About this manual

1.1 Audience

This reference manual is intended for system software and hardware developers and applications programmers who want to develop products with this device. It assumes that the reader understands operating systems, microprocessor system design, and basic principles of software and hardware. The manual describes the features and functionality of the i.MX 7ULP device.

1.2 Organization

This manual has two main sets of chapters.

- Chip-specific chapters: These chapters contain information that applies to all components on the chip.
- Module chapters: These chapters contain details of functional block level information with memory map and register configuration, used in this device

Both sets of chapters are organized into functional groupings that detail particular areas of functionality.

- Examples of these groupings are clocking, timers, and communication interfaces.
- Each grouping first includes the full chip-specific chapter followed by the chapters that provide a technical description of individual modules categorized under that group. For example, for clocking information, there is complete chip-specific Clocking chapter followed by the clock modules: PCC and SCG

1.3 Module descriptions

Each module chapter has three main parts:

- The first section, *Chip-specific [module name] information*, contains:

- A table listing the related references for chip-specific chapters like memory map, clock distribution, power management, and signal multiplexing, to facilitate the user to have a quick look at any of these chapters. See Figure 1-1
- Followed by this table, we have textual information about the module and then a configuration table which contains the general chip-specific information such as the number of module instances on the chip and connections between the module and other modules, configurable features, signal names, etc. See Figure 1-1
- Followed by this are any other specific chip-specific sections that detail the functionality of the device which may be different from what is mentioned in the complete block guide. These sections may also contain additional information needed to understanding of the module in this device. See Figure 1-2

NOTE

Read these sections *first* because its content is crucial to understanding the information in other sections of the chapter.

- The subsequent sections provide general information about the module, including its signals, registers, and functional description.

EXAMPLE

Chapter 14
Direct Memory Access Controller (DMA)

14.1 Chip-specific DMA information

Table 14-1. Reference links to related information

Topic	Related module	Reference
Full description	DMA	DMA
System memory map		System memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port control	Signal multiplexing

14.1.1 DMA

DMA is a second-generation module of the enhanced direct memory access (eDMA2) controller, which is capable of performing complex data transfers with minimal intervention from a host processor. There are two DMA instances in i.MX 7ULP. Each DMA supports 32 DMA channels. The transfer control descriptors for each of the 32 channels are located in system memory. The following table shows the configuration of the DMA.

Table 14-2. DMA configuration

Parameter	Description
Name	Enhanced Direct Memory Access v2 (eDMA2)
Instances	2
Configurable features	• DMA0-1: 32-channels • DMA0-1: 64-bit AHB
Interface speed	NA
External I/O pins	NA

Figure 1-1. Example: Related references and configuration table

Table 11-2. XRDC configuration

Parameter	Description
Name	Extended Resource Domain Control
Instances	1
Configurable features	Refer to Multicore Architecture for details
Interface speed	NA
External I/O pins	NA

11.1.2 XRDC configuration for MDAC, MRC, and PAC registers

Table 11-3. MDAC configuration

XRDC MDA	MDAC_REG_NUM	DEFAULT_DID	MDAC_CPU	MDAC_INST_NUM
CM4CODE	2	0	1	6'd00
CM4SYS	2	0	1	6'd01
CM4DMA	1	0	0	6'd02
CA7	2	1	1	6'd03
LCDIF	1	1	0	6'd04
GPU3D	1	1	0	6'd05
CA7DMA	1	1	0	6'd06
AXBS2NIC1	1	1	0	6'd07
CAAM	1	1	0	6'd08
USB0/1	1	1	0	6'd09
VIU	1	1	0	6'd10
SDHC0	1	1	0	6'd11
SDHC1	1	1	0	6'd12
GPU2D	1	1	0	6'd13

Table 11-4. MRC configuration

MRC#	SLAVE_NUM	Slave Memory	REGION_NUM	SEMA4_NUM	SEMA4_INST
MRC0	1	M4 TCMs	4	16	SEMA4_0

Figure 1-2. Example: chapter additional chip-specific information

1.3.1 Example: chip-specific information that clarifies content in the same chapter

The example below shows chip-specific information that clarifies general module information presented later in the chapter. In this case, the chip-specific register reset values supersede the reset values that appear in the register diagram.

22.1.1 External Bus Interface (FlexBus)

The External Bus Interface (FlexBus) module provides external memory expansion and provides connection to external peripherals with a parallel, memory-mapped interface. The FlexBus supports asynchronous and synchronous interface to external ROM, NOR flash, SRAM, PSRAM, programmble logic devices and other memory-mapped slave devices. The FlexBus supports 8-bit, 16-bit and 32-bit data bus width options and the multiplexing of address and data configuration. The following table shows the configuration of the FlexBus.

Table 22-2. Flexbus configuration

Parameter	Description
Name	External Bus Interface (FlexBus)
Instances	1
Configurable features	NA
Interface speed	Up to 100 MHz
External I/O pins	See the attached IOMUXC spreadsheet for pin details.

22.1.2 Transfer Acknowledge signal

The Transfer Acknowledge Signal ($\overline{\text{FB\_TA}}$) is hard-wired in the design of I.MX 7ULP, so this signal is not available. See the FB_CSPMCR register for the multiplexing of other signals.

22.1.3 Reset value for CSCRn register

The reset valus of CSCR0-CSCR5 for i.MX 7ULP are specified in the table below

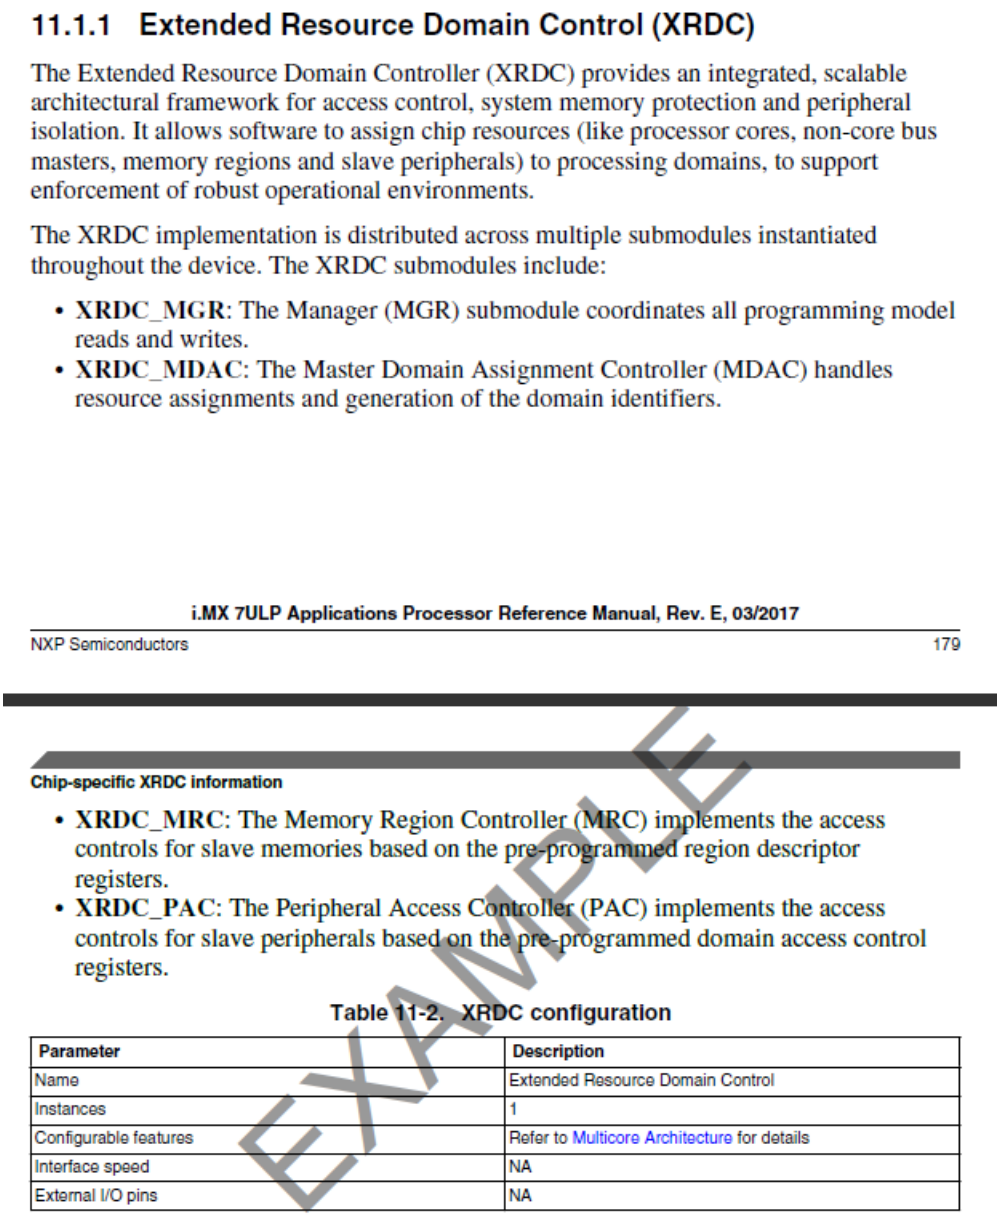
Table 22-3. CSCRn reset values

Register name	Reset value
CSCR0	0x003F_FC00
CSCR1-CSCR5	0x0000_0000

Figure 1-3. Example: chip-specific information that clarifies content in the same chapter

1.3.2 Example: chip-specific information that refers to a different chapter

The chip-specific information below refers to another chapter's chip-specific information. In this case, read both sets of chip-specific information before reading further in the chapter. In the following figure, the XRDC chapter refers to Multicore Architecture chapter in the configuration table



11.1.1 Extended Resource Domain Control (XRDC)

The Extended Resource Domain Controller (XRDC) provides an integrated, scalable architectural framework for access control, system memory protection and peripheral isolation. It allows software to assign chip resources (like processor cores, non-core bus masters, memory regions and slave peripherals) to processing domains, to support enforcement of robust operational environments.

The XRDC implementation is distributed across multiple submodules instantiated throughout the device. The XRDC submodules include:

- **XRDC_MGR**: The Manager (MGR) submodule coordinates all programming model reads and writes.
- **XRDC_MDAC**: The Master Domain Assignment Controller (MDAC) handles resource assignments and generation of the domain identifiers.

i.MX 7ULP Applications Processor Reference Manual, Rev. E, 03/2017

NXP Semiconductors 179

Chip-specific XRDC information

- **XRDC_MRC**: The Memory Region Controller (MRC) implements the access controls for slave memories based on the pre-programmed region descriptor registers.
- **XRDC_PAC**: The Peripheral Access Controller (PAC) implements the access controls for slave peripherals based on the pre-programmed domain access control registers.

Table 11-2. XRDC configuration

Parameter	Description
Name	Extended Resource Domain Control
Instances	1
Configurable features	Refer to Multicore Architecture for details
Interface speed	NA
External I/O pins	NA

Figure 1-4. Example: chip-specific information that refers to a different chapter

1.4 Register descriptions

Module chapters present register information in:

- Memory maps containing:
  - Offset from the module's base address or the absolute address
  - The name and acronym/abbreviation of each register
  - The width of each register (in bits)

    - Each register's reset value
    - Access of each register
- Register figures
- Field-description tables
- Associated text

NOTE

Some modules may contain multiple memory maps for different instances if there are actual differences in the register or bitfields within the instances. For example, PCC module has four memory maps (one for each instance) and similarly SCG module has two memory maps.

The register figures show the field structure using the conventions in the following figure.

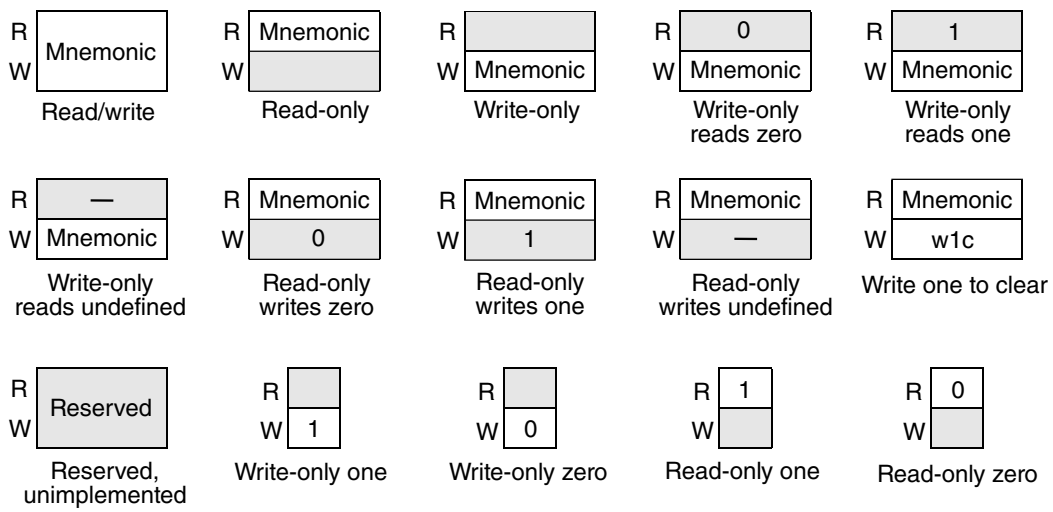


Figure 1-5. Register figure conventions

1.5 Conventions

1.5.1 Notes, Cautions, and Warnings

Note, Caution, and Warning notices appear throughout this manual. Each notice type alerts readers to a specific kind of information.

NOTE

Notes convey information that may be tangential to a topic or that may not apply to all readers.

CAUTION

Caution notices call out information that readers should know before taking further action. Cautions frequently point to trouble spots that may damage the chip or board.

WARNING

Warning notices inform readers about actions that could result in unwanted consequences, especially those that may cause bodily injury.

1.5.2 Numbering systems

The following suffixes identify different numbering systems:

This suffix	Identifies a
b	Binary number. For example, the binary equivalent of the number 5 is written 101b. In some cases, binary numbers are shown with the prefix *0b*.
d	Decimal number. Decimal numbers are followed by this suffix only when the possibility of confusion exists. In general, decimal numbers are shown without a suffix.
h	Hexadecimal number. For example, the hexadecimal equivalent of the number 60 is written 3Ch. In some cases, hexadecimal numbers are shown with the prefix *0x*.

1.5.3 Typographic notation

The following typographic notation is used throughout this document:

Example	Description
placeholder, x	Items in italics are placeholders for information that you provide. Italicized text is also used for the titles of publications and for emphasis. Plain lowercase letters are also used as placeholders for single letters and numbers.
`code`	Fixed-width type indicates text that must be typed exactly as shown. It is used for instruction mnemonics, directives, symbols, subcommands, parameters, and operators. Fixed-width type is also used for example code. Instruction mnemonics and directives in text and tables are shown in all caps; for example, BSR.
SR[SCM]	A mnemonic in brackets represents a named field in a register. This example refers to the Scaling Mode (SCM) field in the Status Register (SR).
REVNO[6:4], XAD[7:0]	Numbers in brackets and separated by a colon represent either: • A subset of a register's named field For example, REVNO[6:4] refers to bits 6–4 that are part of the COREREV field that occupies bits 6–0 of the REVNO register. • A continuous range of individual signals of a bus For example, XAD[7:0] refers to signals 7–0 of the XAD bus.

1.5.4 Special terms

The following terms have special meanings:

Term	Meaning
asserted	Refers to the state of a signal as follows: • An active-high signal is asserted when high (1). • An active-low signal is asserted when low (0).
deasserted	Refers to the state of a signal as follows: • An active-high signal is deasserted when low (0). • An active-low signal is deasserted when high (1). In some cases, deasserted signals are described as *negated*.
reserved	Refers to a memory space, register, field, or programming setting. Device operation is not guaranteed when reserved locations are written to any value. • Do not modify the default value of a reserved programming setting, such as the reset value of a reserved register field. • Consider undefined locations in memory to be reserved.
w1c	Write 1 to clear: Refers to a register bitfield that must be written as 1 to be "cleared."

Chapter 2
Introduction

2.1 Overview

i.MX 7ULP is an asymmetric microprocessor consisting of two separate processing domains. The domains are divided into an application domain and a real time domain. The application domain is built around a small Arm® Cortex® A7 core (hereafter referred as CA7 or A7) optimized for 500 to 800 MHz Linux and Android-based applications, and the real time domain is built around a Arm® Cortex® M4 core (hereafter referred as CM4 or M4) that is optimized for the lowest possible active and standby power. The design enables clean separation between two processing domains, where each has separate power, clocking and peripheral islands, but the bus fabric of each domain is tightly integrated for efficient communication. The part is streamlined to minimize pin count, enabling small packages and simple system integration. This microprocessor is intended for applications where efficiency and simple system integration is important.

2.2 Key features

Following is the block diagram of i.MX 7ULP showing key modules and features:

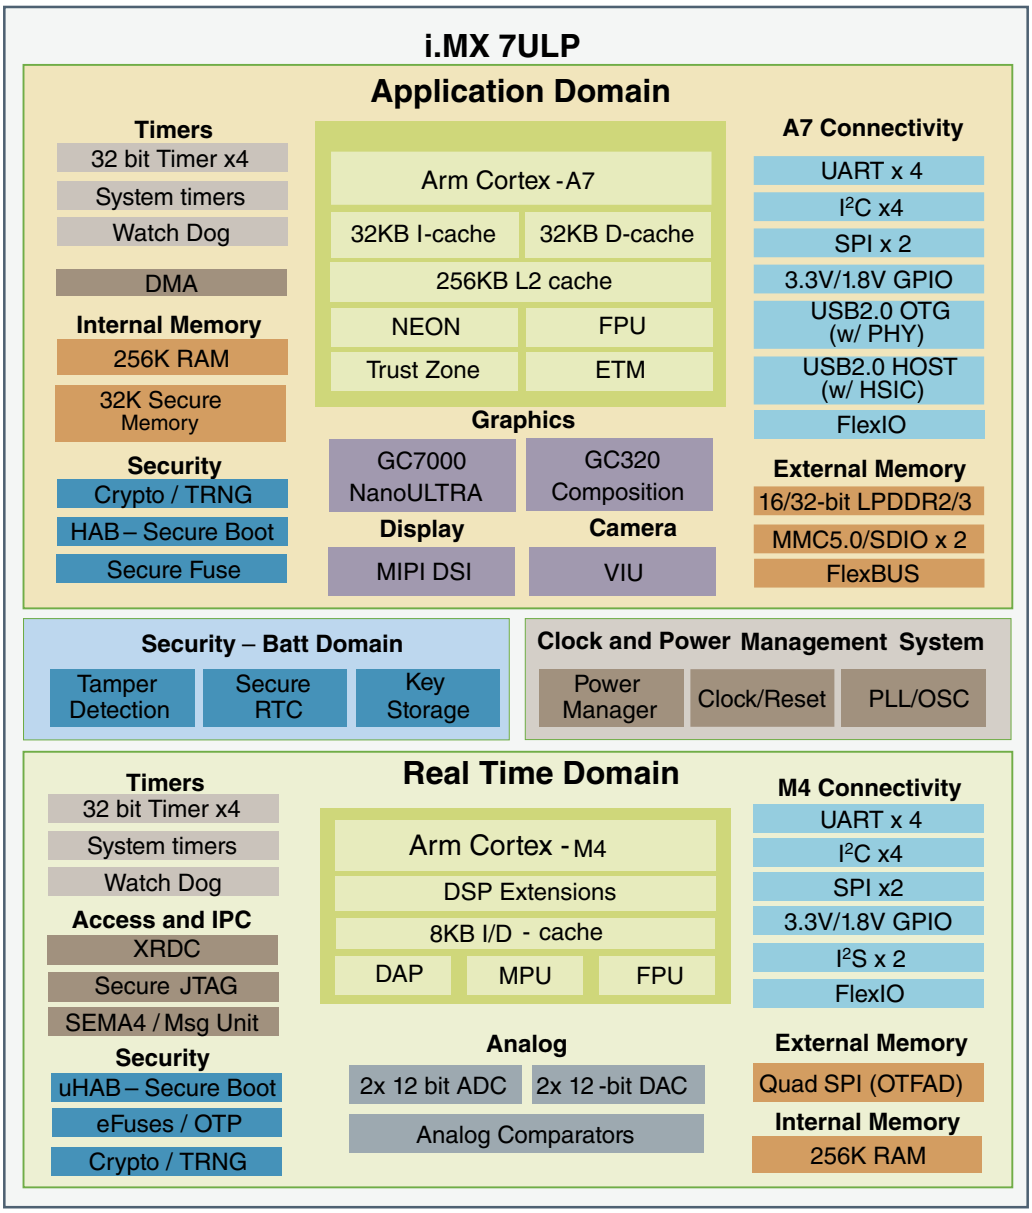

Figure 2-1. i.MX 7ULP Block Diagram

Application domain	
Arm® Cortex® A7	• Normal operating frequency of 500 MHz and overdrive up to 800 MHz. See the i.MX 7ULP Data Sheet for Normal Operating Frequency. • 32 KB instruction cache and 32 KB data cache • 256 KB of L2 cache • NEON SIMD engine • Floating Point Unit (FPU) • 32-channel DMA
Memory architecture and memory controllers	• 256 KB of RAM • 96 KB of boot ROM • DRAM interface supporting x16/x32 LPDDR2/3 running up to 380 MHz. See the i.MX 7ULP Data Sheet for DRAM interface supporting frequency. • Two eMMC/SD host interfaces supporting eMMC5.0 and SD3.0

Table continues on the next page...

Application domain	
Graphic, display and camera interface	• GC7000 Nano Ultra GPU supporting OpenGL ES2.0/1.1, Desktop OpenGL 2.1, OpenVG1.1, and built-in graphics functions for special effects. • Dual lane MIPI DSI interface operating up to 800 Mbps • Parallel camera sensor interface
Communication and timer peripherals	• One High-Speed USB-OTG port with integrated PHY and 1 High-Speed USB port with HSIC interface • HSIC and ULPI interface • Two SD host interface supporting SDIO3.0 • Four UART ports • Two SPI ports • Four I2C ports • Multiple timer peripherals suited for task scheduling and time keeping
Security[1]	• High assurance boot • Cryptographic acceleration supporting symmetric and asymmetric ciphering algorithms and SHA-256 hashing algorithm. • Random number generator • 32 KB secure memory

1. See the i.MX 7ULP Security Reference Manual, for details on security information

Real time domain	
Arm® Cortex® M4	• Normal operating frequency of 100 MHz and overdrive 200 MHz. See the i.MX 7ULP Data Sheet for Normal Operating Frequency. • FPU • Memory Protection Unit (MPU)
Memory architecture and memory controllers	• 256 KB RAM, zero wait state accessed by M4 • 64 KB boot ROM • Serial flash interface to quadSPI and octalSPI flash devices • 8 KB cache
Analog	• Two 12-bit ADC • Two DAC • Two analog comparators
Communication and timer peripherals	• Four UART ports • Two SPI ports • Four I2C ports • Two I2S ports • Multiple timer peripherals suited for task scheduling and time keeping
Security[1]	• High assurance boot • Cryptographic acceleration supporting SHA-256 hashing algorithm • Cryptographic acceleration supporting AES ciphering algorithm • Secure Non-Volatile Storage including cryptographic key, time counter, monotonic counter, and general purpose security information. • True random number generator • On-The-Fly decryption of the encrypted code stored in external flash device • One-Time Programmable electrical fuse used for security keys and configuring other security related functions

1. See the i.MX 7ULP Security Reference Manual, for details on security information

Following are the low-power features:

- On chip power management including regulators, drivers and switches for flexible power supplies, efficient power consumption, and short wake-up time

- Multiple power domains and ultra low power modes allow flexible power saving
- Voltage and frequency scaling in dynamic operating modes
- Software-controlled clock gating for cores and peripherals

2.3 Module description

2.3.1 Memory architecture and memory controllers

Table 2-1. Memory architecture

Module	Description
SRAM0-1	An AXI RAM Controller (RAMC), which acts as an interface between the AXI bus and RAM, is used on each SRAM connected to the NIC crossbar.
TCM RAM	Tightly Coupled Memory (TCM) RAM is tightly integrated to the M4 processor. M4 accesses this memory with zero wait-state. There is a backdoor port that allows M4 DMA and other bus masters in the device to access this memory.
MMDC	The Multi Mode DDR Controller (MMDC) is a configurable DDR controller that provides interface to LPDDR2 or LPDDR3 memory. The MMDC consists of a core and PHY. The core is responsible for communication with the system through AXI interface, DDR commands generation, DDR command optimizations, and read/write data path. The PHY performs timing adjustment using special calibration mechanisms to ensure data capture margin at the supported clock rate.
FlexBus	The External Bus Interface (FlexBus) module provides external memory expansion and provides connection to external peripherals with a parallel, memory-mapped interface. The FlexBus supports asynchronous and synchronous interface to external ROM, NOR flash, SRAM, PSRAM, programmble logic devices and other memory-mapped slave devices.
QSPI	The Quad Serial Peripheral Interface (QSPI) module provides an interface to various types of serial flash memory. The QSPI interface allows only one serial flash connection. It supports 1-bit, 4-bit and 8-bit SPI bus width.
uSDHC0-1	The ultra Secured Digital Host Controller (uSDHC) provides the interface between the host system and SD, SDIO or eMMC cards. The uSDHC acts as a bridge, passing host bus transactions to the cards by sending commands and performing data accesses to/from the cards or devices. It handles SD, SDIO and eMMC protocol at transmission level.

2.3.2 DMA and Bus Fabrics

Table 2-2. DMA and Bus Fabrics

Module	Description
DMA0-1	Direct Memory Access (DMA) is capable of performing complex data transfers with minimal intervention from a host processor. Each DMA module supports 32 DMA channels. The transfer control descriptors for each of the 32 channels are located in system memory.

Table continues on the next page...

Table 2-2. DMA and Bus Fabrics (continued)

Module	Description
DMAMUX0-1	The Direct Memory Access Multiplexer (DMAMUX) module routes DMA sources, called slots, to any of the supported DMA channels.
NIC0-1	The AMBA Network Interconnect Crossbar (NIC) is a highly configurable and high performance AMBA-compliant network infrastructure which arbitrates between multiple AXI or AHB masters to grant access to internal or external memories or other slave devices. It supports connectivity between several slave and master ports for parallel processing. It uses a hybrid round-robin arbitration scheme and contains frequency converters, data width converters, bus protocol converter, and AXI channel buffers.
AXBS-Lite	AHB-Lite Cross Bar Switch (AXBS-Lite) is a crossbar switch module that arbitrates between multiple AHB masters to grant access to downstream AHB slave devices. The crossbar enables multiple masters to connect to slaves and parallel processing.
AIPS-Lite	AHB-Lite to IP Bus Interface (AIPS-Lite) module interfaces an AHB-Lite bus to the peripheral bus. Each AIPS module occupies a total of 64 MB of address space and is equally divided into 128 4-KB slots.
AHB-PBridge	The AHB-Peripheral Bridge (AHB-PBridge) module interfaces an AHB bus to the peripheral bus. There are 2 AHB-PBridge instances in this device. Each AHB-PBridge module supports 128 IP slots. Each slot occupies 64 KB of address space.
PortSplitter	The PortSplitter gasket splits an AHB master port to multiple AHB slave ports based on address decoding.

2.3.3 Multicore peripherals and resource domain control submodules

Table 2-3. Multicore peripherals and resource domain control submodules

Module	Description
BME	The Bit Manipulation Engine (BME) provides hardware support for atomic read-modify-write memory operations to the peripheral address space. This architectural capability is also known as "decorated storage" as it defines a mechanism for providing additional semantics for load and store operations to memory-mapped peripherals beyond just the reading and writing of data values to the addressed memory locations.
MU_A-B	Messaging Unit (MU) is a shared peripheral with a 32-bit IP bus interface and interrupt request signals to each host processor. The MU exposes a set of registers to each processor which facilitate inter-processor communication via 32-bit words, interrupts and flags. Interrupts may be independently masked by each processor to allow polled-mode operation.
SEMA42	The Hardware Semaphore (SEMA42) module provides the hardware support needed in multicore systems for implementing semaphores and provides a simple mechanism to achieve "lock/unlock" operations via a single write access.
XRDC	The Extended Resource Domain Controller (XRDC) provides an integrated, scalable architectural framework for access control, system memory protection and peripheral isolation. It allows software to assign chip resources (like processor cores, non-core bus masters, memory regions and slave peripherals) to processing domains, to support enforcement of robust operational environments. The XRDC

Table continues on the next page...

Table 2-3. Multicore peripherals and resource domain control submodules (continued)

Module	Description
	implementation is distributed across multiple submodules instantiated throughout the device.
MGR	The XRDC Manager (MGR) submodule coordinates all programming model reads and writes.
MDAC	The XRDC Master Domain Assignment Controller (MDAC) submodule handles resource assignments and generation of the domain identifiers.
MRC	The XRDC Memory Region Controller (MRC) submodule implements the access controls for slave memories based on the pre-programmed region descriptor registers.
PAC	The XRDC Peripheral Access Controller (PAC) implements the access controls for slave peripherals based on the pre-programmed domain access control registers.

2.3.4 Connectivity and Communications

Table 2-4. Connectivity and communications modules

Module	Description
FlexIO0-1	The Flexible Input/Output (FlexIO) module is capable of supporting a wide range of protocols including, but not limited to: UART, I2C, SPI, I2S, camera interface, display interface, PWM waveform generation, and so on.
LPI2C0-7	The Low Power Inter-Integrated Circuit (LPI2C) module implements an efficient interface to an I2C bus as a master. The LPI2C can continue operating while the processor is in Stop mode provided an appropriate peripheral clock is available. This module is designed for low CPU overhead with DMA offloading of FIFO register accesses.
LPUART0-7	The Low Power Universal Asynchronous Receiver/Transmitter (LPUART) module provides asynchronous, serial communication capability with external devices. LPUART supports non-return-to-zero (NRZ) encoding format and IrDA-compatible infrared (low-speed) SIR format. The LPUART can continue operating while the processor is in Stop mode if an appropriate peripheral clock is available. This module is designed for low CPU overhead with DMA off loading of FIFO register accesses.
LPSPI0-3	The Low Power Serial Peripheral Interface (LPSPI) module implements an efficient interface to an SPI bus as a master and/or a slave. The LPSPI can continue operating while the processor is in Stop mode if an appropriate peripheral clock is available. This module is designed for low CPU overhead with DMA off loading of FIFO register accesses.
USBOTG1-2	The Universal System Bus On-The-Go (USBOTG) module is a USB 2.0-compliant implemention. The registers and data structures of this USB controller are based on the Enhanced Host Controller Interface Specification for Universal Serial Bus (EHCI). This module can act as a host, a device or an On-The-Go negotiable host/device on the USB bus.
USBPHY	The Universal System Bus Physical Layer (USBPHY) macrocell implements USB physical layer connecting to USB host/device systems at low-speed, full-speed, and high-speed. USB-PHY provides a standard UTMI interface for connection to the USB-OTG controller.

Table continues on the next page...

Table 2-4. Connectivity and communications modules (continued)

Module	Description
USBDCD	The USB Device Charging Detection (USBDCD) module works with the USB transceiver to detect whether the USB device is attached to a Charging Port, either a Dedicated Charging Port (DCP) or a Charging Downstream Port (CDP). System software coordinates the detection activities of the module and controls an off-chip integrated circuit that performs the battery charging.
HSIC-PHY	USB High-Speed Inter Chip Physical Layer (HSIC-PHY) is a complete digital IP designed to implement USB 2.0 HSIC connectivity interface.
CRC	The Cyclic Redundancy Check (CRC) module is a hardware CRC generator circuit using 16/32-bit shilft register. The CRC module supports error detection for all single-, double-, odd-, and most multi-bits errors, programmable initial seed value, and optional feature to transpose input data and CRC result via transpose register.

2.3.5 Timers

Table 2-5. Timer modules

Module	Description
LPTMR0-1	The Low Power Timer (LPTMR) module is a 16-bit timer which operates as real-time interrupt or pulse accumulator. This LPTMR module can remain functional when the chip is in low-power modes, provided the reference clock to this timer is active.
LPTPM0-7	The Timer/Pulse Width Modulation Module (TPM) is a multichannel timer module that supports input capture, output compare, and the generation of PWM signals. The counter, compare and capture registers are clocked by an asynchronous clock that can remain enabled in low-power modes.
LPIT0-1	Low Power Periodic Interrupt Timer (LPIT) is a multichannel timer module that can generate independent pretrigger and trigger outputs. These timer channels can operate individually or can be chained together. The pretrigger and trigger outputs can be used to trigger other modules on the device. The LPIT can also operate in low power modes.
TSTMR	The Time Stamp Timer (TSTMR) module is a free-running incremental counter that starts running after system reset deassertion and can be read at any time by the software for determining the software ticks. The TSTMR is a 64-bit clock cycle counter. It runs off the 1 MHz clock and resets on every system reset. The counter only stops when the clock to the TSTMR is disabled.
WDOG0-2	The Watchdog Timer (WDOG) module is an independent timer that is available for system use. It provides a safety feature to ensure that software is executing as planned and that the CPU is not stuck in an infinite loop or executing unintended code. If the WDOG module is not serviced (refreshed) within a certain period, it resets the MCU.
EWM	The External Watchdog Monitor (EWM) module is designed to monitor external circuits, as well as the software flow. This provides a back-up mechanism to the internal WDOG that can reset the system. The EWM differs from the internal WDOG in that it does not reset the system. The EWM, if allowed to timeout, provides an independent trigger pin that when asserted resets or places an external circuit into a safe mode.

2.3.6 Multimedia

Table 2-6. Multimedia

Module	Description
GPU3D	i.MX 7ULP integrates the GC7000 Nano Ultra 3D Graphic Processing Unit (GPU). The GPU3D supports OpenGL ES2.0/1.1, Desktop OpenGL 2.1, OpenVG1.1, GLSL/ES Shading languages.
GPU2D	GC320 is a Composition Processing Core (CPC) GPU. The GPU2D supports user interface rendering and performs functions like blending, filtering, rotation, overlay, resizing, transparency, and other dynamic effects.
MIPI-DSI	The Mobile Industry Processor Interface (MIPI) Display Serial Interface Controller (DSI Controller) is responsible for serializing display data from the GPU. Data can come from either the GPU or the processor/DMA controller.
DSI PHY	The MIPI Display Serial Interface Physical Layer (DSI PHY) is a two-lane interface that supports up to 800 Mbps of data on each lane. DSI PHY includes a PLL which generates a dedicated clock for DSI purposes.
LCDIF	The enhanced LCD Interface (LCDIF) is a general-purpose display controller used to drive a wide range of display devices varying in size and capabilities. The LCDIF is used as a bridge between the DSI controller and the NIC0 crossbar.
VIU	The Video Input Unit (VIU) provides a parallel interface for digital video. The VIU accepts various types of digital video input on its parallel interface, decodes it and optionally performs processes such as down-scaling, and horizontal up-scaling.
SAI0-1	The Synchronous Audio Interface (SAI) module implements full-duplex serial interfaces with frame synchronization such as I2S, AC97, and CODEC/DSP interfaces.

2.3.7 Analog

Table 2-7. Analog modules

Module	Description
ADC0-1	Analog-to-Digital Converter (ADC) is a 12-bit resolution, successive approximation analog to digital converter. The ADC module supports up to 16 single-ended external analog inputs. The ADC supports only 12-bit non-differential and 13-bit (MSB is a sign bit) differential formatting option. The ADC can achieve 1 µs conversion rate.
DAC0-1	Digital-to-Analog Converter (DAC) is the 12-bit resolution digital-to-analog converters with programmable reference generator output. The output of the DAC can be placed on an external pin or set as one of the inputs to the analog comparator or ADC. The DAC is capable of achieving 1 microsecond conversion rate for high-speed signals and 2 µs conversion rate for low-speed signals.
CMP0-1	The Comparator (CMP) module provides a circuit for comparing two analog input voltages. The comparator circuit is designed to operate across the full range of the supply voltage (rail to rail operation).

2.3.8 Security

Table 2-8. Security

Module	Description
CAAM[1]	Cryptographic Acceleration and Assurance Module (CAAM) is a multi-function accelerator that supports the cryptographic functions common in many security protocols. This includes AES128, AES256, DES, 3DES, SHA1, SHA224, SHA256, and a random number generator with a true entropic seed. CAAM includes a DMA engine that is descriptor based to reduce processor-accelerator interaction. Hardware automatically clears key registers and specified Secure Memory areas when on-chip security monitor detects tampering. The Secure Memory provides secure storage of sensitive information in on-chip RAM.
LTC[1]	Low-power Trusted Cryptography (LTC) is an architecture that allows multiple cryptographic hardware accelerator engines to be instantiated and share common registers. This version of LTC supports 128-bit AES.
TRNG [1]	The True Random Number Generator (TRNG) module is used to generate high quality, cryptographically secure, random data. The TRNG module is capable of generating its own entropy using an integrated ring oscillator.
MMCAU[1]	Memory-Mapped Cryptographic Acceleration Unit (MMCAU) is an optimized security accelerator that supports the cryptographic functions common in many security protocols. This includes DES, 3DES, AES, MD5, SHA-1, SHA-256 algorithms via simple C calls to optimized security functions.
OTFAD[1]	The On-The-Fly AES Decryption (OTFAD) module provides an advanced hardware implementation that minimizes any incremental cycles of latency introduced by the decryption in the overall external memory access time. The OTFAD engine also includes complete hardware support for a standard AES key unwrap mechanism to decrypt a key BLOB data instruction containing the parameters needed for up to 4 unique AES contexts.
SNVS[2]	The Secure Non-Volatile Storage (SNVS) module is designed to safely hold security-related data such as cryptographic key, time counter, monotonic counter, and general-purpose security information. A part of the SNVS module belongs to the VBAT domain, which has its own dedicated power supply that is always on. This enables SNVS to keep this data valid and continue to increment the time counter when the power goes down in the rest of the device. The SNVS includes a Real- Time Clock (RTC) with roll-over protection and 32-bit alarm and a 64-bit monotonic counter with roll-over protection.

1. This chapter is available only in the i.MX 7ULP Security Reference Manual
2. The complete chapter including security features and its chip-specific information is available in the i.MX 7ULP Security Reference Manual

2.3.9 Debug interfaces

Table 2-9. Debug interfaces

Module	Description
DAP	Debug Access Port (DAP) provides debugger access to on-chip system resources via the SWJ-DP port. The DAP provides internal system access to A7 Debug Port, M4 Debug Port, System Bus, JTAG controller, and device Control and Status. The

Table continues on the next page...

Table 2-9. Debug interfaces (continued)

Module	Description
	DAP also enables system access to CoreSight debug subsystem through the APBIC port.
CTM	Cross Trigger Matrix (CTM) is a component of the Embedded Cross Trigger (ECT), which is key in the multi-core debug strategy. The CTM receives signals from various sources (i.e. cores and peripherals) and propagates or routes them to the different debug resources of the device. Those debug resources can include time stamping capability, real-time trace, triggers and debug interrupts.
ETF	The Embedded Trace FIFO (ETF) consists of a formatter, control, and the trace RAM. It is a configuration of the Trace Memory Controller (TMC). The ETF has a memory size of 4 KB. The ETF and associated memory should be connected in the system such that it will retain the information though a warm or cold reset of the system. This is to allow for debug information to be retained for debugging problems that may arise and cause a reset of the system.
ETR	The ETR is a trace sink that redirects the trace stream onto the AXI bus to external storage. It can utilize a single contiguous region or a scattered allocation of blocks for a circular buffer. Reading of the AXI based trace buffer can be done directly over AXI from a normal bus master. The ETR is a configuration option of the TMC as is the ETF.
FUNNEL	The Trace Funnel (FUNNEL) is used when there is more than one trace source. The Trace Funnel combines multiple trace stream onto a single ATB bus. The Trace Funnel includes an arbiter that determines the priority of the ATB inputs.
Replicator	The Trace Replicator (Replicator) enables two trace sinks (TPIU and TMC) to be wired together and receive ATB trace data from the same trace source. It takes incoming data from a single source and replicates it to two master ports.
TPIU	Trace Port Interface Unit (TPIU) acts as a bridge between on-chip trace data, ID distinguishable, and a TPA. It receives ATB trace data and sends it off chip via Arm's standard trace interface. The TPIU includes ATB interface, APB interface, Formatter, Asychronous FIFO, Register bank, Trace out serializer, and a Pattern generator.
SWO	Serial Wire Output (SWO) is a trace data drain that acts as bridge between the on-chip trace data to a data stream that is captured by the Trace Port Analyzer. It is a TPIU-like device that supports a limited subset of the full TPIU functionality for a simple debug solution.
TimeStamp Components	The timestamp components generate and distribute a consistent timestamp value for multiple processors and other blocks in a chip. The components used in i.MX 7ULP timestamp debug system are: one Timestamp Generator, one Timestamp Encoder, one Timestamp Replicator, one Timestamp Asynchronous Bridge (for A7), one Timestamp Synchronous Bridge (for M4), two Timestamp Decoders, and one Timestamp Interpolator (for A7).
JTAGC	Joint Test Action Group Controller (JTAGC) provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard.
SJC	The Secured JTAG Controller (SJC) is an authenticated debug module that implements a challenge/response mechanism using a standard cryptographic algorithm. This allows post production silicon debug without compromising security requirements. The SJC is connected in parallel with the JTAGC module, but it is only used for authenticated debug.

2.3.10 Clock modules

Table 2-10. Clock modules

Module	Description
SCG0-1	The System Clock Generation (SCG) module is responsible for clock generation and distribution across this device. Functions performed by the SCG include: clock reference selection, generation of clock used to derive processor, system, peripheral bus and external memory interface clocks; source selection for peripheral clocks; and, control of power saving clock gating mode.
PCC0-3	The Peripheral Clock Control (PCC) module is responsible for clock selection, optional division and clock gating mode for peripherals in their respected power domain.
RTC OSC[1]	The Real Time Clock Oscillator (RTC OSC) module provides the clock source for the Real-Time Clock module. The RTC OSC module, in conjunction with an external crystal, generates a 32.678 kHz reference clock for the RTC.
SYS OSC[1]	The System Oscillator (SYS OSC) module is a crystal oscillator. The SYS OSC, in conjunction with an external crystal or resonator, generates a reference clock for this device. It also supports optionally external input bypass clock from EXTAL signal directly.
Fixed-Freq PLL (PLL0)[2]	In addition to the main clock output, the Fixed-Frequency PLL also includes 4 Phase Fractional Dividers (PFDs) that can generate other clock frequencies. There is one instance of the Fixed-freq PLL (PLL0) which provides clocks for M4 core and buses and peripherals in the real-time domains.
Frac-N PLL (PLL1-3)[2]	The Fractional-N (Frac-N) PLL can generate an output clock of 528 MHz from a supported reference clock. In addition to the main clock output, this PLL also includes up to 4 Phase Fractional Dividers (PFDs) that can generate other clock frequencies. This PLL also supports tunable clock for audio applications.
FIRC[3]	The Fast Internal Reference Clock (FIRC) module is an internal oscillator that can generate a reference clock in the range from 48 MHz to 60 MHz. The FIRC output clock is used as a reference to the SCG module, and it is also used as a clock option to most on-chip modules.
SIRC[3]	The Slow Internal Reference Clock (SIRC) module is an internal oscillator that can generate a reference clock of 16 MHz. The SIRC output clock is used as a reference to the SCG module, and it is also used as a clock option to most on-chip modules.
IRC1K[3]	The Internal Reference Clock 1 kHz (IRC1K) module is an internal oscillator that can generate a reference clock of 1 kHz. The IRC1K clock is enabled in all modes of operation, including all low power modes.

1. See External clock sources
2. For details, see PLLs
3. See Internal clock sources

2.3.11 Power management

Table 2-11. Power management

Module	Description
Digital PMC	The Digital PMC module allows user software to control power modes of the chip and to optimize power consumption for the level of functionality needed. There are two instances of Digital PMC on this device, one for each main power domain.
Analog PMC	The Analog PMC consists of voltage/current references, core logic supply regulators, memory supply regulators, Back and Forward Biasing regulators, monitors and power switches, etc. There are two Analog PMC subsystems in i.MX 7ULP, one associated with the M4 power domain and the other with the A7 power domain.

2.3.12 System modules

Table 2-12. System control

Module	Description
MSMC	Multicore System Mode Controller (MSMC) is responsible for sequencing the system into and out of all low power Stop and Run modes. MSMC monitors events to trigger transitions between power modes, while controlling the power, clocks, and memories of the system to achieve the power consumption and functionality of that mode. **NOTE:** MSMC, CMC, and RMC are 3 separate but tightly coupled blocks. The memory map documented in MSMC chapter encompasses features related to all 3 blocks, being actually implemented into the CMC block alone. Therefore, there might be some references to CMC and RMC blocks throughout this document.
LLWU	The Low-Leakage Wake-Up Unit (LLWU) module allows user to select up to 32 external pin sources and up to 8 internal modules as a wake-up source from low-leakage power modes.
AWIC	The Asynchronous Wakeup Interrupt Controller (AWIC) module is capable of interrupt detection and wake up a processor when it is in low power mode.
IOMUXC0-1 and IOMUXC_DDR	The Input/Output Multiplexing Controller (IOMUXC) enables the chip to share one pad for multiple signals from different peripheral interfaces. This pad sharing mechanism is done by multiplexing the pad's input and output signals. The IOMUXC also controls the pads setting parameters and digital filter functions of the pad. In addition, the IOMUXC controls input multiplexing logic for input signals multiplexed at multiple locations.
WKPU	Wake Up (WKUP) module is capable of interrupt detection and wake a Cortex-A processor when it is in low power mode.
PCTLA-F	The Port Control (PCTL) module provides control for GPIO interrupt function. GPIO interrupt can be configured independently for each pin in the 32-bit port. There is one instance of the PCTL module for each port..
SIM	The System Integration Module (SIM) provides system control and chip configuration registers. The SIM includes the TSTMR module.

Table continues on the next page...

Table 2-12. System control (continued)

Module	Description
TRGMUX0-1	Peripheral Trigger Multiplexing (TRGMUX): The Trigger MUX module (TRGMUX) allows software to configure the trigger inputs for various peripherals.
OCOTP_CTRL[1]	The On-Chip One-Time-Programmable Controller (OCOTP_CTRL) module provides an interface for reading, programming and/or overriding identification and control information stored in on-chip fuse elements. The module supports electrically-programmable poly fuses. The OCOTP_CTRL also provides a set of volatile software-accessible signals which can be used for software control of hardware elements, not requiring non-volatility.
RGPIO2P0-1	The Rapid General-Purpose Input and Output with 2 Ports (RGPIO2P) is similar to the RGPIO module, except it has an AHB-lite port, in addition to the IPS port, for faster access. The RGPIO2P-0 in CM4 domain has two ports, AHB and IPS ports. The second RGPIO in CA7 domain only has a single port (IPS).

1. For complete chapter including security details, see the i.MX 7ULP Security Reference Manual

2.4 Ordering information

For details on orderable part numbers, see the ordering information table provided in the i.MX 7ULP Data Sheet.

Chapter 4
Multicore Architecture

4.1 Overview

i.MX 7ULP design allows flexibility for peripherals and memories partition in multicore environment; both cores will have access to all peripherals and memory regions unless a specific design calls for some isolated peripherals or dedicated memory. The resource domain control (XRDC) concept provides a framework for supporting isolation and safe sharing of chip resources in a multicore architecture. See Figure 4-1. Chip resources including cores, bus masters, peripherals and memory regions can be assigned to processing domains for the purpose of enforcing robust operational environments. Operating system resources are allocated to a domain and access to those resources are enforced, to prevent accidental collisions due to incorrect memory map references, to protect proprietary software resources from unauthorized sources, or to prevent manipulation of hardware shared resources from malicious attacks.

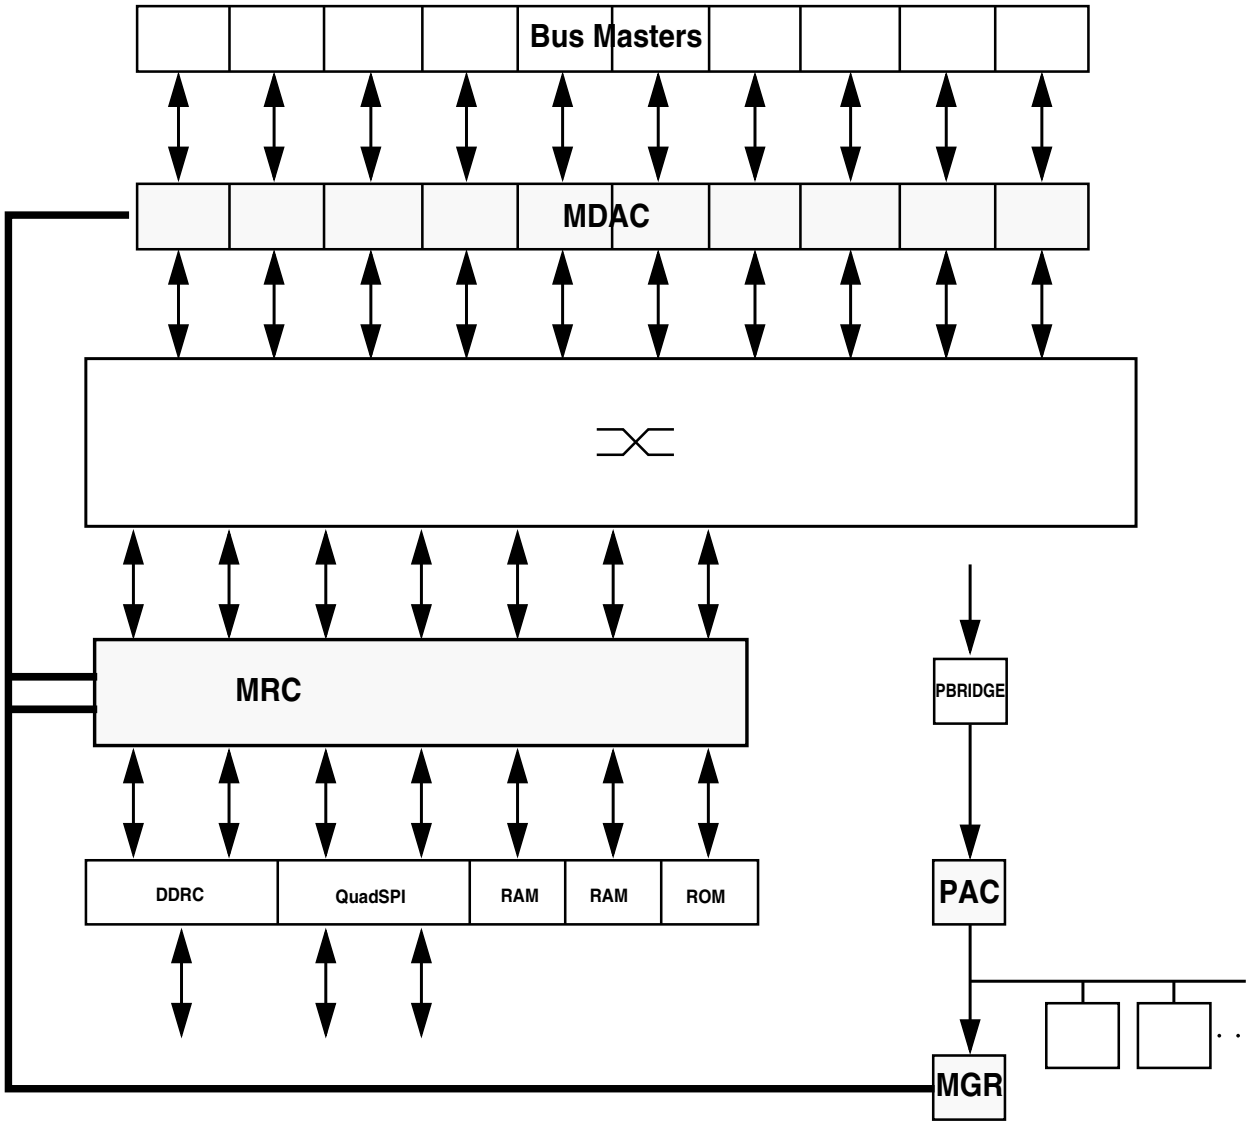

Figure 4-1. Simplified Extended RDC Block Diagram

4.2 Resource sharing and isolation

4.2.1 Extended Resource Domain Controller

The Extended Resource Domain Controller (XRDC) provides an integrated, scalable architectural framework for access control, system memory protection and peripheral isolation. It allows software to assign chip resources including processor cores, non-core bus masters, memory regions and slave peripherals to processing domains to support enforcement of robust operational environments.

- First, each bus mastering resource has an associated Master Domain Assignment Controller (MDAC) for assigning a domain identifier (DID) attribute to each bus transaction.
- Second, each peripheral and memory has an associated access control submodule that enforces access control policies based on the DID and privilege level of the transaction.
- Finally, all accesses throughout the device are monitored concurrently to determine the validity of each and every access. If a reference from a given domain has sufficient access rights, it is allowed to continue, otherwise the access is denied and a bus error is generated.

The access control scheme defined by the XRDC supports a 4-level model, combining the traditional privileged (also known as supervisor) and user modes with an additional signal defining the secure, nonsecure attributes of each memory reference. The result is a 4-level hierarchical access control mechanism, where:

SecurePriv(ileged) > SecureUser > NonsecurePriv(ileged) > NonsecureUser

with different access control policies based on read and write references. Combined with the user/privileged and secure/nonsecure attributes, a domainID is associated with every system bus transaction and forms the hardware basis for implementation of XRDC's access control mechanisms.

Access to shared memory regions and slave peripherals can be dynamically controlled with the optional inclusion of a hardware semaphore. If a hardware semaphore is enabled for a given address space or peripheral, then writes to the targeted address space are only allowed if the requesting domain owns the semaphore. This capability allows the access control policy for a given resource to be dynamically revised, based on hardware semaphore ownership.

The XRDC implementation is distributed across multiple submodules instantiated throughout the device. The XRDC submodules include:

- **XRDC_MGR**: The Manager (MGR) coordinates all programming model reads and writes.
- **XRDC_MDAC**: The Master Domain Assignment Controller (MDAC) handles resource assignments and generation of the domain identifiers based on pre-programmed Master Domain Assignment (MDA) registers.

- **XRDC_MRC**: The Memory Region Controller (MRC) implements the access controls for slave memories based on the pre-programmed Memory Region Descriptor (MRGD) registers.
- **XRDC_PAC**: The Peripheral Access Controller (PAC) implements the access controls for slave peripherals based on the pre-programmed Peripheral Domain Access Control (PDAC) registers.

4.2.2 Shared memory protection

Both processors and non-core bus masters share common memories. Because the memories are used for the exchange of data between the cores or between a processor and a bus master, unless additional protection mechanisms are provided, untrusted programs on one processor could read and write sensitive code or data placed in the shared memory region accessed by the other processor. This would fundamentally compromise the security of the device. To combat this, restricted memory access control is enforced by the XRDC.

The MRC provides domain-based, hardware access control for all system bus references targeted at non-peripheral memory spaces. Using pre-programmed region descriptors which define memory spaces and their associated access rights per domain identifier, the MRC concurrently monitors system bus transactions and evaluates the appropriateness of each transfer. Memory references that have sufficient access control rights are allowed to complete, while references that are not mapped to any region descriptor or have insufficient rights are terminated with an access error response.

For each access, the MRC hardware performs a two-step evaluation process. First, the access is compared to all memory region descriptors to determine hit/miss status, and then, using the DID associated with the reference plus the address attributes {write, nonsecure, privileged}, the access right are examined.

4.2.3 Shared peripheral isolation

For shared peripherals, the PAC performs an access control evaluation similar to that of the memory region controller, but using dedicated memory region descriptors per slave peripheral slot. The presence of a one and only one memory region descriptor per slave peripheral address space slot in the PAC simplifies the required functionality compared to the MRC.

Unimplemented peripheral slots and unimplemented domain identifiers default to all-zero and provide no access rights.

Interrupts and DMA requests are also routed to the appropriate core and DMA engine associated with a core. In addition, the XRDC handles peripheral interface pin assignments and configuration of read/write access to control IO pins.

4.3 System control for multicore operation

System controls on i.MX 7ULP must follow procedures described by individual peripherals below for multi-core operation. The device follows the concept of master core (M4) and slave core (A7). There are some peripherals that are multicore aware allowing both processors to access them. These peripherals typically contain controls that need dynamic changes throughout the applications. If these controls affect other peripherals or pins then the XRDC subsystem will pass ownership information to these multicore aware peripherals.

On the other hand, there are some peripherals that are typically configured once in the application. These peripherals are not multi-core aware and are expected to be configured by the master core.

4.3.1 Power modes, transition, wake-up, etc.

The Multicore System Mode Control (MSMC) module is used to control the power mode settings for each processor's domain. MSMC consists of SMC0 and SMC1, which are associated with M4 and A7 domains, respectively. The MSMC module works in conjunction with PMCs, RMCs and LLWU to faciliate power mode transitions.

4.3.2 System clock management

The System Clock Generation (SCG) modules is used to configure clock sources and divider settings for their respective domain. The PCC modules contain clock configuration settings for individual peripheral clock source options and clock gating. There is one PCC instance designated for peripherals on the same IP bus. SCG and PCC modules are not multicore aware peripherals.

4.3.3 Pin allocation and port control

The IOMUXC peripheral will be used to configure pin settings including pin multiplexing assignments and pad characteristics. IOMUXC is a multi-core aware peripheral. IOMUXC will only allow the core has its ownership to manipulate configuration.

Similar to IOMUXC, the RGPIO2P peripheral uses XRDC ownership data to allow or disallow changes of state to a respective pin's direction or state attempted per core.

4.3.4 System Reset and Initial Boot

A Power-on Reset or System Reset event resets the entire chip except for certain components that are not affected by a specific System Reset source.

Coming out of a system reset, the M4 processor always boots first using the normal reset handling mechanism in the boot ROM. The M4 then releases the A7 sequentially depending on the boot mode setting. More details about reset and system boot are described in the Reset and Boot chapter.

Chapter 5
Arm Cortex A7 Platform (Cortex-A7)

5.1 Chip-specific Arm CA7 information

Table 5-1. Reference links to related information

Topic	Related module	Reference
Full description	Arm CA7	Arm CA7
System memory map		System memory map

5.2 WFE/SEV instruction support

WFE/SEV instructions are not supported in i.MX 7ULP, so any reference of these instructions throughout this document, must be ignored.

5.3 A7 processor

5.3.1 Overview

The application processing domain is built around a Cortex A7 processor optimized to run nominally at 500 MHz, supported by a large L2 cache and an LPDDR memory interface. A functional block diagram of the A7 complex is shown in the following figure.

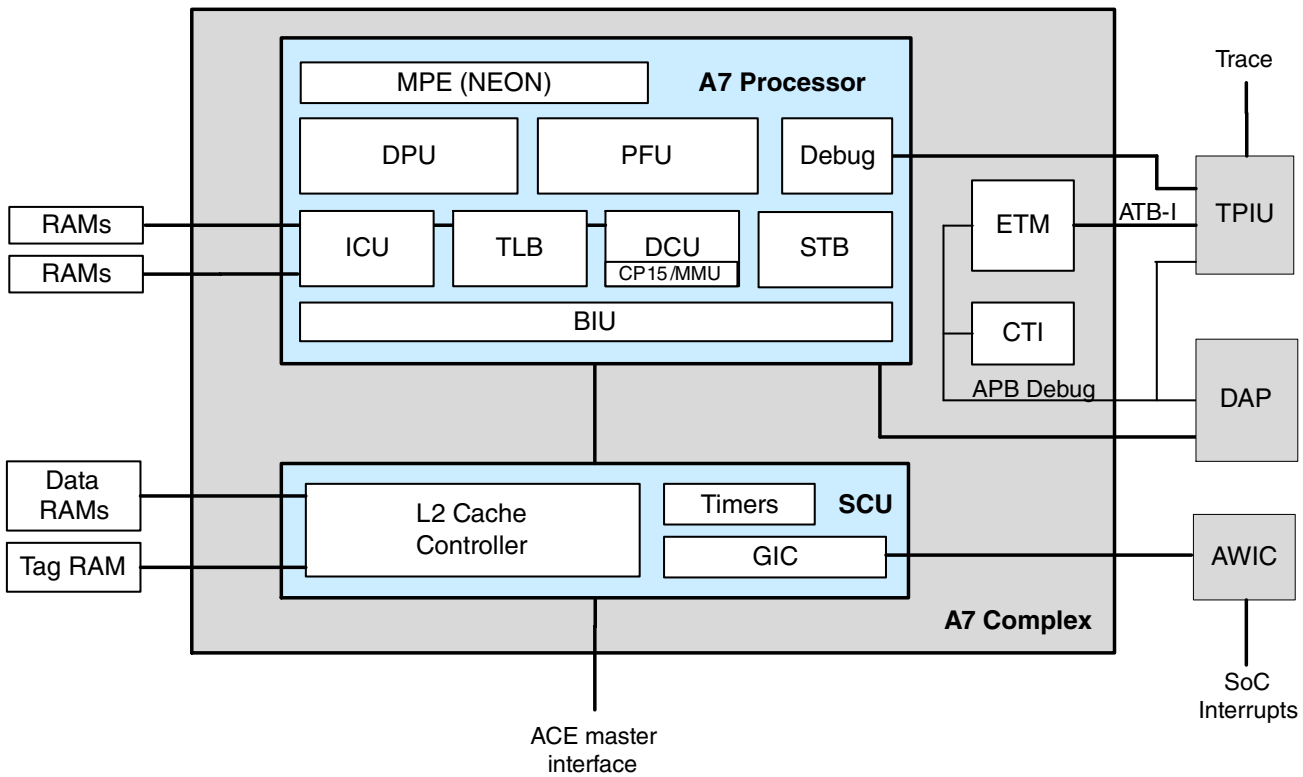

Figure 5-1. A7 complex functional diagram

5.3.2 Implementation information

The A7 complex consists of a Arm Cortex-A7 MPCore processor, which includes a Neon co-processor, FPU, and 32 KB instruction and 32 KB data L1 caches. The Snoop Control Unit (SCU) of the CA7 complex includes a unified 256 KB L2 cache, Generic Timer, and Generic Interrupt Controller (GIC). In addition, it also includes various components composing the Arm CoreSight debug/Trace system, such as ETM and CTI.

The Arm A7 Complex includes the following features:

- Arm Cortex-A7 processor running at 500 MHz in normal operation and up to 800 MHz overdrive mode
- Harvard Level 1 memory system with 32 KB Instruction Cache and 32 KB Data Cache with a Memory Management Unit (MMU).
- Level 2 memory system with 256 KB L2 unified cache.
- Media Processing Engine (MPE) with NEON technology.
- Generic Interrupt Controller (GIC) supports up to 128 external interrupt vectors.
- Generic Timer for scheduling events and trigger interrupts
- APB debug interface that supports integer processor clock ratios
- Embedded Trace Macrocell for instruction trace

- Cross Trigger Interface
- The A7 complex will not support State Retention Power Gating (SRPG).
- The A7 complex contain synchronizers for signals into and out of the complex where synchronization is required. All components in the A7 complex operate synchronously with the A7 core but may be at an integer clock ratio, including 1:1.

5.3.3 A7 Core

The A7 core has following features and functional descriptions:

- Full implementation of the Armv7-A architecture instruction set with the architecture extensions
- The Data Processing Unit (DPU) holds most of the program-visible state of the processor, such as general-purpose registers, status registers and control registers. It decodes and executes instructions, operating on data held in the registers in accordance with the Arm Architecture. Instructions are fed to the DPU from the Prefetch Unit (PFU). The DPU executes instructions that require data to be transferred to or from the memory system by interfacing to the Data Cache Unit (DCU), which manages all load and store operations.
- The Instruction Cache Unit (ICU) contains the Instruction Cache controller and its associated linefill buffer. The Cortex-A7 MPCore ICache is two-way set associative and uses Virtually Indexed Physically Tagged (VIPT) cache-lines holding up to 8 Arm or Thumb 32-bit instructions or up to 16 Thumb 16-bit instructions.
- The Prefetch Unit (PFU) obtains instructions from the instruction cache or from external memory and predicts the outcome of branches in the instruction stream, then passes the instructions to the DPU for processing. In any given cycle, up to a maximum of four instructions can be fetched and two can be passed to the DPU.
- The Data Cache Unit (DCU) consists of the Level 1 data cache controller, the load/store pipeline that interfaces with the DPU and main TLB, the system coprocessor controller (CP15), and interface to receive coherency requests from the Snoop Control Unit (SCU). The DCU also contains a combined local and global exclusive monitor.
- The system control coprocessor, CP15, provides configuration and control of the memory system and its associated functionality. That includes Memory Management Unit (MMU) configuration and management.

- The Store Buffer (STB) holds store operations when they have left the load/store pipeline and have been committed by the DPU. From the STB, a store can request access to the cache RAMs in the DCU, request the BIU to initiate linefills, or request the BIU to write the data out on the external write channel. External data writes are through the SCU.
- The Bus Interface Unit (BIU) contains the SCU interface and buffers to decouple the interface from the cache and STB. The BIU interface and the SCU always operate at the processor frequency.

5.3.4 Memory Management Unit (MMU)

The Cortex-A7 MPCore processor implements the Extended VMSAv7 MMU, which includes the Armv7-A Virtual Memory System Architecture (VMSA), the Security Extensions, the Large Physical Address Extensions (LPAE), and the Virtualization Extensions.

The Extended VMSAv7 MMU controls address translation, access permissions, and memory attributes determination and checking, for memory accesses.

The MMU controls table walk hardware that accesses translation tables in main memory. The MMU works with the L1 and L2 memory system to translate virtual addresses to physical addresses. The MMU enables fine-grained memory system control through a set of virtual-to-physical address mappings and memory attributes held in the Translation Look-aside Buffers (TLBs).

The MMU features in each processor of the multiprocessor device include the following:

- 10-entry fully-associative micro instruction TLB.
- 10-entry fully-associative micro data TLB.
- 2-way set-associative 256-entry unified main TLB.
- 2-way set-associative 64-entry walk cache.
- 2-way set-associative 64-entry IPA cache.
- The TLB entries include global and application specific identifiers to prevent context switch TLB flushes.
- Virtual Machine Identifier (VMID) to prevent TLB flushes on virtual machine switches by the hypervisor.

5.3.5 A7 Level 1 Memory

The L1 memory system consists of separate instruction and data caches of 32KB each.

The L1 memory system has a store buffer that has four 64-bit slots with data merging capability. It handles writes to Device, Strongly-ordered, Cacheable and Non-cacheable memory.

The L1 instruction memory system has the following features:

- Instruction side cache line length of 32-bytes.
- Virtually indexed and physically tagged instruction cache.
- Pseudo random cache replacement policy.
- 2-way set-associative instruction cache.
- Support for four sizes of memory page.
- Export of memory attributes for external memory systems.
- Support for Security Extensions.
- Can be disabled independently, using the system control coprocessor.
- On a cache miss, critical word first filling of the cache is performed

The L1 data memory system has the following features:

- Data side cache line length of 64-bytes.
- Physically indexed and physically tagged data cache.
- Pseudo random cache replacement policy.
- 4-way set-associative data cache.
- Two 32-byte linefill buffers and one 64-byte eviction buffer.
- A 4-entry, 64-bit merging store buffer.
- Can be disabled independently, using the system control coprocessor.
- On a cache miss, critical word first filling of the cache is performed.
- Virtually indexed and physically tagged instruction cache.

5.3.6 A7 Level 2 Memory

The L2 memory system includes 256KB unified cache. It provides:

- Data is only allocated to the L2 cache when evicted from the L1 memory system, not when first fetched from the system. The L1 cache can prefetch data from the system without data being evicted from the L2 cache.
- Instructions are allocated to the L2 cache when fetched from the system and can be invalidated from the L2 during maintenance operations.
- The L2 cache is 8-way set associative. The L2 cache tags are looked up in parallel with the SCU duplicate tags. If both the L2 tag and SCU duplicate tag hit, the L2 tag hit takes priority.

- Additionally, speculative requests to the system from the SCU are not made until the system checks the L2 cache.
- L2 RAMs are invalidated automatically at reset unless the L2 cache reset was disabled.

The L2 memory system interfaces with an AMBA AXI Coherency Extension (ACE) interconnect on a 128-bit wide bus.

5.3.7 Generic Interrupt Controller (GIC)

The integrated GIC collates and arbitrates from a large number of interrupt sources. It provides:

- 128 external interrupt vectors.
- Masking of interrupts.
- Prioritization of interrupts.
- Distribution of the interrupts to the target processors.
- Tracking the status of interrupts.
- Generation of interrupts by software.
- Support for Security Extensions.
- Support for Virtualization Extensions.

5.3.8 Generic Timer

The Generic Timer can schedule events and trigger interrupts based on an incrementing counter value. It provides:

- Generation of timer events as interrupt outputs.
- Generation of event streams.
- Support for Virtualization Extensions.

5.3.9 Debug

The processor debug unit assists in debugging software running on the processor. The debug unit enables users to:

- Stop program execution.
- Examine and alter process and coprocessor state.
- Examine and alter memory and input/output peripheral state.

• Restart the processor.

The processor supports six breakpoints, four watchpoints, and a standard Debug Communications Channel (DCC). Four of the breakpoints match only to virtual address and the other two match against either virtual address or context ID, or Virtual Machine Identifier (VMID). All the watchpoints can be linked to two breakpoints to enable a memory request to be trapped in a given process context.

The ETM module provides instruction trace. It generates trace data in the form of packets and transfer them through an Advanced Trace Bus (ATB) to the Trace Port Interface Unit (TPIU). In addition, A7 debug subsystem includes the CTI block quick takes cross-trigger event inputs from A7 complex or from its own configuration registers, and generates outputs on the appropriate channels.

Chapter 6
Arm Cortex M4 Platform (Cortex-M4)

6.1 Chip-specific Arm M4 information

Table 6-1. Reference links to related information

Topic	Related module	Reference

System memory map		System memory map

6.2 WFE/SEV instruction support

WFE/SEV instructions are not supported in i.MX 7ULP, so any reference of these instructions throughout this document, must be ignored.

6.3 Overview

This block details the Arm Cortex-M4 core. The Cortex-M4 implements the Armv7-ME instruction set architecture (ISA). It provides compatibility with Cortex-M3 and adds significant new capabilities with DSP and SIMD extensions. The basic multiply-accumulate instructions support operations up to 32 x 32 + 64. Cortex-M4 also includes a single-precision floating-point unit (FPU), which includes an extension register file of thirty-two 32-bit floating-point data registers. Cortex-M4 complex includes the FPU and two 32-bit system bus interfaces. The Cortex-M4 implementation includes two tightly-coupled local memories and two cache memories connected to these bus interfaces although the device implementation connects to the 64-bit system bus interconnect and supports a 32-byte cache line size.

- L1 2-way set-associative 8 KB Instruction/Data cache with 32B line size length

6.3.1 Cortex-M4 Block Diagram

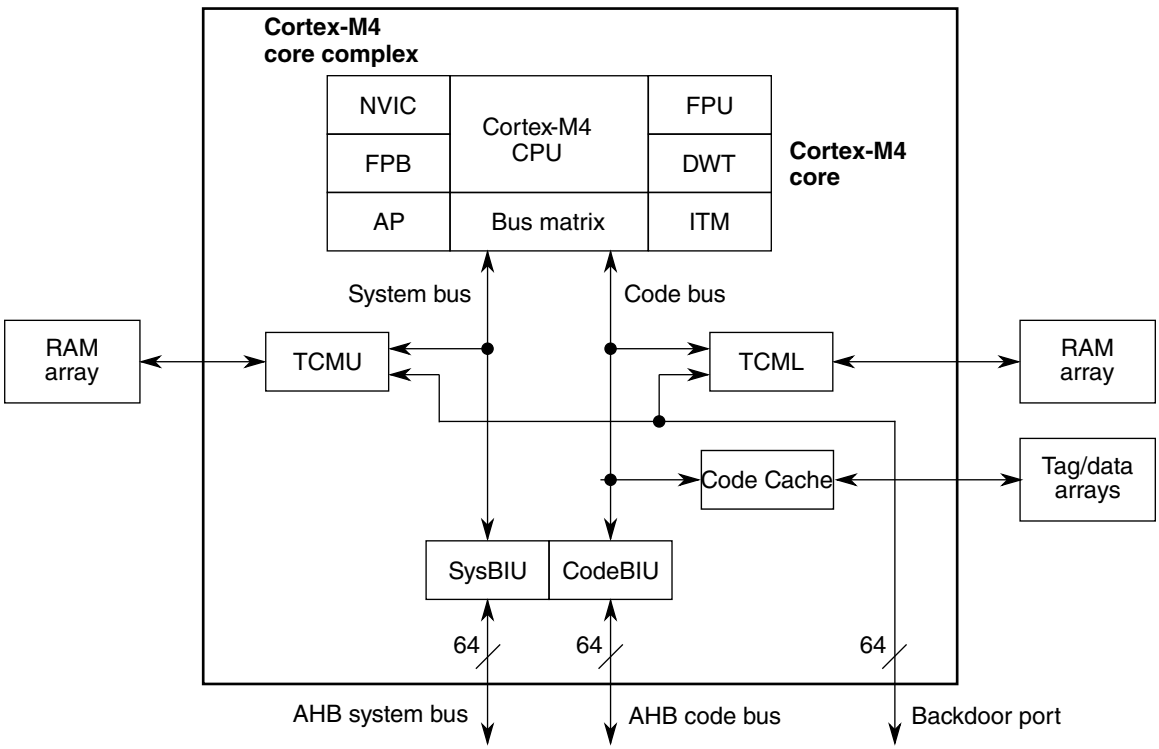

Figure 6-1. Cortex-M4 Block Diagram

Cortex-M4 core features a single issue, three stage pipeline microarchitecture. A high-level spatial pipeline block diagram of the CPU is shown below. The stages of the pipeline include:

- Fe - Instruction fetch stage where data is returned from instruction memory
- De - Instruction decode stage, generation of Load/Store Unit (LSU) address using forwarded register ports and immediate offset of LR register branch forwarding
- Ex - Instruction execute stage, single pipeline with multi-cycle stalls, LSU address/data pipelining to AHB interface, multiply/divide and ALU with branch result

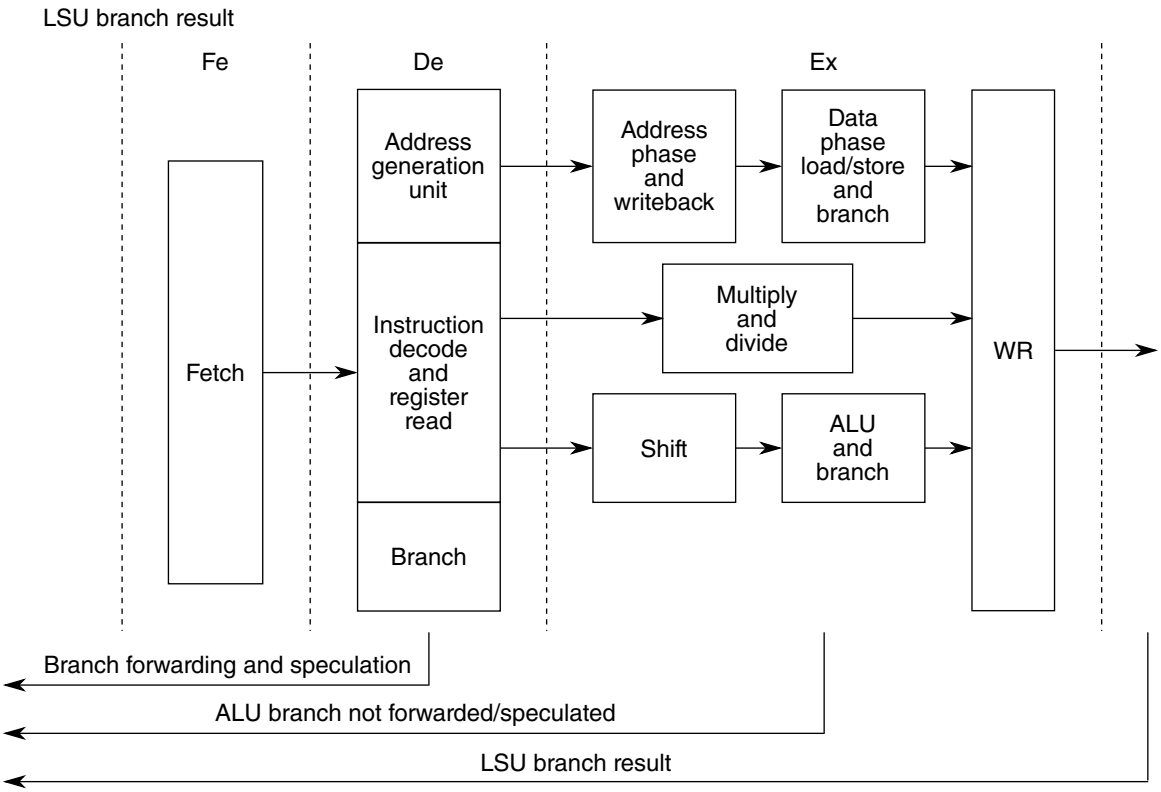

Figure 6-2. Cortex-M4 Pipeline Block Diagram

6.3.2 Integration Layer Block Diagram

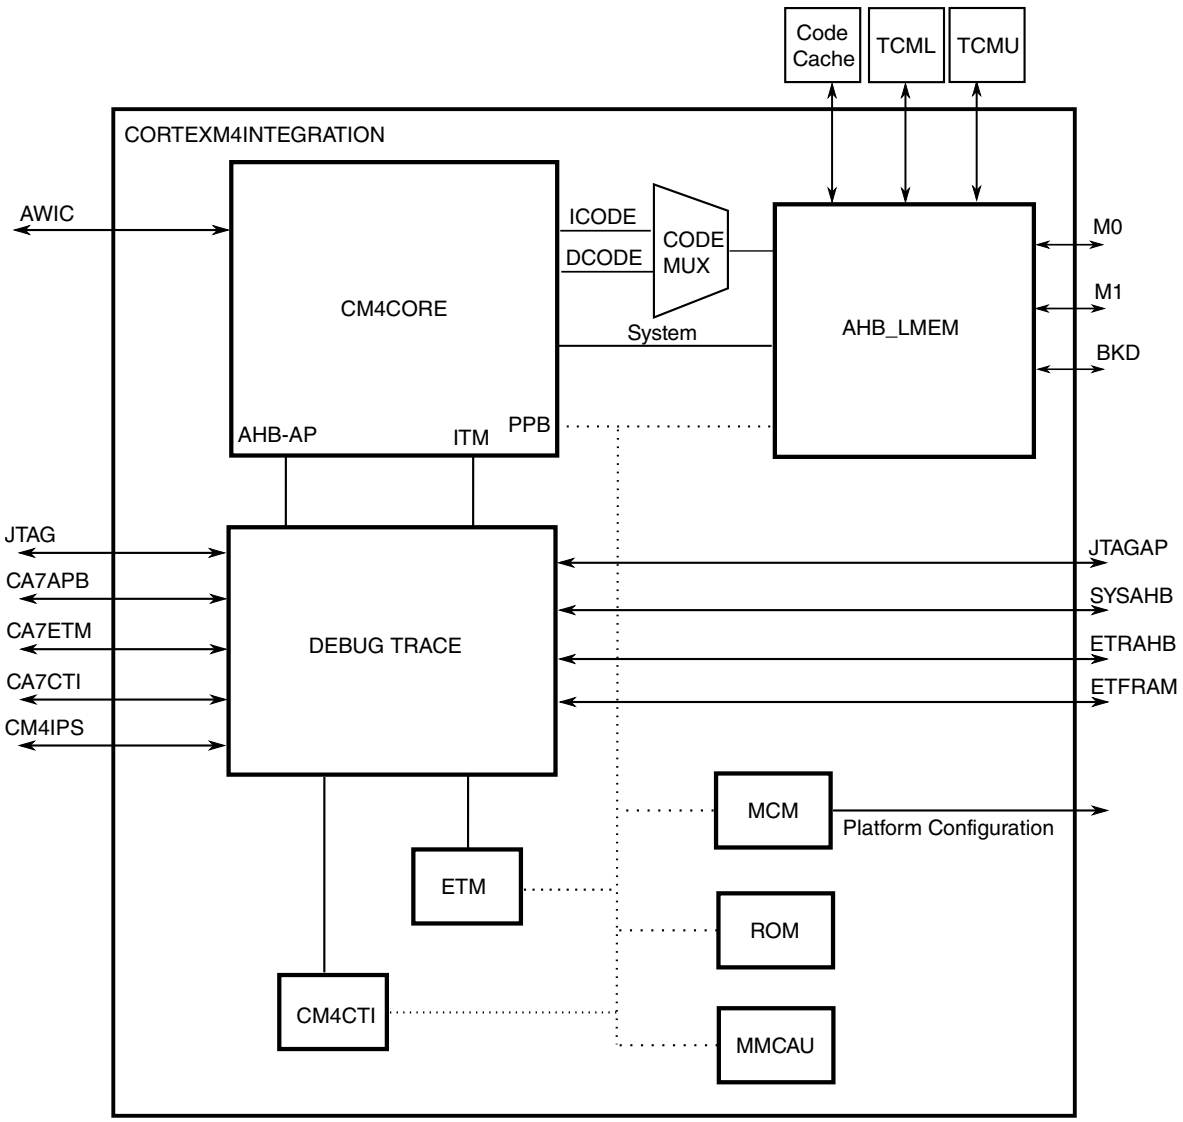

Figure 6-3. Cortex M4 Integration Layer Block Diagram

The Cortex M4 Integration Layer includes the following blocks:

- CM4CORE - Cortex M4 Core
- CODE MUX - Muxing logic for I- and D-Code Busses
- AHB_LMEM - AHB bus Local Memory (Include TCMC and Cache Controller)
- SWJDP - Serial-Wire/JTAG Debug Port
- MDM - Miscellaneous Debug Module
- TPIU - Trace Port Interface Unit
- ETM - Embedded Trace Macrocell
- FUNNEL - Coresight Funnel
- UPSZ - ATB Upsizer
- REP - ATB Replicator

- MCM - Miscellaneous Control Module
- ROM - ROM Table

6.4 Cortex-M4 Platform Features

6.4.1 Core Module Features

The following are the Cortex-M4 core module features:

- Cortex-M4 Core
  - 3-stage pipelined processor supporting Arm v7-M ISA with DSP extensions
  - Single precision FPU supporting the variant of the Armv7-M Floating-Point Extension (FPv4-SP)
  - MPU - Memory Protection Unit supporting up to 8 regions
  - Modified Harvard connections to AHB_LMEM and the crossbar switch
  - NVIC - Nested Vectored Interrupt Controller with 128 interrupt connections and 16 levels
  - SWJ-DP - Serial-Wire/JTAG Debug Port
  - TPIU - Trace Port Interface Unit
  - 4 KB ETF
- AHB LMEM
  - TCMC - Tightly Coupled Memory Controller with support for 256 KB RAM
  - One 8 KB of combined data/instruction cache to minimize the performance impact of memory access latencies.

6.5 Cortex-M4 Instruction Fetches on the System Bus

The Cortex-M4 processors implement multiple 32-bit bus interfaces that support a Harvard memory architecture. Specifically, the cores provide a modified Harvard connection with 2-cycle pipelined AMBA-AHB code and system buses. The modified Harvard memory architecture results since the bus interfaces are activated by address range and include both instruction fetches and operand data references on a given bus port. A traditional Harvard architecture separates instruction fetches and operand data references onto specific bus ports regardless of access address.

The code bus is typically used for instruction fetching and data accesses of PC-relative data, while the system bus is typically used for operand data references to the on- and off-chip memories and peripheral accesses. This bus structure fully supports concurrent

instruction fetch and data accesses, but the Cortex-M4 implementations can generate both types of references on each bus. Additionally, there is a separate 32-bit Private Peripheral Bus (PPB) connection to several important modules (for example, the Nested Vectored Interrupt Controller) accessible to only the core. By placing the various code and data sections in the appropriate locations within the memory map, overall system performance can be maximized.

To provide a “clean timing interface” on the core's system bus, instruction and vector fetch requests to this bus are registered. This increases fetch time by an additional cycle of latency because instructions fetched from the system bus take a minimum of two cycles. This also means that back-to-back instruction fetches from the system bus are not possible.

Instruction fetch requests to the code bus are not registered. It is recommended that performance critical code be located such that it fetches from the ICode bus interface as defined by addresses < 0x2000_0000 (the system bus interface includes the addresses ≥ 0x2000_0000 and < 0xE000_0000 and the Private Peripheral Bus is used for addresses ≥ 0xE000_0000).

NOTE

In the device, the memory map includes aliased address spaces that are mapped into the ICode region for code sections that reside in the system address space. As a simple example, the QSPI address space is located in the system region of the memory map, but a subset of this space is aliased so that it appears in the ICode region that instructions mapped into the QSPI space can be executed as maximum performance.

6.6 Major Platform Bus Interfaces

The platform supports the AMBA AHB and AXI bus protocol.

- HBSTRB is the only v6 extension that is supported
- HRESP[1] (SPLIT/RETRY) is not supported.
- HTRANS[1:0] = 2b01 (BUSY) is not supported
- HBURST - The platform and its memory controllers support the full range of AHB burst sizes

6.7 Clocks and Resets

The platform inputs several reset signals. The following table describes the use of each reset.

Table 6-2. Platform Reset Descriptions

Reset Name	Description
ipg_core_async_reset_b	asynchronous reset for CORTEX-M4
ipg_hard_async_reset_b	asynchronous system reset for platform modules
ipg_hard_async_po_reset_b	asynchronous power-on reset used in CM4 Core

The platform generates an internal reset, debug_reset_b, which is used to reset the following debug modules:

- AHB-AP
- APB-AP
- JTAG-AP
- SWO
- MDM-AP
- SWJ-DP
- TPIU
- CTM
- CTI
- ETF/ETR
- REPLICATORs
- FUNNEL
- TS-GEN
- TS-ENCODER
- TS-DECODER

The platform inputs several clocks. The following table describes each clock input:

Table 6-3. Platform Clock Descriptions

Clock Input Name	Description
sw_clk_tck	Single Wire/ JTAG Test Clock
trace_clk_in	TPIU/SWO Clock
tcmc_hclk	TCMC Clock
cm4_hclk	Gated CPU Clock. Platform output "cm4_gate_hclk" can be used as the enable signal.
cm4_fclk	Free-running CPU Clock

The platform clocks, cm4_fclk, cm4_hclk, tcmc_hclk are equal in frequency and phase.

6.8 Platform JTAG Requirements

The Miscellaneous Debug Module (MDM) contains the DAP (Debug Access Port) status, control and ID registers as well as the DAP mux. Access to these DAP registers is through the SWJ-DP. The read-only DAP status register is located at DAPADDR[31:0] = 32'h0400_0000, while the DAP control register is located at DAPADDR=32'h0400_0004. The IDR is located at DAPADDR = 32'h0400_00FC.

The platform's 32-bit *dap_status[31:1]* input vector is registered in the MDM. Bit 0 is reserved for platform itself.

The *mdm_ap_control[31:0]* platform output vector controls SoC-defined functions. The *mdm_ap_control[0]* is reserved for platform itself.

The IDR is a read-only register with a value of 32'h001C_0040.

6.9 Local Memory Controller (LMEM)

The Local Memory Controller provides the Arm Cortex-M4 processor with tightly-coupled processor-local memories and bus paths to all slave memory spaces. See the AHB Local Memory Controller chapter for details.

6.10 Miscellaneous Control Module (MCM)

The Miscellaneous Control Module (MCM) provides a myriad of miscellaneous control functions.

6.10.1 MCM features

The MCM includes the following features:

- Program-visible information on the platform configuration and revision

6.10.2 MCM Interrupts

The MCM generates the following interrupt requests:

- Normal interrupt

6.10.2.1 Normal interrupt

The MCM's normal interrupt is generated if any of the following is true:

- cache write buffer error
- fpu errors

6.11 LMEM memory map/register definition

For details on AHB LMEM registers, see the LMEM Register Descriptions

6.12 MCM Memory Map/Register Definition

MCM memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

6.12.1 Crossbar Switch (AXBS) Slave Configuration (MCM_PLASC)

PLASC is a 16-bit read-only register identifying the presence/absence of bus slave connections to the device's crossbar switch.

Address: E008_0000h base + 8h offset = E008_0008h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0								ASC							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1

MCM_PLASC field descriptions

Field	Description
15–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
ASC	Each bit in the ASC field indicates whether there is a corresponding connection to the crossbar switch's slave input port. 0 A bus slave connection to AXBS input port *n* is absent 1 A bus slave connection to AXBS input port *n* is present

6.12.2 Crossbar Switch (AXBS) Master Configuration (MCM_PLAMC)

PLAMC is a 16-bit read-only register identifying the presence/absence of bus master connections to the device's crossbar switch.

Address: E008_0000h base + Ah offset = E008_000Ah

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0								AMC							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1

MCM_PLAMC field descriptions

Field	Description
15–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
AMC	Each bit in the AMC field indicates whether there is a corresponding connection to the AXBS master input port.

Table continues on the next page...

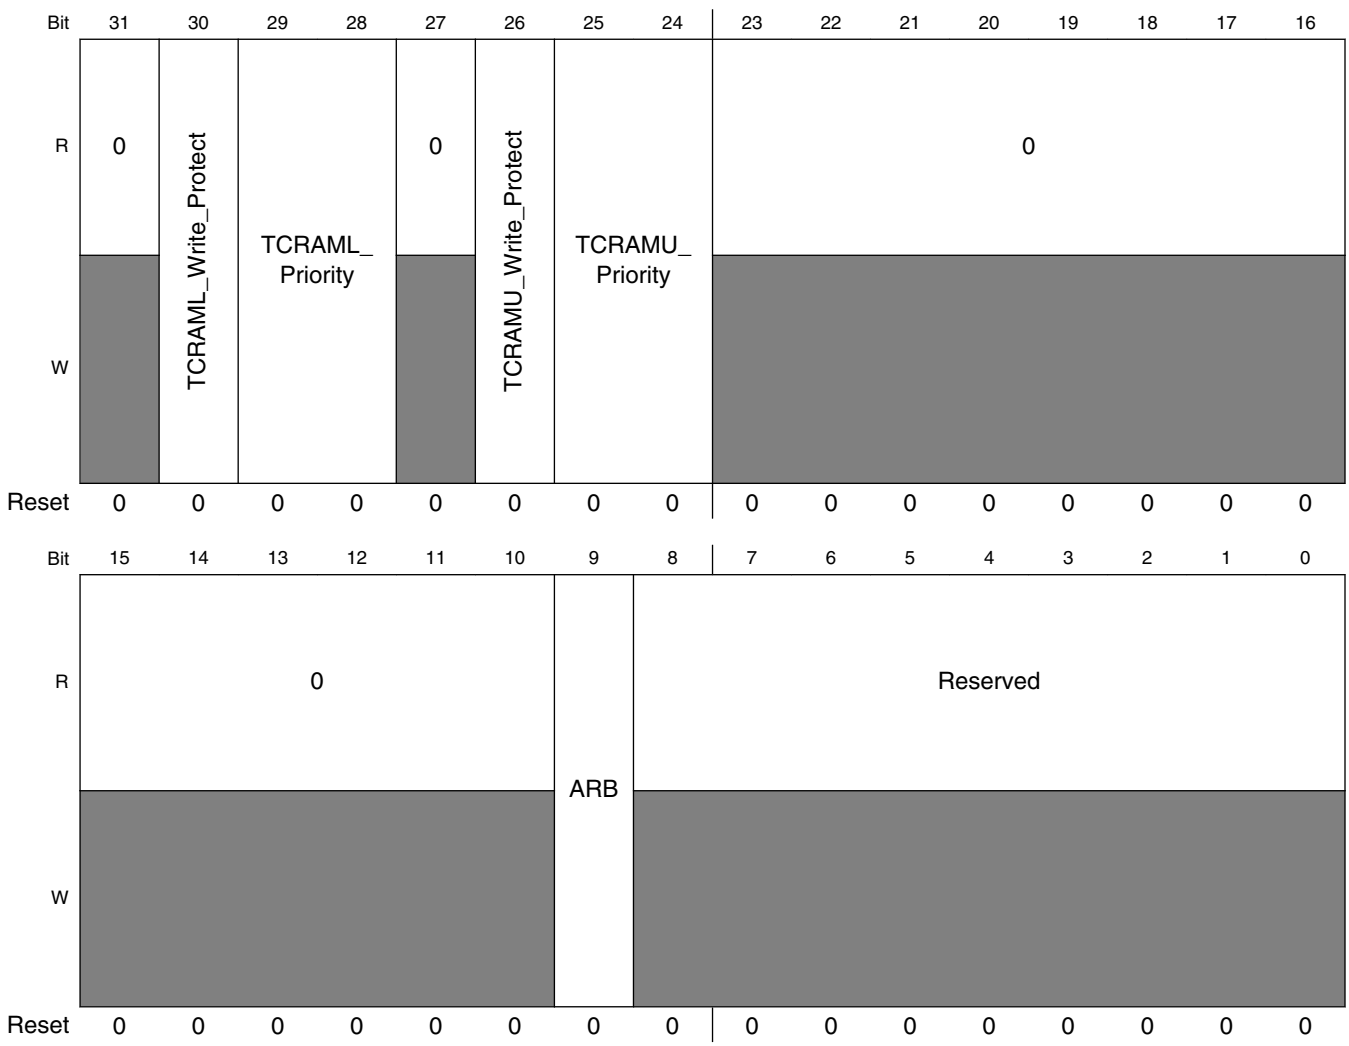
MCM_PLAMC field descriptions (continued)

Field	Description
	0 A bus master connection to AXBS input port *n* is absent 1 A bus master connection to AXBS input port *n* is present

6.12.3 Crossbar Switch (AXBS) Control Register (MCM_PLACR)

The PLACR register selects the arbitration policy for the crossbar masters.

Address: E008_0000h base + Ch offset = E008_000Ch



MCM_PLACR field descriptions

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 TCRAML_Write_Protect	TCRAML_Write_Protect
29–28 TCRAML_Priority	TCRAML_Priority

25–24 TCRAMU_Priority	TCRAMU_Priority
23–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 ARB	Arbitration select 0 Fixed-priority arbitration for the crossbar masters 1 Round-robin arbitration for the crossbar masters
Reserved	This field is reserved.

6.12.4 Fault address register (MCM_FADR)

When a properly-enabled cache write buffer error interrupt event is detected, the faulting address is captured in the MCM_FADR register. The MCM logic supports capturing a single cache write buffer bus error event; if a subsequent error is detected before the captured error information has been read from the corresponding registers and the MCM_ISCR[CWBER] indicator cleared, the MCM_FATR[BEOVR] flag is set. However, no additional information is captured.

The bits in this register are set by hardware and signaled by the assertion of MCM_ISCR[CWBER]. Attempted writes to this location are terminated with an error.

Address: E008_0000h base + 20h offset = E008_0020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

MCM_FATR field descriptions

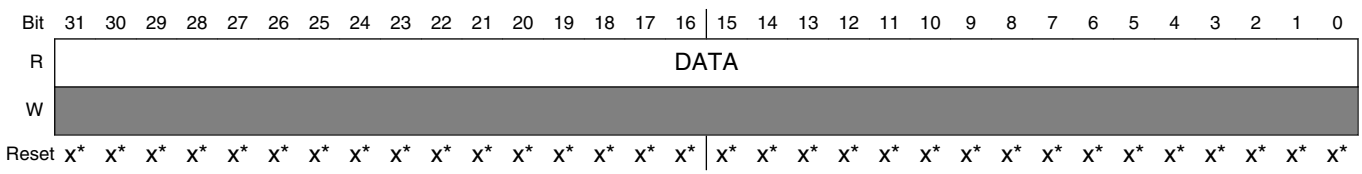
Field	Description
31 BEOVR	Bus error overrun Indicates if another cache write buffer bus error is detected before system software has retrieved all the error information from the original event, this overrun flag is set. The window of time is defined from the detection of the original cache write buffer error termination until the MCM_ISCR[CWBER] is written with a 1 to clear it and rearm the capture logic. This bit is set by the hardware and cleared whenever software writes a 1 to the CWBER bit. 0 No bus error overrun 1 Bus error overrun occurred. The FADR and FDR registers and the other FATR bits are not updated to reflect this new bus error.
30–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–8 BEMN	Bus error master number Crossbar switch bus master number of the captured cache write buffer bus error. For this device, this value is always 0x1.
7 BEWT	Bus error write Indicates the type of system bus access when the error was detected. Since this logic is monitoring data transfers from the cache write buffer, this bit is always a logical one, signaling a write operation. 0 Read access 1 Write access
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–4 BESZ	Bus error size Indicates the size of the cache write buffer access when the error was detected. 00 8-bit access 01 16-bit access 10 32-bit access 11 Reserved
3–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 BEMD	Bus error privilege level Indicates the privilege level of the cache write buffer access when the error was detected. 0 User mode 1 Supervisor/privileged mode
0 BEDA	Bus error access type Indicates the type of cache write buffer access when the error was detected. This attribute is always a logical one signaling a data reference. 0 Instruction 1 Data

6.12.6 Fault data register (MCM_FDR)

When a properly-enabled cache write buffer error interrupt event is detected, the faulting data is captured in the MCM_FDR register.

The bits in this register are set by hardware and signaled by the assertion of MCM_ISCR[CWBER]. For byte and halfword writes, only the accessed byte lanes contain valid data; the contents of the other bytes are undefined. Attempted writes to this location are terminated with an error.

Address: E008_0000h base + 28h offset = E008_0028h



* Notes:
- x = Undefined at reset.

7.2 Introduction

The Local Memory Controller provides the processor with tightly-coupled processor-local memories and bus paths to all slave memory spaces.

7.2.1 Block Diagram

The processor has a modified 32-bit Harvard bus architecture. Using a 32-bit address space, low-order addresses (0x0000_0000 through 0x1FFF_FFFF) use the Processor Code (PC) bus, and high-order addresses (0x2000_0000 through 0xFFFF_FFFF) use the Processor System (PS) bus. As the bus names imply, normal operation has code accesses on the PC bus and data accesses on the PS bus.

This device has been augmented with tightly-coupled memories for the PC and PS buses. The memories include RAMs and caches. These local memories provide zero wait state access to RAM and cacheable address spaces.

The local memory controller includes the following memory controllers and their attached memories:

- SRAM lower (SRAM_L) controller via the PC bus

- SRAM upper (SRAM_U) controller via the PS bus
- Cache memory controller via the PC bus

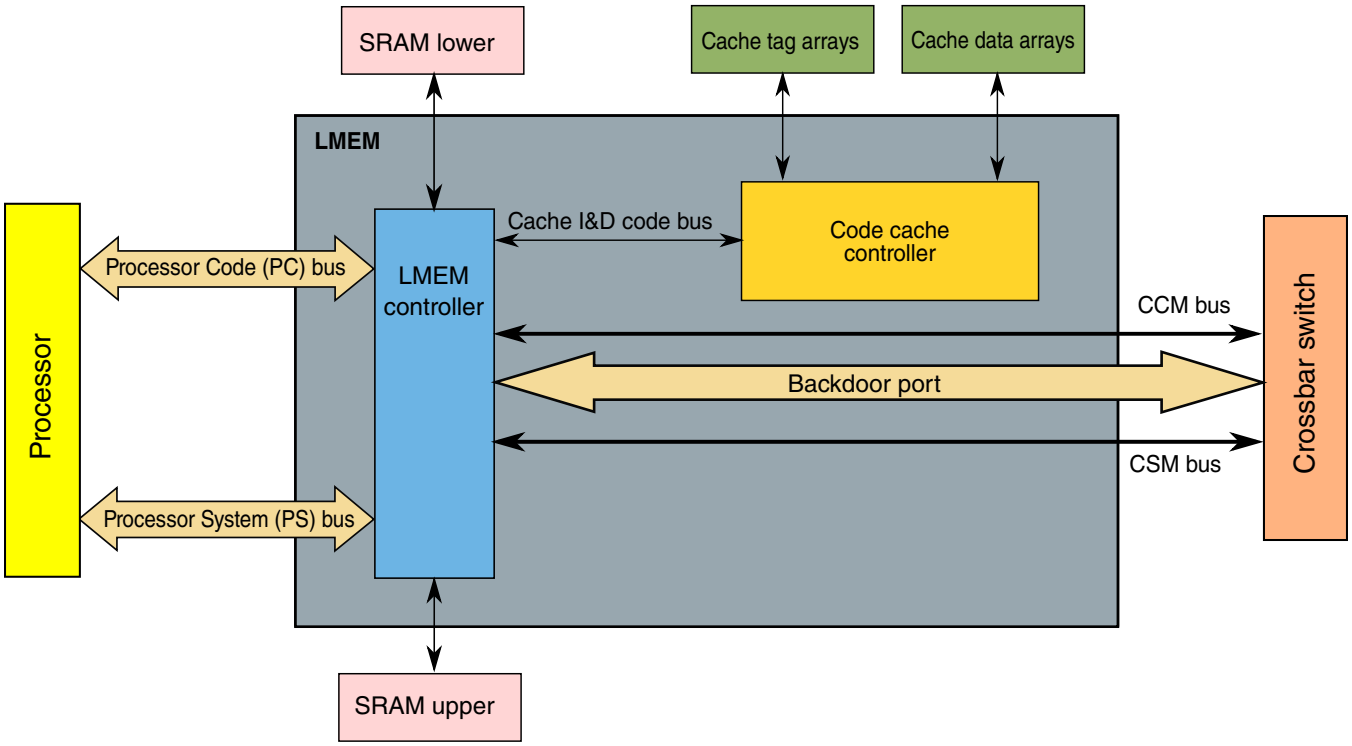

Figure 7-1. Local memory controller block diagram

NOTE

The SRAM and cache controllers reside within the LMEM, but the single-port synchronous RAM arrays used by these controllers are external.

The LMEM contains address decode logic for the PC and PS buses. This logic routes the core's accesses to the various system resources.

7.2.2 Cache features

A cache is a block of high-speed memory locations containing address information (commonly known as a tag) and the associated data. The purpose is to decrease the average time of a memory access. Caches operate on two principles of locality:

- Spatial locality — An access to one location is likely to be followed by accesses from adjacent locations (for example, sequential instruction execution or usage of a data structure).
- Temporal locality — An access to an area of memory is likely to be repeated within a short time period (for example, execution of a code loop).

To minimize the quantity of control information stored, the spatial locality property is used to group several locations together under the same tag. This logical block is commonly known as a cache line.

When data is loaded into a cache, access times for subsequent loads and stores are reduced, resulting in overall performance benefits. An access to information already in a cache is known as a cache hit, and other accesses are called cache misses.

Normally, caches are self-managing, with the updates occurring automatically. Whenever the processor wants to access a cacheable location, the cache is checked. If the access is a cache hit, the access occurs immediately. Otherwise, a location is allocated and the cache line is loaded from memory. Different cache topologies and access policies are possible. However, they must comply with the memory coherency model of the underlying architecture.

Caches introduce a number of potential problems, mainly because of:

- memory accesses occurring at times other than when the programmer would normally expect them,
- the existence of multiple physical locations where a data item can be held.

The local memory controller supports the following modes of operation:

1. Write-through — access to address spaces with this cache mode are cacheable.
    - If all cacheable spaces are read-only spaces, the cache will contain read-only data and all write to the cache will fault.
    - A write-through read miss on the input bus causes a line read on the output bus of a 32-byte-aligned memory address containing the desired address. This miss data is loaded into the cache and is marked as valid and not modified.
    - A write-through read hit to a valid cache location returns data from the cache with no output bus access.
    - A write-through write miss bypasses the cache and writes to the output bus (no allocate on write miss policy for write-through mode spaces).
    - A write-through write hit updates the cache hit line with the write data and writes to the output bus.
    - The caches are processor-local and do not support hardware cache coherency. If the processor has accessed write-through regions and an external bus master (such as DMA) then needs update these regions, software must first perform explicit cache clears to any needed cache memory range to ensure all modified cache lines update their associated memories before being modified by external masters and subsequent processor accesses will get the updated memory.
2. Non-cacheable — access to address spaces with this cache mode are not cacheable. These accesses bypass the cache and access the output bus.

7.3 Memory Map and Registers

The cache programmer's model provides a variety of registers for configuring and controlling the cache, as well as indirect access paths to all cache tag and data storage.

NOTE

The LMEM registers are accessible in supervisor mode only.

7.4 Functional Description

7.4.1 LMEM Function

The Local Memory Controller receives the following requests:

- Core master bus requests on the Processor Code (PC) bus,
- Core master bus requests on the Processor Space (PS) bus, and
- SRAM controller requests from all other bus masters on the backdoor port.

The Local Memory Controller address decode logic routes these accesses and also provides any crossbar switch slave target logic. Finally, the Local Memory controller provides the needed MPU connections for checking all SRAM controller and cacheable accesses.

The programming model for the Code Cache is accessed via the core's Private Peripheral Bus (PPB).

7.4.1.1 Processor Code accesses

Processor Code accesses are routed to the SRAM_L if they are mapped to that space. All other PC accesses are routed to the Code Cache Memory Controller. This controller then processes the cacheable accesses as needed, while bypassing the non-cacheable, cache write-through, cache miss, and cache maintenance accesses to the CCM bus and the crossbar switch using the Master0 port.

7.4.1.2 Processor System accesses

Processor Space accesses are routed to the SRAM_U if they are mapped to that space. All other PS accesses are routed to the CCM bus and the crossbar switch using the Master1 port.

7.4.1.3 Backdoor port accesses

All LMEM backdoor port accesses are for the SRAM controller. These accesses go to the SRAM_L or the SRAM_U depending on their specific address.

7.4.2 SRAM Function

7.4.2.1 SRAM Configuration

The figure below shows how the SRAM controller is configured.

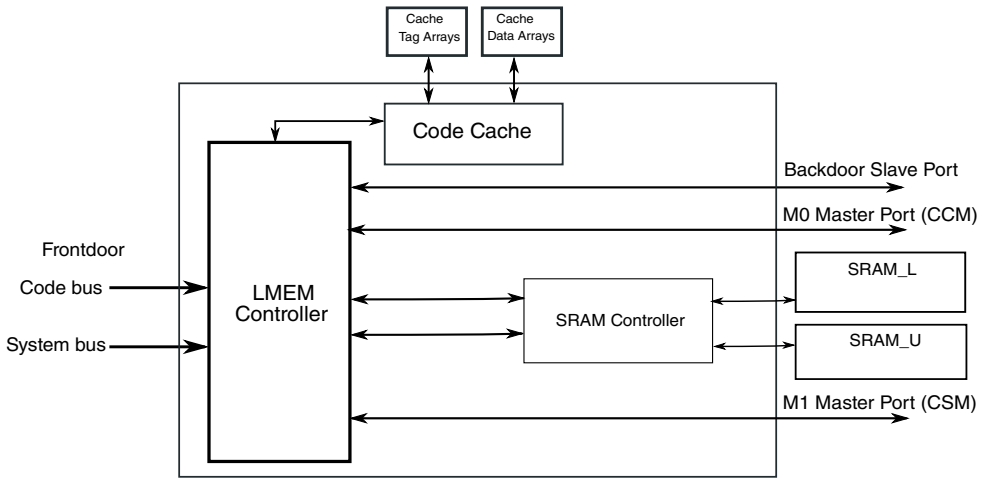

Figure 7-2. LMEM Interface to SRAM

7.4.2.2 SRAM Arrays

The on-chip SRAM is split into two logical arrays, SRAM_L and SRAM_U.

SRAM_L size is 192 KBytes.

SRAM_U size is 64 KBytes.

Valid address ranges for SRAM_L and SRAM_U are then defined as:

- SRAM_L = (0x20000_0000 - 192 KBytes) - 0x1fff_ffff
- SRAM_U = 0x2000_0000 - (0x2000_0000 + 64 KBytes)

SRAML_SIZE and SRAMU_SIZE do not have to be equal.

7.4.2.3 SRAM Accesses

The SRAM is split into two logical arrays that are 64-bits wide:

- SRAM_L — Accessible by the code bus of the core and by the backdoor port.
- SRAM_U — Accessible by the system bus of the core and by the backdoor port.

The backdoor port makes the SRAM accessible to the non-core bus masters (such as DMA).

The diagram below illustrates the SRAM accesses within the device.

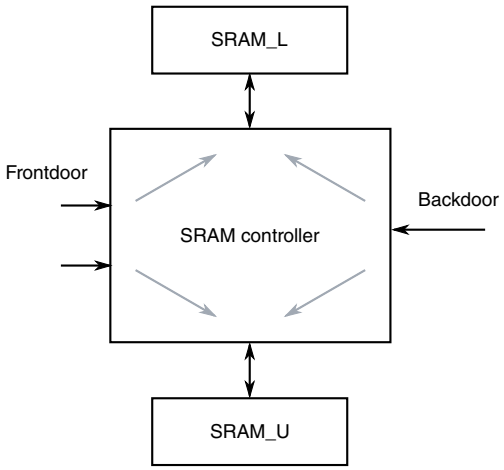

Figure 7-3. SRAM access diagram

The following simultaneous accesses can be made to different logical halves of the SRAM:

- Core code and core system
- Core code and non-core master
- Core system and non-core master

NOTE

Two non-core masters cannot access SRAM simultaneously. The required arbitration and serialization is provided by the crossbar switch. The SRAM_L and SRAM_U arbitration is controlled by the SRAM controller based on the configuration bits in the MCM module.

NOTE

Burst-access cannot occur across the 0x2000_0000 boundary that separates the two SRAM arrays. The two arrays should be treated as separate memory ranges for burst accesses.

7.4.3 Cache Function

The cache on this device is structured as follows. The cache has a 2-way set-associative cache structure with a total size of 8 KBytes for the Code Cache. The cache has 32-bit address, 64-bit data paths and a 32-byte line size. The cache tags and data storage use single-port, synchronous RAMs.

For the Code 8-KByte cache, each cache TAG function uses two 128 x 22-bit RAM arrays and the cache DATA function uses two 512 x 64-bit RAM arrays. The cache TAG entries store 20 bits of upper address as well as a modified and valid bit per cache line. The cache DATA entries store eight byes of code or data.

All normal cache accesses use physical addresses. This leads to the following cache address use:

CODE CACHE - 8 KByte size = (128 sets) x (32-byte lines) x (2-way set associative)

Table 7-2. Tag Cache Address Use

Tag Cache Address Use	Code Cache
Tag Hit Address Range	Address[31:12]
Tag Set Select Address Range	Address[11:5] used to select 1 of 128 sets
Not Used	Address[4:0]

Table 7-3. Data Cache Address Use

Data Cache Address Use	Code Cache
Not Used	Address[31:12]
Data Set Select Address Range	Address[11:5] used to select one of 128 sets
64-bit word select	Address[4:3] used to select one of four 64-bit words within a set
Byte select	Address[2:0] used to select the byte within the 64-bit word

7.4.4 Cache Control

The Code Cache is disabled at reset. Cache tag and data arrays are not cleared at reset. Therefore, to enable the cache, cache commands must be done to clear and initialize the required tag array bits and to configure and enable the caches.

7.4.4.1 Cache set commands

The cache set commands may operate on:

- all of way 0,
- all of way 1, or
- all of both ways (complete cache).

Cache set commands are initiated using the upper bits in the CCR register. Cache set commands perform their operation on the cache independent of the cache enable bit, CCR[ENCACHE].

A cache set command is initiated by setting the CCR[GO] bit. This bit also acts as a busy bit for set commands. It stays set while the command is active and is cleared by the hardware when the set command completes.

Supported cache set commands are given in Table 7-4. Set commands work as follows:

- Invalidate – Unconditionally clear valid and modify bits of a cache entry.
- Push – Push a cache entry if it is valid and modified, then clear the modify bit. If entry not valid or not modified, leave as is.
- Clear – Push a cache entry if it is valid and modified, then clear the valid and modify bits. If entry not valid or not modified, clear the valid bit.

Table 7-4. Cache Set Commands

CCR[27:24]				Command
PUSHW1	INVW1	PUSHW0	INVW0	
0	0	0	0	NOP
0	0	0	1	Invalidate all way 0
0	0	1	0	Push all way 0
0	0	1	1	Clear all way 0
0	1	0	0	Invalidate all way 1
0	1	0	1	Invalidate all way 1; invalidate all way 0 (invalidate cache)
0	1	1	0	Invalidate all way 1; push all way 0
0	1	1	1	Invalidate all way 1; clear all way 0
1	0	0	0	Push all way 1
1	0	0	1	Push all way 1; invalidate all way 0
1	0	1	0	Push all way 1; push all way 0 (push cache)
1	0	1	1	Push all way 1; clear all way 0
1	1	0	0	Clear all way 1
1	1	0	1	Clear all way 1; invalidate all way 0
1	1	1	0	Clear all way 1; push all way 0
1	1	1	1	Clear all way 1; clear all way 0 (clear cache)

After a reset, complete an invalidate cache command before using the cache. It is possible to combine the cache invalidate command with the cache enable. That is, setting CCR to 0x8500_0003 will invalidate the cache and enable the cache and write buffer.

7.4.4.2 Cache line commands

Cache line commands operate on a single line in the cache at a time. Cache line commands can be performed using a physical or cache address.

- A cache address consists of a set address and a way select. The line command acts on the specified cache line.
- Cache line commands with physical addresses first search both ways of the cache set specified by the following physical address bits. If they hit, the commands perform their action on the hit way:
  - For Code Cache - [11:5]

Cache line commands are specified using the upper bits in the CLCR register. Cache line commands perform their operation on the cache independent of the cache enable bit (CCR[ENCACHE]). Using a cache address, the command can be completely specified using the CLCR register. Using a physical address, the command must also use the CSAR register to specify the physical address.

A line cache command is initiated by setting the line command go bit (CLCR[LGO] or CSAR[LGO]). This bit also acts a a busy bit for line commands. It stays set while the command is active and is cleared by the hardware when the command completes.

The CLCR[27:24] bits select the line command as follows:

Table 7-5. Cache Line Commands

CLCR[27:24]			Command
LACC	LADSEL	LCMD	
0	0	00	Search by cache address and way
0	0	01	Invalidate by cache address and way
0	0	10	Push by cache address and way
0	0	11	Clear by cache address and way
0	1	00	Search by physical address
0	1	01	Invalidate by physical address
0	1	10	Push by physical address
0	1	11	Clear by physical address
1	0	00	Write by cache address and way
1	0	01	Reserved, NOP
1	0	10	Reserved, NOP
1	0	11	Reserved, NOP
1	1	*xx*	Reserved, NOP

7.4.4.2.1 Executing a series of line commands using cache addresses

A series of line commands with incremental cache addresses can be performed by just writing to the CLCR.

- Place the command in CLCR[27:24],
- Set the way (CLCR[WSEL]) and tag/data (CLCR[TDSEL]) controls as needed,
- Place the cache address in CLCR[CACHEADDR], and
- Set the line command go bit (CLCR[LGO]).

When one line command completes, initiate the next command by following these steps:

- Increment the cache address (at bit 3 to step through data or at bit 5 to step through lines), and
- Set the line command go bit (CLCR[LGO]).

7.4.4.2.2 Executing a series of line commands using physical addresses

Perform a series of line commands with incremental physical addresses using the following steps:

- Write to the CLCR.
  - Place the command in CLCR[27:24]
  - Set the tag/data (CLCR[TDSEL]) control
- Place the physical address in CSAR[PHYADDR] and set the line command go bit (CSAR[LGO]).

When one line command completes, initiate the next command by following these steps:

- Increment the physical address (at bit 3 to step through data or at bit 5 to step through lines), and
- Set the line command go bit (CSAR[LGO]).

The line command go bit is shared between the CLCR and CSAR registers, so that the above steps can be completed in a single write to the CSAR register.

7.4.4.2.3 Line command results

At completion of a line command, the CLCR register contains information on the initial state of the line targeted by the command. For line commands with cache addresses, this information is read before the line command action is performed from the targeted cache line. For line commands with physical addresses, this information is read on a hit before the line command action is performed from the hit cache line or has initial valid bit

cleared if the command misses. In general, if the valid indicator (CLCR[LCIVB] is cleared, the targeted line was invalid at the start of the line command and no line operation was performed.

Table 7-6. Line command results

CLCR[22:20]			For cache address commands	For physical address commands
LCWAY	LCIMB	LCIVB		
0	0	0	Way 0 line was invalid	No hit
0	0	1	Way 0 valid, not modified	Way 0 valid, not modified
0	1	0	Way 0 line was invalid	No hit
0	1	1	Way 0 valid and modified	Way 0 valid and modified
1	0	0	Way 1 line was invalid	No hit
1	0	1	Way 1 valid, not modified	Way 1 valid, not modified
1	1	0	Way 1 line was invalid	No hit
1	1	1	Way 1 valid and modified	Way 1 valid and modified

At completion of a line command other than a write, the CCVR (Cache R/W Value Register) contains information on the initial state of the line tag or data targeted by the command. For line commands, CLCR[TDSEL] selects between tag and data. If the line command used a physical address and missed, the data is don't care. For write commands, the CCVR holds the write data.

8.2 BME

The Bit Manipulation Engine (BME) provides hardware support for atomic read-modify-write memory operations to the peripheral address space in Arm Cortex-M based microcontrollers. This architectural capability is also known as "decorated storage" as it defines a mechanism for providing additional semantics for load and store operations to memory-mapped peripherals beyond just the reading and writing of data values to the addressed memory locations. In the BME definition, the "decoration", that is, the additional semantic information, is encoded into the peripheral address used to reference the memory.

Table 8-2. BME configuration

External I/O pins	NA

8.3 Introduction

The Bit Manipulation Engine (BME) provides hardware support for atomic read-modify-write memory operations to the peripheral address space in Cortex-M4 based microcontrollers.

This architectural capability is also known as "decorated storage" as it defines a mechanism for providing additional semantics for load and store operations to memory-mapped peripherals beyond just the reading and writing of data values to the addressed memory locations. In the BME definition, the "decoration", that is, the additional semantic information, is encoded into the peripheral address used to reference the memory.

By combining the basic load and store instructions of the Arm Cortex-M instruction set architecture (v6M, v7M) with the concept of decorated storage provided by the BME, the resulting implementation provides a robust and efficient read-modify-write capability to this class of ultra low-end microcontrollers. The resulting architectural capability defined by this core platform function is targeted at the manipulation of n-bit fields in peripheral registers and is consistent with I/O hardware addressing in the Embedded C standard. For most BME commands, a single core read or write bus cycle is converted into an atomic read-modify-write, that is, an indivisible "read followed by a write" bus sequence.

BME decorated references are only available on system bus transactions generated by the processor core and targeted at the standard 512 KB peripheral address space based at 0x4100_0000. The decoration semantic is embedded into address bits[28:19], creating a 448 MB space at addresses 0x4400_0000–0x5FFF_FFFF for AIPS; these bits are stripped out of the actual address sent to the peripheral bus controller and used by the BME to define and control its operation.

8.3.1 Features

The key features of the BME include:

- Lightweight implementation of decorated storage for selected address spaces
- Additional access semantics encoded into the reference address
- Resides between a switch slave port and a peripheral bridge bus controller
- Two-stage pipeline design matching the AHB system bus protocol
- Combinationally passes non-decorated accesses to peripheral bridge bus controller
- Conversion of decorated loads and stores from processor core into atomic read-modify-writes

- Decorated loads support unsigned bit field extracts, load-and-{set,clear} 1-bit operations
- Decorated stores support bit field inserts, logical AND, OR, and XOR operations
- Support for byte, halfword and word-sized decorated operations
- Supports minimum signal toggling on AHB output bus to reduce power dissipation

8.3.2 Modes of operation

The BME module does not support any special modes of operation. As a memory-mapped device located on a crossbar slave AHB system bus port, BME responds strictly on the basis of memory addresses for accesses to the peripheral bridge bus controller.

All functionality associated with the BME module resides in the core platform's clock domain; this includes its connections with the crossbar slave port and the PBRIDGE bus controller.

8.4 Memory map and register definition

The BME module provides a memory-mapped capability and does not include any programming model registers.

The exact set of functions supported by the BME are detailed in the Functional description.

The peripheral address space occupies a 516 KB region: 512 KB based at 0x4100_0000 plus a 4 KB space based at 0x4100_F000 for GPIO accesses; the decorated address space is mapped to the 448 MB region located at 0x4400_0000–0x5FFF_FFFF.

8.5 Functional description

Information found here details the specific functions supported by the BME.

Recall the combination of the basic load and store instructions of the Cortex-M instruction set architecture (v6M, v7M) plus the concept of decorated storage provided by the BME, the resulting implementation provides a robust and efficient read-modify-write capability to this class of ultra low-end microcontrollers. The resulting architectural capability defined by this core platform function is targeted at the manipulation of n-bit fields in peripheral registers and is consistent with I/O hardware addressing in the

Embedded C standard. For most BME commands, a single core read or write bus cycle is converted into an atomic read-modify-write, that is, an indivisible "read followed by a write" bus sequence.

Consider decorated store operations first, then decorated loads.

8.5.1 BME decorated stores

The functions supported by the BME's decorated stores include three logical operators (AND, OR, XOR) plus a bit field insert.

For all these operations, BME converts a single decorated AHB store transaction into a 2-cycle atomic read-modify-write sequence, where the combined read-modify operation is performed in the first AHB data phase, and then the write is performed in the second AHB data phase.

A generic timing diagram of a decorated store showing a peripheral bit field insert operation is shown as follows:

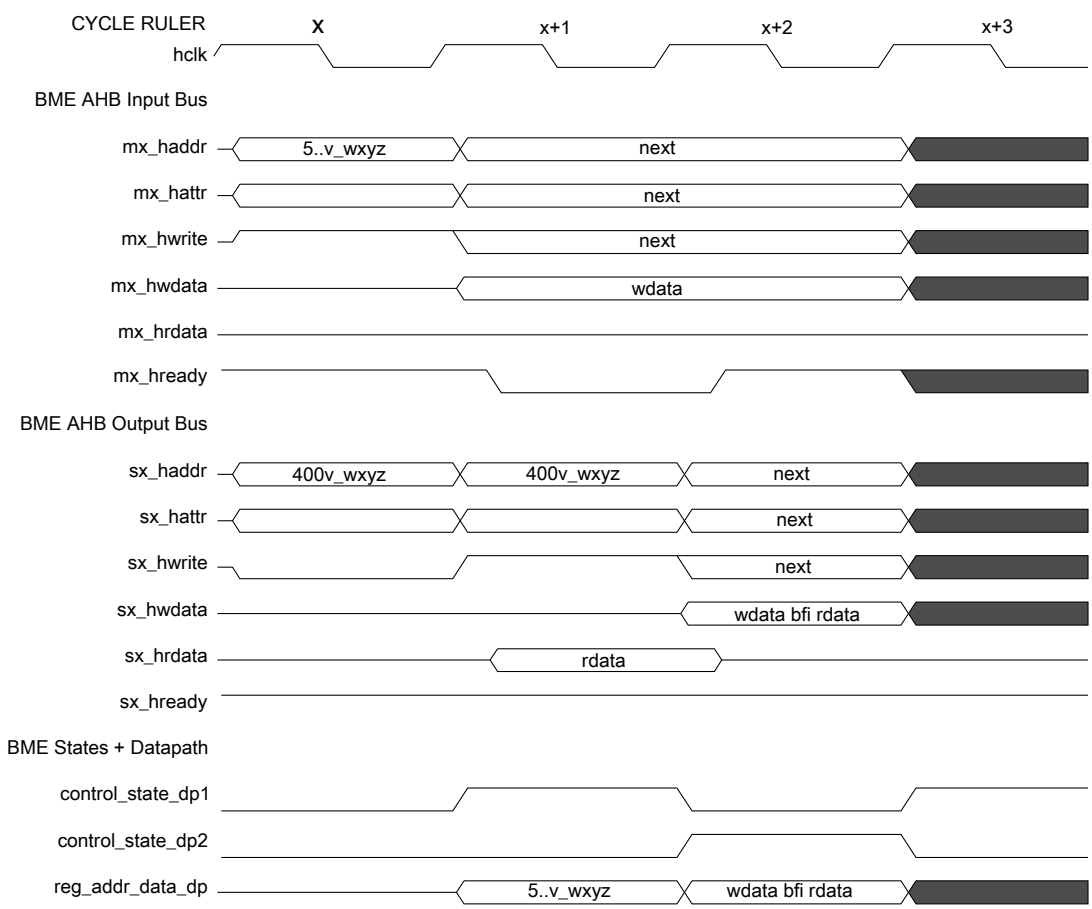

Figure 8-1. Decorated store: bit field insert timing diagram

All the decorated store operations follow the same execution template shown in Figure 8-1, a two-cycle read-modify-write operation:

1. Cycle x, 1st AHB address phase: Write from input bus is translated into a read operation on the output bus using the actual memory address (with the decoration removed) and then captured in a register.
2. Cycle x+1, 2nd AHB address phase: Write access with the registered (but actual) memory address is output
3. Cycle x+1, 1st AHB data phase: Memory read data is modified using the input bus write data and the function defined by the decoration and captured in a data register; the input bus cycle is stalled.
4. Cycle x+2, 2nd AHB data phase: Registered write data is sourced onto the output write data bus.

NOTE

Any wait states inserted by the slave device are simply passed through the BME back to the master input bus, stalling the AHB transaction cycle for cycle.

8.5.1.1 Decorated store logical AND (AND)

This command performs an atomic read-modify-write of the referenced memory location.

1. First, the location is read;
2. It is then modified by performing a logical AND operation using the write data operand sourced for the system bus cycle
3. Finally, the result of the AND operation is written back into the referenced memory location.

The data size is specified by the write operation and can be byte (8-bit), halfword (16-bit) or word (32-bit). The core performs the required write data lane replication on byte and halfword transfers.

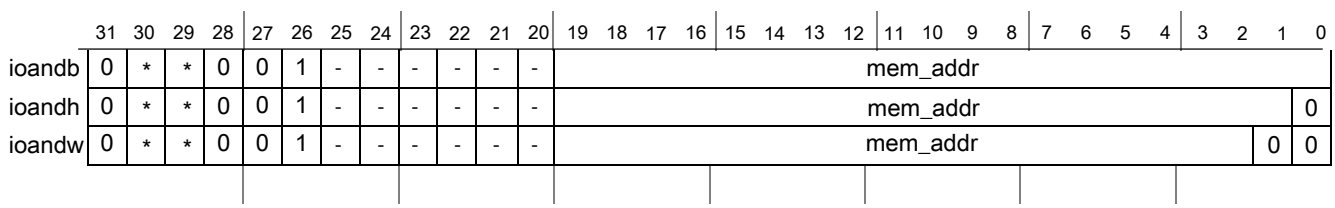

Figure 8-2. Decorated store address: logical AND

See Figure 8-2, where addr[30:29] = 10 for peripheral, addr[28:26] = 001 specifies the AND operation, and mem_addr[19:0] specifies the address offset into the space based at 0x4000_0000 for peripherals. The "-" indicates an address bit "don't care".

The decorated AND write operation is defined in the following pseudo-code as:

```
ioand<sz>(accessAddress, wdata)                  // decorated store AND
tmp   =  mem[accessAddress & 0xE00FFFFF, size]   // memory read
tmp   =  tmp & wdata                             // modify
mem[accessAddress & 0xE00FFFFF, size] = tmp      // memory write
```

where the operand size <sz> is defined as b(yte, 8-bit), h(alfword, 16-bit) and w(ord, 32-bit). This notation is used throughout the document.

In the cycle definition tables, the notations AHB_ap and AHB_dp refer to the address and data phases of the BME AHB transaction. The cycle-by-cycle BME operations are detailed in the following table.

Table 8-3. Cycle definitions of decorated store: logical AND

Pipeline stage	Cycle		
	x	x+1	x+2
BME AHB_ap	Forward addr to memory; Decode decoration; Convert master_wt to slave_rd; Capture address, attributes	Recirculate captured addr + attr to memory as slave_wt	<next>
BME AHB_dp	<previous>	Perform memory read; Form (rdata & wdata) and capture destination data in register	Perform write sending registered data to memory

8.5.1.2 Decorated store logical OR (OR)

This command performs an atomic read-modify-write of the referenced memory location.

1. First, the location is read.
2. It is then modified by performing a logical OR operation using the write data operand sourced for the system bus cycle.
3. Finally, the result of the OR operation is written back into the referenced memory location.

The data size is specified by the write operation and can be byte (8-bit), halfword (16-bit) or word (32-bit). The core performs the required write data lane replication on byte and halfword transfers.

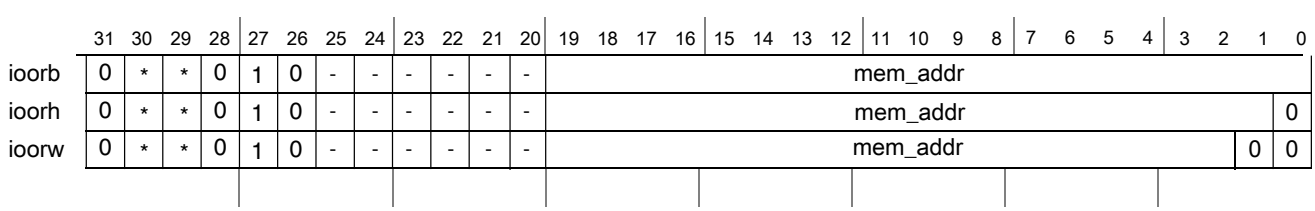

Figure 8-3. Decorated address store: logical OR

See Figure 8-3,where addr[30:29] =10 for peripheral, addr[28:26] = 010 specifies the OR operation, and mem_addr[19:0] specifies the address offset into the space based at 0x4000_0000 for peripherals. The "-" indicates an address bit "don't care".

The decorated OR write operation is defined in the following pseudo-code as:

```
ioor<sz>(accessAddress, wdata)                  // decorated store OR

tmp   =  mem[accessAddress & 0xE00FFFFF, size]  // memory read
tmp   =  tmp | wdata                            // modify
mem[accessAddress & 0xE00FFFFF, size] = tmp     // memory write
```

The cycle-by-cycle BME operations are detailed in the following table.

Table 8-4. Cycle definitions of decorated store: logical OR

Pipeline stage	Cycle		
	x	x+1	x+2
BME AHB_ap	Forward addr to memory; Decode decoration; Convert master_wt to slave_rd; Capture address, attributes	Recirculate captured addr + attr to memory as slave_wt	<next>
BME AHB_dp	<previous>	Perform memory read; Form (rdata | wdata) and capture destination data in register	Perform write sending registered data to memory

8.5.1.3 Decorated store logical XOR (XOR)

This command performs an atomic read-modify-write of the referenced memory location.

1. First, the location is read.
2. It is then modified by performing a logical XOR (exclusive-OR) operation using the write data operand sourced for the system bus cycle.
3. Finally, the result of the XOR operation is written back into the referenced memory location.

The data size is specified by the write operation and can be byte (8-bit), halfword (16-bit) or word (32-bit). The core performs the required write data lane replication on byte and halfword transfers.

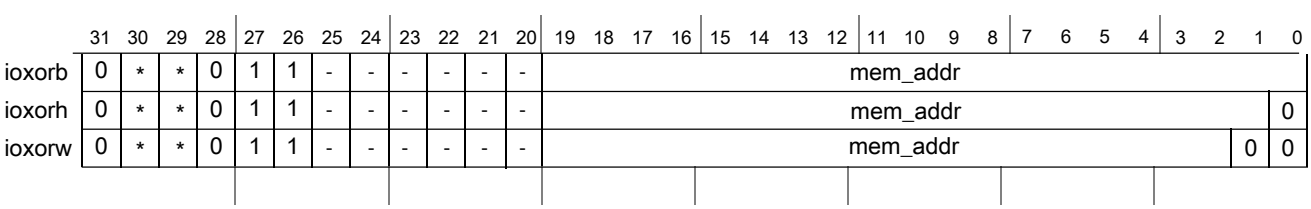

Figure 8-4. Decorated address store: logical XOR

See Figure 8-4, where addr[30:29] =10 for peripheral, addr[28:26] = 011 specifies the XOR operation, and mem_addr[19:0] specifies the address offset into the peripheral space based at 0x4000_0000 for peripherals. The "-" indicates an address bit "don't care".

The decorated XOR write operation is defined in the following pseudo-code as:

```
ioxor<sz>(accessAddress, wdata)                 // decorated store XOR

tmp   =  mem[accessAddress & 0xE00FFFFF, size]  // memory read
tmp   =  tmp ^ wdata                            // modify
mem[accessAddress & 0xE00FFFFF, size] = tmp     // memory write
```

The cycle-by-cycle BME operations are detailed in the following table.

Table 8-5. Cycle definitions of decorated store: logical XOR

Pipeline Stage	Cycle		
	x	x+1	x+2
BME AHB_ap	Forward addr to memory; Decode decoration; Convert master_wt to slave_rd; Capture address, attributes	Recirculate captured addr + attr to memory as slave_wt	<next>
BME AHB_dp	<previous>	Perform memory read; Form (rdata ^ wdata) and capture destination data in register	Perform write sending registered data to memory

8.5.1.4 Decorated store bit field insert (BFI)

This command inserts a bit field contained in the write data operand, defined by LSB position (b) and the bit field width (w+1), into the memory "container" defined by the access size associated with the store instruction using an atomic read-modify-write sequence.

The data size is specified by the write operation and can be byte (8-bit), halfword (16-bit) or word (32-bit).

NOTE

For the word sized operation, the maximum bit field width is 16 bits. The core performs the required write data lane replication on byte and halfword transfers.

The BFI operation can be used to insert a single bit into a peripheral. For this case, the w field is simply set to 0, indicating a bit field width of 1.

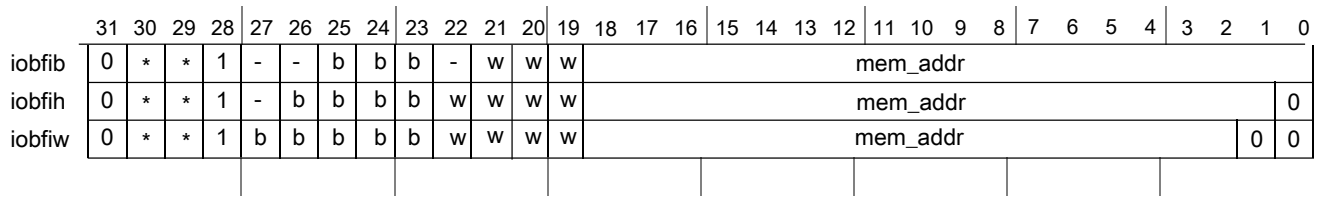

Figure 8-5. Decorated address store: bit field insert

where addr[30:29] =10 for peripheral,addr[28] = 1 signals a BFI operation, addr[27:23] is "b", the LSB identifier, addr[22:19] is "w", the bit field width minus 1 identifier, and addr[18:0] specifies the address offset into the peripheral space based at 0x4000_0000 for peripherals. The "-" indicates an address bit "don't care". Note, unlike the other decorated store operations, BFI uses addr[19] as the least significant bit in the "w" specifier and not as an address bit.

The decorated BFI write operation is defined in the following pseudo-code as:

```
iobfi<sz>(accessAddress, wdata)                 // decorated bit field insert

tmp   =  mem[accessAddress & 0xE007FFFF, size]  // memory read
mask  = ((1 << (w+1)) - 1) << b                 // generate bit mask
tmp   =  tmp   & ~mask                          // modify
      |  wdata &  mask
mem[accessAddress & 0xE007FFFF, size] = tmp     // memory write
```

The write data operand (wdata) associated with the store instruction contains the bit field to be inserted. It must be properly aligned within a right-aligned container, that is, within the lower 8 bits for a byte operation, the lower 16 bits for a halfword, or the entire 32 bits for a word operation.

To illustrate, consider the following example of the insertion of the 3-bit field "xyz" into an 8-bit memory container, initially set to "abcd_efgh". For all cases, w is 2, signaling a bit field width of 3.

```
if b = 0 and the decorated store (strb) Rt register[7:0] = ----_-xyz,
   then destination is "abcd_exyz"
if b = 1 and the decorated store (strb) Rt register[7:0] = ----_xyz-,
   then destination is "abcd_xyzh"
if b = 2 and the decorated store (strb) Rt register[7:0] = ---x_yz--,
   then destination is "abcx_yzgh"
if b = 3 and the decorated store (strb) Rt register[7:0] = --xy_z---,
   then destination is "abxy_zfgh"
if b = 4 and the decorated store (strb) Rt register[7:0] = -xyz_----,
   then destination is "axyz_efgh"
if b = 5 and the decorated store (strb) Rt register[7:0] = xyz-_----,
   then destination is "xyzd_efgh"
if b = 6 and the decorated store (strb) Rt register[7:0] = yz--_----,
   then destination is "yzcd_efgh"
if b = 7 and the decorated store (strb) Rt register[7:0] = z---_----,
   then destination is "zbcd_efgh"
```

Note from the example, when the starting bit position plus the field width exceeds the container size, only part of the source bit field is inserted into the destination memory location. Stated differently, if (b + w+1) > container_width, only the low-order "container_width - b" bits are actually inserted.

The cycle-by-cycle BME operations are detailed in the following table.

Table 8-6. Cycle definitions of decorated store: bit field insert

Pipeline stage	Cycle		
	x	x+1	x+2
BME AHB_ap	Forward addr to memory; Decode decoration; Convert master_wt to slave_rd; Capture address, attributes	Recirculate captured addr + attr to memory as slave_wt	<next>
BME AHB_dp	<previous>	Perform memory read; Form bit mask; Form bitwise ((mask) ? wdata : rdata)) and capture destination data in register	Perform write sending registered data to memory

8.5.2 BME decorated loads

The functions supported by the BME's decorated loads include two single-bit load-and-{set, clear} operators plus unsigned bit field extracts.

For the two load-and-{set, clear} operations, BME converts a single decorated AHB load transaction into a two-cycle atomic read-modify-write sequence, where the combined read-modify operations are performed in the first AHB data phase, and then the write is performed in the second AHB data phase as the original read data is returned to the processor core. For an unsigned bit field extract, the decorated load transaction is stalled for one cycle in the BME as the data field is extracted, then aligned and returned to the processor in the second AHB data phase. This is the only decorated transaction that is not an atomic read-modify-write, as it is a simple data read.

A generic timing diagram of a decorated load showing a peripheral load-and-set 1-bit operation is shown as follows.

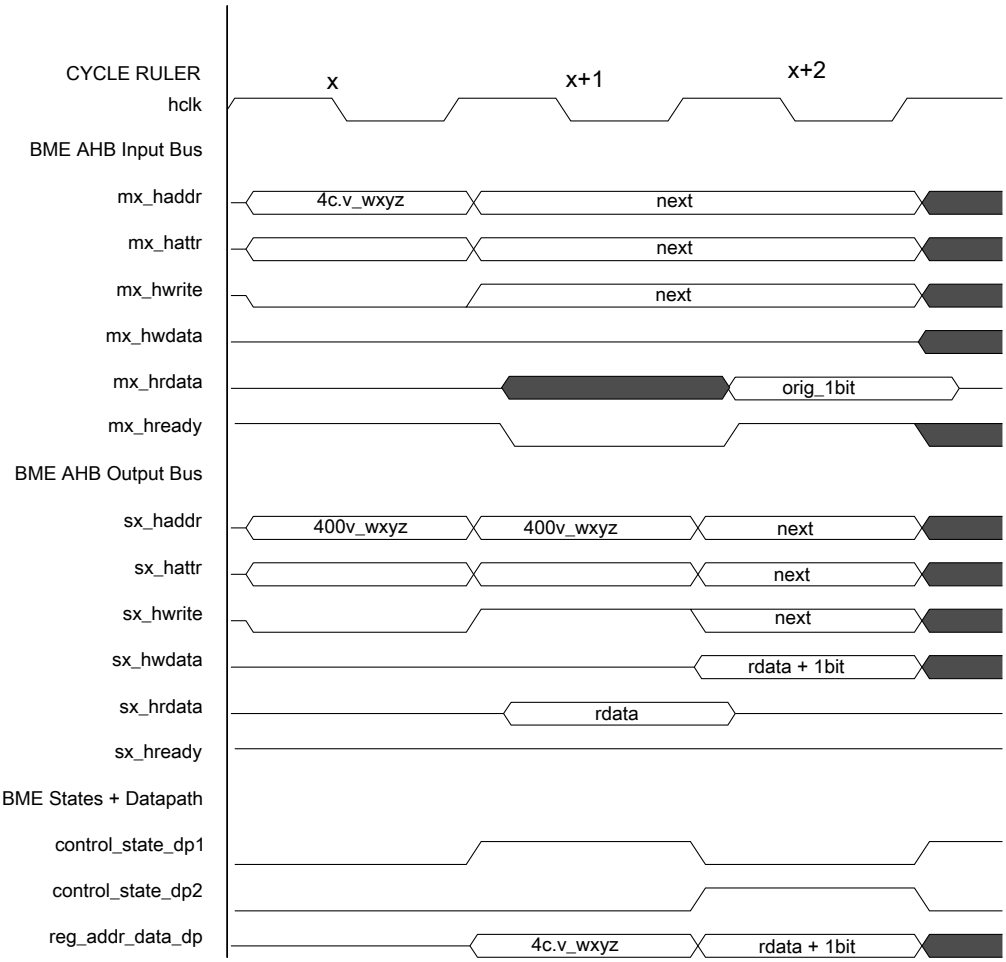

Figure 8-6. Decorated load: load-and-set 1-bit field insert timing diagram

Decorated load-and-{set, clear} 1-bit operations follow the execution template shown in the above figure: a 2-cycle read-modify-write operation:

1. Cycle x, first AHB address phase: Read from input bus is translated into a read operation on the output bus with the actual memory address (with the decoration removed) and then captured in a register
2. Cycle x+1, second AHB address phase: Write access with the registered (but actual) memory address is output
3. Cycle x+1, first AHB data phase: The "original" 1-bit memory read data is captured in a register, while the 1-bit field is set or clear based on the function defined by the decoration with the modified data captured in a register; the input bus cycle is stalled
4. Cycle x+2, second AHB data phase: The selected original 1-bit is right-justified, zero-filled and then driven onto the input read data bus, while the registered write data is sourced onto the output write data bus

NOTE

Any wait states inserted by the slave device are simply passed through the BME back to the master input bus, stalling the AHB transaction cycle for cycle.

A generic timing diagram of a decorated load showing an unsigned peripheral bit field operation is shown in the following figure.

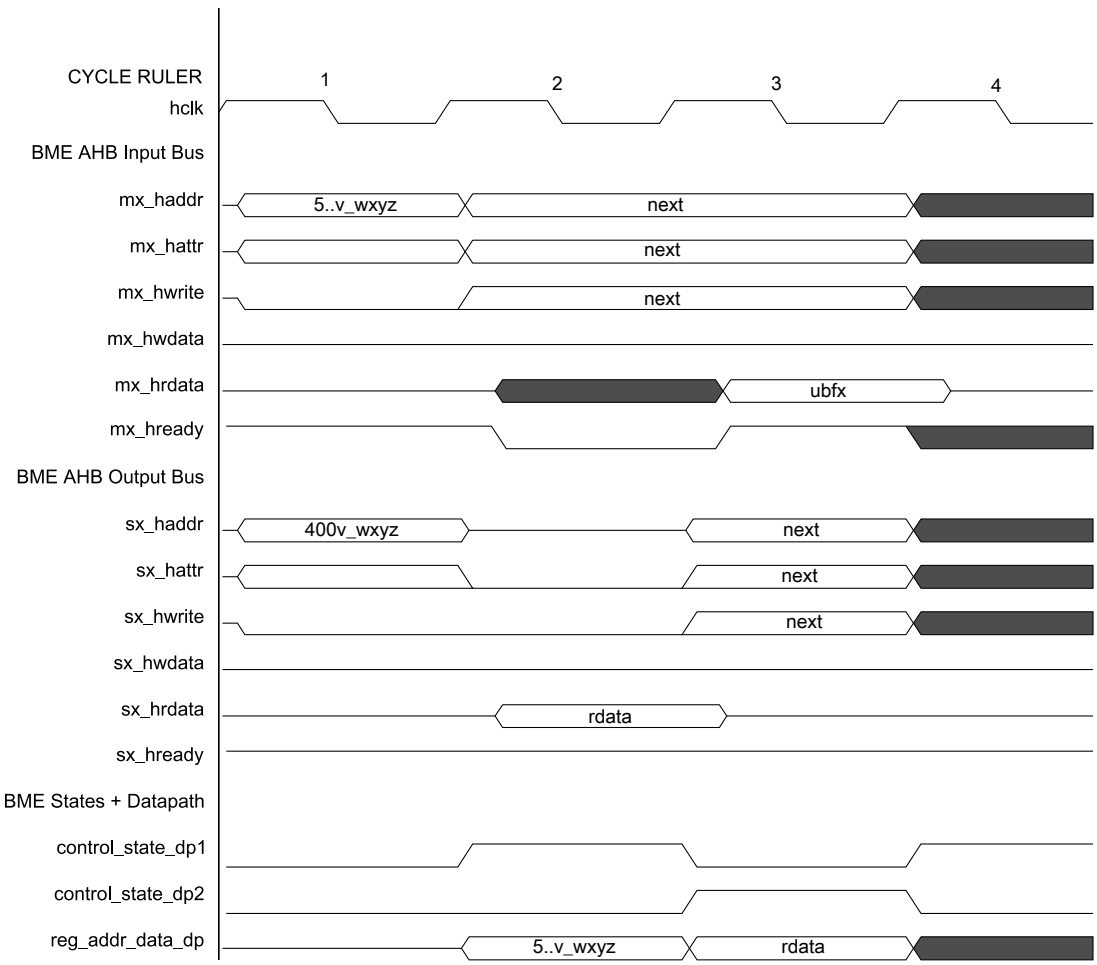

Figure 8-7. Decorated load: unsigned bit field insert timing diagram

The decorated unsigned bit field extract follows the same execution template shown in the above figure, a 2-cycle read operation:

- Cycle x, 1st AHB address phase: Read from input bus is translated into a read operation on the output bus with the actual memory address (with the decoration removed) and then captured in a register
- Cycle x+1, 2nd AHB address phase: Idle cycle

- Cycle x+1, 1st AHB data phase: A bit mask is generated based on the starting bit position and the field width; the mask is AND'ed with the memory read data to isolate the bit field; the resulting data is captured in a data register; the input bus cycle is stalled
- Cycle x+2, 2nd AHB data phase: Registered data is logically right-aligned for proper alignment and driven onto the input read data bus

NOTE

Any wait states inserted by the slave device are simply passed through the BME back to the master input bus, stalling the AHB transaction cycle for cycle.

8.5.2.1 Decorated load: load-and-clear 1 bit (LAC1)

This command loads a 1-bit field defined by the LSB position (b) into the core's general purpose destination register (Rt) and zeroes the bit in the memory space after performing an atomic read-modify-write sequence.

The extracted 1-bit data field from the memory address is right-justified and zero-filled in the operand returned to the core.

The data size is specified by the read operation and can be byte (8-bit), halfword (16-bit) or word (32-bit).

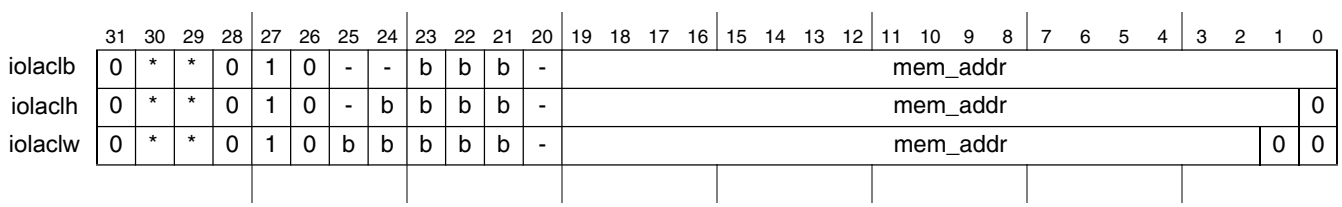

Figure 8-8. Decorated load address: load-and-clear 1 bit

See Figure 8-8, where addr[30:29] = 10 for peripheral, addr[28:26] = 010 specifies the load-and-clear 1 bit operation, addr[25:21] is "b", the bit identifier, and mem_addr[19:0] specifies the address offset into the space based at 0x4000_0000 for peripheral. The "-" indicates an address bit "don't care".

The decorated load-and-clear 1-bit read operation is defined in the following pseudo-code as:

```
rdata =  iolac1<sz>(accessAddress)              // decorated load-and-clear 1

tmp   =  mem[accessAddress & 0xE00FFFFF, size]  // memory read
mask  =  1 << b                                 // generate bit mask
rdata = (tmp &  mask) >> b                      // read data returned to core
tmp   =  tmp & ~mask                            // modify
mem[accessAddress & 0xE00FFFFF, size] = tmp     // memory write
```

The cycle-by-cycle BME operations are detailed in the following table.

Table 8-7. Cycle definitions of decorated load: load-and-clear 1 bit

Pipeline Stage	Cycle		
	x	x+1	x+2
BME AHB_ap	Forward addr to memory; Decode decoration; Capture address, attributes	Recirculate captured addr + attr to memory as slave_wt	<next>
BME AHB_dp	<previous>	Perform memory read; Form bit mask; Extract bit from rdata; Form (rdata & ~mask) and capture destination data in register	Return extracted bit to master; Perform write sending registered data to memory

8.5.2.2 Decorated Load: Load-and-Set 1 Bit (LAS1)

This command loads a 1-bit field defined by the LSB position (b) into the core's general purpose destination register (Rt) and sets the bit in the memory space after performing an atomic read-modify-write sequence.

The extracted one bit data field from the memory address is right justified and zero filled in the operand returned to the core.

The data size is specified by the read operation and can be byte (8-bit), halfword (16-bit) or word (32-bit).

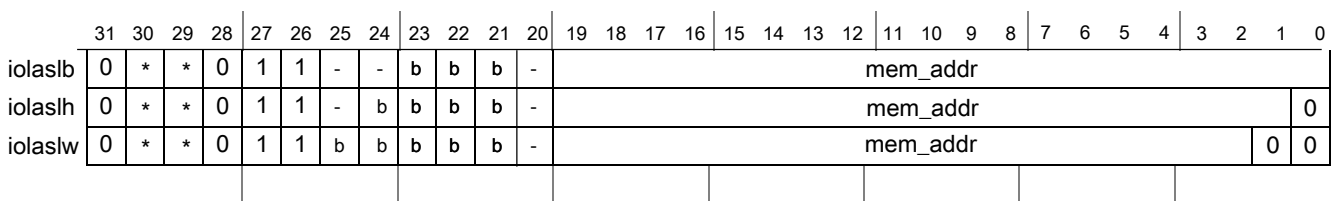

Figure 8-9. Decorated load address: load-and-set 1 bit

where addr[30:29] = 10 for peripheral, addr[28:26] = 011 specifies the load-and-set 1 bit operation, addr[25:21] is "b", the bit identifier, and mem_addr[19:0] specifies the address offset into the space based at 0x4000_0000 for peripheral. The "-" indicates an address bit "don't care".

The decorated Load-and-Set 1 Bit read operation is defined in the following pseudo-code as:

```
rdata =  iolas1<sz>(accessAddress)              // decorated load-and-set 1

tmp   =  mem[accessAddress & 0xE00FFFFF, size]  // memory read
mask  =  1 << b                                 // generate bit mask
rdata = (tmp &  mask) >> b                      // read data returned to core
```

```
tmp    =  tmp |  mask                              // modify
mem[accessAddress & 0xE00FFFFF, size] = tmp       // memory write
```

The cycle-by-cycle BME operations are detailed in the following table.

Table 8-8. Cycle definitions of decorated load: load-and-set 1-bit

Pipeline Stage	Cycle		
	x	x+1	x+2
BME AHB_ap	Forward addr to memory; Decode decoration; Capture address, attributes	Recirculate captured addr + attr to memory as slave_wt	<next>
BME AHB_dp	<previous>	Perform memory read; Form bit mask; Extract bit from rdata; Form (rdata | mask) and capture destination data in register	Return extracted bit to master; Perform write sending registered data to memory

8.5.2.3 Decorated load unsigned bit field extract (UBFX)

This command extracts a bit field defined by LSB position (b) and the bit field width (w +1) from the memory "container" defined by the access size associated with the load instruction using a two-cycle read sequence.

The extracted bit field from the memory address is right-justified and zero-filled in the operand returned to the core. Recall this is the only decorated operation that does not perform a memory write, that is, UBFX only performs a read.

The data size is specified by the write operation and can be byte (8-bit), halfword (16-bit) or word (32-bit). Note for the word sized operation, the maximum bit field width is 16 bits.

The use of a UBFX operation is recommended to extract a single bit. For this case, the w field is simply set to 0, indicating a bit field width of 1.

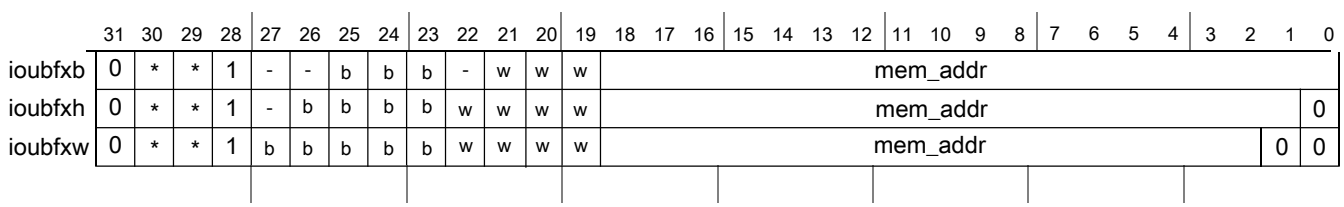

Figure 8-10. Decorated load address: unsigned bit field extract

See Figure 8-10, where addr[30:29] = 10 for peripheral, addr[28] = 1 specifies the unsigned bit field extract operation, addr[27:23] is "b", the LSB identifier, addr[22:19] is "w", the bit field width minus 1 identifier, and mem_addr[18:0] specifies the address

offset into the space based at 0x4000_0000 for peripheral. The "-" indicates an address bit "don't care". Note, unlike the other decorated load operations, UBFX uses addr[19] as the least significant bit in the "w" specifier and not as an address bit.

The decorated unsigned bit field extract read operation is defined in the following pseudo-code as:

```
rdata =  ioubfx<sz>(accessAddress)              // unsigned bit field extract

tmp   =  mem[accessAddress & 0xE007FFFF, size]  // memory read
mask  = ((1 << (w+1)) - 1) << b                 // generate bit mask
rdata = (tmp &  mask) >> b                      // read data returned to core
```

Like the BFI operation, when the starting bit position plus the field width exceeds the container size, only part of the source bit field is extracted from the destination memory location. Stated differently, if (b + w+1) > container_width, only the low-order "container_width - b" bits are actually extracted. The cycle-by-cycle BME operations are detailed in the following table.

Table 8-9. Cycle definitions of decorated load: unsigned bit field extract

Pipeline Stage	Cycle		
	x	x+1	x+2
BME AHB_ap	Forward addr to memory; Decode decoration; Capture address, attributes	Idle AHB address phase	<next>
BME AHB_dp	<previous>	Perform memory read; Form bit mask; Form (rdata & mask) and capture destination data in register	Logically right shift registered data; Return justified rdata to master

8.5.3 Additional details on decorated addresses and GPIO accesses

As previously noted, the peripheral address space occupies a 516 KB region: 512 KB based at 0x4000_0000 plus a 4 KB space based at 0x400F_F000 for GPIO accesses. This memory layout provides compatibility with the Kinetis K Family and provides 129 address "slots", each 4 KB in size.

The GPIO address space is multiply-mapped by the hardware: it appears at the "standard" system address 0x400F_F000 and is physically located in the address slot corresponding to address 0x4000_F000. Decorated loads and stores create a slight complication involving accesses to the GPIO. Recall the use of address[19] varies by decorated operation; for AND, OR, XOR, LAC1 and LAS1, this bit functions as a true address bit, while for BFI and UBFX, this bit defines the least significant bit of the "w" bit field specifier.

As a result, undecorated GPIO references and decorated AND, OR, XOR, LAC1 and LAS1 operations can use the standard 0x400F_F000 base address, while decorated BFI and UBFX operations must use the alternate 0x4000_F000 base address. Another implementation can simply use 0x400F_F000 as the base address for all undecorated GPIO accesses and 0x4000_F000 as the base address for all decorated accesses. Both implementations are supported by the hardware.

Table 8-10. Decorated peripheral and GPIO address details

Peripheral address space	Description
0x4000_0000–0x4007_FFFF	Undecorated (normal) peripheral accesses
0x4008_0000–0x400F_EFFF	Illegal addresses; attempted references are aborted and error terminated
0x400F_F000–0x400F_FFFF	Undecorated (normal) GPIO accesses using standard address
0x4010_0000–0x43FF_FFFF	Illegal addresses; attempted references are aborted and error terminated
0x4400_0000–0x4FFF_FFFF	Decorated AND, OR, XOR, LAC1, LAS1 references to peripherals and GPIO based at either 0x4000_F000 or 0x400F_F000
0x5000_0000–0x5FFF_FFFF	Decorated BFI, UBFX references to peripherals and GPIO only based at 0x4000_F000

8.6 Application information

In this section, GNU assembler macros with C expression operands are presented as examples of the required instructions to perform decorated operations.

This section specifically presents a partial bme.h file defining the assembly language expressions for decorated logical stores: AND, OR, and XOR. Comparable functions for BFI and the decorated loads are more complex and available in the complete BME header file.

These macros use the same function names presented in Functional description.

```
#define IOANDW(ADDR,WDATA)          \
    __asm("ldr    r3, =(1<<26);"    \
          "orr    r3, %[addr];"     \
          "mov    r2, %[wdata];"    \
          "str    r2, [r3];"        \
          :: [addr] "r" (ADDR), [wdata] "r" (WDATA) : "r2", "r3");

#define IOANDH(ADDR,WDATA)          \
    __asm("ldr    r3, =(1<<26);"    \
          "orr    r3, %[addr];"     \
          "mov    r2, %[wdata];"    \
          "strh   r2, [r3];"        \
          :: [addr] "r" (ADDR), [wdata] "r" (WDATA) : "r2", "r3");

#define IOANDB(ADDR,WDATA)          \
    __asm("ldr    r3, =(1<<26);"    \
          "orr    r3, %[addr];"     \
          "mov    r2, %[wdata];"    \
          "strb   r2, [r3];"        \
          :: [addr] "r" (ADDR), [wdata] "r" (WDATA) : "r2", "r3");
```

```
#define IOORW(ADDR,WDATA)            \
    __asm("ldr    r3, =(1<<27);"     \
          "orr    r3, %[addr];"      \
          "mov    r2, %[wdata];"     \
          "str    r2, [r3];"         \
          :: [addr] "r" (ADDR), [wdata] "r" (WDATA) : "r2", "r3");

#define IOORH(ADDR,WDATA)            \
    __asm("ldr    r3, =(1<<27);"     \
          "orr    r3, %[addr];"      \
          "mov    r2, %[wdata];"     \
          "strh   r2, [r3];"         \

Chapter 9
Messaging Unit (MU)

9.1 Chip-specific MU information

Table 9-1. Reference links to related information

Topic	Related module	Reference
Full description	MU	MU
System memory map		System memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port control	Signal multiplexing

9.1.1 Power mode status through Status Register (SR)

MU_SR[PM] bit field in MU_A and MU_B memory maps changes upon power mode entry request, while a power mode is effectively entered only after that request is acknowledged. For accurate power mode status information, the PMC 0 Power Mode Status register (PM_STAT) can be used.

NOTE

It should be noted that Processor B is not able to check Processor A's power mode status through PMC0 whenever the platform clock is gated in the latter's domain. Under such scenario, Processor A's power mode status is only available via MU.

9.1.2 Mode of operation: Wait and Stop

NOTE

For i.MX 7ULP, CA7 WAIT mode is now also seen as STOP (since PSTOP3 is used to emulate WAIT in the application domain). See the description in the PM field.

NOTE

Whenever Processor B's domain (Application Domain) resets and Processor B's reset hold control is active (MU_ACR[RSTH] == 0x1), the following procedure should be observed before deactivating Processor B's reset hold control:

- Ensure Processor B's domain is out of reset (MU_ASR[RS] == 0x0);
- Wait at least 513 Processor B core clock cycles (to ensure the CA7 cache invalidate operation completes).

9.1.3 Messaging Unit

The Messaging Unit (MU) is a shared peripheral with a 32-bit IP bus interface and interrupt request signals to each host processor. The MU exposes a set of registers to each processor which facilitate inter-processor communication via 32-bit words, interrupts and flags. Interrupts may be independently masked by each processor to allow polled-mode operation. The single non-maskable interrupt cannot be masked in the MU.

NOTE

In this chapter, Processor A or core0 refers to CM4 core and Processor B or core1 refers to CA7 core

Table 9-2. Messaging unit configuration

Parameter	Description
Name	Messaging Unit (MU)
Instances	1
Configurable features	NA
Interface speed	NA
External I/O pins	NA

9.2 Overview

The Messaging Unit module enables two processors within the SoC to communicate and coordinate by passing messages (e.g. data, status and control) through the MU interface. The MU also provides the ability for one processor to signal the other processor using interrupts.

Because the MU manages the messaging between processors potentially using different clocks, the MU must synchronize the accesses from one side to the other. The MU accomplishes synchronization using two sets of matching registers (Processor A-facing, Processor B-facing).

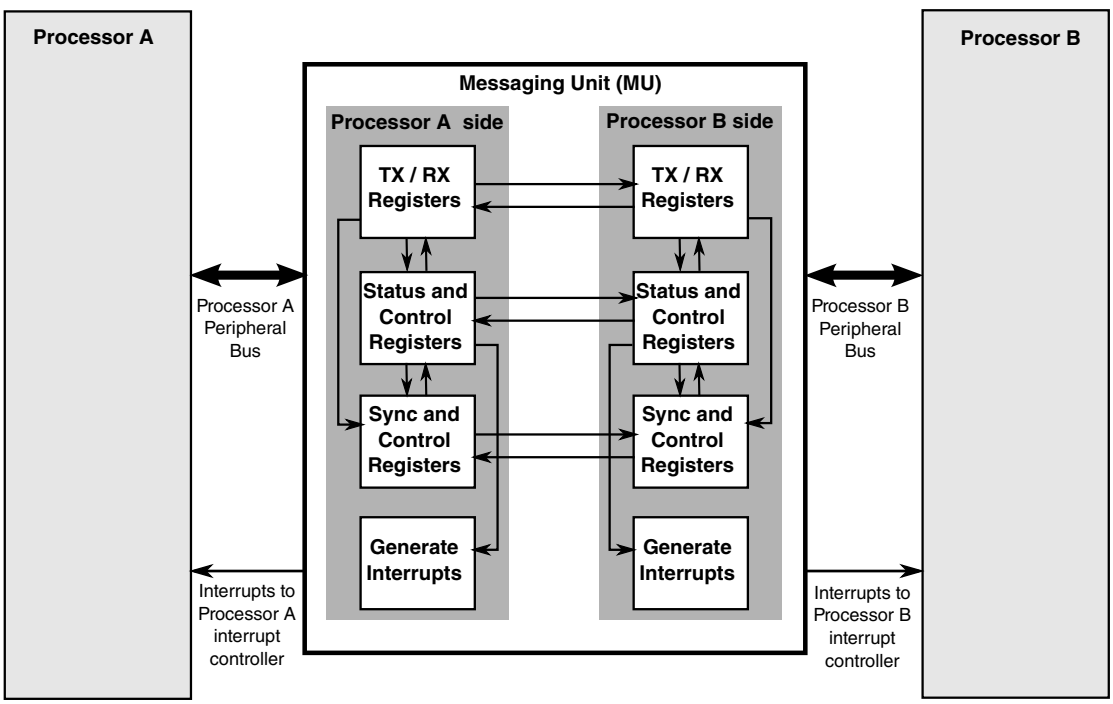

Figure 9-1. MU Block Diagram

9.2.1 Features

The MU includes the following features:

- Messaging control by interrupts or by polling
- Symmetrical processor interfaces with each side supporting the following:
  - Three general-purpose flags reflected to the other side
  - Four general-purpose interrupt requests reflected to the other side

- Four receive registers with maskable interrupt
- Four transmit registers with maskable interrupt

- The Processor B can take the Processor A out of low-power modes by asserting one of the interrupts to the Processor A and vice versa

NOTE

MU chapter references to Processor A may also correspond to Core 0 and references to Processor B may also correspond to Core 1 in other parts of this document.

9.2.2 Modes of Operation

The MU supports the modes described in the indicated sections:

- Low Power Modes

9.3 Register Definition

The MU provides transmit and receive data registers for the communication between Processor A and Processor B. Some control and status registers to the Processor A and Processor B sides for control operations (such as interrupts and reset), and for status checking of the other MU-side. The following diagram shows the MU registers schematic.

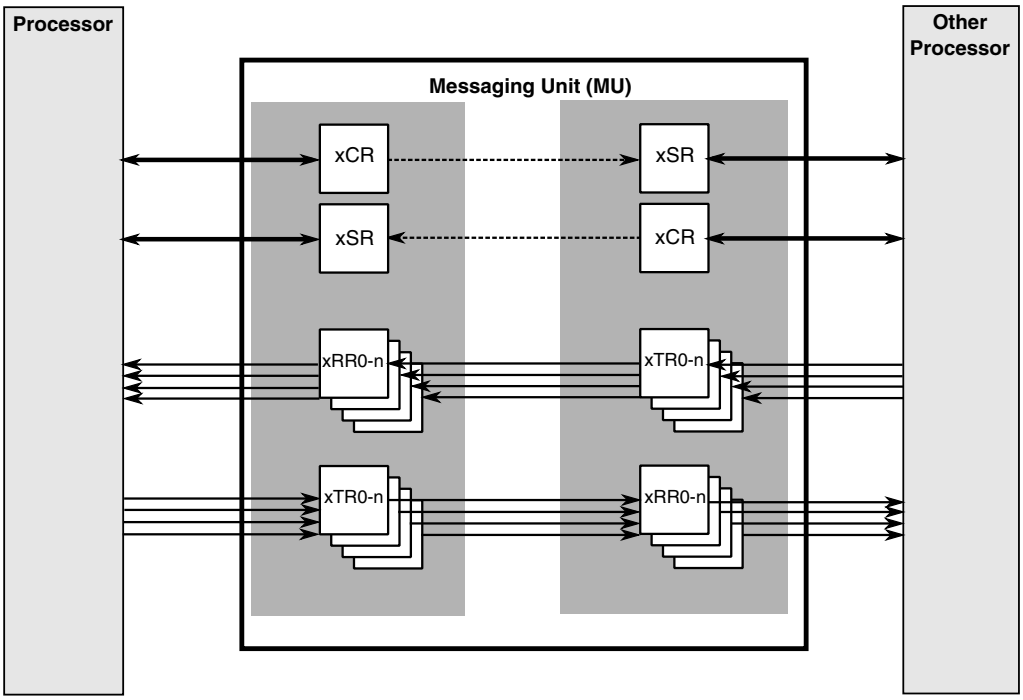

Figure 9-2. MU Registers

The detailed MU Register Definition can be found below.

NOTE

Writing to an RRn register can cause a transfer error.

9.3.1 MUA register descriptions

This section contains the detailed register descriptions for the MUA registers.

9.3.1.1 MU Memory map

MUA base address: 4102_2000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Version ID Register (VER)	32	RO	0100_0001h
4h	Parameter Register (PAR)	32	RO	0000_0000h
20h - 2Ch	Transmit Register (TR0 - TR3)	32	RW	0000_0000h

Table continues on the next page...

Offset	Register	Width (In bits)	Access	Reset value
40h - 4Ch	Receive Register (RR0 - RR3)	32	RO	0000_0000h
60h	Status Register (SR)	32	W1C	00F0_0080h
64h	Control Register (CR)	32	RW	See description.

9.3.1.2 Version ID Register (VER)

9.3.1.2.1 Offset

Register	Offset
VER	0h

9.3.1.2.2 Function

Use Version ID register to determine the version ID and feature set number of MUA.

9.3.1.2.3 Diagram

9.3.1.3.4 Fields

Field	Function
31-0 PARAMETER	This bitfield contains the parameter settings of MUA.

9.3.1.4 Transmit Register (TR0 - TR3)

9.3.1.4.1 Offset

Register	Offset
TR0	20h
TR1	24h
TR2	28h
TR3	2Ch

9.3.1.4.2 Function

Use MUA Transmit Register (TRn, 32-bit, write-only) to transmit a message or data to MUB.

- You can only write to the TRn register when the TEn bit in SR register is set to "1".
- Reading the TRn register returns all zeros.

9.3.1.4.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	DATA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DATA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

9.3.1.4.4 Fields

Field	Function
31-0 DATA	DATA MUA Transmit Register Data. (Write-only) • Data written to the TRn register is reflected in the MUB Receive Register n (RRn). The TRn and RRn registers are not double-buffered, a write to the TRn register overrides the data readable at the RRn register.

Field	Function
	• A write to the transmit register clears a "transmitter empty" bit (TEn) in the MUA Status Register (SR) on the transmitter side, and sets a "receiver full" bit (RFn) in the MUB Status Register (SR) on the receiver side (optionally triggering an interrupt 0 on the MUA side). • Any write to the TRn register will update all status information.

9.3.1.5 Receive Register (RR0 - RR3)

9.3.1.5.1 Offset

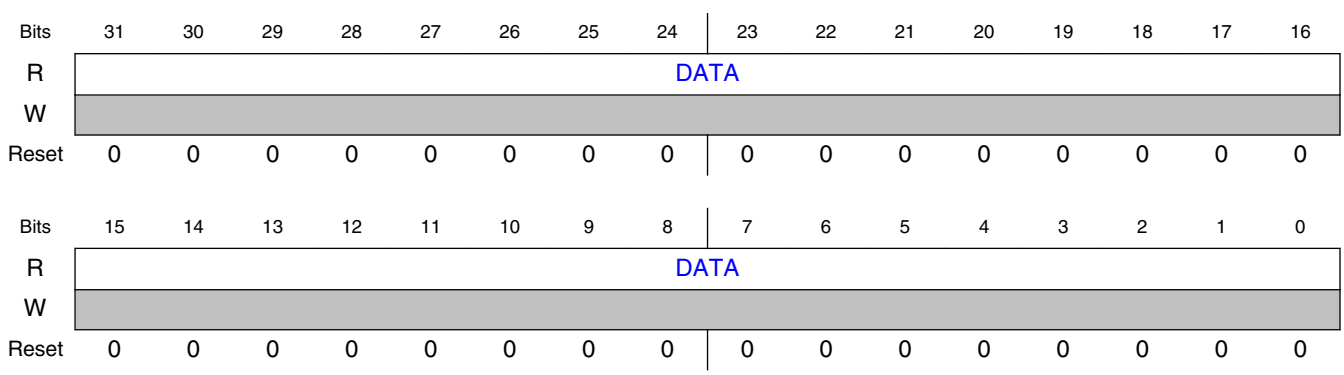
Register	Offset
RR0	40h
RR1	44h
RR2	48h
RR3	4Ch

9.3.1.5.2 Function

Use MUA Receive Register (RRn, 32-bit, read-only) to receive a message or data from the MUB.

- Data written to the MUB TRn register is immediately reflected in the MUA RRn register.
- You can only read the RRn register when the RFn bit in the SR register is set to "1".
- Writing to the RRn register generates an error response to the MUA.

9.3.1.5.3 Diagram



9.3.1.5.4 Fields

Field	Function
31-0 DATA	DATA MUA Receive Register. (Read-only) • Reflects the data written to MUB Transmit Register 0 (TRn). • Reading the RRn register clears the "receiver full" bit (RFn) in the MUA Status Register (SR) on the receiver side, and sets the "transmitter empty" bit (TEn) in the MUB Status Register on the transmitter side (optionally triggering a transmit interrupt 0 on the MUB side). • Any read of the RRn register will update all status information.

9.3.1.6 Status Register (SR)

9.3.1.6.1 Offset

Register	Offset
SR	60h

9.3.1.6.2 Function

Use the Processor A Status Register (SR, 32-bit, read-write) to show interrupt status from the Processor B, general purpose flags, the Processor B power mode, and to set dual function control-status bits.

- Some dual-purpose bits are set by the MU logic, and cleared by the Processor A-side programmer
- Other dual-purpose bits are set by the Processor A-side programmer, and cleared by the MU logic.

9.3.1.6.3 Diagram

9.3.1.6.4 Fields

Field	Function
31-28 GIPn	GIPn For n = {0, 1, 2, 3} MUA General Interrupt Request n Pending. (Read-Write) • GIPn bit signals the MUA that the GIRn bit in the CR register on the MUB side was set from "0" to "1". If the GIEn bit in the MUA CR register is set to "1", a General Interrupt n request is issued. • The GIPn bit is cleared by writing it back as "1". Writing "0", or writing "1" when the GIPn bit is cleared is ignored. Use this feature in the interrupt routine, where the GIPn bit is cleared in order to de-assert the interrupt request source at the interrupt controller. An example of a proper bit clearing sequence is: clear MUA register, set the desired bit, and write it to the MUA SR register, thus clearing the GIPn bit. • GIPn bit is cleared when the MU is reset. 0000b - MUA general purpose interrupt n is not pending. (default) 0001b - MUA general purpose interrupt n is pending.
27-24 RFn	RFn For n = {0, 1, 2, 3} MUA Receive Register n Full. (Read-only) • The RFn bit is set to "1" when the MUB TRn register is written on the MUB side. • After the RFn bit is set to "1", the RFn bit signals the MUA side that new data is ready to be read by the MUA in the MUA RRn register, and a Receive n interrupt is issued on the MUA side (if the RIEn bit in the MUA CR register has been set to "1"). • RFn bit is cleared when the MUA RRn register is read, and when the MU is reset. 0000b - MUA RRn register is not full (default). 0001b - MUA RRn register has received data from MUB TRn register and is ready to be read by the MUA.
23-20 TEn	TEn For n = {0, 1, 2, 3} MUA Transmit Register n Empty. (Read-only) • The TEn bit is set to "1" after the MUB RRn register is read on the MUB side. • After the TEn bit is set to "1", the TEn bit signals the MUA side that the MUA TRn register is ready to be written on the MUA side, and a Transmit n interrupt is issued on the MUA side (if the TEn bit in the MUA CR register is set to "1"). • TEn bit is cleared after the MUA TRn register is written on the MUA side. • TEn bit is set to "1" when the MU is reset. 0000b - MUA TRn register is not empty. 0001b - MUA TRn register is empty (default).
19-15 —	Reserved
14-12 —	Reserved
11 —	Reserved
10 RAIP	RAIP Processor B Reset Asserted Interrupt Pending. (Read-Write) • RAIP bit signals the Processor A-side that the Processor B-side has entered reset.

Table continues on the next page...

Field	Function
	• RAIP bit is set to "1" after the MU Processor B-side enters reset (after synchronization). The interrupt generated by a Processor B-side reset assertion is ORed with the Processor A general purpose interrupt 3. The Processor A general purpose interrupt 3 is issued when the Processor B-side enters reset, if the interrupt is enabled by the RAIE bit. • To clear the RAIP bit, write "1", which also clears general purpose interrupt 3. • When Processor A-side of MU comes out of reset, the RAIP bit has value "0" (default). Processor A will then monitor the reset of Processor B-side and will assert RAIP if its reset asserts. This bitfield is only available on the Processor A side. 0b - Processor B-side did not enter reset 1b - Processor B-side entered reset
9 RDIP	RDIP Processor B Reset De-asserted Interrupt Pending. (Read-Write) • RDIP bit signals the Processor A-side that the Processor B-side has come out of reset. • RDIP bit is set to "1" after the MU Processor B-side comes out of reset, after synchronization. The interrupt generated by a Processor B-side reset de-assertion is ORed with the Processor A general purpose interrupt 3. The Processor A general purpose interrupt 3 is issued when the Processor B-side comes out of reset if the interrupt is enabled by the RDIE bit. • To clear the RDIP bit, write "1", which also clears general purpose interrupt 3. • When Processor A-side of MU comes out of reset, the RDIP bit has value "0"(default). Processor A then monitors the reset of Processor B and will assert RDIP reset deasserts. This takes 5-6 clock cycles, so may result in the RDIP bit being asserted after Processor A exits reset. This bitfield is only available on the Processor A side. 0b - Processor B-side did not exit reset 1b - Processor B-side exited from reset
8 FUP	FUP MUA Flags Update Pending. (Read-only) • FUP bit is set to "1" when the MUA side sends a Flags Update request to the MUB side. • A Flags Update request is generated when there is a change to the Fn[2:0] bits of the MUA CR register. No flag update changes are allowed while the FUP bit is set to "1". Any write to the Fn[2:0] bits of the MUA CR register, while the FUP bit is set to "1", will not generate a Flags Update event, and the Fn[2:0] bits will stay unchanged. • FUP bit is cleared when this Flags Update request is internally acknowledged (that the flag is updated) from the MU MUB side, and during MU reset. 0b - No flags updated, initiated by the MUA, in progress (default) 1b - MUA initiated flags update, processing
7 RS	RS MUB Reset State. (Read-only) • RS bit indicates if the MUB side of the MU is in a reset state or not. • If the RS bit is set to "1", then the MUB side of the MU is still in the reset state. • If the RS bit is cleared, then the MUB side of the MU are out of reset. • The RS bit is set to "1" during: a MUB system reset, or an MU reset (caused by setting the MUR bit at the CR register). • The RS bit is cleared when the reset sequence on the MUB side of the MU ends. After issuing any of the reset events mentioned previously, you should verify that the RS bit is cleared before starting any accesses. • When the MUB processor comes out of reset, the RS bit has value "1"(default). 0b - The MUB side of the MU is not in reset. 1b - The MUB side of the MU is in reset.
6-5	PM

Table continues on the next page...

Field	Function
PM	Processor B-side Power Mode. (Read-only) • PM[1:0] bits indicate the Processor B-side power mode. **NOTE:** The Processor B Power Mode is platform-specific. 00b - The MUB processor is in Run Mode. 01b - The MUB processor is in WAIT Mode. 10b - The MUB processor is in STOP/VLPS Mode. 11b - The MUB processor is in LLS/VLLS Mode.
4 EP	EP MUA Side Event Pending. (Read-only) • EP bit is set to "1" when the MUA side mechanism sends an event update request to the MUB side. • EP bit is cleared when the event update acknowledge is received. An "event" is any hardware message that is reflected in the MUB SR register on the MUB side (for example, "transmit register 0 written"). During normal operations, you do not have to deal with the state of the EP bit because the event update mechanism works automatically. • To ensure events have been posted to MUB before entering STOP mode, you should verify that the EP bit is cleared. If EP bit is set to "1", you should wait and continue to poll it (EP bit) before entering STOP mode. • Reading the MUA SR register (to check the EP bit) should be the last access to the MU that should be performed before entering STOP or WAIT modes; otherwise, the EP bit may be set by subsequent additional actions. • The EP bit is cleared when the MU resets. 0b - The MUA side event is not pending (default). 1b - The MUA side event is pending.
3 NMIC	NMIC Processor A Non-Maskable-Interrupt Clear. (Write-only) • NMIC bit is used by the Processor A-side MU Non-Maskable Interrupt service routine to clear the non-maskable interrupt. • Writing NMIC bit as "1" signals the MU to clear the NMI bit in the MUB CR register, thus de-asserting the interrupts and enabling the NMI bit to receive another interrupt. • The NMIC bit is always read as "0"; therefore it (NMIC bit) cannot be polled. The NMIC bit can only be used as part of the interrupt service routine, in which the NMIC bit should only be written as "1" once. • The NMIC bit is cleared when the MU resets. 0b - Default 1b - Writing "1" clears the NMI bit in the MUB CR register.
2-0 Fn	Fn For n = {0, 1, 2} MUA Side Flag n. (Read-only) • Fn bit is the MUA side flag that reflects the values written to the Fn bit in the MUB control register. • Every time that the Fn bit in the MUB CR register is written, the Fn bit in the MUB CR register write event updates the Fn bit in the MUA SR register after the event update latency, which is measured in terms of the number of clocks of the MUB and the MUA. 000b - Fn bit in the MUB CR register is written 0 (default). 001b - Fn bit in the MUB CR register is written 1.

9.3.1.7 Control Register (CR)

9.3.1.7.1 Offset

Register	Offset
CR	64h

9.3.1.7.2 Function

Use the Control Register (CR, 32-bit, read-write) to enable the MU interrupts on the MUA-side, and trigger events and interrupts on the MUB-side (general purpose interrupt, flag update).

9.3.1.7.3 Diagram

9.3.1.7.4 Fields

Field	Function
31-28 GIEn	GIEn For n = {0, 1, 2, 3} MUA General Purpose Interrupt Enable n. (Read-Write) • GIEn bit enables MUA General Interrupt n. • If GIEn bit is set to "1" (enabled), then a General Interrupt n request is issued when the GIPn bit in the MUA SR register is set to "1". • If GIEn is cleared (disabled), then the value of the GIPn bit is ignored and no General Interrupt n request will be issued. • GIEn bit is cleared when the MU resets. 0000b - Disables MUA General Interrupt n. (default) 0001b - Enables MUA General Interrupt n.
27-24 RIEn	RIEn For n = {0, 1, 2, 3} MUA Receive Interrupt Enable n. (Read-Write) • RIEn bit enables MUA Receive Interrupt n.

Table continues on the next page...

Field	Function
	• If RIEn bit is set to "1" (enabled), then an MUA Receive Interrupt n request is issued when the RFn bit in the MUA SR register is set to "1". • If RIEn bit is cleared (disabled), then the value of the RFn bit is ignored and no MUA Receive Interrupt n request will be issued. • RIEn bit is cleared when the MU resets. 0000b - Disables MUA Receive Interrupt n. (default) 0001b - Enables MUA Receive Interrupt n.
23-20 TIEn	TIEn For n = {0, 1, 2, 3} MUA Transmit Interrupt Enable n. (Read-Write) • TIEn bit enables MUA Transmit Interrupt n. • If TIEn bit is set to "1" (enabled), then an MUA Transmit Interrupt n request is issued when the TEn bit in the MUA SR register is set to "1". • If TIEn bit is cleared (disabled), then the value of the TEn bit is ignored and no MUA Transmit Interrupt n request will be issued. • TIEn bit is cleared when the MU resets. 0000b - Disables MUA Transmit Interrupt n. (default) 0001b - Enables MUA Transmit Interrupt n.
19-16 GIRn	GIRn For n = {0, 1, 2, 3} MUA General Purpose Interrupt Request n. (Read-Write) • Writing "1" to the GIRn bit sets the GIPn bit in the MUB SR register on the Processor B-side. If the GIEn bit in the MUB CR register is set to "1" on the MUB side, a General Purpose Interrupt n request is triggered. • The GIRn bit is cleared if the GIPn bit (in the MUB SR register on the MUB side) is cleared by writing it (GIPn bit) as "1", thereby signalling the MUA that the interrupt was accepted (cleared by the software). The GIPn bit cannot be written as "0" on the MUA side. • To ensure proper operations, you must verify that the GIRn bit is cleared (meaning that there is no pending interrupt) before setting it (GIRn bit). • GIRn bit is cleared when the MU resets. 0000b - MUA General Interrupt n is not requested to the MUB (default). 0001b - MUA General Interrupt n is requested to the MUB.
15-13 —	Reserved
12 RAIE	RAIE Processor B Reset Assertion Interrupt Enable. (Read-Write) • RAIE bit enables Processor A General Interrupt 3. • If RAIE bit is set to "1", then General Interrupt 3 request is issued to the Processor A when the RAIP bit in the SR register is set to "1". • If RAIE is cleared, then the value of the RAIP bit is ignored and no General Interrupt 3 request will be issued. • The RAIE bit is cleared when the MU resets. This bit is only available on the Processor A side. 0b - Disables Processor A General Purpose Interrupt 3 request due to Processor B reset assertion. 1b - Enables Processor A General Purpose Interrupt 3 request due to Processor B reset assertion.
11 —	Reserved
10-9 BBOOT	Processor B Boot Config. Configures the boot source for Processor B.

Table continues on the next page...

Field	Function
	These bits are only available on the Processor A side. 00b - Boot from 0x0 01b - Boot from DMEM Base 10b - Boot from IMEM Base 11b - Reserved
8 CLKE	MUB clock enable When set, forces MUB platform clock to remain enabled even after MUB has entered a stop mode. When clear, allows MUB to gate its platform clock whenever desired after entering a stop mode. Note that if MUA also enters a stop mode, then this bit is overidden to allow MUB to gate its platform clock. 0b - MUB platform clock gated when MUB enters a stop mode. 1b - MUB platform clock kept running after MUB enters a stop mode, until MUA also enters a stop mode.
7 RSTH	Processor B Reset Hold When set, will cause Processor B to be held in reset following any reset event. When cleared, allows Processor B to be released from reset. Setting this bit will not force Processor B into reset. It will only hold Processor B if it resets itself. This bit is only available on the Processor A side. 0b - Release Processor B from reset 1b - Hold Processor B in reset
6 RDIE	RDIE Processor B Reset De-assertion Interrupt Enable. (Read-Write) • RDIE bit enables Processor A General Interrupt 3. • If RDIE bit is set to "1", then General Interrupt 3 request is issued to the Processor A when the RDIP bit in the MUA SR register is set to "1". • If RDIE is cleared, then the value of the RDIP bit is ignored and no General Interrupt 3 request will be issued. • The RDIE bit is cleared when the MU resets. This bit is only available on the Processor A side. 0b - Disables Processor A General Purpose Interrupt 3 request due to Processor B reset de-assertion. 1b - Enables Processor A General Purpose Interrupt 3 request due to Processor B reset de-assertion.
5 MUR	MUR MU Reset. • Setting MUR bit to "1" resets both the Processor A and the Processor B sides of the MU module, forcing all control and status registers to return to their default values and all internal states to be cleared. • The BOOT and RSTH fields will not be affected by the MUR bit. • Before setting the MUR bit to "1", it is advisable to interrupt the Processor B , because setting the MUR bit may affect the ongoing Processor B program. • After setting the MUR bit, you should monitor the value of the RS bit in the MUA SR register to know when the reset sequence on the Processor B-side has ended. • MUR bit can only be written as "1". • MUR bit is always read as "0". • MUR bit is cleared during the MU reset sequence. This bit is only available on the Processor A side. 0b - N/A. Self clearing bit (default). 1b - Asserts the MU reset.

Table continues on the next page...

Field	Function
4 BHR	BHR Processor B Hardware Reset. (Read-Write) • BHR bit asserts and de-asserts the hardware reset of the Processor B. • Set BHR bit to "1" to start a hardware reset of the Processor B. • Clear the BHR bit to de-assert the Processor B hardware reset input. • Assert the BHR bit for a minimum of 3 clock cycles. The RS bit in MUA SR register indicates the state of the Processor B. As soon as the Processor B goes into Reset (MUA RS bit is set to "1"), the BHR bit can be de-asserted. • Strobe-setting the BHR bit will not cause an internal MU reset but will be routed outside MU to Processor B domain reset logic • After clearing the BHR bit, monitor the value of the RS bit at the MUA SR to know when the Processor B reset sequence has ended. • The BHR reset issued by the Processor A to the Processor B is maskable by the Processor B (according to the settings of the BHRM bit in the BCR register). If the BHRM bit (in the BCR register) is set to "1", then the BHR reset is masked; if the BHRM bit (in the BCR register) is cleared (default), then the BHR reset is enabled. • The BHR bit does not return to the reset value during the software (MUR) reset. 0b - De-assert Hardware reset to the Processor B. (default) 1b - Assert Hardware reset to the Processor B.
3 NMI	NMI MUB Non-maskable Interrupt. (Read-Write) • When NMI bit is set to "1", it initiates a Non-Maskable Interrupt to the Processor B. • NMI bit is cleared by the MU after the MUB asserts the NMIC bit in the MUB SR register. • After the NMI bit is cleared, the MUA can initiate another non-maskable interrupt to the MUB. • The NMI bit is cleared when the MU resets. 0b - Non-maskable interrupt is not issued to the Processor B by the Processor A (default). 1b - Non-maskable interrupt is issued to the Processor B by the Processor A.
2-0 Fn	Fn For n = {0, 1, 2} MUA to MUB Flag n. (Read-Write) • Fn bit is a read-write flag that is reflected in Fn bit in the MUB SR register on the MUB side. • Fn bit is cleared when the MU resets. 000b - Clears the Fn bit in the SR register. 001b - Sets the Fn bit in the SR register.

9.3.2 MUB register descriptions

This section contains the detailed register descriptions for the MUB registers.

9.3.2.1 MU Memory map

MUB base address: 4022_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Version ID Register (VER)	32	RO	0100_0001h
4h	Parameter Register (PAR)	32	RO	0000_0000h
20h - 2Ch	Transmit Register (TR0 - TR3)	32	RW	0000_0000h
40h - 4Ch	Receive Register (RR0 - RR3)	32	RO	0000_0000h
60h	Status Register (SR)	32	W1C	00F0_0080h
64h	Control Register (CR)	32	RW	0000_0000h

9.3.2.2 Version ID Register (VER)

9.3.2.2.1 Offset

Register	Offset
VER	0h

9.3.2.2.2 Function

Use Version ID register to determine the version ID and feature set number of MUB.

9.3.2.2.3 Diagram

9.3.2.2.4 Fields

Field	Function
31-24	Major Version Number

Table continues on the next page...

Field	Function
MAJOR	This read only field returns the major version number for MUB.
23-16 MINOR	Minor Version Number This read only field returns the minor version number for MUB.
15-0 FEATURE	Feature Specification Number This read only field returns the feature set number for MUB. 000000000000x1xxb - Core Control and Status Registers are implemented in both MUA and MUB. 000000000000xx1xb - RAIP/RAIE register bits are implemented. 000000000000xxx0b - Standard features implemented

9.3.2.3 Parameter Register (PAR)

9.3.2.3.1 Offset

Register	Offset
PAR	4h

9.3.2.3.2 Function

Use Parameter register to determine the parameter settings of MUB.

9.3.2.3.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	PARAMETER															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

9.3.2.3.4 Fields

Field	Function
31-0 PARAMETER	This bitfield contains the parameter settings of MUB.

9.3.2.4 Transmit Register (TR0 - TR3)

9.3.2.4.1 Offset

Register	Offset
TR0	20h
TR1	24h
TR2	28h
TR3	2Ch

9.3.2.4.2 Function

Use MUB Transmit Register (TRn, 32-bit, write-only) to transmit a message or data to MUA.

- You can only write to the TRn register when the TEn bit in SR register is set to "1".
- Reading the TRn register returns all zeros.

9.3.2.4.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	DATA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DATA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

9.3.2.4.4 Fields

Field	Function
31-0 DATA	DATA MUB Transmit Register Data. (Write-only) • Data written to the TRn register is reflected in the MUA Receive Register n (RRn). The TRn and RRn registers are not double-buffered, a write to the TRn register overrides the data readable at the RRn register.

Field	Function
	• A write to the transmit register clears a "transmitter empty" bit (TEn) in the MUB Status Register (SR) on the transmitter side, and sets a "receiver full" bit (RFn) in the MUA Status Register (SR) on the receiver side (optionally triggering an interrupt 0 on the MUB side). • Any write to the TRn register will update all status information.

9.3.2.5 Receive Register (RR0 - RR3)

9.3.2.5.1 Offset

Register	Offset
RR0	40h
RR1	44h
RR2	48h
RR3	4Ch

9.3.2.5.2 Function

Use MUB Receive Register (RRn, 32-bit, read-only) to receive a message or data from the MUA.

- Data written to the MUA TRn register is immediately reflected in the MUB RRn register.
- You can only read the RRn register when the RFn bit in the SR register is set to "1".
- Writing to the RRn register generates an error response to the MUB.

9.3.2.5.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	DATA															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

9.3.2.5.4 Fields

Field	Function
31-0 DATA	DATA MUB Receive Register. (Read-only) • Reflects the data written to MUA Transmit Register 0 (TRn). • Reading the RRn register clears the "receiver full" bit (RFn) in the MUB Status Register (SR) on the receiver side, and sets the "transmitter empty" bit (TEn) in the MUA Status Register on the transmitter side (optionally triggering a transmit interrupt 0 on the MUA side). • Any read of the RRn register will update all status information.

9.3.2.6 Status Register (SR)

9.3.2.6.1 Offset

Register	Offset
SR	60h

9.3.2.6.2 Function

Use the Processor B Status Register (SR, 32-bit, read-write) to show interrupt status from the Processor A, general purpose flags, the Processor A power mode, and to set dual function control-status bits.

- Some dual-purpose bits are set by the MU logic, and cleared by the Processor B-side programmer
- Other dual-purpose bits are set by the Processor B-side programmer, and cleared by the MU logic.

9.3.2.6.4 Fields

Field	Function
31-28 GIPn	GIPn For n = {0, 1, 2, 3} MUB General Interrupt Request n Pending. (Read-Write) • GIPn bit signals the MUB that the GIRn bit in the CR register on the MUA side was set from "0" to "1". If the GIEn bit in the MUB CR register is set to "1", a General Interrupt n request is issued. • The GIPn bit is cleared by writing it back as "1". Writing "0", or writing "1" when the GIPn bit is cleared is ignored. Use this feature in the interrupt routine, where the GIPn bit is cleared in order to de-assert the interrupt request source at the interrupt controller. An example of a proper bit clearing sequence is: clear MUB register, set the desired bit, and write it to the MUB SR register, thus clearing the GIPn bit. • GIPn bit is cleared when the MU is reset. 0000b - MUB general purpose interrupt n is not pending. (default) 0001b - MUB general purpose interrupt n is pending.
27-24 RFn	RFn For n = {0, 1, 2, 3} MUB Receive Register n Full. (Read-only) • The RFn bit is set to "1" when the MUA TRn register is written on the MUA side. • After the RFn bit is set to "1", the RFn bit signals the MUB side that new data is ready to be read by the MUB in the MUB RRn register, and a Receive n interrupt is issued on the MUB side (if the RIEn bit in the MUB CR register has been set to "1"). • RFn bit is cleared when the MUB RRn register is read, and when the MU is reset. 0000b - MUB RRn register is not full (default). 0001b - MUB RRn register has received data from MUA TRn register and is ready to be read by the MUB.
23-20 TEn	TEn For n = {0, 1, 2, 3} MUB Transmit Register n Empty. (Read-only) • The TEn bit is set to "1" after the MUA RRn register is read on the MUA side. • After the TEn bit is set to "1", the TEn bit signals the MUB side that the MUB TRn register is ready to be written on the MUB side, and a Transmit n interrupt is issued on the MUB side (if the TEn bit in the MUB CR register is set to "1"). • TEn bit is cleared after the MUB TRn register is written on the MUB side. • TEn bit is set to "1" when the MU is reset. 0000b - MUB TRn register is not empty. 0001b - MUB TRn register is empty (default).
19-15 —	Reserved
14-12 —	Reserved
11 —	Reserved
10 —	Reserved
9 —	Reserved

Table continues on the next page...

Field	Function
8 FUP	FUP MUB Flags Update Pending. (Read-only) • FUP bit is set to "1" when the MUB side sends a Flags Update request to the MUA side. • A Flags Update request is generated when there is a change to the Fn[2:0] bits of the MUB CR register. No flag update changes are allowed while the FUP bit is set to "1". Any write to the Fn[2:0] bits of the MUB CR register, while the FUP bit is set to "1", will not generate a Flags Update event, and the Fn[2:0] bits will stay unchanged. • FUP bit is cleared when this Flags Update request is internally acknowledged (that the flag is updated) from the MU MUA side, and during MU reset. 0b - No flags updated, initiated by the MUB, in progress (default) 1b - MUB initiated flags update, processing
7 RS	RS MUA Reset State. (Read-only) • RS bit indicates if the MUA side of the MU is in a reset state or not. • If the RS bit is set to "1", then the MUA side of the MU is still in the reset state. • If the RS bit is cleared, then the MUA side of the MU are out of reset. • The RS bit is set to "1" during: a MUA system reset, or an MU reset (caused by setting the MUR bit at the CR register). • The RS bit is cleared when the reset sequence on the MUA side of the MU ends. After issuing any of the reset events mentioned previously, you should verify that the RS bit is cleared before starting any accesses. • When the MUA processor comes out of reset, the RS bit has value "1"(default). 0b - The MUA side of the MU is not in reset. 1b - The MUA side of the MU is in reset.
6-5 PM	PM Processor A-side Power Mode. (Read-only) • PM[1:0] bits indicate the Processor A-side power mode. **NOTE:** The Processor A Power Mode is platform-specific. 00b - The MUA processor is in Run Mode. 01b - The MUA processor is in WAIT Mode. 10b - The MUA processor is in STOP/VLPS Mode. 11b - The MUA processor is in LLS/VLLS Mode.
4 EP	EP MUB Side Event Pending. (Read-only) • EP bit is set to "1" when the MUB side mechanism sends an event update request to the MUA side. • EP bit is cleared when the event update acknowledge is received. An "event" is any hardware message that is reflected in the MUA SR register on the MUA side (for example, "transmit register 0 written"). During normal operations, you do not have to deal with the state of the EP bit because the event update mechanism works automatically. • To ensure events have been posted to MUA before entering STOP mode, you should verify that the EP bit is cleared. If EP bit is set to "1", you should wait and continue to poll it (EP bit) before entering STOP mode. • Reading the MUB SR register (to check the EP bit) should be the last access to the MU that should be performed before entering STOP or WAIT modes; otherwise, the EP bit may be set by subsequent additional actions. • The EP bit is cleared when the MU resets. 0b - The MUB side event is not pending (default). 1b - The MUB side event is pending.
3	NMIC

Table continues on the next page...

Field	Function
NMIC	Processor B Non-Maskable-Interrupt Clear. (Write-only) • NMIC bit is used by the Processor B-side MU Non-Maskable Interrupt service routine to clear the non-maskable interrupt. • Writing NMIC bit as "1" signals the MU to clear the NMI bit in the MUA CR register, thus de-asserting the interrupts and enabling the NMI bit to receive another interrupt. • The NMIC bit is always read as "0"; therefore it (NMIC bit) cannot be polled. The NMIC bit can only be used as part of the interrupt service routine, in which the NMIC bit should only be written as "1" once. • The NMIC bit is cleared when the MU resets. 0b - Default 1b - Writing "1" clears the NMI bit in the MUA CR register.
2-0 Fn	Fn For n = {0, 1, 2} MUB Side Flag n. (Read-only) • Fn bit is the MUB side flag that reflects the values written to the Fn bit in the MUA control register. • Every time that the Fn bit in the MUA CR register is written, the Fn bit in the MUA CR register write event updates the Fn bit in the MUB SR register after the event update latency, which is measured in terms of the number of clocks of the MUA and the MUB. 000b - Fn bit in the MUA CR register is written 0 (default). 001b - Fn bit in the MUA CR register is written 1.

9.3.2.7 Control Register (CR)

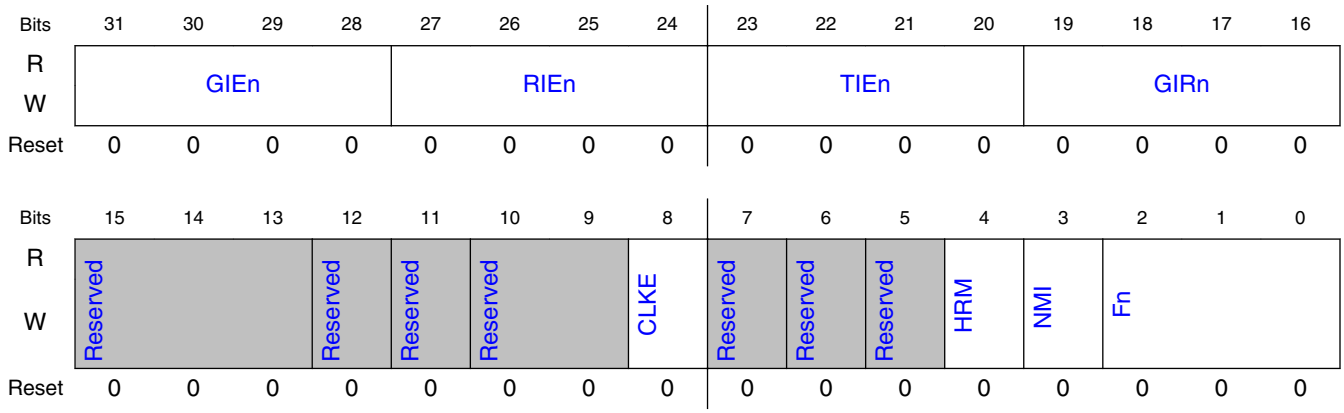
9.3.2.7.1 Offset

Register	Offset
CR	64h

9.3.2.7.2 Function

Use the Control Register (CR, 32-bit, read-write) to enable the MU interrupts on the MUB-side, and trigger events and interrupts on the MUA-side (general purpose interrupt, flag update).

9.3.2.7.3 Diagram



9.3.2.7.4 Fields

Field	Function
31-28 GIEn	GIEn For n = {0, 1, 2, 3} MUB General Purpose Interrupt Enable n. (Read-Write) • GIEn bit enables MUB General Interrupt n. • If GIEn bit is set to "1" (enabled), then a General Interrupt n request is issued when the GIPn bit in the MUB SR register is set to "1". • If GIEn is cleared (disabled), then the value of the GIPn bit is ignored and no General Interrupt n request will be issued. • GIEn bit is cleared when the MU resets. 0000b - Disables MUB General Interrupt n. (default) 0001b - Enables MUB General Interrupt n.
27-24 RIEn	RIEn For n = {0, 1, 2, 3} MUB Receive Interrupt Enable n. (Read-Write) • RIEn bit enables MUB Receive Interrupt n. • If RIEn bit is set to "1" (enabled), then an MUB Receive Interrupt n request is issued when the RFn bit in the MUB SR register is set to "1". • If RIEn bit is cleared (disabled), then the value of the RFn bit is ignored and no MUB Receive Interrupt n request will be issued. • RIEn bit is cleared when the MU resets. 0000b - Disables MUB Receive Interrupt n. (default) 0001b - Enables MUB Receive Interrupt n.
23-20 TIEn	TIEn For n = {0, 1, 2, 3} MUB Transmit Interrupt Enable n. (Read-Write) • TIEn bit enables MUB Transmit Interrupt n. • If TIEn bit is set to "1" (enabled), then an MUB Transmit Interrupt n request is issued when the TEn bit in the MUB SR register is set to "1". • If TIEn bit is cleared (disabled), then the value of the TEn bit is ignored and no MUB Transmit Interrupt n request will be issued. • TIEn bit is cleared when the MU resets. 0000b - Disables MUB Transmit Interrupt n. (default) 0001b - Enables MUB Transmit Interrupt n.

Table continues on the next page...

Field	Function
19-16 GIRn	GIRn For n = {0, 1, 2, 3} MUB General Purpose Interrupt Request n. (Read-Write) • Writing "1" to the GIRn bit sets the GIPn bit in the MUA SR register on the Processor A-side. If the GIEn bit in the MUA CR register is set to "1" on the MUA side, a General Purpose Interrupt n request is triggered. • The GIRn bit is cleared if the GIPn bit (in the MUA SR register on the MUA side) is cleared by writing it (GIPn bit) as "1", thereby signalling the MUB that the interrupt was accepted (cleared by the software). The GIPn bit cannot be written as "0" on the MUB side. • To ensure proper operations, you must verify that the GIRn bit is cleared (meaning that there is no pending interrupt) before setting it (GIRn bit). • GIRn bit is cleared when the MU resets. 0000b - MUB General Interrupt n is not requested to the MUA (default). 0001b - MUB General Interrupt n is requested to the MUA.
15-13 —	Reserved
12 —	Reserved
11 —	Reserved
10-9 —	Reserved
8 CLKE	MUA clock enable When set, forces MUA platform clock to remain enabled even after MUA has entered a stop mode. When clear, allows MUA to gate its platform clock whenever desired after entering a stop mode. Note that if MUB also enters a stop mode, then this bit is overidden to allow MUA to gate its platform clock. 0b - MUA platform clock gated when MUA enters a stop mode. 1b - MUA platform clock kept running after MUA enters a stop mode, until MUB also enters a stop mode.
7 —	Reserved
6 —	Reserved
5 —	Reserved
4 HRM	HRM Processor B Hardware Reset Mask. (Read-Write) • The Processor A can give a hardware reset to the Processor B by setting the BHR bit in the MUA CR Register to “1”. • When the BHRM bit is set to “1” by the Processor B, the BHR reset issued by the Processor A is masked (disabled by the Processor B). • When the BHRM bit is cleared, the BHR reset issued by the Processor A to the Processor B is not masked (enabled by the Processor B). 0b - BHR bit in MUA CR is not masked, enables the hardware reset to the Processor B (default after hardware reset). 1b - BHR bit in MUA CR is masked, disables the hardware reset request to the Processor B.
3	NMI

Table continues on the next page...

Field	Function
NMI	MUA Non-maskable Interrupt. (Read-Write) • When NMI bit is set to "1", it initiates a Non-Maskable Interrupt to the Processor A. • NMI bit is cleared by the MU after the MUA asserts the NMIC bit in the MUA SR register. • After the NMI bit is cleared, the MUB can initiate another non-maskable interrupt to the MUA. • The NMI bit is cleared when the MU resets. 0b - Non-maskable interrupt is not issued to the Processor A by the Processor B (default). 1b - Non-maskable interrupt is issued to the Processor A by the Processor B.
2-0 Fn	Fn For n = {0, 1, 2} MUB to MUA Flag n. (Read-Write) • Fn bit is a read-write flag that is reflected in Fn bit in the MUA SR register on the MUA side. • Fn bit is cleared when the MU resets. 000b - Clears the Fn bit in the SR register. 001b - Sets the Fn bit in the SR register.

9.4 Functional Description

Table 9-3. Major Features of the MU

Major Feature	Description
Interprocessor Interrupts	• The MU has 12 interrupt sources on each side (Processor A-side, Processor B-side) that are used for signaling the other processor. The interrupts can be used for notification of RX/TX events and general-purpose signaling between the processors.
MU Reset	• The Processor A can issue a reset to the entire MU, using a control bit (MUR) in the Processor A Control Register (CR). • The MUR bit is a self-clearing bit.

Processor B Boot Configuration	• The Boot Source for Processor B can be configured with the BOOT bits in the CR register.
	• Boot Source Options are:
	  • DMEM Base Address
	  • IMEM Base Address
	  • Address 0x00

Processor B Reset Hold	• Processor B can be held in reset following any reset event. This is done by setting the RSTH bit in the CR register. • Processor B will be released from reset when this bit is cleared. • The value at reset is loaded from Flash IFR.
Processor A/B Clock Enable	• The Processor A/B platform clock can be enabled to continue running when Processor A/B enters Stop Mode, until Processor B/A also enters Stop Mode. This allows Processor B/A to continue accessing peripherals on Processor A/B's AIPS bus even when it has entered a Stop Mode.
Status and Control Communications between Cores	• The MU provides a way for the two cores to communicate using the status and control registers present on both the Processor B and Processor A sides of the MU. • The status register of one MU side reflects the status of the other MU side. • The control register is used for control operations, such as enabling an interrupt and sending an interrupt to the other processor.

Table continues on the next page...

Table 9-3. Major Features of the MU (continued)

Major Feature	Description
Synchronized Message Transfers between Cores	• The transfer of data messages between cores uses transmit empty and receive full flags provided on both sides of the MU. • The update of these transmit and receive flags is accomplished using a synchronization mechanism. There is inherent latency between updating the flag on one side and reflecting its status on other side. For more about latency, see Event Update Timing
Accessing Shared Memory Directly and Avoiding Collisions	• For sending data or messages from one MU-side to the other MU-side, the MU provides 4 transmit registers and 4 receive registers on each side of the MU. • The Processor A or Processor B can access shared memory resources of the SoC directly. However, to avoid simultaneous access to shared memory by both cores, the MU provides a method (to prevent simultaneous access) using interrupts and transmit-receive registers for both processors.
Memory-Mapped Registers	• The MU is connected as a peripheral under the Peripheral bus on both sides—on the Processor A-side, the Processor A Peripheral Bus, and on the Processor B-side, the Processor B Peripheral Bus.

9.4.1 Processor A Side Memory-Mapping

The messaging, control, and status registers of the Processor A-side for the MU are mapped to the Processor A memory as a regular peripheral. The Peripheral bus data bus is 32 bits wide inside the MU module.

9.4.2 Processor B Side Memory-Mapping

The messaging, control, and status registers of the Processor B-side for the MU are mapped to the Processor B memory as a regular peripheral. The Peripheral bus data bus is 32 bits wide inside the MU module.

9.4.3 MU Messaging

The MU provides 32-bit status and control registers to the Processor B and Processor A sides for control operations (such as interrupts and reset), and for status checking of the other MU-side.

For messaging, the MU has four, 32-bit write-only transmit registers and four, 32-bit read-only receive registers on the Processor B and Processor A-sides. These registers are used for sending messages to each other. These messages can be also be controlled using the 3 general purpose flags provided in the control and status registers of either MU-side.

9.4.3.1 Programmer Model

The messaging logic is used in conjunction with external memory. You have various messaging methods, which you can use to implement a messaging protocol. Some of these messages could mean “I have just written a message of N words, starting at offset X in the memory,” or “I have just finished reading the previous data block that was sent.” Having the messaging logic independent from the memory array does not restrict you to a predefined hardware protocol. On the other hand, the software needed to manage the messaging is short and straightforward.

Most of the messaging mechanisms are symmetric; they are duplicated and are available on both the Processor B-side and the Processor A-side. The messaging mechanisms are:

- Four, 32-bit write-only transmit registers, which are each reflected in four, read-only receive registers in the other processor’s side. You can use these registers to transfer 32-bit word messages or frame information of messages written to the shared memory (number of words, initial address, and message type code).
- A write to a transmit register on the transmitter side clears a “transmitter empty” bit in the Status Register on the transmitter side, and sets a “receiver full” bit in the Status Register on the receiver side. The setting of the bit at the receiver side can optionally trigger an interrupt at the receiver side (maskable receive interrupt).
- A read of one of the receive registers at the receiver side clears the “receiver full” bit in the Status Register at the receiver side, and sets the “transmitter empty” bit in the Status Register on the transmitter side. The setting of the “transmitter empty” bit can optionally trigger an interrupt at the transmitter side (maskable transmit interrupt).
- Four general purpose flags are reflected in the Status Register on the receiver side
- A read/write access to any reserved location and a write to a read-only register on the Processor A-side of the MU will generate a module transfer error acknowledge to the Processor A.
- A read/write access to any reserved location and write to a read-only register on the Processor B-side of the MU will generate a module transfer error acknowledge to the Processor B.

9.4.3.2 Messaging Examples

The following are messaging examples:

- **Passing short messages:** Transmit register(s) can be used to pass short messages from one to four words in length. For example, when a four-word message is desired, only one of the registers needs to have its corresponding interrupt enable bit set at the

receiver side; the message's first three words are written to the registers whose interrupt is masked, and the fourth word is written to the other register (which triggers an interrupt at the receiver side).

- **Passing frame information:** Transmit registers can be used to pass frame information for long messages written to the shared system (SDRAM and SyncFLASH). Such frame information normally includes a start address, number of words, and perhaps a message type code.
- **Passing event notices and requests:** Events and requests that do not include data words can be signaled from the Processor B to the Processor A using the general interrupts, such as acknowledging that a long message was read from the shared system memory.
- **Passing fixed length data:** Formatted data with a fixed length can be written in predetermined locations in the shared memory. A processor can use a general interrupt (Processor A or Processor B) to signal the other processor that the data is ready.
- **Passing announcements:** The three flags can be used by a processor to announce its current program state or other billboard messages to the other processor.

Figure 9-2 shows the MU registers schematic.

9.4.4 Low Power Modes

This section describes the low power operating modes of the MU module.

9.4.4.1 Processor Low Power Modes

The Processors have four power modes:

- Run
- WAIT
- STOP/VLPS
- LLS/VLLS

The Processor can be awakened from a low-power mode by any enabled Processor side MU interrupt, as reflected in the xSR "status" register (RF0–3, TE0–3, GIP0–3 bits are set) and enabled in the xCR control register. Using these bits, the Processor can actively control when to wake the other Processor.

While the Processor is in STOP/VLPS mode (such that the xSR register bits cannot be updated with events), special logic drives the enabled Processor interrupts directly from the other Processor-side (instead of from the xSR register).

While the Processor is in STOP/VLPS mode, the asynchronous Processor interrupt will be asserted to wake the Processor:

- If any transmit data register of the other Processor-side is full, because of a write to it (transmit data register); that is, its “empty” bit in the xSR register is cleared while its corresponding receive interrupt is enabled on the Processor-side.
- If any receive data register of the other Processor-side is empty, because of a read on the other Processor -side; that is, its “full” bit in the xSR register is cleared while its corresponding transmit interrupt is enabled on the Processor-side.
- If any general purpose interrupt is set in the xCR register while the corresponding interrupt is enabled on the Processor-side.
- If the other Processor issues a non-maskable interrupt to the Processor.

The logic enables the other Processor to operate independently while the Processor is in any power mode (including STOP/VLPS). However, the Processor power mode change protocol should be handled with care regarding:

- The interrupts that are enabled on the Processor-side
- The events that could be triggered by the other Processor-side
- The compatibility with the other Processor protocol of entering STOP/VLPS mode

If the Processor is in STOP/VLPS mode and an event on the other Processor is triggered, the EP bit (in the xSR register) will remain high until the Processor wakes up.

Before entering STOP/VLPS mode, the Processor programmer should verify that the EP bit (in the xSR register) is cleared. This check is needed to ensure that all pending updates from the Processor, including the power mode change when STOP/VLPS or WAIT is executed, will be updated in the xSR register.

- If the other Processor is in STOP/VLPS mode or LLS/VLLS mode, the EP bit (in the xSR register) may be stuck high; in this case, the Processor need not check the EP bit before entering STOP/VLPS mode.

9.4.5 Event Update Timing

Each processor’s MU messaging side (Processor A or Processor B) has a hardware mechanism to send “event update requests” to the other processor’s side. An “event” is considered when any information change should be reflected at the Status Register of the receiving processor. The event update latency is the delay between the event being ready at one processor and the resulting update at the Status Register of the other processor.

- The minimum event latency is “1 clock of the sending side” + “2 1/2 clocks of the receiving side”. The minimum case is if there is no event pending when the new event occurs.
- The maximum event latency is “6 clocks of the sending side” + “6 1/2 clocks of the receiving side.” The maximum case is if the event occurred just after a previous event was sent to the other side. The event update latency will vary between the above-mentioned minimum and maximum latencies, depending on the time at which the subsequent event is triggered.

9.4.6 Interrupts

The MU controls the Processor B interrupt requests to the Processor A, and the Processor A interrupt requests to the Processor B.

This section describes all the interrupts that the module generates.

9.4.6.1 Interrupts to the Processors

There are 12 interrupt sources from the MU to the Processors:

- Four receive interrupts (asserted when the Processors receive full bits are set and enabled in the xCR register) for each of the receive registers
- Four transmit interrupts (asserted when the Processor transmit empty bits are set and enabled in the xCR register) for each of the transmit registers
- Four general purpose interrupts (asserted when the GIP bits are set and enabled in the xCR register)

All the interrupts are maskable in the Processor Control Register (xCR). The MU does not assume any internal priority of these interrupts. Multiple interrupts (for example, Receive 0 and Receive 1 interrupts or any of the transmit and general purpose interrupts) can be asserted at one time. The priority of these interrupts should be resolved by the interrupt controller at the chip level.

The General Purpose Interrupt Pending bits (GIP0, GIP1, GIP2, and GIP3) should be cleared by the software (as part of the interrupt service routine) to de-assert the request to the interrupt controller.

9.4.6.2 General Purpose Interrupt Clearing Sequence

When a Processor writes to the general interrupt bit (GIR), the write event is synchronized to the other Processor clock to set the general interrupt request pending bit (GIP). When the GIP bit is set, and if the general purpose interrupt is enabled on the transmitting Processor side (GIE bit is set), then the receiving Processor general purpose interrupt is issued to the transmitting Processor. The transmitting Processor clears this interrupt by writing a “1” on the GIP bit. The interrupt is de-asserted as soon as the GIP bit is written. The write event of the GIP bit is synchronized to the other Processor clock. The synchronized signal clears the GIR bit. The software should not write the GIR bit again until the GIR bit is cleared.

9.4.7 Interrupt Messaging Protocols

9.4.7.1 Messaging Protocols using Interrupts

The example below describes a four-word messaging sequence sent by the Processor to the other Processor.

In this example, the first, second, and third receive interrupts are disabled, and the fourth receive interrupt is enabled. We write registers sequentially for n = 0, 1, 2, 3. For n = 0, 1, 2, the interrupts are disabled, therefore no interrupt will go to the other core (although interrupt conditions occur). For n = 3, the interrupt is enabled, and the last Receive Interrupt request is generated.

1. Write Sequence
   - The Processor writes the message information sequentially to its Transmit Registers 0, 1, 2.
   - When the write to the Transmit Register 3 occurs, the RF3 bit of the xSR is set after synchronization, and it immediately trigger the Receive Full 3 interrupt to the other Processor.
2. Read Sequence
   - The other Processor receives the Receive Full 3 interrupt and starts reading the message transferred from the receive registers.
   - After Receive Register 3 is read, the interrupt bit is cleared.

The following table and diagram describe the messaging model using transmit/receive registers and interrupt messaging protocol.

Table 9-4. Interrupt Messaging Protocol (Generalized)

Sequence	Action	Description
1	Processor A Data write	A data write to the TRn register by Processor A is immediately reflected in the Processor B RRn register.
2	Clear Tx Empty bit and Set Rx Full bit	The data write to the TRn register • Clears the transmitter empty bit (TEn) in the Processor A Transmit Status Register • Sets the receiver full bit (RFn) in the Processor B Receive Status Register
3	Generate Receive Interrupt request	The setting of the receiver full bit (RFn) in the Receive Status Register generates a Receive Interrupt request to Processor B.
4	Processor B Data read	After receiving the Receive Interrupt request, Processor B performs a data read of the RRn register.
5	Clear Rx Full bit and Set Tx Empty bit	Reading the data out of the RRn register • Clears the receiver full bit (RFn) in the Processor B Receive Status Register • Sets the transmitter empty bit (TEn) in the Processor A Transmit Status Register
6	Generate Transmit Interrupt request	The setting of the transmitter empty bit (TEn) in the Transmit Status Register generates a Transmit Interrupt request to Processor A.

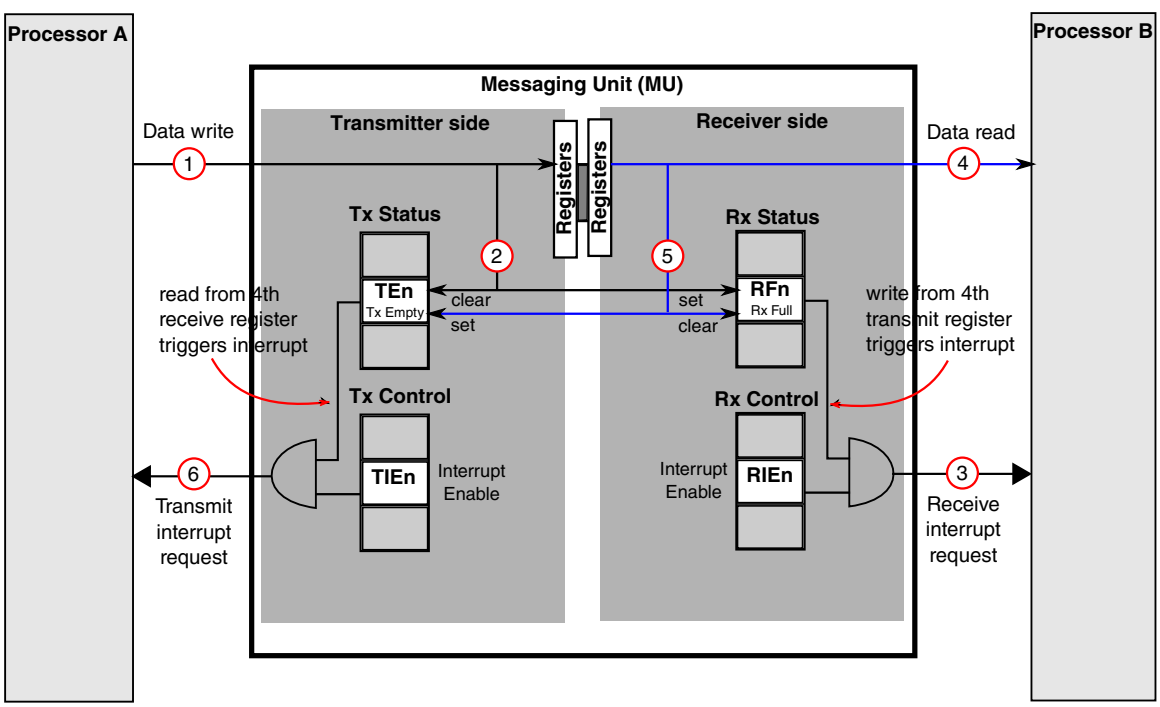


Figure 9-3. Messaging Model Using Transmit and Receive Registers

The messaging hardware can be used by software to implement messaging protocols for a wide array of message types. Full support is given for both interrupt and polling management schemes.

9.4.7.2 Messaging Protocols using Event Interrupts

Events and requests that do not include data words can be signaled from the Processor B to the Processor A using the two general interrupts.

Formatted data with a fixed length can be written in predetermined locations in the shared memory. A processor can use a general purpose interrupt to signal the other processor that the data is ready.

The three flags can be used by a processor to announce to the other processor the program state it is currently in, or to announce similar messages.

Table 9-5 and Figure 9-4 describe the event sequence when the Processor triggers an interrupt.

Table 9-5. Interrupt Messaging Protocol (Generalized)

Sequence	Action	Description
1	Processor A sets General Interrupt request bit	Processor A sets its associated General Interrupt request bit (GIRn = 1) in the control register (ACR).
2	General Interrupt Request Pending status bit is set	The General Interrupt Request Pending status bit (GIPn) in the status register (BSR) is set to "1"
3	General Interrupt request to Processor B is generated	Setting the GIPn bit generates the General Interrupt request to Processor B (Interrupt Request Enable bit, GIEn, must be set for Processor B)
4	Processor B reads status register	The Processor B reads the GIPn bit in the BSR register.
5	Processor B services the interrupt	-
6	Processor B sets GIPn bit to clear interrupt	The Processor B writes "1" to the corresponding GIPn bit to clear the interrupt
7	GIRn bit is cleared	Setting the GIPn bit to "1" clears the General Interrupt request bit (GIRn) in the Processor A control register (ACR).

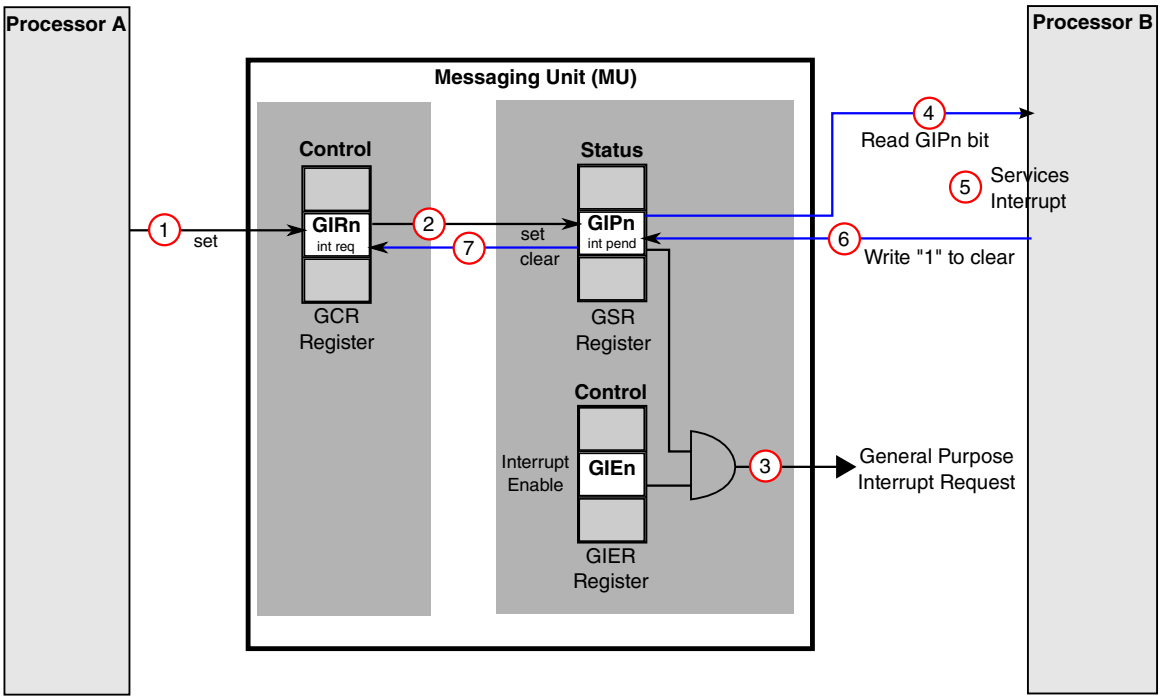

Figure 9-4. Messaging Model Using a General Purpose Interrupt

9.4.8 Exclusive Access to Shared Memory

You can use the MU to signal one processor about its current access to the shared memory, so that the data is not overwritten by the other processor during the exclusive memory access period.

The following tables describe the signaling protocol that the Processor A uses to inform the Processor B about its current access (write) to the shared memory, assuming that the set of bits and registers (GIRn bit, RRn register, TRn register) are reserved to support exclusive access to the shared memory protocol.

Table 9-6. How the Processor A Performs an Exclusive Access to Shared Memory

Sequence	Action	Description
1	Processor A sends GIRn request to Processor B using Processor A control register	When the Processor A wants to perform an exclusive access to the shared memory, the Processor A sends an GIR0 request to the Processor B.
2	Processor A sends an exclusive-access request using a transmit data register (TRn)	The Processor A will send an exclusive-access request (command, location, and length of target access) to Processor B using a selected transmit data register (TR0).
3	Processor A waits for a dedicated interrupt from Processor B	The Processor A waits for a dedicated interrupt (as an acknowledgement) triggered by the Processor B before proceeding.

Table continues on the next page...

Table 9-6. How the Processor A Performs an Exclusive Access to Shared Memory (continued)

Sequence	Action	Description
4	Processor A accesses shared memory	After receiving a dedicated interrupt from the Processor B, Processor A proceeds.

Table 9-7. How the Processor B Scans for Transaction Information

Sequence	Action	Description
1	Processor B receives an interrupt from a receive data register (RRn)	-
2	Processor B reads the receive data register (RRn)	-
3	Processor B scans the receive data register contents	For transaction information (whether Processor A has requested an exclusive-access)

Table 9-8. How the Processor B Accepts Exclusive Access by Processor A

Sequence	Action	Description
1	Processor B triggers a dedicated interrupt	Processor B acknowledges the Processor A request by triggering a dedicated interrupt (ack) to the Processor A.
2	Processor B sends a code message to Processor A	Along with the acknowledge interrupt, the Processor B sends a code message to the Processor A through the selected transmit register (TRn). The message informs the Processor A that it can exclusively access the shared memory.

Table 9-9. How the Processor B Rejects Exclusive Access by Processor A

Sequence	Action	Description
1	Processor B ignores Processor A request for exclusive access	If the Processor B does not want to give go-ahead permission to the Processor A, Processor B ignores the exclusive access request.

9.4.9 Packet Data Transfers

The following example describes the packet transfer sequence between the Processor B and Processor A subsystems:

Table 9-10. Packet Data Transfer Sequence

Action	Sequence	Description
Processor B requests DMA	1	The Processor B sends a DMA request to initiate the packet data transfer

Table continues on the next page...

Table 9-10. Packet Data Transfer Sequence (continued)

Action	Sequence	Description
DMA data transfer	2	DMA acknowledges.
	3	DMA starts transferring data from the specified Processor B location to the specified shared memory
	4	DMA interrupts the Processor B to signal that the packet transfer has finished.
Processor B informs Processor A that data is in shared memory	5	Using an MU Processor B-side transmit register, the Processor B sends a packet information message to the Processor A to inform the Processor A of the arrival of new packet data that is stored in shared memory. The message contains the command, location, and length of packet data information.
Processor A receives interrupt	6	The Processor A receives an interrupt (assuming its corresponding Processor A MU-side receive interrupt is enabled), and the pending processing task becomes active and processes packet data from memory.
Processor A reads data, writes data	7	The Processor A reads or processes packet data from shared memory.
	8	The Processor A writes the result from packet processing to a separate buffer.
Processor A informs Processor B that transfer is finished	9	After the processing of the packet data finishes, the Processor A informs the Processor B (using the MU Processor A-side transmit register, ATRn).
Processor A sends interrupt to Processor B (request for more data)	10	The Processor B receives the next interrupt from the Processor A, in which the Processor A requests more packet data.

9.4.10 Resets

The MU has two sources of reset, and each reset has a different function from the MU or system perspective.

- One asynchronous system that is connected to both sides of the MU interface.
- One programmable hardware reset (MUR bit) in the CR register (on the Processor A-side).

Table 9-11. MU programmable resets

Reset	Description
Processor A MU reset	• Processor A MU Reset bit (MUR) of the CR register • The MUR reset affects the messaging section on both the Processor A and the Processor B sides. The MUR reset causes all control and status registers to return to their default values and all internal states to be cleared. • It is up to the Processor A software to decide whether to use the MUR reset or not. • The instruction immediately following assertion of the MUR bit should not write to MU registers. Such a write may be overwritten by the reset sequence and the register will remain with the reset value. You should wait at least one instruction (after assertion of the MUR bit) before attempting a write to MU registers.

After issuing MUR bit reset events, the Processor A programmer can verify that the reset sequence on the Processor B-side has ended, by checking the RS bit in the SR register.

NOTE

MUR bit assertion is a delicate operation because it affects the other side's registers asynchronously. MUR bit assertion may cause unpredictable behavior if, for example, the Processor B is concurrently testing an MU register bit (TE bit in Processor B SR register). Before asserting the MUR bit, you should verify that the Processor B is not presently engaged in an MU signalling activity.

9.5 Software Restrictions

This section describes certain software restrictions when accessing the MU.

9.5.1 General Restrictions

This section lists the restrictions that apply to both the sides (Processor A, Processor B) of the MU.

9.5.1.1 Write-After-Write to a Transmit Register

A write to a transmit register signals the receiver side that data is ready for retrieval.

- Writing to the transmit register again without verifying that the data was retrieved is prohibited, because the transmitter side has no way of knowing the exact time that the receiver will attempt to retrieve the data.
- Before attempting to write the transmit register again, the transmitter side should wait for a "Transmitter Empty" interrupt, or should poll the "Transmitter Empty" bit in the Status Register.
- Failure to follow this restriction may result in the wrong data being read on the receiver side of the MU.

9.5.1.2 Read-After-Read from a Receive Register

A read of a receive register signals the transmitter side that data can be written to that register. In the same way, the receiver processor should not read a receive register before receiving a "Receiver Full" interrupt or polling the "Receiver Full" bit in the Status Register.

- Reading the receive register again without verifying that the data was written is prohibited, because the receiver side has no way of knowing the exact time that the transmitter will attempt to write the data.
- Before attempting to read the receive register again, the receiver side should wait for a “Receiver Full” interrupt, or should poll the “Receiver Full” bit in the Status Register.
- Failure to follow this restriction may result in the wrong data being written on the transmitter side of the MU.

9.5.2 Processor Restrictions

This section lists the restrictions that apply each side of the processor in the MU.

9.5.2.1 Before Entering Low Power Mode

Before entering Low Power mode, the Processor should verify that the Processor Event Pending (EP) bit in the Status Register is cleared.

- If the Event Pending bit (EP) is still set to “1”, then the Processor should wait and poll the EP bit until it is cleared, before executing the LPM instruction.
- Note that if the other Processor is in Low Power mode (programmed for clock gating in CCM), the EP bit may be stuck high. In this case, the other Processor clock must be turned ON to get the EP bit cleared before the Processor can enter Low Power mode.
- To discover which power mode the other Processor is in, the Processor can check the PM bits in the xSR register.

9.5.2.2 Before Setting a General Interrupt Request Bit (GIR0–3)

Before setting a General Interrupt Request bit (GIR0–3), you must verify that the GIRn bit is cleared, which means that a general interrupt is not pending. Generally, setting the GIRn bit while the bit is set to “1” will be ignored, but in some cases it may issue a second interrupt. This restriction is meant to prevent this indeterministic behavior.

9.5.2.3 Reset Bit Restrictions

The reset bit (MUR, HR) restrictions are:

- Before asserting the MUR bit in the CR register, verify that the Processor B-side is not engaged in some MU activity.
- Do not write to an MU register in the instruction immediately after the assertion of the MUR bit in the CR register, because the written data can be overridden by the reset value.

10.1.1 Hardware Semaphore2 (SEMA42)

The Hardware Semaphore (SEMA42) module provides the hardware support needed in multicore systems for implementing semaphores and provide a simple mechanism to achieve "lock/unlock" operations via a single write access. This approach eliminates architecture specific implementations like atomic (indivisible) read-modify-write instruction or reservation mechanism. The result is an architecture-neutral solution that provides hardware-enforced gates as well as other useful system functions related to the gating mechanisms.

10.2 Introduction

SEMA42 is a memory-mapped module that provides robust hardware support needed in multi-core systems for implementing semaphores and provides a simple mechanism to achieve "lock and unlock" operations via a single - write access. The hardware semaphore module provides hardware-enforced gates as well as other useful system functions related to the gating mechanisms.

10.2.1 Multi-core programming: software gates

Multi-processor systems require a function that can be used to safely and easily provide a locking mechanism for system software to control access to shared data structures, shared hardware resources, and so on. The software uses the gating mechanisms to serialize (and synchronize) accesses to shared data and/or resources to prevent race conditions and preserve memory coherency between different processes and domains.

Consider the following description of a typical use-case: Domain X enters a section of code where shared data values are to be updated. The domain must first acquire a semaphore. Think of this as the locking (or closing) of a software gate. After the gate locks, a properly-architected software system does not allow other processes (or domains) to execute the same code segment or modify the shared data structure protected by the gate. In other words, the system locks out other processes/domains. Many software implementations include a spin-wait loop within the lock function until the gate locks. After domain X obtains the lock, domain X continues execution and updates the data values protected by the particular lock. After domain X completes the updates, it unlocks (or opens) the software gate, allowing other processes/domains access to the updated data values.

A correctly-implemented system solution must follow these important rules:

- A gate variable must protect all writes to shared data values or shared hardware resources.

- After a domain locks a gate, the system must block other processes/domains from accessing the shared data or resources. Software conventions enforce this.
- The domain that locks a particular gate is the only domain that can open (unlock) that gate.

Information in the hardware gate identifying the locking domain can be extremely useful for system-level debugging.

The Hennessy/Patterson text on computer architecture offers the following description for software gating:

"One of the major requirements of a shared-memory architecture multiprocessor is being able to coordinate processes that are working on a common task. Typically, a programmer will use *lock variables* to synchronize the processes.

The difficulty for the architect of a multiprocessor is to provide a mechanism to decide which processor gets the lock and to provide the operation that locks a variable. Arbitration is easy for shared-bus multiprocessors, since the bus is the only path to memory. The processor that gets the bus locks out all the other processors from memory. If the CPU and bus provide an atomic swap operation, programmers can create locks with the proper semantics. The adjective "atomic" is key, for it means that a processor can both read a location and set it to the locked value in the same bus operation, preventing any other processor from reading or writing memory." [Hennessy/Patterson, *Computer Architecture: A Quantitative Approach*]

The classic text continues with a description of the steps required to lock/unlock a variable using an atomic swap instruction:

"Assume that 0 means unlocked and 1 means locked. A processor first reads the lock variable to test its state. A processor keeps reading and testing until the value indicates that the lock is unlocked. The processor then races against all other processes that were similarly "spin waiting" to see who can lock the variable first. All processes use a swap instruction that reads the old value and stores a 1 into the lock variable. The single winner will see the 0, and the losers will see a 1 that was placed there by the winner. (The losers will continue to set the variable to the locked value, but this does not matter.) The winning processor executes the code after the lock and then stores a 0 into the lock when it exits, starting the race all over again. Testing the old value and then setting to a new value is why the atomic swap instruction is called *test and set* in some instruction sets." [Hennessy/Patterson, *Computer Architecture: A Quantitative Approach*]

10.2.2 Features

SEMA42 implements hardware-enforced semaphores as an IPS-mapped slave peripheral device. The feature set includes:

- Support for 16 hardware-enforced gates in a multi-domain configuration that supports up to 15 domains. In this chapter, dm*X* represents domain *X*.
  - Gates appear as a 16-entry byte-size array with read and write accesses.
    - Domains lock gates by writing "domainID_number+1" to the appropriate gate and must read back the gate value to verify that the lock operation succeeded.
    - After the gate locks, the locking domain unlocks the gate by writing zeroes.
  - Each hardware gate appears as a 16-state, 4-bit state machine.
    - 16-state implementation

      If gate = 0h, then state = unlocked
      if gate = 1h, then state = locked by domain (master) 0
      if gate = 2h, then state = locked by domain (master) 1
      …
      if gate = Fh, then state = locked by domain (master) 14
    - SEMA42 uses the logical domain number and the specified data patterns as reference attributes to validate all write operation.
    - After a gate locks, the locking domain must unlock the gate by writing zeroes.
  - Support for secure reset mechanisms to clear the contents of individual gates, as well as a clear-all capability
- Memory-mapped slave peripheral that offers an interface to the IPS bus for programming-model accesses

The following figure shows a simplified SEMA42 block diagram. In the diagram, the register blocks named gate0, gate1,…, gate (n-2) and gate (n-1) include the finite state machines implementing the semaphore gates.

10.3.1.2.2 Function

SEMA42 implements each semaphore gate in a 4-bit finite state machine, right-justified in a byte data structure. The hardware uses the logical domain-identifier number in conjunction with the data patterns to validate all attempted write operations. Only domain masters can modify the gate registers. After a gate locks, only the locking domain must open (unlock) the gate.

You can read multiple gate values in a single access. However, you can update only a single gate at a time, via a write operation. If you attempt to write a data value that is neither the unlock value (00h) nor the appropriate lock value (domainID_number + 1), SEMA42 considers this as "no operation" and does not change any gate state. Attempts to write multiple gates in a single-aligned access with a size larger than 8 bits (byte) generate an error termination and do not allow any gate state changes.

3-0 GTFSM	Gate finite state machine The state of the gate reflects the last domain that locked it. This can be useful during system debug. The hardware gate has a 16-state implementation, defined as: 0000b - The gate is unlocked (free). 0001b - Domain 0 locked the gate. 0010b - Domain 1 locked the gate. 0011b - Domain 2 locked the gate.

Field	Function
	0100b - Domain 3 locked the gate. 0101b - Domain 4 locked the gate. 0110b - Domain 5 locked the gate. 0111b - Domain 6 locked the gate. 1000b - Domain 7 locked the gate. 1001b - Domain 8 locked the gate. 1010b - Domain 9 locked the gate. 1011b - Domain 10 locked the gate. 1100b - Domain 11 locked the gate. 1101b - Domain 12 locked the gate. 1110b - Domain 13 locked the gate. 1111b - Domain 14 locked the gate.

10.3.1.3 Reset Gate Read (RSTGT_R)

10.3.1.3.1 Offset

Register	Offset
RSTGT_R	42h

10.3.1.3.2 Function

This section and Reset Gate Write (RSTGT_W) describe the same register. This section describes the general operation of the register and also shows how the register fields appear when you read the register. Reset Gate Write (RSTGT_W) shows how the register fields appear when you write to the register.

The intent of the hardware gate implementation is to specify a protocol where the locking domain must unlock the gate. However, some systems may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset. To support this special gate reset requirement, SEMA42 implements a secure reset mechanism that allows you to initialize a hardware gate (or all the gates) by following a specific dual-write access pattern. The secure-gate reset:

- Uses a technique similar to that required for the servicing of a software watchdog timer
- Requires two consecutive writes with pre-defined data patterns from the same domain

You must do this to force the clearing of the specified gate(s). The required access pattern as follows:

1. A domain performs a 16-bit write to the RSTGT memory location. The most significant byte (RSTGT_W[RSTGDP]) must be E2h. The value of least significant byte is irrelevant for this reference and can be anything.
2. The same domain then performs a second 16-bit write to the RSTGT location. For this write, the upper byte (RSTGT_W[RSTGDP]) is the logical complement of the first data pattern (1Dh) and the lower byte (RSTGT_W[RSTGTN]) specifies the gate(s) to be reset. This gate field can specify a single gate or all gates to be cleared. If the same domain writes incorrect data on the second access or another domain performs the second write access, SEMA42 aborts the special gate reset sequence and does not assert an error signal.
3. Reads of the RSTGT location return information on the 2-bit state machine (RSTGT_R[RSTGSM]) that implements these functions:
   - The domain performing the reset (RSTGT_R[RSTGMS])
   - The last-cleared gate number(s) (RSTGT_R[RSTGTN])

   Reads of the RSTGT register do not affect the secure-reset finite state machine in any manner.

10.3.1.3.3 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0		RSTGSM		RSTGMS				RSTGTN

10.3.1.3.4 Fields

Field	Function
15-14 ROZ	ROZ This field always returns the value 0 when you read it.
13-12 RSTGSM	Reset gate finite state machine Reads of the RSTGT register return the encoded state machine value. RSTGSM = 10b is valid for only a single machine cycle, so a read can never return this value. SEMA42 maintains the reset state machine in a 2-bit, 3-state implementation, defined as follows: 00b - Idle, waiting for the first data pattern write. 01b - Waiting for the second data pattern write 10b - The 2-write sequence has completed. Generate the specified gate reset(s). After the reset is performed, this machine returns to the idle (waiting for first data pattern write) state. 11b - This state encoding is never used and therefore reserved.
11-8 RSTGMS	Reset gate domain

Table continues on the next page...

Field	Function
	This field records the logical number of the domain performing the gate reset function. The logical number is the domain number. This domain number is determined by the XRDC's Master Domain Assignment Controller (XRDC_MDAC). To succeed, this function requires that the same domain initiate the two consecutive writes to this register. SEMA42 updates the field each time a write to this register occurs.
7-0 RSTGTN	Reset gate number This field specifies the specific hardware gate to be reset. The second write updates this field. If RSTGTN < 64, SEMA42 resets the single gate defined by RSTGTN. Otherwise, SEMA42 resets all the gates.

10.3.1.4 Reset Gate Write (RSTGT_W)

10.3.1.4.1 Offset

Register	Offset
RSTGT_W	42h

10.3.1.4.2 Function

This section describes how the RSTGT fields appear when the register is written. See Reset Gate Read (RSTGT_R) for the description of the register's overall operation and how the register fields appear when you read the register.

10.3.1.4.4 Fields

Field	Function
15-8 RSTGDP	Reset gate data pattern

Table continues on the next page...

Field	Function
	You access this field with the specified data patterns on the two consecutive writes to enable the gate-reset mechanism. For the first write, RSTGDP must be E2h. For the second write, RSTGDP must be 1Dh.
7-0 RSTGTN	Reset gate number This field specifies the specific hardware gate to be reset. The second write updates this field. If RSTGTN < 64, SEMA42 resets the single gate defined by RSTGTN. Otherwise, SEMA42 resets all the gates.

10.4 Functional description

This section describes more about the SEMA42 functional operation and specific details of the state machines of the GATE*n* registers.

As described previously, each of the GATE*n* registers implements a 4-bit, 16-state machine. The following figure shows a simplified diagram of the state transitions for each gate.

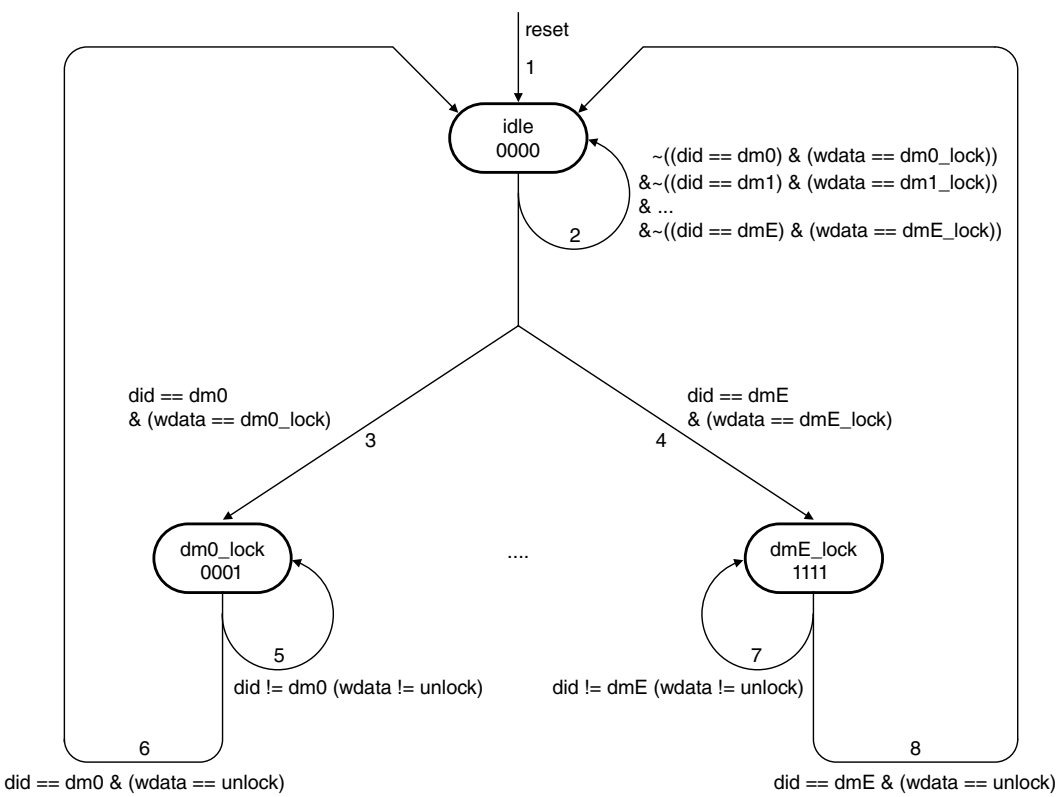

Figure 10-2. GATE*n* state machine

In the figure above, "did" is the domain identifier and "dm" is the domain number. The domain number identifies core domain *X* (dm*X*). Thus, for example, "dmE" represents domain 14 (E in hexadecimal). The platform passes the domain number to SEMA42.

The following table defines the GATE*n* state transitions.

Table 10-3. GATE*n* state transitions

Current state	Next state	Transition	Description
–	idle	1	Any reset, whether a system reset or a software-initiated gate reset, unconditionally forces the gate into the idle state.
idle	idle	2	Unless a write of the appropriate lock value from the corresponding domain occurs, the gate remains in the idle state.
idle	dm0_lock	3	When domain 0h initiates a write of the dm0_lock data value, the gate transitions into the dm0_lock state.
idle	dmE_lock	4	When domain Eh initiates a write of the dmE_lock value, the gate transitions into the dmE_lock state.
dm0_lock	dm0_lock	5	When in this state, the gate remains here if any attempted write is not from domain 0h with the unlock data value.
dm0_lock	idle	6	The gate returns to the idle (unlocked) state after a write from domain 0h with the unlock data value occurs.
dmE_lock	dmE_lock	7	When in this state, the gate remains here if any attempted write is not from domain Eh with the unlock data value.
dmE_lock	idle	8	The gate returns to the idle (unlocked) state after a write from domain Eh with the unlock data value occurs.

SEMA42 uses these gate data values:

- The lock data value is (domain number) + 1.
- The unlock data value is 00h.

11.1.1 Extended Resource Domain Control (XRDC)

The Extended Resource Domain Controller (XRDC) provides an integrated, scalable architectural framework for access control, system memory protection and peripheral isolation. It allows software to assign chip resources (like processor cores, non-core bus masters, memory regions and slave peripherals) to processing domains, to support enforcement of robust operational environments.

The XRDC implementation is distributed across multiple submodules instantiated throughout the device. The XRDC submodules include:

- **XRDC_MGR**: The Manager (MGR) submodule coordinates all programming model reads and writes.
- **XRDC_MDAC**: The Master Domain Assignment Controller (MDAC) handles resource assignments and generation of the domain identifiers.

- **XRDC_MRC**: The Memory Region Controller (MRC) implements the access controls for slave memories based on the pre-programmed region descriptor registers.
- **XRDC_PAC**: The Peripheral Access Controller (PAC) implements the access controls for slave peripherals based on the pre-programmed domain access control registers.

11.1.3 XRDC domain identifier (DID) value

In I.MX 7ULP, the default DID values for Master Domain Assignment registers are defined in the following table.

Table 11-6. Default DID values for MDACFG0-13 registers

MDAn	Default DID value
MDA0-2	0
MDA3-13	1

11.1.4 MRC port number to detect access violation

The DERR_W1[EPORT] identifies the encoded port number of the MRC that detected the access violation. For this device, the MRC port number 0 detects access violation.

11.2 Introduction

The Extended Resource Domain Controller (XRDC) provides an integrated, scalable architectural framework for access control, system memory protection and peripheral isolation. It allows software to assign chip resources including processor cores, non-core bus masters, memory regions and slave peripherals to processing *domains* to support enforcement of robust operational environments. First, each bus mastering resource is assigned to a domain identifier (domainID, DID). For processors, there are additional fields that can optionally be used to assign it to multiple domains. Next, the access control policies for the individual domains are programmed into any number of slave memory region descriptors and slave peripheral domain access control registers. Finally, all accesses throughout the device are monitored concurrently to determine the validity of each and every access. If a reference from a given domain has sufficient access rights, it is allowed to continue, else the access is aborted and error information captured.

The access control scheme defined by the XRDC supports a 4-level model, combining the traditional privileged (also known as supervisor) and user modes with an additional signal defining the secure, nonsecure attributes of each memory reference. The result is a 4-level hierarchical access control mechanism, where:

SecurePriv(ileged) > SecureUser > NonsecurePriv(ileged) > NonsecureUser

with different access control policies based on read and write references. Combined with the user/privileged and secure/nonsecure attributes, a domainID is associated with every system bus transaction and forms the hardware basis for implementation of the XRDC's access control mechanisms.

Access to shared memory regions and slave peripherals can be dynamically controlled with the optional inclusion of a hardware semaphore. If a hardware semaphore is enabled for a given address space or peripheral, then writes to the targeted address space are only allowed if the requesting domain owns the semaphore. This capability allows the access control policy for a given resource to be dynamically revised based on hardware semaphore ownership.

Each core contains its own local memory protection unit to control permissions and manage resources among the various tasks executing on that core. The XRDC adds a second layer of protection for the shared resources in a multicore system by providing an integrated, scalable architectural framework for access control, system memory protection, and peripheral isolation. It allows software to assign chip resources including processor cores, non-core bus masters, memory regions, and slave peripherals to processing domains to support enforcement of robust operational environments.

11.2.1 Features

The key features of the XRDC include:

- Assignment of chip resources to processing "domains"
  - Resources are categorized into four groups:
    - Processor cores
    - non-core bus masters
    - slave memories
    - slave peripherals
  - Each processing domain is assigned a unique domain identifier (domainID, DID)
  - DomainID is a new attribute associated with every system bus transaction
  - Used in conjunction with user/privileged, secure/nonsecure attributes
- Access rights to slave targets defined in region descriptor registers for memories and access control registers for peripherals
- Supports sharing of memory and peripherals with optional inclusion of hardware semaphores to dynamically determine access rights
- Built upon a 4-level hierarchical access control model
  - SecurePriv(ileged) > SecureUser > NonsecurePriv(ileged) > NonsecureUser
  - Encoded into a 3-bit per-domain access control policy (ACP) used throughout the XRDC
  - Certain processors do not support the NonsecurePriv state. For these cores, the model simplifies to a 3-state definition: SecurePriv > SecureUser > NonsecureUser
- Programming model and hardware implementation is distributed across multiple submodules
  - Supports a broad, highly-configurable architecture definition
  - Memory region descriptors support a format leveraged from the Cortex-M Core Memory Protection Unit

11.2.2 Block diagram

As previously noted, the XRDC implementation is distributed across multiple submodules instantiated throughout the device. The XRDC submodules include:

- XRDC_MGR
  - The Manager (MGR) submodule coordinates all programming model reads and writes
- XRDC_MDAC

    - The Master Domain Assignment Controller (MDAC) handles resource assignments and generation of the domain identifiers
- XRDC_MRC
    - The Memory Region Controller (MRC) implements the access controls for slave memories based on the pre-programmed region descriptor registers
- XRDC_PAC
    - The Peripheral Access Controller (PAC) implements the access controls for slave peripherals based on the pre-programmed domain access control registers

For chip-specific implementation details of this module's instances, see the chip configuration information.

See Figure 11-1 for a simplified XRDC block diagram focusing on topology and connections.

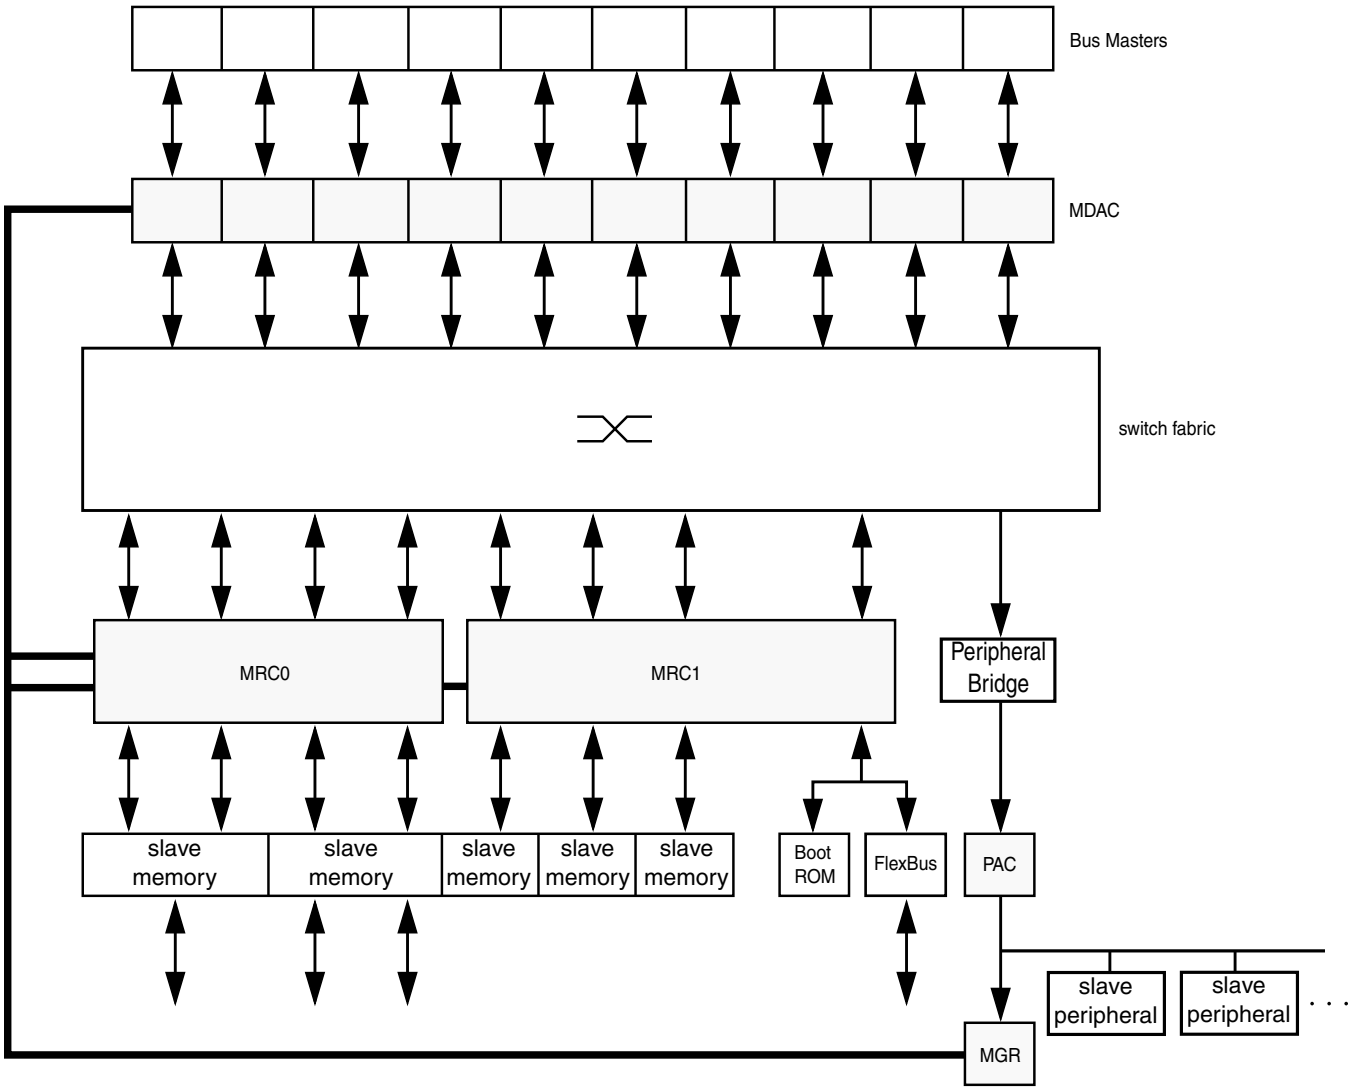

Figure 11-1. Simplified XRDC Block Diagram

11.2.3 Modes of operation

The XRDC module does not support any special modes of operation. As a memory-mapped device located in the core platform's clock domain, it responds based strictly on the memory addresses of the connected system buses. The slave peripheral bus is used to access the XRDC's distributed programming model; these references are only allowed if the requesting bus master is operating in the secure, privileged mode. Domain assignment and access control functions are evaluated on a reference-by-reference basis using the addresses and attributes connected to the system bus port(s). The implementation of the XRDC_MRC submodule supports either AMBA-AHB or AMBA-AXI system bus protocols.

11.3 External signal description

The XRDC module does not directly support any external interfaces.

The *internal* interfaces include a standard 32-bit slave bus for all programming model accesses, connections to the address phase signals associated with AHB and/or AXI system buses and connections to the slave peripheral buses as shown in Figure 11-1.

11.4 Memory map/register definition

The XRDC module supports a large number of architecturally-defined, program-visible registers distributed across four 4 Kbyte address slots. The actual registers present in any given device are chip-specific.

The register resources of the XRDC programming model can only be accessed while in secure, privileged mode. Unless noted otherwise, the programming model registers can be accessed via 8-, 16- or 32-bit reads and 32-bit write references. Attempted accesses in a different operating mode, using unsupported write data sizes, writes to read-only resources, or to reserved spaces are terminated with an error unless noted otherwise.

Accesses to these memory map holes will return an error:

- Any access to an MDAC, PDAC, or MRC that is not there.
- The holes in the 0x0-0xF0 and DERR to PID register space.
- For MDAC, gaps in the registers.
- For MRCs, RGD gaps. So if there are 4 RGDs, access to RGD5 will fail.

Accesses to these memory map holes do not return a bus error:

- For MRCs, current RGDs are 4 words, but have 8 words of address available. Words 4-7.
- For PDAC, reserved slots.

The XRDC programming model is partitioned into 5 groups of registers:

- Basic hardware control and configuration
- Domain errors: location and details
- Master domain assignments
- Peripheral domain access controls
- Memory region descriptors

It should be noted that many of the programming model registers in the XRDC are organized as 2-dimensional data structures. These generic arrays contain "m" words representing the "columns" and "n" instances of the structure representing the "rows". These may be described as `structure[n][m]`. They appear in the address space of the programming model memory map in the standard C language row-major layout, that is, the "m" words representing the "column" appear sequentially with the entire row replicated "n" times. The XRDC register structure uses the naming convention of *XRDC_<regname>_Wm_n*, where the column number "m" appears as a numeric suffix on the W (32-bit word) identifier, and the row identifier "n" appears as the final numerical suffix.

The architectural definition of the complete XRDC programming model is presented in this section. Each implementation is SoC-specific and highly dependent on the device requirements.

11.4.1.2 Control (CR)

11.4.1.2.1 Offset

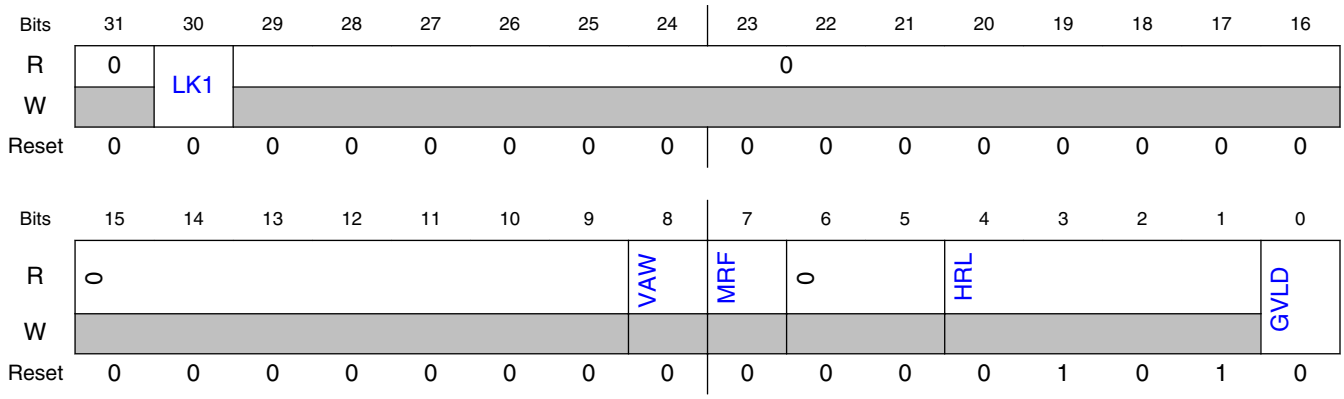
Register	Offset
CR	0h

11.4.1.2.2 Function

This register provides read-only status about the XRDC and a global enable bit for the entire module's operation.

Access: Secure Privileged Read/write

11.4.1.2.3 Diagram



11.4.1.2.4 Fields

Field	Function
31 —	Reserved
30 LK1	1-bit Lock This field provides a locking mechanism that can be used to prohibit the ability to write this register. Once set, this bit remains asserted until the next reset. 0b - Register can be written by any secure privileged write. 1b - Register is locked (read-only) until the next reset.
29-9 —	Reserved
8 VAW	Virtualization aware This read-only field signals that the domain assignments support the optional inclusion of a logical partition identifier (also known as an operating system number). 0b - Implementation is not virtualization aware. 1b - Implementation is virtualization aware.
7 MRF	Memory Region Format This read-only bit signals the format of the memory region descriptors and is defined by SoC requirements. 0b - Kinetis format based on Arm Cortex-M processor core definition. 1b - SMPU family format.
6-5 —	Reserved
4-1 HRL	Hardware Revision Level This read-only field specifies the XRDC's hardware and definition revision level. It can be read by software to determine the functional definition of the module. It is hardwired to 5 as it represents an architectural descendent from previous {system} memory protection units ({S}MPU).
0 GVLD	Global Valid (XRDC global enable/disable). 0b - XRDC is disabled. All accesses from all bus masters to all slaves are allowed. 1b - XRDC is enabled.

11.4.1.3 Hardware Configuration 0 (HWCFG0)

11.4.1.3.1 Offset

Register	Offset
HWCFG0	F0h

11.4.1.3.2 Function

This read-only register contains information on the XRDC's hardware configuration. Specifically, it defines the number of implemented domains and bus masters along with the number of instances of memory region controllers (MRCs) and peripheral access controllers (PACs). The register value at reset is device-specific. Attempted writes are error terminated.

Access: Secure Privileged Read

11.4.1.3.4 Fields

Field	Function
31-28 MID	Module ID
27-24 NPAC	Number of PACs This field defines the number of PACs minus 1 in the device. Add one to the field value to get the actual number of peripheral access controllers [1-4].

Table continues on the next page...

Field	Function
23-16 NMRC	Number of MRCs This field defines the number of MRCs minus 1 in the device. Add one to the field value to get the actual number of memory region controllers [1-16].
15-8 NMSTR	Number of bus masters This read-only field defines the number of bus masters minus 1 in the device. Add one to the field value to get the actual number of bus masters [1-64].
7-0 NDID	Number of domains This read-only field defines the number of domains minus 1 in the device. Add one to the field value to get the actual number of domains [1-16].

11.4.1.4 Hardware Configuration 1 (HWCFG1)

11.4.1.4.1 Offset

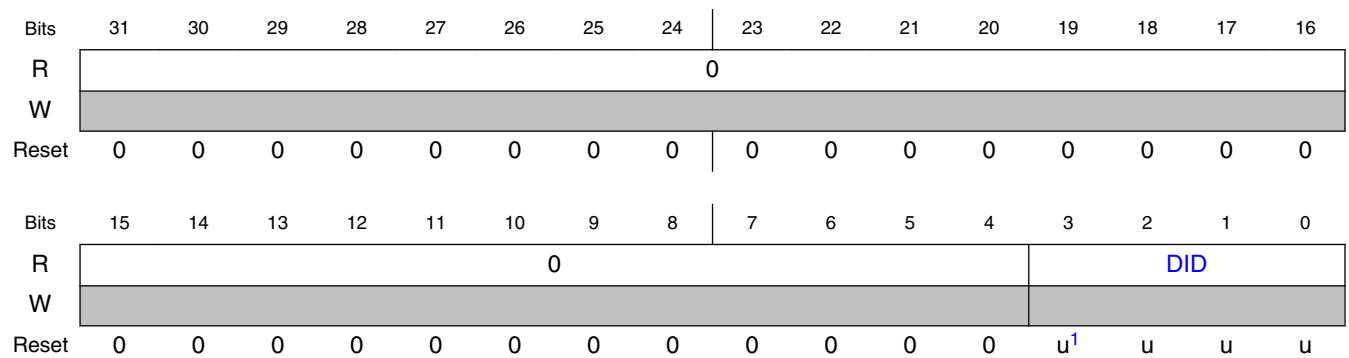
Register	Offset
HWCFG1	F4h

11.4.1.4.2 Function

This register contains information on the XRDC's hardware configuration. It provides a mechanism for software to determine its domain number by simply reading the register. See Domain error capture management for more details on typical usage. Attempted writes are error terminated.

Access: Secure Privileged Read

11.4.1.4.3 Diagram



1. Reset value is determined by current configuration of master accessing.

11.4.1.4.4 Fields

Field	Function
31-4 —	Reserved
3-0 DID	Domain identifier number This field provides the domain number [0-15] of the requesting bus master.

11.4.1.5 Hardware Configuration 2 (HWCFG2)

11.4.1.5.1 Offset

Register	Offset
HWCFG2	F8h

11.4.1.5.2 Function

This register contains information on the XRDC's hardware configuration. It provides a bitmap signaling the presence of a process identifier (PID) register sourced from the given bus master. The HWCFG2 register is associated with bus masters [31-0]. Attempted writes are error terminated.

Access: Secure Privileged Read

11.4.1.5.4 Fields

Field	Function
31 PIDP31	Process identifier Process identifier present from bus master 31. This field provides a bitmap to signal that bus master 31 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 31 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 31 sources a process identifier register to the XRDC_MDAC logic.
30 PIDP30	Process identifier Process identifier present from bus master 30. This field provides a bitmap to signal that bus master 30 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 30 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 30 sources a process identifier register to the XRDC_MDAC logic.
29 PIDP29	Process identifier Process identifier present from bus master 29. This field provides a bitmap to signal that bus master 29 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 29 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 29 sources a process identifier register to the XRDC_MDAC logic.
28 PIDP28	Process identifier Process identifier present from bus master 28. This field provides a bitmap to signal that bus master 28 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 28 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 28 sources a process identifier register to the XRDC_MDAC logic.
27 PIDP27	Process identifier Process identifier present from bus master 27. This field provides a bitmap to signal that bus master 27 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 27 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 27 sources a process identifier register to the XRDC_MDAC logic.
26 PIDP26	Process identifier Process identifier present from bus master 26. This field provides a bitmap to signal that bus master 26 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 26 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 26 sources a process identifier register to the XRDC_MDAC logic.
25 PIDP25	Process identifier Process identifier present from bus master 25. This field provides a bitmap to signal that bus master 25 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 25 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 25 sources a process identifier register to the XRDC_MDAC logic.

Table continues on the next page...

Field	Function
24	Process identifier
PIDP24	Process identifier present from bus master 24. This field provides a bitmap to signal that bus master 24 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 24 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 24 sources a process identifier register to the XRDC_MDAC logic.
23	Process identifier
PIDP23	Process identifier present from bus master 23. This field provides a bitmap to signal that bus master 23 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 23 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 23 sources a process identifier register to the XRDC_MDAC logic.
22	Process identifier
PIDP22	Process identifier present from bus master 22. This field provides a bitmap to signal that bus master 22 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 22 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 22 sources a process identifier register to the XRDC_MDAC logic.
21	Process identifier
PIDP21	Process identifier present from bus master 21. This field provides a bitmap to signal that bus master 21 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 21 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 21 sources a process identifier register to the XRDC_MDAC logic.
20	Process identifier
PIDP20	Process identifier present from bus master 20. This field provides a bitmap to signal that bus master 20 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 20 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 20 sources a process identifier register to the XRDC_MDAC logic.
19	Process identifier
PIDP19	Process identifier present from bus master 19. This field provides a bitmap to signal that bus master 19 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 19 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 19 sources a process identifier register to the XRDC_MDAC logic.
18	Process identifier
PIDP18	Process identifier present from bus master 18. This field provides a bitmap to signal that bus master 18 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 18 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 18 sources a process identifier register to the XRDC_MDAC logic.
17	Process identifier
PIDP17	Process identifier present from bus master 17. This field provides a bitmap to signal that bus master 17 sources a process identifier register to the XRDC_MDAC logic.

Table continues on the next page...

Field	Function
	0b - Bus master 17 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 17 sources a process identifier register to the XRDC_MDAC logic.
16 PIDP16	Process identifier Process identifier present from bus master 16. This field provides a bitmap to signal that bus master 16 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 16 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 16 sources a process identifier register to the XRDC_MDAC logic.
15 PIDP15	Process identifier Process identifier present from bus master 15. This field provides a bitmap to signal that bus master 15 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 15 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 15 sources a process identifier register to the XRDC_MDAC logic.
14 PIDP14	Process identifier Process identifier present from bus master 14. This field provides a bitmap to signal that bus master 14 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 14 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 14 sources a process identifier register to the XRDC_MDAC logic.
13 PIDP13	Process identifier Process identifier present from bus master 13. This field provides a bitmap to signal that bus master 13 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 13 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 13 sources a process identifier register to the XRDC_MDAC logic.
12 PIDP12	Process identifier Process identifier present from bus master 12. This field provides a bitmap to signal that bus master 12 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 12 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 12 sources a process identifier register to the XRDC_MDAC logic.
11 PIDP11	Process identifier Process identifier present from bus master 11. This field provides a bitmap to signal that bus master 11 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 11 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 11 sources a process identifier register to the XRDC_MDAC logic.
10 PIDP10	Process identifier Process identifier present from bus master 10. This field provides a bitmap to signal that bus master 10 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 10 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 10 sources a process identifier register to the XRDC_MDAC logic.
9 PIDP9	Process identifier

Table continues on the next page...

Field	Function
	Process identifier present from bus master 9. This field provides a bitmap to signal that bus master 9 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 9 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 9 sources a process identifier register to the XRDC_MDAC logic.
8 PIDP8	Process identifier Process identifier present from bus master 8. This field provides a bitmap to signal that bus master 8 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 8 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 8 sources a process identifier register to the XRDC_MDAC logic.
7 PIDP7	Process identifier Process identifier present from bus master 7. This field provides a bitmap to signal that bus master 7 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 7 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 7 sources a process identifier register to the XRDC_MDAC logic.
6 PIDP6	Process identifier Process identifier present from bus master 6. This field provides a bitmap to signal that bus master 6 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 6 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 6 sources a process identifier register to the XRDC_MDAC logic.
5 PIDP5	Process identifier Process identifier present from bus master 5. This field provides a bitmap to signal that bus master 5 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 5 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 5 sources a process identifier register to the XRDC_MDAC logic.
4 PIDP4	Process identifier Process identifier present from bus master 4. This field provides a bitmap to signal that bus master 4 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 4 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 4 sources a process identifier register to the XRDC_MDAC logic.
3 PIDP3	Process identifier Process identifier present from bus master 3. This field provides a bitmap to signal that bus master 3 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 3 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 3 sources a process identifier register to the XRDC_MDAC logic.
2 PIDP2	Process identifier Process identifier present from bus master 2. This field provides a bitmap to signal that bus master 2 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 2 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 2 sources a process identifier register to the XRDC_MDAC logic.

Table continues on the next page...

Field	Function
1 PIDP1	Process identifier Process identifier present from bus master 1. This field provides a bitmap to signal that bus master 1 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 1 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 1 sources a process identifier register to the XRDC_MDAC logic.
0 PIDP0	Process identifier Process identifier present from bus master 0. This field provides a bitmap to signal that bus master 0 sources a process identifier register to the XRDC_MDAC logic. 0b - Bus master 0 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores. 1b - Bus master 0 sources a process identifier register to the XRDC_MDAC logic.

11.4.1.6 Master Domain Assignment Configuration (MDACFG0 - MDACFG13)

11.4.1.6.1 Offset

For m = 0 to 13:

Register	Offset
MDACFGm	100h + (m × 1h)

11.4.1.6.2 Function

This register defines the number of implemented domain assignment registers for bus master m, where m+1 can specify from 1 to 64 bus masters. These registers are organized as a byte-sized data array and can be read using 8-, 16- or 32-bit accesses. An all-zero value (NCM = 0, NMDAR = 0) indicates a non-existent bus master. Attempted writes are error terminated.

Typically, processor bus masters have one or more domain assignment registers, while non-processor masters have a single domain assignment register.

Access: Secure Privileged Read

11.4.1.6.3 Diagram

Bits	7	6	5	4	3	2	1	0
R	NCM	0			NMDAR			
W								
Reset	See Register reset values.							

11.4.1.6.4 Register reset values

Register	Reset value
MDACFG0–MDACFG1	02h
MDACFG2	81h
MDACFG3	02h
MDACFG4–MDACFG13	81h
MDACFG14–MDACFG63	Register not supported

11.4.1.6.5 Fields

Field	Function
7 NCM	Non-CPU Master This read-only field signals that bus master m is a non-CPU master. It specifies that the format of the associated MDA_Wr_m register defines a non-processor domain assignment. This field is zero for a non-existent bus master. 0b - Bus master is a processor. 1b - Bus master is a non-processor.
6-4 —	Reserved
3-0 NMDAR	Number of master domain assignment registers for bus master m This read-only field specifies the number of registers associated with the master domain assignment register for a given bus master. The value is limited to the range [0-8], where zero indicates a non-existent bus master and non-zero values indicate the number of implemented registers associated with this MDAm.

11.4.1.7 Memory Region Configuration (MRCFG0 - MRCFG6)

11.4.1.7.1 Offset

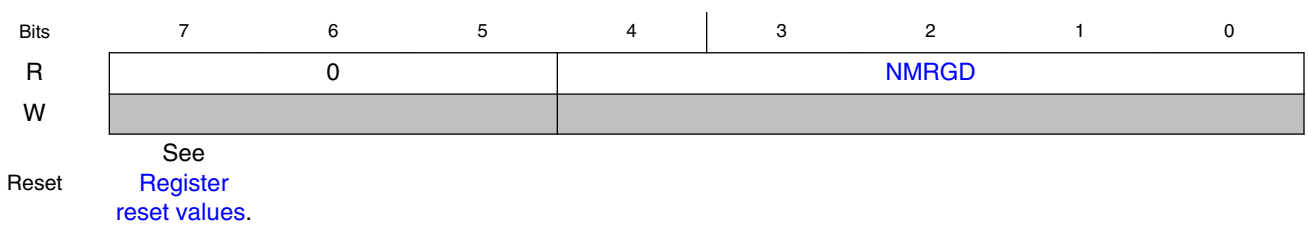
Register	Offset
MRCFG0	140h
MRCFG1	141h
MRCFG2	142h
MRCFG3	143h
MRCFG4	144h
MRCFG5	145h
MRCFG6	146h

11.4.1.7.2 Function

This read-only register defines the number of implemented memory region descriptors for each MRCr, where r+1 can specify up to 16 instances. These registers are organized as a byte-sized data array and can be read using 8-, 16- or 32-bit accesses. A zero value indicates a non-existent memory region controller instance. Attempted writes are error terminated.

Access: Secure Privileged Read

11.4.1.7.3 Diagram



11.4.1.7.4 Register reset values

Register	Reset value
MRCFG0	04h
MRCFG1	08h
MRCFG2–MRCFG5	04h
MRCFG6	08h
MRCFG7–MRCFG15	Register not supported

11.4.1.7.5 Fields

Field	Function
7-5 —	Reserved
4-0 NMRGD	Number of memory region descriptors for memory region controller n Number of memory region descriptors for MRCr. This field specifies the number of memory region descriptors associated with a given memory region controller instance. The value is limited to the range [0-16], where zero indicates a non-existent MRC instance and non-zero values indicate the number of implemented memory region descriptors [4, 8,12,16] associated with the XRDC_MRCr submodule.

11.4.1.8 Domain Error Location (DERRLOC0 - DERRLOC7)

11.4.1.8.1 Offset

For d = 0 to 7:

Register	Offset
DERRLOCd	200h + (d × 4h)

11.4.1.8.2 Function

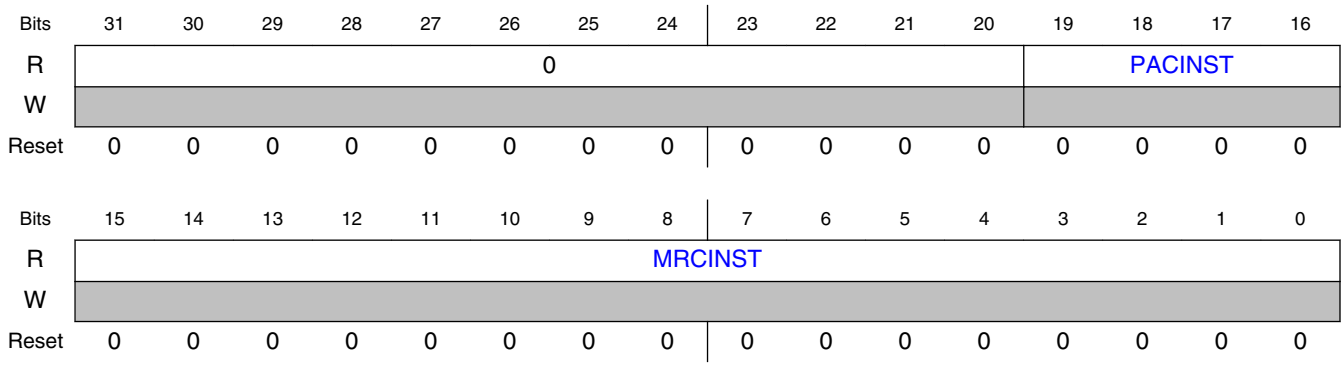
This array of read-only registers provide the instance number of the submodule where (an) access violation(s) occurred. These registers are organized as a word array, which is indexed by the faulting domain number, d. The two fields of this register provide a bitmap of instances associated with all submodules containing captured error information for that domain. These instance numbers are then used as indices into the DERR_W0_*i*, DERR_W1_*i*, DERR_W2_*i* and DERR_W3_*i* register arrays. See Domain error capture management for more details.

When an access violation is detected by either a memory region controller (MRC) or a peripheral access controller (PAC), address and attribute information of the offending access is captured. Using the faulting domainID number as the index, d, this array of read-only registers provide additional information signaling the instance number of the submodule where the access violation(s) occurred. Since the resulting exception handler needs the submodule instance to retrieve the captured address and attribute information from DERR_W0_*i* and DERR_W1_*i*, these registers provide the instance number details.

Attempted writes are error terminated.

Access: Secure Privileged Read

11.4.1.8.3 Diagram



11.4.1.8.4 Fields

Field	Function
31-20 —	Reserved
19-16 PACINST	PAC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the PAC. The least-significant bit of this field (bit 16) corresponds to PAC instance 0. The most-significant bit of this field (bit 19) corresponds to PAC instance 3, and so on. Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the PACs. **NOTE:** When a memory slot controller (MSC) is present, it will appear here in the same way as a PAC instance. For each bit in this field: • 0 - The peripheral access controller has not detected an access violation or is not physically present. • 1 - The peripheral access controller has detected one or more access violations for this domain.
15-0 MRCINST	MRC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MRC. The least-significant bit of this field (bit 0) corresponds to MRC instance 0. The most-significant bit of this field (bit 3) corresponds to MRC instance 3, and so on. Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MRCs. For each bit in this field: • 0 - The memory region controller has not detected an access violation or is not physically present. • 1 - The memory region controller has detected one or more access violations for this domain.

11.4.1.9 Domain Error Word0 (DERR_W0_0 - DERR_W0_19)

11.4.1.9.1 Offset

Register	Offset
DERR_W0_0	400h
DERR_W0_1	410h
DERR_W0_2	420h
DERR_W0_3	430h
DERR_W0_4	440h
DERR_W0_5	450h
DERR_W0_6	460h
DERR_W0_16	500h
DERR_W0_17	510h
DERR_W0_18	520h
DERR_W0_19	530h

11.4.1.9.2 Function

This read-only register array provides the address of an access violation detected by either a memory region controller (MRC) or a peripheral access controller (PAC). These registers are organized as a word array, which is indexed by the violating submodule instance number. That is, the index, i, of this array is the instance number of the submodule that detected the access violation. The submodule instance numbers are provided by the DERRLOC registers. The memory-mapped error capture detail registers are organized as 20 sequential 16-byte entries. The first 16 register sets associated with the MRCs. The following 4 registers sets associated with the PACs. Each 16-byte structure contains DERR_W0_i, DERR_W1_i, DERR_W2_i, and DERR_W3_i.

The error capture registers in the MRC and PAC submodules contain physical registers for each domain, but are organized in the DERR_W0_i and DERR_W1_i registers to provide the information for the requesting domain only. Thus, the access violation exception handler for each domain only has visibility into the captured error information for its own domain. See Domain error capture management for more details.

When an access violation is detected and the offending information captured, subsequent updates to this register are disabled until the required data pattern is written to the DERR_W3_i register. At that time, this register is cleared and re-enabled to capture the next access violation.

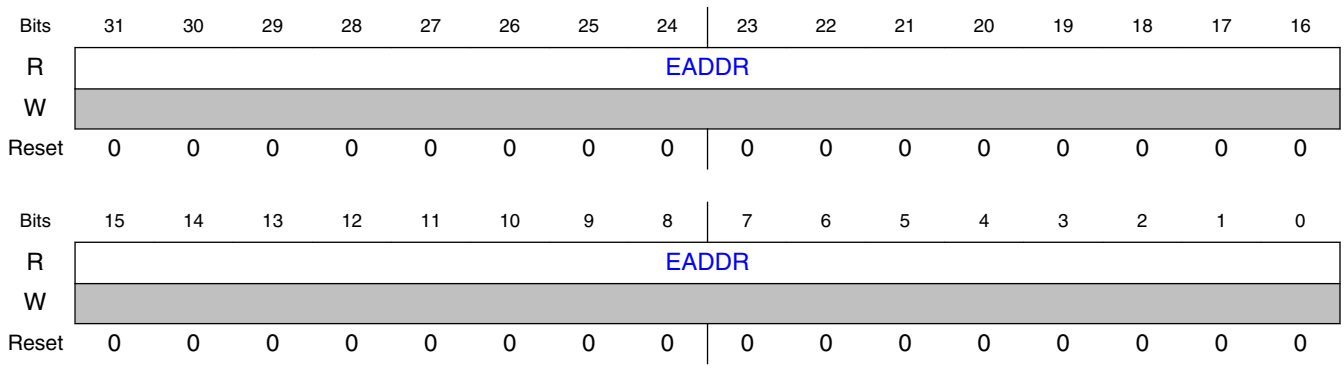
Attempted writes are error terminated as are attempted reads of an MRC or PAC instance that is not physically present.

NOTE

If masters with the same DID cause simultaneous error accesses, DERR_W0_i will record only the error of the lowest slave index.

Access: Secure Privileged Read

11.4.1.9.3 Diagram



11.4.1.9.4 Fields

Field	Function
31-0 EADDR	Error address This is the access address that generated an access violation.

11.4.1.10 Domain Error Word1 (DERR_W1_0 - DERR_W1_19)

11.4.1.10.1 Offset

Register	Offset
DERR_W1_0	404h
DERR_W1_1	414h
DERR_W1_2	424h
DERR_W1_3	434h
DERR_W1_4	444h
DERR_W1_5	454h
DERR_W1_6	464h
DERR_W1_16	504h

Table continues on the next page...

Register	Offset
DERR_W1_17	514h
DERR_W1_18	524h
DERR_W1_19	534h

11.4.1.10.2 Function

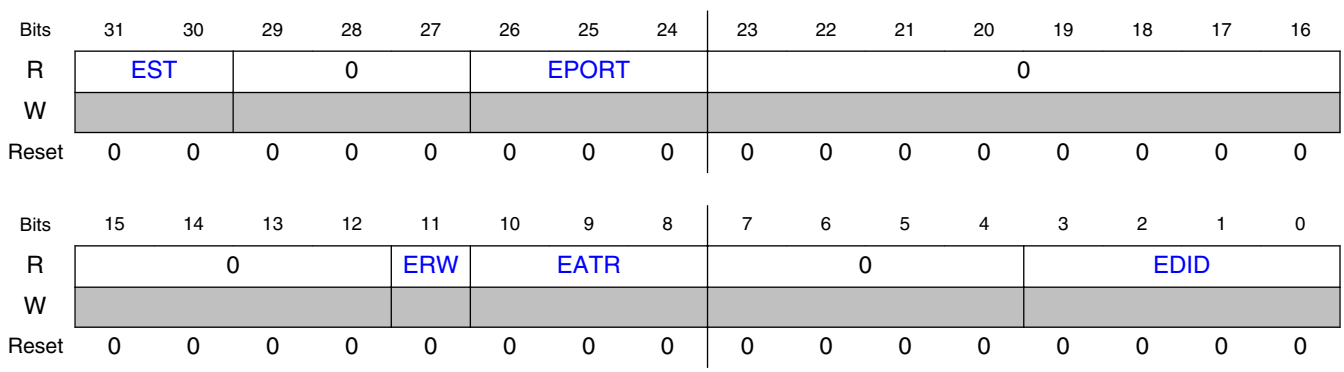
This read-only register array provides the attributes of an access violation detected by either a memory region controller (MRC) or a peripheral access controller (PAC). These registers are organized as a word array, which is indexed by the violating submodule instance number. See Domain Error Location (DERRLOC0 - DERRLOC7), Domain Error Word0 (DERR_W0_0 - DERR_W0_19), and Domain error capture management for more information.

NOTE

If masters with the same DID cause simultaneous error accesses, DERR_W1_i will record only the error of the lowest slave index.

Access: Secure Privileged Read

11.4.1.10.3 Diagram



11.4.1.10.4 Fields

Field	Function
31-30 EST	Error state This field signals the state of access violations for this domain in this instance of the memory region controller or peripheral access controller. Once an access violation has been detected and the faulting address and attribute information stored, subsequent errors are simply recorded as an overrun condition without any data captured.

Table continues on the next page...

Field	Function
	After retrieving the faulting address and attributes, the error capture mechanism must be rearmed by performing a write to DERR_W3_i. 00b - No access violation has been detected. 01b - No access violation has been detected. 10b - A single access violation has been detected. 11b - Multiple access violations for this domain have been detected by this submodule instance. Only the address and attribute information for the first error have been captured in DERR_W0_i and DERR_W1_i.
29-27 —	Reserved
26-24 EPORT	Error port This field identifies the encoded port number of the MRC that detected the access violation. The MRC port number connection is device-specific. See the chip configuration details for more information. For access violations detected by the PAC, this field is cleared.
23-12 —	Reserved
11 ERW	Error read/write This field signals whether the captured access violation occurred on a read or write reference. 0b - Read access 1b - Write access
10-8 EATR	Error attributes This field captures certain attributes of the access violation. 000b - Secure user mode, instruction fetch access. 001b - Secure user mode, data access. 010b - Secure privileged mode, instruction fetch access. 011b - Secure privileged mode, data access. 100b - Nonsecure user mode, instruction fetch access. 101b - Nonsecure user mode, data access. 110b - Nonsecure privileged mode, instruction fetch access. 111b - Nonsecure privileged mode, data access.
7-4 —	Reserved
3-0 EDID	Error domain identifier This field captures the domain identifier of the access violation.

DERR_W3_16	50Ch
DERR_W3_17	51Ch
DERR_W3_18	52Ch
DERR_W3_19	53Ch

11.4.1.11.2 Function

This register is used to rearm the error capture logic and clear the DERR_W0_i and DERR_W1_i registers. After the domain access violation error details have been read, typically in an exception service routine, a 32-bit word write to this register is required to rearm the error capture logic.

A read of this location returns zeroes. Attempted reads of a memory region controller (MRC) or peripheral access controller (PAC) instance that is not physically present are error terminated.

See Domain error capture management for more details.

NOTE

If masters with the same DID cause simultaneous error accesses, DERR_W3_i will record only the error of the lowest slave index.

11.4.1.11.4 Fields

Field	Function
31-30 RECR	Rearm Error Capture registers This 2-bit, write-only field controls the rearming of the domain error capture registers. Once an access violation has been detected with the faulting address and attribute information stored, subsequent errors are simply recorded as an overrun condition without any data captured. Writing 01b to this field rearms the error capture mechanism and clears the DERR_W0_i and DERR_W1_i registers. A write of any value other than 01b has no effect.
29-0 —	Reserved

11.4.1.12 Process Identifier (PID0 - PID3)

11.4.1.12.1 Offset

Register	Offset
PID0	700h
PID1	704h
PID3	70Ch

11.4.1.12.2 Function

In the XRDC's access control definition, each processor has a corresponding process identifier (PID) which performs two important functions: the PID[5] bit defines the secure/nonsecure attribute associated with an executing task, and the entire value can be used to group tasks into different domains.

While certain processors include this register in their programming model definitions, others do not. This register is provided for those processors that do *not* include a PID register in their programming models. Secure privileged software saves and restores the PID as part of any context switch.

This data structure defines an array of 32-bit values, one per MDA module, that define the PID. Since this register resource is only applicable to processor cores, the data structure is typically sparsely populated. The HWCFG2 register provides a bitmap of the implemented PID*n* registers. This data structure is indexed using the corresponding MDA instance number.

For processors only supporting the 3-state access control model (SecurePriv, SecureUser, NonsecureUser), the nonsecure[n] output signal from the MDAC submodule is forced to zero while in privileged mode to enable precise state transitions between user and privileged modes. Specifically, the MDAC logic for bus master n forms the nonsecure attribute output signal as a function of 2 configuration bits: PIDm[TSM] and HWCFG{2,3}[n]. See Table 11-7.

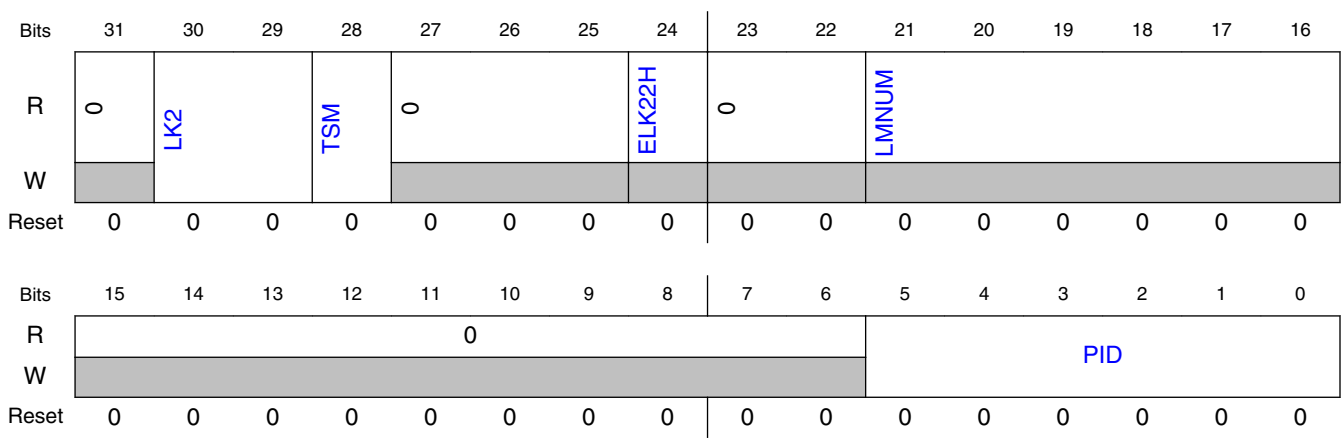
Depending on the operating clock domain of each MDAC instance, there may be optional information stored in the corresponding PIDm register to properly implement the LK2 = 2 functionality.

Reads of the PID*n* register return the contents of this register, or the PID*n* value directly sourced from a processor. For non-processor bus masters, this register does not exist and any attempted read is error terminated.

Table 11-7. Generation of the nonsecure_out[n] Attribute

Configuration {PID*n*[TSM], HWCFG{2,3}[n]}	local_nonsecure[n]	nonsecure_out[n]
00b	nonsecure_in[n]	local_nonsecure[n]
01b	nonsecure_in[n]	local_nonsecure[n] & ~priv_in[n]
10b	PID*n*[5]	local_nonsecure[n] & ~priv_in[n]
11b	pid_in[n][5]	local_nonsecure[n] & ~priv_in[n]

11.4.1.12.3 Diagram



11.4.1.12.4 Fields

Field	Function
31	Reserved

Table continues on the next page...

Field	Function
—	
30-29 LK2	Lock This field provides a locking mechanism that can be used to limit the ability to write the register. Once set, these bits individually remain asserted until the next reset. If the processor sources its PIDm directly, that is, HWCFG{2-3}[PIDPm = 1], then secure privileged reads of this memory location return zero for this field. 00b - Register can be written by any secure privileged write. 01b - Register can be written by any secure privileged write. 10b - Register can only be written by a secure privileged write from bus master m. 11b - Register is locked (read-only) until the next reset.
28 TSM	Three-state model If asserted, this bit indicates the associated processor core only supports the 3-state access control model. This indicator is “sticky”, that is, once set, it remains set until the next reset. For processors only supporting the 3-state access control model, this field must be set before loading any nonsecure value into the PID. See Table 11-7 for the specification of the privileged and nonsecure attributes generated by MDAC.
27-25 —	Reserved
24 ELK22H	Enable (LK2 = 2) special handling LK2 is in its standard form and LMNUM will be reserved and always read as 0.
23-22 —	Reserved
21-16 LMNUM	Locked Master NUMber This read-only field is only enabled when ELK22K = 1. It is written by the MDAC instance with the bus master number of the locking processor that set LK2 = 2, and used to qualify subsequent attempted writes of the register. The field is cleared when LK2 = [0,1,3] or ELK22H = 0.
15-6 —	Reserved
5-0 PID	Process identifier The PIDm[5] bit determines the secure (0) or nonsecure (1) attribute for transactions associated with the corresponding processor. If the processor sources its PID*n* directly, then secure privileged reads of this memory location return the processor register for this field.

11.4.1.13 Master Domain Assignment (MDA_W0_0_DFMT0 - MDA_W1_3_DFMT0)

11.4.1.13.1 Offset

Register	Offset
MDA_W0_0_DFMT0	800h
MDA_W1_0_DFMT0	804h
MDA_W0_1_DFMT0	820h
MDA_W1_1_DFMT0	824h
MDA_W0_3_DFMT0	860h
MDA_W1_3_DFMT0	864h

11.4.1.13.2 Function

The MDA_Wr_m registers provide a 2-dimensional data structure for assigning bus masters to domains. The number of implemented registers is defined by MDACFGm[NMDAR]. This per-master domain assignment is then repeated for each bus master (MDAm). Thus, m specifies the master number and r refers to the specific MDA register for a given bus master.

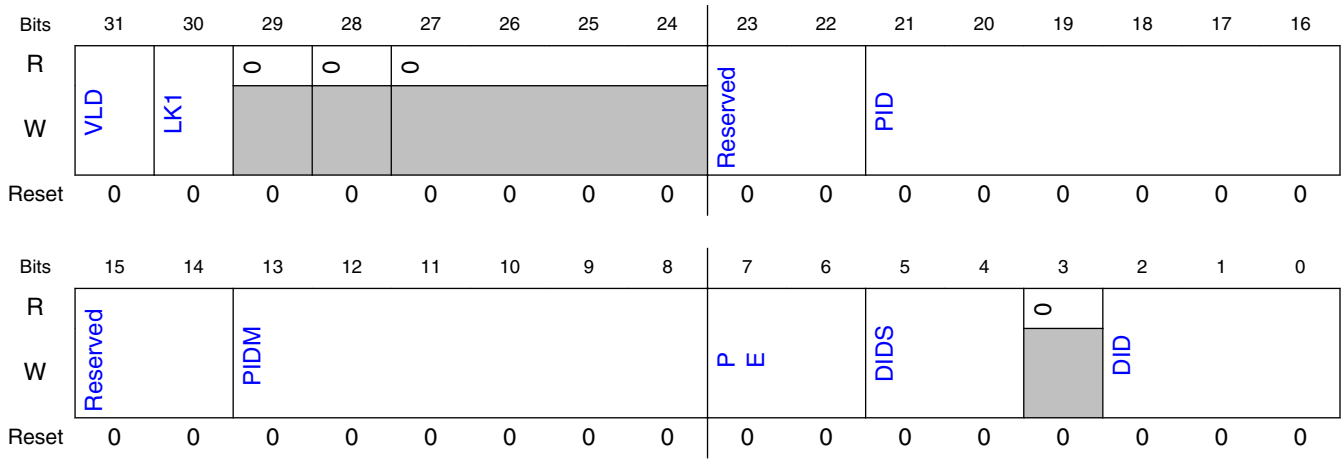
Each Wr within the MDAm structure is a word-sized definition; there are two formats supported, one for processor cores and another for non-processors. Processor masters typically support one or more Wr domain definitions, while non-processor masters support a single Wr.

The MDAC submodule is responsible for the generation of domain identifiers for every transaction from every bus master. If there is a single Wr for a given master, then the specified domain identifier is used directly. If there are multiple Wr values for a given master, then the MDAC evaluates the conditional terms to determine a “hit”. For all Wr hits, their corresponding domain identifiers are simply logically summed together (boolean OR). Use cases are typically expected to *hit in a single Wr* for a processor master. Special care is needed if *none* of the conditional terms hit in any Wr evaluation; for this case, the generated DID = 0 and software needs to be aware of any potential access rights granted for this DID.

Each MDA_Wr_m register has one of two programming models depending on the state of the domain format field, DFMT. The model described in this section is for DFMT = 0. This definition allows three different specifications of the DID for processors. The DFMT = 1 model is described in Master Domain Assignment (MDA_Wr_m_DFMT1).

Access: Secure Privileged Read/write

11.4.1.13.3 Diagram



11.4.1.13.4 Fields

Field	Function
31 VLD	Valid This field indicates the domain assignment is valid. It is further qualified by CR[GVLD] = 1. If CR[GVLD] is cleared, the DID output is defined by the SoC-specific *default DID* value. See the XRDC chip configuration section for more details. If both MDA_Wr_m[VLD] and CR[GVLD] are asserted, the DID output is defined by the remaining contents of this register. 0b - The Wr domain assignment is invalid. 1b - The Wr domain assignment is valid.
30 LK1	1-bit Lock This field provides a locking mechanism that can be used to limit the ability to write the register. Once set, this bit remains asserted until the next reset. 0b - Register can be written by any secure privileged write. 1b - Register is locked (read-only) until the next reset.
29 DFMT	Domain format Identifies this register's domain assignment. 0b - Processor-core domain assignment 1b - Non-processor domain assignment
28 —	Reserved.
27-24 —	Reserved.
23-22 —	Reserved Always write 00b to this field.
21-16 PID	Process Identifier This field specifies that the process identifier is to be combined with the PIDM field and included in the domain hit determination. The optional inclusion of the PID and PIDM is controlled by the MDA_Wr_m[PE] field.

Table continues on the next page...

Field	Function
15-14 —	Reserved Always write 00b to this field.
13-8 PIDM	Process Identifier Mask This field provides a masking capability so that multiple process identifiers can be included as part of the domain hit determination. If a bit in the PIDM is set, then the corresponding bit of the PID is ignored in the comparison. The optional inclusion of the PID and PIDM is controlled by the MDA_Wr_m[PE] field.
7-6 PE	Process identifier enable This field controls the optional inclusion of the PID, qualified by PIDM, into the domain hit evaluation. It provides the ability to include inclusive or exclusive sets of masked PID values. 00b - No process identifier is included in the domain hit evaluation. 01b - No process identifier is included in the domain hit evaluation. 10b - The process identifier is included in the domain hit evaluation as defined by the expression: `partial_domain_hit = (PE == 10b) && ((PID & ~PIDM) == (XRDC_PIDn[PID] & ~PIDM))` 11b - The process identifier is included in the domain hit evaluation as defined by the expression: `partial_domain_hit = (PE == 11b) && ~((PID & ~PIDM) == (XRDC_PIDn[PID] & ~PIDM))`
5-4 DIDS	DID Select This field selects the source of the domain identifier. 00b - Use DID field of this register as the domain identifier. 01b - Use the input DID as the domain identifier. 10b - Use bits [3:2] of this register concatenated with the low-order 2 bits of the input DID (DID_in[1:0]) as the domain identifier. 11b - Reserved for future use.
3 —	Reserved
2-0 DID	Domain identifier

11.4.1.14 Master Domain Assignment (MDA_W0_2_DFMT1 - MDA_W0_13_DFMT1)

11.4.1.14.1 Offset

Register	Offset
MDA_W0_2_DFMT1	840h
MDA_W0_4_DFMT1	880h
MDA_W0_5_DFMT1	8A0h
MDA_W0_6_DFMT1	8C0h
MDA_W0_7_DFMT1	8E0h
MDA_W0_8_DFMT1	900h

Table continues on the next page...

Register	Offset
MDA_W0_9_DFMT1	920h
MDA_W0_10_DFMT1	940h

21-16 —	Reserved
15-14 —	Reserved.
13-9 —	Reserved
8 DIDB	DID Bypass If asserted, this bit enables the bypassing of an input DID value as the domain identifier for this non-processor bus master. This capability allows non-processor bus masters, for example, a DMA to masquerade as a processor. Once set, this field is “sticky” and remains set until the next reset. 0b - Use MDAn[3:0] as the domain identifier. 1b - Use the DID input as the domain identifier.
7-6 SA	Secure attribute This field defines the secure/nonsecure attribute for non-processor cores. **NOTE:** The bus master’s input secure/nonsecure attribute is used if SA = 1X, or this VLD = 0. 00b - Force the bus attribute for this master to secure. 01b - Force the bus attribute for this master to nonsecure. 10b - Use the bus master’s secure/nonsecure attribute directly. 11b - Use the bus master’s secure/nonsecure attribute directly.
5-4 PA	Privileged attribute This field defines the privileged/user attribute for non-processor cores. **NOTE:** The bus master’s input privileged/user attribute is used if PA = 1X, or this VLD = 0. 00b - Force the bus attribute for this master to user. 01b - Force the bus attribute for this master to privileged. 10b - Use the bus master’s privileged/user attribute directly. 11b - Use the bus master’s privileged/user attribute directly.
3 —	Reserved
2-0 DID	Domain identifier

11.4.1.15 Peripheral Domain Access Control (PDAC_W0_8 - PDAC_W0_437)

11.4.1.15.1 Offset

Register	Offset
PDAC_W0_(c * 128) + s	1000h + (c × 400h) + (s × 8h)

11.4.1.15.2 Function

This register array, PDAC_W*r*_*s*, provides a two-dimensional data structure for defining access control policies per domain for each implemented slave peripheral. In the offset equation above, c is the instance number and s is the slot number. See the Access control policy table below. There are two word-sized registers assigned for each peripheral "address slot" (W*r*).

Each W*r* within the PDAC*s* structure is a word-sized definition; a total of two words (64 bits) is needed to define the access control policies for all the domains.

These registers also allow a hardware semaphore to be optionally included in the access control evaluation for peripherals shared by multiple domains. If enabled, the state of the semaphore dynamically modifies the access control policies so that only the domain "owning" it has write permission into the peripheral. The write permissions for all other domains are revoked based on the semaphore state. If the semaphore is not owned by any domain, the DxACP fields are evaluated normally.

The PAC submodule uses the peripheral access address to select the appropriate PDAC*s* register, and then uses the domain identifier associated with the access to select the appropriate DxACP field. The selected DxACP field is then evaluated against the attributes associated with the memory transaction to determine the validity of the access. See DxACP evaluation for more details. If allowed, the access proceeds, else an access violation is signaled, the transfer error terminated and the appropriate address and attribute information captured in the corresponding error detail registers.

Access: Secure Privileged Read/write

11.4.1.17 Memory Region Descriptor (MRGD_W0_0 - MRGD_W0_103)

11.4.1.17.1 Offset

Register	Offset
MRGD_W0_n * 16 + m	2000h + (n × 200h) + (m × 20h)

11.4.1.17.2 Function

The MRGD_W*o*_*n*_*m* registers provide a 2-dimensional data structure for defining access control policies (Table 11-9) per domain for each supported memory region. There are four word-size registers (W*o*) defined in each memory region. There are up to 16 memory region controllers (MRCs), *n*, each supporting up to 16 memory region descriptors (MRGD), *m*. The number of MRCs is defined by HWCFG0[NMRC].

Each instance of a MRC submodule can monitor up to 8 system buses concurrently.

NOTE

An AXI port counts as two system buses since the read address and write address channels operate independently.

Each W*o* within the MRGD*m* structure is a word-sized definition; a total of four words (128 bits, W0-W3) are needed to completely define the memory region descriptor.

XRDC uses a base address plus a size (0-modulo-size) to specify memory regions. This format provides addressing capabilities that are equivalent to those provided in the Arm Cortex-M processor core memory protection unit.

The region descriptor also allows a hardware semaphore to be optionally included in the access control evaluation for memory regions shared by multiple domains. If enabled, the state of the semaphore dynamically modifies the access control policies so that only the domain "owning" it has write permission into the region. The write permissions for all other domains are revoked based on the semaphore state. If the semaphore is not owned by any domain, the D*x*ACP fields are evaluated normally.

The MRC submodule evaluates multiple system bus access addresses versus the programmed address ranges to determine a region hit. Once a region hit has been determined, the MRC then uses the domain identifier associated with the access to select the appropriate D*x*ACP field from the corresponding MRGDn. The selected D*x*ACP field is then evaluated against the attributes associated with the memory transaction to determine the validity of the access. See Memory region descriptor hit determination and Memory region DxACP evaluation for more details. If allowed, the access proceeds, else an access violation is signaled, the transfer error terminated and the appropriate address and attribute information captured in the corresponding error detail registers.

11.4.1.20.4 Fields

Field	Function
31 VLD	Valid This field indicates the memory region descriptor definition is valid. It is further qualified by CR[GVLD] = 1. If CR[GVLD] is cleared, then all accesses to the memory region are allowed. Any write to MRGD_W[0-2]_*n* clears the MRGD_W3_*n*[VLD] indicator so a coherent register state can be supported. 0b - The MRGDn assignment is invalid. 1b - The MRGDn assignment is valid.
30-29 LK2	Lock This 2-bit field provides a mechanism to limit writes to the MRGDn register to protect its contents. Once set, these bits individually remain asserted until the next reset. 00b - Entire MRGDn can be written. 01b - Reserved 10b - Domain *x* can only update the D*x*ACP field for domain *x*; no other ACP fields can be written. 11b - MRGDn is locked (read-only) until the next reset.

11.5 Functional description

This section provides more details on the operation and implementation of the XRDC submodules.

11.5.1 Manager (XRDC_MGR)

The MGR submodule is responsible for coordinating XRDC's programming model reads and writes.

The complete programming model is large, requiring four 4-Kbyte slave peripheral address space slots, although most devices define a sparsely populated subset. Additionally, the programming model is distributed across the various submodule instances (MDAC, MRC, PAC). The MGR submodule provides the required hardware management for all programming model accesses, generating and distributing the appropriate address decodes and write data to the MDAC, MRC and PAC submodule instances, collecting and combining all the register read data buses and responses.

MGR implements the Control Register, all the read-only hardware configuration registers (HWCFG[0-3], MDACFGn, MRCFG) and the program-visible versions of the domain error capture registers. To support the domain error reporting functionality, the MGR submodule collects the individual captured error indicator output signals from all the submodule instances and remaps them so they are organized into a instance bitmap by domain as specified by the DERRLOCn register array.

11.5.2 Master Domain Assignment Controller (XRDC_MDAC)

The MDAC submodule is responsible for the generation of the domainID on every memory transaction for every bus master in the device. The resulting domainID and {nonsecure, privileged} signals are generated and then treated as address attributes and associated with each transaction as it moves through the system.

MDAC modules that drive the domainIDs (DIDs) for processor cores include an option of processor-identifier (PID) matching in order to select between DIDs. This is accomplished by first enabling PID checking by setting XRDC_MDA_Wm_n[PE] = [2,3]. With PID matching enabled, a domain hit is determined by matching XRDC_MDA_Wm_n[PID] with the PID input or PID in the XRDC_PID register. The PIDM field can be used to match specific groups of PIDs.

As a simple example, assume a system with two domainIDs.

- domainID 1 is for critical tasks ("critical" is system-specific and may refer to timing, safety, and so on.).
- domainID 2 is for non-critical tasks.
- Two domainIDs require two MDA_Wm_n registers, MDA_W0 and MDA_W1.

Further assume the processor's task identifier defines whether a task is critical or non-critical as defined by system software.

- PIDs [0-15] are assigned to critical tasks.
- PIDs != [0-15] are assigned to noncritical tasks.

During startup, software initializes the MDA_W[0-1] registers. MDA_W0 defines DID = 1 for PIDs [0-15] and MDA_W1 defines DID = 2 for PIDs != [0-15].

1. MDA_W0 = 0x8000_0F81
    - VLD = 1
    - PID = 0x0
    - PIDM = 0xF
    - PE = 2
    - DIDS = 0
    - DID = 1
2. MDA_W1 = 0x8000_0FC2
    - VLD = 1
    - PID = 0x0
    - PIDM = 0xF
    - PE = 3
    - DIDS = 0
    - DID = 2

As the processor executes, it loads the appropriate task ID into its PID register as the task is started. The processor's PID register value is input to the corresponding MDAC module and used by the MDA_Wm comparison logic. The system then dynamically generates two domainIDs and the downstream XRDC access check logic can distinguish and enforce different access control rights based on the different domainIDs.

A special mode is provided for driving the DID of non-processor masters. This is enabled with the DID bypass (DIDB) bit. The MDAC has a DID input that can be driven by a master and used directly as the DID output. This allows variability in the DID as dictated by the master and is intended to be used by DMA masters that masquerade as, (that is, drive the DID of) the master that programmed it.

11.5.3 DxACP evaluation

Fundamental to the XRDC's operation is the actual access violation check performed by the memory region (MRC) and peripheral access (PAC) controllers.

Previous descriptions have detailed the domain assignment mechanisms and the tracking of the domain identifier as an address attribute through the system bus switching fabric(s). As transactions reach the slave memory and peripheral controllers, the address is used to select the appropriate memory region descriptor or peripheral access control register. Once the appropriate register has been selected, the next function is the actual access evaluation.

For this step, the domainID of the current transaction selects the appropriate 3-bit DxACP (domain "x" access control policy) from the source register. The DxACP field defines the access rights for the domain based on the 4-level model combined with the transaction's access attributes (read = 0/write = 1, secure = 0/nonsecure = 1, user = 0/privileged = 1).

The 4-level model is defined by the concatenation of two address attributes: secure/nonsecure and user/privileged attributes. These two attribute signals (nonsecure, privileged) and the resulting access levels are defined as:

```
if {nonsecure, privileged} == 0b01, then level = SecurePriv(ileged)
if {nonsecure, privileged} == 0b00, then level = SecureUser
if {nonsecure, privileged} == 0b11, then level = NonsecurePriv(ileged)
if {nonsecure, privileged} == 0b10, then level = NonsecureUser
```

Recall the resulting hierarchical access control model specifies:

```
SecurePriv(ileged) > SecureUser > NonsecurePriv(ileged) > NonsecureUser
```

The XRDC's evaluation of the access control policy is defined by Table 11-10.

Table 11-10. Domain x Access Control Policy Definition

	Allowable Accesses			
Policy	Secure Priv	Secure User	Nonsecure Priv	Nonsecure User
111	r, w	r, w	r, w	r, w
110	r, w	r, w	r, w	none

Table continues on the next page...

Table 11-10. Domain x Access Control Policy Definition (continued)

Policy	Allowable Accesses			
	Secure Priv	Secure User	Nonsecure Priv	Nonsecure User
101	r, w	r, w	r	r
100	r, w	r, w	r	none
011	r, w	r, w	none	none
010	r, w	none	none	none
001	r	r	none	none
000	none	none	none	none

Unimplemented domains default to an all-zero DxACP field providing no access rights.

After the DxACP evaluation is complete and the access error signal generated, the transaction is allowed to continue if it has sufficient access rights, else the access is aborted with the address and attribute information captured in the appropriate error registers.

Recall XRDC optionally supports the inclusion of a hardware semaphore to *dynamically alter* the access control policy of a memory region or peripheral access. See Hardware semaphores and dynamic access rights for details.

11.5.4 Hardware semaphores and dynamic access rights

Both memory region descriptors and peripheral access control registers support the ability to optionally include a hardware semaphore in their access evaluations. This capability is provided to allow hardware enforcement of dynamic access rights based on the state of the semaphore for shared memory regions and/or shared peripherals.

If enabled (MRGD_W2_n[SE] = 1 or PDAC_W0_n[SE] = 1), the state of the specified hardware semaphore, as defined by MRGD_W2_n[SNUM] or PDAC_W0_n[SNUM]), is checked *before* the normal DxACP evaluation. On a write transaction, if the semaphore is not idle, that is, the semaphore state is non-zero and not owned by the requesting domain, the access is aborted and error terminated. Stated differently, writes into a semaphore-enabled address space are only allowed if the semaphore is idle, or is owned by the requesting domain. See "Semaphores2 (SEMA42)" chapter for more information.

The semaphore check is detailed in lines 84-92 of the C code description contained in MRC C code description. The comparable function in the PAC C code in Peripheral Access Controller (XRDC_PAC) is found in lines 38-45.

One additional note on this capability: since the semaphore module "only" supports up to 15 domains, that is, domainIDs [0-14], domainID 15 *cannot* be used for this function.

11.5.5 Memory Region Controller (XRDC_MRC)

The XRDC's Memory Region Controller provides domain-based, hardware access control for all system bus references targeted at non-peripheral memory spaces. Using pre-programmed *region descriptors* which define memory spaces and their associated access rights per domain identifier, the MRC concurrently monitors system bus transactions and evaluates the appropriateness of each transfer. Memory references that have sufficient access control rights are allowed to complete, while references that are not mapped to any region descriptor or have insufficient rights are terminated with an access error response.

The XRDC architectural framework supports up to 16 MRC instances, where each MRC instance can support {4, 8, 12, 16} region descriptors, concurrently monitoring up to 8 slave memory ports. Note, monitoring an AXI protocol port counts as two ports since there are independent read address and write address channels. Conversely, an AHB connection counts as a single port.

A partial, simplified one-dimensional block diagram of an instance of the MRC module is shown in Figure 11-2. In this figure, a single slave bus port is shown. When the remaining slave ports are considered, the MRC hardware's two-dimensional connection matrix, broadcasting each system bus slave port access across the implemented memory region descriptors, is the resulting structure with the basic access evaluation macro shown as the replicated submodule block. In Figure 11-2, the system bus fabric slave port is shown on the left, the memory region descriptor registers are in the middle, and the peripheral bus interface on the right side. The evaluation macro contains two magnitude comparators connected to the start and end address registers from each region descriptor as well as the combinational logic blocks to determine the region hit and, based on the domainID associated with the reference, access violations.

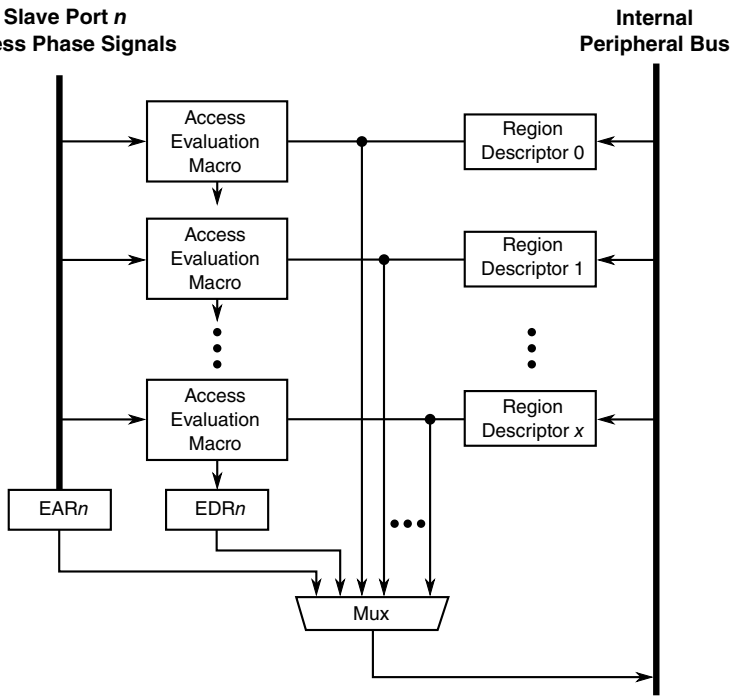

Figure 11-2. MRC access evaluation macro hardware structure

For each access, the MRC hardware performs a two-step evaluation process. First, the access is compared to all memory region descriptors to determine hit/miss status, and then, using the domainID associated with the reference plus the address attributes {write, nonsecure, privileged}, the access rights are examined using the method detailed in DxACP evaluation.

11.5.5.1 Memory region descriptor hit determination

To determine if the current reference hits in a given region, an equality comparator with a bit mask is used in conjunction with the region's BASEADDR and SZ. The boolean equation for this portion of the hit determination is defined as:

```
    region_hit_n = 0;
    if (mrgd_w1_n[sz] >= 4) {
      sz_mask  = (1 << (mrgd_w1_n[sz] + 1)) - 1;
      region_hit_n = (addr[31:5] | sz_mask) == (mrgd_w0_n[baseaddr] | sz_mask) |
(mrgdn_w1_n[sz] == 31);
```

The region_hit evaluation is then further qualified by the subregion disables as required.

Also, the region hit determination is based only on an address comparison of the first byte being accessed; that is, the MRC does *not* check the size of the access to make sure it entirely fits within the region.

11.5.5.2 Memory region DxACP evaluation

For each region descriptor hit, the MRC logic then evaluates the access rights defined by the MRGD_Wm_n registers. Specifically, the domainID attribute selects the appropriate DxACP field from the MRGD_W{2,3}_n registers and then the {write, nonsecure, privileged} address attributes are compared with the access policy defined by the selected DxACP. See DxACP evaluation for additional details on this function.

While CR[GVLD] = 1, and for each bus slave port being monitored, the MRC performs a **reduction-AND** of all the individual *(no_hit | error)* terms from each access evaluation macro. Recall as specified in Memory region descriptor hit determination, an *invalid* MRGD_Wm_n (MRGD_W3_n[VLD] = 0) forces the region_hit_n evaluation to be negated.

This expression then terminates the bus cycle with an error and reports an access error for three conditions:

1. If the access does not hit in *any* region descriptor, an access error is reported.
2. If the access hits in a single region descriptor and that region signals a domain violation, then an access error is reported.
3. If the access hits in multiple (overlapping) regions and *all* regions signal violations, then an access error is reported.

The third condition reflects that priority is given to *permission granting over access denying* for overlapping regions as this approach provides more flexibility to system software in the region descriptor assignments.

Unimplemented domain identifiers default to all-zero DxACP fields providing no access rights. Additionally, these fields are RAZ/WI.

11.5.5.3 MRC C code description

The functionality of the MRC evaluation is described in the C code of Listing 11-1 on page 239. This code begins with the description of the data structures corresponding to the MRC-associated registers (lines 1-12). Note the memory region descriptors are described as a 3-dimensional unsigned 32-bit integer array indexed by the MRC instance number, the RGD number within the instance and then the word offset within the region descriptor.

The access evaluation consists of four basic functions: a check of the XRDC's global valid bit (lines 43-45), the address hit/miss determination (lines 54-72), the selection of the DxACP field and its evaluation (lines 80-96) and finally, the combination of all the individual MRGD_Wm_n hit and error indicators to determine the final state of the memory reference (lines 99-134).

Listing 11-1. MRC Evaluation C Code Description

53
54           // first, determine if system address "hits" in the given MRDGn
55           // define the "effective SRD" - valid only if SZ >= 7
56           mrgd_sz = (xrdc_mrgd[MRCn][i][1] & 0x1F00) >> 8;
57           if (mrgd_sz < 7)
58               eff_srd = 0;                              // disable SRD
```

```
 59           else
 60               eff_srd = xrdc_mrgd[MRCn][i][2] & 0xFF;
 61
 62           mrgd_hit = 0;
 63           if ((mrgd_sz >= 4) {
 64               sz_mask  = (1 << (mrgd_sz + 1)) - 1;
 65               srd_mask =  7 << (mrgd_sz - 2);
 66               mrgd_hit = (sysAddr | sz_mask)
 67                        ==(xrdc_mrgd[MRCn][i][0] | sz_mask)
 68                        | (rgd_sz == 31);
 69
 70               j = (sysAddr & srd_mask) >> (mrgd_sz - 2);
 71               mrgd_hit = mrgd_hit & ((eff_srd >> j) ^ 1) & 1;
 72           }
 79
 80           // second, if there was a hit, evaluate DxACP including any sema4
 81           if (mrgd_hit == 1) {
 82               mrgd_w2 = xrdc_mrgd[MRCn][i][2];
 83               mrgd_w3 = xrdc_mrgd[MRCn][i][3];
 84               // semaphore check using a local copy
 85               mrgd_sema4 = sema4[(mrgd_w2 & 0x3f000000) >> 24];
 86               // check if it is enabled on write and
 87              //       if not idle, nor equal to (did+1)
 88               if (((mrgd_w2 & 0x40000000) == 0x40000000) &&  // se
 89                    (write == 1)                          &&  // wt
 90                    (mrgd_sema4 != 0)                     &&  // sema4 !=idle
 91                    (mrgd_sema4 != (did+1)))              {   // sema4 !=did
 92                   mrgd_error = 1;
 93               } else {
 94                   // perform standard DxACP check
 95                   mrgd_error = evaluate_DxACP(mrgd_w2, mrgd_w3, did,
\                                  nonsecure, privileged, write);
 96               }
 97           }
 98
 99           // accumulate the hit and error indicators
100           mrc_hit   = (mrc_hit   | (mrgd_hit   << i)) & 0xffff;
101           mrc_error = (mrc_error | (mrgd_error << i)) & 0xffff;
102       }
103
104
105       For each slave port monitored, MRC performs a reduction-AND of all
106       the individual (~hit | error) terms from each access evaluation.
107       This expression then terminates the bus cycle with an error & reports
108       an access error for three conditions:
109
110       1) If the access does not hit in *any* region descriptor,
111             then an access error is reported.
112       2) If the access hits in one region descriptor and
113          that region signals a violation,
114             then an access error is reported.
115       3) If the access hits in multiple (overlapping) regions and *all*
116          regions signal violations,
117             then an access error is reported.
118
119       The third condition reflects that priority is given to "permission
120       granting over access denying" for overlapping regions as this
121       approach provides more flexibility to system software in region
122       descriptor assignments.
123       */
124
125       final_error_state   = ((mrc_hit   ^ 0xffff)  // form ~mrc_hit
126                           |  mrc_error) & 0xffff;  // factor in error flags
127
128       if (final_error_state == 0xffff)
129           memory_access_error = 1;
130       else
131           memory_access_error = 0;
132   }
```

```
133   return memory_access_error;
134 }
```

11.5.6 Peripheral Access Controller (XRDC_PAC)

The peripheral access controller performs an access control evaluation similar to that of the memory region controller (Memory Region Controller (XRDC_MRC), but using dedicated "memory region descriptors" with one unique PDAC_W[0-1]_n register per slave peripheral slot. The presence of one region descriptor per slave peripheral address space slot in the PAC simplifies the required functionality compared to the MRC.

The functionality of the PAC evaluation is described in the C code of Listing 11-2 on page 241. This code begins with the description of the data structures corresponding to the PAC-associated registers (lines 1-3). It then performs a check of the global valid bit (CR[GVLD]) (lines 25-27), followed by the extraction of the peripheral slot number from the system address (line 32), then followed by the access of the selected PDAC_W[0-1]_n registers (lines 33-34). Next, a check of the optional inclusion of a hardware semaphore and its current state is performed (lines 37-46). Finally, if the access is still allowed, an evaluation of the appropriate DxACP permission field is made (line 48) as detailed in DxACP evaluation and the state of the peripheral access error control signal returned (line 52).

Listing 11-2. PAC Evaluation C Code Description

```
 1   // PAC registers
 2   unsigned int    xrdc_cr_gvld;
 3   unsigned int    xrdc_pdac[512][2];
 4
 5   evaluate_PAC (sysAddr, write, privileged, nonsecure, did)
 6       unsigned int    sysAddr;                    // system address
 7       unsigned int    write;                      // read/write attribute
 8       unsigned int    privileged;                 // user/privileged attribute
 9       unsigned int    nonsecure;                  // secure/nonsecure attribute
10       unsigned int    did;                        // domain identifier
11   {
12       unsigned int    ips_slot_number;            // f(system address)
13       unsigned int    pdacw0;                     // selected PAC_W0_n register
14       unsigned int    pdacw1;                     // selected PAC_W1_n register
15       unsigned int    pac_sema4;                 // local copy of referenced sema4
16       unsigned int    peripheral_access_error;
17
18       // the evaluation of the PACn involves a 4-step process:
19       //   1) select the appropriate PDACn using the system address
20       //   2) using the DID for the access, select the appropriate DxACP field
21       //   3) evaluate the state of the (optional) SEMA4 for this access
22       //   4) using the {secure/nonsecure, user/priviledged} attributes, eval DxACP
23
24       // first, check the global XRDC valid bit
25       if (xrdc_cr_gvld == 0) {
26           peripheral_access_error = 0;
27           }
28
29       else {
30           // Extract the peripheral slot number from the system memory map.
31           // Example for a standard 4k slot assignment:
```

```
32          // sysAddr[20:12] = slot select [0-511]
33          ips_slot_number = (sysAddr & 0x001ff000) >> 12;
34          pdacw0 = xrdc_pdac[ips_slot_number][0];
35          pdacw1 = xrdc_pdac[ips_slot_number][1];
36          peripheral_access_error = 0;
37          if ((pdacw1 & 0x80000000) == 0x80000000) {          // PDACn is valid
38              // semaphore check
39              pac_sema4 = sema4[(pdacw0 & 0x3f000000) >> 24]; // local copy
40              // check if it is enabled on a write and if not idle, nor == (did+1)
41              if (((pdacw0 & 0x40000000) == 0x40000000)   &&  // se
42                   (write == 1)                           &&  // wt
43                   (pac_sema4 != 0)                        &&  // sema4 != idle
44                   (pac_sema4 != (did+1)))                {     // sema4 != did
45                  peripheral_access_error = 1;
46              } else {
47                  // perform the standard DxACP check
48                  peripheral_access_error = evaluate_DxACP(pdacw0, pdacw1, did,
\                                                    nonsecure, privileged, write);
49              }
50          }
51      }
52      return peripheral_access_error;
53  }
```

11.6 Initialization information

Out of reset, CR[GVLD] is cleared and XRDC disabled allowing secure privileged startup code to configure the entire programming model. The initialization process typically is performed in 3 steps:

1. Read the various hardware configuration registers (HWCFG{0-3}, MDACFGn, MRCFGn) to obtain the implemented hardware capabilities for the device.
2. Using the information retrieved in Step 1 coupled with the desired domain architecture, program all the register data structures for domain assignment (MDA_Wm_n), memory region descriptors (MRGD_Wm_n) and peripheral access control register (PDAC_Wm_n). There are individual valid bits included in all these registers which typically would be asserted. Additionally, there are also lock mechanisms available if register settings need to be configured and marked as read-only.
3. Once the XRDC programming model is loaded, the CR is written with GVLD asserted. At that point, the XRDC is fully operational.

In this context, XRDC being fully operational means the XRDC_MDAC modules are generating the domainIDs and the slave memory and peripheral responders (XRDC_MRC, XRDC_PAC) are checking the access rights. Due to the distributed design hierarchy and the pipelined nature of the hardware system bus fabric, it can take multiple cycles for a generated DID to propagate through the entire design. Any previous DID is based on the master's default DID, and depending on the programmed access policies, could generate an access error response.

If incorrect error responses are being generated, the following approaches can be used to minimize or eliminate these extraneous access errors:

1. Minimize the amount of system bus traffic in the system while XRDC_CR[GVLD] is being set.
2. Guarantee that all addresses being accessed provide sufficient access rights for the default DID(s) as well as the newly-programmed DID(s). Once XRDC is fully operational, as confirmed by a read of XRDC_HWCFG1, the permissions for the default DID(s) can be removed.
3. In defining the DID assignments for the system, try to have the bus master that is programming and configuring the XRDC registers use the same DID, that is, its default DID, for both initialization and configuration as well as normal system operation.

11.7 Application information

As described in Introduction, the XRDC architecture is intended to provide a broad, highly-capable framework for access control, system memory protection and peripheral isolation. The resulting microarchitecture implementation is distributed throughout the core platform, highly configurable via hardware design parameters and software programmability. The considerable number of hardware design parameters allows the XRDC architecture to be a very scalable solution, able to service a wide spectrum of SoC devices from ultra-low end MCUs to multi-core high performance embedded microprocessors.

11.7.1 Master domain assignments

The typical use case related to master domain assignments is to include one (or more) processor core(s) in a single domain, possibly coupled with other bus master devices like DMA, etc. The definition of a domain may be static, based simply on the combination of a processor and other optional bus masters. Alternatively, the processor's operation may be configured to dynamically select between a very small number of domains. The maximum number of possible CPU domain definitions is limited by MDACFGn value. In particular, the optional inclusion of PID value(s) to be used to create multiple classes of CPU with different domain values.

For example, "critical" tasks, whether safety-critical, performance-critical, etc. can be grouped together in one domain and all other tasks into a second domain. Non-processor bus masters typically have a single MDA_Wm_n configuration register associated with

them. The domainID and {nonsecure, privileged} attributes are usually statically assigned, unless the module can "inherit" attributes from a processor programming it (such as certain modules like DMAs).

The MDA_Wm_n registers, along with the memory region descriptors and the peripheral domain access control registers all have lock features that allow the register resources to be converted into read-only resources to protect the written configuration.

11.7.2 Memory region descriptor management

There are two important concepts to consider in managing the memory region descriptors.

First, recall that the association between each MRCn instance and the slave memory regions it monitors is chip-specific. The device-specific configuration specifies the number of implemented memory region descriptors in a given instance and the specific port numbers associated with the slave memories being monitored.

Second, as detailed in Memory region DxACP evaluation, recall that, once the XRDC is enabled, *every memory reference must hit in one or more regions*, else an access violation is reported. These are also two other conditions were access errors are reported:

- If the access hits in a single region descriptor and that region signals a domain violation, then an access error is reported.
- If the access hits in multiple (overlapping) regions and *all* regions signal violations, then an access error is reported.

11.7.3 Domain error capture management

Recall when a domain access violation is detected by either a memory region controller or a peripheral access controller, address and attribute information of the offending access is captured. The DERRLOCn read-only registers provide additional information signaling the instance number of the submodule where the access violation(s) occurred. Since the resulting exception handler needs the submodule instance to retrieve the captured address and attribute information from DERR_W0_n and DERR_W1_n, the DERRLOCn registers provide the instance number details.

These registers are organized as a word array, *indexed by the faulting domain number*, with the contents of each register providing a bitmap signaling the instance number(s) associated with all submodules containing captured error information for that domain.

It is recommended that the exception handler begin by reading the HWCFG1 register to determine its domainID. Next, it uses the just-retrieved domainID to index into the DERRLOCn array. The resulting DERRLOCn value is then examined to determine the instance number of the reporting MRC and/or PAC submodule.

There may be multiple access violations, across multiple instances, pending for a given domain. It is suggested that exception handler use a "find first one" instruction (alternatively known as "count leading zeroes") to quickly and efficiently find the instance number containing access violation details. Once the instance number has been determined, the captured error address (DERR_W0_n) and attribute information (DERR_W1_n) can easily be retrieved from the domain error registers. The 2-bit DERR_W1_n[EST] field provides information signaling whether one or more errors have been detected by the submodule instance. A special write to DERR_W3_n is required to reset (and rearm) the EST error capture state machine.

This process is repeated until all errors associated with a given domainID have been processed.

A graphical representation of this 2-step retrieval of the domain error address and attributes is shown in Figure 11-3.

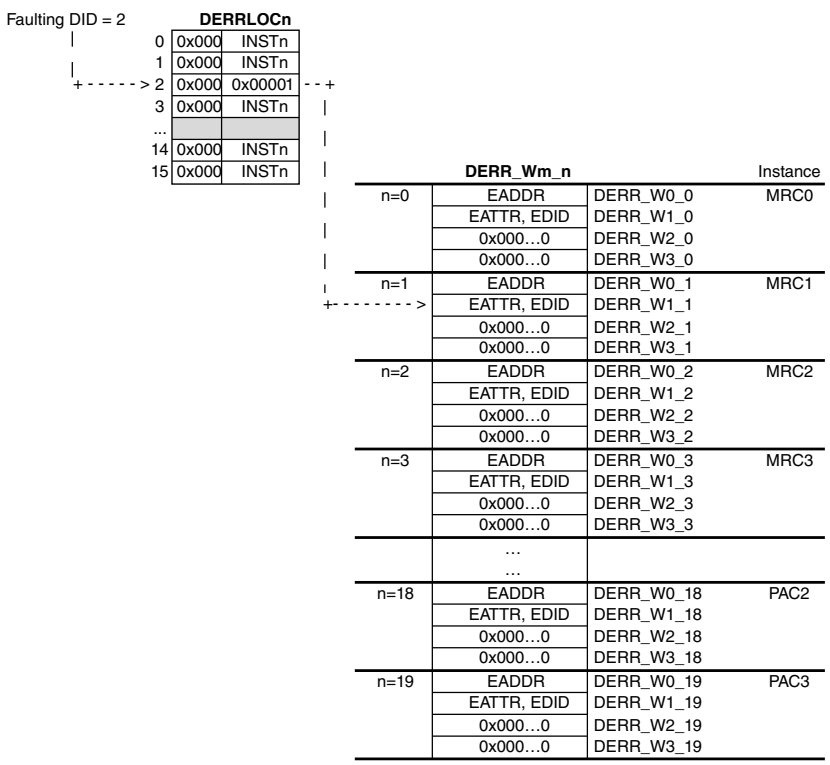

Figure 11-3. Two-step retrieval of domain error address and attributes

Chapter 12
Bus systems

12.1 Bus system

12.1.1 Main crossbar switch

i.MX 7ULP implements two instances of the AMBA Network Interconnect (NIC) for the bus fabric on the A7 domain. The NIC is a highly configurable and high performance AMBA-compliant network infrastructure that arbitrates between multiple AXI or AHB masters, to grant access to internal or external memories or other slave devices.

Figure 13-1 shows the configuration details of NIC0 and NIC1. The bus clock frequency ratios between NIC0 and NIC1 are 2:1 and 1:1.

NOTE

Register slice (RS) are not currently shown in the figure, but it (RS) may be used on critical time paths to meet the timing for the target frequency

12.1.1.1 Arbitration

In the NIC, each slave port (or master interface port) is configured separately in hardware to have an arbitration scheme which is either:

- a non-programmable round-robin (RR) scheme
- a programmable least recently granted (LRG) scheme

For i.MX 7ULP, all slave ports on NIC0 and NIC1 are configured for round-robin arbitration scheme, except the MMDC slave port on NIC0 is configured for LRG scheme.

12.1.1.2 Sparse interconnect

The NIC can be configured as a sparse interconnect, where some slave interface ports are not connected to all master interface ports. For this device, the following tables define the required interconnections for NIC0 and NIC1 crossbar switches.

Table 12-1. NIC0 sparse interconnect

	SRAM0	MMDC/ DDR	NIC1_M0
A7 ACE	Yes	Yes	Yes
NIC1_S1	Yes	Yes	No
DSI/LCDIF	Yes	Yes	Yes
GPU-3D	Yes	Yes	Yes
GPU-2D	Yes	Yes	Yes

Table 12-2. NIC1 sparse interconnect

				S0	S1	S2	S3	S4	S5	S6
Master	**Description**	**Width**	**Protocol**	**SRAM1**	**nic0**	**SecRAM**	**IPS0**	**IPS1**	**FB/ROM/ GPUR**	**AXBS**
M0	From nic0	64	AXI	Yes	No	Yes	Yes	Yes	Yes	Yes
M1	DMA1	64	AHB	Yes	Yes	Yes	Yes	Yes	Yes	Yes
M2	AXBS_IN	64	AHB	Yes	Yes	Yes	Yes	Yes	Yes	No
M3	Security(CAAM)[1]	32	AXI	Yes	Yes	Yes	No	No	Yes	Yes
M4	USB_OTG0/1	32	AXI	Yes	Yes	Yes	No	No	Yes	Yes
M5	VIU	64	AHB	Yes	Yes	Yes	No	No	Yes	Yes
M6	uSDHC0	32	AXI	Yes	Yes	Yes	No	No	Yes	Yes
M7	uSDHC1	32	AXI	Yes	Yes	Yes	No	No	Yes	Yes

1. For complete chapter, see the i.MX7ULP Security Reference Manual

12.1.1.3 Latency through NIC and Related Bus Gaskets

Expected latency associated with the NIC arbiter and related bus gaskets is illustrated below. Table 12-3 shows the Read address, Write address, and Write data channels which are initiated by the bus master. Table 12-4 shows the Read data and Write response channels which are initiated from the bus slaves in response to read or write requests.

Table 12-3. Latencies for Address and Write Data Channels

Component	Master Port Clock Cycles	NIC Clock Cycles	Slave Port Clock Cycles
AHB2AXI Gasket on master port	1	--	--
Synchronizer on master port	1	2	--
Downsizer or Expander on master port	--	1 (Downsizer)	--
Arbiter: address decode	--	1	--
Arbiter: arbitration	--	1	--
Downsizer on slave port	--	1	--
Synchronizer on slave port	--	1	2
AXI2AHB Gasket on slave port	--	--	2 (write data channel)
Register Slice	--	--	1

Table 12-4. Latencies for Read Data and Write Response Channels

Component	Master Port Clock Cycles	NIC Clock Cycles	Slave Port Clock Cycles
Register Slice	--	--	1
AXI2AHB Gasket on slave port	--	--	2 (write response)
Synchronizer on slave port	--	2	1
Downsizer on slave port	--	1 (read data path)	--
Arbiter	--	--	--
Downsizer or Expander on master port	--	1 (read data path)	--
Synchronizer on master port	2	1	--
AHB2AXI on master port	1 (write response)	--	--

12.1.2 AHB crossbar switch

i.MX 7ULP implements a 4x5 AHB XBar Switch (AXBS) in the M4 domain. The AXBS uses a 64-bit internal data path. If the slave port is simultaneously requested by more than one master port, arbitration logic exists in the crossbar to allow the higher priority master port to be granted access to the slave, while stalling the other requestor(s) until that transaction has completed parking.

See the following figure.

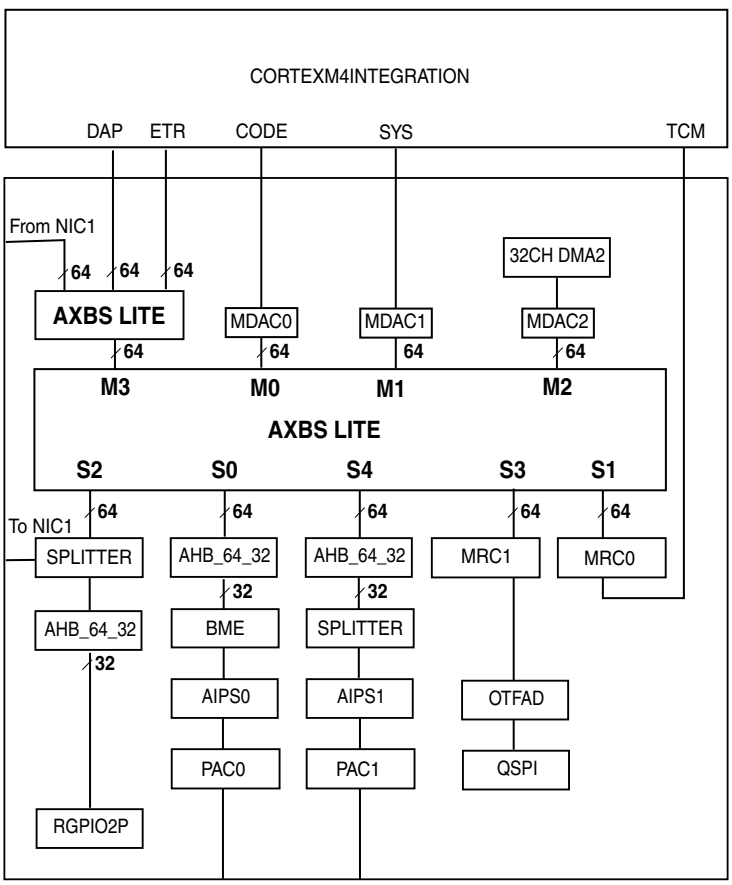

Figure 12-1. Crossbar switch bus diagram

12.1.2.1 Arbitration

The AXBS supports a fixed arbitration scheme. The M4 master ports have lower priority than other bus masters connected to this crossbar switch.

12.1.2.2 Access latency

The AXBS has low latency throughput when slave port is not busy:

- Single clock (zero-wait-state) accesses through AXBS when slave port is not busy or is parked on the requesting master port.
- 1 cycle penalty through AXBS when slave port is not busy, but parked on another master port.

13.1.1 AMBA Network Interconnect (NIC)

The NIC is a highly configurable and high performance AMBA-compliant network infrastructure which arbitrates between multiple AXI or AHB masters to grant access to internal or external memories or other slave devices. It supports connectivity between several slave and master ports for parallel processing. It uses a hybrid round-robin arbitration scheme and contains frequency converters, data width converters, bus protocol converter, and AXI channel buffers. In order to support multicore enhancements, additional side-band signals are needed to communicate the domain attributes. The following table shows the configuration of the NIC.

Table 13-2. NIC configuration

Parameter	Description
Name	AMBA Network Interconnect (NIC)
Instances	2
Configurable features	Refer to Main crossbar switch and AHB crossbar switch

Table continues on the next page...

Table 13-2. NIC configuration (continued)

Parameter	Description
Interface speed	NA
External I/O pins	NA

13.1.2 Write buffer mechanism for NIC1

To achieve higher performance, there are write buffers in the master port of NIC1 for those bufferable write transactions from the real time domain. All those AHB bufferable write data beats receive an automatic OKAY response from the NIC1 irrespective of the slave's response. This means that if the NIC1 receives an error response, it does not feed it back to the master. User can disable the early write response feature of the AHB master port of NIC1 by programming the fn_mod_ahb register bit fields of NIC ASIB to 0x03. The address of this register is 0x41D44028 (Only AHB ASIB port has this early response feature). See Table 13-8

The CA7 L2 memory system has a synchronous abort mechanism and an asynchronous abort mechanism; see External aborts handling in Arm Cortex-A7 MPCore Technical Reference Manual, Revision r0p5. The abort exception is masked by CPSR.A bit by default; see Program Status Register in Arm Architecture v7AR Reference Manual.

13.2 Overview

This section provides an overview of the NIC-301 (Network Inter-Connect) AMBA bus arbiter IP.

The NIC-301 (by Arm Ltd.) is a configurable AMBA bus arbiter between several masters and slaves. The NIC-301 IP is designed so that many configuration options are selected at the hardware design stage, determined by SoC characteristics and needs, while several other configuration options are software-controlled.

This chapter covers in brief the NIC-301 functionality, while providing configuration details on the NIC-301 instances used in the chip. For complete details on the NIC-301 design, see the Arm specification, *AMBA® Network Interconnect (NIC-301) Technical Reference Manual, version r2p3*.

NOTE

The NIC-301 default settings are configured by NXP's board support package (BSP), and in most cases should not be modified by the customer. The default settings have gone

through exhaustive testing during the validation of the part, and have proven to work well for the part's intended target applications. Changes to the default settings may result in a degradation in system performance.

13.2.1 Block diagram

The NIC-301 AMBA arbiter (or "CoreLink Network Interconnect") by Arm, provides configurable AMBA-based interconnect logic, for connecting a number of masters (initiators) to several slaves (targets), via configurable bus switches and bridging components.

The bus system is composed of two instances: NIC0 and NIC1.

Each instance can include one or more bus switches, with additional logic. This block provides details of the various instances and the selected configuration parameters. The top level diagram of the bus system is shown in the following figure.

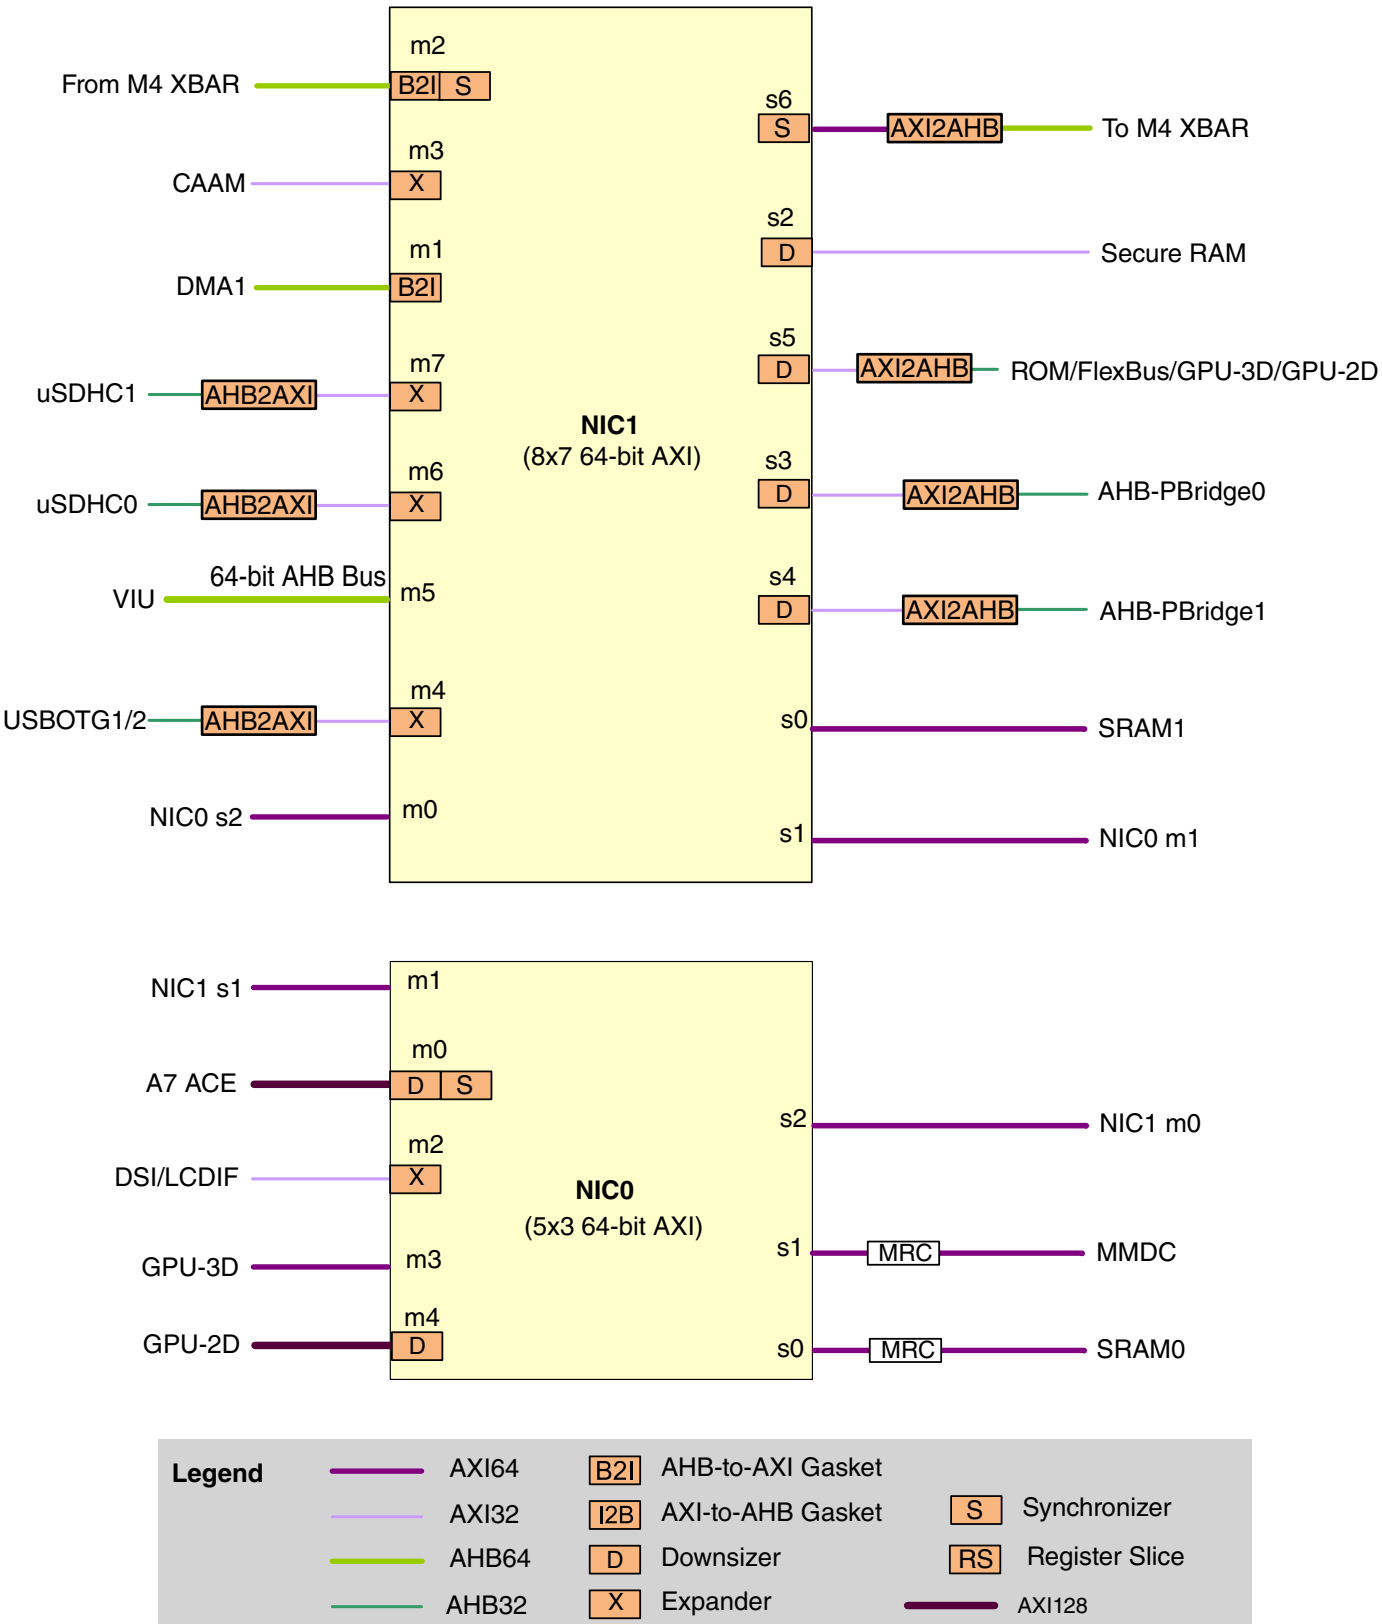

Figure 13-1. NIC-301 Bus System

13.2.2 NIC-301 Main Features

Key features of the NIC-301 module include the following:

- Address space memory mapping.
- Programmer's view, for software-configured parameters, via "GPV" ports.
- Support for cross-clock domain synchronization.

13.2.3 Modes and Operations

The NIC-301 supports a normal functional mode only.

13.3 External Signals

There are no external I/O interfaces for NIC-301.

13.4 Memory Map and Register Definition

This section includes the block memory map and detailed register descriptions.

In this device, no external GPV port is provided. GPV is internally located within the NIC-301. CPU can directly program the NIC0 GPV and NIC1 GPV, using the same memory map.

The base address of NIC0 GPV is 0x41C0_0000. The base address of NIC1 GPV is 0x41D0_0000. Their base address are applicable to both the CA7 and CM4 core

Table 13-3. NIC0/NIC1 GPV memory allocations

GPV	Allocation	Size	Chip Address	
			Start	End
NIC1 GPV	NIC1 internal global programmer's view	1MB	41D0_0000	41DF_FFFF
NIC0 GPV	NIC0 internal global programmer's view	1MB	41C0_0000	41CF_FFFF

13.4.1 Memory Map

The NIC-301 memory map, is dependent on the selected configuration option at time of creation.

A "template" map is provided in Table 13-4 below.

13.4.2 Configuration programmers model

The GPV's contain configuration registers, partitioned into a number of individual 4KB blocks.

The general structure of the registers is provided by the following tables:

- Address map of the programmers model, Table 13-4
- AMIB Registers, Table 13-5 and Table 13-6
- ASIB Registers, Table 13-7 and Table 13-8

Table 13-4. Address map of the programmers model

Address Offset from Base Address	Registers	Notes
0x000F_F000	Internal interface p registers	Maximum p = 61
	...	Note [1]
0x000C_4000	Internal interface 2 registers	
0x000C_3000	Internal interface 1 registers	
0x000C_2000	Internal interface 0 registers	
0x000C_1000	Slave interface m registers	Maximum m = 127
	...	Note [2]
0x0004_4000	Slave interface 2 registers	
0x0004_3000	Slave interface 1 registers	
0x0004_2000	Slave interface 0 registers	
0x0004_1000	Master interface n registers	Maximum n = 63
	...	Note [3]
0x0000_4000	Master interface 2 registers

0x0000_2000	Master interface 0 registers	
0x0000_1000	ID registers	
0x0000_0000	Address control registers	Configurable base address [4]

1. Index refers to BI registers index
2. Index refer to ASIB registers index
3. Index refer to AMIB registers index
4. Reserved for internal use

13.4.2.1 Address control and ID registers

Registers at offsets 0x0–0xFFC are reserved for internal use.

13.4.2.2 AMBA master interface block (AMIB) configuration registers

The table below lists only the registers that affect the user. All other addresses are treated as "reserved". Non-implemented or reserved addresses inside NIC domains are read as ZEROS and writes operations are ignored.

The NIC0 GPV base address is GPV_BASE = 0x41C00000. The NIC1 GPV base address is GPV_BASE = 0x41D00000.

13.4.3 Register Descriptions

The NIC-301 registers are dependent upon the selected configuration, the type of ports, hardware-selected features and whether they have a GPV view. The addressing is associated to a specific port, by looking at the port's index number, under "apb_slave" column.

The memory map template is provided in the Configuration programmers model above.

14.1.1 DMA

DMA is a second-generation module of the enhanced direct memory access (eDMA2) controller, which is capable of performing complex data transfers with minimal intervention from a host processor. There are two DMA instances in i.MX 7ULP. Each DMA supports 32 DMA channels. The transfer control descriptors for each of the 32 channels are located in system memory. The following table shows the configuration of the DMA.

Table 14-2. DMA configuration

Parameter	Description
Name	Enhanced Direct Memory Access v2 (eDMA2)
Instances	2
Configurable features	• DMA0-1: 32-channels • DMA0-1: 64-bit AHB
Interface speed	NA
External I/O pins	NA

14.2 Introduction

The enhanced direct memory access (eDMA) controller is a second-generation module capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes:

- A DMA engine that performs:
  - Source address and destination address calculations
  - Data-movement operations
- Local memory containing transfer control descriptors for each of the 32 channels

14.2.1 eDMA system block diagram

Figure 14-1 illustrates the components of the eDMA system, including the eDMA module ("engine").

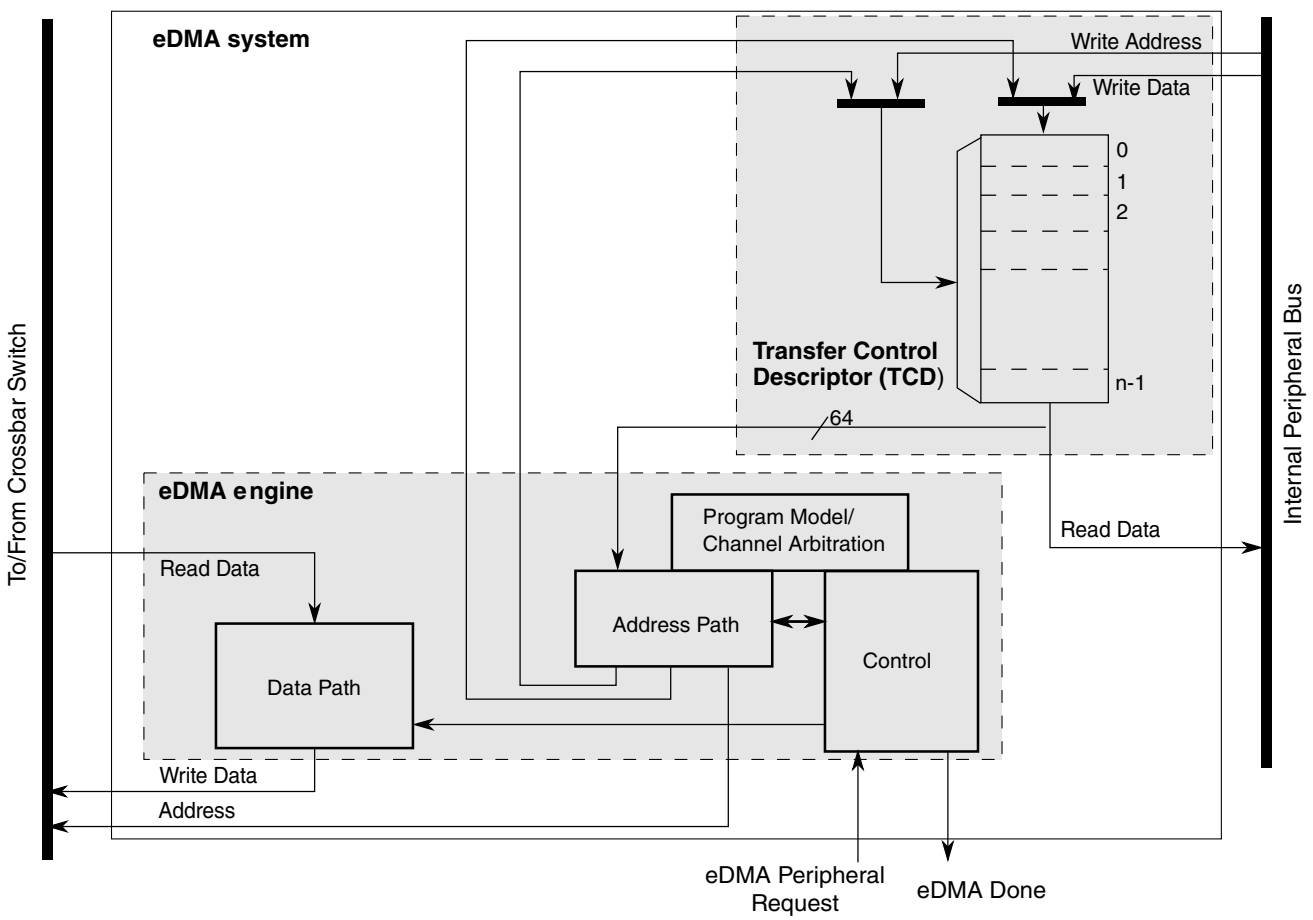

Figure 14-1. eDMA system block diagram

14.2.2 Block parts

The eDMA module is partitioned into two major modules: the eDMA engine and the transfer-control descriptor local memory.

The eDMA engine is further partitioned into four submodules:

Table 14-3. eDMA engine submodules

Submodule	Function
Address path	This block implements registered versions of two channel transfer control descriptors, channel x and channel y, and manages all master bus-address calculations. All the channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel activation is asserted while the first channel is active. After a channel is activated, it runs until the minor loop is completed, unless preempted by a higher priority channel. This provides a mechanism (enabled by DCHPRI*n*[ECP]) where a large data move operation can be preempted to minimize the time another channel is blocked from execution. When any channel is selected to execute, the contents of its TCD are read from local memory and loaded into the address path channel x registers for a normal start and into channel y registers for a preemption start. After the minor loop completes execution, the address path hardware writes the new values for the TCD*n*_{SADDR, DADDR, CITER} back to local memory. If the major iteration count is exhausted, additional processing is performed, including the final address pointer updates, reloading the TCD*n*_CITER field, and a possible fetch of the next TCD*n* from memory as part of a scatter/gather operation.
Data path	This block implements the bus master read/write datapath. It includes a data buffer and the necessary multiplex logic to support any required data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output. The address and data path modules directly support the 2-stage pipelined internal bus. The address path module represents the 1st stage of the bus pipeline (address phase), while the data path module implements the 2nd stage of the pipeline (data phase).
Program model/channel arbitration	This block implements the first section of the eDMA programming model as well as the channel arbitration logic. The programming model registers are connected to the internal peripheral bus. The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via control logic).
Control	This block provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/ destination write operations until the number of bytes specified in the minor loop byte count has moved. For descriptors where the sizes are not equal, multiple accesses of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-bit data and the destination is 32-bit data, two reads are performed, then one 32-bit write.

The transfer-control descriptor local memory is further partitioned into:

Table 14-4. Transfer control descriptor memory

Submodule	Description
Memory controller	This logic implements the required dual-ported controller, managing accesses from the eDMA engine as well as references from the internal peripheral bus. As noted earlier, in the event of

	simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled.
Memory array	TCD storage for each channel's transfer profile.

14.2.3 Features

The eDMA is a highly programmable data-transfer engine optimized to minimize any required intervention from the host processor. It is intended for use in applications where the data size to be transferred is statically known and not defined within the transferred data itself. The eDMA module features:

- All data movement via dual-address transfers: read from source, write to destination
  - Programmable source and destination addresses and transfer size
  - Support for enhanced addressing modes
- 32-channel implementation that performs complex data transfers with minimal intervention from a host processor
  - Internal data buffer, used as temporary storage to support 16- and 32-byte transfers
  - Connections to the crossbar switch for bus mastering the data movement
- Transfer control descriptor (TCD) organized to support two-deep, nested transfer operations
  - 32-byte TCD stored in local memory for each channel
  - An inner data transfer loop defined by a minor byte transfer count
  - An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
  - Explicit software initiation
  - Initiation via a channel-to-channel linking mechanism for continuous transfers
  - Peripheral-paced hardware requests, one per channel
- Fixed-priority and round-robin channel arbitration
- Channel completion reported via programmable interrupt requests

    - One interrupt per channel, which can be asserted at completion of major iteration count
    - Programmable error terminations per channel and logically summed together to form one error interrupt to the interrupt controller
- Programmable support for scatter/gather DMA processing
- Support for complex data structures

In the discussion of this module, *n* is used to reference the channel number.

14.3 Modes of operation

The eDMA operates in the following modes:

Table 14-5. Modes of operation

Mode	Description
Normal	In Normal mode, the eDMA transfers data between a source and a destination. The source and destination can be a memory block or an I/O block capable of operation with the eDMA. A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in the transfer control descriptor (TCD). The minor loop is the sequence of read-write operations that transfers these NBYTES per service request. Each service request executes one iteration of the major loop, which transfers NBYTES of data.
Debug	DMA operation is configurable in Debug mode via the control register: • If CR[EDBG] is cleared, the DMA continues to operate. • If CR[EDBG] is set, the eDMA stops transferring data. If Debug mode is entered while a channel is active, the eDMA continues operation until the channel retires.
Wait	Before entering Wait mode, the DMA attempts to complete its current transfer. After the transfer completes, the device enters Wait mode.

14.4 Memory map/register definition

The eDMA's programming model is partitioned into two regions:

- The first region defines a number of registers providing control functions
- The second region corresponds to the local transfer control descriptor (TCD) memory

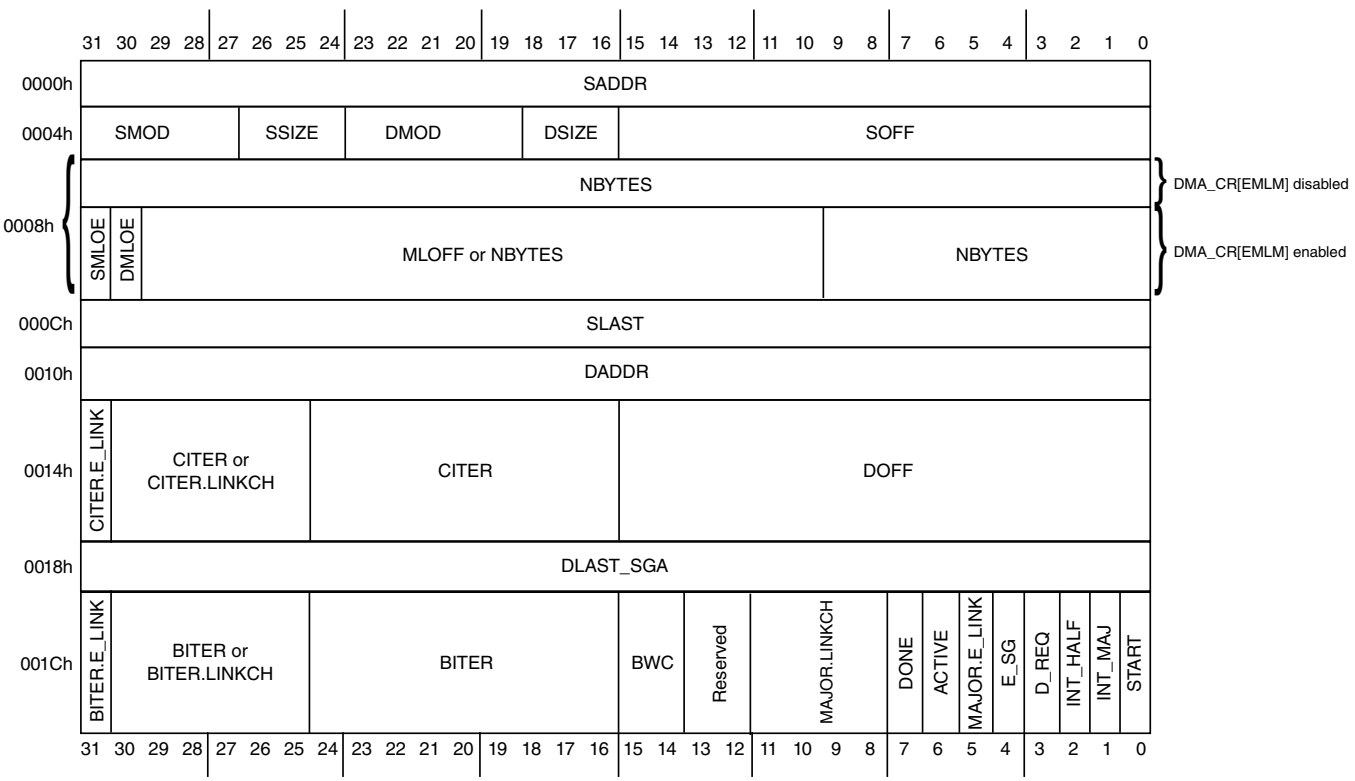
14.4.1 TCD memory

Each channel requires a 32-byte transfer control descriptor for defining the desired data movement operation. The channel descriptors are stored in the local memory in sequential order: channel 0, channel 1, ... channel 31. Each TCD*n* definition is presented as 11 registers of 16 or 32 bits.

14.4.2 TCD initialization

Prior to activating a channel, you must initialize its TCD with the appropriate transfer profile.

14.4.3 TCD structure



14.4.4 Reserved memory and bit fields

- Reading reserved bits in a register returns the value of zero.
- Writes to reserved bits in a register are ignored.
- Reading or writing a reserved memory location generates a bus error.

14.4.5.2 Control Register (CR)

14.4.5.2.1 Offset

Register	Offset
CR	0h

14.4.5.2.2 Function

The CR defines the basic operating configuration of the DMA. The DMA arbitrates channel service requests in two groups of 16 channels each:

- Group 1 contains channels 31-16
- Group 0 contains channels 15-0

Arbitration within a group can be configured to use either a fixed-priority or a round-robin scheme. For fixed-priority arbitration, the highest priority channel requesting service is selected to execute. The channel priority registers assign the priorities; see the DCHPRIn registers. For round-robin arbitration, the channel priorities are ignored and channels within each group are cycled through (from high to low channel number) without regard to priority.

NOTE

For correct operation, writes to the CR register must be performed only when the DMA channels are inactive; that is, when TCDn_CSR[ACTIVE] bits are cleared.

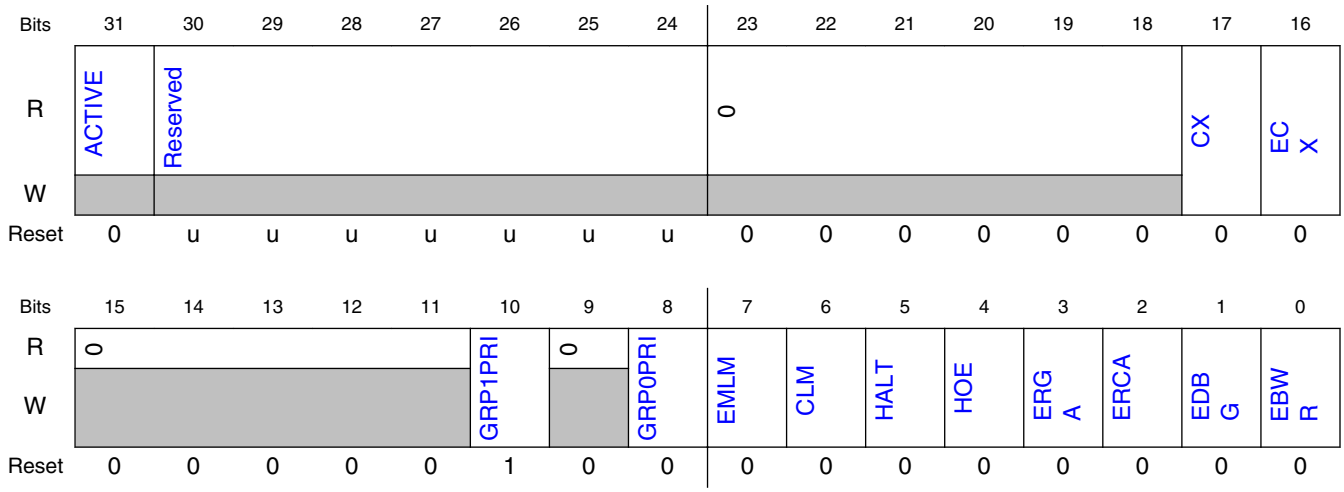
The group priorities operate in a similar fashion. In group fixed priority arbitration mode, channel service requests in the highest priority group are executed first, where priority level 1 is the highest and priority level 0 is the lowest. The group priorities are assigned in the GRPnPRI fields of the DMA Control Register (CR). All group priorities must have unique values prior to any channel service requests occurring; otherwise, a configuration error will be reported. For group round robin arbitration, the group priorities are ignored and the groups are cycled through (from high to low group number) without regard to priority.

Minor loop offsets are address offset values added to the final source address (TCDn_SADDR) or destination address (TCDn_DADDR) upon minor loop completion. When minor loop offsets are enabled, the minor loop offset (MLOFF) is added to the final source address (TCDn_SADDR), to the final destination address (TCDn_DADDR), or to both prior to the addresses being written back into the TCD. If the major loop is complete, the minor loop offset is ignored and the major loop address offsets (TCDn_SLAST and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

When minor loop mapping is enabled (EMLM is 1), TCDn word2 is redefined. A portion of TCDn word2 is used to specify multiple fields: a source enable bit (SMLOE) to specify the minor loop offset should be applied to the source address (TCDn_SADDR) upon minor loop completion, a destination enable bit (DMLOE) to specify the minor loop offset should be applied to the destination address (TCDn_DADDR) upon minor loop completion, and the sign extended minor loop offset value (MLOFF). The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. When both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

When minor loop mapping is disabled (EMLM is 0), all 32 bits of TCDn word2 are assigned to the NBYTES field.

14.4.5.2.3 Diagram



14.4.5.2.4 Fields

Field	Function
31 ACTIVE	DMA Active Status 0b - eDMA is idle. 1b - eDMA is executing a channel.
30-24 —	eDMA version number Reserved
23-18 —	Reserved
17 CX	Cancel Transfer 0b - Normal operation 1b - Cancel the remaining data transfer. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The CX bit clears itself after the cancel has been honored. This cancel retires the channel normally as if the minor loop was completed.
16 ECX	Error Cancel Transfer 0b - Normal operation 1b - Cancel the remaining data transfer in the same fashion as the CX bit. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The ECX bit clears itself after the cancel is honored. In addition to cancelling the transfer, ECX treats the cancel as an error condition, thus updating the Error Status register (DMAx_ES) and generating an optional error interrupt.
15-11 —	Reserved
10 GRP1PRI	Channel Group 1 Priority Group 1 priority level when fixed priority group arbitration is enabled.
9 —	Reserved

Table continues on the next page...

Field	Function
8 GRP0PRI	Channel Group 0 Priority Group 0 priority level when fixed priority group arbitration is enabled.
7 EMLM	Enable Minor Loop Mapping 0b - Disabled. TCDn.word2 is defined as a 32-bit NBYTES field. 1b - Enabled. TCDn.word2 is redefined to include individual enable fields, an offset field, and the NBYTES field. The individual enable fields allow the minor loop offset to be applied to the source address, the destination address, or both. The NBYTES field is reduced when either offset is enabled.
6 CLM	Continuous Link Mode **NOTE:** Do not use continuous link mode with a channel linking to itself if there is only one minor loop iteration per service request, for example, if the channel's NBYTES value is the same as either the source or destination size. The same data transfer profile can be achieved by simply increasing the NBYTES value, which provides more efficient, faster processing. 0b - A minor loop channel link made to itself goes through channel arbitration before being activated again. 1b - A minor loop channel link made to itself does not go through channel arbitration before being activated again. Upon minor loop completion, the channel activates again if that channel has a minor loop channel link enabled and the link channel is itself. This effectively applies the minor loop offsets and restarts the next minor loop.
5 HALT	Halt DMA Operations 0b - Normal operation 1b - Stall the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this bit is cleared.
4 HOE	Halt On Error 0b - Normal operation 1b - Any error causes the HALT bit to set. Subsequently, all service requests are ignored until the HALT bit is cleared.
3 ERGA	Enable Round Robin Group Arbitration 0b - Fixed priority arbitration is used for selection among the groups. 1b - Round robin arbitration is used for selection among the groups.
2 ERCA	Enable Round Robin Channel Arbitration 0b - Fixed priority arbitration is used for channel selection within each group. 1b - Round robin arbitration is used for channel selection within each group.
1 EDBG	Enable Debug 0b - When in debug mode, the DMA continues to operate. 1b - When in debug mode, the DMA stalls the start of a new channel. Executing channels are allowed to complete. Channel execution resumes when the system exits debug mode or the EDBG bit is cleared.
0 EBWR	Enable Buffered Writes 0b - Buffered writes are disabled. 1b - Buffered writes are enabled.

14.4.5.3 Error Status Register (ES)

14.4.5.3.1 Offset

Register	Offset
ES	4h

14.4.5.3.2 Function

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- A configuration error, that is:
  - An illegal setting in the transfer-control descriptor, or
  - An illegal priority register setting in fixed-arbitration
- An error termination to a bus master read or write cycle
- A cancel transfer with error bit that will be set when a transfer is canceled via the corresponding cancel transfer control bit

See Fault reporting and handling for more details.

14.4.5.3.4 Fields

Field	Function
31 VLD	VLD Logical OR of all ERR status bits 0b - No ERR bits are set. 1b - At least one ERR bit is set indicating a valid error exists that has not been cleared.
30-17 —	Reserved

Table continues on the next page...

Field	Function
16 ECX	Transfer Canceled 0b - No canceled transfers 1b - The last recorded entry was a canceled transfer by the error cancel transfer input
15 GPE	Group Priority Error 0b - No group priority error 1b - The last recorded error was a configuration error among the group priorities. All group priorities are not unique.
14 CPE	Channel Priority Error 0b - No channel priority error 1b - The last recorded error was a configuration error in the channel priorities within a group. Channel priorities within a group are not unique.
13 —	Reserved
12-8 ERRCHN	Error Channel Number or Canceled Channel Number The channel number of the last recorded error, excluding GPE and CPE errors, or last recorded error canceled transfer.
7 SAE	Source Address Error 0b - No source address configuration error. 1b - The last recorded error was a configuration error detected in the TCDn_SADDR field. TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE].
6 SOE	Source Offset Error 0b - No source offset configuration error 1b - The last recorded error was a configuration error detected in the TCDn_SOFF field. TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE].
5 DAE	Destination Address Error 0b - No destination address configuration error 1b - The last recorded error was a configuration error detected in the TCDn_DADDR field. TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE].
4 DOE	Destination Offset Error 0b - No destination offset configuration error 1b - The last recorded error was a configuration error detected in the TCDn_DOFF field. TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE].
3 NCE	NBYTES/CITER Configuration Error 0b - No NBYTES/CITER configuration error 1b - The last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields. TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE], orTCDn_CITER[CITER] is equal to zero, orTCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK]
2 SGE	Scatter/Gather Configuration Error 0b - No scatter/gather configuration error 1b - The last recorded error was a configuration error detected in the TCDn_DLASTSGA field. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG] is enabled. TCDn_DLASTSGA is not on a 32 byte boundary.
1 SBE	Source Bus Error 0b - No source bus error 1b - The last recorded error was a bus error on a source read
0 DBE	Destination Bus Error 0b - No destination bus error 1b - The last recorded error was a bus error on a destination write

14.4.5.4 Enable Request Register (ERQ)

14.4.5.4.1 Offset

Register	Offset
ERQ	Ch

14.4.5.4.2 Function

The ERQ register provides a bit map for the 32 channels to enable the request signal for each channel. The state of any given channel enable is directly affected by writes to this register; it is also affected by writes to the SERQ and CERQ registers. These registers are provided so the request enable for a single channel can easily be modified without needing to perform a read-modify-write sequence to this register.

DMA request input signals and this enable request flag must be asserted before a channel's hardware service request is accepted. The state of the DMA enable request flag does not affect a channel service request made explicitly through software or a linked channel request.

NOTE

Disable a channel's hardware service request at the source before clearing the channel's ERQ bit.

14.4.5.5 Enable Error Interrupt Register (EEI)

14.4.5.5.1 Offset

Register	Offset
EEI	14h

14.4.5.5.2 Function

The EEI register provides a bit map for the 32 channels to enable the error interrupt signal for each channel. The state of any given channel's error interrupt enable is directly affected by writes to this register; it is also affected by writes to the SEEI and CEEI. These registers are provided so that the error interrupt enable for a single channel can easily be modified without the need to perform a read-modify-write sequence to the EEI register.

The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller.

14.4.5.6 Clear Enable Error Interrupt Register (CEEI)

14.4.5.6.1 Offset

Register	Offset
CEEI	18h

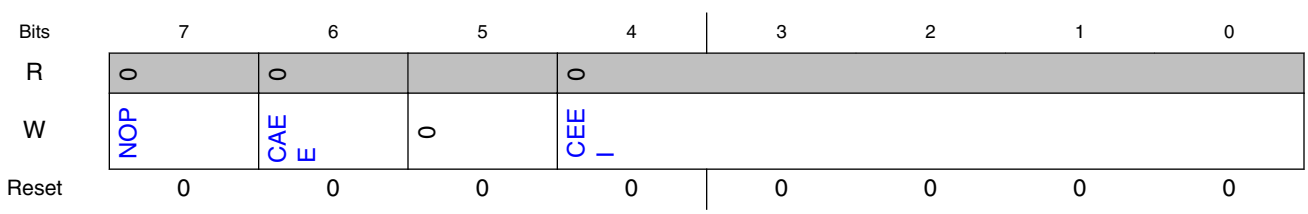
14.4.5.6.2 Function

The CEEI provides a simple memory-mapped mechanism to clear a given bit in the EEI to disable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI to be cleared. Setting the CAEE bit provides a global clear function, forcing the EEI contents to be cleared, disabling all DMA request inputs.

If the NOP bit is set, the command is ignored. This allows you to set a single, byte-wide register with a 32-bit write while not affecting the other registers addressed in the write. In such a case the other three bytes of the word would all have their NOP bit set so that that these register will not be affected by the write.

Reads of this register return all zeroes.

14.4.5.6.3 Diagram



14.4.5.6.4 Fields

Field	Function
7 NOP	No Op enable 0b - Normal operation 1b - No operation, ignore the other bits in this register
6 CAEE	Clear All Enable Error Interrupts 0b - Clear only the EEI bit specified in the CEEI field 1b - Clear all bits in EEI
5 —	Reserved
4-0 CEEI	Clear Enable Error Interrupt Clears the corresponding bit in EEI

14.4.5.7 Set Enable Error Interrupt Register (SEEI)

14.4.5.7.1 Offset

Register	Offset
SEEI	19h

14.4.5.7.2 Function

The SEEI provides a simple memory-mapped mechanism to set a given bit in the EEI to enable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI to be set. Setting the SAEE bit provides a global set function, forcing the entire EEI contents to be set.

If the NOP bit is set, the command is ignored. This allows you to set a single, byte-wide register with a 32-bit write while not affecting the other registers addressed in the write. In such a case the other three bytes of the word would all have their NOP bit set so that that these register will not be affected by the write.

Reads of this register return all zeroes.

14.4.5.8 Clear Enable Request Register (CERQ)

14.4.5.8.1 Offset

Register	Offset
CERQ	1Ah

14.4.5.8.2 Function

The CERQ provides a simple memory-mapped mechanism to clear a given bit in the ERQ to disable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ to be cleared. Setting the CAER bit provides a global clear function, forcing the entire contents of the ERQ to be cleared, disabling all DMA request inputs.

If the NOP bit is set, the command is ignored. This allows you to set a single, byte-wide register with a 32-bit write while not affecting the other registers addressed in the write. In such a case the other three bytes of the word would all have their NOP bit set so that that these register will not be affected by the write.

Reads of this register return all zeroes.

NOTE

Disable a channel's hardware service request at the source before clearing the channel's ERQ bit.

14.4.5.8.3 Diagram

4-0 SERQ	Set Enable Request Sets the corresponding bit in ERQ.

14.4.5.10 Clear DONE Status Bit Register (CDNE)

14.4.5.10.1 Offset

Register	Offset
CDNE	1Ch

14.4.5.10.2 Function

The CDNE provides a simple memory-mapped mechanism to clear the DONE bit in the TCD of the given channel. The data value on a register write causes the DONE bit in the corresponding transfer control descriptor to be cleared. Setting the CADN bit provides a global clear function, forcing all DONE bits to be cleared.

If the NOP bit is set, the command is ignored. This allows you to set a single, byte-wide register with a 32-bit write while not affecting the other registers addressed in the write. In such a case the other three bytes of the word would all have their NOP bit set so that that these register will not be affected by the write.

Reads of this register return all zeroes.

14.4.5.12 Clear Error Register (CERR)

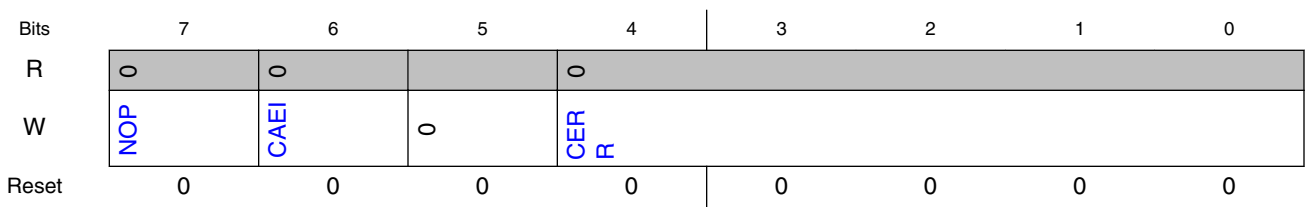
14.4.5.12.1 Offset

Register	Offset
CERR	1Eh

14.4.5.12.2 Function

The CERR provides a simple memory-mapped mechanism to clear a given bit in the ERR to disable the error condition flag for a given channel. The given value on a register write causes the corresponding bit in the ERR to be cleared. Setting the CAEI bit provides a global clear function, forcing the ERR contents to be cleared, clearing all channel error indicators. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

14.4.5.12.3 Diagram



14.4.5.12.4 Fields

Field	Function
7 NOP	No Op enable 0b - Normal operation 1b - No operation, ignore the other bits in this register

14.4.5.13.4 Fields

Field	Function
7 NOP	No Op enable 0b - Normal operation 1b - No operation, ignore the other bits in this register
6 CAIR	Clear All Interrupt Requests 0b - Clear only the INT bit specified in the CINT field 1b - Clear all bits in INT
5 —	Reserved
4-0 CINT	Clear Interrupt Request Clears the corresponding bit in INT

14.4.5.14 Interrupt Request Register (INT)

14.4.5.14.1 Offset

Register	Offset
INT	24h

14.4.5.14.2 Function

The INT register provides a bit map for the 32 channels signaling the presence of an interrupt request for each channel. Depending on the appropriate bit setting in the transfer-control descriptors, the eDMA engine generates an interrupt on data transfer completion. The outputs of this register are directly routed to the interrupt controller. During the interrupt-service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. Typically, a write to the CINT register in the interrupt service routine is used for this purpose.

The state of any given channel's interrupt request is directly affected by writes to this register; it is also affected by writes to the CINT register. On writes to INT, a 1 in any bit position clears the corresponding channel's interrupt request. A zero in any bit position has no affect on the corresponding channel's current interrupt status. The CINT register is provided so the interrupt request for a single channel can easily be cleared without the need to perform a read-modify-write sequence to the INT register.

14.4.5.15 Error Register (ERR)

14.4.5.15.1 Offset

Register	Offset
ERR	2Ch

14.4.5.15.2 Function

The ERR register provides a bit map for the 32 channels, signaling the presence of an error for each channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate bit in this register. The outputs of this register are enabled by the contents of the EEI register, then logically summed across groups of 16 and 32 channels to form several group error interrupt requests, which are then routed to the interrupt controller. During the execution of the interrupt-service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. Typically, a write to the CERR in the interrupt-service routine is used for this purpose. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when an error is detected.

The contents of this register can also be polled because a non-zero value indicates the presence of a channel error regardless of the state of the EEI fields. The state of any given channel's error indicators is affected by writes to this register; it is also affected by writes to the CERR. On writes to the ERR, a one in any bit position clears the corresponding channel's error status. A zero in any bit position has no affect on the corresponding channel's current error status. The CERR is provided so the error indicator for a single channel can easily be cleared.

14.4.5.16 Hardware Request Status Register (HRS)

14.4.5.16.1 Offset

Register	Offset
HRS	34h

14.4.5.16.2 Function

The HRS register provides a bit map for the DMA channels, signaling the presence of a hardware request for each channel. The hardware request status bits reflect the current state of the register and qualified (via the ERQ fields) DMA request signals as seen by the DMA's arbitration logic. This view into the hardware request signals may be used for debug purposes.

NOTE

These bits reflect the state of the request as seen by the arbitration logic. Therefore, this status is affected by the ERQ bits.

DCHPRI28	11Fh

14.4.5.18.2 Function

When fixed-priority channel arbitration is enabled (CR[ERCA] = 0), the contents of these registers define the unique priorities associated with each channel within a group. The channel priorities are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, etc. Software must program the channel priorities with unique values; otherwise, a configuration error is reported. The range of the priority value is limited to the values of 0 through 15. When read, the GRPPRI bits of the DCHPRIn register reflect the current priority level of the group of channels in which the corresponding channel resides. GRPPRI bits are not affected by writes to the DCHPRIn registers. The group priority is assigned in the DMA control register.

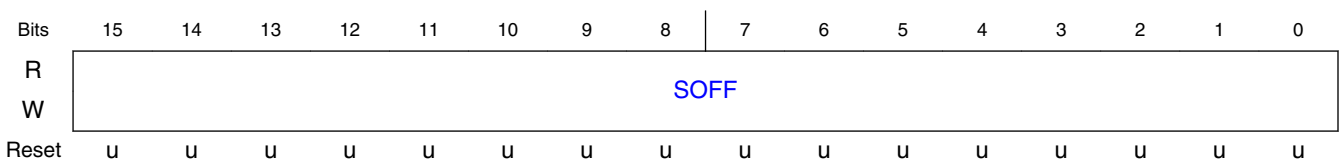
TCDn_SOFF	1004h + (n × 20h)

14.4.5.20.2 Diagram



14.4.5.20.3 Fields

Field	Function
15-0 SOFF	Source address signed offset Sign-extended offset applied to the current source address to form the next-state value as each source read is completed.

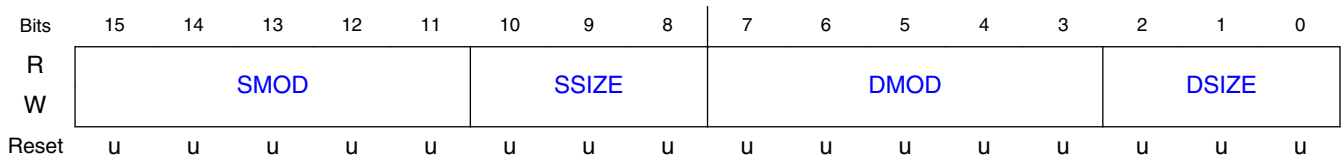
14.4.5.21 TCD Transfer Attributes (TCD0_ATTR - TCD31_ATTR)

14.4.5.21.1 Offset

For n = 0 to 31:

Register	Offset
TCDn_ATTR	1006h + (n × 20h)

14.4.5.21.2 Diagram



14.4.5.21.3 Fields

Field	Function
15-11 SMOD	Source Address Modulo 00000b - Source address modulo feature is disabled 00001-11111b - This value defines a specific address range specified to be the value after SADDR + SOFF calculation is performed on the original register value. Setting this field provides the ability to implement a circular data queue easily. For data queues requiring power-of-2 size bytes, the queue should start at a 0-modulo-size address and the SMOD field should be set to the appropriate value for the queue, freezing the desired number of upper address bits. The value programmed into this field specifies the number of lower address bits allowed to change. For a circular queue application, the SOFF is typically set to the transfer size to implement post-increment addressing with the SMOD function constraining the addresses to a 0-modulo-size range.
10-8 SSIZE	Source data transfer size **NOTE:** Using a Reserved value causes a configuration error. **NOTE:** The eDMA defaults to privileged data access for all transactions. 000b - 8-bit 001b - 16-bit 010b - 32-bit 011b - 64-bit 100b - Reserved 101b - 32-byte burst (4 beats of 64 bits) 110b - Reserved 111b - Reserved
7-3 DMOD	Destination Address Modulo See the SMOD definition
2-0 DSIZE	Destination data transfer size See the SSIZE definition

14.4.5.22 TCD Minor Byte Count (Minor Loop Mapping Disabled) (TCD0_NBYTES_MLNO - TCD31_NBYTES_MLNO)

14.4.5.22.1 Offset

For n = 0 to 31:

Register	Offset
TCDn_NBYTES_MLNO	1008h + (n × 20h)

14.4.5.22.2 Function

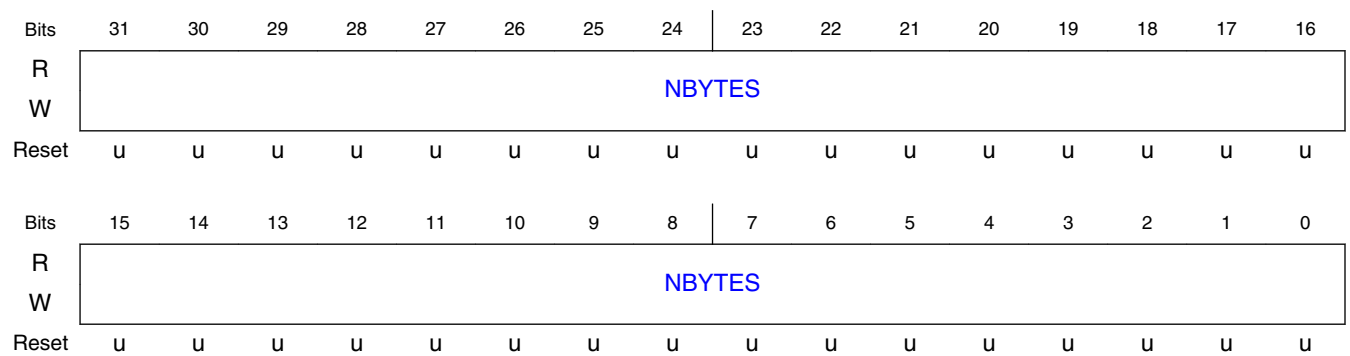
This register, or one of the next two registers (TCD_NBYTES_MLOFFNO, TCD_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is disabled (CR[EMLM] = 0)

If minor loop mapping is enabled, see the TCD_NBYTES_MLOFFNO and TCD_NBYTES_MLOFFYES register descriptions for the definition of TCD word 2.

14.4.5.22.3 Diagram



14.4.5.22.4 Fields

Field	Function
31-0 NBYTES	Minor Byte Transfer Count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.

Field	Function
	NOTE: An NBYTES value of 0x0000_0000 is interpreted as a 4 GB transfer.

14.4.5.23 TCD Signed Minor Loop Offset (Minor Loop Mapping Enabled and Offset Disabled) (TCD0_NBYTES_MLOFFNO - TCD31_NBYTES_MLOFFNO)

14.4.5.23.1 Offset

For n = 0 to 31:

Register	Offset
TCDn_NBYTES_MLOFFNO	1008h + (n × 20h)

14.4.5.23.2 Function

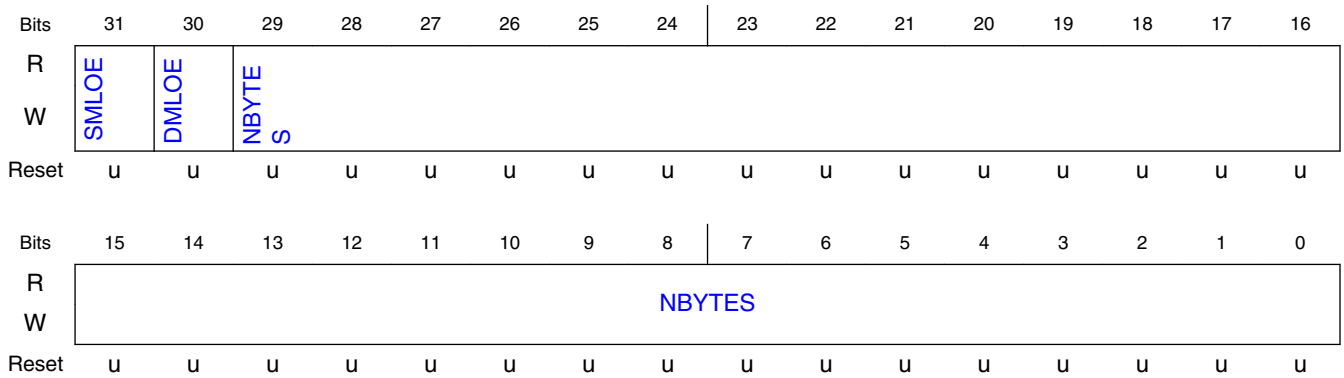
One of three registers (this register, TCD_NBYTES_MLNO, or TCD_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- SMLOE = 0 and DMLOE = 0

If minor loop mapping is enabled and SMLOE or DMLOE is set, then refer to the TCD_NBYTES_MLOFFYES register description. If minor loop mapping is disabled, then refer to the TCD_NBYTES_MLNO register description.

14.4.5.23.3 Diagram



14.4.5.23.4 Fields

Field	Function
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0b - The minor loop offset is not applied to the SADDR 1b - The minor loop offset is applied to the SADDR
30 DMLOE	Destination Minor Loop Offset enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0b - The minor loop offset is not applied to the DADDR 1b - The minor loop offset is applied to the DADDR
29-0 NBYTES	Minor Byte Transfer Count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.

14.4.5.24 TCD Signed Minor Loop Offset (Minor Loop Mapping and Offset Enabled) (TCD0_NBYTES_MLOFFYES - TCD31_NBYTES_MLOFFYES)

14.4.5.24.1 Offset

For n = 0 to 31:

Register	Offset
TCDn_NBYTES_MLOFFYES	1008h + (n × 20h)

14.4.5.24.2 Function

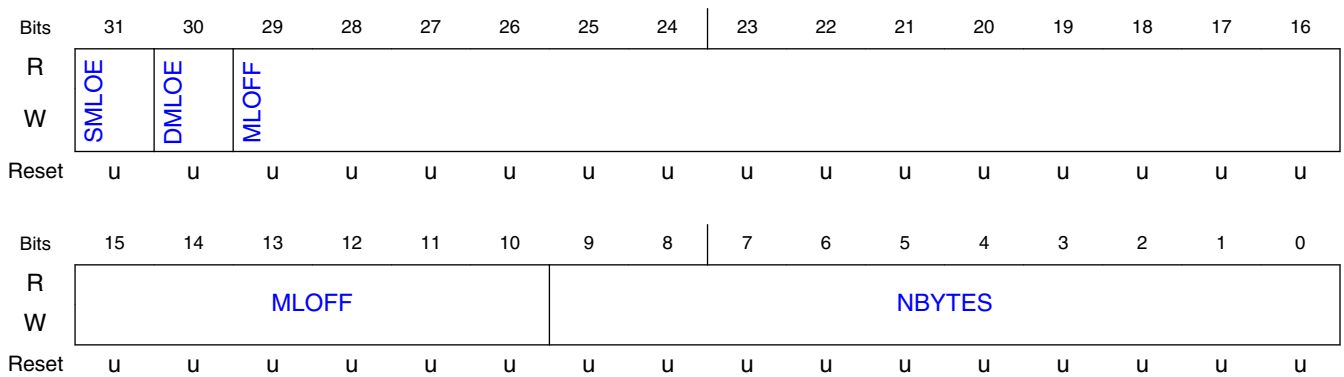
One of three registers (this register, TCD_NBYTES_MLNO, or TCD_NBYTES_MLOFFNO), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- Minor loop offset is enabled (SMLOE or DMLOE = 1)

If minor loop mapping is enabled and SMLOE and DMLOE are cleared, then refer to the TCD_NBYTES_MLOFFNO register description. If minor loop mapping is disabled, then refer to the TCD_NBYTES_MLNO register description.

14.4.5.24.3 Diagram



14.4.5.24.4 Fields

Field	Function
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0b - The minor loop offset is not applied to the SADDR 1b - The minor loop offset is applied to the SADDR
30	Destination Minor Loop Offset enable

Table continues on the next page...

Field	Function
DMLOE	Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0b - The minor loop offset is not applied to the DADDR 1b - The minor loop offset is applied to the DADDR
29-10 MLOFF	If SMLOE or DMLOE is set, this field represents a sign-extended offset applied to the source or destination address to form the next-state value after the minor loop completes.
9-0 NBYTES	Minor Byte Transfer Count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.

14.4.5.25 TCD Last Source Address Adjustment (TCD0_SLAST - TCD31_SLAST)

14.4.5.25.1 Offset

For n = 0 to 31:

Register	Offset
TCDn_SLAST	100Ch + (n × 20h)

14.4.5.25.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

14.4.5.25.3 Fields

Field	Function
31-0 SLAST	Last Source Address Adjustment Adjustment value added to the source address at the completion of the major iteration count. This value can be applied to restore the source address to the initial value, or adjust the address to reference the next data structure. This register uses two's complement notation; the overflow bit is discarded.

14.4.5.26 TCD Destination Address (TCD0_DADDR - TCD31_DADDR)

14.4.5.26.1 Offset

For n = 0 to 31:

Register	Offset
TCDn_DADDR	1010h + (n × 20h)

14.4.5.26.2 Function

This register contains the destination address of the transfer.

14.4.5.26.3 Diagram

14.4.5.26.4 Fields

Field	Function
31-0	Destination Address

Field	Function
DADDR	Memory address pointing to the destination data.

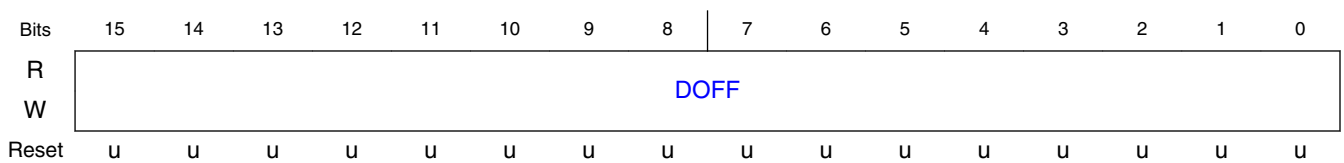
14.4.5.27 TCD Signed Destination Address Offset (TCD0_DOFF - TCD31_DOFF)

14.4.5.27.1 Offset

For n = 0 to 31:

Register	Offset
TCDn_DOFF	1014h + (n × 20h)

14.4.5.27.2 Diagram



14.4.5.27.3 Fields

Field	Function
15-0 DOFF	Destination Address Signed Offset Sign-extended offset applied to the current destination address to form the next-state value as each destination write is completed.

14.4.5.28 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) (TCD0_CITER_ELINKNO - TCD31_CITER_ELINKNO)

14.4.5.28.1 Offset

For n = 0 to 31:

Register	Offset
TCDn_CITER_ELINKNO	1016h + (n × 20h)

14.4.5.28.2 Function

This register contains the minor-loop channel-linking configuration and the channel's current iteration count. It is the same register as TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled) (TCD0_CITER_ELINKYES - TCD31_CITER_ELINKYES), but its fields are defined differently based on the state of the ELINK field. If the ELINK field is cleared, this register is defined as follows.

14.4.5.28.3 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ELINK	CITER														
Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u

14.4.5.28.4 Fields

Field	Function
15 ELINK	Enable channel-to-channel linking on minor-loop complete As the channel completes the minor loop, this flag enables linking to another channel, defined by the LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE:** This bit must be equal to the BITER[ELINK] bit; otherwise, a configuration error is reported. 0b - The channel-to-channel linking is disabled 1b - The channel-to-channel linking is enabled
14-0 CITER	Current Major Iteration Count This field is the current major loop count for the channel. It is decremented each time the minor loop is completed and updated in the transfer control descriptor memory. After the major iteration count is exhausted, the channel performs a number of operations, for example, final source and destination address calculations, optionally generating an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. **NOTE:** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE:** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

14.4.5.29 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled) (TCD0_CITER_ELINKYES - TCD31_CITER_ELINKYES)

14.4.5.29.1 Offset

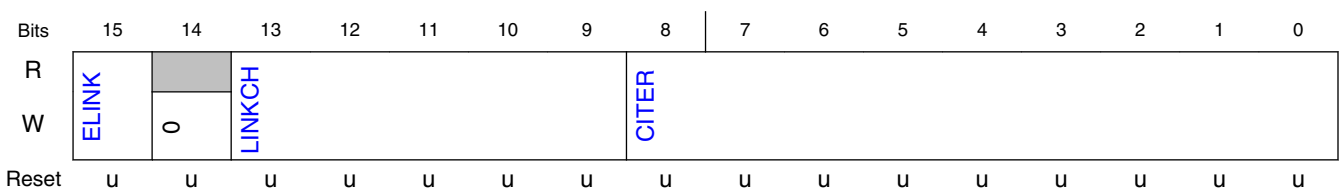
For n = 0 to 31:

Register	Offset
TCDn_CITER_ELINKYES	1016h + (n × 20h)

14.4.5.29.2 Function

This register contains the minor-loop channel-linking configuration and the channel's current iteration count. It is the same register as TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) (TCD0_CITER_ELINKNO - TCD31_CITER_ELINKNO), but its fields are defined differently based on the state of the ELINK field. If the ELINK field is set, this register is defined as follows.

14.4.5.29.3 Diagram



14.4.5.29.4 Fields

Field	Function
15 ELINK	Enable channel-to-channel linking on minor-loop complete As the channel completes the minor loop, this flag enables linking to another channel, defined by the LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE:** This bit must be equal to the BITER[ELINK] bit; otherwise, a configuration error is reported.

Table continues on the next page...

Field	Function
	0b - The channel-to-channel linking is disabled 1b - The channel-to-channel linking is enabled
14 —	Reserved
13-9 LINKCH	Minor Loop Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request to the channel defined by this field by setting that channel's TCDn_CSR[START] bit.
8-0 CITER	Current Major Iteration Count This field is the current major loop count for the channel. It is decremented each time the minor loop is completed and updated in the transfer control descriptor memory. After the major iteration count is exhausted, the channel performs a number of operations, for example, final source and destination address calculations, optionally generating an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. **NOTE:** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE:** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

14.4.5.30 TCD Last Destination Address Adjustment/Scatter Gather Address (TCD0_DLASTSGA - TCD31_DLASTSGA)

14.4.5.30.1 Offset

For n = 0 to 31:

Register	Offset
TCDn_DLASTSGA	1018h + (n × 20h)

14.4.5.30.2 Diagram

14.4.5.30.3 Fields

Field	Function
31-0 DLASTSGA	DLASTSGA Destination last address adjustment or the memory address for the next transfer control descriptor to be loaded into this channel (scatter/gather). If (TCDn_CSR[ESG] = 0) then: • Adjustment value added to the destination address at the completion of the major iteration count. This value can apply to restore the destination address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final destination address adjustment. Otherwise: • This address points to the beginning of a 0-modulo-32-byte region containing the next transfer control descriptor to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo-32-byte, otherwise a configuration error is reported.

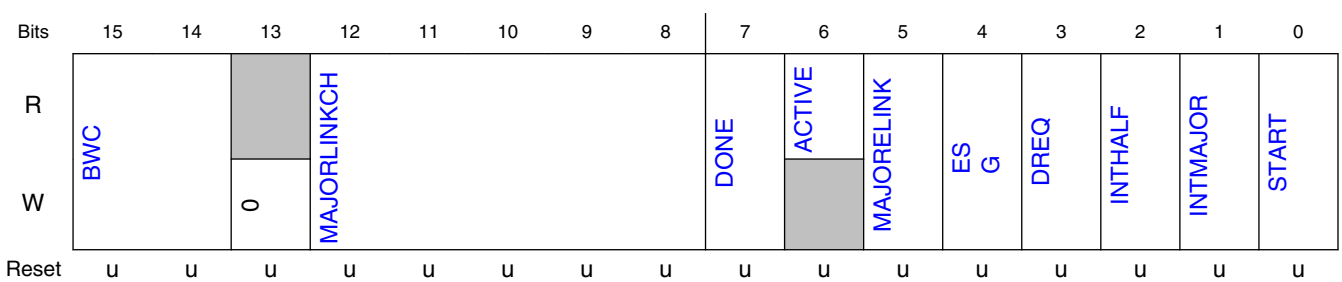
14.4.5.31 TCD Control and Status (TCD0_CSR - TCD31_CSR)

14.4.5.31.1 Offset

For n = 0 to 31:

Register	Offset
TCDn_CSR	101Ch + (n × 20h)

14.4.5.31.2 Diagram



14.4.5.31.3 Fields

Field	Function
15-14 BWC	Bandwidth Control Throttles the amount of bus bandwidth consumed by the eDMA. Generally, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces the eDMA to stall after the completion of each read/write access to control the bus request bandwidth seen by the crossbar switch. **NOTE:** If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency. 00b - No eDMA engine stalls. 01b - Reserved 10b - eDMA engine stalls for 4 cycles after each R/W. 11b - eDMA engine stalls for 8 cycles after each R/W.
13 —	Reserved
12-8 MAJORLINKCH	Major Loop Link Channel Number If (MAJORELINK = 0) then: • No channel-to-channel linking, or chaining, is performed after the major loop counter is exhausted. Otherwise: • After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] bit.
7 DONE	Channel Done This flag indicates the eDMA has completed the major loop. The eDMA engine sets it as the CITER count reaches zero. The software clears it, or the hardware when the channel is activated. **NOTE:** This bit must be cleared to write the MAJORELINK or ESG bits.
6 ACTIVE	Channel Active This flag signals the channel is currently in execution. It is set when channel service begins, and is cleared by the eDMA as the minor loop completes or when any error condition is detected.
5 MAJORELINK	Enable channel-to-channel linking on major loop complete As the channel completes the major loop, this flag enables the linking to another channel, defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. **NOTE:** To support the dynamic linking coherency model, this field is forced to zero when written to while the TCDn_CSR[DONE] bit is set. 0b - The channel-to-channel linking is disabled. 1b - The channel-to-channel linking is enabled.
4 ESG	Enable Scatter/Gather Processing As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses DLASTSGA as a memory pointer to a 0-modulo-32 address containing a 32-byte data structure loaded as the transfer control descriptor into the local memory. **NOTE:** To support the dynamic scatter/gather coherency model, this field is forced to zero when written to while the TCDn_CSR[DONE] bit is set. 0b - The current channel's TCD is normal format. 1b - The current channel's TCD specifies a scatter gather format. The DLASTSGA field provides a memory pointer to the next TCD to be loaded into this channel after the major loop completes its execution.

Table continues on the next page...

Field	Function
3 DREQ	Disable Request If this flag is set, the eDMA hardware automatically clears the corresponding ERQ bit when the current major iteration count reaches zero. 0b - The channel's ERQ bit is not affected. 1b - The channel's ERQ bit is cleared when the major loop is complete.
2 INTHALF	Enable an interrupt when major counter is half complete. If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT register when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER == (BITER >> 1)). This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes or other types of data movement where the processor needs an early indication of the transfer's progress. **NOTE:** If BITER = 1, do not use INTHALF. Use INTMAJOR instead. 0b - The half-point interrupt is disabled. 1b - The half-point interrupt is enabled.
1 INTMAJOR	Enable an interrupt when major iteration count completes. If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT when the current major iteration count reaches zero. 0b - The end-of-major loop interrupt is disabled. 1b - The end-of-major loop interrupt is enabled.
0 START	Channel Start If this flag is set, the channel is requesting service. The eDMA hardware automatically clears this flag after the channel begins execution. 0b - The channel is not explicitly started. 1b - The channel is explicitly started via a software initiated service request.

14.4.5.32 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Disabled) (TCD0_BITER_ELINKNO - TCD31_BITER_ELINKNO)

14.4.5.32.1 Offset

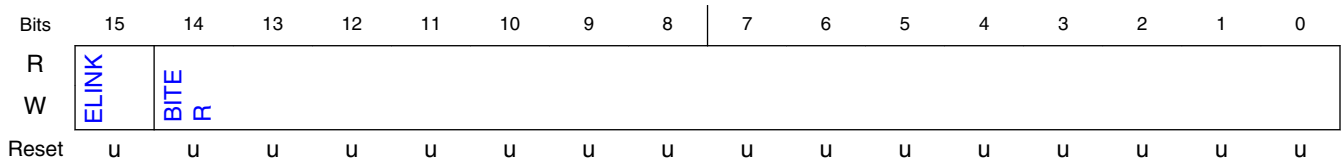
For n = 0 to 31:

Register	Offset
TCDn_BITER_ELINKNO	101Eh + (n × 20h)

14.4.5.32.2 Function

If the TCDn_BITER[ELINK] bit is cleared, the TCDn_BITER register is defined as follows.

14.4.5.32.3 Diagram



14.4.5.32.4 Fields

Field	Function
15 ELINK	Enables channel-to-channel linking on minor loop complete As the channel completes the minor loop, this flag enables the linking to another channel, defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. If channel linking is disabled, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. 0b - The channel-to-channel linking is disabled 1b - The channel-to-channel linking is enabled
14-0 BITER	Starting Major Iteration Count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be equal to the value in the CITER field. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. **NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field is reloaded into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

14.4.5.33 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Enabled) (TCD0_BITER_ELINKYES - TCD31_BITER_ELINKYES)

14.4.5.33.1 Offset

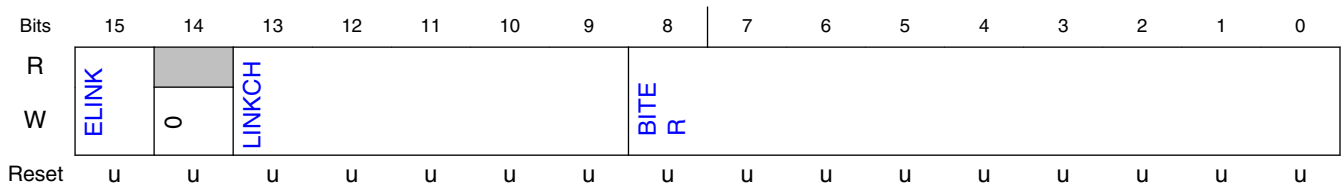
For n = 0 to 31:

Register	Offset
TCDn_BITER_ELINKYES	101Eh + (n × 20h)

14.4.5.33.2 Function

If the TCDn_BITER[ELINK] bit is set, the TCDn_BITER register is defined as follows.

14.4.5.33.3 Diagram



14.4.5.33.4 Fields

Field	Function
15 ELINK	Enables channel-to-channel linking on minor loop complete As the channel completes the minor loop, this flag enables the linking to another channel, defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. If channel linking disables, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. 0b - The channel-to-channel linking is disabled 1b - The channel-to-channel linking is enabled
14 —	Reserved
13-9 LINKCH	Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] bit. **NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field.
8-0 BITER	Starting major iteration count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be equal to the value in the CITER field. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. **NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

14.5 Functional description

The operation of the eDMA is described in the following subsections.

14.5.1 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments.

As shown in the following diagram, the first segment involves the channel activation:

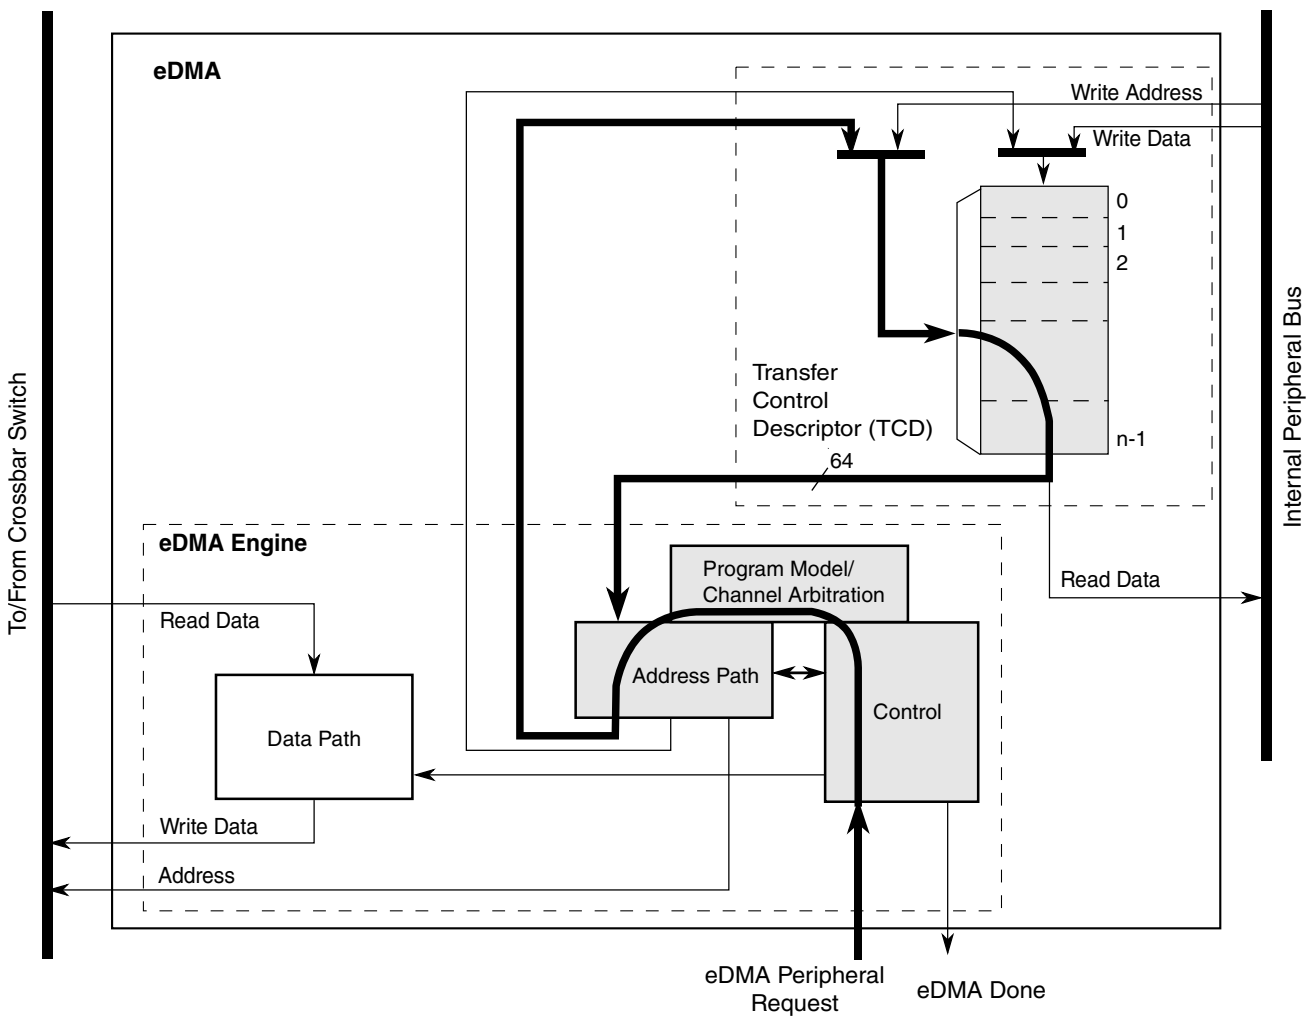


Figure 14-2. eDMA operation, part 1

This example uses the assertion of the eDMA peripheral request signal to request service for channel *n*. Channel activation via software and the TCD*n*_CSR[START] bit follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module,

then into the program model and channel arbitration. In the next cycle, the channel arbitration performs, using the fixed-priority or round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the required address to access the local memory for TCD*n*. Next, the TCD memory is accessed and the required descriptor read from the local memory and loaded into the eDMA engine address path channel x or y registers. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path channel x or y registers.

The following diagram illustrates the second part of the basic data flow:

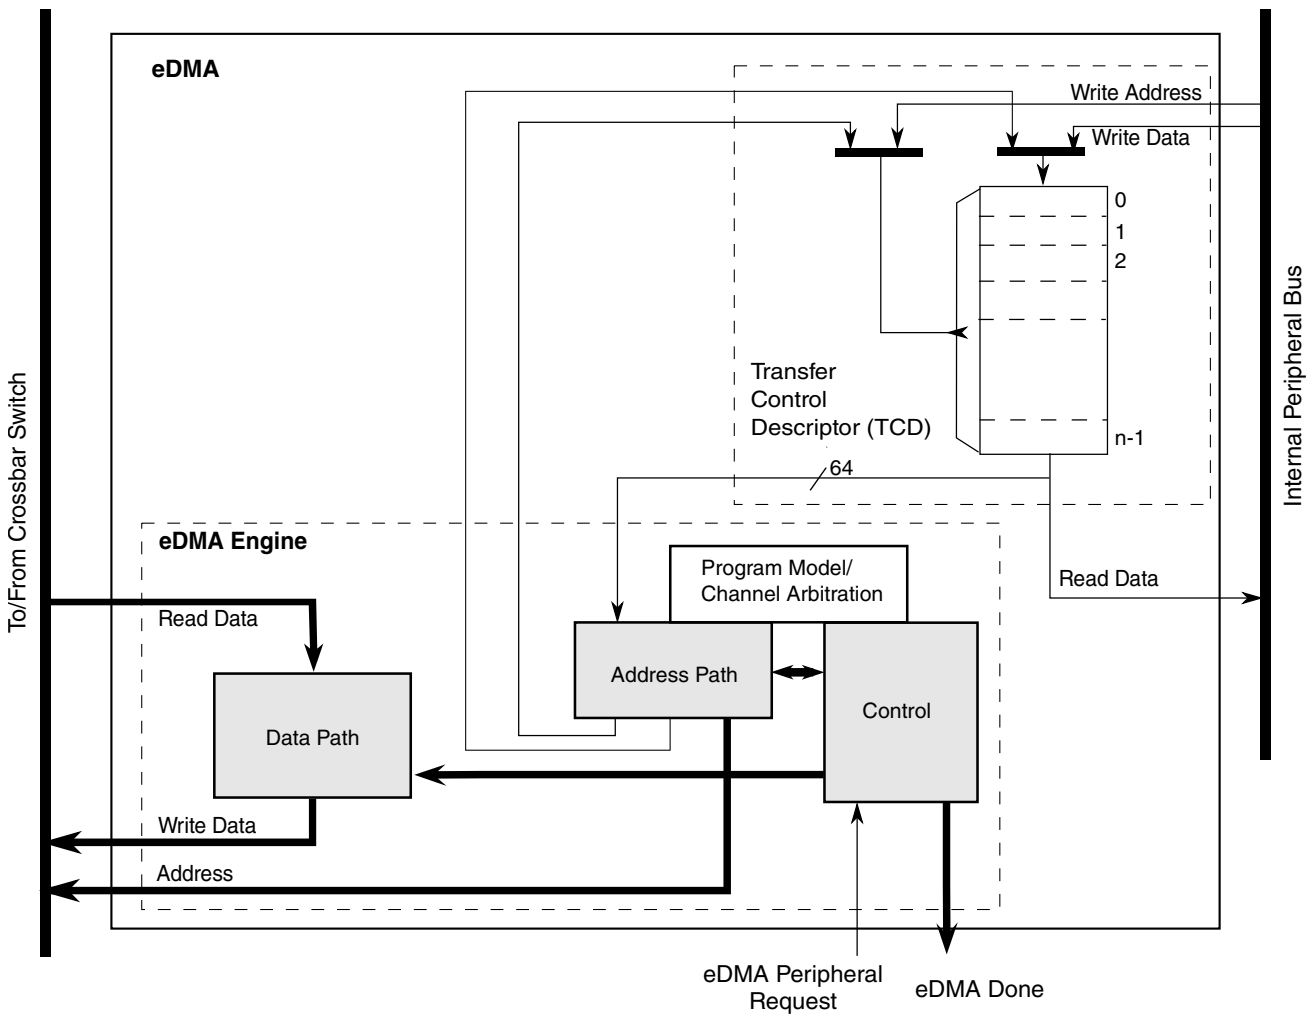

Figure 14-3. eDMA operation, part 2

The modules associated with the data transfer (address path, data path, and control) sequence through the required source reads and destination writes to perform the actual data movement. The source reads are initiated and the fetched data is temporarily stored

in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the minor byte count has transferred.

After the minor byte count has moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs the required updates to certain fields in the appropriate TCD, for example, SADDR, DADDR, CITER. If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor (if scatter/gather is enabled). The updates to the TCD memory and the assertion of an interrupt request are shown in the following diagram.

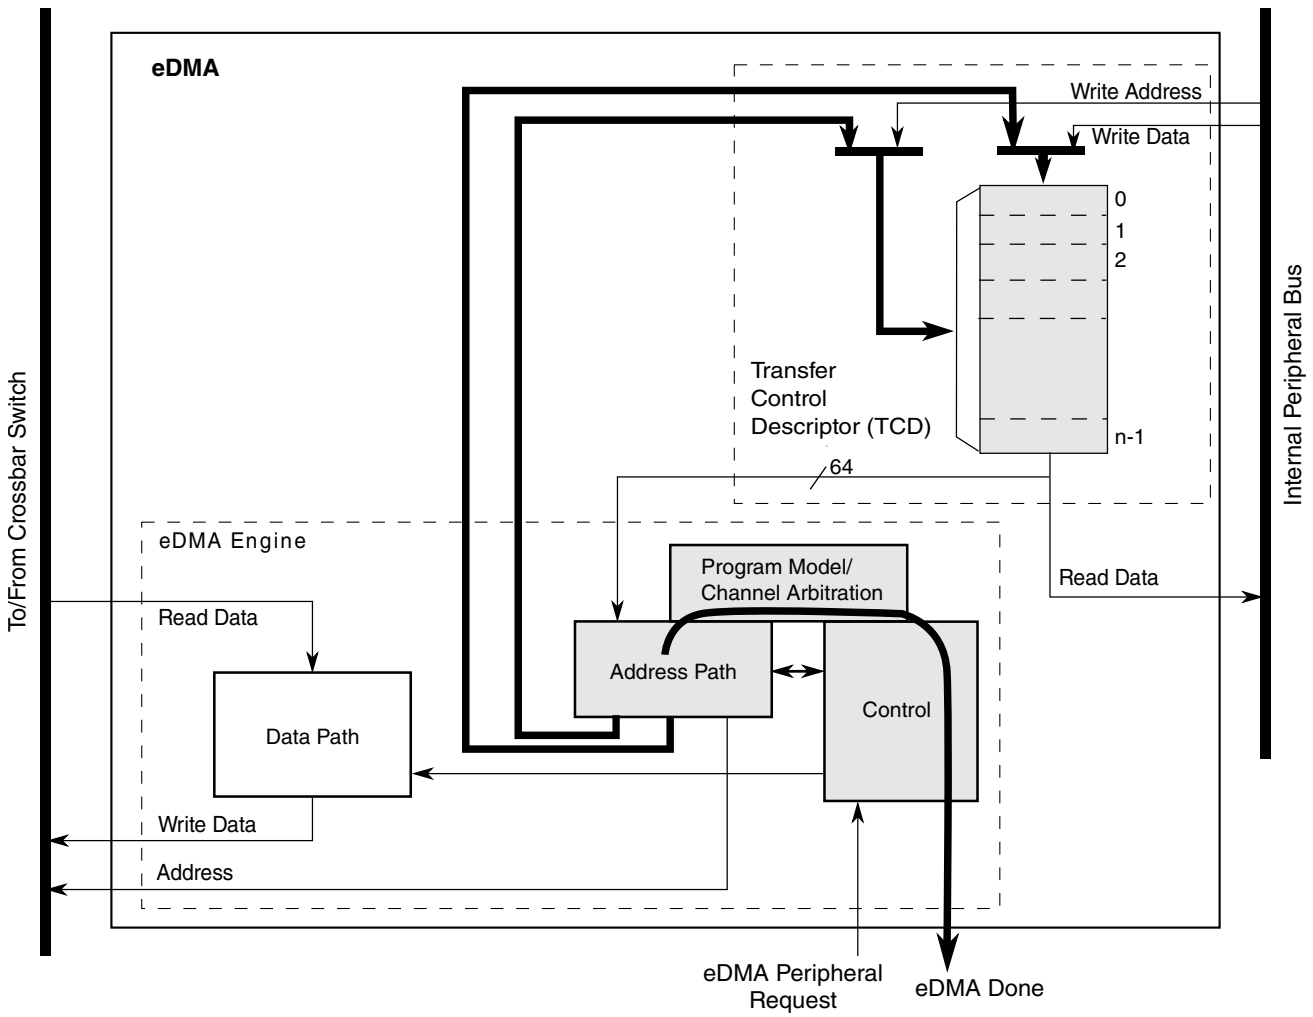

Figure 14-4. eDMA operation, part 3

14.5.2 Fault reporting and handling

Channel errors are reported in the Error Status register (DMAx_ES) and can be caused by:

- A configuration error, which is an illegal setting in the transfer-control descriptor or an illegal priority register setting in Fixed-Arbitration mode, or
- An error termination to a bus master read or write cycle

A configuration error is reported when the starting source or destination address, source or destination offsets, minor loop byte count, or the transfer size represent an inconsistent state. Each of these possible causes are detailed below:

- The addresses and offsets must be aligned on 0-modulo-transfer-size boundaries.
- The minor loop byte count must be a multiple of the source and destination transfer sizes.
- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size respectively.
- In fixed arbitration mode, a configuration error is caused by any two channel priorities being equal. All channel priority levels must be unique when fixed arbitration mode is enabled.

NOTE

When two channels have the same priority, a channel priority error exists and will be reported in the Error Status register. However, the channel number will not be reported in the Error Status register. When all of the channel priorities within a group are not unique, the channel number selected by arbitration in undetermined.

To aid in Channel Priority Error (CPE) debug, set the Halt On Error bit in the DMA's Control Register. If all of the channel priorities within a group are not unique, the DMA will be halted after the CPE error is recorded. The DMA will remain halted and will not process any channel service requests. Once all of the channel priorities are set to unique numbers, the DMA may be enabled again by clearing the Halt bit.

- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (DLAST_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCDn_CITER[E_LINK] bit does not equal the TCDn_BITER[E_LINK] bit.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, report as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion when properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is stopped and the appropriate bus error flag set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address, and current iteration count at the point of the fault. When a system bus error occurs, the channel terminates after the next transfer. Due to pipeline effect, the next transfer is already in progress when the bus error is received by the eDMA. If a bus error occurs on the last read prior to beginning the write sequence, the write executes using the data captured during the bus error. If a bus error occurs on the last write prior to switching to the next read sequence, the read sequence executes before the channel terminates due to the destination bus error.

A transfer may be cancelled by software with the CR[CX] bit. When a cancel transfer request is recognized, the DMA engine stops processing the channel. The current read-write sequence is allowed to finish. If the cancel occurs on the last read-write sequence of a major or minor loop, the cancel request is discarded and the channel retires normally.

The error cancel transfer is the same as a cancel transfer except the Error Status register (DMAx_ES) is updated with the cancelled channel number and ECX is set. The TCD of a cancelled channel contains the source and destination addresses of the last transfer saved in the TCD. If the channel needs to be restarted, you must re-initialize the TCD because the aforementioned fields no longer represent the original parameters. When a transfer is cancelled by the error cancel transfer mechanism, the channel number is loaded into DMA_ES[ERRCHN] and ECX and VLD are set. In addition, an error interrupt may be generated if enabled.

NOTE

The cancel transfer request allows the user to stop a large data transfer in the event the full data transfer is no longer needed. The cancel transfer bit does not abort the channel. It simply stops the transferring of data and then retires the channel through its normal shutdown sequence. The application

software must handle the context of the cancel. If an interrupt is desired (or not), then the interrupt should be enabled (or disabled) before the cancel request. The application software must clean up the transfer control descriptor since the full transfer did not occur.

The occurrence of any error causes the eDMA engine to stop normal processing of the active channel immediately (it goes to its error processing states and the transaction to the system bus still has pipeline effect), and the appropriate channel bit in the eDMA error register is asserted. At the same time, the details of the error condition are loaded into the Error Status register (DMAx_ES). The major loop complete indicators, setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request, are not affected when an error is detected. After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

14.5.3 Channel preemption

Channel preemption is enabled on a per-channel basis by setting the DCHPRIn[ECP] bit. Channel preemption allows the executing channel's data transfers to temporarily suspend in favor of starting a higher priority channel. After the preempting channel has completed all its minor loop data transfers, the preempted channel is restored and resumes execution. After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended and the higher priority channel is serviced. Nested preemption, that is, attempting to preempt a preempting channel, is not supported. After a preempting channel begins execution, it cannot be preempted. Preemption is available only when fixed arbitration is selected.

A channel's ability to preempt another channel can be disabled by setting DCHPRIn[DPA]. When a channel's preempt ability is disabled, that channel cannot suspend a lower priority channel's data transfer, regardless of the lower priority channel's ECP setting. This allows for a pool of low priority, large data-moving channels to be defined. These low priority channels can be configured to not preempt each other, thus preventing a low priority channel from consuming the preempt slot normally available to a true, high priority channel.

14.5.4 Performance

This section addresses the performance of the eDMA module, focusing on two separate metrics:

- In the traditional data movement context, performance is best expressed as the peak data transfer rates achieved using the eDMA. In most implementations, this transfer rate is limited by the speed of the source and destination address spaces.
- In a second context where device-paced movement of single data values to/from peripherals is dominant, a measure of the requests that can be serviced in a fixed time is a more relevant metric. In this environment, the speed of the source and destination address spaces remains important. However, the microarchitecture of the eDMA also factors significantly into the resulting metric.

14.5.4.1 Peak transfer rates

The peak transfer rates for several different source and destination transfers are shown in the following tables. These tables assume:

- Internal SRAM can be accessed with zero wait-states when viewed from the system bus data phase
- All internal peripheral bus reads require two wait-states, and internal peripheral bus writes three wait-states, when viewed from the system bus data phase
- All internal peripheral bus accesses are 32-bits in size

NOTE

All architectures will not meet the assumptions listed above. See the SRAM configuration section for more information.

This table compares peak transfer rates based on different possible system speeds. Specific chips/devices may not support all system speeds listed.

Table 14-6. eDMA peak transfer rates (Mbytes/sec)

System Speed, Width	Internal SRAM-to-Internal SRAM	32 bit internal peripheral bus-to-Internal SRAM	Internal SRAM-to-32 bit internal peripheral bus
66.7 MHz, 64 bit	266.7	66.6	53.3
83.3 MHz, 64 bit	333.3	83.3	66.7
100.0 MHz, 64 bit	400.0	100.0	80.0
133.3 MHz, 64 bit	533.3	133.3	106.7
150.0 MHz, 64 bit	600.0	150.0	120.0

Internal-SRAM-to-internal-SRAM transfers occur at the core's datapath width. For all transfers involving the internal peripheral bus, 32-bit transfer sizes are used. In all cases, the transfer rate includes the time to read the source plus the time to write the destination.

14.5.4.2 Peak request rates

The second performance metric is a measure of the number of DMA requests that can be serviced in a given amount of time. For this metric, assume that the peripheral request causes the channel to move a single internal peripheral bus-mapped operand to/from internal SRAM. The same timing assumptions used in the previous example apply to this calculation. In particular, this metric also reflects the time required to activate the channel.

The eDMA design supports the following hardware service request sequence. Note that the exact timing from Cycle 7 is a function of the response times for the channel's read and write accesses. In the case of an internal peripheral bus read and internal SRAM write, the combined data phase time is 4 cycles. For an SRAM read and internal peripheral bus write, it is 5 cycles.

Table 14-7. Hardware service request process

Cycle		Description
With internal peripheral bus read and internal SRAM write	With SRAM read and internal peripheral bus write	
1		eDMA peripheral request is asserted.
2		The eDMA peripheral request is registered locally in the eDMA module and qualified. TCD*n*_CSR[START] bit initiated requests start at this point with the registering of the user write to TCD*n* word 7.
3		Channel arbitration begins.
4		Channel arbitration completes. The transfer control descriptor local memory read is initiated.
5–6		The first two parts of the activated channel's TCD is read from the local memory. The memory width to the eDMA engine is 64 bits, so the entire descriptor can be accessed in four cycles
7		The first system bus read cycle is initiated, as the third part of the channel's TCD is read from the local memory. Depending on the state of the crossbar switch, arbitration at the system bus may insert an additional cycle of delay here.
8–11	8–12	The last part of the TCD is read in. This cycle represents the first data phase for the read, and the address phase for the destination write.
12	13	This cycle represents the data phase of the last destination write.

Table continues on the next page...

Table 14-7. Hardware service request process (continued)

Cycle		Description
With internal peripheral bus read and internal SRAM write	With SRAM read and internal peripheral bus write	
13	14	The eDMA engine completes the execution of the inner minor loop and prepares to write back the required TCD*n* fields into the local memory. The TCD*n* word 7 is read and checked for channel linking or scatter/gather requests.
14	15	The appropriate fields in the first part of the TCD*n* are written back into the local memory.
15	16	The fields in the second part of the TCD*n* are written back into the local memory. This cycle coincides with the next channel arbitration cycle start.
16	17	The next channel to be activated performs the read of the first part of its TCD from the local memory. This is equivalent to Cycle 4 for the first channel's service request.

Assuming zero wait states on the system bus, DMA requests can be processed every 9 cycles. Assuming an average of the access times associated with internal peripheral bus-to-SRAM (4 cycles) and SRAM-to-internal peripheral bus (5 cycles), DMA requests can be processed every 11.5 cycles (4 + (4+5)/2 + 3). This is the time from Cycle 4 to Cycle x +5. The resulting peak request rate, as a function of the system frequency, is shown in the following table.

Table 14-8. eDMA peak request rate (MReq/sec)

System frequency (MHz)	Request rate with zero wait states	Request rate with wait states
48.0	5.3	4.2
66.6	7.4	5.8
83.3	9.2	7.2
100.0	11.1	8.7
133.3	14.8	11.6
150.0	16.6	13.0

A general formula to compute the peak request rate with overlapping requests is:

PEAKreq = freq / [entry + (1 + read_ws) + (1 + write_ws) + exit]

where:

Table 14-9. Peak request formula operands

Operand	Description
PEAKreq	Peak request rate

Table continues on the next page...

Table 14-9. Peak request formula operands (continued)

Operand	Description
freq	System frequency
entry	Channel startup (4 cycles)
read_ws	Wait states seen during the system bus read data phase
write_ws	Wait states seen during the system bus write data phase
exit	Channel shutdown (3 cycles)

14.5.4.3 eDMA performance example

Consider a system with the following characteristics:

- Internal SRAM can be accessed with one wait-state when viewed from the system bus data phase
- All internal peripheral bus reads require two wait-states, and internal peripheral bus writes three wait-states viewed from the system bus data phase
- System operates at 150 MHz

For an SRAM to internal peripheral bus transfer,

PEAKreq = 150 MHz / [4 + (1 + 1) + (1 + 3) + 3] cycles = 11.5 Mreq/sec

For an internal peripheral bus to SRAM transfer,

PEAKreq = 150 MHz / [4 + (1 + 2) + (1 + 1) + 3] cycles = 12.5 Mreq/sec

Assuming an even distribution of the two transfer types, the average peak request rate would be:

PEAKreq = (11.5 Mreq/sec + 12.5 Mreq/sec) / 2 = 12.0 Mreq/sec

The minimum number of cycles to perform a single read/write, zero wait states on the system bus, from a cold start where no channel is executing and eDMA is idle are:

- 11 cycles for a software, that is, a TCD*n*_CSR[START] bit, request
- 12 cycles for a hardware, that is, an eDMA peripheral request signal, request

Two cycles account for the arbitration pipeline and one extra cycle on the hardware request resulting from the internal registering of the eDMA peripheral request signals. For the peak request rate calculations above, the arbitration and request registering is absorbed in or overlaps the previous executing channel.

Note

When channel linking or scatter/gather is enabled, a two cycle delay is imposed on the next channel selection and startup. This allows the link channel or the scatter/gather channel to be eligible and considered in the arbitration pool for next channel selection.

14.6 Initialization/application information

The following sections discuss initialization of the eDMA and programming considerations.

14.6.1 eDMA initialization

To initialize the eDMA:

1. Write to the CR if a configuration other than the default is desired.
2. Write the channel priority levels to the DCHPRI*n* registers if a configuration other than the default is desired.
3. Enable error interrupts in the EEI register if so desired.
4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the ERQ register.
6. Request channel service via either:
   - Software: setting the TCD*n*_CSR[START]
   - Hardware: slave device asserting its eDMA peripheral request signal

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields, as shown in the following table, for the selected channel into its internal address path module.

As the TCD is read, the first transfer is initiated on the internal bus, unless a configuration error is detected. Transfers from the source, as defined by TCD*n*_SADDR, to the destination, as defined by TCD*n*_DADDR, continue until the number of bytes specified by TCD*n*_NBYTES are transferred.

When the transfer is complete, the eDMA engine's local TCD*n*_SADDR, TCD*n*_DADDR, and TCD*n*_CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, further post processing executes, such as interrupts, major loop channel linking, and scatter/gather operations, if enabled.

Table 14-10. TCD Control and Status fields

TCD*n*_CSR field name	Description
START	Control bit to start channel explicitly when using a software initiated DMA service (Automatically cleared by hardware)
ACTIVE	Status bit indicating the channel is currently in execution
DONE	Status bit indicating major loop completion (cleared by software when using a software initiated DMA service)
D_REQ	Control bit to disable DMA request at end of major loop completion when using a hardware initiated DMA service
BWC	Control bits for throttling bandwidth control of a channel
E_SG	Control bit to enable scatter-gather feature
INT_HALF	Control bit to enable interrupt when major loop is half complete
INT_MAJ	Control bit to enable interrupt when major loop completes

The following figure shows how each DMA request initiates one minor-loop transfer, or iteration, without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

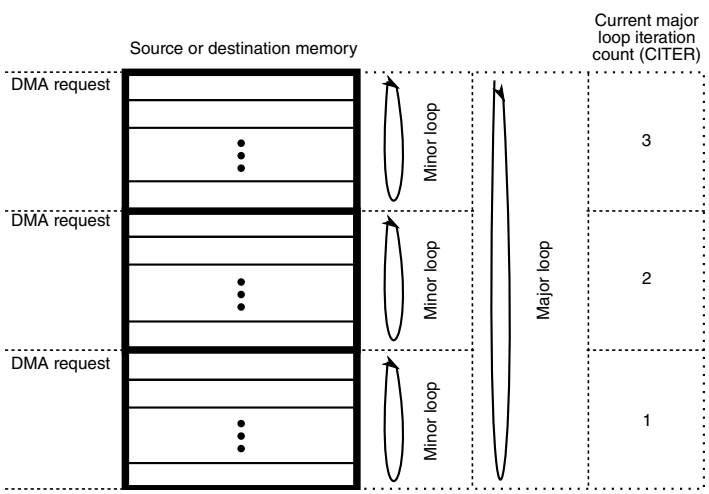

Figure 14-5. Example of multiple loop iterations

The following figure lists the memory array terms and how the TCD settings interrelate.

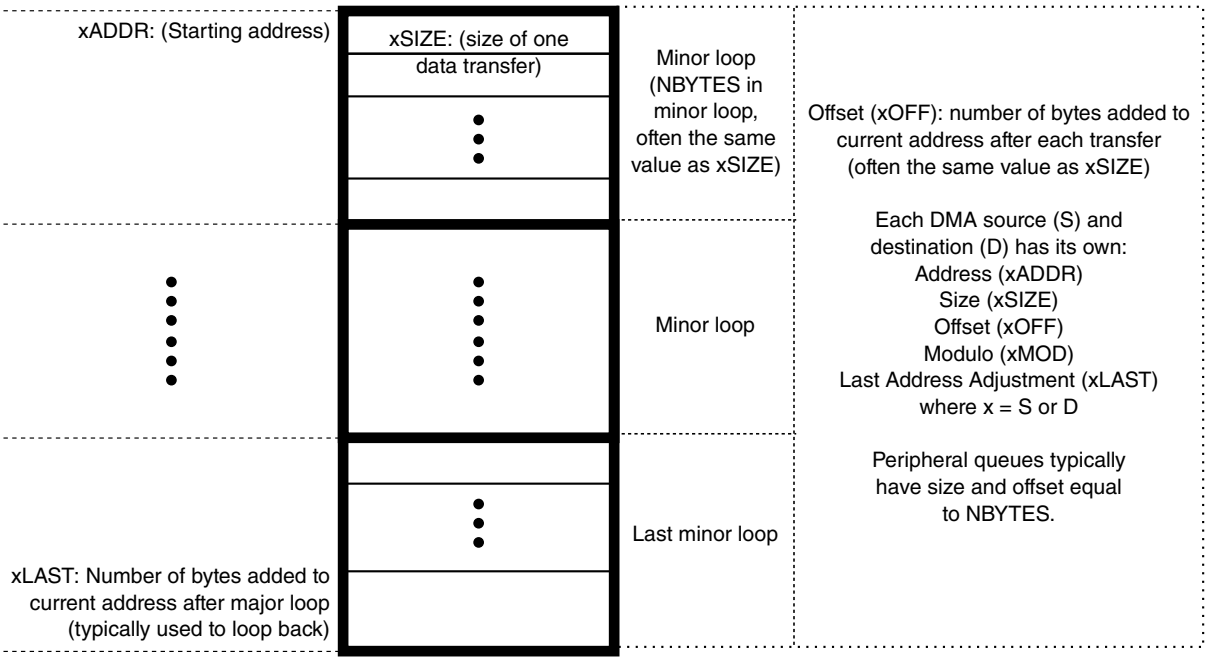

Figure 14-6. Memory array terms

14.6.2 Programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data. Most programming errors are reported on a per channel basis with the exception of channel priority error (ES[CPE]).

For all error types other than group or channel priority errors, the channel number causing the error is recorded in the Error Status register (DMAx_ES). If the error source is not removed before the next activation of the problem channel, the error is detected and recorded again.

Channel priority errors are identified within a group once that group has been selected as the active group. For example:

1. The eDMA is configured for fixed group and fixed channel arbitration modes.
2. Group 1 is the highest priority and all channels are unique in that group.
3. Group 0 is the next highest priority and has two channels with the same priority level.
4. If Group 1 has any service requests, those requests will be executed.
5. After all of Group 1 requests have completed, Group 0 will be the next active group.

6. If Group 0 has a service request, then an undefined channel in Group 0 will be selected and a channel priority error will occur.
7. This repeats until the all of Group 0 requests have been removed or a higher priority Group 1 request comes in.

In this sequence, for item 2, the eDMA acknowledge lines will assert only if the selected channel is requesting service via the eDMA peripheral request signal. If interrupts are enabled for all channels, the user will get an error interrupt, but the channel number for the ERR register and the error interrupt request line may be wrong because they reflect the selected channel. A group priority error is global and any request in any group will cause a group priority error.

If priority levels are not unique, when any channel requests service, a channel priority error is reported. The highest channel/group priority with an active request is selected, but the lowest numbered channel with that priority is selected by arbitration and executed by the eDMA engine. The hardware service request handshake signals, error interrupts, and error reporting is associated with the selected channel.

14.6.3 Arbitration mode considerations

This section discusses arbitration considerations for the eDMA.

14.6.3.1 Fixed group arbitration, Fixed channel arbitration

In this mode, the channel service request from the highest priority channel in the highest priority group is selected to execute. If the eDMA is programmed so that the channels within one group use "fixed" priorities, and that group is assigned the highest "fixed" priority of all groups, that group can take all the bandwidth of the eDMA controller. That is, no other groups will be serviced if there is always at least one DMA request pending on a channel in the highest priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly. Preemption is available in this scenario only.

14.6.3.2 Fixed group arbitration, Round-robin channel arbitration

The highest priority group with a request will be serviced. Lower priority groups will be serviced if no pending requests exist in the higher priority groups.

Within each group, c hannels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to the channel priority levels assigned within the group.

This scenario could cause the same bandwidth consumption problem as indicated in Fixed group arbitration, Fixed channel arbitration, but all the channels in the highest priority group will be serviced. Service latency will be short on the highest priority group, but could potentially be very much longer as the group priority decreases.

14.6.4 Performing DMA transfers

This section presents examples on how to perform DMA transfers with the eDMA.

14.6.4.1 Single request

To perform a simple transfer of n bytes of data with one activation, set the major loop to one (TCD*n*_CITER = TCD*n*_BITER = 1). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete, the TCD*n*_CSR[DONE] bit is set and an interrupt generates if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has a byte wide memory port located at 0x1000. The destination memory has a 32-bit port located at 0x2000. The address offsets are programmed in increments to match the transfer size: one byte for the source and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
TCDn_DLAST_SGA= -16
TCDn_CSR[INT_MAJ] = 1
TCDn_CSR[START] = 1 (Should be written last after all other fields have been initialized)
All other TCDn fields = 0
```

This generates the following event sequence:

1. User write to the TCD*n*_CSR[START] bit requests channel service.

2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
    a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
    b. Write 32-bits to location 0x2000 → first iteration of the minor loop.
    c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
    d. Write 32-bits to location 0x2004 → second iteration of the minor loop.
    e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
    f. Write 32-bits to location 0x2008 → third iteration of the minor loop.
    g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
    h. Write 32-bits to location 0x200C → last iteration of the minor loop → major loop complete.
6. The eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 1 (TCD*n*_BITER).
7. The eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0, TCD*n*_CSR[DONE] = 1, INT[*n*] = 1.
8. The channel retires and the eDMA goes idle or services the next channel.

14.6.4.2 Multiple requests

The following example transfers 32 bytes via two hardware requests, but is otherwise the same as the previous example. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop transferring 16 bytes per iteration. After the channel's hardware requests are enabled in the ERQ register, the slave device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

1. First hardware, that is, eDMA peripheral, request for channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD*n* data from local memory to internal register file.
5. The source to destination transfers are executed as follows:
   a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
   b. Write 32-bits to location 0x2000 → first iteration of the minor loop.
   c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
   d. Write 32-bits to location 0x2004 → second iteration of the minor loop.
   e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
   f. Write 32-bits to location 0x2008 → third iteration of the minor loop.
   g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
   h. Write 32-bits to location 0x200C → last iteration of the minor loop.
6. eDMA engine writes: TCD*n*_SADDR = 0x1010, TCD*n*_DADDR = 0x2010, TCD*n*_CITER = 1.
7. eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0.
8. The channel retires → one iteration of the major loop. The eDMA goes idle or services the next channel.
9. Second hardware, that is, eDMA peripheral, requests channel service.
10. The channel is selected by arbitration for servicing.
11. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.

12. eDMA engine reads: channel TCD data from local memory to internal register file.
13. The source to destination transfers are executed as follows:
    a. Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013.
    b. Write 32-bits to location 0x2010 → first iteration of the minor loop.
    c. Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017.
    d. Write 32-bits to location 0x2014 → second iteration of the minor loop.
    e. Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B.
    f. Write 32-bits to location 0x2018 → third iteration of the minor loop.
    g. Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F.
    h. Write 32-bits to location 0x201C → last iteration of the minor loop → major loop complete.
14. eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 2 (TCD*n*_BITER).
15. eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0, TCD*n*_CSR[DONE] = 1, INT[n] = 1.
16. The channel retires → major loop complete. The eDMA goes idle or services the next channel.

14.6.4.3 Using the modulo feature

The modulo feature of the eDMA provides the ability to implement a circular data queue in which the size of the queue is a power of 2. MOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address+offset calculation. All upper address bits remain the same as in the original value. A setting of 0 for this field disables the modulo feature.

The following table shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value while the 28 upper address bits (0x1234567*x*) retain their original value. In this example the source address is set to 0x12345670, the offset is set to 4 bytes and the MOD field is set to 4, allowing for a 2^4 byte (16-byte) size queue.

Table 14-11. Modulo example

Transfer Number	Address
1	0x12345670
2	0x12345674
3	0x12345678
4	0x1234567C
5	0x12345670
6	0x12345674

14.6.5 Monitoring transfer descriptor status

This section discusses how to monitor eDMA status.

14.6.5.1 Testing for minor loop completion

There are two methods to test for minor loop completion when using software initiated service requests. The first is to read the TCD*n*_CITER field and test for a change. Another method may be extracted from the sequence shown below. The second method is to test the TCD*n*_CSR[START] bit and the TCD*n*_CSR[ACTIVE] bit. The minor-loop-complete condition is indicated by both bits reading zero after the TCD*n*_CSR[START] was set. Polling the TCD*n*_CSR[ACTIVE] bit may be inconclusive, because the active status may be missed if the channel execution is short in duration.

The TCD status bits execute the following sequence for a software activated channel:

Stage	TCD*n*_CSR bits			State
	START	ACTIVE	DONE	
1	1	0	0	Channel service request via software
2	0	1	0	Channel is executing
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

The best method to test for minor-loop completion when using hardware, that is, peripheral, initiated service requests is to read the TCD*n*_CITER field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status bits execute the following sequence for a hardware-activated channel:

Stage	TCD*n*_CSR bits			State
	START	ACTIVE	DONE	
1	0	0	0	Channel service request via hardware (peripheral request asserted)
2	0	1	0	Channel is executing
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

For both activation types, the major-loop-complete status is explicitly indicated via the TCD*n*_CSR[DONE] bit.

The TCD*n*_CSR[START] bit is cleared automatically when the channel begins execution regardless of how the channel activates.

14.6.5.2 Reading the transfer descriptors of active channels

The eDMA reads back the true TCD*n*_SADDR, TCD*n*_DADDR, and TCD*n*_NBYTES values if read while a channel executes. The true values of the SADDR, DADDR, and NBYTES are the values the eDMA engine currently uses in its internal register file and not the values in the TCD local memory for that channel. The addresses, SADDR and DADDR, and NBYTES, which decrement to zero as the transfer progresses, can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

14.6.5.3 Checking channel preemption status

Preemption is available only when fixed arbitration is selected for both group and channel arbitration modes. A preemptive situation is one in which a preempt-enabled channel runs and a higher priority request becomes active. When the eDMA engine is not operating in fixed group, fixed channel arbitration mode, the determination of the actively running relative priority outstanding requests become undefined. Channel and/or group priorities are treated as equal, that is, constantly rotating, when Round-Robin Arbitration mode is selected.

The TCD*n*_CSR[ACTIVE] bit for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended while the preempting channel executes one major loop iteration. If two TCD*n*_CSR[ACTIVE] bits are set simultaneously in the global TCD map, a higher priority channel is actively preempting a lower priority channel.

14.6.6 Channel Linking

Channel linking (or chaining) is a mechanism where one channel sets the TCD*n*_CSR[START] bit of another channel (or itself), therefore initiating a service request for that channel. When properly enabled, the EDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The TCD*n*_CITER[E_LINK] field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, the initial fields of:

```
TCDn_CITER[E_LINK] = 1
TCDn_CITER[LINKCH] = 0xC
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJOR_E_LINK] = 1
TCDn_CSR[MAJOR_LINKCH] = 0x7
```

executes as:

1. Minor loop done → set TCD12_CSR[START] bit
2. Minor loop done → set TCD12_CSR[START] bit
3. Minor loop done → set TCD12_CSR[START] bit
4. Minor loop done, major loop done→ set TCD7_CSR[START] bit

When minor loop linking is enabled (TCD*n*_CITER[E_LINK] = 1), the TCD*n*_CITER[CITER] field uses a nine bit vector to form the current iteration count. When minor loop linking is disabled (TCD*n*_CITER[E_LINK] = 0), the TCD*n*_CITER[CITER] field uses a 15-bit vector to form the current iteration count. The bits associated with the TCD*n*_CITER[LINKCH] field are concatenated onto the CITER value to increase the range of the CITER.

Note

The TCD*n*_CITER[E_LINK] bit and the TCD*n*_BITER[E_LINK] bit must equal or a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop, half-way done interrupt point.

The following table summarizes how a DMA channel can link to another DMA channel, i.e, use another channel's TCD, at the end of a loop.

Table 14-12. Channel Linking Parameters

Desired Link Behavior	TCD Control Field Name	Description
Link at end of Minor Loop	CITER[E_LINK]	Enable channel-to-channel linking on minor loop completion (current iteration)
	CITER[LINKCH]	Link channel number when linking at end of minor loop (current iteration)
Link at end of Major Loop	CSR[MAJOR_E_LINK]	Enable channel-to-channel linking on major loop completion
	CSR[MAJOR_LINKCH]	Link channel number when linking at end of major loop

14.6.7 Dynamic programming

This section provides recommended methods to change the programming model during channel execution.

14.6.7.1 Dynamically changing the channel priority

The following two options are recommended for dynamically changing channel priority levels:

1. Switch to Round-Robin Channel Arbitration mode, change the channel priorities, then switch back to Fixed Arbitration mode,
2. Disable all the channels, change the channel priorities, then enable the appropriate channels.

14.6.7.2 Dynamic channel linking

Dynamic channel linking is the process of setting the TCDn_CSR[MAJORELINK] bit during channel execution (see the diagram in TCD structure). This bit is read from the TCD local memory at the end of channel execution, thus allowing the user to enable the feature during channel execution.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic channel link by enabling the TCDn_CSR[MAJORELINK] bit at the same time the eDMA engine is retiring the channel. The TCDn_CSR[MAJORELINK] would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

The following coherency model is recommended when executing a dynamic channel link request.

1. Write 1 to the TCDn_CSR[MAJORELINK] bit.
2. Read back the TCDn_CSR[MAJORELINK] bit.
3. Test the TCDn_CSR[MAJORELINK] request status:
   - If TCDn_CSR[MAJORELINK] = 1, the dynamic link attempt was successful.
   - If TCDn_CSR[MAJORELINK] = 0, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces the TCDn_CSR[MAJORELINK] bit to zero on any writes to a channel's TCD.word7 after that channel's TCD.done bit is set, indicating the major loop is complete.

NOTE

The user must clear the The TCDn_CSR[DONE] bit before writing the TCDn_CSR[MAJORELINK] bit. The TCDn_CSR[DONE] bit is cleared automatically by the eDMA engine after a channel begins execution.

14.6.7.3 Dynamic scatter/gather

Scatter/gather is the process of automatically loading a new TCD into a channel. It allows a DMA channel to use multiple TCDs; this enables a DMA channel to scatter the DMA data to multiple destinations or gather it from multiple sources. When scatter/gather is enabled and the channel has finished its major loop, a new TCD is fetched from system memory and loaded into that channel's descriptor location in eDMA programmer's model, thus replacing the current descriptor.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic scatter/gather operation by enabling the TCDn_CSR[ESG] bit at the same time the eDMA engine is retiring the channel. The ESG bit would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods for this coherency model are shown in the following subsections. Method 1 has the advantage of reading the MAJORLINKCH field and the ESG bit with a single read. For both dynamic channel linking and scatter/gather requests, the TCD local memory controller forces the TCD MAJOR.E_LINK and E_SG bits to zero on any writes to a channel's TCD word 7 if that channel's TCD.DONE bit is set indicating the major loop is complete.

NOTE

The user must clear the TCDn_CSR[DONE] bit before writing the MAJORELINK or ESG bits. The TCDn_CSR[DONE] bit is cleared automatically by the eDMA engine after a channel begins execution.

14.6.7.3.1 Method 1 (channel not using major loop channel linking)

For a channel not using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request.

When the TCDn_CSR[MAJORELINK] bit is zero, the TCDn_CSR[MAJORLINKCH] field is not used by the eDMA. In this case, the MAJORLINKCH field may be used for other purposes. This method uses the MAJORLINKCH field as a TCD identification (ID).

1. When the descriptors are built, write a unique TCD ID in the TCDn_CSR[MAJORLINKCH] field for each TCD associated with a channel using dynamic scatter/gather.
2. Write 1b to the TCDn_CSR[DREQ] bit.

   Should a dynamic scatter/gather attempt fail, setting the DREQ bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (DADDR) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offset value.
3. Write the TCDn_DLASTSGA register with the scatter/gather address.
4. Write 1b to the TCDn_CSR[ESG] bit.

5. Read back the 16 bit TCD control/status field.
6. Test the ESG request status and MAJORLINKCH value in the TCDn_CSR register:

   If ESG = 1b, the dynamic link attempt was successful.

   If ESG = 0b and the MAJORLINKCH (ID) did not change, the attempted dynamic link did not succeed (the channel was already retiring).

   If ESG = 0b and the MAJORLINKCH (ID) changed, the dynamic link attempt was successful (the new TCD's E_SG value cleared the ESG bit).

14.6.7.3.2 Method 2 (channel using major loop channel linking)

For a channel using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request. This method uses the TCD.DLAST_SGA field as a TCD identification (ID).

1. Write 1b to the TCDn_CSR[DREQ] bit.

   Should a dynamic scatter/gather attempt fail, setting the DREQ bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (DADDR) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offset value.
2. Write the TCDn_DLASTSGA register with the scatter/gather address.
3. Write 1b to the TCDn_CSR[ESG] bit.
4. Read back the ESG bit.
5. Test the ESG request status:

   If ESG = 1b, the dynamic link attempt was successful.

   If ESG = 0b, read the 32 bit TCDn_DLASTSGA field.

   If ESG = 0b and the TCDn_DLASTSGA did not change, the attempted dynamic link did not succeed (the channel was already retiring).

   If ESG = 0b and the TCDn_DLASTSGA changed, the dynamic link attempt was successful (the new TCD's E_SG value cleared the ESG bit).

14.6.8 Suspend/resume a DMA channel with active hardware service requests

The DMA allows the user to move data from memory or peripheral registers to another location in memory or peripheral registers without CPU interaction. Once the DMA and peripherals have been configured and are active, it is rare to suspend a peripheral's service request dynamically. In this scenario, there are certain restrictions to disabling a DMA hardware service request. For coherency, a specific procedure must be followed. This section provides guidance on how to coherently suspend and resume a Direct Memory Access (DMA) channel when the DMA is triggered by a slave module such as the Serial Peripheral Interface (SPI), ADC, or other module.

14.6.8.1 Suspend an active DMA channel

To suspend an active DMA channel:

1. Stop the DMA service request at the peripheral first. Confirm it has been disabled by reading back the appropriate register in the peripheral.
2. Check the DMA's Hardware Request Status Register (DMA_HRSn) to ensure there is no service request to the DMA channel being suspended. Then disable the hardware service request by clearing the ERQ bit on appropriate DMA channel.

14.6.8.2 Resume a DMA channel

To resume a DMA channel:

1. Enable the DMA service request on the appropriate channel by setting the its ERQ bit.
2. Enable the DMA service request at the peripheral.

For example, assume the SPI is set as a master for transmitting data via a DMA service request when the SPI_TXFIFO has an empty slot. The DMA will transfer the next command and data to the TXFIFO upon the request. If the user needs to suspend the DMA/SPI transfer loop, perform the following steps:

1. Disable the DMA service request at the source by writing 0 to SPI_RSER[TFFF_RE]. Confirm that SPI_RSER[TFFF_RE] is 0.
2. Ensure there is no DMA service request from the SPI by verifying that DMA_HRS[HRS*n*] is 0 for the appropriate channel. If no service request is present, disable the DMA channel by clearing the channel's ERQ bit. If a service request is present, wait until the request has been processed and the HRS bit reads zero.

Chapter 15
Direct Memory Access Multiplexer (DMAMUX)

15.1 Chip-specific DMAMUX information

Table 15-1. Reference links to related information

15.1.1 DMAMUX

The direct memory access multiplexer (DMAMUX) routes DMA sources, called slots, to any of the supported DMA channels. There is one 128x32 DMAMUX instance on DMA0 and one 128x32 DMAMUX instance on DMA1. The following table shows the configuration of the DMAMUX.

Table 15-2. DMAMUX configuration

Parameter	Description
Name	Direct Memory Access Multiplexer (DMAMUX)
Instances	2
Configurable features	• DMA0 DMAMUX: 128x32 • DMA1 DMAMUX: 128x32
Interface speed	NA
External I/O pins	NA

15.1.2 DMA0 request assignment

The following table shows DMA requests mapped into DMA0 channels

Table 15-3. DMAMUX0 channel assignments

M4 DMAMUX0 (128-to-32)		
Source/Slot Number	**Source Module**	**Source Description**
0	-	Channel disabled

15.2 Introduction

15.2.1 Overview

The Direct Memory Access Multiplexer (DMAMUX) routes DMA sources, called slots, to any of the 32 DMA channels. This process is illustrated in the following figure.

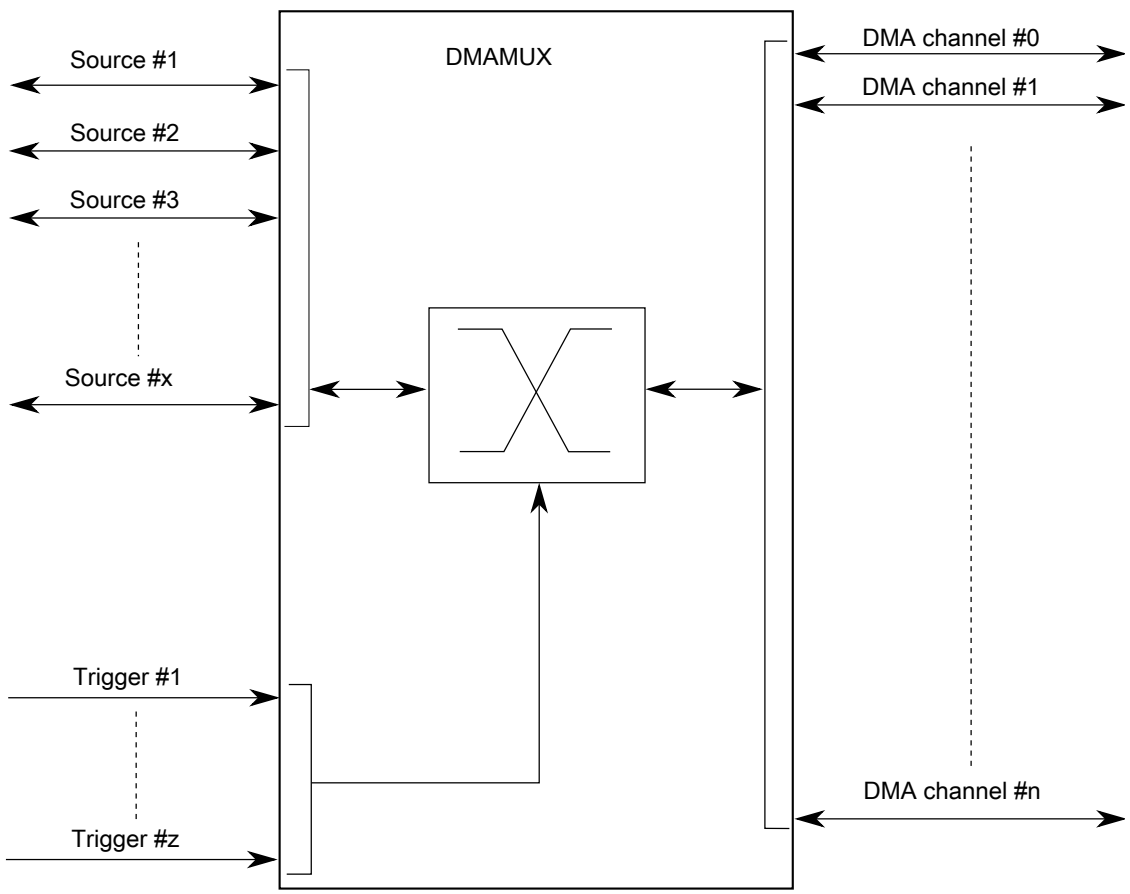

Figure 15-1. DMAMUX block diagram

15.2.2 Features

The DMAMUX module provides these features:

- Up to 128 peripheral slots can be routed to 32 channels.
- 32 independently selectable DMA channel routers.
  - Each channel output can be individually configured to be Always On and not depend on any of the peripheral slots.
  - The first 8 channels additionally provide a trigger functionality.
- Each channel router can be assigned to one of the possible peripheral DMA slots.
- On every memory map configuration change for a any channel, this module signals to the DMA Controller to reset the internal state machine for that channel and it can accept a new request based on the new configuration.

15.2.3 Modes of operation

The following operating modes are available:

- Disabled mode

  In this mode, the DMA channel is disabled. Because disabling and enabling of DMA channels is done primarily via the DMA configuration registers, this mode is used mainly as the reset state for a DMA channel in the DMA channel MUX. It may also be used to temporarily suspend a DMA channel while reconfiguration of the system takes place, for example, changing the period of a DMA trigger.

- Normal mode

  In this mode, a DMA source is routed directly to the specified DMA channel. The operation of the DMAMUX in this mode is completely transparent to the system.

- Periodic Trigger mode

  In this mode, a DMA source may only request a DMA transfer, such as when a transmit buffer becomes empty or a receive buffer becomes full, periodically.

  Configuration of the period is done in the registers of the periodic interrupt timer (PIT). This mode is available only for channels 0 to 7.

15.3 External signal description

The DMAMUX has no external pins.

15.4 Memory map/register definition

This section provides a detailed description of all memory-mapped registers in the DMAMUX.

15.4.1 DMA_CH_MUX register descriptions

15.4.1.1 DMA_CH_MUX Memory map

DMA_CH_MUX0 base address: 4102_0000h

DMA_CH_MUX1 base address: 4021_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h - 7Ch	Channel a Configuration Register (CHCFG0 - CHCFG31)	32	RW	0000_0000h

15.4.1.2 Channel a Configuration Register (CHCFG0 - CHCFG31)

15.4.1.2.1 Offset

For a = 0 to 31:

Register	Offset
CHCFGa	0h + (a × 4h)

15.4.1.2.2 Function

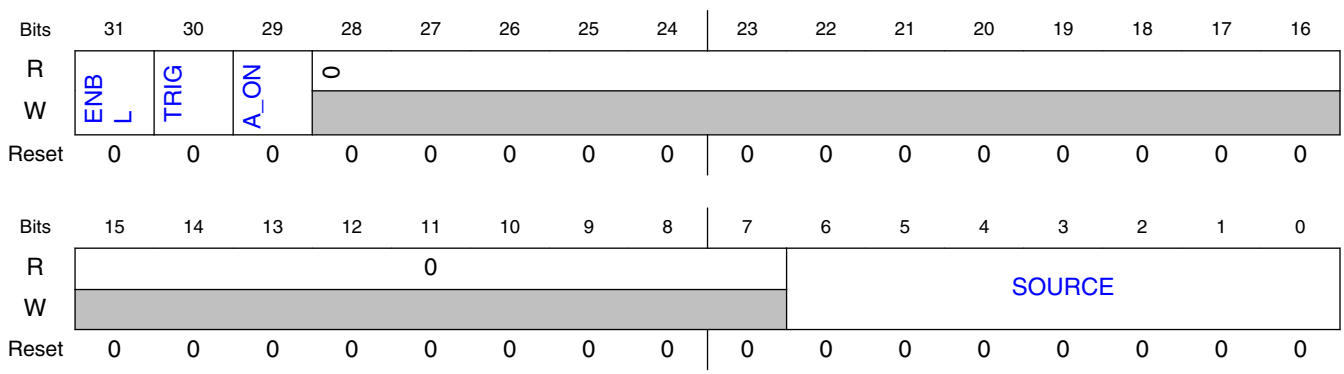
Each of the DMA channels can be independently enabled/disabled and associated with one of the DMA slots (peripheral slots or always-on slots) in the system.

NOTE

Setting multiple CHCFG registers with the same source value will result in unpredictable behavior. This is true, even if a channel is disabled (ENBL==0).

Before changing the trigger or source settings, a DMA channel must be disabled via CHCFGn[ENBL].

15.4.1.2.3 Diagram



15.4.1.2.4 Fields

Field	Function
31 ENBL	DMA Mux Channel Enable Enables the channel for DMA Mux. The DMA has separate channel enables/disables, which should be used to disable or reconfigure a DMA channel. 0b - DMA Mux channel is disabled 1b - DMA Mux channel is enabled
30 TRIG	DMA Channel Trigger Enable Enables the periodic trigger capability for the triggered DMA channel. 0b - Triggering is disabled. If triggering is disabled and ENBL is set, the DMA Channel will simply route the specified source to the DMA channel. (Normal mode) 1b - Triggering is enabled. If triggering is enabled and ENBL is set, the DMA_CH_MUX is in Periodic Trigger mode.
29 A_ON	DMA Channel Always Enable Enables the DMA Channel to be always ON. If TRIG bit is set, the module will assert request on every trigger. 0b - DMA Channel Always ON function is disabled

Table continues on the next page...

Field	Function
	1b - DMA Channel Always ON function is enabled
28-7 —	Reserved field
6-0 SOURCE	DMA Channel Source (Slot Number) Specifies which DMA source, if any, is routed to a particular DMA channel. See the chip-specific DMA_CH_MUX information for details about the peripherals and their slot numbers.

15.5 Functional description

The primary purpose of the DMAMUX is to provide flexibility in the system's use of the available DMA channels.

As such, configuration of the DMAMUX is intended to be a static procedure done during execution of the system boot code. However, if the procedure outlined in Enabling and configuring sources is followed, the configuration of the DMAMUX may be changed during the normal operation of the system.

Functionally, the DMAMUX channels may be divided into two classes:

- Channels that implement the normal routing functionality plus periodic triggering capability
- Channels that implement only the normal routing functionality

15.5.1 DMA channels with periodic triggering capability

Besides the normal routing functionality, the first 8 channels of the DMAMUX provide a special periodic triggering capability that can be used to provide an automatic mechanism to transmit bytes, frames, or packets at fixed intervals without the need for processor intervention.

The trigger is generated by the periodic interrupt timer (PIT); as such, the configuration of the periodic triggering interval is done via configuration registers in the PIT. See the section on periodic interrupt timer for more information on this topic.

Note

Because of the dynamic nature of the system (due to DMA channel priorities, bus arbitration, interrupt service routine lengths, etc.), the number of clock cycles between a trigger and the actual DMA transfer cannot be guaranteed.

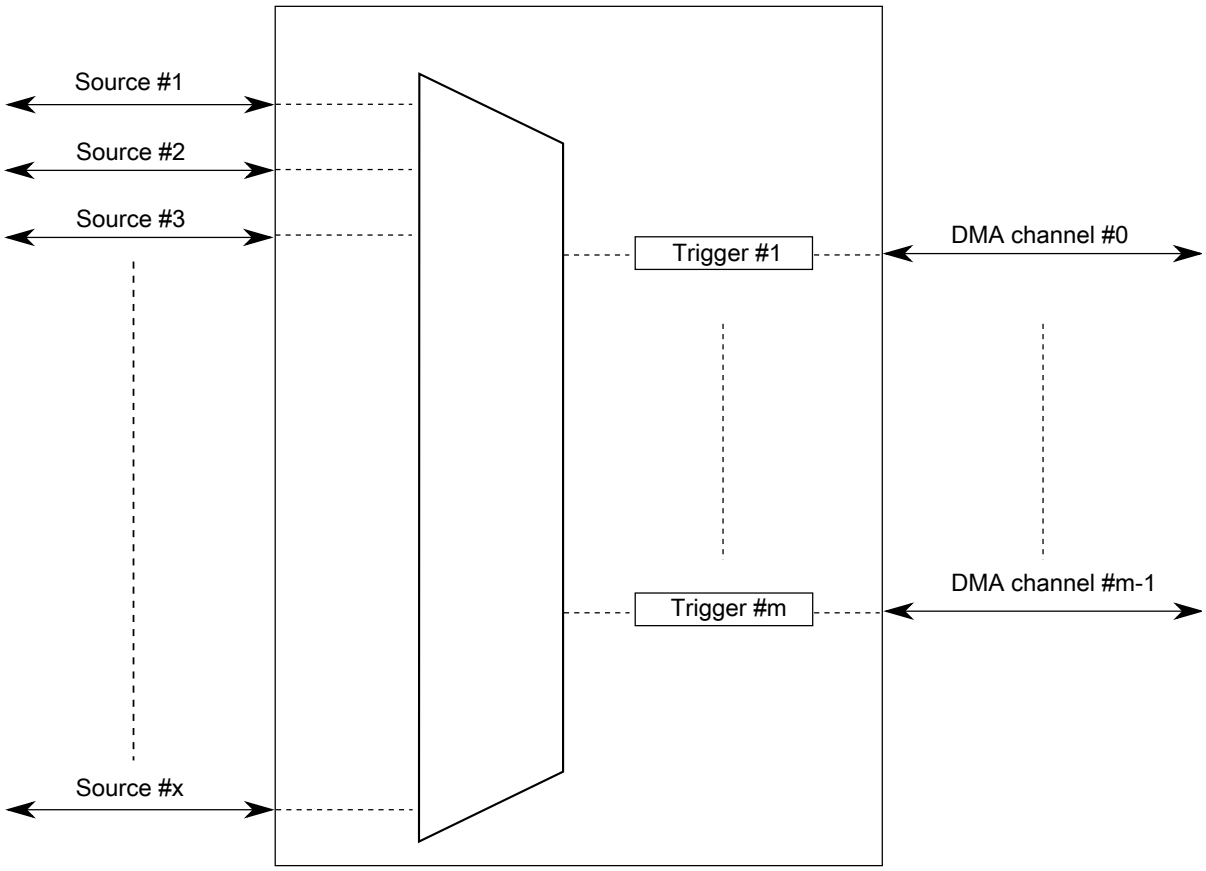


Figure 15-2. DMAMUX triggered channels

The DMA channel triggering capability allows the system to schedule regular DMA transfers, usually on the transmit side of certain peripherals, without the intervention of the processor. This trigger works by gating the request from the peripheral to the DMA until a trigger event has been seen. This is illustrated in the following figure.

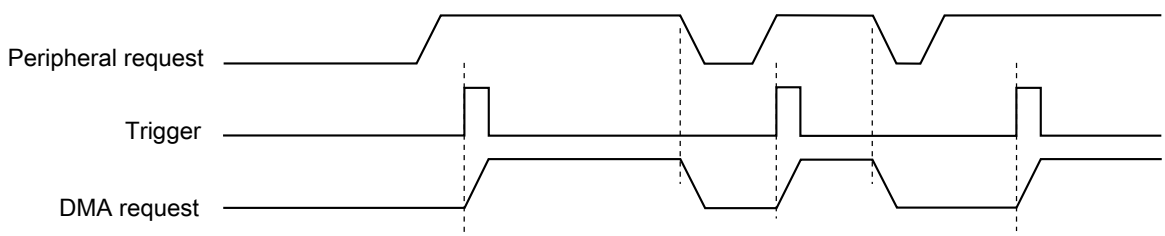

Figure 15-3. DMAMUX channel triggering: normal operation

After the DMA request has been serviced, the peripheral will negate its request, effectively resetting the gating mechanism until the peripheral reasserts its request and the next trigger event is seen. This means that if a trigger is seen, but the peripheral is not requesting a transfer, then that trigger will be ignored. This situation is illustrated in the following figure.

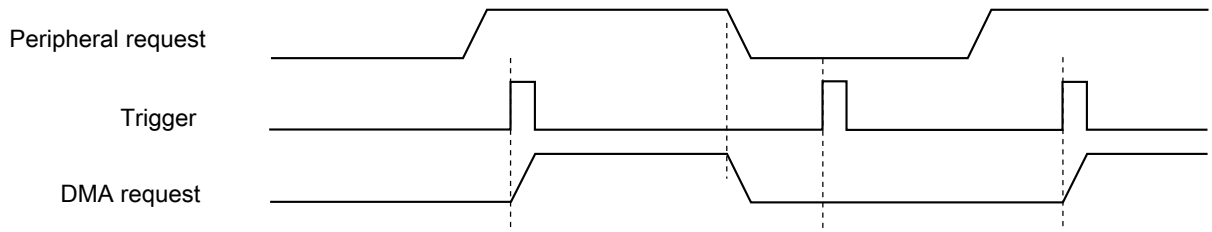

Figure 15-4. DMAMUX channel triggering: ignored trigger

This triggering capability may be used with any peripheral that supports DMA transfers, and is most useful for two types of situations:

- Periodically polling external devices on a particular bus

  As an example, the transmit side of an SPI is assigned to a DMA channel with a trigger, as described above. After it has been set up, the SPI will request DMA transfers, presumably from memory, as long as its transmit buffer is empty. By using a trigger on this channel, the SPI transfers can be automatically performed every 5 µs (as an example). On the receive side of the SPI, the SPI and DMA can be configured to transfer receive data into memory, effectively implementing a method to periodically read data from external devices and transfer the results into memory without processor intervention.

- Using the GPIO ports to drive or sample waveforms

  By configuring the DMA to transfer data to one or more GPIO ports, it is possible to create complex waveforms using tabular data stored in on-chip memory. Conversely, using the DMA to periodically transfer data from one or more GPIO ports, it is possible to sample complex waveforms and store the results in tabular form in on-chip memory.

A more detailed description of the capability of each trigger, including resolution, range of values, and so on, may be found in the periodic interrupt timer section.

15.5.2 Always-enabled DMA sources

In addition to the peripherals that can be used as DMA sources, each DMA Channel can be individually configured to function as an Always Enabled source. Unlike the peripheral DMA sources, where the peripheral controls the flow of data during DMA transfers, the always enabled channel provide no such "throttling" of the data transfers. These sources are most useful in the following cases:

- Performing DMA transfers to/from GPIO—Moving data from/to one or more GPIO pins, either unthrottled (that is, as fast as possible), or periodically (using the DMA triggering capability).
- Performing DMA transfers from memory to memory—Moving data from memory to memory, typically as fast as possible, sometimes with software activation.
- Performing DMA transfers from memory to the external bus, or vice-versa—Similar to memory to memory transfers, this is typically done as quickly as possible.
- Any DMA transfer that requires software activation—Any DMA transfer that should be explicitly started by software.

In cases where software should initiate the start of a DMA transfer, an always-enabled DMA channel can be used to provide maximum flexibility. When activating a DMA channel via software, subsequent executions of the minor loop require that a new start event be sent. This can either be a new software activation, or a transfer request from the DMA channel MUX. The options for doing this are:

- Transfer all data in a single minor loop.

  By configuring the DMA to transfer all of the data in a single minor loop (that is, major loop counter = 1), no reactivation of the channel is necessary. The disadvantage to this option is the reduced granularity in determining the load that the DMA transfer will impose on the system. For this option, the DMA channel must be disabled in the DMA channel MUX.

- Use explicit software reactivation.

  In this option, the DMA is configured to transfer the data using both minor and major loops, but the processor is required to reactivate the channel by writing to the DMA registers *after every minor loop*. For this option, the DMA channel must be disabled in the DMA channel MUX.

- Use an always-enabled DMA source.

  In this option, the DMA is configured to transfer the data using both minor and major loops, and the DMA channel MUX does the channel reactivation. For this option, the DMA channel should be enabled and configured as "always enabled" channel. Note that the reactivation of the channel can be continuous (DMA triggering is disabled) or can use the DMA triggering capability. In this manner, it is possible to execute periodic transfers of packets of data from one source to another, without processor intervention.

NOTE

When a channel is configured as "Always Enabled", then the peripheral DMA sources for that channel are ignored; i.e. SOURCE field has no effect.

15.6 Initialization/application information

This section provides instructions for initializing the DMA channel MUX.

15.6.1 Reset

The reset state of each individual bit is shown in Memory map/register definition. In summary, after reset, all channels are disabled and must be explicitly enabled before use.

15.6.2 Enabling and configuring sources

To enable a source with periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 8 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Configure the corresponding timer.
5. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

NOTE

The following is an example. See the Features section to know the number of DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with periodic triggering capability:

1. Write 0x00000000 to CHCFG1.
2. Configure channel 1 in the DMA, including enabling the channel.
3. Configure a timer for the desired trigger interval.
4. Write 0xC0000005 to CHCFG1.

The following code example illustrates steps 1 and 4 above:

```
void DMAMUX_Init(uint8_t DMA_CH, uint8_t DMAMUX_SOURCE)
{
    DMAMUX_0.CHCFG[DMA_CH].B.SOURCE = DMAMUX_SOURCE;
    DMAMUX_0.CHCFG[DMA_CH].B.ENBL   = 1;
    DMAMUX_0.CHCFG[DMA_CH].B.TRIG   = 1;
}
```

To enable a source without periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 8 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that CHCFG[ENBL] is setwhile CHCFG[TRIG] is cleared.

NOTE

The following is an example. See the Features section to know the number of DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1 with no periodic triggering capability :

1. Write 0x00000000 to CHCFG1.
2. Configure channel 1 in the DMA, including enabling the channel.
3. Write 0x80000005 to CHCFG1.

The following code example illustrates steps 1 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR     0x40021000/* Example only ! */
/* Following example assumes long is 32-bits */
volatile unsigned long *CHCFG0 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned long *CHCFG1 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned long *CHCFG2 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned long *CHCFG3 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x000C);
volatile unsigned long *CHCFG4 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0010);
volatile unsigned long *CHCFG5 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0014);
volatile unsigned long *CHCFG6 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0018);
volatile unsigned long *CHCFG7 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x001C);
volatile unsigned long *CHCFG8 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0020);
volatile unsigned long *CHCFG9 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0024);
volatile unsigned long *CHCFG10= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0028);
volatile unsigned long *CHCFG11= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x002C);
volatile unsigned long *CHCFG12= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0030);
volatile unsigned long *CHCFG13= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0034);
volatile unsigned long *CHCFG14= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0038);
volatile unsigned long *CHCFG15= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x003C);

In File main.c:
#include "registers.h"
:
:
```

```
*CHCFG1 = 0x00000000;
*CHCFG1 = 0x80000005;
```

To disable a source:

A particular DMA source may be disabled by not writing the corresponding source value into any of the CHCFG registers. Additionally, some module-specific configuration may be necessary. See the appropriate section for more details.

To switch the source of a DMA channel:

1. Disable the DMA channel in the DMA and reconfigure the channel for the new source.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] bits of the DMA channel.
3. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

To switch DMA channel 8 from source #5 transmit to source #7 transmit:

1. In the DMA configuration registers, disable DMA channel 8 and reconfigure it to handle the transfers to peripheral slot 7. This example assumes channel 8 doesn't have triggering capability.
2. Write 0x00000000 to CHCFG8.
3. Write 0x80000007 to CHCFG8. (In this example, setting CHCFG[TRIG] would have no effect due to the assumption that channel 8 does not support the periodic triggering functionality.)

The following code example illustrates steps 2 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR     0x40021000/* Example only ! */
/* Following example assumes long is 32-bits */
volatile unsigned long *CHCFG0 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned long *CHCFG1 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned long *CHCFG2 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned long *CHCFG3 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x000C);
volatile unsigned long *CHCFG4 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0010);
volatile unsigned long *CHCFG5 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0014);
volatile unsigned long *CHCFG6 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0018);
volatile unsigned long *CHCFG7 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x001C);
volatile unsigned long *CHCFG8 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0020);
volatile unsigned long *CHCFG9 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0024);
volatile unsigned long *CHCFG10= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0028);
volatile unsigned long *CHCFG11= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x002C);
volatile unsigned long *CHCFG12= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0030);
volatile unsigned long *CHCFG13= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0034);
volatile unsigned long *CHCFG14= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0038);
volatile unsigned long *CHCFG15= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x003C);

In File main.c:
#include "registers.h"
:
:
*CHCFG8 = 0x00000000;
*CHCFG8 = 0x80000007;
```

15.6.2.1 Configuration options

Table 15-5. Channel Configuration Options

ENBL	TRIG	A_ON	Function	Mode
0	X	X	DMA channel is disabled	Disabled Mode
1	0	0	DMA channel is enabled with no triggering (transparent)	Normal Mode
1	1	0	DMA channel is enabled with triggering	Periodic Trigger Mode
1	0	1	DMA channel is always enabled	Always On Mode

16.1.1 AHB-Lite to IP Bus Interface (AIPS-Lite)

The AIPS-Lite module interfaces an AHB-Lite bus to the peripheral bus. There are 2 AIPS-lite instances in this device. Each AIPS module occupies a total of 64 MB of address space. In order to support multicore enhancements, additional side-band signals that are needed to communicate the domain attributes. The following table shows the configuration of the AIPS-Lite.

Table 16-2. AIPS-Lite configuration

Parameter	Description
Name	AHB-Lite to IP Bus Interface (AIPS-Lite)
Instances	2
Configurable features	• AIPS0-1: 2x 32-bit AHB instances
Interface speed	NA
External I/O pins	NA

16.2 Introduction

The peripheral bridge converts the crossbar switch interface to an interface that can access most of the slave peripherals on this chip.

The peripheral bridge occupies 64 MB of the address space, which is divided into peripheral slots of 4 KB. (It might be possible that all the peripheral slots are not used. See the memory map chapter for details on slot assignments.) The bridge includes separate clock enable inputs for each of the slots to accommodate slower peripherals.

16.2.1 Features

Key features of the peripheral bridge are:

- Supports peripheral slots with 8-, 16-, and 32-bit datapath width

16.2.2 General operation

The slave devices connected to the peripheral bridge are modules which contain a programming model of control and status registers. The system masters read and write these registers through the peripheral bridge.

The register maps of the peripherals are located on 4-KB boundaries. Each peripheral is allocated one or more 4-KB block(s) of the memory map.

16.3 Memory map/register definition

The AIPS module(s) on this device do(es) not contain any user-programmable registers.

16.4 Functional description

The peripheral bridge functions as a bus protocol translator between the crossbar switch and the slave peripheral bus.

The peripheral bridge manages all transactions destined for the attached slave devices and generates select signals for modules on the peripheral bus by decoding accesses within the attached address space.

16.4.1 Access support

Aligned and misaligned 32-bit, 16-bit, and byte accesses are supported for 32-bit peripherals. Misaligned accesses are supported to allow memory to be placed on the slave peripheral bus. Peripheral registers must not be misaligned, although no explicit checking is performed by the peripheral bridge. All accesses are performed with a single transfer.

All accesses to the peripheral slots must be sized less than or equal to the designated peripheral slot size. If an access is attempted that is larger than the targeted port, an error response is generated.

17.1.1 AHB Cross Bar Switch (AXBS)

The AXBS is a crossbar switch module that arbitrates between multiple AHB masters to grant access to downstream AHB slave devices. The crossbar enables multiple masters to connect to slaves and parallel processing. In order to support multicore enhancements, additional side-band signals are needed to communicate the domain attributes. The following table shows the configuration of the AXBS.

Table 17-2. AXBS configuration

Parameter	Description
Name	AHB Cross Bar Switch
Instances	2
Configurable features	See AHB crossbar switch for detail
Interface speed	NA
External I/O pins	NA

17.2 Introduction

The information found here provides information on the layout, configuration, and programming of the crossbar switch.

The crossbar switch connects bus masters and bus slaves using a crossbar switch structure. This structure allows up to four bus masters to access different bus slaves simultaneously, while providing arbitration among the bus masters when they access the same slave.

17.2.1 Features

The crossbar switch includes these features:

- Symmetric crossbar bus switch implementation
  - Allows concurrent accesses from different masters to different slaves
- Up to single-clock 64-bit transfer
- Programmable configuration for fixed-priority or round-robin slave port arbitration (see the chip-specific information).
- 64-bit AHB crossbar bus switch compatible with ARM's AMBA Specification v2.0.

17.3 Functional Description

Information about general operation and arbitration can be found here.

17.3.1 General operation

When a master accesses the crossbar switch, the access is immediately taken. If the targeted slave port of the access is available, then the access is immediately presented on the slave port. Single-clock or zero-wait-state accesses are possible through the crossbar. If the targeted slave port of the access is busy or parked on a different master port, the requesting master simply sees wait states inserted until the targeted slave port can service the master's request. The latency in servicing the request depends on each master's priority level and the responding slave's access time.

Because the crossbar switch appears to be just another slave to the master device, the master device has no knowledge of whether it actually owns the slave port it is targeting. While the master does not have control of the slave port it is targeting, it simply waits.

After the master has control of the slave port it is targeting, the master remains in control of the slave port until it relinquishes the slave port by running an IDLE cycle or by targeting a different slave port for its next access.

The master can also lose control of the slave port if another higher-priority master makes a request to the slave port.

The crossbar terminates all master IDLE transfers, as opposed to allowing the termination to come from one of the slave buses. Additionally, when no master is requesting access to a slave port, the crossbar drives IDLE transfers onto the slave bus, even though a default master may be granted access to the slave port.

When a slave bus is being idled by the crossbar, it remains parked with the last master to use the slave port. This is done to save the initial clock of arbitration delay that otherwise would be seen if the same master had to arbitrate to gain control of the slave port.

17.3.2 Arbitration

The crossbar switch supports two arbitration algorithms:

- Fixed priority
- Round-robin

The selection of the global slave port arbitration algorithm is described in the crossbar switch chip-specific information.

17.3.2.1 Arbitration during undefined length bursts

Undefined length bursts can be interrupted.

17.3.2.2 Fixed-priority operation

When operating in fixed-priority mode, each master is assigned a unique priority level with the highest numbered master having the highest priority (for example, in a system with 5 masters, master 1 has lower priority than master 3). If two masters request access to the same slave port, the master with the highest priority gains control over the slave port.

NOTE

In this arbitration mode, a higher-priority master can monopolize a slave port, preventing accesses from any lower-priority master to the port.

When a master makes a request to a slave port, the slave port checks whether the new requesting master's priority level is higher than that of the master that currently has control over the slave port, unless the slave port is in a parked state. The slave port performs an arbitration check at every clock edge to ensure that the proper master, if any, has control of the slave port.

The following table describes possible scenarios based on the requesting master port:

Table 17-3. How the Crossbar Switch grants control of a slave port to a master

When	Then the Crossbar Switch grants control to the requesting master
Both of the following are true: • The current master is not running a transfer. • The new requesting master's priority level is higher than that of the current master.	At the next clock edge
Both of the following are true: • The current master is running an undefined length burst transfer. • The requesting master's priority level is higher than that of the current master.	At the next arbitration point for the undefined length burst transfer
The requesting master's priority level is lower than the current master.	At the conclusion of one of the following cycles: • An IDLE cycle • A non-IDLE cycle to a location other than the current slave port

17.3.2.3 Round-robin priority operation

When operating in round-robin mode, each master is assigned a relative priority based on the master port number. This relative priority is compared to the master port number (ID) of the last master to perform a transfer on the slave bus. The highest priority requesting master becomes owner of the slave bus at the next transfer boundary. Priority is based on how far ahead the ID of the requesting master is to the ID of the last master.

After granted access to a slave port, a master may perform as many transfers as desired to that port until another master makes a request to the same slave port. The next master in line is granted access to the slave port at the next transfer boundary, or possibly on the next clock cycle if the current master has no pending access request.

As an example of arbitration in round-robin mode, assume the crossbar is implemented with master ports 0, 1, 4, and 5. If the last master of the slave port was master 1, and master 0, 4, and 5 make simultaneous requests, they are serviced in the order: 4 then 5 then 0.

The round-robin arbitration mode generally provides a more fair allocation of the available slave-port bandwidth (compared to fixed priority) as the fixed master priority does not affect the master selection.

17.4 Initialization/application information

No initialization is required for the crossbar switch.

Chapter 18
Memory Architecture

18.1 Introduction

This chapter presents memory hierarchical architecture and bus interconnection of the i.MX 7ULP microcontroller. This chapter also details bus master access latency to a variety of memory configurations.

18.2 Memory system

i.MX 7ULP memory system is designed for a balance of sufficient on-chip memory and efficient external memory needs. The architecture pays special attention to the support and implementation of memory system for the desired goals including performance, power and cost.

18.2.1 Memory hierarchy

The memory hierarchy is an arrangement of different types of memories with different capacities and operation speeds, to approximate the ideal memory behavior in a cost-efficient way.

A7 platform includes 32 KB instruction cache, 32 KB data cache in its level 1 memory and 256 KB level 2 cache, which is shared between instruction and data.

On the M4 side, level 1 memory consists of two SRAM blocks: 64 KB SRAMU and 192 KB SRAML, that the M4 processor can access in zero wait states. The SRAML block is further divided into two 32 KB and two 64 KB sub-blocks that allows each sub-block SRAM can be individually power-gated.

The bus system is connected so the SRAM memories on the M4 side can be accessed by the A7 processor as its level 3 memory. In addition, i.MX 7ULP integrates two SRAM blocks of 128 KB each, that either core can access as level 3 memory.

For external memory (like level 4 memory), i.MX 7ULP supports a variety of system memory configurations for application code, data storage, and execution space, including:

- LPDDR3/LPDDR2 via MMDC controller
- eMMC flash via uSDHC controller
- Serial flash via QSPI controller
- SRAM, PSRAM and parallel NOR via FlexBus controller

Chapter 20
Quad Serial Peripheral Interface Controller (QuadSPI)

20.1 Chip-specific QSPI information

Table 20-1. Reference links to related information

Topic	Related module	Reference
Full description	QSPI	QSPI
System memory map		System memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port control	Signal multiplexing

20.1.1 Quad Serial Peripheral Interface Controller (QuadSPI)

The Quad Serial Peripheral Interface (QuadSPI) module acts as an interface to a Quad SPI or Octal SPI serial flash device. The QuadSPI module may be used as the host interface to a serial memory-mapped device, such as FPGA. The QuadSPI module supports both Single Transfer Rate (STR) and Double Transfer Rate (DTR) modes. The following table shows the configuration of the QSPI.

Table 20-2. QuadSPI configuration

Parameter	Description
Name	Quad Serial Peripheral Interface
Instances	1
Configurable features	• 128-byte AHB Buffer • 16x32-bit RX FIFO • 16x32-bit TX FIFO • 64-bit AHB master port • DQS line supported

Table continues on the next page...

Table 20-2. QuadSPI configuration (continued)

Parameter	Description
	• Data learning enabled for DDR feature. • Support On-The-Fly AES Decryption (OTFAD) with 4 keys[1]
Interface speed	See the i.MX 7ULP Data Sheet for QuadSPI frequency specifications.
External I/O pins	See the attached IOMUXC spreadsheet for pin details

1. For details on this feature, see i.MX 7ULP Security Reference Manual

20.1.2 Number of supported flash device interfaces

This device only supports Flash Device A in dual-die package (2x4-bit (quad) mode) or single-die package (1x4-bit (quad) mode). Parallel mode is not supported in this device. So, all the sections on Flash Device B and parallel mode should be ignored.

20.1.3 QuadSPI register reset values

All reset values for the QuadSPI registers that are device specific are shown in the following tables. All other register reset values are shown in the module memory map.

Table 20-3. QuadSPI Module Configuration Register Reset Values

Register	Reset Value
Module Configuration Register (QuadSPI_MCR)	000F_400C

Table 20-4. QuadSPI Buffer Configuration Register Reset Values

Register	Reset Value
Buffer0 Configuration Register (QuadSPI_BUF0CR)	0000_000F
Buffer1 Configuration Register (QuadSPI_BUF1CR)	0000_000F
Buffer2 Configuration Register (QuadSPI_BUF2CR)	0000_000F
Buffer3 Configuration Register (QuadSPI_BUF3CR)	0000_000F

Table 20-5. Serial Flash A1 Top Address Reset Values

Register	Reset Value
QuadSPI_SFA1AD	C800_0000

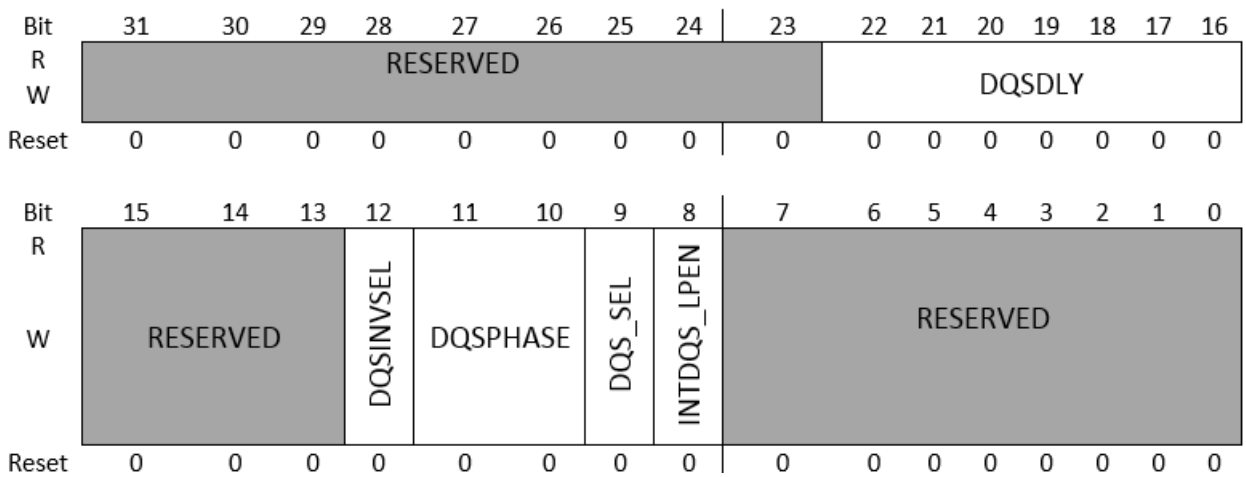
Table 20-6. Serial Flash A2 Top Address Reset Values

Register	Reset Value
QuadSPI_SFA2AD	D000_0000

20.1.4 Data strobe (DQS) sampling method using SOCCR register

For using data strobe sampling method, QuadSPI_SOCCR and QuadSPI_MCR registers should be configured.

On i.MX 7ULP, the QuadSPI_MCR[SCLKCFG] bitfield is not used and all clock-specific settings are defined by registers of the Peripheral Clock Control module (PCC). The QuadSPI_SOCCR register is used and controls settings related to the DQS.



Field	Description
31-23 RESERVED	This field is reserved
22-16 DQSDLY	Delay Chain Tap Selection (fine tuning) for QuadSPI DQS clock 0000000 – Select 1 delay chain tap 0000001 – Select 2 delay chain taps 0000010 – Select 3 delay chain taps …. 1111111 – Select 128 delay chain taps
15-13 RESERVED	This field is reserved
12 DQSINVSEL	Select clock source for the internal DQS generation 0 – Use 1x internal reference clock for the DQS generation 1 – Use 1x inverted internal reference clock for the DQS generation
11-10 DQSPHASE	Select phase shift for the internal DQS generation. These bits are always zero in SDR mode.

Table continues on the next page...

<table>
<tr><th>Field</th><th>Description</th></tr>
<tr><td></td><td>00 – No phase shift
01 – Select 45 degree phase shift
10 – Select 90 degree phase shift
11 – select 135 degree phase shift</td></tr>
<tr><td>9
INTDQS_LPEN</td><td>Internal DQS with Loopback Enable. When this bit is set, the DQS pad is configured to be an output, which will be pushing out the internal DQS clock. The DQS clock is then looped back to the QuadSPI module upon chip select assertion of either Flash A1 or Flash A2.

0 – internal DQS mode with loopback disabled. If DQS_SEL is set, internal DQS mode without loopback is in place. Else, External DQS is enabled.
1 – internal DQS mode with loopback enabled regardless of the DQS_SEL configuration.</td></tr>
<tr><td>8
DQS_SEL</td><td>DQS Selection.
This setting in conjunction with INTDQS_LPEN is used to select the three possible DQS modes: external DQS, internal DQS without loopback, and internal DQS with loopback.
• On external DQS mode, a dedicated DQS line comes from external Flash (see INTDQS_LPEN). For flashes not supporting a dedicated DQS line, the internal DQS modes can alternatively be used.
• On Internal DQS mode with loopback, the internal SFIF 1x clock is sent to the pad and then looped back to the QSPI.
• On internal DQS mode without loopback, the internal SFIF 1x clock is used as the DQS signal without going through a pads.
. The following Truth table shows the possible configurations:
<table>
<tr><th colspan="2">DQS configurations</th><th colspan="3">DQS modes</th></tr>
<tr><th>INTDQS_LPEN</th><th>DQS_SEL</th><th>Internal DQS with loopback</th><th>Internal DQS without loopback</th><th>External DQS</th></tr>
<tr><td>0</td><td>0</td><td>Disabled</td><td>Disabled</td><td>Enabled</td></tr>
<tr><td>0</td><td>1</td><td>Disabled</td><td>Enabled</td><td>Disabled</td></tr>
<tr><td>1</td><td>X</td><td>Enabled</td><td>Disabled</td><td>Disabled</td></tr>
</table>
</td></tr>
<tr><td>7-0
RESERVED</td><td>This field is reserved</td></tr>
</table>

20.1.5 Internal Data Strobe (DQS) Scheme

i.MX 7ULP does provide a dedicated DQS pad. The problem arises when the external memory does not provide such signal. In this condition, the chip can be used by generating an internal DQS signal. This internal signal is generated by looping back the serial clock outgoing to external memory to the QuadSPI after adding some delay.

The internal DQS signal is generated after passing through two delay mechanism: the coarse delay and the fine delay (delay chain). The coarse delay mechanism is adjusted by flops that run off the 2x and inverted 2x clocks in order to provide 45, 90, and 135 degree shift. See Data strobe (DQS) sampling method using SOCCR register for details of how to configure the DQS clock. Even for external flash that provides the DQS clock, this clock is passed through the delay chain in order to match the data valid period. This adjustment is performed by writing into the QuadSPI_SOCCR[DQSDLY]. QuadSPI internally samples the incoming data at both edges of the DQS clock.

The QuadSPI_MCR[DQS_EN]) is used to enable the DQS clock only during read cycles. This signal in turn may be delayed appropriately by writing into the QuadSPI_SMPR[FSDLY] and QuadSPI_SMPR[FSPHS].

NOTE

Any glitch on the muxes used above will not cause any impact to the functionality as when the select line of these muxes are changing, the DQS clock to the QuadSPI is gated off.

20.2 Introduction

The Quad Serial Peripheral Interface (QuadSPI) block acts as an interface to a single serial flash device, with up to eight bidirectional data lines.

20.2.1 Features

The QuadSPI supports the following features:

- Flexible sequence engine to support various flash vendor devices. As there is no specific standard, the module supports various kind of flashes from different vendors. Refer Serial Flash Devices for example sequences.
- Single, dual, quad and octal modes of operation.
- Double data rate (DDR)/Double trasfer rate (DTR) mode wherein the data is generated on every edge of the serial flash clock.
- Support for flash data strobe signal for data sampling in DDR and Single data rate (SDR) mode.
- AHB master to read RX Buffer data via AMBA AHB bus (64-bit width interface) or IP registers space (32-bit access) and fill TX Buffer via IPS register space (32-bit access).

    - AHB master can be a DMA with configurable inner loop size.
- Multimaster accesses with priority
    - Flexible and configurable buffer for each master
- Multiple interrupt conditions (see Table 20-14)
- All AHB accesses to flash devices are directly memory mapped to the chip system memory.
- Programmable sequence engine to cater to future command/protocol changes and able to support all existing vendor commands and operations. Software needs to select the corresponding sequence according to the connected flash device.
    - Supports all types of addressing.

20.2.2 Block Diagram

The following figure is a block diagram of the Quad Serial Peripheral Interface (QuadSPI) module.

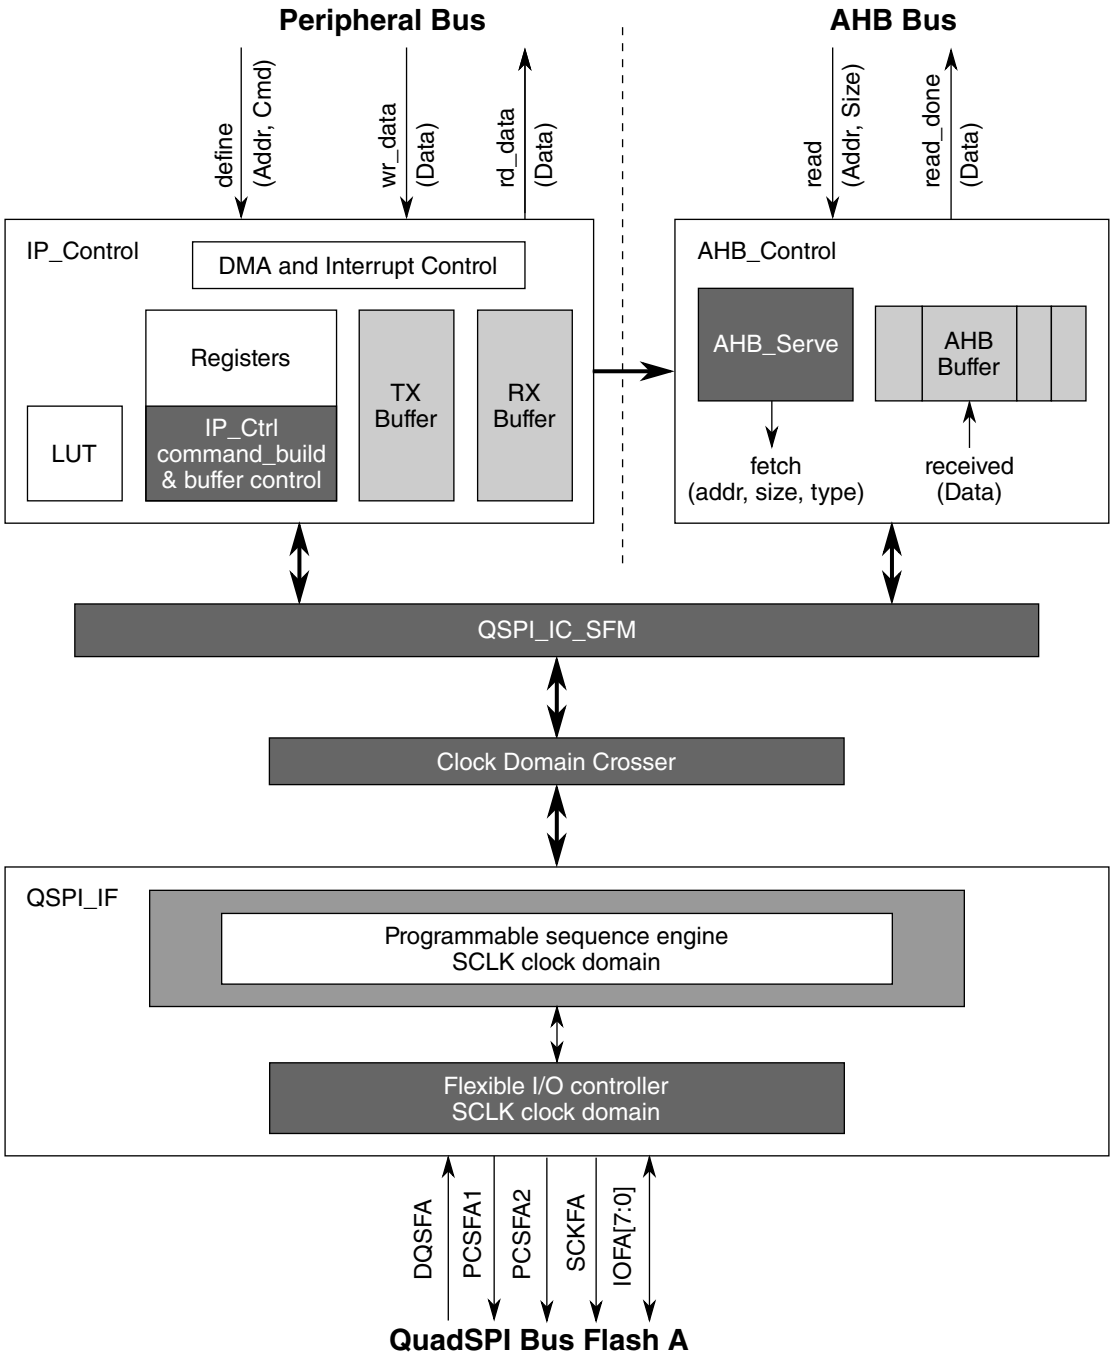


Figure 20-1. QuadSPI Block Diagram

20.2.3 QuadSPI Modes of Operation

For power management through IPS interface access and correct config register programming sequences, QuadSPI supports three modes: normal, module disable and stop mode.

- Normal Mode can be used for write or read accesses to an external serial flash device.
  - Serial Flash Write: Data can be programmed into the flash via the IP interface only. Refer to Flash Programming for further details.
  - Serial Flash Read: Read the contents of the serial flash device. Two separate read channels are available via RX Buffer and AHB Buffer, see Flash Read.
- Stop Mode: The mode is used for power management. When a request is made to enter Stop Mode, the QuadSPI block acknowledges the request and completes the SFM Command in progress, then the system clocks to the QuadSPI block may be shut off
- Module Disable Mode: The mode is used for power management. The clock to the non-memory mapped logic in the QuadSPI can be stopped while in Module Disable Mode. The module enters the mode by setting QSPI_MCR[MDIS].

20.2.4 Acronyms and Abbreviations

The following table contains acronyms and abbreviations used in this document.

Table 20-7. Acronyms and Abbreviations

Terms	Description
AHB	Advanced High-performance Bus, version of AMBA
AMBA	Advanced Microcontroller Bus Architecture
BE	Big Endian Byte Ordering
CS	Chip Select
DMA	Direct Memory Access
MB	Megabyte. Each MB is 1024 * 1024 bytes
IFM	Individual Flash Mode
LSB	Least Significant Bit
MSB	Most Significant Bit
PCS	Peripheral Chip Select
QSPI, QuadSPI	Quad Serial Peripheral Interface
SCK	Serial Communications Clock
w1c	Write 1 to clear, writing a 1 to this field resets the flag
I/O	Input output. In this document, I/O lines are also referred as **pads**.

20.2.5 Glossary for QuadSPI module

Table 20-8. Glossary

Term	Definition
AHB Command	An AHB Command is a SFM Command triggered by a read access to the address range belonging to the memory mapped access defined in Table 20-13. Refer to AHB Commands for details.
Asserted	A signal that is asserted is in its active state. An active low signal changes from logic level one to logic level zero when asserted, and an active high signal changes from logic level zero to logic level one.
Clear	To clear a bit or bits means to establish logic level zero on the bit or bits.
Clock Phase	Determines when the data should be sampled relative to the active edge of SCK
Clock Polarity	Determines the idle state of the SCK signal.
Drain	To remove entries from a FIFO by software or hardware.
Endianness	Byte Ordering scheme.
Field	Two or more register bits grouped together.
Fill	To add entries to a FIFO by software or hardware.
Host	Refers to another functional block in the device containing the QuadSPI module
Instruction Code	8 bits defining the type of command to be executed.
IP Command	An IP Command is a SFM Command triggered by writing into the QSPI_IPCR[SEQID] field.
Logic level one	The voltage that corresponds to Boolean true (1) state.
Logic level zero	The voltage that corresponds to Boolean false (0) state.
Negated	A signal that is negated is in its inactive state. An active low signal changes from logic level 0 to logic level 1 when negated, and an active high signal changes from logic level 1 to logic level 0.
QSPI_AMBA_BASE	The first address of the serial flash device as presented to the QuadSPI controller. This may be the base of the serial flash in the system address map or it may be a remapping, for instance to 0x0, done by the system. Refer to the system address map.
QSPI_ARDB_BASE	First address of QuadSPI Rx Buffer on system memory map.
Set	To set a bit or bits means to establish logic level one on the bit or bits.
RX Buffer PUSH Event	Addition of valid entries into the RX Buffer. In the default case each Buffer PUSH Event adds 2 entries to the RX Buffer since the interface to the serial clock domain is 64 bits in width. Depending on the number of bytes read from the serial flash device it is possible for the very last Buffer PUSH Event that only one entry is added. The QSPI_RBSR[RDBFL] field is incremented by the number of entries added to the RX Buffer.
RX Buffer POP Event	Removal of valid entries from the RX Buffer. Each Buffer POP Event removes (QSPI_RBCT[WMRK] + 1) valid entries from the buffer. The QSPI_RBSR[RDBFL] field is decremented by the same number and the QSPI_RBSR[RDCTR] field is incremented accordingly.
Individual Flash Mode	Access to a single, individual serial flash device. Refer to Serial Flash Access Schemes for details.
SFM Command	Serial Flash Memory Command. A SFM command consists of an instruction code and all other parameters (for example, size or mode bytes) needed for that specific instruction code. Triggering a command either initiates a transaction on the external serial flash or results in an error. Refer to Table 20-20 for details on errors.
Single/Dual/Quad/Octal Instructions	Depending on the serial flash device connected to the QuadSPI module there will be instructions using a different number of data lines. • Single pad: Single line I/O with one data out and one data in line to/from the serial flash device. • Dual pad: Dual line I/O with two bidirectional I/O lines, driven alternatively by the serial flash device or the QuadSPI module

Table continues on the next page...

Table 20-8. Glossary (continued)

Term	Definition
	• Quad pad: Quad line I/O with 4 bidirectional I/O lines, driven alternatively by the serial flash device or the QuadSPI • Octal pad: Octal line I/O with 8 bidirectional I/O lines, driven alternatively by the serial flash device or the QuadSPI
Transaction	A transaction consists of all flags, data and signals in either direction to execute a command for an attached serial flash device. It is a combination of chip select, sclk, instruction code, address, mode- and/or dummy bytes, transmit and/or receive data.
LUT	Look-up table.

20.3 External Signal Description

This section provides the external signal information of the QuadSPI module.

The following table lists the external signals belonging to the module in conjunction with the different modes of operation.

Table 20-9. Signal Properties

Signal Name	Function	Direction	Description
PCSFA1	Peripheral Chip Select Flash A1	O	This signal is the chip select for the serial flash device A1. A1 represents the first device in a dual-die package flash A or the first of the two flash devices that share IOFA. Refer to Dual Die Flashes for more details.
PCSFA2	Peripheral Chip Select Flash A2	O	This signal is the chip select for the serial flash device A2. A2 represents the second device in a dual-die package flash A or the second of the two flash devices that share IOFA. Refer to Dual Die Flashes for more details.
SCKFA	Serial Clock Flash A	O	This signal is the serial clock output to the serial flash device A.
IOFA[7:0]	Serial I/O Flash A	I/O	These signals are the data I/O lines to/from the serial flash device A. Refer to Driving External Signals for details about the signal drive and timing behavior. Note that the signal pins of the serial flash device may change their function according to the SFM Command executed, leaving them as control inputs when Single and Dual Instructions are executed. The module supports driving these inputs to dedicated values. In single I/O mode, QuadSPI drives data on IOFA[0] and expects data on IOFA[1].
DQSFA	Data Strobe signal Flash A	I	Data strobe signal for port A. Some flash vendors provide the DQS signal to which the read data is aligned in DDR mode.

20.3.1 Driving External Signals

The different phases of the serial flash access scheme are shown in the following figure.

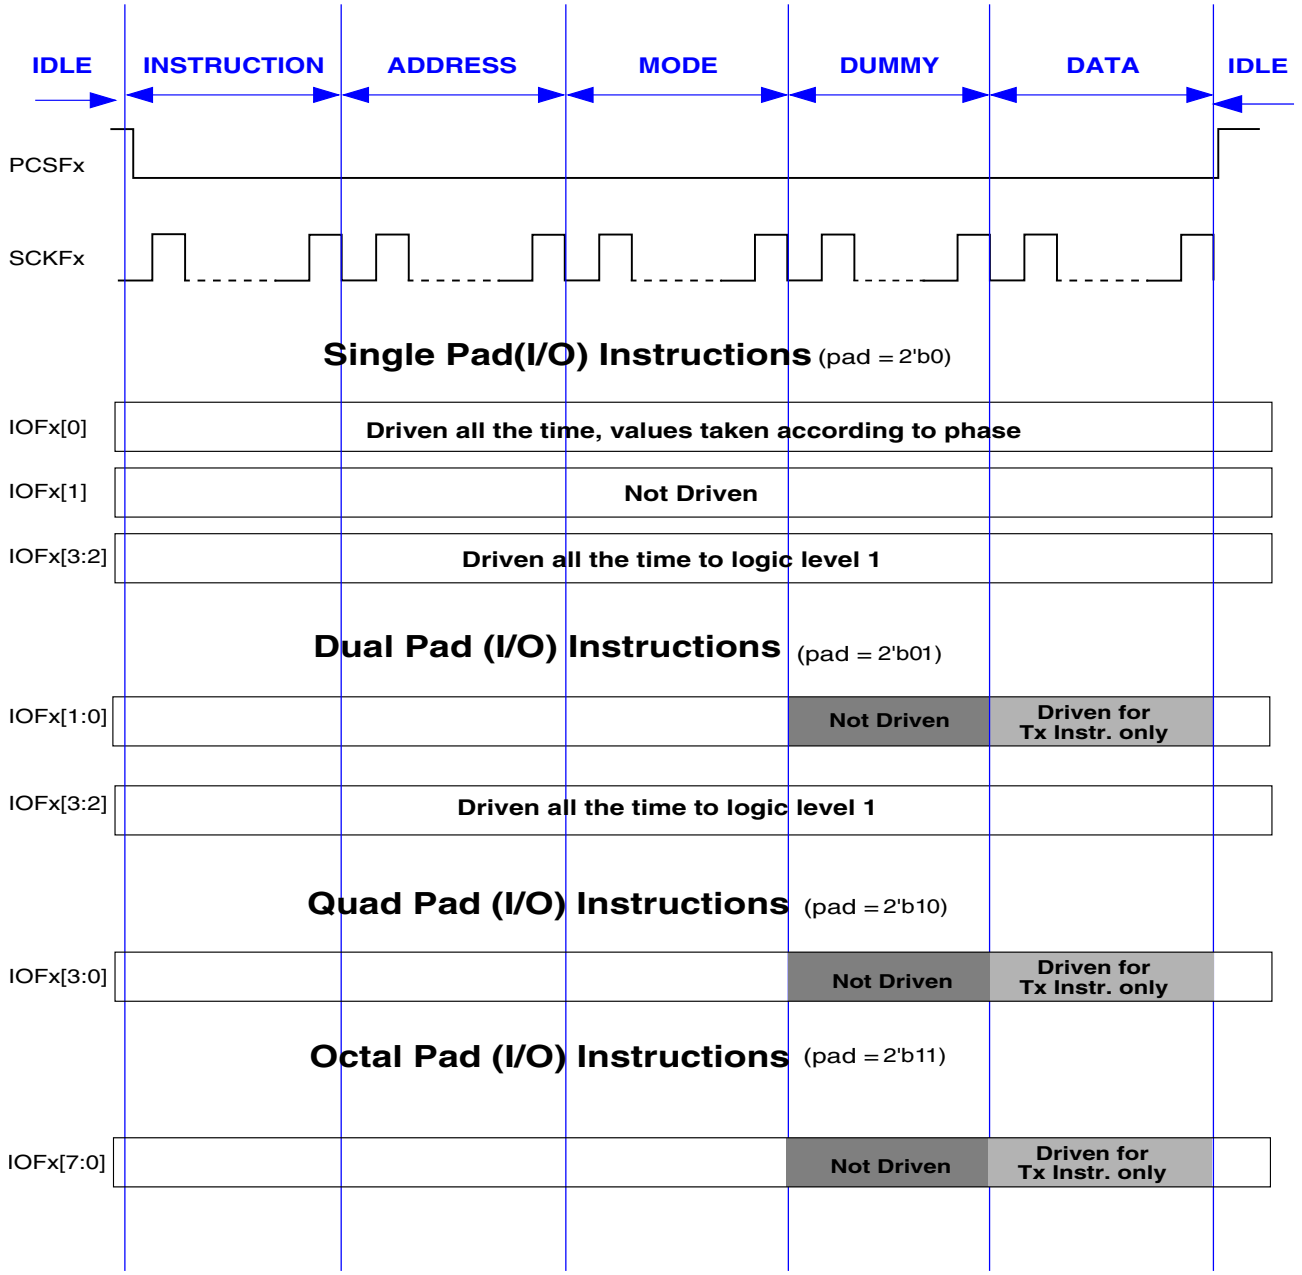

Figure 20-2. Serial Flash Access Scheme

The different phases and the I/O driving characteristics of the QuadSPI module are characterized in the following way:

- IDLE: Serial flash device not selected. No interaction with the serial flash device. All IOFx signals driven.
- INSTRUCTION: Serial flash device selected. The instruction is sent to the serial flash device. All IOFx signals are driven.

- ADDRESS: Serial Flash Address is sent to the device. All IOFx signals are driven. Note that this phase is not applicable for all SFM Commands.
- MODE: Mode bytes are sent to the serial flash device. All IOFx signals are driven. Note that this phase is not applicable for all SFM Commands.
- DUMMY: Dummy clocks are provided to the serial flash device. Refer to the Figure 20-2 for the IOFx signals driven. The actual data lines required for the SFM Command executed are not driven for data read commands. Note that this phase is not applicable for all SFM Commands.
- DATA: Serial flash data are sent to or received from the serial flash device. Refer to the preceding figure for the IOFx signals driven. The actual data lines required for the SFM Command executed are not driven for data read commands. Note that this phase is not applicable for all SFM Commands.

The PCSFx and SCKFx signals are driven permanently throughout all the phases.

In Individual Flash Mode this applies to the selected flash device.

20.4 Memory Map and Register Definition

This section provides the memory map and register definitions of the QuadSPI module.

20.4.1 Register Write Access

This section describes the write access restriction terms that apply to all registers, which can be one of the following:

- **Register Write Access Restriction**

  For each register bit and register field, the write access conditions are specified in the detailed register description. A description of the write access conditions is given in the following table. If, for a specific register bit or field, none of the given write access conditions is fulfilled, any write attempt to this register bit or field is ignored without any notification. The values of the bits or fields are not changed.

  The condition term [A or B] indicates that the register or field can be written to if at least one of the conditions is fulfilled.

Table 20-10. Register Write Access Restrictions

Condition	Description
Anytime	No write access restriction.
Disabled Mode	Write access only if *QSPI_MCR[MDIS] = 1*.
Normal Mode	Write access only if the module is in *Normal Mode*.

- **Register Write Access Requirements**

  All registers can be accessed with 8-bit, 16-bit, and 32-bit wide operations. For some of the registers, at least a 16/32-bit wide write access is required to ensure correct operation. This write access requirement is stated in the detailed register description for each register affected.

20.4.2 Peripheral Bus Register Descriptions

This section provides the memory map and register definitions of the QuadSPI module.

NOTE

Access to location 0x4 does not give transfer error.

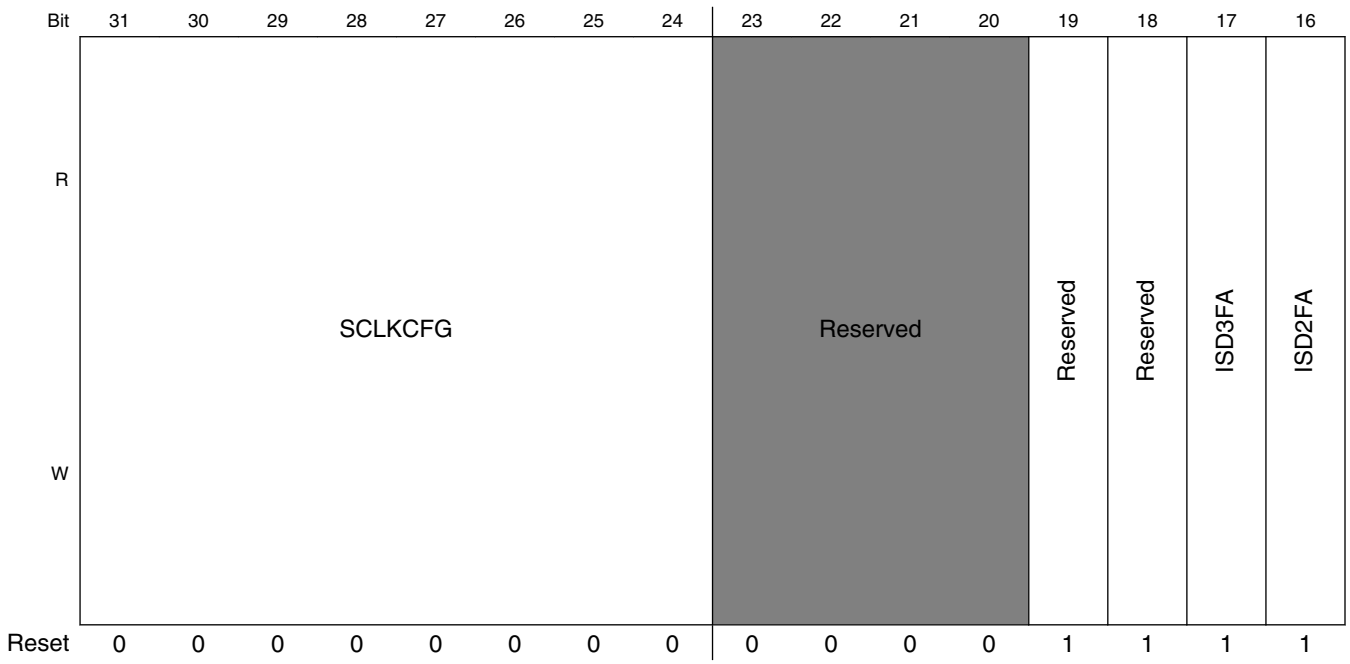
20.4.2.1 Module Configuration Register (QuadSPIx_MCR)

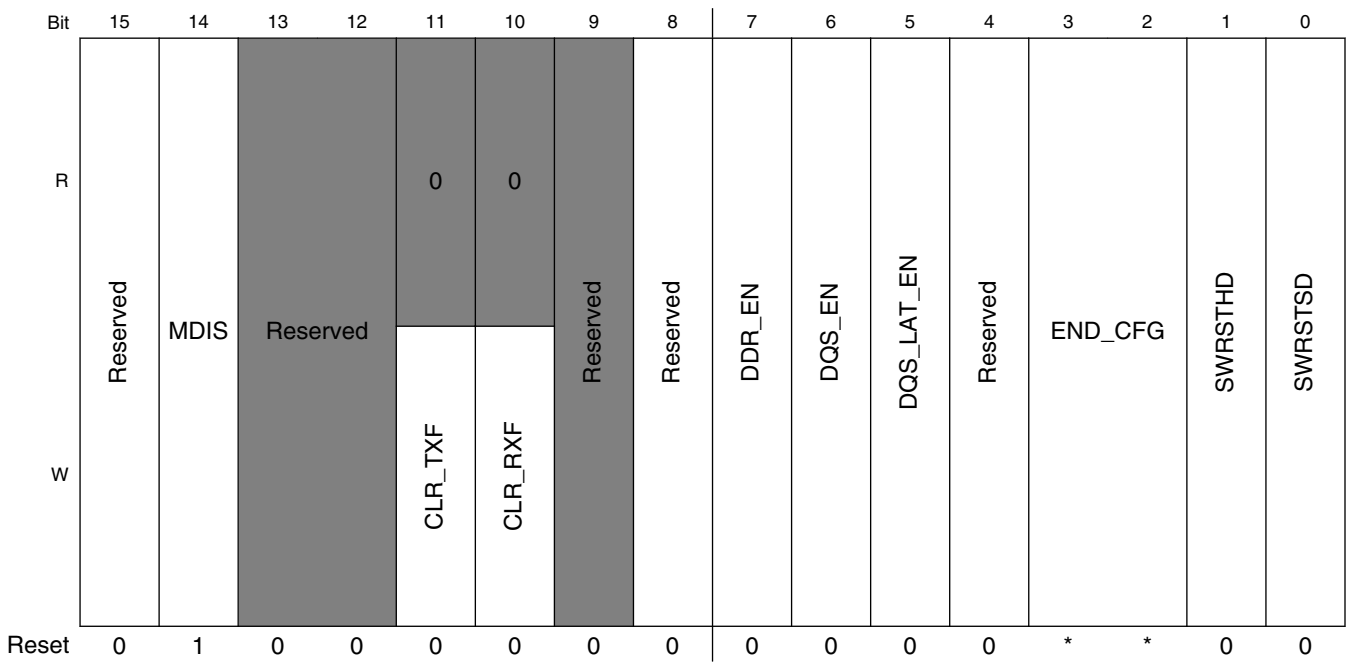
The QuadSPI_MCR holds configuration data associated with QuadSPI operation.

Write:

- *SCLKCFG: Disabled Mode*
- *ISD3FA, ISD2FA: Disabled Mode*
- *All other fields: Anytime*

Address: 410A_5000h base + 0h offset = 410A_5000h





* Notes:
- END_CFG field: See the module configuration for the device specific reset value.

QuadSPIx_MCR field descriptions

Field	Description
31–24 SCLKCFG	Serial Clock Configuration. This field configuration is chip specific. For details, refer to chip-specific QuadSPI information. It may be used for dividing clocks.

Table continues on the next page...

QuadSPIx_MCR field descriptions (continued)

Field	Description
23–20 Reserved	This field is reserved.
19 Reserved	This field is reserved.
18 Reserved	This field is reserved.
17 ISD3FA	Idle Signal Drive IOFA[3] Flash A. This bit determines the logic level the IOFA[3] output of the QuadSPI module is driven to in the inactive state. Refer to Driving Flash Control Signals in Single and Dual Mode . 0 IOFA[3] is driven to logic L 1 IOFA[3] is driven to logic H
16 ISD2FA	Idle Signal Drive IOFA[2] Flash A. This bit determines the logic level the IOFA[2] output of the QuadSPI module is driven to in the inactive state. Refer to Driving Flash Control Signals in Single and Dual Mode . 0 IOFA[2] is driven to logic L 1 IOFA[2] is driven to logic H
15 Reserved	This field is reserved. This field is reserved.
14 MDIS	Module Disable. The MDIS bit allows the clock to the non-memory mapped logic in the QuadSPI to be stopped, putting the QuadSPI in a software controlled power-saving state. 0 Enable QuadSPI clocks. 1 Allow external logic to disable QuadSPI clocks.
13–12 Reserved	This field is reserved.
11 CLR_TXF	Clear TX FIFO/Buffer. Invalidates the TX Buffer content. This is a self-clearing field. 0 No action. 1 Read and write pointers of the TX Buffer are reset to 0. QSPI_TBSR[TRCTR] is reset to 0.
10 CLR_RXF	Clear RX FIFO. Invalidates the RX Buffer. This is a self-clearing field. 0 No action. 1 Read and write pointers of the RX Buffer are reset to 0. QSPI_RBSR[RDBFL] is reset to 0.
9 Reserved	This field is reserved.
8 Reserved	This field is reserved.
7 DDR_EN	DDR mode enable 0 2x and 4x clocks are disabled for SDR instructions only 1 2x and 4x clocks are enabled supports both SDR and DDR instruction.
6 DQS_EN	DQS enable. This field is valid for both SDR and DDR mode. For more details, refer to Data Strobe (DQS) sampling method.

Table continues on the next page...

QuadSPIx_MCR field descriptions (continued)

Field	Description
	0 DQS disabled. 1 DQS enabled. When enabled, the incoming data is sampled on both the edges of DQS input when QSPI_MCR[DDR_EN] is set, else, on only one edge when QSPI_MCR[DDR_EN] is 0. The QSPI_SMPR[DDR_SMP] values are ignored.
5 DQS_LAT_EN	DQS Latency Enable. This field is valid when latency is included in between read access from flash memory in cases when QSPI_MCR[DQS_EN] is 1. For more details, refer to Data Strobe (DQS) sampling method. 0 DQS Latency disabled 1 DQS feature with latency included enabled
4 Reserved	This field is reserved.
3–2 END_CFG	Defines the endianness of the QuadSPI module. For more details refer to Byte Ordering Endianess
1 SWRSTHD	Software reset for AHB domain 0 No action 1 AHB domain flops are reset. Does not reset configuration registers. It is advisable to reset both the serial flash domain and AHB domain at the same time. Resetting only one domain might lead to side effects. **NOTE:** The software resets need the clock to be running to propagate to the design. The MCR[MDIS] should therefore be set to 0 when the software reset bits are asserted. Also, before they can be deasserted again (by setting MCR[SWRSTHD] to 0), it is recommended to set the MCR[MDIS] bit to 1. Once the software resets have been deasserted, the normal operation can be started by setting the MCR[MDIS] bit to 0.
0 SWRSTSD	Software reset for serial flash domain 0 No action 1 Serial Flash domain flops are reset. Does not reset configuration registers. It is advisable to reset both the serial flash domain and AHB domain at the same time. Resetting only one domain might lead to side effects. **NOTE:** The software resets need the clock to be running to propagate to the design. The MCR[MDIS] should therefore be set to 0 when the software reset bits are asserted. Also, before they can be deasserted again (by setting MCR[SWRSTSD] to 0), it is recommended to set the MCR[MDIS] bit to 1. Once the software resets have been deasserted, the normal operation can be started by setting the MCR[MDIS] bit to 0.

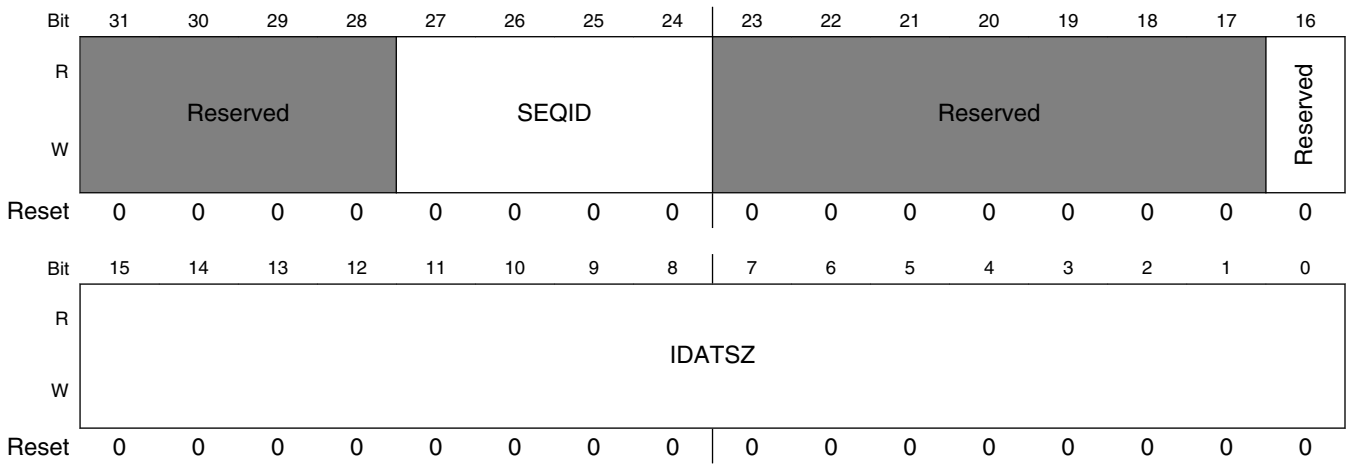
20.4.2.2 IP Configuration Register (QuadSPIx_IPCR)

The IP configuration register provides all the configuration required for an IP initiated command. An IP command can be triggered by writing in the SEQID field of this register. If the SEQID field is written successfully, a new command to the external serial flash is started as per the sequence pointed to by the SEQID field. Refer to Normal Mode , for details about the command triggering and command execution.

Write:

- *QSPI_SR[IP_ACC]=0*

Address: 410A_5000h base + 8h offset = 410A_5008h



QuadSPIx_IPCR field descriptions

Field	Description
31–28 Reserved	This field is reserved.
27–24 SEQID	Points to a sequence in the Look-up table. This field defines bits [6:2] of the LUT index. The bits [1:0] are always assumed to be 0. Refer to Look-up Table for more details. A write to this field triggers a transaction on the serial flash interface.
23–17 Reserved	This field is reserved.
16 Reserved	This field is reserved.
IDATSZ	IP data transfer size. Defines the data transfer size in bytes of the IP command.

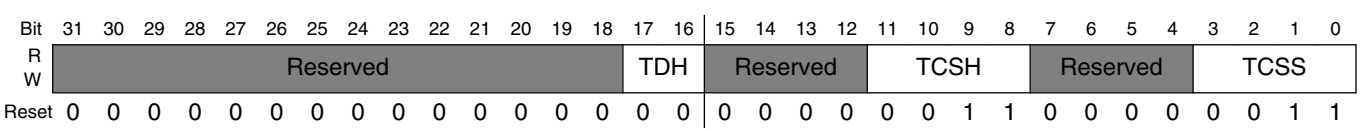
20.4.2.3 Flash Configuration Register (QuadSPIx_FLSHCR)

The Flash configuration register contains the flash device specific timings that must be met by the QuadSPI controller for the device to function correctly.

Write:

- *QSPI_SR[AHB_ACC] = 0*
- *QSPI_SR[IP_ACC] = 0*

Address: 410A_5000h base + Ch offset = 410A_500Ch



QuadSPIx_FLSHCR field descriptions

Field	Description
31–18 Reserved	This field is reserved.
17–16 TDH	Serial flash data in hold time. This helps in meeting the Data In Hold time requirement of a flash. This is valid only in DDR mode. **NOTE:** This field should be set to 0x00 in SDR mode (QuadSPI_MCR[DDR_EN]=0). Refer to Data input hold requirement of Flash for details. The valid TDH programming options are shown below. Other combinations are invalid. 00 Data aligned with the posedge of Internal reference clock of QuadSPI 01 Data aligned with 2x serial flash half clock 10 Data aligned with 4x serial flash half clock
15–12 Reserved	This field is reserved.
11–8 TCSH	Serial flash CS hold time in terms of serial flash clock cycles. Default value '3' should be used in case AHB prefetch size is less than or equal to 32-bytes DDR/16-bytes SDR. **NOTE:** The actual delay between chip select and clock is defined as: • TCSH = 1 SCK clk if N= 0/1 else, N SCK clk if N>1, where N is the setting of TCSH.
7–4 Reserved	This field is reserved. Reserved.
TCSS	Serial flash CS setup time in terms of serial flash clock cycles. **NOTE:** 1. The actual delay between chip select and clock is defined as: • TCSS = 0.5 SCK clk if N= 0/1 else, N+0.5 SCK clk if N>1, where N is the setting of TCSS. 2. Any update to the TCSS register bits is visible on the flash interface only from the second transaction following the update.

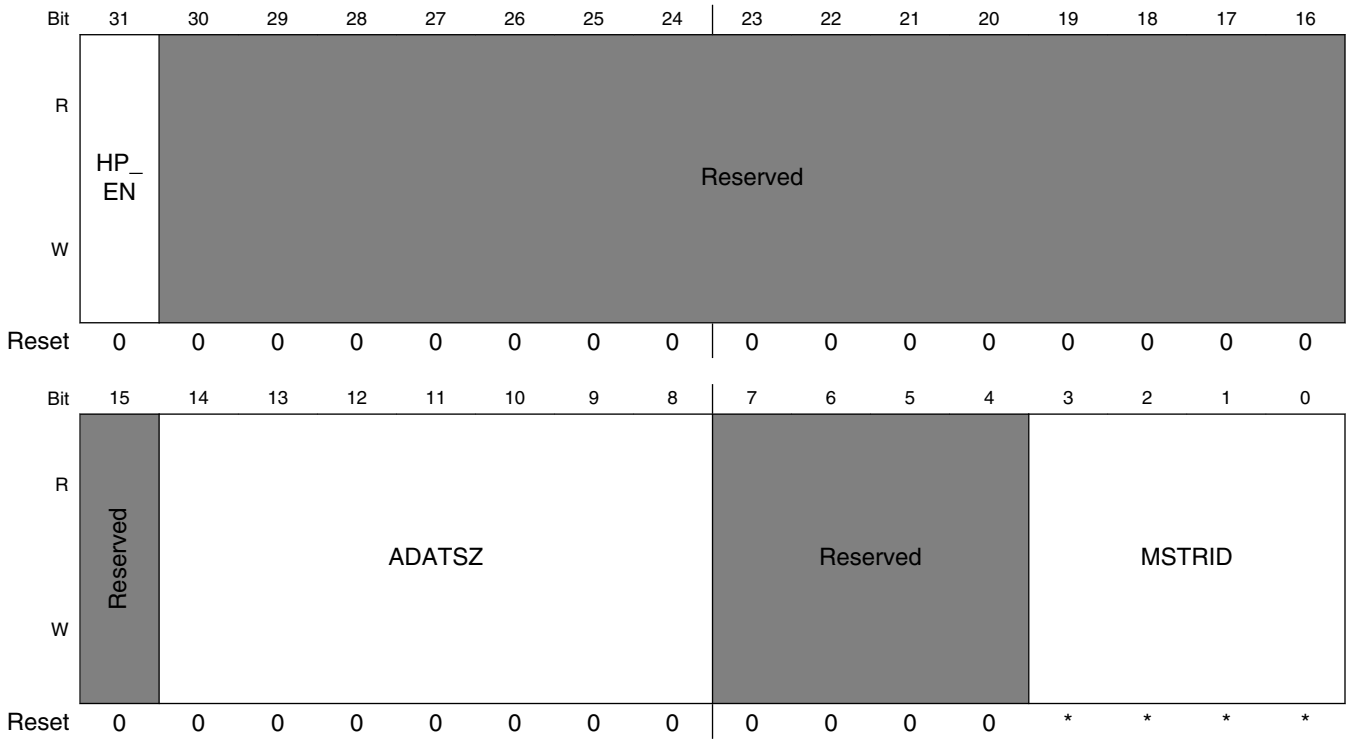
20.4.2.4 Buffer0 Configuration Register (QuadSPIx_BUF0CR)

This register provides the configuration for any access to buffer0. An access is routed to buffer0 when the master port number of the incoming AHB request matches the MSTRID field of BUF0CR. Any buffer "miss" leads to a serial flash transaction being triggered as per the sequence pointed to the SEQID field. Buffer0 may also be configured as a high priority buffer by setting the HP_EN field of this register.

Write:

- *QSPI_SR[AHB_ACC] = 0*

Address: 410A_5000h base + 10h offset = 410A_5010h



* Notes:

- MSTRID field: See the module configuration for reset value.

QuadSPIx_BUF0CR field descriptions

Field	Description
31 HP_EN	High Priority Enable. When set, the master associated with this buffer is assigned a priority higher than the rest of the masters. An access by a high priority master will suspend any ongoing prefetch by another AHB master and will be serviced on high priority. Refer to Flexible AHB Buffers for details.
30–16 Reserved	This field is reserved.
15 Reserved	This field is reserved.
14–8 ADATSZ	AHB data transfer size Defines the data transfer size in 8 bytes of an AHB triggered access to serial flash. For example, a value of 0x2 will set transfer size to 16 bytes. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. Software should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved.
MSTRID	Master ID. The ID of the AHB master associated with BUFFER0. Any AHB access with this master port number is routed to this buffer. It must be ensured that the master IDs associated with all buffers must be different.

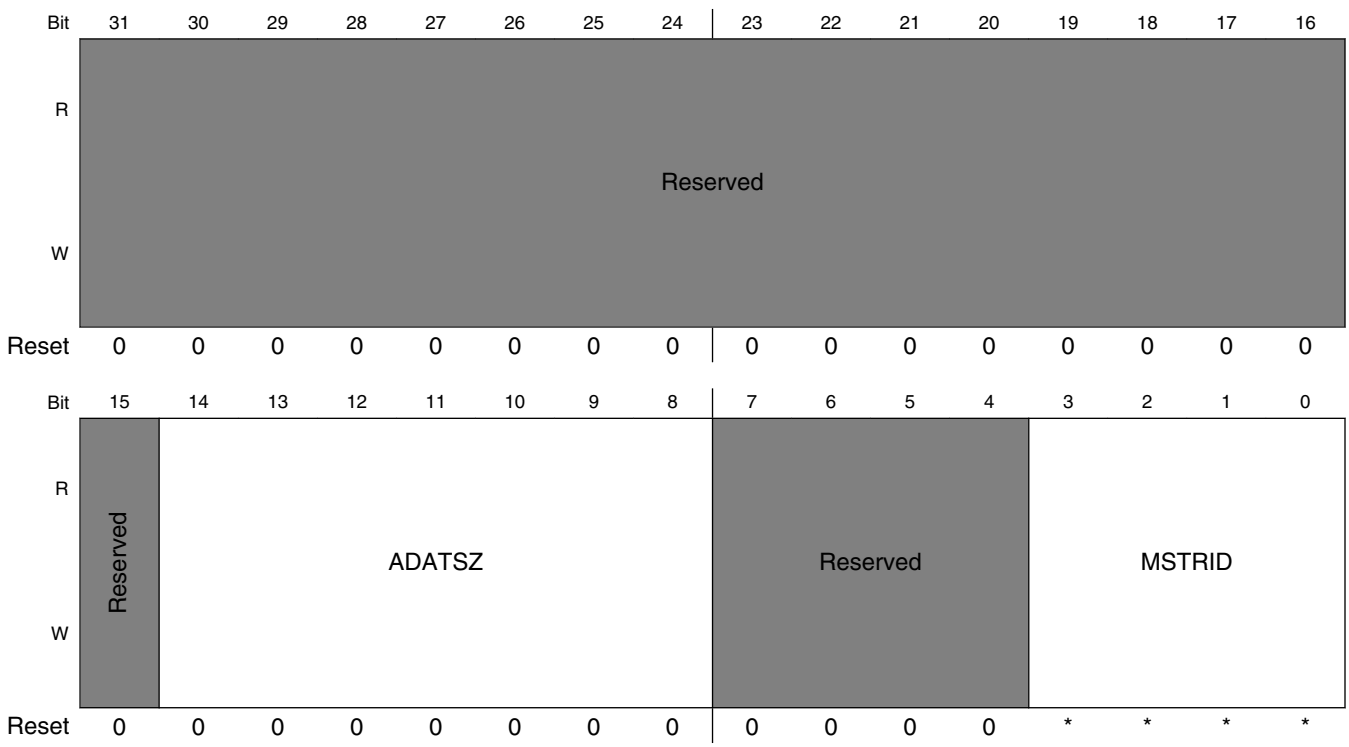
20.4.2.5 Buffer1 Configuration Register (QuadSPIx_BUF1CR)

This register provides the configuration for any access to buffer1. An access is routed to buffer1 when the master port number of the incoming AHB request matches the MSTRID field of BUF1CR. Any buffer "miss" leads to the buffer being flushed and a serial flash transaction being triggered as per the sequence pointed to by the SEQID field.

Write:

- *QSPI_SR[AHB_ACC] = 0*

Address: 410A_5000h base + 14h offset = 410A_5014h



* Notes:

- MSTRID field: See the module configuration for reset value.

QuadSPIx_BUF1CR field descriptions

Field	Description
31–16 Reserved	This field is reserved.
15 Reserved	This field is reserved.
14–8 ADATSZ	AHB data transfer size Defines the data transfer size in 8 bytes of an AHB triggered access to serial flash.For example, a value of 0x2 will set transfer size to 16bytes. When ADATSZ = 0, the data size mentioned the sequence pointed to

Table continues on the next page...

QuadSPIx_BUF1CR field descriptions (continued)

Field	Description
	by the SEQID field overrides this value. Software should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved.
MSTRID	Master ID. The ID of the AHB master associated with BUFFER1. Any AHB access with this master port number is routed to this buffer. It must be ensured that the master IDs associated with all buffers must be different.

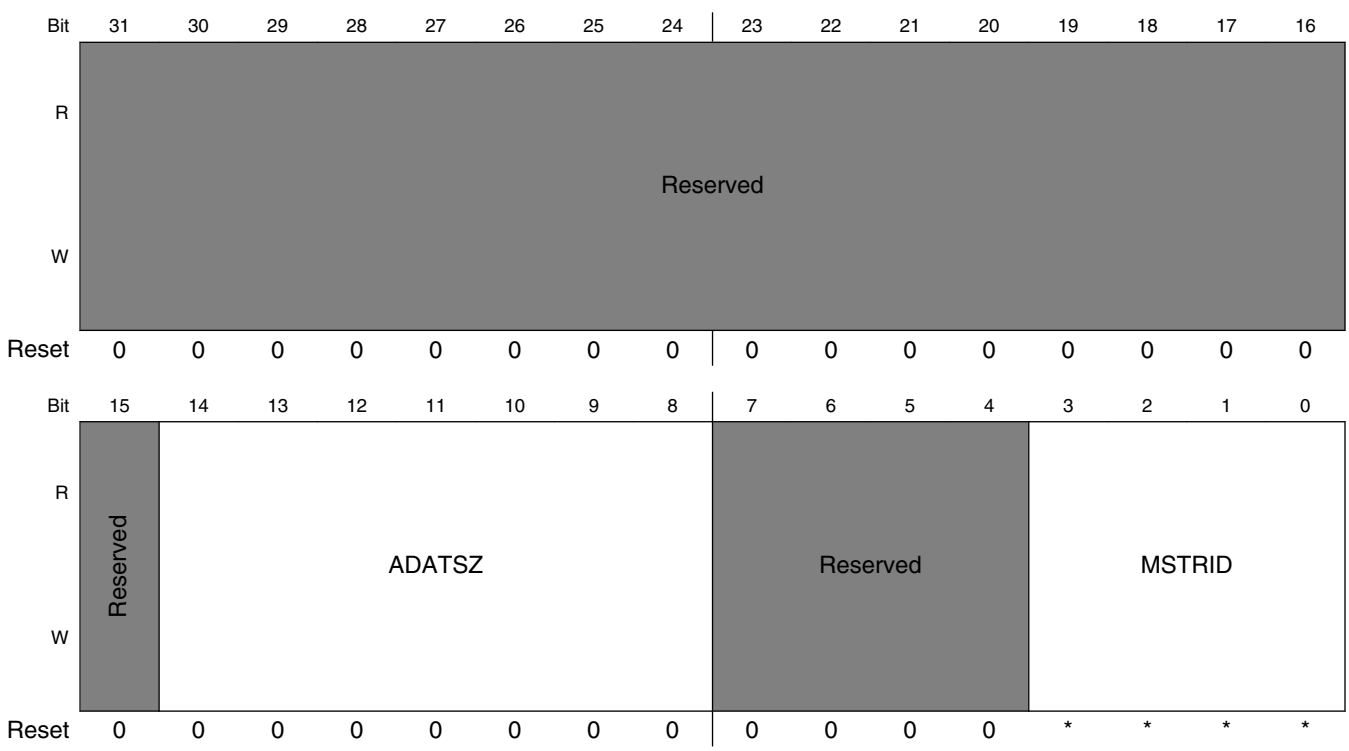
20.4.2.6 Buffer2 Configuration Register (QuadSPIx_BUF2CR)

This register provides the configuration for any access to buffer2. An access is routed to buffer2 when the master port number of the incoming AHB request matches the MSTRID field of BUF2CR. Any buffer "miss" leads to the buffer being flushed and a serial flash transaction being triggered as per the sequence pointed to by the SEQID field.

Write:

- *QSPI_SR[AHB_ACC] = 0*

Address: 410A_5000h base + 18h offset = 410A_5018h



* Notes:

- MSTRID field: See the module configuration for the device specific reset value.

QuadSPIx_BUF2CR field descriptions

Field	Description
31–16 Reserved	This field is reserved. Reserved.
15 Reserved	This field is reserved.
14–8 ADATSZ	AHB data transfer size Defines the data transfer size in 8 bytes of an AHB triggered access to serial flash. For example, a value of 0x2 will set transfer size to 16 bytes. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. Software should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved. Reserved.
MSTRID	Master ID. The ID of the AHB master associated with BUFFER2. Any AHB access with this master port number is routed to this buffer. It must be ensured that the master IDs associated with all buffers must be different.

20.4.2.7 Buffer3 Configuration Register (QuadSPIx_BUF3CR)

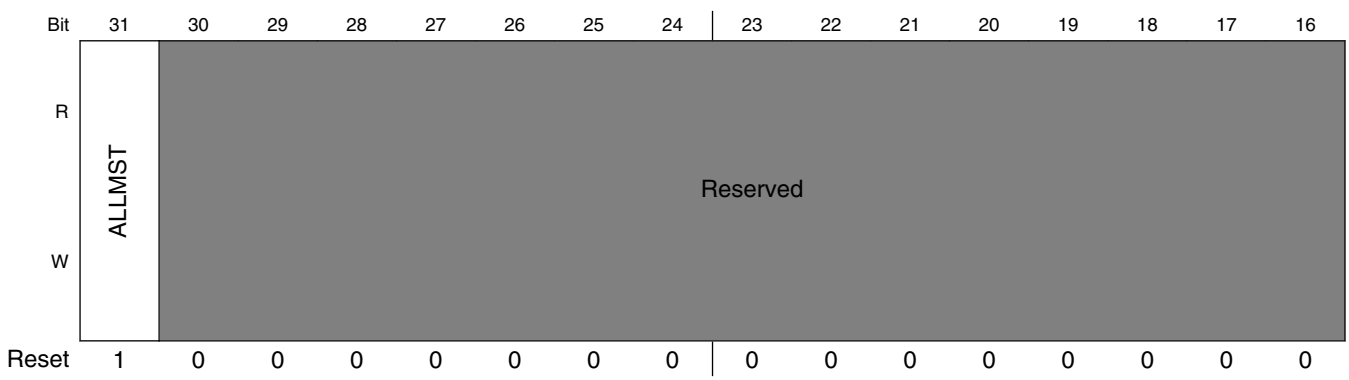
This register provides the configuration for any access to buffer3. An access is routed to buffer3 when the master port number of the incoming AHB request matches the MSTRID field of BUF3CR. Any buffer "miss" leads to the buffer being flushed a serial flash transaction being triggered as per the sequence pointed to by the SEQID field.

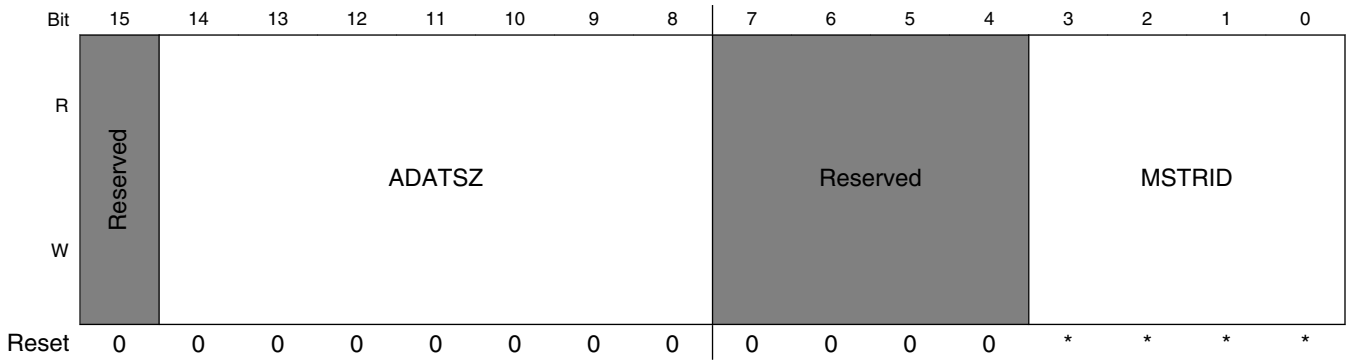
In the case that the ALLMST field is not set, any such transaction (where master port number does not match any of the MSTRID fields) will be returned an ERROR response.

Write:

- *QSPI_SR[AHB_ACC] = 0*

Address: 410A_5000h base + 1Ch offset = 410A_501Ch





* Notes:
- MSTRID field: See the module configuration for the device specific reset value.

QuadSPIx_BUF3CR field descriptions

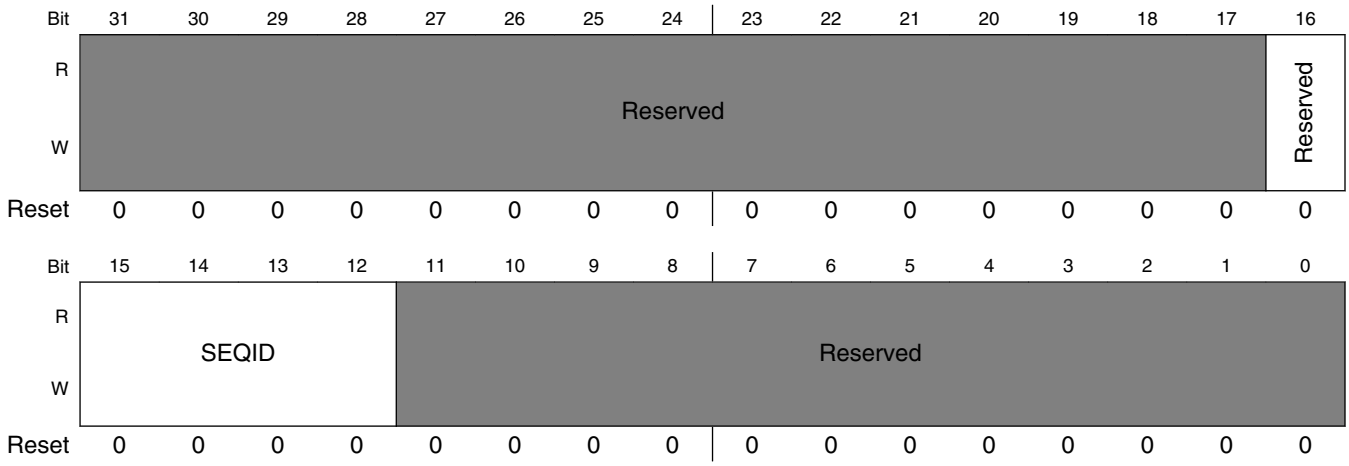
Field	Description
31 ALLMST	All master enable. When set, buffer3 acts as an all-master buffer. Any AHB access with a master port number not matching with the master ID of buffer0 or buffer1 or buffer2 is routed to buffer3. When set, the MSTRID field of this register is ignored.
30–16 Reserved	This field is reserved. Reserved.
15 Reserved	This field is reserved.
14–8 ADATSZ	AHB data transfer size Defines the data transfer size in 8 Bytes of an AHB triggered access to serial flash. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. Software should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved.
MSTRID	Master ID. The ID of the AHB master associated with BUFFER3. Any AHB access with this master port number is routed to this buffer. It must be ensured that the master IDs associated with all buffers must be different.

20.4.2.8 Buffer Generic Configuration Register (QuadSPIx_BFGENCR)

This register provides the generic configuration to any of the buffer accesses. Any buffer "miss" leads to the buffer being flushed and a serial flash transaction being triggered as per the sequence pointed to by the SEQID field.

Write:
- *QSPI_SR[AHB_ACC] = 0*

Address: 410A_5000h base + 20h offset = 410A_5020h



QuadSPIx_BFGENCR field descriptions

Field	Description
31–17 Reserved	This field is reserved.
16 Reserved	This field is reserved.
15–12 SEQID	Points to a sequence in the Look-up-table. The SEQID defines the bits [6:2] of the LUT index. The bits [1:0] are always assumed to be 0. Refer to Look-up Table. **NOTE:** If the sequence pointer differs between the new and previous sequence then the user should reset this. See QSPI_SPTRCLR for more information.
Reserved	This field is reserved.

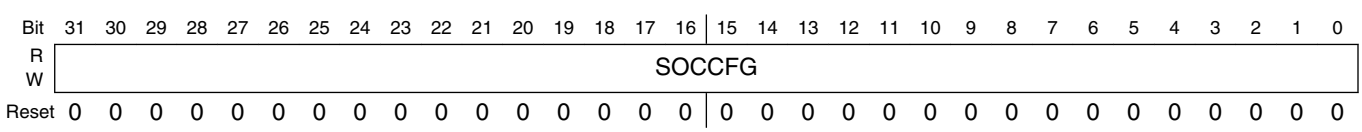
20.4.2.9 SOC Configuration Register (QuadSPIx_SOCCR)

This register is programmed at chip level for QuadSPI delay chain configuration. For details, refer to chip-specific QuadSPI information.

Write:

- *QSPI_SR[AHB_ACC] = 0*

Address: 410A_5000h base + 24h offset = 410A_5024h



QuadSPIx_SOCCR field descriptions

Field	Description
SOCCFG	SOC Configuration

QuadSPIx_SOCCR field descriptions (continued)

Field	Description
	For details, refer to chip-specific QuadSPI information.

20.4.2.10 Buffer0 Top Index Register (QuadSPIx_BUF0IND)

This register specifies the top index of buffer0, which defines its size. Note that that the 3 LSBs of this register are set to zero. This ensures that the buffer is 64-bit aligned, as each buffer entry is 64 bits long.

The register value should be set to the desired number of bytes. For example, setting BUF0IND[31:3] to 0 gives 0 bytes, 1 gives 8 bytes etc.

The size of buffer0 is the difference between BUF0IND and 0.

Software should ensure that BUF0IND value is not greater than the overall size of the buffer. The hardware does not provide any protection against illegal programming.

Write:

- *QSPI_SR[AHB_ACC] = 0*

Address: 410A_5000h base + 30h offset = 410A_5030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	TPINDX0																													Reserved		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPIx_BUF0IND field descriptions

Field	Description
31–3 TPINDX0	Top index of buffer 0.
Reserved	This field is reserved. Reserved.

20.4.2.11 Buffer1 Top Index Register (QuadSPIx_BUF1IND)

This register specifies the top index of buffer1, which defines its size. Note that the 3 LSBs of this register are set to zero. This ensures that the buffer is 64-bit aligned as each buffer entry is 64 bits long.

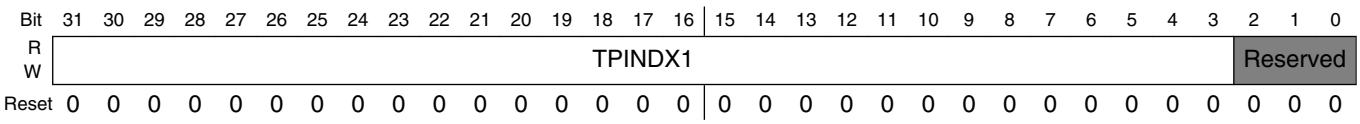
The size of buffer1 is the difference between BUF1IND and BUF0IND. The register value should be entered in bytes. For example, If BUF0IND = 0x100 then setting BUF1IND = 0x130 will set buffer1 size to 0x30 bytes.

It is the responsibility of the software to ensure that BUF1IND value is not greater than the overall size of the buffer. The hardware does not provide any protection against illegal programming.

Write:

- *QSPI_SR[AHB_ACC] = 0*

Address: 410A_5000h base + 34h offset = 410A_5034h



QuadSPIx_BUF1IND field descriptions

Field	Description
31–3 TPINDX1	Top index of buffer 1.
Reserved	This field is reserved.

20.4.2.12 Buffer2 Top Index Register (QuadSPIx_BUF2IND)

This register specifies the top index of buffer2, which defines its size. Note that that the 3 LSBs of this register are set to zero. This ensures that the buffer is 64-bit aligned as each buffer entry is 64 bits long.

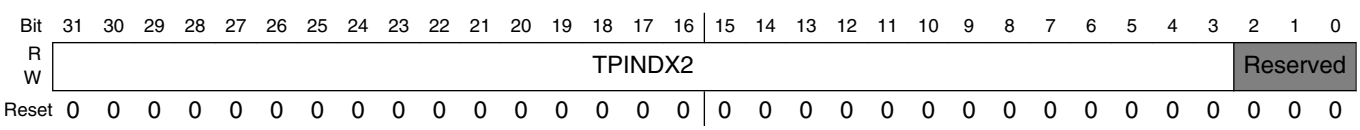
The size of buffer2 is the difference between the BUF2IND and BUF1IND. The register value should be entered in bytes. For example, if BUF1IND = 0x130 then setting BUF2IND = 0x180 will set buffer2 size to 0x50 bytes.

It is the responsibility of the software to ensure that BUF2IND value is not greater than the overall size of the buffer. The hardware does not provide any protection against illegal programming.

Write:

- *QSPI_SR[AHB_ACC] = 0*

Address: 410A_5000h base + 38h offset = 410A_5038h



QuadSPIx_BUF2IND field descriptions

Field	Description
31–3 TPINDX2	Top index of buffer 2.
Reserved	This field is reserved.

20.4.2.13 Serial Flash Address Register (QuadSPIx_SFAR)

The module automatically translates this address on the memory map to the address on the flash itself. When operating in 24-bit mode, only bits 23-0 are sent to the flash. In 32-bit mode, bits 27-0 are used with bits 31-28 driven to 0 when QSPI_SFACR[CAS] is set to 0. Say, if QSPI_SFACR[CAS] is 3 then bits 26-3 are sent to flash as it page address in case flash is operating in 24-bit mode. Total number of address bits request by flash as it page and column address must not be more than 32 bit. Refer to Table 20-11 for the mapping between the access mode and the QSPI_SFAR content and to Normal Mode for details about the command triggering and command execution. The software should ensure that the serial flash address provided in the QSPI_SFAR register lies in the valid flash address range as defined in Table 20-11.

Write:

- *QSPI_SR[IP_ACC] = 0*

Address: 410A_5000h base + 100h offset = 410A_5100h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

QuadSPIx_SFAR field descriptions

Field	Description
SFADR	Serial Flash Address. The register content is used as byte address for all following IP Commands.

20.4.2.14 Serial Flash Address Configuration Register (QuadSPIx_SFACR)

This register contains the serial flash specific address requirements that must be configured according to the flash connected, for the controller to function properly. The module automatically translates the address QSPI_SFAR on the memory map or the incoming address on the AHB bus to the column address on the flash itself. Say, a flash needs 3 bits as its column address than only the lower 3 bits of QSPI_SFAR/AHB address are send to flash as its column address. The software should ensure that the serial flash address provided in the QSPI_SFAR register or the incoming AHB address lies in the valid flash address range.

Write:

- *QSPI_SR[IP_ACC] = 0*
- *QSPI_SR[AHB_ACC] = 0*

Address: 410A_5000h base + 104h offset = 410A_5104h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved															WA
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved												CAS			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPIx_SFACR field descriptions

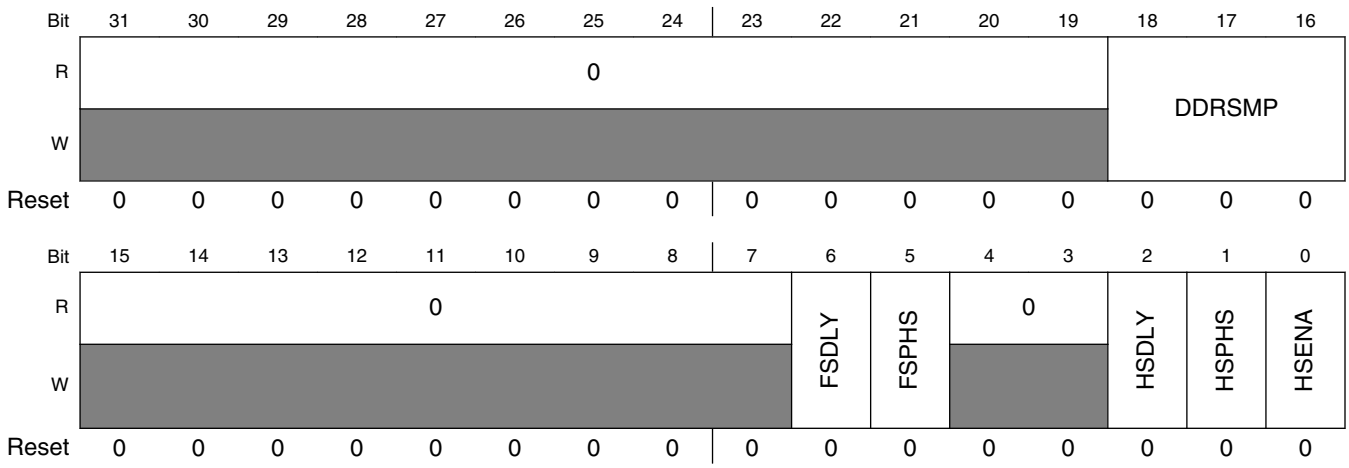
Field	Description
31–17 Reserved	This field is reserved.
16 WA	Word Addressable Defines whether the serial flash is a byte addressable flash or a word addressable flash. According to this bit configuration the address is re-mapped to the flash interface. Refer to Address scheme for details. 0 Byte addressable serial flash mode. 1 Word (2 byte) addressable serial flash mode.
15–4 Reserved	This field is reserved.
CAS	Column Address Space Defines the width of the column address. If the coulmn address is say [2:0] of QSPI_SFAR/AHB address, then CAS must be 3. If there is no column address separation in any serial flash this bit must be programmed to 0.

20.4.2.15 Sampling Register (QuadSPIx_SMPR)

The Sampling Register allows configuration of how the incoming data from the external serial flash devices are sampled in the QuadSPI module.

Write: Disabled Mode

Address: 410A_5000h base + 108h offset = 410A_5108h



QuadSPIx_SMPR field descriptions

Field	Description
31–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–16 DDRSMP	DDR Sampling point Select the sampling point for incoming data when serial flash is executing a DDR instruction. Refer to Figure 20-10 for details on the sampling points.
15–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 FSDLY	Full Speed Delay selection for SDR instructions. Select the delay with respect to the reference edge for the sample point valid for full speed commands. 0 One clock cycle delay 1 Two clock cycles delay.
5 FSPHS	Full Speed Phase selection for SDR instructions. Select the edge of the sampling clock valid for full speed commands. 0 Select sampling at non-inverted clock 1 Select sampling at inverted clock.
4–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 HSDLY	Half Speed Delay selection for SDR instructions.

Table continues on the next page...

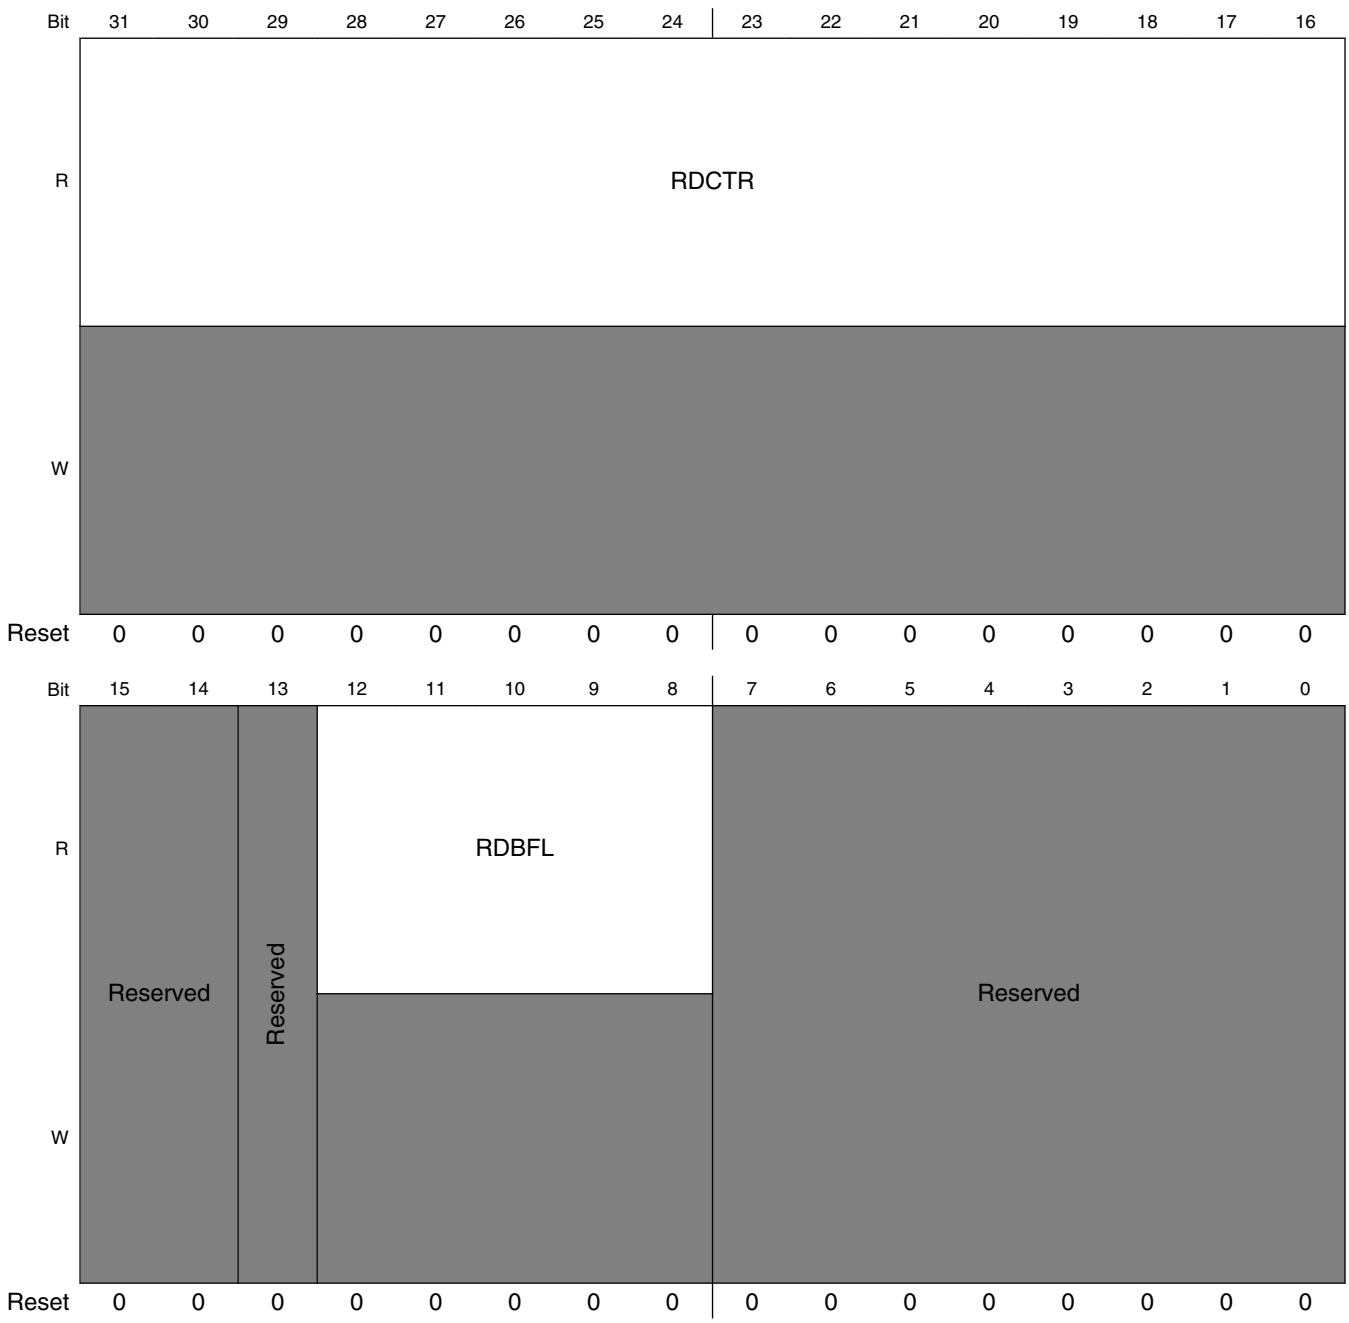
QuadSPIx_SMPR field descriptions (continued)

Field	Description
	Only relevant when HSENA bit is set. Select the delay with respect to the reference edge for the sample point valid for half speed commands. 0 One clock cycle delay 1 Two clock cycle delay
1 HSPHS	Half Speed Phase selection for SDR instructions. Only relevant when HSENA bit is set. Select the delay with respect to the reference edge for the sample point valid for half speed commands. 0 Select sampling at non-inverted clock 1 Select sampling at inverted clock
0 HSENA	Half Speed serial flash clock Enable This bit enables the divide by 2 of the clock to the external serial flash device for all commands, only in SDR. Refer to Serial Flash Clock Frequency Limitations for details. 0 Disable divide by 2 of serial flash clock for half speed commands 1 Enable divide by 2 of serial flash clock for half speed commands

20.4.2.16 RX Buffer Status Register (QuadSPIx_RBSR)

This register contains information related to the receive data buffer.

Address: 410A_5000h base + 10Ch offset = 410A_510Ch



QuadSPIx_RBSR field descriptions

Field	Description
31–16 RDCTR	Read Counter. Indicates how many entries of 4 bytes have been removed from the RX Buffer. For example, a value of 0x2 would indicate 8 bytes have been removed. It is incremented by the number (QSPI_RBCT[WMRK] + 1) on RX Buffer POP event. The RX Buffer can be popped using DMA or pop flag QSPI_FR[RBDF]. The QSPI_RSER[RBDDE] defines which pop has to be done. For further details, refer to AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB15) and "Data Transfer from the QuadSPI Module Internal Buffers" section in Flash Read.
15–14 Reserved	This field is reserved.
13 Reserved	This field is reserved.
12–8 RDBFL	RX Buffer Fill Level. Indicates how many entries of 4 bytes are still available in the RX Buffer.For example, a value of 0x2 would indicate 8bytes are available.
Reserved	This field is reserved.

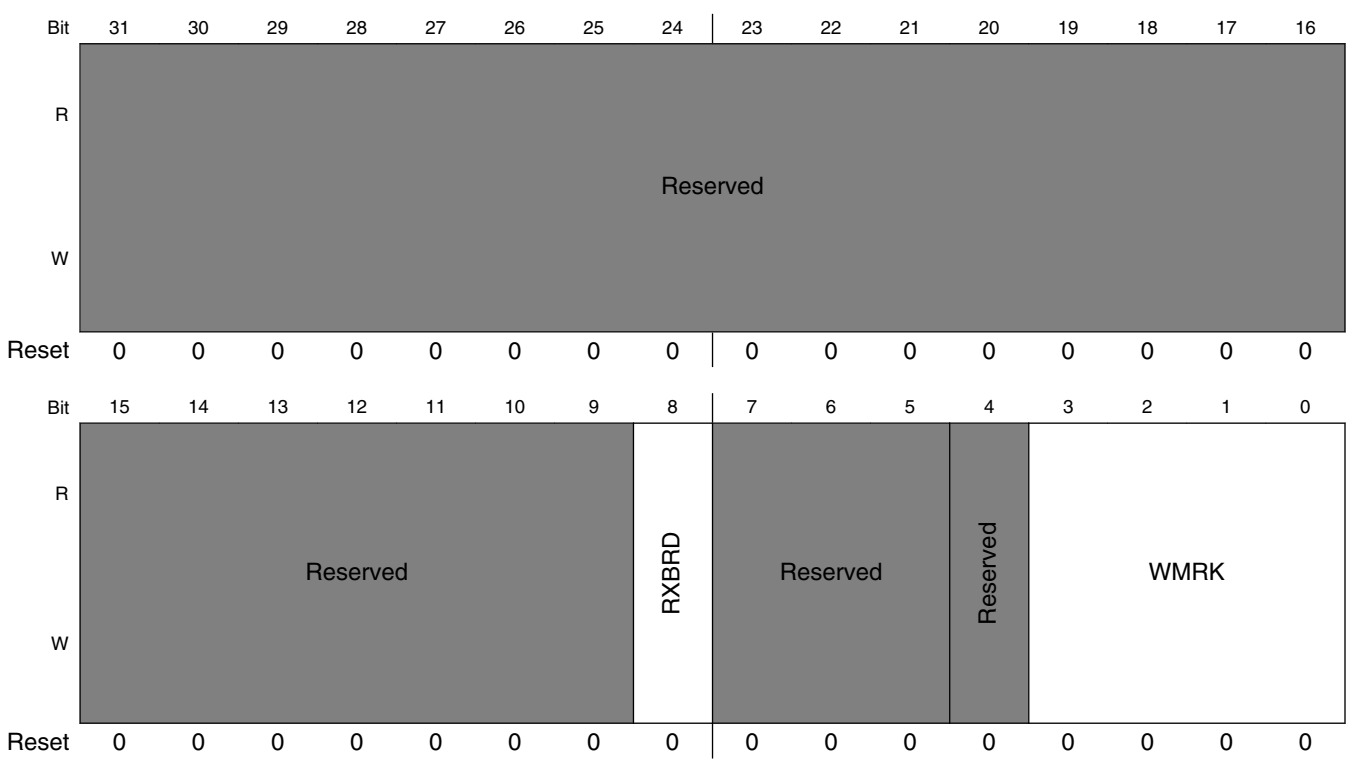
20.4.2.17 RX Buffer Control Register (QuadSPIx_RBCT)

This register contains control data related to the receive data buffer.

Write:

- *QSPI_SR[IP_ACC] = 0*

Address: 410A_5000h base + 110h offset = 410A_5110h



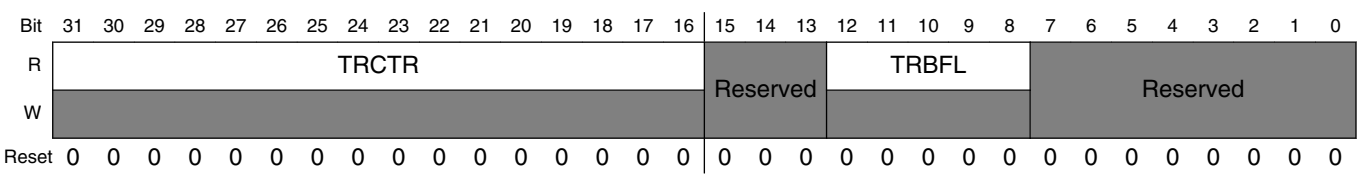
QuadSPIx_RBCT field descriptions

Field	Description
31–9 Reserved	This field is reserved.
8 RXBRD	RX Buffer Readout. This field specifies the access scheme for the RX Buffer readout. 0 RX Buffer content is read using the AHB Bus registers QSPI_ARDB0 to QSPI_ARDB15 . For details, refer to Exclusive Access to Serial Flash for AHB Commands. 1 RX Buffer content is read using the IP Bus registers QSPI_RBDR0 to QSPI_RBDR15 .
7–5 Reserved	This field is reserved.
4 Reserved	This field is reserved.
WMRK	RX Buffer Watermark. This field determines when the readout action of the RX Buffer is triggered. When the number of valid entries in the RX Buffer is equal to or greater than the number given by (WMRK+1) the QSPI_SR[RXWE] flag is asserted.The value should be entered as the number of 4-byte entries minus 1. For example, a value of 0x0 would set the watermark to 4 bytes, 1 to 8 bytes, 2 to 12 bytes, and so on. For details, refer to DMA Usage.

20.4.2.18 TX Buffer Status Register (QuadSPIx_TBSR)

This register contains information related to the transmit data buffer.

Address: 410A_5000h base + 150h offset = 410A_5150h



QuadSPIx_TBSR field descriptions

Field	Description
31–16 TRCTR	Transmit Counter. This field indicates how many entries of 4 bytes have been written into the TX Buffer by host accesses. It is reset to 0 when a 1 is written to QSPI_MCR[CLR_TXF]. It is incremented on each write access to the QSPI_TBDR register when another word has been pushed onto the TX Buffer. When it is not cleared the TRCTR field wraps around to 0. Refer to TX Buffer Data Register (QuadSPI_TBDR) for details.
15–13 Reserved	This field is reserved.
12–8 TRBFL	TX Buffer Fill Level. The TRBFL field contains the number of entries of 4 bytes each available in the TX Buffer for the QuadSPI module to transmit to the serial flash device.
Reserved	This field is reserved.

20.4.2.19 TX Buffer Data Register (QuadSPIx_TBDR)

The QSPI_TBDR register provides access to the circular TX Buffer of depth 64 bytes . This buffer provides the data written into it as write data for the page programming commands to the serial flash device. Refer to Table 20-17 for the byte ordering scheme. A write transaction on the flash with data size of less than 32 bits will lead to the removal of four data entry from the TX buffer. The valid bits will be used and the rest of the bits will be discarded.

Write:

- *QSPI_SR[TXFULL] = 0*

32-bit write access required

Address: 410A_5000h base + 154h offset = 410A_5154h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

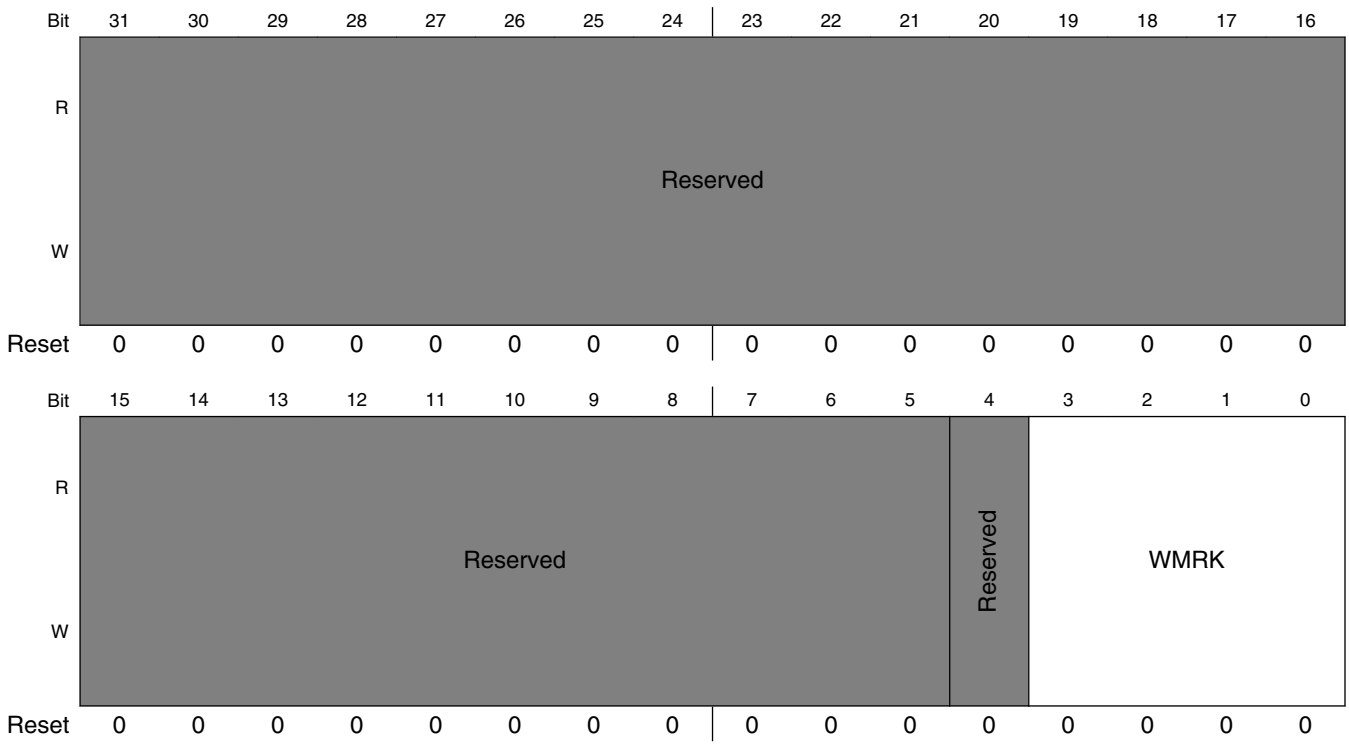
QuadSPIx_TBDR field descriptions

Field	Description
TXDATA	TX Data On write access the data is written into the next available entry of the TX Buffer and the QPSI_TBSR[TRBFL] field is updated accordingly. On a read access, the last data written to the register is returned.

20.4.2.20 Tx Buffer Control Register (QuadSPIx_TBCT)

This register contains control information for transmit data buffer.

Address: 410A_5000h base + 158h offset = 410A_5158h



QuadSPIx_TBCT field descriptions

Field	Description
31–5 Reserved	This field is reserved.
4 Reserved	This field is reserved.
WMRK	Determines the watermark for the TX Buffer. When the number of available space in TX Buffer is greater than the number given by (WMRK+1), QSPI_SR[TXWA] is asserted. The values should be entered as the number of 4Bytes entries minus 1. For example, a value of 0x0 would set the watermark to 4 bytes, 1 to 8 bytes, 2 to 12 Bytes, and so on.For details, refer to DMA Usage.

20.4.2.21 Status Register (QuadSPIx_SR)

The QSPI_SR register provides all available status information about SFM command execution and arbitration, the RX Buffer, TX Buffer, and the AHB Buffer.

Address: 410A_5000h base + 15Ch offset = 410A_515Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

QuadSPIx_SR field descriptions

Field	Description
31–29 DLPSMP	Data learning pattern sampling point. The sampling point found by the controller with the data learning pattern. • This is used for DDR only. • If the learning fails, this field will return garbage and DLPFF bit will be set. • In case of Data learning with DQS this field will return the reset value as sampling point match is not found in case of DQS. For details, refer to Data Learning.
28 Reserved	This field is reserved.
27 TXFULL	TX Buffer Full. Asserted when no more data can be stored.
26 TXDMA	TXDMA Asserted when TXFIFO fill via DMA is active i.e. DMA is requested or running
25 TXWA	TX Buffer watermark Available Asserted when the number of available spaces in TX buffer is greater than or equal to the value give by QSPI_TBCT[WMRK].

Table continues on the next page...

QuadSPIx_SR field descriptions (continued)

Field	Description
24 TXEDA	Tx Buffer Enough Data Available Asserted when TX Buffer contains enough data for any pop operation to take place. There must be at least 128 bit data available in TX FIFO for any pop operation; otherwise, QSPI_FR[TBUF] will be set.
23 RXDMA	RX Buffer DMA. Asserted when RX Buffer read out via DMA is active i.e DMA is requested or running.
22–20 Reserved	This field is reserved.
19 RXFULL	RX Buffer Full. Asserted when the RX Buffer is full, i.e. that QSPI_RBSR[RDBFL] field is equal to 32.
18–17 Reserved	This field is reserved.
16 RXWE	RX Buffer Watermark Exceeded. Asserted when the number of valid entries in the RX Buffer exceeds the number given in the QSPI_RBCT[WMRK] field.
15 Reserved	This field is reserved.
14 AHB3FUL	AHB 3 Buffer Full. Asserted when AHB 3 buffer is full.
13 AHB2FUL	AHB 2 Buffer Full. Asserted when AHB 2 buffer is full.
12 AHB1FUL	AHB 1 Buffer Full. Asserted when AHB 1 buffer is full.
11 AHB0FUL	AHB 0 Buffer Full. Asserted when AHB 0 buffer is full.
10 AHB3NE	AHB 3 Buffer Not Empty. Asserted when AHB 3 buffer contains data.
9 AHB2NE	AHB 2 Buffer Not Empty. Asserted when AHB 2 buffer contains data.
8 AHB1NE	AHB 1 Buffer Not Empty. Asserted when AHB 1 buffer contains data.
7 AHB0NE	AHB 0 Buffer Not Empty. Asserted when AHB 0 buffer contains data.
6 AHBTRN	AHB Access Transaction pending. Asserted when there is a pending request on the AHB interface. Refer to the AMBA specification for details.
5 AHBGNT	AHB Command priority Granted: Asserted when another module has been granted priority of AHB Commands against IP Commands. For details refer to Command Arbitration.
4 Reserved	This field is reserved.
3 RESERVED	This field is reserved.
2 AHB_ACC	AHB Access. Asserted when the transaction currently executed was initiated by AHB bus.
1 IP_ACC	IP Access. Asserted when transaction currently executed was initiated by IP bus.
0 BUSY	Module Busy. Asserted when module is currently busy handling a transaction to an external flash device.

20.4.2.22 Flag Register (QuadSPIx_FR)

The QSPI_FR register provides all available flags about SFM command execution and arbitration which may serve as source for the generation of interrupt service requests. Note that the error flags in this register do not relate directly to the execution of the transaction in the serial flash device itself but only to the behavior and conditions visible in the QuadSPI module.

Write: Enabled Mode

Address: 410A_5000h base + 160h offset = 410A_5160h

QuadSPIx_FR field descriptions

Field	Description
31 DLPFF	Data Learning Pattern Failure Flag. Set when DATA_LEARN instruction was encountered in a sequence but no sampling point was found for the data learning patternin case only 8 bit data learning is requested for non DQS mode. The controller automatically starts sampling using the value in QSPI_SMPR[DDRSMP].If more than 8 bits data learning are requested with QSPI_MCR[DQS_EN] set to 0, and the sampling point found after first 8 bit match doesn't remain the same for the whole instruction duration, this flag is set. In case of Data learn with DQS this flag is set whenever the incoming data from flash on DQS edges doesn't match the pattern in QSPI_DLPR. For details, refer to Data Learning.
30–29 RESERVED	This field is reserved.
28 Reserved	This field is reserved.
27 TBFF	TX Buffer Fill Flag. Before writing to the TX buffer, this bit should be cleared. Then this bit has to be read back. If the bit is set, the TX Buffer can take more data. If the bit remains cleared, the TX buffer is full. Refer to Tx Buffer Operation for details.
26 TBUF	TX Buffer Underrun Flag. Set when the module tried to pull data although TX Buffer was emptyor the buffer contains less than 128 bits of data. The application must ensure that the buffer never goes empty during a transaction except for the last data fetch. The IP Command leading to the TX Buffer underrun is continued (data sent to the serial flash device is all F in case of valid TX underrun). Here valid 'underrun' means that, it should have occurred during the transacting such that few bytes (i.e., less than 4 bytes) are left in FIFO and remaining are filled with “FFFFh". Software should start TX transaction only when 128-bits are written in TX buffer. The application must clear the TX Buffer in response to this event by writing a '1' to the QSPI_MCR[CLR_TXF].
25–24 Reserved	This field is reserved.
23 ILLINE	Illegal Instruction Error Flag. Set when an illegal instruction is encountered by the controller in any of the sequences. As soon as this flag is set, user should assert QSPI_MCR[SWRSTSD], QSPI_MCR[SWRSTHD] and after software resets de-assertion in normal mode, QSPI_MCR[CLR_TXF] and QSPI_MCR[CLR_RXF] should be set to clear any remaining data in buffers i.e., reset to flash and

Table continues on the next page...

QuadSPIx_FR field descriptions (continued)

Field	Description
	AHB domain after re-configuring the correct sequence instruction. Refer to Table 20-15 for a list of legal instructions.
22–18 Reserved	This field is reserved.
17 RBOF	RX Buffer Overflow Flag. Set when not all the data read from the serial flash device could be pushed into the RX Buffer. The IP Command leading to this condition is continued until the number of bytes according to the QSPI_IPCR[IDATSZ] field has been read from the serial flash device. The content of the RX Buffer is not changed.
16 RBDF	RX Buffer Drain Flag. Will be set if the QuadSPI_SR[RXWE] status bit is asserted. Writing 1 into this bit triggers one of the following actions: • If the RX Buffer has up to QuadSPI_RBCT[WMRK] valid entries then the flag is cleared. • If the RX Buffer has more than QuadSPI_RBCT[WMRK] valid entries and the QuadSPI_RSER[RBDDE] bit is not set (flag driven mode) a RX Buffer POP event is triggered. The flag remains set if the RX Buffer contains more than QuadSPI_RBCT[WMRK] valid entries after the RX Buffer POP event is finished. The flag is cleared if the RX Buffer contains less than or equal to QuadSPI_RBCT[WMRK] valid entries after the RX Buffer POP event is finished. Refer to "Receive Buffer Drain Interrupt or DMA Request" section in Normal Mode Interrupt and DMA Requests, for details.
15 ABSEF	AHB Sequence Error Flag. Set when the execution of an AHB Command is started with a WRITE or WRITE_DDR Command in the sequence pointed to by the QSPI_BUFxCR register. (QSPI_BUFxCR implies any one of QSPI_BUF0CR/QSPI_BUF1CR/QSPI_BUF2CR/QSPI_BUF3CR.) Communication with the serial flash device is terminated before the execution of WRITE/WRITE_DDR command by the QuadSPI module. The AHB bus request which triggered this command is answered with an ERROR response.
14 AITEF	AHB Illegal transaction error flag. Set whenever there is no response generated from QSPI to AHB bus in case of illegal transaction and the watchdog timer expires.The timer value is taken as parameter.
13 AIBSEF	AHB Illegal Burst Size Error Flag. Set whenever the total burst size (size x beat) of an AHB transaction is greater than the prefetch data size. The prefecth data size is defined by QSPI_BUFxCR[ADATSZ] or data size mentioned in the sequence pointed to by the SEQID field in case ADATSZ = 0. Refer to HBURST Support for more details on HBURST feature.
12 ABOF	AHB Buffer Overflow Flag. Set when the size of the AHB access exceeds the size of the AHB buffer. This condition can occur only if the QSPI_BUFxCR[ADATSZ] field is programmed incorrectly. The AHB Command leading to this condition is continued until the number of entries according to the QSPI_BUFxCR[ADATSZ] field has been read from the serial flash device. The content of the AHB Buffer is not changed.
11 Reserved	This field is reserved.
10–8 Reserved	This field is reserved.
7 IPAEF	IP Command Trigger during AHB Access Error Flag. Set when the following condition occurs: • A write access occurs to the QSPI_IPCR[SEQID] field and the QSPI_SR[AHB_ACC] bit is set. Any command leading to the assertion of the IPAEF flag is ignored.

Table continues on the next page...

QuadSPIx_FR field descriptions (continued)

Field	Description
6 IPIEF	IP Command Trigger could not be executed Error Flag. Set when the QSPI_SR[IP_ACC] bit is set (i.e. an IP triggered command is currently executing) and any of the following conditions occurs: • Write access to the QSPI_IPCR register. Any command leading to the assertion of the IPIEF flag is ignored • Write access to the QSPI_SFAR register. • Write access to the QSPI_RBCT register.
5 Reserved	This field is reserved.
4 IPGEF	IP Command Trigger during AHB Grant Error Flag. Set when the following condition occurs: • A write access occurs to the QSPI_IPCR[SEQID] field and the QSPI_SR[AHBGNT] bit is set. Any command leading to the assertion of the IPGEF flag is ignored.
3–1 Reserved	This field is reserved.
0 TFF	IP Command Transaction Finished Flag. Set when the QuadSPI module has finished a running IP Command. If an error occurred the related error flags are valid, at the latest, in the same clock cycle when the TFF flag is asserted.

20.4.2.23 Interrupt and DMA Request Select and Enable Register (QuadSPIx_RSER)

The QuadSPI_RSER register provides enables and selectors for the interrupts in the QuadSPI module.

NOTE

Each flag of the QuadSPI_FR register enabled as source for an interrupt prevents the QuadSPI module from entering Stop Mode or Module Disable Mode when this flag is set.

Write: Anytime

Address: 410A_5000h base + 164h offset = 410A_5164h

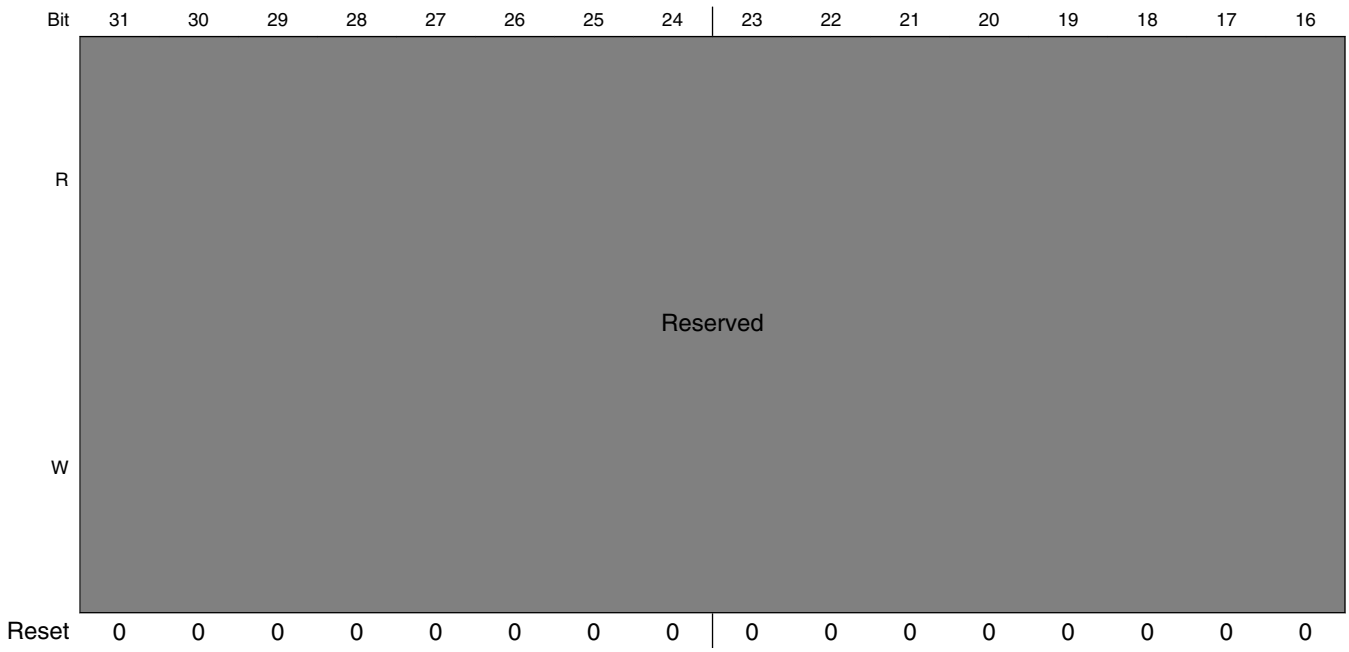
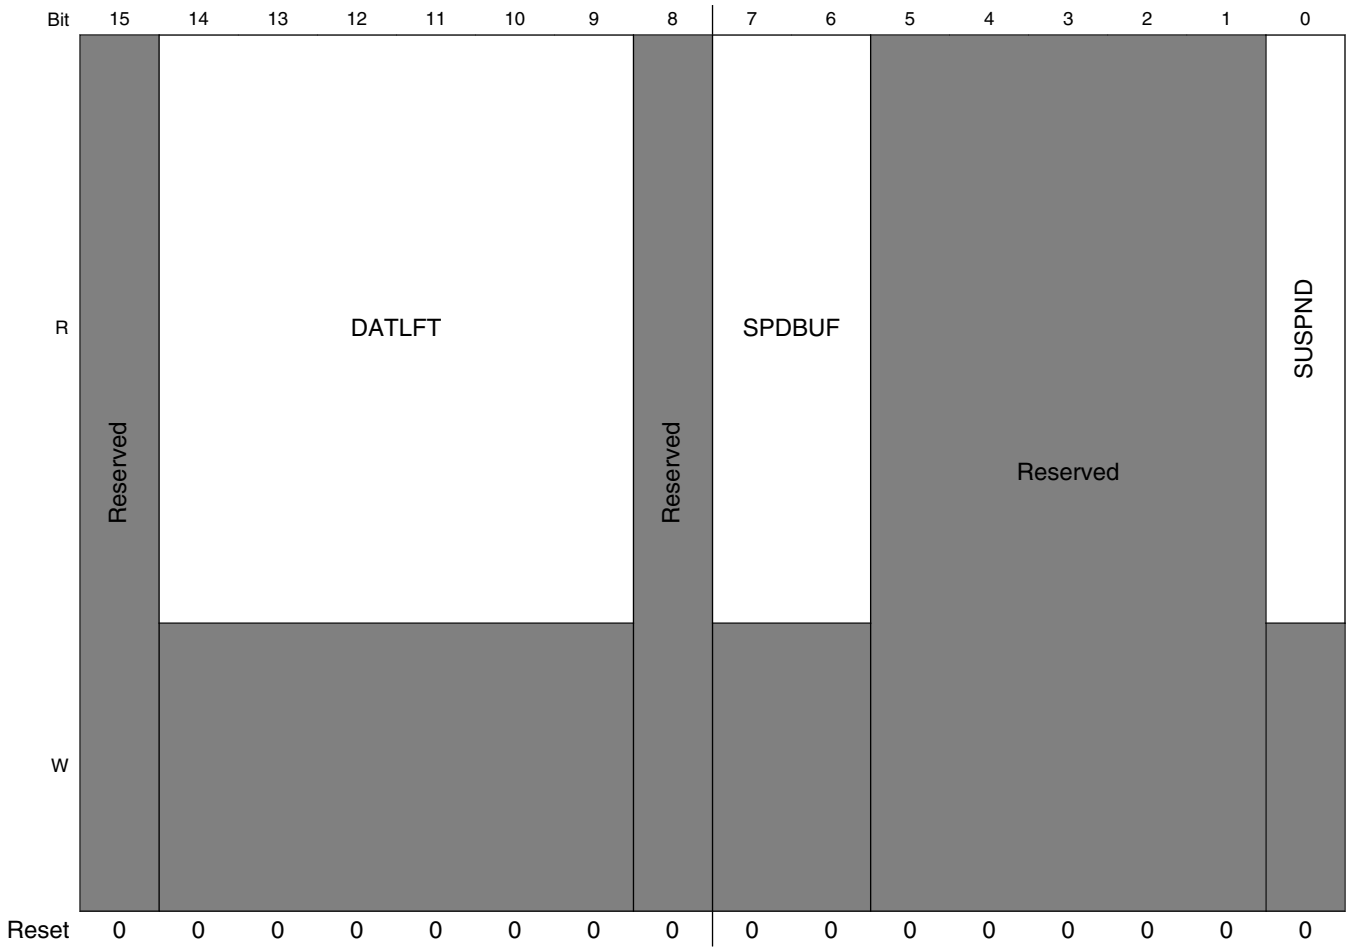
20.4.2.24 Sequence Suspend Status Register (QuadSPIx_SPNDST)

The sequence suspend status register provides information specific to any suspended sequence. An AHB sequence may be suspended when a high priority AHB master makes an access before the AHB sequence completes the data transfer requested.

Address: 410A_5000h base + 168h offset = 410A_5168h





QuadSPIx_SPNDST field descriptions

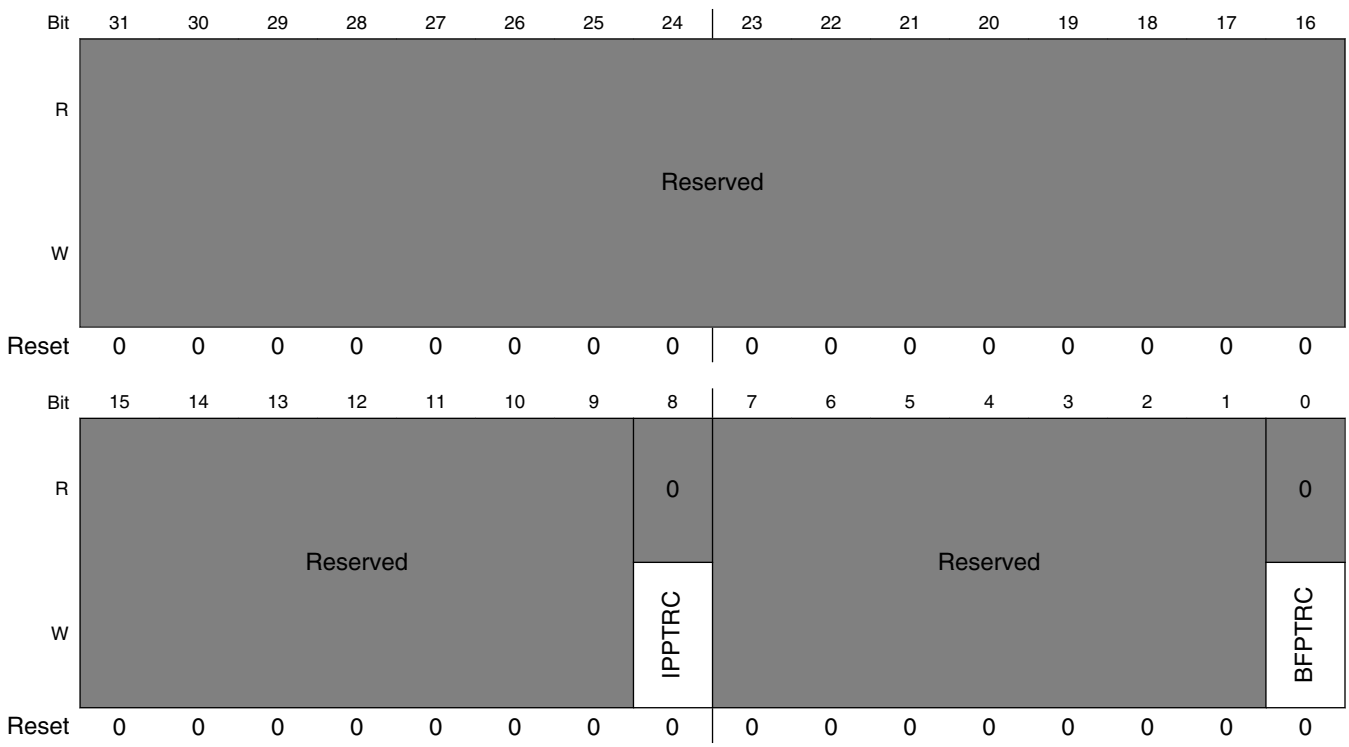
Field	Description
31–16 Reserved	This field is reserved.
15 Reserved	This field is reserved.
14–9 DATLFT	Data left: Provides information about the amount of data left to be read in the suspended sequence. Valid only when SUSPND is set to 1'b1. Value in terms of 64 bits or 8 bytes
8 Reserved	This field is reserved.
7–6 SPDBUF	Suspended Buffer: Provides the suspended buffer number. Valid only when SUSPND is set to 1'b1
5–1 Reserved	This field is reserved.
0 SUSPND	When set, it signifies that a sequence is in suspended state

20.4.2.25 Sequence Pointer Clear Register (QuadSPIx_SPTRCLR)

The sequence pointer clear register provides bits to reset the IP and Buffer sequence pointers. The sequence pointer contains the index of which instruction within the LUT entry is to be executed next. For example, if the LUT entry ends on a JMP_ON_CS value of 2, the index will be stored as 2.

The software should reset the sequence pointers whenever the sequence ID is changed by updating the SEQID field in QSPI_IPCR or QSPI_BFGENCR.

Address: 410A_5000h base + 16Ch offset = 410A_516Ch



QuadSPIx_SPTRCLR field descriptions

Field	Description
31–9 Reserved	This field is reserved.
8 IPPTRC	IP Pointer Clear: 1: Clears the sequence pointer for IP accesses as defined in QuadSPI_IPCR This is a self-clearing field. This bit should be programmed two times to clear the sequence pointers.
7–1 Reserved	This field is reserved. Reserved.
0 BFPTRC	Buffer Pointer Clear: 1: Clears the sequence pointer for AHB accesses as defined in QuadSPI_BFGENCR. This is a self-clearing field. This bit should be programmed two times to clear the sequence pointers.

20.4.2.26 Serial Flash A1 Top Address (QuadSPIx_SFA1AD)

The QSPI_SFA1AD register provides the address mapping for the serial flash A1.The difference between QSPI_SFA1AD[TPADA1] and QSPI_AMBA_BASE defines the size of the memory map for serial flash A1.

Write:

- *QSPI_SR[IP_ACC] = 0*
- *QSPI_SR[AHB_ACC] = 0*

Address: 410A_5000h base + 180h offset = 410A_5180h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

QuadSPIx_SFA2AD field descriptions

Field	Description
31–10 TPADA2	Top address for Serial Flash A2. In effect, TPxxAD is the first location of the next memory.
Reserved	This field is reserved.

20.4.2.28 Data Learn Pattern Register (QuadSPIx_DLPR)

The QSPI_DLPR register contains the information of the data to be used for Data Learning.

Write:

- *QSPI_SR[IP_ACC] = 0*
- *QSPI_SR[AHB_ACC] = 0*

Address: 410A_5000h base + 190h offset = 410A_5190h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DLPV																															
Reset	1	0	1	0	1	0	1	0	0	1	0	1	0	1	0	1	0	0	1	1	0	1	0	0	0	1	0	0	0	0	1	1

QuadSPIx_DLPR field descriptions

Field	Description
DLPV	Data Learning Pattern Value: This value is used for data learning in DDR and DQS mode. If programmer wants to do data learn for more than 32 bit than the same value in the register is repeated. Say if 64 bit data learning is requested by any flash and the value of DLPR is aa55_3443 then the 64 bit value will be aa55_3443_aa55_3443. If 8 bit data learning was enabled by programming in seq_operand fields of DATA_LEARN instruction to 1 , the bits [7:0] are used as data_learning pattern. For details, refer to Data Learning

20.4.2.29 RX Buffer Data Register (QuadSPIx_RBDR)

The QuadSPI_RBDR registers provide access to the individual entries in the RX Buffer. Refer to Table 20-17 for the byte ordering scheme.

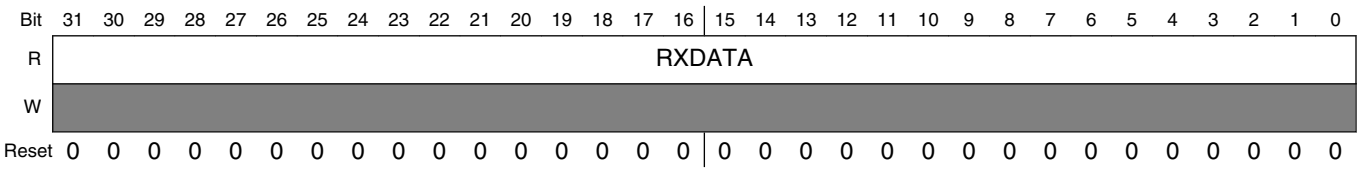
QuadSPI_RBDR0 corresponds to the actual position of the read pointer within the RX Buffer. The number of valid entries available depends from the number of RX Buffer entries implemented and from the number of valid buffer entries available in the RX Buffer.

Example 1, RX Buffer filled completely with 16 words: In this case the address range for valid read access extends from QuadSPI_RBDR0 to QuadSPI_RBDR15 .

Example 2, RX Buffer filled with 5 valid words: RX Buffer fill level QuadSPI_RBSR[RDBFL] is 5. In this case an access to QuadSPI_RBDR4 provides the last valid entry.

Any access beyond the range of valid RX Buffer entries provides undefined results.

Address: 410A_5000h base + 200h offset + (4d × i), where i=0d to 15d



QuadSPIx_RBDR*n* field descriptions

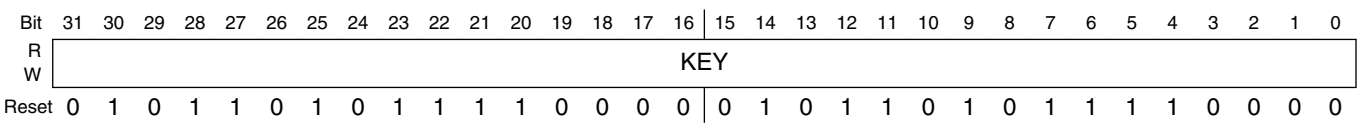
Field	Description
RXDATA	RX Data. The RXDATA field contains the data associated with the related RX Buffer entry. Data format and byte ordering is given in Byte Ordering of Serial Flash Read Data .

20.4.2.30 LUT Key Register (QuadSPIx_LUTKEY)

The LUT Key register contains the key to lock and unlock the Look-up-table. Refer to Look-up Table for details.

Write: Anytime

Address: 410A_5000h base + 300h offset = 410A_5300h



QuadSPIx_LUTKEY field descriptions

Field	Description
KEY	The key to lock or unlock the LUT. The KEY is 0x5AF05AF0. The read value is always 0x5AF05AF0

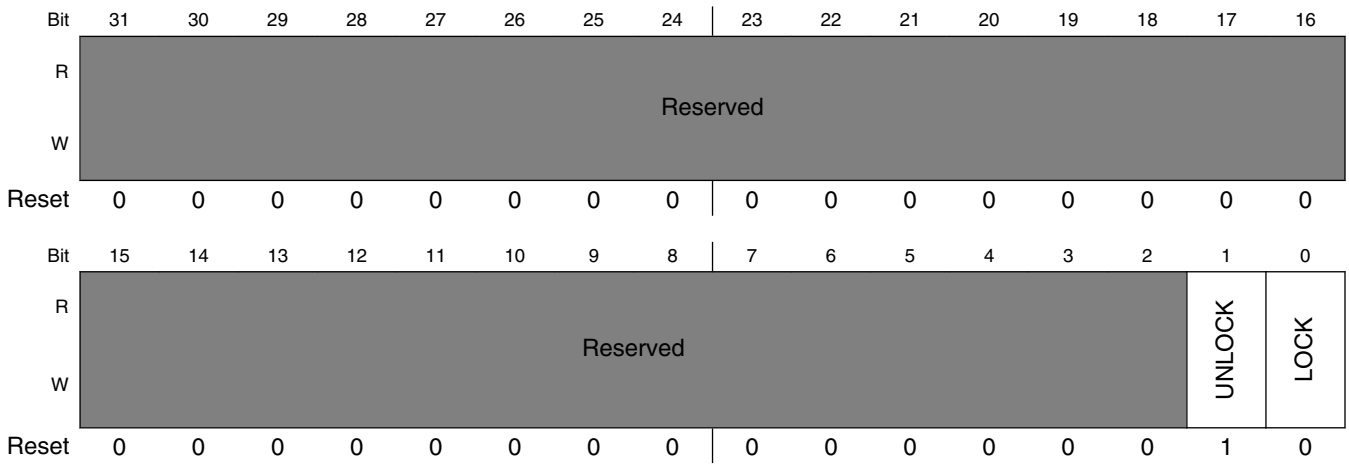
20.4.2.31 LUT Lock Configuration Register (QuadSPIx_LCKCR)

The LUT lock configuration register is used along with QSPI_LUTKEY register to lock or unlock the LUT. This register has to be written immediately after QSPI_LUTKEY register for the lock or unlock operation to be successful. Refer to Look-up Table for details. Setting both the LOCK and UNLOCK bits as "00" or "11" is not allowed.

Write: Just after writing the LUT Key Register

(QSPI_LUTKEY)

Address: 410A_5000h base + 304h offset = 410A_5304h



QuadSPIx_LCKCR field descriptions

Field	Description
31–2 Reserved	This field is reserved.
1 UNLOCK	Unlocks the LUT when the following two conditions are met: 1. This register is written just after the LUT Key Register (QuadSPI_LUTKEY) 2. The LUT key register was written with 0x5AF05AF0 key
0 LOCK	Locks the LUT when the following condition is met: 1. This register is written just after the LUT Key Register (QuadSPI_LUTKEY) 2. The LUT key register was written with 0x5AF05AF0 key

20.4.2.32 Look-up Table register (QuadSPIx_LUT*n*)

A sequence of instruction-operand pairs may be pre-populated in the LUT according to the device connected on board. Each instruction-operand pair is of 16 bits (2 bytes) each. Every sequence pre-programmed by Program Sequence Engine in the LUT is referred to by its index. The LUT registers are a look-up-table for sequences of instructions. The programmable sequence engine executes the instructions in these sequences to generate a valid serial flash transaction. There are a total of 64 LUT registers. These 64 registers are divided into groups of 4 registers that make a valid sequence. Therefore, QSPI_LUT[0], QSPI_LUT[4], QSPI_LUT[8] ..... QSPI_LUT[60] are the starting registers of a valid sequence. Each of these sets of 4 registers can have a maximum of 8 instructions. Reset value of the register shown below is only applicable to LUT2 to LUT63. A maximum of 16 sequences can be defined at one time. Look-up Table describes the LUT registers in detail.

NOTE

The reset values for LUT0 and LUT1 are 0818_0403h and 2400_1C08h, respectively.

Write: Once the LUT is unlocked

Address: 410A_5000h base + 310h offset + (4d × i), where i=0d to 63d

* Notes:
- The reset values for LUT0 and LUT1 are 0818_0403h and 2400_1C08h respectively.

QuadSPIx_LUT*n* field descriptions

Field	Description
31–26 INSTR1	Instruction 1
25–24 PAD1	Pad information for INSTR1. 00 1 Pad 01 2 Pads 10 4 Pads 11 8 Pads

Table continues on the next page...

QuadSPIx_LUT*n* field descriptions (continued)

Field	Description
23–16 OPRND1	Operand for INSTR1.
15–10 INSTR0	Instruction 0
9–8 PAD0	Pad information for INSTR0. 00 1 Pad 01 2 Pads 10 4 Pads 11 8 Pads
OPRND0	Operand for INSTR0.

20.4.3 Serial Flash Address Assignment

The serial flash address assignment may be modified by writing into Serial Flash A1 Top Address (QuadSPI_SFA1AD) and Serial Flash A2 Top Address (QuadSPI_SFA2AD) for device A . The following table shows how different access modes are related to the address specified for the next SFM Command. Note that this address assignment is valid for both IP and AHB commands.

Table 20-11. Serial Flash Address Assignment

Parameter	Function	Access Mode
QSPI_AMBA_BASE ((31:10) - 22 bits)	QuadSPI AHB base address	
TOP_ADDR_MEMA1(TPADA1)	Top address for the external flash A1 (first device of the dual die flash A, or the first of the two independent flashes sharing the IOFA)	Any access to the address space between TOP_ADDR_MEMA1 and QSPI_AMBA_BASE will be routed to **Serial Flash A1**
TOP_ADDR_MEMA2(TPADA2)	Top address for the external flash A2 (second device of the dual die flash A, or the second of the two independent flashes sharing the IOFA).	Any access to the address space between TOP_ADDR_MEMA2 and TOP_ADDR_MEMA1 will be routed to **Serial Flash A2**

20.5 Flash memory mapped AMBA bus

QSPI_AMBA_BASE defines the address to be used as start address of the serial flash device as defined by the system memory map. Note that this may be a remapping of the physical address of the serial flash in the system. Refer to the system address map. Note that this may be a remapping of the physical address of the serial flash in the system. Refer to the system address map.

Table 20-12. QuadSPI AMBA Bus Memory Map

Address	Register Name
Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A	
QSPI_AMBA_BASE to (TOP_ADDR_MEMA2 - 0x01)	Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A Refer to Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A for details and to Table 20-17 and Table 20-18 for information about the byte ordering.
AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB15)	
QSPI_ARDB_BASE to… (32 * 4 Byte) QSPI_ARDB_BASE + 0x0000_01FF	AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB15) Refer to Table 20-17 for information about the byte ordering.

Note

Any read access to non-implemented addresses will provide undefined results.

In 'Individual Flash Modes', the 3/4 address bytes (as programmed in the instruction/operand in the sequence) available for the flash address is determined by SFADR [23:0] or SFADR [31:0]as given in the table above.

20.5.1 AHB Bus Access Considerations

It has to be noted that all logic in the QuadSPI module implementing the AHB Bus access is designed to read the content of an external serial flash device. Therefore, the following restrictions apply to the QuadSPI module with respect to accesses to the AHB bus.

- At present, the QuadSPI does not support AHB writes so any write access is answered with the ERROR condition according to the AMBA AHB Specification. No write occurs.

- Any AHB Command resulting in the assertion of the QSPI_FR[ABSEF] flag is answered with the ERROR condition according to the AMBA_AHB specification. The resulting AHB Command is ignored.
- AHB Bus access types fully supported are NONSEQ and BUSY.
- AHB access type SEQ is treated in the same way like NONSEQ. Refer to the AMBA AHB Specification for further details.

20.5.2 Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A

Starting with address QSPI_AMBA_BASE the content of the first external serial flash devices is mapped into the address space of the device containing the QuadSPI module. Serial flash address byte address 0x0 corresponds to bus address QSPI_AMBA_BASE with increasing order. Assuming that a dual-die flash is connected on the first set of external pads, the address space is divided into two parts, one for each device of the dual die package. Refer to the following table for the address mapping. The byte ordering for 32 bit access is given in Table 20-17 and for 64 bit read access the byte ordering is given in Table 20-18.

Table 20-13. Memory Mapped Individual Flash Mode - Flash A Address Scheme

Memory Mapped Address 32 Bit Access	Memory Mapped Address 64 Bit Access	Serial Flash Byte Address	Flash Device
QSPI_AMBA_BASE + 0x00	QSPI_AMBA_BASE + 0x00	0x00_0000 to 0x00_0003	A1
QSPI_AMBA_BASE + 0x04		0x00_0004 to 0x00_0007	
…	…	…	
TOP_ADDR_MEMA1 - 0x08	TOP_ADDR_MEMA1 - 0x08	(TOP_ADDR_MEMA1- 0x08) to (TOP_ADDR_MEMA1 - 0x04 -0x01)	
TOP_ADDR_MEMA1 - 0x04		(TOP_ADDR_MEMA1 - 0x04) to (TOP_ADDR_MEMA1 - 0x01)	
TOP_ADDR_MEMA1 + 0x00	TOP_ADDR_MEMA1 + 0x00_0000	0x00_0000 to 0x00_0003	A2
TOP_ADDR_MEMA1 + 0x04		0x00_0004 to 0x00_0007	
…..	…	…	
TOP_ADDR_MEMA2 - 0x08	TOP_ADDR_MEMA2 - 0x08	(TOP_ADDR_MEMA2 - 0x08) to (TOP_ADDR_MEMA2 - 0x04 - 0x01)	
TOP_ADDR_MEMA2 - 0x04		(TOP_ADDR_MEMA2 - 0x04) to (TOP_ADDR_MEMA2 - 0x01)	

The available address range depends from the size of the external serial flash device. Any access beyond the size of the external serial flash provides undefined results.

For details concerning the read process refer to Flash Read.

20.5.3 AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB15)

NOTE

See the System Memory map in this document for the base address of the QSPI AHB RX Data Buffer.

memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	AHB RX Data Buffer register (ARDB0)	32	R/W	0000_0000h	20.5.3.1/468

1C	AHB RX Data Buffer register (ARDB7)	32	R/W	0000_0000h	20.5.3.1/468
20	AHB RX Data Buffer register (ARDB8)	32	R/W	0000_0000h	20.5.3.1/468
24	AHB RX Data Buffer register (ARDB9)	32	R/W	0000_0000h	20.5.3.1/468
28	AHB RX Data Buffer register (ARDB10)	32	R/W	0000_0000h	20.5.3.1/468
2C	AHB RX Data Buffer register (ARDB11)	32	R/W	0000_0000h	20.5.3.1/468
30	AHB RX Data Buffer register (ARDB12)	32	R/W	0000_0000h	20.5.3.1/468
34	AHB RX Data Buffer register (ARDB13)	32	R/W	0000_0000h	20.5.3.1/468
38	AHB RX Data Buffer register (ARDB14)	32	R/W	0000_0000h	20.5.3.1/468
3C	AHB RX Data Buffer register (ARDB15)	32	R/W	0000_0000h	20.5.3.1/468

20.5.3.1 AHB RX Data Buffer register (ARDB)

The AHB RX Data Buffer register 0 to 15 can be used to read the buffer content of the RX Buffer from successive addresses. QSPI_ARDB0 corresponds to the RX Buffer register entry corresponding to the current value of the read pointer with increasing order.

The increment of the read pointer depends from the access scheme (DMA or flag-driven). Refer to "Data Transfer from the QuadSPI Module Internal Buffers" section in Flash Read section, RX Buffer, data read via register interface and AHB read, for the description of successive accesses to the RX Buffer content. Refer also to Byte Ordering of Serial Flash Read Data for the byte ordering scheme.

Valid address range accessible in the QSPI_ARDBn range depends from the number of RX Buffer entries implemented and from the number of valid buffer entries available in the RX Buffer.

- Example 1, RX Buffer filled completely with 16 words: In this case the address range for valid read access extends from QSPI_ARDB0 to QSPI_ARDB15.
- Example 2, RX Buffer filled with 5 valid words, RX Buffer fill level QSPI_RBSR[RDBFL] is 5. In this case an access to QSPI_ARDB4 provides the last valid entry.

Address: 0h base + 0h offset + (4d × i), where i=0d to 15d

ARDB*n* field descriptions

Field	Description
ARXD	ARDB provided RX Buffer Data. Byte order (endianness) is identical to the RX Buffer Data Registers.

20.6 Interrupt Signals

The interrupt request lines of the QuadSPI module are mapped to the internal flags according to the following table.

Table 20-14. Assignment of Interrupt Request Lines

IRQ/DMA line	QSPI_FR Flag	Interrupt Description
ipi_int_tfff	TBFF	TX Buffer Fill
ipi_int_tcf	TFF	Peripheral Command Transaction Finished
ipi_int_rfdf	RBDF	RX Buffer Drain
ipi_int_overrun		Buffer Overflow/Underrun Error Logical OR from:
	RBOF	RX Buffer Overrun
	TBUF	TX Buffer Underrun

Table continues on the next page...

Table 20-14. Assignment of Interrupt Request Lines (continued)

IRQ/DMA line	QSPI_FR Flag	Interrupt Description
	ABOF	AHB Buffer Overflow
ipi_int_cerr		Serial Flash Command Error Logical OR from:
	IPAEF	Peripheral access while AHB busy Error
	IPIEF	Peripheral Command could not be triggered Error
	IPGEF	Peripheral access while AHB Grant Error
ipi_int_ored	DLPFF, TBFF, TFF, ILLINE, RBDF, RBOF, TBUF, ABSEF, ABOF, IPAEF, IPIEF, IPGEF, AITEF, AIBSEF	Logical OR from all the QSPI_FR flags mentioned

20.7 Functional Description

This section provides the functional information of the QuadSPI module.

20.7.1 Serial Flash Access Schemes

Note

In the Individual Flash Mode, all supported commands are available.

20.7.2 Normal Mode

This mode is used to allow communication with an external serial flash device. Compared to the standard SPI protocol, this communication method uses up to 4 bidirectional data lines operating at high data rates. The communication to the external serial flash device consists of an instruction code and optional address, mode, dummy and data transfers. The flexible programmable core engine described below is immune to a wide variety of command/protocol differences in the serial flash devices provided by various flash vendors.

20.7.2.1 Programmable Sequence Engine

The core of the QuadSPI module is a programmable sequence engine that works on "instruction-operand" pairs. The core controller executes each programmed instruction sequentially. The complete list of instructions and the corresponding operands is given in the following table.

Table 20-15. Instruction set

Instruction	Instruction encoding	Pins	Operand	Action on Serial Flash(es)
CMD	6'd1	N=2'd{0,1,2,3} 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads 2'd3- Eight pads	8 bit command value	Provide the serial flash with operand on the number of pads specified
ADDR	6'd2		Number of address bits to be sent (for example, 8'd24 => 24 address bits required)	Provide the serial flash with address cycles according to the operand on the number of pads specified. The actual address to be provided will be derived from the incoming address in case of AHB initiated transactions and the value of SFAR in case of IPS initiated transactions , if QSPI_SFACR[CAS] is set to 0, else the actual address will take CAS into consideration.
DUMMY	6'd3		Number of dummy clock cycles (should be <= 64 cycles)	Provide the serial flash with dummy cycles as per the operand. The PAD information defines the number of pads in input mode. (for example, one pad implies that pad 1 is not driven, rest all are driven)
MODE	6'd4		8 bit mode value	Provide the serial flash with 8 bit operand on the number of pads specified
MODE2	6'd5	N=2'd{0,1}	2 bit mode value	Provide the serial flash with 2 bit operand on the number of pads[1] specified
MODE4	6'd6	N=2'd{0,1,2}	4 bit mode value	Provide the serial flash with 4 bit operand on the number of pads[2] specified
READ	6'd7	N=2'd{0,1,2,3} 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads 2'd3- Eight pads	Read data size in bytes (the user's application should ensure that data size is a multiple of 8 bytes)	Read data from flash on the number of pads specified. The data size may be overwritten by writing to the ADATSZ field of the QSPI_BUFxCR registers for AHB initiated transactions and IDATSZ field of IP Configuration Register (QuadSPI_IPCR) for IP initiated transactions.
WRITE	6'd8		Write data size in bytes	Write data on number of pads sepcified. The data size may be overwritten by writing to the IDATSZ field of IP Configuration Register (QuadSPI_IPCR) register
JMP_ON_CS	6'd9	NA	Instruction number	Every time the chip select (CS) is deasserted, jump to the instruction pointed to by the operand. This instruction allows the programmer to specify the behavior of the controller when a new read transaction is initiated following a CS deassertion.
ADDR_DDR	6'd10	N=2'd{0,1,2,3} 2'd0 - One pad 2'd1 - Two pads	Number of address bits to be sent (for example,	Provide the serial flash with address cycles according to the operand on the number of pads specified at each clock edge of serial flash clock. The actual address to be provided will be derived from the incoming address in case of AHB initiated

Table continues on the next page...

Table 20-15. Instruction set (continued)

Instruction	Instruction encoding	Pins	Operand	Action on Serial Flash(es)
		2'd2 - Four pads 2'd3- Eight pads	8'd24 => 24 address bits required)	transactions and the value of QSPI_SFAR in case of IPS initiated transactions , if QSPI_SFACR[CAS] is set to 0, else the actual address will take CAS into consideration.
MODE_DDR	6'd11		8 bit mode value	Provide the serial flash with 8 bit operand on the number of pads specified at each clock edge of serial flash.
MODE2_DDR	6'd12	N=2'd{0}	2 bit mode value	Provide the serial flash with 2 bit operand on the number of pads specified at each clock edge of serial flash[3]
MODE4_DDR	6'd13	N=2'd{0,1}	4 bit mode value	Provide the serial flash with 4 bit operand on the number of pads specified at each clock edge of serial flash[4].
READ_DDR	6'd14	N=2'd{0,1,2,3} 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads 2'd3- Eight pads	Read data size in bytes (the user's application should ensure that data size is in multiple of 8 bytes)	Read data from flash on the number of pads specified at each clock edge of serial flash. The data size may be overwritten by writing to the ADATSZ field of the QSPI_BUFxCR registers for AHB initiated transactions and IDATSZ field of IP Configuration Register (QuadSPI_IPCR) for IP initiated transactions
WRITE_DDR	6'd15		Write data size in bytes	Write data on the number of pads specified at each clock edge of serial flash. The data size may be overwritten by writing to the IDATSZ field of IP Configuration Register (QuadSPI_IPCR) register
DATA_LEARN	6'd16		Number of data in bytes to be used for data learning. Say if operand is 1 than 8 bit data_learning is enabled.	Finds the correct sampling point in case of only DDR operations. When this instruction is encountered, the QSPI_SMPR[DDRSMP] values are ignored and the controller finds the correct sampling point on its own by data learning. But this feature of sampling point is valid for only DDR modes. If DQS mode is enabled, then data learn instruction just matches the incoming data from flash and if it does not matches the QSPI_DLPV then Flag in QSPI_FR[DLPFF] is set.
CMD_DDR	6'd17	N=2'd{0,1,2,3} 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads 2'd3- Eight pads	8 bit command value	Provide the serial flash with the operand with number of pads specified at each clock edge of the serial flash
CADDR	6'd18		Number of Column address bits to be sent(8'd8 means 8 bits of column address is to be sent)	Provide the serial flash with column address cycles according to the operand on the number of pads specified. The actual address to be provided to flash will depend on value of QSPI_SFACR[CAS]. For example, if QSPI_SFACR[CAS] is 3, then the address to flash will be [2:0] of incoming address in case of AHB and the value of QSPI_SFAR in case of IP. This will be appended with zero if QSPI_SFACR[CAS] is less than number of pads for a Flash.
CADDR_DDR	6'd19		Number of Column address bits to be sent(8'd8 means 8 bits of column address is to be sent)	Provide the serial flash with column address cycles according to the operand on the number of pads specified at each clock edge of the serial flash. The actual address to be provided to flash will depend on value of QSPI_SFACR[CAS]. For example, if CAS is 3, then the address to flash will be [2:0] of incoming address in case of AHB and the value of QSPI_SFAR in case of IP. This will be appended with zero if CAS is less than number of pads for a Flash.

Table continues on the next page...

Table 20-15. Instruction set (continued)

Instruction	Instruction encoding	Pins	Operand	Action on Serial Flash(es)
STOP	8'd0	NA	NA	Stop execution; deassert CS

1. For a one pad instruction, MODE2 will take 2 serial flash clock cycles on the flash interface.
2. For a one pad instruction, MODE4 will take 4 serial flash clock cycles on the flash interface. For a 4 pad instruction, MODE4 will take 1 serial flash clock cycle on the flash interface.
3. For a one pad instruction, MODE2_DDR will take 1 serial flash clock cycle on the flash interface.
4. For a one pad instruction, MODE4_DDR will take 2 serial flash clock cycles on the flash interface. For a 4 pad instruction MODE4_DDR will take half a cycle on the serial flash interface.

The programmable sequence engine allows the user to configure the QuadSPI module according to the serial flash connected on board. The flexible structure is easily adaptable to new command/protocol changes from different vendors.

20.7.2.2 Flexible AHB buffers

In order to reduce the latency of the reads for AHB masters, the data read from the serial flash is buffered in flexible AHB buffers. There are four such flexible buffers. The size of each of these buffers is configurable with the minimum size being 0 Bytes and maximum size being the size of the complete buffer instantiated.The size of buffer 0 is defined as being from 0 to QSPI_BUF0IND. The Size of buffer 1 is from QSPI_BUF0IND to QSPI_BUF1IND, buffer2 is from QSPI_BUF1IND to QSPI_BUF2IND and buffer 3 is from QSPI_BUF2IND to the size of the complete buffer, which is given in the chip-specific QuadSPI information.

Each flexible AHB buffer is associated with the following

1. An AHB master. Optionally, buffer3 may be configured as an "all master" buffer by setting the QSPI_BUF3CR[ALLMST] bit. When buffer3 is configured in such a way, any access from a master not associated with any other buffer is routed to buffer3.
2. A datasize field representing the amount of data to be fetched from the flash on every "missed" access.

The master port number of every incoming request is checked and the data is returned/ fetched into the corresponding associated buffer. Every "missed" access to the buffer causes the controller to clear the buffer and fetch QSPI_BUFxCR[ADATSZ] amount of data from the serial flash.As such, there is no benefit in configuring a buffer size of greater than ADATSZ, as the locations greater than ADATSZ will never be used. For any AHB access, the sequence pointed to by the QSPI_BFGENCR[SEQID] field is used for the flash transaction initiated. The data is returned to the master as soon as the requested

amount is read from the serial flash. The controller however, continues to prefetch the rest of the data in anticipation of a next consecutive request. Figure 20-3 shows the flexible AHB buffers.

The QSPI_BFGENCR[SEQID] field points to an index of the LUT. Refer to Look-up Table for details.

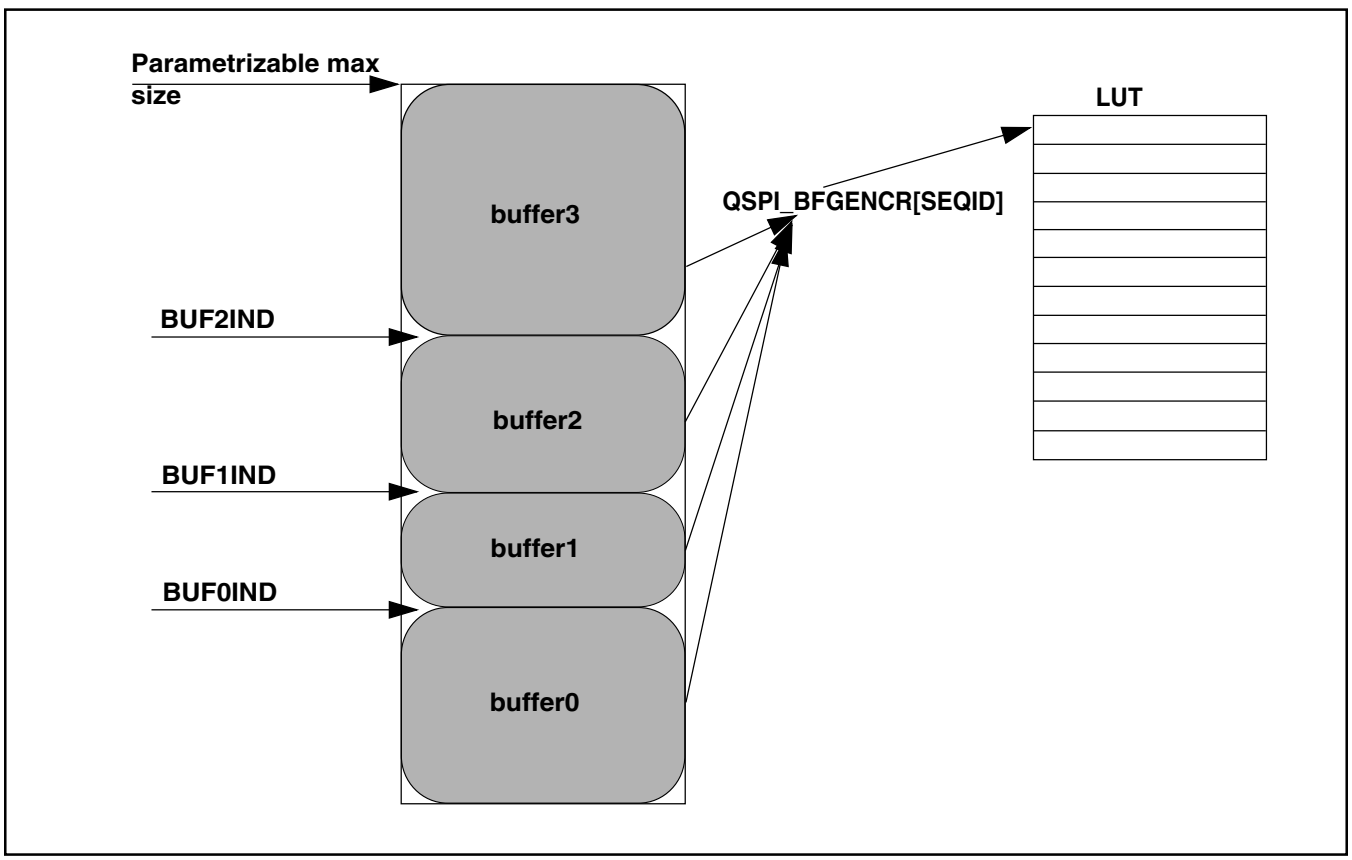

Figure 20-3. Flexible AHB Buffers

Buffer0 may optionally be configured to be associated with a high priority master by setting the QSPU_BUF0CR[HP_EN] bit. An access by a high priority master suspends any ongoing prefetch to any of the other buffers. The ongoing prefetch is suspended and the high priority master is serviced first. Once the high priority masters access completes, the suspended transaction is resumed (before any other AHB access is entertained). The status of the suspended buffer can be read from Sequence Suspend Status Register (QuadSPI_SPNDST).

20.7.2.3 Suspend-Abort Mechanism

Any low priority AHB access can be suspended by a high priority AHB master request. The ongoing transaction is suspended at 64 bit boundary. The suspended transaction is restarted after the high priority master is served and the high priority transaction including data prefetch is completed. While a transaction is in suspended state, it may be aborted if a transaction by the same suspended master is made to a location which is different from the location of the suspended transaction.

Any ongoing transaction is aborted if a request from the same master arrives for a location other than the location at which the transaction is going on. The abort can happen at any point of time.

20.7.2.4 HBURST Support

QuadSPI controller supports HBURST and HSIZE on the AHB interface. HBURST indicates if the transfer forms part of a burst. Four, eight and sixteen beat bursts are supported and the burst may be either incrementing or wrapping. HSIZE indicates the size of the transfer. 8, 16, 32 and 64 bit data size are supported. In case of WRAP accesses, QuadSPI generates aligned accesses to Serial Flash if there is no buffer hit for any incoming non-sequential AHB access. In case there is a buffer hit, the incoming address in the haddr line is latched as it is. If the total burst size is more than the data prefetch size an error response is generated and QSPI_FR[AIBSEF] is set. The data perfetch size can be defined by QSPI_BUFxCR[ADATSZ] or data size mentioned in the sequence pointed to by the SEQID field when ADATSZ is programmed as zero. A few examples are shown in the figure below:

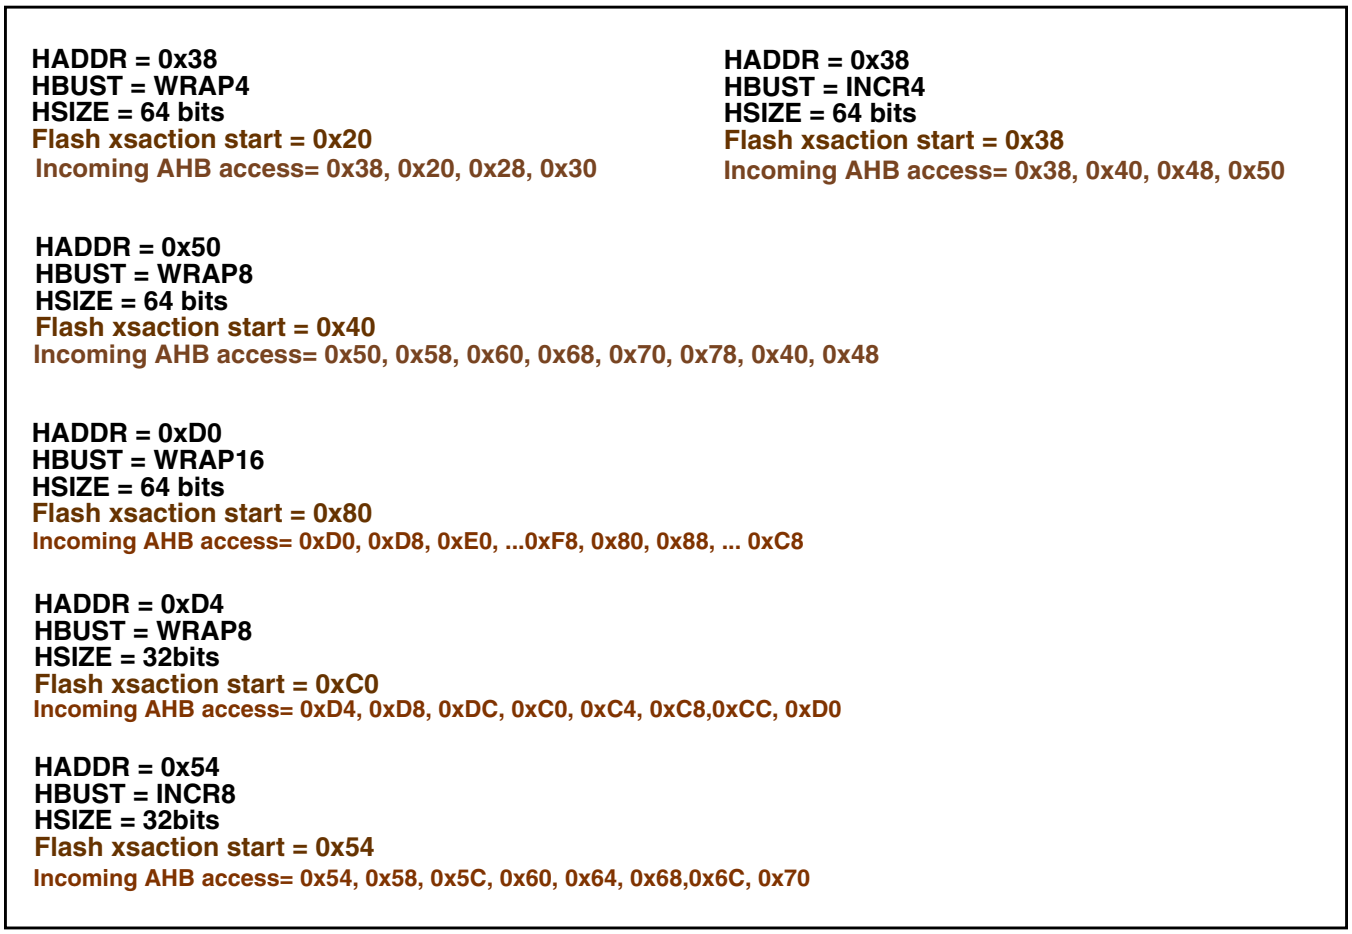

Figure 20-4. QuadSPI HBURST support

NOTE

The software must take care that the prefetch size should never be set less than the minimum data needed by any external interface to start processing.

NOTE

Whenever a core access QuadSPI memory with cache enabled, prefetch size must be configured equal or more than the cache line size, otherwise QSPI_FR[AIBSEF] error gets set.

20.7.2.5 Look-up Table

The Look-up-table or LUT consists of a number of pre-programmed sequences. Each sequence is basically a sequence of instruction-operand pairs which when executed sequentially generates a valid serial flash transaction. Each sequence can have a maximum of 8 instruction-operand pairs. The LUT can hold a maximum of 16 sequences. The figure below shows the basic structure of the sequence in the LUT.

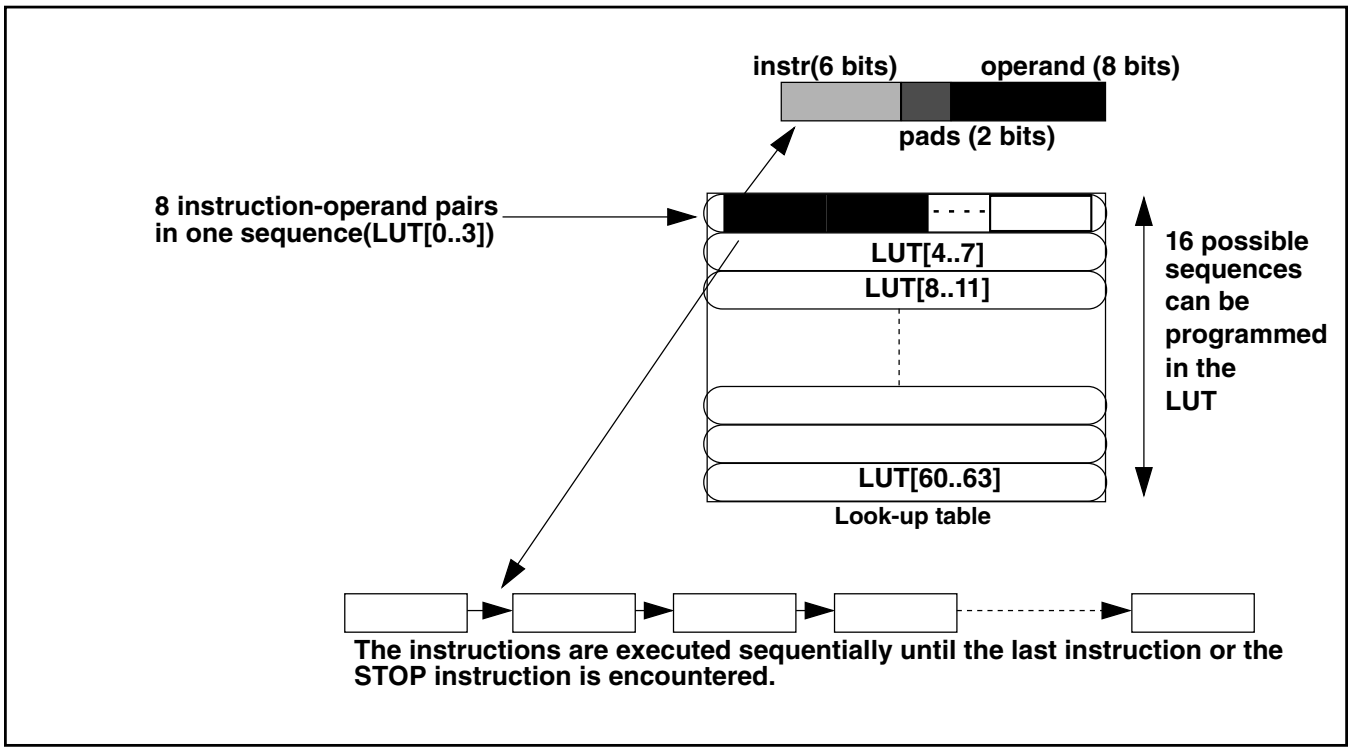

Figure 20-5. LUT and sequence structure

At reset, the index 0 of the look-up-table (LUT[0..3]) is programmed with a basic read sequence as given in Table 20-16. After reset the complete LUT may be reprogrammed according to the device connected on board.In order to protect its contents during a code runover the LUT may be locked, after which a write to the LUT will not be successful until it has been unlocked again.The key for locking or unlocking the LUT is **0x5AF05AF0**. The process for locking and un-locking the LUT is as follows:

Locking the LUT

1. Write the key **(0x5AF05AF0)** in to the LUT Key Register (QuadSPI_LUTKEY).
2. Write 0b01 to the LUT Lock Configuration Register (QuadSPI_LCKCR). Note that this IPS transaction should immediately follow the above IPS transaction (no other IPS transaction can be issued in between). A successful write into this register locks the LUT.

Unlocking the LUT

1. Write the key **(0x5AF05AF0)** into the LUT Key Register (QuadSPI_LUTKEY)
2. Write 0b10 to the LUT Lock Configuration Register (QuadSPI_LCKCR). Note that this IPS transaction should immediately follow the above IPS transaction (no other IPS transaction can be issued in between). A successful write into this register unlocks the LUT.

The lock status of the LUT can be read from QSPI_LCKCR[UNLOCK] and QSPI_LCKCR[LOCK] bit.

Some example sequences are defined in Example Sequences. The reset sequence at LUT index 0 is given in the following table.

Table 20-16. Reset sequence

Instruction	Pad	Operand	Comment
CMD	0x00	0x03	Read Data byte command on one pad
ADDR	0x00	0x18	24 Addr bits to be sent on one pad
READ	0x00	0x08	Read 64 bits
JMP_ON_CS	0x00	0x00	Jump to instruction 0 (CMD)

20.7.2.6 Issuing Serial Flash Memory (SFM) Commands

Each access to the external device follows the same sequence:

1. The user must pre-populate the LUT with the serial flash command sequences that are required for the flash device being used.
2. The QuadSPI module starts executing the instructions in the sequence one by one. The transaction starts and the status bit QSPI_SR[BUSY] is set.
3. Communication with the external serial flash device is started and the transaction is executed.
4. When the transaction is finished (all transmit- and receive operations with the external serial flash device are finished) the status bit QSPI_SR[BUSY] is reset. In case of an IP Command the QSPI_FR[TFF] flag is asserted.

Further details are given in below in Flash Programming and Flash Read.

You can trigger the processing of SFM commands in the QuadSPI module in one of the following ways:

- **Using IP commands**

  For IP Commands the required components need to be written into the following registers:

  - Write the serial flash address to be used by the instruction into QSPI_SFAR, refer to Serial Flash Address Register (QSPI_SFAR). For IP Commands not related to specific addresses, the base address of the related flash need to be

programmed.For example, for an instruction which does not require an address (i.e. write enable instruction) the SFAR should be programmed with the base address of the memory the command is to be sent to.

- Write the sequence ID and data size details in the IP Configuration Register (QSPI_IPCR).
- Note that the write into the QSPI_IPCR[SEQID] field must be the last step of the sequence. It is possible to combine all fields of the QSPI_IPCR into one single write. Refer to IP Configuration Register (QSPI_IPCR) for details.

Note that there are some conditions where no IP Command is executed after writing the QSPI_IPCR[SEQID] field and the write operation itself is ignored. They are described in Command Arbitration.

- **Using AHB commands**

  Any AHB memory mapped access is routed to one of the buffers depending on the master port number of the request. If the access is a "miss", a new serial flash transaction is started. The transaction is based on the sequence pointed to by the BFGENCR[SEQID] field as described in Flexible AHB buffers.

  An AHB access is termed memory mapped when the access is to the memory mapped serial flashes, as described in Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A.

  Again the possible error conditions are described in Command Arbitration .

20.7.2.7 Flash Programming

In all cases the memory sector to be written needs to be erased first. The programming sequence itself is then initiated in the following way:

1. Check QuadSPI_SR[BUSY] is de-asserted or '0'. Check that the TX buffer is empty. If it is required to discard the data present in the TX buffer (QSPI_SR[TXEDA]) bit is set, then the TX buffer must be cleared by writing '1' into the QSPI_MCR[CLR_TXF] bit.
2. Program the address related to the command in the QSPI_SFAR register. Program the QSPI_SFACR[CAS] if required to desired value else to 0. Program the QSPI_SFACR[WA] to 1 if the serial flash is a word addressable flash else to 0 in case serial flash is byte addressable.

3. Provide initial data for the program command into the circular buffer via register TX Buffer Data Register (QSPI_TBDR) . At least four word of data must be written into the TX Buffer up to a maximum of 16.
4. Program the QSPI_IPCR register to trigger the command. The QSPI_IPCR[SEQID] should point to an index of the LUT which has the flash program sequence pre-programmed.The IDATSZ field should be set to denote the size of the write.
5. Depending on the amount of data required, step 3 must be repeated until all the required data have been written into the QSPI_TBDR register.The QSPI_SR[TXFULL] can be used to check if the buffer is ready to receive more data. At any time, the QSPI_TBSR[TRCTR] field can be read to check how many words have been written actually into the TX Buffer.

Upon writing the QSPI_IPCR[SEQID] field (refer to step 4) the QuadSPI module will start to execute the programmed sequence. It is the responsibility of the software to ensure that a correct sequence is programmed into the LUT in accordance with the flash memory connected to the module. The data is fetched from the TX Buffer. It consists of **16** entries of 32-bits and is organized as a circular FIFO, whose read pointer is incremented by four after each fetch. When all data are transmitted, the QuadSPI module will return from 'busy' to 'idle'. However, this is not true for the external device since the internal programming is still ongoing. It is up to the user to monitor the relevant status information available from the serial flash device and to ensure that the programming is finished properly.

20.7.2.8 Flash Read

Host access to the data stored in the external serial flash device is done in two steps. First, the data must be read into the internal buffers and in the second step these internal buffers can be read by the host.

1. **Reading Serial Flash Data into the QuadSPI Module Internal Buffers**

   A read access to the external serial flash device can be triggered in two different ways:

   - **IP Command Read**: For **reading flash data into the RX Buffer** the user must provide the correct sequence ID in the QuadSPI_IPCR[SEQID] register. The sequence ID points to a sequence in the LUT. It is the responsibility of the software to ensure that a correct read sequence is programmed in the LUT in accordance with the serial flash device connected on board. The user should

program the Serial Flash Address Register (QSPI_SFAR) , QSPI_SFACR[CAS] and the IP Configuration Register (QSPI_IPCR) registers. All available read commands supported by the external serial flash are possible.

Optionally it is possible to clear the RX Buffer pointer prior to triggering the IP Command by writing a 1 into the QuadSPI_MCR[CLR_RXF] field.

From these inputs, the complete transaction is built when the QSPI_IPCR[SEQID] field is written. The transaction related to the read access starts and the requested number of bytes is fetched from the external serial flash device into the RX Buffer. Since the read access is triggered by an IP command, the IP_ACC status bit and the BUSY bit are both set (both are located in the Status Register (QSPI_SR)). A count of the number of entries currently in the Rx Buffer can be obtained from QSPI_RBSR[RDBFL].

The communication with the external serial flash is stopped when the specified number of bytes has been read (successful completion of the transaction).

- **AHB Command Read**: For **reading flash data into the AHB Buffer** the user must set up a read access by a master to the address range in the system memory map which the external serial flash devices are mapped to. The user should program the QSPI_SFACR[CAS], if required, to desired value else to 0. The user should also program the buffer registers corresponding to the AHB master initiating the request, this is depends on the configuration of the QSPI_RBCT[RXBRD]. The user should provide the correct sequence ID into the buffer generic configuration register (QSPI_BFGENCR). It is the responsibility of the software to ensure that a correct read sequence in programmed in the LUT in accordance with the serial flash device connected on board. Flash device selection and access mode are determined by the address accessed in the AHB address space associated to the QuadSPI module (refer to Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A,

  On each AHB read access to the memory mapped area the valid data in the AHB Buffer is checked against the address requested in the actual read. When the AHB read request can't be served from the content of the AHB Buffer, the buffer is flushed and the sequence pointed to by the sequence ID is executed by the controller. The requested number of buffer entries defined in the QSPI_BUFxCR[ADATSZ] field is then fetched from the external serial flash device into the internal AHB Buffer. Since the read access is triggered via the AHB bus, the QSPI_SR[AHB_ACC] status bit is set driving in turn the QSPI_SR[BUSY] bit until the transaction is finished. The communication with the external serial flash is stopped when the specified number of entries has been filled.

2. Data Transfer from the QuadSPI Module Internal Buffers

The data read out from the external serial flash device by the QuadSPI module is stored in the internal buffers.The means of accessing the data from the buffer differs depending on which buffer the data has been loaded to. Refer to Block Diagram for details about the two available buffers, the RX Buffer and the AHB Buffer, in the QuadSPI module:

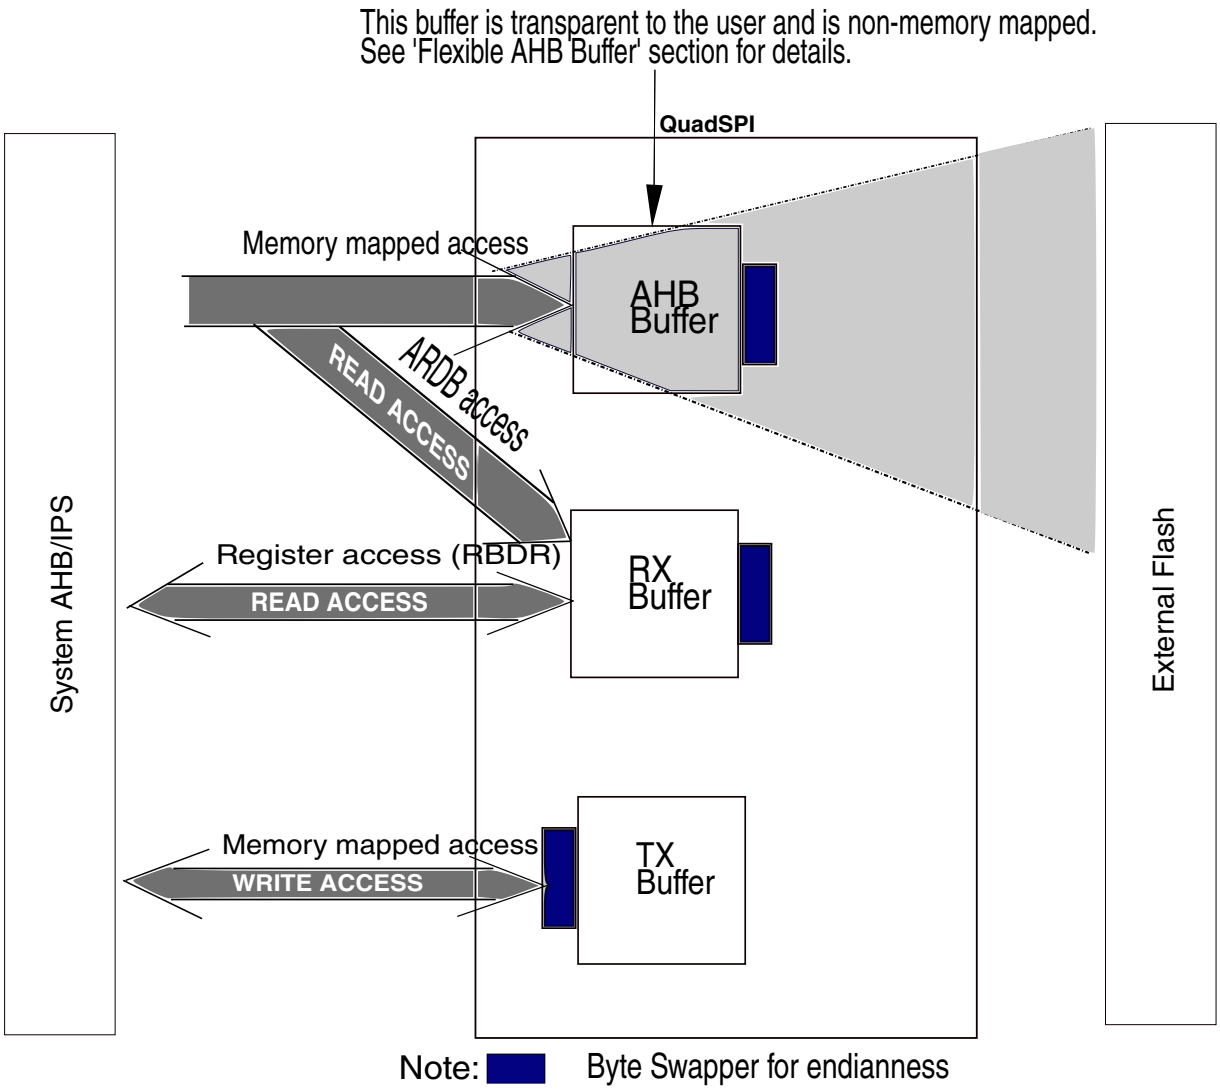

Figure 20-6. QuadSPI memory map

- The RX Buffer is implemented as FIFO of depth 16 entries of 4 bytes. Its content is accessible in two different address areas both referring to the identical data and the same physical memory.

  In the IPS address space in the area associated to QSPI_RBDR0 to QSPI_RBDR15

  In the AHB address space in the area associated to QSPI_ARDB0 to QSPI_ARDB15. Two successive entries are accessed with one single 64 bit AHB read operation.

RX Buffer operation can be summarized as follows: The QSPI_RBCT[WMRK] field determines at which fill level the RXWE bit is asserted and how many entries are removed from the RX Buffer on each Buffer POP operation. So the QSPI_SR[RXWE] bit indicates that the configured number of data entries is available in the RX Buffer and the QSPI_RBSR[RDBFL] field indicates how many valid entries are available in total. Note that the first entry (QSPI_RBDR0 or QSPI_ARDB0) always corresponds to the first valid entry in the RX Buffer. The software needs to manage the number of valid data bytes itself.

Further details can be found in RX Buffer Data Register (QuadSPI_RBDR) and in AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB15).

- **Flag-based Data Read of the RX Buffer** is done by polling the QSPI_SR[RXWE] bit. When it is asserted the valid entries can be read either via the IPS address space (QSPI_RBDRn) or the AHB address space (QSPI_ARDBn). A Buffer POP operation must be triggered by the application by writing a 1 into the QSPI_FR[RBDF] bit - this automatically updates the FIFO to point to the next entry as defined by RBCT[WMRK]. For example, if WMRK is set to 3, then the buffer will discard 16 bytes of data.
- **DMA controlled Data Read of the RX Buffer** is done by using the DMA module.The application must ensure that the DMA controller of the related device is programmed appropriately like it is described in DMA Usage.

  DMA controlled read out is triggered fully automatically by the assertion of the QSPI_SR[RXWE] bit. The related Buffer POP operation is also handled completely inside the QuadSPI module. Like in the case above, accessing the RX Buffer content either on QSPI_RBDRn or QSPI_ARDBn related addresses is equivalent.

- **AHB Buffer data read via memory mapped access:** This kind of access is done by reading one of the addresses assigned to the external serial flash device(s) within the range given in Table 20-12 table *under the condition that the data requested are already present in the AHB Buffer or it is currently being read from the serial flash device by the instruction in progress.* If this is not the case a memory mapped AHB command read is triggered as described above. If the requested data is already available in the AHB Buffer they are provided directly to the host.

  When AHB access are made to the flash memory mapped address, the data will be fetched and returned to the AHB interface. Till the data is being fetched the AHB interface would be stalled. As soon as the data from the requested address has been read by the QuadSPI module the AHB read access is served. So it is

possible to run sequential reads from the AHB buffer at arbitrary speed without the need to monitor any information about the availability of the data. Nevertheless this access scheme stalls the AHB bus for the time required to read the data from the serial flash device. A better way is (when it is known the access is sequential) to have a prefetch enabled (by programming the ADATSZ field) such that before the next sequential AHB access come, the data is already fetched into the buffer.

As long as the host restricts its accesses to the data already in the buffer and the data currently fetched from the serial flash, it is possible to run the host read from the AHB Buffer in parallel to the serial flash read into the AHB Buffer.

20.7.2.9 Byte Ordering of Serial Flash Read Data

In this paragraph the byte ordering of the serial flash data is given. The basic scheme is that the **first** byte read out of the serial flash device - which is addressed by the QSPI_SFAR[SFADR] field - corresponds to bit position QSPI_RBDR0[31:24] register for IP Command read. In contrast to that for AHB Command read the bytes are always positioned according to the byte ordering of the AHB bus.

- **Byte Ordering in Individual Flash Mode**

  The following table gives the byte ordering scheme of how the byte oriented data space of the serial flash device is mapped into one single 32 bit entry of the RX Buffer or the AHB Buffer. The table is valid within the following context:

  - Flash A in Individual Flash Mode
  - All AHB data read commands with access size of 32 bit

Table 20-17. Byte Ordering in Individual Flash Mode

Serial Flash Byte Numbering	3	2	1	0
Buffer Entry Bit Position [31:0] (32 Bit data width)	[31:24]	[23:16]	[15:8]	[7:0]

Note

For IP Commands the read size can be given in number of bytes. If this number is not a multiple of 4, then the last buffer entry is not completely filled with the missing higher numbered bytes at undefined values.

For AHB Commands, reads, starting from an address not aligned to 32 bit boundaries, the requested bytes are given at the appropriate positions according to the AMBA AHB specification.

- **Buffer Entry Ordering for 64 Bit Read Access**

  For read access via the AHB interface 64 bit access is possible. Each 64 bit access reads 2 32 bit entries simultaneously. The ordering of these 32 bit entries within the 64 bit word is given in the following table.

Table 20-18. 64 Bit Read Access Buffer Entry Ordering

AHB Read Data Bit Position [63:0]	[63:32]	[31:0]
Buffer Entry #	Odd (1, 3, 5, ...)	Even (0, 2, 4, ...)

20.7.2.10 Normal Mode Interrupt and DMA Requests

The QuadSPI module has different flags that can only generate interrupt requests and one flag that can generate interrupt as well as DMA requests. The following table lists the eight conditions. Note that the flags mentioned in the table are related to the Flag Register (QSPI_FR).

Table 20-19. Interrupt and DMA Request Conditions

Condition	Flag(QSPI_FR)	DMA
Data Learn patttern Failure	DLPFF	-
TX Buffer Fill	TBFF	-
TX Buffer Underrun	TBUF	-
Illegal Instruction Error	ILLINE	-
RX Buffer Drain	RBDF	X
RX Buffer Overflow	RBOF	-
AHB Buffer Overflow	ABOF	-
AHB Sequence Error	ABSEF	-
AHB Illegal Transaction Error	AITEF	-

Table continues on the next page...

Table 20-19. Interrupt and DMA Request Conditions (continued)

Condition	Flag(QSPI_FR)	DMA
AHB Illegal Burst Size Error	AIBSEF	-
IP Command Trigger during AHB Access Error	IPAEF	-
IP Command Trigger could not be executed Error	IPIEF	-
IP Access during AHB Grant Error	IPGEF	-
IP Command related Transaction Finished	TFF	-

Each condition has a flag bit in the Flag Register (QSPI_FR) and a Request Enable bit in the DMA Request Select and Enable Register (QSPI_RSER) . The RX Buffer Drain Flag (RBDF) has separate enable bits for generating IRQ and DMA requests. Note that not all flags have an individual IRQ line. Check the devices Interrupt Vector Table for more details.

- Transmit Buffer Fill Interrupt Request:

  The Transmit Buffer Fill IRQ indicates that the TX Buffer can accept new data. It is asserted if the QSPI_FR[TBFF] flag is asserted and if the corresponding enable bit (QSIP_RSER[TBFIE]) is set. Refer to TX Buffer Operation, for details about the assertion of the QSPI_FR[TBFF] flag.

  Aside from IRQ it is possible to handle TX Buffer fill by DMA. If the QSPI_RSER[TBFDE] bit is set, a DMA request will be triggered when the number of available space in the TX Buffer is more than the QSPI_TBCT[WMRK] valid entries and QSPI_SR[TXWA] is set. The application must set the environment appropriately (eg. the DMA controller) for the DMA transfer.

- Receive Buffer Drain Interrupt or DMA Request:

  The Receive Buffer Drain IRQ derived from the QSPI_FR[RBDF] flag indicates that the RX Buffer of the QuadSPI module has data available from the serial flash device to be read by the host. It remains set as long as the QSPI_RBSR[RXWE] bit is set. The QSPI_RSER[RBDIE] bit enables the related IRQ.

  Aside from the IRQ it is possible to handle RX Buffer drain by DMA. If the QSPI_RSER[RBDDE] bit is set, a DMA request will be triggered when the RX Buffer contains more than QSPI_RBCT[WMRK] valid entries.The application must set the environment appropriately (for example, the DMA controller) for the DMA transfers.

- Buffer Overflow/Underrun Interrupt Request:

The Buffer Overflow/Underrun IRQ is a combination of the following flags (all located in the QSPI_FR register with the related enable bits in the QSPI_RSER register):

- TBUF - TX Buffer Underrun, enabled by TBUIE
- RBOF - RX Buffer Overflow, enabled by RBOIE
- ABOF - AHB Buffer Overflow, enabled by ABOIE

  The Transmit Buffer Underrun indicates that an underrun condition in the TX Buffer has occurred. It is generated when a write instruction is triggered whilst the Tx Buffer is empty and the QSPI_RSER[TBUIE] bit is set.

  The Receive Buffer Overflow indicates that an overflow condition in the RX Buffer has occurred. It is generated when the RX Buffer is full, an additional read transfer attempts to write into the RX Buffer and the QSPI_RSER[RBOIE] bit is set.

  The AHB Buffer Overflow indicates that an overflow condition in the AHB Buffer has occurred. It is generated when the AHB Buffer is full, an additional read transfer attempts to write into the AHB Buffer and the QSPI_RSER[ABOIE] bit is set.

  The data from the transfers that generated the individual overflow conditions is ignored.

- Serial Flash Command Error Interrupt Request

  If the IPAEF, IPIEF, IPGEF flags in the QSPI_FR are set, and the related interrupt enable bits in the QSPI_RSER are also set, then an interrupt is requested.

- Transaction Finished Interrupt Request

  The IP Command Transaction Finished IRQ indicates the completion of the current IP Command.It is triggered by the QSPI_FR[TFF] flag and is masked by the QSPI_RSER[TFIE] bit.

20.7.2.11 TX Buffer Operation

The TX Buffer provides the data used for page programming. For proper operation it is required to provide at least four entry in the TX Buffer prior to starting the execution of the page programming command. The application must ensure that the required number of data bytes is written into the TX Buffer fast enough as long as the command is executed without a TX Buffer overflow or underrun.

The QuadSPI module sets the QSPI_FR[TBFF] flag so long as the TX Buffer is not full and can accept more data.

When the QuadSPI module tries to pull data out of an empty TX Buffer the TX Buffer underrun is signaled by the QSPI_FR[TBUF] flag.The TX buffer underrun flag is also asserted when TX buffer contains less than 128 bits of data and QuadSPI module tries to pull out data from it. The current IP Command leading to the underrun condition is continued until the specified number of bytes has been sent to the serial flash device, in the underrun condition when QuadSPI module tries to pull out data of empty TX buffer, the data transferred is all F's i.e. once the underrun flag is set under this condition, it will return F's until the required number of bytes are not sent. This has been done to ensure that the software need not to erase whole sector after underrun, just reprogramming from failure point will serve the purpose. When this Sequence Command is finished, the QSPI_FR[TBFF] flag is asserted indicating that the Tx Buffer is ready to be written again.

The TX Buffer overflow isn't signaled explicitly, but the TX Buffer fill level can be monitored by the QSPI_TBSR[TRBFL] field.

Refer to TX Buffer Status Register (QuadSPI_TBSR) and Flag Register (QuadSPI_FR) for details about the TX Buffer related registers.

20.7.2.12 Address scheme

Earlier serial flash memories supported only 24-bit address space hence restricting the maximum memory size of the serial flash as 16 MB. The new memory specification supports two types of 32-bit addressing mode in addition to legacy 24-bit address mode. It also supports segregation of address programmed, into Row address and Column address of the Flash, as per requirement.

- **Extended Address Mode**

  In this mode, the legacy 24-bit commands are converted to accept 32-bit address commands. The flash memory needs to be configured for 32-bit address mode. Also, while programming the LUT sequence in QuadSPI for 32-bit mode, the ADDR and ADDR_DDR command should be programmed with 8’d32 as the operand value with QSPI_SFACR[CAS] programmed to 0. If a flash needs some bits of the address as its column address, then it must always considered that the total bits required by the Flash should not exceed 32, as maximum address supported by QuadSPI is 32 bits. Each of the memory vendors have a different way of enabling this mode (Refer to the memory specification from memory vendors). For example, the command B7h sent to Macronix flash will enable it for 32-bit address mode.

- **Extended Address register**

  In this mode, the upper 8-bit of the 32-bit address is provided by the Extended address register in the memory itself. The memory provides a specific register which is updated according to the address to be accessed. This effectively converts the legacy 24-bit address command into 32-bit address commands. The memories greater in size than 16 MB, consists of banks of 16 MB. The 8-bit written in the extended address register effectively enables a bank. For example in Spansion memory, when the extended address register is updated with a value of 0x01 with the help of the command 17h, it will open Bank1 of the memory. The consequent 24-bit address commands will lead to Bank1. The extended address register needs to be update with the respective value for access to other banks. This effectively converts the legacy 24-bit address command into 32-bit address commands.

- **Separation of address into row and column address**

  This mode has been introduced for flashes which needs addresses segregated into Row and Column. The value in QSPI_SFACR[CAS] defines the width of the column address required by a flash. The actual address to be provided will be derived from the incoming address in case of AHB initiated transactions and the value of SFAR in case of IPS initiated transactions , if QSPI_SFACR[CAS] is set to 0, else the actual address will take CAS into consideration. If QSPI_SFACR[CAS] is 3 then bits 26-3 of the address programmed are sent to flash as it page address in case flash is operating in 24bit mode and bits 2-0 are sent as its column address. If a flash requirement for column address is less than the number of pads in which address has to be sent than the remaining bits are appended with 0 by QuadSPI. The user must program the operand value in CADDR and CADDR_DDR command accordingly. It must be ensured that the total number of address bits request by flash as its page and column address must not be more than 32 bits.

- **Word addressable mode for Flash**

  This mode has been introduced for flashes which has word addressable memory i.e. each address of the flash contains one word (two bytes) of data. The QSPI_SFACR [WA] is set to 1 to enter this mode. QuadSPI internally divides the incoming address in the AHB bus or the address in the QSPI_SFAR to map it to a valid flash location. For example, if the incoming address is 0x2004, the controller re-maps this address to access the flash location 0x1002. If not in this mode, the incoming address 0x2004 will be mapped to flash location 0x2004.

20.8 Initialization/Application Information

This section provides the initialization and application information of the QuadSPI module.

20.8.1 Power Up and Reset

Note that the serial flash devices connected to the QuadSPI module may require special voltage characteristics of their inputs during power up or reset. It is the responsibility of the application to ensure this.

20.8.2 Available Status/Flag Information

This paragraph gives an overview of the different status and flag information available and their interdependencies for different use cases. Related registers are QSPI_SR and QSPI_FR. Refer to the related descriptions how to set up the QuadSPI module appropriately.

20.8.2.1 IP Commands

Refer to IP Configuration Register (QuadSPI_IPCR) for additional details not explicitly covered in this paragraph.

- **IP Commands - Normal Operation**

  Writing the QSPI_IPCR[SEQID] field triggers the execution of a new IP Command. Given that this is a legal command the QSPI_SR[IPACC] and the QSPI_SR[BUSY] bits are asserted simultaneously, immediately after the execution is started.

  When the instruction on the serial flash device has been finished these bits are de-asserted and the QSPI_FR[TFF] flag is set.

- **IP Commands - Error Situations**

  Refer to Table 20-20 below.

20.8.2.2 AHB Commands

Refer to Section 1, Reading Serial Flash Data into the QuadSPI Module, in Flash Read for additional details not explicitly covered in this paragraph.

- **AHB Commands - Normal Operation**

  Memory mapped read access to a serial flash address not contained in the AHB Buffer, triggers the execution of an AHB Command. Given that this is a legal command the QSPI_SR[AHBACC] and the QSPI_SR[BUSY] bits are asserted simultaneously immediately after the execution is started. When the instruction on the serial flash device has been finished these bits are de-asserted.

- **IP Commands - Error Situations**

  Refer to Table 20-20 below.

20.8.2.3 Overview of Error Flags

The following table gives an overview of the different error flags in the QSPI_FR register and additional error-related details.

Table 20-20. Overview of QSPI_FR Error Flags

Error Category	Error Flag in QSPI_FR	Command Execution on Serial Flash Device TFF Behavior (in case of IP commands only)	Description
AHB Error Flag	ABSEF	Flash transaction is aborted	AHB sequence contains • WRITE instruction • WRITE_DDR instruction
AHB Error Flag	ABOF	Flash transaction continues until it finishes	Set when the module tried to push data into the AHB buffer that exceeded the size of the AHB buffer. Only occurs due to wrong programming of the QSPI_BUFxCR[ADATSZ].
AHB Error Flag	AIBSEF	Flash transaction is aborted	Total burst size of AHB transaction is greater than prefetch data size
AHB Error Flag	AITEF	Flash transaction is aborted	No response generated from QSPI to AHB bus in case of illegal transaction and the watchdog timer expires
Miscellaneous Error Flag	DLPFF	Flash transaction continues until it finishes	Set when DATA_LEARN instruction was encountered in a sequence but no sampling point was found for the data learning pattern.

Table continues on the next page...

Table 20-20. Overview of QSPI_FR Error Flags (continued)

Error Category	Error Flag in QSPI_FR	Command Execution on Serial Flash Device TFF Behavior (in case of IP commands only)	Description
Miscellaneous Error Flag	ILLINE	Flash transaction aborted	Illegal instruction Error Flag – Set when an illegal instruction is encountered by the controller in any of the sequences.
Command Arbitration Error	IPIEF	TFF not asserted in conjunction with that command	IP Command Error - caused when IP access is currently in progress (IP_ACC set) and • write attempt to QSPI_IPCR register. • write attempt to QSPI_SFAR register. • write attempt to QSPI_RBCT register.
Command Arbitration Error	IPAEF		• AHB Command already running, another IP Command could not be executed. • AHB Command already running, write attempt to QSPI_IPCR[SEQID] field.
Command Arbitration Error	IPGEF		• Exclusive access to the serial flash granted for AHB Commands, write attempt to QSPI_IPCR[SEQID] field.
Buffer Related Error	RBOF	TFF is asserted on completion	• RX Buffer Overrun
Buffer Related Error	TBUF		• TX Buffer Underrun

Note that only the buffer related errors are related to a transaction on the external serial flash. All the other errors do not trigger an actual transaction.

20.8.2.4 IP Bus and AHB Access Command Collisions

There are two flags related to this topic, the QSPI_FR[IPAEF] and QSPI_FR[IPIEF]. Refer to sub-section "Reading Serial Flash Data into the QuadSPI Module" of Flash Read section, for a description of the flags and Command Arbitration , for details about possible command collisions.

20.8.3 Exclusive Access to Serial Flash for AHB Commands

It is possible that several masters need to access the serial flash device connected to the QuadSPI module separately, one master by triggering IP Commands and reading the RX Buffer (via RBDR*n* register) and the other masters by triggering AHB Commands (via ARDB*n* Registers). These two set of buffer (RBDR and ARDB Buffer) points to the same physical buffer.Refer to Figure 20-6 To avoid command collisions resulting in excessive latencies the QuadSPI module implements a request-handshake mechanism between the master triggering AHB Commands and the QuadSPI module allowing this specific master to request exclusive access to the serial flash device for AHB Commands. If this exclusive access is granted the execution of IP Commands is blocked. This resolves command collisions and excessive times where the AHB interface may be blocked.

If this capability is used in the device there is additional status and flag information available related to this mechanism. The QSPI_SR[AHBGNT] bit reflects the module-internal state that the exclusive access mentioned above is granted, any attempt to trigger an IP Command is rejected and results in the assertion of the QSPI_FR[IPGEF] flag. Refer to the descriptions of the related bit and flag for details.

It is within the responsibility of the application to set up the master using this mechanism appropriately, if used incorrectly no IP Commands at all can be triggered.

Two different cases can be distinguished:

20.8.3.1 RX Buffer Read via QSPI_ARDB Registers

In this case all masters share the AHB bus for RX Buffer as well as for AHB Buffer read. In this case the access to the AHB interface by the master triggering AHB Commands must be deferred until any pending IP Command has been finished **and** the RX Buffer readout has been finished as well. The QSPI ARDB Buffers access the Rx buffer i.e the data from the Rx Buffer is returned and no data from AHB Buffer is touched. This is the conservative use case, corresponding to the reset value 0 of the QSPI_RBCT[RXBRD] bit.

In this case the QSPI_SR[AHBGNT] bit is asserted not earlier than any running IP Command has been finished (QSPI_SR[IP_ACC] is 0), the RX Buffer has been read out completely (QSPI_RBSR[RDBFL] equal to 0) or no DMA read is pending (QSPI_SR[RXDMA] equal to 0 and Rx Buffer readout is via AHB(QSPI_RBCT[RXBRD]) equal to 1.

20.8.3.2 RX Buffer Read via QSPI_RBDR Registers

This is the preferred use case as an access to the AHB buffer (memory mapped flash) does not interfere with any IPS access to read the RBDR buffer. It is not possible that a pending AHB bus access triggered by an AHB Command stalls the AHB bus and blocks the RX Buffer readout since the RX Buffer is read via the IP bus based registers QSPI_RBDR0 to QSPI_RBDR15.

For this case it is recommended to program the QSPI_RBCT[RXBRD] bit to 1. The QSPI_SR[AHBGNT] bit is asserted immediately after any running IP Command has been finished (QSPI_SR[IP_ACC] is 0), the RX Buffer has been read out completely (QSPI_RBSR[RDBFL] equal to 0) or no DMA read is pending (QSPI_SR[RXDMA] equal to 0, allowing the master triggering AHB Commands to trigger AHB Commands as soon as possible without the need to wait for the RX Buffer readout to be finished.

20.8.4 Command Arbitration

In case of overlapping commands, the arbitration scheme is described in the following paragraphs under the assumption that the priority mechanism described in Exclusive Access to Serial Flash for AHB Commands is **not** used:

- During the execution of an IP Command, the running IP Command can't be terminated by issuing another IP Command or AHB Command. The QSPI_FR[IPIEF] flag is asserted when the host tries to write into the QSPI_IPCR register. When the host triggers an AHB Command (refer to sub-section "Reading Serial Flash Data into the QuadSPI Module" of Flash Read section, for details), this command is stalled until the currently running IP Command is finished.
- During the execution of an AHB Command, the running AHB Command can't be terminated by issuing an IP Command. The command is ignored and the QSPI_FR[IPAEF] flag is asserted. Refer to Flag Register (QuadSPI_FR) for the description of these flags.

  When another AHB Command is triggered the address of the memory mapped access is considered. If the requested address is currently read from the serial flash device, the running command is continued. If this is not the case the currently running command is terminated and another AHB Command related to the requested address is executed. Refer to sub-section "Reading Serial Flash Data into the QuadSPI Module" of Flash Read section, for further details.

In case of coinciding commands the IP Command is triggered and the AHB Command is stalled until the IP Command has been finished (QSPI_SR[IP_ACC] has been deasserted).

The IP Commands ignored in case of command collision will not result in the assertion of the QSPI_FR[TFF] flag.

20.8.5 Flash Device Selection

Regardless of the SFM Command (IP or AHB) the access mode is selected by specifying the 32 bit address value for the following SFM Command.

For IP Commands the access mode is selected with the address programmed into the QSPI_SFAR register. Refer to Serial Flash Address Register (QuadSPI_SFAR) for details.

For AHB Commands the access mode is determined by the memory mapped address which is accessed Refer to Flash memory mapped AMBA bus for details.

20.8.6 DMA Usage

For the complete description of the DMA module refer to the related DMA Controller chapter. In this paragraph only the details specific to the DMA usage related to the QuadSPI module are given.

20.8.6.1 DMA Usage in Normal Mode

20.8.6.1.1 Bandwidth considerations

Careful consideration of the throughput rate of the entire chain (serial flash -> AHB bus / IP Bus -> DMA controller) involved in the read/write data process is essential for proper operation. Such analysis must take into account not only the data rate provided by the serial flash but also the data rate of the AHB bus and the performance of the DMA controller in reading/writing data from/to the RX/TX buffer.

Two figures must match for proper operation, that means that the data rate provided by the serial flash device must not exceed the average RX Buffer readout data rate. Otherwise, the longer this state persists, a RX Buffer overflow will result. Similarly, the data consumed by the serial flash device must not exceed the average TX buffer fill rate. If this persists, it would eventually lead to an underrun.

AHB Bus Side (data read):

The following table gives some examples for typical use cases:

Case 1: DMA need to read 4 bytes from SRAM and provide to QuadSPI. It costs total 4 BUS clock cycles. Then DMA handshake added additional 6 BUS clock cycles. Total [6 + 4 * (32/4) = 38] BUS clock cycles.

Table 20-21. Access Duration Examples - Bus Clock Side

QSPI_TBCT[WMRK]	Number of Bytes per DMA Loop	Number of Bus Clock cycles for DMA Minor Loop	Time Duration of DMA Minor Loop for 60Mhz Bus clock Frequency
3	16	6+(16/4)*4 = 22	~366ns
7	32	6+(32/4)*4 = 38	~633ns
11	48	6+(48/4)*4 = 54	~900ns
15	64	6+(64/4)*4 = 70	~1166ns

Case2: DMA need to read 32 bytes from SRAM and provide to QuadSPI DMA handshake takes additional 6 BUS cycles, with 32byte DMA read from SRAM costs (8 + 3) CORE clock cycles. DMA write 32 byte to QSPI takes 2 * (32/4) = 16 BUS cycles with one additional CPU access to QuadSPI, costing 2 BUS clock cycles. Total 6 + (8+3)/2 + 2 * (32/4) +2 = 30 BUS clock cycles.

Table 20-22. Access Duration Examples - Bus Clock Side

QSPI_TBCT[WMRK]	Number of Bytes per DMA Loop >	Number of Bus Clock cycles for DMA Minor Loop	Time Duration of DMA Minor Loop for 80Mhz Bus clock Frequency
3	16	6 + (4+3) /2 + (16/4)*2 + 2 = 20	~333ns
7	32	6 + (8+3) /2 + (32/4)*2 + 2 = 30	~500ns
11	48	6 + (4+3)/2*3 + (48/4)*2 + 2 = 44	~733ns
15	64	6 + (8+3) + (64/4)*2 + 2 = 51	~810ns

NOTE

The table figure represents ideal scenario, actual performance will depend on how the system is integrated.

Serial Flash Device Side (data read):

The number of serial flash cycles can be determined in the following way:

- Number of serial flash clock cycles required to read 4 bytes, corresponding to one RX Buffer entry (setup of command and address not considered): , 2 cycles for Octal DDR mode (Hyperflash) in individual flash mode , 8 cycles for Quad Mode (SDR) instructions in Individual Flash Mode etc.
- Overhead due to clock domain crossing : 1 cycle.

The following table lists the number of clock cycles required to read the data from the serial flash corresponding to the different settings of the QSPI_RBCT[WMRK] field:

Table 20-23. Access Duration Examples - Serial Flash side

QSPI_RBCT[WMRK] setting	Num Bytes per DMA Loop [1]	Num SCKFx for 80MHz SCKFx		Time duration of Flash data readout for 80MHz SCKFx (~12.5ns period)	
		IFM [2] Quad	IFM Quad DDR	IFM Quad	IFM Quad DDR
0	4	8	4	~100ns	~50ns
1	8	16	8	~200ns	~100ns
3	16	32	16	~400ns	~200ns
7	32	64	32	~800ns	~400ns
11	48	96	48	~1200ns	~600ns

1. DMA Loop means one Minor loop completion which is equivalent to one Major Loop iteration.
2. Individual flash mode.

NOTE

The table figure represents ideal scenario, actual performance will depend on how the system is integrated.

A complementary example would be when the watermark is set to be too high. In such a case, the time taken by the DMA to read out the RX buffer entries should be smaller than the time taken by the controller to push in the remaining entries in the buffer.

IPS Bus Side (data write):

The total number of bus cycles for each DMA Minor Loop completion is added from the following components:

- Overhead for each minor loop, given by DMA controller: Assume 10 cycles
- Overhead due to clock domain crossing: Assume 2 cycles
- Number of bus clock cycles required for 16 bytes (128 bit write size): Assume 4 cycles (read/write sequence of DMA controller)

Note that the size of the minor loop is determined by the size of the QSPI_TBCT[WMRK] field, therefore the overhead given above distributes among (QSPI_TBCT[WMRK]+1) write accesses of 32 bit each.

The following table gives some examples for typical use cases:

Table 20-24. Access Duration Examples - Bus Clock Side

QSPI_TBCT[WMRK]	Number of Bytes per DMA Loop [1]	Number of Bus Clock cycles for DMA Minor Loop	Time Duration of DMA Minor Loop for 80Mhz Bus clock Frequency
3	16	12+4 = 16	~200ns
7	32	12+8 = 20	~250ns

Table continues on the next page...

Table 20-24. Access Duration Examples - Bus Clock Side (continued)

QSPI_TBCT[WMRK]	Number of Bytes per DMA Loop [1]	Number of Bus Clock cycles for DMA Minor Loop	Time Duration of DMA Minor Loop for 80Mhz Bus clock Frequency
11	48	12+12 = 24	~300ns
15	64	12+16 = 28	~350ns

1. DMA Loop means one Minor Loop Completion which is equivalent to one.

NOTE

The table figure represents ideal scenario, actual performance will depend on how the system is integrated.

Serial Flash Device Side (data write):

The number of serial flash cycles can be determined in the following way:

- Number of serial flash clock cycles required to write 16 bytes, corresponding to four TX Buffer entry(setup of command and address not considered): 8 cycles for Octal DDR mode (Hyperflash) instructions in Individual Flash Mode, 32 cycles for Quad SDR writes in individual flash mode.
- Overhead due to clock domain crossing : 1 cycle.

The following table lists the number of clock cycles required to read the data from the serial flash corresponding to the different settings of the QSPI_TBCT[WMRK] field:

Table 20-25. Access Duration Examples - Serial Flash side

QSPI_TBCT[WMRK] setting	Num Bytes per DMA Loop [1]	Num SCKFx		Time duration for consuming data at Flash interface 100MHz SCKFx (10ns period)[2]		Time for fifo to get empty[3]	
		IFM [4] Quad	IFM Octal DDR	IFM Quad	IFM Octal DDR	IFM Quad	IFM Octal DDR
3	16	32	8	320ns	80ns	2240ns	560ns
7	32	64	16	640ns	160ns	1920ns	480ns
15	64	128	32	1280ns	320ns	1280ns	320ns

1. DMA Loop means one Minor loop completion which is equivalent to one Major Loop iteration.
2. Not all flash devices support writes at 100Mhz. Please refer to the flash datasheet for the actual page program frequency supported.
3. The assumption for these timings is that the TX Fifo was full when the transaction was initiated
4. Individual flash mode.

NOTE

The tables mentioned above are only examples which must be correlated with the DMA in the system.

From the examples given in the two tables above for TX fifo, it can be seen that depending on the relationship between the Bus clock and Serial flash clock frequencies, there are settings possible where the serial flash consumes data faster than the IPS bus can write data in TX buffer. In these cases, a TX buffer underrun situation will occur. To avoid TX Buffer underrun, the data transaction size should be large enough.

20.9 Byte Ordering - Endianness

QuadSPI provides support for swapping the flash read/write data based on the configuration of the QSPI_MCR[END_CFG]. By default the data is always returned in 64 bit LE format on the AHB bus and 32 bit LE format on the IPS interface when read via the RX buffer and written in 32 bit LE format when written via the TX buffer.

The table(QSPI_MCR[END_CFG]) below shows the complete bit ordering. BE signifies Big Endian which means the high order bits of the associated data vectors are associated with low order address positions. LE signifies Little Endian which means the lower order bits of the associated data vectors are associated with low order address positions.Refer to figure Figure 20-6

Table 20-26. QSPI_MCR[END_CFG]

00	64 bit BE
01	32 bit LE
10	32 bit BE
11	64 bit LE

The tables below (Byte ordering configuration in AHB) and (Byte ordering configuration in IPS) show how this configuration is implemented in QSPI AHB and IPS interfaces respectively. B in the table signifies Byte and the index 1-8 refers to the byte position i.e. 1 refer to bits[7:0], 8 refer to bits[63:56] and so on.

Table 20-27. Byte ordering configuration in AHB

64 bit BE	B1	B2	B3	B4	B5	B6	B7	B8
64 bit LE	B8	B7	B6	B5	B4	B3	B2	B1
32 bit BE	B5	B6	B7	B8	B1	B2	B3	B4
32 bit LE	B4	B3	B2	B1	B8	B7	B6	B5

Table 20-28. Byte ordering configuration in IPS

32BE	B1	B2	B3	B4
32LE	B4	B3	B2	B1

The examples below show the byte ordering in 64 bit BE configuration for AHB Buffer and 32 bit BE for TX/RX Buffer:

20.9.1 Programming Flash Data

CPU write instructions to the QSPI_TBDR register like

- Write QSPI_TBDR -> 0x01_02_03_04
- Write QSPI_TBDR -> 0x05_06_07_08

result in the following content of the TX Buffer:

Table 20-29. Example of QuadSPI TX Buffer

TX Buffer Entry	Content
0	32'h01_02_03_04
1	32'h05_06_07_08

Programming the TX Buffer into the external serial flash device results in the following byte order to be sent to the serial flash:

- 01…02…03…04…05…06…07…08

20.9.2 Reading Flash Data into the RX Buffer

Reading the content from the same address provides the following sequence of bytes, identical to the write case:

- 01…02…03…04…05…06…07…08

This results in the RX Buffer filled with:

Table 20-30. Resulting RX Buffer Content

RX Buffer Entry	Content
0	32'h01_02_03_04
1	32'h05_06_07_08

20.9.2.1 Readout of the RX Buffer via QSPI_RBDRn

The RX Buffer content appears at CPU read access via the Peripheral bus interface in the following order:

- Read QSPI_RBDR0 <- 0x01_02_03_04
- Read QSPI_RBDR1 <- 0x05_06_07_08

20.9.2.2 Readout of the RX Buffer via ARDBn

The RX Buffer content appears at read access on the AMBA AHB interface at the QuadSPI module boundary:

- (1a): 32 Bit Access: Read QSPI_ARDB0 <- 0x01_02_03_04
- (2a): 32 Bit Access: Read QSPI_ARDB1 <- 0x05_06_07_08
- (1b/2b): 64 Bit Access: Read QSPI_ARDB0 <- 0x01_02_03_04_05_06_07_08

20.9.3 Reading Flash Data into the AHB Buffer

Reading the content from the same address as it was written to provides the following sequence of bytes, identical to the write case:

- 01…02…03…04…05…06…07…08

This results in the AHB Buffer filled with:

Table 20-31. Resulting AHB Buffer Content

AHB Buffer Entry	Content
0	64'h01_02_03_04_05_06_07_08

20.9.3.1 Readout of the AHB Buffer via Memory Mapped Read

The AHB Buffer content appears at read access on the AMBA AHB interface at the QuadSPI module boundary:

- (1a): 32 Bit Read Access: <- 0x01_02_03_04

- (2a): 32 Bit Read Access: <- 0x05_06_07_08
- (1/2): 64 Bit Read Access: <- 0x01_02_03_04_05_06_07_08

20.10 Driving Flash Control Signals in Single and Dual Mode

In single and dual mode the serial flash devices which can connect to the QuadSPI module expect additional control signals on the inputs which are connected to IOFA[3], IOFA[2] in quad mode. For easy interfacing the outputs IOFA[3:2] for Flash A are driven to the logic state given by the configuration bits QSPI_MCR[ISD3FA], QSPI_MCR[ISD2FA].

These outputs are driven all the time to the logic level programmed in the QSPI_MCR register except the time when quad commands of the serial flash are executed. Refer to the specification of the related serial flash device for details about the inactive level.

20.11 Serial Flash Devices

Several different vendors make flash devices with a QuadSPI interface. At present there is no set standard for the QuadSPI instruction set. Most common commands currently have the same instruction code for all vendors, however some commands are unique to specific vendors. Some example sequences are provided below.

20.11.1 Example Sequences

This section provides the example sequences of the QuadSPI module.

Table 20-32. Exit 4 x I/O Read Enhance Performance Mode (XIP) (Macronix) and Read Status

INSTR	PAD	OPERAND	COMMENT
CMD	0x0	0xEB	4xIO Read Command
ADDR	0x2	0x18	24 Bit address to be send on 4 pads
MODE	0x2	0x00	2 mode cycles (exit XIP)
DUMMY	0x0	0x04	4 dummy cycles
READ	0x2	0x08	Read 64 bits
CMD	0x0	0x05	Read Status register
READ	0x0	0x01	Status register data
STOP	0x0	0x00	STOP, Instruction over

20.11.1.1 Read Command (Spansion Hyperflash)

This section provides the read command sequences (Spansion Hyperflash) of the QuadSPI module.

Table 20-33. Read Command (Spansion Hyperflash)

INSTR	PAD	OPERAND	COMMENT
CMD_DDR	0x3	0xA0	Read command with continuous burst type
ADDR_DDR	0x3	0x18	24 bit row address
CADDR_DDR	0x3	0x10	16 bit column address with lower 3 bits valid rest 0
DUMMY	0x3	0x0F	15 dummy cycles
READ_DDR	0x3	0x4	32 bit data read on 8 pads
STOP	0x3	0x00	STOP, Instruction over

Hyperflash is a word addressable flash i.e. each address accesses a word wide (2 bytes) data value, the software should ensure that when Hyperflash is connected to the controller, the QSPI_SFACR [WA] bit must be set. If this bit is set the controller remaps a byte addressable access to a word addressable access.

20.11.1.2 Read Status Register(Spansion Hyperflash)

This section provides the read status register of the QuadSPI module.

Table 20-34. Read Status register (Spansion Hyperflash)

INSTR	INSTR SEQUENCE	PAD	OPERAND	COMMENT
CMD_DDR	Read Pre Comman	0x3	0x00	Write command with wrapped burst type.
ADDR_DDR		0x3	0x18	24 bit row address(0000AAh)
CADDR_DDR		0x3	0x10	16 bit column address with lower 3 bits valid rest 0(0005h),treated as command
CMD_DDR		0x3	0x00	Write command with wrapped burst type
CMD_DDR		0x3	0x70	Write data to be sent to flash as pre-command

Table continues on the next page...

Table 20-34. Read Status register (Spansion Hyperflash) (continued)

CMD_DDR	Command phase (fourth/final chip select phase)	0x3	0xA0	Read command with continuous burst type
ADDR_DDR		0x3	0x18	24 bit row address
CADDR_DDR		0x3	0x10	16 bit column address with lower 3 bits valid rest 0
DUMMY		0x3	0x0F	15 dummy cycles
READ_DDR		0x3	0x4	32 bit data read on 8 pads
STOP		0x3	0x00	STOP, Instruction over

20.11.1.3 Word Program (Spansion Hyperflash)

This section provides the Word Program (Spansion Hyperflash) of the QuadSPI module.

Table 20-35. Word Program (Spansion Hyperflash)

INSTR	INSTR SEQUENCE	PAD	OPERAND	COMMENT
CMD_DDR	Unlock Sequence 1 (first chip select phase)	0x3	0x00	Write command with wrapped burst type
CMD_DDR		0x3	0x00	8 bit address 00h treated as command
CMD_DDR		0x3	0x00	8 bit address 00h treated as command
CMD_DDR		0x3	0xAA	8 bit address AAh treated as command
CADDR_DDR		0x3	0x10	16 bit column address with lower 3 bits valid rest 0(0005h),treated as command
CMD_DDR		0x3	0x00	Write command with wrapped burst type.
CMD_DDR		0x3	0xAA	Write data to be sent to flash as pre-command.
CMD_DDR	Unlock Sequence 2 (second chip select phase)	0x3	0x00	Write command with wrapped burst type
CMD_DDR		0x3	0x00	8 bit address 00h treated as command
CMD_DDR		0x3	0x00	8 bit address 00h treated as command
CMD_DDR		0x3	0x55	8 bit address 55h treated as command

Table continues on the next page...

Table 20-35. Word Program (Spansion Hyperflash) (continued)

CADDR_DDR		0x3	0x10	16 bit column address with lower 3 bits valid rest 0(0002h),treated as command
CMD_DDR		0x3	0x00	Write command with wrapped burst type
CMD_DDR		0x3	0x55	Write data to be sent to flash as pre-command
CMD_DDR	Program setup phase (third chip select phase)	0x3	0x00	Write command with wrapped burst type
CMD_DDR		0x3	0x00	8 bit address 00h treated as command
CMD_DDR		0x3	0x00	8 bit address 00h treated as command
CMD_DDR		0x3	0xAA	8 bit address AAh treated as command
CADDR_DDR		0x3	0x10	16 bit column address with lower 3 bits valid rest 0(0005h),treated as command
CMD_DDR		0x3	0x00	Write command with wrapped burst type
CMD_DDR		0x3	0xA0	Write data to be sent to flash as pre-command
CMD_DDR	Command phase (fourth/final chip select phase)	0x3	0x00	Write command with wrapped burst type
ADDR_DDR		0x3	0x18	24 bit row address
CADDR_DDR		0x3	0x10	16 bit column address with lower 3 bits valid rest 0
WRITE_DDR		0x3	0x2	2 bytes data written on 8 pads (D1D2)
STOP		0x3	0x00	STOP, Instruction over

20.11.1.4 Fast Read Sequence (Macronix/Numonyx/Spansion/ Winbond)

The following table shows the fast read sequence for Macronix/Numonyx/Spansion/ Winbond flashes.

Table 20-36. Fast Read sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0x0B	Fast Read command = 0x0B
ADDR	0x0	0x18	24 Addr bits to be sent on one pad

Table continues on the next page...

Table 20-36. Fast Read sequence (continued)

Instruction	Pad	Operand	Comment
DUMMY	0x0	0x08	8 Dummy cycles
READ	0x0	0x04	Read 32 Bits on one pad
JMP_ON_CS	0x0	0x00	Jump to instruction 0 (CMD)

20.11.1.5 Fast Dual I/O DT Read Sequence (Macronix)

The following table shows the Fast Dual I/O DT read sequence for Macronix flashes.

Table 20-37. Fast Dual I/O DT Read sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0xBD	Fast Dual I/O DT read command = 0xBD
ADDR_DDR	0x1	0x18	24 Addr bits to be sent on 2 pads in DDR mode
MODE4_DDR	0x1	0x00	P2=P0 or P3=P1 is necessary. Refer to Macronix datasheet for details. One clock cycle for mode.
DUMMY	0x0	0x06	6 Dummy cycles
READ_DDR	0x1	0x04	Read 32 Bits on 2 pads in DDR mode
JMP_ON_CS	0x0	0x00	Jump to instruction 0 (CMD)

20.11.1.6 Fast Read Quad Output (Winbond)

The following table shows the Fast read quad output sequence for Winbond memories

Table 20-38. Fast Read Quad output sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0x6B	Fast read quad output command = 0x6B
ADDR	0x0	0x18	24 Addr bits to be sent on 1 pad
DUMMY	0x0	0x08	8 Dummy cycles
READ	0x2	0x04	Read 32 Bits on 4 pads
JMP_ON_CS	0x0	0x00	Jump to instruction 0 (CMD)

20.11.1.7 4 x I/O Read Enhance Performance Mode (XIP) (Macronix)

The following table shows the 4 x I/O Read Enhance Performance Mode for Macronix flashes. The enhanced performance mode is also known as XIP mode.

Table 20-39. Fast Read Quad output sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0xEB	4xI/O Read command = 0xEB
ADDR	0x2	0x18	24 Addr bits to be sent on 4 pads
MODE	0x2	0xA5	2 mode cycles
DUMMY	0x0	0x04	4 Dummy cycles
READ	0x2	0x04	Read 32 Bits on 4 pads
JMP_ON_CS	0x0	0x01	Jump to instruction 1 (ADDR)

When in XIP mode the software should ensure that all the flashes connected to the controller are in XIP mode. As a part of initializing the controller, all the flashes may be enabled with XIP by carrying out dummy reads.

20.11.1.8 Dual Command Page Program (Numonyx)

The following table shows the Dual command page program sequence for Numonyx flashes.

Table 20-40. Dual Command Page Program sequence

Instruction	Pad	Operand	Comment
CMD	0x1	0x02	Dual command page program = 0x02 on 2 pads
ADDR	0x1	0x18	24 Addr bits to be sent on 2 pads
WRITE	0x1	0x20	Write 32 Bytes on 2 pads
STOP	0x0	0x00	STOP, Instruction over

20.11.1.9 Sector Erase (Macronix/Spansion/Numonyx)

The following table shows the Sector erase sequence for Macronix/Spansion/Numonyx flashes

Table 20-41. Sector Erase sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0xD8	Sector erase command = 0xD8
ADDR	0x0	0x18	24 Addr bits to be sent on 1 pad
STOP	0x0	0x00	STOP, Instruction over

20.11.1.10 Read Status Register (Macronix/Spansion/Numonyx/Winbond)

The following table shows the Read status register sequence for Macronix/Spansion/Numonyx/Winbond flashes.

Table 20-42. Read Status Register Sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0x05	Read status register command = 0x05
READ	0x0	0x01	Read status register data
STOP	0x0	0x00	STOP, Instruction over

20.11.1.11 Data Learn Instruction Sequence

The following table shows the data learn sequence for 4 I/O flash.

Table 20-43. Data learn Instruction sequence (4 I/O)

Instruction	Pad	Operand	Comment
CMD	0x0	0x6B	Fast Read Quad command = 0x6B
ADDR_DDR	0x2	0x18	24 address bits in DDR mode to be sent on four pads
DUMMY	0x2	0x08	8 Dummy cycle
DATA_LEARN	0x2	0x01	1 Byte data learn
READ_DDR	0x2	0x06	Read 6 bytes in 4 pads
JMP_ON_CS	0x0	0x00	Jump to Inst 0 (CMD)

The following table shows the data learn sequence for 8 I/O (Spansion Hyperflash) flash.

Table 20-44. Data learn Instruction sequence (8 I/O)

Instruction	Pad	Operand	Comment
CMD_DDR	0x3	0xAO	Read command for Hyperflash
ADDR_DDR	0x3	0x18	24 bit row address[1]
CADDR_DDR	0x3	0x10	16 bit column address
DUMMY	0x3	0x0F	15 cycle dummy
DATA_LEARN	0x3	0x01	1 byte data learn
READ_DDR	0x3	0x08	Read 8 bytes in 8 pads
STOP	0x3	0x00	STOP, instruction over

1. Address needs to be aligned i.e. No latency should be there between the RWDS edges.

20.11.2 Dual Die Flashes

Certain serial flash vendors provide dual-die packages which are essentially two devices (dies) stacked within the same package to increase the memory capacity of a single package. These two devices within a package share the same data and clock pins, but have individual Chip Selects. The figure below shows the dual-die package and the naming conventions used in this document. For simplicity, the data pins are shown to be unidirectional.

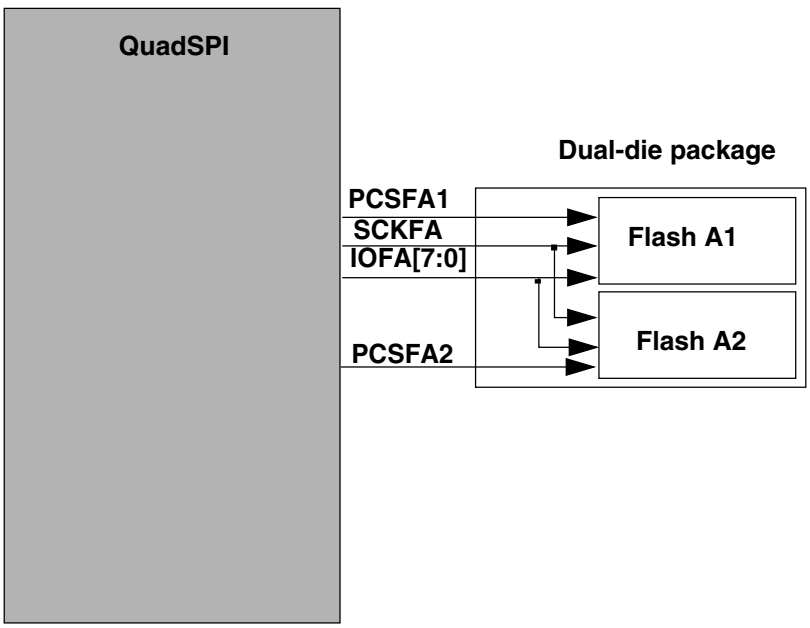

Figure 20-7. Dual-die support

Since the two devices within one package share the same i/o pads, they cannot function in parallel mode.

20.11.3 Boot initialization sequence

The following are the recommended sequence of steps for booting from QuadSPI:

- System out of reset and flash available (300us)
- Clocks still at very low frequency. Clock tree configured, I/O pins configured. First request sent to QuadSPI for address 0x0 of flash.
- The reset command sequence in QuadSPI has 0x03 (basic read command) which is applicable to all flashes at < 50MHz serial flash clock

- The first few bytes of data is read from the flash which contains the following information:
  - The total sizes of all the flashes connected on board
  - Whether DDR mode supported
  - Frequency of DDR operation
  - Continuous mode entry sequence
  - 24bit or 32bit addressing (assuming 24bit for first accesses)
- All the serial flashes are configured
  - Quad Mode enabled
  - Dummy reads to enter into XIP
- QuadSPI is configured
  - LUT configured for highest performance reads
  - DDR mode enabled (if applicable)
  - Buffers configured
- Serial flash clock frequency increased.
- Boot reads happen in DDR enabled, quad output mode @66MHz.

20.11.4 Serial Flash Clock Frequency Limitations

Certain commands of some serial flash devices are limited in the frequency applied to the serial flash device on command execution. In order to support these commands without having to recalibrate the module clocks, the the serial flash device clock can be divided by 2 (half speed) by setting the QSPI_SMPR[HSENA] bit. The SCLK will return to full speed once the the QSPI_SMPR[HSENA] bit is cleared.

20.12 Sampling of Serial Flash Input Data

20.12.1 Basic Description

QuadSPI is used to read data from the serial flash device. Depending on the actual implementation, there is a delay between the internal clocking in the QuadSPI module and the external serial flash device. Refer to the following figure for an overview of this scheme.

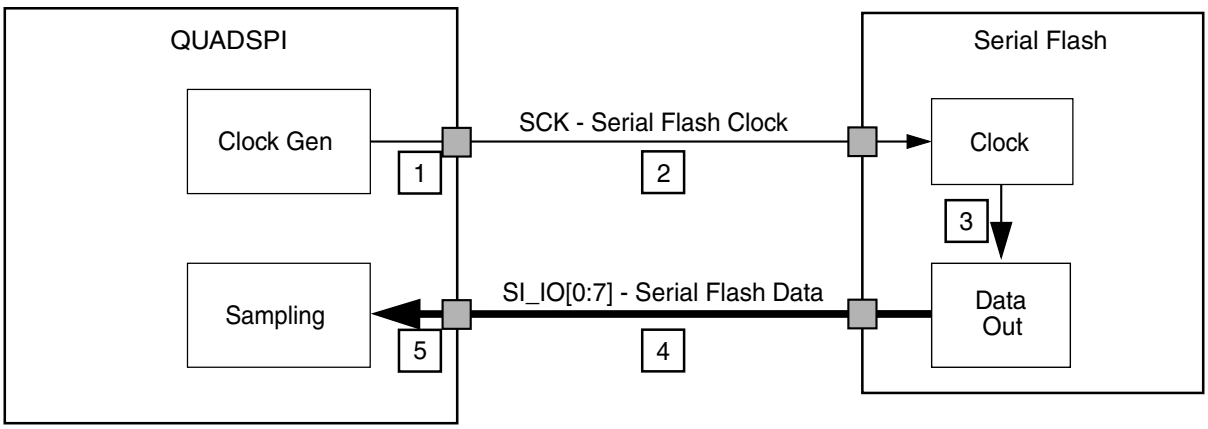

Figure 20-8. Serial Flash Sampling Clock Overview

The rising edge of the internal reference clock is taken as timing reference for the data output of the serial flash. After a time of $t_{Del,total}$ the data arrives at the internal sampling stage of the QuadSPI module. According to the Serial Flash Sampling Clock Overview figure, the following parts of the delay chain contribute to $t_{Del,total}$:

1. Output delay of the serial flash clock output of the device containing the QuadSPI module
2. Wire delay of application/PCB from the device containing the QuadSPI module to the external serial flash device
3. Clock to data out delay of the external serial flash device, including input and output delays
4. Wire delay of application/PCB from the external serial flash device to the device containing the QuadSPI module
5. Device delay corresponding to the input data

NOTE

The amount of total delay $t_{Del,total}$ is specific to the characteristics of the actual implementation. Also, the serial flash device clock (SCK) is inverted with respect to the QuadSPI internal reference clock.

20.12.2 Supported read modes

20.12.2.1 SDR mode

Most flash memories operate in single data rate (SDR) mode. In SDR mode, the data is transferred only on one edge of the clock signal. The SDR serial flash memories sample the incoming data on the rising edge of serial flash clock and drive the output data on the falling edge of the serial flash clock.

20.12.2.1.1 Internal sampling

QuadSPI uses different edges of the internal reference clock for sampling the input data in SDR mode.

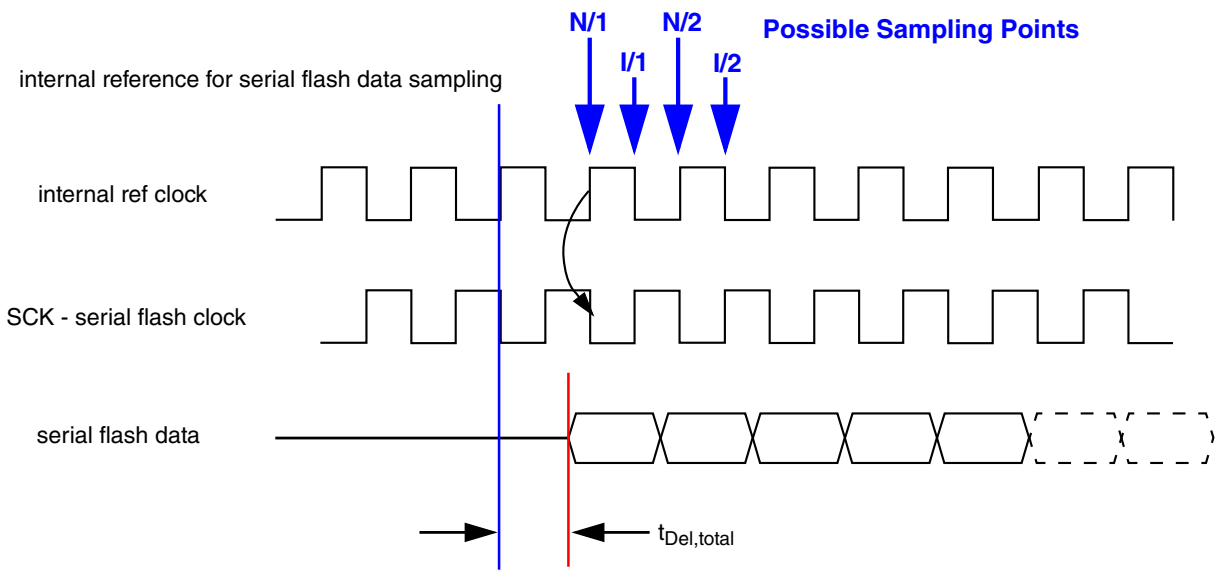

Figure 20-9. Internal sampling in SDR mode

The possible points in time for sampling incoming data are denoted as N/1, I/1, N/2 and I/2 above. The sampling point relevant for the internal sampling is configured in the QSPI_SMPR register. Refer to Sampling Register (QuadSPI_SMPR) for details. The following table gives an overview of the available configurations for the commands running at regular (full) speed:

Table 20-45. Sampling Configuration

Sampling Point	Description	Delay [FSDLY] [HSDLY]	Phase [FSPHS] [HSPHS]	QSPI_SMPR for Full Speed Setting[1]
N/1	sampling with non-inverted clock, 1 sample delay	0	0	0x0000000x
I/1	sampling with inverted clock, 1 sample delay	0	1	0x0000002x
N/2	sampling with non-inverted clock, 2 samples delay	1	0	0x0000004x
I/2	sampling with inverted clock, 2 samples delay	1	1	0x0000006x

1. 'x' is not considered here

Depending on the actual delay and the serial flash clock frequency, the appropriate sampling point can be chosen. The following remarks should be considered when selecting the appropriate setting:

- Theoretically there should be two settings possible to capture the correct data, since the serial flash output is valid for 1 clock cycle, disregarding rise and fall times and timing uncertainties.
- Depending on the timing uncertainties, it may turn out in actual applications that only one possible sample position remains. This is subject to careful consideration depending on the actual implementation.
- The delay $t_{Del,total}$ is an absolute size to shift the point in time when the serial flash data get valid at the QuadSPI input.
- For decreasing frequency of the serial flash clock the distance between the edges increases. So for large differences in the frequency the required setting may change.
- For commands running at half of the regular serial flash clock (QSPI_SMPR[HSENA] bit set) the sampling point must be figured separately to allow for the compensation of the absolute shift in time with respect to the sample-relative setting in the QSPI_SPMPR register.

20.12.2.1.2 DQS sampling method

Data sampling in SDR mode can be supported using the DQS sampling method. Refer to Data Strobe (DQS) sampling method for more details.

20.12.2.2 DDR Mode

The increasing requirement of improved throughput has introduced the double data rate (DDR) mode. In DDR mode, the data is transferred on both the rising and falling edges of the serial flash clock. The DDR serial flashes sample as well as drive the data on both rising and falling edges of serial flash clock.

20.12.2.2.1 Internal sampling (4x sampling method)

When the serial flash memories function in DDR mode, the data is valid for only half a clock cycle. This, along with the fact that the time for which the data is actually valid is smaller than half a clock cycle, requires that we provide closely spaced sampling points. The QuadSPI module provides a mechanism to sample the incoming data at multiple sampling points provided by a 4x serial flash clock in DDR mode. The figure below shows the different sampling points as configured by QuadSPI_SMPR[DDRSMP]. The FSDLY/FSPHS and HSDLY/HSPHS bits are ignored for DDR instructions.

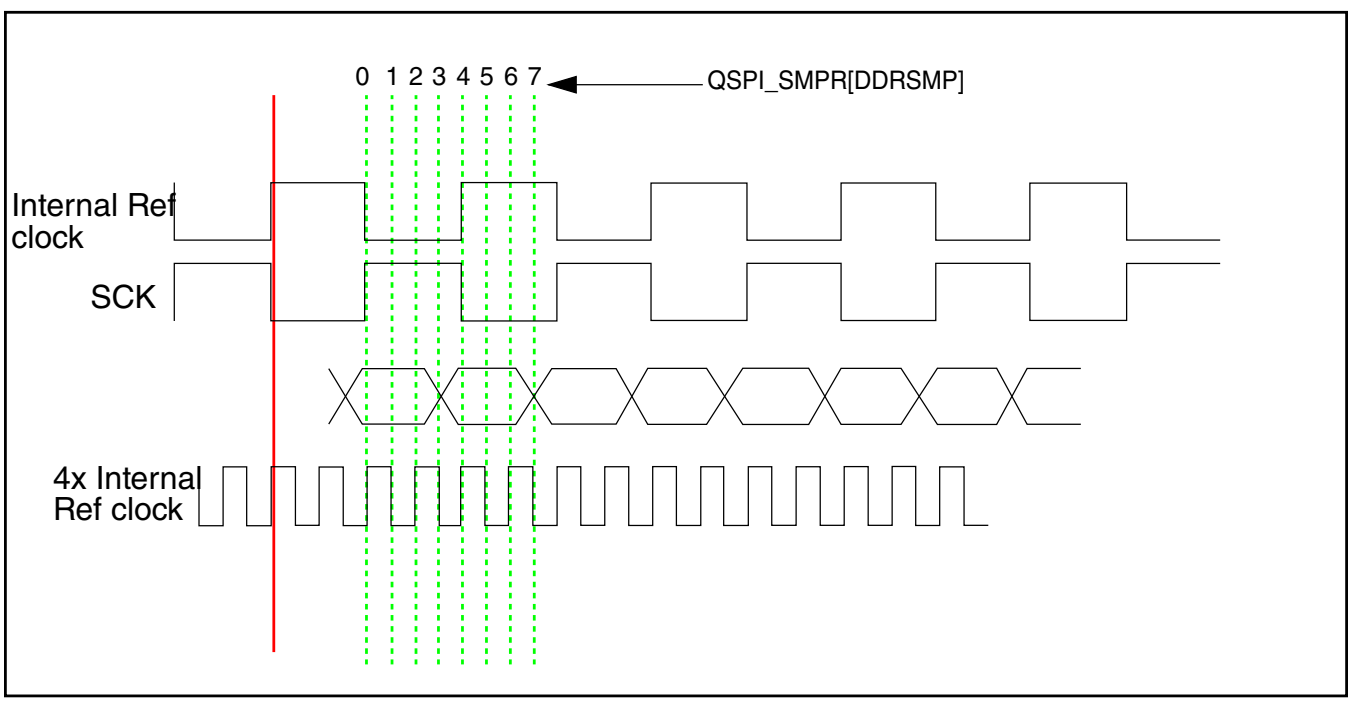

Figure 20-10. 4x sampling edges in DDR mode

Software should ensure that the correct sampling value is configured in the QuadSPI_SMPR[DDRSMP] register.

NOTE

Higher frequency can be achieved using data learning. For details, refer to Data Learning.

20.12.2.2.2 DQS sampling method

Data sampling in DDR mode can be supported using DQS method. Refer to Data Strobe (DQS) sampling method for more details.

A higher frequency can be achieved using Data learning. For details refer to Data Learning.

20.12.3 Data Strobe (DQS) sampling method

20.12.3.1 Basic Description

In DQS mode, the data strobe signal (DQS/RWDS) is used to sample the read data. Here, both DQS and the data sent by the flash move in the same direction, so it is relatively easier to achieve at higher frequencies.

When using DQS for SDR reads, QuadSPI internally samples the incoming data on rising edge of the strobe signal.

The figure below shows sampling read data in SDR mode using DQS.

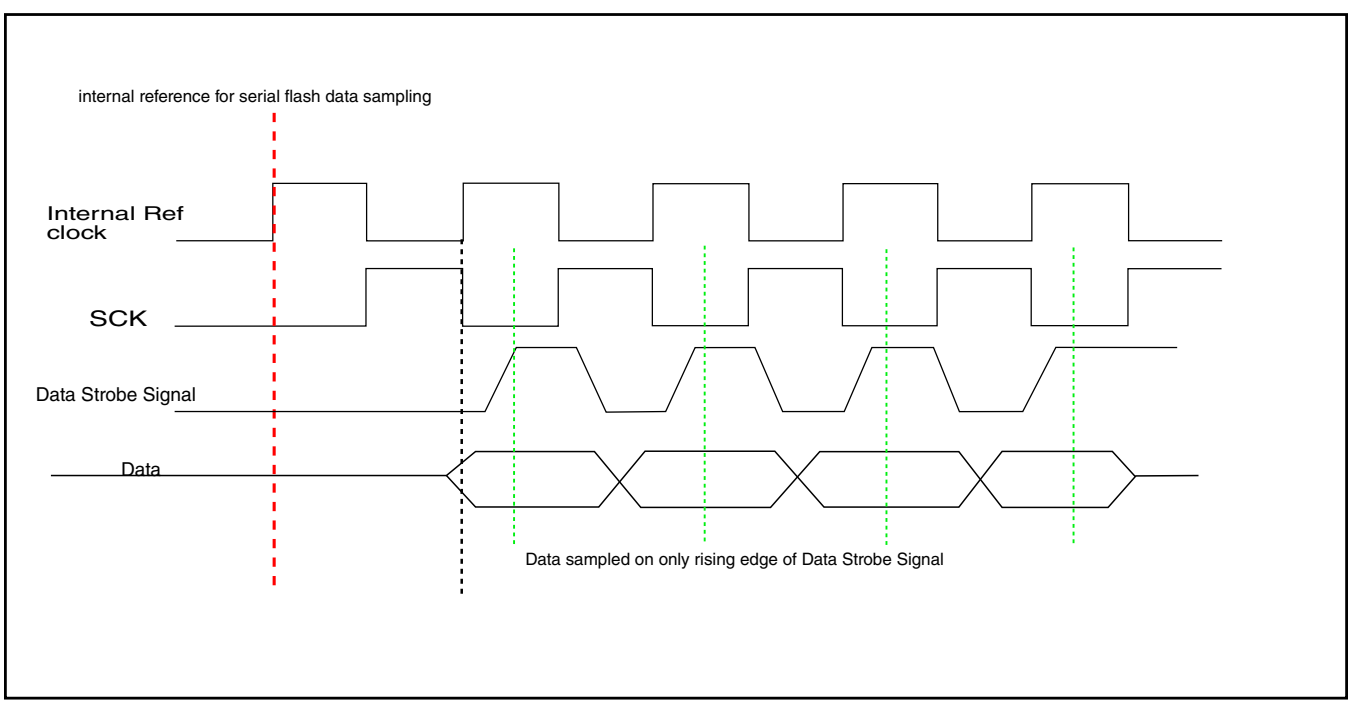

Figure 20-11. Data Strobe functionality in SDR mode

When using DQS for DDR reads, QuadSPI internally samples the incoming data on both the edges of the strobe signal. Refer to the figure below for more detail.

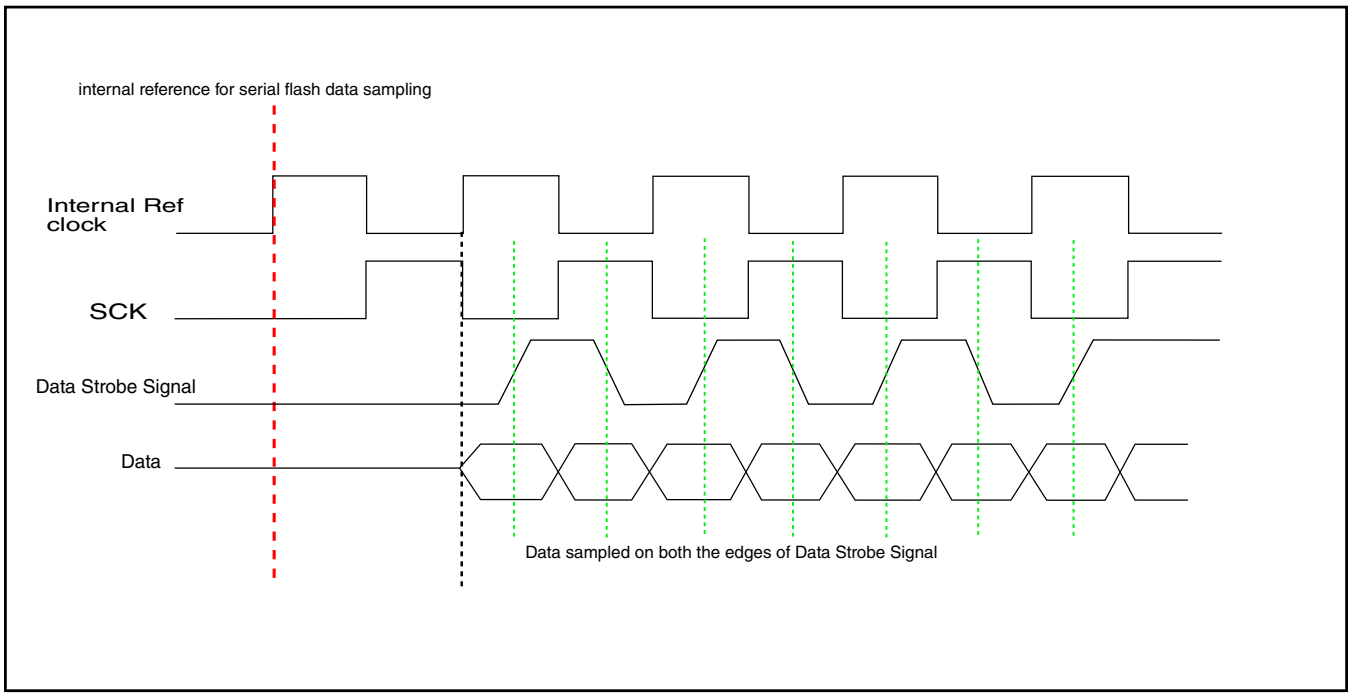

Figure 20-12. Data Strobe functionality in DDR mode

20.12.3.2 Internally generated DQS

In this mode, the internal reference clock is fed as a strobe to QuadSPI for read data sampling. The data strobe must be generated in a way such that the data is correctly sampled by the QuadSPI module. This internally generated data strobe signal can be used by QuadSPI to capture the data in:

- SDR mode
- DDR mode

Refer to QuadSPI chip-specific information for additional details about internally generated DQS.

20.12.3.3 External DQS

In serial flash memories supporting DQS, the data strobe signal is an output from the flash device that indicates when data is being transferred from the flash to the host controller. The data is then captured by the controller on:

- Only one edge (either rising or falling edge) of DQS signal in SDR mode
- Both rising/falling edge of the DQS signal in DDR mode

Some serial flash memories (for example, HyperFlash) provide the data strobe output (RWDS) with latency cycles included in between the ongoing read transaction. The data is sampled on both the edges of this signal taking into consideration that when no signal is provided by flash between ongoing transaction, data is not sampled then and at the end of transaction the required number of data to be fetched remains the same. Refer to the figure below for more detail.

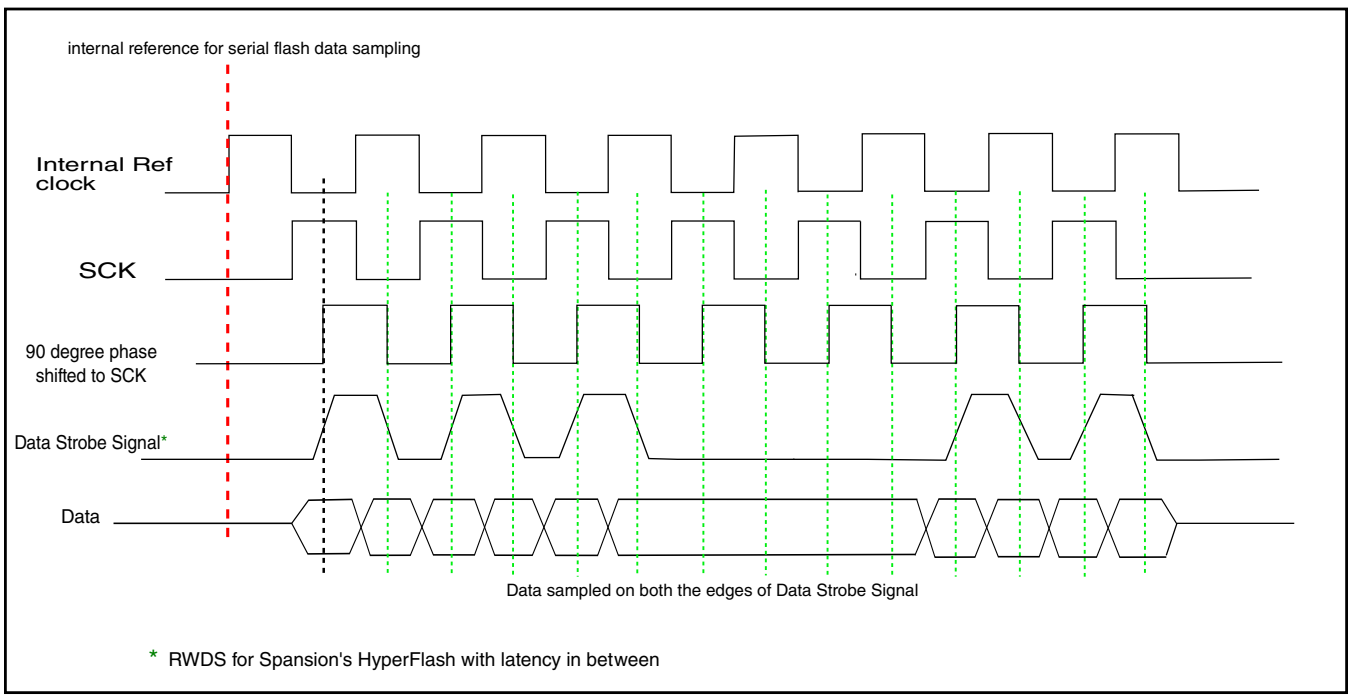

Figure 20-13. Data Strobe functionality with latency included

20.12.3.3.1 External Center Aligned Read Strobe

The QuadSPI supports serial flash memories using the Center Aligned Read Strobe (CRS) protocol. By virtue of this protocol, in addition to the SCK, the host controller provides a 90^{o} phase shifted SCK that allows the flash memory to generate valid data timed off SCK edges and a Data Read Strobe (DQS) signal output that is timed off the 90^{o} phase shifted SCK edges that is centered within the valid read data window. This allows the host controller to easily capture read data from the flash by using the data read strobe transitions and thereby allows for higher performance operation. Since the flash memory is the originator of the center aligned data read strobe as well as the read data, the temporal timing phase alignment between these signals is easier to guarantee across PVT (Process, Voltage and Temperature) corners.

The figure below shows data strobe functionality using CRS protocol.

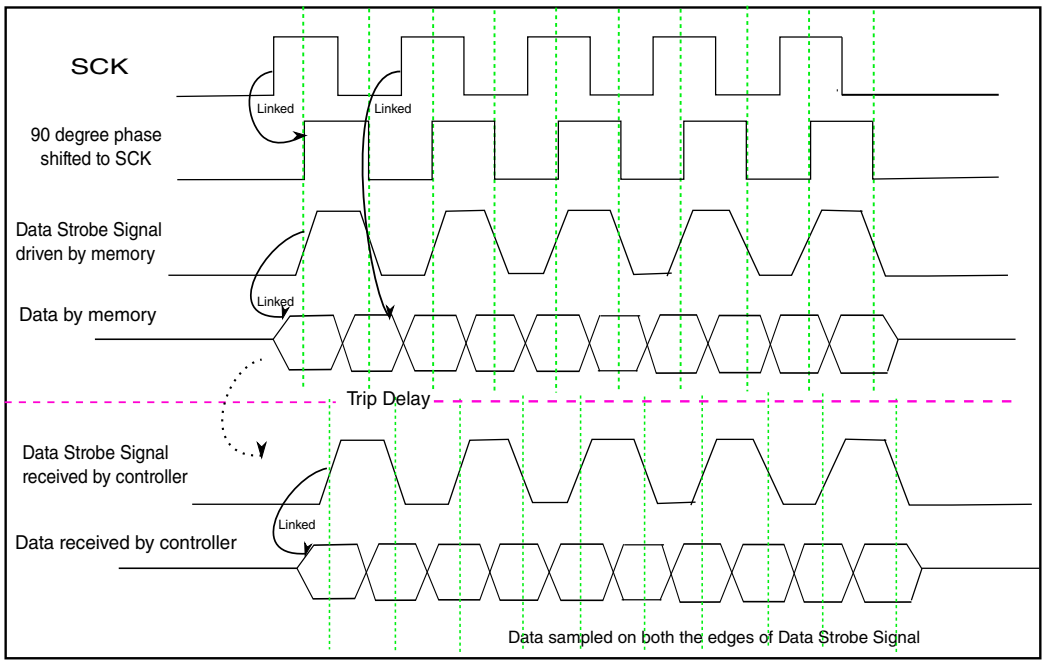

Figure 20-14. Data Strobe functionality using CRS protocol

20.12.4 Data Learning

20.12.4.1 Basic description

“Data learning” is used to manage varying data valid windows from flash memory as well as any variations in the chip based on PVT conditions in DDR mode. QuadSPI provides this feature via the DATA_LEARN instruction for all flash memories, irrespective of whether the flash supports it. The DATA_LEARN instruction accepts an operand that defines the number of bits of the known pattern for which the data learning has to be done. The known pattern is provided in the QSPI_DLPR register.

QuadSPI supports the data learning methods below:

- 4x sampling method
- Data Strobe (DQS) sampling method

The following sections explain data learning in greater detail.

20.12.4.2 4x sampling method

Automatic data learning is supported in 4x sampling mode. To start data learning:

1. Certain flash memories provide data learning as a feature for DDR data reads.

   For flash memories that support data learning, configure a known pattern in the Data Learn register inside flash. The pattern should be chosen to have multiple low and high transitions in the data bus. Set up a QuadSPI DDR data read sequence, inserting a DATA_LEARN instruction before the READ_DDR instruction. The flash will itself return the data learning pattern in between dummy cycles in every read command. Each I/O will output the same DLP value for every clock edge.

   For flash memories that *do not* support data learning, configure a known location in flash memory with a known pattern. The pattern should not have 0x00 or 0xFF in it. The pattern should be chosen to have multiple low and high transitions in the data bus. Set up a QuadSPI DDR data read sequence, inserting a DATA_LEARN instruction before the READ_DDR instruction. The address in the QuadSPI_SFAR register should point to the known location with the pattern. Configure the known pattern in the QuadSPI_DLPR [DLPV] field. Refer to Table 20-46 for details on how the data has to be ordered in memory for correct operation.

2. Select a sampling point using QuadSPI_SMPR[DDRSMP].
3. Initiate the read via a peripheral transaction.
4. QuadSPI reads the data from the flash. It then encounters the DATA_LEARN instruction and samples the incoming data on all 8 possible sampling points for all the data bus bits.
5. The sample point at which data matches the known pattern is reported in QuadSPI_SR[DLPSMP].
6. If data doesn't match at any sample point, QuadSPI_FR[DLPFF] is set.
7. If the correct sampling point is located, QuadSPI uses the new sampling point to sample the read data following the DATA_LEARN instruction.

This feature may be used to auto-calibrate the sampling point for DDR reads. This auto-calibration may be triggered at fixed intervals, or depending on a change in PVT conditions.

The following figure shows data learning with 4x DDR sampling:

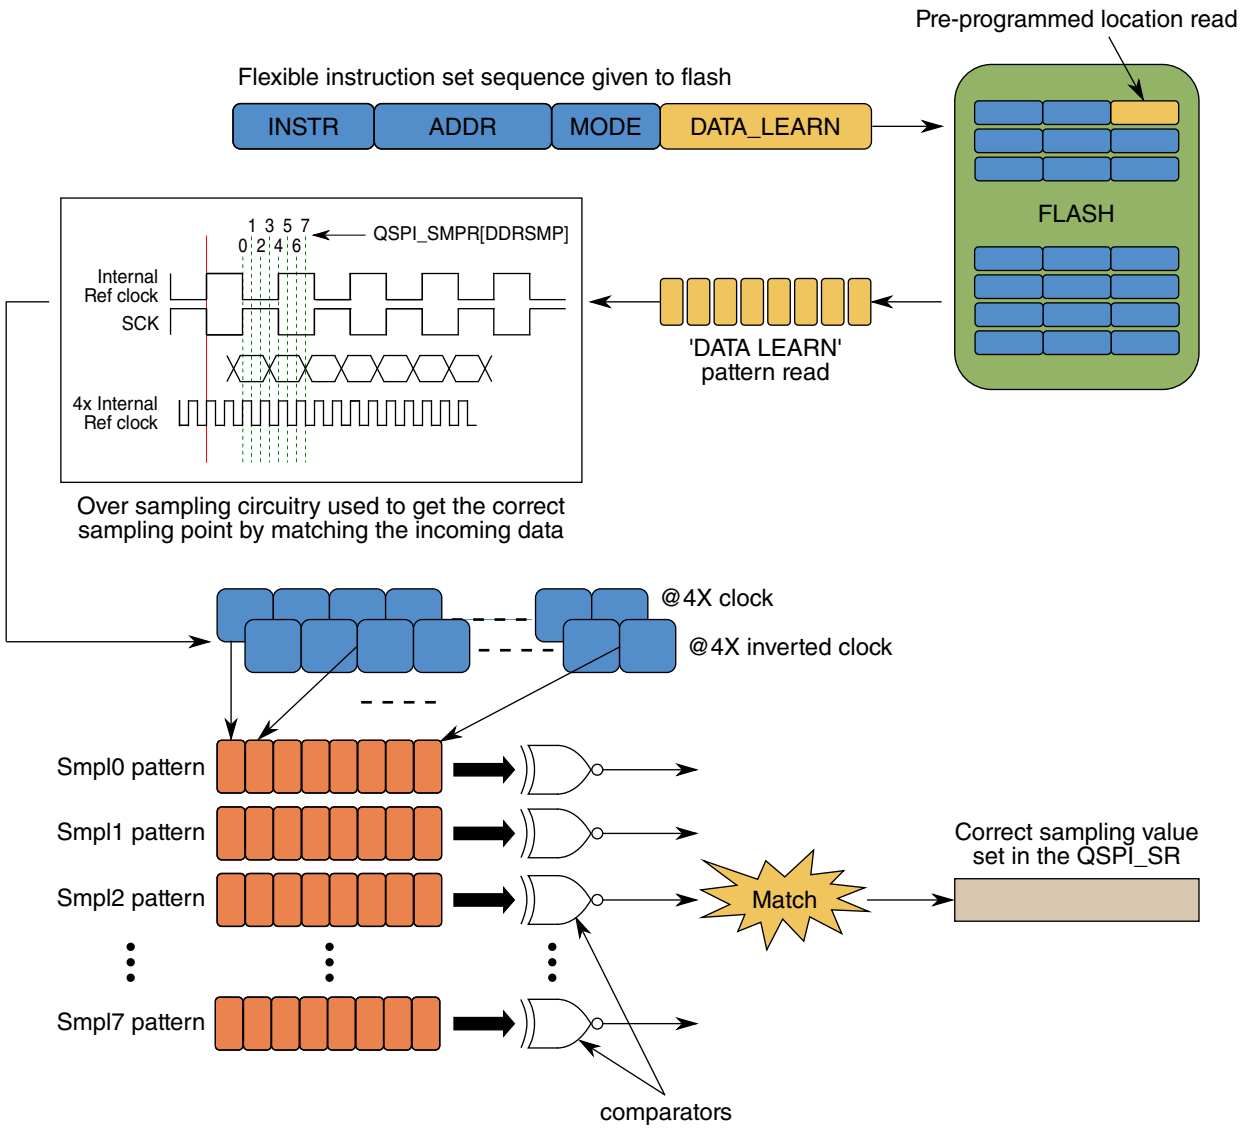

Figure 20-15. Data learning with 4x sampling method

20.12.4.3 Data Strobe (DQS) sampling method

Semi-automatic data learning is supported in DQS sampling method. To start data learning:

1. Certain flash memories provide data learning as a feature for DDR data reads.

   For flash memories that support data learning, configure a known pattern in the Data Learn register inside flash. The pattern should be chosen to have multiple low and high transitions in the data bus. Set up a QuadSPI DDR data read sequence, inserting a DATA_LEARN instruction before the READ_DDR instruction. The flash will itself return the data learning pattern in between dummy cycles in every read command. Each I/O will output the same DLP value for every clock edge.

For flash memories that *do not* support data learning, configure a known location in flash memory with a known pattern. The pattern should not have 0x00 or 0xFF in it. The pattern should be chosen to have multiple low and high transitions in the data bus. Set up a QuadSPI DDR data read sequence, inserting a DATA_LEARN instruction before the READ_DDR instruction. The address in the QSPI_SFAR register should point to the known location with the pattern. Configure the known pattern in the QSPI_DLPR[DLPV] field. Refer to Table 20-46 for details on how the data has to be ordered in memory for correct operation.

2. Select a sampling point. See chip-specific QuadSPI information for selection of the sampling point.
3. Initiate the read via a peripheral transaction.
4. QuadSPI reads the data from the flash. It then encounters the DATA_LEARN instruction and samples the incoming data on both edges (rising and falling) of the DQS.
5. If the data from the flash doesn't match the data learning pattern, the QuadSPI_FR[DLPFF] flag is set.
6. No sampling point is reported automatically by the QuadSPI module.
7. These steps (2-7) are repeated with varying VT conditions for a particular process until the QuadSPI_FR[DLPFF] is set. The sampling points where no QuadSPI_FR[DLPFF] is set signify valid setting.
8. In the case of multiple valid settings, software should choose the middle point.
9. The sampling point should be fixed with the above chosen point for the next READ transactions.

NOTE

It must be ensured that QuadSPI is not accessed during calibration.

NOTE

Ensure that there is no latency in between DQS edges while doing data learning using DQS sampling method.

This feature may be used to auto-calibrate the sampling point for DDR reads. This auto-calibration may be triggered at fixed intervals, or depending on a change in PVT conditions.

The following figure shows data learning in DQS mode:

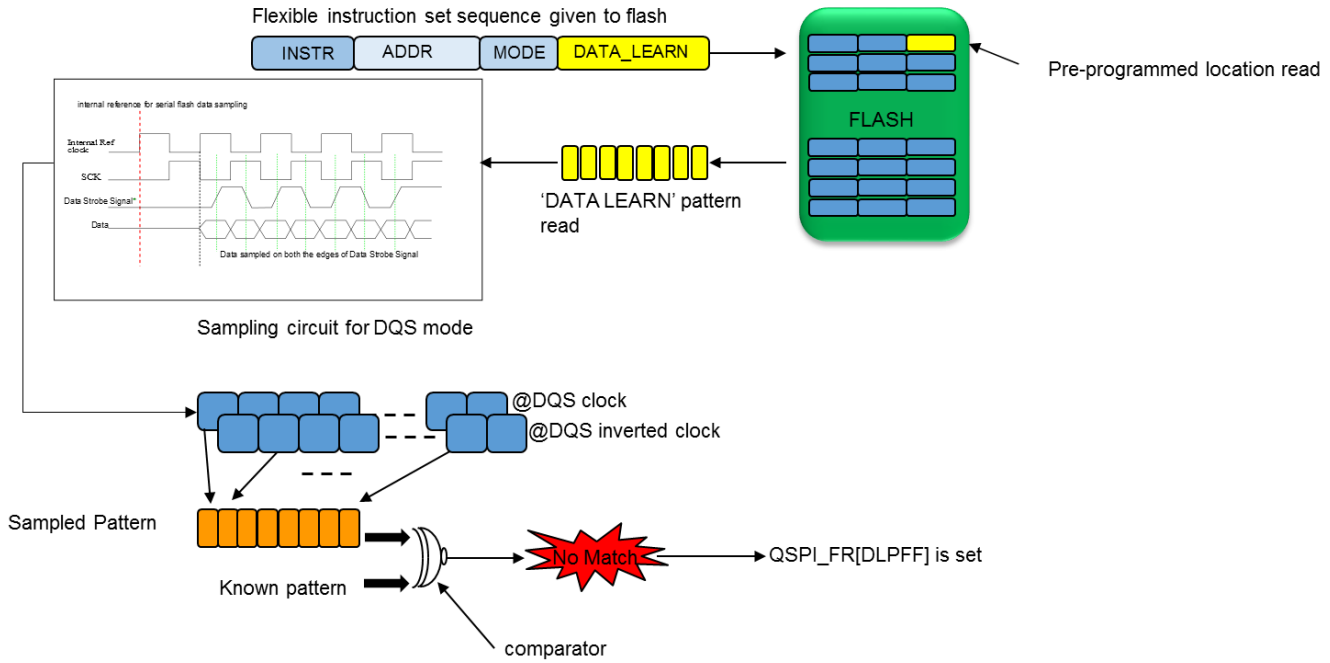

Figure 20-16. Data learning with DQS sampling method

20.12.4.4 Example: programming the data learning pattern in flash memory

If QSPI_DLPR[DLPV] is set to 0x43, QuadSPI tries to match this sample on every incoming data line for single, dual, quad, or octal configurations. The table below shows the data programmed in flash with endianness taken into consideration.

Table 20-46. Programming the Data Learning Pattern in flash memory

Endianness	Single IO	Dual IO	Quad IO	Octal IO
BE	0x43	0x300F	0x0F0000FF	0x00FF00000000FFFF
LE	0x43	0X0F30	0XFF00000F	0XFFFF0000000000FF

20.13 Data Input Hold Requirement of Flash

In DDR mode, the data is valid only for half clock cycle. It is difficult to meet the data input hold time requirement of flash. QuadSPI internally delays the data sent to flash so that it will be easy to meet the hold requirement. The QSPI_FLSHCR[TDH] is used for this purpose. If QSPI_FLSHCR[TDH] is configured to 0, the data sent to flash is aligned

with the internal reference clock of QuadSPI, if it is 1, then, the data is aligned to 2x internal reference half clock, if it is 2, then, the data is aligned to 4x internal reference half clock.

21.1.1 External Bus Interface (FlexBus)

The External Bus Interface (FlexBus) module provides external memory expansion and provides connection to external peripherals with a parallel, memory-mapped interface. The FlexBus supports asynchronous and synchronous interface to external ROM, NOR flash, SRAM, PSRAM, programmble logic devices and other memory-mapped slave devices. The FlexBus supports 8-bit, 16-bit and 32-bit data bus width options and the multiplexing of address and data configuration. The following table shows the configuration of the FlexBus.

Table 21-2. Flexbus configuration

Parameter	Description
Name	External Bus Interface (FlexBus)
Instances	1
Configurable features	NA
Interface speed	Up to 100 MHz
External I/O pins	See the attached IOMUXC spreadsheet for pin details.

21.1.2 Transfer Acknowledge signal

The Transfer Acknowledge Signal ($\overline{\text{FB\_TA}}$) is hard-wired in the design of I.MX 7ULP, so this signal is not available. See the FB_CSPMCR register for the multiplexing of other signals.

21.1.3 Reset value for CSCRn register

The reset values of CSCR0-CSCR5 for i.MX 7ULP are specified in the table below

Table 21-3. CSCRn reset values

Register name	Reset value
CSCR0	0x003F_FC00
CSCR1-CSCR5	0x0000_0000

21.2 Introduction

The FlexBus multifunction external bus interface controller:

- Provides memory expansion and provides connection to external peripherals with a parallel bus
- Provides connections to external peripherals with a parallel bus, and is often used to expand memory
- Can be directly connected to asynchronous or synchronous slave-only devices, using little or no additional circuitry:
  - External ROMs
  - Flash memories
  - Programmable logic devices
  - Other simple target (slave) devices

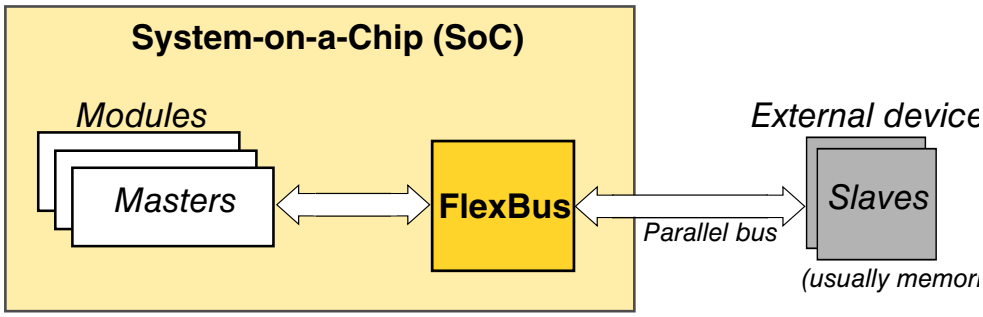

Figure 21-1. Flexbus module in a System-on-a-Chip (SoC)

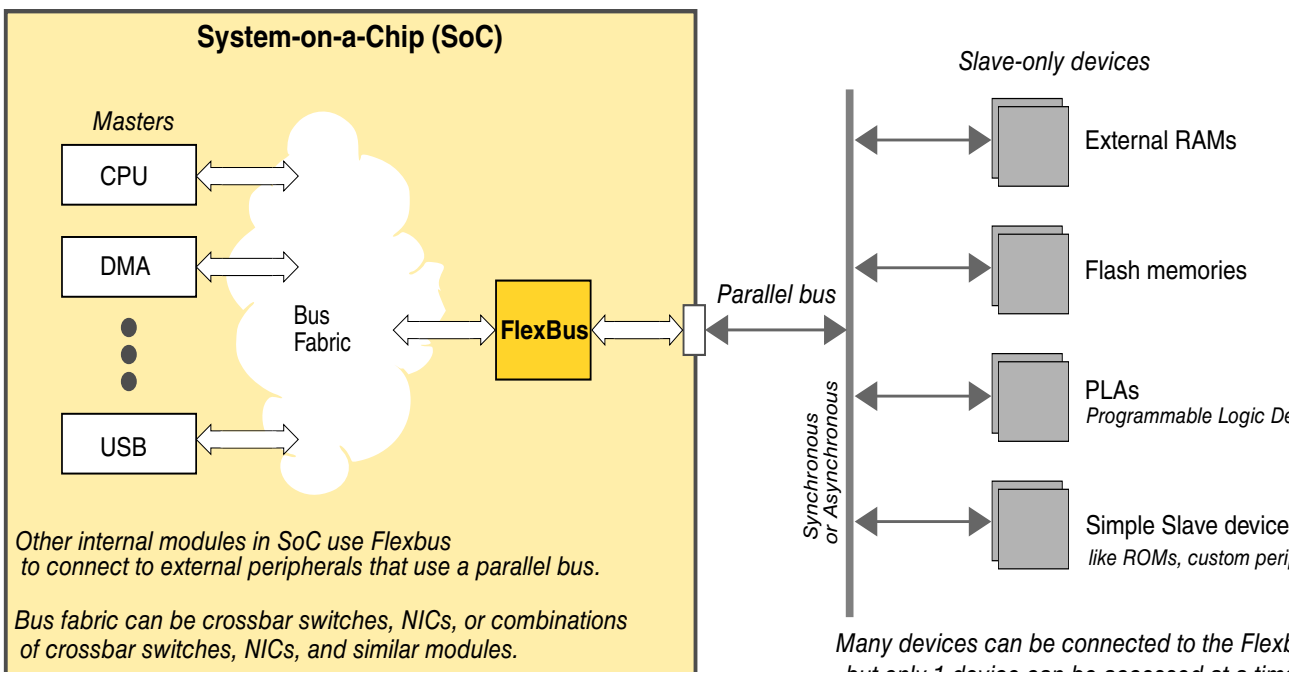

Figure 21-2. Flexbus module in SoC details

FlexBus features:

- 6 independent, user-programmable chip-select signals (active low) (FB_CS 5 – FB_CS0)
- 8-bit, 16-bit, and 32-bit transfers
- Programmable burst and burst-inhibited transfers selectable for each chip-select and transfer direction
- Programmable address-setup time with reference to the assertion of a chip-select
- Programmable address-hold time with reference to the deassertion of a chip-select and transfer direction
- Extended transfer start/address latch enable option to assist with glueless connections to synchronous and asynchronous memory devices

21.3 Signal descriptions

This table describes the external signals involved in data-transfer operations.

NOTE

Not all of the following signals may be available on a particular device. See the Chip Configuration details for information on which signals are available.

NOTE

Throughout this document, active low signals are indicated by one of 3 methods:

- "_b" appended to the end of a signal name
- a black line (called an "overbar") over the signal name
- a phrase "active low" next to the signal name

Table 21-4. FlexBus signal descriptions

Signal	I/O	Function
FB_AD31 - FB_AD0 (multiplexed address/ data bus)	I/O	When FlexBus is used in a multiplexed configuration, this is the address and data bus, FB_AD. The number of byte lanes carrying the data is determined by the port size associated with the matching chip-select. The full 32-bit address is driven on the first clock of a bus cycle (address phase). After the first clock, the data is driven on the bus (data phase). During the data phase, the address is driven on the pins not used for data. For example, in 16-bit mode, the lower address is driven on FB_AD15–FB_AD0, and in 8-bit mode, the lower address is driven on FB_AD23–FB_AD0.
FB_CS5 – FB_CS0	O	General Purpose Chip-Selects (active low)—Indicate which external memory or peripheral is selected. A particular chip-select is asserted when the transfer address is within the external memory's or peripheral's address space, as defined in CSAR[BA] and CSMR[BAM].
FB_BE_31_24 FB_BE_23_16 FB_BE_15_8 FB_BE_7_0	O	Byte Enables (active low)—Indicate that data is to be latched or driven onto a specific byte lane of the data bus. CSCR[BEM] determines if these signals are asserted on reads and writes or on writes only. For external SRAM or flash devices, the active low FB_BE outputs should be connected to individual byte strobe signals.
FB_OE_b	O	Output Enable (active low)—Sent to the external memory or peripheral to enable a read transfer. This signal is asserted during read accesses only when a chip-select matches the current address decode.
FB_R/W_b	O	Read/Write—Indicates whether the current bus operation is a read operation (FB_R/W_b high) or a write operation (FB_R/W_b low).
FB_TS_b	O	Transfer Start—Indicates that the chip has begun a bus transaction and that the address and attributes are valid. An inverted FB_TS_b is available as an address latch enable (FB_ALE), which indicates when the address is being driven on the FB_AD bus.

Table continues on the next page...

Table 21-4. FlexBus signal descriptions (continued)

Signal	I/O	Function
		FB_TS_b /FB_ALE is asserted for one bus clock cycle. The chip can extend this signal until the first positive clock edge after active low FB_CS asserts. See CSCR[EXTS] and Extended Transfer Start/Address Latch Enable.
FB_ALE	O	Address Latch Enable—Indicates when the address is being driven on the FB_A bus (inverse of FB_TS_b).
FB_TSIZ1–FB_TSIZ0	O	Transfer Size—Indicates (along with FB_TBST_b) the data transfer size of the current bus operation. The interface supports 8-, 16-, and 32-bit operand transfers and allows accesses to 8-, 16-, and 32-bit data ports. • 00b = 4 bytes • 01b = 1 byte • 10b = 2 bytes • 11b = 16 bytes (line) For misaligned transfers, FB_TSIZ1–FB_TSIZ0 indicate the size of each transfer. For example, if a 32-bit access through a 32-bit port device occurs at a misaligned offset of 1h, 8 bits are transferred first (FB_TSIZ1–FB_TSIZ0 = 01b), 16 bits are transferred next at offset 2h (FB_TSIZ1–FB_TSIZ0 = 10b), and the final 8 bits are transferred at offset 4h (FB_TSIZ1–FB_TSIZ0 = 01b). For aligned transfers larger than the port size, FB_TSIZ1–FB_TSIZ0 behave as follows: • If bursting is used, FB_TSIZ1–FB_TSIZ0 are driven to the transfer size. • If bursting is inhibited, FB_TSIZ1–FB_TSIZ0 first show the entire transfer size and then show the port size. For burst-inhibited transfers, FB_TSIZ1–FB_TSIZ0 change with each FB_TS_b assertion to reflect the next transfer size. For transfers to port sizes smaller than the transfer size, FB_TSIZ1–FB_TSIZ0 indicate the size of the entire transfer on the first access and the size of the current port transfer on subsequent transfers. For example, for a 32-bit write to an 8-bit port, FB_TSIZ1–FB_TSIZ0 are 00b for the first transaction and 01b for the next three transactions. If bursting is used for a 32-bit write to an 8-bit port, FB_TSIZ1–FB_TSIZ0 are driven to 00b for the entire transfer.
FB_TBST_b	O	Transfer Burst—Indicates that a burst transfer is in progress as driven by the chip. A burst transfer can be 2 to 16 beats depending on FB_TSIZ1–FB_TSIZ0 and the port size. **Note:** When a burst transfer is in progress (FB_TBST_b = 0b), the transfer size is 16 bytes (FB_TSIZ1–FB_TSIZ0 = 11b), and the address is misaligned within the 16-byte boundary, the external memory or peripheral must be able to wrap around the address.
FB_TA_b	I	Transfer Acknowledge—Indicates that the external data transfer is complete. When FB_TA_b is asserted during a read transfer, FlexBus latches the data and then terminates the transfer. When FB_TA_b is asserted during a write transfer, the transfer is terminated. If auto-acknowledge is disabled (CSCR[AA] = 0), the external memory or peripheral drives FB_TA_b to terminate the transfer. If auto-acknowledge is enabled (CSCR[AA] = 1), FB_TA_b is generated internally after a specified number of wait states, or the external memory or peripheral may assert external FB_TA_b before the wait-state countdown to terminate the transfer early. The chip deasserts active low FB_CS one

Table continues on the next page...

Table 21-4. FlexBus signal descriptions (continued)

Signal	I/O	Function
		cycle after the last FB_TA_b is asserted. During read transfers, the external memory or peripheral must continue to drive data until FB_TA_b is recognized. For write transfers, the chip continues driving data one clock cycle after active low FB_CS is deasserted. The number of wait states is determined by CSCR or the external FB_TA_b input. If the external FB_TA_b is used, the external memory or peripheral has complete control of the number of wait states. **Note:** External memory or peripherals should assert FB_TA_b only while the active low FB_CS signal to the external memory or peripheral is asserted. The CSPMCR register controls muxing of FB_TA_b with other signals. When the CSPMCR register does not allow FB_TA_b control, auto-acknowledge must be used (CSCR[AA] =1'b1); otherwise the bus may hang.
FB_CLK	O	FlexBus Clock Output

21.4 Memory Map/Register Definition

The following tables describe the registers and bit meanings for configuring chip-select operation.

The actual number of chip selects available depends upon the device and its pin configuration. If the device does not support certain chip select signals or the pin is not configured for a chip-select function, then that corresponding set of chip-select registers has no effect on an external pin.

Note

You must set CSMR0[V] before the chip select registers take effect.

A bus error occurs when writing to reserved register locations (for example, when writing to the region between the CS registers and the pin mux). Addresses *base address* + (0x48 - 0x5C) are reserved.

21.4.1.2 Chip Select Address Register (CSAR0 - CSAR5)

21.4.1.2.1 Offset

Register	Offset
CSAR0	0h
CSAR1	Ch
CSAR2	18h
CSAR3	24h

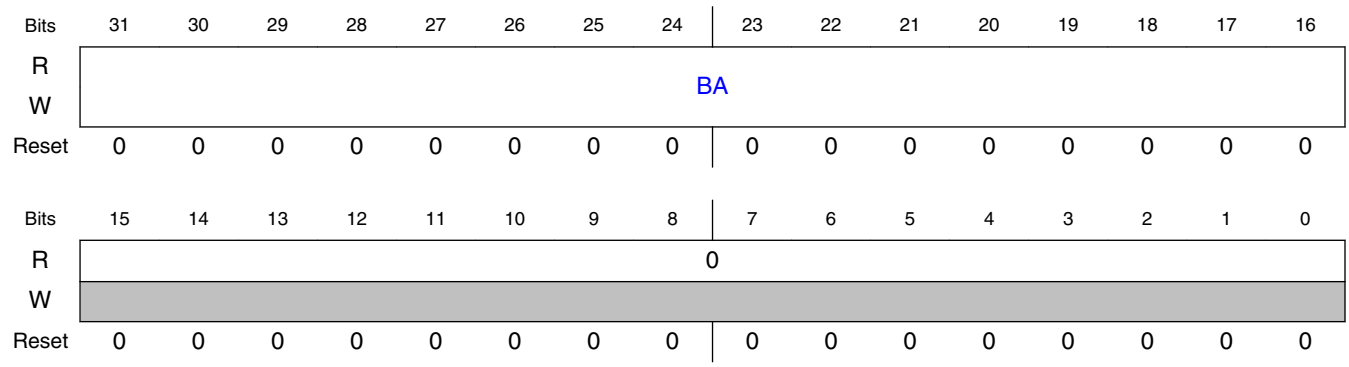
Table continues on the next page...

Register	Offset
CSAR4	30h
CSAR5	3Ch

21.4.1.2.2 Function

Specifies the associated chip-select's base address.

21.4.1.2.3 Diagram



21.4.1.2.4 Fields

Field	Function
31-16 BA	Base Address Defines the base address for memory dedicated to the associated chip-select. BA is compared to bits 31–16 on the internal address bus to determine if the associated chip-select's memory is being accessed. **NOTE:** Because the FlexBus module is one of the slaves connected to the crossbar switch, it is only accessible within a certain memory range. See the chip memory map for the applicable FlexBus "expansion" address range for which the chip-selects can be active. Set the CSARn and CSMRn registers appropriately before accessing this region.
15-0 —	Reserved

21.4.1.3 Chip Select Mask Register (CSMR0 - CSMR5)

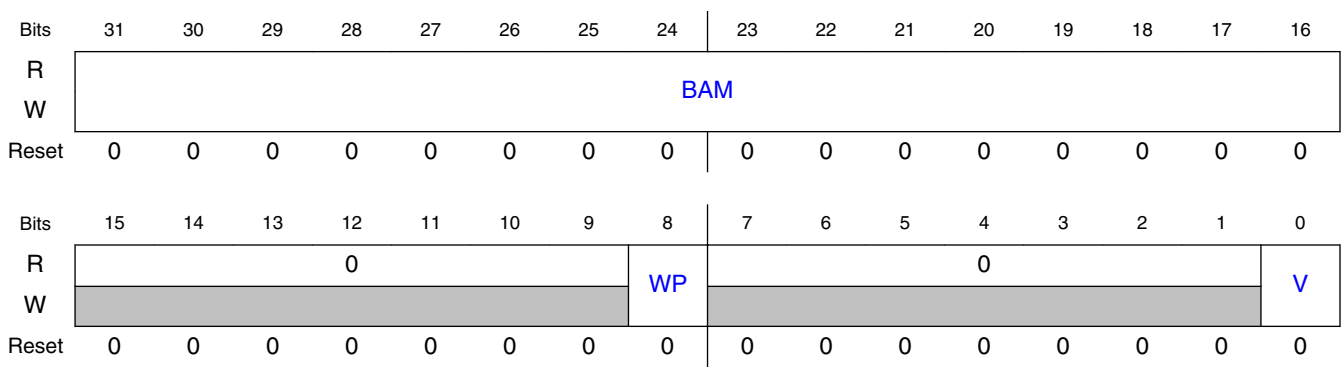
21.4.1.3.1 Offset

Register	Offset
CSMR0	4h
CSMR1	10h
CSMR2	1Ch
CSMR3	28h
CSMR4	34h
CSMR5	40h

21.4.1.3.2 Function

Specifies the address mask and allowable access types for the associated chip-select.

21.4.1.3.3 Diagram



21.4.1.3.4 Fields

Field	Function
31-16 BAM	Base Address Mask Defines the associated chip-select's block size by masking address bits. 0000000000000000b - The corresponding address bit in CSAR is used in the chip-select decode. 0000000000000001b - The corresponding address bit in CSAR is a don’t care in the chip-select decode.
15-9 —	Reserved
8 WP	Write Protect Controls write accesses to the address range in the corresponding CSAR. 0b - Write accesses are allowed. 1b - Write accesses are not allowed. Attempting to write to the range of addresses for which the WP bit is set results in a bus error termination of the internal cycle and no external cycle.

Table continues on the next page...

Field	Function
7-1 —	Reserved
0 V	Valid Specifies whether the corresponding CSAR, CSMR, and CSCR contents are valid. Programmed chip-selects do not assert until the V bit is 1b (except for FB_CS0_B, which acts as the global chip-select). **NOTE:** At reset, FB_CS0_B will fire for any access to the FlexBus memory region. CSMR0[V] must be set as part of the chip select initialization sequence to allow other chip selects to function as programmed. 0b - Chip-select is invalid. 1b - Chip-select is valid.

21.4.1.4 Chip Select Control Register (CSCR0 - CSCR5)

21.4.1.4.1 Offset

Register	Offset
CSCR0	8h
CSCR1	14h
CSCR2	20h
CSCR3	2Ch
CSCR4	38h
CSCR5	44h

21.4.1.4.2 Function

Controls the auto-acknowledge, address setup and hold times, port size, burst capability, and number of wait states for the associated chip select.

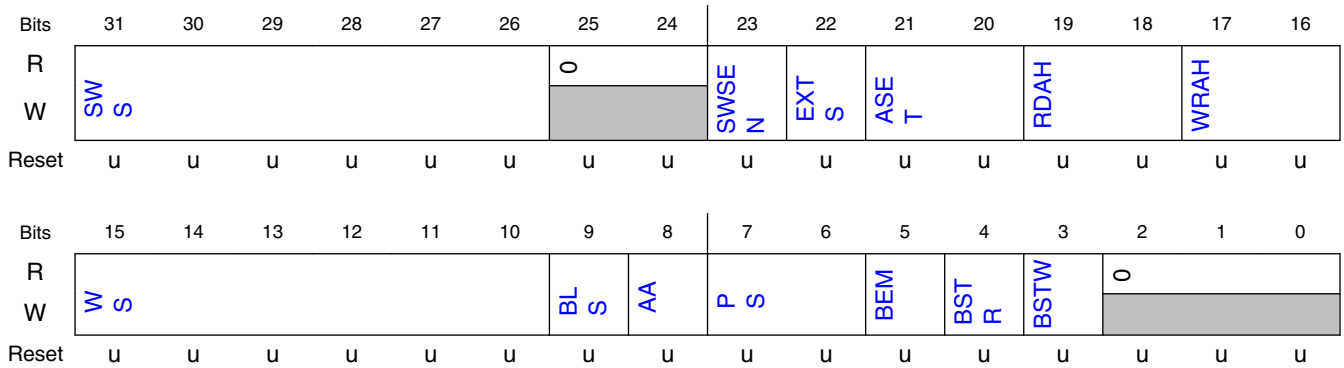
NOTE

To support the global chip-select (FB_CS0_B), the CSCR0 reset values differ from the other CSCRs (CSCR1 - CSCR5 all reset to 0). The reset value of CSCR0 is as follows:

- Bits 31 – 24 are 0b
- Bit 23 – 3 are chip-dependent
- Bits 2 – 0 are 0b

See the chip configuration details for your particular chip for information on the exact CSCR0 reset value.

21.4.1.4.3 Diagram



21.4.1.4.4 Fields

Field	Function
31-26 SWS	Secondary Wait States Used only when the SWSEN bit is 1b. Specifies the number of wait states inserted before an internal transfer acknowledge is generated for a burst transfer (except for the first termination, which is controlled by WS).
25-24 —	Reserved
23 SWSEN	Secondary Wait State Enable 0b - Disabled. A number of wait states (specified by WS) are inserted before an internal transfer acknowledge is generated for all transfers. 1b - Enabled. A number of wait states (specified by SWS) are inserted before an internal transfer acknowledge is generated for burst transfer secondary terminations.
22 EXTS	EXTS Extended Transfer Start/Extended Address Latch Enable Controls how long FB_TS_B/FB_ALE is asserted. 0b - Disabled. FB_TS_B/FB_ALE asserts for one bus clock cycle. 1b - Enabled. FB_TS_B/FB_ALE remains asserted until the first positive clock edge after FB_CSn_B asserts.
21-20 ASET	Address Setup Controls when the chip-select is asserted with respect to assertion of a valid address and attributes. 00b - Assert FB_CSn_B on the first rising clock edge after the address is asserted (default for all but FB_CS0_B). 01b - Assert FB_CSn_B on the second rising clock edge after the address is asserted. 10b - Assert FB_CSn_B on the third rising clock edge after the address is asserted. 11b - Assert FB_CSn_B on the fourth rising clock edge after the address is asserted (default for FB_CS0_B).
19-18 RDAH	Read Address Hold or Deselect Controls the address and attribute hold time after the termination during a read cycle that hits in the associated chip-select's address space.

Table continues on the next page...

Field	Function
	NOTE: • The hold time applies only at the end of a transfer. Therefore, during a burst transfer or a transfer to a port size smaller than the transfer size, the hold time is only added after the last bus cycle. • The number of cycles the address and attributes are held after FB_CSn_B deassertion depends on the value of the AA bit. 00b - When AA is 1b, 1 cycle. When AA is 0b, 0 cycles. 01b - When AA is 1b, 2 cycles. When AA is 0b, 1 cycle. 10b - When AA is 1b, 3 cycles. When AA is 0b, 2 cycles. 11b - When AA is 1b, 4 cycles. When AA is 0b, 3 cycles.
17-16 WRAH	Write Address Hold or Deselect Controls the address, data, and attribute hold time after the termination of a write cycle that hits in the associated chip-select's address space. **NOTE:** The hold time applies only at the end of a transfer. Therefore, during a burst transfer or a transfer to a port size smaller than the transfer size, the hold time is only added after the last bus cycle. 00b - 1 cycle (default for all but FB_CS0_B) 01b - 2 cycles 10b - 3 cycles 11b - 4 cycles (default for FB_CS0_B)
15-10 WS	Wait States Specifies the number of wait states inserted after FlexBus asserts the associated chip-select and before an internal transfer acknowledge is generated (WS = 00h inserts 0 wait states, ..., WS = 3Fh inserts 63 wait states).
9 BLS	Byte-Lane Shift Specifies if data on FB_AD appears left-aligned or right-aligned during the data phase of a FlexBus access. 0b - Not shifted. Data is left-aligned on FB_AD. 1b - Shifted. Data is right-aligned on FB_AD.
8 AA	Auto-Acknowledge Enable Asserts the internal transfer acknowledge for accesses specified by the chip-select address. **NOTE:** If AA is 1b for a corresponding FB_CSn_B and the external system asserts an external FB_TA_B before the wait-state countdown asserts the internal FB_TA_B, the cycle is terminated. Burst cycles increment the address bus between each internal termination. **NOTE:** This field must be 1b if CSPMCR disables FB_TA_B. 0b - Disabled. No internal transfer acknowledge is asserted and the cycle is terminated externally. 1b - Enabled. Internal transfer acknowledge is asserted as specified by WS.
7-6 PS	Port Size Specifies the data port width of the associated chip-select, and determines where data is driven during write cycles and where data is sampled during read cycles. 00b - 32-bit port size. Valid data is sampled and driven on FB_D[31:0]. 01b - 8-bit port size. Valid data is sampled and driven on FB_D[31:24] when BLS is 0b, or FB_D[7:0] when BLS is 1b. 1xb - 16-bit port size. Valid data is sampled and driven on FB_D[31:16] when BLS is 0b, or FB_D[15:0] when BLS is 1b.
5 BEM	Byte-Enable Mode Specifies whether the corresponding FB_BE_B is asserted for read accesses. Certain memories have byte enables that must be asserted during reads and writes. Write 1b to the BEM bit in the relevant CSCR to provide the appropriate mode of byte enable support for these SRAMs. 0b - FB_BE_B is asserted for data write only. 1b - FB_BE_B is asserted for data read and write accesses.

Table continues on the next page...

Field	Function
4 BSTR	Burst-Read Enable Specifies whether burst reads are enabled for memory associated with each chip select. 0b - Disabled. Data exceeding the specified port size is broken into individual, port-sized, non-burst reads. For example, a 32-bit read from an 8-bit port is broken into four 8-bit reads. 1b - Enabled. Enables data burst reads larger than the specified port size, including 32-bit reads from 8- and 16-bit ports, 16-bit reads from 8-bit ports, and line reads from 8-, 16-, and 32-bit ports.
3 BSTW	Burst-Write Enable Specifies whether burst writes are enabled for memory associated with each chip select. 0b - Disabled. Data exceeding the specified port size is broken into individual, port-sized, non-burst writes. For example, a 32-bit write to an 8-bit port takes four byte writes. 1b - Enabled. Enables burst write of data larger than the specified port size, including 32-bit writes to 8- and 16-bit ports, 16-bit writes to 8-bit ports, and line writes to 8-, 16-, and 32-bit ports.
2-0 —	Reserved

21.4.1.5 Chip Select Port Multiplexing Control Register (CSPMCR)

21.4.1.5.1 Offset

Register	Offset
CSPMCR	60h

21.4.1.5.2 Function

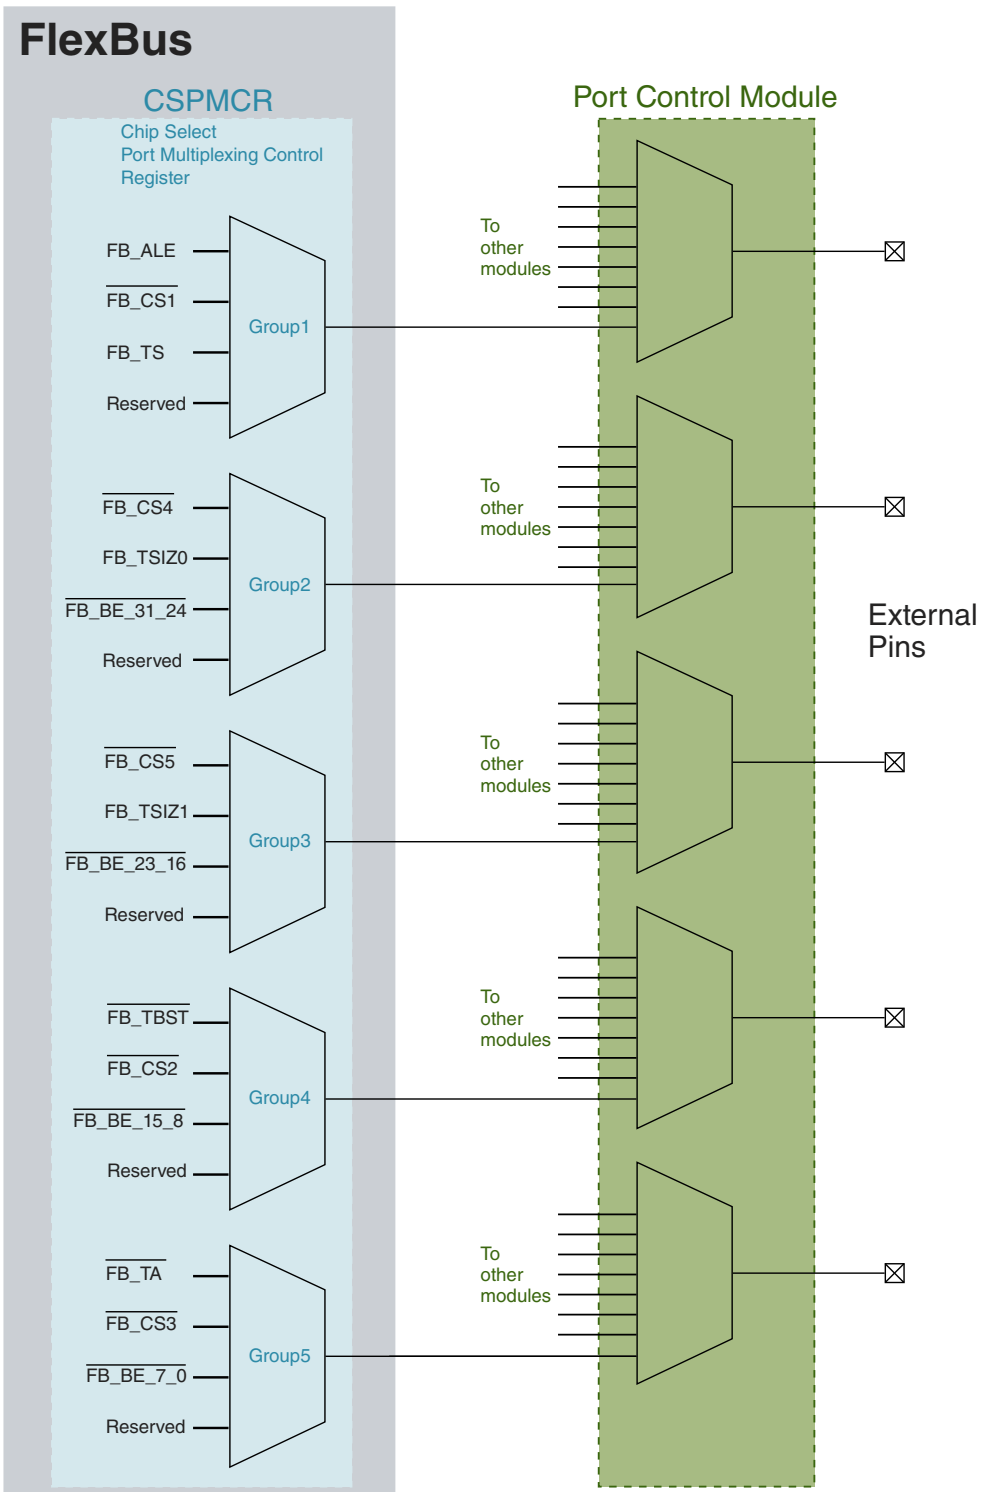
Controls the multiplexing of the FlexBus signals. Use the CSPMCR register (Chip Select Port Multiplexing Control) and port control registers to configure which control signals are available on the external pins.

The multiplexing of the FlexBus address and data signals is controlled by the port control module. However, the multiplexing of some of the FlexBus control signals are controlled by **both** the FlexBus and port control modules. The FlexBus's CSPMCR register configures which FlexBus signals are available from the FlexBus module, and the port control module registers control whether the FlexBus or other module signals are available on the external pin.

NOTE

A bus error occurs when you do any of the following:

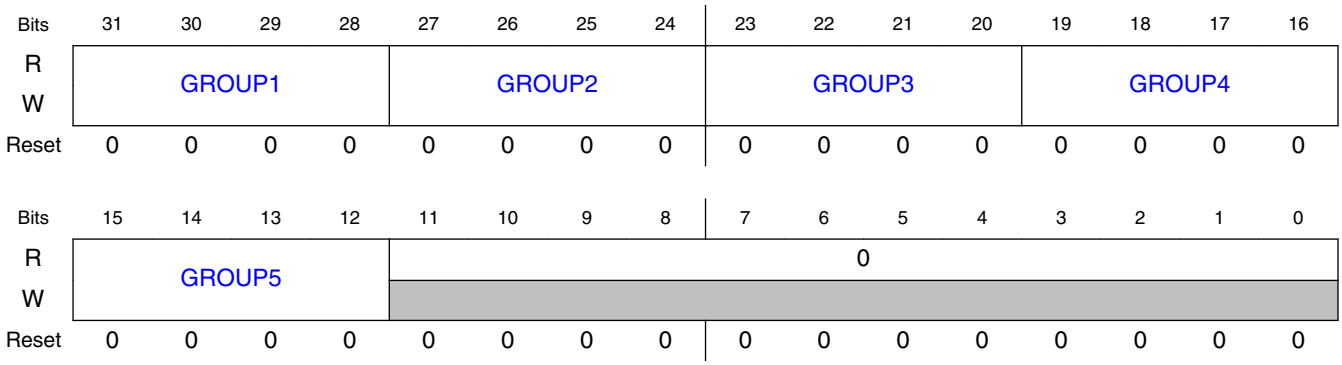
- Write to a reserved address
- Write to a reserved field in this register, or
- Access this register using a size other than 32 bits.



CSPMCR and Port Control Module control the multiplexing of signals to the external pins

Figure 21-3. FlexBus and Port Control module

21.4.1.5.3 Diagram



21.4.1.5.4 Fields

Field	Function
31-28 GROUP1	FlexBus Signal Group 1 Multiplex control Controls the multiplexing of the FB_ALE, FB_CS1_B, and FB_TS_B signals. 0000b - FB_ALE 0001b - FB_CS1_B 0010b - FB_TS_B
27-24 GROUP2	FlexBus Signal Group 2 Multiplex control Controls the multiplexing of the FB_CS4_B, FB_TSIZ0, and FB_BE_31_24_B signals. 0000b - FB_CS4_B 0001b - FB_TSIZ0 0010b - FB_BE_31_24_B
23-20 GROUP3	FlexBus Signal Group 3 Multiplex control Controls the multiplexing of the FB_CS5_B, FB_TSIZ1, and FB_BE_23_16_B signals. 0000b - FB_CS5_B 0001b - FB_TSIZ1 0010b - FB_BE_23_16_B
19-16 GROUP4	FlexBus Signal Group 4 Multiplex control Controls the multiplexing of the FB_TBST_B, FB_CS2_B, and FB_BE_15_8_B signals. 0000b - FB_TBST_B 0001b - FB_CS2_B 0010b - FB_BE_15_8_B
15-12 GROUP5	FlexBus Signal Group 5 Multiplex control Controls the multiplexing of the FB_TA_B, FB_CS3_B, and FB_BE_7_0_B signals. **NOTE:** When GROUP5 is not 0000b, you must write 1b to the CSCR[AA] bit. Otherwise, the bus hangs during a transfer. 0000b - FB_TA_B 0001b - FB_CS3_B. You must also write 1b to CSCR[AA]. 0010b - FB_BE_7_0_B. You must also write 1b to CSCR[AA].
11-0 —	Reserved

21.5 Functional description

21.5.1 Address and data bus configurations

NOTE

Address and data line configurations require signals to actually be available on the pins of your specific device's package. To make sure that the address and data bus signals are available on a specific device's pins, see your device's signal multiplexing table for that device package.

FlexBus supports:

- **Multiplexed address and data lines:**
  - Multiplexed 32-bit address and 32-bit data
  - Multiplexed 32-bit address and 16-bit data (non-multiplexed 16-bit address and 16-bit data)
  - Multiplexed 32-bit address and 8-bit data (non-multiplexed 24-bit address and 8-bit data)

21.5.2 Address comparison

When a bus cycle is routed to FlexBus, FlexBus compares the transfer address to the base address (see CSAR[BA]) and base address mask (see CSMR[BAM]). This table describes how FlexBus decides to assert a chip-select and complete the bus cycle based on the address comparison.

When the transfer address	Then FlexBus
Matches one address register configuration	Asserts the appropriate chip-select, generating a FlexBus bus cycle as defined in the appropriate CSCR. If CSMR[WP] is set and a write access is performed, FlexBus terminates the internal bus cycle with a bus error, does not assert a chip-select, and does not perform an external bus cycle.
Does not match an address register configuration	Terminates the transfer with a bus error response, does not assert a chip-select, and does not perform a FlexBus cycle.
Matches more than one address register configuration	Terminates the transfer with a bus error response, does not assert a chip-select, and does not perform a FlexBus cycle.

21.5.3 Address driven on address bus

Regardless of the external memory's or peripheral's address size,

- For multiplexed address and data busses, FlexBus always drives a 32-bit address on the FB_AD bus.

21.5.4 Connecting address/data lines

The external device must connect its address and data lines as follows:

- Address lines
  - FB_AD from FB_AD0 upward
- Data lines
  - If CSCR[BLS] = 0, FB_AD from FB_AD31 downward
  - If CSCR[BLS] = 1, FB_AD from FB_AD0 upward

21.5.5 Bit ordering

No bit ordering is required when connecting address and data lines to the FB_AD bus. For example, a full 16-bit address/16-bit data device connects its addr15–addr0 to FB_AD16–FB_AD1 and data15–data0 to FB_AD31–FB_AD16. See Data-byte alignment and physical connections for a graphical connection.

21.5.6 Data transfer signals

Data transfers between FlexBus and the external memory or peripheral involve these signals:

- Address/data bus (FB_AD31–FB_AD0 (multiplexed address/data bus))
- Control signals (FB_TS_b/FB_ALE, FB_TA_b, FB_CS_b*n*, FB_OE_b, FB_R/W_b, FB_BE*n*)
- Attribute signals (FB_TBST_b, FB_TSIZ1–FB_TSIZ0)

21.5.7 Signal transitions

These signals change on the rising edge of the FlexBus clock (FB_CLK):

- Address
- Write data

- FB_TS_b/FB_ALE
- active low FB_CSn
- All attribute signals

FlexBus latches the read data on the rising edge of the clock.

21.5.8 Data-byte alignment and physical connections

The device aligns data transfers in FlexBus byte lanes with the number of lanes depending on the data port width.

The following figure shows the byte lanes that external memory or peripheral connects to and the sequential transfers of a 32-bit transfer for the supported port sizes when byte lane shift is disabled. For example, an 8-bit memory connects to the single lane FB_AD31–FB_AD24 (FB_BE_31_24, active low). A 32-bit transfer through this 8-bit port takes 4 transfers, starting with the LSB to the MSB. A 32-bit transfer through a 32-bit port requires one transfer on each 4-byte lane.

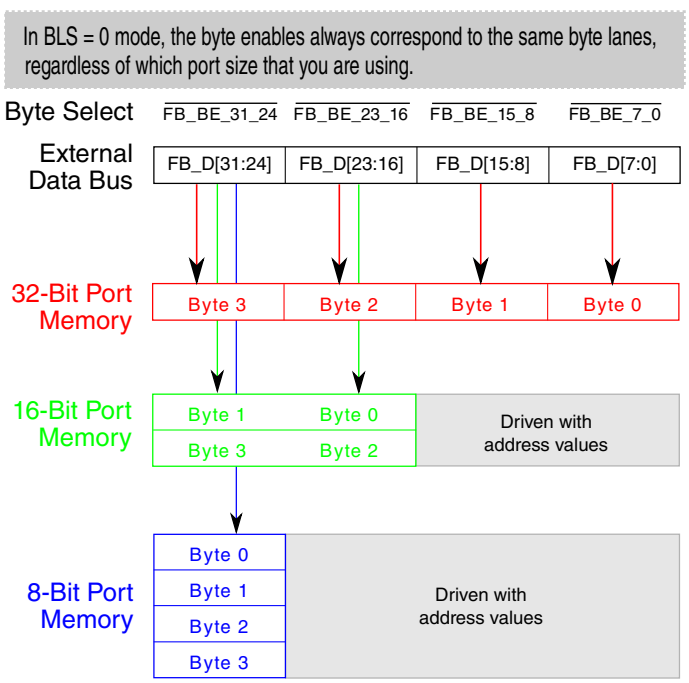


Figure 21-4. Connections for external memory port sizes (CSCRn[BLS] = 0)

The following figure shows the byte lanes that external memory or peripheral connects to and the sequential transfers of a 32-bit transfer for the supported port sizes when byte lane shift is enabled.

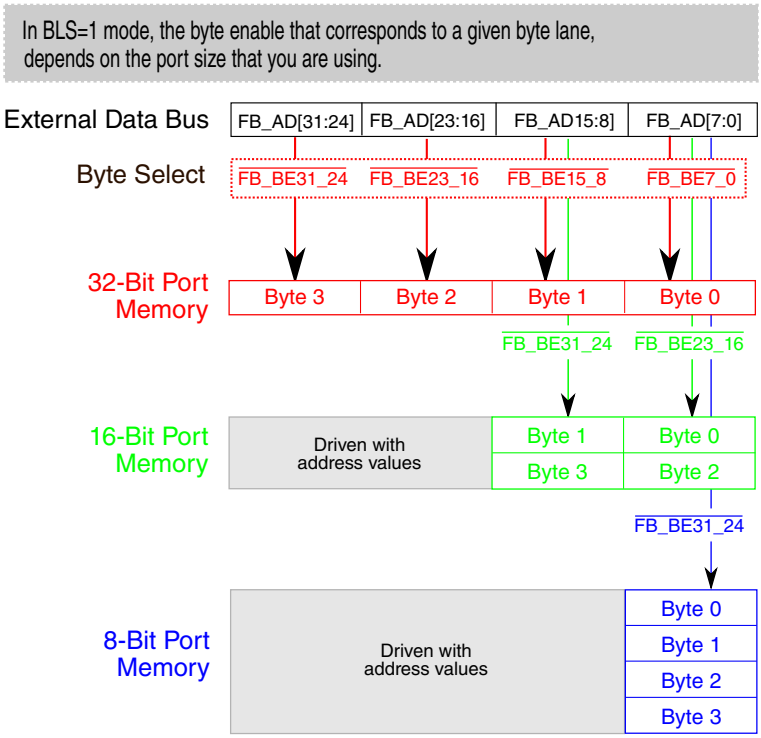

Figure 21-5. Connections for external memory port sizes (CSCRn[BLS] = 1)

21.5.9 Address/data bus multiplexing

FlexBus supports a single 32-bit wide multiplexed address and data bus (FB_AD31–FB_AD0). FlexBus always drives the full 32-bit address on the first clock of a bus cycle. During the data phase, the FB_AD31– FB_AD0 lines used for data are determined by the programmed port size and BLS setting for the corresponding chip-select. FlexBus continues to drive the address on any FB_AD31– FB_AD0 lines not used for data.

21.5.9.1 FlexBus multiplexed operating modes for CSCRn[BLS]=0

This table shows the supported combinations of address and data bus widths when CSCRn[BLS] is 0b.

Port size and phase		FB_AD			
		31–24	23–16	15–8	7–0
32-bit	Address phase	Address			
	Data phase	Data			
16-bit	Address phase	Address			
	Data phase	Data		Address	

Table continues on the next page...

Port size and phase		FB_AD			
		31–24	23–16	15–8	7–0
8-bit	Address phase	Address			
	Data phase	Data	Address		

21.5.9.2 FlexBus multiplexed operating modes for CSCRn[BLS]=1

This table shows the supported combinations of address and data bus widths when CSCRn[BLS] is 1b.

Port size and phase		FB_AD			
		31–24	23–16	15–8	7–0
32-bit	Address phase	Address			
	Data phase	Data			
16-bit	Address phase	Address			
	Data phase	Address		Data	
8-bit	Address phase	Address			
	Data phase	Address			Data

21.5.10 Data transfer states

Basic data transfers occur in 4 clocks or states. (See Basic Read Bus Cycle and Basic Write Bus Cycle for examples of basic data transfers.) The FlexBus state machine controls the data-transfer operation. This figure shows the state-transition diagram for basic read and write cycles.

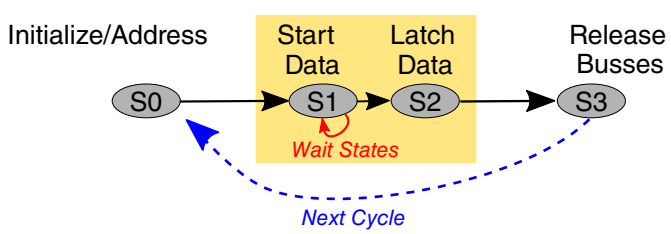

Figure 21-6. Data transfer state transitions

State		Cycle	Description
Initialize/ address	S0	All	The read or write cycle is initiated. On the rising clock edge, FlexBus: • Places a valid address on FB_ADn

Table continues on the next page...

State		Cycle	Description
			• Asserts FB_TS_b/FB_ALE • Drives FB_R/W_b high for a read and low for a write
Start data phase	S1	All	FlexBus: • Negates FB_TS_b/FB_ALE on the rising edge of FB_CLK • Asserts FB_CSn (active low) • Drives the data on FB_AD31– FB_AD*X* for writes • Tristates FB_AD31– FB_AD*X* for reads • Continues to drive the address on FB_AD pins that are unused for data • If the external memory or peripheral asserts FB_TA_b, then the process moves to S2. • If FB_TA_b is not asserted internally or externally, then S1 repeats.
		Read	The external memory or peripheral drives the data before the next rising edge of FB_CLK (the rising edge that begins S2) with FB_TA_b asserted.
Latch data	S2	All	• For internal termination, FlexBus negates FB_CSn (active low) and the transfer is complete. • For external termination, the external memory or peripheral negates FB_TA_b, then FlexBus negates FB_CSn (active low) after the rising edge of FB_CLK at the end of S2.
		Read	FlexBus latches the data on the rising clock edge entering S2. The external memory or peripheral can stop driving the data after this edge, or continue to drive the data until the end of S3 or drive the data through any additional address hold cycles.
Release busses	S3	All	FlexBus invalidates the address, data, and FB_R/W_b on the rising edge of FB_CLK at the beginning of S3, terminating the transfer.

21.5.11 FlexBus Timing Examples

Note

The timing diagrams in this section use signal names that may not be included on your particular device, so ignore these signals.

Note

Throughout this section:

- FB_D[*X*] indicates a 32-, 16-, or 8-bit wide data bus
- FB_A[*Y*] indicates an address bus that can be 32, 24, or 16 bits wide.

21.5.11.1 Basic Read Bus Cycle

During a read cycle, the MCU receives data from memory or a peripheral device.

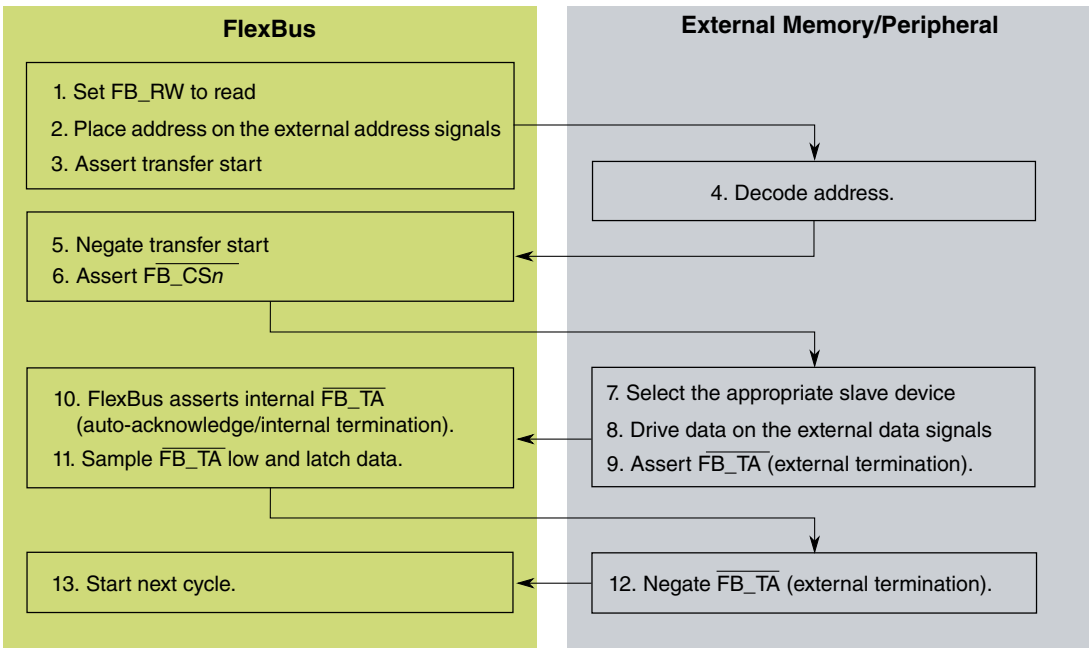

Figure 21-7. Read Cycle Flowchart

Note

FB_TA_b (active low) does not have to be driven by the external device for internally-terminated bus cycles.

Note

The processor drives the data lines during the first clock cycle of the transfer with the full 32-bit address. This may be ignored by standard connected devices using non-multiplexed address and data buses. However, some applications may find this feature beneficial.

The address and data busses are muxed between the FlexBus and another module. At the end of the read bus cycles the address signals are indeterminate.

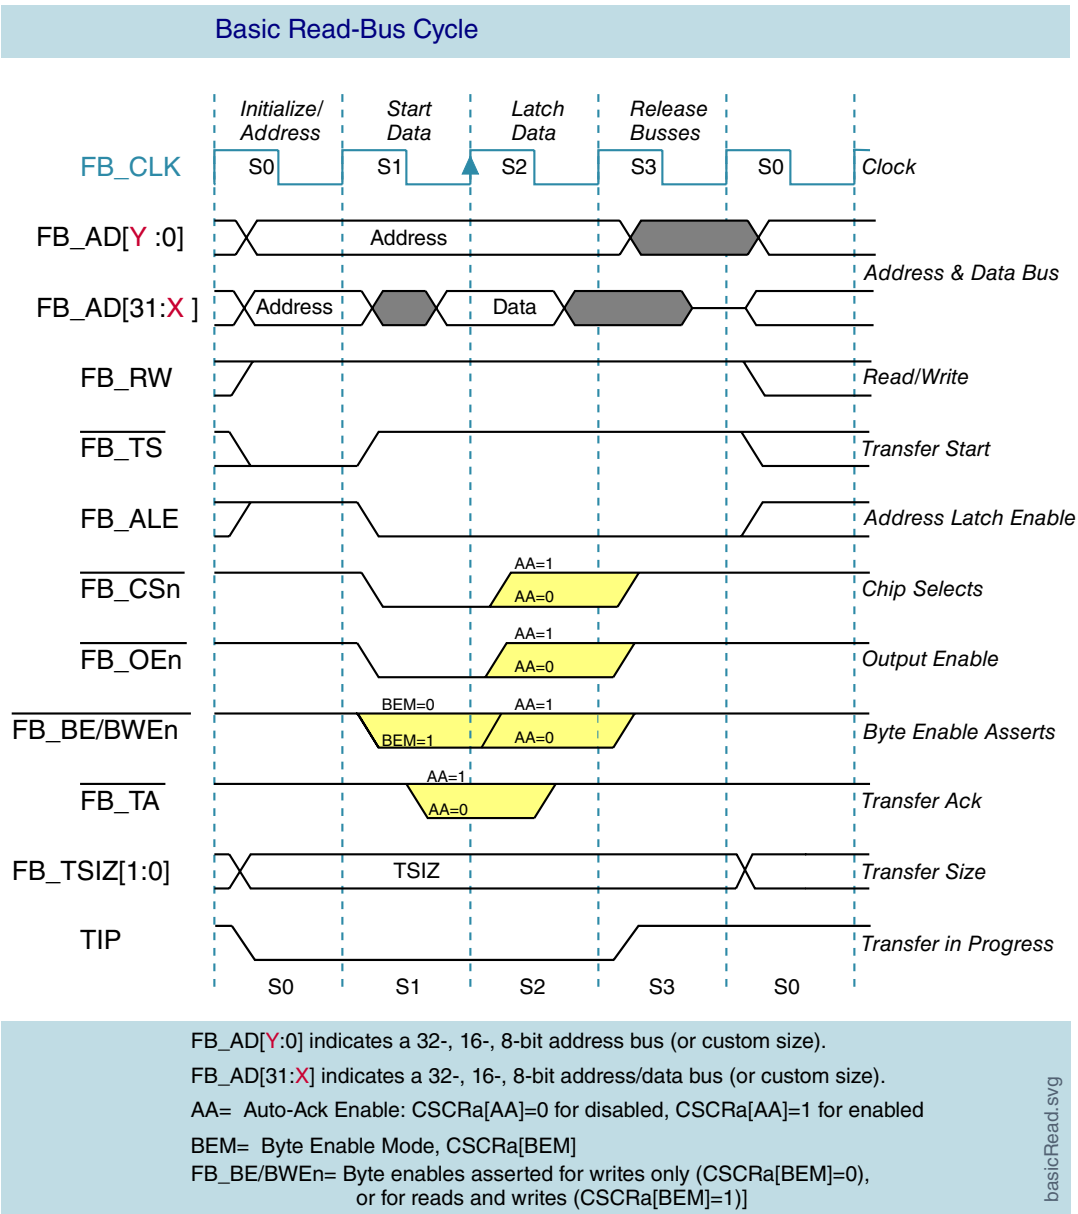

Figure 21-8. Basic Read Bus Cycle

21.5.11.2 Basic Write Bus Cycle

During a write cycle, the device sends data to memory or to a peripheral device.

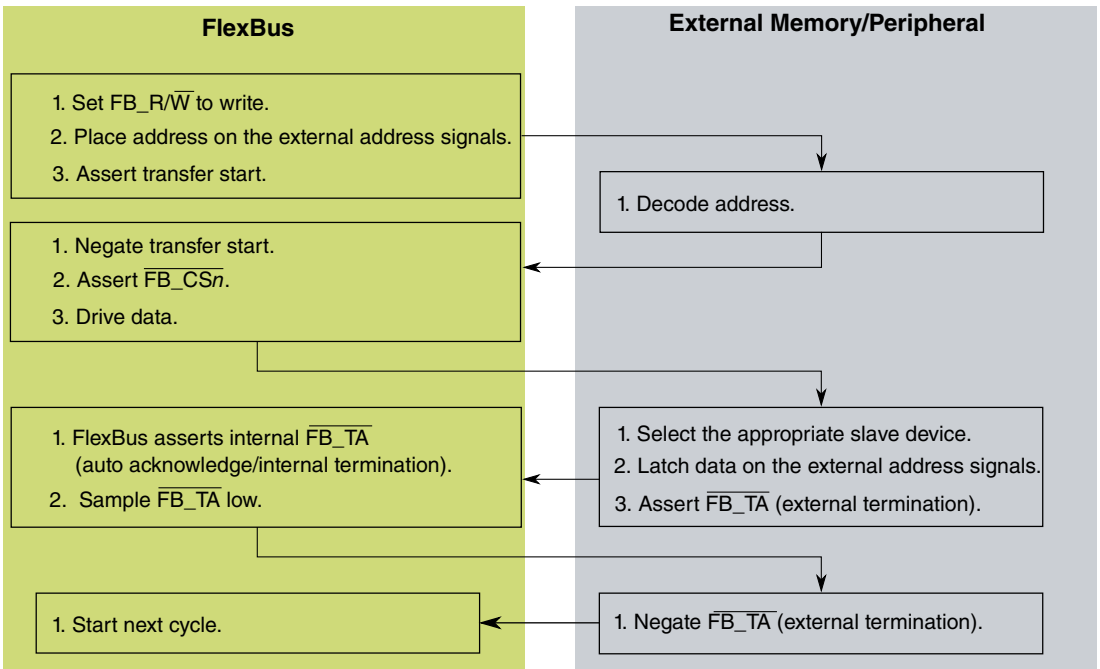

Figure 21-9. Write Cycle Flowchart

Note

The address and data busses are muxed between the FlexBus and another module. At the end of the write bus cycles, the address signals are indeterminate.

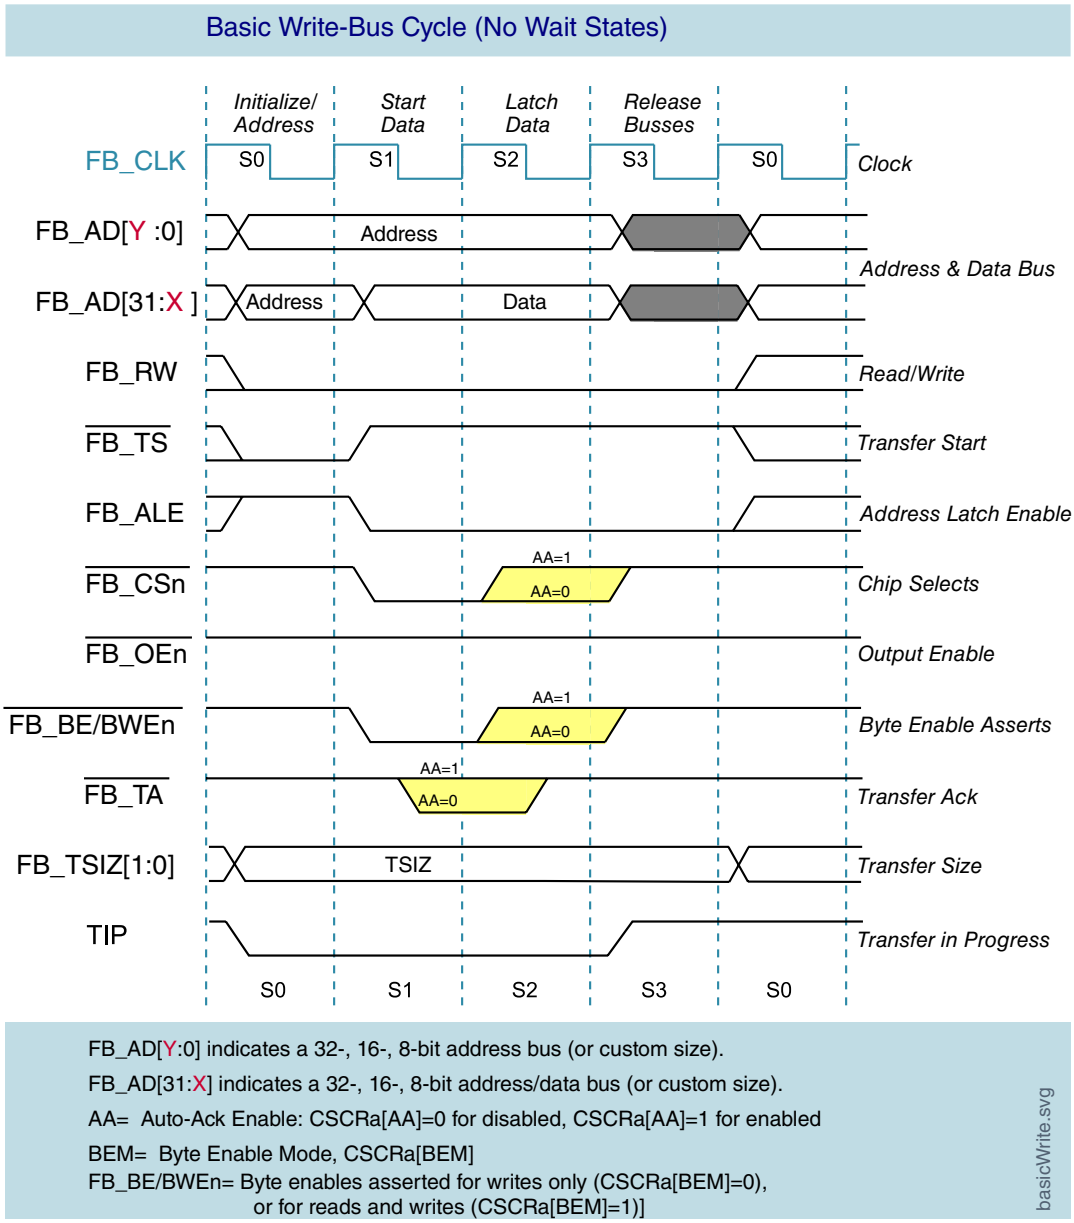

Figure 21-10. Basic Write Bus Cycle

21.5.11.3 Bus Cycle Sizing

This section shows timing diagrams for various port size scenarios.

NOTE

All examples in this "Bus Cycle Sizing" section assume BLS=0.

21.5.11.3.1 Bus Cycle Sizing—Byte Transfer, 8-bit Device, No Wait States

The next figure shows the basic byte read transfer to an 8-bit device with no wait states:

- For multiplexed address and data busses, the address is driven on the full FB_AD[31:0] bus in the 1st clock; the device tristates FB_AD[31:24] on the 2nd clock and continues to drive address on FB_AD[23:0] throughout the bus cycle.
- The external device returns the read data on FB_AD[31:24] and may tristate the data line or continue driving the data 1 clock after FB_TA_b (active low) is sampled asserted.

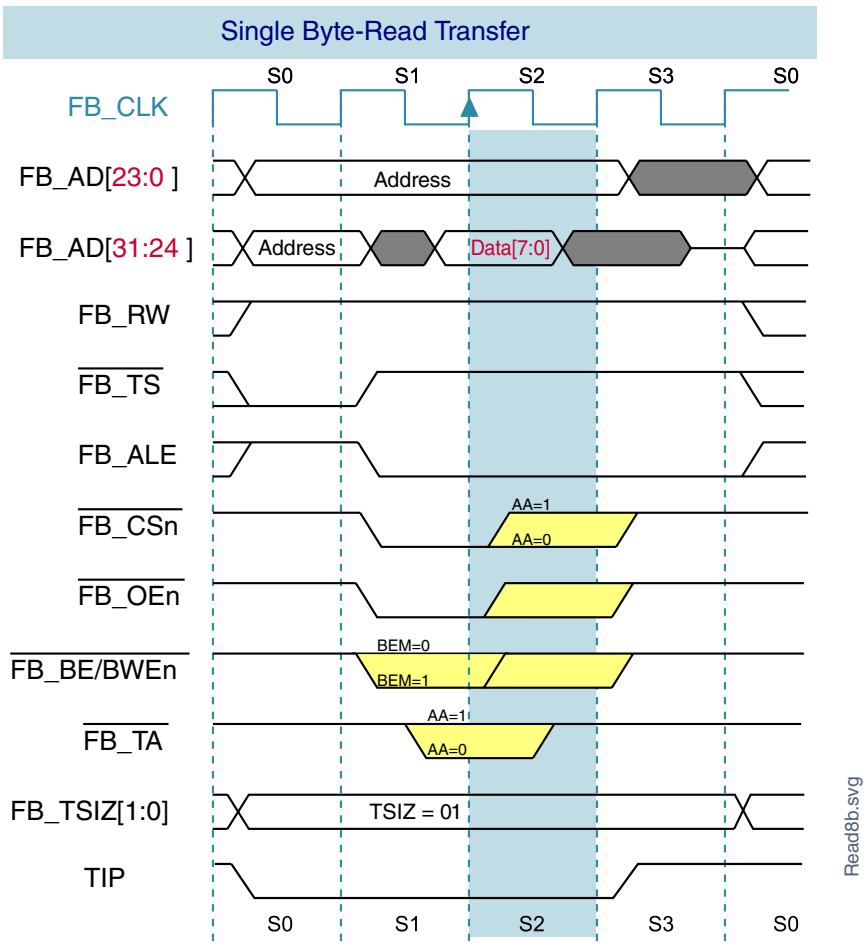

Figure 21-11. Single Byte-Read Transfer

The next figure shows the similar configuration for a write transfer. The data is driven from the 2nd clock on FB_AD[31:24].

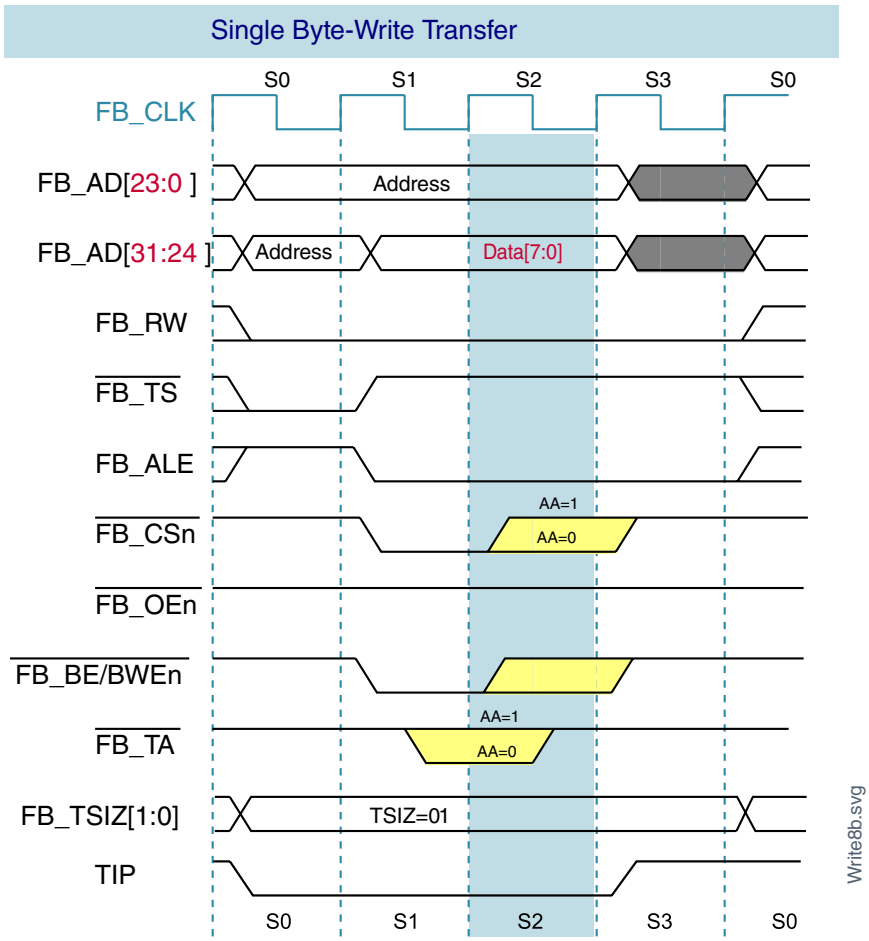

Figure 21-12. Single Byte-Write Transfer

21.5.11.3.2 Bus Cycle Sizing—Word Transfer, 16-bit Device, No Wait States

The next figure shows a basic word read transfer to a 16-bit device with no wait states.

- For multiplexed address and data busses, the address is driven on the full FB_AD[31:0] bus in the first clock; the device tristates FB_AD[31:16] on the second clock and continues to drive address on FB_AD[15:0] throughout the bus cycle.
- The external device returns the read data on FB_AD[31:16] and may tristate the data line or continue driving the data one clock after FB_TA_b (active low) is sampled asserted.

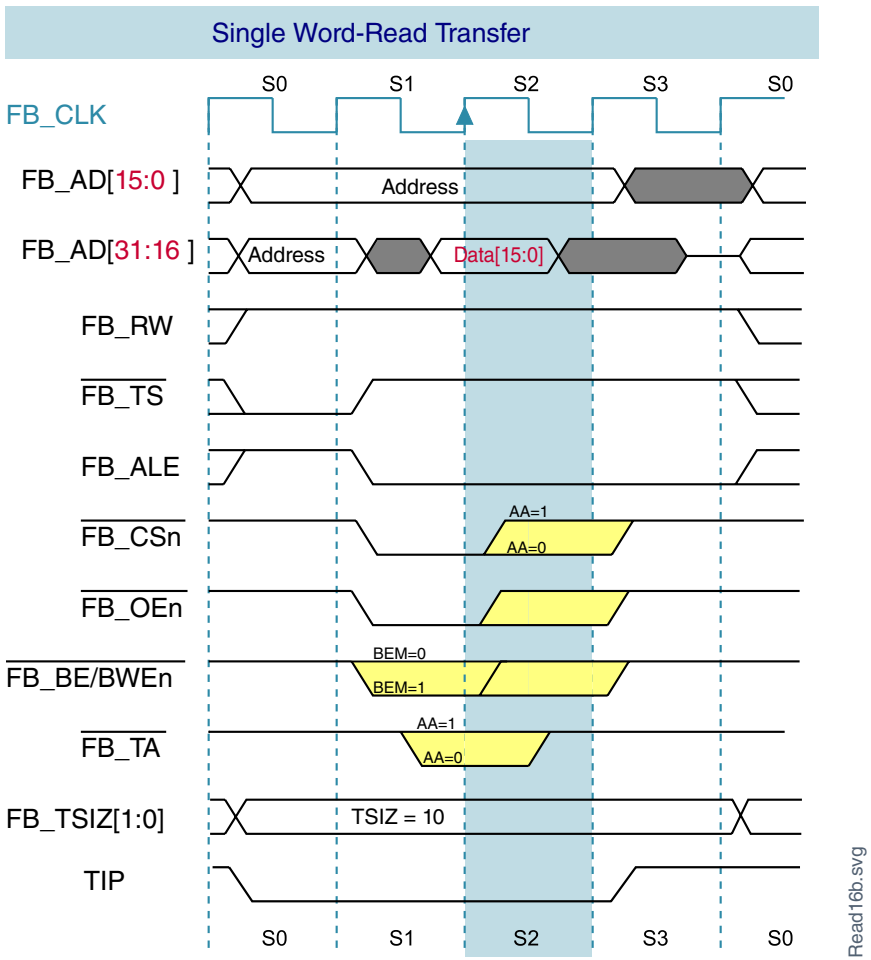

Figure 21-13. Single Word-Read Transfer

The next figure shows a basic word write transfer. The data is driven from the second clock on FB_AD[31:16].

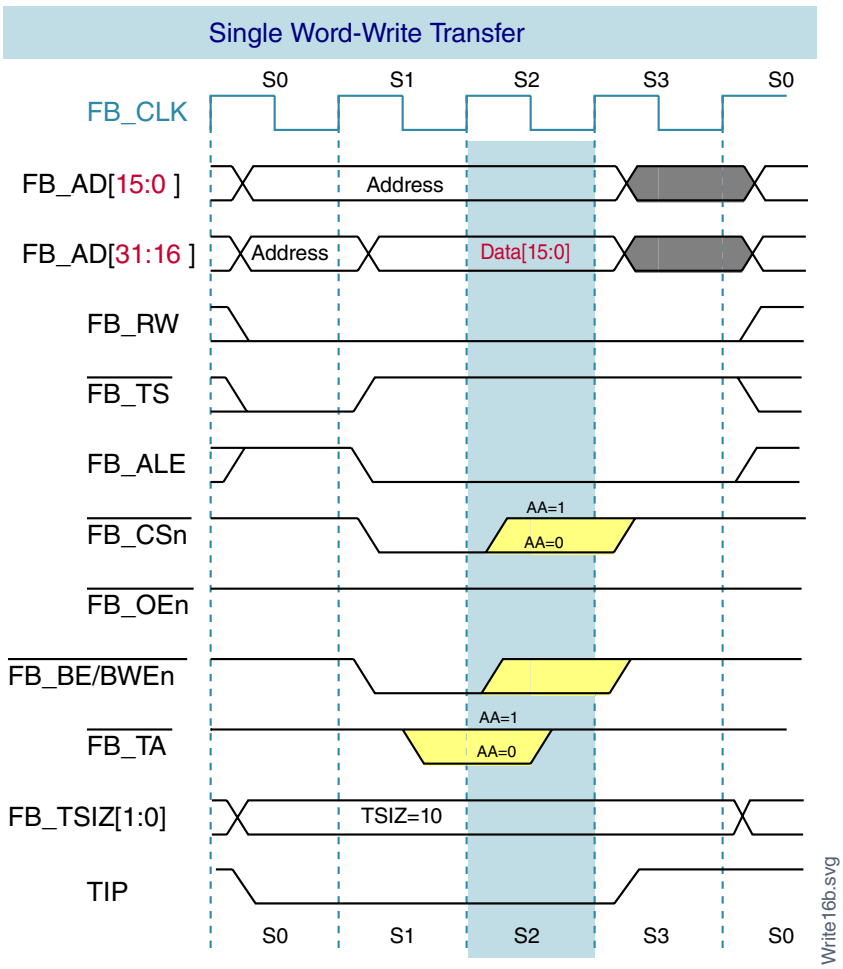

Figure 21-14. Single Word-Write Transfer

21.5.11.3.3 Bus Cycle Sizing—Longword Transfer, 32-bit Device, No Wait States

The next figure shows a longword read from a 32-bit device.

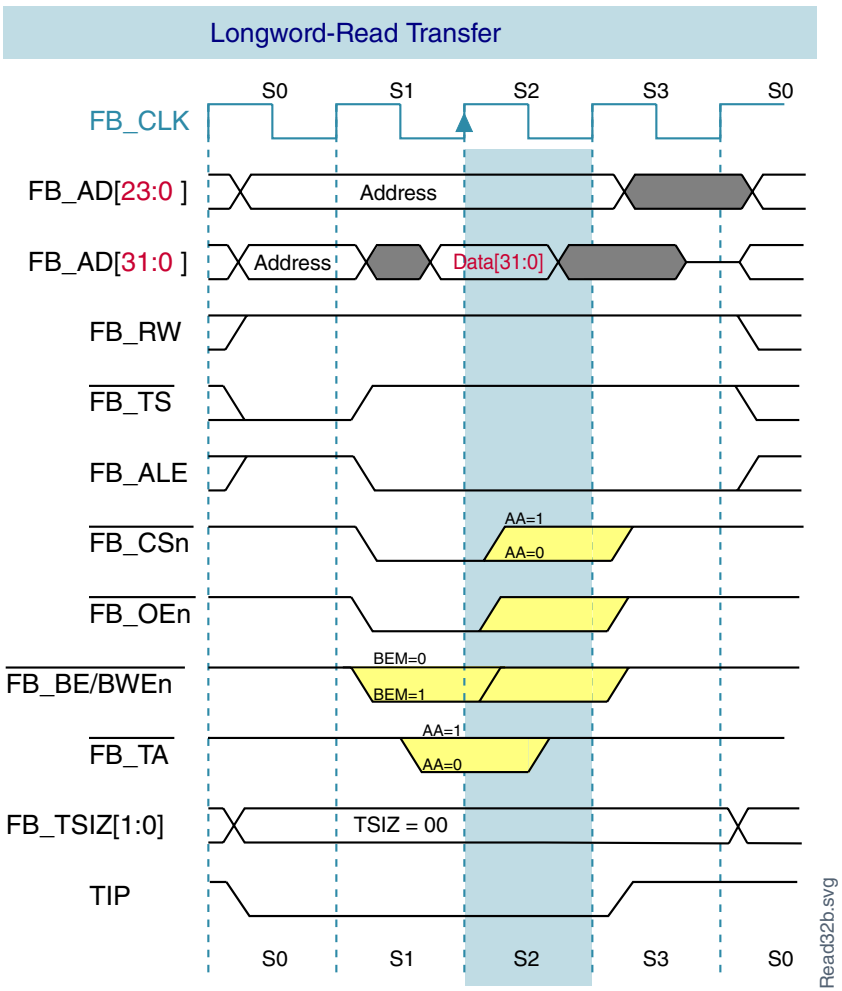

Figure 21-15. Longword-Read Transfer

The next figure shows a longword write to a 32-bit device.

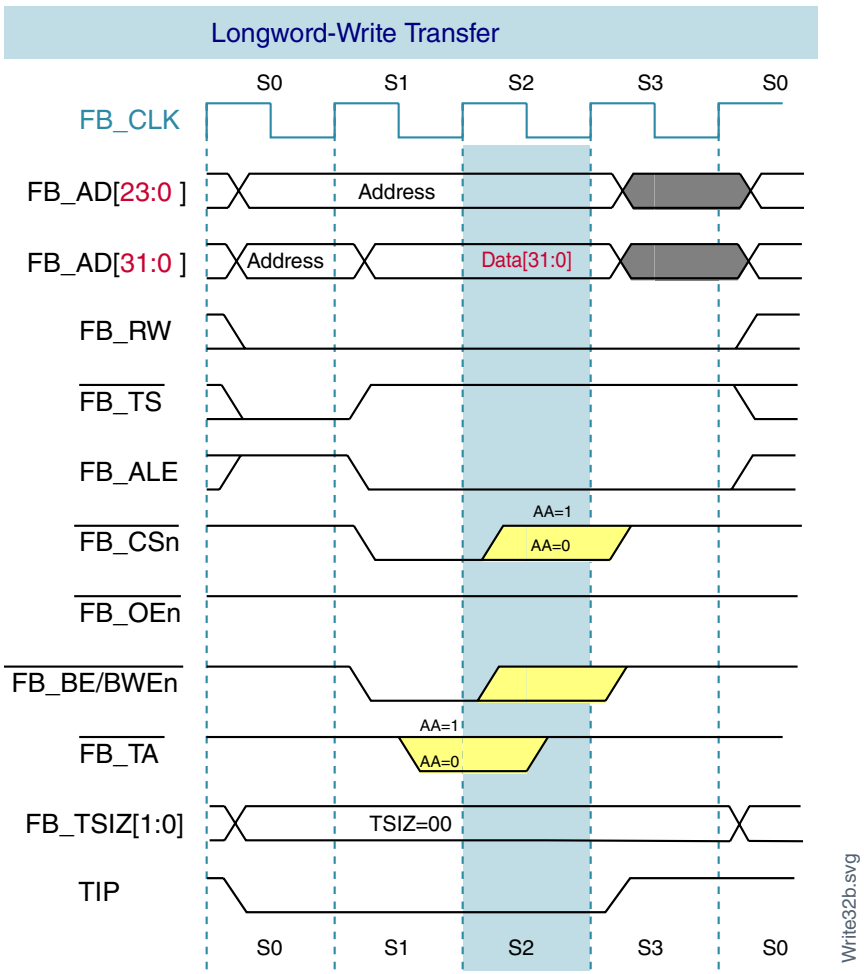

Figure 21-16. Longword-Write Transfer

21.5.11.4 Timing Variations

The FlexBus module has several features that can change the timing characteristics of a basic read- or write-bus cycle to provide additional address setup, address hold, and time for a device to provide or latch data.

21.5.11.4.1 Wait States

Wait states can be inserted before each beat of a transfer by programming the CSCR*n* registers. Wait states can give the peripheral or memory more time to return read data or sample write data.

The following figures show the basic read and write bus cycles (also shown in Basic Read Bus Cycle and Bus Cycle Sizing—Word Transfer, 16-bit Device, No Wait States) with the default of no wait states respectively.

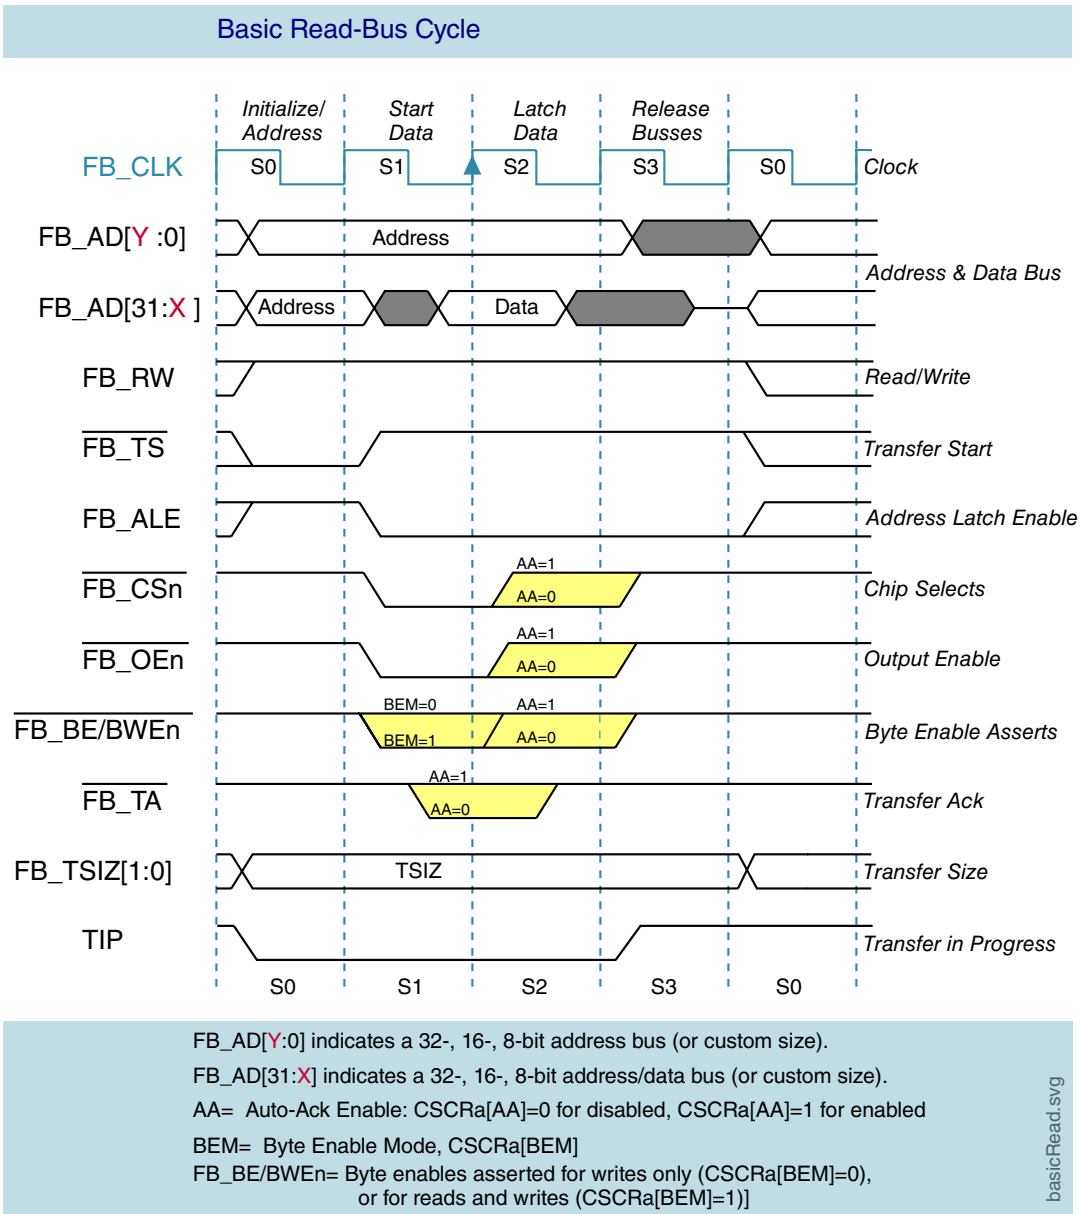

Figure 21-17. Basic Read-Bus Cycle (No Wait States)

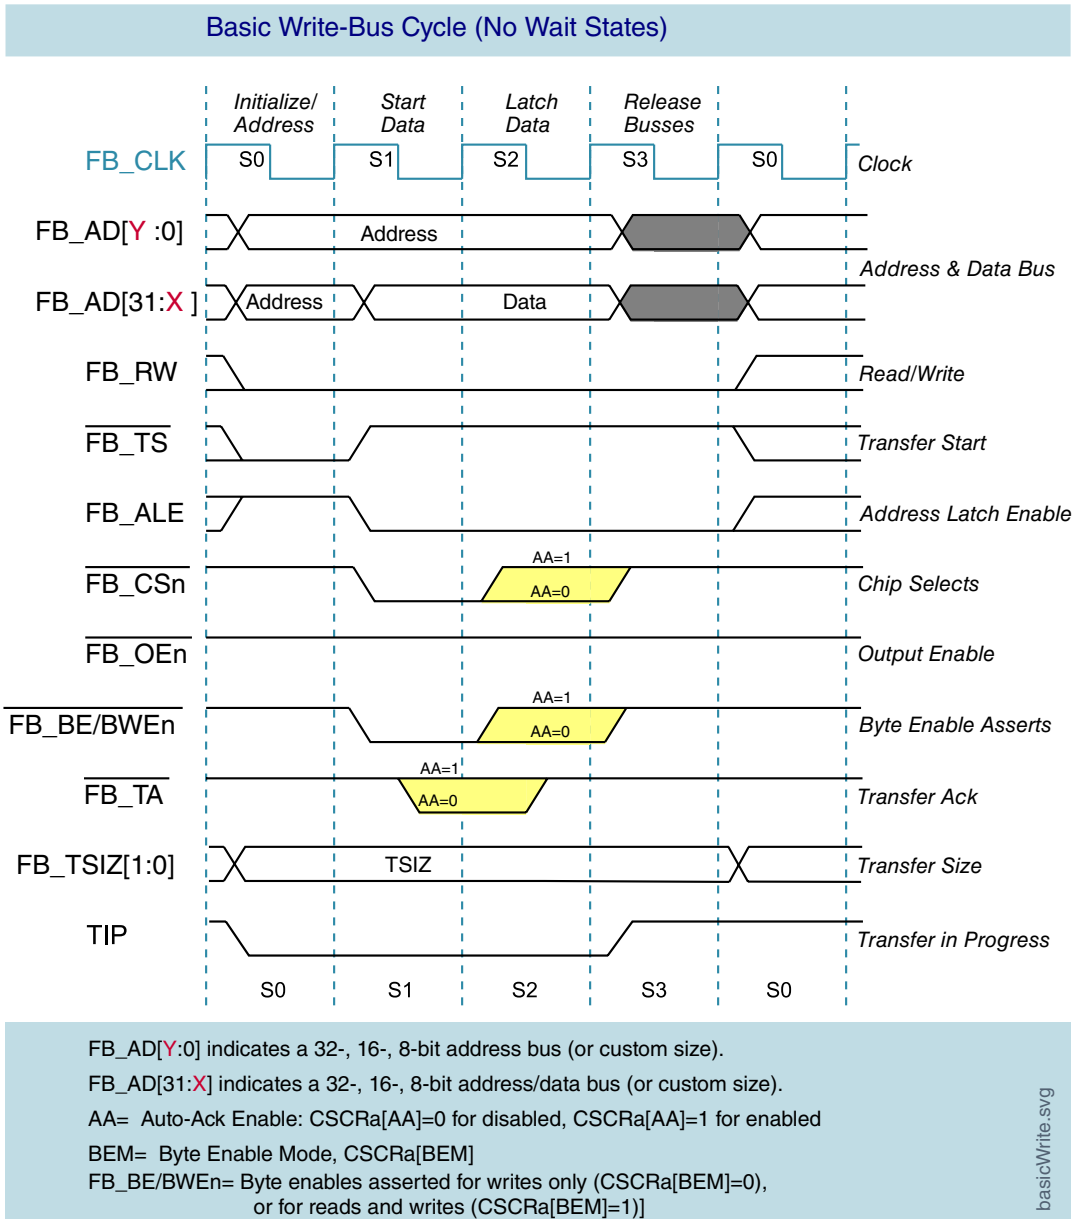

Figure 21-18. Basic Write-Bus Cycle (No Wait States)

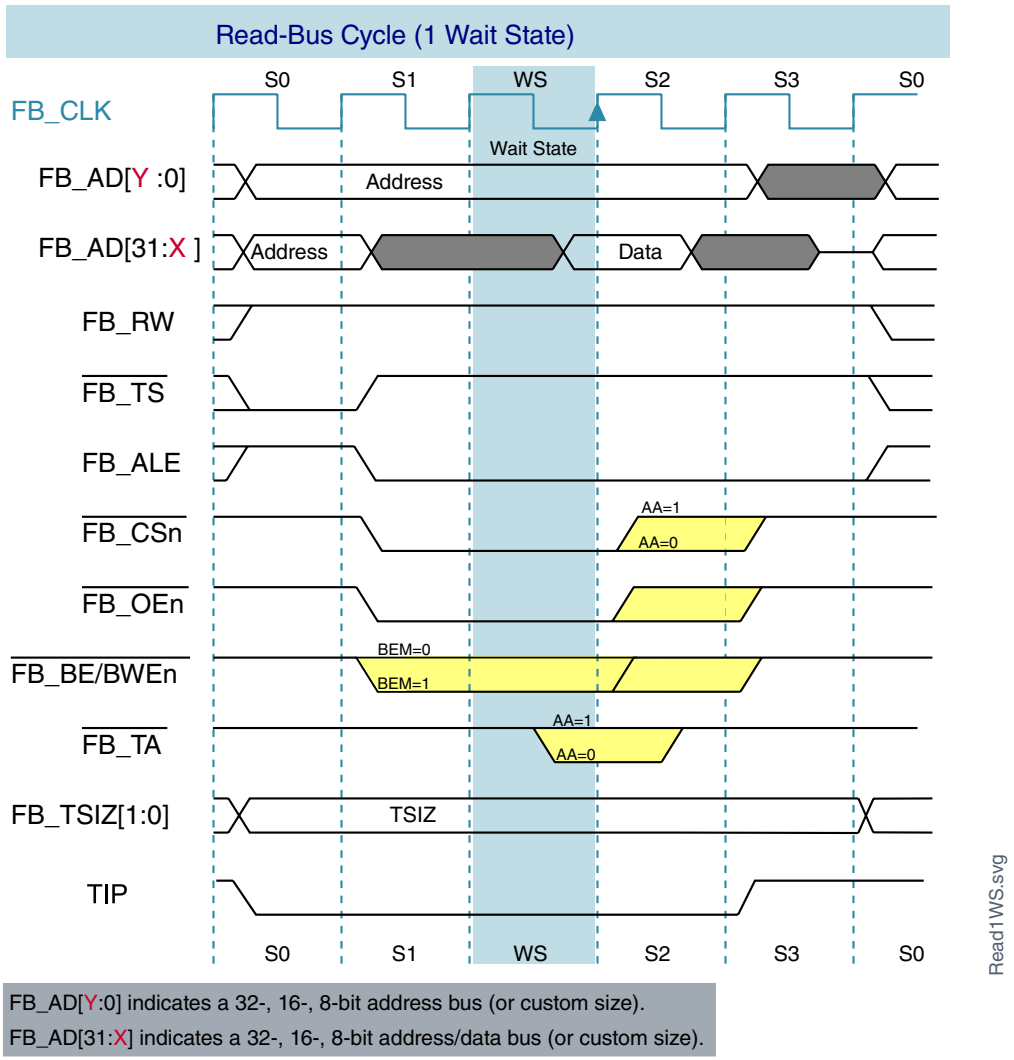
If wait states are used, the S1 state repeats continuously until the chip-select auto-acknowledge unit asserts internal transfer acknowledge or the external FB_TA_b is recognized as asserted. The following figures show a read and write cycle with one wait state respectively.



FB_AD[Y:0] indicates a 32-, 16-, 8-bit address bus (or custom size).
FB_AD[31:X] indicates a 32-, 16-, 8-bit address/data bus (or custom size).

Figure 21-19. Read-Bus Cycle (One Wait State)

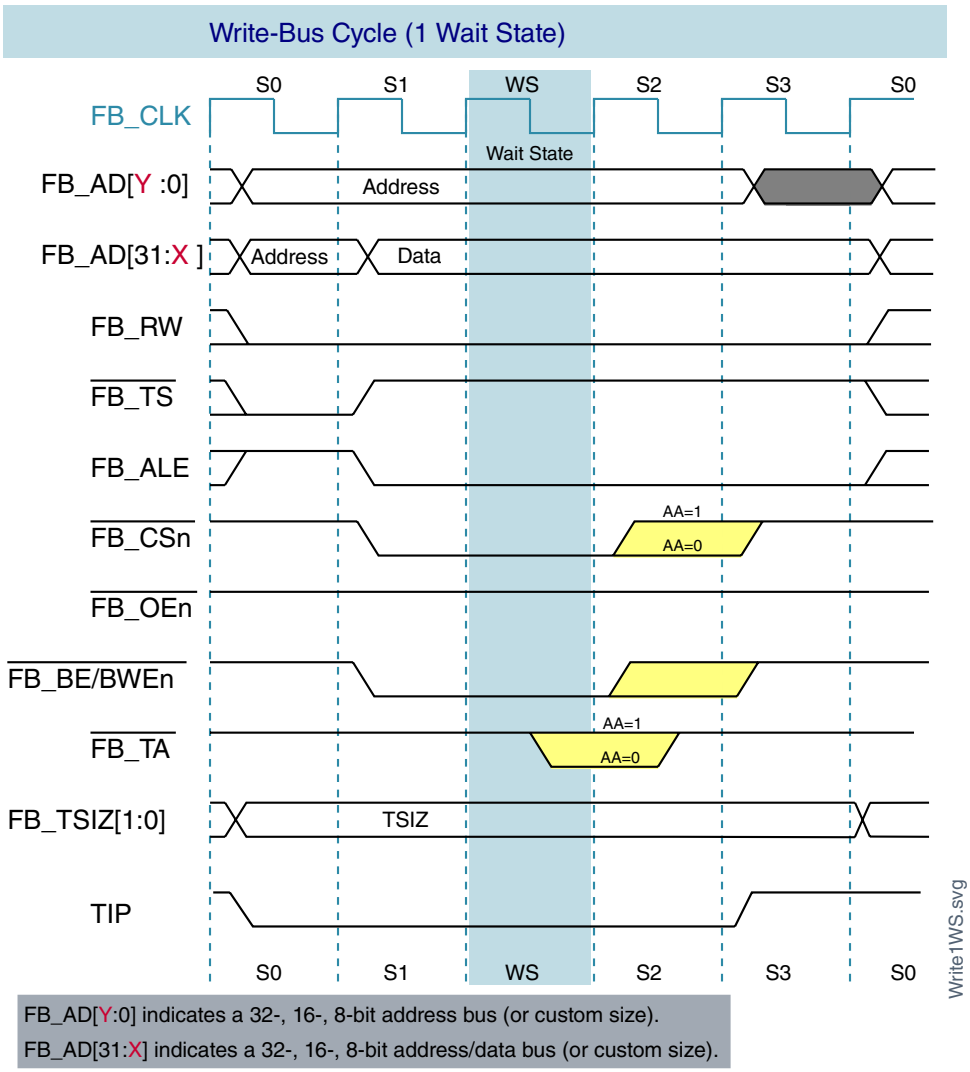


Figure 21-20. Write-Bus Cycle (One Wait State)

21.5.11.4.2 Address Setup and Hold

The timing of the assertion and negation of the chip selects, byte selects, and output enable can be programmed on a chip-select basis. Each chip-select can be programmed to assert one to four clocks after transfer start/address-latch enable (FB_TS_b/FB_ALE) is asserted. The following figures show read- and write-bus cycles with two clocks of address setup respectively.

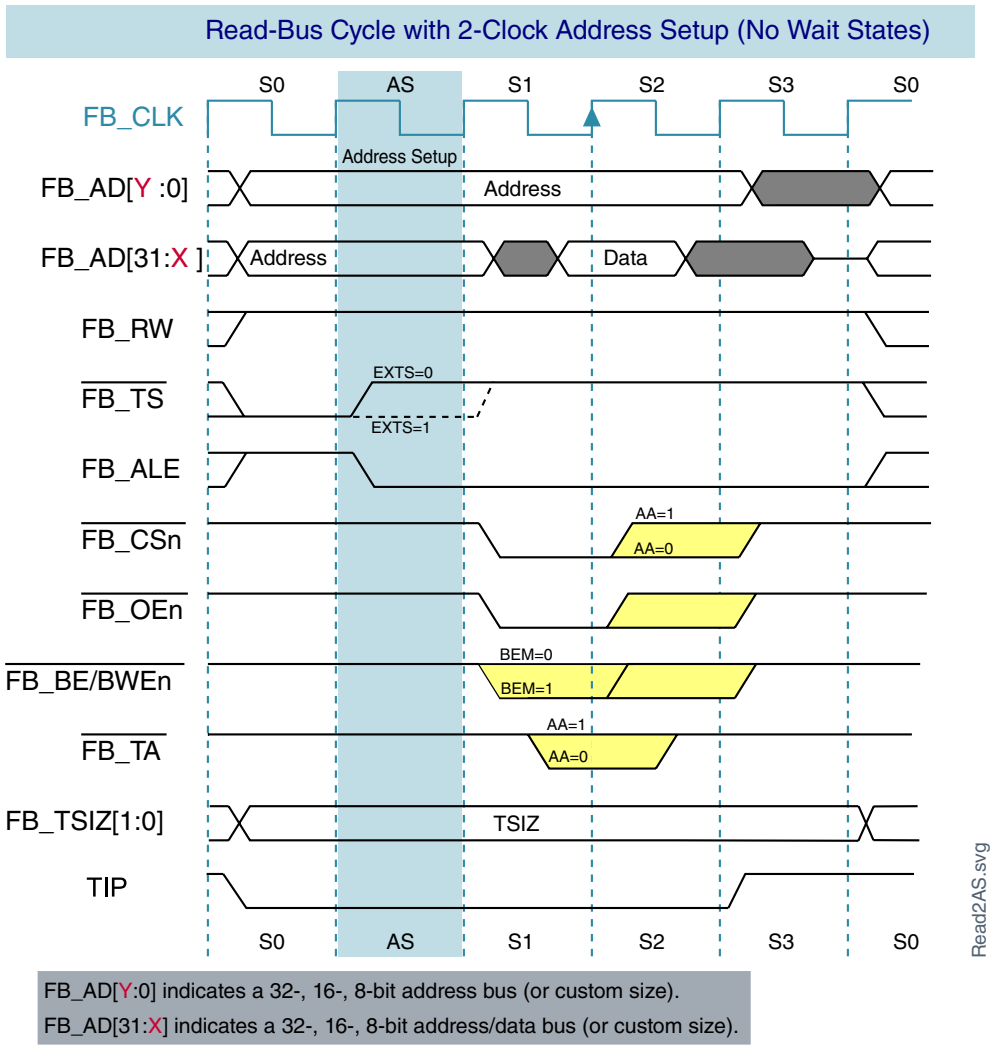

Figure 21-21. Read-Bus Cycle with Two-Clock Address Setup (No Wait States)

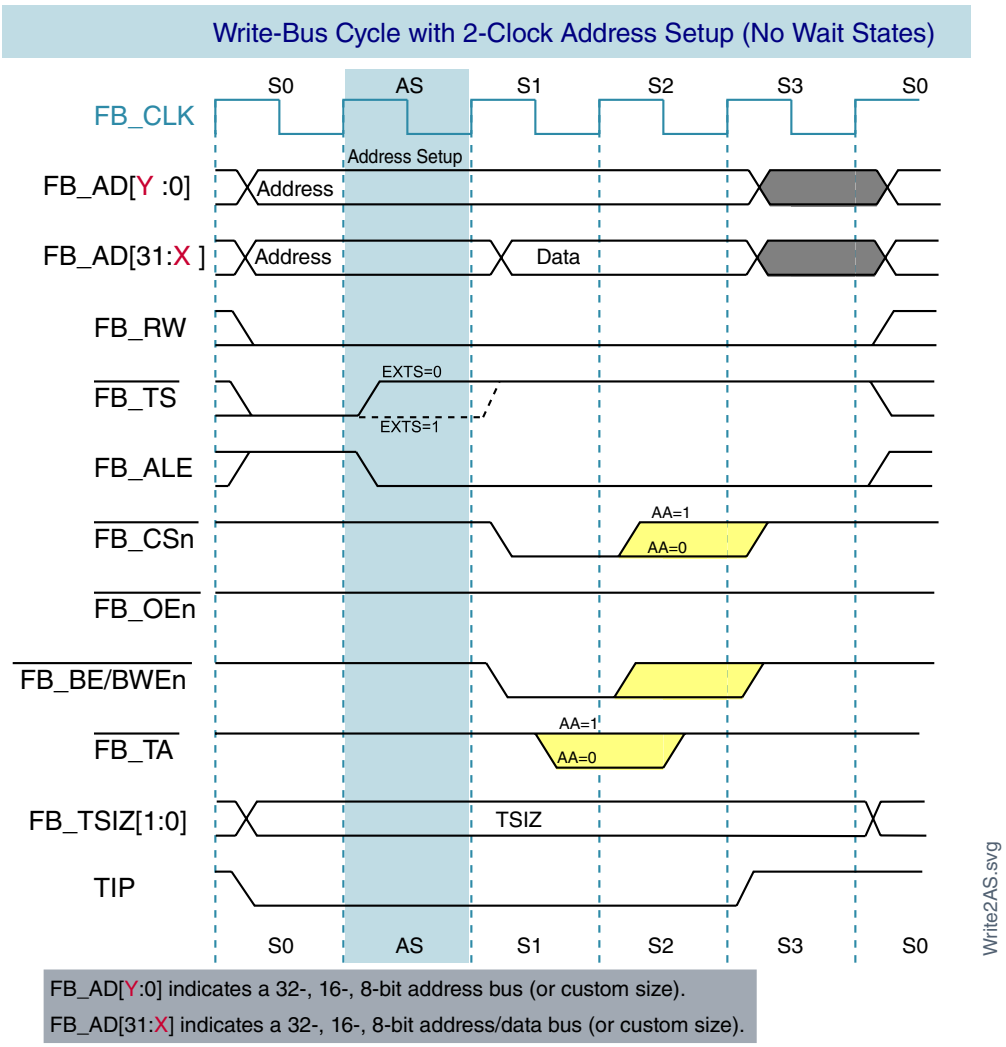

Figure 21-22. Write-Bus Cycle with Two Clock Address Setup (No Wait States)

In addition to address setup, a programmable address hold option for each chip select exists. Address and attributes can be held one to four clocks after chip-select, byte-selects, and output-enable negate. The following figures show read and write bus cycles with two clocks of address hold respectively.

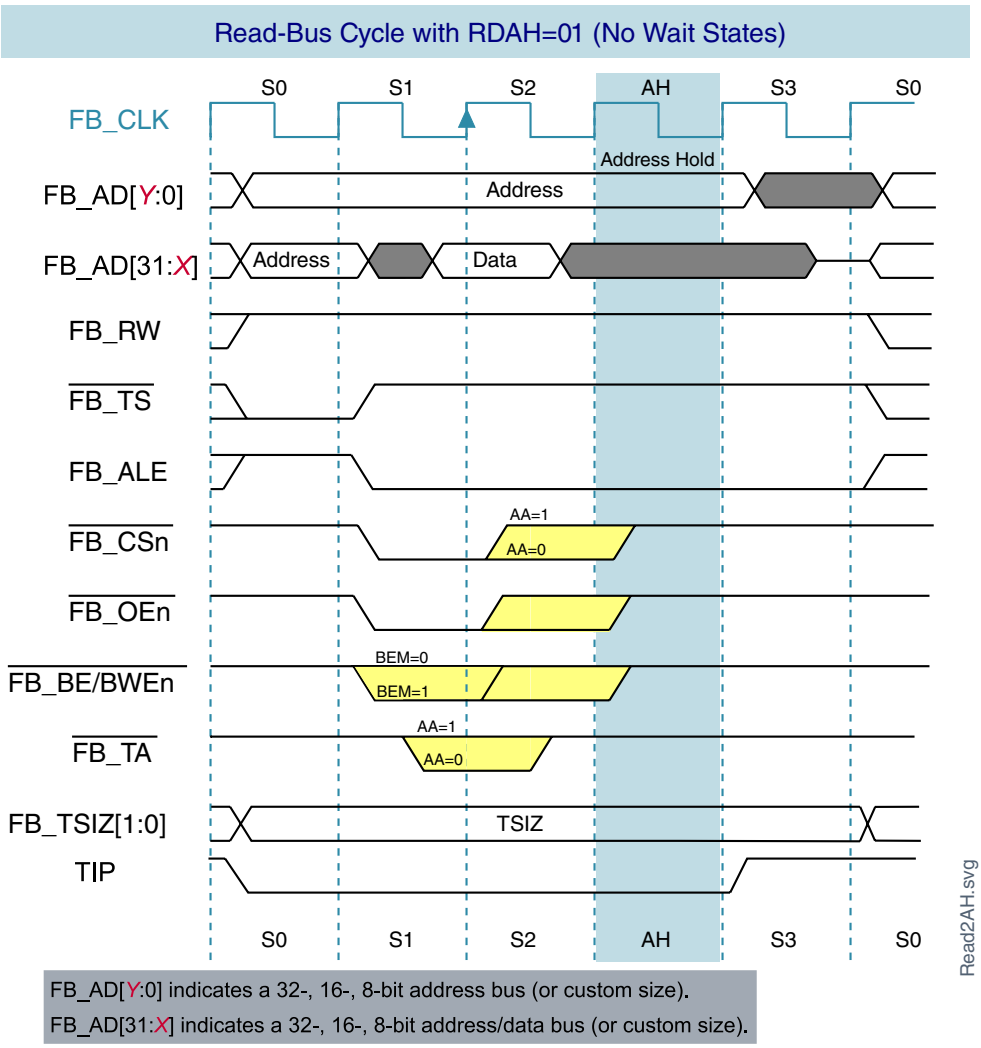

Figure 21-23. Read Cycle with Two-Clock Address Hold (No Wait States)

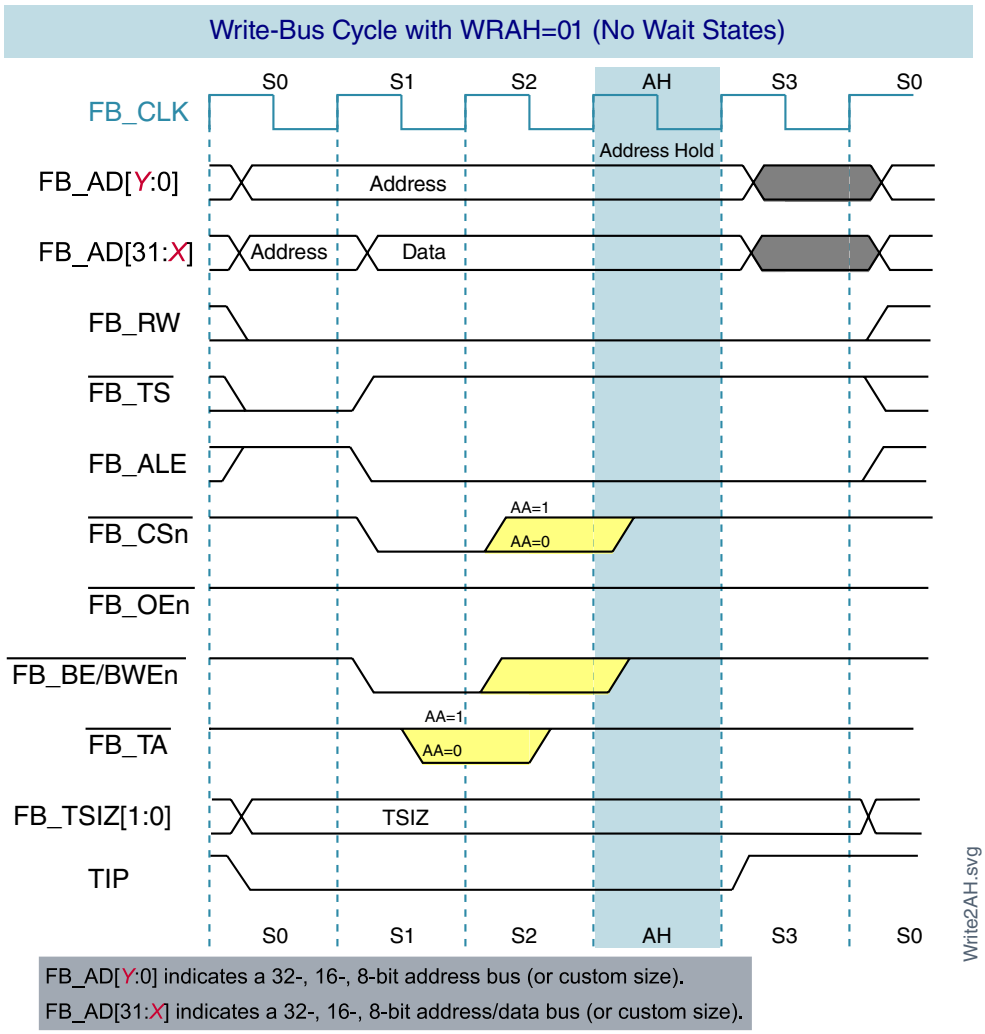

Figure 21-24. Write Cycle with Two-Clock Address Hold (No Wait States)

The following figure shows a bus cycle using address setup, wait states, and address hold.

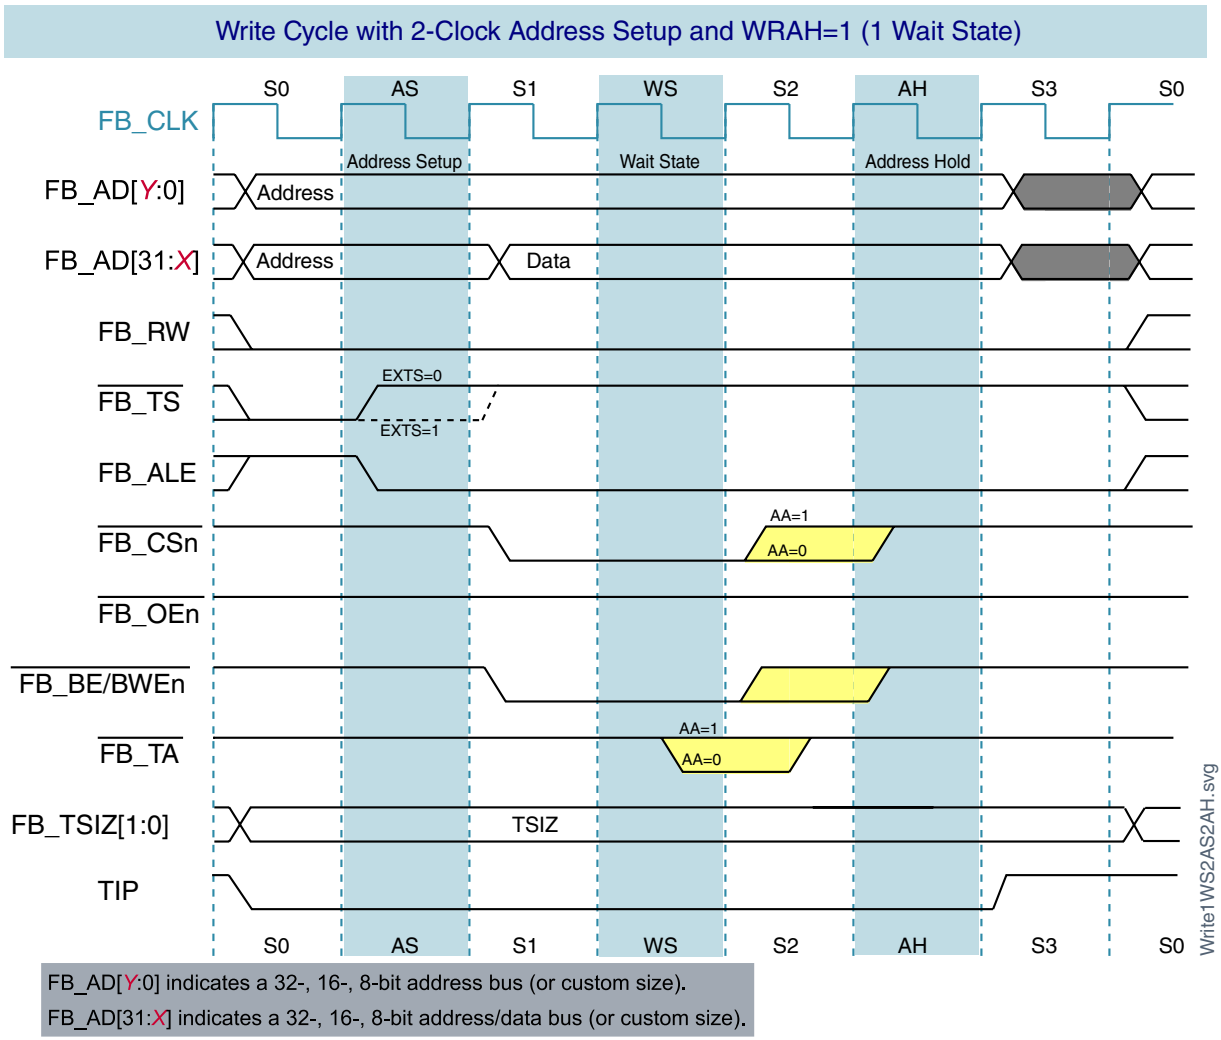

Figure 21-25. Write Cycle with Two-Clock Address Setup and Two-Clock Hold (One Wait State)

21.5.12 Burst cycles

The chip can be programmed to initiate burst cycles if its transfer size exceeds the port size of the selected destination. The initiation of a burst cycle is encoded on the transfer size pins (FB_TSIZ[1:0]). For burst transfers to smaller port sizes, FB_TSIZ[1:0] indicates the size of the entire transfer. For example, with bursting enabled, a 16-bit transfer to an 8-bit port takes two beats (two byte-sized transfers), for which FB_TSIZ[1:0] equals 10b throughout. A 32-bit transfer to an 8-bit port takes four beats (four byte-sized transfers), for which FB_TSIZ[1:0] equals 00b throughout.

21.5.12.1 Enabling and inhibiting burst

The CSCRn registers enable bursting for reads, writes, or both.

Memory spaces can be declared burst-inhibited for reads and writes by writing 0b to the appropriate CSCRn[BSTR] and CSCRn[BSTW] fields.

21.5.12.2 Transfer size and port size translation

With bursting disabled, any transfer larger than the port size breaks into multiple individual transfers (e.g. <Addr><Data><Addr+1><Data><Addr+2><Data>). With bursting enabled, any transfer larger than the port size results in a burst cycle of multiple beats (e.g. <Addr><Data><Data><Data>). The following table shows the result of such transfer translations.

Port size PS[1:0]	Transfer size FB_TSIZ[1:0]	Burst-inhibited: Number of transfers Burst enabled: Number of beats
01b (8 bit)	10b (16 bits)	2
	00b (32 bits)	4
	11b (16 bytes)	16
1Xb (16 bit)	00b (32 bits)	2
	11b (16 bytes)	8
00b (32 bit)	11b (line)	4

The FlexBus can support X-1-1-1 burst cycles to maximize system performance, where X is the primary number of wait states (max 63). Delaying termination of the cycle can add wait states. If internal termination is used, different wait state counters can be used for the first access and the following beats.

21.5.12.3 32-bit-Read burst from 8-Bit port 2-1-1-1 (no wait states)

The following figure shows a 32-bit read to an 8-bit external chip programmed for burst enable. The transfer results in a 4-beat burst and the data is driven on FB_AD[31:24]. The transfer size is driven at 32-bit (00b) throughout the bus cycle.

Note

- In **non-multiplexed address/data mode:** the address on FB_A increments only during internally-terminated burst

cycles. The first address is driven throughout the entire burst for externally-terminated cycles.

- In **multiplexed address/data mode:** the address is driven on FB_AD only during the first cycle for all terminated cycles. In other words, the lower address lines only increment during internally-terminated burst cycles (assuming that the lower address lines are being driven with the address during the data phase).

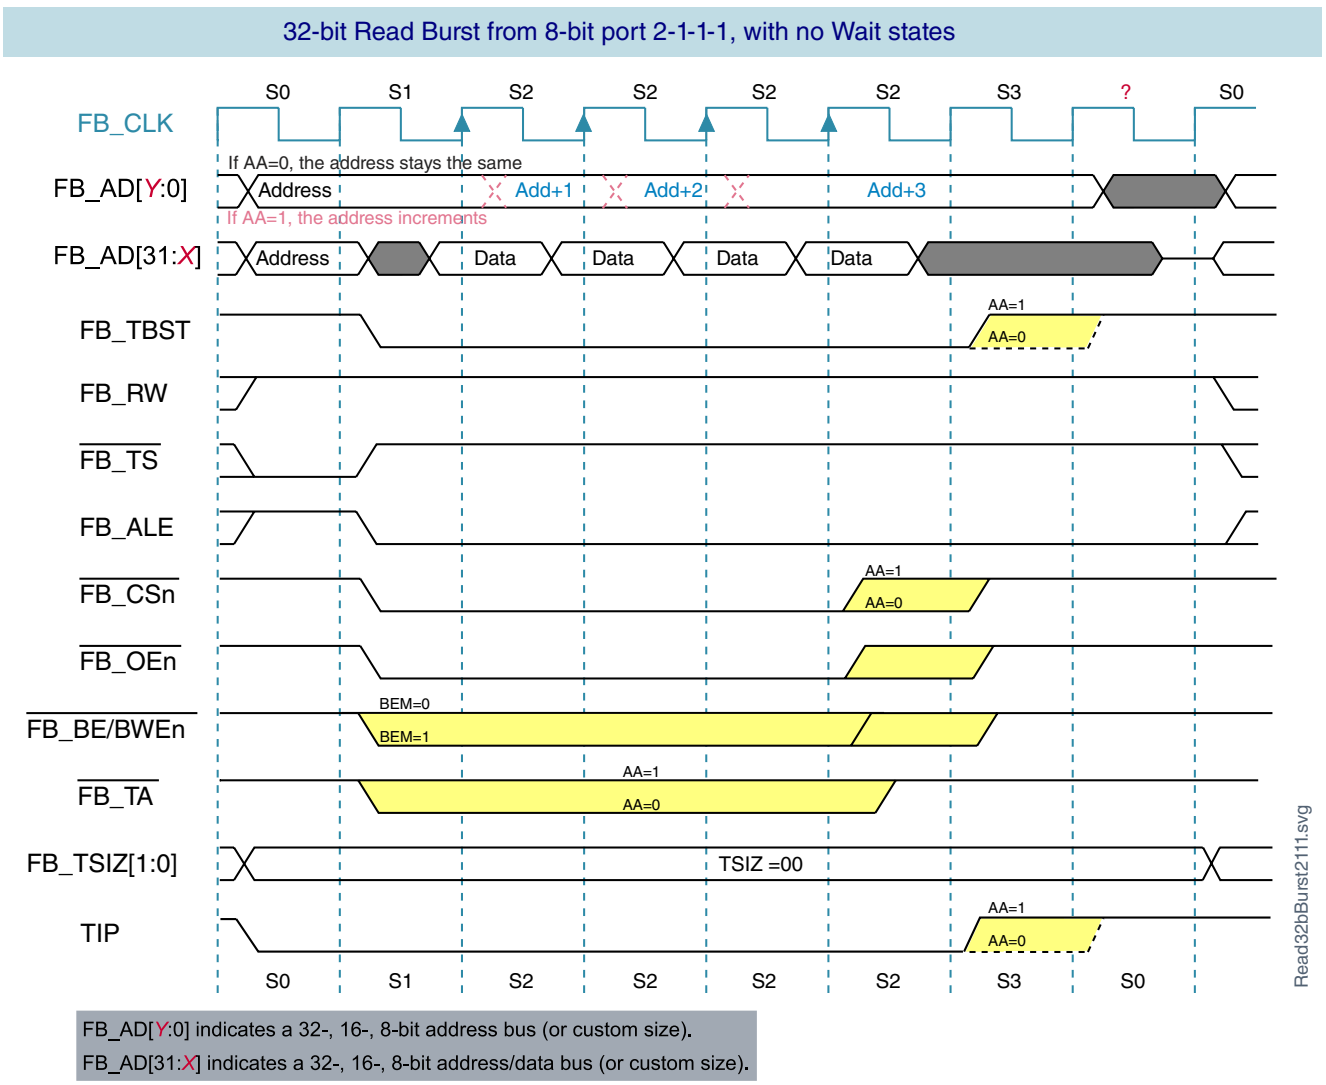

Figure 21-26. 32-bit-Read burst from 8-Bit port 2-1-1-1 (no wait states)

21.5.12.4 32-bit-Write burst to 8-Bit port 3-1-1-1 (no wait states)

The following figure shows a 32-bit write to an 8-bit external chip with burst enabled. The transfer results in a 4-beat burst and the data is driven on FB_AD[31:24]. The transfer size is driven at 32-bit (00b) throughout the bus cycle.

Note

The first beat of any write burst cycle has at least one wait state. If the bus cycle is programmed for zero wait states (CSCRn[WS] = 0b), one wait state is added. Otherwise, the programmed number of wait states are used.

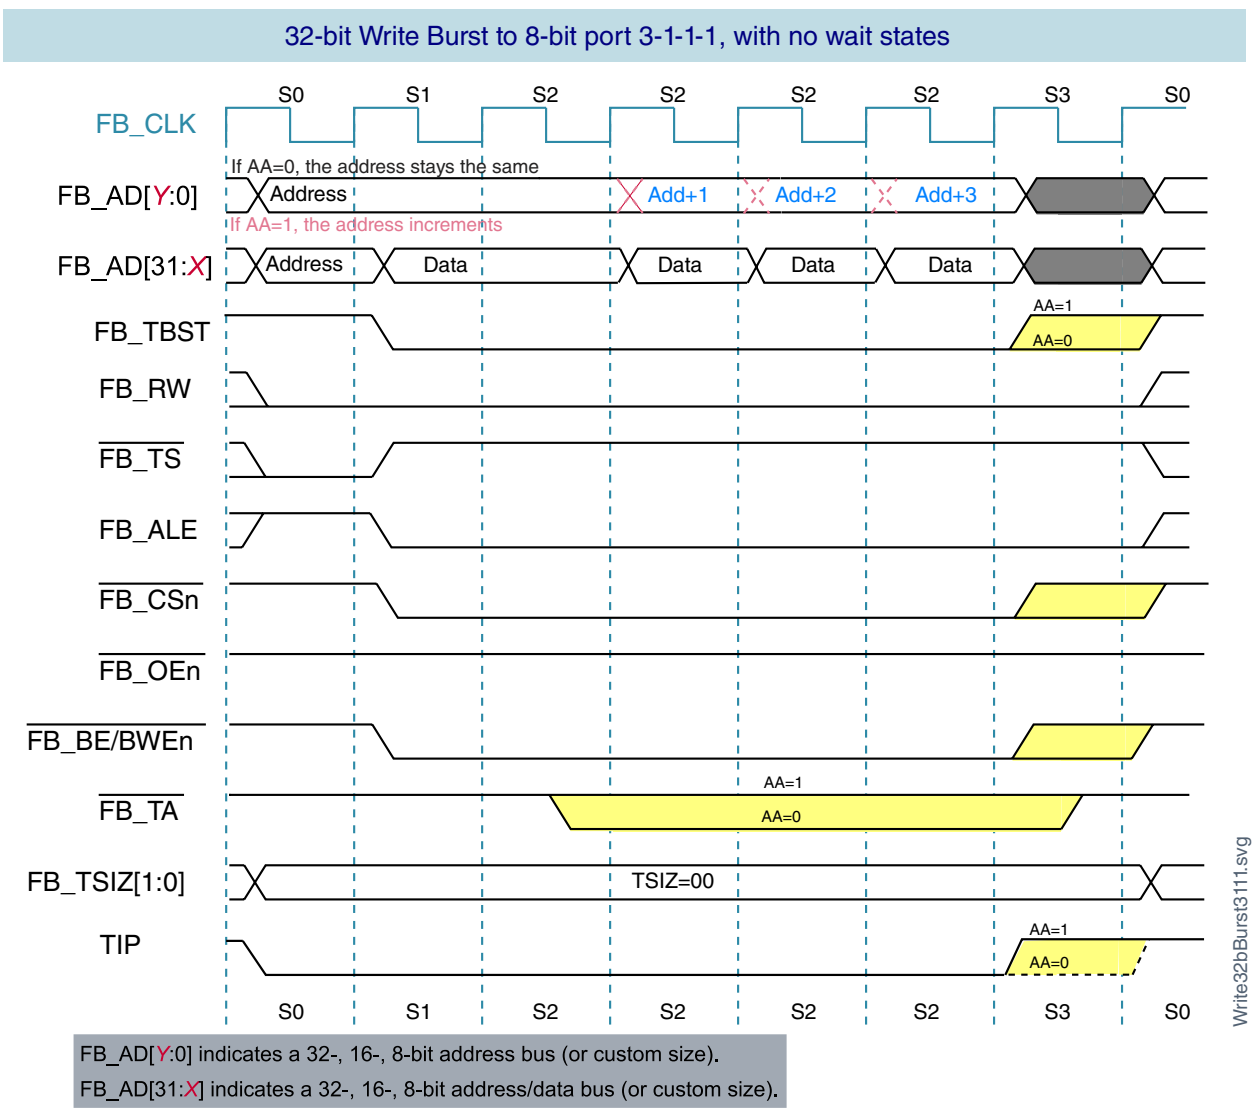

Figure 21-27. 32-bit-Write burst to 8-Bit port 3-1-1-1 (no wait states)

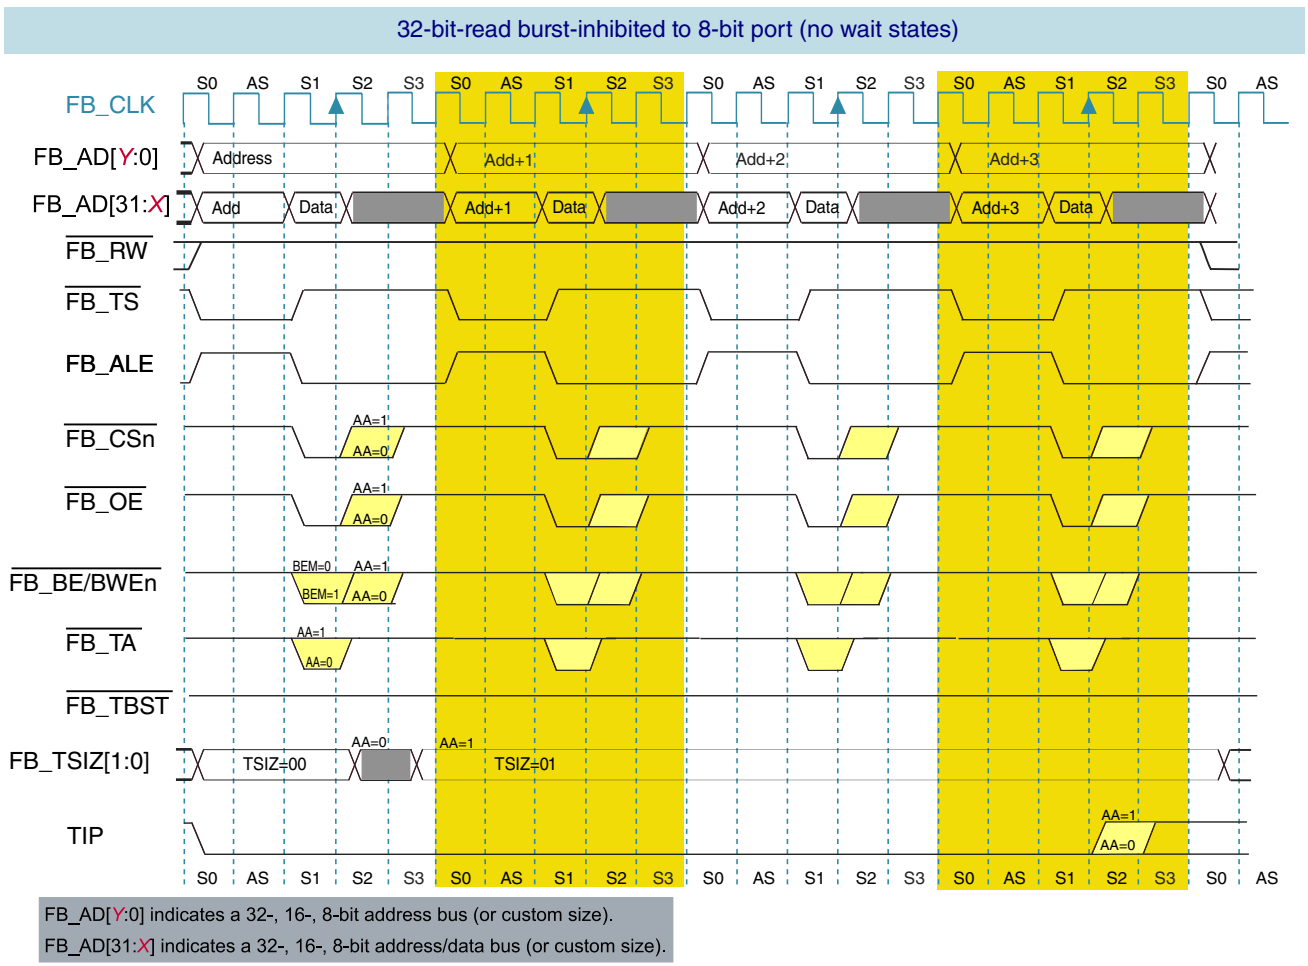
21.5.12.5 32-bit-read burst-inhibited from 8-bit port (no wait states)

The following figure shows a 32-bit read from an 8-bit device with burst inhibited. The transfer results in four individual transfers. The transfer size is driven at 32-bit (00b) during the first transfer and at byte (01b) during the next three transfers.

Note

There is an extra clock of address setup (AS) for each burst-inhibited transfer between states S0 and S1.



21.5.12.6 32-bit-write burst-inhibited to 8-bit port (no wait states)

The following figure shows a 32-bit write to an 8-bit device with burst inhibited. The transfer results in four individual transfers. The transfer size is driven at 32-bit (00b) during the first transfer and at byte (01b) during the next three transfers.

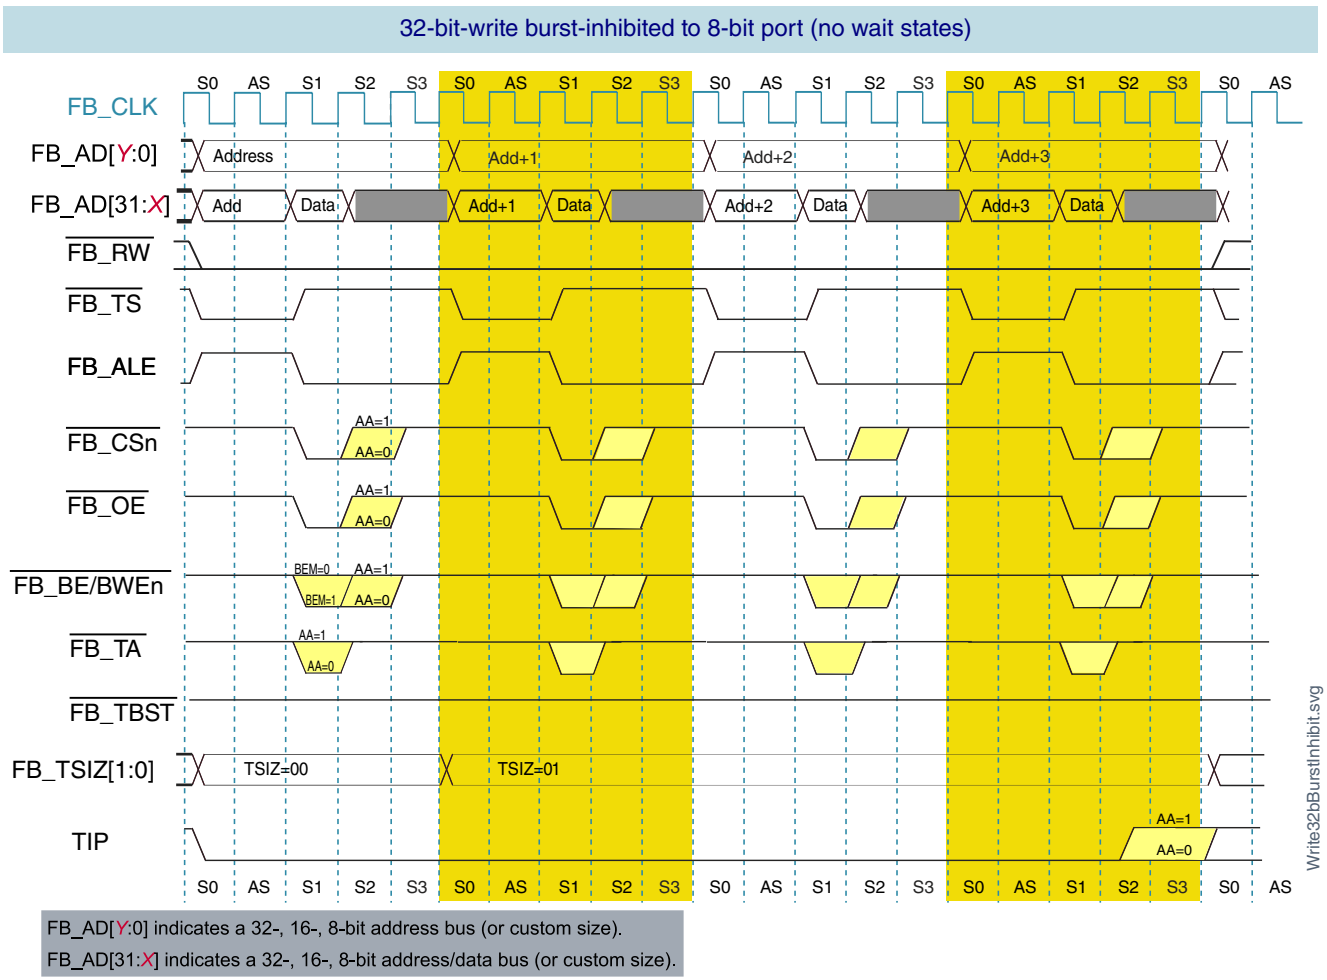


Figure 21-28. 32-bit-write burst-inhibited to 8-bit port (no wait states)

21.5.12.7 32-bit-read burst from 8-bit port 3-2-2-2 (one wait state)

The following figure illustrates another read burst transfer, but in this case a wait state is added between individual beats.

Note

CSCRn[WS] determines the number of wait states in the first beat. However, for subsequent beats, the CSCRn[WS] (or CSCRn[SWS] if CSCRn[SWSEN] = 1b) determines the number of wait states.

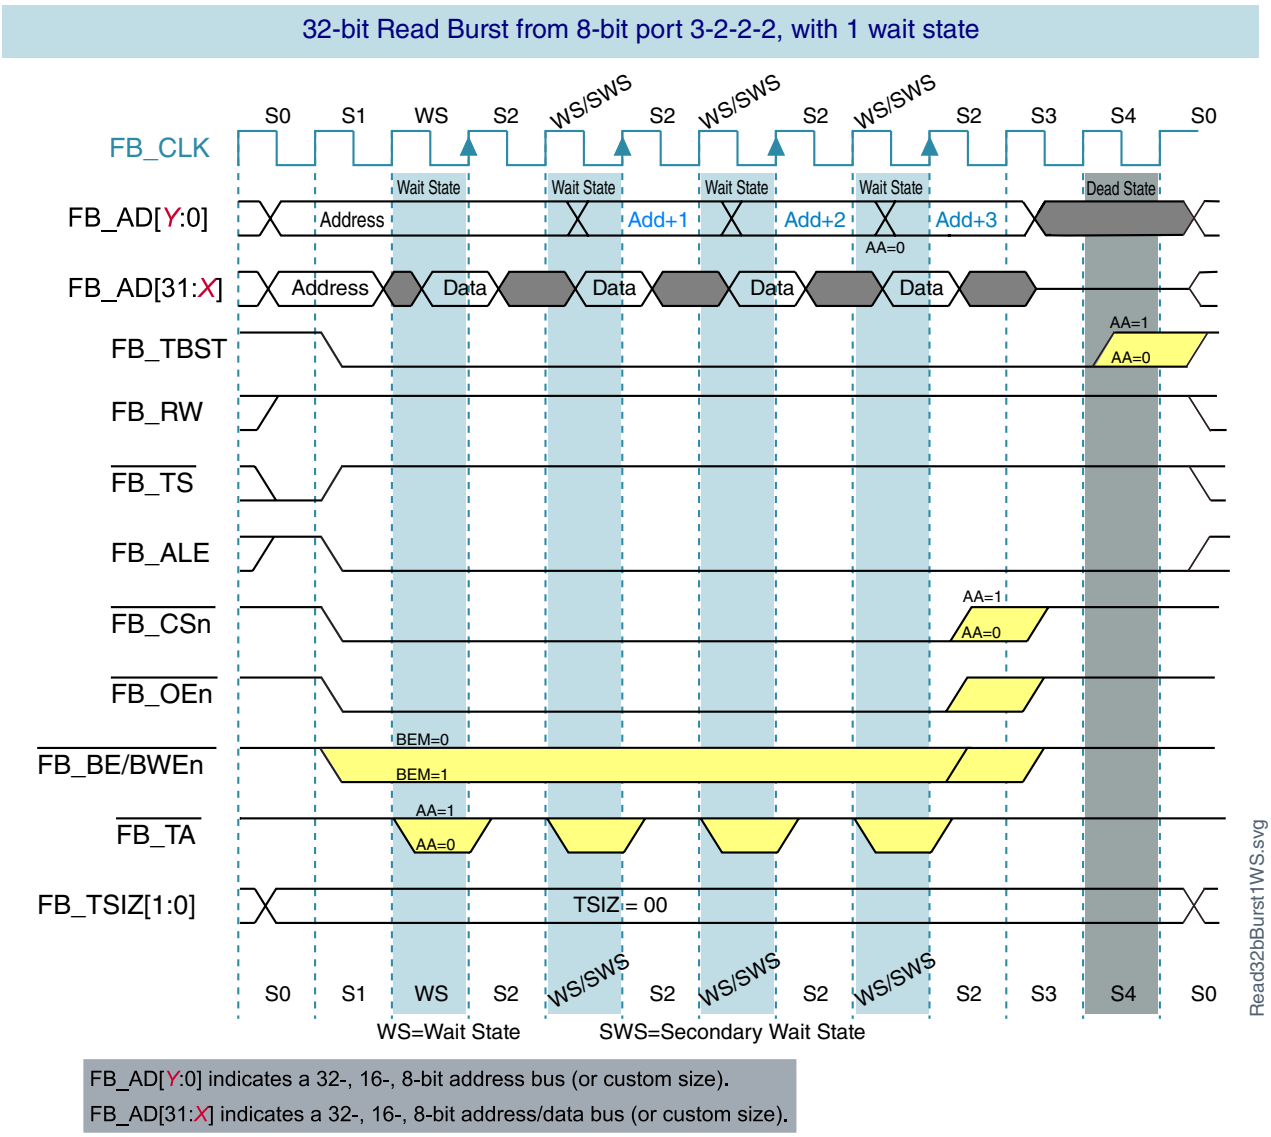

Figure 21-29. 32-bit-read burst from 8-bit port 3-2-2-2 (one wait state)

21.5.12.8 32-bit-write burst to 8-bit port 3-2-2-2 (one wait state)

The following figure illustrates a write burst transfer with one wait state.

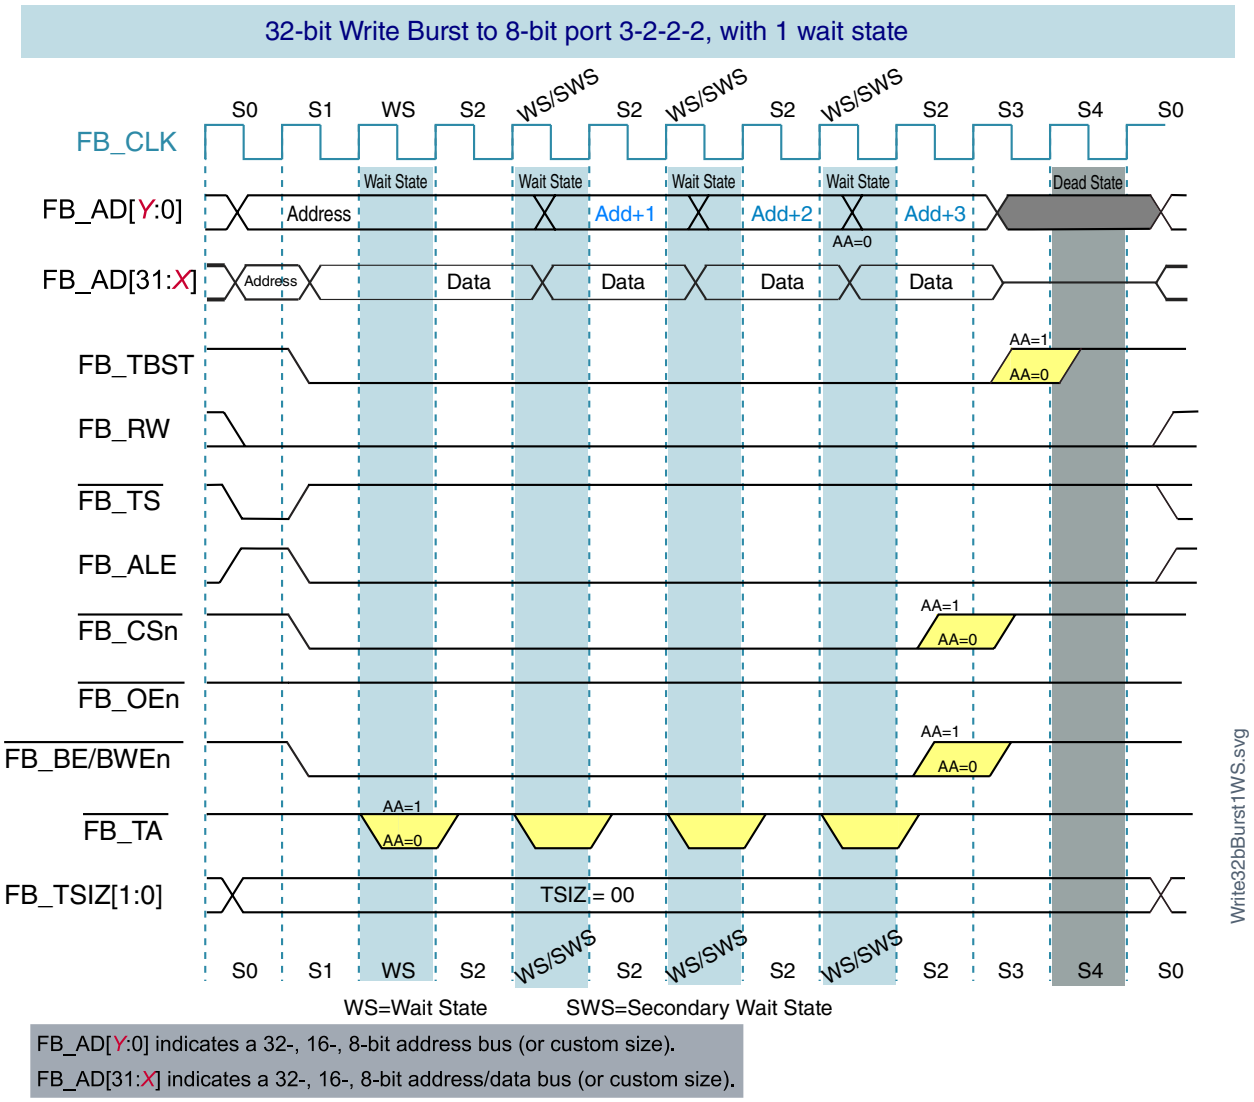

Figure 21-30. 32-bit-write burst to 8-bit port 3-2-2-2 (one wait state)

21.5.12.9 32-bit-read burst from 8-bit port 3-1-1-1 (address setup and hold)

If address setup and hold are used, only the first and last beat of the burst cycle are affected. The following figure shows a read cycle with one clock of address setup and address hold.

Note

- In **multiplexed address/data mode:** the address is driven on FB_AD only during the first cycle for internally- and externally-terminated cycles.

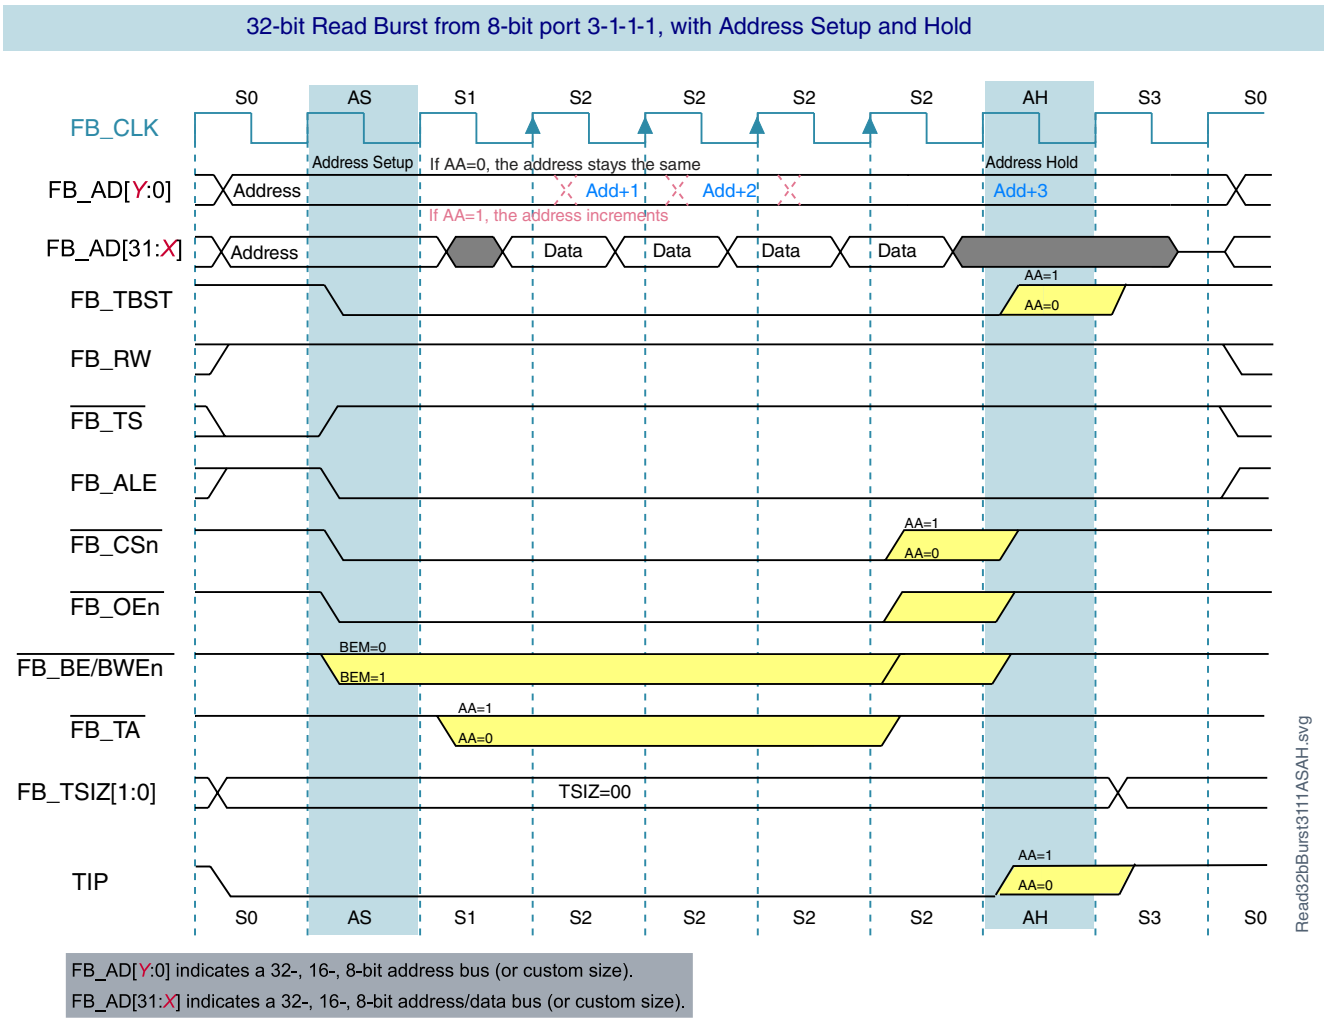

Figure 21-31. 32-bit-read burst from 8-bit port 3-1-1-1 (address setup and hold)

21.5.12.10 32-bit-write burst to 8-bit port 3-1-1-1 (address setup and hold)

The following figure shows a write cycle with one clock of address setup and address hold.

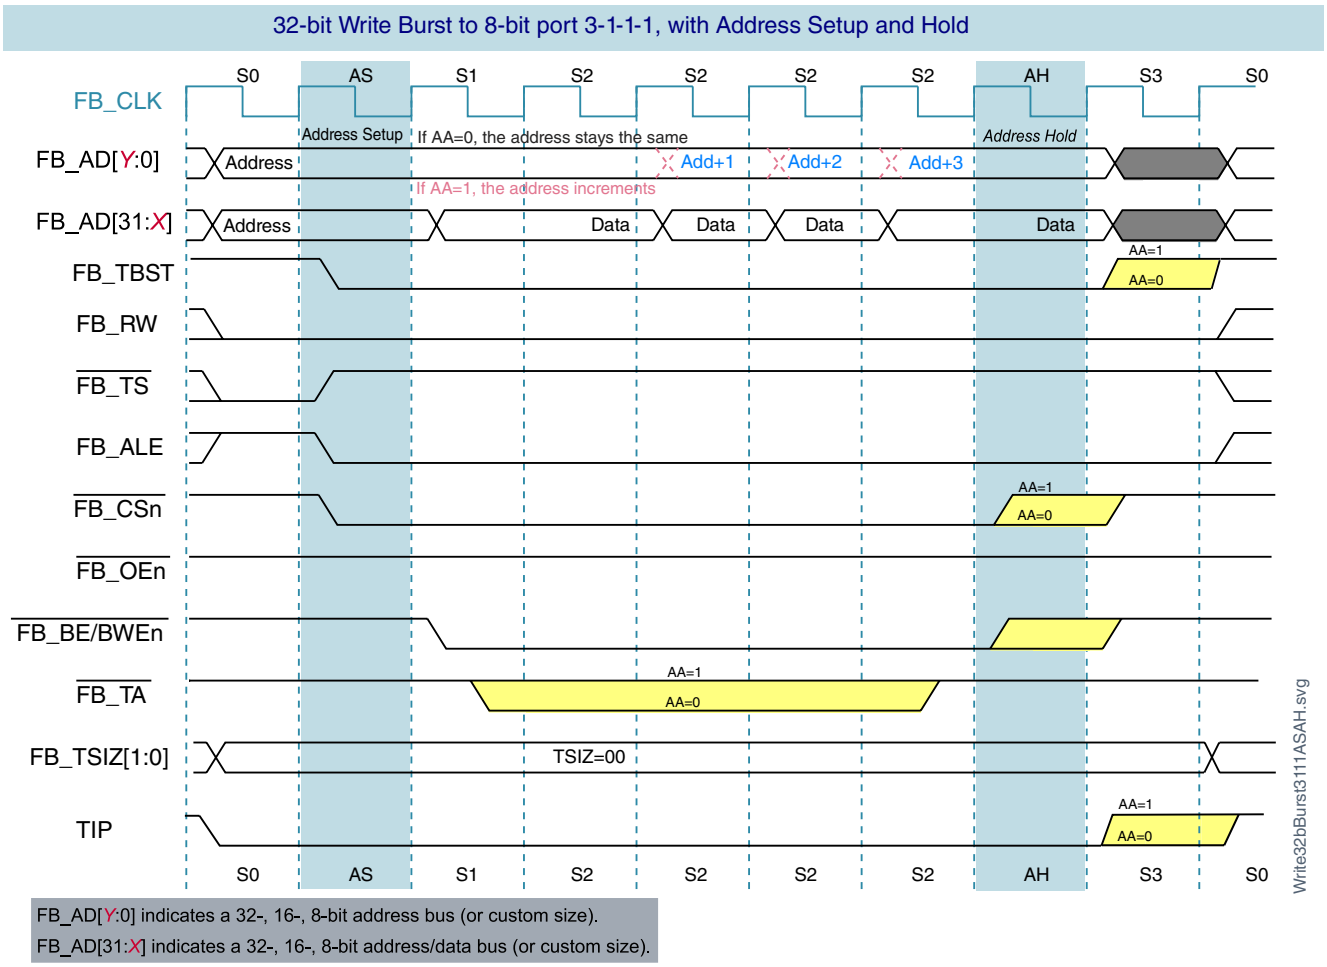

Figure 21-32. 32-bit-write burst to 8-bit port 3-1-1-1 (address setup and hold)

21.5.13 Extended Transfer Start/Address Latch Enable

The FB_TS_b/FB_ALE signal indicates that a bus transaction has begun and the address and attributes are valid. By default, the FB_TS_b/FB_ALE signal asserts for a single bus clock cycle. When CSCR*n*[EXTS] is set, the FB_TS_b/FB_ALE signal asserts and remain asserted until the first positive clock edge after FB_CS_b*n* asserts. See the following figure.

NOTE

When EXTS is set, CSCR*n*[WS] must be programmed to have at least one primary wait state.

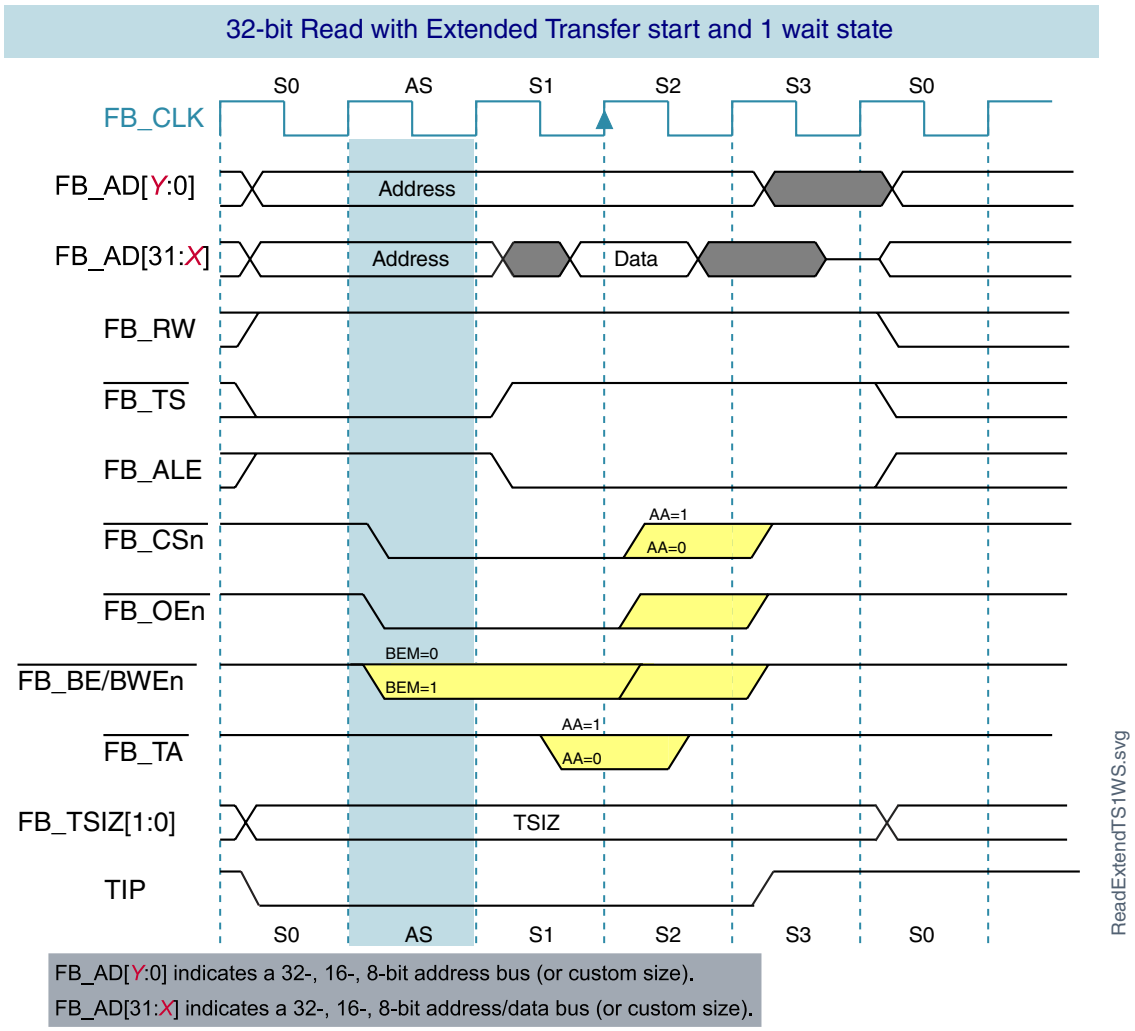

Figure 21-33. Read-Bus Cycle with CSCR*n*[EXTS] = 1 (One Wait State)

21.5.14 Bus errors

These types of accesses cause a transfer to terminate with a bus error:

- Any access when the clock to the module is disabled
- A write to a write-protected address range
- An access whose address is not in a range covered by a chip-select
- An access whose address is in a range covered by more than one chip-selects
- A write to a reserved address in the memory map
- A write to a reserved field in the CSPMCR
- Any FlexBus accesses when FlexBus is secure

If the auto-acknowledge feature is disabled (CSCR[AA] is 0) for an address that generates an error, then the transfer can be terminated by asserting FB_TA_b. If the processor must manage a bus error differently, then asserting an interrupt to the core along with FB_TA when the bus error occurs can invoke an interrupt handler.

The device can hang if FlexBus is configured for external termination and the CSPMCR is not configured for FB_TA.

21.6 Initialization/Application Information

21.6.1 Initializing a chip-select

Before using any other chip select, chip select 0 (CS0) should be initialized, to take it out of global chip select mode.

To initialize a chip-select:

1. Write to the associated CSAR.
2. Write to the associated CSCR.
3. Write to the associated CSMR, including writing "1b" to the Valid field (CSMRn[V]).

21.6.2 Reconfiguring a chip-select

To reconfigure a previously-used chip-select:

1. Invalidate the chip-select by writing 0b to the associated CSMR's Valid field (CSMRn[V]).
2. Write to the associated CSAR.
3. Write to the associated CSCR.
4. Write to the associated CSMR, including writing "1b" to the Valid field (CSMRn[V]).

22.1.1 Multi Mode DDR Controller (MMDC)

The MMDC is a configurable and high performance DDR controller that supports various configurations of LPDDR2 and LPDDR3 memory types. The MMDC consists of a core and PHY. The following table shows the configuration of the MMDC.

Table 22-2. MMDC configuration

Parameter	Description
Name	Multi Mode DDR Controller
Instances	1
Configurable features	• LPDDR2 x32, x16 • LPDDR3 x32
Interface speed	380 MHz
External I/O pins	See the attached IOMUXC pinout spreadsheet for pin details on this device

22.1.2 Fine tuning control

In i.MX 7ULP, write fine tuning, read fine tuning, and ZQ fine tuning are controlled through IOMUXC DDR registers. See the IOMUXC chapter and IOMUXC pin spreadsheet attached for register details.

22.1.3 MMDC register implementation

In this device, the following must be taken into consideration for register implementation.

- MDSCR[CON_ACK] bitfield: After a reset sequence, CON_REQ will be asserted, so as there are no pending AXI accesses to be cleaned, CON_ACK will be asserted indicating that MMDC registers configuration is permitted. See MMDC Core Special Command Register (MMDC_MDSCR)
- MDSCR[WL-EN]: Write leveling feature is not supported in LPDDR3. So, this bit is reserved. See MMDC Core Special Command Register (MMDC_MDSCR)
- MAPSR[4] behaves writeable by the CA7
- MAPSR[LPMD] behaves non-writeable by the CA7
- MAPSR[DVFS] behaves non-writeable by the CA7

22.2 Overview

MMDC is a multi-mode DDR controller that supports LPDDR2/LPDDR3/x32 memory types. MMDC is configurable, high performance, and optimized.

The following figure shows the MMDC block diagram.

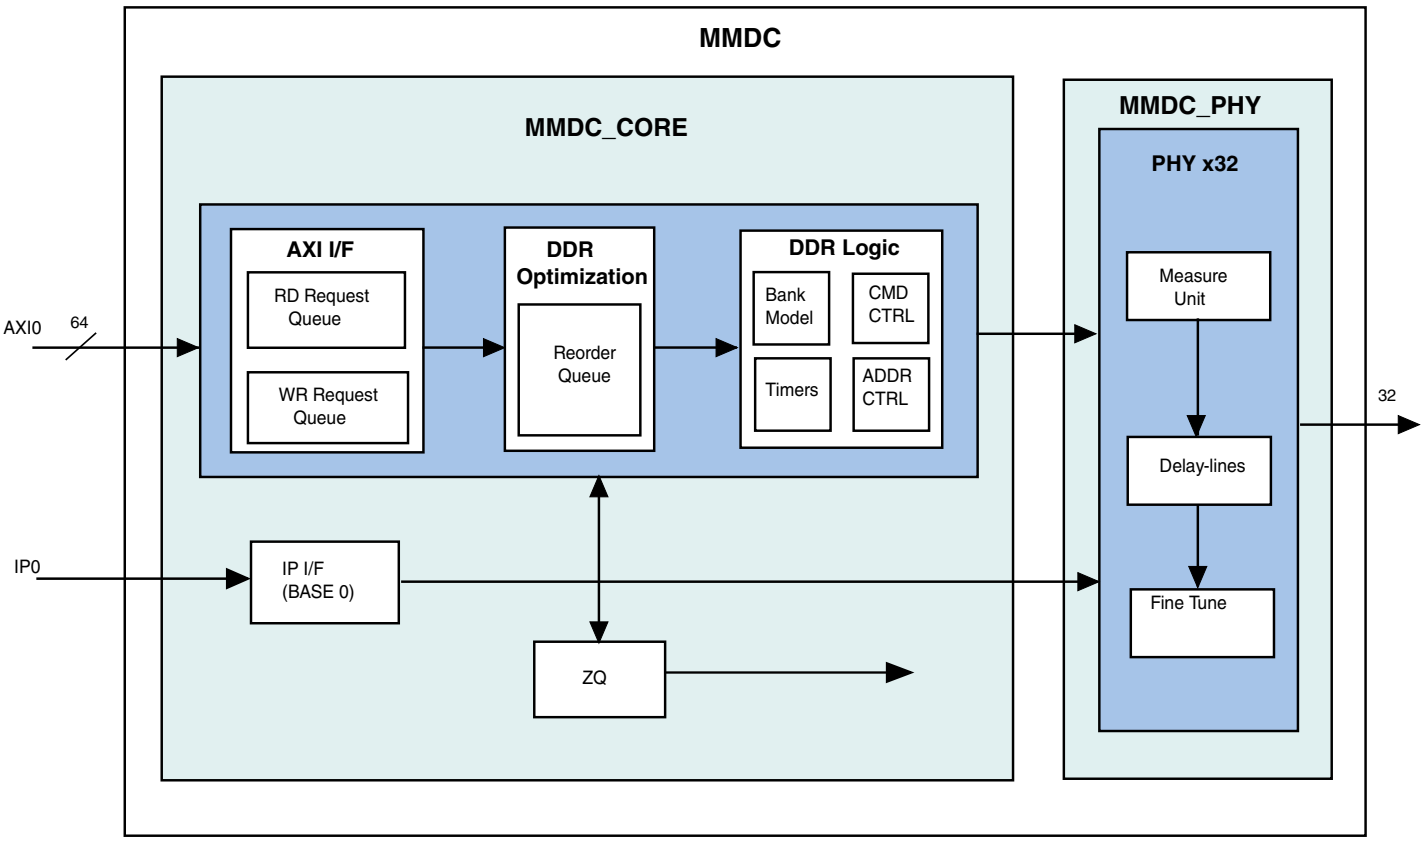

Figure 22-1. MMDC block diagram

MMDC consists of a core (MMDC_CORE) and PHY (MMDC_PHY).

- The core is responsible for communication with the system through an AXI interface, DDR command generation, DDR command optimizations, and a read/write data path.
- The PHY is responsible for the timing adjustment; it uses special calibration mechanisms to ensure data capture margin at a clock rate of up to 380 MHz.

The internal memory map (configuration registers) of the MMDC can be configured through an IP channel (IP0).

22.2.1 MMDC feature summary

The table found here summarizes the MMDC features.

Table 22-3. MMDC feature summary

Feature	Details
DDR standards	• LPDDR2/LPDDR3 x16, x32 • Does not support LPDDR1MDDR or DDR2

Table continues on the next page...

Table 22-3. MMDC feature summary (continued)

Feature	Details

DDR interface	• x32 data bus width
	• Density per DDR device of 256 Mbits–8 Gbits with the following column and row combinations:
	  • Column size of 8–12 bits
	  • Row size of 11–16 bits
	• Two chip selects (LPDDR2/LPDDR3)
	• Supports burst length of 4 for LPDDR2
	• Supports burst length of 8 for LPDDR3

DDR performance	• MMDC running at up to 380 MHz (760MT/s), see SCG block for actual clock frequencies supported. • Supports Real-Time priority by means of QoS sideband priority signals from the chip to enable various priority levels in the re-ordering mechanism: real-time, latency sensitive, normal priority. • Page hit/page miss optimizations • Consecutive read/write access optimizations • Supports deep read and write request queues to enable bank prediction. • Drives back the critical word in a read transaction as soon as it is received by the DDR device (does not wait until the whole data phase has been completed). • Keeps tracking of open memory pages • Supports bank interleaving **NOTE:** Due to reordering and optimization mechanisms (per different AXI Identifier (ID)), the transactions towards the DDR device may be driven in a different ID order than was received by the AXI master. In a similar fashion, the write response, read response or read data may be driven to the AXI master in a different ID order.

AXI interface	• AXI bus compliant
	• Supports bus transfers of 8, 16 , 32 , 64 bits (single accesses and bursts) running at 380 MHz.
	• Supports AXI bursts length of up to 16
	• Supports burst types of WRAP, INCR and FIXED
	• Supports 16 bits AXI ID
	• Write data interleave depth is 1 (no support for Write Data Interleave)
	• Supports write data before address
	• Supports buffered/non-buffered accesses (AWCACHE[0] = 0b means a non-bufferable access and AWCACHE[0] = 1b means a bufferable access). The rest of the CACHE options are not supported
	  • To keep data access coherency between write and read access of the same master, the response signal is sent as follows:
	  • Bufferable write access—BRESP will be sent when last data of the access has entered the MMDC.
	  • Non-bufferable write access—BRESP will be sent when the data was physically written into the external memory device.
	• Supports four exclusive monitors per configurable ID for only a single access with a size of up to 64 bits
	• Supports AXI responses as follows:
	  • Okay in case the access has been successful or exclusive access failure
	  • Slave error in case of security violation
	  • Exclusive okay in case the read or the write portion of an exclusive access has been successful

DDR calibration and delay-lines.	• Supports various calibration processes which can be performed either automatically (hardware) or manually (software) towards either CS0 or CS1. (At the end of the process the delay-lines will work with one set of results.) The following calibration processes are supported:

Table continues on the next page...

Table 22-3. MMDC feature summary (continued)

Feature	Details

	• ZQ calibration for external DDR device (in LPDDR2/LPDDR3 through MRW command)
	  • Can be handled automatically for ZQ Short (periodically) and ZQ Long (at exit from self-refresh)
	  • Can be handled manually at ZQ INIT
	• ZQ calibration for DDR I/O pads for calibrating the DDR driving strength
	  • The sequence can be handled automatically by hardware
	  • The sequence can be handled step by step manually by software
	• Read data calibration. Adjustment of read DQS with read data byte.
	• Write data calibration. Adjustment of write DQS with write data byte.
	• Write leveling calibration. Adjustment of write DQS with CK (DDR differential clock).
	• Read fine tuning. Adjustment of up to 7 delay-line units for each read data bit.
	• Write fine tuning. Adjustment of up to 3 delay-line units for each read data bit.
	• Periodic delay-line measurement for keeping its accuracy during refresh interval.
	• Additional fine tuning delay lines to adjust DDR clock delay, DDR clock duty cycle, DQS duty cycle.

Power saving	• Support of dynamic voltage, frequency change and self-refresh mode entry through hardware and software negotiation with the system (request/acknowledge handshake)
	  • Upon hardware or software self-refresh request assertion, further AXI requests are blocked (even before the assertion of the acknowledge).
	  • During self-refresh mode the system may deassert the operating clock of the MMDC for power saving.
	  • During self-refresh mode the clock (CK) that is driven to the DDR device will be gated for power saving.
	• Supports automatic self-refresh and power down entry and exit
	  • In automatic self-refresh, the internal operating clock will be gated for power saving.
	• Automatic active and precharge power down timer per chip select (one chip select can enter power down while the other is still working)
	• While CS (chip-select) is inactive (high) the command and address buses are not toggling for power saving.

DDR general	• Configurable timing parameters • Configurable refresh scheme • Page boundary crossing support • Automatically generates precharge command and activates the next row • Supports MRW and MRR commands for LPDDR2/LPDDR3 • Software control in LPDDR2/LPDDR3 mode for switching to derated timing parameters and/or update the refresh rate according to temperature sensor • Debug and profiling capabilities

22.3 External Signals

The table found here describes the external signals of MMDC.

Table 22-4. MMDC external signals[1]

Signal name	Description	Direction
DDR_CA0	MMDC Address Bus Signal	I/O

1. For details, see the IOMUXC and Pinout spreadsheet attached with the RM.

22.4 Clocks

The table found here describes the clock sources for MMDC.

See the chip-specific clocking information for details.

NOTE

The terms *clocks* and *cycles* are used interchangeably and refer to the clock period of the main ddr clock , commonly referred to as the DDR frequency.

Table 22-5. MMDC Clocks

Clock name	Clock Root	Description
aclk_fast_core_p0	mmdc_axi_clk_root	Fast clock (channel 1)
ipg_clk_p0	ipg_clk_root	Peripheral clock (channel 1)
aclk_fast_phy_p0	mmdc_axi_clk_root	Fast clock (channel 1 - PHY)

22.5 Functional Description

This section provides a complete functional description of the block.

22.5.1 Write/Read data flow

22.5.1.1 Write data flow

1. Write requests are received into an 8 entry request FIFO. Access is received only when there are at least two available entries. Each entry holds all of the AXI attributes.
   - If the burst length is greater than 8, the access splits into two accesses: one with burst length 8 and the other with the remainder.
   - The access can be performed as soon as the entire data phase of the associated write request is completed (all data beats were received).
2. A simple round-robin arbitration between the pending read and write accesses is performed, and the pointer to this stage's winner access is sent to the re-ordering buffer.
3. The reordering mechanism is activated to find the winner access, which is the access that best utilizes the DDR bus, based on its dynamic score. For further information see Dynamic scoring mode (Arbitration Winning Conditions).
4. The winner write access at the previous stage is received and is held for dispatch to the DDR logic.
5. When the DDR command control unit is ready to accept the write request, it issues (if needed) a precharge/active command to the DDR device according to the status of the bank model and the parameters of the timers.
6. The DDR logic drives the associated data to the DDR device through the DDR PHY.

22.5.1.2 Read data flow

1. Read requests are received into a 16 entry request FIFO in MMDC if there are at least two available entries. Each entry holds all of the AXI attributes.

NOTE

If the burst length is greater than 8, the access splits into 2 accesses (one with burst length 8 and the other with the remainder).

2. A simple round-robin arbitration between the pending read and write accesses is performed and the pointer to this phase's winner access is sent to the re-ordering buffer.
3. The reordering mechanism is activated to find the winner access, which is the access that best utilizes the DDR bus, based on its dynamic score. For further information see Dynamic scoring mode (Arbitration Winning Conditions).
4. The winner read access at the previous stage is sampled and is held for dispatch to the DDR logic. This read access will be dispatched when there is at least one free slot in the read data buffer to store the data.
5. When the DDR command control unit is ready to accept the read request, it issues (if needed) a precharge/active command to the DDR device according to the status of the bank model and the parameters of the timers.
6. The MMDC PHY samples the read data, and the DDR logic transfers the data to the associated slot in the read data buffer.
7. MMDC transfers the data back to the master.

22.5.2 MMDC initialization

Because the MMDC is disabled when the chip exits reset, no clock is driven to the DDR device and the whole interface towards the DDR device is inactive. The following steps are required to activate the MMDC properly.

NOTE

To guarantee that the DRAM_SDCKE signals are kept low during the power-up and reset sequences of the chip (as defined by JEDEC), you must connect those signals to pull-down resistors.

1. Set MDSCR[CON_REQ], which sets the configuration request; note that because the MMDC is disabled, there is no need to poll the configuration acknowledge bit at MDSCR[CON_ACK].

2. Configure the desired timing parameters at the MDCFG0, MDCFG1, and MDCFG2 registers.
3. Configure the DDR type and other miscellaneous parameters at the MDMISC register.
4. Configure the required delay while leaving reset, at the MDOR register.
5. Configure the DDR physical parameters (density and burst length) at the MDCTL register.
6. Perform a ZQ calibration of the MMDC module to correctly initialize drive strengths.
7. Enable MMDC with the desired chip select at MDCTL[SDE_0] (for chip select 0) and MDCTL[SDE_1] (for chip select 1). At this point, MMDC starts the reset and initialization sequence related to DRAM_SDCKE as defined by JEDEC.
8. Complete the initialization sequence as defined by JEDEC by issuing MRS/MRW commands for (ZQ, PRE, and so on). To issue those commands, configure the appropriate command and address at the MDSCR register.

NOTE

A Precharge All command must be issued prior to the MRW command to ensure robust DDR initialization. This command is required to be issued to both chip selects if two chip selects are utilized in the system.

9. Program the DDR mode registers by configuring the appropriate command and address at the MDSCR register.
10. Configure the power down and self-refresh entry and exit parameters at the MDPDC and MAPSR registers.
11. Configure the ZQ scheme at the MPZQHWCTRL and MPZQLP2CTL registers.
12. Configure and activate the periodic refresh scheme at the MDREF register.
13. Deassert the configuration request by clearing MDSCR[CON_REQ].

NOTE

Steps 1 through 6 are non-blocking and can be done in any order.

Upon completion of these steps, MMDC is ready for work and to process AXI accesses.

NOTE

To achieve better timing and better precision, it is recommended that users configure the MMDC PHY delay parameters by operating either the automatic or manual calibration process. Before starting any calibration process, you must disable the periodic refresh scheme (MDREF[REF_SEL] = 11) and then issue a manual refresh command by configuring

MDSCR[CMD] to 2h. For further information, see Calibration Process.

22.5.3 Configuring the MMDC registers

To safely modify MMDC's internal configuration registers, MMDC must be placed into configuration mode.

Use the following steps to enter configuration mode.

1. Issue a configuration request by setting MDSCR[CON_REQ].
2. Poll on configuration acknowledge until it is set at MDSCR[CON_ACK].

At this point, MMDC enters configuration mode and accessing the MMDC registers is permitted.

NOTE

During configuration mode, MMDC prevents further AXI accesses from being acknowledged.

Upon deassertion of MDSCR[CON_REQ], MMDC leaves configuration mode and AXI accesses are processed.

22.5.4 MMDC Address Space

22.5.4.1 Address decoding

MMDC supports up to two consecutive chip selects, each with the same density.

It is optional to configure the partition between the chip selects through MDASP[CS0_END].

The incoming AXI address bus is 32 bits. MMDC decodes each access as follows:

1. chip select
2. bank number
3. row number
4. column number

The following registers in the MMDC define the DDR address space:

- MDMISC[DDR_4_BANK]—Defines either 4 or 8 banks in the DDR device
- MDCTL[DSIZ]—Defines the DDR data bus width of x16, x32 or x64

- MDMISC[BI]—Defines whether bank interleaving is on or off
- MDCTL[COL]—Defines the column size of the DDR device
- MDCTL[ROW]—Defines the row size of the DDR device

The following tables show address decoding examples for x16 and x32 bit DDR devices when bank interleaving is both on and off. It is assumed that the configuration is as follows: 8 banks (3 bits), 15 bit assignment for the row, and 10 bit assignment for the column. The total density is 256 MWords (512 Mbytes for x16 and 1 Gbyte for x32).

NOTE

Chip selection is done by comparing the 7 most significant address bits (ARADDR[31:25]/AWADDR[31:25]) with MDASP[CS0_END].

NOTE

In cases where this is an access to a non-initialized or disconnected chip select, behavior may be unexpected.

22.5.4.2 Chip select settings

MMDC drives the incoming access to either CS0 or CS1 by comparing the 7 most significant address bits (ARADDR[31:25]/AWADDR[31:25]) with MDASP[CS0_END].

Generally, the total density per chip-select must be a power of two and the total density must be the same for each chip-select.

Creating 4 Gbyte address space with 2 Gbyte CS density and Creating 2 Gbyte address spaces with 1 Gbyte CS density show how to create a continous address space and configure the MMDC accordingly.

22.5.4.2.1 Creating 4 Gbyte address space with 2 Gbyte CS density

If the DDR memory space allocation is 4 Gbytes, only one configuration of chip select partition is allowed. The register MDASP[CS0_END] should be set to 2 Gbytes partition (16Gb).

The figure below shows the associated memory space.

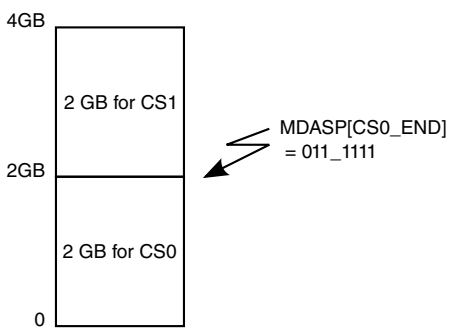

Figure 22-2. Chip select partion—2 Gbytes per chip select

22.5.4.2.2 Creating 2 Gbyte address spaces with 1 Gbyte CS density

If the DDR memory space allocation is 2 Gbytes, there are three options for configuring the chip select partition:MDASP[CS0_END] to 001_1111 (1 Gbyte), MDASP[CS0_END] to 011_1111 (2 Gbytes), and MDASP[CS0_END] to 101_1111 (3 Gbytes).

If DDR memory space allocation is 2 Gbytes, there are three options for configuring the chip select partition:

- MDASP[CS0_END] to 001_1111 (1 Gbyte)
- MDASP[CS0_END] to 011_1111 (2 Gbytes)
- MDASP[CS0_END] to 101_1111 (3 Gbytes)

The figure below shows the associated memory space:

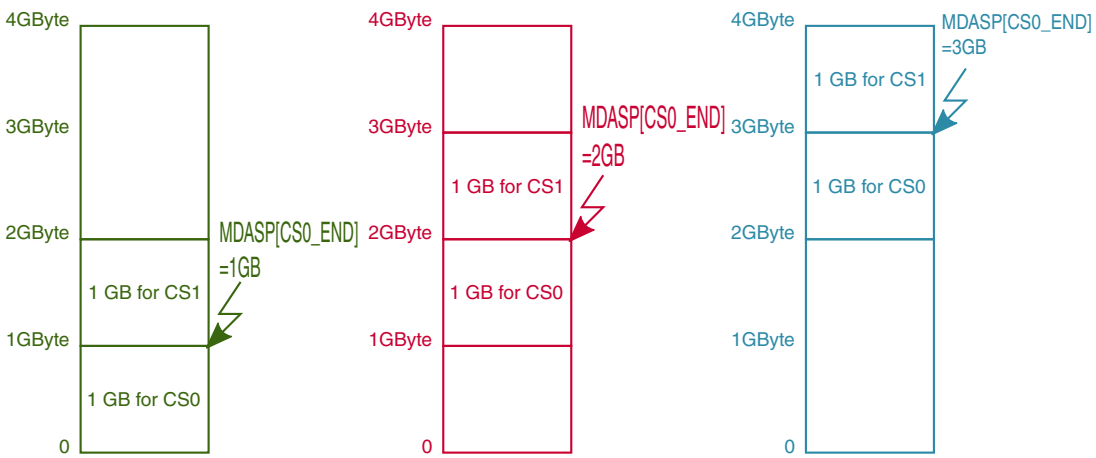

Figure 22-3. Chip select partion—1 Gbyte per chip select

22.5.5 Power Saving and Clock Frequency Change modes

22.5.5.1 Power saving general

MMDC supports multiple DDR power saving modes.

NOTE

At default, the power saving modes are disabled. These modes may dramatically decrease the power consumption of DDR memories.

1. Self-refresh entry to the entire DDR device (for both chip select 0 and 1) can be activated through two mechanisms:
   - LPMD (Low Power Mode)
     - Hardware handshaking (LPMD/LPACK) with the clock module in the system

- Software handshaking by setting the field MAPSR[LPMD] and polling MAPSR[LPACK]
- Automatic entry by configuring the amount of idle cycle for triggering self-refresh entry through MAPSR[PST] and by clearing MAPSR[PSD]

- DVFS (Dynamic Voltage and Frequency Change)
  - Software handshaking by setting the field MAPSR[DVFS] and polling MAPSR[DVACK]

NOTE

If hardware or software requests for self-refresh entry were detected by the MMDC (even before the assertion of the LPACK), no write or read accesses will be acknowledged until the deassertion of those requests.

2. Automatic active/precharge power down entry to a specific chip select can be activated by configuring the ESDPDC register:
   - PWDT_0/PWDT_1 - define the number of idle cycles before entering power down, can be different value per chip select.
   - SLOW_PD
   - BOTH_CS_PS - The MMDC can either set each chip select independently to power down, according to its idle state, or set both chip selects to power down only if both in idle state for the configured period.
   - Few parameters must be configured in addition:
     - Timing parameters at MDCFG0[tXP and tXPDLL].
     - ODT timing at MDOTC[tAOFPD, tAONPD, tANPD and tAXPD]

NOTE

It is possible to enter certain chip selects to low power consumption while the second chip select is activated.

3. Automatic precharge of all DDR banks to a specific chip select. Can be activated by configuring ESDPDC fields: PRCT_0 and PRCT_1. Each field determines a value loaded to a different chip select.

22.5.5.2 Self refresh and Frequency change entry/exit

As described in Power saving general, the MMDC supports two mechanisms that will cause the DDR device to enter self-refresh mode:

- LPMD (Low Power Mode) - For power saving purposes
- DVFS (Dynamic Voltage and Frequency Change) - For clock frequency changes

While the DDR device is in self-refresh mode, there is no need to provide periodic refresh commands.

The MMDC treats hardware/software handshaking of LPMD/DVFS in the same manner:

- Upon the assertion of LPMD/DVFS request, the following is done:
  - The MMDC blocks any further AXI accesses even before the acknowledge is asserted
  - Completes all opened AXI accesses
  - Closes (precharge) all banks in the appropriate timing
  - Drives self-refresh command by deasserting clock enable signal (DRAM_SDCKE is driven to "0") together with a refresh command. This occurs after satisfying tRP/tRPA from the Precharge All command.
  - Deasserts the clock (CK) that is driven to the DDR device
  - Asserts LPMD/DVFS acknowledge (LPACK/DVACK)
  - Allows deassertion of the operating clock of the MMDC (AXI clock)
- Upon the deassertion of LPMD/DVFS request, the following is done:
  - Operating clock of the MMDC must be turned on before LPMD/DVFS is deasserted
  - Starts driving the clock (CK) to the DDR device
  - After satisfying tCKSRX from clock renewal the clock enable signal (DRAM_SDCKE) is asserted
  - LPMD/DVFS acknowledge (LPACK/DVACK) is deasserted
  - After satisfying tXS from the assertion of DRAM_SDCKE, a refresh command is driven to the DDR device.
  - If ZQ calibration is enabled then tRFC is satisfied from the refresh command and a long ZQ command is driven.
  - tZQoper idle cycles are counted after the ZQ command.
  - After satisfying tDLLK from the assertion DRAM_SDCKE, the MMDC returns to normal operation.

The figure below shows the timing diagram of the hardware/software handshaking of LPMD/DVFS:

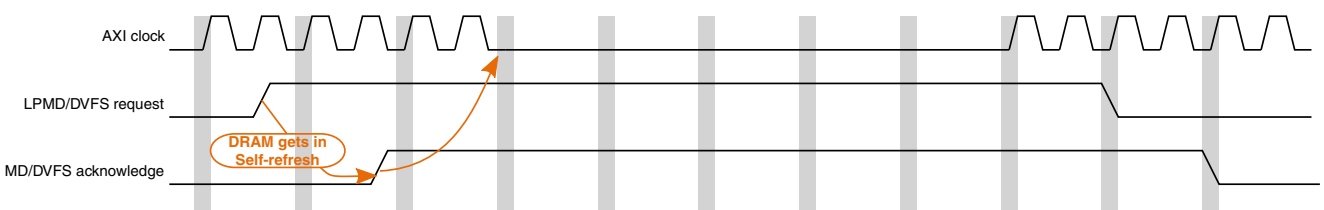

Figure 22-4. LPMD/DVFS Hardware/Software Handshaking

Note for self-refresh:

- As soon as LPMD or DVFS requests are detected by either hardware or software handshaking, the MMDC will deassert the AXI ARREADY/AWREADY signals immediately to block further requests from the system.
- In case of automatic self-refresh, the internal operating clock will be negated to save power.

22.5.6 Reset

22.5.6.1 Hard reset

When hard reset is asserted (aresetn is driven to "0") while warm reset is deasserted (warm_reset is driven to "0"), the entire MMDC will be initialized, including configuration/status registers and state machines.

In order to access the DDR device, the MMDC will then have to be reconfigured.

22.5.6.2 Warm reset

The MMDC supports warm reset signal. The warm reset signal must envelop the hard reset signal and then the MMDC will reset all the internal registers. The only registers that are not reset are those that are essential for returning it to normal operation without repeating the initialization sequence and without losing data stored in the memory (configuration/status registers won't be initialized).

For the successful operation of warm reset, the following steps must be performed:

- The MMDC must enter self-refresh mode. This can be achieved by either LPMD or DFVS requests
- Wait for LPMD or DVFS acknowledge
- Assert warm reset signal (i.e. drive warm_reset to "1")
- Assert hard reset signal (i.e. drive aresetn to "0")
- Deassert hard reset signal
- Deassert warm reset
- Get out of the LPMD/DVFS mode

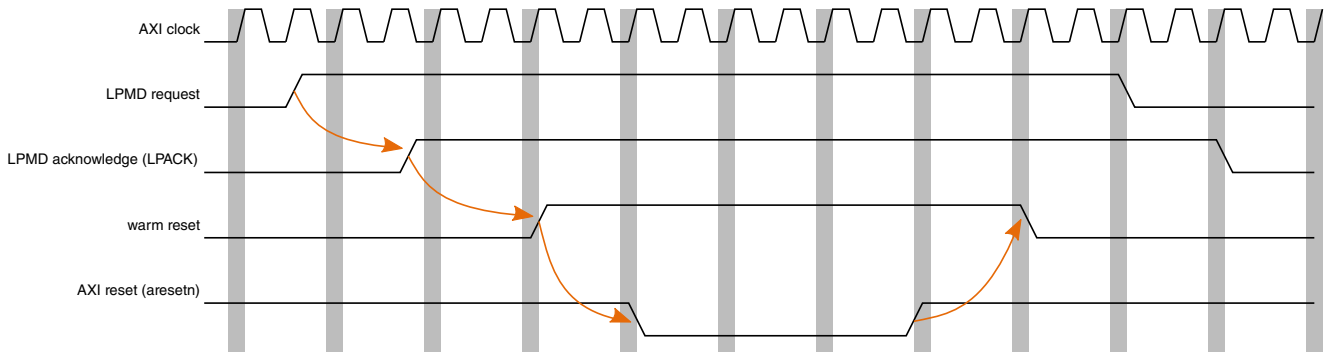

Figure 22-5. Warm Reset Diagram

22.5.6.3 Software reset

The MMDC supports software reset. When software reset is configured then the MMDC will reset all the internal registers except those that are essential for returning to normal operation without repeating the initialization sequence or without losing data stored in the memory (configuration/status registers won't be initialized).

The following steps should be performed for successful operation of software reset:

- The MMDC should enter self-refresh mode. This can be achieved by either LPMD or DFVS request.
- Wait for LPMD or DVFS acknowledge
- Assert software reset, by setting MDMISC[RST]
- Get out of the LPMD/DVFS mode

Normal operation can be resumed.

22.5.7 Refresh Scheme

The MMDC supports various automatic refresh options which can be configured via the MDREF register.

The periodic auto refresh can be triggered by the following clocks:

- 32 kHz clock
- 64 kHz clock
- MMDC operating clock

The refresh scheme of the MMDC is flexible and allows the system to configure the desired AXI accesses delay/latency in each refresh cycle.

The table below shows an example of four configurations of the refresh cycles that will be handled by the MMDC. Each configuration meets a refresh rate of 3.9µs (tREFI, refresh command every 3.9µs).

Table 22-8. MMDC Refresh Scheme

Option number	Description	REFR	REF_SEL	REF_CNT	DDR hang time
1	Issue 8 refresh commands every 31,250 ns	0x7 (8 refreshes)	0x0 (64 kHz)	not needed	tRFC x 8
2	Issue 4 refresh commands every 15,625ns	0x3 (4 refreshes)	0x1(32 kHz)	not needed	tRFC x 4
3	Issue 2 refresh commands every 7800ns	0x1(2 refreshes)	0x2 (REF_CNT)	7800/2.5 = 3120 (0xC30)	tRFC x 2
4	Issue 1 refresh command every 3900 ns	0x0 (1 refresh)	0x2 (REF_CNT)	3900/2.5 = 1560(0x618)	tRFC

22.5.8 Burst Length options towards DDR

The MMDC supports burst lengths which can be configured through MD+CTL[BL] as follows:

- In LPDDR2 mode, only burst length 4 can be used.
- In LPDDR3 mode, only burst length 8 can be used.

In case of AXI INCREMENT, accesses that are not aligned the irrelevant data is masked in write accesses and ignored in read accesses. In case of AXI WRAP accesses, even if the access is not aligned, then the MMDC provides an internal optimization mechanism for better efficiency of the DDR data bus.

22.5.9 Exclusive accesses handling

The MMDC contains four exclusive monitors, each for dedicated ID as configured in MAEXIDR0 and MAEXIDR1.

- If legal read exclusive is received by the MMDC, the associated monitor is turned on.
- While the monitor is turned on upon legal write exclusive, the monitor will be turned off and the write will be completed successfully with EXOKAY.
- The following rules must be met for successful exclusive access:
  - Aligned access (the AXI address is aligned to the AXI size)
  - AXI single access (AXI burst length isn't greater than 1)

- AXI size of up to 64 bits
- AXI non-cachable access (i.e. ARCACHE[1]/AWCACHE[1] is equal "0" or ARCACHE[1]/AWCACHE[1] is equal "1" while ARCACHE[3:2]/ AWCACHE[3:2] are equal "00")
- AXI ID that matches one of the four exclusive IDs

Exclusive read behavior (first bullet also correct for non-exclusive accesses):

- In case of security violation, the read is blocked and is not sent to DDR. There are two options for response:
  - If ARCR_SEC_ERR_EN (MAARCR[30]) is high, SLV error is issued towards the Master, otherwise OKAY response is sent to the Master.
- If AXI exclusive rules violation occurs (as described above), the read access is not blocked and is sent to DDR. The data will be fetched and be driven to the master, but the type of response may be unpredicted.
- If none of the above occurs, the read is sent to the DDR. The exclusive monitor will be turned on and the response is EXOKAY
- If additional legal AXI read exclusive is received with the same ID before the AXI exclusive write, the monitor will be updated with the latest attributes.

Exclusive write behavior (first bullet also correct for non-exclusive accesses):

- In case of security violation, the write is blocked and is not sent to DDR, but the monitor will be kept on. There are two options for response:
  - If ARCR_SEC_ERR_EN (MAARCR[30]) is high then SLV error is issued towards the Master, otherwise OKAY response is sent to the Master.
- In case of AXI exclusive rules violation (as described above), the write is blocked and is not sent to DDR. In that case the type of response may be unpredicted.
- In case the exclusive write access has different AXI attributes, but the same ID as the read exclusive access, the write is blocked and is not sent to DDR and the monitor will be turned off. There are two options for response:
  - If ARCR_EXC_ERR_EN (MAARCR[28]) is high then SLV error is issued towards the Master, otherwise OKAY response is sent to the Master.
- In case of regular (non exclusive) write access is received to the same address or overlapping addresses then the write will be sent to the DDR and the monitor will be turned off.
- In case of legal write exclusive access is received with the same attributes as the read exclusive access while the monitor is on (no write accesses occured to the same address between the read exclusive and write exclusive), then the write is sent to DDR and the response is EXOKAY. But, if the legal write exclusive is received while the monitor is off, the write is blocked and there are two options for response.
  - If ARCR_EXC_ERR_EN (MAARCR[28]) is high then SLV error is issued towards the Master, otherwise OKAY response is sent to the Master.

22.5.10 AXI Error Handling

The MMDC supports the AXI responses listed here.

- In case of AXI exclusive violation there are two options for response:
  - If MAARCR[28] is high then SLV Error is issued towards the Master, Otherwise OKAY response is sent to the Master

NOTE

In case of read error MMDC drives zeros on the read data bus

22.6 Performance

22.6.1 Arbitration and reordering mechanism

22.6.1.1 Arbitration General

The following specifies arbitration and reordering flow in MMDC towards the DDR.

- AXI read and write accesses are sampled in the associated queue.
- Read/write arbitration is handled to select the winning access.
- Winning access is sampled in the reordering queue
- Reordering mechanism is handled between valid requests that reside in the reordering queue to select the access that will be dispatched to the DDR.
  - The reordering is held in order to optimize the accesses and to maximize the utilization of the DDR bus
  - As soon as the reordered access is completed (indicated by end of response or data phase) then it is erased from the associated queue and the MMDC is ready to receive the next available access from the master

In general, the reordering/arbitration mechanism is based on dynamic priority mechanism, which compares dynamic priorities between valid entries in the reordering queue and issues the entry with highest dynamic priority towards the DDR Logic.

The selection of the winning access is based on two modes, which can be activated together, as following:

- Real time channel mode:

    - Accesses with QoS='f' (i.e. awqos[3:0]/arqos[3:0] = "f") will bypass all other requests towards the DDR
- Dynamic scoring mode:
    - The arbitration mechanism is based on dynamic priority. Relevant for the accesses with QoS smaller than 'f' or when real time channel mode is disabled.

NOTE

Due to re-ordering and optimization mechanism (per different AXI ID), the transactions towards the DDR may be driven in a different ID order they were received by the AXI master. In similar way, the write response, read response or read data may be driven to the AXI master in a different ID order.

22.6.1.2 Real time channel mode

When real time mode is enabled (i.e MAARCR[ARCR_RCH_EN] = "1") , all requests with QoS='f' (i.e. awqos[3:0]/aqqos[3:0] = "f") will bypass all other pending accesses towards the DDR. This mode is enabled by default.

22.6.1.3 Dynamic scoring mode (Arbitration Winning Conditions)

The arbitration between pending accesses in the MMDC is handled according to a dynamic priority of each access.

The dynamic priority (may be also called score) is calculated according to a sum of some factors (final_score[3:0]), where part of them may be updated dynamically. The following will specify each scoring factor:

- MAARCR[ARCR_PAG_HIT] (Page hit score) - A static score which is taken into account in case the pending access has a page hit
- MAARCR[ARCR_ACC_HIT] (Access hit score) - A static score, which is taken into account in case the current access type (read/write) is the same as the access that has been dispatched to the DDR previously
- MAARCR[ARCR_DYN_JMP] (Dynamic jump score) - A dynamic score which is given to any pending access in case it was not chosen in the arbitration. The dynamic jump counter is limited by maximum value which is set in MAARCR[ARCR_DYN_MAX] .
- QoS score which is indicated through a sideband 4bits AXI signals (awqos[3:0]/ aqqos[3:0]) and is driven by the AXI master per access

NOTE

In order to prevent an overflow in the total sum of scores, a clipping is held and selects the maximum score value of 'f' once a total scores sum is greater than 'f'.

The figure below shows the dynamic score calculations

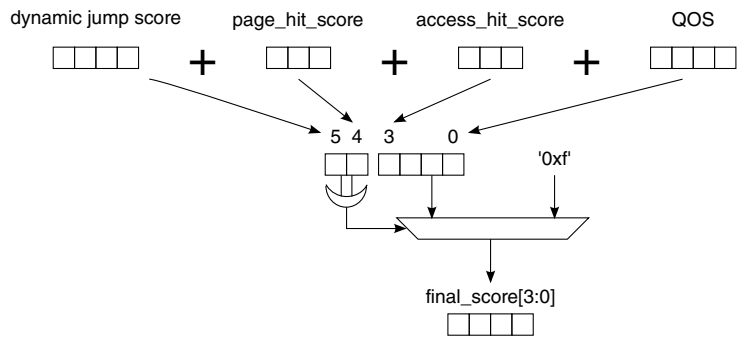

Figure 22-6. Dynamic score/priority calculation

22.6.1.4 Guarding (aging) mechanism

The guarding mechanism (may be also called aging) is used to prevent a starvation of accesses.

As soon as the dynamic jump score reaches its maximum value (MAARCR[ARCR_DYN_MAX]) then each time a pending request was not chosen in the arbitration, the "guarding" counter is incremented by 1. When the "guarding" counter reaches its predefined value, set in MAARCR[ARCR_GUARD], the associated request gets the highest priority and will be chosen in the next arbitration cycle towards the DDR unless a real time channel (i.e access with QoS ="f") is arrived.

Note: In case real time channel has arrived then the dynamic score of the non real time channels won't increment in order to prevent a case where the "guarding" counter of more than one access has reached its limit.

22.6.2 Prediction mechanism

When prediction mechanism is enabled (i.e by configuring MDMISC[MIF3_MODE]) then the MMDC predicts the chip-select, bank address and row address that is going to be issued towards the DDR before the access is physically dispatched towards DDR device.

That mechanism enables to prepare the DDR device with future accesses and improves the overall DDR performance.

This prediction mechanism operates in parallel to the reordering mechanism and may yield a prediction based on 3 levels of pending accesses:

1. Access in first stage of pipeline.
2. Valid access on AXI bus either read channel or write channel.
3. Valid access on special bus from arbitration - this access is chosen by the arbitration as the next miss access in its buffers

22.7 MMDC Debug

22.7.1 Hardware debug monitor

The MMDC has a hardware debugging mechanism that monitors each access that is driven to the MMDC. Every time this mechanism is enabled (setting of MADPCR0[DBG_EN] to "1") then each access that will be dispatched to the DDR will be also observed in the I/O pads (i.e. over ipp_do_ddr_debug[50:0]). The content of this bus is described in the table below.

Table 22-9. Hardware monitor debugging

Signal Name	Number of Bits	Description
acc_addr	[31:0]	AXI ADDRESS of the selected access
acc_type	1	access type of the selected access. "0 indicates write. "1" indicates read.
acc_id	[15:0]	AXI transaction ID of the selected access
valid_strobe	1	indication for a valid request. This signal will be asserted for 1 clock cycle

The fields above are organized as following:

MMDC_DEBUG[50:0] = {1'b0,valid_strobe,acc_id,access_type,addr}

These signals are sent to IOMUX, in IOMUX user can configure it to be output from the chip for debug usage.

22.7.2 Step By Step (SBS) software monitor

The MMDC has a Step By Step (SBS) software debugging mechanism that monitors each access that is driven to the MMDC. Every time this mechanism is trigerred then one AXI access will be dispatched to the DDR and in parallel its attributes will be observed in a status register.

Once the "step by step" is enabled (i.e. MADPCR0[SBS_EN] is "1") then all accesses to the DDR device will be halted. This SBS feature is used during DDR SDCLK frequency scaling to prevent any accesses to the DDR device during the transition. Setting MADPCR0[SBS] to "1" will dispatch the access that is pending in the head of the MMDC queue (read or write). Upon every setting of MADPCR0[SBS]:

- The AXI attributes of the access will be sampled in the associated MASBS0 and MASBS1 fields
- MADPCR0[SBS] will be cleared automatically.

Setting again MADPCR0[SBS] to "1" will dispatch the next pending access in the MMDC queue.

NOTE

Setting the ARCR_ARB_REO_DIS bit in the MMDC0_MAARCR Register disables the SBS function

22.8 MMDC Profiling

The profiling mechanism provides the ability to calculate the DDR utilization together with read and write accesses statistics towards DDR per given period of time.

MMDC supports the following profiling counters:

- MADPSR0 (Total cycles count) - Indicates the total amount of cycles of the profiling period (up to 2^32 cycles)
- MADPSR1 (Busy cycles count) - Indicates the total busy cycles during the profiling period. Busy cycles are any MMDC clock cycles where the internal state machine is not idle. If any read or write requests are pending in the FIFOs, the MMDC is not idle.
- MADPSR2 (Total read accesses count) - Indicates the total read accesses towards MMDC during the profiling period
- MADPSR3 (Total write accesses count) - Indicates the total write accesses towards MMDC during the profiling period
- MADPSR4 (Total read bytes count) - Indicates total bytes that were read from MMDC during the profiling period
- MADPSR5 (Total write bytes count) - Indicates total bytes that were written to MMDC during the profiling period

All profiling items described above are disabled by default. The following describes how to control the profiling mechanism:

- MADPCR0[DBG_EN] enables profiling.

- MADPCR0[PRF_FRZ] stops/freezes the profiling for example in case user wishes to perform DDR profiling per specific task. In order to resume profiling then MADPCR0[PRF_FRZ] should be cleared.
- MADPCR0[DBG_RST] clears all profiling counters
- MADPCR0[CYC_OVF] indicates whether an overflow occured in the total cycles counter (i.e. total amount of cycles are greater than 2^32) . This field can only cleared by writing '0'.

Read/Write statistics can be collected per specific AXI ID (16bits). The following fields in MADPCR1 register determines which AXI-ID or AXI-ID's to monitor:

- PRF_AXI_ID defines which AXI IDs are taken for profiling. Default values is 16'h0.
- PRF_AXI_ID_MASK defines which bits from PRF_AXI_ID will be compared with AXI ID of read/write access. "1" means to monitor the associated bit and "0" means don't care. Default value is 16'h0000, meaning all IDs are not monitored

So the AXI-IDs to be monitored are calculated according to the following equation:

(AXI-ID & PRF_AXI_ID_MASK) Xnor (PRF_AXI_ID & PRF_AXI_ID_MASK)

For example if AXI ID's between A100 till A1FF are wished to be monitored then the following should be configured:

- PRF_AXI_ID = A100
- PRF_AXI_ID_MASK = FF00

22.9 LPDDR2/3 Refresh Rate Update and Timing Derating

LPDDR2 devices may have a temperature sensor that is used to determine an appropriate refresh rate and whether AC timing derating is required. The status of the temperature sensor can be read through MRR command from LPDDR2 MR4 register.

The MMDC supports refresh update and timing derating mechanism on the fly. The following steps specify how to use that mechanism:

- Perform periodic polling on MR4 LPDDR2 register using MRR command
- Read MDMRR register and analyze the MR4 indication
- In case refresh rate update and/or AC timing derating is required then it is needed to update MDREF and/or MDMR4[tRCD_DE, tRC_DE, tRAS_DE, tRP_DE, tRRD_DE] parameters

NOTE

MDMR4[tRCD_DE, tRC_DE, tRAS_DE, tRP_DE, tRRD_DE] are referred to the associated values configured at MDCFG3LP[tRC_LP, tRP_LP, tRCD_LP], MDCFG1[tRAS], MDCFG2[tRRD]

- Assert MDMR4[UPDATE_DE_REQ]
- When the MMDC switch to the new values then an acknowledge will be indicated at MDMR4[UPDATE_DE_ACK]

The enabled power saving features may be interfering with the MR4 reads. When these features are enabled the MMDC will automatically enter self-refresh and hence prevent the MR4 reads. Hence the Power Saving and refresh functionality should be disabled when SW performs the MR4 reads.

To disable the “Power Down” mode, set bit 0 of MAPSR to 1’b.

To disable the “Self-Refresh Power Down Timer” mode, set bits [15:8] of MDPDC to 0x00.

Overall Sequence to Perform MR4 reads

1. Set MAPSR to 0x00010107
2. Set MDPDC to 0x00020076
3. MRR command to read MR4
4. Write MDPDC to 0x00025576 to re-enable this feature
5. Write MAPSR to 0x00010106 to re-enable this feature

22.10 Calibration Process

The MMDC offers various calibration processes that are used to obtain better timing accuracy, board skew compensation and I/O pad driving strength adjustment. Each calibration process can be performed either automatically (hardware) or manually (software), though the manual method is typically reserved for debugging purposes. The following calibration processes are supported:

NOTE

Power saving features must be disabled before beginning the write leveling, DQS gating, and read/write calibration processes. ZQ calibration is allowed with power saving features enabled.

- ZQ calibration for external DDR device (in LPDDR2/LPDDR3 through MRW command)

    - Can be handled automatically for ZQ Short (periodically) and ZQ Long (at exit from self-refresh)
    - Can be handled manually at ZQ INIT
- ZQ calibration for i.MX DDR I/O pads for calibrating the DDR driving strength
    - The sequence can be handled automatically by hardware
    - The sequence can be handled step by step manually by software
- Read DQS gating calibration not supported for LPDDR2/LPDDR3
- Read data calibration. Adjustment of read DQS with read data byte. For further information refer to Read Calibration
- Write data calibration. Adjustment of write DQS with write data byte. For further information refer to Write Calibration
- Read fine tuning. Adjustment of up to 7 delay-line units for each read data bit.
- Write fine tuning. Adjustment of up to 3 delay-line units for each read data bit.

- Disable the periodic refresh scheme (i.e. setting MDREF[REF_SEL] = "11") and then issue manual refresh command burst by configuring MDSCR[CMD]= 0x2. At the end of the calibration it is needed to enable the periodic refresh scheme.
- Disable the automatic power saving mode (i.e set MAPSR[PSD] = "1").

22.10.1 Delay-line

Each of the calibration processes controls several delay-lines for aligning data and strobes.

By default the delay-line is configured to generate 1/4 clock cycle of delay.

Moreover, when the operating clock is at the maximum allowed frequency, as appeared in the features list, then the delay-line is capable to issue a configurable delay of up to 1/2 clock cycle.

NOTE

At the beginning of the calibration process the initial value of the delay-line must be a valid value (i.e. the strobes must be somewhere among the associated data window) though it might not be the optimal value. The delay-line calibration should be done after Read DQS gating.

In order to generate an adequate delay during normal operation of the MMDC the delay-line is going through an automatic measurement process during the refresh period of the DDR device

22.10.2 ZQ calibration

The MMDC supports ZQ calibration process to calibrate the driving strength of the DDR I/O pads as well as driving ZQ commands to calibrate the external DDR device driving strength.

The first ZQ calibration (after booting the processor) is performed prior to turning on the MMDC. Subsequent ZQ calibrations may be executed in parallel to the DDR ZQ calibration. The MMDC supports 2 types of ZQ calibration commands: short and long.

The ZQ long calibration is executed during power up sequence, when exiting self-refresh mode or when exiting slow precharge power down (DLL lock can be done in parallel). The ZQ short calibration is executed periodically according to a configurable timer defined by MPZQHWCTRL[ZQ_HW_PER].

The field MPZQHWCTRL[ZQ_MODE] determines whether the MMDC will execute ZQ calibration to DDR I/O pads and/or issue ZQ short/long command to the DDR device.

The MMDC supports both automatic (hardware) and manual (software) ZQ calibration process for the DDR I/O pads.

It is possible to perform automatic (hardware) ZQ calibration only once (i.e. non-periodical) by asserting MPZQHWCTRL[ZQ_HW_FOR].

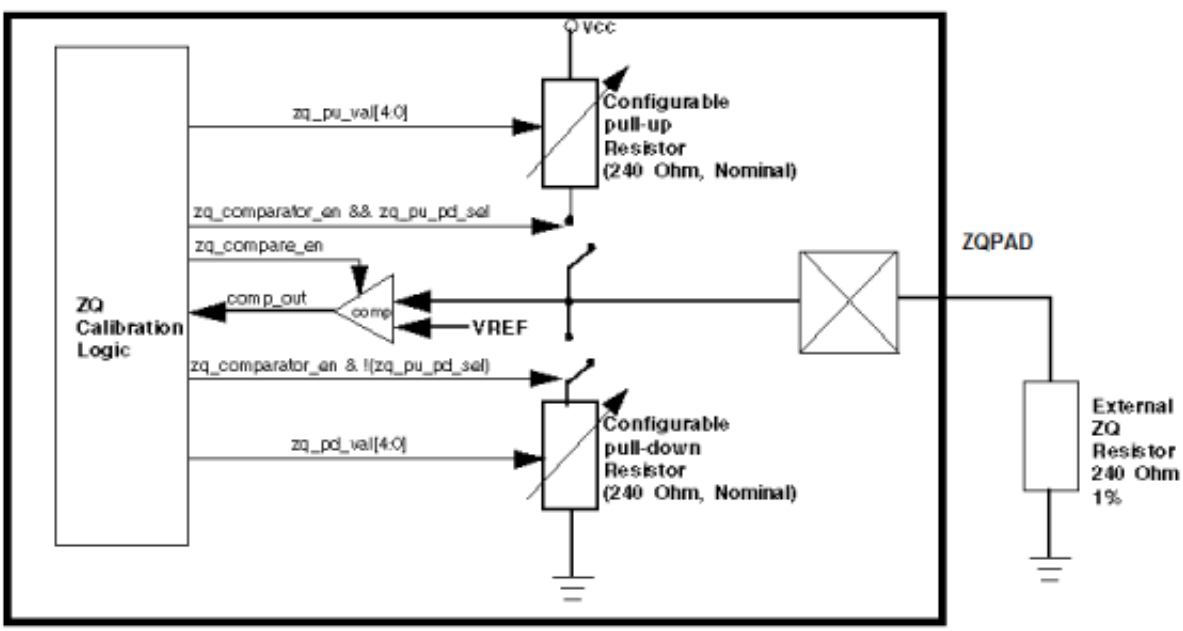

Figure 22-7. MMDC ZQ IF with PAD

22.10.2.1 ZQ automatic (hardware) calibration process

The ZQ automatic calibration occurs over multiple steps isolated by pull-up resistor calibration and by pull-down resistor calibration as follows.

22.10.2.1.1 ZQ automatic Pull-up calibration

The MMDC automatically performs a handshaking mechanism with the ZQ calibration pad as follows:

1. The MMDC drives zq_comparator_en to "1"
2. The MMDC waits few cycles according to MPZQHWCTRL[ZQ_EARLY_COMPARATOR_EN_TIMER]
3. The MMDC drives zq_pu_pd_sel to "1" for indication of pull-up calibration and drives zq_pu_val[4:0] = 5'b00000
4. MMDC drives zq_pu_val[4] to "1"
5. MMDC asserts zq_compare_en
6. MMDC waits few cycles according to MPZQSWCTRL[ZQ_CMP_OUT_SMP] before sampling the comparator output (i.e zq_comp_out). If zq_comp_out is "1" then it means that the output voltage is greater than Vdd/2 (i.e. internal resistor is less than 240 ohm) and drives bit zq_pu_val[4] to "1" else it drives zq_pu_val[4] to "0"
7. MMDC deasserts zq_compare_en
8. MMDC repeats steps 4-7 for zq_pu_val bits 3 to 0
9. MMDC drives ZQ calibration result to MPZQHWCTRL[ZQ_HW_PU_RES]
10. MMDC advances to pull-down calibration

22.10.2.1.2 ZQ automatic Pull-down calibration

1. The MMDC drives zq_pu_pd_sel to "0" for indication of pull-down calibration and drives zq_pd_val[4:0] = 5'b00000
2. MMDC drives zq_pd_val[4] to "1"
3. MMDC asserts zq_compare_en
4. MMDC waits few cycles according to MPZQSWCTRL[ZQ_CMP_OUT_SMP] before sampling the comparator output (i.e zq_comp_out). If zq_comp_out is "1" then it means that the output voltage is greater than Vdd/2 (i.e. internal resistor is less than 240 ohm) and drives bit zq_pd_val[4] to "0" else it drives zq_pd_val[4] to "1"
5. MMDC deasserts zq_compare_en
6. MMDC repeats steps 2-5 for zq_pd_val bits 3 to 0
7. MMDC drives ZQ calibration result to MPZQHWCTRL[ZQ_HW_PD_RES]
8. MMDC deassert zq_comparator_en to indicate the completion of the ZQ calibration

22.10.2.2 ZQ software calibration process

The ZQ calibration can be done also in software. However since software ZQ calibration is much slower than hardware calibration it should be used mainly for debugging.

Software should configure the ZQ calibration parameters (Pull-up or Pull-down and their value) then assert the MPZQSWCTRL[ZQ_SW_FOR] bit. Then software should wait till ZQ_SW_FOR is de-asserted and use ZQ_SW_RES status bit in order to calculate the next ZQ calibration parameters.

22.10.2.3 ZQ calibration commands

Before the MMDC can issue a ZQCL/ZQCS command to the memory it should precharge all memory banks and wait tRP period. A single ZQ command can be issued to all devices as long as the devices don't share the same ZQ resistor.

When the MMDC issues the ZQ command it should also drive A10 (long or short command) and CS (0, 1 or both).

The MMDC must keep the memory lines quiet (except for CK) for the ZQ calibration time as defined in the Jedec (512 cycles for ZQCL after reset, 256 for other ZQCL and 64 for ZQCS).

22.10.3 Read Calibration

The read calibration is used to adjust the read DQS with read data byte. It is assumed that the read DQS gating calibration process is completed prior to the read calibration.

NOTE

In LP2/3_x16, LP2/3_x32 the activation of the calibration is done by setting MPRDDLHWCTL[HW_RD_DL_EN].

22.10.3.1 Hardware (automatic) Read Calibration

There are two modes of operations:

- Calibration with the MPR (Multi Purpose Register)/DQ calibration(LPDDR2/ LPDDR3)
- Calibration with MMDC pre-defined values

22.10.3.1.1 Hardware (automatic) Calibration with DQ Calibration

Execute the following steps:

1. Precharge all active banks (can be done through MDSCR) as required.
2. Enter the DDR device into DQ calibration mode through MRS/MRW commands.
3. Configure the MMDC to work with DQ calibration mode by asserting MPPDCMPR2[MPR_CMP].
4. Make sure that the initial value that is configured in the read delay line absolute offset of each byte (MPRDDLCTL[RD_DL_ABS_OFFSET#]) will place the read DQS somewhere inside the read DQ window.
5. Start the calibration process by asserting MPRDDLHWCTL[HW_RD_DL_EN].

22.10.3.1.2 Hardware (automatic) Calibration with pre-defined value

In case pre-defined mode is used, i.e. MPPDCMPR2[MPR_CMP] is cleared, then the following steps should be executed:

1. Precharge all active banks (Can be done through MDSCR) as required.
2. Configure the pre-defined value, which reflects the value that will be written and compared through the read calibration, to MPPDCMPR1[PDV1, PDV2]
3. Issue write access to the external DDR device by setting MPSWDAR0[SW_DUMMY_WR] = 1 (MMDC will generate internally write access without intervention of the system towards bank 0, row 0, column 0)
4. Make sure that the initial value that is configured in the read delay line absolute offset of each byte (i.e. MPRDDLCTL[RD_DL_ABS_OFFSETn]) will place the read DQS somewhere inside the read DQ window
5. Start the calibration process by asserting MPRDDLHWCTL[HW_RD_DL_EN]

The following steps will be executed automatically by the MMDC for both modes (MPR and Pre-defined value):

1. MMDC waits till the read delay-line is updated with the absolute delay value for all bytes at MPRDDLCTL[RD_DL_ABS_OFFSETn] and also satisfying the Tmod + 4 requirement
2. MMDC drives read command to the external DDR devices and waits 16 or 32 cycles (according to MPRDDLHWCTL[HW_RD_DL_CMP_CYC]) assuming that the data has arrived from the DDR device.
3. MMDC compares the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it indicates that the initial read DQS isn't inside the read DQ window and the MMDC generates an error for the associated byte at MPRDDLHWCTL[HW_RD_DL_ERRn] . If the comparison passes then MMDC advances to next step.
4. MMDC resets the rd fifo (to the inverted pre-defined/MPR value) and it's pointers by setting MPDGCTRL[RST_RD_FIFO] = 1

5. MMDC decrements the read delay line absolute offset of each byte by 1 (i.e. MPRDDLCTL[RD_DL_ABS_OFFSETn]) and issue measurement process of the read delay-line to update itself with the new value.
6. MMDC drives read command to the DDR external devices and waits 16 or 32 cycles (according to MPRDDLHWCTL[HW_RD_DL_CMP_CYC]) assuming that the data has arrived from the DDR device
7. MMDC compares the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it stores the low read boundary of the associated byte for each byte at MPRDDLHWST0/1[HW_RD_DL_LOWn] . If the comparison passes then MMDC repeats steps 4-6. If all read data comparisons fail then the MMDC advances to the next step
8. The MMDC start seeking the upper boundary and sets the read delay line absolute offset of each byte to the initial value + 1 as determined at step 4 and issue measurement process of the read delay-line to update itself with the new value
9. MMDC resets the rd fifo (to the inverted pre-defined value) and it's pointers by setting MPDGCTRL[RST_RD_FIFO] = 1
10. MMDC drives read command to the DDR external devices and waits 16 or 32 cycles (according to MPRDDLHWCTL[HW_RD_DL_CMP_CYC]) assuming that the data has arrived from the DDR device
11. MMDC compares the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it stores the upper read boundary of the associated byte for each byte at MPRDDLHWST0/1[HW_RD_DL_UPn] . If the comparison passes then MMDC increments the read delay line absolute offset of each byte by 1 (i.e. MPRDDLCTL[RD_DL_ABS_OFFSETn]) and issue measurement process of the read delay-line to update itself with the new value.
12. If all read data comparisons fail then the MMDC advances to the next step. otherwise, MMDC repeats steps 9-11.
13. After the MMDC finds the window boundary (lower and upper) of each read data byte then it stores the average between lower and upper boundaries at the associated MPRDDLCTL[RD_DL_ABS_OFFSETn] and issue measurement process of the read delay-line to update itself with the new value.
14. MMDC indicates that the read data calibration had finished by setting MPRDDLHWCTL[HW_RD_DL_EN] = 0
15. Exit the DDR device from MPR/DQ calibration mode through MRS/MRW commands

22.10.3.2 SW Read Calibration

There are two modes of operations:

- Calibration with the MPR (Multi Purpose Register)/DQ calibration (LPDDR2/ LPDDR3)
- Calibration with MMDC pre-defined values

22.10.3.2.1 Calibration with DQ calibration

Execute the following steps:

1. Precharge all active banks (Can be done through MDSCR) as required.
2. Enter the DDR device into DQ calibration mode through MRS/MRW commands
3. Configure the MMDC to work with DQ calibration mode by asserting MPPDCMPR2[MPR_CMP]
4. Make sure that the initial value that is configured in the read delay line absolute offset of each byte (i.e. MPRDDLCTL[RD_DL_ABS_OFFSETn]) will place the read DQS somewhere inside the read DQ window

22.10.3.2.2 Calibration with pre-defined value

In case pre-defined mode is used, i.e. MPPDCMPR2[MPR_CMP] is cleared, then the following steps should be executed:

1. Precharge all active banks (Can be done through MDSCR) as requried by the standard.
2. Configure the pre-defined value, which reflects the value that will be written and compared through the read calibration, to MPPDCMPR1[PDV1, PDV2]
3. Issue write access (with any legal DDR address) to external DDR device.
4. Make sure that the initial value that is configured in the read delay line absolute offset of each byte (i.e. MPRDDLCTL[RD_DL_ABS_OFFSETn]) will place the read DQS somewhere inside the read DQ window

The following steps will be executed manually by SW for both modes (MPR/DQ calibration and Pre-defined value):

1. Force the delay line to measure itself and to issue the requested read delay by configuring MPMUR[FRC_MSR] = 1
2. Wait 16 DDR cycles till the read delay-line is updated with the absolute delay value for all bytes
3. Issue read command (with any legal DDR address) from the external DDR device
4. Compare the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it indicates that the initial read DQS isn't inside the read DQ window. If the comparison passes then advance to next step.
5. Reset the rd fifo (to the inverted pre-defined/MPR value) and it's pointers by setting MPDGCTRL[RST_RD_FIFO] = 1

6. Decrement the read delay line absolute offset of each byte by 1 (i.e. MPRDDLCTL[RD_DL_ABS_OFFSETn])
7. Force the delay line to measure itself and to issue the requested read delay by configuring MPMUR[FRC_MSR] = 1
8. Issue read command (with the legal DDR address chosen in step 7) from the external DDR device and waits 16 or 32 cycles (according to MPRDDLHWCTL[HW_RD_DL_CMP_CYC]) assuming that the data has arrived from the DDR device
9. Compare the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it is needed to store the low read boundary of the associated byte at of each byte . If the comparison passes then repeat steps 5-8. If all read data comparisons fail then advance to the next step.
10. Start seeking the upper boundary and set the read delay line absolute offset of each byte to the initial value + 1 as determined at step 4
11. Force the delay line to measure itself and to issue the requested read delay by configuring MPMUR[FRC_MSR] = 1
12. Resets the rd fifo (to the inverted pre-defined/MPR value) and it's pointers by setting MPDGCTRL[RST_RD_FIFO] = 1
13. Issue read command (with the legal DDR address chosen in step 7) from the external DDR device
14. Compare the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it is needed to store the upper read boundary of the associated byte at of each byte. If the comparison passes then increment the read delay line absolute offset of each byte by 1 (i.e. MPRDDLCTL[RD_DL_ABS_OFFSETn])
15. Force the delay line to measure itself and to issue the requested read delay by configuring MPMUR[FRC_MSR] = 1
16. If all read data comparisons fail then advance to the next step, else repeat steps 12-15.
17. After finding the window boundary (lower and upper) of each read data byte then calculate the average between lower and upper boundaries and store the associated average at MPRDDLCTL[RD_DL_ABS_OFFSETn]
18. Force the delay line to measure itself and to issue the requested read delay by configuring MPMUR[FRC_MSR] = 1
19. Exit the DDR device from MPR/DQ calibration mode through MRS/MRW commands.

22.10.4 Write Calibration

The write calibration is used to adjust the write DQS with write data byte. It is assumed that the read calibration process is completed prior to the write calibration.

NOTE

In LP2/3_x16, LP2/3_x32 the activation of the calibration of each channel is done by setting MPWRDLHWCTL0[HW_WR_DL_EN].

22.10.4.1 HW (automatic) Write Calibration

The following steps should be executed:

1. Make sure that the initial value that is configured in the write delay line absolute offset of each byte (i.e. MPWRDLCTL[WR_DL_ABS_OFFSET#]) will place the write DQS somewhere inside the write DQ window
2. Configure the pre-defined value, which reflects the value that will be written and compared through the write calibration, to MPPDCMPR1[PDV1, PDV2]
3. Assert MPWRDLHWCTL0[HW_WR_DL_EN]

The following steps will be executed automatically:

1. MMDC waits till the write delay-line is updated with the absolute delay value for all bytes at MPWRDCTL[WR_DL_ABS_OFFSET#]
2. MMDC drives write command to the external DDR devices (to bank 0 address 0) and waits 16 or 32 cycles (according to MPWRDLHWCTL[HW_WR_DL_CMP_CYC]) assuming that the data has arrived to the DDR device.
3. MMDC drives read command to the same address from the external DDR
4. MMDC compares the read data byte to the associated byte in the pre-defined value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it indicates that the initial write DQS isn't inside the write DQ window and the MMDC generates an error for the associated byte at MPWRDLHWCTL[HW_WR_DL_ERR#] . If the comparison passes then MMDC advances to next step.
5. MMDC resets the rd fifo (to the inverted pre-defined value) and it's pointers by setting MPDGCTRL[RST_RD_FIFO] = 1
6. MMDC decrements the write delay line absolute offset of each byte by 1 (i.e. MPWRDLCTL[WR_DL_ABS_OFFSET#]) and issue measurement process of the write delay-line to update itself with the new value.
7. MMDC drives write command to the external DDR devices (to bank 0 address 0) and waits 16 or 32 cycles (according to MPWRDLHWCTL[HW_WR_DL_CMP_CYC]) assuming that the data has arrived to the DDR device

8. MMDC drives read command to the same address from the external DDR
9. MMDC compares the read data byte to the associated byte in the pre-defined value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it stores the low write boundary of the associated byte of each byte at MPWRDLHWST0/1[HW_WR_DL_LOW#] . If the comparison passes then MMDC repeats steps 8-11. If all data comparisons fail then the MMDC advances to the next step
10. The MMDC start seeking the upper boundary and sets the write delay line absolute offset of each byte to the initial value + 1 as determined at step 4 and issue measurement process of the write delay-line to update itself with the new value
11. MMDC resets the rd fifo (to the inverted pre-defined value) and its pointers by setting MPDGCTRL[RST_RD_FIFO] = 1
12. MMDC drives write command to the external DDR devices (to bank 0 address 0) and waits 16 or 32 cycles (according to MPWRDLHWCTL[HW_WR_DL_CMP_CYC]) assuming that the data has arrived to the DDR device.
13. MMDC drives read command to the same address from the external DDR
14. MMDC compares the read data byte to the associated byte in the pre-defined value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it stores the upper write boundary of the associated byte of each byte at MPWRDLHWST0/1[HW_WR_DL_UP#] . If the comparison passes then MMDC increments the write delay line absolute offset of each byte by 1 (i.e. MPWRDLCTL[WR_DL_ABS_OFFSET#]) and issue measurement process of the write delay-line to update itself with the new value.
15. MMDC repeats steps 14-17. If all data comparisons fail then the MMDC advances to the next step
16. .After the MMDC finds the window boundary (lower and upper) of each write data byte then it stores the average between lower and upper boundaries at the associated MPWRDLCTL[WR_DL_ABS_OFFSET#] and issue measurement process of the write delay-line to update itself with the new value.
17. MMDC indicates that the write data calibration had finished by setting MPWRDLHWCTL[HW_WR_DL_EN] = 0

22.10.4.2 SW Write Calibration

The following steps should be executed:

NOTE

It is recommended to perform the write calibration using the HW method. The SW method is provided for debug purposes only.

1. Make sure that the initial value that is configured in the write delay line absolute offset of each byte (i.e. MPWRDLCTL[WR_DL_ABS_OFFSETn]) will place the write DQS somewhere inside the write DQ window
2. Configure the pre-defined value, which reflects the value that will be written and compared through the write calibration, to MPPDCMPR1[PDV1, PDV2]
3. Force the delay line to measure itself and to issue the requested write delay by configuring MPMUR0[FRC_MSR] = 1
4. Wait 16 DDR cycles till the write delay-line is updated with the absolute delay value for all bytes
5. Issue write command to any legal DDR address of the external DDR device
6. Issue read command, to the address written previously, from the external DDR device
7. Compare the read data byte to the associated byte in the pre-defined value for all bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it indicates that the initial write DQS isn't inside the write DQ window. If the comparison passes then advance to next step.
8. MMDC resets the rd fifo (to the inverted pre-defined value) and it's pointers by setting MPDGCTRL[RST_RD_FIFO] = 1
9. Decrement the write delay line absolute offset of each byte by 1 (i.e. MPWRDLCTL[WR_DL_ABS_OFFSETn])
10. Force the delay line to measure itself and to issue the requested write delay by configuring MPMUR0[FRC_MSR] = 1
11. Issue write command to any legal DDR address of the external DDR device
12. Issue read command, to the address written previously, from the external DDR device
13. Compare the read data byte to the associated byte in the pre-defined value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it is needed to store the low write boundary of the associated byte of each byte at MPWRDLHWST0/1[HW_WR_DL_LOWn] . If the comparison passes then repeat steps 8-12. If all data comparisons fail then advance to the next step.
14. Start seeking the upper boundary and set the write delay line absolute offset of each byte to the initial value + 1
15. Force the delay line to measure itself and to issue the requested write delay by configuring MPMUR0[FRC_MSR] = 1
16. Reset the rd fifo (to the inverted pre-defined value) and it's pointers by setting MPDGCTRL[RST_RD_FIFO] = 1
17. Issue write command to any legal DDR address of the external DDR device
18. Issue read command, to the address written previously, from the external DDR device
19. Compare the read data byte to the associated byte in the pre-defined value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it is needed

to store the upper write boundary of the associated byte of each byte at MPWRDLHWST0/1[HW_WR_DL_UPn]. If the comparison passes then increment the write delay line absolute offset of each byte by 1.

20. Force the delay line to measure itself and to issue the requested write delay by configuring MPMUR0[FRC_MSR] = 1
21. If all read data comparisons fail then advance to the next step else repeat steps 16-20.
22. .After finding the window boundary (lower and upper) of each write data byte then calculate the average between lower and upper boundaries and store the associated average at MPWRDLCTL[WR_DL_ABS_OFFSETn]
23. Force the delay line to measure itself and to issue the requested write delay by configuring MPMUR0[FRC_MSR] = 1

22.10.5 Write fine tuning

Write fine tuning is an additional circuit that provides the ability to fine tune the timing of each of the DQ/DM bits (relative to DQS) by up to 100 ps. To use the write fine tuning, select the number of delay units in each DQ/DM I/O (maximum 3 delay units of around 30-35 ps each). The delay can be configured independently for each DQ/DM. This configuration is controlled by the IOMUXC.

22.10.6 Read fine tuning

Read fine tuning is an additional circuit that provides the ability to fine tune the timing of each coming dq bits (relative to coming dqs) by up to +/-100 ps.

This is done by reducing the delay between the incoming rd_dqs by 100 ps and adding a configurable delay of up to 200 ps (6 delay units of around 30-35 ps each) for each DQ input. The delay can be configured independently for each DQ. The calibration of this mechanism can be done only by writing and reading data from the memory. Controlled by register MPRDDQBY#DL.

22.10.7 ZQ Fine Tuning

An offset can be added to the PU /PD values determined by the ZQ calibration process. The offset range is programmable from -7 to +7, controlled by the MMDC_MPPDCMPR2[ZQ_PU_OFFSET] and MMDC_MPPDCMPR2[ZQ_PD_OFFSET] fields. The offset is enabled/disabled by MMDC_MPPDCMPR2[ZQ_OFFSET_EN]. See MMDC_MPPDCMPR2 register for more information.

22.10.8 Duty cycle adjustment

Duty cycle adjustments can be made to the SDCLKx and SDQSx signals, see the MMDCx_MPDCCR register for more information.

22.11 MMDC Memory Map/Register Definition

The Memory Map is shown below.

NOTE

The terms *clocks* and *cycles* are used interchangeably and refer to the clock period of the main ddr clock , commonly referred to as the DDR frequency.

MMDC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

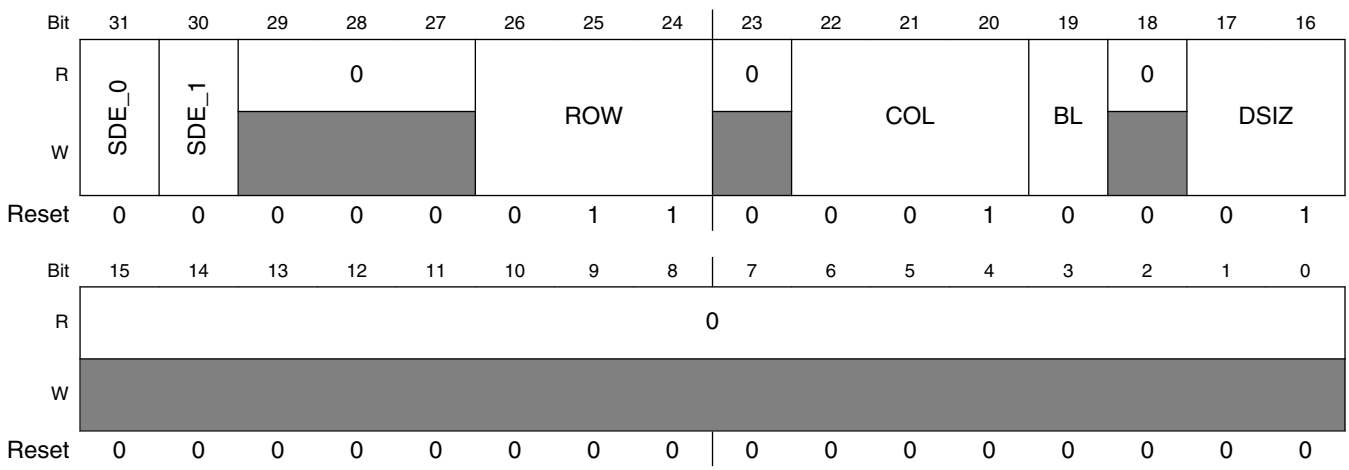
22.11.1 MMDC Core Control Register (MMDCx_MDCTL)

Address: 40AB_0000h base + 0h offset = 40AB_0000h



MMDCx_MDCTL field descriptions

Field	Description
31 SDE_0	MMDC Enable CS0. This bit enables/disables accesses from the MMDC toward Chip Select 0. The reset value of this bit is "0" (i.e. No clocks and clock enable will be driven to the memory). At the enabling point the MMDC will perform an initialization process (including a delay on RESET and/or CKE) for both chip selects. The initialization length depends on the configured memory type. 0 Disabled 1 Enabled
30 SDE_1	MMDC Enable CS1. This bit enables/disables accesses from the MMDC toward Chip Select 1. The reset value of this bit is "0" (i.e. No clocks and clock enable will be driven to the memory). At the enabling point the MMDC will perform an initialization process (including a delay on RESET and/or CKE) for both chip selects. The initialization length depends on the configured memory type.

Table continues on the next page...

MMDCx_MDCTL field descriptions (continued)

Field	Description
	0 Disabled 1 Enabled
29–27 Reserved	This read-only field is reserved and always has the value 0.
26–24 ROW	Row Address Width. This field specifies the number of row addresses used by the memory array. It will affect the way an incoming address will be decoded. Settings 110-111 are reserved 000 11 bits Row 001 12 bits Row 010 13 bits Row 011 14 bits Row 100 15 bits Row 101 16 bits Row
23 Reserved	This read-only field is reserved and always has the value 0.
22–20 COL	Column Address Width. This field specifies the number of column addresses used by the memory array. It will determine how an incoming address will be decoded. 0x0 9 bits column 0x1 10 bits column 0x2 11 bits column 0x3 8 bits column 0x4 12 bits column 0x5-0xF Reserved
19 BL	Burst Length. This field determines the burst length of the DDR device. In LPDDR2 mode the MMDC supports burst length 4. In LPDDR3 mode the MMDC supports burst length 8. 0 Burst Length 4 is used 1 Burst Length 8 is used
18 Reserved	This read-only field is reserved and always has the value 0.
17–16 DSIZ	DDR data bus size. This field determines the size of the data bus of the DDR memory 0 16-bit data bus 1 32-bit data bus — — — 2-3 Reserved
Reserved	This read-only field is reserved and always has the value 0.

22.11.2 MMDC Core Power Down Control Register (MMDCx_MDPDC)

Table 22-10. PRCT field encoding

PRCT[2:0]	Precharge Timer
000	Disabled (Bit field reset value)
001	2 clocks
010	4 clocks
011	8 clocks
100	16 clocks
101	32 clocks
110	64 clocks
111	128 clocks

Table 22-11. PWDT field encoding

PWDT[3:0]	Power Down Time-out
0000	Disabled (bit field reset value)
0001	16 cycles
0010	32 cycles
0011	64 cycles
0100	128 cycles
0101	256 cycles
0110	512 cycles
0111	1024 cycles
1000	2048 cycles
1001	4096 cycles
1010	8196 cycles
1011	16384 cycles
1100	32768 cycles
1101-1111	Reserved

Address: 40AB_0000h base + 4h offset = 40AB_0004h

MMDCx_MDPDC field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value 0.
30–28 PRCT_1	Precharge Timer - Chip Select 1. This field determines the amount of idle cycle for which chip select 1 will be automatically precharged. The amount of cycles are determined according to the PRCT Field Encoding table above.
27 Reserved	This read-only field is reserved and always has the value 0.
26–24 PRCT_0	Precharge Timer - Chip Select 0. This field determines the amount of idle cycle for which chip select 0 will be automatically precharged. The amount of cycles are determined according to the table below.
23–19 Reserved	This read-only field is reserved and always has the value 0.
18–16 tCKE	CKE minimum pulse width. This field determines the minimum pulse width of CKE. 0x0 1 cycle 0x1 2 cycles 0x6 7 cycles 0x7 8 cycles
15–12 PWDT_1	Power Down Timer - Chip Select 1. This field determines the amount of idle cycle for which chip select 1 will be automatically get into precharge/active power down. The amount of cycles are determined according to the PWDT Field Encoding table above.
11–8 PWDT_0	Power Down Timer - Chip Select 0. This field determines the amount of idle cycle for which chip select 0 will be automatically get into precharge/active power down. The amount of cycles are determined according to the PWDT Field Encoding table above.
7 SLOW_PD	Slow/fast power down. LPDDR2 mode: This field is not relevant and should remain in its default reset value. LPDDR3 mode: This field is not relevant and should remain in its default reset value. **NOTE:** Memory should be configured the same. 0 Fast mode. 1 Slow mode.
6 BOTH_CS_PD	Parallel power down entry to both chip selects. When power down timer is used for both chip-selects (i.e. PWDT_0 and PWDT1 don't equal "0") , then if this bit is enabled, the MMDC will enter power down only if the amount of idle cycles of both chip selects was obtained.

Table continues on the next page...

MMDCx_MDPDC field descriptions (continued)

Field	Description
	0 Each chip select can enter power down independently according to its configuration. 1 Chip selects can enter power down only if the amount of idle cycles of both chip selects was obtained.
5–3 tCKSRX	Valid clock cycles before self-refresh exit. This field determines the amount of clock cycles before self-refresh exit. 0x0 0 cycle 0x1 1 cycles 0x6 6 cycles 0x7 7 cycles
tCKSRE	Valid clock cycles after self-refresh entry. This field determines the amount of clock cycles after self-refresh entry. 0x0 0 cycle 0x1 1 cycles 0x6 6 cycles 0x7 7 cycles

22.11.3 MMDC Core Timing Configuration Register 0 (MMDCx_MDCFG0)

Address: 40AB_0000h base + Ch offset = 40AB_000Ch

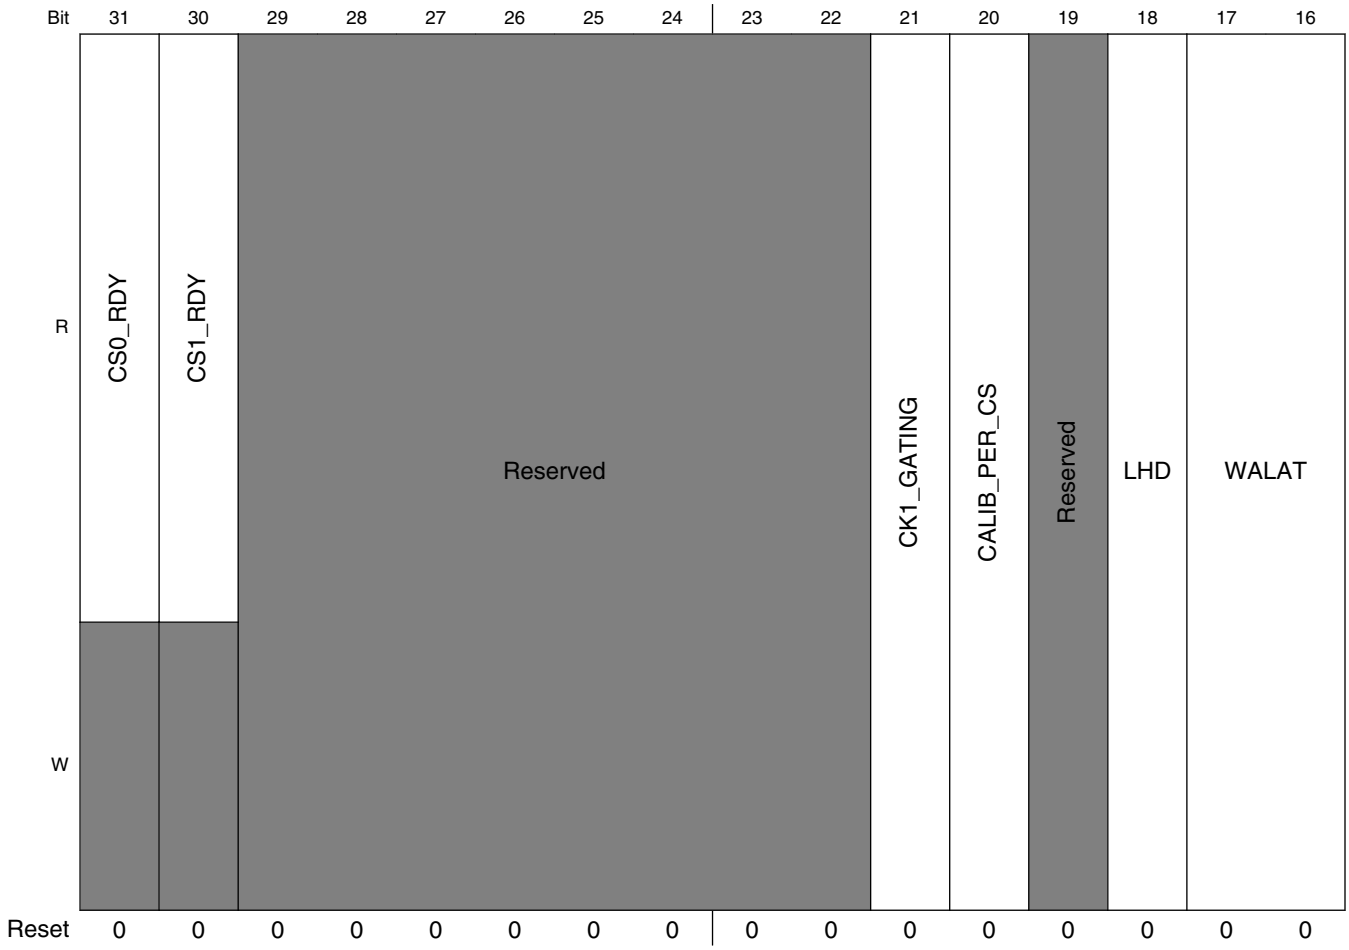
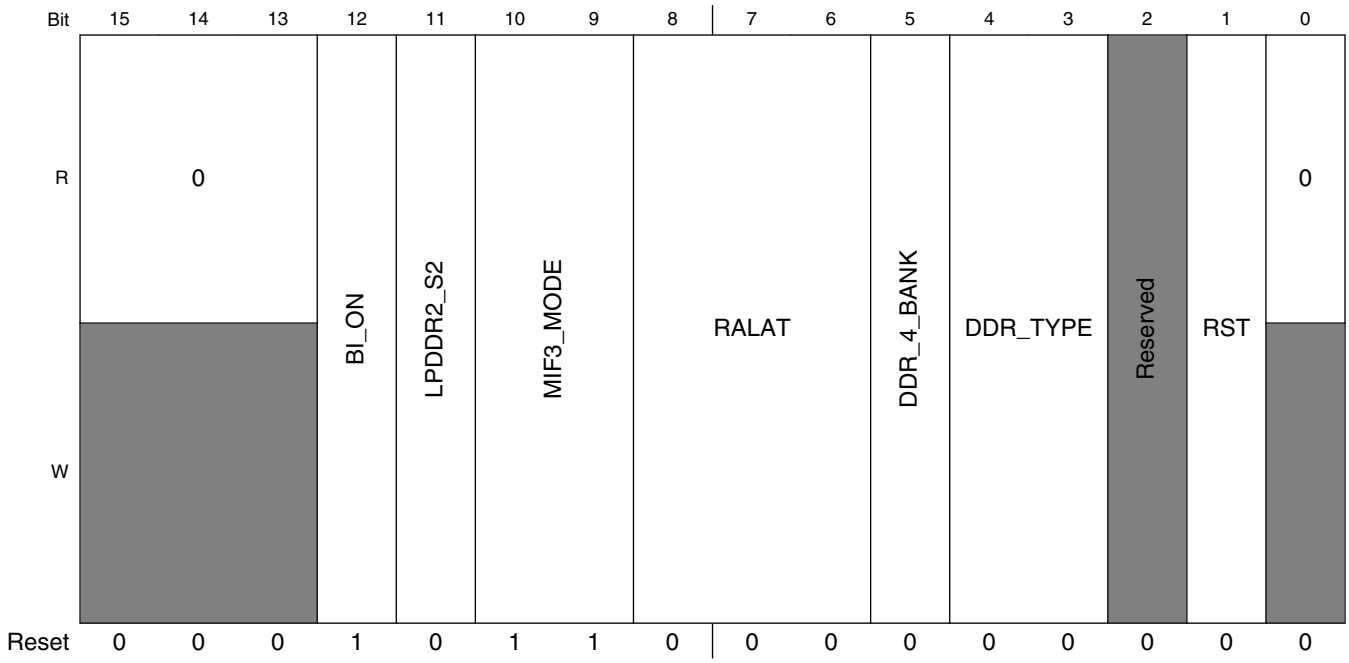
22.11.6 MMDC Core Miscellaneous Register (MMDCx_MDMISC)

Address: 40AB_0000h base + 18h offset = 40AB_0018h





MMDCx_MDMISC field descriptions

Field	Description
31 CS0_RDY	External status device on CS0. This is a read-only status bit, that indicates whether the external memory is in wake-up period. 0 Device in wake-up period. 1 Device is ready for initialization.
30 CS1_RDY	External status device on CS1. This is a read-only status bit, that indicates whether the external memory is in wake-up period. 0 Device in wake-up period. 1 Device is ready for initialization.
29–22 -	This field is reserved.
21 CK1_GATING	Gating the secondary DDR clock. When this bit is asserted then the MMDC will disable the secondary DDR clock 0 MMDC drives two clocks toward the DDR memory 1 MMDC drives only one clock toward the DDR memory (CK0)
20 CALIB_PER_CS	Number of chip-select for calibration process. This bit determines the chip-select index that the associated calibration is targeted to. Relevant for read, write, write leveling and read DQS gating calibrations 0 Calibration is targeted to CS0 1 Calibration is targeted to CS1
19 -	This field is reserved. Reserved
18 LHD	Latency hiding disable. This is a debug feature. When set to "1" the MMDC will handle one read/write access at a time. Meaning that the MMDC pipe-line will be limited to 1 open access (next AXI address phase will be acknowledged if the current AXI data phase had finished)

Table continues on the next page...

MMDCx_MDMISC field descriptions (continued)

Field	Description
	0 Latency hiding on. 1 Latency hiding disable.
17–16 WALAT	Write Additional latency. **NOTE:** The purpose of WALAT is to add time delay at the end of a burst write operation to ensure that the JEDEC time specification for Write Post Amble Delay (tWPST) is met (DQS strobe is held low at the end of a write burst for > 30% a clock cycle before it is released). If the value of any of the WL_DL_ABS_OFFSETn register fields are greater than '1F', WALAT should be set to '1' (cycle additional delay). WALAT should be further increased for any full cycle delays added by the WL_CYC_DELn register fields. 0x0 No additional latency required. 0x1 1 cycle additional delay 0x2 2 cycles additional delay 0x3 3 cycles additional delay
15–13 Reserved	This read-only field is reserved and always has the value 0.
12 BI_ON	Bank Interleaving On. This bit controls the organization of the bank, row and column address bits. For further information see Address decoding . 0 Banks are not interleaved, and address will be decoded as bank-row-column 1 Banks are interleaved, and address will be decoded as row-bank-column
11 LPDDR2_S2	LPDDR2 S2 device type indication. In case LPDDR2 device is used (DDR_TYPE = 0x1), this bit will indicate whether S2 or S4 device is used. 0x0 LPDDR2-S4 device is used. 0x1 LPDDR2-S2 device is used.
10–9 MIF3_MODE	Command prediction working mode. This field determines the level of command prediction that will be used by the MMDC 00 Disable prediction. 01 Enable prediction based on : Valid access on first pipe line stage. 10 Enable prediction based on: Valid access on first pipe line stage, Valid access on axi bus. 11 Enable prediction based on: Valid access on first pipe line stage, Valid access on axi bus, Next miss access from access queue.
8–6 RALAT	Read Additional Latency. This field determines the additional read latency which is added to CAS latency and internal delays for which the MMDC will retrieve the read data from the internal FIFO. This field is used to compensate on board/chip delays. **NOTE:** In LPDDR2 mode 2 extra cycles will be added internally in order to compensate tDQSCK delay. 0x0 no additional latency. 0x1 1 cycle additional latency. 0x2 2 cycles additional latency. 0x3 3 cycles additional latency. 0x4 4 cycles additional latency. 0x5 5 cycles additional latency. 0x6 6 cycles additional latency. 0x7 7 cycles additional latency.

Table continues on the next page...

MMDCx_MDMISC field descriptions (continued)

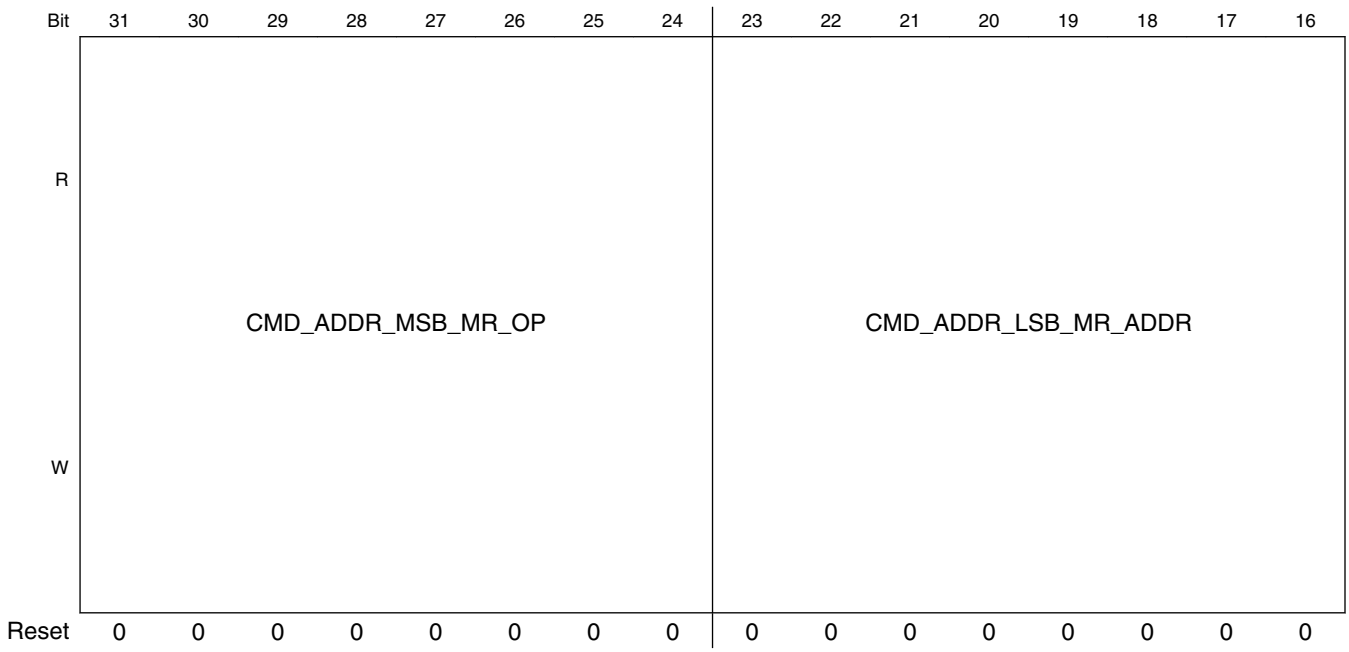
Field	Description
5 DDR_4_BANK	Number of banks per DDR device. When this bit is set to "1" then the MMDC will work with DDR device of 4 banks. 0 8 banks device is being used. (Default) 1 4 banks device is being used
4–3 DDR_TYPE	DDR TYPE. This field determines the type of the external DDR device. 0x0 Reserved 0x1 LPDDR2 device is used. 0x2 Reserved 0x3 LPDDR3 device is used.
2 -	This field is reserved.
1 RST	Software Reset. When this bit is asserted then the internal FSMs and registers of the MMDC will be initialized. **NOTE:** This bit once asserted gets deasserted automatically. 0 Do nothing. 1 Assert reset to the MMDC.
0 Reserved	This read-only field is reserved and always has the value 0.

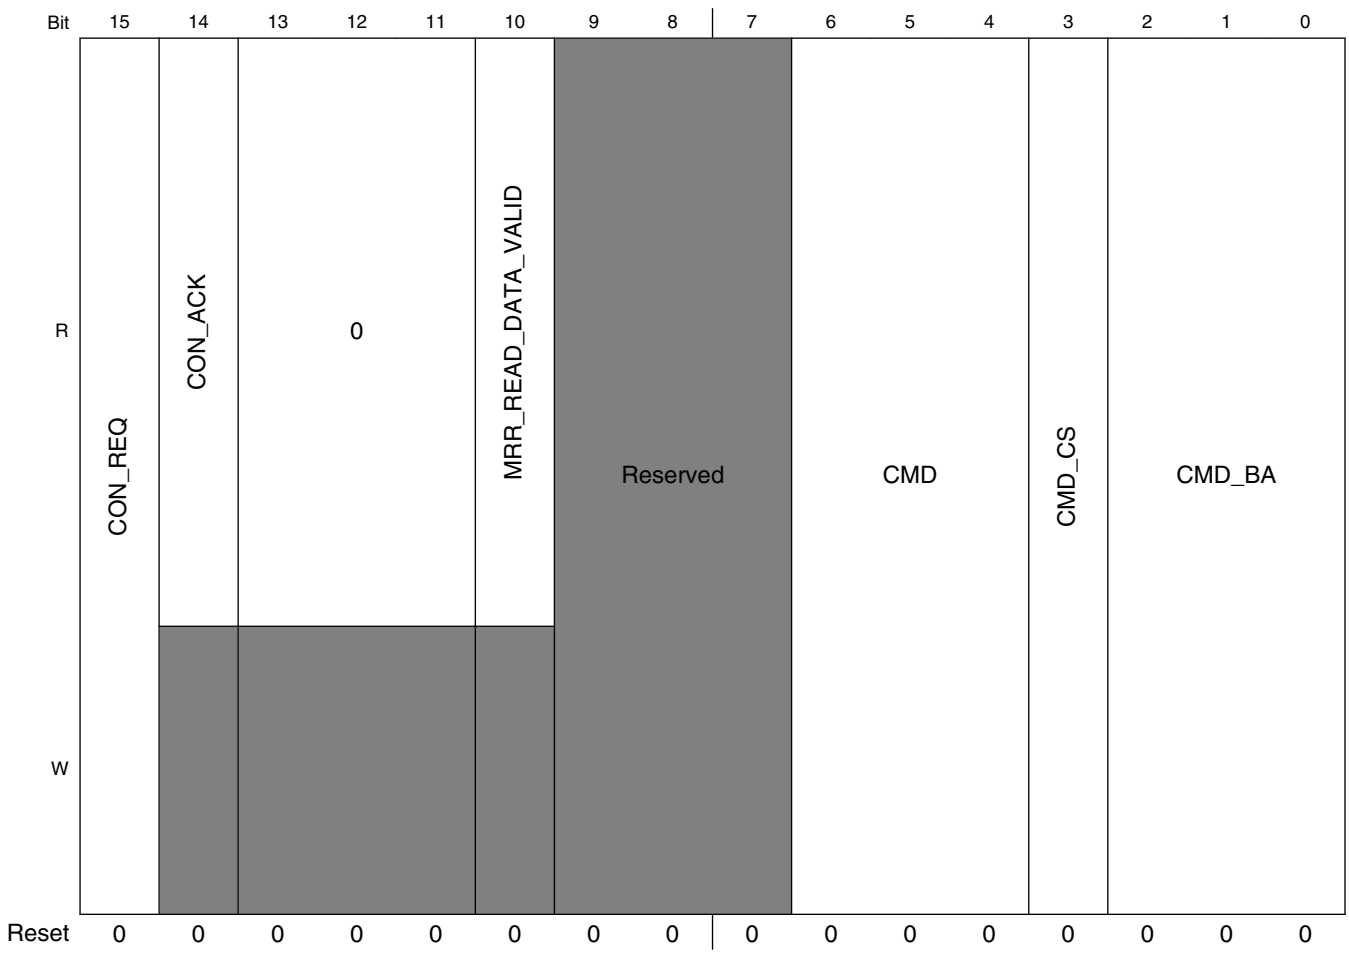
22.11.7 MMDC Core Special Command Register (MMDCx_MDSCR)

This register is used to issue special commands manually toward the external DDR device (such as load mode register, manual self refresh, manual precharge and so on). Every write to this register will be interpreted as a command, and a read from this register will show the last command that was executed.

Every write to this register will result in one special command, and the IP bus will assert ips_xfr_wait as long as the special command is being carried out.

Address: 40AB_0000h base + 1Ch offset = 40AB_001Ch





MMDCx_MDSCR field descriptions

Field	Description
31–24 CMD_ADDR_ MSB_MR_OP	Command/Address MSB. This field indicates the MSB of the command/Address. In LPDDR2/LPDDR3 this field indicates the MRW operand
23–16 CMD_ADDR_ LSB_MR_ADDR	Command/Address LSB. This field indicates the LSB of the command/Address In LPDDR2/LPDDR3 this field indicates the MRR/MRW address
15 CON_REQ	Configuration request. When this bit is set then the MMDC will clean the pending AXI accesses and will prevent from further AXI accesses to be acknowledged. This field guarantee safe configuration (or change configuration) of the MMDC while no access is in process and prevents an unexpected behaviour. After setting this bit, it is needed to poll on CON_ACK until it is set to "1". When CON_ACK is asserted then configuration is permitted. After configuration is completed then this bit must be deasserted in order to process further AXI accesses. **NOTE:** This bit is asserted at the end of the reset sequence, meaning that the MMDC is waiting to configure and initialize the external memory before accepting any AXI accesses. Configuration request/acknowledge mechanism should be used for the following procedures: changing of timing parameters , during calibration process or driving commands via MDSCR[CMD] 0 No request to configure MMDC. 1 A request to configure MMDC is valid
14 CON_ACK	Configuration acknowledge. Whenever this bit is set, it is permitted to configure MMDC IP registers. 0 Configuration of MMDC registers is forbidden. 1 Configuration of MMDC registers is permitted.
13–11 Reserved	This read-only field is reserved and always has the value 0.
10 MRR_READ_ DATA_VALID	MRR read data valid. This field indicates that read data is valid at MDMRR register **NOTE:** This field is relevant only for LPDDR2/LPDDR3 mode 0 Cleared upon the assertion of MRR command 1 Set after MRR data is valid and stored at MDMRR register.
9–7 -	This field is reserved.
6–4 CMD	Command. This field contains the command to be executed. This field will be automatically cleared after the command will be send to the DDR memory. **NOTE:** Only the 0x5 Precharge All command should be used, memory operation is unpredictable when using the 0x1 command **NOTE:** A Precharge All command must be issued prior to the MRW command to ensure robust DDR initialization. This command is required to be issued to both chip selects if two chip selects are utilized in the system. 0x0 Normal operation 0x1 Precharge All, command is sent independently of bank status (set correct CMD_CS). Will be issued even if banks are closed. Primarily used for initialization sequence purposes. Not to be used during run-time operation. 0x2 Auto-Refresh Command (set correct CMD_CS).

Table continues on the next page...

MMDCx_MDSCR field descriptions (continued)

Field	Description
	0x3 Load Mode Register Command (LPDDR2/LPDDR3, set correct CMD_CS, MR_OP, MR_ADDR) 0x4 ZQ calibration 0x5 Precharge All, only if banks open (set correct CMD_CS). 0x6 MRR command (LPDDR2/LPDDR3, set correct CMD_CS, MR_ADDR) 0x7 Reserved
3 CMD_CS	Chip Select. This field determines which chip select the command is targeted to 0 to Chip-select 0 1 to Chip-select 1
CMD_BA	Bank Address. This field determines the address of the bank within the selected chip-select to where the command is targeted. 0x0 bank address 0 0x1 bank address 1 0x2 bank address 2 0x7 bank address 7

22.11.8 MMDC Core Refresh Control Register (MMDCx_MDREF)

This register determines the refresh scheme that will be executed toward the DDR device. It specifies how often a refresh cycle occurs and how many refresh commands will be executed every refresh cycle.

For further information see Refresh Scheme .

The following tables show examples of possible refresh schemes.

Table 22-12. Refresh rate example for REF_SEL = 0

REFR[2:0]	Number of refresh commands every 64KHz	Average periodic refresh rate (tREFI)	System Refresh period
0x0	1	15.6 µs	tRFC
0x1	2	7.8 µs	2*tRFC
0x3	4	3.9µs	4*tRFC
0x7	8	1.95 µs	8*tRFC

Table 22-13. Refresh rate example for REF_SEL = 1

REFR[2:0]	Number of refresh commands every 32KHz	Average periodic refresh rate (tREFI)	System Refresh period
0x1	2	15.6 µs	2*tRFC

Table continues on the next page...

Table 22-13. Refresh rate example for REF_SEL = 1 (continued)

REFR[2:0]	Number of refresh commands every 32KHz	Average periodic refresh rate (tREFI)	System Refresh period
0x3	4	7.8 µs	4*tRFC
0x7	8	3.9µs	8*tRFC

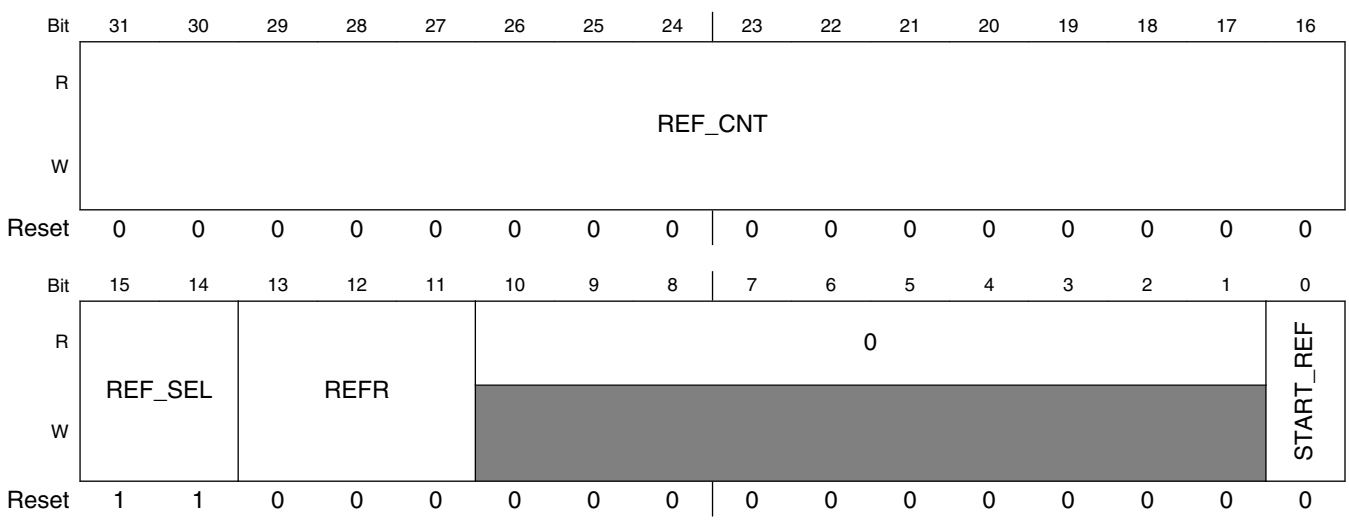
Table 22-14. Refresh rate example for REF_SEL = 2@ 400MHz

REFR[2:0]	Number of refresh commands every refresh cycle	REF_CNT	Average periodic refresh rate (tREFI)	System Refresh period
0x0	1	0x618	3.9 µs	tRFC
0x1	2	0xC30	3.9 µs	2*tRFC
0x2	3	0x1248	3.9µs	3*tRFC
0x3	4	0x1860	3.9 µs	4*tRFC

Other refresh configurations are also allowed; the configuration values in the tables above are only examples for obtaining the desired average periodic refresh rate.

If the required average periodic refresh rate (tREFI) is kept, all of the rows will be refreshed in every refresh window. Because the memory device issues additional refresh commands for every refresh it receives, the tREFI remains the same across the device, regardless of its number of rows. This is particularly relevant in the tRFC parameter, which becomes bigger as the density increases.

Address: 40AB_0000h base + 20h offset = 40AB_0020h



MMDCx_MDREF field descriptions

Field	Description
31–16 REF_CNT	Refresh Counter at DDR clock period If REF_SEL equals '2' a refresh cycle will begin every amount of DDR cycles configured in this field. 0x0 Reserved. 0x1 1 cycle. 0xFFFE 65534 cycles. 0xFFFF 65535 cycles.
15–14 REF_SEL	Refresh Selector. This bit selects the source of the clock that will trigger each refresh cycle: 0 Periodic refresh cycles will be triggered in frequency of 64KHz. 1 Periodic refresh cycles will be triggered in frequency of 32KHz. 2 Periodic refresh cycles will be triggered every amount of cycles that are configured in REF_CNT field. 3 No refresh cycles will be triggered.
13–11 REFR	Refresh Rate. This field determines how many refresh commands will be issued every refresh cycle. After every refresh command the MMDC won't drive any command to the DDR device until satisfying tRFC period 0x0 1 refresh 0x1 2 refreshes 0x2 3 refreshes 0x3 4 refreshes 0x4 5 refreshes 0x5 6 refreshes 0x6 7 refreshes 0x7 8 refreshes
10–1 Reserved	This read-only field is reserved and always has the value 0.
0 START_REF	Manual start of refresh cycle. When this field is set to '1' the MMDC will start a refresh cycle immediately according to number of refresh commands that are configured in 'REFR' field. This bit returns to zero automatically. 0 Do nothing. 1 Start a refresh cycle.

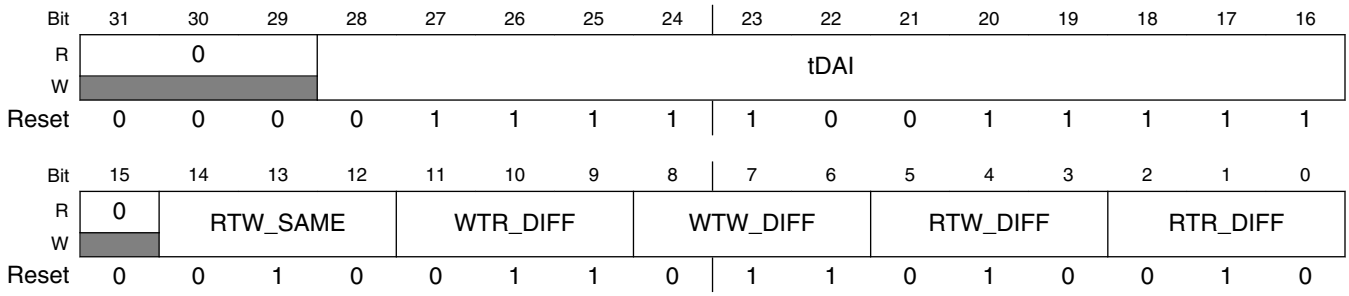
22.11.9 MMDC Core Read/Write Command Delay Register (MMDCx_MDRWD)

This register determines the delay between back to back read and write accesses. The register reset values are set to the minimum required value.

NOTE

As the default values are set to achieve optimal results, changing them is discouraged.

Address: 40AB_0000h base + 2Ch offset = 40AB_002Ch



MMDCx_MDRWD field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value 0.
28–16 tDAI	Device auto initialization period.(maximum) **NOTE:** This field is relevant only to LPDDR2/3 mode 0x0 1 cycle 0xF9F 4000 cycles (Default, JEDEC value for LPDDR2, gives 10us at 400MHz clock). 0x1FFF 8192 cycles
15 Reserved	This read-only field is reserved and always has the value 0.
14–12 RTW_SAME	Read to write delay for the same chip-select. This field controls the delay between read to write commands toward the same chip select. The total delay is calculated according to: BL/2 + RTW_SAME + (tCL-tCWL) + RALAT 0x0 0 cycle 0x1 1 cycle 0x2 2 cycles (Default) 0x3 3 cycles 0x4 4 cycles 0x5 5 cycles 0x6 6 cycles 0x7 7 cycles
11–9 WTR_DIFF	Write to read delay for different chip-select. This field controls the delay between write to read commands toward different chip select. The total delay is calculated according to: BL/2 + WTR_DIFF + (tCL-tCWL) + RALAT 0x0 0 cycle 0x1 1 cycle 0x2 2 cycles 0x3 3 cycles (Default) 0x4 4 cycles 0x5 5 cycles 0x6 6 cycles 0x7 7 cycles
8–6 WTW_DIFF	Write to write delay for different chip-select. This field controls the delay between write to write commands toward different chip select.

Table continues on the next page...

MMDCx_MDRWD field descriptions (continued)

Field	Description
	The total delay is calculated according to: BL/2 + WTW_DIFF 0x0 0 cycle 0x1 1 cycle 0x2 2 cycles 0x3 3 cycles (Default) 0x4 4 cycles 0x5 5 cycles 0x6 6 cycles 0x7 7 cycles
5–3 RTW_DIFF	Read to write delay for different chip-select. This field controls the delay between read to write commands toward different chip select. The total delay is calculated according to: BL/2 + RTW_DIFF + (tCL - tCWL) + RALAT 0x0 0 cycle 0x1 1 cycle 0x2 2 cycles (Default) 0x3 3 cycles 0x4 4 cycles 0x5 5 cycles 0x6 6 cycles 0x7 7 cycles
RTR_DIFF	Read to read delay for different chip-select. This field controls the delay between read to read commands toward different chip select. The total delay is calculated according to: BL/2 + RTR_DIFF 0x0 0 cycle 0x1 1 cycle 0x2 2 cycles (Default) 0x3 3 cycles 0x4 4 cycles 0x5 5 cycles 0x6 6 cycles 0x7 7 cycles

22.11.10 MMDC Core Out of Reset Delays Register (MMDCx_MDOR)

This register defines delays that must be kept when MMDC exits reset.

Address: 40AB_0000h base + 30h offset = 40AB_0030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

MMDCx_MDOR field descriptions

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value 0.
23–16 tXPR	LPDDR2/3: Not relevant to this mode and should remain in default reset value. 0x0 Reserved 0x1 2 cycles 0x2 3 cycles 0xFE 255 cycles 0xFF 256 cycles
15–14 Reserved	This read-only field is reserved and always has the value 0.
13–8 SDE_to_RST	LPDDR2 mode: This field is not relevant and should remain in its default reset value. **NOTE:** Each cycle in this field is 15.258 us. 0x0 Reserved 0x1 Reserved 0x2 Reserved 0x3 1 cycles 0x4 2 cycles 0x10 14 cycles - total of 200 us 0x3E 60 cycles 0x3F 61 cycles
7–6 Reserved	This read-only field is reserved and always has the value 0.
RST_to_CKE	LPDDR2: Idle time after first CKE assertion (JEDEC value is 200 us). **NOTE:** Each cycle in this field is 15.258 us. 0x0 Reserved 0x1 Reserved 0x2 Reserved 0x3 1 cycles 0x10 14 cycles (JEDEC value for LPDDR2) - total of 200 us 0x23 33 cycles - total of 500 us 0x3E 60 cycles 0x3F 61 cycles

22.11.11 MMDC Core MRR Data Register (MMDCx_MDMRR)

This register contains data that was collected after issuing MRR command. The data in this register is valid only when MDSCR[MRR_READ_DATA_VALID] is set to "1".

This register is relevant only in LPDDR2/3 mode. For further information see LPDDR2/3 Refresh Rate Update and Timing Derating.

Address: 40AB_0000h base + 34h offset = 40AB_0034h

Bit	31–24	23–16	15–8	7–0
R	MRR_READ_DATA3	MRR_READ_DATA2	MRR_READ_DATA1	MRR_READ_DATA0
W

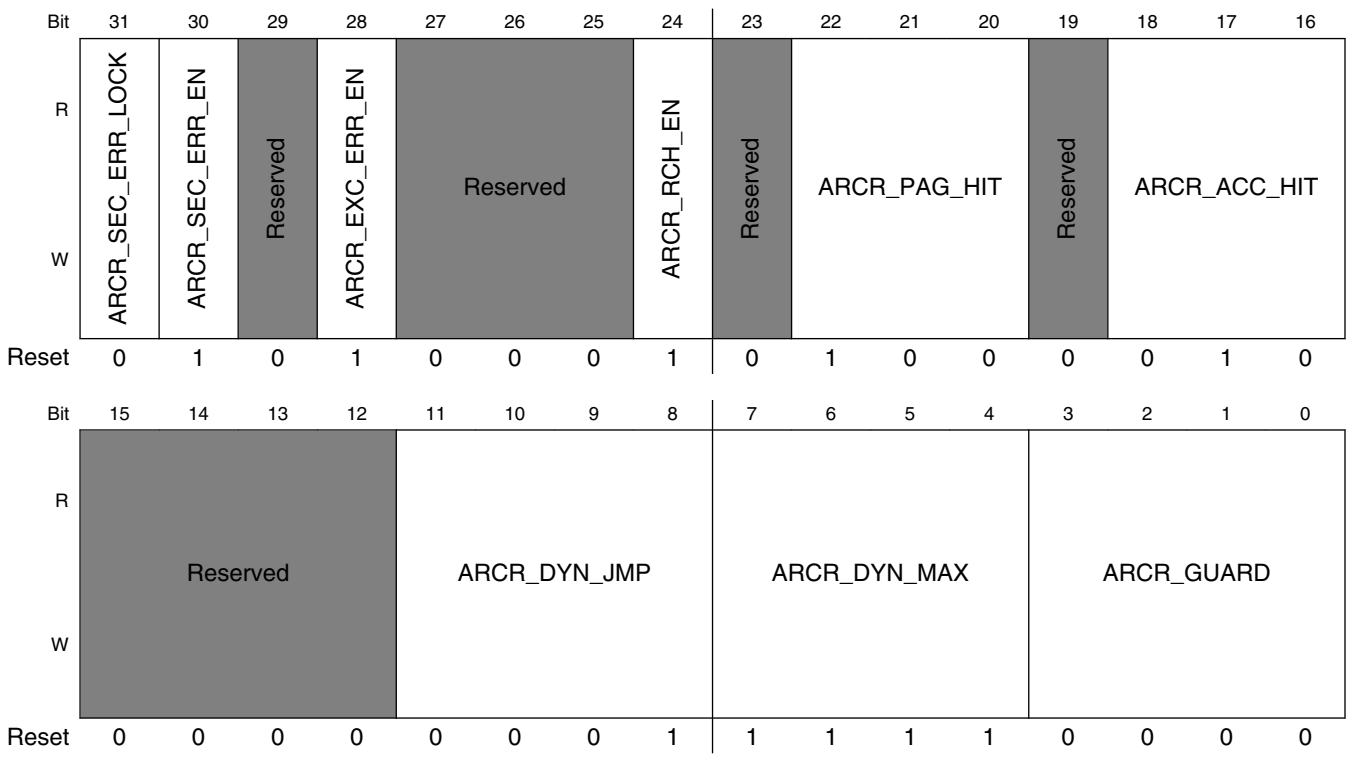
MMDCx_MDASP field descriptions

Field	Description
31–7 Reserved	This read-only field is reserved and always has the value 0.
CS0_END	Defines the absolute last address associated with CS0 with increments of 256Mb. CS0_END=AXI_ADDRESS[31:25] bits. MMDC0_MDASP[CS0_END] should be set to DDR_CS_SIZE/32M + 0x3f (channel 0 base address begins at 0x60000000)

22.11.15 MMDC Core AXI Reordering Control Register (MMDCx_MAARCR)

This register determines the values of the weights used for the re-ordering arbitration engine. For further information see Performance.

Address: 40AB_0000h base + 400h offset = 40AB_0400h



MMDCx_MAARCR field descriptions

Field	Description
31 ARCR_SEC_ ERR_LOCK	Once set, this bit locks ARCR_SEC_ERR_EN and prevents from its updating. This bit can be only cleared by reset Default value is 0x0 - encoding 0 (unlocked) 0 ARCR_SEC_ERR_EN is unlocked, so can be updated any moment 1 ARCR_SEC_ERR_EN is locked, so it can't be updated
30 ARCR_SEC_ ERR_EN	This bit defines whether security read/write access violation result in SLV Error response or in OKAY response Default value is 0x1 - encoding 1(response is SLV Error, rresp/bresp=2'b10) 0 security violation results in OKAY response (rresp/bresp=2'b00) 1 security violation results in SLAVE Error response (rresp/bresp=2'b10)

Table continues on the next page...

MMDCx_MAARCR field descriptions (continued)

Field	Description
29 -	This field is reserved. Reserved
28 ARCR_EXC_ERR_EN	This bit defines whether exclusive read/write access violation of AXI 6.2.4 rule result in SLV Error response or in OKAY response Default value is 0x1 - encoding 1(response is SLV Error) 0 violation of AXI exclusive rules (6.2.4) result in OKAY response (rresp/bresp=2'b00) 1 violation of AXI exclusive rules (6.2.4) result in SLAVE Error response (rresp/bresp=2'b10)
27–25 -	This field is reserved. Reserved
24 ARCR_RCH_EN	This bit defines whether Real time channel is activated and bypassed all other pending accesses, So accesses with QoS=='F' will be granted the highest priority in the optimization/reordering mechanism Default value is 0x1 - encoding 1 (Enabled) 0 normal prioritization, no bypassing 1 accesses with QoS=='F' bypass the arbitration
23 -	This field is reserved. Reserved
22–20 ARCR_PAG_HIT	ARCR Page Hit Rate. This value will be added by the optimization/reordering mechanism to any pending access that is targeted to an open DDR row. Default value of ARCR_PAG_HIT is 0x00100 - encoding 4.
19 -	This field is reserved. Reserved
18–16 ARCR_ACC_HIT	ARCR Access Hit Rate. This value will be added by the optimization/reordering mechanism to any pending access that has the same access type (read/write) as the previous access. Default value of is ARCR_ACC_HIT 0x0010 - encoding 2.
15–12 -	This field is reserved. Reserved
11–8 ARCR_DYN_JMP	ARCR Dynamic Jump. Each time an access is not chosen by the optimization/reordering mechanism then its dynamic score will be incremented by ARCR_DYN_JMP value. **NOTE:** Setting ARCR_DYN_JMP may cause starvation of low priority accesses **NOTE:** ARCR_DYN_JMP must be smaller than ARCR_DYN_MAX Default ARCR_DYN_JMP value is 0x0001 - encoding 1
7–4 ARCR_DYN_MAX	ARCR Dynamic Maximum. ARCR_DYN_MAX is the maximum dynamic score value that each access inside the optimization/reordering mechanism can get. 0000 0 0001 1 1111 15 (default)
ARCR_GUARD	ARCR Guard. After an access reached the maximum dynamic score value, it will wait additional ARCR_GUARD arbitration cycles and then will gain the highest priority in the optimization/reordering mechanism. 0000 15 (default) 0001 16 1111 30

22.11.16 MMDC Core Power Saving Control and Status Register (MMDCx_MAPSR)

The MAPSR determines the power saving features of MMDC. For further information see Power Saving and Clock Frequency Change modes .

NOTE

See chip-specific information for implementation on your device.

Address: 40AB_0000h base + 404h offset = 40AB_0404h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

MMDCx_MAPSR field descriptions

Field	Description
31–26 -	This field is reserved. Reserved
25 DVACK	DVFS/Self-Refresh acknowledge. This read only bit indicates whether a DVFS/self-refresh acknowledge was asserted and that the MMDC is in self-refresh mode.
24 LPACK	General low-power acknowledge. This read only bit indicates whether a low-power acknowledge was asserted and that MMDC is in self-refresh mode
23–22 -	This field is reserved. Reserved
21 DVFS	DVFS/Self-Refresh request. Software request for DVFS/self-refresh. Assertion of this bit will initiate a self-refresh entry sequence. 0 no DVFS/Self-Refresh entry request 1 DVFS/Self-Refresh entry request
20 LPMD	General LPMD request. Software request for LPMD. Assertion of this bit will yield in self-refresh entry sequence 0 no lpmd request 1 lpmd request
19–16 -	This field is reserved. Reserved
15–8 PST	Automatic Power saving timer. Valid only when PSD is set to "0". When the MMDC is idle for amount of cycles specified in that field then the DDR device will be entered automatically into self-refresh mode. The real value which is used is register-value multiplied by 64. 00000000 Reserved - this value is forbidden. 00000001 timer is configured to 64 clock cycles.

Table continues on the next page...

MMDCx_MAPSR field descriptions (continued)

Field	Description
	00000010 timer is configured to 128 clock cycles. 00010000 (Default)- 1024 clock cycles. 11111111 timer clock is configured to 16320 clock cycles.
7 -	This field is reserved. Reserved.
6 WIS	Write Idle Status. This read only bit indicates whether write request buffer is idle (empty) or not. 0 not idle 1 idle
5 RIS	Read Idle Status. This read only bit indicates whether read request buffer is idle (empty) or not. 0 not idle 1 idle
4 PSS	Power Saving Status. This read only bit indicates whether the MMDC is in automatic power saving mode. 0 not in power saving mode 1 power saving mode
3–1 -	This field is reserved. Reserved.
0 PSD	Automatic Power Saving Disable. When the value of PSD is "0" (i.e. automatic power saving is enabled) then the PST is activated and MMDC will enter automatically to self-refresh while the number of idle cycle reached. **NOTE:** This bit must be disabled (i.e. set to "1") during calibration process 0 power saving enabled 1 power saving disabled (default)

22.11.17 MMDC Core Exclusive ID Monitor Register0 (MMDCx_MAEXIDR0)

This register defines the ID to be monitored for exclusive accesses of monitor0 and monitor1. For further information see Exclusive accesses handling .

Address: 40AB_0000h base + 408h offset = 40AB_0408h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

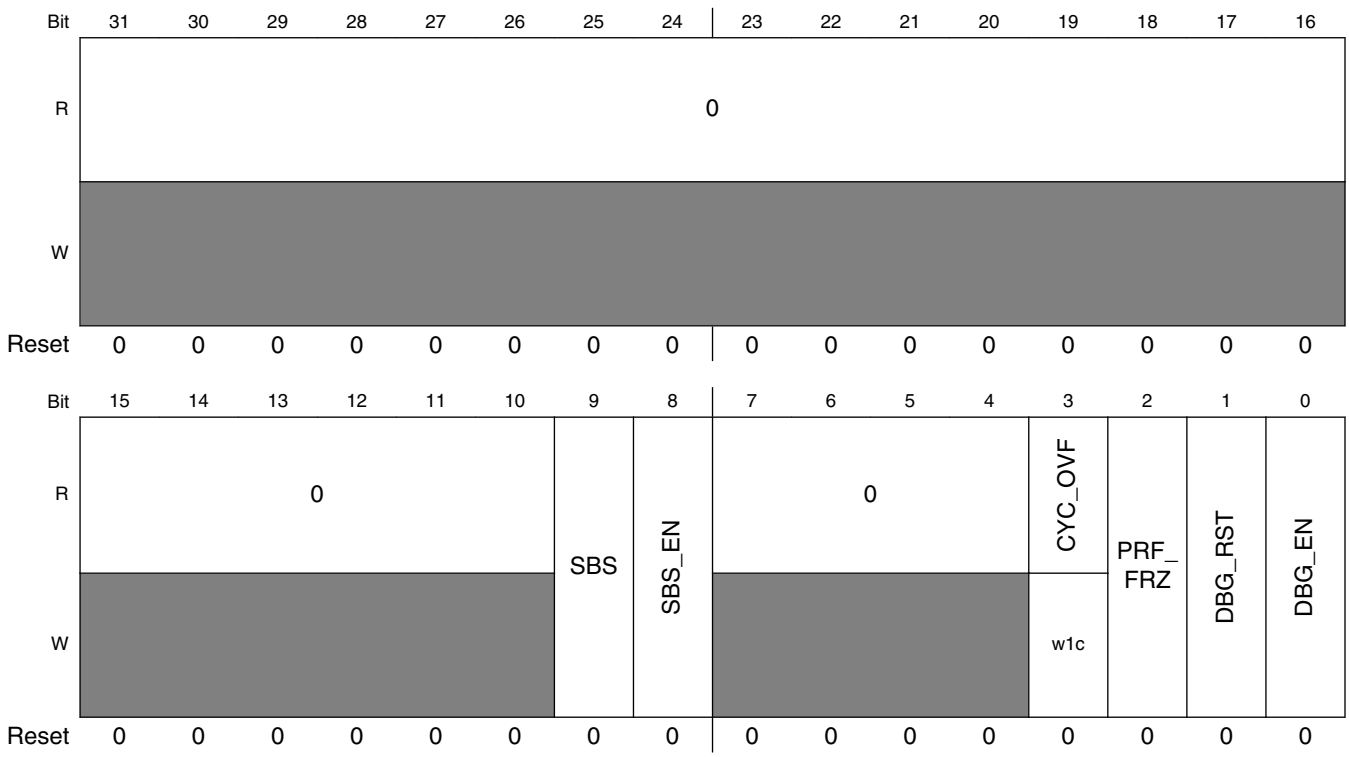
MMDCx_MAEXIDR1 field descriptions

Field	Description
31–16 EXC_ID_ MONITOR3	This field defines ID for Exclusive monitor#3. Default value is 0x0060
EXC_ID_ MONITOR2	This field defines ID for Exclusive monitor#2. Default value is 0x0040

22.11.19 MMDC Core Debug and Profiling Control Register 0 (MMDCx_MADPCR0)

Address: 40AB_0000h base + 410h offset = 40AB_0410h



MMDCx_MADPCR0 field descriptions

Field	Description
31–10 Reserved	This read-only field is reserved and always has the value 0.
9 SBS	Step By Step trigger. If SBS_EN is set to "1" then dispatching AXI pending access toward the DDR will done only if this bit is set to "1", otherwise no access will be dispatched toward the DDR. This bit is cleared when the pending access has been issued toward the DDR device. 1 Launch AXI pending access toward the DDR 0 No access will be launched toward the DDR
8 SBS_EN	Step By Step debug Enable. Enable step by step mode. Every time this mechanism is enabled then setting SBS to "1" will dispatch one pending AXI access to the DDR and in parallel its attributes will be observed in the status registers (MASBS0 and MASBS1). For further information see Step By Step (SBS) software monitor . 0 disable 1 enable
7–4 Reserved	This read-only field is reserved and always has the value 0.
3 CYC_OVF	Total Profiling Cycles Count Overflow. When profiling mechanism is enabled (DBG_EN is set to "1") then this bit is asserted when overflow of CYC_COUNT occurred. Cleared by writing 1 to it.

Table continues on the next page...

MMDCx_MADPCR0 field descriptions (continued)

Field	Description
	0 no overflow 1 overflow
2 PRF_FRZ	Profiling freeze. When this bit is asserted then the profiling mechanism will be froze and the associated status registers (MADPSR0-MADPSR5) will hold the current profiling values. 0 profiling counters are not frozen 1 profiling counters are frozen
1 DBG_RST	Debug and Profiling Reset. Reset all debug and profiling counters and components. 0 no reset 1 reset
0 DBG_EN	Debug and Profiling Enable. Enable debug and profiling mechanism. When this bit is asserted then the MMDC will perform a profiling based on the ID that is configured to MADPCR1. Upon assertion of PRF_FRZ the profiling will be froze and the profiling results will be sampled to the status registers (MADPSR0-MADPSR5). For further information see MMDC Profiling. 0 disable (default) 1 enable

22.11.20 MMDC Core Debug and Profiling Control Register 1 (MMDCx_MADPCR1)

Address: 40AB_0000h base + 414h offset = 40AB_0414h

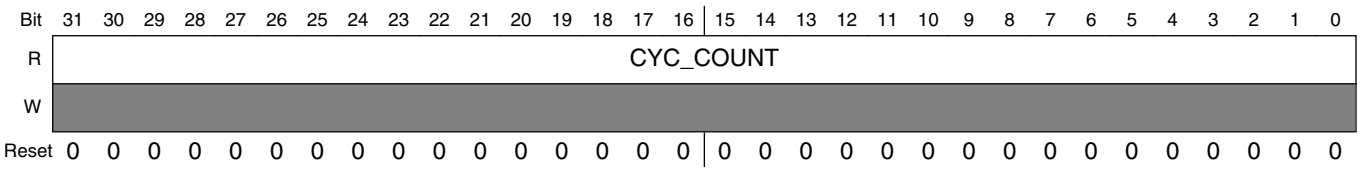
Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	PRF_AXI_ID_MASK																PRF_AXI_ID															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MMDCx_MADPCR1 field descriptions

Field	Description
31–16 PRF_AXI_ID_ MASK	Profiling AXI ID Mask. AXI ID bits which masked by this value are chosen for profiling. 1 AXI ID specific bit is chosen for profiling 0 AXI ID specific bit is ignored (don't care)
PRF_AXI_ID	Profiling AXI ID. AXI IDs that match a bit-wise AND logic operation between PRF_AXI_ID and PRF_AXI_ID_MASK are chosen for profiling. Default value is 0x0, to choose any ID-s for profiling

22.11.21 MMDC Core Debug and Profiling Status Register 0 (MMDCx_MADPSR0)

Address: 40AB_0000h base + 418h offset = 40AB_0418h



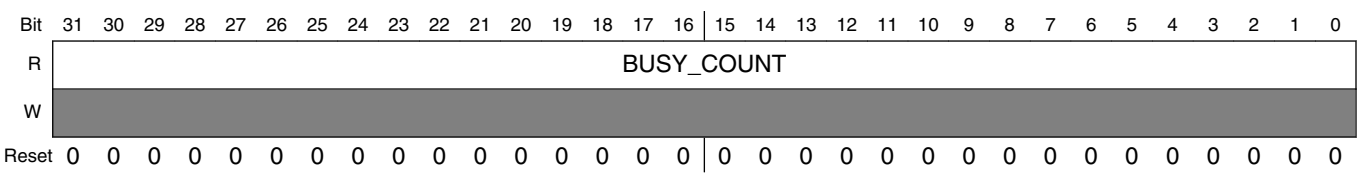
MMDCx_MADPSR0 field descriptions

Field	Description
CYC_COUNT	Total Profiling cycle Count. This field reflects the total cycle count in case the profiling mechanism is enabled from assertion of DBG_EN and until PRF_FRZ is asserted

22.11.22 MMDC Core Debug and Profiling Status Register 1 (MMDCx_MADPSR1)

The register reflects the total cycles during which the MMDC state machines were busy (both writes and reads). This information can be used for DDR Utilization calculation.

Address: 40AB_0000h base + 41Ch offset = 40AB_041Ch



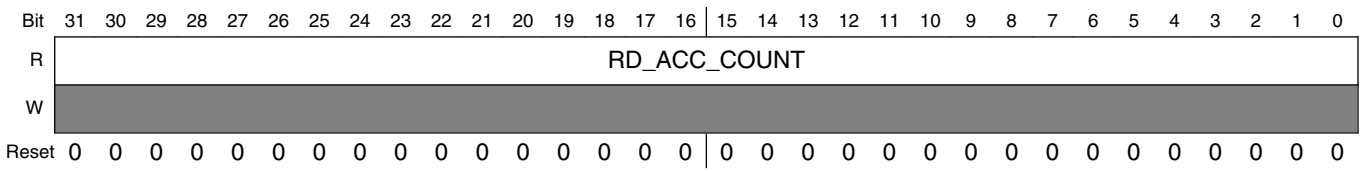
MMDCx_MADPSR1 field descriptions

Field	Description
BUSY_COUNT	Profiling Busy Cycles Count. This field reflects the total number of cycles where the MMDC read and write state machines were busy during the profiling period. Can be used for DDR utilization calculations. Busy cycles are any MMDC clock cycles where the internal state machine is not idle. If any read or write requests are pending in the FIFOs, the MMDC is not idle.

22.11.23 MMDC Core Debug and Profiling Status Register 2 (MMDCx_MADPSR2)

This register reflects the total number of read accesses (per AXI ID) toward MMDC.

Address: 40AB_0000h base + 420h offset = 40AB_0420h



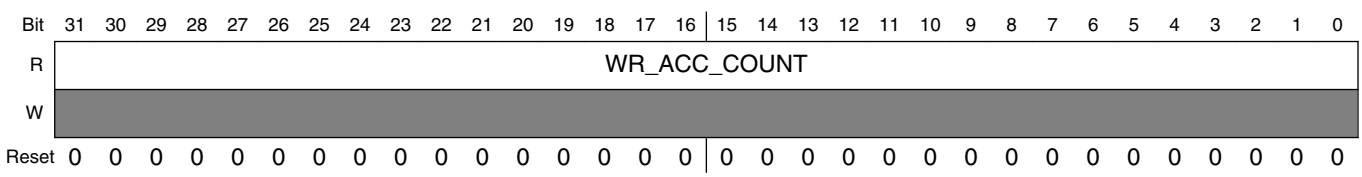
MMDCx_MADPSR2 field descriptions

Field	Description
RD_ACC_ COUNT	Profiling Read Access Count. This register reflects the total number of read accesses (per AXI ID) toward MMDC.

22.11.24 MMDC Core Debug and Profiling Status Register 3 (MMDCx_MADPSR3)

This register reflects the total number of write accesses (per AXI ID) toward MMDC.

Address: 40AB_0000h base + 424h offset = 40AB_0424h



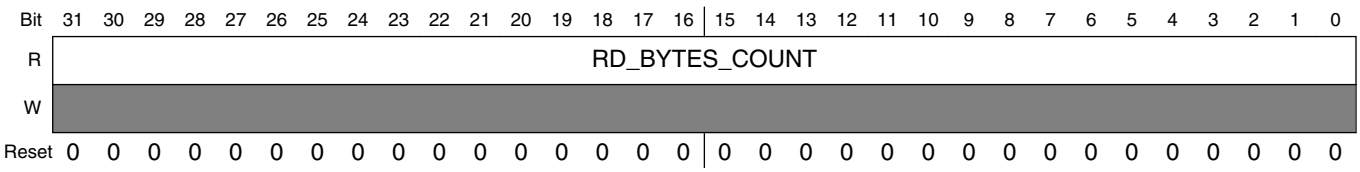
MMDCx_MADPSR3 field descriptions

Field	Description
WR_ACC_ COUNT	Profiling Write Access Count. This register reflects the total number of write accesses (per AXI ID) toward MMDC.

22.11.25 MMDC Core Debug and Profiling Status Register 4 (MMDCx_MADPSR4)

This register reflects the total number of bytes that were transferred during read access (per AXI ID) toward MMDC.

Address: 40AB_0000h base + 428h offset = 40AB_0428h



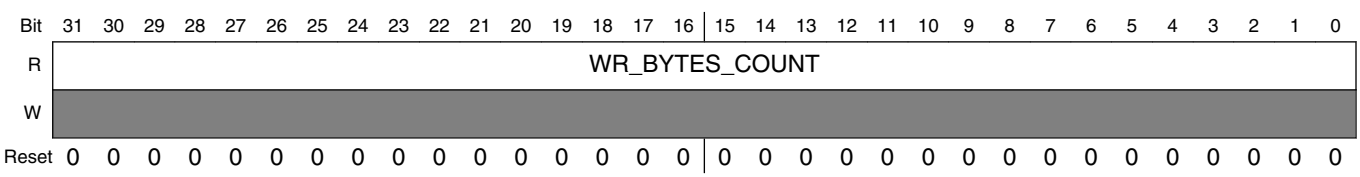
MMDCx_MADPSR4 field descriptions

Field	Description
RD_BYTES_ COUNT	Profiling Read Bytes Count. This register reflects the total number of bytes that were transferred during read access (per AXI ID) toward MMDC.

22.11.26 MMDC Core Debug and Profiling Status Register 5 (MMDCx_MADPSR5)

This register reflects the total number of bytes that were transferred during write access (per AXI ID) toward MMDC.

Address: 40AB_0000h base + 42Ch offset = 40AB_042Ch

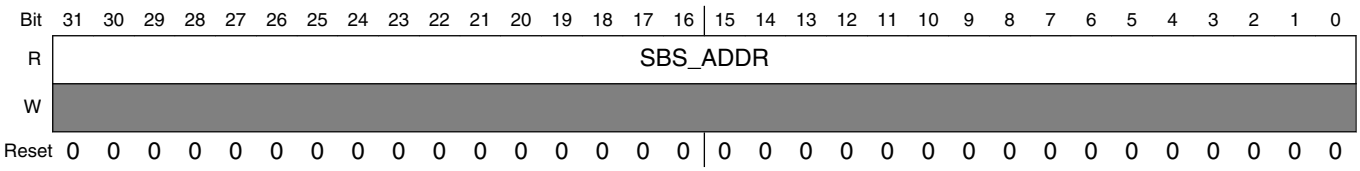


MMDCx_MADPSR5 field descriptions

Field	Description
WR_BYTES_ COUNT	Profiling Write Bytes Count. This register reflects the total number of bytes that were transferred during write access (per AXI ID) toward MMDC.

22.11.27 MMDC Core Step By Step Address Register (MMDCx_MASBS0)

Address: 40AB_0000h base + 430h offset = 40AB_0430h

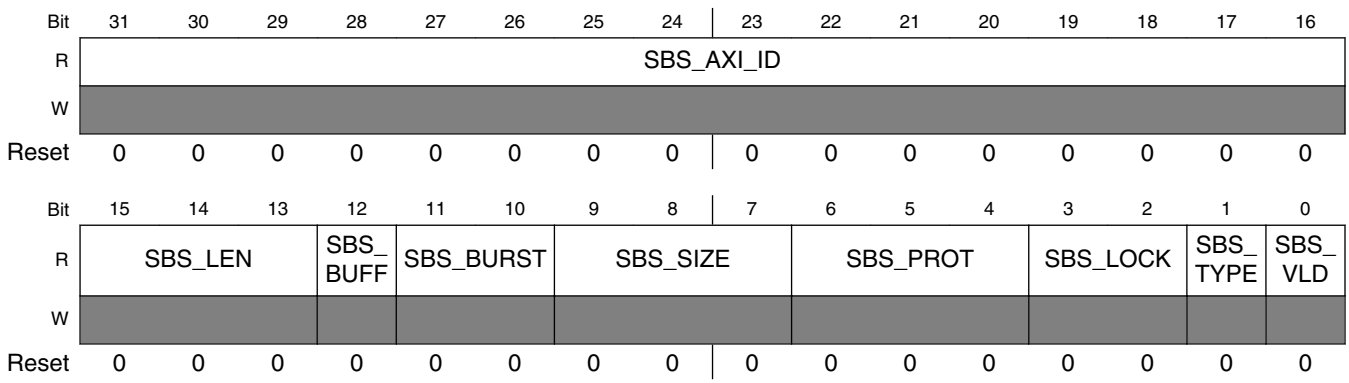


MMDCx_MASBS0 field descriptions

Field	Description
SBS_ADDR	Step By Step Address. These bits reflect the address of the pending request in case of step by step mode.

22.11.28 MMDC Core Step By Step Address Attributes Register (MMDCx_MASBS1)

Address: 40AB_0000h base + 434h offset = 40AB_0434h



MMDCx_MASBS1 field descriptions

Field	Description
31–16 SBS_AXI_ID	Step By Step AXI ID. These bits reflect the AXI ID of the pending request in case of step by step mode.
15–13 SBS_LEN	Step By Step Length. These bits reflect the AXI LENGTH of the pending request in case of step by step mode. 000 burst of length 1 001 burst of length 2 111 burst of length 8
12 SBS_BUFF	Step By Step Buffered. This bit reflect the AXI CACHE[0] of the pending request in case of step by step mode. Relevant only for write requests

Table continues on the next page...

MMDCx_MASBS1 field descriptions (continued)

Field	Description
11–10 SBS_BURST	Step By Step Burst. These bits reflect the AXI BURST of the pending request in case of step by step mode. 00 FIXED 01 INCR burst 10 WRAP burst 11 reserved
9–7 SBS_SIZE	Step By Step Size. These bits reflect the AXI SIZE of the pending request in case of step by step mode. 000 8 bits 001 16 bits 010 32 bits 011 64 bits 100 128bits 101-111 Reserved
6–4 SBS_PROT	Step By Step Protection. These bits reflect the AXI PROT of the pending request in case of step by step mode.
3–2 SBS_LOCK	Step By Step Lock. These bits reflect the AXI LOCK of the pending request in case of step by step mode.
1 SBS_TYPE	Step By Step Request Type. These bits reflect the type (read/write) of the pending request in case of step by step mode. 0 write 1 read
0 SBS_VLD	Step By Step Valid. This bit reflects whether there is a pending request in case of step by step mode. 0 not valid 1 valid

22.11.29 MMDC Core General Purpose Register (MMDCx_MAGENP)

This register is a general 32 bit read/write register.

Address: 40AB_0000h base + 440h offset = 40AB_0440h

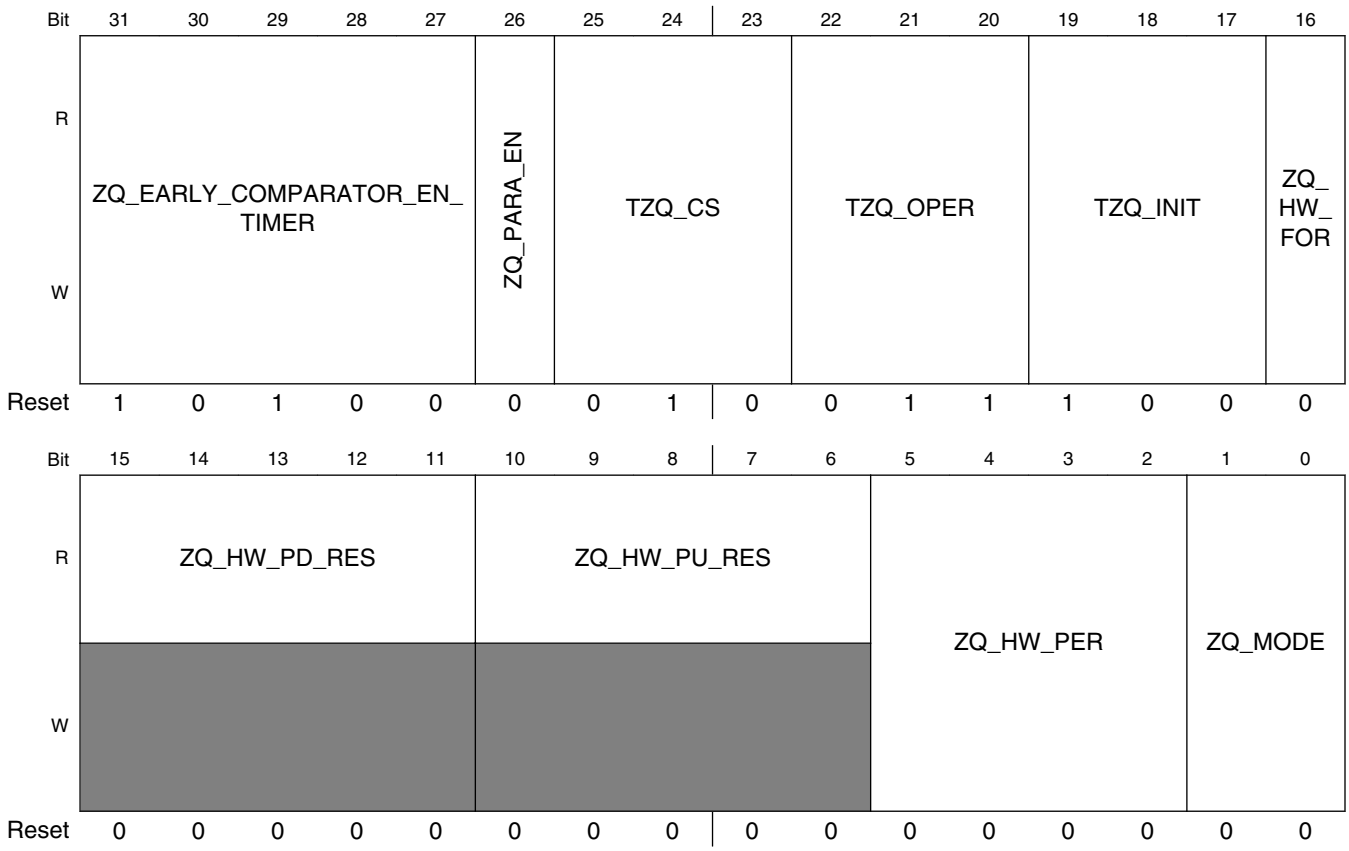
Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	GP31_GP0																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MMDCx_MAGENP field descriptions

Field	Description
GP31_GP0	General purpose read/write bits.

22.11.30 MMDC PHY ZQ HW control register (MMDCx_MPZQHWCTRL)

Address: 40AB_0000h base + 800h offset = 40AB_0800h



MMDCx_MPZQHWCTRL field descriptions

Field	Description
31–27 ZQ_EARLY_COMPARATOR_EN_TIMER	ZQ early comparator enable timer. This timer defines the interval between the warming up of the comparator of the i.MX ZQ calibration pad and the beginning of the ZQ calibration process with the pad 0x0 - 0x6 Reserved 0x7 8 cycles 0x14 21 cycles (Default) 0x1E 31 cycles 0x1F 32 cycles
26 ZQ_PARA_EN	Device ZQ calibration parallel enable. **NOTE:** If only one chip select is enabled, parallel mode (ZQ_PARA_EN=1) must be selected. 0 Device ZQ calibration is done in serial (CS0 first and then CS1). 1 ZQ calibration of both CS is done in parallel

Table continues on the next page...

MMDCx_MPZQHWCTRL field descriptions (continued)

Field	Description
25–23 TZQ_CS	Device ZQ short time. This field holds the number of cycles that are required by the external DDR device to perform ZQ short calibration. Upon driving the command to the DDR device then no further accesses will be issued to the DDR device till satisfying that time. **NOTE:** In LPDDR2 the ZQ short time is taken from MPZQLP2CTL[ZQ_LP2_HW_ZQCS] **NOTE:** This field should not be update during ZQ calibration. 000 Reserved 001 Reserved 010 128 cycles (Default) 011 256 cycles 100 512 cycles 101 1024 cycles 110- 111 Reserved
22–20 TZQ_OPER	Device ZQ long/oper time. This field holds the number of cycles that are required by the external DDR device to perform ZQ long calibration except the first ZQ long command that is issued after reset. Upon driving the command to the DDR device then no further accesses will be issued to the DDR device till satisfying that time. **NOTE:** In LPDDR2/3 the ZQ oper time is taken from MPZQLP2CTL[ZQ_LP2_HW_ZQCL] **NOTE:** This field should not be update during ZQ calibration. 000 Reserved 001 Reserved 010 128 cycles 011 256 cycles - Default 100 512 cycles 101 1024 cycles 110- 111 Reserved
19–17 TZQ_INIT	Device ZQ long/init time. This field holds the number of cycles that are required by the external DDR device to perform ZQ long calibration right after reset. Upon driving the command to the DDR device then no further accesses will be issued to the DDR device till satisfying that time. **NOTE:** In LPDDR2 the ZQ init time is taken from MPZQLP2CTL[ZQ_LP2_HW_ZQINIT] **NOTE:** This field should not be update during ZQ calibration. 000 Reserved 001 Reserved 010 128 cycles 011 256 cycles 100 512 cycles - Default 101 1024 cycles 110- 111 Reserved
16 ZQ_HW_FOR	Force ZQ automatic calibration process with the i.MX ZQ calibration pad. When this bit is asserted then the MMDC will issue one ZQ automatic calibration process with the i.MX ZQ calibration pad. It is the user responsibility to make sure that all the accesses to DDR will be finished before asserting this bit using CON_REQ/CON_ACK mechanism. HW will negate this bit upon completion of the ZQ calibration process. Upon negation of this bit the ZQ HW calibration pull-up and pull-down results (ZQ_HW_PU_RES and ZQ_HW_PD_RES respectively) are valid

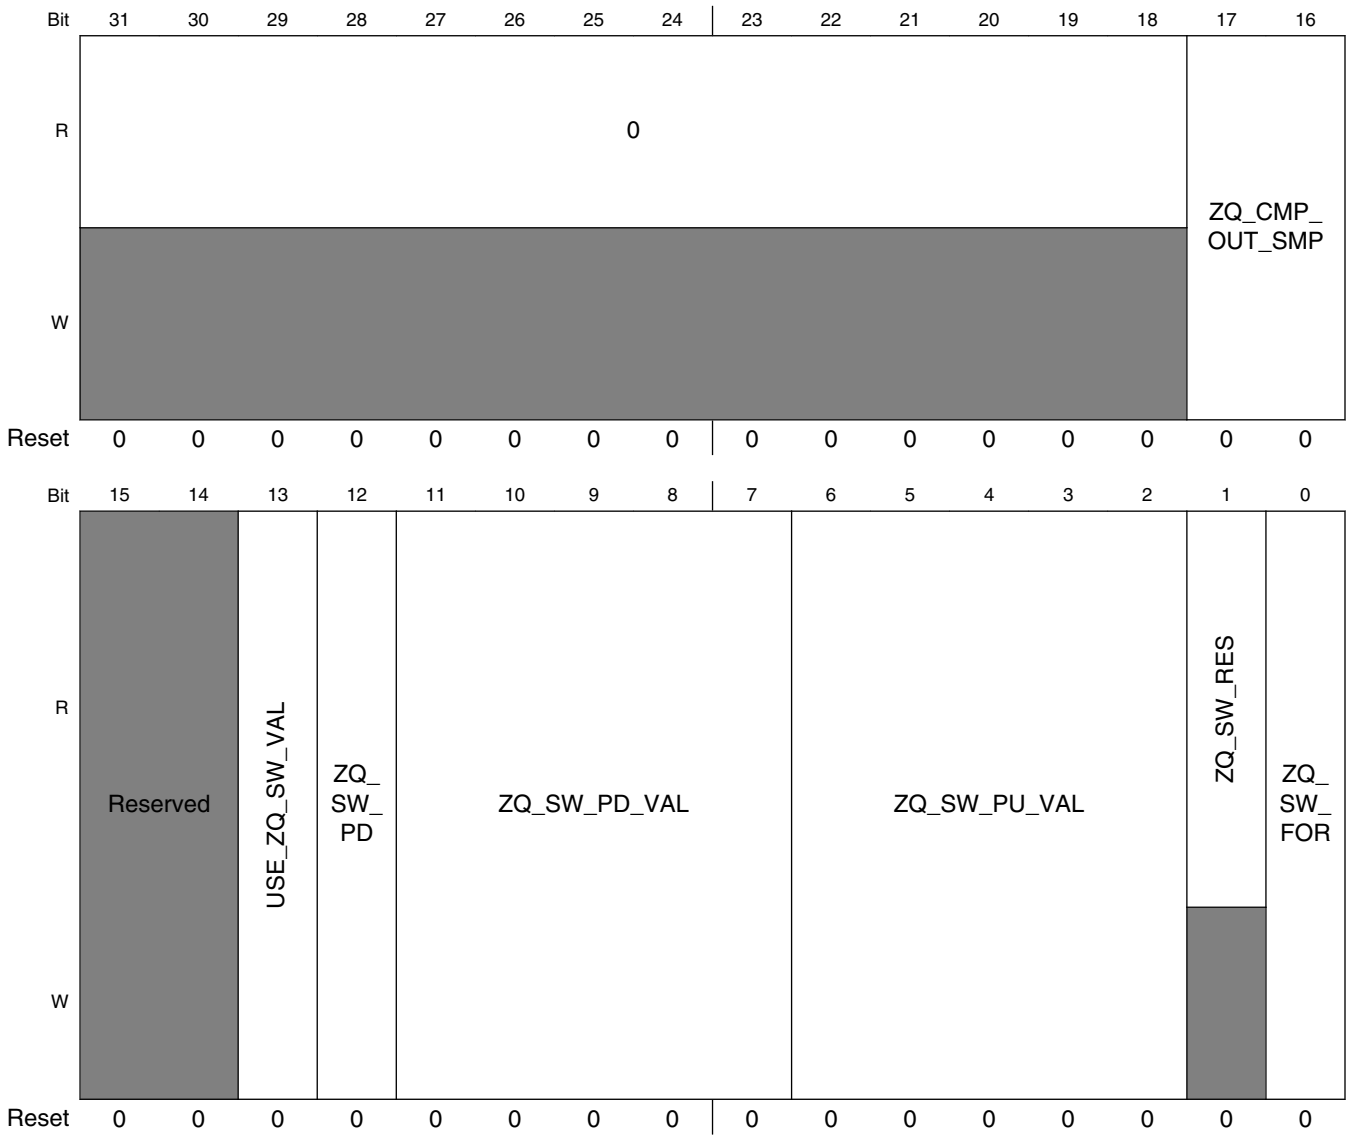
Table continues on the next page...

MMDCx_MPZQHWCTRL field descriptions (continued)

Field	Description
	NOTE: In order to enable this bit ZQ_MODE must be set to either "1" or "3"
15–11 ZQ_HW_PD_RES	ZQ HW calibration pull-down result. This field holds the pull-down resistor value calculated at the end of the ZQ automatic calibration process with the i.MX ZQ calibration pad. **NOTE:** An offset can be applied to this result, see MMDC_MPPDCMPR2[ZQ_PD_OFFSET]. 00000 Max. resistance. 11111 Min. resistance.
10–6 ZQ_HW_PU_RES	ZQ automatic calibration pull-up result. This field holds the pull-up resistor value calculated at the end of the ZQ automatic calibration process with the i.MX ZQ calibration pad. **NOTE:** An offset can be applied to this result, see MMDC_MPPDCMPR2[ZQ_PU_OFFSET] 00000 Min. resistance. 11111 Max. resistance.
5–2 ZQ_HW_PER	ZQ periodic calibration time. This field determines how often the periodic ZQ calibration is performed. This field is applied for both ZQ short calibration and ZQ automatic calibration process with i.MX ZQ calibration pad. Whenever this timer is expired then according to ZQ_MODE the ZQ automatic calibration process with the i.MX ZQ calibration pad will be issued and/or short/long command will be issued to the external DDR device. This field is ignored if ZQ_MODE equals "00" 0000 ZQ calibration is performed every 1 ms. 0001 ZQ calibration is performed every 2 ms. 0010 ZQ calibration is performed every 4 ms. 1010 ZQ calibration is performed every 1 sec. 1110 ZQ calibration is performed every 16 sec. 1111 ZQ calibration is performed every 32 sec.
ZQ_MODE	ZQ calibration mode: 0x0 No ZQ calibration is issued. (Default) 0x1 ZQ calibration is issued to i.MX ZQ calibration pad together with ZQ long command to the external DDR device only when exiting self refresh. 0x2 ZQ calibration command long/short is issued only to the external DDR device periodically and when exiting self refresh 0x3 ZQ calibration is issued to i.MX ZQ calibration pad together with ZQ calibration command long/short to the external DDR device periodically and when exiting self refresh

22.11.31 MMDC PHY ZQ SW control register (MMDCx_MPZQSWCTRL)

Address: 40AB_0000h base + 804h offset = 40AB_0804h



MMDCx_MPZQSWCTRL field descriptions

Field	Description
31–18 Reserved	This read-only field is reserved and always has the value 0.
17–16 ZQ_CMP_OUT_SMP	Defines the amount of cycles between driving the ZQ signals to the ZQ pad and till sampling the comparator enable output while performing ZQ calibration process with the i.MX ZQ calibration pad 00 7 cycles 01 15 cycles

Table continues on the next page...

MMDCx_MPZQSWCTRL field descriptions (continued)

Field	Description
	10 23 cycles 11 31 cycles
15–14 -	This field is reserved. Reserved
13 USE_ZQ_SW_VAL	Use SW ZQ configured value for I/O pads resistor controls. This bit selects whether ZQ SW value or ZQ HW value will be driven to the I/O pads resistor controls. By default this bit is cleared and MMDC drives the HW ZQ status bits on the resistor controls of the I/O pads. **NOTE:** This bit should not be updated during ZQ calibration. 0 Fields ZQ_HW_PD_VAL & ZQ_HW_PU_VAL will be driven to I/O pads resistor controls. 1 Fields ZQ_SW_PD_VAL & ZQ_SW_PU_VAL will be driven to I/O pads resistor controls.
12 ZQ_SW_PD	ZQ software PU/PD calibration. This bit determines the calibration stage (PU or PD). 0 PU resistor calibration 1 PD resistor calibration
11–7 ZQ_SW_PD_VAL	ZQ software pull-down resistance. This field determines the value of the PD resistor during SW ZQ calibration. 00000 Max. resistance. 11111 Min. resistance.
6–2 ZQ_SW_PU_VAL	ZQ software pull-up resistance. This field determines the value of the PU resistor during SW ZQ calibration. 00000 Min. resistance. 11111 Max. resistance.
1 ZQ_SW_RES	ZQ software calibration result. This bit reflects the ZQ calibration voltage comparator value. 0 Current ZQ calibration voltage is less than VDD/2. 1 Current ZQ calibration voltage is more than VDD/2
0 ZQ_SW_FOR	ZQ SW calibration enable. This bit when asserted enables ZQ SW calibration. HW negates this bit upon completion of the ZQ SW calibration. Upon negation of this bit the ZQ SW calibration result (i.e. ZQ_SW_RES) is valid

22.11.32 MMDC PHY Read DQ Byte0 Delay Register (MMDCx_MPRDDQBY0DL)

This register is used to add fine-tuning adjustment to every bit in the read DQ byte0 relative to the read DQS. This delay is in addition to the read data calibration. If operating in 64-bit mode, there is an identical register that is mapped at the second base address.

Address: 40AB_0000h base + 81Ch offset = 40AB_081Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

MMDCx_MPRDDQBY3DL field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value 0.
30–28 rd_dq31_del	Read dqs3 to dq31 delay fine-tuning. This field holds the number of delay units that are added to dq31 relative to dqs3. 000 No change in dq31 delay 001 Add dq31 delay of 1 delay unit 010 Add dq31 delay of 2 delay units. 011 Add dq31 delay of 3 delay units. 100 Add dq31 delay of 4 delay units. 101 Add dq31 delay of 5 delay units. 110 Add dq31 delay of 6 delay units. 111 Add dq31 delay of 7 delay units.
27 Reserved	This read-only field is reserved and always has the value 0.
26–24 rd_dq30_del	Read dqs3 to dq30 delay fine-tuning. This field holds the number of delay units that are added to dq30 relative to dqs3. 000 No change in dq30 delay 001 Add dq30 delay of 1 delay unit 010 Add dq30 delay of 2 delay units. 011 Add dq30 delay of 3 delay units. 100 Add dq30 delay of 4 delay units. 101 Add dq30 delay of 5 delay units. 110 Add dq30 delay of 6 delay units. 111 Add dq30 delay of 7 delay units.
23 Reserved	This read-only field is reserved and always has the value 0.
22–20 rd_dq29_del	Read dqs3 to dq29 delay fine-tuning. This field holds the number of delay units that are added to dq29 relative to dqs3. 000 No change in dq29 delay 001 Add dq29 delay of 1 delay unit 010 Add dq29 delay of 2 delay units. 011 Add dq29 delay of 3 delay units. 100 Add dq29 delay of 4 delay units. 101 Add dq29 delay of 5 delay units. 110 Add dq29 delay of 6 delay units. 111 Add dq29 delay of 7 delay units.
19 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

MMDCx_MPRDDQBY3DL field descriptions (continued)

Field	Description
18–16 rd_dq28_del	Read dqs3 to dq28 delay fine-tuning. This field holds the number of delay units that are added to dq28 relative to dqs3. 000 No change in dq28 delay 001 Add dq28 delay of 1 delay unit 010 Add dq28 delay of 2 delay units. 011 Add dq28 delay of 3 delay units. 100 Add dq28 delay of 4 delay units. 101 Add dq28 delay of 5 delay units. 110 Add dq28 delay of 6 delay units. 111 Add dq28 delay of 7 delay units.
15 Reserved	This read-only field is reserved and always has the value 0.
14–12 rd_dq27_del	Read dqs3 to dq27 delay fine-tuning. This field holds the number of delay units that are added to dq27 relative to dqs3. 000 No change in dq27 delay 001 Add dq27 delay of 1 delay unit 010 Add dq27 delay of 2 delay units. 011 Add dq27 delay of 3 delay units. 100 Add dq27 delay of 4 delay units. 101 Add dq27 delay of 5 delay units. 110 Add dq27 delay of 6 delay units. 111 Add dq27 delay of 7 delay units.
11 Reserved	This read-only field is reserved and always has the value 0.
10–8 rd_dq26_del	Read dqs3 to dq26 delay fine-tuning. This field holds the number of delay units that are added to dq26 relative to dqs3. 000 No change in dq26 delay 001 Add dq26 delay of 1 delay unit 010 Add dq26 delay of 2 delay units. 011 Add dq26 delay of 3 delay units. 100 Add dq26 delay of 4 delay units. 101 Add dq26 delay of 5 delay units. 110 Add dq26 delay of 6 delay units. 111 Add dq26 delay of 7 delay units.
7 Reserved	This read-only field is reserved and always has the value 0.
6–4 rd_dq25_del	Read dqs3 to dq25 delay fine-tuning. This field holds the number of delay units that are added to dq25 relative to dqs3. 000 No change in dq25 delay 001 Add dq25 delay of 1 delay unit 010 Add dq25 delay of 2 delay units. 011 Add dq25 delay of 3 delay units. 100 Add dq25 delay of 4 delay units. 101 Add dq25 delay of 5 delay units.

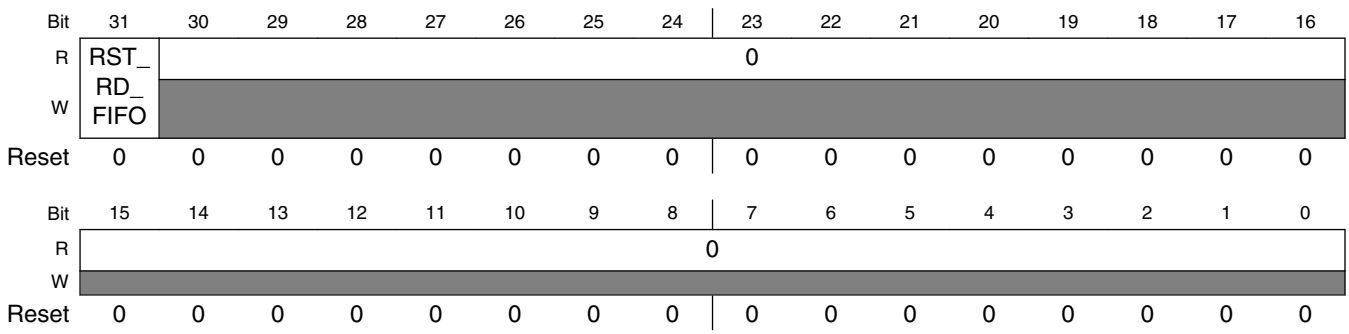
Table continues on the next page...

MMDCx_MPRDDQBY3DL field descriptions (continued)

Field	Description
	110 Add dq25 delay of 6 delay units. 111 Add dq25 delay of 7 delay units.
3 Reserved	This read-only field is reserved and always has the value 0.
rd_dq24_del	Read dqs3 to dq24 delay fine-tuning. This field holds the number of delay units that are added to dq24 relative to dqs3. 000 No change in dq24 delay 001 Add dq24 delay of 1 delay unit 010 Add dq24 delay of 2 delay units. 011 Add dq24 delay of 3 delay units. 100 Add dq24 delay of 4 delay units. 101 Add dq24 delay of 5 delay units. 110 Add dq24 delay of 6 delay units. 111 Add dq24 delay of 7 delay units.

22.11.36 MMDC PHY Read DQS Gating Control Register 0 (MMDCx_MPDGCTRL0)

Address: 40AB_0000h base + 83Ch offset = 40AB_083Ch



MMDCx_MPDGCTRL0 field descriptions

Field	Description
31 RST_RD_FIFO	Reset Read Data FIFO and associated pointers. If this bit is asserted then the MMDC resets the read data FIFO and the associated pointers. This bit is self cleared after the FIFO reset is done.
Reserved	This read-only field is reserved and always has the value 0.

22.11.37 MMDC PHY Read delay-lines Configuration Register (MMDCx_MPRDDLCTL)

This register controls read delay-lines functionality; it determines DQS delay relative to the associated DQ read access. The delay-line compensates for process variations and produces a constant delay regardless of the process, temperature and voltage.

Address: 40AB_0000h base + 848h offset = 40AB_0848h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	RD_DL_ABS_OFFSET3							0	RD_DL_ABS_OFFSET2						
W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	RD_DL_ABS_OFFSET1							0	RD_DL_ABS_OFFSET0						
W																
Reset	0	1	0	0	0	0	0	0	0	1	0	0	0	0	0	0

MMDCx_MPRDDLCTL field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value 0.
30–24 RD_DL_ABS_OFFSET3	Absolute read delay offset for Byte3. This field indicates the absolute delay between read DQS strobe and the read data of Byte3 with fractions of a clock period and up to half cycle. The fraction is process and frequency independent. The delay of the delay-line would be (RD_DL_ABS_OFFSET3 / 256) * MMDC AXI clock (fast clock). So for the default value of 64 we get a quarter cycle delay. This field can also bit written by HW. Upon completion of the read delay-line HW calibration this field gets the value of (HW_RD_DL_LOW3 + HW_RD_DL_UP3) /2 **NOTE:** Not all changes will have effect on the actual delay. If the requested change is smaller than the delay-line resolution, then no change will occur.
23 Reserved	This read-only field is reserved and always has the value 0.
22–16 RD_DL_ABS_OFFSET2	Absolute read delay offset for Byte2. This field indicates the absolute delay between read DQS strobe and the read data of Byte2 with fractions of a clock period and up to half cycle. The fraction is process and frequency independent. The delay of the delay-line would be (RD_DL_ABS_OFFSET2 / 256) * MMDC AXI clock (fast clock). So for the default value of 64 we get a quarter cycle delay. This field can also bit written by HW. Upon completion of the read delay-line HW calibration this field gets the value of (HW_RD_DL_LOW2 + HW_RD_DL_UP2) /2 **NOTE:** Not all changes will have effect on the actual delay. If the requested change is smaller than the delay-line resolution, then no change will occur.
15 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

MMDCx_MPRDDLCTL field descriptions (continued)

Field	Description
14–8 RD_DL_ABS_OFFSET1	Absolute read delay offset for Byte1. This field indicates the absolute delay between read DQS strobe and the read data of Byte1 with fractions of a clock period and up to half cycle. The fraction is process and frequency independent. The delay of the delay-line would be (RD_DL_ABS_OFFSET1 / 256) * MMDC AXI clock (fast clock). So for the default value of 64 we get a quarter cycle delay. This field can also bit written by HW. Upon completion of the read delay-line HW calibration this field gets the value of (HW_RD_DL_LOW1 + HW_RD_DL_UP1) /2 **NOTE:** Not all changes will have effect on the actual delay. If the requested change is smaller than the delay-line resolution, then no change will occur.
7 Reserved	This read-only field is reserved and always has the value 0.
RD_DL_ABS_OFFSET0	Absolute read delay offset for Byte0. This field indicates the absolute delay between read DQS strobe and the read data of Byte0 with fractions of a clock period and up to half cycle. The fraction is process and frequency independent. The delay of the delay-line would be (RD_DL_ABS_OFFSET0 / 256) * MMDC AXI clock (fast clock). So for the default value of 64 we get a quarter cycle delay. This field can also bit written by HW. Upon completion of the read delay-line HW calibration this field gets the value of (HW_RD_DL_LOW0 + HW_RD_DL_UP0) /2 **NOTE:** Not all changes will have effect on the actual delay. If the requested change is smaller than the delay-line resolution, then no change will occur.

22.11.38 MMDC PHY Read delay-lines Status Register (MMDCx_MPRDDLST)

This register holds the status of the 4 read delay-lines.

Address: 40AB_0000h base + 84Ch offset = 40AB_084Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

MMDCx_MPWRDLCTL field descriptions (continued)

Field	Description
30–24 WR_DL_ABS_ OFFSET3	Absolute write delay offset for Byte3. This field indicates the absolute delay between write DQS strobe and the write data of Byte3 with fractions of a clock period and up to half cycle. The fraction is process and frequency independent. The delay of the delay-line would be (WR_DL_ABS_OFFSET3 / 256) * MMDC AXI clock (fast clock). So for the default value of 64 we get a quarter cycle delay. This field can also bit written by HW. Upon completion of the write delay-line HW calibration this field gets the value of (HW_WR_DL_LOW3 + HW_WR_DL_UP3) /2 **NOTE:** Not all changes will have effect on the actual delay. If the requested change is smaller than the delay-line resolution, then no change will occur.
23 Reserved	This read-only field is reserved and always has the value 0.
22–16 WR_DL_ABS_ OFFSET2	Absolute write delay offset for Byte2. This field indicates the absolute delay between write DQS strobe and the write data of Byte2 with fractions of a clock period and up to half cycle. The fraction is process and frequency independent. The delay of the delay-line would be (WR_DL_ABS_OFFSET2/ 256) * MMDC AXI clock (fast clock). So for the default value of 64 we get a quarter cycle delay. This field can also bit written by HW. Upon completion of the write delay-line HW calibration this field gets the value of (HW_WR_DL_LOW2 + HW_WR_DL_UP2) /2 **NOTE:** Not all changes will have effect on the actual delay. If the requested change is smaller than the delay-line resolution, then no change will occur.
15 Reserved	This read-only field is reserved and always has the value 0.
14–8 WR_DL_ABS_ OFFSET1	Absolute write delay offset for Byte1. This field indicates the absolute delay between write DQS strobe and the write data of Byte1 with fractions of a clock period and up to half cycle. The fraction is process and frequency independent. The delay of the delay-line would be (WR_DL_ABS_OFFSET1 / 256) * MMDC AXI clock (fast clock). So for the default value of 64 we get a quarter cycle delay. This field can also bit written by HW. Upon completion of the write delay-line HW calibration this field gets the value of (HW_WR_DL_LOW1 + HW_WR_DL_UP1) /2 **NOTE:** Not all changes of this value will affect the actual delay. If the requested change is smaller than the delay-line resolution, then no change will occur.
7 Reserved	This read-only field is reserved and always has the value 0.
WR_DL_ABS_ OFFSET0	Absolute write delay offset for Byte0. This field indicates the absolute delay between write DQS strobe and the write data of Byte3 with fractions of a clock period and up to half cycle. The fraction is process and frequency independent. The delay of the delay-line would be (WR_DL_ABS_OFFSET0 / 256) * MMDC AXI clock (fast clock). So for the default value of 64 we get a quarter cycle delay. This field can also bit written by HW. Upon completion of the write delay-line HW calibration this field gets the value of (HW_WR_DL_LOW0 + HW_WR_DL_UP0) /2 **NOTE:** Not all changes of this value will affect the actual delay. If the requested change is smaller than the delay-line resolution, then no change will occur.

22.11.40 MMDC PHY Write delay-lines Status Register (MMDCx_MPWRDLST)

This register holds the status of the 4 write delay-line.

Address: 40AB_0000h base + 854h offset = 40AB_0854h

MMDCx_MPWRDLST field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value 0.
30–24 WR_DL_UNIT_NUM3	This field reflects the number of delay units that are actually used by write delay-line 3.
23 Reserved	This read-only field is reserved and always has the value 0.
22–16 WR_DL_UNIT_NUM2	This field reflects the number of delay units that are actually used by write delay-line 2.
15 Reserved	This read-only field is reserved and always has the value 0.
14–8 WR_DL_UNIT_NUM1	This field reflects the number of delay units that are actually used by write delay-line 1.
7 Reserved	This read-only field is reserved and always has the value 0.
WR_DL_UNIT_NUM0	This field reflects the number of delay units that are actually used by write delay-line 0.

22.11.41 MMDC ZQ LPDDR2 HW Control Register (MMDCx_MPZQLP2CTL)

This register controls the idle time that takes the LPDDR2/3 device to perform ZQ calibration.

Address: 40AB_0000h base + 85Ch offset = 40AB_085Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	ZQ_LP2_HW_ZQCS							ZQ_LP2_HW_ZQCL

Reset	0	0	0	0	1	1	0	1	1	0	1	0	1	1	1	1	1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								ZQ_LP2_HW_ZQINIT							
W																
Reset	0	0	0	0	0	0	0	1	0	0	0	0	1	0	0	1

MMDCx_MPZQLP2CTL field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value 0.
30–24 ZQ_LP2_HW_ZQCS	This register defines the period in cycles that it takes the memory device to perform a short ZQ calibration. This is the period of time that the MMDC has to wait after sending a short ZQ calibration and before sending other commands. This delay will also be used if ZQ reset is sent. 0x0-0x1A Reserved 0x1B 112 cycles (default) 0x1C 116 cycles 0x7E 508 cycles 0x7F 512 cycles
23–16 ZQ_LP2_HW_ZQCL	This register defines the period in cycles that it takes the memory device to perform a long ZQ calibration. This is the period of time that the MMDC has to wait after sending a long ZQ calibration and before sending other commands. 0x0-0x36 Reserved 0x37 112 cycles 0x38 114 cycles 0x5F 192 cycles (Default. This may need to be adjusted to achieve the correct timing depending on the DDR clock frequency.) 0xFE 510 cycles 0xFF 512 cycles
15–9 Reserved	This read-only field is reserved and always has the value 0.

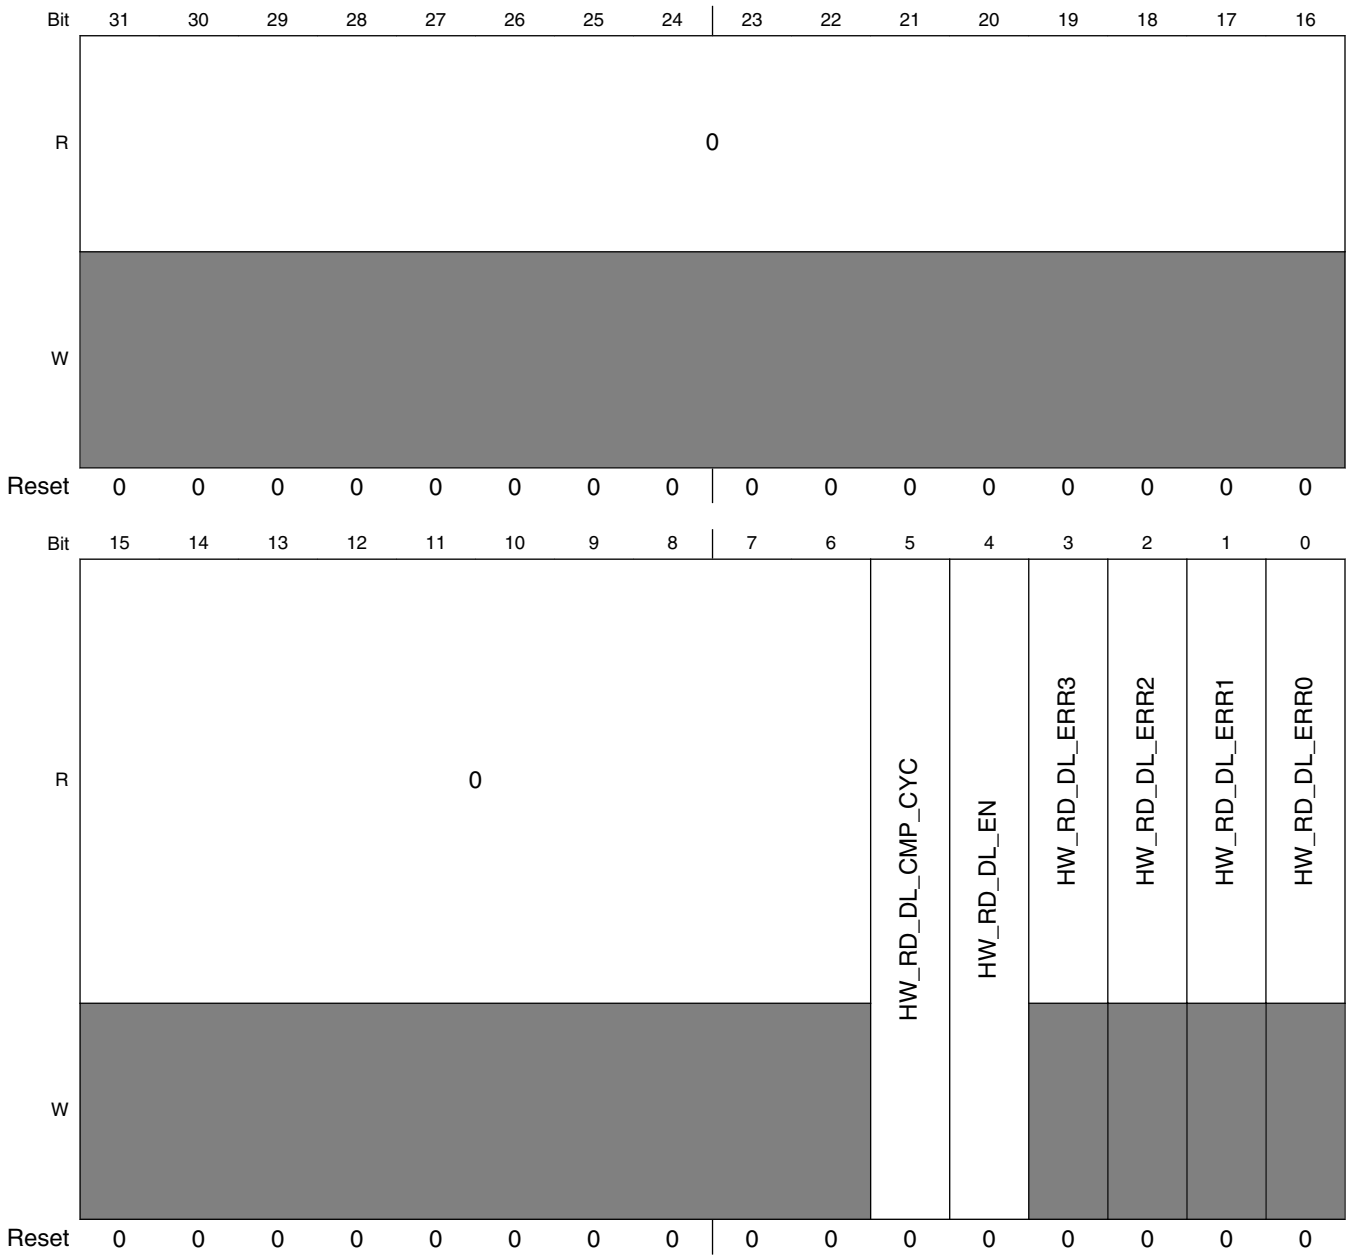
Table continues on the next page...

MMDCx_MPZQLP2CTL field descriptions (continued)

Field	Description
ZQ_LP2_HW_ZQINIT	This register defines the period in cycles that it takes the memory device to perform a Init ZQ calibration. This is the period of time that the MMDC has to wait after sending a init ZQ calibration and before sending other commands. 0x0-0x36 Reserved 0x37 112 cycles 0x38 114 cycles 0x109 532 cycles (Default. This may need to be adjusted to achieve the correct timing depending on the DDR clock frequency.) 0x1FE 1022 cycles 0x1FF 1024 cycles

22.11.42 MMDC PHY Read Delay HW Calibration Control Register (MMDCx_MPRDDLHWCTL)

Address: 40AB_0000h base + 860h offset = 40AB_0860h



MMDCx_MPRDDLHWCTL field descriptions

Field	Description
31–6 Reserved	This read-only field is reserved and always has the value 0.

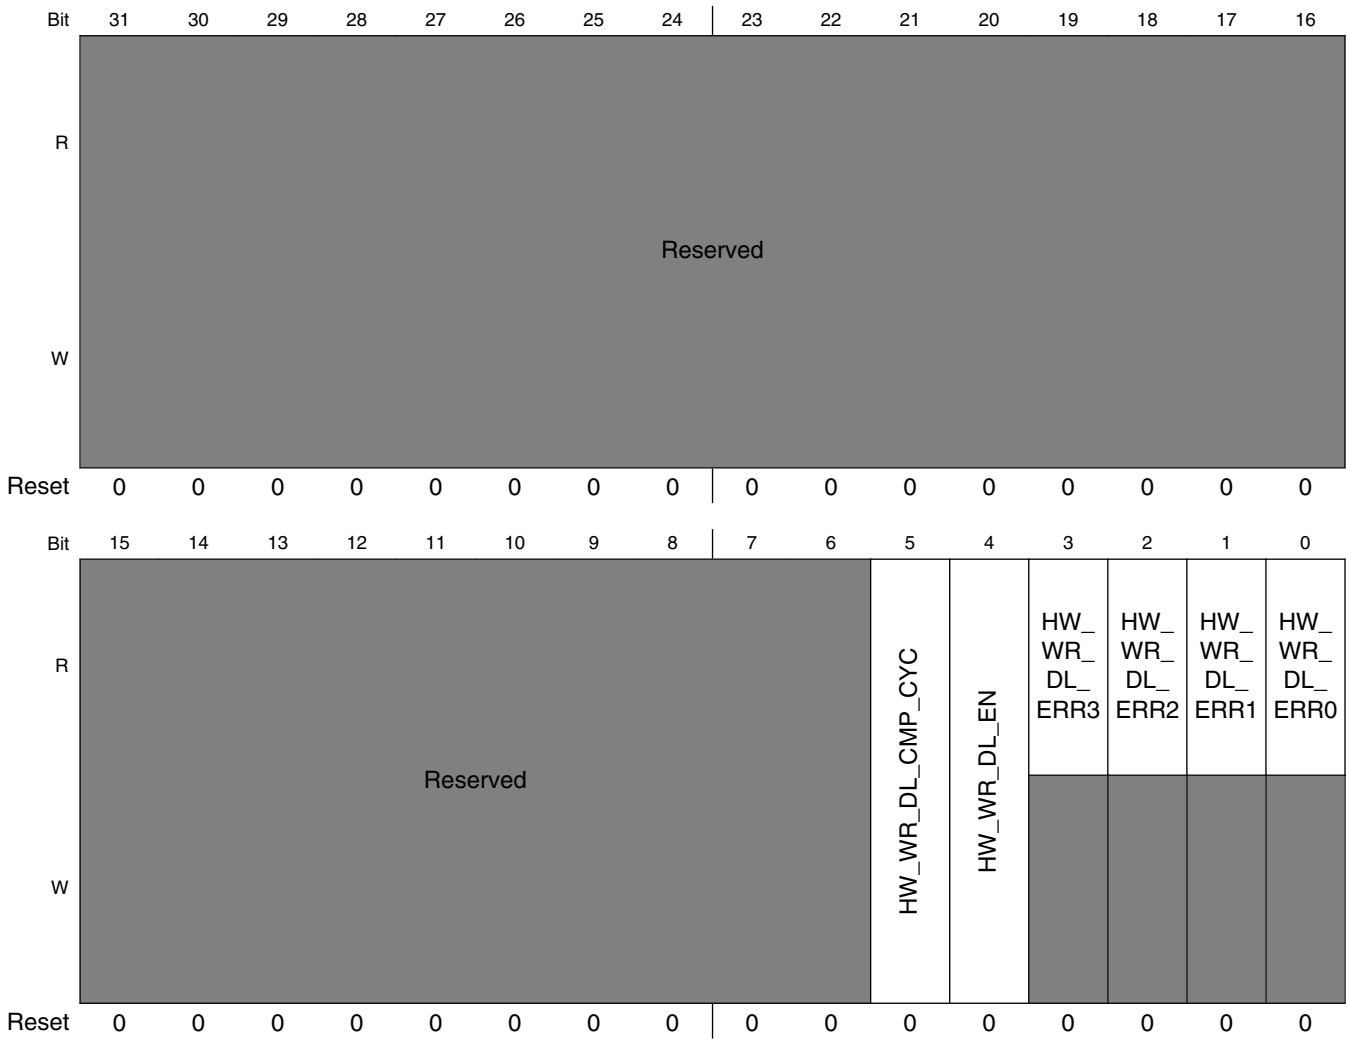
Table continues on the next page...

MMDCx_MPRDDLHWCTL field descriptions (continued)

Field	Description
5 HW_RD_DL_ CMP_CYC	Automatic (HW) read sample cycle. If this bit is asserted then the MMDC will compare the read data 32 cycles after the MMDC sent the read command enable pulse else it compares the data after 16 cycles.
4 HW_RD_DL_EN	Enable automatic (HW) read calibration. If this bit is asserted then the MMDC will perform an automatic read calibration. HW should negate this bit upon completion of the calibration. Negation of this bit also points that the read calibration results are valid **NOTE:** Before issuing the first read command MMDC counts 12 cycles.
3 HW_RD_DL_ ERR3	Automatic (HW) read calibration error of Byte3. If this bit is asserted then it indicates that an error was found during the HW calibration process of read delay-line 3. In case this bit is zero at the end of the calibration process then the boundary results can be found at MPRDDLHWST1 register. This bit is valid only after HW_RD_DL_EN is de-asserted. 0 No error was found in read delay-line 3 during the automatic (HW) read calibration process of read delay-line 3. 1 An error was found in read delay-line 3 during the automatic (HW) read calibration process of read delay-line 3.
2 HW_RD_DL_ ERR2	Automatic (HW) read calibration error of Byte2. If this bit is asserted then it indicates that an error was found during the HW calibration process of read delay-line 2. In case this bit is zero at the end of the calibration process then the boundary results can be found at MPRDDLHWST1 register. This bit is valid only after HW_RD_DL_EN is de-asserted. 0 No error was found in read delay-line 2 during the automatic (HW) read calibration process of read delay-line 2. 1 An error was found in read delay-line 2 during the automatic (HW) read calibration process of read delay-line 2.
1 HW_RD_DL_ ERR1	Automatic (HW) read calibration error of Byte1. If this bit is asserted then it indicates that an error was found during the HW calibration process of read delay-line 1. In case this bit is zero at the end of the calibration process then the boundary results can be found at MPRDDLHWST0 register. This bit is valid only after HW_RD_DL_EN is de-asserted. 0 No error was found in read delay-line 1 during the automatic (HW) read calibration process of read delay-line 1. 1 An error was found in read delay-line 1 during the automatic (HW) read calibration process of read delay-line 1.
0 HW_RD_DL_ ERR0	Automatic (HW) read calibration error of Byte0. If this bit is asserted then it indicates that an error was found during the HW calibration process of read delay-line 0. In case this bit is zero at the end of the calibration process then the boundary results can be found at MPRDDLHWST0 register. This bit is valid only after HW_RD_DL_EN is de-asserted. 0 No error was found in read delay-line 0 during the automatic (HW) read calibration process of read delay-line 0. 1 An error was found in read delay-line 0 during the automatic (HW) read calibration process of read delay-line 0.

22.11.43 MMDC PHY Write Delay HW Calibration Control Register (MMDCx_MPWRDLHWCTL)

Address: 40AB_0000h base + 864h offset = 40AB_0864h



MMDCx_MPWRDLHWCTL field descriptions

Field	Description
31–6 -	This field is reserved.
5 HW_WR_DL_CMP_CYC	Write sample cycle. If this bit is asserted then the MMDC will compare the data 32 cycles after the MMDC sent the read command enable pulse else it compares the data after 16 cycles.
4 HW_WR_DL_EN	Enable automatic (HW) write calibration. If this bit is asserted then the MMDC will perform an automatic write calibration. HW should negate this bit upon completion of the calibration. Negation of this bit also indicates that the write calibration results are valid **NOTE:** Before issuing the first read command MMDC counts 12 cycles.

Table continues on the next page...

MMDCx_MPWRDLHWCTL field descriptions (continued)

Field	Description
3 HW_WR_DL_ ERR3	Automatic (HW) write calibration error of Byte3. If this bit is asserted then it indicates that an error was found during the HW calibration process of write delay-line 3. In case this bit is zero at the end of the calibration process then the boundary results can be found at MPWRDLHWST1 register. This bit is valid only after HW_WR_DL_EN is de-asserted. 0 No error was found during the automatic (HW) write calibration process of write delay-line 3. 1 An error was found during the automatic (HW) write calibration process of write delay-line 3.
2 HW_WR_DL_ ERR2	Automatic (HW) write calibration error of Byte2. If this bit is asserted then it indicates that an error was found during the HW calibration process of write delay-line 2. T In case this bit is zero at the end of the calibration process then the boundary results can be found at MPWRDLHWST1 register. This bit is valid only after HW_WR_DL_EN is de-asserted. 0 No error was found during the automatic (HW) write calibration process of write delay-line 2. 1 An error was found during the automatic (HW) write calibration process of write delay-line 2.
1 HW_WR_DL_ ERR1	Automatic (HW) write calibration error of Byte1. If this bit is asserted then it indicates that an error was found during the HW calibration process of write delay-line 1. In case this bit is zero at the end of the calibration process then the boundary results can be found at MPWRDLHWST0 register. This bit is valid only after HW_WR_DL_EN is de-asserted. 0 No error was found during the automatic (HW) write calibration process of write delay-line 1. 1 An error was found during the automatic (HW) write calibration process of write delay-line 1.
0 HW_WR_DL_ ERR0	Automatic (HW) write calibration error of Byte0. If this bit is asserted then it indicates that an error was found during the HW calibration process of write delay-line 0. In case this bit is zero at the end of the calibration process then the boundary results can be found at MPWRDLHWST0 register. This bit is valid only after HW_WR_DL_EN is de-asserted. 0 No error was found during the automatic (HW) write calibration process of write delay-line 0. 1 An error was found during the automatic (HW) write calibration process of write delay-line 0.

22.11.44 MMDC PHY Read Delay HW Calibration Status Register 0 (MMDCx_MPRDDLHWST0)

Address: 40AB_0000h base + 868h offset = 40AB_0868h

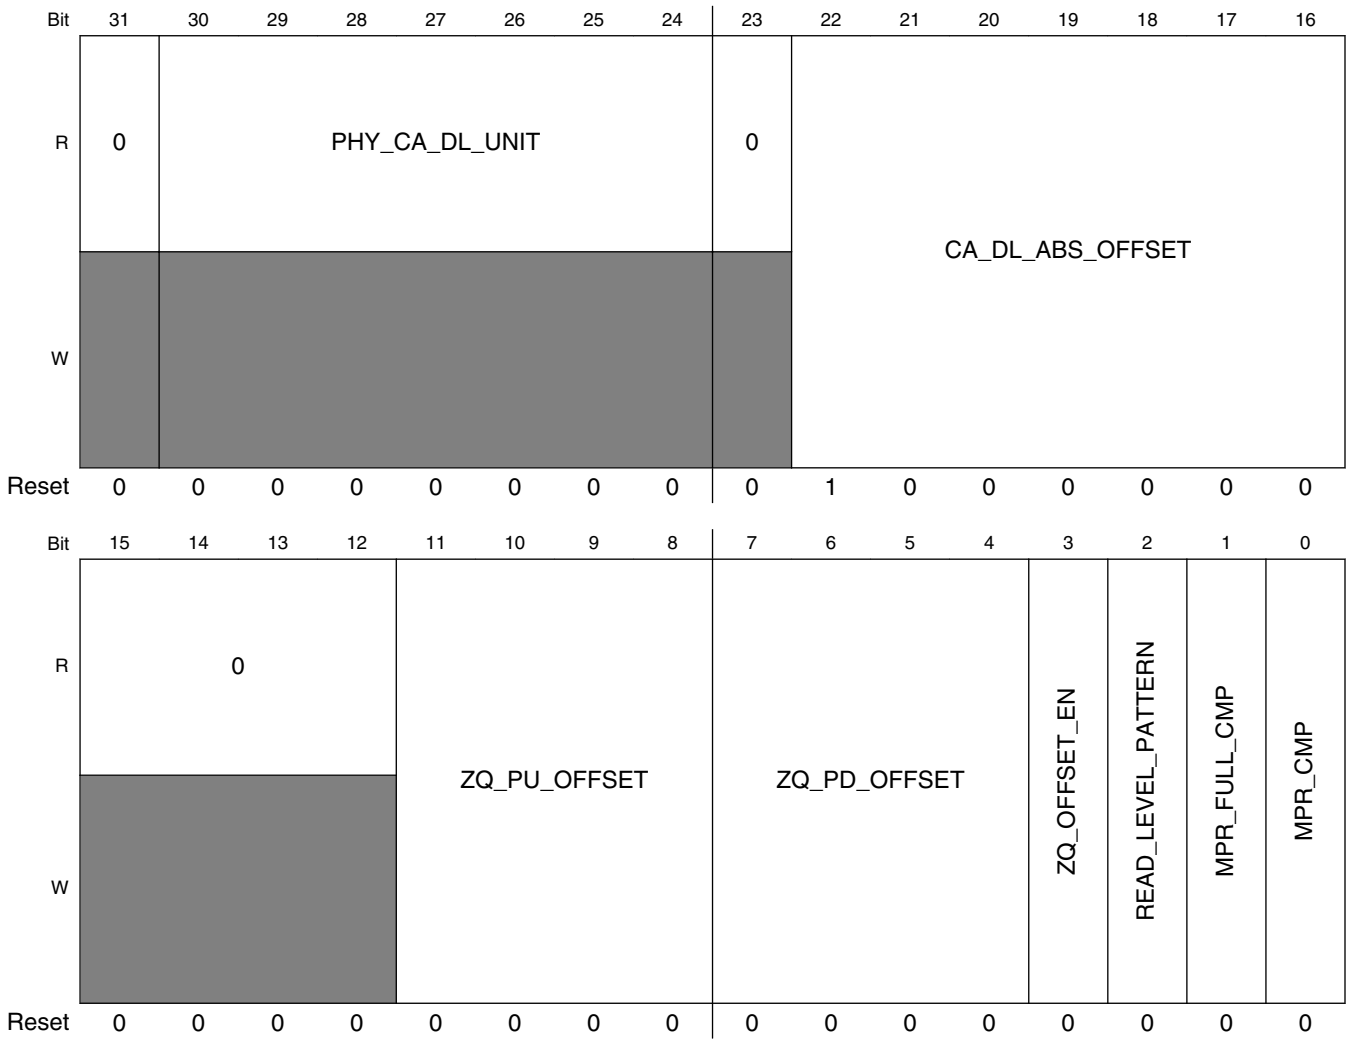
MMDCx_MPPDCMPR1 field descriptions

Field	Description
31–16 PDV2	MMDC Pre defined compare value2. This field holds the 2 MSB of the data that will be driven to the DDR device during automatic read, read DQS gating and write calibrations in case DQ calibration (LPDDR2/ LPDDR3) mode are disabled (MPR_CMP is disabled). Upon read access during the calibration the MMDC will compare the read data with the data that is stored in this field. **NOTE:** Before issue the read access the MMDC will invert the value of this field and drive it to the associate entry in the read comparison FIFO. For further information, see Calibration with pre-defined value and Hardware (automatic) Calibration with DQ Calibration
PDV1	MMDC Pre defined compare value2. This field holds the 2 LSB of the data that will be driven to the DDR device during automatic read, read DQS gating and write calibrations in case DQ calibration (LPDDR2/ LPDDR3) mode are disabled (MPR_CMP is disabled). Upon read access during the calibration the MMDC will compare the read data with the data that is stored in this field. **NOTE:** Before issuing the read access, the MMDC will invert the value of this field and drive it to the associated entry in the read comparison FIFO.

22.11.49 MMDC PHY Pre-defined Compare and CA delay-line Configuration Register (MMDCx_MPPDCMPR2)

Address: 40AB_0000h base + 890h offset = 40AB_0890h



MMDCx_MPPDCMPR2 field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value 0.
30–24 PHY_CA_DL_UNIT	This field reflects the number of delay units that are actually used by CA(Command/Address of LPDDR2) delay-line
23 Reserved	This read-only field is reserved and always has the value 0.
22–16 CA_DL_ABS_OFFSET	Absolute CA (Command/Address of LPDDRR2) offset. This field indicates the absolute delay between CA (Command/Address) bus and the DDR clock (CK) with fractions of a clock period and up to half cycle. The fraction is process and frequency independent. The delay of the delay-line would be

Table continues on the next page...

MMDCx_MPPDCMPR2 field descriptions (continued)

Field	Description
	(CA_DL_ABS_OFFSET / 256) * MMDC AXI clock (fast clock). So for the default value of 64 we get a quarter cycle delay.
15–12 Reserved	This read-only field is reserved and always has the value 0.
11–8 ZQ_PU_OFFSET	Programmable offset from -7 to 7 added to the MMDC_MPZQHWCTRL[ZQ_HW_PU_RES] field when ZQ_OFFSET_EN is enabled. Bit[11] determines direction: 'b0 = Offset is added to ZQ_HW_PU_RES field 'b1 = Offset is subtracted from ZQ_HW_PU_RES field Bits[10:8] = Amount of change to apply. 0000 **0** — Offset is added to ZQ_HW_PU_RES field 0001 **1** — Offset is added to ZQ_HW_PU_RES field 0010 **2** — Offset is added to ZQ_HW_PU_RES field 0011 **3** — Offset is added to ZQ_HW_PU_RES field 0100 **4** — Offset is added to ZQ_HW_PU_RES field 0101 **5** — Offset is added to ZQ_HW_PU_RES field 0110 **6** — Offset is added to ZQ_HW_PU_RES field 0111 **7** — Offset is added to ZQ_HW_PU_RES field 1000 **0** — Offset is subtracted from ZQ_HW_PU_RES field 1001 **1** — Offset is subtracted from ZQ_HW_PU_RES field 1010 **2** — Offset is subtracted from ZQ_HW_PU_RES field 1011 **3** — Offset is subtracted from ZQ_HW_PU_RES field 1100 **4** — Offset is subtracted from ZQ_HW_PU_RES field 1101 **5** — Offset is subtracted from ZQ_HW_PU_RES field 1110 **6** — Offset is subtracted from ZQ_HW_PU_RES field 1111 **7** — Offset is subtracted from ZQ_HW_PU_RES field
7–4 ZQ_PD_OFFSET	Programmable offset from -7 to 7 added to the MMDC_MPZQHWCTRL[ZQ_HW_PD_RES] field when ZQ_OFFSET_EN is enabled. Bit[7] determines direction: 'b0 = Offset is added to ZQ_HW_PD_RES field 'b1 = Offset is subtracted from ZQ_HW_PD_RES field Bits[6:4] = Amount of change to apply. 0000 **0** — Offset is added to ZQ_HW_PD_RES field 0001 **1** — Offset is added to ZQ_HW_PD_RES field 0010 **2** — Offset is added to ZQ_HW_PD_RES field 0011 **3** — Offset is added to ZQ_HW_PD_RES field 0100 **4** — Offset is added to ZQ_HW_PD_RES field 0101 **5** — Offset is added to ZQ_HW_PD_RES field 0110 **6** — Offset is added to ZQ_HW_PD_RES field 0111 **7** — Offset is added to ZQ_HW_PD_RES field 1000 **0** — Offset is subtracted from ZQ_HW_PD_RES field 1001 **1** — Offset is subtracted from ZQ_HW_PD_RES field 1010 **2** — Offset is subtracted from ZQ_HW_PD_RES field 1011 **3** — Offset is subtracted from ZQ_HW_PD_RES field

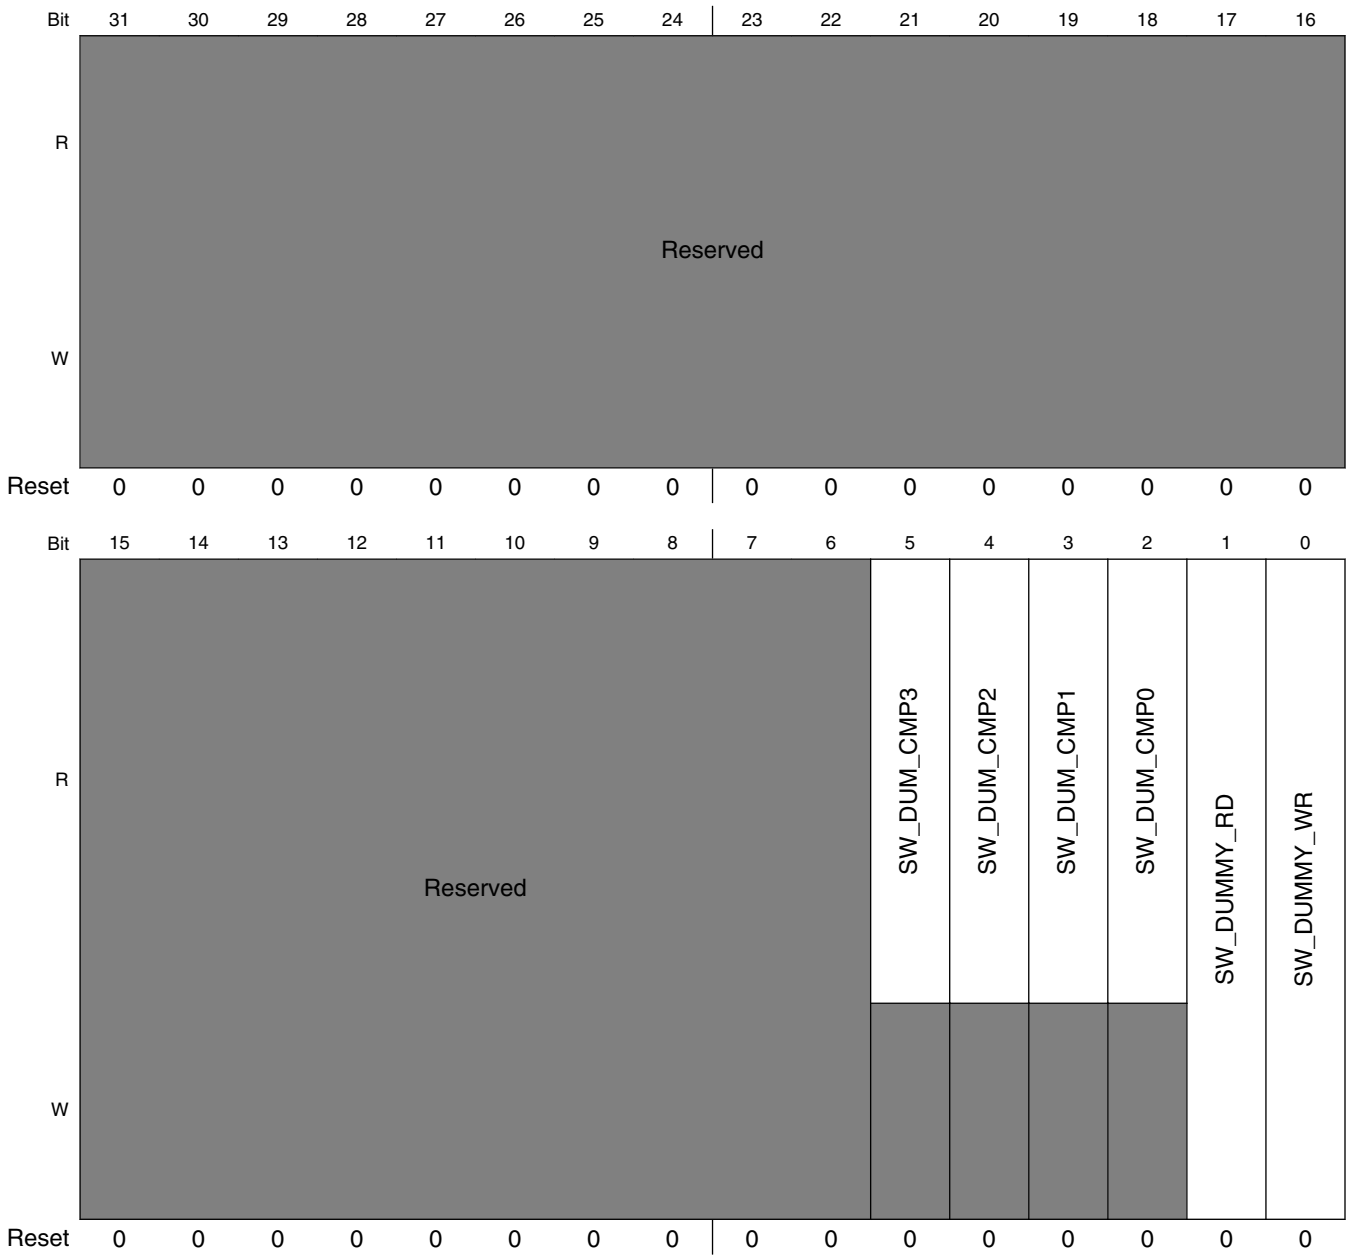
Table continues on the next page...

MMDCx_MPPDCMPR2 field descriptions (continued)

Field	Description
	1100 **4** — Offset is subtracted from ZQ_HW_PD_RES field 1101 **5** — Offset is subtracted from ZQ_HW_PD_RES field 1110 **6** — Offset is subtracted from ZQ_HW_PD_RES field 1111 **7** — Offset is subtracted from ZQ_HW_PD_RES field
3 ZQ_OFFSET_EN	ZQ Offset Enable 0 Hardware ZQ offset disabled 1 Hardware ZQ offset enabled
2 READ_LEVEL_ PATTERN	DQ calibration (LPDDR2/LPDDR3) read compare pattern. In case DQ calibration (LPDDR2/LPDDR3) modes are used during the calibration process (MPR_CMP is asserted) then this field indicates the read pattern for the comparison. 0 Compare with read pattern 1010 1 Compare with read pattern 0011 (Used only in LPDDR2/LPDDR3 mode)
1 MPR_FULL_ CMP	DQ calibration (LPDDR2/LPDDR3) full compare enable. In case DQ calibration (LPDDR2/LPDDR3) modes are used during the calibration process (MPR_CMP is asserted) then this field indicates whether the MMDC will compare all the bits of the data that is read from the DDR device to the MPR pre-defined pattern. When this bit is de-asserted only LSB of each byte is compared.
0 MPR_CMP	DQ calibration (LPDDR2/LPDDR3) compare enable. This bit indicates whether the MMDC will compare the read data during automatic read and read DQS calibration processes to the pre-defined patterns that are driven by the DDR device (READ_LEVEL_PATTERN as defined by JEDEC) or general pre-defined value that are stored in PDV1 and PDV2. When this bit is disabled data is compared to the data of the pre defined compare value field For further information see Read Calibration .

22.11.50 MMDC PHY SW Dummy Access Register (MMDCx_MPSWDAR0)

Address: 40AB_0000h base + 894h offset = 40AB_0894h



MMDCx_MPSWDAR0 field descriptions

Field	Description
31–6 -	This field is reserved.

Table continues on the next page...

MMDCx_MPSWDAR0 field descriptions (continued)

Field	Description
5 SW_DUM_CMP3	SW dummy read byte3 compare results. This bit indicates the result of the read data comparison of Byte3 at the completion of SW_DUMMY_RD. This bit is valid only when SW_DUMMY_RD is de-asserted. 0 Dummy read fail 1 Dummy read pass
4 SW_DUM_CMP2	SW dummy read byte2 compare results. This bit indicates the result of the read data comparison of Byte2 at the completion of SW_DUMMY_RD. This bit is valid only when SW_DUMMY_RD is de-asserted. 0 Dummy read fail 1 Dummy read pass
3 SW_DUM_CMP1	SW dummy read byte1 compare results. This bit indicates the result of the read data comparison of Byte1 at the completion of SW_DUMMY_RD. This bit is valid only when SW_DUMMY_RD is de-asserted. 0 Dummy read fail 1 Dummy read pass
2 SW_DUM_CMP0	SW dummy read byte0 compare results. This bit indicates the result of the read data comparison of Byte0 at the completion of SW_DUMMY_RD. This bit is valid only when SW_DUMMY_RD is de-asserted. 0 Dummy read fail 1 Dummy read pass
1 SW_DUMMY_ RD	SW dummy read. When this bit is asserted the MMDC will generate internally read access without intervention of the system toward bank 0, row 0, column 0. If MPR_CMP = 1then the read data will be compared to MPPDCMPR2[READ_LEVEL_PATTERN] . If MPR_CMP =0 then the read data will be compared to MPPDCMPR1[PDV1], MPPDCMPR1[PDV2]. Upon completion of the access this bit is de-asserted automatically and the read data and comparison results are valid at MPSWDAR0[SW_DUM_CMP#] and MPSWDRDR0-MPSWDRDR7 respectively.
0 SW_DUMMY_ WR	SW dummy write. When this bit is asserted the MMDC will generate internally write access without intervention of the system toward bank 0, row 0, column 0, while the data is driven from MPPDCMPR1[PDV1] and MPPDCMPR1[PDV2]. The bit is de-asserted automatically upon completion of the access.

22.11.51 MMDC PHY SW Dummy Read Data Register 0 (MMDCx_MPSWDRDR0)

Address: 40AB_0000h base + 898h offset = 40AB_0898h

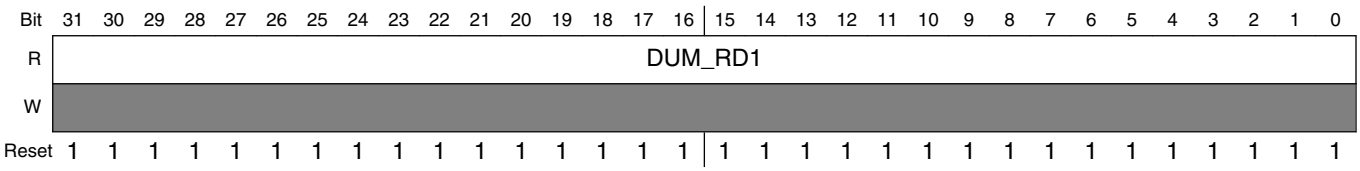
MMDCx_MPSWDRDR0 field descriptions

Field	Description
DUM_RD0	Dummy read data0. This field holds the first data that is read from the DDR during SW dummy read access (i.e. when SW_DUMMY_RD = 1). This field is valid only when SW_DUMMY_RD is de-asserted

22.11.52 MMDC PHY SW Dummy Read Data Register 1 (MMDCx_MPSWDRDR1)

Address: 40AB_0000h base + 89Ch offset = 40AB_089Ch

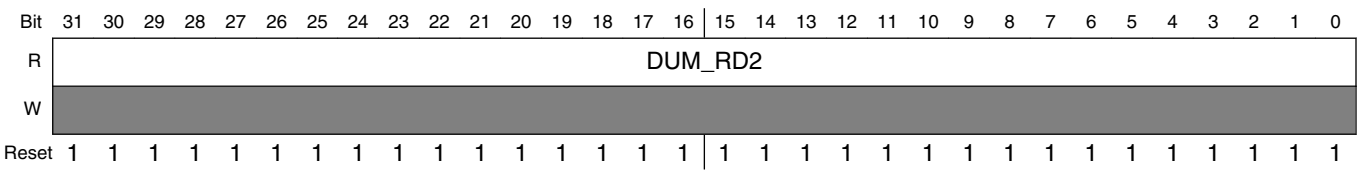


MMDCx_MPSWDRDR1 field descriptions

Field	Description
DUM_RD1	Dummy read data1. This field holds the second data that is read from the DDR during SW dummy read access (i.e. when SW_DUMMY_RD = 1). This field is valid only when SW_DUMMY_RD is de-asserted

22.11.53 MMDC PHY SW Dummy Read Data Register 2 (MMDCx_MPSWDRDR2)

Address: 40AB_0000h base + 8A0h offset = 40AB_08A0h

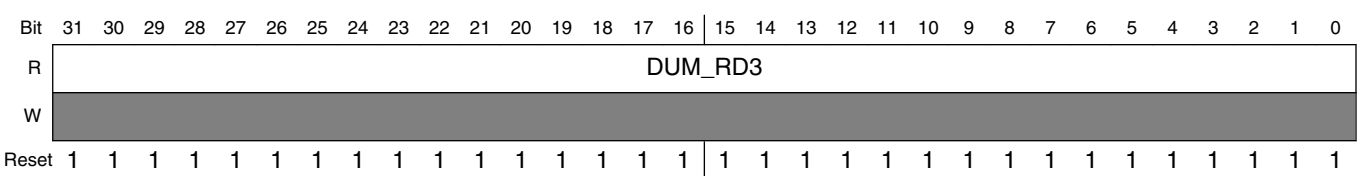


MMDCx_MPSWDRDR2 field descriptions

Field	Description
DUM_RD2	Dummy read data2. This field holds the third data that is read from the DDR during SW dummy read access (i.e. when SW_DUMMY_RD = 1). This field is valid only when SW_DUMMY_RD is de-asserted.

22.11.54 MMDC PHY SW Dummy Read Data Register 3 (MMDCx_MPSWDRDR3)

Address: 40AB_0000h base + 8A4h offset = 40AB_08A4h

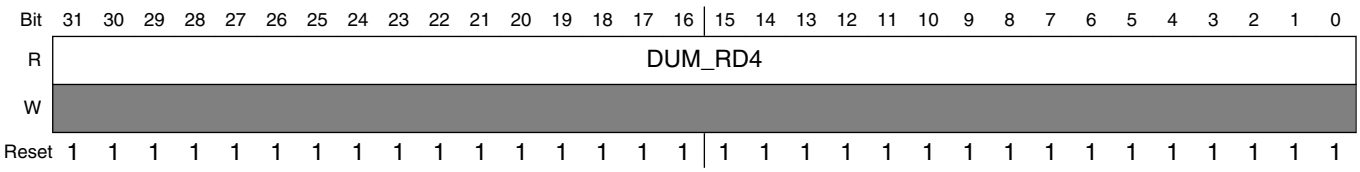


MMDCx_MPSWDRDR3 field descriptions

Field	Description
DUM_RD3	Dummy read data3. This field holds the forth data that is read from the DDR during SW dummy read access (i.e. when SW_DUMMY_RD = 1). This field is valid only when SW_DUMMY_RD is de-asserted.

22.11.55 MMDC PHY SW Dummy Read Data Register 4 (MMDCx_MPSWDRDR4)

Address: 40AB_0000h base + 8A8h offset = 40AB_08A8h

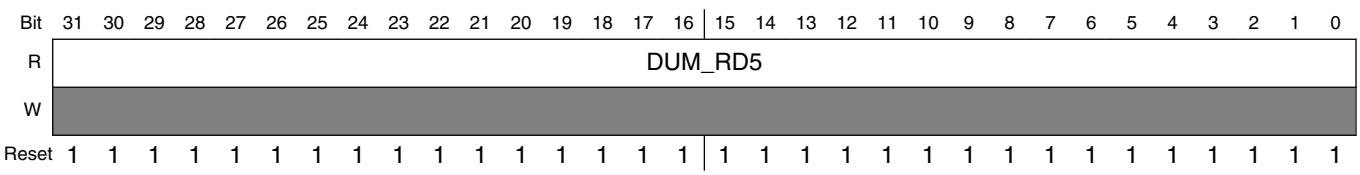


MMDCx_MPSWDRDR4 field descriptions

Field	Description
DUM_RD4	Dummy read data4. This field holds the fifth data (only in case of burst length 8 (BL =1)) that is read from the DDR during SW dummy read access (i.e. when SW_DUMMY_RD = 1). This field is valid only when SW_DUMMY_RD is de-asserted.

22.11.56 MMDC PHY SW Dummy Read Data Register 5 (MMDCx_MPSWDRDR5)

Address: 40AB_0000h base + 8ACh offset = 40AB_08ACh

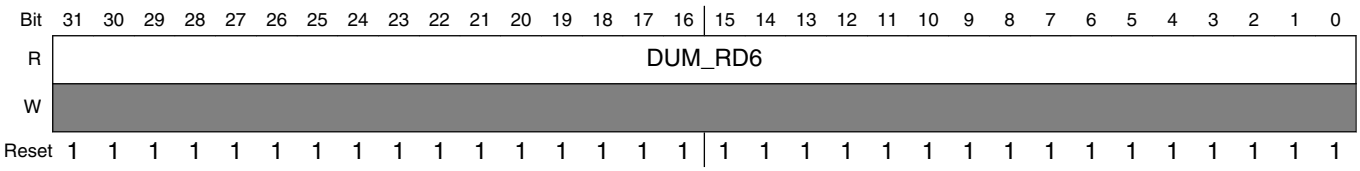


MMDCx_MPSWDRDR5 field descriptions

Field	Description
DUM_RD5	Dummy read data5. This field holds the sixth data (only in case of burst length 8 (BL =1)) that is read from the DDR during SW dummy read access (i.e. when SW_DUMMY_RD = 1). This field is valid only when SW_DUMMY_RD is de-asserted.

22.11.57 MMDC PHY SW Dummy Read Data Register 6 (MMDCx_MPSWDRDR6)

Address: 40AB_0000h base + 8B0h offset = 40AB_08B0h

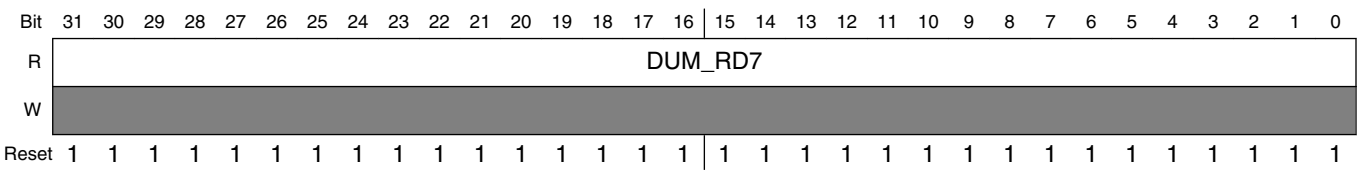


MMDCx_MPSWDRDR6 field descriptions

Field	Description
DUM_RD6	Dummy read data6. This field holds the seventh data (only in case of burst length 8 (BL =1)) that is read from the DDR during SW dummy read access (i.e. when SW_DUMMY_RD = 1). This field is valid only when SW_DUMMY_RD is de-asserted.

22.11.58 MMDC PHY SW Dummy Read Data Register 7 (MMDCx_MPSWDRDR7)

Address: 40AB_0000h base + 8B4h offset = 40AB_08B4h

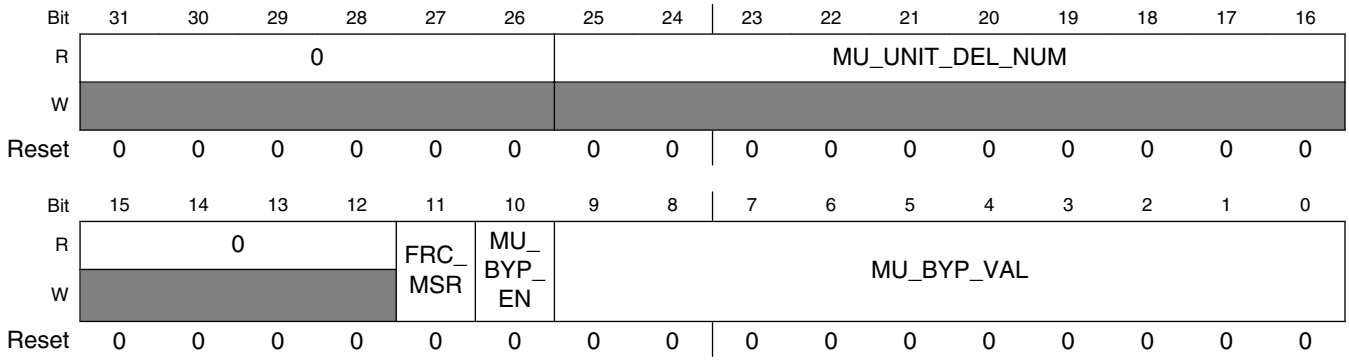


MMDCx_MPSWDRDR7 field descriptions

Field	Description
DUM_RD7	Dummy read data7. This field holds the eight data (only in case of burst length 8 (BL =1)) that is read from the DDR during SW dummy read access (i.e. when SW_DUMMY_RD = 1). This field is valid only when SW_DUMMY_RD is de-asserted.

22.11.59 MMDC PHY Measure Unit Register (MMDCx_MPMUR0)

Address: 40AB_0000h base + 8B8h offset = 40AB_08B8h



MMDCx_MPMUR0 field descriptions

Field	Description
31–26 Reserved	This read-only field is reserved and always has the value 0.
25–16 MU_UNIT_DEL_NUM	Number of delay units measured per cycle. This field is used in debug mode and holds the number of delay units that were measured by the measure unit per DDR clock cycle. The delay-lines that are used in every calibration process use that number for generating the desired delay.
15–12 Reserved	This read-only field is reserved and always has the value 0.
11 FRC_MSR	Force measurement on delay-lines. When this bit is asserted then a measurement process will be performed, where at the completion of the process the delay-lines will issue the desired delay. Upon completion of the measurement process the measure unit and the delay-lines will return to functional mode. This bit is self cleared. **NOTE:** This bit should be used only during manual (SW) calibration and not while the DDR is functional (being accessed). After initial calibration is done the hardware performs periodic measurements to track any operating conditions changes. Hence, force measurements (FRC_MSR) should not be used. See Calibration Process for more information. **NOTE:** User should make sure that there is no active accesses to/from DDR before asserting this bit. 0 No measurement is performed 1 Perform measurement process
10 MU_BYP_EN	Measure unit bypass enable. This field is used in debug mode and when it is asserted then the delay-lines will use the number of delay units that are indicated at MU_BYP_VAL, otherwise the delay-lines will use the number of delay units that was measured by the measurement unit and are indicated at MU_UNIT_DEL_NUM 0 The delay-lines use delay units as indicated at MU_UNIT_DEL_NUM. 1 The delay-lines use delay units as indicated at MU_BYPASS_VAL.
MU_BYP_VAL	Number of delay units for measurement bypass. This field is used in debug mode and holds the number of delay units that will be used by the delay-lines when MU_BYP_EN is asserted.

22.11.60 MMDC Duty Cycle Control Register (MMDCx_MPDCCR)

This register is used to control the duty cycle of the DQS and the primary clock (CK0). Programming of this register is permitted by entering the DDR device into self-refresh mode through LPMD/DVFS mechanism.

MMDC1_MPDCCR only affects SDCLK0.

NOTE

If the duty cycle is modified after DDR initialization, the DDR will have to be placed in self-refresh mode.

NOTE

The duty cycle may be changed during initial DDR initialization without having to be placed in self-refresh mode.

Address: 40AB_0000h base + 8C0h offset = 40AB_08C0h

23.1.1 ultra Secured Digital Host Controller (uSDHC)

The ultra Secured Digital Host Controller (uSDHC) provides the interface between the host system and SD, SDIO or eMMC cards. The uSDHC acts as a bridge, passing host bus transactions to the cards by sending commands and performing data accesses to/from the cards or devices. It handles SD, SDIO and eMMC protocol at the transmission level. See the i.MX 7ULP Data Sheet for bus clock frequency as per the bus mode being used on 1-bit, 4-bit, and 8-bit data bus width.

23.2 Introduction

uSDHC provides the interface between the host system and the SD/SDIO/MMC cards, as depicted in Figure 23-1.

uSDHC acts as a bridge, passing host bus transactions to the SD/SDIO/MMC cards by sending commands and performing data accesses to/from the cards.

It handles the SD/SDIO/MMC protocols at the transmission level.

The following are brief descriptions of the cards supported by uSDHC:

The Multi Media Card (MMC) is a universal low-cost data storage and communication media designed to cover a wide array of applications including mobile video and gaming. Previous MMC cards were based on a 7-pin serial bus with a single data pin, while the new high speed MMC communication is based on an advanced 11-pin serial bus designed to operate in the low-voltage range.

The Secure Digital Card (SD) is an evolution of the old MMC technology. It is specifically designed to meet the security, capacity, performance, and environmental requirements inherent in newly emerging audio and video consumer electronic devices. The physical form factor, pin assignment, and data transfer protocol are forward compatible with the old MMC (with some additions).

Under the SD protocol, it can be categorized into memory card, I/O card, and combo card, which have both memory and I/O functions. The memory card invokes a copyright protection mechanism that complies with the security of the SDMI standard. The I/O card, which is also known as SDIO card, provides high-speed data I/O with low-power consumption for mobile electronic devices. For the sake of simplicity, the next figure does not show cards with reduced size or mini cards.

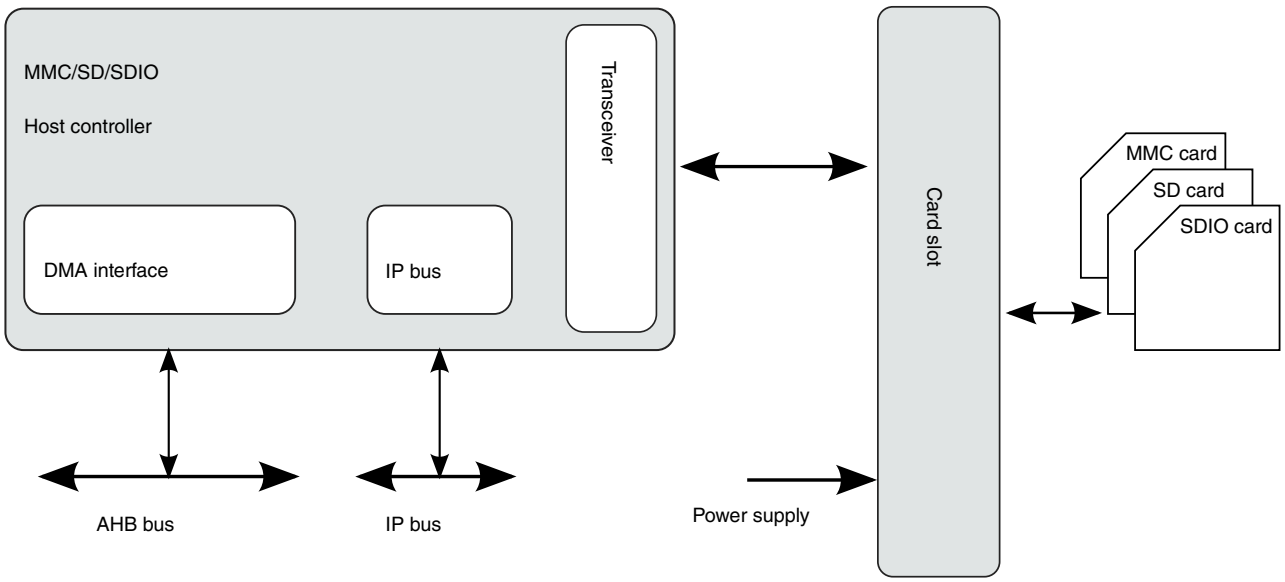

Figure 23-1. System connection of uSDHC

The following figure illustrates the block diagram of uSDHC.

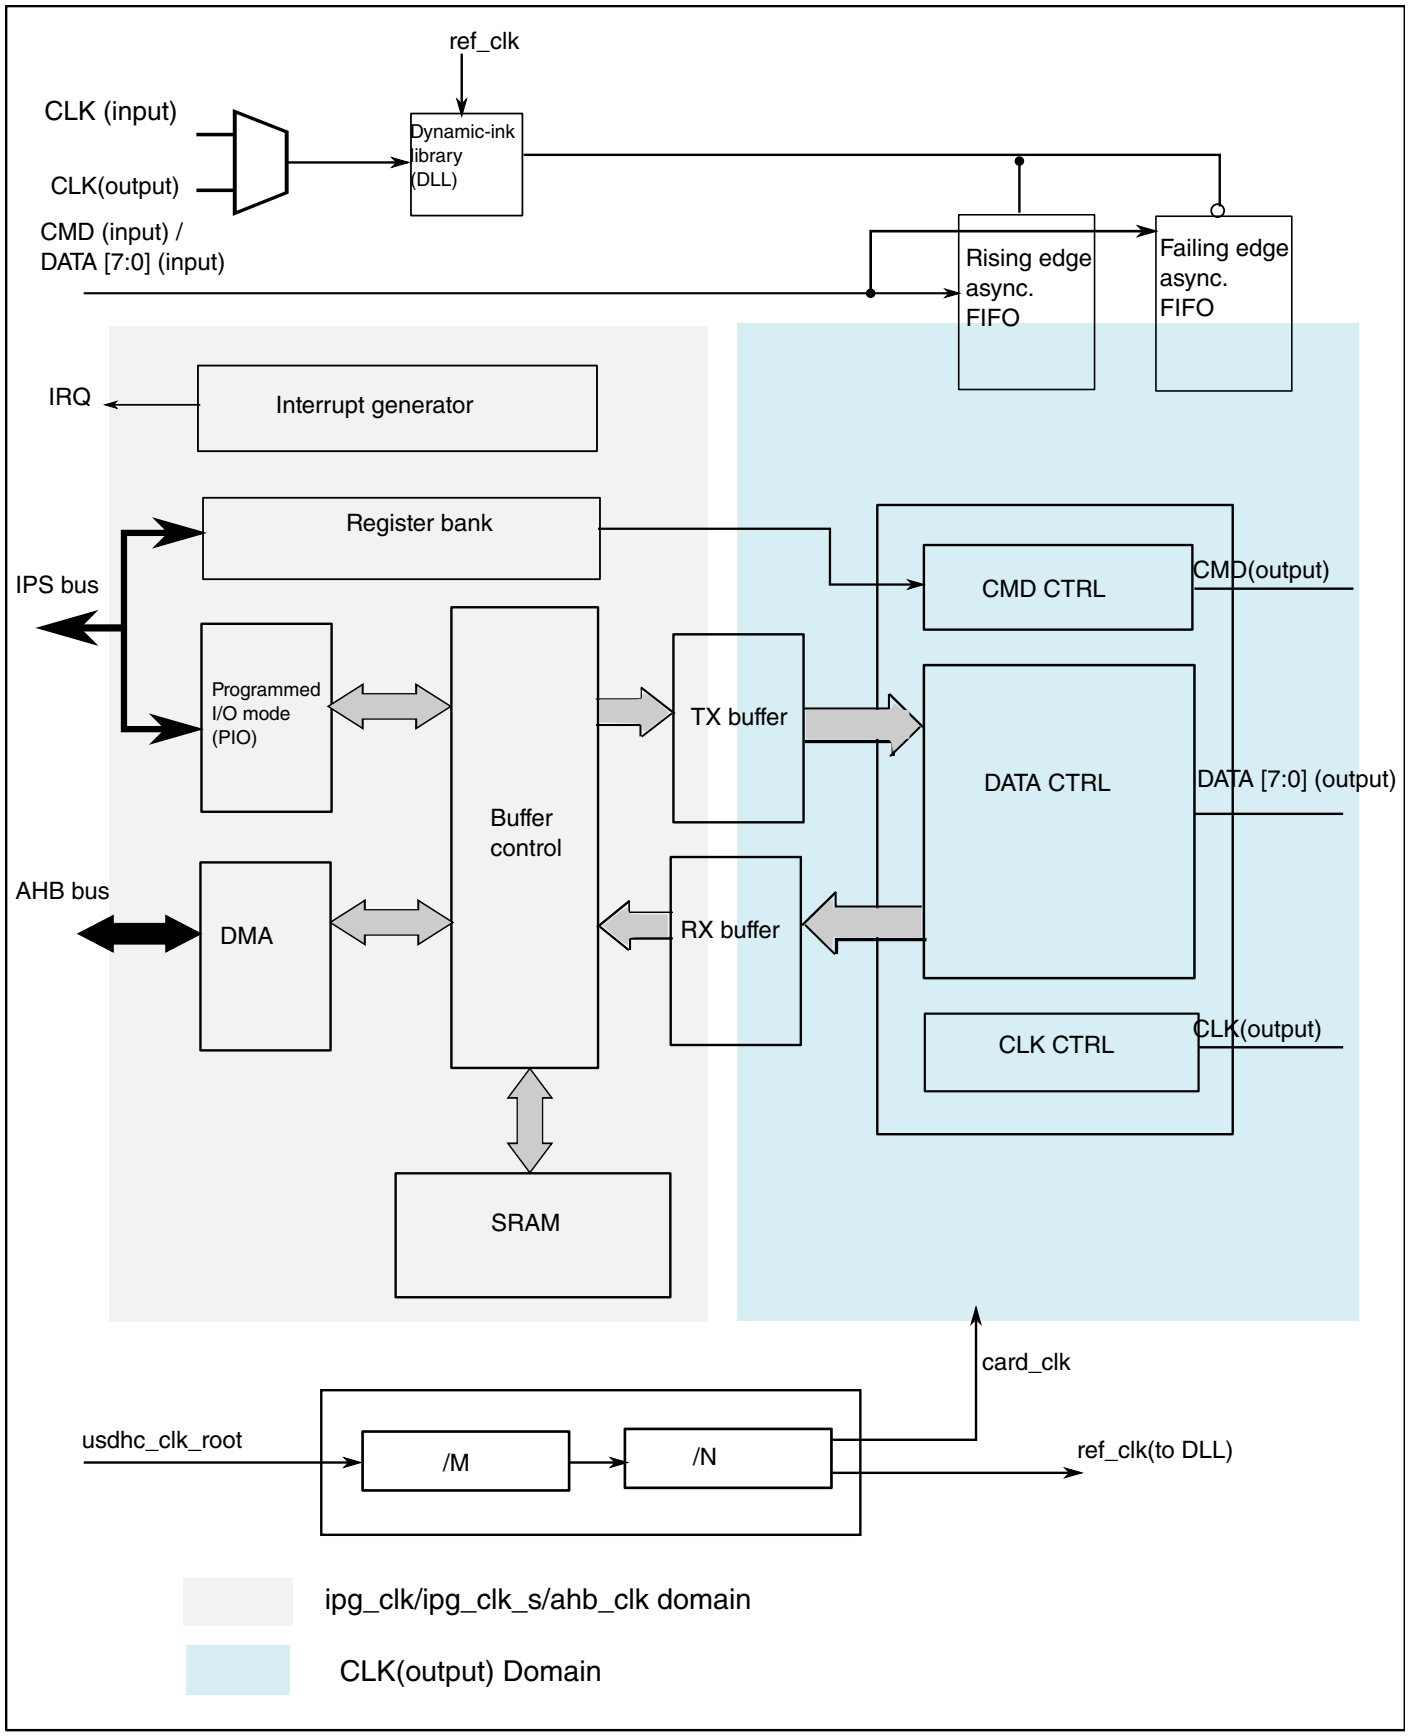

Figure 23-2. uSDHC block diagram

23.2.1 Features

The features of the uSDHC module include the following:

- Conforms to the SD Host Controller Standard Specification version 2.0/3.0
- Compatible with the MMC System Specification version 4.2/4.3/4.4/4.41/4.5/5.0
- Compatible with the SD Memory Card Specification version 3.0 and supports the Extended Capacity SD Memory Card
- Compatible with the SDIO Card Specification version 2.0/3.0
- Designed to work with SD Memory, miniSD Memory, SDIO, miniSDIO, SD Combo, MMC, MMC plus, and MMC RS cards
- Card bus clock frequency up to 208 MHz
- Supports 1-bit/4-bit SD and SDIO modes, and 1-bit/4-bit/8-bit MMC modes
  - Up to 832 Mbps of data transfer for SDIO cards using four parallel data lines in the Single Data Rate (SDR) mode
  - Up to 400 Mbps of data transfer for SDIO card using four parallel data lines in the Dual Data Rate (DDR) mode
  - Up to 832 Mbps of data transfer for SDXC cards using four parallel data lines in the Single Data Rate (SDR) mode
  - Up to 400 Mbps of data transfer for SDXC card using four parallel data lines in the Dual Data Rate (DDR) mode
  - Up to 1600 Mbps of data transfer for MMC cards using eight parallel data lines in the Single Data Rate (SDR) mode
  - Up to 3200 Mbps of data transfer for MMC cards using eight parallel data lines in the Dual Data Rate (DDR) mode
- Supports a single block/multi-block read and write
- Supports block sizes of 1 ~ 4096 bytes
- Supports the write protection switch for write operations
- Supports both synchronous and asynchronous abort
- Supports pause during the data transfer at block gap
- Supports SDIO Read Wait and Suspend Resume operations
- Supports Auto CMD12 for multi-block transfer
- Host can initiate non-data transfer command while data transfer is in progress
- Allows cards to interrupt the host in 1-bit and 4-bit SDIO modes; also supports interrupt period
- Embodies a fully configurable 256x32-bit FIFO for read/write data
- Supports internal DMA capabilities
- Support voltage selection by configuring vendor-specific register bit
- Supports Advanced DMA to perform linked memory access

NOTE

This block can support all the above listed speed mode and maximum data throughput. However, these may be specific to the device. See the corresponding chip-specific information or the device data sheet for accurate details.

23.2.2 Modes and operations

23.2.2.1 Data transfer modes

The uSDHC module can select the following modes for data transfer:

- SD 1-bit
- SD 4-bit
- MMC 1-bit
- MMC 4-bit
- MMC 8-bit
- Identification mode (up to 400 kHz)
- MMC full-speed mode (up to 26 MHz)
- MMC high-speed mode (up to 52 MHz)
- MMC HS200 mode(up to 200 MHz)
- MMC HS400 mode (200 MHz both edges)
- MMC DDR mode (52 MHz both edges)
- SD/SDIO full-speed mode (up to 25 MHz)
- SD/SDIO high-speed mode (up to 50 MHz)
- SD/SDIO UHS-I mode(up to 208 MHz in SDR mode, up to 50 MHz in the DDR mode)

NOTE

This block can support all the above listed speed mode and maximum clock frequency. However, these may be specific to the device. See the corresponding chip-specific information or the device data sheet for accurate details.

23.3 External signals

The following table describes the external signals of uSDHC:

Table 23-3. uSDHC external signals

Signal	Description	Direction
CLK	Clock for MMC/SD/SDIO card	O
CMD	CMD line connect to card	I/O
DATA7	DAT7 line in the 8-bit mode — Not used in other modes	I/O
DATA6	DAT6 line in the 8-bit mode — Not used in other modes	I/O
DATA5	DAT5 line in the 8-bit mode — Not used in other modes	I/O
DATA4	DAT4 line in the 8-bit mode — Not used in other modes	I/O
DATA3	DAT3 line in the 4/8-bit mode or configured as card detection pin. The bit may be configured as card detection pin in the 1-bit mode.	I/O
DATA2	DAT2 line or Read Wait in the 4-bit mode Read Wait in 1-bit mode	I/O
DATA1	DAT1 line in the 4/8-bit mode Also, used to detect interrupt in 1/4-bit mode	I/O
DATA0	DAT0 line in all the modes Also, used to detect busy state	I/O
RESET_B	Card hardware reset signal, active low	O
VSELECT	IO power voltage selection signal	O
STROBE	Input clock for eMMC HS400 mode	I

23.3.1 Signals overview

uSDHC has 15 associated I/O signals.

- The CLK is an internally generated clock used to drive the MMC, SD, and SDIO cards.
- The CMD I/O is used to send commands and receive responses to and from the card. Eight data lines (DAT7~DAT0) are used to perform data transfers between the uSDHC module and the card.
- RST is an output signal used to reset the MMC card.
- VSELECT is an output signal used to change the voltage of the external power supplier.

CD, WP, LCTL, RST, and VSELECT are all optional for system implementation. If uSDHC needs to support a 4-bit data transfer, DAT7~DAT4 can also be optional and tied to high. If the uSDHC does not support the HS400 mode, STROBE can also be optional and tied to low.

23.4 Clocks

The table found here describes the clock sources for uSDHC. For more information on clocking, see the Clocking chapter.

Table 23-4. uSDHC clocks

Clock name	Clock root	Description
hclk	ahb_clk_root	AHB bus clock
ipg_clk	ipg_clk_root	Peripheral clock
ipg_clk_perclk	usdhc_clk_root	Base clock
ipg_clk_s	ipg_clk_root	Peripheral access clock for register accesses

23.5 uSDHC memory map/register definition

23.5.1 uSDHC register descriptions

This section includes the module memory map and detailed descriptions of all registers.

See the table below for the register memory map of uSDHC. All these registers only support 32-bit accesses.

NOTE

The uSDHC registers are 32-bit wide and only support 32-bit access.

23.5.1.1 uSDHC Memory map

uSDHC0 base address: 4037_0000h

R W	DS_ADDR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

23.5.1.2.4 Fields

Field	Function
31-0 DS_ADDR	System address **DMA system address / argument 2** When ACMD23_ARGU2_EN is set to 0, SDMA uses this register as system address and supports only 32-bit addressing mode. Auto CMD23 cannot be used with SDMA. When ACMD23_ARGU2_EN is set to 1, SDMA uses ADMA System Address register (05Fh – 058h) instead of this register to support both 32-bit and 64-bit addressing. This register is used only for Argument2 and SDMA may use Auto CMD23. 1. **SDMA system address** Because the address must be word (4 bytes) aligned, the least 2 bits are reserved, always 0. When uSDHC stops a DMA transfer, this register points out the system address of the next contiguous data position. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operation during transfers may return an invalid value. The host driver initializes this register before starting a DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this register. This register is protected during a data transfer. When data lines are active, write to this register is ignored. The host driver waits until the DLA bit in the Present State register is cleared, before writing to this register. The uSDHC internal DMA does not support a virtual memory system. It only supports continuous physical memory access. And due to AHB burst limitations, if the burst must cross the 1 KB boundary, uSDHC automatically changes SEQ burst type to NSEQ.

Field	Function
	Because this register supports dynamic address reflecting, when TC bit is set, it automatically alters the value of internal address counter, so the software cannot change this register when TC bit is set. Such restriction is also listed in Software restrictions. 2. **Argument 2** This register is used with the Auto CMD23 to set a 32-bit block count value to the argument of the CMD23 while executing Auto CMD23. If Auto CMD23 is used with ADMA, the full 32-bit block count value can be used. If Auto CMD23 is used without ADMA, the available block count value is limited by the Block Count register. 65535 blocks is the maximum value in this case.

23.5.1.3 Block Attributes (BLK_ATT)

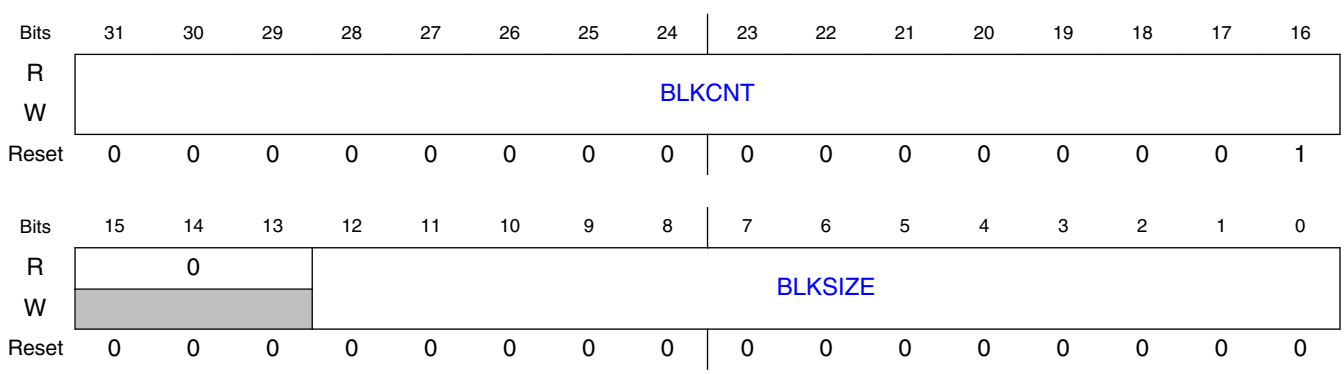
23.5.1.3.1 Offset

Register	Offset
BLK_ATT	4h

23.5.1.3.2 Function

This register is used to configure the number of data blocks and the number of bytes in each block.

23.5.1.3.3 Diagram



23.5.1.3.4 Fields

Field	Function
31-16 BLKCNT	Blocks count for current transfer This register is enabled when the Block Count Enable field in the Transfer Mode register is set to 1 and is valid only for multiple block transfers. For single block transfer, this register always reads as 1. The host driver sets this register to a value between 1 and the maximum block count. The uSDHC module decrements the block count after each block transfer and stops when the count reaches zero. Setting the block count to zero results in no data blocks being transferred. This register should be accessed only when no transaction is executing (that is, after transactions are stopped). During data transfer, read operations on this register may return an invalid value and write operations are ignored. When saving transfer content because of a Suspend command, the number of blocks yet to be transferred can be determined by reading this register. The reading of this register should be applied after transfer is paused by stop at block gap operation and before sending the command marked as suspend. This is because when the Suspend command is sent out, uSDHC treats the current transfer as aborted and change the BLKCNT register back to its original value instead of keeping the dynamical indicator of the remaining block count. When restoring transfer content prior to issuing a Resume command, the host driver restores the previously saved block count. **NOTE:** Although the BLKCNT field is 0 after reset, the read of reset value is 0x1. This is because when MSBSEL field is indicating a single block transfer, the read value of BLKCNT is always 1. 0000000000000000b - Stop count 0000000000000001b - 1 block 0000000000000010b - 2 blocks 1111111111111111b - 65535 blocks
15-13 —	Reserved
12-0 BLKSIZE	Transfer block size This register specifies the block size for block data transfers. Values ranging from 1 byte up to the maximum buffer size can be set. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations are ignored. 0000000000000b - No data transfer 0000000000001b - 1 byte 0000000000010b - 2 bytes 0000000000011b - 3 bytes 0000000000100b - 4 bytes 0000111111111b - 511 bytes 0001000000000b - 512 bytes 0100000000000b - 2048 bytes 1000000000000b - 4096 bytes

23.5.1.4 Command Argument (CMD_ARG)

23.5.1.4.1 Offset

Register	Offset
CMD_ARG	8h

23.5.1.4.2 Function

This register contains the SD/MMC command argument.

23.5.1.4.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	CMDARG															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

23.5.1.4.4 Fields

Field	Function
31-0 CMDARG	Command argument The SD/MMC command argument is specified as bits 39-8 of the command format in the SD or MMC specification. This register is write protected when the Command Inhibit (CMD) field in the Present State register is set.

23.5.1.5 Command Transfer Type (CMD_XFR_TYP)

23.5.1.5.1 Offset

Register	Offset
CMD_XFR_TYP	Ch

23.5.1.5.2 Function

This register is used to control the operation of data transfers. The host driver sets this register before issuing a command followed by a data transfer or before issuing a Resume command. To prevent data loss, uSDHC prevents writing to the bits, which are involved in the data transfer of this register, when data transfer is active. These bits are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

The host driver checks the Command Inhibit DAT field (PRES_STATE[CDIHB]) and the Command Inhibit CMD field (PRES_STATE[CIHB]) in the Present State register before writing to this register. When the CDIHB field in the Present State register is set, any attempt to send a command with data by writing to this register is ignored; when the CIHB field is set, any write to this register is ignored.

On sending commands with data transfer involved, it is mandatory that the block size is non-zero. Block count must also be non-zero, or indicated as a single block transfer (bit 5 of this register is '0' when written), or block count is disabled (bit 1 of this register is '0' when written), otherwise uSDHC ignores the sending of this command and do nothing. For write command, with all above restrictions, it is also mandatory that the write protect switch is not active (PRES_STATE[WPSPL] field of Present State register is '1'); otherwise, uSDHC also ignores the command.

If the commands with data transfer do not receive the response in 64 clock cycles, that is, if response time-out happens, uSDHC treats the external device, does not accept the command, and aborts the data transfer. In this scenario, the driver should issue the command again to retry the transfer. It is also possible that for some reason the card responds to the command but uSDHC does not receive the response, and if it is internal DMA (either simple DMA or ADMA) read operation, the external system memory is over-written by the internal DMA with data sent back from the card.

The table below shows the summary of how register settings determine the type of data transfer.

Table 23-5. Transfer type register setting for various transfer types

Multi/single block select	Block count enable	Block count	Function
0	Do not care	Do not care	Single transfer
1	0	Do not care	Infinite transfer
1	1	Positive number	Multiple transfer
1	1	Zero	No data transfer

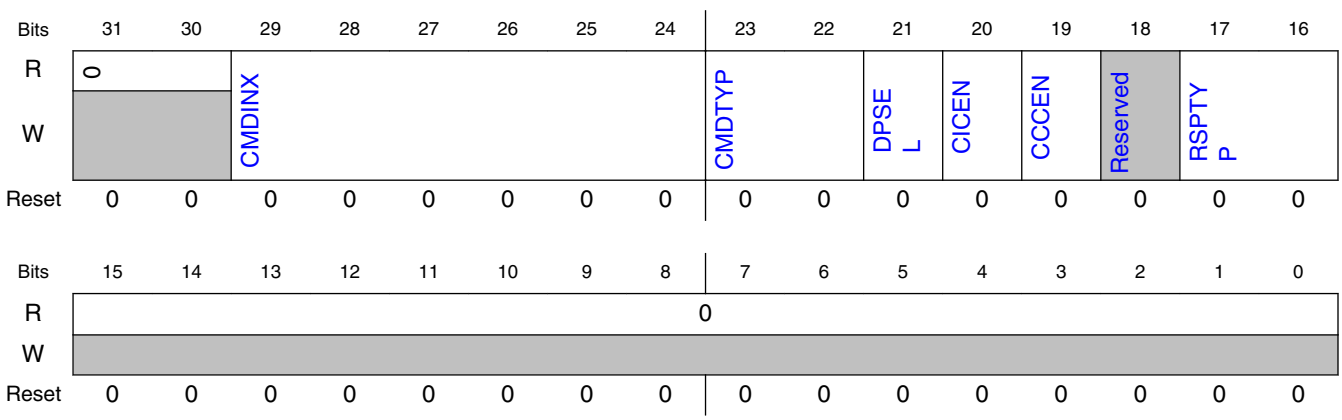
The table below shows the relationship between the Command Index Check Enable and the Command CRC Check Enable, regarding the Response Type bits as well as the name of the response type.

Table 23-6. Relationship between parameters and the name of the response type

Response type	Index check enable	CRC check enable	Name of response type
00	0	0	No response
01	0	1	R2
10	0	0	R3, R4
10	1	1	R1, R5, R6
11	1	1	R1b,R5b

- In the SDIO specification, response type notation for R5b is not defined. R5 includes R5b in the SDIO specification, but R5b is defined in this specification to specify that uSDHC checks the busy status after receiving a response. For example, usually CMD52 is used with R5, but the I/O abort command is used with R5b.
- The CRC fields for R3 and R4 are expected to be all 1 bits. The CRC check is disabled for these response types.

23.5.1.5.3 Diagram



23.5.1.5.4 Fields

Field	Function
31-30 —	Reserved
29-24 CMDINX	Command index These bits are set to the command number that is specified in bits 45-40 of the command-format in the SD Memory Card Physical Layer Specification and SDIO Card Specification.
23-22 CMDTYP	Command type There are three types of special commands: Suspend, Resume, and Abort. These bits are set to 00b for all other commands.

Table continues on the next page...

Field	Function
	• Suspend command: If the Suspend command succeeds, uSDHC assumes that the card bus has been released and that it is possible to issue the next command that uses the DATA line. Because uSDHC does not monitor the content of command response, it does not know if the Suspend command succeeded or not. It is the host driver's responsibility to check the status of the Suspend command and send another command marked as Suspend to inform uSDHC that a Suspend command was successfully issued. See Suspend Resume for more details. After the end bit of command is sent, uSDHC deasserts Read Wait for read transactions and stops checking busy for write transactions. In a 4-bit mode, the interrupt cycle starts. If the Suspend command fails, uSDHC maintains its current state, and the host driver restarts the transfer by setting the Continue Request field in the Protocol Control register. • Resume command: The host driver re-starts the data transfer by restoring the registers saved before sending the Suspend command and then sends the Resume command. The uSDHC module checks for a pending busy state before starting write transfers. • Abort command: If this command is set when executing a read transfer, uSDHC stops reads to the buffer. If this command is set when executing a write transfer, uSDHC stops driving the DATA line. After issuing the Abort command, the host driver should issue a software reset (Abort Transaction). 00b - Normal other commands 01b - Suspend CMD52 for writing bus suspend in CCCR 10b - Resume CMD52 for writing function select in CCCR 11b - Abort CMD12, CMD52 for writing I/O Abort in CCCR
21 DPSEL	Data present select This field is set to 1 to indicate that data is present and is transferred using the DATA line. It is set to 0 for the following: • Commands using only the CMD line (for example, CMD52) • Commands with no data transfer, but using the busy signal on DATA0 line (R1b or R5b (for example, CMD38)) **NOTE:** In resume command, this field is set, and other bits in this register is set the same as when the transfer was initially launched. When the write protect switch is on, (that is, the WPSPL field is active as '0'), any command with a write operation ignored. When this field is set, while the DTDSEL field is 0, writes to the register Transfer Type are ignored. 0b - No data present 1b - Data present
20 CICEN	Command index check enable If this field is set to 1, uSDHC checks the Index field in the response to see if it has the same value as the command index. If it is not, it is reported as a Command Index Error. If this field is set to 0, the Index field is not checked. 0b - Disable command index check 1b - Enables command index check
19 CCCEN	Command CRC check enable If this field is set to 1, uSDHC checks the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this field is set to 0, the CRC field is not checked. The number of bits checked by the CRC field value changes according to the length of the response. See RSPTYP[1:0] and Command Transfer Type (CMD_XFR_TYP). 0b - Disables command CRC check 1b - Enables command CRC check
18 —	Reserved
17-16 RSPTYP	Response type select 00b - No response

Table continues on the next page...

Field	Function
	01b - Response length 136 10b - Response length 48 11b - Response length 48, check busy after response
15-0 —	Reserved

23.5.1.6 Command Response0 (CMD_RSP0)

23.5.1.6.1 Offset

Register	Offset
CMD_RSP0	10h

23.5.1.6.2 Function

This register is used to store part 0 of the response bits from the card.

23.5.1.8.4 Fields

Field	Function
31-0 CMDRSP2	Command response 2 See Command Response3 (CMD_RSP3) for the mapping of command responses from the SD bus to this register for each response type.

23.5.1.9 Command Response3 (CMD_RSP3)

23.5.1.9.1 Offset

Register	Offset
CMD_RSP3	1Ch

23.5.1.9.2 Function

This register is used to store part 3 of the response bits from the card.

The table below describes the mapping of command responses from the SD bus to Command Response registers for each response type. In this table, R[ ] refers to a bit range within the response data as transmitted on the SD bus.

Table 23-7. Response bit definition for each response type

Response type	Meaning of response	Response field	Response register
R1,R1b (normal response)	Card status	R[39:8]	CMDRSP0
R1b (auto CMD12 response)	Card status for auto CMD12	R[39:8]	CMDRSP3
R2 (CID, CSD register)	CID/CSD register [127:8]	R[127:8]	{CMDRSP3[23:0], CMDRSP2, CMDRSP1, CMDRSP0}
R3 (OCR register)	OCR register for memory	R[39:8]	CMDRSP0
R4 (OCR register)	OCR register for I/O etc.	R[39:8]	CMDRSP0
R5, R5b	SDIO response	R[39:8]	CMDRSP0
R6 (publish RCA)	New published RCA[31:16] and card status[15:0]	R[39:9]	CMDRSP0

This table shows that most responses with a length of 48 (R[47:0]) have 32-bits of the response data (R[39:8]) stored in the CMDRSP0 register. Responses of type R1b (Auto CMD12 responses) have response data bits (R[39:8]) stored in the CMDRSP3 register. Responses with length 136 (R[135:0]) have 120-bits of the response data (R[127:8]) stored in the CMDRSP0, 1, 2, and 3 registers.

To be able to read the response status efficiently, uSDHC only stores part of the response data in the Command Response registers. This enables the host driver to efficiently read 32-bits of response data in one read cycle on a 32-bit bus system. Parts of the response, the Index field and the CRC, are checked by uSDHC (as specified by the Command Index Check Enable and the Command CRC Check Enable bits in the Transfer Type register) and generate an error interrupt if any error is detected. The bit range for the CRC check depends on the response length. If the response length is 48, uSDHC checks R[47:1], and if the response length is 136 the uSDHC checks R[119:1].

Because uSDHC may have a multiple block data transfer executing concurrently with a CMD_wo_DAT command, uSDHC stores the Auto CMD12 response in the CMDRSP3 register. The CMD_wo_DAT response is stored in CMDRSP0. This allows uSDHC to avoid overwriting the Auto CMD12 response with the CMD_wo_DAT and vice versa. When uSDHC modifies part of the Command Response registers, as shown in the table above, it preserves the unmodified bits.

23.5.1.9.3 Diagram

23.5.1.9.4 Fields

Field	Function
31-0 CMDRSP3	Command response 3 See Command Response3 (CMD_RSP3) for the mapping of command responses from the SD bus to this register for each response type.

23.5.1.10 Data Buffer Access Port (DATA_BUFF_ACC_PORT)

23.5.1.10.1 Offset

Register	Offset
DATA_BUFF_ACC_PORT	20h

23.5.1.10.2 Function

This is a 32-bit data port register used to access the internal buffer.

23.5.1.10.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	DATCONT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DATCONT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

23.5.1.10.4 Fields

Field	Function
31-0 DATCONT	Data content The Buffer Data Port register is for 32-bit data access by the Arm platform. When the internal DMA is enabled, any write to this register is ignored, and any read from this register always yields 0s.

23.5.1.11 Present State (PRES_STATE)

23.5.1.11.1 Offset

Register	Offset
PRES_STATE	24h

23.5.1.11.2 Function

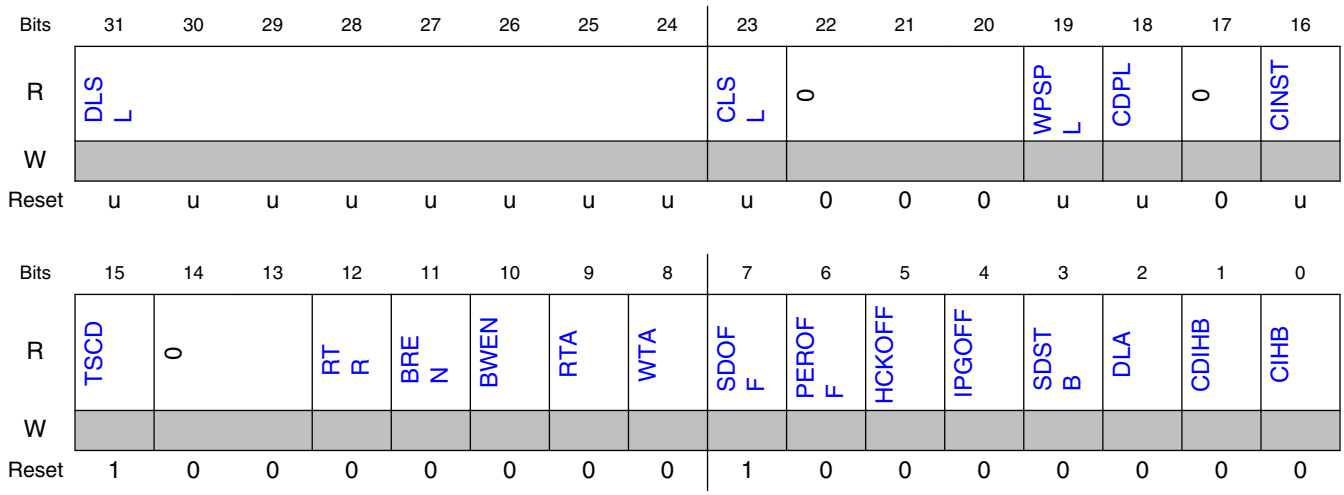
The host driver can get status of uSDHC from this 32-bit read only register.

The host driver can issue CMD0, CMD12, CMD13 (for memory) and CMD52 (for SDIO) when the DATA lines are busy during a data transfer. These commands can be issued when Command Inhibit (CMD) is set to zero. Other commands are issued when Command Inhibit (DATA) is set to zero. Possible changes to the SD Physical Specification may add other commands to this list in the future.

NOTE

The reset value of Present State register depends on board connectivity.

23.5.1.11.3 Diagram



23.5.1.11.4 Fields

Field	Function
31-24 DLSL	DATA[7:0] line signal level This status is used to check the DATA line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from DATA0. The reset value is affected by the external pull-up / pull-down resistors. By default, the read value of this field field after reset is 8'b11110111, when DATA3 is pulled down and the other lines are pulled up. 00000000b - Data 0 line signal level 00000001b - Data 1 line signal level 00000010b - Data 2 line signal level 00000011b - Data 3 line signal level 00000100b - Data 4 line signal level 00000101b - Data 5 line signal level 00000110b - Data 6 line signal level 00000111b - Data 7 line signal level
23 CLSL	CMD line signal level This status is used to check the CMD line level to recover from errors, and for debugging. The reset value is affected by the external pull-up / pull-down resistor, by default, the read value of this field after reset is 1'b1, when the command line is pulled up.
22-20 —	Reserved
19 WPSPL	Write protect switch pin level The Write Protect switch is supported for memory and combo cards. This field reflects the inverted value of the WP pin of the card socket. A software reset does not affect this field. The reset value is affected by the external write protect switch. If the WP pin is not used, it should be tied low, so that the reset value of this field is high and write is enabled. 0b - Write protected (WP = 1) 1b - Write enabled (WP = 0)

Table continues on the next page...

Field	Function
18 CDPL	Card detect pin level This field reflects the inverse value of the CD_B pin for the card socket. Debouncing is not performed on this field. This field may be valid, but is not guaranteed, because of propagation delay. Use of this field is limited to testing because it must be debounced by software. A software reset does not affect this field. A write to the Force Event Register does not affect this field. The reset value is affected by the external card detection pin. This field shows the value on the CD_B pin (that is, when a card is inserted in the socket, it is 0 on the CD_B input, and consequently, the CDPL reads 1. 0b - No card present (CD_B = 1) 1b - Card present (CD_B = 0)
17 —	Reserved
16 CINST	Card inserted This field indicates whether a card has been inserted. The uSDHC module debounces this signal so that the host driver does not need to wait for it to stabilize. Changing from a 0 to 1 generates a Card Insertion interrupt in the Interrupt Status register. Changing from a 1 to 0 generates a Card Removal interrupt in the Interrupt Status register. A write to the Force Event Register does not affect this field. The Software Reset For All in the System Control register does not affect this field. A software reset does not affect this field. 0b - Power on reset or no card 1b - Card inserted
15 TSCD	Tape select change done This field indicates the delay setting is effective after write CLK_TUNE_CTRL_STATUS register. 0b - Delay cell select change is not finished. 1b - Delay cell select change is finished.
14-13 —	Reserved
12 RTR	Re-Tuning Request (only for SD3.0 SDR104 mode and EMMC HS200 mode) Host controller may request host driver to execute re-tuning sequence by setting this field when the data window is shifted by temperature drift and a tuned sampling point does not have a good margin to receive correct data. This field is cleared when a command is issued with setting Execute Tuning field in MIXER_CTRL register. Changing of this field from 0 to 1 generates Re-Tuning Event. See Interrupt status registers for more detail. This field isn't set to 1 if Sampling Clock Select in the MIXER_CTRL register is set to 0 (using fixed sampling clock). 0b - Fixed or well tuned sampling clock 1b - Sampling clock needs re-tuning
11 BREN	Buffer read enable This status field is used for non-DMA read transfers. The uSDHC module implements an internal buffer to transfer data efficiently. This read only flag indicates that valid data exists in the host side buffer. If this field is high, valid data greater than the watermark level exist in the buffer. A change of this field from 1 to 0 occurs when some reads from the buffer (read DATPORT (Base + 0x20)) are made and the buffer hasn't valid data greater than the watermark level. A change of this field from 0 to1 occurs when there is enough valid data ready in the buffer and the Buffer Read Ready interrupt has been generated and enabled. 0b - Read disable

Table continues on the next page...

Field	Function
	1b - Read enable
10 BWEN	Buffer write enable This status field is used for non-DMA write transfers. The uSDHC module implements an internal buffer to transfer data efficiently. This read only flag indicates if space is available for write data. If this field is 1, valid data greater than the watermark level can be written to the buffer. A change of this field from 1 to 0 occurs when some writes to the buffer (write DATPORT(Base + 0x20)) are made and the buffer hasn't valid space greater than the watermark level. A change of this field from 0 to 1 occurs when the buffer can hold valid data greater than the write watermark level and the Buffer Write Ready interrupt is generated and enabled. 0b - Write disable 1b - Write enable
9 RTA	Read transfer active This status field is used for detecting completion of a read transfer. This field is set for either of the following conditions: • After the end field of the read command • When writing a 1 to the Continue Request field in the Protocol Control register to restart a read transfer A transfer complete interrupt is generated when this field changes to 0. This field is cleared for either of the following conditions: • When the last data block as specified by block length is transferred to the System, that is, all data are read away from uSDHC internal buffer. • When all valid data blocks have been transferred from uSDHC internal buffer to the System and no current block transfers are being sent because of the Stop At Block Gap Request being set to 1. 0b - No valid data 1b - Transferring data
8 WTA	Write transfer active This status field indicates a write transfer is active. If this field is 0, it means no valid write data exists in uSDHC. This field is set in either of the following cases: • After the end field of the write command • When writing 1 to the Continue Request field in the Protocol Control register to restart a write transfer This field is cleared in either of the following cases: • After getting the CRC status of the last data block as specified by the transfer count (Single and Multiple) • After getting the CRC status of any block where data transmission is about to be stopped by a Stop At Block Gap Request During a write transaction, a Block Gap Event interrupt is generated when this field is changed to 0, as result of the Stop At Block Gap Request being set. This status is useful for the host driver in determining when to issue commands during Write Busy state. 0b - No valid data 1b - Transferring data
7 SDOFF	SD clock gated off internally This status field indicates that the SD clock is internally gated off, because of buffer over / under-run or read pause without read wait assertion, or the driver set FRC_SDCLK_ON field is 0 to stop the SD clock in idle status. This field is for the host driver to debug data transaction on the SD bus.

Table continues on the next page...

Field	Function
	0b - SD clock is active. 1b - SD clock is gated off.
6 PEROFF	IPG_PERCLK gated off internally This status field indicates that the IPG_PERCLK is internally gated off. This field is for the host driver to debug transaction on the SD bus. When IPG_CLK_SOFT_EN is cleared, IPG_PERCLK is gated off, otherwise IPG_PERCLK is always active. 0b - IPG_PERCLK is active. 1b - IPG_PERCLK is gated off.
5 HCKOFF	HCLK gated off internally This status field indicates that the HCLK is internally gated off. This field is for the host driver to debug during a data transfer. 0b - HCLK is active. 1b - HCLK is gated off.
4 IPGOFF	Peripheral clock gated off internally This status field indicates that the peripheral clock is internally gated off. This field is for the host driver to debug. 0b - Peripheral clock is active. 1b - Peripheral clock is gated off.
3 SDSTB	SD clock stable This status field indicates that the internal card clock is stable. This field is for the host driver to poll clock status when changing the clock frequency. It is recommended to clear FRC_SDCLK_ON field in System Control register to remove glitches on the card clock when the frequency is changing. Before changing clock divisor value (SDCLKFS or DVS), host driver should make sure the SDSTB field is high. 0b - Clock is changing frequency and not stable. 1b - Clock is stable.
2 DLA	Data line active This status field indicates whether one of the DATA lines on the SD bus is in use. In the case of read transactions: This status indicates if a read transfer is executing on the SD bus. Changes in this value from 1 to 0, between data blocks, generates a Block Gap Event interrupt in the Interrupt Status register. This field is set in either of the following cases: • After the end field of the read command • When writing a 1 to the Continue Request field in the Protocol Control register to restart a read transfer This field is cleared in either of the following cases: • When the end field of the last data block is sent from the SD bus to uSDHC. • When the Read Wait state is stopped by a Suspend command and the DATA2 line is released. The uSDHC module waits at the next block gap by driving Read Wait at the start of the interrupt cycle. If the Read Wait signal is already driven (data buffer cannot receive data), uSDHC can wait for a current block gap by continuing to drive the Read Wait signal. It is necessary to support Read Wait to use the suspend / resume function. This field remains 1 during Read Wait. In the case of write transactions: This status indicates that a write transfer is executing on the SD bus. Changes in this value from 1 to 0 generate a Transfer Complete interrupt in the Interrupt Status register.

Table continues on the next page...

Field	Function
	This field is set in either of the following cases: • After the end field of the write command • When writing to 1 to the Continue Request field in the Protocol Control register to continue a write transfer This field is cleared in either of the following cases: • When the SD card releases Write Busy of the last data block, uSDHC also detects if the output is not busy. If the SD card does not drive the busy signal after the CRC status is received, uSDHC assumes the card drive "Not Busy". • When the SD card releases write busy, prior to waiting for write transfer, and because of a Stop At Block Gap Request. In the case of command with busy pending: This status indicates that a busy state follows the command and the data line is in use. This field is cleared when the DATA0 line is released. 0b - DATA line inactive 1b - DATA line active
1 CDIHB	Command inhibit (DATA) This status field is generated if either the DAT Line Active or the Read Transfer Active is set to 1. If this field is 0, it indicates that uSDHC can issue the next SD / MMC Command. Commands with a busy signal belong to Command Inhibit (DATA) (for example. R1b, R5b type). Changing from 1 to 0 generates a Transfer Complete interrupt in the Interrupt Status register. **NOTE:** The SD host driver can save registers for a suspend transaction after this field has changed from 1 to 0. 0b - Can issue command that uses the DATA line 1b - Cannot issue command that uses the DATA line
0 CIHB	Command inhibit (CMD) If this status bit is 0, it indicates that the CMD line is not in use and uSDHC can issue a SD / MMC command using the CMD line. This field is set also immediately after the Transfer Type register is written. This field is cleared when the command response is received. Even if the Command Inhibit (DATA) is set to 1, commands using only the CMD line can be issued if this field is 0. Changing from 1 to 0 generates a Command Complete interrupt in the Interrupt Status register. If uSDHC cannot issue the command because of a command conflict error (see Command CRC Error) or because of a Command Not Issued By Auto CMD12 Error, this field remains 1 and the Command Complete is not set. The Status of issuing an auto CMD12 does not show on this field. 0b - Can issue command using only CMD line 1b - Cannot issue command

23.5.1.12 Protocol Control (PROT_CTRL)

23.5.1.12.1 Offset

Register	Offset
PROT_CTRL	28h

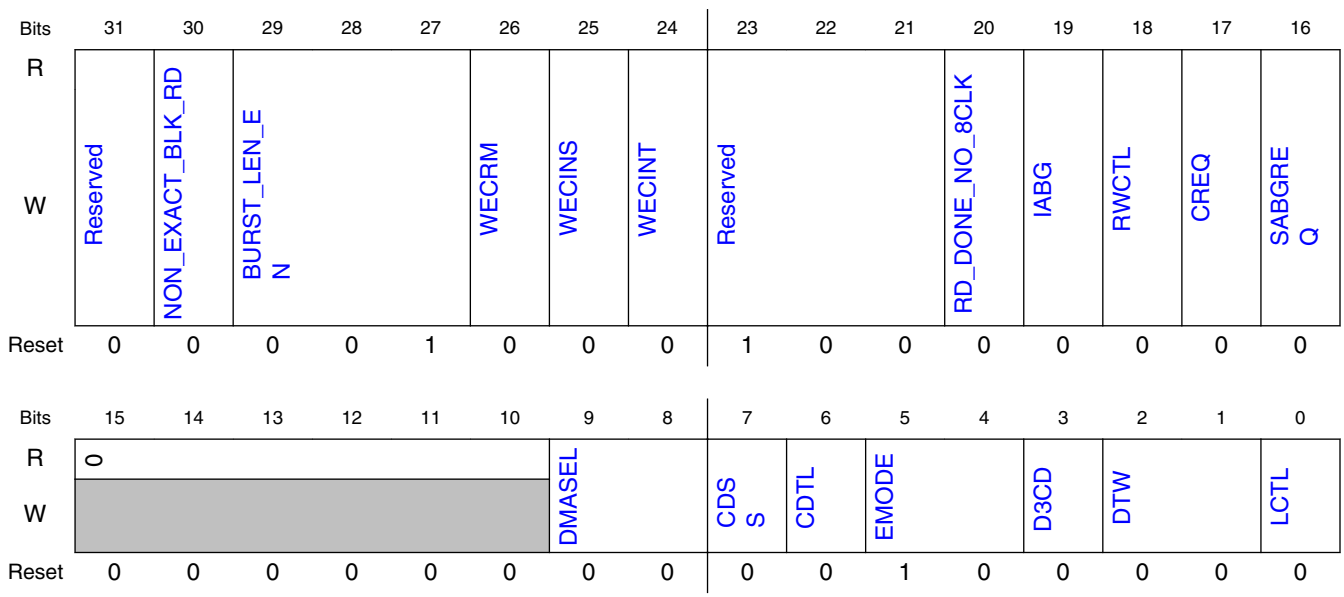
23.5.1.12.2 Function

There are three cases to restart the transfer after stop at the block gap. Which case is appropriate depends on whether uSDHC issues a Suspend command or the SD card accepts the Suspend command.

- If the host driver does not issue a Suspend command, the Continue request is used to restart the transfer.
- If the host driver issues a Suspend command and the SD card accepts it, a Resume command is used to restart the transfer.
- If the host driver issues a Suspend command and the SD card does not accept it, the Continue request is used to restart the transfer.

Any time stop at block gap request stops the data transfer, the host driver waits for a Transfer Complete (in the Interrupt Status register), before attempting to restart the transfer. When restarting the data transfer by Continue Request, the host driver clears the Stop At Block Gap Request before or simultaneously.

23.5.1.12.3 Diagram



23.5.1.12.4 Fields

Field	Function
31	Reserved
—	Always write as 0

Table continues on the next page...

Field	Function
30 NON_EXACT_BLK_RD	Non-exact block read Current block read is non-exact block read. It is only used for SDIO. 0b - The block read is exact block read. Host driver does not need to issue abort command to terminate this multi-block read. 1b - The block read is non-exact block read. Host driver needs to issue abort command to terminate this multi-block read.
29-27 BURST_LEN_EN	BURST length enable for INCR, INCR4 / INCR8 / INCR16, INCR4-WRAP / INCR8-WRAP / INCR16-WRAP This is used to enable / disable the burst length for the external AHB2AXI bridge. It is useful especially for INCR transfer because without burst length indicator, the AHB2AXI bridge does not know the burst length in advance. Without burst length indicator, AHB INCR transfers can only be converted to SINGLEs on the AXI side. 1xxb - Burst length is enabled for INCR4-WRAP / INCR8-WRAP / INCR16-WRAP. x1xb - Burst length is enabled for INCR4 / INCR8 / INCR16. xx1b - Burst length is enabled for INCR.
26 WECRM	Wakeup event enable on SD card removal This field enables a wakeup event, via a card removal, in the Interrupt Status register. FN_WUS (Wake Up Support) in CIS does not affect this field. When this field is set, the Card Removal Status and uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active to assert the Card Removal Status and uSDHC interrupt. 0b - Disables wakeup event enable on SD card removal 1b - Enables wakeup event enable on SD card removal
25 WECINS	Wakeup event enable on SD card insertion This field enables a wakeup event, via a card insertion, in the Interrupt Status register. FN_WUS (Wake Up Support) in CIS does not affect this field. When this field is set, the Card Insertion Status and uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active to assert the Card Insertion Status and uSDHC interrupt. 0b - Disable wakeup event enable on SD card insertion 1b - Enable wakeup event enable on SD card insertion
24 WECINT	Wakeup event enable on card interrupt This field enables a wakeup event, via a card interrupt, in the Interrupt Status register. This field can be set to 1 if FN_WUS (Wake Up Support) in CIS is set to 1. When this field is set, the Card Interrupt Status and uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active to assert the Card Interrupt Status and uSDHC interrupt. 0b - Disables wakeup event enable on card interrupt 1b - Enables wakeup event enable on card interrupt
23-21 —	Reserved Always write as 3'b100
20 RD_DONE_NO_8CLK	Read performed number 8 clock According to the SD/MMC spec, for read data transaction, 8 clocks are needed after the end field of the last data block. So, by default(RD_DONE_NO_8CLK=0), 8 clocks are active after the end field of the last read data transaction. However, these 8 clocks should not be active if user wants to use stop at block gap (include the auto stop at block gap in boot mode) feature for read and the RWCTL field (bit18) is not enabled. In this case, software should set RD_DONE_NO_8CLK to avoid these 8 clocks. Otherwise, the device might send extra data to uSDHC while uSDHC ignores these data. In a summary, this field should be set only if the use case needs to use stop at block gap feature while the device can't support the read wait feature.

Table continues on the next page...

Field	Function
19 IABG	Interrupt at block gap This field is valid only in 4-bit mode, of the SDIO card, and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If the SDIO card cannot signal an interrupt during a multiple block transfer, this field should be set to 0 to avoid an inadvertent interrupt. When the host driver detects an SDIO card insertion, it sets this field according to the CCCR of the card. 0b - Disables interrupt at block gap 1b - Enables interrupt at block gap
18 RWCTL	Read wait control The read wait function is optional for SDIO cards. If the card supports read wait, set this field to enable use of the read wait protocol to stop read data using the DATA2 line. Otherwise, uSDHC has to stop the SD clock to hold read data, which restricts commands generation. When the host driver detects an SDIO card insertion, it sets this field according to the CCCR of the card. If the card does not support read wait, this field should never be set to 1; otherwise, DATA line conflicts might occur. If this field is set to 0, stop at block gap during read operation is also supported, but uSDHC stops the SD clock to pause reading operation. 0b - Disables read wait control and stop SD clock at block gap when SABGREQ field is set 1b - Enables read wait control and assert read wait without stopping SD clock at block gap when SABGREQ field is set
17 CREQ	Continue request This field is used to restart a transaction which was stopped using the stop at block gap request. When a suspend operation is not accepted by the card, it is also by setting this field to restart the paused transfer. To cancel stop at the block gap, set stop at block gap request to 0 and set this field to 1 to restart the transfer. The uSDHC module automatically clears this field, therefore it is not necessary for the host driver to set this field to 0. If both stop at block gap request and this field are 1, the continue request is ignored. 0b - No effect 1b - Restart
16 SABGREQ	Stop at block gap request This field is used to stop executing a transaction at the next block gap for both DMA and non-DMA transfers. Until the transfer complete is set to 1, indicating a transfer completion, the host driver leaves this field set to 1. Clearing both the stop at block gap request and continue request does not cause the transaction to restart. Read Wait is used to stop the read transaction at the block gap. The uSDHC module supports the stop at block gap request for write transfers, but for read transfers it requires that the SDIO card support read wait. Therefore, the host driver does not set this field during read transfers unless the SDIO card supports Read Wait and has set the read wait control to 1; otherwise, uSDHC stops the SD bus clock to pause the read operation during block gap. In the case of write transfers in which the host driver writes data to the Data Port register, the host driver sets this field after all block data is written. If this field is set to 1, the host driver does not write data to the Data Port register after a block is sent. Once this field is set, the host driver does not clear this field before the Transfer Complete field in Interrupt Status register is set, otherwise uSDHC's behavior is undefined. This field effects read transfer active, write transfer active, DATA Line Active and Command Inhibit (DATA) in the Present State register. 0b - Transfer 1b - Stop
15-10 —	Reserved
9-8 DMASEL	DMA select This field is valid while DMA (SDMA or ADMA) is enabled and selects the DMA operation.

Table continues on the next page...

Field	Function
	00b - No DMA or simple DMA is selected. 01b - ADMA1 is selected. 10b - ADMA2 is selected. 11b - Reserved
7 CDSS	Card detect signal selection This field selects the source for the card detection. 0b - Card detection level is selected (for normal purpose). 1b - Card detection test level is selected (for test purpose).
6 CDTL	Card detect test level This bit is enabled while the card detection signal selection is set to 1 and it indicates card insertion. 0b - Card detect test level is 0, no card inserted 1b - Card detect test level is 1, card inserted
5-4 EMODE	Endian mode The uSDHC module supports all three endian modes in data transfer. See Data buffer for more details. 00b - Big endian mode 01b - Half word big endian mode 10b - Little endian mode 11b - Reserved
3 D3CD	DATA3 as card detection pin If this field is set, DATA3 should be pulled down to act as a card detection pin. Be cautious when using this feature, because DATA3 is also a chip-select for the SPI mode. A pull-down on this pin and CMD0 might set the card into the SPI mode, which uSDHC does not support. 0b - DATA3 does not monitor card insertion 1b - DATA3 as card detection pin
2-1 DTW	Data transfer width This field selects the data width of the SD bus for a data transfer. The host driver sets it to match the data width of the card. Possible data transfer width is 1-bit, 4-bits or 8-bits. 00b - 1-bit mode 01b - 4-bit mode 10b - 8-bit mode 11b - Reserved
0 LCTL	LED control This field, fully controlled by the host driver, is used to caution the user not to remove the card while the card is being accessed. If the software is going to issue multiple SD commands, this field can be set during all these transactions. It is not necessary to change for each transaction. When the software issues multiple SD commands, setting the field once before the first command is sufficient: it is not necessary to reset the bit between commands. 0b - LED off 1b - LED on

23.5.1.13 System Control (SYS_CTRL)

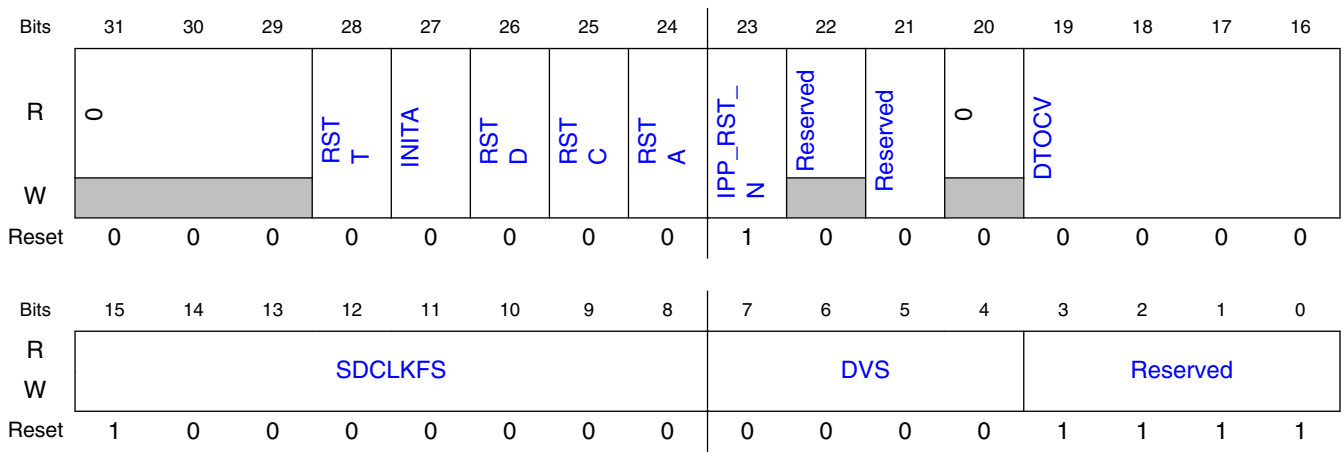
23.5.1.13.1 Offset

Register	Offset
SYS_CTRL	2Ch

23.5.1.13.2 Function

This register provides control of the system. See detail in the field description.

23.5.1.13.3 Diagram



23.5.1.13.4 Fields

Field	Function
31-29 —	Reserved
28 RSTT	Reset tuning When set this field to 1, it resets tuning circuit. After tuning circuits are reset, bit value is 0. Clearing execute_tuning field in AUTOCMD12_ERR_STATUS also sets this field to 1 to reset tuning circuit
27 INITA	Initialization active When this field is set, 80 SD-clocks are sent to the card. After the 80 clocks are sent, this field is self cleared. This field is very useful during the card power-up period when 74 SD-clocks are needed and the clock auto gating feature is enabled. Writing 1 to this bit when this field is already 1 has no effect. Writing 0 to this field at any time has no effect. When either of the CIHB and CDIHB fields in the Present State register are set, writing 1 to this field is ignored (that is, when command line or data lines are active, write to this field is not allowed). On the other-hand, when this field is set, that is, during initialization active period, it is allowed to issue command, and the command bit stream appears on the CMD pad after all 80 clock cycles are done. So, when this command ends, the driver can make sure the 80 clock cycles are sent out. This is very useful when the driver needs to send 80 cycles to the card and does not want to wait till this field is self cleared.
26	Software reset for data line

Table continues on the next page...

Field	Function
RSTD	Only part of the data circuit is reset. DMA circuit is also reset. After this field is set, the software waits for self-clear. The following registers and bits are cleared by this field: • Data Port register • Buffer is cleared and initialized • Present State register • Buffer read enable • Buffer write enable • Read transfer active • Write transfer active • DATA line active • Command Inhibit (DATA) Protocol Control register • Continue request • Stop At Block Gap Request Interrupt Status register • Buffer read ready • Buffer write ready • DMA interrupt • Block gap event • Transfer complete **NOTE:** When reset, the software must make sure there is no incomplete data transferring. If there is data transfer going on, the software needs to wait TC or DC INT_STATUS register is set. 0b - No reset 1b - Reset
25 RSTC	Software reset for CMD line Only part of the command circuit is reset. After this field is set, the software waits for self-clear. The following registers and bits are cleared by this field: • Present State Register Command Inhibit (CMD) • Interrupt Status register Command Complete 0b - No reset 1b - Reset
24 RSTA	Software reset for all This reset effects the entire host controller except for the card detection circuit. Register bits of type ROC, RW, RW1C, RWAC are cleared. During its initialization, the host driver is set this field to 1 to reset uSDHC. The uSDHC module resets this field to 0 when the capabilities registers are valid and the host driver can read them. Additional use of Software Reset For All does not affect the value of the capabilities registers. After this field is set, it is recommended that the host driver reset the external card and re-initialize it. After this field is set, the software should wait for self-clear. In tuning process, after every CMD19 is finished, this field is set to retest uSDHC. **NOTE:** When reset, the software must make sure there is no incomplete data transferring. If there is data transfer going on, the software needs to wait TC or DC INT_STATUS register is set. 0b - No reset 1b - Reset
23 IPP_RST_N	Hardware reset This register's value is output to card through pad directly to hardware reset pin of the card if the card supports this feature.
22 —	Reserved
21	Reserved

Table continues on the next page...

Field	Function
—	
20 —	Reserved
19-16 DTOCV	Data timeout counter value This value determines the interval by which DAT line timeouts are detected. See the Data Timeout Error field in the Interrupt Status register for information on factors that dictate time-out generation. Time-out clock frequency is generated by dividing the base clock SDCLK value by this value. The host driver can clear the Data Timeout Error Status Enable (in the Interrupt Status Enable register) to prevent inadvertent time-out events. 0000b - SDCLK x 2^{14} 0001b - SDCLK x 2^{15} 0010b - SDCLK x 2^{16} 0011b - SDCLK x 2^{17} 0100b - SDCLK x 2^{18} 0101b - SDCLK x 2^{19} 0110b - SDCLK x 2^{20} 0111b - SDCLK x 2^{21} 1000b - SDCLK x 2^{22} 1001b - SDCLK x 2^{23} 1010b - SDCLK x 2^{24} 1011b - SDCLK x 2^{25} 1100b - SDCLK x 2^{26} 1101b - SDCLK x 2^{27} 1110b - SDCLK x 2^{28} 1111b - SDCLK x 2^{29}
15-8 SDCLKFS	SDCLK frequency select This register is used to select the frequency of the SDCLK pin. The frequency is not programmed directly, rather this register holds the prescaler (this register) and divisor (next register) of the Base Clock Frequency register. In Single Data Rate mode (DDR_EN field of MIXERCTRL is '0') Only the following settings are allowed: 80h) Base clock divided by 256 40h) Base clock divided by 128 20h) Base clock divided by 64 10h) Base clock divided by 32 08h) Base clock divided by 16 04h) Base clock divided by 8 02h) Base clock divided by 4 01h) Base clock divided by 2 00h) Base clock divided by 1 While in Dual Data Rate mode (DDR_EN field of MIXERCTRL is '1') Only the following settings are allowed: 80h) Base clock divided by 512 40h) Base clock divided by 256 20h) Base clock divided by 128

Table continues on the next page...

Field	Function
	10h) Base clock divided by 64 08h) Base clock divided by 32 04h) Base clock divided by 16 02h) Base clock divided by 8 01h) Base clock divided by 4 00h) Base clock divided by 2 When the software changes the DDR_EN field, SDCLKFS might need to be changed also. In Single Data Rate mode, setting 00h bypasses the frequency prescaler of the SD clock. Multiple bits must not be set, or the behavior of this prescaler is undefined. The two default divider values can be calculated by the frequency of ipg_perclk and the following Divisor bits. The frequency of SDCLK is set by the following formula: Clock Frequency = (Base Clock) / (prescaler x divisor) For example, in Single Data Rate mode, if the Base Clock Frequency is 96 MHz, and the target frequency is 25 MHz, then choosing the prescaler value of 01h and divisor value of 1h yields 24 MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400 kHz, the prescaler value of 08h and divisor value of eh yields the exact clock value of 400 kHz. The reset value of this field is 80h, so if the input Base Clock (ipg_perclk) is about 96 MHz, the default SD clock after reset is 375 kHz. According to the SD Physical Specification Version 1.1 and the SDIO Card Specification Version 1.2, the maximum SD clock frequency is 50 MHz and is never exceed this limit. Before changing clock divisor value (SDCLKFS or DVS), host driver should make sure the SDSTB field is high. If setting SDCLKFS and DVS can generate the same clock frequency,(for example, in SDR mode, SDCLKFS = 01h is same as DVS = 01h.) SDCLKFS is highly recommended.
7-4 DVS	Divisor This register is used to provide a more exact divisor to generate the desired SD clock frequency. Note the divider can even support odd divisors without deterioration of duty cycle. Before changing clock divisor value (SDCLKFS or DVS), Host driver should make sure the SDSTB field is high. The settings are as follows: 0000b - Divide-by-1 0001b - Divide-by-2 1110b - Divide-by-15 1111b - Divide-by-16
3-0 —	Reserved Always write as 1.

23.5.1.14 Interrupt Status (INT_STATUS)

23.5.1.14.1 Offset

Register	Offset
INT_STATUS	30h

23.5.1.14.2 Function

An interrupt is generated when the normal interrupt signal enable is enabled and at least one of the status fields is set to 1. For all fields, writing 1 to a bit clears it; writing to 0 keeps the bit unchanged. More than one status can be cleared with a single register write. For card interrupt, before writing 1 to clear, it is required that the card stops asserting the interrupt, meaning that when the card driver services the interrupt condition; otherwise, the CINT field is asserted again.

The table below shows the relationship between the command timeout error and the command complete.

Table 23-8. uSDHC status for command timeout error/command complete bit combinations

Command complete	Command timeout error	Meaning of the status
0	0	X
X	1	Response not received within 64 SDCLK cycles
1	0	Response received

The table below shows the relationship between the transfer complete and the data timeout error.

Table 23-9. uSDHC status for data timeout error/transfer complete bit combinations

Transfer complete	Data timeout error	Meaning of the status
0	0	X
0	1	Timeout occurred during transfer
1	X	Data transfer complete

The table below shows the relationship between the command CRC error and command timeout error.

Table 23-10. uSDHC status for command CRC error/command timeout error bit combinations

Command complete	Command timeout error	Meaning of the status
0	0	No error
0	1	Response timeout error

Table continues on the next page...

Table 23-10. uSDHC status for command CRC error/command timeout error bit combinations (continued)

Command complete	Command timeout error	Meaning of the status
1	0	Response CRC error
1	1	CMD line conflict

23.5.1.14.4 Fields

Field	Function
31-29 —	Reserved
28 DMAE	DMA error Occurs when an Internal DMA transfer has failed. This field is set to 1, when some error occurs in the data transfer. This error can be caused by either simple DMA or ADMA, depending on which DMA is in use. The value in DMA System Address register is the next fetch address where the error occurs. Because any error corrupts the whole data block, the host driver restarts the transfer from the corrupted block boundary. The address of the block boundary can be calculated either from the current DS_ADDR value or from the remaining number of blocks and the block size. 0b - No error 1b - Error
27 —	Reserved
26 TNE	Tuning error: (only for SD3.0 SDR104 mode and EMMC HS200 mode) This field is set when an unrecoverable error is detected in a tuning circuit. By detecting Tuning Error, host driver needs to abort a command executing and perform tuning.

Table continues on the next page...

Field	Function
25 —	Reserved
24 AC12E	Auto CMD12 error Occurs when detecting that one of the fields in the Auto CMD12 Error Status register has changed from 0 to 1. This field is set to 1, not only when the errors in Auto CMD12 occur, but also, when the Auto CMD12 is not executed due to the previous command error. 0b - No error 1b - Error
23 —	Reserved
22 DEBE	Data end bit error Occurs either when detecting 0 at the end field position of read data that uses the DATA line, or at the end field position of the CRC. This field is not asserted in tuning process. 0b - No error 1b - Error
21 DCE	Data CRC error Occurs when detecting a CRC error when transferring read data that uses the DATA line, or when detecting the Write CRC status having a value other than 010. This field is not asserted in tuning process. 0b - No error 1b - Error
20 DTOE	Data timeout error Occurs when detecting one of following time-out conditions. • Busy time-out for R1b, R5b type • Busy time-out after Write CRC status • Read Data time-out. This field is not asserted in tuning process. 0b - No error 1b - Time out
19 CIE	Command index error Occurs if a command index error occurs in the command response. This field is not asserted in tuning process. 0b - No error 1b - Error
18 CEBE	Command end bit error Occurs when detecting that the end field of a command response is 0. This field is not asserted in tuning process. 0b - No error 1b - End bit error generated
17 CCE	Command CRC error Command CRC Error is generated in two cases.

Table continues on the next page...

Field	Function
	• If a response is returned and the Command Timeout Error is set to 0 (indicating no time-out), this field is set when detecting a CRC error in the command response. • The uSDHC module detects a CMD line conflict by monitoring the CMD line when a command is issued. If uSDHC drives the CMD line to 1, but detects 0 on the CMD line at the next SDCLK edge, then uSDHC aborts the command (Stop driving CMD line) and set this bit to 1. The Command Timeout Error should also be set to 1 to distinguish CMD line conflict. This field is not asserted in tuning process. 0b - No error 1b - CRC error generated
16 CTOE	Command timeout error Occurs only if no response is returned within 64 SDCLK cycles from the end field of the command. If uSDHC detects a CMD line conflict, in which case a Command CRC Error is also be set (as shown in Interrupt Status (INT_STATUS)), this field is set without waiting for 64 SDCLK cycles. This is because the command is aborted by uSDHC. This field is not asserted in tuning process. 0b - No error 1b - Time out
15 —	Reserved
14 TP	Tuning pass:(only for SD3.0 SDR104 mode and EMMC HS200 mode) Current CMD19 transfer is done successfully. That is, current sampling point is correct.
13 —	Reserved
12 RTE	Re-tuning event: (only for SD3.0 SDR104 mode and EMMC HS200 mode) This status is set if Re-Tuning Request in the Present State register changes from 0 to 1. host controller requests host driver to perform re-tuning for next data transfer. Current data transfer (not large block count) can be completed without re-tuning. 0b - Re-tuning is not required. 1b - Re-tuning should be performed.
11-9 —	Reserved
8 CINT	Card interrupt This status field is set when an interrupt signal is detected from the external card. In 1-bit mode, uSDHC detects the Card Interrupt without the SD clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so the interrupt from card can only be sampled during interrupt cycle, introducing some delay between the interrupt signal from the SDIO card and the interrupt to the host system. Writing this field to 1 can clear this field, but as the interrupt source from the SDIO card does not clear, this field is set again. to clear this field, it is required to reset the interrupt source from the external card followed by a writing 1 to this field. When this status has been set, and the host driver needs to service this interrupt, the Card Interrupt Signal Enable in the Interrupt Signal Enable register should be 0 to stop driving the interrupt signal to the host system. After completion of the card interrupt service (It should reset the interrupt sources in the SDIO card and the interrupt signal might not be asserted), write 1 to clear this field, set the Card Interrupt Signal Enable to 1, and start sampling the interrupt signal again. 0b - No card interrupt 1b - Generate card interrupt
7	Card removal

Table continues on the next page...

Field	Function
CRM	This status field is set if the Card Inserted field in the Present State register changes from 1 to 0. When the host driver writes this field to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state might possibly be changed when the host driver clears this field and the interrupt event might not be generated. When this field is cleared, it is set again if no card is inserted. to leave it cleared, clear the Card Removal Status Enable field in Interrupt Status Enable register. 0b - Card state unstable or inserted 1b - Card removed
6 CINS	Card insertion This status field is set if the Card Inserted field in the Present State register changes from 0 to 1. When the host driver writes this field to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state might possibly be changed when the host driver clears this field and the interrupt event might not be generated. When this field is cleared, it is set again if a card is inserted. to leave it cleared, clear the Card Inserted Status Enable field in Interrupt Status Enable register. 0b - Card state unstable or removed 1b - Card inserted
5 BRR	Buffer read ready This status field is set if the Buffer Read Enable field, in the Present State register, changes from 0 to 1. See the Buffer Read Enable field in the Present State register for additional information. This field indicates that cmd19 is finished in tuning process. 0b - Not ready to read buffer 1b - Ready to read buffer
4 BWR	Buffer write ready This status field is set if the Buffer Write Enable field, in the Present State register, changes from 0 to 1. See the Buffer Write Enable field in the Present State register for additional information. 0b - Not ready to write buffer 1b - Ready to write buffer
3 DINT	DMA interrupt Occurs only when the internal DMA finishes the data transfer successfully. Whenever errors occur during data transfer, this field does not be set. Instead, the DMAE field is set. Either Simple DMA or ADMA finishes data transferring, this field is set. 0b - No DMA interrupt 1b - DMA interrupt is generated.
2 BGE	Block gap event If the Stop At Block Gap Request field in the Protocol Control register is set, this field is set when a read or write transaction is stopped at a block gap. If Stop At Block Gap Request is not set to 1, this field is not set to 1. In the case of a Read Transaction: This field is set at the falling edge of the DATA Line Active Status (When the transaction is stopped at SD bus timing). The Read Wait must be supported to use this function. In the case of Write Transaction: This field is set at the falling edge of Write Transfer Active Status (After getting CRC status at SD Bus timing). 0b - No block gap event 1b - Transaction stopped at block gap
1 TC	Transfer complete This field is set when a read or write transfer is completed.

Table continues on the next page...

Field	Function
	In the case of a Read Transaction: This field is set at the falling edge of the Read Transfer Active Status. There are two cases in which this interrupt is generated. The first is when a data transfer is completed as specified by the data length (after the last data has been read to the host system). The second is when data has stopped at the block gap and completed the data transfer by setting the Stop At Block Gap Request field in the Protocol Control register (after valid data has been read to the host system). In the case of a Write Transaction: This field is set at the falling edge of the DATA Line Active Status. There are two cases in which this interrupt is generated. The first is when the last data is written to the SD card as specified by the data length and the busy signal is released. The second is when data transfers are stopped at the block gap, by setting the Stop At Block Gap Request field in the Protocol Control register, and the data transfers are completed. (after valid data is written to the SD card and the busy signal released). In the case of a command with busy, this field is set when busy is deasserted. This field is not asserted in tuning process. 0b - Transfer does not complete 1b - Transfer complete
0 CC	Command complete This field is set when you receive the end field of the command response (except auto CMD12). See the Command Inhibit (CMD) in the Present State register. This field is not asserted in tuning process. 0b - Command not complete 1b - Command complete

23.5.1.15 Interrupt Status Enable (INT_STATUS_EN)

23.5.1.15.1 Offset

Register	Offset
INT_STATUS_EN	34h

23.5.1.15.2 Function

Setting the fields in this register to 1 enables the corresponding Interrupt Status to be set by the specified event. If any field is cleared, the corresponding Interrupt Status field is also cleared (that is, when the field in this register is cleared, the corresponding field in Interrupt Status register is always 0).

- Depending on IABG field setting, uSDHC might be programmed to sample the card interrupt signal during the interrupt period and hold its value in the flip-flop. There

are some delays on the Card Interrupt, asserted from the card, to the time the host system is informed.

- To detect a CMD line conflict, the host driver must set both Command Timeout Error Status Enable and Command CRC Error Status Enable to 1.

23.5.1.16 Interrupt Signal Enable (INT_SIGNAL_EN)

23.5.1.16.1 Offset

Register	Offset
INT_SIGNAL_EN	38h

23.5.1.16.2 Function

This register is used to select which interrupt status is indicated to the host system as the interrupt. These status fields all share the same interrupt line. Setting any of these fields to 1 enables interrupt generation. The corresponding Status register field generates an interrupt when the corresponding interrupt signal enable field is set.

23.5.1.17 Auto CMD12 Error Status (AUTOCMD12_ERR_STATUS)

23.5.1.17.1 Offset

Register	Offset
AUTOCMD12_ERR_STATUS	3Ch

23.5.1.17.2 Function

When the Auto CMD12 Error Status field in the Status register is set, the host driver checks this register to identify what kind of error the Auto CMD12 / CMD 23 indicated. Auto CMD23 errors are indicated in field 04-01. This register is valid only when the Auto CMD12 Error status field is set.

The table below shows the relationship between the Auto CMGD12 CRC Error and the Auto CMD12 Command Timeout Error.

Table 23-11. Relationship between command CRC error and command timeout error for auto CMD12

Auto CMD12 CRC error	Auto CMD12 timeout error	Type of error
0	0	No error
0	1	Response timeout error
1	0	Response CRC error
1	1	CMD line conflict

Changes in Auto CMD12 Error Status register can be classified in three scenarios:

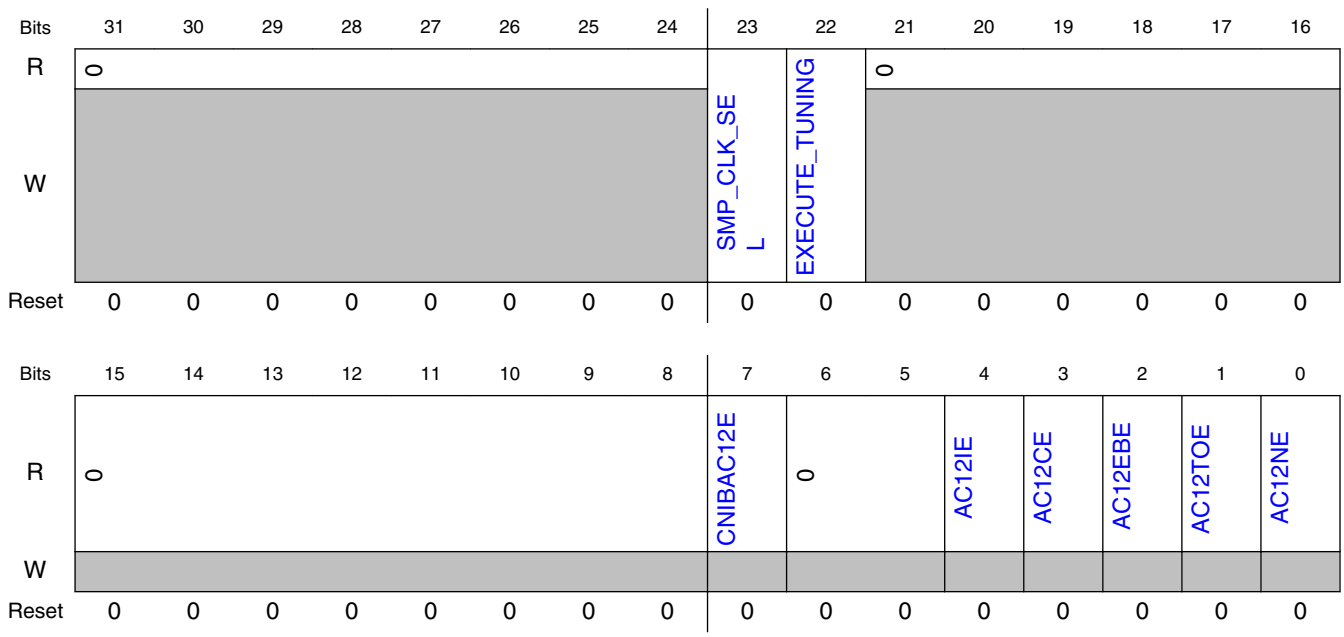
- When uSDHC is going to issue an Auto CMD12
  - Set field 0 to 1 if the Auto CMD12 cannot be issued due to an error in the previous command
  - Set field 0 to 0 if the Auto CMD12 is issued
- At the end field of an Auto CMD12 response
  - Check errors correspond to fields 1-4

- Set fields 1-4 corresponding to detected errors
- Clear fields 1-4 corresponding to detected errors

- Before reading the Auto CMD12 Error Status field 7
  - Set field 7 to 1 if there is a command that can't be issued
  - Clear field 7 if there is no command to issue

The timing for generating the Auto CMD12 Error and writing to the Command register are asynchronous. After that, field 7 is sampled when the driver is not writing to the Command register. So, it is suggested to read this register only when the AC12E field in Interrupt Status register is set. An Auto CMD12 Error Interrupt is generated when one of the error fields (0-4) is set to 1. The Command Not Issued By Auto CMD12 Error does not generate an interrupt.

23.5.1.17.3 Diagram



23.5.1.17.4 Fields

Field	Function
31-24 —	Reserved
23 SMP_CLK_SEL	Sample clock select When std_tuning_en field is set, this field is used to select sampling clock to receive CMD and DATA. Otherwise, this field is reserved. This field is set by ty tuning procedure and valid after the completion of tuning(When Execute Tuning is cleared). Setting 1 means that tuning is completed successfully and setting 0 means that tuning is failed. Writing 1 to this field is meaningless and ignored. A tuning circuit is

Table continues on the next page...

Field	Function
	reset by writing to 0. This field can be cleared with setting Execute Tuning. Once the tuning circuit is reset, it takes time to complete tuning sequence. Therefore, host driver should keep this field to 1 to perform re-tuning sequence to complete re-tuning sequence in a short time. Change of this field is not allowed while the Host controller us receiving response or a read data block. 0b - Fixed clock is used to sample data 1b - Tuned clock is used to sample data
22 EXECUTE_TUNING	Execute tuning When std_tuning_en field is set, this field is used to start tuning procedure. Otherwise, this field is reserved. This field is set to start tuning procedure and automatically cleared when runing procedure is completed. The result of tuning is indicated to sam_clk_sel field. Tuning procedure is aborted by writing 0.
21-8 —	Reserved
7 CNIBAC12E	Command not issued by Auto CMD12 error Setting this field to 1 means CMD_wo_DAT is not executed due to an Auto CMD12 error (D04-D01) in this register. 0b - No error 1b - Not issued
6-5 —	Reserved
4 AC12IE	Auto CMD12 / 23 index error Occurs if the command index error occurs in response to a command. 0b - No error 1b - Error, the CMD index in response is not CMD12/23
3 AC12CE	Auto CMD12 / 23 CRC error Occurs when detecting a CRC error in the command response. 0b - No CRC error 1b - CRC error met in Auto CMD12/23 response
2 AC12EBE	Auto CMD12 / 23 end bit error Occurs when detecting that the end field of command response is 0 which should be 1. 0b - No error 1b - End bit error generated
1 AC12TOE	Auto CMD12 / 23 timeout error Occurs if no response is returned within 64 SDCLK cycles from the end field of the command. If this field is set to1, the other error status fields (2-4) have no meaning. 0b - No error 1b - Time out
0 AC12NE	Auto CMD12 not executed If memory multiple block data transfer is not started, due to a command error, this field is not set because it is not necessary to issue an Auto CMD12. Setting this field to 1 means uSDHC cannot issue the Auto CMD12 to stop a memory multiple block data transfer due to some error. If this field is set to 1, other error status fields (1-4) have no meaning. 0b - Executed 1b - Not executed

23.5.1.18 Host Controller Capabilities (HOST_CTRL_CAP)

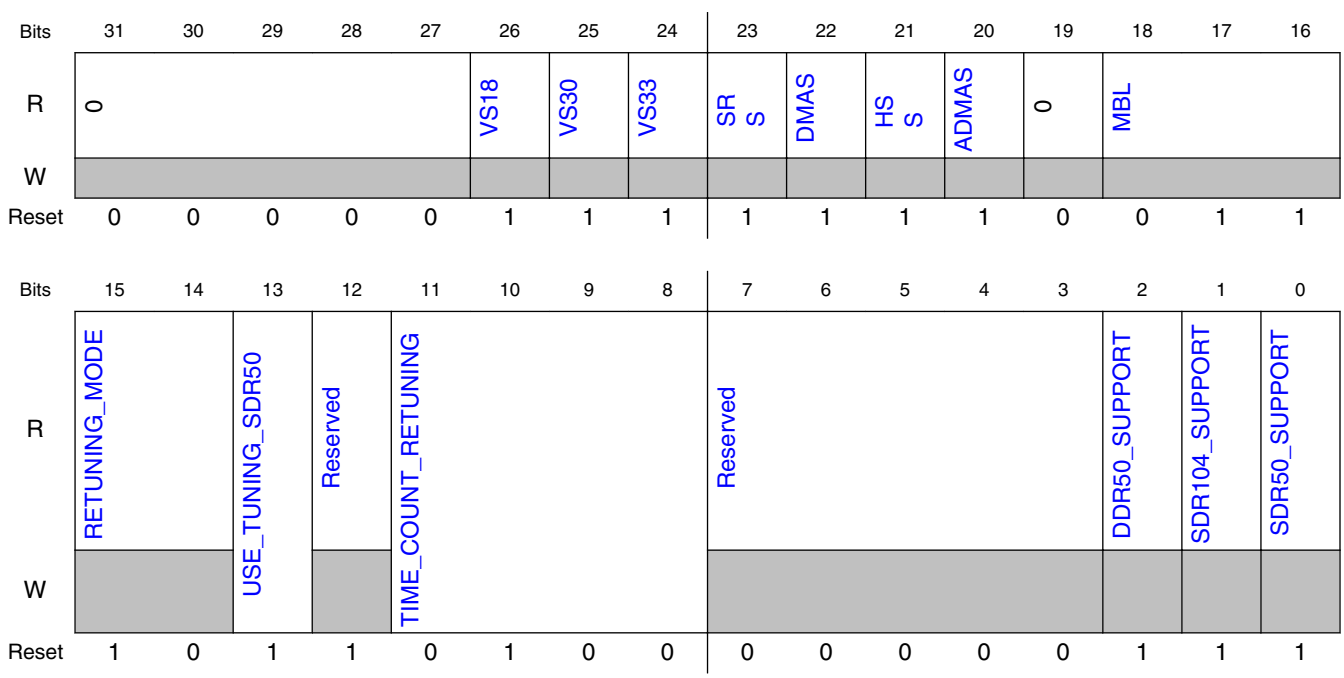
23.5.1.18.1 Offset

Register	Offset
HOST_CTRL_CAP	40h

23.5.1.18.2 Function

This register provides the host driver with information specific to uSDHC implementation. The value in this register is the power-on-reset value and does not change with a software reset.

23.5.1.18.3 Diagram



23.5.1.18.4 Fields

Field	Function
31-27	Reserved

Table continues on the next page...

Field	Function
—	
26 VS18	Voltage support 1.8 V This field depends on the host system ability. 0b - 1.8 V not supported 1b - 1.8 V supported
25 VS30	Voltage support 3.0 V This field depends on the host system ability. 0b - 3.0 V not supported 1b - 3.0 V supported
24 VS33	Voltage support 3.3 V This field depends on the host system ability. 0b - 3.3 V not supported 1b - 3.3 V supported
23 SRS	Suspend / resume support This field indicates whether uSDHC supports Suspend / Resume functionality. If this field is 0, the Suspend and Resume mechanism, as well as the read wait, are not supported, and the host driver does not issue either Suspend or Resume commands. 0b - Not supported 1b - Supported
22 DMAS	DMA support This field indicates whether uSDHC is capable of using the internal DMA to transfer data between system memory and the data buffer directly. 0b - DMA not supported 1b - DMA supported
21 HSS	High speed support This field indicates whether uSDHC supports High Speed mode and the host system can supply a SD clock frequency from 25 MHz to 50 MHz. 0b - High speed not supported 1b - High speed supported
20 ADMAS	ADMA support This field indicates whether uSDHC supports the ADMA feature. 0b - Advanced DMA not supported 1b - Advanced DMA supported
19 —	Reserved
18-16 MBL	Max block length This value indicates the maximum block size that the host driver can read and write to the buffer in uSDHC. The buffer transfers block size without wait cycles. 000b - 512 bytes 001b - 1024 bytes 010b - 2048 bytes 011b - 4096 bytes
15-14	Retuning Mode This field selects retuning method.

Table continues on the next page...

Field	Function
RETUNING_MODE	00b - Mode 1 01b - Mode 2 10b - Mode 3 11b - Reserved
13 USE_TUNING_SDR50	Use Tuning for SDR50 This field is set to 1. Host controller requires tuning to operate SDR50. 0b - SDR does not require tuning. 1b - SDR50 requires tuning.
12 —	Reserved
11-8 TIME_COUNT_RETUNING	Time counter for retuning This field indicates an initial value of the Retuning Timer for Re-Tuning Mode1 and 3.Setting to 0 disables Retuning Timer.
7-3 —	Reserved
2 DDR50_SUPPORT	DDR50 support This field indicates support of DDR50 mode.
1 SDR104_SUPPORT	SDR104 support This field indicates support of SDR104 mode.
0 SDR50_SUPPORT	SDR50 support This field indicates support of SDR50 mode.

23.5.1.19 Watermark Level (WTMK_LVL)

23.5.1.19.1 Offset

Register	Offset
WTMK_LVL	44h

23.5.1.19.2 Function

Both write and read watermark levels (FIFO threshold) are configurable. Their value can range from 1 to 128 words. Both write and read burst lengths are also Configurable. There value can range from 1 to 31 words.

23.5.1.19.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

23.5.1.19.4 Fields

Field	Function
31-29 —	Reserved
28-24 WR_BRST_LEN	Write burst length due to system restriction, the actual burst length might not exceed 16 The number of words uSDHC writes in a single burst. The write burst length must be less than or equal to the write watermark level, and all bursts within a watermark level transfer is in back-to-back mode. On reset, this field is 8. Writing 0 to this field results in '01000' (that is, it is not able to clear this field).
23-16 WR_WML	Write watermark level The number of words used as the watermark level (FIFO threshold) in a DMA write operation. Also, the number of words as a sequence of write bursts in back-to-back mode. The maximum legal value for the write watermark level is 128.
15-13 —	Reserved
12-8 RD_BRST_LEN	Read burst length due to system restriction, the actual burst length might not exceed 16 The number of words uSDHC reads in a single burst. The read burst length must be less than or equal to the read watermark level, and all bursts within a watermark level transfer is in back-to-back mode. On reset, this field is 8. Writing 0 to this field results in '01000' (that is, it is not able to clear this field).
7-0 RD_WML	Read watermark level The number of words used as the watermark level (FIFO threshold) in a DMA read operation. Also, the number of words as a sequence of read bursts in back-to-back mode. The maximum legal value for the read water mark level is 128.

23.5.1.20 Mixer Control (MIX_CTRL)

23.5.1.20.1 Offset

Register	Offset
MIX_CTRL	48h

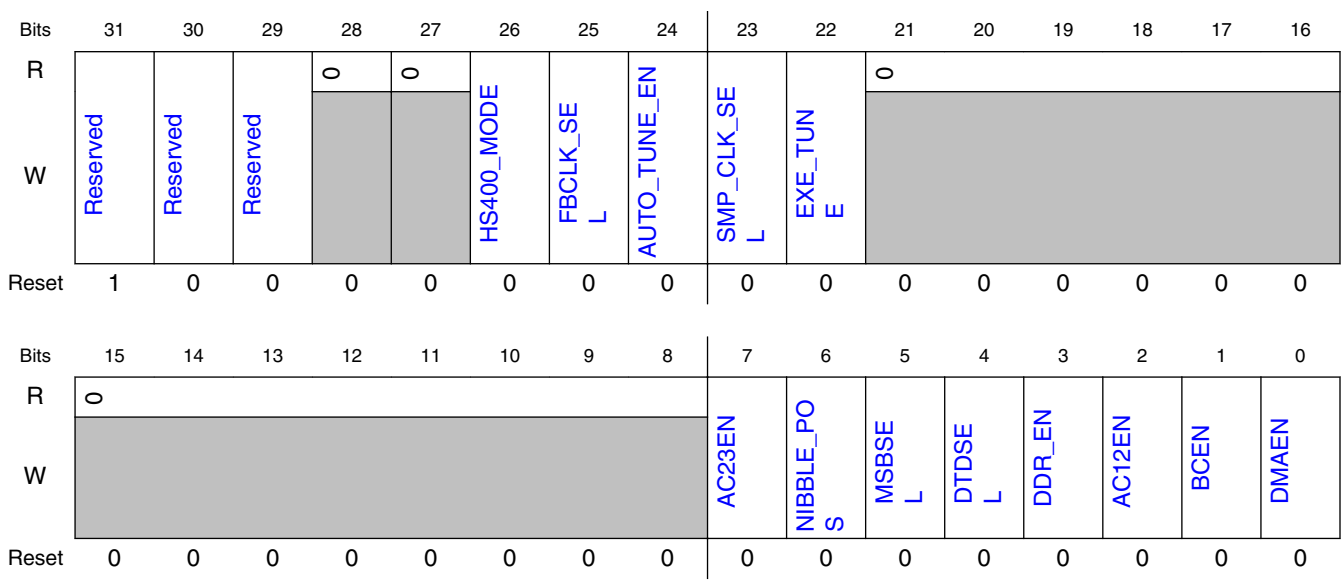
23.5.1.20.2 Function

This register is used to DMA and data transfer. To prevent data loss, The software should check if data transfer is active before writing this register. These fields are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

Table 23-12. Transfer type register setting for various transfer types

Multi/single block select	Block count enable	Block count	Function
0	Do not care	Do not care	Single transfer
1	0	Do not care	Infinite transfer
1	1	Positive number	Multiple transfer
1	1	Zero	No data transfer

23.5.1.20.3 Diagram



23.5.1.20.4 Fields

Field	Function
31	Reserved

Table continues on the next page...

Field	Function
—	Always write as 1.
30 —	Reserved Always write as 0.
29 —	Reserved Always write as 0.
28 —	Reserved
27 —	Reserved
26 HS400_MODE	Enable HS400 mode HS400 Enable
25 FBCLK_SEL	Feedback clock source selection (Only used for SD3.0, SDR104 mode and EMMC HS200 mode) 0b - Feedback clock comes from the loopback CLK 1b - Feedback clock comes from the ipp_card_clk_out
24 AUTO_TUNE_EN	Auto tuning enable (Only used for SD3.0, SDR104 mode and and EMMC HS200 mode) 0b - Disable auto tuning 1b - Enable auto tuning
23 SMP_CLK_SEL	Clock selection When STD_TUNING_EN is 0, this field is used to select Tuned clock or Fixed clock to sample data / cmd (Only used for SD3.0, SDR104 mode and EMMC HS200 mode) 0b - Fixed clock is used to sample data / cmd 1b - Tuned clock is used to sample data / cmd
22 EXE_TUNE	Execute tuning: (Only used for SD3.0, SDR104 mode and EMMC HS200 mode) When STD_TUNING_EN is 0, this field is set to 1 to indicate the host driver is starting tuning procedure. Tuning procedure is aborted by writing 0. 0b - Not tuned or tuning completed 1b - Execute tuning
21-8 —	Reserved
7 AC23EN	Auto CMD23 enable When this field is set to 1, the host controller issues a CMD23 automatically before issuing a command specified in the Command Register.
6 NIBBLE_POS	Nibble position indication In DDR 4-bit mode nibble position indication. 0- the sequence is 'odd high nibble -> even high nibble -> odd low nibble -> even low nibble'; 1- the sequence is 'odd high nibble -> odd low nibble -> even high nibble -> even low nibble'.
5 MSBSEL	Multi / Single block select This field enables multiple block DATA line data transfers. For any other commands, this field can be set to 0. If this field is 0, it is not necessary to set the Block Count register. See Command Transfer Type (CMD_XFR_TYP). 0b - Single block 1b - Multiple blocks
4 DTDSEL	Data transfer direction select

Table continues on the next page...

Field	Function
	This field defines the direction of DATA line data transfers. The field is set to 1 by the host driver to transfer data from the SD card to uSDHC and is set to 0 for all other commands. 0b - Write (Host to card) 1b - Read (Card to host)
3 DDR_EN	Dual data rate mode selection
2 AC12EN	Auto CMD12 enable Multiple block transfers for memory require a CMD12 to stop the transaction. When this field is set to 1, uSDHC issues a CMD12 automatically when the last block transfer has completed. The host driver is not set this field to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File Security Specification (see reference list) do not require CMD12. In single block transfer, uSDHC ignores this field no matter it is set or not. 0b - Disable 1b - Enable
1 BCEN	Block count enable This field is used to enable the Block Count register, which is only relevant for multiple block transfers. When this field is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer. 0b - Disable 1b - Enable
0 DMAEN	DMA enable This field enables DMA functionality. If this field is set to 1, a DMA operation begins when the host driver sets the DPSEL field of this register. Whether the simple DMA or the advanced DMA is active depends on the DMA Select field of the Protocol Control register. 0b - Disable 1b - Enable

23.5.1.21 Force Event (FORCE_EVENT)

23.5.1.21.1 Offset

Register	Offset
FORCE_EVENT	50h

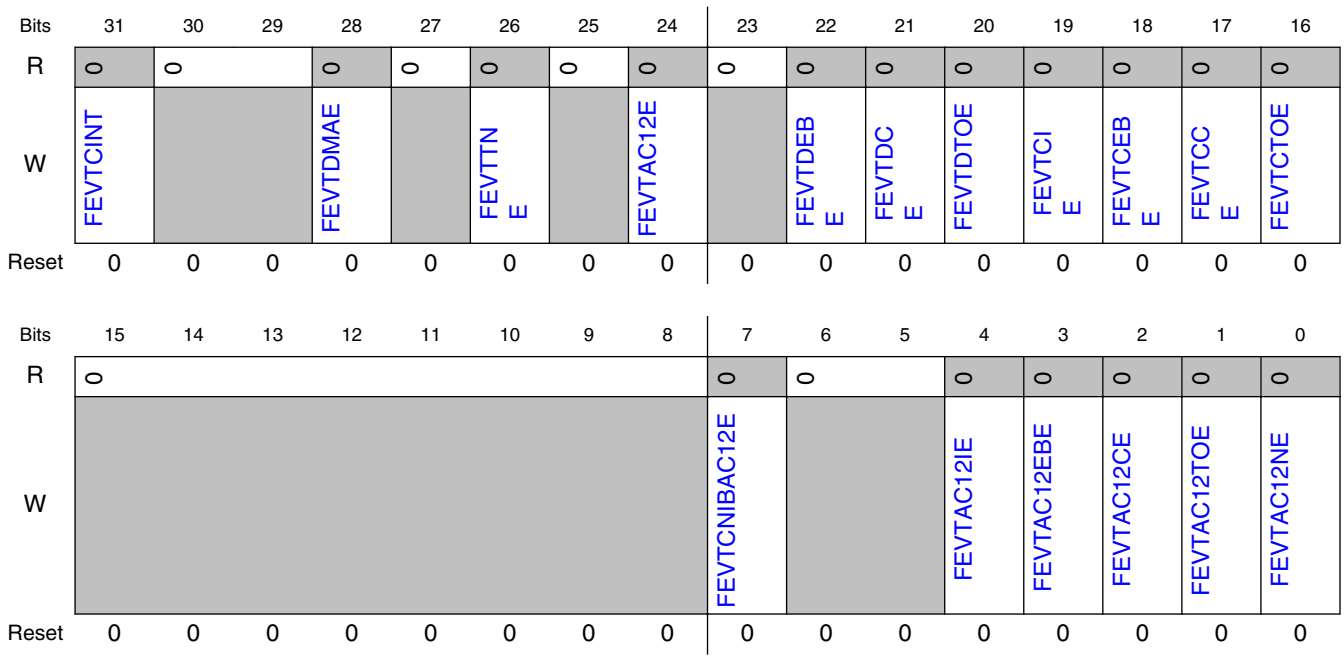
23.5.1.21.2 Function

The Force Event Register is not a physically implemented register. Rather, it is an address at which the Interrupt Status register can be written if the corresponding field of the Interrupt Status Enable Register is set. This register is a write only register and writing 0 to it has no effect. Writing 1 to this register actually sets the corresponding field

of Interrupt Status register. A read from this register always results in 0's. to change the corresponding status fields in the Interrupt Status register, make sure to set IPGEN field in System Control Register so that peripheral clock is always active.

Forcing a card interrupt generates a short pulse on the DATA1 line, and the driver might treat this interrupt as a normal interrupt. The interrupt service routine might skip polling the card interrupt factor as the interrupt is self cleared.

23.5.1.21.3 Diagram



23.5.1.21.4 Fields

Field	Function
31 FEVTCINT	Force event card interrupt Writing 1 to this field generates a short low-level pulse on the internal DATA1 line, as if a self clearing interrupt was received from the external card. If enabled, the CINT field is set and the interrupt service routine might treat this interrupt as a normal interrupt from the external card.
30-29 —	Reserved
28 FEVTDMAE	Force event DMA error Forces the DMAE field of Interrupt Status register to be set.
27 —	Reserved
26	Force tuning error

Table continues on the next page...

Field	Function
FEVTTNE	Forces the TNE field of Interrupt Status register to be set.
25 —	Reserved
24 FEVTAC12E	Force event Auto Command 12 error Forces the AC12E field of Interrupt Status register to be set.
23 —	Reserved
22 FEVTDEBE	Force event data end bit error Forces the DEBE field of Interrupt Status register to be set.
21 FEVTDCE	Force event data CRC error Forces the DCE field of Interrupt Status register to be set.
20 FEVTDTOE	Force event data time out error Force the DTOE field of Interrupt Status register to be set.
19 FEVTCIE	Force event command index error Forces the CCE field of Interrupt Status register to be set.
18 FEVTCEBE	Force event command end bit error Forces the CEBE field of Interrupt Status register to be set.
17 FEVTCCE	Force event command CRC error Forces the CCE field of Interrupt Status register to be set.
16 FEVTCTOE	Force event command time out error Forces the CTOE field of Interrupt Status register to be set.
15-8 —	Reserved
7 FEVTCNIBAC12E	Force event command not executed by Auto Command 12 error Forces the CNIBAC12E field in the Auto Command12 Error Status register to be set.
6-5 —	Reserved
4 FEVTAC12IE	Force event Auto Command 12 index error Forces the AC12IE field in the Auto Command12 Error Status register to be set.
3 FEVTAC12EBE	Force event Auto Command 12 end bit error Forces the AC12EBE field in the Auto Command12 Error Status register to be set.
2 FEVTAC12CE	Force event auto command 12 CRC error Forces the AC12CE field in the Auto Command12 Error Status register to be set.
1 FEVTAC12TOE	Force event auto command 12 time out error Forces the AC12TOE field in the Auto Command12 Error Status register to be set.
0 FEVTAC12NE	Force event auto command 12 not executed Forces the AC12NE field in the Auto Command12 Error Status register to be set.

23.5.1.22 ADMA Error Status (ADMA_ERR_STATUS)

23.5.1.22.1 Offset

Register	Offset
ADMA_ERR_STATUS	54h

23.5.1.22.2 Function

When an ADMA Error Interrupt has occurred, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address register holds the address around the error descriptor.

For recovering from this error, the host driver requires the ADMA state to identify the error descriptor address as follows:

- ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address.
- ST_FDS: Current location set in the ADMA System Address register is the error descriptor address.
- ST_CADR: This state is never set because it only increments the descriptor pointer and does not generate an ADMA error.
- ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address.

In case of a write operation, the host driver should use the ACMD22 to get the number of the written block, rather than using this information, because unwritten data might exist in the host controller.

The host controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) in the ST_FDS state. The host driver can distinguish this error by reading the Valid field of the error descriptor.

Table 23-13. ADMA error state coding

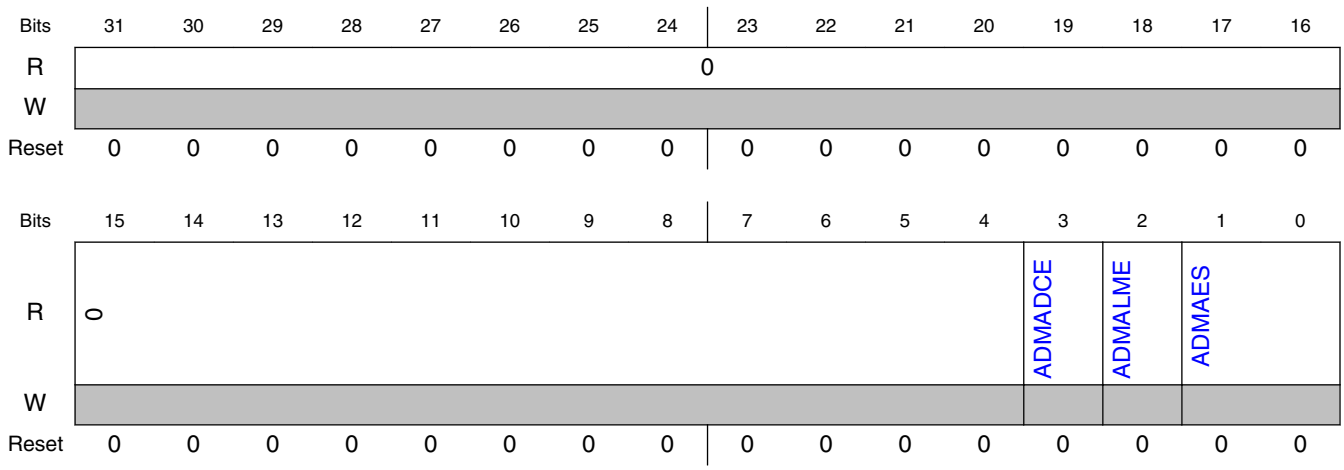
D01-D00	ADMA error state (when error has occurred)	Contents of ADMA System Address register
00	ST_STOP (Stop DMA)	Holds the address of the next executable descriptor command
01	ST_FDS (Fetch descriptor)	Holds the valid descriptor address
10	ST_CADR (Change address)	No ADMA error is generated

Table continues on the next page...

Table 23-13. ADMA error state coding (continued)

D01-D00	ADMA error state (when error has occurred)	Contents of ADMA System Address register
11	ST_TFR (Transfer data)	Holds the address of the next executable descriptor command

23.5.1.22.3 Diagram



23.5.1.22.4 Fields

Field	Function
31-4 —	Reserved
3 ADMADCE	ADMA descriptor error This error occurs when invalid descriptor fetched by ADMA. 0b - No error 1b - Error
2 ADMALME	ADMA length mismatch error This error occurs in the following two cases: • While the block count enable is being set, the total data length specified by the descriptor table is different from that specified by the block count and block length. • Total data length cannot be divided by the block length. 0b - No error 1b - Error
1-0 ADMAES	ADMA error state (when ADMA error is occurred) This field indicates the state of the ADMA when an error has occurred during an ADMA data transfer. See ADMA Error Status (ADMA_ERR_STATUS) for more details.

23.5.1.23 ADMA System Address (ADMA_SYS_ADDR)

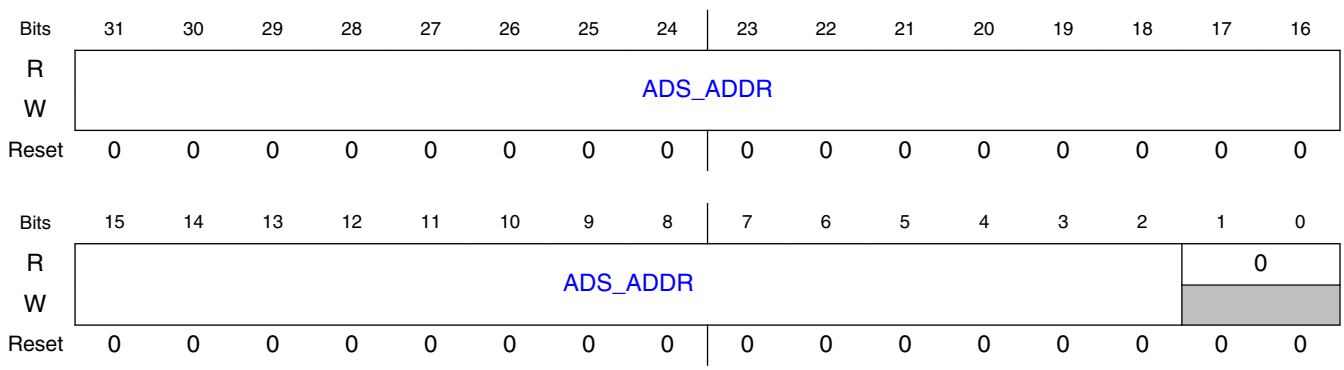
23.5.1.23.1 Offset

Register	Offset
ADMA_SYS_ADDR	58h

23.5.1.23.2 Function

This register contains the physical system memory address used for ADMA transfers.

23.5.1.23.3 Diagram



23.5.1.23.4 Fields

Field	Function
31-2 ADS_ADDR	ADMA system address This register holds the word address of the executing command in the Descriptor table. At the start of ADMA, the host driver sets the start address of the Descriptor table. The ADMA engine increments this register address whenever fetching a Descriptor command. When the ADMA is stopped at the Block Gap, this register indicates the address of the next executable Descriptor command. When the ADMA Error Interrupt is generated, this register holds the valid Descriptor address depending on the ADMA state. The lower 2 bits of this register is tied to '0' so the ADMA address is always word aligned. Because this register supports dynamic address reflecting, when TC field is set, it automatically alters the value of internal address counter, so the software cannot change this register when TC field is set. Such restriction is also listed in Software restrictions.
1-0 —	Reserved

23.5.1.24 DLL (Delay Line) Control (DLL_CTRL)

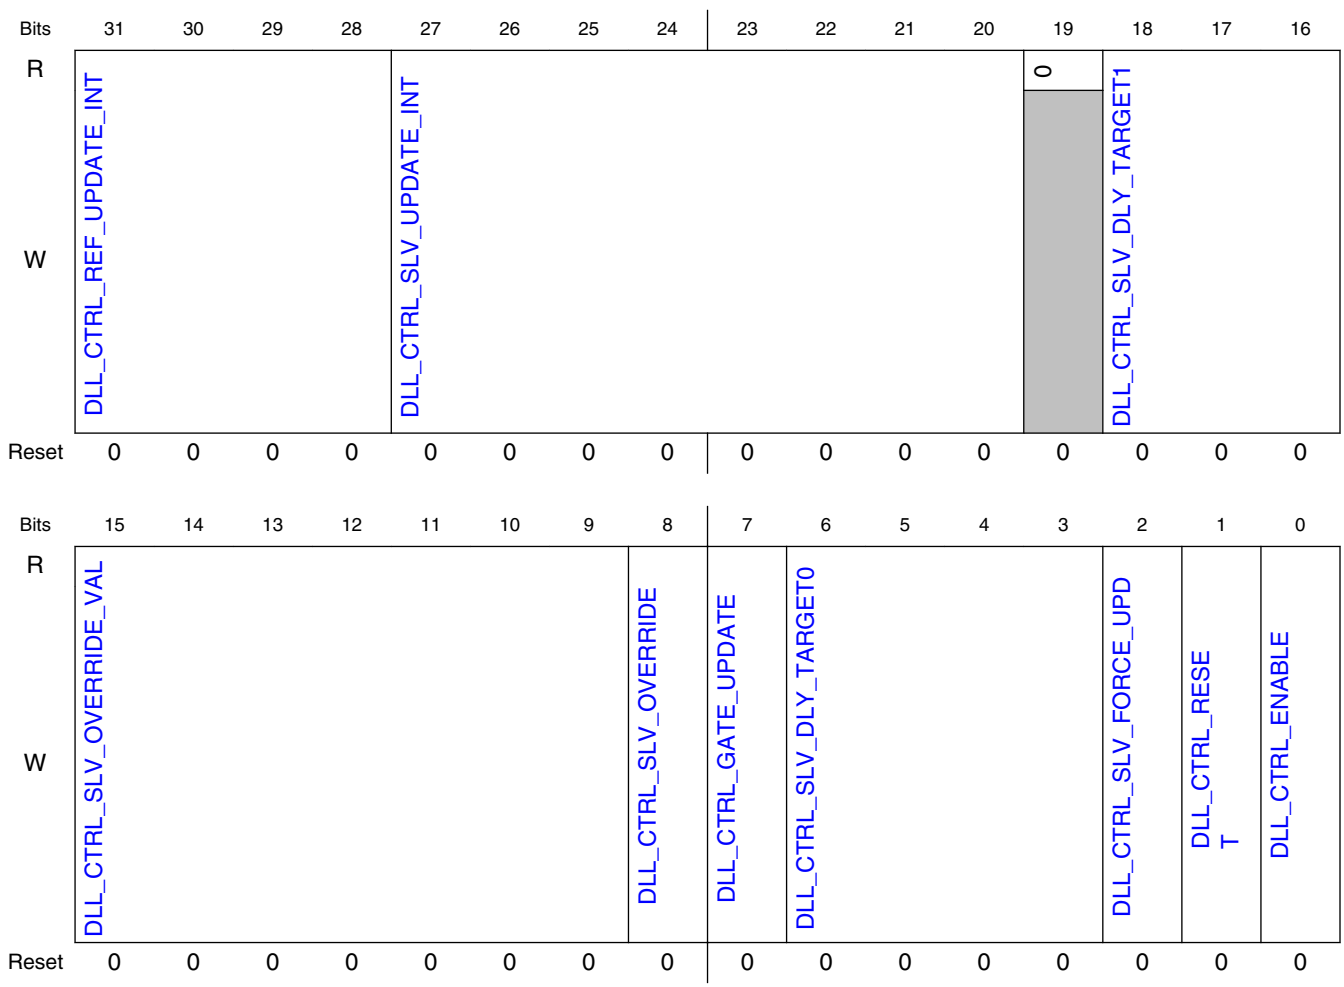
23.5.1.24.1 Offset

Register	Offset
DLL_CTRL	60h

23.5.1.24.2 Function

This register contains control fields for DLL.

23.5.1.24.3 Diagram



23.5.1.24.4 Fields

Field	Function
31-28 DLL_CTRL_REF_UPDATE_INT	DLL control loop update interval The interval cycle is (2 + REF_UPDATE_INT) * REF_CLOCK. By default, the DLL control loop updates every two REF_CLOCK cycles. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that might effect the delay (such as voltage and temperature)
27-20 DLL_CTRL_SLV_UPDATE_INT	Slave delay line update interval If default 0 is used, it means 256 cycles of REF_CLOCK. A value of 0x0f results in 15 cycles and so on. Note that software can always cause an update of the slave-delay line using the SLV_FORCE_UPDATE register. Note that the slave delay line also updates automatically when the reference DLL transitions to a locked state (from an un-locked state).
19 —	Reserved
18-16 DLL_CTRL_SLV_DLY_TARGET1	DLL slave delay target1 See DLL_CTRL_SLV_DLY_TARGET0 below.
15-9 DLL_CTRL_SLV_OVERRIDE_VAL	DLL slave override val When SLV_OVERRIDE = 1, this field is used to select 1 of 128 physical taps manually. A value of 0 selects tap 1, and a value of 0x7f selects tap 128.
8 DLL_CTRL_SLV_OVERRIDE	DLL slave override Set this field to 1 to Enable manual override for slave delay chain using SLV_OVERRIDE_VAL; to set 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE field. In fact to reduce power, if SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE = 0
7 DLL_CTRL_GATE_UPDATE	DLL gate update Set this field to 1 to prevent the DLL from updating (because when clock_in exists, glitches might appear during DLL updates). This field might be used by software if such a condition occurs. Clear the bit to 0 to allow the DLL to update automatically.
6-3 DLL_CTRL_SLV_DLY_TARGET0	DLL slave delay target0 The delay target for uSDHC loopback read clock can be programmed in 1/16th increments of an ref_clock half-period. The delay is (({DLL_CTRL_SLV_DLY_TARGET1,DLL_CTRL_SLV_DLY_TARGET0} +1)* REF_CLOCK / 2) / 16 So the input read-clock can be delayed relative input data from (REF_CLOCK / 2) / 16 to REF_CLOCK * 4.
2 DLL_CTRL_SLV_FORCE_UPD	DLL slave delay line Setting this field to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line updates automatically based on the SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when uSDHC is idle. This function might not work when uSDHC is working on data / cmd / response.
1 DLL_CTRL_RESET	DLL reset Setting this field to 1 force a reset on DLL. This causes the DLL to lose lock and re-calibrate to detect an REF_CLOCK half period phase shift. This signal is used by the DLL as edge-sensitive, so to create a subsequent reset, RESET must be taken low and then asserted again.
0	DLL and delay chain

Field	Function
DLL_CTRL_ENABLE	Set this field to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. Note that using the slave delay line override feature with SLV_OVERRIDE and SLV_OVERRIDE VAL, the DLL does not need to be enabled.

23.5.1.25 DLL Status (DLL_STATUS)

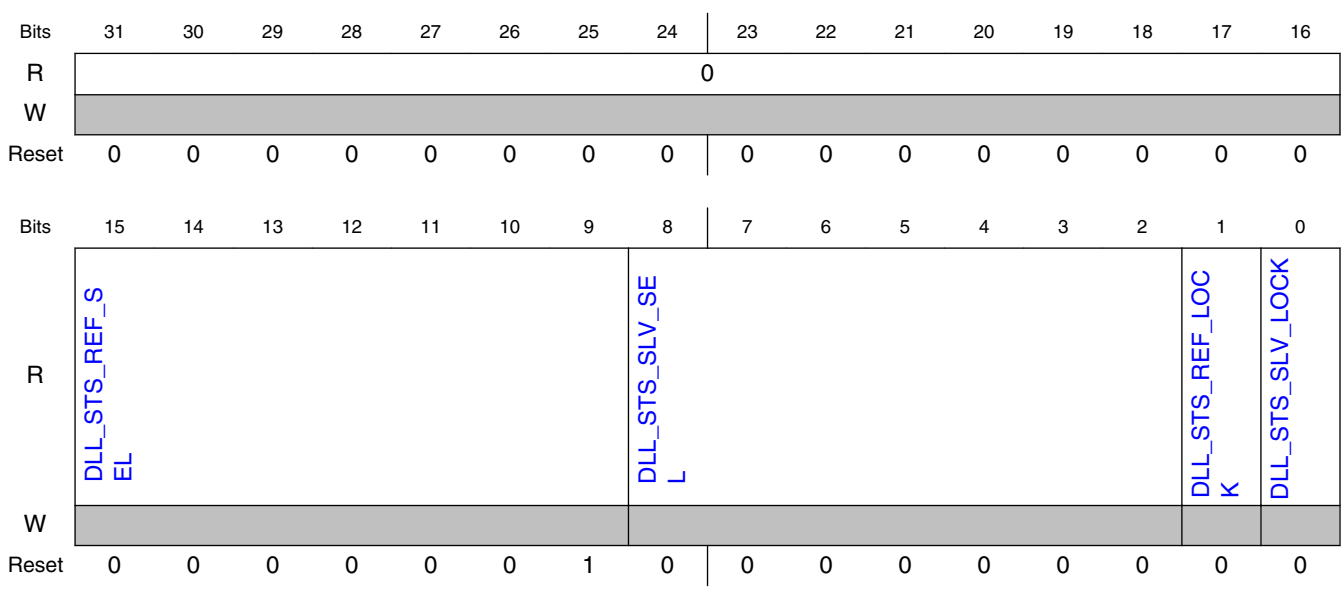
23.5.1.25.1 Offset

Register	Offset
DLL_STATUS	64h

23.5.1.25.2 Function

This register contains the DLL status information. All fields are read only and reads the same as the power-reset value.

23.5.1.25.3 Diagram



23.5.1.25.4 Fields

Field	Function
31-16 —	Reserved
15-9 DLL_STS_REF_SEL	Reference delay line select taps This is encoded by 7 fields for 127 taps.
8-2 DLL_STS_SLV_SEL	Slave delay line select status This is the instant value generated from reference chain. Because the reference chain can only be updated when REF_CLOCK is detected, this value should be the right value to be updated when the reference is locked.
1 DLL_STS_REF_LOCK	Reference DLL lock status This signifies that the DLL has detected and locked to a half-phase ref_clock shift, allowing the slave delay-line to perform programmed clock delays
0 DLL_STS_SLV_LOCK	Slave delay-line lock status This signifies that a valid calibration has been set to the slave-delay line and that the slave-delay line is implementing the programmed delay value

23.5.1.26 CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS)

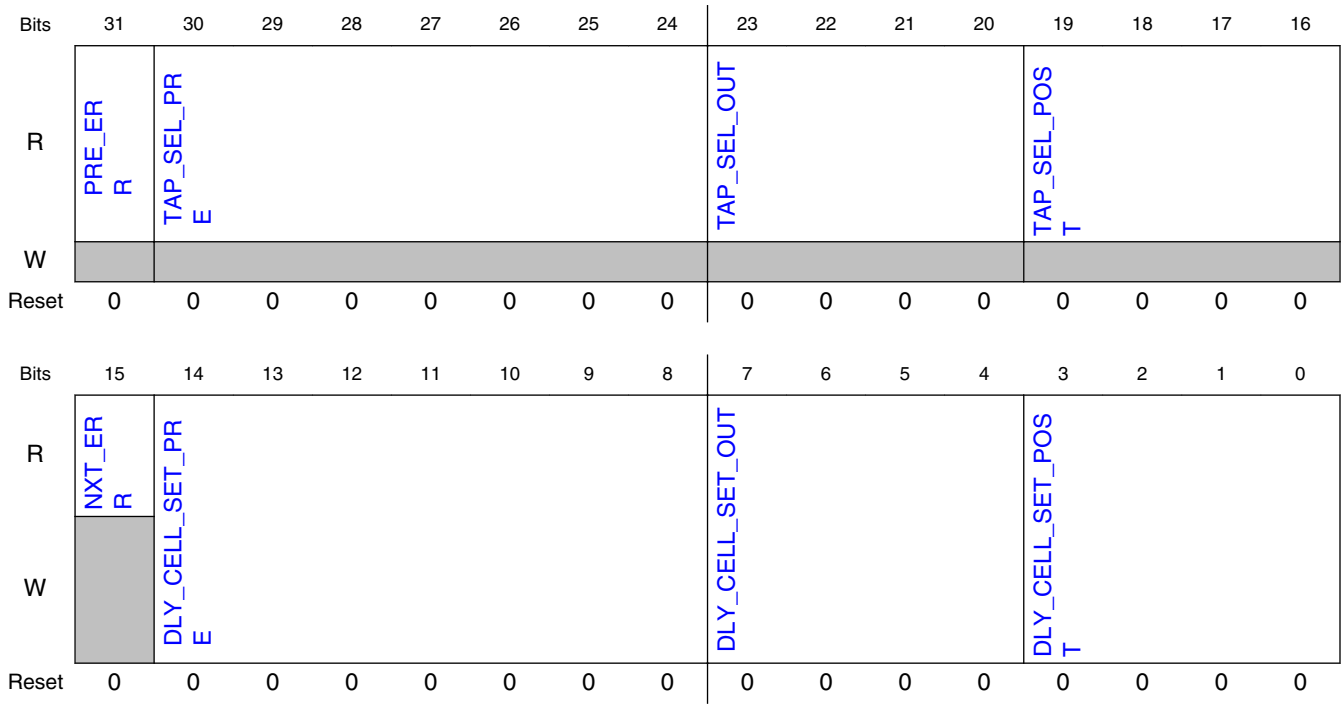
23.5.1.26.1 Offset

Register	Offset
CLK_TUNE_CTRL_STATUS	68h

23.5.1.26.2 Function

This register contains the Clock Tuning Control status information. All fields are read only and reads the same as the power-reset value. This register is added to support SD3.0 UHS-I SDR104 mode and EMMC HS200 mode.

23.5.1.26.3 Diagram



23.5.1.26.4 Fields

Field	Function
31 PRE_ERR	PRE error PRE error which means the number of delay cells added on the feedback clock is too small. It is valid only when SMP_CLK_SEL of Mix control register (bit23 of 0x48) is enabled.
30-24 TAP_SEL_PRE	TAP_SEL_PRE Reflects the number of delay cells added on the feedback clock between the feedback clock and CLK_PRE. When AUTO_TUNE_EN (bit24 of 0x48) is disabled, TAP_SEL_PRE is always equal to DLY_CELL_SET_PRE. When AUTO_TUNE_EN (bit24 of 0x48) is enabled, TAP_SEL_PRE is updated automatically according to the status of the auto tuning circuit to adjust the sample clock phase.
23-20 TAP_SEL_OUT	Delay cells added on the feedback clock between CLK_PRE and CLK_OUT Reflects the number of delay cells added on the feedback clock between CLK_PRE and CLK_OUT.
19-16 TAP_SEL_POST	Delay cells added on the feedback clock between CLK_OUT and CLK_POST Reflects the number of delay cells added on the feedback clock between CLK_OUT and CLK_POST.
15 NXT_ERR	NXT error NXT error which means the number of delay cells added on the feedback clock is too large. It's valid only when SMP_CLK_SEL of Mix control register (bit23 of 0x48) is enabled.
14-8	delay cells on the feedback clock between the feedback clock and CLK_PRE

Table continues on the next page...

Field	Function
DLY_CELL_SET_PRE	Set the number of delay cells on the feedback clock between the feedback clock and CLK_PRE.
7-4 DLY_CELL_SET_OUT	Delay cells on the feedback clock between CLK_PRE and CLK_OUT Set the number of delay cells on the feedback clock between CLK_PRE and CLK_OUT.
3-0 DLY_CELL_SET_POST	Delay cells on the feedback clock between CLK_OUT and CLK_POST Set the number of delay cells on the feedback clock between CLK_OUT and CLK_POST.

23.5.1.27 Strobe DLL control (STROBE_DLL_CTRL)

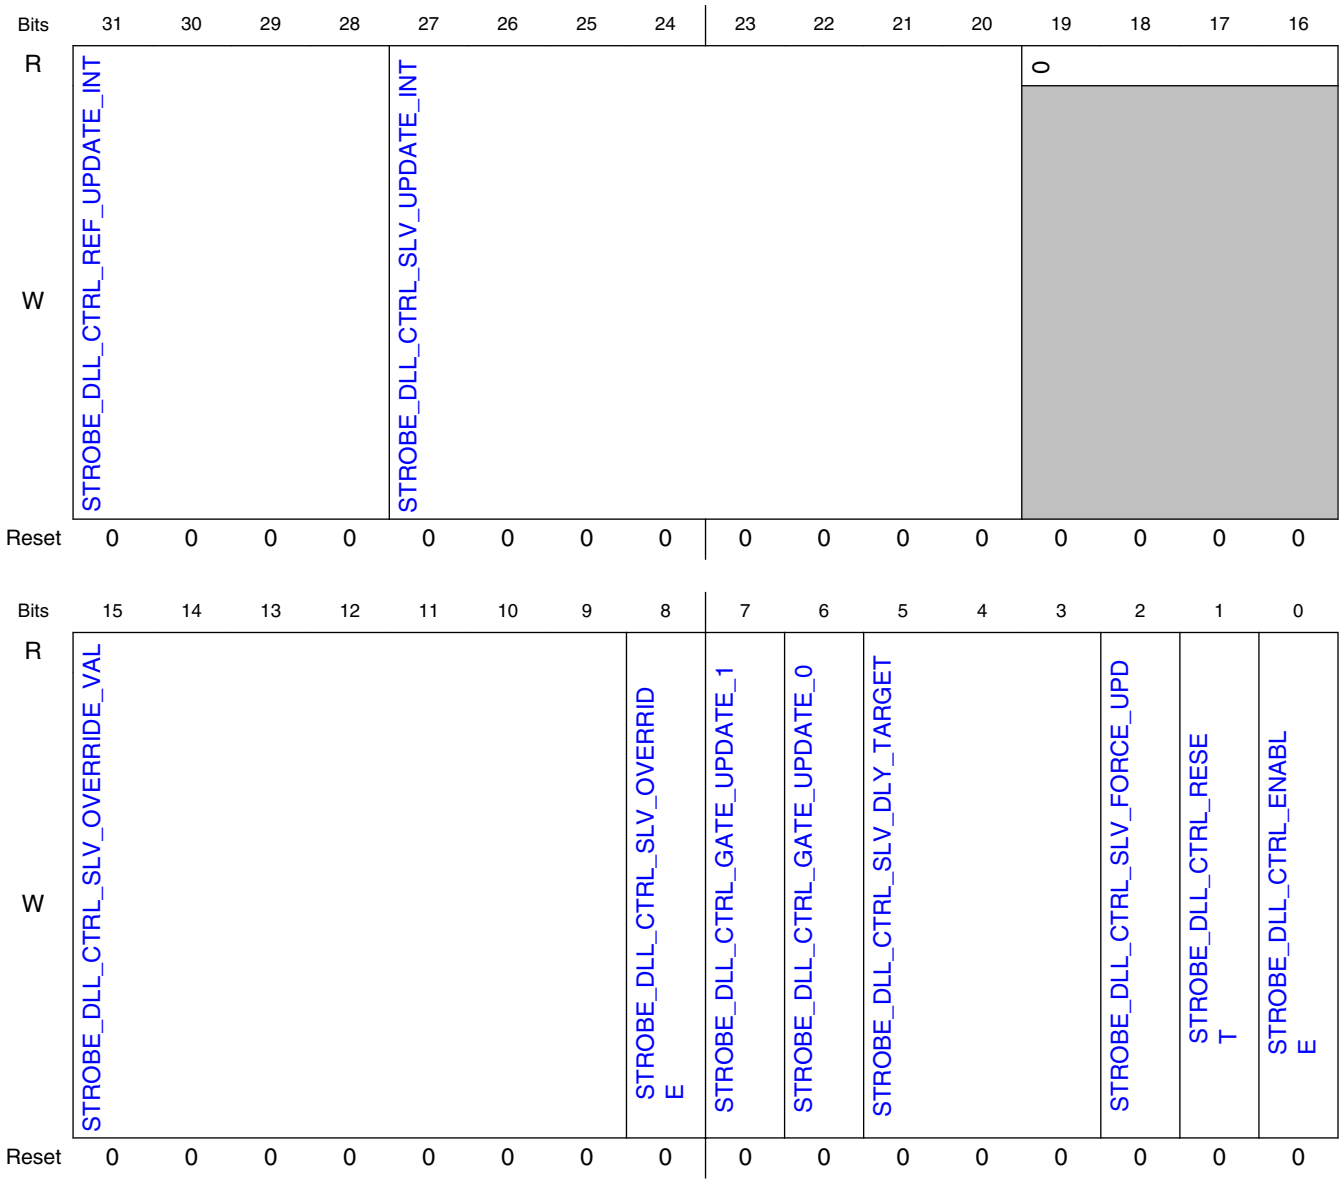
23.5.1.27.1 Offset

Register	Offset
STROBE_DLL_CTRL	70h

23.5.1.27.2 Function

This register contains the strobe DLL control information.

23.5.1.27.3 Diagram



23.5.1.27.4 Fields

Field	Function
31-28 STROBE_DLL_CTRL_REF_UPDATE_INT	Strobe DLL control reference update interval The interval cycle is (2 + STROBE_REF_UPDATE_INT) * STROBE_REF_CLOCK. By default, the DLL control loop updates every two STROBE_REF_CLOCK cycles. **NOTE:** Increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that might effect the delay (such as voltage and temperature)
27-20	Strobe DLL control slave update interval

Table continues on the next page...

Field	Function
STROBE_DLL_CTRL_SLV_UPDATE_INT	Slave delay line update interval. If default 0 is used, it means 256 cycles of STROBE_REF_CLOCK. A value of 0x0F results in 15 cycles and so on. **NOTE:** software can always cause an update of the slave-delay line using the STROBE_SLV_FORCE_UPDATE register. The slave delay line also updates automatically when the reference DLL transitions to a locked state (from an un-locked state).
19-16 —	This field is reserved. This read-only field is reserved and always has the value 0.
15-9 STROBE_DLL_CTRL_SLV_OVERRIDE_VAL	Strobe DLL control slave Override value When STROBE_SLV_OVERRIDE = 1, this field is used to manually select one of 128 physical taps. A value of 0 selects tap 1, and a value of 0x7F selects tap 128.
8 STROBE_DLL_CTRL_SLV_OVERRIDE	Strobe DLL control slave override Set this field to 1 to Enable manual override for slave delay chain using STROBE_SLV_OVERRIDE_VAL; set this field to 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE field. In fact to reduce power, if STROBE_SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE = 0.
7 STROBE_DLL_CTRL_GATE_UPDATE_1	Strobe DLL control gate update Set this field to 1 to prevent the DLL from updating (because when STROBE_CLOCK_IN exists, glitches might appear during DLL updates). This field can be used by software if such a condition occurs. Clear the field to 0 to allow the DLL to update automatically.
6 STROBE_DLL_CTRL_GATE_UPDATE_0	Strobe DLL control gate update Set this field to 1 to prevent the DLL from updating (because when STROBE_CLOCK_IN exists, glitches might appear during DLL updates). This field can be used by software if such a condition occurs. Clear the field to 0 to allow the DLL to update automatically.
5-3 STROBE_DLL_CTRL_SLV_DLY_TARGET	Strobe DLL Control Slave Delay Target The delay target for uSDHC loopback read clock can be programmed in 1/16th increments of an STROBE_REF_CLOCK half-period. The delay is ((STROBE_DLL_CTRL_SLV_DLY_TARGET + 1) * STROBE_REF_CLOCK / 2) / 16, So the input read-clock can be delayed relative input data from (STROBE_REF_CLOCK / 2) / 16 to (STROBE_REF_CLOCK *4)/16.
2 STROBE_DLL_CTRL_SLV_FORCE_UPD	Strobe DLL control slave force updated Setting this field to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line should automatically update the STROBE_SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if STROBE_SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when uSDHC is idle. This function might not work when uSDHC is working on data / cmd / response.
1 STROBE_DLL_CTRL_RESET	Strobe DLL control reset Setting this field to 1 to force a reset on DLL. This causes the DLL to lose lock and re-calibrate to detect an REF_CLOCK half period phase shift. This signal is used by the DLL as edge-sensitive, to create a subsequent reset, RESET must be taken low and then asserted again.
0 STROBE_DLL_CTRL_ENABLE	Strobe DLL control enable Set this field to 1 to enable the DLL and delay chain; otherwise, set to 0 to bypasses DLL. **NOTE:** Using the slave delay line override feature with STROBE_SLV_OVERRIDE and STROBE_SLV_OVERRIDE VAL, the DLL does not need to be enabled.

23.5.1.28 Strobe DLL status (STROBE_DLL_STATUS)

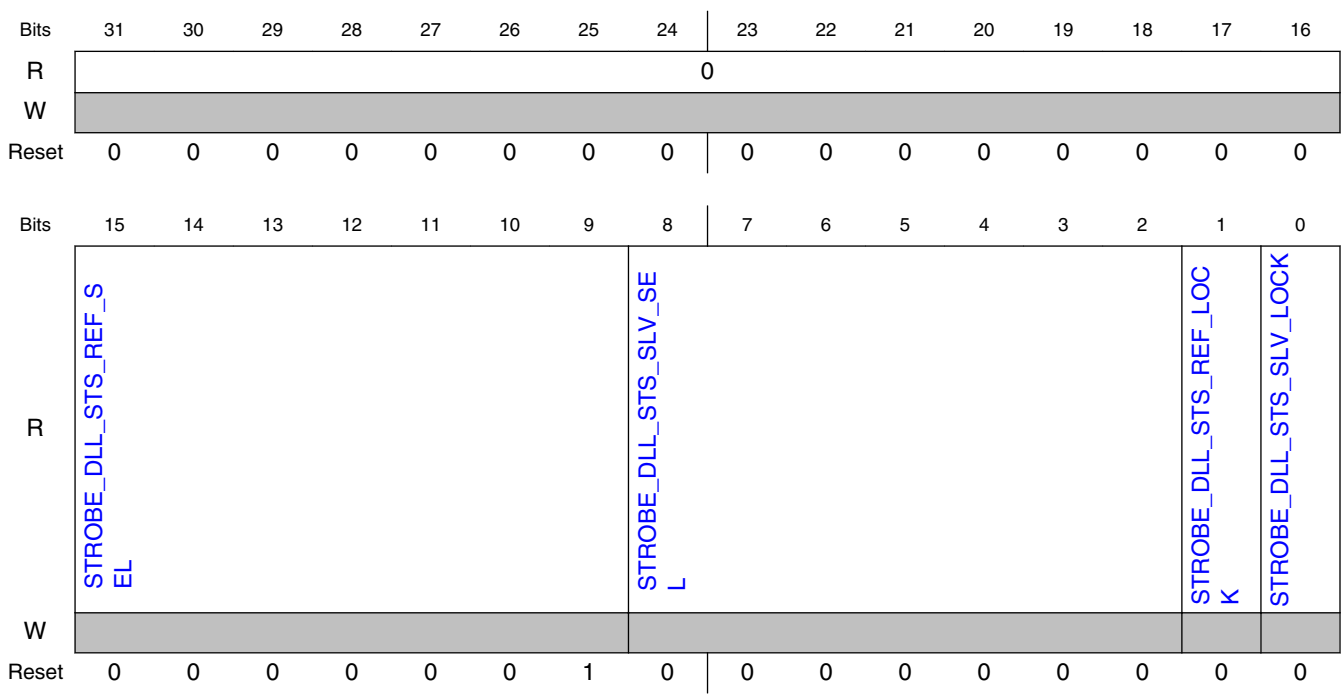
23.5.1.28.1 Offset

Register	Offset
STROBE_DLL_STATUS	74h

23.5.1.28.2 Function

This register contains the strobe DLL status information. All fields are read only and read the same as the power-reset value.

23.5.1.28.3 Diagram



23.5.1.28.4 Fields

Field	Function
31-16	This field is reserved.
—	This read-only field is reserved and always has the value 0.
15-9	Strobe DLL status reference select
	Reference delay line select taps. This is encoded by 7 fields for 127 taps.

Table continues on the next page...

Field	Function
STROBE_DLL_STS_REF_SEL	
8-2 STROBE_DLL_STS_SLV_SEL	Strobe DLL status slave select Slave delay line select status. This is the instant value generated from reference chain. Because the reference chain can only be updated when STROBE_REF_CLOCK is detected, this value can be updated with the right value when the reference is locked.
1 STROBE_DLL_STS_REF_LOCK	Strobe DLL status reference lock This signifies that the DLL has detected and locked to a half-phase REF_CLOCK shift, it allows the slave delay-line to perform programmed clock delays.
0 STROBE_DLL_STS_SLV_LOCK	Strobe DLL status slave lock Slave delay-line lock status. This signifies that a valid calibration has been set to the slave-delay line, and the slave-delay line is implementing the programmed delay value.

23.5.1.29 Vendor Specific Register (VEND_SPEC)

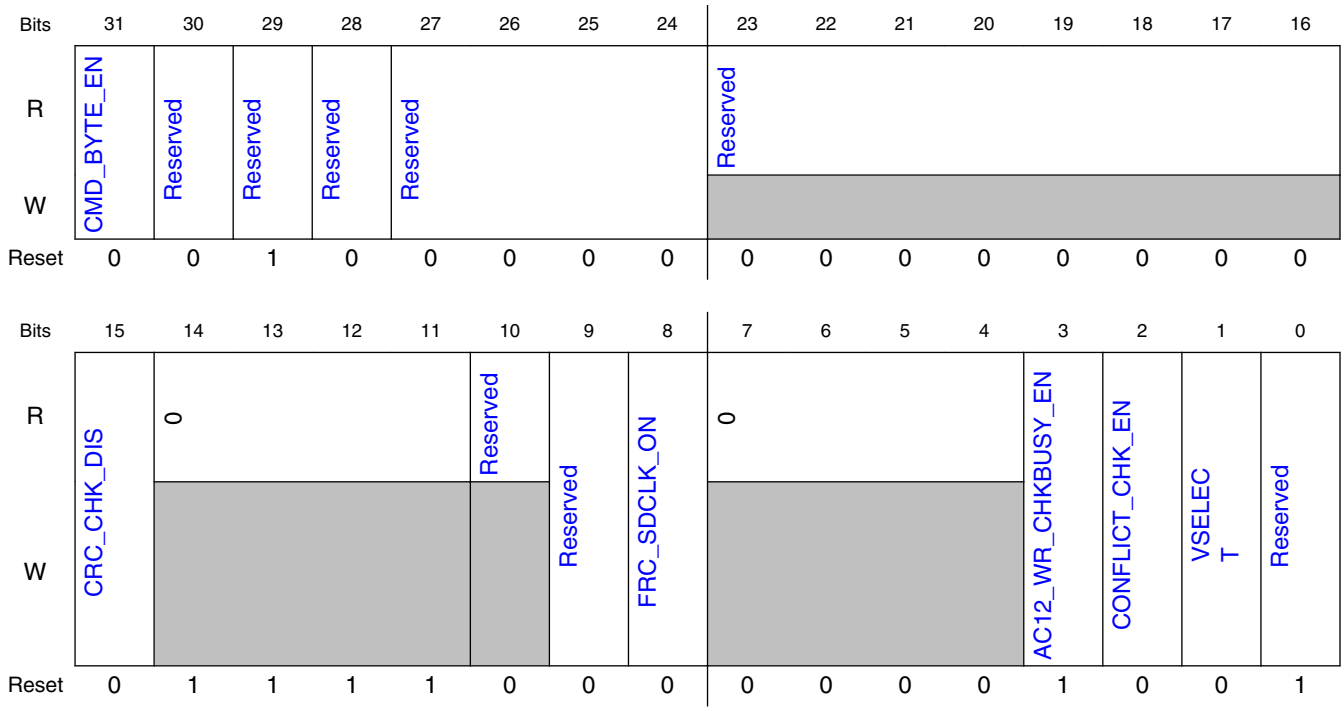
23.5.1.29.1 Offset

Register	Offset
VEND_SPEC	C0h

23.5.1.29.2 Function

This register contains the vendor specific control / status register.

23.5.1.29.3 Diagram



23.5.1.29.4 Fields

Field	Function
31 CMD_BYTE_EN	Byte access This bit controls the byte access. 0b - Disable 1b - Enable
30 —	Reserved Always write as 0.
29 —	Reserved Always write as 1
28 —	Reserved Always write as 0.
27-24 —	Reserved Always write as 4'b0000.
23-16 —	Reserved Always write as 8'h00.
15 CRC_CHK_DIS	CRC Check Disable 0b - Check CRC16 for every read data packet and check CRC fields for every write data packet 1b - Ignore CRC16 check for every read data packet and ignore CRC fields check for every write data packet

Table continues on the next page...

Field	Function
14-11 —	Reserved Reserved
10 —	Reserved Always write as 0.
9 —	Reserved Always write as 0.
8 FRC_SDCLK_ON	Force CLK Force CLK output active 0b - CLK active or inactive is fully controlled by the hardware. 1b - Force CLK active
7-4 —	Reserved
3 AC12_WR_CHKBUSY_EN	Check busy enable Check busy enable after auto CMD12 for write data packet 0b - Do not check busy after auto CMD12 for write data packet 1b - Check busy after auto CMD12 for write data packet
2 CONFLICT_CHK_EN	Conflict check enable It is not implemented in uSDHC IP. 0b - Conflict check disable 1b - Conflict check enable
1 VSELECT	Voltage selection Change the value of output signal VSELECT, to control the voltage on pads for external card. There must be a control circuit out of uSDHC to change the voltage on pads. 0b - Change the voltage to high voltage range, around 3.0 V 1b - Change the voltage to low voltage range, around 1.8 V
0 —	Reserved Always write as 0.

23.5.1.30 MMC Boot (MMC_BOOT)

23.5.1.30.1 Offset

Register	Offset
MMC_BOOT	C4h

23.5.1.30.2 Function

22-20 TUNING_WINDOW	Data window Select data window value for auto tuning
19 —	Reserved
18-16 TUNING_STEP	TUNING_STEP The increasing delay cell steps in tuning procedure.
15-8 TUNING_COUNTER	Tuning counter The MAX repeat CMD19 times in tuning procedure.
7-0 TUNING_START_TAP	Tuning start The start delay cell point when send first CMD19 in tuning procedure.

23.6 Functional description

The following sections provide a brief functional description of the major system blocks, including the data buffer, DMA AHB interface, register bank as well as IP Bus interface, dual-port memory wrapper, data/command controller, clock and reset manager, and clock generator.

23.6.1 Data buffer

The uSDHC module uses one configurable data buffer to transfer data between the system bus (IP bus or advanced high-performance bus (AHB) bus) and the SD card in an optimized manner, maximizing throughput between the two clock domains (IP peripheral clock and the master clock).

The buffer is used as a temporary storage for transferring data between the host system and the card. The watermark levels for read and write are both configurable and can range between 1 to 128 words. The burst lengths for read and write are also configurable and can range between 1 to 31 words. The next figure provides the uSDHC buffer scheme.

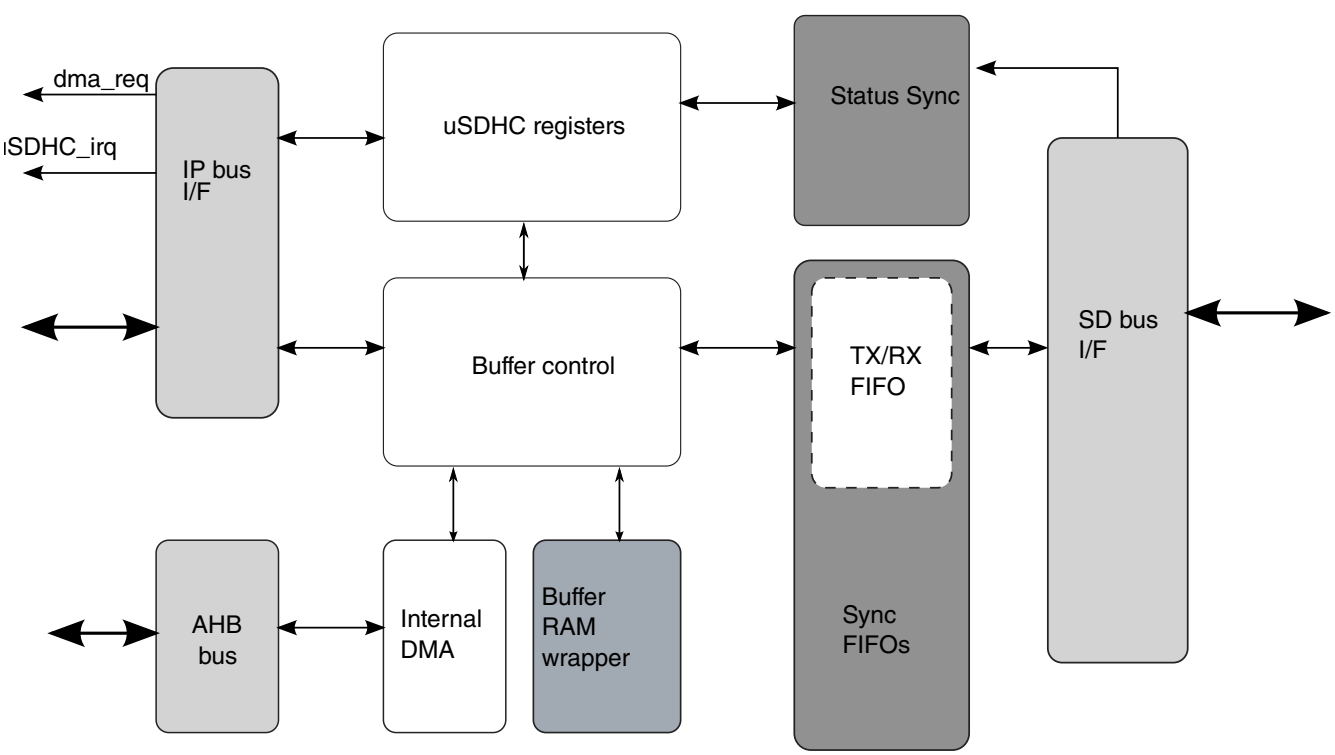

Figure 23-3. uSDHC buffer scheme

Here are 2 the two transfer modes to access the data buffer:

- CPU polling mode:
  - For a host-read operation, when the number of words received in the buffer meets or exceeds the RD_WML watermark value, by polling the BRR bit, the host driver can read the Buffer Data Port register to fetch the amount of words set in the RD_WML register from the buffer. The write operation is similar. For more information on the process of writing operation, see Write operation sequence.
- Internal DMA mode (includes simple and advanced DMA accesses):
  - The internal DMA access, either by simple or advanced DMA, is over the AHB bus.

For a read operation, when there are more words in the buffer than the amount set in the RD_WML register, the internal DMA starts fetching data over the AHB bus. Except for INCR4 and INCR8, the burst type is always the INCR mode and the burst length depends on the shortest of the following factors:

- Burst length configured in the burst length field of the Watermark Level register
- Watermark level boundary
- Block size boundary
- Data boundary configured in the current descriptor (if the ADMA is active)
- 1 KB address boundary defined in the AHB protocol

The Write operation functions in a similar manner—sequential and contiguous access is necessary to ensure that the pointer address value is correct. Random or skipped access is not possible. The byte order, by reset, is little endian mode. The actual byte order is swapped inside the buffer, according to the endian mode configured by software (see the following figures). For a host write operation, the byte order is swapped after the data is fetched from the buffer and ready to send to the SD Bus. For a host read operation, the byte order is swapped before the data is stored in the buffer.

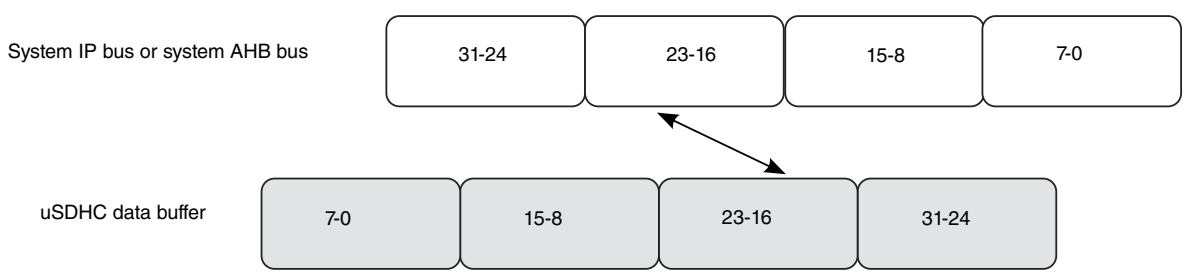

Figure 23-4. Data swap between system bus and uSDHC data buffer in the byte little endian mode

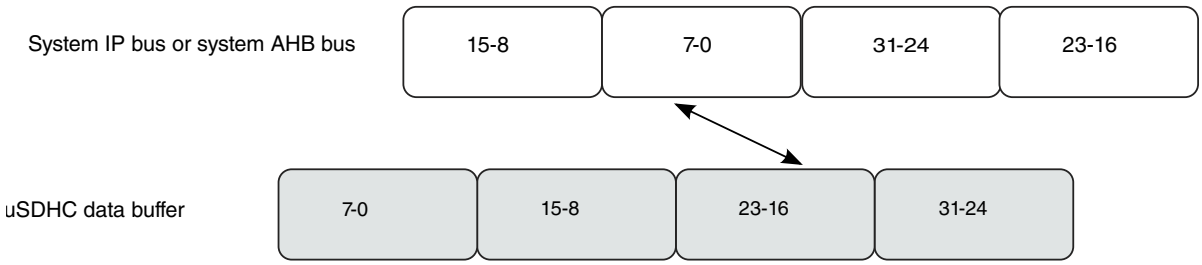

Figure 23-5. Data swap between system bus and uSDHC data buffer in half word big endian mode

23.6.1.1 Write operation sequence

There are 2 ways to write data into the buffer when the user transfers data to the card:

- Processor core polling through the BWR bit in the Interrupt Status register (interrupt or polling)
- Internal DMA

When the internal DMA is not used, the DMAEN bit in the Transfer Type register is not set when the command is sent, uSDHC asserts a DMA request when the amount of buffer space exceeds the value set in the WR_WML register and is ready for receiving new data. At the same time, uSDHC sets the BWR bit. The buffer write ready interrupt is generated if it is enabled by software.

When internal DMA is used, uSDHC does not inform the system before all the required number of bytes are transferred (if no error is encountered). When an error occurs during the data transfer, uSDHC aborts the data transfer and abandons the current block. The host driver should read the contents of the DMA System Address register to obtain the starting address of the abandoned data block. If the current data transfer is in multi-block mode, uSDHC does not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The host driver sends CMD12 in this scenario and restarts the write operation from that address. It is recommended that a software reset for Data be applied before the transfer is restarted.

The uSDHC module does not start data transmission until the number of words set in the WR_WML register can be held in the buffer. If the buffer is empty and the host system does not write data in time, uSDHC stops the CLK to avoid the data buffer underrun situation.

23.6.1.2 Read operation sequence

There are 2 ways to read data from the buffer when the user transfers data to the card:

- Processor core polling through the BRR bit in the Interrupt Status register (interrupt or polling)
- Internal DMA

When internal DMA is not used (DMAEN bit in Transfer Type register is not set when the command is sent), uSDHC asserts a DMA request when the amount of data exceeds the value set in the RD_WML register, which is available and ready for system fetching data. At the same time, uSDHC sets the BRR bit. The buffer read ready interrupt is generated if it is enabled by the software.

When internal DMA is used, uSDHC does not inform the system before all the required number of bytes are transferred (if no error is encountered). When an error occurs during the data transfer, uSDHC aborts the data transfer and abandons the current block. The host driver should read the content of the DMA System Address register to get the starting address of the abandoned data block. If the current data transfer is in multi-block mode, uSDHC does not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The host driver sends CMD12 in this scenario and restarts the read operation from that address. It is recommended that a software reset for data be applied before the transfer is restarted.

For any write transfer mode, uSDHC does not start data transmission until the number of words set in the RD_WML register are in buffer. If the buffer is full and the host system does not read data in time, uSDHC stops the CLK to avoid the data buffer overrun situation.

23.6.1.3 Data buffer and block size

The user needs to know the buffer size for the buffer operation during a data transfer to utilize it in the most optimized way. In the uSDHC module, the only data buffer can hold up to 128 words (32-bit) and the watermark levels for write and read can be configured accordingly.

For both read and write, the watermark level can range between 1 to 128 words. For both read and write, the burst length can range between from 1 to 31 words. The host driver may configure the value according to the system situation and requirement.

During a multi-block data transfer, the block length can be set to any value between 1 and 4096 bytes, satisfying the requirements of the external card. The only restriction is from the external card, which can be limited in size or support of a partial block access (which is not the integer times of 512 bytes).

As uSDHC treats each block individually, for block sizes which are not multiples of four (not word-aligned), stuffed bytes are required at the end of each block. For example, if the block size is 7 bytes and there are 12 blocks to write, the system side must write twice for each block. For each block, the ending byte is abandoned by uSDHC because it only sends 7 bytes to the card and picks data from the following system write, resulting in 24 beats of write access in total.

23.6.1.4 Dividing large data transfer

This SDIO command CMD53 definition limits the maximum data size of data transfers according to the following formula:

Max data size = Block size x Block count

The length of a multiple block transfer needs to be in block size units. If the total data length cannot be divided evenly into a multiple of the block size, then there are two ways to transfer the data. These two ways depend on the function and the card design. Option 1 is for the host driver to split the transaction. The remainder of the block size data is then transferred by using a single block command at the end. Option 2 is to add dummy data in the last block to fill the block size. For option 2, the card must manage the removal of the dummy data.

See the figure below for an example showing the division of large data transfers, assuming a kind of WLAN SDIO card that only supports a block size of up to 64 bytes. Although uSDHC supports a block size of up to 4096 bytes, the SDIO can only accept a block size of less than 64 bytes, so the data must be divided (see the example below).

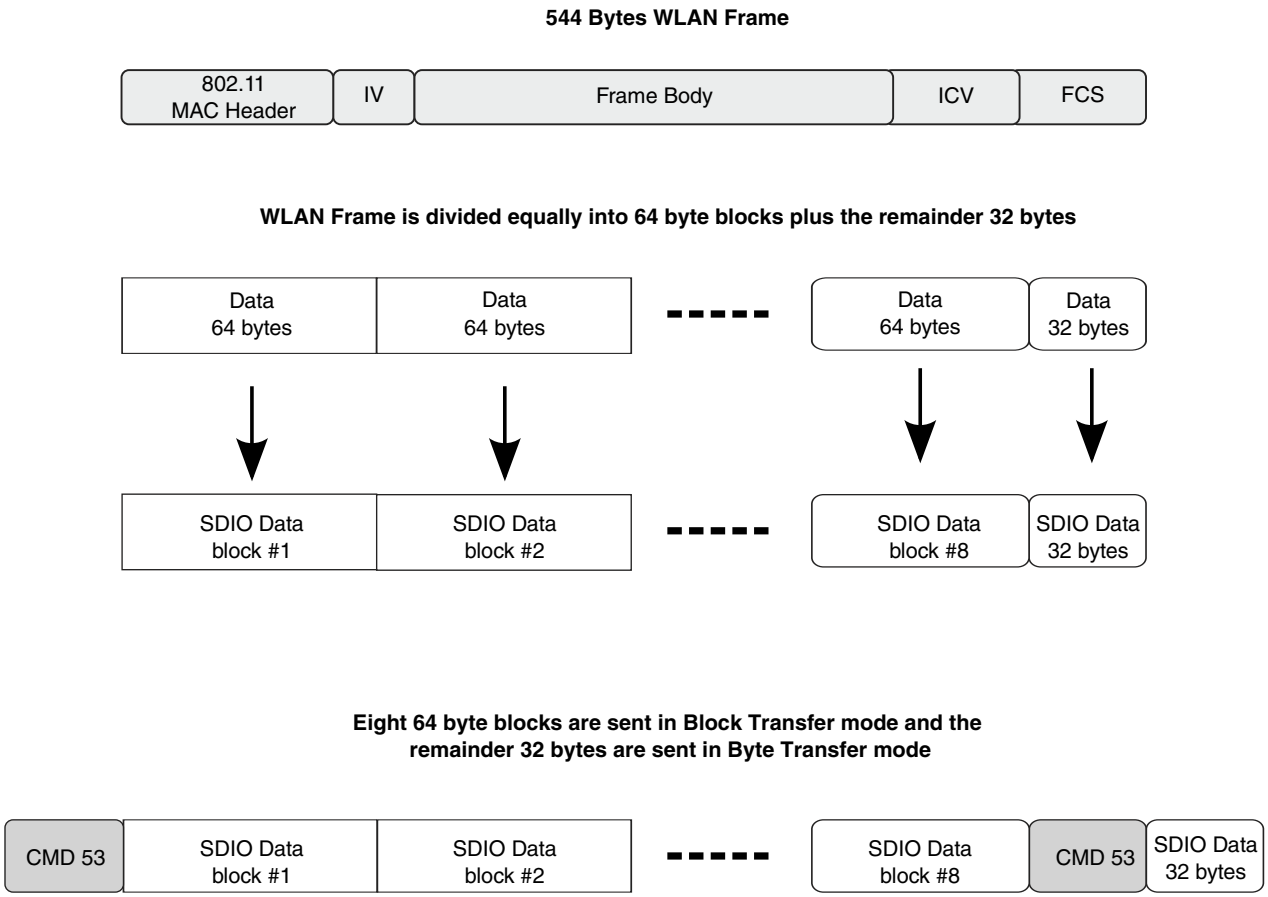

Figure 23-6. Example for dividing large data transfers

23.6.2 DMA AHB interface

The internal DMA implements a DMA engine and the AHB master. When the internal DMA is enabled, the uSDHC_dreq_b is not asserted during the transfer, but the BWR and BRR bits are set if the BWRSEN and BRRSEN bits have been set in the Interrupt Status Enable register.

See the figure below for an illustration of the DMA AHB interface block.

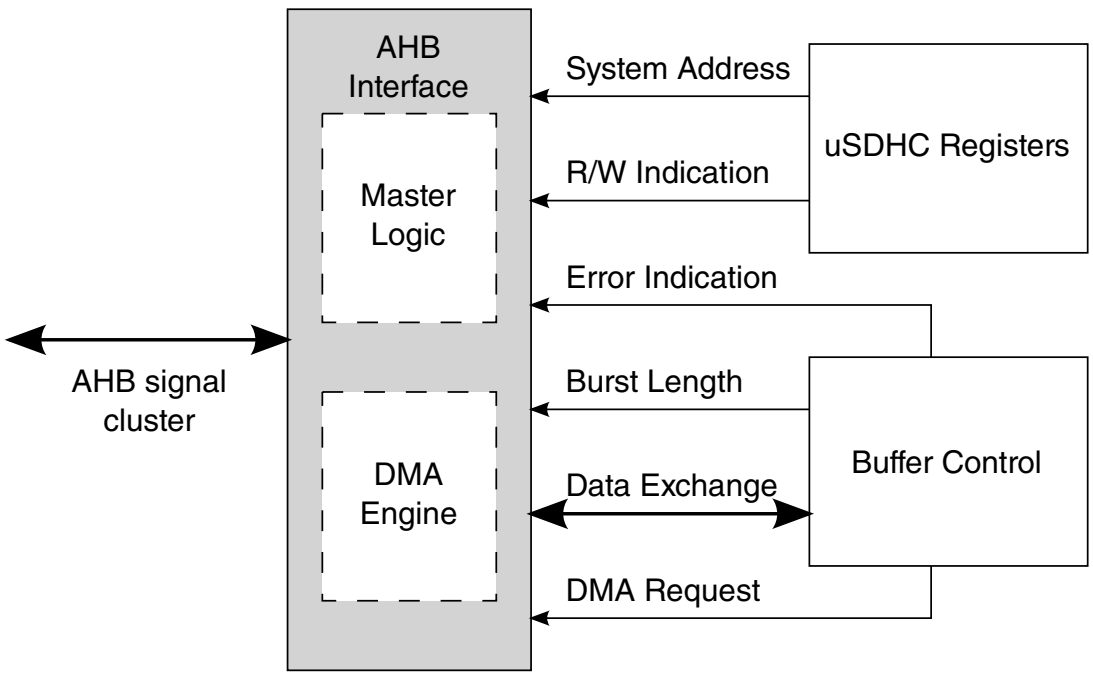

Figure 23-7. DMA AHB interface block

23.6.2.1 Internal DMA request

If the watermark level requirement is met in data transfer or if the last data of current block is ready in the data buffer, and the Internal DMA is enabled, the data buffer block sends a DMA request to AHB interface.

The delay in response from the internal DMA engine depends on the system AHB bus loading and the priority assigned to uSDHC. The DMA engine does not respond to the request during its burst transfer, but is ready to serve as soon as the burst is over. The data buffer de-asserts the request if the data buffer space (for write) or bytes in data buffer is smaller than the watermark level. Upon access to the buffer by internal DMA, the data buffer updates its internal buffer pointer, and when the watermark level is satisfied or the last data of the current block is ready in the data buffer, another DMA request is sent.

The data transfer is in the block unit, and the subsequent watermark level is always set as the remaining number of words. For instance, for a multi block data read with each block size of 31 bytes, and the burst length set to six words. After the first burst transfer, if there are more than two words in the buffer, which might contain some data of the next block), another DMA request is sent. This is because the remaining number of words to send for the current block is (31 - 6 * 4) / 4 = 2. The uSDHC module reads two words out of the buffer, with seven valid bytes and one stuffed byte.

23.6.2.2 DMA burst length

Just like a CPU polling access, the DMA burst length for the internal DMA engine can range between 1 to 16 words. The actual burst length for the DMA depends on the lesser of the configured burst length or the remaining words of the current block.

See the example in Internal DMA request. After six words are read, the burst length is two words, then the next burst length is six words. This is because the next block starts, which is 31 bytes, more than six words. The host driver may take this variable burst length into account. It is also acceptable to configure the burst length as the divisor of the block size, so that each time the burst length is the same.

23.6.2.3 AHB master interface

It is possible that the internal AHB DMA engine could fail during the data transfer. Upon detection of an AHB bus error during DMA transfer, the DMA engine stops the transfer and goes to the idle state. At that point, the internal data buffer stops receiving incoming data and sending out data. The DMAE bit in the Interrupt Status register is generated to host CPU to report a bus error condition.

After the DMAE interrupt is received, the software sends a CMD12 to abort the current transfer and read the DS_ADDR bits of the DMA System Address register to get the starting address of the corrupted block. After the DMA error is fixed, the software should apply a data reset and restart the transfer from this address to recover the corrupted block. DMA operation resumes when the interrupt is serviced by the software.

23.6.2.4 ADMA engine

In the SD host controller standard, a new DMA transfer algorithm called the Advanced DMA (ADMA) is defined. For simple DMA, after the page boundary is reached, a DMA interrupt is generated and the new system address is programmed by the host driver.

The ADMA defines the programmable descriptor table in the system memory. The host driver can calculate the system address at the page boundary and program the descriptor table before executing ADMA. It reduces the frequency of interrupts to the host system. Therefore, higher speed DMA transfers could be realized because the host MCU intervention is not be needed during long DMA-based data transfers.

There are two types of ADMA in host controller: ADMA1 and ADMA2. ADMA1 can support data transfer of 4KB aligned data in system memory, and ADMA2 improves the restriction so that the data of any location and any size can be transferred in system memory. Their formats of Descriptor Table are different.

ADMA can recognize all kinds of descriptors defined in SD host controller Standard, and if the "End" flag is detected in the descriptor, ADMA stops after this descriptor is processed.

23.6.2.4.1 ADMA concept and descriptor format

ADMA1 includes the following descriptors:

- Valid/invalid descriptor
- Nop descriptor
- Set data length descriptor
- Set data address descriptor
- Link descriptor
- Interrupt flag and end flag in descriptor

ADMA2 includes the following descriptors:

- Valid/invalid descriptor
- Nop descriptor
- Rsv descriptor
- Set data length and address descriptor
- Link descriptor
- Interrupt flag and end flag in descriptor

ADMA starts read/write operation after it reaches the tran state, using the data length and data address analyzed from most recent descriptor(s).

For ADMA1, the valid data length descriptor is the last set type descriptor before the tran type descriptor. Every tran type triggers a transfer, and the transfer data length is extracted from the most recent set type descriptor. If there is no set type descriptor after the previous Trans descriptor, the data length is the value for previous transfer, or 0 if no set descriptor is ever met.

For ADMA2, the tran type descriptor contains both data length and transfer data address, so only a tran type descriptor can start a data transfer.

See the figure below for the format of the descriptor table for ADMA1.

Address/ Page Field		Address/ Page Field		Attribute Field					
31	12	11	6	5	4	3	2	1	0
Address or Data Length		000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	31- 28	27- 12
0	0	Nop	No Operation	Don't Care	
0	1	Set	Set Data Length	0000	Data Length
1	0	Tran	Transfer Data	Data Address	
1	1	Link	Link Descriptor	Descriptor Address	

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 23-8. Format of the ADMA1 descriptor table

See the figure below for the concept and access method of the descriptor table for ADMA1.

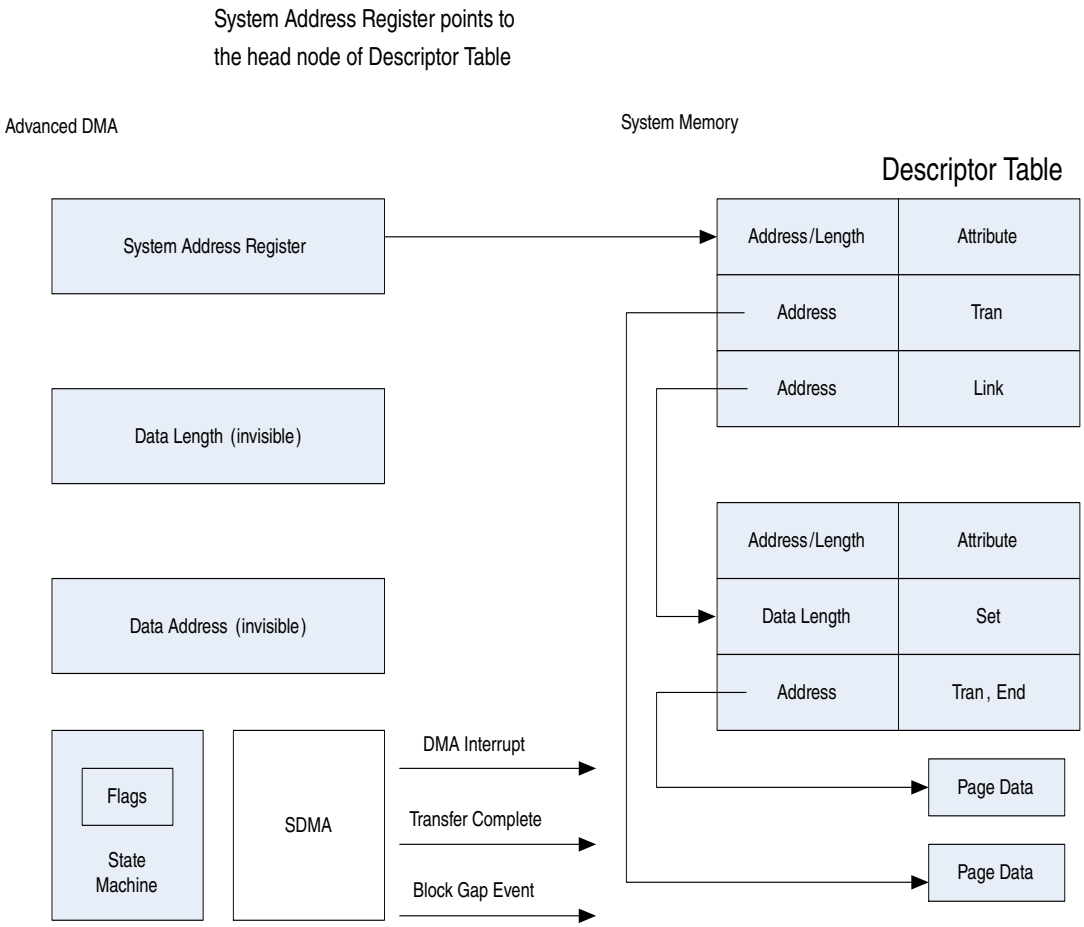

Figure 23-9. Concept and access method of the ADMA1 descriptor table

The figure below explains the ADMA2 format. ADMA2 deals with the lower 32-bit first, and then the higher 32-bit. If the 'Valid' flag of descriptor is 0, it ignores the higher 32-bit. The Address field should be set to word aligned (lower 2-bit is always set to 0). Data length is in byte unit.

Address Field		Length		Reserved		Attribute Field					
63	32	31	16	15	06	05	04	03	02	01	00
32-bit Address		16-bit length		0000000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	Operation
0	0	Nop	No Operation	Don't Care
0	1	Rsv	Reserved	Same as Nop. Read this line and go to next one
1	0	Tran	Transfer Data	Transfer data with address and length set in this descriptor line
1	1	Link	Link Descriptor	Link to another descriptor

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 23-10. Format of the ADMA2 descriptor table

See the figure below for the concept and access method of the descriptor table for ADMA2.

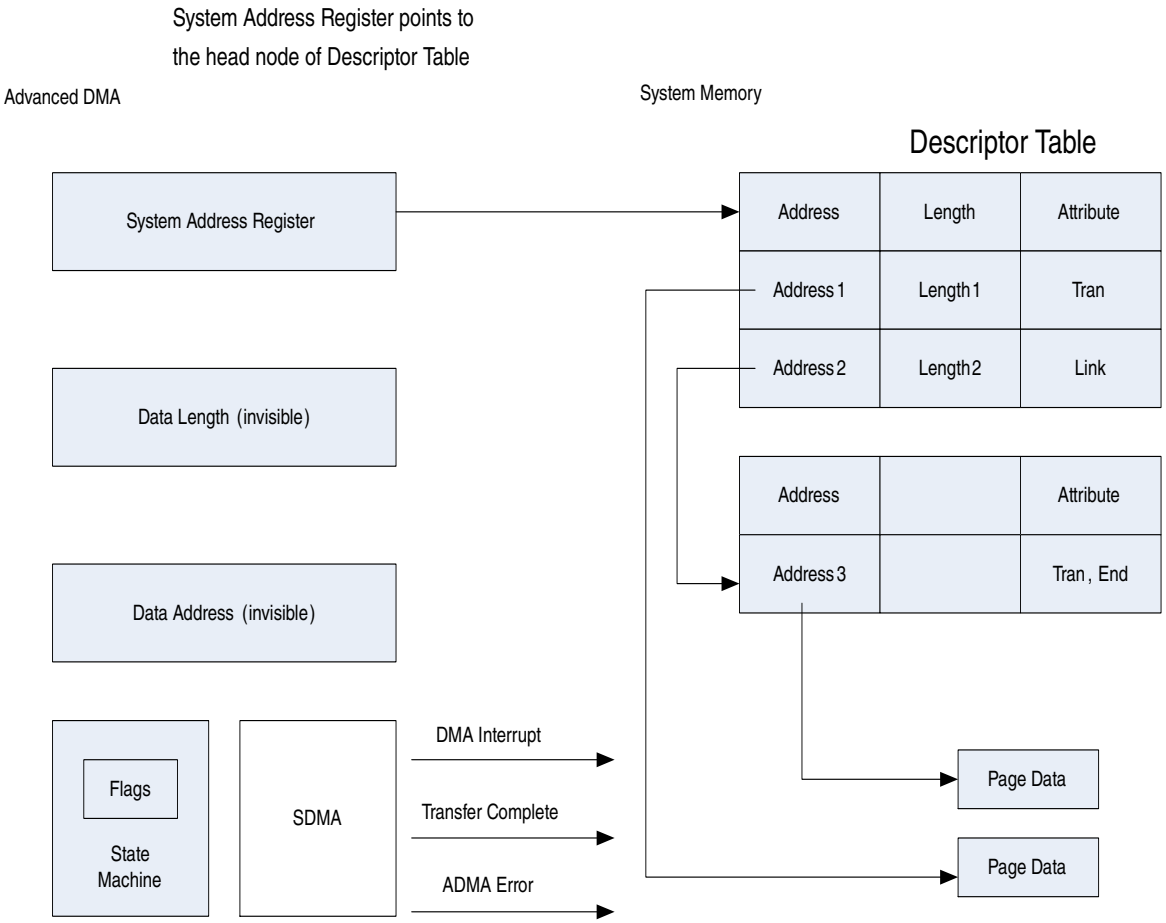

Figure 23-11. Concept and access method of the ADMA2 descriptor table

23.6.2.4.2 ADMA interrupt

If the interrupt flag descriptor is set, ADMA generates an interrupt according to various types of descriptors.

For ADMA1:

- Set type of descriptor: interrupt is generated when data length is set.
- Tran type descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop type of descriptor: interrupt is generated just after this descriptor is fetched.

For ADMA2:

- Tran type of descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop/Rsv type of descriptor: interrupt is generated just after this descriptor is fetched.

23.6.2.4.3 ADMA error

The ADMA stops whenever an error is encountered. These errors include:

- Fetching descriptor error
- AHB response error
- Data length mismatch error

An ADMA descriptor error is generated when it fails to detect a "valid" flag in the descriptor. If an ADMA descriptor error occurs, the interrupt is not generated even if the "Interrupt" flag of this descriptor is set.

When BLKCNTEN bit is set, data length set in buffer must be equal to the whole data length set in descriptor nodes, otherwise data length mismatch error is generated.

When BLKCNTEN bit is not set, then the whole data length set in descriptor is a multiple of block lengths; otherwise, when data set in the descriptor nodes are not performed at block boundaries, then data mismatch errors occur.

23.6.3 Register bank with IP bus interface

Register accesses through the IP bus interface are on the register bank.

See the figure below for the block diagram.

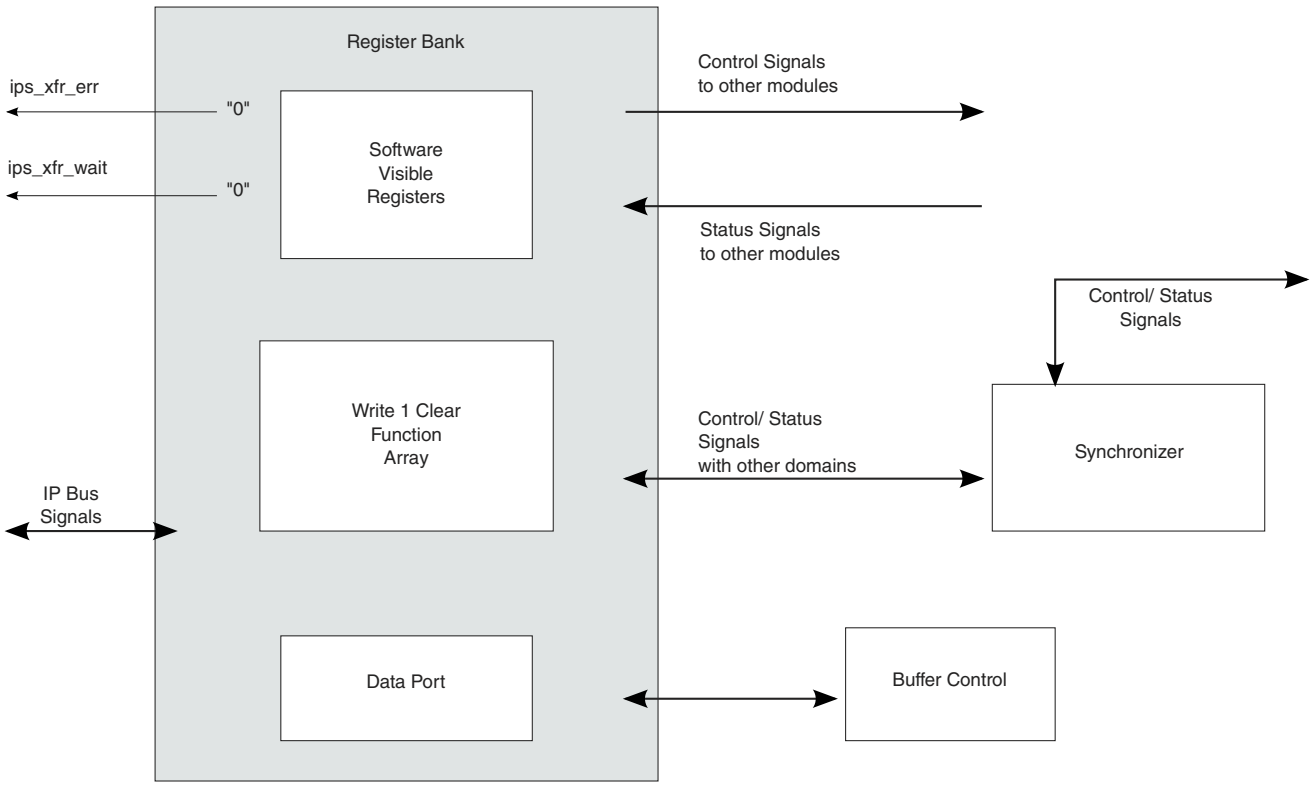

Figure 23-12. Register bank diagram

Only a 32-bit access is allowed, and no partial read/write is supported; therefore, all accesses are word aligned.

23.6.3.1 SD protocol unit

The SD protocol unit deals with all SD protocol affairs.

The SD protocol unit performs the following functions:

- Acts as the bridge between the internal buffer and the SD bus
- Sends the command data as well as its argument serially
- Stores the serial response bit stream into corresponding registers
- Detects the bus state on the CMD/DAT lines
- Monitors the interrupt from the SDIO card
- Asserts the read wait signal
- Gates off the SD clock when buffer is announcing danger status
- Detects the write protect state

The SD protocol unit consists of four submodules:

- SD control misc

- Command control
- Data control
- Clock control

23.6.3.2 SD control misc

In the SD control misc unit, the card detection (including the CD_B and DATA3 used for card detection), write protection, and card interrupt are implemented.

This module monitors the signal level on all the eight data lines and the command lines. It directly routes the level values into the register bank.

The module also detects the Write Protect (WP) line. If WP is active, writes to the register bank are ignored.

This module also drives the LCTL output signal when the LCTL bit is set by the driver.

23.6.3.3 SD clock control

If the internal data buffer is near full (for read) or near empty (for write), the SD clock must be gated off to avoid buffer over/under-run. This module asserts the gate of the output SD clock to shut the clock off. After the buffer has space (for read) or has data (for write), the clock gate of this module opens, and the SD clock is active again.

23.6.3.4 Command control

The Command Control module deals with the transactions on the CMD line.

See the figure below for an illustration of the structure for the Command CRC shift register.

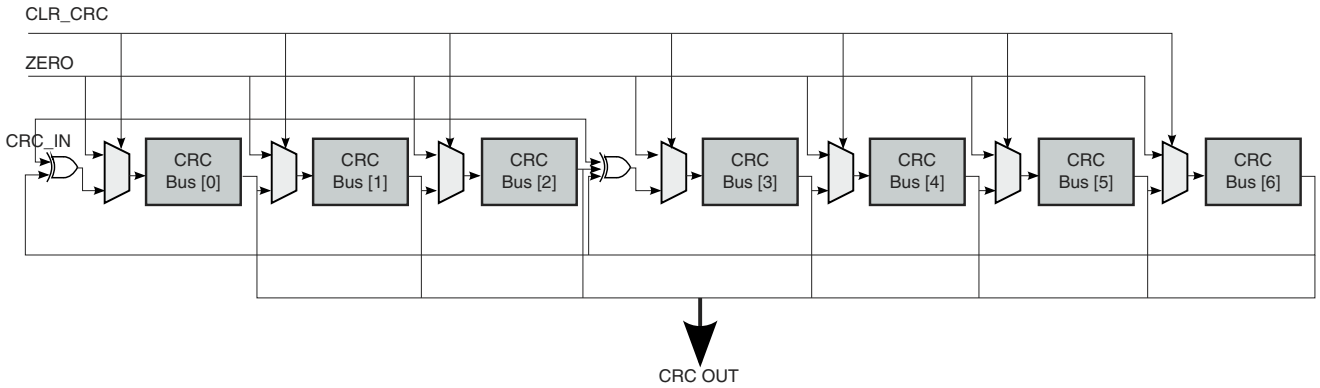

Figure 23-13. Command CRC shift register

The CRC polynomials for the CMD are as follows:

```
Generator polynomial: G(x) = x^7 + x^3 + 1
M(x) = (first bit) * x^n + (second bit) * x^n-1 +...+ (last bit) * x^0
CRC[6:0] = Remainder [(M(x) * x^7) / G(x)]
```

23.6.3.5 Data control

The data agent deals with the transactions on the eight data lines. Moreover, this module also detects the busy state on the DATA0 line, and generates the read wait state by the request from the transceiver.

The CRC polynomials for the data are as follows:

```
Generator polynomial: G(x) = x^16 + x^12 + x^5 +1
M(x) = (first bit) * x^n + (second bit) * x^n-1 +...+ (last bit) * x^0
CRC[15:0] = Remainder [(M(x) * x^16) / G(x)]
```

23.6.4 Clock and reset manager

This module controls all four kinds reset signals within uSDHC:

- Hardware reset
- Software reset for all logic
- Software reset for the data logic
- Software reset for the command logic

All these signals are fed into this module and stable signals are generated inside the module to reset all other modules. The module also gates off all the inside signals.

23.6.5 Clock generator

The clock generator generates the card CLK by peripheral source clock in two stages. The clock divisor can be configured through register SYS_CTRL [SDCLKFS] is for prescaler configuration while the [DVS] is for divisor configuration. Details can be found in the register function description. See the following figure for the structure of the divider. The term "Base" represents the frequency of peripheral source clock.

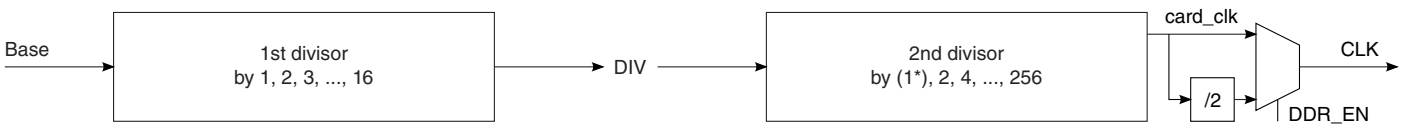

Figure 23-14. Two stages of the clock divider

The first stage outputs an intermediate clock (DIV) that can be Base, Base/2, Base/3, ..., or Base/16.

The second stage is a prescaler and outputs the actual internal working clock (card_clk). This clock is the driving clock for all the sub modules of the SD protocol unit, and helps in syncing FIFOs (see Figure 23-3) to synchronize with the data rate from the internal data buffer. The frequency of the clock output from this stage can be DIV, DIV/2, DIV/4,..., or DIV/256. Therefore, the highest frequency of the card_clk is base, and the next highest is Base/2, while the lowest frequency is Base/4096. If the duty cycle of the base clock is 50%, the duty cycle of card_clk is also 50%, even when the compound divisor is an odd value.

NOTE

CLK is different for the SDR and DDR modes.

- In the SDR mode, CLK is equal to the internal working clock (card_clk).
- In the DDR mode, CLK is equal to card_clk/2.

23.6.6 SDIO card interrupt

Information on interrupts in 1-bit mode, interrupts in 4-bit mode, and card interrupt handling are detailed in the sections below.

23.6.6.1 Interrupts in 1-bit mode

In this case, the DATA1 pin provides the interrupt function. An interrupt is asserted by pulling the DATA1 low from the SDIO card, until the interrupt service is finished to clear the interrupt.

23.6.6.2 Interrupt in 4-bit mode

As the interrupt and data line 1 share pin 8 in a 4-bit mode, an interrupt is only sent by the card and recognized by the host during a specific time. This is known as the interrupt period. The uSDHC module only provides sample the level on pin 8 during the interrupt period. At all other times, the host ignores the level on pin 8 and treats it as the data signal. The definition of the interrupt period is different for operations with single block and multiple block data transfers.

In the case of normal single data block transmissions, the interrupt period becomes active two clock cycles after the completion of a data packet. This interrupt period lasts until after the card receives the end bit of the next command that has a data block transfer associated with it.

For multiple block data transfers in a 4-bit mode, there is only a limited period of time that the interrupt period can be active because of the limited period of data line availability between the multiple blocks of data. This requires stricter definition of the interrupt period. For this case, the interrupt period is limited to two clock cycles. This begins two clocks after the end bit of the previous data block. During this 2-clock cycle interrupt period, if an interrupt is pending, the DATA1 line holds low for one clock cycle with the last clock cycle pulling DATA1 high. On completion of the interrupt period, the card releases the DATA1 line into the high Z state. The uSDHC module provides sample of the DATA1 during the interrupt period when the IABG bit in the Protocol Control register is set.

Refer to SDIO Card Specification v1.10 for further information about the SDIO card interrupt.

23.6.6.3 Card interrupt handling

When the CINTIEN bit in the Interrupt Signal Enable Register is set to 0, uSDHC clears the interrupt request to the host system. The host driver should clear this bit before servicing the SDIO interrupt and should set this bit again after all interrupt requests from the card are cleared to prevent inadvertent interrupts.

The SDIO Card Interrupt Status can be cleared by writing 1 to this bit. But as the interrupt source from the SDIO card does not clear, this bit is set again. To clear this bit, it is required to reset the interrupt source from the external card followed by writing 1 to this bit. In a 1-bit mode, uSDHC detects the SDIO interrupt with or without the SD clock (to support wakeup). In a 4-bit mode, the interrupt signal is sampled during the interrupt period, so there are some sample delays between the interrupt signal from the SDIO card and the interrupt to the Host System Interrupt Controller. When the SDIO status is set and the host driver needs to service this interrupt, the SDIO bit in the Interrupt Control Register of SDIO card is cleared. This is required to clear the SDIO interrupt status latched in uSDHC and to stop driving the interrupt signal to the System Interrupt Controller. The host driver must issue a CMD52 to clear the card interrupt. After completion of the card interrupt service, the SDIO Interrupt Status Enable bit is set to 1 and uSDHC starts sampling the interrupt signal again.

See the figure below for an illustration of the SDIO card interrupt scheme and for the sequences of software and hardware events that take place during a card interrupt handling procedure.

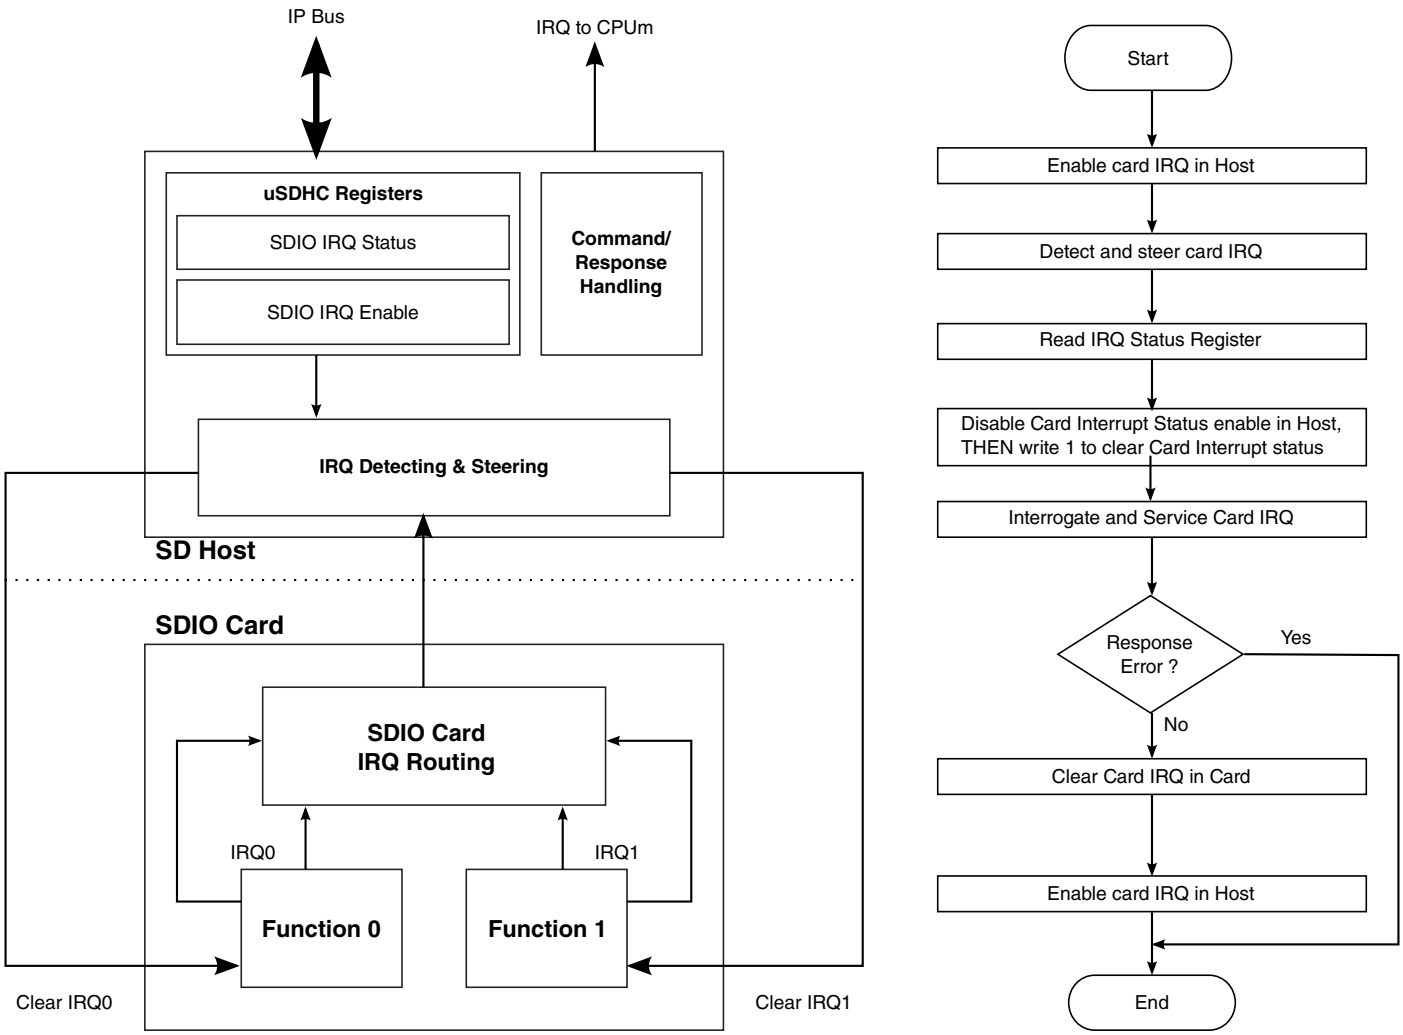

Figure 23-15. Card interrupt scheme, card interrupt detection, and handling procedure

23.6.7 Card insertion and removal detection

The uSDHC module uses either the DATA3 pin or the CD_B pin to detect card insertion or removal. When there is no card on the MMC/SD bus, the DATA3 is pulled to a low voltage level by default.

When any card is inserted to or removed from the socket, uSDHC detects the logic value changes on the DATA3 pin and generates an interrupt. When the DATA3 pin is not used for card detection (for example, it is implemented in GPIO), the CD_B pin must be connected for card detection. Whether DATA3 is configured for card detection or not, the CD_B pin is always a reference for card detection. Whether the DATA3 pin or the CD_B pin is used to detect card insertion, uSDHC sends an interrupt (if enabled) to inform the Host system that a card is inserted.

23.6.8 Power management and wakeup events

When there is no operation between uSDHC and the card through the SD bus, the user can completely disable the peripheral clock and base clock in the chip-level clock control module to save power. When the user needs to use uSDHC to communicate with the card, it can enable the clock and start the operation.

In some circumstances, when the clocks to uSDHC are disabled, for instance, when the system is in low-power mode, there are some events for which the user needs to enable the clock and handle the event. These events are called wakeup interrupts. The uSDHC module can generate these interrupts even when there are no clocks enabled. The three interrupts that can be used as wakeup events are these:

- Card removal interrupt
- Card insertion interrupt
- Interrupt from SDIO card

The uSDHC module offers a power management feature. By clearing the clock enabled bits in the System Control register, the clocks are gated in the low position to uSDHC. For maximum power saving, the user can disable all the clocks to uSDHC when there is no operation in progress.

These three wakeup events (or wakeup interrupts) can also be used to wakeup the system from low-power modes.

NOTE

To make the interrupt a wakeup event, when all the clocks to uSDHC are disabled or when the entire system is in low power mode, the corresponding wakeup enabled bit needs to be set. Refer to Protocol Control (PROT_CTRL) for more information on the uSDHC Protocol Control register.

23.6.8.1 Setting wakeup events

For uSDHC to respond to a wakeup event, the software must set the respective wakeup enable bit before the CPU enters the sleep mode.

Before the software disables the host clock, it should ensure that all the following conditions have been met:

- No read or write transfer is active
- Data and command lines are not active

- No interrupts are pending
- Internal data buffer is empty

23.6.9 MMC fast boot

The Embedded MultiMediaCard (eMMC4.3) specification adds a fast boot feature that requires hardware support. There are two types of fast boot modes in the eMMC4.3 specification: boot operation and alternative boot operation in the eMMC4.3 specification. Each type also has with-acknowledge and without-acknowledge modes.

In the boot operation mode, the master (MultiMediaCard host) can read boot data from the slave (MMC device) by keeping CMD line low after power-on, or sending CMD0 with argument + 0xFFFFFFFA (optional for slave), before issuing CMD1.

NOTE

For the eMMC4.3 card setting, please see the eMMC4.3 specification.

23.6.9.1 Boot operation

If the CMD line is held low for 74 clock cycles and more after power-up before the first command is issued, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within one second after the CMD line goes low, the slave starts to send the first boot data to the master on the DATA line(s). The master must keep the CMD line low to read all of the boot data.

NOTE

For the purposes of this documentation, fast boot is called "normal fast boot mode".

If boot acknowledge is enabled, the slave has to send acknowledge pattern '010' to the master within 50ms after the CMD line goes low. If boot acknowledge is disabled, the slave does not send out acknowledge pattern '010'.

The master can terminate the boot mode with the CMD line high.

The boot operation is terminated when all the contents of the enabled boot data are sent to the master. After the boot operation is executed, the slave gets ready for the CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

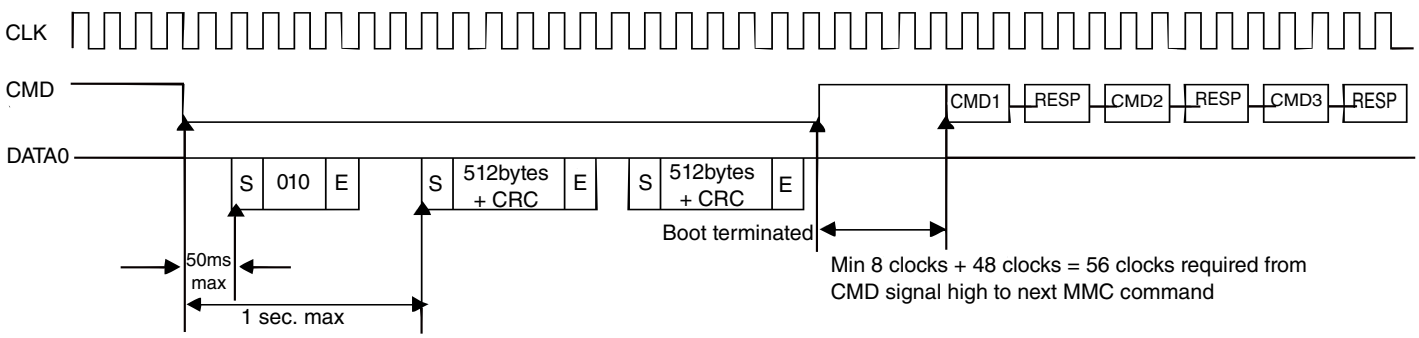

Figure 23-16. MultiMediaCard state diagram (normal boot mode)

23.6.9.2 Alternative boot operation

This boot function is optional for the device. If bit 0 in the extended CSD byte[228] is set to '1', the device supports the alternative boot operation.

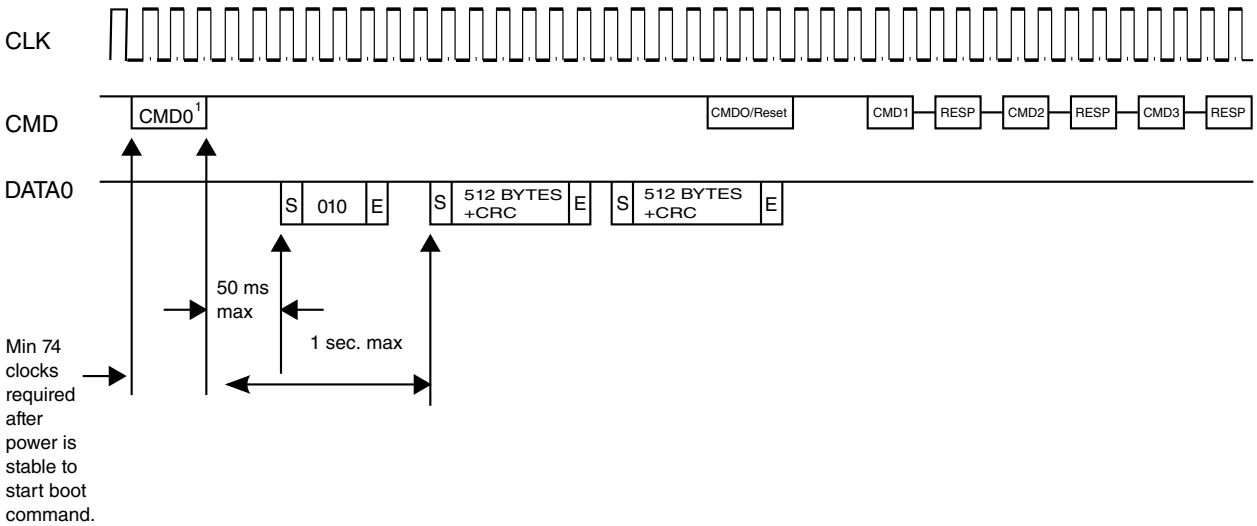
After power-up, if the host issues CMD0 with the argument of 0xFFFFFFFA after 74 clock cycles, before CMD1 is issued or the CMD line goes low, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within one second after CMD0 with the argument of 0xFFFFFFFA is issued, the slave starts to send the first boot data to the master on the DATA line(s).

If boot acknowledge is enabled, the slave has to send the acknowledge pattern '010' to the master within 50ms after the CMD0 with the argument of 0xFFFFFFFA is received. If boot acknowledge is disabled, the slave does not send out acknowledge pattern '010'.

The master can terminate the boot mode by issuing CMD0 (Reset).

Boot operation is terminated when all the contents of the enabled boot data are sent to the master. After the boot operation is executed, the slave gets ready for the CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.



NOTE 1. CMD0 with argument 0xFFFFFFFA

Figure 23-17. MultiMediaCard state diagram (alternative boot mode)

23.7 Initialization/application of uSDHC

All communication between the system and cards are controlled by the host. The host sends commands of two types: broadcast and addressed (point-to-point).

Broadcast commands are intended for all cards, such as GO_IDLE_STATE, SEND_OP_COND, and ALL_SEND_CID. In the Broadcast mode, all cards are in the open-drain mode to avoid bus contention. Refer to Commands for MMC/SD/SDIO for the commands of bc and bcr categories.

After the broadcast command CMD3 is issued, the cards enter the standby mode. Addressed type commands are used from this point. In this mode, the CMD/DATA I/O pads turns to the push-pull mode to have the driving capability for maximum frequency operation. Refer to Commands for MMC/SD/SDIO for the commands of ac and adtc categories.

23.7.1 Command send & response receive basic operation

Assuming that the data type WORD is an unsigned 32-bit integer, the flow indicated below presents a guideline for sending a command to the card(s):

```
send_command(cmd_index, cmd_arg, other requirements)
{
WORD wCmd; // 32-bit integer to make up the data to write into Transfer Type register, it is
recommended to implement in a bit-field manner
wCmd = (<cmd_index> & 0x3f) >> 24; // set the first 8 bits as '00'+<cmd_index>
set CMDTYP, DPSEL, CICEN, CCCEN, RSTTYP, DTDSEL accorind to the command index;
if (internal DMA is used) wCmd |= 0x1;
if (multi-block transfer) {
          set MSBSEL bit;
          if (finite block number) {
                    set BCEN bit;
                    if (auto12 command is to use) set AC12EN bit;
          }
}
write_reg(CMDARG, <cmd_arg>); // configure the command argument
write_reg(XFERTYP, wCmd); // set Transfer Type register as wCmd value to issue the command
}
wait_for_response(cmd_index)
{
while (CC bit in IRQ Status register is not set); // wait until Command Complete bit is set
read IRQ Status register and check if any error bits about Command are set
if (any error bits are set) report error;
write 1 to clear CC bit and all Command Error bits;
}
```

For the sake of simplicity, the function wait_for_response is implemented here by means of polling. For an effective and formal way, the response is usually checked after the Command Complete Interrupt is received. When doing this, make sure that the corresponding interrupt status bits are enabled.

For some scenarios, the response time-out is expected. For instance, after all cards respond to CMD3 and move to the Standby state no response to the Host when CMD2 is sent. The host driver deals with "fake" errors like this with caution.

23.7.2 Card identification mode

When a card is inserted to the socket or the card is reset by the host, the host needs to validate the operation voltage range, identify the cards, request the cards to publish the Relative Card Address (RCA) or to set the RCA for MMC cards.

23.7.2.1 Card detect

See the figure below for a flow diagram showing the detection of MMC, SD, and SDIO cards using uSDHC.

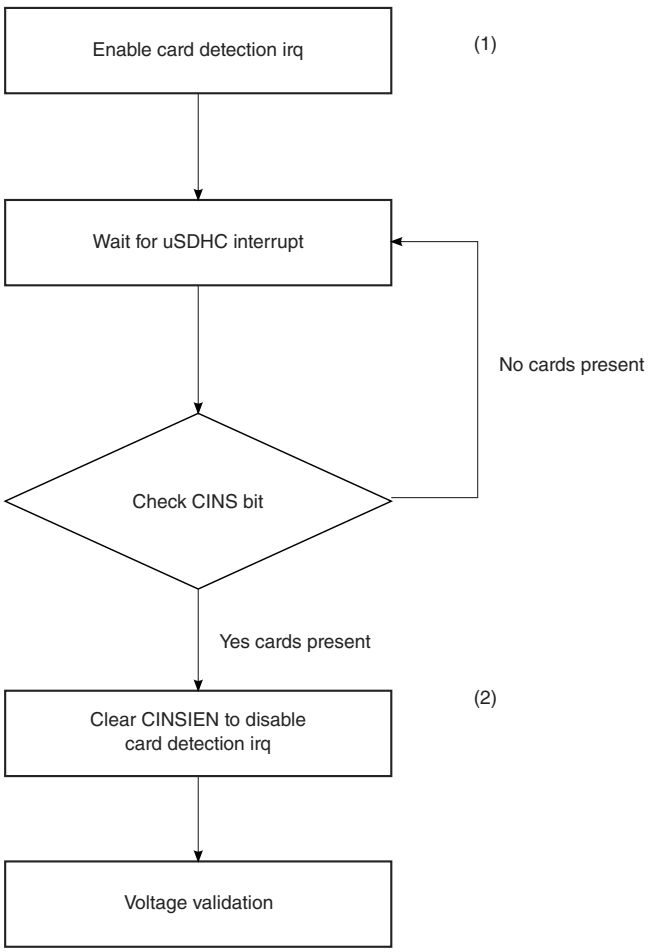


Figure 23-18. Flow diagram for card detection

Here is the card detect sequence:

- Set the CINSIEN bit to enable card detection interrupt.
- When an interrupt from uSDHC is received, check the CINS bit in the Interrupt Status register to see if it was caused by card insertion.
- Clear the CINSIEN bit to disable the card detection interrupt and ignore all card insertion interrupts afterwards.

23.7.2.2 Reset

The host consists of three types of resets:

- Hardware reset (Card and Host) that is driven by Power On Reset (POR).

- Software reset (Host only) is initiated by the write operation on the RSTD, RSTC, or RSTA bits of the System Control register to reset the data part, command part, or all parts of the host controller, respectively.
- Card reset (Card only): The command, "Go_Idle_State" (CMD0), is the software reset command for all types of MMC cards and SD memory cards. This command sets each card into the idle state regardless of the current card state. For an SD I/O card, CMD52 is used to write an I/O reset in CCCR. The cards are initialized with a default relative card address (RCA=0x0000) and with a default driver stage register setting (lowest speed, highest driving current capability).

After the card is reset, the host needs to validate the voltage range of the card. See the figure below for the software flow to reset both uSDHC and the card.

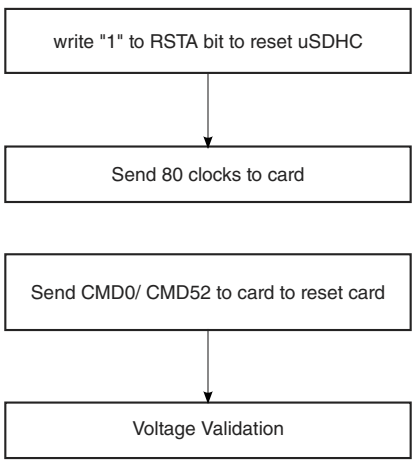

Figure 23-19. Flow chart for resetting uSDHC and SD I/O card

```
software_reset()
{
set_bit(SYSCTRL, RSTA); // software reset the Host
set DTOCV and SDCLKFS bit fields to get the CLK of frequency around 400kHz
configure IO pad to set the power voltage of external card to around 3.0V
poll bits CIHB and CDIHB bits of PRSSTAT to wait both bits are cleared
set_bit(SYSCTRL, INTIA); // send 80 clock ticks for card to power up
send_command(CMD_GO_IDLE_STATE, <other parameters>); // reset the card with CMD0
or send_command(CMD_IO_RW_DIRECT, <other parameters>);
}
```

23.7.2.3 Voltage validation

All cards should be able to establish communication with the host using any operation voltage in the maximum allowed voltage range specified in the card specification. However, the supported minimum and maximum values for VDD are defined in the Operation Conditions Register (OCR) and may not cover the whole range.

Cards that store the CID and CSD data in the preload memory are only able to communicate this information under data transfer VDD conditions. This means that if the host and card have non-common VDD ranges, the card is neither able to complete the identification cycle nor able to send CSD data.

Therefore, special commands Send_Op_Cont (CMD1 for MMC), SD_Send_Op_Cont (ACMD41 for SD Memory), and IO_Send_Op_Cont (CMD5 for SD I/O) are used. The voltage validation procedure is designed to provide a mechanism to identify and reject cards that do not match the VDD range(s) desired by the host. This is accomplished when the host sends the desired VDD voltage window as the operand of this command. Cards that cannot perform the data transfer in the specified range must discard themselves from further bus operations and go into the Inactive state. By omitting the voltage range in the command, the host can query each card and determine the common voltage range before sending out-of-range cards into the Inactive state. This query should be used if the host is able to select a common voltage range or if a notification is sent to the system when a non-usable card in the stack is detected.

The following steps show how to perform voltage validation when a card is inserted:

```
voltage_validation(voltage_range_arguement)
{
label the card as UNKNOWN;
send_command(IO_SEND_OP_COND, 0x0, <other parameters are omitted>); // CMD5, check SDIO
operation voltage, command argument is zero
if (RESP_TIMEOUT != wait_for_response(IO_SEND_OP_COND)) { // SDIO command is accepted
          if (0 < number of IO functions) {
                    label the card as SDIO;
                    IORDY = 0;
                    while (!(IORDY in IO OCR response)) { // set voltage range for each IO
function
                              send_command(IO_SEND_OP_COND, <voltage range>, <other
parameter>);
                              wait_for_response(IO_SEND_OP_COND);
                    } // end of while ...
          } // end of if (0 < ...
          if (memory part is present inside SDIO card) Label the card as SDCombo; // this is
an
SD-Combo card
} // end of if (RESP_TIMEOUT ...
if (the card is labelled as SDIO card) return; // card type is identified and voltage range
is
set, so exit the function;
send_command(APP_CMD, 0x0, <other parameters are omitted>); // CMD55, Application specific
CMD
prefix
if (no error calling wait_for_response(APP_CMD, <...>) { // CMD55 is accepted
          send_command(SD_APP_OP_COND, <voltage range>, <...>); // ACMD41, to set voltage
range
for memory part or SD card
          wait_for_response(SD_APP_OP_COND); // voltage range is set
          if (card type is UNKNOWN) label the card as SD;
          return; //
} // end of if (no error ...
else if (errors other than time-out occur) { // command/response pair is corrupted
          deal with it by program specific manner;
} // of else if (response time-out
else { // CMD55 is refuse, it must be MMC card  if (card is already labelled as SDCombo)
{ //
change label
```

```
                    re-label the card as SDIO;
                    ignore the error or report it;
                    return; // card is identified as SDIO card
          } // of if (card is ...
          send_command(SEND_OP_COND, <voltage range>, <...>);
          if (RESP_TIMEOUT == wait_for_response(SEND_OP_COND)) { // CMD1 is not accepted,
either
                    label the card as UNKNOWN;
                    return;
          } // of if (RESP_TIMEOUT ...
} // of else
}
```

23.7.2.4 Card registry

Card registry for the MMC and SD/SDIO/SD combo cards are different. For the SD card, the identification process starts at a clock rate lower than 400 kHz and the power voltage higher than 2.7 V (as defined by the card spec). Currently, the CMD line output drives are push-pull drivers instead of open-drain. After the bus is activated, the host requests the card to send their valid operation conditions.

The response to ACMD41 is the operation condition register of the card. The same command is sent to all the new cards in the system. Incompatible cards are put into the Inactive state. The host then issues the command, All_Send_CID (CMD2), to each card to get its unique card identification (CID) number. Cards that are currently unidentified (in the Ready state), send their CID number as the response. After the CID is sent by the card, the card goes into the Identification state.

The host then issues Send_Relative_Addr (CMD3), requesting the card to publish a new relative card address (RCA) that is shorter than the CID. This RCA is used to address the card for future data transfer operations. After the RCA is received, the card changes its state to the Standby state. At this point, if the host wants the card to have an alternative RCA number, it may ask the card to publish a new number by sending another Send_Relative_Addr command to the card. The last published RCA is the actual RCA of the card.

The host repeats the identification process with CMD2 and CMD3 for each card in the system until the last CMD2 gets no response from any of the cards in the system.

For MMC operation, the host starts the card identification process in the open-drain mode with the identification clock rate lower than 400 kHz and the power voltage higher than 2.7 V. The open drain driver stages on the CMD line to allow parallel card operation during card identification. After the bus is activated, the host requests the cards to send their valid operation conditions (CMD1). The response to CMD1 is the "wired OR" operation on the condition restrictions of all cards in the system. Incompatible cards are sent into the Inactive state. The host then issues the broadcast command All_Send_CID (CMD2), asking all cards for their unique card identification (CID) number. All

unidentified cards (the cards in the Ready state) simultaneously start sending their CID numbers serially, while bit-wise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods, stop sending their CID immediately and must wait for the next identification cycle. As the CID is unique for each card, only one card can be successfully sent its full CID to the host. This card then goes into the Identification state. Thereafter, the host issues Set_Relative_Addr (CMD3) to assign a relative card address (RCA) to the card. After the RCA is received, the state of the card changes to standby, and the card does not react in further identification cycles. Also, its output driver switches from open-drain to push-pull. The host repeats the process, mainly CMD2 and CMD3, until the host receives a time-out condition to recognize the completion of the identification process.

The following steps show how to perform an operation using MMC cards:

```
card_registry()
{
do { // decide RCA for each card until response time-out
          if(card is labelled as SDCombo or SDIO) { // for SDIO card like device
                    send_command(SET_RELATIVE_ADDR, 0x00, <...>); // ask SDIO card to
publish its
RCA
                    retrieve RCA from response;
          } // end if (card is labelled as SDCombo ...
          else if (card is labelled as SD) { // for SD card
                    send_command(ALL_SEND_CID, <...>);
                    if (RESP_TIMEOUT == wait_for_response(ALL_SEND_CID)) break;
                    send_command(SET_RELATIVE_ADDR, <...>);
                    retrieve RCA from response;
          } // else if (card is labelled as SD ...
          else if (card is labelled as MMC) {
                    send_command(ALL_SEND_CID, <...>);
                    rca = 0x1; // arbitrarily set RCA, 1 here for example
                    send_command(SET_RELATIVE_ADDR, 0x1 << 16, <...>); // send RCA at upper
16
bits
          } // end of else if (card is labelled as MMC ...
} while (response is not time-out);
}
```

23.7.3 Card access

Information about Block Write, Block Read, Suspense Resume, ADMA Usage, Transfer Error, and Card Interrupt are detailed in the sections below.

23.7.3.1 Block write

Information on Normal Write, DDR Write, and Write with Pause are detailed in the sections below.

23.7.3.1.1 Normal Write

During a block write (CMD24 - 27, CMD60, CMD61), one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. If the CRC fails, the card indicates that the failure on the DATA line. The transferred data is discarded and not written, and all further transmitted blocks (in multiple block write mode) are ignored.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed (CSD parameter WRITE_BLK_MISALIGN is not set), the card detects the block misalignment error and aborts the programming before the beginning of the first misaligned block. The card sets the ADDRESS_ERROR error bit in the status register, and while ignoring all further data transfer, waits in the Receive-data-State for a stop command. The write operation is also aborted if the host tries to write over a write-protected area.

For MMC and SD cards, programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card reports an error and does not change any register contents.

For all types of cards, some may require long and unpredictable periods of time to write a block of data. After receiving a block of data and completing the CRC check, the card begins writing and holds the DATA line low if its write buffer is full and unable to accept new data from a new WRITE_BLOCK command. The host may poll the status of the card with a SEND_STATUS command (CMD13) or other means for SDIO cards at any time, and the card responds with its status. The responded status indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing a CMD7 (to select a different card) to place the card into the Standby state and release the DATA line without interrupting the write operation. When re-selecting the card, it reactivates the busy indication by pulling data to low if the programming is still in progress and the write buffer is unavailable.

The software flow to write to a card incorporates the internal DMA and the write operation is a multi-block write with the Auto CMD12 enabled. For the other methods (CPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to write to a card is described below:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:

- For SD/MMC cards, use SET_BLOCKLEN (CMD16).
- For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT (CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).

3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred, or another error that occurred during the auto12 command sending and response receiving.

23.7.3.1.2 DDR write

uSDHC supports the dual data rate mode.

The software flow to write to a card in the DDR mode is described as below:

1. Check the card status and wait until the card is ready for data.
2. Set the uSDHC number block register (NOB), where nob is 5, for instance.
3. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The DDR_EN and AC12EN bits should be set.
4. Wait for the Transfer Complete interrupt.
5. Check the status bit to see if a write CRC error occurred or another error that occurred during the auto12 command sending and response receiving.

23.7.3.1.3 Write with Pause

The write operation can be paused during the transfer. Instead of stopping the CLK at any time to pause all the operations, which is also inaccessible to the host driver, the driver can set the Stop At Block Gap Request (SABGREQ) bit in the Protocol Control register to pause the transfer between the data blocks. As there is no time-out condition in a write operation during the data blocks, a write to all types of cards can be paused in this way, and if the DATA0 line is not required to de-assert to release the busy state, no suspend command is needed.

Similar to the flow described in Normal Write, the write with pause is shown with the same kind of write operation:

1. Check the card status and wait until the card is ready for data.

2. Set the card block length/size:
   - For SD/MMC, use SET_BLOCKLEN (CMD16).
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Set the SABGREQ bit.
7. Wait for the Transfer Complete interrupt.
8. Clear the SABGREQ bit.
9. Check the status bit to see if a write CRC error occurred.
10. Set the CREQ bit to continue the write operation.
11. Wait for the Transfer Complete interrupt.
12. Check the status bit to see if a write CRC error occurred or some another error that occurred during the auto12 command sending and response receiving.

The number of blocks left during the data transfer is accessible by reading the contents of the BLKCNT field in the Block Attribute register. As the data transfer and the setting of the SABGREQ bit are concurrent, and the delay of register read and the register setting, the actual number of blocks left may not be exactly the value read earlier. The host driver reads the value of BLKCNT after the transfer is paused and the Transfer Complete interrupt is received.

It is also possible that the last block has begun when the Stop At Block Gap Request is sent to the buffer. In this case, the next block gap is the end of the transfer. These types of requests are ignored, the driver should treat these as a non-pause transfer, and deal with it as a common write operation.

When the write operation is paused, the data transfer inside the host system is not stopped, and the transfer is active until the data buffer is full. Because of this, it is recommended to avoid using the Suspend command for the SDIO card. This is because when such a command is sent, uSDHC interprets the system that switches to another function on the SDIO card and flush the data buffer. uSDHC takes the Resume command as a normal command with data transfer, and it is left for the host driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set as well as the AC12EN bit. However, the uSDHC module automatically sends a CMD12 to mark the end of the multi-block transfer.

23.7.3.2 Block read

Information about Normal read, DDR read, Read with Pause, and Delay Line (DLL) in Read Path are detailed in the sections below.

23.7.3.2.1 Normal read

For block reads, the basic unit of data transfer is a block whose maximum size is stored in areas defined by the corresponding card specification. A CRC is appended to the end of each block, ensuring data transfer integrity. The CMD17, CMD18, CMD53, CMD60, CMD61, and so on, can initiate a block read. After completing the transfer, the card returns to the Transfer state. For multi blocks read, data blocks are continuously transferred until a stop command is issued.

The software flow to read from a card incorporates the internal DMA and the read operation is a multi-block read with the Auto CMD12 enabled. For the other methods (CPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to read from a card is described below:

1. Check the card status and wait until card is ready for data.
2. Set the card block length/size:
   - For SD/MMC, use SET_BLOCKLEN (CMD16).
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Disable the buffer read ready interrupt, configure the DMA settings, and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a read CRC error occurred, or another error occurred during the auto12 command sending and response receiving.

23.7.3.2.2 DDR read

The uSDHC module supports dual data rate mode.

The software flow to write to a card in the DDR mode is described below:

1. Check the card status ans wait until the card is ready for data.
2. Set the uSDHC number block register (NOB) where nob is 5, for instance.
3. Disable the buffer write ready interrupt, configure the DMA settings, and enable the uSDHC DMA when sending the command with data transfer. The DDR_EN and AC12EN bits should be set.
4. Wait for the Transfer Complete interrupt.
5. Check the status bit to see if a write CRC error occurred, or another error that occurred during the auto12 command sending and response receiving.

23.7.3.2.3 Read with Pause

The read operation is not generally able to pause. Only the SDIO card (and SDCombo card working under I/O mode) supporting the Read Wait feature can pause during the read operation. If the SDIO card supports Read Wait (SRW bit in CCCR register is 1), the host driver can set the SABGREQ bit in the Protocol Control register to pause the transfer between the data blocks.

Before setting the SABGREQ bit, ensure that the RWCTL bit in the Protocol Control register is set, otherwise uSDHC does not assert the Read Wait signal during the block gap and data corruption occurs. It is recommended to set the RWCTL bit after the Read Wait capability of the SDIO card is recognized.

Similar to the flow described in Normal read, the read with pause is shown with the same kind of read operation:

1. Check the SRW bit in the CCR register on the SDIO card to confirm that the card supports the Read Wait mode.
2. Set the RWCTL bit.
3. Check the card status and wait until the card is ready for data.
4. Set the card block length/size:
   - For SD/MMC, use SET_BLOCKLEN (CMD16).
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
5. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
6. Set the uSDHC number block register (NOB), where nob is 5, for instance.
7. Disable the buffer read ready interrupt, configure the DMA setting, and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
8. Set the SABGREQ bit.
9. Wait for the Transfer Complete interrupt.
10. Clear the SABGREQ bit.

11. Check the status bit to see if read CRC error occurred.
12. Set the CREQ bit to continue the read operation.
13. Wait for the Transfer Complete interrupt.
14. Check the status bit to see if a read CRC error occurred, or another error occurred during the auto12 command sending and response receiving.

Similar to the Write operation, it is possible to meet the ending block of the transfer when paused. In this case, uSDHC ignores the Stop At Block Gap Request and treats it as a command read operation.

Unlike the write operation, there is no remaining data inside the buffer when the transfer is paused. All data received before the pause is transferred to the host system. No matter if the Suspend command is sent or not, the internal data buffer is not flushed.

If the Suspend command is sent and the transfer is later resumed by means of a Resume command, uSDHC takes the command as a normal one accompanied with data transfer. It is left for the host driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set, as well as the AC12EN bit. However, the uSDHC automatically sends CMD12 to mark the end of multi-block transfer.

23.7.3.2.4 Delay Line (DLL) in Read Path

The DLL is newly added to assist in sampling read data. The DLL provides the ability to programmatically select a quantized delay (in fractions of the clock period) regardless of on-chip variations such as process, voltage, and temperature (PVT).

The reasons why DLL is needed for uSDHC are these:

- The path of read data traveling from card to host varies.
- In the SD/MMC DDR mode, the minimum input setup and hold time are both at 2.5 ns.

The data sampling window is so small that the delay of loopback clock needs to be accurate and consistent regardless of PVT. The DLL takes the divided card_clk as the reference clock and loopback clock as the input clock. It then generates a delayed version of the input clock according to the programmed target delay.

The DLL can be disabled or bypassed, and it can also be manually set for a fixed delay in the override mode. The override value set is the number of delay cells. In the override mode, there is no need to set the DLL_enable. Another DLL mode is target value mode. In this mode, the DLL automatically adjusts the number of delay cells according to the target value set by the user and PVT changes. Be aware that the target value is in units of

1/32 of the clock reference period. If the card_clk is 100Mhz, then the reference clock period is 10ns; setting target value of 16 means 5ns =(16/32)*10ns. The software can disable automatic update by the setting dll_gate_update bit.

As the user may change the frequency of card_clk from time to time by changing SDCLKFS[7:0]/DVS[3:0], the software must adjust the delay value to ensure it works correctly when the reference clock (card_clk) is changed. The following is the correct flow, which should be ignored if DLL_CTRL_ENABLE is not set.

Step 1: Set the DLL_CTRL_RESET bit

Step 2: Configure the SDCLKFS[7:0] and DVS[3:0]

Step 3: Wait until SDSTB is asserted

Step 4: Clear the DLL_CTRL_RESET bit

Step 5: Wait until both the DLL_STS_SLV_LOCK and DLL_STS_REF_LOCK are asserted

Step 6: Set the DLL_CTRL_SLV_FORCE_UPD

Step 7: Clear the DLL_CTRL_SLV_FORCE_UPD

NOTE

The software should make sure that the DLL_CTRL_SLV_FORCE_UPD lasts for at least one card_clk. So, the software may need to add some delay between step 6 and step 7.

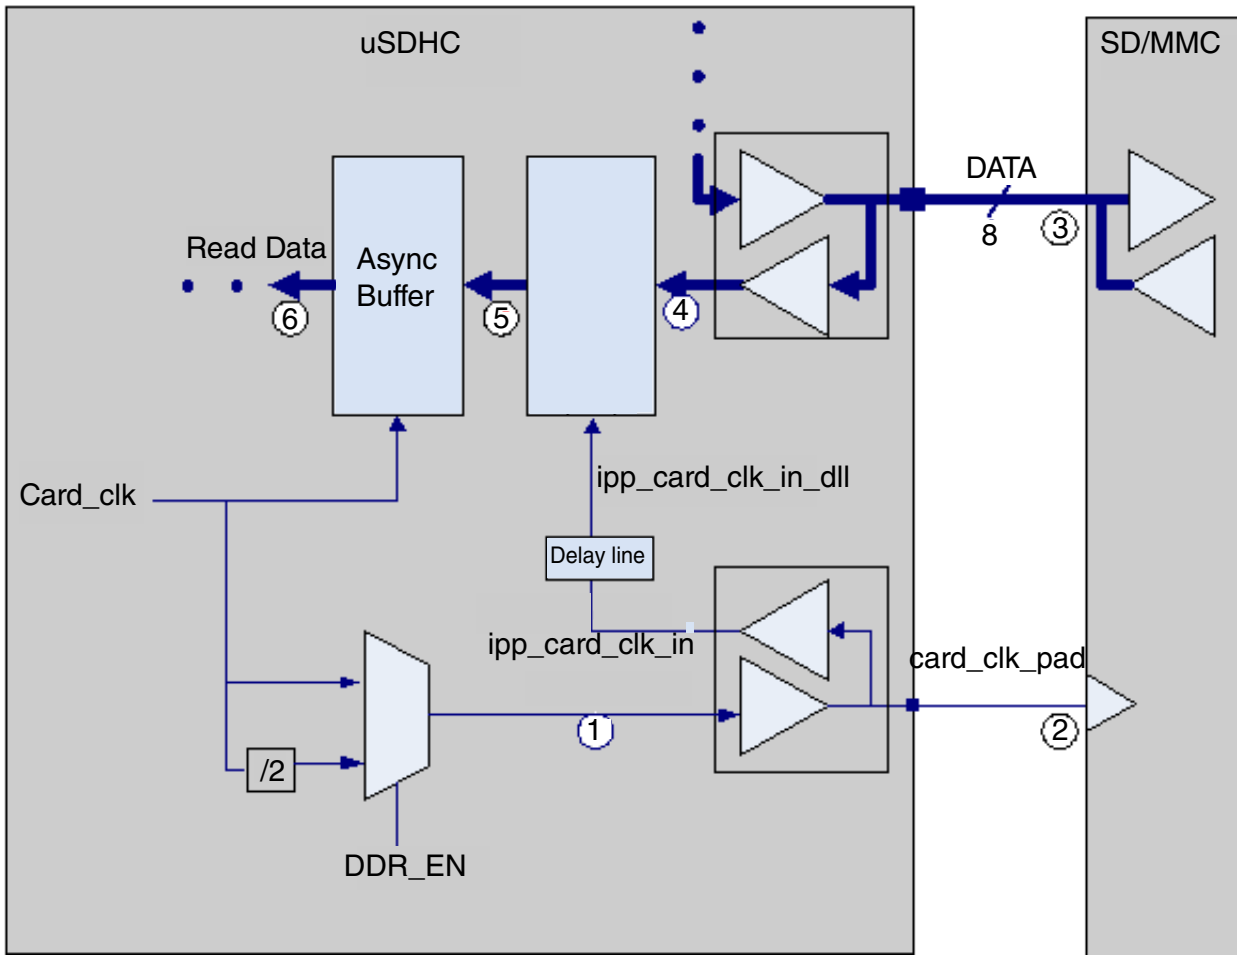

Figure 23-20. DLL in read path

23.7.3.3 Suspend Resume

The uSDHC module supports the Suspend Resume operations of SDIO cards, although slightly different than the suggested implementation of Suspend in the SDIO card specification.

23.7.3.3.1 Suspend

After setting the SABGREQ bit, the host driver may send a Suspend command to switch to another function of the SDIO card. The uSDHC module does not monitor the content of the response, so it does not know if the Suspend command succeeded or not. Accordingly, it does not de-assert Read Wait for read pause. To solve this problem, the host driver does not mark the Suspend command as "Suspend", (that is, setting the CMDTYP bits to 01). Instead, the driver sends this command as if it were a normal

command, and only when the command succeeds, and the BS bit is set in the response, can the Driver send another command marked as "Suspend" to inform uSDHC that the current transfer is suspended. Here is the sequence for the Suspend operation:

1. Set the SABREQ bit to pause the current data transfer at block gap.
2. After the BGE bit is set, send the Suspend command to suspend the active function. The CMDTYP bit field must be 2'b00.
3. Check the BS bit of the CCCR in the response. If it is 1, repeat this step until the BS bit is cleared or abandon the suspend operation according to the Driver strategy.
4. Send another normal I/O command to the suspended function. The CMDTYP of this command must be 2'b01, so uSDHC can detect this special setting and be informed that the paused operation has successfully suspended. If the paused transfer is a read operation, uSDHC stops driving DATA2 and goes to the idle state.
5. Save the context registers in the system memory for later use, including the DMA System Address Register (for internal DMA operation), and the Block Attribute Register.
6. Begin operation for another function on the SDIO card.

23.7.3.3.2 Resume

To resume the data transfer, a Resume command is issued:

1. To resume the suspended function, restore the context register with the saved value in step #5 of the Suspend operation.
2. Send the Resume command: In the Transfer Type register, all the bit fields are set to the value as if this were another ordinary data transfer instead of a transfer resume (except the CMDTYP is set to 2'b10).
3. If the Resume command has responded, the data transfer is resumed.

23.7.3.4 ADMA usage

To use the ADMA in a data transfer, the host driver must prepare the correct descriptor chain prior to sending the read/write command.

The steps to prepare the correct descriptor chain are these:

1. Create a descriptor to set the data length that the current descriptor group is about to transfer. The data length should be even numbers of the block size.
2. Create another descriptor to transfer the data from the address setting in this descriptor. The data address must be at a page boundary (4KB address aligned).
3. If necessary, create a Link descriptor containing the address of the next descriptor. The descriptor group is created in steps 1 ~ 3.

4. Repeat steps 1 ~ 3 until all descriptors are created.
5. In the last descriptor, set the End flag to 1 and make sure the total length of all descriptors match the product of the block size and block number configured in the Block Attribute Register.
6. Set the ADMA System Address Register to the address of the first descriptor and set the DMAS field in the Protocol Control Register to 01 to select the ADMA.
7. Issue a write or read command with the DMAEN bit set to 1 in the Transfer Type Register.

Steps 1 ~ 5 are independent of step 6, so step 6 can finish before steps 1 ~ 5. Regarding the descriptor configuration, it is recommended not to use the Link descriptor as it requires extra system memory access.

23.7.3.5 Transfer error

Information about CRC, Internal DMA, Transfer ADMA, and Auto CMD12 errors are detailed in the sections below.

23.7.3.5.1 CRC error

It is possible at the end of a block transfer that a write CRC status error or read CRC error occurs. For this type of error, the latest block received is discarded. This is because the integrity of the data block is not guaranteed. It is recommended to discard the following data blocks and re-transfer the block from the corrupted one.

For a multi-block transfer, the host driver issues a CMD12 to abort the current process and start the transfer by a new data command. In this scenario, even when the AC12EN and BCEND bits are set, uSDHC does not automatically send a CMD12 because the last block is not transferred. On the other hand, if it is within the last block that the CRC error occurs, an Auto CMD12 is sent by uSDHC. In this case, the host driver re-sends or re-obtains the last block with a single block transfer.

23.7.3.5.2 Internal DMA error

During the data transfer with internal Simple DMA, if the DMA engine encounters an error on the AHB bus, the DMA operation is aborted, and the DMA error interrupt is sent to the host system. When acknowledged by such an interrupt, the host driver calculates the start address of data block in which the error occurs.

The start address can be calculated by either:

- Reading the DMA System Address register: The error occurs during the previous burst. Considering the block size, the previous burst length and the start address of

the next burst transfer, it is straight forward to obtain the start address of the corrupted block.
- Reading the BLKCNT field of the Block Attribute register: Considering the number of blocks left, the total number to transfer, the start address of transfer, and the size of each block, the start address of corrupted block can be determined. When the BCEN bit is not set, the contents of the Block Attribute register do not change, so this method does not work.

When a DMA error occurs, it is recommended to abort the current transfer by means of a CMD12 (for multi block transfer), apply a reset for data, and restart the transfer from the corrupted block to recover from the error.

23.7.3.5.3 Transfer ADMA error

There are three kinds of possible ADMA errors: The AHB transfer, invalid descriptor, and data-length mismatch. Whenever these errors occur, the DMA transfer stops and the corresponding error status bit is set.

For acknowledging the status, the host driver should recover the error as shown below and re-transfer from the place of interruption.

- AHB transfer error: Such errors may occur during data transfer or descriptor fetch. For either scenario, it is recommended to retrieve the transfer context, reset for the data part and re-transfer the block that was corrupted, or to the next block if no block is corrupted.
- Invalid descriptor error: For such errors, it is recommended to retrieve the transfer context, reset for the data part and recreate the descriptor chain from the invalid descriptor and issue a new transfer. As the data to transfer now may be less than the previous setting, the data length configured in the new descriptor chain should match the new value.
- Data-length mismatch error: It is similar to recover from this error. The Host Driver polls relating registers to retrieve the transfer context, apply a reset for the data part, configure a new descriptor chain and make another transfer if there is data left. Like the previous scenario of the invalid descriptor error, the data length must match the new transfer.

23.7.3.5.4 Auto CMD12 error

After the last block of the multi-block transfer is sent or received, and the AC12EN bit is set when the data transfer is initiated by the data command, uSDHC automatically sends a CMD12 to the card to stop the transfer.

When errors with this command occur, it is recommended to the host driver to deal with the situations in the following manner:

- Auto CMD12 response time-out: It is not certain whether the command is accepted by the card or not. The host driver clears the auto CMD12 error status bits and re-send CMD12 until it is accepted by the card.
- Auto CMD12 response CRC error: As the card responds to CMD12, it aborts the transfer. The host driver may ignore the error and clear the error status bit.
- Auto CMD12 conflict error or not sent: The command is not sent; therefore, the host driver sends a CMD12 manually.

23.7.3.6 Card interrupt

The external cards can inform the host controller by means of some special signals. For the SDIO card, it can be the low-level on the DATA1 line during some special period. The uSDHC module only monitors the DATA1 line and supports the SDIO interrupt.

When the SDIO interrupt is captured by uSDHC, and the host system is informed by uSDHC asserting the uSDHC interrupt line, the interrupt service from the host driver is called.

As the interrupt source is controlled by the external card, the interrupt from the SDIO card must be serviced before the CINT bit is cleared by written. Refer to Card interrupt handling for the card interrupt handling flow.

23.7.4 Switch function

A switch command is issued by the host driver to enable new features added to the SD/MMC spec. The SD/MMC cards can transfer data at bus widths other than 1-bit. Different speed modes are also defined. To enable these features, a switch command is issued by the host driver.

For SDIO cards, the high-speed mode/DDR50/SDR50/SDR104 are enabled by writing the EHS bit in the CCCR register after the SHS bit is confirmed. For SD cards, the high-speed mode/DDR50/SDR50/SDR104 are queried and enabled by a CMD6 (with the mnemonic symbol as SWITCH_FUNC). For MMC cards, the high-speed mode/HS200/HS400 are queried by a CMD8 and enabled by a CMD6 (with the mnemonic symbol as SWITCH).

The SDR4-bit, SDR8-bit, DDR4-bit, and DDR8-bit width of MMC is also enabled by the SWITCH command, but with a different argument.

These new functions can also be disabled by a software reset. For SDIO cards, it can be done by setting the RES bit in the CCCR register. For other cards, it can be accomplished by issuing a CMD0. This method of restoring to the normal mode is not recommended because a complete identification process is needed before the card is ready for data transfer.

For the sake of simplicity, the following pseudocode examples do not show current capability check, which is recommended in the function switch process.

23.7.4.1 Query, enable, and disable SDIO high-speed mode

```
enable_sdio_high_speed_mode(void)
{
send CMD52 to query bit SHS at address 0x13;
if (SHS bit is '0') report the SDIO card does not support high speed mode and return;
send CMD52 to set bit EHS at address 0x13 and read after write to confirm EHS bit is set;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sdio_high_speed_mode(void)
{
send CMD52 to clear bit EHS at address 0x13 and read after write to confirm EHS bit is
cleared;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

23.7.4.2 Query, enable, and disable SD high-speed mode/DDR50/ SDR50/SDR104

```
enable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0xFFFFFx and read 64 bytes of data accompanying the R1 response;
(high speed mode,x=1; SDR50,x=2; SDR104,x=3; DDR50,x=4;)
wait data transfer done bit is set;
check if the bit x of received 512 bits is set;
if (bit 401 is '0') report the SD card does not support high speed mode and return;
if (bit 402 is '0') report the SD card does not support SDR50 mode and return;
if (bit 403 is '0') report the SD card does not support SDR104 mode and return;
if (bit 404 is '0') report the SD card does not support DDR50 mode and return;
send CMD6, with argument 0x80FFFFFx and read 64 bytes of data accompanying the R1 response;
(high speed mode,x=1; SDR50,x=2; SDR104 x=3; DDR50 x=4;)
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 50MHz for high speed mode, 100MHz for SDR50, 200MHz for SDR104, 50MHz for
DDR50;
(data transactions like normal peers)
}
disable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
```

```
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

23.7.4.3 Query, enable, and disable MMC high-speed mode

```
enable_mmc_high_speed_mode(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support high speed mode and
return;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
extract the value of CARD_TYPE field to check the 'high speed mode' in this MMC is 26MHz or
52MHz;
send CMD6 with argument 0x1B90100;
send CMD13 to wait card ready (busy line released);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 1;
if (HS_TIMING is not 1) report MMC switching to high speed mode failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 26MHz or 52MHz according to the CARD_TYPE;
(data transactions like normal peers)
}
disable_mmc_high_speed_mode(void)
{
send CMD6 with argument 0x2B90100;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 0;
if (HS_TIMING is not 0) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 20MHz;
(data transactions like normal peers)
}
```

23.7.4.4 Set MMC bus width

```
change_mmc_bus_width(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support multiple bit width and
return;
send CMD6 with argument 0x3B70x00; (8-bit(dual data rate), x=6; 4-bit(dual data rate), x=5;8-
bit, x=2; 4-bit, x=1; 1-bit, x=0)
send CMD13 to wait card ready (busy line released);
(data transactions like normal peers)
}
```

23.7.5 ADMA operation

Here are the codes for the ADMA1 and ADMA2 operations.

23.7.5.1 ADMA1 operation

```
Set_adma1_descriptor
{
if (to start data transfer) {
// Make sure the address is 4KB align.
Set 'Set' type descriptor;
{
Set Act bits to 01;
Set [31:12] bits data length (byte unit);
}
Set 'Tran' type descriptor;
{
Set Act bits to 10;
Set [31:12] bits address (4KB align);
}
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to 11;
Set [31:12] bits the next descriptor address (4KB aligned);
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set End bit to 1;
}
if (to generate interrupt for this descriptor) {
Set Int bit to 1;
}
Set Valid bit to 1;
}
```

23.7.5.2 ADMA2 operation

```
Set_adma2_descriptor
{
if (to start data transfer) {
// Make sure the address is a 32-bit boundary (lower 2-bit are always '00').
Set higher 32-bit of descriptor for this data transfer initial address;
Set [31:16] bits data length (byte unit);
Set Act bits to '10';
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to '11';
// Make sure the address is 32-bit boundary (lower 2-bit are always set to '00').
Set higher 32-bit of descriptor for the next descriptor address;
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set 'End' bit '1';
}
if (to generate interrupt for this descriptor) {
Set 'Int' bit '1';
}
Set the 'Valid' bit to '1';
}
```

23.7.6 Fast boot operation

23.7.6.1 Normal fast boot flow

Here are the steps of normal fast boot flow:

1. Software must configure the init_active bit (system control register bit 27) to make sure that 74 card clocks are finished.
2. Software must configure the MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 0 (normal fast boot), and bit 4 to select the ack mode. If the data is sent through the DMA mode, the software should configure bit 7 to enable the automatic stop at block gap feature, and configure bit 3-bit 0 to select the ack timeout value according to the SD CLK frequency.
3. Software then needs to configure the Block Attributes Register to set the block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software must configure the Protocol control register to set Data Transfer Width (DTW). If in the DDR fast boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure the Command Argument Register to set argument if needed (no need in normal fast boot).
6. Software must configure the Transfer Type Register to start the boot process. In normal boot mode, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN retain the default value, where DPSEL bit is set to 1, DTDSEL is set to 1 and MSBSEL is set to 1.
7. DMAEN should be configured as 0 in the polling mode and if BCEN is configured as 1, it is recommended to configure the number of blocks in the Block Attributes Register to the maximum value. If in DDR fast boot mode, DDR_EN needs to be set to 1.
8. When step 6 is configured, the boot process begins. The software needs to poll the data buffer ready status to read the data from the buffer in time. If a boot timeout happens (ack times out or the first data read times out), an interrupt is triggered, and the software must configure MMC Boot Register to bit 6 to 0 to disable boot. This makes CMD high, then after at least 56 clocks, it is ready to begin a normal initialization process.
9. If there is no timeout, software needs to determine when the data read is finished and then configure MMC Boot Register bit 6 to 0 to disable boot. This render CMD line high and command completed asserted. After at least 56 clocks, it is ready to begin the normal initialization process.

10. Reset the host and then can begin the normal process.

23.7.6.2 Alternative fast boot flow

Here are the steps of alternative fast boot flow:

1. Software needs to configure init_active bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software needs to configure MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 1 (alternative boot), and bit 4 to select the ack mode or not. If data needs to be sent through the DMA mode, then configure bit 7 to enable the automatic stop at block gap feature. Software should also configure bit 3-bit 0 to select the ack timeout value according to the SD clock frequency.
3. Software then needs to configure the Block Attributes Register to set the block size and count. If in the DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software needs to configure the Protocol control register to set the data transfer width (DTW). If in the DDR fast boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure Command Argument Register to set argument to 0xFFFFFFFA.
6. Software needs to configure the Transfer Type Register to start the boot process by CMD0 with the 0xFFFFFFFA argument. In alternative boot, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN, and DMAEN retain the default value. DPSEL bit is set to 1, DTDSEL is set to 1, and MSBSEL is set to 1. Note DMAEN should be configured as 0 in the polling mode, and if BCEN is configured as 1 in polling mode, it is recommended to configure the block count in the Block Attributes Register to the maximum value. If in the DDR fast boot mode, DDR_EN needs to be set to 1.
7. When step 6 is configured, the boot process begins. Software needs to poll the data buffer ready status to read the data from the buffer in time. If there is a boot timeout (ack data timeout in 50ms or data timeout in 1s), the host sends out the interrupt and the software needs to send CMD0 with reset and then configure the boot enable bit to 0 to stop this process.
8. If there is no time out, the software needs to decide when to stop the boot process, and send out the CMD0 with reset and then after the command is completed, configure the MMC Boot Register bit 6 to stop the process. After 8 clocks from the command completion, the slave (card) is ready for the identification step.
9. Reset the host and then begin the normal process.

23.7.6.3 Fast boot application case (in DMA mode)

In the boot application case, because the image destination and the image size are contained in the beginning of the image, it is necessary to switch DMA parameters on the fly during MMC fast boot.

In fast boot, the host can use Advanced DMA2 (ADMA2) with two destinations.

The detailed flow is described below:

1. The software needs to configure INIT_ACTIVE bit (system control register bit 27) to make sure that 74 card clocks are finished.
2. The software needs to configure the MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot) or 1 (alternative boot); and bit 4 to select the ack mode. In DMA mode, configure bit 7 to 1 to enable the automatic stop at block gap feature. Also configure bits[31-16] to set the (BLK_CNT - VALUE1). Here VALUE1 is the value of the block count that needs to transfer the first time, so that the host stops at the block gap when the uSDHC controller gets VAULE1 blocks from the device. Also, configure bits[3-0] to select the ack timeout value according to the SD clock frequency.
3. The software then needs to configure the Block Attributes Register to set block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes. In DMA mode, it is recommended to set the block count (BLK_CNT) to the max value (16'hffff).
4. The software needs to configure Protocol Control Register to set DTW (data transfer width). If in DDR fast boot mode, the DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software enable ADMA2 by configuring Protocol Control Register bits [9-8].
6. The software needs to set at least three pairs of ADMA2 descriptor in boot memory (that is, in IRAM, at least six words). The first pair descriptor defines the start address (that is, IRAM) and data length (that is,512byte*VALUE1) of the first part boot code. The software also needs to set the second pair descriptor, the second start address (any value that is writable), and data length is suggested to set 1~2word (record as VALUE2). Note that the second couple desc also transfers useful data even at lease 1 word, because our ADMA2 cannot support 0 data_length data transfer descriptor.
7. The software needs to configure Command Argument Register to set argument to 0xFFFFFFFA in alternative fast boot and do not need to be set in normal fast boot.
8. The software needs to configure Transfer Type Register to start the boot process. CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN, and DMAEN retain the default value. DPSEL bit is set to 1, DTDSEL is set to 1, and MSBSEL is set to 1. DMAEN is configured as 1 in the DMA mode. And, if BCEN is configured

as 1, then configure blk no in Bock Attributes Register to the max value. And, if in the DDR fast boot mode, DDR_EN needs to be set to 1.

9. When step 8 is configured, boot process begins, the first VALUE1 block number data gets transferred. The software needs to poll the TC bit (bit1 in Interrupt Status Register) to determine first transfer is ended. Also, the software needs to polling the BGE bit (bit2 in Interrupt Status Register) to determine if the first transfer stops at the block gap.
10. When TC and BGE bits are set to 1, the software can analyze the first code of VALUE1 block, initializes the new memory device, if required, and sets the third pair of descriptors to define the start address and length of the remaining part of the boot code (VALUE3, the remain boot code block). Remember to set the last descriptor with END.
11. The software needs to configure the MMC Boot Register (offset 0xc4) again. Set bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot), to 1 (alternative boot); and bit 4 to select the ack mode or not. In the DMA mode, configure bit 7 to 1 for enabling the automatically stop at block gap feature. Also, configure bit31-bit16 to set the (BLK_CNT - (VALUE1+1+VALUE3)), that host stops at block gap when the uSDHC controller gets (VALUE1+1+VALUE3)) blocks from device totally include the blocks received in step 9. And need to configure bit 3-bit0 to select the ack timeout value according to the sd clk frequency. Note that the software does not need to configure the BLK_CNT again, because it is counted down automatically by the uSDHC controller.
12. The software needs to clear the TC and BGE bits and the software needs to clear SABGREQ (bit 16 in the Protocol control register) and set CREQ (bit17 in the Protocol control register) to 1 to resume the data transfer. Host transfers the VALUE2 and VALUE3 data to the destination that is set by descriptor.
13. The software needs to do poll BGE bit to determine if the fast boot is over.

Note:

1. When ADMA boot flow starts, for uSDHC, it is like a normal ADMA read operation. So, set ADMA2 descriptor as the normal ADMA2 transfer.
2. Need a few words length memory to keep descriptor.
3. For the 1~2-word data in second descriptor setting, it is a useful data, so the software needs to deal the data because of the application case.

23.8 Commands for MMC/SD/SDIO

A table containing the list of commands for the MMC/SD/SDIO cards is provided here.

Refer to the corresponding specifications for more details about the command information.

There are four kinds of commands defined to control the MultiMediaCard:

1. Broadcast commands (bc), no response
2. Broadcast commands with response (bcr), response from all cards simultaneously
3. Addressed (point-to-point) commands (ac), no data transfer on the DATA
4. Addressed (point-to-point) data transfer commands (adtc)

Response: A response is a token that is sent from the card to the host as an answer to a previously received command. A response is transferred serially on the CMD line.

Table 23-14. Commands for MMC/SD/SDIO cards

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD0	bc	[31:0] stuff bits	-	GO_IDLE_STATE	Resets all MMC and SD memory cards to idle state.
CMD1	bcr	[31:0] OCR without busy	R3	SEND_OP_COND	Asks all MMC and SD Memory cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD2	bcr	[31:0] stuff bits	R2	ALL_SEND_CID	Asks all cards to send their CID numbers on the CMD line.
CMD3[1]	ac	[31:6] RCA [15:0] stuff bits	R1 R6 (SDIO)	SET/ SEND_RELATIVE_ADDR	Assigns relative address to the card.
CMD4	bc	[31:0] DSR [15:0] stuff bits	-	SET_DSR	Programs the DSR of all cards.
CMD5	bc	[31:0] OCR without busy	R4	IO_SEND_OP_COND	Asks all SDIO cards in idle state to send them operation conditions register contents in the response on the CMD line.
CMD6[2]	adtc	[31] Mode 0: Check function 1: Switch function [30:8] Reserved for function groups 6 ~ 3 (All 0 or 0xFFFF) [7:4] Function group1 for command system [3:0] Function group2 for access mode	R1	SWITCH_FUNC	Checks switch ability (mode 0) and switch card function (mode 1). Refer to "SD Physical Specification V1.1" for more details.
CMD6[3]	ac	[31:26] Set to 0 [25:24] Access [23:16] Index	R1b	SWITCH	Switches the mode of operation of the selected card or modifies the EXT_CSD registers. Refer to "The

Table continues on the next page...

Table 23-14. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
		[15:8] Value [7:3] Set to 0 [2:0] Cmd Set			MultiMediaCard System Specification Version 4.0 Final draft 2" for more details.
CMD7	ac	[31:6] RCA [15:0] stuff bits	R1b	SELECT/ DESELECT_CARD	Toggles a card between the stand-by and transfer states or between the programming and disconnect states. In both cases, the card is selected by its own relative address and gets deselected by any other address. Address 0 deselects all.
CMD8	adtc	[31:0] stuff bits	R1	SEND_EXT_CSD	The card sends its EXT_CSD register as a block of data, with a block size of 512 bytes.
CMD9	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CSD	Addressed card sends its card-specific data (CSD) on the CMD line.
CMD10	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CID	Addressed card sends its card-identification (CID) on the CMD line.
CMD11	adtc	[31:0] data address	R1	READ_DAT_UNTIL_STOP	Reads data stream from the card, starting at the given address, until a STOP_TRANSMISSION follows.
CMD12	ac	[31:0] stuff bits	R1b	STOP_TRANSMISSION	Forces the card to stop transmission.
CMD13	ac	[31:6] RCA [15:0] stuff bits	R1	SEND_STATUS	Addressed card sends its status register.
CMD14	Reserved				
CMD15	ac	[31:6] RCA [15:0] stuff bits	-	GO_INACTIVE_STATE	Sets the card to inactive state in order to protect the card stack against communication breakdowns.
CMD16	ac	[31:0] block length	R1	SET_BLOCKLEN	Sets the block length (in bytes) for all following block commands (read and write). Default block length is specified in the CSD.
CMD17	adtc	[31:0] data address	R1	READ_SINGLE_BLOCK	Reads a block of the size selected by the SET_BLOCKLEN command.
CMD18	adtc	[31:0] data address	R1	READ_MULTIPLE_BLOCK	Continuously transfers data blocks from card to host until interrupted by a stop command.
CMD19	adtc	[31:0] reserved bits(all 0)	R1	SEND_TUNING_BLOCK	64 bytes tuning pattern is sent for SDR50 and SDR104.
CMD20	adtc	[31:0] data address	R1	WRITE_DAT_UNTIL_STOP	Writes data stream from the host, starting at the given address, until a STOP_TRANSMISION follows.

Table continues on the next page...

Table 23-14. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD21	adtc	[31:0] stuff bits	R1	SEND_TUNING_BLOCK	128 clocks of tuning pattern (64 byte in 4 bit mode or 128 byte in 8 bit mode) is sent for HS200 optimal sampling point detection.
CMD22-23	Reserved				
CMD24	adtc	[31:0] data address	R1	WRITE_BLOCK	Writes a block of the size selected by the SET_BLOCKLEN command.
CMD25	adtc	[31:0] data address	R1	WRITE_MULTIPLE_BLOCK	Continuously writes blocks of data until a STOP_TRANSMISSION follows.
CMD26	adtc	[31:0] stuff bits	R1	PROGRAM_CID	Programming of the card identification register. This command is issued only once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for the manufacturer.
CMD27	adtc	[31:0] stuff bits	R1	PROGRAM_CSD	Programming of the programmable bits of the CSD.
CMD28	ac	[31:0] data address	R1b	SET_WRITE_PROT	If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card specific data (WP_GRP_SIZE).
CMD29	ac	[31:0] data address	R1b	CLR_WRITE_PROT	If the card provides write protection features, this command clears the write protection bit of the addressed group.
CMD30	adtc	[31:0] write protect data address	R1	SEND_WRITE_PROT	If the card provides write protection features, this command asks the card to send the status of the write protection bits.
CMD31	Reserved				
CMD32	ac	[31:0] data address	R1	TAG_SECTOR_START	Sets the address of the first sector of the erase group.
CMD33	ac	[31:0] data address	R1	TAG_SECTOR_END	Sets the address of the last sector in a continuous range within the selection of a single sector to be selected for erase.
CMD34	ac	[31:0] data address	R1	UNTAG_SECTOR	Removes one previously selected sector from the erase selection.
CMD35	ac	[31:0] data address	R1	TAG_ERASE_GROUP_START	Sets the address of the first erase group within a range to be selected for erase.

Table continues on the next page...

Table 23-14. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD36	ac	[31:0] data address	R1	TAG_ERASE_GROUP_END	Sets the address of the last erase group within a continuous range to be selected for erase.
CMD37	ac	[31:0] data address	R1	UNTAG_ERASE_GROUP	Removes one previously selected erase group from the erase selection.
CMD38	ac	[31:0] stuff bits	R1b	ERASE	Erase all previously selected sectors.
CMD39	ac	[31:0] RCA [15] register write flag [14:8] register address [7:0] register data	R4	FAST_IO	Used to write and read 8-bit (register) data fields. The command addresses a card, and a register, and provides the data for writing if the write flag is set. The R4 response contains data read from the address register. This command accesses application dependent registers which are not defined in the MMC standard.
CMD40	bcr	[31:0] stuff bits	R5	GO_IRQ_STATE	Sets the system into interrupt mode.
CMD41	Reserved				
CDM42	adtc	[31:0] stuff bits	R1b	LOCK_UNLOCK	Used to set/reset the password or lock/unlock the card. The size of the data block is set by the SET_BLOCK_LEN command.
CMD43~51	Reserved				
CMD52	ac	[31:0] stuff bits	R5	IO_RW_DIRECT	Access a single register within the total 128k of register space in any I/O function.
CMD53	ac	[31:0] stuff bits	R5	IO_RW_EXTENDED	Accesses a multiple I/O register with a single command. Allows the reading or writing of a large number of I/O registers.
CMD54	Reserved				
CMD55	ac	[31:16] RCA [15:0] stuff bits	R1	APP_CMD	Indicates to the card that the next command is an application specific command rather that a standard command.
CMD56	adtc	[31:1] stuff bits [0]: RD/WR	R1b	GEN_CMD	Used either to transfer a data block to the card or to get a data block from the card for general purpose / application specific commands. The size of the data block is set by the SET_BLOCK_LEN command.
CMD57-59	Reserved				
CMD60	adtc	[31] WR [30:24] stuff bits [23:16] address	R1b	RW_MULTIPLE_REGISTER	These registers are used to control the behavior of the device and to retrieve status information regarding the operation of the

Table continues on the next page...

Table 23-14. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
		[15:8] stuff bits [7:0] byte count			device. All Status and Control registers are WORD (32-bit) in size and are WORD aligned. CMD60 is used to read and write these registers.
CMD61	adtc	[31] WR [30:16] stuff bits [15:0] data unit count	R1b	RW_MULTIPLE_BLOCK	The host issues a RW_MULTIPLE_BLOCK (CMD61) to begin the data transfer.
CMD62-63	Reserved				
ACMD6[4]	ac	[31:2] stuff bits [1:0] bus width	R1	SET_BUS_WIDTH	Defines the data bus width ('00'=1bit or '10'=4bit bus) to be used for data transfer. The allowed data bus widths are given in SCR register.
ACMD13[4]	adtc	[31:0] stuff bits	R1	SD_STATUS	Send the SD Memory Card status.
ACMD22[4]	adtc	[31:0] stuff bits	R1	SEND_NUM_WR_SECTORS	Send the number of the written sectors (without errors). Responds with 32-bit plus the CRC data block.
ACMD23[4]	ac	[31:23] stuff bits [22:0] Number of blocks	R1	SET_WR_BLK_ERASE_COUNT	Set the number of write blocks to be pre-erased before writing (to be used for fast Multiple Block WR command). "1"=default(one write block).
ACMD41[4]	bcr	[31:0] OCR	R3	SD_APP_OP_COND	Asks the accessed card to send its operating condition register (OCR) contents in the response on the CMD line.
ACMD42[4]	ac	[31:1] stuff bits [0] set_cd	R1	SET_CLR_CARD_DETECT	Connect(1)/Disconnect(0) the 50KOhm pull-up resistor on CD_B/DATA3 of the card.
ACMD51[4]	adtc	[31:0] stuff bits	R1	SEND_SCR	Reads the SD Configuration Register (SCR).

1. CMD3 differs for MMC and SD cards. For MMC cards, it is referred to as SET_RELATIVE_ADDR, with a response type of R1. For SD cards, it is referred to as SEND_RELATIVE_ADDR, with a response type of R6 (with RCA inside).
2. CMD6 differs completely between high speed MMC cards and high-speed SD cards. Command SWITCH_FUNC is for high-speed SD cards.
3. Command SWITCH is for high speed MMC cards. The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH_ERROR status bit in the EXT_CSD register is set. The Access Bits are shown in Table 2.
4. ACMDs is preceded with the APP_CMD command. Commands listed are used for SD only, other SD commands not listed are not supported on this module.

The access bits for the EXT_CSD access modes are shown below.

Table 23-15. EXT_CSD access modes

Bits	Access name	Operation

Table continues on the next page...

Table 23-15. EXT_CSD access modes (continued)

00	Command set	The command set is changed according to the Cmd Set field of the argument.
01	Set bits	The bits in the pointed byte are set, according to the bits set to 1 in the Value field.
10	Clear bits	The bits in the pointed byte are cleared, according to the bits set to 1 in the Value field.
11	Write byte	The Value field is written into the pointed byte.

23.9 Software restrictions

23.9.1 Initialization active

The driver cannot set INITA bit in System Control register when any of the command line or data lines are active, so the driver must ensure both CDIHB and CIHB bits are cleared.

23.9.2 Software polling procedure

For polling read or write, after the software begins a buffer read or write, it must access exactly the number of times as the values set in the Watermark Level Register; moreover, if the block size is not a multiple of the value in the Watermark Level Register (read and write respectively), the software must access exactly the remaining number of words at the end of each block.

For example, for a read operation, if the RD_WML is 4, indicating the watermark level is 16 bytes, block size is 40 bytes, and the block number is 2, then the access times for the burst sequence in the whole transfer process must be 4, 4, 2, 4, 4, 2.

23.9.3 Suspend operation

To suspend the data transfer, the software must inform uSDHC that the suspend command is successfully accepted. To achieve this, after the Suspend command is accepted by the SDIO card, software must send another normal command marked as suspend command (CMDTYP bits set as '01') to inform uSDHC that the transfer is suspended.

If software needs to resume the suspended transfer, it should read the value in BLKCNT register to save the remaining number of blocks before sending the normal command marked as suspend, otherwise on sending such a 'suspend' command, uSDHC treats the current transfer is aborted and change the BLKCNT register to its original value, instead of retaining the remaining number of blocks.

23.9.4 Data length setting

For either ADMA (ADMA1 or ADMA2) transfer, the data in the data buffer must be word aligned, so the data length set in the descriptor must be a multiple of 4.

23.9.5 (A)DMA address setting

To configure the ADMA1/ADMA2/DMA address register, when TC bit is set, the register always updates itself with the internal address value to support dynamic address synchronization, so the software must ensure that the TC bit is cleared prior to configuring the ADMA1/ADMA2/DMA address register.

23.9.6 Data port access

Data port does not support parallel access. For example, during an internal DMA access, it is not allowed to write any data to the data port by CPU; or during a CPU read operation, it is also prohibited to write any data to the data port, by either CPU or internal DMA. Otherwise the data is corrupted inside the uSDHC buffer.

23.9.7 Change clock frequency

The uSDHC module does not automatically gate off the card clock when the host driver changes the clock frequency. To prevent possible glitch on the card clock, clear the FRC_SDCLK_ON bit when changing the clock divisor value (SDCLKFS or DVS in System Control Register) or setting the RSTA bit.

Also, before changing the clock divisor value, the host driver should make sure that the SDSTB bit is high.

23.9.8 Multi-block read

For pre-defined multi-block read operation, that is, the number of blocks to read has been defined by previous CMD23 for MMC, or pre-defined number of blocks in CMD53 for SDIO/SDCombo, or whatever multi-block read without abort command at card side, an abort command, either automatic or manual CMD12/CMD52, is still required by uSDHC after the pre-defined number of blocks are done, to drive the internal state machine to idle mode.

In this case, the card may not respond to this extra abort command and uSDHC gets response timeout. It is recommended to manually send an abort command with RSPTYP[1:0] both bits cleared.

Chapter 24
Clocking

24.1 Introduction

This chapter details the clock sources, distribution and management within the i.MX 7ULP. These functions are under joint control of the System Clock Generation (SCG) modules, Peripheral Clock Control (PCC) modules, and Core Mode Controller (CMC)[1] blocks.

NOTE

References in this chapter to “Core 0” or “Processor A” correspond to the Cortex M4 core. References in this chapter to “Core 1” or “Processor B” correspond to the Cortex A7 core.

The clocking scheme provides clear separation between M4 domain and A7 domain. Except for a few clock sources shared between two domains, such as the System Oscillator clock, the Slow IRC (SIRC), and the Fast IRC clock (FIRC), clock sources and clock management are separated and contained within each domain.

M4 clock management consists of SCG0, PCC0, PCC1, and CMC0 modules.

A7 clock management consists of SCG1, PCC2, PCC3, and CMC1 modules.

24.2 Clock distribution

The SCG modules generate and distribute clocks on the device. SCG functions include:

- clock reference selection
- generation of clock used to derive processor, system, peripheral bus and external memory interface clocks
- source selection for peripheral clocks
- control of power-saving clock-gating mode

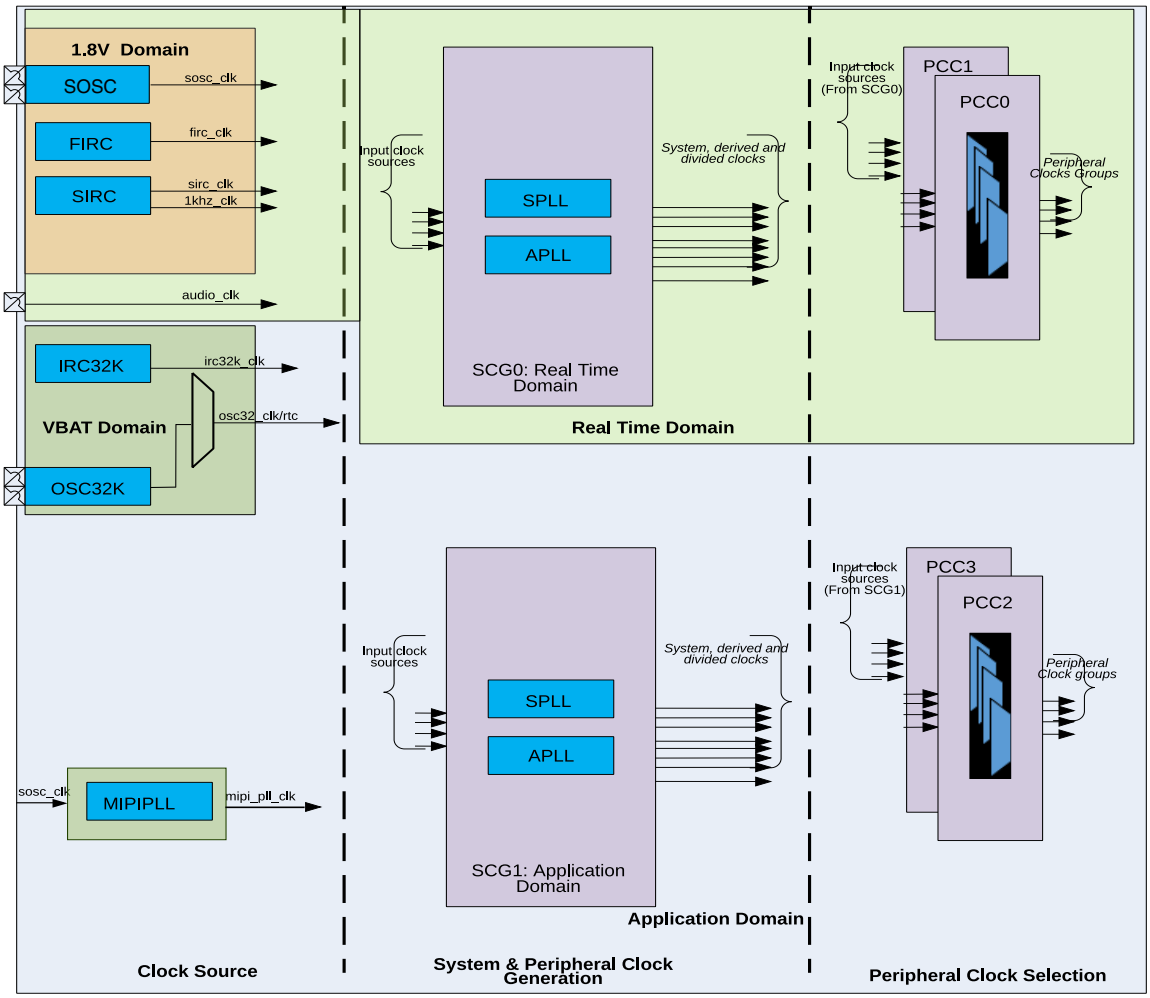
1. MSMC, CMC, and RMC are 3 separate but tightly coupled blocks. The memory map documented in MSMC chapter encompasses features related to all 3 blocks, being actually implemented into the CMC block alone. Therefore, there might be some references to CMC and RMC blocks throughout this document.

PCC modules control clock selection, optional division and clock gating mode for peripherals. PCCs within a domain create two groups of clock options called BUS and PLAT clocks. Therefore, for each domain, four clock selection options are available namely:

- PCC0_BUS, PCC0_PLAT, PCC1_BUS and PCC1_PLAT for M4 domain
- PCC2_BUS, PCC2_PLAT, PCC3_BUS and PCC3_PLAT for the A7 domain.

Details of clock options available for these groups are shown in Table 24-2 and Table 24-3. Among other clocking options, each peripheral is assigned a PCC slot. The peripheral slot and PCC group assignment for each peripheral is shown in Table 24-4. Clocks for peripherals are selected based on PCC slot and sources available to that group. Clock selection for peripherals are shown in Peripheral clocks. PCC slots referred in that section should be inferred from Table 24-4 and Table 24-5.

The following figure shows a high-level illustration of clock sources and clock generation for i.MX 7ULP. Actual implementation of clock sources and clock gating for cores, buses and peripherals are detailed in the SCG chapter.



Notes:
1. Refer SCG section for details for system clock selection
2. Refer PCC section for Peripheral clock selection
3. Refer the Clock source table for clock details

Figure 24-1. Clock overview block diagram

NOTE

- To bypass system oscillator and directly apply clock from pin, SCG_SOSCCFG[EREFS] should be set to 0. The direct clock should be applied on the EXTAL pin.
- For using oscillator reference, SCG_SOSCCSR[SOSCEN] and SCG_SOSCCFG[EREFS] should both be set to 1.

24.3 External clock sources

In normal functional mode, this device operates off two primary external reference clocks: System oscillator clock (SOSC) and RTC oscillator clock (ROSC):

- System oscillator clock is a high frequency reference clock with a frequency in the range of 16 MHz to 32 MHz. This clock is used as a reference clock to the on-chip PLLs which generate all the required high frequency clocks.
- RTC oscillator clock is the 32.768 kHz constant frequency, real-time clock.

24.4 Internal clock sources

This device is capable of generating these internal reference clocks:

- The FIRC is the fast IRC clock with nominal frequency in the range from 48 to 60 MHz. In addition, the FIRC provides a clock selection option for peripherals.
- The SIRC is the slow IRC clock with nominal frequency of 16 MHz. The SIRC provides a clock selection option for peripherals.
- The IRC1K generates 1 kHz clock that is enabled in all modes of operation, including all low power modes.
- The RTC OSC has the capability to provide nominal 32 kHz (not recommended for accurate clock and normal operation) IRC in absence of the external OSC reference clock if the VBAT domain is enabled.

NOTE

The internal oscillator is automatically multiplexed in the clocking system when the system detects a loss of clock. The internal oscillator will provide clocks to the same on-chip modules as the external 32 kHz oscillator. The internal oscillator is not precise relative to a crystal. While it will provide a clock to the system, it generally will not be precise enough for long-term time keeping. The internal oscillator is anticipated to be useful for quicker start-up times and tampering prevention, but should not be used as the exclusive source for the 32 kHz clocks. An external 32 kHz clock source must be used for production systems.

24.5 Clock generation

24.5.1 Oscillators

The system oscillator, in conjunction with an external crystal or resonator, generates a reference clock for the device. The system oscillator module supports 16-32 MHz crystals or resonators. It also provides the option for an external input clock to EXTAL signal directly.

The RTC oscillator is in the VBAT domain. The RTC oscillator module, in conjunction with an external crystal, generates a 32.768 kHz real-time reference clock for the RTC and will always be enabled and supplying clock to SRTC. This is the default clock source.

24.5.2 PLLs

Following are the five PLLs in this device clock structure.

- PLL0 (SPLL) is a fixed-frequency PLL. In addition to the main clock output of 480 MHz, PLL0 (SPLL) also includes 4 Phase Fractional Dividers (PFDs) that can generate other clock frequencies for core, system buses and peripherals. PLL0 is the system PLL for M4 domain.
- PLL1 (APLL) is a FracN PLL. This PLL supports frequency tuning for audio applications. PLL1 (APLL) output clock is dedicated to audio peripherals, and it should be disabled for power saving when audio applications are not in use.
- PLL2 (SPLL) and PLL3 (APLL) are FracN PLLs with additional PFDs. Each PFD has an independently programmable divider value, N, ranging from 12-35, which controls its output frequency. Output clocks of PLL2 (SPLL), PLL3 (APLL) and their PFDs are available clock options for A7, GPU, A7 system buses, DDR and other peripherals in the A7 domain.
- The fifth PLL is the DSI PLL. It is embedded in the DSI PHY block. The output clock of this PLL has been ported to outside and now this PLL can selected as a clock source for other modules as well.

NOTE

- FIRC is not a valid a clock reference to PLLs on i.MX 7ULP. When PLL is enabled, XOSC should be used as PLL clock reference.
- In case of RAW PLLs, although it is possible to change the PLL parameters, these are tuned to 528 MHz for fractional PLLs and 480 MHz for integer PLLs. So, for the fractional

PLLs, MULT*refclk must always be equal to 528 MHz and for the integer PLL MULT*refclk = 480 MHz.
- PLL output frequencies must always be higher than 16 MHz.

24.6 Core, Platform and System Bus clocks

There are several asynchronous system clock domains on this device. The primary domains are:

- A7 Core and complex
- DDR, GPU-3D, GPU-2D, NIC0, NIC1 and System buses
- M4 Core, Platform and System buses

These clocks are generated in similar scheme as shown in the following figures.

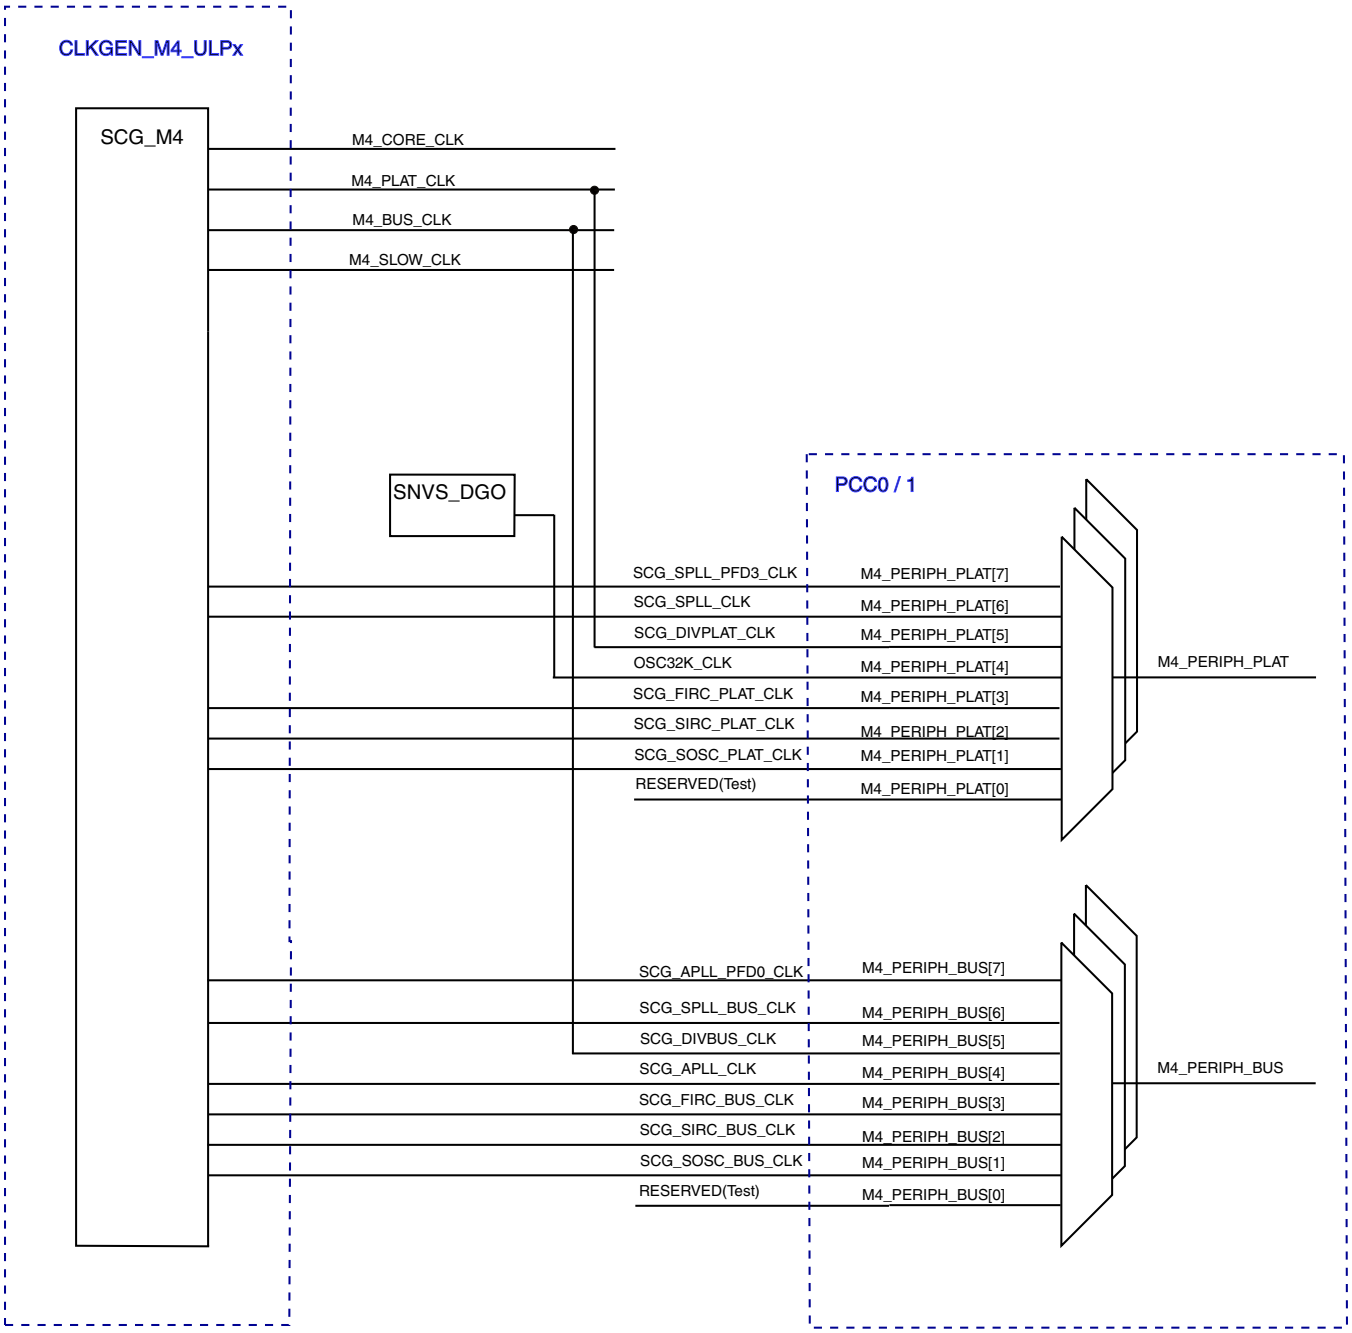


Figure 24-2. System clock generation for M4 domain

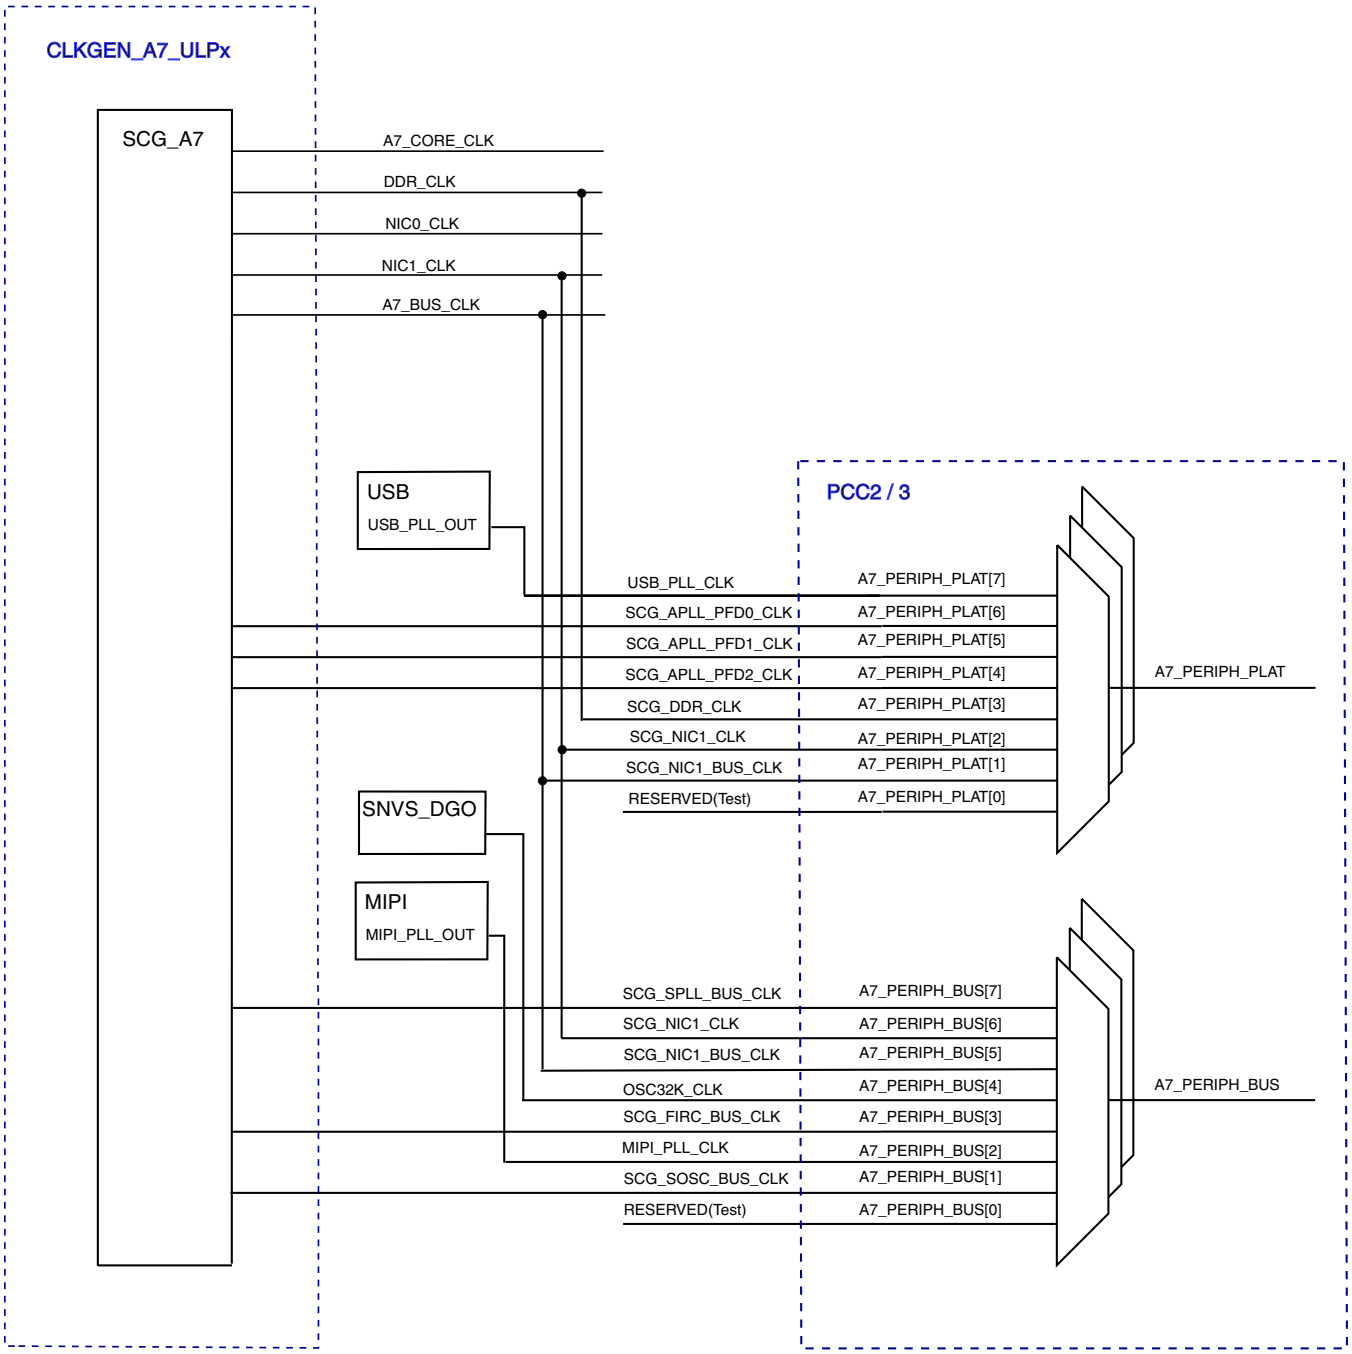

Figure 24-3. System clock generation for A7 domain

NOTE

See Figure 26-2 and Figure 26-3 for details on SCG clocking architecture on M4 and A7 domains.

When this device comes out of reset, the M4 core always boots up first and is responsible for setting up the initial system clocks. It configures system clocking and informs the A7 of its clock frequency and the available clock options. In the event that both cores boot independently, each core will have the option to change the system clocks and the peripheral clocks in its domain.

24.6.1 Clock ratio restrictions

The clock ratio restrictions among the core, platform and IP bus clocks are listed as follows:

- A7 core clock frequency is higher than A7 platform clock frequency.
- Clock ratio must be integers between A7 fast platform (NIC0) and A7 slow platform (NIC1).

NOTE

Use A7 SPLL for core clock and A7 APLL for DDR/NIC clocks.

- Clock ratio must be integers between A7 slow platform and A7 system IP bus.
- Clock ratio must be integers between M4 core/platform and M4 system IP bus.
- M4 slow clock must be slower and an integer division of M4 system IP bus.
- A7 Slow platform (NIC1) clock frequency should be higher than A7 System IP bus clock (NIC1_BUS clock).

NOTE

See Operational requirements for additional restrictions on M4 bus clock/M4 slow clock ratio.

24.7 Generating audio frequencies

Fractional PLL (PLL1) in M4 domain have the ability to generate fractional multiplier that can be used to generate accurate audio frequencies.

$$PLL\ Output\ Freq = Fref\ x\ (MULT + \frac{NUM}{DENOM})$$

where:

- Fref = PLL input reference frequency
- MULT = 7-bit PLL multiplier

- NUM = 30-bit Numerator for fractional multiplier
- DENOM = 30-bit Denominator for fractional multiplier

Here's an example of PLL settings to generate desired audio frequency.

- Desired Freq = 44.1 KHz
- Over Sampled Freq = 256 x 44.1 KHz = 11.289 MHz
- Multiplier = 22.578 [MULT = 22, NUM = 578, DENOM = 1000]
- VCO Output = 24 MHz x 22.578 = 541.872 MHz
- VCO Output/DIV = 11.289 MHz = Over sampled Audio Freq where DIV = 48 (APLL Post Clock Dividers)

NOTE

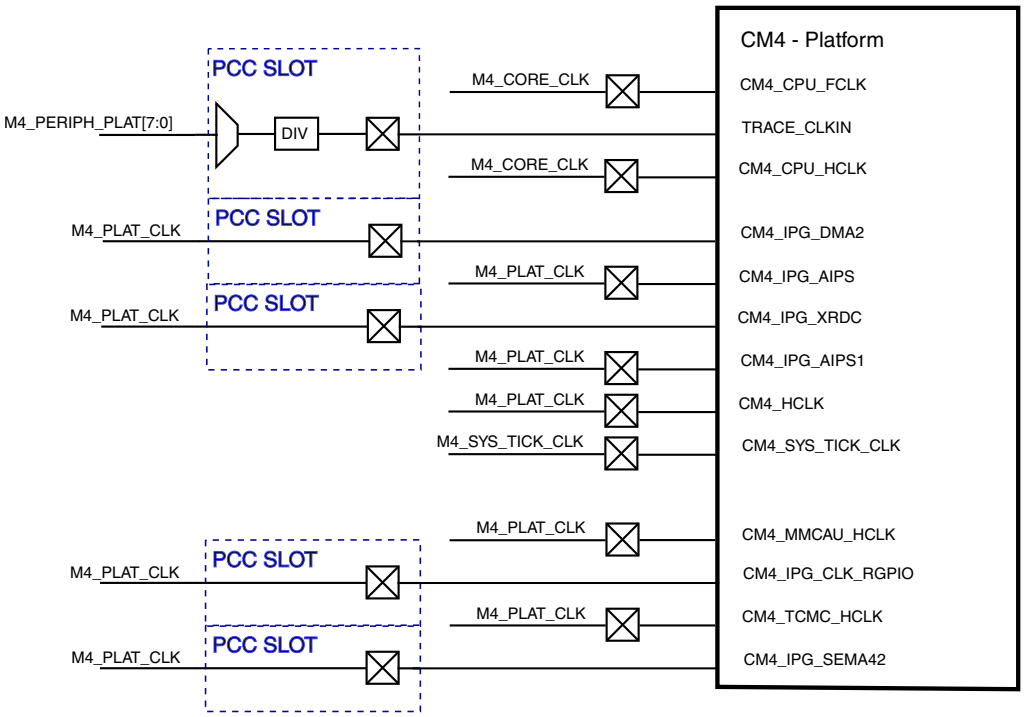
If this clock signal is being directed to either of the SAI PCC channels, APLL Post Clock dividers have to be configured to output a clock signal with a frequency under 50 MHz, due to limitations to the input frequency of the SAI PCC dividers.

Other audio frequencies can be similarly generated by manipulating multiplier (MULT), numerator (NUM) and denominator (DENOM).

24.8 Peripheral clocks

Most peripherals require fixed frequency clocks for their functional logics, such as generating the serial bit stream or reference timer. Therefore, peripheral functional clocks must be independent from the peripheral system bus clock, which can be changed during power mode transition. For peripherals that don't support independent system bus clocks, an asynchronous IPS gasket can be implemented at the IP bus interface.

Each module that requires a functional peripheral clock is provided a separate clock tree with source selection and programmable divider. Peripheral clocks are generated inside the PCC modules and routed to the corresponding peripheral. The following figures show examples of peripheral clock generation for M4 and A7 cores.



Note: Refer to PCC block diagram for clock source mapping

Figure 24-4. M4 peripheral clock generation

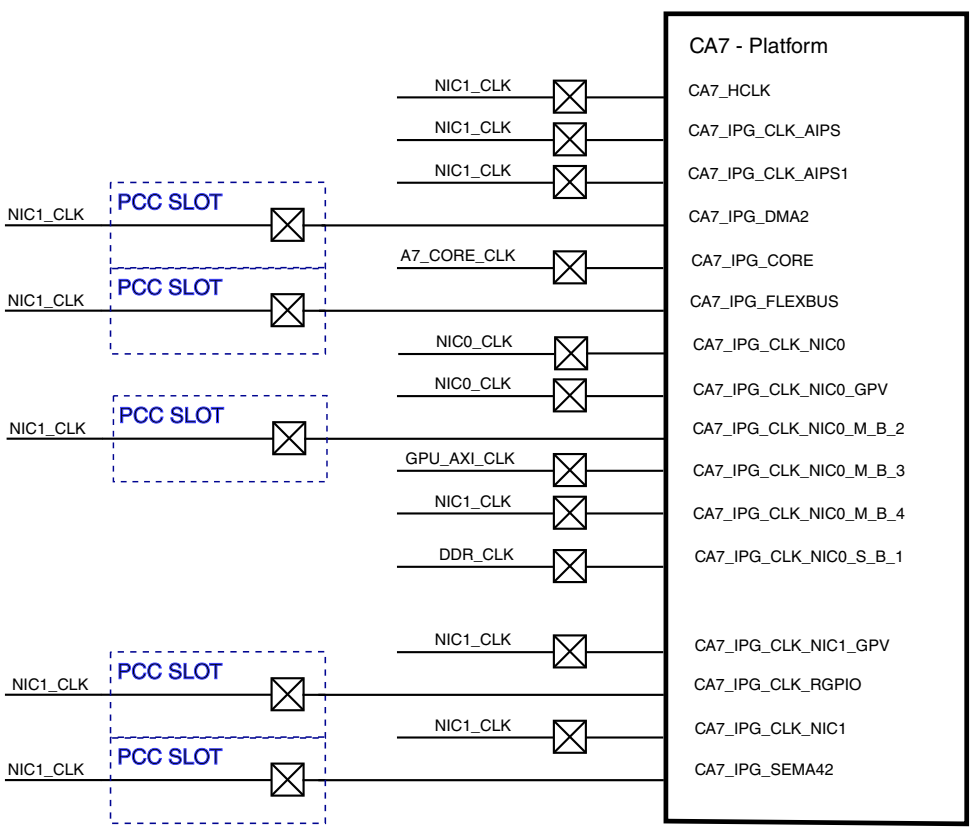


Figure 24-5. A7 peripheral clock generation

The following table lists peripheral clock frequencies and the indication of platform and IP bus clocks. Some peripherals have a local clock generator that can further divide the clock, as required, for the desired serial rate.

24.9 Audio tunable clock

For audio applications where the data stream is coming from a remote source, the device has to locally tune a clock signal to match the remote system clock. The Auxiliary PLL, which provides the clock for master audio, has synchronization logic to support on-the-fly configuration changes. This allows the device to generate a tunable clock for audio stream. The clock from one of the Auxiliary PLLs (PLL1) can be divided by the post-dividers in analog and also the dividers in SCG module.

See the i.MX 7ULP Data Sheet, to see the requirement specifications for the divided tunable clock generated.

24.10 CoreSight debug clocks

As shown in the following table, the CoreSight debug clocks operate using IP Bus clock frequencies.

Table 24-7. CoreSight debug clocks

Clock	Used By	Sources
ATCLK	ATB interface	M4_PLAT_CLK
HCLK	DAP	M4_PLAT_CLK
PCLKDBG	APB interface, DAP, Trace Funnel, ETM, TPIU	M4_PLAT_CLK
DAPCLK		M4_PLAT_CLK
TPIUCLK	TPIU/SWO	TPIU/SWO Clock generation

24.11 Clock restrictions/guidelines

24.11.1 Limitation of NIC/GPU/DDR clock configuration for HSRUN and VLPR mode

There are limitations of NIC/GPU/DDR clock configuration for HSRUN and VLPR modes, because there are no separate registers for those clocks. CA7 Core clock and CM4 system clocks have three registers for each power mode (SCG_RCCR, SCG_VCCR, and SCG_HCCR).

For NIC/GPU/DDR clocks, the user must be careful with the following frequency configurations.

- For transition from RUN to HSRUN mode: NIC/GPU/DDR clocks need to be programmed at HSRUN maximum frequency after A7 domain entered the HSRUN mode. On the other hand, frequencies need to be reduced (RUN frequencies) before HSRUN mode exit.
- For transition from RUN to VLPR mode: NIC clocks need to be programmed before entering the VLPR mode. After that, the user needs to exit the VLPR mode, and then increase the frequencies to RUN mode values.

24.12 Clock dividers

The SCG and PCCs utilize clock dividers to divide the input source clocks and generate required functional clocks for various modules.

- The dividers implemented in SCG and PCCs are integer dividers and can provide any integer division value starting from divide-by-1.
- Division value of a divider is generally controlled by programming a register field.
- The maximum amount of time required to change the divided output clock frequency after programming a register bit is 1 clock cycle of input undivided clock + 1 cycle of output clock.

24.13 Default setting and clock gating

Extensive clock gating is used on this device. Clock gating is implemented at clock tree branches in the SCG for system clocks and in the PCCs for peripheral clocks. The clock gating is controlled by register bit programming and the low power mode of the respective domain.

After the system reset of this device, the following clocks will be enabled by default:

M4 Domain
- Core clock (FIRC)
- Platform clock (FIRC)
- Bus clock(FIRC)
- Slow clock (FIRC)

A7 Domain
- Core clock (FIRC)
- NIC0 clock (FIRC)
- NIC1 clock (FIRC)
- GPU clock (FIRC)
- NIC1 divbus (FIRC)
- NIC1 divext (FIRC)

The remainder of the clocks will be gated and can be enabled by the software or boot code.

24.14 Clock monitoring

The System oscillator clock and the RTC oscillator clock are monitored for their presence by clock monitoring logics in the SCG. Loss of crystal reference clock could generate system reset or an interrupt.

Chapter 25
Peripheral Clock Control

25.1 Chip-specific PCC information

Table 25-1. Reference links to related information

Topic	Related module	Reference
Full description	PCC	PCC

Power management		Power management
Signal multiplexing	Port control	Signal multiplexing

25.1.1 Peripheral Clock Control

The Peripheral Clock Control (PCC) is responsible for clock selection, optional division and clock gating mode for peripherals in their respected power domain.

Table 25-2. PCC configuration

Parameter	Description
Name	PCC
Instances	4
Configurable features	Device specific
Interface speed	NA
External I/O pins	NA

25.1.2 PCC_WDOG register reset values

The reset values of PCC_WDOG1, and PCC_WDOG2 are different, depending on which core is reading the PCC_WDOG1 and PCC_WDOG2 registers, as depicted in the following table.

Table 25-3. PCC_WDOG register reset values

Register name	Reset value when accessed by CM4	Reset value when accessed by CA7
PCC_WDOG1	C0000000h	A0000000h
PCC_WDOG2	C0000000h	A0000000h

25.1.3 PCC reserved registers

PCC0 and PCC1 contains several registers which are reserved for internal use only and are not documented in the PCC memory maps. The offsets and reset values of these registers are given in the table below.

Table 25-4. PCC0 Reserved registers

PCC0 Register Offset	Reset Value
0x41026084	E0000000h
0x41026090	E0000000h
0x41026098	E0000000h
0x4102609C	E0000000h
0x410260F4	E0000000h
0x41026120	E0000000h

Table 25-5. PCC1 Reserved registers

PCC1 Register Offset	Reset Value
0x410B2040	E0000000h
0x410B2080	E0000000h
0x410B2084	E0000000h
0x410B208C	E0000000h
0x410B2090	E0000000h
0x410B2098	E0000000h
0x410B209C	E0000000h
0x410B20C8	E0000000h

25.1.4 Clock source selection through PCS field

The PCS bitfields in all the PCC registers is used for peripherals that support various clock selections. PCS can support upto 8 different clock selections, depending on the value of this field from 000 to 111. On this device, there are 4 instances of PCC: PCC0, PCC1, PCC2, and PCC3.

See Table 24-2 for clock sources mapped to different PCC0/PCC1 clock selects PCS and see Table 24-3 for clock sources mapped to different PCC2/PCC3 clock select PCS.

25.1.5 PCC register implementation on this device

- PCC_TPIU register: In i.MX 7ULP, PCC1_TPIU register is also used for the clock configuration of SWO.
- PCC_USB register: In this device, the HSIC clock programming is done via PCC_USB0[PCS]. PCC_USB1[PCS] is not used.

25.1.6 Peripheral usage restrictions

As documented in each and every PCC register, the INUSE bitfield (bit 29) shows whether a given peripheral instance is currently being used or not by another CPU. Therefore, if a given CPU reads such bitfield as "set", interactions going beyond ordinary register reads between the domain such CPU belongs to and the respective peripheral should be avoided until the bitfield becomes "clear" again. Failing to observe such peripheral usage restrictions may result in unexpected results.

25.2 Introduction

The Peripheral Clock Control (PCC) module provides clock control and configuration for on-chip peripherals. Each peripheral has its own clock control and configuration register.

25.3 Features

The PCC module enables software to configure the following clocking options for each peripheral:

- Interface clock gating

- Functional clock source selection
- Functional clock divide values

Below is a block diagram of the PCC module:

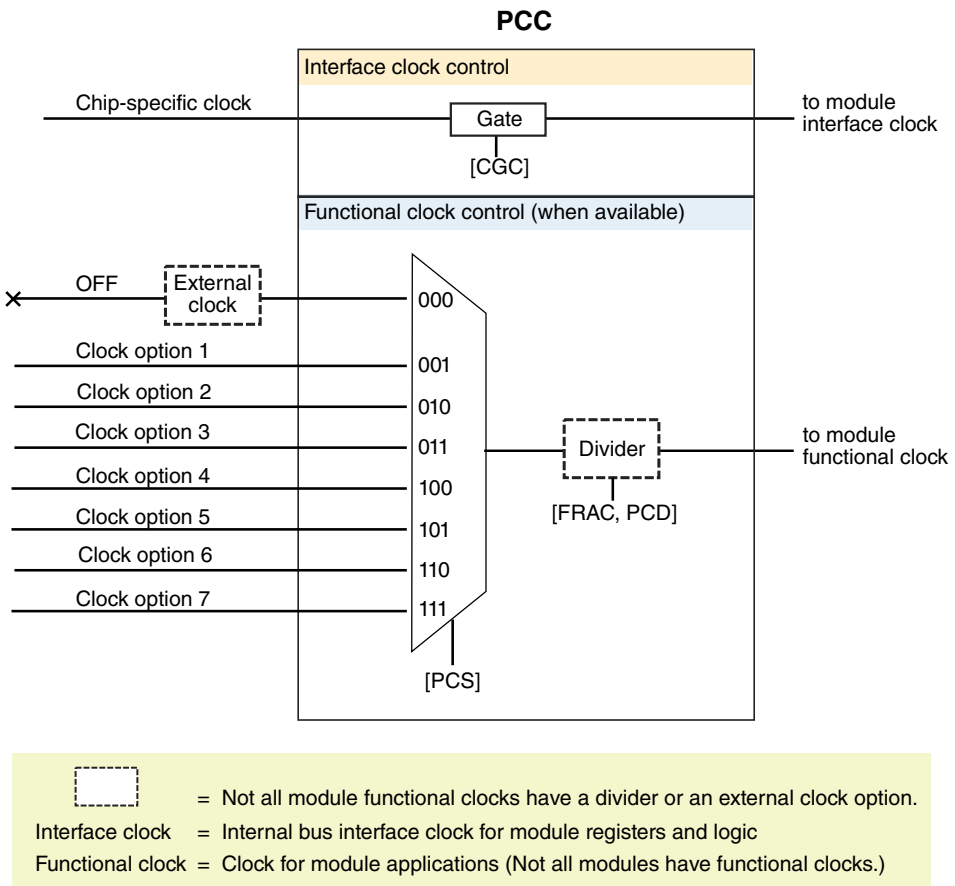

Figure 25-1. PCC Block Diagram

25.4 Functional description

The PCC module provides on-chip peripherals (modules) their own dedicated PCC registers for clock gating and configuration options. Each module's PCC register contains a clock gating control bit (CGC) for the module's interface clock. Before a module can be used, its interface clock must be enabled (CGC = 1) in the module's PCC register.

If a module has a functional clock, its PCC register may provide options for the clock source, selected by programming the Peripheral Clock Select (PCS) field. Optionally, a module may also have a clock divider, selected by programming the Peripheral Clock Divider (PCD) field along with a Fraction (FRAC) field. Before configuring a functional clock, the module's interface clock must be disabled (CGC = 0).

25.5 Memory map and register definition

Each module has its own dedicated PCC register, which controls the clock gating, clock source and divider (when applicable) for that specific module. See each module's PCC register for details.

PCC registers can be written only in supervisor mode using 32-bit accesses.

NOTE

To configure the clocking options available to a given module or to modify an existing configuration, first disable the module's interface clock by writing 0 to its CGC bit.

25.6 PCC register descriptions

25.6.2.4 Fields

Field	Function
31 PR	Present This bit shows whether the peripheral is present on this device. 0b - Peripheral is not present. 1b - Peripheral is present.
30 CGC	Clock Gate Control This read/write bit enables the interface clock for the peripheral, allowing access to the module's registers. It also controls whether the clock selection and divider options can be modified. 0b - Clock disabled. The current clock selection and divider options are not locked and can be modified. 1b - Clock enabled. The current clock selection and divider options are locked and cannot be modified.
29 INUSE	In use flag This read-only bit shows that this peripheral is being used by another core. That is, software on another core has already configured the clocking options of this peripheral. For example, if CPU0 software has set this peripheral's CGC bit first, it sees the INUSE bit as cleared. However, if software on another core has set this peripheral's CGC bit first, CPU0 software sees the INUSE bit as set. 0b - Peripheral is not being used. 1b - Peripheral is being used. Software cannot modify the existing clocking configuration.
28-27 —	This read-only bit field is reserved and always has the value 0.
26-24 —	This read-only bit field is reserved and always has the value 0.
23-4 —	This read-only bit field is reserved and always has the value 0.
3	This read-only bit field is reserved and always has the value 0.

Table continues on the next page...

Field	Function
—	
2-0 —	This read-only bit field is reserved and always has the value 0.

25.6.3 PCC RGPIO2P0 Register (PCC_RGPIO2P0)

25.6.3.1 Offset

Register	Offset
PCC_RGPIO2P0	3Ch

25.6.3.2 Function

This register is for the RGPIO2P0 module.

25.6.3.4 Fields

Field	Function
31 PR	Present This bit shows whether the peripheral is present on this device.

Table continues on the next page...

Field	Function
	0b - Peripheral is not present. 1b - Peripheral is present.
30 CGC	Clock Gate Control This read/write bit enables the interface clock for the peripheral, allowing access to the module's registers. It also controls whether the clock selection and divider options can be modified. 0b - Clock disabled. The current clock selection and divider options are not locked and can be modified. 1b - Clock enabled. The current clock selection and divider options are locked and cannot be modified.
29 INUSE	In use flag This read-only bit shows that this peripheral is being used by another core. That is, software on another core has already configured the clocking options of this peripheral. For example, if CPU0 software has set this peripheral's CGC bit first, it sees the INUSE bit as cleared. However, if software on another core has set this peripheral's CGC bit first, CPU0 software sees the INUSE bit as set. 0b - Peripheral is not being used. 1b - Peripheral is being used. Software cannot modify the existing clocking configuration.
28-27 —	This read-only bit field is reserved and always has the value 0.
26-24 —	This read-only bit field is reserved and always has the value 0.
23-4 —	This read-only bit field is reserved and always has the value 0.
3 —	This read-only bit field is reserved and always has the value 0.
2-0 —	This read-only bit field is reserved and always has the value 0.

25.6.4 PCC XRDC Register (PCC_XRDC)

25.6.4.1 Offset

Register	Offset
PCC_XRDC	50h

25.6.4.2 Function

This register is for the XRDC module.

25.6.8 PCC WDOG0 Register (PCC_WDOG0)

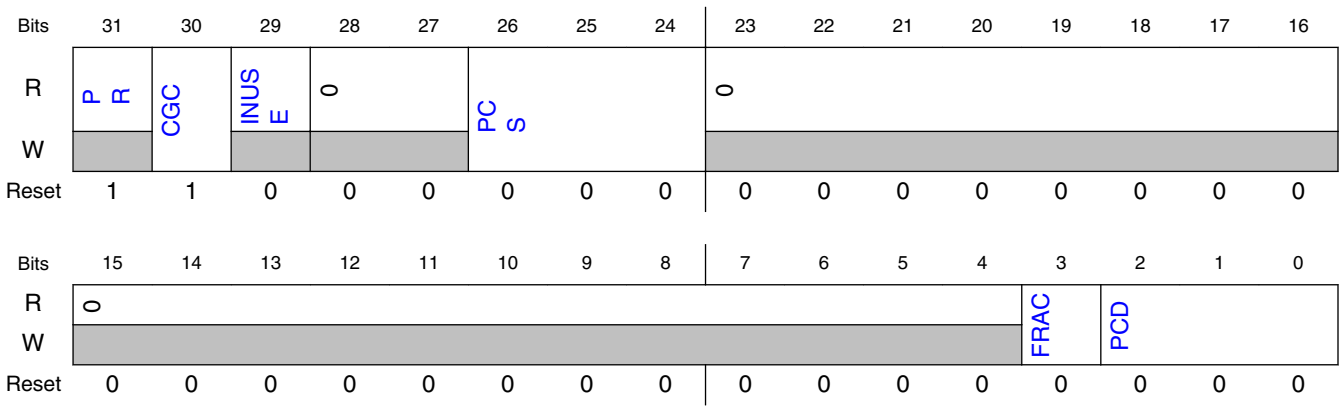
25.6.8.1 Offset

Register	Offset
PCC_WDOG0	94h

25.6.8.2 Function

This register is for the WDOG0 module.

25.6.8.3 Diagram



25.6.8.4 Fields

Field	Function
31 PR	Present This bit shows whether the peripheral is present on this device. 0b - Peripheral is not present. 1b - Peripheral is present.
30 CGC	Clock Gate Control This read/write bit enables the interface clock for the peripheral, allowing access to the module's registers. It also controls whether the clock selection and divider options can be modified. 0b - Clock disabled. The current clock selection and divider options are not locked and can be modified. 1b - Clock enabled. The current clock selection and divider options are locked and cannot be modified.
29 INUSE	In use flag This read-only bit shows that this peripheral is being used by another core. That is, software on another core has already configured the clocking options of this peripheral. For example, if CPU0 software has set this peripheral's CGC bit first, it sees the INUSE bit as cleared. However, if software on another core has set this peripheral's CGC bit first, CPU0 software sees the INUSE bit as set. 0b - Peripheral is not being used. 1b - Peripheral is being used. Software cannot modify the existing clocking configuration.
28-27 —	This read-only bit field is reserved and always has the value 0.
26-24 PCS	Peripheral Clock Source Select This read/write bit field is used for peripherals that support various clock selections. This field can be written only when the clock is disabled (CGC = 0). Similarly, if the INUSE flag is set, this field is locked. 000b - Clock is off. 001b - Clock option 1

Table continues on the next page...

Field	Function
	010b - Clock option 2 011b - Clock option 3 100b - Clock option 4 101b - Clock option 5 110b - Clock option 6 111b - Clock option 7
23-4 —	This read-only bit field is reserved and always has the value 0.
3 FRAC	Peripheral Clock Divider Fraction This read/write bit field sets the fraction multiply value for the fractional clock divider used as a clock source. Divider output clock = Divider input clock x [(FRAC+1)/(PCD+1)]. This field can be written only when the clock is disabled (CGC = 0). Similarly, if the INUSE flag is set, this field is locked. **NOTE:** When dividing by 1 (PCD = 000), do not set the FRAC bit; otherwise, the output clock is disabled. 0b - Fractional value is 0. 1b - Fractional value is 1.
2-0 PCD	Peripheral Clock Divider Select This read/write bit field is used for peripherals that require a clock divider. Divider output clock = Divider input clock x [(FRAC+1)/(PCD+1)]. This field can be written only when the clock is disabled (CGC = 0). Similarly, if the INUSE flag is set, this field is locked. 000b - Divide by 1. 001b - Divide by 2. 010b - Divide by 3. 011b - Divide by 4. 100b - Divide by 5. 101b - Divide by 6. 110b - Divide by 7. 111b - Divide by 8.

25.6.9 PCC CRC Register (PCC_CRC)

25.6.9.1 Offset

Register	Offset
PCC_CRC	A4h

25.6.9.2 Function

This register is for the CRC module.

25.6.9.3 Diagram

30 CGC	Clock Gate Control This read/write bit enables the interface clock for the peripheral, allowing access to the module's registers. It also controls whether the clock selection and divider options can be modified. 0b - Clock disabled. The current clock selection and divider options are not locked and can be modified. 1b - Clock enabled. The current clock selection and divider options are locked and cannot be modified.
29 INUSE	In use flag

Table continues on the next page...

Field	Function
	This read-only bit shows that this peripheral is being used by another core. That is, software on another core has already configured the clocking options of this peripheral. For example, if CPU0 software has set this peripheral's CGC bit first, it sees the INUSE bit as cleared. However, if software on another core has set this peripheral's CGC bit first, CPU0 software sees the INUSE bit as set. 0b - Peripheral is not being used. 1b - Peripheral is being used. Software cannot modify the existing clocking configuration.
28-27 —	This read-only bit field is reserved and always has the value 0.
26-24 PCS	Peripheral Clock Source Select This read/write bit field is used for peripherals that support various clock selections. This field can be written only when the clock is disabled (CGC = 0). Similarly, if the INUSE flag is set, this field is locked. 000b - Clock is off. 001b - Clock option 1 010b - Clock option 2 011b - Clock option 3 100b - Clock option 4 101b - Clock option 5 110b - Clock option 6 111b - Clock option 7
23-4 —	This read-only bit field is reserved and always has the value 0.
3 —	This read-only bit field is reserved and always has the value 0.
2-0 —	This read-only bit field is reserved and always has the value 0.

25.6.22.4 Fields

Field	Function
31 PR	Present This bit shows whether the peripheral is present on this device. 0b - Peripheral is not present. 1b - Peripheral is present.
30 CGC	Clock Gate Control This read/write bit enables the interface clock for the peripheral, allowing access to the module's registers. It also controls whether the clock selection and divider options can be modified. 0b - Clock disabled. The current clock selection and divider options are not locked and can be modified. 1b - Clock enabled. The current clock selection and divider options are locked and cannot be modified.
29 INUSE	In use flag This read-only bit shows that this peripheral is being used by another core. That is, software on another core has already configured the clocking options of this peripheral. For example, if CPU0 software has set this peripheral's CGC bit first, it sees the INUSE bit as cleared. However, if software on another core has set this peripheral's CGC bit first, CPU0 software sees the INUSE bit as set. 0b - Peripheral is not being used. 1b - Peripheral is being used. Software cannot modify the existing clocking configuration.
28-27 —	This read-only bit field is reserved and always has the value 0.
26-24 PCS	Peripheral Clock Source Select This read/write bit field is used for peripherals that support various clock selections. This field can be written only when the clock is disabled (CGC = 0). Similarly, if the INUSE flag is set, this field is locked. 000b - Clock is off. An external clock can be enabled for this peripheral. 001b - Clock option 1 010b - Clock option 2 011b - Clock option 3 100b - Clock option 4 101b - Clock option 5 110b - Clock option 6 111b - Clock option 7
23-16 FRAC	Peripheral Clock Divider Fraction This read/write bit field sets the fraction multiply value for the fractional clock divider used as a clock source. Divider output clock = Divider input clock x [(FRAC+1)/(PCD+1)]. This field can be written only when the clock is disabled (CGC = 0). Similarly, if the INUSE flag is set, this field is locked. **NOTE:** When dividing by 1 (PCD = 000), do not set the FRAC bit; otherwise, the output clock is disabled. 00000000b - Fractional value is 0. 00000001b - Fractional value is 1.
15-0 PCD	Peripheral Clock Divider Select

Field	Function
	This read/write bit field is used for peripherals that require a clock divider. Divider output clock = Divider input clock x [(FRAC+1)/(PCD+1)]. This field can be written only when the clock is disabled (CGC = 0). Similarly, if the INUSE flag is set, this field is locked.

30 CGC	Clock Gate Control This read/write bit enables the interface clock for the peripheral, allowing access to the module's registers. It also controls whether the clock selection and divider options can be modified. 0b - Clock disabled. The current clock selection and divider options are not locked and can be modified.

Table continues on the next page...

Field	Function
	1b - Clock enabled. The current clock selection and divider options are locked and cannot be modified.
29 INUSE	In use flag This read-only bit shows that this peripheral is being used by another core. That is, software on another core has already configured the clocking options of this peripheral. For example, if CPU0 software has set this peripheral's CGC bit first, it sees the INUSE bit as cleared. However, if software on another core has set this peripheral's CGC bit first, CPU0 software sees the INUSE bit as set. 0b - Peripheral is not being used. 1b - Peripheral is being used. Software cannot modify the existing clocking configuration.
28-27 —	This read-only bit field is reserved and always has the value 0.

Field	Function
	1b - Clock enabled. The current clock selection and divider options are locked and cannot be modified.
29 INUSE	In use flag This read-only bit shows that this peripheral is being used by another core. That is, software on another core has already configured the clocking options of this peripheral. For example, if CPU0 software has set this peripheral's CGC bit first, it sees the INUSE bit as cleared. However, if software on another core has set this peripheral's CGC bit first, CPU0 software sees the INUSE bit as set. 0b - Peripheral is not being used. 1b - Peripheral is being used. Software cannot modify the existing clocking configuration.
28-27 —	This read-only bit field is reserved and always has the value 0.
26-24 PCS	Peripheral Clock Source Select This read/write bit field is used for peripherals that support various clock selections. This field can be written only when the clock is disabled (CGC = 0). Similarly, if the INUSE flag is set, this field is locked. 000b - Clock is off. 001b - Clock option 1 010b - Clock option 2 011b - Clock option 3 100b - Clock option 4 101b - Clock option 5 110b - Clock option 6 111b - Clock option 7
23-4 —	This read-only bit field is reserved and always has the value 0.
3 —	This read-only bit field is reserved and always has the value 0.
2-0 —	This read-only bit field is reserved and always has the value 0.

25.7.6.4 Fields

Field	Function
31 PR	Present This bit shows whether the peripheral is present on this device. 0b - Peripheral is not present. 1b - Peripheral is present.
30 CGC	Clock Gate Control This read/write bit enables the interface clock for the peripheral, allowing access to the module's registers. It also controls whether the clock selection and divider options can be modified. 0b - Clock disabled. The current clock selection and divider options are not locked and can be modified. 1b - Clock enabled. The current clock selection and divider options are locked and cannot be modified.
29 INUSE	In use flag This read-only bit shows that this peripheral is being used by another core. That is, software on another core has already configured the clocking options of this peripheral. For example, if CPU0 software has set this peripheral's CGC bit first, it sees the INUSE bit as cleared. However, if software on another core has set this peripheral's CGC bit first, CPU0 software sees the INUSE bit as set. 0b - Peripheral is not being used. 1b - Peripheral is being used. Software cannot modify the existing clocking configuration.
28-27 —	This read-only bit field is reserved and always has the value 0.
26-24	Peripheral Clock Source Select

Table continues on the next page...

Field	Function
PCS	This read/write bit field is used for peripherals that support various clock selections. This field can be written only when the clock is disabled (CGC = 0). Similarly, if the INUSE flag is set, this field is locked. 000b - Clock is off. An external clock can be enabled for this peripheral. 001b - Clock option 1 010b - Clock option 2 011b - Clock option 3 100b - Clock option 4 101b - Clock option 5 110b - Clock option 6 111b - Clock option 7
23-16 FRAC	Peripheral Clock Divider Fraction This read/write bit field sets the fraction multiply value for the fractional clock divider used as a clock source. Divider output clock = Divider input clock x [(FRAC+1)/(PCD+1)]. This field can be written only when the clock is disabled (CGC = 0). Similarly, if the INUSE flag is set, this field is locked. **NOTE:** When dividing by 1 (PCD = 000), do not set the FRAC bit; otherwise, the output clock is disabled. 00000000b - Fractional value is 0. 00000001b - Fractional value is 1.
15-0 PCD	Peripheral Clock Divider Select This read/write bit field is used for peripherals that require a clock divider. Divider output clock = Divider input clock x [(FRAC+1)/(PCD+1)]. This field can be written only when the clock is disabled (CGC = 0). Similarly, if the INUSE flag is set, this field is locked.

25.7.7 PCC LPUART2 Register (PCC_LPUART2)

25.7.7.1 Offset

Field	Function
31 PR	Present This bit shows whether the peripheral is present on this device. 0b - Peripheral is not present. 1b - Peripheral is present.
30 CGC	Clock Gate Control This read/write bit enables the interface clock for the peripheral, allowing access to the module's registers. It also controls whether the clock selection and divider options can be modified. 0b - Clock disabled. The current clock selection and divider options are not locked and can be modified. 1b - Clock enabled. The current clock selection and divider options are locked and cannot be modified.
29 INUSE	In use flag This read-only bit shows that this peripheral is being used by another core. That is, software on another core has already configured the clocking options of this peripheral. For example, if CPU0 software has set this peripheral's CGC bit first, it sees the INUSE bit as cleared. However, if software on another core has set this peripheral's CGC bit first, CPU0 software sees the INUSE bit as set. 0b - Peripheral is not being used. 1b - Peripheral is being used. Software cannot modify the existing clocking configuration.
28-27 —	This read-only bit field is reserved and always has the value 0.
26-24 PCS	Peripheral Clock Source Select This read/write bit field is used for peripherals that support various clock selections. This field can be written only when the clock is disabled (CGC = 0). Similarly, if the INUSE flag is set, this field is locked. 000b - Clock is off.

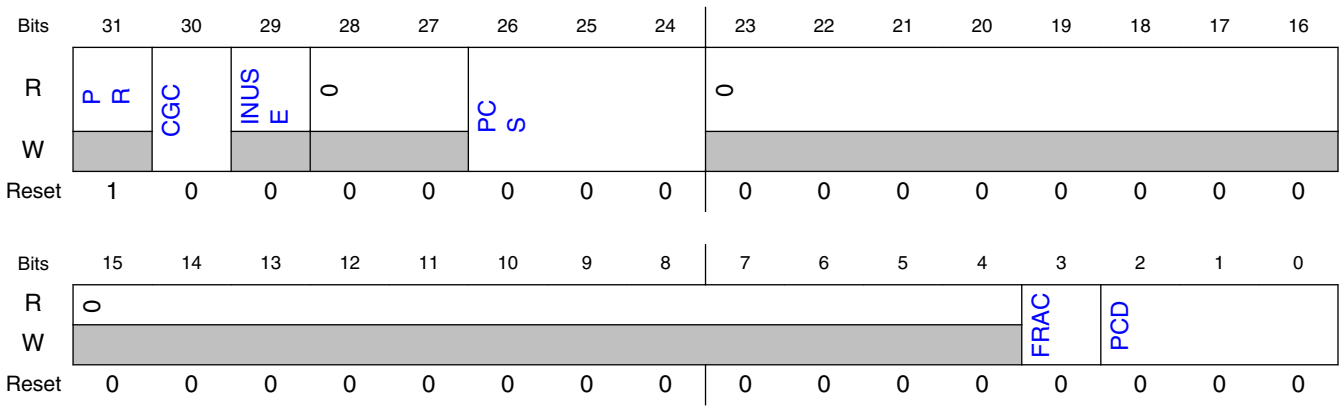
PCC_USDHC0	DCh

25.8.22.2 Function

This register is for the USDHC0 module.

25.8.22.3 Diagram



25.8.22.4 Fields

Field	Function
31 PR	Present This bit shows whether the peripheral is present on this device. 0b - Peripheral is not present. 1b - Peripheral is present.
30 CGC	Clock Gate Control This read/write bit enables the interface clock for the peripheral, allowing access to the module's registers. It also controls whether the clock selection and divider options can be modified. 0b - Clock disabled. The current clock selection and divider options are not locked and can be modified. 1b - Clock enabled. The current clock selection and divider options are locked and cannot be modified.
29 INUSE	In use flag This read-only bit shows that this peripheral is being used by another core. That is, software on another core has already configured the clocking options of this peripheral. For example, if CPU0 software has set this peripheral's CGC bit first, it sees the INUSE bit as cleared. However, if software on another core has set this peripheral's CGC bit first, CPU0 software sees the INUSE bit as set. 0b - Peripheral is not being used. 1b - Peripheral is being used. Software cannot modify the existing clocking configuration.
28-27 —	This read-only bit field is reserved and always has the value 0.
26-24 PCS	Peripheral Clock Source Select This read/write bit field is used for peripherals that support various clock selections. This field can be written only when the clock is disabled (CGC = 0). Similarly, if the INUSE flag is set, this field is locked. 000b - Clock is off. An external clock can be enabled for this peripheral. 001b - Clock option 1

Table continues on the next page...

Field	Function
	010b - Clock option 2 011b - Clock option 3 100b - Clock option 4 101b - Clock option 5 110b - Clock option 6 111b - Clock option 7
23-4 —	This read-only bit field is reserved and always has the value 0.
3 FRAC	Peripheral Clock Divider Fraction This read/write bit field sets the fraction multiply value for the fractional clock divider used as a clock source. Divider output clock = Divider input clock x [(FRAC+1)/(PCD+1)]. This field can be written only when the clock is disabled (CGC = 0). Similarly, if the INUSE flag is set, this field is locked. **NOTE:** When dividing by 1 (PCD = 000), do not set the FRAC bit; otherwise, the output clock is disabled. 0b - Fractional value is 0. 1b - Fractional value is 1.
2-0 PCD	Peripheral Clock Divider Select This read/write bit field is used for peripherals that require a clock divider. Divider output clock = Divider input clock x [(FRAC+1)/(PCD+1)]. This field can be written only when the clock is disabled (CGC = 0). Similarly, if the INUSE flag is set, this field is locked. 000b - Divide by 1. 001b - Divide by 2. 010b - Divide by 3. 011b - Divide by 4. 100b - Divide by 5. 101b - Divide by 6. 110b - Divide by 7. 111b - Divide by 8.

25.9.7.4 Fields

Field	Function
31 PR	Present This bit shows whether the peripheral is present on this device. 0b - Peripheral is not present. 1b - Peripheral is present.
30 CGC	Clock Gate Control This read/write bit enables the interface clock for the peripheral, allowing access to the module's registers. It also controls whether the clock selection and divider options can be modified. 0b - Clock disabled. The current clock selection and divider options are not locked and can be modified. 1b - Clock enabled. The current clock selection and divider options are locked and cannot be modified.
29 INUSE	In use flag This read-only bit shows that this peripheral is being used by another core. That is, software on another core has already configured the clocking options of this peripheral. For example, if CPU0 software has set this peripheral's CGC bit first, it sees the INUSE bit as cleared. However, if software on another core has set this peripheral's CGC bit first, CPU0 software sees the INUSE bit as set. 0b - Peripheral is not being used. 1b - Peripheral is being used. Software cannot modify the existing clocking configuration.
28-27 —	This read-only bit field is reserved and always has the value 0.
26-24 PCS	Peripheral Clock Source Select This read/write bit field is used for peripherals that support various clock selections. This field can be written only when the clock is disabled (CGC = 0). Similarly, if the INUSE flag is set, this field is locked. 000b - Clock is off. 001b - Clock option 1 010b - Clock option 2 011b - Clock option 3 100b - Clock option 4 101b - Clock option 5 110b - Clock option 6 111b - Clock option 7
23-4 —	This read-only bit field is reserved and always has the value 0.
3 —	This read-only bit field is reserved and always has the value 0.
2-0 —	This read-only bit field is reserved and always has the value 0.

Chapter 26
System Clock Generator (SCG)

26.1 Chip-specific SCG information

Table 26-1. Reference links to related information

Topic	Related module	Reference
Full description	SCG	SCG
System memory map		System memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port control	Signal multiplexing

26.1.1 System Clock Generation

The System Clock Generation (SCG) is responsible for clock generation and distribution across this device. Functions performed by the SCG include: clock reference selection, generation of clock used to derive processor, system, peripheral bus and external memory interface clocks, source selection for peripheral clocks, and control of power saving clock gating mode.

Table 26-2. SCG configuration

Parameter	Description
Name	SCG
Instances	2
Configurable features	• SCG for dual cores, dual power domains • SCG0 in CM4 domain and SCG1 in CA7 domain
Interface speed	NA
External I/O pins	NA

26.1.2 DDR clock divider change procedure

When changing the DDR clock divider (including changes from 0 to another value), the following procedure must be followed.

1. Gate off MMDC clock (clear PCC_MMDC[CGC] in PCC3).
2. If NIC is using DDR as clock source (SCG1_NICCCR[NICCS] = 0x1), change NIC clock to a source other than DDR clock (for example, FIRC).
3. Disable SCG1 APLL (DDR clock source) and gate off SCG1 APLL PFDs (via APLLPFD register) in case a PFD output is selected (APLLCSR[PLLS] = 0x1). If CA7 core clock is using SCG1 APLL as its clock source (SCG1 CSR[SCS] = 0x5), this must be changed likewise before disabling SCG1 APLL.
4. Change DDR clock divider (via SCG1_DDRCCR[DDRDIV] register field).
5. Re-enable SCG1 APLL; wait for it to be valid (SCG1_APLLCSR[APLLVLD] = 0x1), and ungate APLL PFDs (if applicable).
6. Change NIC clock source back to DDR clock (SCG1_NICCR[NICCS] = 0x1) (if applicable).
7. Ungate MMDC clock (set PCC_MMDC[CGC] in PCC3).

26.1.3 SOSC operation in VLLS mode

SOSC remains active in M4 VLLS mode, should all SOSCCSR[SOSCEN], SOSCCSR[SOSCSTEN], and SOSCCSR[SOSCLPEN] bits are set upon entering such mode. Therefore, clearing any of these bits before an M4 VLLS entry prevents SOSC from remaining active under such power mode.

26.1.4 Instantiation information for SCG0 (M4) and SCG1 (A7)

There are two instances of SCG available on this device: SCG0 (M4 domain) and SCG1 (A7 domain). Following are some of the differences in both the instances.

For SCG0:

- The reset value of SCG_SPLLCFG register is 0x0003_0000 and width of SCG_SPLLCFG[MULT] is 3 (bits 16-18).
- PLL Output Frequency = Divided Reference Frequency * MULT

- SCG0 SPLL can generate a low jitter output clock of 480 MHz from a 16, 19.2, 24, 30, 32 MHz reference clock. It is an integer-N synthesizer. The frequency multiplier factor should be 30, 25, 20, 16, 15.
- The reset value of SCG_APLLLOCK_CNFG register is 16'h468 and the reset value of SCG_SPLLLOCK_CNFG is 16'h168. However, just the SCG_SPLLLOCK_CNFG register is overwritten to 16’h12C0 during the boot flow. These registers should be reprogramed when reconfiguring the PLLs with the result of the following equation:

  SCG_xPLLLOCK_CNFG = 150 µs / (1/PLL Ref Clock).

For SCG1:

- The reset value of SCG1 SPLLCFG register is 0x0116_0000. The SPLLCFG[MULT] is 7 bits [22:16].
- PLL Output Frequency = Divided Reference Frequency * (MULT + NUM/DENOM)
- SCG1 SPLL can generate a low jitter output clock of 528 MHz from a 24 MHz reference clock. It also generated 528, 518.4, 520, 510, and 512 MHz from a 16, 19.2, 26, 30, 32 MHz reference clock respectively. It is an Integer-N loop.
- The reset value of SCG_APLLLOCK_CNFG register is 16'h468 and the reset value of SCG_SPLLLOCK_CNFG is 16'h468. However, both the registers are overwritten to 16’h12C0 during the boot flow. These registers should be reprogrammed when reconfiguring the PLLs with the result of the following equation:

  SCG_xPLLLOCK_CNFG = 150 µs / (1/PLL Ref Clock).

  .
- SCG1_NICCSR[NIC1_DIVEXT] exists, but it is not used by the device as an internal clock. However, SCG1_NICCSR[NIC1_DIVEXT] is used as a Flex Bus clock through CLKOUT pin, controlled by SCG1_CLKOUTCNFG. Refer Figure 26-2 and Figure 26-3 for details.
- SIRCSSR[LK] bitfield is read-only and can't be written on SCG1.
- SPLLCFG [24] bit changes its reset value to 0 as soon as the protocol clock is available to the module.
- Bit 28 of PARAM[DIVPRES] is reserved with reset 1, and should be ignored.
- FIRCCSR[FIRCTREN] bitfields are read-only and can't be written for this instance (SCG1).

26.2 Introduction

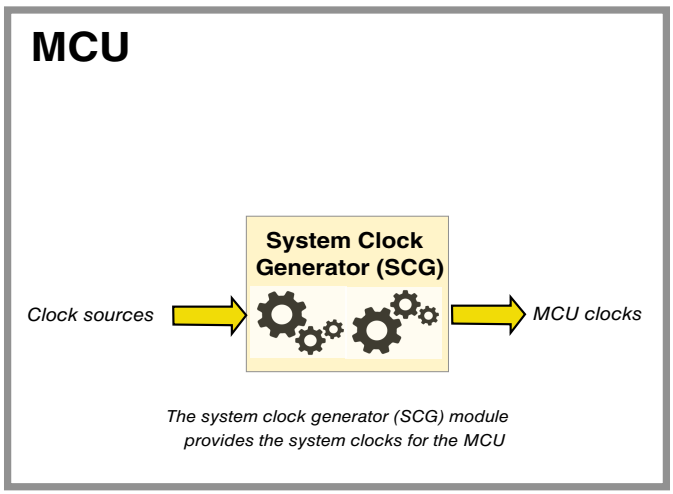

Figure 26-1. System Clock Generator (SCG) in MCU

The system clock generator (SCG) module provides the system clocks for the MCU. The SCG contains:

- an auxiliary phase-locked loop (APLL) with PLL Fractional Divide (PFD) outputs
- a system phase-locked loop (SPLL) with PLL Fractional Divide (PFD) outputs
- a slow internal reference clock (SIRC)
- a fast internal reference clock (FIRC)
- a system oscillator clock (SOSC)

The PLLs are sourced by the SOSC reference clock.

The SCG can select a source for the MCU system clocks, from one of the following: :

- the output clock of the Auxiliary PLL (APLL)
- the output clock of the System PLL (SPLL)
- a SCG reference clock (SIRC, FIRC, and SOSC)

To produce the external reference clock (which is also available as a clock source for the MCU systems clocks), the SCG can also work with crystal oscillators, using either an external crystal, a ceramic resonator, or some other external clock source.

26.2.1 Features

Key features of the SCG module are:

- Auxiliary Phase-locked loop (APLL):
  - Voltage-controlled oscillator (VCO)
  - Selectable Internal or External reference clock is used as the APLL source

    - Modulo VCO frequency divider
    - Phase/Frequency detector
    - Integrated loop filter
    - Can be selected as the clock source for the MCU system clocks
    - 3 programmable post-dividers clock outputs, which can be used as clock sources for other on-chip peripherals
    - 4 programmable fractional post-dividers clock outputs, which can be used as clock sources for system or other on-chip peripherals
- System Phase-locked loop (SPLL):
    - Voltage-controlled oscillator (VCO)
    - Selectable Internal or External reference clock is used as the PLL source
    - Modulo VCO frequency divider
    - Phase/Frequency detector
    - Integrated loop filter
    - Can be selected as the clock source for the MCU system clocks
    - 3 programmable post-dividers clock outputs, which can be used as clock sources for other on-chip peripherals
    - 4 programmable fractional post-dividers clock outputs, which can be used as clock sources for system or other on-chip peripherals
- 2 Internal reference clock (IRC) generators:
    - Slow IRC clock with programmable High and Low frequency range, with each range having a set of 8 trim bits for accuracy
    - Fast IRC clock with programmable High and Low frequency range, with 3 sets of trim bits for accuracy
    - Either the slow or the fast clock can be selected as the clock source for the MCU system clocks
    - 3 programmable post-divider clock outputs for each IRC, which can be used as clock sources for other on-chip peripherals
- System Crystal Oscillator:
    - Can be used as a source for the Auxiliary PLL

    - Can be used as a source for the System PLL
    - Can be selected as the clock source for the MCU system clocks
- External clock from the Real Time Counter (RTC):
    - Can be selected as the clock source for the MCU
- Clock monitor with reset and interrupt request capability for SOSC, ROSC clocks
- Each of the clock sources have reference dividers for clocking on-chip modules and peripherals, namely:
    - APLLDIV1_CLK / APLLDIV2_CLK / APLLDIV3_CLK
    - SPLLDIV1_CLK / SPLLDIV2_CLK / SPLLDIV3_CLK
    - FIRCDIV1_CLK / SCG_FIRCDIV2_CLK / SCG_FIRCDIV3_CLK
    - SIRCDIV1_CLK / SIRCDIV2_CLK / SIRCDIV3_CLK
    - SOSCDIV1_CLK / SOSCDIV2_CLK / SOSCDIV3_CLK

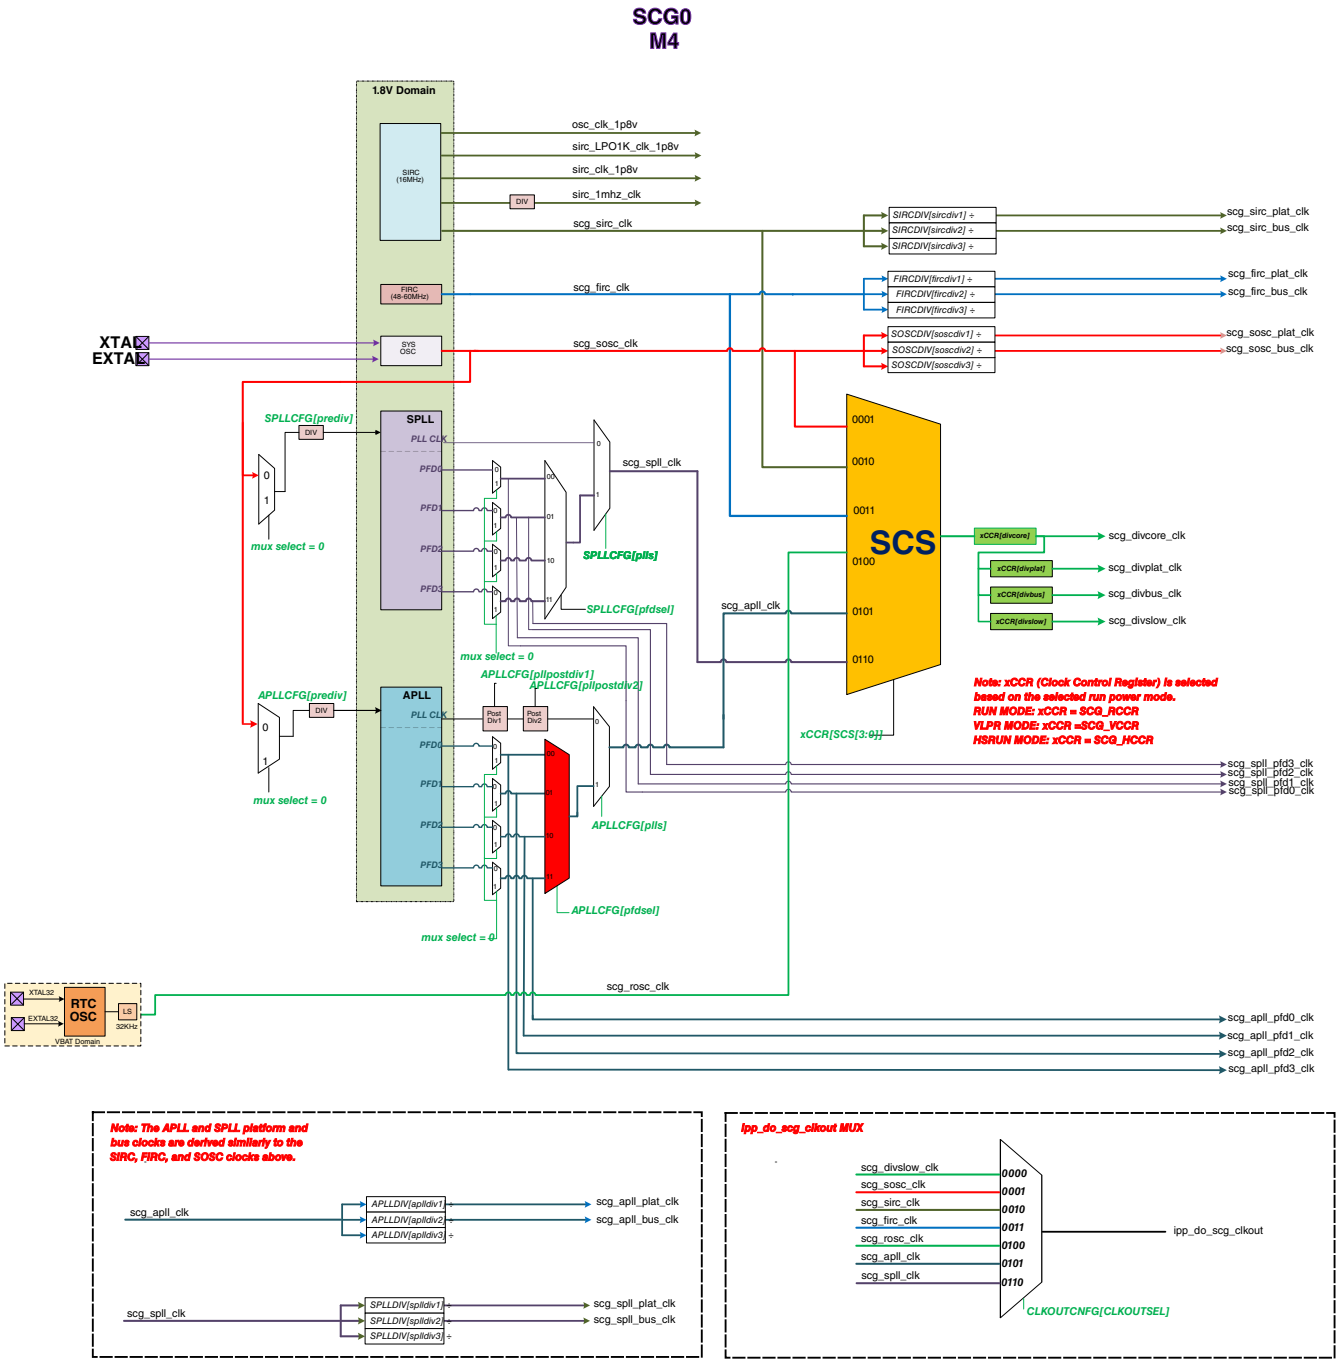

Figure 26-2. System Clock Generator block diagram for SCG0, M4 Domain

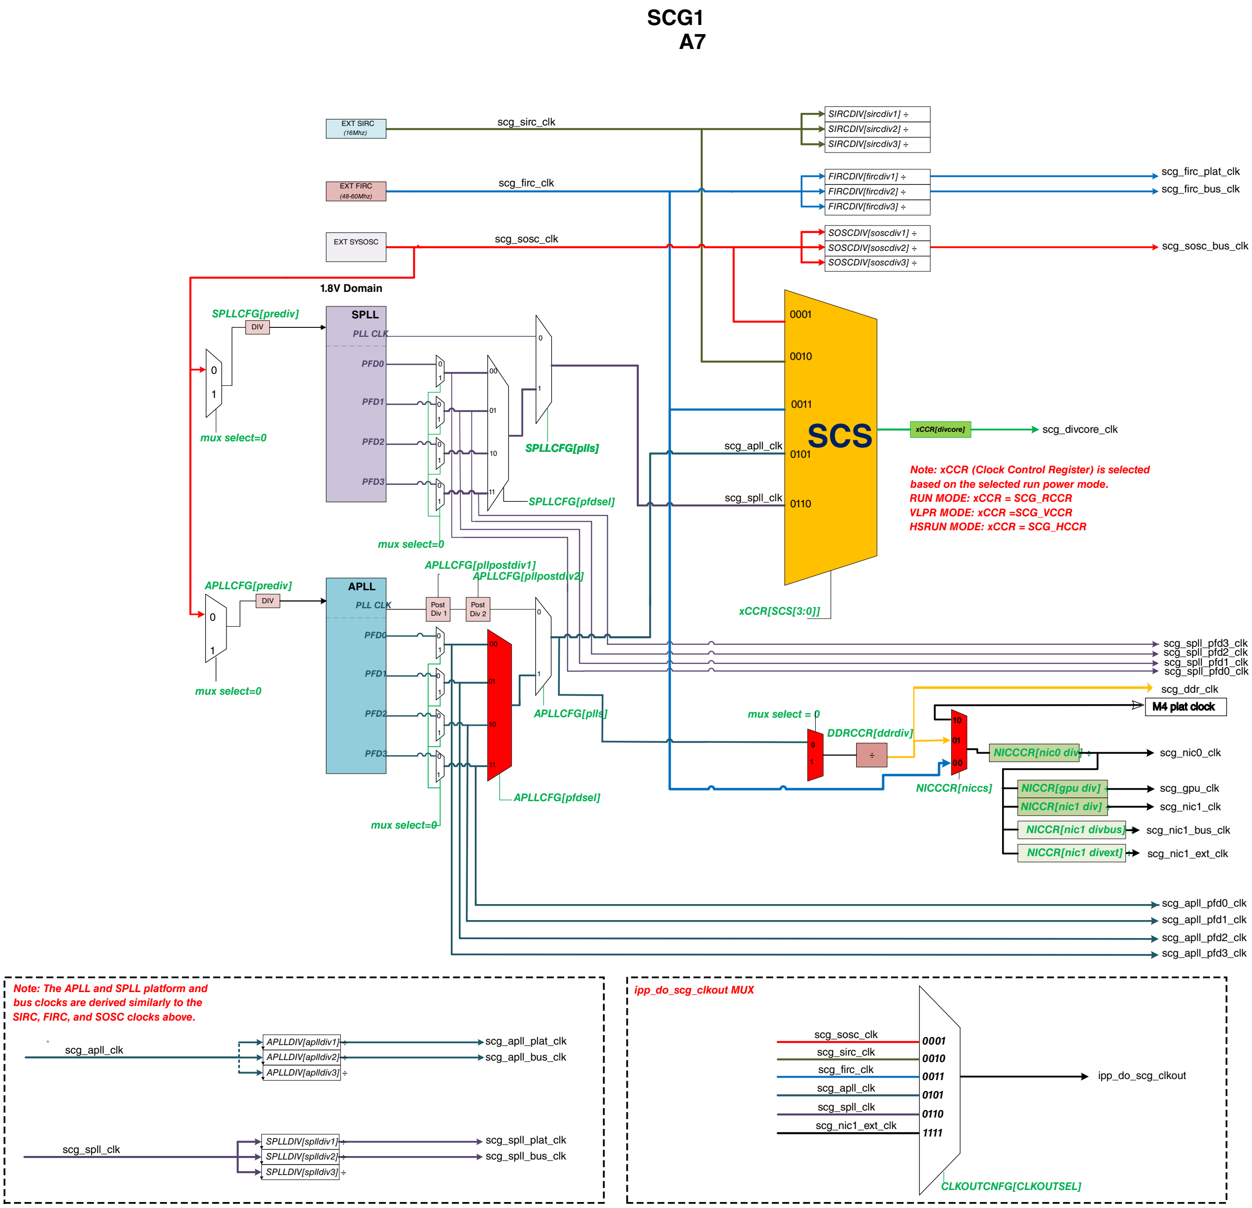

Figure 26-3. System Clock Generator block diagram for SCG1, A7 Domain

NOTE

To identify the oscillators used in your specific MCU device, see the configuration or clocking chapters.

26.3 Functional description

26.3.1 SCG Clock Mode Transitions

The following figure shows the valid clock mode transitions supported by SCG.

Slow IRC (SIRC) boot mode is not supported on this device.

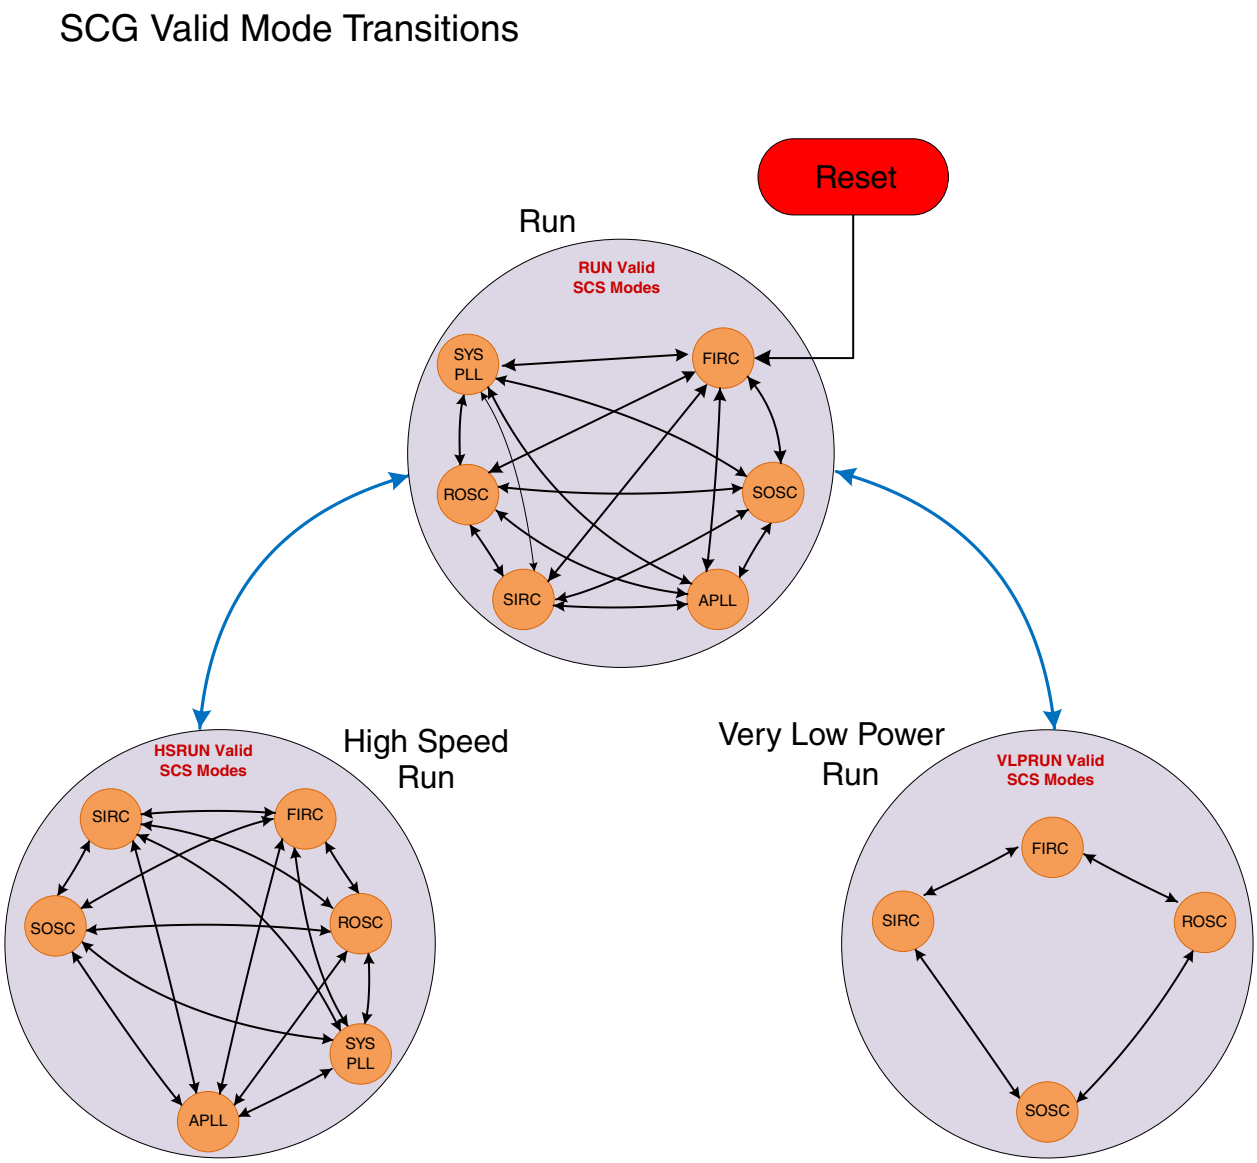

Figure 26-4. SCG Valid Mode Transitions for SCG0 (M4 domain)

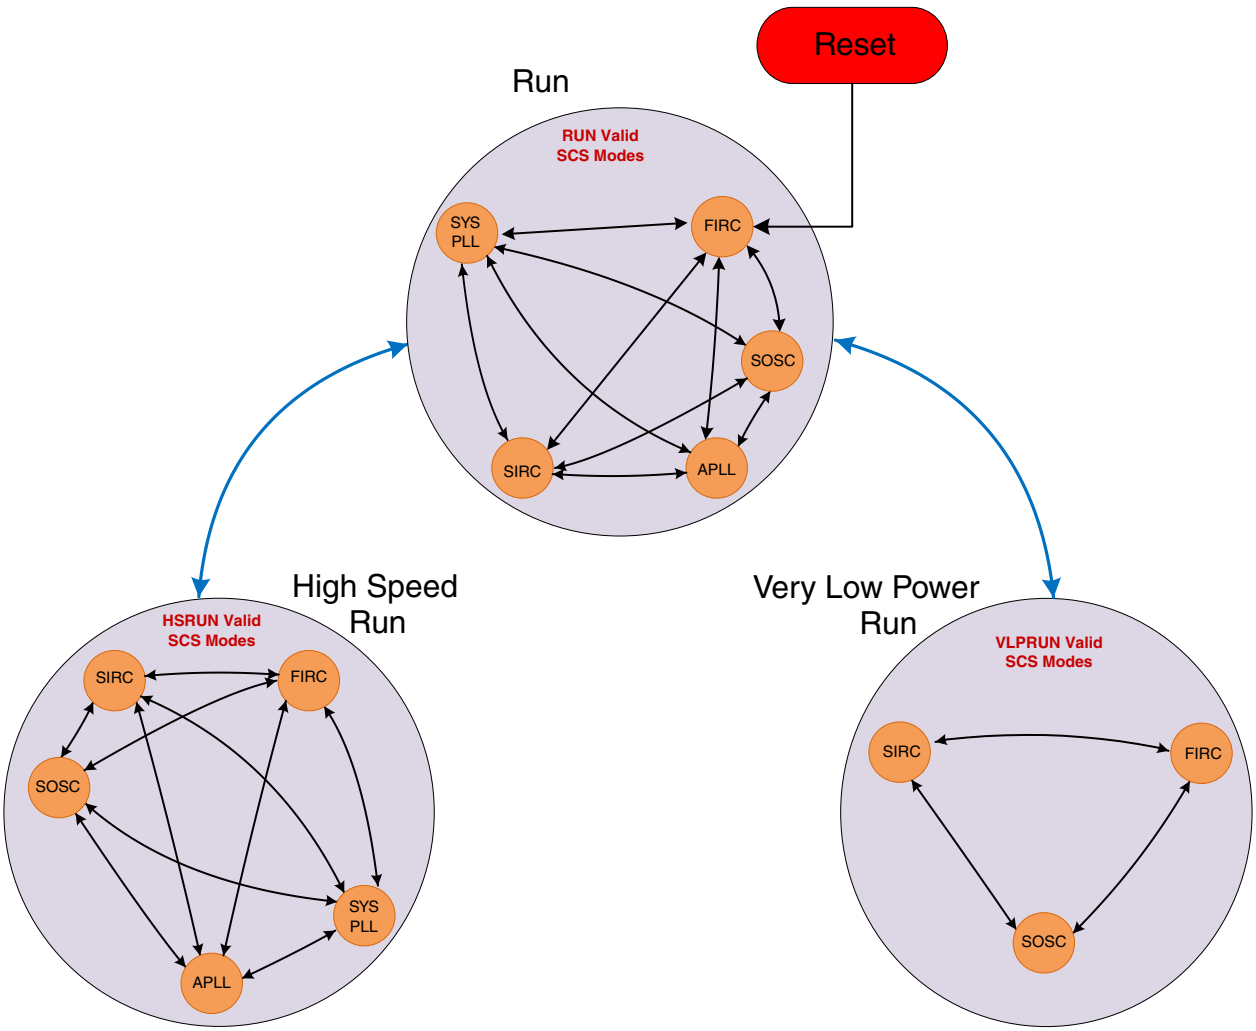

Figure 26-5. SCG Valid Mode Transitions for SCG1 (A7 domain)

The SCG will restrict programming into invalid clock modes and writes to SCS bits will be ignored. When a transition between run modes or a transition into wait mode occurs, the SCG completes the switch to the clock mode as defined in the SCG clock control register. When completed, the system switches to the selected run/wait mode.

The modes of operation listed in the following table are the valid modes for this implementation of the SCG.

Table 26-3. SCG modes of operation

Mode	Description

System Oscillator Clock (SOSC)	System Oscillator Clock (SOSC) mode is entered when all the following conditions occur:
	• RUN MODE:
	  • 0001 is written to RCCR[SCS]
	VLRUN MODE: One of the following scenarios is true
	  • 0001 is written to VCCR[SCS] and VCCR[SCS] matches RCCR[SCS]
	  • 0001 is written to VCCR[SCS], VCCR[SCS] differs from RCCR[SCS]) and 1 is written to SOSCCSR[SOSCLPEN]
	HSRUN MODE:
	  • 0001 is written to HCCR[SCS]
	• SOSCEN = 1
	• SOSCVLD = 1
	
	In SOSC mode, SCSCLKOUT and system clocks are derived from the external System Oscillator Clock (SOSC).

Slow Internal Reference Clock (SIRC)	Slow Internal Reference Clock (SIRC) mode is entered when all the following conditions occur:
	• RUN MODE:
	  • 0010 is written to RCCR[SCS]
	VLRUN MODE: One of the following scenarios is true
	  • 0010 is written to VCCR[SCS] and VCCR[SCS] matches RCCR[SCS]
	  • 0010 is written to VCCR[SCS], VCCR[SCS] differs from RCCR[SCS]) and 1 is written to SIRCCSR[SIRCLPEN]
	HSRUN MODE:
	  • 0010 is written to HCCR[SCS]
	• SIRCEN = 1
	• SIRCVLD = 1
	
	In SIRC mode, SCSCLKOUT and system clocks are derived from the slow internal reference clock. Two frequency ranges are available for SIRC clock as described in the SIRCCFG[RANGE] register definition. Changes to SIRC range settings will be ignored when SIRC clock is enabled.

Fast Internal Reference Clock (FIRC)	Fast Internal Reference Clock (FIRC) mode is the default clock mode of operation and is entered when all the following conditions occur:
	• RUN MODE:
	  • 0011 is written to RCCR[SCS]
	VLRUN MODE: One of the following scenarios is true
	  • 0011 is written to VCCR[SCS] and VCCR[SCS] matches RCCR[SCS]
	  • 0011 is written to VCCR[SCS], VCCR[SCS] differs from RCCR[SCS]) and 1 is written to FIRCCSR[FIRCLPEN]
	HSRUN MODE:
	  • 0011 is written to HCCR[SCS]
	• FIRCEN = 1
	• FIRCVLD = 1
	
	In FIRC mode, SCSCLKOUT and system clocks are derived from the fast internal reference clock. frequency range settings are available for FIRC clock as described in the FIRC[RANGE] register definition. Changes to FIRC range settings will be ignored when FIRC clock is enabled.

Real Time Clock Oscillator (RTCOSC)	Real Time Clock Oscillator (RTCOSC) mode is entered when all the following conditions occur:

Table continues on the next page...

Table 26-3. SCG modes of operation (continued)

Mode	Description

	• RUN MODE:
	  • 0100 is written to RCCR[SCS]
	VLRUN MODE:
	  • 0100 is written to VCCR[SCS]
	HSRUN MODE:
	  • 0100 is written to HCCR[SCS]
	• ROSCVLD = 1
	
	In RTCOSC mode, SCSCLKOUT and systems clocks are derived from the external RTC Oscillator Clock (RTCOSC).

Auxiliary PLL (APLL)	Auxiliary PLL (APLL) mode is entered when all the following conditions occur:
	• RUN MODE:
	  • 0101 is written to RCCR[SCS]
	VLRUN MODE:
	  • Invalid mode. Programming SCG into APLL mode will be ingored
	HSRUN MODE:
	  • 0101 is written to HCCR[SCS]
	• APLLEN = 1
	• APLLVLD = 1
	
	In APLL mode, SCSCLKOUT and system clocks are derived from the Auxiliary PLL (APLL) that is controlled by the System Oscillator (SOSC) clock. The APLL clock frequency locks to a multiplication factor, as specified by its corresponding SCG_APLLCFG[MULT], times the selected APLL reference frequency. The APLL programmable reference divider must be configured to produce a valid APLL reference clock. This divide value is defined by the SCG_APLLCFG[PREDIV] bits.

Sys PLL (SPLL)	Sys PLL (SPLL) mode is entered when all the following conditions occur:
	• RUN MODE:
	  • 0110 is written to RCCR[SCS]
	VLRUN MODE:
	  • Invalid mode. Programming SCG into SPLL mode will be ingored
	HSRUN MODE:
	  • 0110 is written to HCCR[SCS]
	• SPLLEN = 1
	• SPLLVLD = 1
	
	In SPLL mode, the SCSCLKOUT and system clocks are derived from the output of PLL which is controlled by the System Oscillator (SOSC) clock. The selected PLL clock frequency locks to a multiplication factor, as specified by its corresponding SCG_SPLLCFG[MULT], times the selected PLL reference frequency. The PLL's programmable reference divider must be configured to produce a valid PLL reference clock. This divide value is defined by the SCG_SPLLCFG[PREDIV] bits.

Stop	Entered whenever the MCU enters a Stop state. The power modes are chip-specific. For power mode assignments, see the chapter that describes how modules are configured and SCG behaviour during Stop recovery. Entering Stop mode, all SCG clock signals are static, including SCG system clocks (DIVCORE,DIVPLAT,,DIVBUS,DIVSLOW). There are exceptions; the following clocks can continue to run and stay enabled in the following cases:

Table 26-3. SCG modes of operation

Mode	Description
	SIRC is available in Normal Stop and VLPS modes when all the following conditions become true: • SIRCCSR[SIRCEN] = 1 • SIRCCSR[SIRCSTEN] = 1 • SIRCCSR[SIRCLPEN] = 1 in VLPS FIRC is available in Normal Stop and VLPS modes when all the following conditions become true: • FIRCCSR[FIRCEN] = 1 • FIRCCSR[FIRCSTEN] = 1 • FIRCCSR[FIRCLPEN] = 1 in VLPS SOSC is available in following low power stop modes (Normal Stop, VLPS, LLS) when all the below conditions are true. In VLLS stop mode, SOSCLK is disabled. • SOSCCSR[SOSCEN] = 1 • SOSCCSR[SOSCSTEN] = 1 • SOSCCSR[SOSCLPEN] = 1 (required only for Low Power Stop modes (VLPS and LLS) APLL is available in Normal Stop mode when all the following conditions become true: • APLLCSR[APLLEN] = 1 • APLLCSR[APLLSTEN] = 1 • APLLSTEN control bit has no effect in LLS or VLPS Power mode. SPLL is available in Normal Stop mode when all the following conditions are true: • SPLLCSR[SPLLEN] = 1 • SPLLCSR[SPLLSTEN] = 1 • SPLLSTEN control bit has no affect in LLS or VLPS Power mode.

26.4 Memory Map/Register Definition

This section includes the memory map and register definition.

The SCG registers can only be written when in supervisor mode. Write accesses when in user mode will result in a bus transfer error. Read accesses may be performed in both supervisor and user mode.

26.4.1 SCG register descriptions

- For any writeable SCG registers, only 32-bit writes are allowed. 8-bit or 16-bit writes will result in transfer errors.
- For PLL programming, enable the PLL first, and then the PFD can be programmed.

26.4.1.1 SCG Memory map

26.4.1.5 Run Clock Control Register (RCCR)

26.4.1.5.1 Offset

Register	Offset
RCCR	14h

26.4.1.5.2 Function

This register controls the system clock source and the system clock dividers for the core, platform, external and bus clock domains when in Run mode only. This register can only be written using a 32-bit write. Selecting a different clock source when in RUN requires that clock source to be enabled first and be valid before system clocks switch to that clock source. If system clock divide ratios also change when selecting a different clock mode when in RUN, new system clock divide ratios will not take affect until a new clock source is valid.

NOTE

Switching to new system clock source and system clock dividers must be done after previous RCCR changes have been completed.

26.4.1.7 HSRUN Clock Control Register (HCCR)

26.4.1.7.1 Offset

Register	Offset
HCCR	1Ch

26.4.1.7.2 Function

This register controls the system clock source and the system clock dividers for the core, platform, external and bus clock domains when in HSRUN mode only. This register can only be written using a 32-bit write. Selecting a different clock source when in HSRUN requires that clock source to be enabled first and be valid before system clocks switch to that clock source. If system clock divide ratios also change when selecting a different clock mode when in HSRUN, new system clock divide ratios will not take affect until new clock source is valid.

NOTE

Switching to a new system clock source and system clock dividers must be done after previous RCCR changes have been completed.

Field	Function
	Selects the PFD or APLL as the PLL output clock used to generate system clocks. The PFD output clock used if PLLS=1 is determined by the PFDSEL bits. 0b - APLL clock selected. 1b - APLL PFD output clock selected
0 SOURCE	Clock Source Configures the input clock source for the Auxiliary PLL. Valid reference frequency must be 24 MHz, 32 MHz, 30 MHz,26 MHz, 19.2 MHz and 16 MHz. 0b - System OSC 1b - Reserved

26.4.1.21 Auxiliary PLL PFD Register (APLLPFD)

26.4.1.21.1 Offset

Register	Offset
APLLPFD	50Ch

26.4.1.21.2 Function

This register defines the control bits for the PFD3-PFD0 clocks derived from the Auxiliary PLL.

When changing PFD values, the following is recommended:

1. The PFDx clock is gated first by writing a value of 1 to PFDx_CLKGATE register
2. Program the new PFD value
3. Write a value of 0 to PFDx_CLKGATE to ungate the PFDx
4. Follow by polling the PFDx_VALID flag to set and allow the PFDx clock to run.

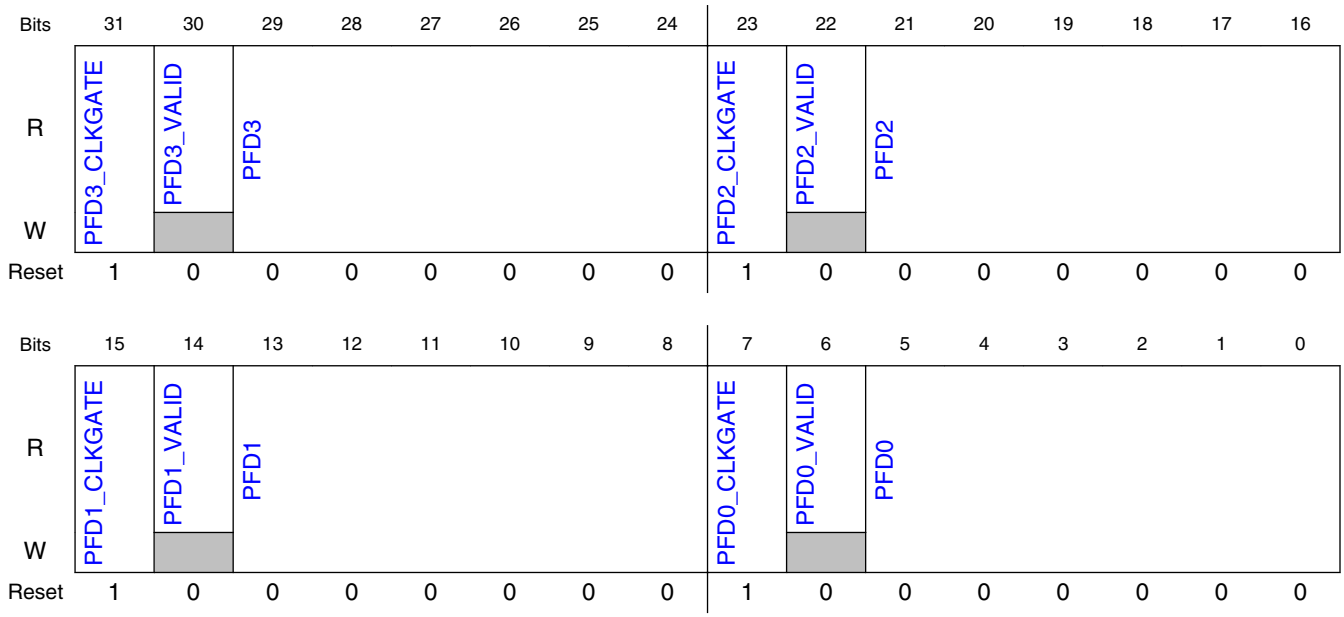
NOTE

It is recommended that PFD settings are kept between 12-35 for all PFDs.

APLL Frequency = Fref * (MULT + NUM/DENOM)

PFD Clock Frequency = PLL output frequency * 18/frac value

26.4.1.21.3 Diagram



26.4.1.21.4 Fields

Field	Function
31 PFD3_CLKGATE	PFD3_CLKGATE PFD3 Clock Gate. 0b - PFD3 clock is not gated. 1b - PFD3 clock is gated.
30 PFD3_VALID	PFD3_VALID Indicates when PFD3 clock is valid. Will clear when PFD3 is written with a new value and will set after PFD3 clock becomes stable.
29-24 PFD3	PLL Fractional Divider 3 Controls the fractional divide value. Valid pfd values are 12-35. PFD output frequency = PLL output frequency * 18/pfd0_frac
23 PFD2_CLKGATE	PFD2_CLKGATE PFD2 Clock Gate. 0b - PFD2 clock is not gated. 1b - PFD2 clock is gated.
22 PFD2_VALID	PFD2_VALID Indicates when PFD2 clock is valid. Will clear when PFD2 is written with a new value and will set after PFD2 clock becomes stable.
21-16 PFD2	PLL Fractional Divider 2 Controls the fractional divide value. Valid pfd values are 12-35. PFD output frequency = PLL output frequency * 18/pfd0_frac
15	PFD1_CLKGATE PFD1 Clock Gate.

Table continues on the next page...

Field	Function
PFD1_CLKGATE	0b - PFD1 clock is not gated. 1b - PFD1 clock is gated.
14 PFD1_VALID	PFD1_VALID Indicates when PFD1 clock is valid. Will clear when PFD1 is written with a new value and will set after PFD1 clock becomes stable.
13-8 PFD1	PLL Fractional Divider 1 Controls the fractional divide value. Valid pfd values are 12-35. PFD output frequency = PLL output frequency * 18/pfd0_frac
7 PFD0_CLKGATE	PFD0_CLKGATE PFD0 Clock Gate. 0b - PFD0 clock is not gated. 1b - PFD0 clock is gated.
6 PFD0_VALID	PFD0_VALID Indicates when PFD0 clock is valid. Will clear when PFD0 is written with a new value and will set after PFD0 clock becomes stable.
5-0 PFD0	PLL Fractional Divider 0 Controls the fractional divide value. Valid pfd values are 12-35. PFD output frequency = PLL output frequency * 18/pfd0_frac

26.4.1.32.3 Fields

Field	Function
31-16 STOP	STOP and STEP together control the modulation depth (maximum frequency change) and Modulation Depth. Modulation Depth = (STOP/DENOM)*Fref where DENOM is the DENOM field value in DENOM register. Modulation Frequency = (STEP/(2*STOP))*Fref, where Fref = 24Mhz.
15 ENABLE	Enables the spread spectrum modulation. 0b - Spectrum modulation is disabled 1b - Spectrum modulation is enabled
14-0 STEP	STOP and STEP together control the modulation depth (maximum frequency change) and Modulation Depth. Modulation Depth = (STOP/DENOM)*Fref where DENOM is the DENOM field value in DENOM register. Modulation Frequency = (STEP/(2*STOP))*Fref, where Fref = 24Mhz.

26.4.1.33 System PLL LOCK Configuration Register (SPLLLOCK_CNFG)

26.4.1.33.1 Offset

Register	Offset
SPLLLOCK_CNFG	6F8h

26.4.1.33.2 Function

NOTE

The reset value for this register is chip-specific. See chip-specific section for more information.

15-0 LOCK_TIME	Configures the number of reference clocks to count before SPLL is considered locked and valid.

26.4.2 SCG register descriptions

- For any writeable SCG registers, only 32-bit writes are allowed. 8-bit or 16-bit writes will result in transfer errors.
- For PLL programming, enable the PLL first, and then the PFD can be programmed.

1. The reset value is controlled by which SCG System Dividers are used by the SoC.
2. The reset value is controlled by which SCG Clock Sources are used by the SoC. Please reference the Reference manual clocking chapter.

26.4.2.3.4 Fields

Field	Function
31-27 DIVPRES	Divider Present Indicates which system clock dividers are present in this instance of SCG. 1xxxxb - System DIVCORE is present. x1xxxb - System DIVPLAT is present. xxx1xb - System DIVBUS is present. xxxx1b - System DIVSLOW is present.
26-16 —	Reserved
15-8 —	Reserved
7-0 CLKPRES	Clock Present Indicates which clock sources are present in this instance of SCG. Any bits not defined in this bit field are Reserved and always has the value 0 when read. 00000000-00000001b - Reserved. x1xxxxxxb - System PLL (SPLL) is present. xx1xxxxxb - Auxiliary PLL (APLL) is present. xxx1xxxxb - RTC OSC (ROSC) is present. xxxx1xxxb - Fast IRC (FIRC) is present. xxxxx1xxb - Slow IRC (SIRC) is present. xxxxxx1xb - System OSC (SOSC) is present.

26.4.2.4 Clock Status Register (CSR)

26.4.2.4.1 Offset

Register	Offset
CSR	10h

26.4.2.4.2 Function

The Clock Status Register (CSR) returns the currently configured system clock source and the system clock dividers for the core (DIVCORE) and peripheral interface clock (DIVSLOW). The SCG_CSR reports the configuration set by one of the clock control registers SCG_RCCR, SCG_VCCR, SCG_HCCR.

Note: Writing to the Clock Status Register (CSR) will result in a transfer error.

26.4.2.5 Run Clock Control Register (RCCR)

26.4.2.5.1 Offset

Register	Offset
RCCR	14h

26.4.2.5.2 Function

This register controls the system clock source and the system clock dividers for the core, platform, external and bus clock domains when in Run mode only. This register can only be written using a 32-bit write. Selecting a different clock source when in RUN requires that clock source to be enabled first and be valid before system clocks switch to that clock source. If system clock divide ratios also change when selecting a different clock mode when in RUN, new system clock divide ratios will not take affect until a new clock source is valid.

NOTE

Switching to new system clock source and system clock dividers must be done after previous RCCR changes have been completed.

26.4.2.5.3 Diagram

Register	Offset
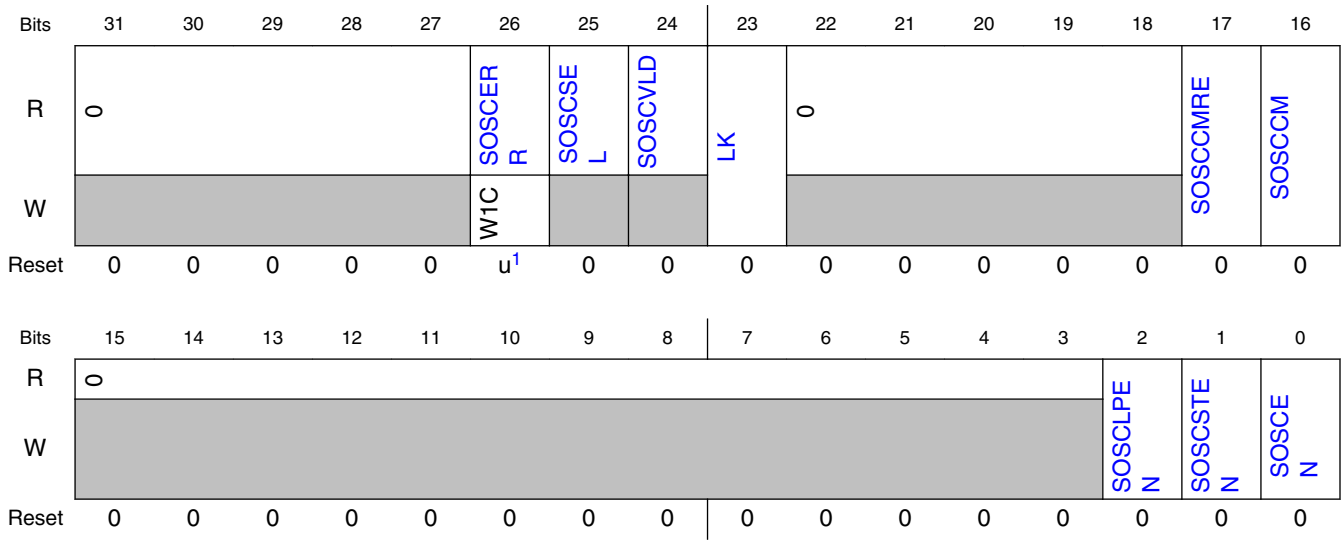
SOSCCSR	100h

26.4.2.9.2 Diagram



1. This flag is reset on Chip POR only

26.4.2.9.3 Fields

Field	Function
31-27 —	Reserved
26 SOSCERR	System OSC Clock Error This flag is reset on Chip POR only, software can also clear this flag by writing a logic one. 0b - System OSC Clock Monitor is disabled or has not detected an error 1b - System OSC Clock Monitor is enabled and detected an error
25 SOSCSEL	System OSC Selected 0b - System OSC is not the system clock source 1b - System OSC is the system clock source
24 SOSCVLD	System OSC Valid 0b - System OSC is not enabled or clock is not valid 1b - System OSC is enabled and output clock is valid
23 LK	Lock Register This bit field can be cleared/set at any time. 0b - This Control Status Register can be written. 1b - This Control Status Register cannot be written.
22-18 —	Reserved
17 SOSCCMRE	System OSC Clock Monitor Reset Enable 0b - Clock Monitor generates interrupt when error detected 1b - Clock Monitor generates reset when error detected
16 SOSCCM	System OSC Clock Monitor Enables the clock monitor when SOSCVLD is set.

Table continues on the next page...

Field	Function
	NOTE: SOSC clock monitor remains enabled in VLPR and VLPS if SOSCCM is enabled. The clock monitor is always disabled in LLS/VLLS modes. When the clock monitor is disabled in a low power mode, it remains disabled until the clock valid flag is set following exit from the low power mode. **NOTE:** The reference clock used to monitor the SOSC is the SIRC. This clock must be programmed to be enabled in order to monitor the SOSC. SIRC is automatically disabled in LLS and VLLS power modes and clock monitor of SOSC will be disabled. 0b - System OSC Clock Monitor is disabled 1b - System OSC Clock Monitor is enabled
15-3 —	Reserved
2 SOSCLPEN	System OSC Low Power Enable SOSCLPEN is required for low power modes. In VLPS mode (low power stop mode), if you want the clock to remain ON, then both SOSCLPEN and SOSCSTEN bits must be enabled. 0b - System OSC is disabled in VLP modes 1b - System OSC is enabled in VLP modes
1 SOSCSTEN	System OSC Stop Enable 0b - System OSC is disabled in Stop modes 1b - System OSC is enabled in Stop modes if SOSCEN=1. In VLLS0, system oscillator is disabled even if SOSCSTEN=1 and SOSCEN=1. When selected as the reference clock to the System PLL and if the System PLL is enabled in STOP mode, the SOSC will stay enabled even if SOSCSTEN=0.
0 SOSCEN	System OSC Enable 0b - System OSC is disabled 1b - System OSC is enabled

26.4.2.10 System OSC Divide Register (SOSCDIV)

26.4.2.10.1 Offset

Register	Offset
SOSCDIV	104h

26.4.2.10.2 Function

The SCG_SOSCDIV register provides the control of 3 clock trees which can be used to provide optional peripheral functional clocks, or alternative module clocks. Each clock tree has optional dividers of the input SOSC clock. Changes to SOSCDIV should be done when System OSC is disabled to prevent glitches to output divided clock.

26.4.2.24 Auxiliary PLL PFD Register (APLLPFD)

26.4.2.24.1 Offset

Register	Offset
APLLPFD	50Ch

26.4.2.24.2 Function

This register defines the control bits for the PFD3-PFD0 clocks derived from the Auxiliary PLL.

When changing PFD values, the following is recommended:

1. The PFDx clock is gated first by writing a value of 1 to PFDx_CLKGATE register
2. Program the new PFD value
3. Write a value of 0 to PFDx_CLKGATE to ungate the PFDx
4. Follow by polling the PFDx_VALID flag to set and allow the PFDx clock to run.

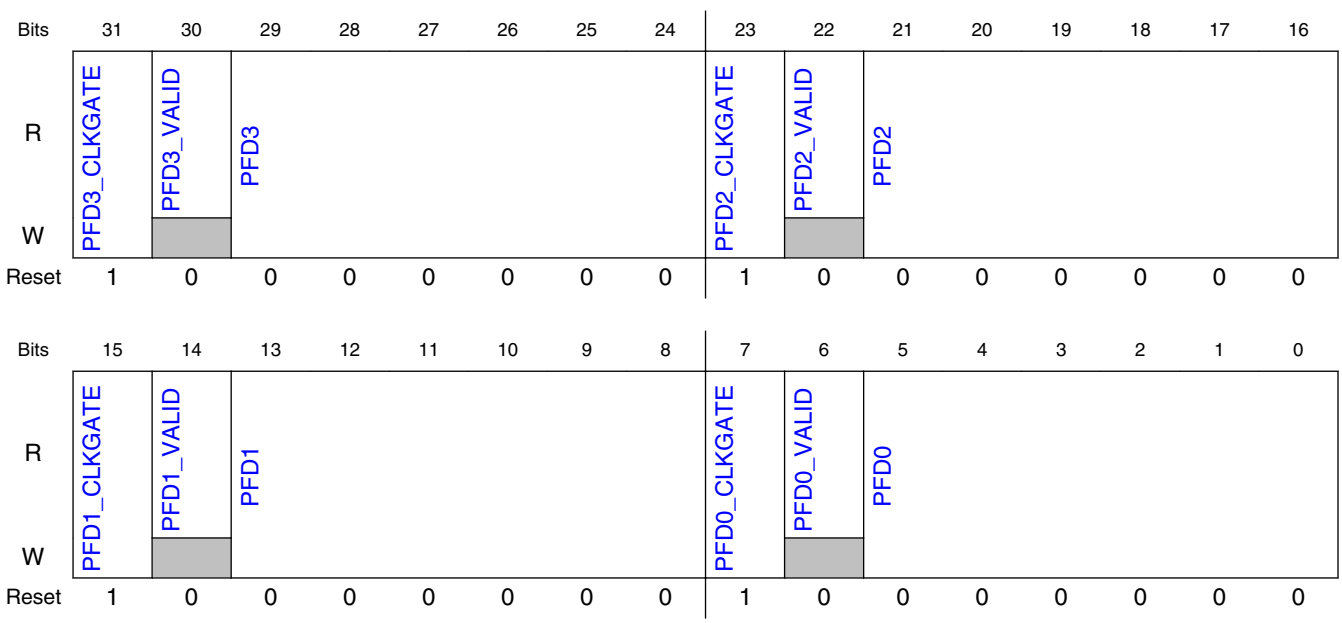
NOTE

It is recommended that PFD settings are kept between 12-35 for all PFDs.

APLL Frequency = Fref * (MULT + NUM/DENOM)

PFD Clock Frequency = PLL output frequency * 18/frac value

26.4.2.24.3 Diagram



26.4.2.24.4 Fields

Field	Function
31 PFD3_CLKGATE	PFD3_CLKGATE PFD3 Clock Gate. 0b - PFD3 clock is not gated.

Table continues on the next page...

Field	Function
	1b - PFD3 clock is gated.
30 PFD3_VALID	PFD3_VALID Indicates when PFD3 clock is valid. Will clear when PFD3 is written with a new value and will set after PFD3 clock becomes stable.
29-24 PFD3	PLL Fractional Divider 3 Controls the fractional divide value. Valid pfd values are 12-35. PFD output frequency = PLL output frequency * 18/pfd0_frac
23 PFD2_CLKGATE	PFD2_CLKGATE PFD2 Clock Gate. 0b - PFD2 clock is not gated. 1b - PFD2 clock is gated.
22 PFD2_VALID	PFD2_VALID Indicates when PFD2 clock is valid. Will clear when PFD2 is written with a new value and will set after PFD2 clock becomes stable.
21-16 PFD2	PLL Fractional Divider 2 Controls the fractional divide value. Valid pfd values are 12-35. PFD output frequency = PLL output frequency * 18/pfd0_frac
15 PFD1_CLKGATE	PFD1_CLKGATE PFD1 Clock Gate. 0b - PFD1 clock is not gated. 1b - PFD1 clock is gated.
14 PFD1_VALID	PFD1_VALID Indicates when PFD1 clock is valid. Will clear when PFD1 is written with a new value and will set after PFD1 clock becomes stable.
13-8 PFD1	PLL Fractional Divider 1 Controls the fractional divide value. Valid pfd values are 12-35. PFD output frequency = PLL output frequency * 18/pfd0_frac
7 PFD0_CLKGATE	PFD0_CLKGATE PFD0 Clock Gate. 0b - PFD0 clock is not gated. 1b - PFD0 clock is gated.
6 PFD0_VALID	PFD0_VALID Indicates when PFD0 clock is valid. Will clear when PFD0 is written with a new value and will set after PFD0 clock becomes stable.
5-0 PFD0	PLL Fractional Divider 0 Controls the fractional divide value. Valid pfd values are 12-35. PFD output frequency = PLL output frequency * 18/pfd0_frac

26.4.2.25 Auxiliary PLL Numerator Register (APLLNUM)

26.4.2.25.1 Offset

Register	Offset
APLLNUM	510h

Chapter 27
Power Management

27.1 Overview

This device implements a simplified power architecture to minimize the PMIC requirements. The intention is to use inexpensive external components. There are two completely separate main power domains: one for the Cortex-M4 power domain and the other for the Cortex-A7 power domain. Either domain can be completely shut off by removing external voltage or by turning off the internal voltage supply. In addition, there are other power islands that maintain power on for specific logics in very low power modes. Several low power techniques are implemented on this device to enable power efficient applications.

NOTE

References in this chapter to “Core 0” or “Processor A” correspond to the Cortex M4 core. References in this chapter to “Core 1” or “Processor B” correspond to the Cortex A7 core.

27.2 Low power techniques

This device reduces power consumption and thermal dissipation by applying the following low power techniques:

- Multiple power domains and low power modes allow flexible power optimization for power-conscious applications
- Voltage and frequency scaling in dynamic operating modes
- Software-controlled clock gating for cores and peripherals
- Efficient on-chip LDO regulators and power management control

27.3 Low power use case through PSTOP3 mode

This section provides a very low-power use case where power critical applications may control and manage data in Real-Time Domain (RTD) while requiring that part of the Application Domain (APD) to be enabled to access its peripherals. An example of such application would be to use FlexBus at APD domain to interface with an external PSRAM while M4 core does all the data management by copying data from PSRAM to M4's memories. In order to accomplish that and save power, the device is required to enter Partial STOP mode #3 (PSTOP3). When the device is in this mode and if none of the A7 NIC0 peripherals such as GPU 2D, GPU 3D, LCDIF, and MMDC, are enabled, A7 NIC0 sub-system is turned off by gating off its clock. Extra power saving is further obtained by selecting M4 Platform clock as the clock source for the A7 NICs' sub-system. This clock selection is done by writing to the SCG1_NICCCR[NICCS] bitfield. Furthermore, to prevent A7 core from waking-up during an ongoing cross-domain transaction, such as due to an interrupt from the peripheral, wake-up sources to WKPU unit shall be disabled by writing to the WKPU_WAKEUP_ENABLE register in the SIM module. The following procedure is used to enter PSTOP3 mode:

1. Ensure that there are no pending interrupts to the CA7 domain.
2. Ensure that peripherals connected to the NIC0 sub-system are disabled via PCC[1]
3. Configure WKPU channels via WKPU_WAKEUP_ENABLE register in the SIM module to disable all wake-up sources, except channel assigned to MU_B NMI[2]
4. Configure the MU_B NMI handler in the GIC unit
5. Configure the SCG1_NICCCR[NICCS] bitfield to select FIRC
6. Disable A7 PLLs
7. Configure the SCG1_NICCCR[NICCS] field to select M4 Platform clock. Ensure that clock source is ready for use.[3]
8. Configure A7 peripheral(s) in NIC1 sub-system for cross-domain transaction
9. Switch the A7 domain into PSTOP3 power mode

27.4 VLLS mode

The following points must be considered about entering/exiting the VLLS mode.

- Before entering VLLS mode, all interrupts belonging to peripherals powered by the same supply rail turned off by this mode must be disabled. If any of these interrupts wake up the domain when it has logically entered VLLS mode but has not effectively

1. NIC0's peripherals may still be used at the cost of increasing power. If any of the NIC0 peripherals are enabled via PCC, NIC0 sub-system is totally functional.
2. By keeping MU_B NMI channel in WKPU enabled, M4 core has total control over A7 domain and can wake-up A7 via MU_ACR[NMI]
3. Optional step in case a clock source different from FIRC is needed.

powered off yet, the associated interrupt flag will be reset (during the VLLS wake-up procedure), preventing the identification of the wake-up source once the domain is back to RUN mode. This affects both the Real Time and the Application domains, but the former one is more susceptible, due to the (external) capacitor connected to its power rail.

- When entering VLLS mode, both the respective domain and the associated pins are automatically isolated.
- When exiting (or resuming) from VLLS mode, the resume flow may include a jump to a user-specified entry point, as described in Resume support in ROM and SIM DGO GPR used by ROM
- Once VLLS mode is exited, domain's isolation is automatically removed, while pins' isolation removal is user controlled. See Supported modes of operation for details.

NOTE

It is a safe procedure to set SIM's WKPU_WAKEUP_ENABLE[7] bit to 0 and disable M4 NVIC IRQ 69 (USB PHY) before entering VLLS mode or enabling A7 switch

27.5 Power management scheme

Following figure shows the base Power Management scheme for this device.

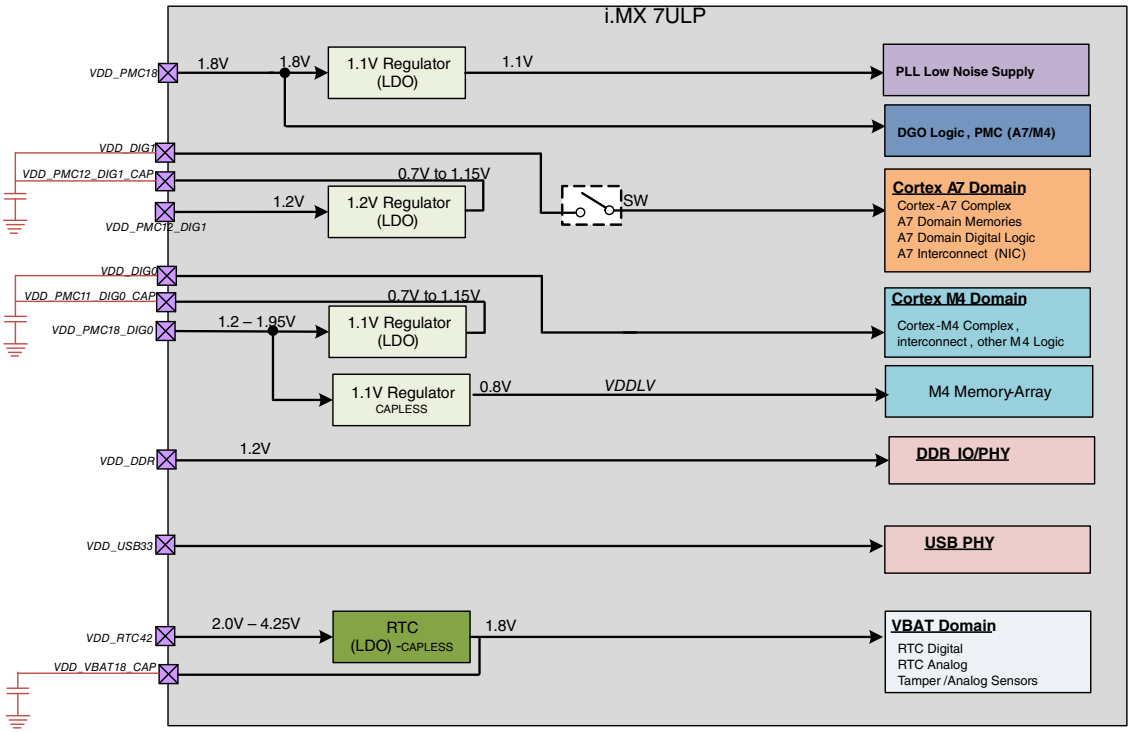

Figure 27-1. i.MX 7ULP power management scheme

27.6 VBAT mode

VBAT is a separate mode decouple from CM4/CA7 power domains. This is accessible to the user via external VBAT Pin on i.MX 7ULP.

Table 27-1. VBAT mode description in i.MX 7ULP

Mode	Description	Typical IDD	Recovery Method	Recovery Time
VBAT	Only RTC domain retained and powered through coin-cell/ Lithium-Ion battery	5 µA	Availability of VDD Supply/RTC Alarm	NA

27.7 Allowed power modes between multicore

Separate power modes on Arm CA7 and CM4 cores can result in several combinations, however not all are valid on i.MX 7ULP. The following table provides a summary of recommended power modes between the two cores.

In the table:

- NR: Not recommended
- NO: Not supported in hardware

Table 27-2. Allowed power modes in CM4 and CA7 core

CM4→	*HSRUN*	*RUN*	*VLPR*	*WAIT*	*VLPW*	*PSTOPx*	*STOP*	*VLPS*	*LLS*	*VLLS*
CA7↓[1], [2]										
HSRUN	YES	YES	YES[3]	YES	YES	YES	YES	YES	YES[4]	NO[5]
RUN	YES	YES	YES	YES	YES	YES	YES	YES	YES[4]	NO[5]
VLPR	YES	YES	YES	YES	YES	YES	YES	YES	NO[5], [6]	NO[5], [6]
PSTOPx	YES	YES	YES[4]	YES	YES[7]	YES	YES[7]	YES[7]	YES[7], [4]	NO[5]
STOP	YES	YES	YES	YES	YES	YES	YES	YES	YES	NO[5]
VLPS	YES	YES	YES	YES	YES	YES	YES	YES	YES	NO[5]
LLS	YES	YES	YES	YES	YES	YES	YES	YES	YES	NO[5]
VLLS	YES	YES	YES	YES	YES	YES	YES	YES	YES	YES

1. CA7 only supports static (w/o clock) reverse body bias.
2. APD may have its system clocks (i.e. core, plat0/1, bus, ...) gated, even if in a Run mode (HSRUN, RUN, VLPR), should the dependency between APD and RTD's primary clock sources (for example, SIRC, FIRC, SOSC, ...) is not observed.
3. Main benefit of CM4 [VLPR] is to provide lowest power run mode by using RBB while main advantage for CA7 [HSRUN] is to provide higher performance by using FBB. However using this combination will provide no power advantage so benefits with CM4 [VLPR] will be in the noise when CA7 is in HSRUN.
4. For cases where CM4 is in LLS mode, the external oscillator being the only clock source available to CA7, register field SCG0[SOSCCSR] should be programmed to remain enabled.
5. i.MX 7ULP does not support any isolation from the CM4 to CA7 domain so any scenarios where CM4 is kept in VLLS mode while CA7 is in higher power modes cannot be supported. There are no particular power advantages supporting these scenarios.
6. SIRC/FIRC clocks not available for CA7 when CM4 is in LLS/VLLS mode. No significant power advantage to have CA7 running while CM4 is in LLS/VLLS mode.
7. CA7 can choose to keep peripherals running in full operation in CA7 [PSTOPx] mode, but will significantly increase power consumption (since PLLs will be ON with the external oscillator as the reference clock) while CM4 is in low power mode (VLPR/VLPW/STOP/ VLPS mode), thus making this mode not useful to the application.

27.8 Biasing options

I.MX 7ULP supports both Forward and Reverse bias; however only variants of options would be available based on power modes.

The following table shows applicable power modes for both the biasing options.

Table 27-3. Biasing options

Biasing Options[1]	Bias Voltage Range (Typical)	Applicable Power modes
Forward Body Bias (FBB)	50 mV to 350 mV, with 50 mV voltage steps	HSRUN Mode
Reverse Body Bias(RBB)	500 mV to 1.3 V, with 100 mV voltage steps	VLPR (CM4 domain only), VLPS and LLS modes

1. *All options for FBB/RBB are fully programmable*

The following figure shows the basic operation of NMOS/PMOS transistor in C28SOI. VBBp/VBBn corresponds to the bias voltage.

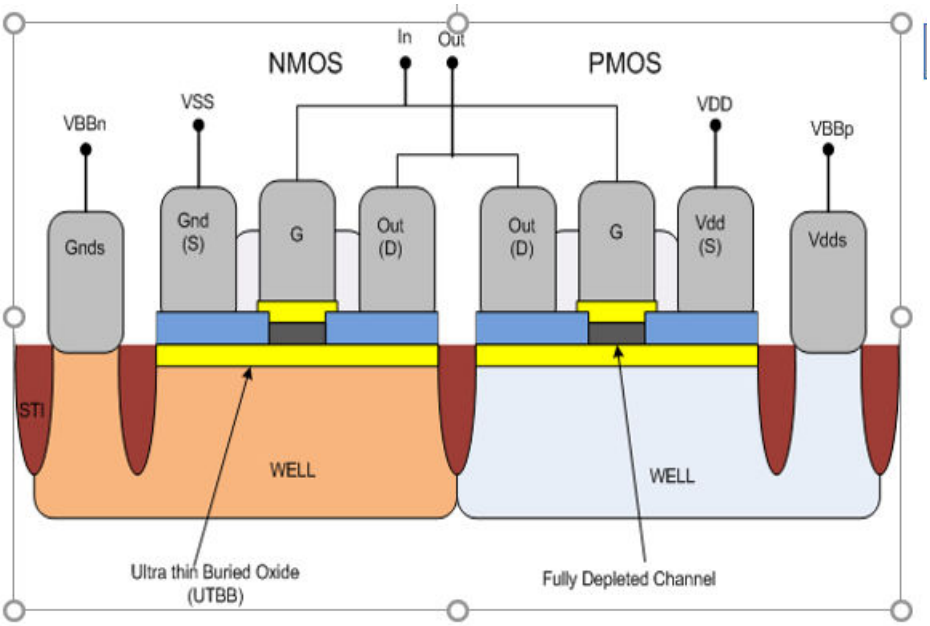

Figure 27-2. NMOS/PMOS transistor operation

The following table shows the valid RBB/FBB combinations for i.MX 7ULP

Table 27-4. Valid RBB/FBB combinations for i.MX 7ULP

A7 Domain	M4 Domain	Valid i.MX 7ULP use-case	Applicable A7/M4 Power mode
No Biasing	No Biasing	YES	No Restriction
FBB	No Biasing	YES	• A7 (HSRUN Mode) • M4 (RUN Mode)
FBB	FBB	YES	• A7 (HSRUN Mode) • M4 (HSRUN Mode)
FBB	RBB	YES	N/A
Power Gated	FBB	YES	M4 (HSRUN Mode)
Power Gated	RBB	YES	M4 (VLPR, VLPS, LLS modes)
RBB	No Biasing	YES	• A7 (VLPS, LLS modes) • M4 (RUN mode)
RBB	FBB	YES	N/A
RBB	RBB	YES	• A7 (VLPS, LLS modes) • M4 (VLPR, VLPS, LLS modes)

27.9 Power Management Controller (PMC)

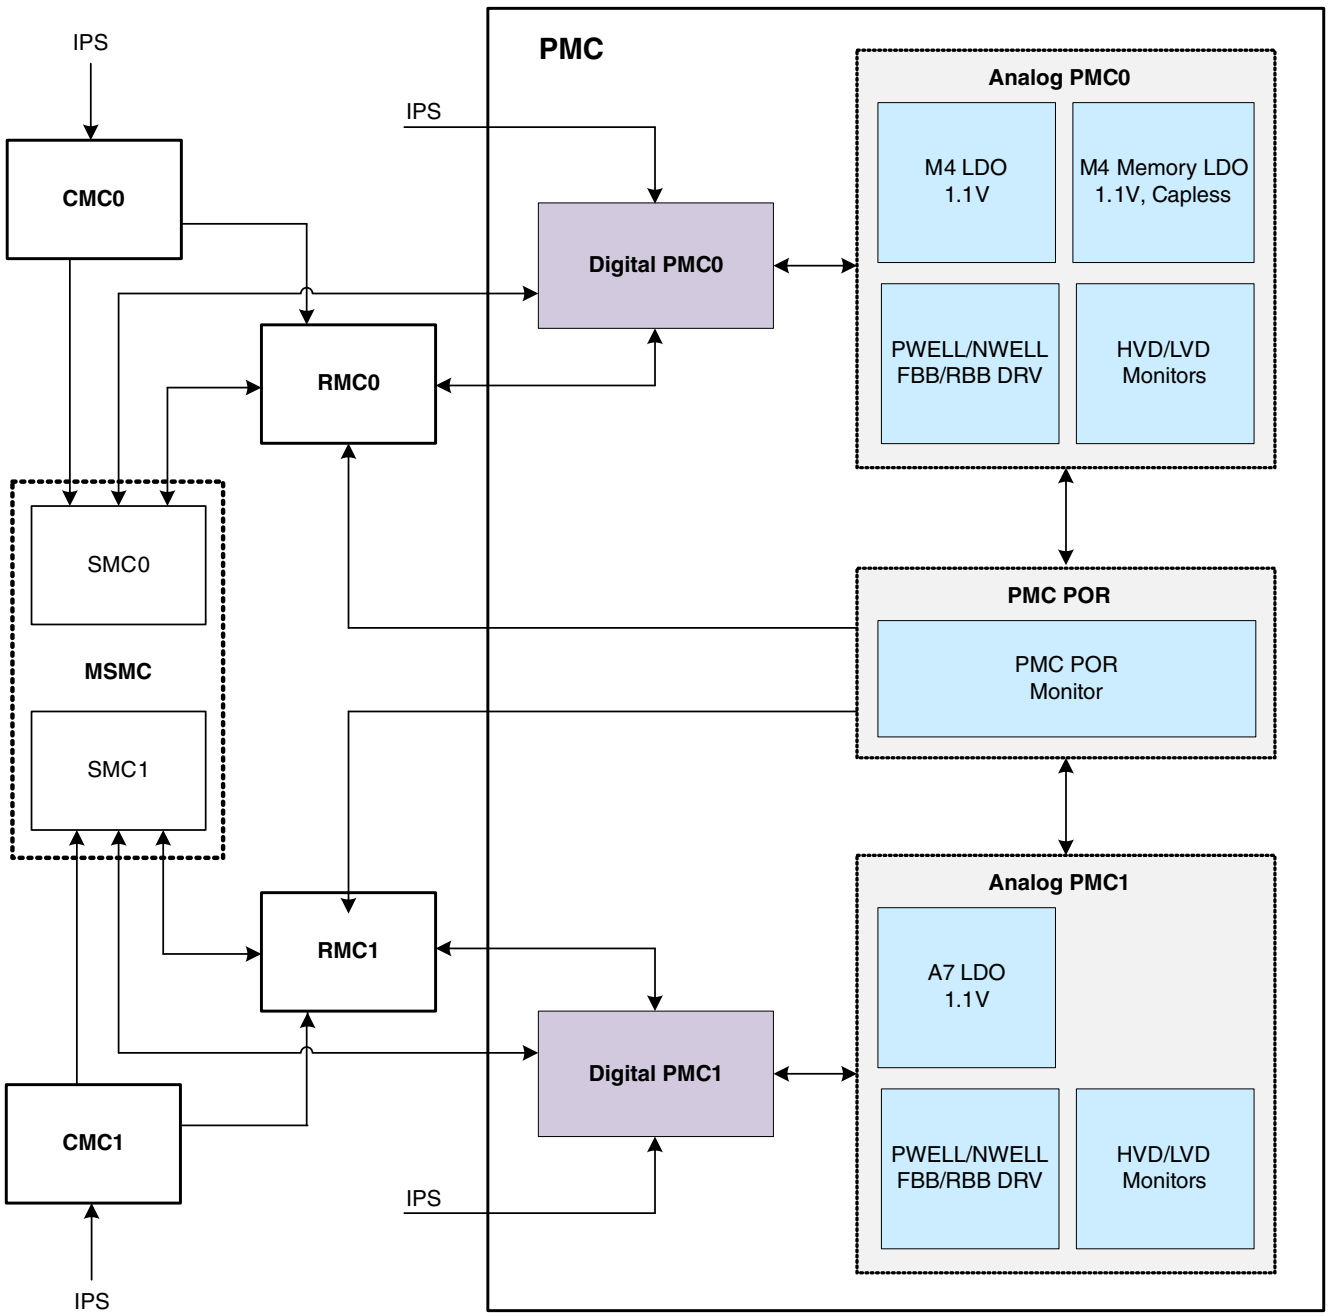

Figure 27-3. PMC System and Interface

PMC comprises Digital PMC modules and Analog PMC components. The Digital PMC module allows user software to control power modes of the chip and to optimize power consumption for the level of functionality needed.

There are two instances of Digital PMC on this device: Digital PMC0 controlling M4 and M4 Memory power domains and Digital PMC1 controlling A7 power domain. Digital PMCs work in conjunction with CMCs, MSMC and RMCs to facilitate the transition of operating modes and power modes of the device. A part of the Digital PMC module resides in the "always-on" DGO power domain.

The Analog PMC consists of voltage and current references, core logic supply regulators, memory supply regulators, back bias and forward bias regulators, monitors and power switches. The Analog PMC is made of Analog PMC0, Analog PMC1, and PMC POR circuit. Analog PMC0 manages supply to M4 domain and M4 Memory domain, and Analog PMC1 manages supply to the entire A7 domain.

The Digital PMC and Analog PMC supply is constantly monitored by the PMC POR. This circuit is always enabled. When the PMC POR monitor detects a supply less than 1.8 V it will generate a power-on reset to the CMCs.

27.10 Power supply use cases

The i.MX 7ULP microcontroller can be supplied by a simple PMIC, which has switched and linear regulators. This device can also be supplied by a combination of linear regulators for cost optimization purpose. The following figures show some possible power supply options for i.MX 7ULP.

Use case 1: Companion PMIC:

- An external PMIC that has at least 1 switched regulator and 1.2 V, 1.8 V, and 3.3 V linear regulators.
- M4 domain is always powered by an internal regulator which gets its supply from the PMIC 1.8V rail.
- A7 domain is supplied directly from the PMIC switched regulator.
- GPIO ports are on either 1.8 V or 3.3 V supply rails.
- DDR IO is on 1.2 V supply rail.

Use case 2: A combination of linear regulators shared between M4 and A7 domains::

- Common 1.2 V, 1.8 V, and 3.3 V regulators shared between A7 and M4 power domains
- M4 domain is always powered by an internal regulator which gets its supply from the 1.8 V rail.
- A7 is powered by an internal regulator which gets its supply from the 1.2V rail.

- GPIO ports are on either 1.8 V or 3.3 V supply rails.
- DDR IO is on 1.2 V supply rail.

Use case 3: Independent supply sources for M4 and A7 domains:

- Separate sets of linear regulators for M4 and A7 power domains
- M4 domain is always powered by an internal regulator which gets its supply from the 1.8V rail dedicated for M4 side.
- M4 GPIO ports are on either 1.8V or 3.3V supply rails dedicated for M4 side.
- A7 is powered by an internal regulator which gets its supply from the 1.2V rail.
- A7 GPIO ports are on either 1.8V or 3.3V supply rails dedicated for A7 side.
- DDR IO is on 1.2V supply rail.

27.11 Power modes

27.11.1 A7 domain power

The A7 domain has multiple power modes. The following table describes the state of A7 domain in those modes.

Table 27-5. A7 power modes

A7 Power Mode	Description	Recovery Method	Recovery Time
HSRUN	• All logic is functional in this mode. • Bus clock and peripherals functional. • Allows FBB (optional) • Allows Dynamic Voltage Scaling(DVS)	N/A	N/A
RUN	• All logic is functional in this mode. • Bus clock and peripherals functional. • FBB/RBB not allowed. • Allows Dynamic Voltage Scaling(DVS)	N/A	N/A
VLPR	• All logic is functional in this mode. • Max Frequency restricted to FIRC (48 MHz). PLLs disabled. • Option to disable LVD/HVD	N/A	N/A

Table continues on the next page...

Table 27-5. A7 power modes (continued)

A7 Power Mode	Description	Recovery Method	Recovery Time
	• DDR in self-refresh mode. DDR self-refresh must be done by software by writing to MMDC_MAPSR[LPMD] bit • RBB not allowed		
WAIT[1], [2]	• Allows Peripherals to function while keeping core in sleep (clock-gated). • A7 processor in Wait-for-Interrupt (WFI) state.	Interrupt[3]/ Reset, [4]	0 ns
STOP[5]/VLPS	• I.MX 7ULP is in static state with all registers retained with maintaining LVD protection. • RBB only allowed in VLPS mode. • FIRCCSR[FIRCLPEN] in the SCG module, keeps FIRC enabled in VLPS mode. • LVDs could be turned off in VLPS mode.	Interrupt/ Reset[4]	7 µs(STOP) and 23 µs (VLPS with RBB)/21.5 µs (VLPS without RBB)[6]
LLS[7]	• A7 supply ON • RBB is allowed • LVD protection • IO supplies ON • A7 processor is in a wait-for-interrupt (WFI) state. The core clock is gated. • Bus and DMA clocks are gated • All peripheral clocks are gated. • SRAM contents are retained. • DDR can be in self-refresh	Interrupt/ Reset[4]	Wake up time: 41.5 µs (LLS with RBB)/40 µs (LLS without RBB)[8]
VLLS	• A7 domain fully power gated. • Wake-up only via MU_A (CM4 domain) or reset. • DDR can be in self-refresh	MU_A[9]/ Reset, [4]	60 µs
BAT	• A7 supply OFF • IO supplies OFF • Logic registers and RAMs are not retained • DDR can be in self-refresh		• M4 turns on A7 and A7 IO power supplies • PMIC power on sequence • Wake up time: NA

1. i.MX 7ULP supports additional variant of WAIT mode called VLPS mode that allows peripheral operation at reduced frequency. See MSMC or PMC for details.
2. See SLEEPDEEP mode
3. Interrupts from A7, M4 or external device via GPIO pin could act as a wake-up. GIC detects wake-up source for A7 processor.
4. A7 reset sources or M4 reset sources
5. i.MX 7ULP supports variation of STOP mode called Partial STOP [1/2/3] that allows additional options (enable/disable) to control system and bus clock. PSTOP1/2 mode recovery time is less than the one for STOP mode, while PSTOP3 recovery time is around the same as that for WAIT mode. See MSMC or PMC for details.
6. These values depend on LDO setting during low-power mode
7. VLPS and LLS modes work in a very similar way, except that LLS causes the memories to enter RETENTION mode and their supply to be reduced (supply reduction applies to M4 domain only). Besides, pins remain isolated while the domain is in LLS mode.

8. On CA7, LLS uses PMC0_CTRL[LDOOKDIS]=1
9. MU_ACR[BHR] or MU_ACR[NMI]

1. See SLEEPDEEP mode
2. VLPS and LLS modes work in a very similar way, except that LLS causes the memories to enter RETENTION mode and their supply to be reduced (supply reduction applies to M4 domain only). Besides, pins remain isolated while the domain is in LLS mode.
3. Static: clock(s) is(are) ON, but the module is not operating.
4. Here, Async Operation means the block supports the DMA transfers from/to IPs that are working in Assynchronous Operation state
5. NIC0 is clock gated if none of its peripherals (GPU 2D, GPU3D, LCDIF, and MMDC) is enabled.
6. PCTLs are capable of detection external interrupts
7. DDR_CKE will be pulled down at the board level if DDR is in self-refresh mode

27.11.2 M4 domain power

The M4 domain has multiple power modes. The following table describes the state of M4 domain in those modes.

Table 27-7. M4 power modes

M4 Power Mode	Description	Recovery Method	Recovery Time
HSRUN	• All logic is functional in this mode. • Bus clock and peripherals functional. • Allows FBB (optional) • Allows Dynamic Voltage Scaling(DVS)	N/A	N/A
RUN	• All logic is functional in this mode. • Bus clock and peripherals functional. • FBB/RBB not allowed. • Allows Dynamic Voltage Scaling (DVS)	N/A	N/A
VLPR	• All logic is functional in this mode. • Maximum frequency restricted to FIRC (48 MHz). PLL disabled • Allows RBB (Optional) • Allows to disable LVD/ HVD(optional)	N/A	N/A
WAIT	• Allows Peripherals to function while keeping core in sleep (clock-gated). • M4 processor in WFI state.	Interrupt[1]/Reset[2]	0 ns
STOP[3]/VLPS	• i.MX 7ULP is static state with all registers retained with maintaining LVD protection. • Peripheral optionally operational in STOP mode[4] • RBB only allowed in VLPS mode. • FIRC enabled in VLPS mode via SCG0_FIRCCSR register. • LVDs could be turned off in VLPS mode.	Interrupt[5] /Reset[2]	4 µs (STOP) and 11.5 µs (VLPS with RBB)/9 µs (VLPS without RBB)[6]
LLS [7]	• Static mode with no active transition. • CM4 in WFI mode with core clock gated • RBB allowed	Interrupt[5] /Reset[2]	62 µs (LLS with RBB)/58 µs (LLS without RBB)[8]

Table continues on the next page...

Table 27-7. M4 power modes (continued)

M4 Power Mode	Description	Recovery Method	Recovery Time
VLLS[9]	• M4 core supply OFF with majority of the logic power gated. • AWIC detects wake-up sources for M4 (via LLWU) • Selectable Memory retention (32K/64K/256K) • ADC, Comparators, LP Timers Optionally functional • RBB allowed (Optional) • DGO [10](aka Always ON) Logic Active	Wake-up Interrupt[11]/Reset[12]	375 µs

1. Interrupts from A7, M4 or external device via GPIO pin could act as a wake-up. NVIC detects wake-up source for M4.
2. M4 reset sources or A7 reset sources (when A7_TO_M4_RESET_EN fuse is blown).
3. i.MX 7ULP supports variation of STOP mode called Partial STOP [1/2/3] that allows additional options (enable/disable) to control system and bus clock. PSTOP1/2 mode recovery time is less than the one for STOP mode, while PSTOP3 recovery time is around the same as that for WAIT mode See MSMC or PMC chapter for details.
4. Peripherals capable of asynchronous operation during STOP (at full frequency) and VLPS (at limited frequency). This includes low power peripherals (LPUART, LPSPI, and LPI2C) operational on SIRC/FIRC/SOSC clock in STOP/VLPS mode.
5. Wakeup via Interrupts from M4 peripherals or external GPIO pins. NVIC disabled, AWIC detects the wake-up source.
6. This value depends on LDO setting during low-power mode
7. VLPS and LLS modes work in a very similar way, except that LLS causes the memories to enter RETENTION mode and their supply to be reduced (supply reduction applies to M4 domain only). Besides, pins remain isolated while the domain is in LLS mode.
8. On CM4, LLS uses LDO HP mode
9. See MSMC or PMC chapter for details.
10. Only Peripherals in DGO domain (CMPx, LPTMRx) are functional.
11. VLLS wake-up through LLWU and NMI pin (PTA9). SIM_DGO_GP11[NMI_VLLS_WAKEUP_EN] in the SIM module must be set prior to entering VLLS mode when using the NMI pin. VLLS exit forces a system reboot.
12. RESET0_b or RESET1_b (when both M4 and A7 domains are in VLLS mode, regardless of A7_TO_M4_RESET_EN fuse's state).

1. VLPS and LLS modes work in a very similar way, except that LLS causes the memories to enter RETENTION mode and their supply to be reduced (supply reduction applies to M4 domain only). Besides, pins remain isolated while the domain is in LLS mode.
2. Static: clock(s) is(are) on, but the module is not operating.
3. Here, Async Operation means the block supports the DMA transfers from/to IPs that are working in Assynchronous Operation state
4. PCTLs are capable of detection external interrupts
5. LLWU wake-up pins are active in VLLS mode.

M4 VLLS mode has different levels of granularity. The following table shows the continuum of options in VLLS. The user has the option to select various features that meet the requirements of the application. This table shows what is possible in VLLS from the lowest leakage to more functionality with more power consumption. There are many more options available in the continuum. As an example, the memories can be turned on or off in 32KB blocks.

Table 27-9. M4 VLLS mode

M4 VLLS Mode		Description
VLLS	Highest leakage	• Common VLLS logic state. • Comparator and LPTMR peripherals are running. • Selected low power clock sources are on. • All memory are retained.
		• Common VLLS logic state. • Selected Comparator and LPTMR peripherals are running • Selected low power clock sources are on. • Selected memory are retained.
	...	...
		• Common VLLS logic state. • No peripherals active. • Selected memory are retained.
	Lowest leakage	• Common VLLS logic state. • No peripheral active. • Only 32KB memory retained.

Warning

It is recommended to keep PTA29 low (=0) while waking up the RTD from VLLS mode to avoid unexpected behavior.

27.11.3 VBAT domain power

The VBAT domain supplies a small, very low leakage piece of logic that contains a RTC, wake-up logic, temperature and voltage sensors, a small amount of memory, and a voltage regulator. The input range to the VBAT domain is 2.0 to 4.2 Volts so it can be powered directly from the systems battery or from an independent source, such as a super cap, or from the main supply.

Table 27-10. VBAT mode

VBAT mode	Description
VBAT	• Battery mode. • Secure RTC is on. • Tamper logic retained.

28.1.1 Digital Power Management Controller (Digital PMC)

The Digital PMC module allows user software to control power modes of the chip and to optimize power consumption for the level of functionality needed. There are two instances of Digital PMC on this device, one for each main power domain.

Table 28-2. Digital PMC configuration

Parameter	Description
Name	Digital Power Management Controller (Digital PMC)
Instances	2
Configurable features	Refer to Power Management for detail
Interface speed	NA
External I/O pins	NA

28.1.2 Supported modes of operation

- VLPS and LLS modes work in a very similar way, except that LLS causes the memories to enter RETENTION mode and their supply to be reduced (supply reduction applies to M4 domain only). Besides, pins remain isolated while the domain is in LLS mode.
- RBB should not be enabled on A7 domain when any clock is active. Only static RBB is supported for A7 domain.
- After exiting VLLS mode, IOMUXC will be reset and all pad configurations will default to reset values. Before asserting CTRL[ISOACK] bit, IOMUX needs to be reconfigured to resume pad configuration prior to entering VLLS mode. See Pads Isolation for more details.
- When exiting VLLS mode, the isolation in PTA26, PTA27 and PTA28 pads is released automatically if one of PTA26 or PTA27 is configured as JTAG/SWD function before entering VLLS mode. See Pads Isolation

28.1.3 Memory power control

Memory power controls are divided into three main groups:

- M4 power domain memories that are controlled by PMC registers PMC0_SRAMCTRL_0|1|2: These are basically the core TCM memories. The idea is that application has control over the amount of TCM memory it can power-gate in lower power modes. The table below shows how each bit of these registers are mapped and the corresponding TCM system address range.

Table 28-3. Bit mapping of PMC_0_SRAMCTRL_0|1|2 registers and corresponding TCM address range

PWR GROUPS	PMC0_SRAMCTRL_0|1|2	i.MX 7ULP system	Size
	bit	Address	
cm4_tcm_bank0	0	0x1FFD_0000 - 0x1FFD_7FFF	32 KB
cm4_tcm_bank1	1	0x1FFD_8000 - 0x1FFD_FFFF	32 KB
cm4_tcm_bank2	2	0x1FFE_0000 - 0x1FFE_FFFF	64 KB
cm4_tcm_bank3	3	0x1FFF_0000 - 0x1FFF_FFFF	64 KB
cm4_tcm_bank4	4	0x2000_0000 - 0x2000_FFFF	64 KB

- M4 domain memories without register control (CM4_NO_TCM): This comprises the DMA, Caches, Trace Memory, and ROM.
- A7 domain memories: All of A7 domain have PMC register control. The table below shows how PMC register bits are mapped to chip-specific memories.

Table 28-4. Bit mapping of PMC_1_SRAMCTRL_0 register to chip-specific memories

PWR GROUPS	PMC1_SRAMCTRL_0
	bit
CA7 core	0
GPU3D	1
GPU2D	2
CA7 OCRAMs	3
USB	4
VIU	5
LCDIF	6
MISC(DSI, DMA1, CAAM, uSDHC0/1)	7

NOTE

USB PHY-related interrupt (NVIC/GIC) and wake-up channels (AWIC/WKPU) must be disabled before turning PMC_1 ON (CTRL[PMC1ON] in PMC_0).

28.1.4 Operation voltage requirements

The default operation voltage levels defined via PMC0 *power mode* [COREREGVL] and PMC1 *power mode*[LDOVL] fields don't necessarily satisfy the operation voltage levels required by the system. Such operation voltage requirements can be found on i.MX 7ULP Data Sheet. In this sense, no power transition should be performed before ensuring the mentioned register fields are matching the required operation voltage levels expressed on the data sheet.

In a scenario that the application domain is supplied by an external PMIC, the same operation voltage requirements hold; the only difference being that the operational voltage levels must be observed by the respective PMIC supply rather than adjusted via PMC1 *power mode*[LDOVL] fields.

28.2 Introduction

The Power Management Controller (PMC) can be divided into two parts: PMC 0 and PMC 1. The PMC 0 controls the Core 0 SoG supply, the Core 0 SRAMs power modes and the Core 0 biasing. The PMC 1 controls the Core 1 SoG supply, the Core 1 SRAMs power modes and the Core 1 biasing. The PMC also has voltage monitors in both power domains (PMC 0 and PMC 1).

Both PMCs receive requests from the MSMC to change the current power mode. Each PMC allows the customer to choose what features will be enabled or disabled by each power mode.

The Figure 28-1 shows the PMC block diagram.

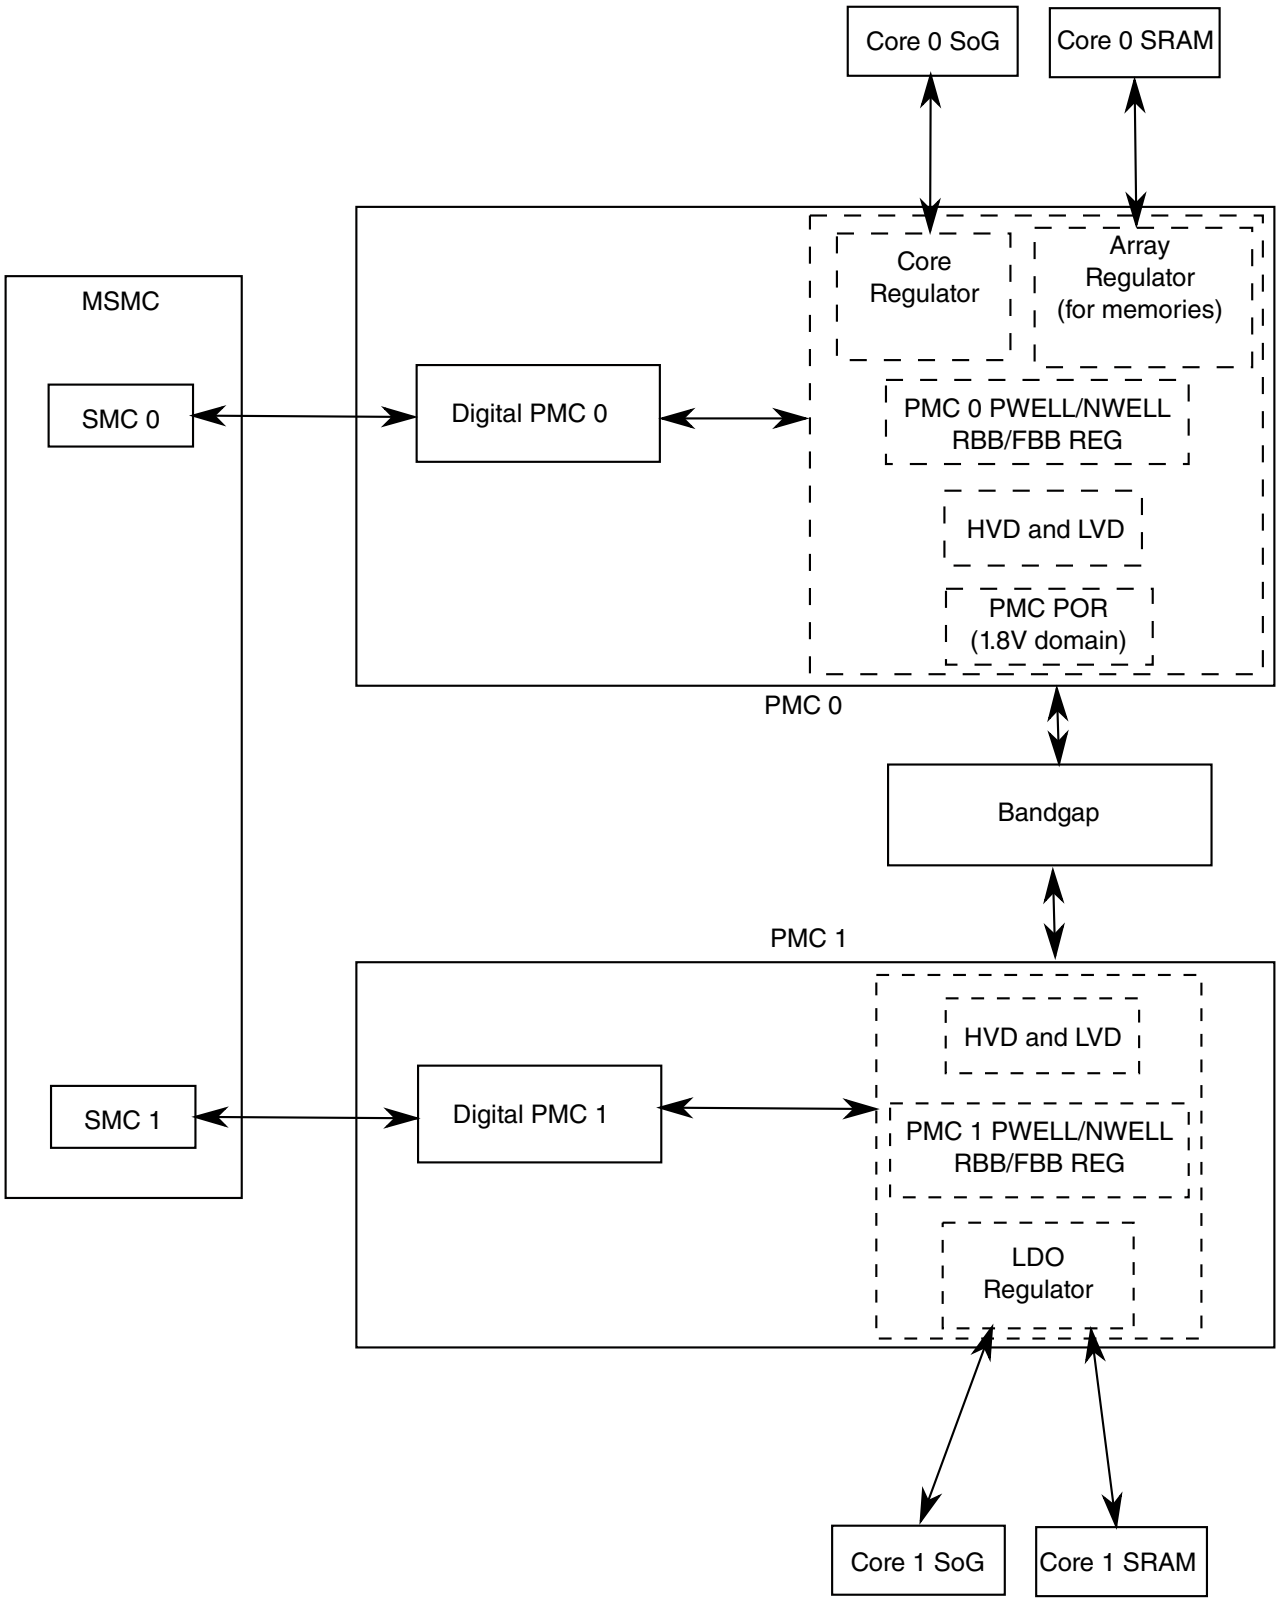

Figure 28-1. PMC Block Diagram

28.3 Features

The PMC 0 has the following features:

- a high-power (HP) and a low-power (LP) Core Regulator;
- a high-power (HP) and a low-power (LP) Array Regulator;
- a high-power (HP) and a low-power (LP) 1.2V Low Voltage Detector (LVD) monitor (in regulator input);
- a high-power (HP) 1.8V High Voltage Detector (HVD) monitor (in regulator supply);
- a bandgap;
- a forward back bias (FBB) and a reverse back bias (RBB) regulator.
- a temperature sensor.

The PMC 1 has the following features:

- a high-power (HP) and a low-power (LP) Linear LDO regulator;
- a set of power switches;
- a high-power (HP) and a low-power (LP) Low Voltage Detector (LVD) monitor;
- a high-power (HP) 1.2V High Voltage Detector (HVD) monitor;
- configurable LVD/HVD sense point between regulator supply and regulator output;
- a forward back bias (FBB) and a reverse back bias (RBB) regulator.

In addition, the PMC has a 1.8V POR (Power-On Reset) monitor to detect the voltage level in the Always-On power domain.

28.4 PMC register descriptions

This section describes the PMC registers.

NOTE

All registers must be written only during the RUN mode. Any intention to write the registers during VLPR or HSRUN modes could result in an unxpected behavior of the system. The exceptions to this rule are the COREREGVL (PMC0_HSRUN) and LDOVL (PMC1_HSRUN) bitfields that also could be written during the PMC 0 and PMC 1 HSRUN modes respectively.

28.4.1 PMC1 Memory map

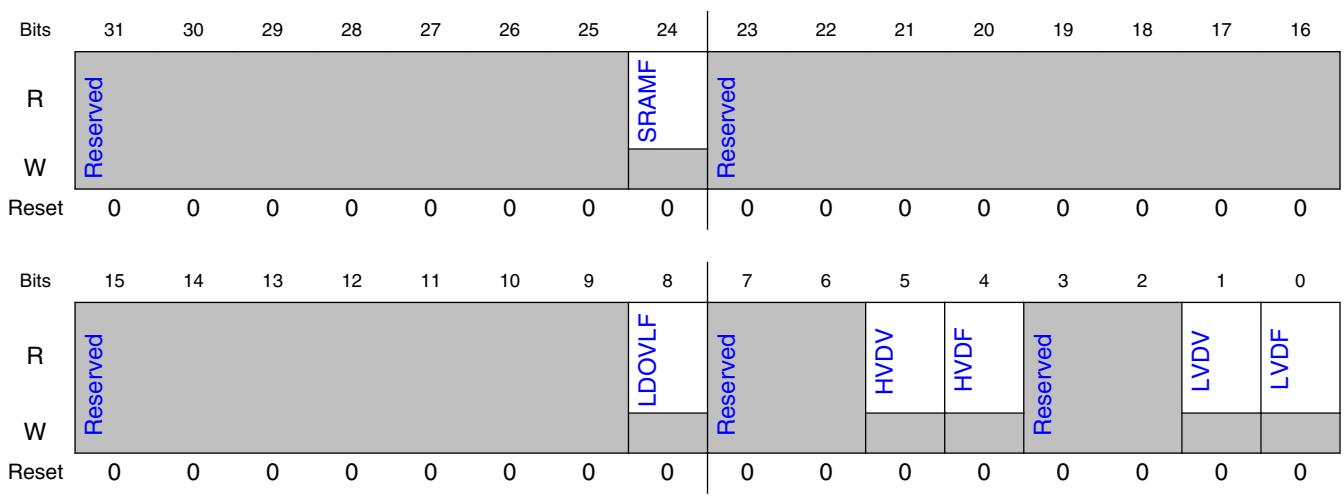
STATUS	20h

28.4.20.2 Diagram



28.4.20.3 Fields

Field	Function
31-25 —	Reserved field
24 SRAMF	SRAM Flag This flag indicates if a request to some SRAM entry(or exit) to some power mode is being processed. For more information see Change SRAMs power mode in RUN . **NOTE:** The user must wait for this to be cleared to start a new power mode request in the SRAMs. To start a request when this flag is asserted could cause an unxpected behavior in the system. **NOTE:** This bit is asserted one clock after to change the PMC1_SRAMCTRL_0 value. 0b - No change request in the SRAMs. 1b - A change mode request is being processed in the SRAMs.
23-9 —	Reserved field
8 LDOVLF	LDO Voltage Level Flag This flag is asserted when the PMC is changing the LDO Voltage Level due a different value writing in the field PMC1_RUN[LDOVL] (or PMC1_HSRUN[LDOVL], depending on the PMC 1 mode). The software needs to wait for the end of the voltage level changing (when this flag is cleared) to write a new value to PMC1_RUN[LDOVL] (or PMC1_HSRUN[LDOVL]) to start a new change process. For more information see Change regulator voltage in RUN or HSRUN . **NOTE:** Before a power mode transition, the user needs to confirm this bit is cleared. **NOTE:** This bit is asserted one clock after to change the PMC1_RUN[LDOVL] value (or PMC1_HSRUN[LDOVL], depending on the PMC 1 mode). **NOTE:** In case PMC0_CTRL[LDOOKDIS] bit is cleared, the PMC checks the regulated LDO output to clear this flag. Otherwise, when LDOOKDIS bit is asserted, PMC doesn't check the LDO output and it will take ~2µs by each 30mV in a voltage increment or ~3µs by each 20mV in a voltage decrement to clear this flag. 0b - LDO Voltage Level is stable 1b - LDO Voltage Level is changing
7-6 —	Reserved field
5 HVDV	1.2V High-Voltage Detector Value This bit is the current value of the 1.2V HVD monitor in the PMC 1. For more information see Voltage Monitors . 0b - High-voltage event was not detected by the 1.2V HVD monitor in PMC 1 1b - High-voltage event was detected by the 1.2V HVD monitor in PMC 1
4 HVDF	1.2V High-Voltage Detector Flag This flag is set when a high-voltage event was detected by the 1.2V HVD monitor in the PMC 1. This flag is cleared when 1 is written to the bit HVDACK in the register PMC1_CTRL. For more information see Voltage Monitors . **NOTE:** This bit will only be cleared if HVDV is cleared. 0b - High-voltage event was not detected by the 1.2V HVD monitor in PMC 1 1b - High-voltage event was detected by the 1.2V HVD monitor in PMC 1
3-2 —	Reserved field
1	1.2V Low-Voltage Detector Value

Table continues on the next page...

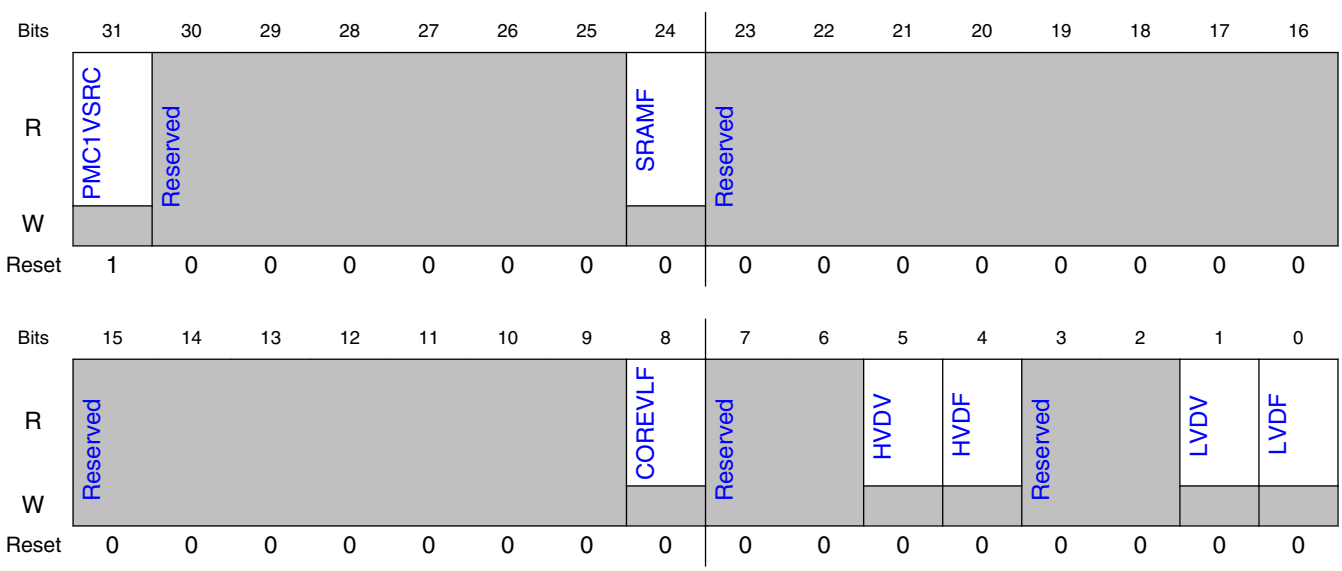
Field	Function
LVDV	This bit is the current value of the 1.2V LVD monitor in the PMC 1. For more information see Voltage Monitors . 0b - Low-voltage event was not detected by the 1.2V LVD monitor in the PMC 1 1b - Low-voltage event was detected by the 1.2V LVD monitor in the PMC 1
0 LVDF	1.2V Low-Voltage Detector Flag This flag is set when a low-voltage event was detected by the 1.2V LVD monitor in the PMC 1. This flag is cleared when 1 is written to the bit LVDACK in the register PMC1_CTRL. For more information see Voltage Monitors . **NOTE:** This bit will only be cleared if LVDV is cleared. 0b - Low-voltage event was not detected by the 1.2V LVD monitor in the PMC 1 1b - Low-voltage event was detected by the 1.2V LVD monitor in the PMC 1

28.4.21 PMC 0 Status register (STATUS)

28.4.21.1 Offset

Register	Offset
STATUS	24h

28.4.21.2 Diagram



28.4.21.3 Fields

Field	Function
31 PMC1VSRC	PMC 1 Voltage Source This flag indicates what is the voltage source selected to supply the PMC 1 and where the sense point of the PMC 1's LVD/HVD is placed. **NOTE:** The voltage source and LVD/HVD sense point of the PMC 1 are selected by the PMC0_CTRL[LDOEN] bit during a PMC 1 power-up. After that, the voltage source and sense point can be changed after a POR event only. For more information see Voltage Monitors . 0b - The internal LDO supplies the PMC 1, the PMC 1's LVD/HVD sense point is at the supply of the LDO regulator. 1b - The external PMIC supplies the PMC 1; the PMC 1's LVD/HVD sense point is at the pin connected to the PMIC.
30-25 —	Reserved field
24 SRAMF	SRAM Flag This flag indicates if a request to some SRAM entry(or exit) to some power mode is being processed. For more information see Change SRAMs power mode in RUN . **NOTE:** The user must wait for this flag to be cleared to start a new power mode request in the SRAMs. To start a request when this flag is asserted could cause an unxpected behavior in the system. **NOTE:** This bit could be asserted several clocks after to change the PMC0_SRAMCTRL_0 or the PMC0_SRAMCTRL_2 value. 0b - No change request in the SRAMs. 1b - A change mode request is being processed in the SRAMs.
23-9 —	Reserved field
8 COREVLF	Core Regulator Voltage Level Flag This flag is asserted when the PMC is changing the Core Regulator Voltage Level due a different value writing in the fields PMC0_RUN[COREREGVL] (or PMC0_HSRUN[COREREGVL], depending on the PMC 0 mode). The software needs to wait for the end of the voltage level changing (when this flag is cleared) to write a new value in PMC0_RUN[COREREGVL] (or PMC0_HSRUN[COREREGVL]) to start a new change process. For more information see Change regulator voltage in RUN or HSRUN . **NOTE:** Before a power mode transition the user needs to confirm this bit is cleared. **NOTE:** This bit could be asserted several clocks after to change the PMC0_RUN[COREREGVL] value (or PMC0_HSRUN[COREREGVL], depending on the PMC 0 mode). **NOTE:** In case of a voltage level increment, the PMC waits for the internal regulated output to reach the desired voltage, then this flag is cleared. Otherwise, in case of a voltage level decrement, there is a ~3µs timeout by each 21.66mV to wait for the internal regulated output to reach the desired voltage, then this flag is cleared. The timeout will be reached in case the regulator takes a very long time to decrease the voltage level by small loads in the regulator. 0b - Core Regulator Voltage Level is stable 1b - Core Regulator Voltage Level is changing
7-6 —	Reserved field
5 HVDV	1.8V High-Voltage Detector Value This bit is the current value of the 1.8V HVD monitor in the PMC 0. For more information see Voltage Monitors . 0b - High-voltage event was not detected by the 1.8V HVD monitor in the PMC 0 1b - High-voltage event was detected by the 1.8V HVD monitor in the PMC 0

Table continues on the next page...

Field	Function
4 HVDF	1.8V High-Voltage Detector Flag This flag is set when a high-voltage event was detected by the 1.8V HVD monitor in the PMC 0. This flag is cleared when 1 is written to the bit HVDACK in the register PMC0_CTRL. For more information see Voltage Monitors . **NOTE:** This bit will only be cleared if HVDV is cleared. 0b - High-voltage event was not detected by the 1.8V HVD monitor in the PMC 0 1b - High-voltage event was detected by the 1.8V HVD monitor in the PMC 0
3-2 —	Reserved field
1 LVDV	1.2V Low-Voltage Detector Value This bit is the current value of the 1.2V LVD monitor in the PMC 0. For more information see Voltage Monitors . 0b - Low-voltage event was not detected by the 1.2V LVD monitor in the PMC 0 1b - Low-voltage event was detected by the 1.2V LVD monitor in the PMC 0
0 LVDF	1.2V Low-Voltage Detector Flag This flag is set when a low-voltage event was detected by the 1.2V LVD monitor in the PMC 0. This flag is cleared when 1 is written to the bit LVDACK in the register PMC0_CTRL. For more information see Voltage Monitors . **NOTE:** This bit will only be cleared if LVDV is cleared. 0b - Low-voltage event was not detected by the 1.2V LVD monitor in the PMC 0 1b - Low-voltage event was detected by the 1.2V LVD monitor in the PMC 0

31-5 —	Reserved field
4-0 SRAM_STDY	PMC 0 SRAM Bank in Standby Mode The bit i controls the PMC 0 SRAM bank i. PMC0_SRAM_STDY[i] = 0 — PMC 0 SRAM bank i is in RETENTION mode during LLS power mode, in DEEP_SLEEP mode during VLLS power mode, or in RUN mode during any other power mode. PMC0_SRAM_STDY[i] = 1 — PMC 0 SRAM bank i is in STANDBY mode during any power mode except VLLS and LLS; in RETENTION mode during LLS power mode ; or in DEEP_SLEEP mode during VLLS power mode. For more information see SRAM Banks . **NOTE:** This field will be reset by a PMC 0's domain warm reset.

28.5 Functional Description

28.5.1 Power-on Reset

The digital and analog PMC supply is constantly monitored by a 1.8V Power-On Reset (POR) monitor. This monitor is always enabled and if the supply is out of the range (around 1.8V) then a power-on reset is generated.

After a POR event, only the PMC 0 domain will be turned on, the PMC 1 domain should be turned on by the procedure described in Procedures.

28.5.2 Regulators

28.5.2.1 Core and Array Regulator

The PMC 0 has the following regulators:

- Core Regulator, supplies the PMC 0 SoG and the periphery of the PMC 0 SRAM memories. It can operate in High Power (HP) or Low Power (LP) modes.
- Array Regulator, supplies the array of the PMC 0 SRAM memories. It can operate in High Power (HP) and Low Power (LP) modes.

The mode of the regulator depends on the PMC 0 mode and the COREREG or ARRAYREG fields in the PMC 0 Registers as shown in Table 28-5. In the RUN, HSRUN and STOP modes, both regulators are in HP mode. In VLLS, the Core Regulator is turned off and the Array Regulator can be turned off optionally. After a POR event, the PMC 0 power mode is in RUN mode.

NOTE

In case the Array Regulator will be turned off, the content of all the memories will be lost.

Table 28-5. PMC 0 regulators

PMC 0 Mode	Core Regulator Mode (COREREG)	Array Regulator Mode (ARRAYREG)	Core Regulator Voltage Level (COREREGVL) *	Array Regulator Voltage Level *
HSRUN (High Speed Run)	HP	HP	0.90V	1.0V
RUN	HP	HP	0.90V	1.0V
VLPR (Very Low Power Run	HP/LP*	HP/LP*	0.70V	1.0V
STOP	HP	HP	0.90V	1.0V
VLPS (Very Low Power Stop)	HP/LP*	HP/LP*	0.70V	1.0V
LLS (Low Leakage Stop)	HP/LP*	HP/LP*	0.70V	0.75V
VLLS (Very Low Leakage Stop)	OFF	HP/LP*/OFF	-	0.75V

In Table 28-5, the cells marked with * are the default values after a POR event.

The level voltage of the Core Regulator can be changed by mode through the COREREGVL field. To change this value in RUN mode see Core Regulator (PMC 0). In the Array Regulator case, the voltage level will be changed automatically to predefined values as shown in Table 28-5.

28.5.2.2 LDO Regulator

The PMC 1 is turned on by the PMC 0 (see Procedures). The PMC 1 can use the internal LDO Regulator or the external PMIC to supply the PMC 1 SoG and SRAMs.

The LDO Regulator will be turned on in the PMC 1 initialization sequence only when the bit LDOEN in PMC 0 registers is asserted (see Using internal LDO regulator). This regulator can operate in High Power (HP) and Low Power (LP) modes. The operation mode depends on the PMC 1 power mode and the LDOM field in the PMC 1 registers as shown in Table 28-6.

The LDO Regulator can be turned off in a mode transition to VLLS by the procedure described in Using internal LDO regulator.

The bit field LDOLV in PMC 1 registers selects the voltage level generated by the LDO regulator, see LDO Regulator (PMC 1) to change the voltage level value in RUN mode.

Table 28-6. PMC 1 regulators

PMC 1 Mode	LDO Regulator Mode (LDOM)	LDO Regulator Voltage Level (LDOVL) *
HSRUN (High Speed Run)	HP	1.0V
RUN	HP	1.0V
VLPR (Very Low Power Run	HP/LP*	0.70V
STOP	HP	1.0V
VLPS (Very Low Power Stop)	HP/LP*	0.70V
LLS (Low Leakage Stop)	HP/LP*	0.70V
VLLS (Very Low Leakage Stop)	HP/LP*	The same as RUN

In Table 28-6, the cells marked with * are the default values after a POR event.

NOTE

In VLLS mode of the PMC 1, althought the LDO regulator is turned on, the PMC 1 SoG and SRAMs aren't supplied, due to the internal supply switches are opened.

28.5.3 Voltage Monitors

The PMC 0 has the following voltage monitors:

- 1.2V Low Voltage Detector (LVD);
- 1.8V High Voltage Detector (HVD).

The LVD can operate in High Power (HP) or Low Power (LP) modes and can not be disabled, but the HVD can operate in HP only and can be disabled. The operation mode depends on PMC 0 mode and the fields MONLVD and MONHVD in the PMC 0 registers as shown in Table 28-7.

The sense point of the LVD/HVD is in the supply of the Core regulator.

These monitors can be configured to generate resets (PMC0_CTRL register - bits LVDRE and HVDRE), asynchronous and synchronous interrupts (PMC0_CTRL register - bits LVDIE and HVDIE) or none of them.

Table 28-7. PMC 0 monitors

PMC 0 Mode	LVD Mode (MONLVD)	HVD Mode (MONHVD)
HSRUN (High Speed Run)	HP	HP
RUN	HP	HP
VLPR (Very Low Power Run	HP/LP*	HP/OFF*
STOP	HP	HP
VLPS (Very Low Power Stop)	HP/LP*	HP/OFF*
LLS (Low Leakage Stop)	HP/LP*	HP/OFF*
VLLS (Very Low Leakage Stop)	HP/LP*	HP/OFF*

In Table 28-7, the cells marked with * are the default values after a POR event.

The PMC 1 has the following voltage monitors:

- Low Voltage Detector (LVD);
- 1.2V High Voltage Detector (HVD).

Like PMC 0, the LVD can operate in High Power (HP) or Low Power (LP) modes and can not be disabled, but the HVD can operate in HP only and can be disabled. After a POR event, the LVD is in Low Power mode and the HVD is disabled. After PMC 1 power up, the monitors operation mode depends on the PMC 1 mode and the fields MONLVD and MONHVD in the PMC 1 registers as is shown in Table 28-8.

The sense point of the LVD/HVD is configurable, it can be placed at the supply of the LDO regulator or at the pin connected to the external PMIC. This sense point is configured by the LDOEN bit (in PMC0_CTRL register) during a PMC1 power up, then this configuration can be changed after a POR event only. When the PMC 1 is powered up using the internal LDO (LDOEN=1, see Using internal LDO regulator), the sense

point is placed at the supply of the LDO regulator; otherwise, when the PMC 1 is powered up with the external PMIC (LDOEN=0, see Using external PMIC), the sense point is placed at the pin connected to the external PMIC. The actual sense point configured is indicated by the PMC1VSRC (in PMC0_STATUS register).

When the sense point is placed at the supply of the LDO regulator, the trip point of the LVD is around 1.2V.

These monitors can be configured to generate reset (PMC1_CTRL register - bits LVDRE and HVDRE), asynchronous and synchronous interrupts (PMC1_CTRL register - bits LVDIE and HVDIE) or none of them.

Table 28-8. PMC 1 monitors

PMC 1 Mode	LVD Mode (MONLVD)	HVD Mode (MONHVD)
HSRUN (High Speed Run)	HP	HP
RUN	HP	HP
VLPR (Very Low Power Run	HP/LP*	HP/OFF*
STOP	HP	HP
VLPS (Very Low Power Stop)	HP/LP*	HP/OFF*
LLS (Low Leakage Stop)	HP/LP*	HP/OFF*
VLLS (Very Low Leakage Stop)	HP/LP*	HP/OFF*

In Table 28-8, the cells marked with * are the default values after a POR event.

28.5.4 Biasing

The PMC 0 and PMC 1 have Forward Back Bias (FBB) and Reverse Back Bias (RBB) functionalities. RBB provides core leakage and total SoC consumption reduction. FBB provides SoC core performance enhancement by increasing device speed (at a cost of higher leakage consumption). RBB and FBB functionalities are not available at same time in the same PMC domain. The FBB could be enabled in the HSRUN mode only. The RBB can be enabled in low power modes only (VLPR, LLS and VLPS) as shown in Table 28-9.

Table 28-9. PMC Biasing

PMC 0/1 Mode	Forward Back Bias	Reverse Back Bias
HSRUN (High Speed Run)	ON/OFF*	OFF
RUN	OFF	OFF
VLPR (Very Low Power Run)	OFF	ON/OFF*
STOP	OFF	OFF

Table continues on the next page...

Table 28-9. PMC Biasing (continued)

PMC 0/1 Mode	Forward Back Bias	Reverse Back Bias
VLPS (Very Low Power Stop)	OFF	ON/OFF*
LLS (Low Leakage Stop)	OFF	ON/OFF*
VLLS (Very Low Leakage Stop)	OFF	OFF

In Table 28-9, the cells marked with * are the default values after a POR event.

NOTE

RBB is not avaliable in the PMC 1's VLPR mode.

28.5.5 Bandgap

The PMC has a HP and a LP bandgap to provide voltage references to analog blocks. The LP bandgap is always turned on. The HP bandgap will be enabled when the Core Regulator is in HP mode or the Array Regulator is in HP mode or the LDO Regulator is turned on or the Temperature Sensor is enabled or the FBB is enabled or some monitor is in HP or the FBGHP (PMC 0 registers) is asserted in the current mode. In other cases the HP bandgap will be disabled to reduce the power consumption i.e. the references will be provided by the LP bandgap only.

28.5.6 SRAM Banks

The PMC controls the power modes of the SRAM banks. The power modes are shown in Table 28-10 and are described in the following:

- RUN mode is the default power mode, the periphery and array are supplied with the operation voltage. Memory accesses are only allowed in this mode.
- In STANDBY mode, the periphery power consumption is reduced. The array is turned on at the operation voltage.
- In ASD or ARRAY-SHUTDOWN mode, the array is shutdown. The periphery is turned on at the operation voltage.
- In RETENTION mode, the periphery and array are supplied with the retention voltage.
- In DEEP_SLEEP mode, the periphery is shutdown and the array is supplied with the retention voltage.
- In POWER_DOWN mode, the periphery and array are shutdown.

Table 28-10. Power Modes

SRAM Mode	Periphery State	Array State
RUN	ON at Operation Voltage	ON at Operation Voltage
STANDBY	ON at Operation Voltage	ON at Operation Voltage
ASD	ON at Operation Voltage	OFF
RETENTION	ON at Retention Voltage	ON at Retention Voltage
DEEP_SLEEP	OFF	ON at Retention Voltage
POWER_DOWN	OFF	OFF

It is important to remark that the ASD mode has higher priority over other modes and STANDBY has priority over the RUN mode.

In the PMC 0 domain there are two memory groups: TCM (Tightly-Coupled Memories) and No-TCM. The PMC 0 supports the following power modes for the TCM: RUN, ASD, STANDBY, RETENTION and POWER_DOWN as shown in Table 28-11.

The PMC0_SRAM_PD[i] bit (PMC0_SRAMCTRL_0) or the PMC0_SRAM_PDS[i] (PMC0_SRAMCTRL_1) should be used to the bank 'i' enter to ASD mode. The PMC0_SRAM_STDY[i] bit (PMC0_SRAMCTRL_2) should be used to the bank 'i' enter to STANDBY mode.

Table 28-11. PMC 0 TCM

PMC 0 Mode	SRAM Modes (PMC0_SRAM_PD[i] , PMC0_SRAM_PDS[i] and PMC0_SRAM_STDY[i])
HSRUN (High Speed Run)	RUN*/STANDBY/ASD
RUN	RUN*/STANDBY/ASD
VLPR (Very Low Power Run)	RUN*/STANDBY/ASD
STOP	RUN*/STANDBY/ASD
VLPS (Very Low Power Stop)	RUN*/STANDBY/ASD
LLS (Low Leakage Stop)	RETENTION*/ASD
VLLS (Very Low Leakage Stop)	DEEP_SLEEP*/POWER_DOWN

In Table 28-11 the cells marked with * are the default values after a POR event.

The No-TCM group only supports RUN, RETENTION and POWER_DOWN modes as shown in Table 28-12.

Table 28-12. PMC 0 No-TCM

PMC 0 Mode	SRAM Modes
HSRUN (High Speed Run)	RUN
RUN	RUN

Table continues on the next page...

Table 28-12. PMC 0 No-TCM (continued)

PMC 0 Mode	SRAM Modes
VLPR (Very Low Power Run)	RUN
STOP	RUN
VLPS (Very Low Power Stop)	RUN
LLS (Low Leakage Stop)	RETENTION
VLLS (Very Low Leakage Stop)	POWER_DOWN

NOTE

In the PMC 0, all SRAMs will be in POWER_DOWN when the Array Regulator is turned off (ARRAYREG bitfield in the PMC0_VLLS register).

Since the Array Regulator supplies only to the PMC 0 SRAM's arrays, in the PMC 1, the array and periphery share the same supply. The PMC 1 supports four power modes: RUN, STANDBY , RETENTION and POWER_DOWN as shown in Table 28-13.

Table 28-13. PMC 1 SRAMs

PMC 1 Mode	SRAM Modes (PMC1_SRAM_STDY[i])
HSRUN (High Speed Run)	RUN*/STANDBY
RUN	RUN*/STANDBY
VLPR (Very Low Power Run)	RUN*/STANDBY
STOP	RUN*/STANDBY
VLPS (Very Low Power Stop)	RUN*/STANDBY
LLS (Low Leakage Stop)	RETENTION
VLLS (Very Low Leakage Stop)	POWER_DOWN

In Table 28-13, the cells marked with * are the default values after a POR event.

28.5.7 Pads Isolation

Some pads are isolated during LLS/VLLS mode entry. On LLS mode exit, the isolation in pads is released automatically. On VLLS mode exit, the isolation in pads in each power domain (PMC 0 or PMC 1) can be released by writing 1 in the respective ISOACK bit (PMC0_CTRL or PMC1_CTRL registers) or by the respective system warm reset.

28.5.8 System Reset

On a system reset during HSRUN mode or some Stop mode, it is expected that the MSMC will start an exit sequence to RUN mode. During this transition the respective regulator voltage value will be adjusted to its POR value.

28.5.9 Procedures

28.5.9.1 Turn on PMC 1

NOTE

The PMC 1 is only once configured during a PMC 1 power up for using either the internal LDO or the external PMIC. This configuration can be changed only after a POR event.

28.5.9.1.1 Using internal LDO regulator

After a POR event, when the PMC 0 is running in RUN mode and the PMC 1 is turned off, the process to turn on the PMC 1 using the internal LDO regulator is as follows:

- Assert the LDOEN bit (PMC0_CTRL).
- Assert the LDOOKDIS bit (PMC0_CTRL) if required.
- Assert the PMC1ON bit (PMC0_CTRL).

NOTE

The LDOOKDIS and LDOEN bitfields must be kept stable until the PMC1 finishes its RUN mode entry.

28.5.9.1.2 Using external PMIC

After a POR event, when the PMC 0 is running in RUN mode and the PMC 1 is turned off, the process to turn on the PMC 1 using the external PMIC is as follows:

- Clear the LDOEN bit (PMC0_CTRL).
- Assert the PMC1ON bit (PMC0_CTRL).

NOTE

The LDOEN bitfield must be kept cleared until PMC 1 finishes its entry to RUN mode.

28.5.9.2 Turn off PMC 1 regulator in VLLS

28.5.9.2.1 Using internal LDO regulator

When the internal LDO regulator is being used (PMC1VSRC=0) and the PMC 1 is running in RUN mode, the LDO Regulator can be programmed to be turned off in the next transition from RUN to VLLS power mode. The procedure is:

- Clear the LDOEN bit (PMC0_CTRL).
- Execute the command to transition the PMC 1 to VLLS mode (see MSMC).

NOTE

The LDO Regulator is not turned off immediately. It is turned off only when a RUN to VLLS power mode transition is requested.

28.5.9.2.2 Using external PMIC

When the external PMIC is being used (PMC1VSRC=1) , it is possible to turn off the PMIC when the PMC1 is in VLLS mode. The procedure is:

- Clear the LVDIE and LVDRE bits (PMC1_CTRL).
- Execute the command to transition the PMC 1 to VLLS mode (see MSMC).
- Turn off the PMIC (see PMIC specification).

NOTE

The PMIC must be turned off only when the PMC 1 domain is effectively in VLLS mode.

28.5.9.3 Turn on PMC 1 regulator in a VLLS wake-up

28.5.9.3.1 Using internal LDO regulator

When the internal LDO regulator is being used (PMC1VSRC=0), the PMC 1 is running in VLLS mode and the LDO regulator is turned off; the LDO regulator must be turned on in a transition to RUN mode following the next procedure:

- Execute the command to transition the PMC 1 to RUN mode (see MSMC).
- Once in RUN mode, assert the LDOEN bit (PMC0_CTRL).

NOTE

This procedure is strictly neccesary to transition back PMC 1 to RUN mode.

NOTE

The LDOOKDIS and LDOEN bitfields must be kept stable until the PMC1 finishes its entry to RUN mode (see MSMC).

28.5.9.3.2 Using external PMIC

When the external PMIC is being used (PMC1VSRC=1), the PMC 1 is running in VLLS mode and the PMIC is turned off; the PMIC must be turned on following the next procedure:

- Turn on the PMIC (see PMIC specification).
- Execute the command to transition the PMC 1 to RUN mode (see MSMC).

NOTE

This procedure is strictly neccesary to transition back PMC 1 to RUN mode.

28.5.9.4 Change regulator voltage in RUN or HSRUN

28.5.9.4.1 Core Regulator (PMC 0)

The procedure to change the Core Regulator voltage level when the PMC 0 is in RUN mode is:

- Confirm COREVLF (PMC0_STATUS) is cleared.
- Change the value of the COREREGVL bitfield (PMC0_RUN).
- Wait for COREVLF (PMC0_STATUS) to be cleared.

The procedure to change the Core Regulator voltage level when the PMC 0 is in HSRUN mode is:

- Confirm COREVLF (PMC0_STATUS) is cleared.
- Change the value of the COREREGVL bitfield (PMC0_HSRUN).
- Wait for COREVLF (PMC0_STATUS) to be cleared.

28.5.9.4.2 LDO Regulator (PMC 1)

The procedure to change the LDO Regulator voltage level when the PMC 1 is in RUN mode is:

- Confirm LDOVLF (PMC1_STATUS) is cleared.
- Assert the LDOOKDIS bit (PMC0_CTRL) if required.
- Change the value of the LDOVL bitfield (PMC1_RUN).
- Wait for LDOVLF (PMC1_STATUS) to be cleared.

The procedure to change the LDO Regulator voltage level when the PMC 1 is in HSRUN mode is:

- Confirm LDOVLF (PMC1_STATUS) is cleared.
- Assert the LDOOKDIS bit (PMC0_CTRL) if required.
- Change the value of the LDOVL bitfield (PMC1_HSRUN).
- Wait for LDOVLF (PMC1_STATUS) to be cleared.

NOTE

The LDOOKDIS bit must be kept stable until the LDOVLF bitfield be cleared.

28.5.9.5 Change SRAMs power mode in RUN

28.5.9.5.1 PMC 0 SRAMs

The procedure to change the SRAMs power mode during the PMC 0 RUN mode is:

- Confirm SRAMF (PMC0_STATUS) is cleared.
- Change the value of PMC0_SRAM_PD (PMC0_SRAMCTRL_0) or PMC0_SRAM_STDY (PMC0_SRAMCTRL_2).
- Wait for SRAMF (PMC0_STATUS) to be cleared.

28.5.9.5.2 PMC 1 SRAMs

The procedure to change the SRAMs power mode during the PMC 1 RUN mode is:

- Confirm SRAMF (PMC1_STATUS) is cleared.
- Change the value of the PMC1_SRAM_STDY bitfield (PMC1_SRAMCTRL).
- Wait for SRAMF (PMC1_STATUS) to be cleared.

28.5.9.6 Enable or Configure RBB

To enable or configure RBB, i.e. to change the voltage level or enable/disable pull-down, the procedure is following:

- Go to RUN mode.
- Change the value of RBBNLEVEL or RBBPLEVEL bitfields in PMC0_BCTRL register if required.
- Assert RBBPDDIS bitfield in PMC0_BCTRL register if required.
- Assert RBBEN bit of the respective low power mode register (PMCx_VLPR, PMCx_LLS or PMCx_VLPS) if it has not been not asserted previously.
- Go to the required low power mode (VLPR, LLS or VPLS).

The RBB regulators will be enabled in the mode transition.

28.5.9.7 Enable or Configure FBB

To enable or configure FBB, i.e. to change the voltage level, the procedure is following:

- Go to RUN mode.
- Change the value of FBBNLEVEL or FBBPLEVEL bitfields in PMC0_BCTRL register if required.

- Assert FBBEN bit in the PMCx_HSRUN register if it has not been asserted previously.
- Go to HSRUN mode.

The FBB regulators will be enabled in the mode transition.

Chapter 29
Asynchronous Wakeup Interrupt Controller (AWIC)

29.1 Asynchronous Wake-up Interrupt Controller (AWIC)

When either processor enters deep sleep mode, the power management unit in the system can power down most of that processor domain. When the Asynchronous Wake-up Interrupt Controller (AWIC) detects an interrupt belongs to that processor, it wakes up the processor and restores its state, before the processor can process the interrupt. There is one instance of AWIC used on M4 side.

Table 29-1. AWIC configuration

Chapter 30
Multicore System Mode Controller (MSMC)

30.1 Chip-specific MSMC information

Table 30-1. Reference links to related information

Topic	Related module	Reference
Full description	MSMC	MSMC
System memory map		System memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port control	Signal multiplexing

30.1.1 Multicore System Mode Controller (MSMC)

NOTE

MSMC, CMC, and RMC are three separate but tightly coupled blocks. The memory map documented in this chapter encompasses features related to all 3 blocks, being actually implemented into the CMC block alone

NOTE

References in this chapter to "Core 0" correspond to the Cortex M4 core and references to "Core 1" correspond to the Cortex A7 core.

Table 30-2. MSMC configuration

Parameter	Description
Name	Multicore System Mode Controller (MSMC)
Instances	1
Configurable features	• SMC0 and SMC1: Supports dual cores and dual power domains

Table continues on the next page...

Table 30-2. MSMC configuration (continued)

Parameter	Description
Interface speed	NA
External I/O pins	NA

30.1.2 LLS mode operation

VLPS and LLS modes work in a very similar way, except that LLS causes the memories to enter RETENTION mode and their supply to be reduced (supply reduction applies to M4 domain only). Besides, pins remain isolated while the domain is in LLS mode.

30.1.3 Power mode status through PMSTAT registers

Power Mode Status register (PMSTAT) registers in SMC0 and SMC1 memory map: With the exception of HSRUN mode, PMSTAT[PMSTAT] changes upon power mode entry request, while a power mode is effectively entered only after that request is acknowledged. For accurate power mode status information,PMC 0 Power Mode Status register (PM_STAT) register in the PMC chapter, can be used.

NOTE

It must be noted that Core1 (CA7) is not able to check Core0 (CM4)’s power mode status through PMC0 whenever the platform clock is gated in the latter’s domain. Under such scenario, Core0’s power mode status is only available via MU.

30.1.4 HSRUN mode restriction

i.MX 7ULP doesn't have on-chip flash programming, so any restriction related to flash programming/erasing for entering HSRUN mode mentioned in the chapter, must be ignored.

30.1.5 SLEEPDEEP mode

While CM4 core supports both Sleep and Deep Sleep low power modes, CA7 core supports Standby low power mode only. On this device, CA7 Standby mode affects the application domain (APD) in a similar way CM4 Deep Sleep acts on real-time domain

(RTD), therefore causing WAIT mode to be not supported by APD. In this sense, all references to SLEEPDEEP=0 in the CA7 (or Core1) context throughout this chapter must be ignored. PSTOP3 can be used to emulate WAIT mode on APD, since both modes work in a very similar manner.

30.1.6 Loss of lock (LOL) reset

LOL faults are not supported on this device. All references to loss of lock (LOL) in SRS[SCG] bitfield (See SCG and SCG) and throughout the chapter should be ignored.

30.1.7 WFE/SEV instructions support

WFE/SEV instructions are not supported in i.MX 7ULP, so any reference to these instructions throughout this document must be ignored.

30.1.8 Power mode trigger conditions on i.MX 7ULP

On this device, power mode transition triggers are described by the following tables.

Table 30-3. Power mode transition triggers for Core 0

Transition #	From	To	Trigger conditions
1	RUN	WAIT	Sleep-now or sleep-on-exit executed with SLEEPDEEP=0 by Core 0. See note.[1]
	WAIT	RUN	Core 0 interrupt or reset[2]
2	RUN	STOP	Core 0 STOPM=STOP[3] and Sleep-now or sleep-on-exit with SLEEPDEEP=1 executed by Core 0. See note.[1]
	STOP	RUN	Core 0 interrupt or reset.[2]
3	RUN	VLPR	Core 0 RUNM=VLPR.
	VLPR	RUN	Core 0 RUNM=RUN or reset.[2]
4	VLPR	VLPW	Sleep-now or sleep-on-exit executed with SLEEPDEEP=0 by Core 0. See note.[1]
	VLPW	VLPR	Core 0 Interrupt.
5	VLPW	RUN	reset.[2]

Table continues on the next page...

Table 30-3. Power mode transition triggers for Core 0 (continued)

Transition #	From	To	Trigger conditions
6	VLPR	VLPS	Core 0 STOPM=VLPS and Sleep-now or sleep-on-exit with SLEEPDEEP=1 executed by Core 0. See note.[1]
	VLPS	VLPR	Interrupt and VLPS mode was entered directly from VLPR.
7	RUN	VLPS	Core 0 STOPM=VLPS and Sleep-now or sleep-on-exit with SLEEPDEEP=1 executed by Core 0. See note.[1]
	VLPS	RUN	Interrupt and VLPS mode was entered directly from RUN or reset.[2]
8	RUN	VLLS	Core 0 STOPM=VLLS and Sleep-now or sleep-on-exit with SLEEPDEEP=1 executed by Core 0. See note.[1]
	VLLS	RUN	LLWU wakeup, NMI (PTA9)[4], or reset[5].
9	VLPR	VLLS	Core 0 STOPM=VLLS and Sleep-now or sleep-on-exit with SLEEPDEEP=1 executed by Core 0. See note.[1]
10	RUN	LLS	Core 0 STOPM=LLS and Sleep-now or sleep-on-exit with SLEEPDEEP=1 executed by Core 0. See note.[1]
	LLS	RUN	Interrupt and LLS mode was entered directly from RUN or RESET0_b.[2]
11	VLPR	LLS	Core 0 STOPM=LLS and Sleep-now or sleep-on-exit with SLEEPDEEP=1 executed by Core 0. See note.[1]
	LLS	VLPR	Interrupt and LLS mode was entered directly from VLPR.
12	RUN	HSRUN	Core 0 RUNM=HSRUN
	HSRUN	RUN	Core 0 RUNM=RUN or reset. [2]

1. If debug is enabled, the core clock remains to support debug.
2. M4 reset sources or A7 reset sources (when A7_TO_M4_RESET_EN fuse is blown).
3. If PMCTRL[STOPM]=STOP and PMCTRL[PSTOPO]!=00, then only a Partial Stop mode is entered instead of STOP
4. SIM_DGO_GP11[NMI_VLLS_WAKEUP_EN] bitfield must be set prior to entering VLLS mode when using NMI pin as (VLLS) wake-up source.
5. RESET0_b pin, or RESET1_b pin (when Core 1 is also in VLLS mode)

Table 30-4. Power mode transition triggers for Core 1

Transition #	From	To	Trigger conditions
1	RUN	WAIT	Sleep-now or sleep-on-exit executed with SLEEPDEEP=0 by Core 1. See note.[1]
	WAIT	RUN	Core 1 interrupt or reset[2]
2	RUN	STOP	Core 1 STOPM=STOP[3] and Sleep-now or sleep-on-exit with SLEEPDEEP=1 executed by Core 1. See note.[1]
	STOP	RUN	Core 1 interrupt or reset.[2]
3	RUN	VLPR	Core 1 RUNM=VLPR.
	VLPR	RUN	Core 1 RUNM=RUN or reset.[2]
4	VLPR	VLPW	Sleep-now or sleep-on-exit executed with SLEEPDEEP=0 by Core 1. See note.[1]
	VLPW	VLPR	Core 1 Interrupt.
5	VLPW	RUN	reset[2]
6	VLPR	VLPS	Core 1 STOPM=VLPS/STOP and Sleep-now or sleep-on-exit with SLEEPDEEP=1 executed by Core 1. See note.[1]
	VLPS	VLPR	Interrupt and VLPS mode was entered directly from VLPR.
7	RUN	VLPS	Core 1 STOPM=VLPS and Sleep-now or sleep-on-exit with SLEEPDEEP=1 executed by Core 1. See note.[1]
	VLPS	RUN	Interrupt and VLPS mode was entered directly from RUN or reset.[2]
8	RUN	VLLS	Core 1 STOPM=VLLS and Sleep-now or sleep-on-exit with SLEEPDEEP=1 executed by Core 1. See note.[1]
	VLLS	RUN	MU_A NMI/Reset wakeup or reset.[2]
9	VLPR	VLLS	Core 1 STOPM=VLLS and Sleep-now or sleep-on-exit with SLEEPDEEP=1 executed by Core 1. See note.[1]
10	RUN	LLS	Core 1 STOPM=LLS and Sleep-now or sleep-on-exit with SLEEPDEEP=1 executed by Core 1. See note.[1]

Table continues on the next page...

Table 30-4. Power mode transition triggers for Core 1 (continued)

Transition #	From	To	Trigger conditions
	LLS	RUN	Interrupt and LLS mode was entered directly from RUN or reset[2].
11	VLPR	LLS	Core 1 STOPM=LLS and Sleep-now or sleep-on-exit with SLEEPDEEP=1 executed by Core 1. See note.[1]
	LLS	VLPR	Interrupt and LLS mode was entered directly from VLPR.
12	RUN	HSRUN	Core 1 RUNM=HSRUN
	HSRUN	RUN	Core 1 RUNM=RUN or reset[2].

1. If debug is enabled, the core clock remains to support debug.
2. A7 reset sources or M4 reset sources.
3. If PMCTRL[STOPM]=STOP and PMCTRL[PSTOPO]!=00 for MSMC1, then only a Partial Stop mode is entered instead of STOP

30.1.9 Debug in Low Power modes

It is required that the system provides control so that debugger can have control of the device when entering and exiting low power modes. During low power modes, the clock and power (based on modes) will not be available to multiple components, the following handshake allows the debugger to maintain connection during low power. There are two modes supported:

- Clock gated mode
- Power gated mode.

30.2 Introduction

The Multi-System Mode Controller (MSMC) is responsible for sequencing the MCU into and out of all stop and run power modes.

Specifically, it monitors events to trigger transitions between power modes while controlling the power, clocks, and memories of the MCU to achieve the power consumption and functionality of that mode.

This chapter describes all the available power modes, the sequence followed to enter/exit each mode, and the functionality available while in each of the modes.

The following diagram illustrates the connections of the MSMC with other components in the system that are necessary to sequence the system through all power modes.

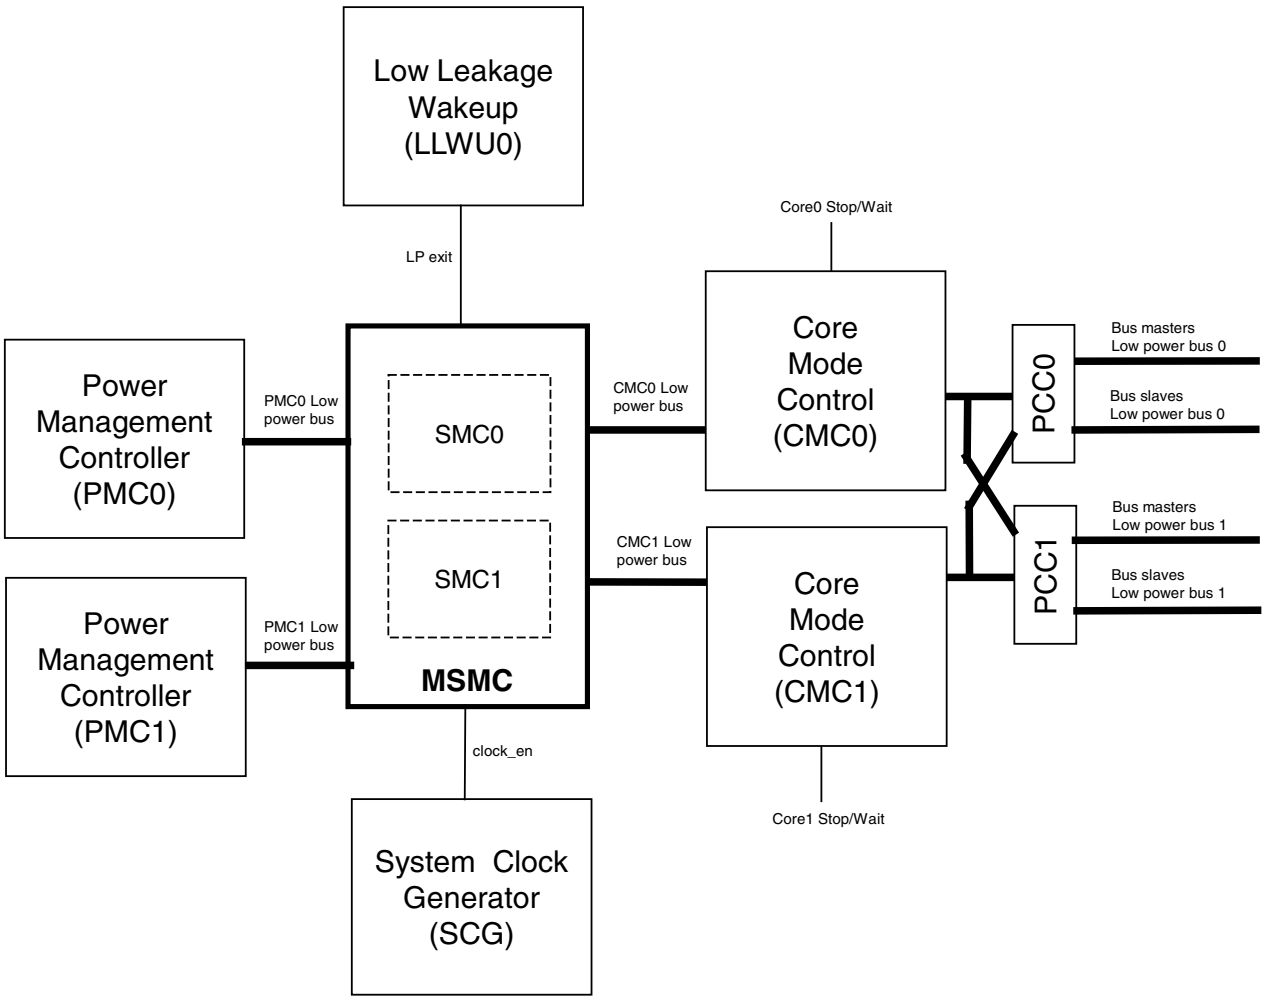

Figure 30-1. Power management system components and connections

30.3 Modes of operation

An Arm Cortex-M CPU has three primary modes of operation:

- Run
- Sleep
- Deep Sleep

An Arm Cortex-A CPU has two primary modes of operation:

- Run
- Standby

The WFI or WFE instruction is used to invoke a Sleep, Deep Sleep or Standby modes for either Cortex family. Run, Wait, and Stop are the common terms used for the primary operating modes of the MSMC.

The following table shows the translation between the Arm CPU modes and MSMC power modes:

Arm CPU mode	MSMC mode
Sleep	Wait
Deep Sleep or Standby	Stop

In addition, the MSMC also augments Stop, Wait, and Run modes in a number of ways. Depending on the needs of the user application, a variety of run and stop modes are available that allow the user to adjust functionality, performance and power consumption.

The following table describes the power modes available to each core within the MCU.

Table 30-5. Power modes

Mode	Description
Run (RUN)	The core can be run at full frequency and all functionality is available. This mode is also referred to as Normal Run mode.
High Speed Run (HSRUN)	Provides the highest performance mode at the fastest supported frequency. The core, system, bus, and flash clock maximum frequencies are unrestricted in this mode.[1]
Wait (WAIT)	Allows a core to enter a static, low power state with instant wakeup time, while still allowing peripherals to operate with full functionality. The core clock is gated off. The system clock continues to operate. Bus clocks, if enabled, continue to operate.
Stop (STOP)	Allows a core and its peripherals to enter a static, low power state with relatively fast wakeup times, while still allowing peripherals to operate with full asynchronous functionality. The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid.
Very Low Power Run (VLPR)	Provides the lowest power operating mode to the core at a reduced frequency. The core, system, bus, and flash clock maximum frequencies are restricted in this mode.[1]
Very Low Power Wait (VLPW)	Allows a core to enter a static, very low power state, while still allowing peripherals to operate with full functionality at a reduced frequency. The core clock is gated off. The system, bus, and flash clocks continue to operate, although their maximum frequency is restricted.[1]
Very Low Power Stop (VLPS)	Allows a core and its peripherals to enter a static, very low power state with relatively fast wakeup times, while still allowing peripherals to operate with limited asynchronous functionality. The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid.
Low Leakage Stop (LLS)	Allows a core and its peripherals to enter a low leakage, power gated state with relatively fast wakeup times, while still retaining the state of all logic. The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid. Logic and I/O are retained, with wakeup only supported via the LLWU, NMI or Reset pins.
Very Low Leakage Stop (VLLS)	Allows a core and its peripherals to enter a very low leakage, power gated state.The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid. Logic is power gated, with wakeup only supported via the LLWU, NMI or Reset pins. I/O states are latched.

1. See the devices' chip configuration details for the maximum allowable frequencies.

30.4 Memory map and register descriptions

Information about the registers related to the system mode controller can be found here.

30.4.1 SMC register descriptions

Different MSMC registers reset on different reset types. Each register's description provides details. For more information about the types of reset on this chip, refer to the Reset section details.

NOTE

The MSMC registers can be written only in supervisor mode. Write accesses in user mode are blocked and will result in a bus error.

NOTE

Before executing the WFI instruction, the last register written to must be read back. This ensures that all register writes associated with setting up the low power mode being entered have completed before the MCU enters the low power mode. Failure to do this may result in the low power mode not being entered correctly.

30.4.1.1 MSMC Memory map

MSMC0 base address: 410A_4000h

30.4.1.3.3 Fields

Field	Function
31-1 —	Reserved
0 PWRD_INDPT	Power Domains Independent When set, means each core is able to enter power modes independently of the other. When clear, means certain dependancies are enforced by the MSMC before each core is able to enter some power modes. See "Power mode transitions" section for detailed requirements for each core to enter a power mode.

30.4.1.4 Power Mode Protection register (PMPROT)

30.4.1.4.1 Offset

Register	Offset
PMPROT	8h

30.4.1.4.2 Function

This register provides protection for entry into any run or stop power mode. The enabling of the run or stop mode occurs by configuring the Power Mode Control register (PMCTRL).

The PMPROT register can be written only once after any system reset.

If a core is configured for a disallowed or reserved power mode, the core remains in its current power mode. For example, if the core is in normal RUN mode and AVLP is 0, an attempt to enter VLPR mode using PMCTRL[RUNM] is blocked and PMCTRL[RUNM] remains 00b, indicating the core is still in Normal Run mode.

NOTE

This register is reset on Chip Reset and by reset sources that trigger Chip Reset (see the Reset section for more information).

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	u[1]	0

1. The reset value is 1 on VLLS wakeup, otherwise it is 0.

30.4.1.4.4 Fields

Field	Function
31-8 —	Reserved
7 AHSRUN	Allow High Speed Run mode When set, allows the PMCTRL[RUNM] field to be written to HSRUN. 0b - HSRUN is not allowed 1b - HSRUN is allowed
6 —	Reserved
5 AVLP	Allow Very-Low-Power Modes When set, allows the PMCTRL[RUNM] field to be written to VLPR and/or the PMCTRL[STOPM] field to be written with VLPS. 0b - VLPR, VLPW, and VLPS are not allowed. 1b - VLPR, VLPW, and VLPS are allowed.
4 —	Reserved
3 ALLS	Allow Low-Leakage Stop Mode When set, allows the PMCTRL[STOPM] field to be written to LLS. 0b - LLS is not allowed 1b - LLS is allowed
2 —	Reserved
1 AVLLS	Allow Very-Low-Leakage Stop Mode When set, allows the PMCTRL[STOPM] field to be written to VLLS. 0b - VLLS mode is not allowed 1b - VLLS mode is allowed
0 —	Reserved

30.4.1.5 Power Mode Control register (PMCTRL)

30.4.1.5.1 Offset

Register	Offset
PMCTRL	10h

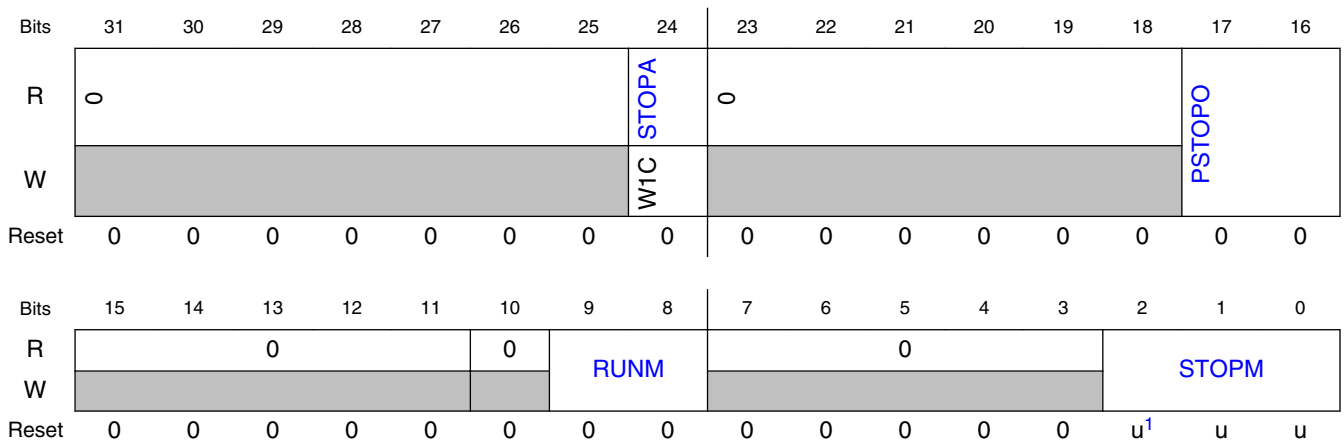
30.4.1.5.2 Function

The PMCTRL register controls entry into low-power Run and Stop modes, provided that the selected power mode is allowed via an appropriate setting of the protection (PMPROT) register.

NOTE

This register is reset on Chip POR and by reset types that trigger Chip POR. See the Reset section details for more information.

30.4.1.5.3 Diagram



1. The reset value is 100 on VLLS wakeup , otherwise it is 000.

30.4.1.5.4 Fields

Field	Function
31-25 —	Reserved
24 STOPA	Stop Abort Flag
23-18 —	Reserved
17-16 PSTOPO	Partial Stop Option These bits control whether a Partial Stop mode is entered when STOPM=STOP. When entering a Partial Stop mode from RUN mode, the PMC and SCG remain fully powered, allowing the device to wakeup almost instantaneously at the expense of higher power consumption. In PSTOP2, only system clocks are gated allowing peripherals running on bus clock to remain fully functional. In PSTOP1, both system and bus clocks are gated. 00b - STOP - Normal Stop mode 01b - PSTOP1 - Partial Stop with system and bus clock disabled

Table continues on the next page...

Field	Function
	10b - PSTOP2 - Partial Stop with system clock disabled and bus clock enabled 11b - PSTOP3 - Partial Stop with system clock enabled and bus clock enabled
15-11 —	Reserved
10 —	Reserved
9-8 RUNM	Run Mode Control When written, causes entry into the selected run mode. Writes to this field are blocked if the protection level has not been enabled using the PMPROT register. **NOTE:** Stop mode entry should not be attempted while RUNM=HSRUN or PMSTAT=HSRUN. 00b - Normal Run mode (RUN) 01b - Reserved 10b - Very-Low-Power Run mode (VLPR) 11b - High Speed Run mode (HSRUN)
7-3 —	Reserved
2-0 STOPM	Stop Mode Control Selects the desired stop mode when a core enters deepsleep. Writes to this field are blocked if the protection level has not been enabled using the PMPROT register. After any system reset, this field is cleared by hardware on any successful write to the PMPROT register. **NOTE:** When set to STOP, the PSTOPO bits can be used to select a Partial Stop mode if desired. 000b - Normal Stop (STOP) 001b - Reserved 010b - Very-Low-Power Stop (VLPS) 011b - Low-Leakage Stop (LLS) 100b - Very-Low-Leakage Stop (VLLS) 101b - Reserved 110b - Reserved 111b - Reserved

30.4.1.6 Power Mode Status register (PMSTAT)

30.4.1.6.1 Offset

Register	Offset
PMSTAT	18h

30.4.1.6.2 Function

PMSTAT is a read-only, one-hot register which indicates the current power mode of the system.

30.4.1.6.3 Diagram

Field	Function
31 TAMPER	Tamper Reset Indicates a reset has been caused by Tamper Detection logic. This is a fatal reset source and SRAM contents are not guaranteed. 0b - Reset not generated by tamper detection. 1b - Reset generated by tamper detection.
30 SECVIO	Security Violation Reset Indicates a reset has been caused by a Security Violation logic. This is a fatal reset source and SRAM contents are not guaranteed. 0b - Reset not generated by security violation. 1b - Reset generated by security violation.
29 —	Reserved
28 JTAG	JTAG System Reset Indicates a reset has been caused by a JTAG system reset request. This is a fatal reset source and SRAM contents are not guaranteed. 0b - Reset not generated by JTAG system reset.

Table continues on the next page...

Field	Function
	1b - Reset generated by JTAG system reset.
27-25 —	Reserved
24 VBAT	VBAT System Reset VBAT POR will generate a system reset. 0b - Reset not generated by VBAT system reset. 1b - Reset generated by VBAT system reset.
23-18 —	Reserved
17 —	Reserved
16 CORE1	Core1 System Reset Indicates the reset source was generated by a Core1 specific reset. 0b - Reset not generated from Core1 system reset source. 1b - Reset generated from Core1 system reset source.
15 LOCKUP	Lockup Reset Indicates a reset has been caused by the Arm core indication of a LOCKUP event. 0b - Reset not generated by core lockup or exception. 1b - Reset generated by core lockup or exception.
14 SW	Software Reset Indicates a reset has been caused by a software reset request from the Arm core (SYSRESETREQ). 0b - Reset not generated by software request from core. 1b - Reset generated by software request from core.
13 WDOG	Watchdog Reset Indicates a reset has been caused by a WatchDog timeout. 0b - Reset is not generated from the WatchDog timeout. 1b - Reset is generated from the WatchDog timeout.
12 SCG	SCG Reset Indicates a reset has been caused by a loss-of-clock or loss-of-lock event in the SCG. This is a fatal reset source and SRAM contents are not guaranteed. 0b - Reset is not generated from an SCG loss of lock or loss of clock. 1b - Reset is generated from an SCG loss of lock or loss of clock.
11 STOPACK	Stop Timeout Reset Indicates a reset has been caused by a timeout in the Stop mode entry logic. This timeout is generated if a peripheral does not acknowledge entry into any Stop mode within approximately one second. 0b - Reset not generated by Stop Controller Timeout. 1b - Reset generated by Stop Controller Timeout.
10 RSTACK	Reset Timeout Indicates a reset has been caused by a timeout in the system reset generaton logic. This is a fatal reset source and SRAM contents are not guaranteed. 0b - Reset not generated from Reset Controller Timeout. 1b - Reset generated from Reset Controller Timeout.
9 MDM	MDM Reset Indicates a reset has been caused by a reset request from the Miscellaneous Debug Module (MDM). 0b - Reset was not generated from the MDM reset request. 1b - Reset was generated from the MDM reset request.

Table continues on the next page...

Field	Function
8 PIN	Pin Reset Indicates a reset has been caused by external assertion of the RESET_b pin. 0b - Reset was not generated from the assertion of RESET_B pin. 1b - Reset was generated from the assertion of RESET_B pin.
7 CORE	Core Reset Indicates the last reset was a reset that only reset the core. 0b - Reset source was not core only reset. 1b - Reset source was core reset and reset the core only.
6 —	Reserved
5 FATAL	Fatal Reset Fatal Reset will assert if the system reset source was fatal. SRAM contents cannot be guaranteed following a fatal reset source. 0b - Reset was not generated by a fatal reset source. 1b - Reset was generated by a fatal reset source.
4 WARM	Warm Reset Warm Reset flag will assert whenever any of the system reset sources in this register assert (SRS[31:8]). 0b - Reset not generated by Warm Reset source. 1b - Reset generated by Warm Reset source.
3 HVD	HVD Reset Indicates a reset has been caused by a High Voltage Detect. SRAM contents cannot be guaranteed following a HVD reset source. 0b - Reset not generated by HVD. 1b - Reset generated by HVD.
2 LVD	LVD Reset Indicates a reset has been caused by a Low Voltage Detect. SRAM contents cannot be guaranteed following a LVD reset source. 0b - Reset not generated by LVD. 1b - Reset generated by LVD.
1 POR	POR Reset Indicates a reset has been caused by Power On Reset detection logic. SRAM contents cannot be guaranteed following a POR reset source. 0b - Reset not generated by POR. 1b - Reset generated by POR.
0 WAKEUP	Wakeup Reset Indicates a reset has been caused by a wakeup from VLLS mode. 0b - Reset not generated by wakeup from VLLS mode. 1b - Reset generated by wakeup from VLLS mode.

30.4.1.10 System Reset Interrupt Enable (SRIE)

30.4.1.10.1 Offset

Register	Offset
SRIE	2Ch

30.4.1.10.2 Function

This registers delays the assertion of a system reset for between 9 and 10 LPO clock cycles while an interrupt is generated. This allows software to perform a graceful shutdown or to abort the system reset provided the pending reset source is cleared by resetting the source of the reset and then clearing the pending flag. A Chip POR or fatal reset source cannot be delayed by this feature. The SRS will only update after the system reset occurs.

31-0 FORCECFG	Boot Configuration This register can force the corresponding bit in the Mode Register to assert on next system reset. 00000000000000000000000000000000b - No effect. 00000000000000000000000000000001b - Assert corresponding bit in Mode Register on next system reset.

30.4.2 SMC register descriptions

Different MSMC registers reset on different reset types. Each register's description provides details. For more information about the types of reset on this chip, refer to the Reset section details.

NOTE

The MSMC registers can be written only in supervisor mode. Write accesses in user mode are blocked and will result in a bus error.

NOTE

Before executing the WFI instruction, the last register written to must be read back. This ensures that all register writes associated with setting up the low power mode being entered have completed before the MCU enters the low power mode. Failure to do this may result in the low power mode not being entered correctly.

30.4.2.3.3 Fields

Field	Function
31-1 —	Reserved
0 PWRD_INDPT	Power Domains Independent

Field	Function
	When set, means each core is able to enter power modes independently of the other. When clear, means certain dependancies are enforced by the MSMC before each core is able to enter some power modes. See "Power mode transitions" section for detailed requirements for each core to enter a power mode.

30.4.2.4 Power Mode Protection register (PMPROT)

30.4.2.4.1 Offset

Register	Offset
PMPROT	8h

30.4.2.4.2 Function

This register provides protection for entry into any run or stop power mode. The enabling of the run or stop mode occurs by configuring the Power Mode Control register (PMCTRL).

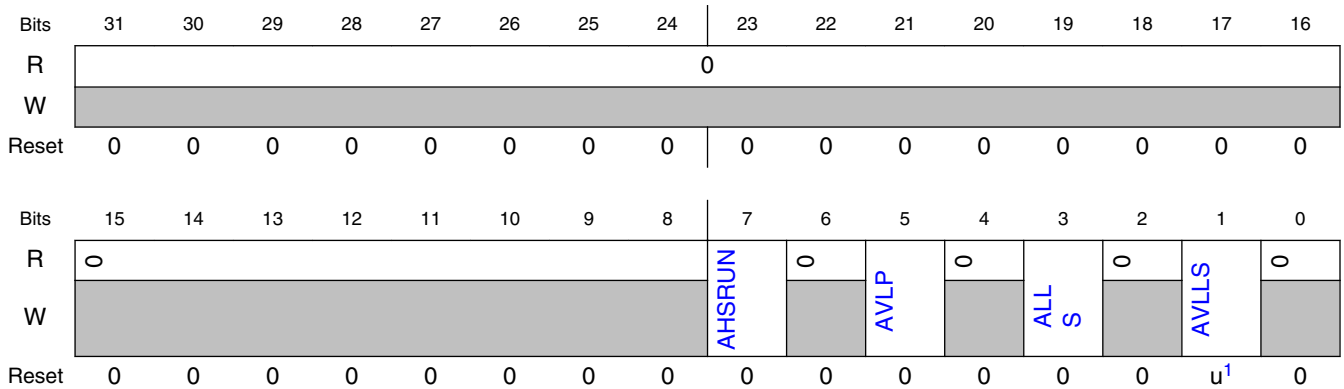
The PMPROT register can be written only once after any system reset.

If a core is configured for a disallowed or reserved power mode, the core remains in its current power mode. For example, if the core is in normal RUN mode and AVLP is 0, an attempt to enter VLPR mode using PMCTRL[RUNM] is blocked and PMCTRL[RUNM] remains 00b, indicating the core is still in Normal Run mode.

NOTE

This register is reset on Chip Reset and by reset sources that trigger Chip Reset (see the Reset section for more information).

30.4.2.4.3 Diagram



1. The reset value is 1 on VLLS wakeup, otherwise it is 0.

30.4.2.4.4 Fields

Field	Function
31-8 —	Reserved
7 AHSRUN	Allow High Speed Run mode When set, allows the PMCTRL[RUNM] field to be written to HSRUN. 0b - HSRUN is not allowed 1b - HSRUN is allowed
6 —	Reserved
5 AVLP	Allow Very-Low-Power Modes When set, allows the PMCTRL[RUNM] field to be written to VLPR and/or the PMCTRL[STOPM] field to be written with VLPS. 0b - VLPR, VLPW, and VLPS are not allowed. 1b - VLPR, VLPW, and VLPS are allowed.
4 —	Reserved
3 ALLS	Allow Low-Leakage Stop Mode When set, allows the PMCTRL[STOPM] field to be written to LLS. 0b - LLS is not allowed 1b - LLS is allowed
2 —	Reserved
1 AVLLS	Allow Very-Low-Leakage Stop Mode When set, allows the PMCTRL[STOPM] field to be written to VLLS. 0b - VLLS mode is not allowed 1b - VLLS mode is allowed
0 —	Reserved

30.4.2.5 Power Mode Control register (PMCTRL)

30.4.2.5.1 Offset

Register	Offset
PMCTRL	10h

30.4.2.5.2 Function

The PMCTRL register controls entry into low-power Run and Stop modes, provided that the selected power mode is allowed via an appropriate setting of the protection (PMPROT) register.

NOTE

This register is reset on Chip POR and by reset types that trigger Chip POR. See the Reset section details for more information.

30.4.2.10 System Reset Interrupt Enable (SRIE)

30.4.2.10.1 Offset

Register	Offset
SRIE	2Ch

30.4.2.10.2 Function

This registers delays the assertion of a system reset for between 9 and 10 LPO clock cycles while an interrupt is generated. This allows software to perform a graceful

shutdown or to abort the system reset provided the pending reset source is cleared by resetting the source of the reset and then clearing the pending flag. A Chip POR or fatal reset source cannot be delayed by this feature. The SRS will only update after the system reset occurs.

30.5 Functional description

This section provides a complete functional description of the block.

30.5.1 Power mode transitions

A figure showing the power mode state transitions and a table defining triggers for the various state transitions can be found here.

The following figure shows the power mode state transitions available to each core. Any chip reset will initially bring both cores back to a RUN state. An exception is a POR event which could force core 1 to be disabled until re-enabled by core 0.

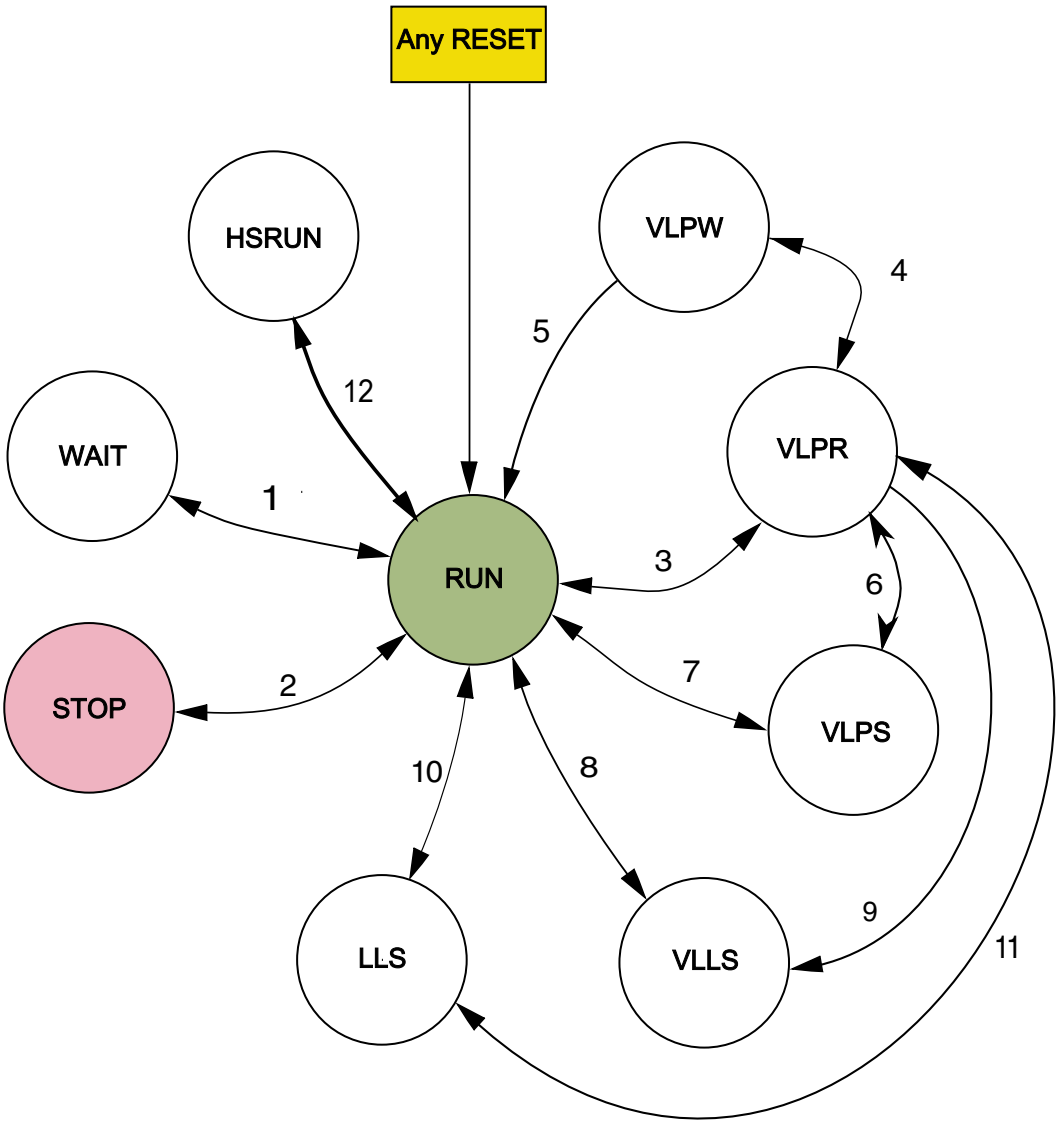

Figure 30-2. Power mode state diagram

The MSMC allows each core to enter/exit both stop and run modes independently of the other. The user should take care to ensure that any common system resources (e.g. clock sources) are always available whenever required for a core's current power mode. For example, if core 1 is being driven by a clock source in core 0's power domain, the user should ensure that core 0 does not enter a run/stop mode which could cause that clock to be disabled.

The specific trigger conditions required for each core to transition into or out of power modes depend on the device. See the chip-specific MSMC information for details.

30.5.2 Run modes

The MSMC supports the following run modes:

- Normal Run (RUN)
- Very Low-Power Run (VLPR)
- High Speed Run (HSRUN)

30.5.2.1 Run (RUN) mode

This is the normal operating mode for the device.

This mode is selected after any reset. When the Arm processor exits reset, it sets up the stack, program counter (PC), and link register (LR):

- The processor reads the start SP (SP_main) from vector-table offset 0x000
- The processor reads the start PC from vector-table offset 0x004
- LR is set to 0xFFFF_FFFF.

To reduce power in this mode, clocks to unused modules can be disabled using their corresponding clock gating control bits in the Peripheral Clock Control modules (see PCC chapter) or compute operation can be enabled via the Miscellaneous Control Module (see MCM chapter).

30.5.2.2 Very Low Power Run (VLPR) mode

VLPR mode is designed to provide the lowest power operating mode to the core at a reduced frequency. See the PMC chapter for additional power options available in this mode. Before entering this mode, the following conditions must be met:

- The maximum frequencies of the system, bus, flash, and core are restricted. See the Power Management details about which frequencies are supported.
- Mode protection must be set to allow VLP modes, that is, PMPROT[AVLP] is 1.
- PMCTRL[RUNM] must be set to VLPR.
- Flash programming/erasing is not allowed.

NOTE

While in VLPR mode, do not modify the clock source in the SCG module or any clock divider registers. Module clock enables in the PCC can be set, however should only be cleared one at a time to limit load transitions.

To reenter Normal Run mode, clear PMCTRL[RUNM]. PMSTAT is a read-only status register that can be used to determine when the system has completed an exit to RUN mode. When PMSTAT=RUN, the system can run at full speed in any clock mode.

Any reset always causes an exit from VLPR and returns a core to RUN mode after the exiting its reset flow.

To further reduce power in this mode, clocks to unused modules can be disabled using their corresponding clock gating control bits in the Peripheral Clock Control modules (see PCC chapter) or compute operation can be enabled via the Miscellaneous Control Module (see MCM chapter).

30.5.2.3 High Speed Run (HSRUN) mode

HSRUN mode is designed to provide the highest performance mode to the core at the fastest supported frequency. See the PMC chapter for additional power options available in this mode. Before entering this mode, the following conditions must be met:

- The maximum allowable change in frequency of the system, bus, flash or core clocks is restricted to x2.
- Mode protection must be set to allow HSRUN modes, that is, PMPROT[AHSRUN] is 1.
- PMCTRL[RUNM] must be set to HSRUN
- Flash programming/erasing is not allowed. (Not all devices contain on-chip flash.)
- Stop mode entry is not allowed.

To reenter normal RUN mode, clear the RUNM register. PMSTAT is a read-only status register that can be used to determine when the system has completed an exit to RUN mode. Any reset will also clear RUNM and cause the core to exit to normal RUN mode after exiting its reset flow.

30.5.3 Wait modes

The MSMC supports the following wait modes.

- Wait (WAIT)
- Very-Low Power Wait (VLPW)

30.5.3.1 Wait (WAIT) mode

WAIT mode is designed to allow a core to enter a static, low power state with instant wakeup times, while still allowing peripherals to operate with full functionality. WAIT mode is entered when the Arm core enters the Sleep-Now or Sleep-On-Exit mode while SLEEDEEP is cleared. The core enters a low-power state in which it is not clocked, but peripherals continue to be clocked provided they are enabled. Clock gating to the peripheral is enabled via the PCC module.

When an interrupt request occurs, the core exits WAIT mode and resumes processing in RUN mode, beginning with the stacking operations leading to the interrupt service routine.

A system reset will also cause an exit from WAIT mode, returning the core to normal RUN mode.

30.5.3.2 Very Low Power Wait (VLPW) mode

VLPW mode is designed to allow a core to enter a static, very low power state, while still allowing peripherals to operate with full functionality at a reduced frequency. VLPW mode is entered when the Arm core enters the Sleep-Now or Sleep-On-Exit mode while SLEEPDEEP is cleared and the core is in VLPR mode. The ARM CPU enters a low-power state in which it is not clocked, but peripherals continue to be clocked provided they are enabled. Clock gating to the peripheral is enabled via the PCC module.

VLPR mode restrictions also apply to VLPW.

When an interrupt from VLPW occurs, the device returns to VLPR mode to execute the interrupt service routine.

When an interrupt request occurs, the CPU exits VLPW mode and resumes processing in VLPR mode, beginning with the stacking operations leading to the interrupt service routine.

A system reset will cause an exit from VLPW mode, returning the device to normal RUN mode.

30.5.4 Stop modes

The MSMC supports a wide variety of stop modes for each core ranging from:

- a stopped core, with all I/O, logic, and memory states retained, and certain asynchronous mode peripherals operating

to:

- a powered down core, with only I/O and a small register file retained, very few asynchronous mode peripherals operating

The choice of stop mode depends upon the user's application, and how power usage and state retention versus functional needs and recovery time may be traded off.

The stop mode for a core can be selected by setting the appropriate fields in PMPROT and PMCTRL register fields in SMC0 and SMC1 (see "Power mode transitions" section for details).

The following stop modes are supported:

- Normal Stop (STOP)
- Very Low Power Stop (VLPS)
- Low Leakage Stop (LLS)
- Very Low Leakage Stop (VLLS)

30.5.4.1 Stop (STOP) mode

STOP mode is designed to allow a core and its system to enter a static, low power state with relatively fast wakeup times, while still allowing peripherals to operate with full asynchronous functionality. Refer to the device's Power Management chapter for peripheral, I/O, and memory operation in STOP mode and see the PMC chapter for additional power options available in this mode.

A core can enter STOP mode by executing Sleep-Now or Sleep-On-Exit with SLEEPDEEP=1 while the core's STOPM equates to STOP (see "Power mode transitions" section for details). Note that a core's PSTOPO field can be set to enable a partial stop mode, allowing instantaneous wakeup at the expense of power consumption.

A module capable of providing an asynchronous interrupt can trigger an exit from STOP mode and return the device to normal RUN mode. When an interrupt request occurs, the core exits STOP mode and resumes processing, beginning with the stacking operations leading to the interrupt service routine.

A system reset will also cause an exit from STOP mode, returning the device to normal RUN mode.

30.5.4.2 Very Low Power Stop (VLPS) mode

VLPS mode is designed to allow a core and its system to enter a static, very low power state with relatively fast wakeup times, while still allowing peripherals to operate with limited asynchronous functionality. Refer to the device's Power Management chapter for peripheral, I/O, and memory operation in VLPS mode and see the PMC chapter for additional power options available in this mode.

A core can enter VLPS mode by executing Sleep-Now or Sleep-On-Exit with SLEEPDEEP=1 while the core's STOPM either equates to VLPS or equates to STOP with RUNM=VLPR (see "Power mode transitions" section for details).

A module capable of providing an asynchronous interrupt can trigger an exit from VLPS mode and return the device to the run mode from which VLPS was entered (i.e. RUN or VLPR mode). When an interrupt request occurs, the core exits VLPS mode and resumes processing, beginning with the stacking operations leading to the interrupt service routine.

A system reset will also cause an exit from VLPS mode, returning the device to normal RUN mode.

30.5.4.3 Low Leakage Stop (LLS) mode

LLS mode is designed to allow a core and its system to enter a low leakage, power gated state with relatively fast wakeup times, while still retaining the state of all logic. Refer to the device's Power Management chapter for peripheral, I/O, and memory operation in LLS mode and see the PMC chapter for additional power options available in this mode.

A core can enter LLS mode by executing Sleep-Now or Sleep-On-Exit with SLEEPDEEP=1 while the core's STOPM equates to LLS (see "Power mode transitions" section for details).

Before entering LLS mode, the user should configure the Low Leakage Wake-up unit (LLWU) to enable the desired pins and/or peripherals as wake-up sources for core 0. The available wake-up sources to the LLWU are detailed in the chip configuration details for this device. For core 1, the Messaging Unit (MU) needs to configured to allow core 0 to assert an interrupt or reset to wakeup core 1.

Once configured, the LLWU can trigger an exit from LLS mode and return the device to the run mode from which LLS was entered (i.e. RUN or VLPR mode) with a pending LLWU interrupt. When an LLWU wakeup request occurs, the core exits LLS mode and resumes processing, beginning with the stacking operations leading to the interrupt service routine. In the LLWU interrupt service routine (ISR), the user can read the LLWU module wake-up flags to determine the source of the wakeup.

A pin reset will also cause an exit from LLS mode, returning the device to normal RUN mode. When exiting LLS via the reset pin, the PIN and WAKEUP bits within the SRS register will be set.

NOTE

The LLWU interrupt must not be masked by the interrupt controller to avoid a scenario where the system does not fully recover from LLS mode after an LLWU wakeup event.

30.5.4.4 Very Low Leakage Stop (VLLS) modes

VLLS mode is designed to allow a core and its system to enter a very low leakage, power gated state. Refer to the device's Power Management chapter for peripheral, I/O, and memory operation in VLLS mode and see the PMC chapter for additional power options available in this mode.

A core can enter VLLS mode by executing Sleep-Now or Sleep-On-Exit with SLEEPDEEP=1 while the core's STOPM equates to VLLS (see "Power mode transitions" section for details).

Before entering VLLS mode, the user should configure the Low Leakage Wake-up unit (LLWU) to enable the desired pins and/or peripherals as wake-up sources for core 0. The available wake-up sources to the LLWU are detailed in the chip configuration details for this device. For core 1, the Messaging Unit (MU) needs to configured to allow core 0 to assert an interrupt or reset to wakeup core 1.

Once configured, the LLWU can trigger an exit from VLLS mode and return the device to RUN mode with a pending LLWU interrupt. When an LLWU wakeup request occurs, the core exits VLLS mode and begins executing the reset flow. In the LLWU interrupt service routine (ISR), the user can read the LLWU module wake-up flags to determine the source of the wakeup.

A pin reset will also cause an exit from VLLS mode, returning the device to normal RUN mode. When exiting VLLS via the reset pin, the PIN and WAKEUP bits within the SRS register will be set.

When entering VLLS, each I/O pin in the core's power domain is statically latched as configured before executing VLLS. Because all logic is powered off, all port and peripheral data is lost during VLLS. This data should be restored before writing the ACKISO bit in the power management module, after which I/O states are released to be driven by the restored logic.

31.1.1 System Integration Module

The System Integration Module (SIM) provides system control and chip configuration registers. The SIM also includes an instance of TSTMR.

Table 31-2. SIM configuration

Parameter	Description
Name	SIM
Instances	1
Configurable features	Device specific
Interface speed	NA
External I/O pins	NA

31.2 Introduction

The system integration module (SIM) provides system control and chip configuration registers.

31.3 SIM DGO Register Protocol

A set of registers have been made available in DGO domain for SW use, with the objective to maintain its value between system resets. DGO registers are reseted only in POR event. Since LV and DGO registers are in asynchronous domains a synchronization plus rising edge detector is present in the update register path. In addition DGO domain is in slower clock, so an interrupt is available for software to detect DGO register is updated. In addition a reset de-assert detect circuit is used to update LV registers with DGO value in the event of system reset. In case of POR event, both LV and DGO versions are reset to all zeroes.

DGO register update need to follow the sequence below:

1. Write to SIM_DGO_GPx register

2. Set SIM_DGO_CTRLx[UPDATE] bit

3. Poll SIM_DGO_CTRLx[ACK] bit or wait for interrupt (in this case need to enable interrupt prior to the sequence)

4. Clear SIM_DGO_CTRLx[UPDATE] bit

5. Write 1 to clear SIM_DGO_CTRLx[ACK] bit

31.4 GPIO pads operating range configuration

GPIO pads can operate in 3 ranges of I/O supply:

- 1.8 V range (1.71 V ~ 1.89 V)
- 3.3 V range (3.00 V ~ 3.60 V)
- Continuous range (1.71 V ~ 3.60 V)

NOTE

See i.MX 7ULP Data Sheet for recommended operating values for each I/O supply

- Ports A, C, E, F GPIO pads must be configured to operate in one of the 3 possible operating ranges.
- Port B GPIO pads must be configured to operate in either "Continuous range" or in "1.8 V range".
- Port D GPIO pads are not configurable and can operate in "1.8 V range" or "3.3 V range".
- Each GPIO port can be individually configured in the SIM_DGO_GP11 register according to the values shown in the following table.
- Operating in the "Continuous range" turns on a voltage detection circuitry resulting in additional power consumption. If this additional power consumption is not desired, for example in low power modes, it's recommended to configure either Low or High range.

Table 31-3. Pads Range Configuration

Mode	SIM_DGO_GP11 [PT*_RANGE_CTRL]	Operation
Continuous Range	00	Pads can be powered in the "Continuous range". The I/O supply voltage detector is enabled.
Low Range	01	Pads can be powered in the "1.8 V range" only. Powering the I/O port in the "3.3 V range" may damage the pads. The I/O supply voltage detector is disabled.
High Range	10	Pads can be powered in the "3.3 V range" only. Powering the pads in the "1.8 V range" may cause malfunction. The I/O supply voltage detector is disabled.
Prohibited	11	Invalid configuration. Will cause extra power consumption and may cause pads damage.

Reset value for SIM_DGO_GP11[PT*_RANGE_CTRL] bits are loaded from fuses during reset, but values can be overriden.

NOTE

SIM_DGO_GP11 register is write-once after reset

31.5 Memory Map and register definition

This section includes the SIM module memory map and detailed descriptions of all registers.

31.5.1 SIM Memory Map register descriptions

The memory map comprises of 32-bit aligned registers which can be accessed via 8-bit, 16-bit, or 32-bit accesses. Write access to reserved locations will generate transfer error. Read access to reserved locations will also generate transfer error and the read data bus will show all 0s.

The module will not check for correctness of programmed values in the registers and software must ensure that correct values are being written.

31.5.1.1 SIM Memory map

31.5.1.2 SIM Systems Options Register 1 (SOPT1)

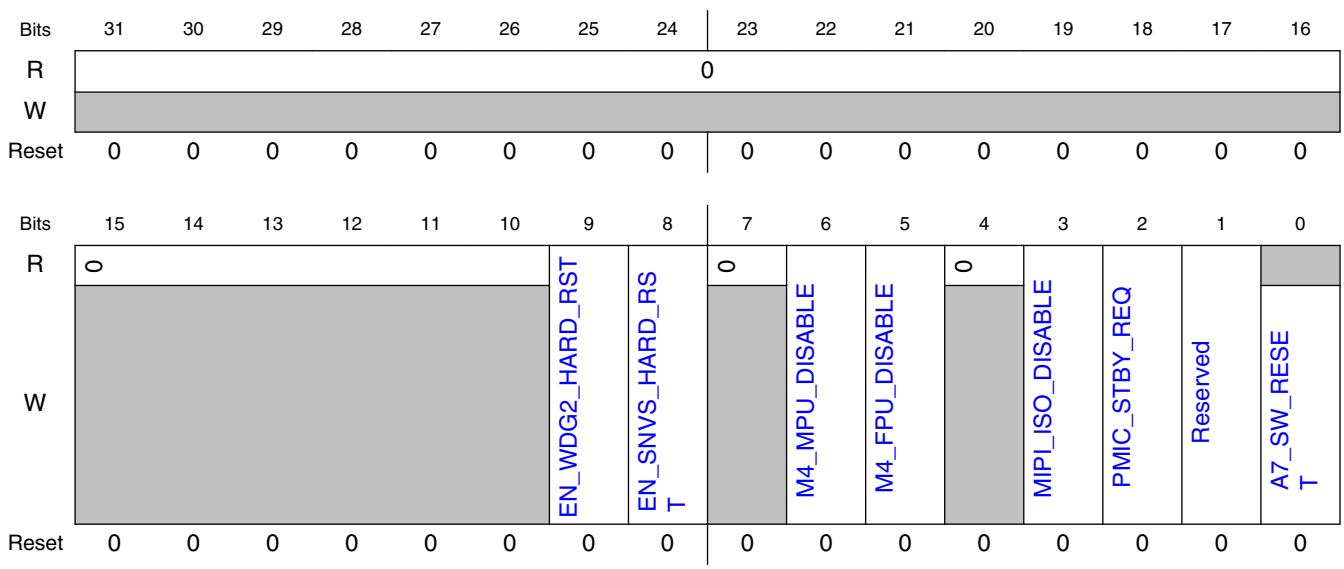
31.5.1.2.1 Offset

Register	Offset
SOPT1	0h

31.5.1.2.2 Function

This control register provides System Options for various functions on i.MX7ULP.

31.5.1.2.3 Diagram



31.5.1.2.4 Fields

Field	Function
31-10 —	Reserved.
9 EN_WDG2_HARD_RST	Watchdog 2 Reset Enable. 1'b0 : WDG2 system reset disabled 1'b1 : WDG2 system reset enabled
8 EN_SNVS_HARD_RST	SNVS_HP system reset enable (Write Once). 1'b0 : SNVS_HP system reset disabled 1'b1 : SNVS_HP system reset enabled
7 —	Reserved.
6 M4_MPU_DISABLE	Disables M4 MPU unit. 1'b0 : MPU enabled 1'b1 : MPU disabled
5 M4_FPU_DISABLE	Disables M4 FPU unit. 1'b0 : FPU enabled 1'b1 : FPU disabled
4 —	Reserved.
3 MIPI_ISO_DISABLE	MIPI Isolation Disable. To disable isolation to MIPI core for the cases where MIPI is powered up. Initially isolation will come as enabled. 1'b0 - MIPI isolation enabled. In this scenario the recommendation is to have VDD_DSI and VDD11_DSI connected to ground. 1'b1 - MIPI isolation disabled.
2 PMIC_STBY_REQ	PMIC Standby Request. This bit defines PMIC_STBY_REQ pin, which notifies external power management IC to move from functional voltage to standby voltage. 1'b0 : PMIC_STBY_REQ will negate - functional voltage 1'b1 : PMIC_STBY_REQ will assert - Voltage will be requested to change to standby voltage
1 —	Reserved.
0 A7_SW_RESET	SW reset for A7 domain. 1'b0 : No action 1'b1 : Writing value 1'b1 triggers A7 domain reset (even if previous bit value was 1'b1). **NOTE:** It is recommended to clear the bit with additional register write after bit is set, to prevent further SOPT1 read-modify-write to trigger undesirable reset.

31.5.1.3 SIM SOPT1 Configuration Register (SOPT1CFG)

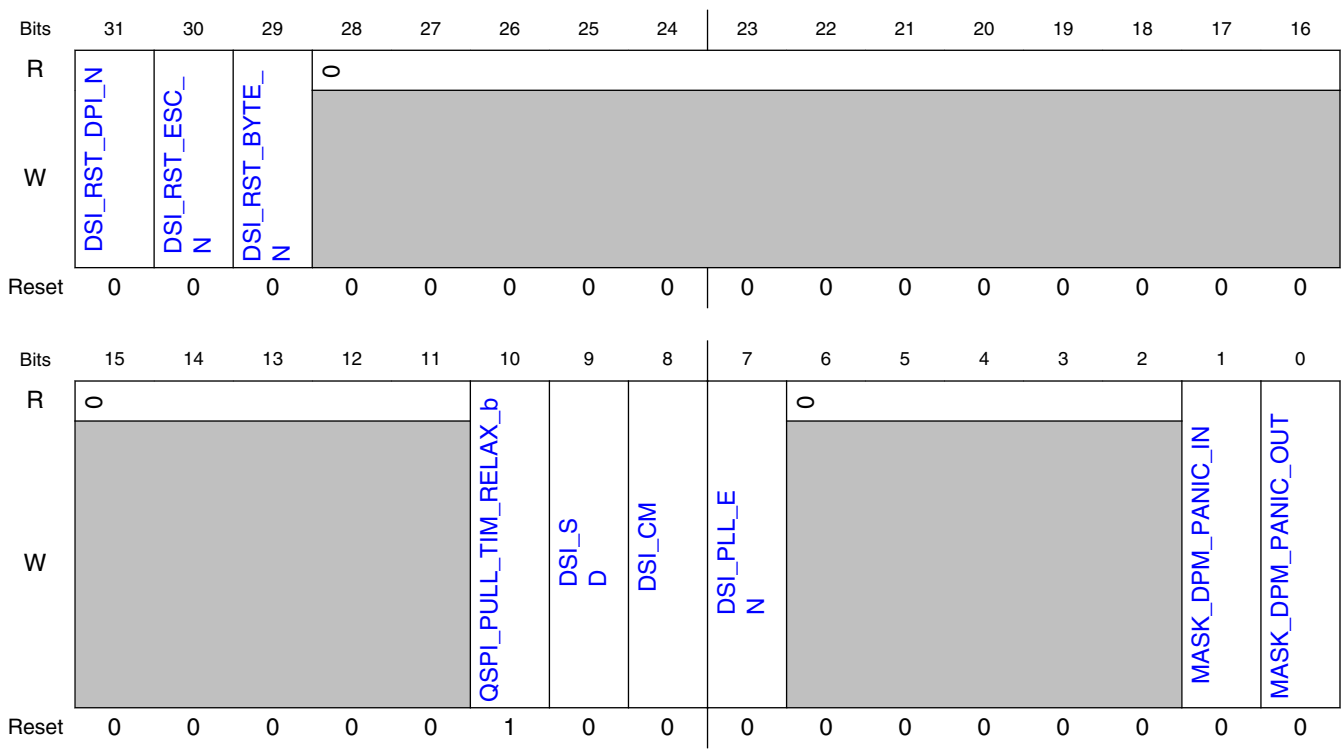
31.5.1.3.1 Offset

Register	Offset
SOPT1CFG	4h

31.5.1.3.2 Function

This register is used to configure system options on i.MX7ULP1.

31.5.1.3.3 Diagram



31.5.1.3.4 Fields

Field	Function
31 DSI_RST_DPI_N	DSI Reset DPI Control. The DSI Host Controller initialization requires that all its reset sources to be controlled independently in order to have its functional blocks coming out of reset in different times. This reset source affects all logic in the DPI domain. Coming out of system reset, the DPI domain will be in reset state, and this bit shall be configured to take this domain out of reset state. See MIPI-DSI chapter for further detail on how resets should be released to correct operation of the module.

Table continues on the next page...

Field	Function
	1'b0: DPI domain is under reset state (default). 1'b1: DPI domain is out of reset state.
30 DSI_RST_ESC_N	DSI Reset Escape Control. The DSI Host Controller initialization requires that all its reset sources be controlled independently in order to have its functional blocks coming out of reset in different times. This reset source affects all logic in the Escape domain. Coming out of system reset, the Escape domain will be in reset state, and this bit shall be configured to take this domain out of reset state. See MIPI-DSI chapter for further detail of how resets should be released to correct operation of the module. 1'b0: Escape domain is under reset state (default). 1'b1: Escape domain is out of reset state.
29 DSI_RST_BYTE_N	DSI Reset Byte Control. The DSI Host Controller initialization requires that all its reset sources be controlled independently in order to have its functional blocks coming out of reset in different times. This reset source affects all logic in the Byte domain. Coming out of system reset, the Byte domain will be in reset state, and this bit shall be configured to take this domain out of reset state. See DSI chapter for further detail of how resets should be released to correct operation of the module. 1'b0: Byte domain is under reset state (default). 1'b1: Byte domain is out of reset state.
28-11 —	Reserved.
10 QSPI_PULL_TIM_RELAX_b	QSPI OBE Assertion Control. This feature is used to pull by half a cycle the assertion of the Output Buffer Enable (OBE) for the QSPIA_DATA1 port. No effect on the de-assertion phase. This feature does not affect the OBE configurations for the other QSPI ports. 1'b0: OBE assertion is pulled by a half a cycle. OBE assertion is generated off the inverted internal reference clock of QSPI (ipg_clk_sfif_b). 1'b1: OBE assertion is not relaxed. OBE assertion is generated off the internal reference clock of QSPI (ipg_clk_sfif) (default).
9 DSI_SD	DSI Shutdown Control. Shutdown Control for Type-4 Display only. This feature triggers the display module to shut down the streaming video interface to reduce power consumption. 1'b0: Shutdown command not to be sent to the Type-4 display (default). 1'b1: Shutdown command to be sent to the Type-4 display.
8 DSI_CM	DSI Color Mode Control. Color Mode Control for Type-4 Display only. This feature is used to configure the display on Normal Mode or Low-color mode. When bit is configured to low-color mode, display works in 8-bit mode and display power is reduced. 1'b0: Normal mode (full color) (default). 1'b1: Low color mode (8-bit).
7 DSI_PLL_EN	DSI PLL Enable. This configuration enables the DSI PLL. By default, in order to avoid any power issues during power up, the DSI PLL is disabled. 1'b0: DSI PLL disabled 1'b1: DSI PLL enabled

Table continues on the next page...

Field	Function
6-2 —	Reserved.
1 MASK_DPM_PANIC_IN	DPM Panic In Mask (Write Once). Indicates if Panic Input from PMC should be ignored. 1'b0: Not Masked 1'b1: Masked
0 MASK_DPM_PANIC_OUT	DPM Panic Out Mask (Write Once). Indicates if Panic alarm from DPM is to be masked. 1'b0: Not Masked 1'b1: Masked

31.5.1.4 HW SIM HSIC CAL Register (HSIC_CAL)

31.5.1.4.1 Offset

Register	Offset
HSIC_CAL	Ch

31.5.1.4.2 Function

Calibration Settings for HSIC DDR pads.

DDR pads have calibration settings, which can be performed either automatically (via HW) or manually (via SW). An example of automatic calibration is the one performed by MMDC module.

Manual calibration is provided via SIM. The process then consists in carrying out an automatic calibration via MMDC, read the values from that calibration, and use them to set up HSIC DDR pads via SIM registers.

NOTE

Check the "Calibration Process" section in MMDC chapter for details on automatic calibration.

Calibration procedure:

- Copy MMDC_MPZQSWCTRL or MMDC_MPZQHWCTRL to the corresponding HSIC_CAL bit fields + HSIC_ZQ_COMPARE = 1'b1

- Copy MMDC_MPZQSWCTRL or MMDC_MPZQHWCTRL to the corresponding HSIC_CAL bit fields + HSIC_ZQ_COMPARE = 1'b0
- This is required to latch the values to the pads through HSIC_ZQ_CAL_EN pulse.

31 —	Reserved.
30-29 —	Reserved.
28-24 HSIC_ZQ_VOL_M1	HSIC ZQ pull-down resistance incremented. This field determines the value of the Pull-down resistor during SW ZQ calibration. Should be copied from MMDC_MPZQSWCTRL[ZQ_SW_PD_VAL] bit + 5'h01. 5'b00000 - Minimum resistance. 5'b11111 - Maximum resistance.
23-21 —	Reserved.
20-16 HSIC_ZQ_VOL	HSIC ZQ pull-down resistance. This field determines the value of the Pull-down resistor during SW ZQ calibration.

Table continues on the next page...

Field	Function
	Should be copied from MMDC_MPZQSWCTRL[ZQ_SW_PD_VAL] bitfield. 5'b00000 - Minimum resistance. 5'b11111 - Maximum resistance.
15-13 —	Reserved.
12-8 HSIC_ZQ_VOH_M1	HSIC ZQ pull-up resistance incremented. This field determines the value of the Pull-up resistor during SW ZQ calibration. Should be copied from MMDC_MPZQSWCTRL[ZQ_SW_PU_VAL] bit + 5'h01. 5'b00000 - Minimum resistance. 5'b11111 - Maximum resistance.
7 HSIC_ZQ_CAL_EN	HSIC ZQ compare enable. Controls the latching of the compare result.
6 —	Reserved.
5 HSIC_ZQ_COMPARE	HSIC ZQ Compare. Not Used.
4-0 HSIC_ZQ_VOH	HSIC ZQ pull-up resistance. This field determines the value of the Pull-up resistor during SW ZQ calibration. Should be copied from MMDC_MPZQSWCTRL[ZQ_SW_PU_VAL] bitfield. 5'b00000 - Minimum resistance. 5'b11111 - Maximum resistance.

31.5.1.5 SNVS Misc Control Register (SNVS_MISC_CTRL)

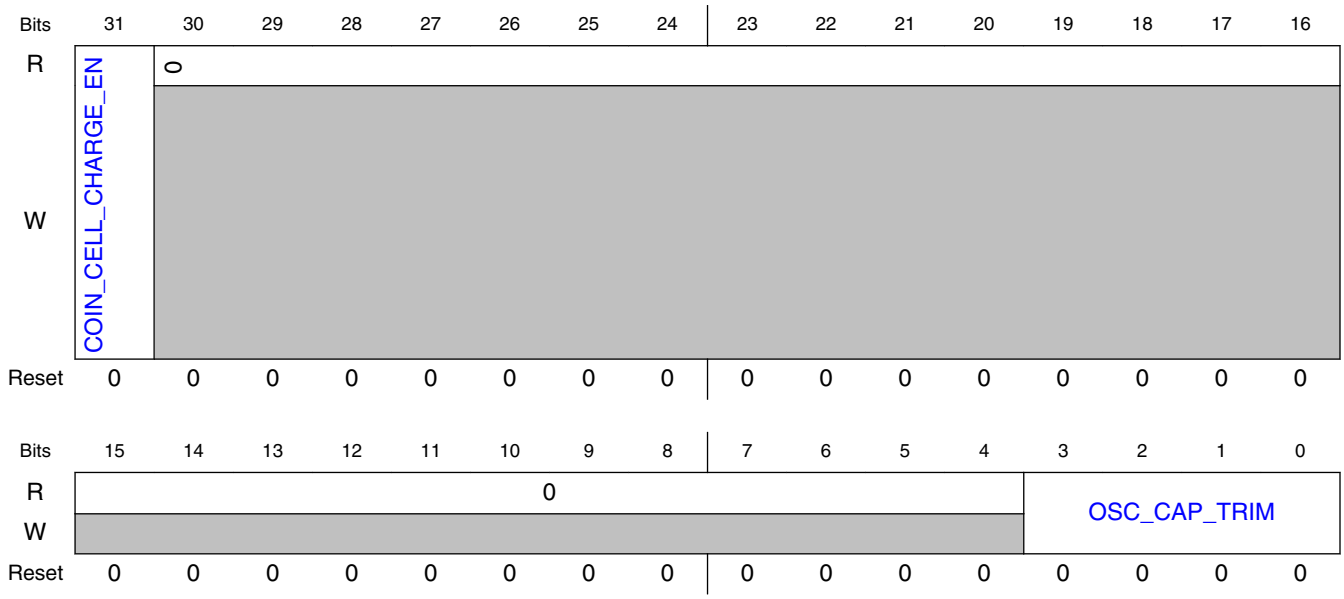
31.5.1.5.1 Offset

Register	Offset
SNVS_MISC_CTRL	28h

31.5.1.5.2 Function

This register defines additional control for the SNVS domain.

31.5.1.5.3 Diagram



31.5.1.5.4 Fields

Field	Function
31 COIN_CELL_CHARGE_EN	Enables Signal Isolation on SNVS Software Trims and Pull controls (PUS/PUE) until the software writes "1" to this register field. This ensures trim values are held until registers get updated by software after boot up. 1'b0 : Enable Isolation on Software Trims/Pull controls. 1'b1 : Remove Isolation on Software Trims/Pull controls. **NOTE:** 1. Software must remove isolation by writing "1" on every power-up. 2. Software must write "0" to this bit every time application enters LPSR mode where SoC power is removed.
30-4 —	Reserved.
3-0 OSC_CAP_TRIM	Trims to control the CAP on 32K Oscillator.

31.5.1.6 HW SIM General Purpose Register 0 (GPR0)

31.5.1.6.1 Offset

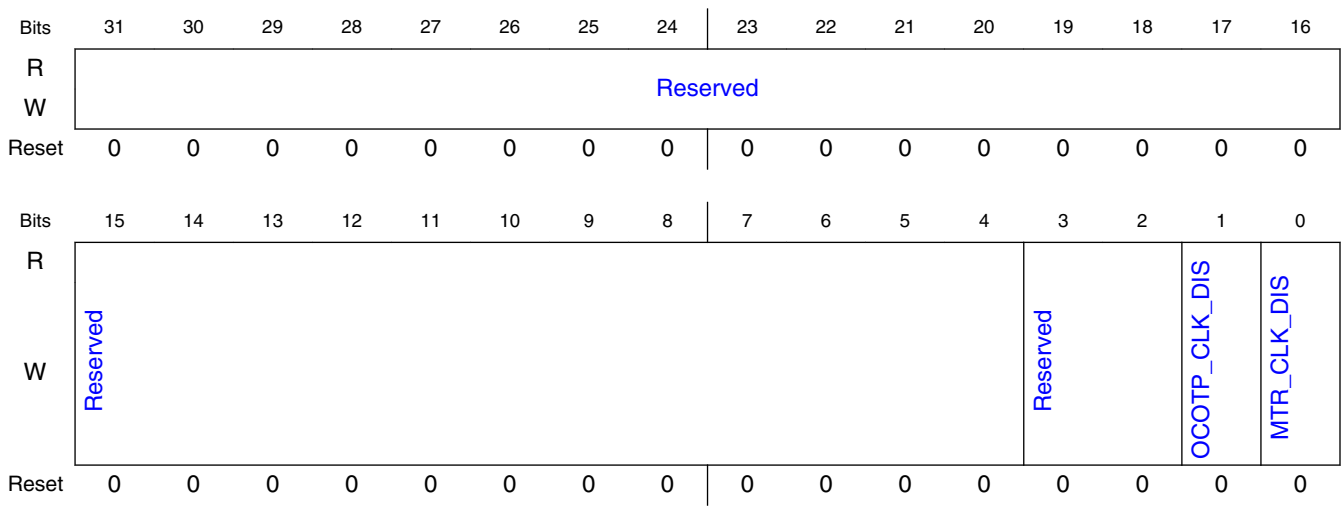
Register	Offset
GPR0	2Ch

31.5.1.6.2 Function

General Purpose Read/Write Register 0.

Hardware GPR to store chip specific control bits.

31.5.1.6.3 Diagram



31.5.1.6.4 Fields

Field	Function
31-4 —	Reserved.
3-2 —	Reserved.
1 OCOTP_CLK_DIS	OCOTP clocks disable. Disables OCOTP clocks to save power. 1'b0: OCOTP clock is enabled. 1'b1: OCOTP clock is disabled.
0 MTR_CLK_DIS	MBIST clocks disable. Disables MBIST clocks to save power.

Field	Function
	1'b0: MBIST clocks are enabled. 1'b1: MBIST clocks are disabled.

31.5.1.7 HW SIM General Purpose Register 1 (GPR1)

31.5.1.7.1 Offset

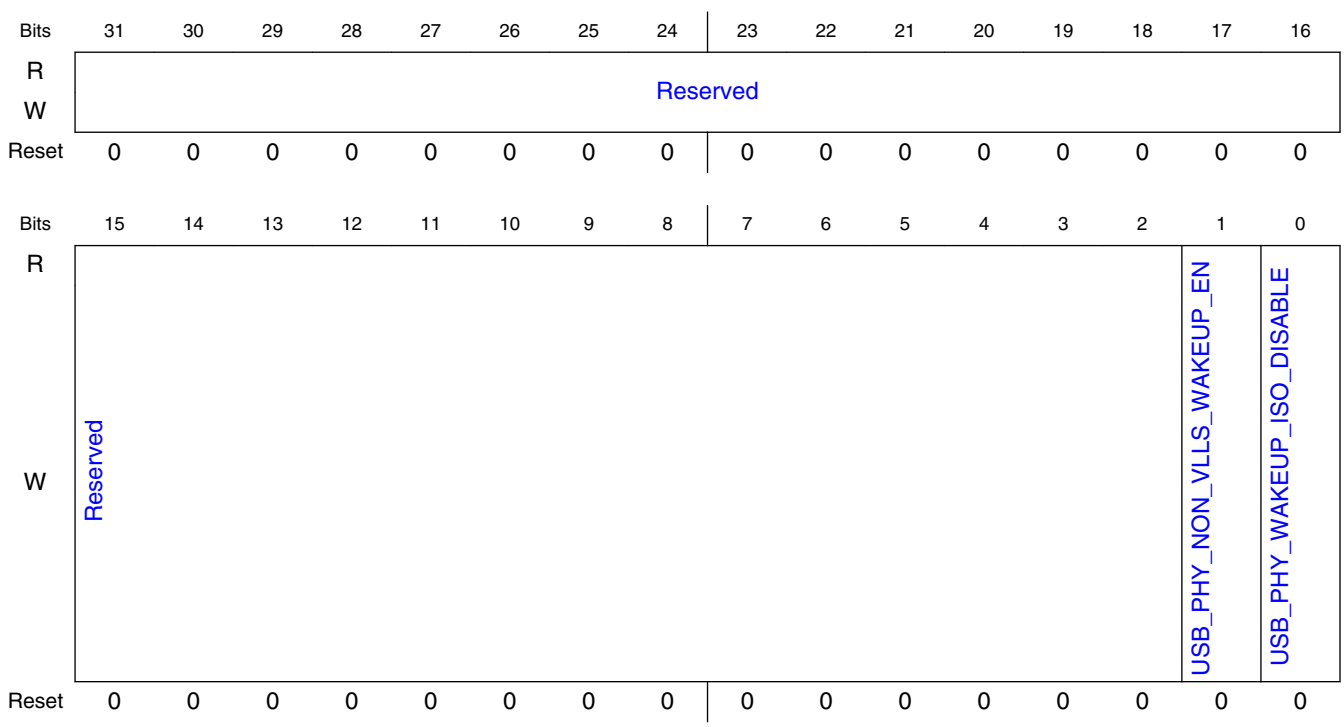
Register	Offset
GPR1	30h

31.5.1.7.2 Function

General Purpose Read/Write Register 1.

Hardware GPR to store chip specific control bits.

31.5.1.7.3 Diagram



31.5.1.7.4 Fields

Field	Function
31-2 —	Reserved.
1 USB_PHY_NON_VLLS_WAKEUP_EN	USB PHY non VLLS wakeup enable. 1'b0 : Disabled. 1'b1 : Enabled.
0 USB_PHY_WAKEUP_ISO_DISABLE	USB PHY wakeup ISO disable. USB PHY VLLS wakeup source pins isolation control. Wakeup pins are powered by VDD_USB18 and wakeup logic is powered by VDD_PMC18. 1'b0 : Wakeup pins are isolated from wakeup logic. 1'b1 : Wakeup pins are connected to wakeup logic.

31.5.1.8 HW SIM General Purpose Register 2 (GPR2)

31.5.1.8.1 Offset

Register	Offset
GPR2	34h

31.5.1.8.2 Function

General Purpose Read/Write Register 2.

Hardware GPR to store chip specific control bits.

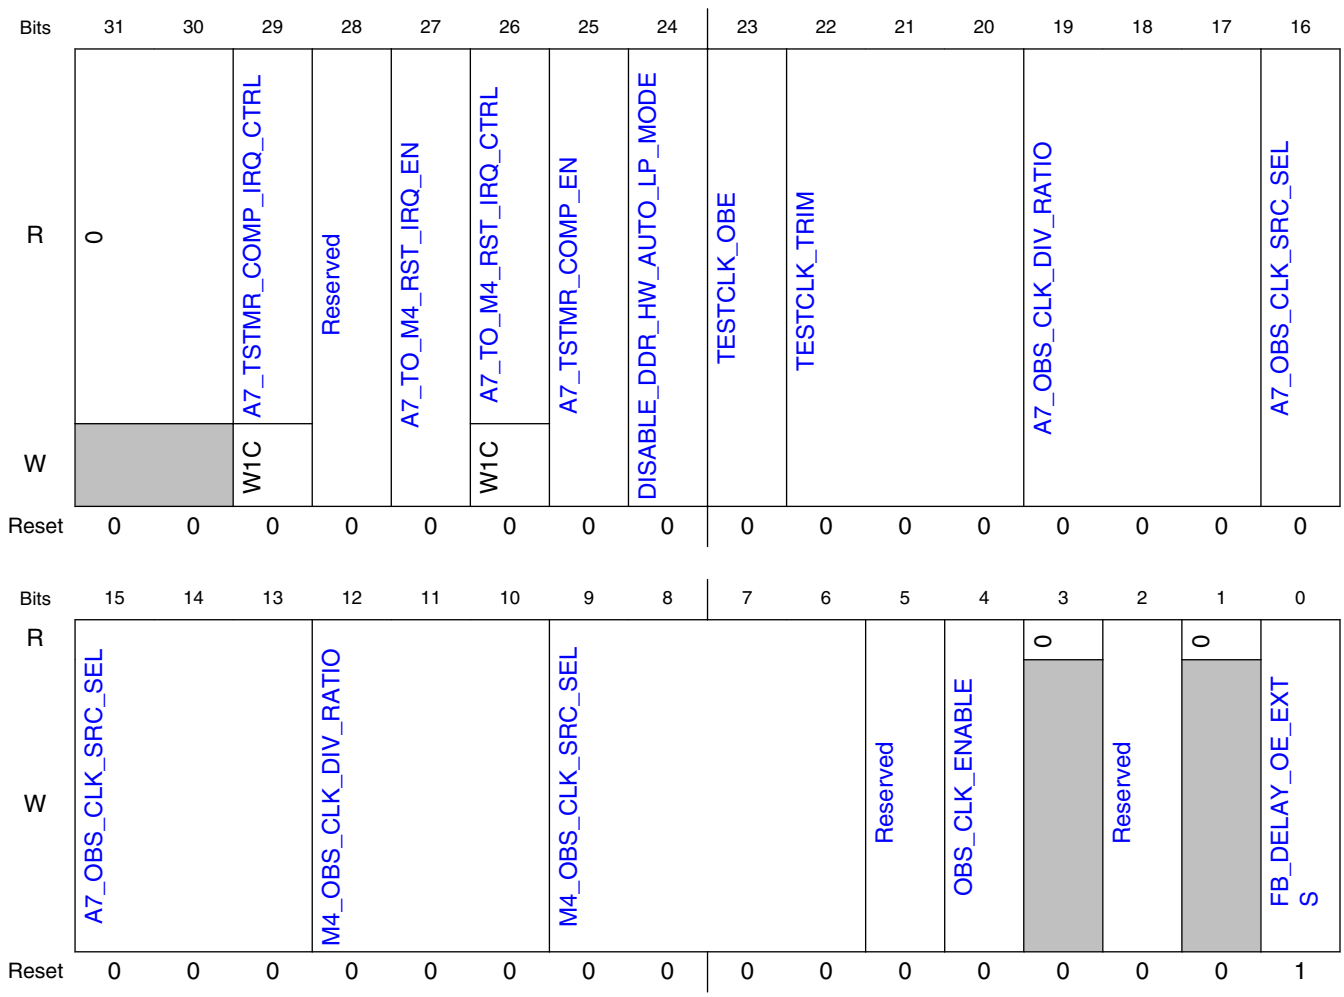
31.5.1.10.1 Offset

Register	Offset
MISC_CTRL0	3Ch

31.5.1.10.2 Function

This register is used to store Miscellaneous Control Bits.

31.5.1.10.3 Diagram



31.5.1.10.4 Fields

Field	Function
31-30 —	Reserved.
29 A7_TSTMR_COMP_IRQ_CTRL	Controls the compare of A7 reset as IRQ. This bit is set when A7 TSTimer counter value matches the value stored in A7_TSTMR_CMP_VAL registers. Staying high until a 1'b1 bit write. **NOTE:** This bit should be cleared in the interrupt routine.
28 —	Reserved.
27 A7_TO_M4_RST_IRQ_EN	Enables the assertion of A7 reset as IRQ/Wake-up to M4. If set this bit enables the A7 reset as IRQ/Wake-up source to M4. 1'b0: Compare operation is disabled. 1'b1: Compare operation is enabled.
26 A7_TO_M4_RST_IRQ_CTRL	Controls the assertion of A7 reset as IRQ/Wake-up to M4. This bit is set when A7 reset occurs. Staying high until a 1'b1 bit write.
25 A7_TSTMR_COMP_EN	Enables the compare of A7 TS Timer versus a programmed value. If set, this bit enables the compare of A7 TS Timer versus the value stored in SIM registers A7_TSTMR_CMP_VAL_L and A7_TSTMR_CMP_VAL_H. 1'b0: Compare operation is disabled. 1'b1: Compare operation is enabled.
24 DISABLE_DDR_HW_AUTO_LP_MODE	Disable control to put DDR in self-refresh mode automatically by HW during low power modes. 1'b0: Self-refresh mode enabled. 1'b1: Self-refresh mode disabled.
23 TESTCLK_OBE	Output Buffer Enable for LVDS TESTCLK_P/TESTCLK_N pad.
22-20 TESTCLK_TRIM	Trim Delay for LVDS TESTCLK_P/TESTCLK_N pad. TESTCLK_TRIM[1:0]: Control pins for output current trimming (process case compensation): 1'b11: Best case. 1'b10: Typical case. 1'b00: Worst case. **NOTE:** TESTCLK_TRIM[2]: Not used.
19-17 A7_OBS_CLK_DIV_RATIO	Selection of division rate (2**n) of A7 observation clock div rate = 2**n (n=0..7). 3'b000: divide by 1. 3'b001: divide by 2. 3'b010: divide by 4. 3'b011: divide by 8. 3'b100: divide by 16.

Table continues on the next page...

Field	Function
	3'b101: divide by 32. 3'b110: divide by 64. 3'b111: divide by 128.
16-13 A7_OBS_CLK_SRC_SEL	Selects the clock to be observed on A7 domain. 4'b0000 - PMC0_TST_DIG_OUT 4'b0001 - PMC1_TST_DIG_OUT 4'b0010 - Reserved 4'b0011 - Reserved 4'b0100 - Reserved 4'b0101 - PLL2 VCO **NOTE:** PLL2 VCO comes from scg_spll_clk signal (after plls mux sel) differently of the PFD signals. 4'b0110 - PLL2 PFD0 4'b0111 - PLL2 PFD1 4'b1000 - PLL2 PFD2 4'b1001 - PLL2 PFD3 4'b1010 - PLL3 VCO **NOTE:** PLL3 VCO comes from scg_apll_clk signal (after plls mux sel) differently of the PFD signals. 4'b1011 - PLL3 PFD0 4'b1100 - PLL3 PFD1 4'b1101 - PLL3 PFD2 4'b1110 - PLL3 PFD3 4'b1111 - Reserved
12-10 M4_OBS_CLK_DIV_RATIO	Selection of division rate (2**n) of M4 observation clock div rate = 2**n (n=0..7). 3'b000: divide by 1. 3'b001: divide by 2. 3'b010: divide by 4. 3'b011: divide by 8. 3'b100: divide by 16. 3'b101: divide by 32. 3'b110: divide by 64. 3'b111: divide by 128.
9-6 M4_OBS_CLK_SRC_SEL	Selects the clock to be observed on M4 domain. 4'b0000 - LPO1KHZ clock 4'b0001 - SIRC clock 4'b0010 - FIRC clock 4'b0011 - System OSC 4'b0100 - RTC OSC - 32KHz 4'b0101 - PLL0 VCO **NOTE:** PLL0 VCO comes from scg_spll_clk signal (after plls mux sel) differently of the PFD signals.

Table continues on the next page...

Field	Function
	4'b0110 - PLL0 PFD0 4'b0111 - PLL0 PFD1 4'b1000 - PLL0 PFD2 4'b1001 - PLL0 PFD3 4'b1010 - PLL1 VCO **NOTE:** PLL1 VCO comes from scg_apll_clk signal (after plls mux sel) differently of the PFD signals. 4'b1011 - PLL1 PFD0 4'b1100 - PLL1 PFD1 4'b1101 - PLL1 PFD2 4'b1110 - PLL1 PFD3 4'b1111 - Reserved
5 —	Reserved.
4 OBS_CLK_ENABLE	Enable that clocks can be observed at M4 CLKOUT, A7 CLKOUT and LVDS clock pads. 1'b0 : Clock observation feature disabled. 1'b1 : Clock observation feature enabled.
3 —	Reserved.
2 —	Reserved.
1 —	Reserved.
0 FB_DELAY_OE_EXTS	Flexbus control of FB_OE_b signal delay when CSCR[EXTS] is enabled. 1'b0: Delay disabled. 1'b1: Delay enabled.

31.5.1.11 SIM DGO Control Register 0 (SIM_DGO_CTRL0)

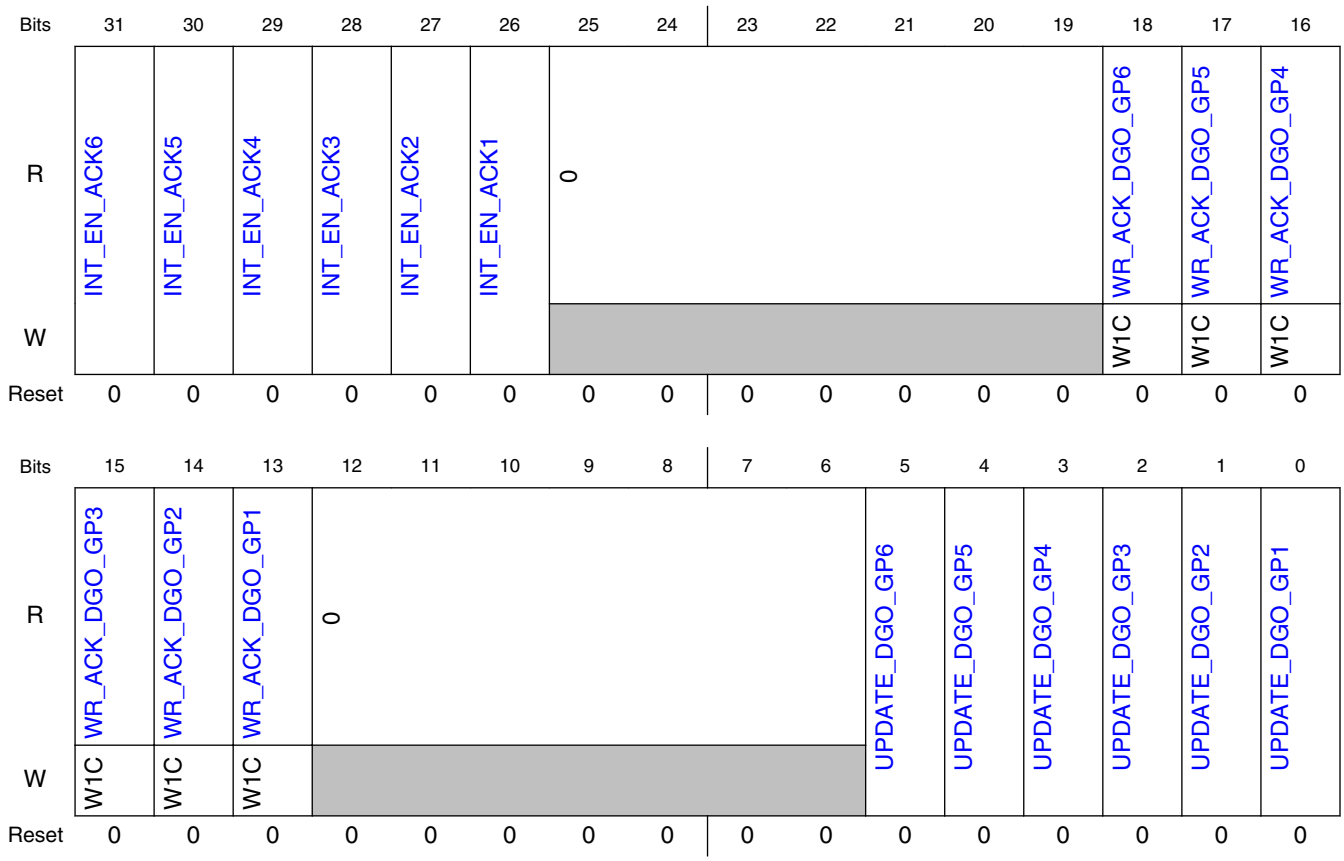
31.5.1.11.1 Offset

Register	Offset
SIM_DGO_CTRL0	50h

31.5.1.11.2 Function

Control Register for DGO GPs 1 to 6.

31.5.1.11.3 Diagram



31.5.1.11.4 Fields

Field	Function
31 INT_EN_ACK6	Interrupt enable for WR_ACK_DGO_GP6 bit field.
30 INT_EN_ACK5	Interrupt enable for WR_ACK_DGO_GP5 bit field.
29 INT_EN_ACK4	Interrupt enable for WR_ACK_DGO_GP4 bit field.
28 INT_EN_ACK3	Interrupt enable for WR_ACK_DGO_GP3 bit field.
27 INT_EN_ACK2	Interrupt enable for WR_ACK_DGO_GP2 bit field.
26 INT_EN_ACK1	Interrupt enable for WR_ACK_DGO_GP1 bit field.
25-19	Reserved.

Table continues on the next page...

Field	Function
—	
18 WR_ACK_DGO_GP6	This bit field is set automatically when corresponding DGO_GP6 register is shadowed in DGO domain. SW needs to write "1" to clear.
17 WR_ACK_DGO_GP5	This bit field is set automatically when corresponding DGO_GP5 register is shadowed in DGO domain. SW needs to write "1" to clear.
16 WR_ACK_DGO_GP4	This bit field is set automatically when corresponding DGO_GP4 register is shadowed in DGO domain. SW needs to write "1" to clear.
15 WR_ACK_DGO_GP3	This bit field is set automatically when corresponding DGO_GP3 register is shadowed in DGO domain. SW needs to write "1" to clear.
14 WR_ACK_DGO_GP2	This bit field is set automatically when corresponding DGO_GP2 register is shadowed in DGO domain. SW needs to write "1" to clear.
13 WR_ACK_DGO_GP1	This bit field is set automatically when corresponding DGO_GP1 register is shadowed in DGO domain. SW needs to write "1" to clear.
12-6 —	Reserved.
5 UPDATE_DGO_GP6	Writing 1 to this bit field indicates corresponding DGO_GP6 register has been updated with new values.
4 UPDATE_DGO_GP5	Writing 1 to this bit field indicates corresponding DGO_GP5 register has been updated with new values.
3 UPDATE_DGO_GP4	Writing 1 to this bit field indicates corresponding DGO_GP4 register has been updated with new values.
2 UPDATE_DGO_GP3	Writing 1 to this bit field indicates corresponding DGO_GP3 register has been updated with new values.
1 UPDATE_DGO_GP2	Writing 1 to this bit field indicates corresponding DGO_GP2 register has been updated with new values.
0 UPDATE_DGO_GP1	Writing 1 to this bit field indicates corresponding DGO_GP1 register has been updated with new values.

R W	A7_TSTMR_CMP_VAL_H															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

31.5.1.27.4 Fields

Field	Function
31-0 A7_TSTMR_CMP_VAL_H	Upper A7 TS Timer compare value. Stores the upper 32 bits to compare with A7 TS Timer. The compare is enabled when MISC_CTRL0[A7_TSTMR_CMP_EN] is set. If enabled the compare match will issue a IRQ/wake-up signal to A7 domain.

31.5.1.28 Override Control for Compensation Codes (COMP_CELL_OVERRIDE)

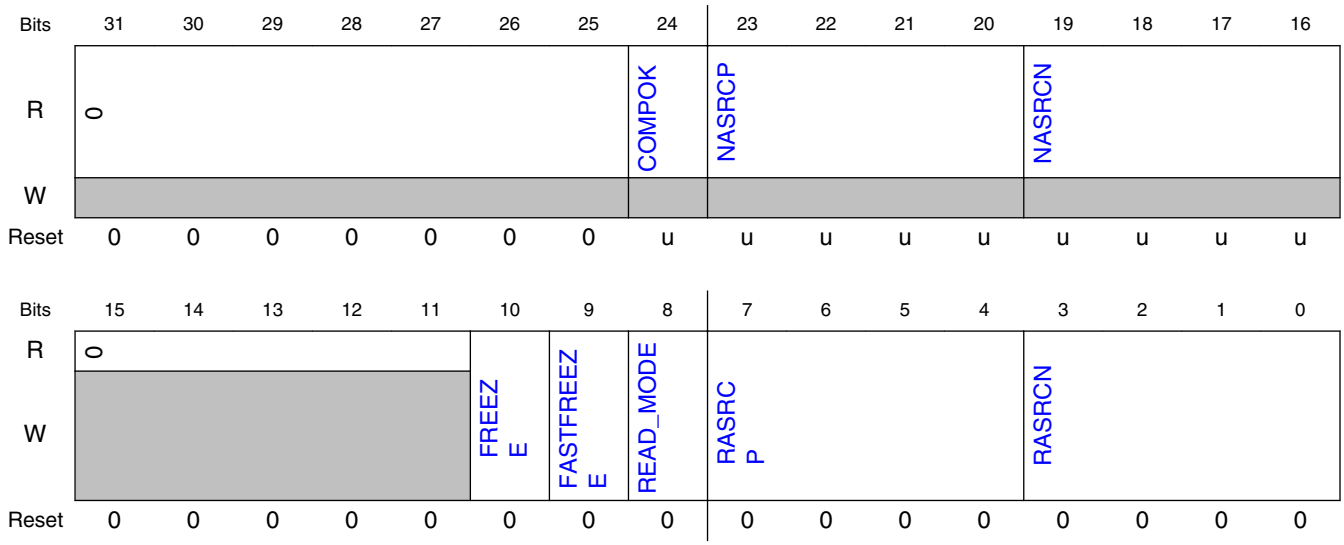
31.5.1.28.1 Offset

Register	Offset
COMP_CELL_OVERRIDE	98h

31.5.1.28.2 Function

Implements the override of Compensation cells.

31.5.1.28.3 Diagram



31.5.1.28.4 Fields

Field	Function
31-25 —	Reserved.
24 COMPOK	Compensation OK. 1'b0 - compensation cell is not in normal mode or is entering normal mode (Delay to measure a new code). 1'b1 - compensation cell is in the Normal mode and a new measured code is available on the ASRC lines. **NOTE:** This field value varies with parameters such as temperature and voltage supply. It is thus undefined.
23-20 NASRCP	4-bit PMOS compensation measured/generated codes. **NOTE:** This field value varies with parameters such as temperature and voltage supply. It is thus undefined.
19-16 NASRCN	4-bit NMOS compensation measured/generated codes. **NOTE:** This field value varies with parameters such as temperature and voltage supply. It is thus undefined.
15-11 —	Reserved.
10 FREEZE	Freeze. When set to "1", it freezes the compensation code at its running value. Freeze mode is activated on bit setting to "1". The compensation cell delivers refreshed compensation code at a delay after bit is cleared.
9 FASTFREEZE	Fast-Freeze. When set to "1", it fast-freezes the compensation code at its running value.

Table continues on the next page...

Field	Function
	Fast Freeze mode is activated on bit setting to "1". The compensation cell delivers a refreshed compensation code, at a comparatively lesser delay after signal falling edge than the delay of FREEZE bit.
8 READ_MODE	Read Mode. When set to "1", it forces Compensation Cell to "READ MODE". It has priority over FREEZE and FASTFREEZE configuration. In read mode, compensation codes are received from RASRCN and RASRCP.
7-4 RASRCP	4-bit PMOS compensation codes.
3-0 RASRCN	4-bit NMOS compensation codes.

Chapter 32
Low-Leakage Wake-Up Unit (LLWU)

32.1 Chip-specific LLWU information

Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port control	Signal multiplexing

32.1.1 Low-Leakage Wake-Up Unit

The Low-Leakage Wake-Up Unit (LLWU) module allows user to select up to 32 external pin sources and up to 8 internal modules as a wake up source from low-leakage power modes. Each of the available wake-up sources can be individually enabled. I.MX 7ULP integrates 1 instance of LLWU in the "always-on" DGO power domain. LLWU external pins can be used as wake-up sources for external devices associated with M4 or A7 domain. See Table 32-3 for details.

Table 32-2. LLWU configuration

Parameter	Description
Name	LLWU
Instances	1
Configurable features	• Port A and B pins can be configured as LLWU GPIO interrupts. • Other LLWU sources include RTC alarm, RTC seconds, CMP0-1 and LPTMR0-1 interrupts
Interface speed	NA
External I/O pins	See the attached IOMUXC and pinout spreadsheet

1. SNVS wake-up alarm

32.1.2 DMA support

The Low-Leakage Wake-Up Unit (LLWU) module on i.MX 7ULP doesn't support DMA/TRIGGER request as wake-up sources. Any text mentioning DMA trigger request as wake-up source throughout the chapter, should be ignored. Ideally, the reset value of DMAS field should be 0, however, the PARAM register is implemented with a reset value of 2020_2004 (as shown in memory map), showing that it could support 32 channels.

32.1.3 Operational requirements

LLWU module on i.MX 7ULP requires an M4 system IP bus clock/M4 slow clock maximum ratio of 3:1 (bus clock 3x faster than slow clock) prior to entering LLS/VLLS mode. This constraint applies only if any LLWU option is enabled as LLS/VLLS wakeup source.

32.2 Introduction

The LLWU module allows the user to select external pins and internal modules as interrupt wake-up sources from LLS/VLLS power modes. It also allows pins and/or modules to generate a temporary wake-up from LLS to allow servicing of DMA or trigger events. Digital filtering is also available for the external wakeup pins.

The RESET_B pin is an additional source for triggering an exit from low-leakage power modes, and causes the MCU to exit both LLS and VLLS through a reset flow. Input sources to the LLWU are described in the device's chip configuration details.

See AN4503: Power Management for Kinetis MCUs for further details on using the LLWU.

32.2.1 Features

The LLWU module features include:

- Support for up to 8'd32 external input pins and up to 8 internal modules with individual enable bits for MCU interrupt from low leakage modes.

- Input sources may be external pins or from internal modules capable of running in LLS or VLLS. See the chip configuration information for wakeup input sources for this device.
- Support to configure internal modules as DMA or trigger sources for temporary wakeup from LLS.
- External input pins programmable for falling-edge, rising-edge, or any-edge detection.
- Optional digital filters provided to qualify an external pin detect. Note that when the LPO clock is disabled, filters are disabled and bypassed.

32.2.2 Modes of operation

The LLWU module becomes functional on entry into a low-leakage power mode. After recovery from LLS, the LLWU is immediately disabled. After recovery from VLLS, the LLWU continues to detect wake-up events until the user has reinitialized the system and deasserted isolation.

32.2.2.1 LLS mode

Wake-up events due to external pin inputs (LLWU_Px) and internal modules (LLWU_MxIF) result in an interrupt flow when exiting LLS. Wake-up events due to internal module requests (LLWU_MxDF) and external pin inputs cause the system to temporarily exit LLS with the CPU clock disabled, allowing the DMA/trigger request to be serviced. When the DMA/trigger event is complete, the system will re-enter LLS.

NOTE

The LLWU interrupt must not be masked by the interrupt controller to avoid a scenario where the system does not fully recover from LLS after an external pin event.

32.2.2.2 VLLS modes

All wakeup and reset events result in VLLS exit via a reset flow.

32.2.2.3 Non-low leakage modes

The LLWU is inactive in all non-low leakage modes. The LLWU registers are accessible in non-low leakage modes and are available for configuring and reading status when bus transactions are possible.

When an external wake-up pin filter is first enabled in the LLWU_FILT register, filter operation begins immediately. To allow the filter to initialize, the user should wait at least five LPO clock cycles before entering a low leakage mode.

32.2.3 Block diagram

The following figure is the block diagram for the LLWU module.

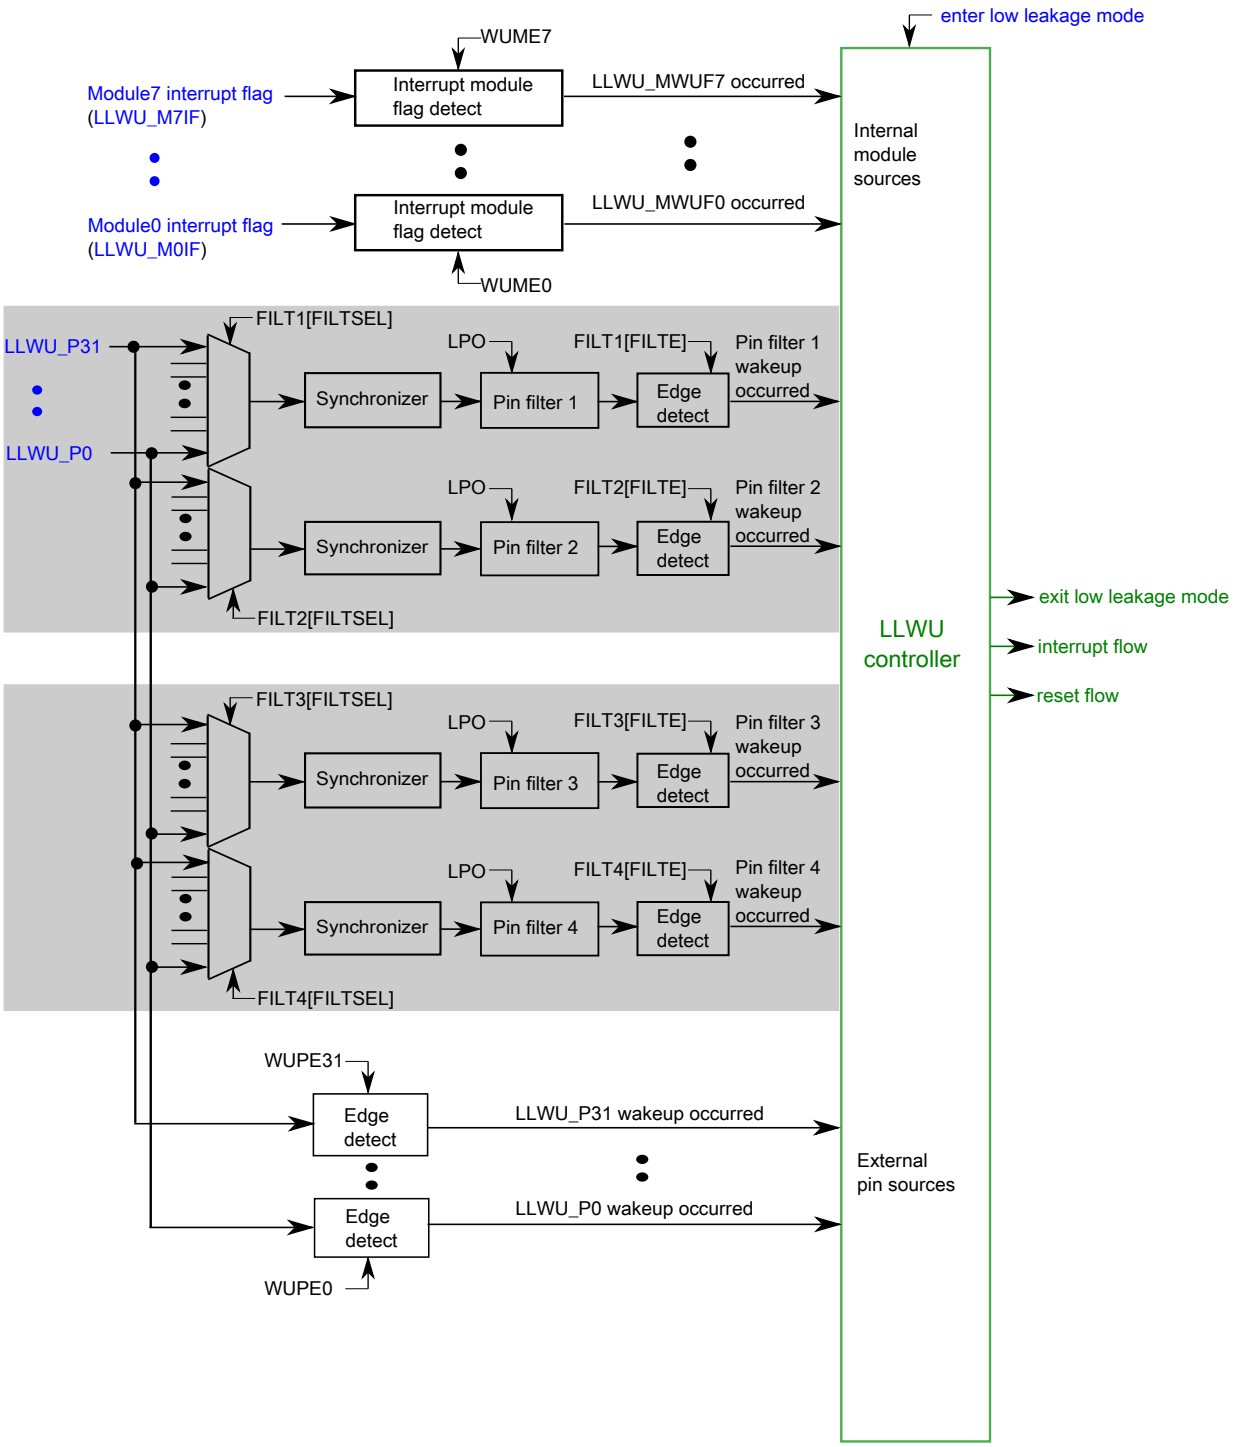

Figure 32-1. LLWU block diagram

32.3 LLWU signal descriptions

The signal properties of LLWU are shown in the table found here.

The external wakeup input pins can be enabled to detect either rising-edge, falling-edge, or on any change.

Table 32-4. LLWU signal descriptions

Signal	Description	I/O
LLWU_Pn	External Pin Wakeup inputs (n = 0-31)	I
LLWU_MnIF	Internal Module Interrupt flag (n = 0-7)	I
LLWU_MnDR	Internal Module DMA/trigger request (n = 0-7)	I

32.4 Memory map/register definition

Information about LLWU registers can be found here.

32.4.1 LLWU register descriptions

NOTE

The LLWU registers can be written only in supervisor mode. Write accesses in user mode are blocked and will result in a bus error.

Registers for Pin/Module sources marked "Reserved" in the LLWU chip configuration information will not be writable and will return 0 when read.

All LLWU registers are reset by Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. LLWU registers are unaffected by reset types that do not trigger Chip Reset not VLLS.

ME	18h

32.4.1.6.2 Function

The ME register contains the bits to enable an internal module interrupt as a wakeup source for inputs LLWU_M7IF - LLWU_M0IF.

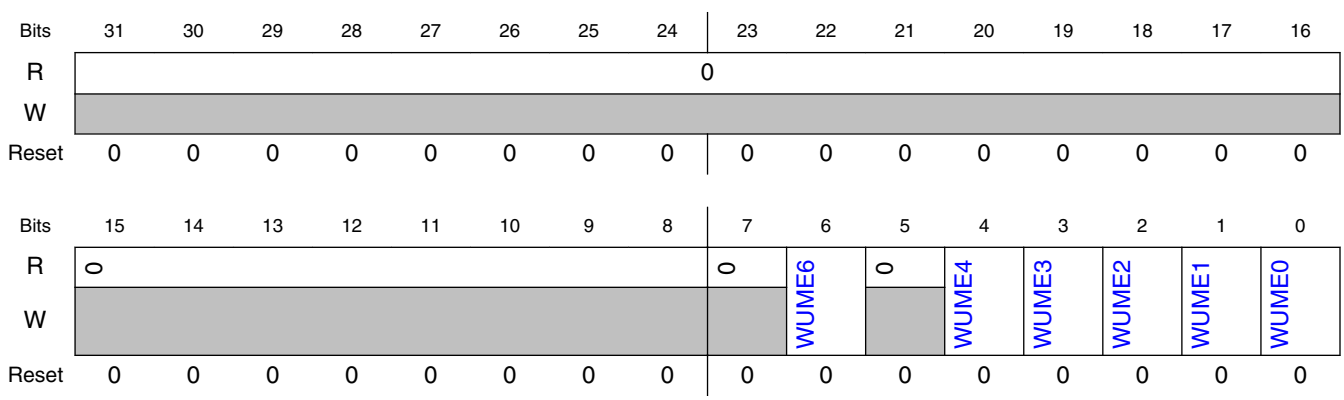
NOTE

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS.

NOTE

If a module interrupt is not supported on a given device, the corresponding WUME*n* bit always reads as a 0.

32.4.1.6.3 Diagram



32.4.1.6.4 Fields

32.4.1.8 Pin Flag register (PF)

32.4.1.8.1 Offset

Register	Offset
PF	20h

32.4.1.8.2 Function

The PF register contains the wakeup flags indicating which wakeup source caused the MCU to exit LLS or VLLS mode. For LLS, this is the source causing the CPU interrupt flow. For VLLS, this is the source causing the MCU reset flow.

The external wakeup flags are read-only and clearing a flag is accomplished by a write of a 1 to the corresponding WUF*n* bit. The wakeup flag (WUF*n*), if set, will remain set if the associated WUPE*n* bit is cleared.

NOTE

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS.

NOTE

If an external wakeup pin is not supported on a given device, the corresponding WUF*n* bit always reads as a 0.

Field	Function
31-0 WUFn	Wakeup flag for LLWU_Pn Indicates that an enabled external wakeup pin was a source of exiting a low-leakage power mode. To clear the flag write a one to WUF*n*. 0b - LLWU_Pn input was not a wakeup source 1b - LLWU_Pn input was a wakeup source

32.4.1.9 Module Interrupt Flag register (MF)

32.4.1.9.1 Offset

Register	Offset
MF	28h

32.4.1.9.2 Function

The MF register contains the wakeup flags indicating which internal module interrupt caused the MCU to exit LLS or VLLS mode. For LLS, this is the source causing the CPU interrupt flow. For VLLS, this is the source causing the MCU reset flow.

For internal peripherals that are capable of running in a low-leakage power mode, such as a real time clock module or CMP module, the flag from the associated peripheral is accessible as the MWUF*n* bit. The flag will need to be cleared in the peripheral instead of writing a 1 to the MWUF*n* bit.

NOTE

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS.

NOTE

If a module interrupt is not supported on a given device, the corresponding MWUF*n* bit always reads as a 0.

32.5 Functional description

The low-leakage wakeup unit (LLWU) module allows internal peripherals and external input pins as a source of wakeup from low-leakage modes.

The LLWU module contains pin enables for each external pin and internal module. For each external pin, the user can disable or select the edge type for the wakeup with the following options:

- Falling-edge
- Rising-edge
- Either-edge

When an external pin is enabled as a wakeup source, the pin must be configured as an input pin.

The LLWU implements optional 3-cycle glitch filters, based on the LPO clock. A detected external pin is required to remain asserted until the enabled glitch filter times out. Additional latency of up to 2 cycles is due to synchronization, which results in a total of up to 5 cycles of delay before the detect circuit alerts the system to the wakeup or reset event when the filter function is enabled. Four wakeup detect filters are available for selected external pins. Glitch filtering is not provided on the internal modules.

For internal module interrupts, the WUMEx bit enables the associated module interrupt as a wakeup source.

32.5.1 LLS mode

Wakeup events triggered from either an external pin input or an internal module interrupt, result in a CPU interrupt flow to begin user code execution.

Wakeup events triggered from an internal module DMA/Trigger request, result in a temporary wake-up from LLS with CPU remaining clock gated to allow the DMA/ Trigger request to be serviced. After the DMA/Trigger request is cleared, the system will re-enter LLS mode.

An LLS reset event due to RESET_B pin assertion causes an exit via a system reset. State retention data is lost, and the I/O states return to their reset state.

32.5.2 VLLS modes

For any LLWU wakeup from VLLS, recovery is always via a reset flow. A VLLS exit event due to RESET_B pin assertion causes an exit via a system reset with I/O returning to their reset state immediately.

32.5.3 Initialization

For an enabled peripheral wakeup input, the peripheral flag must be cleared by software before entering LLS or VLLS mode to avoid an immediate exit from the mode.

Flags associated with external input pins, filtered and unfiltered, must also be cleared by software prior to entry to LLS or VLLS mode.

After enabling an external pin filter or changing the source pin, wait at least five LPO clock cycles to allow the filter to initialize before entering LLS or VLLS mode .

NOTE

After recovering from a VLLS mode, user must restore chip configuration before clearing the PMC ACKISO bit. In particular, pin configuration for enabled LLWU wake-up pins must be restored to avoid any LLWU flag from being falsely set when ACKISO is cleared.

33.1.1 Wakeup Unit

The Wakeup Unit manages wakeup events and wakes up the device upon a valid wake-up event. The WKPU supports 21 resources. See Table 33-3 for list of wake-up channel assignments. The WKPU combines its wakeup events to supply a single wake-up to the system.

NOTE

Masking of the WKPU interrupt sources is enabled via SIM_WKPU_WAKEUP_EN register.

34.1.1 On-Chip One Time Programmable Controller (OCOTP_CTRL)

The OCOTP_CTRL or fuse box control (FBC) module[1] provides an interface for reading, programming and/or overriding identification and control information stored in on-chip fuse elements. The module supports electrically-programmable poly fuses (e-Fuses). Among the uses for the fuses are flash security and phantom configuration of the crypto modules. For security purposes, the fuses protect the confidentiality or integrity of critical security data against both software attacks and board-level hardware attacks. The following table shows the configuration of the FBC.

Table 34-2. OCOTP controller configuration

Parameter	Description
Name	OCOTP_CTRL
Instances	1

Table continues on the next page...

Table 34-2. OCOTP controller configuration (continued)

Parameter	Description
Configurable features	8-kbit eFUSE OTP
Interface speed	NA
External I/O pins	NA
Interrupts	NA

34.2 Overview

This section contains information describing the requirements for the on-chip eFuse OTP controller along with details about the block functionality and implementation.

In this document, the words "eFuse" and "OTP" are interchangeable. OCOTP refers to the hardware block itself.

34.2.1 Features

The OCOTP provides the following features :

- 32-bit word restricted program and read to 8 kbit of eFuse OTP.
- Loading and housing of fuse content into shadow registers
- Memory-mapped (restricted) access to shadow registers
- Generation of STICKY_REG which consists of sticky register bits
- Provides program-protect and read-protect eFuse
- Provides override and read protection of shadow register
- Supports ECC mode programming and reading for MTR fuse words by SkyBlue IPS bus.
- Supports ECC mode programming and reading for all the user fuse words .
- Supports redundancy mode programming and reading for all the supplementary fuse words

34.3 Clocks

The table found here describes the clock sources for OCOTP. Please see the chip-specific clocking section for clock setting, configuration and gating information.

Table 34-3. OCOTP Clocks

Clock name	Clock Root	Description
ipg_clk	ipg_clk_root	Peripheral clock
ipg_clk_s	ipg_clk_root	Peripheral access clock

34.4 Top-Level Symbol and Functional Overview

The figure below shows the OCOTP system level diagram.

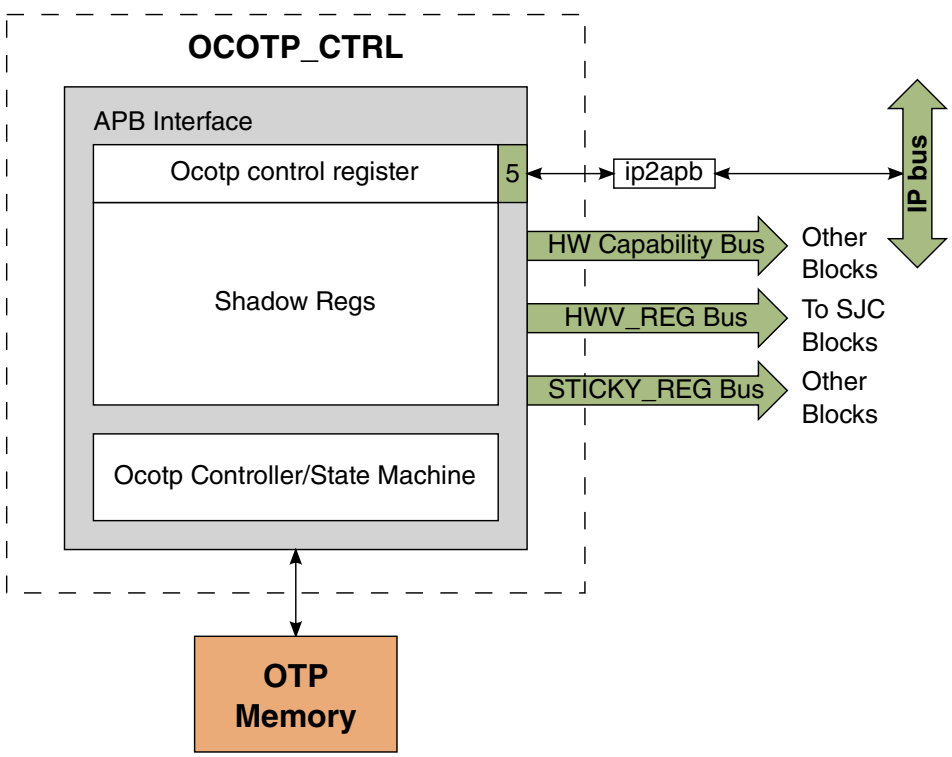

Figure 34-1. OCOTP System Level Diagram

34.4.1 Operation

The IP bus interface of the OCOTP has the following functions.

- Configure control registers for programming and reading all the fuse words
- Override and read shadow registers
- Programming and reading MTR fuse words by SkyBlue IPS bus.

OCOTP configuration for programs and reads are performed on 32-bit words for software (SW) convenience. For writes, the 32-bit word reflects the "write-mask." Bit fields with 0 will not be programmed and bit fields with 1 will be programmed.

NOTE

If ECC is supported, the fuse word can only be programmed once, otherwise it will report SEC/DED issues in read or reload.

NOTE

If redundancy is supported, the fuse word can be programmed more than once (not the same fuse).

In this document, 8 kbit fuse are divided into 32 banks by function. Each bank has 8 fuse words. Physically, 8 kbits fuse are in one 8k OTP memory.

34.4.1.1 Shadow Register Reload

All fuse words in efusebox are shadowed. Therefore, fuse information is available through memory mapped shadow registers. If fuses are subsequently programmed, the shadow registers should be reloaded to keep them coherent with the fuse bank arrays.

The "reload shadows" feature allows the user to force a reload of the shadow registers without having to reset the device. To force a reload, complete the following steps:

1. Check that HW_OCOTP_CTRL[BUSY] and HW_OCOTP_CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write, read or reload must be completed before a new access can be requested.
2. Set the HW_OCOTP_CTRL[RELOAD_SHADOWS] bit. OCOTP will read all the fuses one by one and put it into corresponding shadow register.
3. Wait for HW_OCOTP_CTRL[BUSY] and HW_OCOTP_CTRL[RELOAD_SHADOWS] to be cleared by the controller.
4. After reload, it needs to check if HW_OCOTP_OUT_STATUS[SEC_RELOAD] and HW_OCOTP_OUT_STATUS[DED_RELOAD] are asserted.
   - If HW_OCOTP_OUT_STATUS[SEC_RELOAD] is asserted, it indicates single bit correction ever happened when reloading.
   - If HW_OCOTP_OUT_STATUS[DED_RELOAD] is asserted, it indicates double bits detection ever happened when reloading. That is to say, one or more fuse word are not correct when reading from eFuse OTP.

The controller will automatically clear the HW_OCOTP_CTRL[RELOAD_SHADOWS] bit after the successful completion of the operation.

34.4.1.2 Fuse and Shadow Register Read

All shadow registers are always readable through the IPS bus except some secret keys regions. When their corresponding fuse lock bits are set, the shadow registers also become read locked. After read locking, reading from these registers will return 0xBADABADA.

In addition HW_OCOTP_CTRL[ERROR] will be set. It must be cleared by software before any new write, read or reload access can be issued. Subsequent reads to unlocked shadow locations will still work successfully however.

To read fuse words directly from the fusebox, complete the following steps:

1. Check that HW_OCOTP_CTRL[BUSY] and HW_OCOTP_CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write, read or reload must be completed before a read access can be requested.
2. Write the requested fuse address to HW_OCOTP_CTRL[ADDR].
3. When reading supplementary fuse, HW_OCOTP_CTRL[SUPPAD] must be set. When reading fuse word, HW_OCOTP_CTRL[SUPPAD] must be 0.
4. Set HW_OCOTP_READ_CTRL[READ_FUSE] to 1. OCOTP will auto read the fuse word according to HW_OCOTP_CTRL[ADDR] in fusebox. Then put read value into HW_OCOTP_READ_FUSE_DATA
5. Once complete, the controller will clear BUSY. A read request to a protected or locked region will result in no OTP access and no setting of HW_OCOTP_CTRL[BUSY]. In addition HW_OCOTP_CTRL[ERROR] will be set. It must be cleared by software before any new access can be issued.
6. Read HW_OCOTP_READ_FUSE_DATA to get fuse word value. HW_OCOTP_READ_FUSE_DATA will be 0xBADABADA when HW_OCOTP_CTRL[ERROR] is set.
7. After reading is completed, it needs to check HW_OCOTP_OUT_STATUS[DED] value to confirm if read fuse value is correct. If it is 1, read fuse value is wrong, otherwise it is correct.

34.4.1.3 Fuse and Shadow Register Writes

Shadow register bits can be overridden by software until the corresponding fuse lock bit for the region is set. When the lock shadow bit is set, the shadow registers for that lock region become write locked. The HW_OCOTP_LOCKn register also has no overwrite or fuse lock bits, but it is always read-only.

In order to avoid "rogue" code performing erroneous writes to OTP, a special unlocking sequence is required for writes to the fuse banks. To program fuse bank complete the following steps:

1. Check that HW_OCOTP_CTRL[BUSY] and HW_OCOTP_CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write or reload must be completed before a write access can be requested.
2. Write the requested address to HW_OCOTP_CTRL[ADDR] and program the unlock code into HW_OCOTP_CTRL[WR_UNLOCK]. The unlock code must be programmed for each write access. The unlock code is documented in the register description. Both the unlock code and address can be written in the same operation. When programming supplementary fuse, HW_OCOTP_CTRL[SUPPAD] must be set. When programming fuse word, HW_OCOTP_CTRL[SUPPAD] must be 0. HW_OCOTP_CTRL[SUPPAD] must be set with unlock code and address in same operation.
3. When programming fuse word, OCOTP_CTRL will auto select ECC or redundancy mode to program the fuse word according to fuse map definition. In ECC mode, the 32 fuse bits in one word can only be written once. In redundancy mode, the word can be written more than once as long as they are different fuse bits.For the fuse word which needs be programmed with ECC mode, it is recommended to set HW_OCOTP_CTRL[WORDLOCK] with unlock code and address in same operation.
4. Write the data to the HW_OCOTP_DATA register. This will automatically set HW_OCOTP_CTRL[BUSY] and clear HW_OCOTP_CTRL[WR_UNLOCK]. Bit fields with 1's will result in that OTP bit being programmed. Bit fields with 0's will be ignored. At the same time that the write is accepted, the controller makes an internal copy of HW_OCOTP_CTRL[ADDR] which cannot be updated until the next write sequence is initiated. This copy guarantees that erroneous writes to HW_OCOTP_CTRL[ADDR] will not affect an active write operation. During the write operation, HW_OCOTP_DATA cannot be modified.
5. Once complete, the controller will clear HW_OCOTP_CTRL[BUSY]. A write request to a protected or locked region will result in no OTP access and no setting of HW_OCOTP_CTRL[BUSY]. In addition HW_OCOTP_CTRL[ERROR] will be set. It must be cleared by software before any new write access can be issued.
6. After programming is completed, it needs to check if HW_OCOTP_OUT_STATUS[PROGFAIL] or HW_OCOTP_OUT_STATUS[LOCKED] is asserted. If either of these two bits is asserted, it indicates that programming has failed.

It should be noted that write latencies to OTP are numbers of 10 micro-seconds per word. The write latency is based on the number of "1" bits being written. For example : to program half the fuse bits in one 32-bt word needs 10 us x 16.

HW_OCOTP_CTRL[ERROR] will be set under the following conditions:

- A write is performed to a shadow register during a shadow reload (essentially, while HW_OCOTP_CTRL[RELOAD_SHADOWS] is set). In addition, the contents of the shadow register shall not be updated.
- A write is performed to a shadow register which has been locked.
- A read is performed to a shadow register which has been read locked.
- A program is performed to a fuse word which has been locked.
- A read is performed to a fuse word which has been read locked.

34.4.1.4 Write Postamble

Due to internal electrical characteristics of the OTP during writes, all OTP operations (direct reads, shadow reloads, or other writes) following a write must wait at least 2 µs after the clearing of HW_OCOTP_CTRL[BUSY] following the write. The delay guarantees programming voltages on-chip reach a steady state when exiting a write sequence.

A recommended software sequence to meet the postamble requirements is as follows:

1. Issue the write and poll for HW_OCOTP_CTRL[BUSY].
2. Perform the next OTP operation.

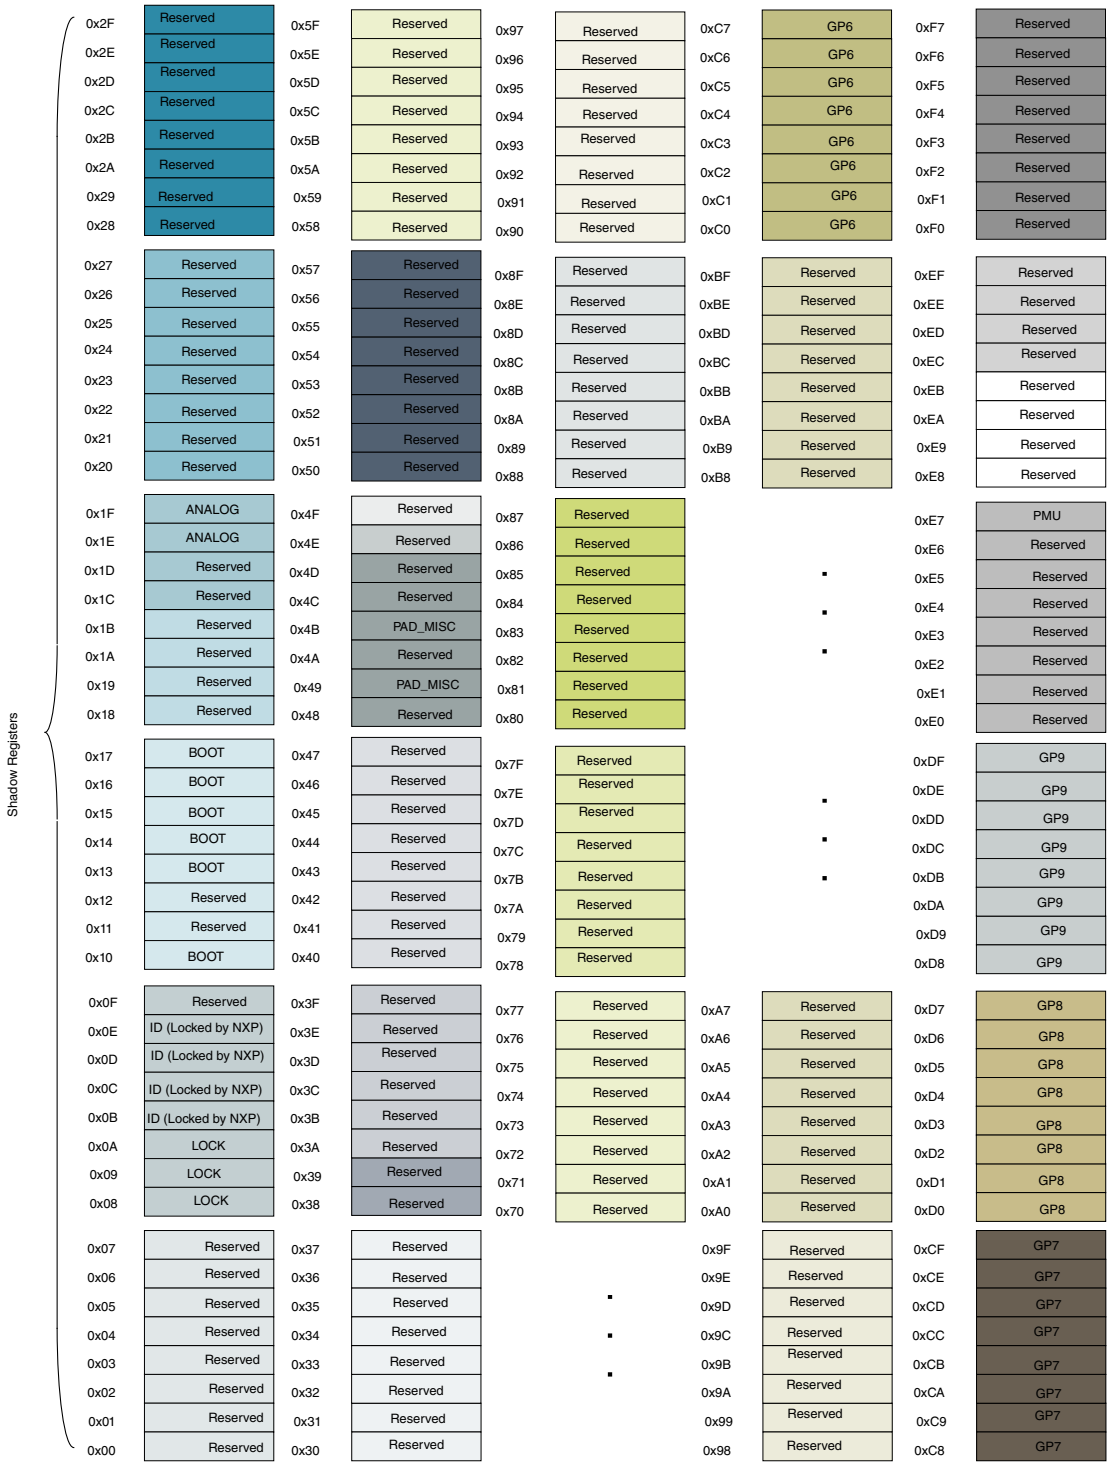
34.4.1.5 Power control of OTP memory

For every fuse operation, OCOTP_CTRL will automatically enable power of OTP memory. It is SW responsibility to shut off power OTP memory in idle status to save power.

1. After system power-up, SW needs to write 1 to HW_OCOTP_PDN[PDN] to shut off power OTP if there is not any fuse operation request.
2. After fuse program/read or MTR program/read triggered by SW are completed, SW needs to write 1 to HW_OCOTP_PDN[PDN] to shut off power OTP if there is not any new fuse operation request.

34.4.2 Fuse Shadow Memory Footprint

The OTP memory footprint is shown in the following figure. The registers are grouped by lock region. Their names correspond to the fusemap names.



Some of the reserved areas may contain secure keys. To see full memory footprint including security details, refer the i.MX7ULP Security RM.

Figure 34-2. OTP Memory Footprint

34.4.3 Behavior During Reset

The OCOTP is always active. The shadow registers automatically load the appropriate OTP contents after reset is deasserted. During this load-time HW_OCOTP_CTRL[BUSY] is set.

34.4.4 Secure JTAG control

The JTAG control fuses are used to allow or disallow JTAG access to secured resources.

Three JTAG security levels are implemented as shown in the table below.

Table 34-4. JTAG Security Level Control Bits

Security Mode	JTAG_SMODE	Description
No Debug	2'b11	The highest security level.
Secure JTAG	2'b01	Limit the JTAG access by using key based authentication mechanism.
JTAG Enable	2'b00	Low Security, all JTAG features are enabled.

34.5 Fuse Map

See the Fusemap attached with this reference manual for more information.

34.6 Unique Identification (UNIQUE_ID)

UNIQUE_ID contains 64 bits, allowing unique identification for every chip. The UNIQUE_ID number is bound to the device and cannot be altered without destroying the chip. The UNIQUE_ID is also used as a secure JTAG challenge. The user reads the chip's UNIQUE_ID to reference a server-stored response which can be used to open the chip for debug.

34.7 OCOTP Memory Map/Register Definition

The OCOTP Memory Map/Register Definition can be found here.

NOTE

Writing or reading unimplemented register address in OCOTP Controller will not send error and read data will be 0.

34.7.1.2 OTP Controller Control Register (HW_OCOTP_CTRL)

34.7.1.2.1 Offset

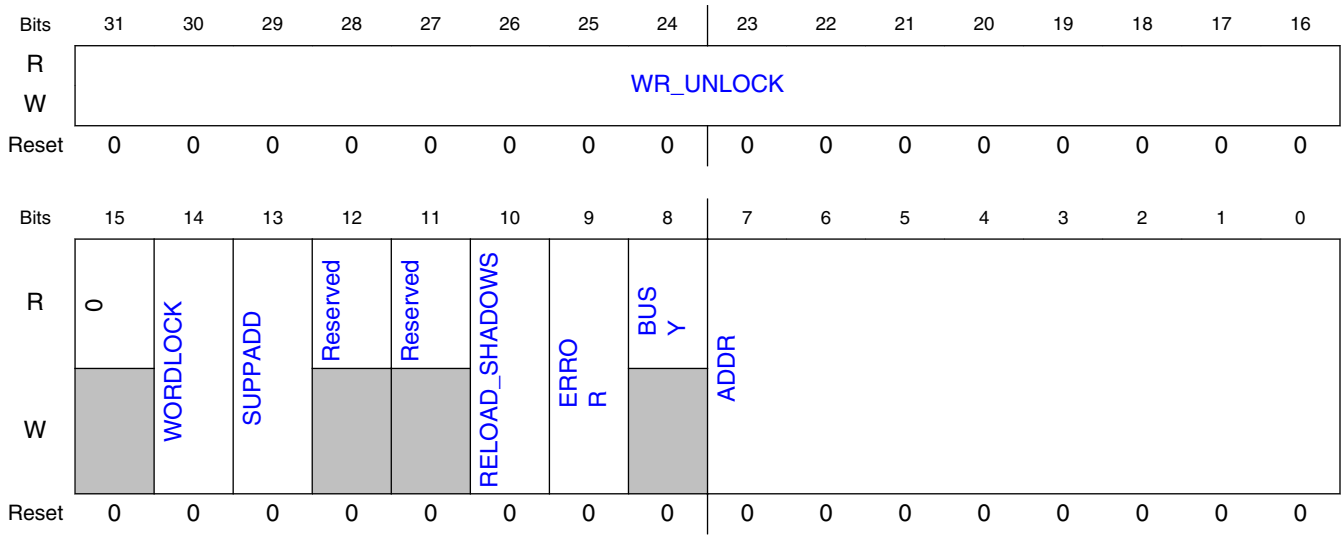
Register	Offset
HW_OCOTP_CTRL	0h

34.7.1.2.2 Function

The OCOTP Control and Status Register provides the necessary software interface for performing read and write operations to the On-Chip OTP (One-Time Programmable ROM). The control fields such as WR_UNLOCK, ADDR and BUSY/ERROR may be used in conjunction with the HW_OCOTP_DATA register to perform write operations. Read operations to the On-Chip OTP are involving ADDR, BUSY/ERROR bit field and HW_OCOTP_READ_CTRL register. Read value is saved in HW_OCOTP_READ_FUSE_DATA register.

Writing this register will set/clear/reverse all the bits of HW_OCOTP_CTRL_SET/CLR/TOG respectively which are 1 in write data. Other bits will not change. Reading this register will return the value of HW_OCOTP_CTRL.

34.7.1.2.3 Diagram



34.7.1.2.4 Fields

Field	Function
31-16 WR_UNLOCK	Write Unlock Write 0x3E77 to enable OTP write accesses. **NOTE:** This register must be unlocked on a write-by-write basis (a write is initiated when HW_OCOTP_DATA is written), so the UNLOCK bit field must contain the correct key value during all writes to HW_OCOTP_DATA, otherwise a write shall not be initiated. This field is automatically cleared after a successful write completion (clearing of BUSY). 0000000000000000b - OTP write accesses are locked. 0011111001110111b - OPT write access is unlocked.
15 —	- Reserved
14 WORDLOCK	WORDLOCK Indicates if word has to to be locked when programming. When programming with ECC mode, it is recommended to set this bit.
13 SUPPADD	Supplementary Address This bit should be set when programming or reading supplementary address space.
12 —	Reserved
11 —	Reserved
10 RELOAD_SHADOWS	RELOAD_SHADOWS Set to force reloading the shadow registers. This operation will automatically set BUSY. Once the shadow registers have been reloaded, BUSY and RELOAD_SHADOWS are automatically cleared by the controller.
9	ERROR

Table continues on the next page...

Field	Function
ERROR	Set by the controller when an access to a locked region(OTP or shadow register) is requested. Must be cleared before any further access can be performed. This bit can only be set by the controller. This bit is also set if the Pin interface (interface to the FUSES block) is active (that is, a transaction is in execution) and software requests an access to the OTP. In this instance, the ERROR bit cannot be cleared until the Pin interface access has completed. Reset this bit by writing a 1 to the HW_OCOTP_CTRL_CLR[ERROR] bit and not by a general write.
8 BUSY	BUSY OTP controller status bit. When set, no new write access or read access to OTP(including RELOAD_SHADOWS) can be performed. Cleared by controller when access complete. After reset (or after setting RELOAD_SHADOWS), this bit is set by the controller until the HW/SW and LOCK registers are successfully copied, after which time it is automatically cleared by the controller.
7-0 ADDR	ADDRESS OTP write and read access address field. Specifies one of 256 word address locations (0x00 - 0xFF).

34.7.1.3 OTP Controller Control Register (HW_OCOTP_CTRL_SET)

34.7.1.3.1 Offset

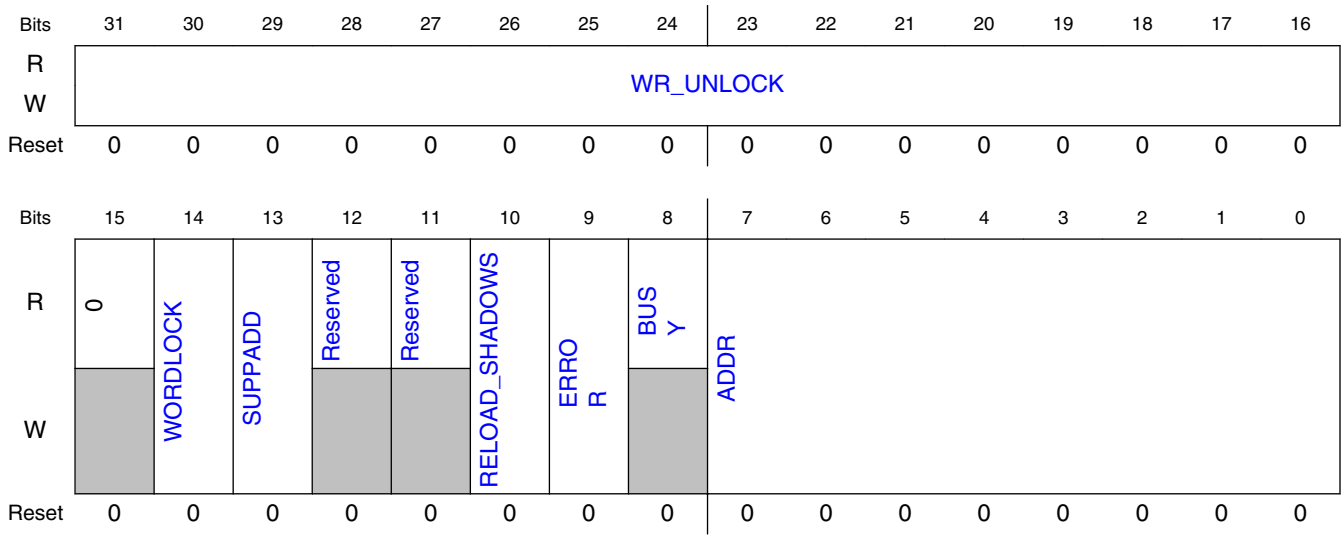
Register	Offset
HW_OCOTP_CTRL_SET	4h

34.7.1.3.2 Function

The OCOTP Control and Status Register provides the necessary software interface for performing read and write operations to the On-Chip OTP (One-Time Programmable ROM). The control fields such as WR_UNLOCK, ADDR and BUSY/ERROR may be used in conjunction with the HW_OCOTP_DATA register to perform write operations. Read operations to the On-Chip OTP are involving ADDR, BUSY/ERROR bit field and HW_OCOTP_READ_CTRL register. Read value is saved in HW_OCOTP_READ_FUSE_DATA register.

Writing this register will set/clear/reverse all the bits of HW_OCOTP_CTRL_SET/CLR/TOG respectively which are 1 in write data. Other bits will not change. Reading this register will return the value of HW_OCOTP_CTRL.

34.7.1.3.3 Diagram



34.7.1.3.4 Fields

Field	Function
31-16 WR_UNLOCK	Write Unlock Write 0x3E77 to enable OTP write accesses. **NOTE:** This register must be unlocked on a write-by-write basis (a write is initiated when HW_OCOTP_DATA is written), so the UNLOCK bit field must contain the correct key value during all writes to HW_OCOTP_DATA, otherwise a write shall not be initiated. This field is automatically cleared after a successful write completion (clearing of BUSY).
15 —	- Reserved
14 WORDLOCK	WORDLOCK Indicates if word has to to be locked when programming. When programming with ECC mode, it is recommended to set this bit.
13 SUPPADD	Supplementary Address This bit should be set when programming or reading supplementary address space.
12 —	Reserved
11 —	Reserved
10 RELOAD_SHADOWS	RELOAD_SHADOWS Set to force reloading the shadow registers. This operation will automatically set BUSY. Once the shadow registers have been reloaded, BUSY and RELOAD_SHADOWS are automatically cleared by the controller.
9 ERROR	ERROR

Table continues on the next page...

Field	Function
	Set by the controller when an access to a locked region(OTP or shadow register) is requested. Must be cleared before any further access can be performed. This bit can only be set by the controller. This bit is also set if the Pin interface (interface to the FUSES block) is active (that is, a transaction is in execution) and software requests an access to the OTP. In this instance, the ERROR bit cannot be cleared until the Pin interface access has completed. Reset this bit by writing a 1 to the HW_OCOTP_CTRL_CLR[ERROR] bit and not by a general write.
8 BUSY	BUSY OTP controller status bit. When set, no new write access or read access to OTP(including RELOAD_SHADOWS) can be performed. Cleared by controller when access complete. After reset (or after setting RELOAD_SHADOWS), this bit is set by the controller until the HW/SW and LOCK registers are successfully copied, after which time it is automatically cleared by the controller.
7-0 ADDR	ADDRESS OTP write and read access address field. Specifies one of 256 word address locations (0x00 - 0xFF).

34.7.1.4 OTP Controller Control Register (HW_OCOTP_CTRL_CLR)

34.7.1.4.1 Offset

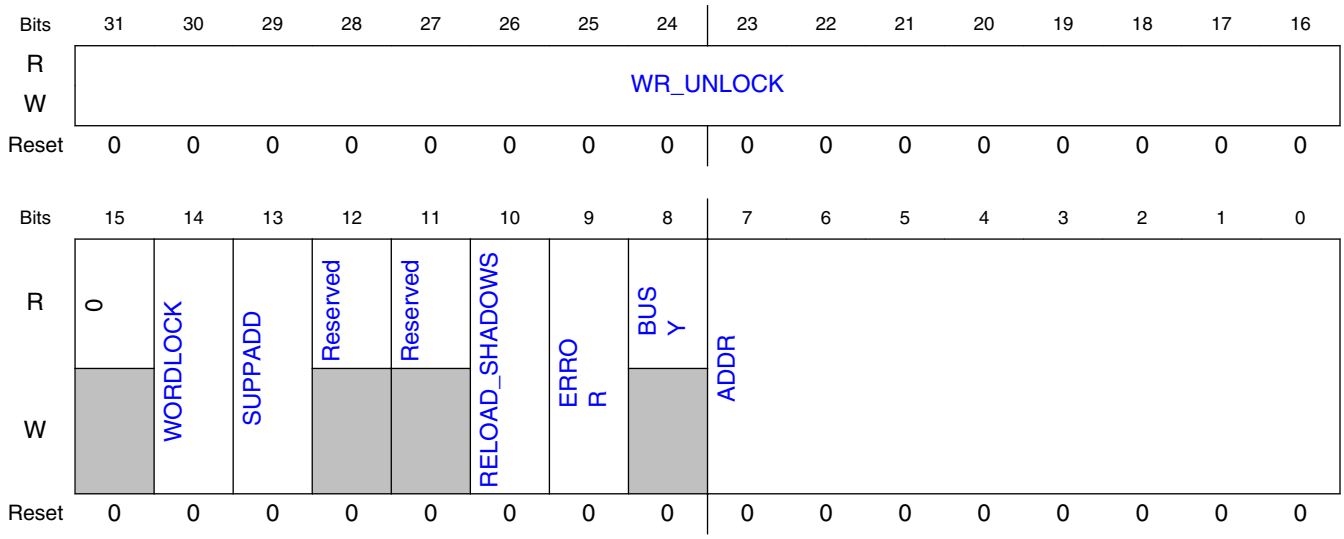
Register	Offset
HW_OCOTP_CTRL_CLR	8h

34.7.1.4.2 Function

The OCOTP Control and Status Register provides the necessary software interface for performing read and write operations to the On-Chip OTP (One-Time Programmable ROM). The control fields such as WR_UNLOCK, ADDR and BUSY/ERROR may be used in conjunction with the HW_OCOTP_DATA register to perform write operations. Read operations to the On-Chip OTP are involving ADDR, BUSY/ERROR bit field and HW_OCOTP_READ_CTRL register. Read value is saved in HW_OCOTP_READ_FUSE_DATA register.

Writing this register will set/clear/reverse all the bits of HW_OCOTP_CTRL_SET/CLR/TOG respectively which are 1 in write data. Other bits will not change. Reading this register will return the value of HW_OCOTP_CTRL.

34.7.1.4.3 Diagram



34.7.1.4.4 Fields

Field	Function
31-16 WR_UNLOCK	Write Unlock Write 0x3E77 to enable OTP write accesses. **NOTE:** This register must be unlocked on a write-by-write basis (a write is initiated when HW_OCOTP_DATA is written), so the UNLOCK bit field must contain the correct key value during all writes to HW_OCOTP_DATA, otherwise a write shall not be initiated. This field is automatically cleared after a successful write completion (clearing of BUSY).
15 —	- Reserved
14 WORDLOCK	WORDLOCK Indicates if word has to to be locked when programming. When programming with ECC mode, it is recommended to set this bit.
13 SUPPADD	Supplementary Address This bit should be set when programming or reading supplementary address space.
12 —	Reserved
11 —	Reserved
10 RELOAD_SHADOWS	RELOAD_SHADOWS Set to force reloading the shadow registers. This operation will automatically set BUSY. Once the shadow registers have been reloaded, BUSY and RELOAD_SHADOWS are automatically cleared by the controller.
9 ERROR	ERROR

Table continues on the next page...

Field	Function
	Set by the controller when an access to a locked region(OTP or shadow register) is requested. Must be cleared before any further access can be performed. This bit can only be set by the controller. This bit is also set if the Pin interface (interface to the FUSES block) is active (that is, a transaction is in execution) and software requests an access to the OTP. In this instance, the ERROR bit cannot be cleared until the Pin interface access has completed. Reset this bit by writing a 1 to the HW_OCOTP_CTRL_CLR[ERROR] bit and not by a general write.
8 BUSY	BUSY OTP controller status bit. When set, no new write access or read access to OTP(including RELOAD_SHADOWS) can be performed. Cleared by controller when access complete. After reset (or after setting RELOAD_SHADOWS), this bit is set by the controller until the HW/SW and LOCK registers are successfully copied, after which time it is automatically cleared by the controller.
7-0 ADDR	ADDRESS OTP write and read access address field. Specifies one of 256 word address locations (0x00 - 0xFF).

34.7.1.5 OTP Controller Control Register (HW_OCOTP_CTRL_TOG)

34.7.1.5.1 Offset

Register	Offset
HW_OCOTP_CTRL_TOG	Ch

34.7.1.5.2 Function

The OCOTP Control and Status Register provides the necessary software interface for performing read and write operations to the On-Chip OTP (One-Time Programmable ROM). The control fields such as WR_UNLOCK, ADDR and BUSY/ERROR may be used in conjunction with the HW_OCOTP_DATA register to perform write operations. Read operations to the On-Chip OTP are involving ADDR, BUSY/ERROR bit field and HW_OCOTP_READ_CTRL register. Read value is saved in HW_OCOTP_READ_FUSE_DATA register.

Writing this register will set/clear/reverse all the bits of HW_OCOTP_CTRL_SET/CLR/TOG respectively which are 1 in write data. Other bits will not change. Reading this register will return the value of HW_OCOTP_CTRL.

34.7.1.5.3 Diagram

34.7.1.6.4 Fields

Field	Function
31-1 —	- Reserved
0 PDN	PDN This bit indicates PDN value of OTP memory. If a 1 is written to this bit, PDN will be 0. Writing a 0 has no effect. **NOTE:** The software (SW) needs to write 1 to this bit to shut off power of OTP memory after system power up. At the beginning of every fuse operation, the hardware (HW) will auto enable power of OTP memory. After every fuse operation, the software (SW) also needs to write 1 to this bit to shut off power of OTP memory to avoid unnecessary power wastage.

34.7.1.7 OTP Controller Write Data Register (HW_OCOTP_DATA)

34.7.1.7.1 Offset

Register	Offset
HW_OCOTP_DATA	20h

34.7.1.7.2 Function

This register is used in conjunction with HW_OCOTP_CTRL to perform one-time writes to the OTP. See the Fuse and Shadow Register Writes section for operating details.

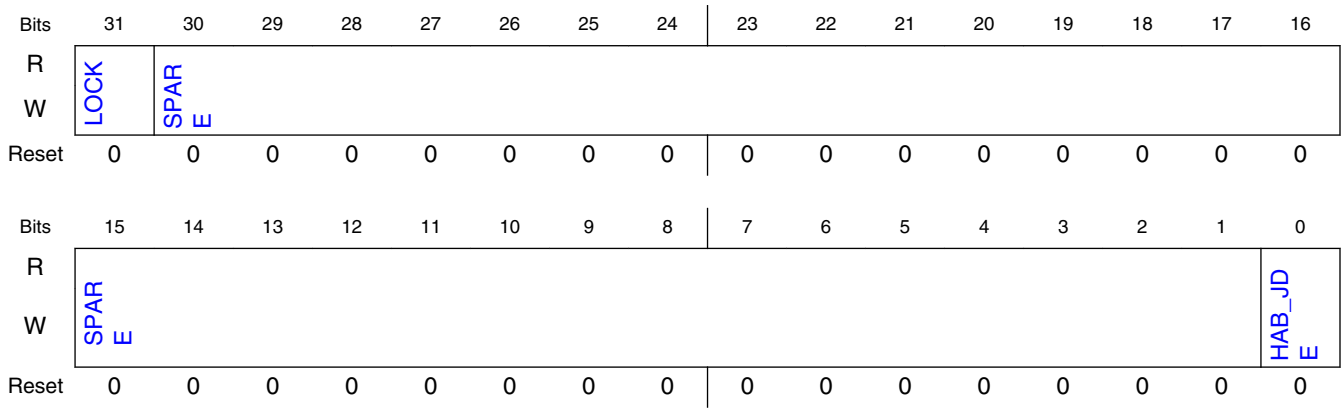
HW_OCOTP_SCS	60h

34.7.1.11.2 Function

This register holds volatile configuration values that can be set and locked by trusted software. All values are returned to their default values after reset. Writing this register will set/clear/reverse all the bits of HW_OCOTP_SCS_SET/CLR/TOG respectively, which are 1 in write data. Other bits will not change. Reading this register will return the value of HW_OCOTP_SCS.

34.7.1.11.3 Diagram



34.7.1.11.4 Fields

Field	Function
31 LOCK	LOCK When set, all the bits in this register are locked and can not be changed through SW programming. This bit is only reset after a reset is issued.
30-1 SPARE	SPARE Unallocated read/write bits for implementation specific software use.
0 HAB_JDE	HAB_JDE HAB JTAG Debug Enable. This bit is used by the HAB to enable JTAG debugging, assuming that a properly signed command to do so is found and validated by the HAB. The HAB must lock the register before passing control to the OS whether or not JTAG debugging has been enabled. Once JTAG is enabled by this bit, it can not be disabled unless the system is reset by reset. 0b - JTAG debugging is not enabled by the HAB (it may still be enabled by other mechanisms). 1b - JTAG debugging is enabled by the HAB (though this signal may be gated off).

34.7.1.12 OTP Controller Software Controllable Signals Register (HW_OCOTP_SCS_SET)

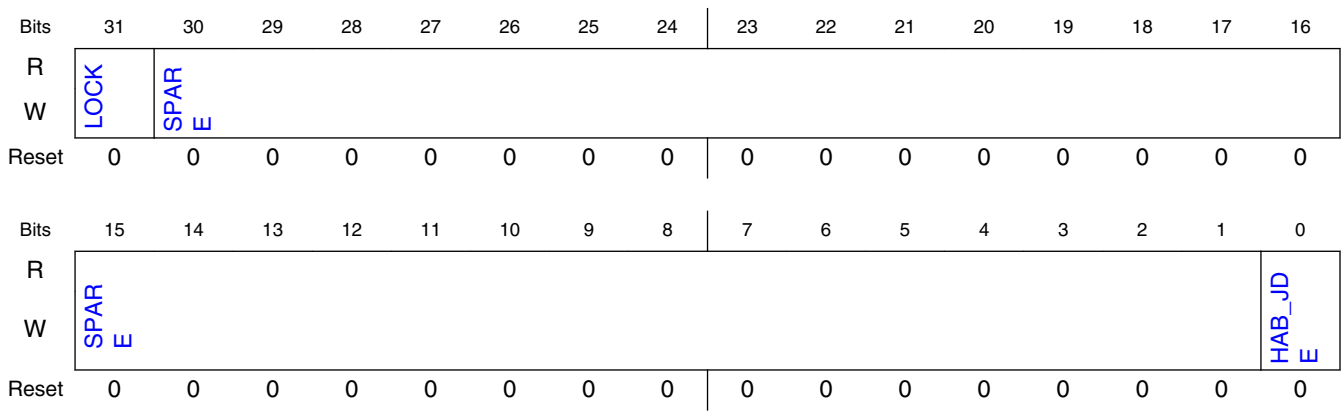
34.7.1.12.1 Offset

Register	Offset
HW_OCOTP_SCS_SET	64h

34.7.1.12.2 Function

This register holds volatile configuration values that can be set and locked by trusted software. All values are returned to their default values after reset. Writing this register will set/clear/reverse all the bits of HW_OCOTP_SCS_SET/CLR/TOG respectively, which are 1 in write data. Other bits will not change. Reading this register will return the value of HW_OCOTP_SCS.

34.7.1.12.3 Diagram



34.7.1.12.4 Fields

Field	Function
31 LOCK	LOCK When set, all the bits in this register are locked and can not be changed through SW programming. This bit is only reset after a reset is issued.
30-1 SPARE	SPARE Unallocated read/write bits for implementation specific software use.
0 HAB_JDE	HAB_JDE HAB JTAG Debug Enable. This bit is used by the HAB to enable JTAG debugging, assuming that a properly signed command to do so is found and validated by the HAB. The HAB must lock the register before passing control to the OS whether or not JTAG debugging has been enabled. Once JTAG is enabled by this bit, it can not be disabled unless the system is reset by reset.

34.7.1.13 OTP Controller Software Controllable Signals Register (HW_OCOTP_SCS_CLR)

34.7.1.13.1 Offset

Register	Offset
HW_OCOTP_SCS_CLR	68h

34.7.1.13.2 Function

This register holds volatile configuration values that can be set and locked by trusted software. All values are returned to their default values after reset. Writing this register will set/clear/reverse all the bits of HW_OCOTP_SCS_SET/CLR/TOG respectively, which are 1 in write data. Other bits will not change. Reading this register will return the value of HW_OCOTP_SCS.
