## 1 GENERAL DESCRIPTION

The NuMicro M051™ series is a 32-bit microcontroller with embedded ARM® Cortex™-M0 core for industrial control and applications which need rich communication interfaces. The Cortex™-M0 is the newest ARM embedded processor with 32-bit performance and at a cost equivalent to traditional 8-bit microcontroller. The NuMicro M051™ series includes M052, M054, M058 and M0516 families.

The NuMicro M051™ series can run up to 50 MHz. Thus it can afford to support a variety of industrial control and applications which need high CPU performance. The NuMicro M051™ series has 8K/16K/32K/64K-byte embedded flash, 4K-byte data flash, 4K-byte flash for the ISP, and 4K-byte embedded SRAM.

Many system level peripheral functions, such as I/O Port, EBI (External Bus Interface), Timer, UART, SPI, I<sup>2</sup>C, PWM, ADC, Watchdog Timer and Brownout Detector, have been incorporated into the NuMicro M051™ series in order to reduce component count, board space and system cost. These useful functions make the NuMicro M051™ series powerful for a wide range of applications.

Additionally, the NuMicro M051™ series is equipped with ISP (In-System Programming) and ICP (In-Circuit Programming) functions, which allow the user to update the program memory without removing the chip from the actual end product.

## 2 FEATURES

- Core
  - ARM® Cortex™-M0 core runs up to 50 MHz.
  - One 24-bit system timer.
  - Supports low power sleep mode.
  - A single-cycle 32-bit hardware multiplier.
  - NVIC for the 32 interrupt inputs, each with 4-levels of priority.
  - Supports Serial Wire Debug (SWD) interface and 2 watchpoints/4 breakpoints.
- Built-in LDO for Wide Operating Voltage Range: 2.5V to 5.5V
- Memory
  - 8KB/16KB/32KB/64KB Flash memory for program memory (APROM)
  - 4KB Flash memory for data memory (DataFlash)
  - 4KB Flash memory for loader (LDROM)
  - 4KB SRAM for internal scratch-pad RAM (SRAM)
- Clock Control
  - Programmable system clock source
  - External 4~24 MHz high speed crystal input
  - Internal 22.1184 MHz high speed oscillator (trimmed to 1% accuracy)
  - Internal 10 kHz low speed oscillator for Watchdog Timer
  - PLL allows CPU operation up to the maximum 50MHz
- I/O Port
  - Up to 40 general-purpose I/O (GPIO) pins for LQFP-48 package
  - Four I/O modes:
    - ◆ Quasi bi-direction

# NuMicro M051™ Series Technical Reference Manual

- ◆ Push-Pull output
- ◆ Open-Drain output
- ◆ Input only with high impedance
- TTL/Schmitt trigger input selectable
- I/O pin can be configured as interrupt source with edge/level setting
- Supports high driver and high sink IO mode
- Timer
  - Provides four channel 32-bit timers, one 8-bit pre-scale counter with 24-bit up-timer for each timer.
  - Independent clock source for each timer.
  - 24-bit timer value is readable through TDR (Timer Data Register)
  - Provides one-shot, periodic and toggle operation modes.
- Watchdog Timer
  - Multiple clock sources
  - Supports wake-up from power down or idle mode
  - Interrupt or reset selectable on watchdog time-out
- PWM
  - Built-in up to four 16-bit PWM generators; providing eight PWM outputs or four complementary paired PWM outputs
  - Individual clock source, clock divider, 8-bit pre-scalar and dead-zone generator for each PWM generator
  - PWM interrupt synchronized to PWM period
  - 16-bit digital Capture timers (shared with PWM timers) with rising/falling capture inputs
  - Supports capture interrupt
- UART

# NuMicro M051™ Series Technical Reference Manual

- Up to two sets of UART device
- Programmable baud-rate generator
- Buffered receiver and transmitter, each with 15 bytes FIFO
- Optional flow control function (CTS and RTS)
- Supports IrDA(SIR) function
- Supports RS485 function
- SPI
  - Up to two sets of SPI device.
  - Supports master/slave mode
  - Master mode clock rate up to 20 MHz, and slave mode clock rate up to 10 MHz
  - Full duplex synchronous serial data transfer
  - Variable length of transfer data from 1 to 32 bits
  - MSB or LSB first data transfer
  - Rx latching data can be either at rising edge or at falling edge of serial clock
  - Tx sending data can be either at rising edge or at falling edge of serial clock
  - Supports Byte suspend mode in 32-bit transmission
- I<sup>2</sup>C
  - Supports master/slave mode
  - Bidirectional data transfer between masters and slaves
  - Multi-master bus (no central master).
  - Arbitration between simultaneously transmitting masters without corruption of serial data on the bus
  - Serial clock synchronization allows devices with different bit rates to communicate via one serial bus.

# NuMicro M051™ Series Technical Reference Manual

- Serial clock synchronization can be used as a handshake mechanism to suspend and resume serial transfer.
- Programmable clocks allow versatile rate control.
- Supports multiple address recognition (four slave address with mask option)
- ADC
  - 12-bit SAR ADC with 600k SPS
  - Up to 8-ch single-ended input or 4-ch differential input
  - Supports single mode/burst mode/single-cycle scan mode/continuous scan mode
  - Each channel with an individual result register
  - Supports conversion value monitoring (or comparison) for threshold voltage detection
  - Conversion can be started either by software trigger or external pin trigger
- EBI (External Bus Interface) for external memory-mapped device access
  - Accessible space: 64KB in 8-bit mode or 128KB in 16-bit mode
  - Supports 8-bit/16-bit data width
- In-System Programming (ISP) and In-Circuit Programming (ICP)
- Brownout Detector
  - With 4 levels: 4.5V/3.8V/2.7V/2.2V
  - Supports brownout interrupt and reset option
- LVR (Low Voltage Reset)
  - Threshold voltage levels: 2.0V
- Operating Temperature: -40°C~85°C
- Packages:
  - Green package (RoHS)
  - 48-pin LQFP, 33-pin QFN

## 5.2 LQFP 48 pin

Figure 5-2 NuMicro™ M051 Series LQFP-48 Pin Diagram

# NuMicro M051™ Series Technical Reference Manual

## 5.3 Pin Description

Pin number		Symbol	Alternate Function		Type <sup>[1]</sup>	Description
QFN33	LQFP48		1	2		
11	16	XTAL1			I (ST)	<b>CRYSTAL1:</b> This is the input pin to the internal inverting amplifier. The system clock is from external crystal or resonator when FOSC[1:0] (CONFIG3[1:0]) are both logic 1 by default.
10	15	XTAL2			O	<b>CRYSTAL2:</b> This is the output pin from the internal inverting amplifier. It emits the inverted signal of XTAL1.
27	41	VDD			P	<b>POWER SUPPLY:</b> Supply voltage <b>Digital</b> V <sub>DD</sub> for operation.
12	17	VSS			P	<b>GROUND: Digital</b> Ground potential.
33						
28	42	AVDD			P	<b>POWER SUPPLY:</b> Supply voltage <b>Analog</b> AV <sub>DD</sub> for operation.
4	6	AVSS			P	<b>GROUND: Analog</b> Ground potential.
13	18	LDO_C AP			P	<b>LDO:</b> LDO output pin <b>Note: It needs to be connected with a 10uF capacitor.</b>
2	4	/RST			I (ST)	<b>RESET:</b> /RST pin is a Schmitt trigger input pin for hardware device reset. A "Low" on this pin for 768 clock counter of Internal 22.1184 MHz high speed oscillator while the system clock is running will reset the device. /RST pin has an internal pull-up resistor allowing power-on reset by simply connecting an external capacitor to GND.
26	40	P0.0	CTS1	AD0	D, I/O	<b>PORT0:</b> Port 0 is an 8-bit four mode output pin and two mode input. Its multifunction pins are for CTS1, RTS1, CTS0, RTS0, SPISS1, MOSI_1, MISO_1, and SPICLK1. P0 has an alternative function as AD[7:0] while external memory interface (EBI) is enabled.  These pins which are SPISS1, MOSI_1, MISO_1, and SPICLK1 for the SPI function used.  CTS0/1: Clear to Send input pin for UART0/1
25	39	P0.1	RTS1	AD1	D, I/O	
NC	38	P0.2	CTS0	AD2	D, I/O

## 6 FUNCTIONAL DESCRIPTION

### 6.1 ARM® Cortex™-M0 Core

The Cortex™ -M0 processor is a configurable, multistage, 32-bit RISC processor. It has an AMBA AHB-Lite interface and includes an NVIC component. It also has optional hardware debug functionality. The processor can execute Thumb code and is compatible with other Cortex-M profile processor. The profile supports two modes -Thread and Handler modes. Handler mode is entered as a result of an exception. An exception return can only be issued in Handler mode. Thread mode is entered on Reset, and can be entered as a result of an exception return.

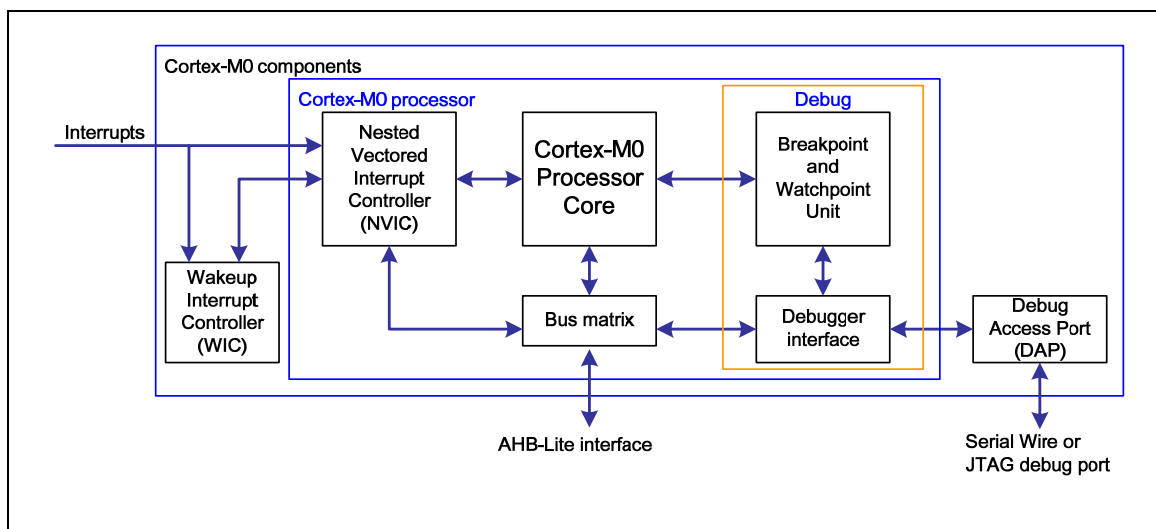

Figure 6-1 Functional Block Diagram

The implemented device provides:

#### A low gate count processor the features:

- The ARMv6-M Thumb® instruction set.
- Thumb-2 technology.
- ARMv6-M compliant 24-bit SysTick timer.
- A 32-bit hardware multiplier.
- The system interface supports little-endian data accesses.
- The ability to have deterministic, fixed-latency, interrupt handling.

- Load/store-multiples and multicycle-multiplies that can be abandoned and restarted to facilitate rapid interrupt handling.
- C Application Binary Interface compliant exception model.  
This is the ARMv6-M, C Application Binary Interface(C-ABI) compliant exception model that enables the use of pure C functions as interrupt handlers.
- Low power sleep mode entry using Wait For Interrupt (WFI), Wait For Event(WFE) instructions, or the return from interrupt sleep-on-exit feature.

#### **NVIC features:**

- 32 external interrupt inputs, each with four levels of priority.
- Dedicated non-Maskable Interrupt (NMI) input.
- Support for both level-sensitive and pulse-sensitive interrupt lines
- Wake-up Interrupt Controller (WIC), supports ultra-low power sleep mode.

#### **Debug support:**

- Four hardware breakpoints.
- Two watchpoints.
- Program Counter Sampling Register (PCSR) for non-intrusive code profiling.
- Single step and vector catch capabilities.

#### **Bus interfaces:**

- Single 32-bit AMBA-3 AHB-Lite system interface that provides simple integration to all system peripherals and memory.
- Single 32-bit slave port that supports the DAP (Debug Access Port).

## 6.2 System Manager

### 6.2.1 Overview

The following functions are included in system manager section

- System Resets
- System Memory Map
- System management registers for Part Number ID, chip reset and on-chip module reset , multi-functional pin control
- System Timer (SysTick)
- Nested Vectored Interrupt Controller (NVIC)
- System Control registers

### 6.2.2 System Reset

The system reset includes one of the list below event occurs. For these reset event flags can be read by RSTRC register.

- The Power-On Reset (POR)
- The low level on the /RESET pin
- Watchdog Time Out Reset (WDT)
- Low Voltage Reset (LVR)
- Brown-Out-Detected Reset (BOD)
- CPU Reset
- System Reset

### 6.2.3 System Power Architecture

In this device, the power architecture is divided into three segments.

- Analog power from AVDD and AVSS provides the power for analog module operation.
- Digital power from VDD and VSS supplies the power to the internal regulator which provides a fixed 2.5V power for digital operation and I/O pins.

# NuMicro M051™ Series Technical Reference Manual

The outputs of internal voltage regulator, which is LDO, require an external capacitor which should be located close to the corresponding pin. The Figure 6-2 shows the power architecture of this device.

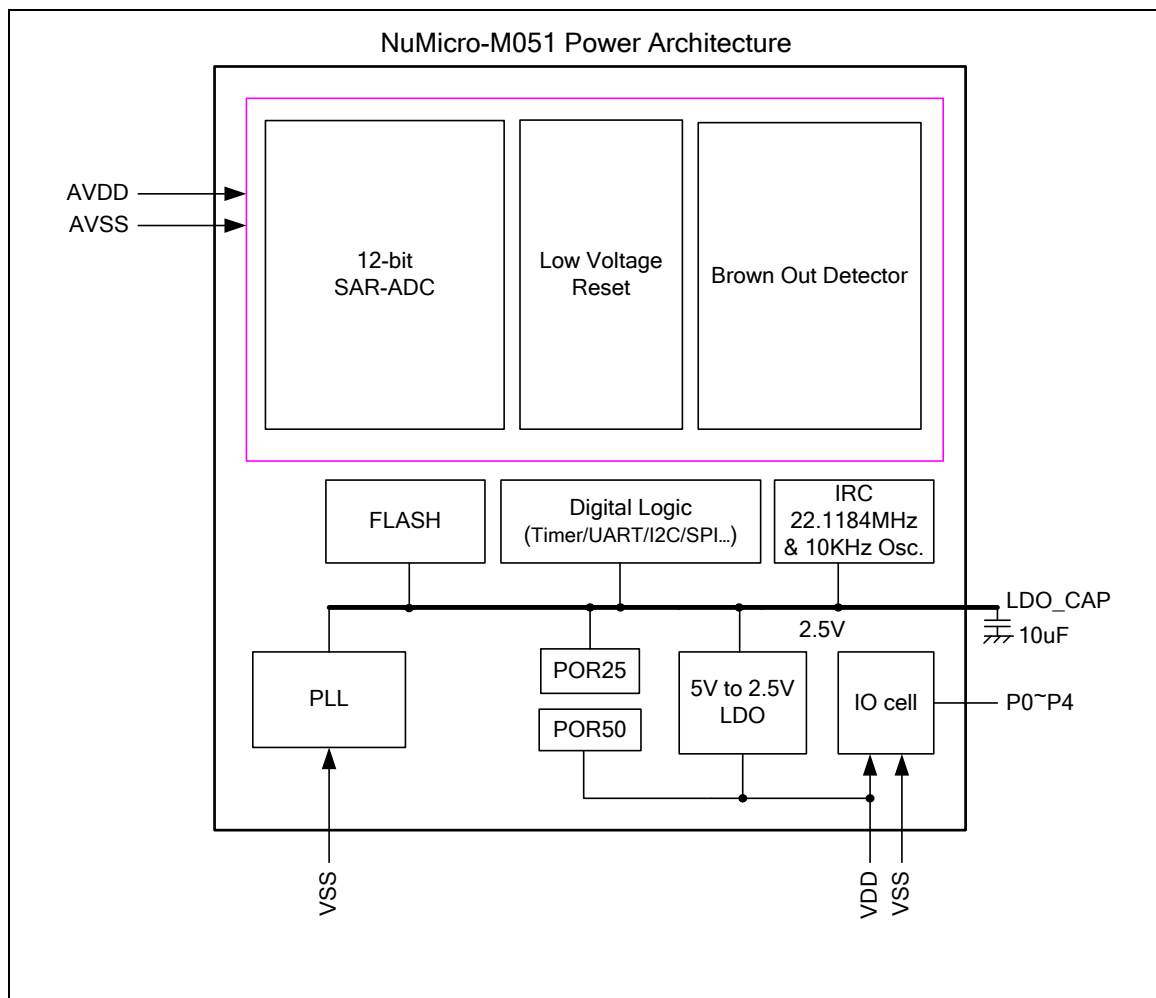

Figure 6-2 NuMicro M051™ Series Power Architecture Diagram

## 6.2.4 Whole System Memory Map

NuMicro M051™ series provides a 4G-byte address space. The memory locations assigned to each on-chip modules are shown in Table 6-1. The detailed register memory addressing and programming will be described in the following sections for individual on-chip peripherals. NuMicro M051™ series only supports little-endian data format.

Address Space	Token	Modules
<b>Flash and SRAM Memory Space</b>		
0x0000_0000 – 0x0000_FFFF	FLASH_BA	FLASH Memory Space (64KB)
0x2000_0000 – 0x2000_0FFF	SRAM_BA	SRAM Memory Space (4KB)
<b>AHB Modules Space (0x5000_0000 – 0x501F_FFFF)</b>		
0x5000_0000 – 0x5000_01FF	GCR_BA	System Global Control Registers
0x5000_0200 – 0x5000_02FF	CLK_BA	Clock Control Registers
0x5000_0300 – 0x5000_03FF	INT_BA	Interrupt Multiplexer Control Registers
0x5000_4000 – 0x5000_7FFF	GPIO_BA	GPIO (P0~P4) Control Registers
0x5000_C000 – 0x5000_FFFF	FMC_BA	Flash Memory Control Registers
0x5001_0000 – 0x5001_3FFF	EBI_CTL_BA	EBI Control Registers (128KB)
<b>EBI Space (0x6000_0000 ~ 0x6001_FFFF)</b>		
0x6000_0000 – 0x6001_FFFF	EBI_BA	EBI Space
<b>APB Modules Space (0x4000_0000 ~ 0x400F_FFFF)</b>		
0x4000_4000 – 0x4000_7FFF	WDT_BA	Watch-Dog Timer Control Registers
0x4001_0000 – 0x4001_3FFF	TMR01_BA	Timer0/Timer1 Control Registers
0x4002_0000 – 0x4002_3FFF	I2C_BA	I <sup>2</sup> C Interface Control Registers
0x4003_0000 – 0x4003_3FFF	SPI0_BA	SPI0 with master/slave function Control Registers
0x4003_4000 – 0x4003_7FFF	SPI1_BA	SPI1 with master/slave function Control Registers
0x4004_0000 – 0x4004_3FFF	PWMA_BA	PWM0/1/2/3 Control Registers

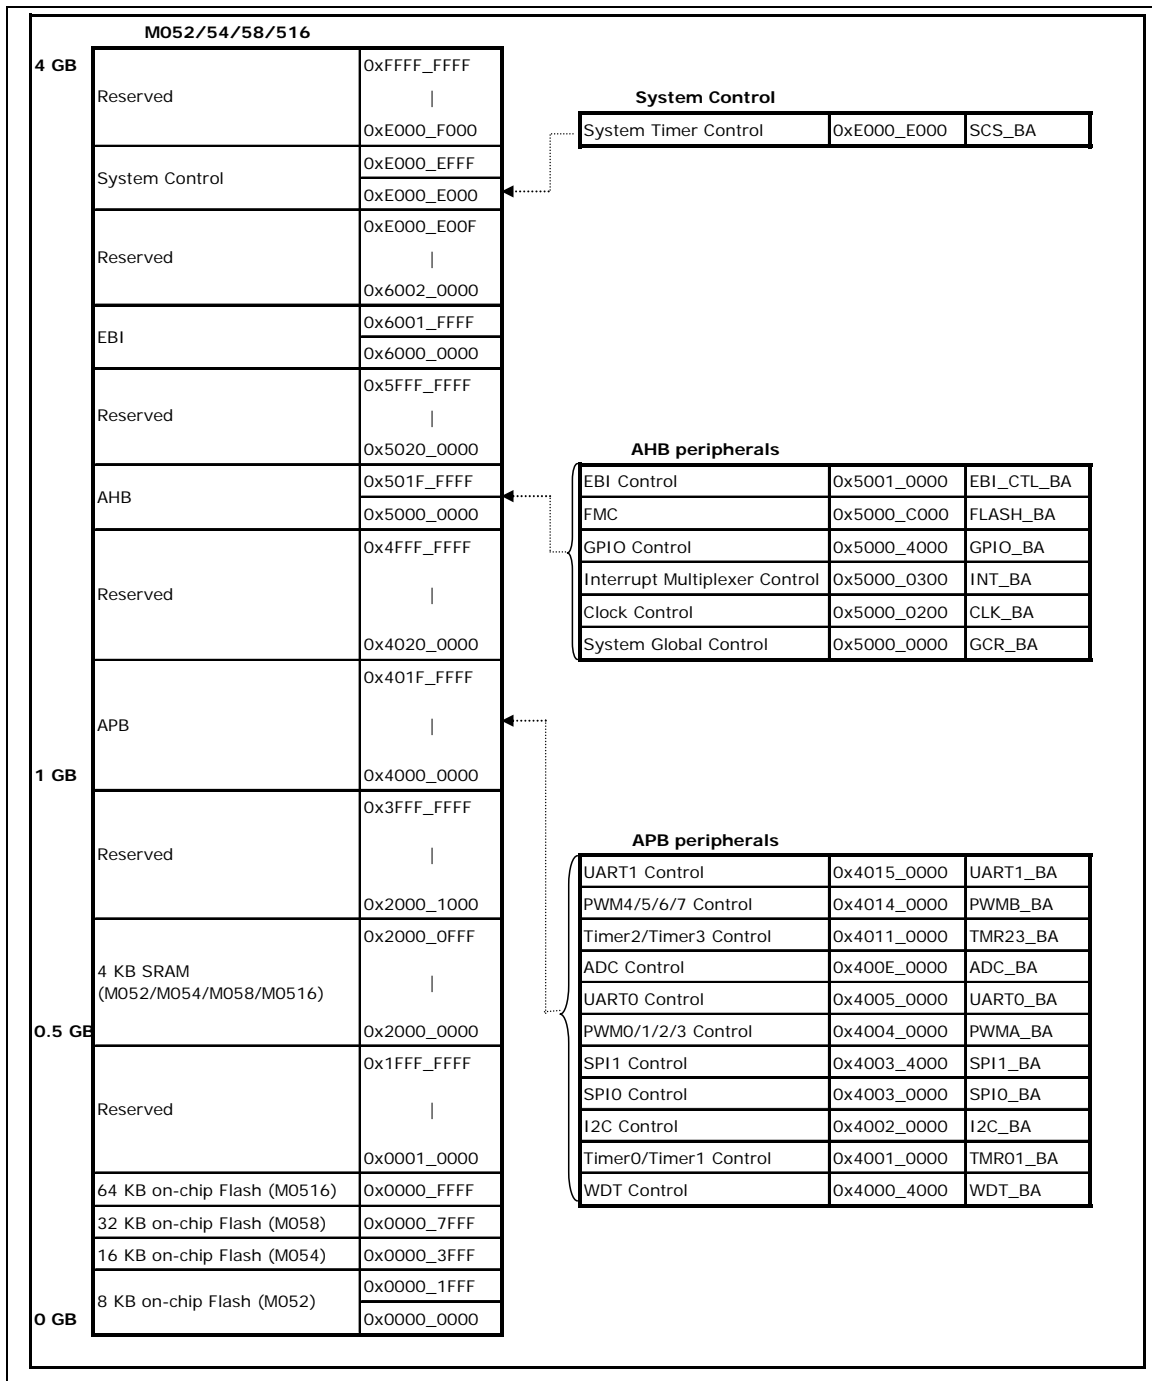

# NuMicro M051™ Series Technical Reference Manual

0x4005_0000 – 0x4005_3FFF	UART0_BA	UART0 Control Registers
0x400E_0000 – 0x400E_FFFF	ADC_BA	Analog-Digital-Converter (ADC) Control Registers
0x4011_0000 – 0x4011_3FFF	TMR23_BA	Timer2/Timer3 Control Registers
0x4014_0000 – 0x4014_3FFF	PWMB_BA	PWM4/5/6/7 Control Registers
0x4015_0000 – 0x4015_3FFF	UART1_BA	UART1 Control Registers
<b>System Control Space (0xE000_E000 ~ 0xE000_EFFF)</b>		
0xE000_E010 – 0xE000_E0FF	SCS_BA	System Timer Control Registers
0xE000_E100 – 0xE000_ECFF	SCS_BA	External Interrupt Controller Control Registers
0xE000_ED00 – 0xE000_ED8F	SCS_BA	System Control Registers

## Power-On-Reset Control Register (PORCR)

Register	Offset	R/W	Description	Reset Value
PORCR	GCR_BA+0x24	R/W	Power-On-Reset Controller Register	0x0000_00XX

31	30	29	28	27	26	25	24
Reserved							
23	22	21	20	19	18	17	16
Reserved							
15	14	13	12	11	10	9	8
POR_DIS_CODE[15:8]							
7	6	5	4	3	2	1	0
POR_DIS_CODE[7:0]							

Bits	Descriptions	
[31:16]	Reserved	Reserved
[15:0]	POR_DIS_CODE	<p>The register is used for the Power-On-Reset enable control (write-protected)</p> <p>When power on, the POR circuit generates a reset signal to reset the whole chip function, but noise on the power may cause the POR active again. If set the POR_DIS_CODE equal to 0x5AA5, the POR reset function will be disabled and the POR function will re-active till the power voltage is lower to set the POR_DIS_CODE to another value or reset by chip other reset function. Include:</p> <p>/RESET, Watch dog, LVR reset BOD reset, ICE reset command and the software-chip reset function</p> <p>This bit is the protected bit. It means programming this needs to write "59h", "16h", "88h" to address 0x5000_0100 to disable register protection. Reference the register REGWRPROT at address GCR_BA+0x100.</p>

## Multiple Function Port0 Control Register (P0\_MFP)

Register	Offset	R/W	Description	Reset Value

## Register Write-Protection Control Register (REGWRPROT)

Some of the system control registers need to be protected to avoid inadvertent write and disturb the chip operation. These system control registers are protected after the power on reset till user to disable register protection. For user to program these protected registers, a register protection disable sequence needs to be followed by a special programming. The register protection disable sequence is writing the data “59h”, “16h” “88h” to the register REGWRPROT address at 0x5000\_0100 continuously. Any different data value, different sequence or any other write to other address during these three data writing will abort the whole sequence.

After the protection is disabled, user can check the protection disable bit at address 0x5000\_0100 bit0, “1” is protection disable, “0” is protection enable. Then user can update the target protected register value and then write any data to the address “0x5000\_0100” to enable register protection.

Write this register to disable/enable register protection, and reading it to get the REGPROTDIS status.

## 6.2.7 System Timer (SysTick)

The Cortex-M0 includes an integrated system timer, SysTick. SysTick provides a simple, 24-bit clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism. The counter can be used as a Real Time Operating System (RTOS) tick timer or as a simple counter.

When system timer is enabled, it will count down from the value in the SysTick Current Value Register (SYST\_CVR) to zero, and reload (wrap) to the value in the SysTick Reload Value Register (SYST\_RVR) on the next clock edge, then decrement on subsequent clocks. When the counter transitions to zero, the COUNTFLAG status bit is set. The COUNTFLAG bit clears on reads.

The SYST\_CVR value is UNKNOWN on reset. Software should write to the register to clear it to zero before enabling the feature. This ensures the timer will count from the SYST\_RVR value rather than an arbitrary value when it is enabled.

If the SYST\_RVR is zero, the timer will be maintained with a current value of zero after it is reloaded with this value. This mechanism can be used to disable the feature independently from the timer enable bit.

For more detailed information, please refer to the documents “ARM® Cortex™-M0 Technical Reference Manual” and “ARM® v6-M Architecture Reference Manual”.

[23:0]	CURRENT	Current counter value. This is the value of the counter at the time it is sampled. The counter does not provide read-modify-write protection. The register is write-clear. A software write of any value will clear the register to 0. Unsupported bits RAZ (see SysTick Reload Value register).

## 6.2.8 Nested Vectored Interrupt Controller (NVIC)

Cortex-M0 provides an interrupt controller as an integral part of the exception mode, named as “Nested Vectored Interrupt Controller (NVIC)”. It is closely coupled to the processor kernel and provides following features:

- Nested and Vectored interrupt support
- Automatic processor state saving and restoration
- Dynamic priority changing
- Reduced and deterministic interrupt latency

The NVIC prioritizes and handles all supported exceptions. All exceptions are handled in “Handler Mode”. This NVIC architecture supports 32 (IRQ[31:0]) discrete interrupts with 4 levels of priority. All of the interrupts and most of the system exceptions can be configured to different priority levels. When an interrupt occurs, the NVIC will compare the priority of the new interrupt to the current running one’s priority. If the priority of the new interrupt is higher than the current one, the new interrupt handler will override the current handler.

When any interrupts is accepted, the starting address of the interrupt service routine (ISR) is fetched from a vector table in memory. There is no need to determine which interrupt is accepted and branch to the starting address of the correlated ISR by software. While the starting address is fetched, NVIC will also automatically save processor state including the registers “PC, PSR, LR, R0~R3, R12” to the stack. At the end of the ISR, the NVIC will restore the mentioned registers from stack and resume the normal execution. Thus it will take less and deterministic time to process the interrupt request.

The NVIC supports “Tail Chaining” which handles back-to-back interrupts efficiently without the overhead of states saving and restoration and therefore reduces delay time in switching to pending ISR at the end of current ISR. The NVIC also supports “Late Arrival” which improves the efficiency of concurrent ISRs. When a higher priority interrupt request occurs before the current ISR starts to execute (at the stage of state saving and starting address fetching), the NVIC will give priority to the higher one without delay penalty. Thus it advances the real-time capability.

For more detailed information, please refer to the documents “ARM® Cortex™-M0 Technical Reference Manual” and “ARM® v6-M Architecture Reference Manual”.

## 6.2.8.1 Exception Model and System Interrupt Map

The Table 6-2 lists the exception model supported by NuMicro M051™ series. Software can set four levels of priority on some of these exceptions as well as on all interrupts. The highest user-configurable priority is denoted as “0” and the lowest priority is denoted as “3”. The default priority of all the user-configurable interrupts is “0”. Note that priority “0” is treated as the fourth priority on the system, after three system exceptions “Reset”, “NMI” and “Hard Fault”.

Exception Number	Vector Address	Interrupt Number (Bit in Interrupt Registers)	Interrupt Name	Source IP	Interrupt description	Power Down Wakeup

## 6.2.8.2 Vector Table

When any interrupts is accepted, the processor will automatically fetch the starting address of the interrupt service routine (ISR) from a vector table in memory. For ARMv6-M, the vector table base

Publication Release Date: May, 04, 2011

Revision V2.00

# NuMicro M051™ Series Technical Reference Manual

address is fixed at 0x00000000. The vector table contains the initialization value for the stack pointer on reset, and the entry point addresses for all exception handlers. The vector number on previous page defines the order of entries in the vector table associated with exception handler entry as illustrated in previous section.

Vector Table Word Offset	Description
0	SP_main – The Main stack pointer
Vector Number	Exception Entry Pointer using that Vector Number

Table 6-4 Vector Table Format

## 6.2.8.3 Operation Description

NVIC interrupts can be enabled and disabled by writing to their corresponding Interrupt Set-Enable or Interrupt Clear-Enable register bit-field. The registers use a write-1-to-enable and write-1-to-clear policy, both registers reading back the current enabled state of the corresponding interrupts. When an interrupt is disabled, interrupt assertion will cause the interrupt to become Pending, however, the interrupt will not activate. If an interrupt is Active when it is disabled, it remains in its Active state until cleared by reset or an exception return. Clearing the enable bit prevents new activations of the associated interrupt.

NVIC interrupts can be pended/un-pended using a complementary pair of registers to those used to enable/disable the interrupts, named the Set-Pending Register and Clear-Pending Register respectively. The registers use a write-1-to-enable and write-1-to-clear policy, both registers reading back the current pended state of the corresponding interrupts. The Clear-Pending Register has no effect on the execution status of an Active interrupt.

NVIC interrupts are prioritized by updating an 8-bit field within a 32-bit register (each register supporting four interrupts).

The general registers associated with the NVIC are all accessible from a block of memory in the System Control Space and will be described in next section.

## 6.2.8.4 NVIC Control Registers

## 6.2.8.5 Interrupt Source Control Registers

Besides the interrupt control registers associated with the NVIC, NuMicro M051™ series also implement some specific control registers to facilitate the interrupt functions, including “interrupt source identify”, “NMI source selection” and “interrupt test mode”. They are described as below.

**R**: read only, **W**: write only, **R/W**: both read and write

Register	Offset	R/W	Description	Reset Value
INT_BA = 0x5000_0300				
<b>IRQ0_SRC</b>	INT_BA+0x00	R	IRQ0 (BOD) interrupt source identity	0xXXXX_XXXX
<b>IRQ1_SRC</b>	INT_BA+0x04	R	IRQ1 (WDT) interrupt source identity	0xXXXX_XXXX
<b>IRQ2_SRC</b>	INT_BA+0x08	R	IRQ2 (EINT0) interrupt source identity	0xXXXX_XXXX
<b>IRQ3_SRC</b>	INT_BA+0x0C	R	IRQ3 (EINT1) interrupt source identity	0xXXXX_XXXX
<b>IRQ4_SRC</b>	INT_BA+0x10	R	IRQ4 (P0/1) interrupt source identity	0xXXXX_XXXX
<b>IRQ5_SRC</b>	INT_BA+0x14	R	IRQ5 (P2/3/4) interrupt source identity	0xXXXX_XXXX
<b>IRQ6_SRC</b>	INT_BA+0x18	R	IRQ6 (PWMA) interrupt source identity	0xXXXX_XXXX
<b>IRQ7_SRC</b>	INT_BA+0x1C	R	IRQ7 (PWMB) interrupt source identity	0xXXXX_XXXX
<b>IRQ8_SRC</b>	INT_BA+0x20	R	IRQ8 (TMR0) interrupt source identity	0xXXXX_XXXX
<b>IRQ9_SRC</b>	INT_BA+0x24	R	IRQ9 (TMR1) interrupt source identity	0xXXXX_XXXX
<b>IRQ10_SRC</b>	INT_BA+0x28	R	IRQ10 (TMR2) interrupt source identity	0xXXXX_XXXX
<b>IRQ11_SRC</b>	INT_BA+0x2C	R	IRQ11 (TMR3) interrupt source identity	0xXXXX_XXXX
<b>IRQ12_SRC</b>	INT_BA+0x30	R	IRQ12 (URT0) interrupt source identity	0xXXXX_XXXX
<b>IRQ13_SRC</b>	INT_BA+0x34	R	IRQ13 (URT1) interrupt source identity	0xXXXX_XXXX
<b>RQ14_SRC</b>	INT_BA+0x38	R	IRQ14 (SPI0) interrupt source identity	0xXXXX_XXXX
<b>IRQ15_SRC</b>	INT_BA+0x3C	R	IRQ15 (SPI1) interrupt source identity	0xXXXX_XXXX
<b>IRQ16_SRC</b>	INT_BA+0x40	-	Reserved	0xXXXX_XXXX

# NuMicro M051™ Series Technical Reference Manual

<b>IRQ17_SRC</b>	INT_BA+0x44	-	Reserved	0xFFFF_XXXX

MCU_IRQ[15:8]							
7	6	5	4	3	2	1	0
MCU_IRQ[7:0]							

Bits	Descriptions
[31:0]	<p><b>MCU_IRQ Source Register</b></p> <p>The MCU_IRQ collects all the interrupts from the peripherals and generates the synchronous interrupt to Cortex-M0 core. There are two modes to generate interrupt to Cortex-M0, the normal mode and test mode.</p> <p>The MCU_IRQ collects all interrupts from each peripheral and synchronizes them then interrupts the Cortex-M0.</p> <p>When the MCU_IRQ[n] is "0": Set MCU_IRQ[n] "1" will generate an interrupt to Cortex_M0 NVIC[n].</p> <p>When the MCU_IRQ[n] is "1" (mean an interrupt is assert), set 1 to the MCU_bit[n] will clear the interrupt and set MCU_IRQ[n] "0" : no any effect</p>

# NuMicro M051™ Series Technical Reference Manual

## 6.2.9 System Controller Registers Map

Cortex-M0 status and operating mode control are managed by System Control Registers. Including CPUID, Cortex-M0 interrupt priority and Cortex-M0 power management can be controlled through these system control register

For more detailed information, please refer to the documents “ARM® Cortex™-M0 Technical Reference Manual” and “ARM® v6-M Architecture Reference Manual”.

**R**: read only, **W**: write only, **R/W**: both read and write

## 6.3 Clock Controller

### 6.3.1 Overview

The clock controller generates the clocks for the whole chip, including system clocks and all peripheral clocks. The clock controller also implements the power control function with the individually clock ON/OFF control, clock source selection and clock divider. The chip will not enter power down mode until CPU sets the power down enable bit (PWR\_DOWN\_EN) and Cortex-M0 core executes the WFI instruction. After that, chip enters power down mode and wait for wake-up interrupt source triggered to leave power down mode. In the power down mode, the clock controller turns off the external 4~24 MHz high speed crystal and internal 22.1184 MHz high speed oscillator to reduce the overall system power consumption.

### 6.3.2 Clock Generator Block Diagram

The clock generator consists of 4 sources which list below:

- One external 4~24 MHz high speed crystal
- One internal 22.1184 MHz high speed oscillator
- One programmable PLL FOUT(PLL source consists of external 4~24 MHz high speed crystal and internal 22.1184 MHz high speed oscillator)
- One internal 10 kHz low speed oscillator

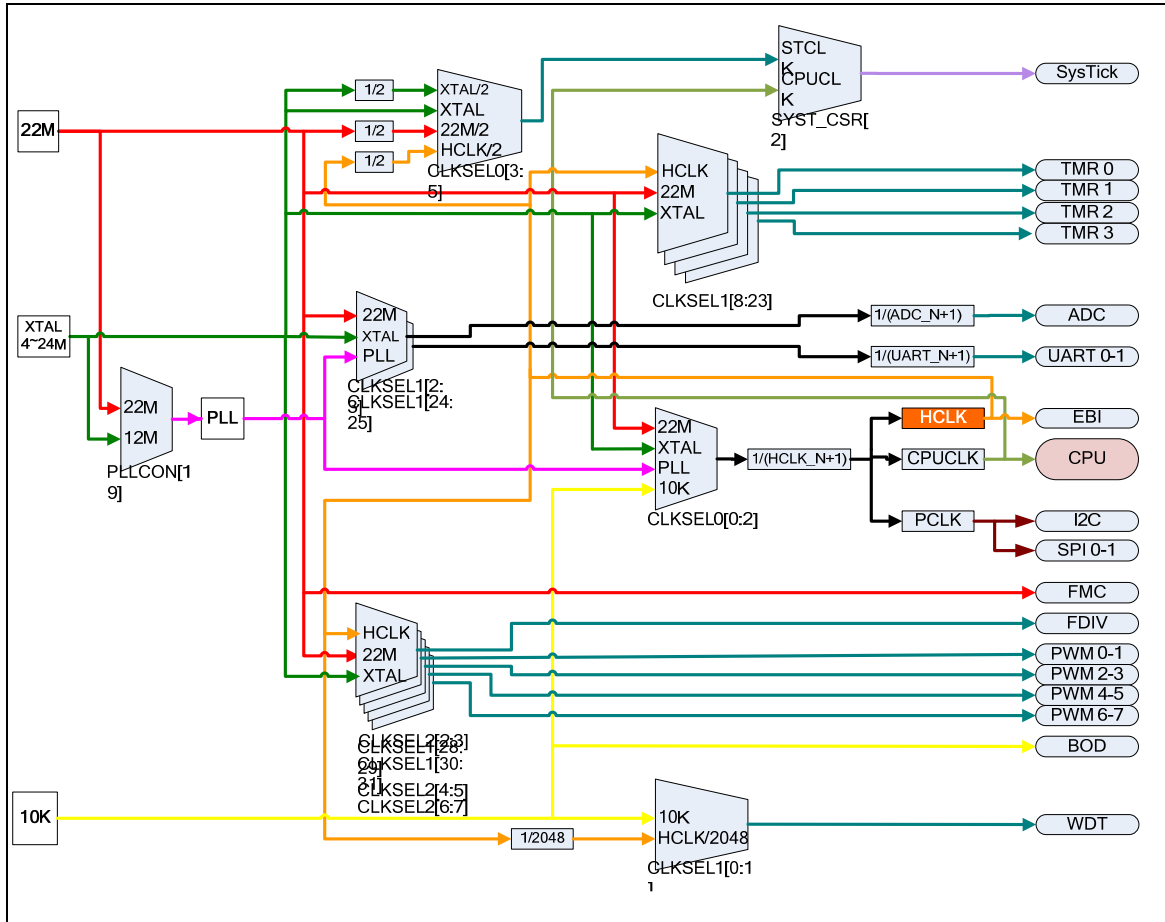

Figure 6-3 Whole Chip Clock generator block diagram

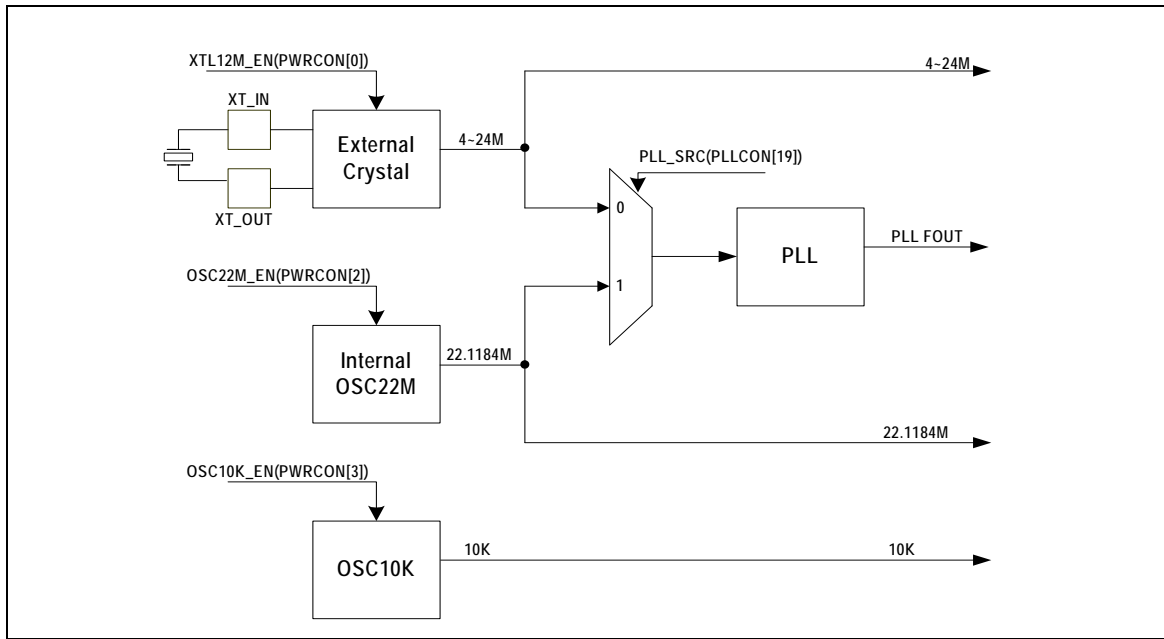

Figure 6-4 Clock generator block diagram

## 6.3.3 System Clock and SysTick Clock

The system clock has 4 clock sources which were generated from clock generator block. The clock source switch depends on the register HCLK\_S(CLKSEL0[2:0]). The block diagram is shown in the Figure 6-5.

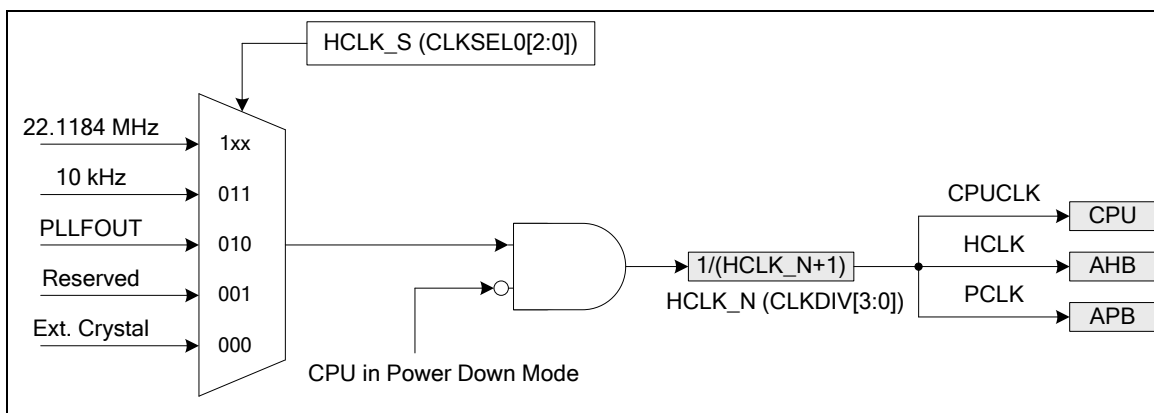

Figure 6-5 System Clock Block Diagram

The clock source of SysTick in Cortex-M0 core can use CPU clock or external clock (SYST\_CSR[2]). If using external clock, the SysTick clock (STCLK) has 4 clock sources. The clock source switch depends on the setting of the register STCLK\_S (CLKSEL0[5:3]). The block diagram is shown in the Figure 6-6.

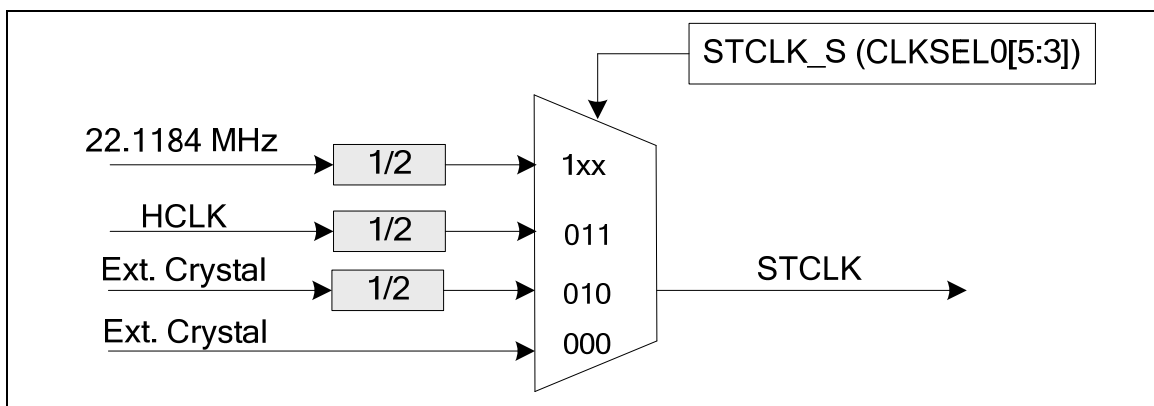

Figure 6-6 SysTick clock Control Block Diagram

## 6.3.4 AHB Clock Source Select

Figure 6-7 AHB Clock Source for HCLK

## 6.3.5 Peripherals Clock Source Select

The peripherals clock had different clock source switch setting which depends on the different peripheral. Please refer the CLKSEL1 and APBCLK register description in chapter 6.3.9.

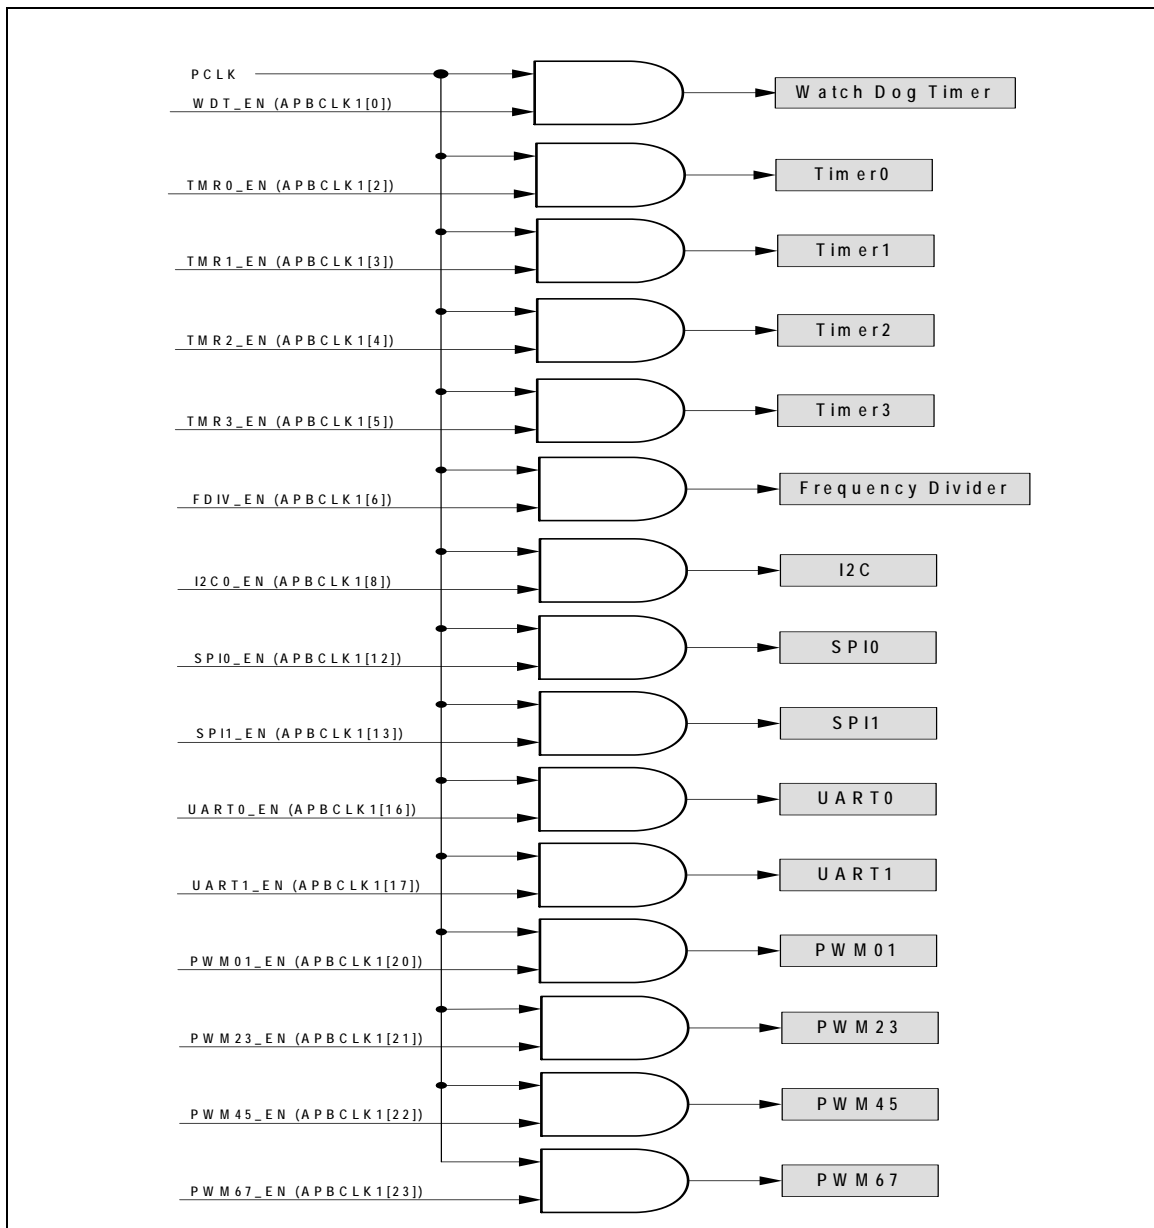

Figure 6-8 Peripherals Clock Source Select for PCLK

## 6.3.6 Power Down Mode Clock

When chip enter into power down mode, most of clock sources, peripheral clocks and system clock will be disabled. Some of clock sources and peripherals clock are still active in power down mode.

For theses clocks which still keep active list below:

Clock Generator

- Internal 10 kHz low speed oscillator clock

Peripherals Clock (When these IP adopt internal 10 kHz low speed oscillator as clock source)

## 6.3.7 Frequency Divider Output

This device is equipped a power-of-2 frequency divider which is composed by 16 chained divide-by-2 shift registers. One of the 16 shift register outputs selected by a sixteen to one multiplexer is reflected to P3.6. Therefore there are 16 options of power-of-2 divided clocks with the frequency from  $F_{in}/2^1$  to  $F_{in}/2^{17}$  where  $F_{in}$  is input clock frequency to the clock divider.

The output formula is  $F_{out} = F_{in}/2^{(N+1)}$ , where  $F_{in}$  is the input clock frequency,  $F_{out}$  is the clock divider output frequency and N is the 4-bit value in `FREQDIV.FSEL[3:0]`.

When write 1 to `DIVIDER_EN` (`FRQDIV[4]`), the chained counter starts to count. When write 0 to `DIVIDER_EN` (`FRQDIV[4]`), the chained counter continuously runs till divided clock reaches low state and stay in low state.

Bits	Descriptions	
[19]	PLL_SRC	PLL Source Clock Select 1 = PLL source clock from internal 22.1184 MHz high speed oscillator 0 = PLL source clock from external 4~24 MHz high speed crystal
[18]	OE	PLL OE (FOUT enable) pin Control 0 = PLL FOUT enable 1 = PLL FOUT is fixed low
[17]	BP	PLL Bypass Control 0 = PLL is in normal mode (default) 1 = PLL clock output is same as clock input (XTALin)

# NuMicro M051™ Series Technical Reference Manual

[16]	<b>PD</b>	Power Down Mode. If set the IDLE bit "1" in PWRCON register, the PLL will enter power down mode too 0 = PLL is in normal mode 1 = PLL is in power down mode (default)
[15:14]	<b>OUT_DV</b>	PLL Output Divider Control Pins
[13:9]	<b>IN_DV</b>	PLL Input Divider Control Pins
[8:0]	<b>FB_DV</b>	PLL Feedback Divider Control Pins

## PLL Output Clock Frequency Setting

$$F_{OUT} = F_{IN} \times \frac{NF}{NR} \times \frac{1}{NO}$$

Constraint:

1.  $3.2\text{MHz} < F_{IN} < 150\text{MHz}$

2.  $800\text{kHz} < \frac{F_{IN}}{2 * NR} < 8\text{MHz}$

3.  $100\text{MHz} < F_{CO} = F_{IN} * \frac{NF}{NR} < 200\text{MHz}$ ,  $120\text{MHz} < F_{CO}$  is preferred.

Symbol	Description
<b>F<sub>OUT</sub></b>	Output Clock Frequency
<b>F<sub>IN</sub></b>	Input (Reference) Clock Frequency
<b>NR</b>	Input Divider (IN_DV + 2)
<b>NF</b>	Feedback Divider (FB_DV + 2)
<b>NO</b>	OUT_DV="00": NO = 1 OUT_DV="01": NO = 2 OUT_DV="10": NO = 2 OUT_DV="11": NO = 4

Default PLL Frequency Setting:

The default value of PLLCON is 0xC22E.

F<sub>IN</sub> = 12 MHz

NR = (1+2) = 3

NF = (46+2) = 48

NO = 4

F<sub>OUT</sub> = 12/4 x 48 x 1/3 = 48 MHz

## 6.4 General Purpose I/O

### 6.4.1 Overview

There are 40 General Purpose I/O pins shared with special feature functions in this MCU. The 40 pins are arranged in 5 ports named with P0, P1, P2, P3 and P4. Each port equips maximum 8 pins. Each one of the 40 pins is independent and has the corresponding register bits to control the pin mode function and data

The I/O type of each of I/O pins can be software configured individually as input, output, open-drain or quasi-bidirectional mode. After reset, the all pins of I/O type stay in quasi-bidirectional mode and port data register Px\_DOUT[7:0] resets to 0x000\_00FF. Each I/O pin equips a very weakly individual pull-up resistor which is about 110KΩ~300KΩ for V<sub>DD</sub> is from 5.0V to 2.5V.

#### 6.4.1.1 Input Mode Explanation

Set Px\_PMD(PMDn[1:0]) to 00b the Px[n] pin is in Input mode and the I/O pin is in tri-state(high impedance) without output drive capability. The Px\_PIN value reflects the status of the corresponding port pins.

#### 6.4.1.2 Output Mode Explanation

Set Px\_PMD(PMDn[1:0]) to 01b the Px[n] pin is in Output mode and the I/O pin supports digital output function with source/sink current capability. The bit value in the corresponding bit [n] of Px\_DOUT is driven on the pin.

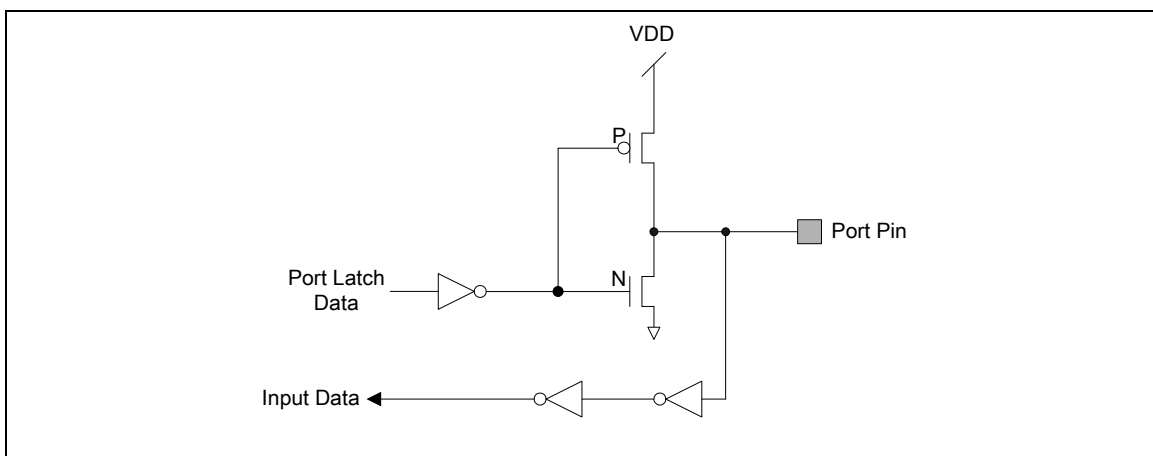

Figure 6-11 Push-Pull Output

## 6.4.1.3 Open-Drain Mode Explanation

Set Px\_PMD(PMDn[1:0]) to 10b the Px[n] pin is in Open-Drain mode and the I/O pin supports digital output function but only with sink current capability, an additional pull-up resistor is needed for driving high state. If the bit value in the corresponding bit [n] of Px\_DOUT is “0”, the pin drive a “low” output on the pin. If the bit value in the corresponding bit [n] of Px\_DOUT is “1”, the pin output drives high that is controlled by the internal pull-up resistor or the external pull high resistor.

Figure 6-12 Open-Drain Output

## 6.4.1.4 Quasi-bidirectional Mode Explanation

Set Px\_PMD(PMDn[1:0]) to 11b the Px[n] pin is in Quasi-bidirectional mode and the I/O pin supports digital output and input function at the same time but the source current is only up to hundreds uA. Before the digital input function is performed the corresponding bit in Px\_DOUT must be set to 1. The quasi-bidirectional output is common on the 80C51 and most of its derivatives. If the bit value in the corresponding bit [n] of Px\_DOUT is “0”, the pin drive a “low” output on the pin. If the bit value in the corresponding bit [n] of Px\_DOUT is “1”, the pin will check the pin value. If pin value is high, no action takes. If pin state is low, then pin will drive strong high with 2 clock cycles on the pin and then disable the strong output drive and then the pin status is control by internal pull-up resistor. Note that the source current capability in quasi-bidirectional mode is only about 200uA to 30uA for VDD is form 5.0V to 2.5V

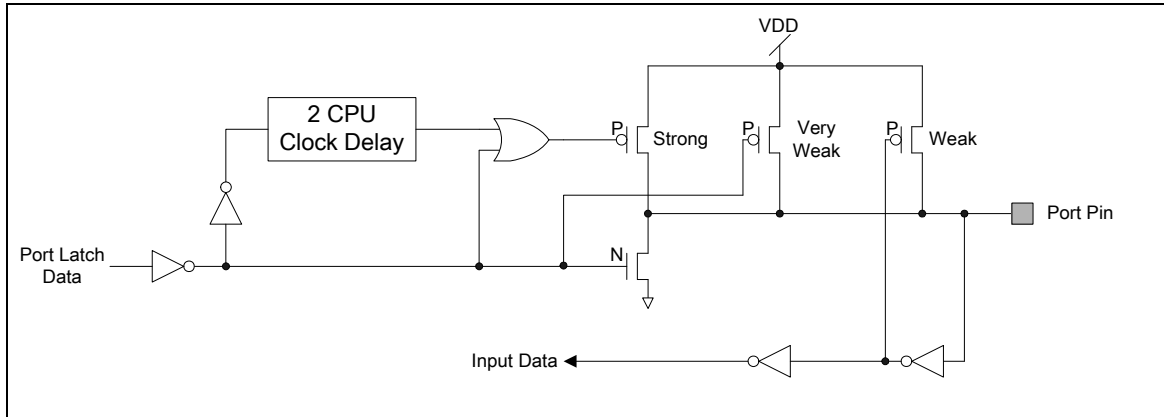

Figure 6-13 Quasi-bidirectional I/O Mode

## 6.5 I<sup>2</sup>C Serial Interface Controller (Master/Slave)

### 6.5.1 Overview

I<sup>2</sup>C is a two-wire, bi-directional serial bus that provides a simple and efficient method of data exchange between devices. The I<sup>2</sup>C standard is a true multi-master bus including collision detection and arbitration that prevents data corruption if two or more masters attempt to control the bus simultaneously.

Data is transferred between a Master and a Slave synchronously to SCL on the SDA line on a byte-by-byte basis. Each data byte is 8 bits long. There is one SCL clock pulse for each data bit with the MSB being transmitted first. An acknowledge bit follows each transferred byte. Each bit is sampled during the high period of SCL; therefore, the SDA line may be changed only during the low period of SCL and must be held stable during the high period of SCL. A transition on the SDA line while SCL is high is interpreted as a command (START or STOP). Please refer to the Figure 6-14 for more detail I<sup>2</sup>C BUS Timing.

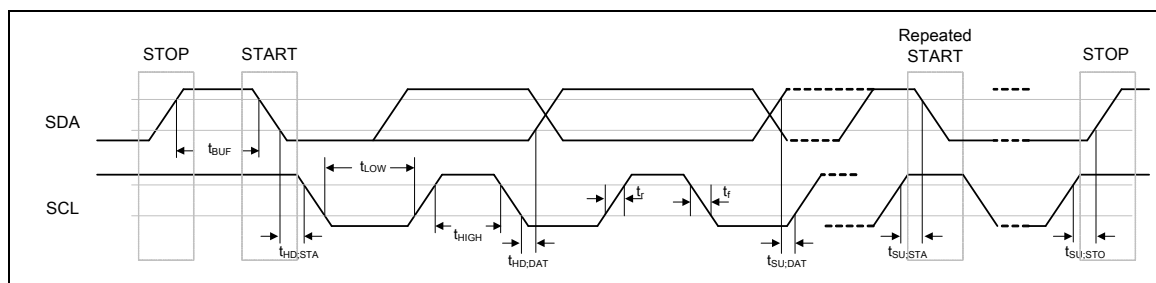

Figure 6-14 I<sup>2</sup>C Bus Timing

The device's on-chip I<sup>2</sup>C provides the serial interface that meets the I<sup>2</sup>C bus standard mode specification. The I<sup>2</sup>C port handles byte transfers autonomously. To enable this port, the bit ENS1 in I2CON should be set to '1'. The I<sup>2</sup>C H/W interfaces to the I<sup>2</sup>C bus via two pins: SDA (serial data line) and SCL (serial clock line). Pull up resistor is needed on pin SDA and SCL for I<sup>2</sup>C operation as these are open drain pins. When the I/O pins are used as I<sup>2</sup>C port, user must set the pins function to I<sup>2</sup>C in advance.

### 6.5.2 Features

The I<sup>2</sup>C bus uses two wires (SDA and SCL) to transfer information between devices connected to the bus. The main features of the bus are:

- Support Master and Slave mode
- Bidirectional data transfer between masters and slaves
- Multi-master bus (no central master)
- Arbitration between simultaneously transmitting masters without corruption of serial data on the bus

- Serial clock synchronization allows devices with different bit rates to communicate via one serial bus
- Serial clock synchronization can be used as a handshake mechanism to suspend and resume serial transfer
- Built-in a 14-bit time-out counter will request the I<sup>2</sup>C interrupt if the I<sup>2</sup>C bus hangs up and timer-out counter overflows.
- External pull-up are needed for high output
- Programmable clocks allow versatile rate control
- Supports 7-bit addressing mode
- I<sup>2</sup>C-bus controllers support multiple address recognition ( Four slave address with mask option)

## 6.5.3 Function Description

### 6.5.3.1 I<sup>2</sup>C Protocol

Normally, a standard communication consists of four parts:

- 1) START or Repeated START signal generation
- 2) Slave address and R/W bit transfer
- 3) Data transfer

### 6.5.3.2 Data transfer on the I<sup>2</sup>C -bus

A master-transmitter addressing a slave receiver with a 7-bit address

Publication Release Date: May, 04, 2011  
Revision V2.00

The transfer direction is not changed

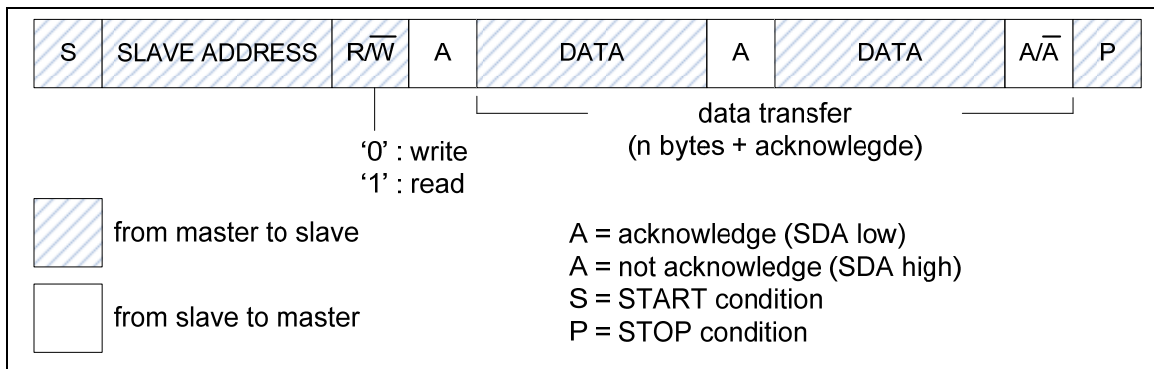

Figure 6-16 Master Transmits Data to Slave

A master reads a slave immediately after the first byte (address)

The transfer direction is changed

Figure 6-17 Master Reads Data from Slave

### 6.5.3.3 START or Repeated START signal

When the bus is free/idle, meaning no master device is engaging the bus (both SCL and SDA lines are high), a master can initiate a transfer by sending a START signal. A START signal, usually referred to as the S-bit, is defined as a HIGH to LOW transition on the SDA line while SCL is HIGH. The START signal denotes the beginning of a new data transfer.

A Repeated START (Sr) is no STOP signal between two START signals. The master uses this method to communicate with another slave or the same slave in a different transfer direction (e.g. from writing to a device to reading from a device) without releasing the bus.

#### STOP signal

The master can terminate the communication by generating a STOP signal. A STOP signal, usually referred to as the P-bit, is defined as a LOW to HIGH transition on the SDA line while SCL is HIGH.

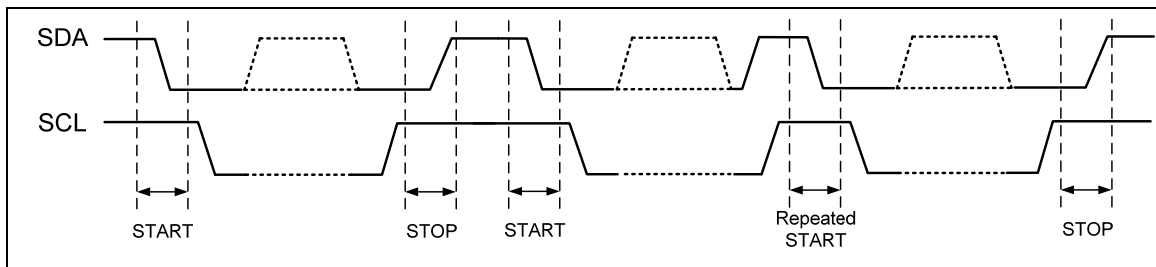

Figure 6-18 START and STOP condition

### 6.5.3.4 Slave Address Transfer

The first byte of data transferred by the master immediately after the START signal is the slave address. This is a 7-bits calling address followed by a RW bit. The RW bit signals the slave the data transfer direction. No two slaves in the system can have the same address. Only the slave with an address that matches the one transmitted by the master will respond by returning an acknowledge bit by pulling the SDA low at the 9th SCL clock cycle.

### 6.5.3.5 Data Transfer

Once successful slave addressing has been achieved, the data transfer can proceed on a byte-by-byte basis in the direction specified by the RW bit sent by the master. Each transferred byte is followed by an acknowledge bit on the 9th SCL clock cycle. If the slave signals a Not Acknowledge (NACK), the master can generate a STOP signal to abort the data transfer or generate a Repeated START signal and start a new transfer cycle.

If the master, as the receiving device, does Not Acknowledge (NACK) the slave, the slave releases the SDA line for the master to generate a STOP or Repeated START signal.

Figure 6-19 Bit Transfer on the I<sup>2</sup>C bus

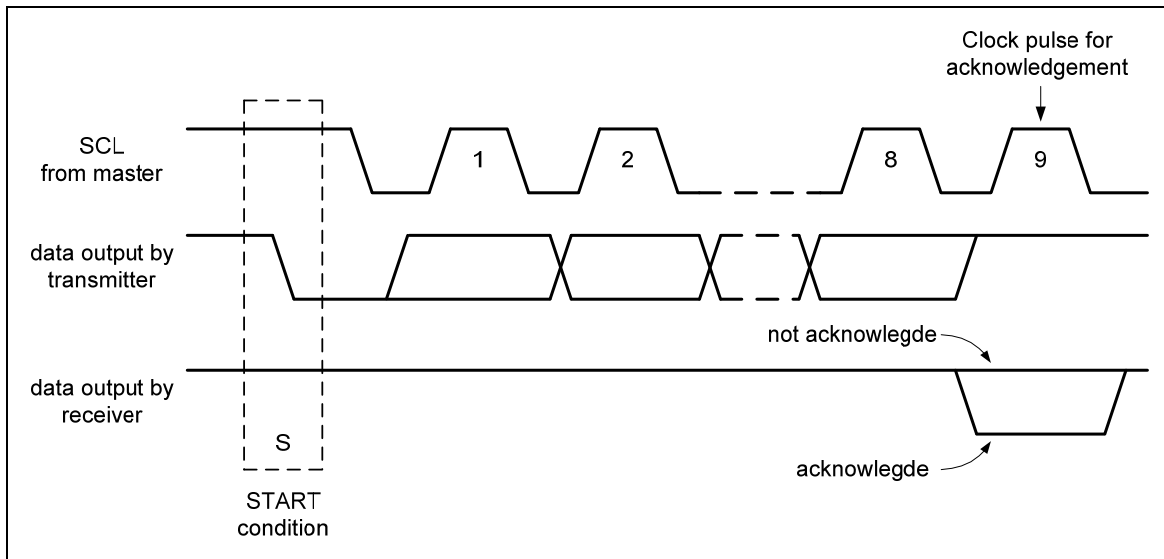

Figure 6-20 Acknowledge on the I<sup>2</sup>C bus

## 6.5.4 I<sup>2</sup>C Protocol Registers

The CPU interfaces to the I<sup>2</sup>C port through the following thirteen special function registers: I2CON (control register), I2CSTATUS (status register), I2CDAT (data register), I2CADDRn (address registers, n=0~3), I2CADMn (address mask registers, n=0~3), I2CLK (clock rate register) and I2CTOC (Time-out counter register). All bit 31~ bit 8 of these I<sup>2</sup>C special function registers are reserved. These bits do not have any functions and are all zero if read back.

When I<sup>2</sup>C port is enabled by setting ENS1 (I2CON [6]) to high, the internal states will be controlled by I2CON and I<sup>2</sup>C logic hardware. Once a new status code is generated and stored in I2CSTATUS, the I<sup>2</sup>C Interrupt Flag bit SI (I2CON [3]) will be set automatically. If the Enable Interrupt bit EI (I2CON [7]) is set high at this time, the I<sup>2</sup>C interrupt will be generated. The bit field I2CSTATUS[7:3] stores the internal state code, the lowest 3 bits of I2CSTATUS are always zero and the content keeps stable until SI is cleared by software. The base address of I<sup>2</sup>C is 4002\_0000.

### 6.5.4.1 Address Registers (I2CADDR)

I<sup>2</sup>C port is equipped with four slave address registers I2CADDRn (n=0~3). The contents of the register are irrelevant when I<sup>2</sup>C is in master mode. In the slave mode, the bit field I2CADDRn[7:1] must be loaded with the MCU's own slave address. The I<sup>2</sup>C hardware will react if the contents of I2CADDR are matched with the received slave address.

The I<sup>2</sup>C ports support the "General Call" function. If the GC bit (I2CADDRn [0]) is set the I<sup>2</sup>C port hardware will respond to General Call address (00H). Clear GC bit to disable general call function.

When GC bit is set and the I<sup>2</sup>C is in Slave mode, it can receive the general call address by 00H after Master send general call address to I<sup>2</sup>C bus, then it will follow status of GC mode.

I<sup>2</sup>C-bus controllers support multiple address recognition with four address mask registers I2CADMn (n=0~3). When the bit in the address mask register is set to one, it means the received corresponding address bit is don't-care. If the bit is set to zero, that means the received corresponding register bit should be exact the same as address register.

### 6.5.4.2 Data Register (I2CDAT)

This register contains a byte of serial data to be transmitted or a byte which just has been received. The CPU can read from or write to this 8-bit (I2CDAT [7:0]) directly while it is not in the process of shifting a byte. When I<sup>2</sup>C is in a defined state and the serial interrupt flag (SI) is set. Data in I2CDAT [7:0] remains stable as long as SI bit is set. While data is being shifted out, data on the bus is simultaneously being shifted in; I2CDAT [7:0] always contains the last data byte present on the bus. Thus, in the event of arbitration lost, the transition from master transmitter to slave receiver is made with the correct data in I2CDAT [7:0].

I2CDAT [7:0] and the acknowledge bit form a 9-bit shift register, the acknowledge bit is controlled by the I<sup>2</sup>C hardware and cannot be accessed by the CPU. Serial data is shifted through the acknowledge bit into I2CDAT [7:0] on the rising edges of serial clock pulses on the SCL line.

When a byte has been shifted into I2CDAT [7:0], the serial data is available in I2CDAT [7:0], and the acknowledge bit (ACK or NACK) is returned by the control logic during the ninth clock pulse. Serial data is shifted out from I2CDAT [7:0] on the falling edges of SCL clock pulses, and is shifted into I2CDAT [7:0] on the rising edges of SCL clock pulses.

Figure 6-21 I<sup>2</sup>C Data Shifting Direction

### 6.5.4.3 Control Register (I2CON)

The CPU can read from and write to this 8-bit field of I2CON [7:0] directly. Two bits are affected by hardware: the SI bit is set when the I<sup>2</sup>C hardware requests a serial interrupt, and the STO bit is cleared when a STOP condition is present on the bus. The STO bit is also cleared when ENS1 = '0'.

- EI        Enable Interrupt.
- ENS1    Set to enable I<sup>2</sup>C serial function block. When ENS1=1 the I<sup>2</sup>C serial function enables. The Multi Function pin function of SDA and SCL must be set to I<sup>2</sup>C function.
- STA     I<sup>2</sup>C START Control Bit. Setting STA to logic 1 to enter master mode, the I<sup>2</sup>C hardware sends a START or repeat START condition to bus when the bus is free.
- STO     I<sup>2</sup>C STOP Control Bit. In master mode, setting STO to transmit a STOP condition to bus then I<sup>2</sup>C hardware will check the bus condition if a STOP condition is detected this flag will be cleared by hardware automatically. In a slave mode, setting STO resets I<sup>2</sup>C hardware to the defined "not addressed" slave mode. This means it is NO LONGER in the slave receiver mode to receive data from the master transmit device.
- SI       I<sup>2</sup>C Interrupt Flag. When a new I<sup>2</sup>C state is present in the I2CSTATUS register, the SI flag is set by hardware, and if bit EI (I2CON [7]) is set, the I<sup>2</sup>C interrupt is requested. SI must be cleared by software. Clear SI is by writing one to this bit.
- AA       Assert Acknowledge Control Bit. When AA=1 prior to address or data received, an acknowledged (low level to SDA) will be returned during the acknowledge clock pulse on the SCL line when 1.) A slave is acknowledging the address sent from master, 2.) The receiver devices are acknowledging the data sent by transmitter. When AA=0 prior to address or data received, a Not acknowledged (high level to SDA) will be returned during the acknowledge clock pulse on the SCL line.

## 6.5.4.4 Status Register (I2CSTATUS)

I2CSTATUS [7:0] is an 8-bit read-only register. The three least significant bits are always 0. The bit field I2CSTATUS [7:3] contain the status code. There are 26 possible status codes, All states are listed in section 6.5.6. When I2CSTATUS [7:0] contains F8H, no serial interrupt is requested. All other I2CSTATUS [7:3] values correspond to defined I<sup>2</sup>C states. When each of these states is entered, a status interrupt is requested (SI = 1). A valid status code is present in I2CSTATUS[7:3] one cycle after SI is set by hardware and is still present one cycle after SI has been reset by software.

In addition, state 00H stands for a Bus Error. A Bus Error occurs when a START or STOP condition is present at an illegal position in the format frame. Examples of illegal positions are during the serial transfer of an address byte, a data byte or an acknowledge bit. To recover I<sup>2</sup>C from bus error, STO should be set and SI should be clear to enter not addressed slave mode. Then clear STO to release bus and to wait new communication. I<sup>2</sup>C bus can not recognize stop condition during this action when bus error occurs.

## 6.5.4.5 I<sup>2</sup>C Clock Baud Rate Bits (I2CLK)

The data baud rate of I<sup>2</sup>C is determines by I2CLK [7:0] register when I<sup>2</sup>C is in a master mode. It is not important when I<sup>2</sup>C is in a slave mode. In the slave modes, I<sup>2</sup>C will automatically synchronize with any clock frequency up to 1 MHz from master I<sup>2</sup>C device.

The data baud rate of I<sup>2</sup>C setting is Data Baud Rate of I<sup>2</sup>C = APBCLK / (4x (I2CLK [7:0] +1)). If PCLK=16 MHz, the I2CLK [7:0] = 40 (28H), so data baud rate of I<sup>2</sup>C = 16 MHz/ (4x (40 +1)) = 97.5 Kbits/sec.

## 6.5.4.6 The I<sup>2</sup>C Time-out Counter Register (I2CTOC)

There is a 14-bit time-out counter which can be used to deal with the I<sup>2</sup>C bus hang-up. If the time-out counter is enabled, the counter starts up counting until it overflows (TIF=1) and generates I<sup>2</sup>C interrupt to CPU or stops counting by clearing ENTI to 0. When time-out counter is enabled, setting flag SI to high will reset counter and re-start up counting after SI is cleared. If I<sup>2</sup>C bus hangs up, it causes the I2CSTATUS and flag SI are not updated for a period, the 14-bit time-out counter may overflow and acknowledge CPU the I<sup>2</sup>C interrupt. Refer to the Figure 6-22 for the 14-bit time-out counter. User can clear TIF by writing 1 to this bit.

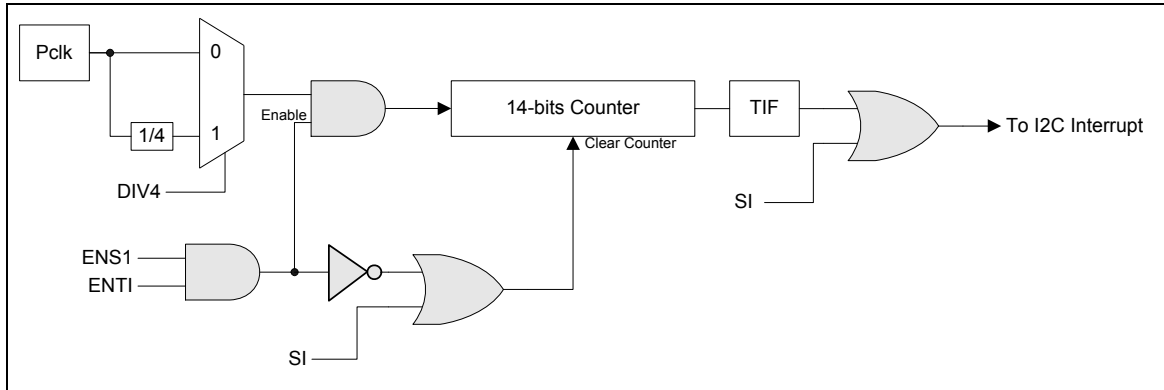

Figure 6-22: I<sup>2</sup>C Time-out Count Block Diagram

[0]	Reserved	Reserved

## 6.5.7 Modes of Operation

The on-chip I<sup>2</sup>C ports support five operation modes, Master transmitter, Master receiver, Slave transmitter, Slave receiver, and GC call.

In a given application, I<sup>2</sup>C port may operate as a master or as a slave. In the slave mode, the I<sup>2</sup>C port hardware looks for its own slave address and the general call address. If one of these addresses is detected, and if the slave is willing to receive or transmit data from/to master (by setting the AA bit), acknowledge pulse will be transmitted out on the 9th clock, hence an interrupt is requested on both master and slave devices if interrupt is enabled. When the microcontroller wishes to become the bus master, the hardware waits until the bus is free before the master mode is entered so that a possible slave action didn't be interrupted. If bus arbitration is lost in the master mode, I<sup>2</sup>C port switches to the slave mode immediately and can detect its own slave address in the same serial transfer.

### 6.5.7.1 Master Transmitter Mode

Serial data output through SDA while SCL outputs the serial clock. The first byte transmitted contains the slave address of the receiving device (7 bits) and the data direction bit. In this case the data direction bit (R/W) will be logic 0, and it is represented by "W" in the Figure 6-24. Thus the first byte transmitted is SLA+W. Serial data is transmitted 8 bits at a time. After each byte is transmitted, an acknowledge bit is received. START and STOP conditions are output to indicate the beginning and the end of a serial transfer.

### 6.5.7.2 Master Receiver Mode

In this case the data direction bit (R/W) will be logic 1, and it is represented by "R" in the Figure 6-25. Thus the first byte transmitted is SLA+R. Serial data is received via SDA while SCL outputs the serial clock. Serial data is received 8 bits at a time. After each byte is received, an acknowledge bit is transmitted. START and STOP conditions are output to indicate the beginning and end of a serial transfer.

### 6.5.7.3 Slave Receiver Mode

Serial data and the serial clock are received through SDA and SCL. After each byte is received, an acknowledge bit is transmitted. START and STOP conditions are recognized as the beginning and end of a serial transfer. Address recognition is performed by hardware after reception of the slave address and direction bit.

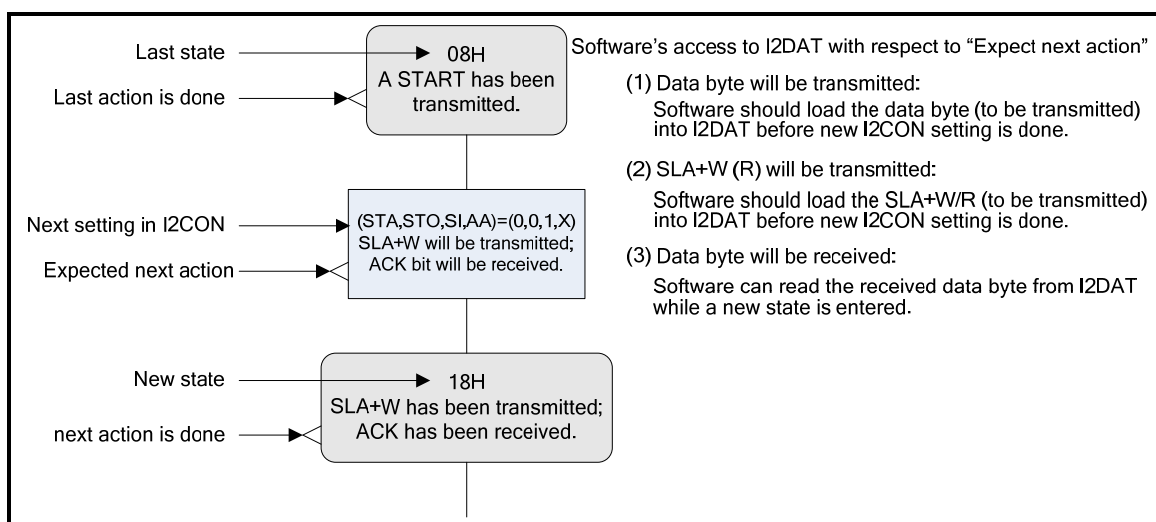

### 6.5.7.4 Slave Transmitter Mode

The first byte is received and handled as in the slave receiver mode. However, in this mode, the direction bit will indicate that the transfer direction is reversed. Serial data is transmitted via SDA while the serial clock is input through SCL. START and STOP conditions are recognized as the beginning and end of a serial transfer.

## 6.5.8 Data Transfer Flow in Five Operating Modes

The five operating modes are: Master/Transmitter, Master/Receiver, Slave/Transmitter, Slave/Receiver and GC Call. Bits STA, STO and AA in I2CON register will determine the next state of the I<sup>2</sup>C hardware after SI flag is cleared. Upon completion of the new action, a new status code will be updated and the SI flag will be set. If the I<sup>2</sup>C interrupt control bit EI (I2CON [7]) is set, appropriate action or software branch of the new status code can be performed in the Interrupt service routine.

Data transfers in each mode are shown in the Figure 6-23.

## 6.6 PWM Generator and Capture Timer

### 6.6.1 Overview

NuMicro M051™ series has 2 sets of PWM group supports 4 sets of PWM Generators which can be configured as 8 independent PWM outputs, PWM0~PWM7, or as 4 complementary PWM pairs, (PWM0, PWM1), (PWM2, PWM3), (PWM4, PWM5) and (PWM6, PWM7) with 4 programmable dead-zone generators.

Each PWM Generator has one 8-bit prescaler, one clock divider with 5 divided frequencies (1, 1/2, 1/4, 1/8, 1/16), two PWM Timers including two clock selectors, two 16-bit PWM down-counters for PWM period control, two 16-bit comparators for PWM duty control and one dead-zone generator. The 4 sets of PWM Generators provide eight independent PWM interrupt flags which are set by hardware when the corresponding PWM period down counter reaches zero. Each PWM interrupt source with its corresponding enable bit can cause CPU to request PWM interrupt. The PWM generators can be configured as one-shot mode to produce only one PWM cycle signal or auto-reload mode to output PWM waveform continuously.

When PCR.DZEN01 is set, PWM0 and PWM1 perform complementary PWM paired function; the paired PWM period, duty and dead-time are determined by PWM0 timer and Dead-zone generator 0. Similarly, the complementary PWM pairs of (PWM2, PWM3), (PWM4, PWM5) and (PWM6, PWM7) are controlled by PWM2, PWM4 and PWM6 timers and Dead-zone generator 2, 4 and 6, respectively. Refer to figures bellowed for the architecture of PWM Timers.

To prevent PWM driving output pin with unsteady waveform, the 16-bit period down counter and 16-bit comparator are implemented with double buffer. When user writes data to counter/comparator buffer registers the updated value will be load into the 16-bit down counter/comparator at the time down counter reaching zero. The double buffering feature avoids glitch at PWM outputs.

When the 16-bit period down counter reaches zero, the interrupt request is generated. If PWM-timer is set as auto-reload mode, when the down counter reaches zero, it is reloaded with PWM Counter Register (CNRx) automatically then start decreasing, repeatedly. If the PWM-timer is set as one-shot mode, the down counter will stop and generate one interrupt request when it reaches zero.

The value of PWM counter comparator is used for pulse high width modulation. The counter control logic changes the output to high level when down-counter value matches the value of compare register.

The alternate feature of the PWM-timer is digital input Capture function. If Capture function is enabled the PWM output pin is switched as capture input mode. The Capture0 and PWM0 share one timer which is included in PWM 0; and the Capture1 and PWM1 share PWM1 timer, and etc. Therefore user must setup the PWM-timer before enable Capture feature. After capture feature is enabled, the capture always latched PWM-counter to Capture Rising Latch Register (CRLR) when input channel has a rising transition and latched PWM-counter to Capture Falling Latch Register (CFLR) when input channel has a falling transition. Capture channel 0 interrupt is programmable by setting CCR0.CRL\_IE0[1] (Rising latch Interrupt enable) and CCR0.CFL\_IE0[2]] (Falling latch

Interrupt enable) to decide the condition of interrupt occur. Capture channel 1 has the same feature by setting CCR0.CRL\_IE1[17] and CCR0.CFL\_IE1[18]. And capture channel 0 to channel 3 on each group have the same feature by setting the corresponding control bits in CCR0 and CCR2. For each group, whenever Capture issues Interrupt 0/1/2/3, the PWM counter 0/1/2/3 will be reload at this moment.

The maximum captured frequency that PWM can capture is confined by the capture interrupt latency. When capture interrupt occurred, software will do at least three steps, they are: Read PIIR to get interrupt source and Read CRLRx/CFLRx(x=0 and 3) to get capture value and finally write 1 to clear PIIR. If interrupt latency will take time  $T_0$  to finish, the capture signal mustn't transition during this interval ( $T_0$ ). In this case, the maximum capture frequency will be  $1/T_0$ . For example:

HCLK = 50 MHz, PWM\_CLK = 25 MHz, Interrupt latency is 900 ns

So the maximum capture frequency will is  $1/900\text{ns} \approx 1000$  kHz

## 6.6.2 Features

### 6.6.2.1 PWM function features:

PWM group has two PWM generators. Each PWM generator supports one 8-bit prescaler, one clock divider, two PWM-timers (down counter), one dead-zone generator and two PWM outputs.

- Up to 16 bits resolution
- PWM Interrupt request synchronized with PWM period
- One-shot or Auto-reload mode PWM
- Up to 2 PWM group (PWMA/PWMB) to support 8 PWM channels

### 6.6.2.2 Capture Function Features:

- Timing control logic shared with PWM Generators
- 8 capture input channels shared with 8 PWM output channels
- Each channel supports one rising latch register (CRLR), one falling latch register (CFLR) and Capture interrupt flag (CAPIFx)

## 6.6.3 Block Diagram

The Figure 6-29 illustrate the architecture of PWM in pair (Timer 0/1 are in one pair and timer 2/3 are in another one, and so on.).

## 6.6.4 Function Description

### 6.6.4.1 PWM-Timer Operation

The PWM period and duty control are configured by PWM down-counter register (CNR) and PWM comparator register (CMR). The PWM-timer timing operation is shown in the Figure 6-38. The pulse width modulation follows the formula as below and the legend of PWM-Timer Comparator is shown in the Figure 6-37 note that the corresponding GPIO pins must be configured as PWM function (enable POE and disable CAPENR) for the corresponding PWM channel.

PWM frequency =  $\text{PWM}_{xy\_CLK} / [(\text{prescale} + 1) * (\text{clock divider}) * (\text{CNR} + 1)]$ ; where xy, could be 01, 23, 45 or 67, depends on selected PWM channel.

- Duty ratio =  $(\text{CMR} + 1) / (\text{CNR} + 1)$
- $\text{CMR} \geq \text{CNR}$ : PWM output is always high
- $\text{CMR} < \text{CNR}$ : PWM low width =  $(\text{CNR} - \text{CMR})$  unit<sup>1</sup>; PWM high width =  $(\text{CMR} + 1)$  unit
- $\text{CMR} = 0$ : PWM low width =  $(\text{CNR})$  unit; PWM high width = 1 unit

Note: 1. Unit = one PWM clock cycle.

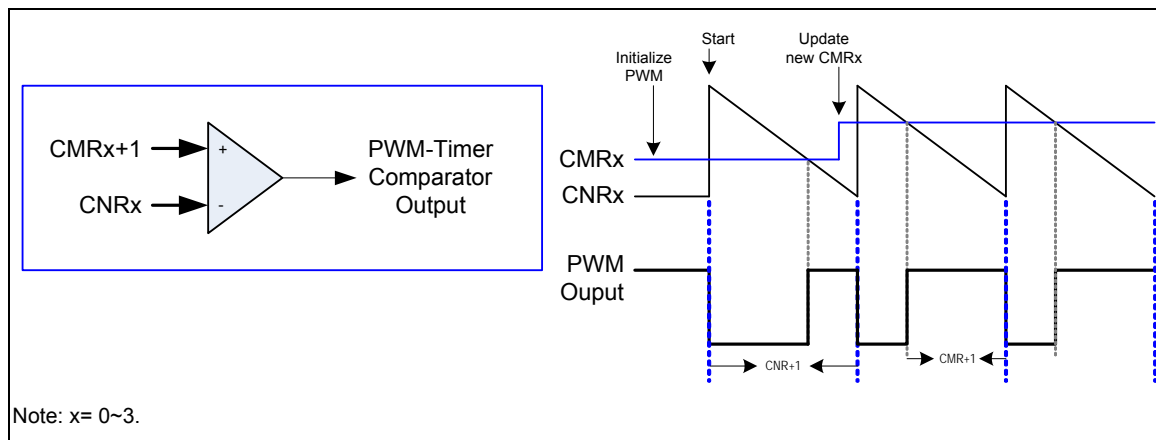

Figure 6-37 Legend of Internal Comparator Output of PWM-Timer

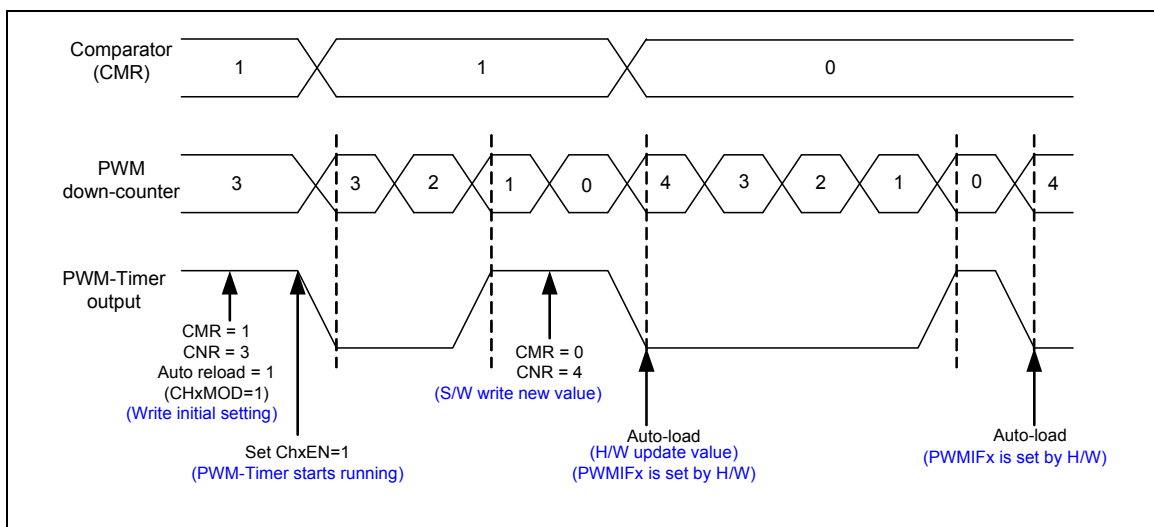

Figure 6-38 PWM-Timer Operation Timing

### 6.6.4.2 PWM Double Buffering, Auto-reload and One-shot Operation

NuMicro M051™ series PWM Timers have double buffering function the reload value is updated at the start of next period without affecting current timer operation. The PWM counter value can be written into CNRx and current PWM counter value can be read from PDRx.

The bit CH0MOD in PWM Control Register (PCR) defines PWM0 operates in auto-reload or one-shot mode. If CH0MOD is set to one, the auto-reload operation loads CNR0 to PWM counter when PWM counter reaches zero. If CNR0 are set to zero, PWM counter will be halt when PWM counter counts to zero. If CH0MOD is set as zero, counter will be stopped immediately. PWM1~PWM7 performs the same function as PWM0.

Figure 6-39 PWM Double Buffering Illustration

## 6.6.4.3 Modulate Duty Ratio

The double buffering function allows CMRx written at any point in current cycle. The loaded value will take effect from next cycle.

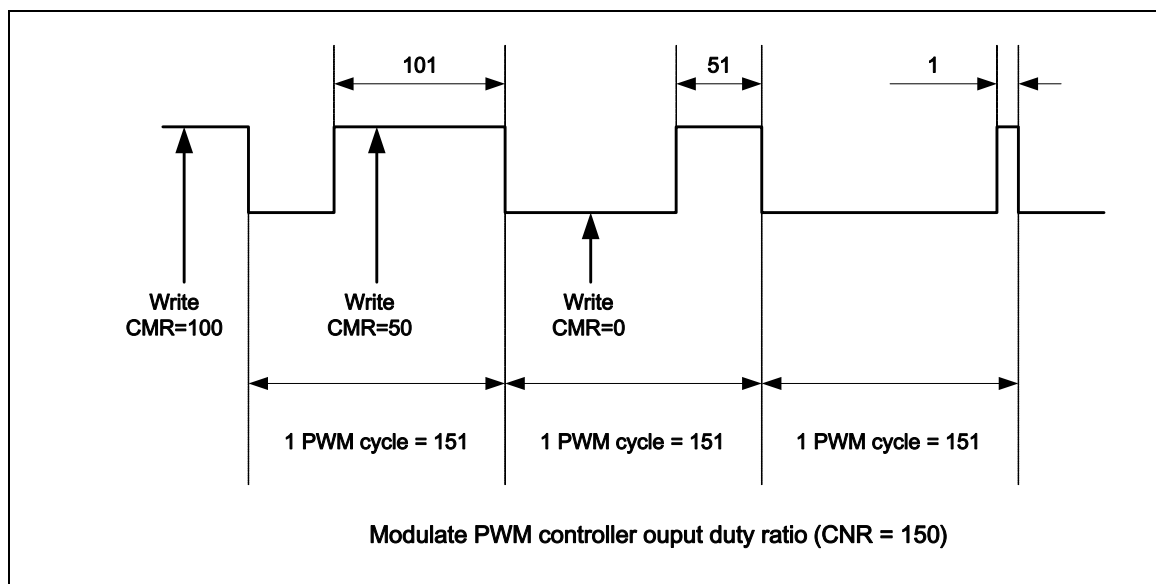

Figure 6-40 PWM Controller Output Duty Ratio

## 6.6.4.4 Dead-Zone Generator

NuMicro M051™ series PWM is implemented with Dead Zone generator. They are built for power device protection. This function generates a programmable time gap to delay PWM rising output. User can program PPRx.DZI to determine the Dead Zone interval.

Figure 6-41 Paired-PWM Output with Dead Zone Generation Operation

## 6.6.4.5 Capture Operation

The Capture 0 and PWM 0 share one timer that included in PWM 0; and the Capture 1 and PWM 1 share another timer, and etc. The capture always latches PWM-counter to CRLRx when input channel has a rising transition and latches PWM-counter to CFLRx when input channel has a falling transition. Capture channel 0 interrupt is programmable by setting CCR0[1] (Rising latch Interrupt enable) and CCR0[2] (Falling latch Interrupt enable) to decide the condition of interrupt occur. Capture channel 1 has the same feature by setting CCR0[17] and CCR0[18], and etc. Whenever the Capture module issues a capture interrupt, the corresponding PWM counter will be reloaded with CNRx at this moment. Note that the corresponding GPIO pins must be configured as capture function (disable POE and enable CAPENR) for the corresponding capture channel.

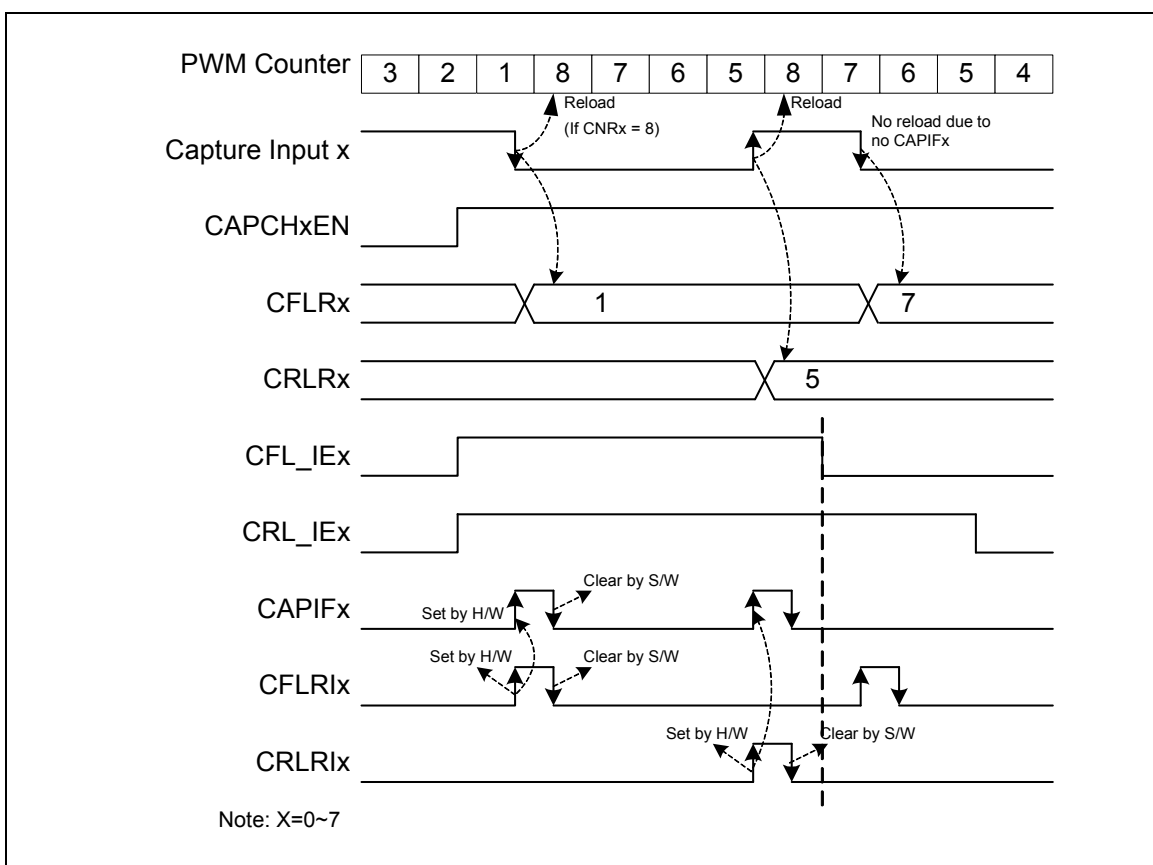

Figure 6-42 Capture Operation Timing

At this case, the CNR is 8:

1. The PWM counter will be reloaded with CNRx when a capture interrupt flag (CAPIFx) is set.
2. The channel low pulse width is  $(CNR + 1 - CRLR)$ .
3. The channel high pulse width is  $(CNR + 1 - CFLR)$ .

## 6.6.4.6 PWM-Timer Interrupt Architecture

There are eight PWM interrupts, PWM0\_INT~PWM7\_INT, which are divided into PWMA\_INT and PWMB\_INT for Advanced Interrupt Controller (AIC). PWM 0 and Capture 0 share one interrupt, PWM1 and Capture 1 share the same interrupt and so on. Therefore, PWM function and Capture function in the same channel cannot be used at the same time. The Figure 6-43 and Figure 6-44 demonstrate the architecture of PWM-Timer interrupts.

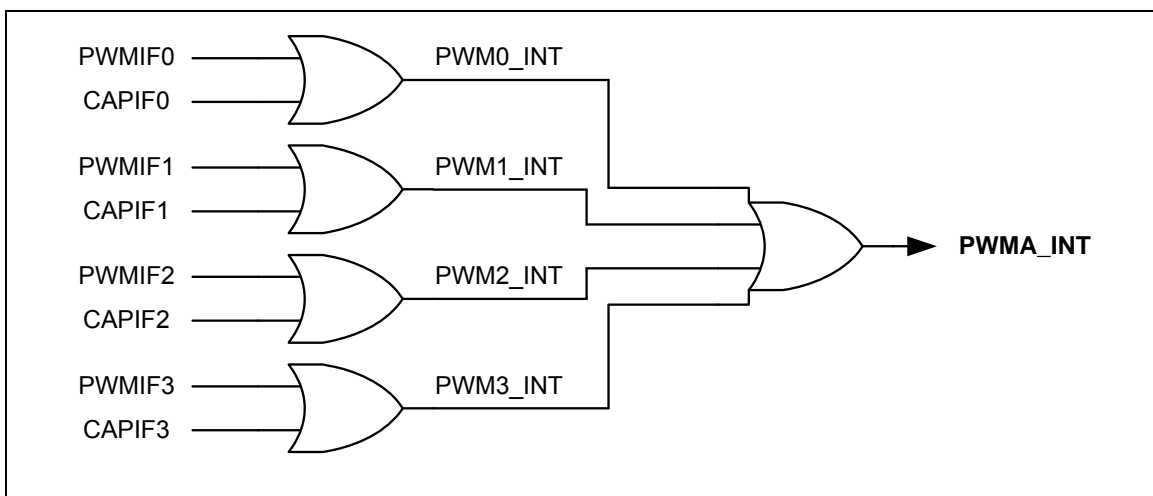

Figure 6-43 PWM Group A PWM-Timer Interrupt Architecture Diagram

Figure 6-44 PWM Group B PWM-Timer Interrupt Architecture Diagram

## 6.6.4.7 PWM-Timer Start Procedure

The following procedure is recommended for starting a PWM drive.

1. Setup clock selector (CSR)
2. Setup prescaler (PPR)
3. Setup inverter on/off, dead zone generator on/off, auto-reload/one-shot mode and Stop PWM-timer (PCR)
4. Setup comparator register (CMR) for setting PWM duty.
5. Setup PWM down-counter register (CNR) for setting PWM period.
6. Setup interrupt enable register (PIER)
7. Setup corresponding GPIO pins as PWM function (enable POE and disable CAPENR) for the corresponding PWM channel.
8. Enable PWM timer start running (Set CHxEN = 1 in PCR)

## 6.6.4.8 PWM-Timer Stop Procedure

### Method 1:

Set 16-bit down counter (CNR) as 0, and monitor PDR (current value of 16-bit down-counter). When PDR reaches to 0, disable PWM-Timer (CHxEN in PCR). *(Recommended)*

### Method 2:

Set 16-bit down counter (CNR) as 0. When interrupt request happens, disable PWM-Timer (CHxEN in PCR). *(Recommended)*

### Method 3:

Disable PWM-Timer directly ((CHxEN in PCR). *(Not recommended)*

The reason why method 3 is not recommended is that disable CHxEN will immediately stop PWM output signal and lead to change the duty of the PWM output, this may cause damage to the control circuit of motor

## 6.6.4.9 Capture Start Procedure

1. Setup clock selector (CSR)
2. Setup prescaler (PPR)
3. Setup channel enabled, rising/falling interrupt enable and input signal inverter on/off (CCR0, CCR2)
4. Setup PWM down-counter (CNR)
5. Setup corresponding GPIO pins as capture function (disable POE and enable CAPENR) for the corresponding PWM channel.
6. Enable PWM timer start running (Set CHxEN = 1 in PCR)

## 6.7 Serial Peripheral Interface (SPI) Controller

### 6.7.1 Overview

The Serial Peripheral Interface (SPI) is a synchronous serial data communication protocol which operates in full duplex mode. Devices communicate in master/slave mode with 4-wire bi-direction interface. NuMicro M051™ series contains up to two sets of SPI controller performing a serial-to-parallel conversion on data received from a peripheral device, and a parallel-to-serial conversion on data transmitted to a peripheral device. Each set of SPI controller can be set as a master; it also can be configured as a slave device controlled by an off-chip master device.

### 6.7.2 Features

- Up to two sets of SPI controller
- Support master or slave mode operation
- Configurable bit length up to 32 bits of a transfer word and configurable word numbers up to 2 of a transaction, so the maximum bit length is 64 bits for each data transfer
- Provide burst mode operation, transmit/receive can be transferred up to two times word transaction in one transfer
- Support MSB or LSB first transfer
- Byte or word Suspend Mode
- Variable output serial clock frequency in master mode
- Support two programmable serial clock frequencies in master mode

## 6.7.3 SPI Block Diagram

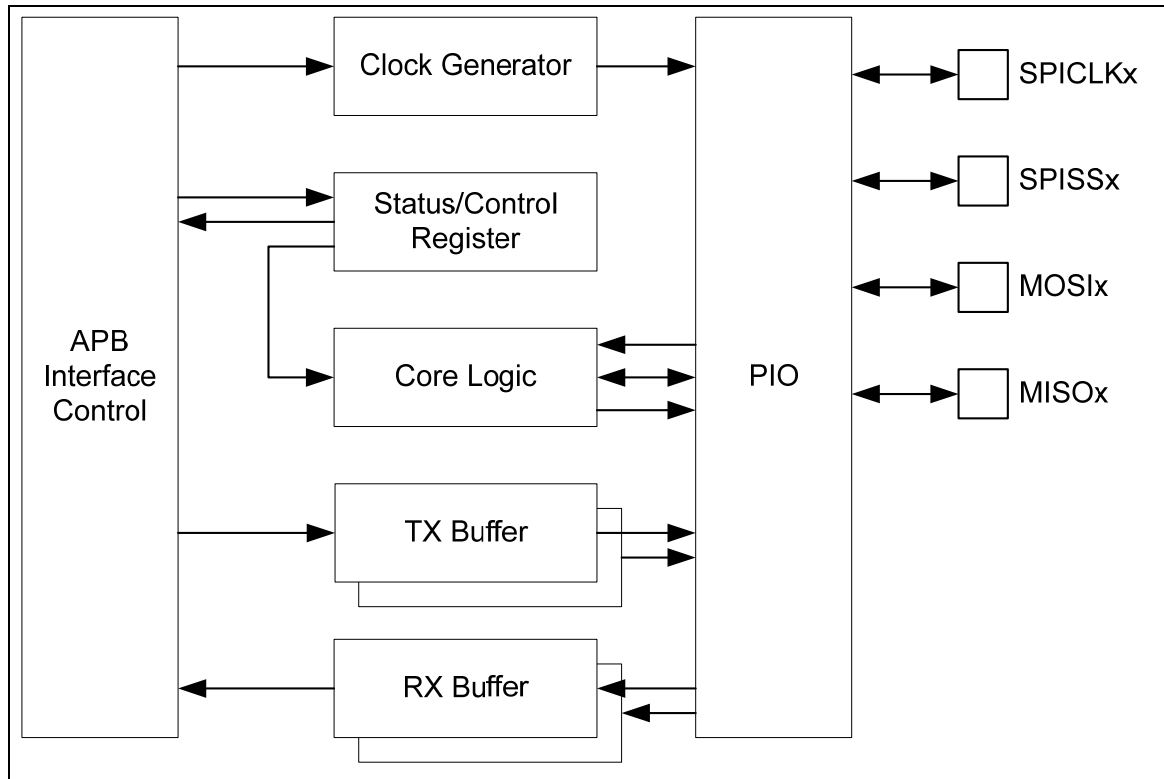

Figure 6-45 SPI Block Diagram

## 6.7.4 SPI Function Descriptions

### Master/Slave Mode

This SPI controller can be set as master or slave mode by setting the SLAVE bit (SPI\_CNTRL[18]) to communicate with the off-chip SPI slave or master device. The application block diagrams in master and slave mode are shown in the both Figure 6-46 and Figure 6-47. This SPI controller does not support multi-slave in SPI bus if the controller is set as slave mode. In slave mode, the SPI clock pin must be kept at idle state when the slave select pin is at inactive state.

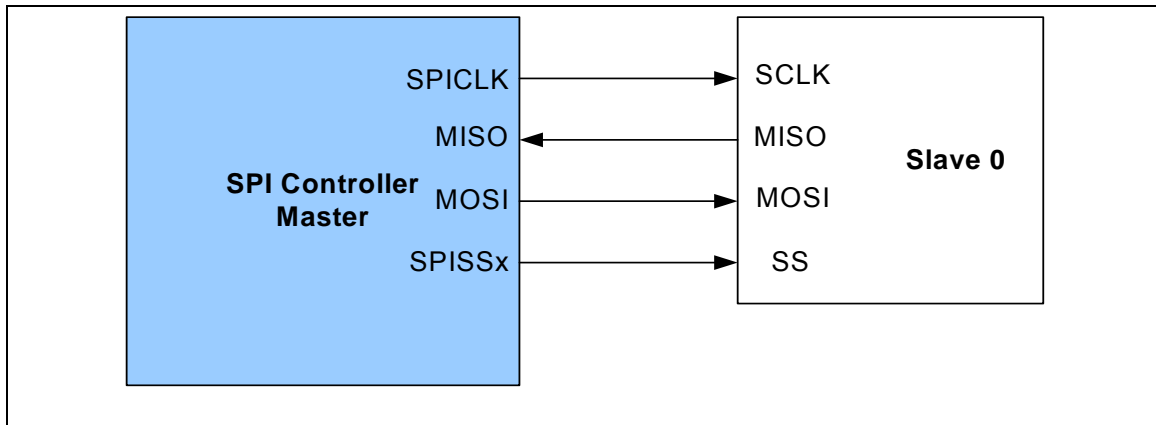

Figure 6-46 SPI Master Mode Application Block Diagram

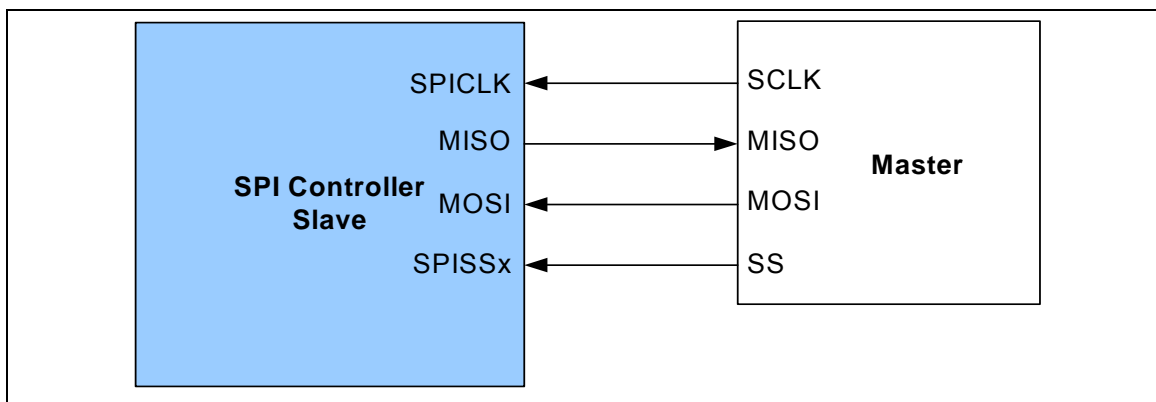

Figure 6-47 SPI Slave Mode Application Block Diagram

## Slave Select

In master mode, this SPI controller can drive one off-chip slave device through the slave select output pin SPISS. In slave mode, the off-chip master device drives the slave select signal from the SPISS input port to this SPI controller. In master/slave mode, the active state of slave select signal can be programmed to low active or high active in SS\_LVL bit (SPI\_SSR [2]), and the SS\_LTRIG bit (SPI\_SSR [4]) define the slave select signal SPISS is level trigger or edge trigger. The selection of trigger condition depends on what type of peripheral slave/master device is connected.

In slave mode, if the SS\_LTRIG bit is configured as level trigger, the LTRIG\_FLAG bit (SPI\_SSR[5]) is used to indicate if both the received number and received bits met the requirement which defines in TX\_NUM and TX\_BIT\_LEN among one transaction done (the transaction done means the slave select has deactivated.)

## Level-trigger / Edge-trigger

In slave mode, the slave select signal can be configured as level-trigger or edge-trigger. In edge-trigger, the data transfer starts from an active edge and ends on an inactive edge. If master does not send an inactive edge to slave, the transfer procedure will not be completed and the interrupt flag of slave will not be set. In level-trigger, the following two conditions will terminate the transfer procedure and the interrupt flag of slave will be set. The first condition, if master set the slave select pin to inactive level, it will force slave device to terminate the current transfer no matter how many bits have been transferred and the interrupt flag will be set. User can read the status of LTRIG\_FLAG bit to check if the data has been completely transferred. The second condition is that if the number of transferred bits matches the settings of TX\_NUM and TX\_BIT\_LEN, the interrupt flag of slave will be set.

## Automatic Slave Select

In master mode, if the bit AUTOSS(SPI\_SSR[3]) is set, the slave select signal will be generated automatically and output to SPISS pin according to **SSR[0]** (SPI\_SSR[0]) whether be enabled or not. It means that the slave select signal, which is selected in **SSR [0]**, will be asserted by the SPI controller when transmit/receive is started by setting the **GO\_BUSY** bit (SPI\_CNTRL [0]) and will be de-asserted after the data transfer is finished. If the AUTOSS bit is cleared, the slave select output signal will be asserted/de-asserted by manual setting/clearing the related bits of SPI\_SSR[1:0]. The active state of the slave select output signal is specified in SS\_LVL bit (SPI\_SSR [2]).

## Serial Clock

In master mode, set the DIVIDER (SPI\_DIVIDER [15:0]) register to program the output frequency of serial clock to the SPICLK output port. It also supports the variable frequency function if the VARCLK\_EN bit (SPI\_CNTRL[23]) is enabled. In this case the each bit output frequency of serial clock can be programmed at one frequency of two different frequencies which depend on the DIVIDER and DIVIDER2 (SPI\_DIVIDER[31:16]) settings. The serial clock rate of each cycle is depended on the setting of the SPI\_VARCLK register.

In slave mode, the off-chip master device drives the serial clock through the SPICLK input port to this SPI controller.

### **Clock Polarity**

The CLKP bit (SPI\_CNTRL [11]) defines the serial clock idle stat. If CLKP = 1, the output SPICLK is idle at high state, otherwise it is at low state if CLKP = 0.

## Transmit/Receive Bit Length

The bit length of a transaction word is defined in TX\_BIT\_LEN bit field (SPI\_CNTRL [7:3]). It can be configured up to 32 bits length in a transfer word for transmitting and receiving.

## Burst Mode

SPI controller can switch to burst mode by setting TX\_NUM bit field (SPI\_CNTRL [9:8]) to 0x01. In burst mode, SPI can transmit/receive two transactions in one transfer. The SPI burst mode waveform is shown below:

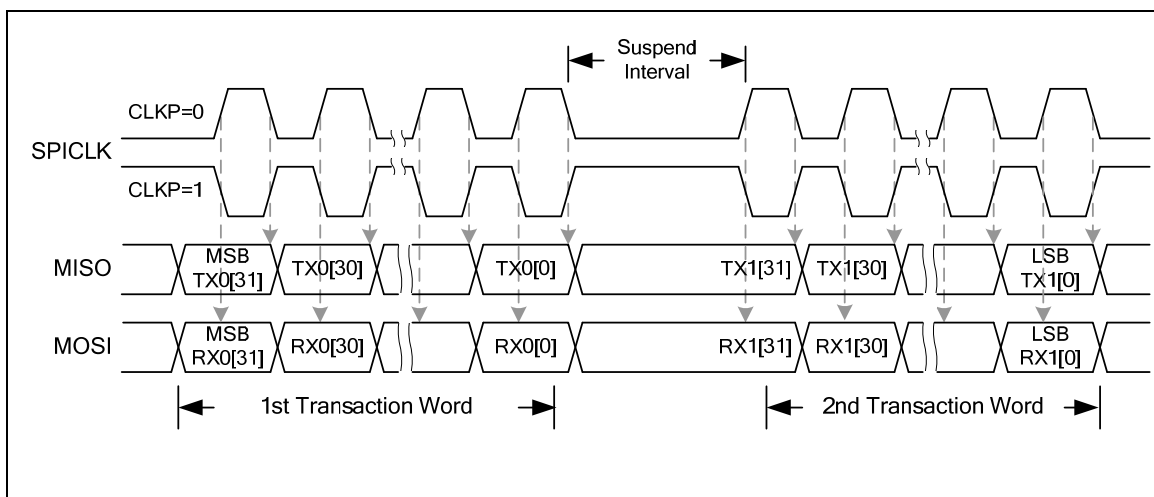

Figure 6-48 Two Transactions in One Transfer (Burst Mode)

## LSB First

The LSB bit (SPI\_CNTRL [10]) defines the data transmission either from LSB or MSB firstly to start to transmit/receive data.

## Transmit Edge

The TX\_NEG bit (SPI\_CNTRL [2]) defines the data transmitted out either at negative edge or at positive edge of serial clock SPICLK.

## Receive Edge

The RX\_NEG bit (SPI\_CNTRL [1]) defines the data received in either at negative edge or at positive edge of serial clock SPICLK.

Note: the settings of TX\_NEG and RX\_NEG are mutual exclusive. In other words, don't transmit and receive data at the same clock edge.

## Word Suspend

These four bits field of SP\_CYCLE (SPI\_CNTRL [15:12]) provide a configurable suspend interval 2 ~ 17 serial clock periods between two successive transaction words in master mode. The suspend interval is from the last falling clock edge of the preceding transaction word to the first rising clock edge of the following transaction word if CLKP = 0. If CLKP = 1, the interval is from the rising clock edge of the preceding transaction word to the falling clock edge of the following transfer word. The default value of SP\_CYCLE is 0x0 (2 serial clock cycles), but set these bits field has no any effects on data transaction process if TX\_NUM = 0x00. Byte reorder function is only available when TX\_BIT\_LEN is configured as 16, 24, and 32 bits.

## Byte Reorder

When the transfer is set as MSB first (LSB = 0) and the REORDER is enabled, the data stored in the TX buffer and RX buffer will be rearranged in the order as [BYTE0, BYTE1, BYTE2, BYTE3] in TX\_BIT\_LEN = 32 bits mode, and the sequence of transmitted/received data will be BYTE0, BYTE1, BYTE2, and then BYTE3. If the TX\_BIT\_LEN is set as 24-bits mode, the data in TX buffer and RX buffer will be rearranged as [unknown byte, BYTE0, BYTE1, BYTE2]. The SPI controller will transmit/receive data with the sequence of BYTE0, BYTE1 and then BYTE2. Each byte will be transmitted/received with MSB first. The rule of 16-bits mode is the same as above.

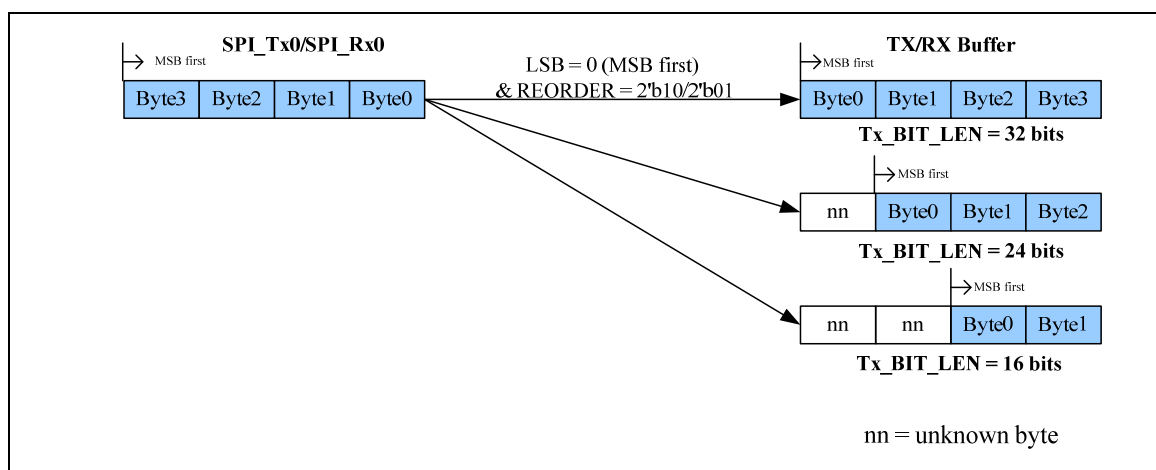

Figure 6-49 Byte Reorder

## Byte Suspend

In master mode, if SPI\_CNTRL[19] is set to 1, the hardware will insert a suspend interval 2 ~ 17 serial clock periods between two successive bytes in a transaction word. Both settings of byte suspend and word suspend are configured in SP\_CYCLE. Note that when enable the byte suspend function, the setting of TX\_BIT\_LEN must be programmed as 0x00 only (32-bit per transaction word).

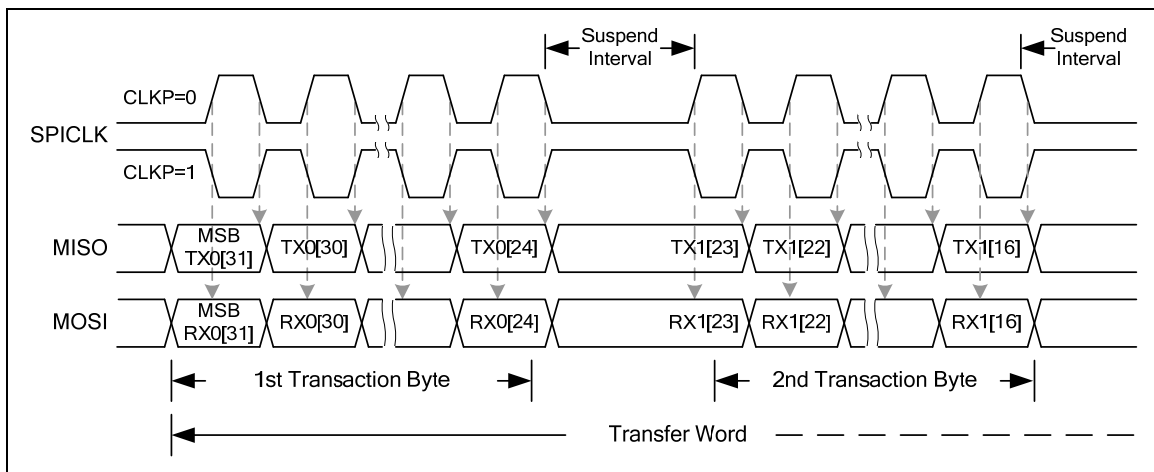

Figure 6-50 Timing Waveform for Byte Suspend

REORDER	Description
00	Disable both byte reorder function and byte suspend interval.
01	Enable byte reorder function and insert a byte suspend interval (2~17 SPICLK) among each byte. The setting of TX_BIT_LEN must be configured as 0x00 ( 32 bits/ word)
10	Enable byte reorder function but disable byte suspend function.
11	Disable byte reorder function, but insert a suspend interval (2~17 SPICLK) among each byte. The setting of TX_BIT_LEN must be configured as 0x00 ( 32 bits/ word)

Table 11-1 Byte Order and Byte Suspend Conditions

## Interrupt

Each SPI controller can generate an individual interrupt when data transfer is finished and the respective interrupt event flag **IF** (SPI\_CNTRL [16]) will be set. The interrupt event flag will generate an interrupt to CPU if the interrupt enable bit **IE** (SPI\_CNTRL [17]) is set. The interrupt event flag **IF** can be cleared only by writing 1 to it.

## Variable Serial Clock Frequency

In master mode, the output of serial clock can be programmed as variable frequency pattern if the Variable Clock Enable bit VARCLK\_EN (SPI\_CNTRL [23]) is enabled. The frequency pattern format is defined in VARCLK (SPI\_VARCLK [31:0]) register. If the bit content of VARCLK is '0' the output frequency is according with the DIVIDER (SPI\_DIVIDER[15:0]) and if the bit content of VARCLK is '1', the output frequency is according to the DIVIDER2 (SPI\_DIVIDER[31:16]). The Figure 6-51 is the timing relationship among the serial clock (SPICLK), the VARCLK, the DIVIDER and the DIVIDER2 registers. A two-bit combination in the VARCLK defines one clock cycle. The bit field VARCLK [31:30] defines the first clock cycle of SPICLK. The bit field VARCLK [29:28] defines the second clock cycle of SPICLK and so on. The clock source selections are defined in VARCLK and it must be set 1 cycle before the next clock option. For example, if there are 5 CLK1 cycle in SPICLK, the VARCLK shall set 9 '0' in the MSB of VARCLK. The 10th shall be set as '1' in order to switch the next clock source is CLK2. Note that when enable the VARCLK\_EN bit, the setting of TX\_BIT\_LEN must be programmed as 0x10 (16 bits mode only).

Figure 6-51 Variable Serial Clock Frequency

## 6.7.5 SPI Timing Diagram

The active state of slave select signal can be defined by the settings of SS\_LVL bit (SPI\_SSR[2]) and SS\_LTRIG bit (SPI\_SSR[4]). The serial clock (SPICLK) idle state can be configured as high state or low state by setting the CLKP bit (SPI\_CNTRL [11]). It also provides the bit length of a transfer word in TX\_BIT\_LEN (SPI\_CNTRL [7:3]), the transfer number in TX\_NUM (SPI\_CNTRL [8]), and transmit/receive data from MSB or LSB first in LSB bit (SPI\_CNTRL [10]). Users also can select which edge of serial clock to transmit/receive data in TX\_NEG/RX\_NEG (SPI\_CNTRL [2:1]) registers. Four SPI timing diagrams for master/slave operations and the related settings are shown from Figure 6-52 to Figure 6-55.

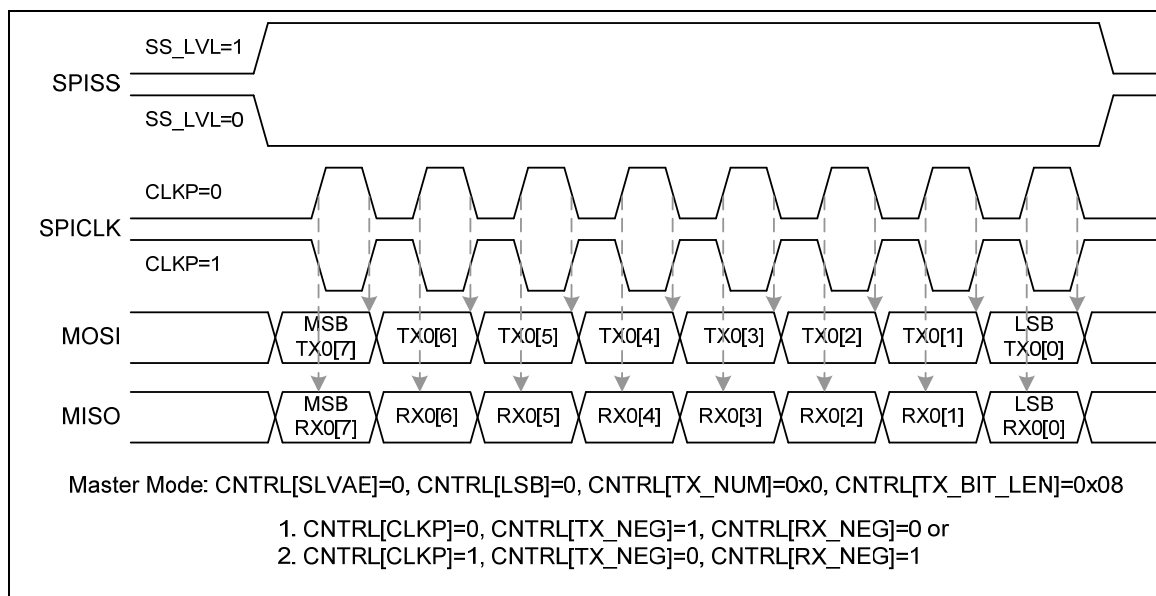

Figure 6-52 SPI Timing in Master Mode

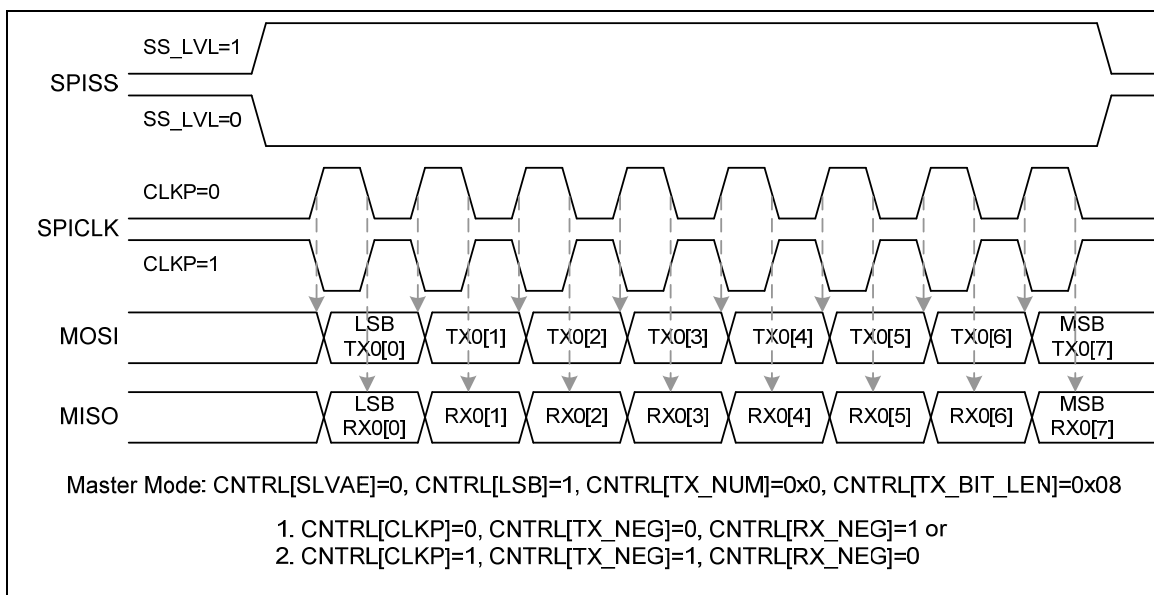

Figure 6-53 SPI Timing in Master Mode (Alternate Phase of SPICLK)

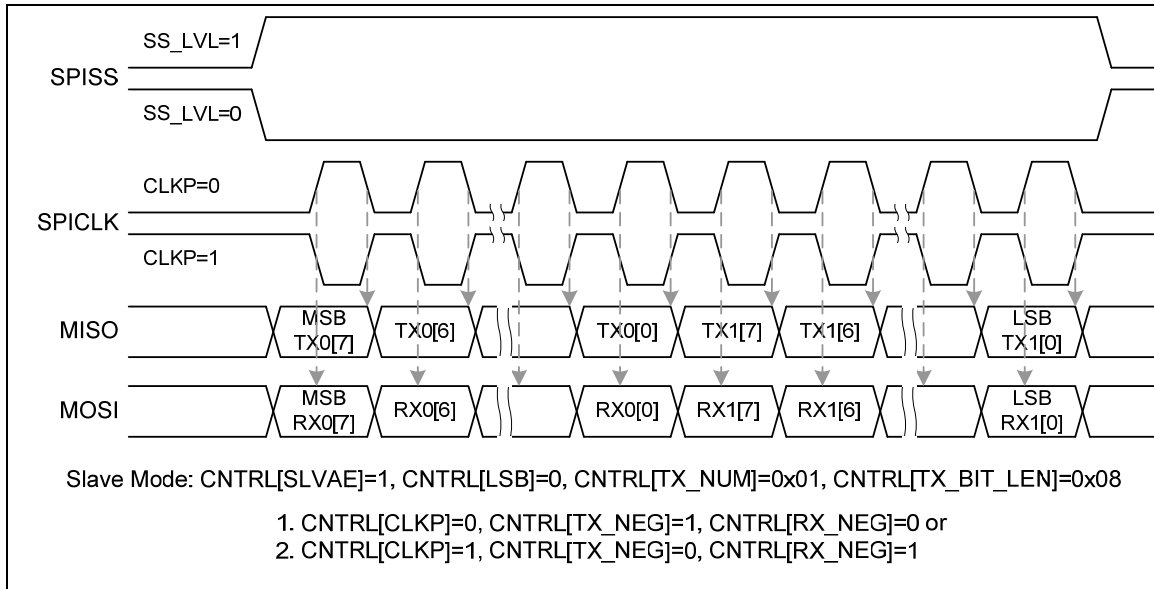

Figure 6-54 SPI Timing in Slave Mode

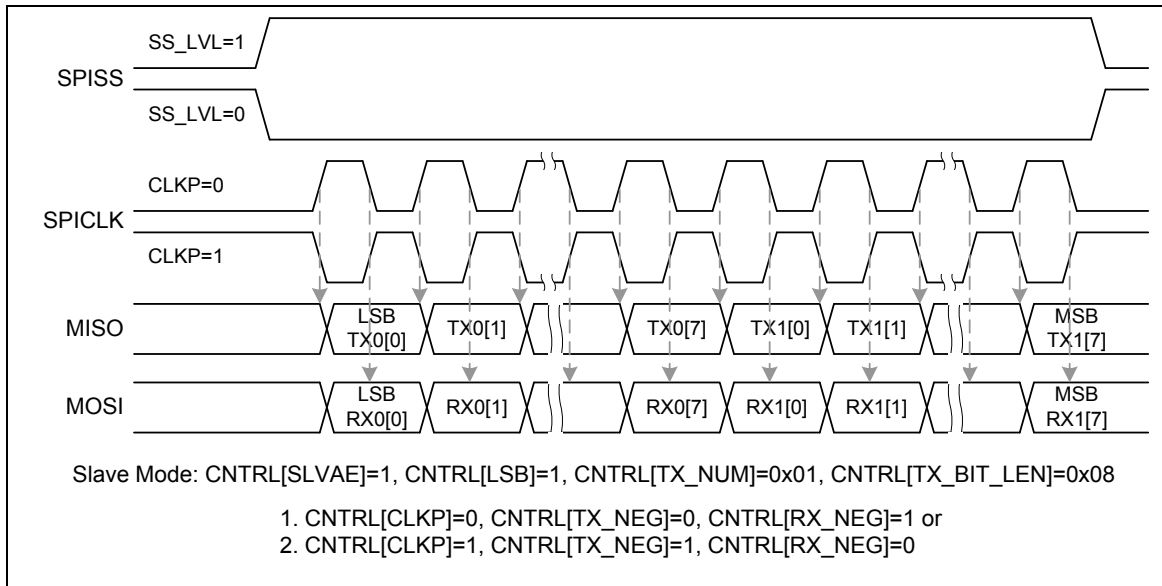

Figure 6-55 SPI Timing in Slave Mode (Alternate Phase of SPICLK)

## 6.7.6 SPI Programming Examples

**Example 1**, SPI controller is set as a master to access an off-chip slave device with following specifications:

- Data bit is latched on positive edge of serial clock
- Data bit is driven on negative edge of serial clock
- Data is transferred from MSB first
- SPICLK is idle at low state
- Only one byte of data to be transmitted/received in a transfer
- Use the first SPI slave select pin to connect with an off-chip slave device. Slave select signal is active low

Basically, the specification of the connected off-chip slave device should be referred in details before the following steps:

- 1) Set the DIVIDER (SPI\_DIVIDER [15:0]) register to determine the output frequency of serial clock.
- 2) Write the SPI\_SSR register a proper value for the related settings of master mode
  1. Disable the Automatic Slave Select bit AUTOSS(SPI\_SSR[3] = 0)
  2. Select low level trigger output of slave select signal in the Slave Select Active Level bit SS\_LVL (SPI\_SSR[2] = 0) and Slave Select Level Trigger bit SS\_LTRIG (SPI\_SSR[4] = 1)
  3. Select slave select signal to be output active at the IO pin by setting the respective Slave Select Register bits SSR[0] (SPI\_SSR[0]) to active the off-chip slave devices
- 3) Write the related settings into the SPI\_CNTRL register to control this SPI master actions
  1. Set this SPI controller as master device in SLAVE bit (SPI\_CNTRL[18] = 0)
  2. Force the serial clock idle state at low in CLKP bit (SPI\_CNTRL[11] = 0)
  3. Select data transmitted at negative edge of serial clock in TX\_NEG bit (SPI\_CNTRL[2] = 1)
  4. Select data latched at positive edge of serial clock in RX\_NEG bit (SPI\_CNTRL[1] = 0)

5. Set the bit length of word transfer as 8 bits in TX\_BIT\_LEN bit field (SPI\_CNTRL[7:3] = 0x08)
6. Set only one time of word transfer in TX\_NUM (SPI\_CNTRL[9:8] = 0x0)
7. Set MSB transfer first in MSB bit (SPI\_CNTRL[10] = 0), and don't care the SP\_CYCLE bit field (SPI\_CNTRL[15:12]) due to not burst mode in this case
- 4) If this SPI master will transmits (writes) one byte data to the off-chip slave device, write the byte data that will be transmitted into the TX0[7:0] (SPI\_TX0[7:0]) register.
- 5) If this SPI master just only receives (reads) one byte data from the off-chip slave device, you don't need to care what data will be transmitted and just write 0xFF into the SPI\_TX0[7:0] register.
- 6) Enable the GO\_BUSY bit (SPI\_CNTRL [0] = 1) to start the data transfer at the SPI interface.
- 7) Waiting for SPI interrupt occurred (if the Interrupt Enable IE bit is set) or just polling the GO\_BUSY bit till it be cleared to 0 by hardware automatically.
- 8) Read out the received one byte data from RX0 [7:0] (SPI\_RX0[7:0]) register.
- 9) Go to 4) to continue another data transfer or set SSR [0] to 0 to inactivate the off-chip slave devices.

**Example 2**, SPI controller is set as a slave device that are controlled by an off-chip master device, and supposes the off-chip master device to access the on-chip SPI slave controller through the SPI interface with the following specifications:

- Data bit is latched on positive edge of serial clock
- Data bit is driven on negative edge of serial clock
- Data is transferred from LSB first
- SPICLK is idle at high state
- Only one byte of data to be transmitted/received in a transfer
- Slave select signal is high level trigger

Basically, the specification of the connected off-chip master device should be configured detailed before the following steps

- 1) Write the SPI\_SSR register a proper value for the related settings of slave mode

Select high level and level trigger for the input of slave select signal by setting the Slave Select Active Level bit `SS_LVL` (`SPI_SSR[2] = 1`) and the Slave Select Level Trigger bit `SS_LTRIG` (`SPI_SSR[4] = 1`).

- 2) Write the related settings into the `SPI_CNTRL` register to control this SPI slave actions
  1. Set this SPI controller as slave device in `SLAVE` bit (`SPI_CNTRL[18] = 1`)
  2. Select the serial clock idle state at high in `CLKP` bit (`SPI_CNTRL[11] = 1`)
  3. Select data transmitted at negative edge of serial clock in `TX_NEG` bit (`SPI_CNTRL[2] = 1`)
  4. Select data latched at positive edge of serial clock in `RX_NEG` bit (`SPI_CNTRL[1] = 0`)
  5. Set the bit length of word transfer as 8 bits in `TX_BIT_LEN` bit field (`SPI_CNTRL[7:3] = 0x08`)
  6. Set only one time of word transfer in `TX_NUM` (`SPI_CNTRL[9:8] = 0x0`)
  7. Set LSB transfer first in `LSB` bit (`SPI_CNTRL[10] = 1`), and don't care the `SP_CYCLE` bit field (`SPI_CNTRL[15:12]`) due to not burst mode in this case.
- 3) If this SPI slave will transmits (be read) one byte data to the off-chip master device, write the byte data that will be transmitted into the `TX0 [7:0]` (`SPI_TX0[7:0]`) register.
- 4) If this SPI slave just only receives (be written) one byte data from the off-chip master device, you don't care what data will be transmitted and just write `0xFF` into the `SPI_TX0[7:0]` register.
- 5) Enable the `GO_BUSY` bit (`SPI_CNTRL[0] = 1`) to wait for the slave select trigger input and serial clock input from the off-chip master device to start the data transfer at the SPI interface.

Waiting for SPI interrupt occurred (if the Interrupt Enable `IE` bit is set) or just polling the `GO_BUSY` bit till it be cleared to 0 by hardware automatically.
- 6) Read out the received one byte data from `RX[7:0]` (`SPI_RX0[7:0]`) register
- 7) Go to 3) to continue another data transfer or disable the `GO_BUSY` bit to stop data transfer.

Bits	Descriptions	
[31:0]	VARCLK	<p><b>Variable Clock Pattern</b></p> <p>The value in this field is the frequency patterns of the SPI clock. If the bit pattern of VARCLK is '0', the output frequency of SPICLK is according the value of DIVIDER. If the bit patterns of VARCLK are '1', the output frequency of SPICLK is according the value of DIVIDER2. Refer to register <a href="#">SPI_DIVIDER</a>.</p> <p>Refer to Figure 6-51 for Variable Clock timing diagram.</p>

## 6.8 Timer Controller

### 6.8.1 Overview

The timer controller includes four 32-bit timers, TIMER0~TIMER3, which allows user to easily implement a timer control for applications. The timer can perform functions like frequency measurement, interval measurement, clock generation, delay timing, and so on. The timer can generate an interrupt signal upon timeout, or provide the current value of count during operation.

### 6.8.2 Features

- 4 sets of 32-bit timers with 24-bit up-timer and one 8-bit pre-scale counter
- Independent clock source for each timer.
- 24-bit timer value is readable through TDR (Timer Data Register)
- Provides one-shot, periodic, toggle and continuous counting operation modes.
- Time out period = (Period of timer clock input) \* (8-bit pre-scale counter + 1) \* (24-bit TCMP)
- Maximum counting cycle time =  $(1 / T \text{ MHz}) * (2^8) * (2^{24})$ , T is the period of timer clock

## 6.8.3 Timer Controller Block Diagram

Each channel is equipped with an 8-bit pre-scale counter, a 24-bit up-timer, a 24-bit compare register and an interrupt request signal. Refer to Figure 6.8-1 for the timer controller block diagram. There are three options of clock sources for each channel. Figure 6.8-2 illustrates the clock source control function. Software can program the 8-bit pre-scale counter to decide the clock period to 24-bit up timer.

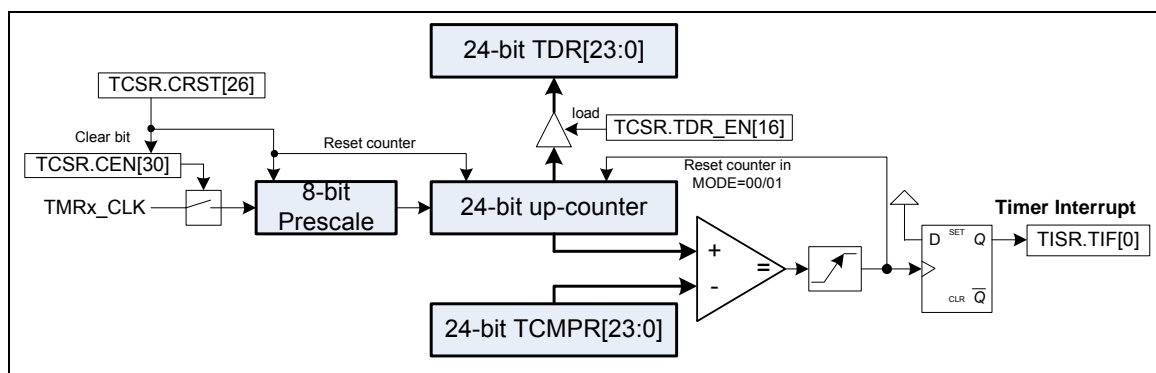

Figure 6-56 Timer Controller Block Diagram

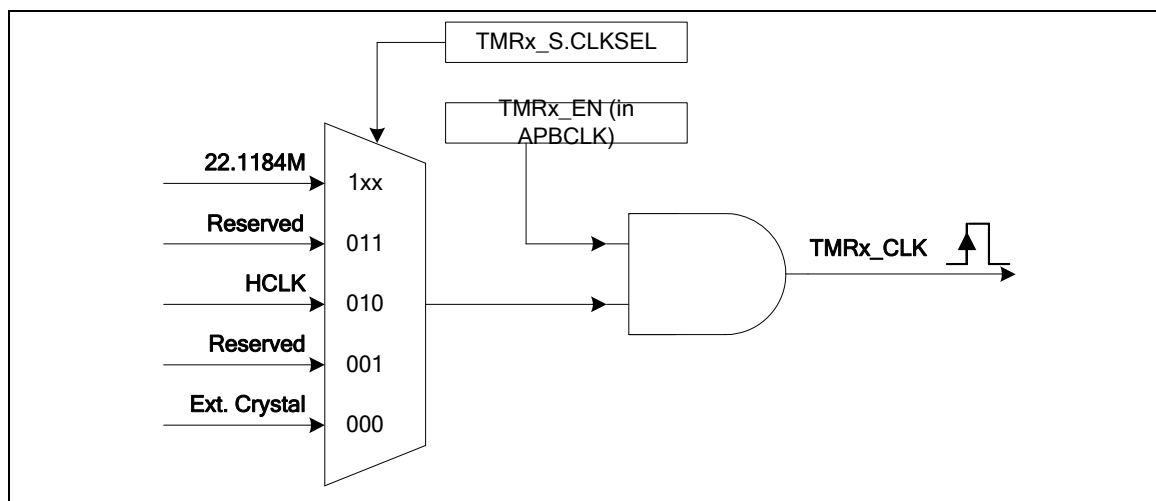

Figure 6-57 Clock Source of Timer Controller

## 6.8.4 Timer Operation Mode

Timer controller provides one-shot, period, toggle and continuous counting operation modes. Each operating function mode is shown as following:

### 6.8.4.1 One –Shot Mode

If timer is operated at one-shot mode and CEN (TCSR[30] timer enable bit) is set to 1, the timer counter starts up counting. Once the timer counter value reaches timer compare register (TCMPR) value, if IE (TCSR[29] interrupt enable bit) is set to 1, then the timer interrupt flag is set and the interrupt signal is generated and sent to NVIC to inform CPU. It indicates that the timer counting overflow happens. If IE (TCSR[29] interrupt enable bit) is set to 0, no interrupt signal is generated. In this operating mode, once the timer counter value reaches timer compare register (TCMPR) value, the timer counter value goes back to counting initial value and CEN (timer enable bit) is cleared to 0 by timer controller. Timer counting operation stops, once the timer counter value reaches timer compare register (TCMPR) value. That is to say, timer operates timer counting and compares with TCMPR value function only one time after programming the timer compare register (TCMPR) value and CEN (timer enable bit) is set to 1. So, this operating mode is called One-Shot mode.

### 6.8.4.2 Periodic mode

If timer is operated at period mode and CEN (TCSR[30] timer enable bit) is set to 1, the timer counter starts up counting. Once the timer counter value reaches timer compare register (TCMPR) value, if IE (TCSR[29] interrupt enable bit) is set to 1, then the timer interrupt flag is set and the interrupt signal is generated and sent to NVIC to inform CPU. It indicates that the timer counting overflow happens. If IE (TCSR[29] interrupt enable bit) is set to 0, no interrupt signal is generated. In this operating mode, once the timer counter value reaches timer compare register (TCMPR) value, the timer counter value goes back to counting initial value and CEN is kept at 1 (counting enable continuously). The timer counter operates up counting again. If the interrupt flag is cleared by software, once the timer counter value reaches timer compare register (TCMPR) value and IE (interrupt enable bit) is set to 1, then the timer interrupt flag is set and the interrupt signal is generated and sent to NVIC to inform CPU again. That is to say, timer operates timer counting and compares with TCMPR value function periodically. The timer counting operation doesn't stop until the CEN is set to 0. The interrupt signal is also generated periodically. So, this operating mode is called Periodic mode.

### 6.8.4.3 Toggle mode

If timer is operated at toggle mode and CEN (TCSR[30] timer enable bit) is set to 1, the timer counter starts up counting. Once the timer counter value reaches timer compare register (TCMPR) value, if IE (TCSR[29] interrupt enable bit) is set to 1, then the timer interrupt flag is set and the interrupt signal is generated and sent to NVIC to inform CPU. It indicates that the timer counting overflow happens. The associated toggle output (tout) signal is set to 1. In this operating mode, once the timer counter value reaches timer compare register (TCMPR) value, the timer counter value goes back to counting initial value and CEN is kept at 1 (counting enable continuously). The timer counter operates up counting again. If the interrupt flag is cleared by software, once the timer counter value reaches timer compare register (TCMPR) value and IE (interrupt enable bit) is

set to 1, then the timer interrupt flag is set and the interrupt signal is generated and sent to NVIC to inform CPU again. The associated toggle output (tout) signal is set to 0. The timer counting operation doesn't stop until the CEN is set to 0. Thus, the toggle output (tout) signal is changing back and forth with 50% duty cycle. So, this operating mode is called Toggle mode.

## 6.8.4.4 Continuous Counting mode

If the timer is operated at continuous counting mode and CEN (TCSR[30] timer enable bit) is set to 1, the associated interrupt signal is generated depending on  $TDR = TCMPR$  if IE (TCSR[29] interrupt enable bit) is enabled. User can change different TCMPR value immediately without disabling timer counting and restarting timer counting. For example, TCMPR is set as 80, first. (The TCMPR should be less than  $2^{24}$  and be greater than 1). The timer generates the interrupt if IE is enabled and TIF (timer interrupt flag) will set to 1 then the interrupt signal is generated and sent to NVIC to inform CPU when TDR value is equal to 80. But the CEN is kept at 1 (counting enable continuously) and TDR value will not goes back to 0, it continues to count 81, 82, 83, ... to  $2^{24} - 1$ , 0, 1, 2, 3, ... to  $2^{24} - 1$  again and again. Next, if user programs TCMPR as 200 and the TIF is cleared to 0, then timer interrupt occurred and TIF is set to 1, then the interrupt signal is generated and sent to NVIC to inform CPU again when TDR value reaches to 200. At last, user programs TCMPR as 500 and clears TIF to 0 again, then timer interrupt occurred and TIF sets to 1 then the interrupt signal is generated and sent to NVIC to inform CPU when TDR value reaches to 500. From application view, the interrupt is generated depending on TCMPR. In this mode, the timer counting is continuous. So, this operation mode is called as continuous counting mode.

## 6.9 Watchdog Timer (WDT)

### 6.9.1 Overview

The purpose of Watchdog Timer is to perform a system reset when system runs into an unknown state. This prevents system from hanging for an infinite period of time. Besides, this Watchdog Timer supports another function to wakeup chip from power down mode. The watchdog timer includes an 18-bit free running counter with programmable time-out intervals. Table 6-6 show the watchdog timeout interval selection and Figure 6.9-1 shows the timing of watchdog interrupt signal and reset signal.

Setting WTE (WDTCR [7]) enables the watchdog timer and the WDT counter starts counting up. When the counter reaches the selected time-out interval, Watchdog timer interrupt flag WTIF will be set immediately to request a WDT interrupt if the watchdog timer interrupt enable bit WTIE is set, in the meanwhile, a specified delay time ( $1024 * T_{WDT}$ ) follows the time-out event. User must set WTR (WDTCR [0]) (Watchdog timer reset) high to reset the 18-bit WDT counter to avoid chip from Watchdog timer reset before the delay time expires. WTR bit is cleared automatically by hardware after WDT counter is reset. There are eight time-out intervals with specific delay time which are selected by Watchdog timer interval select bits WTIS (WDTCR [10:8]). If the WDT counter has not been cleared after the specific delay time expires, the watchdog timer will set Watchdog Timer Reset Flag (WTRF) high and reset chip. This reset will last 63 WDT clocks ( $T_{RST}$ ) then chip restarts executing program from reset vector (0x0000 0000). WTRF will not be cleared by Watchdog reset. User may poll WTRF by software to recognize the reset source. WDT also provides wakeup function. When chip is powered down and the Watchdog Timer Wake-up Function Enable bit (WDTR[4]) is set, if the WDT counter reaches the specific time interval defined by WTIS (WDTCR [10:8]), the chip is waken up from power down state. First example, if WTIS is set as 000, the specific time interval for chip to wake up from power down state is  $2^4 * T_{WDT}$ . When power down command is set by software, then, chip enters power down state. After  $2^4 * T_{WDT}$  time is elapsed, chip is waken up from power down state. Second example, if WTIS (WDTCR [10:8]) is set as 111, the specific time interval for chip to wake up from power down state is  $2^{18} * T_{WDT}$ . If power down command is set by software, then, chip enters power down state. After  $2^{18} * T_{WDT}$  time is elapsed, chip is waken up from power down state. Notice if WTRE (WDTCR [1]) is set to 1, after chip is waken up, software should chip the Watchdog Timer counter by setting WTR(WDTCR [0]) to 1 as soon as possible. Otherwise, if the Watchdog Timer counter is not cleared by setting WTR (WDTCR [0]) to 1 before time starting from waking up to software clearing Watchdog Timer counter is over  $1024 * T_{WDT}$ , the chip is reset by Watchdog Timer.

WTIS	Timeout Interval Selection $T_{TIS}$	Interrupt Period $T_{INT}$	WTR Timeout Interval (WDT_CLK=10 kHz) MIN. $T_{WTR}$ ~ MAX. $T_{WTR}$
000	$2^4 * T_{WDT}$	$1024 * T_{WDT}$	1.6 ms ~ 104 ms
001	$2^6 * T_{WDT}$	$1024 * T_{WDT}$	6.4 ms ~ 108.8 ms
010	$2^8 * T_{WDT}$	$1024 * T_{WDT}$	25.6 ms ~ 128 ms
011	$2^{10} * T_{WDT}$	$1024 * T_{WDT}$	102.4 ms ~ 204.8 ms
100	$2^{12} * T_{WDT}$	$1024 * T_{WDT}$	409.6 ms ~ 512 ms

# NuMicro M051™ Series Technical Reference Manual

101	$2^{14} * T_{WDT}$	$1024 * T_{WDT}$	1.6384 s ~ 1.7408 s
110	$2^{16} * T_{WDT}$	$1024 * T_{WDT}$	6.5536 s ~ 6.656 s
111	$2^{18} * T_{WDT}$	$1024 * T_{WDT}$	26.2144 s ~ 26.3168 s

Table 6-6 Watchdog Timeout Interval Selection

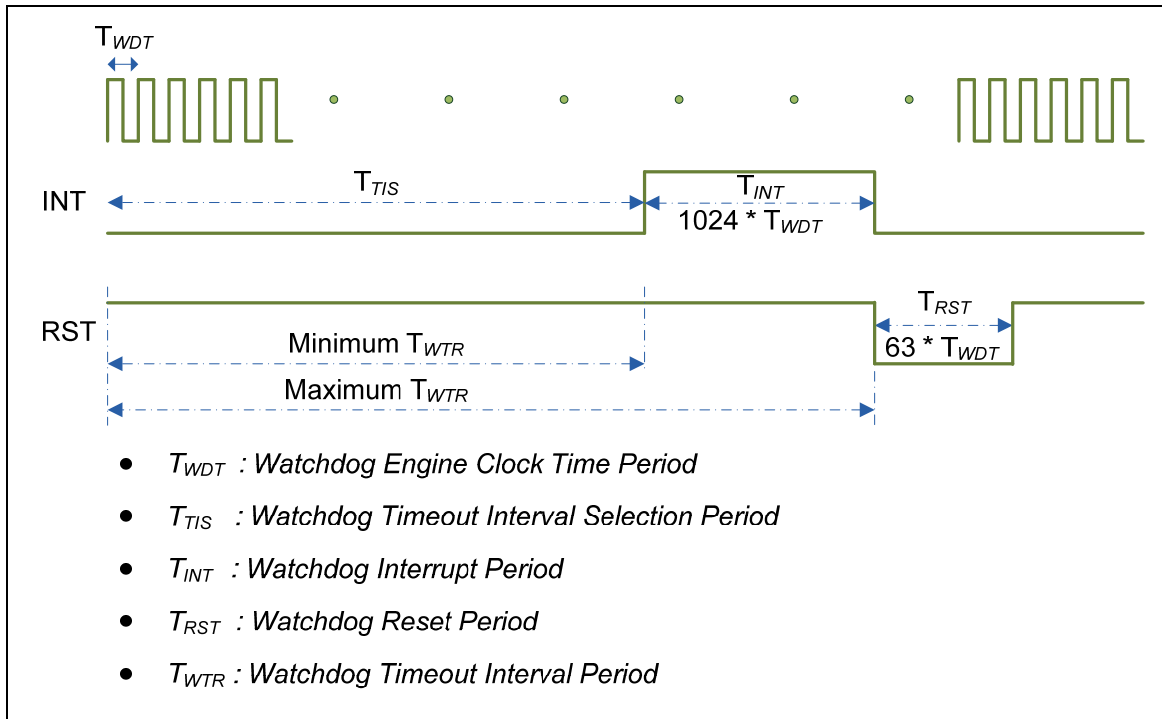

Figure 6-59 Timing of Interrupt and Reset Signal

## 6.9.2 Features

- 18-bit free running counter to avoid chip from Watchdog timer reset before the delay time expires.
- Selectable time-out interval ( $2^4 \sim 2^{18}$ ) and the time out interval is 104 ms ~ 26.3168 s (if WDT\_CLK = 10 kHz).
- Reset period =  $(1 / 10 \text{ kHz}) * 63$ , if WDT\_CLK = 10 kHz.

## 6.9.3 WDT Block Diagram

The Watchdog Timer clock control and block diagram is shown in the Figure 6-60.

## 6.10 UART Interface Controller

NuMicro M051™ series provides up to two channels of Universal Asynchronous Receiver/Transmitters (UART). UART0~1 performs Normal Speed UART, and support flow control function.

### 6.10.1 Overview

The Universal Asynchronous Receiver/Transmitter (UART) performs a serial-to-parallel conversion on data received from the peripheral, and a parallel-to-serial conversion on data transmitted from the CPU. The UART controller also supports IrDA SIR Function, and RS-485 mode functions. Each UART channel supports five types of interrupts including transmitter FIFO empty interrupt (INT\_THRE), receiver threshold level reaching interrupt (INT\_RDA), line status interrupt (parity error or framing error or break interrupt) (INT\_RLS), receiver buffer time out interrupt (INT\_TOUT), and MODEM/Wakeup status interrupt (INT\_MODEM). Interrupt number 12 (vector number is 28) supports UART0 interrupt. Interrupt number 13 (vector number is 29) supports UART1 interrupt. Refer to Nested Vectored Interrupt Controller chapter for System Interrupt Map.

The UART0~1 are equipped 15-bytes transmitter FIFO (TX\_FIFO) and 15-bytes receiver FIFO (RX\_FIFO). The CPU can read the status of the UART at any time during the operation. The reported status information includes the type and condition of the transfer operations being performed by the UART, as well as 3 error conditions (parity error, framing error, and break interrupt) probably occur while receiving data. The UART includes a programmable baud rate generator that is capable of dividing clock input by divisors to produce the serial clock that transmitter and receiver need. The baud rate equation is  $\text{Baud Rate} = \text{UART\_CLK} / M * [\text{BRD} + 2]$ , where M and BRD are defined in Baud Rate Divider Register (UA\_BAUD). The Table 6-7 and Table 6-8 list the equations in the various conditions and the UART baud rate setting table.

Mode	DIV_X_EN	DIV_X_ONE	Divider X	BRD	Baud rate equation
0	0	0	B	A	$\text{UART\_CLK} / [16 * (A+2)]$
1	1	0	B	A	$\text{UART\_CLK} / [(B+1) * (A+2)]$ , B must $\geq 8$
2	1	1	Don't care	A	$\text{UART\_CLK} / (A+2)$ , A must $\geq 3$

Table 6-7 UART Baud Rate Equation

# NuMicro M051™ Series Technical Reference Manual

Table 6-8 UART Baud Rate Setting Table

The UART0 and UART1 controllers support auto-flow control function that uses two low-level signals, /CTS (clear-to-send) and /RTS (request-to-send), to control the flow of data transfer between the UART and external devices (ex: Modem). When auto-flow is enabled, the UART is not allowed to receive data until the UART asserts /RTS to external device. When the number of bytes in the RX FIFO equals the value of RTS\_TRI\_LEV (UA\_FCR [19:16]), the /RTS is de-asserted. The UART sends data out when UART controller detects /CTS is asserted from external device. If a valid asserted /CTS is not detected the UART controller will not send data out.

The UART controllers also provides Serial IrDA (SIR, Serial Infrared) function (User must set IrDA\_EN (UA\_FUN\_SEL[1:0]) to enable IrDA function). The SIR specification defines a short-range infrared asynchronous serial transmission mode with one start bit, 8 data bits, and 1 stop bit. The maximum data rate is 115.2 Kbps (half duplex). The IrDA SIR block contains an IrDA SIR Protocol encoder/decoder. The IrDA SIR protocol is half-duplex only. So it cannot transmit and receive data at the same time. The IrDA SIR physical layer specifies a minimum 10ms transfer delay between transmission and reception. This delay feature must be implemented by software.

Publication Release Date: May, 04, 2011

Revision V2.00

Another alternate function of UART controllers is RS-485 9 bit mode function, and direction control provided by RTS pin or can program GPIO (P0.3 for RTS0 and P0.1 for RTS 1) to implement the function by software. The RS-485 mode is selected by setting the UA\_FUN\_SEL register to select RS-485 function. The RS-485 driver control is implemented using the RTS control signal from an asynchronous serial port to enable the RS-485 driver. In RS-485 mode, many characteristics of the RX and TX are same as UART.

## 6.10.2 Features

- Full duplex, asynchronous communications
- Separate receive / transmit 15 bytes (UART0/UART1) entry FIFO for data payloads
- Support hardware auto flow control/flow control function (CTS, RTS) and programmable RTS flow control trigger level (UART0 and UART1 support)
- Programmable receiver buffer trigger level
- Support programmable baud-rate generator for each channel individually
- Support CTS wake up function (UART0 and UART1 support)
- Support 7 bit receiver buffer time out detection function
- Programmable transmitting data delay time between the last stop and the next start bit by setting UA\_TOR [DLY] register
- Support break error, frame error, and parity error detect function
- Fully programmable serial-interface characteristics
- Programmable number of data bit, 5, 6, 7, 8 bit character
- Programmable parity bit, even, odd, no parity or stick parity bit generation and detection
- Programmable stop bit, 1, 1.5, or 2 stop bit generation
- Support IrDA SIR function mode
- Support for 3/16 bit duration for normal mode
- Support RS-485 function mode.
- Support RS-485 9bit mode
- Support hardware or software direct enable control provided by RTS pin

## 6.10.3 UART Block Diagram

The UART clock control and block diagram are shown in the both Figure 6-62 and Figure 6-63.

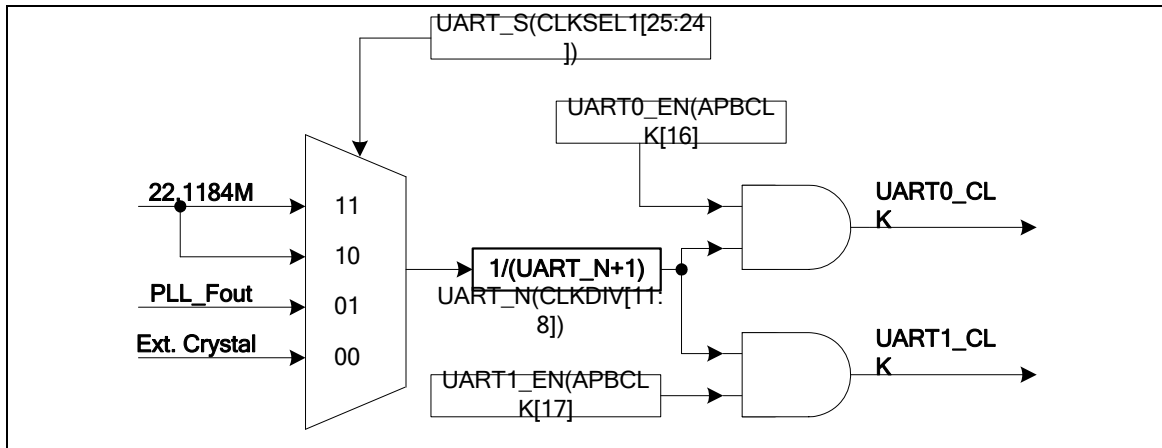

Figure 6-62 UART Clock Control Diagram

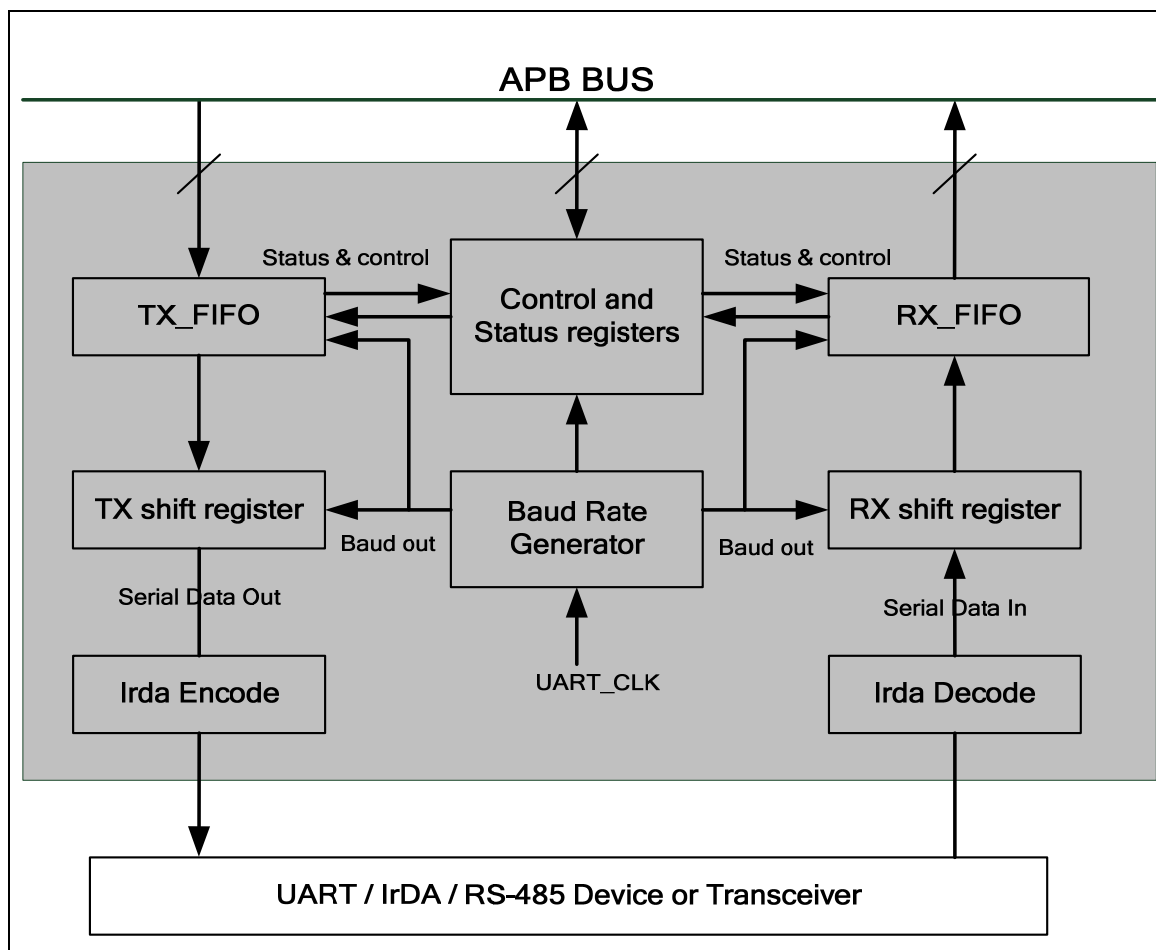

Figure 6-63 UART Block Diagram

### TX\_FIFO

The transmitter is buffered with a 15 bytes FIFO to reduce the number of interrupts presented to the CPU.

### RX\_FIFO

The receiver is buffered with a 15 bytes FIFO (plus three error bits per byte) to reduce the number of interrupts presented to the CPU.

### TX shift Register

This block is the shifting the transmitting data out serially control block.

### RX shift Register

This block is the shifting the receiving data in serially control block.

### Modem Control Register

This register controls the interface to the MODEM or data set (or a peripheral device emulating a MODEM).

#### **Baud Rate Generator**

Divide the external clock by the divisor to get the desired baud rate clock. Refer to baud rate equation.

#### **IrDA Encode**

This block is IrDA encode control block.

#### **IrDA Decode**

This block is IrDA decode control block.

#### **Control and Status Register**

This field is register set that including the FIFO control registers (UA\_FCR), FIFO status registers (UA\_FSR), and line control register (UA\_LCR) for transmitter and receiver. The time out control register (UA\_TOR) identifies the condition of time out interrupt. This register set also includes the interrupt enable register (UA\_IER) and interrupt status register (UA\_ISR) to enable or disable the responding interrupt and to identify the occurrence of the responding interrupt. There are seven types of interrupts, transmitter FIFO empty interrupt (INT\_THRE), receiver threshold level reaching interrupt (INT\_RDA), line status interrupt (parity error or framing error or break interrupt) (INT\_RLS), time out interrupt (INT\_TOUT), MODEM/Wakeup status interrupt (INT\_MODEM), and Buffer error interrupt (INT\_BUF\_ERR).

The Figure 6-64 demonstrates the auto-flow control block diagram.

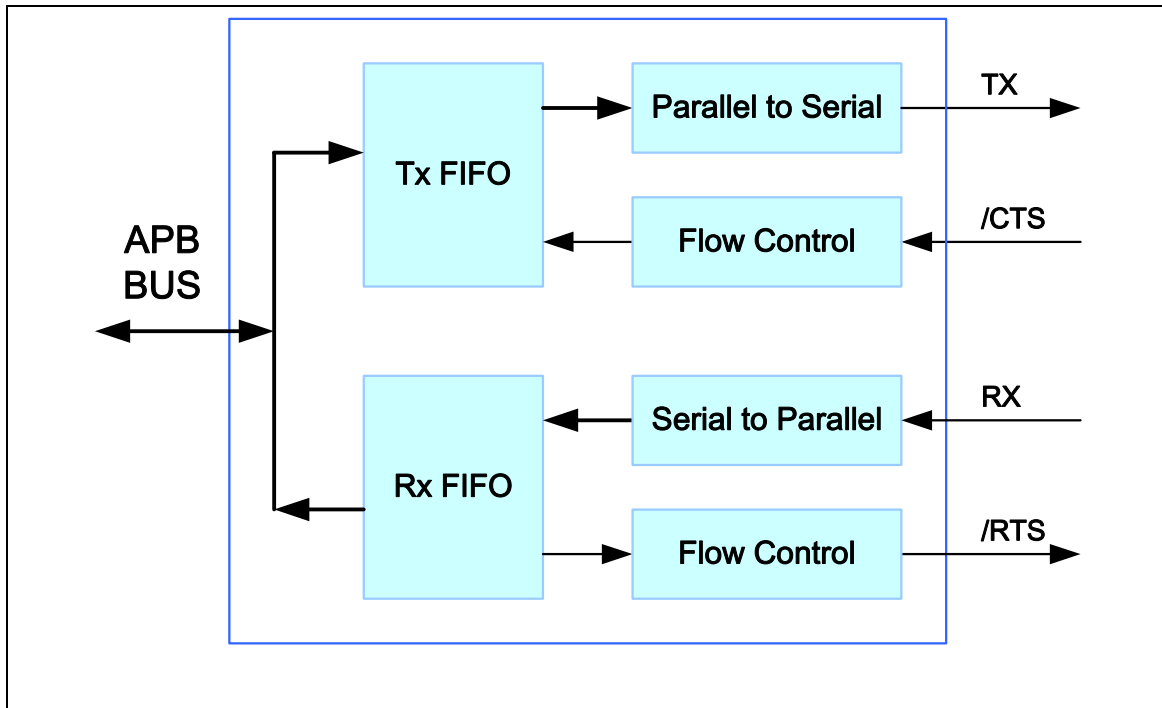

Figure 6-64 Auto Flow Control Block Diagram

## 6.10.4 IrDA Mode

The UART supports IrDA SIR (Serial Infrared) Transmit Encoder and Receive Decoder, and IrDA mode is selected by setting the **IrDA\_EN** bit in **UA\_FUN\_SEL** register.

When in IrDA mode, the **UA\_BAUD [DIV\_X\_EN]** register must disable.

**Baud Rate = Clock / (16 \* BRD)**, where BRD is Baud Rate Divider in **UA\_BAUD** register.

The Figure 6-65 demonstrates the IrDA control block diagram.

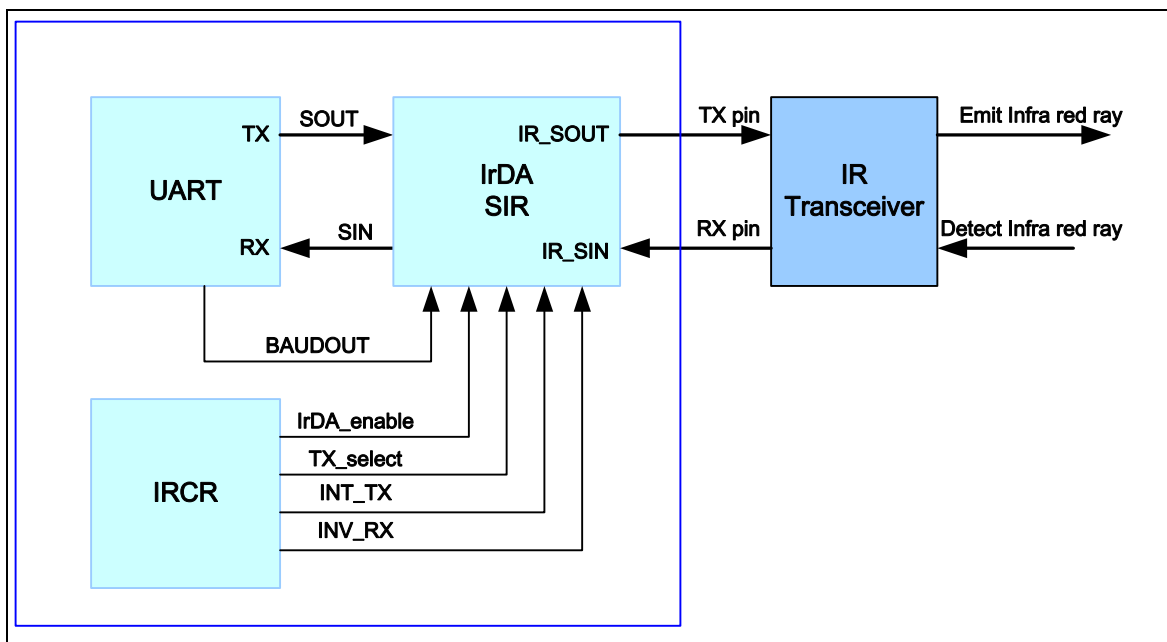

Figure 6-65 IrDA Block Diagram

### 6.10.4.1 IrDA SIR Transmit Encoder

The IrDA SIR Transmit Encoder modulate Non-Return-to Zero (NRZ) transmit bit stream output from UART. The IrDA SIR physical layer specifies use of Return-to-Zero, Inverted (RZI) modulation scheme which represent logic 0 as an infra light pulse. The modulated output pulse stream is transmitted to an external output driver and infrared Light Emitting Diode.

In normal mode, the transmitted pulse width is specified as 3/16 period of baud rate.

### 6.10.4.2 IrDA SIR Receive Decoder

The IrDA SIR Receive Decoder demodulates the return-to-zero bit stream from the input detector

and outputs the NRZ serial bits stream to the UART received data input. The decoder input is normally high in the idle state. (Because of this, IRCR bit 6 should be set as 1 by default)

A start bit is detected when the decoder input is LOW

### 6.10.4.3 IrDA SIR Operation

The IrDA SIR Encoder/decoder provides functionality which converts between UART data stream and half duplex serial SIR interface. The Figure 6-66 is IrDA encoder/decoder waveform:

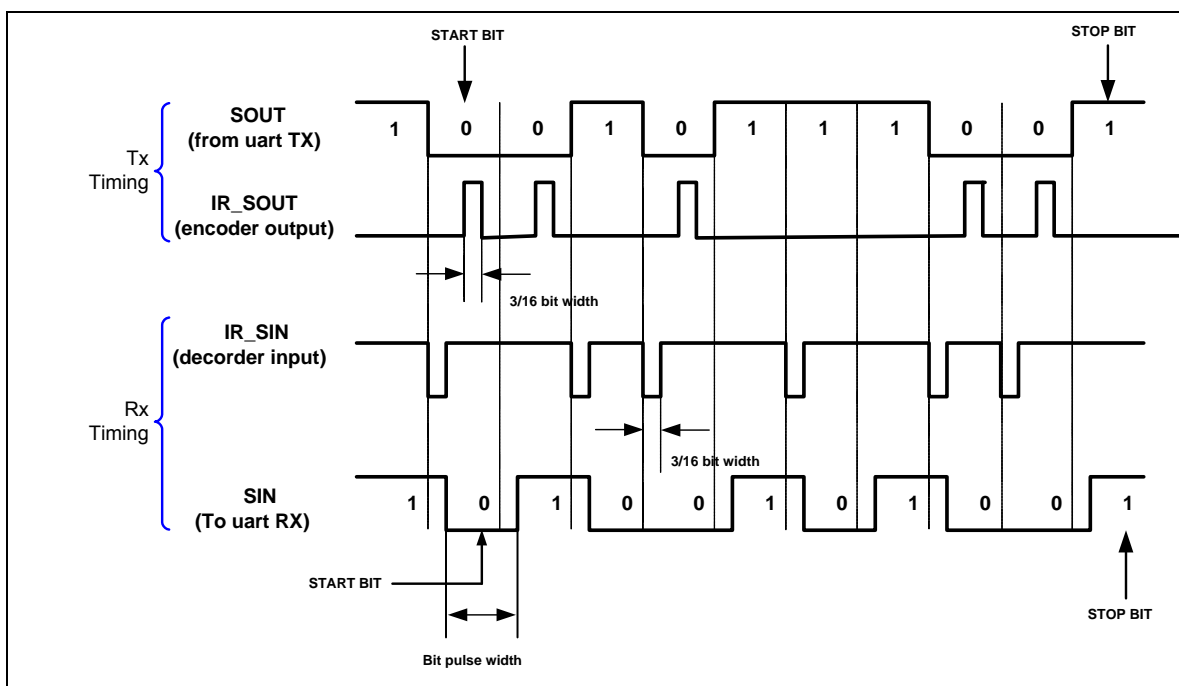

Figure 6-66 IrDA TX/RX Timing Diagram

## 6.10.5 RS-485 Function Mode

The UART support **RS-485 9 bit mode function**. The RS-485 mode is selected by setting the UA\_FUN\_SEL register to select RS-485 function. The RS-485 driver control is implemented using the RTS control signal from an asynchronous serial port to enable the RS-485 driver. In RS-485 mode, many characteristics of the RX and TX are same as UART.

When in RS-485 mode, the controller can configuration of it as an RS-485 addressable slave and the RS-485 master transmitter will identify an address character by setting the parity (9<sup>th</sup> bit) to 1. For data characters, the parity is set to 0. Software can use UA\_LCR register to control the 9-th bit (When the PBE, EPE and SPE are set, the 9-th bit is transmitted 0 and when PBE and SPE are set and EPE is cleared, the 9-th bit is transmitted 1). The Controller support three operation mode that is RS-485 Normal Multidrop Operation Mode (NMM), RS-485 Auto Address Detection Operation Mode (AAD) and RS-485 Auto Direction Control Operation Mode (AUD), software can choose any operation mode by programming UA\_RS-485\_CSR register, and software can driving the transfer delay time between the last stop bit leaving the TX-FIFO and the de-assertion of by setting UA\_TOR [DLY] register.

### RS-485 Normal Multidrop Operation Mode (NMM)

In RS-485 Normal Multidrop operation mode, in first, software must decided the data which before the address byte be detected will be stored in RX-FIFO or not. If software want to ignore any data before address byte detected, the flow is set UART\_FCR[RS485\_RX\_DIS] then enable UA\_RS-485[RS485\_NMM] and the receiver will ignore any data until an address byte is detected (bit9 =1) and the address byte data will be stored in the RX-FIFO. If software wants to receive any data before address byte detected, the flow is disable UART\_FCR [RS485\_RX\_DIS] then enable UA\_RS-485[RS485\_NMM] and the receiver will received any data. If an address byte is detected (bit9 =1), it will generator an interrupt to CPU and software can decide whether enable or disable receiver to accept the following data byte by setting UA\_RS-485\_FCR [RX\_DIS]. If the receiver is be enabled, all received byte data will be accepted and stored in the RX-FIFO, and if the receiver is disabled, all received byte data will be ignore until the next address byte be detected. If software disable receiver by setting UA\_RS-485\_FCR [RX\_DIS] register, when a next address byte be detected, the controller will clear the UA\_RS-485\_FCR [RX\_DIS] bit and the address byte data will be stored in the RX-FIFO.

### RS-485 Auto Address Detection Operation Mode (AAD)

In RS-485 Auto Address Detection Operation Mode, the receiver will ignore any data until an address byte is detected (bit9 =1) and the address byte data match the UA\_RS-485[ADDR\_MATCH] value. The address byte data will be stored in the RX-FIFO. The all received byte data will be accepted and stored in the RX-FIFO until address doesn't match the UA\_RS-485[ADDR\_MATCH] value.

### RS-485 Auto Direction Mode (AUD)

Another option function of RS-485 controllers is **RS-485 auto direction control function**. The

RS-485 driver control is implemented using the RTS control signal from an asynchronous serial port to enable the RS-485 driver. The RTS line is connected to the RS-485 driver enable such that setting the RTS line to high (logic 1) enables the RS-485 driver. Setting the RTS line to low (logic 0) puts the driver into the tri-state condition. User can setting LEV\_RTS in UA\_MCR register to change the RTS driving level.

**Program Sequence example:**

1. Program FUN\_SEL in UA\_FUN\_SEL to select RS-485 function.
2. Program the RX\_DIS bit in UA\_FCR register to determine enable or disable RS-485 receiver
3. Program the RS-485\_NMM or RS-485\_AAD mode.
4. If the RS-485\_AAD mode is selected, the ADDR\_MATCH is programmed for auto address match value.
5. Determine auto direction control by programming RS-485\_AUD.

Figure 6-67 Structure of RS-485 Frame

## 6.10.7 UART Interface Controller Registers Description

### Receive Buffer Register (UA\_RBR)

Register	Offset	R/W	Description	Reset Value
UA_RBR	UART0_BA+0x00	R	UART0 Receive Buffer Register	Undefined
	UART1_BA+0x00	R	UART1 Receive Buffer Register	Undefined

31	30	29	28	27	26	25	24
Reserved							
23	22	21	20	19	18	17	16
Reserved							
15	14	13	12	11	10	9	8
Reserved							
7	6	5	4	3	2	1	0
RBR							

Bits	Descriptions	
[31:8]	Reserved	Reserved
[7:0]	RBR	<b>Receive Buffer Register (Read Only)</b> By reading this register, the UART will return an 8-bit data received from RX pin (LSB first).

## Transmit Holding Register (UA\_THR)

Register	Offset	R/W	Description	Reset Value
UA_THR	UART0_BA+0x00	W	UART0 Transmit Holding Register	Undefined
	UART1_BA+0x00	W	UART1 Transmit Holding Register	Undefined

31	30	29	28	27	26	25	24
Reserved							
23	22	21	20	19	18	17	16
Reserved							
15	14	13	12	11	10	9	8
Reserved							
7	6	5	4	3	2	1	0
THR							

Bits	Descriptions	
[31:8]	Reserved	Reserved
[7:0]	THR	<b>Transmit Holding Register</b> By writing to this register, the UART will send out an 8-bit data through the TX pin (LSB first).

## Interrupt Enable Register (UA\_IER)

Register	Offset	R/W	Description	Reset Value
UA_IER	UART0_BA+0x04	R/W	UART0 Interrupt Enable Register	0x0000_0000
	UART1_BA+0x04	R/W	UART1 Interrupt Enable Register	0x0000_0000

31	30	29	28	27	26	25	24
Reserved							
23	22	21	20	19	18	17	16

## 6.11 Analog-to-Digital Converter (ADC)

### 6.11.1 Overview

NuMicro M051™ series contain one 12-bit successive approximation analog-to-digital converters (SAR A/D converter) with 8 input channels. The A/D converter supports four operation modes: single, burst, single-cycle scan and continuous scan mode. The A/D converters can be started by software and external STADC/P3.2 pin.

### 6.11.2 Features

- Analog input voltage range: 0~AVDD (Max to 5.0V).
- 12-bit resolution and 10-bit accuracy is guaranteed.
- Up to 8 single-end analog input channels or 4 differential analog input channels.
- Maximum ADC clock frequency is 16 MHz.
- Up to 600k SPS conversion rate.
- Four operating modes
  - Single mode: A/D conversion is performed one time on a specified channel.
  - Single-cycle scan mode: A/D conversion is performed one cycle on all specified channels with the sequence from the lowest numbered channel to the highest numbered channel.
  - Continuous scan mode: A/D converter continuously performs Single-cycle scan mode until software stops A/D conversion.
  - Burst mode: A/D conversion will sample and convert the specified single channel and sequentially store in FIFO.
- An A/D conversion can be started by
  - Software Write 1 to ADST bit
  - External pin STADC
- Conversion results are held in data registers for each channel with valid and overrun indicators.
- Conversion result can be compared with specify value and user can select whether to generate an interrupt when conversion result matches the compare register setting.
- Channel 7 supports 2 input sources: external analog voltage and internal bandgap voltage.

- Support Self-calibration to minimize conversion error.

## 6.11.3 ADC Block Diagram

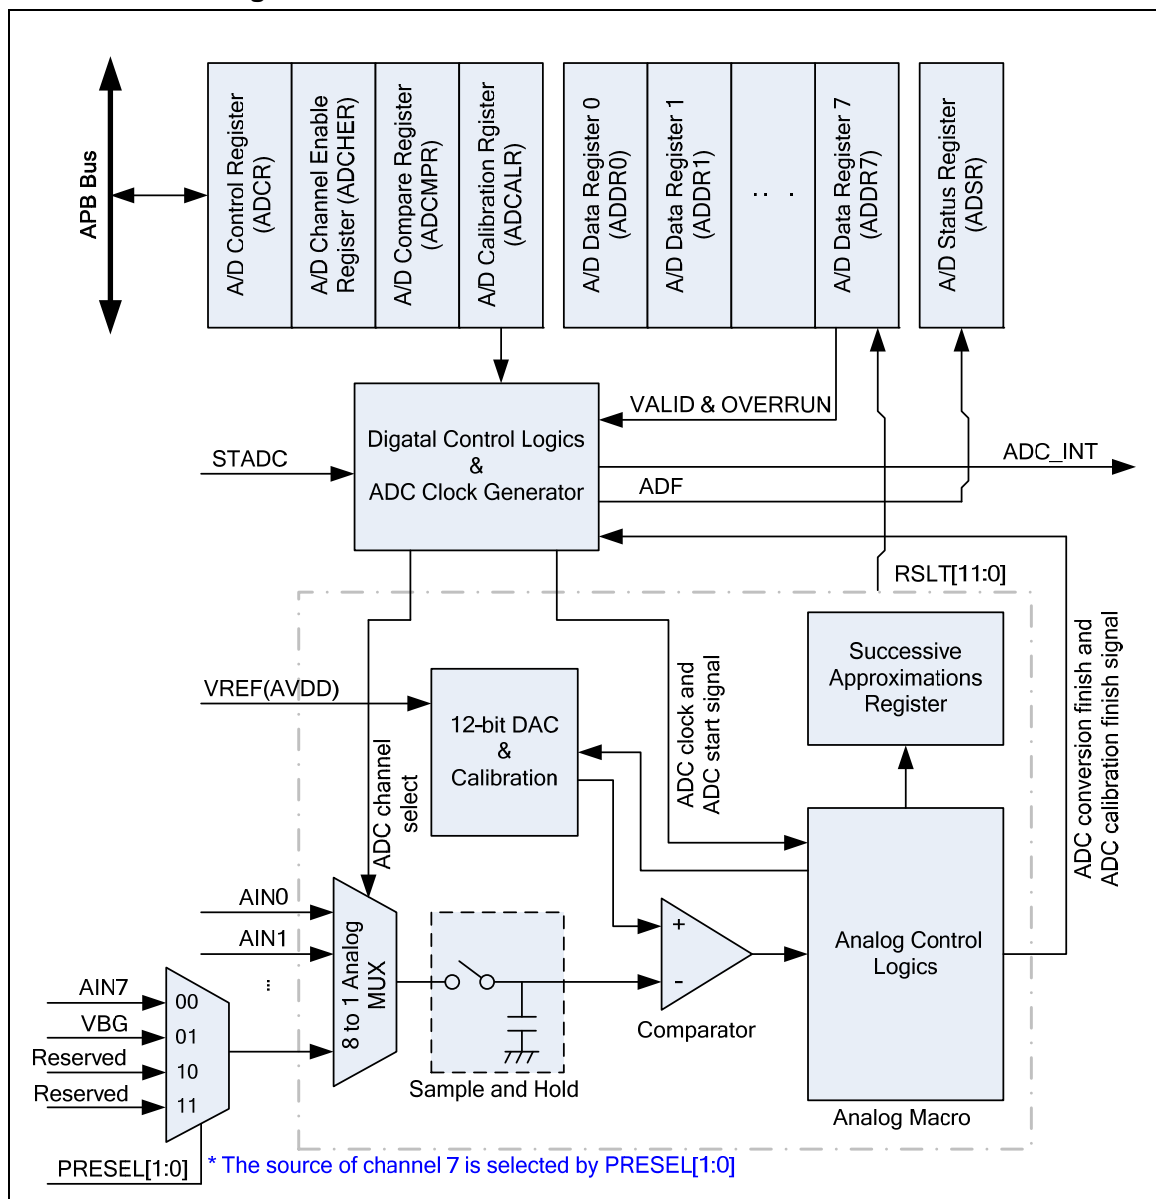

Figure 6-68 ADC Controller Block Diagram

## 6.11.4 ADC Operation Procedure

The A/D converter operates by successive approximation with 12-bit resolution. This A/D converter equips with self calibration function to minimize conversion error, user can write 1 to CAL\_EN bit in ADCALR register to enable calibration function, while internal calibration is finished, the CAL\_DONE bit will assert. The ADC has four operation modes: single, burst, single-cycle scan mode and continuous scan mode. When changing the operating mode or analog input channel enable, in order to prevent incorrect operation, software must clear ADST bit to 0 in ADCR register.

### 6.11.4.1 Self-Calibration

When chip power on or switch conversion mode between single-end mode and differential mode, it needs to do ADC self calibration to minimize the conversion error. User can write 1 to CAL\_EN bit in ADCALR register to enable self calibration. The operation is process internally and it needs 127 ADC clocks to complete calibration. After CAL\_EN is set to 1, software must wait CAL\_DONE bit set by internal hardware. The detail timing is shown as below:

Figure 6-69 ADC Converter Self-Calibration Timing Diagram

### 6.11.4.2 ADC Clock Generator

The maximum sampling rate is up to 600K. The ADC engine has three clock sources selected by 2-bit ADC\_S (CLKSEL[3:2]), the ADC clock frequency is divided by an 8-bit prescaler with the formula:

$$\text{The ADC clock frequency} = (\text{ADC clock source frequency}) / (\text{ADC\_N} + 1);$$
  
 where the 8-bit ADC\_N is located in register CLKDIV[23:16].

In generally, software can set ADC\_S and ADC\_N to get 16 MHz or slightly less.

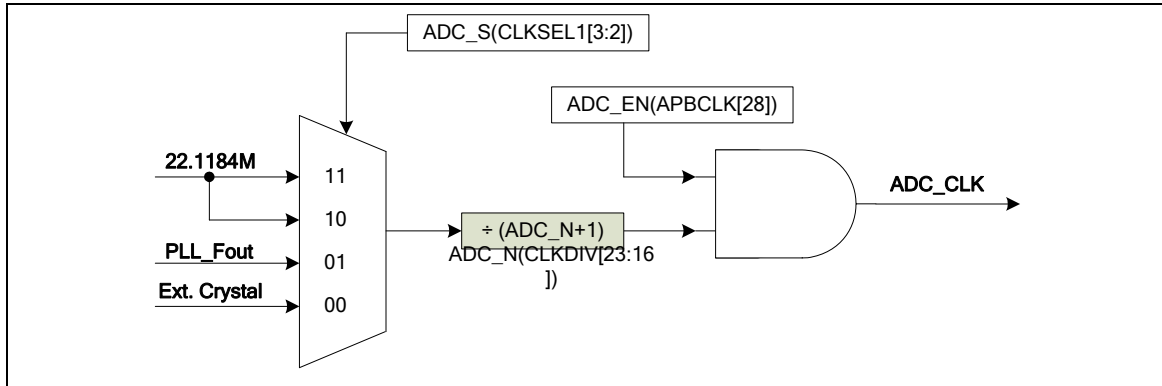

Figure 6-70 ADC Clock Control

### 6.11.4.3 Single Mode

In single mode, A/D conversion is performed only once on the specified single channel. The operations are as follows:

1. A/D conversion will be started when the ADST bit of ADCR is set to 1 by software or external trigger input.
2. When A/D conversion is finished, the result is stored in the A/D data register corresponding to the channel.
3. The ADF bit of ADSR register will be set to 1. If the ADIE bit of ADCR register is set to 1, the ADC interrupt will be asserted.
4. The ADST bit remains 1 during A/D conversion. When A/D conversion ends, the ADST bit is automatically cleared to 0 and the A/D converter enters idle state.

**Note:** If software enables more than one channel in single mode, the channel with the lowest number will be selected and the other enabled channels will be ignored.

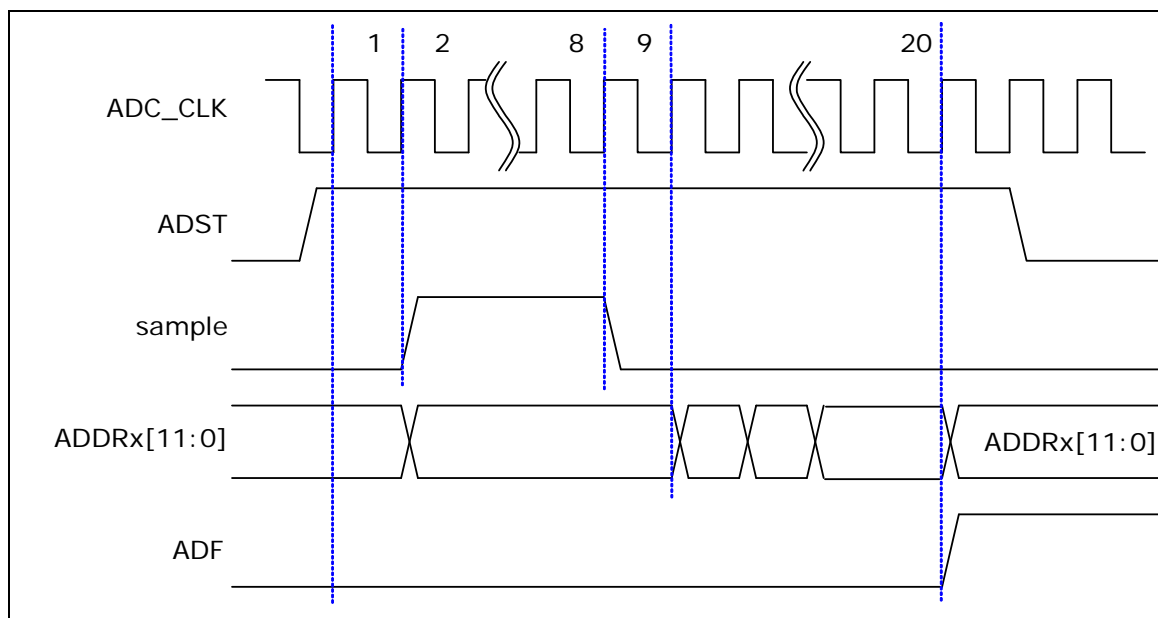

Figure 6-71 Single Mode Conversion Timing Diagram

#### 6.11.4.4 Burst Mode

In burst mode, A/D conversion will sample and convert the specified single channel and sequentially store in FIFO (up to 8 samples). The operations are as follows:

1. When the ADST bit in ADCR is set to 1 by software or external trigger input, A/D conversion starts on the channel with the lowest number.
2. When A/D conversion for special enabled channel is completed, the result is sequentially transferred to FIFO and can be accessed from the A/D data register 0.
3. When more than 4 samples in FIFO, the ADF bit in ADSR is set to 1. If the ADIE bit is set to 1 at this time, an ADC interrupt is requested after A/D conversion ends.
4. Steps 2 to 3 are repeated as long as the ADST bit remains set to 1. When the ADST bit is cleared to 0, A/D conversion stops and the A/D converter enters the idle state.

**Note:** If software enables more than one channel in burst mode, the channel with the lowest number is converted and other enabled channels will be ignored.

#### 6.11.4.5 Single-Cycle Scan Mode

In single-cycle scan mode, A/D conversion will sample and convert the specified channels once in the sequence from the lowest number enabled channel to the highest number enabled channel. Operations are as follows:

1. When the ADST bit in ADCR is set to 1 by software or external trigger input, A/D conversion starts on the channel with the lowest number.
2. When A/D conversion for each enabled channel is completed, the result is sequentially transferred to the A/D data register corresponding to each channel.
3. When the conversions of all the enabled channels are completed, the ADF bit in ADSR is set to 1. If the ADC interrupt function is enabled, the ADC interrupt occurs.
4. After A/D conversion ends, the ADST bit is automatically cleared to 0 and the A/D converter enters idle state. If ADST is cleared to 0 before all enabled ADC channels conversion done, ADC controller will finish current conversion and the result of the lowest enabled ADC channel will become unpredictable.

An example timing diagram for single-cycle scan on enabled channels (0, 2, 3 and 7) is shown in the Figure 6-72

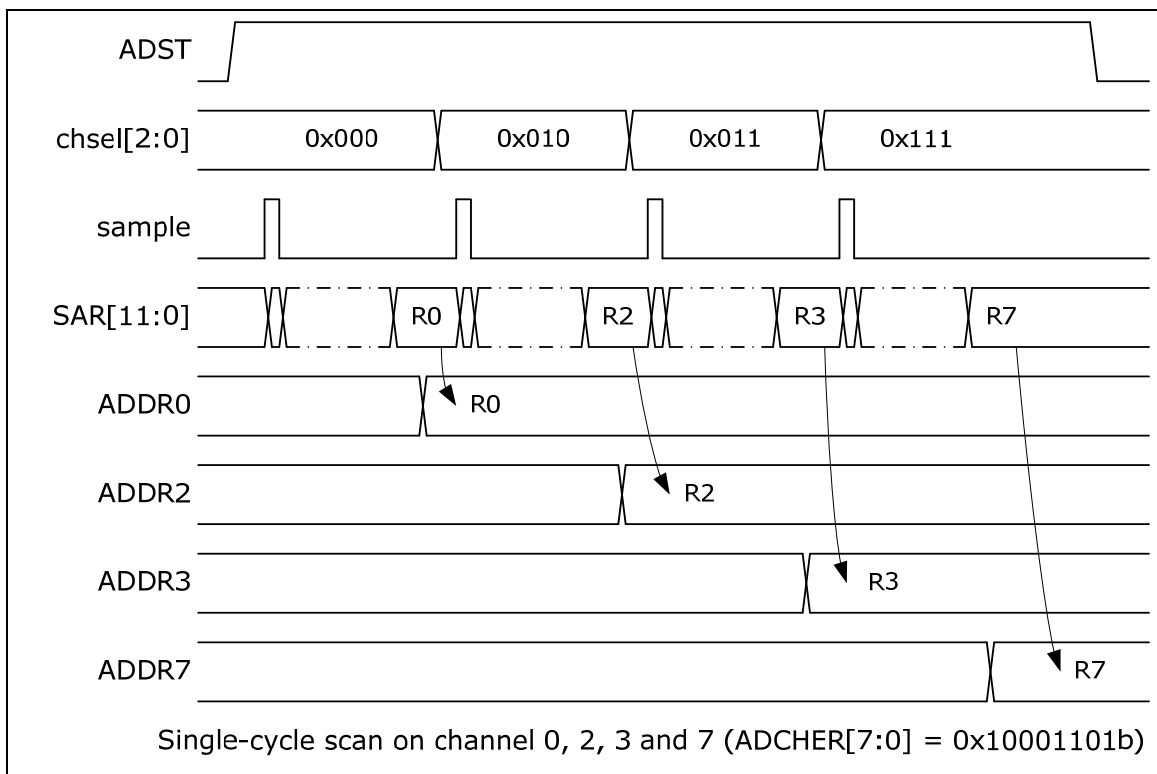

Figure 6-72 Single-Cycle Scan on Enabled Channels Timing Diagram

## 6.11.4.6 Continuous Scan Mode

In continuous scan mode, A/D conversion is performed sequentially on the specified channels that enabled by CHEN bits in ADCHER register (maximum 8 channels for ADC). The operations are as follows:

1. When the ADST bit in ADCR is set to 1 by software or external trigger input, A/D conversion starts on the channel with the lowest number.
2. When A/D conversion for each enabled channel is completed, the result of each enabled channel is stored in the A/D data register corresponding to each enabled channel.
3. When A/D converter completes the conversions of all enabled channels sequentially, the ADF bit (ADSR[0]) will be set to 1. If the ADC interrupt function is enabled, the ADC interrupt occurs. The conversion of the enabled channel with the lowest number will start again if software has not cleared the ADST bit.
4. As long as the ADST bit remains at 1, the step 2 ~ 3 will be repeated. When ADST is cleared to 0, ADC controller will finish current conversion and the result of the lowest enabled ADC channel will become unpredictable.

An example timing diagram for continuous scan on enabled channels (0, 2, 3 and 7) is shown in the Figure 6-73 .

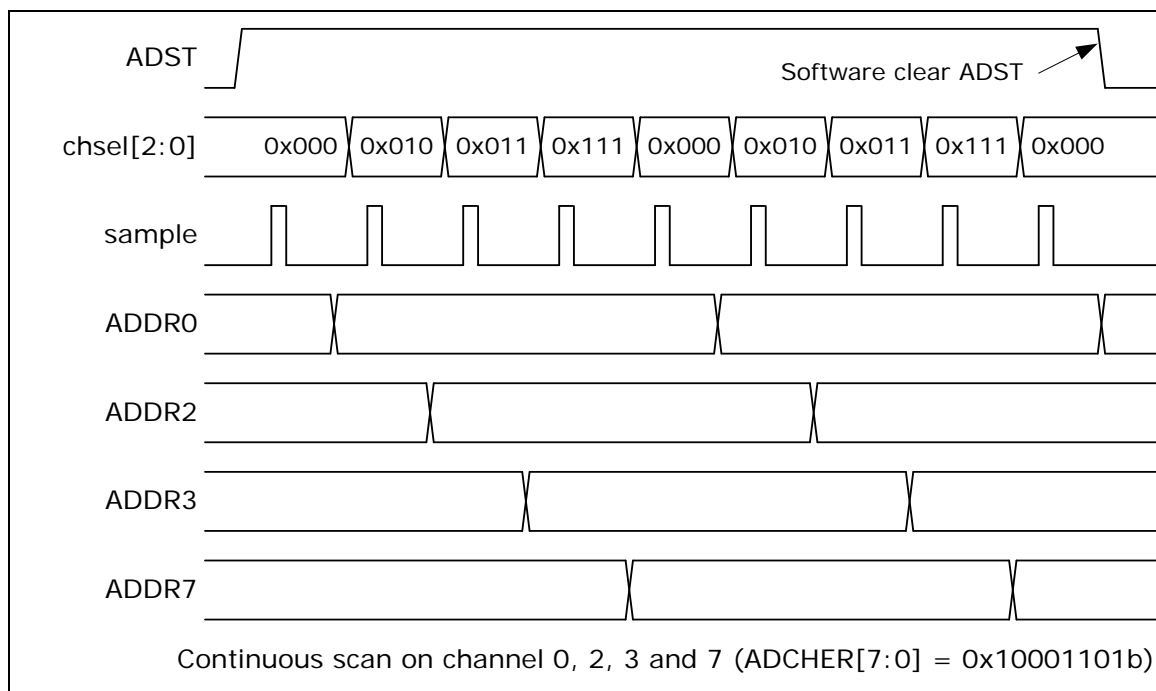

Figure 6-73 Continuous Scan on Enabled Channels Timing Diagram

## 6.11.4.7 External Trigger Input Sampling and A/D Conversion Time

In single-cycle scan mode, A/D conversion can be triggered by external pin request. When the ADCR.TRGEN is set to high to enable ADC external trigger function, setting the TRGS[1:0] bits to 00b is to select external trigger input from the STADC pin. Software can set TRGCOND[1:0] to select trigger condition is **falling/rising edge or low/high** level. If level trigger condition is selected, the STADC pin must be kept at defined state at least 8 PCLKs. The ADST bit will be set to 1 at the 9<sup>th</sup> PCLK and start to conversion. Conversion is continuous if external trigger input is kept at active state in level trigger mode. It is stopped only when external condition trigger condition disappears. If edge trigger condition is selected, the high and low state must be kept at least 4 PCLKs. Pulse that is shorter than this specification will be ignored.

## 6.11.4.8 Conversion Result Monitor by Compare Mode Function

NuMicro M051™ series controller provide two sets of compare register, ADCMPR0 and ADCMPR1, and 1 to monitor maximum two specified channels conversion result from A/D conversion module, refer to Figure 6-74. Software can select which channel to be monitored by set CMPCH(ADCMPRx[5:0]) and CMPCOND bit is used to check conversion result is less than specify value or greater than (equal to) value specified in CMPD[11:0]. When the conversion of the channel specified by CMPCH is completed, the comparing action will be triggered one time automatically. When the compare result meets the setting, compare match counter will increase 1, otherwise, the compare match counter will be clear to 0. When counter value reach the setting of (CMPMATCNT+1) then CMPF bit will be set to 1, if CMPFIE bit is set then an ADC\_INT interrupt request is generated. Software can use it to monitor the external analog input pin voltage transition in scan mode without imposing a load on software. Detail logics diagram is shown in the Figure 6-74.

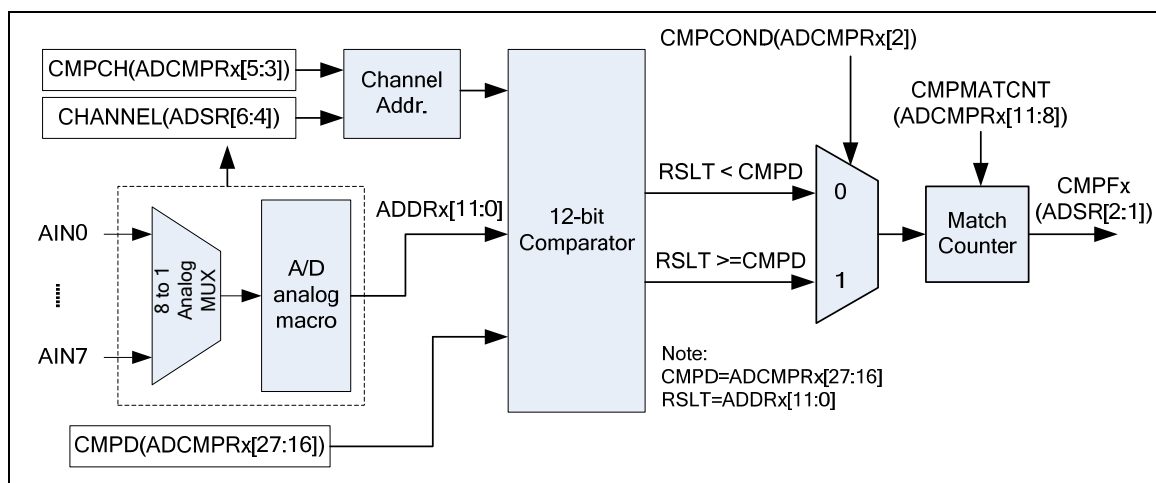

Figure 6-74 A/D Conversion Result Monitor Logics Diagram

## 6.11.4.9 Interrupt Sources

There are three interrupt sources of ADC interrupt. When an ADC operation mode finishes its conversion, the A/D conversion end flag, ADF, will be set to 1. The CMPF0 and CMPF1 are the compare flags of compare function. When the conversion result meets the settings of ADCMPR0/1, the corresponding flag will be set to 1. When one of the flags, ADF, CMPF0 and CMPF1, is set to 1 and the corresponding interrupt enable bit, ADIE of ADCR and CMPIE of ADCMPR0/1, is set to 1, the ADC interrupt will be asserted. Software can clear the flag to revoke the interrupt request.

Figure 6-75 A/D Controller Interrupt

Bits	Descriptions	
[31:2]	Reserved	-
[1]	CALDONE	<p><b>Calibration is Done (read only)</b></p> <p>1 = A/D converter self calibration is done</p> <p>0 = A/D converter has not been calibrated or calibration is in progress if CALEN bit is set.</p> <p>When 0 is written to CALEN bit, CALDONE bit is cleared by hardware immediately. It is a read only bit.</p>
[0]	CALEN	<p><b>Self Calibration Enable</b></p> <p>1 = Enable self calibration</p> <p>0 = Disable self calibration</p> <p>Software can set this bit to 1 enables A/D converter to do self calibration function. It needs 127 ADC clocks to complete calibration. This bit must be kept at 1 after CALDONE asserted. Clearing this bit will disable self calibration function.</p>

## 6.12 External Bus Interface (EBI)

### 6.12.1 Overview

NuMicro M051™ series equips an external bus interface (EBI) for external device used.

To save the connections between external device and this chip, EBI support address bus and data bus multiplex mode. And, address latch enable (ALE) signal supported differentiate the address and data cycle.

### 6.12.2 Features

External Bus Interface has the following functions:

1. External devices with max. 64K-byte size (8 bit data width)/128K-byte (16 bit data width) supported
2. Variable external bus base clock (MCLK) supported
3. 8 bit or 16 bit data width supported
4. Variable data access time (tACC), address latch enable time (tALE) and address hold time (tAHD) supported
5. Address bus and data bus multiplex mode supported to save the address pins
6. Configurable idle cycle supported for different access condition: Write command finish (W2X), Read-to-Read (R2R)

## 6.12.3 EBI Block Diagram

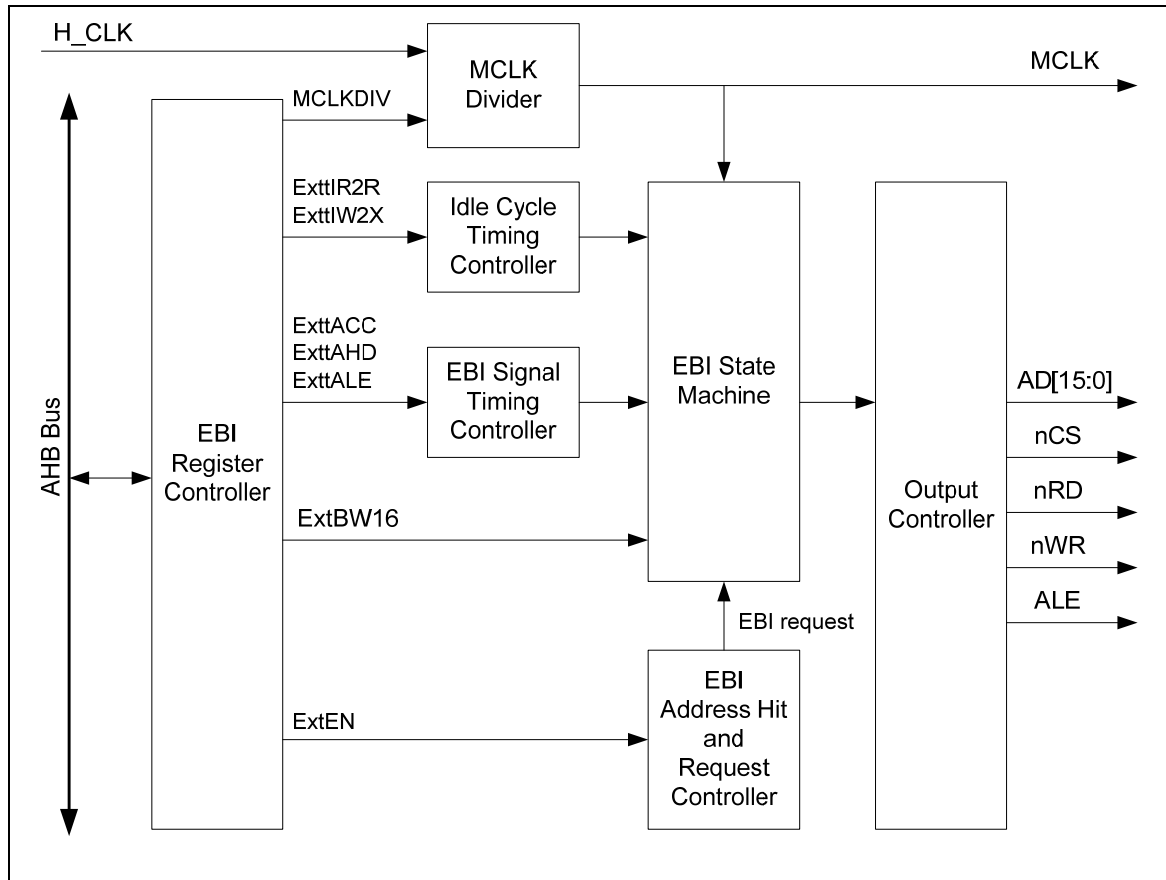

Figure 6-78 EBI Block Diagram

## 6.12.4 Operation Procedure

### 6.12.4.1 EBI Area and Address Hit

NuMicro M051™ series EBI mapping address is located at 0x6000\_0000 ~ 0x6001\_FFFF and the total memory space is 128Kbyte. When system request address hit EBI's memory space, the corresponding EBI chip select signal is assert and EBI state machine operates.

For an 8-bit device (64Kbyte), EBI mapped this 64Kbyte device to 0x6000\_0000 ~ 0x6000\_FFFF and 0x6001\_0000 ~ 0x6001\_FFFF simultaneously.

### 6.12.4.2 EBI Data Width Connection

NuMicro M051™ series EBI support device whose address bus and data bus are multiplexed. For the external device with separated address and data bus, the connection to device needs additional logic to latch the address. In this case, pin ALE is connected to the latch device such as 74HC373. Pin AD is the input of the latch device, and the output of the latch device is connected to the address of external device. For 16-bit device, the AD [15:0] shared by address and 16-bit data. For 8-bit device, only AD [7:0] shared by address and 8-bit data, AD [15:8] is dedicated for address and could be connected to 8-bit device directly.

For 8-bit data width, NuMicro M051™ system address bit [15:0] is used as the device's address [15:0]. For 16-bit data width, NuMicro M051™ system address bit [16:1] is used as the device's address [15:0] and NuMicro M051™ system address bit [0] is useless.

EBI bit width	System address (AHBADR)	EBI address (AD)
8 bit	AHBADR[15:0]	AD[15:0]
16 bit	AHBADR[16:1]	AD[15:0]

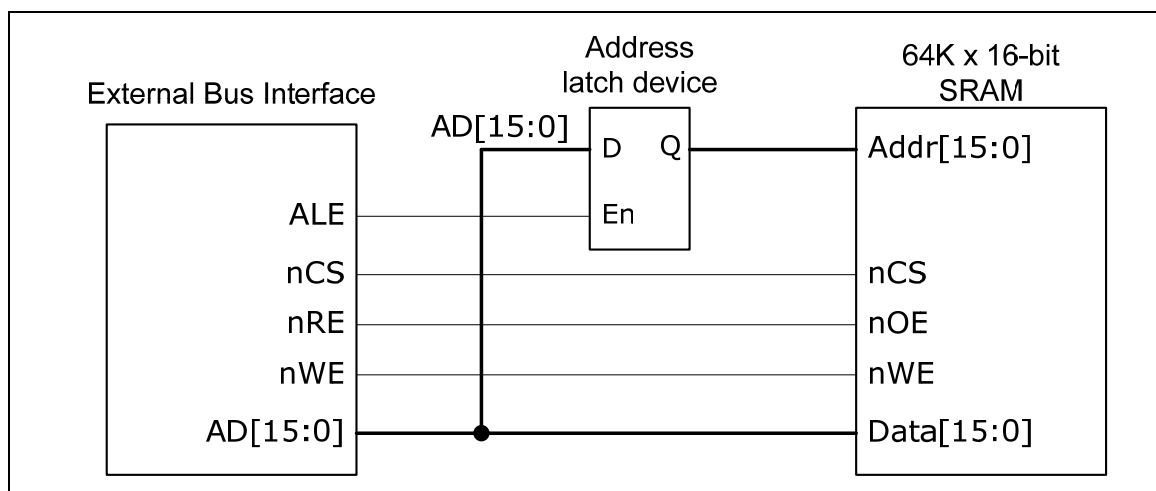

Figure 6-79 Connection of 16-bit EBI Data Width with 16-bit Device

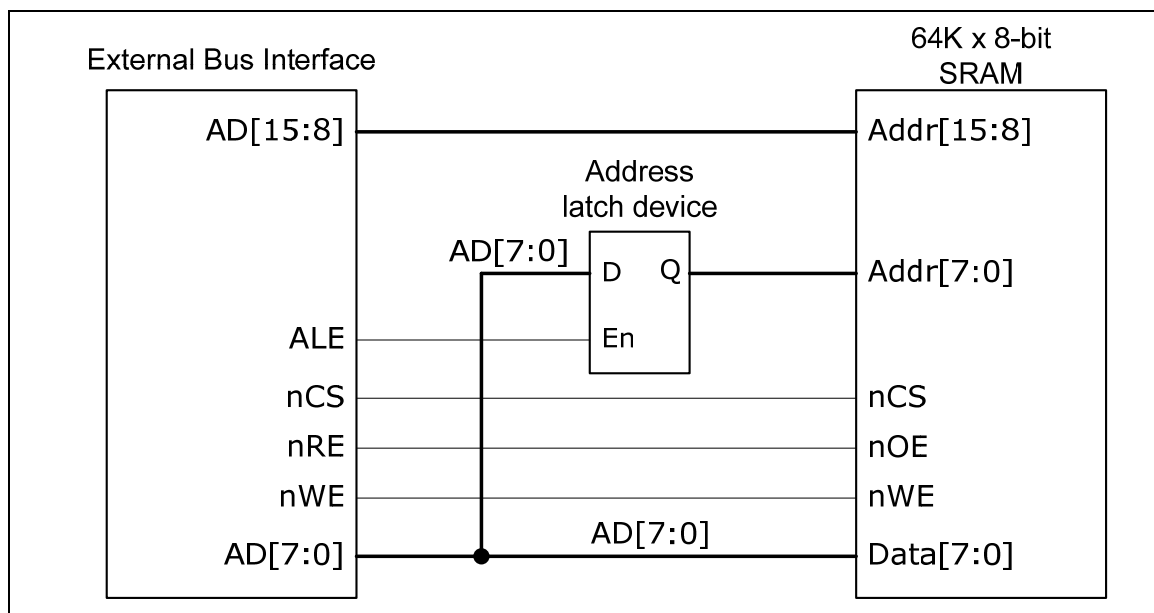

Figure 6-80 Connection of 8-bit EBI Data Width with 8-bit Device

When system access data width is larger than EBI data width, EBI controller will finish a system access command by operating EBI access more than once. For example, if system requests a 32-bit data through EBI device, EBI controller will operate accessing four times when setting EBI data width with 8-bit.

### 6.12.4.3 EBI Operating Control

#### MCLK Control

In NuMicro M051™ series, all EBI signals will be synchronized by MCLK when EBI is operating. When NuMicro M051™ series connects to the external device with slower operating frequency, the MCLK can divide most to HCLK/32 by setting MCLKDIV of register EBICON. Therefore, NuMicro M051™ can suitable for a wide frequency range of EBI device. If MCLK is set to HCLK/1, EBI signals are synchronized by positive edge of MCLK, else by negative edge of MCLK.

#### Operation and Access Timing Control

In the start of access, chip select (nCS) asserts to low and wait one MCLK for address setup time (tASU) for address stable. Then ALE asserts to high after address is stable and keeps for a period of time (tALE) for address latch. After latch address, ALE asserts to low and wait one MCLK for latch hold time (tLHD) and another one MCLK cycle (tA2D) that is inserted behind address hold time to be the bus turn-around time for address change to data. Then nRD asserts to low when read access or nWR asserts to low when write access. Then nRD or nWR asserts to high after keeps access time (tACC) for reading output stable or writing finish. After that, EBI signals keep

# NuMicro M051™ Series Technical Reference Manual

for data access hold time (tAHD) and chip select asserts to high, address is released by current access control.

NuMicro M051™ series provide a flexible EBI timing control for different external device. In NuMicro M051™ EBI timing control, tASU, tLHD and tA2D are fixed to 1 MCLK cycle, tAHD can modulate to 1~8 MCLK cycles by setting ExttAHD of register EXTIME, tACC can modulate to 1~32 MCLK cycles by setting ExttACC of register EXTIME, and tALE can modulate to 1~8 MCLK cycles by setting tALE of register EBICON.

Parameter	Value	Unit	Description
tASU	1	MCLK	Address Latch Setup Time.
tALE	1 ~ 8	MCLK	ALE High Period. Controlled by ExttALE of EBICON.
tLHD	1	MCLK	Address Latch Hold Time.
tA2D	1	MCLK	Address To Data Delay (Bus Turn-Around Time).
tACC	1 ~ 32	MCLK	Data Access Time. Controlled by ExttACC of EXTIME.
tAHD	1 ~ 8	MCLK	Data Access Hold Time. Controlled by ExttAHD of EXTIME.
IDLE	0 ~ 15	MCLK	Idle Cycle. Controlled by ExtIR2R and ExtIW2X of EXTIME.

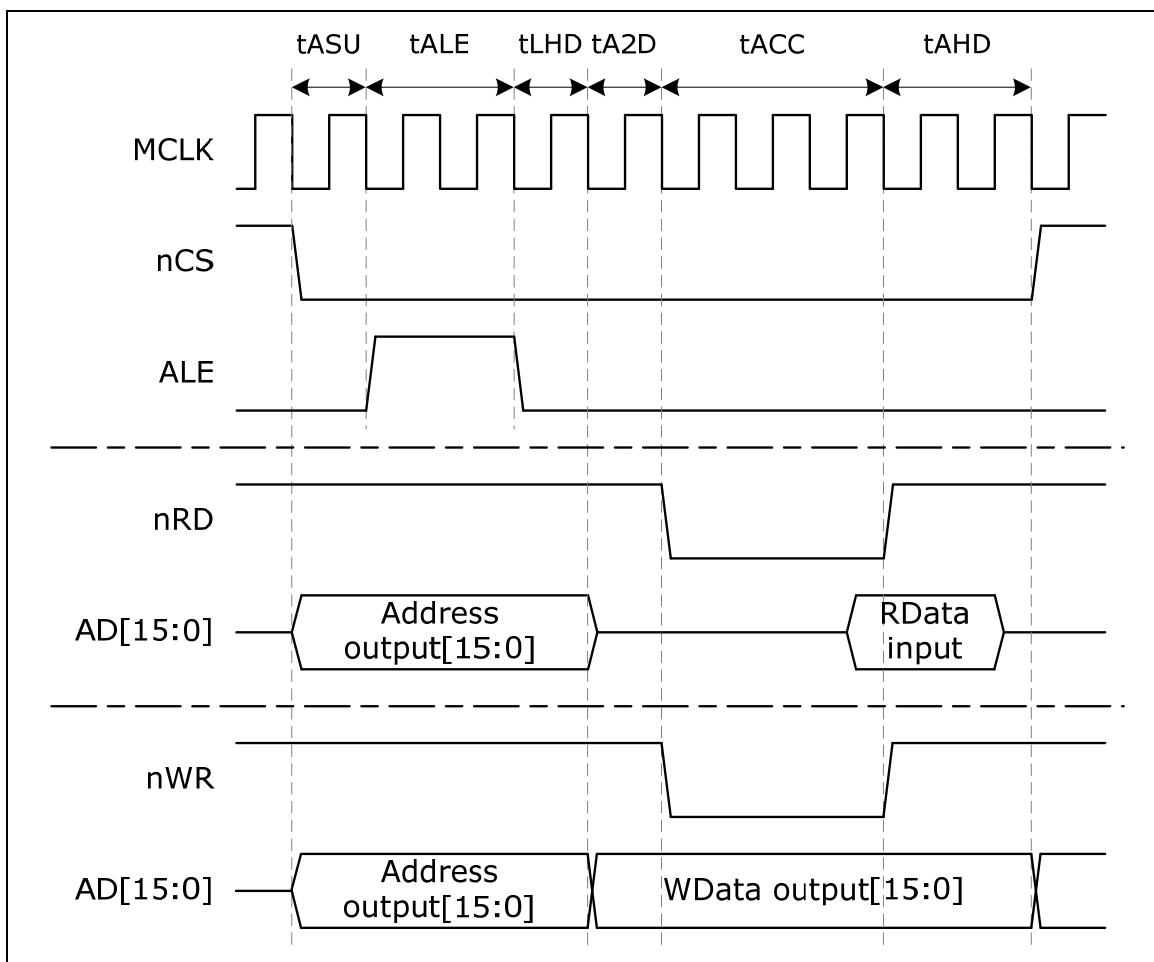

Figure 6-81 Timing Control Waveform for 16bit Data Width

Above timing waveform is an example of setting 16bit data width. In this example, AD bus is used for being address[15:0] and data[15:0]. When ALE asserts to high, AD is address output. After address is latched, ALE asserts to low and the AD bus change to high impedance to wait device output data in read access operation, or it is used for being write data output.

Figure 6-82 Timing Control Waveform for 8bit Data Width

Above timing waveform is an example of setting 8bit data width. The difference between 8bit and 16bit data width is AD[15:8]. In 8bit data width setting, AD[15:8] always be Address[15:8] output so that external latch need only 8 bit width.

## Insert Idle Cycle

When EBI accessing continuously, there may occur bus conflict if the device access time is much slow with system operating. NuMicro M051™ supply additional idle cycle to solve this problem. During idle cycle, all control signals of EBI are inactive. The Figure 6-83 shows the idle cycle waveform.

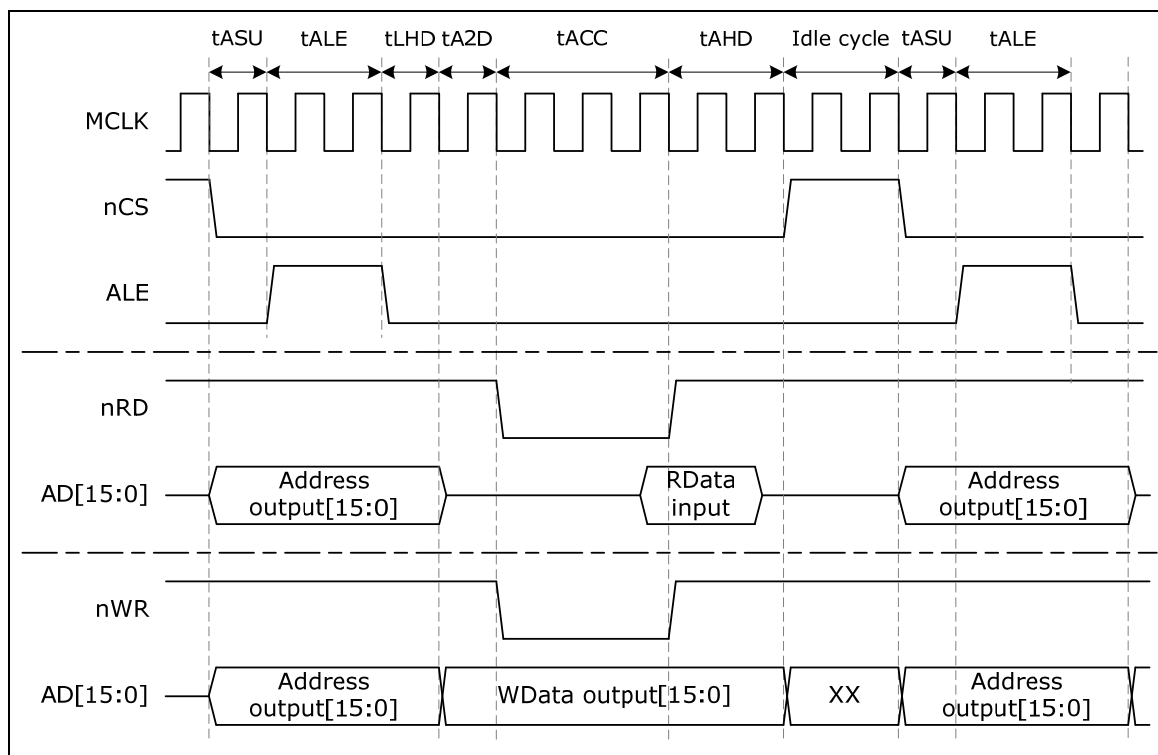

Figure 6-83 Timing Control Waveform for Insert Idle Cycle

There are two conditions that EBI can insert idle cycle by timing control:

1. After write access
2. After read access and before next read access

By setting ExtIW2X and ExtIR2R of register EXTIME, the time of idle cycle can be specified from 0~15 MCLK.

## 6.13 Flash Memory Controller (FMC)

### 6.13.1 Overview

NuMicro M051™ series equips with 64K/32K/16K/8K bytes on chip embedded Flash for application program memory (APROM) that can be updated through ISP/IAP procedure. In System Programming (ISP) function enables user to update program memory when chip is soldered on PCB. After chip power on Cortex-M0 CPU fetches code from APROM or LDRROM decided by boot select (CBS) in Config0. By the way, NuMicro M051™ series also provide additional 4K bytes DATA Flash for user to store some application depended data before chip power off in 64/32/16/8K bytes APROM model.

### 6.13.2 Features

- Run up to 50 MHz with zero wait state for continuous address read access
- 64/32/16/8KB application program memory (APROM)
- 4KB in system programming (ISP) loader program memory (LDRROM)
- Fixed 4KB data flash with 512 bytes page erase unit
- In System Program (ISP)/In Application Program (IAP) to update on chip Flash
- In Circuit Program (ICP) via serial wire debug interface (SWD)

## 6.13.3 FMC Block Diagram

The flash memory controller consist of AHB slave interface, ISP control logic, writer interface and flash macro interface timing control logic. The block diagram of flash memory controller is shown in the Figure 6-84.

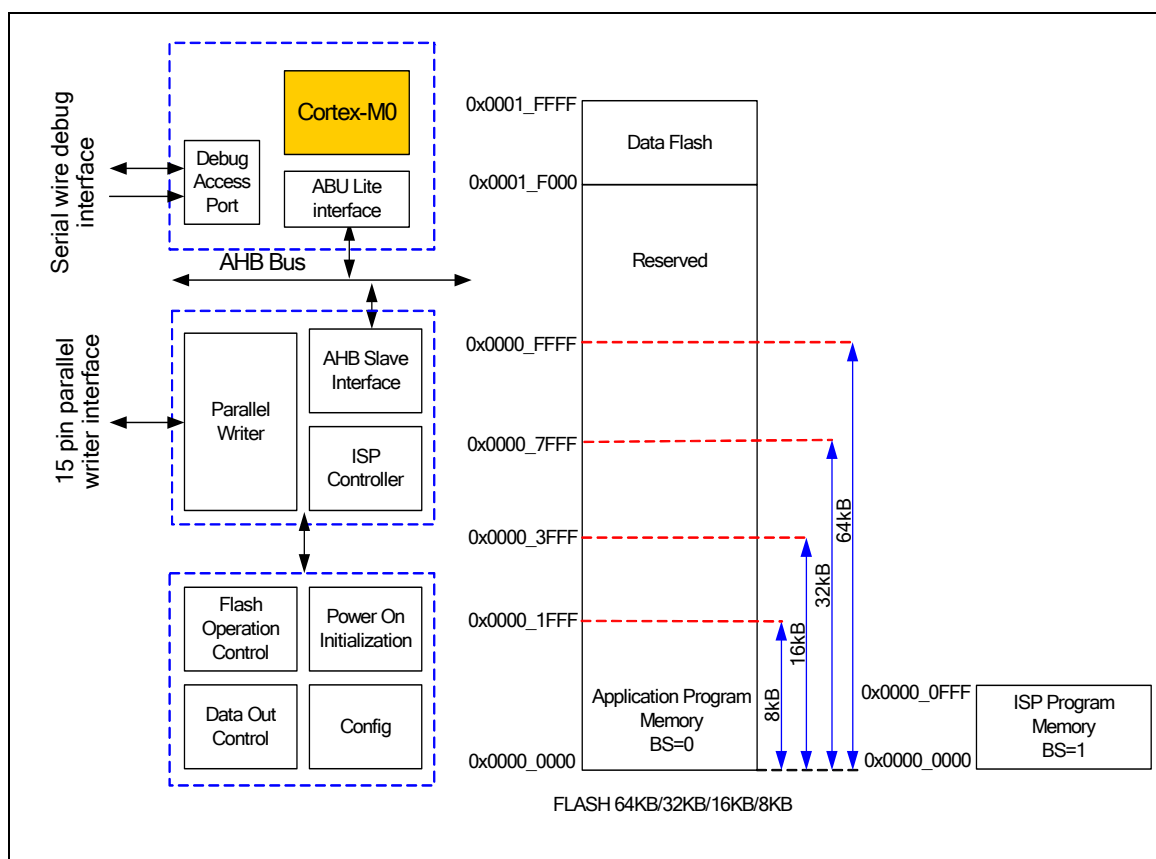

Figure 6-84 Flash Memory Control Block Diagram

## 6.13.4 FMC Organization

The NuMicro M051™ series flash memory consists of Program memory (64/32/16/8KB), data flash, ISP loader program memory, user configuration. User configuration block provides several bytes to control system logic, like flash security lock, boot select, brown out voltage level..., and so on. It works like a fuse for power on setting. It is loaded from flash memory to its corresponding control registers during chip power on. User can set these bits according to application request by writer before chip is mounted on PCB. The data flash start address and its size can be defined by user depends on application. But for 64/32/16/8KB flash memory devices, its size is 4KB and start address is fixed at 0x0001\_F000.

Block Name	Size	Start Address	End Address
AP-ROM	8/16/32/64KB	0x0000_0000	0x0000_1FFF (8KB) 0x0000_3FFF (16KB) 0x0000_7FFF (32KB) 0x0000_FFFF (64KB)
Data Flash	4KB	0x0001_F000	0x0001_FFFF
LD-ROM	4KB	0x0010_0000	0x0010_0FFF
User Configuration	1 Words	0x0030_0000	0x0030_0000

Table 6-11 Memory Address Map

The Flash memory organization is shown as below:

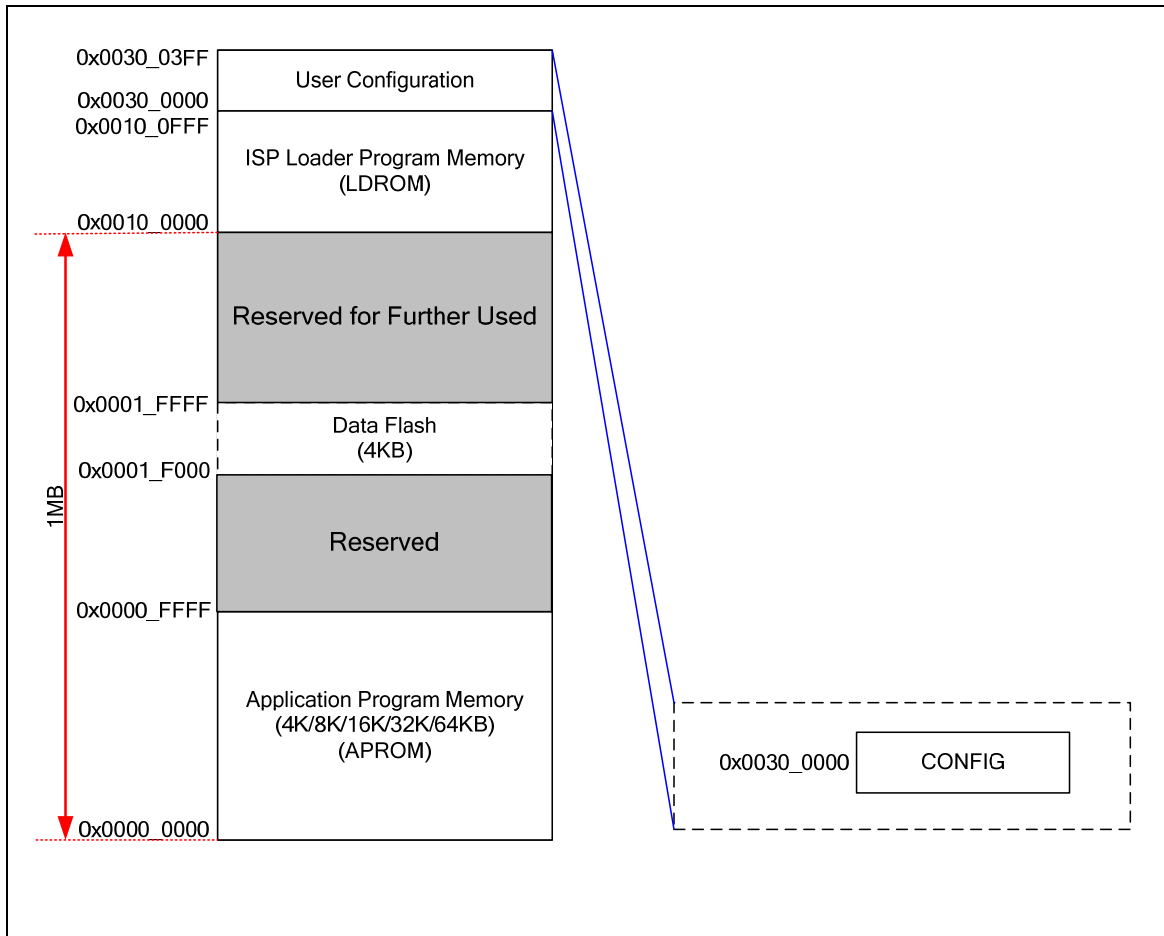

Figure 6-85 Flash Memory Organization

## 6.13.5 Boot Selection

NuMicro M051™ series provides in system programming (ISP) feature to enable user to update program memory when chip is mounted on PCB. A dedicated 4KB program memory is used to store ISP firmware. Users can select to start program fetch from APROM or LDROM by (CBS) in Config0.

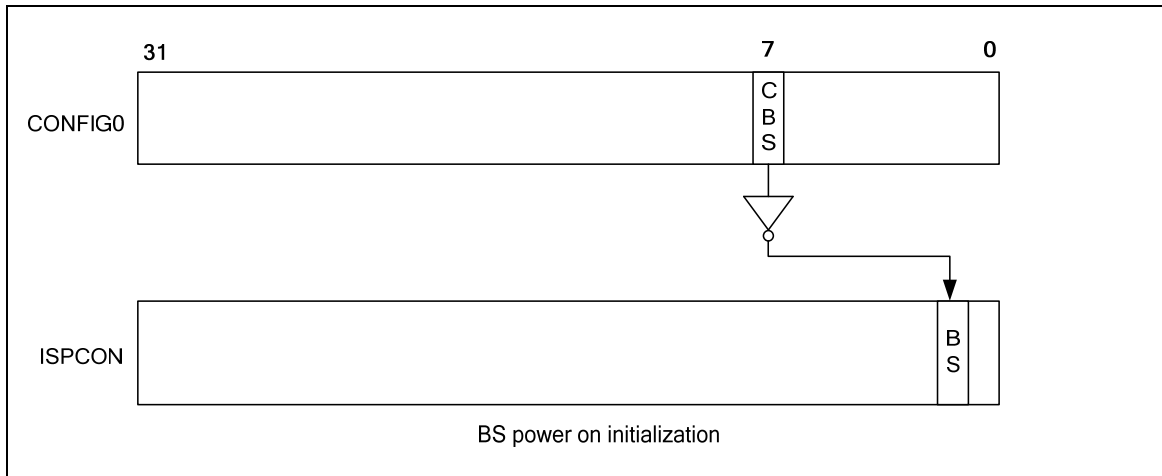

Figure 6-86 Boot Select (BS) for power-on action

## 6.13.6 Data Flash

NuMicro M051™ series provides data flash for user to store data. It is read/write thru ISP procedure. The erase unit is 512 bytes. When a word will be changed, all 128 words need to be copied to another page or SRAM in advance. For 8/16/32/64KB flash memory device, data flash size is 4KB and start address is fixed at 0x0001\_F000.

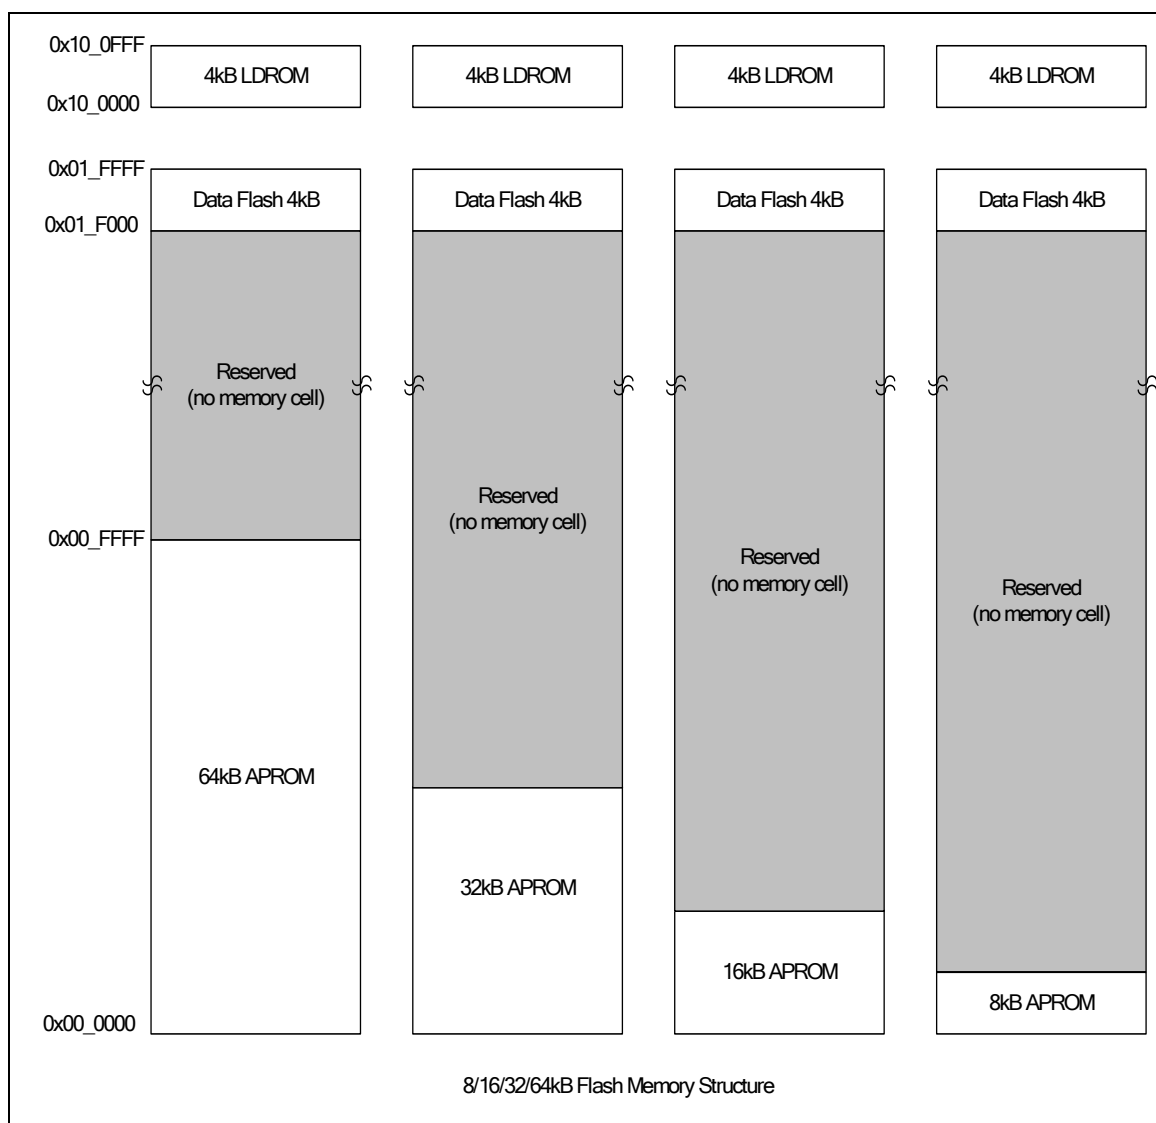

Figure 6-87 Flash Memory Structure

## 6.13.7 In System Program (ISP)

Note: Before use this ISP function, please turn-on the ISP clock in ISP\_EN(AHBCLK[2]).

Figure 6-88 shows the ISP Clock Source Block Diagram

Figure 6-88 ISP Clock Source Control

The program memory and data flash supports both in hardware programming and in system programming (ISP). Hardware programming mode uses gang-writers to reduce programming costs and time to market while the products enter into the mass production state. However, if the product is just under development or the end product needs firmware updating in the hand of an end user, the hardware programming mode will make repeated programming difficult and inconvenient. ISP method makes it easy and possible. NuMicro M051™ series supports ISP mode allowing a device to be reprogrammed under software control. Furthermore, the capability to update the application firmware makes wide range of applications possible.

ISP is performed without removing the microcontroller from the system. Various interfaces enable LDROM firmware to get new program code easily. The most common method to perform ISP is via UART along with the firmware in LDROM. General speaking, PC transfers the new APROM code through serial port. Then LDROM firmware receives it and re-programs into APROM through ISP commands. Nuvoton provides ISP firmware and PC application program for NuMicro M051™ series. It makes users quite easy perform ISP through Nuvoton ISP tool.

### ISP Procedure

NuMicro M051™ series supports boot from APROM or LDROM initially defined by user configuration bit (CBS). If user wants to update application program in APROM, he can write BS=1 and starts software reset to make chip boot from LDROM. The first step to start ISP function is write ISPEN bit to 1. S/W is required to write REGWRPROT register in Global Control Register (GCR, 0x5000\_0100) with 0x59, 0x16 and 0x88 before writing ISPCON register. This procedure is used to protect flash memory from destroying owing to unintended write during power on/off duration.

Several error conditions are checked after s/w writes ISPGO bit. If error condition occurs, ISP

# NuMicro M051™ Series Technical Reference Manual

operation is not been started and ISP fail flag will be set instead of. ISPFF flag is cleared by s/w, it will not be over written in next ISP operation. The next ISP procedure can be started even ISPFF bit keeps at 1. It is recommended that software to check ISPFF bit and clear it after each ISP operation if it is set to 1.

When ISPGO bit is set, CPU will wait for ISP operation finish, during this period; peripheral still keeps working as usual. If any interrupt request occur, CPU will not service it till ISP operation finish.

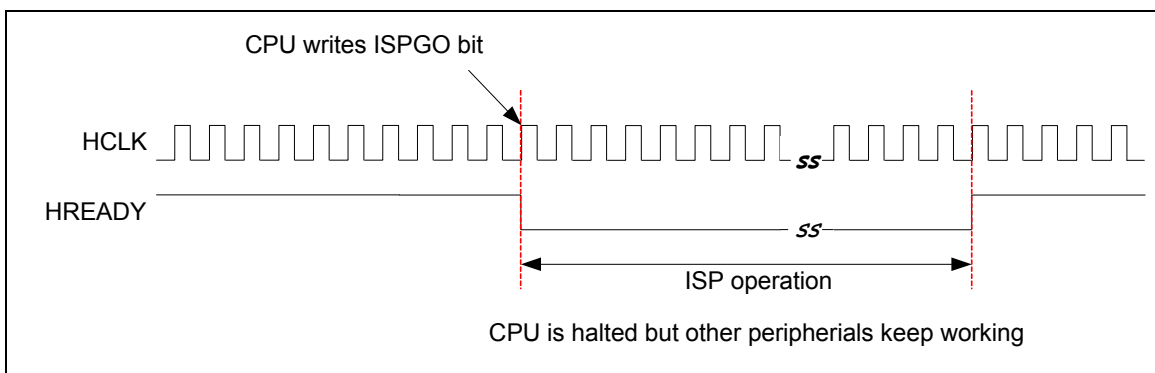

Figure 6-89 ISPGo Timing Diagram

Note that NuMicro™ NUC100 Series allows user to update CONFIG value by ISP.

# NuMicro M051™ Series Technical Reference Manual

Negative going threshold (Schmitt input), /RST	$V_{ILS}$	-0.5	-	$0.3V_{DD}$	V	
Positive going threshold (Schmitt input), /RST	$V_{IHS}$	$0.7V_{DD}$	-	$V_{DD}+0.5$	V	
Internal /RST pin pull up resistor	$R_{RST}$	40		150	K $\Omega$	
Negative going threshold (Schmitt input), P0/1/2/3/4	$V_{ILS}$	-0.5	-	$0.2V_{DD}$	V	
Positive going threshold (Schmitt input), P0/1/2/3/4	$V_{IHS}$	$0.4V_{DD}$	-	$V_{DD}+0.5$	V	
Source Current P0/1/2/3/4 (Quasi-bidirectional Mode)	$I_{SR11}$	-300	-370	-450	$\mu$ A	$V_{DD} = 4.5V, V_S = 2.4V$
	$I_{SR12}$	-50	-70	-90	$\mu$ A	$V_{DD} = 2.7V, V_S = 2.2V$
	$I_{SR12}$	-40	-60	-80	$\mu$ A	$V_{DD} = 2.5V, V_S = 2.0V$
Source Current P0/1/2/3/4 (Push-pull Mode)	$I_{SR21}$	-20	-24	-28	mA	$V_{DD} = 4.5V, V_S = 2.4V$
	$I_{SR22}$	-4	-6	-8	mA	$V_{DD} = 2.7V, V_S = 2.2V$
	$I_{SR22}$	-3	-5	-7	mA	$V_{DD} = 2.5V, V_S = 2.0V$
Sink Current P0/1/2/3/4 (Quasi-bidirectional and Push-pull Mode)	$I_{SK1}$	10	16	20	mA	$V_{DD} = 4.5V, V_S = 0.45V$
	$I_{SK1}$	7	10	13	mA	$V_{DD} = 2.7V, V_S = 0.45V$
	$I_{SK1}$	6	9	12	mA	$V_{DD} = 2.5V, V_S = 0.45V$
Brownout voltage with BOV_VL [1:0] =00b	$V_{BO2.2}$	2.1	2.2	2.3	V	
Brownout voltage with BOV_VL [1:0] =01b	$V_{BO2.7}$	2.6	2.7	2.8	V	
Brownout voltage with BOV_VL [1:0] =10b	$V_{BO3.8}$	3.7	3.8	3.9	V	
Brownout voltage with BOV_VL [1:0] =11b	$V_{BO4.5}$	4.4	4.5	4.6	V	
Hysteresis range of BOD voltage	$V_{BH}$	30	-	150	mV	$V_{DD} = 2.5V\sim 5.5V$

Notes:

1. /RST pin is a Schmitt trigger input.
2. XTAL1 is a CMOS input.
3. Pins of P0, P1, P2, P3 and P4 can source a transition current when they are being externally driven from 1 to 0. In the condition of  $V_{DD}=5.5V$ , 5he transition current reaches its maximum value when  $V_{in}$  approximates to 2V .

## 9.3 AC Electrical Characteristics

### 9.3.1 External 4~24 MHz High Speed Crystal

Note: Duty cycle is 50%.

PARAMETER	SYMBOL	MIN.	TYP.	MAX.	UNITS	CONDITION
Clock High Time	$t_{CHCX}$	20	-	125	nS	
Clock Low Time	$t_{CLCX}$	20	-	125	nS	
Clock Rise Time	$t_{CLCH}$	-	-	10	nS	
Clock Fall Time	$t_{CHCL}$	-	-	10	nS	

### 9.3.2 External 4~24 MHz High Speed Oscillator

PARAMETER	CONDITION	MIN.	TYP.	MAX.	UNIT
Input clock frequency	External crystal	4	12	24	MHz
Temperature	-	-40	-	85	°C
$V_{DD}$	-	2.5	5	5.5	V
Operating current	12 MHz@ $V_{DD} = 5V$	-	5	-	mA

### 9.3.3 Typical Crystal Application Circuits

CRYSTAL	C1	C2
4 MHz ~ 24 MHz	Optional (Depend on crystal specification)	

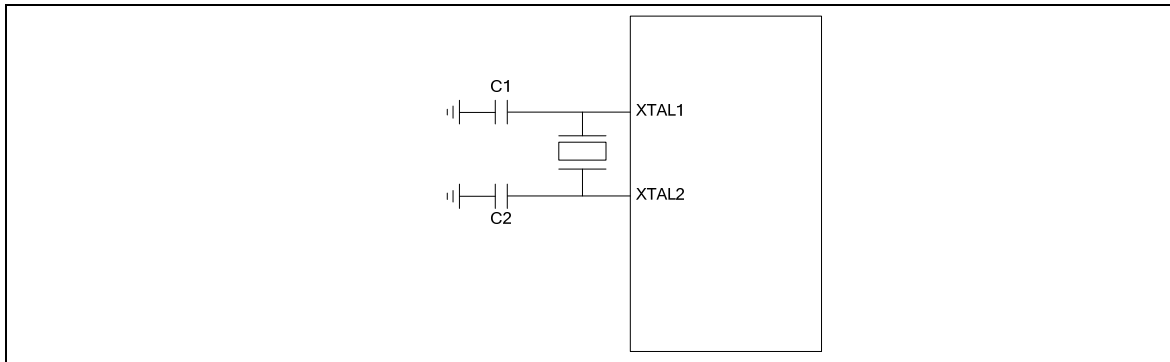

Figure 9-1 Typical Crystal Application Circuit

## 9.3.4 Internal 22.1184 MHz High Speed Oscillator

PARAMETER	CONDITION	MIN.	TYP.	MAX.	UNIT
Supply voltage <sup>[1]</sup>	-	2.5	-	5.5	V
Center Frequency	-	-	22.1184	-	MHz
Calibrated Internal Oscillator Frequency	+25 C; V <sub>DD</sub> =5V	-1	-	+1	%
	-40 C~+85 C; V <sub>DD</sub> =2.5V~5.5V	-3	-	+3	%
Accuracy of Un-calibrated Internal Oscillator Frequency	-40 C~+85 C; V <sub>DD</sub> =2.5V~5.5V	-25	-	+25	%
Operating current	V <sub>DD</sub> =5V	-	500	-	uA

## 9.3.5 Internal 10 kHz Low Speed Oscillator

PARAMETER	CONDITION	MIN.	TYP.	MAX.	UNIT
Supply voltage <sup>[1]</sup>	-	2.5	-	5.5	V
Center Frequency	-	-	10	-	kHz
Calibrated Internal Oscillator Frequency	+25 C; V <sub>DD</sub> =5V	-30	-	+30	%
	-40 C~+85 C; V <sub>DD</sub> =2.5V~5.5V	-50	-	+50	%
Operating current	V <sub>DD</sub> =5V	-	5	-	uA

**Notes:**

1. Internal operation voltage comes from LDO.

## 9.4 Analog Characteristics

### 9.4.1 Specification of 600 kHz sps 12-bit SARADC

PARAMETER	SYM.	MIN.	TYP.	MAX.	UNIT
Resolution	-	-	-	12	Bit
Differential nonlinearity error	DNL	-	±1.2	-	LSB
Integral nonlinearity error	INL	-	±1.5	-	LSB
Offset error	EO	-	+4	10	LSB
Gain error (Transfer gain)	EG	-	+7	1.005	-
Monotonic	-	Guaranteed			-
ADC clock frequency	FADC	-	-	20	MHz
Calibration time	TCAL	-	127	-	Clock
Sample time	TS	-	7	-	Clock
Conversion time	TADC	-	13	-	Clock
Sample rate	FS	-	-	600	k sps
Supply voltage	V <sub>LDO</sub>	-	2.5	-	V
	V <sub>ADD</sub>	3	-	5.5	V
Supply current (Avg.)	I <sub>DD</sub>	-	0.5	-	mA
	I <sub>DDA</sub>	-	1.5	-	mA
Input voltage range	V <sub>IN</sub>	0	-	AVDD	V
Capacitance	C <sub>IN</sub>	-	5	-	pF

## 9.4.2 Specification of LDO and Power management

PARAMETER	MIN	TYP	MAX	UNIT	NOTE
Input Voltage	2.7	5	5.5	V	V <sub>DD</sub> input voltage
Output Voltage	-10%	2.5	+10%	V	V <sub>DD</sub> > 2.7V
Temperature	-40	25	85	°C	
Quiescent Current (PD=0)	-	100	-	uA	
Quiescent Current (PD=1)	-	5	-	uA	
Iload (PD=0)	-	-	100	mA	
Iload (PD=1)	-	-	100	uA	
Cbp	-	10	-	uF	Resr=1ohm

Note:

1. It is recommended that a 10uF (or higher) capacitor and a 100nF bypass capacitor are connected between VDD and the closest VSS pin of the device.
2. For ensuring power stability, a 4.7uF or higher capacitor must be connected between LDO pin and the closest VSS pin of the device.

## 9.4.3 Specification of Low Voltage Reset

PARAMETER	CONDITION	MIN.	TYP.	MAX.	UNIT
Operation voltage	-	1.7	-	5.5	V
Quiescent current	VDD5V=5.5V	-	-	5	uA
Threshold voltage	Temperature=25°	1.7	2.0	2.3	V
	Temperature=-40°	-	2.4	-	V
	Temperature=85°	-	1.6	-	V
Hysteresis	-	0	0	0	V

## 9.4.4 Specification of Brownout Detector

PARAMETER	CONDITION	MIN.	TYP.	MAX.	UNIT
Operation voltage	-	2.5	-	5.5	V
Quiescent current	AVDD=5.5V	-	-	125	μA
Temperature	-	-40	25	85	°C
Brown-out voltage	BOV_VL[1:0]=11	4.4	4.5	4.6	V
	BOV_VL [1:0]=10	3.7	3.8	3.9	V
	BOV_VL [1:0]=01	2.6	2.7	2.8	V
	BOV_VL [1:0]=00	2.1	2.2	2.3	V
Hysteresis	-	30m	-	150m	V

## 9.4.5 Specification of Power-On Reset (5V)

PARAMETER	CONDITION	MIN.	TYP.	MAX.	UNIT
Reset voltage	V+	-	2	-	V
Quiescent current	Vin>reset voltage	-	1	-	nA

# NuMicro M051™ Series Technical Reference Manual

## 9.5 SPI Dynamic characteristics

PARAMETER	CONDITION	MIN.	TYP.	MAX.	UNIT
SPI master mode (VDD = 4.5V ~ 5.5V, 30pF loading Capacitor)					
t <sub>DS</sub>	Data setup time	26	-	-	ns
t <sub>DH</sub>	Data hold time	0	-	-	ns
t <sub>V</sub>	Data output valid time	-	-	6	ns
SPI master mode (VDD = 3.0V ~ 3.6V, 30pF loading Capacitor)					
t <sub>DS</sub>	Data setup time	39	-	-	ns
t <sub>DH</sub>	Data hold time	0	-	-	ns
t <sub>V</sub>	Data output valid time	-	-	10	ns
SPI slave mode (VDD = 4.5V ~ 5.5V, 30pF loading Capacitor)					
t <sub>DS</sub>	Data setup time	0	-	-	ns
t <sub>DH</sub>	Data hold time	2*PCLK+4	-	-	ns
t <sub>V</sub>	Data output valid time	-	-	2*PCLK+27	ns
SPI slave mode (VDD = 3.0V ~ 3.6V, 30pF loading Capacitor)					
t <sub>DS</sub>	Data setup time	0	-	-	ns
t <sub>DH</sub>	Data hold time	2*PCLK+8	-	-	ns
t <sub>V</sub>	Data output valid time	-	-	2*PCLK+40	ns

## 11 REVISION HISTORY

VERSION	DATE	PAGE/ CHAPTER	DESCRIPTION
V1.00	Aug 23, 2010		Initial issued
V1.01	Sep. 8, 2010	Chapter 6.10	1. Modify FIFO size of UART from 16bytes to 15bytes. 2. Reserve Bus Error Interrupt of UART.
V1.02	Sep. 14, 2010	Chapter 6.10	1. Reverse the definition of CTS trigger level (UA_MSR.8).
V1.03	Apr. 18, 2011	Page 365	1. Modify typo 2. Removed the Note 2 of Table 9.4.2 3. Revise PLLCON[16] description.
V2.00	May. 04, 2011	Chapter 6.3 Chapter 6.3.9 Figure 6-3 Chapter 6.2.6 Chapter 6.2.6 Chapter 6.2.7 Table 6-5 Chapter 6.13 Chapter 6.13.9 Chapter 6.5.5 All Chapter 6.8.5 Chapter 6.9 Chapter 6.9.4 All Chapter 6.4.3 Chapter 9.4.2 Chapter 9.5	1. Remove reserved clock source description and diagram for Timer and Watchdog and revise timer block description from "five options" to "four options" 2. Revise the description of CLKSTATUS to compatible with PWRCON 3. Add "Whole Chip Clock generator block diagram" 4. Revise PLL setting constraint 3 5. Add "write-protected bit" for BOD_LPM and POR_DIS_CODE 6. Revise the default value of register SYST_CSR 7. Revise "Power Down Mode Control Table" 8. Remove "Standby" and "Read Company ID" of ISP command 9. Revise the description of FPSEN and ISPADR 10. Revise the default value of I2CSTATUS 11. Change SIO to I <sup>2</sup> C 12. Add DBGACK_TM in TCSR register 13. Revise description of WDT time out period and interrupt period 14. Add DBGACK_WDT in WTCR register 15. Remove ExtIR2W description 16. Revise the description of GPIOxx_DOUT, DMASK[n] and IF_EN[n] register 17. Revise the spec of LDO 18. Add SPI Dynamic Characteristics

Publication Release Date: May. 04, 2011  
Revision V2.00

## Important Notice

Nuvoton Products are neither intended nor warranted for usage in systems or equipment, any malfunction or failure of which may cause loss of human life, bodily injury or severe property damage. Such applications are deemed, "Insecure Usage".

Insecure usage includes, but is not limited to: equipment for surgical implementation, atomic energy control instruments, airplane or spaceship instruments, the control or operation of dynamic, brake or safety systems designed for vehicular use, traffic signal instruments, all types of safety devices, and other applications intended to support or sustain life.

All Insecure Usage shall be made at customer's risk, and in the event that third parties lay claims to Nuvoton as a result of customer's Insecure Usage, customer shall indemnify the damages and liabilities thus incurred by Nuvoton.
