AES.

### 8.2.2.4 Cyclic Redundancy Check (CRC) Error Detection

The CRC technique can be used to validate correct receipt of messages (nothing lost or modified in transit), to validate data after decompression, to validate that Flash memory contents have not been changed, and for other cases where the data needs to be validated. A CRC is preferred over a simple checksum (e.g. XOR all bits) because it catches changes more readily. See the *TM4C1233C3PM ROM User's Guide* for more information on CRC.

## 8.2.3 Flash Memory

At system clock speeds of 40 MHz and below, the Flash memory is read in a single cycle. The Flash memory is organized as a set of 1-KB blocks that can be individually erased. An individual 32-bit word can be programmed to change bits from 1 to 0. In addition, a write buffer provides the ability to program 32 continuous words in Flash memory in half the time of programming the words individually. Erasing a block causes the entire contents of the block to be reset to all 1s. The 1-KB blocks are paired into sets of 2-KB blocks that can be individually protected. The protection allows blocks to be marked as read-only or execute-only, providing different levels of code protection. Read-only blocks cannot be erased or programmed, protecting the contents of those blocks from being modified. Execute-only blocks cannot be erased or programmed and can only be read by the controller instruction fetch mechanism, protecting the contents of those blocks from being read by either the controller or a debugger.

### 8.2.3.1 Prefetch Buffer

The Flash memory controller has a prefetch buffer that is automatically used when the CPU frequency is greater than 40 MHz. In this mode, the Flash memory operates at half of the system clock. The prefetch buffer fetches two 32-bit words per clock allowing instructions to be fetched with no wait states while code is executing linearly. The fetch buffer includes a branch speculation mechanism that recognizes a branch and avoids extra wait states by not reading the next word pair. Also, short loop branches often stay in the buffer. As a result, some branches can be executed with no wait states. Other branches incur a single wait state.

### 8.2.3.2 Flash Memory Protection

The user is provided two forms of Flash memory protection per 2-KB Flash memory block in one pair of 32-bit wide registers. The policy for each protection form is controlled by individual bits (per policy per block) in the **FMPPEn** and **FMPREn** registers.

- **Flash Memory Protection Program Enable (FMPPEn)**: If a bit is set, the corresponding block may be programmed (written) or erased. If a bit is cleared, the corresponding block may not be changed.

- **Flash Memory Protection Read Enable (FMPREn):** If a bit is set, the corresponding block may be executed or read by software or debuggers. If a bit is cleared, the corresponding block may only be executed, and contents of the memory block are prohibited from being read as data.

The policies may be combined as shown in Table 8-1 on page 503.

**Table 8-1. Flash Memory Protection Policy Combinations**

| FMPPEn | FMPREn | Protection                                                                                                                                                                                         |
|--------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0      | 0      | Execute-only protection. The block may only be executed and may not be written or erased. This mode is used to protect code.                                                                       |
| 1      | 0      | The block may be written, erased or executed, but not read. This combination is unlikely to be used.                                                                                               |
| 0      | 1      | Read-only protection. The block may be read or executed but may not be written or erased. This mode is used to lock the block from further modification while allowing any read or execute access. |
| 1      | 1      | No protection. The block may be written, erased, executed or read.                                                                                                                                 |

A Flash memory access that attempts to read a read-protected block (**FMPREn** bit is set) is prohibited and generates a bus fault. A Flash memory access that attempts to program or erase a program-protected block (**FMPPEn** bit is set) is prohibited and can optionally generate an interrupt (by setting the **AMASK** bit in the **Flash Controller Interrupt Mask (FCIM)** register) to alert software developers of poorly behaving software during the development and debug phases.

The factory settings for the **FMPREn** and **FMPPEn** registers are a value of 1 for all implemented banks. These settings create a policy of open access and programmability. The register bits may be changed by clearing the specific register bit. The changes are effective immediately, but are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. The changes are committed using the **Flash Memory Control (FMC)** register. Details on programming these bits are discussed in “Non-Volatile Register Programming” on page 506.

### 8.2.3.3 Execute-Only Protection

Execute-only protection prevents both modification and visibility to a protected flash block. This mode is intended to be used in situations where a device requires debug capability, yet portions of the application space must be protected from external access. An example of this is a company who wishes to sell Tiva™ C Series devices with their proprietary software pre-programmed, yet allow the end user to add custom code to an unprotected region of the flash (such as a motor control module with a customizable motor configuration section in flash).

Literal data introduces a complication to the protection mechanism. When C code is compiled and linked, literal data (constants, and so on) is typically placed in the text section, between functions, by the compiler. The literal data is accessed at run time through the use of the LDR instruction, which loads the data from memory using a PC-relative memory address. The execution of the LDR instruction generates a read transaction across the Cortex-M3's DCode bus, which is subject to the execute-only protection mechanism. If the accessed block is marked as execute only, the transaction is blocked, and the processor is prevented from loading the constant data and, therefore, inhibiting correct execution. Therefore, using execute-only protection requires that literal data be handled differently. There are three ways to address this:

1. Use a compiler that allows literal data to be collected into a separate section that is put into one or more read-enabled flash blocks. Note that the LDR instruction may use a PC-relative address—in which case the literal pool cannot be located outside the span of the offset—or the

software may reserve a register to point to the base address of the literal pool and the LDR offset is relative to the beginning of the pool.

2. Use a compiler that generates literal data from arithmetic instruction immediate data and subsequent computation.
3. Use method 1 or 2, but in assembly language, if the compiler does not support either method.

#### 8.2.3.4 Read-Only Protection

Read-only protection prevents the contents of the flash block from being re-programmed, while still allowing the content to be read by processor or the debug interface. Note that if a **FMPREn** bit is cleared, all read accesses to the Flash memory block are disallowed, including any data accesses. Care must be taken not to store required data in a Flash memory block that has the associated **FMPREn** bit cleared.

The read-only mode does not prevent read access to the stored program, but it does provide protection against accidental (or malicious) erasure or programming. Read-only is especially useful for utilities like the boot loader when the debug interface is permanently disabled. In such combinations, the boot loader, which provides access control to the Flash memory, is protected from being erased or modified.

#### 8.2.3.5 Permanently Disabling Debug

For extremely sensitive applications, the debug interface to the processor and peripherals can be permanently disabled, blocking all accesses to the device through the JTAG or SWD interfaces. With the debug interface disabled, it is still possible to perform standard IEEE instructions (such as boundary scan operations), but access to the processor and peripherals is blocked.

The **DBG0** and **DBG1** bits of the **Boot Configuration (BOOTCFG)** register control whether the debug interface is turned on or off.

The debug interface should not be permanently disabled without providing some mechanism—such as the boot loader—to provide customer-installable updates or bug fixes. Disabling the debug interface is permanent and cannot be reversed.

#### 8.2.3.6 Interrupts

The Flash memory controller can generate interrupts when the following conditions are observed:

- Programming Interrupt - signals when a program or erase action is complete.
- Access Interrupt - signals when a program or erase action has been attempted on a 2-kB block of memory that is protected by its corresponding **FMPPEn** bit.

The interrupt events that can trigger a controller-level interrupt are defined in the **Flash Controller Masked Interrupt Status (FCMIS)** register (see page 522) by setting the corresponding **MASK** bits. If interrupts are not used, the raw interrupt status is always visible via the **Flash Controller Raw Interrupt Status (FCRIS)** register (see page 519).

Interrupts are always cleared (for both the **FCMIS** and **FCRIS** registers) by writing a 1 to the corresponding bit in the **Flash Controller Masked Interrupt Status and Clear (FCMISC)** register (see page 524).

### 8.2.3.7 Flash Memory Programming

The Tiva™ C Series devices provide a user-friendly interface for Flash memory programming. All erase/program operations are handled via three registers: **Flash Memory Address (FMA)**, **Flash Memory Data (FMD)**, and **Flash Memory Control (FMC)**. Note that if the debug capabilities of the microcontroller have been deactivated, resulting in a "locked" state, a recovery sequence must be performed in order to reactivate the debug module. See "Recovering a "Locked" Microcontroller" on page 197.

During a Flash memory operation (write, page erase, or mass erase) access to the Flash memory is inhibited. As a result, instruction and literal fetches are held off until the Flash memory operation is complete. If instruction execution is required during a Flash memory operation, the code that is executing must be placed in SRAM and executed from there while the flash operation is in progress.

**Note:** When programming Flash memory, the following characteristics of the memory must be considered:

- Only an erase can change bits from 0 to 1.
- A write can only change bits from 1 to 0. If the write attempts to change a 0 to a 1, the write fails and no bits are changed.
- A flash operation can be started before entering the Sleep or Deep-sleep mode (using the wait for interrupt instruction, `WFI`). It can also be completed while in Sleep or Deep-sleep. If the Flash program/erase event comes in succession to EEPROM access, the Flash event gets completed after waking from Sleep/Deep-sleep and is started after the wake-up.

### 8.2.3.8 Basic Program / Erase Operations

#### *To program a 32-bit word*

1. Write source data to the **FMD** register.
2. Write the target address to the **FMA** register.
3. Write the Flash memory write key and the `WRITE` bit to the **FMC** register. Depending on the value of the `KEY` bit in the **BOOTCFG** register, the value 0xA442 or 0x71D5 must be written into the `WRKEY` field for a Flash memory write to occur.
4. Poll the **FMC** register until the `WRITE` bit is cleared.

#### *To perform an erase of a 1-KB page*

1. Write the page address to the **FMA** register.
2. Write the Flash memory write key and the `ERASE` bit to the **FMC** register. Depending on the value of the `KEY` bit in the **BOOTCFG** register, the value 0xA442 or 0x71D5 must be written into the `WRKEY` field for a Flash memory write to occur.
3. Poll the **FMC** register until the `ERASE` bit is cleared or, alternatively, enable the programming interrupt using the `PMASK` bit in the **FCIM** register.

**To perform a mass erase of the Flash memory**

1. Write the Flash memory write key and the `MERASE` bit to the **FMC** register. Depending on the value of the `KEY` bit in the **BOOTCFG** register, the value `0xA442` or `0x71D5` must be written into the `WRKEY` field for a Flash memory write to occur.
2. Poll the **FMC** register until the `MERASE` bit is cleared or, alternatively, enable the programming interrupt using the `PMASK` bit in the **FCIM** register.

**8.2.3.9 32-Word Flash Memory Write Buffer**

A 32-word write buffer provides the capability to perform faster write accesses to the Flash memory by programming 2 32-bit words at a time, allowing 32 words to be programmed in the same time as 16 would take using the method described above. The data for the buffered write is written to the **Flash Write Buffer (FWBn)** registers.

The registers are 32-word aligned with Flash memory, and therefore the register **FWB0** corresponds with the address in **FMA** where bits [6:0] of **FMA** are all 0. **FWB1** corresponds with the address in **FMA + 0x4** and so on. Only the **FWBn** registers that have been updated since the previous buffered Flash memory write operation are written. The **Flash Write Buffer Valid (FWBVAL)** register shows which registers have been written since the last buffered Flash memory write operation. This register contains a bit for each of the 32 **FWBn** registers, where bit[n] of **FWBVAL** corresponds to **FWBn**. The **FWBn** register has been updated if the corresponding bit in the **FWBVAL** register is set.

**To program 32 words with a single buffered Flash memory write operation**

1. Write the source data to the **FWBn** registers.
2. Write the target address to the **FMA** register. This must be a 32-word aligned address (that is, bits [6:0] in **FMA** must be 0s).
3. Write the Flash memory write key and the `WRBUF` bit to the **FMC2** register. Depending on the value of the `KEY` bit in the **BOOTCFG** register, the value `0xA442` or `0x71D5` must be written into the `WRKEY` field for a Flash memory write to occur.
4. Poll the **FMC2** register until the `WRBUF` bit is cleared or wait for the `PMIS` interrupt to be signaled.

**8.2.3.10 Non-Volatile Register Programming**

**Note:** The **Boot Configuration (BOOTCFG)** register requires a POR before the committed changes take effect.

This section discusses how to update the registers shown in Table 8-2 on page 507 that are resident within the Flash memory itself. These registers exist in a separate space from the main Flash memory array and are not affected by an ERASE or MASS ERASE operation. With the exception of the **Boot Configuration (BOOTCFG)** register, the settings in these registers can be written, their functions verified, and their values read back before they are committed, at which point they become non-volatile. If a value in one of these registers has not been committed, a power-on reset restores the last committed value or the default value if the register has never been committed. Other types of reset have no effect. Once the register contents are committed, the only way to restore the factory default values is to perform the sequence described in "Recovering a "Locked" Microcontroller" on page 197.

To write to a non-volatile register:

- Bits can only be changed from 1 to 0.

- For all registers except the **BOOTCFG** register, write the data to the register address provided in the register description. For the **BOOTCFG** register, write the data to the **FMD** register.
- The registers can be read to verify their contents. To verify what is to be stored in the **BOOTCFG** register, read the **FMD** register. Reading the **BOOTCFG** register returns the previously committed value or the default value if the register has never been committed.
- The new values are effectively immediately for all registers except **BOOTCFG**, as the new value for the register is not stored in the register until it has been committed.
- Prior to committing the register value, a power-on reset restores the last committed value or the default value if the register has never been committed.

To commit a new value to a non-volatile register:

- Write the data as described above.
- Write to the **FMA** register the value shown in Table 8-2 on page 507.
- Write the Flash memory write key and set the **COMT** bit in the **FMC** register. These values must be written to the **FMC** register at the same time.
- Committing a non-volatile register has the same timing as a write to regular Flash memory, defined by  $T_{\text{PROG64}}$ , as shown in Table 22-27 on page 1185. Software can poll the **COMT** bit in the **FMC** register to determine when the operation is complete, or an interrupt can be enabled by setting the **PMASK** bit in the **FCIM** register.
- When committing the **BOOTCFG** register, the **INVDRIS** bit in the **FCRIS** register is set if a bit that has already been committed as a 0 is attempted to be committed as a 1.
- Once the value has been committed, a power-on reset has no effect on the register contents.
- Changes to the **BOOTCFG** register are effective after the next power-on reset.
- Once the **NW** bit has been changed to 0 and committed, further changes to the **BOOTCFG** register are not allowed.

---

**Important:** After being committed, these registers can only be restored to their factory default values by performing the sequence described in “Recovering a “Locked” Microcontroller” on page 197. The mass erase of the main Flash memory array caused by the sequence is performed prior to restoring these registers.

---

**Table 8-2. User-Programmable Flash Memory Resident Registers**

| Register to be Committed | FMA Value   | Data Source |
|--------------------------|-------------|-------------|
| FMPRE0                   | 0x0000.0000 | FMPRE0      |
| FMPPE0                   | 0x0000.0001 | FMPPE0      |
| USER_REG0                | 0x8000.0000 | USER_REG0   |
| USER_REG1                | 0x8000.0001 | USER_REG1   |
| USER_REG2                | 0x8000.0002 | USER_REG2   |
| USER_REG3                | 0x8000.0003 | USER_REG3   |
| BOOTCFG                  | 0x7510.0000 | FMD         |

## 8.2.4 EEPROM

The TM4C1233C3PM microcontroller includes an EEPROM with the following features:

- 2Kbytes of memory accessible as 512 32-bit words
- 32 blocks of 16 words (64 bytes) each
- Built-in wear leveling
- Access protection per block
- Lock protection option for the whole peripheral as well as per block using 32-bit to 96-bit unlock codes (application selectable)
- Interrupt support for write completion to avoid polling
- Endurance of 500K writes (when writing at fixed offset in every alternate page in circular fashion) to 15M operations (when cycling through two pages ) per each 2-page block.

### 8.2.4.1 Functional Description

The EEPROM module provides a well-defined register interface to support accesses to the EEPROM with both a random access style of read and write as well as a rolling or sequential access scheme.

A protection mechanism allows locking EEPROM blocks to prevent writes under a set of circumstances as well as reads under the same or different circumstances. The password model allows the application to lock one or more EEPROM blocks to control access on 16-word boundaries.

---

**Important:** The configuration of the system clock must not be changed while an EEPROM operation is in process. Software must wait until the `WORKING` bit in the **EEPROM Done Status (EEDONE)** register is clear before making any changes to the system clock.

---

#### **Blocks**

There are 32 blocks of 16 words each in the EEPROM. Bytes and half-words can be read, and these accesses do not have to occur on a word boundary. The entire word is read and any unneeded data is simply ignored. They are writable only on a word basis. To write a byte, it is necessary to read the word value, modify the appropriate byte, and write the word back.

Each block is addressable as an offset within the EEPROM, using a block select register. Each word is offset addressable within the selected block.

The current block is selected by the **EEPROM Current Block (EEBLOCK)** register. The current offset is selected and checked for validity by the **EEPROM Current Offset (EEOFFSET)** register. The application may write the **EEOFFSET** register any time, and it is also automatically incremented when the **EEPROM Read-Write with Increment (EERDWRINC)** register is accessed. However, the **EERDWRINC** register does not increment the block number, but instead wraps within the block.

Blocks are individually protectable. Attempts to read from a block for which the application does not have permission return 0xFFFF.FFFF. Attempts to write into a block for which the application does not have permission results in an error in the **EEDONE** register.

#### **Timing Considerations**

After enabling or resetting the EEPROM module, software must wait until the `WORKING` bit in the **EEDONE** register is clear before accessing any EEPROM registers.

In the event that there are Flash memory writes or erases and EEPROM writes active, it is possible for the EEPROM process to be interrupted by the Flash memory write/erase and then continue after the Flash memory write is completed. This action may change the amount of time that the EEPROM operation takes.

EEPROM operations must be completed before entering Sleep or Deep-Sleep mode. Ensure the EEPROM operations have completed by checking the **EEPROM Done Status (EEDONE)** register before issuing a `WFI` instruction to enter Sleep or Deep-Sleep.

Reads of words within a block are at direct speed, which means that wait states are automatically generated if the system clock is faster than the speed of the EEPROM. The read access time is specified in Table 22-28 on page 1185.

Writing the **EEOFFSET** register also does not incur any penalties.

Writing the **EEBLOCK** register is not delayed, but any attempt to access data within that block is delayed by 4 clocks after writing **EEBLOCK**. This time is used to load block specific information.

Writes to words within a block are delayed by a variable amount of time. The application may use an interrupt to be notified when the write is done, or alternatively poll for the done status in the **EEDONE** register. The variability ranges from the write timing of the EEPROM to the erase timing of EEPROM, where the erase timing is less than the write timing of most external EEPROMs.

### **Locking and Passwords**

The EEPROM can be locked at both the module level and the block level. The lock is controlled by a password that is stored in the **EEPROM Password (EEPASSn)** registers and can be any 32-bit to 96-bit value other than all 1s. Block 0 is the master block, the password for block 0 protects the control registers as well as all other blocks. Each block can be further protected with a password for that block.

If a password is registered for block 0, then the whole module is locked at reset. The locking behavior is such that blocks 1 to 31 are inaccessible until block 0 is unlocked, and block 0 follows the rules defined by its protection bits. As a result, the **EEBLOCK** register cannot be changed from 0 until block 0 is unlocked.

A password registered with any block, including block 0, allows for protection rules that control access of that block based on whether it is locked or unlocked. Generally, the lock can be used to prevent write accesses when locked or can prevent read and write accesses when locked.

All password-protected blocks are locked at reset. To unlock a block, the correct password value must be written to the **EEPROM Unlock (EEUNLOCK)** register by writing to it one to three times to form the 32-bit, 64-bit, or 96-bit password registered using the **EEPASSn** register. The value used to configure the **EEPASS0** register must always be written last. For example, for a 96-bit password, the value used to configure the **EEPASS2** register must be written first, followed by the **EEPASS1** and the **EEPASS0** register values. A block or the module may be re-locked by writing 0xFFFF.FFFF to the **EEUNLOCK** register because 0xFFFF.FFFF is not a valid password.

### **Protection and Access Control**

The protection bits provide discrete control of read and write access for each block which allows various protection models per block, including:

- Without password: Readable and writable at any time. This mode is the default when there is no password.
- Without password: Readable but not writable.

- With password: Readable, but only writable when unlocked by the password. This mode is the default when there is a password.
- With password: Readable or writable only when unlocked.
- With password: Readable only when unlocked, not writable.

Additionally, access protection may be applied based on the processor mode. This configuration allows for supervisor-only access or supervisor and user access, which is the default. Supervisor-only access mode also prevents access by the  $\mu$ DMA and Debugger.

Additionally, the master block may be used to control access protection for the protection mechanism itself. If access control for block 0 is for supervisor only, then the whole module may only be accessed in supervisor mode. In addition, the protection level for block 0 sets the minimum protection level for the entire EEPROM. For example, if the `PROT` field in the **EEPROT** register is configured to 0x1 for block 0, then block 1 could be configured with the `PROT` field to be 0x1, 0x2, or 0x3, but not 0x0.

Note that for blocks 1 to 31, they are inaccessible for read or write if block 0 has a password and it is not unlocked. If block 0 has a master password, then the strictest protection defined for block 0 or an individual block is implemented on the remaining blocks.

### **Hidden Blocks**

Hiding provides a temporary form of protection. Every block except block 0 can be hidden, which prevents all accesses until the next reset.

This mechanism can allow a boot or initialization routine to access some data which is then made inaccessible to all further accesses. Because boot and initialization routines control the capabilities of the application, hidden blocks provide a powerful isolation of the data when debug is disabled.

A typical use model would be to have the initialization code store passwords, keys, and/or hashes to use for verification of the rest of the application. Once performed, the block is then hidden and made inaccessible until the next reset which then re-enters the initialization code.

### **Power and Reset Safety**

Once the **EEDONE** register indicates that a location has been successfully written, the data is retained until that location is written again. There is no power or reset race after the **EEDONE** register indicates a write has completed.

### **Interrupt Control**

The EEPROM module allows for an interrupt when a write completes to eliminate the need for polling. The interrupt can be used to drive an application ISR which can then write more words or verify completion. The interrupt mechanism is used any time the **EEDONE** register goes from working to done, whether because of an error or the successful completion of a program or erase operation. This interrupt mechanism works for data writes, writes to password and protection registers, forced erase by the **EEPROM Support Control and Status (EESUPP)** register, and mass erase using the **EEPROM Debug Mass Erase (EEDGBME)** register. The EEPROM interrupt is signaled to the core using the Flash memory interrupt vector. Software can determine that the source of the interrupt was the EEPROM by examining bit 2 of the **Flash Controller Masked Interrupt Status and Clear (FCMISC)** register.

### **Theory of Operation**

The EEPROM operates using a traditional Flash bank model which implements EEPROM-type cells, but uses sector erase. Additionally, words are replicated in the pages to allow 500K+ erase

cycles when needed, which means that each word has a latest version. As a result, a write creates a new version of the word in a new location, making the previous value obsolete.

Each sector contains two blocks. Each block contains locations for the active copy plus six redundant copies. Passwords, protection bits, and control data are all stored in the pages.

When a page runs out of room to store the latest version of a word, a copy buffer is used. The copy buffer copies the latest words of each block. The original page is then erased. Finally, the copy buffer contents are copied back to the page. This mechanism ensures that data cannot be lost due to power down, even during an operation. The EEPROM mechanism properly tracks all state information to provide complete safety and protection. Although it should not normally be possible, errors during programming can occur in certain circumstances, for example, the voltage rail dropping during programming. In these cases, the **EESUPP** register can be used to finish an operation as described in the section called “Error During Programming” on page 511.

### **Manual Copy Buffer Erase**

The copy buffer is only used when a main block is full because a word has been written seven times and there is no more room to store its latest version. In this situation, the latest versions of all the words in the block are copied to the copy buffer, allowing the main block to be erased safely, providing power down safety. If the copy buffer itself is full, then it must first be erased, which adds extra time. By performing a manual erase of the copy buffer, this overhead does not occur during a future write access. The **EREQ** bit in the **EESUPP** register is set if the copy buffer must be erased. If so, the **START** bit can be written by the application to force the erase at a more convenient time. The **EEDONE** and **EEINT** registers can be used to detect completion.

### **Debug Mass Erase**

The EEPROM debug mass erase allows the developer to mass erase the EEPROM. For the mass erase to occur correctly, there can be no active EEPROM operations. After the last EEPROM operation, the application must ensure that no EEPROM registers are updated, including modifying the **EEBLOCK** and the **EEOFFSET** registers without doing an actual read or write operation. To hold off these operations, the application should reset the EEPROM module by setting the **R0** bit in the **EEPROM Software Reset (SREEPROM)** register, wait until **WORKING** bit in the **EEPROM Done Status (EEDONE)** register is clear, and then enable the debug mass erase by setting the **ME** bit in the **EEPROM Debug Mass Erase (EEDBGME)** register.

### **Error During Programming**

Operations such as data-write, password set, protection set, and copy buffer erase may perform multiple operations. For example, a normal write performs two underlying writes: the control word write and the data write. If the control word writes but the data fails (for example, due to a voltage drop), the overall write fails with indication provided in the **EEDONE** register. Failure and the corrective action is broken down by the type of operation:

- If a normal write fails such that the control word is written but the data fails to write, the safe course of action is to retry the operation once the system is otherwise stable, for example, when the voltage is stabilized. After the retry, the control word and write data are advanced to the next location.
- If a password or protection write fails, the safe course of action is to retry the operation once the system is otherwise stable. In the event that multi-word passwords may be written outside of a manufacturing or bring-up mode, care must be taken to ensure all words are written in immediate succession. If not, then partial password unlock would need to be supported to recover.

- If the word write requires the block to be written to the copy buffer, then it is possible to fail or lose power during the subsequent operations. A control word mechanism is used to track what step the EEPROM was in if a failure occurs. If not completed, the **EESUPP** register indicates the partial completion, and the **EESUPP** *START* bit can be written to allow it to continue to completion.
- If a copy buffer erase fails or power is lost while erasing, the **EESUPP** register indicates it is not complete and allows it to be restarted

After a reset and prior to writing any data to the EEPROM, software must read the **EESUPP** register and check for the presence of any error condition which may indicate that a write or erase was in progress when the system was reset due to a voltage drop. If either the *PRETRY* or *ERETRY* bits are set, the peripheral should be reset by setting and then clearing the *R0* bit in the **EEPROM Software Reset (SREEPROM)** register and waiting for the *WORKING* bit in the **EEDONE** register to clear before again checking the **EESUPP** register for error indicators. This procedure should allow the EEPROM to recover from the write or erase error. In very isolated cases, the **EESUPP** register may continue to register an error after this operation, in which case the reset should be repeated. After recovery, the application should rewrite the data which was being programmed when the initial failure occurred.

### **Endurance**

Endurance is per meta-block which is 2 blocks. Endurance is measured in two ways:

1. To the application, it is the number of writes that can be performed.
2. To the microcontroller, it is the number of erases that can be performed on the meta-block.

Because of the second measure, the number of writes depends on how the writes are performed. For example:

- One word can be written more than 500K times, but, these writes impact the meta-block that the word is within. As a result, writing one word 500K times, then trying to write a nearby word 500K times is not assured to work. To ensure success, the words should be written more in parallel.
- All words can be written in a sweep with a total of more than 500K sweeps which updates all words more than 500K times.
- Different words can be written such that any or all words can be written more than 500K times when write counts per word stay about the same. For example, offset 0 could be written 3 times, then offset 1 could be written 2 times, then offset 2 is written 4 times, then offset 1 is written twice, then offset 0 is written again. As a result, all 3 offsets would have 4 writes at the end of the sequence. This kind of balancing within 7 writes maximizes the endurance of different words within the same meta-block.

#### **8.2.4.2 EEPROM Initialization and Configuration**

Before writing to any EEPROM registers, the clock to the EEPROM module must be enabled, see page 340.

A common setup is as follows:

- Block 0 has a password.
- Block 0 is readable by all, but only writable when unlocked.

- Block 0 has an ID and other public data.

In this configuration, the ID is readable any time, but the rest of the EEPROM is locked to accesses by the application. The rest of the blocks only become available when parts of the application that are allowed to access the EEPROM choose to unlock block 0.

## 8.3 Register Map

Table 8-3 on page 513 lists the ROM Controller register and the Flash memory and control registers. The offset listed is a hexadecimal increment to the particular memory controller's base address. The Flash memory register offsets are relative to the Flash memory control base address of 0x400F.D000. The EEPROM registers are relative to the EEPROM base address of 0x400A.F000. The ROM and Flash memory protection register offsets are relative to the System Control base address of 0x400F.E000.

**Table 8-3. Flash Register Map**

| Offset                                               | Name      | Type  | Reset       | Description                                        | See page |
|------------------------------------------------------|-----------|-------|-------------|----------------------------------------------------|----------|

## 8.4 Flash Memory Register Descriptions (Flash Control Offset)

This section lists and describes the Flash Memory registers, in numerical order by address offset. Registers in this section are relative to the Flash control base address of 0x400F.D000.

## Register 1: Flash Memory Address (FMA), offset 0x000

During a single word write operation, this register contains a 4-byte-aligned address and specifies where the data is written. During a write operation that uses the write buffer, this register contains a 128-byte (32-word) aligned address that specifies the start of the 32-word block to be written. During erase operations, this register contains a 1 KB-aligned CPU byte address and specifies which block is erased. Note that the alignment requirements must be met by software or the results of the operation are unpredictable.

### Flash Memory Address (FMA)

Base 0x400F.D000

### Register 3: Flash Memory Control (FMC), offset 0x008

When this register is written, the Flash memory controller initiates the appropriate access cycle for the location specified by the **Flash Memory Address (FMA)** register (see page 515). If the access is a write access, the data contained in the **Flash Memory Data (FMD)** register (see page 516) is written to the specified address.

This register must be the final register written and initiates the memory operation. The four control bits in the lower byte of this register are used to initiate memory operations.

Care must be taken not to set multiple control bits as the results of such an operation are unpredictable.

## Register 5: Flash Controller Interrupt Mask (FCIM), offset 0x010

This register controls whether the Flash memory controller generates interrupts to the controller.

### Flash Controller Interrupt Mask (FCIM)

Base 0x400F.D000

Offset 0x010

Type R/W, reset 0x0000.0000

## Register 6: Flash Controller Masked Interrupt Status and Clear (FCMISC), offset 0x014

This register provides two functions. First, it reports the cause of an interrupt by indicating which interrupt source or sources are signalling the interrupt. Second, it serves as the method to clear the interrupt reporting.

### Flash Controller Masked Interrupt Status and Clear (FCMISC)

|           |       |       | 1     | When read, a 1 indicates that an unmasked interrupt was signaled because a program or erase action was attempted on a block of Flash memory that contradicts the protection policy for that block as set in the <b>FMPPEn</b> registers.<br>Writing a 1 to this bit clears <b>AMISC</b> and also the <b>ARIS</b> bit in the <b>FCRIS</b> register (see page 519). |

## Register 7: Flash Memory Control 2 (FMC2), offset 0x020

When this register is written, the Flash memory controller initiates the appropriate access cycle for the location specified by the **Flash Memory Address (FMA)** register (see page 515). If the access is a write access, the data contained in the **Flash Write Buffer (FWB)** registers is written.

This register must be the final register written as it initiates the memory operation.

#### Value Description

|   |                                                                                                                                                                                                                                            |
|---|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 | A write of 0 has no effect on the state of this bit.<br>When read, a 0 indicates that the previous buffered Flash memory write access is complete.                                                                                         |
| 1 | Set this bit to write the data stored in the <b>FWBn</b> registers to the location specified by the contents of the <b>FMA</b> register.<br>When read, a 1 indicates that the previous buffered Flash memory write access is not complete. |

For information on programming time, see "Flash Memory and EEPROM" on page 1185.

## Register 8: Flash Write Buffer Valid (FWBVAL), offset 0x030

This register provides a bitwise status of which **FWB<sub>n</sub>** registers have been written by the processor since the last write of the Flash memory write buffer. The entries with a 1 are written on the next write of the Flash memory write buffer. This register is cleared after the write operation by hardware. A protection violation on the write operation also clears this status.

Software can program the same 32 words to various Flash memory locations by setting the **FWB<sub>[n]</sub>** bits after they are cleared by the write operation. The next write operation then uses the same data as the previous one. In addition, if a **FWB<sub>n</sub>** register change should not be written to Flash memory, software can clear the corresponding **FWB<sub>[n]</sub>** bit to preserve the existing data when the next write operation occurs.

### Flash Write Buffer Valid (FWBVAL)

#### Value Description

| Value | Description                                                                                                                                          |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0     | The corresponding <b>FWB<sub>n</sub></b> register has no new data to be written.                                                                     |
| 1     | The corresponding <b>FWB<sub>n</sub></b> register has been updated since the last buffer write operation and is ready to be written to Flash memory. |

Bit 0 corresponds to **FWB0**, offset 0x100, and bit 31 corresponds to **FWB31**, offset 0x13C.

## Register 9: Flash Write Buffer n (FWBn), offset 0x100 - 0x17C

These 32 registers hold the contents of the data to be written into the Flash memory on a buffered Flash memory write operation. The offset selects one of the 32-bit registers. Only **FWBn** registers that have been updated since the preceding buffered Flash memory write operation are written into the Flash memory, so it is not necessary to write the entire bank of registers in order to write 1 or 2 words. The **FWBn** registers are written into the Flash memory with the **FWB0** register corresponding to the address contained in **FMA**. **FWB1** is written to the address **FMA+0x4** etc. Note that only data bits that are 0 result in the Flash memory being modified. A data bit that is 1 leaves the content of the Flash memory bit at its previous value.

## Register 10: Flash Size (FSIZE), offset 0xFC0

This register indicates the size of the on-chip Flash memory.

**Important:** This register should be used to determine the size of the Flash memory that is implemented on this microcontroller. However, to support legacy software, the **DC0** register is available. A read of the **DC0** register correctly identifies legacy memory sizes. Software must use the **FSIZE** register for memory sizes that are not listed in the **DC0** register description.

## Register 12: ROM Software Map (ROMSWMAP), offset 0xFCC

This register indicates the presence of third-party software in the on-chip ROM.

**Important:** This register should be used to determine the presence of third-party software in the on-chip ROM on this microcontroller. However, to support legacy software, the **NVMSTAT** register is available. A read of the **TPSW** bit in the **NVMSTAT** register correctly identifies the presence of legacy third-party software. Software should use the **ROMSWMAP** register for software that is not on legacy devices.

## 8.5 EEPROM Register Descriptions (EEPROM Offset)

This section lists and describes the EEPROM registers, in numerical order by address offset. Registers in this section are relative to the EEPROM base address of 0x400A.F000.

Note that the EEPROM module clock must be enabled before the registers can be programmed (see page 340). There must be a delay of 3 system clocks after the EEPROM module clock is enabled before any EEPROM module registers are accessed. In addition, after enabling or resetting the EEPROM module, software must wait until the **WORKING** bit in the **EEDONE** register is clear before accessing any EEPROM registers.

**Register 13: EEPROM Size Information (EESIZE), offset 0x000**

The **EESIZE** register indicates the number of 16-word blocks and 32-bit words in the EEPROM.

### Register 14: EEPROM Current Block (EEBLOCK), offset 0x004

The **EEBLOCK** register is used to select the EEPROM block for subsequent reads, writes, and protection control. The value is a block offset into the EEPROM, such that the first block is 0, then second block is 1, etc. Each block contains 16 words. Attempts to set an invalid block causes the **BLOCK** field to be configured to 0. To verify that the intended block is being accessed, software can read the **BLOCK** field after it has been written. An invalid block can be either a non-existent block or a block that has been hidden using the **EEHIDE** register. Note that block 0 cannot be hidden.

| 31:16     | reserved | RO   | 0x00000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 15:0      | BLOCK    | R/W  | 0x0000  | <p>Current Block</p> <p>This field specifies the block in the EEPROM that is selected for subsequent accesses. Once this field is configured, the read-write registers operate against the specified block, using the <b>EEOFFSET</b> register to select the word within the block. Additionally, the protection and unlock registers are used for the selected block. The maximum value that can be written into this register is determined by the block count, as indicated by the <b>EESIZE</b> register. Attempts to write this field larger than the maximum number of blocks or to a locked block causes this field to be configured to 0.</p> |

## Register 15: EEPROM Current Offset (EEOFFSET), offset 0x008

The **EEOFFSET** register is used to select the EEPROM word to read or write within the block selected by the **EEBLOCK** register. The value is a word offset into the block. Because accesses to the **EERDWRINC** register change the offset, software can read the contents of this register to determine the current offset.

| 31:4      | reserved | RO   | 0x0000.000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.                                                                                                                                                                                                                                   |
| 3:0       | OFFSET   | R/W  | 0x0        | Current Address Offset<br>This value is the current address specified as an offset into the block selected by the <b>EEBLOCK</b> register. Once configured, the read-write registers, <b>EERDRWR</b> and <b>EERDWRINC</b> , operate against that address. The offset is automatically incremented by the <b>EERDWRINC</b> register, with wrap around within the block, which means the offset is incremented from 15 back to 0. |

## Register 16: EEPROM Read-Write (EERDWR), offset 0x010

The **EERDWR** register is used to read or write the EEPROM word at the address pointed to by the **EEBLOCK** and **EEOFFSET** registers. If the protection or access rules do not permit access, the operation is handled as follows: if reading is not allowed, the value 0xFFFF.FFFF is returned in all cases; if writing is not allowed, the **EEDONE** register is configured to indicate an error.

| 31:0      | VALUE | R/W  | -     | EEPROM Read or Write Data<br>On a read, this field contains the value at the word pointed to by <b>EEOFFSET</b> . On a write, this field contains the data to be stored at the word pointed to by <b>EEOFFSET</b> . For writes, configuring this field starts the write process. If protection and access rules do not permit reads, all 1s are returned. If protection and access rules do not permit writes, the write fails and the <b>EEDONE</b> register indicates failure. |

**Register 17: EEPROM Read-Write with Increment (EERDWRINC), offset 0x014**

The **EERDWRINC** register is used to read or write the EEPROM word at the address pointed to by the **EEBLOCK** and **EEOFFSET** registers, and then increment the **OFFSET** field in the **EEOFFSET** register. If the protection or access rules do not permit access, the operation is handled as follows: if reading is not allowed, the value 0xFFFF.FFFF is returned in all cases; if writing is not allowed, the **EEDONE** register is configured to indicate an error. In all cases, the **OFFSET** field is incremented. If the last value is reached, **OFFSET** wraps around to 0 and points to the first word.

| 31:0      | VALUE | R/W  | -     | <p>EEPROM Read or Write Data with Increment</p> <p>On a read, this field contains the value at the word pointed to by <b>EEOFFSET</b>. On a write, this field contains the data to be stored at the word pointed to by <b>EEOFFSET</b>. For writes, configuring this field starts the write process. If protection and access rules do not permit reads, all 1s are returned. If protection and access rules do not permit writes, the write fails and the <b>EEDONE</b> register indicates failure.</p> <p>Regardless of error, the <b>OFFSET</b> field in the <b>EEOFFSET</b> register is incremented by 1, and the value wraps around if the last word is reached.</p> |

### Register 18: EEPROM Done Status (EEDONE), offset 0x018

The **EEDONE** register indicates the successful or failed completion of a write using the **EERDWR** or **EERDWRINC** register, protection set using the **EEPROT** register, password registered using the **EEPASS** register, copy buffer erase or program retry using the **EESUPP** register, or a debug mass erase using the **EEDBGME** register. The **EEDONE** register can be used with the **EEINT** register to generate an interrupt to report the status. The normal usage is to poll the **EEDONE** register or read the register after an interrupt is triggered. When the **EEDONE** bit 0 is set, then the operation is still in progress. When the **EEDONE** bit 0 is clear, then the value of **EEDONE** indicates the completion status. If **EEDONE**==0, then the write completed successfully. If **EEDONE**!=0, then an error occurred and the source of the error is given by the set bit(s). If an error occurs, corrective action may be taken as explained on page 540.

### Register 19: EEPROM Support Control and Status (EESUPP), offset 0x01C

The **EESUPP** register indicates if internal operations are required because an internal copy buffer must be erased or a programming failure has occurred and the operation must be completed. These conditions are explained below as well as in more detail in the section called “Manual Copy Buffer Erase” on page 511 and the section called “Error During Programming” on page 511.

- The **EREQ** bit is set if the internal copy buffer must be erased the next time it is used because it is full. To avoid the delay of waiting for the copy buffer to be erased on the next write, it can be erased manually using this register by setting the **START** bit.
- If either **PRETRY** or **ERETRY** is set indicating that an operation must be completed, setting the **START** bit causes the operation to be performed again.
- The **PRETRY** and **ERETRY** bits are cleared automatically after the failed operation has been successfully completed.

These bits are not changed by reset, so any condition that occurred before a reset is still indicated after a reset.

| 0         | START | R/W  | 0     | Start Erase<br>Setting this bit starts error recovery if the PRETRY or ERETRY bit is set. If both the PRETRY and the ERETRY bits are clear, setting this bit starts erasing the copy buffer if EREQ is set. If none of the other bits in this register are set, setting this bit is ignored. After this bit is set, the WORKING bit in the EEDONE register is set and is cleared when the operation is complete. In addition, the EEINT register can be used to generate an interrupt on completion.<br>If this bit is set while an operation is in progress, the write is ignored. The START bit is automatically cleared when the operation completes. |

## Register 20: EEPROM Unlock (EEUNLOCK), offset 0x020

The **EEUNLOCK** register can be used to unlock the whole EEPROM or a single block using a password. Unlocking is only required if a password is registered using the **EEPASSn** registers for the block that is selected by the **EEBLOCK** register. If block 0 has a password, it locks the remaining blocks from any type of access, but uses its own protection mechanism, for example readable, but not writable when locked. In addition, if block 0 has a password, it must be unlocked before unlocking any other block.

The **EEUNLOCK** register is written between 1 and 3 times to form the 32-bit, 64-bit, or 96-bit password registered using the **EEPASSn** registers. The value used to configure the **EEPASS0** register must always be written last. For example, for a 96-bit password, the value used to configure the **EEPASS2** register must be written first followed by the **EEPASS1** and **EEPASS0** register values. The block or the whole EEPROM can be re-locked by writing 0xFFFF.FFFF to this register.

In the event that an invalid value is written to this register, the block remains locked. The state of the EEPROM lock can be determined by reading back the **EEUNLOCK** register. If a multi-word password is set and the number of words written is incorrect, writing 0xFFFF.FFFF to this register reverts the EEPROM lock to the locked state, and the proper unlock sequence can be retried.

Note that the internal logic is balanced to prevent any electrical or time-based attack being used to find the correct password or its length.

| Bit/Field | Name   | Type | Reset | Description   |
|-----------|--------|------|-------|---------------|
| 31:0      | UNLOCK | R/W  | -     | EEPROM Unlock |

| Value | Description             |
|-------|-------------------------|
| 0     | The EEPROM is locked.   |
| 1     | The EEPROM is unlocked. |

The EEPROM is locked if the block referenced by the **EEBLOCK** register has a password registered, or if the master block (block 0) has a password. Unlocking is performed by writing the password to this register. The block or the EEPROM stays unlocked until it is locked again or until the next reset. It can be locked again by writing 0xFFFF.FFFF to this register.

**Register 21: EEPROM Protection (EEPROT), offset 0x030**

The **EEPROT** register is used to set or read the protection for the current block, as selected by the **EEBLOCK** register. Protection and access control is used to determine when a block's contents can be read or written. The protection level for block 0 sets the minimum protection level for the entire EEPROM. For example, if the **PROT** field is configured to 0x1 for block 0, then block 1 could be configured with the **PROT** field to be 0x1, 0x2, or 0x3, but not 0x0.

## EEPROM Protection (EEPROT)

Base 0x400A.F000

Offset 0x030

Type R/W, reset 0x0000.0000

**Register 22: EEPROM Password (EEPASS0), offset 0x034****Register 23: EEPROM Password (EEPASS1), offset 0x038****Register 24: EEPROM Password (EEPASS2), offset 0x03C**

The **EEPASSn** registers are used to configure a password for a block. A password may only be set once and cannot be changed. The password may be 32-bits, 64-bits, or 96-bits. Each word of the password can be any 32-bit value other than 0xFFFF.FFFF (all 1s). To set a password, the **EEPASS0** register is written to with a value other than 0xFFFF.FFFF. When the write completes, as indicated in the **EEDONE** register, the application may choose to write to the **EEPASS1** register with a value other than 0xFFFF.FFFF. When that write completes, the application may choose to write to the **EEPASS2** register with a value other than 0xFFFF.FFFF to create a 96-bit password. The registers do not have to be written consecutively, and the **EEPASS1** and **EEPASS2** registers may be written at a later date. Based on whether 1, 2, or all 3 registers have been written, the unlock code also requires the same number of words to unlock.

**Note:** Once the password is written, the block is not actually locked until either a reset occurs or 0xFFFF.FFFF is written to **EEUNLOCK**.

## EEPROM Password (EEPASSn)

Base 0x400A.F000

Offset 0x034

Type R/W, reset -

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------|-------------|
| 31:0      | PASS | R/W  | -     | Password    |

This register reads as 0x1 if a password is registered for this block and 0x0 if no password is registered. A write to this register if it reads as 0x0 sets the password. If an attempt is made to write to this register when it reads as 0x1, the write is ignored and the **NOPERM** bit in the **EEDONE** register is set.

### Register 25: EEPROM Interrupt (EEINT), offset 0x040

The **EEINT** register is used to control whether an interrupt should be generated when a write to EEPROM completes as indicated by the **EEDONE** register value changing from 0x1 to any other value. If the **INT** bit in this register is set, the **ERIS** bit in the **Flash Controller Raw Interrupt Status (FCRIS)** register is set whenever the **EEDONE** register value changes from 0x1 as the Flash memory and the EEPROM share an interrupt vector.

|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0     | No interrupt is generated.                                                                                                                                                                                                                   |
| 1     | An interrupt is generated when the <b>EEDONE</b> register transitions from 1 to 0 or an error occurs. The <b>EEDONE</b> register provides status after a write to an offset location as well as a write to the password and protection bits. |

**Register 26: EEPROM Block Hide (EEHIDE), offset 0x050**

The **EEHIDE** register is used to hide one or more blocks other than block 0. Once hidden, the block is not accessible until the next reset. This model allows initialization code to have access to data which is not visible to the rest of the application. This register also provides for additional security in that there is no password to search for in the code or data.

|-----------|------|------|------------|-------------|
| 31:1      | Hn   | R/W  | 0x0000.000 | Hide Block  |

**Value Description**

0 The corresponding block is not hidden.

1 The block number that corresponds to the bit number is hidden. A hidden block cannot be accessed, and the **OFFSET** value in the **EEBLOCK** register cannot be set to that block number. If an attempt is made to configure the **OFFSET** field to a hidden block, the **EEBLOCK** register is cleared.

Any attempt to clear a bit in this register that is set is ignored.

## Register 27: EEPROM Debug Mass Erase (EEDBGME), offset 0x080

The **EEDBGME** register is used to mass erase the EEPROM block back to its default state from the factory. This register is intended to be used only for debug and test purposes, not in production environments. The erase takes place in such a way as to be secure. It first erases all data and then erases the protection mechanism. This register can only be written from supervisor mode by the core, and can also be written by the TM4C1233C3PM debug controller when enabled. A key is used to avoid accidental use of this mechanism. Note that if a power down takes place while erasing, the mechanism should be used again to complete the operation. Powering off prematurely does not expose secured data.

To start a mass erase, the whole register must be written as 0xE37B.0001. The register reads back as 0x1 until the erase is fully completed at which time it reads as 0x0. The **EEDONE** register is set to 0x1 when the erase is started and changes to 0x0 or an error when the mass erase is complete.

Note that mass erasing the EEPROM block means that the wear-leveling counters are also reset to the factory default.

## 8.6 Memory Register Descriptions (System Control Offset)

The remainder of this section lists and describes the registers that reside in the System Control address space, in numerical order by address offset. Registers in this section are relative to the System Control base address of 0x400F.E000.

### Register 29: ROM Control (RMCTL), offset 0x0F0

This register provides control of the ROM controller state. This register offset is relative to the System Control base address of 0x400F.E000.

At reset, the following sequence is performed:

1. The **BOOTCFG** register is read. If the **EN** bit is clear, the ROM Boot Loader is executed.
2. In the ROM Boot Loader, the status of the specified GPIO pin is compared with the specified polarity. If the status matches the specified polarity, the ROM is mapped to address 0x0000.0000 and execution continues out of the ROM Boot Loader.
3. If the **EN** bit is set or the status doesn't match the specified polarity, the data at address 0x0000.0004 is read, and if the data at this address is 0xFFFF.FFFF, the ROM is mapped to address 0x0000.0000 and execution continues out of the ROM Boot Loader.
4. If there is data at address 0x0000.0004 that is not 0xFFFF.FFFF, the stack pointer (**SP**) is loaded from Flash memory at address 0x0000.0000 and the program counter (**PC**) is loaded from address 0x0000.0004. The user application begins executing.

## Register 30: Flash Memory Protection Read Enable 0 (FMPRE0), offset 0x130 and 0x200

**Note:** The **FMPRE0** register is aliased for backwards compatibility.

**Note:** Offset is relative to System Control base address of 0x400F.E000.

This register stores the read-only protection bits for each 2-KB flash block (**FMPPEn** stores the execute-only bits).

This register is loaded during the power-on reset sequence. The factory settings for the **FMPREN** and **FMPPEn** registers are a value of 1 for all implemented 2-KB blocks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. The reset value shown only applies to power-on reset; any other type of reset does not affect this register. Once committed, the only way to restore the factory default value of this register is to perform the sequence detailed in "Recovering a "Locked" Microcontroller" on page 197.

Each **FMPREn** register controls a 64-k block of Flash. For additional information, see "Flash Memory Protection" on page 502.

### ■ FMPRE0: 0 to 64 KB

| 31:0      | READ_ENABLE | R/W  | 0xFFFF.FFFF | Flash Read Enable<br>Each bit configures a 2-KB flash block to be read only.<br>The policies may be combined as shown in Table 8-1 on page 503. |

### Register 31: Flash Memory Protection Program Enable 0 (FMPPE0), offset 0x134 and 0x400

**Note:** The **FMPPE0** register is aliased for backwards compatibility.

**Note:** Offset is relative to System Control base address of 0x400FE000.

This register stores the execute-only protection bits for each 2-KB flash block (**FMPREn** stores the read-only protection bits).

This register is loaded during the power-on reset sequence. The factory settings for the **FMPREn** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. The reset value shown only applies to power-on reset; any other type of reset does not affect this register. Once committed, the only way to restore the factory default value of this register is to perform the sequence detailed in "Recovering a "Locked" Microcontroller" on page 197. For additional information, see "Flash Memory Protection" on page 502.

Each **FMPPEn** register controls a 64-k block of Flash. For additional information, see "Flash Memory Protection" on page 502.

■ **FMPPE0: 0 to 64 KB**

#### Flash Memory Protection Program Enable n (FMPPEn)

Base 0x400F.E000  
 Offset 0x134 and 0x400  
 Type R/W, reset 0xFFFF.FFFF

| Bit/Field | Name        | Type | Reset       | Description                                                                                                                                               |
|-----------|-------------|------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0      | PROG_ENABLE | R/W  | 0xFFFF.FFFF | Flash Programming Enable<br>Each bit configures a 2-KB flash block to be execute only.<br>The policies may be combined as shown in Table 8-1 on page 503. |

**Register 32: Boot Configuration (BOOTCFG), offset 0x1D0**

**Note:** Offset is relative to System Control base address of 0x400F.E000.

**Note:** The **Boot Configuration (BOOTCFG)** register requires a POR before the committed changes take effect.

This register is not written directly, but instead uses the **FMD** register as explained in “Non-Volatile Register Programming” on page 506. This register provides configuration of a GPIO pin to enable the ROM Boot Loader as well as a write-once mechanism to disable external debugger access to the device. At reset, the user has the opportunity to direct the core to execute the ROM Boot Loader or the application in Flash memory by using any GPIO signal from Ports A-Q as configured by the bits in this register. At reset, the following sequence is performed:

1. The **BOOTCFG** register is read. If the **EN** bit is clear, the ROM Boot Loader is executed.
2. In the ROM Boot Loader, the status of the specified GPIO pin is compared with the specified polarity. If the status matches the specified polarity, the ROM is mapped to address 0x0000.0000 and execution continues out of the ROM Boot Loader.
3. If the **EN** bit is set or the status doesn't match the specified polarity, the data at address 0x0000.0004 is read, and if the data at this address is 0xFFFF.FFFF, the ROM is mapped to address 0x0000.0000 and execution continues out of the ROM Boot Loader.
4. If there is data at address 0x0000.0004 that is not 0xFFFF.FFFF, the stack pointer (**SP**) is loaded from Flash memory at address 0x0000.0000 and the program counter (**PC**) is loaded from address 0x0000.0004. The user application begins executing.

The **DBG0** bit is cleared by the factory and the **DBG1** bit is set, which enables external debuggers. Clearing the **DBG1** bit disables any external debugger access to the device, starting with the next power-up cycle of the device. The **NW** bit indicates that bits in the register can be changed from 1 to 0.

By committing the register values using the **COMT** bit in the **FMC** register, the register contents become non-volatile and are therefore retained following power cycling. Prior to being committed, bits can only be changed from 1 to 0. The reset value shown only applies to power-on reset when the register is not yet committed; any other type of reset does not affect this register. Once committed, the register retains its value through power-on reset. Once committed, the only way to restore the factory default value of this register is to perform the sequence detailed in “Recovering a “Locked” Microcontroller” on page 197.

**Register 33: User Register 0 (USER\_REG0), offset 0x1E0**

**Register 34: User Register 1 (USER\_REG1), offset 0x1E4**

**Register 35: User Register 2 (USER\_REG2), offset 0x1E8**

**Register 36: User Register 3 (USER\_REG3), offset 0x1EC**

**Note:** Offset is relative to System Control base address of 0x400F.E000.

These registers each provide 32 bits of user-defined data that is non-volatile. Bits can only be changed from 1 to 0. The reset value shown only applies to power-on reset when the register is not yet committed; any other type of reset does not affect this register. Once committed, the register retains its value through power-on reset. Once committed, the only way to restore the factory default value of this register is to perform the sequence detailed in “Recovering a “Locked” Microcontroller” on page 197.

User Register n (USER\_REGn)

Base 0x400F.E000  
 Offset 0x1E0  
 Type R/W, reset 0xFFFF.FFFF

| Bit/Field | Name | Type | Reset       | Description                                                                                                                                  |
|-----------|------|------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0      | DATA | R/W  | 0xFFFF.FFFF | User Data<br>Contains the user data value. This field is initialized to all 1s and once committed, retains its value through power-on reset. |

## 9 Micro Direct Memory Access (μDMA)

The TM4C1233C3PM microcontroller includes a Direct Memory Access (DMA) controller, known as micro-DMA (μDMA). The μDMA controller provides a way to offload data transfer tasks from the Cortex™-M4F processor, allowing for more efficient use of the processor and the available bus bandwidth. The μDMA controller can perform transfers between memory and peripherals. It has dedicated channels for each supported on-chip module and can be programmed to automatically perform transfers between peripherals and memory as the peripheral is ready to transfer more data. The μDMA controller provides the following features:

- ARM® PrimeCell® 32-channel configurable μDMA controller
- Support for memory-to-memory, memory-to-peripheral, and peripheral-to-memory in multiple transfer modes
  - Basic for simple transfer scenarios
  - Ping-pong for continuous data flow
  - Scatter-gather for a programmable list of up to 256 arbitrary transfers initiated from a single request
- Highly flexible and configurable channel operation
  - Independently configured and operated channels
  - Dedicated channels for supported on-chip modules
  - Flexible channel assignments
  - One channel each for receive and transmit path for bidirectional modules
  - Dedicated channel for software-initiated transfers
  - Per-channel configurable priority scheme
  - Optional software-initiated requests for any channel
- Two levels of priority
- Design optimizations for improved bus access performance between μDMA controller and the processor core
  - μDMA controller access is subordinate to core access
  - RAM striping
  - Peripheral bus segmentation
- Data sizes of 8, 16, and 32 bits
- Transfer size is programmable in binary steps from 1 to 1024
- Source and destination address increment size of byte, half-word, word, or no increment

- Maskable peripheral requests
- Interrupt on transfer completion, with a separate interrupt per channel

## 9.1 Block Diagram

Figure 9-1.  $\mu$ DMA Block Diagram

## 9.2 Functional Description

The  $\mu$ DMA controller is a flexible and highly configurable DMA controller designed to work efficiently with the microcontroller's Cortex-M4F processor core. It supports multiple data sizes and address increment schemes, multiple levels of priority among DMA channels, and several transfer modes to allow for sophisticated programmed data transfers. The  $\mu$ DMA controller's usage of the bus is always subordinate to the processor core, so it never holds up a bus transaction by the processor. Because the  $\mu$ DMA controller is only using otherwise-idle bus cycles, the data transfer bandwidth it provides is essentially free, with no impact on the rest of the system. The bus architecture has been optimized to greatly enhance the ability of the processor core and the  $\mu$ DMA controller to efficiently share the on-chip bus, thus improving performance. The optimizations include RAM striping and peripheral bus segmentation, which in many cases allow both the processor core and the  $\mu$ DMA controller to access the bus and perform simultaneous data transfers.

The  $\mu$ DMA controller can transfer data to and from the on-chip SRAM. However, because the Flash memory and ROM are located on a separate internal bus, it is not possible to transfer data from the Flash memory or ROM with the  $\mu$ DMA controller.

Each peripheral function that is supported has a dedicated channel on the  $\mu$ DMA controller that can be configured independently. The  $\mu$ DMA controller implements a unique configuration method using channel control structures that are maintained in system memory by the processor. While simple transfer modes are supported, it is also possible to build up sophisticated "task" lists in memory that allow the  $\mu$ DMA controller to perform arbitrary-sized transfers to and from arbitrary locations as part of a single transfer request. The  $\mu$ DMA controller also supports the use of ping-pong buffering to accommodate constant streaming of data to or from a peripheral.

Each channel also has a configurable arbitration size. The arbitration size is the number of items that are transferred in a burst before the  $\mu$ DMA controller re-arbitrates for channel priority. Using the arbitration size, it is possible to control exactly how many items are transferred to or from a peripheral each time it makes a  $\mu$ DMA service request.

## 9.2.1 Channel Assignments

Each DMA channel has up to five possible assignments which are selected using the **DMA Channel Map Select n (DMACHMAPn)** registers with 4-bit assignment fields for each  $\mu$ DMA channel.

Table 9-1 on page 559 shows the  $\mu$ DMA channel mapping. The Enc. column shows the encoding for the respective **DMACHMAPn** bit field. Encodings 0x5 - 0xF are all reserved. To support legacy software which uses the **DMA Channel Assignment (DMACHASGN)** register, Enc. 0 is equivalent to a **DMACHASGN** bit being clear, and Enc. 1 is equivalent to a **DMACHASGN** bit being set. If the **DMACHASGN** register is read, bit fields return 0 if the corresponding **DMACHMAPn** register field value are equal to 0, otherwise they return 1 if the corresponding **DMACHMAPn** register field values are not equal to 0. The Type indication in the table indicates if a particular peripheral uses a single request (S), burst request (B) or either (SB).

**Note:** Channels noted in the table as "Software" may be assigned to peripherals in the future. However, they are currently available for software use. Channel 30 is dedicated for software use.

The USB endpoints mapped to  $\mu$ DMA channels 0-3 can be changed with the **USBDMASEL** register (see page 1119).

### 9.2.2 Priority

The  $\mu$ DMA controller assigns priority to each channel based on the channel number and the priority level bit for the channel. Channel number 0 has the highest priority and as the channel number increases, the priority of a channel decreases. Each channel has a priority level bit to provide two levels of priority: default priority and high priority. If the priority level bit is set, then that channel has higher priority than all other channels at default priority. If multiple channels are set for high priority, then the channel number is used to determine relative priority among all the high priority channels.

The priority bit for a channel can be set using the **DMA Channel Priority Set (DMAPRIOSET)** register and cleared with the **DMA Channel Priority Clear (DMAPRIOCLR)** register.

### 9.2.3 Arbitration Size

When a  $\mu$ DMA channel requests a transfer, the  $\mu$ DMA controller arbitrates among all the channels making a request and services the  $\mu$ DMA channel with the highest priority. Once a transfer begins, it continues for a selectable number of transfers before re-arbitrating among the requesting channels again. The arbitration size can be configured for each channel, ranging from 1 to 1024 item transfers. After the  $\mu$ DMA controller transfers the number of items specified by the arbitration size, it then checks among all the channels making a request and services the channel with the highest priority.

If a lower priority  $\mu$ DMA channel uses a large arbitration size, the latency for higher priority channels is increased because the  $\mu$ DMA controller completes the lower priority burst before checking for higher priority requests. Therefore, lower priority channels should not use a large arbitration size for best response on high priority channels.

The arbitration size can also be thought of as a burst size. It is the maximum number of items that are transferred at any one time in a burst. Here, the term arbitration refers to determination of  $\mu$ DMA channel priority, not arbitration for the bus. When the  $\mu$ DMA controller arbitrates for the bus, the processor always takes priority. Furthermore, the  $\mu$ DMA controller is held off whenever the processor must perform a bus transaction on the same bus, even in the middle of a burst transfer.

### 9.2.4 Request Types

The  $\mu$ DMA controller responds to two types of requests from a peripheral: single or burst. Each peripheral may support either or both types of requests. A single request means that the peripheral

is ready to transfer one item, while a burst request means that the peripheral is ready to transfer multiple items.

The  $\mu$ DMA controller responds differently depending on whether the peripheral is making a single request or a burst request. If both are asserted, and the  $\mu$ DMA channel has been set up for a burst transfer, then the burst request takes precedence. See Table 9-2 on page 561, which shows how each peripheral supports the two request types.

**Table 9-2. Request Type Support**

| Peripheral            | Event that generates Single Request | Event that generates Burst Request |
|-----------------------|-------------------------------------|------------------------------------|
| ADC                   | None                                | FIFO half full                     |
| General-Purpose Timer | None                                | Trigger event                      |
| GPIO                  | Raw interrupt pulse                 | None                               |
| SSI TX                | TX FIFO Not Full                    | TX FIFO Level (fixed at 4)         |
| SSI RX                | RX FIFO Not Empty                   | RX FIFO Level (fixed at 4)         |
| UART TX               | TX FIFO Not Full                    | TX FIFO Level (configurable)       |
| UART RX               | RX FIFO Not Empty                   | RX FIFO Level (configurable)       |
| USB TX                | None                                | FIFO TXRDY                         |
| USB RX                | None                                | FIFO RXRDY                         |

#### 9.2.4.1 Single Request

When a single request is detected, and not a burst request, the  $\mu$ DMA controller transfers one item and then stops to wait for another request.

#### 9.2.4.2 Burst Request

When a burst request is detected, the  $\mu$ DMA controller transfers the number of items that is the lesser of the arbitration size or the number of items remaining in the transfer. Therefore, the arbitration size should be the same as the number of data items that the peripheral can accommodate when making a burst request. For example, the UART generates a burst request based on the FIFO trigger level. In this case, the arbitration size should be set to the amount of data that the FIFO can transfer when the trigger level is reached. A burst transfer runs to completion once it is started, and cannot be interrupted, even by a higher priority channel. Burst transfers complete in a shorter time than the same number of non-burst transfers.

It may be desirable to use only burst transfers and not allow single transfers. For example, perhaps the nature of the data is such that it only makes sense when transferred together as a single unit rather than one piece at a time. The single request can be disabled by using the **DMA Channel Useburst Set (DMAUSEBURSTSET)** register. By setting the bit for a channel in this register, the  $\mu$ DMA controller only responds to burst requests for that channel.

#### 9.2.5 Channel Configuration

The  $\mu$ DMA controller uses an area of system memory to store a set of channel control structures in a table. The control table may have one or two entries for each  $\mu$ DMA channel. Each entry in the table structure contains source and destination pointers, transfer size, and transfer mode. The control table can be located anywhere in system memory, but it must be contiguous and aligned on a 1024-byte boundary.

Table 9-3 on page 562 shows the layout in memory of the channel control table. Each channel may have one or two control structures in the control table: a primary control structure and an optional alternate control structure. The table is organized so that all of the primary entries are in the first

half of the table, and all the alternate structures are in the second half of the table. The primary entry is used for simple transfer modes where transfers can be reconfigured and restarted after each transfer is complete. In this case, the alternate control structures are not used and therefore only the first half of the table must be allocated in memory; the second half of the control table is not necessary, and that memory can be used for something else. If a more complex transfer mode is used such as ping-pong or scatter-gather, then the alternate control structure is also used and memory space should be allocated for the entire table.

Any unused memory in the control table may be used by the application. This includes the control structures for any channels that are unused by the application as well as the unused control word for each channel.

**Table 9-3. Control Structure Memory Map**

| Offset | Channel       |
|--------|---------------|
| 0x0    | 0, Primary    |
| 0x10   | 1, Primary    |
| ...    | ...           |
| 0x1F0  | 31, Primary   |
| 0x200  | 0, Alternate  |
| 0x210  | 1, Alternate  |
| ...    | ...           |
| 0x3F0  | 31, Alternate |

Table 9-4 shows an individual control structure entry in the control table. Each entry is aligned on a 16-byte boundary. The entry contains four long words: the source end pointer, the destination end pointer, the control word, and an unused entry. The end pointers point to the ending address of the transfer and are inclusive. If the source or destination is non-incrementing (as for a peripheral register), then the pointer should point to the transfer address.

**Table 9-4. Channel Control Structure**

| Offset | Description             |
|--------|-------------------------|
| 0x000  | Source End Pointer      |
| 0x004  | Destination End Pointer |
| 0x008  | Control Word            |
| 0x00C  | Unused                  |

The control word contains the following fields:

- Source and destination data sizes
- Source and destination address increment size
- Number of transfers before bus arbitration
- Total number of items to transfer
- Useburst flag
- Transfer mode

The control word and each field are described in detail in “ $\mu$ DMA Channel Control Structure” on page 580. The  $\mu$ DMA controller updates the transfer size and transfer mode fields as the transfer is performed. At the end of a transfer, the transfer size indicates 0, and the transfer mode indicates "stopped." Because the control word is modified by the  $\mu$ DMA controller, it must be reconfigured before each new transfer. The source and destination end pointers are not modified, so they can be left unchanged if the source or destination addresses remain the same.

Prior to starting a transfer, a  $\mu$ DMA channel must be enabled by setting the appropriate bit in the **DMA Channel Enable Set (DMAENASET)** register. A channel can be disabled by setting the channel bit in the **DMA Channel Enable Clear (DMAENACLR)** register. At the end of a complete  $\mu$ DMA transfer, the controller automatically disables the channel.

## 9.2.6 Transfer Modes

The  $\mu$ DMA controller supports several transfer modes. Two of the modes support simple one-time transfers. Several complex modes support a continuous flow of data.

### 9.2.6.1 Stop Mode

While Stop is not actually a transfer mode, it is a valid value for the mode field of the control word. When the mode field has this value, the  $\mu$ DMA controller does not perform any transfers and disables the channel if it is enabled. At the end of a transfer, the  $\mu$ DMA controller updates the control word to set the mode to Stop.

### 9.2.6.2 Basic Mode

In Basic mode, the  $\mu$ DMA controller performs transfers as long as there are more items to transfer, and a transfer request is present. This mode is used with peripherals that assert a  $\mu$ DMA request signal whenever the peripheral is ready for a data transfer. Basic mode should not be used in any situation where the request is momentary even though the entire transfer should be completed. For example, a software-initiated transfer creates a momentary request, and in Basic mode, only the number of transfers specified by the `ARBSIZE` field in the **DMA Channel Control Word (DMACHCTL)** register is transferred on a software request, even if there is more data to transfer.

When all of the items have been transferred using Basic mode, the  $\mu$ DMA controller sets the mode for that channel to Stop.

### 9.2.6.3 Auto Mode

Auto mode is similar to Basic mode, except that once a transfer request is received, the transfer runs to completion, even if the  $\mu$ DMA request is removed. This mode is suitable for software-triggered transfers. Generally, Auto mode is not used with a peripheral.

When all the items have been transferred using Auto mode, the  $\mu$ DMA controller sets the mode for that channel to Stop.

### 9.2.6.4 Ping-Pong

Ping-Pong mode is used to support a continuous data flow to or from a peripheral. To use Ping-Pong mode, both the primary and alternate data structures must be implemented. Both structures are set up by the processor for data transfer between memory and a peripheral. The transfer is started using the primary control structure. When the transfer using the primary control structure is complete, the  $\mu$ DMA controller reads the alternate control structure for that channel to continue the transfer. Each time this happens, an interrupt is generated, and the processor can reload the control structure for the just-completed transfer. Data flow can continue indefinitely this way, using the primary and alternate control structures to switch back and forth between buffers as the data flows to or from the peripheral.

Refer to Figure 9-2 on page 564 for an example showing operation in Ping-Pong mode.

Figure 9-2. Example of Ping-Pong  $\mu$ DMA Transaction

### 9.2.6.5 Memory Scatter-Gather

Memory Scatter-Gather mode is a complex mode used when data must be transferred to or from varied locations in memory instead of a set of contiguous locations in a memory buffer. For example,

a gather  $\mu$ DMA operation could be used to selectively read the payload of several stored packets of a communication protocol and store them together in sequence in a memory buffer.

In Memory Scatter-Gather mode, the primary control structure is used to program the alternate control structure from a table in memory. The table is set up by the processor software and contains a list of control structures, each containing the source and destination end pointers, and the control word for a specific transfer. The mode of each control word must be set to Scatter-Gather mode. Each entry in the table is copied in turn to the alternate structure where it is then executed. The  $\mu$ DMA controller alternates between using the primary control structure to copy the next transfer instruction from the list and then executing the new transfer instruction. The end of the list is marked by programming the control word for the last entry to use Auto transfer mode. Once the last transfer is performed using Auto mode, the  $\mu$ DMA controller stops. A completion interrupt is generated only after the last transfer. It is possible to loop the list by having the last entry copy the primary control structure to point back to the beginning of the list (or to a new list). It is also possible to trigger a set of other channels to perform a transfer, either directly, by programming a write to the software trigger for another channel, or indirectly, by causing a peripheral action that results in a  $\mu$ DMA request.

By programming the  $\mu$ DMA controller using this method, a set of up to 256 arbitrary transfers can be performed based on a single  $\mu$ DMA request.

Refer to Figure 9-3 on page 566 and Figure 9-4 on page 567, which show an example of operation in Memory Scatter-Gather mode. This example shows a *gather* operation, where data in three separate buffers in memory is copied together into one buffer. Figure 9-3 on page 566 shows how the application sets up a  $\mu$ DMA task list in memory that is used by the controller to perform three sets of copy operations from different locations in memory. The primary control structure for the channel that is used for the operation is configured to copy from the task list to the alternate control structure.

Figure 9-4 on page 567 shows the sequence as the  $\mu$ DMA controller performs the three sets of copy operations. First, using the primary control structure, the  $\mu$ DMA controller loads the alternate control structure with task A. It then performs the copy operation specified by task A, copying the data from the source buffer A to the destination buffer. Next, the  $\mu$ DMA controller again uses the primary control structure to load task B into the alternate control structure, and then performs the B operation with the alternate control structure. The process is repeated for task C.

Figure 9-3. Memory Scatter-Gather, Setup and Configuration

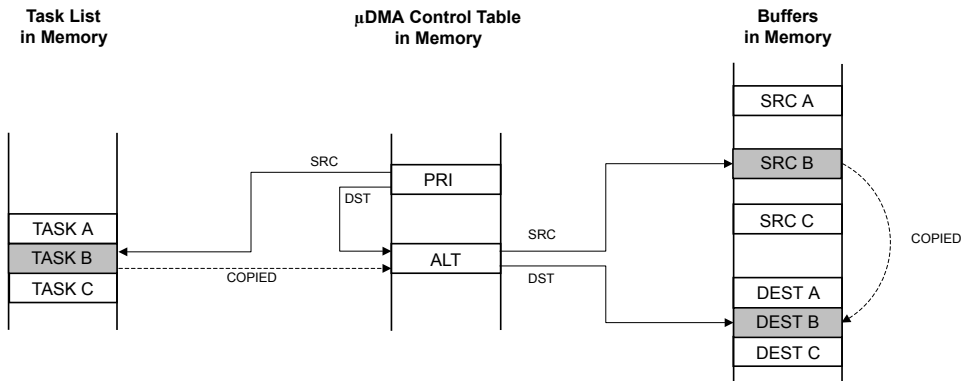

- NOTES:
1. Application has a need to copy data items from three separate locations in memory into one combined buffer.
  2. Application sets up  $\mu$ DMA "task list" in memory, which contains the pointers and control configuration for three  $\mu$ DMA copy "tasks."
  3. Application sets up the channel primary control structure to copy each task configuration, one at a time, to the alternate control structure, where it is executed by the  $\mu$ DMA controller.
  4. The SRC and DST pointers in the task list must point to the last location in the corresponding buffer.

Figure 9-4. Memory Scatter-Gather,  $\mu$ DMA Copy Sequence

Using the channel's primary control structure, the  $\mu$ DMA controller copies task A configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the  $\mu$ DMA controller copies data from the source buffer A to the destination buffer.

Using the channel's primary control structure, the  $\mu$ DMA controller copies task B configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the  $\mu$ DMA controller copies data from the source buffer B to the destination buffer.

Using the channel's primary control structure, the  $\mu$ DMA controller copies task C configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the  $\mu$ DMA controller copies data from the source buffer C to the destination buffer.

### 9.2.6.6 Peripheral Scatter-Gather

Peripheral Scatter-Gather mode is very similar to Memory Scatter-Gather, except that the transfers are controlled by a peripheral making a  $\mu$ DMA request. Upon detecting a request from the peripheral, the  $\mu$ DMA controller uses the primary control structure to copy one entry from the list to the alternate control structure and then performs the transfer. At the end of this transfer, the next transfer is started only if the peripheral again asserts a  $\mu$ DMA request. The  $\mu$ DMA controller continues to perform transfers from the list only when the peripheral is making a request, until the last transfer is complete. A completion interrupt is generated only after the last transfer.

By using this method, the  $\mu$ DMA controller can transfer data to or from a peripheral from a set of arbitrary locations whenever the peripheral is ready to transfer data.

Refer to Figure 9-5 on page 569 and Figure 9-6 on page 570, which show an example of operation in Peripheral Scatter-Gather mode. This example shows a gather operation, where data from three separate buffers in memory is copied to a single peripheral data register. Figure 9-5 on page 569 shows how the application sets up a  $\mu$ DMA task list in memory that is used by the controller to perform three sets of copy operations from different locations in memory. The primary control structure for the channel that is used for the operation is configured to copy from the task list to the alternate control structure.

Figure 9-6 on page 570 shows the sequence as the  $\mu$ DMA controller performs the three sets of copy operations. First, using the primary control structure, the  $\mu$ DMA controller loads the alternate control structure with task A. It then performs the copy operation specified by task A, copying the data from the source buffer A to the peripheral data register. Next, the  $\mu$ DMA controller again uses the primary control structure to load task B into the alternate control structure, and then performs the B operation with the alternate control structure. The process is repeated for task C.

Figure 9-5. Peripheral Scatter-Gather, Setup and Configuration

## NOTES:

1. Application has a need to copy data items from three separate locations in memory into a peripheral data register.
2. Application sets up  $\mu$ DMA "task list" in memory, which contains the pointers and control configuration for three  $\mu$ DMA copy "tasks."
3. Application sets up the channel primary control structure to copy each task configuration, one at a time, to the alternate control structure, where it is executed by the  $\mu$ DMA controller.

Figure 9-6. Peripheral Scatter-Gather,  $\mu$ DMA Copy Sequence

Using the channel's primary control structure, the  $\mu$ DMA controller copies task A configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the  $\mu$ DMA controller copies data from the source buffer A to the peripheral data register.

Using the channel's primary control structure, the  $\mu$ DMA controller copies task B configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the  $\mu$ DMA controller copies data from the source buffer B to the peripheral data register.

Using the channel's primary control structure, the  $\mu$ DMA controller copies task C configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the  $\mu$ DMA controller copies data from the source buffer C to the peripheral data register.

## 9.2.7 Transfer Size and Increment

The  $\mu$ DMA controller supports transfer data sizes of 8, 16, or 32 bits. The source and destination data size must be the same for any given transfer. The source and destination address can be auto-incremented by bytes, half-words, or words, or can be set to no increment. The source and destination address increment values can be set independently, and it is not necessary for the address increment to match the data size as long as the increment is the same or larger than the data size. For example, it is possible to perform a transfer using 8-bit data size, but using an address increment of full words (4 bytes). The data to be transferred must be aligned in memory according to the data size (8, 16, or 32 bits).

Table 9-5 shows the configuration to read from a peripheral that supplies 8-bit data.

**Table 9-5.  $\mu$ DMA Read Example: 8-Bit Peripheral**

| Field                         | Configuration                    |
|-------------------------------|----------------------------------|
| Source data size              | 8 bits                           |
| Destination data size         | 8 bits                           |
| Source address increment      | No increment                     |
| Destination address increment | Byte                             |
| Source end pointer            | Peripheral read FIFO register    |
| Destination end pointer       | End of the data buffer in memory |

## 9.2.8 Peripheral Interface

Each peripheral that supports  $\mu$ DMA has a single request and/or burst request signal that is asserted when the peripheral is ready to transfer data (see Table 9-2 on page 561). The request signal can be disabled or enabled using the **DMA Channel Request Mask Set (DMAREQMASET)** and **DMA Channel Request Mask Clear (DMAREQMASKCLR)** registers. The  $\mu$ DMA request signal is disabled, or masked, when the channel request mask bit is set. When the request is not masked, the  $\mu$ DMA channel is configured correctly and enabled, and the peripheral asserts the request signal, the  $\mu$ DMA controller begins the transfer.

**Note:** When using  $\mu$ DMA to transfer data to and from a peripheral, the peripheral must disable all interrupts to the NVIC.

When a  $\mu$ DMA transfer is complete, the  $\mu$ DMA controller generates an interrupt, see “Interrupts and Errors” on page 572 for more information.

For more information on how a specific peripheral interacts with the  $\mu$ DMA controller, refer to the DMA Operation section in the chapter that discusses that peripheral.

## 9.2.9 Software Request

One  $\mu$ DMA channel is dedicated to software-initiated transfers. This channel also has a dedicated interrupt to signal completion of a  $\mu$ DMA transfer. A transfer is initiated by software by first configuring and enabling the transfer, and then issuing a software request using the **DMA Channel Software Request (DMASWREQ)** register. For software-based transfers, the Auto transfer mode should be used.

It is possible to initiate a transfer on any available software channel using the **DMASWREQ** register. If a request is initiated by software using a peripheral  $\mu$ DMA channel, then the completion interrupt occurs on the interrupt vector for the peripheral instead of the software interrupt vector. Any peripheral channel may be used for software requests as long as the corresponding peripheral is not using  $\mu$ DMA for data transfer.

## 9.2.10 Interrupts and Errors

Depending on the peripheral, the  $\mu$ DMA can indicate transfer completion at the end of an entire transfer or when a FIFO or buffer reaches a certain level (see Table 9-2 on page 561 and the individual peripheral chapters). When a  $\mu$ DMA transfer is complete, the  $\mu$ DMA controller generates a completion interrupt on the interrupt vector of the peripheral. Therefore, if  $\mu$ DMA is used to transfer data for a peripheral and interrupts are used, then the interrupt handler for that peripheral must be designed to handle the  $\mu$ DMA transfer completion interrupt. If the transfer uses the software  $\mu$ DMA channel, then the completion interrupt occurs on the dedicated software  $\mu$ DMA interrupt vector (see Table 9-6 on page 572).

When  $\mu$ DMA is enabled for a peripheral, the  $\mu$ DMA controller stops the normal transfer interrupts for a peripheral from reaching the interrupt controller (the interrupts are still reported in the peripheral's interrupt registers). Thus, when a large amount of data is transferred using  $\mu$ DMA, instead of receiving multiple interrupts from the peripheral as data flows, the interrupt controller receives only one interrupt when the transfer is complete. Unmasked peripheral error interrupts continue to be sent to the interrupt controller.

When a  $\mu$ DMA channel generates a completion interrupt, the `CHIS` bit corresponding to the peripheral channel is set in the **DMA Channel Interrupt Status (DMACHIS)** register (see page 607). This register can be used by the peripheral interrupt handler code to determine if the interrupt was caused by the  $\mu$ DMA channel or an error event reported by the peripheral's interrupt registers. The completion interrupt request from the  $\mu$ DMA controller is automatically cleared when the interrupt handler is activated.

If the  $\mu$ DMA controller encounters a bus or memory protection error as it attempts to perform a data transfer, it disables the  $\mu$ DMA channel that caused the error and generates an interrupt on the  $\mu$ DMA error interrupt vector. The processor can read the **DMA Bus Error Clear (DMAERRCLR)** register to determine if an error is pending. The `ERRCLR` bit is set if an error occurred. The error can be cleared by writing a 1 to the `ERRCLR` bit.

Table 9-6 shows the dedicated interrupt assignments for the  $\mu$ DMA controller.

**Table 9-6.  $\mu$ DMA Interrupt Assignments**

| Interrupt | Assignment                          |
|-----------|-------------------------------------|
| 46        | $\mu$ DMA Software Channel Transfer |
| 47        | $\mu$ DMA Error                     |

## 9.3 Initialization and Configuration

### 9.3.1 Module Initialization

Before the  $\mu$ DMA controller can be used, it must be enabled in the System Control block and in the peripheral. The location of the channel control structure must also be programmed.

The following steps should be performed one time during system initialization:

1. Enable the  $\mu$ DMA clock using the **RCGCDMA** register (see page 328).
2. Enable the  $\mu$ DMA controller by setting the `MASTEREN` bit of the **DMA Configuration (DMACFG)** register.
3. Program the location of the channel control table by writing the base address of the table to the **DMA Channel Control Base Pointer (DMACTLBASE)** register. The base address must be aligned on a 1024-byte boundary.

## 9.3.2 Configuring a Memory-to-Memory Transfer

μDMA channel 30 is dedicated for software-initiated transfers. However, any channel can be used for software-initiated, memory-to-memory transfer if the associated peripheral is not being used.

### 9.3.2.1 Configure the Channel Attributes

First, configure the channel attributes:

1. Program bit 30 of the **DMA Channel Priority Set (DMAPRIOSET)** or **DMA Channel Priority Clear (DMAPRIOCLR)** registers to set the channel to High priority or Default priority.
2. Set bit 30 of the **DMA Channel Primary Alternate Clear (DMAALTCLR)** register to select the primary channel control structure for this transfer.
3. Set bit 30 of the **DMA Channel Useburst Clear (DMAUSEBURSTCLR)** register to allow the μDMA controller to respond to single and burst requests.
4. Set bit 30 of the **DMA Channel Request Mask Clear (DMAREQMASKCLR)** register to allow the μDMA controller to recognize requests for this channel.

### 9.3.2.2 Configure the Channel Control Structure

Now the channel control structure must be configured.

This example transfers 256 words from one memory buffer to another. Channel 30 is used for a software transfer, and the control structure for channel 30 is at offset 0x1E0 of the channel control table. The channel control structure for channel 30 is located at the offsets shown in Table 9-7.

**Table 9-7. Channel Control Structure Offsets for Channel 30**

| Offset                     | Description                        |
|----------------------------|------------------------------------|
| Control Table Base + 0x1E0 | Channel 30 Source End Pointer      |
| Control Table Base + 0x1E4 | Channel 30 Destination End Pointer |
| Control Table Base + 0x1E8 | Channel 30 Control Word            |

#### **Configure the Source and Destination**

The source and destination end pointers must be set to the last address for the transfer (inclusive).

1. Program the source end pointer at offset 0x1E0 to the address of the source buffer + 0x3FC.
2. Program the destination end pointer at offset 0x1E4 to the address of the destination buffer + 0x3FC.

The control word at offset 0x1E8 must be programmed according to Table 9-8.

**Table 9-8. Channel Control Word Configuration for Memory Transfer Example**

| Field in DMACHCTL | Bits  | Value | Description                          |
|-------------------|-------|-------|--------------------------------------|
| DSTINC            | 31:30 | 2     | 32-bit destination address increment |
| DSTSIZE           | 29:28 | 2     | 32-bit destination data size         |
| SRCINC            | 27:26 | 2     | 32-bit source address increment      |
| SRCSIZE           | 25:24 | 2     | 32-bit source data size              |
| reserved          | 23:18 | 0     | Reserved                             |

**Table 9-8. Channel Control Word Configuration for Memory Transfer Example (continued)**

| Field in DMACHCTL | Bits  | Value | Description                    |
|-------------------|-------|-------|--------------------------------|
| ARBSIZE           | 17:14 | 3     | Arbitrates after 8 transfers   |
| XFERSIZE          | 13:4  | 255   | Transfer 256 items             |
| NXTUSEBURST       | 3     | 0     | N/A for this transfer type     |
| XFERMODE          | 2:0   | 2     | Use Auto-request transfer mode |

### 9.3.2.3 Start the Transfer

Now the channel is configured and is ready to start.

1. Enable the channel by setting bit 30 of the **DMA Channel Enable Set (DMAENASET)** register.
2. Issue a transfer request by setting bit 30 of the **DMA Channel Software Request (DMASWREQ)** register.

The  $\mu$ DMA transfer begins. If the interrupt is enabled, then the processor is notified by interrupt when the transfer is complete. If needed, the status can be checked by reading bit 30 of the **DMAENASET** register. This bit is automatically cleared when the transfer is complete. The status can also be checked by reading the **XFERMODE** field of the channel control word at offset 0x1E8. This field is automatically cleared at the end of the transfer.

## 9.3.3 Configuring a Peripheral for Simple Transmit

This example configures the  $\mu$ DMA controller to transmit a buffer of data to a peripheral. The peripheral has a transmit FIFO with a trigger level of 4. The example peripheral uses  $\mu$ DMA channel 7.

### 9.3.3.1 Configure the Channel Attributes

First, configure the channel attributes:

1. Configure bit 7 of the **DMA Channel Priority Set (DMAPRIOSET)** or **DMA Channel Priority Clear (DMAPRIOCLR)** registers to set the channel to High priority or Default priority.
2. Set bit 7 of the **DMA Channel Primary Alternate Clear (DMAALTCLR)** register to select the primary channel control structure for this transfer.
3. Set bit 7 of the **DMA Channel Useburst Clear (DMAUSEBURSTCLR)** register to allow the  $\mu$ DMA controller to respond to single and burst requests.
4. Set bit 7 of the **DMA Channel Request Mask Clear (DMAREQMASKCLR)** register to allow the  $\mu$ DMA controller to recognize requests for this channel.

### 9.3.3.2 Configure the Channel Control Structure

This example transfers 64 bytes from a memory buffer to the peripheral's transmit FIFO register using  $\mu$ DMA channel 7. The control structure for channel 7 is at offset 0x070 of the channel control table. The channel control structure for channel 7 is located at the offsets shown in Table 9-9.

**Table 9-9. Channel Control Structure Offsets for Channel 7**

| Offset                     | Description                  |
|----------------------------|------------------------------|
| Control Table Base + 0x070 | Channel 7 Source End Pointer |

**Table 9-9. Channel Control Structure Offsets for Channel 7 (continued)**

| Offset                     | Description                       |
|----------------------------|-----------------------------------|
| Control Table Base + 0x074 | Channel 7 Destination End Pointer |
| Control Table Base + 0x078 | Channel 7 Control Word            |

**Configure the Source and Destination**

The source and destination end pointers must be set to the last address for the transfer (inclusive). Because the peripheral pointer does not change, it simply points to the peripheral's data register.

1. Program the source end pointer at offset 0x070 to the address of the source buffer + 0x3F.
2. Program the destination end pointer at offset 0x074 to the address of the peripheral's transmit FIFO register.

The control word at offset 0x078 must be programmed according to Table 9-10.

**Table 9-10. Channel Control Word Configuration for Peripheral Transmit Example**

| Field in DMACHCTL | Bits  | Value | Description                            |
|-------------------|-------|-------|----------------------------------------|
| DSTINC            | 31:30 | 3     | Destination address does not increment |
| DSTSIZE           | 29:28 | 0     | 8-bit destination data size            |
| SRCINC            | 27:26 | 0     | 8-bit source address increment         |
| SRCSIZE           | 25:24 | 0     | 8-bit source data size                 |
| reserved          | 23:18 | 0     | Reserved                               |
| ARBSIZE           | 17:14 | 2     | Arbitrates after 4 transfers           |
| XFERSIZE          | 13:4  | 63    | Transfer 64 items                      |
| NXTUSEBURST       | 3     | 0     | N/A for this transfer type             |
| XFERMODE          | 2:0   | 1     | Use Basic transfer mode                |

**Note:** In this example, it is not important if the peripheral makes a single request or a burst request. Because the peripheral has a FIFO that triggers at a level of 4, the arbitration size is set to 4. If the peripheral does make a burst request, then 4 bytes are transferred, which is what the FIFO can accommodate. If the peripheral makes a single request (if there is any space in the FIFO), then one byte is transferred at a time. If it is important to the application that transfers only be made in bursts, then the Channel Useburst `SET[7]` bit should be set in the **DMA Channel Useburst Set (DMAUSEBURSTSET)** register.

**9.3.3.3 Start the Transfer**

Now the channel is configured and is ready to start.

1. Enable the channel by setting bit 7 of the **DMA Channel Enable Set (DMAENASET)** register.

The  $\mu$ DMA controller is now configured for transfer on channel 7. The controller makes transfers to the peripheral whenever the peripheral asserts a  $\mu$ DMA request. The transfers continue until the entire buffer of 64 bytes has been transferred. When that happens, the  $\mu$ DMA controller disables the channel and sets the `XFERMODE` field of the channel control word to 0 (Stopped). The status of the transfer can be checked by reading bit 7 of the **DMA Channel Enable Set (DMAENASET)** register. This bit is automatically cleared when the transfer is complete. The status can also be checked by reading the `XFERMODE` field of the channel control word at offset 0x078. This field is automatically cleared at the end of the transfer.

If peripheral interrupts are enabled, then the peripheral interrupt handler receives an interrupt when the entire transfer is complete.

### 9.3.4 Configuring a Peripheral for Ping-Pong Receive

This example configures the  $\mu$ DMA controller to continuously receive 8-bit data from a peripheral into a pair of 64-byte buffers. The peripheral has a receive FIFO with a trigger level of 8. The example peripheral uses  $\mu$ DMA channel 8.

#### 9.3.4.1 Configure the Channel Attributes

First, configure the channel attributes:

1. Configure bit 8 of the **DMA Channel Priority Set (DMAPRIOSET)** or **DMA Channel Priority Clear (DMAPRIOCLR)** registers to set the channel to High priority or Default priority.
2. Set bit 8 of the **DMA Channel Primary Alternate Clear (DMAALTCLR)** register to select the primary channel control structure for this transfer.
3. Set bit 8 of the **DMA Channel Useburst Clear (DMAUSEBURSTCLR)** register to allow the  $\mu$ DMA controller to respond to single and burst requests.
4. Set bit 8 of the **DMA Channel Request Mask Clear (DMAREQMASKCLR)** register to allow the  $\mu$ DMA controller to recognize requests for this channel.

#### 9.3.4.2 Configure the Channel Control Structure

This example transfers bytes from the peripheral's receive FIFO register into two memory buffers of 64 bytes each. As data is received, when one buffer is full, the  $\mu$ DMA controller switches to use the other.

To use Ping-Pong buffering, both primary and alternate channel control structures must be used. The primary control structure for channel 8 is at offset 0x080 of the channel control table, and the alternate channel control structure is at offset 0x280. The channel control structures for channel 8 are located at the offsets shown in Table 9-11.

**Table 9-11. Primary and Alternate Channel Control Structure Offsets for Channel 8**

| Offset                     | Description                                 |
|----------------------------|---------------------------------------------|
| Control Table Base + 0x080 | Channel 8 Primary Source End Pointer        |
| Control Table Base + 0x084 | Channel 8 Primary Destination End Pointer   |
| Control Table Base + 0x088 | Channel 8 Primary Control Word              |
| Control Table Base + 0x280 | Channel 8 Alternate Source End Pointer      |
| Control Table Base + 0x284 | Channel 8 Alternate Destination End Pointer |
| Control Table Base + 0x288 | Channel 8 Alternate Control Word            |

#### **Configure the Source and Destination**

The source and destination end pointers must be set to the last address for the transfer (inclusive). Because the peripheral pointer does not change, it simply points to the peripheral's data register. Both the primary and alternate sets of pointers must be configured.

1. Program the primary source end pointer at offset 0x080 to the address of the peripheral's receive buffer.

2. Program the primary destination end pointer at offset 0x084 to the address of ping-pong buffer A + 0x3F.
3. Program the alternate source end pointer at offset 0x280 to the address of the peripheral's receive buffer.
4. Program the alternate destination end pointer at offset 0x284 to the address of ping-pong buffer B + 0x3F.

The primary control word at offset 0x088 and the alternate control word at offset 0x288 are initially programmed the same way.

1. Program the primary channel control word at offset 0x088 according to Table 9-12.
2. Program the alternate channel control word at offset 0x288 according to Table 9-12.

**Table 9-12. Channel Control Word Configuration for Peripheral Ping-Pong Receive Example**

| Field in DMACHCTL | Bits  | Value | Description                         |
|-------------------|-------|-------|-------------------------------------|
| DSTINC            | 31:30 | 0     | 8-bit destination address increment |
| DSTSIZE           | 29:28 | 0     | 8-bit destination data size         |
| SRCINC            | 27:26 | 3     | Source address does not increment   |
| SRCSIZE           | 25:24 | 0     | 8-bit source data size              |
| reserved          | 23:18 | 0     | Reserved                            |
| ARBSIZE           | 17:14 | 3     | Arbitrates after 8 transfers        |
| XFERSIZE          | 13:4  | 63    | Transfer 64 items                   |
| NXTUSEBURST       | 3     | 0     | N/A for this transfer type          |
| XFERMODE          | 2:0   | 3     | Use Ping-Pong transfer mode         |

**Note:** In this example, it is not important if the peripheral makes a single request or a burst request. Because the peripheral has a FIFO that triggers at a level of 8, the arbitration size is set to 8. If the peripheral does make a burst request, then 8 bytes are transferred, which is what the FIFO can accommodate. If the peripheral makes a single request (if there is any data in the FIFO), then one byte is transferred at a time. If it is important to the application that transfers only be made in bursts, then the Channel Useburst `SET[8]` bit should be set in the **DMA Channel Useburst Set (DMAUSEBURSTSET)** register.

### 9.3.4.3 Configure the Peripheral Interrupt

An interrupt handler should be configured when using  $\mu$ DMA Ping-Pong mode, it is best to use an interrupt handler. However, the Ping-Pong mode can be configured without interrupts by polling. The interrupt handler is triggered after each buffer is complete.

1. Configure and enable an interrupt handler for the peripheral.

### 9.3.4.4 Enable the $\mu$ DMA Channel

Now the channel is configured and is ready to start.

1. Enable the channel by setting bit 8 of the **DMA Channel Enable Set (DMAENASET)** register.

### 9.3.4.5 Process Interrupts

The  $\mu$ DMA controller is now configured and enabled for transfer on channel 8. When the peripheral asserts the  $\mu$ DMA request signal, the  $\mu$ DMA controller makes transfers into buffer A using the primary channel control structure. When the primary transfer to buffer A is complete, it switches to the alternate channel control structure and makes transfers into buffer B. At the same time, the primary channel control word mode field is configured to indicate Stopped, and an interrupt is pending.

When an interrupt is triggered, the interrupt handler must determine which buffer is complete and process the data or set a flag that the data must be processed by non-interrupt buffer processing code. Then the next buffer transfer must be set up.

In the interrupt handler:

1. Read the primary channel control word at offset 0x088 and check the `XFERMODE` field. If the field is 0, this means buffer A is complete. If buffer A is complete, then:
  - a. Process the newly received data in buffer A or signal the buffer processing code that buffer A has data available.
  - b. Reprogram the primary channel control word at offset 0x88 according to Table 9-12 on page 577.
2. Read the alternate channel control word at offset 0x288 and check the `XFERMODE` field. If the field is 0, this means buffer B is complete. If buffer B is complete, then:
  - a. Process the newly received data in buffer B or signal the buffer processing code that buffer B has data available.
  - b. Reprogram the alternate channel control word at offset 0x288 according to Table 9-12 on page 577.

### 9.3.5 Configuring Channel Assignments

Channel assignments for each  $\mu$ DMA channel can be changed using the `DMACHMAPn` registers. Each 4-bit field represents a  $\mu$ DMA channel.

Refer to Table 9-1 on page 559 for channel assignments.

## 9.4 Register Map

Table 9-13 on page 579 lists the  $\mu$ DMA channel control structures and registers. The channel control structure shows the layout of one entry in the channel control table. The channel control table is located in system memory, and the location is determined by the application, thus the base address is n/a (not applicable) and noted as such above the register descriptions. In the table below, the offset for the channel control structures is the offset from the entry in the channel control table. See “Channel Configuration” on page 561 and Table 9-3 on page 562 for a description of how the entries in the channel control table are located in memory. The  $\mu$ DMA register addresses are given as a hexadecimal increment, relative to the  $\mu$ DMA base address of 0x400F.F000. Note that the  $\mu$ DMA module clock must be enabled before the registers can be programmed (see page 328). There must be a delay of 3 system clocks after the  $\mu$ DMA module clock is enabled before any  $\mu$ DMA module registers are accessed.

Table 9-13.  $\mu$ DMA Register Map

| Offset                                                                                        | Name           | Type  | Reset       | Description                                 | See page |
|-----------------------------------------------------------------------------------------------|----------------|-------|-------------|---------------------------------------------|----------|

## 9.5 $\mu$ DMA Channel Control Structure

The  $\mu$ DMA Channel Control Structure holds the transfer settings for a  $\mu$ DMA channel. Each channel has two control structures, which are located in a table in system memory. Refer to “Channel Configuration” on page 561 for an explanation of the Channel Control Table and the Channel Control Structure.

The channel control structure is one entry in the channel control table. Each channel has a primary and alternate structure. The primary control structures are located at offsets 0x0, 0x10, 0x20 and so on. The alternate control structures are located at offsets 0x200, 0x210, 0x220, and so on.

## Register 1: DMA Channel Source Address End Pointer (DMASRCENDP), offset 0x000

**DMA Channel Source Address End Pointer (DMASRCENDP)** is part of the Channel Control Structure and is used to specify the source address for a  $\mu$ DMA transfer.

The  $\mu$ DMA controller can transfer data to and from the on-chip SRAM. However, because the Flash memory and ROM are located on a separate internal bus, it is not possible to transfer data to/from the Flash memory or ROM with the  $\mu$ DMA controller.

**Note:** The offset specified is from the base address of the control structure in system memory, not the  $\mu$ DMA module base address.

| 13:4      | XFERSIZE                                               | R/W  | -     | <p>Transfer Size (minus 1)</p> <p>This field configures the total number of items to transfer. The value of this field is 1 less than the number to transfer (value 0 means transfer 1 item). The maximum value for this 10-bit field is 1023 which represents a transfer size of 1024 items.</p> <p>The transfer size is the number of items, not the number of bytes. If the data size is 32 bits, then this value is the number of 32-bit words to transfer.</p> <p>The <math>\mu</math>DMA controller updates this field immediately prior to entering the arbitration process, so it contains the number of outstanding items that is necessary to complete the <math>\mu</math>DMA cycle.</p>                                                                                                                                                                                                                                                                                                                                                                                   |       |             |     |                                                        |     |             |     |             |     |             |     |              |     |              |     |              |     |               |     |               |     |               |         |                |
| 3         | NXTUSEBURST                                            | R/W  | -     | <p>Next Useburst</p> <p>This field controls whether the Useburst <math>SET[n]</math> bit is automatically set for the last transfer of a peripheral scatter-gather operation. Normally, for the last transfer, if the number of remaining items to transfer is less than the arbitration size, the <math>\mu</math>DMA controller uses single transfers to complete the transaction. If this bit is set, then the controller uses a burst transfer to complete the last transfer.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |       |             |     |                                                        |     |             |     |             |     |             |     |              |     |              |     |              |     |               |     |               |     |               |         |                |

**XFERMODE Bit Field Values.**

**Stop**

Channel is stopped or configuration data is invalid. No more transfers can occur.

**Basic**

For each trigger (whether from a peripheral or a software request), the  $\mu$ DMA controller performs the number of transfers specified by the `ARBSIZE` field.

**Auto-Request**

The initial request (software- or peripheral-initiated) is sufficient to complete the entire transfer of `XFERSIZE` items without any further requests.

**Ping-Pong**

This mode uses both the primary and alternate control structures for this channel. When the number of transfers specified by the `XFERSIZE` field have completed for the current control structure (primary or alternate), the  $\mu$ DMA controller switches to the other one. These switches continue until one of the control structures is not set to ping-pong mode. At that point, the  $\mu$ DMA controller stops. An interrupt is generated on completion of the transfers configured by each control structure. See “Ping-Pong” on page 563.

**Memory Scatter-Gather**

When using this mode, the primary control structure for the channel is configured to allow a list of operations (tasks) to be performed. The source address pointer specifies the start of a table of tasks to be copied to the alternate control structure for this channel. The `XFERMODE` field for the alternate control structure should be configured to 0x5 (Alternate memory scatter-gather) to perform the task. When the task completes, the  $\mu$ DMA switches back to the primary channel control structure, which then copies the next task to the alternate control structure. This process continues until the table of tasks is empty. The last task must have an `XFERMODE` value other than 0x5. Note that for continuous operation, the last task can update the primary channel control structure back to the start of the list or to another list. See “Memory Scatter-Gather” on page 564.

**Alternate Memory Scatter-Gather**

This value must be used in the alternate channel control data structure when the  $\mu$ DMA controller operates in Memory Scatter-Gather mode.

**Peripheral Scatter-Gather**

This value must be used in the primary channel control data structure when the  $\mu$ DMA controller operates in Peripheral Scatter-Gather mode. In this mode, the  $\mu$ DMA controller operates exactly the same as in Memory Scatter-Gather mode, except that instead of performing the number of transfers specified by the `XFERSIZE` field in the alternate control structure at one time, the  $\mu$ DMA controller only performs the number of transfers specified by the `ARBSIZE` field per trigger; see Basic mode for details. See “Peripheral Scatter-Gather” on page 568.

**Alternate Peripheral Scatter-Gather**

This value must be used in the alternate channel control data structure when the  $\mu$ DMA controller operates in Peripheral Scatter-Gather mode.

## 9.6 $\mu$ DMA Register Descriptions

The register addresses given are relative to the  $\mu$ DMA base address of 0x400F.F000.

### Register 4: DMA Status (DMASTAT), offset 0x000

The **DMA Status (DMASTAT)** register returns the status of the  $\mu$ DMA controller. You cannot read this register when the  $\mu$ DMA controller is in the reset state.

#### DMA Status (DMASTAT)

Base 0x400F.F000

Offset 0x000

Type RO, reset 0x001F.0000

**Register 6: DMA Channel Control Base Pointer (DMACTLBASE), offset 0x008**

The **DMACTLBASE** register must be configured so that the base pointer points to a location in system memory.

The amount of system memory that must be assigned to the  $\mu$ DMA controller depends on the number of  $\mu$ DMA channels used and whether the alternate channel control data structure is used. See “Channel Configuration” on page 561 for details about the Channel Control Table. The base address must be aligned on a 1024-byte boundary. This register cannot be read when the  $\mu$ DMA controller is in the reset state.

### Register 7: DMA Alternate Channel Control Base Pointer (DMAALTBASE), offset 0x00C

The **DMAALTBASE** register returns the base address of the alternate channel control data. This register removes the necessity for application software to calculate the base address of the alternate channel control structures. This register cannot be read when the  $\mu$ DMA controller is in the reset state.

#### DMA Alternate Channel Control Base Pointer (DMAALTBASE)

| 31:0      | ADDR | RO   | 0x0000.0200 | Alternate Channel Address Pointer<br>This field provides the base address of the alternate channel control structures. |

## Register 8: DMA Channel Wait-on-Request Status (DMAWAITSTAT), offset 0x010

This read-only register indicates that the  $\mu$ DMA channel is waiting on a request. A peripheral can hold off the  $\mu$ DMA from performing a single request until the peripheral is ready for a burst request to enhance the  $\mu$ DMA performance. The use of this feature is dependent on the design of the peripheral and is not controllable by software in any way. This register cannot be read when the  $\mu$ DMA controller is in the reset state.

### DMA Channel Wait-on-Request Status (DMAWAITSTAT)

### Register 9: DMA Channel Software Request (DMASWREQ), offset 0x014

Each bit of the **DMASWREQ** register represents the corresponding  $\mu$ DMA channel. Setting a bit generates a request for the specified  $\mu$ DMA channel.

#### DMA Channel Software Request (DMASWREQ)

Base 0x400F.F000

Offset 0x014

Type WO, reset -

| Bit/Field | Name     | Type | Reset | Description                                                                                                                                                                                                                                                                                                                             |
|-----------|----------|------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0      | SWREQ[n] | WO   | -     | <p>Channel [n] Software Request</p> <p>These bits generate software requests. Bit 0 corresponds to channel 0.</p> <p>Value Description</p> <p>1 Generate a software request for the corresponding channel.</p> <p>0 No request generated.</p> <p>These bits are automatically cleared when the software request has been completed.</p> |

**Register 10: DMA Channel Useburst Set (DMAUSEBURSTSET), offset 0x018**

Each bit of the **DMAUSEBURSTSET** register represents the corresponding  $\mu$ DMA channel. Setting a bit disables the channel's single request input from generating requests, configuring the channel to only accept burst requests. Reading the register returns the status of USEBURST.

If the amount of data to transfer is a multiple of the arbitration (burst) size, the corresponding  $SET[n]$  bit is cleared after completing the final transfer. If there are fewer items remaining to transfer than the arbitration (burst) size, the  $\mu$ DMA controller automatically clears the corresponding  $SET[n]$  bit, allowing the remaining items to transfer using single requests. In order to resume transfers using burst requests, the corresponding bit must be set again. A bit should not be set if the corresponding peripheral does not support the burst request model.

Refer to “Request Types” on page 560 for more details about request types.

**DMA Channel Useburst Set (DMAUSEBURSTSET)**

Base 0x400F.F000  
Offset 0x018

| Bit/Field | Name   | Type | Reset       | Description              |
|-----------|--------|------|-------------|--------------------------|
| 31:0      | SET[n] | R/W  | 0x0000.0000 | Channel [n] Useburst Set |

| Value | Description                                                 |
|-------|-------------------------------------------------------------|
| 0     | $\mu$ DMA channel [n] responds to single or burst requests. |
| 1     | $\mu$ DMA channel [n] responds only to burst requests.      |

Bit 0 corresponds to channel 0. This bit is automatically cleared as described above. A bit can also be manually cleared by setting the corresponding  $CLR[n]$  bit in the **DMAUSEBURSTCLR** register.

### Register 11: DMA Channel Useburst Clear (DMAUSEBURSTCLR), offset 0x01C

Each bit of the **DMAUSEBURSTCLR** register represents the corresponding  $\mu$ DMA channel. Setting a bit clears the corresponding **SET[n]** bit in the **DMAUSEBURSTSET** register.

#### DMA Channel Useburst Clear (DMAUSEBURSTCLR)

Base 0x400F.F000

Offset 0x01C

Type WO, reset -

| Bit/Field | Name   | Type | Reset | Description                |
|-----------|--------|------|-------|----------------------------|
| 31:0      | CLR[n] | WO   | -     | Channel [n] Useburst Clear |

Value Description

0 No effect.

1 Setting a bit clears the corresponding **SET[n]** bit in the **DMAUSEBURSTSET** register meaning that  $\mu$ DMA channel [n] responds to single and burst requests.

## Register 12: DMA Channel Request Mask Set (DMAREQMASKSET), offset 0x020

Each bit of the **DMAREQMASKSET** register represents the corresponding  $\mu$ DMA channel. Setting a bit disables  $\mu$ DMA requests for the channel. Reading the register returns the request mask status. When a  $\mu$ DMA channel's request is masked, that means the peripheral can no longer request  $\mu$ DMA transfers. The channel can then be used for software-initiated transfers.

|-----------|--------|------|-------------|------------------------------|
| 31:0      | SET[n] | R/W  | 0x0000.0000 | Channel [n] Request Mask Set |

#### Value Description

| Value | Description                                                                                                                                      |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| 0     | The peripheral associated with channel [n] is enabled to request $\mu$ DMA transfers.                                                            |
| 1     | The peripheral associated with channel [n] is not able to request $\mu$ DMA transfers. Channel [n] may be used for software-initiated transfers. |

Bit 0 corresponds to channel 0. A bit can only be cleared by setting the corresponding `CLR[n]` bit in the **DMAREQMASKCLR** register.

### Register 13: DMA Channel Request Mask Clear (DMAREQMASKCLR), offset 0x024

Each bit of the **DMAREQMASKCLR** register represents the corresponding  $\mu$ DMA channel. Setting a bit clears the corresponding **SET[n]** bit in the **DMAREQMASKSET** register.

#### DMA Channel Request Mask Clear (DMAREQMASKCLR)

Base 0x400F.F000

Offset 0x024

Type WO, reset -

| Bit/Field | Name   | Type | Reset | Description                    |
|-----------|--------|------|-------|--------------------------------|
| 31:0      | CLR[n] | WO   | -     | Channel [n] Request Mask Clear |

Value Description

0 No effect.

1 Setting a bit clears the corresponding **SET[n]** bit in the **DMAREQMASKSET** register meaning that the peripheral associated with channel [n] is enabled to request  $\mu$ DMA transfers.

**Register 14: DMA Channel Enable Set (DMAENASET), offset 0x028**

Each bit of the **DMAENASET** register represents the corresponding  $\mu$ DMA channel. Setting a bit enables the corresponding  $\mu$ DMA channel. Reading the register returns the enable status of the channels. If a channel is enabled but the request mask is set (**DMAREQMASKSET**), then the channel can be used for software-initiated transfers.

|-----------|--------|------|-------------|------------------------|
| 31:0      | SET[n] | R/W  | 0x0000.0000 | Channel [n] Enable Set |

| Value | Description                        |
|-------|------------------------------------|
| 0     | $\mu$ DMA Channel [n] is disabled. |
| 1     | $\mu$ DMA Channel [n] is enabled.  |

Bit 0 corresponds to channel 0. A bit can only be cleared by setting the corresponding **CLR[n]** bit in the **DMAENACL** register or when the end of a  $\mu$ DMA transfer occurs.

### Register 15: DMA Channel Enable Clear (DMAENACL<sub>R</sub>), offset 0x02C

Each bit of the **DMAENACL<sub>R</sub>** register represents the corresponding  $\mu$ DMA channel. Setting a bit clears the corresponding **SET[n]** bit in the **DMAENASET** register.

#### DMA Channel Enable Clear (DMAENACL<sub>R</sub>)

Base 0x400F.F000

Offset 0x02C

Type WO, reset -

|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0     | No effect.                                                                                                                                              |
| 1     | Setting a bit clears the corresponding <b>SET[n]</b> bit in the <b>DMAENASET</b> register meaning that channel [n] is disabled for $\mu$ DMA transfers. |

**Note:** The controller disables a channel when it completes the  $\mu$ DMA cycle.

**Register 16: DMA Channel Primary Alternate Set (DMAALTSET), offset 0x030**

Each bit of the **DMAALTSET** register represents the corresponding  $\mu$ DMA channel. Setting a bit configures the  $\mu$ DMA channel to use the alternate control data structure. Reading the register returns the status of which control data structure is in use for the corresponding  $\mu$ DMA channel.

|-----------|--------|------|-------------|---------------------------|
| 31:0      | SET[n] | R/W  | 0x0000.0000 | Channel [n] Alternate Set |

**Value Description**

|   |                                                                 |
|---|-----------------------------------------------------------------|
| 0 | $\mu$ DMA channel [n] is using the primary control structure.   |
| 1 | $\mu$ DMA channel [n] is using the alternate control structure. |

Bit 0 corresponds to channel 0. A bit can only be cleared by setting the corresponding CLR[n] bit in the **DMAALTCLR** register.

**Note:** For Ping-Pong and Scatter-Gather cycle types, the  $\mu$ DMA controller automatically sets these bits to select the alternate channel control data structure.

## Register 17: DMA Channel Primary Alternate Clear (DMAALTCLR), offset 0x034

Each bit of the **DMAALTCLR** register represents the corresponding  $\mu$ DMA channel. Setting a bit clears the corresponding **SET[n]** bit in the **DMAALTSET** register.

### DMA Channel Primary Alternate Clear (DMAALTCLR)

Base 0x400F.F000

Offset 0x034

|           |        |      |       | 1 Setting a bit clears the corresponding <b>SET[n]</b> bit in the <b>DMAPRIOSET</b> register meaning that channel [n] is using the default priority level. |

**Register 20: DMA Bus Error Clear (DMAERRCLR), offset 0x04C**

The **DMAERRCLR** register is used to read and clear the  $\mu$ DMA bus error status. The error status is set if the  $\mu$ DMA controller encountered a bus error while performing a transfer. If a bus error occurs on a channel, that channel is automatically disabled by the  $\mu$ DMA controller. The other channels are unaffected.

### Register 21: DMA Channel Assignment (DMACHASGN), offset 0x500

Each bit of the **DMACHASGN** register represents the corresponding  $\mu$ DMA channel. Setting a bit selects the secondary channel assignment as specified in Table 9-1 on page 559.

**Note:** This register is provided to support legacy software. New software should use the **DMACHMAPn** registers. If a bit is clear in this register, the corresponding field in the **DMACHMAPn** registers is configured to 0x0. If a bit is set in this register, the corresponding field is configured to 0x1. If this register is read, a bit reads as 0 if the corresponding **DMACHMAPn** register field value is equal to 0, otherwise it reads as 1 if the corresponding **DMACHMAPn** register field value is not equal to 0.

|           |           |      |       | 1 Use the secondary channel assignment. |

**Register 22: DMA Channel Interrupt Status (DMACHIS), offset 0x504**

Each bit of the **DMACHIS** register represents the corresponding  $\mu$ DMA channel. A bit is set when that  $\mu$ DMA channel causes a completion interrupt. The bits are cleared by a writing a 1.

## Value Description

1 The corresponding  $\mu$ DMA channel caused an interrupt.0 The corresponding  $\mu$ DMA channel has not caused an interrupt.

This bit is cleared by writing a 1 to it.

### Register 23: DMA Channel Map Select 0 (DMACHMAP0), offset 0x510

Each 4-bit field of the **DMACHMAP0** register configures the  $\mu$ DMA channel assignment as specified in Table 9-1 on page 559.

**Note:** To support legacy software which uses the **DMA Channel Assignment (DMACHASGN)** register, a value of 0x0 is equivalent to a **DMACHASGN** bit being clear, and a value of 0x1 is equivalent to a **DMACHASGN** bit being set.

### Register 25: DMA Channel Map Select 2 (DMACHMAP2), offset 0x518

Each 4-bit field of the **DMACHMAP2** register configures the  $\mu$ DMA channel assignment as specified in Table 9-1 on page 559.

**Note:** To support legacy software which uses the **DMA Channel Assignment (DMACHASGN)** register, a value of 0x0 is equivalent to a **DMACHASGN** bit being clear, and a value of 0x1 is equivalent to a **DMACHASGN** bit being set.

## 10 General-Purpose Input/Outputs (GPIOs)

The GPIO module is composed of six physical GPIO blocks, each corresponding to an individual GPIO port (Port A, Port B, Port C, Port D, Port E, Port F). The GPIO module supports up to 43 programmable input/output pins, depending on the peripherals being used.

The GPIO module has the following features:

- Up to 43 GPIOs, depending on configuration
- Highly flexible pin muxing allows use as GPIO or one of several peripheral functions
- 5-V-tolerant in input configuration
- Ports A-G accessed through the Advanced Peripheral Bus (APB)
- Fast toggle capable of a change every clock cycle for ports on AHB, every two clock cycles for ports on APB
- Programmable control for GPIO interrupts
  - Interrupt generation masking
  - Edge-triggered on rising, falling, or both
  - Level-sensitive on High or Low values
- Bit masking in both read and write operations through address lines
- Can be used to initiate an ADC sample sequence or a  $\mu$ DMA transfer
- Pin state can be retained during Hibernation mode
- Pins configured as digital inputs are Schmitt-triggered
- Programmable control for GPIO pad configuration
  - Weak pull-up or pull-down resistors
  - 2-mA, 4-mA, and 8-mA pad drive for digital communication; up to four pads can sink 18-mA for high-current applications
  - Slew rate control for 8-mA pad drive
  - Open drain enables
  - Digital input enables

### 10.1 Signal Description

GPIO signals have alternate hardware functions. The following table lists the GPIO pins and their analog and digital alternate functions. All GPIO signals are 5-V tolerant when configured as inputs except for PD4, PD5, PB0 and PB1, which are limited to 3.6 V. The digital alternate hardware functions are enabled by setting the appropriate bit in the **GPIO Alternate Function Select (GPIOAFSEL)** and **GPIOEN** registers and configuring the **PMC<sub>x</sub>** bit field in the **GPIO Port Control (GPIOCTL)**

register to the numeric encoding shown in the table below. Analog signals in the table below are also 5-V tolerant and are configured by clearing the DEN bit in the **GPIO Digital Enable (GPIODEN)** register. The AIN<sub>x</sub> analog signals have internal circuitry to protect them from voltages over V<sub>DD</sub> (up to the maximum specified in Table 22-1 on page 1160), but analog performance specifications are only guaranteed if the input signal swing at the I/O pad is kept inside the range 0 V < V<sub>IN</sub> < V<sub>DD</sub>. Note that each pin must be programmed individually; no type of grouping is implied by the columns in the table. Table entries that are shaded gray are the default values for the corresponding GPIO pin.

**Important:** All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL=0**, **GPIODEN=0**, **GPIOPDR=0**, **GPIOPUR=0**, and **GPIOPCTL=0**), with the exception of the pins shown in the table below. A Power-On-Reset (POR) or asserting RST puts the pins back to their default state.

**Table 10-1. GPIO Pins With Non-Zero Reset Values**

| GPIO Pins | Default State     | GPIOAFSEL | GPIODEN | GPIOPDR | GPIOPUR | GPIOPCTL |
|-----------|-------------------|-----------|---------|---------|---------|----------|
| PA[1:0]   | UART0             | 0         | 0       | 0       | 0       | 0x1      |
| PA[5:2]   | SSI0              | 0         | 0       | 0       | 0       | 0x2      |
| PB[3:2]   | I <sup>2</sup> C0 | 0         | 0       | 0       | 0       | 0x3      |
| PC[3:0]   | JTAG/SWD          | 1         | 1       | 0       | 1       | 0x1      |

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware signals including the GPIO pins that can function as JTAG/SWD signals and the NMI signal. The commit control process must be followed for these pins, even if they are programmed as alternate functions other than JTAG/SWD or NMI; see “Commit Control” on page 628.

a. The digital signals that are shaded gray are the power-on default values for the corresponding GPIO pin. Encodings 10-13 are not used on this device.

## 10.2 Functional Description

Each GPIO port is a separate hardware instantiation of the same physical block (see Figure 10-1 on page 624 and Figure 10-2 on page 625). The TM4C1233C3PM microcontroller contains six ports and thus six of these physical GPIO blocks. Note that not all pins are implemented on every

block. Some GPIO pins can function as I/O signals for the on-chip peripheral modules. For information on which GPIO pins are used for alternate hardware functions, refer to Table 21-5 on page 1153.

Figure 10-1. Digital I/O Pads

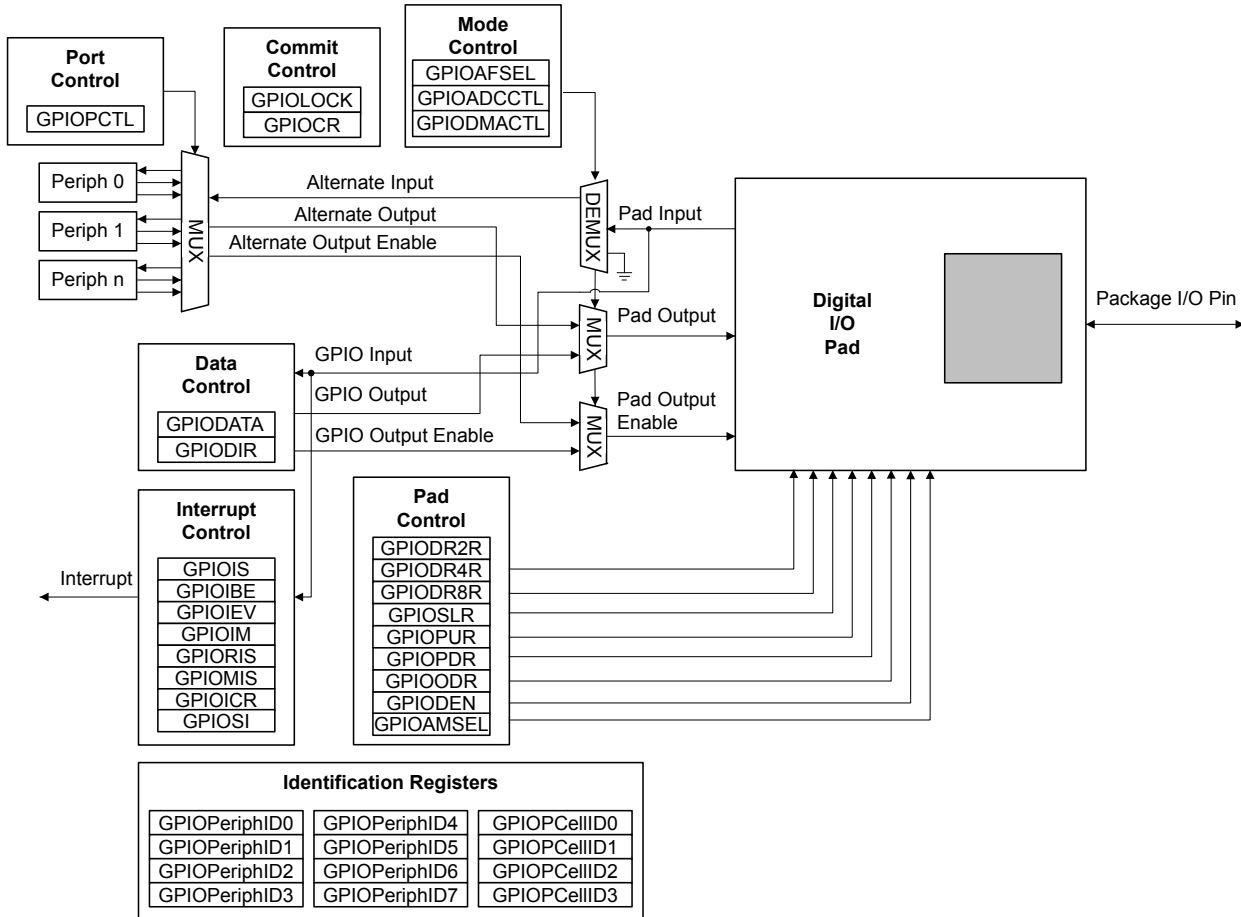

Figure 10-2. Analog/Digital I/O Pads

## 10.2.1 Data Control

The data control registers allow software to configure the operational modes of the GPIOs. The data direction register configures the GPIO as an input or an output while the data register either captures incoming data or drives it out to the pads.

**Caution** – It is possible to create a software sequence that prevents the debugger from connecting to the TM4C1233C3PM microcontroller. If the program code loaded into flash immediately changes the JTAG pins to their GPIO functionality, the debugger may not have enough time to connect and halt the controller before the JTAG pin functionality switches. As a result, the debugger may be locked out of the part. This issue can be avoided with a software routine that restores JTAG functionality based on an external or software trigger. In the case that the software routine is not implemented and the device is locked out of the part, this issue can be solved by using the TM4C1233C3PM Flash Programmer "Unlock" feature. Please refer to [LMFLASHPROGRAMMER](#) on the TI web for more information.

### 10.2.1.1 Data Direction Operation

The **GPIO Direction (GPIODIR)** register (see page 634) is used to configure each individual pin as an input or output. When the data direction bit is cleared, the GPIO is configured as an input, and the corresponding data register bit captures and stores the value on the GPIO port. When the data

direction bit is set, the GPIO is configured as an output, and the corresponding data register bit is driven out on the GPIO port.

### 10.2.1.2 Data Register Operation

To aid in the efficiency of software, the GPIO ports allow for the modification of individual bits in the **GPIO Data (GPIODATA)** register (see page 633) by using bits [9:2] of the address bus as a mask. In this manner, software drivers can modify individual GPIO pins in a single instruction without affecting the state of the other pins. This method is more efficient than the conventional method of performing a read-modify-write operation to set or clear an individual GPIO pin. To implement this feature, the **GPIODATA** register covers 256 locations in the memory map.

During a write, if the address bit associated with that data bit is set, the value of the **GPIODATA** register is altered. If the address bit is cleared, the data bit is left unchanged.

For example, writing a value of 0xEB to the address GPIODATA + 0x098 has the results shown in Figure 10-3, where u indicates that data is unchanged by the write. This example demonstrates how **GPIODATA** bits 5, 2, and 1 are written.

Figure 10-3. GPIODATA Write Example

During a read, if the address bit associated with the data bit is set, the value is read. If the address bit associated with the data bit is cleared, the data bit is read as a zero, regardless of its actual value. For example, reading address GPIODATA + 0x0C4 yields as shown in Figure 10-4. This example shows how to read **GPIODATA** bits 5, 4, and 0.

Figure 10-4. GPIODATA Read Example

### 10.2.2 Interrupt Control

The interrupt capabilities of each GPIO port are controlled by a set of seven registers. These registers are used to select the source of the interrupt, its polarity, and the edge properties. When one or more GPIO inputs cause an interrupt, a single interrupt output is sent to the interrupt controller for the entire GPIO port. For edge-triggered interrupts, software must clear the interrupt to enable any

further interrupts. For a level-sensitive interrupt, the external source must hold the level constant for the interrupt to be recognized by the controller.

Three registers define the edge or sense that causes interrupts:

- **GPIO Interrupt Sense (GPIOIS)** register (see page 635)
- **GPIO Interrupt Both Edges (GPIOIBE)** register (see page 636)
- **GPIO Interrupt Event (GPIOIEV)** register (see page 637)

Interrupts are enabled/disabled via the **GPIO Interrupt Mask (GPIOIM)** register (see page 638).

When an interrupt condition occurs, the state of the interrupt signal can be viewed in two locations: the **GPIO Raw Interrupt Status (GPIORIS)** and **GPIO Masked Interrupt Status (GPIOMIS)** registers (see page 639 and page 640). As the name implies, the **GPIOMIS** register only shows interrupt conditions that are allowed to be passed to the interrupt controller. The **GPIORIS** register indicates that a GPIO pin meets the conditions for an interrupt, but has not necessarily been sent to the interrupt controller.

For a GPIO level-detect interrupt, the interrupt signal generating the interrupt must be held until serviced. Once the input signal deasserts from the interrupt generating logical sense, the corresponding **RIS** bit in the **GPIORIS** register clears. For a GPIO edge-detect interrupt, the **RIS** bit in the **GPIORIS** register is cleared by writing a '1' to the corresponding bit in the **GPIO Interrupt Clear (GPIOICR)** register (see page 641). The corresponding **GPIOMIS** bit reflects the masked value of the **RIS** bit.

When programming the interrupt control registers (**GPIOIS**, **GPIOIBE**, or **GPIOIEV**), the interrupts should be masked (**GPIOIM** cleared). Writing any value to an interrupt control register can generate a spurious interrupt if the corresponding bits are enabled.

#### 10.2.2.1 ADC Trigger Source

Any GPIO pin can be configured to be an external trigger for the ADC using the **GPIO ADC Control (GPIOADCCTL)** register. If any GPIO is configured as a non-masked interrupt pin (the appropriate bit of **GPIOIM** is set), and an interrupt for that port is generated, a trigger signal is sent to the ADC. If the **ADC Event Multiplexer Select (ADCEMUX)** register is configured to use the external trigger, an ADC conversion is initiated. See page 804.

Note that if the Port B **GPIOADCCTL** register is cleared, PB4 can still be used as an external trigger for the ADC. This is a legacy mode which allows code written for previous devices to operate on this microcontroller.

#### 10.2.2.2 $\mu$ DMA Trigger Source

Any GPIO pin can be configured to be an external trigger for the  $\mu$ DMA using the **GPIO DMA Control (GPIODMACTL)** register. If any GPIO is configured as a non-masked interrupt pin (the appropriate bit of **GPIOIM** is set), an interrupt for that port is generated and an external trigger signal is sent to the  $\mu$ DMA. If the  $\mu$ DMA is configured to start a transfer based on the GPIO signal, a transfer is initiated.

#### 10.2.3 Mode Control

The GPIO pins can be controlled by either software or hardware. Software control is the default for most signals and corresponds to the GPIO mode, where the **GPIODATA** register is used to read or write the corresponding pins. When hardware control is enabled via the **GPIO Alternate Function**

**Select (GPIOAFSEL)** register (see page 642), the pin state is controlled by its alternate function (that is, the peripheral).

Further pin muxing options are provided through the **GPIO Port Control (GPIOCTL)** register which selects one of several peripheral functions for each GPIO. For information on the configuration options, refer to Table 21-5 on page 1153.

**Note:** If any pin is to be used as an ADC input, the appropriate bit in the **GPIOAMSEL** register must be set to disable the analog isolation circuit.

#### 10.2.4 Commit Control

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is provided for the GPIO pins that can be used as the four JTAG/SWD pins and the **NMI** pin (see “Signal Tables” on page 1138 for pin numbers). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 642), **GPIO Pull Up Select (GPIOPUR)** register (see page 648), **GPIO Pull-Down Select (GPIOPDR)** register (see page 650), and **GPIO Digital Enable (GPIODEN)** register (see page 653) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 655) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 656) have been set.

#### 10.2.5 Pad Control

The pad control registers allow software to configure the GPIO pads based on the application requirements. The pad control registers include the **GPIODR2R**, **GPIODR4R**, **GPIODR8R**, **GPIODR**, **GPIOPUR**, **GPIOPDR**, **GPIOSLR**, and **GPIODEN** registers. These registers control drive strength, open-drain configuration, pull-up and pull-down resistors, slew-rate control and digital input enable for each GPIO. If 5 V is applied to a GPIO configured as an open-drain output, the output voltage will depend on the strength of your pull-up resistor. The GPIO pad is not electrically configured to output 5 V.

#### 10.2.6 Identification

The identification registers configured at reset allow software to detect and identify the module as a GPIO block. The identification registers include the **GPIOPeriphID0-GIOPeriphID7** registers as well as the **GPIOCellID0-GIOPCellID3** registers.

### 10.3 Initialization and Configuration

The GPIO modules may be accessed via two different memory apertures. The legacy aperture, the Advanced Peripheral Bus (APB), is backwards-compatible with previous devices. The other aperture, the Advanced High-Performance Bus (AHB), offers the same register map but provides better back-to-back access performance than the APB bus. These apertures are mutually exclusive. The aperture enabled for a given GPIO port is controlled by the appropriate bit in the **GPIOHBCTL** register (see page 249). Note that GPIO can only be accessed through the AHB aperture.

To configure the GPIO pins of a particular port, follow these steps:

1. Enable the clock to the port by setting the appropriate bits in the **RCGCGPIO** register (see page 326). In addition, the **SCGCGPIO** and **DCGCGPIO** registers can be programmed in the same manner to enable clocking in Sleep and Deep-sleep modes.
2. Set the direction of the GPIO port pins by programming the **GPIODIR** register. A write of a 1 indicates output and a write of a 0 indicates input.

3. Configure the **GPIODFSEL** register to program each bit as a GPIO or alternate pin. If an alternate pin is chosen for a bit, then the  $PMC_x$  field must be programmed in the **GPIODCTL** register for the specific peripheral required. There are also two registers, **GPIODACCTL** and **GPIODMACTL**, which can be used to program a GPIO pin as a ADC or  $\mu$ DMA trigger, respectively.
4. Set the drive strength for each of the pins through the **GPIODR2R**, **GPIODR4R**, and **GPIODR8R** registers.
5. Program each pad in the port to have either pull-up, pull-down, or open drain functionality through the **GPIODPUR**, **GPIODPDR**, **GPIODODR** register. Slew rate may also be programmed, if needed, through the **GPIODSLR** register.
6. To enable GPIO pins as digital I/Os, set the appropriate **DEN** bit in the **GPIODEN** register. To enable GPIO pins to their analog function (if available), set the **GPIODAMSEL** bit in the **GPIODAMSEL** register.
7. Program the **GPIODIS**, **GPIODIBE**, **GPIODIBE**, **GPIODEV**, and **GPIODIM** registers to configure the type, event, and mask of the interrupts for each port.
8. Optionally, software can lock the configurations of the NMI and JTAG/SWD pins on the GPIO port pins, by setting the **LOCK** bits in the **GPIODLOCK** register.

When the internal POR signal is asserted and until otherwise configured, all GPIO pins are configured to be undriven (tristate): **GPIODFSEL**=0, **GPIODEN**=0, **GPIODPDR**=0, and **GPIODPUR**=0, except for the pins shown in Table 10-1 on page 622. Table 10-3 on page 629 shows all possible configurations of the GPIO pads and the control register settings required to achieve them. Table 10-4 on page 630 shows how a rising edge interrupt is configured for pin 2 of a GPIO port.

**Table 10-3. GPIO Pad Configuration Examples**

| Configuration                                 | GPIO Register Bit Value <sup>a</sup> |     |     |     |     |     |      |      |      |     |
|-----------------------------------------------|--------------------------------------|-----|-----|-----|-----|-----|------|------|------|-----|
|                                               | AFSEL                                | DIR | ODR | DEN | PUR | PDR | DR2R | DR4R | DR8R | SLR |
| Digital Input (GPIO)                          | 0                                    | 0   | 0   | 1   | ?   | ?   | X    | X    | X    | X   |
| Digital Output (GPIO)                         | 0                                    | 1   | 0   | 1   | ?   | ?   | ?    | ?    | ?    | ?   |
| Open Drain Output (GPIO)                      | 0                                    | 1   | 1   | 1   | X   | X   | ?    | ?    | ?    | ?   |
| Open Drain Input/Output (I <sup>2</sup> CSDA) | 1                                    | X   | 1   | 1   | X   | X   | ?    | ?    | ?    | ?   |
| Digital Input (Timer CCP)                     | 1                                    | X   | 0   | 1   | ?   | ?   | X    | X    | X    | X   |
| Digital Output (Timer PWM)                    | 1                                    | X   | 0   | 1   | ?   | ?   | ?    | ?    | ?    | ?   |
| Digital Input/Output (SSI)                    | 1                                    | X   | 0   | 1   | ?   | ?   | ?    | ?    | ?    | ?   |
| Digital Input/Output (UART)                   | 1                                    | X   | 0   | 1   | ?   | ?   | ?    | ?    | ?    | ?   |
| Analog Input (Comparator)                     | 0                                    | 0   | 0   | 0   | 0   | 0   | X    | X    | X    | X   |
| Digital Output (Comparator)                   | 1                                    | X   | 0   | 1   | ?   | ?   | ?    | ?    | ?    | ?   |

a. X=Ignored (don't care bit)

?=Can be either 0 or 1, depending on the configuration

Table 10-4. GPIO Interrupt Configuration Example

| Register | Desired Interrupt Event Trigger                              | Pin 2 Bit Value <sup>a</sup> |   |   |   |   |   |   |   |
|----------|--------------------------------------------------------------|------------------------------|---|---|---|---|---|---|---|
|          |                                                              | 7                            | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

a. X=Ignored (don't care bit)

## 10.4 Register Map

Table 10-6 on page 631 lists the GPIO registers. Each GPIO port can be accessed through one of two bus apertures. The legacy aperture, the Advanced Peripheral Bus (APB), is backwards-compatible with previous devices. The other aperture, the Advanced High-Performance Bus (AHB), offers the same register map but provides better back-to-back access performance than the APB bus.

**Important:** The GPIO registers in this chapter are duplicated in each GPIO block; however, depending on the block, all eight bits may not be connected to a GPIO pad. In those cases, writing to unconnected bits has no effect, and reading unconnected bits returns no meaningful data. See “Signal Description” on page 621 for the GPIOs included on this device.

The offset listed is a hexadecimal increment to the register's address, relative to that GPIO port's base address:

- GPIO Port A (APB): 0x4000.4000
- GPIO Port A (AHB): 0x4005.8000
- GPIO Port B (APB): 0x4000.5000
- GPIO Port B (AHB): 0x4005.9000
- GPIO Port C (APB): 0x4000.6000
- GPIO Port C (AHB): 0x4005.A000
- GPIO Port D (APB): 0x4000.7000
- GPIO Port D (AHB): 0x4005.B000
- GPIO Port E (APB): 0x4002.4000
- GPIO Port E (AHB): 0x4005.C000
- GPIO Port F (APB): 0x4002.5000
- GPIO Port F (AHB): 0x4005.D000

Note that each GPIO module clock must be enabled before the registers can be programmed (see page 326). There must be a delay of 3 system clocks after the GPIO module clock is enabled before any GPIO module registers are accessed.

**Important:** All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL=0**, **GPIODEN=0**, **GPIOPDR=0**, **GPIOPUR=0**, and **GPIOPCTL=0**), with the exception of the pins shown in the table below. A Power-On-Reset ( $\overline{POR}$ ) or asserting  $\overline{RST}$  puts the pins back to their default state.

**Table 10-5. GPIO Pins With Non-Zero Reset Values**

| GPIO Pins | Default State     | GPIOAFSEL | GPIODEN | GPIOPDR | GPIOPUR | GPIOPCTL |
|-----------|-------------------|-----------|---------|---------|---------|----------|
| PA[1:0]   | UART0             | 0         | 0       | 0       | 0       | 0x1      |
| PA[5:2]   | SSI0              | 0         | 0       | 0       | 0       | 0x2      |
| PB[3:2]   | I <sup>2</sup> C0 | 0         | 0       | 0       | 0       | 0x3      |
| PC[3:0]   | JTAG/SWD          | 1         | 1       | 0       | 1       | 0x1      |

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware signals including the GPIO pins that can function as JTAG/SWD signals and the NMI signal. The commit control process must be followed for these pins, even if they are programmed as alternate functions other than JTAG/SWD or NMI; see “Commit Control” on page 628.

The default register type for the **GPIOCR** register is RO for all GPIO pins with the exception of the NMI pin and the four JTAG/SWD pins (see “Signal Tables” on page 1138 for pin numbers). These six pins are the only GPIOs that are protected by the **GPIOCR** register. Because of this, the register type for the corresponding GPIO Ports is R/W.

The default reset value for the **GPIOCR** register is 0x0000.00FF for all GPIO pins, with the exception of the NMI pin and the four JTAG/SWD pins (see “Signal Tables” on page 1138 for pin numbers). To ensure that the JTAG and NMI pins are not accidentally programmed as GPIO pins, these pins default to non-committable. Because of this, the default reset value of **GPIOCR** changes for the corresponding ports.

**Table 10-6. GPIO Register Map**

| Offset | Name      | Type | Reset       | Description                    | See page |
|--------|-----------|------|-------------|--------------------------------|----------|
| 0x000  | GPIODATA  | R/W  | 0x0000.0000 | GPIO Data                      | 633      |

## 10.5 Register Descriptions

The remainder of this section lists and describes the GPIO registers, in numerical order by address offset.

## Register 1: GPIO Data (GPIODATA), offset 0x000

The **GPIODATA** register is the data register. In software control mode, values written in the **GPIODATA** register are transferred onto the GPIO port pins if the respective pins have been configured as outputs through the **GPIO Direction (GPIODIR)** register (see page 634).

In order to write to **GPIODATA**, the corresponding bits in the mask, resulting from the address bus bits [9:2], must be set. Otherwise, the bit values remain unchanged by the write.

Similarly, the values read from this register are determined for each bit by the mask bit derived from the address used to access the data register, bits [9:2]. Bits that are set in the address mask cause the corresponding bits in **GPIODATA** to be read, and bits that are clear in the address mask cause the corresponding bits in **GPIODATA** to be read as 0, regardless of their value.

A read from **GPIODATA** returns the last bit value written if the respective pins are configured as outputs, or it returns the value on the corresponding input pin when these are configured as inputs. All bits are cleared by a reset.

### GPIO Data (GPIODATA)

GPIO Port A (APB) base: 0x4000.4000  
 GPIO Port A (AHB) base: 0x4005.8000  
 GPIO Port B (APB) base: 0x4000.5000  
 GPIO Port B (AHB) base: 0x4005.9000  
 GPIO Port C (APB) base: 0x4000.6000  
 GPIO Port C (AHB) base: 0x4005.A000  
 GPIO Port D (APB) base: 0x4000.7000  
 GPIO Port D (AHB) base: 0x4005.B000  
 GPIO Port E (APB) base: 0x4002.4000  
 GPIO Port E (AHB) base: 0x4005.C000  
 GPIO Port F (APB) base: 0x4002.5000  
 GPIO Port F (AHB) base: 0x4005.D000  
 Offset 0x000  
 Type R/W, reset 0x0000.0000

| 7:0       | DATA     | R/W  | 0x00      | GPIO Data<br>This register is virtually mapped to 256 locations in the address space. To facilitate the reading and writing of data to these registers by independent drivers, the data read from and written to the registers are masked by the eight address lines [9:2]. Reads from this register return its current state. Writes to this register only affect bits that are not masked by ADDR[9:2] and are configured as outputs. See "Data Register Operation" on page 626 for examples of reads and writes. |

## Register 2: GPIO Direction (GPIODIR), offset 0x400

The **GPIODIR** register is the data direction register. Setting a bit in the **GPIODIR** register configures the corresponding pin to be an output, while clearing a bit configures the corresponding pin to be an input. All bits are cleared by a reset, meaning all GPIO pins are inputs by default.

### GPIO Direction (GPIODIR)

### Register 4: GPIO Interrupt Both Edges (GPIOIBE), offset 0x408

The **GPIOIBE** register allows both edges to cause interrupts. When the corresponding bit in the **GPIO Interrupt Sense (GPIOIS)** register (see page 635) is set to detect edges, setting a bit in the **GPIOIBE** register configures the corresponding pin to detect both rising and falling edges, regardless of the corresponding bit in the **GPIO Interrupt Event (GPIOIEV)** register (see page 637). Clearing a bit configures the pin to be controlled by the **GPIOIEV** register. All bits are cleared by a reset.

## Register 5: GPIO Interrupt Event (GPIOIEV), offset 0x40C

The **GPIOIEV** register is the interrupt event register. Setting a bit in the **GPIOIEV** register configures the corresponding pin to detect rising edges or high levels, depending on the corresponding bit value in the **GPIO Interrupt Sense (GPIOIS)** register (see page 635). Clearing a bit configures the pin to detect falling edges or low levels, depending on the corresponding bit value in the **GPIOIS** register. All bits are cleared by a reset.

### GPIO Interrupt Event (GPIOIEV)

### Register 6: GPIO Interrupt Mask (GPIOIM), offset 0x410

The **GPIOIM** register is the interrupt mask register. Setting a bit in the **GPIOIM** register allows interrupts that are generated by the corresponding pin to be sent to the interrupt controller on the combined interrupt signal. Clearing a bit prevents an interrupt on the corresponding pin from being sent to the interrupt controller. All bits are cleared by a reset.

## Register 7: GPIO Raw Interrupt Status (GPIORIS), offset 0x414

The **GPIORIS** register is the raw interrupt status register. A bit in this register is set when an interrupt condition occurs on the corresponding GPIO pin. If the corresponding bit in the **GPIO Interrupt Mask (GPIOIM)** register (see page 638) is set, the interrupt is sent to the interrupt controller. Bits read as zero indicate that corresponding input pins have not initiated an interrupt. For a GPIO level-detect interrupt, the interrupt signal generating the interrupt must be held until serviced. Once the input signal deasserts from the interrupt generating logical sense, the corresponding **RIS** bit in the **GPIORIS** register clears. For a GPIO edge-detect interrupt, the **RIS** bit in the **GPIORIS** register is cleared by writing a '1' to the corresponding bit in the **GPIO Interrupt Clear (GPIOICR)** register. The corresponding **GPIOMIS** bit reflects the masked value of the **RIS** bit.

### Register 8: GPIO Masked Interrupt Status (GPIOMIS), offset 0x418

The **GPIOMIS** register is the masked interrupt status register. If a bit is set in this register, the corresponding interrupt has triggered an interrupt to the interrupt controller. If a bit is clear, either no interrupt has been generated, or the interrupt is masked.

Note that if the Port B **GPIOADCCTL** register is cleared, PB4 can still be used as an external trigger for the ADC. This is a legacy mode which allows code written for previous devices to operate on this microcontroller.

**GPIOMIS** is the state of the interrupt after masking.

| 7:0       | MIS      | RO   | 0x00  | GPIO Masked Interrupt Status                                                                                                                                                                  |

| Value | Description                                                                                             |
|-------|---------------------------------------------------------------------------------------------------------|
| 0     | An interrupt condition on the corresponding pin is masked or has not occurred.                          |
| 1     | An interrupt condition on the corresponding pin has triggered an interrupt to the interrupt controller. |

For edge-detect interrupts, this bit is cleared by writing a 1 to the corresponding bit in the **GPIOICR** register.

For a GPIO level-detect interrupt, the bit is cleared when the level is deasserted.

**Register 9: GPIO Interrupt Clear (GPIOICR), offset 0x41C**

The **GPIOICR** register is the interrupt clear register. For edge-detect interrupts, writing a 1 to the **IC** bit in the **GPIOICR** register clears the corresponding bit in the **GPIOIRIS** and **GPIOMIS** registers. If the interrupt is a level-detect, the **IC** bit in this register has no effect. In addition, writing a 0 to any of the bits in the **GPIOICR** register has no effect.

**GPIO Interrupt Clear (GPIOICR)**

|---|--------------------------------------------|
| 0 | The corresponding interrupt is unaffected. |
| 1 | The corresponding interrupt is cleared.    |

**Register 10: GPIO Alternate Function Select (GPIOAFSEL), offset 0x420**

The **GPIOAFSEL** register is the mode control select register. If a bit is clear, the pin is used as a GPIO and is controlled by the GPIO registers. Setting a bit in this register configures the corresponding GPIO line to be controlled by an associated peripheral. Several possible peripheral functions are multiplexed on each GPIO. The **GPIO Port Control (GPIOPCTL)** register is used to select one of the possible functions. Table 21-5 on page 1153 details which functions are muxed on each GPIO pin. The reset value for this register is 0x0000.0000 for GPIO ports that are not listed in the table below.

**Important:** All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL**=0, **GPIODEN**=0, **GPIOPDR**=0, **GPIOPUR**=0, and **GPIOPCTL**=0), with the exception of the pins shown in the table below. A Power-On-Reset ( $\overline{POR}$ ) or asserting  $\overline{RST}$  puts the pins back to their default state.

**Table 10-7. GPIO Pins With Non-Zero Reset Values**

| GPIO Pins | Default State     | GPIOAFSEL | GPIODEN | GPIOPDR | GPIOPUR | GPIOPCTL |
|-----------|-------------------|-----------|---------|---------|---------|----------|
| PA[1:0]   | UART0             | 0         | 0       | 0       | 0       | 0x1      |
| PA[5:2]   | SSI0              | 0         | 0       | 0       | 0       | 0x2      |
| PB[3:2]   | I <sup>2</sup> C0 | 0         | 0       | 0       | 0       | 0x3      |
| PC[3:0]   | JTAG/SWD          | 1         | 1       | 0       | 1       | 0x1      |

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware signals including the GPIO pins that can function as JTAG/SWD signals and the **NMI** signal. The commit control process must be followed for these pins, even if they are programmed as alternate functions other than JTAG/SWD or NMI; see “Commit Control” on page 628.

**Caution – It is possible to create a software sequence that prevents the debugger from connecting to the TM4C1233C3PM microcontroller. If the program code loaded into flash immediately changes the JTAG pins to their GPIO functionality, the debugger may not have enough time to connect and halt the controller before the JTAG pin functionality switches. As a result, the debugger may be locked out of the part. This issue can be avoided with a software routine that restores JTAG functionality based on an external or software trigger. In the case that the software routine is not implemented and the device is locked out of the part, this issue can be solved by using the TM4C1233C3PM Flash Programmer "Unlock" feature. Please refer to [LMFLASHPROGRAMMER](#) on the TI web for more information.**

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is provided for the GPIO pins that can be used as the four JTAG/SWD pins and the **NMI** pin (see “Signal Tables” on page 1138 for pin numbers). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 642), **GPIO Pull Up Select (GPIOPUR)** register (see page 648), **GPIO Pull-Down Select (GPIOPDR)** register (see page 650), and **GPIO Digital Enable (GPIODEN)** register (see page 653) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 655) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 656) have been set.

When using the I<sup>2</sup>C module, in addition to setting the **GPIOAFSEL** register bits for the I<sup>2</sup>C clock and data pins, the data pins should be set to open drain using the **GPIO Open Drain Select (GPIOODR)** register (see examples in “Initialization and Configuration” on page 628).

## Value Description

0 The associated pin functions as a GPIO and is controlled by the GPIO registers.

1 The associated pin functions as a peripheral signal and is controlled by the alternate hardware function.

The reset value for this register is 0x0000.0000 for GPIO ports that are not listed in Table 10-1 on page 622.

### Register 11: GPIO 2-mA Drive Select (GPIODR2R), offset 0x500

The **GPIODR2R** register is the 2-mA drive control register. Each GPIO signal in the port can be individually configured without affecting the other pads. When setting the **DRV2** bit for a GPIO signal, the corresponding **DRV4** bit in the **GPIODR4R** register and **DRV8** bit in the **GPIODR8R** register are automatically cleared by hardware. By default, all GPIO pins have 2-mA drive.

| Value | Description                                                                                                |
|-------|------------------------------------------------------------------------------------------------------------|
| 0     | The drive for the corresponding GPIO pin is controlled by the <b>GPIODR4R</b> or <b>GPIODR8R</b> register. |
| 1     | The corresponding GPIO pin has 2-mA drive.                                                                 |

Setting a bit in either the **GPIODR4** register or the **GPIODR8** register clears the corresponding 2-mA enable bit. The change is effective on the second clock cycle after the write if accessing GPIO via the APB memory aperture. If using AHB access, the change is effective on the next clock cycle.

## Register 12: GPIO 4-mA Drive Select (GPIODR4R), offset 0x504

The **GPIODR4R** register is the 4-mA drive control register. Each GPIO signal in the port can be individually configured without affecting the other pads. When setting the **DRV4** bit for a GPIO signal, the corresponding **DRV2** bit in the **GPIODR2R** register and **DRV8** bit in the **GPIODR8R** register are automatically cleared by hardware.

#### Value Description

- |   |                                                                                                            |
|---|------------------------------------------------------------------------------------------------------------|
| 0 | The drive for the corresponding GPIO pin is controlled by the <b>GPIODR2R</b> or <b>GPIODR8R</b> register. |
| 1 | The corresponding GPIO pin has 4-mA drive.                                                                 |

Setting a bit in either the **GPIODR2** register or the **GPIODR8** register clears the corresponding 4-mA enable bit. The change is effective on the second clock cycle after the write if accessing GPIO via the APB memory aperture. If using AHB access, the change is effective on the next clock cycle.

### Register 13: GPIO 8-mA Drive Select (GPIODR8R), offset 0x508

The **GPIODR8R** register is the 8-mA drive control register. Each GPIO signal in the port can be individually configured without affecting the other pads. When setting the **DRV8** bit for a GPIO signal, the corresponding **DRV2** bit in the **GPIODR2R** register and **DRV4** bit in the **GPIODR4R** register are automatically cleared by hardware. The 8-mA setting is also used for high-current operation.

**Note:** There is no configuration difference between 8-mA and high-current operation. The additional current capacity results from a shift in the  $V_{OH}/V_{OL}$  levels. See “Recommended Operating Conditions” on page 1162 for further information.

| Value | Description                                                                                                |
|-------|------------------------------------------------------------------------------------------------------------|
| 0     | The drive for the corresponding GPIO pin is controlled by the <b>GPIODR2R</b> or <b>GPIODR4R</b> register. |
| 1     | The corresponding GPIO pin has 8-mA drive.                                                                 |

Setting a bit in either the **GPIODR2** register or the **GPIODR4** register clears the corresponding 8-mA enable bit. The change is effective on the second clock cycle after the write if accessing GPIO via the APB memory aperture. If using AHB access, the change is effective on the next clock cycle.

## Register 14: GPIO Open Drain Select (GPIOODR), offset 0x50C

The **GPIOODR** register is the open drain control register. Setting a bit in this register enables the open-drain configuration of the corresponding GPIO pad. When open-drain mode is enabled, the corresponding bit should also be set in the **GPIO Digital Enable (GPIODEN)** register (see page 653). Corresponding bits in the drive strength and slew rate control registers (**GPIODR2R**, **GPIODR4R**, **GPIODR8R**, and **GPIOSLR**) can be set to achieve the desired fall times. The GPIO acts as an input if the corresponding bit in the **GPIODIR** register is cleared. If open drain is selected while the GPIO is configured as an input, the GPIO will remain an input and the open-drain selection has no effect until the GPIO is changed to an output.

When using the I<sup>2</sup>C module, in addition to configuring the data pin to open drain, the **GPIO Alternate Function Select (GPIOAFSEL)** register bits for the I<sup>2</sup>C clock and data pins should be set (see examples in “Initialization and Configuration” on page 628).

**Register 15: GPIO Pull-Up Select (GPIOPUR), offset 0x510**

The **GPIOPUR** register is the pull-up control register. When a bit is set, a weak pull-up resistor on the corresponding GPIO signal is enabled. Setting a bit in **GPIOPUR** automatically clears the corresponding bit in the **GPIO Pull-Down Select (GPIOPDR)** register (see page 650). Write access to this register is protected with the **GPIOCR** register. Bits in **GPIOCR** that are cleared prevent writes to the equivalent bit in this register.

**Important:** All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL**=0, **GPIODEN**=0, **GPIOPDR**=0, **GPIOPUR**=0, and **GPIOPCTL**=0), with the exception of the pins shown in the table below. A Power-On-Reset ( $\overline{POR}$ ) or asserting  $\overline{RST}$  puts the pins back to their default state.

**Table 10-8. GPIO Pins With Non-Zero Reset Values**

| GPIO Pins | Default State     | GPIOAFSEL | GPIODEN | GPIOPDR | GPIOPUR | GPIOPCTL |
|-----------|-------------------|-----------|---------|---------|---------|----------|
| PA[1:0]   | UART0             | 0         | 0       | 0       | 0       | 0x1      |
| PA[5:2]   | SSI0              | 0         | 0       | 0       | 0       | 0x2      |
| PB[3:2]   | I <sup>2</sup> C0 | 0         | 0       | 0       | 0       | 0x3      |
| PC[3:0]   | JTAG/SWD          | 1         | 1       | 0       | 1       | 0x1      |

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware signals including the GPIO pins that can function as JTAG/SWD signals and the **NMI** signal. The commit control process must be followed for these pins, even if they are programmed as alternate functions other than JTAG/SWD or **NMI**; see “Commit Control” on page 628.

**Note:** The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is provided for the GPIO pins that can be used as the four JTAG/SWD pins and the **NMI** pin (see “Signal Tables” on page 1138 for pin numbers). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 642), **GPIO Pull Up Select (GPIOPUR)** register (see page 648), **GPIO Pull-Down Select (GPIOPDR)** register (see page 650), and **GPIO Digital Enable (GPIODEN)** register (see page 653) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 655) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 656) have been set.

| 7:0       | PUE      | R/W  | -         | Pad Weak Pull-Up Enable                                                                                                                                                                       |

## Value Description

|   |                                                            |
|---|------------------------------------------------------------|
| 0 | The corresponding pin's weak pull-up resistor is disabled. |
| 1 | The corresponding pin's weak pull-up resistor is enabled.  |

Setting a bit in the **GPIOPDR** register clears the corresponding bit in the **GPIOPUR** register. The change is effective on the second clock cycle after the write if accessing GPIO via the APB memory aperture. If using AHB access, the change is effective on the next clock cycle.

The reset value for this register is 0x0000.0000 for GPIO ports that are not listed in Table 10-1 on page 622.

**Register 16: GPIO Pull-Down Select (GPIOPDR), offset 0x514**

The **GPIOPDR** register is the pull-down control register. When a bit is set, a weak pull-down resistor on the corresponding GPIO signal is enabled. Setting a bit in **GPIOPDR** automatically clears the corresponding bit in the **GPIO Pull-Up Select (GPIOPUR)** register (see page 648).

**Important:** All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL**=0, **GIODEN**=0, **GPIOPDR**=0, **GPIOPUR**=0, and **GPIOPCTL**=0), with the exception of the pins shown in the table below. A Power-On-Reset ( $\overline{POR}$ ) or asserting  $\overline{RST}$  puts the pins back to their default state.

**Table 10-9. GPIO Pins With Non-Zero Reset Values**

| GPIO Pins | Default State     | GPIOAFSEL | GIODEN | GPIOPDR | GPIOPUR | GPIOPCTL |
|-----------|-------------------|-----------|--------|---------|---------|----------|
| PA[1:0]   | UART0             | 0         | 0      | 0       | 0       | 0x1      |
| PA[5:2]   | SSI0              | 0         | 0      | 0       | 0       | 0x2      |
| PB[3:2]   | I <sup>2</sup> C0 | 0         | 0      | 0       | 0       | 0x3      |
| PC[3:0]   | JTAG/SWD          | 1         | 1      | 0       | 1       | 0x1      |

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware signals including the GPIO pins that can function as JTAG/SWD signals and the **NMI** signal. The commit control process must be followed for these pins, even if they are programmed as alternate functions other than JTAG/SWD or **NMI**; see “Commit Control” on page 628.

**Note:** The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is provided for the GPIO pins that can be used as the four JTAG/SWD pins and the **NMI** pin (see “Signal Tables” on page 1138 for pin numbers). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 642), **GPIO Pull Up Select (GPIOPUR)** register (see page 648), **GPIO Pull-Down Select (GPIOPDR)** register (see page 650), and **GPIO Digital Enable (GIODEN)** register (see page 653) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 655) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 656) have been set.

## Value Description

|   |                                                              |
|---|--------------------------------------------------------------|
| 0 | The corresponding pin's weak pull-down resistor is disabled. |
| 1 | The corresponding pin's weak pull-down resistor is enabled.  |

Setting a bit in the **GPIOPUR** register clears the corresponding bit in the **GPIOPDR** register. The change is effective on the second clock cycle after the write if accessing GPIO via the APB memory aperture. If using AHB access, the change is effective on the next clock cycle.

### Register 17: GPIO Slew Rate Control Select (GPIOSLR), offset 0x518

The **GPIOSLR** register is the slew rate control register. Slew rate control is only available when using the 8-mA drive strength option. The selection of drive strength is done through the **GPIO 8-mA Drive Select (GPIODR8R)** register.

#### GPIO Slew Rate Control Select (GPIOSLR)

**Register 18: GPIO Digital Enable (GPIODEN), offset 0x51C**

**Note:** Pins configured as digital inputs are Schmitt-triggered.

The **GPIODEN** register is the digital enable register. By default, all GPIO signals except those listed below are configured out of reset to be undriven (tristate). Their digital function is disabled; they do not drive a logic value on the pin and they do not allow the pin voltage into the GPIO receiver. To use the pin as a digital input or output (either GPIO or alternate function), the corresponding **GPIODEN** bit must be set.

**Important:** All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL**=0, **GPIODEN**=0, **GPIOPDR**=0, **GPIOPUR**=0, and **GPIOPCTL**=0), with the exception of the pins shown in the table below. A Power-On-Reset ( $\overline{POR}$ ) or asserting  $\overline{RST}$  puts the pins back to their default state.

**Table 10-10. GPIO Pins With Non-Zero Reset Values**

| GPIO Pins | Default State     | GPIOAFSEL | GPIODEN | GPIOPDR | GPIOPUR | GPIOPCTL |
|-----------|-------------------|-----------|---------|---------|---------|----------|
| PA[1:0]   | UART0             | 0         | 0       | 0       | 0       | 0x1      |
| PA[5:2]   | SSI0              | 0         | 0       | 0       | 0       | 0x2      |
| PB[3:2]   | I <sup>2</sup> C0 | 0         | 0       | 0       | 0       | 0x3      |
| PC[3:0]   | JTAG/SWD          | 1         | 1       | 0       | 1       | 0x1      |

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware signals including the GPIO pins that can function as JTAG/SWD signals and the **NMI** signal. The commit control process must be followed for these pins, even if they are programmed as alternate functions other than JTAG/SWD or **NMI**; see “Commit Control” on page 628.

**Note:** The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is provided for the GPIO pins that can be used as the four JTAG/SWD pins and the **NMI** pin (see “Signal Tables” on page 1138 for pin numbers). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 642), **GPIO Pull Up Select (GPIOPUR)** register (see page 648), **GPIO Pull-Down Select (GPIOPDR)** register (see page 650), and **GPIO Digital Enable (GPIODEN)** register (see page 653) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 655) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 656) have been set.

| 7:0       | DEN      | R/W  | -         | Digital Enable                                                                                                                                                                                |

| Value | Description                                                   |
|-------|---------------------------------------------------------------|
| 0     | The digital functions for the corresponding pin are disabled. |
| 1     | The digital functions for the corresponding pin are enabled.  |

The reset value for this register is 0x0000.0000 for GPIO ports that are not listed in Table 10-1 on page 622.

**Register 19: GPIO Lock (GPIOLOCK), offset 0x520**

The **GPIOLOCK** register enables write access to the **GPIOCR** register (see page 656). Writing 0x4C4F.434B to the **GPIOLOCK** register unlocks the **GPIOCR** register. Writing any other value to the **GPIOLOCK** register re-enables the locked state. Reading the **GPIOLOCK** register returns the lock status rather than the 32-bit value that was previously written. Therefore, when write accesses are disabled, or locked, reading the **GPIOLOCK** register returns 0x0000.0001. When write accesses are enabled, or unlocked, reading the **GPIOLOCK** register returns 0x0000.0000.

|-----------|------|------|-------------|-------------|
| 31:0      | LOCK | R/W  | 0x0000.0001 | GPIO Lock   |

A write of the value 0x4C4F.434B unlocks the **GPIO Commit (GPIOCR)** register for write access. A write of any other value or a write to the **GPIOCR** register reapplies the lock, preventing any register updates. A read of this register returns the following values:

**Value Description**

- 0x1 The **GPIOCR** register is locked and may not be modified.
- 0x0 The **GPIOCR** register is unlocked and may be modified.

### Register 20: GPIO Commit (GPIOCR), offset 0x524

The **GPIOCR** register is the commit register. The value of the **GPIOCR** register determines which bits of the **GPIOAFSEL**, **GPIOPUR**, **GPIOPDR**, and **GPIODEN** registers are committed when a write to these registers is performed. If a bit in the **GPIOCR** register is cleared, the data being written to the corresponding bit in the **GPIOAFSEL**, **GPIOPUR**, **GPIOPDR**, or **GPIODEN** registers cannot be committed and retains its previous value. If a bit in the **GPIOCR** register is set, the data being written to the corresponding bit of the **GPIOAFSEL**, **GPIOPUR**, **GPIOPDR**, or **GPIODEN** registers is committed to the register and reflects the new value.

The contents of the **GPIOCR** register can only be modified if the status in the **GPIOLOCK** register is unlocked. Writes to the **GPIOCR** register are ignored if the status in the **GPIOLOCK** register is locked.

**Important:** This register is designed to prevent accidental programming of the registers that control connectivity to the NMI and JTAG/SWD debug hardware. By initializing the bits of the **GPIOCR** register to 0 for the NMI and JTAG/SWD pins (see “Signal Tables” on page 1138 for pin numbers), the NMI and JTAG/SWD debug port can only be converted to GPIOs through a deliberate set of writes to the **GPIOLOCK**, **GPIOCR**, and the corresponding registers.

Because this protection is currently only implemented on the NMI and JTAG/SWD pins (see “Signal Tables” on page 1138 for pin numbers), all of the other bits in the **GPIOCR** registers cannot be written with 0x0. These bits are hardwired to 0x1, ensuring that it is always possible to commit new values to the **GPIOAFSEL**, **GPIOPUR**, **GPIOPDR**, or **GPIODEN** register bits of these other pins.

|           |      |      | 1            | The corresponding <b>GPIODEN</b> , <b>GPIOPUR</b> , <b>GPIOPDR</b> , or <b>GPIODEN</b> bits can be written.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|           |      |      | <b>Note:</b> | <p>The default register type for the <b>GPIOCR</b> register is RO for all GPIO pins with the exception of the <b>NMI</b> pin and the four JTAG/SWD pins (see “Signal Tables” on page 1138 for pin numbers). These six pins are the only GPIOs that are protected by the <b>GPIOCR</b> register. Because of this, the register type for the corresponding GPIO Ports is R/W.</p> <p>The default reset value for the <b>GPIOCR</b> register is 0x0000.00FF for all GPIO pins, with the exception of the <b>NMI</b> pin and the four JTAG/SWD pins (see “Signal Tables” on page 1138 for pin numbers). To ensure that the JTAG and <b>NMI</b> pins are not accidentally programmed as GPIO pins, these pins default to non-committable. Because of this, the default reset value of <b>GPIOCR</b> changes for the corresponding ports.</p> |

## Register 21: GPIO Analog Mode Select (GPIOAMSEL), offset 0x528

**Important:** This register is only valid for ports and pins that can be used as ADC AINx inputs.

If any pin is to be used as an ADC input, the appropriate bit in **GPIOAMSEL** must be set to disable the analog isolation circuit.

The **GPIOAMSEL** register controls isolation circuits to the analog side of a unified I/O pad. Because the GPIOs may be driven by a 5-V source and affect analog operation, analog circuitry requires isolation from the pins when they are not used in their analog function.

Each bit of this register controls the isolation circuitry for the corresponding GPIO signal. For information on which GPIO pins can be used for ADC functions, refer to Table 21-5 on page 1153.

**Value Description**

- 0 The analog function of the pin is disabled, the isolation is enabled, and the pin is capable of digital functions as specified by the other GPIO configuration registers.
- 1 The analog function of the pin is enabled, the isolation is disabled, and the pin is capable of analog functions.

**Note:** This register and bits are only valid for GPIO signals that share analog function through a unified I/O pad.

The reset state of this register is 0 for all signals.

**Register 22: GPIO Port Control (GPIOCTL), offset 0x52C**

The **GPIOCTL** register is used in conjunction with the **GPIOAFSEL** register and selects the specific peripheral signal for each GPIO pin when using the alternate function mode. Most bits in the **GPIOAFSEL** register are cleared on reset, therefore most GPIO pins are configured as GPIOs by default. When a bit is set in the **GPIOAFSEL** register, the corresponding GPIO signal is controlled by an associated peripheral. The **GPIOCTL** register selects one out of a set of peripheral functions for each GPIO, providing additional flexibility in signal definition. For information on the defined encodings for the bit fields in this register, refer to Table 21-5 on page 1153. The reset value for this register is 0x0000.0000 for GPIO ports that are not listed in the table below.

**Note:** If a particular input signal to a peripheral is assigned to two different GPIO port pins, the signal is assigned to the port with the lowest letter and the assignment to the higher letter port is ignored. If a particular output signal from a peripheral is assigned to two different GPIO port pins, the signal will output to both pins. Assigning an output signal from a peripheral to two different GPIO pins is not recommended.

**Important:** All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL**=0, **GPIODEN**=0, **GPIOPDR**=0, **GPIOPUR**=0, and **GPIOCTL**=0), with the exception of the pins shown in the table below. A Power-On-Reset ( $\overline{POR}$ ) or asserting  $\overline{RST}$  puts the pins back to their default state.

**Table 10-11. GPIO Pins With Non-Zero Reset Values**

| GPIO Pins | Default State     | GPIOAFSEL | GPIODEN | GPIOPDR | GPIOPUR | GPIOCTL |
|-----------|-------------------|-----------|---------|---------|---------|---------|
| PA[1:0]   | UART0             | 0         | 0       | 0       | 0       | 0x1     |
| PA[5:2]   | SSI0              | 0         | 0       | 0       | 0       | 0x2     |
| PB[3:2]   | I <sup>2</sup> C0 | 0         | 0       | 0       | 0       | 0x3     |
| PC[3:0]   | JTAG/SWD          | 1         | 1       | 0       | 1       | 0x1     |

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware signals including the GPIO pins that can function as JTAG/SWD signals and the **NMI** signal. The commit control process must be followed for these pins, even if they are programmed as alternate functions other than JTAG/SWD or **NMI**; see “Commit Control” on page 628.

**Register 23: GPIO ADC Control (GPIOADCCTL), offset 0x530**

This register is used to configure a GPIO pin as a source for the ADC trigger.

Note that if the Port B **GPIOADCCTL** register is cleared, PB4 can still be used as an external trigger for the ADC. This is a legacy mode which allows code written for previous devices to operate on this microcontroller.

# 11 General-Purpose Timers

Programmable timers can be used to count or time external events that drive the Timer input pins. The TM4C1233C3PM General-Purpose Timer Module (GPTM) contains six 16/32-bit GPTM blocks and six 32/64-bit Wide GPTM blocks. Each 16/32-bit GPTM block provides two 16-bit timers/counters (referred to as Timer A and Timer B) that can be configured to operate independently as timers or event counters, or concatenated to operate as one 32-bit timer or one 32-bit Real-Time Clock (RTC). Each 32/64-bit Wide GPTM block provides 32-bit timers for Timer A and Timer B that can be concatenated to operate as a 64-bit timer. Timers can also be used to trigger  $\mu$ DMA transfers.

In addition, timers can be used to trigger analog-to-digital conversions (ADC) when a time-out occurs in periodic and one-shot modes. The ADC trigger signals from all of the general-purpose timers are ORed together before reaching the ADC module, so only one timer should be used to trigger ADC events.

The GPT Module is one timing resource available on the Tiva™ C Series microcontrollers. Other timer resources include the System Timer (SysTick) (see 115).

The General-Purpose Timer Module (GPTM) contains six 16/32-bit GPTM blocks and six 32/64-bit Wide GPTM blocks with the following functional options:

- 16/32-bit operating modes:
  - 16- or 32-bit programmable one-shot timer
  - 16- or 32-bit programmable periodic timer
  - 16-bit general-purpose timer with an 8-bit prescaler
  - 32-bit Real-Time Clock (RTC) when using an external 32.768-KHz clock as the input
  - 16-bit input-edge count- or time-capture modes with an 8-bit prescaler
  - 16-bit PWM mode with an 8-bit prescaler and software-programmable output inversion of the PWM signal
- 32/64-bit operating modes:
  - 32- or 64-bit programmable one-shot timer
  - 32- or 64-bit programmable periodic timer
  - 32-bit general-purpose timer with a 16-bit prescaler
  - 64-bit Real-Time Clock (RTC) when using an external 32.768-KHz clock as the input
  - 32-bit input-edge count- or time-capture modes with a 16-bit prescaler
  - 32-bit PWM mode with a 16-bit prescaler and software-programmable output inversion of the PWM signal
- Count up or down
- Twelve 16/32-bit Capture Compare PWM pins (CCP)
- Twelve 32/64-bit Capture Compare PWM pins (CCP)

- Daisy chaining of timer modules to allow a single timer to initiate multiple timing events
- Timer synchronization allows selected timers to start counting on the same clock cycle
- ADC event trigger
- User-enabled stalling when the microcontroller asserts CPU Halt flag during debug (excluding RTC mode)
- Ability to determine the elapsed time between the assertion of the timer interrupt and entry into the interrupt service routine
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
  - Dedicated channel for each timer
  - Burst request generated on timer interrupt

## 11.1 Block Diagram

In the block diagram, the specific Capture Compare PWM (CCP) pins available depend on the TM4C1233C3PM device. See Table 11-1 on page 677 for the available CCP pins and their timer assignments.

Figure 11-1. GPTM Module Block Diagram

**Table 11-1. Available CCP Pins**

| Timer                  | Up/Down Counter | Even CCP Pin | Odd CCP Pin |
|------------------------|-----------------|--------------|-------------|
| 16/32-Bit Timer 0      | Timer A         | T0CCP0       | -           |
|                        | Timer B         | -            | T0CCP1      |

## 11.2 Signal Description

The following table lists the external signals of the GP Timer module and describes the function of each. The GP Timer signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these GP Timer signals. The **AFSEL** bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 642) should be set to choose the GP Timer function. The number in parentheses is the encoding that must be programmed into the **PMC<sub>n</sub>** field in the **GPIO Port Control (GPIOCTL)** register (page 659) to assign the GP Timer signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 621.

**Table 11-2. General-Purpose Timers Signals (64LQFP)**

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 11.3 Functional Description

The main components of each GPTM block are two free-running up/down counters (referred to as Timer A and Timer B), two prescaler registers, two match registers, two prescaler match registers, two shadow registers, and two load/initialization registers and their associated control functions.

The exact functionality of each GPTM is controlled by software and configured through the register interface. Timer A and Timer B can be used individually, in which case they have a 16-bit counting range for the 16/32-bit GPTM blocks and a 32-bit counting range for 32/64-bit Wide GPTM blocks. In addition, Timer A and Timer B can be concatenated to provide a 32-bit counting range for the 16/32-bit GPTM blocks and a 64-bit counting range for the 32/64-bit Wide GPTM blocks. Note that the prescaler can only be used when the timers are used individually.

The available modes for each GPTM block are shown in Table 11-3 on page 679. Note that when counting down in one-shot or periodic modes, the prescaler acts as a true prescaler and contains the least-significant bits of the count. When counting up in one-shot or periodic modes, the prescaler acts as a timer extension and holds the most-significant bits of the count. In input edge count, input edge time and PWM mode, the prescaler always acts as a timer extension, regardless of the count direction.

Table 11-3. General-Purpose Timer Capabilities

| Mode       | Timer Use    | Count Direction | Counter Size   |                     | Prescaler Size <sup>a</sup> |                     | Prescaler Behavior (Count Direction)   |
|------------|--------------|-----------------|----------------|---------------------|-----------------------------|---------------------|----------------------------------------|
|            |              |                 | 16/32-bit GPTM | 32/64-bit Wide GPTM | 16/32-bit GPTM              | 32/64-bit Wide GPTM |                                        |
| One-shot   | Individual   | Up or Down      | 16-bit         | 32-bit              | 8-bit                       | 16-bit              | Timer Extension (Up), Prescaler (Down) |
|            | Concatenated | Up or Down      | 32-bit         | 64-bit              | -                           | -                   | N/A                                    |
| Periodic   | Individual   | Up or Down      | 16-bit         | 32-bit              | 8-bit                       | 16-bit              | Timer Extension (Up), Prescaler (Down) |
|            | Concatenated | Up or Down      | 32-bit         | 64-bit              | -                           | -                   | N/A                                    |
| RTC        | Concatenated | Up              | 32-bit         | 64-bit              | -                           | -                   | N/A                                    |
| Edge Count | Individual   | Up or Down      | 16-bit         | 32-bit              | 8-bit                       | 16-bit              | Timer Extension (Both)                 |
| Edge Time  | Individual   | Up or Down      | 16-bit         | 32-bit              | 8-bit                       | 16-bit              | Timer Extension (Both)                 |
| PWM        | Individual   | Down            | 16-bit         | 32-bit              | 8-bit                       | 16-bit              | Timer Extension                        |

a. The prescaler is only available when the timers are used individually

Software configures the GPTM using the **GPTM Configuration (GPTMCFG)** register (see page 698), the **GPTM Timer A Mode (GPTMTAMR)** register (see page 700), and the **GPTM Timer B Mode (GPTMTBMR)** register (see page 704). When in one of the concatenated modes, Timer A and Timer B can only operate in one mode. However, when configured in an individual mode, Timer A and Timer B can be independently configured in any combination of the individual modes.

### 11.3.1 GPTM Reset Conditions

After reset has been applied to the GPTM module, the module is in an inactive state, and all control registers are cleared and in their default states. Counters Timer A and Timer B are initialized to all 1s, along with their corresponding registers:

- Load Registers:
  - **GPTM Timer A Interval Load (GPTMTAILR)** register (see page 727)
  - **GPTM Timer B Interval Load (GPTMTBILR)** register (see page 728)
- Shadow Registers:
  - **GPTM Timer A Value (GPTMTAV)** register (see page 737)
  - **GPTM Timer B Value (GPTMTBV)** register (see page 738)

The following prescale counters are initialized to all 0s:

- **GPTM Timer A Prescale (GPTMTAPR)** register (see page 731)
- **GPTM Timer B Prescale (GPTMTBPR)** register (see page 732)
- **GPTM Timer A Prescale Snapshot (GPTMTAPS)** register (see page 740)
- **GPTM Timer B Prescale Snapshot (GPTMTBPS)** register (see page 741)
- **GPTM Timer A Prescale Value (GPTMTAPV)** register (see page 742)

- **GPTM Timer B Prescale Value (GPTMTBPV)** register (see page 743)

### 11.3.2 Timer Modes

This section describes the operation of the various timer modes. When using Timer A and Timer B in concatenated mode, only the Timer A control and status bits must be used; there is no need to use Timer B control and status bits. The GPTM is placed into individual/split mode by writing a value of 0x4 to the **GPTM Configuration (GPTMCFG)** register (see page 698). In the following sections, the variable "n" is used in bit field and register names to imply either a Timer A function or a Timer B function. Throughout this section, the timeout event in down-count mode is 0x0 and in up-count mode is the value in the **GPTM Timer n Interval Load (GPTMTnILR)** and the optional **GPTM Timer n Prescale (GPTMTnPR)** registers.

#### 11.3.2.1 One-Shot/Periodic Timer Mode

The selection of one-shot or periodic mode is determined by the value written to the  $T_nMR$  field of the **GPTM Timer n Mode (GPTMTnMR)** register (see page 700). The timer is configured to count up or down using the  $T_nCDIR$  bit in the **GPTMTnMR** register.

When software sets the  $T_nEN$  bit in the **GPTM Control (GPTMCTL)** register (see page 708), the timer begins counting up from 0x0 or down from its preloaded value. Alternatively, if the  $T_nWOT$  bit is set in the **GPTMTnMR** register, once the  $T_nEN$  bit is set, the timer waits for a trigger to begin counting (see "Wait-for-Trigger Mode" on page 689). Table 11-4 on page 680 shows the values that are loaded into the timer registers when the timer is enabled.

**Table 11-4. Counter Values When the Timer is Enabled in Periodic or One-Shot Modes**

| Register        | Count Down Mode                                                                                                | Count Up Mode                                              |
|-----------------|----------------------------------------------------------------------------------------------------------------|------------------------------------------------------------|
| <b>GPTMTnR</b>  | <b>GPTMTnILR</b>                                                                                               | 0x0                                                        |
| <b>GPTMTnV</b>  | <b>GPTMTnILR</b> in concatenated mode; <b>GPTMTnPR</b> in combination with <b>GPTMTnILR</b> in individual mode | 0x0                                                        |
| <b>GPTMTnPS</b> | <b>GPTMTnPR</b> in individual mode; not available in concatenated mode                                         | 0x0 in individual mode; not available in concatenated mode |
| <b>GPTMTnPV</b> | <b>GPTMTnPR</b> in individual mode; not available in concatenated mode                                         | 0x0 in individual mode; not available in concatenated mode |

When the timer is counting down and it reaches the timeout event (0x0), the timer reloads its start value from the **GPTMTnILR** and the **GPTMTnPR** registers on the next cycle. When the timer is counting up and it reaches the timeout event (the value in the **GPTMTnILR** and the optional **GPTMTnPR** registers), the timer reloads with 0x0. If configured to be a one-shot timer, the timer stops counting and clears the  $T_nEN$  bit in the **GPTMCTL** register. If configured as a periodic timer, the timer starts counting again on the next cycle.

In periodic, snap-shot mode ( $T_nMR$  field is 0x2 and the  $T_nSNAPS$  bit is set in the **GPTMTnMR** register), the value of the timer at the time-out event is loaded into the **GPTMTnR** register and the value of the prescaler is loaded into the **GPTMTnPS** register. The free-running counter value is shown in the **GPTMTnV** register and the free-running prescaler value is shown in the **GPTMTnPV** register. In this manner, software can determine the time elapsed from the interrupt assertion to the ISR entry by examining the snapshot values and the current value of the free-running timer. Snapshot mode is not available when the timer is configured in one-shot mode.

In addition to reloading the count value, the GPTM generates interrupts and triggers when it reaches the time-out event. The GPTM sets the  $T_nTORIS$  bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register (see page 719), and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register (see page 725). If the time-out interrupt is enabled in the **GPTM Interrupt Mask (GPTMIMR)**

register (see page 716), the GPTM also sets the  $TnTOMIS$  bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register (see page 722). The time-out interrupt can be disabled entirely by setting the  $TnTACINTD$  bit in the **GPTM Timer n Mode (GPTMTnMR)** register. In this case, the  $TnTORIS$  bit does not even set in the **GPTMRIS** register.

By setting the  $TnMIE$  bit in the **GPTMTnMR** register, an interrupt condition can also be generated when the Timer value equals the value loaded into the **GPTM Timer n Match (GPTMTnMATCHR)** and **GPTM Timer n Prescale Match (GPTMTnPMR)** registers. This interrupt has the same status, masking, and clearing functions as the time-out interrupt, but uses the match interrupt bits instead (for example, the raw interrupt status is monitored via  $TnMRIS$  bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register). Note that the interrupt status bits are not updated by the hardware unless the  $TnMIE$  bit in the **GPTMTnMR** register is set, which is different than the behavior for the time-out interrupt. The ADC trigger is enabled by setting the  $TnNOTE$  bit in **GPTMCTL**. If the ADC trigger is enabled, only a one-shot or periodic time-out event can produce an ADC trigger assertion. The  $\mu$ DMA trigger is enabled by configuring and enabling the appropriate  $\mu$ DMA channel. See “Channel Configuration” on page 561.

If software updates the **GPTMTnILR** or the **GPTMTnPR** register while the counter is counting down, the counter loads the new value on the next clock cycle and continues counting from the new value if the  $TnILD$  bit in the **GPTMTnMR** register is clear. If the  $TnILD$  bit is set, the counter loads the new value after the next timeout. If software updates the **GPTMTnILR** or the **GPTMTnPR** register while the counter is counting up, the timeout event is changed on the next cycle to the new value. If software updates the **GPTM Timer n Value (GPTMTnV)** register while the counter is counting up or down, the counter loads the new value on the next clock cycle and continues counting from the new value. If software updates the **GPTMTnMATCHR** or the **GPTMTnPMR** registers, the new values are reflected on the next clock cycle if the  $TnMRSU$  bit in the **GPTMTnMR** register is clear. If the  $TnMRSU$  bit is set, the new value will not take effect until the next timeout.

When using a 32/64-bit wide timer block in a 64-bit mode, certain registers must be accessed in the manner described in “Accessing Concatenated 32/64-Bit Wide GPTM Register Values” on page 691.

If the  $TnSTALL$  bit in the **GPTMCTL** register is set and the  $RTCEN$  bit is not set in the **GPTMCTL** register, the timer freezes counting while the processor is halted by the debugger. The timer resumes counting when the processor resumes execution. If the  $RTCEN$  bit is set, it prevents the  $TnSTALL$  bit from freezing the count when the processor is halted by the debugger.

The following table shows a variety of configurations for a 16-bit free-running timer while using the prescaler. All values assume an 80-MHz clock with  $T_c=12.5$  ns (clock period). The prescaler can only be used when a 16/32-bit timer is configured in 16-bit mode and when a 32/64-bit timer is configured in 32-bit mode.

**Table 11-5. 16-Bit Timer With Prescaler Configurations**

| Prescale (8-bit value) | # of Timer Clocks ( $T_c$ ) <sup>a</sup> | Max Time | Units |
|------------------------|------------------------------------------|----------|-------|
| 00000000               | 1                                        | 0.8192   | ms    |
| 00000001               | 2                                        | 1.6384   | ms    |
| 00000010               | 3                                        | 2.4576   | ms    |
| -----                  | --                                       | --       | --    |
| 11111101               | 254                                      | 208.0768 | ms    |
| 11111110               | 255                                      | 208.896  | ms    |
| 11111111               | 256                                      | 209.7152 | ms    |

a.  $T_c$  is the clock period.

The following table shows a variety of configurations for a 32-bit free-running timer using the prescaler while configured in 32/64-bit mode. All values assume an 80-MHz clock with  $T_c=12.5$  ns (clock period).

**Table 11-6. 32-Bit Timer (configured in 32/64-bit mode) With Prescaler Configurations**

| Prescale (16-bit value) | # of Timer Clocks ( $T_c$ ) <sup>a</sup> | Max Time | Units             |
|-------------------------|------------------------------------------|----------|-------------------|
| 0x0000                  | 1                                        | 53.687   | s                 |
| 0x0001                  | 2                                        | 107.374  | s                 |
| 0x0002                  | 3                                        | 214.748  | s                 |
| -----                   | --                                       | --       | --                |
| 0xFFFFD                 | 65534                                    | 0.879    | 10 <sup>6</sup> s |
| 0xFFFFE                 | 65535                                    | 1.759    | 10 <sup>6</sup> s |
| 0xFFFFF                 | 65536                                    | 3.518    | 10 <sup>6</sup> s |

a.  $T_c$  is the clock period.

### 11.3.2.2 Real-Time Clock Timer Mode

In Real-Time Clock (RTC) mode, the concatenated versions of the Timer A and Timer B registers are configured as an up-counter. When RTC mode is selected for the first time after reset, the counter is loaded with a value of 0x1. All subsequent load values must be written to the **GPTM Timer n Interval Load (GPTMTnILR)** registers (see page 727). If the **GPTMTnILR** register is loaded with a new value, the counter begins counting at that value and rolls over at the fixed value of 0xFFFFFFFF. Table 11-7 on page 682 shows the values that are loaded into the timer registers when the timer is enabled.

**Table 11-7. Counter Values When the Timer is Enabled in RTC Mode**

| Register        | Count Down Mode | Count Up Mode |
|-----------------|-----------------|---------------|
| <b>GPTMTnR</b>  | Not available   | 0x1           |
| <b>GPTMTnV</b>  | Not available   | 0x1           |
| <b>GPTMTnPS</b> | Not available   | Not available |
| <b>GPTMTnPV</b> | Not available   | Not available |

The input clock on a CCP0 input is required to be 32.768 KHz in RTC mode. The clock signal is then divided down to a 1-Hz rate and is passed along to the input of the counter.

When software writes the **TAEN** bit in the **GPTMCTL** register, the counter starts counting up from its preloaded value of 0x1. When the current count value matches the preloaded value in the **GPTMTnMATCHR** registers, the GPTM asserts the **RTCRES** bit in **GPTMRIS** and continues counting until either a hardware reset, or it is disabled by software (clearing the **TAEN** bit). When the timer value reaches the terminal count, the timer rolls over and continues counting up from 0x0. If the RTC interrupt is enabled in **GPTMIMR**, the GPTM also sets the **RTCMIS** bit in **GPTMMIS** and generates a controller interrupt. The status flags are cleared by writing the **RTCCINT** bit in **GPTMICR**.

In this mode, the **GPTMTnR** and **GPTMTnV** registers always have the same value.

When using a 32/64-bit wide timer block in a RTC mode, certain registers must be accessed in the manner described in “Accessing Concatenated 32/64-Bit Wide GPTM Register Values” on page 691.

The value of the RTC predivider can be read in the **GPTM RTC Predivide (GPTMRTCPD)** register. To ensure that the RTC value is coherent, software should follow the process detailed in Figure 11-2 on page 683.

Figure 11-2. Reading the RTC Value

In addition to generating interrupts, the RTC can generate a  $\mu$ DMA trigger. The  $\mu$ DMA trigger is enabled by configuring and enabling the appropriate  $\mu$ DMA channel. See “Channel Configuration” on page 561.

### 11.3.2.3 Input Edge-Count Mode

**Note:** For rising-edge detection, the input signal must be High for at least two system clock periods following the rising edge. Similarly, for falling-edge detection, the input signal must be Low for at least two system clock periods following the falling edge. Based on this criteria, the maximum input frequency for edge detection is 1/4 of the system frequency.

In Edge-Count mode, the timer is configured as a 24-bit or 48-bit up- or up- or down-counter including the optional prescaler with the upper count value stored in the **GPTM Timer n Prescale (GPTMTnPR)** register and the lower bits in the **GPTMTnR** register. In this mode, the timer is capable of capturing three types of events: rising edge, falling edge, or both. To place the timer in Edge-Count mode, the **TnCMR** bit of the **GPTMTnMR** register must be cleared. The type of edge that the timer counts is determined by the **TnEVENT** fields of the **GPTMCTL** register. During initialization in down-count mode, the **GPTMTnMATCHR** and **GPTMTnPMR** registers are configured so that the difference between the value in the **GPTMTnILR** and **GPTMTnPR** registers and the **GPTMTnMATCHR** and **GPTMTnPMR** registers equals the number of edge events that must be counted. In up-count mode, the timer counts from 0x0 to the value in the **GPTMTnMATCHR** and **GPTMTnPMR** registers. Note that when executing an up-count, that the value of **GPTMTnPR** and **GPTMTnILR** must be greater

than the value of **GPTMTnPMR** and **GPTMTnMATCHR**. Table 11-8 on page 684 shows the values that are loaded into the timer registers when the timer is enabled.

**Table 11-8. Counter Values When the Timer is Enabled in Input Edge-Count Mode**

| Register        | Count Down Mode                                      | Count Up Mode |
|-----------------|------------------------------------------------------|---------------|
| <b>GPTMTnR</b>  | <b>GPTMTnPR</b> in combination with <b>GPTMTnILR</b> | 0x0           |
| <b>GPTMTnV</b>  | <b>GPTMTnPR</b> in combination with <b>GPTMTnILR</b> | 0x0           |
| <b>GPTMTnPS</b> | <b>GPTMTnPR</b>                                      | 0x0           |
| <b>GPTMTnPV</b> | <b>GPTMTnPR</b>                                      | 0x0           |

When software writes the **TnEN** bit in the **GPTM Control (GPTMCTL)** register, the timer is enabled for event capture. Each input event on the CCP pin decrements or increments the counter by 1 until the event count matches **GPTMTnMATCHR** and **GPTMTnPMR**. When the counts match, the GPTM asserts the **CnMRIS** bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register, and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register. If the capture mode match interrupt is enabled in the **GPTM Interrupt Mask (GPTMIMR)** register, the GPTM also sets the **CnMMIS** bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register. In this mode, the **GPTMTnR** and **GPTMTnPS** registers hold the count of the input events while the **GPTMTnV** and **GPTMTnPV** registers hold the free-running timer value and the free-running prescaler value. In up count mode, the current count of input events is held in both the **GPTMTnR** and **GPTMTnV** registers.

In addition to generating interrupts, a  $\mu$ DMA trigger can be generated. The  $\mu$ DMA trigger is enabled by configuring and enabling the appropriate  $\mu$ DMA channel. See “Channel Configuration” on page 561.

After the match value is reached in down-count mode, the counter is then reloaded using the value in **GPTMTnILR** and **GPTMTnPR** registers, and stopped because the GPTM automatically clears the **TnEN** bit in the **GPTMCTL** register. Once the event count has been reached, all further events are ignored until **TnEN** is re-enabled by software. In up-count mode, the timer is reloaded with 0x0 and continues counting.

Figure 11-3 on page 685 shows how Input Edge-Count mode works. In this case, the timer start value is set to **GPTMTnILR** = 0x000A and the match value is set to **GPTMTnMATCHR** = 0x0006 so that four edge events are counted. The counter is configured to detect both edges of the input signal.

Note that the last two edges are not counted because the timer automatically clears the **TnEN** bit after the current count matches the value in the **GPTMTnMATCHR** register.

**Figure 11-3. Input Edge-Count Mode Example, Counting Down**

#### 11.3.2.4 Input Edge-Time Mode

**Note:** For rising-edge detection, the input signal must be High for at least two system clock periods following the rising edge. Similarly, for falling edge detection, the input signal must be Low for at least two system clock periods following the falling edge. Based on this criteria, the maximum input frequency for edge detection is 1/4 of the system frequency.

In Edge-Time mode, the timer is configured as a 24-bit or 48-bit up- or down-counter including the optional prescaler with the upper timer value stored in the **GPTMTnPR** register and the lower bits in the **GPTMTnILR** register. In this mode, the timer is initialized to the value loaded in the **GPTMTnILR** and **GPTMTnPR** registers when counting down and 0x0 when counting up. The timer is capable of capturing three types of events: rising edge, falling edge, or both. The timer is placed into Edge-Time mode by setting the **TnCMR** bit in the **GPTMTnMR** register, and the type of event that the timer captures is determined by the **TnEVENT** fields of the **GPTMCTL** register. Table 11-9 on page 685 shows the values that are loaded into the timer registers when the timer is enabled.

**Table 11-9. Counter Values When the Timer is Enabled in Input Event-Count Mode**

| Register | Count Down Mode | Count Up Mode |
|----------|-----------------|---------------|
| TnR      | GPTMTnILR       | 0x0           |
| TnV      | GPTMTnILR       | 0x0           |
| TnPS     | GPTMTnPR        | 0x0           |
| TnPV     | GPTMTnPR        | 0x0           |

When software writes the **TnEN** bit in the **GPTMCTL** register, the timer is enabled for event capture. When the selected input event is detected, the current timer counter value is captured in the **GPTMTnR** and **GPTMTnPS** register and is available to be read by the microcontroller. The GPTM then asserts the **CnERIS** bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register, and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register. If the capture mode event interrupt is enabled in the **GPTM Interrupt Mask (GPTMIMR)** register, the GPTM also sets the **CnEMIS** bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register. In this mode, the

**GPTMTnR** and **GPTMTnPS** registers hold the time at which the selected input event occurred while the **GPTMTnV** and **GPTMTnPV** registers hold the free-running timer value and the free-running prescaler value. These registers can be read to determine the time that elapsed between the interrupt assertion and the entry into the ISR.

In addition to generating interrupts, a  $\mu$ DMA trigger can be generated. The  $\mu$ DMA trigger is enabled by configuring the appropriate  $\mu$ DMA channel. See “Channel Configuration” on page 561.

After an event has been captured, the timer does not stop counting. It continues to count until the **TnEN** bit is cleared. When the timer reaches the timeout value, it is reloaded with 0x0 in up-count mode and the value from the **GPTMTnILR** and **GPTMTnPR** registers in down-count mode.

Figure 11-4 on page 686 shows how input edge timing mode works. In the diagram, it is assumed that the start value of the timer is the default value of 0xFFFF, and the timer is configured to capture rising edge events.

Each time a rising edge event is detected, the current count value is loaded into the **GPTMTnR** and **GPTMTnPS** registers, and is held there until another rising edge is detected (at which point the new count value is loaded into the **GPTMTnR** and **GPTMTnPS** registers).

**Figure 11-4. 16-Bit Input Edge-Time Mode Example**

**Note:** When operating in Edge-time mode, the counter uses a modulo  $2^{24}$  count if prescaler is enabled or  $2^{16}$ , if not. If there is a possibility the edge could take longer than the count, then another timer configured in periodic-timer mode can be implemented to ensure detection of the missed edge. The periodic timer should be configured in such a way that:

- The periodic timer cycles at the same rate as the edge-time timer
- The periodic timer interrupt has a higher interrupt priority than the edge-time timeout interrupt.
- If the periodic timer interrupt service routine is entered, software must check if an edge-time interrupt is pending and if it is, the value of the counter must be subtracted by 1 before being used to calculate the snapshot time of the event.

### 11.3.2.5 PWM Mode

The GPTM supports a simple PWM generation mode. In PWM mode, the timer is configured as a 24-bit or 48-bit down-counter with a start value (and thus period) defined by the **GPTMTnILR** and **GPTMTnPR** registers. In this mode, the PWM frequency and period are synchronous events and therefore guaranteed to be glitch free. PWM mode is enabled with the **GPTMTnMR** register by setting the **TnAMS** bit to 0x1, the **TnCMR** bit to 0x0, and the **TnMR** field to 0x2. Table 11-10 on page 687 shows the values that are loaded into the timer registers when the timer is enabled.

**Table 11-10. Counter Values When the Timer is Enabled in PWM Mode**

| Register        | Count Down Mode  | Count Up Mode |
|-----------------|------------------|---------------|
| <b>GPTMTnR</b>  | <b>GPTMTnILR</b> | Not available |
| <b>GPTMTnV</b>  | <b>GPTMTnILR</b> | Not available |
| <b>GPTMTnPS</b> | <b>GPTMTnPR</b>  | Not available |
| <b>GPTMTnPV</b> | <b>GPTMTnPR</b>  | Not available |

When software writes the **TnEN** bit in the **GPTMCTL** register, the counter begins counting down until it reaches the 0x0 state. Alternatively, if the **TnWOT** bit is set in the **GPTMTnMR** register, once the **TnEN** bit is set, the timer waits for a trigger to begin counting (see “Wait-for-Trigger Mode” on page 689). On the next counter cycle in periodic mode, the counter reloads its start value from the **GPTMTnILR** and **GPTMTnPR** registers and continues counting until disabled by software clearing the **TnEN** bit in the **GPTMCTL** register. The timer is capable of generating interrupts based on three types of events: rising edge, falling edge, or both. The event is configured by the **TnEVENT** field of the **GPTMCTL** register, and the interrupt is enabled by setting the **TnPWMIE** bit in the **GPTMTnMR** register. When the event occurs, the **ChERIS** bit is set in the **GPTM Raw Interrupt Status (GPTMRIS)** register, and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register. If the capture mode event interrupt is enabled in the **GPTM Interrupt Mask (GPTMIMR)** register, the GPTM also sets the **ChEMIS** bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register. Note that the interrupt status bits are not updated unless the **TnPWMIE** bit is set.

In this mode, the **GPTMTnR** and **GPTMTnV** registers always have the same value, as do the **GPTMPnPS** and the **GPTMTnPV** registers.

The output PWM signal asserts when the counter is at the value of the **GPTMTnILR** and **GPTMTnPR** registers (its start state), and is deasserted when the counter value equals the value in the **GPTMTnMATCHR** and **GPTMTnPMR** registers. Software has the capability of inverting the output PWM signal by setting the **TnPWML** bit in the **GPTMCTL** register.

**Note:** If PWM output inversion is enabled, edge detection interrupt behavior is reversed. Thus, if a positive-edge interrupt trigger has been set and the PWM inversion generates a positive edge, no event-trigger interrupt asserts. Instead, the interrupt is generated on the negative edge of the PWM signal.

Figure 11-5 on page 688 shows how to generate an output PWM with a 1-ms period and a 66% duty cycle assuming a 50-MHz input clock and **TnPWML** = 0 (duty cycle would be 33% for the **TnPWML** = 1 configuration). For this example, the start value is **GPTMTnILR**=0xC350 and the match value is **GPTMTnMATCHR**=0x411A.

Figure 11-5. 16-Bit PWM Mode Example

When synchronizing the timers using the **GPTMSYNC** register, the timer must be properly configured to avoid glitches on the CCP outputs. Both the **PLO** and the **MRSU** bits must be set in the **GPTMTnMR** register. Figure 11-6 on page 688 shows how the CCP output operates when the **PLO** and **MRSU** bits are set and the **GPTMTnMATCHR** value is greater than the **GPTMTnILR** value.

Figure 11-6. CCP Output, GPTMTnMATCHR > GPTMTnILR

Figure 11-7 on page 689 shows how the CCP output operates when the **PLO** and **MRSU** bits are set and the **GPTMTnMATCHR** value is the same as the **GPTMTnILR** value. In this situation, if the **PLO** bit is 0, the CCP signal goes high when the **GPTMTnILR** value is loaded and the match would be essentially ignored.

**Figure 11-7. CCP Output, GPTMTnMATCHR = GPTMTnILR**

Figure 11-8 on page 689 shows how the CCP output operates when the `PLO` and `MRSU` bits are set and the `GPTMTnILR` is greater than the `GPTMTnMATCHR` value.

**Figure 11-8. CCP Output, GPTMTnILR > GPTMTnMATCHR**

### 11.3.3 Wait-for-Trigger Mode

The Wait-for-Trigger mode allows daisy chaining of the timer modules such that once configured, a single timer can initiate multiple timing events using the Timer triggers. Wait-for-Trigger mode is enabled by setting the `TnWOT` bit in the `GPTMTnMR` register. When the `TnWOT` bit is set, Timer N+1 does not begin counting until the timer in the previous position in the daisy chain (Timer N) reaches its time-out event. The daisy chain is configured such that GPTM1 always follows GPTM0, GPTM2 follows GPTM1, and so on. If Timer A is configured as a 32-bit (16/32-bit mode) or 64-bit (32/64-bit wide mode) timer (controlled by the `GPTMCFG` field in the `GPTMCFG` register), it triggers Timer A in the next module. If Timer A is configured as a 16-bit (16/32-bit mode) or 32-bit (32/64-bit wide mode) timer, it triggers Timer B in the same module, and Timer B triggers Timer A in the next module. Care must be taken that the `TAWOT` bit is never set in GPTM0. Figure 11-9 on page 690 shows how the `GPTMCFG` bit affects the daisy chain. This function is valid for one-shot, periodic, and PWM modes.

Figure 11-9. Timer Daisy Chain

### 11.3.4 Synchronizing GP Timer Blocks

The **GPTM Synchronizer Control (GPTMSYNC)** register in the GPTM0 block can be used to synchronize selected timers to begin counting at the same time. Setting a bit in the **GPTMSYNC** register causes the associated timer to perform the actions of a timeout event. An interrupt is not generated when the timers are synchronized. If a timer is being used in concatenated mode, only the bit for Timer A must be set in the **GPTMSYNC** register.

**Note:** All timers must use the same clock source for this feature to work correctly.

Table 11-11 on page 690 shows the actions for the timeout event performed when the timers are synchronized in the various timer modes.

Table 11-11. Timeout Actions for GPTM Modes

| Mode                                                | Count Dir | Time Out Action   |
|-----------------------------------------------------|-----------|-------------------|
| 32- and 64-bit One-Shot (concatenated timers)       | —         | N/A               |
| 32- and 64-bit Periodic (concatenated timers)       | Down      | Count value = ILR |
|                                                     | Up        | Count value = 0   |
| 32- and 64-bit RTC (concatenated timers)            | Up        | Count value = 0   |
| 16- and 32-bit One Shot (individual/split timers)   | —         | N/A               |
| 16- and 32-bit Periodic (individual/split timers)   | Down      | Count value = ILR |
|                                                     | Up        | Count value = 0   |
| 16- and 32-bit Edge-Count (individual/split timers) | Down      | Count value = ILR |
|                                                     | Up        | Count value = 0   |
| 16- and 32-bit Edge-Time (individual/split timers)  | Down      | Count value = ILR |
|                                                     | Up        | Count value = 0   |
| 16- and 32-bit PWM                                  | Down      | Count value = ILR |

### 11.3.5 DMA Operation

The timers each have a dedicated  $\mu$ DMA channel and can provide a request signal to the  $\mu$ DMA controller. The request is a burst type and occurs whenever a timer raw interrupt condition occurs.

The arbitration size of the  $\mu$ DMA transfer should be set to the amount of data that should be transferred whenever a timer event occurs.

For example, to transfer 256 items, 8 items at a time every 10 ms, configure a timer to generate a periodic timeout at 10 ms. Configure the  $\mu$ DMA transfer for a total of 256 items, with a burst size of 8 items. Each time the timer times out, the  $\mu$ DMA controller transfers 8 items, until all 256 items have been transferred.

No other special steps are needed to enable Timers for  $\mu$ DMA operation. Refer to “Micro Direct Memory Access ( $\mu$ DMA)” on page 557 for more details about programming the  $\mu$ DMA controller.

### 11.3.6 Accessing Concatenated 16/32-Bit GPTM Register Values

The GPTM is placed into concatenated mode by writing a 0x0 or a 0x1 to the `GPTMCFG` bit field in the **GPTM Configuration (GPTMCFG)** register. In both configurations, certain 16/32-bit GPTM registers are concatenated to form pseudo 32-bit registers. These registers include:

- **GPTM Timer A Interval Load (GPTMTAILR)** register [15:0], see page 727
- **GPTM Timer B Interval Load (GPTMTBILR)** register [15:0], see page 728
- **GPTM Timer A (GPTMTAR)** register [15:0], see page 735
- **GPTM Timer B (GPTMTBR)** register [15:0], see page 736
- **GPTM Timer A Value (GPTMTAV)** register [15:0], see page 737
- **GPTM Timer B Value (GPTMTBV)** register [15:0], see page 738
- **GPTM Timer A Match (GPTMTAMATCHR)** register [15:0], see page 729
- **GPTM Timer B Match (GPTMTBMATCHR)** register [15:0], see page 730

In the 32-bit modes, the GPTM translates a 32-bit write access to **GPTMTAILR** into a write access to both **GPTMTAILR** and **GPTMTBILR**. The resulting word ordering for such a write operation is:

```
GPTMTBILR[15:0]:GPTMTAILR[15:0]
```

Likewise, a 32-bit read access to **GPTMTAR** returns the value:

```
GPTMTBR[15:0]:GPTMTAR[15:0]
```

A 32-bit read access to **GPTMTAV** returns the value:

```
GPTMTBV[15:0]:GPTMTAV[15:0]
```

### 11.3.7 Accessing Concatenated 32/64-Bit Wide GPTM Register Values

On the 32/64-bit wide GPTM blocks, concatenated register values (64-bits and 48-bits) are not readily available as the bit width for these accesses is greater than the bus width of the processor core. In the concatenated timer modes and the individual timer modes when using the prescaler, software must perform atomic accesses for the value to be coherent. When reading timer values that are greater than 32 bits, software should follow these steps:

1. Read the appropriate Timer B register or prescaler register.
2. Read the corresponding Timer A register.

3. Re-read the Timer B register or prescaler register.
4. Compare the Timer B or prescaler values from the first and second reads. If they are the same, the timer value is coherent. If they are not the same, repeat steps 1-4 once more so that they are the same.

The following pseudo code illustrates this process:

```
high = timer_high;

low = timer_low;

if (high != timer_high); //low overflowed into high
{
    high = timer_high;
    low = timer_low;
}
```

The registers that must be read in this manner are shown below:

- 64-bit reads
  - **GPTMTAV** and **GPTMTBV**
  - **GPTMTAR** and **GPTMTBR**
- 48-bit reads
  - **GPTMTAR** and **GPTMTAPS**
  - **GPTMTBR** and **GPTMTBPS**
  - **GPTMTAV** and **GPTMTAPV**
  - **GPTMTBV** and **GPTMTBPV**

Similarly, write accesses must also be performed by writing the upper bits prior to writing the lower bits as follows:

1. Write the appropriate Timer B register or prescaler register.
2. Write the corresponding Timer A register.

The registers that must be written in this manner are shown below:

- 64-bit writes
  - **GPTMTAV** and **GPTMTBV**
  - **GPTMTAMATCHR** and **GPTMTBMATCHR**
  - **GPTMTAILR** and **GPTMTBILR**

- 48-bit writes
  - **GPTMTAV** and **GPTMTAPV**
  - **GPTMTBV** and **GPTMTBPV**
  - **GPTMTAMATCHR** and **GPTMTAPMR**
  - **GPTMTBMATCHR** and **GPTMTBPMR**
  - **GPTMTAILR** and **GPTMTAPR**
  - **GPTMTBILR** and **GPTMTBPR**

When writing a 64-bit value, if there are two consecutive writes to any of the registers listed above under the "64-bit writes" heading, whether the register is in Timer A or Timer B, or if a register in Timer A is written prior to writing the corresponding register in Timer B, then an error is reported using the **WUERRIS** bit in the **GPTMRIS** register. This error can be promoted to interrupt if it is not masked. Note that this error is not reported for the prescaler registers because use of the prescaler is optional. As a result, programmers must take care to follow the protocol outlined above.

## 11.4 Initialization and Configuration

To use a GPTM, the appropriate **TIMERN** bit must be set in the **RCGCTIMER** or **RCGCWTIMER** register (see page 324 and page 341). If using any CCP pins, the clock to the appropriate GPIO module must be enabled via the **RCGCGPIO** register (see page 326). To find out which GPIO port to enable, refer to Table 21-4 on page 1149. Configure the **PMCn** fields in the **GPIOPCTL** register to assign the CCP signals to the appropriate pins (see page 659 and Table 21-5 on page 1153).

This section shows module initialization and configuration examples for each of the supported timer modes.

### 11.4.1 One-Shot/Periodic Timer Mode

The GPTM is configured for One-Shot and Periodic modes by the following sequence:

1. Ensure the timer is disabled (the **TnEN** bit in the **GPTMCTL** register is cleared) before making any changes.
2. Write the **GPTM Configuration Register (GPTMCFG)** with a value of 0x0000.0000.
3. Configure the **TnMR** field in the **GPTM Timer n Mode Register (GPTMTnMR)**:
  - a. Write a value of 0x1 for One-Shot mode.
  - b. Write a value of 0x2 for Periodic mode.
4. Optionally configure the **TnSNAPS**, **TnWOT**, **TnMTE**, and **TnCDIR** bits in the **GPTMTnMR** register to select whether to capture the value of the free-running timer at time-out, use an external trigger to start counting, configure an additional trigger or interrupt, and count up or down.
5. Load the start value into the **GPTM Timer n Interval Load Register (GPTMTnILR)**.
6. If interrupts are required, set the appropriate bits in the **GPTM Interrupt Mask Register (GPTMIMR)**.

7. Set the `TnEN` bit in the **GPTMCTL** register to enable the timer and start counting.
8. Poll the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the appropriate bit of the **GPTM Interrupt Clear Register (GPTMICR)**.

If the `TnMIE` bit in the **GPTMTnMR** register is set, the `RTCRES` bit in the **GPTMRIS** register is set, and the timer continues counting. In One-Shot mode, the timer stops counting after the time-out event. To re-enable the timer, repeat the sequence. A timer configured in Periodic mode reloads the timer and continues counting after the time-out event.

### 11.4.2 Real-Time Clock (RTC) Mode

To use the RTC mode, the timer must have a 32.768-KHz input signal on an even CCP input. To enable the RTC feature, follow these steps:

1. Ensure the timer is disabled (the `TAEN` bit is cleared) before making any changes.
2. If the timer has been operating in a different mode prior to this, clear any residual set bits in the **GPTM Timer n Mode (GPTMTnMR)** register before reconfiguring.
3. Write the **GPTM Configuration Register (GPTMCFG)** with a value of 0x0000.0001.
4. Write the match value to the **GPTM Timer n Match Register (GPTMTnMATCHR)**.
5. Set/clear the `RTCEN` and `TnSTALL` bit in the **GPTM Control Register (GPTMCTL)** as needed.
6. If interrupts are required, set the `RTCIM` bit in the **GPTM Interrupt Mask Register (GPTMIMR)**.
7. Set the `TAEN` bit in the **GPTMCTL** register to enable the timer and start counting.

When the timer count equals the value in the **GPTMTnMATCHR** register, the GPTM asserts the `RTCRES` bit in the **GPTMRIS** register and continues counting until Timer A is disabled or a hardware reset. The interrupt is cleared by writing the `RTCCINT` bit in the **GPTMICR** register. Note that if the **GPTMTnILR** register is loaded with a new value, the timer begins counting at this new value and continues until it reaches 0xFFFF.FFFF, at which point it rolls over.

### 11.4.3 Input Edge-Count Mode

A timer is configured to Input Edge-Count mode by the following sequence:

1. Ensure the timer is disabled (the `TnEN` bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x0000.0004.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, write the `TnCMR` field to 0x0 and the `TnMR` field to 0x3.
4. Configure the type of event(s) that the timer captures by writing the `TnEVENT` field of the **GPTM Control (GPTMCTL)** register.
5. If a prescaler is to be used, write the prescale value to the **GPTM Timer n Prescale Register (GPTMTnPR)**.
6. Load the timer start value into the **GPTM Timer n Interval Load (GPTMTnILR)** register.

7. Load the prescaler match value (if any) in the **GPTM Timer n Prescale Match (GPTMTnPMR)** register.
8. Load the event count into the **GPTM Timer n Match (GPTMTnMATCHR)** register. Note that when executing an up-count, the value of **GPTMTnPR** and **GPTMTnILR** must be greater than the value of **GPTMTnPMR** and **GPTMTnMATCHR**.
9. If interrupts are required, set the **CnMIM** bit in the **GPTM Interrupt Mask (GPTMIMR)** register.
10. Set the **TnEN** bit in the **GPTMCTL** register to enable the timer and begin waiting for edge events.
11. Poll the **CnMRIS** bit in the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the **CnMCINT** bit of the **GPTM Interrupt Clear (GPTMICR)** register.

When counting down in Input Edge-Count Mode, the timer stops after the programmed number of edge events has been detected. To re-enable the timer, ensure that the **TnEN** bit is cleared and repeat #4 on page 694 through #9 on page 695.

#### 11.4.4 Input Edge Timing Mode

A timer is configured to Input Edge Timing mode by the following sequence:

1. Ensure the timer is disabled (the **TnEN** bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x0000.0004.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, write the **TnCMR** field to 0x1 and the **TnMR** field to 0x3.
4. Configure the type of event that the timer captures by writing the **TnEVENT** field of the **GPTM Control (GPTMCTL)** register.
5. If a prescaler is to be used, write the prescale value to the **GPTM Timer n Prescale Register (GPTMTnPR)**.
6. Load the timer start value into the **GPTM Timer n Interval Load (GPTMTnILR)** register.
7. If interrupts are required, set the **CnEIM** bit in the **GPTM Interrupt Mask (GPTMIMR)** register.
8. Set the **TnEN** bit in the **GPTM Control (GPTMCTL)** register to enable the timer and start counting.
9. Poll the **CnERIS** bit in the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the **CnECINT** bit of the **GPTM Interrupt Clear (GPTMICR)** register. The time at which the event happened can be obtained by reading the **GPTM Timer n (GPTMTnR)** register.

In Input Edge Timing mode, the timer continues running after an edge event has been detected, but the timer interval can be changed at any time by writing the **GPTMTnILR** register. The change takes effect at the next cycle after the write.

#### 11.4.5 PWM Mode

A timer is configured to PWM mode using the following sequence:

1. Ensure the timer is disabled (the **TnEN** bit is cleared) before making any changes.

2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x0000.0004.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, set the  $TnAMS$  bit to 0x1, the  $TnCMR$  bit to 0x0, and the  $TnMR$  field to 0x2.
4. Configure the output state of the PWM signal (whether or not it is inverted) in the  $TnPWML$  field of the **GPTM Control (GPTMCTL)** register.
5. If a prescaler is to be used, write the prescale value to the **GPTM Timer n Prescale Register (GPTMTnPR)**.
6. If PWM interrupts are used, configure the interrupt condition in the  $TnEVENT$  field in the **GPTMCTL** register and enable the interrupts by setting the  $TnPWMIE$  bit in the **GPTMTnMR** register. Note that edge detect interrupt behavior is reversed when the PWM output is inverted (see page 708).
7. Load the timer start value into the **GPTM Timer n Interval Load (GPTMTnILR)** register.
8. Load the **GPTM Timer n Match (GPTMTnMATCHR)** register with the match value.
9. Set the  $TnEN$  bit in the **GPTM Control (GPTMCTL)** register to enable the timer and begin generation of the output PWM signal.

In PWM Timing mode, the timer continues running after the PWM signal has been generated. The PWM period can be adjusted at any time by writing the **GPTMTnILR** register, and the change takes effect at the next cycle after the write.

## 11.5 Register Map

Table 11-12 on page 697 lists the GPTM registers. The offset listed is a hexadecimal increment to the register's address, relative to that timer's base address:

- 16/32-bit Timer 0: 0x4003.0000
- 16/32-bit Timer 1: 0x4003.1000
- 16/32-bit Timer 2: 0x4003.2000
- 16/32-bit Timer 3: 0x4003.3000
- 16/32-bit Timer 4: 0x4003.4000
- 16/32-bit Timer 5: 0x4003.5000
- 32/64-bit Wide Timer 0: 0x4003.6000
- 32/64-bit Wide Timer 1: 0x4003.7000
- 32/64-bit Wide Timer 2: 0x4004.C000
- 32/64-bit Wide Timer 3: 0x4004.D000
- 32/64-bit Wide Timer 4: 0x4004.E000
- 32/64-bit Wide Timer 5: 0x4004.F000

The  $SIZE$  field in the **GPTM Peripheral Properties (GPTMPP)** register identifies whether a module has a 16/32-bit or 32/64-bit wide timer.

Note that the GP Timer module clock must be enabled before the registers can be programmed (see page 324 or page 341). There must be a delay of 3 system clocks after the Timer module clock is enabled before any Timer module registers are accessed.

Table 11-12. Timers Register Map

| Offset | Name         | Type | Reset       | Description                    | See page |
|--------|--------------|------|-------------|--------------------------------|----------|
| 0x000  | GPTMCFG      | R/W  | 0x0000.0000 | GPTM Configuration             | 698      |

## 11.6 Register Descriptions

The remainder of this section lists and describes the GPTM registers, in numerical order by address offset.

### Register 1: GPTM Configuration (GPTMCFG), offset 0x000

This register configures the global operation of the GPTM module. The value written to this register determines whether the GPTM is in 32- or 64-bit mode (concatenated timers) or in 16- or 32-bit mode (individual, split timers).

**Important:** Bits in this register should only be changed when the TAEN and TBEN bits in the GPTMCTL register are cleared.

#### GPTM Configuration (GPTMCFG)

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000  
 16/32-bit Timer 2 base: 0x4003.2000

## Register 2: GPTM Timer A Mode (GPTMTAMR), offset 0x004

This register configures the GPTM based on the configuration selected in the **GPTMCFG** register. When in PWM mode, set the **TAAMS** bit, clear the **TACMR** bit, and configure the **TAMR** field to 0x1 or 0x2.

This register controls the modes for Timer A when it is used individually. When Timer A and Timer B are concatenated, this register controls the modes for both Timer A and Timer B, and the contents of **GPTMTBMR** are ignored.

**Important:** Bits in this register should only be changed when the **TAEN** bit in the **GPTMCTL** register is cleared.

### GPTM Timer A Mode (GPTMTAMR)

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000  
 16/32-bit Timer 2 base: 0x4003.2000  
 16/32-bit Timer 3 base: 0x4003.3000  
 16/32-bit Timer 4 base: 0x4003.4000  
 16/32-bit Timer 5 base: 0x4003.5000  
 32/64-bit Wide Timer 0 base: 0x4003.6000  
 32/64-bit Wide Timer 1 base: 0x4003.7000  
 32/64-bit Wide Timer 2 base: 0x4004.C000  
 32/64-bit Wide Timer 3 base: 0x4004.D000  
 32/64-bit Wide Timer 4 base: 0x4004.E000  
 32/64-bit Wide Timer 5 base: 0x4004.F000  
 Offset 0x004  
 Type R/W, reset 0x0000.0000

### Register 3: GPTM Timer B Mode (GPTMTBMR), offset 0x008

This register configures the GPTM based on the configuration selected in the **GPTMCFG** register. When in PWM mode, set the **TBAMS** bit, clear the **TBCMR** bit, and configure the **TBMR** field to 0x1 or 0x2.

This register controls the modes for Timer B when it is used individually. When Timer A and Timer B are concatenated, this register is ignored and **GPTMTAMR** controls the modes for both Timer A and Timer B.

**Important:** Bits in this register should only be changed when the **TBEN** bit in the **GPTMCTL** register is cleared.

#### GPTM Timer B Mode (GPTMTBMR)

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000  
 16/32-bit Timer 2 base: 0x4003.2000

### Register 4: GPTM Control (GPTMCTL), offset 0x00C

This register is used alongside the **GPTMCFG** and **GMTMTnMR** registers to fine-tune the timer configuration, and to enable other features such as timer stall and the output trigger. The output trigger can be used to initiate transfers on the ADC module.

**Important:** Bits in this register should only be changed when the **TnEN** bit for the respective timer is cleared.

#### GPTM Control (GPTMCTL)

Thus, if a positive-edge interrupt trigger has been set and the PWM inversion generates a positive edge, no event-trigger interrupt asserts. Instead, the interrupt is generated on the negative edge of the PWM signal.</p>                      | Value | Description | 0x0 | Positive edge                                                             | 0x1 | Negative edge                                                                                                | 0x2 | Reserved | 0x3 | Both edges |

### Register 5: GPTM Synchronize (GPTMSYNC), offset 0x010

**Note:** This register is only implemented on GPTM Module 0 only.

This register allows software to synchronize a number of timers.

#### GPTM Synchronize (GPTMSYNC)

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000  
 16/32-bit Timer 2 base: 0x4003.2000  
 16/32-bit Timer 3 base: 0x4003.3000  
 16/32-bit Timer 4 base: 0x4003.4000  
 16/32-bit Timer 5 base: 0x4003.5000  
 32/64-bit Wide Timer 0 base: 0x4003.6000  
 32/64-bit Wide Timer 1 base: 0x4003.7000  
 32/64-bit Wide Timer 2 base: 0x4004.C000  
 32/64-bit Wide Timer 3 base: 0x4004.D000  
 32/64-bit Wide Timer 4 base: 0x4004.E000  
 32/64-bit Wide Timer 5 base: 0x4004.F000  
 Offset 0x010  
 Type R/W, reset 0x0000.0000

## Register 6: GPTM Interrupt Mask (GPTMIMR), offset 0x018

This register allows software to enable/disable GPTM controller-level interrupts. Setting a bit enables the corresponding interrupt, while clearing a bit disables it.

### GPTM Interrupt Mask (GPTMIMR)

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000  
 16/32-bit Timer 2 base: 0x4003.2000  
 16/32-bit Timer 3 base: 0x4003.3000  
 16/32-bit Timer 4 base: 0x4003.4000

## Register 7: GPTM Raw Interrupt Status (GPTMRIS), offset 0x01C

This register shows the state of the GPTM's internal interrupt signal. These bits are set whether or not the interrupt is masked in the **GPTMIMR** register. Each bit can be cleared by writing a 1 to its corresponding bit in **GPTMICR**.

**Note:** The state of the **GPTMRIS** register is not affected by disabling and then re-enabling the timer using the **TnEN** bits in the **GPTM Control (GPTMCTL)** register. If an application requires that all or certain status bits should not carry over after re-enabling the timer, then the appropriate bits in the **GPTMRIS** register should be cleared using the **GPTMICR** register prior to re-enabling the timer. If this is not done, any status bits set in the **GPTMRIS** register and unmasked in the **GPTMIMR** register generate an interrupt once the timer is re-enabled.

### GPTM Raw Interrupt Status (GPTMRIS)

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000

### Register 8: GPTM Masked Interrupt Status (GPTMMIS), offset 0x020

This register show the state of the GPTM's controller-level interrupt. If an interrupt is unmasked in **GPTMIMR**, and there is an event that causes the interrupt to be asserted, the corresponding bit is set in this register. All bits are cleared by writing a 1 to the corresponding bit in **GPTMICR**.

## Register 9: GPTM Interrupt Clear (GPTMICR), offset 0x024

This register is used to clear the status bits in the **GPTMRIS** and **GPTMMIS** registers. Writing a 1 to a bit clears the corresponding bit in the **GPTMRIS** and **GPTMMIS** registers.

**Register 10: GPTM Timer A Interval Load (GPTMTAILR), offset 0x028**

When the timer is counting down, this register is used to load the starting count value into the timer. When the timer is counting up, this register sets the upper bound for the timeout event.

When a 16/32-bit GPTM is configured to one of the 32-bit modes, **GPTMTAILR** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B Interval Load (GPTMTBILR)** register). In a 16-bit mode, the upper 16 bits of this register read as 0s and have no effect on the state of **GPTMTBILR**.

When a 32/64-bit Wide GPTM is configured to one of the 64-bit modes, **GPTMTAILR** contains bits 31:0 of the 64-bit count and the **GPTM Timer B Interval Load (GPTMTBILR)** register contains bits 63:32.

### Register 11: GPTM Timer B Interval Load (GPTMTBILR), offset 0x02C

When the timer is counting down, this register is used to load the starting count value into the timer. When the timer is counting up, this register sets the upper bound for the timeout event.

When a 16/32-bit GPTM is configured to one of the 32-bit modes, the contents of bits 15:0 in this register are loaded into the upper 16 bits of the **GPTMTAILR** register. Reads from this register return the current value of Timer B and writes are ignored. In a 16-bit mode, bits 15:0 are used for the load value. Bits 31:16 are reserved in both cases.

When a 32/64-bit Wide GPTM is configured to one of the 64-bit modes, **GPTMTAILR** contains bits 31:0 of the 64-bit count and the **GPTMTBILR** register contains bits 63:32.

**Register 12: GPTM Timer A Match (GPTMTAMATCHR), offset 0x030**

This register is loaded with a match value. Interrupts can be generated when the timer value is equal to the value in this register in one-shot or periodic mode.

In Edge-Count mode, this register along with **GPTMTAILR**, determines how many edge events are counted. The total number of edge events counted is equal to the value in **GPTMTAILR** minus this value. Note that in edge-count mode, when executing an up-count, the value of **GPTMTnPR** and **GPTMTnILR** must be greater than the value of **GPTMTnPMR** and **GPTMTnMATCHR**.

In PWM mode, this value along with **GPTMTAILR**, determines the duty cycle of the output PWM signal.

When a 16/32-bit GPTM is configured to one of the 32-bit modes, **GPTMTAMATCHR** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B Match (GPTMTBMATCHR)** register). In a 16-bit mode, the upper 16 bits of this register read as 0s and have no effect on the state of **GPTMTBMATCHR**.

When a 32/64-bit Wide GPTM is configured to one of the 64-bit modes, **GPTMTAMATCHR** contains bits 31:0 of the 64-bit match value and the **GPTM Timer B Match (GPTMTBMATCHR)** register contains bits 63:32.

### Register 13: GPTM Timer B Match (GPTMTBMATCHR), offset 0x034

This register is loaded with a match value. Interrupts can be generated when the timer value is equal to the value in this register in one-shot or periodic mode.

In Edge-Count mode, this register along with **GPTMTBILR** determines how many edge events are counted. The total number of edge events counted is equal to the value in **GPTMTBILR** minus this value. Note that in edge-count mode, when executing an up-count, the value of **GPTMTnPR** and **GPTMTnILR** must be greater than the value of **GPTMTnPMR** and **GPTMTnMATCHR**.

In PWM mode, this value along with **GPTMTBILR**, determines the duty cycle of the output PWM signal.

When a 16/32-bit GPTM is configured to one of the 32-bit modes, the contents of bits 15:0 in this register are loaded into the upper 16 bits of the **GPTMTAMATCHR** register. Reads from this register return the current match value of Timer B and writes are ignored. In a 16-bit mode, bits 15:0 are used for the match value. Bits 31:16 are reserved in both cases.

When a 32/64-bit Wide GPTM is configured to one of the 64-bit modes, **GPTMTAMATCHR** contains bits 31:0 of the 64-bit match value and the **GPTMTBMATCHR** register contains bits 63:32.

**Register 14: GPTM Timer A Prescale (GPTMTAPR), offset 0x038**

This register allows software to extend the range of the timers when they are used individually. When in one-shot or periodic down count modes, this register acts as a true prescaler for the timer counter. When acting as a true prescaler, the prescaler counts down to 0 before the value in the **GPTMTAR** and **GPTMTAV** registers are incremented. In all other individual/split modes, this register is a linear extension of the upper range of the timer counter, holding bits 23:16 in the 16-bit modes of the 16/32-bit GPTM and bits 47:32 in the 32-bit modes of the 32/64-bit Wide GPTM.

### Register 15: GPTM Timer B Prescale (GPTMTBPR), offset 0x03C

This register allows software to extend the range of the timers when they are used individually. When in one-shot or periodic down count modes, this register acts as a true prescaler for the timer counter. When acting as a true prescaler, the prescaler counts down to 0 before the value in the **GPTMTBR** and **GPTMTBV** registers are incremented. In all other individual/split modes, this register is a linear extension of the upper range of the timer counter, holding bits 23:16 in the 16-bit modes of the 16/32-bit GPTM and bits 47:32 in the 32-bit modes of the 32/64-bit Wide GPTM.

**Register 18: GPTM Timer A (GPTMTAR), offset 0x048**

This register shows the current value of the Timer A counter in all cases except for Input Edge Count and Time modes. In the Input Edge Count mode, this register contains the number of edges that have occurred. In the Input Edge Time mode, this register contains the time at which the last edge event took place.

When a 16/32-bit GPTM is configured to one of the 32-bit modes, **GPTMTAR** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B (GPTMTBR)** register). In the 16-bit Input Edge Count, Input Edge Time, and PWM modes, bits 15:0 contain the value of the counter and bits 23:16 contain the value of the prescaler, which is the upper 8 bits of the count. Bits 31:24 always read as 0. To read the value of the prescaler in 16-bit One-Shot and Periodic modes, read bits [23:16] in the **GPTMTAV** register. To read the value of the prescaler in periodic snapshot mode, read the **Timer A Prescale Snapshot (GPTMTAPS)** register.

When a 32/64-bit Wide GPTM is configured to one of the 64-bit modes, **GPTMTAR** contains bits 31:0 of the 64-bit timer value and the **GPTM Timer B (GPTMTBR)** register contains bits 63:32. In a 32-bit mode, the value of the prescaler is stored in the **GPTM Timer A Prescale Snapshot (GPTMTAPS)** register.

**GPTM Timer A (GPTMTAR)**

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000  
 16/32-bit Timer 2 base: 0x4003.2000

 Type RO, reset 0xFFFF.FFFF

| Bit/Field | Name | Type | Reset       | Description           |
|-----------|------|------|-------------|-----------------------|
| 31:0      | TAR  | RO   | 0xFFFF.FFFF | GPTM Timer A Register |

A read returns the current value of the **GPTM Timer A Count Register**, in all cases except for Input Edge Count and Time modes. In the Input Edge Count mode, this register contains the number of edges that have occurred. In the Input Edge Time mode, this register contains the time at which the last edge event took place.

### Register 19: GPTM Timer B (GPTMTBR), offset 0x04C

This register shows the current value of the Timer B counter in all cases except for Input Edge Count and Time modes. In the Input Edge Count mode, this register contains the number of edges that have occurred. In the Input Edge Time mode, this register contains the time at which the last edge event took place.

When a 16/32-bit GPTM is configured to one of the 32-bit modes, the contents of bits 15:0 in this register are loaded into the upper 16 bits of the **GPTMTAR** register. Reads from this register return the current value of Timer B. In a 16-bit mode, bits 15:0 contain the value of the counter and bits 23:16 contain the value of the prescaler in Input Edge Count, Input Edge Time, and PWM modes, which is the upper 8 bits of the count. Bits 31:24 always read as 0. To read the value of the prescaler in 16-bit One-Shot and Periodic modes, read bits [23:16] in the **GPTMTBV** register. To read the value of the prescaler in periodic snapshot mode, read the **Timer B Prescale Snapshot (GPTMTBPS)** register.

When a 32/64-bit Wide GPTM is configured to one of the 64-bit modes, **GPTMTAR** contains bits 31:0 of the 64-bit timer value and the **GPTM Timer B (GPTMTBR)** register contains bits 63:32. In a 32-bit mode, the value of the prescaler is stored in the **GPTM Timer B Prescale Snapshot (GPTMTBPS)** register.

|-----------|------|------|------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0      | TBR  | RO   | 0x0000.FFFF<br>(for 16/32-bit)<br>0xFFFF.FFFF<br>(for 32/64-bit) | GPTM Timer B Register<br>A read returns the current value of the <b>GPTM Timer B Count Register</b> , in all cases except for Input Edge Count and Time modes. In the Input Edge Count mode, this register contains the number of edges that have occurred. In the Input Edge Time mode, this register contains the time at which the last edge event took place. |

## Register 20: GPTM Timer A Value (GPTMTAV), offset 0x050

When read, this register shows the current, free-running value of Timer A in all modes. Software can use this value to determine the time elapsed between an interrupt and the ISR entry when using the snapshot feature with the periodic operating mode. When written, the value written into this register is loaded into the **GPTMTAR** register on the next clock cycle.

When a 16/32-bit GPTM is configured to one of the 32-bit modes, **GPTMTAV** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B Value (GPTMTBV)** register). In a 16-bit mode, bits 15:0 contain the value of the counter and bits 23:16 contain the current, free-running value of the prescaler, which is the upper 8 bits of the count in Input Edge Count, Input Edge Time, PWM and one-shot or periodic up count modes. In one-shot or periodic down count modes, the prescaler stored in 23:16 is a true prescaler, meaning bits 23:16 count down before decrementing the value in bits 15:0. The prescaler in bits 31:24 always reads as 0.

When a 32/64-bit Wide GPTM is configured to one of the 64-bit modes, **GPTMTAV** contains bits 31:0 of the 64-bit timer value and the **GPTM Timer B Value (GPTMTBV)** register contains bits 63:32. In a 32-bit mode, the current, free-running value of the prescaler is stored in the **GPTM Timer A Prescale Value (GPTMTAPV)** register.mint

|-----------|------|------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0      | TAV  | RW   | 0xFFFF.FFFF | GPTM Timer A Value<br>A read returns the current, free-running value of Timer A in all modes. When written, the value written into this register is loaded into the <b>GPTMTAR</b> register on the next clock cycle.<br><b>Note:</b> In 16-bit mode, only the lower 16-bits of the <b>GPTMTAV</b> register can be written with a new value. Writes to the prescaler bits have no effect. |

### Register 21: GPTM Timer B Value (GPTMTBV), offset 0x054

When read, this register shows the current, free-running value of Timer B in all modes. Software can use this value to determine the time elapsed between an interrupt and the ISR entry. When written, the value written into this register is loaded into the **GPTMTBR** register on the next clock cycle.

When a 16/32-bit GPTM is configured to one of the 32-bit modes, the contents of bits 15:0 in this register are loaded into the upper 16 bits of the **GPTMTAV** register. Reads from this register return the current free-running value of Timer B. In a 16-bit mode, bits 15:0 contain the value of the counter and bits 23:16 contain the current, free-running value of the prescaler, which is the upper 8 bits of the count in Input Edge Count, Input Edge Time, PWM and one-shot or periodic up count modes. In one-shot or periodic down count modes, the prescaler stored in 23:16 is a true prescaler, meaning bits 23:16 count down before decrementing the value in bits 15:0. The prescaler in bits 31:24 always reads as 0.

When a 32/64-bit Wide GPTM is configured to one of the 64-bit modes, **GPTMTBV** contains bits 63:32 of the 64-bit timer value and the **GPTM Timer A Value (GPTMTAV)** register contains bits 31:0. In a 32-bit mode, the current, free-running value of the prescaler is stored in the **GPTM Timer B Prescale Value (GPTMTBPV)** register.

### Register 25: GPTM Timer A Prescale Value (GPTMTAPV), offset 0x064

For the 32/64-bit Wide GPTM, this register shows the current free-running value of the Timer A prescaler in the 32-bit modes. Software can use this value in conjunction with the **GPTMTAV** register to determine the time elapsed between an interrupt and the ISR entry. This register is unused in 16/32-bit GPTM mode.

**Register 26: GPTM Timer B Prescale Value (GPTMTBPV), offset 0x068**

For the 32/64-bit Wide GPTM, this register shows the current free-running value of the Timer B prescaler in the 32-bit modes. Software can use this value in conjunction with the **GPTMTBV** register to determine the time elapsed between an interrupt and the ISR entry. This register is unused in 16/32-bit GPTM mode.

## 12 Watchdog Timers

A watchdog timer can generate a non-maskable interrupt (NMI), a regular interrupt or a reset when a time-out value is reached. The watchdog timer is used to regain control when a system has failed due to a software error or due to the failure of an external device to respond in the expected way. The TM4C1233C3PM microcontroller has two Watchdog Timer Modules, one module is clocked by the system clock (Watchdog Timer 0) and the other (Watchdog Timer 1) is clocked by the P1OSC. The two modules are identical except that WDT1 is in a different clock domain, and therefore requires synchronizers. As a result, WDT1 has a bit defined in the **Watchdog Timer Control (WDTCTL)** register to indicate when a write to a WDT1 register is complete. Software can use this bit to ensure that the previous access has completed before starting the next access.

The TM4C1233C3PM controller has two Watchdog Timer modules with the following features:

- 32-bit down counter with a programmable load register
- Separate watchdog clock with an enable
- Programmable interrupt generation logic with interrupt masking and optional NMI function
- Lock register protection from runaway software
- Reset generation logic with an enable/disable
- User-enabled stalling when the microcontroller asserts the CPU Halt flag during debug

The Watchdog Timer can be configured to generate an interrupt to the controller on its first time-out, and to generate a reset signal on its second time-out. Once the Watchdog Timer has been configured, the lock register can be written to prevent the timer configuration from being inadvertently altered.

## 12.1 Block Diagram

Figure 12-1. WDT Module Block Diagram

## 12.2 Functional Description

The Watchdog Timer module generates the first time-out signal when the 32-bit counter reaches the zero state after being enabled; enabling the counter also enables the watchdog timer interrupt. The watchdog interrupt can be programmed to be a non-maskable interrupt (NMI) using the `INTTYPE` bit in the **WDTCTL** register. After the first time-out event, the 32-bit counter is re-loaded with the value of the **Watchdog Timer Load (WDTLOAD)** register, and the timer resumes counting down from that value. Once the Watchdog Timer has been configured, the **Watchdog Timer Lock (WDTLOCK)** register is written, which prevents the timer configuration from being inadvertently altered by software.

If the timer counts down to its zero state again before the first time-out interrupt is cleared, and the reset signal has been enabled by setting the `RESEN` bit in the **WDTCTL** register, the Watchdog timer asserts its reset signal to the system. If the interrupt is cleared before the 32-bit counter reaches its second time-out, the 32-bit counter is loaded with the value in the **WDTLOAD** register, and counting resumes from that value.

If **WDTLOAD** is written with a new value while the Watchdog Timer counter is counting, then the counter is loaded with the new value and continues counting.

Writing to **WDTLOAD** does not clear an active interrupt. An interrupt must be specifically cleared by writing to the **Watchdog Interrupt Clear (WDTICR)** register.

The Watchdog module interrupt and reset generation can be enabled or disabled as required. When the interrupt is re-enabled, the 32-bit counter is preloaded with the load register value and not its last state.

The watchdog timer is disabled by default out of reset. To achieve maximum watchdog protection of the device, the watchdog timer can be enabled at the start of the reset vector.

### 12.2.1 Register Access Timing

Because the Watchdog Timer 1 module has an independent clocking domain, its registers must be written with a timing gap between accesses. Software must guarantee that this delay is inserted between back-to-back writes to WDT1 registers or between a write followed by a read to the registers. The timing for back-to-back reads from the WDT1 module has no restrictions. The **WRC** bit in the **Watchdog Control (WDTCTL)** register for WDT1 indicates that the required timing gap has elapsed. This bit is cleared on a write operation and set once the write completes, indicating to software that another write or read may be started safely. Software should poll **WDTCTL** for **WRC=1** prior to accessing another register. Note that WDT0 does not have this restriction as it runs off the system clock.

## 12.3 Initialization and Configuration

To use the WDT, its peripheral clock must be enabled by setting the **Rn** bit in the **Watchdog Timer Run Mode Clock Gating Control (RCGCWD)** register, see page 323.

The Watchdog Timer is configured using the following sequence:

1. Load the **WDTLOAD** register with the desired timer load value.
2. If WDT1, wait for the **WRC** bit in the **WDTCTL** register to be set.
3. If the Watchdog is configured to trigger system resets, set the **RESEN** bit in the **WDTCTL** register.
4. If WDT1, wait for the **WRC** bit in the **WDTCTL** register to be set.
5. Set the **INTEN** bit in the **WDTCTL** register to enable the Watchdog, enable interrupts, and lock the control register.

If software requires that all of the watchdog registers are locked, the Watchdog Timer module can be fully locked by writing any value to the **WDTLOCK** register. To unlock the Watchdog Timer, write a value of 0x1ACC.E551.

To service the watchdog, periodically reload the count value into the **WDTLOAD** register to restart the count. The interrupt can be enabled using the **INTEN** bit in the **WDTCTL** register to allow the processor to attempt corrective action if the watchdog is not serviced often enough. The **RESEN** bit in **WDTCTL** can be set so that the system resets if the failure is not recoverable using the ISR.

## 12.4 Register Map

Table 12-1 on page 748 lists the Watchdog registers. The offset listed is a hexadecimal increment to the register's address, relative to the Watchdog Timer base address:

- WDT0: 0x4000.0000
- WDT1: 0x4000.1000

Note that the Watchdog Timer module clock must be enabled before the registers can be programmed (see page 323).

**Table 12-1. Watchdog Timers Register Map**

## 12.5 Register Descriptions

The remainder of this section lists and describes the WDT registers, in numerical order by address offset.

**Register 1: Watchdog Load (WDTLOAD), offset 0x000**

This register is the 32-bit interval value used by the 32-bit counter. When this register is written, the value is immediately loaded and the counter restarts counting down from the new value. If the **WDTLOAD** register is loaded with 0x0000.0000, an interrupt is immediately generated.

**Watchdog Load (WDTLOAD)**

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0x000

Type R/W, reset 0xFFFF.FFFF

|       | 31      | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  |

## Register 2: Watchdog Value (WDTVALUE), offset 0x004

This register contains the current count value of the timer.

### Watchdog Value (WDTVALUE)

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0x004

Type RO, reset 0xFFFF.FFFF

| Bit/Field | Name     | Type | Reset       | Description                                                 |
|-----------|----------|------|-------------|-------------------------------------------------------------|
| 31:0      | WDTVALUE | RO   | 0xFFFF.FFFF | Watchdog Value<br>Current value of the 32-bit down counter. |

### Register 3: Watchdog Control (WDTCTL), offset 0x008

This register is the watchdog control register. The watchdog timer can be configured to generate a reset signal (on second time-out) or an interrupt on time-out.

When the watchdog interrupt has been enabled by setting the `INTEN` bit, all subsequent writes to the `INTEN` bit are ignored. The only mechanisms that can re-enable writes to this bit are a hardware reset or a software reset initiated by setting the appropriate bit in the **Watchdog Timer Software Reset (SRWD)** register.

**Important:** Because the Watchdog Timer 1 module has an independent clocking domain, its registers must be written with a timing gap between accesses. Software must guarantee that this delay is inserted between back-to-back writes to WDT1 registers or between a write followed by a read to the registers. The timing for back-to-back reads from the WDT1 module has no restrictions. The `WRC` bit in the **Watchdog Control (WDTCTL)** register for WDT1 indicates that the required timing gap has elapsed. This bit is cleared on a write operation and set once the write completes, indicating to software that another write or read may be started safely. Software should poll **WDTCTL** for `WRC=1` prior to accessing another register. Note that WDT0 does not have this restriction as it runs off the system clock and therefore does not have a `WRC` bit.

#### Watchdog Control (WDTCTL)

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0x008

Type R/W, reset 0x0000.0000 (WDT0) and 0x8000.0000 (WDT1)

Once this bit is set, it can only be cleared by a hardware reset or a software reset initiated by setting the appropriate bit in the <b>Watchdog Timer Software Reset (SRWD)</b> register.<br>1 Interrupt event enabled. Once enabled, all writes are ignored. Setting this bit enables the Watchdog Timer. |

**Register 4: Watchdog Interrupt Clear (WDTICR), offset 0x00C**

This register is the interrupt clear register. A write of any value to this register clears the Watchdog interrupt and reloads the 32-bit counter from the **WDTLOAD** register. Write to this register when a watchdog time-out interrupt has occurred to properly service the Watchdog. Value for a read or reset is indeterminate.

**Note:** Locking the watchdog registers by using the **WDTLOCK** register does not affect the **WDTICR** register and allows interrupts to always be serviced. Thus, a write at any time of the **WDTICR** register clears the **WDTMIS** register and reloads the 32-bit counter from the **WDTLOAD** register. The **WDTICR** register should only be written when interrupts have triggered and need to be serviced.

**Watchdog Interrupt Clear (WDTICR)**

To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.                                                                                          |

**Register 8: Watchdog Lock (WDTLOCK), offset 0xC00**

Writing 0x1ACC.E551 to the **WDTLOCK** register enables write access to all other registers. Writing any other value to the **WDTLOCK** register re-enables the locked state for register writes to all the other registers, except for the **Watchdog Test (WDTTEST)** register. The locked state will be enabled after 2 clock cycles. Reading the **WDTLOCK** register returns the lock status rather than the 32-bit value written. Therefore, when write accesses are disabled, reading the **WDTLOCK** register returns 0x0000.0001 (when locked; otherwise, the returned value is 0x0000.0000 (unlocked)).

**Watchdog Lock (WDTLOCK)**

| Bit/Field | Name    | Type | Reset       | Description   |
|-----------|---------|------|-------------|---------------|
| 31:0      | WDTLOCK | R/W  | 0x0000.0000 | Watchdog Lock |

A write of the value 0x1ACC.E551 unlocks the watchdog registers for write access. A write of any other value reapplies the lock, preventing any register updates, except for the **WDTTEST** register. Avoid writes to the **WDTTEST** register when the watchdog registers are locked.

A read of this register returns the following values:

| Value       | Description |
|-------------|-------------|
| 0x0000.0001 | Locked      |
| 0x0000.0000 | Unlocked    |

### Register 9: Watchdog Peripheral Identification 4 (WDTPeriphID4), offset 0xFD0

The **WDTPeriphIDn** registers are hard-coded and the fields within the register determine the reset value.

## 13 Analog-to-Digital Converter (ADC)

An analog-to-digital converter (ADC) is a peripheral that converts a continuous analog voltage to a discrete digital number. Two identical converter modules are included, which share 12 input channels.

The TM4C1233C3PM ADC module features 12-bit conversion resolution and supports 12 input channels, plus an internal temperature sensor. Each ADC module contains four programmable sequencers allowing the sampling of multiple analog input sources without controller intervention. Each sample sequencer provides flexible programming with fully configurable input source, trigger events, interrupt generation, and sequencer priority. In addition, the conversion value can optionally be diverted to a digital comparator module. Each ADC module provides eight digital comparators. Each digital comparator evaluates the ADC conversion value against its two user-defined values to determine the operational range of the signal. The trigger source for ADC0 and ADC1 may be independent or the two ADC modules may operate from the same trigger source and operate on the same or different inputs. A phase shifter can delay the start of sampling by a specified phase angle. When using both ADC modules, it is possible to configure the converters to start the conversions coincidentally or within a relative phase from each other, see “Sample Phase Control” on page 775.

The TM4C1233C3PM microcontroller provides two ADC modules with each having the following features:

- 12 shared analog input channels
- 12-bit precision ADC
- Single-ended and differential-input configurations
- On-chip internal temperature sensor
- Maximum sample rate of one million samples/second
- Optional phase shift in sample time programmable from 22.5° to 337.5°
- Four programmable sample conversion sequencers from one to eight entries long, with corresponding conversion result FIFOs
- Flexible trigger control
  - Controller (software)
  - Timers
  - Analog Comparators
  - GPIO
- Hardware averaging of up to 64 samples
- Eight digital comparators
- Power and ground for the analog circuitry is separate from the digital power and ground
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)

- Dedicated channel for each sample sequencer
- ADC module uses burst requests for DMA

## 13.1 Block Diagram

The TM4C1233C3PM microcontroller contains two identical Analog-to-Digital Converter modules. These two modules, ADC0 and ADC1, share the same 12 analog input channels. Each ADC module operates independently and can therefore execute different sample sequences, sample any of the analog input channels at any time, and generate different interrupts and triggers. Figure 13-1 on page 771 shows how the two modules are connected to analog inputs and the system bus.

**Figure 13-1. Implementation of Two ADC Blocks**

Figure 13-2 on page 772 provides details on the internal configuration of the ADC controls and data registers.

Figure 13-2. ADC Module Block Diagram

### 13.2 Signal Description

The following table lists the external signals of the ADC module and describes the function of each. The AIN<sub>x</sub> signals are analog functions for some GPIO signals. The column in the table below titled "Pin Mux/Pin Assignment" lists the GPIO pin placement for the ADC signals. These signals are configured by clearing the corresponding DEN bit in the **GPIO Digital Enable (GPIODEN)** register and setting the corresponding AMSEL bit in the **GPIO Analog Mode Select (GPIOAMSEL)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 621.

Table 13-1. ADC Signals (64LQFP)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                          |
|----------|------------|--------------------------|----------|--------------------------|--------------------------------------|

| AIN8     | 60         | PE5                      | I        | Analog                   | Analog-to-digital converter input 8. |

Table 13-1. ADC Signals (64LQFP) (continued)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                           |
|----------|------------|--------------------------|----------|--------------------------|---------------------------------------|
| AIN9     | 59         | PE4                      | I        | Analog                   | Analog-to-digital converter input 9.  |
| AIN10    | 58         | PB4                      | I        | Analog                   | Analog-to-digital converter input 10. |
| AIN11    | 57         | PB5                      | I        | Analog                   | Analog-to-digital converter input 11. |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 13.3 Functional Description

The TM4C1233C3PM ADC collects sample data by using a programmable sequence-based approach instead of the traditional single or double-sampling approaches found on many ADC modules. Each *sample sequence* is a fully programmed series of consecutive (back-to-back) samples, allowing the ADC to collect data from multiple input sources without having to be re-configured or serviced by the processor. The programming of each sample in the sample sequence includes parameters such as the input source and mode (differential versus single-ended input), interrupt generation on sample completion, and the indicator for the last sample in the sequence. In addition, the  $\mu$ DMA can be used to more efficiently move data from the sample sequencers without CPU intervention.

### 13.3.1 Sample Sequencers

The sampling control and data capture is handled by the sample sequencers. All of the sequencers are identical in implementation except for the number of samples that can be captured and the depth of the FIFO. Table 13-2 on page 773 shows the maximum number of samples that each sequencer can capture and its corresponding FIFO depth. Each sample that is captured is stored in the FIFO. In this implementation, each FIFO entry is a 32-bit word, with the lower 12 bits containing the conversion result.

Table 13-2. Samples and FIFO Depth of Sequencers

| Sequencer | Number of Samples | Depth of FIFO |
|-----------|-------------------|---------------|
| SS3       | 1                 | 1             |
| SS2       | 4                 | 4             |
| SS1       | 4                 | 4             |
| SS0       | 8                 | 8             |

For a given sample sequence, each sample is defined by bit fields in the **ADC Sample Sequence Input Multiplexer Select (ADCSSMUXn)** and **ADC Sample Sequence Control (ADCSSCTLn)** registers, where "n" corresponds to the sequence number. The **ADCSSMUXn** fields select the input pin, while the **ADCSSCTLn** fields contain the sample control bits corresponding to parameters such as temperature sensor selection, interrupt enable, end of sequence, and differential input mode. Sample sequencers are enabled by setting the respective **ASENn** bit in the **ADC Active Sample Sequencer (ADCACTSS)** register and should be configured before being enabled. Sampling is then initiated by setting the **SSn** bit in the **ADC Processor Sample Sequence Initiate (ADCPSSI)** register. In addition, sample sequences may be initiated on multiple ADC modules simultaneously using the **GSYNC** and **SYNCWAIT** bits in the **ADCPSSI** register during the configuration of each ADC module. For more information on using these bits, refer to page 814.

When configuring a sample sequence, multiple uses of the same input pin within the same sequence are allowed. In the **ADCSSCTLn** register, the **IE<sub>n</sub>** bits can be set for any combination of samples, allowing interrupts to be generated after every sample in the sequence if necessary. Also, the **END** bit can be set at any point within a sample sequence. For example, if Sequencer 0 is used, the **END**

bit can be set in the nibble associated with the fifth sample, allowing Sequencer 0 to complete execution of the sample sequence after the fifth sample.

After a sample sequence completes execution, the result data can be retrieved from the **ADC Sample Sequence Result FIFO (ADCSSFIFO<sub>n</sub>)** registers. The FIFOs are simple circular buffers that read a single address to "pop" result data. For software debug purposes, the positions of the FIFO head and tail pointers are visible in the **ADC Sample Sequence FIFO Status (ADCSSFSTAT<sub>n</sub>)** registers along with `FULL` and `EMPTY` status flags. If a write is attempted when the FIFO is full, the write does not occur and an overflow condition is indicated. Overflow and underflow conditions are monitored using the **ADCOSTAT** and **ADCUSTAT** registers.

### 13.3.2 Module Control

Outside of the sample sequencers, the remainder of the control logic is responsible for tasks such as:

- Interrupt generation
- DMA operation
- Sequence prioritization
- Trigger configuration
- Comparator configuration
- Sample phase control
- Module clocking

Most of the ADC control logic runs at the ADC clock rate of 16 MHz. The internal ADC divider is configured for 16-MHz operation automatically by hardware when the system `XTAL` is selected with the PLL.

#### 13.3.2.1 Interrupts

The register configurations of the sample sequencers and digital comparators dictate which events generate raw interrupts, but do not have control over whether the interrupt is actually sent to the interrupt controller. The ADC module's interrupt signals are controlled by the state of the `MASK` bits in the **ADC Interrupt Mask (ADCIM)** register. Interrupt status can be viewed at two locations: the **ADC Raw Interrupt Status (ADCRIS)** register, which shows the raw status of the various interrupt signals; and the **ADC Interrupt Status and Clear (ADCISC)** register, which shows active interrupts that are enabled by the **ADCIM** register. Sequencer interrupts are cleared by writing a 1 to the corresponding `IN` bit in **ADCISC**. Digital comparator interrupts are cleared by writing a 1 to the **ADC Digital Comparator Interrupt Status and Clear (ADCDCISC)** register.

#### 13.3.2.2 DMA Operation

DMA may be used to increase efficiency by allowing each sample sequencer to operate independently and transfer data without processor intervention or reconfiguration. The ADC module provides a request signal from each sample sequencer to the associated dedicated channel of the  $\mu$ DMA controller. The ADC does not support single transfer requests. A burst transfer request is asserted when the interrupt bit for the sample sequence is set (`IE` bit in the **ADCSSCTL<sub>n</sub>** register is set).

The arbitration size of the  $\mu$ DMA transfer must be a power of 2, and the associated `IE` bits in the **ADCSSCTL<sub>n</sub>** register must be set. For example, if the  $\mu$ DMA channel of SS0 has an arbitration

size of four, the  $IE3$  bit (4th sample) and the  $IE7$  bit (8th sample) must be set. Thus the  $\mu$ DMA request occurs every time 4 samples have been acquired. No other special steps are needed to enable the ADC module for  $\mu$ DMA operation.

Refer to the “Micro Direct Memory Access ( $\mu$ DMA)” on page 557 for more details about programming the  $\mu$ DMA controller.

### 13.3.2.3 Prioritization

When sampling events (triggers) happen concurrently, they are prioritized for processing by the values in the **ADC Sample Sequencer Priority (ADCSSPRI)** register. Valid priority values are in the range of 0-3, with 0 being the highest priority and 3 being the lowest. Multiple active sample sequencer units with the same priority do not provide consistent results, so software must ensure that all active sample sequencer units have a unique priority value.

### 13.3.2.4 Sampling Events

Sample triggering for each sample sequencer is defined in the **ADC Event Multiplexer Select (ADCEMUX)** register. Trigger sources include processor (default), analog comparators, an external signal on a GPIO specified by the **GPIO ADC Control (GPIOADCCTL)** register, a GP Timer, and continuous sampling. The processor triggers sampling by setting the  $SS_x$  bits in the **ADC Processor Sample Sequence Initiate (ADCPSSI)** register.

Care must be taken when using the continuous sampling trigger. If a sequencer's priority is too high, it is possible to starve other lower priority sequencers. Generally, a sample sequencer using continuous sampling should be set to the lowest priority. Continuous sampling can be used with a digital comparator to cause an interrupt when a particular voltage is seen on an input.

### 13.3.2.5 Sample Phase Control

The trigger source for ADC0 and ADC1 may be independent or the two ADC modules may operate from the same trigger source and operate on the same or different inputs. If the converters are running at the same sample rate, they may be configured to start the conversions coincidentally or with one of 15 different discrete phases relative to each other. The sample time can be delayed from the standard sampling time in  $22.5^\circ$  increments up to  $337.5^\circ$  using the **ADC Sample Phase Control (ADCSPC)** register. Figure 13-3 on page 775 shows an example of various phase relationships at a 1 Msps rate.

**Figure 13-3. ADC Sample Phases**

This feature can be used to double the sampling rate of an input. Both ADC module 0 and ADC module 1 can be programmed to sample the same input. ADC module 0 could sample at the standard position (the  $PHASE$  field in the **ADCSPC** register is 0x0). ADC module 1 can be configured to sample at 180 ( $PHASE = 0x8$ ). The two modules can be synchronized using the  $GSYNC$  and  $SYNCWAIT$

bits in the **ADC Processor Sample Sequence Initiate (ADCPSSI)** register. Software could then combine the results from the two modules to create a sample rate of one million samples/second at 16 MHz as shown in Figure 13-4 on page 776.

**Figure 13-4. Doubling the ADC Sample Rate**

Using the **ADCSPC** register, ADC0 and ADC1 may provide a number of interesting applications:

- Coincident continuous sampling of different signals. The sample sequence steps run coincidentally in both converters.
  - ADC Module 0, **ADCSPC** = 0x0, sampling *A<sub>IN0</sub>*
  - ADC Module 1, **ADCSPC** = 0x0, sampling *A<sub>IN1</sub>*
- Skewed sampling of the same signal. The sample sequence steps are 0.5  $\mu$ s out of phase with each other for 1 Msps. This configuration doubles the conversion bandwidth of a single input when software combines the results as shown in Figure 13-5 on page 776.
  - ADC Module 0, **ADCSPC** = 0x0, sampling *A<sub>IN0</sub>*
  - ADC Module 1, **ADCSPC** = 0x8, sampling *A<sub>IN0</sub>*

**Figure 13-5. Skewed Sampling**

### 13.3.2.6 Module Clocking

The module is clocked by a 16-MHz clock which can be sourced by a divided version of the PLL output, the PIOSC or an external source connected to MOSC (with the PLL in bypass mode). When the PLL is operating, the ADC clock is derived from the PLL  $\div$  25 by default. However, the PIOSC can be used for the module clock using the **ADC Clock Configuration (ADCCC)** register. To use the PIOSC to clock the ADC, first power up the PLL and then enable the PIOSC in the CS bit field in the **ADCCC** register, then disable the PLL. When the PLL is bypassed, the module clock source clock attached to the MOSC must be 16 MHz unless the PIOSC is used for the clock source. To use the MOSC to clock the ADC, first power up the PLL and then enable the clock to the ADC module, then disable the PLL and switch to the MOSC for the system clock. The ADC module can continue to operate in Deep-Sleep mode if the PIOSC is the ADC module clock source.

The system clock must be at the same frequency or higher than the ADC clock. All ADC modules share the same clock source to facilitate the synchronization of data samples between conversion units, the selection and programming of which is provided by ADC0's **ADCCC** register. The ADC modules do not run at different conversion rates.

### 13.3.2.7 Busy Status

The **BUSY** bit of the **ADCACTSS** register is used to indicate when the ADC is busy with a current conversion. When there are no triggers pending which may start a new conversion in the immediate cycle or next few cycles, the **BUSY** bit reads as 0. Software must read the status of the **BUSY** bit as clear before disabling the ADC clock by writing to the **Analog-to-Digital Converter Run Mode Clock Gating Control (RCGCADC)** register.

### 13.3.2.8 Dither Enable

The **DITHER** bit in the **ADCCTL** register is used to reduce random noise in ADC sampling and keep the ADC operation within the specified performance limits defined in “Analog-to-Digital Converter (ADC)” on page 1190. When taking multiple consecutive samples with the ADC Module, the **DITHER** bit should be enabled in the **ADCCTL** register along with hardware averaging in the **ADC Sample Averaging Control (ADCSAC)** register. The **DITHER** bit is disabled by default at reset.

## 13.3.3 Hardware Sample Averaging Circuit

Higher precision results can be generated using the hardware averaging circuit, however, the improved results are at the cost of throughput. Up to 64 samples can be accumulated and averaged to form a single data entry in the sequencer FIFO. Throughput is decreased proportionally to the number of samples in the averaging calculation. For example, if the averaging circuit is configured to average 16 samples, the throughput is decreased by a factor of 16.

By default the averaging circuit is off, and all data from the converter passes through to the sequencer FIFO. The averaging hardware is controlled by the **ADC Sample Averaging Control (ADCSAC)** register (see page 816). A single averaging circuit has been implemented, thus all input channels receive the same amount of averaging whether they are single-ended or differential.

Figure 13-6 shows an example in which the **ADCSAC** register is set to 0x2 for 4x hardware oversampling and the **IE1** bit is set for the sample sequence, resulting in an interrupt after the second averaged value is stored in the FIFO.

Figure 13-6. Sample Averaging Example

### 13.3.4 Analog-to-Digital Converter

The Analog-to-Digital Converter (ADC) module uses a Successive Approximation Register (SAR) architecture to deliver a 12-bit, low-power, high-precision conversion value. The successive approximation uses a switched capacitor array to perform the dual functions of sampling and holding the signal as well as providing the 12-bit DAC operation.

Figure 13-7 shows the ADC input equivalency diagram; for parameter values, see “Analog-to-Digital Converter (ADC)” on page 1190.

Figure 13-7. ADC Input Equivalency Diagram

The ADC operates from both the 3.3-V analog and 1.2-V digital power supplies. The ADC clock can be configured to reduce power consumption when ADC conversions are not required (see “System Control” on page 218). The analog inputs are connected to the ADC through specially balanced input paths to minimize the distortion and cross-talk on the inputs. Detailed information on the ADC power supplies and analog inputs can be found in “Analog-to-Digital Converter (ADC)” on page 1190.

#### 13.3.4.1 Voltage Reference

The ADC uses internal signals VREFP and VREFN as references to produce a conversion value from the selected analog input. VREFP is connected to  $V_{DDA}$  and VREFN is connected to  $G_{NDA}$ , as shown in Figure 13-8.

Figure 13-8. ADC Voltage Reference

The range of this conversion value is from 0x000 to 0xFFF. In single-ended-input mode, the 0x000 value corresponds to the voltage level on VREFN; the 0xFFF value corresponds to the voltage level on VREFP. This configuration results in a resolution that can be calculated using the following equation:

$$\text{mV per ADC code} = (VREFP - VREFN) / 4096$$

While the analog input pads can handle voltages beyond this range, the analog input voltages must remain within the limits prescribed by Table 22-33 on page 1190 to produce accurate results. Figure 13-9 on page 781 shows the ADC conversion function of the analog inputs.

Figure 13-9. ADC Conversion Result

### 13.3.5 Differential Sampling

In addition to traditional single-ended sampling, the ADC module supports differential sampling of two analog input channels. To enable differential sampling, software must set the  $D_n$  bit in the **ADCSSCTL0n** register in a step's configuration nibble.

When a sequence step is configured for differential sampling, the input pair to sample must be configured in the **ADCSSMUXn** register. Differential pair 0 samples analog inputs 0 and 1; differential pair 1 samples analog inputs 2 and 3; and so on (see Table 13-3 on page 781). The ADC does not support other differential pairings such as analog input 0 with analog input 3.

Table 13-3. Differential Sampling Pairs

| Differential Pair | Analog Inputs |
|-------------------|---------------|
| 0                 | 0 and 1       |
| 1                 | 2 and 3       |
| 2                 | 4 and 5       |
| 3                 | 6 and 7       |
| 4                 | 8 and 9       |
| 5                 | 10 and 11     |

The voltage sampled in differential mode is the difference between the odd and even channels:

- Input Positive Voltage:  $V_{IN+} = V_{IN\_EVEN}$  (even channel)
- Input Negative Voltage:  $V_{IN-} = V_{IN\_ODD}$  (odd channel)

The input differential voltage is defined as:  $V_{IN_D} = V_{IN+} - V_{IN-}$ , therefore:

- If  $V_{IN_D} = 0$ , then the conversion result = 0x800
- If  $V_{IN_D} > 0$ , then the conversion result  $> 0x800$  (range is 0x800–0xFFFF)
- If  $V_{IN_D} < 0$ , then the conversion result  $< 0x800$  (range is 0–0x800)

When using differential sampling, the following definitions are relevant:

- Input Common Mode Voltage:  $V_{IN_{CM}} = (V_{IN+} + V_{IN-}) / 2$
- Reference Positive Voltage:  $V_{REFP}$
- Reference Negative Voltage:  $V_{REFN}$
- Reference Differential Voltage:  $V_{REF_D} = V_{REFP} - V_{REFN}$
- Reference Common Mode Voltage:  $V_{REF_{CM}} = (V_{REFP} + V_{REFN}) / 2$

The following conditions provide optimal results in differential mode:

- Both  $V_{IN\_EVEN}$  and  $V_{IN\_ODD}$  must be in the range of ( $V_{REFP}$  to  $V_{REFN}$ ) for a valid conversion result
- The maximum possible differential input swing, or the maximum differential range, is:  $-V_{REF_D}$  to  $+V_{REF_D}$ , so the maximum peak-to-peak input differential signal is  $(+V_{REF_D} - -V_{REF_D}) = 2 * V_{REF_D} = 2 * (V_{REFP} - V_{REFN})$
- In order to take advantage of the maximum possible differential input swing,  $V_{IN_{CM}}$  should be very close to  $V_{REF_{CM}}$ , see Table 22-33 on page 1190.

If  $V_{IN_{CM}}$  is not equal to  $V_{REF_{CM}}$ , the differential input signal may clip at either maximum or minimum voltage, because either single ended input can never be larger than  $V_{REFP}$  or smaller than  $V_{REFN}$ , and it is not possible to achieve full swing. Thus any difference in common mode between the input voltage and the reference voltage limits the differential dynamic range of the ADC.

Because the maximum peak-to-peak differential signal voltage is  $2 * (V_{REFP} - V_{REFN})$ , the ADC codes are interpreted as:

$$\text{mV per ADC code} = (2 * (V_{REFP} - V_{REFN})) / 4096$$

Figure 13-10 shows how the differential voltage,  $\Delta V$ , is represented in ADC codes.

Figure 13-10. Differential Voltage Representation

### 13.3.6 Internal Temperature Sensor

The temperature sensor serves two primary purposes: 1) to notify the system that internal temperature is too high or low for reliable operation and 2) to provide temperature measurements for calibration of the Hibernate module RTC trim value.

The temperature sensor does not have a separate enable, because it also contains the bandgap reference and must always be enabled. The reference is supplied to other analog modules; not just the ADC. In addition, the temperature sensor has a second power-down input in the 3.3 V domain which provides control by the Hibernation module.

The internal temperature sensor converts a temperature measurement into a voltage. This voltage value,  $V_{TSENS}$ , is given by the following equation (where TEMP is the temperature in °C):

$$V_{TSENS} = 2.7 - ((TEMP + 55) / 75)$$

This relation is shown in Figure 13-11 on page 784.

Figure 13-11. Internal Temperature Sensor Characteristic

The temperature sensor reading can be sampled in a sample sequence by setting the  $TS_n$  bit in the **ADCSSCTLn** register. The temperature reading from the temperature sensor can also be given as a function of the ADC value. The following formula calculates temperature (TEMP in °C) based on the ADC reading ( $ADC_{CODE}$ , given as an unsigned decimal number from 0 to 4095) and the maximum ADC voltage range ( $V_{REFP} - V_{REFN}$ ):

$$TEMP = 147.5 - ((75 * (V_{REFP} - V_{REFN}) \times ADC_{CODE}) / 4096)$$

### 13.3.7 Digital Comparator Unit

An ADC is commonly used to sample an external signal and to monitor its value to ensure that it remains in a given range. To automate this monitoring procedure and reduce the amount of processor overhead that is required, each module provides eight digital comparators.

Conversions from the ADC that are sent to the digital comparators are compared against the user programmable limits in the **ADC Digital Comparator Range (ADCDCMPn)** registers. The ADC can be configured to generate an interrupt depending on whether the ADC is operating within the low, mid or high-band region configured in the  $ADCDCMP_n$  bit fields. The digital comparators four operational modes (Once, Always, Hysteresis Once, Hysteresis Always) can be additionally applied to the interrupt configuration.

#### 13.3.7.1 Output Functions

ADC conversions can either be stored in the ADC Sample Sequence FIFOs or compared using the digital comparator resources as defined by the  $S_nDCOP$  bits in the **ADC Sample Sequence n Operation (ADCSSOPn)** register. These selected ADC conversions are used by their respective digital comparator to monitor the external signal. Each comparator has two possible output functions: processor interrupts and triggers.

Each function has its own state machine to track the monitored signal. Even though the interrupt and trigger functions can be enabled individually or both at the same time, the same conversion

data is used by each function to determine if the right conditions have been met to assert the associated output.

### **Interrupts**

The digital comparator interrupt function is enabled by setting the `CIE` bit in the **ADC Digital Comparator Control (ADCDCCTLn)** register. This bit enables the interrupt function state machine to start monitoring the incoming ADC conversions. When the appropriate set of conditions is met, and the `DCONSSx` bit is set in the **ADCIM** register, an interrupt is sent to the interrupt controller.

**Note:** Only a single `DCONSSn` bit should be set at any given time. Setting more than one of these bits results in the `INRDC` bit from the **ADCRIS** register being masked, and no interrupt is generated on any of the sample sequencer interrupt lines. It is recommended that when interrupts are used, they are enabled on alternating samples or at the end of the sample sequence.

### **13.3.7.2 Operational Modes**

Four operational modes are provided to support a broad range of applications and multiple possible signaling requirements: Always, Once, Hysteresis Always, and Hysteresis Once. The operational mode is selected using the `CIM` field in the **ADCDCCTLn** register.

#### **Always Mode**

In the Always operational mode, the associated interrupt or trigger is asserted whenever the ADC conversion value meets its comparison criteria. The result is a string of assertions on the interrupt or trigger while the conversions are within the appropriate range.

#### **Once Mode**

In the Once operational mode, the associated interrupt or trigger is asserted whenever the ADC conversion value meets its comparison criteria, and the previous ADC conversion value did not. The result is a single assertion of the interrupt or trigger when the conversions are within the appropriate range.

#### **Hysteresis-Always Mode**

The Hysteresis-Always operational mode can only be used in conjunction with the low-band or high-band regions because the mid-band region must be crossed and the opposite region entered to clear the hysteresis condition. In the Hysteresis-Always mode, the associated interrupt or trigger is asserted in the following cases: 1) the ADC conversion value meets its comparison criteria or 2) a previous ADC conversion value has met the comparison criteria, and the hysteresis condition has not been cleared by entering the opposite region. The result is a string of assertions on the interrupt or trigger that continue until the opposite region is entered.

#### **Hysteresis-Once Mode**

The Hysteresis-Once operational mode can only be used in conjunction with the low-band or high-band regions because the mid-band region must be crossed and the opposite region entered to clear the hysteresis condition. In the Hysteresis-Once mode, the associated interrupt or trigger is asserted only when the ADC conversion value meets its comparison criteria, the hysteresis condition is clear, and the previous ADC conversion did not meet the comparison criteria. The result is a single assertion on the interrupt or trigger.

### 13.3.7.3 Function Ranges

The two comparison values, COMP0 and COMP1, in the **ADC Digital Comparator Range (ADCDCMPn)** register effectively break the conversion area into three distinct regions. These regions are referred to as the low-band (less than COMP0), mid-band (greater than COMP0 but less than or equal to COMP1), and high-band (greater than or equal to COMP1) regions. COMP0 and COMP1 may be programmed to the same value, effectively creating two regions, but COMP1 must always be greater than or equal to the value of COMP0. A COMP1 value that is less than COMP0 generates unpredictable results.

#### Low-Band Operation

To operate in the low-band region, the CIC field field in the **ADCDCCTLn** register must be programmed to 0x0. This setting causes interrupts or triggers to be generated in the low-band region as defined by the programmed operational mode. An example of the state of the interrupt/trigger signal in the low-band region for each of the operational modes is shown in Figure 13-12 on page 786. Note that a "0" in a column following the operational mode name (Always, Once, Hysteresis Always, and Hysteresis Once) indicates that the interrupt or trigger signal is deasserted and a "1" indicates that the signal is asserted.

Figure 13-12. Low-Band Operation (CIC=0x0)

#### Mid-Band Operation

To operate in the mid-band region, the CIC field field in the **ADCDCCTLn** register must be programmed to 0x1. This setting causes interrupts or triggers to be generated in the mid-band region according the operation mode. Only the Always and Once operational modes are available in the mid-band region. An example of the state of the interrupt/trigger signal in the mid-band region for each of the allowed operational modes is shown in Figure 13-13 on page 787. Note that a "0" in a column following the operational mode name (Always or Once) indicates that the interrupt or trigger signal is deasserted and a "1" indicates that the signal is asserted.

Figure 13-13. Mid-Band Operation (CIC=0x1)

### High-Band Operation

To operate in the high-band region, the `CIC` field in the `ADCDCCTLn` register must be programmed to `0x3`. This setting causes interrupts or triggers to be generated in the high-band region according to the operation mode. An example of the state of the interrupt/trigger signal in the high-band region for each of the allowed operational modes is shown in Figure 13-14 on page 788. Note that a "0" in a column following the operational mode name (Always, Once, Hysteresis Always, and Hysteresis Once) indicates that the interrupt or trigger signal is deasserted and a "1" indicates that the signal is asserted.

Figure 13-14. High-Band Operation (CIC=0x3)

## 13.4 Initialization and Configuration

In order for the ADC module to be used, the PLL must be enabled and programmed to a supported crystal frequency in the **RCC** register (see page 245). Using unsupported frequencies can cause faulty operation in the ADC module.

### 13.4.1 Module Initialization

Initialization of the ADC module is a simple process with very few steps: enabling the clock to the ADC, disabling the analog isolation circuit associated with all inputs that are to be used, and reconfiguring the sample sequencer priorities (if needed).

The initialization sequence for the ADC is as follows:

1. Enable the ADC clock using the **RCGCADC** register (see page 338).
2. Enable the clock to the appropriate GPIO modules via the **RCGCGPIO** register (see page 326). To find out which GPIO ports to enable, refer to “Signal Description” on page 772.
3. Set the GPIO **AFSEL** bits for the ADC input pins (see page 642). To determine which GPIOs to configure, see Table 21-4 on page 1149.
4. Configure the **AIN<sub>x</sub>** signals to be analog inputs by clearing the corresponding **DEN** bit in the **GPIO Digital Enable (GPIODEN)** register (see page 653).
5. Disable the analog isolation circuit for all ADC input pins that are to be used by writing a 1 to the appropriate bits of the **GPIOAMSEL** register (see page 658) in the associated GPIO block.

- If required by the application, reconfigure the sample sequencer priorities in the **ADCSSPRI** register. The default configuration has Sample Sequencer 0 with the highest priority and Sample Sequencer 3 as the lowest priority.

### 13.4.2 Sample Sequencer Configuration

Configuration of the sample sequencers is slightly more complex than the module initialization because each sample sequencer is completely programmable.

The configuration for each sample sequencer should be as follows:

- Ensure that the sample sequencer is disabled by clearing the corresponding **ASEN<sub>n</sub>** bit in the **ADCACTSS** register. Programming of the sample sequencers is allowed without having them enabled. Disabling the sequencer during programming prevents erroneous execution if a trigger event were to occur during the configuration process.
- Configure the trigger event for the sample sequencer in the **ADCEMUX** register.
- For each sample in the sample sequence, configure the corresponding input source in the **ADCSSMUX<sub>n</sub>** register.
- For each sample in the sample sequence, configure the sample control bits in the corresponding nibble in the **ADCSSCTL<sub>n</sub>** register. When programming the last nibble, ensure that the **END** bit is set. Failure to set the **END** bit causes unpredictable behavior.
- If interrupts are to be used, set the corresponding **MASK** bit in the **ADCIM** register.
- Enable the sample sequencer logic by setting the corresponding **ASEN<sub>n</sub>** bit in the **ADCACTSS** register.

## 13.5 Register Map

Table 13-4 on page 789 lists the ADC registers. The offset listed is a hexadecimal increment to the register's address, relative to that ADC module's base address of:

- ADC0: 0x4003.8000
- ADC1: 0x4003.9000

Note that the ADC module clock must be enabled before the registers can be programmed (see page 338). There must be a delay of 3 system clocks after the ADC module clock is enabled before any ADC module registers are accessed.

**Table 13-4. ADC Register Map**

| Offset | Name     | Type  | Reset       | Description                    | See page |
|--------|----------|-------|-------------|--------------------------------|----------|
| 0x000  | ADCACTSS | R/W   | 0x0000.0000 | ADC Active Sample Sequencer    | 792      |
| 0x004  | ADCRIS   | RO    | 0x0000.0000 | ADC Raw Interrupt Status       | 794      |
| 0x008  | ADCIM    | R/W   | 0x0000.0000 | ADC Interrupt Mask             | 796      |
| 0x00C  | ADCISC   | R/W1C | 0x0000.0000 | ADC Interrupt Status and Clear | 799      |

## 13.6 Register Descriptions

The remainder of this section lists and describes the ADC registers, in numerical order by address offset.

### Register 1: ADC Active Sample Sequencer (ADCACTSS), offset 0x000

This register controls the activation of the sample sequencers. Each sample sequencer can be enabled or disabled independently.

#### ADC Active Sample Sequencer (ADCACTSS)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0x000  
 Type R/W, reset 0x0000.0000

## Register 2: ADC Raw Interrupt Status (ADCRIS), offset 0x004

This register shows the status of the raw interrupt signal of each sample sequencer. These bits may be polled by software to look for interrupt conditions without sending the interrupts to the interrupt controller.

### ADC Raw Interrupt Status (ADCRIS)

ADC0 base: 0x4003.8000

### Register 3: ADC Interrupt Mask (ADCIM), offset 0x008

This register controls whether the sample sequencer and digital comparator raw interrupt signals are sent to the interrupt controller. Each raw interrupt signal can be masked independently.

**Note:** Only a single `DCONSSn` bit should be set at any given time. Setting more than one of these bits results in the `INRDC` bit from the **ADCRIS** register being masked, and no interrupt is generated on any of the sample sequencer interrupt lines. It is recommended that when interrupts are used, they are enabled on alternating samples or at the end of the sample sequence.

## Register 4: ADC Interrupt Status and Clear (ADCISC), offset 0x00C

This register provides the mechanism for clearing sample sequencer interrupt conditions and shows the status of interrupts generated by the sample sequencers and the digital comparators which have been sent to the interrupt controller. When read, each bit field is the logical AND of the respective **INR** and **MASK** bits. Sample sequencer interrupts are cleared by writing a 1 to the corresponding bit position. Digital comparator interrupts are cleared by writing a 1 to the appropriate bits in the **ADCDCISC** register. If software is polling the **ADCRIS** instead of generating interrupts, the sample sequence **INR<sub>n</sub>** bits are still cleared via the **ADCISC** register, even if the **IN<sub>n</sub>** bit is not set.

### ADC Interrupt Status and Clear (ADCISC)

### Register 6: ADC Event Multiplexer Select (ADCEMUX), offset 0x014

The **ADCEMUX** selects the event (trigger) that initiates sampling for each sample sequencer. Each sample sequencer can be configured with a unique trigger source.

#### ADC Event Multiplexer Select (ADCEMUX)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0x014  
 Type R/W, reset 0x0000.0000

**Register 7: ADC Underflow Status (ADCUSTAT), offset 0x018**

This register indicates underflow conditions in the sample sequencer FIFOs. The corresponding underflow condition is cleared by writing a 1 to the relevant bit position.

**ADC Underflow Status (ADCUSTAT)**

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x018

Type R/W1C, reset 0x0000.0000

### Register 8: ADC Sample Sequencer Priority (ADCSSPRI), offset 0x020

This register sets the priority for each of the sample sequencers. Out of reset, Sequencer 0 has the highest priority, and Sequencer 3 has the lowest priority. When reconfiguring sequence priorities, each sequence must have a unique priority for the ADC to operate properly.

### Register 9: ADC Sample Phase Control (ADCSPC), offset 0x024

This register allows the ADC module to sample at one of 16 different discrete phases from 0.0° through 337.5°. For example, the sample rate could be effectively doubled by sampling a signal using one ADC module configured with the standard sample time and the second ADC module configured with a 180.0° phase lag.

**Note:** Care should be taken when the PHASE field is non-zero, as the resulting delay in sampling the AIN<sub>x</sub> input may result in undesirable system consequences. The time from ADC trigger to sample is increased and could make the response time longer than anticipated. The added latency could have ramifications in the system design. Designers should carefully consider the impact of this delay.

### Register 10: ADC Processor Sample Sequence Initiate (ADCPSSI), offset 0x028

This register provides a mechanism for application software to initiate sampling in the sample sequencers. Sample sequences can be initiated individually or in any combination. When multiple sequences are triggered simultaneously, the priority encodings in **ADCSSPRI** dictate execution order.

This register also provides a means to configure and then initiate concurrent sampling on all ADC modules. To do this, the first ADC module should be configured. The **ADCPSSI** register for that module should then be written. The appropriate **SS** bits should be set along with the **SYNCWAIT** bit. Additional ADC modules should then be configured following the same procedure. Once the final ADC module is configured, its **ADCPSSI** register should be written with the appropriate **SS** bits set along with the **GSYNC** bit. All of the ADC modules then begin concurrent sampling according to their configuration.

#### ADC Processor Sample Sequence Initiate (ADCPSSI)

### Register 11: ADC Sample Averaging Control (ADCSAC), offset 0x030

This register controls the amount of hardware averaging applied to conversion results. The final conversion result stored in the FIFO is averaged from  $2^{AVG}$  consecutive ADC samples at the specified ADC speed. If AVG is 0, the sample is passed directly through without any averaging. If AVG=6, then 64 consecutive ADC samples are averaged to generate one result in the sequencer FIFO. An AVG=7 provides unpredictable results.

#### ADC Sample Averaging Control (ADCSAC)

**Register 13: ADC Control (ADCCTL), offset 0x038**

This register configures the voltage reference. Note that values set in this register apply to all ADC modules, it is not possible to set one module to use internal references and another to use external references.

**ADC Control (ADCCTL)**

### Register 14: ADC Sample Sequence Input Multiplexer Select 0 (ADCSSMUX0), offset 0x040

This register defines the analog input configuration for each sample in a sequence executed with Sample Sequencer 0. This register is 32 bits wide and contains information for eight possible samples.

#### ADC Sample Sequence Input Multiplexer Select 0 (ADCSSMUX0)

### Register 15: ADC Sample Sequence Control 0 (ADCSSCTL0), offset 0x044

This register contains the configuration information for each sample for a sequence executed with a sample sequencer. When configuring a sample sequence, the `END` bit must be set for the final sample, whether it be after the first sample, eighth sample, or any sample in between. This register is 32 bits wide and contains information for eight possible samples.

**Register 16: ADC Sample Sequence Result FIFO 0 (ADCSSFIFO0), offset 0x048**

**Register 17: ADC Sample Sequence Result FIFO 1 (ADCSSFIFO1), offset 0x068**

**Register 18: ADC Sample Sequence Result FIFO 2 (ADCSSFIFO2), offset 0x088**

**Register 19: ADC Sample Sequence Result FIFO 3 (ADCSSFIFO3), offset 0x0A8**

**Important:** This register is read-sensitive. See the register description for details.

This register contains the conversion results for samples collected with the sample sequencer (the **ADCSSFIFO0** register is used for Sample Sequencer 0, **ADCSSFIFO1** for Sequencer 1, **ADCSSFIFO2** for Sequencer 2, and **ADCSSFIFO3** for Sequencer 3). Reads of this register return conversion result data in the order sample 0, sample 1, and so on, until the FIFO is empty. If the FIFO is not properly handled by software, overflow and underflow conditions are registered in the **ADCSTAT** and **ADCUSTAT** registers.

#### ADC Sample Sequence Result FIFO n (ADCSSFIFO<sub>n</sub>)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x048

Type RO, reset -

**Register 20: ADC Sample Sequence FIFO 0 Status (ADCSSFSTAT0), offset 0x04C**

**Register 21: ADC Sample Sequence FIFO 1 Status (ADCSSFSTAT1), offset 0x06C**

**Register 22: ADC Sample Sequence FIFO 2 Status (ADCSSFSTAT2), offset 0x08C**

**Register 23: ADC Sample Sequence FIFO 3 Status (ADCSSFSTAT3), offset 0x0AC**

This register provides a window into the sample sequencer, providing full/empty status information as well as the positions of the head and tail pointers. The reset value of 0x100 indicates an empty FIFO with the head and tail pointers both pointing to index 0. The **ADCSSFSTAT0** register provides status on FIFO0, which has 8 entries; **ADCSSFSTAT1** on FIFO1, which has 4 entries; **ADCSSFSTAT2** on FIFO2, which has 4 entries; and **ADCSSFSTAT3** on FIFO3 which has a single entry.

## Register 25: ADC Sample Sequence 0 Digital Comparator Select (ADCSSDC0), offset 0x054

This register determines which digital comparator receives the sample from the given conversion on Sample Sequence 0, if the corresponding  $S_nDCOP$  bit in the **ADCSSOP0** register is set.

### ADC Sample Sequence 0 Digital Comparator Select (ADCSSDC0)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0x054  
 Type R/W, reset 0x0000.0000

**Register 26: ADC Sample Sequence Input Multiplexer Select 1 (ADCSSMUX1), offset 0x060**

**Register 27: ADC Sample Sequence Input Multiplexer Select 2 (ADCSSMUX2), offset 0x080**

This register defines the analog input configuration for each sample in a sequence executed with Sample Sequencer 1 or 2. These registers are 16 bits wide and contain information for four possible samples. See the **ADCSSMUX0** register on page 820 for detailed bit descriptions. The **ADCSSMUX1** register affects Sample Sequencer 1 and the **ADCSSMUX2** register affects Sample Sequencer 2.

ADC Sample Sequence Input Multiplexer Select n (ADCSSMUXn)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0x060  
 Type R/W, reset 0x0000.0000

**Register 28: ADC Sample Sequence Control 1 (ADCSSCTL1), offset 0x064****Register 29: ADC Sample Sequence Control 2 (ADCSSCTL2), offset 0x084**

These registers contain the configuration information for each sample for a sequence executed with Sample Sequencer 1 or 2. When configuring a sample sequence, the **END** bit must be set for the final sample, whether it be after the first sample, fourth sample, or any sample in between. These registers are 16-bits wide and contain information for four possible samples. See the **ADCSSCTL0** register on page 822 for detailed bit descriptions. The **ADCSSCTL1** register configures Sample Sequencer 1 and the **ADCSSCTL2** register configures Sample Sequencer 2.

## ADC Sample Sequence Control n (ADCSSCTLn)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0x064  
 Type R/W, reset 0x0000.0000

If the <b>MASK0</b> bit in the <b>ADCIM</b> register is set, the interrupt is promoted to the interrupt controller.</p> <p>It is legal to have multiple samples within a sequence generate interrupts.</p>                   |
| 1         | END0 | R/W  | 0     | <p>1st Sample is End of Sequence</p> <p>Value Description</p> <p>0 Another sample in the sequence is the final sample.</p> <p>1 The first sample is the last sample of the sequence.</p> <p>It is possible to end the sequence on any sample position. Software must set an <b>ENDn</b> bit somewhere within the sequence. Samples defined after the sample containing a set <b>ENDn</b> bit are not requested for conversion even though the fields may be non-zero.</p> |
| 0         | D0   | R/W  | 0     | <p>1st Sample Differential Input Select</p> <p>Value Description</p> <p>0 The analog inputs are not differentially sampled.</p> <p>1 The analog input is differentially sampled. The corresponding <b>ADCSSMUXn</b> nibble must be set to the pair number "i", where the paired inputs are "2i and 2i+1".</p> <p>Because the temperature sensor does not have a differential option, this bit must not be set when the <b>TS0</b> bit is set.</p>                         |

**Register 30: ADC Sample Sequence 1 Operation (ADCSSOP1), offset 0x070****Register 31: ADC Sample Sequence 2 Operation (ADCSSOP2), offset 0x090**

This register determines whether the sample from the given conversion on Sample Sequence n is saved in the Sample Sequence n FIFO or sent to the digital comparator unit. The **ADCSSOP1** register controls Sample Sequencer 1 and the **ADCSSOP2** register controls Sample Sequencer 2.

**Register 32: ADC Sample Sequence 1 Digital Comparator Select (ADCSSDC1), offset 0x074**

**Register 33: ADC Sample Sequence 2 Digital Comparator Select (ADCSSDC2), offset 0x094**

These registers determine which digital comparator receives the sample from the given conversion on Sample Sequence n if the corresponding  $S_nDCOP$  bit in the **ADCSSOPn** register is set. The **ADCSSDC1** register controls the selection for Sample Sequencer 1 and the **ADCSSDC2** register controls the selection for Sample Sequencer 2.

### Register 34: ADC Sample Sequence Input Multiplexer Select 3 (ADCSSMUX3), offset 0x0A0

This register defines the analog input configuration for the sample executed with Sample Sequencer 3. This register is 4 bits wide and contains information for one possible sample. See the **ADCSSMUX0** register on page 820 for detailed bit descriptions.

**Register 35: ADC Sample Sequence Control 3 (ADCSSCTL3), offset 0x0A4**

This register contains the configuration information for a sample executed with Sample Sequencer 3. This register is 4 bits wide and contains information for one possible sample. See the **ADCSSCTL0** register on page 822 for detailed bit descriptions.

**Note:** When configuring a sample sequence in this register, the **END0** bit must be set.

## ADC Sample Sequence Control 3 (ADCSSCTL3)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0x0A4  
 Type R/W, reset 0x0000.0000

|           |      |      |       | Value Description                                                                                                                                                      |
|           |      |      |       | 0 The analog inputs are not differentially sampled.                                                                                                                    |
|           |      |      |       | 1 The analog input is differentially sampled. The corresponding <b>ADCSSMUXn</b> nibble must be set to the pair number "i", where the paired inputs are "2i and 2i+1". |
|           |      |      |       | Because the temperature sensor does not have a differential option, this bit must not be set when the <b>TS0</b> bit is set.                                           |

**Register 36: ADC Sample Sequence 3 Operation (ADCSSOP3), offset 0x0B0**

This register determines whether the sample from the given conversion on Sample Sequence 3 is saved in the Sample Sequence 3 FIFO or sent to the digital comparator unit.

## ADC Sample Sequence 3 Operation (ADCSSOP3)

## Register 38: ADC Digital Comparator Reset Initial Conditions (ADCDCRIC), offset 0xD00

This register provides the ability to reset any of the digital comparator interrupt or trigger functions back to their initial conditions. Resetting these functions ensures that the data that is being used by the interrupt and trigger functions in the digital comparator unit is not stale.

### ADC Digital Comparator Reset Initial Conditions (ADCDCRIC)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0xD00  
 Type WO, reset 0x0000.0000

**Register 47: ADC Digital Comparator Range 0 (ADCDCCMP0), offset 0xE40**

**Register 48: ADC Digital Comparator Range 1 (ADCDCCMP1), offset 0xE44**

**Register 49: ADC Digital Comparator Range 2 (ADCDCCMP2), offset 0xE48**

**Register 50: ADC Digital Comparator Range 3 (ADCDCCMP3), offset 0xE4C**

**Register 51: ADC Digital Comparator Range 4 (ADCDCCMP4), offset 0xE50**

**Register 52: ADC Digital Comparator Range 5 (ADCDCCMP5), offset 0xE54**

**Register 53: ADC Digital Comparator Range 6 (ADCDCCMP6), offset 0xE58**

**Register 54: ADC Digital Comparator Range 7 (ADCDCCMP7), offset 0xE5C**

This register defines the comparison values that are used to determine if the ADC conversion data falls in the appropriate operating region.

**Note:** The value in the COMP1 field must be greater than or equal to the value in the COMP0 field or unexpected results can occur.

ADC Digital Comparator Range n (ADCDCCMPn)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0xE40  
 Type R/W, reset 0x0000.0000

## Register 56: ADC Peripheral Configuration (ADCPC), offset 0xFC4

The **ADCPC** register provides information regarding the configuration of the peripheral.

### ADC Peripheral Configuration (ADCPC)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0xFC4

Type R/W, reset 0x0000.0007

### Register 57: ADC Clock Configuration (ADCCC), offset 0xFC8

The **ADCCC** register controls the clock source for the ADC module.

To use the PIOSC to clock the ADC, first power up the PLL and then enable the PIOSC in the **CS** bit field, then disable the PLL.

To use the MOSC to clock the ADC, first power up the PLL and then enable the clock to the ADC module, then disable the PLL and switch to the MOSC for the system clock.

#### ADC Clock Configuration (ADCCC)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0xFC8  
 Type R/W, reset 0x0000.0000

## 14 Universal Asynchronous Receivers/Transmitters (UARTs)

The TM4C1233C3PM controller includes eight Universal Asynchronous Receiver/Transmitter (UART) with the following features:

- Programmable baud-rate generator allowing speeds up to 5 Mbps for regular speed (divide by 16) and 10 Mbps for high speed (divide by 8)
- Separate 16x8 transmit (TX) and receive (RX) FIFOs to reduce CPU interrupt service loading
- Programmable FIFO length, including 1-byte deep operation providing conventional double-buffered interface
- FIFO trigger levels of 1/8, 1/4, 1/2, 3/4, and 7/8
- Standard asynchronous communication bits for start, stop, and parity
- Line-break generation and detection
- Fully programmable serial interface characteristics
  - 5, 6, 7, or 8 data bits
  - Even, odd, stick, or no-parity bit generation/detection
  - 1 or 2 stop bit generation
- IrDA serial-IR (SIR) encoder/decoder providing
  - Programmable use of IrDA Serial Infrared (SIR) or UART input/output
  - Support of IrDA SIR encoder/decoder functions for data rates up to 115.2 Kbps half-duplex
  - Support of normal 3/16 and low-power (1.41-2.23  $\mu$ s) bit durations
  - Programmable internal clock generator enabling division of reference clock by 1 to 256 for low-power mode bit duration
- Support for communication with ISO 7816 smart cards
- Modem flow control (on UART1)
- EIA-485 9-bit support
- Standard FIFO-level and End-of-Transmission interrupts
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for transmit and receive
  - Receive single request asserted when data is in the FIFO; burst request asserted at programmed FIFO level

- Transmit single request asserted when there is space in the FIFO; burst request asserted at programmed FIFO level

## 14.1 Block Diagram

Figure 14-1. UART Module Block Diagram

## 14.2 Signal Description

The following table lists the external signals of the UART module and describes the function of each. The UART signals are alternate functions for some GPIO signals and default to be GPIO signals at reset, with the exception of the **U0Rx** and **U0Tx** pins which default to the UART function. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these UART signals. The **AFSEL** bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 642) should be set to choose the UART function. The number in parentheses is the encoding that must be programmed into the **PMCn** field in the **GPIO Port Control (GPIOCTL)** register (page 659) to assign the UART signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 621.

Table 14-1. UART Signals (64LQFP)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                                                   |
|----------|------------|--------------------------|----------|--------------------------|---------------------------------------------------------------|
| U0Rx     | 17         | PA0 (1)                  | I        | TTL                      | UART module 0 receive.                                        |
| U0Tx     | 18         | PA1 (1)                  | O        | TTL                      | UART module 0 transmit.                                       |
| U1CTS    | 15<br>29   | PC5 (8)<br>PF1 (1)       | I        | TTL                      | UART module 1 Clear To Send modem flow control input signal.  |
| U1RTS    | 16<br>28   | PC4 (8)<br>PF0 (1)       | O        | TTL                      | UART module 1 Request to Send modem flow control output line. |
| U1Rx     | 16<br>45   | PC4 (2)<br>PB0 (1)       | I        | TTL                      | UART module 1 receive.                                        |
| U1Tx     | 15<br>46   | PC5 (2)<br>PB1 (1)       | O        | TTL                      | UART module 1 transmit.                                       |
| U2Rx     | 53         | PD6 (1)                  | I        | TTL                      | UART module 2 receive.                                        |
| U2Tx     | 10         | PD7 (1)                  | O        | TTL                      | UART module 2 transmit.                                       |
| U3Rx     | 14         | PC6 (1)                  | I        | TTL                      | UART module 3 receive.                                        |
| U3Tx     | 13         | PC7 (1)                  | O        | TTL                      | UART module 3 transmit.                                       |
| U4Rx     | 16         | PC4 (1)                  | I        | TTL                      | UART module 4 receive.                                        |
| U4Tx     | 15         | PC5 (1)                  | O        | TTL                      | UART module 4 transmit.                                       |
| U5Rx     | 59         | PE4 (1)                  | I        | TTL                      | UART module 5 receive.                                        |
| U5Tx     | 60         | PE5 (1)                  | O        | TTL                      | UART module 5 transmit.                                       |
| U6Rx     | 43         | PD4 (1)                  | I        | TTL                      | UART module 6 receive.                                        |
| U6Tx     | 44         | PD5 (1)                  | O        | TTL                      | UART module 6 transmit.                                       |
| U7Rx     | 9          | PE0 (1)                  | I        | TTL                      | UART module 7 receive.                                        |
| U7Tx     | 8          | PE1 (1)                  | O        | TTL                      | UART module 7 transmit.                                       |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 14.3 Functional Description

Each TM4C1233C3PM UART performs the functions of parallel-to-serial and serial-to-parallel conversions. It is similar in functionality to a 16C550 UART, but is not register compatible.

The UART is configured for transmit and/or receive via the TXE and RXE bits of the **UART Control (UARTCTL)** register (see page 886). Transmit and receive are both enabled out of reset. Before any control registers are programmed, the UART must be disabled by clearing the UARTEEN bit in **UARTCTL**. If the UART is disabled during a TX or RX operation, the current transaction is completed prior to the UART stopping.

The UART module also includes a serial IR (SIR) encoder/decoder block that can be connected to an infrared transceiver to implement an IrDA SIR physical layer. The SIR function is programmed using the **UARTCTL** register.

### 14.3.1 Transmit/Receive Logic

The transmit logic performs parallel-to-serial conversion on the data read from the transmit FIFO. The control logic outputs the serial bit stream beginning with a start bit and followed by the data bits (LSB first), parity bit, and the stop bits according to the programmed configuration in the control registers. See Figure 14-2 on page 864 for details.

The receive logic performs serial-to-parallel conversion on the received bit stream after a valid start pulse has been detected. Overrun, parity, frame error checking, and line-break detection are also performed, and their status accompanies the data that is written to the receive FIFO.

**Figure 14-2. UART Character Frame**

### 14.3.2 Baud-Rate Generation

The baud-rate divisor is a 22-bit number consisting of a 16-bit integer and a 6-bit fractional part. The number formed by these two values is used by the baud-rate generator to determine the bit period. Having a fractional baud-rate divisor allows the UART to generate all the standard baud rates.

The 16-bit integer is loaded through the **UART Integer Baud-Rate Divisor (UARTIBRD)** register (see page 882) and the 6-bit fractional part is loaded with the **UART Fractional Baud-Rate Divisor (UARTFBRD)** register (see page 883). The baud-rate divisor (BRD) has the following relationship to the system clock (where *BRDI* is the integer part of the BRD and *BRDF* is the fractional part, separated by a decimal place.)

$$BRD = BRDI + BRDF = \text{UARTSysClk} / (\text{ClkDiv} * \text{Baud Rate})$$

where *UARTSysClk* is the system clock connected to the UART, and *ClkDiv* is either 16 (if *HSE* in **UARTCTL** is clear) or 8 (if *HSE* is set). By default, this will be the main system clock described in “Clock Control” on page 211. Alternatively, the UART may be clocked from the internal precision oscillator (PIOSC), independent of the system clock selection. This will allow the UART clock to be programmed independently of the system clock PLL settings. See the **UARTCC** register for more details.

The 6-bit fractional number (that is to be loaded into the *DIVFRAC* bit field in the **UARTFBRD** register) can be calculated by taking the fractional part of the baud-rate divisor, multiplying it by 64, and adding 0.5 to account for rounding errors:

$$\text{UARTFBRD}[\text{DIVFRAC}] = \text{integer}(\text{BRDF} * 64 + 0.5)$$

The UART generates an internal baud-rate reference clock at 8x or 16x the baud-rate (referred to as *Baud8* and *Baud16*, depending on the setting of the *HSE* bit (bit 5) in **UARTCTL**). This reference clock is divided by 8 or 16 to generate the transmit clock, and is used for error detection during receive operations. Note that the state of the *HSE* bit has no effect on clock generation in ISO 7816 smart card mode (when the *SMART* bit in the **UARTCTL** register is set).

Along with the **UART Line Control, High Byte (UARTLCRH)** register (see page 884), the **UARTIBRD** and **UARTFBRD** registers form an internal 30-bit register. This internal register is only updated when a write operation to **UARTLCRH** is performed, so any changes to the baud-rate divisor must be followed by a write to the **UARTLCRH** register for the changes to take effect.

To update the baud-rate registers, there are four possible sequences:

- **UARTIBRD** write, **UARTFBRD** write, and **UARTLCRH** write
- **UARTFBRD** write, **UARTIBRD** write, and **UARTLCRH** write
- **UARTIBRD** write and **UARTLCRH** write

- **UARTFBRD** write and **UARTLCRH** write

### 14.3.3 Data Transmission

Data received or transmitted is stored in two 16-byte FIFOs, though the receive FIFO has an extra four bits per character for status information. For transmission, data is written into the transmit FIFO. If the UART is enabled, it causes a data frame to start transmitting with the parameters indicated in the **UARTLCRH** register. Data continues to be transmitted until there is no data left in the transmit FIFO. The **BUSY** bit in the **UART Flag (UARTFR)** register (see page 879) is asserted as soon as data is written to the transmit FIFO (that is, if the FIFO is non-empty) and remains asserted while data is being transmitted. The **BUSY** bit is negated only when the transmit FIFO is empty, and the last character has been transmitted from the shift register, including the stop bits. The UART can indicate that it is busy even though the UART may no longer be enabled.

When the receiver is idle (the  $UnRx$  signal is continuously 1), and the data input goes Low (a start bit has been received), the receive counter begins running and data is sampled on the eighth cycle of  $Baud_{16}$  or fourth cycle of  $Baud_8$  depending on the setting of the **HSE** bit (bit 5) in **UARTCTL** (described in “Transmit/Receive Logic” on page 863).

The start bit is valid and recognized if the  $UnRx$  signal is still low on the eighth cycle of  $Baud_{16}$  (**HSE** clear) or the fourth cycle of  $Baud_8$  (**HSE** set), otherwise it is ignored. After a valid start bit is detected, successive data bits are sampled on every 16th cycle of  $Baud_{16}$  or 8th cycle of  $Baud_8$  (that is, one bit period later) according to the programmed length of the data characters and value of the **HSE** bit in **UARTCTL**. The parity bit is then checked if parity mode is enabled. Data length and parity are defined in the **UARTLCRH** register.

Lastly, a valid stop bit is confirmed if the  $UnRx$  signal is High, otherwise a framing error has occurred. When a full word is received, the data is stored in the receive FIFO along with any error bits associated with that word.

### 14.3.4 Serial IR (SIR)

The UART peripheral includes an IrDA serial-IR (SIR) encoder/decoder block. The IrDA SIR block provides functionality that converts between an asynchronous UART data stream and a half-duplex serial SIR interface. No analog processing is performed on-chip. The role of the SIR block is to provide a digital encoded output and decoded input to the UART. When enabled, the SIR block uses the  $UnTx$  and  $UnRx$  pins for the SIR protocol. These signals should be connected to an infrared transceiver to implement an IrDA SIR physical layer link. The SIR block can receive and transmit, but it is only half-duplex so it cannot do both at the same time. Transmission must be stopped before data can be received. The IrDA SIR physical layer specifies a minimum 10-ms delay between transmission and reception. The SIR block has two modes of operation:

- In normal IrDA mode, a zero logic level is transmitted as a high pulse of 3/16th duration of the selected baud rate bit period on the output pin, while logic one levels are transmitted as a static LOW signal. These levels control the driver of an infrared transmitter, sending a pulse of light for each zero. On the reception side, the incoming light pulses energize the photo transistor base of the receiver, pulling its output LOW and driving the UART input pin LOW.
- In low-power IrDA mode, the width of the transmitted infrared pulse is set to three times the period of the internally generated  $IrLPBaud_{16}$  signal (1.63  $\mu$ s, assuming a nominal 1.8432 MHz frequency) by changing the appropriate bit in the **UARTCTL** register (see page 886).

Whether the device is in normal or low-power IrDA mode, a start bit is deemed valid if the decoder is still Low, one period of  $IrLPBaud_{16}$  after the Low was first detected. This enables a normal-mode UART to receive data from a low-power mode UART that can transmit pulses as small as 1.41  $\mu$ s.

Thus, for both low-power and normal mode operation, the `ILPDVSR` field in the `UARTILPR` register must be programmed such that  $1.42 \text{ MHz} < F_{\text{IrLPBaud16}} < 2.12 \text{ MHz}$ , resulting in a low-power pulse duration of 1.41–2.11  $\mu\text{s}$  (three times the period of `IrLPBaud16`). The minimum frequency of `IrLPBaud16` ensures that pulses less than one period of `IrLPBaud16` are rejected, but pulses greater than 1.4  $\mu\text{s}$  are accepted as valid pulses.

Figure 14-3 on page 866 shows the UART transmit and receive signals, with and without IrDA modulation.

**Figure 14-3. IrDA Data Modulation**

In both normal and low-power IrDA modes:

- During transmission, the UART data bit is used as the base for encoding
- During reception, the decoded bits are transferred to the UART receive logic

The IrDA SIR physical layer specifies a half-duplex communication link, with a minimum 10-ms delay between transmission and reception. This delay must be generated by software because it is not automatically supported by the UART. The delay is required because the infrared receiver electronics might become biased or even saturated from the optical power coupled from the adjacent transmitter LED. This delay is known as latency or receiver setup time.

### 14.3.5 ISO 7816 Support

The UART offers basic support to allow communication with an ISO 7816 smartcard. When bit 3 (`SMART`) of the `UARTCTL` register is set, the `UnTx` signal is used as a bit clock, and the `UnRx` signal is used as the half-duplex communication line connected to the smartcard. A GPIO signal can be used to generate the reset signal to the smartcard. The remaining smartcard signals should be provided by the system design. The maximum clock rate in this mode is system clock / 16.

When using ISO 7816 mode, the `UARTLCRH` register must be set to transmit 8-bit words (`WLEN` bits 6:5 configured to 0x3) with EVEN parity (`PEN` set and `EPS` set). In this mode, the UART automatically uses 2 stop bits, and the `STP2` bit of the `UARTLCRH` register is ignored.

If a parity error is detected during transmission, `UnRx` is pulled Low during the second stop bit. In this case, the UART aborts the transmission, flushes the transmit FIFO and discards any data it contains, and raises a parity error interrupt, allowing software to detect the problem and initiate retransmission of the affected data. Note that the UART does not support automatic retransmission in this case.

### 14.3.6 Modem Handshake Support

This section describes how to configure and use the modem flow control signals for UART1 when connected as a DTE (data terminal equipment) or as a DCE (data communications equipment). In general, a modem is a DCE and a computing device that connects to a modem is the DTE.

#### 14.3.6.1 Signaling

The status signals provided by UART1 differ based on whether the UART is used as a DTE or DCE. When used as a DTE, the modem flow control signals are defined as:

- $\overline{\text{UICTS}}$  is Clear To Send
- $\overline{\text{UIRTS}}$  is Request To Send

When used as a DCE, the the modem flow control signals are defined as:

- $\overline{\text{UICTS}}$  is Request To Send
- $\overline{\text{UIRTS}}$  is Clear To Send

#### 14.3.6.2 Flow Control

Flow control can be accomplished by either hardware or software. The following sections describe the different methods.

##### **Hardware Flow Control (RTS/CTS)**

Hardware flow control between two devices is accomplished by connecting the  $\overline{\text{UIRTS}}$  output to the Clear-To-Send input on the receiving device, and connecting the Request-To-Send output on the receiving device to the  $\overline{\text{UICTS}}$  input.

The  $\overline{\text{UICTS}}$  input controls the transmitter. The transmitter may only transmit data when the  $\overline{\text{UICTS}}$  input is asserted. The  $\overline{\text{UIRTS}}$  output signal indicates the state of the receive FIFO.  $\overline{\text{UICTS}}$  remains asserted until the preprogrammed watermark level is reached, indicating that the Receive FIFO has no space to store additional characters.

The **UARTCTL** register bits 15 (**CTSEN**) and 14 (**RTSEN**) specify the flow control mode as shown in Table 14-2 on page 867.

**Table 14-2. Flow Control Mode**

| CTSEN | RTSEN | Description                            |
|-------|-------|----------------------------------------|
| 1     | 1     | RTS and CTS flow control enabled       |
| 1     | 0     | Only CTS flow control enabled          |
| 0     | 1     | Only RTS flow control enabled          |
| 0     | 0     | Both RTS and CTS flow control disabled |

Note that when **RTSEN** is 1, software cannot modify the  $\overline{\text{UIRTS}}$  output value through the **UARTCTL** register Request to Send (**RTS**) bit, and the status of the **RTS** bit should be ignored.

##### **Software Flow Control (Modem Status Interrupts)**

Software flow control between two devices is accomplished by using interrupts to indicate the status of the UART. Interrupts may be generated for the  $\overline{\text{UICTS}}$  signal using bit 3 of the **UARTIM** register. The raw and masked interrupt status may be checked using the **UARTRIS** and **UARTMIS** register. These interrupts may be cleared using the **UARTICR** register.

### 14.3.7 9-Bit UART Mode

The UART provides a 9-bit mode that is enabled with the `9BITEN` bit in the **UART9BITADDR** register. This feature is useful in a multi-drop configuration of the UART where a single master connected to multiple slaves can communicate with a particular slave through its address or set of addresses along with a qualifier for an address byte. All the slaves check for the address qualifier in the place of the parity bit and, if set, then compare the byte received with the preprogrammed address. If the address matches, then it receives or sends further data. If the address does not match, it drops the address byte and any subsequent data bytes. If the UART is in 9-bit mode, then the receiver operates with no parity mode. The address can be predefined to match with the received byte and it can be configured with the **UART9BITADDR** register. The matching can be extended to a set of addresses using the address mask in the **UART9BITAMASK** register. By default, the **UART9BITAMASK** is `0xFF`, meaning that only the specified address is matched.

When not finding a match, the rest of the data bytes with the 9th bit cleared are dropped. If a match is found, then an interrupt is generated to the NVIC for further action. The subsequent data bytes with the cleared 9th bit are stored in the FIFO. Software can mask this interrupt in case  $\mu$ DMA and/or FIFO operations are enabled for this instance and processor intervention is not required. All the send transactions with 9-bit mode are data bytes and the 9th bit is cleared. Software can override the 9th bit to be set (to indicate address) by overriding the parity settings to sticky parity with odd parity enabled for a particular byte. To match the transmission time with correct parity settings, the address byte can be transmitted as a single then a burst transfer. The Transmit FIFO does not hold the address/data bit, hence software should take care of enabling the address bit appropriately.

### 14.3.8 FIFO Operation

The UART has two 16x8 FIFOs; one for transmit and one for receive. Both FIFOs are accessed via the **UART Data (UARTDR)** register (see page 874). Read operations of the **UARTDR** register return a 12-bit value consisting of 8 data bits and 4 error flags while write operations place 8-bit data in the transmit FIFO.

Out of reset, both FIFOs are disabled and act as 1-byte-deep holding registers. The FIFOs are enabled by setting the `FEN` bit in **UARTLCRH** (page 884).

FIFO status can be monitored via the **UART Flag (UARTFR)** register (see page 879) and the **UART Receive Status (UARTRSR)** register. Hardware monitors empty, full and overrun conditions. The **UARTFR** register contains empty and full flags (`TXFE`, `TXFF`, `RXFE`, and `RXFF` bits), and the **UARTRSR** register shows overrun status via the `OE` bit. If the FIFOs are disabled, the empty and full flags are set according to the status of the 1-byte-deep holding registers.

The trigger points at which the FIFOs generate interrupts is controlled via the **UART Interrupt FIFO Level Select (UARTIFLS)** register (see page 890). Both FIFOs can be individually configured to trigger interrupts at different levels. Available configurations include  $\frac{1}{8}$ ,  $\frac{1}{4}$ ,  $\frac{1}{2}$ ,  $\frac{3}{4}$ , and  $\frac{7}{8}$ . For example, if the  $\frac{1}{4}$  option is selected for the receive FIFO, the UART generates a receive interrupt after 4 data bytes are received. Out of reset, both FIFOs are configured to trigger an interrupt at the  $\frac{1}{2}$  mark.

### 14.3.9 Interrupts

The UART can generate interrupts when the following conditions are observed:

- Overrun Error
- Break Error
- Parity Error

- Framing Error
- Receive Timeout
- Transmit (when condition defined in the `TXIFLSEL` bit in the **UARTIFLS** register is met, or if the `EOT` bit in **UARTCTL** is set, when the last bit of all transmitted data leaves the serializer)
- Receive (when condition defined in the `RXIFLSEL` bit in the **UARTIFLS** register is met)

All of the interrupt events are ORed together before being sent to the interrupt controller, so the UART can only generate a single interrupt request to the controller at any given time. Software can service multiple interrupt events in a single interrupt service routine by reading the **UART Masked Interrupt Status (UARTMIS)** register (see page 898).

The interrupt events that can trigger a controller-level interrupt are defined in the **UART Interrupt Mask (UARTIM)** register (see page 892) by setting the corresponding `IM` bits. If interrupts are not used, the raw interrupt status is always visible via the **UART Raw Interrupt Status (UARTRIS)** register (see page 895).

Interrupts are always cleared (for both the **UARTMIS** and **UARTRIS** registers) by writing a 1 to the corresponding bit in the **UART Interrupt Clear (UARTICR)** register (see page 901).

The receive timeout interrupt is asserted when the receive FIFO is not empty, and no further data is received over a 32-bit period when the `HSE` bit is clear or over a 64-bit period when the `HSE` bit is set. The receive timeout interrupt is cleared either when the FIFO becomes empty through reading all the data (or by reading the holding register), or when a 1 is written to the corresponding bit in the **UARTICR** register.

The receive interrupt changes state when one of the following events occurs:

- If the FIFOs are enabled and the receive FIFO reaches the programmed trigger level, the `RXRIS` bit is set. The receive interrupt is cleared by reading data from the receive FIFO until it becomes less than the trigger level, or by clearing the interrupt by writing a 1 to the `RXIC` bit.
- If the FIFOs are disabled (have a depth of one location) and data is received thereby filling the location, the `RXRIS` bit is set. The receive interrupt is cleared by performing a single read of the receive FIFO, or by clearing the interrupt by writing a 1 to the `RXIC` bit.

The transmit interrupt changes state when one of the following events occurs:

- If the FIFOs are enabled and the transmit FIFO progresses through the programmed trigger level, the `TXRIS` bit is set. The transmit interrupt is based on a transition through level, therefore the FIFO must be written past the programmed trigger level otherwise no further transmit interrupts will be generated. The transmit interrupt is cleared by writing data to the transmit FIFO until it becomes greater than the trigger level, or by clearing the interrupt by writing a 1 to the `TXIC` bit.
- If the FIFOs are disabled (have a depth of one location) and there is no data present in the transmitters single location, the `TXRIS` bit is set. It is cleared by performing a single write to the transmit FIFO, or by clearing the interrupt by writing a 1 to the `TXIC` bit.

### 14.3.10 Loopback Operation

The UART can be placed into an internal loopback mode for diagnostic or debug work by setting the `LBE` bit in the **UARTCTL** register (see page 886). In loopback mode, data transmitted on the `UnTx` output is received on the `UnRx` input. Note that the `LBE` bit should be set before the UART is enabled.

### 14.3.11 DMA Operation

The UART provides an interface to the  $\mu$ DMA controller with separate channels for transmit and receive. The DMA operation of the UART is enabled through the **UART DMA Control (UARTDMACTL)** register. When DMA operation is enabled, the UART asserts a DMA request on the receive or transmit channel when the associated FIFO can transfer data. For the receive channel, a single transfer request is asserted whenever any data is in the receive FIFO. A burst transfer request is asserted whenever the amount of data in the receive FIFO is at or above the FIFO trigger level configured in the **UARTIFLS** register. For the transmit channel, a single transfer request is asserted whenever there is at least one empty location in the transmit FIFO. The burst request is asserted whenever the transmit FIFO contains fewer characters than the FIFO trigger level. The single and burst DMA transfer requests are handled automatically by the  $\mu$ DMA controller depending on how the DMA channel is configured.

To enable DMA operation for the receive channel, set the **RXDMAE** bit of the **DMA Control (UARTDMACTL)** register. To enable DMA operation for the transmit channel, set the **TXDMAE** bit of the **UARTDMACTL** register. The UART can also be configured to stop using DMA for the receive channel if a receive error occurs. If the **DMAERR** bit of the **UARTDMACR** register is set and a receive error occurs, the DMA receive requests are automatically disabled. This error condition can be cleared by clearing the appropriate UART error interrupt.

If the  $\mu$ DMA is enabled, then the controller triggers an interrupt when the TX FIFO or RX FIFO has reached a trigger point as programmed in the **UARTIFLS** register. The interrupt occurs on the UART interrupt vector. Therefore, if interrupts are used for UART operation and DMA is enabled, the UART interrupt handler must be designed to handle the  $\mu$ DMA completion interrupt.

**Note:** To trigger an interrupt on transmit completion from the UART's serializer, the **EOT** bit must be set in the **UARTCTL** register. In this configuration, the transmit interrupt is generated once the FIFO is completely empty and all data including the stop bits have left the transmit serializer. In this case, setting the **TXIFLSEL** bit in the **UARTIFLS** register is ignored.

See “Micro Direct Memory Access ( $\mu$ DMA)” on page 557 for more details about programming the  $\mu$ DMA controller.

## 14.4 Initialization and Configuration

To enable and initialize the UART, the following steps are necessary:

1. Enable the UART module using the **RCGCUART** register (see page 330).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register (see page 326). To find out which GPIO port to enable, refer to Table 21-5 on page 1153.
3. Set the GPIO **AFSEL** bits for the appropriate pins (see page 642). To determine which GPIOs to configure, see Table 21-4 on page 1149.
4. Configure the GPIO current level and/or slew rate as specified for the mode selected (see page 644 and page 652).
5. Configure the **PMC<sub>n</sub>** fields in the **GPIOPCTL** register to assign the UART signals to the appropriate pins (see page 659 and Table 21-5 on page 1153).

To use the UART, the peripheral clock must be enabled by setting the appropriate bit in the **RCGCUART** register (page 330). In addition, the clock to the appropriate GPIO module must be enabled via the **RCGCGPIO** register (page 326) in the System Control module. To find out which GPIO port to enable, refer to Table 21-5 on page 1153.

This section discusses the steps that are required to use a UART module. For this example, the UART clock is assumed to be 20 MHz, and the desired UART configuration is:

- 115200 baud rate
- Data length of 8 bits
- One stop bit
- No parity
- FIFOs disabled
- No interrupts

The first thing to consider when programming the UART is the baud-rate divisor (BRD), because the **UARTIBRD** and **UARTFBRD** registers must be written before the **UARTLCRH** register. Using the equation described in “Baud-Rate Generation” on page 864, the BRD can be calculated:

$$\text{BRD} = 20,000,000 / (16 * 115,200) = 10.8507$$

which means that the **DIVINT** field of the **UARTIBRD** register (see page 882) should be set to 10 decimal or 0xA. The value to be loaded into the **UARTFBRD** register (see page 883) is calculated by the equation:

$$\text{UARTFBRD}[\text{DIVFRAC}] = \text{integer}(0.8507 * 64 + 0.5) = 54$$

With the BRD values in hand, the UART configuration is written to the module in the following order:

1. Disable the UART by clearing the **UARTEN** bit in the **UARTCTL** register.
2. Write the integer portion of the BRD to the **UARTIBRD** register.
3. Write the fractional portion of the BRD to the **UARTFBRD** register.
4. Write the desired serial parameters to the **UARTLCRH** register (in this case, a value of 0x0000.0060).
5. Configure the UART clock source by writing to the **UARTCC** register.
6. Optionally, configure the  $\mu$ DMA channel (see “Micro Direct Memory Access ( $\mu$ DMA)” on page 557) and enable the DMA option(s) in the **UARTDMACTL** register.
7. Enable the UART by setting the **UARTEN** bit in the **UARTCTL** register.

## 14.5 Register Map

Table 14-3 on page 872 lists the UART registers. The offset listed is a hexadecimal increment to the register's address, relative to that UART's base address:

- UART0: 0x4000.C000
- UART1: 0x4000.D000
- UART2: 0x4000.E000
- UART3: 0x4000.F000
- UART4: 0x4001.0000
- UART5: 0x4001.1000
- UART6: 0x4001.2000

■ UART7: 0x4001.3000

The UART module clock must be enabled before the registers can be programmed (see page 330). There must be a delay of 3 system clocks after the UART module clock is enabled before any UART module registers are accessed.

The UART must be disabled (see the `UARTEN` bit in the `UARTCTL` register on page 886) before any of the control registers are reprogrammed. When the UART is disabled during a TX or RX operation, the current transaction is completed prior to the UART stopping.

**Table 14-3. UART Register Map**

| Offset | Name            | Type | Reset       | Description                       | See page |

## 14.6 Register Descriptions

The remainder of this section lists and describes the UART registers, in numerical order by address offset.

## Register 1: UART Data (UARTDR), offset 0x000

**Important:** This register is read-sensitive. See the register description for details.

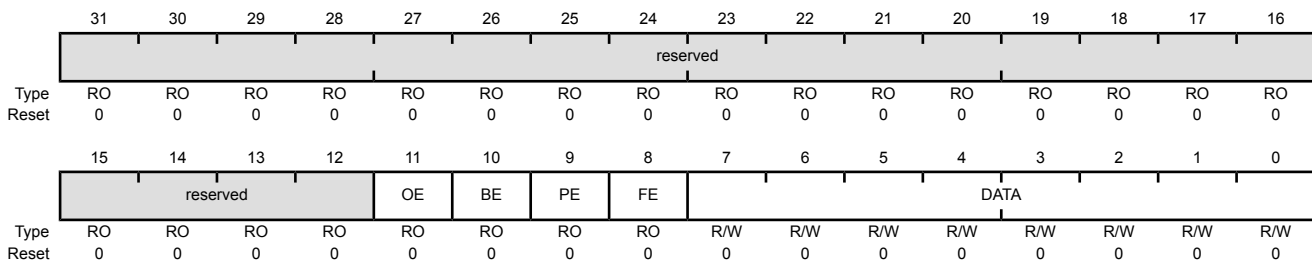

This register is the data register (the interface to the FIFOs).

For transmitted data, if the FIFO is enabled, data written to this location is pushed onto the transmit FIFO. If the FIFO is disabled, data is stored in the transmitter holding register (the bottom word of the transmit FIFO). A write to this register initiates a transmission from the UART.

For received data, if the FIFO is enabled, the data byte and the 4-bit status (break, frame, parity, and overrun) is pushed onto the 12-bit wide receive FIFO. If the FIFO is disabled, the data byte and status are stored in the receiving holding register (the bottom word of the receive FIFO). The received data can be retrieved by reading this register.

### UART Data (UARTDR)

UART0 base: 0x4000.C000  
 UART1 base: 0x4000.D000  
 UART2 base: 0x4000.E000  
 UART3 base: 0x4000.F000  
 UART4 base: 0x4001.0000  
 UART5 base: 0x4001.1000  
 UART6 base: 0x4001.2000  
 UART7 base: 0x4001.3000  
 Offset 0x000  
 Type R/W, reset 0x0000.0000

| Bit/Field | Name     | Type | Reset    | Description                                                                                                                                                                                   |
|-----------|----------|------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:12     | reserved | RO   | 0x0000.0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 11        | OE       | RO   | 0        | UART Overrun Error                                                                                                                                                                            |
|           |          |      |          | Value Description                                                                                                                                                                             |
|           |          |      |          | 0 No data has been lost due to a FIFO overrun.                                                                                                                                                |
|           |          |      |          | 1 New data was received when the FIFO was full, resulting in data loss.                                                                                                                       |

| Bit/Field | Name | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Register 2: UART Receive Status/Error Clear (UARTRSR/UARTECR), offset 0x004

The **UARTRSR/UARTECR** register is the receive status register/error clear register.

In addition to the **UARTDR** register, receive status can also be read from the **UARTRSR** register. If the status is read from this register, then the status information corresponds to the entry read from **UARTDR** prior to reading **UARTRSR**. The status information for overrun is set immediately when an overrun condition occurs.

The **UARTRSR** register cannot be written.

A write of any value to the **UARTECR** register clears the framing, parity, break, and overrun errors. All the bits are cleared on reset.

### Read-Only Status Register

#### UART Receive Status/Error Clear (UARTRSR/UARTECR)

| Value | Description                                                           |
|-------|-----------------------------------------------------------------------|
| 0     | No data has been lost due to a FIFO overrun.                          |
| 1     | New data was received when the FIFO was full, resulting in data loss. |

This bit is cleared by a write to **UARTECR**.

The FIFO contents remain valid because no further data is written when the FIFO is full, only the contents of the shift register are overwritten. The CPU must read the data in order to empty the FIFO.

### Register 3: UART Flag (UARTFR), offset 0x018

The **UARTFR** register is the flag register. After reset, the **TXFF**, **RXFF**, and **BUSY** bits are 0, and **TXFE** and **RXFE** bits are 1. The **CTS** bit indicate the modem flow control. Note that the modem bits are only implemented on UART1 and are reserved on UART0 and UART2.

## Register 4: UART IrDA Low-Power Register (UARTILPR), offset 0x020

The **UARTILPR** register stores the 8-bit low-power counter divisor value used to derive the low-power SIR pulse width clock by dividing down the system clock (SysClk). All the bits are cleared when reset.

The internal  $F_{IrLPBaud16}$  clock is generated by dividing down SysClk according to the low-power divisor value written to **UARTILPR**. The duration of SIR pulses generated when low-power mode is enabled is three times the period of the  $F_{IrLPBaud16}$  clock. The low-power divisor value is calculated as follows:

$$ILPDVSR = SysClk / F_{IrLPBaud16}$$

where  $F_{IrLPBaud16}$  is nominally 1.8432 MHz.

Because the  $F_{IrLPBaud16}$  clock is used to sample transmitted data irrespective of mode, the **ILPDVSR** field must be programmed in both low power and normal mode, such that  $1.42 \text{ MHz} < F_{IrLPBaud16} < 2.12 \text{ MHz}$ , resulting in a low-power pulse duration of 1.41–2.11  $\mu\text{s}$  (three times the period of  $F_{IrLPBaud16}$ ). The minimum frequency of  $F_{IrLPBaud16}$  ensures that pulses less than one period of  $F_{IrLPBaud16}$  are rejected, but pulses greater than 1.4  $\mu\text{s}$  are accepted as valid pulses.

**Note:** Zero is an illegal value. Programming a zero value results in no  $F_{IrLPBaud16}$  pulses being generated.

### Register 5: UART Integer Baud-Rate Divisor (UARTIBRD), offset 0x024

The **UARTIBRD** register is the integer part of the baud-rate divisor value. All the bits are cleared on reset. The minimum possible divide ratio is 1 (when **UARTIBRD**=0), in which case the **UARTFBRD** register is ignored. When changing the **UARTIBRD** register, the new value does not take effect until transmission/reception of the current character is complete. Any changes to the baud-rate divisor must be followed by a write to the **UARTLCRH** register. See “Baud-Rate Generation” on page 864 for configuration details.

**Register 6: UART Fractional Baud-Rate Divisor (UARTFBRD), offset 0x028**

The **UARTFBRD** register is the fractional part of the baud-rate divisor value. All the bits are cleared on reset. When changing the **UARTFBRD** register, the new value does not take effect until transmission/reception of the current character is complete. Any changes to the baud-rate divisor must be followed by a write to the **UARTLCRH** register. See “Baud-Rate Generation” on page 864 for configuration details.

### Register 7: UART Line Control (UARTLCRH), offset 0x02C

The **UARTLCRH** register is the line control register. Serial parameters such as data length, parity, and stop bit selection are implemented in this register.

When updating the baud-rate divisor (**UARTIBRD** and/or **UARTIFRD**), the **UARTLCRH** register must also be written. The write strobe for the baud-rate divisor registers is tied to the **UARTLCRH** register.

### Register 8: UART Control (UARTCTL), offset 0x030

The **UARTCTL** register is the control register. All the bits are cleared on reset except for the Transmit Enable (**TXE**) and Receive Enable (**RXE**) bits, which are set.

To enable the UART module, the **UARTEN** bit must be set. If software requires a configuration change in the module, the **UARTEN** bit must be cleared before the configuration changes are written. If the UART is disabled during a transmit or receive operation, the current transaction is completed prior to the UART stopping.

**Note:** The **UARTCTL** register should not be changed while the UART is enabled or else the results are unpredictable. The following sequence is recommended for making changes to the **UARTCTL** register.

1. Disable the UART.
2. Wait for the end of transmission or reception of the current character.
3. Flush the transmit FIFO by clearing bit 4 (**FEN**) in the line control register (**UARTLCRH**).
4. Reprogram the control register.
5. Enable the UART.

#### UART Control (UARTCTL)

### Register 9: UART Interrupt FIFO Level Select (UARTIFLS), offset 0x034

The **UARTIFLS** register is the interrupt FIFO level select register. You can use this register to define the FIFO level at which the **TXRIS** and **RXRIS** bits in the **UARTRIS** register are triggered.

The interrupts are generated based on a transition through a level rather than being based on the level. That is, the interrupts are generated when the fill level progresses through the trigger level. For example, if the receive trigger level is set to the half-way mark, the interrupt is triggered as the module is receiving the 9th character.

Out of reset, the **TXIFLSEL** and **RXIFLSEL** bits are configured so that the FIFOs trigger an interrupt at the half-way mark.

#### UART Interrupt FIFO Level Select (UARTIFLS)

UART0 base: 0x4000.C000  
 UART1 base: 0x4000.D000  
 UART2 base: 0x4000.E000  
 UART3 base: 0x4000.F000  
 UART4 base: 0x4001.0000  
 UART5 base: 0x4001.1000  
 UART6 base: 0x4001.2000  
 UART7 base: 0x4001.3000  
 Offset 0x034  
 Type R/W, reset 0x0000.0012

In this case, the setting of TXIFLSEL is ignored. |

### Register 10: UART Interrupt Mask (UARTIM), offset 0x038

The **UARTIM** register is the interrupt mask set/clear register.

On a read, this register gives the current value of the mask on the relevant interrupt. Setting a bit allows the corresponding raw interrupt signal to be routed to the interrupt controller. Clearing a bit prevents the raw interrupt signal from being sent to the interrupt controller.

#### UART Interrupt Mask (UARTIM)

UART0 base: 0x4000.C000

**Register 11: UART Raw Interrupt Status (UARTRIS), offset 0x03C**

The **UARTRIS** register is the raw interrupt status register. On a read, this register gives the current raw status value of the corresponding interrupt. A write has no effect.

**UART Raw Interrupt Status (UARTRIS)**

### Register 12: UART Masked Interrupt Status (UARTMIS), offset 0x040

The **UARTMIS** register is the masked interrupt status register. On a read, this register gives the current masked status value of the corresponding interrupt. A write has no effect.

#### UART Masked Interrupt Status (UARTMIS)

UART0 base: 0x4000.C000  
 UART1 base: 0x4000.D000  
 UART2 base: 0x4000.E000  
 UART3 base: 0x4000.F000  
 UART4 base: 0x4001.0000  
 UART5 base: 0x4001.1000  
 UART6 base: 0x4001.2000  
 UART7 base: 0x4001.3000  
 Offset 0x040  
 Type RO, reset 0x0000.0000

## Register 13: UART Interrupt Clear (UARTICR), offset 0x044

The **UARTICR** register is the interrupt clear register. On a write of 1, the corresponding interrupt (both raw interrupt and masked interrupt, if enabled) is cleared. A write of 0 has no effect.

### UART Interrupt Clear (UARTICR)

UART0 base: 0x4000.C000  
 UART1 base: 0x4000.D000  
 UART2 base: 0x4000.E000  
 UART3 base: 0x4000.F000  
 UART4 base: 0x4001.0000

### Register 15: UART 9-Bit Self Address (UART9BITADDR), offset 0x0A4

The **UART9BITADDR** register is used to write the specific address that should be matched with the receiving byte when the 9-bit Address Mask (**UART9BITAMASK**) is set to 0xFF. This register is used in conjunction with **UART9BITAMASK** to form a match for address-byte received.

#### UART 9-Bit Self Address (UART9BITADDR)

UART0 base: 0x4000.C000  
 UART1 base: 0x4000.D000  
 UART2 base: 0x4000.E000

**Register 18: UART Clock Configuration (UARTCC), offset 0xFC8**

The **UARTCC** register controls the baud clock source for the UART module. For more information, see the section called “Communication Clock Sources” on page 214.

**Note:** If the PIOSC is used for the UART baud clock, the system clock frequency must be at least 9 MHz in Run mode.

**UART Clock Configuration (UARTCC)**

## 15 Synchronous Serial Interface (SSI)

The TM4C1233C3PM microcontroller includes four Synchronous Serial Interface (SSI) modules. Each SSI module is a master or slave interface for synchronous serial communication with peripheral devices that have either Freescale SPI, MICROWIRE, or Texas Instruments synchronous serial interfaces.

The TM4C1233C3PM SSI modules have the following features:

- Programmable interface operation for Freescale SPI, MICROWIRE, or Texas Instruments synchronous serial interfaces
- Master or slave operation
- Programmable clock bit rate and prescaler
- Separate transmit and receive FIFOs, each 16 bits wide and 8 locations deep
- Programmable data frame size from 4 to 16 bits
- Internal loopback test mode for diagnostic/debug testing
- Standard FIFO-based interrupts and End-of-Transmission interrupt
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for transmit and receive
  - Receive single request asserted when data is in the FIFO; burst request asserted when FIFO contains 4 entries
  - Transmit single request asserted when there is space in the FIFO; burst request asserted when four or more entries are available to be written in the FIFO

## 15.1 Block Diagram

Figure 15-1. SSI Module Block Diagram

## 15.2 Signal Description

The following table lists the external signals of the SSI module and describes the function of each. Most SSI signals are alternate functions for some GPIO signals and default to be GPIO signals at

reset. The exceptions to this rule are the SSI0Clk, SSI0Fss, SSI0Rx, and SSI0Tx pins, which default to the SSI function. The "Pin Mux/Pin Assignment" column in the following table lists the possible GPIO pin placements for the SSI signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 642) should be set to choose the SSI function. The number in parentheses is the encoding that must be programmed into the PMCh field in the **GPIO Port Control (GPIOCTL)** register (page 659) to assign the SSI signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 621.

Table 15-1. SSI Signals (64LQFP)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                |
|----------|------------|--------------------------|----------|--------------------------|----------------------------|
| SSI0Clk  | 19         | PA2 (2)                  | I/O      | TTL                      | SSI module 0 clock         |
| SSI0Fss  | 20         | PA3 (2)                  | I/O      | TTL                      | SSI module 0 frame signal  |

| SSI2Rx   | 1          | PB6 (2)                  | I        | TTL                      | SSI module 2 receive.      |
| SSI2Tx   | 4          | PB7 (2)                  | O        | TTL                      | SSI module 2 transmit.     |
| SSI3Clk  | 61         | PD0 (1)                  | I/O      | TTL                      | SSI module 3 clock.        |
| SSI3Fss  | 62         | PD1 (1)                  | I/O      | TTL                      | SSI module 3 frame signal. |
| SSI3Rx   | 63         | PD2 (1)                  | I        | TTL                      | SSI module 3 receive.      |
| SSI3Tx   | 64         | PD3 (1)                  | O        | TTL                      | SSI module 3 transmit.     |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 15.3 Functional Description

The SSI performs serial-to-parallel conversion on data received from a peripheral device. The CPU accesses data, control, and status information. The transmit and receive paths are buffered with internal FIFO memories allowing up to eight 16-bit values to be stored independently in both transmit and receive modes. The SSI also supports the  $\mu$ DMA interface. The transmit and receive FIFOs can be programmed as destination/source addresses in the  $\mu$ DMA module.  $\mu$ DMA operation is enabled by setting the appropriate bit(s) in the **SSIDMACTL** register (see page 950).

### 15.3.1 Bit Rate Generation

The SSI includes a programmable bit rate clock divider and prescaler to generate the serial output clock. Bit rates are supported to 2 MHz and higher, although maximum bit rate is determined by peripheral devices.

The serial bit rate is derived by dividing down the input clock (SysClk). The clock is first divided by an even prescale value CPSDVSR from 2 to 254, which is programmed in the **SSI Clock Prescale**

(**SSICPSR**) register (see page 943). The clock is further divided by a value from 1 to 256, which is  $1 + SCR$ , where  $SCR$  is the value programmed in the **SSI Control 0 (SSICR0)** register (see page 936).

The frequency of the output clock  $SSInClk$  is defined by:

$$SSInClk = SysClk / (CPSDVR * (1 + SCR))$$

**Note:** The System Clock or the PIOSC can be used as the source for the  $SSInClk$ . When the  $CS$  field in the **SSI Clock Configuration (SSICC)** register is configured to 0x5, PIOSC is selected as the source. For master mode, the system clock or the PIOSC must be at least two times faster than the  $SSInClk$ , with the restriction that  $SSInClk$  cannot be faster than 25 MHz. For slave mode, the system clock or the PIOSC must be at least 12 times faster than the  $SSInClk$ , with the restriction that  $SSInClk$  cannot be faster than 6.67 MHz.

See “Synchronous Serial Interface (SSI)” on page 1193 to view SSI timing parameters.

## 15.3.2 FIFO Operation

### 15.3.2.1 Transmit FIFO

The common transmit FIFO is a 16-bit wide, 8-locations deep, first-in, first-out memory buffer. The CPU writes data to the FIFO by writing the **SSI Data (SSIDR)** register (see page 940), and data is stored in the FIFO until it is read out by the transmission logic.

When configured as a master or a slave, parallel data is written into the transmit FIFO prior to serial conversion and transmission to the attached slave or master, respectively, through the  $SSInTx$  pin.

In slave mode, the SSI transmits data each time the master initiates a transaction. If the transmit FIFO is empty and the master initiates, the slave transmits the 8th most recent value in the transmit FIFO. If less than 8 values have been written to the transmit FIFO since the SSI module clock was enabled using the  $R_n$  bit in the **RCGCSSI** register, then 0 is transmitted. Care should be taken to ensure that valid data is in the FIFO as needed. The SSI can be configured to generate an interrupt or a  $\mu$ DMA request when the FIFO is empty.

### 15.3.2.2 Receive FIFO

The common receive FIFO is a 16-bit wide, 8-locations deep, first-in, first-out memory buffer. Received data from the serial interface is stored in the buffer until read out by the CPU, which accesses the read FIFO by reading the **SSIDR** register.

When configured as a master or slave, serial data received through the  $SSInRx$  pin is registered prior to parallel loading into the attached slave or master receive FIFO, respectively.

## 15.3.3 Interrupts

The SSI can generate interrupts when the following conditions are observed:

- Transmit FIFO service (when the transmit FIFO is half full or less)
- Receive FIFO service (when the receive FIFO is half full or more)
- Receive FIFO time-out
- Receive FIFO overrun
- End of transmission
- Receive DMA transfer complete

- Transmit DMA transfer complete

All of the interrupt events are ORed together before being sent to the interrupt controller, so the SSI generates a single interrupt request to the controller regardless of the number of active interrupts. Each of the four individual maskable interrupts can be masked by clearing the appropriate bit in the **SSI Interrupt Mask (SSIIM)** register (see page 944). Setting the appropriate mask bit enables the interrupt.

The individual outputs, along with a combined interrupt output, allow use of either a global interrupt service routine or modular device drivers to handle interrupts. The transmit and receive dynamic dataflow interrupts have been separated from the status interrupts so that data can be read or written in response to the FIFO trigger levels. The status of the individual interrupt sources can be read from the **SSI Raw Interrupt Status (SSIRIS)** and **SSI Masked Interrupt Status (SSIMIS)** registers (see page 945 and page 947, respectively).

The receive FIFO has a time-out period that is 32 periods at the rate of `SSInClk` (whether or not `SSInClk` is currently active) and is started when the RX FIFO goes from EMPTY to not-EMPTY. If the RX FIFO is emptied before 32 clocks have passed, the time-out period is reset. As a result, the ISR should clear the Receive FIFO Time-out Interrupt just after reading out the RX FIFO by writing a 1 to the `RTIC` bit in the **SSI Interrupt Clear (SSIICR)** register. The interrupt should not be cleared so late that the ISR returns before the interrupt is actually cleared, or the ISR may be re-activated unnecessarily.

The End-of-Transmission (EOT) interrupt indicates that the data has been transmitted completely and is only valid for Master mode devices/operations. This interrupt can be used to indicate when it is safe to turn off the SSI module clock or enter sleep mode. In addition, because transmitted data and received data complete at exactly the same time, the interrupt can also indicate that read data is ready immediately, without waiting for the receive FIFO time-out period to complete.

**Note:** In Freescale SPI mode only, a condition can be created where an EOT interrupt is generated for every byte transferred even if the FIFO is full. If the `EOT` bit has been set to 0 in an integrated slave SSI and the  $\mu$ DMA has been configured to transfer data from this SSI to a Master SSI on the device using external loopback, an EOT interrupt is generated by the SSI slave for every byte even if the FIFO is full.

### 15.3.4 Frame Formats

Each data frame is between 4 and 16 bits long depending on the size of data programmed and is transmitted starting with the MSB. There are three basic frame types that can be selected by programming the `FRF` bit in the **SSICR0** register:

- Texas Instruments synchronous serial
- Freescale SPI
- MICROWIRE

For all three formats, the serial clock (`SSInClk`) is held inactive while the SSI is idle, and `SSInClk` transitions at the programmed frequency only during active transmission or reception of data. The idle state of `SSInClk` is utilized to provide a receive timeout indication that occurs when the receive FIFO still contains data after a timeout period.

For Freescale SPI and MICROWIRE frame formats, the serial frame (`SSInFss`) pin is active Low, and is asserted (pulled down) during the entire transmission of the frame.

For Texas Instruments synchronous serial frame format, the `SSInFss` pin is pulsed for one serial clock period starting at its rising edge, prior to the transmission of each frame. For this frame format, both the SSI and the off-chip slave device drive their output data on the rising edge of `SSInClk` and latch data from the other device on the falling edge.

Unlike the full-duplex transmission of the other two frame formats, the MICROWIRE format uses a special master-slave messaging technique which operates at half-duplex. In this mode, when a frame begins, an 8-bit control message is transmitted to the off-chip slave. During this transmit, no incoming data is received by the SSI. After the message has been sent, the off-chip slave decodes it and, after waiting one serial clock after the last bit of the 8-bit control message has been sent, responds with the requested data. The returned data can be 4 to 16 bits in length, making the total frame length anywhere from 13 to 25 bits.

#### 15.3.4.1 Texas Instruments Synchronous Serial Frame Format

Figure 15-2 on page 925 shows the Texas Instruments synchronous serial frame format for a single transmitted frame.

**Figure 15-2. TI Synchronous Serial Frame Format (Single Transfer)**

In this mode, `SSInClk` and `SSInFss` are forced Low, and the transmit data line `SSInTx` is tristated whenever the SSI is idle. Once the bottom entry of the transmit FIFO contains data, `SSInFss` is pulsed High for one `SSInClk` period. The value to be transmitted is also transferred from the transmit FIFO to the serial shift register of the transmit logic. On the next rising edge of `SSInClk`, the MSB of the 4 to 16-bit data frame is shifted out on the `SSInTx` pin. Likewise, the MSB of the received data is shifted onto the `SSInRx` pin by the off-chip serial slave device.

Both the SSI and the off-chip serial slave device then clock each data bit into their serial shifter on each falling edge of `SSInClk`. The received data is transferred from the serial shifter to the receive FIFO on the first rising edge of `SSInClk` after the LSB has been latched.

Figure 15-3 on page 926 shows the Texas Instruments synchronous serial frame format when back-to-back frames are transmitted.

Figure 15-3. TI Synchronous Serial Frame Format (Continuous Transfer)

#### 15.3.4.2 Freescale SPI Frame Format

The Freescale SPI interface is a four-wire interface where the SSInFss signal behaves as a slave select. The main feature of the Freescale SPI format is that the inactive state and phase of the SSInClk signal are programmable through the SPO and SPH bits in the **SSICR0** control register.

##### **SPO Clock Polarity Bit**

When the SPO clock polarity control bit is clear, it produces a steady state Low value on the SSInClk pin. If the SPO bit is set, a steady state High value is placed on the SSInClk pin when data is not being transferred.

##### **SPH Phase Control Bit**

The SPH phase control bit selects the clock edge that captures data and allows it to change state. The state of this bit has the most impact on the first bit transmitted by either allowing or not allowing a clock transition before the first data capture edge. When the SPH phase control bit is clear, data is captured on the first clock edge transition. If the SPH bit is set, data is captured on the second clock edge transition.

#### 15.3.4.3 Freescale SPI Frame Format with SPO=0 and SPH=0

Single and continuous transmission signal sequences for Freescale SPI format with SPO=0 and SPH=0 are shown in Figure 15-4 on page 927 and Figure 15-5 on page 927.

**Figure 15-4. Freescale SPI Format (Single Transfer) with SPO=0 and SPH=0**

**Note:** Q is undefined.

**Figure 15-5. Freescale SPI Format (Continuous Transfer) with SPO=0 and SPH=0**

In this configuration, during idle periods:

- SSInClk is forced Low
- SSInFss is forced High
- The transmit data line SSInTx is arbitrarily forced Low
- When the SSI is configured as a master, it enables the SSInClk pad
- When the SSI is configured as a slave, it disables the SSInClk pad

If the SSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the SSInFss master signal being driven Low, causing slave data to be enabled onto the SSInRx input line of the master. The master SSInTx output pad is enabled.

One half SSInClk period later, valid master data is transferred to the SSInTx pin. Once both the master and slave data have been set, the SSInClk master clock pin goes High after one additional half SSInClk period.

The data is now captured on the rising and propagated on the falling edges of the SSInClk signal.

In the case of a single word transmission, after all bits of the data word have been transferred, the  $SSInFss$  line is returned to its idle High state one  $SSInClk$  period after the last bit has been captured.

However, in the case of continuous back-to-back transmissions, the  $SSInFss$  signal must be pulsed High between each data word transfer because the slave select pin freezes the data in its serial peripheral register and does not allow it to be altered if the  $SPH$  bit is clear. Therefore, the master device must raise the  $SSInFss$  pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the  $SSInFss$  pin is returned to its idle state one  $SSInClk$  period after the last bit has been captured.

#### 15.3.4.4 Freescale SPI Frame Format with $SPO=0$ and $SPH=1$

The transfer signal sequence for Freescale SPI format with  $SPO=0$  and  $SPH=1$  is shown in Figure 15-6 on page 928, which covers both single and continuous transfers.

**Figure 15-6. Freescale SPI Frame Format with  $SPO=0$  and  $SPH=1$**

**Note:** Q is undefined.

In this configuration, during idle periods:

- $SSInClk$  is forced Low
- $SSInFss$  is forced High
- The transmit data line  $SSInTx$  is arbitrarily forced Low
- When the SSI is configured as a master, it enables the  $SSInClk$  pad
- When the SSI is configured as a slave, it disables the  $SSInClk$  pad

If the SSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the  $SSInFss$  master signal being driven Low. The master  $SSInTx$  output is enabled. After an additional one-half  $SSInClk$  period, both master and slave valid data are enabled onto their respective transmission lines. At the same time, the  $SSInClk$  is enabled with a rising edge transition.

Data is then captured on the falling edges and propagated on the rising edges of the  $SSInClk$  signal.

In the case of a single word transfer, after all bits have been transferred, the  $SSInFss$  line is returned to its idle High state one  $SSInClk$  period after the last bit has been captured.

For continuous back-to-back transfers, the  $SSInFss$  pin is held Low between successive data words, and termination is the same as that of the single word transfer.

#### 15.3.4.5 Freescale SPI Frame Format with $SPO=1$ and $SPH=0$

Single and continuous transmission signal sequences for Freescale SPI format with  $SPO=1$  and  $SPH=0$  are shown in Figure 15-7 on page 929 and Figure 15-8 on page 929.

**Figure 15-7. Freescale SPI Frame Format (Single Transfer) with  $SPO=1$  and  $SPH=0$**

**Note:** Q is undefined.

**Figure 15-8. Freescale SPI Frame Format (Continuous Transfer) with  $SPO=1$  and  $SPH=0$**

In this configuration, during idle periods:

- $SSInClk$  is forced High
- $SSInFss$  is forced High
- The transmit data line  $SSInTx$  is arbitrarily forced Low
- When the SSI is configured as a master, it enables the  $SSInClk$  pad
- When the SSI is configured as a slave, it disables the  $SSInClk$  pad

If the SSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the  $SSInFss$  master signal being driven Low, causing slave data to be immediately transferred onto the  $SSInRx$  line of the master. The master  $SSInTx$  output pad is enabled.

One-half period later, valid master data is transferred to the  $SSInTx$  line. Once both the master and slave data have been set, the  $SSInClk$  master clock pin becomes Low after one additional half

$SSInClk$  period, meaning that data is captured on the falling edges and propagated on the rising edges of the  $SSInClk$  signal.

In the case of a single word transmission, after all bits of the data word are transferred, the  $SSInFss$  line is returned to its idle High state one  $SSInClk$  period after the last bit has been captured.

However, in the case of continuous back-to-back transmissions, the  $SSInFss$  signal must be pulsed High between each data word transfer because the slave select pin freezes the data in its serial peripheral register and does not allow it to be altered if the  $SPH$  bit is clear. Therefore, the master device must raise the  $SSInFss$  pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the  $SSInFss$  pin is returned to its idle state one  $SSInClk$  period after the last bit has been captured.

#### 15.3.4.6 Freescale SPI Frame Format with $SPO=1$ and $SPH=1$

The transfer signal sequence for Freescale SPI format with  $SPO=1$  and  $SPH=1$  is shown in Figure 15-9 on page 930, which covers both single and continuous transfers.

**Figure 15-9. Freescale SPI Frame Format with  $SPO=1$  and  $SPH=1$**

**Note:** Q is undefined.

In this configuration, during idle periods:

- $SSInClk$  is forced High
- $SSInFss$  is forced High
- The transmit data line  $SSInTx$  is arbitrarily forced Low
- When the SSI is configured as a master, it enables the  $SSInClk$  pad
- When the SSI is configured as a slave, it disables the  $SSInClk$  pad

If the SSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the  $SSInFss$  master signal being driven Low. The master  $SSInTx$  output pad is enabled. After an additional one-half  $SSInClk$  period, both master and slave data are enabled onto their respective transmission lines. At the same time,  $SSInClk$  is enabled with a falling edge transition. Data is then captured on the rising edges and propagated on the falling edges of the  $SSInClk$  signal.

After all bits have been transferred, in the case of a single word transmission, the  $SSInFss$  line is returned to its idle high state one  $SSInClk$  period after the last bit has been captured.

For continuous back-to-back transmissions, the `SSInFss` pin remains in its active Low state until the final bit of the last word has been captured and then returns to its idle state as described above.

For continuous back-to-back transfers, the `SSInFss` pin is held Low between successive data words and termination is the same as that of the single word transfer.

#### 15.3.4.7 MICROWIRE Frame Format

Figure 15-10 on page 931 shows the MICROWIRE frame format for a single frame. Figure 15-11 on page 932 shows the same format when back-to-back frames are transmitted.

**Figure 15-10. MICROWIRE Frame Format (Single Frame)**

MICROWIRE format is very similar to SPI format, except that transmission is half-duplex instead of full-duplex and uses a master-slave message passing technique. Each serial transmission begins with an 8-bit control word that is transmitted from the SSI to the off-chip slave device. During this transmission, no incoming data is received by the SSI. After the message has been sent, the off-chip slave decodes it and, after waiting one serial clock after the last bit of the 8-bit control message has been sent, responds with the required data. The returned data is 4 to 16 bits in length, making the total frame length anywhere from 13 to 25 bits.

In this configuration, during idle periods:

- `SSInClk` is forced Low
- `SSInFss` is forced High
- The transmit data line `SSInTx` is arbitrarily forced Low

A transmission is triggered by writing a control byte to the transmit FIFO. The falling edge of `SSInFss` causes the value contained in the bottom entry of the transmit FIFO to be transferred to the serial shift register of the transmit logic and the MSB of the 8-bit control frame to be shifted out onto the `SSInTx` pin. `SSInFss` remains Low for the duration of the frame transmission. The `SSInRx` pin remains tristated during this transmission.

The off-chip serial slave device latches each control bit into its serial shifter on each rising edge of `SSInClk`. After the last bit is latched by the slave device, the control byte is decoded during a one clock wait-state, and the slave responds by transmitting data back to the SSI. Each bit is driven onto the `SSInRx` line on the falling edge of `SSInClk`. The SSI in turn latches each bit on the rising edge of `SSInClk`. At the end of the frame, for single transfers, the `SSInFss` signal is pulled High one clock period after the last bit has been latched in the receive serial shifter, causing the data to be transferred to the receive FIFO.

**Note:** The off-chip slave device can tristate the receive line either on the falling edge of  $SSInClk$  after the LSB has been latched by the receive shifter or when the  $SSInFss$  pin goes High.

For continuous transfers, data transmission begins and ends in the same manner as a single transfer. However, the  $SSInFss$  line is continuously asserted (held Low) and transmission of data occurs back-to-back. The control byte of the next frame follows directly after the LSB of the received data from the current frame. Each of the received values is transferred from the receive shifter on the falling edge of  $SSInClk$ , after the LSB of the frame has been latched into the SSI.

**Figure 15-11. MICROWIRE Frame Format (Continuous Transfer)**

In the MICROWIRE mode, the SSI slave samples the first bit of receive data on the rising edge of  $SSInClk$  after  $SSInFss$  has gone Low. Masters that drive a free-running  $SSInClk$  must ensure that the  $SSInFss$  signal has sufficient setup and hold margins with respect to the rising edge of  $SSInClk$ .

Figure 15-12 on page 932 illustrates these setup and hold time requirements. With respect to the  $SSInClk$  rising edge on which the first bit of receive data is to be sampled by the SSI slave,  $SSInFss$  must have a setup of at least two times the period of  $SSInClk$  on which the SSI operates. With respect to the  $SSInClk$  rising edge previous to this edge,  $SSInFss$  must have a hold of at least one  $SSInClk$  period.

**Figure 15-12. MICROWIRE Frame Format, SSInFss Input Setup and Hold Requirements**

### 15.3.5 DMA Operation

The SSI peripheral provides an interface to the  $\mu$ DMA controller with separate channels for transmit and receive. The  $\mu$ DMA operation of the SSI is enabled through the **SSI DMA Control (SSIDMACTL)** register. When  $\mu$ DMA operation is enabled, the SSI asserts a  $\mu$ DMA request on the receive or transmit channel when the associated FIFO can transfer data. For the receive channel, a single

transfer request is asserted whenever any data is in the receive FIFO. A burst transfer request is asserted whenever the amount of data in the receive FIFO is 4 or more items. For the transmit channel, a single transfer request is asserted whenever at least one empty location is in the transmit FIFO. The burst request is asserted whenever the transmit FIFO has 4 or more empty slots. The single and burst  $\mu$ DMA transfer requests are handled automatically by the  $\mu$ DMA controller depending how the  $\mu$ DMA channel is configured. To enable  $\mu$ DMA operation for the receive channel, the `RXDMAE` bit of the **DMA Control (SSIDMACTL)** register should be set. To enable  $\mu$ DMA operation for the transmit channel, the `TXDMAE` bit of **SSIDMACTL** should be set. If  $\mu$ DMA is enabled, then the  $\mu$ DMA controller triggers an interrupt when a transfer is complete. The interrupt occurs on the SSI interrupt vector. Therefore, if interrupts are used for SSI operation and  $\mu$ DMA is enabled, the SSI interrupt handler must be designed to handle the  $\mu$ DMA completion interrupt.

See “Micro Direct Memory Access ( $\mu$ DMA)” on page 557 for more details about programming the  $\mu$ DMA controller.

## 15.4 Initialization and Configuration

To enable and initialize the SSI, the following steps are necessary:

1. Enable the SSI module using the **RCGCSSI** register (see page 332).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register (see page 326). To find out which GPIO port to enable, refer to Table 21-5 on page 1153.
3. Set the GPIO `AFSEL` bits for the appropriate pins (see page 642). To determine which GPIOs to configure, see Table 21-4 on page 1149.
4. Configure the `PMCn` fields in the **GPIOPCTL** register to assign the SSI signals to the appropriate pins. See page 659 and Table 21-5 on page 1153.
5. Program the **GPIODEN** register to enable the pin's digital function. In addition, the drive strength, drain select and pull-up/pull-down functions must be configured. Refer to “General-Purpose Input/Outputs (GPIOs)” on page 621 for more information.

**Note:** Pull-ups can be used to avoid unnecessary toggles on the SSI pins which can take the slave to a wrong state.

For each of the frame formats, the SSI is configured using the following steps:

1. Ensure that the `SSE` bit in the **SSICR1** register is clear before making any configuration changes.
2. Select whether the SSI is a master or slave:
  - a. For master operations, set the **SSICR1** register to 0x0000.0000.
  - b. For slave mode (output enabled), set the **SSICR1** register to 0x0000.0004.
  - c. For slave mode (output disabled), set the **SSICR1** register to 0x0000.000C.
3. Configure the SSI clock source by writing to the **SSICC** register.
4. Configure the clock prescale divisor by writing the **SSICPSR** register.
5. Write the **SSICR0** register with the following configuration:
  - Serial clock rate (`SCR`)

- Desired clock phase/polarity, if using Freescale SPI mode (*SPH* and *SPO*)
  - The protocol mode: Freescale SPI, TI SSF, MICROWIRE (*FRF*)
  - The data size (*DSS*)
6. Optionally, configure the  $\mu$ DMA channel (see “Micro Direct Memory Access ( $\mu$ DMA)” on page 557) and enable the DMA option(s) in the **SSIDMACTL** register.
  7. Enable the SSI by setting the *SSE* bit in the **SSICR1** register.

As an example, assume the SSI must be configured to operate with the following parameters:

- Master operation
- Freescale SPI mode (*SPO*=1, *SPH*=1)
- 1 Mbps bit rate
- 8 data bits

Assuming the system clock is 20 MHz, the bit rate calculation would be:

$$\begin{aligned} \text{SSInClk} &= \text{SysClk} / (\text{CPSDVSR} * (1 + \text{SCR})) \\ 1 \times 10^6 &= 20 \times 10^6 / (\text{CPSDVSR} * (1 + \text{SCR})) \end{aligned}$$

In this case, if *CPSDVSR*=0x2, *SCR* must be 0x9.

The configuration sequence would be as follows:

1. Ensure that the *SSE* bit in the **SSICR1** register is clear.
2. Write the **SSICR1** register with a value of 0x0000.0000.
3. Write the **SSICPSR** register with a value of 0x0000.0002.
4. Write the **SSICR0** register with a value of 0x0000.09C7.
5. The SSI is then enabled by setting the *SSE* bit in the **SSICR1** register.

## 15.5 Register Map

Table 15-2 on page 935 lists the SSI registers. The offset listed is a hexadecimal increment to the register's address, relative to that SSI module's base address:

- SSI0: 0x4000.8000
- SSI1: 0x4000.9000
- SSI2: 0x4000.A000
- SSI3: 0x4000.B000

Note that the SSI module clock must be enabled before the registers can be programmed (see page 332). The *Rn* bit of the **PRSSI** register must be read as 0x1 before any SSI module registers are accessed.

**Note:** The SSI must be disabled (see the *SSE* bit in the **SSICR1** register) before any of the control registers are reprogrammed.

**Table 15-2. SSI Register Map**

| Offset | Name         | Type | Reset       | Description                     | See page |
|--------|--------------|------|-------------|---------------------------------|----------|
| 0x000  | SSICR0       | R/W  | 0x0000.0000 | SSI Control 0                   | 936      |
| 0x004  | SSICR1       | R/W  | 0x0000.0000 | SSI Control 1                   | 938      |

## 15.6 Register Descriptions

The remainder of this section lists and describes the SSI registers, in numerical order by address offset.

### Register 1: SSI Control 0 (SSICR0), offset 0x000

The **SSICR0** register contains bit fields that control various functions within the SSI module. Functionality such as protocol mode, clock rate, and data size are configured in this register.

#### SSI Control 0 (SSICR0)

SSI0 base: 0x4000.8000  
 SSI1 base: 0x4000.9000  
 SSI2 base: 0x4000.A000  
 SSI3 base: 0x4000.B000  
 Offset 0x000  
 Type R/W, reset 0x0000.0000

| Bit/Field | Name     | Type | Reset  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------|----------|------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:16     | reserved | RO   | 0x0000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.                                                                                                                                                                                                                                                                                        |

## Register 2: SSI Control 1 (SSICR1), offset 0x004

The **SSICR1** register contains bit fields that control various functions within the SSI module. Master and slave mode functionality is controlled by this register.

### SSI Control 1 (SSICR1)

SSI0 base: 0x4000.8000  
 SSI1 base: 0x4000.9000  
 SSI2 base: 0x4000.A000  
 SSI3 base: 0x4000.B000  
 Offset 0x004  
 Type R/W, reset 0x0000.0000

### Register 3: SSI Data (SSIDR), offset 0x008

**Important:** This register is read-sensitive. See the register description for details.

The **SSIDR** register is 16-bits wide. When the **SSIDR** register is read, the entry in the receive FIFO that is pointed to by the current FIFO read pointer is accessed. When a data value is removed by the SSI receive logic from the incoming data frame, it is placed into the entry in the receive FIFO pointed to by the current FIFO write pointer.

When the **SSIDR** register is written to, the entry in the transmit FIFO that is pointed to by the write pointer is written to. Data values are removed from the transmit FIFO one value at a time by the transmit logic. Each data value is loaded into the transmit serial shifter, then serially shifted out onto the **SSInTx** pin at the programmed bit rate.

When a data size of less than 16 bits is selected, the user must right-justify data written to the transmit FIFO. The transmit logic ignores the unused bits. Received data less than 16 bits is automatically right-justified in the receive buffer.

When the SSI is programmed for MICROWIRE frame format, the default size for transmit data is eight bits (the most significant byte is ignored). The receive data size is controlled by the programmer. The transmit FIFO and the receive FIFO are not cleared even when the **SSE** bit in the **SSICR1** register is cleared, allowing the software to fill the transmit FIFO before enabling the SSI.

**Register 5: SSI Clock Prescale (SSICPSR), offset 0x010**

The **SSICPSR** register specifies the division factor which is used to derive the **SSInClk** from the system clock. The clock is further divided by a value from 1 to 256, which is  $1 + \text{SCR}$ . **SCR** is programmed in the **SSICR0** register. The frequency of the **SSInClk** is defined by:

$$\text{SSInClk} = \text{SysClk} / (\text{CPSDVSR} * (1 + \text{SCR}))$$

The value programmed into this register must be an even number between 2 and 254. The least-significant bit of the programmed number is hard-coded to zero. If an odd number is written to this register, data read back from this register has the least-significant bit as zero.

**SSI Clock Prescale (SSICPSR)**

### Register 6: SSI Interrupt Mask (SSIIM), offset 0x014

The **SSIIM** register is the interrupt mask set or clear register. It is a read/write register and all bits are cleared on reset.

On a read, this register gives the current value of the mask on the corresponding interrupt. Setting a bit clears the mask, enabling the interrupt to be sent to the interrupt controller. Clearing a bit sets the corresponding mask, preventing the interrupt from being signaled to the controller.

#### SSI Interrupt Mask (SSIIM)

## Register 7: SSI Raw Interrupt Status (SSIRIS), offset 0x018

The **SSIRIS** register is the raw interrupt status register. On a read, this register gives the current raw status value of the corresponding interrupt prior to masking. A write has no effect.

**Register 11: SSI Clock Configuration (SSICC), offset 0xFC8**

The **SSICC** register controls the baud clock source for the SSI module.

**Note:** If the PIOSC is used for the SSI baud clock, the system clock frequency must be at least 16 MHz in Run mode.

## SSI Clock Configuration (SSICC)

## 16 Inter-Integrated Circuit (I<sup>2</sup>C) Interface

The Inter-Integrated Circuit (I<sup>2</sup>C) bus provides bi-directional data transfer through a two-wire design (a serial data line SDA and a serial clock line SCL), and interfaces to external I<sup>2</sup>C devices such as serial memory (RAMs and ROMs), networking devices, LCDs, tone generators, and so on. The I<sup>2</sup>C bus may also be used for system testing and diagnostic purposes in product development and manufacturing. The TM4C1233C3PM microcontroller includes providing the ability to communicate (both transmit and receive) with other I<sup>2</sup>C devices on the bus.

The TM4C1233C3PM controller includes I<sup>2</sup>C modules with the following features:

- Devices on the I<sup>2</sup>C bus can be designated as either a master or a slave
  - Supports both transmitting and receiving data as either a master or a slave
  - Supports simultaneous master and slave operation
- Four I<sup>2</sup>C modes
  - Master transmit
  - Master receive
  - Slave transmit
  - Slave receive
- Four transmission speeds:
  - Standard (100 Kbps)
  - Fast-mode (400 Kbps)
  - Fast-mode plus (1 Mbps)
  - High-speed mode (3.33 Mbps)
- Clock low timeout interrupt
- Dual slave address capability
- Glitch suppression
- Master and slave interrupt generation
  - Master generates interrupts when a transmit or receive operation completes (or aborts due to an error)
  - Slave generates interrupts when data has been transferred or requested by a master or when a START or STOP condition is detected
- Master with arbitration and clock synchronization, multimaster support, and 7-bit addressing mode

## 16.1 Block Diagram

Figure 16-1. I<sup>2</sup>C Block Diagram

## 16.2 Signal Description

The following table lists the external signals of the I<sup>2</sup>C interface and describes the function of each. The I<sup>2</sup>C interface signals are alternate functions for some GPIO signals and default to be GPIO signals at reset, with the exception of the I2C0SCL and I2CSDA pins which default to the I<sup>2</sup>C function. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for the I<sup>2</sup>C signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 642) should be set to choose the I<sup>2</sup>C function. The number in parentheses is the encoding that must be programmed into the PMC<sub>n</sub> field in the **GPIO Port Control (GPIOCTL)** register (page 659) to assign the I<sup>2</sup>C signal to the specified GPIO port pin. Note that the I2CSDA pin should be set to open drain using the **GPIO Open Drain Select (GPIOODR)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 621.

Table 16-1. I2C Signals (64LQFP)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                      |
|----------|------------|--------------------------|----------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| I2C0SCL  | 47         | PB2 (3)                  | I/O      | OD                       | I <sup>2</sup> C module 0 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| I2C0SDA  | 48         | PB3 (3)                  | I/O      | OD                       | I <sup>2</sup> C module 0 data.                                                                                                                  |
| I2C1SCL  | 23         | PA6 (3)                  | I/O      | OD                       | I <sup>2</sup> C module 1 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| I2C1SDA  | 24         | PA7 (3)                  | I/O      | OD                       | I <sup>2</sup> C module 1 data.                                                                                                                  |
| I2C2SCL  | 59         | PE4 (3)                  | I/O      | OD                       | I <sup>2</sup> C module 2 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| I2C2SDA  | 60         | PE5 (3)                  | I/O      | OD                       | I <sup>2</sup> C module 2 data.                                                                                                                  |
| I2C3SCL  | 61         | PD0 (3)                  | I/O      | OD                       | I <sup>2</sup> C module 3 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| I2C3SDA  | 62         | PD1 (3)                  | I/O      | OD                       | I <sup>2</sup> C module 3 data.                                                                                                                  |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 16.3 Functional Description

Each I<sup>2</sup>C module is comprised of both master and slave functions and is identified by a unique address. A master-initiated communication generates the clock signal, SCL. For proper operation, the SDA pin must be configured as an open-drain signal. Due to the internal circuitry that supports high-speed operation, the SCL pin must not be configured as an open-drain signal, although the internal circuitry causes it to act as if it were an open drain signal. Both SDA and SCL signals must be connected to a positive supply voltage using a pull-up resistor. A typical I<sup>2</sup>C bus configuration is shown in Figure 16-2. Refer to the *I<sup>2</sup>C-bus specification and user manual* to determine the size of the pull-ups needed for proper operation.

See “Inter-Integrated Circuit (I<sup>2</sup>C) Interface” on page 1196 for I<sup>2</sup>C timing diagrams.

**Figure 16-2. I<sup>2</sup>C Bus Configuration**

### 16.3.1 I<sup>2</sup>C Bus Functional Overview

The I<sup>2</sup>C bus uses only two signals: SDA and SCL, named I2CSDA and I2CSCL on TM4C1233C3PM microcontrollers. SDA is the bi-directional serial data line and SCL is the bi-directional serial clock line. The bus is considered idle when both lines are High.

Every transaction on the I<sup>2</sup>C bus is nine bits long, consisting of eight data bits and a single acknowledge bit. The number of bytes per transfer (defined as the time between a valid START and STOP condition, described in “START and STOP Conditions” on page 966) is unrestricted, but each data byte has to be followed by an acknowledge bit, and data must be transferred MSB first. When a receiver cannot receive another complete byte, it can hold the clock line SCL Low and force the transmitter into a wait state. The data transfer continues when the receiver releases the clock SCL.

#### 16.3.1.1 START and STOP Conditions

The protocol of the I<sup>2</sup>C bus defines two states to begin and end a transaction: START and STOP. A High-to-Low transition on the SDA line while the SCL is High is defined as a START condition, and a Low-to-High transition on the SDA line while SCL is High is defined as a STOP condition. The bus is considered busy after a START condition and free after a STOP condition. See Figure 16-3.

**Figure 16-3. START and STOP Conditions**

The **STOP** bit determines if the cycle stops at the end of the data cycle or continues on to a repeated **START** condition. To generate a single transmit cycle, the **I<sup>2</sup>C Master Slave Address (I2CMSA)** register is written with the desired address, the **R/S** bit is cleared, and the Control register is written with **ACK=X** (0 or 1), **STOP=1**, **START=1**, and **RUN=1** to perform the operation and stop. When the operation is completed (or aborted due an error), the interrupt pin becomes active and the data may be read from the **I<sup>2</sup>C Master Data (I2CMDR)** register. When the **I<sup>2</sup>C** module operates in Master receiver mode, the **ACK** bit is normally set causing the **I<sup>2</sup>C** bus controller to transmit an acknowledge automatically after each byte. This bit must be cleared when the **I<sup>2</sup>C** bus controller requires no further data to be transmitted from the slave transmitter.

When operating in slave mode, the **STARTRIS** and **STOPRIS** bits in the **I<sup>2</sup>C Slave Raw Interrupt Status (I2CSRIS)** register indicate detection of start and stop conditions on the bus and the **I<sup>2</sup>C Slave Masked Interrupt Status (I2CSMIS)** register can be configured to allow **STARTRIS** and **STOPRIS** to be promoted to controller interrupts (when interrupts are enabled).

### 16.3.1.2 Data Format with 7-Bit Address

Data transfers follow the format shown in Figure 16-4. After the **START** condition, a slave address is transmitted. This address is 7-bits long followed by an eighth bit, which is a data direction bit (**R/S** bit in the **I2CMSA** register). If the **R/S** bit is clear, it indicates a transmit operation (send), and if it is set, it indicates a request for data (receive). A data transfer is always terminated by a **STOP** condition generated by the master, however, a master can initiate communications with another device on the bus by generating a repeated **START** condition and addressing another slave without first generating a **STOP** condition. Various combinations of receive/transmit formats are then possible within a single transfer.

**Figure 16-4. Complete Data Transfer with a 7-Bit Address**

The first seven bits of the first byte make up the slave address (see Figure 16-5). The eighth bit determines the direction of the message. A zero in the **R/S** position of the first byte means that the master transmits (sends) data to the selected slave, and a one in this position means that the master receives data from the slave.

**Figure 16-5. R/S Bit in First Byte**

### 16.3.1.3 Data Validity

The data on the SDA line must be stable during the high period of the clock, and the data line can only change when SCL is Low (see Figure 16-6).

Figure 16-6. Data Validity During Bit Transfer on the I<sup>2</sup>C Bus

#### 16.3.1.4 Acknowledge

All bus transactions have a required acknowledge clock cycle that is generated by the master. During the acknowledge cycle, the transmitter (which can be the master or slave) releases the SDA line. To acknowledge the transaction, the receiver must pull down SDA during the acknowledge clock cycle. The data transmitted out by the receiver during the acknowledge cycle must comply with the data validity requirements described in “Data Validity” on page 967.

When a slave receiver does not acknowledge the slave address, SDA must be left High by the slave so that the master can generate a STOP condition and abort the current transfer. If the master device is acting as a receiver during a transfer, it is responsible for acknowledging each transfer made by the slave. Because the master controls the number of bytes in the transfer, it signals the end of data to the slave transmitter by not generating an acknowledge on the last data byte. The slave transmitter must then release SDA to allow the master to generate the STOP or a repeated START condition.

If the slave is required to provide a manual ACK or NACK, the **I<sup>2</sup>C Slave ACK Control (I2CSACKCTL)** register allows the slave to NACK for invalid data or command or ACK for valid data or command. When this operation is enabled, the MCU slave module I<sup>2</sup>C clock is pulled low after the last data bit until this register is written with the indicated response.

#### 16.3.1.5 Repeated Start

The I<sup>2</sup>C master module has the capability of executing a repeated START (transmit or receive) after an initial transfer has occurred.

A repeated start sequence for a Master transmit is as follows:

1. When the device is in the idle state, the Master writes the slave address to the **I2CMSA** register and configures the R/S bit for the desired transfer type.
2. Data is written to the **I2CMDR** register.
3. When the BUSY bit in the **I2CMCS** register is 0, the Master writes 0x3 to the **I2CMCS** register to initiate a transfer.
4. The Master does not generate a STOP condition but instead writes another slave address to the **I2CMSA** register and then writes 0x3 to initiate the repeated START.

A repeated start sequence for a Master receive is similar:

1. When the device is in idle, the Master writes the slave address to the **I2CMSA** register and configures the R/S bit for the desired transfer type.
2. The master reads data from the **I2CMDR** register.

3. When the `BUSY` bit in the **I2CMCS** register is 0, the Master writes 0x3 to the **I2CMCS** register to initiate a transfer.
4. The Master does not generate a STOP condition but instead writes another slave address to the **I2CMSA** register and then writes 0x3 to initiate the repeated START.

For more information on repeated START, refer to Figure 16-12 on page 979 and Figure 16-13 on page 980.

### 16.3.1.6 Clock Low Timeout (CLTO)

The I<sup>2</sup>C slave can extend the transaction by pulling the clock low periodically to create a slow bit transfer rate. The I<sup>2</sup>C module has a 12-bit programmable counter that is used to track how long the clock has been held low. The upper 8 bits of the count value are software programmable through the **I<sup>2</sup>C Master Clock Low Timeout Count (I2CMCLKOCNT)** register. The lower four bits are not user visible and are 0x0. The `CNTL` value programmed in the **I2CMCLKOCNT** register has to be greater than 0x01. The application can program the eight most significant bits of the counter to reflect the acceptable cumulative low period in transaction. The count is loaded at the START condition and counts down on each falling edge of the internal bus clock of the Master. Note that the internal bus clock generated for this counter keeps running at the programmed I<sup>2</sup>C speed even if SCL is held low on the bus. Upon reaching terminal count, the master state machine forces ABORT on the bus by issuing a STOP condition at the instance of SCL and SDA release.

As an example, if an I<sup>2</sup>C module was operating at 100 kHz speed, programming the **I2CMCLKOCNT** register to 0xDA would translate to the value 0xDA0 since the lower four bits are set to 0x0. This would translate to a decimal value of 3488 clocks or a cumulative clock low period of 34.88 ms at 100 kHz.

The `CLKRIS` bit in the **I<sup>2</sup>C Master Raw Interrupt Status (I2CMRIS)** register is set when the clock timeout period is reached, allowing the master to start corrective action to resolve the remote slave state. In addition, the `CLKTO` bit in the **I<sup>2</sup>C Master Control/Status (I2CMCS)** register is set; this bit is cleared when a STOP condition is sent or during the I<sup>2</sup>C master reset. The status of the raw SDA and SCL signals are readable by software through the `SDA` and `SCL` bits in the **I<sup>2</sup>C Master Bus Monitor (I2CMBMON)** register to help determine the state of the remote slave.

In the event of a CLTO condition, application software must choose how it intends to attempt bus recovery. Most applications may attempt to manually toggle the I<sup>2</sup>C pins to force the slave to let go of the clock signal (a common solution is to attempt to force a STOP on the bus). If a CLTO is detected before the end of a burst transfer, and the bus is successfully recovered by the master, the master hardware attempts to finish the pending burst operation. Depending on the state of the slave after bus recovery, the actual behavior on the bus varies. If the slave resumes in a state where it can acknowledge the master (essentially, where it was before the bus hang), it continues where it left off. However, if the slave resumes in a reset state (or if a forced STOP by the master causes the slave to enter the idle state), it may ignore the master's attempt to complete the burst operation and NAK the first data byte that the master sends or requests.

Since the behavior of slaves cannot always be predicted, it is suggested that the application software always write the `STOP` bit in the **I<sup>2</sup>C Master Configuration (I2CMCR)** register during the CLTO interrupt service routine. This limits the amount of data the master attempts to send or receive upon bus recovery to a single byte, and after the single byte is on the wire, the master issues a STOP. An alternative solution is to have the application software reset the I<sup>2</sup>C peripheral before attempting to manually recover the bus. This solution allows the I<sup>2</sup>C master hardware to be returned to a known good (and idle) state before attempting to recover a stuck bus and prevents any unwanted data from appearing on the wire.

**Note:** The Master Clock Low Timeout counter counts for the entire time SCL is held Low continuously. If SCL is deasserted at any point, the Master Clock Low Timeout Counter is reloaded with the value in the **I2CMCLKOCNT** register and begins counting down from this value.

### 16.3.1.7 Dual Address

The I<sup>2</sup>C interface supports dual address capability for the slave. The additional programmable address is provided and can be matched if enabled. In legacy mode with dual address disabled, the I<sup>2</sup>C slave provides an ACK on the bus if the address matches the OAR field in the **I2CSOAR** register. In dual address mode, the I<sup>2</sup>C slave provides an ACK on the bus if either the OAR field in the **I2CSOAR** register or the OAR2 field in the **I2CSOAR2** register is matched. The enable for dual address is programmable through the OAR2EN bit in the **I2CSOAR2** register and there is no disable on the legacy address.

The OAR2SEL bit in the **I2CSCSR** register indicates if the address that was ACKed is the alternate address or not. When this bit is clear, it indicates either legacy operation or no address match.

### 16.3.1.8 Arbitration

A master may start a transfer only if the bus is idle. It's possible for two or more masters to generate a START condition within minimum hold time of the START condition. In these situations, an arbitration scheme takes place on the SDA line, while SCL is High. During arbitration, the first of the competing master devices to place a 1 (High) on SDA, while another master transmits a 0 (Low), switches off its data output stage and retires until the bus is idle again.

Arbitration can take place over several bits. Its first stage is a comparison of address bits, and if both masters are trying to address the same device, arbitration continues on to the comparison of data bits.

### 16.3.1.9 Glitch Suppression in Multi-Master Configuration

When a multi-master configuration is being used, the GFE bit in the **I<sup>2</sup>C Master Configuration (I2CMCR)** register can be set to enable glitch suppression on the SCL and SDA lines and assure proper signal values. The filter can be programmed to different filter widths using the GFPW bit in the **I<sup>2</sup>C Master Configuration 2 (I2CMCR2)** register. The glitch suppression value is in terms of buffered system clocks. Note that all signals will be delayed internally when glitch suppression is nonzero. For example, if GFPW is set to 0x7, 31 clocks should be added onto the calculation for the expected transaction time.

## 16.3.2 Available Speed Modes

The I<sup>2</sup>C bus can run in Standard mode (100 kbps), Fast mode (400 kbps), Fast mode plus (1 Mbps) or High-Speed mode (3.33 Mbps). The selected mode should match the speed of the other I<sup>2</sup>C devices on the bus.

### 16.3.2.1 Standard, Fast, and Fast Plus Modes

Standard, Fast, and Fast Plus modes are selected using a value in the **I<sup>2</sup>C Master Timer Period (I2CMTPR)** register that results in an SCL frequency of 100 kbps for Standard mode, 400 kbps for Fast mode, or 1 Mbps for Fast mode plus.

The I<sup>2</sup>C clock rate is determined by the parameters *CLK\_PRD*, *TIMER\_PRD*, *SCL\_LP*, and *SCL\_HP* where:

*CLK\_PRD* is the system clock period

$SCL\_LP$  is the low phase of SCL (fixed at 6)

$SCL\_HP$  is the high phase of SCL (fixed at 4)

$TIMER\_PRD$  is the programmed value in the **I2CMTPR** register (see page 993). This value is determined by replacing the known variables in the equation below and solving for  $TIMER\_PRD$ .

The I<sup>2</sup>C clock period is calculated as follows:

$$SCL\_PERIOD = 2 \times (1 + TIMER\_PRD) \times (SCL\_LP + SCL\_HP) \times CLK\_PRD$$

For example:

$$CLK\_PRD = 50 \text{ ns}$$

$$TIMER\_PRD = 2$$

$$SCL\_LP=6$$

$$SCL\_HP=4$$

yields a SCL frequency of:

$$1/SCL\_PERIOD = 333 \text{ Khz}$$

Table 16-2 gives examples of the timer periods that should be used to generate Standard, Fast mode, and Fast mode plus SCL frequencies based on various system clock frequencies.

**Table 16-2. Examples of I<sup>2</sup>C Master Timer Period Versus Speed Mode**

| System Clock | Timer Period | Standard Mode | Timer Period | Fast Mode | Timer Period | Fast Mode Plus |
|--------------|--------------|---------------|--------------|-----------|--------------|----------------|
| 4 MHz        | 0x01         | 100 Kbps      | -            | -         | -            | -              |
| 6 MHz        | 0x02         | 100 Kbps      | -            | -         | -            | -              |
| 12.5 MHz     | 0x06         | 89 Kbps       | 0x01         | 312 Kbps  | -            | -              |
| 16.7 MHz     | 0x08         | 93 Kbps       | 0x02         | 278 Kbps  | -            | -              |
| 20 MHz       | 0x09         | 100 Kbps      | 0x02         | 333 Kbps  | -            | -              |
| 25 MHz       | 0x0C         | 96.2 Kbps     | 0x03         | 312 Kbps  | -            | -              |
| 33 MHz       | 0x10         | 97.1 Kbps     | 0x04         | 330 Kbps  | -            | -              |
| 40 MHz       | 0x13         | 100 Kbps      | 0x04         | 400 Kbps  | 0x01         | 1000 Kbps      |
| 50 MHz       | 0x18         | 100 Kbps      | 0x06         | 357 Kbps  | 0x02         | 833 Kbps       |
| 80 MHz       | 0x27         | 100 Kbps      | 0x09         | 400 Kbps  | 0x03         | 1000 Kbps      |

### 16.3.2.2 High-Speed Mode

The TM4C1233C3PM I<sup>2</sup>C peripheral has support for High-speed operation as both a master and slave. High-Speed mode is configured by setting the **HS** bit in the **I<sup>2</sup>C Master Control/Status (I2CMCS)** register. High-Speed mode transmits data at a high bit rate with a 66.6%/33.3% duty cycle, but communication and arbitration are done at Standard, Fast mode, or Fast-mode plus speed, depending on which is selected by the user. When the **HS** bit in the **I2CMCS** register is set, current mode pull-ups are enabled.

The clock period can be selected using the equation below, but in this case,  $SCL\_LP=2$  and  $SCL\_HP=1$ .

$$SCL\_PERIOD = 2 \times (1 + TIMER\_PRD) \times (SCL\_LP + SCL\_HP) \times CLK\_PRD$$

So for example:

```
CLK_PRD = 25 ns
TIMER_PRD = 1
SCL_LP=2
SCL_HP=1
```

yields a SCL frequency of:

$$1/T = 3.33 \text{ Mhz}$$

Table 16-3 on page 972 gives examples of timer period and system clock in High-Speed mode. Note that the HS bit in the I2CMTPR register needs to be set for the TPR value to be used in High-Speed mode.

**Table 16-3. Examples of I<sup>2</sup>C Master Timer Period in High-Speed Mode**

| System Clock | Timer Period | Transmission Mode |
|--------------|--------------|-------------------|
| 40 MHz       | 0x01         | 3.33 Mbps         |
| 50 MHz       | 0x02         | 2.77 Mbps         |
| 80 MHz       | 0x03         | 3.33 Mbps         |

When operating as a master, the protocol is shown in Figure 16-7. The master is responsible for sending a master code byte in either Standard (100 Kbps) or Fast-mode (400 Kbps) before it begins transferring in High-speed mode. The master code byte must contain data in the form of 0000.1XXX and is used to tell the slave devices to prepare for a High-speed transfer. The master code byte should never be acknowledged by a slave since it is only used to indicate that the upcoming data is going to be transferred at a higher data rate. To send the master code byte, software should place the value of the master code byte into the I2CMSA register and write the I2CMCS register with a value of 0x13. This places the I<sup>2</sup>C master peripheral in High-speed mode, and all subsequent transfers (until STOP) are carried out at High-speed data rate using the normal I2CMCS command bits, without setting the HS bit in the I2CMCS register. Again, setting the HS bit in the I2CMCS register is only necessary during the master code byte.

When operating as a High-speed slave, there is no additional software required.

**Figure 16-7. High-Speed Data Format**

**Note:** High-Speed mode is 3.4 Mbps, provided correct system clock frequency is set and there is appropriate pull strength on SCL and SDA lines.

### 16.3.3 Interrupts

The I<sup>2</sup>C can generate interrupts when the following conditions are observed:

- Master transaction completed
- Master arbitration lost

- Master transaction error
- Master bus timeout
- Slave transaction received
- Slave transaction requested
- Stop condition on bus detected
- Start condition on bus detected

The I<sup>2</sup>C master and I<sup>2</sup>C slave modules have separate interrupt signals. While both modules can generate interrupts for multiple conditions, only a single interrupt signal is sent to the interrupt controller.

### 16.3.3.1 I<sup>2</sup>C Master Interrupts

The I<sup>2</sup>C master module generates an interrupt when a transaction completes (either transmit or receive), when arbitration is lost, or when an error occurs during a transaction. To enable the I<sup>2</sup>C master interrupt, software must set the `IM` bit in the **I<sup>2</sup>C Master Interrupt Mask (I2CMIMR)** register. When an interrupt condition is met, software must check the `ERROR` and `ARBLST` bits in the **I<sup>2</sup>C Master Control/Status (I2CMCS)** register to verify that an error didn't occur during the last transaction and to ensure that arbitration has not been lost. An error condition is asserted if the last transaction wasn't acknowledged by the slave. If an error is not detected and the master has not lost arbitration, the application can proceed with the transfer. The interrupt is cleared by writing a 1 to the `IC` bit in the **I<sup>2</sup>C Master Interrupt Clear (I2CMICR)** register.

If the application doesn't require the use of interrupts, the raw interrupt status is always visible via the **I<sup>2</sup>C Master Raw Interrupt Status (I2CMRIS)** register.

### 16.3.3.2 I<sup>2</sup>C Slave Interrupts

The slave module can generate an interrupt when data has been received or requested. This interrupt is enabled by setting the `DATAIM` bit in the **I<sup>2</sup>C Slave Interrupt Mask (I2CSIMR)** register. Software determines whether the module should write (transmit) or read (receive) data from the **I<sup>2</sup>C Slave Data (I2CSDR)** register, by checking the `RREQ` and `TREQ` bits of the **I<sup>2</sup>C Slave Control/Status (I2CSCSR)** register. If the slave module is in receive mode and the first byte of a transfer is received, the `FBR` bit is set along with the `RREQ` bit. The interrupt is cleared by setting the `DATAIC` bit in the **I<sup>2</sup>C Slave Interrupt Clear (I2CSICR)** register.

In addition, the slave module can generate an interrupt when a start and stop condition is detected. These interrupts are enabled by setting the `STARTIM` and `STOPIM` bits of the **I<sup>2</sup>C Slave Interrupt Mask (I2CSIMR)** register and cleared by writing a 1 to the `STOPIC` and `STARTIC` bits of the **I<sup>2</sup>C Slave Interrupt Clear (I2CSICR)** register.

If the application doesn't require the use of interrupts, the raw interrupt status is always visible via the **I<sup>2</sup>C Slave Raw Interrupt Status (I2CSRIS)** register.

### 16.3.4 Loopback Operation

The I<sup>2</sup>C modules can be placed into an internal loopback mode for diagnostic or debug work by setting the `LBPBK` bit in the **I<sup>2</sup>C Master Configuration (I2CMCR)** register. In loopback mode, the SDA and SCL signals from the master and are tied to the SDA and SCL signals of the slave module to allow internal testing of the device without having to go through I/O.

### **16.3.5 Command Sequence Flow Charts**

This section details the steps required to perform the various I<sup>2</sup>C transfer types in both master and slave mode.

#### **16.3.5.1 I<sup>2</sup>C Master Command Sequences**

The figures that follow show the command sequences available for the I<sup>2</sup>C master.

### 16.3.5.2 I<sup>2</sup>C Slave Command Sequences

Figure 16-15 on page 982 presents the command sequence available for the I<sup>2</sup>C slave.

**Figure 16-15. Slave Command Sequence**

## 16.4 Initialization and Configuration

### 16.4.1 Configure the I<sup>2</sup>C Module to Transmit a Single Byte as a Master

The following example shows how to configure the I<sup>2</sup>C module to transmit a single byte as a master. This assumes the system clock is 20 MHz.

1. Enable the I<sup>2</sup>C clock using the **RCGCI2C** register in the System Control module (see page 334).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register in the System Control module (see page 326). To find out which GPIO port to enable, refer to Table 21-5 on page 1153.
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register (see page 642). To determine which GPIOs to configure, see Table 21-4 on page 1149.

4. Enable the I2CSDA pin for open-drain operation. See page 647.
5. Configure the PMC<sub>n</sub> fields in the GPIOCTL register to assign the I<sup>2</sup>C signals to the appropriate pins. See page 659 and Table 21-5 on page 1153.
6. Initialize the I<sup>2</sup>C Master by writing the I2CMCR register with a value of 0x0000.0010.
7. Set the desired SCL clock speed of 100 Kbps by writing the I2CMTPR register with the correct value. The value written to the I2CMTPR register represents the number of system clock periods in one SCL clock period. The TPR value is determined by the following equation:

$$\begin{aligned} \text{TPR} &= (\text{System Clock} / (2 * (\text{SCL\_LP} + \text{SCL\_HP}) * \text{SCL\_CLK})) - 1; \\ \text{TPR} &= (20\text{MHz} / (2 * (6+4) * 100000)) - 1; \\ \text{TPR} &= 9 \end{aligned}$$

Write the I2CMTPR register with the value of 0x0000.0009.

8. Specify the slave address of the master and that the next operation is a Transmit by writing the I2CMSA register with a value of 0x0000.0076. This sets the slave address to 0x3B.
9. Place data (byte) to be transmitted in the data register by writing the I2CMDR register with the desired data.
10. Initiate a single byte transmit of the data from Master to Slave by writing the I2CMCS register with a value of 0x0000.0007 (STOP, START, RUN).
11. Wait until the transmission completes by polling the I2CMCS register's BUSBSY bit until it has been cleared.
12. Check the ERROR bit in the I2CMCS register to confirm the transmit was acknowledged.

#### 16.4.2 Configure the I<sup>2</sup>C Master to High Speed Mode

To configure the I<sup>2</sup>C master to High Speed mode:

1. Enable the I<sup>2</sup>C clock using the RCGCI2C register in the System Control module (see page 334).
2. Enable the clock to the appropriate GPIO module via the RCGCGPIO register in the System Control module (see page 326). To find out which GPIO port to enable, refer to Table 21-5 on page 1153.
3. In the GPIO module, enable the appropriate pins for their alternate function using the GPIOAFSEL register (see page 642). To determine which GPIOs to configure, see Table 21-4 on page 1149.
4. Enable the I2CSDA pin for open-drain operation. See page 647.
5. Configure the PMC<sub>n</sub> fields in the GPIOCTL register to assign the I<sup>2</sup>C signals to the appropriate pins. See page 659 and Table 21-5 on page 1153.
6. Initialize the I<sup>2</sup>C Master by writing the I2CMCR register with a value of 0x0000.0010.
7. Set the desired SCL clock speed of 3.33 Mbps by writing the I2CMTPR register with the correct value. The value written to the I2CMTPR register represents the number of system clock periods in one SCL clock period. The TPR value is determined by the following equation:

```
TPR = (System Clock / (2 * (SCL_LP + SCL_HP) * SCL_CLK)) - 1;
TPR = (80 MHz / (2 * (2 + 1) * 3330000)) - 1;
TPR = 3
```

Write the **I2CMTPR** register with the value of 0x0000.0003.

8. To send the master code byte, software should place the value of the master code byte into the **I2CMSA** register and write the **I2CMCS** register with a value of 0x13.
9. This places the I2C master peripheral in High-speed mode, and all subsequent transfers (until STOP) are carried out at High-speed data rate using the normal **I2CMCS** command bits, without setting the **HS** bit in the **I2CMCS** register.
10. The transaction is ended by setting the **STOP** bit in the **I2CMCS** register.
11. Wait until the transmission completes by polling the **I2CMCS** register's **BUSBSY** bit until it has been cleared.
12. Check the **ERROR** bit in the **I2CMCS** register to confirm the transmit was acknowledged.

## 16.5 Register Map

Table 16-4 on page 984 lists the I<sup>2</sup>C registers. All addresses given are relative to the I<sup>2</sup>C base address:

- I<sup>2</sup>C 0: 0x4002.0000
- I<sup>2</sup>C 1: 0x4002.1000
- I<sup>2</sup>C 2: 0x4002.2000
- I<sup>2</sup>C 3: 0x4002.3000

Note that the I<sup>2</sup>C module clock must be enabled before the registers can be programmed (see page 334). There must be a delay of 3 system clocks after the I<sup>2</sup>C module clock is enabled before any I<sup>2</sup>C module registers are accessed.

The `hw_i2c.h` file in the TivaWare™ Driver Library uses a base address of 0x800 for the I<sup>2</sup>C slave registers. Be aware when using registers with offsets between 0x800 and 0x818 that TivaWare™ for C Series uses an offset between 0x000 and 0x018 with the slave base address.

**Table 16-4. Inter-Integrated Circuit (I<sup>2</sup>C) Interface Register Map**

| Offset                       | Name    | Type | Reset       | Description                        | See page |

## 16.6 Register Descriptions (I<sup>2</sup>C Master)

The remainder of this section lists and describes the I<sup>2</sup>C master registers, in numerical order by address offset.

### Register 1: I<sup>2</sup>C Master Slave Address (I2CMSA), offset 0x000

This register consists of eight bits: seven address bits (A6-A0), and a Receive/Send bit, which determines if the next operation is a Receive (High), or Transmit (Low).

#### I2C Master Slave Address (I2CMSA)

I2C 0 base: 0x4002.0000  
 I2C 1 base: 0x4002.1000  
 I2C 2 base: 0x4002.2000  
 I2C 3 base: 0x4002.3000  
 Offset 0x000  
 Type R/W, reset 0x0000.0000

|       |          |    |    |    |    |    |    |    |     |     |     |     |     |     |     |     |

|-----------|----------|------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:8      | reserved | RO   | 0x0000.00 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 7:1       | SA       | R/W  | 0x00      | I <sup>2</sup> C Slave Address<br>This field specifies bits A6 through A0 of the slave address.                                                                                               |
| 0         | R/S      | R/W  | 0         | Receive/Send<br>The R/S bit specifies if the next master operation is a Receive (High) or Transmit (Low).                                                                                     |
|           |          |      |           | Value Description                                                                                                                                                                             |
|           |          |      |           | 0 Transmit                                                                                                                                                                                    |
|           |          |      |           | 1 Receive                                                                                                                                                                                     |

## Register 2: I<sup>2</sup>C Master Control/Status (I2CMCS), offset 0x004

This register accesses status bits when read and control bits when written. When read, the status register indicates the state of the I<sup>2</sup>C bus controller. When written, the control register configures the I<sup>2</sup>C controller operation.

The **START** bit generates the **START** or **REPEATED START** condition. The **STOP** bit determines if the cycle stops at the end of the data cycle or continues to the next transfer cycle, which could be a repeated **START**. To generate a single transmit cycle, the **I<sup>2</sup>C Master Slave Address (I2CMSA)** register is written with the desired address, the **R/S** bit is cleared, and this register is written with **ACK=X** (0 or 1), **STOP=1**, **START=1**, and **RUN=1** to perform the operation and stop. When the operation is completed (or aborted due an error), an interrupt becomes active and the data may be read from the **I2CMDR** register. When the I<sup>2</sup>C module operates in Master receiver mode, the **ACK** bit is normally set, causing the I<sup>2</sup>C bus controller to transmit an acknowledge automatically after each byte. This bit must be cleared when the I<sup>2</sup>C bus controller requires no further data to be transmitted from the slave transmitter.

|                                                       | 0                                                     | X           | 1    | 1     | 1   | Repeated START condition followed by TRANSMIT and STOP condition (master goes to Idle state).                        |
| All other combinations not listed are non-operations. |                                                       |             |      |       |     | NOP.                                                                                                                 |

a. An X in a table cell indicates the bit can be 0 or 1.

b. In Master Receive mode, a STOP condition should be generated only after a Data Negative Acknowledge executed by the master or an Address Negative Acknowledge executed by the slave.

### Register 3: I<sup>2</sup>C Master Data (I2CMDR), offset 0x008

**Important:** This register is read-sensitive. See the register description for details.

This register contains the data to be transmitted when in the Master Transmit state and the data received when in the Master Receive state.

## Register 4: I<sup>2</sup>C Master Timer Period (I2CMTPR), offset 0x00C

This register is programmed to set the timer period for the SCL clock and assign the SCL clock to either standard or high-speed mode.

### Register 10: I<sup>2</sup>C Master Clock Low Timeout Count (I2CMCLKOCNT), offset 0x024

This register contains the upper 8 bits of a 12-bit counter that can be used to keep the timeout limit for clock stretching by a remote slave. The lower four bits of the counter are not user visible and are always 0x0.

**Note:** The Master Clock Low Timeout counter counts for the entire time SCL is held Low continuously. If SCL is deasserted at any point, the Master Clock Low Timeout Counter is reloaded with the value in the I2CMCLKOCNT register and begins counting down from this value.

## 16.7 Register Descriptions (I<sup>2</sup>C Slave)

The remainder of this section lists and describes the I<sup>2</sup>C slave registers, in numerical order by address offset.

**Register 13: I<sup>2</sup>C Slave Own Address (I2CSOAR), offset 0x800**

This register consists of seven address bits that identify the TM4C1233C3PM I<sup>2</sup>C device on the I<sup>2</sup>C bus.

**I2C Slave Own Address (I2CSOAR)**

I2C 0 base: 0x4002.0000  
 I2C 1 base: 0x4002.1000  
 I2C 2 base: 0x4002.2000  
 I2C 3 base: 0x4002.3000  
 Offset 0x800  
 Type R/W, reset 0x0000.0000

## Value Description

|   |                                                |
|---|------------------------------------------------|
| 0 | Disables the I <sup>2</sup> C slave operation. |
| 1 | Enables the I <sup>2</sup> C slave operation.  |

Once this bit has been set, it should not be set again unless it has been cleared by writing a 0 or by a reset, otherwise transfer failures may occur.

## Register 15: I<sup>2</sup>C Slave Data (I2CSDR), offset 0x808

**Important:** This register is read-sensitive. See the register description for details.

This register contains the data to be transmitted when in the Slave Transmit state, and the data received when in the Slave Receive state.

### Register 21: I<sup>2</sup>C Slave ACK Control (I2CSACKCTL), offset 0x820

This register enables the I<sup>2</sup>C slave to NACK for invalid data or command or ACK for valid data or command. The I<sup>2</sup>C clock is pulled low after the last data bit until this register is written.

#### I2C Slave ACK Control (I2CSACKCTL)

## 16.8 Register Descriptions (I<sup>2</sup>C Status and Control)

The remainder of this section lists and describes the I<sup>2</sup>C status and control registers, in numerical order by address offset.

**Register 22: I<sup>2</sup>C Peripheral Properties (I2CPP), offset 0xFC0**

The **I2CPP** register provides information regarding the properties of the I<sup>2</sup>C module.

**I2C Peripheral Properties (I2CPP)**

I2C 0 base: 0x4002.0000

I2C 1 base: 0x4002.1000

I2C 2 base: 0x4002.2000

I2C 3 base: 0x4002.3000

Offset 0xFC0

**Value Description**

- 0 The interface is set to Standard, Fast or Fast mode plus operation.
- 1 The interface is set to High-Speed operation. Note that this encoding may only be used if the HS bit in the I2CPP register is set. Otherwise, this encoding is not available.

## 17 Controller Area Network (CAN) Module

Controller Area Network (CAN) is a multicast, shared serial bus standard for connecting electronic control units (ECUs). CAN was specifically designed to be robust in electromagnetically-noisy environments and can utilize a differential balanced line like RS-485 or a more robust twisted-pair wire. Originally created for automotive purposes, it is also used in many embedded control applications (such as industrial and medical). Bit rates up to 1 Mbps are possible at network lengths less than 40 meters. Decreased bit rates allow longer network distances (for example, 125 Kbps at 500 meters).

The TM4C1233C3PM microcontroller includes one CAN unit with the following features:

- CAN protocol version 2.0 part A/B
- Bit rates up to 1 Mbps
- 32 message objects with individual identifier masks
- Maskable interrupt
- Disable Automatic Retransmission mode for Time-Triggered CAN (TTCAN) applications
- Programmable loopback mode for self-test operation
- Programmable FIFO mode enables storage of multiple message objects
- Gluelessly attaches to an external CAN transceiver through the CAN<sub>n</sub>TX and CAN<sub>n</sub>RX signals

## 17.1 Block Diagram

Figure 17-1. CAN Controller Block Diagram

## 17.2 Signal Description

The following table lists the external signals of the CAN controller and describes the function of each. The CAN controller signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for the CAN signals. The **AFSEL** bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 642) should be set to choose the CAN controller function. The number in parentheses is the encoding that must be programmed into the **PMC<sub>n</sub>** field in the **GPIO Port Control (GPIOCTL)** register (page 659) to assign the CAN signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 621.

**Table 17-1. Controller Area Network Signals (64LQFP)**

| Pin Name | Pin Number     | Pin Mux / Pin Assignment      | Pin Type | Buffer Type <sup>a</sup> | Description            |
|----------|----------------|-------------------------------|----------|--------------------------|------------------------|
| CAN0Rx   | 28<br>58<br>59 | PF0 (3)<br>PB4 (8)<br>PE4 (8) | I        | TTL                      | CAN module 0 receive.  |
| CAN0Tx   | 31<br>57<br>60 | PF3 (3)<br>PB5 (8)<br>PE5 (8) | O        | TTL                      | CAN module 0 transmit. |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 17.3 Functional Description

The TM4C1233C3PM CAN controller conforms to the CAN protocol version 2.0 (parts A and B). Message transfers that include data, remote, error, and overload frames with an 11-bit identifier (standard) or a 29-bit identifier (extended) are supported. Transfer rates can be programmed up to 1 Mbps.

The CAN module consists of three major parts:

- CAN protocol controller and message handler
- Message memory
- CAN register interface

A data frame contains data for transmission, whereas a remote frame contains no data and is used to request the transmission of a specific message object. The CAN data/remote frame is constructed as shown in Figure 17-2.

**Figure 17-2. CAN Data/Remote Frame**

The protocol controller transfers and receives the serial data from the CAN bus and passes the data on to the message handler. The message handler then loads this information into the appropriate message object based on the current filtering and identifiers in the message object memory. The message handler is also responsible for generating interrupts based on events on the CAN bus.

The message object memory is a set of 32 identical memory blocks that hold the current configuration, status, and actual data for each message object. These memory blocks are accessed via either of the CAN message object register interfaces.

The message memory is not directly accessible in the TM4C1233C3PM memory map, so the TM4C1233C3PM CAN controller provides an interface to communicate with the message memory via two CAN interface register sets for communicating with the message objects. These two interfaces must be used to read or write to each message object. The two message object interfaces allow parallel access to the CAN controller message objects when multiple objects may have new information that must be processed. In general, one interface is used for transmit data and one for receive data.

### 17.3.1 Initialization

To use the CAN controller, the peripheral clock must be enabled using the **RCGC0** register (see page 434). In addition, the clock to the appropriate GPIO module must be enabled via the **RCGC2** register (see page 440). To find out which GPIO port to enable, refer to Table 21-4 on page 1149. Set the GPIO **AFSEL** bits for the appropriate pins (see page 642). Configure the **PMCn** fields in the **GPIOCTL** register to assign the CAN signals to the appropriate pins. See page 659 and Table 21-5 on page 1153.

Software initialization is started by setting the **INIT** bit in the **CAN Control (CANCTL)** register (with software or by a hardware reset) or by going bus-off, which occurs when the transmitter's error counter exceeds a count of 255. While **INIT** is set, all message transfers to and from the CAN bus are stopped and the **CANnTX** signal is held High. Entering the initialization state does not change the configuration of the CAN controller, the message objects, or the error counters. However, some configuration registers are only accessible while in the initialization state.

To initialize the CAN controller, set the **CAN Bit Timing (CANBIT)** register and configure each message object. If a message object is not needed, label it as not valid by clearing the **MSGVAL** bit in the **CAN IFn Arbitration 2 (CANIFnARB2)** register. Otherwise, the whole message object must be initialized, as the fields of the message object may not have valid information, causing unexpected results. Both the **INIT** and **CCE** bits in the **CANCTL** register must be set in order to access the **CANBIT** register and the **CAN Baud Rate Prescaler Extension (CANBRPE)** register to configure the bit timing. To leave the initialization state, the **INIT** bit must be cleared. Afterwards, the internal Bit Stream Processor (BSP) synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (indicating a bus idle condition) before it takes part in bus activities and starts message transfers. Message object initialization does not require the CAN to be in the initialization state and can be done on the fly. However, message objects should all be configured to particular identifiers or set to not valid before message transfer starts. To change the configuration of a message object during normal operation, clear the **MSGVAL** bit in the **CANIFnARB2** register to indicate that the message object is not valid during the change. When the configuration is completed, set the **MSGVAL** bit again to indicate that the message object is once again valid.

### 17.3.2 Operation

Two sets of CAN Interface Registers (**CANIF1x** and **CANIF2x**) are used to access the message objects in the Message RAM. The CAN controller coordinates transfers to and from the Message RAM to and from the registers. The two sets are independent and identical and can be used to

queue transactions. Generally, one interface is used to transmit data and one is used to receive data.

Once the CAN module is initialized and the `INIT` bit in the **CANCTL** register is cleared, the CAN module synchronizes itself to the CAN bus and starts the message transfer. As each message is received, it goes through the message handler's filtering process, and if it passes through the filter, is stored in the message object specified by the `MNUM` bit in the **CAN IFn Command Request (CANIFnCRQ)** register. The whole message (including all arbitration bits, data-length code, and eight data bytes) is stored in the message object. If the Identifier Mask (the `MSK` bits in the **CAN IFn Mask 1** and **CAN IFn Mask 2 (CANIFnMSKn)** registers) is used, the arbitration bits that are masked to "don't care" may be overwritten in the message object.

The CPU may read or write each message at any time via the CAN Interface Registers. The message handler guarantees data consistency in case of concurrent accesses.

The transmission of message objects is under the control of the software that is managing the CAN hardware. Message objects can be used for one-time data transfers or can be permanent message objects used to respond in a more periodic manner. Permanent message objects have all arbitration and control set up, and only the data bytes are updated. At the start of transmission, the appropriate `TXRQST` bit in the **CAN Transmission Request n (CANTXRQn)** register and the `NEWDAT` bit in the **CAN New Data n (CANNWDAn)** register are set. If several transmit messages are assigned to the same message object (when the number of message objects is not sufficient), the whole message object has to be configured before the transmission of this message is requested.

The transmission of any number of message objects may be requested at the same time; they are transmitted according to their internal priority, which is based on the message identifier (`MNUM`) for the message object, with 1 being the highest priority and 32 being the lowest priority. Messages may be updated or set to not valid any time, even when their requested transmission is still pending. The old data is discarded when a message is updated before its pending transmission has started. Depending on the configuration of the message object, the transmission of a message may be requested autonomously by the reception of a remote frame with a matching identifier.

Transmission can be automatically started by the reception of a matching remote frame. To enable this mode, set the `RMTEEN` bit in the **CAN IFn Message Control (CANIFnMCTL)** register. A matching received remote frame causes the `TXRQST` bit to be set, and the message object automatically transfers its data or generates an interrupt indicating a remote frame was requested. A remote frame can be strictly a single message identifier, or it can be a range of values specified in the message object. The CAN mask registers, **CANIFnMSKn**, configure which groups of frames are identified as remote frame requests. The `UMASK` bit in the **CANIFnMCTL** register enables the `MSK` bits in the **CANIFnMSKn** register to filter which frames are identified as a remote frame request. The `MXTD` bit in the **CANIFnMSK2** register should be set if a remote frame request is expected to be triggered by 29-bit extended identifiers.

### 17.3.3 Transmitting Message Objects

If the internal transmit shift register of the CAN module is ready for loading, and if a data transfer is not occurring between the CAN Interface Registers and message RAM, the valid message object with the highest priority that has a pending transmission request is loaded into the transmit shift register by the message handler and the transmission is started. The message object's `NEWDAT` bit in the **CANNWDAn** register is cleared. After a successful transmission, and if no new data was written to the message object since the start of the transmission, the `TXRQST` bit in the **CANTXRQn** register is cleared. If the CAN controller is configured to interrupt on a successful transmission of a message object, (the `TXIE` bit in the **CAN IFn Message Control (CANIFnMCTL)** register is set), the `INTPND` bit in the **CANIFnMCTL** register is set after a successful transmission. If the CAN module has lost the arbitration or if an error occurred during the transmission, the message is

re-transmitted as soon as the CAN bus is free again. If, meanwhile, the transmission of a message with higher priority has been requested, the messages are transmitted in the order of their priority.

### 17.3.4 Configuring a Transmit Message Object

The following steps illustrate how to configure a transmit message object.

1. In the **CAN IFn Command Mask (CANIFnCMASK)** register:
  - Set the `WRNRD` bit to specify a write to the **CANIFnCMASK** register; specify whether to transfer the `IDMASK`, `DIR`, and `MXTD` of the message object into the **CAN IFn** registers using the `MASK` bit
  - Specify whether to transfer the `ID`, `DIR`, `XTD`, and `MSGVAL` of the message object into the interface registers using the `ARB` bit
  - Specify whether to transfer the control bits into the interface registers using the `CONTROL` bit
  - Specify whether to clear the `INTPND` bit in the **CANIFnMCTL** register using the `CLRINTPND` bit
  - Specify whether to clear the `NEWDAT` bit in the **CANNWDAn** register using the `NEWDAT` bit
  - Specify which bits to transfer using the `DATAA` and `DATAB` bits
2. In the **CANIFnMSK1** register, use the `MSK[15:0]` bits to specify which of the bits in the 29-bit or 11-bit message identifier are used for acceptance filtering. Note that `MSK[15:0]` in this register are used for bits [15:0] of the 29-bit message identifier and are not used for an 11-bit identifier. A value of 0x00 enables all messages to pass through the acceptance filtering. Also note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the `UMASK` bit in the **CANIFnMCTL** register.
3. In the **CANIFnMSK2** register, use the `MSK[12:0]` bits to specify which of the bits in the 29-bit or 11-bit message identifier are used for acceptance filtering. Note that `MSK[12:0]` are used for bits [28:16] of the 29-bit message identifier; whereas `MSK[12:2]` are used for bits [10:0] of the 11-bit message identifier. Use the `MXTD` and `MDIR` bits to specify whether to use `XTD` and `DIR` for acceptance filtering. A value of 0x00 enables all messages to pass through the acceptance filtering. Also note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the `UMASK` bit in the **CANIFnMCTL** register.
4. For a 29-bit identifier, configure `ID[15:0]` in the **CANIFnARB1** register for bits [15:0] of the message identifier and `ID[12:0]` in the **CANIFnARB2** register for bits [28:16] of the message identifier. Set the `XTD` bit to indicate an extended identifier; set the `DIR` bit to indicate transmit; and set the `MSGVAL` bit to indicate that the message object is valid.
5. For an 11-bit identifier, disregard the **CANIFnARB1** register and configure `ID[12:2]` in the **CANIFnARB2** register for bits [10:0] of the message identifier. Clear the `XTD` bit to indicate a standard identifier; set the `DIR` bit to indicate transmit; and set the `MSGVAL` bit to indicate that the message object is valid.
6. In the **CANIFnMCTL** register:

- Optionally set the `UMASK` bit to enable the mask (`MSK`, `MXTD`, and `MDIR` specified in the **CANIFnMSK1** and **CANIFnMSK2** registers) for acceptance filtering
  - Optionally set the `TXIE` bit to enable the `INTPND` bit to be set after a successful transmission
  - Optionally set the `RMTEN` bit to enable the `TXRQST` bit to be set on the reception of a matching remote frame allowing automatic transmission
  - Set the `EOB` bit for a single message object
  - Configure the `DLC[3:0]` field to specify the size of the data frame. Take care during this configuration not to set the `NEWDAT`, `MSGLST`, `INTPND` or `TXRQST` bits.
7. Load the data to be transmitted into the **CAN IFn Data (CANIFnDA1, CANIFnDA2, CANIFnDB1, CANIFnDB2)** registers. Byte 0 of the CAN data frame is stored in `DATA[7:0]` in the **CANIFnDA1** register.
  8. Program the number of the message object to be transmitted in the `MNUM` field in the **CAN IFn Command Request (CANIFnCRQ)** register.
  9. When everything is properly configured, set the `TXRQST` bit in the **CANIFnMCTL** register. Once this bit is set, the message object is available to be transmitted, depending on priority and bus availability. Note that setting the `RMTEN` bit in the **CANIFnMCTL** register can also start message transmission if a matching remote frame has been received.

### 17.3.5 Updating a Transmit Message Object

The CPU may update the data bytes of a Transmit Message Object any time via the CAN Interface Registers and neither the `MSGVAL` bit in the **CANIFnARB2** register nor the `TXRQST` bits in the **CANIFnMCTL** register have to be cleared before the update.

Even if only some of the data bytes are to be updated, all four bytes of the corresponding **CANIFnDAn/CANIFnDBn** register have to be valid before the content of that register is transferred to the message object. Either the CPU must write all four bytes into the **CANIFnDAn/CANIFnDBn** register or the message object is transferred to the **CANIFnDAn/CANIFnDBn** register before the CPU writes the new data bytes.

In order to only update the data in a message object, the `WRNRD`, `DATAA` and `DATAB` bits in the **CANIFnMSKn** register are set, followed by writing the updated data into **CANIFnDA1**, **CANIFnDA2**, **CANIFnDB1**, and **CANIFnDB2** registers, and then the number of the message object is written to the `MNUM` field in the **CAN IFn Command Request (CANIFnCRQ)** register. To begin transmission of the new data as soon as possible, set the `TXRQST` bit in the **CANIFnMSKn** register.

To prevent the clearing of the `TXRQST` bit in the **CANIFnMCTL** register at the end of a transmission that may already be in progress while the data is updated, the `NEWDAT` and `TXRQST` bits have to be set at the same time in the **CANIFnMCTL** register. When these bits are set at the same time, `NEWDAT` is cleared as soon as the new transmission has started.

### 17.3.6 Accepting Received Message Objects

When the arbitration and control field (the `ID` and `XTD` bits in the **CANIFnARB2** and the `RMTEN` and `DLC[3:0]` bits of the **CANIFnMCTL** register) of an incoming message is completely shifted into the CAN controller, the message handling capability of the controller starts scanning the message RAM for a matching valid message object. To scan the message RAM for a matching message object, the controller uses the acceptance filtering programmed through the mask bits in the **CANIFnMSKn** register and enabled using the `UMASK` bit in the **CANIFnMCTL** register. Each valid

message object, starting with object 1, is compared with the incoming message to locate a matching message object in the message RAM. If a match occurs, the scanning is stopped and the message handler proceeds depending on whether it is a data frame or remote frame that was received.

### 17.3.7 Receiving a Data Frame

The message handler stores the message from the CAN controller receive shift register into the matching message object in the message RAM. The data bytes, all arbitration bits, and the DLC bits are all stored into the corresponding message object. In this manner, the data bytes are connected with the identifier even if arbitration masks are used. The NEWDAT bit of the CANIFnMCTL register is set to indicate that new data has been received. The CPU should clear this bit when it reads the message object to indicate to the controller that the message has been received, and the buffer is free to receive more messages. If the CAN controller receives a message and the NEWDAT bit is already set, the MSGLST bit in the CANIFnMCTL register is set to indicate that the previous data was lost. If the system requires an interrupt on successful reception of a frame, the RXIE bit of the CANIFnMCTL register should be set. In this case, the INTPND bit of the same register is set, causing the CANINT register to point to the message object that just received a message. The TXRQST bit of this message object should be cleared to prevent the transmission of a remote frame.

### 17.3.8 Receiving a Remote Frame

A remote frame contains no data, but instead specifies which object should be transmitted. When a remote frame is received, three different configurations of the matching message object have to be considered:

**Table 17-2. Message Object Configurations**

| Configuration in CANIFnMCTL                                                                                                                                                                                                                                                                                                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>■ DIR = 1 (direction = transmit); programmed in the CANIFnARB2 register</li> <li>■ RMTEN = 1 (set the TXRQST bit of the CANIFnMCTL register at reception of the frame to enable transmission)</li> <li>■ UMASK = 1 or 0</li> </ul>                                                                    | At the reception of a matching remote frame, the TXRQST bit of this message object is set. The rest of the message object remains unchanged, and the controller automatically transfers the data in the message object as soon as possible.                                                                                                                                                                                                                                                                                                                                                                                      |
| <ul style="list-style-type: none"> <li>■ DIR = 1 (direction = transmit); programmed in the CANIFnARB2 register</li> <li>■ RMTEN = 0 (do not change the TXRQST bit of the CANIFnMCTL register at reception of the frame)</li> <li>■ UMASK = 0 (ignore mask in the CANIFnMSKn register)</li> </ul>                                             | At the reception of a matching remote frame, the TXRQST bit of this message object remains unchanged, and the remote frame is ignored. This remote frame is disabled, the data is not transferred and nothing indicates that the remote frame ever happened.                                                                                                                                                                                                                                                                                                                                                                     |
| <ul style="list-style-type: none"> <li>■ DIR = 1 (direction = transmit); programmed in the CANIFnARB2 register</li> <li>■ RMTEN = 0 (do not change the TXRQST bit of the CANIFnMCTL register at reception of the frame)</li> <li>■ UMASK = 1 (use mask (MSK, MXTD, and MDIR in the CANIFnMSKn register) for acceptance filtering)</li> </ul> | At the reception of a matching remote frame, the TXRQST bit of this message object is cleared. The arbitration and control field (ID + XTD + RMTEN + DLC) from the shift register is stored into the message object in the message RAM, and the NEWDAT bit of this message object is set. The data field of the message object remains unchanged; the remote frame is treated similar to a received data frame. This mode is useful for a remote data request from another CAN device for which the TM4C1233C3PM controller does not have readily available data. The software must fill the data and answer the frame manually. |

### 17.3.9 Receive/Transmit Priority

The receive/transmit priority for the message objects is controlled by the message number. Message object 1 has the highest priority, while message object 32 has the lowest priority. If more than one transmission request is pending, the message objects are transmitted in order based on the message object with the lowest message number. This prioritization is separate from that of the message identifier which is enforced by the CAN bus. As a result, if message object 1 and message object 2 both have valid messages to be transmitted, message object 1 is always transmitted first regardless of the message identifier in the message object itself.

### 17.3.10 Configuring a Receive Message Object

The following steps illustrate how to configure a receive message object.

1. Program the **CAN IFn Command Mask (CANIFnCMASK)** register as described in the “Configuring a Transmit Message Object” on page 1020 section, except that the WRNRD bit is set to specify a write to the message RAM.
2. Program the **CANIFnMSK1** and **CANIFnMSK2** registers as described in the “Configuring a Transmit Message Object” on page 1020 section to configure which bits are used for acceptance filtering. Note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the UMASK bit in the **CANIFnMCTL** register.
3. In the **CANIFnMSK2** register, use the MSK[12:0] bits to specify which of the bits in the 29-bit or 11-bit message identifier are used for acceptance filtering. Note that MSK[12:0] are used for bits [28:16] of the 29-bit message identifier; whereas MSK[12:2] are used for bits [10:0] of the 11-bit message identifier. Use the MXTD and MDIR bits to specify whether to use XTD and DIR for acceptance filtering. A value of 0x00 enables all messages to pass through the acceptance filtering. Also note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the UMASK bit in the **CANIFnMCTL** register.
4. Program the **CANIFnARB1** and **CANIFnARB2** registers as described in the “Configuring a Transmit Message Object” on page 1020 section to program XTD and ID bits for the message identifier to be received; set the MSGVAL bit to indicate a valid message; and clear the DIR bit to specify receive.
5. In the **CANIFnMCTL** register:
  - Optionally set the UMASK bit to enable the mask (MSK, MXTD, and MDIR specified in the **CANIFnMSK1** and **CANIFnMSK2** registers) for acceptance filtering
  - Optionally set the RXIE bit to enable the INTPND bit to be set after a successful reception
  - Clear the RMTEN bit to leave the TXRQST bit unchanged
  - Set the EOB bit for a single message object
  - Configure the DLC[3:0] field to specify the size of the data frame

Take care during this configuration not to set the NEWDAT, MSGLST, INTPND or TXRQST bits.
6. Program the number of the message object to be received in the MNUM field in the **CAN IFn Command Request (CANIFnCRQ)** register. Reception of the message object begins as soon as a matching frame is available on the CAN bus.

When the message handler stores a data frame in the message object, it stores the received Data Length Code and eight data bytes in the **CANIFnDA1**, **CANIFnDA2**, **CANIFnDB1**, and **CANIFnDB2** register. Byte 0 of the CAN data frame is stored in `DATA[7:0]` in the **CANIFnDA1** register. If the Data Length Code is less than 8, the remaining bytes of the message object are overwritten by unspecified values.

The CAN mask registers can be used to allow groups of data frames to be received by a message object. The CAN mask registers, **CANIFnMSKn**, configure which groups of frames are received by a message object. The `UMASK` bit in the **CANIFnMCTL** register enables the `MSK` bits in the **CANIFnMSKn** register to filter which frames are received. The `MXTD` bit in the **CANIFnMSK2** register should be set if only 29-bit extended identifiers are expected by this message object.

### 17.3.11 Handling of Received Message Objects

The CPU may read a received message any time via the CAN Interface registers because the data consistency is guaranteed by the message handler state machine.

Typically, the CPU first writes 0x007F to the **CANIFnCMSK** register and then writes the number of the message object to the **CANIFnCRQ** register. That combination transfers the whole received message from the message RAM into the Message Buffer registers (**CANIFnMSKn**, **CANIFnARBn**, and **CANIFnMCTL**). Additionally, the `NEWDAT` and `INTPND` bits are cleared in the message RAM, acknowledging that the message has been read and clearing the pending interrupt generated by this message object.

If the message object uses masks for acceptance filtering, the **CANIFnARBn** registers show the full, unmasked ID for the received message.

The `NEWDAT` bit in the **CANIFnMCTL** register shows whether a new message has been received since the last time this message object was read. The `MSGLST` bit in the **CANIFnMCTL** register shows whether more than one message has been received since the last time this message object was read. `MSGLST` is not automatically cleared, and should be cleared by software after reading its status.

Using a remote frame, the CPU may request new data from another CAN node on the CAN bus. Setting the `TXRQST` bit of a receive object causes the transmission of a remote frame with the receive object's identifier. This remote frame triggers the other CAN node to start the transmission of the matching data frame. If the matching data frame is received before the remote frame could be transmitted, the `TXRQST` bit is automatically reset. This prevents the possible loss of data when the other device on the CAN bus has already transmitted the data slightly earlier than expected.

#### 17.3.11.1 Configuration of a FIFO Buffer

With the exception of the `EOB` bit in the **CANIFnMCTL** register, the configuration of receive message objects belonging to a FIFO buffer is the same as the configuration of a single receive message object (see “Configuring a Receive Message Object” on page 1023). To concatenate two or more message objects into a FIFO buffer, the identifiers and masks (if used) of these message objects have to be programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest message object number is the first message object in a FIFO buffer. The `EOB` bit of all message objects of a FIFO buffer except the last one must be cleared. The `EOB` bit of the last message object of a FIFO buffer is set, indicating it is the last entry in the buffer.

#### 17.3.11.2 Reception of Messages with FIFO Buffers

Received messages with identifiers matching to a FIFO buffer are stored starting with the message object with the lowest message number. When a message is stored into a message object of a FIFO buffer, the `NEWDAT` of the **CANIFnMCTL** register bit of this message object is set. By setting

NEWDAT while EOB is clear, the message object is locked and cannot be written to by the message handler until the CPU has cleared the NEWDAT bit. Messages are stored into a FIFO buffer until the last message object of this FIFO buffer is reached. Until all of the preceding message objects have been released by clearing the NEWDAT bit, all further messages for this FIFO buffer are written into the last message object of the FIFO buffer and therefore overwrite previous messages.

### 17.3.11.3 Reading from a FIFO Buffer

When the CPU transfers the contents of a message object from a FIFO buffer by writing its number to the **CANIFnCRQ** register, the **TXRQST** and **CLRINTPND** bits in the **CANIFnCMSK** register should be set such that the **NEWDAT** and **INTPEND** bits in the **CANIFnMCTL** register are cleared after the read. The values of these bits in the **CANIFnMCTL** register always reflect the status of the message object before the bits are cleared. To assure the correct function of a FIFO buffer, the CPU should read out the message objects starting with the message object with the lowest message number. When reading from the FIFO buffer, the user should be aware that a new received message is placed in the message object with the lowest message number for which the **NEWDAT** bit of the **CANIFnMCTL** register is clear. As a result, the order of the received messages in the FIFO is not guaranteed. Figure 17-3 on page 1026 shows how a set of message objects which are concatenated to a FIFO Buffer can be handled by the CPU.

Figure 17-3. Message Objects in a FIFO Buffer

### 17.3.12 Handling of Interrupts

If several interrupts are pending, the **CAN Interrupt (CANINT)** register points to the pending interrupt with the highest priority, disregarding their chronological order. The status interrupt has the highest

priority. Among the message interrupts, the message object's interrupt with the lowest message number has the highest priority. A message interrupt is cleared by clearing the message object's `INTPND` bit in the `CANIFnMCTL` register or by reading the **CAN Status (CANSTS)** register. The status Interrupt is cleared by reading the **CANSTS** register.

The interrupt identifier `INTID` in the **CANINT** register indicates the cause of the interrupt. When no interrupt is pending, the register reads as `0x0000`. If the value of the `INTID` field is different from 0, then an interrupt is pending. If the `IE` bit is set in the **CANCTL** register, the interrupt line to the interrupt controller is active. The interrupt line remains active until the `INTID` field is 0, meaning that all interrupt sources have been cleared (the cause of the interrupt is reset), or until `IE` is cleared, which disables interrupts from the CAN controller.

The `INTID` field of the **CANINT** register points to the pending message interrupt with the highest interrupt priority. The `SIE` bit in the **CANCTL** register controls whether a change of the `RXOK`, `TXOK`, and `LEC` bits in the **CANSTS** register can cause an interrupt. The `EIE` bit in the **CANCTL** register controls whether a change of the `BOFF` and `EWARN` bits in the **CANSTS** register can cause an interrupt. The `IE` bit in the **CANCTL** register controls whether any interrupt from the CAN controller actually generates an interrupt to the interrupt controller. The **CANINT** register is updated even when the `IE` bit in the **CANCTL** register is clear, but the interrupt is not indicated to the CPU.

A value of `0x8000` in the **CANINT** register indicates that an interrupt is pending because the CAN module has updated, but not necessarily changed, the **CANSTS** register, indicating that either an error or status interrupt has been generated. A write access to the **CANSTS** register can clear the `RXOK`, `TXOK`, and `LEC` bits in that same register; however, the only way to clear the source of a status interrupt is to read the **CANSTS** register.

The source of an interrupt can be determined in two ways during interrupt handling. The first is to read the `INTID` bit in the **CANINT** register to determine the highest priority interrupt that is pending, and the second is to read the **CAN Message Interrupt Pending (CANMSGnINT)** register to see all of the message objects that have pending interrupts.

An interrupt service routine reading the message that is the source of the interrupt may read the message and clear the message object's `INTPND` bit at the same time by setting the `CLRINTPND` bit in the **CANIFnCMSK** register. Once the `INTPND` bit has been cleared, the **CANINT** register contains the message number for the next message object with a pending interrupt.

### 17.3.13 Test Mode

A Test Mode is provided which allows various diagnostics to be performed. Test Mode is entered by setting the `TEST` bit in the **CANCTL** register. Once in Test Mode, the `TX[1:0]`, `LBACK`, `SILENT` and `BASIC` bits in the **CAN Test (CANTST)** register can be used to put the CAN controller into the various diagnostic modes. The `RX` bit in the **CANTST** register allows monitoring of the `CANnRX` signal. All **CANTST** register functions are disabled when the `TEST` bit is cleared.

#### 17.3.13.1 Silent Mode

Silent Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits (Acknowledge Bits, Error Frames). The CAN Controller is put in Silent Mode setting the `SILENT` bit in the **CANTST** register. In Silent Mode, the CAN controller is able to receive valid data frames and valid remote frames, but it sends only recessive bits on the CAN bus and cannot start a transmission. If the CAN Controller is required to send a dominant bit (ACK bit, overload flag, or active error flag), the bit is rerouted internally so that the CAN Controller monitors this dominant bit, although the CAN bus remains in recessive state.

### 17.3.13.2 Loopback Mode

Loopback mode is useful for self-test functions. In Loopback Mode, the CAN Controller internally routes the `CANnTX` signal on to the `CANnRX` signal and treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) into the message buffer. The CAN Controller is put in Loopback Mode by setting the `LBACK` bit in the `CANTST` register. To be independent from external stimulation, the CAN Controller ignores acknowledge errors (a recessive bit sampled in the acknowledge slot of a data/remote frame) in Loopback Mode. The actual value of the `CANnRX` signal is disregarded by the CAN Controller. The transmitted messages can be monitored on the `CANnTX` signal.

### 17.3.13.3 Loopback Combined with Silent Mode

Loopback Mode and Silent Mode can be combined to allow the CAN Controller to be tested without affecting a running CAN system connected to the `CANnTX` and `CANnRX` signals. In this mode, the `CANnRX` signal is disconnected from the CAN Controller and the `CANnTX` signal is held recessive. This mode is enabled by setting both the `LBACK` and `SILENT` bits in the `CANTST` register.

### 17.3.13.4 Basic Mode

Basic Mode allows the CAN Controller to be operated without the Message RAM. In Basic Mode, The CANIF1 registers are used as the transmit buffer. The transmission of the contents of the IF1 registers is requested by setting the `BUSY` bit of the `CANIF1CRQ` register. The CANIF1 registers are locked while the `BUSY` bit is set. The `BUSY` bit indicates that a transmission is pending. As soon the CAN bus is idle, the CANIF1 registers are loaded into the shift register of the CAN Controller and transmission is started. When the transmission has completed, the `BUSY` bit is cleared and the locked CANIF1 registers are released. A pending transmission can be aborted at any time by clearing the `BUSY` bit in the `CANIF1CRQ` register while the CANIF1 registers are locked. If the CPU has cleared the `BUSY` bit, a possible retransmission in case of lost arbitration or an error is disabled.

The CANIF2 Registers are used as a receive buffer. After the reception of a message, the contents of the shift register are stored in the CANIF2 registers, without any acceptance filtering. Additionally, the actual contents of the shift register can be monitored during the message transfer. Each time a read message object is initiated by setting the `BUSY` bit of the `CANIF2CRQ` register, the contents of the shift register are stored into the CANIF2 registers.

In Basic Mode, all message-object-related control and status bits and of the control bits of the `CANIFnCMSK` registers are not evaluated. The message number of the `CANIFnCRQ` registers is also not evaluated. In the `CANIF2MCTL` register, the `NEWDAT` and `MSGLST` bits retain their function, the `DLC[3:0]` field shows the received DLC, the other control bits are cleared.

Basic Mode is enabled by setting the `BASIC` bit in the `CANTST` register.

### 17.3.13.5 Transmit Control

Software can directly override control of the `CANnTX` signal in four different ways.

- `CANnTX` is controlled by the CAN Controller
- The sample point is driven on the `CANnTX` signal to monitor the bit timing
- `CANnTX` drives a low value
- `CANnTX` drives a high value

The last two functions, combined with the readable CAN receive pin `CANnRX`, can be used to check the physical layer of the CAN bus.

The Transmit Control function is enabled by programming the `TX[1:0]` field in the `CANTST` register. The three test functions for the `CANnTX` signal interfere with all CAN protocol functions. `TX[1:0]` must be cleared when CAN message transfer or Loopback Mode, Silent Mode, or Basic Mode are selected.

### 17.3.14 Bit Timing Configuration Error Considerations

Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of a CAN network can be reduced significantly. In many cases, the CAN bit synchronization amends a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. In the case of arbitration, however, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point may cause one of the transmitters to become error passive. The analysis of such sporadic errors requires a detailed knowledge of the CAN bit synchronization inside a CAN node and of the CAN nodes' interaction on the CAN bus.

### 17.3.15 Bit Time and Bit Rate

The CAN system supports bit rates in the range of lower than 1 Kbps up to 1000 Kbps. Each member of the CAN network has its own clock generator. The timing parameter of the bit time can be configured individually for each CAN node, creating a common bit rate even though the CAN nodes' oscillator periods may be different.

Because of small variations in frequency caused by changes in temperature or voltage and by deteriorating components, these oscillators are not absolutely stable. As long as the variations remain inside a specific oscillator's tolerance range, the CAN nodes are able to compensate for the different bit rates by periodically resynchronizing to the bit stream.

According to the CAN specification, the bit time is divided into four segments (see Figure 17-4 on page 1030): the Synchronization Segment, the Propagation Time Segment, the Phase Buffer Segment 1, and the Phase Buffer Segment 2. Each segment consists of a specific, programmable number of time quanta (see Table 17-3 on page 1030). The length of the time quantum ( $t_q$ ), which is the basic time unit of the bit time, is defined by the CAN controller's input clock ( $f_{sys}$ ) and the Baud Rate Prescaler (`BRP`):

$$t_q = BRP / f_{sys}$$

The  $f_{sys}$  input clock is the system clock frequency as configured by the `RCC` or `RCC2` registers (see page 245 or page 251).

The Synchronization Segment Sync is that part of the bit time where edges of the CAN bus level are expected to occur; the distance between an edge that occurs outside of `Sync` and the `Sync` is called the phase error of that edge.

The Propagation Time Segment Prop is intended to compensate for the physical delay times within the CAN network.

The Phase Buffer Segments Phase1 and Phase2 surround the Sample Point.

The (Re-)Synchronization Jump Width (SJW) defines how far a resynchronization may move the Sample Point inside the limits defined by the Phase Buffer Segments to compensate for edge phase errors.

A given bit rate may be met by different bit-time configurations, but for the proper function of the CAN network, the physical delay times and the oscillator's tolerance range have to be considered.

Figure 17-4. CAN Bit Time

Table 17-3. CAN Protocol Ranges<sup>a</sup>

| Parameter | Range          | Remark                                                                                                              |
|-----------|----------------|---------------------------------------------------------------------------------------------------------------------|
| BRP       | [1 .. 64]      | Defines the length of the time quantum $t_q$ . The <b>CANBRPE</b> register can be used to extend the range to 1024. |
| Sync      | 1 $t_q$        | Fixed length, synchronization of bus input to system clock                                                          |
| Prop      | [1 .. 8] $t_q$ | Compensates for the physical delay times                                                                            |
| Phase1    | [1 .. 8] $t_q$ | May be lengthened temporarily by synchronization                                                                    |
| Phase2    | [1 .. 8] $t_q$ | May be shortened temporarily by synchronization                                                                     |
| SJW       | [1 .. 4] $t_q$ | May not be longer than either Phase Buffer Segment                                                                  |

a. This table describes the minimum programmable ranges required by the CAN protocol.

The bit timing configuration is programmed in two register bytes in the **CANBIT** register. In the **CANBIT** register, the four components TSEG2, TSEG1, SJW, and BRP have to be programmed to a numerical value that is one less than its functional value; so instead of values in the range of [1..n], values in the range of [0..n-1] are programmed. That way, for example, SJW (functional range of [1..4]) is represented by only two bits in the SJW bit field. Table 17-4 shows the relationship between the **CANBIT** register values and the parameters.

Table 17-4. CANBIT Register Values

| CANBIT Register Field | Setting           |
|-----------------------|-------------------|
| TSEG2                 | Phase2 - 1        |
| TSEG1                 | Prop + Phase1 - 1 |
| SJW                   | SJW - 1           |
| BRP                   | BRP               |

Therefore, the length of the bit time is (programmed values):

$$[TSEG1 + TSEG2 + 3] \times t_q$$

or (functional values):

$$[Sync + Prop + Phase1 + Phase2] \times t_q$$

The data in the **CANBIT** register is the configuration input of the CAN protocol controller. The baud rate prescaler (configured by the BRP field) defines the length of the time quantum, the basic time

unit of the bit time; the bit timing logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

The processing of the bit time, the calculation of the position of the sample point, and occasional synchronizations are controlled by the CAN controller and are evaluated once per time quantum.

The CAN controller translates messages to and from frames. In addition, the controller generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. The bit value is received or transmitted at the sample point. The information processing time (IPT) is the time after the sample point needed to calculate the next bit to be transmitted on the CAN bus. The IPT includes any of the following: retrieving the next data bit, handling a CRC bit, determining if bit stuffing is required, generating an error flag or simply going idle.

The IPT is application-specific but may not be longer than  $2 t_q$ ; the CAN's IPT is  $0 t_q$ . Its length is the lower limit of the programmed length of Phase2. In case of synchronization, Phase2 may be shortened to a value less than IPT, which does not affect bus timing.

### 17.3.16 Calculating the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a required bit rate or bit time. The resulting bit time (1/bit rate) must be an integer multiple of the system clock period.

The bit time may consist of 4 to 25 time quanta. Several combinations may lead to the required bit time, allowing iterations of the following steps.

The first part of the bit time to be defined is Prop. Its length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandable CAN bus systems. The resulting time for Prop is converted into time quanta (rounded up to the nearest integer multiple of  $t_q$ ).

Sync is  $1 t_q$  long (fixed), which leaves  $(\text{bit time} - \text{Prop} - 1) t_q$  for the two Phase Buffer Segments. If the number of remaining  $t_q$  is even, the Phase Buffer Segments have the same length, that is, Phase2 = Phase1, else Phase2 = Phase1 + 1.

The minimum nominal length of Phase2 has to be regarded as well. Phase2 may not be shorter than the CAN controller's Information Processing Time, which is, depending on the actual implementation, in the range of  $[0..2] t_q$ .

The length of the synchronization jump width is set to the least of 4, Phase1 or Phase2.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formula given below:

$$(1 - df) \times f_{nom} \leq f_{osc} \leq (1 + df) \times f_{nom}$$

where:

- $df$  = Maximum tolerance of oscillator frequency
- $f_{osc}$  = Actual oscillator frequency
- $f_{nom}$  = Nominal oscillator frequency

Maximum frequency tolerance must take into account the following formulas:

$$df \leq \frac{(Phase\_seg1, Phase\_seg2) \min}{2 \times (13 \times t_{bit} - Phase\_Seg2)}$$

$$df \max = 2 \times df \times f_{nom}$$

where:

- Phase1 and Phase2 are from Table 17-3 on page 1030
- t<sub>bit</sub> = Bit Time
- df<sub>max</sub> = Maximum difference between two oscillators

If more than one configuration is possible, that configuration allowing the highest oscillator tolerance range should be chosen.

CAN nodes with different system clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system's oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the oscillator frequencies' stability has to be increased in order to find a protocol-compliant configuration of the CAN bit timing.

### 17.3.16.1 Example for Bit Timing at High Baud Rate

In this example, the frequency of CAN clock is 25 MHz, and the bit rate is 1 Mbps.

$$\text{bit time} = 1 \mu\text{s} = n * t_q = 5 * t_q$$

$$t_q = 200 \text{ ns}$$

$$t_q = (\text{Baud rate Prescaler}) / \text{CAN Clock}$$

$$\text{Baud rate Prescaler} = t_q * \text{CAN Clock}$$

$$\text{Baud rate Prescaler} = 200\text{E-}9 * 25\text{E}6 = 5$$

$$t_{\text{Sync}} = 1 * t_q = 200 \text{ ns}$$

\\fixed at 1 time quanta

delay of bus driver 50 ns

delay of receiver circuit 30 ns

delay of bus line (40m) 220 ns

$$t_{\text{Prop}} 400 \text{ ns} = 2 * t_q$$

\\400 is next integer multiple of t<sub>q</sub>

$$\text{bit time} = t_{\text{Sync}} + t_{\text{TSeg1}} + t_{\text{TSeg2}} = 5 * t_q$$

$$\text{bit time} = t_{\text{Sync}} + t_{\text{Prop}} + t_{\text{Phase 1}} + t_{\text{Phase 2}}$$

$$t_{\text{Phase 1}} + t_{\text{Phase 2}} = \text{bit time} - t_{\text{Sync}} - t_{\text{Prop}}$$

$$t_{\text{Phase 1}} + t_{\text{Phase 2}} = (5 * t_q) - (1 * t_q) - (2 * t_q)$$

$$t_{\text{Phase 1}} + t_{\text{Phase 2}} = 2 * t_q$$

$$t_{\text{Phase1}} = 1 * t_q$$

$$t_{\text{Phase2}} = 1 * t_q$$

\\tPhase2 = tPhase1

```

tTSeg1 = tProp + tPhase1
tTSeg1 = (2 * tq) + (1 * tq)
tTSeg1 = 3 * tq

tTSeg2 = tPhase2
tTSeg2 = (Information Processing Time + 1) * tq
tTSeg2 = 1 * tq                \\Assumes IPT=0

tSJW = 1 * tq                \\Least of 4, Phase1 and Phase2

```

In the above example, the bit field values for the **CANBIT** register are:

|       |                                           |
|-------|-------------------------------------------|
| TSEG2 | = TSeg2 -1<br>= 1-1<br>= 0                |
| TSEG1 | = TSeg1 -1<br>= 3-1<br>= 2                |
| SJW   | = SJW -1<br>= 1-1<br>= 0                  |
| BRP   | = Baud rate prescaler - 1<br>= 5-1<br>= 4 |

The final value programmed into the **CANBIT** register = 0x0204.

### 17.3.16.2 Example for Bit Timing at Low Baud Rate

In this example, the frequency of the CAN clock is 50 MHz, and the bit rate is 100 Kbps.

```

bit time = 10 μs = n * tq = 10 * tq
tq = 1 μs
tq = (Baud rate Prescaler)/CAN Clock
Baud rate Prescaler = tq * CAN Clock
Baud rate Prescaler = 1E-6 * 50E6 = 50

tSync = 1 * tq = 1 μs                \\fixed at 1 time quanta

delay of bus driver 200 ns
delay of receiver circuit 80 ns
delay of bus line (40m) 220 ns
tProp 1 μs = 1 * tq                \\1 μs is next integer multiple of tq

bit time = tSync + tTSeg1 + tTSeg2 = 10 * tq
bit time = tSync + tProp + tPhase 1 + tPhase2
tPhase 1 + tPhase2 = bit time - tSync - tProp
tPhase 1 + tPhase2 = (10 * tq) - (1 * tq) - (1 * tq)
tPhase 1 + tPhase2 = 8 * tq
tPhase1 = 4 * tq
tPhase2 = 4 * tq                \\tPhase1 = tPhase2

```

$$\begin{aligned}
 tTSeg1 &= tProp + tPhase1 \\
 tTSeg1 &= (1 * t_q) + (4 * t_q) \\
 tTSeg1 &= 5 * t_q \\
 tTSeg2 &= tPhase2 \\
 tTSeg2 &= (Information Processing Time + 4) * t_q \\
 tTSeg2 &= 4 * t_q \qquad \qquad \qquad \backslash\backslash \text{Assumes IPT}=0 \\
 \\ 
 tSJW &= 4 * t_q \qquad \qquad \qquad \backslash\backslash \text{Least of 4, Phase1, and Phase2}
 \end{aligned}$$

|       |                                            |
|-------|--------------------------------------------|
| TSEG2 | = TSeg2 -1<br>= 4-1<br>= 3                 |
| TSEG1 | = TSeg1 -1<br>= 5-1<br>= 4                 |
| SJW   | = SJW -1<br>= 4-1<br>= 3                   |
| BRP   | = Baud rate prescaler - 1<br>= 50-1<br>=49 |

The final value programmed into the **CANBIT** register = 0x34F1.

## 17.4 Register Map

Table 17-5 on page 1034 lists the registers. All addresses given are relative to the CAN base address of:

- CAN0: 0x4004.0000

Note that the CAN controller clock must be enabled before the registers can be programmed (see page 337). There must be a delay of 3 system clocks after the CAN module clock is enabled before any CAN module registers are accessed.

**Table 17-5. CAN Register Map**

| Offset | Name       | Type | Reset       | Description                       | See page |

## 17.5 CAN Register Descriptions

The remainder of this section lists and describes the CAN registers, in numerical order by address offset. There are two sets of Interface Registers that are used to access the Message Objects in the Message RAM: **CANIF1x** and **CANIF2x**. The function of the two sets are identical and are used to queue transactions.

### Register 1: CAN Control (CANCTL), offset 0x000

This control register initializes the module and enables test mode and interrupts.

The bus-off recovery sequence (see CAN Specification Rev. 2.0) cannot be shortened by setting or clearing `INIT`. If the device goes bus-off, it sets `INIT`, stopping all bus activities. Once `INIT` has been cleared by the CPU, the device then waits for 129 occurrences of Bus Idle (129 \* 11 consecutive High bits) before resuming normal operations. At the end of the bus-off recovery sequence, the Error Management Counters are reset.

During the waiting time after `INIT` is cleared, each time a sequence of 11 High bits has been monitored, a `BITERROR0` code is written to the **CANSTS** register (the `LEC` field = 0x5), enabling the CPU to readily check whether the CAN bus is stuck Low or continuously disturbed, and to monitor the proceeding of the bus-off recovery sequence.

#### CAN Control (CANCTL)

## Register 2: CAN Status (CANSTS), offset 0x004

**Important:** This register is read-sensitive. See the register description for details.

The status register contains information for interrupt servicing such as Bus-Off, error count threshold, and error types.

The LEC field holds the code that indicates the type of the last error to occur on the CAN bus. This field is cleared when a message has been transferred (reception or transmission) without error. The unused error code 0x7 may be written by the CPU to manually set this field to an invalid error so that it can be checked for a change later.

An error interrupt is generated by the BOFF and EWARN bits, and a status interrupt is generated by the RXOK, TXOK, and LEC bits, if the corresponding enable bits in the **CAN Control (CANCTL)** register are set. A change of the EPASS bit or a write to the RXOK, TXOK, or LEC bits does not generate an interrupt.

Reading the **CAN Status (CANSTS)** register clears the **CAN Interrupt (CANINT)** register, if it is pending.

### CAN Status (CANSTS)

CAN0 base: 0x4004.0000  
Offset 0x004  
Type R/W, reset 0x0000.0000

When the arbitration field is transmitted, data conflicts are a part of the arbitration protocol. When other frame fields are transmitted, data conflicts are considered errors. |  | A Bit 1 Error indicates that the device wanted to send a High level (logical 1) but the monitored bus value was Low (logical 0). | 0x5 | Bit 0 Error |  | A Bit 0 Error indicates that the device wanted to send a Low level (logical 0), but the monitored bus value was High (logical 1). |  | During bus-off recovery, this status is set each time a sequence of 11 High bits has been monitored. By checking for this status, software can monitor the proceeding of the bus-off recovery sequence without any disturbances to the bus. | 0x6 | CRC Error |  | The CRC checksum was incorrect in the received message, indicating that the calculated value received did not match the calculated CRC of the data. | 0x7 | No Event |  | When the LEC bit shows this value, no CAN bus event was detected since this value was written to the LEC field. |
| Value     | Description                                                                                                                                                                                                                                                                         |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |       |             |     |          |     |             |  |                                                                                                               |     |              |  |                                                                 |     |           |  |                                                               |     |             |  |                                                                                                                                                                                                                                                                                     |  |                                                                                                                                  |     |             |  |                                                                                                                                   |  |                                                                                                                                                                                                                                             |     |           |  |                                                                                                                                                     |     |          |  |                                                                                                                 |

|           | When a message is transmitted, the CAN controller monitors the data lines to detect any conflicts. When the arbitration field is transmitted, data conflicts are a part of the arbitration protocol. When other frame fields are transmitted, data conflicts are considered errors. |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |       |             |     |          |     |             |  |                                                                                                               |     |              |  |                                                                 |     |           |  |                                                               |     |             |  |                                                                                                                                                                                                                                                                                     |  |                                                                                                                                  |     |             |  |                                                                                                                                   |  |                                                                                                                                                                                                                                             |     |           |  |                                                                                                                                                     |     |          |  |                                                                                                                 |
|           | A Bit 1 Error indicates that the device wanted to send a High level (logical 1) but the monitored bus value was Low (logical 0).                                                                                                                                                    |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |       |             |     |          |     |             |  |                                                                                                               |     |              |  |                                                                 |     |           |  |                                                               |     |             |  |                                                                                                                                                                                                                                                                                     |  |                                                                                                                                  |     |             |  |                                                                                                                                   |  |                                                                                                                                                                                                                                             |     |           |  |                                                                                                                                                     |     |          |  |                                                                                                                 |

|           | A Bit 0 Error indicates that the device wanted to send a Low level (logical 0), but the monitored bus value was High (logical 1).                                                                                                                                                   |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |       |             |     |          |     |             |  |                                                                                                               |     |              |  |                                                                 |     |           |  |                                                               |     |             |  |                                                                                                                                                                                                                                                                                     |  |                                                                                                                                  |     |             |  |                                                                                                                                   |  |                                                                                                                                                                                                                                             |     |           |  |                                                                                                                                                     |     |          |  |                                                                                                                 |
|           | During bus-off recovery, this status is set each time a sequence of 11 High bits has been monitored. By checking for this status, software can monitor the proceeding of the bus-off recovery sequence without any disturbances to the bus.                                         |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |       |             |     |          |     |             |  |                                                                                                               |     |              |  |                                                                 |     |           |  |                                                               |     |             |  |                                                                                                                                                                                                                                                                                     |  |                                                                                                                                  |     |             |  |                                                                                                                                   |  |                                                                                                                                                                                                                                             |     |           |  |                                                                                                                                                     |     |          |  |                                                                                                                 |

|           | When the LEC bit shows this value, no CAN bus event was detected since this value was written to the LEC field.                                                                                                                                                                     |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |       |             |     |          |     |             |  |                                                                                                               |     |              |  |                                                                 |     |           |  |                                                               |     |             |  |                                                                                                                                                                                                                                                                                     |  |                                                                                                                                  |     |             |  |                                                                                                                                   |  |                                                                                                                                                                                                                                             |     |           |  |                                                                                                                                                     |     |          |  |                                                                                                                 |

**Register 3: CAN Error Counter (CANERR), offset 0x008**

This register contains the error counter values, which can be used to analyze the cause of an error.

**CAN Error Counter (CANERR)**

CAN0 base: 0x4004.0000

Offset 0x008

Type RO, reset 0x0000.0000

### Register 4: CAN Bit Timing (CANBIT), offset 0x00C

This register is used to program the bit width and bit quantum. Values are programmed to the system clock frequency. This register is write-enabled by setting the `CCE` and `INIT` bits in the `CANCTL` register. See “Bit Time and Bit Rate” on page 1029 for more information.

#### CAN Bit Timing (CANBIT)

CAN0 base: 0x4004.0000  
 Offset 0x00C  
 Type R/W, reset 0x0000.2301

| Bit/Field | Name     | Type | Reset  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------|----------|------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:15     | reserved | RO   | 0x0000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.                                                                                                                                                                                                                                                                                                                                                |
| 14:12     | TSEG2    | R/W  | 0x2    | Time Segment after Sample Point<br>0x00-0x07: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.<br>So, for example, the reset value of 0x2 means that 3 (2+1) bit time quanta are defined for <code>Phase2</code> (see Figure 17-4 on page 1030). The bit time quanta is defined by the <code>BRP</code> field.                                                                                                                                                          |
| 11:8      | TSEG1    | R/W  | 0x3    | Time Segment Before Sample Point<br>0x00-0x0F: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.<br>So, for example, the reset value of 0x3 means that 4 (3+1) bit time quanta are defined for <code>Phase1</code> (see Figure 17-4 on page 1030). The bit time quanta is defined by the <code>BRP</code> field.                                                                                                                                                         |
| 7:6       | SJW      | R/W  | 0x0    | (Re)Synchronization Jump Width<br>0x00-0x03: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.<br>During the start of frame (SOF), if the CAN controller detects a phase error (misalignment), it can adjust the length of <code>TSEG2</code> or <code>TSEG1</code> by the value in <code>SJW</code> . So the reset value of 0 adjusts the length by 1 bit time quanta.                                                                                                  |
| 5:0       | BRP      | R/W  | 0x1    | Baud Rate Prescaler<br>The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quantum.<br>0x00-0x03F: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.<br><code>BRP</code> defines the number of CAN clock periods that make up 1 bit time quanta, so the reset value is 2 bit time quanta (1+1).<br>The <code>CANBRPE</code> register can be used to further divide the bit time. |

**Register 5: CAN Interrupt (CANINT), offset 0x010**

This register indicates the source of the interrupt.

If several interrupts are pending, the **CAN Interrupt (CANINT)** register points to the pending interrupt with the highest priority, disregarding the order in which the interrupts occurred. An interrupt remains pending until the CPU has cleared it. If the **INTID** field is not 0x0000 (the default) and the **IE** bit in the **CANCTL** register is set, the interrupt is active. The interrupt line remains active until the **INTID** field is cleared by reading the **CANSTS** register, or until the **IE** bit in the **CANCTL** register is cleared.

**Note:** Reading the **CAN Status (CANSTS)** register clears the **CAN Interrupt (CANINT)** register, if it is pending.

**CAN Interrupt (CANINT)**

### Register 6: CAN Test (CANTST), offset 0x014

This register is used for self-test and external pin access. It is write-enabled by setting the `TEST` bit in the `CANCTL` register. Different test functions may be combined, however, CAN transfers are affected if the `TX` bits in this register are not zero.

#### CAN Test (CANTST)

CAN0 base: 0x4004.0000  
 Offset 0x014  
 Type R/W, reset 0x0000.0000

### Register 7: CAN Baud Rate Prescaler Extension (CANBRPE), offset 0x018

This register is used to further divide the bit time set with the `BRP` bit in the `CANBIT` register. It is write-enabled by setting the `CCE` bit in the `CANCTL` register.

| 3:0       | BRPE     | R/W  | 0x0        | Baud Rate Prescaler Extension<br>0x00-0x0F: Extend the <code>BRP</code> bit in the <code>CANBIT</code> register to values up to 1023. The actual interpretation by the hardware is one more than the value programmed by <code>BRPE</code> (MSBs) and <code>BRP</code> (LSBs). |

**Register 8: CAN IF1 Command Request (CANIF1CRQ), offset 0x020****Register 9: CAN IF2 Command Request (CANIF2CRQ), offset 0x080**

A message transfer is started as soon as there is a write of the message object number to the MNUM field when the TXRQST bit in the CANIF1MCTL register is set. With this write operation, the BUSY bit is automatically set to indicate that a transfer between the CAN Interface Registers and the internal message RAM is in progress. After a wait time of 3 to 6 CAN\_CLK periods, the transfer between the interface register and the message RAM completes, which then clears the BUSY bit.

## CAN IFn Command Request (CANIFnCRQ)

**Register 10: CAN IF1 Command Mask (CANIF1CMSK), offset 0x024**

**Register 11: CAN IF2 Command Mask (CANIF2CMSK), offset 0x084**

Reading the Command Mask registers provides status for various functions. Writing to the Command Mask registers specifies the transfer direction and selects which buffer registers are the source or target of the data transfer.

Note that when a read from the message object buffer occurs when the WRNRD bit is clear and the CLRINTPND and/or NEWDAT bits are set, the interrupt pending and/or new data flags in the message object buffer are cleared.

CAN IFn Command Mask (CANIFnCMSK)

CAN0 base: 0x4004.0000  
 Offset 0x024  
 Type R/W, reset 0x0000.0000

**Register 12: CAN IF1 Mask 1 (CANIF1MSK1), offset 0x028****Register 13: CAN IF2 Mask 1 (CANIF2MSK1), offset 0x088**

The mask information provided in this register accompanies the data (**CANIFnDAn**), arbitration information (**CANIFnARBn**), and control information (**CANIFnMCTL**) to the message object in the message RAM. The mask is used with the **ID** bit in the **CANIFnARBn** register for acceptance filtering. Additional mask information is contained in the **CANIFnMSK2** register.

## CAN IFn Mask 1 (CANIFnMSK1)

CAN0 base: 0x4004.0000

Offset 0x028

Type R/W, reset 0x0000.FFFF

All unused message objects should have this bit cleared during initialization and before clearing the `INIT` bit in the `CANCTL` register. The `MSGVAL` bit must also be cleared before any of the following bits are modified or if the message object is no longer required: the `ID` fields in the `CANIFnARBn` registers, the `XTD` and `DIR` bits in the `CANIFnARB2` register, or the `DLC` field in the `CANIFnMCTL` register.

| Bit/Field | Name                                                                                                                                                                                                                                                                                              | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |       |             |   |                                                                                                                                                                                                                                                                  |   |                                                                                                                                                                                                                                                                                                   |

**Register 20: CAN IF1 Message Control (CANIF1MCTL), offset 0x038****Register 21: CAN IF2 Message Control (CANIF2MCTL), offset 0x098**

This register holds the control information associated with the message object to be sent to the Message RAM.

## CAN IFn Message Control (CANIFnMCTL)

CAN0 base: 0x4004.0000

Offset 0x038

Type R/W, reset 0x0000.0000

| 0x0-0x8   | Specifies the number of bytes in the data frame.                                                |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |       |             |         |                                                                                                 |         |                                                                |
| 0x9-0xF   | Defaults to a data frame with 8 bytes.                                                          |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |       |             |         |                                                                                                 |         |                                                                |

**Register 22: CAN IF1 Data A1 (CANIF1DA1), offset 0x03C**

**Register 23: CAN IF1 Data A2 (CANIF1DA2), offset 0x040**

**Register 24: CAN IF1 Data B1 (CANIF1DB1), offset 0x044**

**Register 25: CAN IF1 Data B2 (CANIF1DB2), offset 0x048**

**Register 26: CAN IF2 Data A1 (CANIF2DA1), offset 0x09C**

**Register 27: CAN IF2 Data A2 (CANIF2DA2), offset 0x0A0**

**Register 28: CAN IF2 Data B1 (CANIF2DB1), offset 0x0A4**

**Register 29: CAN IF2 Data B2 (CANIF2DB2), offset 0x0A8**

These registers contain the data to be sent or that has been received. In a CAN data frame, data byte 0 is the first byte to be transmitted or received and data byte 7 is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte is transmitted first.

**Register 30: CAN Transmission Request 1 (CANTXRQ1), offset 0x100****Register 31: CAN Transmission Request 2 (CANTXRQ2), offset 0x104**

The **CANTXRQ1** and **CANTXRQ2** registers hold the **TXRQST** bits of the 32 message objects. By reading out these bits, the CPU can check which message object has a transmission request pending. The **TXRQST** bit of a specific message object can be changed by three sources: (1) the CPU via the **CANIFnMCTL** register, (2) the message handler state machine after the reception of a remote frame, or (3) the message handler state machine after a successful transmission.

The **CANTXRQ1** register contains the **TXRQST** bits of the first 16 message objects in the message RAM; the **CANTXRQ2** register contains the **TXRQST** bits of the second 16 message objects.

**Register 34: CAN Message 1 Interrupt Pending (CANMSG1INT), offset 0x140****Register 35: CAN Message 2 Interrupt Pending (CANMSG2INT), offset 0x144**

The **CANMSG1INT** and **CANMSG2INT** registers hold the **INTPND** bits of the 32 message objects. By reading these bits, the CPU can check which message object has an interrupt pending. The **INTPND** bit of a specific message object can be changed through two sources: (1) the CPU via the **CANIFnMCTL** register, or (2) the message handler state machine after the reception or transmission of a frame.

This field is also encoded in the **CANINT** register.

The **CANMSG1INT** register contains the **INTPND** bits of the first 16 message objects in the message RAM; the **CANMSG2INT** register contains the **INTPND** bits of the second 16 message objects.

**Register 36: CAN Message 1 Valid (CANMSG1VAL), offset 0x160**

**Register 37: CAN Message 2 Valid (CANMSG2VAL), offset 0x164**

The **CANMSG1VAL** and **CANMSG2VAL** registers hold the **MSGVAL** bits of the 32 message objects. By reading these bits, the CPU can check which message object is valid. The message valid bit of a specific message object can be changed with the **CANIFnARB2** register.

The **CANMSG1VAL** register contains the **MSGVAL** bits of the first 16 message objects in the message RAM; the **CANMSG2VAL** register contains the **MSGVAL** bits of the second 16 message objects in the message RAM.

## 18 Universal Serial Bus (USB) Controller

The TM4C1233C3PM USB controller operates as a full-speed function controller during point-to-point communications with USB Host functions. The controller complies with the USB 2.0 standard, which includes SUSPEND and RESUME signaling. 16 endpoints including two hard-wired for control transfers (one endpoint for IN and one endpoint for OUT) plus 14 endpoints defined by firmware along with a dynamic sizable FIFO support multiple packet queueing.  $\mu$ DMA access to the FIFO allows minimal interference from system software. Software-controlled connect and disconnect allows flexibility during USB device startup.

The TM4C1233C3PM USB module has the following features:

- Complies with USB-IF (Implementer's Forum) certification standards
- USB 2.0 full-speed (12 Mbps) operation with integrated PHY
- 4 transfer types: Control, Interrupt, Bulk, and Isochronous
- 16 endpoints
  - 1 dedicated control IN endpoint and 1 dedicated control OUT endpoint
  - 7 configurable IN endpoints and 7 configurable OUT endpoints
- 4 KB dedicated endpoint memory: one endpoint may be defined for double-buffered 1023-byte isochronous packet size
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for transmit and receive for up to three IN endpoints and three OUT endpoints
  - Channel requests asserted when FIFO contains required amount of data

### 18.1 Block Diagram

Figure 18-1. USB Module Block Diagram

## 18.2 Signal Description

The following table lists the external signals of the USB controller and describes the function of each. These signals have dedicated functions and are not alternate functions for any GPIO signals.

**Table 18-1. USB Signals (64LQFP)**

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                                                              |
|----------|------------|--------------------------|----------|--------------------------|--------------------------------------------------------------------------|
| USB0DM   | 43         | PD4                      | I/O      | Analog                   | Bidirectional differential data pin (D- per USB specification) for USB0. |
| USB0DP   | 44         | PD5                      | I/O      | Analog                   | Bidirectional differential data pin (D+ per USB specification) for USB0. |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 18.3 Functional Description

The TM4C1233C3PM USB controller provides the ability for the controller to serve as a Device-only controller. The controller can only be used in Device mode to connect USB-enabled peripherals to the USB controller. For Device mode, the USB controller requires a B connector in the system to provide Device connectivity.

**Note:** When the USB module is in operation, MOSC must be the clock source, either with or without using the PLL, and the system clock must be at least 20 MHz.

### 18.3.1 Operation

This section describes the TM4C1233C3PM USB controller's actions. IN endpoints, OUT endpoints, entry into and exit from SUSPEND mode, and recognition of Start of Frame (SOF) are all described.

IN transactions are controlled by an endpoint's transmit interface and use the transmit endpoint registers for the given endpoint. OUT transactions are handled with an endpoint's receive interface and use the receive endpoint registers for the given endpoint.

When configuring the size of the FIFOs for endpoints, take into account the maximum packet size for an endpoint.

- **Bulk.** Bulk endpoints should be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used (described further in the following section).
- **Interrupt.** Interrupt endpoints should be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used.
- **Isochronous.** Isochronous endpoints are more flexible and can be up to 1023 bytes.
- **Control.** It is also possible to specify a separate control endpoint for a USB Device. However, in most cases the USB Device should use the dedicated control endpoint on the USB controller's endpoint 0.

#### 18.3.1.1 Endpoints

The USB controller provides two dedicated control endpoints (IN and OUT) and 14 configurable endpoints (7 IN and 7 OUT) that can be used for communications with a Host controller. The endpoint number and direction associated with an endpoint is directly related to its register designation. For example, when the Host is transmitting to endpoint 1, all configuration and data is in the endpoint 1 transmit register interface.

Endpoint 0 is a dedicated control endpoint used for all control transactions to endpoint 0 during enumeration or when any other control requests are made to endpoint 0. Endpoint 0 uses the first 64 bytes of the USB controller's FIFO RAM as a shared memory for both IN and OUT transactions.

The remaining 14 endpoints can be configured as control, bulk, interrupt, or isochronous endpoints. They should be treated as 7 configurable IN and 7 configurable OUT endpoints. The endpoint pairs are not required to have the same type for their IN and OUT endpoint configuration. For example, the OUT portion of an endpoint pair could be a bulk endpoint, while the IN portion of that endpoint pair could be an interrupt endpoint. The address and size of the FIFOs attached to each endpoint can be modified to fit the application's needs.

### 18.3.1.2 IN Transactions

Data for IN transactions is handled through the FIFOs attached to the transmit endpoints. The sizes of the FIFOs for the 7 configurable IN endpoints are determined by the **USB Transmit FIFO Start Address (USBTXFIFOADD)** register. The maximum size of a data packet that may be placed in a transmit endpoint's FIFO for transmission is programmable and is determined by the value written to the **USB Maximum Transmit Data Endpoint n (USBTXMAXPn)** register for that endpoint. The endpoint's FIFO can also be configured to use double-packet or single-packet buffering. When double-packet buffering is enabled, two data packets can be buffered in the FIFO, which also requires that the FIFO is at least two packets in size. When double-packet buffering is disabled, only one packet can be buffered, even if the packet size is less than half the FIFO size.

**Note:** The maximum packet size set for any endpoint must not exceed the FIFO size. The **USBTXMAXPn** register should not be written to while data is in the FIFO as unexpected results may occur.

#### *Single-Packet Buffering*

If the size of the transmit endpoint's FIFO is less than twice the maximum packet size for this endpoint (as set in the **USB Transmit Dynamic FIFO Sizing (USBTXFIFOSZ)** register), only one packet can be buffered in the FIFO and single-packet buffering is required. When each packet is completely loaded into the transmit FIFO, the **TXRDY** bit in the **USB Transmit Control and Status Endpoint n Low (USBTXCSRLn)** register must be set. If the **AUTOSET** bit in the **USB Transmit Control and Status Endpoint n High (USBTXCSRHn)** register is set, the **TXRDY** bit is automatically set when a maximum-sized packet is loaded into the FIFO. For packet sizes less than the maximum, the **TXRDY** bit must be set manually. When the **TXRDY** bit is set, either manually or automatically, the packet is ready to be sent. When the packet has been successfully sent, both **TXRDY** and **FIFONE** are cleared, and the appropriate transmit endpoint interrupt signaled. At this point, the next packet can be loaded into the FIFO.

#### *Double-Packet Buffering*

If the size of the transmit endpoint's FIFO is at least twice the maximum packet size for this endpoint, two packets can be buffered in the FIFO and double-packet buffering is allowed. As each packet is loaded into the transmit FIFO, the **TXRDY** bit in the **USBTXCSRLn** register must be set. If the **AUTOSET** bit in the **USBTXCSRHn** register is set, the **TXRDY** bit is automatically set when a maximum-sized packet is loaded into the FIFO. For packet sizes less than the maximum, **TXRDY** must be set manually. When the **TXRDY** bit is set, either manually or automatically, the packet is ready to be sent. After the first packet is loaded, **TXRDY** is immediately cleared and an interrupt is generated. A second packet can now be loaded into the transmit FIFO and **TXRDY** set again (either manually or automatically if the packet is the maximum size). At this point, both packets are ready to be sent. After each packet has been successfully sent, **TXRDY** is automatically cleared and the appropriate transmit endpoint interrupt signaled to indicate that another packet can now be loaded into the transmit FIFO. The state of the **FIFONE** bit in the **USBTXCSRLn** register at this point

indicates how many packets may be loaded. If the `FIFONE` bit is set, then another packet is in the FIFO and only one more packet can be loaded. If the `FIFONE` bit is clear, then no packets are in the FIFO and two more packets can be loaded.

**Note:** Double-packet buffering is disabled if an endpoint's corresponding `EPn` bit is set in the **USB Transmit Double Packet Buffer Disable (USBTXDPKTBUFDIS)** register. This bit is set by default, so it must be cleared to enable double-packet buffering.

### 18.3.1.3 OUT Transactions

OUT transactions are handled through the USB controller receive FIFOs. The sizes of the receive FIFOs for the 7 configurable OUT endpoints are determined by the **USB Receive FIFO Start Address (USBRXFIFOADD)** register. The maximum amount of data received by an endpoint in any packet is determined by the value written to the **USB Maximum Receive Data Endpoint n (USBRXMAXPn)** register for that endpoint. When double-packet buffering is enabled, two data packets can be buffered in the FIFO. When double-packet buffering is disabled, only one packet can be buffered even if the packet is less than half the FIFO size.

**Note:** In all cases, the maximum packet size must not exceed the FIFO size.

#### *Single-Packet Buffering*

If the size of the receive endpoint FIFO is less than twice the maximum packet size for an endpoint, only one data packet can be buffered in the FIFO and single-packet buffering is required. When a packet is received and placed in the receive FIFO, the `RXRDY` and `FULL` bits in the **USB Receive Control and Status Endpoint n Low (USBRXCSSLn)** register are set and the appropriate receive endpoint is signaled, indicating that a packet can now be unloaded from the FIFO. After the packet has been unloaded, the `RXRDY` bit must be cleared in order to allow further packets to be received. This action also generates the acknowledge signaling to the Host controller. If the `AUTOCL` bit in the **USB Receive Control and Status Endpoint n High (USBRXCSSLn)** register is set and a maximum-sized packet is unloaded from the FIFO, the `RXRDY` and `FULL` bits are cleared automatically. For packet sizes less than the maximum, `RXRDY` must be cleared manually.

#### *Double-Packet Buffering*

If the size of the receive endpoint FIFO is at least twice the maximum packet size for the endpoint, two data packets can be buffered and double-packet buffering can be used. When the first packet is received and loaded into the receive FIFO, the `RXRDY` bit in the **USBRXCSSLn** register is set and the appropriate receive endpoint interrupt is signaled to indicate that a packet can now be unloaded from the FIFO.

**Note:** The `FULL` bit in **USBRXCSSLn** is not set when the first packet is received. It is only set if a second packet is received and loaded into the receive FIFO.

After each packet has been unloaded, the `RXRDY` bit must be cleared to allow further packets to be received. If the `AUTOCL` bit in the **USBRXCSSLn** register is set and a maximum-sized packet is unloaded from the FIFO, the `RXRDY` bit is cleared automatically. For packet sizes less than the maximum, `RXRDY` must be cleared manually. If the `FULL` bit is set when `RXRDY` is cleared, the USB controller first clears the `FULL` bit, then sets `RXRDY` again to indicate that there is another packet waiting in the FIFO to be unloaded.

**Note:** Double-packet buffering is disabled if an endpoint's corresponding `EPn` bit is set in the **USB Receive Double Packet Buffer Disable (USBRXDPKTBUFDIS)** register. This bit is set by default, so it must be cleared to enable double-packet buffering.

#### 18.3.1.4 Scheduling

The Device has no control over the scheduling of transactions as scheduling is determined by the Host controller. The TM4C1233C3PM USB controller can set up a transaction at any time. The USB controller waits for the request from the Host controller and generates an interrupt when the transaction is complete or if it was terminated due to some error. If the Host controller makes a request and the Device controller is not ready, the USB controller sends a busy response (NAK) to all requests until it is ready.

#### 18.3.1.5 Additional Actions

The USB controller responds automatically to certain conditions on the USB bus or actions by the Host controller such as when the USB controller automatically stalls a control transfer or unexpected zero length OUT data packets.

##### ***Stalled Control Transfer***

The USB controller automatically issues a STALL handshake to a control transfer under the following conditions:

1. The Host sends more data during an OUT data phase of a control transfer than was specified in the Device request during the SETUP phase. This condition is detected by the USB controller when the Host sends an OUT token (instead of an IN token) after the last OUT packet has been unloaded and the `DATAEND` bit in the **USB Control and Status Endpoint 0 Low (USBCSRL0)** register has been set.
2. The Host requests more data during an IN data phase of a control transfer than was specified in the Device request during the SETUP phase. This condition is detected by the USB controller when the Host sends an IN token (instead of an OUT token) after the CPU has cleared `TXRDY` and set `DATAEND` in response to the ACK issued by the Host to what should have been the last packet.
3. The Host sends more than **USBRXMAXP<sub>n</sub>** bytes of data with an OUT data token.
4. The Host sends more than a zero length data packet for the OUT STATUS phase.

##### ***Zero Length OUT Data Packets***

A zero-length OUT data packet is used to indicate the end of a control transfer. In normal operation, such packets should only be received after the entire length of the Device request has been transferred.

However, if the Host sends a zero-length OUT data packet before the entire length of Device request has been transferred, it is signaling the premature end of the transfer. In this case, the USB controller automatically flushes any IN token ready for the data phase from the FIFO and sets the `DATAEND` bit in the **USBCSRL0** register.

##### ***Setting the Device Address***

When a Host is attempting to enumerate the USB Device, it requests that the Device change its address from zero to some other value. The address is changed by writing the value that the Host requested to the **USB Device Functional Address (USBFADDR)** register. However, care should be taken when writing to **USBFADDR** to avoid changing the address before the transaction is complete. This register should only be set after the `SET_ADDRESS` command is complete. Like all control transactions, the transaction is only complete after the Device has left the STATUS phase. In the case of a `SET_ADDRESS` command, the transaction is completed by responding to the IN

request from the Host with a zero-byte packet. Once the Device has responded to the IN request, the **USBFADDR** register should be programmed to the new value as soon as possible to avoid missing any new commands sent to the new address.

**Note:** If the **USBFADDR** register is set to the new value as soon as the Device receives the OUT transaction with the SET\_ADDRESS command in the packet, it changes the address during the control transfer. In this case, the Device does not receive the IN request that allows the USB transaction to exit the STATUS phase of the control transfer because it is sent to the old address. As a result, the Host does not get a response to the IN request, and the Host fails to enumerate the Device.

#### 18.3.1.6 SUSPEND

When no activity has occurred on the USB bus for 3 ms, the USB controller automatically enters SUSPEND mode. If the SUSPEND interrupt has been enabled in the **USB Interrupt Enable (USBIE)** register, an interrupt is generated at this time. When in SUSPEND mode, the PHY also goes into SUSPEND mode. When RESUME signaling is detected, the USB controller exits SUSPEND mode and takes the PHY out of SUSPEND. If the RESUME interrupt is enabled, an interrupt is generated. The USB controller can also be forced to exit SUSPEND mode by setting the RESUME bit in the **USB Power (USBPOWER)** register. When this bit is set, the USB controller exits SUSPEND mode and drives RESUME signaling onto the bus. The RESUME bit must be cleared after 10 ms (a maximum of 15 ms) to end RESUME signaling.

To meet USB power requirements, the controller can be put into Deep Sleep mode which keeps the controller in a static state. Hibernation mode should not be used for SUSPEND mode because all internal state information is lost in hibernation.

#### 18.3.1.7 Start-of-Frame

When the USB controller is operating in Device mode, it receives a Start-Of-Frame (SOF) packet from the Host once every millisecond. When the SOF packet is received, the 11-bit frame number contained in the packet is written into the **USB Frame Value (USBFRAME)** register, and an SOF interrupt is also signaled and can be handled by the application. Once the USB controller has started to receive SOF packets, it expects one every millisecond. If no SOF packet is received after 1.00358 ms, the packet is assumed to have been lost, and the **USBFRAME** register is not updated. The USB controller continues and resynchronizes these pulses to the received SOF packets when these packets are successfully received again.

#### 18.3.1.8 USB RESET

When a RESET condition is detected on the USB bus, the USB controller automatically performs the following actions:

- Clears the **USBFADDR** register.
- Clears the **USB Endpoint Index (USBEPIDX)** register.
- Flushes all endpoint FIFOs.
- Clears all control/status registers.
- Enables all endpoint interrupts.
- Generates a RESET interrupt.

When the application software driving the USB controller receives a RESET interrupt, any open pipes are closed and the USB controller waits for bus enumeration to begin.

### 18.3.1.9 Connect/Disconnect

The USB controller connection to the USB bus is handled by software. The USB PHY can be switched between normal mode and non-driving mode by setting or clearing the `SOFTCONN` bit of the **USBPOWER** register. When the `SOFTCONN` bit is set, the PHY is placed in its normal mode, and the `USB0DP/USB0DM` lines of the USB bus are enabled. At the same time, the USB controller is placed into a state, in which it does not respond to any USB signaling except a USB RESET.

When the `SOFTCONN` bit is cleared, the PHY is put into non-driving mode, `USB0DP` and `USB0DM` are tristated, and the USB controller appears to other devices on the USB bus as if it has been disconnected. The non-driving mode is the default so the USB controller appears disconnected until the `SOFTCONN` bit has been set. The application software can then choose when to set the PHY into its normal mode. Systems with a lengthy initialization procedure may use this to ensure that initialization is complete, and the system is ready to perform enumeration before connecting to the USB bus. Once the `SOFTCONN` bit has been set, the USB controller can be disconnected by clearing this bit.

**Note:** The USB controller does not generate an interrupt when the Device is connected to the Host. However, an interrupt is generated when the Host terminates a session.

### 18.3.2 DMA Operation

The USB peripheral provides an interface connected to the  $\mu$ DMA controller with separate channels for 3 transmit endpoints and 3 receive endpoints. Software selects which endpoints to service with the  $\mu$ DMA channels using the **USB DMA Select (USBDMASEL)** register. The  $\mu$ DMA operation of the USB is enabled through the **USBTXCSRHn** and **USBRXCSRHn** registers, for the TX and RX channels respectively. When  $\mu$ DMA operation is enabled, the USB asserts a  $\mu$ DMA request on the enabled receive or transmit channel when the associated FIFO can transfer data. When either FIFO can transfer data, the burst request for that channel is asserted. The  $\mu$ DMA channel must be configured to operate in Basic mode, and the size of the  $\mu$ DMA transfer must be restricted to whole multiples of the size of the USB FIFO. Both read and write transfers of the USB FIFOs using  $\mu$ DMA must be configured in this manner. For example, if the USB endpoint is configured with a FIFO size of 64 bytes, the  $\mu$ DMA channel can be used to transfer 64 bytes to or from the endpoint FIFO. If the number of bytes to transfer is less than 64, then a programmed I/O method must be used to copy the data to or from the FIFO.

If the `DMAMOD` bit in the **USBTXCSRHn/USBRXCSRHn** register is clear, an interrupt is generated after every packet is transferred, but the  $\mu$ DMA continues transferring data. If the `DMAMOD` bit is set, an interrupt is generated only when the entire  $\mu$ DMA transfer is complete. The interrupt occurs on the USB interrupt vector. Therefore, if interrupts are used for USB operation and the  $\mu$ DMA is enabled, the USB interrupt handler must be designed to handle the  $\mu$ DMA completion interrupt.

Care must be taken when using the  $\mu$ DMA to unload the receive FIFO as data is read from the receive FIFO in 4 byte chunks regardless of value of the `MAXLOAD` field in the **USBRXCSRHn** register. The `RXRDY` bit is cleared as follows.

**Table 18-2. Remainder (MAXLOAD/4)**

| Value | Description        |
|-------|--------------------|
| 0     | MAXLOAD = 64 bytes |
| 1     | MAXLOAD = 61 bytes |
| 2     | MAXLOAD = 62 bytes |

**Table 18-2. Remainder (MAXLOAD/4) (continued)**

| Value | Description        |
|-------|--------------------|
| 3     | MAXLOAD = 63 bytes |

**Table 18-3. Actual Bytes Read**

| Value | Description |
|-------|-------------|
| 0     | MAXLOAD     |
| 1     | MAXLOAD+3   |
| 2     | MAXLOAD+2   |
| 3     | MAXLOAD+1   |

**Table 18-4. Packet Sizes That Clear RXRDY**

| Value | Description                              |
|-------|------------------------------------------|
| 0     | MAXLOAD, MAXLOAD-1, MAXLOAD-2, MAXLOAD-3 |
| 1     | MAXLOAD                                  |
| 2     | MAXLOAD, MAXLOAD-1                       |
| 3     | MAXLOAD, MAXLOAD-1, MAXLOAD-2            |

To enable DMA operation for the endpoint receive channel, the **DMAEN** bit of the **USBRXCSRHn** register should be set. To enable DMA operation for the endpoint transmit channel, the **DMAEN** bit of the **USBTXCSRHn** register must be set.

See “Micro Direct Memory Access ( $\mu$ DMA)” on page 557 for more details about programming the  $\mu$ DMA controller.

## 18.4 Initialization and Configuration

To use the USB Controller, the peripheral clock must be enabled via the **RCGCUSB** register (see page 336).

The initial configuration in all cases requires that the processor enable the USB controller and USB controller's physical layer interface (PHY) before setting any registers. The next step is to enable the USB PLL so that the correct clocking is provided to the PHY.

The USB controller provides a method to set the current operating mode of the USB controller. This register should be written with the desired default mode so that the controller can respond to external USB events.

### 18.4.1 Endpoint Configuration

To start communication, the endpoint registers must first be configured. An endpoint must be configured before enumerating to the Host controller.

The endpoint 0 configuration is limited because it is a fixed-function, fixed-FIFO-size endpoint. The endpoint requires little setup but does require a software-based state machine to progress through the setup, data, and status phases of a standard control transaction. The configuration of the remaining endpoints is done once before enumerating and then only changed if an alternate configuration is selected by the Host controller. Once the type of endpoint is configured, a FIFO area must be assigned to each endpoint. In the case of bulk, control and interrupt endpoints, each has a maximum of 64 bytes per transaction. Isochronous endpoints can have packets with up to

1023 bytes per packet. In either mode, the maximum packet size for the given endpoint must be set prior to sending or receiving data.

Configuring each endpoint's FIFO involves reserving a portion of the overall USB FIFO RAM to each endpoint. The total FIFO RAM available is 2 Kbytes with the first 64 bytes reserved for endpoint 0. The endpoint's FIFO must be at least as large as the maximum packet size. The FIFO can also be configured as a double-buffered FIFO so that interrupts occur at the end of each packet and allow filling the other half of the FIFO.

The USB Device controller's soft connect must be enabled when the Device is ready to start communications, indicating to the Host controller that the Device is ready to start the enumeration process.

## 18.5 Register Map

Table 18-5 on page 1073 lists the registers. All addresses given are relative to the USB base address of 0x4005.0000. Note that the USB controller clock must be enabled before the registers can be programmed (see page 336). There must be a delay of 3 system clocks after the USB module clock is enabled before any USB module registers are accessed.

**Table 18-5. Universal Serial Bus (USB) Controller Register Map**

| Offset | Name        | Type | Reset       | Description                      | See page |

## 18.6 Register Descriptions

The TM4C1233C3PM USB controller has Device only capabilities as specified in the USB0 bit field in the DC6 register (see page 420).

**Register 1: USB Device Functional Address (USBFADDR), offset 0x000**

**USBFADDR** is an 8-bit register that contains the 7-bit address of the Device part of the transaction.

This register must be written with the address received through a SET\_ADDRESS command, which is then used for decoding the function address in subsequent token packets.

---

**Important:** See the section called “Setting the Device Address” on page 1069 for special considerations when writing this register.

---

## USB Device Functional Address (USBFADDR)

Base 0x4005.0000  
Offset 0x000  
Type R/W, reset 0x00

|       |          |          |     |     |     |     |     |     |
|-------|----------|----------|-----|-----|-----|-----|-----|-----|
|       | 7        | 6        | 5   | 4   | 3   | 2   | 1   | 0   |
|       | reserved | FUNCADDR |     |     |     |     |     |     |
| Type  | RO       | R/W      | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset | 0        | 0        | 0   | 0   | 0   | 0   | 0   | 0   |

| Bit/Field | Name     | Type | Reset | Description                                                                                                                                                                                   |

## Register 2: USB Power (USBPOWER), offset 0x001

**USBPOWER** is an 8-bit register used for controlling SUSPEND and RESUME signaling and some basic operational aspects of the USB controller.

### USB Power (USBPOWER)

Base 0x4005.0000  
 Offset 0x001

### Register 3: USB Transmit Interrupt Status (USBTXIS), offset 0x002

**Important:** This register is read-sensitive. See the register description for details.

**USBTXIS** is a 16-bit read-only register that indicates which interrupts are currently active for endpoint 0 and the transmit endpoints 1–7. The meaning of the  $EP_n$  bits in this register is based on the mode of the device. The  $EP_1$  through  $EP_7$  bits always indicate that the USB controller is sending data; however, the bits refer to IN endpoints. The  $EP_0$  bit is special and indicates that either a control IN or control OUT endpoint has generated an interrupt.

**Note:** Bits relating to endpoints that have not been configured always return 0. Note also that all active interrupts are cleared when this register is read.

**Register 5: USB Transmit Interrupt Enable (USBTXIE), offset 0x006**

**USBTXIE** is a 16-bit register that provides interrupt enable bits for the interrupts in the **USBTXIS** register. When a bit is set, the USB interrupt is asserted to the interrupt controller when the corresponding interrupt bit in the **USBTXIS** register is set. When a bit is cleared, the interrupt in the **USBTXIS** register is still set but the USB interrupt to the interrupt controller is not asserted. On reset, all interrupts are enabled.

## USB Transmit Interrupt Enable (USBTXIE)

Base 0x4005.0000

|           |      |      |       | 1 An interrupt is sent to the interrupt controller when the EP0 bit in the <b>USBTXIS</b> register is set. |

**Register 6: USB Receive Interrupt Enable (USBRXIE), offset 0x008**

**USBRXIE** is a 16-bit register that provides interrupt enable bits for the interrupts in the **USBRXIS** register. When a bit is set, the USB interrupt is asserted to the interrupt controller when the corresponding interrupt bit in the **USBRXIS** register is set. When a bit is cleared, the interrupt in the **USBRXIS** register is still set but the USB interrupt to the interrupt controller is not asserted. On reset, all interrupts are enabled.

## USB Receive Interrupt Enable (USBRXIE)

Base 0x4005.0000

Offset 0x008

Type R/W, reset 0xFFFE

## Register 7: USB General Interrupt Status (USBIS), offset 0x00A

**Important:** This register is read-sensitive. See the register description for details.

**USBIS** is an 8-bit read-only register that indicates which USB interrupts are currently active. All active interrupts are cleared when this register is read.

### USB General Interrupt Status (USBIS)

### Register 10: USB Endpoint Index (USBEPIDX), offset 0x00E

Each endpoint's buffer can be accessed by configuring a FIFO size and starting address. The **USBEPIDX** 8-bit register is used with the **USBTXFIFOSZ**, **USBRXFIFOSZ**, **USBTXFIFOADD**, and **USBRXFIFOADD** registers.

**Register 11: USB Test Mode (USBTEST), offset 0x00F**

**USBTEST** is an 8-bit register that is primarily used to put the USB controller into one of the four test modes for operation described in the *USB 2.0 Specification*, in response to a SET FEATURE: USBTESTMODE command. This register is not used in normal operation.

**Note:** Only one of these bits should be set at any time.

**Register 18: USB FIFO Endpoint 6 (USBFIFO6), offset 0x038**

**Register 19: USB FIFO Endpoint 7 (USBFIFO7), offset 0x03C**

**Important:** This register is read-sensitive. See the register description for details.

These 32-bit registers provide an address for CPU access to the FIFOs for each endpoint. Writing to these addresses loads data into the Transmit FIFO for the corresponding endpoint. Reading from these addresses unloads data from the Receive FIFO for the corresponding endpoint.

Transfers to and from FIFOs may be 8-bit, 16-bit or 32-bit as required, and any combination of accesses is allowed provided the data accessed is contiguous. All transfers associated with one packet must be of the same width so that the data is consistently byte-, halfword- or word-aligned. However, the last transfer may contain fewer bytes than the previous transfers in order to complete an odd-byte or odd-word transfer.

Depending on the size of the FIFO and the expected maximum packet size, the FIFOs support either single-packet or double-packet buffering (see the section called “Single-Packet Buffering” on page 1068). Burst writing of multiple packets is not supported as flags must be set after each packet is written.

Following a STALL response or a transmit error on endpoint 1–7, the associated FIFO is completely flushed.

| 3:0       | WTID  | R/W  | 0xC   | Wait ID<br>This field configures the delay required from the enable of the ID detection to when the ID value is valid, in units of 4.369 ms. The default corresponds to 52.43 ms. |

## Register 25: USB Full-Speed Last Transaction to End of Frame Timing (USBFSEOF), offset 0x07D

This 8-bit configuration register specifies the minimum time gap allowed between the start of the last transaction and the EOF for full-speed transactions.

### USB Full-Speed Last Transaction to End of Frame Timing (USBFSEOF)

Base 0x4005.0000  
 Offset 0x07D  
 Type R/W, reset 0x77

| Bit/Field | Name   | Type | Reset | Description                                                                                                                                                                                                                    |

**Register 27: USB Maximum Transmit Data Endpoint 1 (USBTXMAXP1), offset 0x110**

**Register 28: USB Maximum Transmit Data Endpoint 2 (USBTXMAXP2), offset 0x120**

**Register 29: USB Maximum Transmit Data Endpoint 3 (USBTXMAXP3), offset 0x130**

**Register 30: USB Maximum Transmit Data Endpoint 4 (USBTXMAXP4), offset 0x140**

**Register 31: USB Maximum Transmit Data Endpoint 5 (USBTXMAXP5), offset 0x150**

**Register 32: USB Maximum Transmit Data Endpoint 6 (USBTXMAXP6), offset 0x160**

**Register 33: USB Maximum Transmit Data Endpoint 7 (USBTXMAXP7), offset 0x170**

The **USBTXMAXPn** 16-bit register defines the maximum amount of data that can be transferred through the transmit endpoint in a single operation.

Bits 10:0 define (in bytes) the maximum payload transmitted in a single transaction. The value set can be up to 1024 bytes but is subject to the constraints placed by the *USB Specification* on packet sizes for bulk, interrupt and isochronous transfers in full-speed operation.

The total amount of data represented by the value written to this register must not exceed the FIFO size for the transmit endpoint, and must not exceed half the FIFO size if double-buffering is required.

If this register is changed after packets have been sent from the endpoint, the transmit endpoint FIFO must be completely flushed (using the **FLUSH** bit in **USBTXCSRLn**) after writing the new value to this register.

**Note:** **USBTXMAXPn** must be set to an even number of bytes for proper interrupt generation in  $\mu$ DMA Basic Mode.

USB Maximum Transmit Data Endpoint n (USBTXMAXPn)

## Register 35: USB Control and Status Endpoint 0 High (USBCSRH0), offset 0x103

**USBSR0H** is an 8-bit register that provides control and status bits for endpoint 0.

### USB Control and Status Endpoint 0 High (USBCSRH0)

Base 0x4005.0000

Offset 0x103

Type W1C, reset 0x00

| Bit/Field | Name     | Type | Reset | Description                                                                                                                                                                                   |
|-----------|----------|------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:1       | reserved | RO   | 0x00  | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 0         | FLUSH    | R/W  | 0     | Flush FIFO                                                                                                                                                                                    |

#### Value Description

| Value | Description                                                                                                                                                        |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0     | No effect.                                                                                                                                                         |
| 1     | Flushes the next packet to be transmitted/read from the endpoint 0 FIFO. The FIFO pointer is reset and the <code>TXRDY</code> / <code>RXRDY</code> bit is cleared. |

This bit is automatically cleared after the flush is performed.

---

**Important:** This bit should only be set when `TXRDY` is clear and `RXRDY` is set. At other times, it may cause data to be corrupted.

---

### Register 36: USB Receive Byte Count Endpoint 0 (USBCOUNT0), offset 0x108

**USBCOUNT0** is an 8-bit read-only register that indicates the number of received data bytes in the endpoint 0 FIFO. The value returned changes as the contents of the FIFO change and is only valid while the `RXRDY` bit is set.

#### USB Receive Byte Count Endpoint 0 (USBCOUNT0)

Base 0x4005.0000

Offset 0x108

Type RO, reset 0x00

| Bit/Field | Name     | Type | Reset | Description                                                                                                                                                                                   |
|-----------|----------|------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7         | reserved | RO   | 0     | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 6:0       | COUNT    | RO   | 0x00  | FIFO Count<br>COUNT is a read-only value that indicates the number of received data bytes in the endpoint 0 FIFO.                                                                             |

**Register 37: USB Transmit Control and Status Endpoint 1 Low (USBTXCSRL1), offset 0x112**

**Register 38: USB Transmit Control and Status Endpoint 2 Low (USBTXCSRL2), offset 0x122**

**Register 39: USB Transmit Control and Status Endpoint 3 Low (USBTXCSRL3), offset 0x132**

**Register 40: USB Transmit Control and Status Endpoint 4 Low (USBTXCSRL4), offset 0x142**

**Register 41: USB Transmit Control and Status Endpoint 5 Low (USBTXCSRL5), offset 0x152**

**Register 42: USB Transmit Control and Status Endpoint 6 Low (USBTXCSRL6), offset 0x162**

**Register 43: USB Transmit Control and Status Endpoint 7 Low (USBTXCSRL7), offset 0x172**

**USBTXCSRLn** is an 8-bit register that provides control and status bits for transfers through the currently selected transmit endpoint.

#### Value Description

0 The **TXRDY** bit must be set manually.

1 Enables the **TXRDY** bit to be automatically set when data of the maximum packet size (value in **USBTXMAXPn**) is loaded into the transmit FIFO. If a packet of less than the maximum packet size is loaded, then the **TXRDY** bit must be set manually.

**Register 51: USB Maximum Receive Data Endpoint 1 (USBRXMAXP1), offset 0x114**

**Register 52: USB Maximum Receive Data Endpoint 2 (USBRXMAXP2), offset 0x124**

**Register 53: USB Maximum Receive Data Endpoint 3 (USBRXMAXP3), offset 0x134**

**Register 54: USB Maximum Receive Data Endpoint 4 (USBRXMAXP4), offset 0x144**

**Register 55: USB Maximum Receive Data Endpoint 5 (USBRXMAXP5), offset 0x154**

**Register 56: USB Maximum Receive Data Endpoint 6 (USBRXMAXP6), offset 0x164**

**Register 57: USB Maximum Receive Data Endpoint 7 (USBRXMAXP7), offset 0x174**

The **USBRXMAXPn** is a 16-bit register which defines the maximum amount of data that can be transferred through the selected receive endpoint in a single operation.

Bits 10:0 define (in bytes) the maximum payload transmitted in a single transaction. The value set can be up to 1024 bytes but is subject to the constraints placed by the *USB Specification* on packet sizes for bulk, interrupt and isochronous transfers in full-speed operations.

The total amount of data represented by the value written to this register must not exceed the FIFO size for the receive endpoint, and must not exceed half the FIFO size if double-buffering is required.

**Note:** **USBRXMAXPn** must be set to an even number of bytes for proper interrupt generation in  $\mu$ DMA Basic mode.

#### Value Description

|   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 | No effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 1 | Enables the <code>RXRDY</code> bit to be automatically cleared when a packet of <code>USBXMAXPn</code> bytes has been unloaded from the receive FIFO. When packets of less than the maximum packet size are unloaded, <code>RXRDY</code> must be cleared manually. Care must be taken when using <code>μDMA</code> to unload the receive FIFO as data is read from the receive FIFO in 4 byte chunks regardless of the value of the <code>MAXLOAD</code> field in the <code>USBXMAXPn</code> register, see “DMA Operation” on page 1071. |

**Register 72: USB Receive Byte Count Endpoint 1 (USBRCOUNT1), offset 0x118**

**Register 73: USB Receive Byte Count Endpoint 2 (USBRCOUNT2), offset 0x128**

**Register 74: USB Receive Byte Count Endpoint 3 (USBRCOUNT3), offset 0x138**

**Register 75: USB Receive Byte Count Endpoint 4 (USBRCOUNT4), offset 0x148**

**Register 76: USB Receive Byte Count Endpoint 5 (USBRCOUNT5), offset 0x158**

**Register 77: USB Receive Byte Count Endpoint 6 (USBRCOUNT6), offset 0x168**

**Register 78: USB Receive Byte Count Endpoint 7 (USBRCOUNT7), offset 0x178**

**Note:** The value returned changes as the FIFO is unloaded and is only valid while the `RXRDY` bit in the `USBXCSSLn` register is set.

**USBRCOUNTn** is a 16-bit read-only register that holds the number of data bytes in the packet currently in line to be read from the receive FIFO. If the packet is transmitted as multiple bulk packets, the number given is for the combined packet.

### Register 81: USB Device RESUME Raw Interrupt Status (USBDRRIS), offset 0x410

The **USBDRRIS** 32-bit register is the raw interrupt status register. On a read, this register gives the current raw status value of the corresponding interrupt prior to masking. A write has no effect.

#### USB Device RESUME Raw Interrupt Status (USBDRRIS)

Base 0x4005.0000  
 Offset 0x410

| Value | Description                        |
|-------|------------------------------------|
| 0     | An interrupt has not occurred.     |
| 1     | A RESUME status has been detected. |

This bit is cleared by writing a 1 to the **RESUME** bit in the **USBDRISC** register.

**Register 82: USB Device RESUME Interrupt Mask (USBDRIM), offset 0x414**

The **USBDRIM** 32-bit register is the masked interrupt status register. On a read, this register gives the current value of the mask on the corresponding interrupt. Setting a bit sets the mask, preventing the interrupt from being signaled to the interrupt controller. Clearing a bit clears the corresponding mask, enabling the interrupt to be sent to the interrupt controller.

## Value Description

- |   |                                                                                                                                                                                                   |
|---|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 | The raw interrupt signal from a detected RESUME is sent to the interrupt controller. This bit should only be set when a SUSPEND has been detected (the SUSPEND bit in the USBIS register is set). |
| 0 | A detected RESUME does not affect the interrupt status.                                                                                                                                           |

### Register 83: USB Device RESUME Interrupt Status and Clear (USBDRISC), offset 0x418

The **USBDRISC** 32-bit register is the interrupt clear register. On a write of 1, the corresponding interrupt is cleared. A write of 0 has no effect.

|-------|------------------------------------------------------------------------------------------------------------------------------------------|
| 1     | The <b>RESUME</b> bits in the <b>USBDRRIS</b> and <b>USBDRCIM</b> registers are set, providing an interrupt to the interrupt controller. |
| 0     | No interrupt has occurred or the interrupt is masked.                                                                                    |

This bit is cleared by writing a 1. Clearing this bit also clears the **RESUME** bit in the **USBDRCRIS** register.

**Register 84: USB DMA Select (USBDMASEL), offset 0x450**

This 32-bit register specifies which endpoints are mapped to the 6 allocated  $\mu$ DMA channels, see Table 9-1 on page 559 for more information on channel assignments.

**Register 85: USB Peripheral Properties (USBPP), offset 0xFC0**

The **USBPP** register provides information regarding the properties of the USB module.

## USB Peripheral Properties (USBPP)

Base 0x4005.0000

Offset 0xFC0

Type RO, reset 0x0000.1050

## 19 Analog Comparators

An analog comparator is a peripheral that compares two analog voltages and provides a logical output that signals the comparison result.

**Note:** Not all comparators have the option to drive an output pin. See “Signal Description” on page 1123 for more information.

The comparator can provide its output to a device pin, acting as a replacement for an analog comparator on the board. In addition, the comparator can signal the application via interrupts or trigger the start of a sample sequence in the ADC. The interrupt generation and ADC triggering logic is separate and independent. This flexibility means, for example, that an interrupt can be generated on a rising edge and the ADC triggered on a falling edge.

The TM4C1233C3PM microcontroller provides two independent integrated analog comparators with the following functions:

- Compare external pin input to external pin input or to internal programmable voltage reference
- Compare a test voltage against any one of the following voltages:
  - An individual external reference voltage
  - A shared single external reference voltage
  - A shared internal reference voltage

## 19.1 Block Diagram

Figure 19-1. Analog Comparator Module Block Diagram

**Note:** This block diagram depicts the maximum number of analog comparators and comparator outputs for the family of microcontrollers; the number for this specific device may vary. See page 1136 for what is included on this device.

## 19.2 Signal Description

The following table lists the external signals of the Analog Comparators and describes the function of each. The Analog Comparator output signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for the Analog Comparator signals. The `AFSEL` bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 642) should be set to choose the Analog Comparator function. The number in parentheses is the encoding that must be programmed into the `PMCn` field in the **GPIO Port Control (GPIOPCTL)** register (page 659) to assign the Analog Comparator signal to the specified GPIO port pin. The positive and negative input signals are configured by clearing the `DEN` bit in the **GPIO Digital Enable (GPIODEN)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 621.

Table 19-1. Analog Comparators Signals (64LQFP)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                         |
|----------|------------|--------------------------|----------|--------------------------|-------------------------------------|

| C1-      | 16         | PC4                      | I        | Analog                   | Analog comparator 1 negative input. |
| C1o      | 29         | PF1 (9)                  | O        | TTL                      | Analog comparator 1 output.         |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 19.3 Functional Description

The comparator compares the VIN- and VIN+ inputs to produce an output, VOUT.

$$VIN- < VIN+, VOUT = 1$$

$$VIN- > VIN+, VOUT = 0$$

As shown in Figure 19-2 on page 1124, the input source for VIN- is an external input, Cn-, where n is the analog comparator number. In addition to an external input, Cn+, input sources for VIN+ can be the C0+ or an internal reference, V<sub>REF</sub>.

Figure 19-2. Structure of Comparator Unit

A comparator is configured through two status/control registers, **Analog Comparator Control (ACCTL)** and **Analog Comparator Status (ACSTAT)**. The internal reference is configured through one control register, **Analog Comparator Reference Voltage Control (ACREFCTL)**. Interrupt status and control are configured through three registers, **Analog Comparator Masked Interrupt Status (ACMIS)**, **Analog Comparator Raw Interrupt Status (ACRIS)**, and **Analog Comparator Interrupt Enable (ACINTEN)**.

Typically, the comparator output is used internally to generate an interrupt as controlled by the I<sub>SEN</sub> bit in the **ACCTL** register. The output may also be used to drive one of the external pins (C<sub>no</sub>), or generate an analog-to-digital converter (ADC) trigger.

**Important:** The ASRCP bits in the **ACCTL** register must be set before using the analog comparators.

### 19.3.1 Internal Reference Programming

The structure of the internal reference is shown in Figure 19-3 on page 1125. The internal reference is controlled by a single configuration register (**ACREFCTL**).

**Figure 19-3. Comparator Internal Reference Structure**

**Note:** In the figure above,  $N \cdot R$  represents a multiple of the  $R$  value that produces the results specified in Table 19-2 on page 1125.

The internal reference can be programmed in one of two modes (low range or high range) depending on the **RNG** bit in the **ACREFCTL** register. When **RNG** is clear, the internal reference is in high-range mode, and when **RNG** is set the internal reference is in low-range mode.

In each range, the internal reference,  $V_{IREF}$ , has 16 pre-programmed thresholds or step values. The threshold to be used to compare the external input voltage against is selected using the **VREF** field in the **ACREFCTL** register.

In the high-range mode, the  $V_{IREF}$  threshold voltages start at the ideal high-range starting voltage of  $V_{DDA}/4.2$  and increase in ideal constant voltage steps of  $V_{DDA}/29.4$ .

In the low-range mode, the  $V_{IREF}$  threshold voltages start at 0 V and increase in ideal constant voltage steps of  $V_{DDA}/22.12$ . The ideal  $V_{IREF}$  step voltages for each mode and their dependence on the **RNG** and **VREF** fields are summarized in Table 19-2.

**Table 19-2. Internal Reference Voltage and ACREFCTL Field Values**

| ACREFCTL Register |               | Output Reference Voltage Based on VREF Field Value                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EN Bit Value      | RNG Bit Value |                                                                                                                                                                                                                                                                                                                                                                                                                      |
| EN=0              | RNG=X         | 0 V (GND) for any value of <b>VREF</b> . It is recommended that <b>RNG</b> =1 and <b>VREF</b> =0 to minimize noise on the reference ground.                                                                                                                                                                                                                                                                          |
| EN=1              | RNG=0         | $V_{IREF}$ High Range: 16 voltage threshold values indexed by <b>VREF</b> = 0x0 .. 0xF<br>Ideal starting voltage ( <b>VREF</b> =0): $V_{DDA} / 4.2$<br>Ideal step size: $V_{DDA} / 29.4$<br>Ideal $V_{IREF}$ threshold values: $V_{IREF} (V_{REF}) = V_{DDA} / 4.2 + V_{REF} * (V_{DDA} / 29.4)$ , for <b>VREF</b> = 0x0 .. 0xF<br>For minimum and maximum $V_{IREF}$ threshold values, see Table 19-3 on page 1126. |
|                   | RNG=1         | $V_{IREF}$ Low Range: 16 voltage threshold values indexed by <b>VREF</b> = 0x0 .. 0xF<br>Ideal starting voltage ( <b>VREF</b> =0): 0 V<br>Ideal step size: $V_{DDA} / 22.12$<br>Ideal $V_{IREF}$ threshold values: $V_{IREF} (V_{REF}) = V_{REF} * (V_{DDA} / 22.12)$ , for <b>VREF</b> = 0x0 .. 0xF<br>For minimum and maximum $V_{IREF}$ threshold values, see Table 19-4 on page 1126.                            |

Note that the values shown in Table 19-2 are the ideal values of the  $V_{IREF}$  thresholds. These values actually vary between minimum and maximum values for each threshold step, depending on process and temperature. The minimum and maximum values for each step are given by:

- $V_{IREF}(V_{REF}) [\text{Min}] = \text{Ideal } V_{IREF}(V_{REF}) - (\text{Ideal Step size} - 2 \text{ mV}) / 2$
- $V_{IREF}(V_{REF}) [\text{Max}] = \text{Ideal } V_{IREF}(V_{REF}) + (\text{Ideal Step size} - 2 \text{ mV}) / 2$

Examples of minimum and maximum  $V_{IREF}$  values for  $V_{DDA} = 3.3\text{V}$  for high and low ranges, are shown in Table 19-3 and Table 19-4. Note that these examples are only valid for  $V_{DDA} = 3.3\text{V}$ ; values scale up and down with  $V_{DDA}$ .

**Table 19-3. Analog Comparator Voltage Reference Characteristics,  $V_{DDA} = 3.3\text{V}$ ,  $\text{EN} = 1$ , and  $\text{RNG} = 0$**

## 19.4 Initialization and Configuration

The following example shows how to configure an analog comparator to read back its output value from an internal register.

1. Enable the analog comparator clock by writing a value of 0x0000.0001 to the **RCGCACMP** register in the System Control module (see page 339).
2. Enable the clock to the appropriate GPIO modules via the **RCGCGPIO** register (see page 326). To find out which GPIO ports to enable, refer to Table 21-5 on page 1153.
3. In the GPIO module, enable the GPIO port/pin associated with the input signals as GPIO inputs. To determine which GPIO to configure, see Table 21-4 on page 1149.
4. Configure the **PMC<sub>n</sub>** fields in the **GPIOPCTL** register to assign the analog comparator output signals to the appropriate pins (see page 659 and Table 21-5 on page 1153).
5. Configure the internal voltage reference to 1.65 V by writing the **ACREFCTL** register with the value 0x0000.030C.
6. Configure the comparator to use the internal voltage reference and to *not* invert the output by writing the **ACCTL<sub>n</sub>** register with the value of 0x0000.040C.
7. Delay for 10  $\mu$ s.
8. Read the comparator output value by reading the **ACSTAT<sub>n</sub>** register's **OVAL** value.

Change the level of the comparator negative input signal **C-** to see the **OVAL** value change.

## 19.5 Register Map

Table 19-5 on page 1127 lists the comparator registers. The offset listed is a hexadecimal increment to the register's address, relative to the Analog Comparator base address of 0x4003.C000. Note that the analog comparator clock must be enabled before the registers can be programmed (see page 339). There must be a delay of 3 system clocks after the analog comparator module clock is enabled before any analog comparator module registers are accessed.

**Table 19-5. Analog Comparators Register Map**

| Offset | Name  | Type  | Reset       | Description                               | See page |

## 19.6 Register Descriptions

The remainder of this section lists and describes the Analog Comparator registers, in numerical order by address offset.

**Register 1: Analog Comparator Masked Interrupt Status (ACMIS), offset 0x000**

This register provides a summary of the interrupt status (masked) of the comparators.

## Analog Comparator Masked Interrupt Status (ACMIS)

Base 0x4003.C000

Offset 0x000

Type R/W1C, reset 0x0000.0000

Clearing this bit also clears the <b>IN0</b> bit in the <b>ACRIS</b> register.</p> |

## Register 2: Analog Comparator Raw Interrupt Status (ACRIS), offset 0x004

This register provides a summary of the interrupt status (raw) of the comparators. The bits in this register must be enabled to generate interrupts using the **ACINTEN** register.

**Register 7: Analog Comparator Control 0 (ACCTL0), offset 0x024**

**Register 8: Analog Comparator Control 1 (ACCTL1), offset 0x044**

These registers configure the comparator's input and output.

Analog Comparator Control n (ACCTLn)

Base 0x4003.C000  
 Offset 0x024  
 Type R/W, reset 0x0000.0000

## 20 Pin Diagram

The TM4C1233C3PM microcontroller pin diagram is shown below.

Each GPIO signal is identified by its GPIO port unless it defaults to an alternate function on reset. In this case, the GPIO port name is followed by the default alternate function. To see a complete list of possible functions for each pin, see Table 21-5 on page 1153.

Figure 20-1. 64-Pin LQFP Package Pin Diagram

## 21 Signal Tables

The following tables list the signals available for each pin. Signals are configured as GPIOs on reset, except for those noted below. Use the **GPIOAMSEL** register (see page 658) to select analog mode. For a GPIO pin to be used for an alternate digital function, the corresponding bit in the **GPIOAFSEL** register (see page 642) must be set. Further pin muxing options are provided through the  $PMC_x$  bit field in the **GPIOPCTL** register (see page 659), which selects one of several available peripheral functions for that GPIO.

**Important:** All GPIO pins are configured as GPIOs by default with the exception of the pins shown in the table below. A Power-On-Reset ( $\overline{POR}$ ) or asserting  $\overline{RST}$  puts the pins back to their default state.

**Table 21-1. GPIO Pins With Default Alternate Functions**

| GPIO Pin | Default State     | GPIOAFSEL Bit | GPIOPCTL $PMC_x$ Bit Field |
|----------|-------------------|---------------|----------------------------|
| PA[1:0]  | UART0             | 0             | 0x1                        |
| PA[5:2]  | SSIO              | 0             | 0x1                        |
| PB[3:2]  | I <sup>2</sup> C0 | 0             | 0x1                        |
| PC[3:0]  | JTAG/SWD          | 1             | 0x3                        |

Table 21-2 on page 1139 shows the pin-to-signal-name mapping, including functional characteristics of the signals. Each possible alternate analog and digital function is listed for each pin.

Table 21-3 on page 1144 lists the signals in alphabetical order by signal name. If it is possible for a signal to be on multiple pins, each possible pin assignment is listed. The "Pin Mux" column indicates the GPIO and the encoding needed in the  $PMC_x$  bit field in the **GPIOPCTL** register.

Table 21-4 on page 1149 groups the signals by functionality, except for GPIOs. If it is possible for a signal to be on multiple pins, each possible pin assignment is listed.

Table 21-5 on page 1153 lists the GPIO pins and their analog and digital alternate functions. The  $A_{IN_x}$  analog signals are not 5-V tolerant and go through an isolation circuit before reaching their circuitry. These signals are configured by clearing the corresponding  $DEN$  bit in the **GPIO Digital Enable (GPIODEN)** register and setting the corresponding  $AMSEL$  bit in the **GPIO Analog Mode Select (GPIOAMSEL)** register. Other analog signals are 5-V tolerant and are connected directly to their circuitry ( $C0-$ ,  $C0+$ ,  $C1-$ ,  $C1+$ ). These signals are configured by clearing the  $DEN$  bit in the **GPIO Digital Enable (GPIODEN)** register. The digital signals are enabled by setting the appropriate bit in the **GPIO Alternate Function Select (GPIOAFSEL)** and **GPIODEN** registers and configuring the  $PMC_x$  bit field in the **GPIO Port Control (GPIOPCTL)** register to the numeric encoding shown in the table below. Table entries that are shaded gray are the default values for the corresponding GPIO pin.

Table 21-6 on page 1156 lists the signals based on number of possible pin assignments. This table can be used to plan how to configure the pins for a particular functionality. Application Note AN01274 Configuring Tiva™ C Series Microcontrollers with Pin Multiplexing provides an overview of the pin muxing implementation, an explanation of how a system designer defines a pin configuration, and examples of the pin configuration process.

**Note:** All digital inputs are Schmitt triggered.

## 21.1 Signals by Pin Number

Table 21-2. Signals by Pin Number

| Pin Number | Pin Name | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                                                                                                                              |
|------------|----------|----------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1          | PB6      | I/O      | TTL                      | GPIO port B bit 6.                                                                                                                                                                                                                                                                                                                       |
|            | SSI2Rx   | I        | TTL                      | SSI module 2 receive.                                                                                                                                                                                                                                                                                                                    |
|            | T0CCP0   | I/O      | TTL                      | 16/32-Bit Timer 0 Capture/Compare/PWM 0.                                                                                                                                                                                                                                                                                                 |
| 2          | VDDA     | -        | Power                    | The positive supply for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions. VDDA pins must be supplied with a voltage that meets the specification in Table 22-5 on page 1162, regardless of system implementation. |
| 3          | GND      | -        | Power                    | The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.                                                                                                                                        |
| 4          | PB7      | I/O      | TTL                      | GPIO port B bit 7.                                                                                                                                                                                                                                                                                                                       |
|            | SSI2Tx   | O        | TTL                      | SSI module 2 transmit.                                                                                                                                                                                                                                                                                                                   |
|            | T0CCP1   | I/O      | TTL                      | 16/32-Bit Timer 0 Capture/Compare/PWM 1.                                                                                                                                                                                                                                                                                                 |
| 5          | PF4      | I/O      | TTL                      | GPIO port F bit 4.                                                                                                                                                                                                                                                                                                                       |

Table 21-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type <sup>a</sup> | Description                                   |
|------------|----------|----------|--------------------------|-----------------------------------------------|
| 64         | PD3      | I/O      | TTL                      | GPIO port D bit 3.                            |
|            | AIN4     | I        | Analog                   | Analog-to-digital converter input 4.          |
|            | SSI1Tx   | O        | TTL                      | SSI module 1 transmit.                        |
|            | SSI3Tx   | O        | TTL                      | SSI module 3 transmit.                        |
|            | WT3CCP1  | I/O      | TTL                      | 32/64-Bit Wide Timer 3 Capture/Compare/PWM 1. |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 21.2 Signals by Signal Name

Table 21-3. Signals by Signal Name

| Pin Name         | Pin Number           | Pin Mux / Pin Assignment      | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                   |
|------------------|----------------------|-------------------------------|----------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AIN0             | 6                    | PE3                           | I        | Analog                   | Analog-to-digital converter input 0.                                                                                                                                                                          |
| AIN1             | 7                    | PE2                           | I        | Analog                   | Analog-to-digital converter input 1.                                                                                                                                                                          |
| AIN2             | 8                    | PE1                           | I        | Analog                   | Analog-to-digital converter input 2.                                                                                                                                                                          |
| AIN3             | 9                    | PE0                           | I        | Analog                   | Analog-to-digital converter input 3.                                                                                                                                                                          |
| AIN4             | 64                   | PD3                           | I        | Analog                   | Analog-to-digital converter input 4.                                                                                                                                                                          |

| CAN0Rx           | 28<br>58<br>59       | PF0 (3)<br>PB4 (8)<br>PE4 (8) | I        | TTL                      | CAN module 0 receive.                                                                                                                                                                                         |
| CAN0Tx           | 31<br>57<br>60       | PF3 (3)<br>PB5 (8)<br>PE5 (8) | O        | TTL                      | CAN module 0 transmit.                                                                                                                                                                                        |
| GND              | 12<br>27<br>39<br>55 | fixed                         | -        | Power                    | Ground reference for logic and I/O pins.                                                                                                                                                                      |
| GND <sub>A</sub> | 3                    | fixed                         | -        | Power                    | The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on V <sub>DD</sub> from affecting the analog functions. |

Table 21-3. Signals by Signal Name (continued)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                                      |
|----------|------------|--------------------------|----------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GNDX     | 35         | fixed                    | -        | Power                    | GND for the Hibernation oscillator. When using a crystal clock source, this pin should be connected to digital ground along with the crystal load capacitors. When using an external oscillator, this pin should be connected to digital ground. |
| HTB      | 33         | fixed                    | O        | TTL                      | An output that indicates the processor is in Hibernate mode.                                                                                                                                                                                     |
| I2C0SCL  | 47         | PB2 (3)                  | I/O      | OD                       | I <sup>2</sup> C module 0 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.                                                                                                 |
| I2C0SDA  | 48         | PB3 (3)                  | I/O      | OD                       | I <sup>2</sup> C module 0 data.                                                                                                                                                                                                                  |
| I2C1SCL  | 23         | PA6 (3)                  | I/O      | OD                       | I <sup>2</sup> C module 1 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.                                                                                                 |

| USB0DM   | 43                   | PD4                      | I/O      | Analog                   | Bidirectional differential data pin (D- per USB specification) for USB0.                                                                                                                                                                                                                                                                 |
| USB0DP   | 44                   | PD5                      | I/O      | Analog                   | Bidirectional differential data pin (D+ per USB specification) for USB0.                                                                                                                                                                                                                                                                 |
| VBAT     | 37                   | fixed                    | -        | Power                    | Power source for the Hibernation module. It is normally connected to the positive terminal of a battery and serves as the battery backup/Hibernation module power-source supply.                                                                                                                                                         |
| VDD      | 11<br>26<br>42<br>54 | fixed                    | -        | Power                    | Positive supply for I/O and some logic.                                                                                                                                                                                                                                                                                                  |
| VDDA     | 2                    | fixed                    | -        | Power                    | The positive supply for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions. VDDA pins must be supplied with a voltage that meets the specification in Table 22-5 on page 1162, regardless of system implementation. |
| VDDC     | 25<br>56             | fixed                    | -        | Power                    | Positive supply for most of the logic function, including the processor core and most peripherals. The voltage on this pin is 1.2 V and is supplied by the on-chip LDO. The VDDC pins should only be connected to each other and an external capacitor as specified in Table 22-12 on page 1174 .                                        |
| WAKE     | 32                   | fixed                    | I        | TTL                      | An external input that brings the processor out of Hibernate mode when asserted.                                                                                                                                                                                                                                                         |

Table 21-3. Signals by Signal Name (continued)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                |
|----------|------------|--------------------------|----------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WT4CCP0  | 43         | PD4 (7)                  | I/O      | TTL                      | 32/64-Bit Wide Timer 4 Capture/Compare/PWM 0.                                                                                                                                              |
| WT4CCP1  | 44         | PD5 (7)                  | I/O      | TTL                      | 32/64-Bit Wide Timer 4 Capture/Compare/PWM 1.                                                                                                                                              |
| WT5CCP0  | 53         | PD6 (7)                  | I/O      | TTL                      | 32/64-Bit Wide Timer 5 Capture/Compare/PWM 0.                                                                                                                                              |
| WT5CCP1  | 10         | PD7 (7)                  | I/O      | TTL                      | 32/64-Bit Wide Timer 5 Capture/Compare/PWM 1.                                                                                                                                              |
| XOSC0    | 34         | fixed                    | I        | Analog                   | Hibernation module oscillator crystal input or an external clock reference input. Note that this is either a 32.768-kHz crystal or a 32.768-kHz oscillator for the Hibernation module RTC. |
| XOSC1    | 36         | fixed                    | O        | Analog                   | Hibernation module oscillator crystal output. Leave unconnected when using a single-ended clock source.                                                                                    |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 21.3 Signals by Function, Except for GPIO

Table 21-4. Signals by Function, Except for GPIO

| Function                | Pin Name | Pin Number     | Pin Type | Buffer Type <sup>a</sup> | Description                           |
|-------------------------|----------|----------------|----------|--------------------------|---------------------------------------|
| ADC                     | AIN0     | 6              | I        | Analog                   | Analog-to-digital converter input 0.  |
|                         | AIN1     | 7              | I        | Analog                   | Analog-to-digital converter input 1.  |
|                         | AIN2     | 8              | I        | Analog                   | Analog-to-digital converter input 2.  |
|                         | AIN3     | 9              | I        | Analog                   | Analog-to-digital converter input 3.  |
|                         | AIN4     | 64             | I        | Analog                   | Analog-to-digital converter input 4.  |
|                         | AIN5     | 63             | I        | Analog                   | Analog-to-digital converter input 5.  |
|                         | AIN6     | 62             | I        | Analog                   | Analog-to-digital converter input 6.  |
|                         | AIN7     | 61             | I        | Analog                   | Analog-to-digital converter input 7.  |
|                         | AIN8     | 60             | I        | Analog                   | Analog-to-digital converter input 8.  |
|                         | AIN9     | 59             | I        | Analog                   | Analog-to-digital converter input 9.  |
|                         | AIN10    | 58             | I        | Analog                   | Analog-to-digital converter input 10. |
|                         | AIN11    | 57             | I        | Analog                   | Analog-to-digital converter input 11. |
| Analog Comparators      | C0+      | 14             | I        | Analog                   | Analog comparator 0 positive input.   |
|                         | C0-      | 13             | I        | Analog                   | Analog comparator 0 negative input.   |
|                         | C0o      | 28             | O        | TTL                      | Analog comparator 0 output.           |
|                         | C1+      | 15             | I        | Analog                   | Analog comparator 1 positive input.   |
|                         | C1-      | 16             | I        | Analog                   | Analog comparator 1 negative input.   |
|                         | C1o      | 29             | O        | TTL                      | Analog comparator 1 output.           |
| Controller Area Network | CAN0Rx   | 28<br>58<br>59 | I        | TTL                      | CAN module 0 receive.                 |
|                         | CAN0Tx   | 31<br>57<br>60 | O        | TTL                      | CAN module 0 transmit.                |
| Core                    | TRCLK    | 31             | O        | TTL                      | Trace clock.                          |
|                         | TRD0     | 30             | O        | TTL                      | Trace data 0.                         |
|                         | TRD1     | 29             | O        | TTL                      | Trace data 1.                         |

Table 21-4. Signals by Function, Except for GPIO (continued)

| Function               | Pin Name | Pin Number | Pin Type | Buffer Type <sup>a</sup> | Description                                   |
|------------------------|----------|------------|----------|--------------------------|-----------------------------------------------|
| General-Purpose Timers | T0CCP0   | 1<br>28    | I/O      | TTL                      | 16/32-Bit Timer 0 Capture/Compare/PWM 0.      |

|                        | WT0CCP1  | 15         | I/O      | TTL                      | 32/64-Bit Wide Timer 0 Capture/Compare/PWM 1. |
|                        | WT1CCP0  | 14         | I/O      | TTL                      | 32/64-Bit Wide Timer 1 Capture/Compare/PWM 0. |
|                        | WT1CCP1  | 13         | I/O      | TTL                      | 32/64-Bit Wide Timer 1 Capture/Compare/PWM 1. |
|                        | WT2CCP0  | 61         | I/O      | TTL                      | 32/64-Bit Wide Timer 2 Capture/Compare/PWM 0. |
|                        | WT2CCP1  | 62         | I/O      | TTL                      | 32/64-Bit Wide Timer 2 Capture/Compare/PWM 1. |
|                        | WT3CCP0  | 63         | I/O      | TTL                      | 32/64-Bit Wide Timer 3 Capture/Compare/PWM 0. |
|                        | WT3CCP1  | 64         | I/O      | TTL                      | 32/64-Bit Wide Timer 3 Capture/Compare/PWM 1. |
|                        | WT4CCP0  | 43         | I/O      | TTL                      | 32/64-Bit Wide Timer 4 Capture/Compare/PWM 0. |
|                        | WT4CCP1  | 44         | I/O      | TTL                      | 32/64-Bit Wide Timer 4 Capture/Compare/PWM 1. |
|                        | WT5CCP0  | 53         | I/O      | TTL                      | 32/64-Bit Wide Timer 5 Capture/Compare/PWM 0. |
|                        | WT5CCP1  | 10         | I/O      | TTL                      | 32/64-Bit Wide Timer 5 Capture/Compare/PWM 1. |

Table 21-4. Signals by Function, Except for GPIO (continued)

| Function     | Pin Name | Pin Number | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                                      |
|--------------|----------|------------|----------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Hibernate    | GNDX     | 35         | -        | Power                    | GND for the Hibernation oscillator. When using a crystal clock source, this pin should be connected to digital ground along with the crystal load capacitors. When using an external oscillator, this pin should be connected to digital ground. |
|              | HIB      | 33         | O        | TTL                      | An output that indicates the processor is in Hibernate mode.                                                                                                                                                                                     |
|              | VBAT     | 37         | -        | Power                    | Power source for the Hibernation module. It is normally connected to the positive terminal of a battery and serves as the battery backup/Hibernation module power-source supply.                                                                 |
|              | WAKE     | 32         | I        | TTL                      | An external input that brings the processor out of Hibernate mode when asserted.                                                                                                                                                                 |
|              | XOSC0    | 34         | I        | Analog                   | Hibernation module oscillator crystal input or an external clock reference input. Note that this is either a 32.768-kHz crystal or a 32.768-kHz oscillator for the Hibernation module RTC.                                                       |
|              | XOSC1    | 36         | O        | Analog                   | Hibernation module oscillator crystal output. Leave unconnected when using a single-ended clock source.                                                                                                                                          |
| I2C          | I2C0SCL  | 47         | I/O      | OD                       | I <sup>2</sup> C module 0 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.                                                                                                 |
|              | I2C0SDA  | 48         | I/O      | OD                       | I <sup>2</sup> C module 0 data.                                                                                                                                                                                                                  |
|              | I2C1SCL  | 23         | I/O      | OD                       | I <sup>2</sup> C module 1 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.                                                                                                 |
|              | I2C1SDA  | 24         | I/O      | OD                       | I <sup>2</sup> C module 1 data.                                                                                                                                                                                                                  |
|              | I2C2SCL  | 59         | I/O      | OD                       | I <sup>2</sup> C module 2 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.                                                                                                 |
|              | I2C2SDA  | 60         | I/O      | OD                       | I <sup>2</sup> C module 2 data.                                                                                                                                                                                                                  |
|              | I2C3SCL  | 61         | I/O      | OD                       | I <sup>2</sup> C module 3 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.                                                                                                 |
| JTAG/SWD/SWO | I2C3SDA  | 62         | I/O      | OD                       | I <sup>2</sup> C module 3 data.                                                                                                                                                                                                                  |
|              | SWCLK    | 52         | I        | TTL                      | JTAG/SWD CLK.                                                                                                                                                                                                                                    |
|              | SWDIO    | 51         | I/O      | TTL                      | JTAG TMS and SWDIO.                                                                                                                                                                                                                              |
|              | SWO      | 49         | O        | TTL                      | JTAG TDO and SWO.                                                                                                                                                                                                                                |
|              | TCK      | 52         | I        | TTL                      | JTAG/SWD CLK.                                                                                                                                                                                                                                    |
|              | TDI      | 50         | I        | TTL                      | JTAG TDI.                                                                                                                                                                                                                                        |
|              | TDO      | 49         | O        | TTL                      | JTAG TDO and SWO.                                                                                                                                                                                                                                |
| TMS          | 51       | I          | TTL      | JTAG TMS and SWDIO.      |                                                                                                                                                                                                                                                  |

| Function | Pin Name | Pin Number           | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                                                                                                                              |
|----------|----------|----------------------|----------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Power    | GND      | 12<br>27<br>39<br>55 | -        | Power                    | Ground reference for logic and I/O pins.                                                                                                                                                                                                                                                                                                 |
|          | GNDA     | 3                    | -        | Power                    | The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.                                                                                                                                        |
|          | VDD      | 11<br>26<br>42<br>54 | -        | Power                    | Positive supply for I/O and some logic.                                                                                                                                                                                                                                                                                                  |
|          | VDDA     | 2                    | -        | Power                    | The positive supply for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions. VDDA pins must be supplied with a voltage that meets the specification in Table 22-5 on page 1162, regardless of system implementation. |
|          | VDDC     | 25<br>56             | -        | Power                    | Positive supply for most of the logic function, including the processor core and most peripherals. The voltage on this pin is 1.2 V and is supplied by the on-chip LDO. The VDDC pins should only be connected to each other and an external capacitor as specified in Table 22-12 on page 1174 .                                        |

|                         | USB0DP   | 44         | I/O      | Analog                   | Bidirectional differential data pin (D+ per USB specification) for USB0.                  |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 21.4 GPIO Pins and Alternate Functions

Table 21-5. GPIO Pins and Alternate Functions

| IO  | Pin | Analog Function | Digital Function (GPIOCTL PMCx Bit Field Encoding) <sup>a</sup> |         |   |   |   |   |   |   |   |    |    |   |

## 21.6 Connections for Unused Signals

Table 21-7 on page 1158 shows how to handle signals for functions that are not used in a particular system implementation for devices that are in a 64-pin LQFP package. Two options are shown in the table: an acceptable practice and a preferred practice for reduced power consumption and improved EMC characteristics. If a module is not used in a system, and its inputs are grounded, it is important that the clock to the module is never enabled by setting the corresponding bit in the **RCGCx** register.

Table 21-7. Connections for Unused Signals (64-Pin LQFP)

| Function       | Signal Name       | Pin Number                                    | Acceptable Practice | Preferred Practice                         |
|----------------|-------------------|-----------------------------------------------|---------------------|--------------------------------------------|
| GPIO           | All unused GPIOs  | -                                             | NC                  | GND                                        |
| Hibernate      | $\overline{HTB}$  | 33                                            | NC                  | NC                                         |
|                | VBAT              | 37                                            | NC                  | VDD                                        |
|                | $\overline{WAKE}$ | 32                                            | NC                  | GND                                        |
|                | XOSC0             | 34                                            | NC                  | GND                                        |
|                | XOSC1             | 36                                            | NC                  | NC                                         |
|                | GNDX              | 35                                            | GND                 | GND                                        |
| No Connects    | NC                | See NC pin numbers in Table 21-3 on page 1144 | NC                  | NC                                         |
| System Control | OSC0              | 40                                            | NC                  | GND                                        |
|                | OSC1              | 41                                            | NC                  | NC                                         |
|                | $\overline{RST}$  | 38                                            | VDD                 | Pull up as shown in Figure 5-1 on page 207 |

**Table 21-7. Connections for Unused Signals (64-Pin LQFP) (continued)**

| Function | Signal Name | Pin Number | Acceptable Practice | Preferred Practice |
|----------|-------------|------------|---------------------|--------------------|
| USB      | USB0DM      | 43         | NC                  | GND                |
|          | USB0DP      | 44         | NC                  | GND                |

## 22 Electrical Characteristics

### 22.1 Maximum Ratings

The maximum ratings are the limits to which the device can be subjected without permanently damaging the device. Device reliability may be adversely affected by exposure to absolute-maximum ratings for extended periods.

**Note:** The device is not guaranteed to operate properly at the maximum ratings.

**Table 22-1. Absolute Maximum Ratings**

| Parameter             | Parameter Name <sup>a</sup>                                                                 | Value |                       | Unit       |
|-----------------------|---------------------------------------------------------------------------------------------|-------|-----------------------|------------|
|                       |                                                                                             | Min   | Max                   |            |
| V <sub>DD</sub>       | V <sub>DD</sub> supply voltage                                                              | 0     | 4                     | V          |
| V <sub>DDA</sub>      | V <sub>DDA</sub> supply voltage <sup>b</sup>                                                | 0     | 4                     | V          |
| V <sub>BAT</sub>      | V <sub>BAT</sub> battery supply voltage                                                     | 0     | 4                     | V          |
| V <sub>BATRMP</sub>   | V <sub>BAT</sub> battery supply voltage ramp time                                           | 0     | 0.7                   | V/ $\mu$ s |
| V <sub>IN_GPIO</sub>  | Input voltage on GPIOs, regardless of whether the microcontroller is powered <sup>cde</sup> | -0.3  | 5.5                   | V          |
|                       | Input voltage for PD4, PD5, PB0 and PB1 when configured as GPIO                             | -0.3  | V <sub>DD</sub> + 0.3 | V          |
| I <sub>GPIO MAX</sub> | Maximum current per output pin                                                              | -     | 25                    | mA         |
| T <sub>S</sub>        | Unpowered storage temperature range                                                         | -65   | 150                   | °C         |
| T <sub>JMAX</sub>     | Maximum junction temperature                                                                | -     | 150                   | °C         |

a. Voltages are measured with respect to GND.

b. To ensure proper operation, V<sub>DDA</sub> must be powered before V<sub>DD</sub> if sourced from different supplies, or connected to the same supply as V<sub>DD</sub>. Note that the minimum operating voltage for V<sub>DD</sub> differs from the minimum operating voltage for V<sub>DDA</sub>. This change should be accounted for in the system design if both are sourced from the same supply. There is not a restriction on order for powering off.

c. Applies to static and dynamic signals including overshoot.

d. Refer to Figure 22-16 on page 1187 for a representation of the ESD protection on GPIOs.

e. For additional details, see the note on GPIO pad tolerance in "GPIO Module Characteristics" on page 1186.

**Important:** This device contains circuitry to protect the I/Os against damage due to high-static voltages; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum-rated voltages to this high-impedance circuit. Reliability of operation is enhanced if unused inputs are connected to an appropriate logic voltage level (see "Connections for Unused Signals" on page 1158).

**Table 22-2. ESD Absolute Maximum Ratings**

|                                                 | Parameter                        | Min | Nom | Max | Unit |
|-------------------------------------------------|----------------------------------|-----|-----|-----|------|
| Component-Level ESD Stress Voltage <sup>a</sup> | V <sub>ESDHBM</sub> <sup>b</sup> | -   | -   | 2.0 | kV   |
|                                                 | V <sub>ESDCDM</sub> <sup>c</sup> | -   | -   | 500 | V    |

a. Electrostatic discharge (ESD) to measure device sensitivity/immunity to damage caused by electrostatic discharges in device.

b. Level listed is passing level per ANSI/ESDA/JEDEC JS-001. JEDEC document JEP155 states that 500V HBM allows safe manufacturing with a standard ESD control process.

c. Level listed is the passing level per EIA-JEDEC JESD22-C101E. JEDEC document JEP157 states that 250V CDM allows safe manufacturing with a standard ESD control process.

## 22.2 Operating Characteristics

**Table 22-3. Temperature Characteristics**

| Characteristic                       | Symbol | Value      | Unit |
|--------------------------------------|--------|------------|------|
| Ambient operating temperature range  | $T_A$  | -40 to +85 | °C   |
| Case operating temperature range     | $T_C$  | -40 to +93 | °C   |
| Junction operating temperature range | $T_J$  | -40 to +96 | °C   |

**Table 22-4. Thermal Characteristics<sup>a</sup>**

| Characteristic                                        | Symbol        | Value                                                                                                                                     | Unit |
|-------------------------------------------------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------|------|
| Thermal resistance (junction to ambient) <sup>b</sup> | $\Theta_{JA}$ | 54.8                                                                                                                                      | °C/W |
| Thermal resistance (junction to board) <sup>b</sup>   | $\Theta_{JB}$ | 27.5                                                                                                                                      | °C/W |
| Thermal resistance (junction to case) <sup>b</sup>    | $\Theta_{JC}$ | 15.8                                                                                                                                      | °C/W |
| Thermal metric (junction to top of package)           | $\Psi_{JT}$   | 0.7                                                                                                                                       | °C/W |
| Thermal metric (junction to board)                    | $\Psi_{JB}$   | 27.1                                                                                                                                      | °C/W |
| Junction temperature formula                          | $T_J$         | $T_C + (P \cdot \Psi_{JT})$<br>$T_{PCB} + (P \cdot \Psi_{JB})^c$<br>$T_A + (P \cdot \Theta_{JA})^d$<br>$T_B + (P \cdot \Theta_{JB})^{ef}$ | °C   |

a. For more details about thermal metrics and definitions, see the *Semiconductor and IC Package Thermal Metrics Application Report* (literature number [SPRA953](#)).

b. Junction to ambient thermal resistance ( $\Theta_{JA}$ ), junction to board thermal resistance ( $\Theta_{JB}$ ), and junction to case thermal resistance ( $\Theta_{JC}$ ) numbers are determined by a package simulator.

c.  $T_{PCB}$  is the temperature of the board acquired by following the steps listed in the EAI/JESD 51-8 standard summarized in the *Semiconductor and IC Package Thermal Metrics Application Report* (literature number [SPRA953](#)).

d. Because  $\Theta_{JA}$  is highly variable and based on factors such as board design, chip/pad size, altitude, and external ambient temperature, it is recommended that equations containing  $\Psi_{JT}$  and  $\Psi_{JB}$  be used for best results.

e.  $T_B$  is temperature of the board.

f.  $\Theta_{JB}$  is not a pure reflection of the internal resistance of the package because it includes the resistance of the testing board and environment. It is recommended that equations containing  $\Psi_{JT}$  and  $\Psi_{JB}$  be used for best results.

## 22.3 Recommended Operating Conditions

For special high-current applications, the GPIO output buffers may be used with the following restrictions. With the GPIO pins configured as 8-mA output drivers, a total of four GPIO outputs may be used to sink current loads up to 18 mA each. At 18-mA sink current loading, the  $V_{OL}$  value is specified as 1.2 V. The high-current GPIO package pins must be selected such that there are only a maximum of two per side of the physical package with the total number of high-current GPIO outputs not exceeding four for the entire package.

**Table 22-5. Recommended DC Operating Conditions**

| Parameter        | Parameter Name                            | Min  | Nom | Max  | Unit |
|------------------|-------------------------------------------|------|-----|------|------|
| $V_{DD}$         | $V_{DD}$ supply voltage                   | 3.15 | 3.3 | 3.63 | V    |
| $V_{DDA}$        | $V_{DDA}$ supply voltage                  | 2.97 | 3.3 | 3.63 | V    |
| $V_{DDC}$        | $V_{DDC}$ supply voltage                  | 1.08 | 1.2 | 1.32 | V    |
| $V_{DDCDS}^{ab}$ | $V_{DDC}$ supply voltage, Deep-sleep mode | 1.08 | -   | 1.32 | V    |

a. These values are valid when LDO is in operation.

b. There are peripheral timing restrictions for SSI and LPC in Deep-sleep mode. Please refer to those peripheral characteristic sections for more information.

**Table 22-6. Recommended GPIO Pad Operating Conditions**

| Parameter | Parameter Name                              | Min             | Nom | Max             | Unit |
|-----------|---------------------------------------------|-----------------|-----|-----------------|------|
| $V_{IH}$  | GPIO high-level input voltage               | $0.65 * V_{DD}$ | -   | 5.5             | V    |
| $V_{IL}$  | GPIO low-level input voltage                | 0               | -   | $0.35 * V_{DD}$ | V    |
| $V_{HYS}$ | GPIO input hysteresis                       | 0.2             | -   | -               | V    |
| $V_{OH}$  | GPIO high-level output voltage              | 2.4             | -   | -               | V    |
| $V_{OL}$  | GPIO low-level output voltage               | -               | -   | 0.4             | V    |
| $I_{OH}$  | High-level source current, $V_{OH}=2.4 V^a$ |                 |     |                 |      |
|           | 2-mA Drive                                  | 2.0             | -   | -               | mA   |
|           | 4-mA Drive                                  | 4.0             | -   | -               | mA   |
|           | 8-mA Drive                                  | 8.0             | -   | -               | mA   |
| $I_{OL}$  | Low-level sink current, $V_{OL}=0.4 V^a$    |                 |     |                 |      |
|           | 2-mA Drive                                  | 2.0             | -   | -               | mA   |
|           | 4-mA Drive                                  | 4.0             | -   | -               | mA   |
|           | 8-mA Drive                                  | 8.0             | -   | -               | mA   |
|           | 8-mA Drive, $V_{OL}=1.2 V$                  | 18.0            | -   | -               | mA   |

a.  $I_O$  specifications reflect the maximum current where the corresponding output voltage meets the  $V_{OH}/V_{OL}$  thresholds.  $I_O$  current can exceed these limits (subject to absolute maximum ratings).

**Table 22-7. GPIO Current Restrictions<sup>a</sup>**

| Parameter  | Parameter Name                                                | Min | Nom | Max | Unit |
|------------|---------------------------------------------------------------|-----|-----|-----|------|
| $I_{MAXL}$ | Cumulative maximum GPIO current per side, left <sup>b</sup>   | -   | -   | 30  | mA   |
| $I_{MAXB}$ | Cumulative maximum GPIO current per side, bottom <sup>b</sup> | -   | -   | 35  | mA   |
| $I_{MAXR}$ | Cumulative maximum GPIO current per side, right <sup>b</sup>  | -   | -   | 40  | mA   |
| $I_{MAXT}$ | Cumulative maximum GPIO current per side, top <sup>b</sup>    | -   | -   | 40  | mA   |

a. Based on design simulations, not tested in production.

b. Sum of sink and source current for GPIOs as shown in Table 22-8 on page 1163.

**Table 22-8. GPIO Package Side Assignments**

| Side   | GPIOs                                |
|--------|--------------------------------------|
| Left   | PB[6-7], PC[4-7], PD7, PE[0-3], PF4  |
| Bottom | PA[0-7], PF[0-3]                     |
| Right  | PB[0-3], PD[4-5]                     |
| Top    | PB[4-5], PC[0-3], PD[0-3,6], PE[4-5] |

## 22.4 Load Conditions

Unless otherwise specified, the following conditions are true for all timing measurements.

**Figure 22-1. Load Conditions**

## 22.5 JTAG and Boundary Scan

Table 22-9. JTAG Characteristics

| Parameter No. | Parameter       | Parameter Name                                                            | Min | Nom         | Max | Unit |
|---------------|-----------------|---------------------------------------------------------------------------|-----|-------------|-----|------|
| J1            | $F_{TCK}$       | TCK operational clock frequency <sup>a</sup>                              | 0   | -           | 10  | MHz  |
| J2            | $T_{TCK}$       | TCK operational clock period                                              | 100 | -           | -   | ns   |

## 22.6 Power and Brown-Out

Table 22-10. Power-On and Brown-Out Levels

| Parameter No. | Parameter          | Parameter Name                         | Min   | Nom  | Max      | Unit    |
|---------------|--------------------|----------------------------------------|-------|------|----------|---------|
| P1            | $T_{VDDA\_RISE}$   | Analog Supply Voltage (VDDA) Rise Time | -     | -    | $\infty$ | $\mu s$ |
| P2            | $T_{VDD\_RISE}$    | I/O Supply Voltage (VDD) Rise Time     | -     | -    | $\infty$ | $\mu s$ |
| P3            | $T_{VDDC\_RISE}^a$ | Core Supply Voltage (VDDC) Rise Time   | 10.00 | -    | 150.00   | $\mu s$ |
| P4            | $V_{POR}$          | Power-On Reset Threshold               | 2.00  | 2.30 | 2.60     | V       |
| P5            | $V_{VDDA\_POK}$    | VDDA Power-OK Threshold (Rising Edge)  | 2.70  | 2.85 | 3.00     | V       |
|               |                    | VDDA Power-OK Threshold (Falling Edge) | 2.71  | 2.80 | 2.89     | V       |
| P6            | $V_{VDD\_POK}^b$   | VDD Power-OK Threshold (Rising Edge)   | 2.85  | 3.00 | 3.15     | V       |
|               |                    | VDD Power-OK Threshold (Falling Edge)  | 2.70  | 2.78 | 2.87     | V       |
| P7            | $V_{VDD\_BOR0}$    | Brown-Out 0 Reset Threshold            | 2.93  | 3.02 | 3.11     | V       |
| P8            | $V_{VDD\_BOR1}$    | Brown-Out 1 Reset Threshold            | 2.83  | 2.92 | 3.01     | V       |
| P9            | $V_{VDDC\_POK}$    | VDDC Power-OK Threshold (Rising Edge)  | 0.80  | 0.95 | 1.10     | V       |
|               |                    | VDDC Power-OK Threshold (Falling Edge) | 0.71  | 0.80 | 0.89     | V       |

a. The MIN and MAX values are guaranteed by design assuming the external filter capacitor load is within the range of CLDO. Please refer to "On-Chip Low Drop-Out (LDO) Regulator" on page 1174 for the CLDO value.

b. Digital logic, Flash memory, and SRAM are all designed to operate at VDD voltages below 2.70 V. The internal POK reset protects the device from unpredictable operation on power down.

### 22.6.1 VDDA Levels

The  $V_{DDA}$  supply has two monitors:

- Power-On Reset (POR)
- Power-OK (POK)

The POR monitor is used to keep the analog circuitry in reset until the  $V_{DDA}$  supply has reached the correct range for the analog circuitry to begin operating. The POK monitor is used to keep the digital circuitry in reset until the  $V_{DDA}$  power supply is at an acceptable operational level. The digital Power-On Reset (Digital POR) is only released when the Power-On Reset has deasserted and all of the Power-OK monitors for each of the supplies indicate that power levels are in operational ranges.

Once the  $V_{DDA}$  POK monitor has released the digital Power-On Reset on the initial power-up, voltage drops on the  $V_{DDA}$  supply will only be reflected in the following bits. The digital Power-On Reset will not be re-asserted.

- VDDARIS bit in the **Raw Interrupt Status (RIS)** register (see page 235).
- VDDAMIS bit in the **Masked Interrupt Status and Clear (MISC)** register (see page 240). This bit is set only if the VDDAIM bit in the **Interrupt Mask Control (IMC)** register has been set.

Figure 22-4 on page 1168 shows the relationship between  $V_{DDA}$ , POR, POK, and an interrupt event.

Figure 22-4. Power Assertions versus VDDA Levels

## 22.6.2 VDD Levels

The  $V_{DD}$  supply has three monitors:

- Power-OK (POK)
- Brown-Out Reset0 (BOR0)
- Brown-Out Reset1 (BOR1)

The POK monitor is used to keep the digital circuitry in reset until the  $V_{DD}$  power supply is at an acceptable operational level. The digital Power-On Reset ( $\overline{\text{Digital POR}}$ ) is only released when the Power-On Reset has deasserted and all of the Power-OK monitors for each of the supplies indicate that power levels are in operational ranges. The BOR0 and the BOR1 monitors are used to generate a reset to the device or assert an interrupt if the  $V_{DD}$  supply drops below its operational range. The BOR1 monitor's threshold is in between the BOR0 and POK thresholds.

If either a BOR0 event or a BOR1 event occurs, the following bits are affected:

- BOR0RIS or BOR1RIS bits in the **Raw Interrupt Status (RIS)** register (see page 235).
- BOR0MIS or BOR1MIS bits in the **Masked Interrupt Status and Clear (MISC)** register (see page 240). These bits are set only if the respective BOR0IM or BOR1IM bits in the **Interrupt Mask Control (IMC)** register have been set.
- BOR bit in the **Reset Cause (RESC)** register (see page 243). This bit is set only if either of the BOR0 or BOR1 events have been configured to initiate a reset.

In addition, the following bits control both the BOR0 and BOR1 events:

- BOR0IM or BOR1IM bits in the **Interrupt Mask Control (IMC)** register (see page 238).

- BOR0 or BOR1 bits in the **Power-On and Brown-Out Reset Control (PBORCTL)** register (see page 234).

Figure 22-5 on page 1169 shows the relationship between:

- $V_{DD}$ , POK, and a BOR0 event
- $V_{DD}$ , POK, and a BOR1 event

**Figure 22-5. Power and Brown-Out Assertions versus VDD Levels**

### 22.6.3 VDDC Levels

The  $V_{DDC}$  supply has one monitor: the Power-OK (POK). The POK monitor is used to keep the digital circuitry in reset until the  $V_{DDC}$  power supply is at an acceptable operational level. The digital Power-On Reset (Digital POR) is only released when the Power-On Reset has deasserted and all of the Power-OK monitors for each of the supplies indicate that power levels are in operational ranges. Figure 22-6 on page 1170 shows the relationship between POK and  $V_{DDC}$ .

Figure 22-6. POK assertion vs VDDC

### 22.6.4 VDD Glitches

Figure 22-7 on page 1170 shows the response of the BOR0, BOR1, and the POR circuit to glitches on the  $V_{DD}$  supply.

Figure 22-7. POR-BOR0-BOR1 VDD Glitch Response

### 22.6.5 VDD Droop Response

Figure 22-8 on page 1171 shows the response of the BOR0, BOR1, and the POR monitors to a drop on the  $V_{DD}$  supply.

Figure 22-8. POR-BOR0-BOR1 VDD Droop Response

## 22.7 Reset

Table 22-11. Reset Characteristics

| Parameter No. | Parameter     | Parameter Name                                               | Min  | Nom  | Max  | Unit          |
|---------------|---------------|--------------------------------------------------------------|------|------|------|---------------|
| R1            | $T_{DPORDLY}$ | Digital POR to Internal Reset assertion delay <sup>a</sup>   | 0.80 | -    | 5.35 | $\mu\text{s}$ |
| R2            | $T_{IRTOU}$   | Internal Reset timeout                                       | -    | -    | 500  | $\mu\text{s}$ |
| R3            | $T_{BOR0DLY}$ | BOR0 to Internal Reset assertion delay <sup>a</sup>          | 0.25 | -    | 1.95 | $\mu\text{s}$ |
| R3            | $T_{BOR1DLY}$ | BOR1 to Internal Reset assertion delay <sup>a</sup>          | 0.75 | -    | 5.95 | $\mu\text{s}$ |
| R4            | $T_{RSTMIN}$  | Minimum $\overline{\text{RST}}$ pulse width                  | -    | 250  | -    | ns            |
| R5            | $T_{IRHWDLY}$ | $\overline{\text{RST}}$ to Internal Reset assertion delay    | -    | 250  | -    | ns            |
| R6            | $T_{IRSWR}$   | Internal reset timeout after software-initiated system reset | -    | 2.07 | -    | $\mu\text{s}$ |
| R7            | $T_{IRWDR}$   | Internal reset timeout after Watchdog reset                  | -    | 2.10 | -    | $\mu\text{s}$ |
| R8            | $T_{IRMFR}$   | Internal reset timeout after MOSC failure reset              | -    | 1.92 | -    | $\mu\text{s}$ |

a. Timing values are dependent on the  $V_{DD}$  power-down ramp rate.

Figure 22-9. Digital Power-On Reset Timing

**Note:** The digital Power-On Reset is only released when the analog Power-On Reset has deasserted and all of the Power-OK monitors for each of the supplies indicate that power levels are in operational ranges.

## 22.8 On-Chip Low Drop-Out (LDO) Regulator

**Table 22-12. LDO Regulator Characteristics**

| Parameter    | Parameter Name                                                        | Min  | Nom | Max  | Unit             |
|--------------|-----------------------------------------------------------------------|------|-----|------|------------------|
| $C_{LDO}$    | External filter capacitor size for internal power supply <sup>a</sup> | 2.5  | -   | 4.0  | $\mu\text{F}$    |
| ESR          | Filter capacitor equivalent series resistance                         | 10   | -   | 100  | $\text{m}\Omega$ |
| ESL          | Filter capacitor equivalent series inductance                         | -    | -   | 0.5  | nH               |
| $V_{LDO}$    | LDO output voltage                                                    | 1.08 | 1.2 | 1.32 | V                |
| $I_{INRUSH}$ | Inrush current                                                        | 50   | -   | 250  | mA               |

a. The capacitor should be connected as close as possible to pin 56.

## 22.9 Clocks

The following sections provide specifications on the various clock sources and mode.

### 22.9.1 PLL Specifications

The following tables provide specifications for using the PLL.

**Table 22-13. Phase Locked Loop (PLL) Characteristics**

| Parameter             | Parameter Name                                                                                                       | Min            | Nom | Max                      | Unit                          |
|-----------------------|----------------------------------------------------------------------------------------------------------------------|----------------|-----|--------------------------|-------------------------------|
| F <sub>REF_XTAL</sub> | Crystal reference                                                                                                    | 5 <sup>a</sup> | -   | 25                       | MHz                           |
| F <sub>REF_EXT</sub>  | External clock reference <sup>a</sup>                                                                                | 5 <sup>a</sup> | -   | 25                       | MHz                           |
| F <sub>PLL</sub>      | PLL frequency <sup>b</sup>                                                                                           | -              | 400 | -                        | MHz                           |
| T <sub>READY</sub>    | PLL lock time, enabling the PLL                                                                                      | -              | -   | 512 * (N+1) <sup>c</sup> | reference clocks <sup>d</sup> |
|                       | PLL lock time, changing the XTAL field in the <b>RCC/RCC2</b> register or changing the OSCSRC between MOSC and PIOSC | -              | -   | 128 * (N+1) <sup>c</sup> | reference clocks <sup>d</sup> |

a. If the PLL is not used, the minimum input frequency can be 4 MHz.

b. PLL frequency is automatically calculated by the hardware based on the XTAL field of the **RCC** register. The PLL frequency that is set by the hardware can be calculated using the values in the **PLLREQ0** and **PLLREQ1** registers.

c. N is the value in the N field in the **PLLREQ1** register.

d. A reference clock is the clock period of the crystal being used, which can be MOSC or PIOSC. For example, a 16-MHz crystal connected to MOSC yields a reference clock of 62.5 ns.

Table 22-14 on page 1175 shows the actual frequency of the PLL based on the crystal frequency used (defined by the XTAL field in the **RCC** register).

**Table 22-14. Actual PLL Frequency**

| XTAL | Crystal Frequency (MHz) | MINT | MFRAC | Q   | N   | PLL Multiplier | PLL Frequency (MHz) | Error   |
|------|-------------------------|------|-------|-----|-----|----------------|---------------------|---------|
| 0x09 | 5.0                     | 0x50 | 0x0   | 0x0 | 0x0 | 80             | 400                 | -       |

Table 22-14. Actual PLL Frequency (continued)

| XTAL | Crystal Frequency (MHz) | MINT | MFRAC | Q   | N   | PLL Multiplier | PLL Frequency (MHz) | Error |
|------|-------------------------|------|-------|-----|-----|----------------|---------------------|-------|
| 0x1A | 25                      | 0x50 | 0x0   | 0x0 | 0x4 | 80             | 400                 | -     |

## 22.9.2 PIOSC Specifications

Table 22-15. PIOSC Clock Characteristics

| Parameter          | Parameter Name                                                                                                                                                      | Min | Nom | Max              | Unit |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|-----|------------------|------|
| F <sub>PIOSC</sub> | Factory calibration:<br>Internal 16-MHz precision oscillator frequency variance across the specified voltage and temperature range when factory calibration is used | -   | -   | ±3%              | -    |
|                    | Recalibration:<br>Internal 16-MHz precision oscillator frequency variance when 7-bit recalibration is used                                                          | -   | -   | ±1% <sup>a</sup> | -    |
| T <sub>START</sub> | PIOSC startup time <sup>b</sup>                                                                                                                                     | -   | -   | 1                | µs   |

a. ±1% is only guaranteed at the specific voltage/temperature condition where the recalibration occurs.

b. PIOSC startup time is part of reset and is included in the internal reset timeout value (T<sub>IRTOU</sub>) given in Table 22-11 on page 1172. Note that the T<sub>START</sub> value is based on simulation.

## 22.9.3 Low-Frequency Internal Oscillator (LFIOSC) Specifications

Table 22-16. Low-Frequency internal Oscillator Characteristics

| Parameter           | Parameter Name                                       | Min | Nom | Max | Unit |
|---------------------|------------------------------------------------------|-----|-----|-----|------|
| F <sub>LFIOSC</sub> | Low-frequency internal oscillator (LFIOSC) frequency | 10  | 33  | 90  | KHz  |

## 22.9.4 Hibernation Clock Source Specifications

Table 22-17. Hibernation Oscillator Input Characteristics

| Parameter                       | Parameter Name                                                                       | Min          | Nom | Max               | Unit |
|---------------------------------|--------------------------------------------------------------------------------------|--------------|-----|-------------------|------|
| F <sub>HIBLFIOSC</sub>          | Hibernation low frequency internal oscillator (HIB LFIOSC) frequency                 | 10           | 33  | 90                | KHz  |
| C <sub>1</sub> , C <sub>2</sub> | External load capacitance on XOSC0, XOSC1 pins <sup>a</sup>                          | 12           | -   | 24                | pF   |
| C <sub>PKG</sub>                | Device package stray shunt capacitance <sup>a</sup>                                  | -            | 0.5 | -                 | pF   |
| C <sub>PCB</sub>                | PCB stray shunt capacitance <sup>a</sup>                                             | -            | 0.5 | -                 | pF   |
| C <sub>0</sub>                  | Crystal shunt capacitance <sup>a</sup>                                               | -            | 3   | -                 | pF   |
| C <sub>SHUNT</sub>              | Total shunt capacitance <sup>a</sup>                                                 | -            | -   | 4                 | pF   |
| ESR                             | Crystal effective series resistance, OSCDRV = 0 <sup>b</sup>                         | -            | -   | 50                | kΩ   |
|                                 | Crystal effective series resistance, OSCDRV = 1 <sup>b</sup>                         | -            | -   | 75                | kΩ   |
| DL                              | Oscillator output drive level                                                        | -            | -   | 0.25              | µW   |
| T <sub>START</sub>              | Oscillator startup time, when using a crystal <sup>c</sup>                           | -            | 600 | 1500 <sup>d</sup> | ms   |
| V <sub>IH</sub> <sup>e</sup>    | CMOS input high level, when using an external oscillator with Supply > 3.3 V         | 2.64         | -   | -                 | V    |
|                                 | CMOS input high level, when using an external oscillator with 1.8 V ≤ Supply ≤ 3.3 V | 0.8 * Supply | -   | -                 | V    |

**Table 22-17. Hibernation Oscillator Input Characteristics (continued)**

| Parameter                | Parameter Name                                                                                                            | Min | Nom | Max                   | Unit |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------|-----|-----|-----------------------|------|
| $V_{IL}^e$               | CMOS input low level, when using an external oscillator with $1.8\text{ V} \leq \text{Supply} \leq 3.63\text{ V}$         | -   | -   | $0.2 * \text{Supply}$ | V    |
| $V_{HYS}^e$              | CMOS input buffer hysteresis, when using an external oscillator with $1.8\text{ V} \leq \text{Supply} \leq 3.63\text{ V}$ | 360 | 960 | 1390                  | mV   |
| DC <sub>HIBOSC_EXT</sub> | External clock reference duty cycle                                                                                       | 30  | -   | 70                    | %    |

- See information below table.
- Crystal ESR specified by crystal manufacturer.
- Oscillator startup time is specified from the time the oscillator is enabled to when it reaches a stable point of oscillation such that the internal clock is valid.
- Only valid for recommended supply conditions. Measured with OSCDRV bit set (high drive strength enabled, 24 pF).
- Specification is relative to the larger of  $V_{DD}$  or  $V_{BAT}$ .

The load capacitors added on the board,  $C_1$  and  $C_2$ , should be chosen such that the following equation is satisfied (see Table 22-17 on page 1176 for typical values).

- $C_L$  = load capacitance specified by crystal manufacturer
- $C_L = (C_1 * C_2) / (C_1 + C_2) + C_{PKG} + C_{PCB}$
- $C_{SHUNT} = C_{PKG} + C_{PCB} + C_0$  (total shunt capacitance seen across XOSC0, XOSC1)
- $C_{PKG}$ ,  $C_{PCB}$  as measured across the XOSC0, XOSC1 pins excluding the crystal
- Clear the OSCDRV bit in the **Hibernation Control (HIBCTL)** register for  $C_{1,2} \leq 18\text{ pF}$ ; set the OSCDRV bit for  $C_{1,2} > 18\text{ pF}$ .
- $C_0$  = Shunt capacitance of crystal specified by the crystal manufacturer

## 22.9.5 Main Oscillator Specifications

**Table 22-18. Main Oscillator Input Characteristics**

| Parameter   | Parameter Name                                             | Min            | Nom                | Max | Unit     |
|-------------|------------------------------------------------------------|----------------|--------------------|-----|----------|
| $F_{MOSC}$  | Parallel resonance frequency                               | 4 <sup>a</sup> | -                  | 25  | MHz      |
| $C_1, C_2$  | External load capacitance on OSC0, OSC1 pins <sup>b</sup>  | 10             | -                  | 24  | pF       |
| $C_{PKG}$   | Device package stray shunt capacitance <sup>b</sup>        | -              | 0.5                | -   | pF       |
| $C_{PCB}$   | PCB stray shunt capacitance <sup>b</sup>                   | -              | 0.5                | -   | pF       |
| $C_0$       | Crystal shunt capacitance <sup>bc</sup>                    | -              | 4                  | -   | pF       |
| $C_{SHUNT}$ | Total shunt capacitance <sup>b</sup>                       | -              | -                  | 4   | pF       |
| ESR         | Crystal effective series resistance, 4 MHz <sup>dc</sup>   | -              | -                  | 300 | $\Omega$ |
|             | Crystal effective series resistance, 6 MHz <sup>dc</sup>   | -              | -                  | 200 | $\Omega$ |
|             | Crystal effective series resistance, 8 MHz <sup>dc</sup>   | -              | -                  | 130 | $\Omega$ |
|             | Crystal effective series resistance, 12 MHz <sup>dc</sup>  | -              | -                  | 120 | $\Omega$ |
|             | Crystal effective series resistance, 16 MHz <sup>dc</sup>  | -              | -                  | 100 | $\Omega$ |
|             | Crystal effective series resistance, 25 MHz <sup>dc</sup>  | -              | -                  | 50  | $\Omega$ |
| DL          | Oscillator output drive level <sup>e</sup>                 | -              | OSC <sub>PWR</sub> | -   | mW       |
| $T_{START}$ | Oscillator startup time, when using a crystal <sup>f</sup> | -              | -                  | 18  | ms       |

**Table 22-18. Main Oscillator Input Characteristics (continued)**

| Parameter             | Parameter Name                                                  | Min                    | Nom | Max                    | Unit |
|-----------------------|-----------------------------------------------------------------|------------------------|-----|------------------------|------|
| V <sub>IH</sub>       | CMOS input high level, when using an external oscillator        | 0.65 * V <sub>DD</sub> | -   | V <sub>DD</sub>        | V    |
| V <sub>IL</sub>       | CMOS input low level, when using an external oscillator         | GND                    | -   | 0.35 * V <sub>DD</sub> | V    |
| V <sub>HYS</sub>      | CMOS input buffer hysteresis, when using an external oscillator | 150                    | -   | -                      | mV   |
| DC <sub>OSC_EXT</sub> | External clock reference duty cycle                             | 45                     | -   | 55                     | %    |

- a. 5 MHz is the minimum when using the PLL.
- b. See information below table.
- c. Crystal vendors can be contacted to confirm these specifications are met for a specific crystal part number if the vendors generic crystal datasheet show limits outside of these specifications.
- d. Crystal ESR specified by crystal manufacturer.
- e.  $OSC_{PWR} = (2 * \pi * F_P * C_L * 2.5)^2 * ESR / 2$ . An estimation of the typical power delivered to the crystal is based on the C<sub>L</sub>, F<sub>P</sub> and ESR parameters of the crystal in the circuit as calculated by the OSC<sub>PWR</sub> equation. Ensure that the value calculated for OSC<sub>PWR</sub> does not exceed the crystal's drive-level maximum.
- f. Oscillator startup time is specified from the time the oscillator is enabled to when it reaches a stable point of oscillation such that the internal clock is valid.

The load capacitors added on the board, C<sub>1</sub> and C<sub>2</sub>, should be chosen such that the following equation is satisfied (see Table 22-18 on page 1177 for typical values and Table 22-19 on page 1179 for detailed crystal parameter information).

- C<sub>L</sub> = load capacitance specified by crystal manufacturer
- $C_L = (C_1 * C_2) / (C_1 + C_2) + C_{SHUNT}$
- C<sub>SHUNT</sub> = C<sub>0</sub> + C<sub>PKG</sub> + C<sub>PCB</sub> (total shunt capacitance seen across OSC0, OSC1 crystal inputs)
- C<sub>PKG</sub>, C<sub>PCB</sub> = the mutual caps as measured across the OSC0, OSC1 pins excluding the crystal.
- C<sub>0</sub> = Shunt capacitance of crystal specified by the crystal manufacturer

Table 22-19 on page 1179 lists part numbers of crystals that have been simulated and confirmed to operate within the specifications in Table 22-18 on page 1177. Other crystals that have nearly identical crystal parameters can be expected to work as well.

In the table below, the crystal parameters labeled C0, C1 and L1 are values that are obtained from the crystal manufacturer. These numbers are usually a result of testing a relevant batch of crystals on a network analyzer. The parameters labeled ESR, DL and C<sub>L</sub> are maximum numbers usually available in the data sheet for a crystal.

The table also includes three columns of Recommended Component Values. These values apply to system board components. C<sub>1</sub> and C<sub>2</sub> are the values in pico Farads of the load capacitors that should be put on each leg of the crystal pins to ensure oscillation at the correct frequency. Rs is the value in kΩ of a resistor that is placed in series with the crystal between the OSC1 pin and the crystal pin. Rs dissipates some of the power so the Max DI crystal parameter is not exceeded. Only use the recommended C<sub>1</sub>, C<sub>2</sub>, and Rs values with the associated crystal part. The values in the table were used in the simulation to ensure crystal startup and to determine the worst case drive level (WC DI). The value in the WC DI column should not be greater than the Max DI Crystal parameter. The WC DI value can be used to determine if a crystal with similar parameter values but a lower Max DI value is acceptable.

Table 22-19. Crystal Parameters

| MFG  | MFG Part#                          | Holder   | PKG Size<br>(mm x mm) | Freq (MHz) | Crystal Spec | Crystal Parameters  |                     |                     |            |             |                     | Recommended<br>Component<br>Values |                     |                     | WC DI (µW) |
|------|------------------------------------|----------|-----------------------|------------|--------------|---------------------|---------------------|---------------------|------------|-------------|---------------------|------------------------------------|---------------------|---------------------|------------|

| 0x14     | 14.31818 MHz                              |                                       |
| 0x15     | 16.0 MHz (reset value)(USB)               |                                       |
| 0x16     | 16.384 MHz                                |                                       |
| 0x17     | 18.0 MHz (USB)                            |                                       |
| 0x18     | 20.0 MHz (USB)                            |                                       |
| 0x19     | 24.0 MHz (USB)                            |                                       |
| 0x1A     | 25.0 MHz (USB)                            |                                       |

a. Frequencies that may be used with the USB interface are indicated in the table.

## 22.9.6 System Clock Specification with ADC Operation

Table 22-21. System Clock Characteristics with ADC Operation

| Parameter           | Parameter Name                                                                               | Min     | Nom | Max     | Unit |
|---------------------|----------------------------------------------------------------------------------------------|---------|-----|---------|------|
| F <sub>sysadc</sub> | System clock frequency when the ADC module is operating (when PLL is bypassed). <sup>a</sup> | 15.9952 | 16  | 16.0048 | MHz  |

a. Clock frequency (plus jitter) must be stable inside specified range. ADC can be clocked from the PLL, directly from an external clock source, or from the PIOSC, as long as frequency absolute precision is inside specified range.

## 22.9.7 System Clock Specification with USB Operation

Table 22-22. System Clock Characteristics with USB Operation

| Parameter           | Parameter Name                                                                                                                          | Min | Nom | Max | Unit |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------|-----|-----|-----|------|
| F <sub>sysusb</sub> | System clock frequency when the USB module is operating (note that MOSC must be the clock source, either with or without using the PLL) | 20  | -   | -   | MHz  |

## 22.10 Sleep Modes

**Table 22-23. Sleep Modes AC Characteristics<sup>a</sup>**

| Parameter No | Parameter                | Parameter Name                                                                                                         | Min | Nom  | Max                | Unit          |
|--------------|--------------------------|------------------------------------------------------------------------------------------------------------------------|-----|------|--------------------|---------------|
| D1           | T <sub>WAKE_S</sub>      | Time to wake from interrupt in sleep mode <sup>b</sup>                                                                 | -   | -    | 2                  | system clocks |
|              | T <sub>WAKE_DS</sub>     | Time to wake from interrupt in deep-sleep mode, using PIOSC for both Run mode and Deep-sleep mode <sup>b c</sup>       | -   | 1.25 | -                  | μs            |
|              |                          | Time to wake from interrupt in deep-sleep mode, using PIOSC for Run mode and LFIOSC for Deep-sleep mode <sup>b c</sup> | -   | 350  | -                  | μs            |
| D2           | T <sub>WAKE_PLL_DS</sub> | Time to wake from interrupt in deep-sleep mode when using the PLL <sup>b</sup>                                         | -   | -    | T <sub>READY</sub> | ms            |

a. Values in this table assume the LFIOSC is the clock source during sleep or deep-sleep mode.

b. Specified from registering the interrupt to first instruction.

c. If the main oscillator is used for run mode, add the main oscillator startup time, T<sub>START</sub>.

**Table 22-24. Time to Wake with Respect to Low-Power Modes<sup>ab</sup>**

| Mode  | Run Mode Clock/Frequency | Sleep/Deep-Sleep Mode Clock/Frequency | FLASHPM | SRAMPM | Time to Wake |        | Unit |
|-------|--------------------------|---------------------------------------|---------|--------|--------------|--------|------|
|       |                          |                                       |         |        | Min          | Max    |      |
| Sleep | MOSC, PLL on - 80MHz     | MOSC, PLL on - 80MHz                  | 0x0     | 0x0    | 0.28         | 0.30   | μs   |
|       |                          |                                       |         | 0x1    | 33.57        | 35.00  | μs   |
|       |                          |                                       |         | 0x3    | 33.75        | 35.05  | μs   |
|       |                          |                                       | 0x2     | 0x0    | 105.02       | 109.23 | μs   |
|       |                          |                                       |         | 0x1    | 137.85       | 143.93 | μs   |
|       |                          |                                       |         | 0x3    | 138.06       | 143.86 | μs   |

Table 22-24. Time to Wake with Respect to Low-Power Modes (continued)

| Mode       | Run Mode Clock/Frequency | Sleep/Deep-Sleep Mode Clock/Frequency  | FLASHPM | SRAMPM | Time to Wake |        | Unit |
|------------|--------------------------|----------------------------------------|---------|--------|--------------|--------|------|
|            |                          |                                        |         |        | Min          | Max    |      |
| Deep-Sleep | MOSC, PLL on - 80MHz     | PIOSC - 16MHz                          | 0x0     | 0x0    | 2.47         | 2.60   | µs   |
|            |                          |                                        |         | 0x1    | 35.31        | 36.35  | µs   |
|            |                          |                                        |         | 0x3    | 35.40        | 36.76  | µs   |
|            |                          |                                        | 0x2     | 0x0    | 107.05       | 111.54 | µs   |
|            |                          |                                        |         | 0x1    | 139.34       | 145.64 | µs   |
|            |                          |                                        |         | 0x3    | 140.41       | 145.53 | µs   |
|            | PIOSC - 16MHz            | PIOSC - 16MHz                          | 0x0     | 0x0    | 2.47         | 2.61   | µs   |
|            |                          |                                        |         | 0x1    | 35.25        | 36.65  | µs   |
|            |                          |                                        |         | 0x3    | 35.38        | 36.79  | µs   |
|            |                          |                                        | 0x2     | 0x0    | 107.43       | 111.52 | µs   |
|            |                          |                                        |         | 0x1    | 139.83       | 145.85 | µs   |
|            |                          |                                        |         | 0x3    | 139.35       | 145.54 | µs   |
|            | PIOSC - 16MHz            | LFIOSC, PIOSC off <sup>c</sup> - 30kHz | 0x0     | 0x0    | 415.06       | 728.38 | µs   |
|            |                          |                                        |         | 0x1    | 436.60       | 740.88 | µs   |
|            |                          |                                        |         | 0x3    | 433.80       | 755.32 | µs   |
|            |                          |                                        | 0x2     | 0x0    | 503.73       | 812.82 | µs   |

|            |                          |                                        |         | 0x3    | 536.10       | 839.25 | µs   |
|            | MOSC, PLL on - 80MHz     | LFIOSC, PIOSC off <sup>c</sup> - 30kHz | 0x0     | 0x0    | 18.95        | 19.55  | ms   |
|            |                          |                                        |         | 0x1    | 18.94        | 19.54  | ms   |
|            |                          |                                        |         | 0x3    | 18.95        | 19.53  | ms   |
|            |                          |                                        | 0x2     | 0x0    | 18.95        | 19.54  | ms   |
|            |                          |                                        |         | 0x1    | 18.94        | 19.53  | ms   |
|            |                          |                                        |         | 0x3    | 18.95        | 19.54  | ms   |

a. Time from wake event to first instruction of code execution.

b. If the LDO voltage is adjusted, it will take an extra 4 us to wake up from Sleep or Deep-sleep mode.

c. PIOSC is turned off by setting the `PIOSCPD` bit in the `DSLPCCLKCFG` register.

## 22.11 Hibernation Module

The Hibernation module requires special system implementation considerations because it is intended to power down all other sections of its host device, refer to “Hibernation Module” on page 467.

**Table 22-25. Hibernation Module Battery Characteristics**

| Parameter                        | Parameter Name                                    | Min | Nominal | Max              | Unit |
|----------------------------------|---------------------------------------------------|-----|---------|------------------|------|
| V <sub>BAT</sub>                 | Battery supply voltage                            | 1.8 | 3.0     | 3.6 <sup>a</sup> | V    |
| V <sub>BATRMP</sub> <sup>b</sup> | V <sub>BAT</sub> battery supply voltage ramp time | 0   | -       | 0.7              | V/μs |
| V <sub>LOWBAT</sub>              | Low battery detect voltage, VBATSEL=0x0           | 1.8 | 1.9     | 2.0              | V    |
|                                  | Low battery detect voltage, VBATSEL=0x1           | 2.0 | 2.1     | 2.2              | V    |
|                                  | Low battery detect voltage, VBATSEL=0x2           | 2.2 | 2.3     | 2.4              | V    |
|                                  | Low battery detect voltage, VBATSEL=0x3           | 2.4 | 2.5     | 2.6              | V    |

a. To ensure proper functionality, any voltage input within the range of  $3.6\text{ V} < \text{VBAT} \leq 4\text{ V}$  must be connected through a diode.

b. For recommended V<sub>BAT</sub> RC circuit values, refer to the diagrams located in “Hibernation Clock Source” on page 470.

**Table 22-26. Hibernation Module AC Characteristics**

| Parameter No | Parameter                | Parameter Name                                                                     | Min | Nom                                        | Max | Unit                     |
|--------------|--------------------------|------------------------------------------------------------------------------------|-----|--------------------------------------------|-----|--------------------------|
| H1           | T <sub>WAKE</sub>        | $\overline{\text{WAKE}}$ assertion time                                            | 100 | -                                          | -   | ns                       |
| H2           | T <sub>WAKE_TO_HIB</sub> | $\overline{\text{WAKE}}$ assert to $\overline{\text{HIB}}$ deassert (wake up time) | -   | -                                          | 1   | hibernation clock period |
| H3           | T <sub>VDD_RAMP</sub>    | V <sub>DD</sub> ramp to 3.0 V                                                      | -   | Depends on characteristics of power supply | -   | μs                       |
| H4           | T <sub>VDD_CODE</sub>    | V <sub>DD</sub> at 3.0 V to internal POR deassert; first instruction executes      | -   | -                                          | 500 | μs                       |

**Figure 22-15. Hibernation Module Timing**

## 22.12 Flash Memory and EEPROM

**Table 22-27. Flash Memory Characteristics**

| Parameter           | Parameter Name                                                    | Min     | Nom | Max  | Unit   |
|---------------------|-------------------------------------------------------------------|---------|-----|------|--------|
| PE <sub>CYC</sub>   | Number of program/erase cycles before failure <sup>a</sup>        | 100,000 | -   | -    | cycles |
| T <sub>RET</sub>    | Data retention, -40°C to +85°C                                    | 20      | -   | -    | years  |
| T <sub>PROG64</sub> | Program time for double-word-aligned 64 bits of data <sup>b</sup> | 30      | 50  | 300  | μs     |
| T <sub>ERASE</sub>  | Page erase time, <1k cycles                                       | -       | 8   | 15   | ms     |
|                     | Page erase time, 10k cycles                                       | -       | 15  | 40   | ms     |
|                     | Page erase time, 100k cycles                                      | -       | 75  | 500  | ms     |
| T <sub>ME</sub>     | Mass erase time, <1k cycles                                       | -       | 10  | 25   | ms     |
|                     | Mass erase time, 10k cycles                                       | -       | 20  | 70   | ms     |
|                     | Mass erase time, 100k cycles                                      | -       | 300 | 2500 | ms     |

a. A program/erase cycle is defined as switching the bits from 1-> 0 -> 1.

b. If programming fewer than 64 bits of data, the programming time is the same. For example, if only 32 bits of data need to be programmed, the other 32 bits are masked off.

**Table 22-28. EEPROM Characteristics<sup>a</sup>**

| Parameter                       | Parameter Name                                                                                                                                     | Min     | Nom | Max  | Unit          |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|---------|-----|------|---------------|
| EPE <sub>CYC</sub> <sup>b</sup> | Number of mass program/erase cycles of a single word before failure <sup>c</sup>                                                                   | 500,000 | -   | -    | cycles        |
| ET <sub>RET</sub>               | Data retention, -40°C to +85°C                                                                                                                     | 20      | -   | -    | years         |
| ET <sub>PROG</sub>              | Program time for 32 bits of data - space available                                                                                                 | -       | 110 | 600  | μs            |
|                                 | Program time for 32 bits of data - requires a copy to the copy buffer, copy buffer has space and less than 10% of EEPROM endurance used            | -       | 30  | -    | ms            |
|                                 | Program time for 32 bits of data - requires a copy to the copy buffer, copy buffer has space and greater than 90% of EEPROM endurance used         | -       | -   | 900  | ms            |
|                                 | Program time for 32 bits of data - requires a copy to the copy buffer, copy buffer requires an erase and less than 10% of EEPROM endurance used    | -       | 60  | -    | ms            |
|                                 | Program time for 32 bits of data - requires a copy to the copy buffer, copy buffer requires an erase and greater than 90% of EEPROM endurance used | -       | -   | 1800 | ms            |
| ET <sub>READ</sub>              | Read access time                                                                                                                                   | -       | 4   | -    | system clocks |
| ET <sub>ME</sub>                | Mass erase time, <1k cycles                                                                                                                        | -       | 8   | 15   | ms            |
|                                 | Mass erase time, 10k cycles                                                                                                                        | -       | 15  | 40   | ms            |
|                                 | Mass erase time, 100k cycles                                                                                                                       | -       | 75  | 500  | ms            |

a. Because the EEPROM operates as a background task and does not prevent the CPU from executing from Flash memory, the operation will complete within the maximum time specified provided the EEPROM operation is not stalled by a Flash memory program or erase operation.

b. One word can be written more than 500K times, but these writes impact the endurance of the words in the meta-block that the word is within. Different words can be written such that any or all words can be written more than 500K times when write counts per word stay about the same. See the section called "Endurance" on page 512 for more information.

c. A program/erase cycle is defined as switching the bits from 1-> 0 -> 1.

## 22.13 Input/Output Pin Characteristics

### 22.13.1 GPIO Module Characteristics

**Note:** All GPIO signals are 5-V tolerant when configured as inputs except for PD4, PD5, PB0 and PB1, which are limited to 3.6 V. See “Signal Description” on page 621 for more information on GPIO configuration.

**Note:** GPIO pads are tolerant to 5-V digital inputs without creating reliability issues, as long as the supply voltage, VDD, is present. There are limitations to how long a 5-V input can be present on any given I/O pad if VDD is not present. Not meeting these conditions will affect reliability of the device and affect the GPIO characteristics specifications.

- If the voltage applied to a GPIO pad is in the high voltage range (5V +/- 10%) while VDD is not present, such condition should be allowed for a maximum of 10,000 hours at 27°C or 5,000 hours at 85°C, over the lifetime of the device.
- If the voltage applied to a GPIO pad is in the normal voltage range (3.3V +/- 10%) while VDD is not present or if the voltage applied is in the high voltage range (5V +/- 10%) while VDD is present, there are no constraints on the lifetime of the device.

**Table 22-29. GPIO Module Characteristics<sup>a</sup>**

| Parameter          | Parameter Name                                                                                                                | Min | Nom  | Max  | Unit |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------|-----|------|------|------|
| R <sub>GPIOU</sub> | GPIO internal pull-up resistor                                                                                                | 13  | 20   | 30   | kΩ   |
| R <sub>GPIOD</sub> | GPIO internal pull-down resistor                                                                                              | 13  | 20   | 35   | kΩ   |
| I <sub>LKG+</sub>  | GPIO input leakage current, 0 V ≤ V <sub>IN</sub> ≤ V <sub>DD</sub> GPIO pins <sup>b</sup>                                    | -   | -    | 1.0  | μA   |
|                    | GPIO input leakage current, 0 V < V <sub>IN</sub> ≤ V <sub>DD</sub> , GPIO pins configured as ADC or analog comparator inputs | -   | -    | 2.0  | μA   |
| T <sub>GPIOR</sub> | GPIO rise time, 2-mA drive <sup>c</sup>                                                                                       | -   | 14.2 | 16.1 | ns   |
|                    | GPIO rise time, 4-mA drive <sup>c</sup>                                                                                       |     | 11.9 | 15.5 | ns   |
|                    | GPIO rise time, 8-mA drive <sup>c</sup>                                                                                       |     | 8.1  | 11.2 | ns   |
|                    | GPIO rise time, 8-mA drive with slew rate control <sup>c</sup>                                                                |     | 9.5  | 11.8 | ns   |
| T <sub>GPIOF</sub> | GPIO fall time, 2-mA drive <sup>d</sup>                                                                                       | -   | 25.2 | 29.4 | ns   |
|                    | GPIO fall time, 4-mA drive <sup>d</sup>                                                                                       |     | 13.3 | 16.8 | ns   |
|                    | GPIO fall time, 8-mA drive <sup>d</sup>                                                                                       |     | 8.6  | 11.2 | ns   |
|                    | GPIO fall time, 8-mA drive with slew rate control <sup>d</sup>                                                                |     | 11.3 | 12.9 | ns   |

a. V<sub>DD</sub> must be within the range specified in Table 22-5 on page 1162.

b. The leakage current is measured with V<sub>IN</sub> applied to the corresponding pin(s). The leakage of digital port pins is measured individually. The port pin is configured as an input and the pull-up/pull-down resistor is disabled.

c. Time measured from 20% to 80% of V<sub>DD</sub>.

d. Time measured from 80% to 20% of V<sub>DD</sub>.

### 22.13.2 Types of I/O Pins and ESD Protection

With respect to ESD and leakage current, three types of I/O pins exist on the device: Power I/O pins, I/O pins with fail-safe ESD protection (GPIOs other than PD4 and PD5, and XOSCn pins) and I/O pins with non-fail-safe ESD protection (any non-power, non-GPIO (other than PD4 and PD5) and non-XOSCn pins). This section covers I/O pins with fail-safe ESD protection and I/O pins with

non-fail-safe ESD protection. Power I/O pin voltage and current limitations are specified in “Recommended Operating Conditions” on page 1162.

### 22.13.2.1 Fail-Safe Pins

GPIOs other than PD4 and PD5, pins for the Hibernate 32-kHz oscillator (XOSCn), Hibernate input pins, and I/O pins for the USB PHY use ESD protection as shown in Figure 22-16 on page 1187.

An unpowered device cannot be parasitically powered through any of these pins. This ESD protection prevents a direct path between these I/O pads and any power supply rails in the device. GPIO/XOSCn pad input voltages should be kept inside the maximum ratings specified in Table 22-1 on page 1160 to ensure current leakage and current injections are within acceptable range. Current leakages and current injection for these pins are specified in Table 22-29 on page 1186.

Figure 22-16 on page 1187 shows a diagram of the ESD protection on fail-safe pins.

Some GPIOs when configured as inputs require a strong pull-up resistor to maintain a threshold above the minimum value of  $V_{IH}$  during power-on. See Table 22-31 on page 1188.

**Figure 22-16. ESD Protection on Fail-Safe Pins**

**Table 22-30. Pad Voltage/Current Characteristics for Fail-Safe Pins<sup>a</sup>**

| Parameter  | Parameter Name                                                | Min | Nom | Max          | Unit    |
|------------|---------------------------------------------------------------|-----|-----|--------------|---------|
| $I_{LKG+}$ | GPIO input leakage current, $V_{DD} < V_{IN} \leq 4.5 V^{bb}$ | -   | -   | 700          | $\mu A$ |
|            | GPIO input leakage current, $4.5 V < V_{IN} \leq 5.5 V^{bc}$  | -   | -   | 100          | $\mu A$ |
| $I_{LKG-}$ | GPIO input leakage current, $V_{IN} < -0.3 V^{bd}$            | -   | -   | <sup>e</sup> | $\mu A$ |
|            | GPIO input leakage current, $-0.3 V \leq V_{IN} < 0 V^b$      | -   | -   | 10           | $\mu A$ |
| $I_{INJ+}$ | DC injection current, $V_{DD} < V_{IN} \leq 5.5 V^{fg}$       | -   | -   | $I_{LKG+}$   | $\mu A$ |
| $I_{INJ-}$ | DC injection current, $V_{IN} \leq 0 V^g$                     | -   | -   | 0.5          | mA      |

- VIN must be within the range specified in Table 22-1 on page 1160.
- To protect internal circuitry from over-voltage, the GPIOs have an internal voltage clamp that limits internal swings to  $V_{DD}$  without affecting swing at the I/O pad. This internal clamp starts turning on while  $V_{DD} < V_{IN} < 4.5 V$  and causes a somewhat larger (but bounded) current draw. To save power, static input voltages between  $V_{DD}$  and 4.5 V should be avoided.
- Leakage current above maximum voltage ( $V_{IN} = 5.5 V$ ) is not guaranteed, this condition is not allowed and can result in permanent damage to the device.
- Leakage outside the minimum range (-0.3V) is unbounded and must be limited to  $I_{INJ-}$  using an external resistor.
- In this case,  $I_{LKG-}$  is unbounded and must be limited to  $I_{INJ-}$  using an external resistor.
- Current injection is internally bounded for GPIOs, and maximum current into the pin is given by  $I_{LKG+}$  for  $V_{DD} < V_{IN} < 5.5 V$ .

g. If the I/O pad is not voltage limited, it should be current limited (to IINJ+ and IINJ-) if there is any possibility of the pad voltage exceeding the VIO limits (including transient behavior during supply ramp up, or at any time when the part is unpowered).

**Table 22-31. Fail-Safe GPIOs that Require an External Pull-up**

| GPIO | Pin | Pull-Up Resistor Value | Unit     |
|------|-----|------------------------|----------|
| PB0  | 45  | $1k \leq R \leq 10k$   | $\Omega$ |
| PB1  | 46  | $1k \leq R \leq 10k$   | $\Omega$ |
| PE3  | 6   | $1k \leq R \leq 10k$   | $\Omega$ |

**22.13.2.2 Non-Fail-Safe Pins**

The Main Oscillator (MOSC) crystal connection pins and GPIO pins PD4 and PD5 have ESD protection as shown in Figure 22-17 on page 1188. These pins have a potential path between the I/O pad and an internal power rail if either one of the ESD diodes is accidentally forward biased. The voltage and current of these pins should follow the specifications in Table 22-32 on page 1188 to prevent potential damage to the device. In addition to the specifications outlined in Table 22-32 on page 1188, it is recommended that the ADC external reference specifications in Table 22-33 on page 1190 be adhered to in order to prevent any gain error.

Figure 22-17 on page 1188 shows a diagram of the ESD protection on non-fail-safe pins.

**Figure 22-17. ESD Protection on Non-Fail-Safe Pins**

**Table 22-32. Non-Fail-Safe I/O Pad Voltage/Current Characteristics<sup>abcd</sup>**

| Parameter         | Parameter Name                                               | Min  | Nom             | Max                  | Unit    |
|-------------------|--------------------------------------------------------------|------|-----------------|----------------------|---------|
| V <sub>IO</sub>   | IO pad voltage limits                                        | -0.3 | V <sub>DD</sub> | V <sub>DD</sub> +0.3 | V       |
| I <sub>LKG+</sub> | Positive IO leakage for V <sub>IO</sub> Max <sup>ef</sup>    | -    | -               | 10                   | $\mu$ A |
| I <sub>LKG-</sub> | Negative IO leakage for V <sub>IO</sub> Min <sup>ef</sup>    | -    | -               | 10                   | $\mu$ A |
| I <sub>INJ+</sub> | Max positive injection <sup>g</sup>                          | -    | -               | 2                    | mA      |
| I <sub>INJ-</sub> | Max negative injection if not voltage protected <sup>g</sup> | -    | -               | -0.5                 | mA      |

- a. V<sub>IN</sub> must be within the range specified in Table 22-1 on page 1160. Leakage current outside of this maximum voltage is not guaranteed and can result in permanent damage of the device.
- b. V<sub>DD</sub> must be within the range specified in Table 22-5 on page 1162.
- c. To avoid potential damage to the part, either the voltage or current on the ESD-protected, non-Power, non-Hibernate/XOSC input/outputs should be limited externally as shown in this table.

- d. I/O pads should be protected if at any point the IO voltage has a possibility of going outside the limits shown in the table. If the part is unpowered, the IO pad Voltage or Current must be limited (as shown in this table) to avoid powering the part through the IO pad, causing potential irreversible damage.
- e. This value applies to an I/O pin that is voltage-protected within the Min and Max  $V_{IO}$  ratings. Leakage outside the specified voltage range is unbounded and must be limited to  $I_{INJ}$  using an external resistor.
- f. MIN and MAX leakage current for the case when the I/O is voltage-protected to VIO Min or VIO Max.
- g. If an I/O pin is not voltage-limited, it should be current-limited (to  $I_{INJ+}$  and  $I_{INJ-}$ ) if there is any possibility of the pad voltage exceeding the  $V_{IO}$  limits (including transient behavior during supply ramp up, or at any time when the part is unpowered).

## 22.14 Analog-to-Digital Converter (ADC)

**Table 22-33. ADC Electrical Characteristics<sup>ab</sup>**

| Parameter                                              | Parameter Name                                                                                          | Min               | Nom                      | Max                                                  | Unit       |

| TEMPERATURE SENSOR |                                                                                                         |     |       |     |       |
| V <sub>TSENS</sub> | Temperature sensor voltage, junction temperature 25 °C                                                  | -   | 1.633 | -   | V     |
| S <sub>TSENS</sub> | Temperature sensor slope                                                                                | -   | -13.3 | -   | mV/°C |
| E <sub>TSENS</sub> | Temperature sensor accuracy <sup>v</sup>                                                                | -   | -     | ±5  | °C    |

- a. V<sub>REF+</sub> = 3.3V, F<sub>ADC</sub> = 16 MHz unless otherwise noted.
- b. Best design practices suggest that static or quiet digital I/O signals be configured adjacent to sensitive analog inputs to reduce capacitive coupling and cross talk. Analog signals configured adjacent to ADC input channels should meet the same source resistance and bandwidth limitations that apply to the ADC input signals.
- c. Two capacitors in parallel.
- d. Internal reference is connected directly between V<sub>DDA</sub> and GNDA (VREFi = V<sub>DDA</sub> - GNDA). In this mode, E<sub>O</sub>, E<sub>G</sub>, E<sub>T</sub>, and dynamic specifications are adversely affected due to internal voltage drop and noise on V<sub>DDA</sub> and GNDA.
- e. V<sub>ADCIN</sub> = V<sub>INP</sub> - V<sub>INN</sub>
- f. With signal common mode as V<sub>DDA</sub>/2.
- g. This parameter is defined as the average of the differential inputs.
- h. As shown in Figure 22-18 on page 1192, R<sub>ADC</sub> is the total equivalent resistance in the input line all the way up to the sampling node at the input of the ADC.
- i. See "System Clock Specification with ADC Operation" on page 1180 for full ADC clock frequency specification.
- j. ADC conversion time (T<sub>c</sub>) includes the ADC sample time (T<sub>s</sub>).
- k. 12-bit DNL
- l. Gain error is measured at max code after compensating for offset. Gain error is equivalent to "Full Scale Error." It can be given in % of slope error, or in LSB, as done here.
- m. Total Unadjusted Error is the maximum error at any one code versus the ideal ADC curve. It includes all other errors (offset error, gain error and INL) at any given ADC code.
- n. A low-noise environment is assumed in order to obtain values close to spec. The board must have good ground isolation between analog and digital grounds and a clean reference voltage. The input signal must be band-limited to Nyquist bandwidth. No anti-aliasing filter is provided internally.
- o. ADC dynamic characteristics are measured using low-noise board design, with low-noise reference voltage (< -74dB noise level in signal BW) and low-noise analog supply voltage. Board noise and ground bouncing couple into the ADC and affect dynamic characteristics. Clean external reference must be used to achieve shown specs.
- p. Differential signal with correct common mode, applied between two ADC inputs.
- q. SDR = -THD in dB.
- r. For higher frequency inputs, degradation in SDR should be expected.
- s. SNDR = S/(N+D) = SINAD (in dB)
- t. Effective number of bits (ENOB) can be calculated from SNDR: ENOB = (SNDR - 1.76) / 6.02.
- u. Single-ended inputs are more sensitive to board and trace noise than differential inputs; SNR and SNDR measurements on single-ended inputs are highly dependent on how clean the test set-up is. If the input signal is not well-isolated on the board, higher noise than specified could potentially be seen at the ADC output.
- v. Note that this parameter does not include ADC error.

| S8            | T <sub>RXDMS</sub>    | Master Mode: Master Rx Data In (from slave)<br>setup time                       | 17.15              | -   | -                  | ns   |
| S9            | T <sub>RXDMH</sub>    | Master Mode: Master Rx Data In (from slave) hold<br>time                        | 0                  | -   | -                  | ns   |
| S10           | T <sub>TXDSOV</sub>   | Slave Mode: Master Tx Data Output (to Master)<br>Valid Time from edge of SSIClk | -                  | -   | 77.74 <sup>d</sup> | ns   |
| S11           | T <sub>TXDSOH</sub>   | Slave Mode: Slave Tx Data Output (to Master)<br>Hold Time from next SSIClk      | 55.5 <sup>e</sup>  | -   | -                  | ns   |
| S12           | T <sub>RXDSSU</sub>   | Slave Mode: Rx Data In (from master) setup time                                 | 0                  | -   | -                  | ns   |
| S13           | T <sub>RXDSSH</sub>   | Slave Mode: Rx Data In (from master) hold time                                  | 51.55 <sup>f</sup> | -   | -                  | ns   |

a. In master mode, the system clock must be at least twice as fast as the SSIClk.

b. In slave mode, the system clock must be at least 12 times faster than the SSIClk.

c. Note that the delays shown are using 8-mA drive strength.

d. This MAX value is for the minimum T<sub>SYSClk</sub> (12.5 ns). To find the MAX T<sub>TXDSOV</sub> value for a larger T<sub>SYSClk</sub>, use the equation: 4\*T<sub>SYSClk</sub>+27.74.

e. This MIN value is for the minimum slave mode T<sub>SYSClk</sub> (12.5 ns). To find the MIN T<sub>TXDSOH</sub> value for a larger T<sub>SYSClk</sub>, use the equation: 4\*T<sub>SYSClk</sub>+5.50.

f. This MIN value is for the minimum slave mode T<sub>SYSClk</sub> (12.5 ns). To find the MIN T<sub>RXDSSH</sub> value for a larger T<sub>SYSClk</sub>, use the equation: 4\*T<sub>SYSClk</sub>+1.55.

| I5 <sup>c</sup> | T <sub>SFT</sub>  | I <sup>2</sup> C <sub>SCL</sub> /I <sup>2</sup> C <sub>SDA</sub> fall time (V <sub>IH</sub> = 2.4 V to V <sub>IL</sub> = 0.5 V) | -   | 9                   | 10           | ns            |
| I6 <sup>a</sup> | T <sub>HT</sub>   | Clock High time                                                                                                                 | 24  | -                   | -            | system clocks |
| I7              | T <sub>DS</sub>   | Data setup time                                                                                                                 | 18  | -                   | -            | system clocks |
| I8 <sup>a</sup> | T <sub>SCSR</sub> | Start condition setup time (for repeated start condition only)                                                                  | 36  | -                   | -            | system clocks |
| I9 <sup>a</sup> | T <sub>SCS</sub>  | Stop condition setup time                                                                                                       | 24  | -                   | -            | system clocks |
| I10             | T <sub>DV</sub>   | Data Valid (slave)                                                                                                              | -   | 2                   | -            | system clocks |
|                 |                   | Data Valid (master)                                                                                                             | -   | (6 * (1 + TPR)) + 1 | -            | system clocks |

- a. Values depend on the value programmed into the TPR bit in the I<sup>2</sup>C Master Timer Period (I2CMTPR) register; a TPR programmed for the maximum I<sup>2</sup>C<sub>SCL</sub> frequency (TPR=0x2) results in a minimum output timing as shown in the table above. The I<sup>2</sup>C interface is designed to scale the actual data transition time to move it to the middle of the I<sup>2</sup>C<sub>SCL</sub> Low period. The actual position is affected by the value programmed into the TPR; however, the numbers given in the above values are minimum values.
- b. Because I<sup>2</sup>C<sub>SCL</sub> and I<sup>2</sup>C<sub>SDA</sub> operate as open-drain-type signals, which the controller can only actively drive Low, the time I<sup>2</sup>C<sub>SCL</sub> or I<sup>2</sup>C<sub>SDA</sub> takes to reach a high level depends on external signal capacitance and pull-up resistor values.
- c. Specified at a nominal 50 pF load.

Figure 22-23. I<sup>2</sup>C Timing

## 22.17 Universal Serial Bus (USB) Controller

The TM4C1233C3PM USB controller electrical specifications are compliant with the *Universal Serial Bus Specification Rev. 2.0* (full-speed and low-speed support). Some components of the USB system are integrated within the TM4C1233C3PM microcontroller and specific to the TM4C1233C3PM microcontroller design.

## 22.18 Analog Comparator

**Table 22-36. Analog Comparator Characteristics<sup>ab</sup>**

| Parameter          | Parameter Name                                | Min              | Nom | Max              | Unit |
|--------------------|-----------------------------------------------|------------------|-----|------------------|------|
| $V_{INP}, V_{INN}$ | Input voltage range                           | GND <sub>A</sub> | -   | $V_{DDA}$        | V    |
| $V_{CM}$           | Input common mode voltage range               | GND <sub>A</sub> | -   | $V_{DDA}$        | V    |
| $V_{OS}$           | Input offset voltage                          | -                | ±10 | ±50 <sup>d</sup> | mV   |
| $I_{INP}, I_{INN}$ | Input leakage current over full voltage range | -                | -   | 2.0              | µA   |
| $C_{MRR}$          | Common mode rejection ratio                   | -                | 50  | -                | dB   |
| $T_{RT}$           | Response time                                 | -                | -   | 1.0 <sup>e</sup> | µs   |
| $T_{MC}$           | Comparator mode change to Output Valid        | -                | -   | 10               | µs   |

- a. Best design practices suggest that static or quiet digital I/O signals be configured adjacent to sensitive analog inputs to reduce capacitive coupling and cross talk.
- b. To achieve best analog results, the source resistance driving the analog inputs,  $V_{INP}$  and  $V_{INN}$ , should be kept low.
- c. The external voltage inputs to the Analog Comparator are designed to be highly sensitive and can be affected by external noise on the board. For this reason,  $V_{INP}$  and  $V_{INN}$  must be set to different voltage levels during idle states to ensure the analog comparator triggers are not enabled. If an internal voltage reference is used, it should be set to a mid-supply level. When operating in Sleep/Deep-Sleep modes, the Analog Comparator module external voltage inputs set to different levels (greater than the input offset voltage) to achieve minimum current draw.
- d. Measured at  $V_{REF}=100$  mV.
- e. Measured at external  $V_{REF}=100$  mV, input signal switching from 75 mV to 125 mV.

**Table 22-37. Analog Comparator Voltage Reference Characteristics**

| Parameter | Parameter Name               | Min | Nom             | Max          | Unit |
|-----------|------------------------------|-----|-----------------|--------------|------|
| $R_{HR}$  | Resolution in high range     | -   | $V_{DDA}/29.4$  | -            | V    |
| $R_{LR}$  | Resolution in low range      | -   | $V_{DDA}/22.12$ | -            | V    |
| $A_{HR}$  | Absolute accuracy high range | -   | -               | ± $R_{HR}/2$ | V    |
| $A_{LR}$  | Absolute accuracy low range  | -   | -               | ± $R_{LR}/2$ | V    |

a. The value for I<sub>DDA</sub> is included in the above values for I<sub>DD\_RUN</sub>, I<sub>DD\_SLEEP</sub>, and I<sub>DD\_DEEPSLEEP</sub>.

b. Note that if the MOSC is the source of the Run-mode system clock and is powered down in Sleep mode, wake time is increased by T<sub>MOSC\_SETTLE</sub>.

# A Package Information

## A.1 Orderable Devices

**Note:** See the Package Option Addendum for additional detail on orderable part numbers.

**Figure A-1. Key to Part Numbers**

**Table A-1. Orderable Part Numbers**

| Part Number    | Description                                                                                  |
|----------------|----------------------------------------------------------------------------------------------|
| TM4C1233C3PMI  | Tiva™ C Series TM4C1233C3PM Microcontroller Industrial Temperature 64-pin LQFP               |
| TM4C1233C3PMIR | Tiva™ C Series TM4C1233C3PM Microcontroller Industrial Temperature 64-pin LQFP Tape-and-reel |

## A.2 Part Markings

Tiva™ C Series microcontrollers are marked with an identifying number, as shown in the figure below.

This identifying number contains the following information:

- **Lines 1 and 5:** Internal tracking numbers
- **Lines 2 and 3:** Part number

For example, TM4C123G on the second line followed by E6PZI on the third line indicates orderable part number TM4C123GE6PZI. The first letter in the part number indicates the product status. A T indicates the part is fully qualified and released to production; an X indicates the part is experimental (pre-production) and requires a waiver. Pre-production parts also include a revision number in the part number, for example, XM4C123G followed by E6PZI5 indicates revision 5. Production parts do not include a revision number in the part number. Some devices also include an internal code after the temperature character field. The **DID0** register identifies the version of the microcontroller. The **MAJOR** and **MINOR** bit fields indicate the die revision number. Combined, the **MAJOR** and **MINOR** bit fields indicate the TM4C123x microcontroller part revision number.

| MAJOR Bitfield Value | MINOR Bitfield Value | Die Revision | Part Revision |
|----------------------|----------------------|--------------|---------------|
| 0x0                  | 0x0                  | A0           | 1             |
| 0x0                  | 0x1                  | A1           | 2             |
| 0x0                  | 0x2                  | A2           | 3             |
| 0x0                  | 0x3                  | A3           | 4             |
| 0x1                  | 0x0                  | B0           | 5             |
| 0x1                  | 0x1                  | B1           | 6             |
| 0x1                  | 0x2                  | B2           | 7             |

- **Line 4:** Date code

The first two characters on the fourth line indicate the date code, followed by internal tracking numbers. The two-digit date code YM indicates the last digit of the year, then the month. For example, a 34 for the first two digits of the fourth line indicates a date code of April 2013.

### MECHANICAL DATA

MTQF008A – JANUARY 1995 – REVISED DECEMBER 1996

PM (S-PQFP-G64)

PLASTIC QUAD FLATPACK

- NOTES:
- A. All linear dimensions are in millimeters.
  - B. This drawing is subject to change without notice.
  - C. Falls within JEDEC MS-026
  - D. May also be thermally enhanced plastic with leads connected to the die pads.

## A.4 Packaging Materials

(1) The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE:** TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

**TBD:** The Pb-Free/Green conversion plan has not been defined.

**Pb-Free (RoHS):** TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

**Pb-Free (RoHS Exempt):** This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

**Green (RoHS & no Sb/Br):** TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

**Important Information and Disclaimer:** The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

PM (S-PQFP-G64)

- NOTES: A. All linear dimensions are in millimeters.  
 B. This drawing is subject to change without notice.  
 C. Falls within JEDEC MS-026  
 D. May also be thermally enhanced plastic with leads connected to the die pads.

PM (S-PQFP-G64)

PLASTIC QUAD FLATPACK

- NOTES:
- A. All linear dimensions are in millimeters.
  - B. This drawing is subject to change without notice.
  - C. Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Example stencil design based on a 50% volumetric metal load solder paste. Refer to IPC-7525 for other stencil recommendations.
  - D. Customers should contact their board fabrication site for solder mask tolerances between and around signal pads.

## IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as "components") are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have **not** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
