0 HAB_JDE	HAB_JDE HAB JTAG Debug Enable. This bit is used by the HAB to enable JTAG debugging, assuming that a properly signed command to do so is found and validated by the HAB. The HAB must lock the register before passing control to the OS whether or not JTAG debugging has been enabled. Once JTAG is enabled by this bit, it can not be disabled unless the system is reset by reset.

34.7.1.14 OTP Controller Software Controllable Signals Register (HW_OCOTP_SCS_TOG)

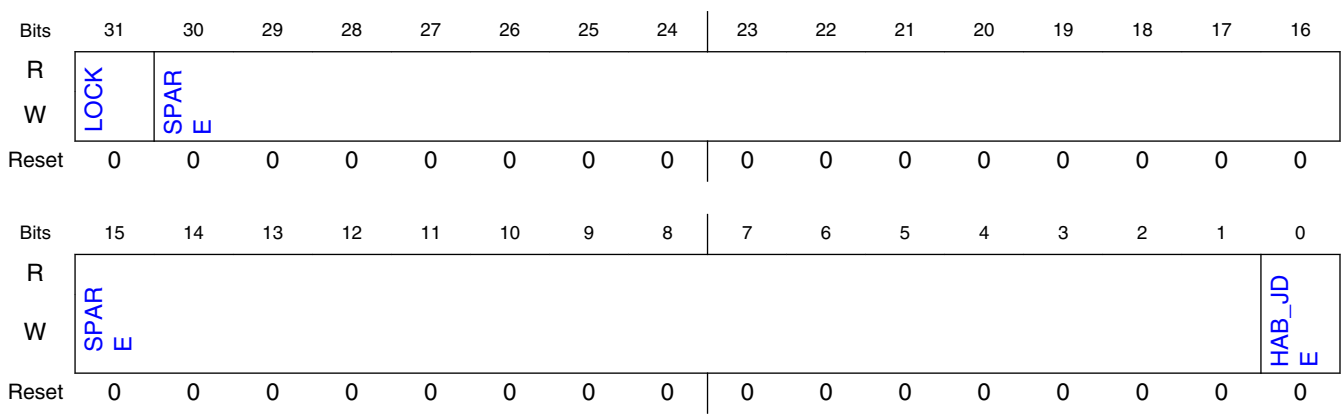
34.7.1.14.1 Offset

Register	Offset
HW_OCOTP_SCS_TOG	6Ch

34.7.1.14.2 Function

This register holds volatile configuration values that can be set and locked by trusted software. All values are returned to their default values after reset. Writing this register will set/clear/reverse all the bits of HW_OCOTP_SCS_SET/CLR/TOG respectively, which are 1 in write data. Other bits will not change. Reading this register will return the value of HW_OCOTP_SCS.

34.7.1.14.3 Diagram



34.7.1.14.4 Fields

Field	Function
31 LOCK	LOCK When set, all the bits in this register are locked and can not be changed through SW programming. This bit is only reset after a reset is issued.
30-1 SPARE	SPARE Unallocated read/write bits for implementation specific software use.

Table continues on the next page...

Field	Function
0 HAB_JDE	HAB_JDE HAB JTAG Debug Enable. This bit is used by the HAB to enable JTAG debugging, assuming that a properly signed command to do so is found and validated by the HAB. The HAB must lock the register before passing control to the OS whether or not JTAG debugging has been enabled. Once JTAG is enabled by this bit, it can not be disabled unless the system is reset by reset.

34.7.1.15 OTP Controller Output Status Register (HW_OCOTP_OUT_STATUS)

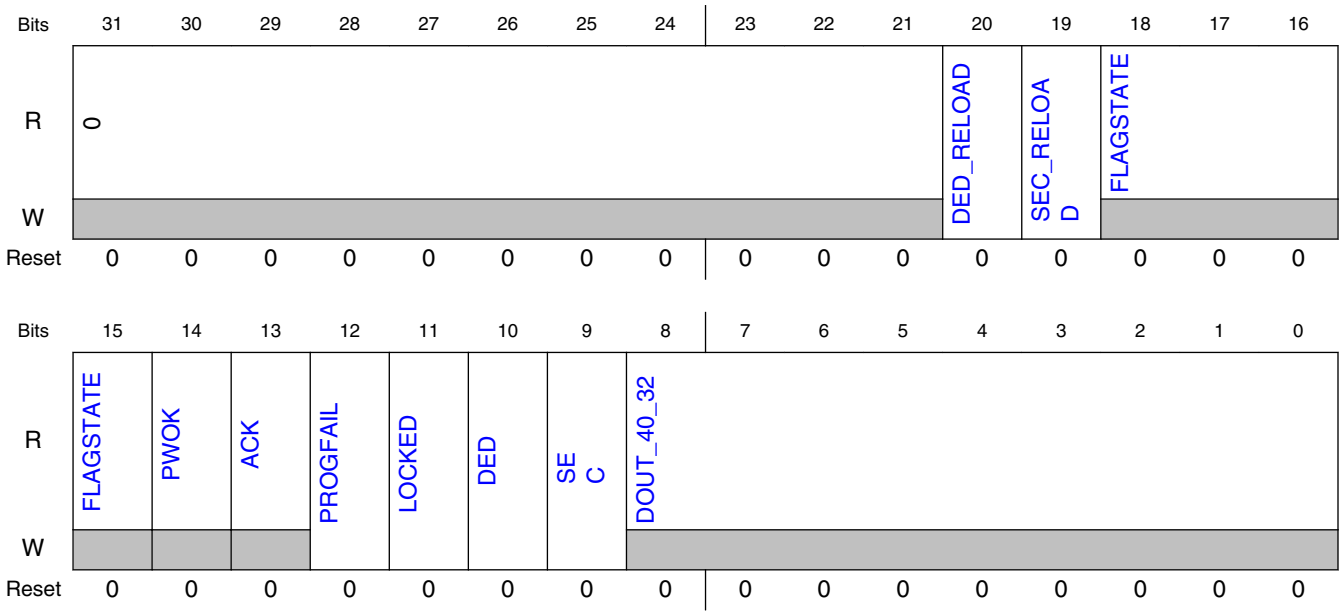
34.7.1.15.1 Offset

Register	Offset
HW_OCOTP_OUT_STATUS	90h

34.7.1.15.2 Function

This register stores output signals of OTP memory for programming and reading OTP memory. Writing this register will set/clear/reverse all the bits of HW_OCOTP_OUT_STATUS_SET/CLR/TOG respectively which are 1 in write data. Other bits will not change. Reading this register will return the value of HW_OCOTP_OUT_STATUS.

34.7.1.15.3 Diagram



34.7.1.15.4 Fields

Field	Function
31-21 —	- Reserved
20 DED_RELOAD	DED_RELOAD Indicates double error detection ever happens in reset reload or reload by setting HW_OCOTP_CTRL[RELOAD_SHADOWS] bit. This bit can only be set by the controller. Reset this bit by writing a 1 to HW_OCOTP_CTRL_CLR[ERROR] and not by a general write.
19 SEC_RELOAD	SEC_RELOAD Indicates single error correction ever happens in reset reload or reload by setting HW_OCOTP_CTRL[RELOAD_SHADOWS] bit.This bit can only be set by the controller. Reset this bit by writing a 1 to HW_OCOTP_CTRL_CLR[ERROR] and not by a general write.
18-15 FLAGSTATE	FLAGSTATE Indicates OTP memory current state.
14 PWOK	PWOK Indicates that power vdd and vdd1 of OTP memory are in operating range.
13 ACK	ACK indicates operation acknowledgement from OTP memory
12 PROGFAIL	PROGFAIL Indicates programming is failed. This bit can only be set by the controller. Reset this bit by writing a 1 to HW_OCOTP_CTRL_CLR[ERROR] and not by a general write.
11 LOCKED	LOCKED

Table continues on the next page...

Field	Function
	Indicates if word is locked or not when programming or reading. When this bit is asserted when programming one fuse word, it means current programming operation is failed since the fuse word is already locked. This bit can only be set by the controller. Reset this bit by writing a 1 to HW_OCOTP_CTRL_CLR[ERROR] and not by a general write.
10 DED	DED Indicates 2 errors have been detected (no correction) when reading one fuse word.This bit can only be set by the controller. Reset this bit by writing a 1 to HW_OCOTP_CTRL_CLR[ERROR] and not by a general write.
9 SEC	SEC Indicates one error has been corrected in data or ECC syndrome when reading one fuse word.This bit can only be set by the controller. Reset this bit by writing a 1 to HW_OCOTP_CTRL_CLR[ERROR] and not by a general write.
8-0 DOUT_40_32	DOUT_40_32 Stored out[40:32] from OTP memory when reading one fuse word.

34.7.1.16 OTP Controller Output Status Register (HW_OCOTP_OUT_STATUS_SET)

34.7.1.16.1 Offset

Register	Offset
HW_OCOTP_OUT_STATUS_SET	94h

34.7.1.16.2 Function

This register stores output signals of OTP memory for programming and reading OTP memory. Writing this register will set/clear/reverse all the bits of HW_OCOTP_OUT_STATUS_SET/CLR/TOG respectively which are 1 in write data. Other bits will not change. Reading this register will return the value of HW_OCOTP_OUT_STATUS.

Chapter 35
Reset and Boot

35.1 Reset

Resetting the device provides a way to start processing from a known set of initial conditions. System reset begins with the on-chip regulators in full regulation and system clocking generation from the internal reference FIRC clock. The CMC[1] and RMC, [1] modules control the reset sequence of the device. There are various reset sources on this device. They can be categorized into three groups:

- Power-On Reset (POR)
- System Reset
- Local Reset

Reset types and their sources are described in more detail in the following sections.

i.MX 7ULP is designed in a way that a POR or System Reset event on the A7 power domain only resets that domain, while a POR or System Reset event on the M4 power domain will reset both power domains.

NOTE

A7 Reset is also mapped as interrupt on M4 domain, so in case A7 Reset must reset M4, it could be done via M4 ISR. Additionally, A7 Reset can automatically affect M4 domain when the A7_TO_M4_RESET_EN fuse is blown.

NOTE

If a reset that only affects the Application domain (that is, does not propagate in any way to the Real Time domain) takes place and the Real Time domain's bus clock is gated (Real Time domain in PSTOP1 or more restrictive modes), then that

1. MSMC, CMC, and RMC are 3 separate but tightly coupled blocks. The memory map documented in MSMC chapter encompasses features related to all 3 blocks, being actually implemented into the CMC block alone. Therefore, there might be some references to CMC and RMC blocks throughout this document.

(Application domain) reset sequence does not conclude. In order to avoid such a scenario, the following two solutions are available:

- Enable the Application domain's reset to propagate to the Real Time domain (by blowing the A7_TO_M4_RESET_EN fuse), or
- Configure Real Time domain to wake up upon an Application domain reset (by setting MU_A CR[RAIE] and properly configuring the corresponding IRQ). Real Time domain can re-enter the mode it was before being woken up by any of these procedures once the Application domain's reset sequence has been concluded (MU_A SR[RS] == 0), if necessary.

35.1.1 Power-On Reset

A Power-On Reset (POR) will reset the entire domain(s) affected by that reset source. All data is lost. A POR event will be initiated by one of the following conditions:

- When power is initially applied to the device.
- When supply voltage has risen above the Low Voltage Detect (LVD) threshold, after the LVD condition was detected. There are four LVD sources that could trigger POR reset:
  - A7 LDO LVD monitor: Trigger POR reset to A7 domain
  - M4 LDO LVD monitor: Trigger POR reset to M4 and A7 domains
  - M4 MEM LDO LVD monitor: Trigger POR reset to M4 and A7 domains
  - PMC POR monitor: Trigger POR reset to M4 and A7 domains

  Following a POR event, the POR and LVD flag bit will be set in the Reset Status register.

35.1.2 System Reset

A system reset can be initiated by one of the following sources:

Table 35-1. M4 system reset sources

Reset source	Reset name	Comments
System_Reset_A7	SYS_RESET_A7	ORed version of all system reset sources from A7. Only enabled when A7_TO_M4_RESET_EN fuse is blown.
Power-On-Reset	POR_M4	—

Table continues on the next page...

Table 35-1. M4 system reset sources (continued)

Reset source	Reset name	Comments
Reset pin (External)	RESET_M4_b	—
Software JTAG	SW_JTAG_RST	The JTAG module generates a system reset when certain IR codes are selected. This functional reset is asserted when EXTEST, HIGHZ and CLAMP instructions are active. The reset source from the JTAG module is released when any other IR code is selected.
WDOG (M4)	WDOG_M4_RST	—
Loss of Clock (LOC)	LOC_EXT_XTL	Loss of Clock on external Crystal
Core Software Reset	SW_RST_M4	Software reset initiated by CM4
CPU Exception	CPU_EXP_M4	—
Low Leakage Wakeup Unit (LLWU)	WAKEUP_M4	Reset due to wakeup from CM4 Power down modes
Stop Mode Ack Error	STOP_ACK_M4	—

Table 35-2. A7 system sources

Reset source	Reset name	Comments
Power-On-Reset	POR_A7	—
Reset pin (External)	RESET_A7_b	—
System_Reset_M4	SYS_RESET_M4	ORed version of all system reset sources from M4
WDOG (A7)	WDOG_A7_RST	—
Core Software Reset	SW_RST_A7	Software reset initiated by CA7
CPU Exception	CPU_EXP_A7	—
Secure WDOG	WDOG_RST	Optional reset
Stop Mode Ack Error	STOP_ACK_A7	—
Power Down Wakeup	VLLS_WAKEUP_A7	Wake-up from VLLS/Power down mode via MU

NOTE

Even though all source clock control logic resides in M4, there could be cases where M4 is running from FIRC clock while A7 is running from XTAL, so A7 must know LOC for MHz Crystal.

The reset pin filter supports filtering from the IP bus clock. In the low power modes when the IP bus clock is not present, this logic either switches to bypass operation or has continued filtering operation depending on the filtering mode selected.

The RMC[2] provides the option for delaying watchdog reset request from either watchdog module. The reset request output from watchdog module will start delay timer. The timer countdown period can be configured during the system start up for a fixed set of options. The default value of the timer countdown period is 0. Upon receiving a watchdog reset request, the RMC will generate a watchdog interrupt to both CPUs. Software cannot cancel the delay timer after it started the countdown. When delay timer reaches 0, the watchdog reset output resets the system.

A System Reset event triggered by an A7 source would reset that power domain. While a System Reset event triggered by an M4 source would reset both domains except for certain components that are not affected by a specific System Reset source.

35.1.3 Local Resets

A variety of resets are generated to reset certain modules or logics of the chip. There are separate resets for each power domain. They are asserted the same way by their respective reset sources with the exception of VLLS wakeup.

Table 35-3. Local Resets

Local Reset	Assertion Sources	Resets What?
VBAT POR	Asserts on a VBAT POR reset source.	Resets only the modules within the VBAT power domain. These VBAT power domain modules are not affected by the other resets.
POR Only	Asserts on the POR reset source only.	Resets the PMC and System Register File.
Chip POR Not VLLS	Asserts on POR and LVD reset sources.	Resets parts of the MSMC and SIM, and also resets some low power peripherals (like LPTMR).
Chip POR	Asserts on POR, LVD, and VLLS Wakeup reset sources.	Resets the Reset Pin Filter registers and parts of the SIM and SCG.
Chip Reset Not VLLS	Asserts on all reset sources except a VLLS Wakeup that does not occur via the RESET_b pin.	Resets parts of the MSMC, LLWU, and other modules that remain powered on during VLLS mode.
Chip	Asserts on all reset sources.	Resets the remaining modules that are not reset by the other MCU reset types.

2. MSMC, CMC, and RMC are 3 separate but tightly coupled blocks. The memory map documented in MSMC chapter encompasses features related to all 3 blocks, being actually implemented into the CMC block alone. Therefore, there might be some references to CMC and RMC blocks throughout this document.

35.2 System boot

35.2.1 Overview

There are two ROMs on i.MX 7ULP: one running on Cortex-A7 core and another on Cortex-M4 core.

The A7 and M4 processors on i.MX 7ULP start booting from a power on reset. The M4 core always starts first and holds off the A7 core until the M4 core determines the boot modes from BOOT_MODE[1:0] pin settings and boot configurations from boot configuration pin/fuses settings. The boot ROMs support features such as: selectable boot sources, setting device configurations and secure boot. The boot ROMs are responsible for reading the settings of boot pins (boot mode pins and boot configuration pins) and OTP values to determine the behavior of the boot flow.

The main features of the ROMs include:

- Support for booting from various boot devices
- Serial downloader support (USB OTG, A7 ROM only)
- Device configuration data (DCD) and plugin
- Digital signature and encryption based High Assurance Boot (HAB)
- Wake-up from low power modes

The boot ROM supports the following boot devices:

- QuadSPI flash for M4 ROM
- SD/eMMC for A7 ROM.

Both boot ROMs use the state of BOOT_MODE and eFUSEs to determine the boot device. For development purposes, eFUSEs used to determine the boot device may be overridden by using GPIO pin inputs (boot configuration pins).

The device configuration data (DCD) feature allows boot ROM code to obtain SOC configuration data from an external Program Image residing on the boot device. As an example, DCD can be used to program the DDR controller for optimal settings improving the boot performance. DCD is restricted to memory areas and peripheral addresses that are considered essential for boot purposes (see Write Data Command).

A key feature of the boot ROM is the ability to perform a secure boot or High Assurance Boot (HAB). This is supported by the HAB security library which is a subcomponent of the ROM code. HAB uses a combination of hardware and software together with a Public Key Infrastructure (PKI) protocol to protect the system from executing unauthorized programs. Before the HAB allows a user's image to execute, the image must be signed. The signing process is done during the image build process by the private key holder and

the signatures are then included as part of the final Program Image. If configured to do so, the ROM verifies the signatures using the public keys included in the Program Image. In addition to supporting digital signature verification to authenticate Program Images, Encrypted boot is also supported. Encrypted boot can be used to prevent cloning of the Program Image directly off the boot device. A secure boot with HAB can be performed on all boot devices supported on the chip in addition to the Serial Downloader. The HAB library in the boot ROM also provides API functions, allowing additional boot chain components (bootloaders) to extend the secure boot chain. The out-of-fab setting for SEC_CONFIG is the Open configuration in which the ROM/HAB performs image authentication, but all authentication errors are ignored and the image is still allowed to execute.

NOTE

For details on security features, see i.MX 7ULP Security Reference Manual

35.2.2 High level description of Boot: Boot mode and boot flow

35.2.2.1 Boot modes

The boot sequence on i.MX 7ULP is determined and controlled through the following mechanisms:

- **BOOT_MODE [1:0]**: Type of boot is controlled by the boot mode pins "BOOT_MODE [1:0]" sampled at exit of reset (stored in Boot Mode Register in CMC [3] module). The available boot modes are: Boot From Fuses, serial boot via USB, and Internal Boot. See the table below for settings.

Table 35-4. i.MX 7ULP boot modes

BOOT_MODE[1:0]	Boot Mode	Boot details
00	Boot from fuses	Boot Configuration is loaded from fuse instead of boot configuration pins. If BT_FUSE_SEL=0, boot flow will jump to Serial Downloader.

Table continues on the next page...

3. MSMC, CMC, and RMC are 3 separate but tightly coupled blocks. The memory map documented in MSMC chapter encompasses features related to all 3 blocks, being actually implemented into the CMC block alone. Therefore, there might be some references to CMC and RMC blocks throughout this document.

Table 35-4. i.MX 7ULP boot modes (continued)

BOOT_MODE[1:0]	Boot Mode	Boot details
01	Serial Downloader	A7 core will go into USB serial download mode (by SDP protocol), as a high-speed, HID device. M4 core will go into an endless loop.
10	Internal Boot Mode	• BT_FUSE_SEL=1 : Additional Boot configuration will be loaded from fuses. • BT_FUSE_SEL=0 : Additional Boot configuration will be loaded from GPIO. This mode is intended for development only.
11	Reserved	—

- Additional boot configuration is obtained via either programmable e-fuses or by pins value sampled during reset. The boot pins are sampled one CM4 bus clock cycle before the RESET0_b/RESET1_b signal is de-asserted. The selection between the two options, is done based on the value of BT_FUSE_SEL fuse, as follows.
  - In case BT_FUSE_SEL is blown, all boot options are configured by efuses. Boot ROM code software may read the values from the Boot Mode Register, or from the e-fuses, via the OCOTP_CTRL module.
  - In case BT_FUSE_SEL is left unblown and BOOT_CFG[1:0]=01 or 10, the various boot options are determined by sample of dedicated pins at the exit of reset. Every e-fuse option is overridden with a dedicated pin(s), such that same functionality is available for both boot options. See the fuse map attached with this reference manual for boot option pins. For this case, regardless of fuse values, Boot ROM code must read the options' values from Boot Mode Register of the CMC[3] module.

NOTE

Boot pins, including Boot Mode pins and Boot Config pins, are sampled and stored into CMC Mode register on every cold reset (POR, VLLS exiting, etc). After these input pins are sampled, their subsequent state does not affect the contents of the CMC Mode register. Specifically, Boot Mode pins and M4 ROM Boot Config pins (BT0_CFG0-15) are sampled on every M4 domain reset and the A7 ROM Boot Config pins (BT1_CFG0-15) are sampled on every A7 domain reset.

35.2.2.1.1 Boot From Fuses Mode (BOOT_MODE[1:0] = 00b)

A value of 00b in the BOOT_MODE[1:0] register selects the Boot From Fuses mode.

This mode is similar to the Internal Boot mode described in Internal Boot Mode (BOOT_MODE[1:0] = 0b10) with one difference. In this mode the GPIO boot override pins are ignored. The boot ROM code uses the boot eFUSE settings only. This mode also supports a secure boot using HAB.

If set to Boot From Fuses, the boot flow is controlled by the BT_FUSE_SEL eFUSE value.

- If BT_FUSE_SEL = 0, indicating that the boot device (for example, Flash, SD/MMC) has not yet been programmed, the boot flow jumps directly to the Serial Downloader.
- If BT_FUSE_SEL = 1, the normal boot flow is followed, where the ROM attempts to boot from the selected boot device.

The first time a board is used, the default eFUSEs may be configured incorrectly for the hardware on the platform, or most likely, boot fuses not been blown. In such a case, the Boot ROM code may try to boot from a device that does not exist. This may cause an electrical/logic violation on some pads. Using Boot From Fuses mode addresses this problem.

Setting BT_FUSE_SEL=0 in Boot From Fuse Mode forces the ROM code to jump directly to the Serial Downloader. This allows a bootloader to be downloaded which can then provision the boot device with a Program Image and blow the BT_FUSE_SEL and the other boot configuration eFUSEs. After reset, the Boot ROM code determines that BT_FUSE_SEL is blown (BT_FUSE_SEL = 1) and the ROM code performs internal boot according to the new eFUSE settings. This allows a user to set BOOT_MODE[1:0]=00b on a production device and burn fuses on the same device (by forcing entry to the Serial Downloader), without changing the value of BOOT_MODE[1:0] or pullups/pulldowns on the BOOT_MODE pins.

35.2.2.1.2 Serial downloader

The Serial Downloader provides a means to download a Program Image to the chip over USB connection, usually for the manufacturing scenario.

In this mode, A7 ROM programs WDOG1 for a time-out specified by fuse WDOG Timeout Select (See attached fuse map for details) if WDOG_ENABLE eFuse is 1 and continuously polls for USB connection. If no activity is found on USBOTG2 and the watchdog timer expires, the A7 core is reset. If valid SDP command be received by A7 ROM though USB, A7 ROM will execute them. Note that some SDP commands can be disabled by fuse (SDP_READ_DISABLE), some may need authentication if HAB closed (for SDP_JUMP), and USB SDP feature can be totally disabled by fuse SDP_DISABLE.

NOTE

After being loaded, the downloaded image is responsible to manage the watchdog resets properly if the watchdog been ever enabled.

NOTE

Serial Downloader is available on A7 ROM only, and available on USBOTG2 only.

The following figure shows the USB serial download boot flow.

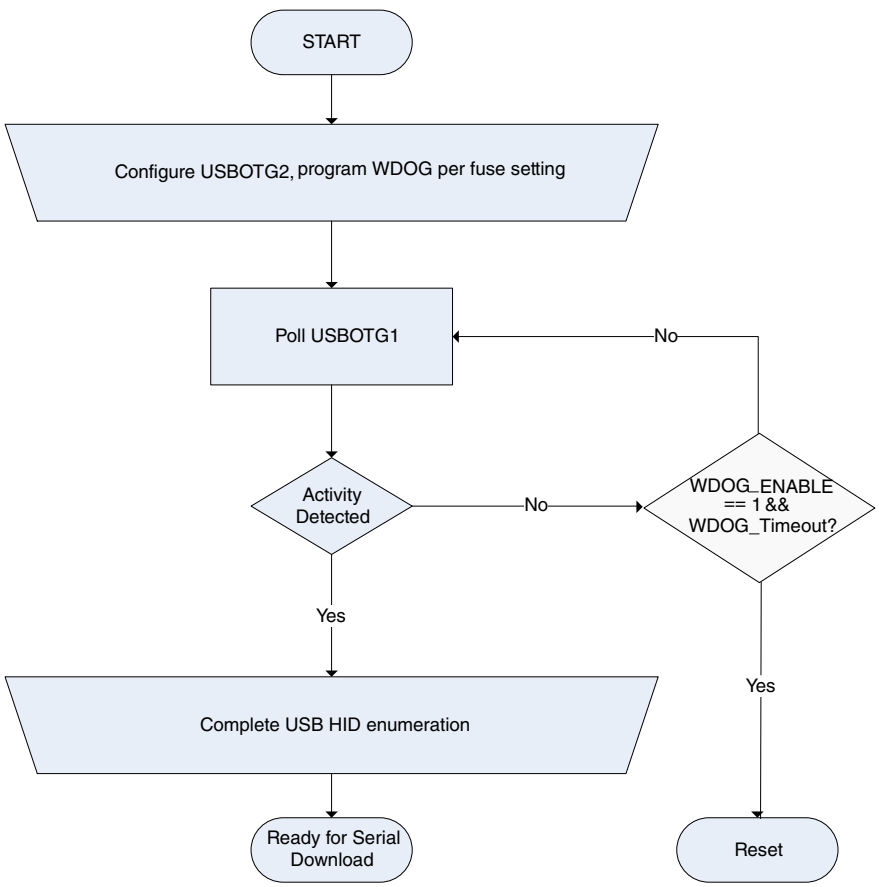

Figure 35-1. Serial download sequence

35.2.2.1.3 Internal Boot Mode (BOOT_MODE[1:0] = 0b10)

A value of 0b10 in the BOOT_MODE[1:0] register selects the internal boot mode. In this mode, the processor continues to execute boot code from the internal boot ROM. The boot code performs hardware initialization, loads the Program Image from the chosen boot device, performs image validation using the HAB library (see Boot security

settings), and then jumps to an address derived from the Program Image. If any error occurs during internal boot, the boot code jumps to the Serial Downloader (see Serial downloader). A secure boot using the HAB is possible in all the three boot modes.

When set to internal boot, the boot flow may be controlled by a combination of eFUSE settings with an option of overriding the fuse settings using General Purpose I/O (GPIO) pins. The GPIO Boot Select FUSE (BT_FUSE_SEL) determines whether the ROM uses GPIO pins for a select number of configuration parameters or eFUSEs in this mode. See Table 35-6 for more details.

- If BT_FUSE_SEL = 1, all boot options are controlled by the eFUSEs described in Table 35-6
- If BT_FUSE_SEL = 0, specific boot configuration parameters may be set using GPIO pins rather than eFUSEs. The fuses that can be overridden when in this mode are indicated in the GPIO column of Table 35-6. See Table 35-8 for GPIO overrides.

The use of GPIO overrides is intended for development since these pads are used for other purposes in deployed products. NXP recommends controlling the boot configuration by eFUSEs in deployed products and reserving the use of the GPIO mode for development and testing purposes only.

35.2.2.2 Boot flow

35.2.2.2.1 M4 boot flow

The M4 processor starts booting from the internal ROM and initializes the QSPI controller for booting from serial flash memory. Any errors occurring during this boot procedure will lead to serial download via the designated interface.

35.2.2.2.2 A7 boot flow

The A7 processor starts booting from the internal ROM and initializes the memory controller for the selected memory device. Any errors occurring during this boot procedure will lead to serial download via the designated interface.

35.2.2.2.3 Boot flow configurations

Depending on the setting of BT0_CFG [1:0], there are three different boot flows on i.MX 7ULP, listed in the table below.

Table 35-5. Boot flow configuration

BT0_CFG[1:0]	Boot Flow	Description
00	Single Memory Boot	• M4 ROM kicks A7 (lets A7 core start to run) and waits until M4 image been provisioned by A7 image. • A7 ROM loads A7 image from eMMC/SD, then A7 image loads M4 image and sets M4 entry point.
x1	Low Power Boot	M4 ROM will not kick A7 domain in this mode.
10	Dual Memory Boot	The M4 loads from the serial flash through the QSPI interface, and the A7 starts (Kicked by M4 ROM) loading from the eMMC/SDmemory through the uSDHC0/1 interface

35.2.2.2.3.1 Dual memory boot

In this boot mode, the two processors on i.MX 7ULP boot independently of each other, except for any software-imposed handshaking inserted explicitly to synchronize the process. The M4 loads from the serial flash through the QSPI interface, and the A7 starts loading from the eMMC memory through the uSDHC0 interface.

Under normal operation, each of the two processors boots using the High-Assurance Boot (HAB) contained within each of their boot ROMs. The HAB verifies the authenticity of the code in external memory, then allows it to execute. i.MX 7ULP also supports an HAB-bypass mode in which the processors can boot directly from external memory.

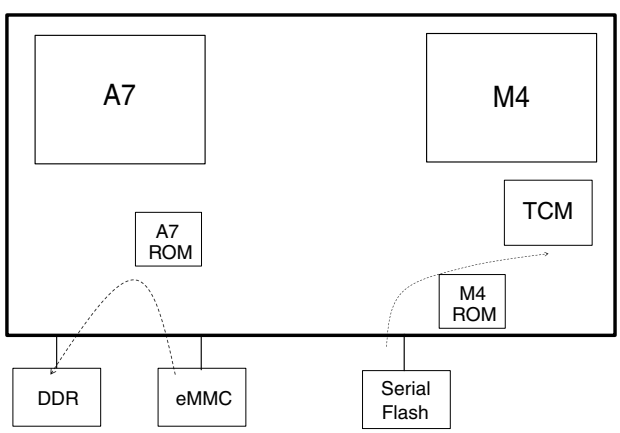

Figure 35-2. Dual Memory Boot

35.2.2.2.3.2 Single memory boot

The A7 core loads the M4 core in this mode.

1. The A7 will start loading from the eMMC memory.
2. The A7 loads the M4 internal memory and starts the M4 once it is ready.
3. If HAB is enabled, the A7 ROM will verify the authenticity of M4 code and its code.

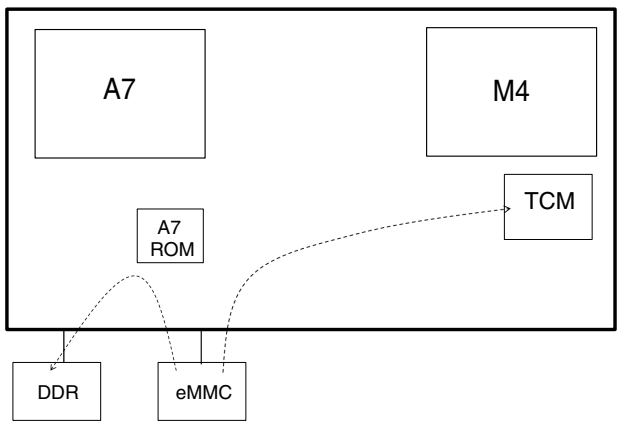

Figure 35-3. Single Memory Boot

35.2.2.2.3.3 Low power boot

In Low Power Boot boot mode, only the M4 core will boot up and run on the FIRC clock frequency to conserve battery energy. The boot sequence of the M4 in Lower Power Boot is similar to its normal boot sequence, except the processor, bus, and peripherals operate on the FIRC clock or a divided version of the FIRC clock.

35.2.2.3 Boot security settings

Following are the boot security settings specified by SEC_CONFIG[1:0]/ FIELD_RETURN fuses and provisioning the chip life cycle. For more details on security features and security fuses, see the i.MX 7ULP Security Reference Manual.

Available boot security settings include:

- **Closed**: This level is intended for use with shipping secure products. All HAB functions are executed and security hardware is initialized (the Security Controller, or SNVS, enters Secure state), DCD is processed if present, and the program image is authenticated by HAB prior to its execution. All detected errors will be logged, and

the boot flow aborted with control passing to the serial downloader (For M4 ROM, control passing to endless loop). At this level, execution does not leave the internal ROM unless the target executable image has been authenticated.

- **Open**: This level is intended for use in non-secure products or during the development phases of a secure product. All HAB functions are executed as for a closed device. Security hardware is initialized (except the SNVS is left in Non-Secure state), DCD is processed if present, and the program image is authenticated by HAB prior to its execution. All detected errors will be logged, but have no influence on the boot flow, which continues as if the errors did not occur. This configuration is useful for secure product development, since the Program Image will run even if the authentication data is missing or incorrect, and the error log can be examined to determine the cause of authentication failure.
- Field Return: This level is intended for parts returned from shipped products.

NOTE

If the DIR_BT_DIS eFuse is not blown, authentication may be bypassed. In this case the system is not secure.

35.2.3 Boot configuration and eFuse

This section describes the external inputs that control the behavior of the Boot ROM code. This includes boot device selection, boot device configuration (SD bus width, speed, etc.), and so on. In general, the source for this configuration comes from eFUSEs embedded inside the chip. However, certain configuration parameters can be sourced from GPIO pins allowing further flexibility during the development process.

35.2.3.1 Boot eFuse description

All Boot eFuses are included in fuse map attached with this Reference Manual or i.MX 7ULP Security Reference Manual. Here is a comprehensive list of the configuration parameters that the ROM uses.

Table 35-6. Configuration parameters or eFUSEs used by ROM1

FUSE	Definition	GPIO	Shipped Value	Settings
A7 LDO Enable	Once blown, M4 ROM will enable A7 LDO by setting PMC_0_CTRL[LDOEN] bit when kicking A7. This fuse value shall be aligned with power design of the board.	N	0	0—Disable 1—Enable

Table continues on the next page...

Table 35-6. Configuration parameters or eFUSEs used by ROM1 (continued)

M4_LOW_FREQ_BT		N	0	0—Normal frequency 1—Half frequency
A7_LOW_FREQ_BT		N	0	0—Normal frequency 1—Half frequency
A7 D Cache Disable	If blown, A7 ROM will not enable D-cache/MMU when authenticating image.	N	0	0—Enable 1—Disable
M4 D Cache Disable	If blown, M4 ROM will not enable D-cache when authenticating image.	N	0	0—Enable 1—Disable
WDOG Timeout Select	To select WDOG timeout value, valid when WDOG_ENABLE been blown.	N	0	00—32s 01—16s 10—8s 11—4s Others—0.5s
A7 WDOG_ENABLE		N	0	0—Disabled 1—Enabled
M4 WDOG_ENABLE		N	0	0—Disabled 1—Enabled
A7 I-Cache Disable		N	0	0—Enable 1—Disable
M4 I-Cache Disable		N	0	0—Enable 1—Disable
LP Boot		Y	0	0—No Low Power Boot 1—Boot from M4 with A7 on demand
Dual Boot		Y	0	0—Boot from eMMC 1—Boot from A7/eMMC and M4/QSPI
Infinite-Loop (Debug use only)	This is for debug purpose only, and can be disabled if DIR_BT_DIS been blown.	Y	0	0—Disable 1—Enable
M4 boot interface		Y	0	0—QSPI Others—reserved for future use
External OSC Freq Selection	**NOTE:** This setting must be aligned with the frequency of external OSC on the board, otherwise the BootROM may not work properly.	Y	0	00—24 MHz 01—30 MHz 10—19.2 MHz 11—26 MHz
uSDHC device type		Y	0	0—eMMC 1—SD

Table continues on the next page...

Table 35-6. Configuration parameters or eFUSEs used by ROM1 (continued)

A7 boot interface		Y	0	000—uSDHC0 001—uSDHC1 Others—reserved
SEC_CONFIG[0]	Security Configuration as defined in Boot security settings	N	1	SEC_CONFIG[1:0] mapping: 00—Reserved 01—Open (allows any program image, even if authentication fails) 1x—Closed (Program image executes only if authenticated)
SEC_CONFIG[1]		N	0	
DIR_BT_DIS	Disables the NXP reserved modes	N/A	0	0—The reserved NXP modes are enabled. 1—The reserved NXP modes are disabled. This fuse must be blown for normal operation.
BT_FUSE_SEL	In internal Boot mode • BOOT_MODE[1:0] = 10, the BT_FUSE_SEL fuse determines whether the boot settings indicated by a Yes in the GPIO column are controlled by GPIO pins or eFUSE settings in the On-Chip OTP Controller(OCOTP). In Boot From Fuse mode • BOOT_MODE[1:0] = 00, BT_FUSE_SEL fuse indicates whether bit configuration eFuses have been programmed .	N	0	If BOOT_MODE[1:0] = 0b10 • 0—Bits of SBMR are overridden by GPIO pins. • 1—Specific bits of CMC0_MODE[15:0] and CMC1_MODE[15:0] are controlled by eFUSE settings If BOOT_MODE[1:0] = 0b00 • 0—BOOT configuration eFuses are not yet programmed. Boot flow jumps to downloader • 1—BOOT configuration eFuses have been programmed. Regular boot flow is performed. .
SOSC Source Selection	To select the source of SOSC	N	0	0—Crystal 1—External Clock generator

1. See the attached fusemap for more details.

NOTE

See Boot Device section for the detail of fuses relevant to the device.

The following table presents the recommended settings for the lock fuses.

Table 35-7. Recommended settings for lock fuses

Fuse name	Number of fuses	Fuse function	Settings
BOOT_CFG_LOCK	2	Perform lock on BOOT related fuses	00—Unlock (The controlled field can be read, sensed, burned or overridden in the corresponded IIM register) x1—Lock (Overwrite Protect) 1x—Lock (Write Protect)
GPR9_LOCK	1	Lock for General Purpose fuse register #1 (GP9)	0—Unlock (The controlled field can be read, sensed, burned or overridden in the corresponded IIM register) 1—Lock (Write Protect, Overwrite Protect)
GPR8_LOCK	1	Lock for General Purpose fuse register #1 (GP8)	0—Unlock (The controlled field can be read, sensed, burned or overridden in the corresponded IIM register) 1—Lock (Write Protect, Overwrite Protect)
GPR7_LOCK	1	Lock for General Purpose fuse register #1 (GP7)	0—Unlock (The controlled field can be read, sensed, burned or overridden in the corresponded IIM register) 1—Lock (Write Protect, Overwrite Protect)
GPR6_LOCK	1	Lock for General Purpose fuse register #1 (GP6)	0—Unlock (The controlled field can be read, sensed, burned or overridden in the corresponded IIM register) 1—Lock (Write Protect, Overwrite Protect)
PMU_LOCK	2	Lock for Banks 10 and 28 fuses	00—Unlock (The controlled field can be read, sensed, burned or overridden in the corresponded IIM register) x1—Lock (Write Protect) 1x—Lock (Overwrite Protect) **NOTE:** PMU_LOCK is not locked by NXP and must be locked by the user if required.
ANALOG_LOCK	2	Lock for USB_VID, USB0_PID, USB1_PID fuses	00—Unlock (The controlled field can be read, sensed, burned or overridden in the corresponded IIM register) x1—Lock (Write Protect)

Table continues on the next page...

Table 35-7. Recommended settings for lock fuses (continued)

Fuse name	Number of fuses	Fuse function	Settings
			1x—Lock (Overwrite Protect)
PAD_MISC_LOCK	2	Lock for PAD_SETTINGS, PT*_RANGE_CONTROL_RST_VALUE fuses	00—Unlock (The controlled field can be read, sensed, burned or overridden in the corresponded IIM register) x1—Lock (Write Protect) 1x—Lock (Overwrite Protect)

35.2.3.2 Boot configuration

Each of the CM4 and CA7 domains of i.MX 7ULP includes 16 boot configuration pins that can be used to load boot configuration during "*Boot from Pins*" mode (BOOT_MODE [1:0] = "10")

Table 35-8. GPIO override assignments

M4 Boot Configuration Pins		**A7 Boot Configuration Pins**	
GPIO	*Boot Configuration*	*GPIO*	*Boot Configuration*
PTA0	BT0_CFG0	PTF0	BT1_CFG0
PTA1	BT0_CFG1	PTF1	BT1_CFG1
PTA2	BT0_CFG2	PTF2	BT1_CFG2
PTA3	BT0_CFG3	PTF3	BT1_CFG3
PTA4	BT0_CFG4	PTF4	BT1_CFG4
PTA5	BT0_CFG5	PTF5	BT1_CFG5
PTA6	BT0_CFG6	PTF6	BT1_CFG6
PTA7	BT0_CFG7	PTF7	BT1_CFG7
PTA8	BT0_CFG8	PTF8	BT1_CFG8
PTA9	BT0_CFG9	PTF9	BT1_CFG9
PTA10	BT0_CFG10	PTF10	BT1_CFG10
PTA11	BT0_CFG11	PTF11	BT1_CFG11
PTA12	BT0_CFG12	PTF12	BT1_CFG12
PTA13	BT0_CFG13	PTF13	BT1_CFG13
PTA14	BT0_CFG14	PTF14	BT1_CFG14
PTA15	BT0_CFG15	PTF15	BT1_CFG15
SEC_CONFIG[0]	BT0_CFG16	SEC_CONFIG[0]	BT1_CFG16
SEC_CONFIG[1]	BT0_CFG17	SEC_CONFIG[1]	BT1_CFG17
Reserved	BT0_CFG18	Reserved	BT1_CFG18
DIR_BT_DIS	BT0_CFG19	DIR_BT_DIS	BT1_CFG19

Table continues on the next page...

Table 35-8. GPIO override assignments (continued)

BT_FUSE_SEL	BT0_CFG20	BT_FUSE_SEL	BT1_CFG20
Reserved	BT0_CFG21	Reserved	BT1_CFG21
Reserved	BT0_CFG22	Reserved	BT1_CFG22
Reserved	BT0_CFG23	Reserved	BT1_CFG23
Reserved	BT0_CFG24	Reserved	BT1_CFG24
Reserved	BT0_CFG25	Reserved	BT1_CFG25
Reserved	BT0_CFG26	Reserved	BT1_CFG26
Reserved	BT0_CFG27	Reserved	BT1_CFG27
Reserved	BT0_CFG28	Reserved	BT1_CFG28
Reserved	BT0_CFG29	Reserved	BT1_CFG29
BOOT_MODE[0]	BT0_CFG30	BOOT_MODE[0]	BT1_CFG30
BOOT_MODE[1]	BT0_CFG31	BOOT_MODE[1]	BT1_CFG31

Each individual domain includes 32 boot configurations bits (BT0[1]_CFG[31:0]. When the “boot from Pins” is selected BT0[1]_CFG[15:0] always default to taking the values from the pins while rest of the boot configuration (BT0[1]_CFG[31:16]) always come from fuses irrespective of state of BOOT_MODE[1:0].

BT0_CFG[15:0] is mapped to PTA[15:0] that is part of CM4 power domain. BT1_CFG [15:0] is mapped to PTF[15:0] that is part of CA7 power domain. This ensures that when CA7 domain is powered gated, M4 can still boot and load boot configuration from its individual pins(PTA[15:0]).

NOTE

BOOT_MODE [1:0] pins apply to both CM4/CA7 domain, however the value of BOOT_MODE [1:0] should always be consistent between both the domains. For the cases where CA7 exits from power down mode, internal logic will ignore the values on the BOOT_MODE [1:0] pins and would rather latch the values from CM4 domain. Specific to Boot_mode[1:0] = “10” individual boot configuration (BT1[15:0]) for CA7 will still come from the pins(PTF[14:0]).

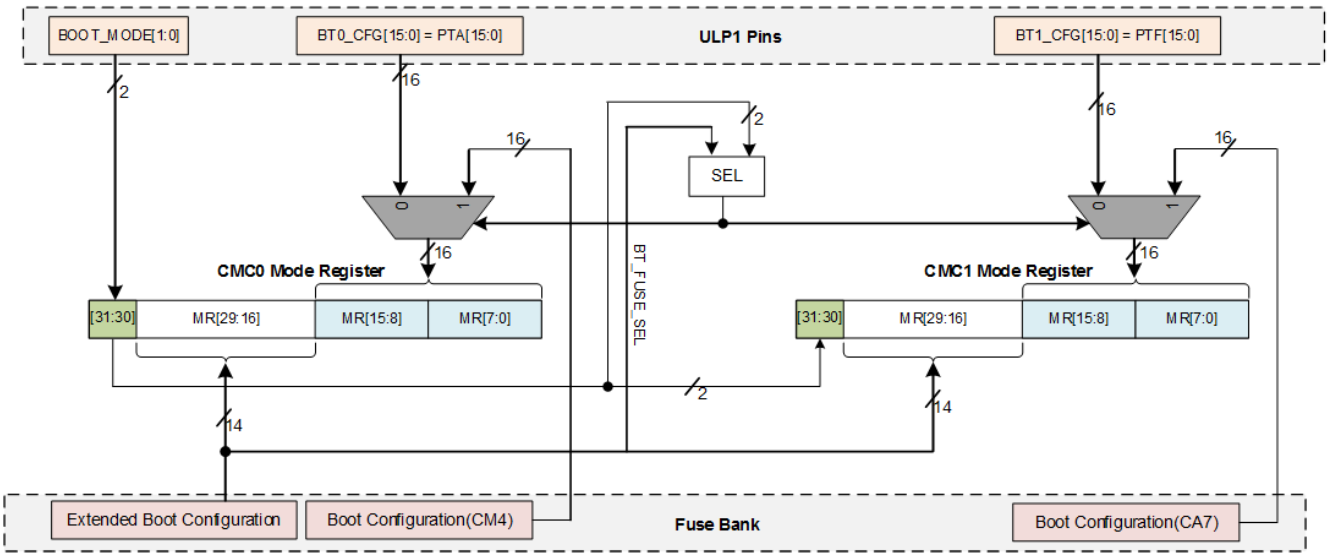

Figure 35-4. Boot configuration

35.2.4 Platform initialization in ROM

This section describes the details on the ROM and provides initialization details. This includes details on:

- The ROM Memory Map
- The RAM Memory Map
- On-chip blocks that the ROM should make use of or change POR register default values
- Clock options
- MMU/cache/LMEM
- Exception handling and interrupt handling

35.2.4.1 Internal ROM/RAM memory map

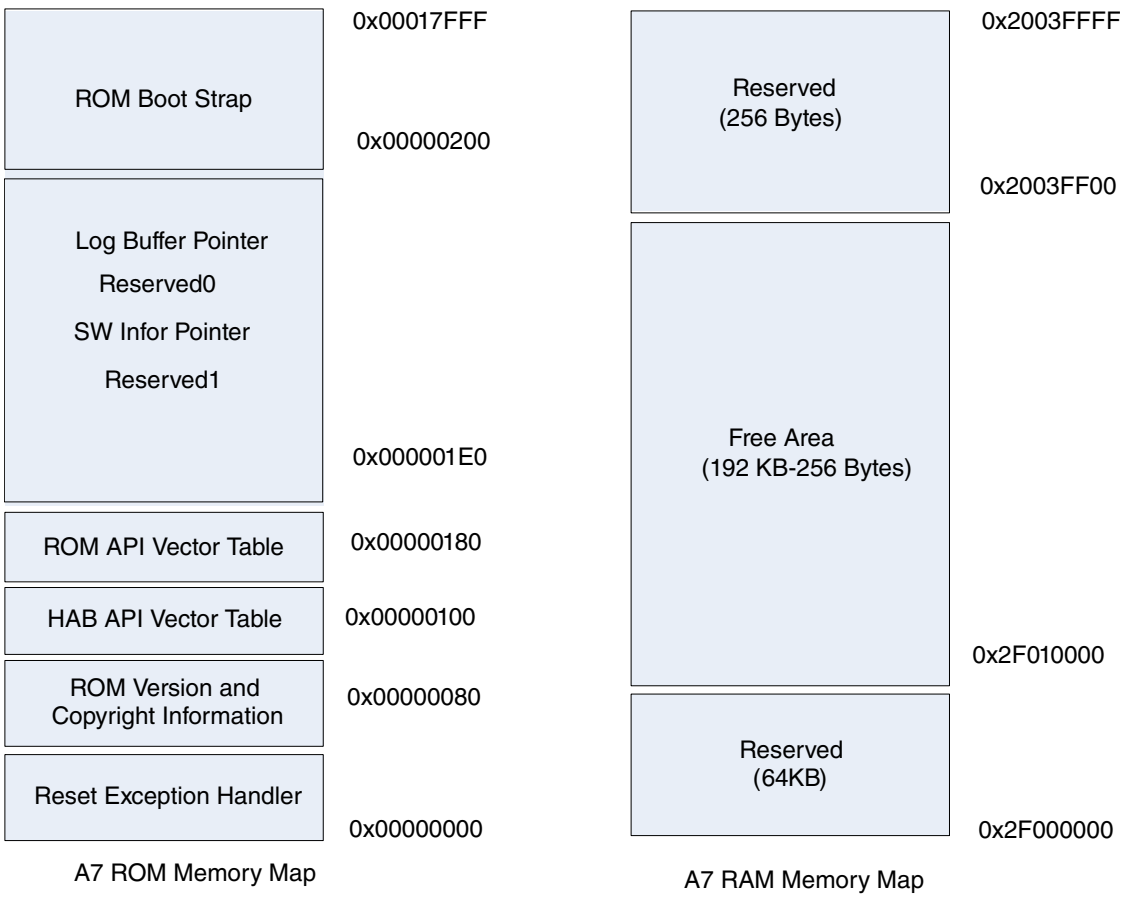

Figure 35-5. A7 ROM/RAM memory layout

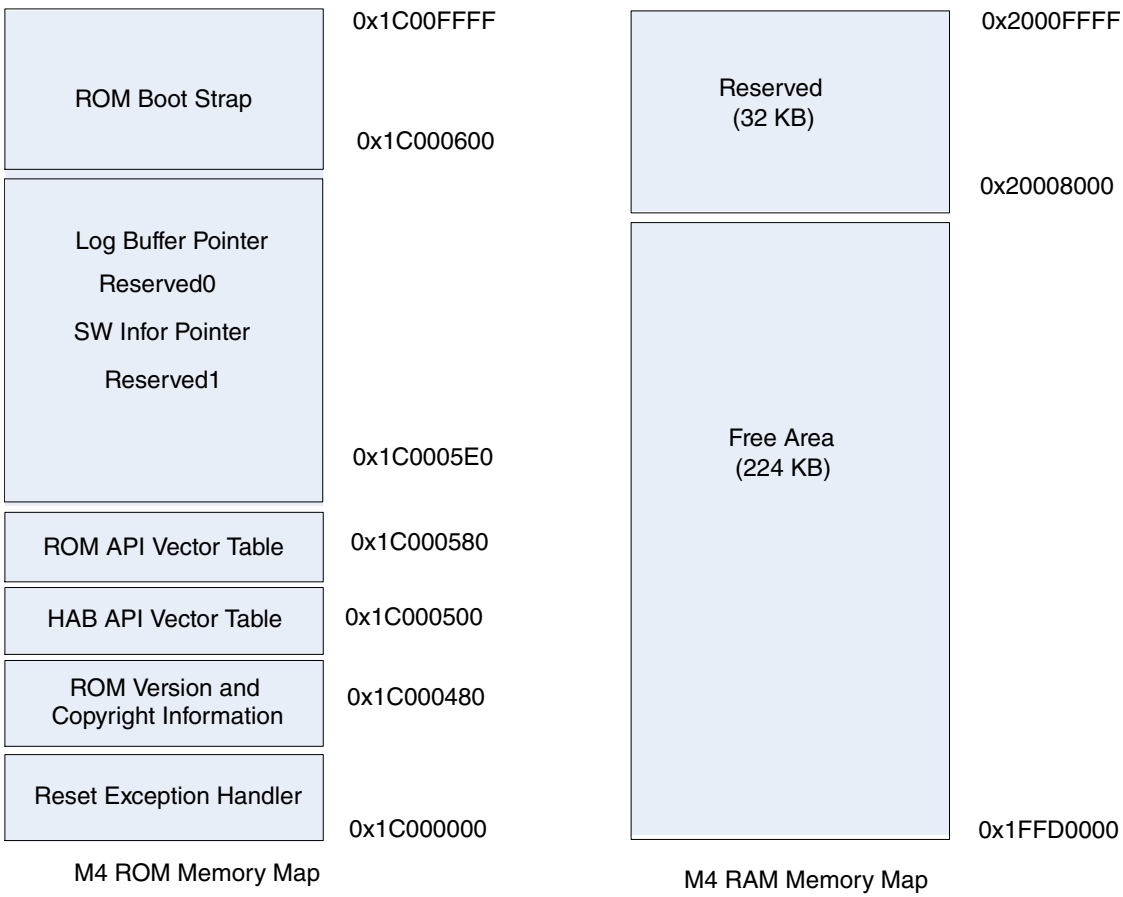

Figure 35-6. M4 ROM/RAM memory layout

NOTE

For both M4 and A7, the entire RAM region (including the reserved RAM) can be freely used after boot in case ROM/HAB APIs are not being called in a post boot stage. Special attention need to be paid in M4 suspend/resume case: If M4 application uses reserved RAM, it needs to back up the reserved RAM on suspend and restore them on resume, because ROM will overwrite the reserved RAM on resume.

35.2.4.2 Boot block activation

The boot ROM affects a number of different hardware blocks which are activated and play a vital role in the boot flow. The ROM configures and uses the following blocks during the boot process. Note that the blocks actually used depend on the boot mode and boot device selection.

Following is the list of blocks used by M4 ROM:

- IOMUXC - I/O Multiplexer Control
- LMEM - Local Memory Controller
- QuadSPI - QuadSPI Flash controller
- OTFAD – On-the-fly AES Decryptor
- WDOG-0 - Watchdog Timer
- CMC0 - Core Mode Controller
- SCG0 – System Clock Generator
- LPSPI – Low Power Serial Peripheral Interface
- RGPIO2P – Rapid General-Purpose Input and Output with 2 Ports
- SIM - System Integration Module
- OCOTP - On-Chip One-Time-Programmable Controller
- SNVS - Secure Non-Volatile Storage

Following is the list of blocks used by A7 ROM:

- IOMUXC - I/O Multiplexer Control
- CAAM - Cryptographic Acceleration and Assurance Module
- CMC1 - Core Mode Controller
- SCG1 – System Clock Generator
- USBOTG2 - Used for serial download of a boot device provisioning program
- USDHC - Ultra Secure Digital Host Controller
- WDOG-1 - Watchdog Timer
- LPSPI – Low Power Serial Peripheral Interface
- RGPIO2P – Rapid General-Purpose Input and Output with 2 Ports
- SIM - System Integration Module
- OCOTP - On-Chip One-Time-Programmable Controller

35.2.4.3 Boot clock options

i.MX 7ULP defaults to 48 MHz FIRC as the initial boot clock as an option for low power boot. However, hardware allows additional options to clock the system slower to reduce the boot clock frequency to be able to provide further options to the application if low power becomes higher priority than boot time.

Table 35-9. M4 boot clock options

Boot Mode	Clock Source (Fuse)	QSPI_DIV(part of IP)	Fuse Controls[1] (Fuse/Dividers)	M4 Core/ System	QSPI Clock	Notes
LP Boot[2]	FIRC (48 MHz)	Div 1, 2, or 4	DIVCORE = 0	48 MHz/48 MHz	12/24/48 MHz	3
LP Boot	FIRC (48 MHz)	Div 1, 2, or 4	DIVCORE =1	24 MHz/24 MHz	12/24/48 MHz	3

Table continues on the next page...

Table 35-9. M4 boot clock options (continued)

Boot Mode	Clock Source (Fuse)	QSPI_DIV(part of IP)	Fuse Controls[1] (Fuse/Dividers)	M4 Core/ System	QSPI Clock	Notes
LP Boot	FIRC (48 MHz)	Div 1, 2, or 4	DIVCORE =0	48 MHz/48 MHz	12/24/48 MHhz	3
LP Boot	FIRC(48 MHz)	Div 1, 2, or 4	DIVCORE =1	24 MHz/24 MHz	12/24/48 MHz	3
Dual/Single Boot[4], [5]	SPLL[PFD0] (246 MHz)	Div 1 or 2	M4_LOW_FREQ_BT =0 DIVCORE=1 (DIV/2) DIVPLAT =0(DIV/1)	123 MHz/123 MHz	SDR: 12/48/72/80 MHz DDR: 12/45/63.5/69.5 MHz	3
Dual/Single Boot	SPLL[PFD0] (246 MHz)	Div 1 or 2	M4_LOW_FREQ_BT =1 DIVCORE=3 (DIV/4) DIVPLAT =0(DIV/1)	61.5 MHz/ 61.5 MHz	SDR: 12/48/72/80 MHz DDR: 12/45/63.5/69.5 MHz	3

1. FIRC_DIV set to 1 (Divide by 1) for all boot cases.
2. LP Boot selection is based on "*LP Boot*" boot configuration fuse
3. QSPI clock can be changed in QSPI Configuration header
4. Based on "*dual boot*" fuse. Only selectable when "*LP Boot*" fuse is unblown.
5. For Dual/Single boot option, customer can select/change clock settings based on QSPI configuration header.

Table 35-10. A7 boot clock options

Boot Mode	Clock Source	Fuse Controls (Fuse/Dividers)	A7 Core	NIC0/NIC1	DDR Clock	Comments
Dual Boot	A7 SPLL[PFD0] (413 MHz)	NIC0DIV=1 NIC1DIV=0 A7_LOW_FREQ_BT = 0	413 MHz	NIC0 = DDR/2 =176 MHz NIC1 = DDR/2 =176 MHz	APLL[PFD0] (352 MHz)	See Table 35-11 for SD clock options
Dual Boot	A7 SPLL[PFD0] (413 MHz)	NIC0DIV=1 NIC1DIV=0 A7_LOW_FREQ_BT = 1	206.5 MHz	NIC0 = DDR/2 = 176 MHz NIC1 = DDR/2 =176 MHz	APLL[PFD0] (352 MHz)	See Table 35-11 for SD clock options

Table 35-11. SD boot clock options

Table continues on the next page...

Table 35-11. SD boot clock options (continued)

Modes	Clock Source	PCC DIVIDER	Internal DIV	SD Clock
SD Normal/SDR12	AP PLL3[PFD0] (352 MHz)	DIV = 1 (Div by 2)	SDCLKFS=0x01, DVS=0x3, Div by (2 * 4)	22 MHz
MMC High	AP PLL3[PFD0] (352 MHz)	DIV = 1 (Div by 2)	SDCLKFS=0x00, DVS=0x4, Div by (1 * 5)	35.2 MHz
SD High/SDR25	AP PLL3[PFD0] (352 MHz)	DIV = 1 (Div by 2)	SDCLKFS=0x01, DVS=0x1, Div by (2 * 2)	44 MHz
MMC DDR high	AP PLL3[PFD0] (352 MHz)	DIV = 1 (Div by 2)	SDCLKFS=0x00, DVS=0x1, Div by (2 * 2)	44 MHz

35.2.4.4 MMU and cache

By default, both A7/M4 ROM enable I cache at the start of image download, unless been disabled by fuse A7_I-Cache_Disable/M4_I-Cache_Disable.

Both A7 and M4 ROM always enable MMU/MPU at very beginning. By default, ROM code sets all memories (except ROM code) as non-executable. Before valid entry point provisioned (for HAB closed, which means image be authenticated by ROM), ROM code will remove the non-executable by disabling MMU/MPU. So, if boot fails and customer loads some images by JTAG (or jump to QSPI NOR flash), the memories are non-executable. Customers can disable MMU/MPU by JTAG and then run the loadable image.

By default, A7's L1 data cache and L2 cache are enabled during image authentication unless these are disabled by fuse A7 D Cache Disable and M4 D Cache Disable. LMEM data cache is also enabled for M4 boot. Once HAB authentication completes, A7 ROM disables the L1 data cache and L2 cache, and M4 ROM disables the LMEM data cache.

Enabling the MMU and data cache when booting non-securely with SEC_CONFIG=Open, and setting the CSF pointer in the Image Vector Table to NULL, has no impact on the boot performance. With this configuration it is recommended to blow A7_D-Cache_Disable/M4_D-Cache_Disable fuses.

35.2.4.5 Exception handling

Once exception is thrown on A7 side during boot phase, A7 ROM goes into USB serial download mode, and if thrown on M4 side, M4 ROM will go into an endless loop.

After boot, the program image can overwrite the vectors as required.

35.2.4.6 Interrupt handling during boot

No special interrupt handling routines are required during the boot process. Interrupts are disabled during boot ROM execution on both A7 and M4 ROM.

35.2.4.7 SIM DGO GPR used by ROM

NOTE

SIM DGO general-purpose registers (GPRs) are in M4 "Always ON" domain with values retained in lowest power modes (M4 VLLS), where the core supply is not available.

SIM DGO_GPR	Usage by ROM	Description
SIM_DGO_GP1	M4 resume entry point	To store M4 entry point for resuming from low power mode. Must be in M4 TCM range
SIM_DGO_GP2	Argument for M4 resume	M4 ROM stores this value into CPU register R0 when jumping to M4 entry point. This is optional and can be used as other purpose if argument is not needed when resuming.
SIM_DGO_GP3	A7 core0 resume entry point	To store A7 entry point for a resuming from low power mode.
SIM_DGO_GP4	Argument for A7 core0 resume	A7 ROM stores this value into CPU register R0 when jumping to A7 entry point. This is optional and can be used as other purpose if argument is not needed when resuming.
SIM_DGO_GP5	Bits 31-8: Reserved for future BootROM Bits 7-4: Attack Counter for A7 ROM Bits 3-0: Attack Counter for M4 ROM	If ROM code detects any attack by hacker, the ROM code will add these 'counter' into SNVS domain and then issue a WDOG reset. After been reset, ROM goes into infinite loop on non-closed part, and issues WDOG reset immediately on closed part.
SIM_DGO_GP6	Reserved for future BootROM	—
SIM_DGO_GP7	M4 entry point	Provided by A7 image in Single Boot mode

Table continues on the next page...

SIM_DGO_GP8	Argument for M4	Provided by A7 image in Single Boot mode. This is optional and can be used as other purpose if argument is not needed when resuming.
SIM_DGO_GP9	Restored Boot_CFG	SW can override BOOT_CFG and issue a SW reset; then BootROM will retrieve boot configuration here. Will be disabled if DIR_BT_DIS blown.
SIM_DGO_GP10	Boot ROM internal Flag	See Table 35-12
SIM_DGO_GP11	Reserved	—

Table 35-12. Boot ROM Internal Flag (SIM_DGO_GP10) Definition

Bit position	Name	Description
Bit 31	Reserved	—
30	Secondary Boot	This bit identifies which image should be used, primary or secondary. Used only for boot device that supports secondary boot. For this device, secondary boot is only supported on SD/eMMC boot.
29	Reserved	—
28	WDOG_RESET_BOOT	Set by bootable image before issuing a WDOG reset, to indicate ROM to retrieve boot configuration from SIM_DGO_GP9 instead of from CMC0/1 Mode register. Can be disabled if DIR_BT_DIS is blown.
27-26	Reserved	—
25	A7 resume failure flag	If A7 resume failed (usually an invalid resume entry been provisioned), A7 ROM will set this bit to indicate such failure and then issues a WDOG reset.
24	M4 resume failure flag	If M4 resume failed (usually an invalid resume entry been provisioned), M4 ROM will set this bit to indicate such failure and then issues a WDOG reset.
23-0	Reserved	—

35.2.5 Boot device

35.2.5.1 Expansion device

35.2.5.1.1 Expansion Device eFUSE Configuration

SD/MMC/eSD/eMMC boot can be performed using either uSDHC ports, based on setting of the BOOT_CFG1[11-9] (A7 Boot Interface Selection) fuse or its associated GPIO input value at boot, and SD/MMC/eSD/eMMC boot supported on A7 ROM side only.

All uSDHC ports support eMMC4.4 and eMMC4.5 fast boot. See the table below for details.

Table 35-13. uSDHC Boot eFUSE Descriptions

Fuse	Config	Definition	GPIO	Shipped Value	Settings
BOOT_CFG1[11:9]	OEM	A7 Boot Interface Selection	Yes	000	**A7 Boot interface** 000—uSDHC0 001—uSDHC1 others—Reserved

0x560[15]	OEM	USDHC1 voltage selection	No	0	**uSDHC1 IO Voltage Selection** 0—3.3 V 1—1.8 V

Boot code supports following standards. ROM doesn't support booting with 1-bit bus width for all kinds of SD/eSD/MMC/eMMC devices.

- MMCv4.4 or less
- eMMCv4.4 or less
- SDv2.0 or less
- eSDv2.10 rev-0.9, with or without FAST_BOOT.

MMC/SD/eSD/SDXC/eMMC can be connected to any of the USDHC blocks and can be booted by copying 4 KB of data from MMC/SD/eSD/eMMC device to internal RAM. After checking the Image Vector Table header value (0xD1) from Program Image, the ROM code performs a DCD check. After successful DCD extraction, the ROM code extracts from Boot Data Structure the destination pointer and length of image to be copied to RAM device from where code execution occurs.

The maximum image size to load in SD/MMC boot is 32 MB. This is due to the limited number of uSDHC ADMA Buffer Descriptors allocated by ROM.

NOTE

The Initial 4 KB of Program Image must contain the IVT, DCD and the Boot Data structures.

NOTE

i.MX 7ULP A7 ROM supports SDXC card (SD3.0) in normal SD(SD2.0) compatible way.

Table 35-14. SD/MMC Frequencies

	SD	MMC	MMC (DDR Mode)
Identification (KHz)	305.5 kHz		
Normal Speed Mode (MHz)	22	17.6	22
High Speed Mode (MHz)	44	35.2	44

NOTE

The boot ROM code reads application image length and application destination pointer from image.

35.2.5.1.2 MMC and eMMC Boot

The following table provides MMC and eMMC boot details.

Table 35-15. MMC and eMMC Boot Details

Normal Boot Mode	During initialization (normal boot mode) the MMC frequency is set to 305.5 kHz. When the MMC card enters the identification portion of the initialization, voltage validation is performed and the ROM boot code checks high voltage settings and card capacity. The ROM boot code supports both high capacity and low capacity MMC/eMMC cards. After initialization phase is complete, the ROM boot code switches to a higher frequency (17.6 MHz in Normal boot mode or 35.2 MHz in High Speed mode). eMMC is also interfaced via USDHC and follows the same flow as MMC. The boot partition can be selected for an MMC4.x card after the card initialization is complete. The ROM code reads the BOOT_PARTITION_ENABLE field in the Ext_CSD[179] to get the boot partition to be set. If there is no boot partition mentioned in BOOT_PARTITION_ENABLE field or the user partition has been mentioned, ROM boots from the user partition.
eMMC4.3 or eMMC4.4 Device Supporting Special Boot Mode	If using an eMMC4.3 or eMMC4.4 device supporting special boot mode, it can be initiated by pulling the CMD line low. If BOOT ACK is enabled, the eMMC4.3/eMMC4.4 device sends the BOOT ACK via DATA lines and ROM can read the BOOT ACK [S010E] to identify the eMMC4.3/eMMC4.4 device. eMMC4.3/eMMC4.4 device with "Boot mode" feature can only be supported via ESDHCV3-3 and with or without BOOT

Table continues on the next page...

Table 35-15. MMC and eMMC Boot Details (continued)

	ACK. If BOOT ACK is enabled, ROM waits 50 ms to get the BOOT ACK and if BOOT ACK is received by ROM. If BOOT ACK is disabled, ROM waits 1 second for data. If BOOT ACK or data was received then eMMC4.3/eMMC4.4 is booted in "Boot mode", otherwise eMMC4.3/eMMC4.4 boots as a normal MMC card from the selected boot partition. This boot mode can be selected by BOOT_CFG1[4] (Fast Boot) fuse. BOOT ACK is selected by BOOT_CFG2[1].
eMMC4.4 Device	If using eMMC4.4 device, Double Data Rate (DDR) mode can be used. This mode can be selected by BOOT_CFG2[7:5] (Bus Width) fuse.

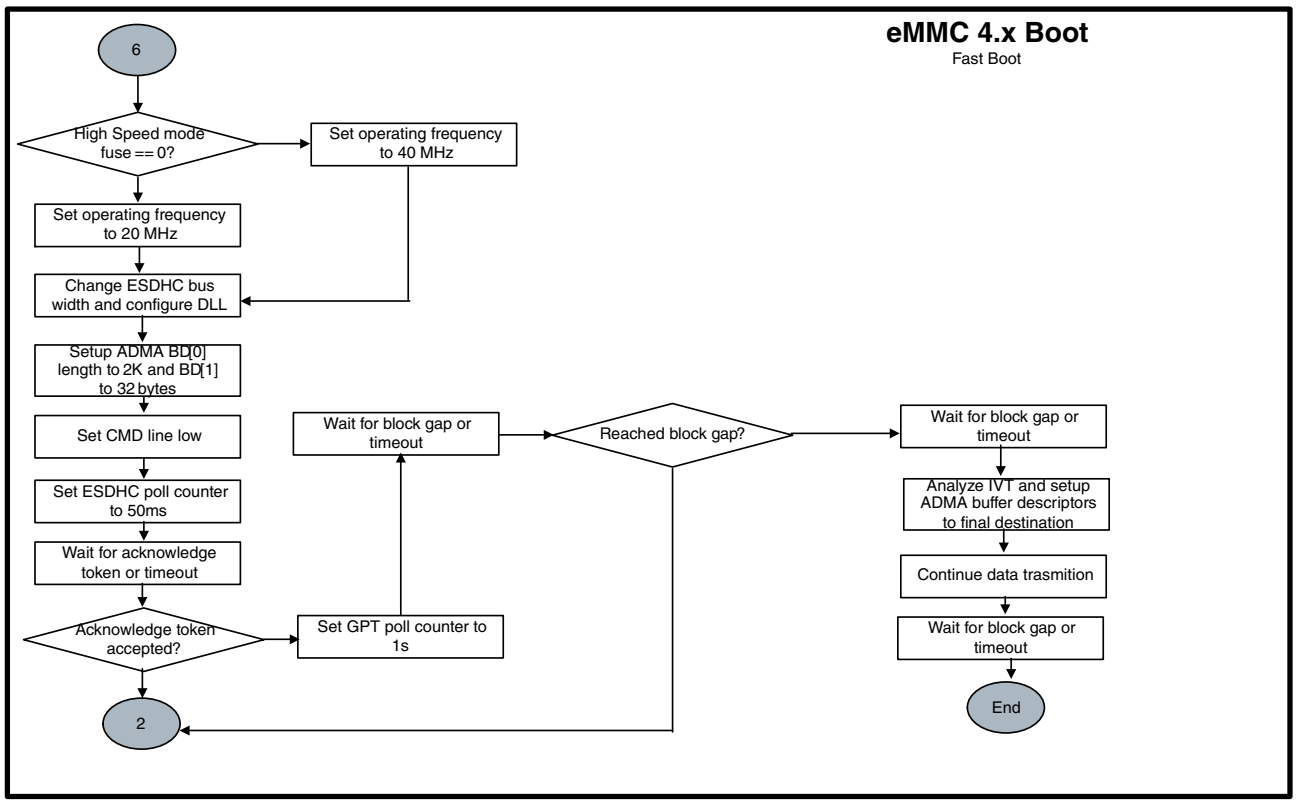

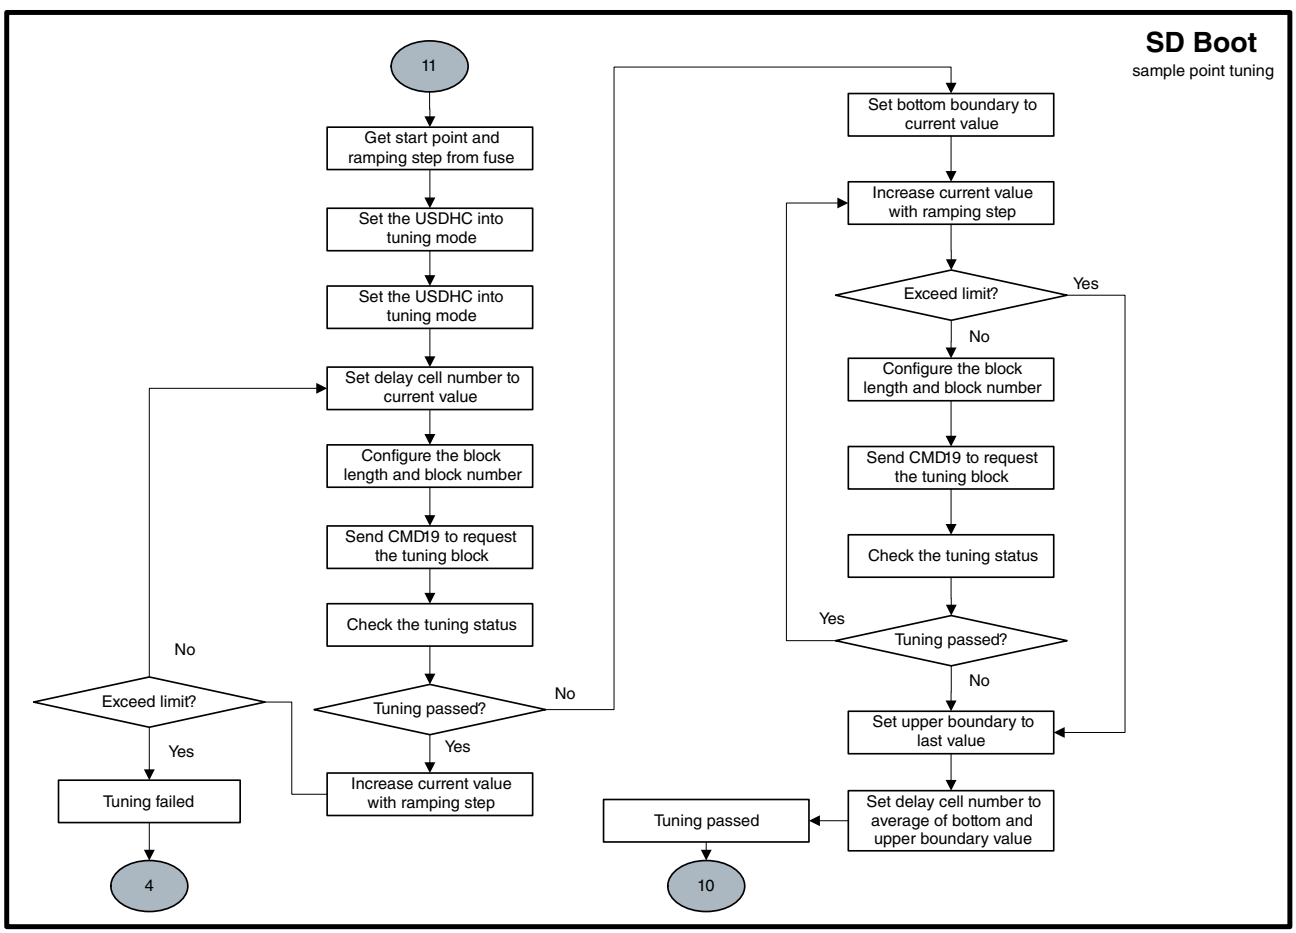

Figure 35-13. Expansion Device Boot Flow (6 of 6)

35.2.5.1.3 SD, eSD and SDXC

NOTE

A7 ROM supports SD3.0 card in SD2.0 compatible way, thus SDXC card will be taken as a normal SD2.0 card.

After the normal boot mode initialization begins, the SD/eSD/SDXC frequency is set to 305.5 kHz. During the identification phase, SD/eSD/SDXC card voltage validation is performed. During voltage validation, boot code first checks with high voltage settings; if that fails, it checks with low voltage settings. The capacity of the card is also checked. Boot code supports high capacity and low capacity SD/eSD/SDXC cards after voltage validation card initialization is done.

During card initialization, the ROM boot code attempts to set the boot partition for all SD, eSD, and SDXC devices. If this fails, the boot code assumes the card is a normal SD card or SDXC card. If it does not fail, the boot code assumes it is an eSD card. After the initialization phase is over, boot code switches to a higher frequency (22 MHz in Normal Speed mode or 44 MHz in High Speed Mode). ROM also supports FAST_BOOT mode booting from eSD card. This mode can be selected by BOOT_CFG1[4] (Fast Boot) fuse described in Table 35-13.

UHSI calibration start value (MMC_DLL_DLY[6:0]) and step value (BOOT_CFG2[7:5]) can be set to optimize the sample point tuning process.

If SD Power Cycle Enable eFuse is 1, ROM will set SD_RST pad low, wait 5ms and then set SD_RST pad high. If SD_RST pad is connected to SD power supply enable logic on board, it enables power cycle of SD card. This may be crucial when SD logic is in 1.8 V states and must be reset to 3.3 V states.

SDR50 and SDR104 boot are not supported on the USDHC0 and USDHC1 ports because there are no reset signals for those ports when connected in the IOMUX.

35.2.5.1.4 IOMUX Configuration for SD/MMC

Table 35-16. IOMUX Configuration for uSDHC

Signal	uSDHC0	uSDHC1
CLK	PTD2.alt8	PTE2.alt8
CMD	PTD1.alt8	PTE3.alt8

VSELECT	No VSELECE signal	PTE14.alt8
RESET_B	PTD0.alt1	PTE11.alt1

35.2.5.1.5 Redundant Boot Support for Expansion Device

ROM supports redundant boot for expansion device. Primary or Secondary image is selected depending on PERSIST_SECONDARY_BOOT setting provisioned in the GPRs.

If PERSIST_SECONDARY_BOOT is 0, the boot ROM uses address 0x0 for primary image.

If PERSIST_SECONDARY_BOOT is 1, the boot ROM will read secondary image table from address 0x200 on boot media and will use address specified in the table for the secondary image.

Table 35-17. Secondary Image Table Format

Reserved (chipNum)
Reserved (driveType)
tag
firstSectorNumber
Reserved (sectorCount)

Where:

- tag: used as indication of valid secondary image table. Must be 0x00112233.
- firstSectorNumber is the first 512B sector number of the secondary image.

For secondary image support, the primary image must reserve space for secondary image table. See the figure below for typical structures layout on expansion device.

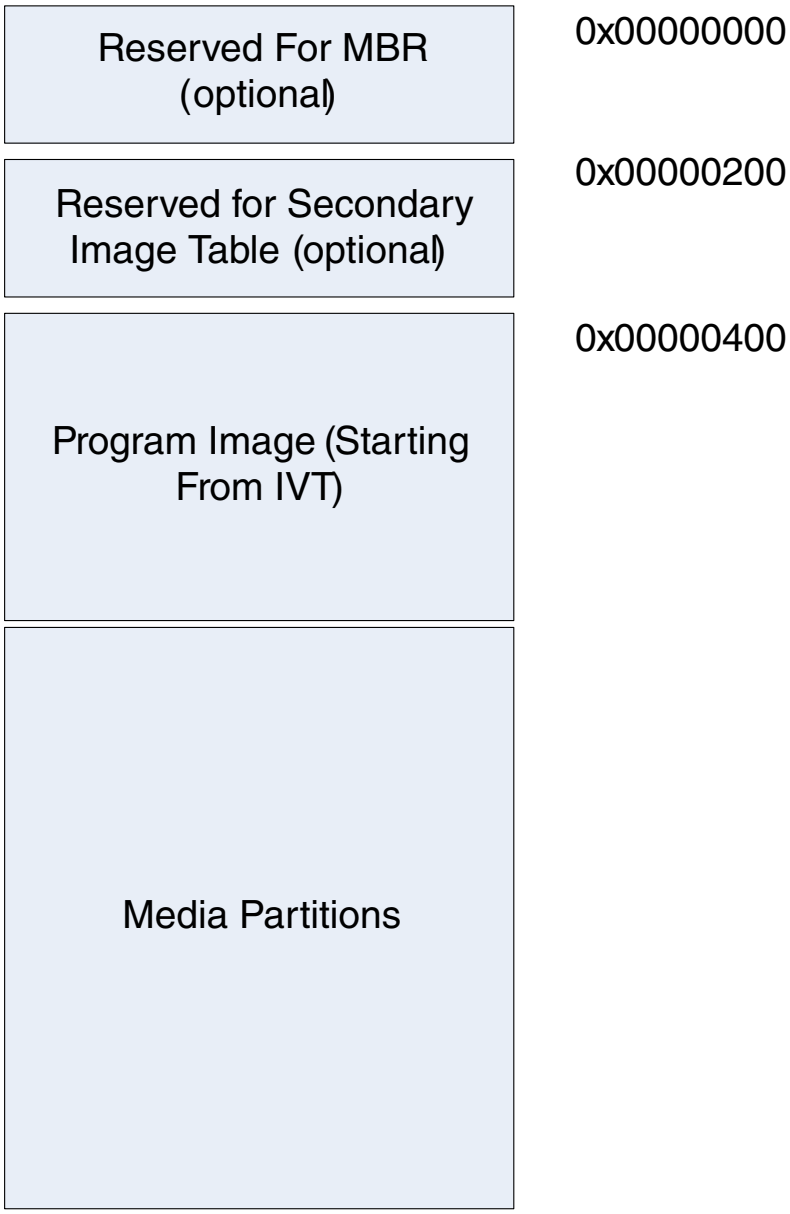

Figure 35-14. Expansion Device Structures Layout

For Closed mode, if there are failures during primary image authentication, the boot ROM will turn on PERSIST_SECONDARY_BOOT bit and perform software reset. (After software reset, secondary image will be used.)

35.2.5.2 QuadSPI serial flash memory boot

35.2.5.2.1 QuadSPI eFUSE Configuration

Table 35-18. QuadSPI efUSE Configuration

Fuse	Config	Definition	GPIO	Shipped value	Settings
BOOT_CFG0[15:14]	OEM	QSPI instance selection	Yes	00	**QSPI instance** 00—QSPI0 Others—Reserved
BOOT_CFG0[13:12]	OEM	QSPI device type Selection	Yes	00	**QSPI device type** 00—Flash with 3B READ (0x03) default supported 01—Hyperflash 1.8 V 10—Hyperflash 3.3 V 11—Flash with 4B READ (0x13) default supported

35.2.5.2.2 QuadSPI Serial Flash BOOT Operation

The M4 Boot ROM attempts to boot from QuadSPI flash if the BOOT_CFG0[15:14] fuses are programmed to 00 as shown in Table 35-18. The ROM will initialize the requested the QuadSPI Interface as selected in Fuse bit BOOT_CFG0[13:12] in the Table 35-18. QuadSPI interface initialization is a two step process.

The ROM expects the QuadSPI configuration parameters as explained in the QuadSPI Configuration Parameters to be present in the Serial Flash memory from offset 0x1000 of serial flash of length 512 bytes. The ROM reads these configuration parameters using the default read command configured in the LUT of the QuadSPI interface with SCLOCK operating at 18 MHz.

In the second step, ROM configures the selected QuadSPI interface with the configuration parameters read from the serial flash and starts the boot procedure. See Table 35-19 for details regarding QuadSPI configuration parameters and to the QuadSPI boot flow chart for detailed boot flow chart of QuadSPI.

Both booting an XIP and non XIP image is supported from serial flash. For XIP boot, the image has to be built for QuadSPI address space and for non XIP the image can be built to execute from TCM.

For QUAD mode boot, the Boot ROM expects the Quad Enable bit inside the QSPI Flash to be already set before booting starts. Therefore, the QUAD enable bit must be set in the non-volatile register of the flash at the time of programming.

NOTE

If the SPI flash device requires quad enable command, it can be sent via configuration structure fields: device_quad_mode_en, device_cmd, write_cmd_ipcr, write_enable_ipcr, busy_bit_offset, read_status_ipcr.

35.2.5.2.3 QuadSPI Configuration Parameters

The QuadSPI Configuration Parameters Table is built in boot image at fixed offset 0x400 from QSPI NOR A1 base address (368 bytes). Table below lists various QuadSPI Configuration Parameters.

Table 35-19. QuadSPI Configuration Parameters

Name	Offset	Size in Bytes	Description
DQS Loopback	0	4	DQS LoopBack Mode to enable Dummy Pad, 0 - Disable, 1 - Enable
Hold Delay	4	4	Hold Delay for QSPI[0,1] A/B Value / QSPI1 B / QSPI1 A 00 / Disable / Disable 01 / Disable / Enable 10 / Enable / Disable 11 / Enable / Enable
Reserved	8	4	Reserved to 0
Reserved	12	4	Reserved to 0
device_quad_mode_en	16	4	Send Quad enable command to SPI device.
device_cmd	20	4	Command to send to SPI device.
write_cmd_ipcr	24	4	IPCR register value for write command
write_enable_ipcr	28	4	IPCR register value for Enable
Chip Select hold time	32	4	This is chip select hold time in terms of Serial clock (For Example 1 serial clock cycle 0-15).
Chip Select setup time	36	4	Chip select setup time in terms of Serial clock (For example 1 serial clock).
Serial Flash A1 size	40	4	Serial Flash A1 size in units of bytes
Serial Flash A2 size	44	4	Serial Flash A2 size in units of bytes
Reserved	48	-	-
Reserved	52	-	-
Serial Clock Frequency	56	4	This is serial clock frequency select parameter.

DATA7	PTB4.alt8

35.2.5.2.5 QSPI NOR flash

M4 ROM supports encrypted boot on QSPI NOR flash using OTFAD hardware. For details, see the OTFAD chapter in i.MX 7ULP Security Reference Manual.

35.2.5.2.6 QuadSPI boot flow chart

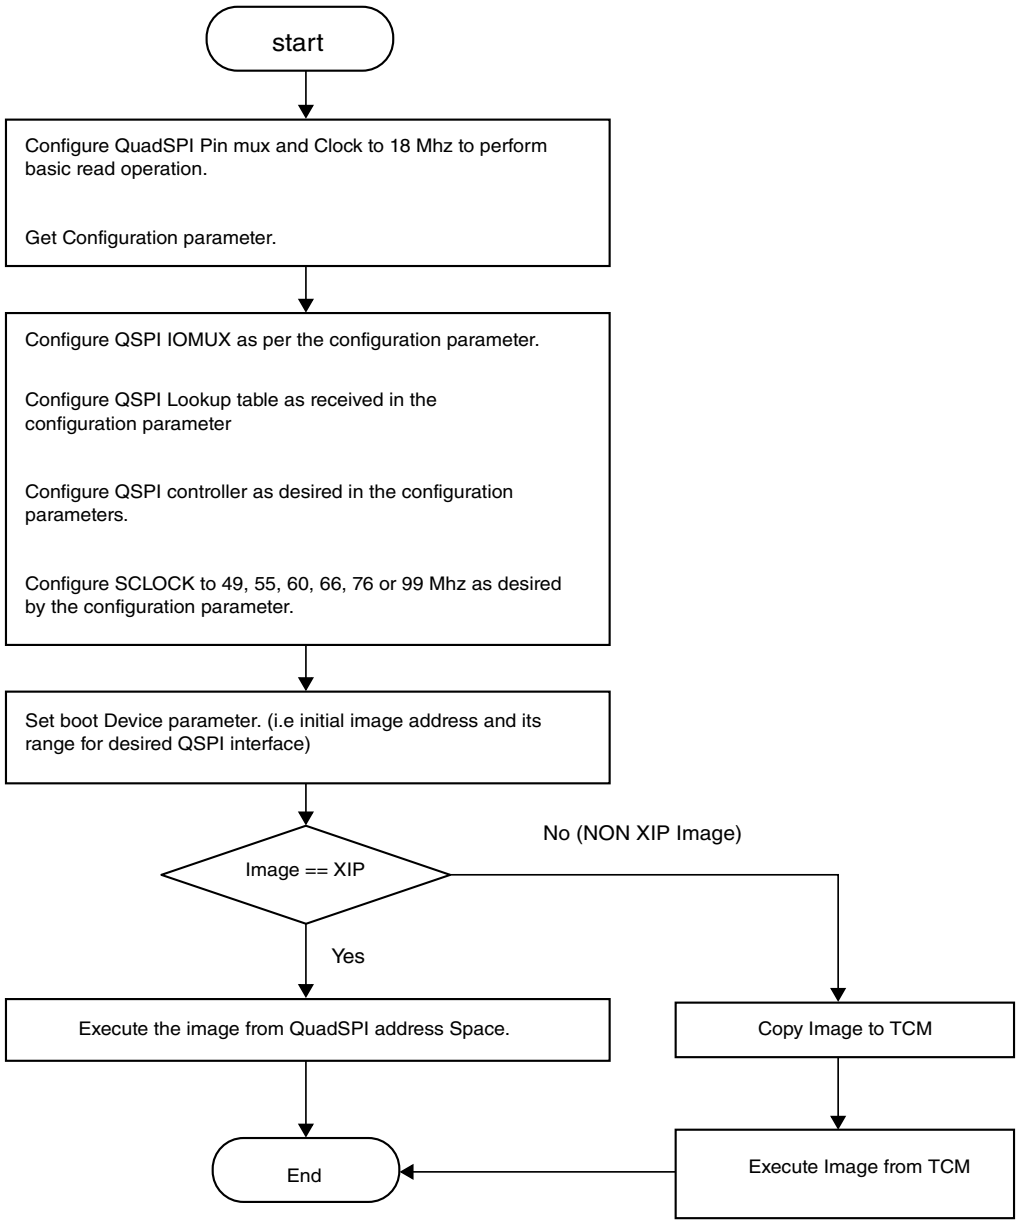

Figure 35-15. QuadSPI boot flow chart

NOTE

If flash is configured for "High performance mode (where command is generated only once)" in LUT program sequence, then external reset should be routed to flash reset to allow rebooting in case of any device reset other than Power On Reset. Also this high performance mode must be exited by application before any Low power mode entry where the device is supposed to reboot from QSPI flash on Low power mode exit. In general, any preserved configuration in external flash will not be understood by device after reset.

35.2.5.3 Recovery flash on LPSPI flash

This device supports recovery devices. If primary boot device fails, A7 ROM and M4 ROM will try to boot from recovery device using one of LPSPI ports, if not been disabled by fuse 'Disable M4 SPI Recovery boot' or 'Disable A7 SPI Recovery boot'.

35.2.5.3.1 LPSPI eFuse configuration

Fuse	Config	Definition	GPIO	Shipped value	Settings
0x560[13]	OEM	Disable/Enable M4 SPI boot	No	0	**Disable M4 SPI Recovery boot** 0—Disable 1—Enable
0x560[12]	OEM	Disable/Enable A7 SPI boot	No	0	**Disable A7 SPI Recovery boot** 0—Disable 1—Enable

35.2.6 Program image

This section describes the data structures that are required to be included in a user's program image. A program image consists of:

- Image vector table—A list of pointers located at a fixed address that the ROM examines to determine where other components of the program image are located
- Boot data—A table indicating the program image location, program image size in bytes, and the plugin flag

- Device configuration data—IC configuration data
- User code and data

35.2.6.1 Image Vector Table and Boot Data

The Image Vector Table (IVT) is the data structure that the ROM reads from the boot device supplying the program image containing the required data components to perform a successful boot.

The IVT includes the program image entry point, a pointer to Device Configuration Data (DCD) and other pointers used by the ROM during the boot process.The ROM locates the IVT at a fixed address that is determined by the boot device connected to the Chip. The IVT offset from the base address and initial load region size for each boot device type is defined in the table below. The location of the IVT is the only fixed requirement by the ROM. The remainder or the image memory map is flexible and is determined by the contents of the IVT.

Table 35-21. Image Vector Table Offset and Initial Load Region Size

Boot Device Type	Image Vector Table Offset	Initial Load Region Size
QSPI NOR	4 Kbyte = 0x1000 bytes	Entire Image Size
NAND	1 Kbyte = 0x400 bytes	4 Kbyte
SD/MMC/eSD/eMMC	1 Kbyte = 0x400 bytes	4 Kbyte
SPI Flash	1 Kbyte = 0x400 bytes	4 Kbyte

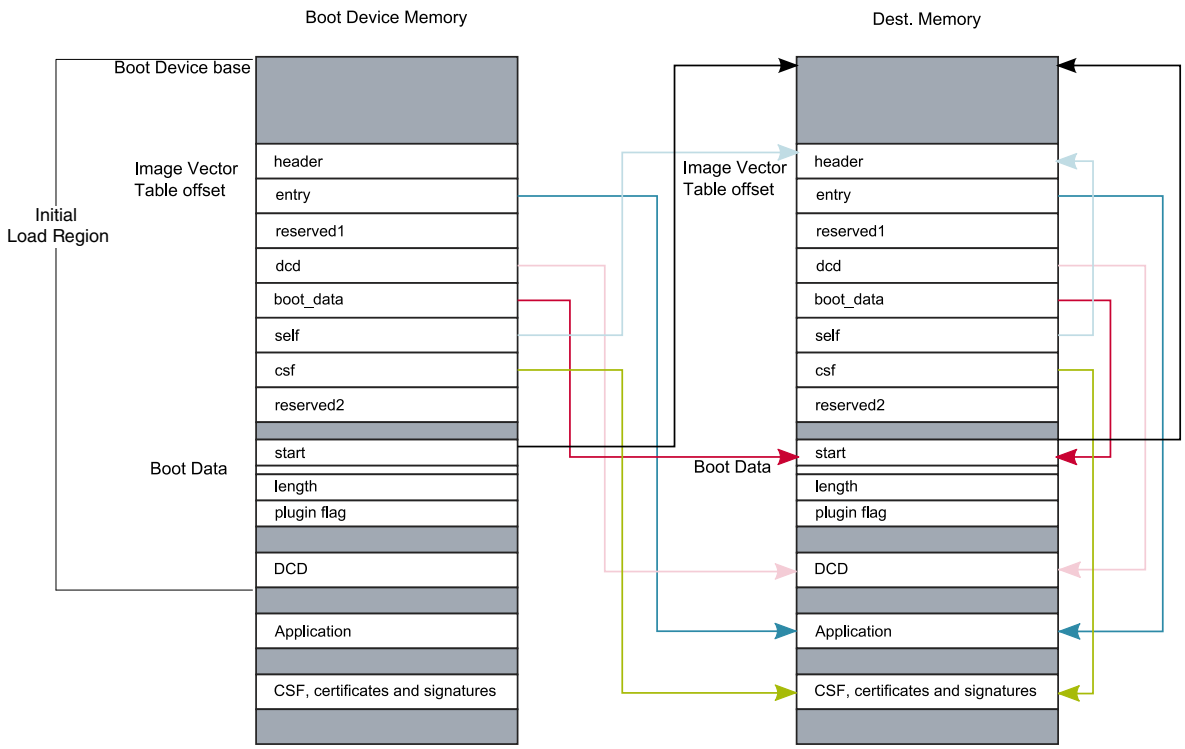

Figure 35-16. Image Vector Table

35.2.6.1.1 Image Vector Table Structure

The IVT has the following format where each entry is a 32 bit word:

Table 35-22. IVT Format

header
entry: Absolute address of the first instruction to execute from the image
reserved1: Reserved and should be zero
dcd: Absolute address of the image DCD. The DCD is optional so this field may be set to NULL if no DCD is required. See Device Configuration Data (DCD) for further details on DCD.
boot data: Absolute address of the Boot Data
self: Absolute address of the IVT. Used internally by the ROM
csf: Absolute address of Command Sequence File (CSF) used by the HAB library. See High Assurance Boot (HAB) for details on secure boot using HAB. This field must be set to NULL when not performing a secure boot
reserved2: Reserved and should be zero

Figure 35-17 shows the IVT header format:

Figure 35-17. IVT Header Format

where:

```
Tag: A single byte field set to 0xD1
Length: a two byte field in big endian format containing the overall length of the IVT,
in bytes, including the header. (the length is fixed and must have a value of
32 bytes)
Version: A single byte field set to 0x40 or 0x41
```

35.2.6.1.2 Boot Data Structure

The Boot Data must follow the format defined in the table found here, each entry is a 32-bit word.

Table 35-23. Boot Data Format

start	Absolute address of the image
length	Size of the program image
plugin	Plugin flag (see Plugin Image)

35.2.6.2 Device Configuration Data (DCD)

Upon reset, the Chip uses the default register values for all peripherals in the system. However, these settings typically are not ideal for achieving optimal system performance and there are even some peripherals that must be configured before they can be used.

The DCD is configuration information contained in a Program Image, external to the ROM, that the ROM interprets to configure various peripherals on the Chip.

For example, some components such as DDR require some sequence of register programming as part of configuration before it is ready to be used. The DCD feature can be used to program the MMDC registers to the optimal settings.

The ROM determines the location of the DCD table based on information located in the Image Vector Table (IVT). See Image Vector Table and Boot Data for more details. The DCD table shown below is a big endian byte array of the allowable DCD commands. The maximum size of the DCD is limited to 1768 bytes.

NOTE

ROM code does not allow DCD running once ROM jumps to boot image (even for plug-in scenario).

Figure 35-18. DCD Data Format

The DCD header is 4 bytes with the following format:

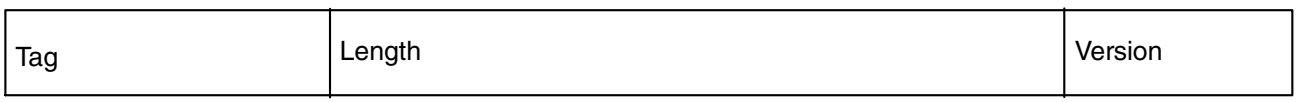

Figure 35-19. DCD Header Format

where:

```
Tag: A single byte field set to 0xD2
Length: a two byte field in big endian format containing the overall length of the DCD,
in bytes, including the header
Version: A single byte field set to 0x41
```

35.2.6.2.1 Write Data Command

The Write Data Command is used to write a list of given 1-, 2- or 4-byte values or bitmasks to a corresponding list of target addresses.

The format of Write Data Command, again a big endian byte array, is shown in the table below.

Table 35-24. Write Data Command Format

Tag	Length	Parameter
Address		
Value/Mask		
[Address]		

Table continues on the next page...

Table 35-24. Write Data Command Format (continued)

[Value/Mask]
...
[Address]
[Value/Mask]

where:

```
Tag: A single byte field set to 0xCC
Length: A two byte field in big endian format containing the length of the Write Data
Command, in bytes, including the header
Address: target address to which data should be written
Value/Mask: data value or bitmask to be written to preceding address
```

The Parameter field is a single byte divided into bitfields as follows:

Table 35-25. Write Data Command Parameter field

7	6	5	4	3	2	1	0
flags					bytes		

where

```
bytes: width of target locations in bytes. Either 1, 2 or 4
flags: control flags for command behavior.
Data Mask = bit 3: if set, only specific bits may be overwritten at target address
(otherwise all bits may be overwritten)
Data Set = bit 4: if set, bits at the target address overwritten with this flag
(otherwise it is ignored)
```

One or more target address and value/bitmask pairs can be specified. The same bytes and flags parameters apply to all locations in the command.

When successful, this command writes to each target address in accordance with the flags as follows:

Table 35-26. Interpretation of Write Data Command Flags

"Mask"	"Set"	Action	Interpretation
0	0	*address = val_msk	Write value
0	1	*address = val_msk	Write value
1	0	*address &= ~val_msk	Clear bitmask
1	1	*address |= val_msk	Set bitmask

NOTE

If any of the target addresses do not have the same alignment as the data width indicated in the parameter field, none of the values are written.

If any of the values is larger or any of the bitmasks is wider than permitted by the data width indicated in the parameter field, none of the values are written.

If any of the target addresses do not lie within an allowed region, none of the values are written. The list of allowable blocks and target addresses for the Chip are given below.

Table 35-27. Valid DCD Address Ranges

Address range	Start address	Last Address
MMDC registers	0x40AB0000	0x40ABFFFF
IOMUXC0 registers	0x4103D000	0x4103DFFF
IOMUXC1 registers	0x40AC0000	0x40ACFFF
IOMUXC DDR registers	0x40AD0000	0x40ADFFFF
PCC3 registers	0x40B30000	0x40B3FFFF
SCG1 registers	0x403E0000	0x403EFFFF
LPTPM5 registers	0x40260000	0x4026FFFF

35.2.6.2.2 Check Data Command

The Check Data Command is used to test for a given -1, 2- or 4-byte bitmasks from a source address.

The Check Data Command is a big endian byte array with format shown in the table below.

Table 35-28. Check Data Command Format

Tag	Length	Parameter
Address		
Mask		
[Count]		

where:

```
Tag: A single byte field set to 0xCF
Length: A two byte field in big endian format containing the length of the Check Data
Command, in bytes, including the header
Address: source address to test
Mask: bit mask to test
Count: optional poll count. If count is not specified this command will poll indefinitely
until the exit condition is met. If count = 0, this command behaves as for NOP.
```

The Parameter field is a single byte divided into bitfields as follows:

Table 35-29. Check Data Command Parameter field

7	6	5	4	3	2	1	0
flags					bytes		

where

```
bytes: width of target locations in bytes. Either 1, 2 or 4
flags: control flags for command behavior.
Data Mask = bit 3: if set, only specific bits may be overwritten at target address
(otherwise all bits may be overwritten)
Data Set = bit 4: if set, bits at the target address overwritten with this flag
(otherwise it is ignored)
```

This command polls the source address until either the exit condition is satisfied, or the poll count is reached. The exit condition is determined by the flags as follows:

Table 35-30. Interpretation of Check Data Command Flags

"Mask"	"Set"	Action	Interpretation
0	0	(*address & mask) == 0	All bits clear
0	1	(*address & mask) == mask	All bits set
1	0	(*address & mask)!= mask	Any bit clear
1	1	(*address & mask)!= 0	Any bit set

NOTE

If the source address does not have the same alignment as the data width indicated in the parameter field, the value is not read.

If the bitmask is wider than permitted by the data width indicated in the parameter field, the value is not read.

35.2.6.2.3 NOP Command

This command has no effect.

The format of NOP Command is a big endian four byte array as shown in the table below.

Table 35-31. NOP Command Format

Tag	Length	Undefined

where:

```
Tag: A single byte field set to 0xC0
Length: A two byte field in big endian containing the length of the NOP Command in bytes.
Fixed to a
```

```
value of 4.
Undefined: This byte is ignored and can be set to any value.
```

35.2.6.2.4 Unlock Command

The Unlock Command is used to prevent specific engine features being locked when exiting ROM.

The format of Unlock Command, again a big endian byte array, is shown in the table below.

Table 35-32. Unlock Command Format

Tag	Length	Eng
Value		
Value		
...		
Value		

where:

```
Tag: A single byte field set to 0xB2
Eng: Engine to be left unlocked.
Values: [optional] unlock values required by engine.
```

NOTE

This command may not be used in DCD structure if the SEC_CONFIG is configured as closed.

35.2.7 Plugin Image

The ROM supports a limited number of boot devices. When using other devices as a boot source (for example, Ethernet, CDROM, or USB), then the supported boot device must be used (typically serial ROM) as firmware to provide the missing boot drivers. Additionally, the plugin can be customized to support boot drivers, which is more flexible when doing device initialization, such as condition judging, delay assertion, or to apply custom settings to the boot device and memory system.

In addition to standard images, the chip also supports plugin images. Plugin images return execution to the ROM whereas a standard image does not.

The boot ROM detects the image type using the plugin flag of the boot data structure (see Boot Data Structure). If the plugin flag is 1, then the ROM uses the image as a plugin function. The function must initialize the boot device and copy the program image to the

final location. At the end the plugin function must return with the program image parameters. (See High level description of Boot: Boot mode and boot flow for details about boot flow).

The boot ROM authenticates the plugin image prior to running the plugin function and then authenticates the program image.

The plugin function must follow the API described below:

typedef BOOLEAN (*plugin_download_f)(void **start, size_t *bytes, UINT32 *ivt_offset);

ARGUMENTS PASSED:

- start - Image load address on exit.
- bytes - Image size on exit.
- ivt_offset - Offset in bytes of the IVT from the image start address on exit.

RETURN VALUE:

- 1 - on success
- 0 - on failure

35.2.8 Serial Downloader

The Serial Downloader provides a means to download a Program Image to the chip over USB serial connection. This feature is available on A7 ROM only.

In this mode the ROM programs WDOG1 for a time-out specified by fuse WDOG Time-out Select (See the attached fusemap for details) if WDOG_ENABLE eFuse is 1 and continuously polls for USB connection. If no activity is found on USBOTG2 and the watchdog timer expires, the Arm core is reset.

NOTE

After being loaded, the downloaded image is responsible to manage the watchdog resets properly.

Figure 35-1 shows USB boot flow.

35.2.8.1 USB

USB support is composed of the USBO2 (USB OTG core controller, compliant with the USB 2.0 specification) and the USBPHY (HS USB transceiver).

The ROM supports the USB OTG port for boot purposes. The other USB ports on the chip are not supported for boot purposes.

The USB Driver is implemented as a USB HID class. A collection of 4 HID reports are used to implement SDP protocol for data transfers as described in Table 35-33.

Table 35-33. USB HID Reports

Report ID (first byte)	Transfer Endpoint	Direction	Length	Description
1	control OUT	Host to device	17 bytes	SDP command from host to device
2	control OUT	Host to device	Up to 1025 bytes	Data associated with report 1 SDP command
3	interrupt	Device to host	5 bytes	HAB security configuration. Device sends 0x12343412 in closed mode and 0x56787856 in open mode.
4	interrupt	Device to host	Up to 65 bytes	Data in response to SDP command in report 1

35.2.8.1.1 USB Configuration Details

The USB OTG function device driver supports a high speed (HS for UTMI) non-stream mode with a maximal packet size of 512 B and a low-level USB OTG function.

The VID/PID and strings for USB device driver are listed in the table below.

Table 35-34. VID/PID and Strings for USB Device Driver

Descriptor	Value
VID	Defined by fuses USB_VID[15:0] (NXP vendor ID: 0x1FC9, if fuse not blown)
PID	Defined by fuses USB0_PID[15:0], 0x0126 if fuse not blown
String Descriptor1 (manufacturer)	NXP Semiconductor Inc.
String Descriptor2 (product)	S Blank SE Blank NS Blank
String Descriptor4	NXP Flash
String Descriptor5	NXP Flash

35.2.8.1.2 IOMUX Configuration for USB

The interface signals of the UTMI PHY are not configured in the IOMUX. The UTMI PHY interface uses dedicated contacts on the IC. See the chip data sheet for details.

35.2.8.2 Serial Download protocol

The 16 byte SDP command from host to device is sent using HID report 1.

The table below describes 16 byte SDP command data structure:

Table 35-35. 16 Byte SDP Command Data Structure

BYTE Offset	Size	Name	Description
0	2	COMMAND TYPE	The following commands are supported for ROM: • 0x0101 READ_REGISTER • 0x0202 WRITE_REGISTER • 0x0404 WRITE_FILE • 0x0505 ERROR_STATUS • 0x0A0A DCD_WRITE • 0x0B0B JUMP_ADDRESS • 0x0C0C SKIP_DCD_HEADER
2	4	ADDRESS	Only relevant for following commands: READ_REGISTER, WRITE_REGISTER, WRITE_FILE, DCD_WRITE, and JUMP_ADDRESS. For READ_REGISTER and WRITE_REGISTER commands, this field is address to a register. For WRITE_FILE and JUMP_ADDRESS commands, this field is an address to internal or external memory address.
6	1	FORMAT	Format of access, 0x8 for 8-bit access, 0x10 for 16-bit and 0x20 for 32-bit access. Only relevant for READ_REGISTER and WRITE_REGISTER commands.
7	4	DATA COUNT	Size of data to read or write. Only relevant for WRITE_FILE, READ_REGISTER, WRITE_REGISTER and DCD_WRITE commands. For WRITE_FILE and DCD_WRITE commands DATA COUNT is in byte units.
11	4	DATA	Value to write. Only relevant for WRITE_REGISTER command.
15	1	RESERVED	Reserved

35.2.8.2.1 SDP Command

SDP commands are decribed in the following sections.

35.2.8.2.1.1 READ REGISTER

The transaction for command READ_REGISTER consists of following reports: Report1 for command, Report3 for security configuration and Report4 for response or register value.

The register to read is specified in ADDRESS field of SDP command. First device sends Report3 with security configuration followed by Report4 with bytes read at given address. If count is greater than 64 then multiple reports with report id 4 are sent until entire data requested by host is sent. The STATUS is either 0x12343412 for closed parts and 0x56787856 for open or field return parts.

Report1, Command, Host to Device:

1	Valid values for READ_REGISTER COMMAND, ADDRESS, FORMAT, DATA_COUNT

ID 16 byte SDP Command

Report3, Response, Device to Host:

3	4 bytes indicating security configuration

ID 4 bytes status

Report4, Response, Device to Host: first response report

4	Register Value

ID 4 bytes of data containing register value. If number of bytes requested is less than 4 then remaining bytes should be ignored by host.

Multiple reports of report id 4 are sent until entire data requested is sent

Report4, Response, Device to Host: Last response report

4	Register Value

ID 64 bytes of data containing register value. If number of bytes requested is less than 64 then remaining bytes should be ignored by host.

35.2.8.2.1.2 WRITE REGISTER

The transaction for command WRITE_REGISTER consists of the following reports: Report1 for command, Report3 for security configuration and Report4 for write status.

Host sends Report1 with WRITE_REGISTER command. The register to write is specified in ADDRESS field of SDP command of Report1, with FORMAT field set to data type (number of bits to write 8, 16 or 32) and value to write in DATA field of SDP command. Device writes the DATA to register address and returns WRITE_COMPLETE code using Report4 and security configuration using Report3 to complete the transaction.

Report1, Command, Host to Device:

1	Valid values for WRITE_REGISTER COMMAND, ADDRESS, FORMAT, DATA_COUNT and DATA

ID 16 byte SDP Command

Report3, Response, Device to Host:

3	4 bytes indicating security configuration

ID 4 bytes status

Report4, Response, Device to Host:

4	WRITE_COMPLETE (0x128A8A12) status

ID 64 bytes data with first 4 bytes to indicate write is completed with code 0x128A8A12. On failure device will report HAB error status.

NOTE

ROMs is no longer in the SDP read white list.

35.2.8.2.1.3 WRITE_FILE

The transaction for command WRITE_FILE consists of following reports: Report1 for command-phase, Report2 for data-phase, Report3 for hab mode and Report4 to indicate data received in full.

The size of each Report2 is limited to 1024 bytes (limitation of USB HID protocol) hence multiple Report2 packets will be sent by host in data phase until entire data is transferred to device. Once entire data (DATA_COUNT bytes) is received then device sends report 3 with hab mode and report 4 with 0x88888888, indicating file download completed.

Report1, Host to Device:

1	Valid values for WRITE_FILE COMMAND, ADDRESS, DATA_COUNT

ID 16 byte SDP Command

==========Optional Begin==========

Host sends ERROR_STATUS command to query if HAB rejected the address

========== Optional End==========

Report2, Host to Device:

2	File data

ID Max 1024 bytes data per report

Report2, Host to Device:

2	File data

ID Max 1024 bytes data per report

Report3, Device to Host:

3	4 bytes indicating security configuration

ID 4 bytes status

Report4, Response, Device to Host:

4	COMPLETE (0x88888888) status

ID 64 bytes data with first 4 bytes to indicate file download has completed with code 0x88888888. On failure device will report HAB error status.

35.2.8.2.1.4 ERROR_STATUS

The transaction for SDP command ERROR_STATUS consists of three reports.

Report1 is used by host to send the command; device sends global error status in 4 bytes of Report4 after returning security configuration in Report3. When device receives ERROR_STATUS command it will return global error status that is updated for each command. This command is useful to find out if last command resulted in device error or succeeded.

Report1, Command, Host to Device:

1	ERROR_STATUS COMMAND

ID 16 byte SDP Command

Report3, Response, Device to Host:

3	4 bytes indicating security configuration

ID 4 bytes status

Report4, Response, Device to Host:

4	4 bytes Error status

ID first 4 bytes status in 64 bytes report 4

35.2.8.2.1.5 DCD WRITE

The SDP command DCD_WRITE is used by host to send multiple register writes in one shot. This command is provided to speed up the process of programming register writes such as to configure external RAM device.

The command goes with Report1 from host with COMMAND TYPE set to DCD_WRITE, ADDRESS which is used for temporary location of DCD data and DATA_COUNT to number of bytes sent in data out phase. In data phase host sends data for number of registers using Report2. Device completes the transaction with Report3 indicating security configuration and report 4 with WRITE_COMPLETE code 0x12828212.

Report1, Command, Host to Device:

1	DCD_WRITE COMMAND, ADDRESS, DATA_COUNT

ID 16 byte SDP Command

Report2, Data, Host to Device:

2	DCD binary data

ID Max 1024 bytes per report

Report3, Response, Device to Host:

3	4 bytes indicating security configuration

ID 4 bytes status

Report4, Response, Device to Host:

4	WRITE_COMPLETE (0x128A8A12) status

ID 64 bytes report with first 4 bytes to indicate write is completed with code 0x128A8A12. On failure device will report HAB error status.

See Device Configuration Data (DCD) for DCD format description.

35.2.8.2.1.6 SKIP_DCD_HEADER

The SDP command SKIP_DCD_HEADER is used by host to inform device skip the DCD configuration within download image.

Normally, if the download image should be run on DDR, the DCD configuration data should be built-in the image. In case the host has issued DCD_WRITE to push DCD configuration data to device for DDR initialization, the image with DCD information will cause ROM to initialize DDR twice and may cause initialization processing hung.

The SKIP_DCD_HEADER command informs the device to skip the DCD configuration with the download image, and avoid this issue.

This command should typically be sent after JUMP_ADDRESS. The command is sent by host in command-phase of transaction using Report1, there is no data phase for this command. Device completes the transaction with Report3 indicating security configuration and Report4 with OK_ACK code 0x900DD009.

Report1, Command, Host to Device:

1	SKIP_DCD_HEADER

ID 16 byte SDP Command

Report3, Response, Device to Host:

3	4 bytes indicating security configuration

ID 4 bytes status

Report4, Response, Device to Host:

4	OK_ACK (0x900DD009)

35.2.8.2.1.7 JUMP ADDRESS

The SDP command JUMP_ADDRESS will be the last command host can send to the device, after this command device will jump to the address specified in the ADDRESS field of SDP command and start executing.

This command should typically follow after WRITE_FILE command. The command is sent by host in command-phase of transaction using Report1, there is no data phase for this command but the device sends status Report3 to complete the transaction. And if HAB authentication fails, then it will also send Report4 with HAB error status.

Report1, Command, Host to Device:

1	JUMP_ADDRESS COMMAND, ADDRESS

ID 16 byte SDP Command

Report3, Response, Device to Host:

3	4 bytes indicating security configuration

ID 4 bytes status

This report is sent by device only in case of an error jumping to the given address, device reports error in Report4, Response, Device to Host:

4	4 bytes HAB error status

ID 4 bytes status, 64 bytes report length

35.2.9 SD/MMC Manufacture Mode

When internal boot and recover boot (if enabled) failed, and the "Disable SDMMC Manufacture mode" fuse bit (DISABLE_SDMMC_MFG) isn't set, boot will go to SD/MMC manufacture mode before serial download mode. In manufacture mode, one bit bus width is used despite of the fuse setting. This mode will be skipped if Boot_Mode=01(Serial Download Mode), irrespective of the "Disable SDMMC Manufacture mode" fuse value.

In manufacture mode, SD or MMC card will be scanned on uSDHC0 and uSDHC1. If card is detected and valid boot image is found in card, then the boot image will be loaded and then executed. Pad of SD1_CD is used to detect whether card is inserted.

By default, SD/MMC manufacture mode is enabled. Blow the fuse of DISABLE_SDMMC_MFG to disable it.

NOTE

Secondary boot is not supported on SD/MMC manufacture mode.

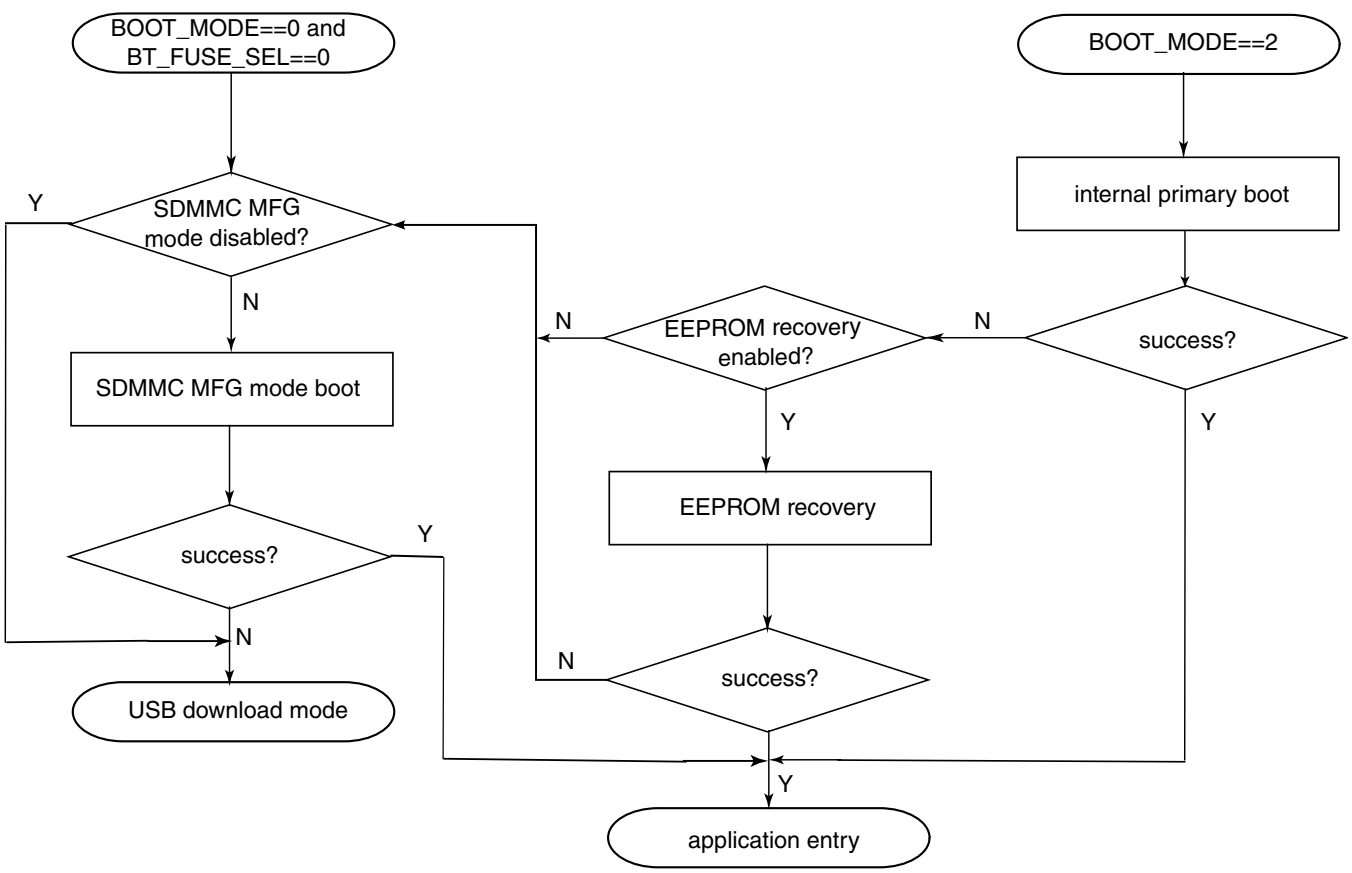

Figure 35-20. SD/MMC Manufacture boot flow

35.2.10 High Assurance Boot (HAB)

The High Assurance Boot (HAB) component of the ROM protects against the potential threat of attackers modifying areas of code or data in programmable memory to make it behave in an incorrect manner. The HAB also prevents attempts to gain access to features which should not be available.

The integration of the HAB feature with the ROM code ensures that the chip does not enter an operational state if the existing hardware security blocks have detected a condition that may be a security threat or areas of memory deemed to be important have been modified. The HAB uses RSA digital signatures to enforce these policies.

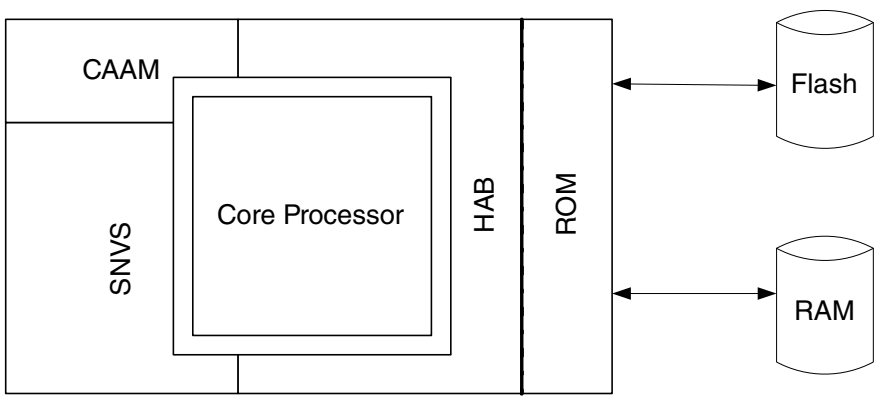

Figure 35-21. Secure Boot Components

NOTE

NXP provides a reference Code Signing Tool (CST) for key generation, certificate generation and code signing for use with the HAB library. The CST can be found by searching for "IMX_CST_TOOL" at http://www.nxp.com.

NOTE

For further details on making use of the secure boot feature using HAB, contact your local NXP representative.

35.2.10.1 HAB API Vector Table Addresses

For devices that perform a secure boot, the HAB library may be called by boot stages that execute after ROM code.

The RVT table contains the pointers to the HAB API functions and is located at 0x00000100 for A7 ROM and 0x1C000500 for M4 ROM.

NOTE

For additional information on secure boot including the HAB API, contact your local NXP representative.

35.2.11 Resume support in ROM

When resuming (exiting from VLLS mode), A7 core or M4 core will be re-powered and fetches instruction from the ROM code. ROM code then resumes the flow. The M4 ROM resume flow is as described as follows:

1. M4 ROM gets started and does the initialization job (related to HAB/security).
2. If SIM_DGO_GP1 is 0, go to step 4, otherwise clear SIM_DGO_GP1 register and then go to step 3.
3. If valid resuming entry be provisioned in SIM_DGO_GP1 (within 0x1FFD0000-0x20007FFF), M4 ROM jumps to this entry, otherwise issues WDOG reset.
4. Do the normal boot flow.

A7 ROM resume flow is described as follows:

1. A7 ROM gets started.
2. If SIM_DGO_GP3 is 0, go to step 4, otherwise clear SIM_DGO_GP3 register and then go to step 3.
3. If valid resuming entry be provisioned in SIM_DGO_GP3 (within 0x1FFD0000-0x20007FFF), or within OCRAM/QSPI/DDR, A7 ROM jumps to this entry, otherwise issues WDOG reset.
4. Do the normal boot flow.

NOTE

Even for resuming, M4 ROM will do some initialization (mainly related to HAB/security) and thus will take last 32 KB of TCMU.

NOTE

M4 resume entry must be in M4 ROM Free Area (0x1FFD0000-0x20007FFF). For A7 ROM, valid resume entry

is within M4 ROM Free Area, OCRAM, QSPI and DDR. Given that M4's involvement is necessary to wake-up A7 from VLLS, M4 image always has chance to check A7's resume entry in SIM_DGO_GP3 to make sure it is in the range as per expectation. For example, in some scenarios, it is preferred that the entry is in internal memory (M4 TCM or A7 OCRAM) for security concerns.

Chapter 36
Signal Multiplexing

36.1 Introduction

To optimize functionality in small packages, pins have several functions available via signal multiplexing. This chapter illustrates which of this device's signals are multiplexed on which external pin.

The Input/Output Multiplexing Controller (IOMUXC) controls which signal is present on the external pin. Please see the attached spreadsheet to know how the pins available on this device are configured. The available device packages and pinout diagrams are also provided in the attached spreadsheet.

36.2 Signal multiplexing constraints

1. A given peripheral function must be assigned to a maximum of one package pin. Do not program the same function to more than one pin.
2. To ensure the best signal timing for a given peripheral's interface, choose the pins in closest proximity to each other.

Chapter 37
Input/Output Multiplexing Controller (IOMUXC)

37.1 Chip-specific IOMUXC information

Signal multiplexing	Port control	Signal multiplexing

37.1.1 Input/Output Multiplexing Controller (IOMUXC)

The IOMUXC, working in conjunction with the IOMUX, enables the chip to share one pad for multiple signals from different peripheral interfaces. This pad sharing mechanism is done by multiplexing the pad's input and output signals. For each pad, there are up to 16 multiplexing options, which are called ALT modes. The IOMUX consists of combinatorial logic combined from several basic IOMUX cells. Each basic IOMUX cell handles one pad signal's multiplexing.

A peripheral's input signal may come from multiple pads. In order to avoid an input signal enabled on multiple locations the IOMUXC also control input multiplexing logic.

Every peripheral signal require a specific pad setting, such as pull-up or drive-strength. The IOMUXC also controls the pads setting parameters and digital filter functions of the pad.

i.MX 7ULP has three IOMUXC instances: IOMUXC0 for M4 ports, IOMUXC1 for A7 ports and IOMUXC DDR for DDR interface.

Table 37-2. IOMUXC configuration

Parameter	Description
Name	IOMUXC
Instances	3
Configurable features	IOMUXC0: Port A, B with Digital Filter enabled. IOMUXC1: Port C, D, E, F IOMUXC DDR: DDR & HSIC interfaces
Interface speed	NA
External I/O pins	NA

37.2 Overview

The IOMUX Controller (IOMUXC), together with the IOMUX, enables the device to share one pad to several functional blocks. The sharing is done by multiplexing the pad input/output signals. Every module requires a specific pad setting (such as pull up, keeper, and so on). The pad settings parameters are controlled by the IOMUXC. The IOMUX consists only of combinatorial logic combined from several basic iomux cells. Each basic iomux cell handles only one pad signal's muxing.

NOTE

DSE for DDR pads needs to be configured for highest speed (3'b111) for proper operation of DDR transactions.

Field	Description
	0 **IBE_0_Disabled** — Disabled 1 **IBE_1_Enabled** — Enabled
15 LK	Lock Field When enabled, prevents writes to fields: PS, PE, SRE, ODE, DSE, MUX_MODE and LK. Select one out of next values for pad: PADn 0 **LK_0_Disabled** — Disabled 1 **LK_1_Enabled** — Enabled
14–12 -	This field is reserved. Reserved
11–8 MUX_MODE	MUX Mode Select Field. Selects one of the maximum sixteen modes available for any pad. (The field width would vary for different pads depending on different alt modes available on it). Refer to "PCR MUX_MODE" column from IOMUX sheet.
7 -	This field is reserved. Reserved
6 DSE	Drive Strength Enable Field Select one out of next values for pad: PADn 0 **DSE_0_Standard** — Standard 1 **DSE_1_Hi_Drive** — Hi Drive
5 ODE	Open-drain Enable Field Select one out of next values for pad: PADn 0 **ODE_0_Push_pull** — Push-pull 1 **ODE_1_Open_drain** — Open-drain
4–3 -	This field is reserved. Reserved
2 SRE	Slew Rate Enable Field Select one out of next values for pad: PADn 0 **SRE_0_Standard** — Standard 1 **SRE_1_Slow** — Slow
1 PE	Pull Enable field Select one out of next values for pad: PADn 0 **PE_0_pull_disabled** — pull disabled 1 **PE_1_pull_enabled** — pull enabled
0 PS	Pull Select Field Select one out of next values for pad: PADn 0 **PS_0_pull_down** — pull-down 1 **PS_1_pull_up** — pull-up

37.3.4 SW_MUX_CTL_PAD SW MUX Control Register (IOMUXC0_SW_MUX_CTL_PAD_*n*)

This register is used to control the settings for a PAD (bit-wise details given below) and select ALT modes using MUX_MODE bits. Not all bits are implemented in all pads. Please refer to "IO Signal table" tab PCR fields under "Bit Name" column to verify if bit applies to a specific pad.

Address: 4103_D000h base + 74h offset + (0d × i), where i=0d to 0d

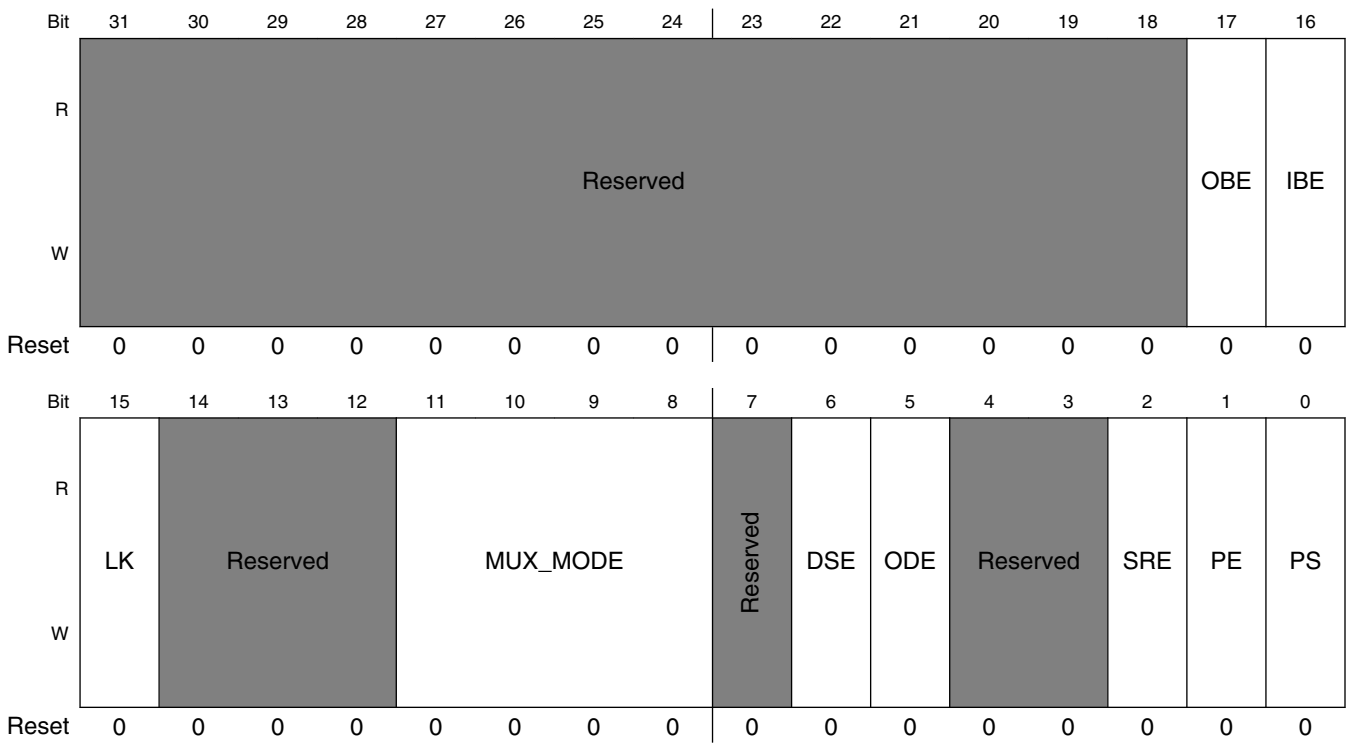
40AC_039C	SW_MUX_CTL_PAD_RESET1_b SW MUX Control Register (IOMUXC1_SW_MUX_CTL_PAD_RESET1_b)	32	R/W	0000_0023h	37.4.3/1570

37.4.1 SW_MUX_CTL_PAD SW MUX Control Register (IOMUXC1_SW_MUX_CTL_PAD_*n*)

This register is used to control the settings for a PAD (bit-wise details given below) and select ALT modes using MUX_MODE bits. Not all bits are implemented in all pads. Please refer to "IO Signal table" tab PCR fields under "Bit Name" column in the attached IOMUXC spreadsheet to verify if bit applies to a specific pad.

Address: 40AC_0000h base + 0h offset + (4d × i), where i=0d to 115d



IOMUXC1_SW_MUX_CTL_PAD_*n* field descriptions

Field	Description
31–18 -	This field is reserved. Reserved
17 OBE	Output Buffer Enable Field Select one out of next values for pad: PADn

Table continues on the next page...

IOMUXC1_SW_MUX_CTL_PAD_*n* field descriptions (continued)

Field	Description
	0 **OBE_0_Disabled** — Disabled 1 **OBE_1_Enabled** — Enabled
16 IBE	Input Buffer Enable Field Select one out of next values for pad: PADn 0 **IBE_0_Disabled** — Disabled 1 **IBE_1_Enabled** — Enabled
15 LK	Lock Field When enabled, prevents writes to fields: PS, PE, SRE, ODE, DSE, MUX_MODE and LK. Select one out of next values for pad: PADn 0 **LK_0_Disabled** — Disabled 1 **LK_1_Enabled** — Enabled
14–12 -	This field is reserved. Reserved
11–8 MUX_MODE	MUX Mode Select Field. Selects one of the maximum sixteen modes available for any pad. (The field width would vary for different pads depending on different alt modes available on it). Refer to "PCR MUX_MODE" column from IOMUX sheet.
7 -	This field is reserved. Reserved
6 DSE	Drive Strength Enable Field Select one out of next values for pad: PADn 0 **DSE_0_Standard** — Standard 1 **DSE_1_Hi_Drive** — Hi Drive
5 ODE	Open-drain Enable Field Select one out of next values for pad: PADn 0 **ODE_0_Push_pull** — Push-pull 1 **ODE_1_Open_drain** — Open-drain
4–3 -	This field is reserved. Reserved
2 SRE	Slew Rate Enable Field Select one out of next values for pad: PADn 0 **SRE_0_Standard** — Standard 1 **SRE_1_Slow** — Slow
1 PE	Pull-up Enable Field Select one out of next values for pad: PADn 0 **PE_0_pull_disabled** — pull disabled 1 **PE_1_pull_enabled** — pull enabled

Table continues on the next page...

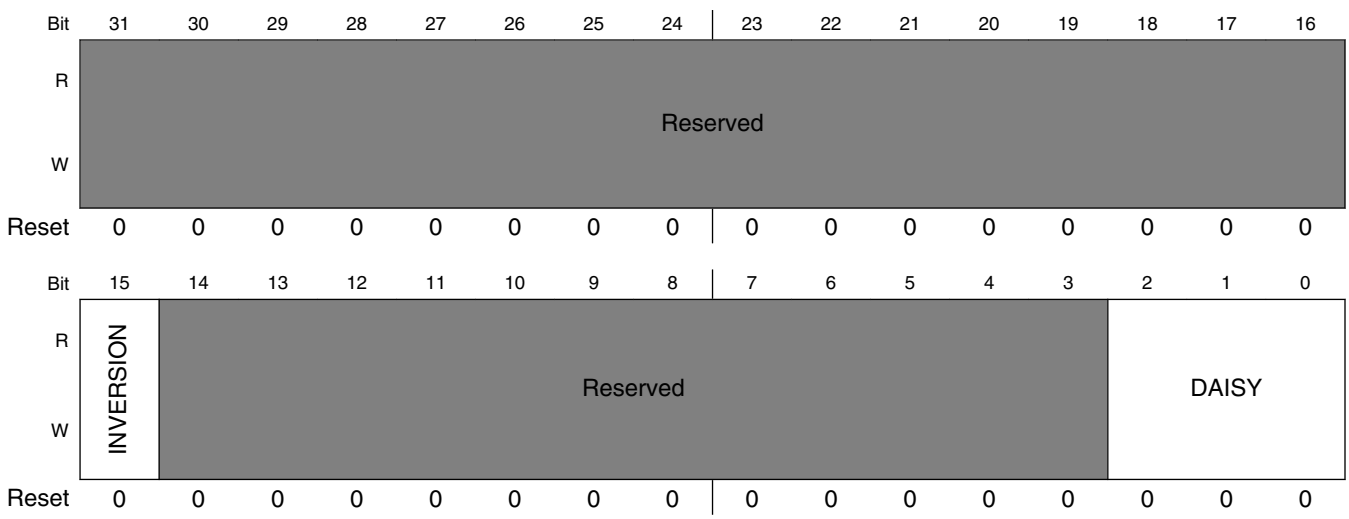
IOMUXC1_SW_MUX_CTL_PAD_*n* field descriptions (continued)

Field	Description
0 PS	Pull Select Field Select one out of next values for pad: PADn 0 **PS_0_pull_down** — pull-down 1 **PS_1_pull_up** — pull-up

37.4.2 N_SELECT_INPUT DAISY Register (IOMUXC1_*n*_SELECT_INPUT)

This register is used to select a source pad for a specific module input function. Refer to "Input Mux" tab on IOMUX Sheet.

Address: 40AC_0000h base + 200h offset + (4d × i), where i=0d to 79d



IOMUXC1_*n*_SELECT_INPUT field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
15 INVERSION	Control the inversion of the pad->module input 0 **DISABLE_INV** — Disable inversion. 1 **ENABLE_INV** — Enable inversion.
14–3 -	This field is reserved. Reserved
DAISY	Selects source pad for Module Input Function. Refer to "Input SSS" column from "Input Mux" tab on IOMUX Sheet.

37.4.3 SW_MUX_CTL_PAD_RESET1_b SW MUX Control Register (IOMUXC1_SW_MUX_CTL_PAD_RESET1_b)

SW_MUX_CTL Register

Address: 40AC_0000h base + 39Ch offset = 40AC_039Ch

IOMUXC1_SW_MUX_CTL_PAD_RESET1_b field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
15 LK	Lock Field When enabled, prevents writes to fields: PS, PE, SRE, ODE, DSE, MUX_MODE and LK. Select one out of next values for pad: RESET1_b 0 **LK_0_Disabled** — Disabled 1 **LK_1_Enabled** — Enabled
14–7 -	This field is reserved. Reserved
6 DSE	Drive Strength Enable Field Select one out of next values for pad: RESET1_b 0 **DSE_0_Standard** — Standard 1 **DSE_1_Hi_Drive** — Hi Drive
5 ODE	Open-drain Enable Field Select one out of next values for pad: RESET1_b 0 **ODE_0_Push_pull** — Push-pull 1 **ODE_1_Open_drain** — Open-drain
4–3 -	This field is reserved. Reserved
2 SRE	Slew Rate Enable Field Select one out of next values for pad: RESET1_b 0 **SRE_0_Standard** — Standard 1 **SRE_1_Slow** — Slow

Table continues on the next page...

IOMUXC1_SW_MUX_CTL_PAD_RESET1_b field descriptions (continued)

Field	Description
1 PE	Pull-up Enable Field Select one out of next values for pad: RESET1_b 0 **PE_0_pull_disabled** — pull disabled 1 **PE_1_pull_enabled** — pull enabled
0 PS	Pull Select Field Select one out of next values for pad: RESET1_b 0 **PS_0_pull_down** — pull-down 1 **PS_1_pull_up** — pull-up

37.6 Functional description

37.6.1 GPIO pads

The figure below shows the GPIO Pad .

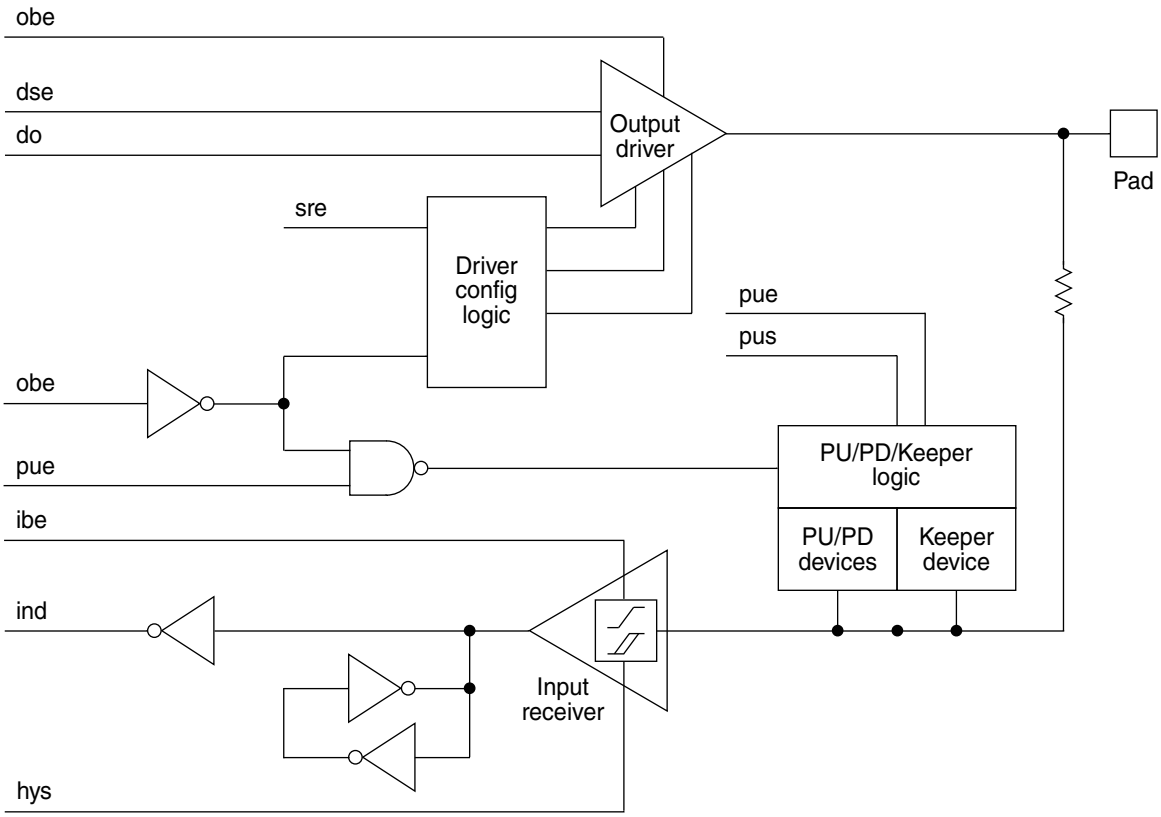

Figure 37-1. GPIO PAD

Table 37-3. Signal Description

Signal Name	Description	Description
Pad	Input/Output	I/O to external world
do	Input	Data coming from the core into the pad
obe	Input	Output enable
ode	Input	Select open drain or CMOS output
dse	Input	Drive Strength select
sre	Input	Slew rate control
pue	Input	Enable pull-up/down or keeper
pus	Input	Pull-up/down select
ibe	Input	Input enable
ind	Output	Data coming out of the pad into the core

NOTE

For DDR pads, there are additional control signals as explained in IOMUXC register map to control DDR functionality.

Table 37-4. Truth Table - Core to Pad

ode	obe	pue	pus	do	dse	pad
Output Buffer Mode (functional)						
0	1	X	X	do	X	do
0	0	X	X	X	X	Z
Output Buffer Mode + pull-up/pull-down resistors						
0	0	1	0	X	X	weak pull-down
0	0	1	1	X	X	weak pull-up
Open Drain Mode						
1	1	X	X	do	X	do
1	0	X	X	X	X	Z
Open Drain Mode + Pull-up						
1	1	1	1	0	X	0 (open drain + pull-up
1	0	X	X	X	X	Z

Table 37-5. Truth Table - Pad to Core

ibe	pad	ind
0	X	Safe value
1	pad	pad

IOMUX module is used to configure the Pad settings through the IOMUX registers and multiplex multiple modules on to a single PAD and drive input to a module from multiple PADs. Muxing is done only on obe, ibe, ind and do and rest of the pad settings are through IOMUX registers. DDR pads are dedicated pads for DDR and there is no muxing on them.

Table 37-6. Signal Description

Name	Direction	Description
vdd1p8	input	1.8V PD predriver and level shifters supply voltage
pad	inout	I/O to the external world (single-ended and calibration cells)
padp, padn	inout	Positive and negative output pads to the external world (DDR CLK cell)
ipp_do	input	Data coming from the core into the pad
ipp_obe	input	Control signal for active high output enable (0=disable, 1=enable)
ddr_input	input	Control signal to select differential or CMOS input receiver mode: '0': CMOS input receiver mode (ipp_ibe=1). '1': differential DDR input receiver mode (ipp_ibe=1).
ipp_pke	input	Control signal to enable the pullup, pulldown resistors or pad keeper (in pbigjtv12_clamp_ddr, pbigjtv12_trigger_ddr cells only) capability: 0: capability disabled 1: capability enabled When ipp_pke=0, ipp_pue, ipp_pus0, ipp_pus1 have no functionality. Pad keeper is located only in pbigjtv12_ddr_single cell. There is no keeper in pbigjtv12_ddr_clk and calibration_ddr cells.
ipp_pue	input	Control signal to select pullup/ down resistors or pad keeper 0: pad keeper enable (pbigjtv12_ddr_single cell only; no functionality for pbigjtv12_ddr_clk cell) 1: pullup/down resistors enabled
ipp_pus0, ipp_pus1	input	Control signals to select pullup or pulldown resistors strength (in DDR CLK cell values are applicable for padp, for padn pu values mean pd and vice versa) **LPDDR2/LPDDR3/DDR3 modes:** 00: 100K Ohm PD res 01: 47K Ohm PU res 10: 100K Ohm PU res 11: 22K Ohm PU res **HSIC-USB mode:** 00: 30K Ohm PD res 01: 3K Ohm PU res 10: 100K Ohm PU res 11: 30K Ohm PU res
ipp_ind	output	Data coming out of the pad into the core

Table continues on the next page...

Table 37-6. Signal Description (continued)

Name	Direction	Description
ipp_ibe	input	Control signal for active high input enable (0=disable, 1=enable)
ipp_hys	input	Control signal to select Schmitt trigger or CMOS input (when CMOS input receiver selected) 0: CMOS input (for DDR CLK cell this is single-ended input mode and 'padp-]ipp_ind' path) 1: Schmitt trigger input
ddr_sel[1:0]	input	2-bit control signal to select DDR operational modes: 00 - DDR3 mode; 10 - LPDDR2/LPDDR3 modes; 01 - reserved 11 - HSIC-USB mode
ipp_dse[2:0]	input	3-bit control signal to select output drive strength (by enabling pullup/ pulldown driver units) 000 - output driver disabled; 001 - 240 Ohm 010 - 240/2 = 120 Ohm 011 - 240/3 = 80 Ohm 100 - 240/4 = 60 Ohm 101 - 240/5 = 48 Ohm 110 - 240/6 = 40 Ohm 111 - 240/7 = 34 Ohm (max drive strength)
ipp_odt[2:0]	input	3-bit control signal to select ODT strength in DDR3 mode: 001 - 120 Ohm ODT 010 - 60 Ohm ODT 011 - 40 Ohm ODT 100 - 30 Ohm ODT 101 - 24 Ohm ODT 110 - 20 Ohm ODT 111 - 17 Ohm ODT
do_trim[1:0] **(in ddr_single cell only)**	input	2-bit control signal for ipp_do-]pad delay in DDR single cell with ~50ps step (independent from PVT case): 00 : min delay; 01 : + ~50 ps delay; 10 : + ~100 ps delay; 11 : + ~150 ps delay;
pu_cal[4:0]	input	5-bit control signal for PU output driver sections ##4, 5, 6, 7 calibration
pu_m1_cal[4:0]	input	5-bit control signal for PU output driver sections ##1, 2, 3 calibration
pd_calb[4:0]	input	5-bit control signal for PD output driver sections ##4, 5, 6, 7 calibration
pd_m1_calb[4:0]	input	5-bit control signal for PD output driver sections ##1, 2, 3 calibration

Table continues on the next page...

Table 37-6. Signal Description (continued)

Name	Direction	Description
vref	input	DDR padring reference voltage (from cell: 'an_ddr_vref'), that is used for single-ended cell only. vref=ovdd/2

Table 37-7. DDR Cells Truth table - core to pad

ipp_obe	ipp_pke	ipp_pue	ipp_pus1	ipp_pus0	ipp_do	ipp_dse[2:0]	pad (single ended cell) / padp (CLK cell)	padn (CLK cell)
Output Buffer Mode (functional)								
1	0	X	X	X	ipp_do	001, 010, 011, 100, 101, 110, 111	ipp_do	! ipp_do
1	0	X	X	X	ipp_do	000	Z	Z
0	0	X	X	X	X	X	Z	Z
Output Buffer Mode + keeper (DDR single-ended cell only)								
0	1	0	X	X	X		pad (keep previous state)	-
Output Buffer Mode + pull-up/pull-down resistors								
0	1	1	0	0	X		weak0 (pull-down 100 KOhm)	weak1 (pull-up 100 KOhm)
0	1	1	0	1	X		weak1 (pull-up 47 KOhm)	weak0 (pull-down 47 KOhm)
0	1	1	1	0	X		weak1 (pull-up 100 KOhm)	weak0 (pull-down 100 KOhm)
0	1	1	1	1	X		weak1 (pull-up 22 KOhm)	weak0 (pull-down 22 KOhm)

Table 37-8. Truth table - pad to core (CMOS input)

ipp_ibe	pad (single ended cell) / padp (CLK cell)	ipp_ind
0	X	ipp_ind (keep previous state)
1	pad / padp	pad / padp

37.6.3 IOMUX Sheet

The following is a snippet from the IOMUX excel sheet attached with this document, where Port PTA0 has GPIO and the LPSPI0 Peripheral Chip Select 1 muxed onto it. Either of them can be selected by configuring MUX_MODE[2:0] bits of IOMUXC register for PTA0. Use the spreadsheet to set the SSS bits for input muxing and the SW_MUX bits to select the output muxing.

Port	CR	CR#	SW_MUX	Addr	Function	Module	Description	Direction
PTA0	PCR0_PTA0	0	0000_0000	0x4103_d000	CMP0_IN1_3V	CMP0	CMP0 Analog Voltage Input 1 (3v Range)	I
			0000_0001		PTA0	PTA	General Purpose I/O	I/O
			0000_0011		LPSPI0_PCS1	LPSPI0	LPSPI0 Peripheral Chip Select 1 or Host Request	I/O
			0000_0100		LPUART0_CTS_b	LPUART0	LPUART0 Clear to Send	I
			0000_0101		LPI2C0_SCL	LPI2C0	LPI2C0 Serial Clock Line	I/O
			0000_0110		TPM0_CLKIN	TPM0	TPM0 External Clock	I
			0000_0111		I2S0_RX_BCLK	I2S0	I2S0 Receive Bit Clock	I/O
			0000_1101		LLWU0_P0	LLWU0	LLWU Wakeup Input 0	I
			-		BT0_CFG0	CMC0	CM4 Boot Configuration 0	I

Figure 37-4. IOMUX Sheet Snippet

37.7 Special Pad Settings

This section describes the special pad setting requirements for several modules in this device. DDR Pins are dedicated pins and do not have any alternate functionality on them. The control for DDR pins are described in Miscellaneous Pins Configuration (Chapter 19). GPIO Pin settings (sre, ode, hys, dse, pus, pke,pue) are controlled by IOMUX registers, however, special care needs to be taken for ibe/obe. The ibe/obe bits on IOMUX registers are used to optionally enable pin's ibe/obe. Modules are responsible for controlling ibe/obe.

37.7.1 I2C

I2C pins, SCL and SDA are both Open-drain and bi-directional. Hence, ODE bit should be set in IOMUX registers.

37.7.2 SCI

Pull-ups should be enabled to ensure there are no spurious transitions.

37.7.3 Reset Pins Configuration

By default, a pull up is enabled on RESET0_B and RESET1_B pins. Additionally dse is set for those pins. Ibe and obe are controlled by reset controller.

Chapter 38
Trigger MUX (TRGMUX)

38.1 Chip-specific TRIGMUX information

Table 38-1. Reference links to related information

Topic	Related module	Reference
Full description	TRIGMUX	TRIGMUX

Signal multiplexing	Port control	Signal multiplexing

38.1.1 Trigger MUX (TRGMUX)

The Trigger MUX module (TRGMUX) allows software to configure the trigger inputs for various peripherals. Trigger inputs and outputs are defined according to the i.MX 7ULP Trigger MUX table.

Table 38-2. TRGMUX0 outputs

Register	Offset	Select	Output	Pretrigger	TRGMUX0 Outputs	Functions

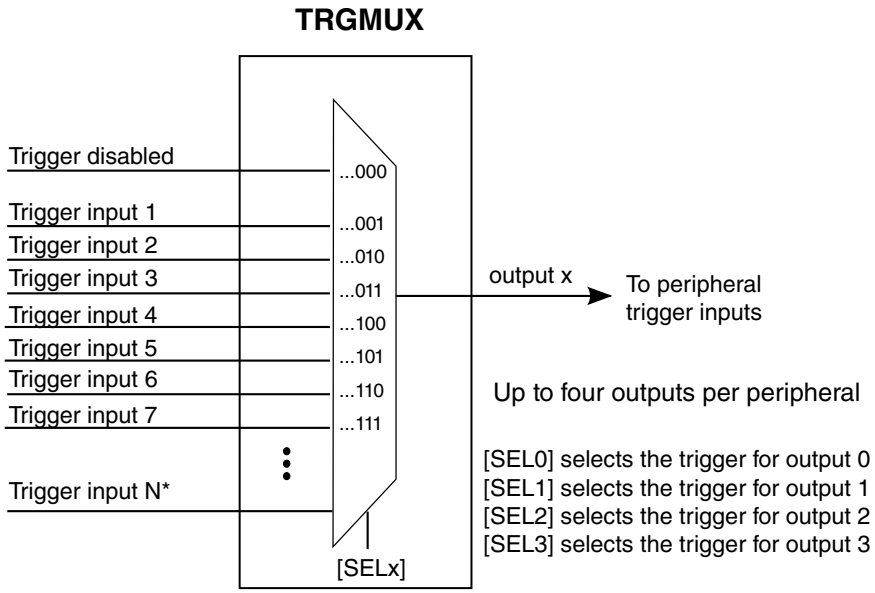
38.2 Introduction

The trigger multiplexer (TRGMUX) module allows software to configure the trigger inputs for various peripherals.

38.3 Features

The TRGMUX module allows software to select the trigger source for peripherals. The block diagram below shows the trigger selection logic of the TRGMUX module.



* Up to 255 trigger inputs may be available for SEL0, SEL1, and SEL2. For SEL3, up to 127 trigger inputs may be available. When the number of trigger inputs is 255, SEL3 is not available and becomes reserved. See the chip-specific TRGMUX information for the maximum number of trigger inputs supported on this device.

Figure 38-1. TRGMUX block diagram

Each peripheral has its own dedicated TRGMUX register. See each peripheral's TRGMUX register for details.

38.4 Memory map and register definition

The TRGMUX registers contain fields for selecting trigger sources for peripheral modules.

TRGMUX registers can be written only in supervisor mode.

38.4.1 TRGMUX register descriptions

38.4.1.1 TRGMUX Memory map

38.4.1.2.4 Fields

Field	Function
31 LK	TRGMUX register lock. This bit shows whether the register can be written or not. The LK bit can only be written once after any system reset. Once LK is set, the SELx bits in this TRGMUX register cannot be changed until the next system reset clears LK. 0b - Register can be written. 1b - Register cannot be written until the next system Reset.
30-24 SEL3	Trigger MUX Input 3 Source Select This read/write bit field is used to configure the MUX select for peripheral trigger input 3. For the field setting definitions, see Memory map and register definition.
23 —	This read-only bit field is reserved and always has the value 0.
22-16 SEL2	Trigger MUX Input 2 Source Select This read/write bit field is used to configure the MUX select for peripheral trigger input 2. For the field setting definitions, see Memory map and register definition.
15 —	This read-only bit field is reserved and always has the value 0.
14-8 SEL1	Trigger MUX Input 1 Source Select This read/write bit field is used to configure the MUX select for peripheral trigger input 1. For the field setting definitions, see Memory map and register definition.
7 —	This read-only bit field is reserved and always has the value 0.
6-0 SEL0	Trigger MUX Input 0 Source Select This read/write bit field is used to configure the MUX select for peripheral trigger input 0. For the field setting definitions, see Memory map and register definition.

38.4.1.3 TRGMUX DMAMUX0_B Register (DMAMUX0_B)

38.4.1.3.1 Offset

Register	Offset
DMAMUX0_B	4h

38.4.1.3.2 Function

This register is for the DMAMUX0_B module.

38.4.1.3.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

38.4.1.15.4 Fields

Field	Function
31 LK	TRGMUX register lock. This bit shows whether the register can be written or not. The LK bit can only be written once after any system reset. Once LK is set, the SELx bits in this TRGMUX register cannot be changed until the next system reset clears LK. 0b - Register can be written. 1b - Register cannot be written until the next system Reset.
30-24 —	This read-only bit field is reserved and always has the value 0.
23 —	This read-only bit field is reserved and always has the value 0.
22-16 —	This read-only bit field is reserved and always has the value 0.
15 —	This read-only bit field is reserved and always has the value 0.
14-8 —	This read-only bit field is reserved and always has the value 0.
7 —	This read-only bit field is reserved and always has the value 0.
6-0 SEL0	Trigger MUX Input 0 Source Select This read/write bit field is used to configure the MUX select for peripheral trigger input 0. For the field setting definitions, see Memory map and register definition.

38.4.2.2 TRGMUX DMAMUX1_A Register (DMAMUX1_A)

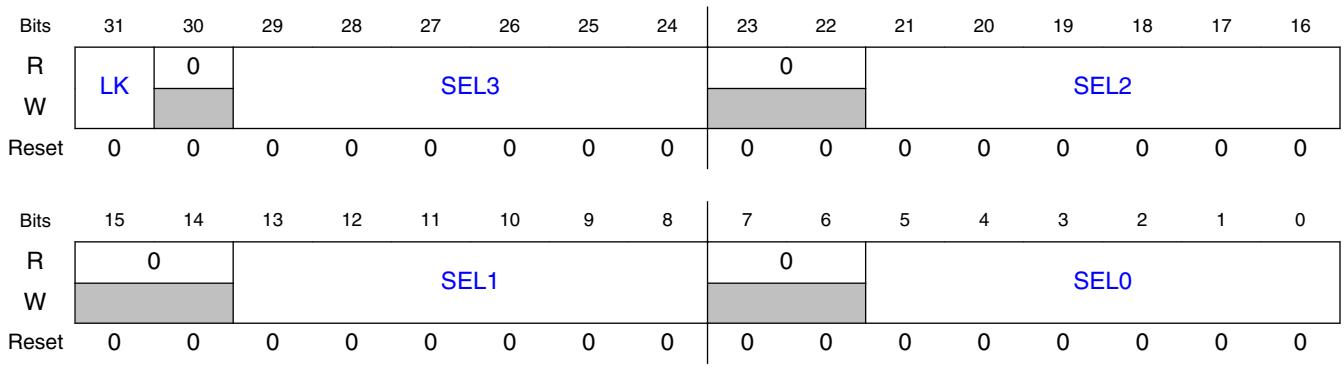
38.4.2.2.1 Offset

Register	Offset
DMAMUX1_A	0h

38.4.2.2.2 Function

This register is for the DMAMUX1_A module.

38.4.2.2.3 Diagram



38.4.2.2.4 Fields

Field	Function
31 LK	TRGMUX register lock. This bit shows whether the register can be written or not. The LK bit can only be written once after any system reset. Once LK is set, the SELx bits in this TRGMUX register cannot be changed until the next system reset clears LK. 0b - Register can be written. 1b - Register cannot be written until the next system Reset.
30 —	This read-only bit field is reserved and always has the value 0.
29-24 SEL3	Trigger MUX Input 3 Source Select This read/write bit field is used to configure the MUX select for peripheral trigger input 3. For the field setting definitions, see Memory map and register definition.
23-22 —	This read-only bit field is reserved and always has the value 0.
21-16 SEL2	Trigger MUX Input 2 Source Select This read/write bit field is used to configure the MUX select for peripheral trigger input 2. For the field setting definitions, see Memory map and register definition.
15-14 —	This read-only bit field is reserved and always has the value 0.
13-8 SEL1	Trigger MUX Input 1 Source Select This read/write bit field is used to configure the MUX select for peripheral trigger input 1. For the field setting definitions, see Memory map and register definition.
7-6 —	This read-only bit field is reserved and always has the value 0.

Table continues on the next page...

Field	Function
5-0 SEL0	Trigger MUX Input 0 Source Select This read/write bit field is used to configure the MUX select for peripheral trigger input 0. For the field setting definitions, see Memory map and register definition.

38.4.2.3 TRGMUX DMAMUX1_B Register (DMAMUX1_B)

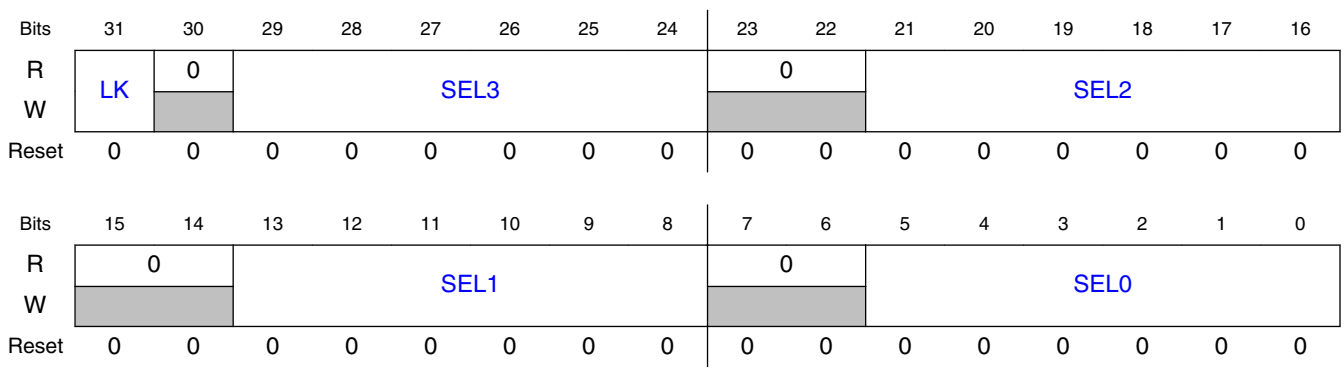
38.4.2.3.1 Offset

Register	Offset
DMAMUX1_B	4h

38.4.2.3.2 Function

This register is for the DMAMUX1_B module.

38.4.2.3.3 Diagram



38.4.2.3.4 Fields

Field	Function
31 LK	TRGMUX register lock. This bit shows whether the register can be written or not. The LK bit can only be written once after any system reset. Once LK is set, the SELx bits in this TRGMUX register cannot be changed until the next system reset clears LK. 0b - Register can be written. 1b - Register cannot be written until the next system Reset.
30	This read-only bit field is reserved and always has the value 0.

Table continues on the next page...

Field	Function
—	
29-24 SEL3	Trigger MUX Input 3 Source Select This read/write bit field is used to configure the MUX select for peripheral trigger input 3. For the field setting definitions, see Memory map and register definition.
23-22 —	This read-only bit field is reserved and always has the value 0.
21-16 SEL2	Trigger MUX Input 2 Source Select This read/write bit field is used to configure the MUX select for peripheral trigger input 2. For the field setting definitions, see Memory map and register definition.
15-14 —	This read-only bit field is reserved and always has the value 0.
13-8 SEL1	Trigger MUX Input 1 Source Select This read/write bit field is used to configure the MUX select for peripheral trigger input 1. For the field setting definitions, see Memory map and register definition.
7-6 —	This read-only bit field is reserved and always has the value 0.
5-0 SEL0	Trigger MUX Input 0 Source Select This read/write bit field is used to configure the MUX select for peripheral trigger input 0. For the field setting definitions, see Memory map and register definition.

38.4.2.4 TRGMUX TPM4 Register (TPM4)

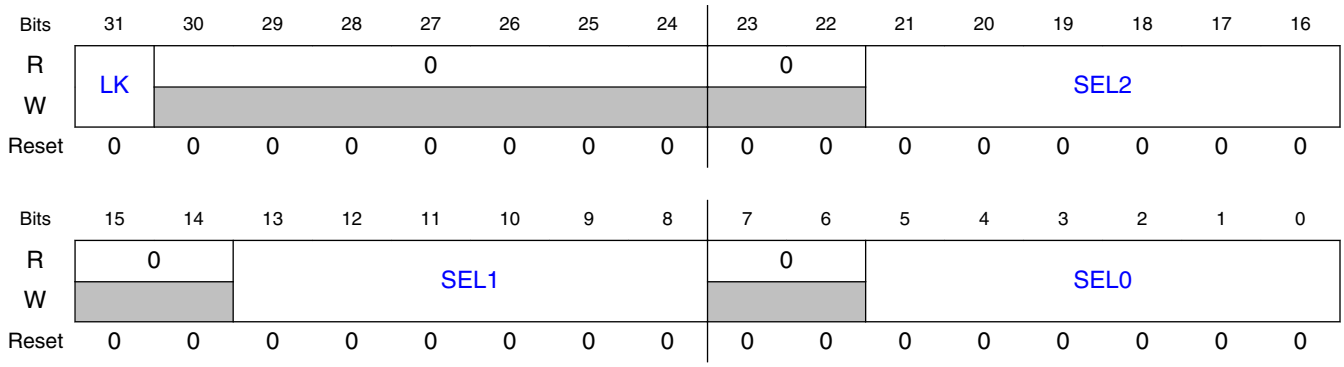
38.4.2.4.1 Offset

Register	Offset
TPM4	8h

38.4.2.4.2 Function

This register is for the TPM4 module.

38.4.2.4.3 Diagram



38.4.2.4.4 Fields

Field	Function
31 LK	TRGMUX register lock. This bit shows whether the register can be written or not. The LK bit can only be written once after any system reset. Once LK is set, the SELx bits in this TRGMUX register cannot be changed until the next system reset clears LK. 0b - Register can be written. 1b - Register cannot be written until the next system Reset.
30-24 —	This read-only bit field is reserved and always has the value 0.
23-22 —	This read-only bit field is reserved and always has the value 0.
21-16 SEL2	Trigger MUX Input 2 Source Select This read/write bit field is used to configure the MUX select for peripheral trigger input 2. For the field setting definitions, see Memory map and register definition.
15-14 —	This read-only bit field is reserved and always has the value 0.
13-8 SEL1	Trigger MUX Input 1 Source Select This read/write bit field is used to configure the MUX select for peripheral trigger input 1. For the field setting definitions, see Memory map and register definition.
7-6 —	This read-only bit field is reserved and always has the value 0.
5-0 SEL0	Trigger MUX Input 0 Source Select This read/write bit field is used to configure the MUX select for peripheral trigger input 0. For the field setting definitions, see Memory map and register definition.

38.4.2.5 TRGMUX TPM5 Register (TPM5)

38.4.2.5.1 Offset

Register	Offset
TPM5	Ch

38.4.2.5.2 Function

This register is for the TPM5 module.

39.1.1 Port Control

The Port Control (PORT) module provides support for port control and digital filtering functions. All functions can be configured independently for each pin in the 32-bit port and affect the pin regardless of its pin multiplexing state. There is one instance of the PORT module for each port. Not all pins within each port are implemented on a specific device.

Table 39-2. PORT configuration

Parameter	Description
Name	Port Control
Instances	6 (PortA-F)

39.2 Introduction

39.2.1 Overview

The Port Control and Interrupt (PORT) module provides support for port control, and external interrupt functions.

Most functions can be configured independently for each pin in the 32-bit port and affect the pin regardless of its pin muxing state.

There is one instance of the PORT module for each port. Not all pins within each port are implemented on a specific device.

39.2.2 Features

The PORT module has the following features:

- Pin interrupt
  - Interrupt flag and enable registers for each pin
  - Support for edge sensitive (rising, falling, both) or level sensitive (low, high) configured per pin
  - Support for interrupt or DMA request configured per pin
  - Asynchronous wake-up in low-power modes
  - Pin interrupt is functional in all digital pin muxing modes
  - Peripheral trigger output (active high, low) configured per pin
- Port control
  - Individual mux control field supporting analog or pin disabled, GPIO, and up to 6 chip-specific digital functions
  - Pad configuration fields are functional in all digital pin muxing modes

39.2.3 Modes of operation

39.2.3.1 Run mode

In Run mode, the PORT operates normally.

39.2.3.2 Wait mode

In Wait mode, PORT continues to operate normally and may be configured to exit the Low-Power mode if an enabled interrupt is detected. DMA requests are still generated during the Wait mode, but do not cause an exit from the Low-Power mode.

39.2.3.3 Stop mode

In Stop mode, the PORT can be configured to exit the Low-Power mode via an asynchronous wake-up signal if an enabled interrupt is detected.

In Stop mode, the PORT configuration is static.

39.2.3.4 Debug mode

In Debug mode, PORT operates normally.

39.3 External signal description

The table found here describes the PORT external signal.

Table 39-3. Signal properties

Name	Function	I/O	Reset	Pull
PORTx[31:0]	External interrupt	I/O	0	-

NOTE

Not all pins within each port are implemented on each device.

39.3.1 Detailed signal description

The table found here contains the detailed signal description for the PORT interface.

Table 39-4. PORT interface—detailed signal description

Signal	I/O	Description	
PORTx[31:0]	I/O	External interrupt.	
		State meaning	Asserted—pin is logic 1. Negated—pin is logic 0.

Table continues on the next page...

Signal	I/O	Description	
		Timing	Assertion—may occur at any time and can assert asynchronously to the system clock. Negation—may occur at any time and can assert asynchronously to the system clock.

39.4 Memory map and register definition

Any read or write access to the PORT memory space that is outside the valid memory map results in a bus error. All register accesses complete with zero wait states.

39.4.1 PORT register descriptions

39.4.1.7.4 Fields

Field	Function
31-0 ISF	Interrupt Status Flag Each bit in the field indicates the detection of the configured interrupt of the same number as the field. 0b - Configured interrupt is not detected. 1b - Configured interrupt is detected. If the pin is configured to generate a DMA request, then the corresponding flag will be cleared automatically at the completion of the requested DMA transfer. Otherwise, the flag remains set until a logic 1 is written to the flag. If the pin is configured for a level sensitive interrupt and the pin remains asserted, then the flag is set again immediately after it is cleared.

39.5 Functional description

39.5.1 Pin control

Each port pin has a corresponding Pin Control register, PORT_PCRn, associated with it. The Pin Control register configures the following functions for each pin within the 32-bit port.

- Pullup enable on selected pins
- Pin Muxing mode

The functions apply across all digital pin muxing modes and individual peripherals do not override the configuration in the Pin Control register. For example, if an I^2C function is enabled on a pin, that does not override the pullup configuration for that pin.

When the Pin Muxing mode is configured for analog or is disabled, all the digital functions on that pin are disabled. This includes the pullup and pulldown enables, output buffer enable, input buffer enable, and passive filter enable.

The configuration of each Pin Control register is retained when the PORT module is disabled.

Whenever a pin is configured in any digital pin muxing mode, the input buffer for that pin is enabled allowing the pin state to be read via the corresponding GPIO Port Data Input Register (GPIO_PDIR) or allowing a pin interrupt or DMA request to be generated. If a pin is ever floating when its input buffer is enabled, then this can cause an increase in power consumption and must be avoided. A pin can be floating due to an input pin that is not connected or an output pin that has tri-stated (output buffer is disabled).

Enabling the internal pull resistor (or implementing an external pull resistor) will ensure a pin does not float when its input buffer is enabled; note that the internal pull resistor is automatically disabled whenever the output buffer is enabled allowing the Pull Enable bit to remain set. Configuring the Pin Muxing mode to disabled or analog will disable the pin's input buffer and results in the lowest power consumption.

39.5.2 Global pin control

The two global pin control registers allow a single register write to update the lower 16-bits of the Pin Control Register for up to 16 pins, all with the same value.

The global pin control registers are designed to enable software to quickly configure multiple pins within the same port with the same peripheral function.

The global pin control registers are write-only registers, that always read as 0.

39.5.3 Global interrupt control

The two global interrupt control registers allow a single register write to update the upper 16-bits of the Pin Control Register for up to 16 pins, all with the same value.

The global interrupt control registers are designed to enable software to quickly configure multiple pins within the same port with the same interrupt configuration.

The global interrupt control registers are write-only registers and always read as 0.

39.5.4 External interrupts

The external interrupt capability of the PORT module is available in all digital pin muxing modes provided the PORT module is enabled.

Each pin can be individually configured for any of the following external interrupt modes:

- Interrupt disabled, default out of reset
- Rising edge flag (for software polling)
- Falling edge flag (for software polling)
- Rising and falling edge flag (for software polling)
- Active high level peripheral trigger (status flag disabled)
- Active low level peripheral trigger (status flag disabled)
- Active high level sensitive interrupt
- Active low level sensitive interrupt
- Rising edge sensitive interrupt
- Falling edge sensitive interrupt
- Rising and falling edge sensitive interrupt
- Rising edge sensitive DMA request
- Falling edge sensitive DMA request
- Rising and falling edge sensitive DMA request

The interrupt status flag is set when the configured edge or level is detected on the pin . When not in Stop mode, the input is first synchronized to the bus clock to detect the configured level or edge transition.

The PORT module generates a single pin interrupt that asserts when the interrupt status flag is set for any enabled interrupt for that port. The interrupt negates after the interrupt status flags for all enabled interrupts have been cleared by writing a logic 1 to the ISF flag in either the PORT_ISFR or PORT_PCRn registers.

The PORT module generates a single DMA request that asserts when the interrupt status flag is set for any enabled DMA request in that port. The DMA request negates after the DMA transfer is completed, because that clears the interrupt status flags for all enabled DMA requests.

During Stop mode, the interrupt status flag for any enabled interrupt is asynchronously set if the required level or edge is detected. This also generates an asynchronous wake-up signal to exit the Low-Power mode.

The PORT module generates a single peripheral trigger output that asserts if any pin configured for active high trigger is logic one, or any pin triggered for active low trigger is logic zero. The peripheral trigger output asynchronously updates from the value on the configured pins.

Chapter 40
Rapid General-Purpose Input and Output with 2 Ports (RGPIO2P)

40.1 Chip-specific RGPIO2P information

Table 40-1. Reference links to related information

Topic	Related module	Reference

40.1.1 RGPIO2P

The Rapid General-Purpose Input and Output with 2 Ports (RGPIO2P) is similar to the RGPIO module, except it has an IPS port and AHB port. When connecting to the AHB interface, the processor can access RGPIO2P in zero-wait-state.

Table 40-2. RGPIO2P configuration

Parameter	Description
Name	RGPIO2P
Instances	2
Interface speed	RGPIO2P0-1: Set by I/O max
External I/O pins	PTAx, PTBx, PTCx, PTDx, PTEx, and PTFx. See IOMUXC spreadsheet attached with this document for details.

40.1.2 RGPIO2P Port implementation and instantiation in i.MX 7ULP

This device has two instances of RGPIO2P: one in CM4 platform and the other in CA7 platform. In total, RGPIO2P implements 6 ports, A-F. The following figure illustrates the implementation of GPIOA-F through IOMUXC.

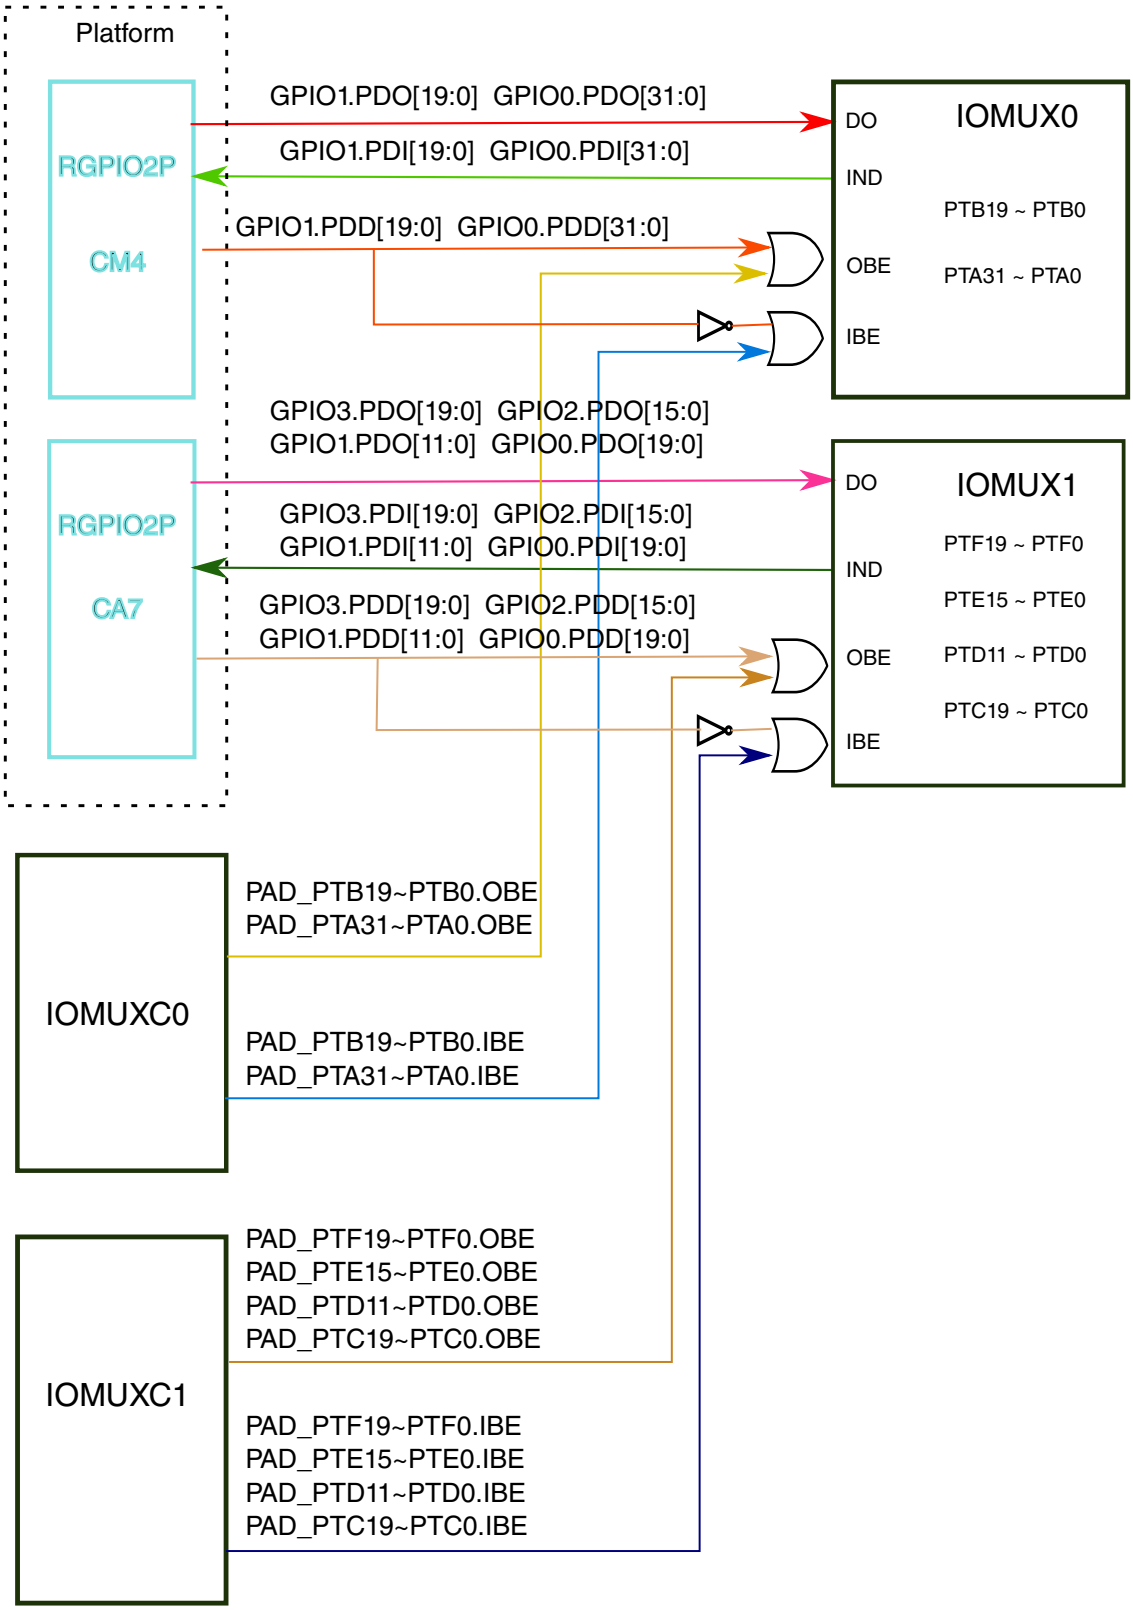

Figure 40-1. RGPIO2P port implementation in dual core

40.1.3 Port interface domain

XRDC protection is available for RGPIO2P for having independent access attributes for each interface domain. See the register section for more details.

- IPS interface
- IOPORT interface
- AHB interface
- APB interface

40.1.4 Port description implementation on this device

On this device, there are two types of GPIOs:

- Fail-safe GPIOs (FSGPIO) on ports A, B, C, E and F can have the GPIO port power supply removed (VDD_PTA, VDD_PTB, etc) and the inputs will not draw any current from either the VDD or ground.
- Standard GPIOs (STGPIO) on Port D are not fail-safe.

The following table depicts the number of ports along with the GPIOs, available on this device.

NOTE

The RGPIO2P has 2 access ports: one is connected to AIPS-Lite Bus and the other is connected to AHB Bus. GPIOA and GPIOB are accessible by both AHB and AIPS buses and hence have two base addresses. So, the user can access the RGPIO2P through AIPS-Lite0 using address 0x4100F000 for GPIOA and 0x4100F040 for GPIOB and access the RGPIO2P through AHB bus using address 0xF9000000 for GPIOA and 0xF9000040 for GPIOB.

Port name	Base address	Voltage (V)	Domain	Number of GPIOs/ Pins
GPIOA	0x4100_F000[1]	3.3/1.8	CM4	32

1. 0xF9000000 through the AHB bus
2. 0xF9000040 through AHB bus

40.2 Introduction

The general-purpose input and output (GPIO) module communicates to the processor core via a zero wait state interface (IOPORT) for maximum pin performance.The general-purpose input and output (GPIO) module is also accessible via the peripheral bus. The GPIO registers support 8-bit, 16-bit or 32-bit accesses.

The GPIO data direction and output data registers control the direction and output data of each pin when the pin is configured for the GPIO function. The GPIO input data register displays the logic value on each pin when the pin is configured for any digital function, provided the corresponding Port Control and Interrupt module for that pin is enabled.

Efficient bit manipulation of the general-purpose outputs is supported through the addition of set, clear, and toggle write-only registers for each port output data register.

40.2.1 Features

Features of the GPIO module include:

- Port Data Input register visible in all digital pin-multiplexing modes
- Port Data Output register with corresponding set/clear/toggle registers
- Port Data Direction register
- Zero wait state access to GPIO registers through IOPORT

NOTE

The GPIO module is clocked by system clock.

40.2.2 Modes of operation

The following table depicts different modes of operation and the behavior of the GPIO module in these modes.

Table 40-3. Modes of operation

Modes of operation	Description
Run	The GPIO module operates normally.
Wait	The GPIO module operates normally.
Stop	The GPIO module is disabled.
Debug	The GPIO module operates normally.

40.2.3 GPIO signal descriptions

Table 40-4. GPIO signal descriptions

GPIO signal descriptions	Description	I/O
PORTA31–PORTA0	General-purpose input/output	I/O
PORTB31–PORTB0	General-purpose input/output	I/O

NOTE

Not all pins within each port are implemented on each device. See the chapter on signal multiplexing for the number of GPIO ports available in the device.

40.2.3.1 Detailed signal description

Table 40-5. GPIO interface-detailed signal descriptions

Signal	I/O	Description	
PORTA31–PORTA0 PORTB31–PORTB0	I/O	General-purpose input/output	
		State meaning	Asserted: The pin is logic 1. Deasserted: The pin is logic 0.
		Timing	Assertion: When output, this signal occurs on the rising-edge of the system clock. For input, it may occur at any time and input may be asserted asynchronously to the system clock. Deassertion: When output, this signal occurs on the rising-edge of the system clock. For input, it may occur at any time and input may be asserted asynchronously to the system clock.

NOTE

Not all pins within each port are implemented on each device. See the chapter on signal multiplexing for the number of GPIO ports available in the device.

40.3 Memory map and register definition

The registers for each GPIO port occupy 64-byte of the memory map. Any read or write access to the GPIO slot outside this space results in a bus error.

NOTE

For simplicity, each GPIO port's registers appear with the same width of 32 bits, corresponding to 32 pins. The actual number of pins per port (and therefore the number of usable control bits per port register) is chip-specific. Refer to the chip-specific GPIO information to see the exact control bits for each port.

40.3.1 GPIO register descriptions

40.3.1.1 GPIO Memory map

GPIOA base address: 4100_F000h

GPIOB base address: 4100_F040h

Offset	Register	Width (In bits)	Access	Reset value

5-3 D1ACP	Domain Access Control Policy This 3-bit field defines the attributes required to access the corresponding byte of each port in each domain.
2-0 D0ACP	Domain Access Control Policy This 3-bit field defines the attributes required to access the corresponding byte of each port in each domain.

40.4 FGPIO memory map and register definition

The GPIO registers of certain ports are also aliased to the IOPORT interface. See chip-specific information on FGPIO ports for details.

Accesses via the IOPORT interface occur in parallel with any instruction fetches and will therefore complete in a single cycle. This aliased Fast GPIO memory map is called FGPIO.

Any read or write access to the FGPIO memory space that is outside the valid memory map results in a bus error. All register accesses complete with zero wait states, except error accesses which complete with one wait state.

NOTE

For simplicity, each FGPIO port's registers appear with the same width of 32 bits, corresponding to 32 pins. The actual number of pins per port (and therefore the number of usable control bits per port register) is chip-specific. Refer to the Chip Configuration chapter to see the exact control bits for the non-identical port instance.

40.5 Functional description

40.5.1 General-purpose input

The logic state of each pin is available via the Port Data Input registers, provided the pin is configured for a digital function and the corresponding Port Control and Interrupt module is enabled.

The input pin synchronizers are shared with the Port Control and Interrupt module, so that if the corresponding Port Control and Interrupt module is disabled, then synchronizers are also disabled. This reduces power consumption when a port is not required for general-purpose input functionality.

40.5.2 General-purpose output

The logic state of each pin can be controlled via the port data output registers and port data direction registers, provided the pin is configured for the GPIO function. The following table depicts the conditions for a pin to be configured as input/output.

If	Then
A pin is configured for the GPIO function and the corresponding port data direction register bit is clear.	The pin is configured as an input.
A pin is configured for the GPIO function and the corresponding port data direction register bit is set.	The pin is configured as an output and the logic state of the pin is equal to the corresponding port data output register.

To facilitate efficient bit manipulation on the general-purpose outputs, pin data set, pin data clear, and pin data toggle registers exist to allow one or more outputs within one port to be set, cleared, or toggled from a single register write.

The corresponding Port Control and Interrupt module does not need to be enabled to update the state of the port data direction registers and port data output registers including the set/clear/toggle registers.

40.5.3 IOPORT

The GPIO registers of certain ports are also aliased to the IOPORT interface, see chip-specific information on FGPIO ports for details. Accesses via the IOPORT interface occur in parallel with any instruction fetches and will therefore complete in a single cycle. If another bus master attempts to access the GPIO registers on the same cycle as an IOPORT access, then the DMA access will stall until any IOPORT accesses have completed.

Chapter 41
Debug

41.1 Overview

This chapter outlines the debug capabilities implemented within the i.MX 7ULP microprocessor. Debug features on i.MX 7ULP consist of static debug and real-time trace for the Arm cores, cross-domain triggering, and input and output of the control and trace data.

Following are the debug features implemented on this device:

- The Arm CoreSight Architecture adapted for software trace and debug.
- Software trace and full instruction trace are supported for A7 and M4 processors.
- A cross-trigger subsystem is included for cross domain triggering of debug resources
- Serial Wire Debug (JTAG/SWD) and Debug Access Port (DAP) to support debugger tools.
- 16/8/4-bit TPIU trace port to efficiently access trace information from the system.
- Data logging trace and debug information through USB or UART serial port.

41.2 System level debug architecture

The following figure depicts the system level debug architecture on this device.

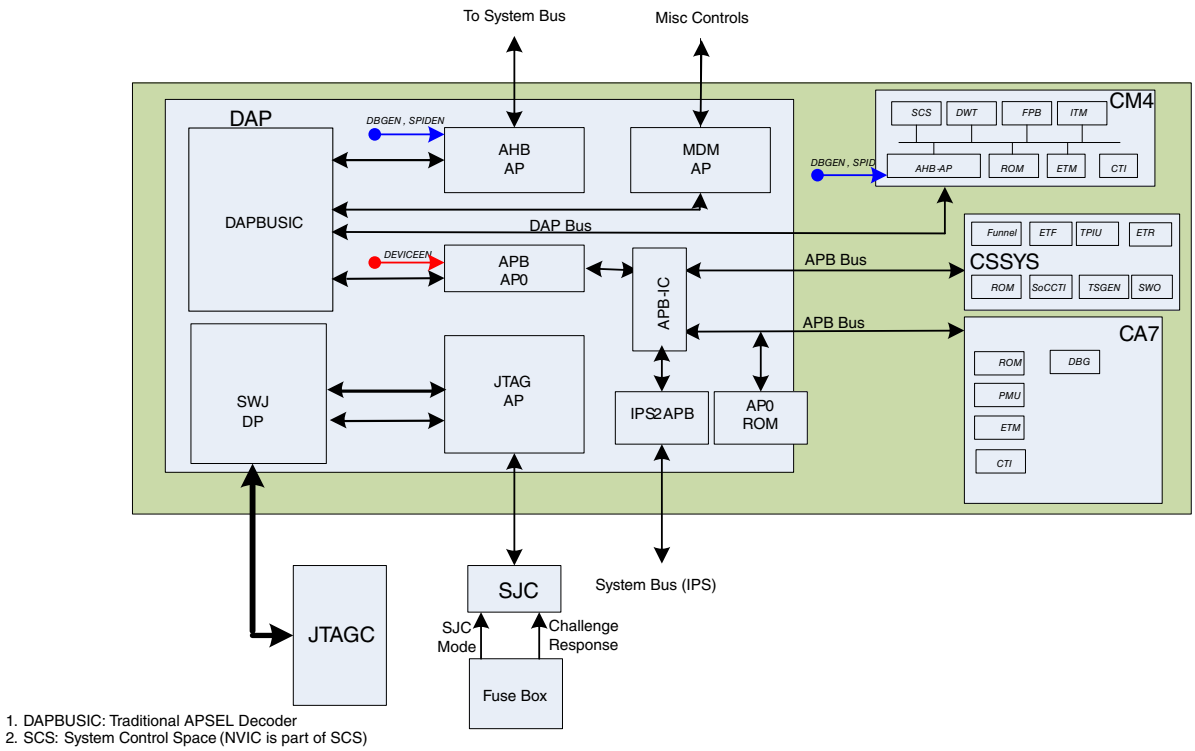

Figure 41-1. System level debug architecture

41.3 Test and debug port connectivity

The following figure shows the shared debug/test port connectivity, including the SWD/JTAG protocol switch block. The debugger can select one of them (JTAG or SWD) to access the DAP. The JTAG protocol is selected by default. JTAG-to-SWD change sequence describes how to change the protocol. The JTAGC can be only accessed by JTAG protocol.

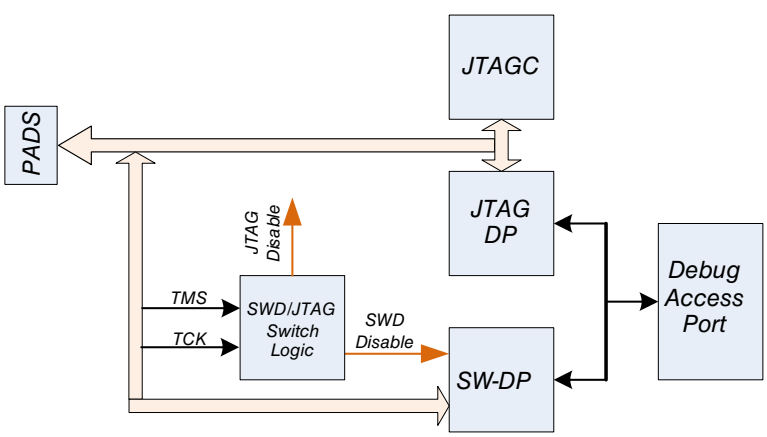

Figure 41-2. Test and debug port connectivity

The table below summarizes the setup of pins used in each protocol.

Table 41-1. JTAG pads summary

Pin Name	JTAG		SWD		Internal pull up/ down
	Type	Description	Type	Description	
TMS/SWDIO	I/O	mode selection	I/O	Data	Pull-up
TCLK/SWCLK	I	Clock	I	Clock	Pull-down
TDI	I	Data input	--	--	Pull-up
TDO/SWO[1]	O	Data output/Trace SWO	--	--	NC

1. The pin will turn in SWO mode, only at “Reduced pin count JTAG – IEEE 1149.7” or Arm SWD protocols.

The following table shows the debug's components ID code and your respective composition.

Table 41-2. ID code of debug components

Project	ID	Version Number	NXP's Use of JTAG ID Part Number			Manufacturer ID	IEEE req'd
			Design Center	Core Number	Chip Derivative Number	1110	1
		[31:28]	[27:22]	[21:17]	[16:12]	[11:1]	[0]
i.MX 7ULP	SJC: 0x188E101D	0001	100010	00111	00001	00000001110	1
	JTAG-DP: 0x6BA0_0477	0110	101110	10000	00000	01000111011	1
	SW-DP: 0x6BA0_2477	0110	101110	10000	00010	01000111011	1

41.3.1 JTAG to SWD switching sequence

41.3.1.1 JTAG-to-SWD change sequence

1. Send more than 50 TCK cycles with TMS(SWDIO)=1
2. Send the 16-bit sequence on TMS(SWDIO)=0111_1001_1110_0111(MSB transmitted first)
3. Send more than 50 TCK cycles with TMS(SWDIO)=1

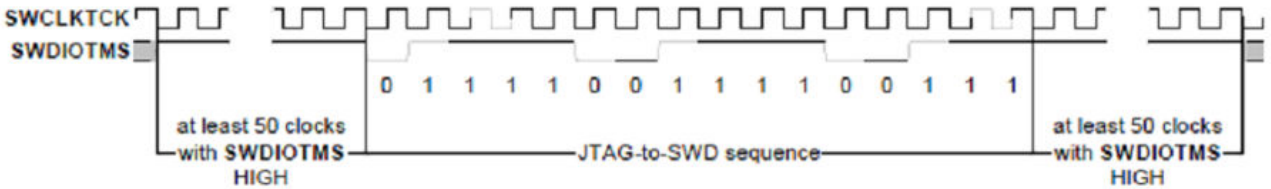

Figure 41-3. JTAG-to-SWD change sequence timing

41.3.2 System JTAG controller (JTAGC)

The system JTAG controller (JTAGC) is connected in parallel with Arm TAP controller (JTAG DP of Arm DAP). The IR length is 4-bits. The JTAGC IR codes overlay the Arm DAP controller IR codes. JTAGC uses 12 instructions and the DAP uses rest 4. The outputs of the TAPs (TDO) are muxed based on the selected IR Code. This design is fully JTAG compliant and appears to the JTAG chain as a single TAP.

The following table lists the IR codes for the system JTAG controller. For the instructions used by Arm DAP TAP, see Table 41-4 Arm DAP IR Codes.

Table 41-3. JTAG instructions for system JTAG controller (JTAGC)

Code	JTAGC IR
4'b0000	IDCODE
4'b0001	CENSOR_CTRL
4'b0010	SAMPLE/PRELOAD
4'b0011	SAMPLE
4'b0100	EXTEST
4'b0101	HIGHZ
4'b0110	Reserved
4'b0111	Reserved
4'b1000	*Not used by JTAGC (used by DAP)*
4'b1001	*AUX ACCESS 1 (TCU selection)*
4'b1010	*Not used by JTAGC (used by DAP)*
4'b1011	*Not used by JTAGC (used by DAP)*
4'b1100	Reserved
4'b1101	CLAMP
4'b1110	*Not used by JTAGC (used by DAP)*
4'b1111	BYPASS

The test functionality is implemented through MDM-AP registers and there is no dedicated TCU.

41.3.3 Debug Access Port (DAP) TAP

DAP is a standard Arm component. The DAP provides multiple master driving ports, all accessible and controlled through a single external interface port to provide system-wide debug. As described earlier, the DAP IR overlays with the system JTAG controller IR. The DAP Instruction Registers are listed in Table 41-4, Arm DAP IR Codes. DAP uses five Instructions but since BYPASS is identical with JTAGC it has been dropped out.

Table 41-4. Arm DAP IR Codes

Code	DAP IR
4'b1000	ABORT
4'b1010	DPACC
4'b1011	APACC
4'b1110	IDCODE

The DAP offers AHB and APB master interfaces to access system buses. It also exports the internal DAP bus to allow to extend the access ports as per the system requirement. It offers JTAG-AP to allow adding auxiliary TAPs. For more information on DAP TAP refer to Arm Debug Interface v5 Architecture specification on arm.com

For i.MX 7ULP, the AHB-AP provides the debugger access to all memory and registers in the system. System access is independent of the processor status. The AHB-AP's AHB transfers are burst size of 1 only with no out-of-order transactions and no multiple outstanding accesses. The APB-AP is used to access the CoreSight components for the CA7 core, and also the shared debug components of the system trace like TPIU and SWO.

The exported DAP bus is used to host AHB-AP (integrated as part of CM4 integration) and the Miscellaneous Debug Module Access Port (MDM-AP). The MDM-AP implement registers are used for Test mode control on i.MX 7ULP. The MDM-AP hosts system-level JTAG status and control registers (see Debug Status and Control registers) which can be used for cross triggering, synchronized debug, low power, and other miscellaneous control/status. The selection of different access ports in the DAP is done based on the APSEL value set in the SELECT register of (JTAG/SWD)-DP. APSEL is 31:24 bit field of the DAP SELECT register. The APSEL will be decoded as given in the following table, APSEL decode.

Table 41-5. APSEL decode

APSEL (SELECT[31:24])	Selection	Identification Register (IDR) value
8'h00 (M0)	AHB-AP to System Bus (NIC-301)	0x8477_0001

Table continues on the next page...

Table 41-5. APSEL decode (continued)

APSEL (SELECT[31:24])	Selection	Identification Register (IDR) value
8'h01 (M1)	APB-AP0 (CSSYS)	0x5477_0002
8'h02 (M2)	JTAG-AP to SJC	0x3476_0010
8'h03 (M3)	AHB-AP to CM4	0x2477_0011
8'h04 (M4)	Miscellaneous Debug module AP (MDM-AP)	0x001C_0040
8'h06 - 8'hff	Reserved (Default AP response)	-

41.4 ROM tables

The ROM tables hold information about different debug components and help identify them. There are three ROM tables:

1. CM4 ROM table: This table resides in the CM4 AHB-AP and contains entries for CM4 debug components. See Table 41-7.
2. ROM tables containing entries corresponding to the APB-APs. See Table 41-8.
3. CA7 ROM tables: These entries identify the common debug components and the CA7 core debug components. See Table 41-9.

Table 41-6. ROM Table Entry format

Bits	Name	Description
31:12	Address offset	Base address of the component, relative to the ROM address. Negative values are permitted using two's complement. ComponentAddress = ROMAddress + (AddressOffset SHL 12).
11:2	-	Reserved
1	Format	1 = 32-bit format. In the DAP Debug ROM, this is set to 1. 0 = 8-bit format.
0	Entry Present	Set HIGH to indicate that an entry is present.

Table 41-7. CM4 ROM table

Address (For Debugger)	i.MX 7ULP Memory Map	Content	Component
0xE00FF000	0xE000E000	0xFFF0F003	SCS

41.5 Trace architecture/topology

The following figure depicts the debug trace architecture of this device. Components shown in Brown are on A7 clock domain. Everything else is on CM4 clock domain. The 64 bit AHB port is a trace master port on CM4 platform.

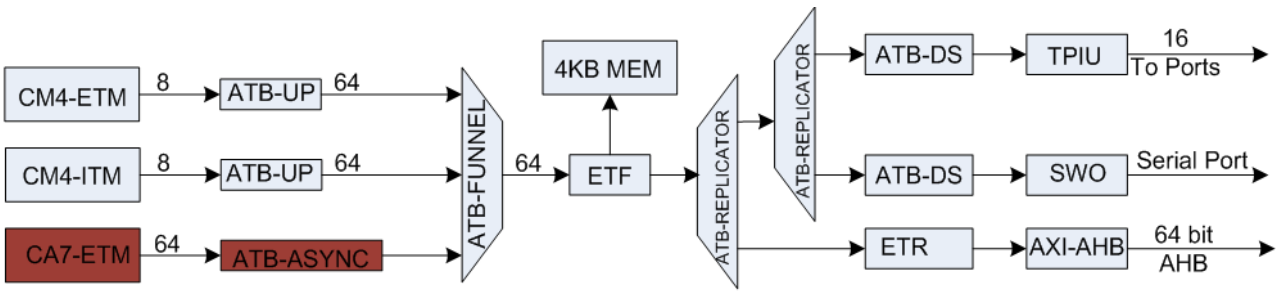

Figure 41-4. Trace architecture/topology

41.6 Debug trace timestamping

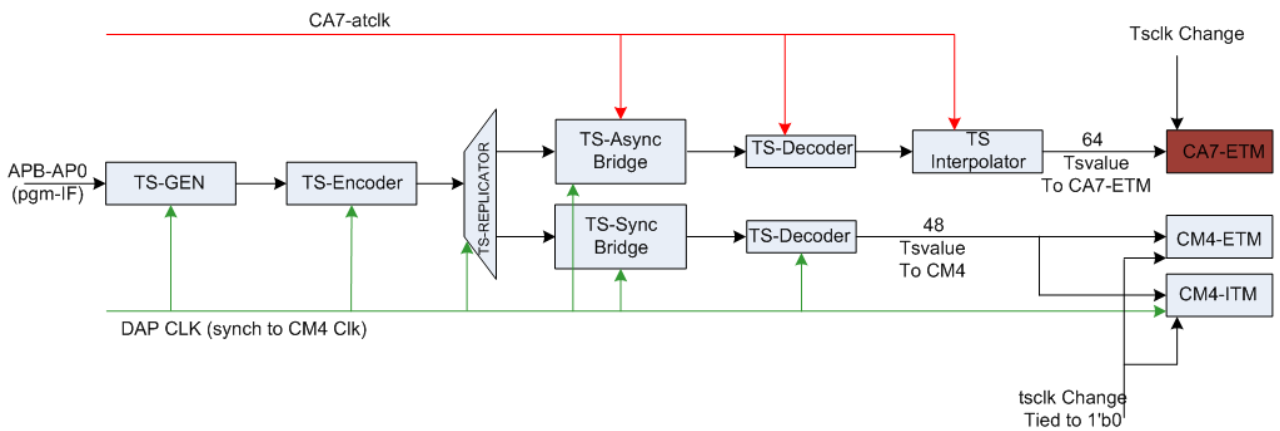

Figure 41-5. Debug trace timestamping

Timestamp solution establishes correlation between the trace data across the two cores. The above figure represents the timestamp topology for the timestamp values observed along with the traces.

- The timestamp generator is a 64-bit counter, working in the CM4 clock domain.
- The TS-Async Bridge separates the two clock domains. The TS-Sync Bridge acts as a register slice to achieve timing closure.
- The CA7 atclk must be faster than cm4clk to assure the correctness of timestamp counter value, otherwise the FIFO inside TS-Async Bridge would overrun.
- Ts value[63:48] are unconnected when connecting to CM4 ETM and ITM

- Since the frequency ratio of the timestamp generator clock to CM4-ETM/ITM clock is always 1:1, tsclk_change input of CM4-ETM and CM4-ITM needs to be tied to 0.
- The SoC clock controller should inform the CA7-ETM through its input clk_change when CA7-ETM's clock is changed.
- The TS-GEN has control register to enable/disable the timestamp counter.

NOTE

The CLKCHANGE (Tsclk Change) signal of CA7-ETM is used when either the processor clock period or timestamp period changes, as mentioned in the Arm documentation: DDI0468A_coresight_etm_a7_trm.

See the following Arm document for timestamp descriptions:

- Chapter 7 of DDI0480G_coresight_soc_r3p2_trm
- DDI0468A_coresight_etm_a7_trm

41.7 Debug Status and Control registers

The Miscellaneous Debug Module (MDM-AP) provides useful interface between debugger and the core and controls debug information in multi-core environment. Besides the core control, the interface also implements registers controlling the Test Registers . The debugger can write to MDM-AP registers only if the DBGEN is set, that is, the debugger security authentication has been cleared. In case the debugger makes an access while DBGEN=0, the access will be simply ignored and no error will be reported. The MDM-AP status registers are always available as long as the JTAG port is available.

NOTE

The DAP Control and Status registers are not memory mapped within the system memory map and are only accessible via the Debug Access Port using JTAG or SWD. The MDM-AP is accessible as Debug access port 04 as shown in Table 41-5, APSEL Decode.

Table 41-10. DAP Status and Control registers

Address	Register
0x00	Status register
0x04	Control register
0x10	Core halt req reg
0x20	Core restart req reg
0x30	Core halt status reg
0x40	Core low power status1 reg

Table continues on the next page...

Table 41-10. DAP Status and Control registers (continued)

Address	Register
0xFC	IDR: Fixed ID register (0x001C0040)

41.8 Register details

The following table presents the descriptions of bit fields contained in Debug registers. All the bits which are not mentioned in the register tables below are reserved.

Table 41-11. Register details

Bit Number	Field	Description
Status (dap_status)		
1	CM4 System in reset	Indicates if CM4 system is in reset 0: System is not in reset 1: System is in reset **NOTE:** CM4 in reset implicitly means CA7 system is in reset too.
2	CA7 System in reset	Indicates if the CA7 system is in reset 0: System is not in reset 1: System is in reset **NOTE:** CA7 can continue to remain in reset while CM4 system is up and running.
3	DBGEN / NIDEN	Debug Access enable: Indicates if the debugger can access to AHB-AP and APB-AP. NIDEN is same as DBGEN in MX7. DBGEN: Invasive Debug Enable NIDEN: Non-invasive Debug Enable
4	SPIDEN / SPNIDEN	Debug secured access enable. Indicates if the debugger can make secured accesses to the debug logic and can trace out secured traces. This bit reflects the status of SPIDEN/ SPINDEN
10	STANDBY Mode Exit	This bit indicates that an exit from Standby (VLLS) mode has occurred. The debugger has lost connection while the system was in Standby mode. Once this connection is re-established, this bit indicates that the system is back and ready to exit Standby. Debugger should use this bit to complete low power exit protocol. This bit is held until the debugger had a chance to recognize that a standby (VLLS) mode is exited and is cleared by writing 1 to the STANDBYDBGACK (bit [6], dap_ctrl).
22	CTI trigger out	CTI interface trigger out
30	CM4 DBGRESTARTED	Indicates that CM4 leaves Debug mode
31	CA7 DBGRESTARTED	Indicates that CA7 leaves Debug mode

Table continues on the next page...

Table 41-11. Register details (continued)

Bit Number	Field	Description
Control(dap_ctrl)		
2	CM4 System Reset Request	Set to force the CM4 system reset. The system remains in reset till this bit remains asserted. When this bit is deasserted, the entire system comes out of reset.
3	CA7 System Reset Request	Set to force the CA7 system reset. The CA7 system remains in reset till this bit remains asserted. When this bit is reset, the CA7 system comes out of reset.
5	STANDBYDBGREQ	This bit is set to configure the system to be held in reset after the next recovery from Low power mode. This bit is sampled by the Reset Control Module (RCM)[1] just before the part moves into low power states and remains latched in always ON domain during low power phase. On exit from low power, the core is held under reset until STANDBYDBGACK is asserted (The STANDBYDBGREQ bit is cleared due to reset generated as a part of low power recovery).
6	STANDBYDBGACK	This bit is set to release the cores being held in reset following a standby recovery. This bit indicates that debugger has finished the configuration of debug components. This bit directly drives the RCM control. This bit is also used to clear “STANDBY Mode Exit” bit. A POR or JTAG can clear this bit.
7	Inhibit Debug in Deepsleep	When this bit is set, the STOP mode entry will ignore debug connection.
10	CM4 Hold Reset	When set, this bit leaves the CM4 core under reset during power-up. Rest of the system will come out of reset as usual.
11	CA7 Hold Reset	When set, this bit leaves the CA7 core under reset during power-up; rest of the system will come out of reset as usual.
12	CM4 Core Reset Request	Set to cause a CM4 core reset.
13	CA7 Core Reset Request	Set to cause a CA7 core reset.
24	CTI Trigger Input	Connects to CTI trigger input
25	CTI Trigger Out ACK	Connects to CTI trigger ACK input
Core halt request (dap_ctrl_halt_req)		
0	CM4 EDBGRQ	The external debug request debug event which causes CM4 to enter Debug state.
2	CA7 EDBGRQ	The external debug request debug event which causes CA7 to enter Debug state.
Core restart request(dap_ctrl_restart_req)		
0	CM4 DBGRESTART	CM4 debug restart input to CM4 core causing CM4 to leave debug state
2	CA7 DBGRESTART[0]	CA7 debug restart input to CA7 core
Core halt (dap_status_halt)		
0	CM4 HALTED	Indicates CM4 has entered debug halted mode
2	CA7 DBGACK[0]	Indicates CA7 CPU#0 has entered debug halted mode
Core low power status (dap_status_lp1)		
0	CM4 SLEEPDEEP	Reflects the status of Cortex M4. Driven by CM4

Table continues on the next page...

Table 41-11. Register details (continued)

Bit Number	Field	Description
1	CM4 SLEEPING	Reflects the status of Cortex M4. Driven by CM4
8	CA7 STANDBYWFI[0]	Indicates that CA7 CPU#0 is in WFI standby mode.
9	CA7 STANDBYWFE[0]	Indicates that CA7 CPU#0 is in WFE standby mode.
10	CA7 STANDBYWFIL2	Indicates if the L2 memory system is in WFI standby mode
Identification Register		
0-3	Type	4'h0. (MDM-AP)
4-7	Variant	4'h4
8-15	Reserved	Read as 8'h00.
16	Class	1'b0. Indicates not a memory access
17-27	JEP 106 Identity + Continuation	11'b00000001110(NXP)
28-31	Revision	4'h0

1. MSMC, CMC, and RMC are 3 separate but tightly coupled blocks. The memory map documented in MSMC chapter encompasses features related to all 3 blocks, being actually implemented into the CMC block alone. Therefore, there might be some references to CMC and RMC blocks throughout this document.

NOTE

STANDBYDBGREQ and ack are not implemented for CA7 system as the MDM-AP is in the M4 domain and A7 can be controlled using the existing signals. If M4 happens to be powered down as well, it is implicit that M4 will always power up first and the debug controls for the A7 core can be restored during this period.

41.9 Debug resets

The debug system receives the following sources of reset:

- Debug Reset (CDBGRSTREQ bit within the SWJ-DP CTRL/STAT register; See Arm Debug Interface Architecture Specification) which is in the TCLK domain that allows the debugger to reset the debug logic.
- System POR request. The debug system gets reset on POR and the JTAG interface on TCK clock domain is available after POR subject to security clearance.

The debug system is capable of generating system reset using the MDM-AP control registers. A functional reset leads to loss of debugger connection and debugger needs to re-initiate the connection as soon as the system is out of reset.

41.10 Embedded cross triggers

Embedded Cross Trigger (ECT) is used for multicore run control and allow subsystems to interact and trigger each other. It allows start/stop for all cores or trigger program trace on a trigger event from multiple trigger sources (other modules). ECT is made up of Cross Trigger Interfaces (CTI) and Cross Trigger Matrix (CTM).

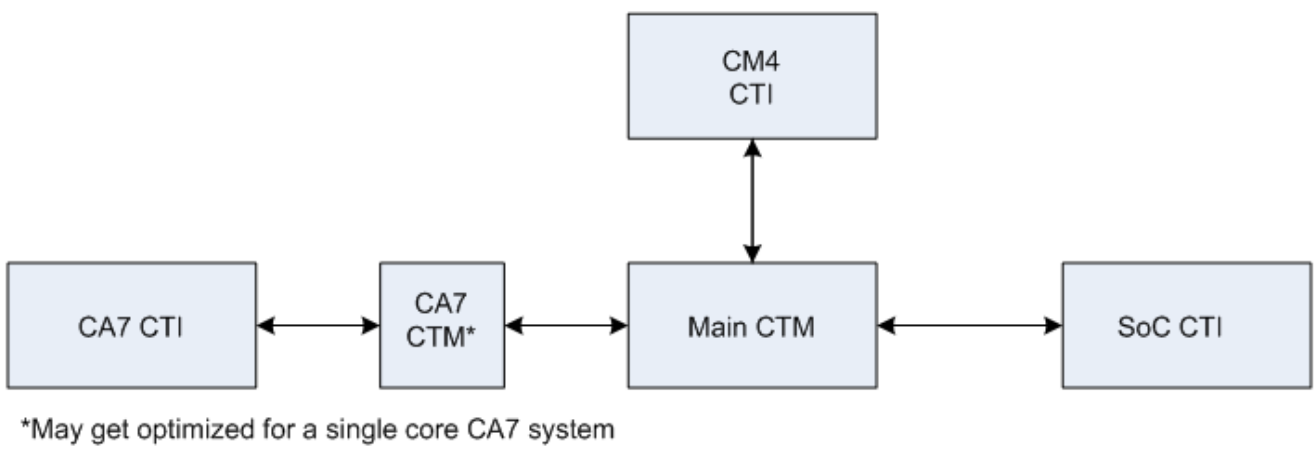
Cross Trigger Interface (CTI) is an Arm IP and provides:

- 8 trigger inputs, 8 trigger outputs, basic signal conditioning
- Programmable channel routing (mapping trigger inputs to channels and channels to trigger outputs)
- Limited to 4 channels

Cross Trigger Matrix (CTM) is an Arm IP and provides:

- Channel routing when more than 2 CTIs are used
- Limited to 4 channels

i.MX 7ULP implements 3 CTIs. Each core has a dedicated CTI and one is available for various triggers at the chip level.



NOTE

It is not possible to trigger between CM4 CTI and SoC CTI when CA7 power domain is turned OFF.

41.10.1 CM4 CTI triggers

Table 41-12. CM4 CTI input triggers

Trigger Bit	Source Signal	Source Module	Description
7	ETMTRIGOUT	CM4 ETM	CM4 ETM trigger
6	ETMTRIGGER[2]	CM4 DWT	CM4 DWT trigger
5	ETMTRIGGER[1]	CM4 DWT	CM4 DWT trigger
4	ETMTRIGGER[0]	CM4 DWT	CM4 DWT trigger
3	--	--	--
2	--	--	--
1	--	--	--
0	HALTED	CM4 core	CM4 core's output indicating that it has entered the debug mode.

Here the "Source Signal" is the output port of the "Source Module". They are connected to the input triggers of the CTI

Table 41-13. CM4 CTI output triggers

Trigger Bit	Destination Signal	Destination Module	Description
7	DBGRESTART	CM4 core	Request CM4 core to quit the debug mode
6	--	--	--
5	EXTIN[1]	CM4 ETM	CM4 ETM external input
4	EXTIN[0]	CM4 ETM	CM4 ETM external input
3	cti_irq	NVIC	CTI interrupt
2	cti_irq	NVIC	CTI interrupt
1	--	--	--
0	EDBGRQ	CM4 core	External request CM4 core to enter the debug mode

Here the "Destination Signal" is the input port of the "Destination Module". The output triggers of the CTI are connected to the input port of the destination modules.

41.10.2 CA7 CTI triggers

Table 41-14. CA7 CTI input triggers

Trigger Bit	Source Signal	Source Module	Description
7	--	--	--
6	ETMTRIGGER	CA7 ETM	CA7 ETM trigger

Table continues on the next page...

Table 41-14. CA7 CTI input triggers (continued)

Trigger Bit	Source Signal	Source Module	Description
5	COMMRX	CA7 Debug	Debug communication receive channel is full
4	COMMTX	CA7 Debug	Debug communication transmit channel is empty
3	EXTOUT[1]	CA7 ETM	CA7 ETM external output
2	EXTOUT[0]	CA7 ETM	CA7 ETM external output
1	nPMUIRQ	CA7 PMU	CA7 PMU generated interrupt
0	DBGTRIGGER	CA7 Debug	Trigger entry to debug state

Table 41-15. CA7 CTI output trigger

Trigger Bit	Destination Signal	Destination Module	Description
7	DBGRESTART	CA7 Debug	Cause the CA7 processor to exit debug state
6	nCTIIRQ	GIC	CTI interrupt
5	CTIEXTTRIG		CA7 CTI external trigger
4	EXTIN[3]	CA7 ETM	CA7 ETM external input
3	EXTIN[2]	CA7 ETM	CA7 ETM external input
2	EXTIN[1]	CA7 ETM	CA7 ETM external input
1	EXTIN[0]	CA7 ETM	CA7 ETM external input
0	DBGRQ	CA7 Debug	Cause the CA7 processor to enter debug state

41.11 Low power debug

It is required that the system provides control so that debugger can have control of the device when entering and exiting low power modes. During low power modes, the clock and power (based on modes) will not be available to multiple components, the following handshake allows the debugger to maintain connection during low power. There are two modes supported:

- Clock gated mode
- Power gated mode

41.11.1 Clock gated modes

- If the DAP CxxxPWRUPREQ is high and the system attempts to enter in STOP mode, the core will enter the SLEEP mode but the mode of the system will not change, except if the MDM-AP dap_ctrl bit [7], Inhibit Debug in Deepsleep, is set. In this case, the system will ignore the debugger connection and will enter the STOP mode.
- If the device is in STOP mode (clock gated), the debugger can assert EDBGRQ (CM4 EDBGRQ, CA7 EDBGRQ) in dap_ctrl_halt_req register. This will wake up the core and will move it into a halted state.

41.11.2 Power gated modes

This mode is applicable for CM4 domain only. During Power gated modes, the debugger will lose connection and it cannot gather any data in the duration when the device stays in low-power mode. If the device is expected to go into low-power mode and it is desired to gain control of device when it exits low power modes, the following sequence/handshake should be followed.

- Low power entry
  a. Set the DAP CxxxPWRUPREQ (inhibit_sleep) to indicate to the device that low power handshake should take place, before entering power gated modes
  b. Low-power entry requested by CM4.
  c. Set the MDM-AP dap_ctrl bit [5], STANDBYDBGREQ, which tells the device to remain in reset until the handshake takes place on standby(VLLS) exit. Note that this bit needs to have a local version inside DGO (RCM) which will keep this information during low power exit. When the reset sequence completes (after debug handshake), the DGO version of the bit should be cleared.
  d. As the device is going to get into low power mode, debugger should store all contexts
  e. Reset the DAP CxxxPWRUPREQ, without modifying any other bit, the device will enter Standby (VLLS) mode.
- Low power exit
  a. A wakeup event wakes up the device
  b. Debugger tries to re-establish connection. Once the connection has been established, it will know if the device is ready to come out of low power mode, by reading the status of bit 10 “STANDBY Mode Exit” in dap_status. If this bit is set, the device is ready for low power exit.
  c. Set the MDM-AP, dap_ctrl_halt_req bit [0], CM4 EDBGRQ, to indicate that the CM4 should enter the debug mode out of reset.
  d. To complete the exit protocol write to STANDBYDBGACK, bit[6] of MDM-AP dap_ctrl.

e. Debugger should check MDM-AP, dap_status bit[1], CM4 System in reset, to check if CM4 is out of reset.
f. Debugger should monitor MDM-AP, dap_status_halt bit[0], CM4 HALTED, indicating that CM4 has entered into debug halt mode.
g. Debugger can now restore contents of CM4 debug peripherals
h. Restart the CM4 from debug mode by setting MDM-AP, dap_ctrl_restart_req bit [0], CM4 DBGRESTART
i. Monitor dap_status, bit[30], CM4 DBGRESTARTED to ensure CM4 exited the debug mode.

41.12 Instruction trace

The A7 instruction trace has the same functional capabilities as the M4 instruction trace.

41.13 Secured JTAG

The SJC block offers a range of security levels. The SJC blocks the access to debug based on eFuse configuration and authentication. This is summarized in the table below:

Name	Security level	Field return	Comments	Fuse used	Debug signals	Note
No JTAG	Highest	The field return is supported using the Fuse bit FIELD_RETURN[1]	All JTAG features are disabled.	SJC_DISABLE = 1	DBGEN = 0 NIDEN = 0 SPIDEN = 0 SPNIDEN = 0	TCK had been gated
No debug	High		All JTAG features are disabled except for BS	SJC_DISABLE = 0 JTAG_SMODE = 11	DBGEN = 0 NIDEN = 0 SPIDEN = 0 SPNIDEN = 0	
Secure JTAG	Medium		Authentication based on challenge-response	SJC_DISABLE = 0 JTAG_SMODE = 01	DBGEN = 1 NIDEN = 1 SPIDEN/ SPNIDEN[2]= SIM_DGO_GP11[0] (register)	SPIDEN/ SPNIDEN based on challenge-response.
JTAG enabled	No secure	Full supported possible for field return	Open	SJC_DISABLE = 0 JTAG_SMODE = 00	DBGEN = 1 NIDEN = 1	

				SEC_CONFIG[0] = 1	SPIDEN = 1 SPNIDEN = 1	

1. For details on FIELD_RETURN and other eFuse bits, see the i.MX 7ULP Security Reference Manual.
2. These bits use only one SIM register: SIM_DGO_GP11[0] register, which is:
   - Under supervisor access control
   - Can be retained through Low power (DGO)
   - The reset value of this register should be 0
   - These are used by device running in secure mode

NOTE

The field return is supported using Fuse bit "FIELD_RETURN". This fuse is blown based on an authenticated image. The part which is received as field return is not returned to the customer. The field return part offers complete access to TCU and debug

i.MX 7ULP comes out of POR in "No JTAG" security level for security reasons. Security level is set after fuses are read during the reset phase coming out of POR.

41.14 Additional Authentication Interface

Authentication interface aims to restrict access to debug and trace functionality. This is done by controlling the Arm debug authentication signals. For more details, see the CoreSight v1.0 Architecture Specification. These are listed below:

Table 41-16. Arm debug authentication signals

Control Signal name	Meaning	Controlled by
DBGEN	Invasive Debug Enable	SJC based on security authentication
NIDEN	Non invasive Debug Enable	SJC based on security authentication
SPIDEN	Secure invasive debug enable	control bit in SIM_DGO_GP11[0] register (can be SET by only s/w running in secure world)
SPNIDEN	Secure non-invasive debug enable	control bit In SIM_DGO_GP11[0] register (can be SET by only s/w running in secure world)

The SJC controls the DBGEN and NIDEN based on the security authentication and perceived security incident related to power up. This allows debugger access to non-secure coresight components and allows non-secure traces to be traced out. In case debug is required in the secure world, SPIDEN and SPNIDEN need to be set. This is feasible only by the software running in the secure world.

NOTE

For details about security features, see the i.MX 7ULP Security Reference Manual.

Chapter 42
Secured JTAG Controller (SJC)

42.1 Chip-specific SJC information

Table 42-1. Reference links to related information

Topic	Related module	Reference
Full description	SJC	SJC
System memory map		System memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port control	Signal multiplexing

42.1.1 Secured JTAG Controller (SJC)

SJC is an authenticated debug module that implements a challenge/response mechanism using a standard cryptographic algorithm. This allows post production silicon debug without compromising security requirements. The SJC is connected as a tap of DAP JTAG-AP and is used for authenticated debug.

Table 42-2. SJC configuration

Parameter	Description
Name	SJC
Supported standard version	IEEE 1149.1-2001
Instances	1
Configurable features	NA
Interface speed	NA
External I/O pins	-

42.1.2 No Debug mode of operation

On i.MX 7ULP, MBIST and LBIST modes are not allowed at No Debug mode.

NOTE

In No Debug mode, the access to DAP (DP and APs) will be enabled but to rest of the system, blocked. The access to registers of MDM-AP will be read-only.

42.1.3 Challenge/Response mechanism

In fixed challenge-response pair mode, each chip has its individual challenge/response pair which is determined at manufacturing time. In this device, the SJC compares the user's response to the expected response. The update of the authentication result will be delayed two cycles of TCK clock after the Update-DR state.

42.2 Introduction

Secure JTAG Controller (SJC) provides the security authentication for debug access to the chip. It is accessible through the JTAG Access Port (AP) of the ARM DAP.

This figure shows SJC connections to external contacts and other blocks.

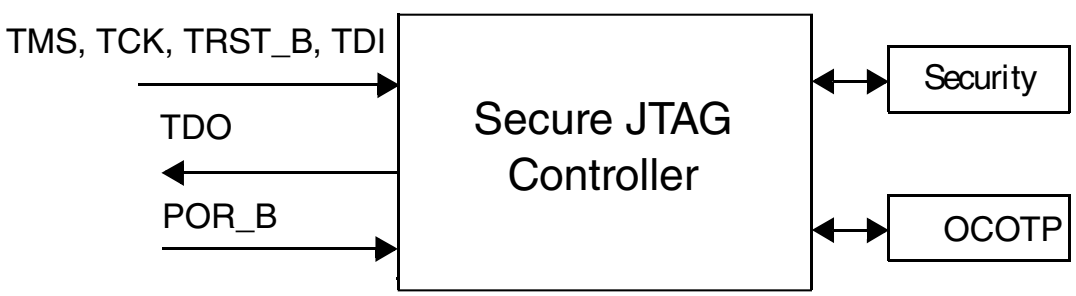


Figure 42-1. SJC connections

42.3 External signal description

42.3.1 External signal overview

SJC provides test and debug control with a minimum number of contacts.

This table describes the SJC external connections along with the signal properties.

Table 42-3. SJC signal properties

Name/Port	Function
POR_B	POR reset input.
TCK	Test Clock (TCK). This is used to synchronize the test logic.
TDI	Test Data Input (TDI). Serial test instruction and data are received through the test data input (TDI) pin. TDI is sampled on the rising edge of TCK.
TDO	Test Data Output (TDO). The serial output for test instructions and data. TDO is tri-statable and is actively driven in the shift-IR and shift-DR controller states. TDO changes on the falling edge of TCK.
TMS	Test Mode Select (TMS). This is used to sequence the test controller's state machine. TMS is sampled on the rising edge of TCK.

42.3.2 TAP controller

The TAP controller is responsible for interpreting the sequence of logical values on the TMS signal. It is a synchronous state machine that controls the operation of the JTAG logic. For a description of the TAP controller states, refer to the appropriate IEEE 1149.1 document.

The state machine is shown in this figure. The value shown adjacent to each arc represents the value of the TMS signal sampled on the rising edge of TCK signal.

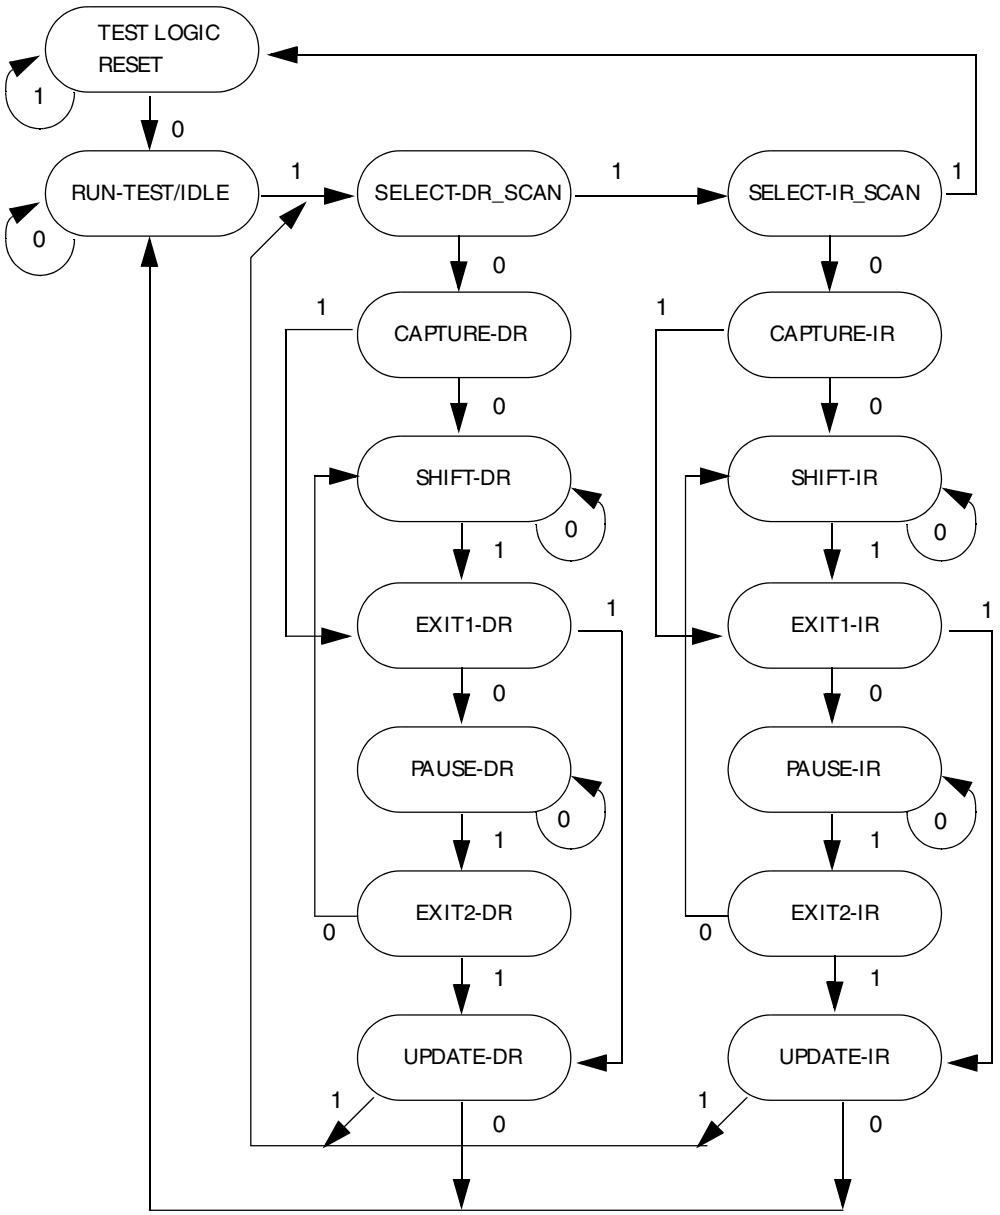

Figure 42-2. TAP controller state machine

State changes occurs on the rising edge of TCK. TMS and TDI change on the falling edge of TCK. TDO also changes on the falling edge of TCK following entry into the Shift_DR or Shift_IR states.

This figure shows the SJC signal timings.

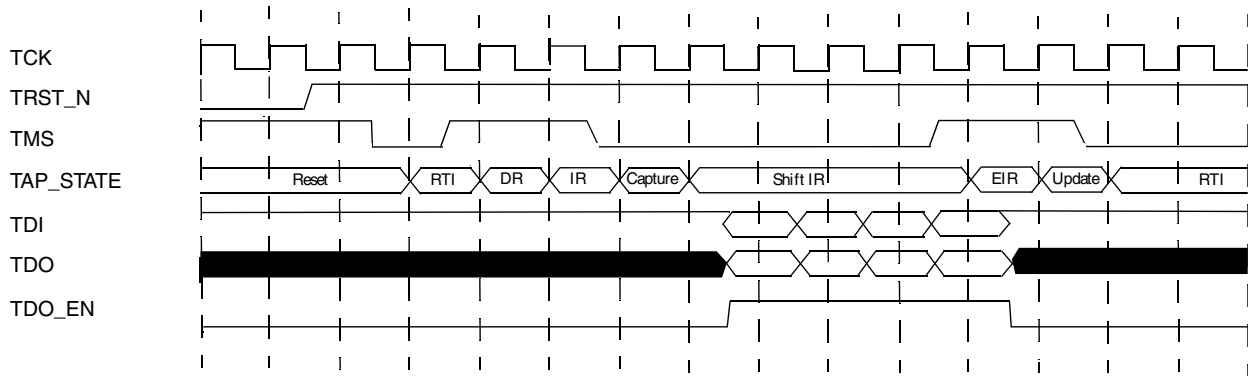

Figure 42-3. SJC signals timing diagram

42.3.3 Accessing ExtraDebug register

Accessed through the Select-DR-Scan path, the ExtraDebug shift register consists of 38 bits (maximum) including a 32-bit data field (max length, see the ExtraDebug register description), a 5 bit address field and read/write bit.

The write occurs when the JTAG TAP controller enters the Update-DR state. On a read, the data field is ignored (the user should shift only 5 times to enter Read=1 and the address), the read takes place on the next path through DR at the Capture-DR state, and the data is shifted-out during the Shift-DR state.

On the second path for a read access, simultaneous write access is not supported. Command converter software shifts in zeros so the TAP decodes a write to the CSR (read-only register) which does not have any effect.

The number of shift depends on the width of the accessed register as explained in the following diagrams. First a write access (one path through Select-DR-Scan):

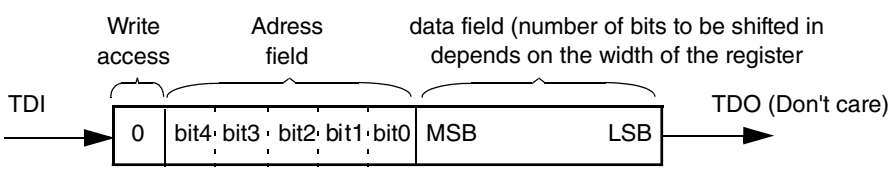

Figure 42-4. TDI/TDO on write access

Then a read access (requires two paths through JTAG DR Scan path):

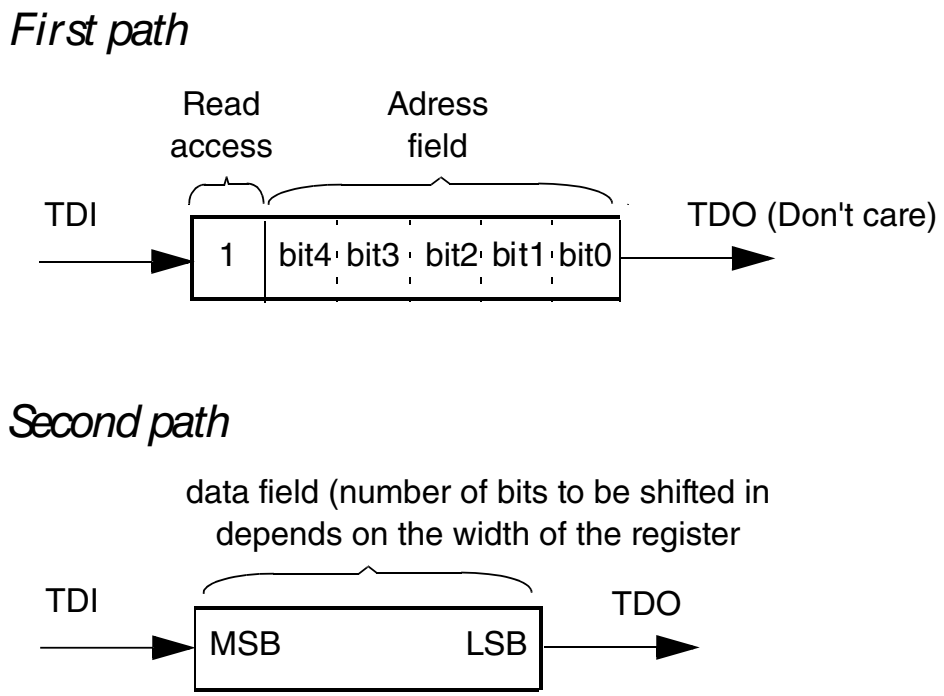

Figure 42-5. TDI/TDO on read access

For example, write value 1010_1100b to Debug Control Register (address = 00110b).

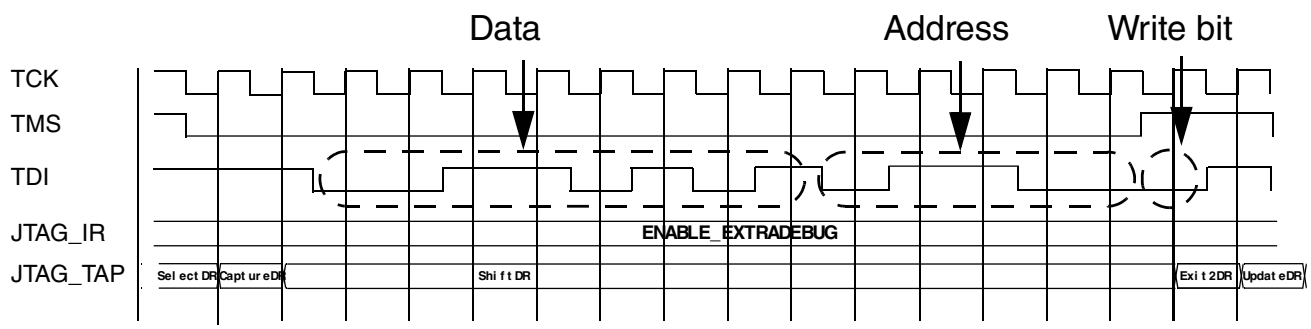

Figure 42-6. Example: Write access to DCR

The SJC registers have different levels of security (refer to JTAG Security Modes):

- Secured—accessible only in Mode 2 (correct response entered), Mode 3 and Mode 4.
- Unsecured—accessible in all modes

42.4 JTAG Instruction Register (SJIR)

The JTAG Instruction register is 5 bits wide.

Code					SJC IR
B4	B3	B2	B1	B0	
0	0	0	0	0	Reserved
0	0	0	0	1	Reserved
0	0	0	1	0	Reserved
0	0	0	1	1	Reserved
0	0	1	0	0	Enable Extra misc registers
0	0	1	0	1	Reserved
0	0	1	1	0	Reserved
0	0	1	1	1	Reserved
0	1	0	0	0	Reserved
0	1	0	0	1	Reserved
0	1	0	1	0	Reserved
0	1	0	1	1	Reserved
0	1	1	0	0	Security Output Challenge
0	1	1	0	1	Security input response
01110–01111					Reserved
1	1	1	1	1	BYPASS

The instruction register is reset to 00000b in the test-logic-reset controller state which is equivalent to the IDCODE instruction.

During the capture-IR controller state, the parallel inputs to the instruction register are loaded with the code 01b in the least significant bits as required by the standard; the most significant bits are loaded with the values 00b, leading to a capture value of 00001b.

42.4.1 BYPASS instruction

This instruction selects the single bit bypass register and the system logic controls the I/O pins. This creates a shift-register path from TDI to the bypass register and, finally, to TDO, circumventing the boundary scan register.

When the bypass register is selected, the shift-register stage is set to a logic zero on the rising edge of TCK in the capture-DR controller state. Therefore, the first bit to be shifted out after selecting the bypass register is always a logic zero.

For more details on the function and use of BYPASS, refer to the appropriate IEEE 1149.1 document.

42.4.2 ENABLE_ExtraDebug instruction

This instruction connects the TDI and TDO pins directly to the ExtraDebug registers, the SJC TAP controller remaining connected to TDI and TMS.

The ExtraDebug shift register consists of 38 bits (maximum) including a 32-bits data field (maximum length, see Accessing ExtraDebug register), a 5 bits address field and read/write bit. On a register read, the data field does not need to be filled in. The particular ExtraDebug register connected between TDI and TDO at a given time is selected by the ExtraDebug controller depending on the ExtraDebug address being currently decoded. All communication with the ExtraDebug controller is done through the Select-DR-Scan path of the JTAG TAP Controller.

42.5 Security

The SJC provideds means to block any malicious JTAG access. The JTAG security modes are as follows:

- Mode 1: No Debug—maximum security. All security sensitive JTAG features are permanently blocked.
- Mode 2: Secure JTAG—high security. JTAG use is regulated by secret key based authentication mechanism.
- Mode 3: JTAG Enabled—low security. JTAG always enabled.

The JTAG security modes are configured using fuses, which can burned after packaging by applying electrical signals. Fuse burning is irreversible process. Once a fuse is burned it is not possible to change the fuse back to the un-burned state.

42.5.1 JTAG Security Modes

42.5.1.1 Mode 1: no debug—maximum security

No debug security mode provides the highest security level.

In this mode:

- All security sensitive JTAG features are permanently blocked
- Boundary scan still allowed

These features do not reduce the security level, and they allow important tests and board connectivity checks.

42.5.1.2 Mode 2: secure JTAG–high security

The secure JTAG mode limits the JTAG access by using challenge/response based authentication mechanism. Any access to JTAG port is checked. Only authorized debug devices (that is, devices having the right response) can access the JTAG. Unauthorized JTAG access attempts are denied.

42.5.1.2.1 Challenge/response mechanism

When SJC is in system JTAG mode, the authentication process is as follows:

1. Shift the output challenge instruction to the IR
2. Pass through Capture-DR state and by performing Shift-DR operations Challenge code can be accessed from TDO.
3. Shift the enter response instruction to the IR. By performing Shift-DR, operations enter response code value through TDI. As Update-DR state is entered, response code is compared with the correct one.

In fixed challenge-response pair mode, each chip has its individual challenge/response pair which is determined at manufacturing time. The SJC compares the user's response to the expected response.

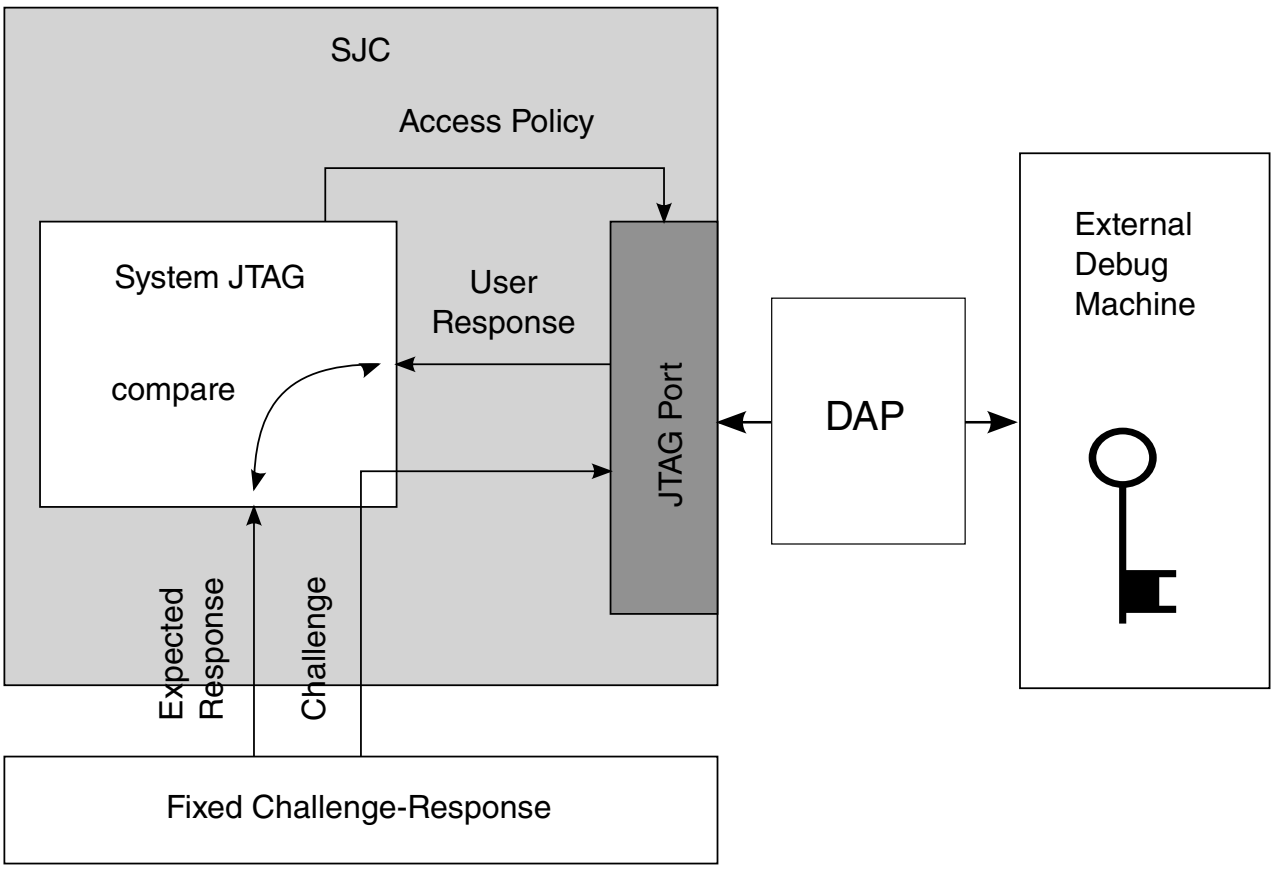

Figure 42-7. Mode #2 - Secure JTAG with fixed challenge/response pair

42.5.1.3 Mode 3: JTAG enabled—low security

In the JTAG enabled security mode, all JTAG features are enabled.

42.5.2 Software enabled JTAG

To increase the flexibility of SJC, an option to enable the JTAG using software is available in secure JTAG mode. By writing a 1 to the HAB_JDE (HAB JTAG DEBUG ENABLE) bit in the eFuse controller module (OCOTP_CTRL), the JTAG is opened, regardless of its security mode. It is the responsibility of software to assert or negate this bit.

Additionally, a corresponding LOCK bit is available (in the eFuse control module) to ensure that only trusted software is able to set the HAB_JDE bit. When the LOCK bit is set, no future change of HAB_JDE is possible, until the next POR (power-on-reset) cycle.

The platform initialization software should set the LOCK bit before transferring control to the application code.

The software JTAG enable allows JTAG enabling without activating the challenge/response mechanism (which requires JTAG access tool enhancement or special hardware). The JTAG software enable does not allow debug in case of boot or memory fault as it requires reset before entering debug.

This feature can be permanently blocked by burning the dedicated fuse.

NOTE

The software enabled JTAG feature reduces the overall security level of the system as it relies on software protections. If this feature is not required, it is strongly recommended to burn the JTAG_HEO fuse to disable this feature.

42.6 Programmable registers

This section lists additional registers to the standard accessible JTAG registers (per IEEE1149.1 standard). The following registers are accessed using the ExtraDebug mechanism, controlled by the ENABLE_ExtraDebug IR instruction.

NOTE

SJC registers are only accessible by JTAG interface and are not memory mapped to processor address space.

SJC memory map

JTAG Controller (JTAGC)

43.1 Chip-specific JTAGC information

Table 43-1. Reference links to related information

Topic	Related module	Reference
Full description	JTAGC	JTAGC
System memory map		System memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port control	Signal multiplexing

43.1.1 JTAG Controller (JTAGC)

The JTAGC provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format. The following table shows the configuration of the JTAGC.

Table 43-2. JTAGC configuration

Parameter	Description
Name	JTAGC
Supported standard verison	IEEE 1149.1-2001
Instances	1
Configurable features	NA
Interface speed	
External I/O pins	TCK, TDI, TDO, TMS
Interrupts	NA
DMA requests	NA

NOTE

The JTAGC is used in final testing, though the scan chains will be connected to the DAP, taking advantage of the Arm tool suites for independently disabling/enabling the various scan chains. e-fuses are to be used to permanently disable each of the scan chains as well as the interface between the DAP and external memory.

43.1.2 Boundary scan

It is required to have CA7 domain powered to run Boundary Scan on CA7 domain related pads: PTD* ~ PTF* GPIOs, RESET1_B, DDR* and HSIC*.

CA7 domain can be powered ON by application code or alternatively by means of JTAGC instruction "0110". This instruction selects a special register for connection as the shift path between TDI and TDO. This register implements 2 bits to enable CA7 regulator and/or CA7 power switch as follows:

Bit 0 : Forces Power Switch ON

Bit 1 : Forces A7 regulator ON

Once enabled, regulator cannot be disabled, so the device needs to go through a true POR.

If A7 is not powered ON, then Boundary scan will be performed only on CM4 domain pads : PTA*, PTB* , RESET1_B

43.2 Introduction

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format.

43.2.1 Block diagram

The following is a simplified block diagram of the JTAG Controller (JTAGC) block. See the chip-specific configuration information as well as Register description for more information about the JTAGC registers.

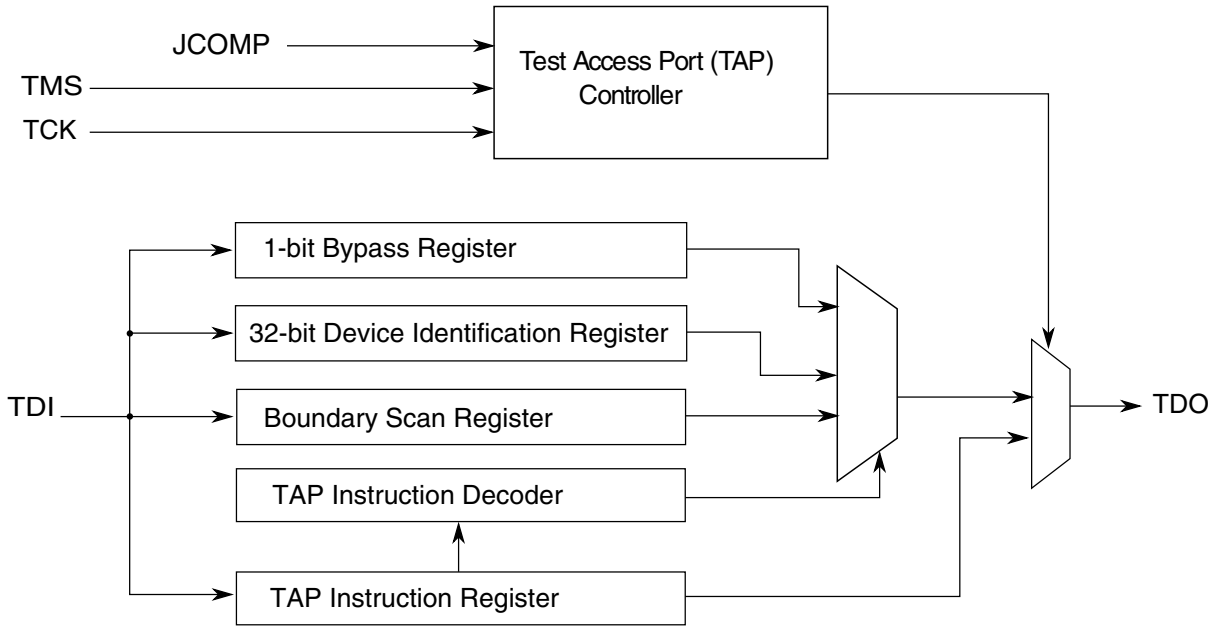

Figure 43-1. JTAG (IEEE 1149.1) block diagram

43.2.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 Test Access Port (TAP) interface
  - Four pins (TDI, TMS, TCK, and TDO)
- JCOMP input that provides reset control
- Instruction register that supports several IEEE 1149.1–2001 defined instructions as well as several public and private device-specific instructions (see JTAGC block instructions for a list of supported instructions).
- Bypass register, boundary scan register, and device identification register
- TAP controller state machine that controls the operation of the data registers, instruction register, and associated circuitry

43.2.3 Modes of operation

The JTAGC block uses JCOMP and a power-on reset indication as its primary reset signals. Several IEEE 1149.1–2001 defined test modes are supported, as well as a bypass mode.

43.2.3.1 Reset

The JTAGC block is placed in reset when:

- Power-on reset is asserted
- JCOMP is negated
- TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state

Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset or setting JCOMP to a value other than the value required to enable the JTAGC block results in asynchronous entry into the reset state.

When in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered.
- The instruction register is loaded with the IDCODE instruction.

43.2.3.2 IEEE 1149.1–2001 defined test modes

The JTAGC block supports several IEEE 1149.1–2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register when the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE, and SAMPLE/PRELOAD.

Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic when the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the following instructions are active:

- BYPASS
- HIGHZ
- CLAMP

The functionality of each test mode is explained in more detail in JTAGC block instructions.

43.2.3.3 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. When in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

43.3 External signal description

The JTAGC consists of a set of signals that connect to off-chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

Table 43-3. JTAG signal properties

Name	I/O	Function	Reset state
TCK	Input	Test clock	Weak pullup
TDI	Input	Test data in	Weak pullup
TDO	Output	Test data out	High Z[1]
TMS	Input	Test mode select	Weak pullup
JCOMP	Input	JTAG compliancy	Weak pulldown

1. TDO output buffer enable is negated when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

43.3.1 Test clock input (TCK)

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

43.3.2 Test data input (TDI)

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

43.3.3 Test data output (TDO)

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is tristateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in TAP controller state machine.

43.3.4 Test mode select (TMS)

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

43.3.5 JCOMP JTAG compliancy

The JCOMP signal provides IEEE 1149.1-2001 compatibility and provides the ability to share the TAP. The JTAGC TAP controller is enabled when JCOMP is set to the JTAGC enable encoding—otherwise the JTAGC TAP controller remains in reset.

43.4 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

43.4.1 Instruction register

The JTAGC block uses a 4-bit instruction register as shown in the following figure.

The instruction register allows instructions to be loaded into the block to select the test to be performed, or the test data register to be accessed, or both. Instructions are shifted in through TDI when the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states.

Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR

TAP controller state, the instruction shift register is loaded with the value 0b1, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

	3	2	1	0
R	0	0	0	1
W	Instruction Code			
Reset:	0	0	0	1

Figure 43-2. Instruction register

43.4.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the following instructions are active:

- BYPASS
- HIGHZ
- CLAMP

After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

43.4.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP.

The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state when the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Part Revision Number				Design Center						Part Identification Number					
W																
Reset	PRN				DC						PIN					

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Part Identification Number				Manufacturer Identity Code											1
W																
Reset	PIN (contd.)				MIC											1

The following table describes the device identification register functions.

Table 43-4. Device identification register field descriptions

Field	Description
PRN	Part Revision Number. Contains the revision number of the part. Value is cccc.
DC	Design Center. Indicates the design center. Value is 0x22.
PIN	Part Identification Number. Contains the part number of the device. Value is 0bccccccccccc.
MIC	Manufacturer Identity Code. Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID. Value is 0x00E.
IDCODE ID	IDCODE Register ID. Identifies this register as the device identification register and not the bypass register. Always set to 1.

43.4.4 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are active. It is used to:

- Capture input pin data
- Force fixed values on output pins
- Select a logic value and direction for bidirectional pins

Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in Boundary scan. The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

43.5 Functional description

This section explains the JTAGC functional description.

43.5.1 JTAGC reset configuration

When in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

43.5.2 IEEE 1149.1-2001 (JTAG) TAP

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction.

Data is shifted between TDI and TDO through the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.

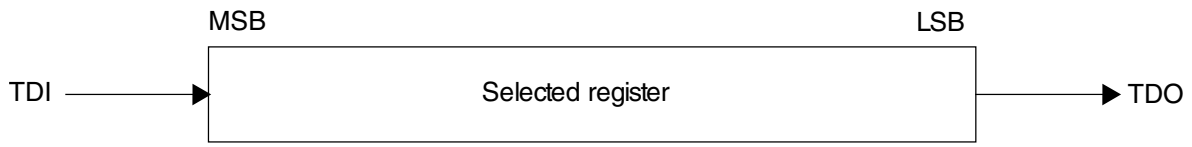

Figure 43-3. Shifting data through a register

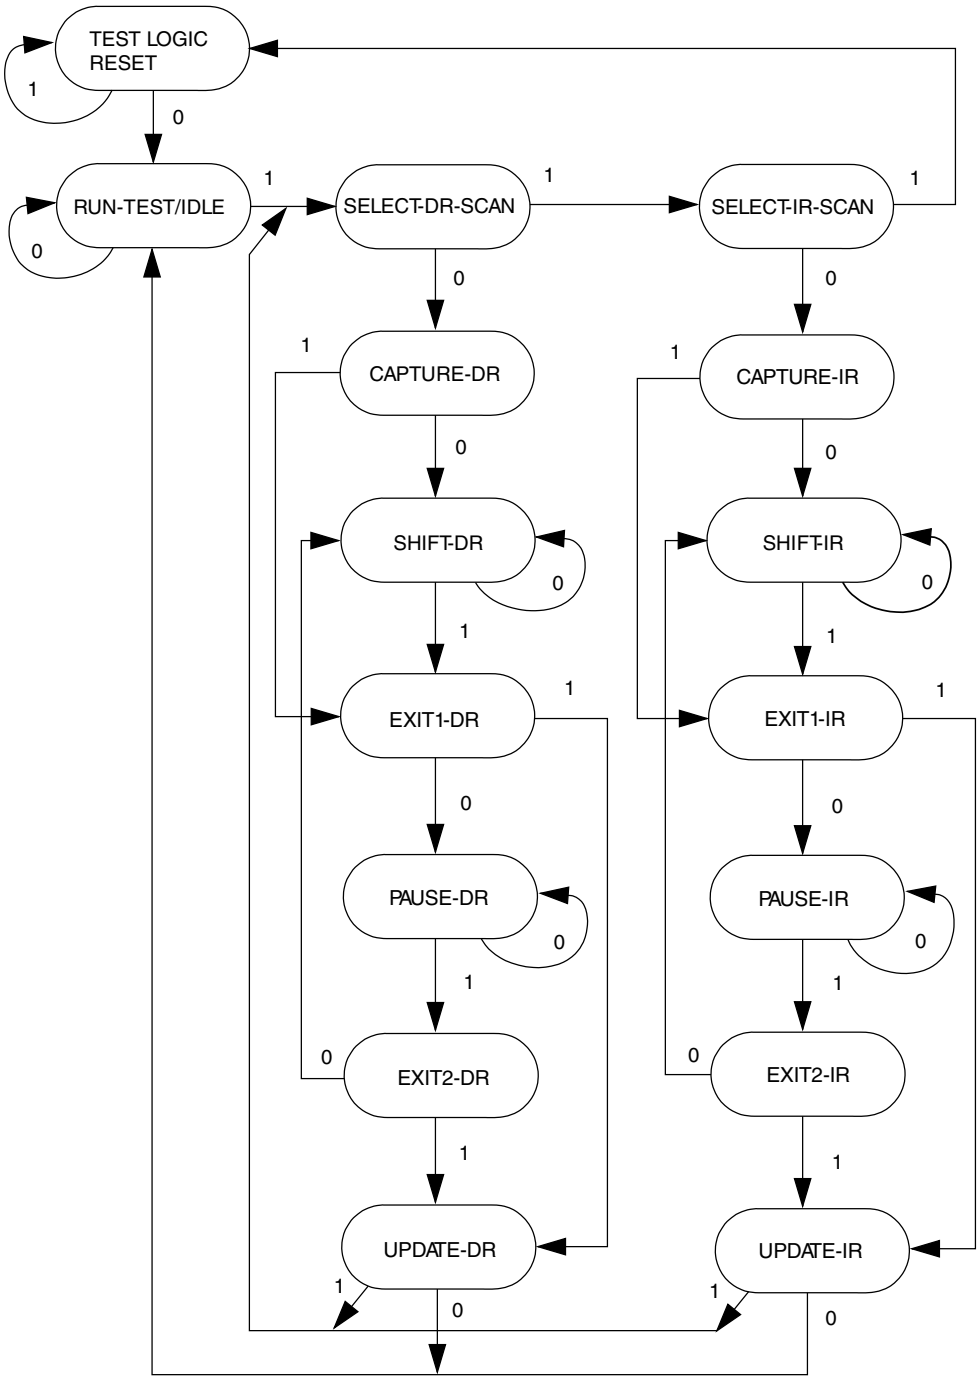
43.5.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin.

The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the figure shows, holding TMS at logic 1 when clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.



The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

Figure 43-4. IEEE 1149.1-2001 TAP controller finite state machine

43.5.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting JCOMP to a logic 1 value.

43.5.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions when the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated after the required number of bits have been acquired.

43.5.4 JTAGC block instructions

The JTAGC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction. See the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 43-5. 4-bit JTAG instructions

Instruction	Code[3:0]	Instruction summary
IDCODE	0000	Selects device identification register for shift
SAMPLE/PRELOAD	0010	Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation
SAMPLE	0011	Selects boundary scan register for shifting and sampling without disturbing functional operation
EXTEST	0100	Selects boundary scan register and applies preloaded values to output pins. **NOTE:** Execution of this instruction asserts functional reset.
TEST_LEAKAGE[1,2]	0101	Selects bypass register when tristating all output pins and asserts the jtag_leakage signal
Factory debug reserved	0110	Intended for factory debug only. See chip-specific information for possible alternate usage of this code.
Factory debug reserved	0111	Intended for factory debug only
Arm JTAG-DP Reserved	1000	This instruction goes the Arm JTAG-DP controller. See the Arm JTAG-DP documentation for more information.
HIGHZ	1001	Selects bypass register and tristates all output pins. **NOTE:** Execution of this instruction asserts functional reset.

Table continues on the next page...

Table 43-5. 4-bit JTAG instructions (continued)

Instruction	Code[3:0]	Instruction summary
Arm JTAG-DP Reserved	1010	This instruction goes the Arm JTAG-DP controller. See the Arm JTAG-DP documentation for more information.
Arm JTAG-DP Reserved	1011	This instruction goes the Arm JTAG-DP controller. See the Arm JTAG-DP documentation for more information.
CLAMP	1100	Selects bypass register and applies preloaded values to output pins. **NOTE:** Execution of this instruction asserts functional reset.
Arm JTAG-DP Reserved	1110	This instruction goes the Arm JTAG-DP controller. See the Arm JTAG-DP documentation for more information.
BYPASS	1111	Selects bypass register for data operations

1. Instruction for manufacturing purposes only.
2. Assertion of power-on reset or setting JCOMP for non-JTAGC operation required to exit this instruction.

43.5.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

43.5.4.2 SAMPLE/PRELOAD instruction

The SAMPLE/PRELOAD instruction has two functions:

- The SAMPLE portion of the instruction obtains a sample of the system data and control signals present at the MCU input pins, and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE/PRELOAD instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. Both the data capture and the shift operation are transparent to system operation.
- The PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

43.5.4.3 SAMPLE instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins, and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the Update-DR state. Both the data capture and the shift operation are transparent to system operation.

43.5.4.4 EXTEST external test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state when performing external boundary scan operations.

43.5.4.5 TEST_LEAKAGE instruction

The TEST_LEAKAGE instruction forces the jtag_leakage output signal to high. It is intended to tristate all output pad buffers and disable all of the part's pad input buffers except JCOMP and TEST. The jtag_leakage signal is asserted at the falling edge of TCK following the TAP controller state machine transition from the Update-IR state to the Run-Test-Idle state. When asserted, the part disables TCK, TMS, and TDI inputs and forces them to a logic 1. The TAP controller state machine remains in the Run-Test-Idle state until the JCOMP input is set to a value other than the JTAGC enable encoding. TEST_LEAKAGE also asserts the internal system reset for the MCU to force a predictable internal state.

43.5.4.6 ENABLE_SOC_DATA1 instruction

The ENABLE_SOC_DATA1 instruction captures SoC data and selects the SOC_DATA register for connection as the shift path between TDI and TDO.

43.5.4.7 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. When HIGHZ is active all output drivers are placed in an inactive drive state (for example, high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

43.5.4.8 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register when the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a single bit (the bypass register) when conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

43.5.4.9 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. When the BYPASS instruction is active the system logic operates normally.

43.5.5 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

43.6 Initialization/application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC block and enable access to registers, the following sequence is required:

1. Set the JCOMP signal to the JTAGC enable value, thereby enabling the JTAGC TAP controller.
2. Load the appropriate instruction for the test or action to be performed.

44.1.1 Synchronous Audio Interface (SAI/I2S)

The Synchronous Audio Interface (SAI) implements full-duplex serial interfaces with frame synchronization such as I2S, AC97, and CODEC/DSP interfaces. This device implements 2 SAI modules. The following table shows the configuration of the SAI.

Table 44-2. SAI configuration

Parameter	Description
Name	Synchronous Audio Interface (SAI)
Instances	2
Configurable features	SAI0: • 2 TX/RX channels • 16 word FIFOs • Max 32 words per frame SAI1: • 4 TX/RX channels • 16 word FIFOs • Max 32 words per frame

Table continues on the next page...

Table 44-2. SAI configuration (continued)

Parameter	Description
Interface speed	25 MHz
External I/O pins	• SAI0: TXD[1:0], TX_BCLK, TX_FS, RX_FS, RX_BCLK, RXD[1:0], MCLK. See attached IOMUXC spreadsheet for pin details. • SAI1: TXD[1:0], TX_BCLK, RX_FS, TX_FS, RX_BCLK, RXD[1:0], MCLK, TXD[3:2], and RXD[3:2]. See attached IOMUXC spreadsheet for detail

44.1.2 Signal names

The signal names used in this device are different from the signal names mentioned in the block guide. Refer the following tables for getting the actual signal names implemented in i.MX 7ULP for both instances.

Table 44-3. SAI0/I2S0 signal names

Signal name in block guide	Actual signal names used in i.MX 7ULP
TXDATA[1:0]	I2S0_TXD[1:0]
TXBCLK	I2S0_TX_BCLK
RXBCLK	I2S0_RX_BCLK
TXSYNC	I2S0_TX_FS
RXSYNC	I2S0_RX_FS
RXDATA[1:0]	I2S0_RXD[1:0]
MCLK	I2S0_MCLK

Table 44-4. SAI1/I2S1 signal names

Signal name in block guide	Actual signal names used in i.MX 7ULP
TXDATA[1:0]	I2S1_TXD[1:0]
TXBCLK	I2S1_TX_BCLK
RXBCLK	I2S1_RX_BCLK
TXSYNC	I2S1_TX_FS
RXSYNC	I2S1_RX_FS
RXDATA[1:0]	I2S1_RXD[1:0]
MCLK	I2S1_MCLK

44.1.3 Master clock options

For details on clocking and availability of master clock (MCLK) options in SAI0 and SAI1, see SAI clocking. MCLK option can be selected through RCR2[MSEL] bitfield. To enable I2S_MCLK0 or I2S_MCLK1 as an output on a PAD, it is necessary to configure the function on IOMUXC0 and set pad OBE=1.

44.2 Introduction

The I^2S (or I2S) module provides a synchronous audio interface (SAI) that supports full-duplex serial interfaces with frame synchronization such as I^2S, AC97, TDM, and codec/DSP interfaces.

44.2.1 Features

Note that some of the features are not supported across all SAI instances; see the chip-specific information in the first section of this chapter.

- Transmitter with independent bit clock and frame sync supporting 2 data lines
- Receiver with independent bit clock and frame sync supporting 2 data lines
- Each data line can support a maximum Frame size of 32 words
- Word size of between 8-bits and 32-bits
- Word size configured separately for first word and remaining words in frame
- Asynchronous 16 x 32-bit FIFO for each transmit and receive data line
- Supports graceful restart after FIFO error
- Supports automatic restart after FIFO error without software intervention
- Supports packing of 8-bit and 16-bit data into each 32-bit FIFO word
- Supports combining multiple data line FIFOs into single data line FIFO

44.2.2 Block diagram

The following block diagram also shows the module clocks.

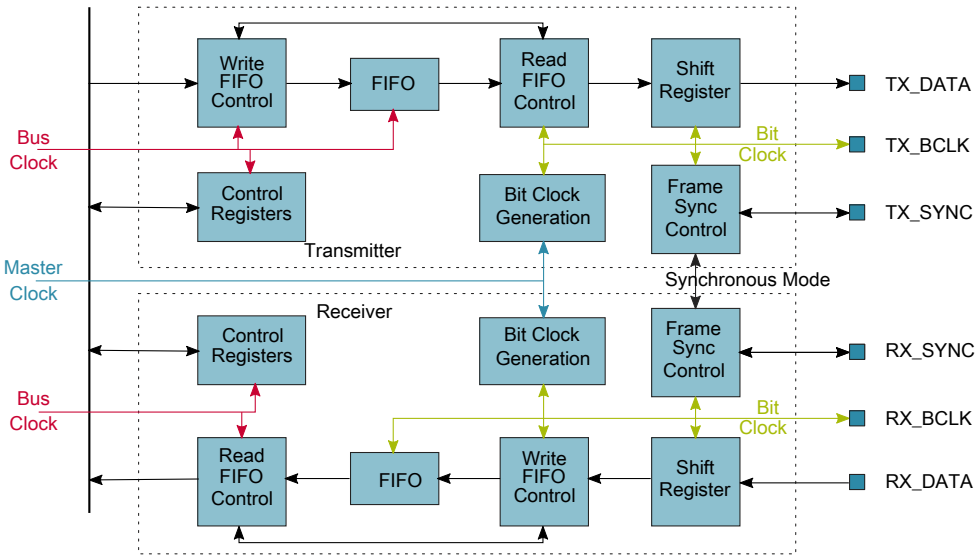

Figure 44-1. I²S/SAI block diagram

44.2.3 Modes of operation

Module power modes include Run mode, Stop modes, low-leakage stop modes, and Debug mode.

44.2.3.1 Run mode

In Run mode, the SAI transmitter and receiver operate normally.

44.2.3.2 Stop modes

In Stop mode, the SAI transmitter and/or receiver can continue operating provided the appropriate Stop Enable bit is set (TCSR[STOPE] and/or RCSR[STOPE], respectively), and provided the transmitter and/or receiver is/are using an externally generated bit clock or an Audio Master Clock that remains operating in Stop mode. The SAI transmitter and/or receiver can generate an asynchronous interrupt to wake the CPU from Stop mode.

In Stop mode, if the Transmitter Stop Enable (TCSR[STOPE]) bit is clear, the transmitter is disabled after completing the current transmit frame, and, if the Receiver Stop Enable (RCSR[STOPE]) bit is clear, the receiver is disabled after completing the current receive frame. Entry into Stop mode is prevented (not acknowledged) while waiting for the transmitter and receiver to be disabled at the end of the current frame.

44.2.3.3 Low-leakage stop modes

When entering low-leakage stop modes, the Stop Enable (TCSR[STOPE] and RCSR[STOPE]) bits are ignored and the SAI is disabled after completing the current transmit and receive Frames. Entry into stop mode is prevented (not acknowledged) while waiting for the transmitter and receiver to be disabled at the end of the current frame.

44.2.3.4 Debug mode

In Debug mode, the SAI transmitter and/or receiver can continue operating provided the Debug Enable bit is set. When TCSR[DBGE] or RCSR[DBGE] bit is clear and Debug mode is entered, the SAI is disabled after completing the current transmit or receive frame. The transmitter and receiver bit clocks are not affected by Debug mode.

44.3 External signals

Name	Function	I/O
TX_BCLK	Transmit Bit Clock. The bit clock is an input when externally generated and an output when internally generated.	I/O
TX_SYNC	Transmit Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated.	I/O
TX_DATA[1:0]	Transmit Data. The transmit data is generated synchronously by the bit clock and is tristated whenever not transmitting a word.	O
RX_BCLK	Receive Bit Clock. The bit clock is an input when externally generated and an output when internally generated.	I/O
RX_SYNC	Receive Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated.	I/O
RX_DATA[1:0]	Receive Data. The receive data is sampled synchronously by the bit clock.	I

44.4 Memory map and register definition

A read or write access to an address from offset 0x100 and above will result in a bus error.

44.4.1.4.3 Fields

Field	Function
31 TE	Transmitter Enable Enables/disables the transmitter. When software clears this field, the transmitter remains enabled, and this bit remains set, until the end of the current frame. 0b - Transmitter is disabled. 1b - Transmitter is enabled, or transmitter has been disabled and has not yet reached end of frame.
30 STOPE	Stop Enable Configures transmitter operation in Stop mode. The Stop Enable field is ignored and the transmitter is disabled in all low-leakage stop modes. 0b - Transmitter disabled in Stop mode. 1b - Transmitter enabled in Stop mode.
29 DBGE	Debug Enable Enables/disables transmitter operation in Debug mode. The transmit bit clock is not affected by debug mode. 0b - Transmitter is disabled in Debug mode, after completing the current frame. 1b - Transmitter is enabled in Debug mode.
28 BCE	Bit Clock Enable

Table continues on the next page...

Field	Function
	Enables the transmit bit clock, separately from the TE. This field is automatically set whenever TE is set. When software clears this field, the transmit bit clock remains enabled, and this bit remains set, until the end of the current frame. 0b - Transmit bit clock is disabled. 1b - Transmit bit clock is enabled.
27-26 —	Reserved
25 FR	FIFO Reset Empties the FIFO, and sets the FIFO read and write pointers to the same value, which may or may not be zero. Reading this field will always return zero. FIFO pointers should only be reset when the transmitter is disabled or the FIFO error flag is set. 0b - No effect. 1b - FIFO reset.
24 SR	Software Reset When set, resets the internal transmitter logic including the FIFO read and write pointers. Software-visible registers are not affected, except for the status registers. 0b - No effect. 1b - Software reset.
23-21 —	Reserved
20 WSF	Word Start Flag Indicates that the start of the configured word has been detected. Write a logic 1 to this field to clear this flag. 0b - Start of word not detected. 1b - Start of word detected.
19 SEF	Sync Error Flag Indicates that an error in the externally-generated frame sync has been detected. Write a logic 1 to this field to clear this flag. 0b - Sync error not detected. 1b - Frame sync error detected.
18 FEF	FIFO Error Flag Indicates that an enabled transmit FIFO has underrun. Write a logic 1 to this field to clear this flag. 0b - Transmit underrun not detected. 1b - Transmit underrun detected.
17 FWF	FIFO Warning Flag Indicates that an enabled transmit FIFO is empty. 0b - No enabled transmit FIFO is empty. 1b - Enabled transmit FIFO is empty.
16 FRF	FIFO Request Flag Indicates that the number of words in an enabled transmit channel FIFO is less than or equal to the transmit FIFO watermark. 0b - Transmit FIFO watermark has not been reached. 1b - Transmit FIFO watermark has been reached.
15-13 —	Reserved
12 WSIE	Word Start Interrupt Enable Enables/disables word start interrupts.

Table continues on the next page...

Field	Function
	0b - Disables interrupt. 1b - Enables interrupt.
11 SEIE	Sync Error Interrupt Enable Enables/disables sync error interrupts. 0b - Disables interrupt. 1b - Enables interrupt.
10 FEIE	FIFO Error Interrupt Enable Enables/disables FIFO error interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.
9 FWIE	FIFO Warning Interrupt Enable Enables/disables FIFO warning interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.
8 FRIE	FIFO Request Interrupt Enable Enables/disables FIFO request interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.
7-5 —	Reserved
4-2 —	Reserved
1 FWDE	FIFO Warning DMA Enable Enables/disables DMA requests. 0b - Disables the DMA request. 1b - Enables the DMA request.
0 FRDE	FIFO Request DMA Enable Enables/disables DMA requests. 0b - Disables the DMA request. 1b - Enables the DMA request.

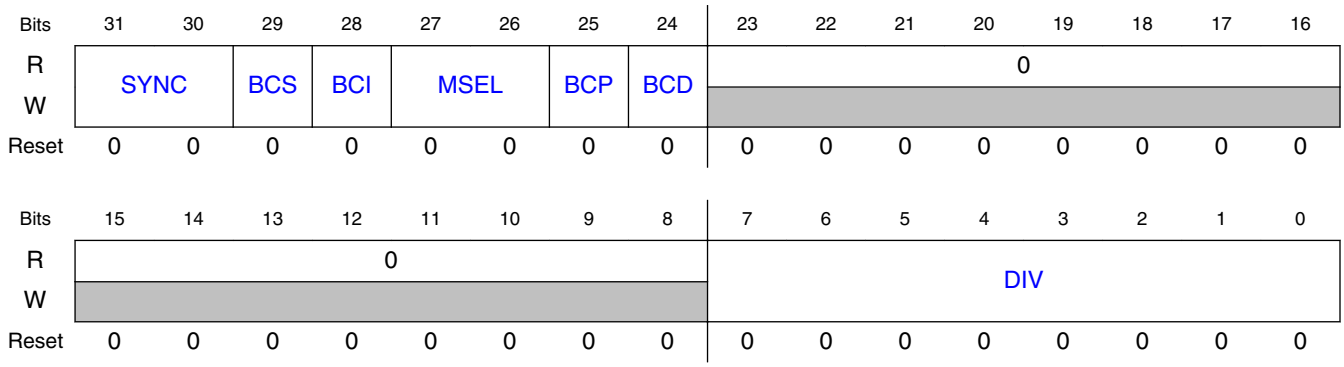
TCR2	10h

44.4.1.6.2 Function

This register must not be altered when TCSR[TE] is set.

44.4.1.6.3 Diagram



44.4.1.6.4 Fields

Field	Function
31-30 SYNC	Synchronous Mode Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the receiver or other SAI peripheral must be configured for asynchronous operation. 00b - Asynchronous mode. 01b - Synchronous with receiver. 10b - Synchronous with another SAI transmitter. 11b - Synchronous with another SAI receiver.
29 BCS	Bit Clock Swap This field swaps the bit clock used by the transmitter. When the transmitter is configured in asynchronous mode and this bit is set, the transmitter is clocked by the receiver bit clock (RX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the transmitter continues to use the transmit frame sync (TX_SYNC). When the transmitter is configured in synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the transmitter bit clock (TX_BCLK) but use the receiver frame sync (RX_SYNC). This field has no effect when synchronous to another SAI peripheral. 0b - Use the normal bit clock source. 1b - Swap the bit clock source.
28 BCI	Bit Clock Input When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the transmitter is delayed by the pad output delay (the transmitter is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time. The slave mode timing from the datasheet should be used for the transmitter when this bit is set. In synchronous mode, this bit allows the transmitter to use the slave mode timing from the datasheet, while the receiver uses the master mode timing. This field has no effect when configured for an externally generated bit clock or when synchronous to another SAI peripheral . 0b - No effect. 1b - Internal logic is clocked as if bit clock was externally generated.
27-26	MCLK Select

Table continues on the next page...

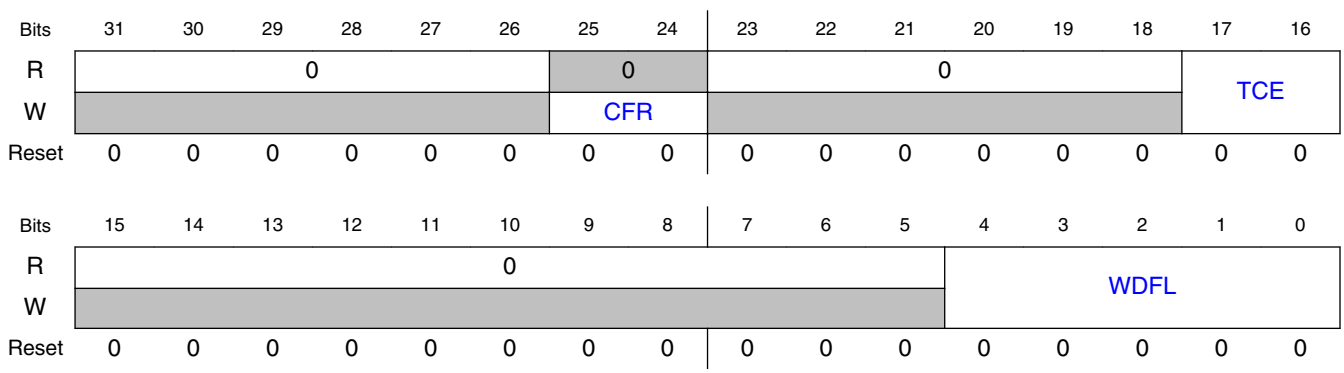
Field	Function
MSEL	Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock. **NOTE:** Depending on the device, some Master Clock options might not be available. See the chip-specific information for the meaning of each option. 00b - Bus Clock selected. 01b - Master Clock (MCLK) 1 option selected. 10b - Master Clock (MCLK) 2 option selected. 11b - Master Clock (MCLK) 3 option selected.
25 BCP	Bit Clock Polarity Configures the polarity of the bit clock. 0b - Bit clock is active high with drive outputs on rising edge and sample inputs on falling edge. 1b - Bit clock is active low with drive outputs on falling edge and sample inputs on rising edge.
24 BCD	Bit Clock Direction Configures the direction of the bit clock. 0b - Bit clock is generated externally in Slave mode. 1b - Bit clock is generated internally in Master mode.
23-8 —	Reserved
7-0 DIV	Bit Clock Divide Divides down the audio master clock to generate the bit clock when configured for an internal bit clock. The division value is (DIV + 1) * 2.

44.4.1.7 SAI Transmit Configuration 3 Register (TCR3)

44.4.1.7.1 Offset

Register	Offset
TCR3	14h

44.4.1.7.2 Diagram



44.4.1.7.3 Fields

Field	Function
31-26 —	Reserved
25-24 CFR	Channel FIFO Reset Resets the FIFO pointers for a specific channel. Reading this field will always return zero. FIFO pointers should only be reset when a channel is disabled or the FIFO error flag is set. The width of CFR field = the number of transmit channels (call it N). For example, if CFR is 2 bits wide, then bit position 24 refers to transmit channel 1 FIFO pointer and bit position 25 refers to transmit channel 2 FIFO pointer. Setting bit 24 resets transmit channel 1 FIFO pointer, and setting bit 25 enables transmit channel 2 FIFO pointer. Setting bit N will reset transmit channel N FIFO pointer. 0b - No effect. 1b - Transmit data channel N FIFO is reset.
23-18 —	Reserved
17-16 TCE	Transmit Channel Enable Enables the corresponding data channel for transmit operation. Changing TCE field will take effect immediately for generating the FIFO request and warning flags, but at the end of each frame for transmit operation. The width of TCE field = the number of transmit channels (call it N). For example, if TCE field is 2 bits wide, then bit position 16 refers to transmit channel 1 and bit position 17 refers to transmit channel 2. Setting bit 16 enables transmit channel 1, and setting bit 17 enables transmit channel 2. Setting bit N will enable transmit channel N. 0b - Transmit data channel N is disabled. 1b - Transmit data channel N is enabled.
15-5 —	Reserved
4-0 WDFL	Word Flag Configuration Configures which word sets the start of word flag. The value written must be one less than the word number. For example, writing 0 configures the first word in the frame. When configured to a value greater than TCR4[FRSZ], then the start of word flag is never set.

44.4.1.8 SAI Transmit Configuration 4 Register (TCR4)

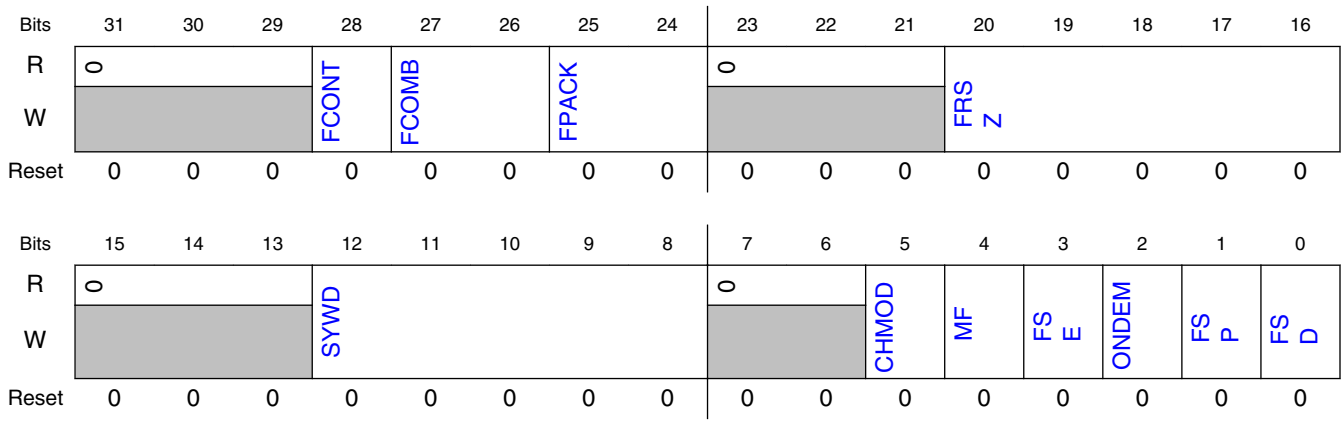
44.4.1.8.1 Offset

Register	Offset
TCR4	18h

44.4.1.8.2 Function

This register must not be altered when TCSR[TE] is set.

44.4.1.8.3 Diagram



44.4.1.8.4 Fields

Field	Function
31-29 —	Reserved
28 FCONT	FIFO Continue on Error Configures when the SAI will continue transmitting after a FIFO error has been detected. 0b - On FIFO error, the SAI will continue from the start of the next frame after the FIFO error flag has been cleared. 1b - On FIFO error, the SAI will continue from the same word that caused the FIFO error to set after the FIFO warning flag has been cleared.
27-26 FCOMB	FIFO Combine Mode When FIFO combine mode is enabled for FIFO writes, software writing to any FIFO data register will alternate the write among the enabled data channel FIFOs. For example, if two data channels are enabled then the first write will be performed to the first enabled data channel FIFO and the second write will be performed to the second enabled data channel FIFO. Reseting the FIFO or disabling FIFO combine mode for FIFO writes will reset the pointer back to the first enabled data channel. When FIFO combine mode is enabled for FIFO reads from the transmit shift registers, the transmit data channel output will alternate between the enabled data channel FIFOs. For example, if two data channels are enabled then the first unmasked word will be transmitted from the first enabled data channel FIFO and the second unmasked word will be transmitted from the second enabled data channel FIFO. Since the first word of the frame is always transmitted from the first enabled data channel FIFO, it is recommended that the number of unmasked words per frame is evenly divisible by the number of enabled data channels. 00b - FIFO combine mode disabled. 01b - FIFO combine mode enabled on FIFO reads (from transmit shift registers). 10b - FIFO combine mode enabled on FIFO writes (by software). 11b - FIFO combine mode enabled on FIFO reads (from transmit shift registers) and writes (by software).

Table continues on the next page...

Field	Function
25-24 FPACK	FIFO Packing Mode Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8-bit or 16-bit then only the first 8-bit or 16-bits are loaded from the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO write pointer will only increment when the full 32-bit FIFO word has been written by software. 00b - FIFO packing is disabled 01b - Reserved 10b - 8-bit FIFO packing is enabled 11b - 16-bit FIFO packing is enabled
23-21 —	Reserved
20-16 FRSZ	Frame size Configures the number of words in each frame. The value written must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 32 words.
15-13 —	Reserved
12-8 SYWD	Sync Width Configures the length of the frame sync in number of bit clocks. The value written must be one less than the number of bit clocks. For example, write 0 for the frame sync to assert for one bit clock only. The sync width cannot be configured longer than the first word of the frame.
7-6 —	Reserved
5 CHMOD	Channel Mode Configures if transmit data pins are configured for TDM mode or Output mode. 0b - TDM mode, transmit data pins are tri-stated when slots are masked or channels are disabled. 1b - Output mode, transmit data pins are never tri-stated and will output zero when slots are masked or channels are disabled.
4 MF	MSB First Configures whether the LSB or the MSB is transmitted first. 0b - LSB is transmitted first. 1b - MSB is transmitted first.
3 FSE	Frame Sync Early 0b - Frame sync asserts with the first bit of the frame. 1b - Frame sync asserts one bit before the first bit of the frame.
2 ONDEM	On Demand Mode When set, and the frame sync is generated internally, a frame sync is only generated when the FIFO warning flag is clear. 0b - Internal frame sync is generated continuously. 1b - Internal frame sync is generated when the FIFO warning flag is clear.
1 FSP	Frame Sync Polarity Configures the polarity of the frame sync. 0b - Frame sync is active high. 1b - Frame sync is active low.
0 FSD	Frame Sync Direction Configures the direction of the frame sync.

Field	Function
	0b - Frame sync is generated externally in Slave mode. 1b - Frame sync is generated internally in Master mode.

44.4.1.12.4 Fields

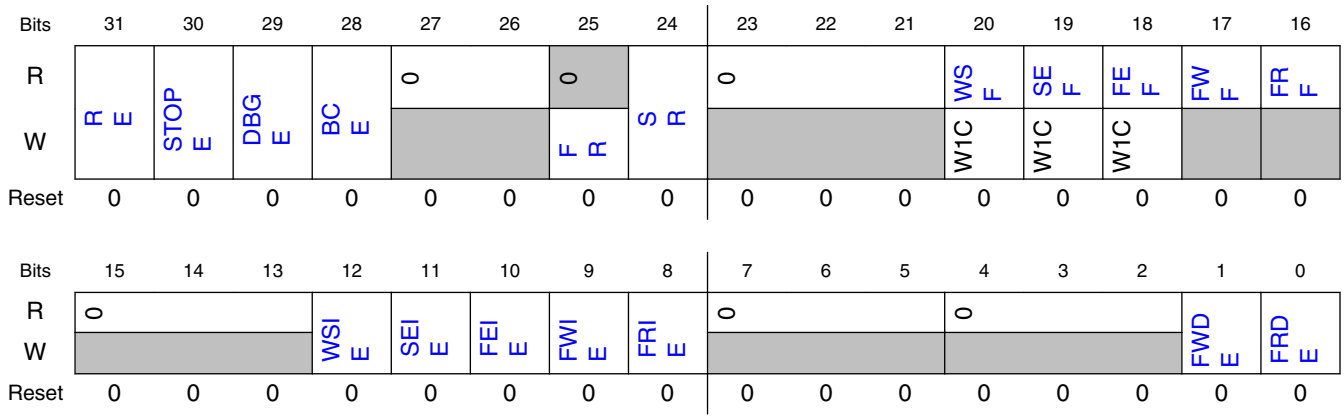
Field	Function
31-0 TWM	Transmit Word Mask Configures whether the transmit word is masked (transmit data pins are tri-stated or drive zero and transmit data not read from FIFO) for the corresponding word in the frame. 00000000000000000000000000000000b - Word N is enabled. 00000000000000000000000000000001b - Word N is masked. The transmit data pins are tri-stated or drive zero when masked.

44.4.1.13 SAI Receive Control Register (RCSR)

44.4.1.13.1 Offset

Register	Offset
RCSR	88h

44.4.1.13.2 Diagram



44.4.1.13.3 Fields

Field	Function
31 RE	Receiver Enable Enables/disables the receiver. When software clears this field, the receiver remains enabled, and this bit remains set, until the end of the current frame. 0b - Receiver is disabled. 1b - Receiver is enabled, or receiver has been disabled and has not yet reached end of frame.
30 STOPE	Stop Enable Configures receiver operation in Stop mode. The Stop Enable field is ignored and the receiver is disabled in all low-leakage stop modes. 0b - Receiver disabled in Stop mode. 1b - Receiver enabled in Stop mode.
29 DBGE	Debug Enable Enables/disables receiver operation in Debug mode. The receive bit clock is not affected by Debug mode. 0b - Receiver is disabled in Debug mode, after completing the current frame. 1b - Receiver is enabled in Debug mode.
28 BCE	Bit Clock Enable Enables the receive bit clock, separately from RE. This field is automatically set whenever RE is set. When software clears this field, the receive bit clock remains enabled, and this field remains set, until the end of the current frame. 0b - Receive bit clock is disabled. 1b - Receive bit clock is enabled.
27-26 —	Reserved
25 FR	FIFO Reset Empties the FIFO, and sets the FIFO read and write pointers to the same value, which may or may not be zero. Reading this field will always return zero. FIFO pointers should only be reset when the receiver is disabled or the FIFO error flag is set. 0b - No effect. 1b - FIFO reset.
24	Software Reset

Table continues on the next page...

Field	Function
SR	Resets the internal receiver logic including the FIFO pointers. Software-visible registers are not affected, except for the status registers. 0b - No effect. 1b - Software reset.
23-21 —	Reserved
20 WSF	Word Start Flag Indicates that the start of the configured word has been detected. Write a logic 1 to this field to clear this flag. 0b - Start of word not detected. 1b - Start of word detected.
19 SEF	Sync Error Flag Indicates that an error in the externally-generated frame sync has been detected. Write a logic 1 to this field to clear this flag. 0b - Sync error not detected. 1b - Frame sync error detected.
18 FEF	FIFO Error Flag Indicates that an enabled receive FIFO has overflowed. Write a logic 1 to this field to clear this flag. 0b - Receive overflow not detected. 1b - Receive overflow detected.
17 FWF	FIFO Warning Flag Indicates that an enabled receive FIFO is full. 0b - No enabled receive FIFO is full. 1b - Enabled receive FIFO is full.
16 FRF	FIFO Request Flag Indicates that the number of words in an enabled receive channel FIFO is greater than the receive FIFO watermark. 0b - Receive FIFO watermark not reached. 1b - Receive FIFO watermark has been reached.
15-13 —	Reserved
12 WSIE	Word Start Interrupt Enable Enables/disables word start interrupts. 0b - Disables interrupt. 1b - Enables interrupt.
11 SEIE	Sync Error Interrupt Enable Enables/disables sync error interrupts. 0b - Disables interrupt. 1b - Enables interrupt.
10 FEIE	FIFO Error Interrupt Enable Enables/disables FIFO error interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.
9 FWIE	FIFO Warning Interrupt Enable Enables/disables FIFO warning interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.

Table continues on the next page...

Field	Function
8 FRIE	FIFO Request Interrupt Enable Enables/disables FIFO request interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.
7-5 —	Reserved
4-2 —	Reserved
1 FWDE	FIFO Warning DMA Enable Enables/disables DMA requests. 0b - Disables the DMA request. 1b - Enables the DMA request.
0 FRDE	FIFO Request DMA Enable Enables/disables DMA requests. 0b - Disables the DMA request. 1b - Enables the DMA request.

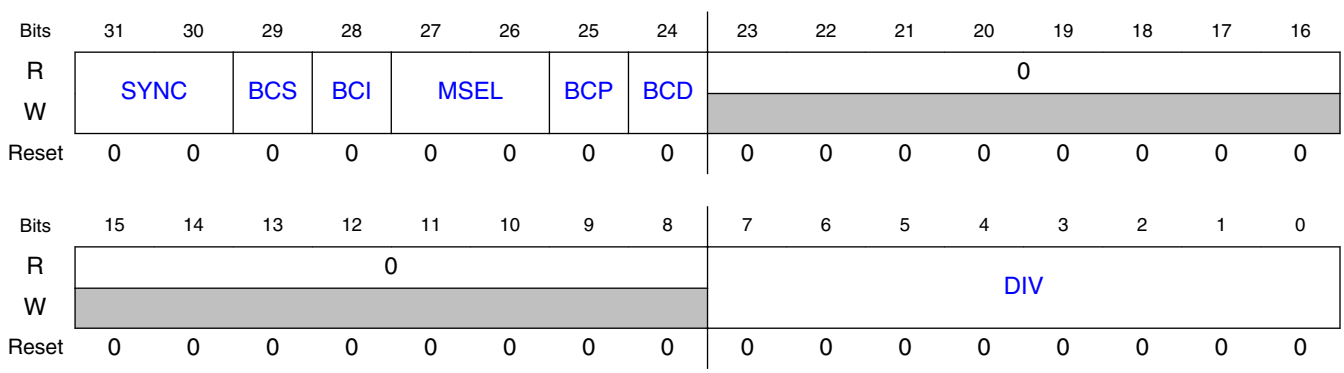
RCR2	90h

44.4.1.15.2 Function

This register must not be altered when RCSR[RE] is set.

44.4.1.15.3 Diagram



44.4.1.15.4 Fields

Field	Function
31-30 SYNC	Synchronous Mode Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the transmitter or other SAI peripheral must be configured for asynchronous operation.

Table continues on the next page...

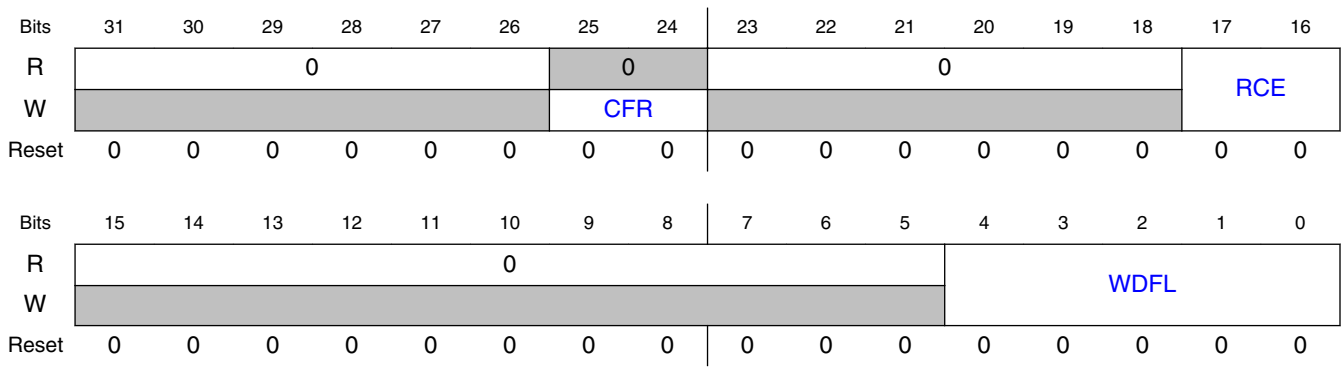
Field	Function
	00b - Asynchronous mode. 01b - Synchronous with transmitter. 10b - Synchronous with another SAI receiver. 11b - Synchronous with another SAI transmitter.
29 BCS	Bit Clock Swap This field swaps the bit clock used by the receiver. When the receiver is configured in asynchronous mode and this bit is set, the receiver is clocked by the transmitter bit clock (TX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the receiver continues to use the receiver frame sync (RX_SYNC). When the receiver is configured in synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the receiver bit clock (RX_BCLK) but use the transmitter frame sync (TX_SYNC). This field has no effect when synchronous to another SAI peripheral. 0b - Use the normal bit clock source. 1b - Swap the bit clock source.
28 BCI	Bit Clock Input When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the receiver is delayed by the pad output delay (the receiver is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time. The slave mode timing from the datasheet should be used for the receiver when this bit is set. In synchronous mode, this bit allows the receiver to use the slave mode timing from the datasheet, while the transmitter uses the master mode timing. This field has no effect when configured for an externally generated bit clock or when synchronous to another SAI peripheral . 0b - No effect. 1b - Internal logic is clocked as if bit clock was externally generated.
27-26 MSEL	MCLK Select Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock. **NOTE:** Depending on the device, some Master Clock options might not be available. See the chip-specific information for the availability and chip-specific meaning of each option. 00b - Bus Clock selected. 01b - Master Clock (MCLK) 1 option selected. 10b - Master Clock (MCLK) 2 option selected. 11b - Master Clock (MCLK) 3 option selected.
25 BCP	Bit Clock Polarity Configures the polarity of the bit clock. 0b - Bit Clock is active high with drive outputs on rising edge and sample inputs on falling edge. 1b - Bit Clock is active low with drive outputs on falling edge and sample inputs on rising edge.
24 BCD	Bit Clock Direction Configures the direction of the bit clock. 0b - Bit clock is generated externally in Slave mode. 1b - Bit clock is generated internally in Master mode.
23-8 —	Reserved
7-0 DIV	Bit Clock Divide Divides down the audio master clock to generate the bit clock when configured for an internal bit clock. The division value is (DIV + 1) * 2.

44.4.1.16 SAI Receive Configuration 3 Register (RCR3)

44.4.1.16.1 Offset

Register	Offset
RCR3	94h

44.4.1.16.2 Diagram



44.4.1.16.3 Fields

Field	Function
31-26 —	Reserved
25-24 CFR	Channel FIFO Reset Resets the FIFO pointers for a specific channel. Reading this field will always return zero. FIFO pointers should only be reset when a channel is disabled or the FIFO error flag is set. The width of CFR field = the number of receive channels (call it N). For example, if CFR is 2 bits wide, then bit position 24 refers to receive channel 1 FIFO pointer and bit position 25 refers to receive channel 2 FIFO pointer. Setting bit 24 resets receive channel 1 FIFO pointer, and setting bit 25 enables receive channel 2 FIFO pointer. Setting bit N will reset receive channel N FIFO pointer. 0b - No effect. 1b - Receive data channel N FIFO is reset.
23-18 —	Reserved
17-16 RCE	Receive Channel Enable Enables the corresponding data channel for receive operation. Changing this field will take effect immediately for generating the FIFO request and warning flags, but at the end of each frame for receive operation.

Table continues on the next page...

Field	Function
	The width of RCE field = the number of receive channels (call it N). For example, if RCE field is 2 bits wide, then bit position 16 refers to receive channel 1 and bit position 17 refers to receive channel 2. Setting bit 16 enables receive channel 1, and setting bit 17 enables receive channel 2. Setting bit N will enable receive channel N. 0b - Receive data channel N is disabled. 1b - Receive data channel N is enabled.
15-5 —	Reserved
4-0 WDFL	Word Flag Configuration Configures which word the start of word flag is set. The value written should be one less than the word number (for example, write zero to configure for the first word in the frame). When configured to a value greater than the Frame Size field, then the start of word flag is never set.

44.4.1.17 SAI Receive Configuration 4 Register (RCR4)

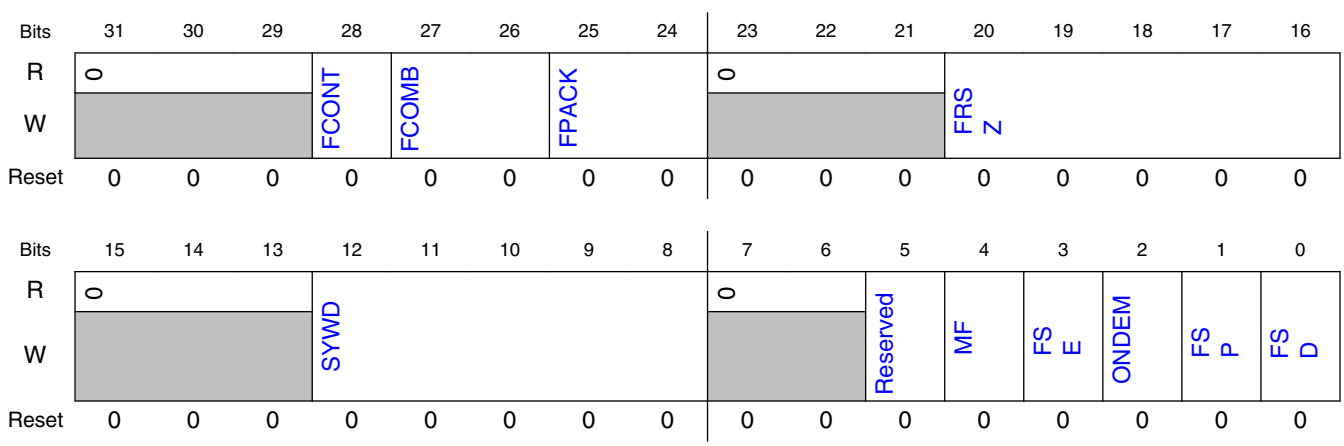
44.4.1.17.1 Offset

Register	Offset
RCR4	98h

44.4.1.17.2 Function

This register must not be altered when RCSR[RE] is set.

44.4.1.17.3 Diagram



44.4.1.17.4 Fields

Field	Function
31-29 —	Reserved
28 FCONT	FIFO Continue on Error Configures when the SAI will continue receiving after a FIFO error has been detected. 0b - On FIFO error, the SAI will continue from the start of the next frame after the FIFO error flag has been cleared. 1b - On FIFO error, the SAI will continue from the same word that caused the FIFO error to set after the FIFO warning flag has been cleared.
27-26 FCOMB	FIFO Combine Mode When FIFO combine mode is enabled for FIFO reads, software reading any FIFO data register will alternate the read among the enabled data channel FIFOs. For example, if two data channels are enabled then the first read will be performed to the first enabled data channel FIFO and the second read will be performed to the second enabled data channel FIFO. Reseting the FIFO or disabling FIFO combine mode for FIFO reads will reset the pointer back to the first enabled data channel. When FIFO combine mode is enabled for FIFO writes from the receive shift registers, the first enabled data channel input will alternate between the enabled data channel FIFOs. For example, if two data channels are enabled then the first unmasked received word will be stored in the first enabled data channel FIFO and the second unmasked received word will be stored in the second enabled data channel FIFO. Since the first word of the frame is always stored in the first enabled data channel FIFO, it is recommended that the number of unmasked words per frame is evenly divisible by the number of enabled data channels. 00b - FIFO combine mode disabled. 01b - FIFO combine mode enabled on FIFO writes (from receive shift registers). 10b - FIFO combine mode enabled on FIFO reads (by software). 11b - FIFO combine mode enabled on FIFO writes (from receive shift registers) and reads (by software).
25-24 FPACK	FIFO Packing Mode Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8-bit or 16-bit then only the first 8-bit or 16-bits are stored to the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO read pointer will only increment when the full 32-bit FIFO word has been read by software. 00b - FIFO packing is disabled 01b - Reserved. 10b - 8-bit FIFO packing is enabled 11b - 16-bit FIFO packing is enabled
23-21 —	Reserved
20-16 FRSZ	Frame Size Configures the number of words in each frame. The value written must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 32 words.
15-13 —	Reserved
12-8 SYWD	Sync Width

Table continues on the next page...

Field	Function
	Configures the length of the frame sync in number of bit clocks. The value written must be one less than the number of bit clocks. For example, write 0 for the frame sync to assert for one bit clock only. The sync width cannot be configured longer than the first word of the frame.
7-6 —	Reserved
5 —	Reserved. Software should only write zero to this bit.
4 MF	MSB First Configures whether the LSB or the MSB is received first. 0b - LSB is received first. 1b - MSB is received first.
3 FSE	Frame Sync Early 0b - Frame sync asserts with the first bit of the frame. 1b - Frame sync asserts one bit before the first bit of the frame.
2 ONDEM	On Demand Mode When set, and the frame sync is generated internally, a frame sync is only generated when the FIFO warning flag is clear. 0b - Internal frame sync is generated continuously. 1b - Internal frame sync is generated when the FIFO warning flag is clear.
1 FSP	Frame Sync Polarity Configures the polarity of the frame sync. 0b - Frame sync is active high. 1b - Frame sync is active low.
0 FSD	Frame Sync Direction Configures the direction of the frame sync. 0b - Frame Sync is generated externally in Slave mode. 1b - Frame Sync is generated internally in Master mode.

44.4.1.19.3 Fields

Field	Function
31-0 RDR	Receive Data Register Reads from this register when the receive FIFO is not empty will return the data from the top of the receive FIFO. Reads from this register when the receive FIFO is empty are ignored.

44.4.1.20 SAI Receive FIFO Register (RFR0 - RFR1)

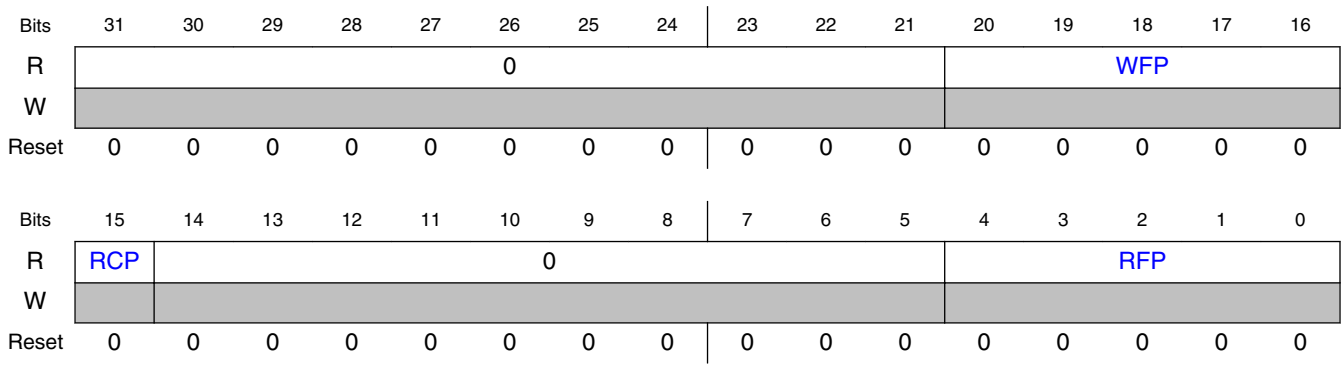
44.4.1.20.1 Offset

Register	Offset
RFR0	C0h
RFR1	C4h

44.4.1.20.2 Function

The MSB of the read and write pointers is used to distinguish between FIFO full and empty conditions. If the read and write pointers are identical, then the FIFO is empty. If the read and write pointers are identical except for the MSB, then the FIFO is full.

44.4.1.20.3 Diagram



44.4.1.20.4 Fields

Field	Function
31-21 —	Reserved
20-16 WFP	Write FIFO Pointer FIFO write pointer for receive data channel.
15 RCP	Receive Channel Pointer When FIFO Combine mode is enabled for reads, indicates that this data channel is the next FIFO to be read. 0b - No effect. 1b - FIFO combine is enabled for FIFO reads and this FIFO will be read on the next FIFO read.
14-5 —	Reserved
4-0 RFP	Read FIFO Pointer FIFO read pointer for receive data channel.

44.4.1.21 SAI Receive Mask Register (RMR)

44.4.1.21.1 Offset

Register	Offset
RMR	E0h

44.4.1.21.2 Function

This register is double-buffered and updates:

1. When RCSR[RE] is first set
2. At the end of each frame

This allows the masked words in each frame to change from frame to frame.

44.4.1.21.3 Diagram

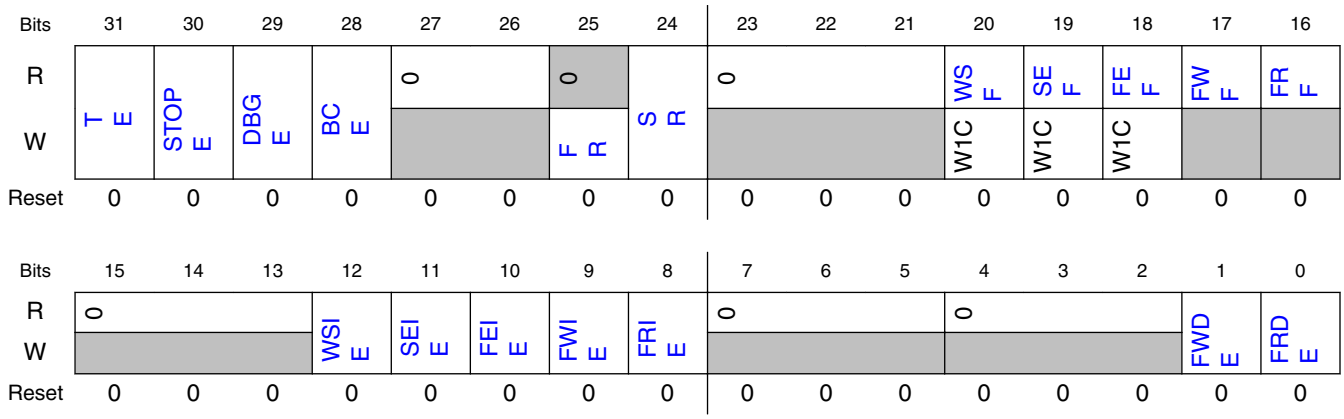
31-20 —	Reserved
19-16 FRAME	Frame Size The maximum number of slots per frame is 2^FRAME.
15-12 —	Reserved
11-8 FIFO	FIFO Size The number of words in each FIFO is 2^FIFO.
7-4 —	Reserved
3-0 DATALINE	Number of Datalines The number of datalines implemented.

44.4.2.4 SAI Transmit Control Register (TCSR)

44.4.2.4.1 Offset

Register	Offset
TCSR	8h

44.4.2.4.2 Diagram



44.4.2.4.3 Fields

Field	Function
31 TE	Transmitter Enable Enables/disables the transmitter. When software clears this field, the transmitter remains enabled, and this bit remains set, until the end of the current frame. 0b - Transmitter is disabled. 1b - Transmitter is enabled, or transmitter has been disabled and has not yet reached end of frame.
30 STOPE	Stop Enable Configures transmitter operation in Stop mode. The Stop Enable field is ignored and the transmitter is disabled in all low-leakage stop modes. 0b - Transmitter disabled in Stop mode. 1b - Transmitter enabled in Stop mode.
29 DBGE	Debug Enable Enables/disables transmitter operation in Debug mode. The transmit bit clock is not affected by debug mode. 0b - Transmitter is disabled in Debug mode, after completing the current frame. 1b - Transmitter is enabled in Debug mode.
28 BCE	Bit Clock Enable Enables the transmit bit clock, separately from the TE. This field is automatically set whenever TE is set. When software clears this field, the transmit bit clock remains enabled, and this bit remains set, until the end of the current frame. 0b - Transmit bit clock is disabled. 1b - Transmit bit clock is enabled.
27-26 —	Reserved
25 FR	FIFO Reset Empties the FIFO, and sets the FIFO read and write pointers to the same value, which may or may not be zero. Reading this field will always return zero. FIFO pointers should only be reset when the transmitter is disabled or the FIFO error flag is set. 0b - No effect. 1b - FIFO reset.

Table continues on the next page...

Field	Function
24 SR	Software Reset When set, resets the internal transmitter logic including the FIFO read and write pointers. Software-visible registers are not affected, except for the status registers. 0b - No effect. 1b - Software reset.
23-21 —	Reserved
20 WSF	Word Start Flag Indicates that the start of the configured word has been detected. Write a logic 1 to this field to clear this flag. 0b - Start of word not detected. 1b - Start of word detected.
19 SEF	Sync Error Flag Indicates that an error in the externally-generated frame sync has been detected. Write a logic 1 to this field to clear this flag. 0b - Sync error not detected. 1b - Frame sync error detected.
18 FEF	FIFO Error Flag Indicates that an enabled transmit FIFO has underrun. Write a logic 1 to this field to clear this flag. 0b - Transmit underrun not detected. 1b - Transmit underrun detected.
17 FWF	FIFO Warning Flag Indicates that an enabled transmit FIFO is empty. 0b - No enabled transmit FIFO is empty. 1b - Enabled transmit FIFO is empty.
16 FRF	FIFO Request Flag Indicates that the number of words in an enabled transmit channel FIFO is less than or equal to the transmit FIFO watermark. 0b - Transmit FIFO watermark has not been reached. 1b - Transmit FIFO watermark has been reached.
15-13 —	Reserved
12 WSIE	Word Start Interrupt Enable Enables/disables word start interrupts. 0b - Disables interrupt. 1b - Enables interrupt.
11 SEIE	Sync Error Interrupt Enable Enables/disables sync error interrupts. 0b - Disables interrupt. 1b - Enables interrupt.
10 FEIE	FIFO Error Interrupt Enable Enables/disables FIFO error interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.
9 FWIE	FIFO Warning Interrupt Enable Enables/disables FIFO warning interrupts. 0b - Disables the interrupt.

Table continues on the next page...

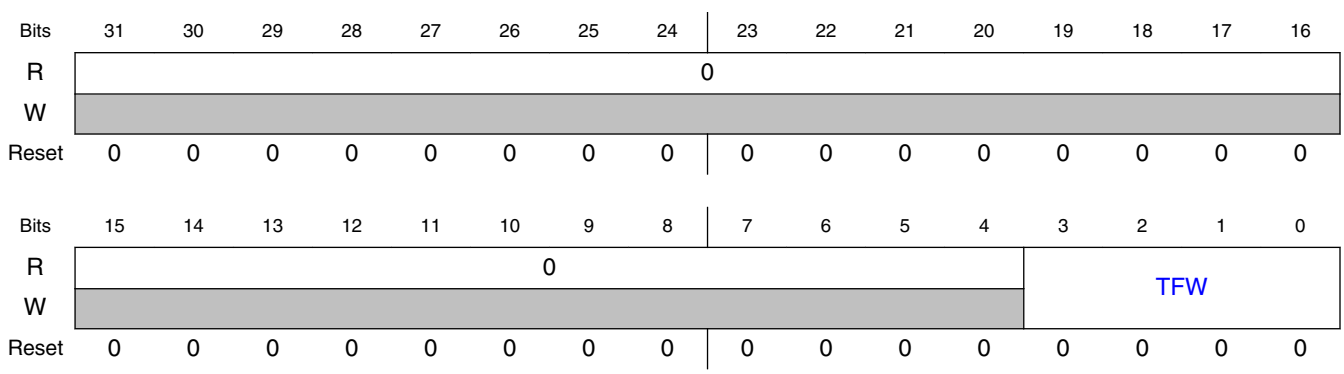
Field	Function
	1b - Enables the interrupt.
8 FRIE	FIFO Request Interrupt Enable Enables/disables FIFO request interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.
7-5 —	Reserved
4-2 —	Reserved
1 FWDE	FIFO Warning DMA Enable Enables/disables DMA requests. 0b - Disables the DMA request. 1b - Enables the DMA request.
0 FRDE	FIFO Request DMA Enable Enables/disables DMA requests. 0b - Disables the DMA request. 1b - Enables the DMA request.

44.4.2.5 SAI Transmit Configuration 1 Register (TCR1)

44.4.2.5.1 Offset

Register	Offset
TCR1	Ch

44.4.2.5.2 Diagram



44.4.2.5.3 Fields

Field	Function
31-4 —	Reserved

44.4.2.6 SAI Transmit Configuration 2 Register (TCR2)

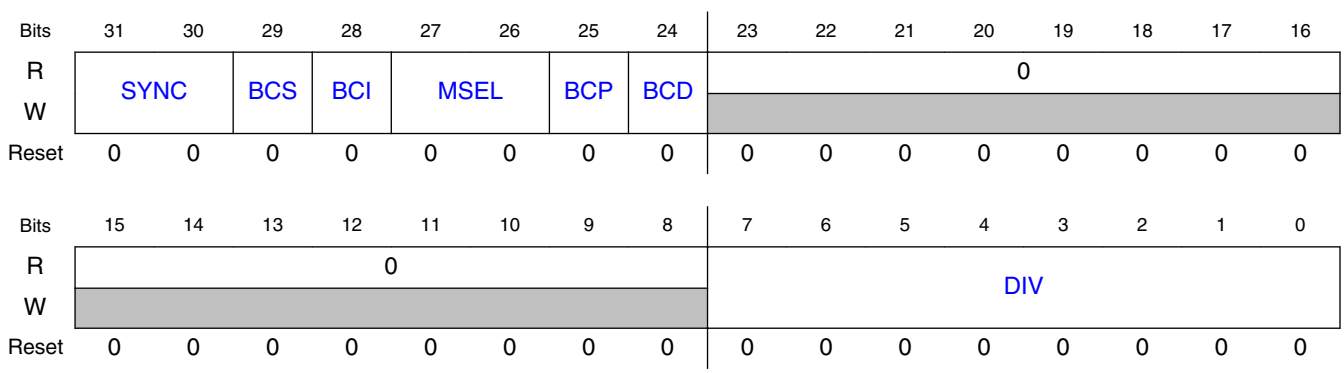
44.4.2.6.1 Offset

Register	Offset
TCR2	10h

44.4.2.6.2 Function

This register must not be altered when TCSR[TE] is set.

44.4.2.6.3 Diagram



44.4.2.6.4 Fields

Field	Function
31-30 SYNC	Synchronous Mode Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the receiver or other SAI peripheral must be configured for asynchronous operation.

Table continues on the next page...

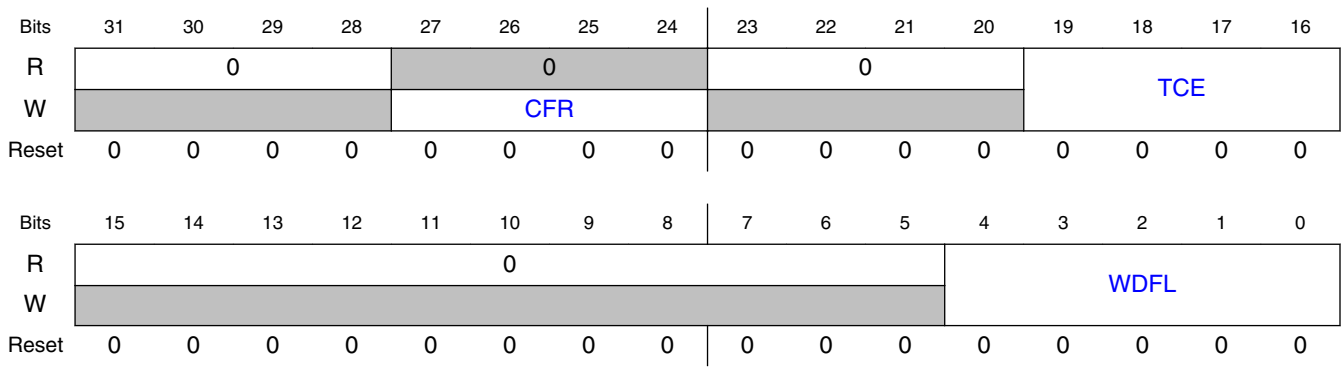
Field	Function
	00b - Asynchronous mode. 01b - Synchronous with receiver. 10b - Synchronous with another SAI transmitter. 11b - Synchronous with another SAI receiver.
29 BCS	Bit Clock Swap This field swaps the bit clock used by the transmitter. When the transmitter is configured in asynchronous mode and this bit is set, the transmitter is clocked by the receiver bit clock (RX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the transmitter continues to use the transmit frame sync (TX_SYNC). When the transmitter is configured in synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the transmitter bit clock (TX_BCLK) but use the receiver frame sync (RX_SYNC). This field has no effect when synchronous to another SAI peripheral. 0b - Use the normal bit clock source. 1b - Swap the bit clock source.
28 BCI	Bit Clock Input When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the transmitter is delayed by the pad output delay (the transmitter is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time. The slave mode timing from the datasheet should be used for the transmitter when this bit is set. In synchronous mode, this bit allows the transmitter to use the slave mode timing from the datasheet, while the receiver uses the master mode timing. This field has no effect when configured for an externally generated bit clock or when synchronous to another SAI peripheral . 0b - No effect. 1b - Internal logic is clocked as if bit clock was externally generated.
27-26 MSEL	MCLK Select Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock. **NOTE:** Depending on the device, some Master Clock options might not be available. See the chip-specific information for the meaning of each option. 00b - Bus Clock selected. 01b - Master Clock (MCLK) 1 option selected. 10b - Master Clock (MCLK) 2 option selected. 11b - Master Clock (MCLK) 3 option selected.
25 BCP	Bit Clock Polarity Configures the polarity of the bit clock. 0b - Bit clock is active high with drive outputs on rising edge and sample inputs on falling edge. 1b - Bit clock is active low with drive outputs on falling edge and sample inputs on rising edge.
24 BCD	Bit Clock Direction Configures the direction of the bit clock. 0b - Bit clock is generated externally in Slave mode. 1b - Bit clock is generated internally in Master mode.
23-8 —	Reserved
7-0 DIV	Bit Clock Divide Divides down the audio master clock to generate the bit clock when configured for an internal bit clock. The division value is (DIV + 1) * 2.

44.4.2.7 SAI Transmit Configuration 3 Register (TCR3)

44.4.2.7.1 Offset

Register	Offset
TCR3	14h

44.4.2.7.2 Diagram



44.4.2.7.3 Fields

Field	Function
31-28 —	Reserved
27-24 CFR	Channel FIFO Reset Resets the FIFO pointers for a specific channel. Reading this field will always return zero. FIFO pointers should only be reset when a channel is disabled or the FIFO error flag is set. The width of CFR field = the number of transmit channels (call it N). For example, if CFR is 2 bits wide, then bit position 24 refers to transmit channel 1 FIFO pointer and bit position 25 refers to transmit channel 2 FIFO pointer. Setting bit 24 resets transmit channel 1 FIFO pointer, and setting bit 25 enables transmit channel 2 FIFO pointer. Setting bit N will reset transmit channel N FIFO pointer. 0b - No effect. 1b - Transmit data channel N FIFO is reset.
23-20 —	Reserved
19-16 TCE	Transmit Channel Enable Enables the corresponding data channel for transmit operation. Changing TCE field will take effect immediately for generating the FIFO request and warning flags, but at the end of each frame for transmit operation.

Table continues on the next page...

Field	Function
	The width of TCE field = the number of transmit channels (call it N). For example, if TCE field is 2 bits wide, then bit position 16 refers to transmit channel 1 and bit position 17 refers to transmit channel 2. Setting bit 16 enables transmit channel 1, and setting bit 17 enables transmit channel 2. Setting bit N will enable transmit channel N. 0b - Transmit data channel N is disabled. 1b - Transmit data channel N is enabled.
15-5 —	Reserved
4-0 WDFL	Word Flag Configuration Configures which word sets the start of word flag. The value written must be one less than the word number. For example, writing 0 configures the first word in the frame. When configured to a value greater than TCR4[FRSZ], then the start of word flag is never set.

44.4.2.8 SAI Transmit Configuration 4 Register (TCR4)

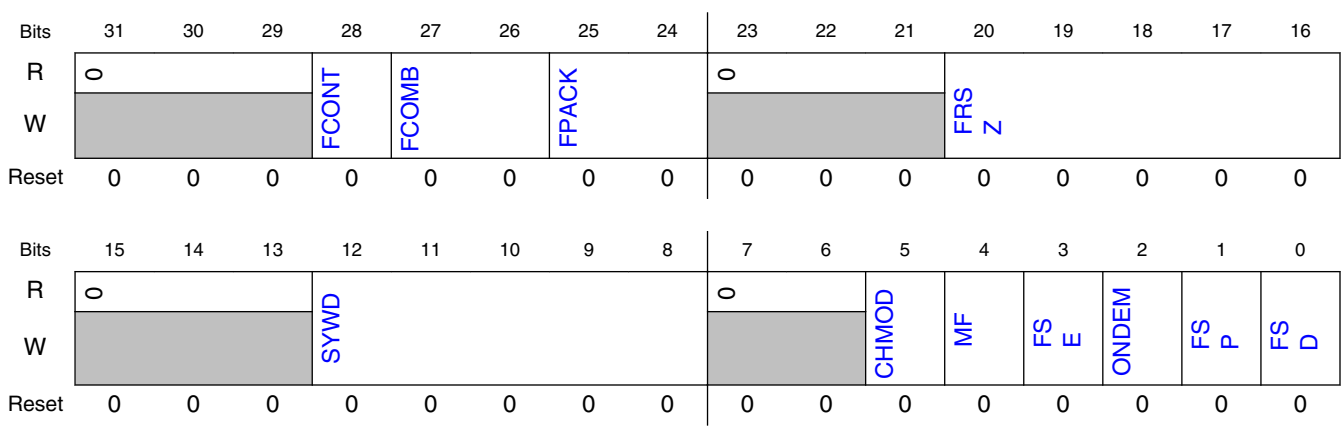
44.4.2.8.1 Offset

Register	Offset
TCR4	18h

44.4.2.8.2 Function

This register must not be altered when TCSR[TE] is set.

44.4.2.8.3 Diagram



44.4.2.8.4 Fields

Field	Function
31-29 —	Reserved
28 FCONT	FIFO Continue on Error Configures when the SAI will continue transmitting after a FIFO error has been detected. 0b - On FIFO error, the SAI will continue from the start of the next frame after the FIFO error flag has been cleared. 1b - On FIFO error, the SAI will continue from the same word that caused the FIFO error to set after the FIFO warning flag has been cleared.
27-26 FCOMB	FIFO Combine Mode When FIFO combine mode is enabled for FIFO writes, software writing to any FIFO data register will alternate the write among the enabled data channel FIFOs. For example, if two data channels are enabled then the first write will be performed to the first enabled data channel FIFO and the second write will be performed to the second enabled data channel FIFO. Reseting the FIFO or disabling FIFO combine mode for FIFO writes will reset the pointer back to the first enabled data channel. When FIFO combine mode is enabled for FIFO reads from the transmit shift registers, the transmit data channel output will alternate between the enabled data channel FIFOs. For example, if two data channels are enabled then the first unmasked word will be transmitted from the first enabled data channel FIFO and the second unmasked word will be transmitted from the second enabled data channel FIFO. Since the first word of the frame is always transmitted from the first enabled data channel FIFO, it is recommended that the number of unmasked words per frame is evenly divisible by the number of enabled data channels. 00b - FIFO combine mode disabled. 01b - FIFO combine mode enabled on FIFO reads (from transmit shift registers). 10b - FIFO combine mode enabled on FIFO writes (by software). 11b - FIFO combine mode enabled on FIFO reads (from transmit shift registers) and writes (by software).
25-24 FPACK	FIFO Packing Mode Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8-bit or 16-bit then only the first 8-bit or 16-bits are loaded from the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO write pointer will only increment when the full 32-bit FIFO word has been written by software. 00b - FIFO packing is disabled 01b - Reserved 10b - 8-bit FIFO packing is enabled 11b - 16-bit FIFO packing is enabled
23-21 —	Reserved
20-16 FRSZ	Frame size Configures the number of words in each frame. The value written must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 32 words.
15-13 —	Reserved
12-8 SYWD	Sync Width

Table continues on the next page...

Field	Function
	Configures the length of the frame sync in number of bit clocks. The value written must be one less than the number of bit clocks. For example, write 0 for the frame sync to assert for one bit clock only. The sync width cannot be configured longer than the first word of the frame.
7-6 —	Reserved
5 CHMOD	Channel Mode Configures if transmit data pins are configured for TDM mode or Output mode. 0b - TDM mode, transmit data pins are tri-stated when slots are masked or channels are disabled. 1b - Output mode, transmit data pins are never tri-stated and will output zero when slots are masked or channels are disabled.
4 MF	MSB First Configures whether the LSB or the MSB is transmitted first. 0b - LSB is transmitted first. 1b - MSB is transmitted first.
3 FSE	Frame Sync Early 0b - Frame sync asserts with the first bit of the frame. 1b - Frame sync asserts one bit before the first bit of the frame.
2 ONDEM	On Demand Mode When set, and the frame sync is generated internally, a frame sync is only generated when the FIFO warning flag is clear. 0b - Internal frame sync is generated continuously. 1b - Internal frame sync is generated when the FIFO warning flag is clear.
1 FSP	Frame Sync Polarity Configures the polarity of the frame sync. 0b - Frame sync is active high. 1b - Frame sync is active low.
0 FSD	Frame Sync Direction Configures the direction of the frame sync. 0b - Frame sync is generated externally in Slave mode. 1b - Frame sync is generated internally in Master mode.

44.4.2.9 SAI Transmit Configuration 5 Register (TCR5)

44.4.2.9.1 Offset

Register	Offset
TCR5	1Ch

44.4.2.9.2 Function

This register must not be altered when TCSR[TE] is set.

44.4.2.9.3 Diagram

44.4.2.9.4 Fields

Field	Function
31-29 —	Reserved
28-24 WNW	Word N Width Configures the number of bits in each word, for each word except the first in the frame. The value written must be one less than the number of bits per word. Word width of less than 8 bits is not supported.
23-21 —	Reserved
20-16 W0W	Word 0 Width Configures the number of bits in the first word in each frame. The value written must be one less than the number of bits in the first word. Word width of less than 8 bits is not supported if there is only one word per frame.
15-13 —	Reserved
12-8 FBT	First Bit Shifted Configures the bit index for the first bit transmitted for each word in the frame. If configured for MSB First, the index of the next bit transmitted is one less than the current bit transmitted. If configured for LSB First, the index of the next bit transmitted is one more than the current bit transmitted. The value written must be greater than or equal to the word width when configured for MSB First. The value written must be less than or equal to 31-word width when configured for LSB First.
7-0 —	Reserved

44.4.2.10 SAI Transmit Data Register (TDR0 - TDR3)

44.4.2.10.1 Offset

Register	Offset
TDR0	20h
TDR1	24h
TDR2	28h
TDR3	2Ch

44.4.2.10.2 Diagram

44.4.2.10.3 Fields

Field	Function
31-0 TDR	Transmit Data Register Writes to this register when the transmit FIFO is not full will push the data written into the transmit data FIFO. Writes to this register when the transmit FIFO is full are ignored.

44.4.2.11 SAI Transmit FIFO Register (TFR0 - TFR3)

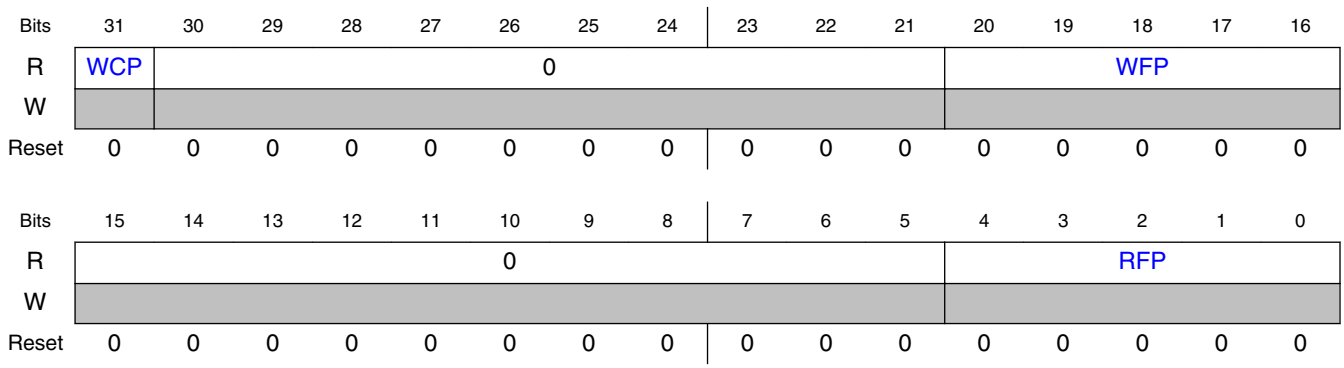
44.4.2.11.1 Offset

Register	Offset
TFR0	40h
TFR1	44h
TFR2	48h
TFR3	4Ch

44.4.2.11.2 Function

The MSB of the read and write pointers is used to distinguish between FIFO full and empty conditions. If the read and write pointers are identical, then the FIFO is empty. If the read and write pointers are identical except for the MSB, then the FIFO is full.

44.4.2.11.3 Diagram



44.4.2.11.4 Fields

Field	Function
31 WCP	Write Channel Pointer When FIFO Combine mode is enabled for writes, indicates that this data channel is the next FIFO to be written. 0b - No effect. 1b - FIFO combine is enabled for FIFO writes and this FIFO will be written on the next FIFO write.
30-21 —	Reserved
20-16 WFP	Write FIFO Pointer FIFO write pointer for transmit data channel.
15-5 —	Reserved
4-0 RFP	Read FIFO Pointer FIFO read pointer for transmit data channel.

44.4.2.12 SAI Transmit Mask Register (TMR)

44.4.2.12.1 Offset

Register	Offset
TMR	60h

44.4.2.12.2 Function

This register is double-buffered and updates:

1. When TCSR[TE] is first set
2. At the end of each frame.

This allows the masked words in each frame to change from frame to frame.

44.4.2.12.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

—	
25 FR	FIFO Reset Empties the FIFO, and sets the FIFO read and write pointers to the same value, which may or may not be zero. Reading this field will always return zero. FIFO pointers should only be reset when the receiver is disabled or the FIFO error flag is set. 0b - No effect. 1b - FIFO reset.
24 SR	Software Reset Resets the internal receiver logic including the FIFO pointers. Software-visible registers are not affected, except for the status registers. 0b - No effect. 1b - Software reset.
23-21 —	Reserved
20 WSF	Word Start Flag Indicates that the start of the configured word has been detected. Write a logic 1 to this field to clear this flag. 0b - Start of word not detected. 1b - Start of word detected.
19 SEF	Sync Error Flag Indicates that an error in the externally-generated frame sync has been detected. Write a logic 1 to this field to clear this flag. 0b - Sync error not detected. 1b - Frame sync error detected.
18 FEF	FIFO Error Flag Indicates that an enabled receive FIFO has overflowed. Write a logic 1 to this field to clear this flag. 0b - Receive overflow not detected. 1b - Receive overflow detected.
17 FWF	FIFO Warning Flag Indicates that an enabled receive FIFO is full. 0b - No enabled receive FIFO is full. 1b - Enabled receive FIFO is full.
16 FRF	FIFO Request Flag Indicates that the number of words in an enabled receive channel FIFO is greater than the receive FIFO watermark. 0b - Receive FIFO watermark not reached. 1b - Receive FIFO watermark has been reached.
15-13 —	Reserved
12 WSIE	Word Start Interrupt Enable Enables/disables word start interrupts. 0b - Disables interrupt. 1b - Enables interrupt.
11 SEIE	Sync Error Interrupt Enable Enables/disables sync error interrupts. 0b - Disables interrupt. 1b - Enables interrupt.

Table continues on the next page...

Field	Function
10 FEIE	FIFO Error Interrupt Enable Enables/disables FIFO error interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.
9 FWIE	FIFO Warning Interrupt Enable Enables/disables FIFO warning interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.
8 FRIE	FIFO Request Interrupt Enable Enables/disables FIFO request interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.
7-5 —	Reserved
4-2 —	Reserved
1 FWDE	FIFO Warning DMA Enable Enables/disables DMA requests. 0b - Disables the DMA request. 1b - Enables the DMA request.
0 FRDE	FIFO Request DMA Enable Enables/disables DMA requests. 0b - Disables the DMA request. 1b - Enables the DMA request.

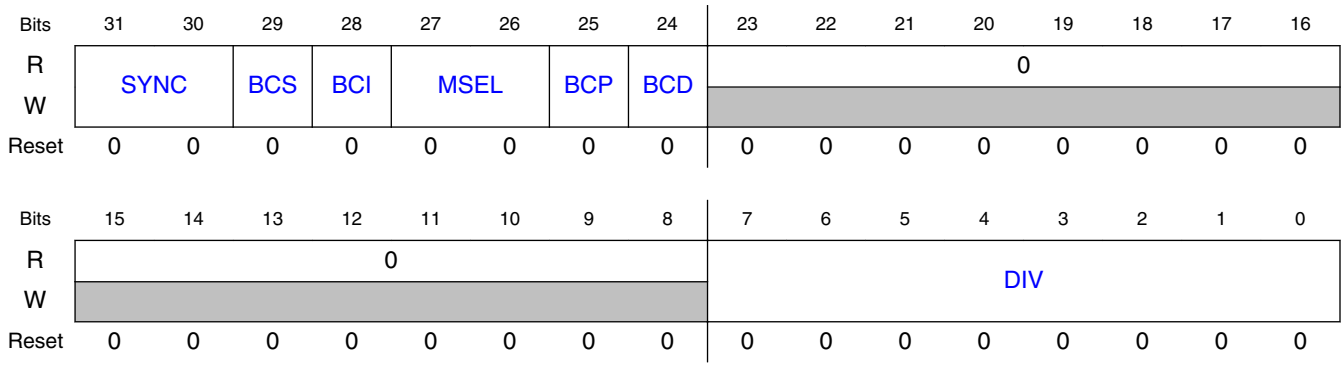
RCR2	90h

44.4.2.15.2 Function

This register must not be altered when RCSR[RE] is set.

44.4.2.15.3 Diagram



44.4.2.15.4 Fields

Field	Function
31-30 SYNC	Synchronous Mode Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the transmitter or other SAI peripheral must be configured for asynchronous operation. 00b - Asynchronous mode. 01b - Synchronous with transmitter. 10b - Synchronous with another SAI receiver. 11b - Synchronous with another SAI transmitter.
29 BCS	Bit Clock Swap This field swaps the bit clock used by the receiver. When the receiver is configured in asynchronous mode and this bit is set, the receiver is clocked by the transmitter bit clock (TX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the receiver continues to use the receiver frame sync (RX_SYNC). When the receiver is configured in synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the receiver bit clock (RX_BCLK) but use the transmitter frame sync (TX_SYNC). This field has no effect when synchronous to another SAI peripheral. 0b - Use the normal bit clock source. 1b - Swap the bit clock source.
28 BCI	Bit Clock Input When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the receiver is delayed by the pad output delay (the receiver is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time. The slave mode timing from the datasheet should be used for the receiver when this bit is set. In synchronous mode, this bit allows the receiver to use the slave mode timing from the datasheet, while the transmitter uses the master mode timing. This field has no effect when configured for an externally generated bit clock or when synchronous to another SAI peripheral . 0b - No effect. 1b - Internal logic is clocked as if bit clock was externally generated.
27-26	MCLK Select

Table continues on the next page...

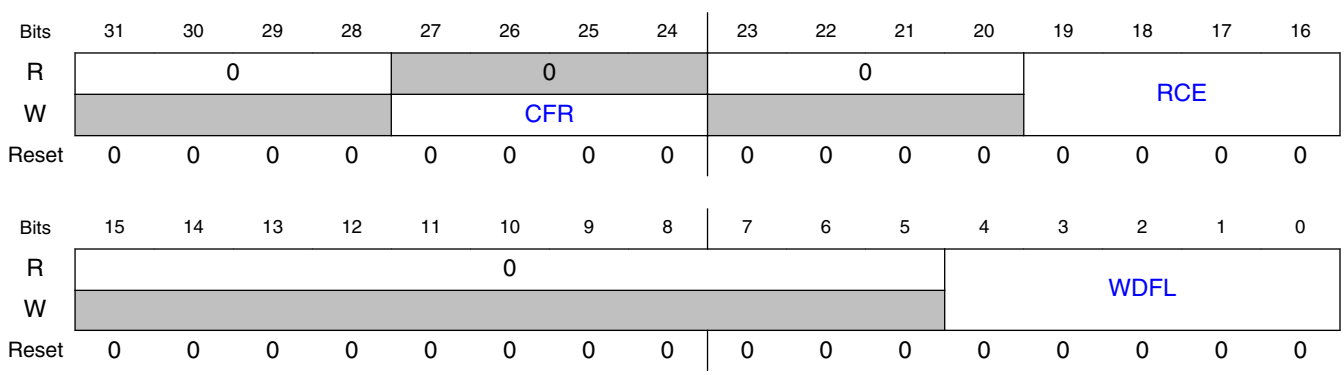
Field	Function
MSEL	Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock. **NOTE:** Depending on the device, some Master Clock options might not be available. See the chip-specific information for the availability and chip-specific meaning of each option. 00b - Bus Clock selected. 01b - Master Clock (MCLK) 1 option selected. 10b - Master Clock (MCLK) 2 option selected. 11b - Master Clock (MCLK) 3 option selected.
25 BCP	Bit Clock Polarity Configures the polarity of the bit clock. 0b - Bit Clock is active high with drive outputs on rising edge and sample inputs on falling edge. 1b - Bit Clock is active low with drive outputs on falling edge and sample inputs on rising edge.
24 BCD	Bit Clock Direction Configures the direction of the bit clock. 0b - Bit clock is generated externally in Slave mode. 1b - Bit clock is generated internally in Master mode.
23-8 —	Reserved
7-0 DIV	Bit Clock Divide Divides down the audio master clock to generate the bit clock when configured for an internal bit clock. The division value is (DIV + 1) * 2.

44.4.2.16 SAI Receive Configuration 3 Register (RCR3)

44.4.2.16.1 Offset

Register	Offset
RCR3	94h

44.4.2.16.2 Diagram



44.4.2.16.3 Fields

Field	Function
31-28 —	Reserved
27-24 CFR	Channel FIFO Reset Resets the FIFO pointers for a specific channel. Reading this field will always return zero. FIFO pointers should only be reset when a channel is disabled or the FIFO error flag is set. The width of CFR field = the number of receive channels (call it N). For example, if CFR is 2 bits wide, then bit position 24 refers to receive channel 1 FIFO pointer and bit position 25 refers to receive channel 2 FIFO pointer. Setting bit 24 resets receive channel 1 FIFO pointer, and setting bit 25 enables receive channel 2 FIFO pointer. Setting bit N will reset receive channel N FIFO pointer. 0b - No effect. 1b - Receive data channel N FIFO is reset.
23-20 —	Reserved
19-16 RCE	Receive Channel Enable Enables the corresponding data channel for receive operation. Changing this field will take effect immediately for generating the FIFO request and warning flags, but at the end of each frame for receive operation. The width of RCE field = the number of receive channels (call it N). For example, if RCE field is 2 bits wide, then bit position 16 refers to receive channel 1 and bit position 17 refers to receive channel 2. Setting bit 16 enables receive channel 1, and setting bit 17 enables receive channel 2. Setting bit N will enable receive channel N. 0b - Receive data channel N is disabled. 1b - Receive data channel N is enabled.
15-5 —	Reserved
4-0 WDFL	Word Flag Configuration Configures which word the start of word flag is set. The value written should be one less than the word number (for example, write zero to configure for the first word in the frame). When configured to a value greater than the Frame Size field, then the start of word flag is never set.

44.4.2.17 SAI Receive Configuration 4 Register (RCR4)

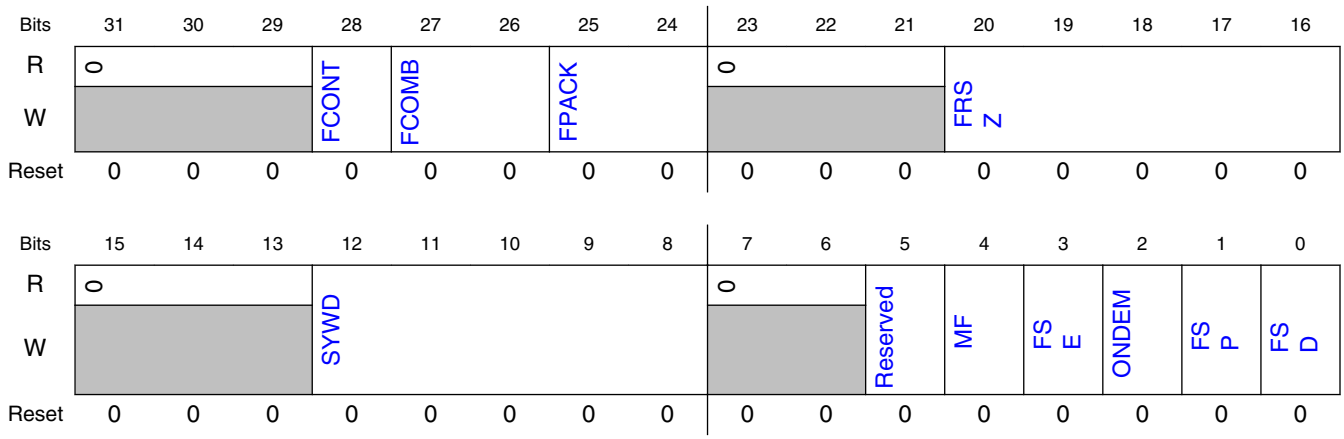
44.4.2.17.1 Offset

Register	Offset
RCR4	98h

44.4.2.17.2 Function

This register must not be altered when RCSR[RE] is set.

44.4.2.17.3 Diagram



44.4.2.17.4 Fields

Field	Function
31-29 —	Reserved
28 FCONT	FIFO Continue on Error Configures when the SAI will continue receiving after a FIFO error has been detected. 0b - On FIFO error, the SAI will continue from the start of the next frame after the FIFO error flag has been cleared. 1b - On FIFO error, the SAI will continue from the same word that caused the FIFO error to set after the FIFO warning flag has been cleared.
27-26 FCOMB	FIFO Combine Mode When FIFO combine mode is enabled for FIFO reads, software reading any FIFO data register will alternate the read among the enabled data channel FIFOs. For example, if two data channels are enabled then the first read will be performed to the first enabled data channel FIFO and the second read will be performed to the second enabled data channel FIFO. Reseting the FIFO or disabling FIFO combine mode for FIFO reads will reset the pointer back to the first enabled data channel. When FIFO combine mode is enabled for FIFO writes from the receive shift registers, the first enabled data channel input will alternate between the enabled data channel FIFOs. For example, if two data channels are enabled then the first unmasked received word will be stored in the first enabled data channel FIFO and the second unmasked received word will be stored in the second enabled data channel FIFO. Since the first word of the frame is always stored in the first enabled data channel FIFO, it is recommended that the number of unmasked words per frame is evenly divisible by the number of enabled data channels. 00b - FIFO combine mode disabled. 01b - FIFO combine mode enabled on FIFO writes (from receive shift registers). 10b - FIFO combine mode enabled on FIFO reads (by software). 11b - FIFO combine mode enabled on FIFO writes (from receive shift registers) and reads (by software).

Table continues on the next page...

Field	Function
25-24 FPACK	FIFO Packing Mode Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8-bit or 16-bit then only the first 8-bit or 16-bits are stored to the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO read pointer will only increment when the full 32-bit FIFO word has been read by software. 00b - FIFO packing is disabled 01b - Reserved. 10b - 8-bit FIFO packing is enabled 11b - 16-bit FIFO packing is enabled
23-21 —	Reserved
20-16 FRSZ	Frame Size Configures the number of words in each frame. The value written must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 32 words.
15-13 —	Reserved
12-8 SYWD	Sync Width Configures the length of the frame sync in number of bit clocks. The value written must be one less than the number of bit clocks. For example, write 0 for the frame sync to assert for one bit clock only. The sync width cannot be configured longer than the first word of the frame.
7-6 —	Reserved
5 —	Reserved. Software should only write zero to this bit.
4 MF	MSB First Configures whether the LSB or the MSB is received first. 0b - LSB is received first. 1b - MSB is received first.
3 FSE	Frame Sync Early 0b - Frame sync asserts with the first bit of the frame. 1b - Frame sync asserts one bit before the first bit of the frame.
2 ONDEM	On Demand Mode When set, and the frame sync is generated internally, a frame sync is only generated when the FIFO warning flag is clear. 0b - Internal frame sync is generated continuously. 1b - Internal frame sync is generated when the FIFO warning flag is clear.
1 FSP	Frame Sync Polarity Configures the polarity of the frame sync. 0b - Frame sync is active high. 1b - Frame sync is active low.
0 FSD	Frame Sync Direction Configures the direction of the frame sync. 0b - Frame Sync is generated externally in Slave mode. 1b - Frame Sync is generated internally in Master mode.

44.4.2.21.4 Fields

Field	Function
31-0 RWM	Receive Word Mask Configures whether the receive word is masked (received data ignored and not written to receive FIFO) for the corresponding word in the frame. 00000000000000000000000000000000b - Word N is enabled. 00000000000000000000000000000001b - Word N is masked.

44.5 Functional description

This section provides a complete functional description of the block.

44.5.1 SAI clocking

The SAI clocks include:

- The audio master clock
- The bit clock
- The bus clock

44.5.1.1 Audio master clock

The audio master clock is used to generate the bit clock when the receiver or transmitter is configured for an internally generated bit clock. The transmitter and receiver can independently select between the bus clock and up to three audio master clocks to generate the bit clock.

The audio master clock generation and selection is chip-specific. Refer to chip-specific clocking information about how the audio master clocks are generated.

44.5.1.2 Bit clock

The SAI transmitter and receiver support asynchronous free-running bit clocks that can be generated internally from an audio master clock or supplied externally. There is also the option for synchronous bit clock and frame sync operation between the receiver and transmitter or between multiple SAI peripherals.

- If both transmitter and receiver are configured for asynchronous operation, then the transmitter and receiver will each use *their own* bit clock and frame sync.
- If the *transmitter* is configured for asynchronous mode and the receiver is configured for synchronous mode, then both transmitter and receiver will use the *transmitter* bit clock and frame sync.
- If the *receiver* is configured for asynchronous mode and the transmitter is configured for synchronous mode, then both transmitter and receiver will use the *receiver* bit clock and frame sync.

Note that the software configures synchronous or asynchronous mode, and that choice selects the bit clock/frame sync used.

Externally generated bit clocks must be:

- Enabled before the SAI transmitter or receiver is enabled
- Disabled after the SAI transmitter or receiver is disabled and completes its current frames

If the SAI transmitter or receiver is using an externally generated bit clock in asynchronous mode and that bit clock is generated by an SAI that is disabled in stop mode, then the transmitter or receiver should be disabled by software before entering stop mode. This issue does not apply when the transmitter or receiver is in a synchronous mode because all synchronous SAIs are enabled and disabled simultaneously.

44.5.1.3 Bus clock

The bus clock is used by the control and configuration registers and to generate synchronous interrupts and DMA requests.

NOTE

Although there is no specific minimum bus clock frequency specified, the bus clock frequency must be fast enough (relative to the bit clock frequency) to ensure that the FIFOs can be serviced, without generating either a transmitter FIFO underrun or receiver FIFO overflow condition.

44.5.2 SAI resets

The SAI is asynchronously reset on system reset. The SAI has a software reset and a FIFO reset.

44.5.2.1 Software reset

The SAI transmitter includes a software reset that resets all transmitter internal logic, including the bit clock generation, status flags, and FIFO pointers. It does not reset the configuration registers. The software reset remains asserted until cleared by software.

The SAI receiver includes a software reset that resets all receiver internal logic, including the bit clock generation, status flags and FIFO pointers. It does not reset the configuration registers. The software reset remains asserted until cleared by software.

44.5.2.2 FIFO reset

The SAI transmitter includes a FIFO reset that synchronizes the FIFO write pointer to the same value as the FIFO read pointer. This empties the FIFO contents and is to be used after TCSR[FEF] is set, and before the FIFO is re-initialized and TCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI transmitter can also reset the FIFO of individual data channels by setting the appropriate TCR3[CFR] bit. This should only be done when the corresponding TCR3[TCE] bit is clear.

The SAI receiver includes a FIFO reset that synchronizes the FIFO read pointer to the same value as the FIFO write pointer. This empties the FIFO contents and is to be used after the RCSR[FEF] is set and any remaining data has been read from the FIFO, and before the RCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI receiver can also reset the FIFO of individual data channels by setting the appropriate RCR3[CFR] bit. This should only be done when the corresponding RCR3[RCE] bit is clear.

44.5.3 Synchronous modes

The SAI transmitter and receiver can operate synchronously to each other or synchronously to other SAI peripherals.

44.5.3.1 Synchronous mode

The SAI transmitter and receiver can be configured to operate with synchronous bit clock and frame sync.

If the transmitter bit clock and frame sync are to be used by both the transmitter and receiver:

- The transmitter must be configured for asynchronous operation and the receiver for synchronous operation.
- In synchronous mode, the receiver is enabled only when both the transmitter and receiver are enabled.
- It is recommended that the transmitter is the last enabled and the first disabled.

If the receiver bit clock and frame sync are to be used by both the transmitter and receiver:

- The receiver must be configured for asynchronous operation and the transmitter for synchronous operation.
- In synchronous mode, the transmitter is enabled only when both the receiver and transmitter are both enabled.
- It is recommended that the receiver is the last enabled and the first disabled.

When operating in synchronous mode, only the bit clock, frame sync, and transmitter/receiver enable are shared. The transmitter and receiver otherwise operate independently, although configuration registers must be configured consistently across both the transmitter and receiver.

44.5.3.2 Multiple SAI Synchronous mode

Synchronous operation between multiple SAI peripherals is not supported on all devices. This mode requires the source of the bit clock and frame sync to be configured for asynchronous operation and the remaining users of the bit clock and frame sync to be configured for synchronous operation.

Synchronous operation between multiple SAI transmitters or receivers also requires the source of the bit clock and frame sync to be enabled for any of the synchronous transmitters or receivers to also be enabled. It is recommended that the source of the bit clock and frame sync is the last enabled and the first disabled.

When operating in synchronous mode, only the bit clock, frame sync, and transmitter/receiver enable are shared. The separate SAI peripherals otherwise operate independently, although configuration registers must be configured consistently across both the transmitter and receiver.

44.5.4 Frame sync configuration

When enabled, the SAI continuously transmits and/or receives frames of data. Each frame consists of a fixed number of words and each word consists of a fixed number of bits. Within each frame, any given word can be masked causing the receiver to ignore that word and the transmitter to tri-state for the duration of that word.

The frame sync signal is used to indicate the start of each frame. A valid frame sync requires a rising edge (if active high) or falling edge (if active low) to be detected and the transmitter or receiver cannot be busy with a previous frame. A valid frame sync is also ignored (slave mode) or not generated (master mode) for the first four bit clock cycles after enabling the transmitter or receiver.

The transmitter and receiver frame sync can be configured independently with any of the following options:

- Externally generated or internally generated
- Active high or active low
- Assert with the first bit in frame or asserts one bit early
- Assert for a duration between 1 bit clock and the first word length
- Frame length from 1 to 32 words per frame
- Word length to support 8 to 32 bits per word
    - First word length and remaining word lengths can be configured separately
- Words can be configured to transmit/receive MSB first or LSB first

These configuration options cannot be changed after the SAI transmitter or receiver is enabled.

44.5.5 Data FIFO

Each transmit and receive channel includes a FIFO of size 16 x 32-bit. The FIFO data is accessed using the SAI Transmit/Receive Data Registers.

44.5.5.1 Data alignment

Data in the FIFO can be aligned anywhere within the 32-bit wide register through the use of the First Bit Shifted configuration field, which selects the bit index (between 31 and 0) of the first bit shifted.

Examples of supported data alignment and the required First Bit Shifted configuration are illustrated in Figure 44-2 for LSB First configurations and Figure 44-3 for MSB First configurations.

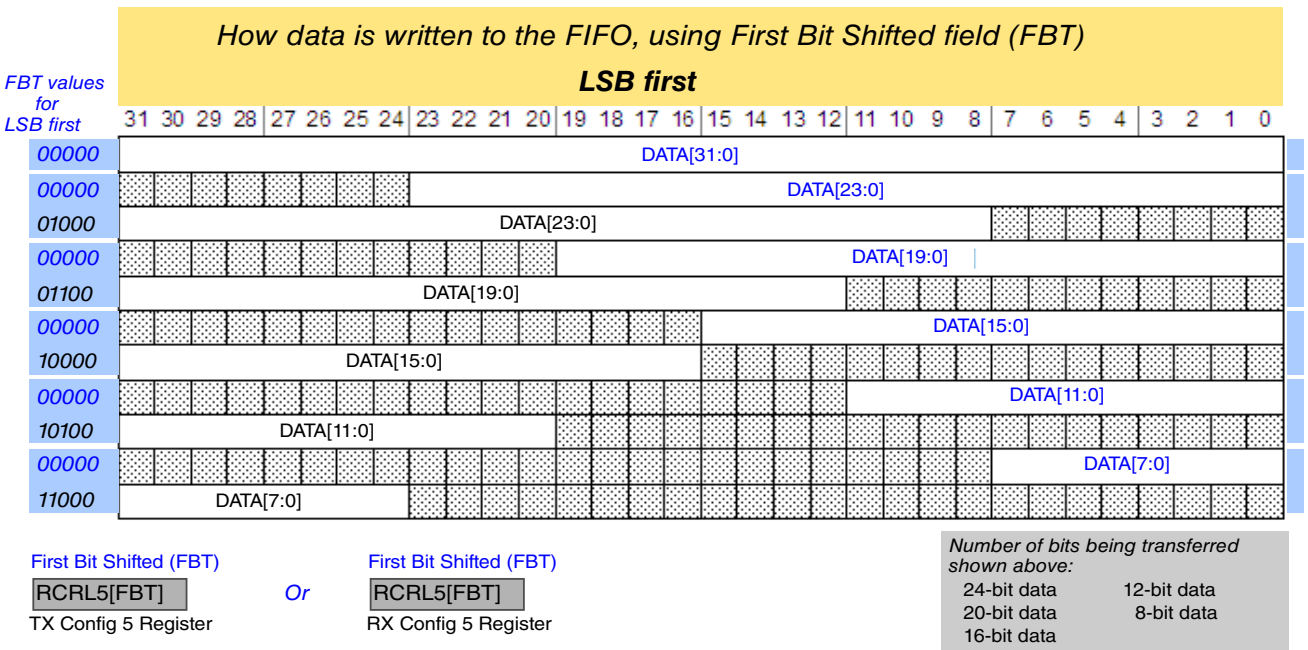

Figure 44-2. SAI first bit shifted, LSB first

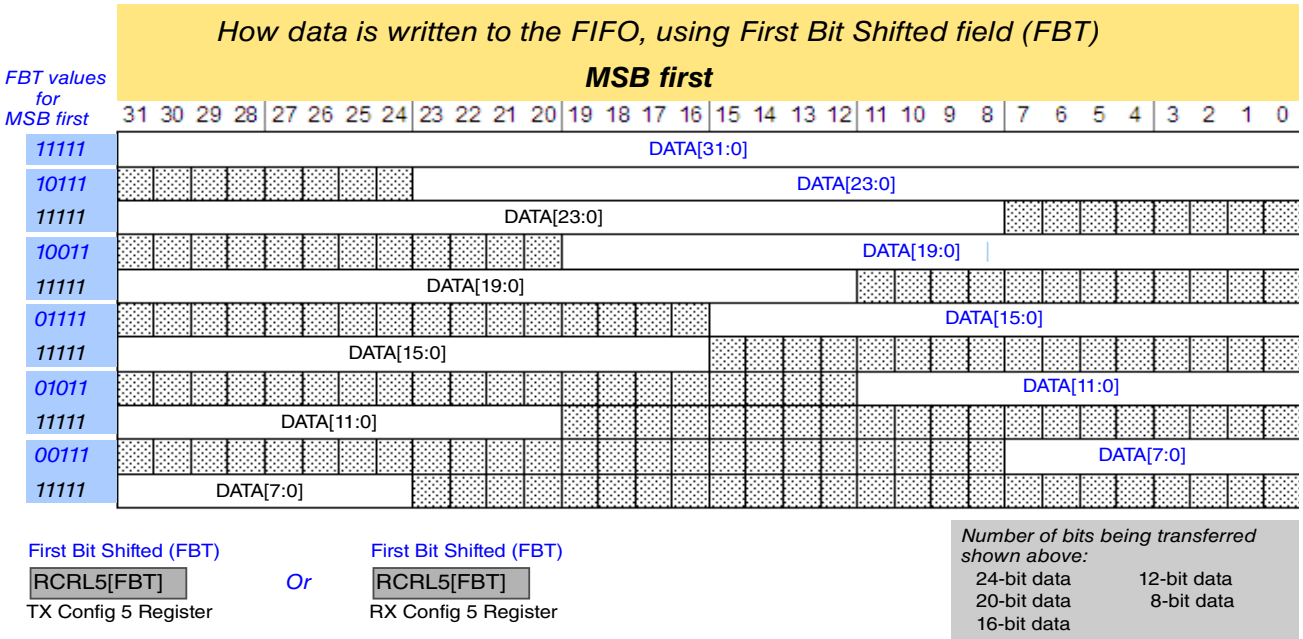

Figure 44-3. SAI first bit shifted, MSB first

44.5.5.2 FIFO pointers

When writing to a Transmit Data Register (TDR*n*), the Write FIFO Pointer (WFP) of the corresponding Transmit FIFO Register (TFR*n*) increments after each valid write. The SAI supports 8-bit, 16-bit and 32-bit writes to the Transmit Data Register and the FIFO pointer will increment after each individual write. Note that 8-bit writes should only be used when transmitting up to 8-bit data; 16-bit writes should only be used when transmitting up to 16-bit data.

- If the Transmit FIFO is full, then writes to a Transmit Data Register are ignored.
- If the Transmit FIFO is empty, then to avoid a FIFO underrun, the Transmit Data Register must be written at least 3 bit clocks before the start of the next unmasked word. Before enabling the transmitter, the Transmit FIFO should be initialized with data (since after the transmitter is enabled, the transmitter will start a new frame, and if no data is in the FIFO, then the transmitter will immediately give an error).

When reading a Receive Data Register (RDR*n*), the Read FIFO Pointer (RFP) of the corresponding Receive FIFO Register (RFR*n*) increments after each valid read. The SAI supports 8-bit, 16-bit and 32-bit reads from the RDR and the FIFO pointer will increment after each individual read. Note that 8-bit reads should only be used when receiving up to 8-bit data; 16-bit reads should only be used when receiving up to 16-bit data.

- If the Receive FIFO is empty, then reads from a Receive Data Register are ignored.
- If the Receive FIFO is full, then to avoid a FIFO overrun, the Receive Data Register must be read at least 3 bit clocks before the end of an unmasked word.

44.5.5.3 FIFO packing

FIFO packing supports storing multiple 8-bit or 16-bit data words in one 32-bit FIFO word for the transmitter and/or receiver. While this can be emulated by adjusting the number of bits per word and number of words per frame (for example, one 32-bit word per frame versus two 16-bit words per frame), FIFO packing does not require even multiples of words per frame and fully supports word masking. When FIFO packing is enabled, the FIFO pointers only increment when the full 32-bit FIFO word has been written (transmit) or read (receive) by software, supporting scenarios where different words within each frame are loaded/stored in different areas of memory.

When 16-bit FIFO packing is enabled for transmit, the transmit shift register is loaded at the start of each frame and after every second unmasked transmit word. The first word transmitted is taken from 16-bit word at byte offset $0 (first bit is selected by TCFG5[FBT] must be configured within this 16-bit word) and the second word transmitted is taken from the 16-bit word at byte offset $2 (first bit is selected by TCSR5[FBT][3:0]). The transmitter will transmit logic zero until the start of the next word once the 16-bit word has been transmitted.

When 16-bit FIFO packing is enabled for receive, the receive shift register is stored after every second unmasked received word, and at the end of each frame if there is an odd number of unmasked received words in each frame. The first word received is stored in the 16-bit word at byte offset $0 (first bit is selected by RCFG5[FBT] and must be configured within this 16-bit word) and the second word received is stored in the 16-bit word at byte offset $2 (first bit is selected by RCSR5[FBT][3:0]). The receiver will ignore received data until the start of the next word once the 16-bit word has been received.

The 8-bit FIFO packing is similar to 16-bit packing except four words are loaded or stored into each 32-bit FIFO word. The first word is loaded/stored in byte offset $0, second word in byte offset $1, third word in byte offset $2 and fourth word in byte offset $3. The TCFG5[FBT] and/or RCFG5[FBT] must be configured within byte offset $0.

44.5.5.4 FIFO Combine

FIFO combining mode allows the separate FIFOs for multiple data channels to be used as a single FIFO for either software accesses or a single data channel or both. Note that the enabled data channels must be contiguous and data channel 0 must be enabled when FIFO Combine mode is enabled.

Combining FIFOs for software access (writing transmit FIFO registers, reading receive FIFO registers) allows a DMA controller or software to read or write multiple FIFOs without incrementing the address that is accessed. Once enabled, the first software access to a FIFO register will access the first enabled channel FIFO, while the second access to a FIFO register will access the second enabled channel FIFO. This continues until software accesses the last enabled channel FIFO and the pointer resets back to the first enabled channel FIFO. To reset the pointer manually, software can reset the FIFOs or disable the FIFO combining on software accesses.

Combining FIFOs for transmit data channels allows one data channel to use the FIFOs of all enabled channel FIFOs, with identical data output on each enabled data channel. The transmit shift registers for all enabled data channels are loaded at the start of each frame and every N unmasked words (where N is the number of enabled data channels). The first word transmitted is loaded from the first enabled channel FIFO, while the second word transmitted is loaded from the second enabled channel FIFO, and so on until the end of the frame. Since the first word in each frame is always loaded from the first enabled data channel, it is recommended that the number of unmasked words in each frame is evenly divisible by the number of enabled data channels.

Combining FIFOs for receive data channels allows one data channel to use the FIFOs of all enabled channel FIFOs, with received data from channel 0 stored into each enabled data channel. The receive shift register for all enabled data channels are stored after every N unmasked words (where N is the number of enabled data channels). The first word received is stored to the first enabled channel FIFO, while the second word received is stored to the second enabled channel FIFO, and so on until the end of the frame. Since the first word in each frame is always stored the first enabled data channel, it is recommended that the number of unmasked words in each frame is evenly divisible by the number of enabled data channels.

Note that combining FIFOs for data channels will load or store each channel FIFO at the same time. This means that FIFO error conditions are only checked every N words (where N is the number of enabled data channels) and that the FIFO warning and request flags will assert if any of the enabled data channel meets the warning flag or request flag conditions.

44.5.6 Word mask register

The SAI transmitter and receiver each contain a word mask register, namely TMR and RMR, that can be used to mask any word in the frame. Because the word mask register is double buffered, software can update it before the end of each frame to mask a particular word in the next frame.

The TMR causes the Transmit Data pin to be tri-stated for the length of each selected word and the transmit FIFO is not read for masked words.

The RMR causes the received data for each selected word to be discarded and not written to the receive FIFO.

44.5.7 Interrupts and DMA requests

The SAI transmitter and receiver generate separate interrupts and separate DMA requests, but support the same status flags. Asynchronous versions of the transmitter and receiver interrupts are generated to wake up the CPU from stop mode.

44.5.7.1 FIFO request flag

The FIFO request flag is set based on the number of entries in the FIFO and the FIFO watermark configuration.

The transmit FIFO request flag is set when the number of entries in any of the enabled transmit FIFOs is less than or equal to the transmit FIFO watermark configuration and is cleared when the number of entries in each enabled transmit FIFO is greater than the transmit FIFO watermark configuration.

The receive FIFO request flag is set when the number of entries in any of the enabled receive FIFOs is greater than the receive FIFO watermark configuration and is cleared when the number of entries in each enabled receive FIFO is less than or equal to the receive FIFO watermark configuration.

The FIFO request flag can generate an interrupt or a DMA request.

44.5.7.2 FIFO warning flag

The FIFO warning flag is set based on the number of entries in the FIFO.

The transmit warning flag is set when the number of entries in any of the enabled transmit FIFOs is empty and is cleared when the number of entries in each enabled transmit FIFO is not empty.

The receive warning flag is set when the number of entries in any of the enabled receive FIFOs is full and is cleared when the number of entries in each enabled receive FIFO is not full.

The FIFO warning flag can generate an Interrupt or a DMA request.

44.5.7.3 FIFO error flag

The transmit FIFO error flag is set when the any of the enabled transmit FIFOs underflow. After it is set, all enabled transmit channels will transmit zero data before TCSR[FEF] is cleared.

When TCR4[FCONT] is set, the FIFO will continue transmitting data following an underflow without software intervention. To ensure that data is transmitted in the correct order, the transmitter will continue from the same word number in the frame that caused the FIFO to underflow, but only after new data has been written to the transmit FIFO. Software should still clear the TCSR[FEF] flag, but without reinitializing the transmit FIFOs.

RCSR[FEF] is set when the any of the enabled receive FIFOs overflow. After it is set, all enabled receive channels discard received data until RCSR[FEF] is cleared and the next next receive frame starts. All enabled receive FIFOs should be emptied before RCSR[FEF] is cleared.

When RCR4[FCONT] is set, the FIFO will continue receiving data following an overflow without software intervention. To ensure that data is received in the correct order, the receiver will continue from the same word number in the frame that caused the FIFO to overflow, but only after data has been read from the receive FIFO. Software should still clear the RCSR[FEF] flag, but without emptying the receive FIFOs.

The FIFO error flag can generate only an interrupt.

44.5.7.4 Sync error flag

The sync error flag, TCSR[SEF] or RCSR[SEF], is set when configured for an externally generated frame sync and the external frame sync asserts when the transmitter or receiver is busy with the previous frame. The external frame sync assertion is ignored and the sync error flag is set. When the sync error flag is set, the transmitter or receiver continues checking for frame sync assertion when idle or at the end of each frame.

The sync error flag can generate an interrupt only.

44.5.7.5 Word start flag

The word start flag is set at the start of the second bit clock for the selected word, as configured by the Word Flag register field.

The word start flag can generate an interrupt only.

Chapter 45
MIPI-DSI Controller

45.1 Chip-specific MIPI-DSI information

Table 45-1. Reference links to related information

Topic	Related module	Reference
Full description	MIPI-DSI	MIPI-DSI
System memory map		System memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port control	Signal multiplexing

45.1.1 Display serial interface (DSI) controller

The MIPI Display Serial Interface Controller (DSI Controller) is responsible for serializing display data.

Table 45-2. DSI Controller configuration

Parameter	Description
Name	DSI Controller
Supported standard version	MIPI DSI Specification v1.2r06, MIPI DCS Specification v1.2a, MIPI DPI Specification v2.00
Instances	1
Configurable features	• 2 data lanes, 1 clock lane • DPI interface to device
Interface speed	See the i.MX 7ULP Data Sheet (Document number: IMX7ULPCEC) for details.
External I/O pins	NA

45.1.2 SOPT1CFG register functionality in MIPI

The SIM_SOPT1CFG register allows access to the reset ports of the DSI Host Packet Interface (reset_esc, reset_byte), part of the DPI interface signals (such as reset_dpi, dpi_sd and dpi_cm) and also the DSI D-PHY PLL enable input port.

NOTE

The DPI-2 Interface is the DOTCLK (or RGB) interface mentioned in the LCDIF chapter.

45.1.3 Display Serial Interface PHY (DPHY)

The MIPI Display Serial Interface Physical Layer (DPHY) is a two-lane interface that supports up to 800 Mbps (precisely 792 Mbps or 396 MHz with 24 MHz crystal reference input) of data on each lane.

Table 45-3. DPHY configuration

Parameter	Description
Name	DPHY
Supported standard version	MIPI DPHY specification version 1.1
Instances	1
Configurable features	1 clock lane, 2 data lanes.
Interface speed	800 Mbps (precisely 792 Mbps or 396 MHz with 24 MHz crystal reference input)
External I/O pins	DSI_CLK_P, DSI_CLK_N, DSI_DATA0_P, DSI_DATA0_N, DSI_DATA1_P, DSI_DATA1_N. See the attached IOMUXC spreadsheet for pinout details

The MIPI DPHY generates the DSI byte clock (clk_byte) via the DPHY PLL. For details, see Figure 24-14

45.1.4 Features not supported on i.MX 7ULP

On this device, the DSI works only on MASTER mode (as a DSI HOST) and DSI Peripheral mode is not supported. Other features which are not supported on this device:

- DBI-2 interface (DBI-2/IF) is not supported including MPU, VSYNC, and Digital Video interface. Support to generic commands (short/long commands) as well as to DCS Commands will be handled through the Packet I/F via an APB2PacketIF Gasket.

- Status configuration via pins: Any status flags will not be pinned out. Any status shall be checked via DSI registers.
- DMA is also not supported. There is no requirement to use system DMA for display data transfer via DSI. The reason is that the LCDIF module serves as a bridge between the DSI controller and the system bus. As such, the DMA engine in the LCDIF will be the one used to transfer display data, instead. Moreover, the APB interface has FIFOs for the Packet Interface. This should provide sufficient storage to have the short/long commands for programming as well as receiving them over the slow APB interface.

45.1.5 DSI clock scheme

The DSI module along with the DPHY comprises 4 clock domains.

- DPI domain: logic in this domain is clocked by the pixel clock (*dpi_clk*) from the LCDIF module. This clock runs off a maximum frequency of 200 MHz, which is enough to support 1024x768 resolution. The DPI Bridge handles transferring video data received in the *dpi_clk* clock domain over to the DPHY domain (clk_byte)
- APB domain: logic in this domain is clocked by the APB clock (*pclk*). The Status & Control Register interface is at this domain.
- Escape Mode domain: logic in this domain is clocked by the Escape Mode logic, which includes the Low-Power Data Transmit (LPDT) state machines and low-power transmissions (*TxClkEsc*) as well as DPHY for reverse low-power reception (*RxClkEsc*). These clocks are synchronous between each other, while asynchronous with any other clocks. On i.MX 7ULP, these clocks are limited to the following range:
  - 60 MHz ≤ RxClkEsc ≤ 80 MHz
  - 15 MHz ≤ TxClkEsc ≤ 20 MHz
- DPHY domain: logic in this domain is clocked by the internal DPHY's PLL, which uses an external clock as the reference for the PLL (CLKREF). This clock is used by the DPHY to generate the High Speed MIPI clock and High Speed Data Lane signaling. This clock is also used to generate the MIPI Tx DPHY High Speed PPI interface (clk_byte), which is internal to the DSI TOP. This is a 1/8th the data rate of the DPHY Data Lane High Speed data rate

See Figure 45-3 for details.

45.1.6 DSI reset domains

The DSI has the following four reset domains:

- clk_byte reset domain (reset_byte_n): This is an active-low asynchronous reset that applies to all logic in the clk_byte clock domain.
- Escape reset domain (reset_esc_n): this is an active-low asynchronous reset that applies to all logic in the Escape Mode clock domain (TxClkEsc and RxClkEsc domains).
- APB reset domain (pclk_reset_n): this is an active-low asynchronous reset that applies to all logic in the APB clock domain (pclk)
- DPI reset domain (reset_dpi_n): this is an active-low asynchronous reset that applies to all logic in the DPI clock domain (dpi_pclk).

45.2 Overview

The Mobile Industry Processor Interface (MIPI) Display Serial Interface (DSI) controller is a flexible, high-performance, and easy-to-use digital core that implements all protocol functions defined in the MIPI DSI Specification. The MIPI DSI controller provides an interface that allows communication with MIPI DSI-compliant peripherals.

The MIPI DSI D-PHY is a high frequency, low power, low-cost, source-synchronous, physical layer supporting the MIPI Alliance standard for D-PHY.

45.3 Features

Key features of the MIPI DSI Controller Core include:

- Implements all three DSI Layers (Pixel to Byte packing, Low Level Protocol, Lane Management)
- Support for Command and Video Modes
- Host Version
- Scalable data lane support, 1 to 2 Data Lanes
  - Optional bidirectional support on lane 0
- Supports High Speed and Low Power operation
- Support for all DSI data types and formats
- Virtual Channel support
- Full Low-Level Protocol Error and Contention detection and reporting
- Supports continuous and non-continuous Clock Lane operation
- Supports multiple packets per transmission
- Support for all three Video Mode packet sequences
  - Non-Burst Mode with Sync Pulses

    - Non-Burst Mode with Sync Events
    - Burst mode
- Support for bus turnaround signaling
- Flexible packet based user interface
    - APB interface option (status and control)
    - Display Pixel Interface Core (DPI-2) option
- Supports PHY Protocol Interface (PPI) compatible MIPI D-PHYs
- MIPI Alliance Specification for Display Serial Interface Version 1.1 compliant

The following are the key features of the MIPI DSI D-PHY:

- 1 Clock lane
- 2 data lanes
- Supports MIPI Standard for D-PHY
- Supports both high speed and low power modes
- High Speed Serializers and Deserializers

45.4 DSI Host Controller Core

The figure below illustrates the DSI Host Controller Core structure. The DSI Host Controller Core operates on the host (transmit) side of a DSI link.

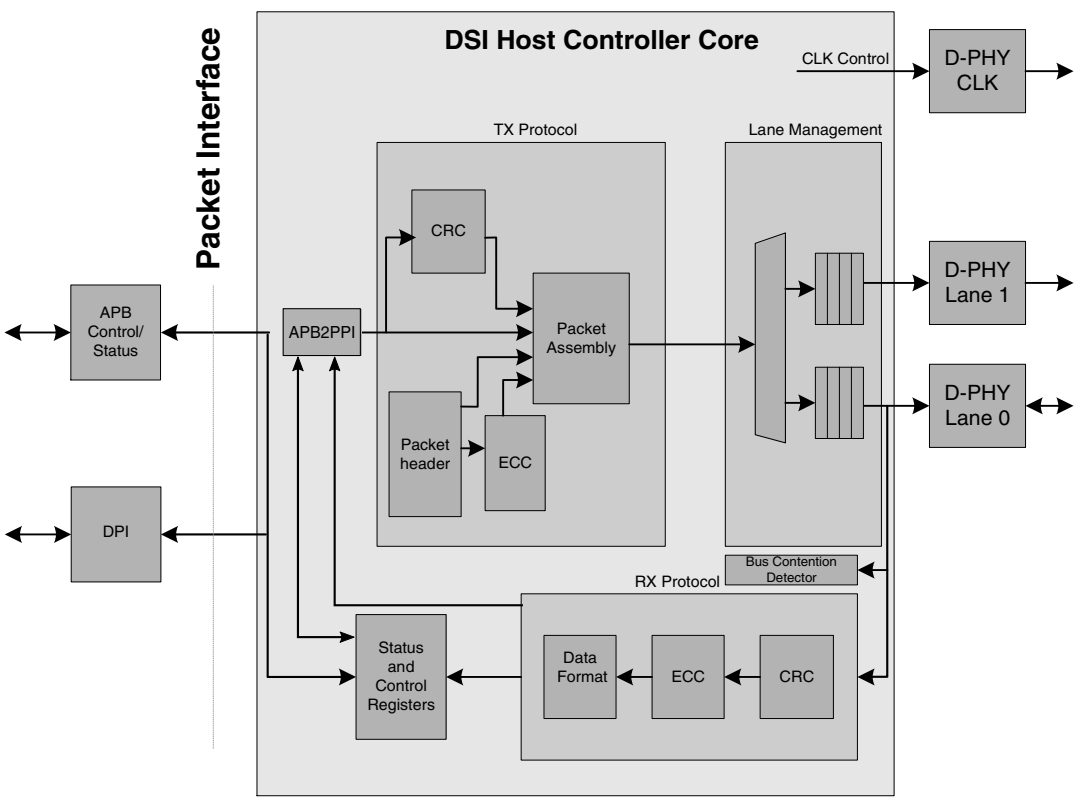

Figure 45-1. DSI Host Controller Core Block Diagram

The DSI Host Controller Core implements all three layers defined by the DSI Specification: Pixel to Byte Packing in the Application layer, Low Level Protocol, and Lane Management. The DSI Host Controller Core sends and receives DSI commands via the Packet Interface. The Packet Interface can be connected to a DPI translator or to an APB to PPI gasket.

The D-PHY interface of the DSI Host Controller Core supports up to four PHY Protocol Interface (PPI) compatible MIPI D-PHYs.

The Packet Interface is an easy-to-use data interface that accepts commands and data, and sends it over the DSI link. It supports 1 to 4 virtual channels, and the use of 1-2 D-PHY lanes. The DSI Host Controller Core takes care of all packet formatting details and transmission over the MIPI bus.

The DPI Translator connects to the DSI Host Controller Core via the Packet Interface. DPI masters may connect directly to the DPI Translator to send commands across the DSI link.

Sending commands and receiving information through the DSI link is also possible through the APB to PPI gasket. See MIPI DSI Host APB PKT IF Memory Map/Register section for details about the DSI registers which allow the APB to PPI setup and communication.

45.4.1 D-PHY Interface

The DSI Host Controller Core D-PHY Interface connects directly to MIPI PPI compliant D-PHYs. The DSI Host Controller Core uses this interface to transmit data, send Escape sequences, receive and transmit triggers, and detect and report D-PHY error conditions.

45.4.1.1 High-Speed Transmit Interface

The High-Speed Transmit interface is used to transmit High-Speed data across the MIPI interface. All signals are synchronous to the PPI TX byte clock, TxByteClkHS, and are PPI compliant.

45.4.1.2 Escape Mode Transmit Interface

The DSI Host Controller Core uses the Escape Mode Transmit Interface to generate Escape sequences on the MIPI Interface via the D-PHY. Escape sequences are used to change the DPHY transmit mode, go into low-power mode, or initiate a bus turnaround. The Controller generates Escape sequence requests when necessary to implement the DSI protocol. These signals are synchronous to the clk_esc.

45.4.2 Packet Interface

The DSI Host Controller Core Packet Interface consists of Transmit, Receive, and Control and Status sections. Through these interfaces, the user application can take complete control of the DSI interface, sending all video timing, sending DSI commands, receiving DSI reads, monitoring the status of the interface and responding to error reporting.

User application may have access to DSI Host Controller Core Packet Interface through DSI_HOST_APB_PKT_IF registers. For details refer to the section MIPI_DSI_HOST_APB_PKT_IF

45.4.2.1 Transmit Ports

The Transmit Packet Interface is the mechanism with which the user creates packets to send over the MIPI Interface.

For Long Packets, the user provides the Virtual Channel (VC) number, Data Type (DT), and Word Count (WC) to the controller. The Controller then creates a packet header and pulls the packet data from the Packet Interface and out to the D-PHY to transmit.

For Short Packets, the user provides the Virtual Channel (VC) number, Data Type (DT), and required parameters (if any) to the controller. The Controller then creates the short packet and sends it to the D-PHY to transmit. This interface enables the user application to transmit and receive any type of DSI packet.

The Packet Interface Transmit Interface ports are listed in the table below. Signals are synchronous to the Tx Byte clock.

NOTE

Only a subset of the Packet Interface Signals are accessible by user application through DSI_HOST_APB_PKT_IFx registers or chip-specific registers. For reset_byte_n and reset_esc_n signals, refer to chip-specific MIPI DSI information. For

tx_payload, tx_cmd_data_type, tx_cmd_vc, and tx_cmd_byte_count signals, refer to DSI_HOST_APB_PKT_IFx registers.

Table 45-4. DSI Host Controller Core Transmit Packet Interface

PORT	TYPE	DESCRIPTION
clk_byte	Input	Byte clock input. The D-PHY PPI interface, the tx_cmd and tx_payload interfaces are synchronous to clk_byte. This clock can be independent and unrelated to clk_esc.
clk_esc	Input	The low-speed D-PHY Escape Mode clock, which becomes TxClkEsc on the D-PHY interface. This clock can be independent and unrelated to clk_byte.
reset_byte_n	Input	Asynchronous reset, active low. This reset applies to all logic in the clk_byte clock domain.
reset_esc_n	Input	Asynchronous reset, active low. This reset applies to all logic in the clk_esc clock domain.
tx_payload[31:0]	Input	Packet data input.
tx_payload_en	Output	Packet data read enable. This active high signal indicates that the controller requires a valid packet during the next clk_byte period.
tx_payload_en_last	Output	Last packet read enable, active high signals last cycle of tx_payload_en.
tx_cmd_data_type[5:0]	Input	Transmit packet DSI data type. It is written into the command buffer when tx_cmd_ack is asserted high.
tx_cmd_vc[1:0]	Input	Transmit packet command virtual channel. It is written into the command buffer when tx_cmd_ack is asserted high.
tx_cmd_byte_count[15:0]	Input	Transmit packet payload byte count. It is written into the command buffer when tx_cmd_ack is asserted high. For DSI Long packet types, tx_cmd_byte_count defines the number of bytes of packet data to pull from the tx_payload port. For DSI Short packets, the format of tx_cmd_byte_count contains any optional parameters. If the SDI Short packet type does not have any parameters, it is recommended to set tx_cmd_byte_count to all 0s.
tx_cmd_req	Input	Transmit packet command request. This active high signal informs the controller that the packet command is valid. The packet command consists of the ports tx_cmd_data_type, tx_cmd_vc, and tx_cmd_byte_count. The controller will assert tx_cmd_ack when it accepts the command, after which, the user should either update port values for the next transmit packet command or deassert tx_cmd_req.
tx_cmd_ack	Output	Transmit packet command request acknowledge. This active high signal indicates that the controller has accepted the TX packet request and the user logic should either submit a new request or deassert tx_cmd_req on the next rising edge of clk_byte.

45.4.2.2 Receive Ports

The Receive Packet Interface returns data from the Peripheral to the user. The user is provided the Virtual Channel (VC) number, Data Type (DT), Word Count (WC), and Rx Payload Data.

This interface enables the user application to receive any type of DSI packet. These signals are synchronous to the clk_byte clock. The Packet Interface Receive Interface ports are listed in the table below.

NOTE

Only a subset of the Packet Interface signals are accessible by user application through DSI_HOST_APB_PKT_IFx registers and DSI_HOST device registers:

- rx_payload
- rx_cmd_vc
- rx_cmd_data_type
- rx_cmd_byte_count
- ecc_one_bit_error
- ecc_two_bit_error
- ecc_one_bit_error_pos[4:0]
- crc_err

See DSI_HOST_APB_PKT_IFx and DSI_HOST device sections for details.

Table 45-5. DSI Host Controller Core Receive Packet interface

PORT	TYPE	DESCRIPTION
rx_payload[31:0]	Output	Received packet data output. The Host Receive Packet Interface presents 4 bytes at a time. Bytes are valid in this interface according to the rx_cmd_byte_count signal, beginning with the lowest byte.
rx_payload_valid	Output	Packet data valid. This active high signal indicates that the controller is presenting valid packet during the next clk_byte period.
rx_payload_valid_last	Output	This data is the last of the packet, active high signals last cycle of rx_payload_valid.
rx_cmd_valid	Output	Packet header data is valid on the packet header ports below when this signal is asserted.
rx_cmd_vc[1:0]	Output	Packet virtual channel number, valid when rx_cmd_valid is asserted.
rx_cmd_data_type[5:0]	Output	Packet data type, valid when rx_cmd_valid is asserted. See the MIPI DSI-2 specification for a definition of possible values.
rx_cmd_byte_count[15:0]	Output	Packet Word Count (byte count). Contains the number of bytes of data in the received packet. Valid when rx_cmd_valid is asserted.

Table continues on the next page...

Table 45-5. DSI Host Controller Core Receive Packet interface (continued)

PORT	TYPE	DESCRIPTION
ecc_one_bit_error	Output	Single bit error in the packet header was detected and corrected. Active high. Valid when rx_cmd_valid is high.
ecc_two_bit_error	Output	Two packet header bit errors were detected and not corrected, active high. Valid when rx_cmd_valid is high.
ecc_one_bit_error_pos[4: 0]	Output	Position of the corrected single bit error in the packet header. Valid when ecc_one_bit_error is high.
crc_err	Output	Asserts high when the CRC calculated on the received data does not reach the end of the packet.

45.4.3 Status Interface Ports

The Status Interface Core provides for reading the Status of the DSI Host Controller Core via a simple interface. All signals in the Status Interface are synchronous to the clk_byte clock. The Status Interface ports are listed in the table below.

NOTE

Only a subset of the Packet Interface signals are accessible by user application through DSI_HOST_APB_PKT_IFx registers and DSI_HOST device registers:

- status_out
- hs_tx_timeout
- lp_rx_timeout

Refer to DSI_HOST_APB_PKT_IFx and DSI_HOST device sections for details.

Table 45-6. DSI Host Controller Status Interface Port

PORT	TYPE	DESCRIPTION
status_rd	Input	Initiates a read of the status register. Asserting this input high will result in the contents of the status register being presented on status_out[15:0] along with status_out_valid asserting high to indicate that status_out[15:0] contains a valid value.
status_addr[3:0]	Input	When status_rd is asserted, indicates which status register is to be returned. Address 0x0 is a valid address while 0x1-0xF are reserved.
status_out[31:0]	Output	Contains the contents of the addressed status register.
status_out_valid	Output	When asserted high, indicates that the data on status_out is valid.
tx_active	Output	tx_active asserts high when the Host Controller is actively transmitting data or when it has accepted a request from the user but has not yet started transmitting.

Table continues on the next page...

Table 45-6. DSI Host Controller Status Interface Port (continued)

PORT	TYPE	DESCRIPTION
hs_tx_timeout	Output	Asserts high for one clk_byte period to indicate that a High Speed transmit has timed out.
lp_rx_timeout	Output	Asserts high for one clk_byte period to indicate that a Low Power RX curred.

45.4.4 Control and Status Ports

The Control and Status Packet Interface allows the user to control and receive the status of the underlying link between the DSI Host and DSI Peripheral. It works on the same clk_byte clock as the Host Transmit Packet Interface. The Packet Interface Control and Status Interface ports are listed in the table below.

NOTE

Only a subset of the Packet Interface signals may be accessible by user application through DSI_HOST_APB_PKT_IFx registers and DSI_HOST device registers:

- dphy_direction
- tx_hs_mode
- dphy_turnaround

Please refer to DSI_HOST_APB_PKT_IFx and DSI_HOST device sections for details.

Table 45-7. DSI Host Controller Core Control And Status Packet Interface

PORT	TYPE	DESCRIPTION
tx_hs_mode	Input	Switches the DPHY into High Speed Data Transfer mode or Low Power Data Transfer mode. 1'b1 = request HS mode 1'b0 = request LP mode. The Packet interface will not acknowledge packet commands or data while switching modes.
dphy_turnaround	Input	Requests bus turnaround. 1'b1 = Request reverse direction LP mode, from Host TX to Host RX. 1'b0 = No effect. This signal is ignored if the bus is already in Reverse (Host RX) direction.
dphy_direction	Output	Reports the current bus direction. 1'b1 = Bus is in Reverse direction (Host RX). 1'b0 = Bus is in Forward direction (Host TX).

45.4.5 Interface Cores

There are several interface cores for the DSI Host Controller Core. These interface cores provide industry standard interfaces to the DSI Host Controller Core to simplify interfacing and integration the DSI Host Controller Core to your application. When selected, these interface cores provide additional ports to the DSI Host Controller core.

45.4.5.1 DPI-2 Interface Host Bridge Core

The DPI-2 Interface Host Bridge Core provides a DPI-2 compliant interface to the DSI Host controller. The DPI-2 Interface Host Bridge Core handles converting the DPI-2 interface into a packet format that is compatible with the DSI Host Controller Core's Packet Interface, and that adheres to the DSI specification. The DPI-2 Interface Core handles all pixel-to-byte packing for all DPI data types.

The DSI Host Controller DPI-2 Interface Core provides the following features:

- Support for Type 2,3, and 4 displays
- Support for 16-, 18- and 24- bit Pixel data and all alignment configurations
- Support for 16, 18, 24, and 18 bit loosely packed DSI data types
- Supports DSI video modes
  - Non-Burst Mode with Sync Pulses
  - Non-Burst Mode with Sync Events
  - Burst Mode
- Supports normal or inverted HSYNC and VSYNC signals
- Handles clock domain crossing from DPI Pixel clock to the Host controller TX Byte clock
- Interfaces directly to the Host Controller's DSI Packet Interface
- Comes already integrated with the DSI Host Controller

A block diagram of the DPI-2 Interface Host Bridge Core is shown below. The DPI-2 Host Bridge Core accepts a MIPI compliant DPI-2 set of signals (vsync, hsync, pixel data), creates DSI packets for the video timing events and video data and transmits those packets via the DSI Host Controller's Packet Interface.

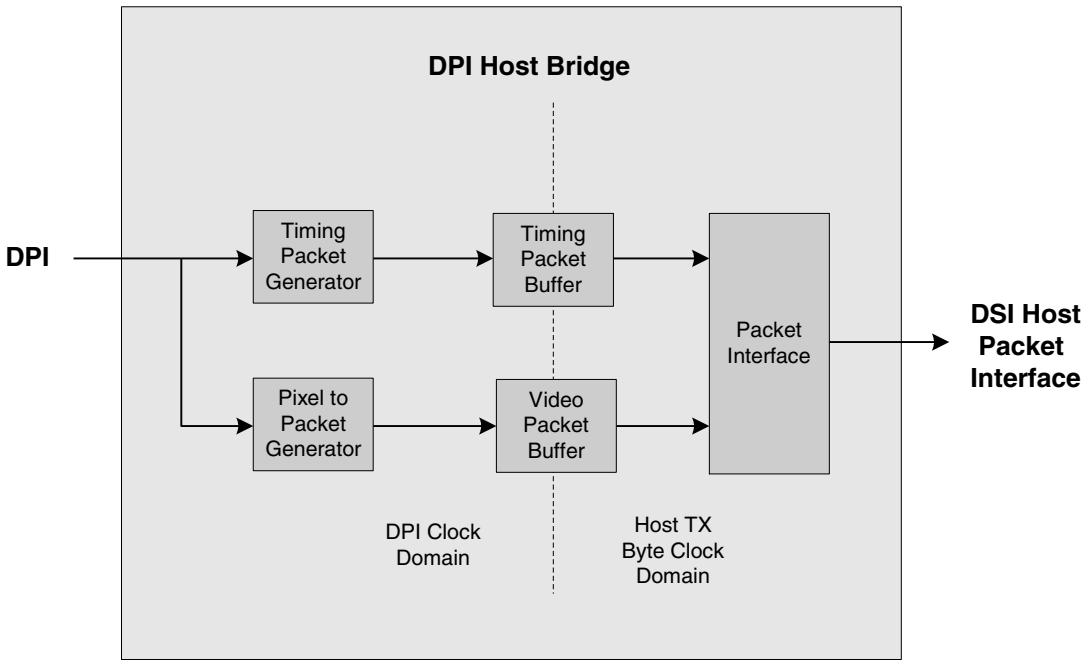

Figure 45-2. DPI-2 Host Bridge Core Block Diagram

45.4.5.1.1 DPI-2 Interface Ports

The DPI-2 Interface module provides a MIPI compliant DPI-2 interface to the DSI Host Controller Core. In addition to the standard DPI-2 interface signals (prefixed with a dpi_) there are several configuration and status ports that allow the user to adjust the behavior of the DPI-2 Interface module to better suit a particular application.

NOTE

The DPI configuration signals herein described are accessible to User Application through chip-specific registers (please refer to chip-specific MIPI-DSI information section for details) and DSI_HOST_DPI_INTFC device registers (please refer to MIPI DSI Host Memory Map/Register section for details).

Table 45-8. DSI Host Controller Core Receive Packet interface

PORT	TYPE	DESCRIPTION
dpi_sd	Input	Shut Down – Control to shutdown display (type 4 only) 1'b1= Send shutdown command. 1'b0= No effect
dpi_cm	Input	Color Mode control. 1'b0== Normal Mode 1'b1== Low-color Mode
cfg_dpi_pixel_payload_size [15:0]	Input	Maximum number of pixels that should send as one DSI packet. Recommended to be evenly divisible by the line size (in pixels).

Table continues on the next page...

Table 45-8. DSI Host Controller Core Receive Packet interface (continued)

PORT	TYPE	DESCRIPTION
cfg_dpi_pixel_fifo_send_ level[15:0]	Input	In order to optimize DSI utility, the DPI bridge buffers a certain number of DPI pixels before initiating a DSI packet. This configuration port controls the level at which the DPI Host bridge begins sending pixels.
cfg_dpi_interface_color_ coding[2:0]	Input	Sets the distribution of RGB bits within the 24-bit d bus, as specified by the DPI specification. 0= 16-bit Configuration 1 1= 16-bit Configuration 2 2= 16-bit Configuration 3 3= 18-bit Configuration 1 4= 18-bit Configuration 2 5= 24-bit
cfg_dpi_pixel_format[1:0]	Input	Sets the DSI packet type of the pixels. 0= 16-bit 1= 18-bit 2= 18-bit loosely packed, 3= 24-bit
dpi_host_underrun_err	Output	During DSI Host transmission of DPI data insufficient DPI data was received. This may indicate that DPI_CLK is too slow, or that the cfg_dpi_* parameters are incorrectly set.
cfg_dpi_vsync_polarity	Input	Sets polarity of dpi_vsync input, 0 – active low, 1 active high
cfg_dpi_hsync_polarity	Input	Sets Polarity of dpi_hsync input, 0 – active low, 1 – active high
cfg_host_dpi_video_mode[1:0]	Input	Select DSI video mode that the host DPI module should generate packets for. 2'b00 – Non-Burst mode with Sync Pulses 2'b01 – Non-Burst mode with Sync Events 2'b10 – Burst mode 2'b11 – Reserved, not valid
cfg_host_dpi_hfp[15:0]	Input	Sets the DSI packet payload size, in bytes, of the horizontal front porch blanking packet.
cfg_host_dpi_hbp[15:0]	Input	Sets the DSI packet payload size, in bytes, of the horizontal back porch blanking packet.
cfg_host_dpi_hsa[15:0]	Input	Sets the DSI packet payload size, in bytes, of the horizontal sync g packet.
cfg_enable_mult_packets	Input	Enable Multiple packets per video line. When enabled, cfg_dpi_pixel_payload_size must be set to exactly half the size of the video line. 0 – Video Line is sent in a single packet 1 – Video Line is sent in two packets
cfg_bllp_mode	Input	Optimize bllp periods to Low Power mode when possible 0 – blanking packets are sent during BLLP periods 1 – LP mode is used for BLLP periods

45.4.5.1.2 DPI-2 Video Timing Recreation over DSI

The DSI Host DPI-2 module is designed to preserve the receive video timing by properly spacing the DSI packets that carry the DPI video information and by inserting blanking packets into the packet stream. In order to achieve this goal, the DSI Host controller needs to have the cfg_host_dpi_hfp, cfg_host_dpi_hbp, and cfg_host_dpi_hsa ports properly set. The values of these ports reflect the size of the hfp, hbp, and has in terms of DSI packet bytes, values such that the number of DSI bytes when transmitted takes approximately the same amount of absolute time as the video event took on the DPI interface.

To relate pixel sizes on the DPI interface to DSI packet bytes, use the following relationship:

Time of DPI event - time to transmit x number of bytes on the DSI interface

dpi_event_size * dpi_pclk_period = number_of_dsi_bytes * 8 * dsi_hs_bit_period / cfg_num_lanes

Solving for number_of_dsi_bytes:

number_of_dsi_bytes = dpi_event_size * dpi_pclk_period * cfg_num_lanes / (8 * dsi_hs_bit_period)

number_of_dsi_bytes - value to set the cfg_host_dpi_hfp (hbp, or hsa) port to
dpi_event_size - size of the video event in pixels (hfp, hbp, hsa)
dpi_pclk_period - period of dpi_pclk
dsi_hs_bit_period - bit period of the mipi data lanes in High Speed mode
cfg_num_lanes - host controller setting for number of active lanes, 0 = 1 lane, 1 = 2 lanes, 2 = 3 lanes, 3 = 4 lanes)

45.4.6 RAM Usage

The DSI Host Controller Core requires on-chip RAM arrays. These RAM arrays and their corresponding sizes are listed in the table below.

All RAM arrays used in this core are configured as two-port, having the following attributes:

- Two address busses, one for the write port and one for read port
- Two data busses, one for write data on the write port and one for read data on the read port
- Two clock inputs, one for the write port and one for the read port. (Note: In some cases, the core logic will connect the same clock to both the read and write clock inputs of the RAM.)

Ram Purpose	Size (Depth x Width)
DPI Core Pixel Data FIFO	2048 x 32
APB to Packet Interface TX FIFO	64 x 32
APB to Packet Interface RX FIFO	64 x 32

45.4.7 DSI Host Clocking

The DSI Host Controller requires the following clocks:

- Reference clock (ref_clk) - used by the DPHY (DPHY PLL generates byte clock)

- Byte clock (clk_byte) - generated by the DPHY, used for packet generation and transfer to the DPHY
- TX escape mode clock (clk_tx_esc) - for internal LPDT state machines and low-power transmissions;
- Pixel clock (dpi_pclk)

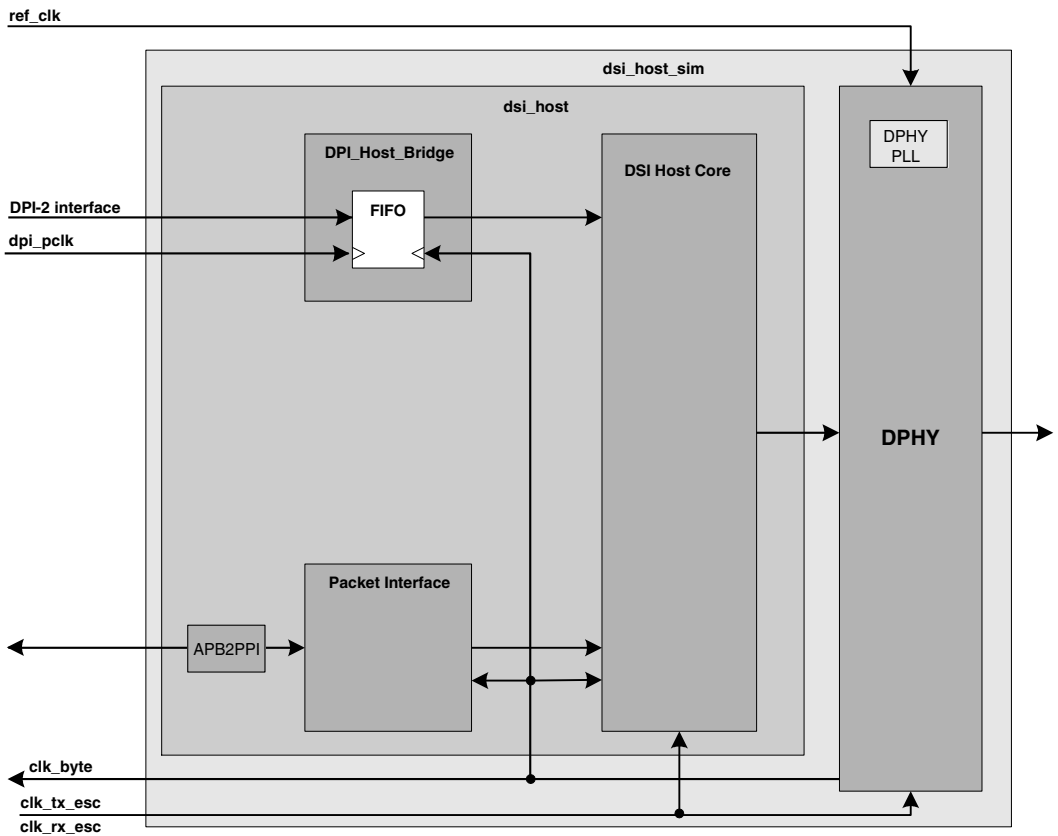

Figure 45-3. DSI Host Controller Clocking Block Diagram

45.4.7.1 ref_clk

The reference clock is used by the DPHY (DPHY PLL) to generate the High Speed MIPI clock and High Speed Data Lane signaling. The frequency of the resulting clock generated from DPHY PLL is typically equal to the high speed bit rate of the data lanes. The DPHY will also use this clock to generate the clk_byte clock output used by the Host DSI Controller and user application logic.

The MIPI DPHY PLL must be setup through the MIPI_DSI_HOST_FSL_IP1_DPHY INTFCx registers, prior to starting DSI Host Controller and DPHY operation. For details, please refer to MIPI DSI Host IP1 DPHY INTFC Memory section.

45.4.7.2 clk_byte

The clk_byte clock is generated by the DPHY (DPHY PLL) and the frequency is 1/8th the data rate of the DPHY Data Lane High Speed data rate. A DPHY configured to generate High Speed data at 1Gbps/lane would generate a 125MHz clk_byte clock.

The clk_byte clock is used by the DSI Host Controller to interface to the MIPI Tx DPHY High Speed PPI interface. The DSI Host Controller's Packet Interface is synchronous to the clk_byte clock.

45.4.7.3 dpi_pclk

The dpi_pclk clock is used on the Host DPI-2 interface. All of the Host DPI-2 signals are synchronous to this clock. The DSI Host Controller's DPI Bridge module handles transferring video data received in the dpi_pclk clock domain over to the clk_byte clock domain.

The dpi_pclk and clk_byte frequencies are related by the following formula:
clk_byte_freq >= dpi_pclk_freq * DPI_pixel_size / (8 * (cfg_num_lanes + 1))

cfg_num_lanes = the configuration port setting that selects the number of active MIPI DPHY data lanes clk_byte_freq = frequency of clk_byte which is 1/8th the High Speed data lane rate. dpi_pclk_freq = frequency of the dpi_pclk clock on the DPI-2 interface. DPI_pixel_size = size of pixels, in bits, on the DPI-2 interface

If the clk_byte frequency does not meet this requirement, the MIPI interface will not be able to keep up with the video stream on the DPI-2 interface resulting in dropped video lines.

45.4.7.4 clk_tx_esc

The clk_tx_esc clock is used by the MIPI Tx DPHY for state control and low power data transmission. The DSI Host Controller also uses clk_tx_esc for the portion of controller logic that interfaces to the MIPI Tx DPHY that are synchronous to clk_tx_esc. The frequency of clk_tx_esc is defined by the requirements of the MIPI interface and the MIPI Tx DPHY. For details about the clk_tx_esc source, please refer to the chip-specific MIPI-DSI clocking section.

45.4.8 Reset and Initialization

Reset and Initialization procedure for the DSI Host Controller is as follows:

1. Assert all resets through the chip-specific registers provided for this purpose:
   - reset_dpi_n
   - reset_byte_n
   - reset_esc_n
2. Setup DSI related clocks through chip-specific registers provided for this purpose (refer to SCG for details).
3. Setup MIPI DSI application by programming all DSI Host Controller and DSI DPHY required parameters (refer to MIPI DSI Host Memory Map/Register for details).
4. Deassert all remaining resets through the Chip-specific registers provided for this purpose:
   - reset_dpi_n
   - reset_byte_n
   - reset_esc_n
5. DSI Host Controller should be ready for use

45.5 DSI D-PHY

The figure below shows the block diagram of the MIPI DSI D-PHY. It consists of a clock lane module and two data lane modules. Each of these PHY Lane Modules communicates through a differential line to a complementary PHY at the other side of the lane interconnect.

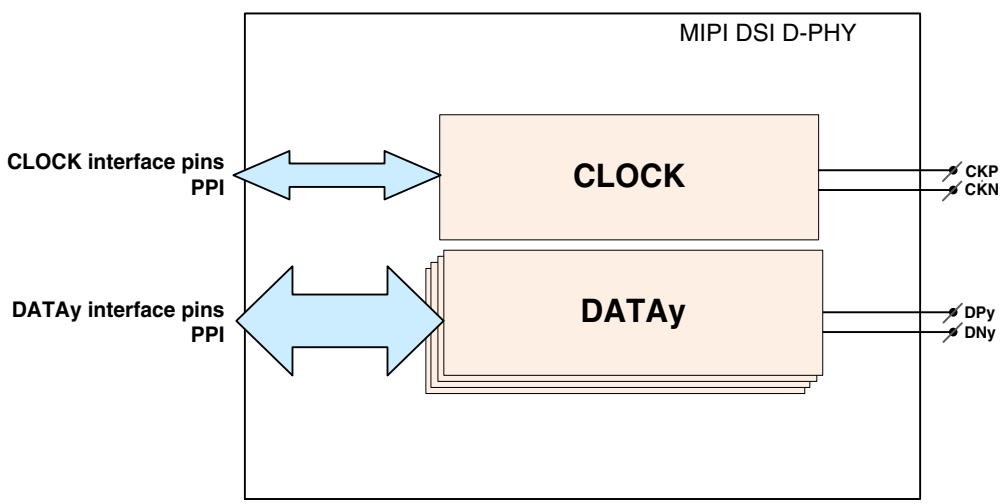

Figure 45-4. MIPI D-PHY Block Diagram

The figure below shows the D-PHY Lane components:

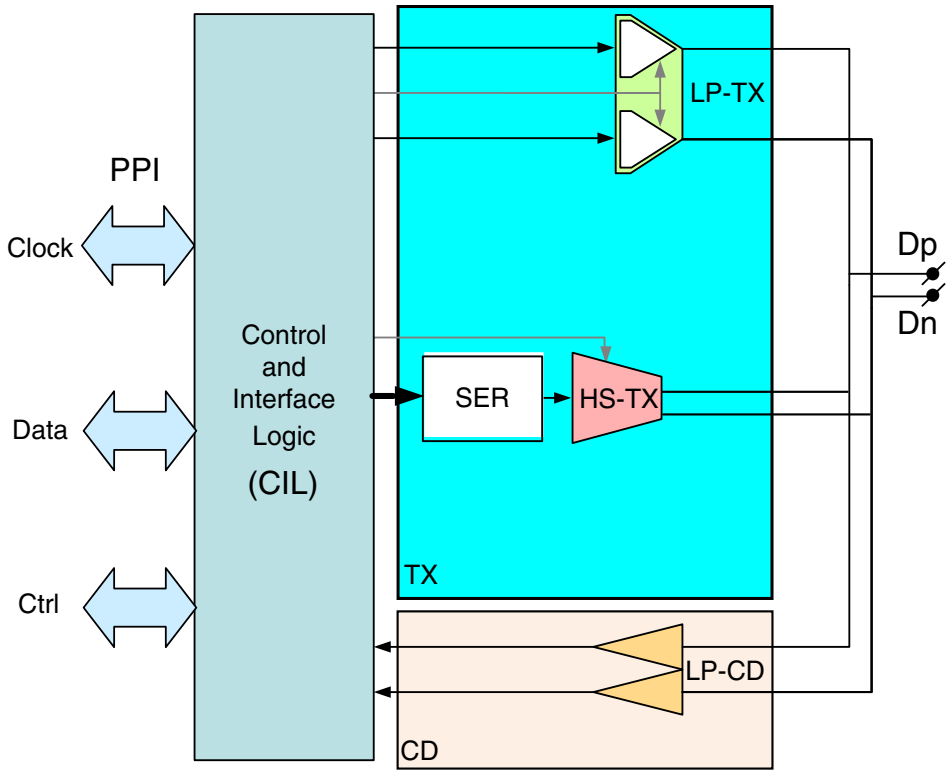

Figure 45-5. D-PHY Lane Diagram

The DATAy are bidirectional lanes and consist of High-Speed Transmitter (HS-TX), Low-Power Transmitter (LP-TX), Serializer (SER), and Low- Power Contention Detector (LP-CD).

The Clock lane is a bidirectional lane and consists of High-Speed Transmitter (HS-TX), and Low-Power Transmitter (LP-TX).

The Control and Interface Logic (CIL) module interfaces with the Protocol and determines the global operation of the Lane Module. The interface between the D-PHY and the protocol is called the PHY-Protocol Interface (PPI).

During normal operation, a Lane switches between Low-Power and High-Speed mode. Bidirectional Lanes can also switch communication direction. The change of operating mode or direction requires enabling and disabling of certain electrical functions. These enable and disable events do not cause glitches on the Lines that would result in a detection of an incorrect signal level. Therefore, all mode and direction changes are smooth to always ensure a proper detection of the Line signals.

45.5.1 High-Speed Transmitter (HS-TX)

The differential output voltage VOD is defined as the difference of the voltages V_{DP} and V_{DN} at the Dp and Dn pins, respectively.

VOD =VDP −VDN

The output voltages V_{DP} and V_{DN} at the Dp and Dn pins will not exceed the high-speed output high voltage V_{OHHS}. The common-mode voltage V_{CMTX} is defined as the arithmetic mean value of the voltages at the Dp and Dn pins:

VCMTX = (VDP + V DN)/2

V_{OD} and V_{CMTX} are graphically shown in Figure 45-6 for ideal HS signals. Figure 45-7 shows single ended HS signals with the possible kinds of distortion of the differential output and common mode voltages. V_{OD} and V_{CMTX} may be slightly different for driving a Differential-1 or a Differential-0 on the pins.

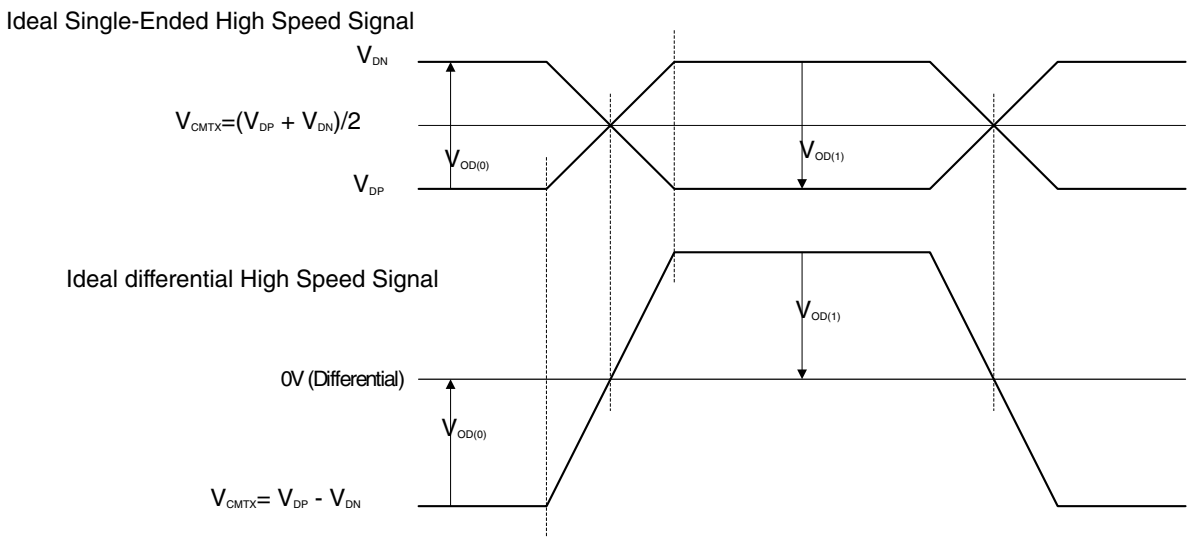

Figure 45-6. Ideal Single-ended and Resulting Differential HS Signals

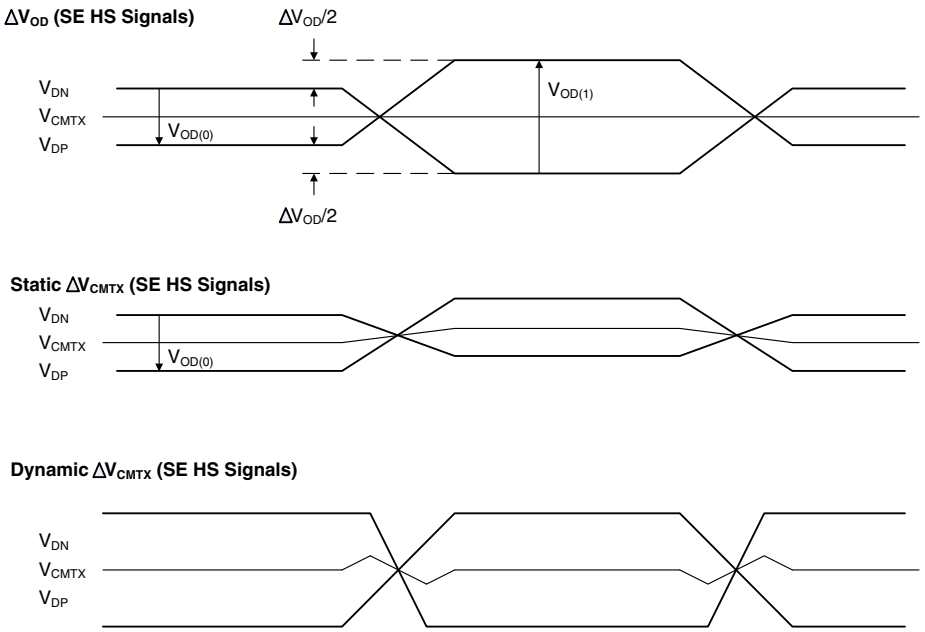

Figure 45-7. Possible ΔVcmtx and ΔVod Distortions of the Single-Ended HS Signals

The output differential voltage mismatch ΔVOD is defined as the difference of the absolute values of the differential output voltage in the Differential-1 state VOD(1) and the differential output voltage in the Differential-0 state VOD(0). This is expressed by:

$\Delta V = |V_{OD(1)}| - |V_{OD(0)}|$

If VCMTX(1) and VCMTX(0) are the common-mode voltages for static Differential-1 and Differential- 0 states respectively, then the common-mode reference voltage is defined by:

$V_{CMTX,\,REF} = (V_{CMTX(1)} + V_{CMTX(0)})/2$

The transient common-mode voltage variation is defined by:

$\Delta V_{CMTX\,(t)} = V_{CMTX\,(t)} - V_{CMTX,REF(t)}$

The static common-mode voltage mismatch between the Differential-1 and Differential-0 state is given by:

$\Delta V_{CMTX\,(1,0)} = (V_{CMTX\,(1)} - V_{CMTX\,(0)})/2$

A test circuit for the measurement of VOD and VCMTX is shown:

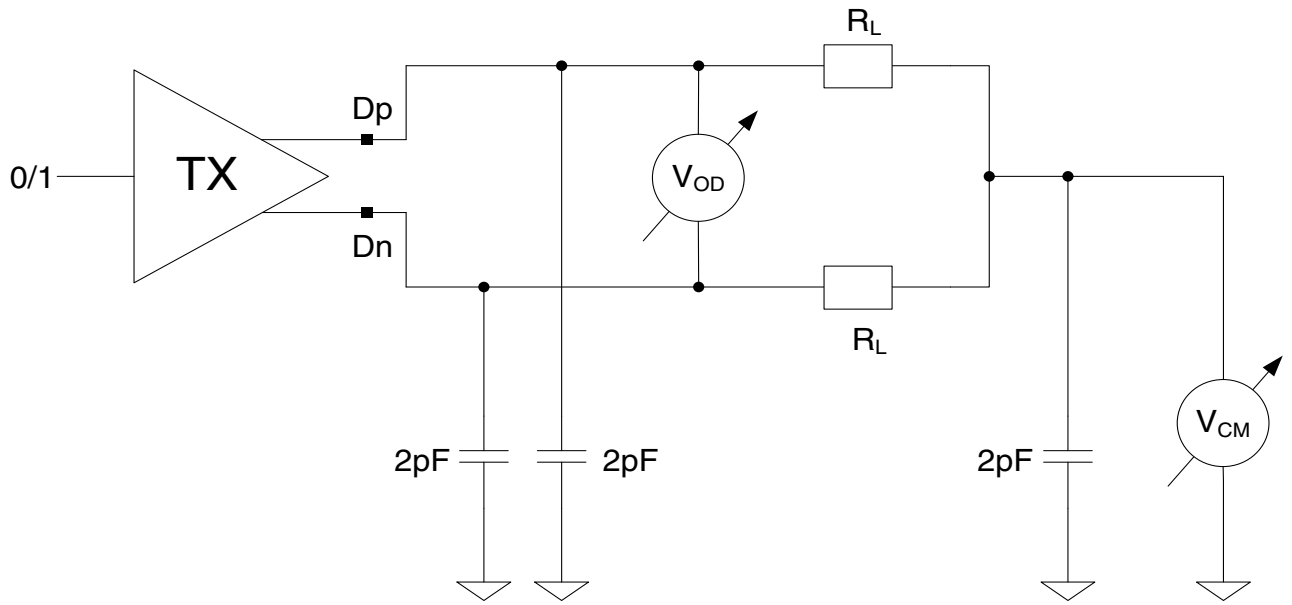

Figure 45-8. Test Circuit for Vcmtx and Vod measurement

The single-ended output impedance of the transmitter at both the Dp and Dn pins is denoted by Z_{OS}. ΔZ_{OS} is the mismatch of the single ended output impedances at the Dp and Dn pins, denoted by ZOSDP and ZOSDN respectively. This mismatch is defined as the ratio of the absolute value of the difference of Z_{OSDP} and Z_{OSDN} and the average of those impedances:

$$\Delta Z_{OS} = (2*|Z_{OSDP} - Z_{OSDN}|)/(Z_{OSDP} + Z_{OSDN})$$

The output impedance ZOS and the output impedance mismatch ΔZOS is compliant with High Speed Transmitter DC Specifications for both the Differential-0 and Differential-1 states for all allowed loading conditions. It is recommended the design keep the output impedance during state transitions as close as possible to the steady state value. The output impedance ZOS can be determined by injecting an AC current into the Dp and Dn pins and measuring the peak-to-peak voltage amplitude. The test circuit for such a measurement is shown in the following figure, where RL are load resistors and VTEST,PP is a test signal applied at the common-mode node via an AC coupling capacitor CAC. The frequency of the test signal is fTEST.

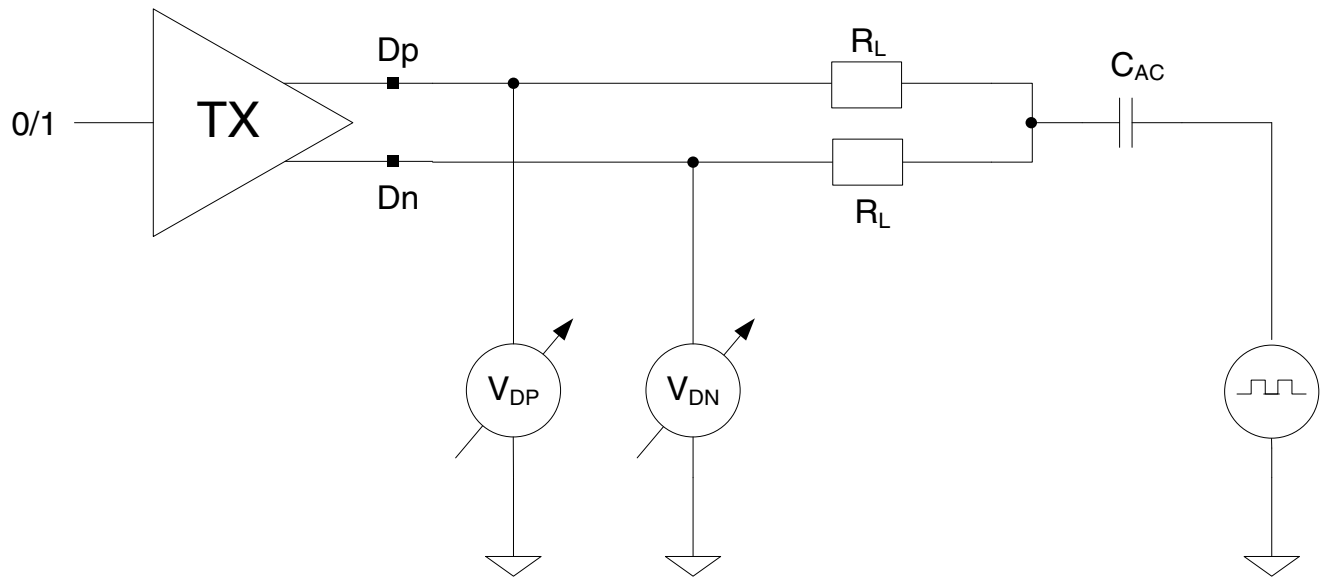

Figure 45-9. Test Circuit for Output Impedance measurements

Assuming negligible effect of the coupling capacitor, the example circuit gives the following relation between peak-to-peak pin voltage VPIN,PP and ZOS. This equation can be used for both Dn and Dp pins individually.

$Z_{OS} = (V_{PIN,PP} * RL)/(V_{TEST,PP} - Z_{PIN,PP})$

Where VPIN,PP is the peak-to-peak voltage at the pin Dp or Dn.

45.5.2 Low-Power Transmitter (LP-TX)

The Low-Power transmitter is a slew-rate controlled push-pull driver. It is used for driving the Lines in all Low-Power operating modes. The LP transmitter has been optimized to minimize static power consumption. The slew-rate of signal transitions is bounded in order to keep EMI low. The LP transmitter will not drive the pad pin potential statically beyond the maximum value of V_{OH}. V_{OH} is the thevenin output, high-level voltage in the high-level state, when the pad pin is not loaded. V_{OL} is the thevenin output, low-level voltage in the LP transmit mode. This is the voltage at an unloaded pad pin in the low-level state.

45.5.3 Low-Power Contention Detector (LP-CD)

Contention can be inferred from any of the following conditions:

- LP high fault is detected when the LP transmitter is driving high and the pin voltage is less than VIL.
- LP low fault is detected when the LP transmitter is driving low and the pad pin voltage is greater than VIHCD. An LP low fault will not be detected when the pin voltage is less than VILCD.

The general operation of a contention detector is similar to that of an LP receiver with lower threshold voltages. Although the DC specifications differ, the AC specifications of the LP-CD are defined to match those of the LP receiver. The LP-CD sufficiently filters the input signal to avoid false triggering on short events

The LP-CD threshold voltages (VILCD, VIHCD) are shown along with the normal signaling voltages:

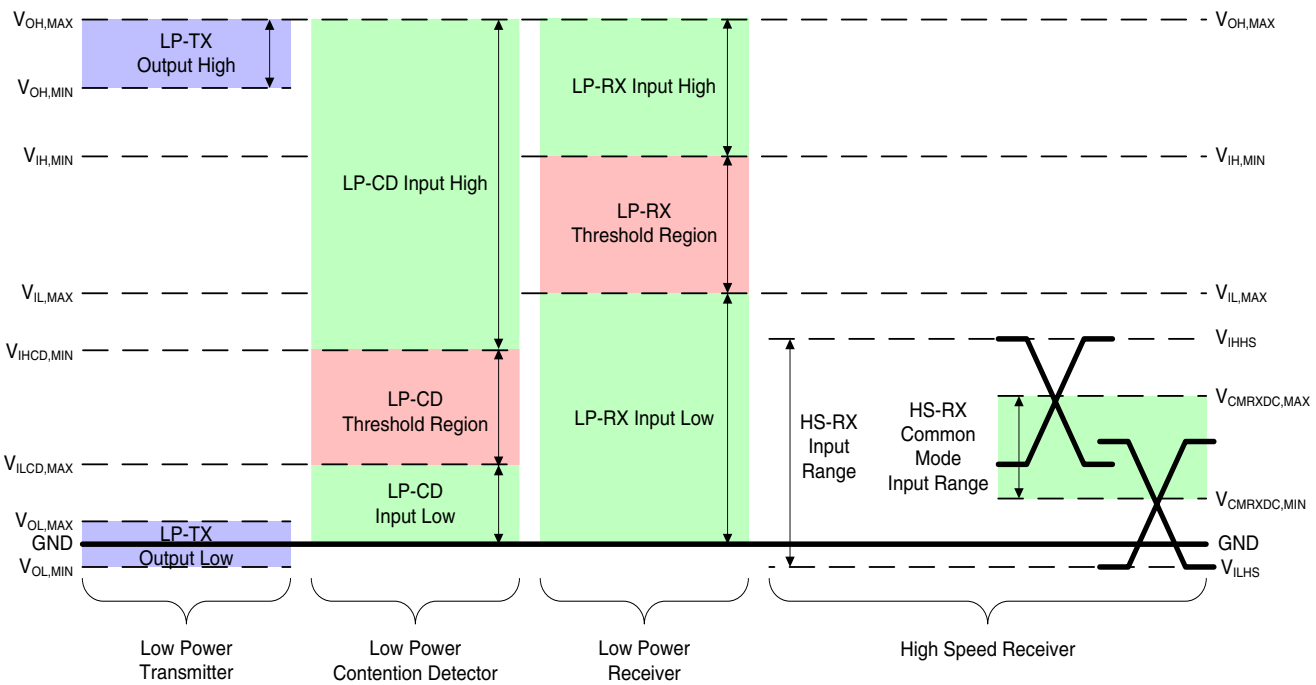

Figure 45-10. Signaling and MIPI Contention Voltage Levels

45.5.4 Input Characteristics

No structure within the PHY may be damaged when a DC signal that is within the signal voltage range VPIN is applied to a pad pin for an indefinite period of time. $V_{PIN(absmax)}$ is the maximum transient output voltage at the transmitter pin. The voltage on the transmitter's output pin will not excel $V_{PIN,MAX}$ for a period greater than $T_{VPIN(absmax)}$. When the PHY is in the low-power receive mode the pad pin leakage current will be I_{LEAK} when the pad signal voltage is within the signal voltage range of V_{PIN}. The

specification of ILEAK assures interoperability of any PHY in the LP mode by restricting the maximum load current of an LP transmitter. The test circuit for leakage current measurement is shown:

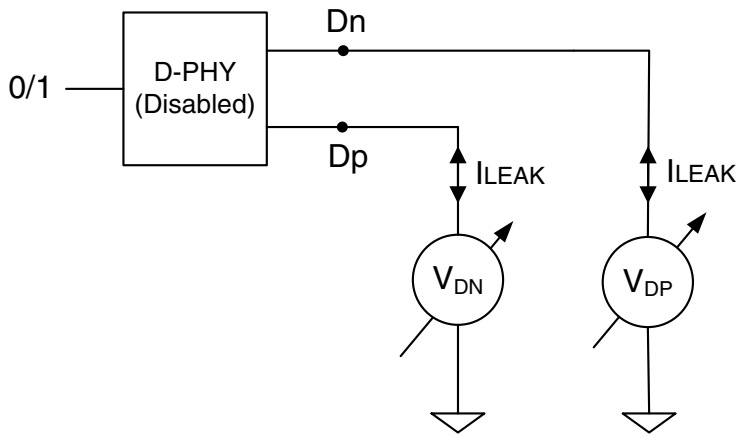

Figure 45-11. Pin-Leakage Measurement DC specification

45.5.5 High-Speed Serializer

The HS-Serializer converts 8-bits parallel data into 1 bit data stream to be transmitted by HSTX module. The CIL engine should clock out 8-bits parallel data, HSTX_DATA[7:0], on D0_HS_BYTE_CLKS rising edges. Then the Serializer will capture HSTX_DATA[7:0] on D0_HS_BYTE_CLKS rising edges and the signal connected to HSTX_DATA[0] is transmitted first. There is setup timing constraint and hold timing constraint designated to the rising edge of D0_HS_BYTE_CLKS as constrained in the liberty view provided.

The figure shows the relationship between HS_TXCLKP, HS_TXCLKN, HS_SER_LD, HS_BYTE_CLKS and HSTX_DATA[7:0]. It also shows how the 8-bits of parallel bits are mapped into the serial link:

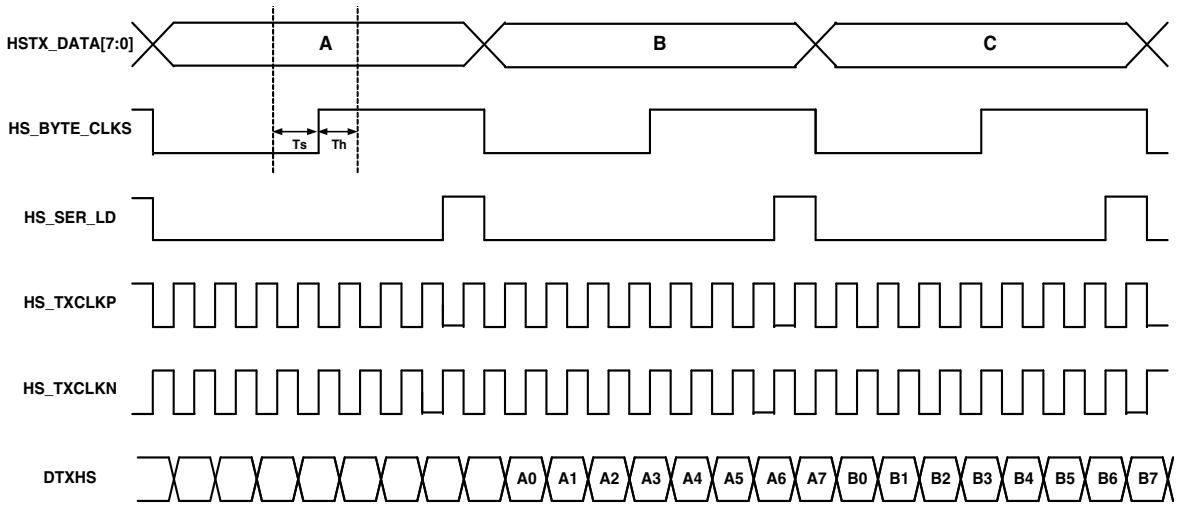

Figure 45-12. Serializer Timing Diagram

45.5.6 DSI D-PHY Signals

This section details the interface signals for MIPI DSI D-PHY. For detailed signal spec, please refer to the chip datasheet.

Table 45-9. DSI DPHY PPI Signals

Signal	Type	Description
TxClkEsc	Clock	Escape mode Transmit Clock. This clock is directly used to generate escape sequences. The period of this clock determines the symbol time for low power signals. It is therefore constrained by the normative part of the DPHY specification. **NOTE:** The max frequency of TxClkEsc is 20 MHz **NOTE:** The Min frequency of TxClkEsc is 12 MHz.
TxByteClkHS	Clock	High-Speed Transmit Byte Clock. This is used to synchronize PPI signals in the High-Speed transmit clock domain. It is recommended that all transmitting Data Lane Modules share on TxByteClkHS signal. The frequency of TxByteClkHS is exactly 1/8 the High-Speed bit rate.

45.5.7 Operating Modes

45.5.7.1 High-Speed Transmit from the Master Side

The figure shows an example of a High-Speed transmission on the Master side. While TxRequestHS is low, the Lane Module ignores the value of TxDataHS. To begin transmission, the protocol drives TxDataHS with the first byte of data and asserts TxRequestHS. This data byte is accepted by the PHY on the first rising edge of TxByteClkHS with TxReadyHS also asserted. At this point, the protocol logic drives the next data byte onto TxDataHS. After every rising clock cycle with TxReadyHS active, the protocol supplies a new valid data byte or ends the transmission. After the last data byte has been transferred to the Lane Module, TxRequestHS is driven low to cause the Lane Module to stop the transmission and enter Stop state. The minimum number of bytes transmitted could be as small as one.

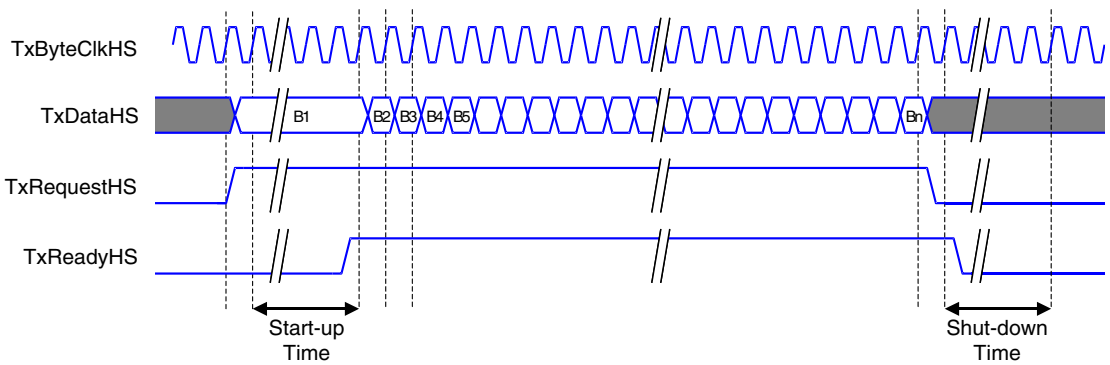

Figure 45-13. High-Speed Transmission from the Master Side

45.5.7.2 Low-Power Data Transmission

For Low-Power data transmission the TxClkEsc is used. The Protocol directs the Data Lane to enter Low-Power data transmission Escape mode by asserting TxRequestEsc with TxLpdtEsc high. The Low-Power transmit data is transferred on the TxDataEsc lines when TxValidEsc and TxReadyEsc are both active at a rising edge of TxClkEsc. The byte is transmitted in the time after the TxDataEsc is accepted by the Lane Module (TxValidEsc = TxReadyEsc = high). The Protocol knows the byte transmission is finished when TxReadyEsc is asserted. After the last byte has been transmitted, the protocol de-asserts TxRequestEsc to end the Low-Power data transmission. This causes TxReadyEsc to return low. Whenever TxRequestEsc transitions from high-to-low, it always remains in the low state for a minimum of two TxClkEsc clock cycles. The figure shows an example Low-Power data transmission operation.

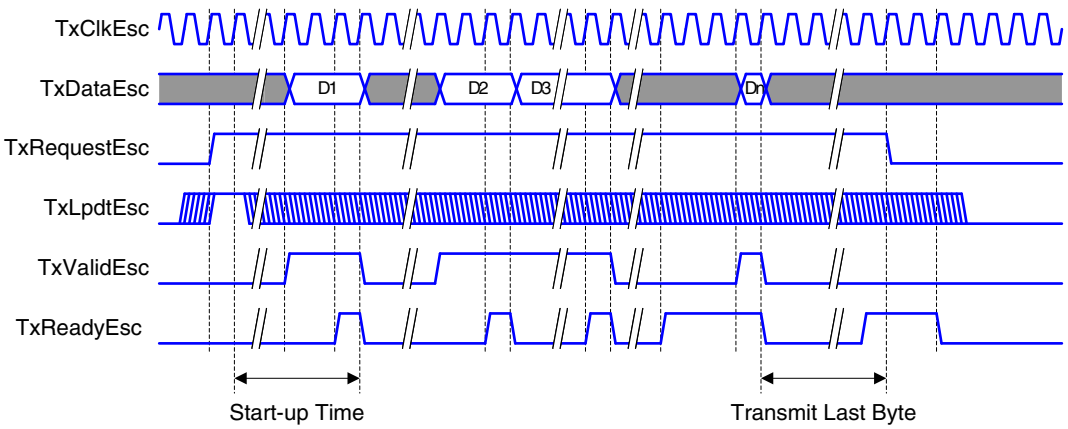

Figure 45-14. Low-Power Data Transmission

45.5.7.3 Turn-around

If the Master side and Slave side Lane Modules are both bi-directional, it is possible to turn around the Link for Escape mode signaling. Which side is allowed to transmit is determined by passing a “token” back and forth. That is, the side currently transmitting passes the token to the receiving side. If the receiving side acknowledges the turn-around request, as indicated by driving the appropriate line state, the direction is switched. The figure shows an example of two turn-around events. At the beginning, the local side is the transmitter, as shown by Direction=0. When the protocol on this side wishes to turn the Lane around (i.e. give the token to the other side), it asserts TurnRequest for at least one cycle of TxClkEsc. This initiates the turn around procedure. The remote side acknowledges the turn-around request by driving the appropriate states on the Lines. When this happens, the local Direction signal changes from transmit (0) to receive (1). The remote side initiates a turn-around request, passing the token back to the local side. When this happens, the local Direction signal changes back to transmit (0). The transmitter is in control of the Link direction and decides when to turn the Link around, passing control to the receiver. If the remote side does not acknowledge the turnaround request, the Direction signal does not change.

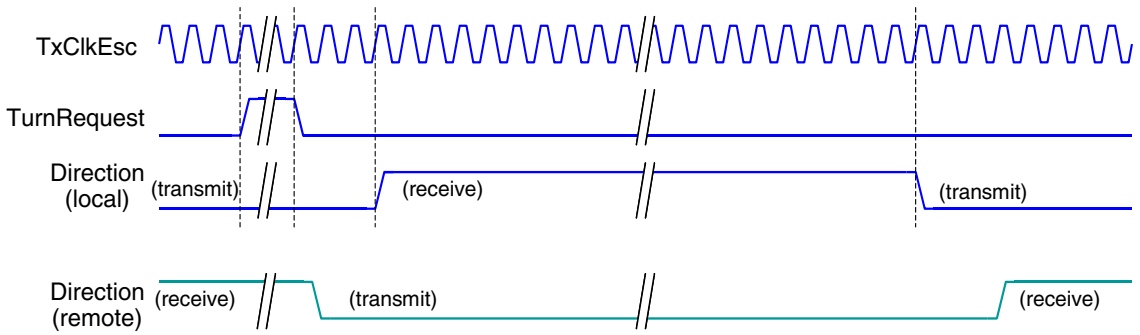

Figure 45-15. Turn-around Actions Transmit-to-Receive and Back to Transmit

45.6 DPHY PLL

The MIPI DSI DPHY PLL is a high performance PLL based frequency synthesizer that incorporates a lock detector, independent output divider, and supports power down modes. The PLL block diagram is shown below.

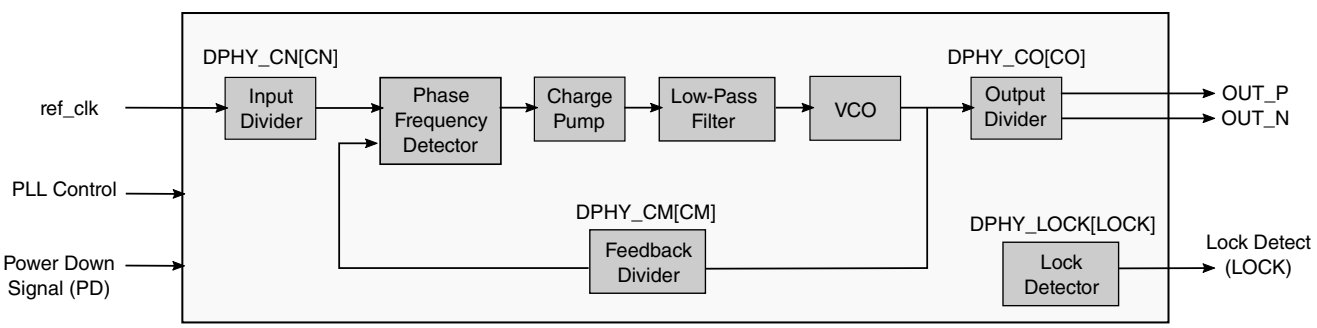

Figure 45-16. MIPI DSI DPHY PLL Block Diagram

The DPHY PLL input clock is ref_clk. The PLL output multiplies the input frequency by `(CM / (CN * CO))`.

NOTE

The input frequency ranges from 24 MHz till 200 MHz. The input divider has to be programmed such that the frequency after the input divider ranges from 24 MHz till 30 MHz.

NOTE

The VCO maximum output frequency is 800 MHz.

The power down signal (PD) is active-high and used to power down the PLL. Asserting PD will reset the PLL to it's initial state. To ensure proper PLL functionality, ref_clk needs to be stable before PLL power up. The expected power-on sequence for the DSI DPHY PLL is illustrated below.

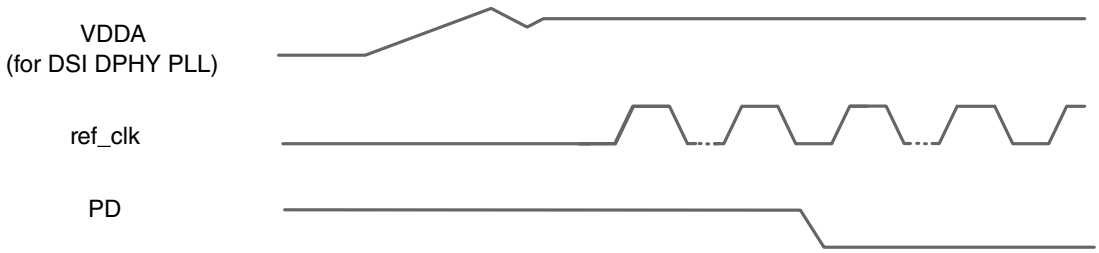

Figure 45-17. MIPI DSI DPHY PLL Power-on Sequence

45.7 DPHY Programming

The following sections detail the programming of the MIPI DSI DPHY high-speed timers.

45.7.1 High-Speed Prepare Timer ($T_{HS-PREPARE}$)

Calculate the value for clock lane high-speed prepare timer (mc_PRG_HS_PREPARE) using the formula below:

Assuming TxClkEsc = 20 MHz (T_{per} = 50 ns)
When mc_PRG_HS_PREPARE = 0, $T_{CLK-PREPARE}$= 1 * TxClkEsc Period = 50 ns
When mc_PRG_HS_PREPARE = 1, $T_{CLK-PREPARE}$ = 1.5 * TxClkEsc Period = 75 ns

Calculate the value for data lane high-speed prepare timer (m_PRG_HS_PREPARE) using the formula below:

Assuming TxClkEsc (TLPX) = 20 MHz (T_{per} = 50 ns)
When m_PRG_HS_PREPARE = 00, $T_{HS-PREPARE}$ = 1 * TxClkEsc Period = 50 ns
When m_PRG_HS_PREPARE = 01, $T_{HS-PREPARE}$ = 1.5 * TxClkEsc Period = 75 ns
When m_PRG_HS_PREPARE = 10, $T_{HS-PREPARE}$ = 2 * TxClkEsc Period = 100 ns
When m_PRG_HS_PREPARE = 11, $T_{HS-PREPARE}$ = 2.5 * TxClkEsc Period = 125 ns

45.7.2 High-Speed Zero Timer($T_{HS-ZERO}$)

Calculate the value for clock lane high-speed zero timer (mc_PRG_HS_ZERO) using the formula below:

$T_{CLK-ZERO}$= (mc_PRG_HS_ZERO + 3)*(TxByteClkHS Period)
TxByteClkHS = 1/8 Data Rate

When mc_PRG_HS_ZERO = 000110 @ 250 Mb/s, $T_{CLK-ZERO}$ = (6+3) * 32 ns = 288 ns
When mc_PRG_HS_ZERO = 100000 @ 1 Gb/s, $T_{CLK-ZERO}$ = (32+3) * 8 ns = 280 ns

Calculate the value for data lane high-speed zero timer (m_PRG_HS_ZERO) using the formula below:

$T_{HS-ZERO}$ = (m_PRG_HS_ZERO + 6)*(TxByteClkHS Period)
TxByteClkHS = 1/8 Data Rate
When m_PRG_HS_ZERO = 00001 @ 250 Mb/s, $T_{HS-ZERO}$ = (1+6) * 32 ns = 224 ns
When m_PRG_HS_ZERO = 01001 @ 1 Gb/s, $T_{HS-ZERO}$ = (9+6) * 8 ns = 120 ns

45.7.3 High-Speed Trail Timer ($T_{HS-TRAIL}$)

Calculate the value for the high-speed trail timer (PRG_HS_TRAIL) using the formula below:

$T_{HS-TRAIL}$= (PRG_HS_TRAIL)*(TxByteClkHS Period)
TxByteClkHS = 1/8 Data Rate
When PRG_HS_TRAIL = 0100 @ 250 Mb/s, >$T_{HS-TRAIL}$ = 4 * 32 ns = 128 ns
When PRG_HS_TRAIL = 1100 @ 1 Gb/s, >$T_{HS-TRAIL}$ = 12 * 8 ns = 96 ns

45.8 Packet Data and Pixel Formats

The DSI Host Controller Core and the external DSI Peripheral explicitly handle and exchanges 32-bit words encapsulated as packet data. The mapping between pixel formats and pixel data must be done on both sides by user application on both sides of the DSI link. The DSI spec gives many examples of common pixel formats. The DSI Host Controller Core and external DSI Peripheral have no preference or limitation on which pixel formats it will handle. The IP which provides video source packet data through DPI-2 interface (e.g. LCDIF) onto DSI should also be configured by the user application to match the pixel formats expected by the DSI Host Controller.

The DPI-2 interface core handles pixel to byte packing and byte to pixel unpacking according to the MIPI DSI specification.

MIPI_DSI_HOSTx_DSI_HOST_CFG_T_POST field descriptions

Field	Description
31–7 -	This field is reserved.

Table continues on the next page...

MIPI_DSI_HOSTx_DSI_HOST_CFG_T_POST field descriptions (continued)

Field	Description
dsi_host_cfg_t_post	Sets the number of byte clock periods ('clk_byte' input) to wait before putting the clock lane into LP mode after the data lanes have been detected to be in Stop State. This setting represents the DPHY timing parameters TLPX (TxClkEsc) + TCLK-PREPARE + TCLK-ZERO + TCLK-PRE requirement for the clock lane before the data lane is allowed to change from LP11 to start a high speed transmission. The minimum value for this port is 1.

45.9.5 MIPI_DSI_HOSTx_DSI_HOST_CFG_TX_GAP

NOTE

Please refer to the MIPI Alliance Specification for D-PHY (Global Operation Timing Parameters) for details on calculating the parameter described below

Address: 40A9_0000h base + 10h offset = 40A9_0010h

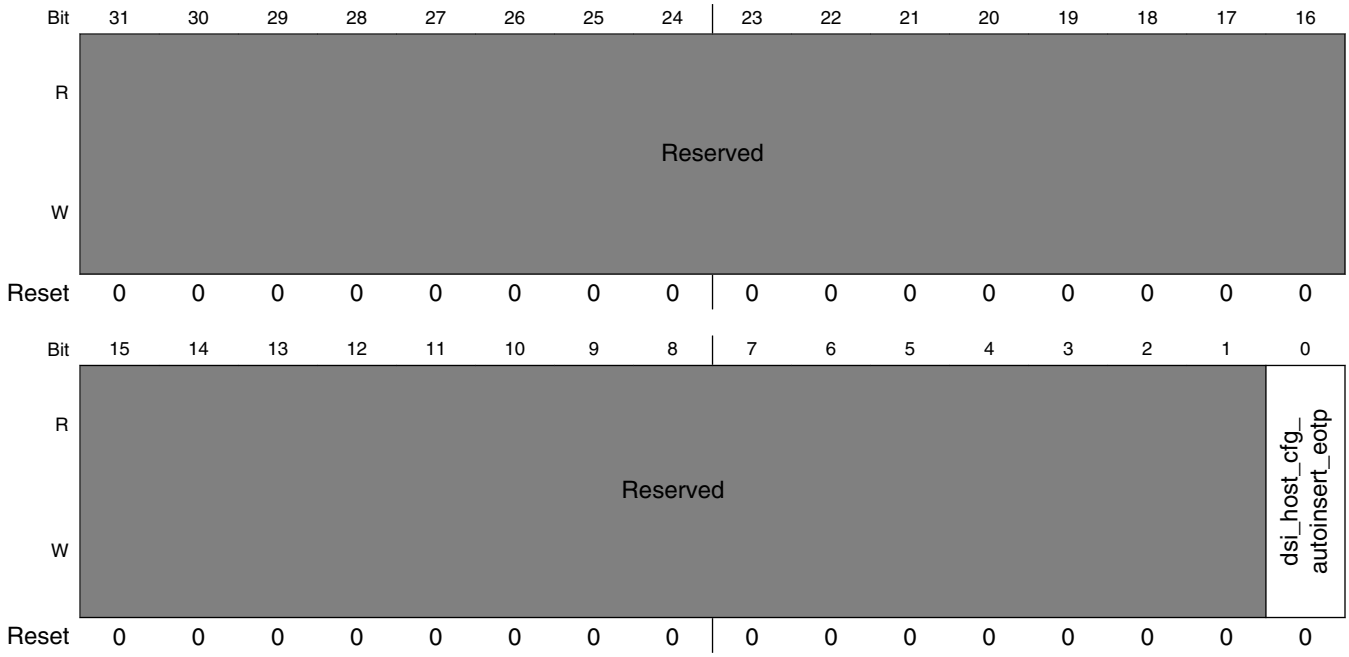
Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved																									dsi_host_cfg_tx_gap							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MIPI_DSI_HOSTx_DSI_HOST_CFG_TX_GAP field descriptions

Field	Description
31–7 -	This field is reserved.
dsi_host_cfg_tx_gap	Sets the number of byte clock periods ('clk_byte' input) that the controller will wait after the clock lane has been put into LP mode before enabling the clock lane for HS mode again. This setting represents the THS-EXIT parameter. The minimum value for this port is 1.

45.9.6 MIPI_DSI_HOSTx_DSI_HOST_CFG_AUTOINSERT_EOTP

Address: 40A9_0000h base + 14h offset = 40A9_0014h

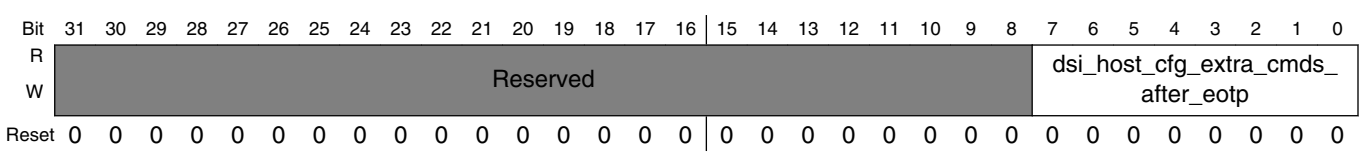


MIPI_DSI_HOSTx_DSI_HOST_CFG_AUTOINSERT_EOTP field descriptions

Field	Description
31–1 -	This field is reserved.
0 dsi_host_cfg_ autoinsert_eotp	Enables the Host Controller to automatically insert an EoTp short packet when switching from HS to LP mode. • 1'b0 - EoTp is not automatically inserted • 1'b1 - EoTp is automatically inserted

45.9.7 MIPI_DSI_HOSTx_DSI_HOST_CFG_EXTRA_CMDS_AFTER_EOTP

Address: 40A9_0000h base + 18h offset = 40A9_0018h

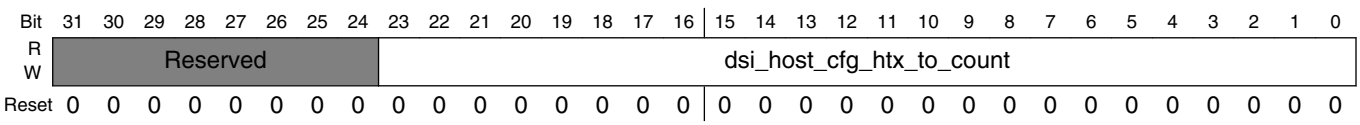


MIPI_DSI_HOSTx_DSI_HOST_CFG_EXTRA_CMDS_AFTER_EOTP field descriptions

Field	Description
31–8 -	This field is reserved.
dsi_host_cfg_ extra_cmds_ after_eotp	Configures the DSI Host Controller to send extra End Of Transmission Packets after the end of a packet. The value is the number of extra EOTP packets sent.

45.9.8 MIPI_DSI_HOSTx_DSI_HOST_CFG_HTX_TO_COUNT

Address: 40A9_0000h base + 1Ch offset = 40A9_001Ch

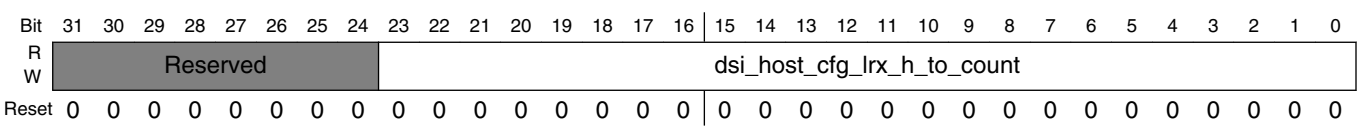


MIPI_DSI_HOSTx_DSI_HOST_CFG_HTX_TO_COUNT field descriptions

Field	Description
31–24 -	This field is reserved.
dsi_host_cfg_ htx_to_count	Sets the value of the DSI Host High Speed TX timeout count in clk_byte clock periods that once reached will initiate a timeout error and follow the recovery procedure documented in the DSI specification. This timeout parameter should be configured to represent the time taken to transmit the biggest HS data payload. If this timeout is reached the DSI byte count is cleared and the HS transmission is aborted. This timer can be also disabled, when set to 0.

45.9.9 MIPI_DSI_HOSTx_DSI_HOST_CFG_LRX_H_TO_COUNT

Address: 40A9_0000h base + 20h offset = 40A9_0020h



MIPI_DSI_HOSTx_DSI_HOST_CFG_LRX_H_TO_COUNT field descriptions

Field	Description
31–24 -	This field is reserved.
dsi_host_cfg_lrx_ h_to_count	Sets the value of the DSI Host low power RX timeout count in clk_byte clock periods that once reached will initiate a timeout error and follow the recovery procedure documented in the DSI specification. This timeout parameter should be configured to represent the time taken to receive the biggest LP (Escape mode) data payload. If this timeout is reached, the DSI byte count is cleared and the LP reception is aborted. This timer can be also disabled, when set to 0

45.9.10 MIPI_DSI_HOSTx_DSI_HOST_CFG_BTA_H_TO_COUNT

Address: 40A9_0000h base + 24h offset = 40A9_0024h

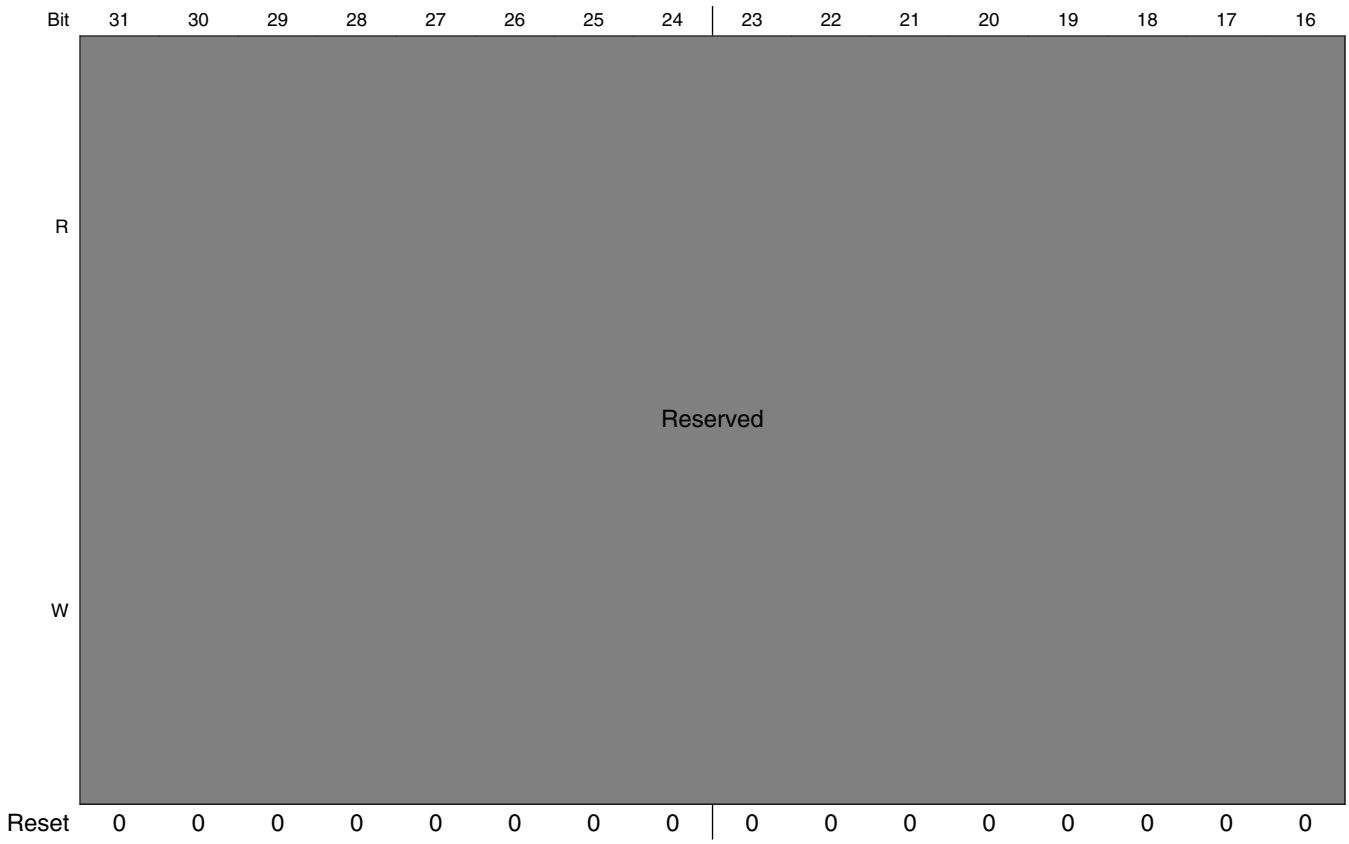
Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved								dsi_host_cfg_bta_h_to_count																									
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

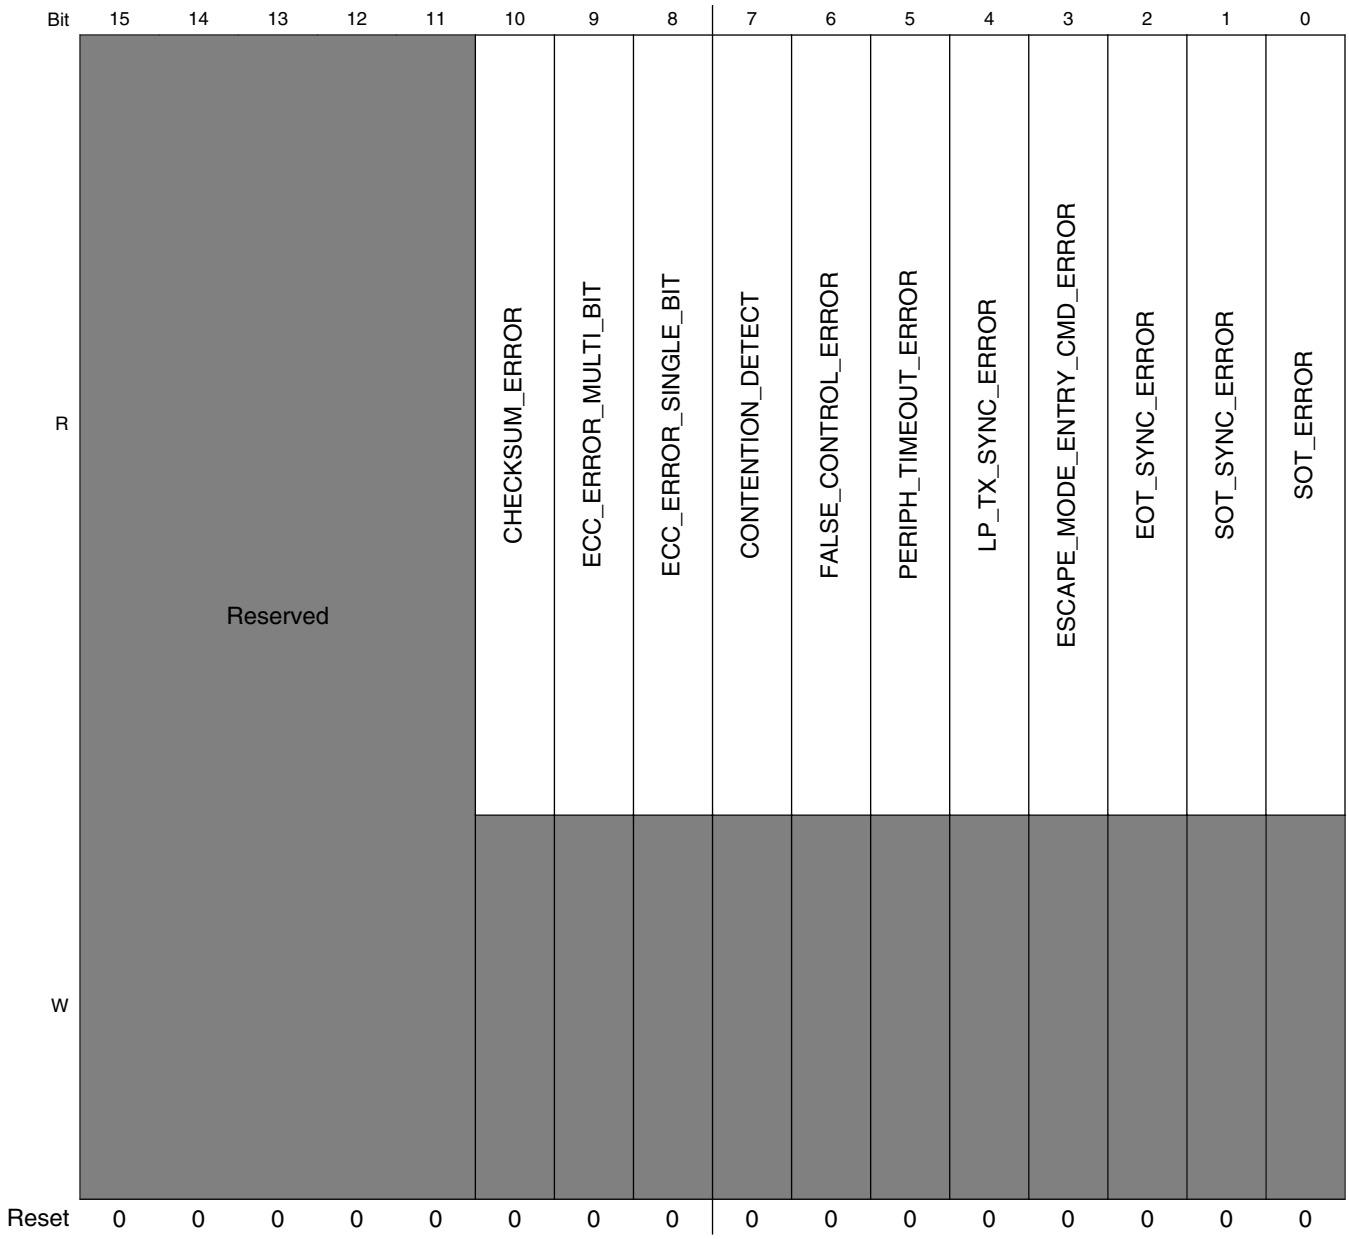
MIPI_DSI_HOSTx_DSI_HOST_CFG_BTA_H_TO_COUNT field descriptions

Field	Description
31–24 -	This field is reserved.
dsi_host_cfg_ bta_h_to_count	Sets the value of the DSI Host Bus Turn Around (BTA) timeout in clk_byte clock periods that once reached will initiate a timeout error.

45.9.11 MIPI_DSI_HOSTx_DSI_HOST_CFG_STATUS_OUT

Address: 40A9_0000h base + 2Ch offset = 40A9_002Ch





MIPI_DSI_HOSTx_DSI_HOST_CFG_STATUS_OUT field descriptions

Field	Description
31–11 -	This field is reserved. Reserved
10 CHECKSUM_ ERROR	Checksum Error (long packet only) – Checksum error from peripheral error report, cleared upon read
9 ECC_ERROR_ MULTI_BIT	ECC Error, multi-bit (detected, not corrected) – ECC multi-bit error from peripheral error report, cleared upon read

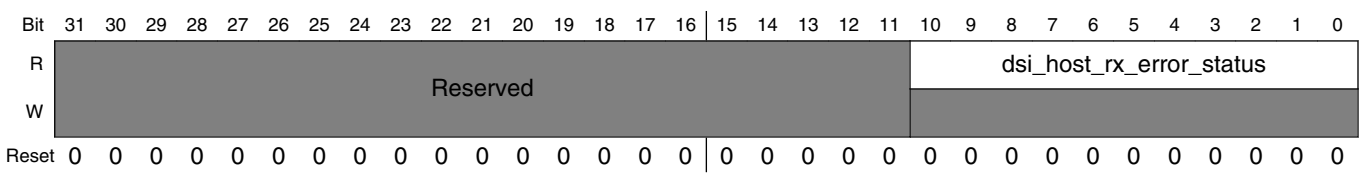
Table continues on the next page...

MIPI_DSI_HOSTx_DSI_HOST_CFG_STATUS_OUT field descriptions (continued)

Field	Description
8 ECC_ERROR_ SINGLE_BIT	ECC single bit error from peripheral error report, cleared upon read.
7 CONTENTION_ DETECT	Contention Detected – Contention Detection from peripheral error report, cleared upon read
6 FALSE_ CONTROL_ ERROR	False Control Error – False Control Error from peripheral error report, cleared upon read
5 PERIPH_ TIMEOUT_ ERROR	Peripheral Timeout Error – Peripheral Timeout error from peripheral error report, cleared upon read
4 LP_TX_SYNC_ ERROR	Low-Power Transmit Sync Error – Low Power Transmit Sync error from peripheral error report, cleared upon read.
3 ESCAPE_ MODE_ENTRY_ CMD_ERROR	Escape Mode Entry Command Error – Escape Mode Entry Command Error from peripheral error report, cleared upon read
2 EOT_SYNC_ ERROR	EoT Sync Error – End of Transmission (EoT) Sync Error from peripheral error report, cleared upon read
1 SOT_SYNC_ ERROR	SoT Sync Error – Start of Transmission (SoT) Sync Error from peripheral error report, cleared upon read
0 SOT_ERROR	SoT Error – Start of Transmission (SoT) Error from peripheral error report, cleared upon read.

45.9.12 MIPI_DSI_HOSTx_DSI_HOST_RX_ERROR_STATUS

Address: 40A9_0000h base + 30h offset = 40A9_0030h



MIPI_DSI_HOSTx_DSI_HOST_RX_ERROR_STATUS field descriptions

Field	Description
31–11 -	This field is reserved.
dsi_host_rx_ error_status	Status Register for Host receive error detection, ECC errors, CRC errors and for timeout indicators

Table continues on the next page...

MIPI_DSI_HOSTx_DSI_HOST_RX_ERROR_STATUS field descriptions (continued)

Field	Description
	• [0] ECC single bit error detected • [1] ECC multi bit error detected • [6:2] Errored bit position for single bit ECC error • [7] CRC error detected • [8] High Speed forward TX timeout detected • [9] Reverse Low power data receive timeout detected • [10] BTA timeout detected

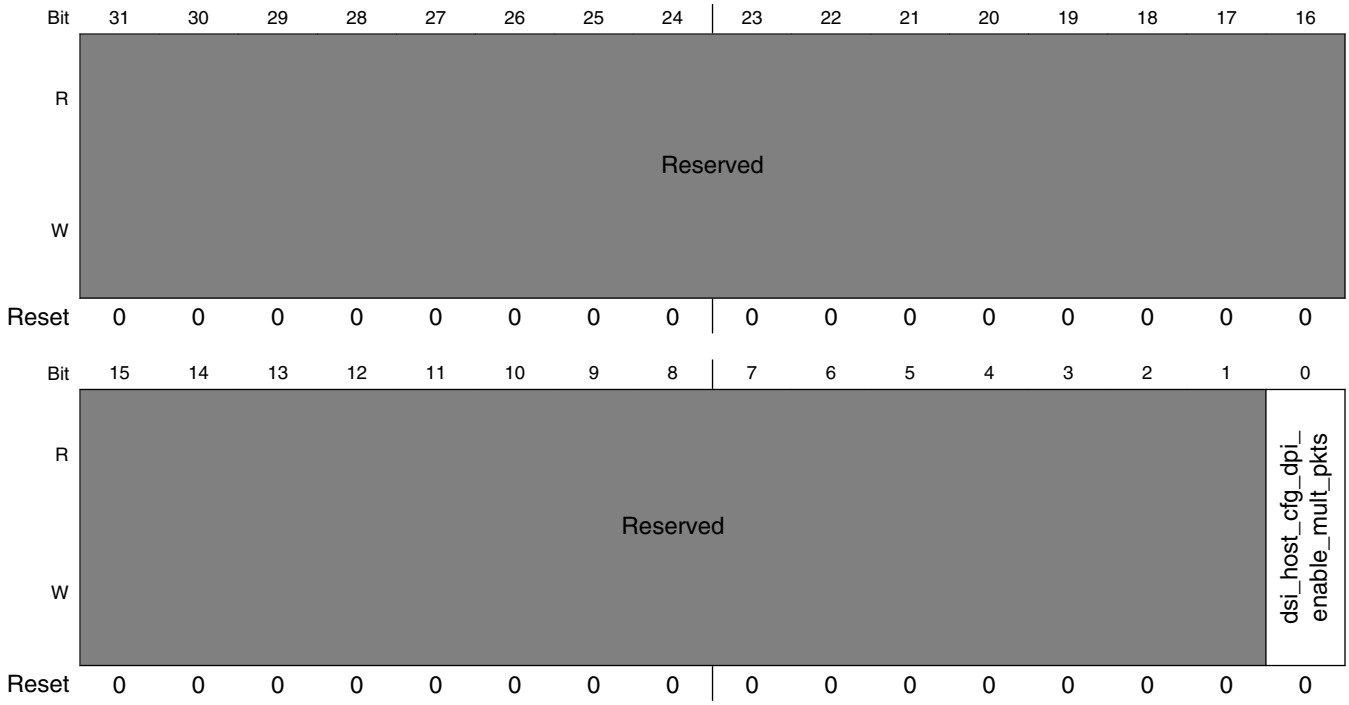
MIPI_DSI_HOST_DPI_INTFCx_DSI_HOST_CFG_DPI_HSA field descriptions

Field	Description
31–16 -	This field is reserved.
dsi_host_cfg_ dpi_hsa	Sets the DSI packet payload size, in bytes, of the horizontal sync width filler blanking packet.

45.10.11 MIPI_DSI_HOST_DPI_INTFCx_DSI_HOST_CFG_DPI_ENABLE_MULT

Address: 40A9_0000h base + 228h offset = 40A9_0228h

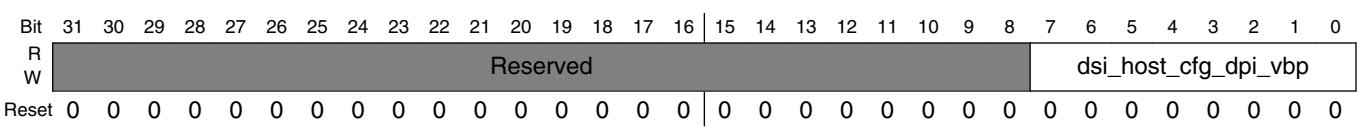


MIPI_DSI_HOST_DPI_INTFCx_DSI_HOST_CFG_DPI_ENABLE_MULT_PKTS field descriptions

Field	Description
31–1 -	This field is reserved.
0 dsi_host_cfg_dpi_enable_mult_pkts	Enable Multiple packets per video line. When enabled, cfg_dpi_pixel_payload_size must be set to exactly half the size of the video line. 0 - Video Line is sent in a single packet 1 - Video Line is sent in two packets

45.10.12 MIPI_DSI_HOST_DPI_INTFCx_DSI_HOST_CFG_DPI_VBP

Address: 40A9_0000h base + 22Ch offset = 40A9_022Ch

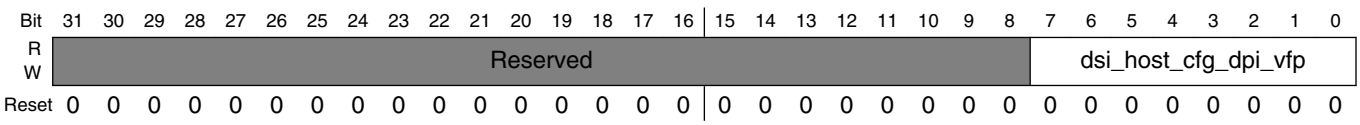


MIPI_DSI_HOST_DPI_INTFCx_DSI_HOST_CFG_DPI_VBP field descriptions

Field	Description
31–8 -	This field is reserved.
dsi_host_cfg_ dpi_vbp	Sets the number of lines in the vertical back porch.

45.10.13 MIPI_DSI_HOST_DPI_INTFCx_DSI_HOST_CFG_DPI_VFP

Address: 40A9_0000h base + 230h offset = 40A9_0230h

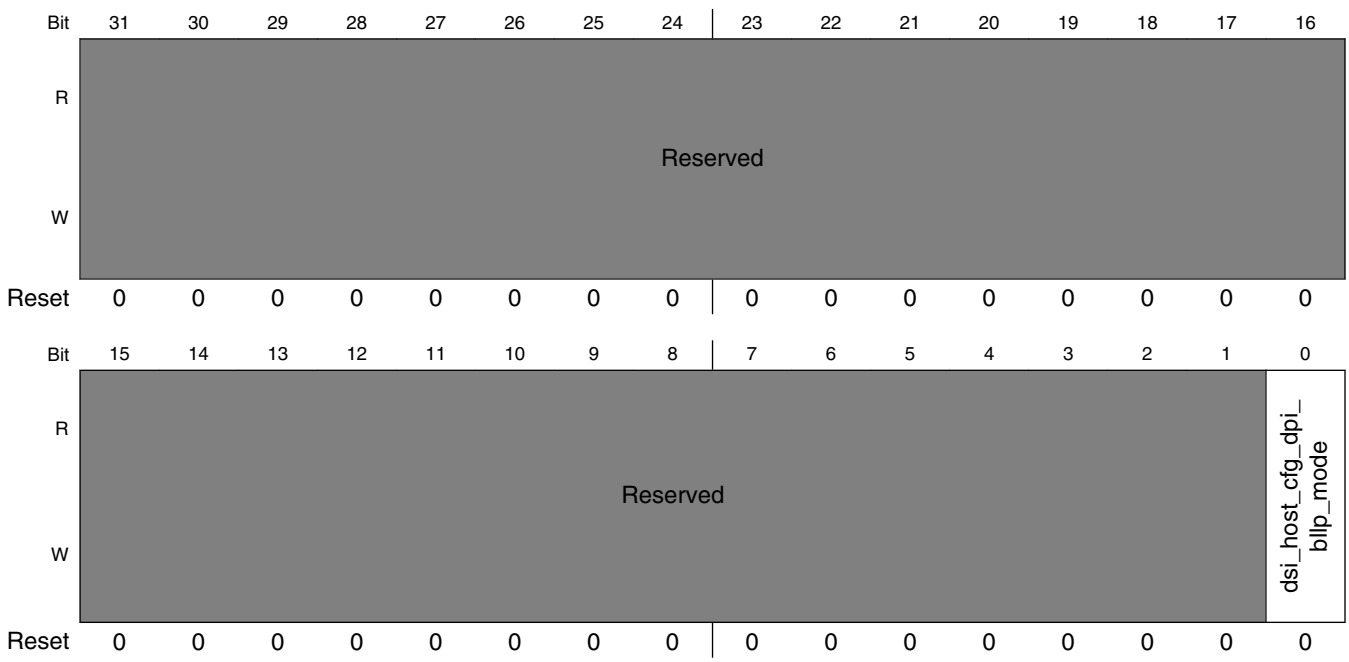


MIPI_DSI_HOST_DPI_INTFCx_DSI_HOST_CFG_DPI_VFP field descriptions

Field	Description
31–8 -	This field is reserved.
dsi_host_cfg_ dpi_vfp	Sets the number of lines in the vertical front porch.

45.10.14 MIPI_DSI_HOST_DPI_INTFCx_DSI_HOST_CFG_DPI_BLLP_MODE

Address: 40A9_0000h base + 234h offset = 40A9_0234h

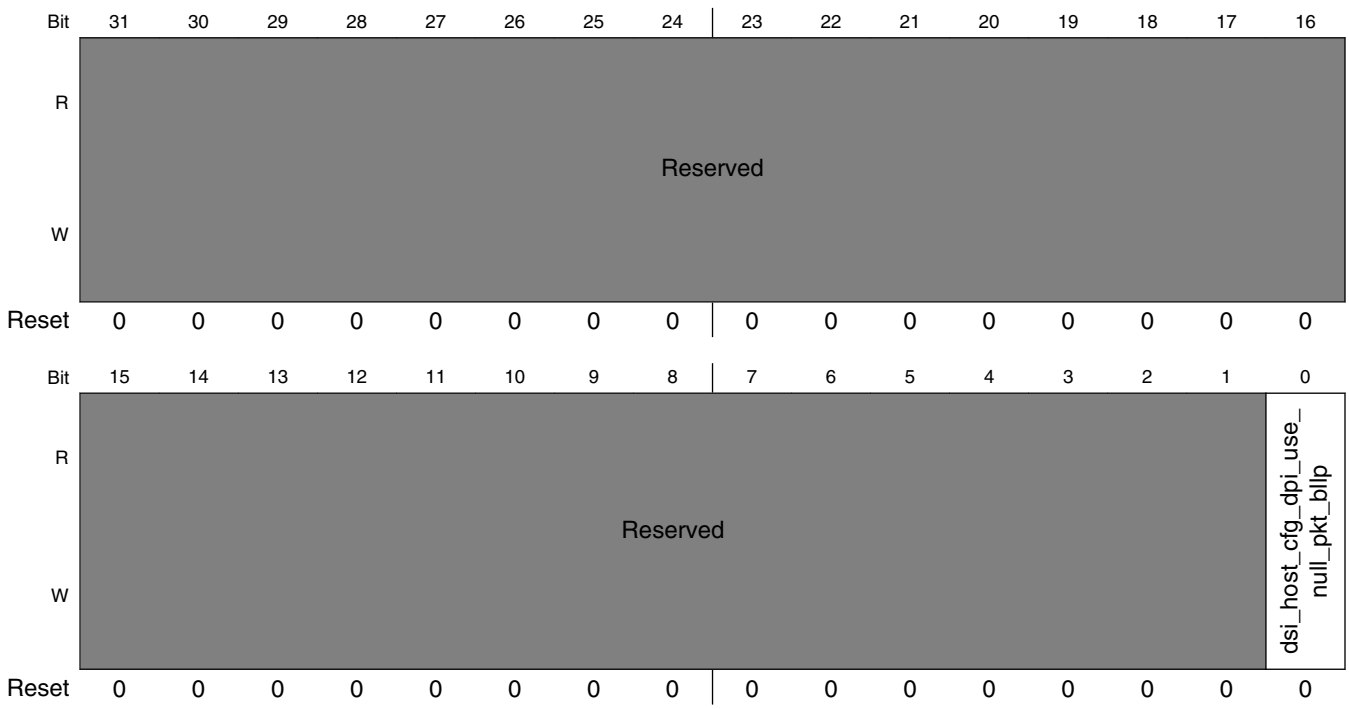


MIPI_DSI_HOST_DPI_INTFCx_DSI_HOST_CFG_DPI_BLLP_MODE field descriptions

Field	Description
31–1 -	This field is reserved.
0 dsi_host_cfg_ dpi_bllp_mode	Optimize bllp periods to Low Power mode when possible 0 - blanking packets are sent during BLLP periods 1 - LP mode is used for BLLP periods

45.10.15 MIPI_DSI_HOST_DPI_INTFCx_DSI_HOST_CFG_DPI_USE_NULL_PKT

Address: 40A9_0000h base + 238h offset = 40A9_0238h

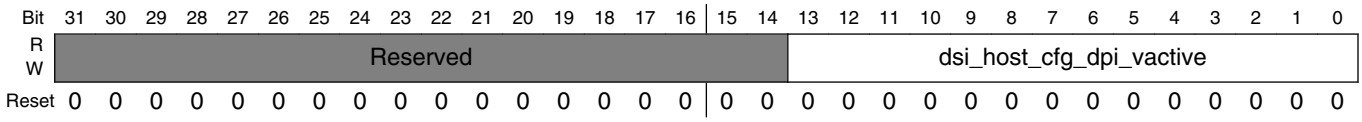


MIPI_DSI_HOST_DPI_INTFCx_DSI_HOST_CFG_DPI_USE_NULL_PKT_BLLP field descriptions

Field	Description
31–1 -	This field is reserved.
0 dsi_host_cfg_ dpi_use_null_ pkt_bllp	Selects type of blanking packet to be sent during bllp region 0 - Blanking packet used in bllp region 1 - Null packet used in bllp region

45.10.16 MIPI_DSI_HOST_DPI_INTFCx_DSI_HOST_CFG_DPI_VACTIVE

Address: 40A9_0000h base + 23Ch offset = 40A9_023Ch

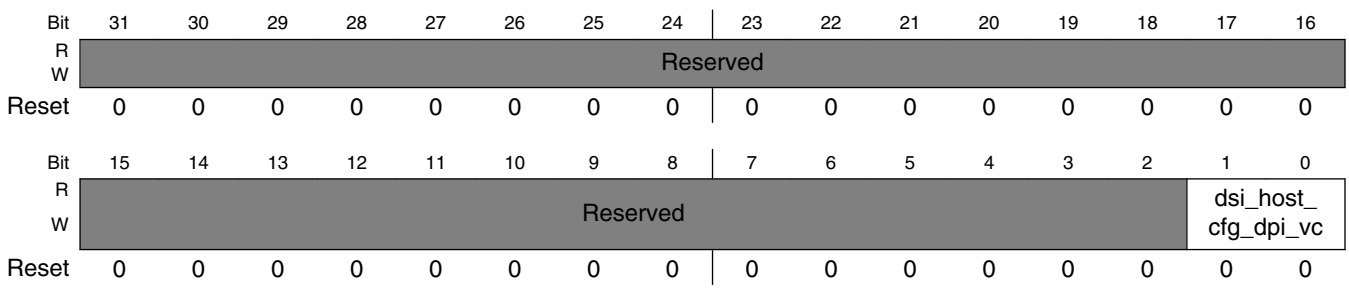


MIPI_DSI_HOST_DPI_INTFCx_DSI_HOST_CFG_DPI_VACTIVE field descriptions

Field	Description
31–14 -	This field is reserved.
dsi_host_cfg_ dpi_vactive	Sets the number of lines in the vertical active area. This field is equivalent to (real vertical size) - 1. For example, for an image of size 640x480, the bit field should be set as 479.

45.10.17 MIPI_DSI_HOST_DPI_INTFCx_DSI_HOST_CFG_DPI_VC

Address: 40A9_0000h base + 240h offset = 40A9_0240h



MIPI_DSI_HOST_DPI_INTFCx_DSI_HOST_CFG_DPI_VC field descriptions

Field	Description
31–2 -	This field is reserved.
dsi_host_cfg_ dpi_vc	Sets the Virtual Channel (VC) of packets that will be sent to the receive packet interface. Packets with VC not equal to this value are discarded and the "DSI VC ID Invalid" bit (bit 12) in the DSI error report is set.

45.11 MIPI DSI Host APB PKT IF Memory Map/Register Definition

MIPI_DSI_HOST_APB_PKT_IF memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

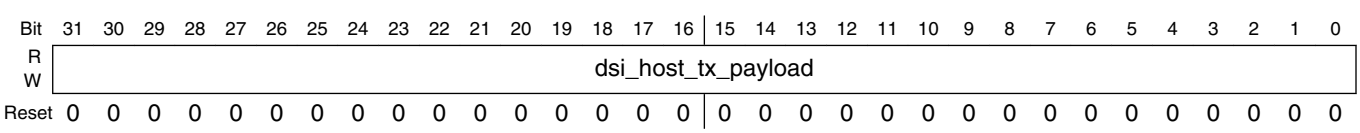
45.11.1 MIPI_DSI_HOST_APB_PKT_IFx_DSI_HOST_TX_PAYLOAD

Address: 40A9_0000h base + 280h offset = 40A9_0280h

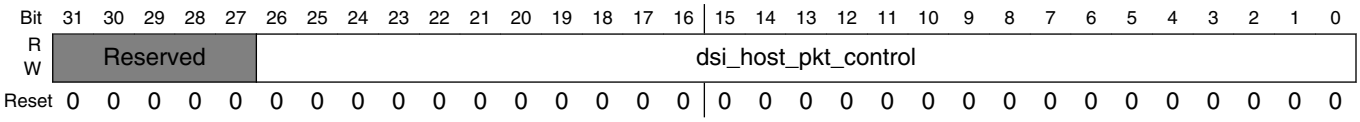


MIPI_DSI_HOST_APB_PKT_IFx_DSI_HOST_TX_PAYLOAD field descriptions

Field	Description
dsi_host_tx_payload	Tx Payload data write register. Writes to this registers load the payload fifo with 32 bit values.

45.11.2 MIPI_DSI_HOST_APB_PKT_IFx_DSI_HOST_PKT_CONTROL

Address: 40A9_0000h base + 284h offset = 40A9_0284h

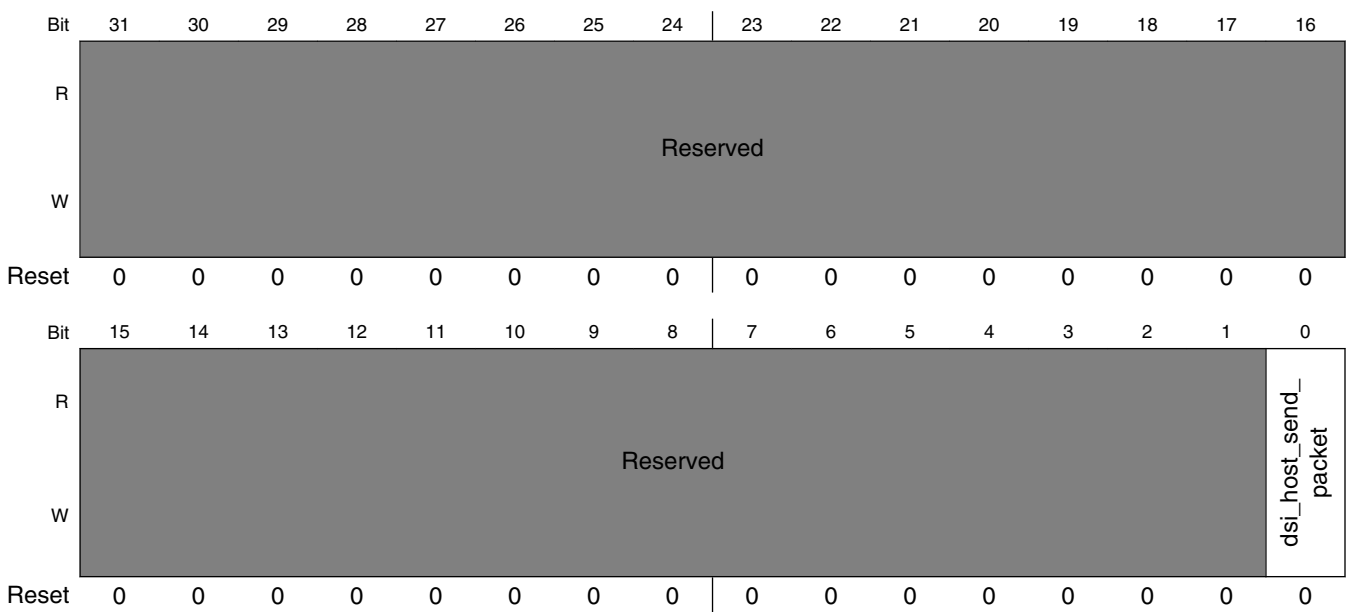


MIPI_DSI_HOST_APB_PKT_IFx_DSI_HOST_PKT_CONTROL field descriptions

Field	Description
31–27 -	This field is reserved.
dsi_host_pkt_ control	Tx packet control register. • [15:0] - Packet word count • [17:16] - Packet Virtual Channel • [23:18] - Packet Header DSI Data Type • [24] - Lp or HS select. 0 - LP mode, 1 - HS mode • [25] - perform BTA after packet is sent • [26] - perform BTA only, no packet tx

45.11.3 MIPI_DSI_HOST_APB_PKT_IFx_DSI_HOST_SEND_PACKET

Address: 40A9_0000h base + 288h offset = 40A9_0288h

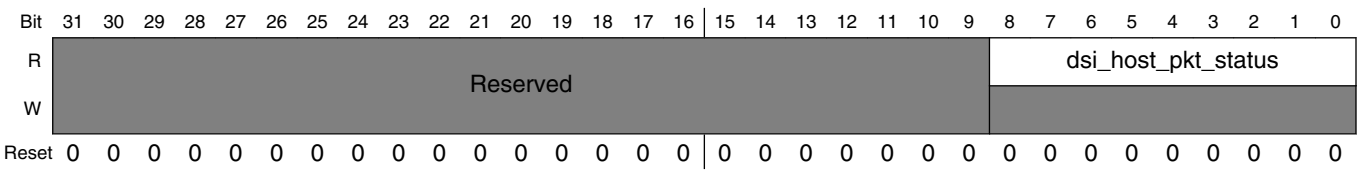


MIPI_DSI_HOST_APB_PKT_IFx_DSI_HOST_SEND_PACKET field descriptions

Field	Description
31–1 -	This field is reserved.
0 dsi_host_send_packet	Tx send packet. Writing to this register causes the packet described in dsi_host_pkt_control to be sent.

45.11.4 MIPI_DSI_HOST_APB_PKT_IFx_DSI_HOST_PKT_STATUS

Address: 40A9_0000h base + 28Ch offset = 40A9_028Ch

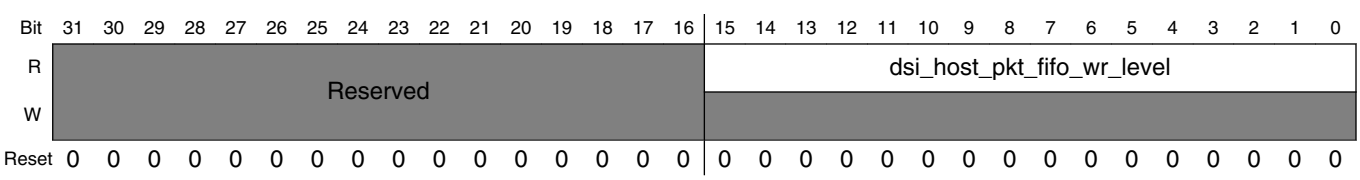


MIPI_DSI_HOST_APB_PKT_IFx_DSI_HOST_PKT_STATUS field descriptions

Field	Description
31–9 -	This field is reserved.
dsi_host_pkt_status	Status of APB to packet interface • [0] - state machine not idle • [1] - Tx packet done • [2] - dphy direction 0 - tx had control, 1 - rx has control • [3] - tx fifo overflow • [4] - tx fifo underflow • [5] - rx fifo overflow • [6] - rx fifo underflow • [7] - rx packet header has been received • [8] - all rx packet payload data has been receive d

45.11.5 MIPI_DSI_HOST_APB_PKT_IFx_DSI_HOST_PKT_FIFO_WR_LEVEL

Address: 40A9_0000h base + 290h offset = 40A9_0290h

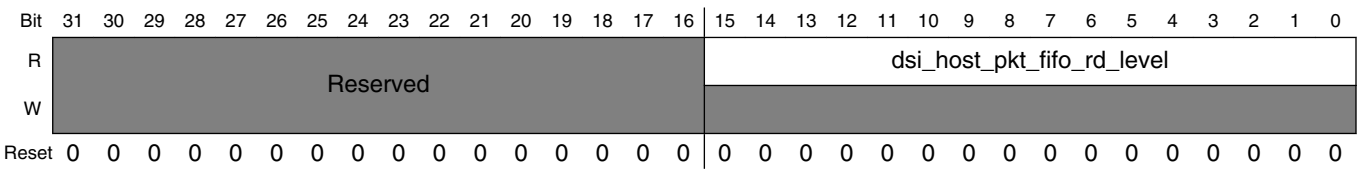


MIPI_DSI_HOST_APB_PKT_IFx_DSI_HOST_PKT_FIFO_WR_LEVEL field descriptions

Field	Description
31–16 -	This field is reserved.
dsi_host_pkt_ fifo_wr_level	Write level of APB to pkt interface fifo

45.11.6 MIPI_DSI_HOST_APB_PKT_IFx_DSI_HOST_PKT_FIFO_RD_LEVEL

Address: 40A9_0000h base + 294h offset = 40A9_0294h

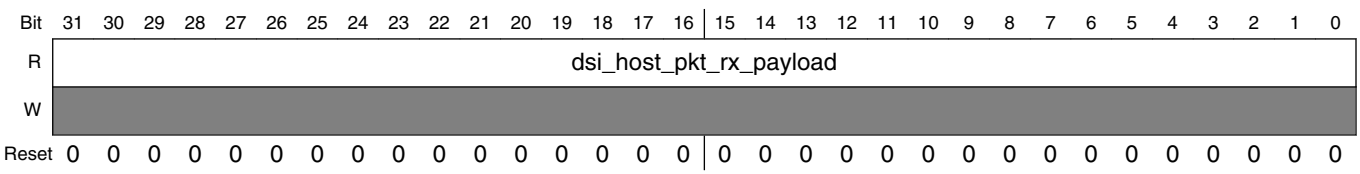


MIPI_DSI_HOST_APB_PKT_IFx_DSI_HOST_PKT_FIFO_RD_LEVEL field descriptions

Field	Description
31–16 -	This field is reserved.
dsi_host_pkt_ fifo_rd_level	Read level of APB to pkt interface fifo

45.11.7 MIPI_DSI_HOST_APB_PKT_IFx_DSI_HOST_PKT_RX_PAYLOAD

Address: 40A9_0000h base + 298h offset = 40A9_0298h

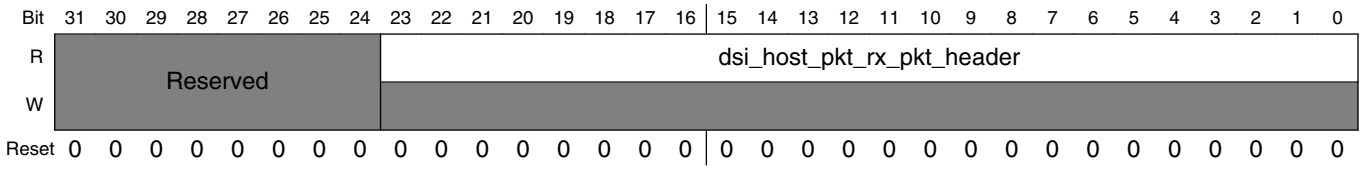


MIPI_DSI_HOST_APB_PKT_IFx_DSI_HOST_PKT_RX_PAYLOAD field descriptions

Field	Description
dsi_host_pkt_rx_ payload	APB to pkt interface rx payload read

45.11.8 MIPI_DSI_HOST_APB_PKT_IFx_DSI_HOST_PKT_RX_PKT_HEADER

Address: 40A9_0000h base + 29Ch offset = 40A9_029Ch

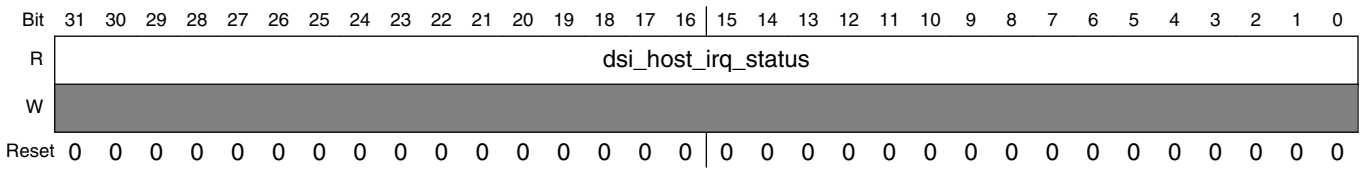


MIPI_DSI_HOST_APB_PKT_IFx_DSI_HOST_PKT_RX_PKT_HEADER field descriptions

Field	Description
31–24 -	This field is reserved.
dsi_host_pkt_rx_ pkt_header	APB to pkt interface rx packet header • [15:0] word count • [21:16] data type • [23:22] Virtual Channel

45.11.9 MIPI_DSI_HOST_APB_PKT_IFx_DSI_HOST_IRQ_STATUS

Address: 40A9_0000h base + 2A0h offset = 40A9_02A0h

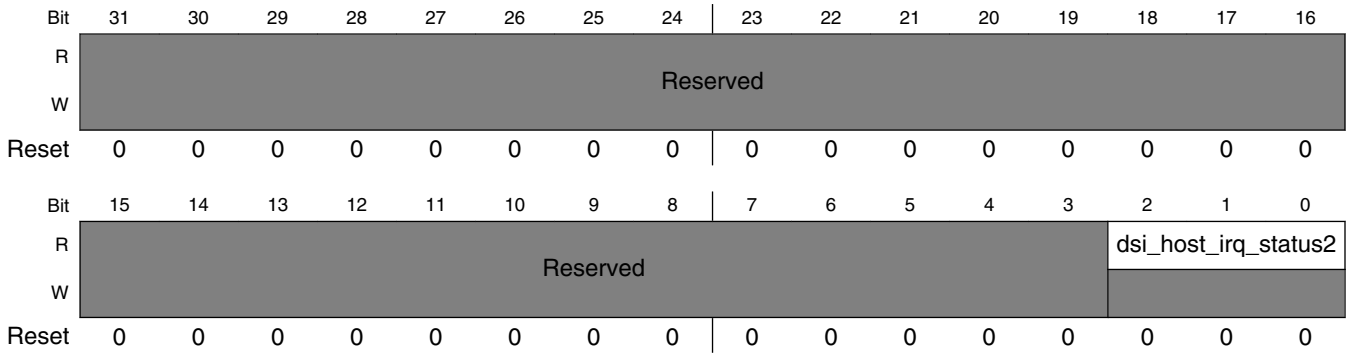


MIPI_DSI_HOST_APB_PKT_IFx_DSI_HOST_IRQ_STATUS field descriptions

Field	Description
dsi_host_irq_ status	Status of APB to packet interface • [0] - state machine not idle • [1] - Tx packet done • [2] - dphy direction 0 - tx had control, 1 - rx has control • [3] - tx fifo overflow • [4] - tx fifo underflow • [5] - rx fifo overflow • [6] - rx fifo underflow • [7] - rx packet header has been received • [8] - all rx packet payload data has been received • [28:9] - map directory to dsi host controller status_out port bit descriptions • [29] - host bta timeout, host controller host_bta_timeout port • [30] - low power rx timeout, host controller lp_rx_timeout port • [31] - high speed tx timeout, host controller hs_tx_timeout port

45.11.10 MIPI_DSI_HOST_APB_PKT_IFx_DSI_HOST_IRQ_STATUS2

Address: 40A9_0000h base + 2A4h offset = 40A9_02A4h

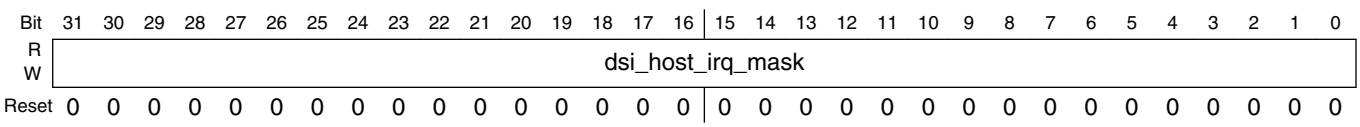


MIPI_DSI_HOST_APB_PKT_IFx_DSI_HOST_IRQ_STATUS2 field descriptions

Field	Description
31–3 -	This field is reserved.
dsi_host_irq_ status2	Status of APB to packet interface part 2. Read part 2 first then dsi_host_irq_status. Reading dsi_host_irq_status will clear both status and status 2. • [0] - single bit ecc error • [1] - multi bit ecc error • [2] - crc error

45.11.11 MIPI_DSI_HOST_APB_PKT_IFx_DSI_HOST_IRQ_MASK

Address: 40A9_0000h base + 2A8h offset = 40A9_02A8h



MIPI_DSI_HOST_APB_PKT_IFx_DSI_HOST_IRQ_MASK field descriptions

Field	Description
dsi_host_irq_ mask	irq mask • [0] - state machine not idle • [1] - Tx packet done • [2] - dphy direction 0 - tx had control, 1 - rx has control • [3] - tx fifo overflow • [4] - tx fifo underflow • [5] - rx fifo overflow • [6] - rx fifo underflow • [7] - rx packet header has been received • [8] - all rx packet payload data has been received • [28:9] - map directory to dsi host controller status_out port bit descriptions

MIPI_DSI_HOST_APB_PKT_IFx_DSI_HOST_IRQ_MASK field descriptions (continued)

Field	Description
	• [29] - host bta timeout, host controller host_bta_timeout port • [30] - low power rx timeout, host controller lp_rx_timeout port • [31] - high speed tx timeout, host controller hs_tx_timeout port

45.11.12 MIPI_DSI_HOST_APB_PKT_IFx_DSI_HOST_IRQ_MASK2

Address: 40A9_0000h base + 2ACh offset = 40A9_02ACh

46.1.1 2D Graphic processing unit (GPU-2D)

i.MX 7ULP integrates GPU for 2D graphic composition processing. The GC320 GPU-2D supports user interface rendering and performs functions like blending, filtering, rotation, overlay, resizing, transparency, and other dynamic effects.

The module uses 128-bit AXI master bus interface and 32-bit AHB slave bus interface

46.2 Overview

The 2D Graphics Processing Unit (GPU2D) is a high-performance multi-pipe 2D graphics core that accelerates the 2D graphics display on a variety of devices. The GPU2D supports a wide-range of addressable screen sizes and resolutions.

The R2D GPU Hardware acceleration is brought to numerous 2D applications including graphical user interfaces (GUI), menu displays, flash animation, and gaming.

46.3 GPU2D Block Diagram

46.3.1 R2D GPU

The R2D Graphics Processing Unit (GPU) defines a high-performance 2D raster graphics core that accelerates the 2D graphics display.

R2D GPU supports acceleration of the following graphics APIs:

- DirectFB (Linux / Linux Embedded)
- GDI / DirectDraw (Windows Embedded Compact 7 / Embedded CE 6)
- Android

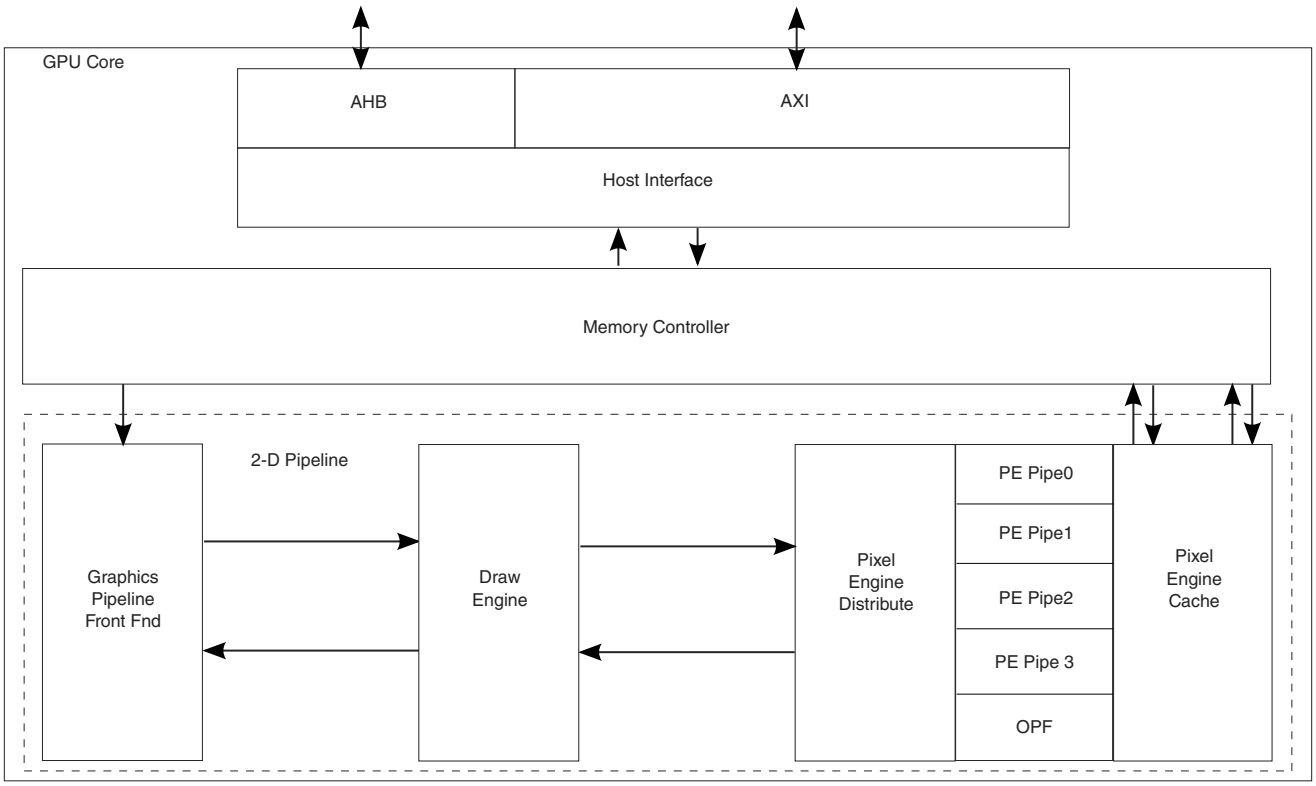

Figure 46-1. R2D GPU Block Diagram

46.4 GPU2D Features

The following sections describe the functional features of the R2D GPU.

46.4.1 Full Featured R2D GPU Pipeline

- Bit BLT
- Stretch BLT
- Rectangle fill and clear
- Line drawing
- Filter BLT
- Mono expansion for text rendering
- ROP2, ROP3, and ROP4
- Alpha blending, including Java 2 Porter-Duff compositing blending rules
- 32K x 32K coordinate system
- 90 / 180 / 270 degree rotation
- Transparency by monochrome mask, chroma key, or pattern mask
- Support 2x2 in 4x4 tile format

- A8 output with rotation in filter BLT and bit BLT
- SrC/Dest color key full bypass support

46.5 GPU2D OPERATIONS

46.5.1 R2D GPU Operations

Information detailing the R2D GPU operations can be found in this section.

46.5.1.1 Line

The LINE operation draws a line. Coordinates for two points are given: start point and end point. The end point is not drawn. Lines are rendered using the Bresenham algorithm. The Bresenham algorithm has the advantage of using integer arithmetic and has no accumulation of rounding errors.

In the case of line, only ROP2 and ROP4 are supported. It operates on pattern and destination. The pattern should have a transparency mask in order to use ROP4.

Clipping is supported for lines on a per pixel basis.

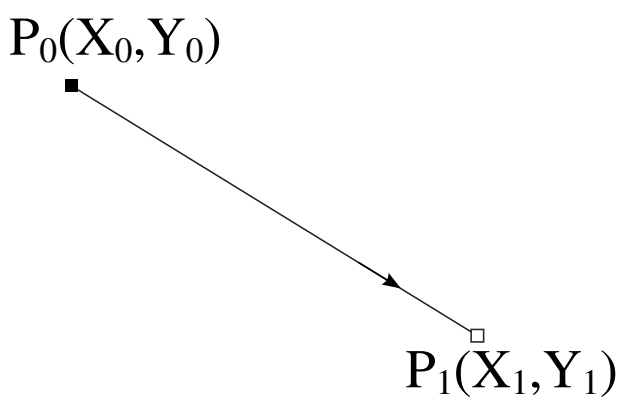

Figure 46-2. Line

46.5.1.2 Rectangle Fill and Clear

Rectangle fill creates a rectangle area with a given color or a pattern fill. Essentially rectangle fill is a pattern fill, where an 8x8 pattern is initialized with the specified color. It supports ROP2 and ROP4 with the pattern and destination as its inputs. If ROP4 is used, the pattern should have a transparency mask.

Clear is similar to Rectangle Fill except that it does not use a pattern. A 32-bit clear value with 4-bit byte mask is used to fill the entire rectangle area.

Both Rectangle Fill and Clear support clipping, which is performed on a per primitive basis.

46.5.1.3 BitBLT

Bit blit (BitBLT) transfers data from one area of a memory (source) to another area of the memory (destination).

The source and destination can be from the same or different memory locations. Both source and destination must be described by a rectangular area. The source and destination rectangles can be of the same size (most bit blits are of this nature) or of different sizes, in which case, the operation becomes a stretch or shrink blit.

BitBLT supports ROP2, ROP3, and ROP4 which includes source, destination and pattern, and an optional transparency color. Clipping can be performed on a primitive basis.

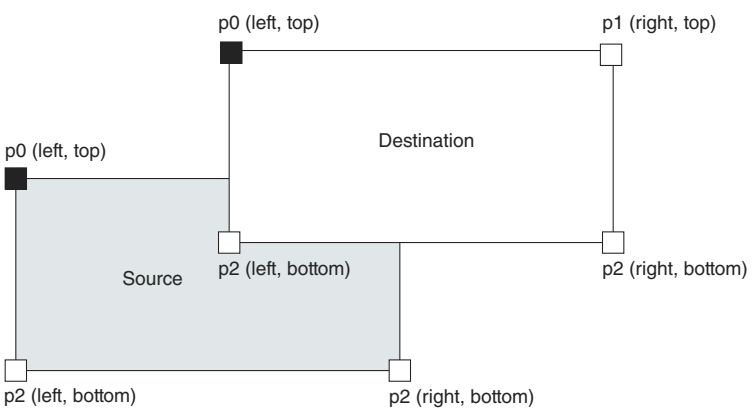

Figure 46-3. BitBLT

The graphics engine supports the following source and destination formats for data bit blits and filter blits. In addition to these source and destination RGB formats, their swizzle formats (ARGB, RGBA, ABGR, BGRA) are also supported. For YUV formats, the GPU supports their U/V swap formats.

Table 46-3. BitBLT Formats

Formats	Source Image	Destination Image
A1R5G5B5	Yes	Yes
A4R4G4B4	Yes	Yes
X1R5G5B5	Yes	Yes
X4R4G4B4	Yes	Yes
R5G6B5	Yes	Yes
A8R8G8B8	Yes	Yes
X8R8G8B8	Yes	Yes
A8	Yes	Yes
1-bit monochrome	Yes	No
8-bit color index	No	No
YUY2 (packed YUV422)	Yes	Yes
UYVY (packed YUV422)	Yes	Yes
YV12 (planar YUV420)	Yes	MD
NV12 (semi-planar YUV420)	Yes	MD
NV16 (semi-planar YUV422)	Yes	MD

MD = Multi-Destination support

46.5.1.4 Stretch BLT

The stretch blit (Stretch BLT) primitive performs a bit blt operation with stretch or shrink. The modified Bresenham algorithm is used to generate corresponding coordinates for fast stretching. The stretch factor is specified in a 15.0 fixed-point format. Stretch blit is not allowed to overlap, therefore no part of source and destination can share any piece of memory. Non-stretch blits can overlap. For stretch blit, clipping is performed on a per pixel basis.

46.5.1.5 Monochrome Expansion and Mask BLT

Monochrome expansion and mask blit are different operations, although both use the bit stream from command buffer and both can be the source for ROP4 source selection. This means that each output pixel can be a combination of source, pattern, monochrome mask (for masked blits) and destination.

46.5.1.5.1 Monochrome expansion

For monochrome expansion, the bit from the stream is used to switch on/off a solid color that is defined in a register. This mechanism enables the use of just one bit per pixel to represent colors. In effect, the MONO EXPANSION primitive increases color representation from one bit per pixel to multiple bits per pixel. A typical application for mono color is font drawing.

Monochrome expansion does not support overlapping of the source and destination. It is the responsibility of the driver to make sure that the command will never be executed with overlapping source and destination.

46.5.1.5.2 Mask BLT

For Mask BLT, the bit from the stream is used to toggle on/off a color in the source frame buffer. Mask BLT takes its color source from memory and its monochrome mask from the command stream. Clipping is supported and is performed on a per pixel basis.

46.5.1.6 Filter BLT

Filter blit performs high quality scaling, up or down, using an FIR re-sampling filter with up to 9 taps. The sub-pixel coordinates (locations between the pixel grids) are generated by the drawing engine. The filter block in the drawing engine uses the sub-pixel information to select the appropriate filter kernel. R2D GPU processes 1 pixel every cycle when performing filter blit.

A stretch- or shrink-factor of 15.16 fixed-point format is supported. To generate a single destination pixel requires 9 source pixels. An image is scaled in two passes, one for X-dimension (HOR_FILTER_BLT) and the other for Y-dimension (VER_FILTER_BLT). The software sets up the filter kernel/coefficient table and the kernel size, as well as a temporary buffer for storing intermediate results. After the first pass is completed, intermediate results are sent back to memory, and then the second pass starts to scale the first-pass image. Because of this two-step procedure, the throughput of FILTER BLT is lower than that of STRETCH BLT. Also the Filter Kernel Table may need to be reloaded, and some cycles are consumed in calculating the stepping parameters.

When the stretch or shrink factor is 1, the filterBlit works as a bitBlit copy. It can be used as format converter in that case, for instance, YUV to RGB converter. To use as a format converter, only one pass (HOR_FILTER_BLT or VER_FILTER_BLT) is needed. To optimize the memory bandwidth, when using filterBlit to do YUV to RGB filtering, the temporary target buffer format can be specified as YUY2 to process Y-dimension

filtering (VER_FILTER_BLT). This is to avoid converting YUV to A8R8G8B8 in the 1st vertical pass to reduce the memory bandwidth and increase the pixel processing rate. This is the only special case that GPU may use YUY2 as target format.

When the stretch or shrink factor (scale ratio) is not 1:1, filter blit requires both a vertical and a horizontal pass to do the scaling. Shrink performance will be less than 1 pixel per cycle for each vertical and horizontal pass. Stretch performance will be near to the performance for the 1:1 scale ratio.

The Filter BLT primitive supports the following source and destination image formats:

Table 46-4. Filter BLT Formats

Formats		Source Image	Destination Image
A1R5G5B5		Yes	Yes
A4R4G4B4		Yes	Yes
A8R8G8B8		Yes	Yes
R5G6B5		Yes	Yes
X1R5G5B5		Yes	Yes
X4R4G4B4		Yes	Yes
X8R8G8B8		Yes	Yes
YUV	NV12 (4:2:0, semi-planar)	Yes	No
	NV16 (4:2:2, semi-planar)	Yes	No
	UYVY (4:2:2, packed)	Yes	No
	YUY2 (4:2:2, packed)	Yes	Yv[1]
	YV12 (4:2:0)	Yes	No
	8-bit color index	Yes	No
	A8	Yes	Yes

1. Yv is possible only when vertical filter blit is done on YUV input.

46.5.1.7 R2D Performance of different operations

Table 46-5. Performance of different operations with/without rotation

Primitive	Peak Performance	Source/destination overlap	Clipping
Line	1 pixel / cycle	N/A	Done on pixel basis
Rectangle	2 pixel / cycle	N/A	Done on primitive basis
Clear	2 pixel / cycle	N/A	Done on primitive basis
Blit	2 pixel / cycle	Overlap is allowed	Done on primitive basis
Stretch blit	1~2 pixel / cycle	No overlap allowed	Done on pixel basis
Monochrome expansion	1 pixel / cycle	No overlap allowed	Done on pixel basis
Filter blit	1 pixel / cycle	N/A	Done on primitive basis

NOTE

The performance decreases for filter blit operations which require two passes.

46.5.1.8 Rotation

- 90° / 180° / 270° / Mirror rotation is supported for all primitives.
- Independent source rotation

46.5.1.9 Transparency Mode

For monochrome expansion:

- Opaque
- Conditional transparency: Transparent if the current pixel matches the specified value.

For blits:

- Opaque
- Masked transparency: Transparent if the mask for the current pixel or pattern is zero.
- Source Conditional transparency: Transparent if the source pixel is within the specified value range.
- Destination Conditional transparency: Transparent if the destination pixel is not within the specified value range.

46.5.1.10 Clipping

One clipping rectangle is supported for all bit blit primitives.

46.5.1.11 R2D GPU Data Formats

The graphics engine supports the following source and destination formats for data bit blits and filter blits. In addition to these source and destination RGB formats, their swizzle formats (ARGB, RGBA, ABGR, BGRA) are also supported. For YUV formats, the GPU supports their U/V swap formats.

Table 46-6. Data Formats

Format	Bit Blit Input	Bit Blit Output	Stretch Blit Input	Stretch Blit Dst	Filter Blit Input	Filter Blit Dst	OPF Input	OPF Dst	Multi-Source Input	Multi-Source Dst
A1R5G5B5	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
A4R4G4B4	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
A8R8G8B8	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
X1R5G5B5	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
X4R4G4B4	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
X8R8G8B8	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
R5G6B5	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
A8	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
YUY2 (packed YUV422)	Y	Y	Y	N	Y	Yv	Y	Y	Y	Y
UYVY (packed YUV422)	Y	Y	Y	N	Y	N	Y	Y	Y	Y
YV12 (planar YUV420)	Y	MD	Y	N	Y	N	Y	N	Y	N
NV12 (semi-planar YUV420)	Y	MD	Y	N	Y	N	Y	N	Y	N
NV16 (semi-planar YUV422)	Y	MD	Y	N	Y	N	Y	N	Y	N
8-bit color index	N	N	Y	N	Y	N	N	N	Y	N
1-bit monochrome	Y	N	N	N	N	N	N	N	N	N

Yv: Only possible when vertical filter blit is done on YUV input.
MD: Multi-Destination support

YUV output is available for packed or planar YUV input formats per the following table.

Table 46-7. YUV Output Support for Packed or Planar YUV Source per 2D Operation

2D Operation	Destination
Bit blit	Packed YUV
One Pass Filter (OPF)	Packed YUV
Multi-source	Packed YUV (no scaling)
Multi-destination	Planar YUV
Stretch blit	No
Two Pass Filter	No

46.5.1.12 ARGB Data Conversion of R2D GPU

The pixels read from source or destination will be expanded into A8R8G8B8 format to maintain lossless pixel operations. The resulting pixels will be converted into the destination format.

46.5.1.13 YUV to RGB Conversion of R2D GPU

YUV data can be converted into 8-bit per component RGB format at the output of the cache only. Once converted, there is no way back to YUV format. GPU supports BT.601 and BT.709 YUV to RGB color conversion standards.

In BT.601, the YUV to RGB conversion is done using the following approximation:

16 <= Y <= 235
16 <= U <= 240
16 <= V <= 240

A = Y - 16
B = U - 128
C = V - 128

R = clip((298*A + 410*C + 128) >> 8)
G = clip((298*A - 101*B - 209*C + 128) >> 8)
B = clip((298*A + 519*B + 128) >> 8)

The Y, U and V components are clamped prior to the conversion.
Y is clamped between 16 and 235, inclusively.
U and V are clamped between 16 and 240, inclusively.

In BT.709, the R, G, B equations are slightly changed to

R = clip((298*A + 461*C + 128) >> 8)
G = clip((298*A - 55*B - 137*C + 128) >> 8)
B = clip((298*A + 543*B + 128) >> 8)

46.5.1.14 Source/Destination Pre-multiply and De-Multiply Support

GPU supports source pre-multiply source alpha or global alpha, or source global color for global colorizing. On destination, the GPU supports destination pre-multiply destination alpha, destination de-multiply alpha.

46.5.1.15 Alpha Blending

The GPU supports alpha blending together with ROP. The alpha blending function is performed on ROP function result source.

The general alpha blending equations are:

Cd = Fs * Cs' + Fd * Cd'

Ad = Fs * As'' + Fd * Ad''

Where

- Cs' is the source color component (adjusted for NPM if necessary)
- Cd' is the destination color component (adjusted for NPM if necessary)
- As'' is the modified source alpha component
- Ad'' is the modified destination alpha component
- Fs is fraction of the source that contributes to the final value
- Fd is fraction of the destination that contributes to the final value

The blending is done in 5 logical stages (not real implementation stages):

1. Transparent/opaque conversion
   - In this stage, the incoming alpha (source or destination independently) can be inverted if needed to match the internal alpha rule. Internally, an alpha of 0 means transparent, while an alpha of "0xFF" means opaque. External content might follow the opposite rule. The output of the block is either As (Ad for destination) or 1-As (1-Ad for destination).
2. Global value substitution
   - A global alpha value from a register can be used to substitute or scale the incoming alpha. An incoming alpha As can pass-through, be directly substituted by Ags (global alpha) or scaled by the global alpha value (As * Ags). The source and destination have distinct global alpha values.
3. Blending factor generation
   - At this stage, the blending factors are generated (refer to table below). Each alpha can take the values 0, 1, A or 1-A depending on the blending mode.
4. Final blending
   - This is the final stage which implements blending equations.

   The fractions take the values described in the following table, depending on the blending mode.

Table 46-8. Blending Modes Fractions Description

Blending Mode	Fs	Fd
Clear	0	0
SRC	1	0
DST	0	1
SRC_OVER	1	1 - As"
DST_OVER	1 - Ad"	1
SRC_IN	Ad"	0
DST_IN	0	As"
SRC_OUT	1 - Ad"	0
DST_OUT	0	1 - As"
SRC_ATOP	Ad"	1 - As"
DST_ATOP	1 - Ad"	As"
XOR	1 - Ad"	1 - As"

To control the blending modes, the following register fields are used:

- 1 bit for transparent/opaque conversion for source alpha
- 1 bit for transparent/opaque conversion for destination alpha
- 2 bits for source alpha modifications, to specify the 3 cases (As, Ags, As*Ags)
- 2 bits for destination alpha modifications, to specify the 3 cases (Ad, Agd, Ad*Agd)
- 4 bits to select between the 12 blending modes
- 8 bits for global source alpha
- 8 bits for global destination alpha

Alpha blending is supported on bit blit and filter blit primitives.

46.5.1.16 GPU Multi-Source Blending

- Up to eight sources are supported.
- Programmable block size guarantees cache efficiency so each source is read once and each destination is written once.

- It supports 90, 180, 270 degree destination and source rotation and mirror with different block size to have high cache efficiency.
- It also supports ROP2, ROP3, and ROP4 which includes source, destination and pattern, and an optional transparency color. Alpha blending between every source is supported.

46.5.1.17 GPU Cache Management

The software cache flush is supported to flush the GPU cache to memory. Auto-flush of GPU cache is also supported. The software sets up the auto-flush interval, and hardware will do the cache flush automatically at programmable intervals.

47.2 Overview

The GPU3D is a high-performance core that delivers hardware acceleration for 3D graphics display.

Addressable screen sizes range from the smallest cell phones to HD 720p displays. It provides high performance, high quality graphics, low power consumption, and the smallest silicon footprint.

GPU3D accelerates numerous 3D graphics applications, including graphical user interfaces (GUI), menu displays, flash animation, and gaming. This module supports the following graphics APIs:

- OpenGL ES 2.0
- OpenGL ES 1.1
- OpenVG 1.1
- DirectX 11 (9_3)
- OpenGL 2.1
- EGL 1.4

47.3 GPU3D Block Diagram

The main functional units of the GPU3D are shown in the figure below and their description is as follows:

- Host Interface: Allows GPU3D to communicate with external memory and the CPU through AXI or AHB bus. In this block data crosses clock domain boundaries.
- Memory Controller: Internal memory management unit that controls the block-to-host memory request interface.
- Graphic Pipeline Front End: Inserts high level primitives and commands into the graphics pipeline.
- Ultra-threaded Unified Shader: SIMD processor that performs as both vertex shader and fragment shader. When used as a vertex shader it performs geometry transformations and lighting computations. When used as a fragment shader, it applies texture data and computes color values for each pixel. GPU3D has one such shader.
- 3D Rendering Engine: Converts triangles and lines into pixels. Computes slopes of color attributes and texture coordinates. Performs clipping.

- Texture Engine: Retrieves texture information from memory upon request by the fragment shader. Performs interpolation and filtering, and transfers the computed value to the fragment shader or the vertex shader.
- Pixel Engine/Resolve: Pixel engine does alpha blending and visible surface determination. Resolve does tiling and de-tiling.

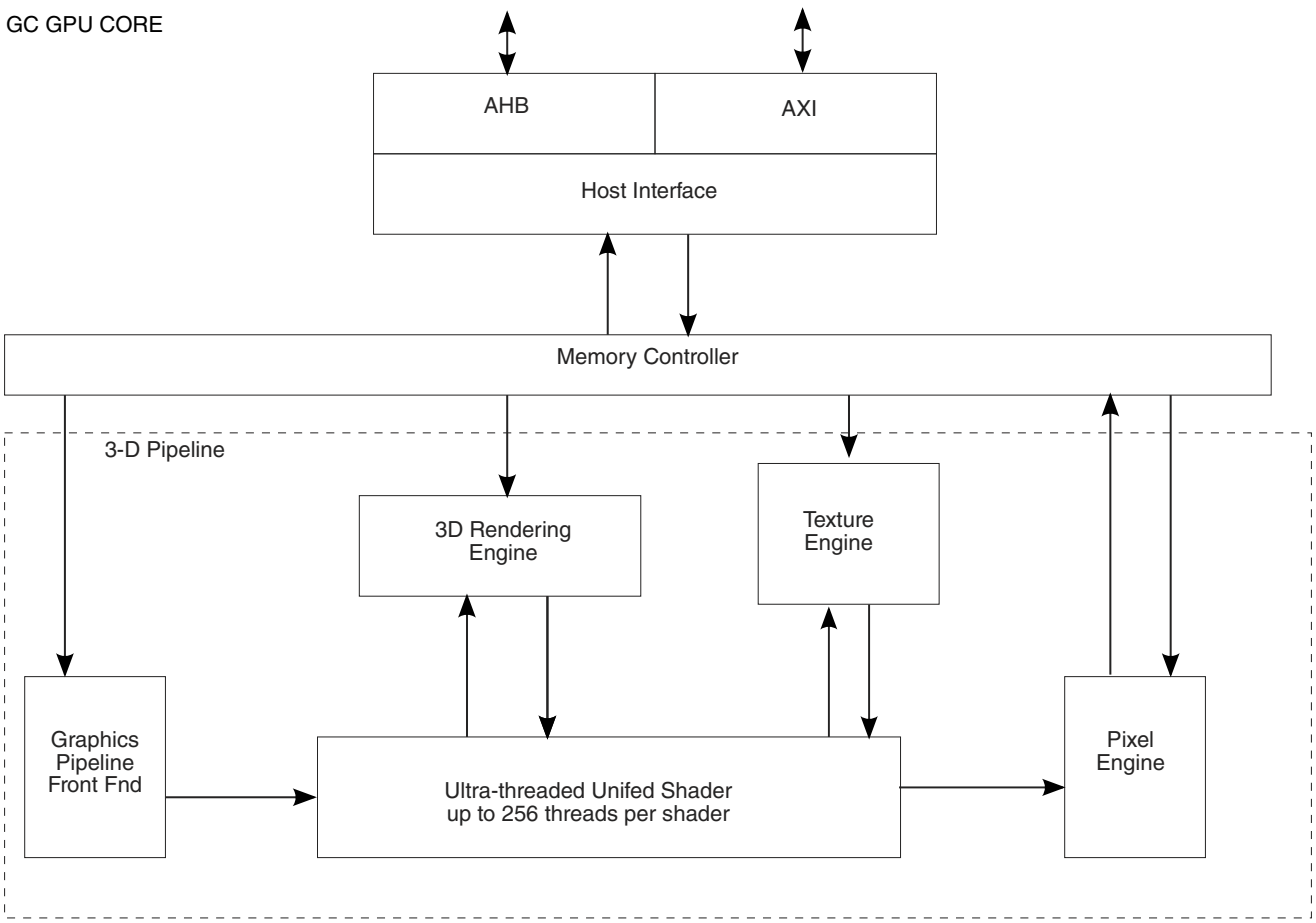

Figure 47-1. GPU3D Top Level Block Diagram

The core clock (core_clk) is the main clock for the processing control. The core clock configuration for the GPU is determined by the configuration of PFD on SCG and clock mux/dividers on PCC.

The GPU3D provides architectural support for the following features:

Table 47-3. GPU3D Architectural Support

Feature	GPU Support
Primary API	OpenGL ES1.1 and 2.0
Additional API's	OpenVG1.1
	DirectX 11 (9_3)

	OpenVG1.1
	EGL1.4
	DirectX 11 (9_3)
	OpenGL 2.1
Operating Systems	Windows Embedded Compact7, Embedded CE6
	Linux Embedded
	Android 4.x / 3.x / 2.x
Z (depth)	Early Z support included
Stencil	Early stencil support included
GLSL ES Shader languages	1.0
Shader types and execution units	One programmable Scalable Ultra-threaded Unified Shaders (SIMD4:ctl-flow,tx-load) one instruction issue per shader per clock; IEEE 32-bit floating-point pipeline supports long shader instructions
Big endian support	Available upon request
Shader model compatibility	SM3.0

47.4 GPU3D Hardware Features

The GPU3D block has the following hardware features:

- OpenGL ES 2.0 / 1.1 compliance, including extensions; OpenVG 1.1
- IEEE 32-bit floating-point pipeline
- Ultra-threaded, unified vertex and fragment shaders
- Low bandwidth at both high and low data rates
- Low CPU loading
- Up to 12 programmable elements per vertex
- Dependent texture operation with high-performance
- Alpha blending
- Depth and stencil compare
- Point sampling, bi-linear sampling, tri-linear filtering, and cubic textures
- Resolve and fast clear
- 8k x 8k texture size and 8k x 8k rendering target
- 4 Vertex DMA streams
- MMU functionality supported

Table 47-4. Unified vertex-fragment shader features

Feature	GPU Support
Shader type and execution units	Unified shader, SIMD4, SFP32 Trans
Swizzle capabilities	Full 32-bit word level swizzle in a 128-bit vector
GPR's per shader	Up to 512 general purpose registers, 128 bits each
Uniform registers	Total uniform registers: 320 (Uniform Vertex Shader: 256 registers, 128 bits each, and Uniform Fragment Shader: 256 registers, 128 bits each)
FP denorm and rounding options	Denorms are set to zero. Supports rounding to zero.
Maximum number of data input attributes	Maximum of 12 vertex shader input elements; Maximum of 8 fragment shader input elements;
Maximum number of instructions	256 for vertex and 256 for fragment shaders
Maximum number of vertex streams	4
Maximum number of threads in flight per shader core	256
Subroutines	4 levels
Conditional branch support	GT, LT, EQ, GE, LE, NE
Shader instruction rate	1-cycle throughput for all shader instructions
Floating-point instruction precision	SIMD4 (vector): 23.5 bits
Fragment shader video	Supports video texture
Samplers	Total 12:4 VS Samplers and 8PS Samplers

Table 47-5. Vertex Processing Features

Feature	GPU Support
Vx D3D, OGL ES formats supported	BYTE, UBYTE, SHORT, USHORT, INT, UINT, DEC, UDEC, FLOAT, FLOAT16, D3DCOLOR, FIXED16DOT16
Vertex data size limits	256 bytes
Pre shader cache	1 kB
Post shader cache	8 vertices

Table 47-6. Primitive Processing Features

Feature	GPU Support
Primitives supported	triangle strip, fan, and list; line strip and list; point list
Vertex/primitive geometry input index sizes	8-bit ,16-bit and 32-bit indices
Setup parameters available to fragment shader	8 vec4 parameters; all available to fragment shader

48.1.1 Liquid Crystal Display Interface (LCDIF)

The LCDIF is a general purpose display controller used to drive a wide range of display devices varying in size and capabilities. The LCDIF is used as a bridge (or gasket) between the DSI controller and the NIC0 crossbar. It uses 64-bit AXI master bus (Read only) as well as 32-bit IP Bus.

Table 48-2. LCDIF configuration

Parameter	Description
Name	Liquid Crystal Display Interface (LCDIF)
Supported standard version	MIPI DPI equivalent signal interface
Instances	1
Configurable features	No Read mode
Interface speed	NA
External I/O pins	LCDIF IO signals are internally connected to DSI controller DPI interface. There are no external signals available from the LCDIF.

48.1.2 Register Access

Any accesses made to LCDIF reserved addresses may incur on unknown effects.

48.2 Overview

The enhanced Liquid Crystal Display Interface (LCDIF) is a general purpose display controller

The LCDIF block supports the following:

- Displays that support moving pictures and require the RGB interface mode (DOTCLK interface).

The LCDIF provides fully programmable functionality to supported interfaces:

- Bus master interface to source frame buffer data for display refresh.
- 8/16/18/24 bit LCD data bus support available.
- Programmable timing and parameters for DOTCLK LCD interfaces.

48.3 External Signals

No LCDIF pin signals are pinned out on this chip.

48.4 Functional Description

Bus Interface Mechanisms through Initializing the LCDIF, describe the internal pipeline for the LCDIF interfaces. Differences for each mode are then described in separate sections, as follows:

- DOTCLK Interface

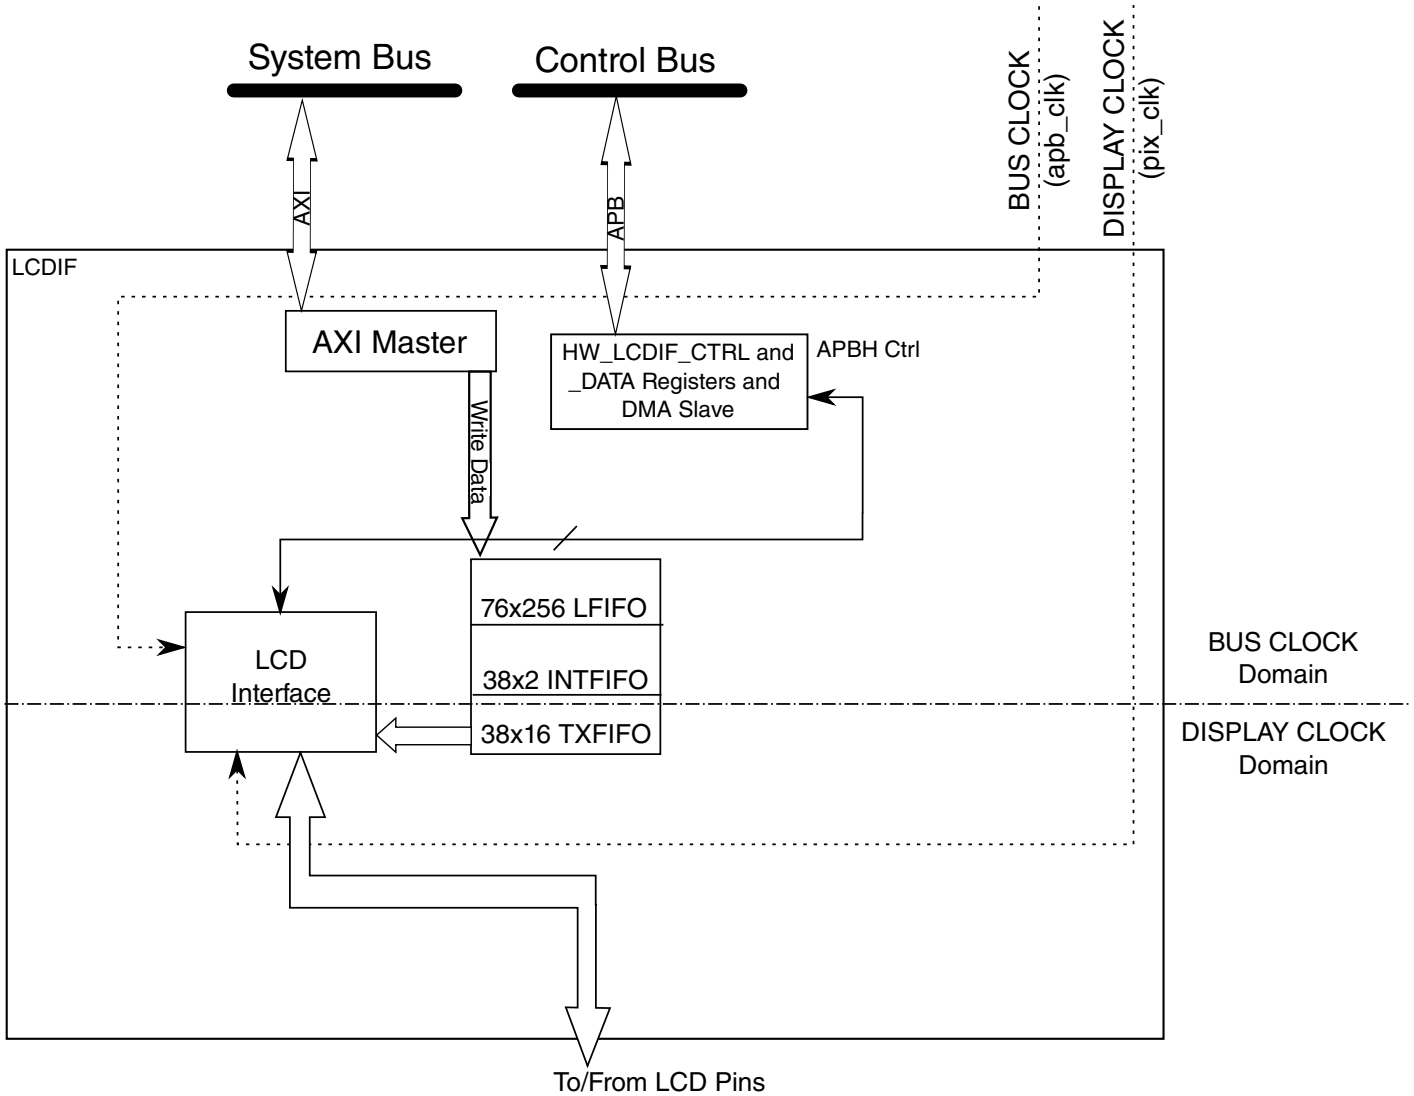

Figure 48-1. Top-Level Block Diagram of LCDIF subsystem

48.4.1 Bus Interface Mechanisms

The LCDIF module has memory-mapped control, data and status registers. It provides several interfaces to transfer data between the display and SoC.

The bus master interface is used to initiate the requests to transfer data from external memory to the display. It is completely autonomous, or no CPU intervention is required, to manage the cyclical nature of refreshing standard display types.

The host CPU executes display drivers to manage the display solution. The following sections describe the system bus interface mechanisms.

48.4.1.1 Bus Master Operation in Write/Display Modes

The LCDIF block has a bus master interface that initiates requests for data to drive the display. The LCDIF_MASTER bit must be set to 1 to enable the bus master interface. Software should program all control registers required to transfer the frame sequence.

The DOTCLK mode is used to refresh the display at the desired refresh rate and resolution, and drive displays that don't integrate a display buffer memory. When the display is refreshed, the LCDIF will automatically update the LCDIF_CUR_BUF_ADDR register with the value in LCDIF_NEXT_BUF_ADDR at the end of current frame and start fetching the next frame from the new address. If the LCDIF_NEXT_BUF_ADDR register was not updated within a frame refresh cycle, LCDIF will keep transmitting the last frame until a new value is programmed into that register.

48.4.1.2 System Bus Master Performance

The performance of the LCDIF block can be controlled by changing the burst length and the outstanding cycle issuing capability depending on the memory bandwidth requirements. Two fields in the LCDIF_CTRL2 register will throttle system memory requests. The LCDIF_CTRL2_OUTSTANDING_REQS field will control how many requests the LCDIF can have in flight on any given clock cycle. This should be programmed based on the expected system bus latency for returned read data. Also, the LCDIF_CTRL2_BURST_LEN_8 bit will set the number of 64 bit words requested for each LCDIF system bus request to either 8 or 16 QWORDS. Generally, 4 outstanding requests of length 16 will provide enough performance to drive any standard display resolution. These configuration bits are intended to change the access pattern of the LCDIF to optimize system bus throughput when other system masters will contend for system memory resources.

48.4.2 Write Data Path

LCDIF supports raster based frame buffers and there is no support for tiled buffers.

There are several options to accommodate endianness of display buffers in memory before the data is processed for the external display. The LCDIF_CTRL[INPUT_DATA_SWIZZLE] field provides the following options for data word multiplexing:

```
00 (0): No swizzle (little-endian)
01 (1): Swap bytes 0 and 3, swap bytes 1 and 2 (big-endian)
10 (2): Swap half-words
11 (3): Swap bytes within each half-word
```

The LCDIF_CTRL[WORD_LENGTH] field indicates the input data/pixel format. LCDIF_TRANSFER_COUNT register denotes how much data is contained in each frame. The LCDIF_TRANSFER_COUNT[H_COUNT] field indicates the number of pixels per line and LCDIF_TRANSFER_COUNT[V_COUNT] indicates the total number of lines per frame. The LCDIF_CTRL1[BYTE_PACKING_FORMAT] field can be used to specify which bytes within the 32-bit word are going to be valid. For example, if the entire 32-bit word is valid, LCDIF_CTRL1[BYTE_PACKING_FORMAT] should be set to 0xF, if only lower 3 bytes of each word in the frame buffer are valid, then LCDIF_CTRL1[BYTE_PACKING_FORMAT] should be set to 0x7.

The LCDIF_CTRL[LCD_DATABUS_WIDTH] field suggests the width of the bus going to the display controller. There is an option to source all 32 bits of the input word and transfer it to the output display interface. If the LCDIF_CTRL[LCD_DATABUS_WIDTH] is not the same as LCDIF_CTRL[WORD_LENGTH], LCDIF will perform RGB to RGB color space conversion. For example, if the input frame has fewer bits per pixel than the display, as in a 16 bpp input frame going to 24 bpp LCD, LCDIF will pad the MSBs of each color to the LSBs of the same color for each pixel. If the input frame has more bits per pixel than the display, for example, 24 bpp input frame going to 16 bpp LCD, LCDIF will drop the LSBs of each color channel to convert to the lower color depth. LCDIF also has the capability to support delta pixel displays by swizzling the R, G and B colors of each pixel in the odd and even lines of the frame separately by programming the LCDIF_CTRL2[ODD_LINE_PATTERN] and the LCDIF_CTRL2[EVEN_LINE_PATTERN] bit fields. This operation occurs after the RGB-to-RGB color space conversion operation.

The following list shows how the different input/output combinations can be obtained:

- LCDIF_CTRL[WORD_LENGTH]=1 indicates that the input is 8-bit data. This is most likely going to be used for a gray scale image. Any combination of LCDIF_CTRL1[BYTE_PACKING_FORMAT] is permissible.

  Limitation: LCDIF_TRANSFER_COUNT[H_COUNT] must be a multiple of the sum of BYTE_PACKING_FORMAT [3], BYTE_PACKING_FORMAT [2], BYTE_PACKING_FORMAT [1] and BYTE_PACKING_FORMAT [0]. LCDIF_CTRL[LCD_DATABUS_WIDTH] must be 1, indicating an 8-bit data bus.

- LCDIF_CTRL[WORD_LENGTH]=0 implies the input frame buffer is RGB 16 bits per pixel. LCDIF_CTRL[DATA_FORMAT_16_BIT] field determines the pixels are RGB 555 or RGB 565.

Limitation: LCDIF_CTRL1[BYTE_PACKING_FORMAT] should be 0x3 or 0xC if there is only one pixel per word. If there are two pixels per word, it should be 0xF and LCDIF_TRANSFER_COUNT[H_COUNT] will be restricted to be a multiple of 2 pixels.

- LCDIF_CTRL[WORD_LENGTH]=2 indicates that input frame buffer is RGB 18 bits per pixel, that is, RGB 666. The valid RGB values can be left-aligned or right-aligned within a 32-bit word. The alignment of the valid 18 bits within a word is indicated by the LCDIF_CTRL[DATA_FORMAT_18_BIT] bit.

  Limitation: LCDIF_CTRL1[BYTE_PACKING_FORMAT] can be 0x7, 0xE or 0xF. Packed pixels are not supported in this case.
  LCDIF_TRANSFER_COUNT[H_COUNT] can be any number.

- LCDIF_CTRL[WORD_LENGTH]=3 indicates that the input frame-buffer is RGB 24 bits per pixel (RGB 888). If LCDIF_CTRL1[BYTE_PACKING_FORMAT] is 0x7, it indicates that there is only one pixel per 32-bit word and there is no restriction on LCDIF_TRANSFER_COUNT[H_COUNT].

  Limitation: If LCDIF_CTRL1[BYTE_PACKING_FORMAT] is 0xF, it indicates that the pixels are packed, that is, there are 4 pixels in 3 words or 12 bytes and LCDIF_TRANSFER_COUNT[H_COUNT] must be a multiple of 4 pixels.

After the RGB to RGB color space conversions, there is one more opportunity to swizzle the data before sending it out to the display or the encoder. This can be done with the LCDIF_CTRL[CSC_DATA_SWIZZLE] field, and it provides the same options as the LCDIF_CTRL[INPUT_DATA_SWIZZLE] register.

Finally, there is an option to shift the output data before sending it out to the display. This is done based on the LCDIF_CTRL[SHIFT_DIR] and LCDIF_CTRL[SHIFT_NUM_BITS] fields.

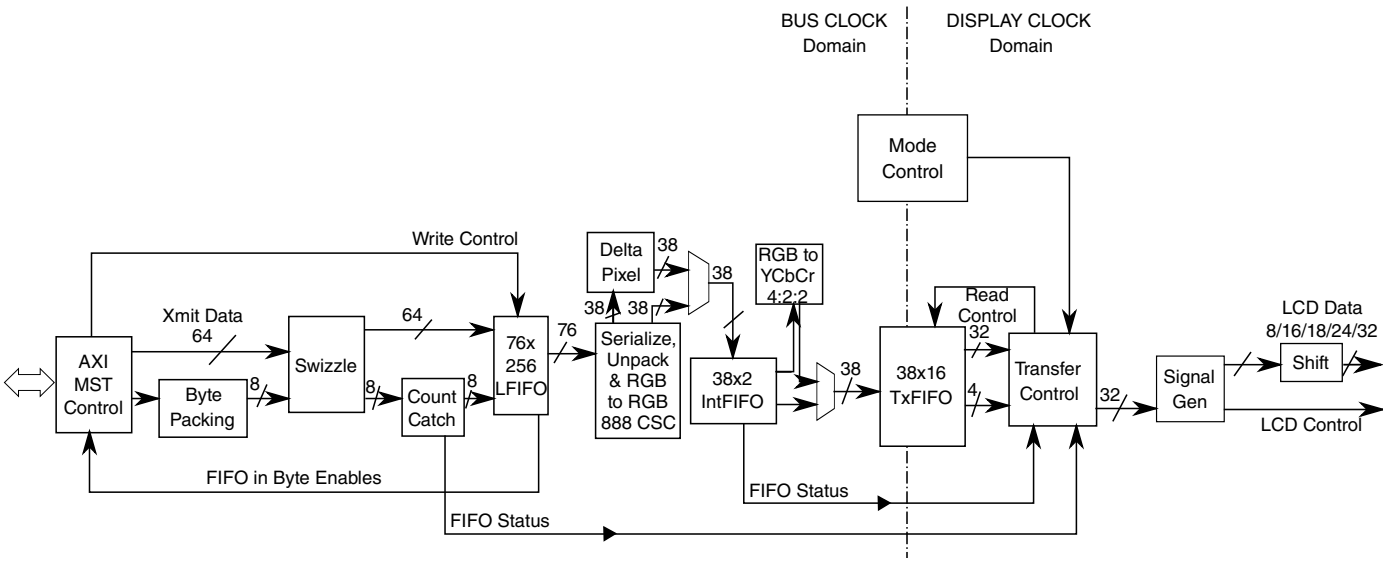

Figure 48-2. General Operations in Write Data Path

The examples in the following figures illustrate some different combinations of register programming for write mode. Assume that the data transferred over the system bus within a 32 bit word is organized as {A7-A0, B7-B0, C7-C0, D7-D0} in 8-bit mode and {A15-A0, B15-B0} in 16-bit mode.

In this example, all 32 bits of the input word are transferred out over an 8 bit display bus. Each byte within the 32 bit word is shifted to the right with zeros appended to bits D[7:6]. The input data bits [7:2] are shifted to the right by 2 bits and presented on the D[5:0].

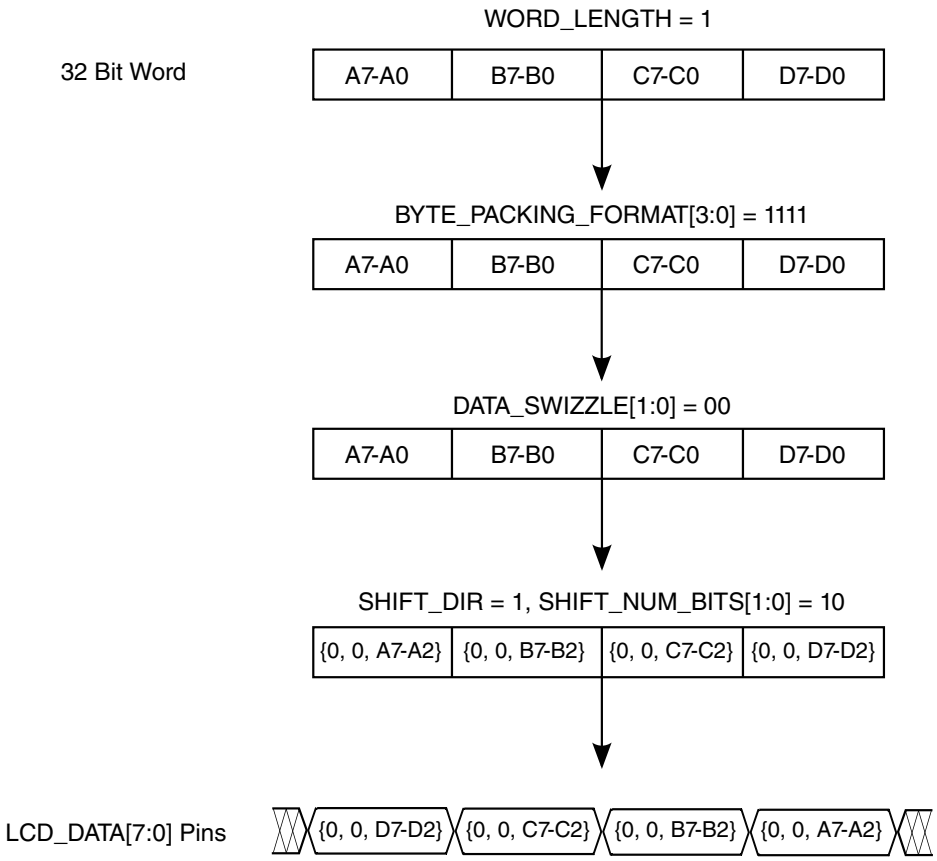

Figure 48-3. Register programming for write mode

In this 8 bit display interface example, one byte of the input word is deleted and not transferred over the external 8 bit display interface. This mode could be used to transfer 24bpp pixels over the 8 bit interface. In this case, the 4th unused byte is not transferred.

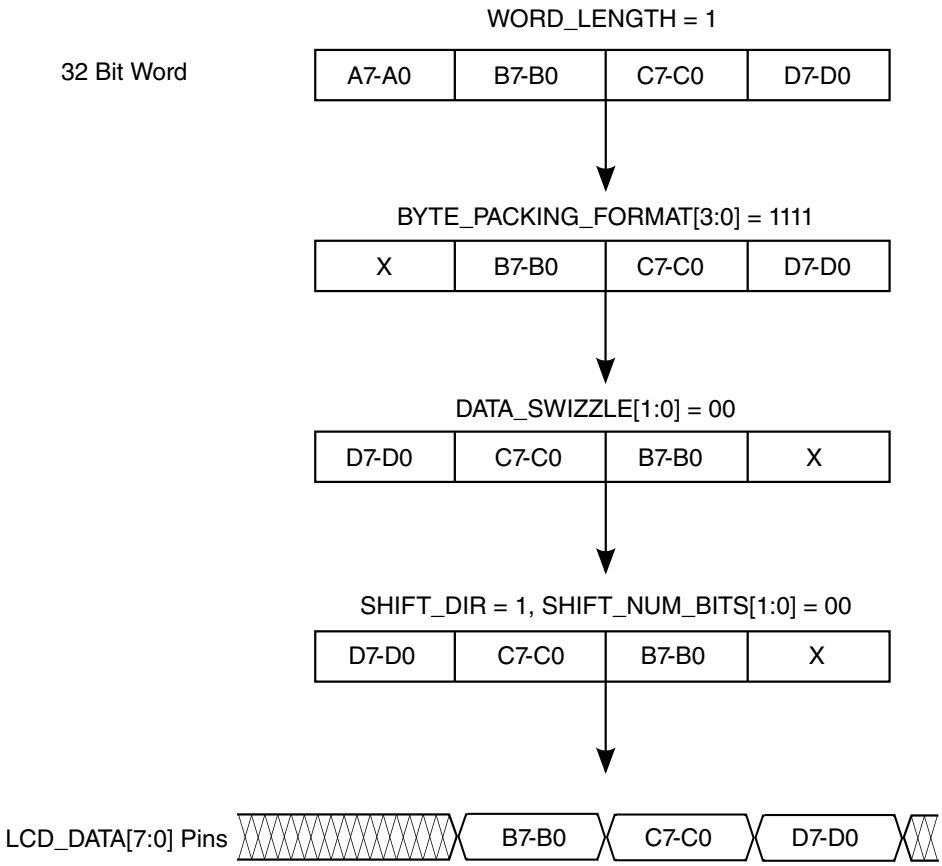

Figure 48-4. Register programming for write mode

The following example uses a 16 bit display interface. Each 16 bit half word is shifted to the right by two bits with zeros appended to the most significant two bits.

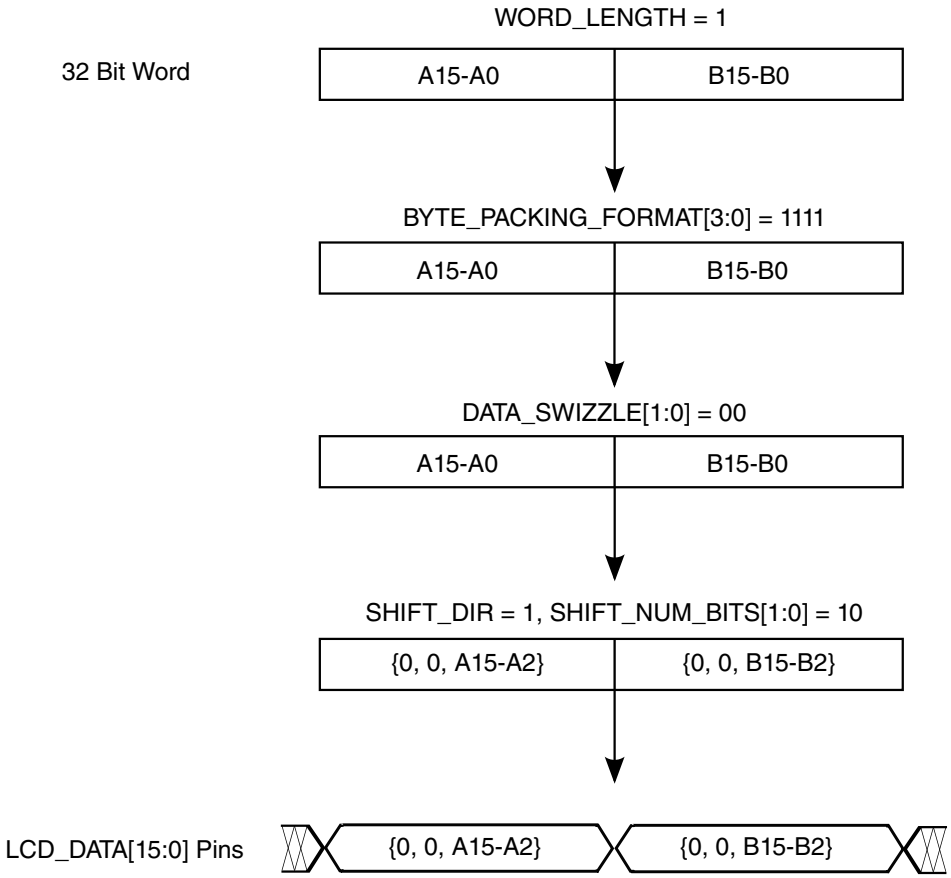

Figure 48-5. Register programming for write mode

This example indicates how an unpacked frame buffer can sourced for display. Only a single 16 bit half word within the 32 bit word is tranferred out via the 16 display bus.

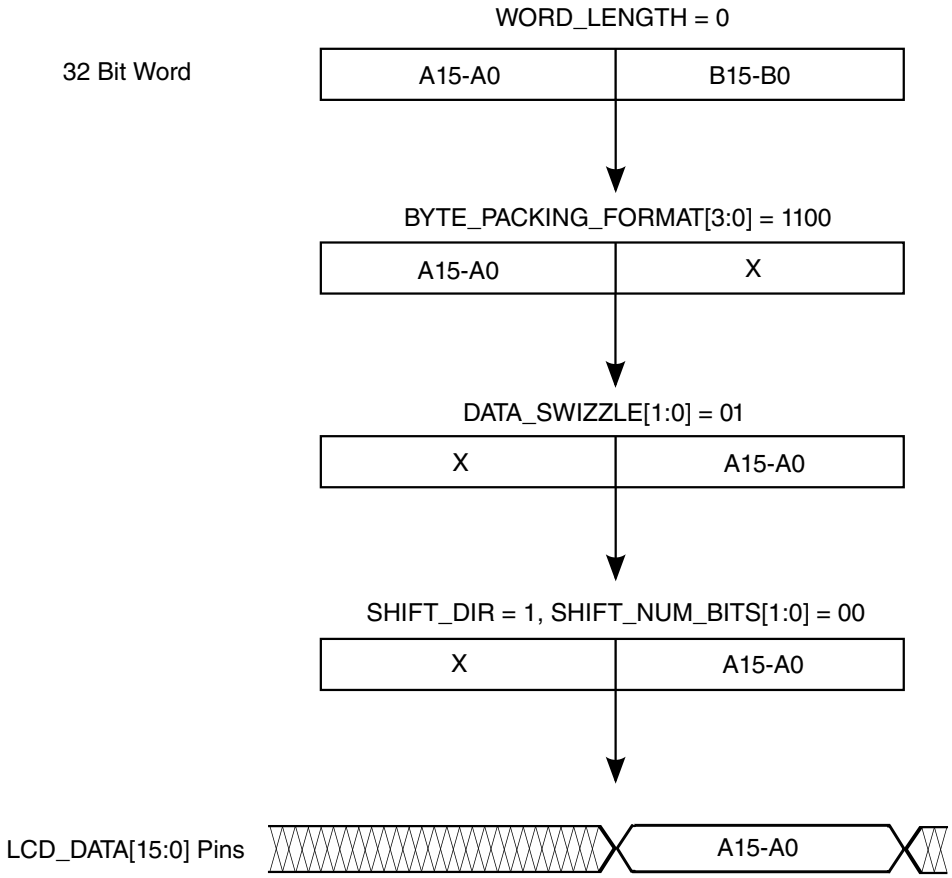

Figure 48-6. Register programming for write mode

48.4.3 LCDIF Interrupts

LCDIF supports a number of interrupts to aid controlling and status reporting of the block.

All the interrupts have individual mask bits for enabling or disabling each of them. They all get funneled through a single interrupt line connected to the interrupt collector (ICOLL).

The following list describes the different interrupts supported by LCDIF:

- Underflow interrupt is asserted when the clock domain crossing FIFO (TXFIFO) becomes empty but the block is in active display portion during that time. Software should take corrective action to make sure that this does not happen.
- In the bus master mode, the overflow interrupt will be asserted if the block has requested more data than it's FIFOs could hold.
- Cur_frame_done interrupt occurs at the end of every frame .

48.4.4 Initializing the LCDIF

This section describes write modes.

48.4.4.1 Write Modes

The following initialization steps are common to all LCDIF write modes of operation before entering any particular mode.

Initialization steps:

1. Configure the external I/Os to correctly interface the external display, when required.
2. Start the DISPLAY CLOCK (pix_clk) clock and set the appropriate frequency by programming the registers in SCG module.
3. Start the BUS CLOCK (apb_clk) and set the appropriate frequency by programming the registers in SCG module.
4. Bring the LCDIF out of soft reset and disable the clock gate bit.
5. Reset the LCD controller by setting LCDIF_CTRL1[RESET] bit appropriately, being careful to observe the reset requirements of the controller. See Behavior During Reset for more information on Reset requirements.
6. Set the transfer mode of operation to bus master. The LCDIF_CTRL[MASTER] bit determines the transfer mode selected. Bus master (LCDIF_CTRL[MASTER] =1) is the transfer mode to select.
7. Set the LCDIF_CTRL[INPUT_DATA_SWIZZLE] according to the endianness of the LCD controller. Also, set the LCDIF_CTRL[DATA_SHIFT_DIR] and LCDIF_CTRL[SHIFT_NUM_BITS] if it is required to shift the data left or right before it is output.
8. Set the LCDIF_CTRL[WORD_LENGTH] field appropriately: 0 = 16-bit input, 1 = 8-bit input, 2 = 18-bit input, 3 = 24/32-bit input. Also, select the correct 16/18/24 bit data format with the corresponding fields in LCDIF_CTRL register.
9. Set the LCDIF_CTRL1[BYTE_PACKING_FORMAT] field according to the input frame.
10. Set the LCDIF_CTRL[LCD_DATABUS_WIDTH] appropriately: 0 = 16-bit output, 1 = 8-bit output, 2 = 18-bit output, 3 = 24/32-bit output.
11. Enable the necessary IRQs.

48.4.5 DOTCLK Interface

The DOTCLK interface is another mode used in moving picture displays.

It includes the VSYNC, HSYNC, DOTCLK and (optional) ENABLE signals. The interface is popularly called the RGB interface if the ENABLE signal is present.

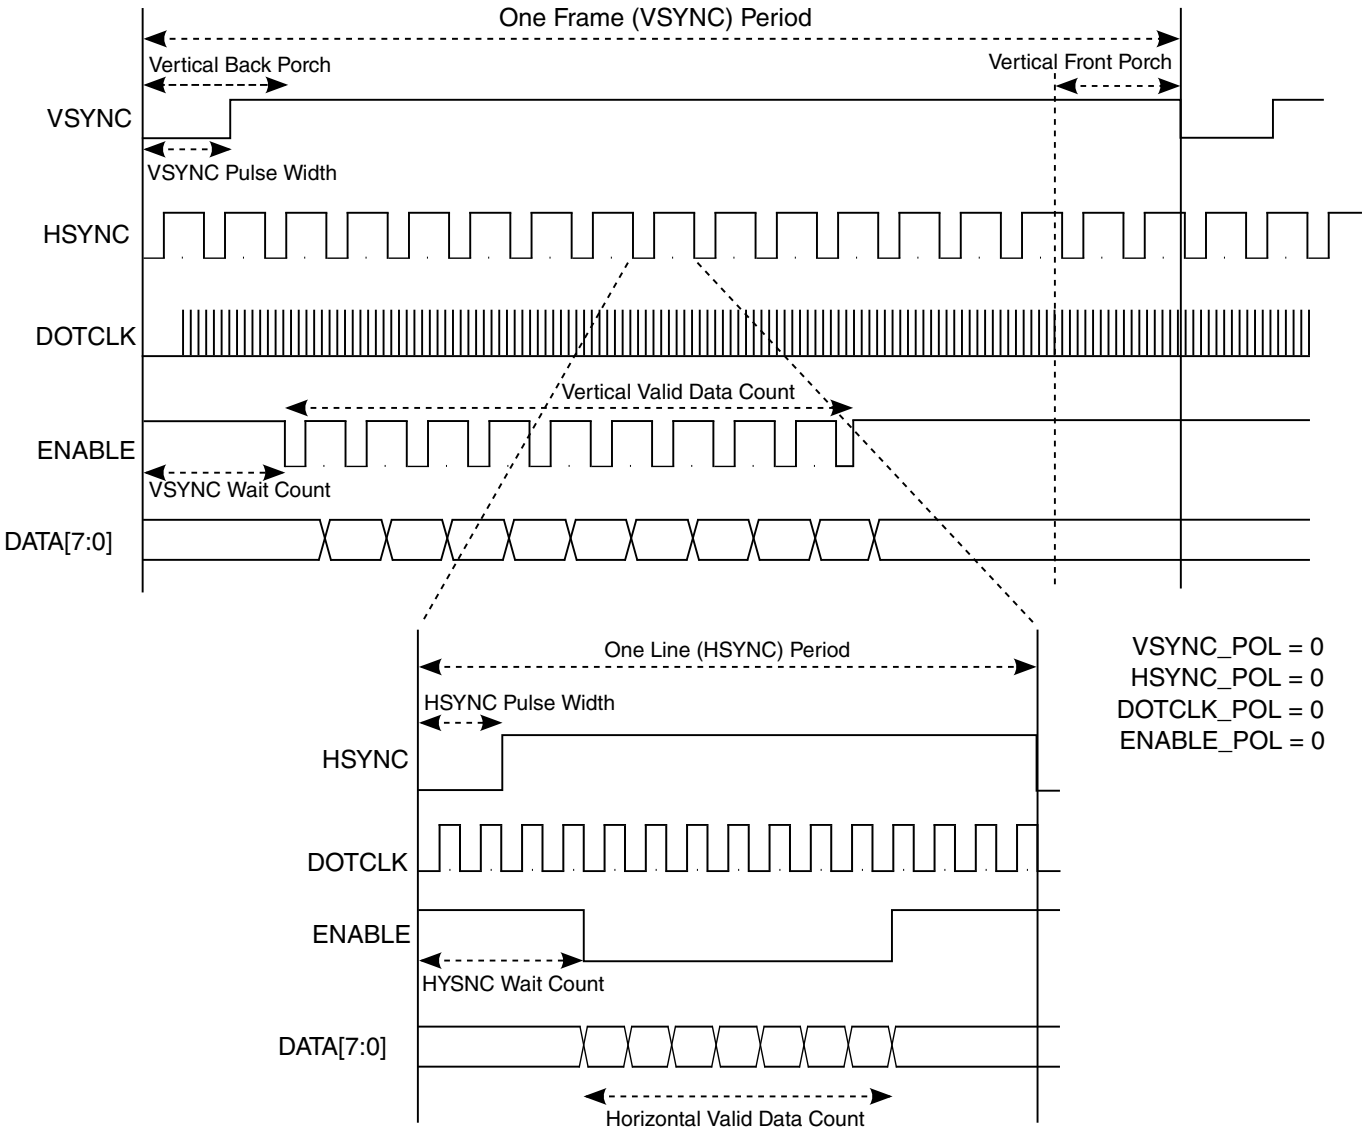

Figure 48-7. DOTCLK protocol with programmable parameters

The DOTCLK mode writes data at high speed to the LCD, and the display operation is synchronized with the VSYNC, HSYNC, ENABLE and DOTCLK signals. The polarities, periods and pulse-widths of the sync signals are programmable using the LCDIF_VDCTRL0-4 registers. The units for the VSYNC signal must be number of horizontal lines and can be selected using the VSYNC_PULSE_WIDTH_UNIT and VSYNC_PERIOD_UNIT bit fields. The VERTICAL_WAIT_CNT is by default given the same unit as the VSYNC_PERIOD. The DISPLAY CLOCK (pix_clk) frequency is managed by the SCG module.

In DOTCLK mode, LCDIF_CTRL_BYPASS_COUNT bit must be set to 1. To end the current transfer, the software should make the DOTCLK_MODE bit 0, so that all data that is currently in the LCDIF LFIFO and TXFIFO is transmitted. Once that transfer is complete, the block will automatically clear the RUN bit and issue the cur_frame_done interrupt.

48.4.5.1 Code Example

The following code shows an example for programming a 320x240 display.

NOTE

Setting up the display must be done via SPI.

```
// Note: Common initialization steps in Initializing the LCDIF must also be
// executed along with the following code
BF_CS1 (LCDIF_CTRL, DOTCLK_MODE, 1);
BF_CS1 (LCDIF_CTRL, BYPASS_COUNT, 1); //Always for DOTCLK mode
BF_CS1 (LCDIF_VDCTRL0, VSYNC_OEB, 0); //Vsync is always an output in the DOTCLK mode
BF_CS4 (LCDIF_VDCTRL0, VSYNC_POL, 0, HSYNC_POL, 0, DOTCLK_POL, 0, ENABLE_POL, 0);
BF_CS1 (LCDIF_VDCTRL0, ENABLE_PRESENT, 1);
BF_CS2 (LCDIF_VDCTRL0, VSYNC_PERIOD_UNIT, 1, VSYNC_PULSE_WIDTH_UNIT, 1);
BF_CS1 (LCDIF_VDCTRL0, VSYNC_PULSE_WIDTH, 2);
BF_CS1 (LCDIF_VDCTRL1, VSYNC_PERIOD, 280);
BF_CS2 (LCDIF_VDCTRL2, HSYNC_PULSE_WIDTH, 10, HSYNC_PERIOD, 360); //Assuming
                                                    //  LCD_DATABUS_WIDTH is 24bit
BF_CS2 (LCDIF_VDCTRL3, VSYNC_ONLY, 0);
BF_CS2 (LCDIF_VDCTRL3, HORIZONTAL_WAIT_CNT, 20, VERTICAL_WAIT_CNT, 20);
BF_CS1 (LCDIF_VDCTRL4, DOTCLK_H_VALID_DATA_CNT, 320);//Note that DOTCLK_V_VALID_DATA_CNT is
                              //implicitly assumed to be HW_LCDIF_TRANSFER_COUNT_V_COUNT
BF_CS1 (LCDIF_VDCTRL4, SYNC_SIGNALS_ON, 1);
BF_CS1 (LCDIF_CTRL, RUN, 1);
```

To stop the transfer completely, the ideal way is to make DOTCLK_MODE = 0. In that case, the block will transmit the contents in the FIFO and reset the RUN bit.

48.4.6 Alpha Blending Interface

The LCDIF have the capability to add an extra overlay on the normal display buffer,LCDIF can fetch data from two buffers and combine them before display,one buffer data can have the alpha value with the RGB pixels. With LCDIF_AS_CTRL[AS_ENABLE] is set, the LCDIF will start fetching alpha surface buffer data in bus master mode and combine it with another buffer.

The LCDIF_AS_CTRL[ALPHA_CTRL] bits determines how the alpha value is constructed for the alpha surface.

48.4.6.1 Alpha Blending/Color Key

Regardless of pixel input format, the PS and AS pixels are normalized to 32-bits, organized as one alpha and three data bytes. Alpha blending occurs in the RGB space, if blending is required, PS pixels should be converted to RGB space. If no alpha blending is required, then YUV pixels can bypass the alpha blending ALU without color space conversion.

48.4.6.2 Alpha Blend

The alpha value for an individual pixel represents a mathematical weighting factor applied to the AS pixel. An alpha value of 0x00 corresponds to a transparent pixel and a value of 0xFF corresponds to an opaque pixel.

The effective alpha value for an AS pixel is determined by the AS_CTRL[ALPHA] and AS_CTRL[ALPHA_CTRL] register fields. If AS_CTRL[ALPHA_CTRL] = ALPHA_OVERRIDE , the alpha value for the pixel is taken from the AS_CTRL[ALPHA] . This can be useful for applying a constant alpha to an entire image or for image formats that don't include an alpha value. If AS_CTRL[ALPHA_CTRL] = ALPHA_MULTIPLY, the pixel's alpha value will be multiplied by the pixel's ALPHA value in order to allow scaling of the pixel's alpha or to provide better control for pixel formats such as RGB1555, which only contains a single bit of alpha.

For each color channel, the equation used to blend two source pixels is defined below:

Gá = PIO programmed global alpha (8-bit value).
Eá = Embedded alpha associated with AS pixel.
á = Gá * Eá + 0x80

The result for the red channel as an example:

R[7:0] = (á * PS.r) + ((1 - á) * AS.r)

When á is 0xff, the PS pixel will not be blended with the AS pixel, but PS will be passed as the output pixel and will not be blended with AS. In this case, AS will be discarded. Likewise, if á is 0x00 for a given pixel, PS will be loaded as the output pixel.

AS_CTRL[ALPHA_INVERT] provides the option to invert the final alpha value. This essentially inverts the effect the alpha value has on the AS and PS blending operation.

48.4.6.3 Color Key

The color key function is provided to create transparent effects on the output pixel.

Color keying is applied on the input pixels after they are converted to 8-bits for each red, green, and blue color channels (color keys are not applied directly to 16-bit pixel formats but to their corresponding 24-bit representation). A color key range is programmable for both PS and AS pixels. If the PS 24-bit pixel is within the PS color key range, then AS is passed through the pixel pipeline. In this case, alpha blending does NOT occur. Conversely, if PS is within the AS color key range, then PS is passed via the LCDIF data pipeline. If both PS and AS color key tests pass, then the back ground color register is passed onto following LCDIF processing components in the pipeline.

The condition for color keying to be satisfied is:

CK0.r.low <= PS.r <= CK0.r.high

CK0.g.low <= PS.g <= CK0.g.high

CK0.b.low <= PS.b <= CK0.b.high

For example, if the "red" 8-bit value for the PS pixel (or PS.r) is between the color key low and high values (CK0.r.l and CK0.r.h), the condition is true for the red color plane. When ALL three color planes meet this condition, then only the PS pixel is loaded into the output register.

To disable color keying, program the low color key register value to 0xff and the high value to 0x00. This will guarantee that the color key range test will never be true.

48.4.6.4 Color Key Processing (AS_CTRL)

The AS_CTRL register also contains an ENABLE_COLORKEY bit that can be used to enable or disable color key substitution for the AS.

When enabled, the pixel values are compared to the ASCOLORKEYLOW and ASCOLORKEYHIGH registers to determine if a match has occurred. When an AS pixel matches the color key range, the pixel from the AS image is considered transparent and the corresponding PS pixel is rendered. If both the PS and AS pixels match their corresponding color key ranges, the AS pixel is displayed unmodified.

AS color keys are handled in a manner similar to PS color keys. The same images used in the PS color key example could be used with the images swapped. In this case, matches on the AS image to the ASCOLORKEY register would display the PS pixels.

48.5 Behavior During Reset

BUS CLOCK (apb_clk) and DISPLAY CLOCK (pix_clk) must be running before making any changes to SFTRST or CLKGATE bits.

A soft reset (SFTRST) can take multiple clock periods to complete, so do not set CLKGATE when setting SFTRST.

The reset process gates the clocks automatically.

48.6 LCDIF Memory Map/Register Definition

Some of the LCDIF registers (XXX_SET, XXX_CLR, and XXX_TOG) allow direct bit field masking and access.

- When writing 1 to XXX_SET bit fields, these registers allow setting the masked 1 bit fields, while keeping unchanged all bit fields which remain on 0 logic state.
- When writing 1 to XXX_CLR bit fields, these registers allow clearing the masked 1 bit fields, while keeping unchanged all other bit fields which remained on 0 logic state.
- When writing 1 to XXX_TOG bit fields, these registers allow inverting the logic state of all masked 1 bit fields, while they keep unchanged the remaining bit fields which were kept on 0 logic state.

LCDIF Hardware Register Format Summary

LCDIF memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
40AA_0000	LCDIF General Control Register (LCDIF0_CTRL)	32	R/W	C000_0000h	48.6.1/1971

48.6.1 LCDIF General Control Register (LCDIFx_CTRLn)

The LCD Interface Control Register provides overall control of the LCDIF block. The LCDIF Control Register provides a variety of control functions to the programmer. These functions allow the interface to be very flexible to work with a variety of LCD controllers, and to minimize overhead and increase performance of LCD programming. The register has been organized such that switching between the different LCD modes can be done with minimum PIO writes.

Address: 40AA_0000h base + 0h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LCDIFx_CTRLn field descriptions

Field	Description
31 SFTRST	This bit must be set to zero to enable normal operation of the LCDIF. When set to one, it forces a block level reset.
30 CLKGATE	This bit must be set to zero for normal operation. When set to one it gates off the clocks to the block.
29 -	Reserved
28 -	This field is reserved. Reserved

Table continues on the next page...

LCDIFx_CTRLn field descriptions (continued)

Field	Description
27 -	This field is reserved. Reserved
26 DATA_SHIFT_DIR	Use this bit to determine the direction of shift of transmit data. 0x0 **TXDATA_SHIFT_LEFT** — Data to be transmitted is shifted LEFT by SHIFT_NUM_BITS bits. 0x1 **TXDATA_SHIFT_RIGHT** — Data to be transmitted is shifted RIGHT by SHIFT_NUM_BITS bits.
25–21 SHIFT_NUM_BITS	The data to be transmitted is shifted left or right by this number of bits.
20 -	This field is reserved. Reserved
19 BYPASS_COUNT	When this bit is 0, it means that LCDIF will stop the block operation and turn off the RUN bit after the amount of data indicated by the LCDIF_TRANSFER_COUNT register has been transferred out. When this bit is set to 1, the block will continue normal operation indefinitely until it is told to stop. This bit must be 0 in MPU and VSYNC modes, and must be 1 in DOTCLK and DVI modes of operation.
18 -	This field is reserved. Reserved
17 DOTCLK_MODE	Set this bit to 1 to make the hardware go into the DOTCLK mode, i.e. VSYNC/HSYNC/DOTCLK/ENABLE interface mode. ENABLE is optional, selected by the ENABLE_PRESENT bit. Toggle this bit from 1 to 0 to make the hardware go out of DOTCLK mode after completing all data transfer and deasserting the RUN bit.
16 -	This field is reserved. Reserved
15–14 INPUT_DATA_SWIZZLE	This field specifies how to swap the bytes fetched by the bus master interface. The swizzle function is independent of the WORD_LENGTH bit. The supported swizzle configurations are: 0x0 **NO_SWAP** — No byte swapping.(Little endian) 0x0 **LITTLE_ENDIAN** — Little Endian byte ordering (same as NO_SWAP). 0x1 **BIG_ENDIAN_SWAP** — Big Endian swap (swap bytes 0,3 and 1,2). 0x1 **SWAP_ALL_BYTES** — Swizzle all bytes, swap bytes 0,3 and 1,2 (aka Big Endian). 0x2 **HWD_SWAP** — Swap half-words. 0x3 **HWD_BYTE_SWAP** — Swap bytes within each half-word.
13–12 CSC_DATA_SWIZZLE	This field specifies how to swap the bytes after the data has been converted into an internal representation of 24 bits per pixel and before it is transmitted over the LCD interface bus. The data is always transmitted with the least significant byte/hword (half word) first after the swizzle takes place. So, INPUT_DATA_SWIZZLE takes place first on the incoming data, and then CSC_DATA_SWIZZLE is applied. The swizzle function is independent of the WORD_LENGTH or the LCD_DATABUS_WIDTH fields. If RGB_TO_YCRCB422_CSC bit is set, the swizzle occurs on the Y, Cb, Cr values. The supported swizzle configurations are: 0x0 **NO_SWAP** — No byte swapping.(Little endian) 0x0 **LITTLE_ENDIAN** — Little Endian byte ordering (same as NO_SWAP). 0x1 **BIG_ENDIAN_SWAP** — Big Endian swap (swap bytes 0,3 and 1,2). 0x1 **SWAP_ALL_BYTES** — Swizzle all bytes, swap bytes 0,3 and 1,2 (aka Big Endian). 0x2 **HWD_SWAP** — Swap half-words. 0x3 **HWD_BYTE_SWAP** — Swap bytes within each half-word.
11–10 LCD_DATABUS_WIDTH	LCD Data bus transfer width. 0x0 **16_BIT** — 16-bit data bus mode.

Table continues on the next page...

LCDIF*x*_CTRL*n* field descriptions (continued)

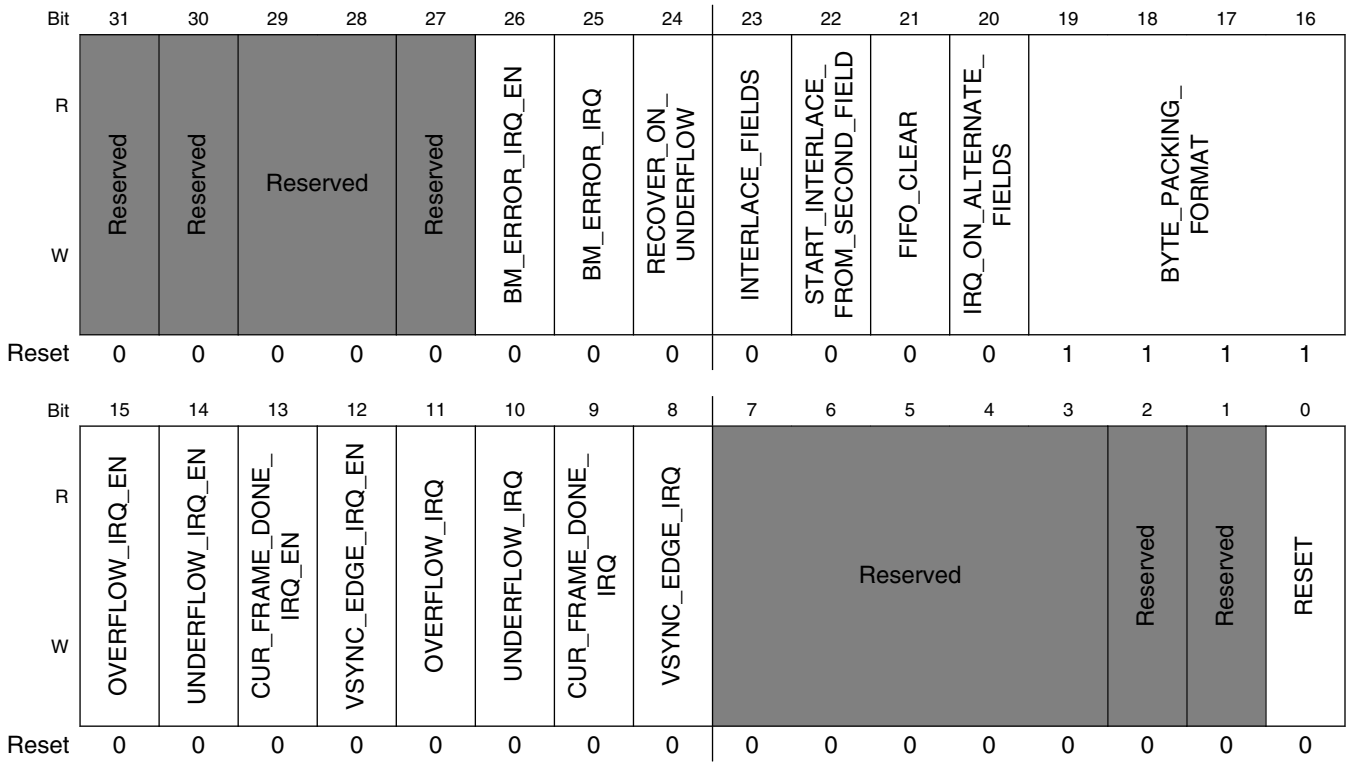
Field	Description
	0x1 **8_BIT** — 8-bit data bus mode. 0x2 **18_BIT** — 18-bit data bus mode. 0x3 **24_BIT** — 24-bit data bus mode.
9–8 WORD_LENGTH	Input data format. 0x0 **16_BIT** — Input data is 16 bits per pixel. 0x1 **8_BIT** — Input data is 8 bits wide. 0x2 **18_BIT** — Input data is 18 bits per pixel. 0x3 **24_BIT** — Input data is 24 bits per pixel.
7 -	This field is reserved. Reserved
6 -	This field is reserved. Reserved
5 MASTER	Set this bit to make the LCDIF act as a bus master.
4 RSRVD0	This field is reserved. Reserved bits. Write as 0.
3 DATA_ FORMAT_16_ BIT	When this bit is 1 and WORD_LENGTH = 0, it implies that the 16-bit data is in ARGB555 format. When this bit is 0 and WORD_LENGTH = 0, it implies that the 16-bit data is in RGB565 format. When WORD_LENGTH is not 0, this bit does not care.
2 DATA_ FORMAT_18_ BIT	Used only when WORD_LENGTH = 2, i.e. 18-bit. 0x0 **LOWER_18_BITS_VALID** — Data input to the block is in 18 bpp format, such that lower 18 bits contain RGB 666 and upper 14 bits do not contain any useful data. 0x1 **UPPER_18_BITS_VALID** — Data input to the block is in 18 bpp format, such that upper 18 bits contain RGB 666 and lower 14 bits do not contain any useful data.
1 DATA_ FORMAT_24_ BIT	Used only when WORD_LENGTH = 3, i.e. 24-bit. Note that this applies to both packed and unpacked 24-bit data. 0x0 **ALL_24_BITS_VALID** — Data input to the block is in 24 bpp format, such that all RGB 888 data is contained in 24 bits. 0x1 **DROP_UPPER_2_BITS_PER_BYTE** — Data input to the block is actually RGB 18 bpp, but there is 1 color per byte, hence the upper 2 bits in each byte do not contain any useful data, and should be dropped.
0 RUN	When this bit is set by software, the LCDIF will begin transferring data between the SoC and the display. This bit must remain set until the operation is complete.

48.6.2 LCDIF General Control1 Register (LCDIF*x*_CTRL1*n*)

The LCDIF Control Register provides overall control of the LCDIF block.

The LCDIF Control1 Register provides additional programming to the LCDIF. It implements some bits which are unlikely to change often in a particular application. It also carries interrupt-related bits which are common across more than one mode of operation.

Address: 40AA_0000h base + 10h offset + (4d × i), where i=0d to 3d



LCDIFx_CTRL1*n* field descriptions

Field	Description
31 -	This field is reserved. Reserved bits. Write as 0.
30 -	This field is reserved. Reserved bits. Write as 0.
29–28 -	This field is reserved. Reserved bits. Write as 0.
27 -	This field is reserved. Reserved.
26 BM_ERROR_IRQ_EN	This bit is set to enable bus master error interrupt in the LCDIF master mode.
25 BM_ERROR_IRQ	This bit is set to indicate that an interrupt is requested by the LCDIF block. This bit is cleared by software by writing a one to its SCT clear address. This bit will be set when the LCDIF is in master mode and an error response was returned by the slave. 0x0 **NO_REQUEST** — No Interrupt Request Pending. 0x1 **REQUEST** — Interrupt Request Pending.
24 RECOVER_ON_UNDERFLOW	Set this bit to enable the LCDIF block to recover in the next field/frame if there was an underflow in the current field/frame.
23 INTERLACE_FIELDS	Set this bit if it is required that the LCDIF block fetches odd lines in one field and even lines in the other field. It will work only in LCDIF_MASTER is set to 1.

Table continues on the next page...

LCDIF*x*_CTRL1*n* field descriptions (continued)

Field	Description
22 START_ INTERLACE_ FROM_ SECOND_FIELD	The default is to grab the odd lines first and then the even lines. Set this bit if it is required to grab the even lines first and then the odd lines. (Line numbers start from 1, so odd lines are 1,3,5,etc. and even lines are 2,4,6, etc.)
21 FIFO_CLEAR	Set this bit to clear all the data in the latency FIFO (LFIFO), TXFIFO and the RXFIFO.
20 IRQ_ON_ ALTERNATE_ FIELDS	If this bit is set, the LCDIF block will assert the cur_frame_done interrupt only on alternate fields, otherwise it will issue the interrupt on both odd and even field. This bit is mostly relevant if INTERLACE_FIELDS is set.
19–16 BYTE_ PACKING_ FORMAT	This bitfield is used to show which data bytes in a 32-bit word are valid. Default value 0xf indicates that all bytes are valid. For 8-bit transfers, any combination in this bitfield will mean valid data is present in the corresponding bytes. In the 16-bit mode, a 16-bit half-word is valid only if adjacent bits [1:0] or [3:2] or both are 1. A value of 0x0 will mean that none of the bytes are valid and should not be used. For example, set the bit field value to 0x7 if the display data is arranged in the 24-bit unpacked format (A-R-G-B where A value does not have be transmitted).
15 OVERFLOW_ IRQ_EN	This bit is set to enable an overflow interrupt in the TXFIFO in the write mode.
14 UNDERFLOW_ IRQ_EN	This bit is set to enable an underflow interrupt in the TXFIFO in the write mode.
13 CUR_FRAME_ DONE_IRQ_EN	This bit is set to 1 enable an interrupt every time the hardware enters in the vertical blanking state.
12 VSYNC_EDGE_ IRQ_EN	This bit is set to enable an interrupt every time the hardware encounters the leading VSYNC edge in the VSYNC and DOTCLK modes, or the beginning of every field in DVI mode.
11 OVERFLOW_ IRQ	This bit is set to indicate that an interrupt is requested by the LCDIF block. This bit is cleared by software by writing a one to its SCT clear address. A latency FIFO (LFIFO) overflow in the write mode (MPU/VSYNC/DOTCLK/DVI mode) was detected, data samples have been lost. 0x0 **NO_REQUEST** — No Interrupt Request Pending. 0x1 **REQUEST** — Interrupt Request Pending.
10 UNDERFLOW_ IRQ	This bit is set to indicate that an interrupt is requested by the LCDIF block. This bit is cleared by software by writing a one to its SCT clear address. A TXFIFO underflow in the write mode (MPU/VSYNC/DOTCLK/DVI mode) was detected. Could produce an error in the DOTCLK / DVI modes. 0x0 **NO_REQUEST** — No Interrupt Request Pending. 0x1 **REQUEST** — Interrupt Request Pending.
9 CUR_FRAME_ DONE_IRQ	This bit is set to indicate that an interrupt is requested by the LCDIF block. This bit is cleared by software by writing a one to its SCT clear address. It indicates that the hardware has completed transmitting the current frame and is in the vertical blanking period in the DOTCLK/DVI modes. In the MPU and VSYNC modes, this IRQ is asserted at the end of the data transfer indicated by LCDIF_TRANSFER_COUNT register. 0x0 **NO_REQUEST** — No Interrupt Request Pending. 0x1 **REQUEST** — Interrupt Request Pending.

Table continues on the next page...

LCDIF*x*_CTRL1*n* field descriptions (continued)

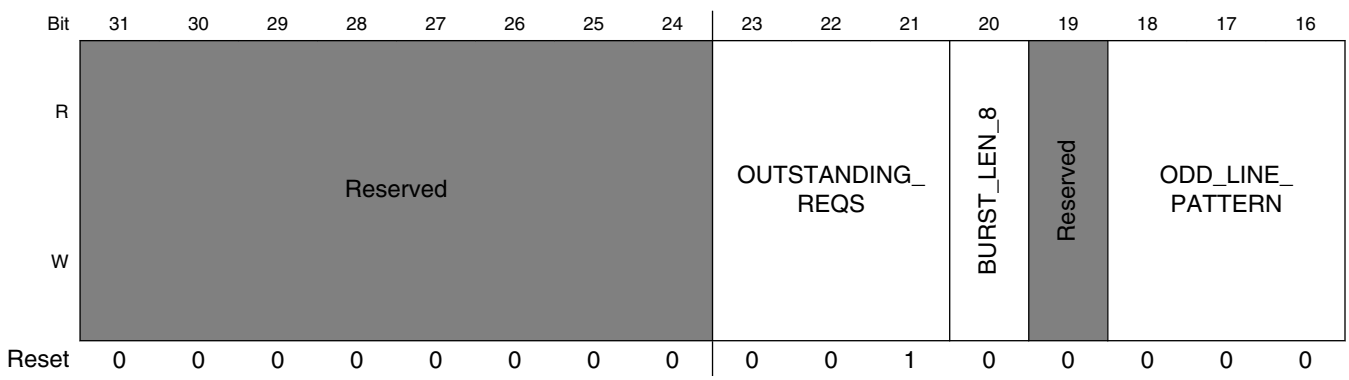
Field	Description
8 VSYNC_EDGE_IRQ	This bit is set to indicate that an interrupt is requested by the LCDIF block. This bit is cleared by software by writing a one to its SCT clear address. It is set whenever the leading VSYNC edge is detected in the VSYNC and DOTCLK modes. In the DVI mode, it is asserted every time the block enters a new field. 0x0 **NO_REQUEST** — No Interrupt Request Pending. 0x1 **REQUEST** — Interrupt Request Pending.
7–3 RSRVD0	This field is reserved. Reserved bits. Write as 0.
2 -	This field is reserved. Reserved
1 -	This field is reserved. Reserved.
0 RESET	Reset bit for the external LCD controller. This bit can be changed at any time. It CANNOT be reset by SFTRST. 0x0 **LCDRESET_LOW** — LCD_RESET output signal is low. 0x1 **LCDRESET_HIGH** — LCD_RESET output signal is high.

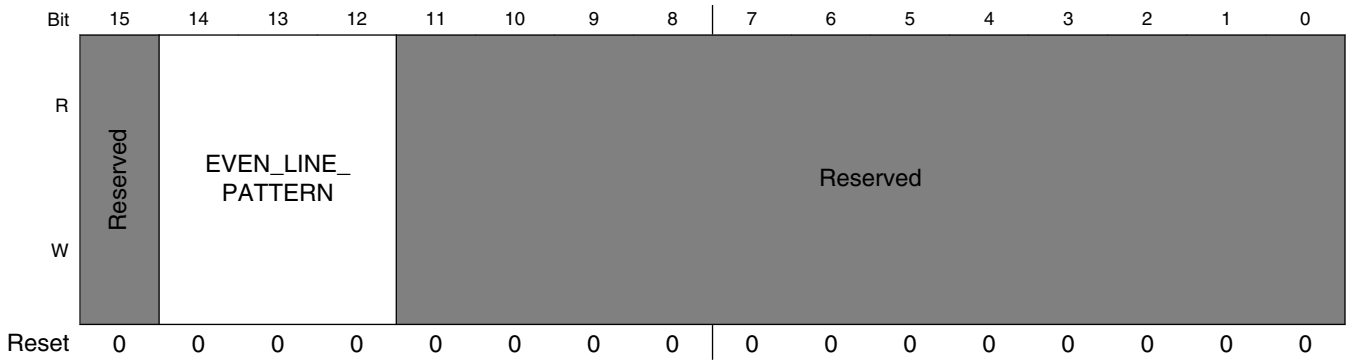
48.6.3 LCDIF General Control2 Register (LCDIF*x*_CTRL2*n*)

The LCDIF Control Register provides overall control of the LCDIF block.

The LCDIF Control2 Register provides additional programming to the LCDIF. It implements some bits which are unlikely to change often in a particular application.

Address: 40AA_0000h base + 20h offset + (4d × i), where i=0d to 3d





LCDIFx_CTRL2*n* field descriptions

Field	Description
31–24 RSRVD5	This field is reserved. Reserved bits. Write as 0.
23–21 OUTSTANDING_ REQS	This bitfield indicates the maximum number of outstanding transactions that LCDIF should request when it is acting as a bus master. Default is 2 outstanding transactions. 0x0 **REQ_1** — 0x1 **REQ_2** — 0x2 **REQ_4** — 0x3 **REQ_8** — 0x4 **REQ_16** —
20 BURST_LEN_8	By default, when the LCDIF is in the bus master mode, it will issue AXI bursts of length 16 (except when in packed 24 bpp mode, it will issue bursts of length 15). When this bit is set to 1, the block will issue bursts of length 8 (except when in packed 24 bpp mode, it will issue bursts of length 9). Note that this bitfield is only applicable when LCDIF_MASTER is set to 1.
19 RSRVD4	This field is reserved. Reserved bits. Write as 0.
18–16 ODD_LINE_ PATTERN	This field determines the order of the RGB components of each pixel in ODD lines (line numbers 1,3,5,..). 0x0 **RGB** — 0x1 **RBG** — 0x2 **GBR** — 0x3 **GRB** — 0x4 **BRG** — 0x5 **BGR** —
15 RSRVD3	This field is reserved. Reserved bits. Write as 0.
14–12 EVEN_LINE_ PATTERN	This field determines the order of the RGB components of each pixel in EVEN lines (line numbers 2,4,6,..). 0x0 **RGB** — 0x1 **RBG** — 0x2 **GBR** — 0x3 **GRB** — 0x4 **BRG** — 0x5 **BGR** —

Table continues on the next page...

LCDIFx_CTRL2n field descriptions (continued)

Field	Description
RSRVD0	This field is reserved. Reserved bits. Write as 0.

48.6.4 LCDIF Horizontal and Vertical Valid Data Count Register (LCDIFx_TRANSFER_COUNT)

This register tells the LCDIF how much data will be sent for this frame, or transaction. The total number of words is a product of the V_COUNT and H_COUNT fields. The word size is specified by the WORD_LENGTH field.

This register gives the dimensions of the input frame. For normal operation, but V_COUNT and H_COUNT should be non-zero.

Address: 40AA_0000h base + 30h offset = 40AA_0030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	V_COUNT																H_COUNT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIFx_TRANSFER_COUNT field descriptions

Field	Description
31–16 V_COUNT	Number of horizontal lines per frame which contain valid data. In DOTCLK mode, V_COUNT should be the same as the number of active horizontal lines in a progressive frame.
H_COUNT	Total valid data (pixels) in each horizontal line. The data size is given by the WORD_LENGTH. In 24-bit packed format (WORD_LENGTH=0x3, BYTE_PACKING_FORMAT=0xF), the H_COUNT must be a multiple of 4 pixels. In 16-bit packed format (WORD_LENGTH=0x0, BYTE_PACKING_FORMAT=0xF), the H_COUNT must be a multiple of 2 pixels.

48.6.5 LCD Interface Current Buffer Address Register (LCDIFx_CUR_BUF)

This register indicates the address of the current frame being transmitted by LCDIF.

When the LCDIF is behaving as a master, this address points to the address of the current frame of data being sent out via the LCDIF. When the current frame is done, the LCDIF block will assert the cur_frame_done interrupt for software to take action. The block will also copy the LCDIF_NEXT_BUF_ADDR into this bitfield so that the software can program the next frame address into the LCDIF_NEXT_BUF_ADDR bitfield. This address must always be double-word aligned.

Address: 40AA_0000h base + 40h offset = 40AA_0040h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIF*x*_CUR_BUF field descriptions

Field	Description
ADDR	Address of the current frame being transmitted by LCDIF.

48.6.6 LCD Interface Next Buffer Address Register (LCDIF*x*_NEXT_BUF)

This register indicates the address of next frame that will be transmitted by LCDIF.

When the LCDIF is behaving as a master, this address points to the address of the next frame of data that will be sent out via the LCDIF. It is up to the software to make sure that this register is programmed before the end of the current frame, otherwise it might result in old data going out the LCDIF. This address must always be double-word aligned.

Address: 40AA_0000h base + 50h offset = 40AA_0050h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIF*x*_NEXT_BUF field descriptions

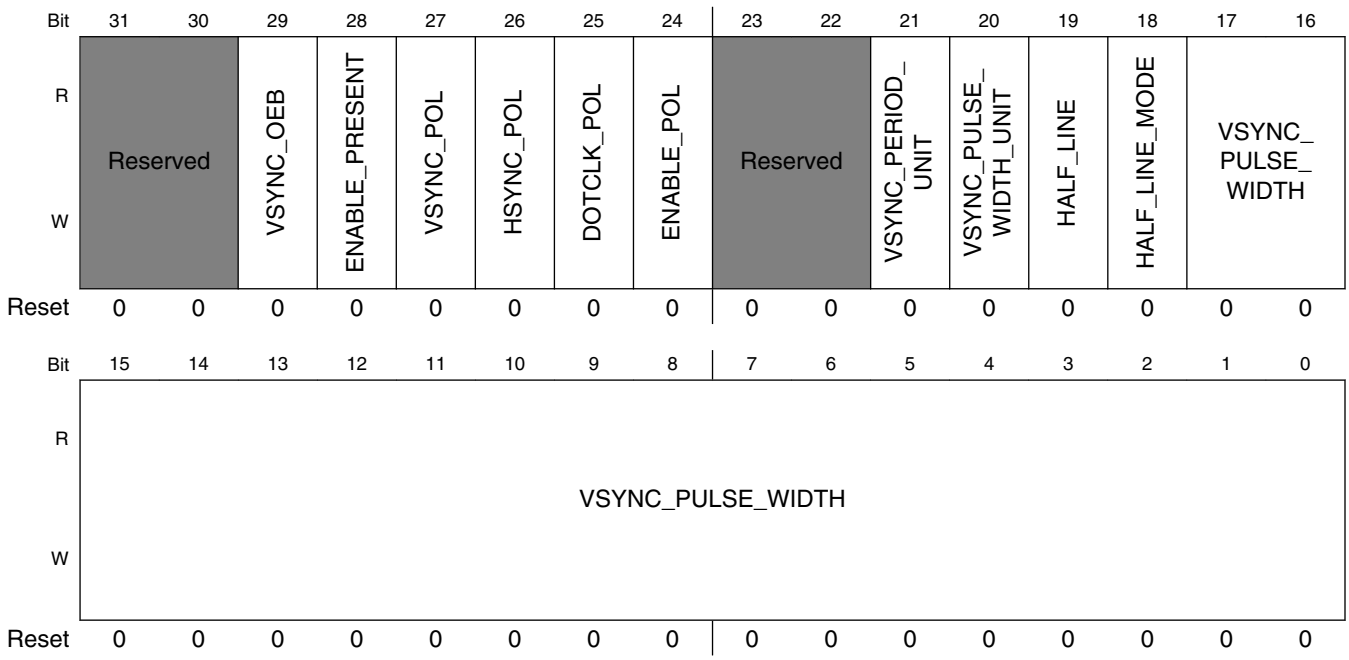
Field	Description
ADDR	Address of the next frame that will be transmitted by LCDIF.

48.6.7 LCDIF VSYNC Mode and Dotclk Mode Control Register0 (LCDIF*x*_VDCTRL0*n*)

This register is used to control the VSYNC and DOTCLK modes of the LCDIF so as to work with different types of LCDs like moving picture displays and delta pixel displays.

This register gives general programmability to the VSYNC signal including polarity, direction, pulse width, etc.

Address: 40AA_0000h base + 70h offset + (4d × i), where i=0d to 3d



LCDIFx_VDCTRL0*n* field descriptions

Field	Description
31–30 RSRVD2	This field is reserved. Reserved bits. Write as 0.
29 VSYNC_OEB	0 means the VSYNC signal is an output, 1 means it is an input. Should be set to 0 in the DOTCLK mode. 0x0 **VSYNC_OUTPUT** — The VSYNC pin is in the output mode and the VSYNC signal has to be generated by the LCDIF block. 0x1 **VSYNC_INPUT** — The VSYNC pin is in the input mode and the LCD controller sends the VSYNC signal to the block.
28 ENABLE_ PRESENT	Setting this bit to 1 will make the hardware generate the ENABLE signal in the DOTCLK mode, thereby making it the true RGB interface along with the remaining three signals VSYNC, HSYNC and DOTCLK.
27 VSYNC_POL	Default 0 active low during VSYNC_PULSE_WIDTH time and will be high during the rest of the VSYNC period. Set it to 1 to invert the polarity.
26 HSYNC_POL	Default 0 active low during HSYNC_PULSE_WIDTH time and will be high during the rest of the HSYNC period. Set it to 1 to invert the polarity.
25 DOTCLK_POL	Default is data launched at negative edge of DOTCLK and captured at positive edge. Set it to 1 to invert the polarity. Set it to 0 in DVI mode.
24 ENABLE_POL	Default 0 active low during valid data transfer on each horizontal line.
23–22 RSRVD1	This field is reserved. Reserved bits. Write as 0.
21 VSYNC_ PERIOD_UNIT	Default 0 for counting VSYNC_PERIOD in terms of DISPLAY CLOCK (pix_clk) cycles. Set it to 1 to count in terms of complete horizontal lines. DISPLAY CLOCK (pix_clk) cycles should be used in the VSYNC mode, while horizontal line should be used in the DOTCLK mode.
20 VSYNC_PULSE_ WIDTH_UNIT	Default 0 for counting VSYNC_PULSE_WIDTH in terms of DISPLAY CLOCK (pix_clk) cycles. Set it to 1 to count in terms of complete horizontal lines.

Table continues on the next page...

LCDIFx_VDCTRL0*n* field descriptions (continued)

Field	Description
19 HALF_LINE	Setting this bit to 1 will make the total VSYNC period equal to the VSYNC_PERIOD field plus half the HORIZONTAL_PERIOD field (i.e. VSYNC_PERIOD field plus half horizontal line), otherwise it is just VSYNC_PERIOD. Should be only used in the DOTCLK mode, not in the VSYNC interface mode.
18 HALF_LINE_ MODE	When this bit is 0, the first field (VSYNC period) will end in half a horizontal line and the second field will begin with half a horizontal line. When this bit is 1, all fields will end with half a horizontal line, and none will begin with half a horizontal line.
VSYNC_PULSE_ WIDTH	Number of units for which VSYNC signal is active. For the DOTCLK mode, the unit is determined by the VSYNC_PULSE_WIDTH_UNIT. If the VSYNC_PULSE_WIDTH_UNIT is 0 for DOTCLK mode, VSYNC_PULSE_WIDTH must be less than HSYNC_PERIOD. For the VSYNC interface mode, it should be in terms of number of DISPLAY CLOCK (pix_clk) cycles only.

48.6.8 LCDIF VSYNC Mode and Dotclk Mode Control Register1 (LCDIFx_VDCTRL1)

This register is used to control the VSYNC signal in the VSYNC and DOTCLK modes of the block.

This register determines the period and duty cycle of the VSYNC signal when it is generated in the block.

Address: 40AA_0000h base + 80h offset = 40AA_0080h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	VSYNC_PERIOD																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIFx_VDCTRL1 field descriptions

Field	Description
VSYNC_PERIOD	Total number of units between two positive or two negative edges of the VSYNC signal. If HALF_LINE is set, it is implicitly calculated to be VSYNC_PERIOD plus half HSYNC_PERIOD.

48.6.9 LCDIF VSYNC Mode and Dotclk Mode Control Register2 (LCDIFx_VDCTRL2)

This register is used to control the HSYNC signal in the DOTCLK mode of the block.

This register determines the period and duty cycle of the HSYNC signal when it is generated in the block.

Address: 40AA_0000h base + 90h offset = 40AA_0090h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	HSYNC_PULSE_WIDTH																HSYNC_PERIOD															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIFx_VDCTRL2 field descriptions

Field	Description
31–18 HSYNC_PULSE_ WIDTH	Number of DISPLAY CLOCK (pix_clk) cycles for which HSYNC signal is active.
HSYNC_PERIOD	Total number of DISPLAY CLOCK (pix_clk) cycles between two positive or two negative edges of the HSYNC signal.

48.6.10 LCDIF VSYNC Mode and Dotclk Mode Control Register3 (LCDIFx_VDCTRL3)

This register is used to determine the vertical and horizontal wait counts.

This register determines the back porches of HSYNC and VSYNC signals when they are generated by the block.

Address: 40AA_0000h base + A0h offset = 40AA_00A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved		MUX_SYNC_ SIGNALS	VSYNC_ONLY	HORIZONTAL_WAIT_CNT

R W	VERTICAL_WAIT_CNT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIFx_VDCTRL3 field descriptions

Field	Description
31–30 RSRVD0	This field is reserved. Reserved bits, write as 0.

Table continues on the next page...

LCDIFx_VDCTRL3 field descriptions (continued)

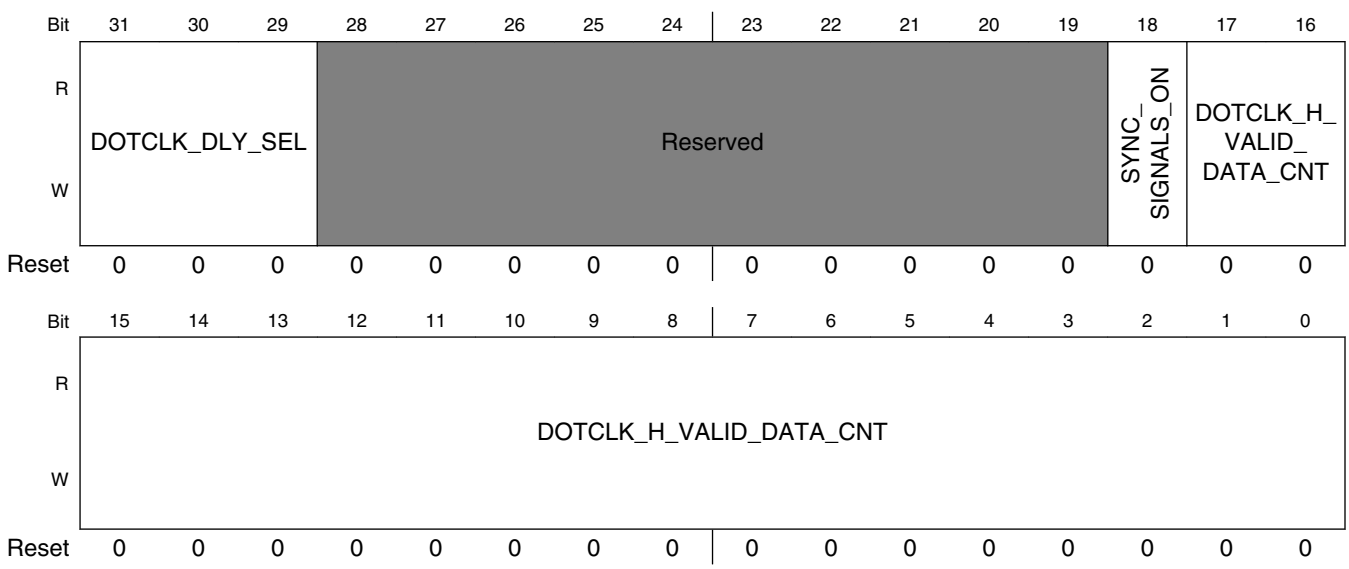
Field	Description
29 MUX_SYNC_ SIGNALS	When this bit is set, the LCDIF block will internally mux HSYNC with LCD_D14, DOTCLK with LCD_D13 and ENABLE with LCD_D12, otherwise these signals will go out on separate pins. This feature can be used to maintain backward compatible with 37xx.
28 VSYNC_ONLY	This bit must be set to 1 in the VSYNC mode of operation, and 0 in the DOTCLK mode of operation.
27–16 HORIZONTAL_ WAIT_CNT	In the DOTCLK mode, wait for this number of clocks from falling edge (or rising if HSYNC_POL is 1) of HSYNC signal to account for horizontal back porch plus the number of DOTCLKs before the moving picture information begins.
VERTICAL_ WAIT_CNT	In the VSYNC interface mode, wait for this number of DISPLAY CLOCK (pix_clk) cycles from the falling VSYNC edge (or rising if VSYNC_POL is 1) before starting LCD transactions and is applicable only if WAIT_FOR_VSYNC_EDGE is set. Minimum is CMD_SETUP+5. In the DOTCLK mode, it accounts for the vertical back porch lines plus the number of horizontal lines before the moving picture begins. The unit for this parameter is inherently the same as the VSYNC_PERIOD_UNIT.

48.6.11 LCDIF VSYNC Mode and Dotclk Mode Control Register4 (LCDIFx_VDCTRL4)

This register is used to control the DOTCLK mode of the block.

This register determines the active data in each horizontal line in the DOTCLK mode. Note that the total number of active horizontal lines in the DOTCLK mode is the same as the V_COUNT bitfield in the LCDIF_TRANSFER_COUNT register.

Address: 40AA_0000h base + B0h offset = 40AA_00B0h



LCDIFx_VDCTRL4 field descriptions

Field	Description
31–29 DOTCLK_DLY_SEL	This bitfield selects the amount of time by which the DOTCLK signal should be delayed before coming out of the LCD_DOTCK pin. 0 = 2ns; 1=4ns;2=6ns;3=8ns. Remaining values are reserved.
28–19 RSRVD0	This field is reserved. Reserved bits, write as 0.
18 SYNC_SIGNALS_ON	Set this field to 1 if the LCD controller requires that the VSYNC or VSYNC/HSYNC/DOTCLK control signals should be active at least one frame before the data transfers actually start and remain active at least one frame after the data transfers end. The hardware does not count the number of frames automatically. Rather, the VSYNC edge interrupt can be monitored by software to count the number of frames that have occurred after this bit is set and then the RUN bit can be set to start the data transactions. This bit must always be set in the DOTCLK mode of operation, and it must be set in the VSYNC mode of operation when VSYNC signal is an output.
DOTCLK_H_VALID_DATA_CNT	Total number of DISPLAY CLOCK (pix_clk) cycles on each horizontal line that carry valid data in DOTCLK mode.

48.6.12 Bus Master Error Status Register (LCDIFx_BM_ERROR_STAT)

This register reflects the virtual address at which the AXI master received an error response from the slave.

When the BM_ERROR_IRQ is asserted, the address of the bus error is updated in the register.

Address: 40AA_0000h base + 190h offset = 40AA_0190h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LCDIFx_BM_ERROR_STAT field descriptions

Field	Description
ADDR	Virtual address at which bus master error occurred.

48.6.13 CRC Status Register (LCDIFx_CRC_STAT)

This register reflects the CRC value of each frame sent out by LCDIF. The CRC is done on the final output bus, so the value will be dependent on the LCD_DATABUS_WIDTH bitfield even if the input data is the same.

This register will be updated when the CUR_FRAME_DONE_IRQ is asserted.

Address: 40AA_0000h base + 1A0h offset = 40AA_01A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LCDIFx_CRC_STAT field descriptions

Field	Description
CRC_VALUE	Calculated CRC value.

48.6.14 LCD Interface Status Register (LCDIFx_STAT)

The LCD interface status register can be used to check the current status of the LCDIF block.

The LCD interface status register that contains read only views of some parameters or current state of the block.

Address: 40AA_0000h base + 1B0h offset = 40AA_01B0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

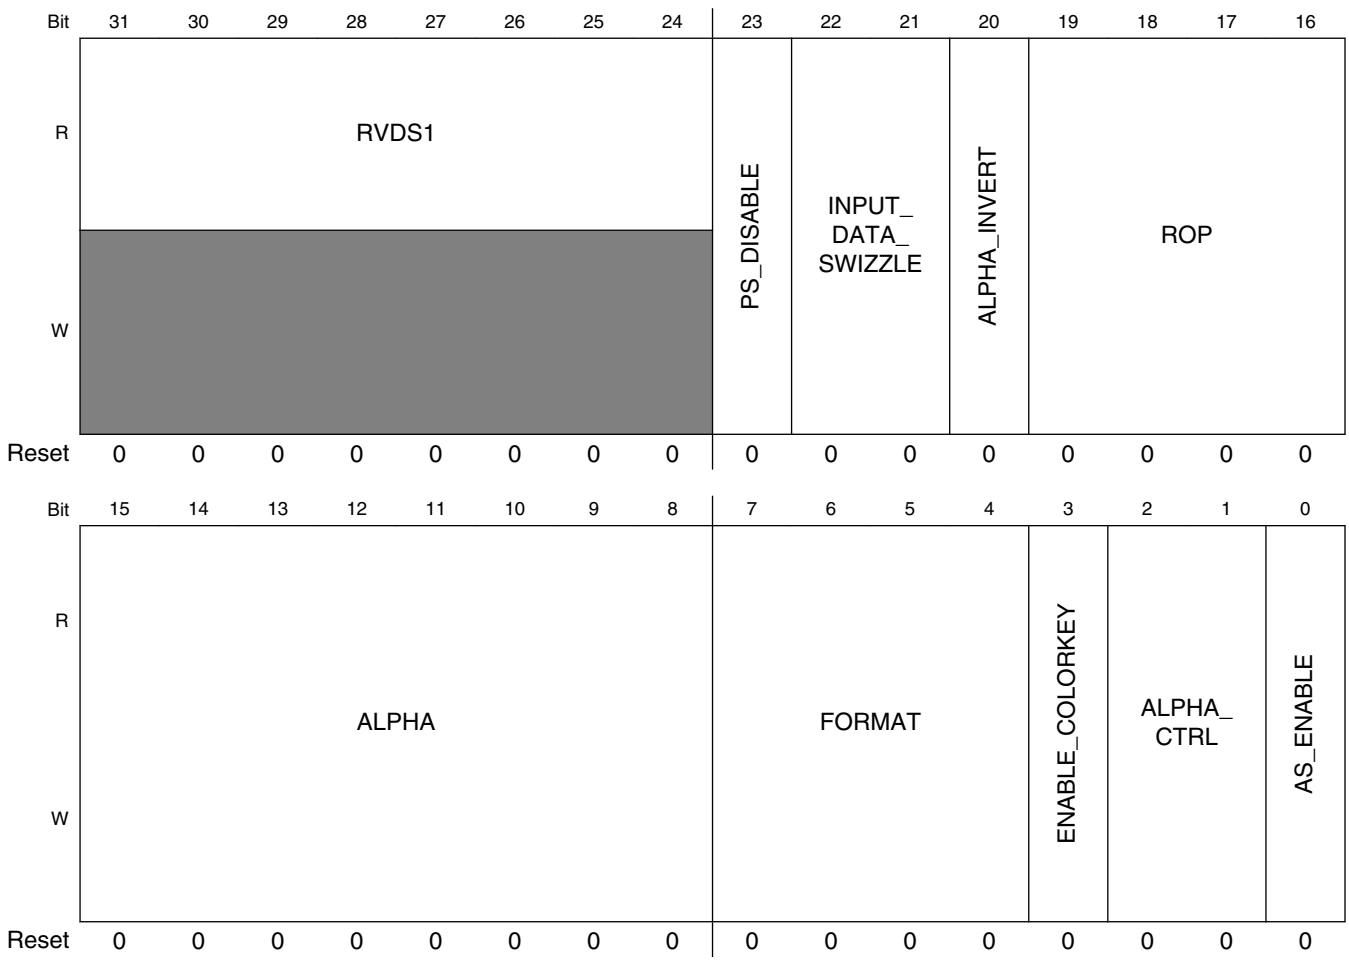
LCDIFx_STAT field descriptions

Field	Description
31 PRESENT	0: LCDIF not present on this product 1: LCDIF is present.
30 -	This field is reserved. Reserved.
29 LFIFO_FULL	Read only view of the signals that indicates LCD LFIFO is full.
28 LFIFO_EMPTY	Read only view of the signals that indicates LCD LFIFO is empty.
27 TXFIFO_FULL	Read only view of the signals that indicates LCD TXFIFO is full.
26 TXFIFO_EMPTY	Read only view of the signals that indicates LCD TXFIFO is empty.
25 -	This field is reserved. Reserved
24–9 RSRVD0	This field is reserved. Reserved bits. Write as 0.
LFIFO_COUNT	Read only view of the current count in Latency buffer (LFIFO).

48.6.15 LCDIF AS Buffer Control Register (LCDIFx_AS_CTRL)

The Alpha Surface Parameter register provides additional controls for AS.

Address: 40AA_0000h base + 210h offset = 40AA_0210h



LCDIFx_AS_CTRL field descriptions

Field	Description
31–24 RVDS1	Reserved, always set to zero.
23 PS_DISABLE	When this bit is set by software, the LCDIF will disable PS buffer data.
22–21 INPUT_DATA_ SWIZZLE	This field specifies how to swap the bytes either in the HW_LCDIF_DATA register or those fetched by the AXI master part of LCDIF. The swizzle function is independent of the WORD_LENGTH bit. See the explanation of the HW_LCDIF_DATA below for names and definitions of data register fields. The supported swizzle configurations are: NO_SWAP = 0x0 No byte swapping.(Little endian)

Table continues on the next page...

LCDIFx_AS_CTRL field descriptions (continued)

Field	Description
	LITTLE_ENDIAN = 0x0 Little Endian byte ordering (same as NO_SWAP). BIG_ENDIAN_SWAP = 0x1 Big Endian swap (swap bytes 0, 3 and 1, 2). SWAP_ALL_BYTES = 0x1 Swizzle all bytes, swap bytes 0, 3 and 1, 2 (aka Big Endian). HWD_SWAP = 0x2 Swap half-words. HWD_BYTE_SWAP = 0x3 Swap bytes within each half-word.
20 ALPHA_INVERT	Setting this bit to logic 0 will not alter the alpha value. A logic 1 will invert the alpha value and apply (1-alpha) for image composition.
19–16 ROP	Indicates a raster operation to perform when enabled. Raster operations are enabled through the ALPHA_CTRL field. MASKAS = 0x0 AS AND PS MASKNOTAS = 0x1 nAS AND PS MASKASNOT = 0x2 AS AND nPS MERGEAS = 0x3 AS OR PS MERGENOTAS = 0x4 nAS OR PS MERGEASNOT = 0x5 AS OR nPS NOTCOPYAS = 0x6 nAS NOT = 0x7 nPS NOTMASKAS = 0x8 AS NAND PS NOTMERGEAS = 0x9 AS NOR PS XORAS = 0xA AS XOR PS NOTXORAS = 0xB AS XNOR PS
15–8 ALPHA	Alpha modifier used when the ALPHA_MULTIPLY or ALPHA_OVERRIDE values are programmed in REG_AS_CTRL[ALPHA_CTRL]. The output alpha value will either be replaced (ALPHA_OVERRIDE) or scaled (ALPHA_MULTIPLY) when selected.
7–4 FORMAT	Indicates the input buffer format for AS. ARGB8888 = 0x0 32-bit pixels with alpha RGB888 = 0x4 32-bit pixels without alpha (unpacked 24-bit format) ARGB1555 = 0x8 16-bit pixels with alpha ARGB4444 = 0x9 16-bit pixels with alpha RGB555 = 0xC 16-bit pixels without alpha RGB444 = 0xD 16-bit pixels without alpha RGB565 = 0xE 16-bit pixels without alpha
3 ENABLE_ COLORKEY	Indicates that colorkey functionality is enabled for this alpha surface. Pixels found in the alpha surface colorkey range will be displayed as transparent (the PS pixel will be used).
2–1 ALPHA_CTRL	Determines how the alpha value is constructed for this alpha surface. Indicates that the value in the ALPHA field should be used instead of the alpha values present in the input pixels. Embedded = 0x0 Indicates that the AS pixel alpha value will be used to blend the AS with PS. The ALPHA field is ignored. Override = 0x1 Indicates that the value in the ALPHA field should be used instead of the alpha values present in the input pixels.

Table continues on the next page...

LCDIFx_AS_CTRL field descriptions (continued)

Field	Description
	Multiply = 0x2 Indicates that the value in the ALPHA field should be used to scale all pixel alpha values. Each pixel alpha is multiplied by the value in the ALPHA field. ROPs = 0x3 Enable ROPs. The ROP field indicates an operation to be performed on the alpha surface and PS pixels.
0 AS_ENABLE	When this bit is set by software, the LCDIF will start fetching AS buffer data in bus master mode and combine it with another buffer.

48.6.16 Alpha Surface Buffer Pointer (LCDIFx_AS_BUF)

This register is used to indicate the base address of the AS buffer.

Address: 40AA_0000h base + 220h offset = 40AA_0220h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LCDIFx_AS_BUF field descriptions

Field	Description
ADDR	Address pointer for the alpha surface 0 buffer.

48.6.17 LCDIFx_AS_NEXT_BUF

When the LCDIF is behaving as a master, this address points to the address of the next frame of data that will be sent out via the LCDIF. It is upto the software to make sure that this register is programmed before the end of the current frame, otherwise it might result in old data going out the LCDIF. This address must always be double-word aligned.

Address: 40AA_0000h base + 230h offset = 40AA_0230h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

49.1.1 Video Interface Unit (VIU)

The Video Interface Unit (VIU) provides a parallel interface for digital video. The VIU accepts 8-bit ITU656 compatible video input, 18-bit/24-bit RGB888/RGB666/RGB565 digital input, and 24-bit YUV444 input on its parallel interface, decodes it and optionally performs processes such as down-scaling, horizontal up-scaling, brightness and contrast adjustment, YUV to RGB conversion, deinterlacing and horizontal mirroring. The resultant video stream is then stored to system memory for subsequent post-processing and display by the Display Control Unit. The following table shows the configuration of the VIU.

It uses 64-bit AHB master bus and IP bus

Table 49-2. VIU configuration

Parameter	Description
Name	Video Interface Unit (VIU)
Instances	1
Configurable features	• Supports up to 24-bit • VGA configuration support only

Table continues on the next page...

Table 49-2. VIU configuration (continued)

Parameter	Description
	• VIUY 1024x8 • VIUU 1024x8 • VIUV 1024x8 • BC RAM 64x32 • FIFO RAM 256x64
Interface speed	66.7 MHz[1]
External I/O pins	PCLK, VSYNC, HSYNC, FID, D[23:0]. See the attached IOMUXC spreadsheet for pin details

1. This is the value of pix_clk

49.2 Introduction

The VIU is a bridge between video decoder and system memory. It accepts an ITU656 compatible video stream, or parallel YUV/RGB input, converting image data between YUV and RGB color spaces, scaling image size, adjusting the brightness/contrast, and writing image data to memory with many kinds of image data formats.

The figure below shows a block diagram of the Video-In (VIU).

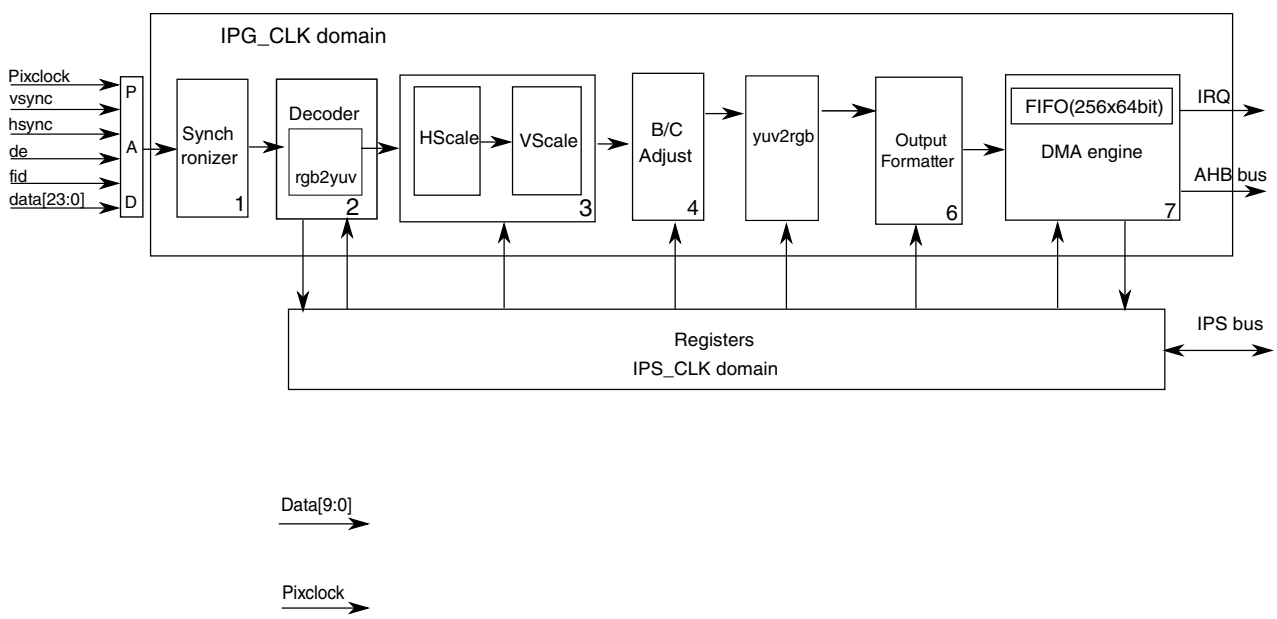

Figure 49-1. VIU Block Diagram

NOTE

To support full function of VIU, IPG_CLK frequency should be bigger than 3 times of Pixclock.

49.3 Features

- Supports QVGA to XGA input resolution
- 8-/10-bit ITU656 video input[1]
- RGB888/RGB666/RGB565 parallel input
- RGB888 serial input with one color component transferred per clock
- 24-bit YUV parallel input from analog video decoder
- 8-bit mono image input
- Multiple output formats: 8-/16-32-bit per pixel in RAM
- Up to 1/8 video down-scaling on horizontal and vertical direction
- Up to 2/1 horizontal video up-scaling
- Horizontal mirroring
- Brightness/contrast adjust
- YUV to RGB 888/565 conversion
- RGB to YUV conversion when input is RGB
- Simple de-interlace function (weaving) for interlaced or pseudo interlaced video input
- Internal DMA engine for transferring data from FIFO to system memory

49.4 Video Input Signal Mapping

Table 49-3. Video Input Signals

Signal	RGB565	RGB666	RGB888	RGB888 (serial)	ITU656 (10-bit)	ITU656 (8-bit)	Parallel YUV (24-bit)	Mono (8-bit)
ipp_pix_data[23]	R4	R5	R7	—	—	—	Y7	Y7
ipp_pix_data[22]	R3	R4	R6	—	—	—	Y6	Y6
ipp_pix_data[21]	R2	R3	R5	—	—	—	Y5	Y5
ipp_pix_data[20]	R1	R2	R4	—	—	—	Y4	Y4
ipp_pix_data[19]	R0	R1	R3	—	—	—	Y3	Y3
ipp_pix_data[18]	0	R0	R2	—	—	—	Y2	Y2
ipp_pix_data[17]	0	0	R1	—	—	—	Y1	Y1

Table continues on the next page...

1. When scaling and/or B/C adjust is enabled, the two LSB's of the 10-bit input are ignored.

Table 49-3. Video Input Signals (continued)

Signal	RGB565	RGB666	RGB888	RGB888 (serial)	ITU656 (10-bit)	ITU656 (8-bit)	Parallel YUV (24-bit)	Mono (8-bit)

49.5 Memory map and register definition

The memory map for the VIU module is given below. The total address for each register is the sum of the base address for the VIU module and the address offset for each register. Also, please note that the bit order for each register bit field is [highest:lowest], whereas the overall register bits are numbered [lowest:highest].

49.5.1 VIU register descriptions

49.5.1.1 VIU Memory map

VIU base address: 40A8_0000h

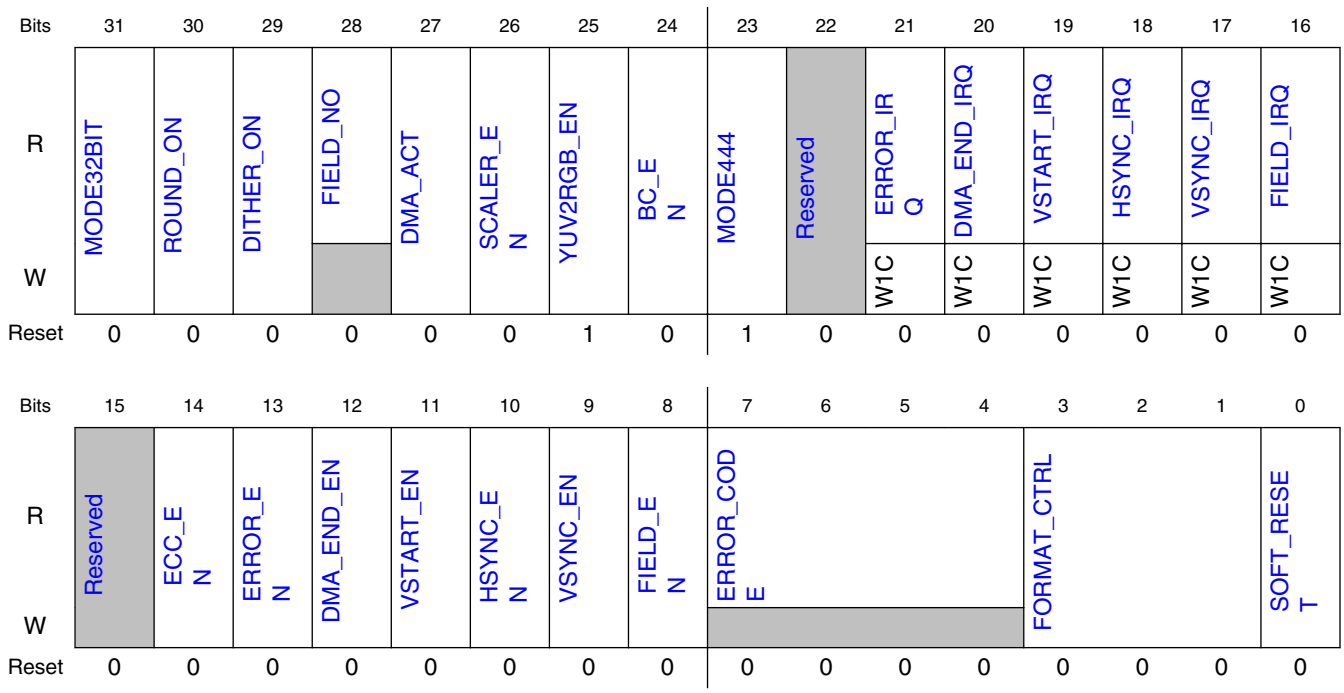
Offset	Register	Width (In bits)	Access	Reset value
0h	Status And Configuration Register (SCR)	32	RW	0280_0000h
8h	Detected Input Video Pixel and Line Counts (DINVSZ)	32	RW	0000_0000h
Ch	Detected Input Video Frame Length (DINVFL)	32	RW	0000_0000h
14h	Base Address Of Every Field/Frame Of Picture In Memory (DMA_ADDR)	32	RW	0000_0000h
18h	Horizontal DMA Increment (DMA_INC)	32	RW	0000_0000h
1Ch	Input Video Pixel and Line Count (INVSZ)	32	RW	00F0_02D0h
20h	High Priority Bus Request Alarm (HPRALRM)	32	RW	0000_0090h
24h	Programable Alpha Value (ALPHA)	32	RW	0000_00FFh
28h	Scaling Factor In Horizontal Direction (HFACTOR)	32	RW	0000_0100h
2Ch	Down Scaling Factor In Vertical Direction (VFACTOR)	32	RW	0000_0100h
30h	Scaling Destination Pixel and Line Count (VID_SIZE)	32	RW	00F0_02D0h
34h	B/C Adjust Look-up-table Current Address (LUT_ADDR)	32	RW	0000_0000h
38h	B/C Adjust Look-up-table Data Entry (LUT_DATA)	32	RW	See description.
3Ch	Extended Configuration Register (EXT_CONFIG)	32	RW	0000_0500h
4Ch	Active Image Origin (ACT_ORG)	32	RW	0000_0000h
50h	Active Image Size (ACT_SIZE)	32	RW	0000_0000h

49.5.1.2 Status And Configuration Register (SCR)

49.5.1.2.1 Offset

Register	Offset
SCR	0h

49.5.1.2.2 Diagram



49.5.1.2.3 Fields

Field	Function
31 MODE32BIT	MODE32BIT Select 32-bit or 16-bit output from the output formatter (block 6 in Figure 49-1) **NOTE:** For RGB666 parallel input, when MODE32BIT is cleared, the output is {R[5:1], G[5:0], B[5:1]}; when MODE32BIT is set, the output is {R[5:0], 2'b00, G[5:0], 2'b00, B[5:0], 2'b00} **NOTE:** This bit only acts when MODE_8BIT of EXT_CONFIG is 1'b0. See description of MODE_8BIT. 0b - 16-bit RGB or YUV 4:2:2 output 1b - 32-bit RGB or YUV 4:4:4 output. DITHER_ON and ROUND_ON are ignored if output is 32-bit RGB.
30 ROUND_ON	ROUND_ON Round is on. Used when video data is stored in buffer as RGB565 format.

Table continues on the next page...

Field	Function
29 DITHER_ON	DITHER_ON Dithering is on. Used when video data is stored in buffer as RGB565 format and ROUND_ON is not set.
28 FIELD_NO	FIELD_NO Field number, extracted from ITU-656 stream.
27 DMA_ACT	DMA_ACT DMA transfer of current field/frame is busy (write by software, cleared at end of transfer). When DMA_ACT is cleared, input video data is ignored and not put into FIFO.
26 SCALER_EN	SCALER_EN Scaling enable.
25 YUV2RGB_EN	YUV2RGB_EN YUV to RGB conversion enable.
24 BC_EN	BC_EN Bright/Contrast adjust enable.
23 MODE444	MODE444 YUV 4:4:4 mode enable bit. When it is set ITU decoder sends out YUV 4:4:4 format data, otherwise YUV 4:2:2 is sent by default. Scaler works on YUV 4:4:4 format. So this bit shall be set when scaling is enabled.
22 —	RESERVED
21 ERROR_IRQ	ERROR_IRQ Interrupt status bit. Write '1' to clear ERROR_IRQ.
20 DMA_END_IRQ	DMA_END_IRQ Interrupt status bit. Write '1' to clear DMA_END_IRQ.
19 VSTART_IRQ	VSTART_IRQ Interrupt status bit. Write '1' to clear VSTART_IRQ.
18 HSYNC_IRQ	HSYNC_IRQ Interrupt status bit. Write '1' to clear HSYNC_IRQ.
17 VSYNC_IRQ	VSYNC_IRQ Interrupt status bit. Write '1' to clear VSYNC_IRQ.
16 FIELD_IRQ	FIELD_IRQ Interrupt status bit. Write '1' to clear FIELD_IRQ.
15 —	RESERVED
14 ECC_EN	ECC_EN When this bit is set ECC errors generate ERROR_IRQ and the nature of ECC error gets reflected on the ERROR_CODE bit field.
13 ERROR_EN	ERROR_EN Interrupt enable bit for ERROR_IRQ.
12 DMA_END_EN	DMA_END_EN Interrupt enable bit for DMA_END_IRQ.
11	VSTART_EN

Table continues on the next page...

Field	Function
VSTART_EN	Interrupt enable bit for VSTART_IRQ.
10 HSYNC_EN	HSYNC_EN Interrupt enable bit for HSYNC_IRQ.
9 VSYNC_EN	VSYNC_EN Interrupt enable bit for VSYNC_IRQ.
8 FIELD_EN	FIELD_EN Interrupt enable bit for FIELD_IRQ.
7-4 ERROR_CODE	ERROR_CODE Error code. Signals errors that triggered error IRQ. Other values not given are reserved. 0000b - No error 0001b - DMA arm command given during vertical active, DMA_ACT does not accept the value on IPS bus. 0010b - DMA arm command given during vertical blanking when DMA_ACT is set. 0100b - Line too long 0101b - Too many lines in a field/frame 0110b - Line too short 0111b - Not enough lines in a field/frame 1000b - FIFO overflow 1001b - FIFO underflow 1010b - One bit ECC error 1011b - Two or more bits ECC error
3-1 FORMAT_CTRL	FORMAT_CTRL Output pixel data format control. See below or refer to Figure 49-1 for detailed definition. Here 32-bit means MODE32BIT is set and 16-bit means MODE32BIT is cleared. RGB mode means YUV2RGB_EN is set and YUV mode means YUV2RGB_EN is cleared. C means U or V. Dummy means "don't care" data. **NOTE:** This format control field only acts when MODE_8BIT of EXT_CONFIG is 1'b0. When MODE_8BIT is 1'b1, the output is 8-bit width. 16-bit RGB mode: 3'b000: {R[7:3], G[7:2], B[7:3]}; 3'b001: {G[4:2], B[7:3], R[7:3], G[7:5]}; 32-bit RGB mode: 3'b000: {alpha, R, G, B}; 3'b001: {alpha, B, G, R}; 3'b010: {R, G, B, alpha}; 3'b011: {B, G, R, alpha}; 16-bit YUV mode: 3'b000: {C,Y}; 3'b001: {Y,C}; 32-bit YUV mode: 3'b000: {dummy, Y, U, V}; 3'b001: {dummy, Y, V, U};

Table continues on the next page...

Field	Function
	3'b010: {dummy, U, V, Y}; 3'b011: {dummy, V, U, Y}; 3'b100: {Y, U, V, dummy}; 3'b101: {Y, V, U, dummy}; 3'b110: {U, V, Y, dummy}; 3'b111: {V, U, Y, dummy};
0 SOFT_RESET	SOFT_RESET Writing 1 to this bit generates an internal reset to all components except registers in the VIU block. This bit should be set by software when an error interrupt is detected, and it needs to be cleared by software to release the software reset.

49.5.1.3 Detected Input Video Pixel and Line Counts (DINVSZ)

49.5.1.3.1 Offset

Register	Offset
DINVSZ	8h

49.5.1.3.2 Diagram

R W	INC													Reserved		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

49.5.1.6.3 Fields

Field	Function
31-16 —	RESERVED
15-3 INC	INC (INC[15:3]) Value of this field should be zero or memory size that one active line occupies in memory. It will be added to the memory mapped rounded address at the end of every line. Memory size of one active line depends on line pixel number. It is PIXEL_COUNT[15:2] + PIXEL_COUNT[1:0] when MODE32BIT=0; PIXEL_COUNT[15:1] + PIXEL_COUNT[0] when MODE32BIT=1; It shall only be configured when DMA is inactive, during vertical blanking.
2-0 —	RESERVED

49.5.1.7 Input Video Pixel and Line Count (INVSZ)

49.5.1.7.1 Offset

Register	Offset
INVSZ	1Ch

49.5.1.7.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	PIXELC															
Reset	0	0	0	0	0	0	1	0	1	1	0	1	0	0	0	0

49.5.1.7.3 Fields

Field	Function
31-16 LINEC	LINEC (LINEC[15:0]) Expected number of active lines in each input video field/frame. It shall only be configured when DMA is non-active, during vertical blanking If more lines are found during data receive part, a "too many lines" error interrupt is generated when ERROR_IRQ is set. Redundant lines are discarded. If fewer lines are found during data receive part, a "not enough lines error interrupt is generated when ERROR_IRQ is set.
15-0 PIXELC	PIXELC (PIXELC[15:0]) Expected number of active pixels in each input video line, it shall be an integer multiple of 4. It shall only be configured when DMA is non-active, during vertical blanking. If more pixels are found during data receive part, a "line too long" error interrupt is generated when ERROR_IRQ isset. Redundant pixels are discarded. If less pixels are found during data receive part, a line too short error interrupt is generated when ERROR_IRQ is set.

49.5.1.8 High Priority Bus Request Alarm (HPRALRM)

49.5.1.8.1 Offset

Register	Offset
HPRALRM	20h

49.5.1.8.2 Diagram

R W	PIXELC															
Reset	0	0	0	0	0	0	1	0	1	1	0	1	0	0	0	0

49.5.1.12.3 Fields

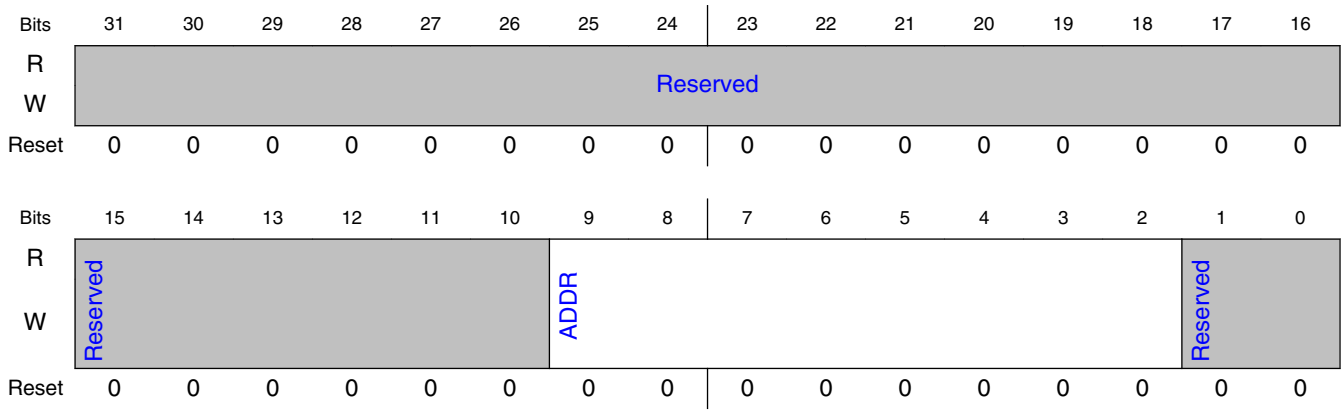
Field	Function
31-16 LINEC	LINEC (LINEC[15:0]) Expected number of lines in each output video frame after scaling.
15-0 PIXELC	PIXELC (PIXELC[15:0]) Expected number of pixels in each output video line after scaling. It shall be a multiple of 2 in 32-bit output mode, and a multiple of 4 in 16-bit output mode.

49.5.1.13 B/C Adjust Look-up-table Current Address (LUT_ADDR)

49.5.1.13.1 Offset

Register	Offset
LUT_ADDR	34h

49.5.1.13.2 Diagram



49.5.1.13.3 Fields

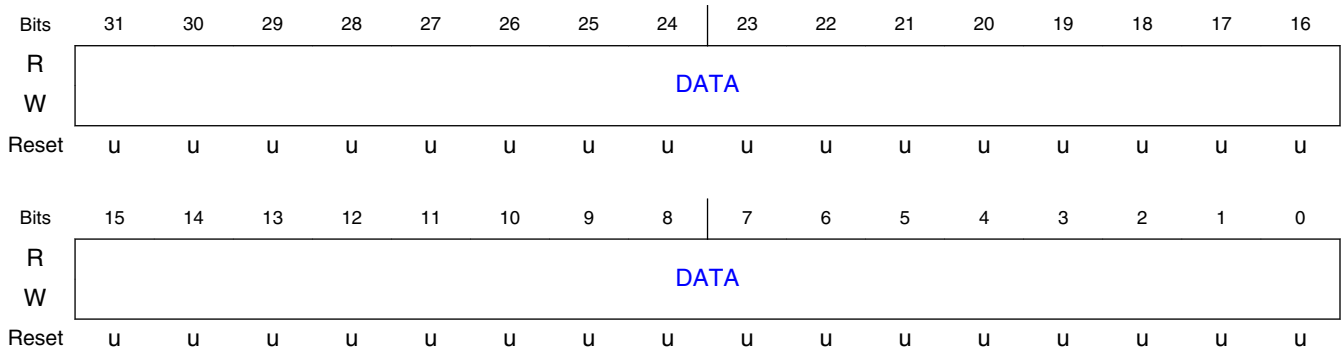
Field	Function
31-10 —	RESERVED
9-2 ADDR	ADDR (ADDR[9:2]) Current address pointer of the B/C adjust look-up-table. Value of this register increments (by 4) automatically at the end of each LUT_DATA write/read operation. This function allows fast update to the whole look-up-table, to the table of one color component, or even to any random field of the table. Note: ADDR reflects correct address only when clock of B/C adjust block is valid.
1-0 —	RESERVED

49.5.1.14 B/C Adjust Look-up-table Data Entry (LUT_DATA)

49.5.1.14.1 Offset

Register	Offset
LUT_DATA	38h

49.5.1.14.2 Diagram



49.5.1.14.3 Fields

Field	Function
31-0 DATA	DATA (DATA[31:0]) B/C adjust look-up-table data entry. Data in this register is actually written/read to/from the address pointed to by the current LUT_ADDR value in the table. Note: DATA reflects correct data value only when clock of B/C adjust block is valid.

49.5.1.15 Extended Configuration Register (EXT_CONFIG)

49.5.1.15.1 Offset

Register	Offset
EXT_CONFIG	3Ch

Field	Function
31-15 —	Reserved
14 MONO_LSB	Data location selector on input data bus. This bit decides the 8bit MONO input data is on 8 MSB or LSB. 0b - 8-bit MONO data is on LSB of input bus 1b - 8-bit MONO data is on MSB of input bus
13 MODE_8BIT	8 bit mode output format selector This mode select bit has higher priority than MODE32BIT of SCR register. When this bit is set, the output data will be 8 bit data per pixel. The user needs to clear this bit when using 16-bit or 32-bit mode. 0b - 8-bit output mode is not selected 1b - 8-bit output mode is selected
12 CS_EN	CS_EN Chroma swap enable bit. It's used to control how combining Y and C when output format is YUV422 mode. By default, for YUV422 mode(for example, assume 4 pixels per line here), the data in memory is Y0U0, Y1V0, Y2U2, Y3V2. When CS_EN is set, it becomes Y0V0, Y1U0, Y2V2, Y3U2. An application senario of CS_EN is that when mirror is on, the data will be Y3V2, Y2U2, Y1V0, Y0U0 by default. The first chrmo is V, instead of U. If CS_EN is set, the output data become Y3U2, Y2V2, Y1U0, Y0V0. 0b - Chroma swap is disabled. 1b - Chroma swap is enabled.
11 LENDIAN	LENDIAN Data endian control bit. This bit controls the endian of the IPM data bus. 0b - Big endian 1b - Little endian
10 —	Reserved Always write the reset value to this field.
9	RGB2YUV_EN

Table continues on the next page...

Field	Function
RGB2YUV_EN	RGB to YUV conversion enable
8 DE_VALID	DE_VALID External data enable indicator is valid at parallel input modes. 0b - DE is invalid 1b - DE is valid
7-5 INP_FORMAT	INP_FORMAT Input video format select bits. It should be set correctly according to the video input. 000b - 10/8bit ITU stream 001b - 24bit parallel YUV. Normally it is YUV444 010b - 8bit mono input. It is luminance Y. 011b - Reserved 100b - 24bit parallel RGB. It is RGB888 101b - 8bit serial RGB. It is RGB888 serial 110b - 18bit parallel RGB. It is RGB666 111b - 16bit parallel RGB. It is RGB565
4 PCLK_POL	PCLK_POL Pixel clock polarity control bit. pix_clk will be reversed when the bit is set. 0b - Active high 1b - Active low
3 VSYNC_POL	VSYNC_POL Vsync polarity control bit. Vsync will be reversed when the bit is set. 0b - Active high 1b - Active low
2 HSYNC_POL	HSYNC_POL Hsync polarity control bit. Hsync will be reversed when the bit is set. 0b - Active high 1b - Active low
1 DE_POL	DE_POL Data enable polarity control bit. DE will be reversed when the bit is set. 0b - Active high 1b - Active low
0 HMIRROR_EN	HMIRROR_EN Horizontal mirror enable.

49.5.1.17.3 Fields

Field	Function
31-16 ACT_IMG_HEIGHT	ACT_IMG_HEIGHT Height of image captured. Value '0' means no image clipping on Y direction.
15-0 ACT_IMG_WIDTH	ACT_IMG_WIDTH Width of image captured. Value '0' means no image clipping on X direction.

49.6 Functional Description

The VIU accepts parallel RGB, serial RGB, parallel YUV and ITU-R BT.656 compatible video streams on its parallel interface, decodes it and optionally performs processes like scaling, brightness and contrast adjust, RGB2YUV or YUV2RGB conversion, and de-interlace (weaving), then stores the result video stream to the system memory which can then be displayed by a display controller, or post processed.

Functions of the VIU are designed in a way that they can be flexibly enabled or disabled by software. But there are a few limitations as listed below:

- The scaler works on YUV 4:4:4 format or RGB888 formats, so to enable the scaler, decoder shall be configured in YUV 4:4:4 or RGB888 mode.
- To use the scaler, progressive video input shall be used for display quality's sake, and the de-interlace shall be disabled.

49.6.1 Input Formats

VIU accepts parallel RGB, serial RGB, parallel YUV and ITU-R BT.656 compatible video streams on its parallel interface. Below is the description for the timing of input video formats.

49.6.1.1 ITU656

The ITU-R BT.656-4 recommendation describes the means of interconnecting digital television equipment operating on the 525-line or 625-line standards and combines with the 4:2:2 encoding parameters as defined in the ITU-R BT.601 recommendation.

The data stream structure on ITU-R BT.656-4 interface is shown in the following figure. There are two timing reference signals, one at the beginning of each video data block (start of active video, SAV) and one at the end of each video data block (end of active video, EAV).

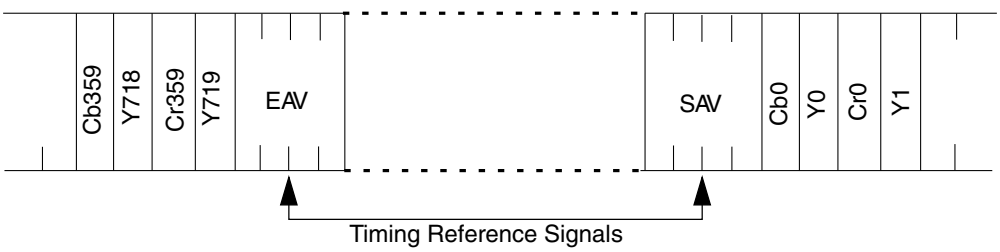

Figure 49-2. Interface Data Stream of ITU-R BT.656-4

Each timing reference signal consists of a four-word sequence in the following format: FF 00 00 XY. Values are expressed in hexadecimal notation. Value FF and 00 are reserved to be used in the timing reference signals.

The first three words are a fixed preamble. The fourth word contains information defining field 2 identification, the state of field blanking, and the state of line blanking. The assignment of bits within the timing reference signal is shown in the table below.

Table 49-4. Video Timing Reference Codes

Data Bit Number	First Word (FF)	Second Word (00)	Third Word (00)	Fourth Word (XY)
9(MSB)	1	0	0	1
8	1	0	0	F(0: field 1, 1: field 2)
7	1	0	0	V(0: elsewhere, 1: field blanking)
6	1	0	0	H(0: in SAV, 1: in EAV)
5	1	0	0	P3
4	1	0	0	P2

Table continues on the next page...

Table 49-4. Video Timing Reference Codes (continued)

Data Bit Number	First Word (FF)	Second Word (00)	Third Word (00)	Fourth Word (XY)
3	1	0	0	P1
2	1	0	0	P0
1	1	0	0	0
0	1	0	0	0

In above table, bits P0, P1, P2, P3 have states dependent on the states of the bits F, V and H. At the receiver side this arrangement permits one-bit errors to be corrected and two-bit errors to be detected.

Progressive video is also composed of fields; but instead of containing even lines in one field and odd lines in the other, the fields contain contiguous lines, i.e., field0 contains lines 1,2,3,... and field1 contains rest of the lines starting from (last line number of field0 + 1). And the F bit cannot be ignored in case of progressive frame.

Refer to the ITU-R BT.656-4 recommendation for more details.

49.6.1.2 Parallel Input Format

VIU also accepts parallel input video formats. It includes 24bit RGB888, YUV444, 18bit RGB666 and 16bit RGB565 formats. Their data streams are similar. The following caveats apply to the timing diagram below:

- FID must change state 3 Hsync pulses into Vsync.
- The first -//- break represents at least 10 lines.
- A field should contain more than 16 active lines.
- Hsync pulse should be longer than 60 pixel clock cycles.
- A active line should contain more than 24 pixels.

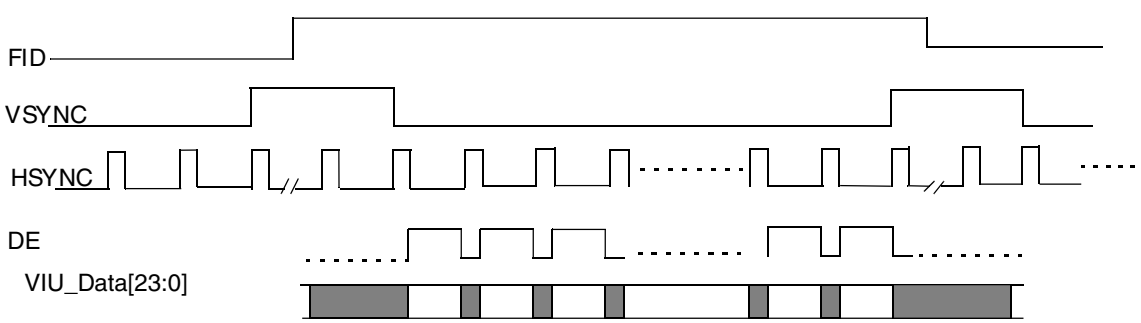

Figure 49-3. Parallel Input Timing

49.6.1.3 Parallel YC Format

Parallel YC video should be in YUV222 format. The timing diagram is provided below.

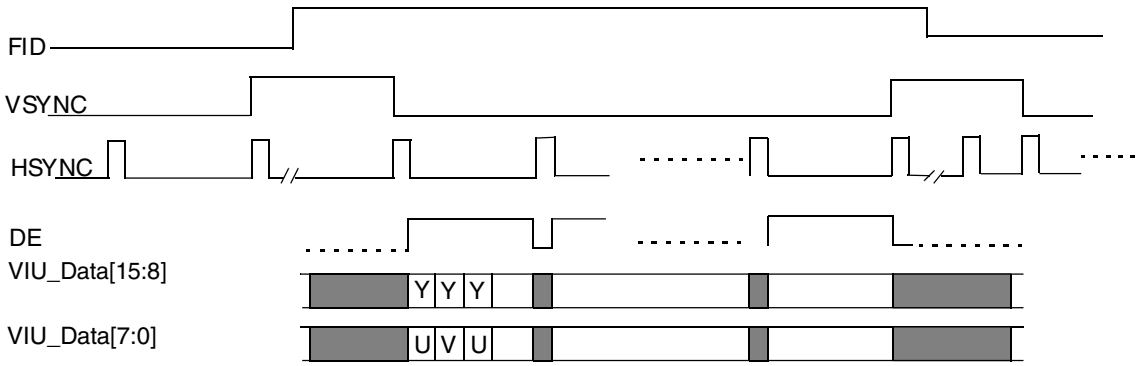

Figure 49-4. Parallel YC Timing

49.6.1.4 Serial RGB888 Format

The timing diagram of serial RGB888 is shown below.

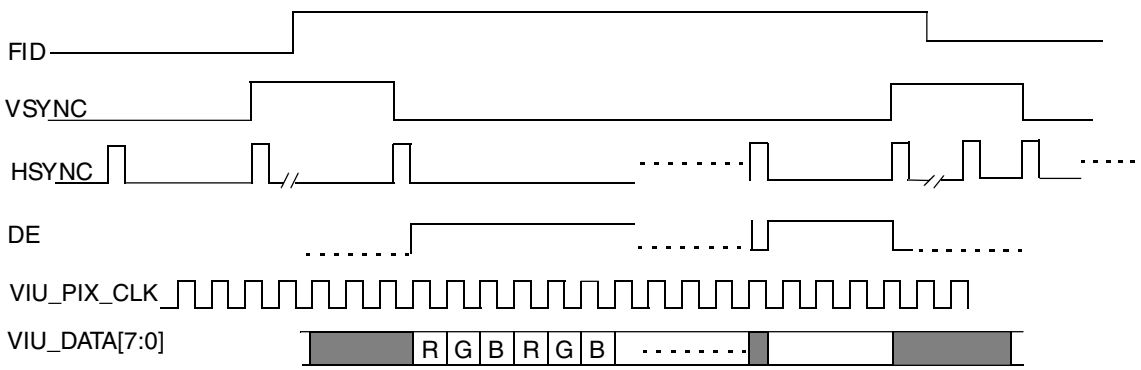

Figure 49-5. Serial RGB888 Timing

49.6.1.5 Mono Image Input Format

The timing diagram of mono input format is shown below.

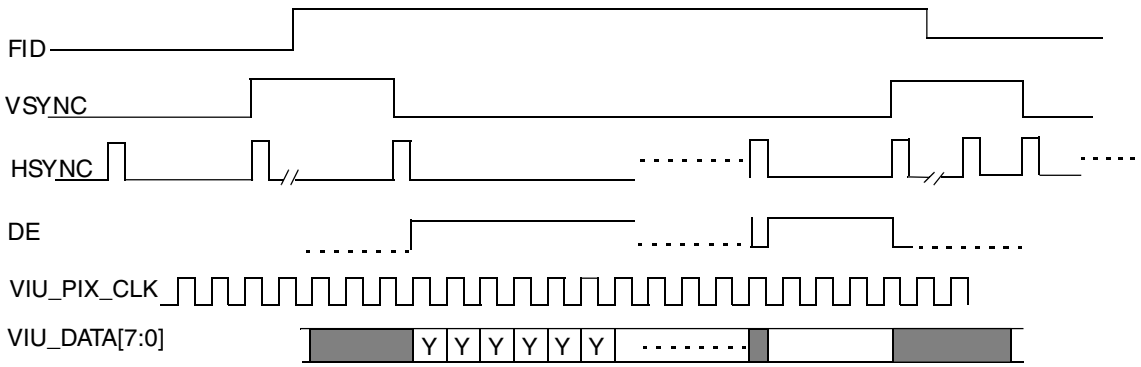

Figure 49-6. Mono Image Input Timing

49.6.2 Input Synchronizer

The Synchronizer block (1) captures ITU656 protocol signals from the interface, and synchronizes them to the IPG_CLK domain.

49.6.3 Decoder

The ITU Decoder block (2) detects the ITU656 timing reference signal (consists of a four-word sequence in the following format: FF-00-00-XY) and extracts HSYNC, VSYNC, field number signals and video data from the ITU data stream. The format of active pixel data from the ITU stream is YUV 4:2:2. The decoder block can directly send out this YUV 4:2:2 data, or interpolate it to YUV 4:4:4 format and send it out. This is determined by the MODE444 field in the SCR register. This bit shall be set if the scaler is enabled, because the scaler works on YUV 4:4:4 data format.

49.6.4 Scaling

VIU supports up to 1/8 horizontal and vertical down-scaling, as well as 2x horizontal up-scaling.

49.6.4.1 Down Scaling

The Down-scaler block (3) performs down-scaling to the incoming video stream. It is able to scale down the input video stream by a fractional scaling ratio up to 1/8. The down-scaler block can be enabled/disabled by software via the SCALER_EN bit in the SCR register. To use the down-scaler video data extracted from ITU decoder shall be in YUV 4:4:4 format, or the input format is non-ITU (INP_FORMAT is not 3'b000).

The down-scaler uses a bi-linear filter with simple linear interpolation between the two nearest neighbors, on both horizontal and vertical direction. Scaling is firstly done on the horizontal direction (called XScale), and then the vertical direction (called YScale). Different scaling factors are supported on horizontal direction and vertical direction.

Assuming the scaling factors are (factor_h, factor_v), in theory for every pixel (x, y) of the scaled picture the coordinates of the corresponding pixel in the incoming picture (x1, y1) can be calculated by multiplying the coordinates with the scaling factors, say (x1 = x * factor_h, y1 = y * factor_v). Now because the scaling factors can be fractions, the coordinates (x1, y1) are not integer anymore, they are fractional values. The scalers use the integer part of (x1, y1) to find the two neighboring pixels from the incoming picture as input to the filters, and the fractional part to derive the weighting factors for interpolation.

The scaling factors, (factor_h, factor_v), are both 11 bit with the lower 8 bit as the factional part and the highest 3 bit the integer part. It is capable of scaling the input picture by up to 8, in steps of 1/256. It is by 8 if the factor is programmed as all zeros.

Instead of using multipliers to calculate (x1, y1), two 20-bit phase accumulator is used to step through the source pixels/or lines, where the lower 8 bit is the fractional part. For every output pixel/or line the phase adder is added to the accumulator. With the 12 bit integer part of the accumulator, up to 4096 source pixels/or lines can be supported.

So for each target pixel, the current accumulator position is used to determine how the pixel is going to be produced. As an example, accumulator value 0x123.3a means the step position is between pixel[0x123] and pixel[0x124], and the output pixel will be calculated by (pixel[0x124] * (0x100 - 0x3a) + pixel[0x123] * 0x3a) >> 8. The same concept is used for horizontal and vertical scaling.

Because of the vertical scaling, a line buffer is used for each color component to store the data from horizontal scaling, it stores one line of data. Size of the line buffer determines the maximum video output size after scaling.

The scaling factors are programmed via the HFACTOR and VFACTOR registers. Video size after scaling is programmed via the VID_SIZE register.

Three scalers are instantiated in the down-scaler block, one for each component.

49.6.4.2 Up-scaling

The theory of up-scaling is the same with down-scaling. When HFACTOR is smaller than 1, up-scaling is implemented by VIU scaler. But note that VIU does not support vertical up-scaling, and HFACTOR should not be less than 0.5.

Note

The scaled pixel count per line shall be an integer multiple of 2 in 32-bit output mode, or 4 in 16-bit output mode. The user shall divide the input pixel count by the horizontal scaling factor and truncate the result to a multiple of 2 or 4.

Note

To achieve good display quality, progressive video input shall be used if down-scaling is needed.

49.6.5 Brightness and Contrast Adjust

The B/C Adjust block (4) performs brightness and contrast adjustment on the input video stream via three internal look-up-tables, one table per color component. Each table contains 256 8-bit entries, it maps every incoming pixel to the value of one of its entries according to the original value of the pixel. This feature allows the user to adjust brightness and/or contrast of the incoming picture according to three arbitrary adjustment curves, one adjustment curve per color component.

To use this feature, the B/C adjust look-up-table shall be programmed in software in the following format.

Table 49-5. B/C Adjust Look-up-table Format

Color Component	BC LUT Offset	Local Address [1:0]			
		00	01	10	11
Y	0x000	$BC0_Y$	$BC1_Y$	$BC2_Y$	$BC3_Y$
	.....				
	0x0FC	$BC252_Y$	$BC253_Y$	$BC254_Y$	$BC255_Y$
U	0x100	$BC0_U$	$BC1_U$	$BC2_U$	$BC3_U$
	.....				
	0x1FC	$BC252_U$	$BC253_U$	$BC254_U$	$BC255_U$
V	0x200	$BC0_V$	$BC1_V$	$BC2_V$	$BC3_V$
	.....				
	0x2FC	$BC252_V$	$BC253_V$	$BC254_V$	$BC255_V$

Two registers are provided to program the look-up-table, they are LUT_ADDR and LUT_DATA. LUT_ADDR is the current address pointer, which always points to the current table offset to be programmed. It can be set by software, and it increases (by 4) automatically when each word is written to the table, and it falls back to 0x000 if the current value is 0x2FC and the last word is written to the table. LUT_DATA is the table

data entry, data written to this register will be stored into the table, to the address pointed to by LUT_ADDR. This register shall only be written by 4-byte word. With the combination of these two registers the user can program the B/C look-up-table conveniently, either program the whole table, or reprogram the table for one color component only, or even change one single arbitrary word in the table.

The B/C adjust can be enabled/disabled by software via the BC_EN bit in the SCR register.

49.6.6 YUV to RGB Conversion

The YUV2RGB block (5) is used to convert YUV (4:2:2 or 4:4:4) to RGB (888 or 565). When the input is YUV 4:2:2, it is interpolated to YUV 4:4:4 first.

49.6.7 Round and Dither

In RGB565 output mode, when pixel data is converted from RGB888 to RGB565 the image is anamorphic more or less, because of losing color information conveyed by the least significant two or three bits of the original color components, which are dropped. VIU block provides two simple algorithms, round and dither, to compensate this color information loss.

49.6.7.1 Round

In round mode, VIU will round to 1 in LSB if the decimal fraction is bigger than 0.5 and ignore the smaller fraction when ROUND_ON is set in the SCR register.

49.6.7.2 Dither

Dither is a little more complex but better than round for recovering image. It is a statistical compensation algorithm. It does not render all pixels with the same grey or color level, but some with the lower one, and some with a color level of 1 LSB more. The selection of adding one LSB or not depends on the position of the pixel on the screen.

The figure below shows the implementation of dither in the VIU block.

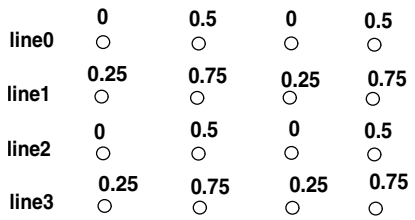

Figure 49-7. Dither Implementation

The number above the pixel position in the diagram is the compensation value for this pixel. When pixels have a value of 0.25, they are rendered 0 in 75% of the pixels and 1 in 25% of pixels. This averages to 0.25. Similarly, pixel values of 0.5, 0.75, and 1.0 are rendered 50%, 75% and 100% of the pixels as 1. For human eyes, this rendering result of dither makes the holistic image smoother and closer to the original one.

49.6.8 Output Formatter

The Output Formatter block (6) accepts YUV or RGB data from the YUV2RGB block, arranges them in expected format, and then sends it to the DMA engine. The FORMAT_CTRL field in SCR register controls how the VIU stores data to system memory; see the following figure for details.>

Table 49-6. VIU Output Data Stream Format

Pixel Format	FORMAT _CTRL[1]	Local Address [2:0]							
		000	001	010	011	100	101	110	111
RGB 565	000	R0[7:3], G0[7:2], B0[7:3]		R1[7:3], G1[7:2], B1[7:3]		R2[7:3], G2[7:2], B2[7:3]		R3[7:3], G3[7:2], B3[7:3]	
	001[2]	G0[4:2], B0[7:3], R0[7:3], G0[7:5]		G1[4:2], B1[7:3], R1[7:3], G1[7:5]		G2[4:2], B2[7:3], R2[7:3], G2[7:5]		G3[4:2], B3[7:3], R3[7:3], G3[7:5]	
RGB 8888	000	A0	R0	G0	B0	A1	R1	G1	B1
	001	A0	B0	G0	R0	A1	B1	G1	R1
	010	R0	G0	B0	A0	R1	G1	B1	A1
	011	B0	G0	R0	A0	B1	G1	R1	A1
YUV 4:2:2	000	U0	Y0	V0	Y1	U2	Y2	V2	Y3
	001	Y0	U0	Y1	V0	Y2	U2	Y3	V2
YUV 4:4:4	000	dummy	Y0	U0	V0	dummy	Y1	U1	V1
	001	dummy	Y0	V0	U0	dummy	Y1	V1	U1
	010	dummy	U0	V0	Y0	dummy	U1	V1	Y1
	011	dummy	V0	U0	Y0	dummy	V1	U1	Y1
	100	Y0	U0	V0	dummy	Y1	U1	V1	dummy
	101	Y0	V0	U0	dummy	Y1	V1	U1	dummy
	110	U0	V0	Y0	dummy	U1	V1	Y1	dummy
	111	V0	U0	Y0	dummy	V1	U1	Y1	dummy
8-bit Mode	XXX	Y0	Y1	Y2	Y3	Y4	Y5	Y6	Y7

1. All values not shown in the table shall be considered as reserved and shall not be used.
2. This format is basically intended for data communication with any little-endian peripheral in the system, assuming big-endian system memory is used.

NOTE

RGB666 input can be stored in memory in RGB565 or RGB8888 formats. When stored as RGB565, the R[0] and B[0] component of RGB666 input will be discarded. When stored as RGB8888, the RGB666 input data will be reflected in memory as {R[5:0], 2'b00, G[5:0], 2'b00, B[5:0], 2'b00}. The position of Alpha bit will depend on the FORMAT_CTRL setting.

49.6.9 High Priority Alarm

FIFO_FILL is a status field which indicates the amount of data in the FIFO. The HI_PRIO_ALARM register is a threshold such that, when the data number in the FIFO is larger than HI_PRIO_ALARM, the DMA request will be high-priority on the AMBA crossbar side. The purpose of this register is to enhance DMA performance. Normally the reset value should be sufficient; however, if the FIFO is seen to overflow, the user should lower the threshold in order to allow the DMA to service the FIFO more frequently.

49.6.10 DMA and De-interlace

The DMA engine block (7) functions as the FIFO controller and DMA engine. It stores the data from the output formatter block into a FIFO and then writes them to system memory via the IPM interface.

VIU block has an embedded DMA. When video data is converted to RGB format and placed into a 256 × 64 bit FIFO, it waits to be transferred to memory by the internal DMA.

After doing some necessary register configuration, such as coefficients, INVSZ and DMA_ADDR, user can activate DMA by setting the DMA_ACT of the status and configuration register. But note that DMA_ACT can be configured only during vertical blanking since the VIU block will not transfer a fragment of video field to memory. If it is configured during field active time, DMA transfer cannot be started and an error interrupt will be asserted.

The VIU block asserts a transfer request when there is enough data in the FIFO for one transfer. Normally one transfer conveys 32 bytes from FIFO to memory. At the end of a line, all remaining data is transferred, though it may not be as much as 32 bytes.

VIU also provides a simple way to de-interlace for interlaced or pseudo-interlaced video images. It is implemented by setting the DMA_ADDR and DMA_INC registers.

The figure below shows the implementation of de-interlace. The value of DMA_INC is added to the rounded address at the end of every active line. So, when DMA_INC is zero, pixel data is stored in memory line by line, meaning de-interlace is off, as shown in figure (1) and (2); otherwise, when DMA_INC equals to one-line memory mapped pixel size and DMA_ADDR(2) = DMA_ADDR(1) + DMA_INC, the odd field and even field will be merged into one frame in memory, as shown in figure (3).

Here DMA_ADDR(1) means base address of field 1, and DMA_ADDR(2) means base address of field 2. Memory mapped line size means memory size that is occupied by one active line pixels. It depends on pixel number of one line and video data format (RGB888 or RGB565). See the register description section for more details.

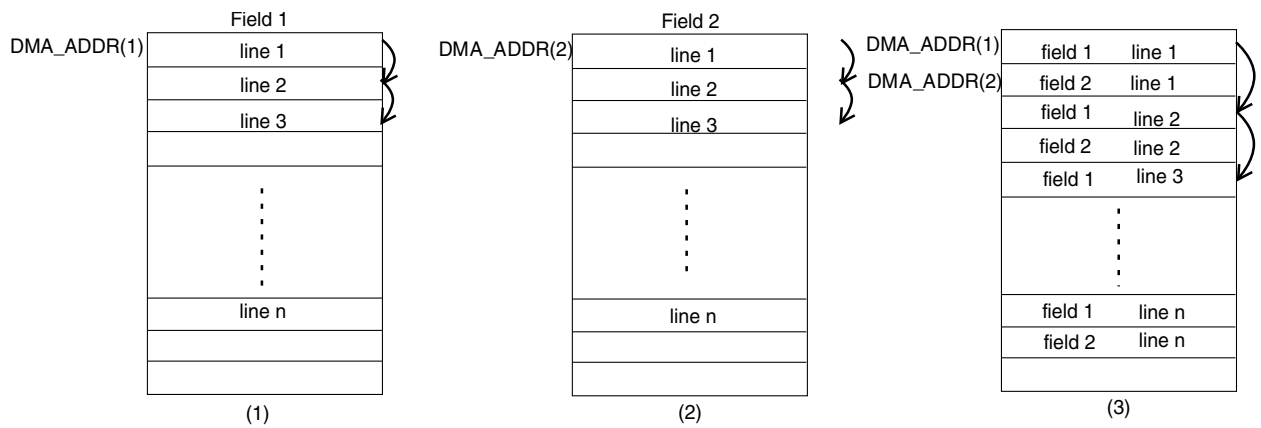

Figure 49-8. Implementation of De-interlace

When the HMIRROR_EN bit is set in the EXT_CONFIG register, the image can be mirrored in the horizontal direction, as illustrated below.

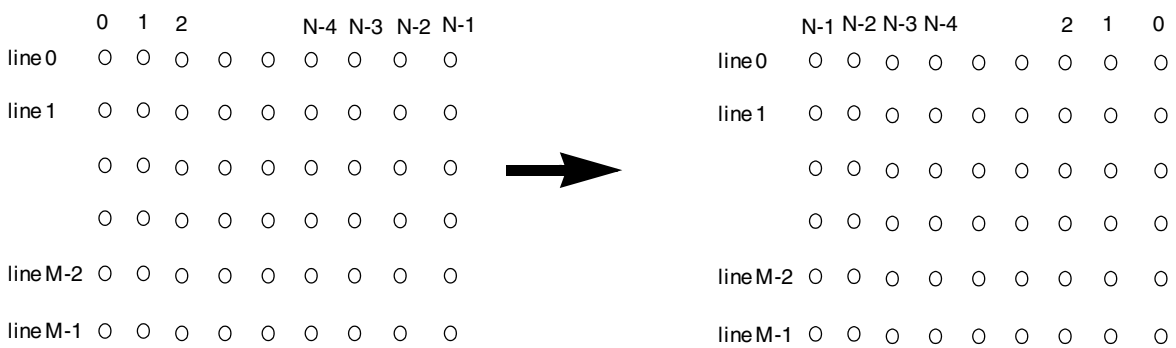

Figure 49-9. Horizontal Image Mirror

49.6.11 Error Case

Normally, the user should provide a standard and totally ITU-compatible video stream to the VIU block. However, it is difficult to avoid unexpected errors all the time. VIU can manage error cases like ECC error, line too long, line too short, too many lines, not enough lines in a field, and FIFO overflow.

- ECC error: ITU stream provides 4-bit error correcting code P[3:0] in its SAV and EAV. It is decoded in VIU to use the correct field number, horizontal sync and vertical sync bits. It can correct one bit errors and find two bit errors. When an ECC error is found, an interrupt is asserted.
- Line too long error: When pixels of active line is longer than PIXELC, a line too long error interrupt is asserted and redundant pixels are discarded.
- Too many lines error: When active lines of a field are bigger than LINEC, a too many lines error interrupt is asserted and redundant lines are discarded.
- Line too short error: When pixels of active line is less than PIXELC, a line too short error interrupt is asserted.
- Not enough line error: When active lines of a field is less than LINEC, a not enough line error interrupt is asserted.
- FIFO overflow error: If the system bus is blocked for a long time, video data is stored in FIFO and causes FIFO overflow. When FIFO overflow occurs, an interrupt is asserted and incoming data is discarded until FIFO works normally again. Current field is jumbled. However, VIU recovers to work at the next field if the bus is unblocked at that time.
- FIFO underflow: When the FIFO is read when it is empty, a FIFO underflow error interrupt is asserted. Normally, this error should not occur.

VIU can manage the above error cases to a certain extent. However, when it does not recover to a working state the user should write the SOFT_RESET bit of the status and configuration register to reset the VIU block.

49.7 Initialization/Application Information

Initialization steps and startup information are given below.

49.7.1 Initialization Information

When the VIU block comes out of reset, software should implement the following steps to start this block.

1. Program the SCR register to set the VIU to the desired operation mode
   - To enable YUV 4:2:2 to 4:4:4 interpolation in the ITU decoder, set the MODE444 bit[2]
   - To enable the scaler, set the SCALER_EN bit
   - To enable B/C adjust, set the BC_EN bit
   - To enable RGB565 output mode, set the YUV2RGB_EN bit and clear the MODE32BIT bit. Optionally set the DITHER_ON bit or the ROUND_ON bit to enable dither or round[3]
   - To enable RGB8888 output mode, set the YUV2RGB_EN and MODE32BIT bits
   - To enable YUV output mode, clear the YUV2RGB_EN bit
2. Set the FORMAT_CTRL field so that the VIU outputs data in the correct format. Configure the input video size via the INVSZ register.
3. If it is desired to use the scaling function, program the scaling factors and destination video size after scaling.
4. If it is desired to use the B/C adjust function, program the B/C adjust look-up-table via the LUT_DATA and LUT_ADDR registers.
5. Configure the HPRALRM and ALPHA registers if necessary.
6. Set the VSYNC_EN and/or FIELD_EN bits in the SCR register to enable vsync or field interrupt. Meanwhile, disable error interrupt.
7. When software receives a vsync interrupt and/or field interrupt, read FIELD_NO bit of the SCR register[4].
8. According to the FIELD_NO bit, program the DMA_ADDR register. This is the field start address in system memory, or frame start address in progressive video input mode.

2. MODE444 bit shall be set when the scaler is enabled.
3. If DITHER_ON or ROUND_ON are both set, only round will be enabled.
4. Reading the FIELD_NO bit is optional, especially in progressive video input mode.

9. If it is desired to use the de-interlace (weaving) function, program the line start address offset value in the DMA_INC register[5].
10. Clear error status first if necessary.
11. Write the DMA_ACT bit of the SCR register to start FIFO and DMA transfer. This operation actually starts the VIU to operate.

49.7.2 Application Information

Normally, the user shall not change the register values of the function enable bits, input/output video size, DMA_INC, MODE32BIT, scaling factors and B/C adjust look-up-table contents after VIU is started up. When the video input source is changed, the user should reset the VIU and re-configure the related registers.

49.7.2.1 Register Configuration Timing Window

As mentioned above, dynamic configuration of registers is not recommended because it may cause error if it is not configured in a certain timing window, especially for INVSZ and DMA_INC.

Register configuration timing window is shown in the below diagram. All registers, except for the SOFT_RESET bit, are recommended to be configured during vertical blanking, after DMA transfer is done and the field identification bit is changed (field interrupt is asserted).

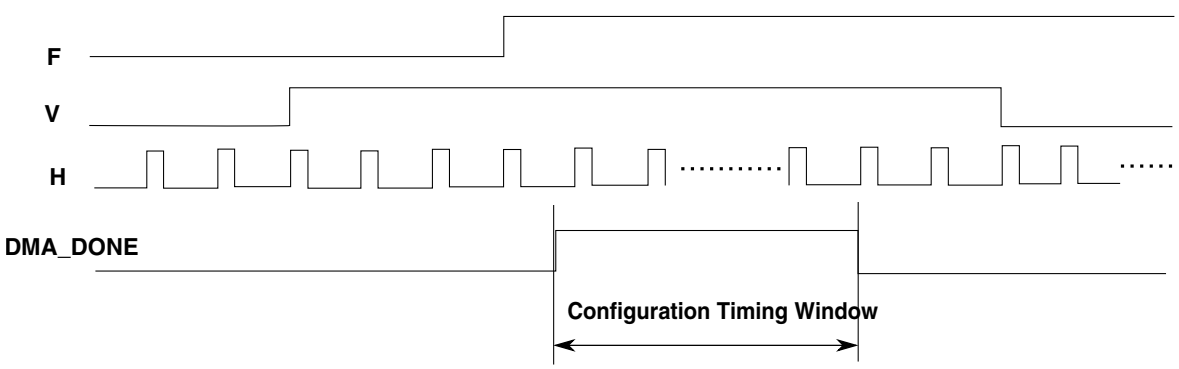

Figure 49-10. Register Configuration Timing Window

5. Progressive video input shall be used when scaling is enabled for better display quality.

Power management		Power management
Signal multiplexing	Port control	Signal multiplexing

50.1.1 FlexIO

The FlexIO module is capable of supporting a wide range of protocols including, but not limited to: UART, I2C, SPI, I2S, camera interface, display interface, PWM waveform generation, etc. The module can remain functional when the chip is in a low power mode provided the clock it is using remains active. It uses 32-bit IP bus.

Table 50-2. FlexIO configuration

Parameter	Description
Name	FlexIO
Instances	2
Configurable features	FLEXIO0-1: 8 shift registers, 8 timers, 32 pins per instance
Interface speed	FLEXIO0-1: set by I/O max
External I/O pins	FLEXIO0-1: D[0-31]. See attached IOMUXC spreadsheet for pinout details

50.1.2 Trigger connections

On i.MX 7ULP, TPM trigger sources get routed through the TRIGMUX module. See the Table 38-2 and Table 38-4 for external/internal trigger connections to this module.

50.2 Introduction

50.2.1 Overview

The FlexIO is a highly configurable module providing a wide range of functionality including:

- Emulation of a variety of serial/parallel communication protocols
- Flexible 16-bit timers with support for a variety of trigger, reset, enable and disable conditions
- Programmable logic blocks allowing the implementation of digital logic functions on-chip and configurable interaction of internal and external modules
- Programmable state machine for offloading basic system control functions from CPU

50.2.2 Features

The FlexIO module is capable of supporting a wide range of protocols including, but not limited to:

- UART
- I2C
- SPI
- I2S
- Camera IF
- Motorola 68K/Intel 8080 bus
- PWM/Waveform generation

The following key features are provided:

- Array of 32-bit shift registers with transmit, receive and data match modes
- Double buffered shifter operation for continuous data transfer
- Shifter concatenation to support large transfer sizes
- Automatic start/stop bit generation
- 1, 2, 4, 8, 16 or 32 multi-bit shift widths for parallel interface support
- Interrupt, DMA or polled transmit/receive operation

- Programmable baud rates independent of bus clock frequency, with support for asynchronous operation during stop modes
- Highly flexible 16-bit timers with support for a variety of internal or external trigger, reset, enable and disable conditions
- Programmable logic mode for integrating external digital logic functions on-chip or combining pin/shifter/timer functions to generate complex outputs
- Programmable state machine for offloading basic system control functions from CPU with support for up to 8 states, 8 outputs and 3 selectable inputs per state

50.2.3 Block Diagram

The following diagram gives a high-level overview of the configuration of FlexIO timers and shifters.

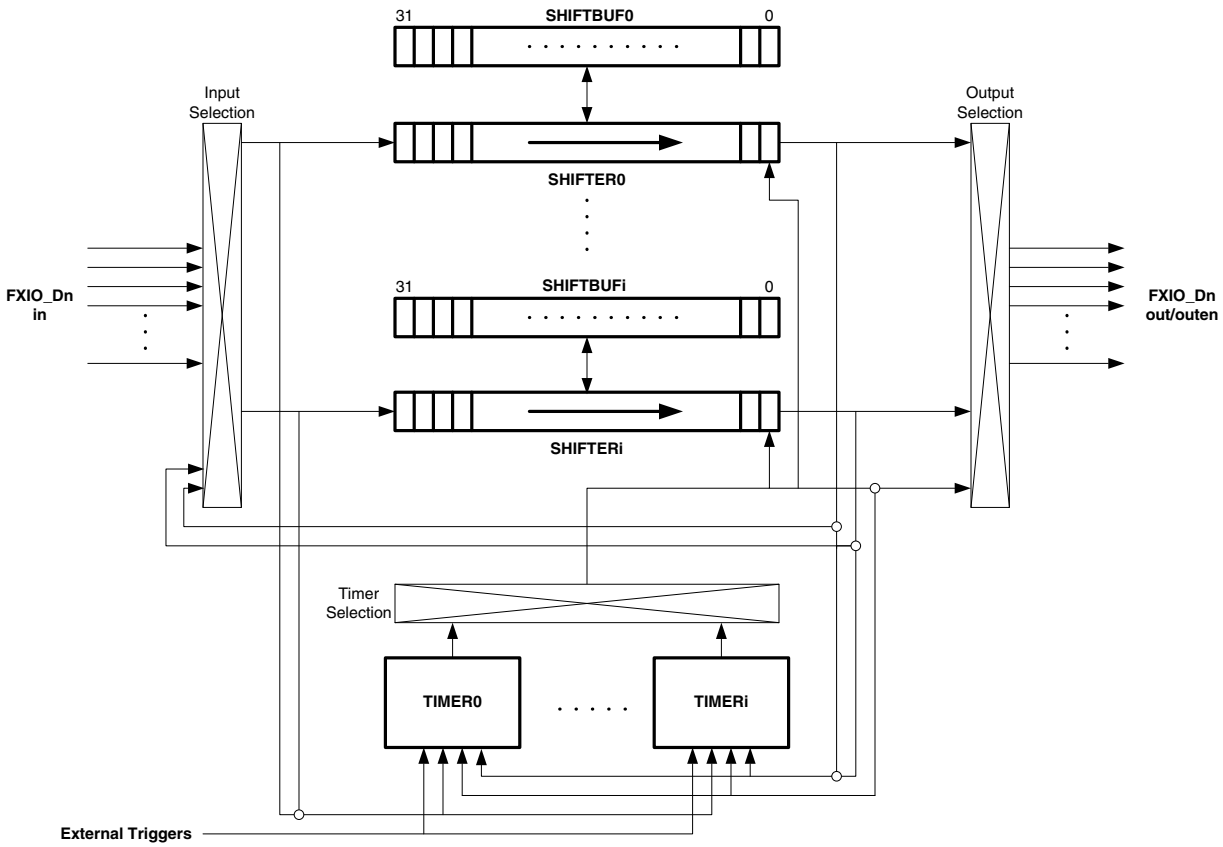

Figure 50-1. FlexIO block diagram

50.2.4 Modes of operation

The FlexIO module supports the chip modes described in the following table.

Table 50-3. Chip modes supported by the FlexIO module

Chip mode	FlexIO Operation
Run	Normal operation
Stop/Wait	Can continue operating provided the Doze Enable bit (CTRL[DOZEN]) is clear and the FlexIO is using an external or internal clock source which remains operating during stop/wait modes.
LLS	The Doze Enable (CTRL[DOZEN]) bit is ignored and the FlexIO will wait for all Timers to complete any pending operation before acknowledging LLS mode entry.
Debug	Can continue operating provided the Debug Enable bit (CTRL[DBGE]) is set.

50.2.5 FlexIO Signal Descriptions

Signal	Description	I/O
FXIO_Dn (n=0...31)	Bidirectional FlexIO Shifter and Timer pin inputs/outputs	I/O

50.3 Memory Map and Registers

50.3.1 FLEXIO register descriptions

NOTE

An invalid register access will result in a bus error. This includes reading a write-only register, writing a read-only register or accessing an invalid address.

50.3.1.1 FLEXIO Memory map

FLEXIO0 base address: 4103_2000h

FLEXIO1 base address: 4031_0000h

50.3.1.6.3 Fields

Field	Function
31-8 —	Reserved.
7-0 SSF	Shifter Status Flag The shifter status flag is updated when one of the following events occurs: For SMOD=Receive, the status flag is set when SHIFTBUF has been loaded with data from Shifter (SHIFTBUF is full), and the status flag is cleared when SHIFTBUF register is read. For SMOD=Transmit, the status flag is set when SHIFTBUF data has been transferred to the Shifter (SHIFTBUF is empty) or when initially configured for SMOD=Transmit, and the status flag is cleared when the SHIFTBUF register is written. For SMOD=Match Store, the status flag is set when a match has occured between SHIFTBUF and Shifter, and the status flag is cleared when the SHIFTBUF register is read. For SMOD=Match Continuous, returns the current match result between the SHIFTBUF and Shifter. The status flag cannot be cleared by reading SHIFTBUF. For SMOD=State, the status flag for a shifter will set when it is selected by the current state pointer. For SMOD=Logic, returns the current value of the programmable logic block output. The status flag can also be cleared by writing a logic one to the flag for all modes except Match Continuous/State/Logic. 0b - Status flag is clear. 1b - Status flag is set.

50.3.1.7.3 Fields

Field	Function
31-8 —	Reserved.
7-0 SEF	Shifter Error Flags The shifter error flag is set when one of the following events occurs: For SMOD=Receive, indicates Shifter was ready to store new data into SHIFTBUF before the previous data was read from SHIFTBUF (SHIFTBUF Overrun), or indicates that the received start or stop bit does not match the expected value. For SMOD=Transmit, indicates Shifter was ready to load new data from SHIFTBUF before new data had been written into SHIFTBUF (SHIFTBUF Underrun). For SMOD=Match Store, indicates a match event occured before the previous match data was read from SHIFTBUF (SHIFTBUF Overrun). For SMOD=Match Continuous, the error flag is set when a match has occured between SHIFTBUF and Shifter. For SMOD=Logic, the error flag is set when the output of the programmable logic block has asserted. Can be cleared by writing logic one to the flag. For SMOD=Match Continuous, can also be cleared when the SHIFTBUF register is read. 0b - Shifter Error Flag is clear. 1b - Shifter Error Flag is set.

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

50.3.1.16.3 Fields

Field	Function
31-0 SHIFTBUF	Shift Buffer Shift buffer data is used for a variety of functions depending on the SMOD setting: For SMOD=Receive, Shifter data is transferred into SHIFTBUF at the expiration of Timer. The SHIFTBUF register should only be read when the corresponding shifter status flag is set, indicating new Shifter data is available. For SMOD=Transmit, SHIFTBUF data is transferred into the Shifter before the Timer begins. For SMOD=Match Store, SHIFTBUF[31:16] contains the data to be matched with the Shifter contents and SHIFTBUF[15:0] can be used to mask the match result (1=mask, 0=no mask). The Match is checked when the Timer expires and Shifter data [31:16] is written to SHIFTBUF[31:16] whenever a match event occurs. The SHIFTBUF register should only be read when the corresponding shifter status flag is set, indicating new Shifter data is available. For SMOD=Match Continuous, SHIFTBUF[31:16] contains the data to be matched with the Shifter contents and SHIFTBUF[15:0] can be used to mask the match result (1=mask, 0=no mask). For SMOD=Logic, SHIFTBUF[31:0] is used to implement a 5-input, 32-bit programmable logic look-up table. See 'Logic Mode' section for more detail. For SMOD=State, SHIFTBUF[31:24] is used to drive the output value when this shifter is selected by the current state pointer and SHIFTBUF[23:0] is used to configure the value of the next state transition. See 'State Mode' section for more detail.

50.3.1.20.3 Fields

Field	Function
31-30 —	Reserved.
29-24 TRGSEL	Trigger Select The valid values for TRGSEL will depend on the FLEXIO_PARAM register. • When TRGSRC = 1, the valid values for N will depend on PIN, TIMER, SHIFTER fields in the FLEXIO_PARAM register. • When TRGSRC = 0, the valid values for N will depend on TRIGGER field in FLEXIO_PARAM register. Refer to the chip-specific FlexIO information for external trigger selection. **NOTE:** For a pin, N=0 to 31. For a Shifter, N=0 to 7. For a Timer, N=0 to 7. When TRGSRC = 0 the trigger selection is configured as follows: • N - External trigger N input When TRGSRC = 1 the internal trigger can be configured to select an input pin as follows: • 2*N - Pin N input When TRGSRC = 1 the internal trigger can be configured to select a shifter/timer signal as follows: • 4*N+1 - Shifter N status flag • 4*N+3 - Timer N trigger output In other words, the expanded internal trigger selection (TRGSRC = 1) is as follows: • 0000 = Pin 0 • 0001 = Shifter 0 Flag • 0010 = Pin 1 • 0011 = Timer 0 Trigger • 0100 = Pin 2 • 0101 = Shifter 1 Flag • 0110 = Pin 3 • 0111 = Timer 1 Trigger • ... • This continues up to the Pin 31, Shifter 7 and Timer 7.
23	Trigger Polarity

Table continues on the next page...

Field	Function
TRGPOL	0b - Trigger active high 1b - Trigger active low
22 TRGSRC	Trigger Source 0b - External trigger selected 1b - Internal trigger selected
21-18 —	Reserved.
17-16 PINCFG	Timer Pin Configuration Configures the direction of the Timer pin. For pins configured as an output (PINCFG=11), this field will take effect when the register is written. 00b - Timer pin output disabled 01b - Timer pin open drain or bidirectional output enable 10b - Timer pin bidirectional output data 11b - Timer pin output
15-13 —	Reserved.
12-8 PINSEL	Timer Pin Select Selects which pin is used by the Timer input or output. PINSEL=i will select the FXIO_Di pin. For pins configured as an output (PINCFG=11), this field will take effect when the register is written.
7 PINPOL	Timer Pin Polarity For pins configured as an output (PINCFG=11), this field will take effect when the register is written. 0b - Pin is active high 1b - Pin is active low
6-2 —	Reserved.
1-0 TIMOD	Timer Mode In 8-bit baud counter mode, the lower 8-bits of the counter and compare register are used to configure the baud rate of the timer shift clock, and the upper 8-bits are used to configure the shifter bit count. In 8-bit PWM high mode, the lower 8-bits of the counter and compare register are used to configure the high period of the timer shift clock, and the upper 8-bits are used to configure the low period of the timer shift clock. The shifter bit count is configured using another timer or external signal. In 16-bit counter mode, the full 16-bits of the counter and compare register are used to configure either the baud rate of the shift clock or the shifter bit count. 00b - Timer Disabled. 01b - Dual 8-bit counters baud mode. 10b - Dual 8-bit counters PWM high mode. 11b - Single 16-bit counter mode.

50.3.1.21 Timer Configuration N Register (TIMCFG0 - TIMCFG7)

50.3.1.21.1 Offset

For a = 0 to 7:

Register	Offset
TIMCFGa	480h + (a × 4h)

50.3.1.21.2 Function

The options to enable or disable the timer using the Timer N-1 enable or disable are reserved when N is evenly divisible by 4 (eg: Timer 0).

NOTE

The pin and trigger level/edges specified below refer to the signal state after being modified by the PINPOL or TRGPOL setting in the TIMCTL register. For example, "Trigger low" means a trigger is actually at logic level 1 if the TRGPOL is set to 1 (active low).

50.3.1.21.3 Diagram

50.4 Functional description

50.4.1 Clocking and Resets

50.4.1.1 Functional clock

The FlexIO functional clock is asynchronous to the bus clock and can remain enabled in low power modes. The FlexIO functional clock must be enabled before accessing any FlexIO registers. Provided the FlexIO functional clock is at least two times faster than the bus clock, the CTRL[FASTACC] bit can be set to support fast register accesses.

50.4.1.2 Bus clock

The bus clock is only used for bus accesses to the control and configuration registers.

50.4.1.3 Chip reset

The logic and registers for the FlexIO are reset to their default state on a chip reset.

50.4.1.4 Software reset

The FlexIO implements a software reset bit in its Control Register. The CTRL[RST] will reset all logic and registers to their default state, except for the CTRL itself.

50.4.2 Shifter operation

Shifters are responsible for buffering and shifting data into or out of the FlexIO. The timing of shift, load and store events are controlled by the Timer assigned to the Shifter via the SHIFTCTL[TIMSEL] register. The Shifters are designed to support either DMA, interrupt or polled operation. The following block diagram provides a detailed view of the Shifter microarchitecture.

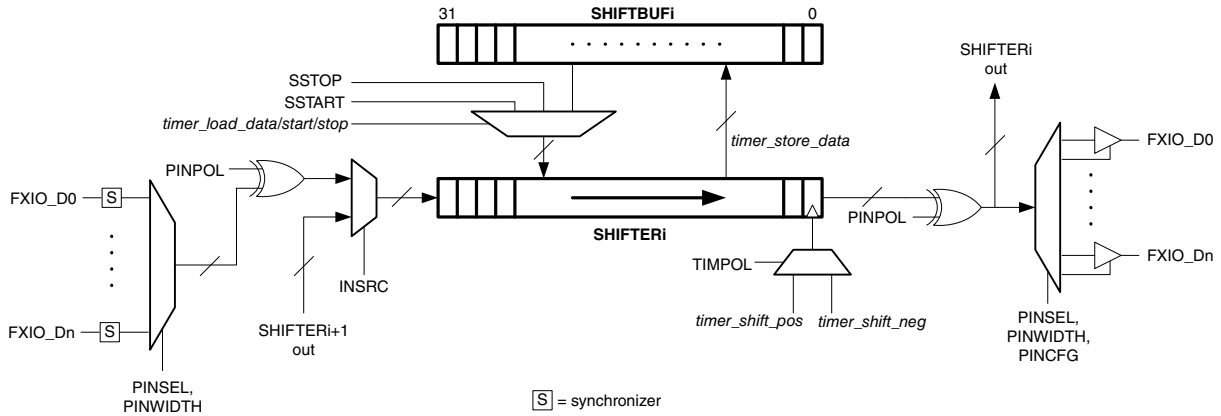

Figure 50-2. Shifter Microarchitecture

50.4.2.1 Transmit Mode

When configured for Transmit mode (SHIFTCTL[SMOD]=Transmit), the shifter will load data from the SHIFTBUF register and shift data out when a load event is signalled by the assigned Timer. An optional start/stop bit can also be automatically loaded before/after SHIFTBUF data by configuring the SHIFTCFG[SSTART], TIMCFG[TSTART] or SHIFTCFG[SSTOP], TIMCFG[TSTOP] registers in the Shifter and Timer. Note that the shifter will immediately load a stop bit when the Shifter is initially configured for Transmit mode if a stop bit is enabled.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests will set when data has been loaded from the SHIFTBUF register into the Shifter or when the Shifter is initially configured into Transmit mode. The flag will clear when new data has been written into the SHIFTBUF register.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts will set when an attempt to load data from an empty SHIFTBUF register occurs (buffer underrun). The flag can be cleared by writing it with logic 1.

50.4.2.2 Receive Mode

When configured for Receive mode (SHIFTCTL[SMOD]=Receive), the shifter will shift data in and store data into the SHIFTBUF register when a store event is signalled by the assigned Timer. Checking for a start/stop bit can be enabled before/after shifter data is sampled by configuring the SHIFTCFG[SSTART], TIMCFG[TSTART] or SHIFTCFG[SSTOP], TIMCFG[TSTOP] registers in the Shifter and Timer.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests will set when data has been stored into the SHIFTBUF register from the Shifter. The flag will clear when the data has been read from the SHIFTBUF register.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts will set when an attempt to store data into a full SHIFTBUF register occurs (buffer overrun) or when a mismatch occurs on a start/stop bit check. The flag can be cleared by writing it with logic 1.

50.4.2.3 Match Store Mode

When configured for Match Store mode (SHIFTCTL[SMOD]=Match Store), the shifter will shift data in, check for a match result and store matched data into the SHIFTBUF register when a store event is signalled by the assigned Timer. Checking for a start/stop bit can be enabled before/after shifter data is sampled by configuring the SHIFTCFG[SSTART], TIMCFG[TSTART] or SHIFTCFG[SSTOP], TIMCFG[TSTOP] registers in the Shifter and Timer. Up to 16-bits of data can be compared using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests will set when a match occurs and matched data has been stored into the SHIFTBUF register from the Shifter. The flag will clear when the matched data has been read from the SHIFTBUF register.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts will set when an attempt to store matched data into a full SHIFTBUF register occurs (buffer overrun) or when a mismatch occurs on a start/stop bit check. The flag can be cleared by writing it with logic 1.

50.4.2.4 Match Continuous Mode

When configured for Match Continuous mode (SHIFTCTL[SMOD]=Match Continuous), the shifter will shift data in and continuously check for a match result whenever a shift event is signalled by the assigned Timer. Up to 16-bits of data can be compared using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests will set when a match occurs. The flag will clear automatically as soon as there is no longer a match between Shifter data and SHIFTBUF register. The flag cannot be cleared by reading SHIFTBUF register.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts will set when a match occurs. The flag will clear when there is a read from the SHIFTBUF register or it written with logic 1.

50.4.2.5 State Mode

Using State mode enables the user to implement any state machine with up to 8 states, 8 outputs and 3 selectable inputs per state. This feature allows basic control functions to be offloaded from the CPU, which could potentially remain in a STOP/VLPS low power mode.

When configured for State mode (SHIFTCTL[SMOD]=State), the SHIFTBUF register is used to drive the output and compute next state values when the Shifter has been selected by the current state pointer (SHIFTSTATE[STATE]). The following diagram provides a detailed view of Shifter microarchitecture when configured for State mode.

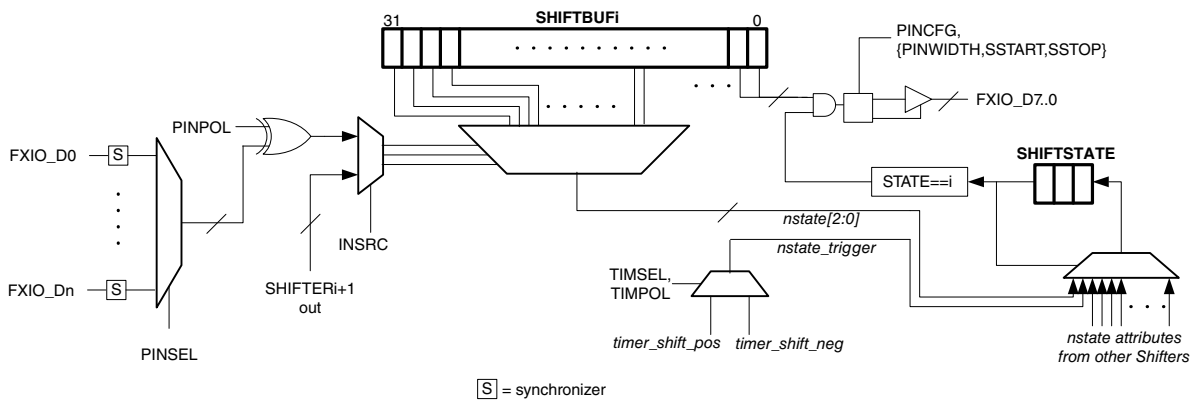

Figure 50-3. State Microarchitecture

When Shifter i has been selected by the current state pointer, output pins FXIO_D[7:0] will be driven by SHIFTBUFi[31:24] using the configuration set by SHIFTCTLi[PINCFG]. When set, SHIFTCFGi{PWIDTH[3:0],SSTOP[1:0],SSTART[1:0]} are respectively used to disable the output drive on pins FXIO_D[7:0] for state machine applications which require less than 8 output pins.

The next state value is computed using the 3 input pins selected by SHIFTCTLi[PINSEL] together with SHIFTBUFi[23:0]. Note that each state could potentially use a different set of 3 input pins. The following table details how the next state value is computed when the current state pointer is pointing to Shifter i.

Table 50-4. Next State computation for SHIFTSTATE[STATE]=i

FXIO_D[PINSEL+2]	FXIO_D[PINSEL+1]	FXIO_D[PINSEL]	Next State Value

Table continues on the next page...

Table 50-4. Next State computation for SHIFTSTATE[STATE]=i (continued)

0	0	0	SHIFTBUFi[2:0]
0	0	1	SHIFTBUFi[5:3]
0	1	0	SHIFTBUFi[8:6]
0	1	1	SHIFTBUFi[11:9]
...	...	...	...
1	1	1	SHIFTBUFi[23:21]

Note that other shifters/timers could potentially be configured to drive the input pins of a given state, allowing the user to create complex combinations of shifters/timers as desired e.g. the output of a Shifter configured for logic mode could potentially be used to drive a state machine input.

The next state transition is triggered using the Timer output selected by SHIFTCTLi[TIMSEL] with polarity controlled by SHIFTCTLi[TIMPOL]. Note that each state could potentially use a different Timer to trigger each next state transition, allowing a variety of internal/external trigger sources and clocking configurations to be used (see Timer section for more detail).

The current state pointer defaults to Shifter 0 at reset, however it can be written by the user to select a different Shifter for the initial state. If the current state pointer selects a Shifter which is not configured for State mode, then outputs will not be driven and a next state transition is never triggered.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests will set whenever the Shifter has been selected by the current state pointer. The flag will clear when the current state pointer is updated to a different Shifter.

50.4.2.6 Logic Mode

Using logic mode enables the user to implement a small amount of programmable digital logic within a FlexIO Shifter.

When configured for Logic mode (SHIFTCTL[SMOD]=Logic), the SHIFTBUF register is used to implement a 5-input, 32-bit programmable logic look-up table. The following diagram provides a detailed view of Shifter microarchitecture when configured for Logic mode.

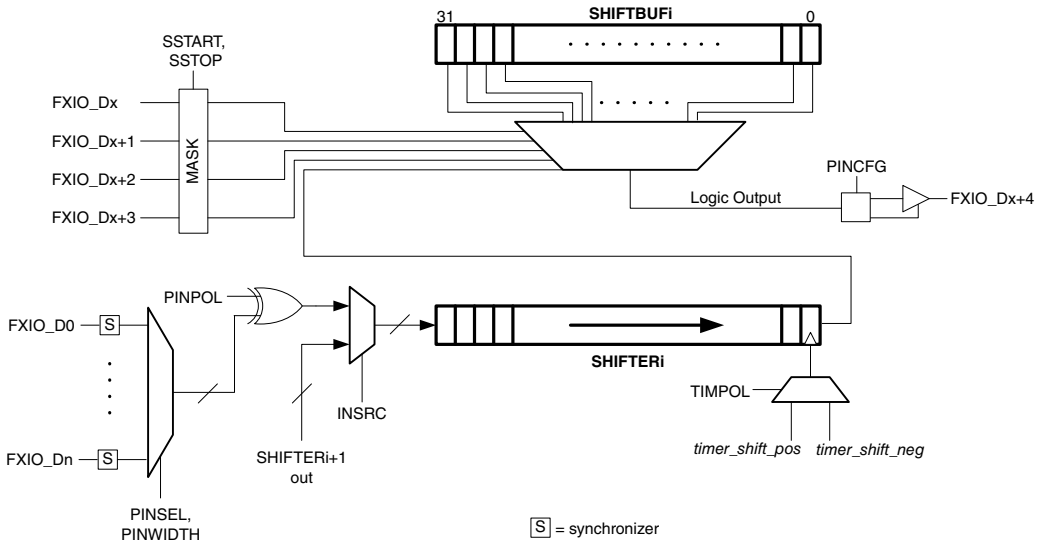

Figure 50-4. Logic Microarchitecture

The look-up table is driven using 4 pin inputs (maskable using SHIFTCFG[SSTOP] and SHFITCFG[SSTART]) plus 1 input from the internal shifter and can be configured to drive an output pin using the SHIFTCTL[PINCFG] field. Pin inputs and outputs are fixed for each logic look-up table and are not selectable. The following table lists the logic output value selected by the look-up table for Shifter 'i'.

Table 50-5. Logic Look-up table for Shifter 'i'

SHIFTERi[0]	FXIO_D[x+3][1]	FXIO_D[x+2]	FXIO_D[x+1]	FXIO_D[x]	Logic Output to FXIO_D[x+4]
0	0	0	0	0	SHIFTBUFi[0]
0	0	0	0	1	SHIFTBUFi[1]
0	0	0	1	0	SHIFTBUFi[2]
0	0	0	1	1	SHIFTBUFi[3]
...	...	...	...	...	...
1	1	1	1	1	SHIFTBUFi[31]

1. for Shifter i=0...3, x=i

   for Shifter i=4...7, x=i+4

To minimize output glitches, SHIFTCFG[SSTOP] and SHIFTCFG[SSTART] can be used to mask unused input pins. When set, {SSTOP[1:0], SSTART[1:0]} will mask FXIO_D[x+3]...FXIO_D[x] inputs respectively, so that any transitions on these pins will not cause the logic output to glitch.

Note that other shifters/timers could potentially be configured to drive the input pins of a given look-up table, allowing the user to concatenate look-up tables or create complex combinations of shifters/timers as desired.

SHIFTCFG[PWIDTH] will control the number of delay stages introduced by the internal shifter input (SHIFTERi[0]). For example, when configured for 1-bit shift (PWIDTH=0), the internal shifter will introduce a 32 Shift clock delay before passing its input (selected by SHIFTCTL[PINSEL]) to the look-up table. When configured for 32-bit shift (PWIDTH=16...31), the internal shifter will introduce a 1 Shift clock delay to its input.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests will set whenever the output pin allocated to the logic look-up table has a value of 1 (after being synchronized to the FlexIO clock). The flag will clear when the output pin has a value of 0. This also allows the SSF flag to be used as a trigger to a Timer if desired.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts will set when the output pin allocated to the logic look-up table has a value of 1. The flag can be cleared by writing it with logic 1.

50.4.3 Timer Operation

The FlexIO 16-bit timers control the loading, shifting and storing of the shift registers, the counters load the contents of the compare register and decrement down to zero on the FlexIO clock. They can perform generic timer functions such as generating a clock or select output or a PWM waveform. Timers can be configured to enable in response to a trigger, pin or shifter condition; decrement always or only on a trigger or pin edge; reset in response to a trigger or pin condition; and disable on a trigger or pin condition or on a timer compare. Timers can optionally include a start condition and/or stop condition.

Each timer operates independently, although a timer can be configured to enable or disable at the same time as the previous timer (eg: timer1 can enable or disable at the same time as timer 0) and a timer output can be used to trigger any other timer. The trigger used by each timer is configured independently and can be configured to be a timer output, shifter status flag, pin input or an external trigger input (refer to the chip-specific FlexIO information for details on the external trigger connections). The trigger configuration is separate from the pin configuration, which can be configured for input, output data or output enable.

The Timer Configuration Register (TIMCFGn) should be configured before setting the Timer Mode (TIMOD).

50.4.3.1 Timer 8-bit Baud Counter Mode

In 8-bit Baud Counter Mode, the 16-bit counter is divided into two 8-bit counters. The lower 8-bits are used to configure the baud rate of the shift clock and the upper 8-bits are used to configure the number of shift clock edges in the transfer. When the lower 8-bits

decrement to zero, the timer output is toggled and the lower 8-bits reload from the compare register. The upper 8-bits decrement when the lower 8-bits equal zero and decrement.

Note that a timer reset event in 8-bit Baud Counter Mode will only reset the lower 8-bit counter, the upper 8-bit counter is not affected and can decrement if the timer reset is configured to update the state of the timer output, and the timer output toggles as a result of the timer reset event.

A timer compare event occurs when the upper 8-bits equal zero and decrements. The timer status flag is set on a timer compare event.

50.4.3.2 Timer 8-bit High PWM Mode

In 8-bit High PWM Mode, the 16-bit counter is divided into two 8-bit counters. The lower 8-bits are used to configure the timer output high period and the upper 8-bits are used to configure the timer output low period. The lower 8-bits decrement when the output is high. When the lower 8-bits equal zero and decrement, the timer output is cleared and the lower 8-bits are reloaded from the compare register. The upper 8-bits decrement when the output is low. When the upper 8-bits equal zero and decrement, the timer output is set and the upper 8-bits are reloaded from the compare register.

A timer compare event occurs when the upper 8-bits equal zero and decrements. The timer status flag is set on a timer compare event.

50.4.3.3 Timer 16-bit Counter Mode

In 16-bit Counter Mode, the 16-bit counter can be used to configure either the baud rate of the shift clock (eg: TIMDEC[1:0] != 10 or 11) or the number of shift clock edges in the transfer (eg: TIMDEC[1:0] = 10 or 11). When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads from the compare register.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer compare event.

50.4.3.4 Timer Enable and Start Bit

When the TIMOD is configured for the desired mode, and the condition configured by timer enable (TIMENA) is detected then the following events occur.

- Timer counter will load the current value of the compare Register and start decrementing as configured by TIMDEC.
- Timer output may update to its initial state depending on the TIMOUT configuration. Shifters that are controlled by this timer do not see this as a rising edge on the timer shift clock.
- Transmit shifters controlled by this timer will either output their start bit value, or load the shift register from the shift buffer and output the first bit, as configured by SSTART.

If the Timer start bit is enabled, the timer counter will reload with the compare register on the first rising edge of the shift clock after the timer starts decrementing. If there is no falling edge on the shift clock before the first rising edge (for example, when TIMOUT=1), a shifter that is configured to shift on falling edge and load on the first shift will not load correctly.

50.4.3.5 Timer Decrement and Reset

The Timer will then generate the timer output and timer shift clock depending on the TIMOD and TIMDEC fields. The shifter clock is either equal to the timer output (when TIMDEC != 10 or 11) or equal to the decrement clock (when TIMDEC = 10 or 11). When TIMDEC is configured to decrement from a pin or trigger, the timer will decrement on both rising and falling edges.

When the Timer is configured to reset as configured in the TIMRST field then the Timer counter will load the current value of the compare register again. The timer output and timer shift clock can be configured to update on timer reset, as configured by TIMOUT. This can result in a timer shift clock edge if the timer output toggles as a result of the timer reset. In 8-bit Baud Counter mode this would also decrement the upper 8-bits of the counter.

In general, when the timer counter decrements to zero a timer compare event is triggered. The timer compare event will cause the timer counter to load the contents of the timer compare register, the timer output to toggle, any configured transmit shift registers to load, and any configured receive shift registers to store. Depending on the timer mode, the timer status flag may also be set.

50.4.3.6 Timer Disable and Stop Bit

When the is Timer is configured to add a stop bit on each compare, the following additional events will occur.

- Transmit shifters controlled by this timer will output their stop bit value (if configured by SSTOP).
- Receive shifters controlled by this timer will store the contents of the shift register in their shift buffer, as configured by SSTOP.
- On the first rising edge of the shifter clock after the compare, the timer counter will reload the current value of the Compare Register.

Transmit shifters must be configured to load on the first shift when the timer is configured to insert a stop bit on each compare.

When the condition configured by timer disable (TIMDIS) is detected, the following events occur.

- Timer counter will reload the current value of the Compare Register and start decrementing as configured by TIMDEC.
- Timer output will clear. Shifters that are controlled by this timer do not see this as a falling edge on the timer shift clock, but can generate a shift event if the timer shift clock would otherwise generate one.
- Transmit shifters controlled by this timer will output their stop bit value (if configured by SSTOP).
- Receive shifters controlled by this timer will store the contents of the shift register in their shift buffer, as configured by SSTOP.

If the timer stop bit is enabled, the timer counter will continue decrementing until the next rising edge of the shift clock is detected, at which point it will finish. Although the timer output is forced low during the stop bit, the timer shift clock can toggle during the stop bit, but does not generate shift events.

A timer enable condition can be detected in the same cycle as a timer disable condition (if timer stop bit is disabled), or on the first rising edge of the shift clock after the disable condition (if stop bit is enabled). Receive shift registers with stop bit enabled will store the contents of the shift register into the shift buffer and verify the state of the input data on the configured shift edge while the timer is in the stop state condition. If there is no configured edge between the timer disable and the next rising edge of the shift clock then the final store and verify do not occur.

50.4.4 Pin operation

The pin configuration for each timer and shifter can be configured to use any FlexIO pin with either polarity. Each timer and shifter can be configured as an input, output data, output enable or bidirectional output. A pin configured for output enable can be used as an open drain (with inverted polarity, since the output enable assertion would cause logic

zero to be output on the pin) or to control the enable on the bidirectional output. Any timer or shifter could be configured to control the output enable for a pin where the bidirectional output data is driven by another timer or shifter.

50.4.4.1 Parallel Interface

Shifters can be configured to use multiple FlexIO pins in parallel using the SHIFTCFG[PWIDTH] field. PWIDTH is used to configure the following settings of a shifter:

1. Number of bits shifted per Shift clock.
2. Number of pins driven by the shifter per Shift clock (only on shifters supporting parallel transmit i.e. SHIFTER0, SHIFTER4).
3. Number of pins sampled by the shifter per Shift clock (only on Shifter supporting parallel receive i.e. SHIFTER3, SHIFTER7).

When configured for parallel shift, either 4, 8, 16 or 32-bits can be shifted on every Shift clock. If an adjacent shifter is selected as the input source (SHIFTCFG[INSRC]=1), the least significant 4, 8, 16 or 32-bits from the adjacent shifter will be sampled on each Shift clock.

For shifters supporting parallel receive (SHIFTER3, SHIFTER7), the shifter can be configured to sample multiple pins (SHIFTCFG[INSRC]=0), with PWIDTH and PINSEL selecting the pins as follows: FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL]. Note that if PWIDTH is less than the number of bits being shifted on each Shift clock, then the most significant bits will be masked with 0 e.g. if PINSEL=7 and PWIDTH=6, then SHIFTER[31:24] will sample {0,0,FXIO_D[12:7]} on each Shift clock.

For shifters supporting parallel transmit (SHIFTER0, SHIFTER4), the shifter can be configured to drive multiple pins using SHIFTCTL[PINCFG], with PWIDTH and PINSEL selecting the pins as follows: FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL]. Note that if PWIDTH is less than the number of bits being shifted on each Shift clock, then the most significant pins will not be driven e.g. if PINSEL=7 and PWIDTH=6, then SHIFTER[5:0] will drive only FXIO_D[12:7] on each Shift clock.

50.4.4.2 Pin Synchronization

When configuring a pin as an input (this includes a timer trigger configured as a pin input), the input signal is first synchronized to the FlexIO clock before the signal is used by a timer or shifter. This introduces a small latency of between 0.5 to 1.5 FlexIO clock cycles when using an external pin input to generate an output or control a shifter. This sets the maximum setup time at 1.5 FlexIO clock cycles.

If an input is used by more than one timer or shifter then the synchronization occurs once to ensure any edge is seen on the same cycle by all timers and shifters using that input.

Note that FlexIO pins are also connected internally, configuring a FlexIO shifter or timer to output data on an unused pin will make an internal connection that allows other shifters and timer to use this pin as an input. This allows a shifter output to be used to trigger a timer or a timer output to be shifted into a shifter. This path is also synchronized to the FlexIO clock and therefore incurs a 1 cycle latency.

So when using a Pin input as a Timer Trigger, Timer Clock or Shifter Data Input, the following synchronization delays occur:

1. 0.5 to 1.5 FlexIO clock cycles for external pin
2. 1 FlexIO clock cycle for an internally driven pin

For timing considerations such as output valid time and input setup time for specific applications (SPI Master, SPI Slave, I2C Master, I2S Master, I2S Slave) please refer to the FlexIO Application Information Section.

50.4.5 Interrupts and DMA Requests

The following table illustrates the status flags that can generate the FlexIO interrupt and DMA requests.

Table 50-6. FlexIO Interrupts and DMA Requests

Flag	Description	Interrupt	DMA Request	Low Power Wakeup
SSF	Shifter Status Flag.	Y	Y	Y
SEF	Shifter Error Flag.	Y	N	Y
TSF	Timer Status Flag.	Y	N	Y

50.4.6 Peripheral Triggers

The connection of the FlexIO peripheral triggers with other peripherals are device specific.

50.4.6.1 Output Triggers

Each FlexIO Timer generates an output trigger equal to the timer output. The output trigger is not affected by the timer pin polarity configuration.

50.4.6.2 Input Trigger

FlexIO supports multiple external trigger inputs that can be used to trigger one or more FlexIO timers. The external triggers are synchronized to the FlexIO functional clock and must assert for at least two cycles of the FlexIO functional clock to be sampled correctly.

50.5 Application Information

This section provides examples for a variety of FlexIO module applications.

50.5.1 UART Transmit

UART transmit can be supported using one Timer, one Shifter and one Pin (two Pins if supporting CTS). The start and stop bit insertion is handled automatically and multiple transfers can be supported using DMA controller. The timer status flag can be used to indicate when the stop bit of each word is transmitted.

Break and idle characters require software intervention, before transmitting a break or idle character the SSTART and SSTOP fields should be altered to transmit the required state and the data to transmit must equal 0xFF or 0x00. Supporting a second stop bit requires the stop bit to be inserted into the data stream using software (and increasing the number of bits to transmit). Note that when performing byte writes to SHIFTBUFn (or SHIFTBUFBIS for transmitting MSB first), the rest of the register remains unaltered allowing an address mark bit or additional stop bit to remain undisturbed.

FlexIO does not support automatic insertion of parity bits.

Table 50-7. UART Transmit Configuration

Register	Value	Comments
SHIFTCFGn	0x0000_0032	Configure start bit of 0 and stop bit of 1.
SHIFTCTLn	0x0003_0002	Configure transmit using Timer 0 on posedge of clock with output data on Pin 0. Can invert output data by setting PINPOL, or can support open drain by setting PINPOL=0x1 and PINCFG=0x1.
TIMCMPn	0x0000_0F01	Configure 8-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0x0000_2222	Configure start bit, stop bit, enable on trigger asserted and disable on

Table continues on the next page...

Table 50-7. UART Transmit Configuration (continued)

Register	Value	Comments
		compare. Can support CTS by configuring TIMEN=0x3.
TIMCTLn	0x01C0_0001	Configure dual 8-bit counter using Shifter 0 status flag as inverted internal trigger source. Can support CTS by configuring PINSEL=0x1 (for Pin 1) and PINPOL=0x1.
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUF[7:0] to initiate an 8-bit transfer, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Can support MSB first transfer by writing to SHIFTBUFBBS[7:0] register instead.

50.5.2 UART Receive

UART receive can be supported using one Timer, one Shifter and one Pin (two Timers and two Pins if supporting RTS). The start and stop bit verification is handled automatically and multiple transfers can be supported using the DMA controller. The timer status flag can be used to indicate when the stop bit of each word is received.

Triple voting of the received data is not supported by FlexIO, data is sampled only once in the middle of each bit. Another timer can be used to implement a glitch filter on the incoming data, another Timer can also be used to detect an idle line of programmable length. Break characters will cause the error flag to set and the shifter buffer register will return 0x00.

FlexIO does not support automatic verification of parity bits.

Table 50-8. UART Receiver Configuration

Register	Value	Comments
SHIFTCFGn	0x0000_0032	Configure start bit of 0 and stop bit of 1.
SHIFTCTLn	0x0080_0001	Configure receive using Timer 0 on negedge of clock with input data on Pin 0. Can invert input data by setting PINPOL.
TIMCMPn	0x0000_0F01	Configure 8-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.

Table continues on the next page...

Table 50-8. UART Receiver Configuration (continued)

Register	Value	Comments
TIMCFGn	0x0204_2422	Configure start bit, stop bit, enable on pin posedge and disable on compare. Enable resynchronization to received data with TIMOUT=0x2 and TIMRST=0x4.
TIMCTLn	0x0000_0081	Configure dual 8-bit counter using inverted Pin 0 input.
SHIFTBUFn	Data to receive	Received data can be read from SHIFTBUFBYS[7:0], use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Can support MSB first transfer by reading from SHIFTBUFBIS[7:0] register instead.

The UART Receiver with RTS configuration uses a 2nd Timer to generate the RTS output. The RTS will assert when the start bit is detected and negate when the data is read from the shifter buffer register. No start bit will be detected while the RTS is asserted, the received data is simply ignored.

Table 50-9. UART Receiver with RTS Configuration

Register	Value	Comments
SHIFTCFGn	0x0000_0032	Configure start bit of 0 and stop bit of 1.
SHIFTCTLn	0x0080_0001	Configure receive using Timer 0 on negedge of clock with input data on Pin 0. Can invert input data by setting PINPOL.
TIMCMPn	0x0000_0F01	Configure 8-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0x0204_2522	Configure start bit, stop bit, enable on pin posedge with trigger asserted and disable on compare. Enable resynchronization to received data with TIMOUT=0x2 and TIMRST=0x4.
TIMCTLn	0x02C0_0081	Configure dual 8-bit counter using inverted Pin 0 input. Trigger is internal using inverted Pin 1 input.
TIMCMP(n+1)	0x0000_FFFF	Never compare.
TIMCFG(n+1)	0x0030_6100	Enable on Timer N enable and disable on trigger falling edge. Decrement on trigger to ensure no compare.
TIMCTL(n+1)	0x0143_0003	Configure 16-bit counter and output on Pin 1. Trigger is internal using Shifter 0 flag.

Table 50-9. UART Receiver with RTS Configuration (continued)

Register	Value	Comments
SHIFTBUFn	Data to receive	Received data can be read from SHIFTBUFBYS[7:0], use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Can support MSB first transfer by reading from SHIFTBUFBIS[7:0] register instead.

50.5.3 SPI Master

SPI master mode can be supported using two Timers, two Shifters and four Pins. Either CPHA=0 or CPHA=1 can be supported and transfers can be supported using the DMA controller. For CPHA=1, the select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

The stop bit is used to guarantee a minimum of 1 clock cycle between the slave select negating and before the next transfer. Writing to the transmit buffer by either core or DMA is used to initiate each transfer.

Due to synchronization delays, the setup time for the serial input data is 1.5 FlexIO clock cycles, so the maximum baud rate is divide by 4 of the FlexIO clock frequency.

Table 50-10. SPI Master (CPHA=0) Configuration

Register	Value	Comments
SHIFTCFGn	0x0000_0000	Start and stop bit disabled.
SHIFTCTLn	0x0083_0002	Configure transmit using Timer 0 on negedge of clock with output data on Pin 0.
SHIFTCFG(n+1)	0x0000_0000	Start and stop bit disabled.
SHIFTCTL(n+1)	0x0000_0101	Configure receive using Timer 0 on posedge of clock with input data on Pin 1.
TIMCMPn	0x0000_3F01	Configure 32-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0x0100_2222	Configure start bit, stop bit, enable on trigger high and disable on compare, initial clock state is logic 0.
TIMCTLn	0x01C3_0201	Configure dual 8-bit counter using Pin 2 output (shift clock), with Shifter 0 flag as

Table continues on the next page...

Register	Value	Comments
SHIFTCFGn	0x0000_0021	Start bit loads data on first shift.
SHIFTCTLn	0x0003_0002	Configure transmit using Timer 0 on posedge of clock with output data on Pin 0.
SHIFTCFG(n+1)	0x0000_0000	Start and stop bit disabled.
SHIFTCTL(n+1)	0x0080_0101	Configure receive using Timer 0 on negedge of clock with input data on Pin 1.
TIMCMPn	0x0000_3F01	Configure 32-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0x0100_2222	Configure start bit, stop bit, enable on trigger high and disable on compare, initial clock state is logic 0.
TIMCTLn	0x01C3_0201	Configure dual 8-bit counter using Pin 2 output (shift clock), with Shifter 0 flag as the inverted trigger. Set PINPOL to invert the output shift clock. Set TIMDIS=3 to keep slave select asserted for as long as there is data in the transmit buffer.
TIMCMP(n+1)	0x0000_FFFF	Never compare.

Table continues on the next page...

Table 50-11. SPI Master (CPHA=1) Configuration (continued)

Register	Value	Comments
TIMCFG(n+1)	0x0000_1100	Enable when Timer 0 is enabled and disable when Timer 0 is disabled.
TIMCTL(n+1)	0x0003_0383	Configure 16-bit counter (never compare) using inverted Pin 3 output (as slave select).
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUF, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Can support MSB first transfer by writing to SHIFTBUFBBS register instead.
SHIFTBUF(n+1)	Data to receive	Received data can be read from SHIFTBUFBYS, use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Can support MSB first transfer by reading from SHIFTBUFBIS register instead.

50.5.4 SPI Slave

SPI slave mode can be supported using one Timer, two Shifters and four Pins. Either CPHA=0 or CPHA=1 can be supported and transfers can be supported using the DMA controller. For CPHA=1, the select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

The transmit data must be written to the transmit buffer register before the external slave select asserts, otherwise the shifter error flag will be set.

Due to synchronization delays, the output valid time for the serial output data is 2.5 FlexIO clock cycles, so the maximum baud rate is divide by 6 of the FlexIO clock frequency.

Table 50-12. SPI Slave (CPHA=0) Configuration

Register	Value	Comments
SHIFTCFGn	0x0000_0000	Start and stop bit disabled.
SHIFTCTLn	0x0083_0002	Configure transmit using Timer 0 on falling edge of shift clock with output data on Pin 0.
SHIFTCFG(n+1)	0x0000_0000	Start and stop bit disabled.
SHIFTCTL(n+1)	0x0000_0101	Configure receive using Timer 0 on rising edge of shift clock with input data on Pin 1.

50.5.5 I2C Master

I2C master mode can be supported using two Timers, two Shifters and two Pins. One timer is used to generate the SCL output and one timer is used to control the shifters. The two shifters are used to transmit and receive for every word, when receiving the transmitter must transmit 0xFF to tristate the output. FlexIO inserts a stop bit after every word to generate/verify the ACK/NACK. FlexIO waits for the first write to the transmit data buffer before enabling SCL generation. Data transfers can be supported using the DMA controller and the shifter error flag will set on transmit underrun or receive overflow.

The first timer generates the bit clock for the entire packet (START to Repeated START/ STOP), so the compare register needs to be programmed with the total number of clock edges in the packet (minus one). The timer supports clock stretching using the reset counter when pin equal to output (although this increases both the clock high and clock low periods by at least 1 FlexIO clock cycle each). The second timer uses the SCL input pin to control the transmit/receive shift registers, this enforces an SDA data hold time by an extra 2 FlexIO clock cycles.

Both the transmit and receive shifters need to be serviced for each word in the transfer, the transmit shifter must transmit 0xFF when receiving and the receive shifter returns the data actually present on the SDA pin. The transmit shifter will load 1 additional word on the last falling edge of SCL pin, this word should be 0x00 if generating a STOP condition or 0xFF if generating a repeated START condition. During the last word of a master-receiver transfer, the transmit SSTOP bit should be set by software to generate a NACK.

The receive shift register will assert an error interrupt if a NACK is detected, but software is responsible for generating the STOP or repeated START condition. If a NACK is detected during master-transmit, the interrupt routine should immediately write the transmit shifter register with 0x00 (if generating STOP) or 0xFF (if generating repeated START). Software should then wait for the next rising edge on SCL and then disable both timers. The transmit shifter should then be disabled after waiting the setup delay for a repeated START or STOP condition.

Due to synchronization delays, the data valid time for the transmit output is 2 FlexIO clock cycles, so the maximum baud rate is divide by 6 of the FlexIO clock frequency.

The I2C master data valid is delayed 2 cycles because the clock output is passed through a synchronizer before clocking the transmit/receive shifter (to guarantee some SDA hold time). Since the SCL output is synchronous with FlexIO clock, the synchronization delay is 1 cycle and then 1 cycle to generate the output.

Table 50-14. I2C Master Configuration

Register	Value	Comments
SHIFTCFGn	0x0000_0032	Start bit enabled (logic 0) and stop bit enabled (logic 1).
SHIFTCTLn	0x0101_0082	Configure transmit using Timer 1 on rising edge of clock with inverted output enable (open drain output) on Pin 0.
SHIFTCFG(n+1)	0x0000_0020	Start bit disabled and stop bit enabled (logic 0) for ACK/NACK detection.
SHIFTCTL(n+1)	0x0180_0001	Configure receive using Timer 1 on falling edge of clock with input data on Pin 0.
TIMCMPn	0x0000_2501	Configure 2 word transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of words x 18) + 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0x0102_2222	Configure start bit, stop bit, enable on trigger high, disable on compare, reset if output equals pin. Initial clock state is logic 0 and is not affected by reset.
TIMCTLn	0x01C1_0101	Configure dual 8-bit counter using Pin 1 output enable (SCL open drain), with Shifter 0 flag as the inverted trigger.
TIMCMP(n+1)	0x0000_000F	Configure 8-bit transfer. Set TIMCMP[15:0] = (number of bits x 2) - 1.
TIMCFG(n+1)	0x0020_1112	Enable when Timer 0 is enabled, disable when Timer 0 is disabled, enable start bit and stop bit at end of each word, decrement on pin input.
TIMCTL(n+1)	0x01C0_0183	Configure 16-bit counter using inverted Pin 1 input (SCL).
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUFBBS[7:0], use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request.
SHIFTBUF(n+1)	Data to receive	Received data can be read from SHIFTBUFBIS[7:0], use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request.

50.5.6 I2S Master

I2S master mode can be supported using two Timers, two Shifters and four Pins. One timer is used to generate the bit clock and control the shifters and one timer is used to generate the frame sync. FlexIO waits for the first write to the transmit data buffer before enabling bit clock and frame sync generation. Data transfers can be supported using the DMA controller and the shifter error flag will set on transmit underrun or receive overflow.

The bit clock frequency is an even integer divide of the FlexIO clock frequency, and the initial frame sync assertion occurs at the same time as the first bit clock edge. The timer uses the start bit to ensure the frame sync is generated one clock cycle before the first output data.

Due to synchronization delays, the setup time for the receiver input is 1.5 FlexIO clock cycles, so the maximum baud rate is divide by 4 of the FlexIO clock frequency.

Table 50-15. I2S Master Configuration

Register	Value	Comments
SHIFTCFGn	0x0000_0001	Load transmit data on first shift and stop bit disabled.
SHIFTCTLn	0x0003_0002	Configure transmit using Timer 0 on rising edge of clock with output data on Pin 0.
SHIFTCFG(n+1)	0x0000_0000	Start and stop bit disabled.
SHIFTCTL(n+1)	0x0080_0101	Configure receive using Timer 0 on falling edge of clock with input data on Pin 1.
TIMCMPn	0x0000_3F01	Configure 32-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0x0000_0202	Configure start bit, enable on trigger high and never disable. Initial clock state is logic 1.
TIMCTLn	0x01C3_0201	Configure dual 8-bit counter using Pin 2 output (bit clock), with Shifter 0 flag as the inverted trigger. Set PINPOL to invert the output shift clock.
TIMCMP(n+1)	0x0000_007F	Configure 32-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:0] = (number of bits x baud rate divider) - 1.
TIMCFG(n+1)	0x0000_0100	Enable when Timer 0 is enabled and never disable.

Table continues on the next page...

Table 50-15. I2S Master Configuration (continued)

Register	Value	Comments
TIMCTL(n+1)	0x0003_0383	Configure 16-bit counter using inverted Pin 3 output (as frame sync).
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUFBIS, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Can support LSB first transfer by writing to SHIFTBUF register instead.
SHIFTBUF(n+1)	Data to receive	Received data can be read from SHIFTBUFBIS, use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Can support LSB first transfer by reading from SHIFTBUF register instead.

50.5.7 I2S Slave

I2S slave mode can be supported using three Timers, two Shifters and four Pins (for single transmit and single receive, other combinations of transmit and receive are possible).

The transmit data must be written to the transmit buffer register before the external frame sync asserts, otherwise the shifter error flag will be set.

Due to synchronization delays, the output valid time for the serial output data is 2.5 FlexIO clock cycles, so the maximum baud rate is divide by 6 of the FlexIO clock frequency.

The output valid time of I2S slave is max 2.5 cycles because there is a maximum 1.5 cycle delay on the clock synchronization plus 1 cycle to output the data

Timer 2 detects the falling edge of frame sync (start of new frame) and asserts output until falling edge of bit clock (when frame sync is normally sampled). Timer 0 detects falling edge of bit clock with Timer 2 output asserted and asserts output for length of frame. Timer 1 detects rising edge of bit clock with Timer 0 output asserted and controls shift registers for 32-bit transfers.

Table 50-16. I2S Slave Configuration

Register	Value	Comments
SHIFTCFGn	0x0000_0000	Start and stop bit disabled.

Table continues on the next page...

Table 50-16. I2S Slave Configuration (continued)

Register	Value	Comments
SHIFTCTLn	0x0103_0002	Configure transmit using Timer 1 on rising edge of shift clock with output data on Pin 0.
SHIFTCFG(n+1)	0x0000_0000	Start and stop bit disabled.
SHIFTCTL(n+1)	0x0180_0101	Configure receive using Timer 1 on falling edge of shift clock with input data on Pin 1.
TIMCMPn	0x0000_007F	Configure two 32-bit transfers per frame. Set TIMCMP[15:0] = (number of bits x 4) - 1.
TIMCFGn	0x0020_2500	Configure enable on pin rising edge (inverted bit clock) with trigger high (Timer 2) and disable on compare, initial clock state is logic 1 and decrement on pin input (bit clock).
TIMCTLn	0x0B40_0283	Configure 16-bit counter using inverted Pin 2 input (bit clock), with Timer 2 output as the trigger.
TIMCMP(n+1)	0x0000_003F	Configure 32-bit transfers. Set TIMCMP[15:0] = (number of bits x 2) - 1.
TIMCFG(n+1)	0x0020_2500	Configure enable on pin (bit clock) rising edge with trigger (Timer 0) high and disable on compare, initial clock state is logic 1 and decrement on pin input (bit clock).
TIMCTL(n+1)	0x0340_0283	Configure 16-bit counter using inverted Pin 2 input (bit clock), with Timer 0 output as the trigger.
TIMCMP(n+2)	0x0000_0000	Compare on zero (first edge).
TIMCFG(n+2)	0x0020_6400	Configure enable on inverted pin (frame sync) rising edge and disable on trigger falling edge (bit clock), initial clock state is logic 1 and decrement on inverted pin input (frame sync).
TIMCTL(n+2)	0x0440_0383	Configure 16-bit counter using inverted Pin 3 input (frame sync), with Pin 2 input (bit clock) as the trigger.
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUFBIS, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Can support LSB first transfer by writing to SHIFTBUF register instead.
SHIFTBUF(n+1)	Data to receive	Received data can be read from SHIFTBUFBIS, use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Can support LSB first transfer by reading from SHIFTBUF register instead.

50.5.8 Camera Interface

Camera Interface can be supported using one Timer, one or more Shifters and multiple Pins. Multiple transfers can be supported using DMA controller.

The example below describes FlexIO configuration for interfacing to an 8-bit CMOS sensor with PCLK, VSYNC, HREF and D[7:0] outputs. The example uses a 128-bit buffer to capture 16-pixels of image data before interrupt or DMA transfer, however a bigger or smaller buffer may be used depending on system DMA performance and FlexIO resource usage by other applications. Note that additional timers may be used to track number of pixels per row and number of rows per frame or HREF/VSYNC may be assigned as GPIO interrupts for software tracking.

Table 50-17. Camera Interface Configuration for 8-bit CMOS sensor

Register	Value	Comments
SHIFTCFGn...n+2[1]	0x0007_0100	Configure 8-bit parallel shift in from adjacent shifter.
SHIFTCFGn+3	0x0007_0000	Configure 8-bit parallel shift in from pins FXIO_D[7:0] (D[7:0]).
SHIFTCTLn...n+3	0x0080_0001	Configure receive using Timer 0 on negedge of clock.
TIMCMPn	0x0000_001F	Configure 16-pixel (8 bits/pixel x 16 pixels = 128-bits) transfer. Set TIMCMP[15:0] = (number of pixels x 2) - 1.
TIMCFGn	0x0120_6600	Configure enable on trigger (HREF) rising edge and disable on trigger falling edge, initial Shift clock state is logic 0 and decrement on PCLK input.
TIMCTLn	0x12C0_0803	Configure 16-bit counter using FXIO_D[8] input (PCLK), with FXIO_D[9] input (HREF) as the inverted trigger.
SHIFTBUFn...n+3	Data to receive	Received data can be read from SHIFTBUFn...n+3, use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request.

1. n=0 or 4

50.5.9 Motorola 68K/Intel 8080 Bus Interface

The Motorola 68K and Intel 8080 bus are two parallel interfaces commonly used by Smart/Asynchronous LCD controllers. In conjunction with GPIO, FlexIO is able to drive these interfaces using one Timer and one Shifter, although additional Shifters could be used to support large transfers via the DMA controller.

The configuration below provides an example of how to drive a 16-bit 68K or 8080 bus. For a 8080 bus, two GPIO are used to drive the nCS and RS pins. For a 68K bus, an additional GPIO is required to drive the RDWR pin.

Table 50-18. Motorola 68K/Intel 8080 Write Configuration

Register	Value	Comments
SHIFTCFG0...7	0x000F_0100	Configure 16-bit parallel shift in from adjacent shifter.
SHIFTCTL0	0x0003_0002	Configure transmit using Timer 0 on posedge of clock with data output to FXIO_D[15:0].
SHIFTCTL1...7	0x0000_0002	Configure transmit using Timer 0 on posedge of clock.
TIMCMP0	0x0000_0101 (1-beat) 0x0000_1F01 (16-beats)	Configure 1 or 16-beat transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of beats x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFG0	0x0000_2200	Configure enable on trigger high and disable on compare. Timer output high on enable.
TIMCTL0	0x01C3_1001 (Motorola 68K, 1-beat) 0x1DC3_1001 (Motorola 68K, 16-beats) 0x01C3_1081 (Intel 8080, 1-beat) 0x1DC3_1081 (Intel 8080, 16-beats)	Configure dual 8-bit counter using FXIO_D[16] output (EN pin for 68K, nWR pin for 8080), with Shifter 0 (1-beat) or Shifter 7 (16-beats) flag as the inverted trigger.
SHIFTBUF0...7	Data to transmit	Transmit data can be written to SHIFTBUF0 (1-beat) or SHIFTBUF0...7 (16-beats) to initiate a transfer, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request.

Table 50-19. Motorola 68K/Intel 8080 Read Configuration

Register	Value	Comments
SHIFTCFG0...6	0x000F_0100	Configure 16-bit parallel shift in from adjacent shifter.
SHIFTCFG7	0x000F_0000	Configure 16-bit parallel shift in from pin.

Table continues on the next page...

Table 50-19. Motorola 68K/Intel 8080 Read Configuration (continued)

Register	Value	Comments
SHIFTCTL0...7	0x0080_0001	Configure receive using Timer 0 on negedge of clock with data input from FXIO_D[15:0].
TIMCMP0	0x0000_0101 (1-beat) 0x0000_1F01 (16-beats)	Configure 1 or 16-beat transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of beats x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFG0	0x0000_2220	Configure stop_bit, enable on trigger high and disable on compare. Timer output high on enable.
TIMCTL0	0x1DC3_1001 (Motorola 68K, 1 beat) 0x01C3_1001 (Motorola 68K, 16 beats) 0x1DC3_1181 (Intel 8080, 1 beat) 0x01C3_1181 (Intel 8080, 16 beats)	Configure dual 8-bit counter using either FXIO_D[16] output (EN pin for 68K) or FXIO_D[17] output (nRD pin for 8080), with Shifter 7 flag (1-beat) or Shifter 0 flag (16-beats) as the inverted trigger.
SHIFTBUF0...7	Data received	Received data can be read from SHIFTBUF0 (1-beat) or SHIFTBUF0...7 (16-beats), use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request.

In general, any operation to a 68K/8080 bus slave will begin with a register write cycle followed by one or more data read or write cycles. To accomplish this, the following program flow should be used:

1. Configure FlexIO with 1-beat write configuration
2. Configure GPIO to assert nCS, RS pins (and deassert RDWR pin for 68K)
3. Write register index data to SHIFTBUF0[15:0]
4. Configure GPIO to deassert RS pin (and assert RDWR pin for 68K data read)
5. Configure FlexIO with desired read or write configuration (e.g. 1 or 16-beats)
6. Use the Shifter Status Flag to trigger interrupt or DMA driven data transfers to/from SHIFTBUF registers
7. Configure GPIO to deassert nCS pin

50.5.10 Low Power State Machine

The configuration below details a hypothetical state machine example to illustrate the flexibility allowed when using Shifter state mode.

In this example, FlexIO waits for the FXIO_D[2] pin to assert and then drives a complementary square wave output at a frequency of FLEXIO_CLK/131072 on the FXIO_D[1:0] pins while the comparator output is asserted (This assumes comparator is

connected to external trigger 15. See the chip-specific FlexIO information for actual FlexIO trigger mappings). Throughout this operation, the CPU can be kept in a STOP/ VLPS mode, by clearing the CTRL[DOZEN] bit and ensuring the FLEXIO_CLK is enabled. The state diagram below shows the states and transitions implemented by this example.

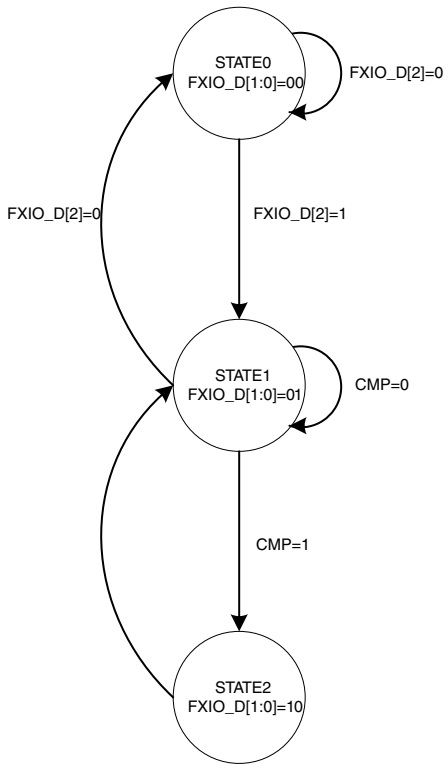

Figure 50-5. State Diagram

51.1.1 LPUART

The LPUART provides asynchronous, serial communication capability with external devices.

- Supports non-return-to-zero (NRZ) encoding format and IrDA-compatible infrared (low-speed) SIR format
- Can continue operating while the chip is in stop modes, if an appropriate clock is available
- Designed for low CPU overhead, with DMA offloading of FIFO register accesses

Table 51-2. LPUART configuration

Parameter	Description
Name	LPUART
Instances	8
Configurable features	• LPUART0-1: 4-word TX FIFO and RX FIFO • LPUART2-7: 8-word TX FIFO and RX FIFO • LPUART 0-7: Hardware Flow Control, IrDA

Table continues on the next page...

Table 51-2. LPUART configuration (continued)

Parameter	Description
Interface speed	LPUART0-7: maximum 12 Mbps
External I/O pins	LPUART0-7: TX, RX, CTS_b, RTS_b. See the attached IOMUXC spreadsheet for pinout details.

51.2 Introduction

51.2.1 Features

Features of the LPUART module include:

- Full-duplex, standard non-return-to-zero (NRZ) format
- Programmable baud rates (13-bit modulo divider) with configurable oversampling ratio from 4x to 32x
- Transmit and receive baud rate can operate asynchronous to the bus clock:
  - Baud rate can be configured independently of the bus clock frequency
  - Supports operation in Stop modes
- Interrupt, DMA or polled operation:
  - Transmit data register empty and transmission complete
  - Receive data register full
  - Receive overrun, parity error, framing error, and noise error
  - Idle receiver detect
  - Active edge on receive pin
  - Break detect supporting LIN
  - Receive data match
- Hardware parity generation and checking
- Programmable 7-bit, 8-bit, 9-bit or 10-bit character length
- Programmable 1-bit or 2-bit stop bits
- Three receiver wakeup methods:
  - Idle line wakeup
  - Address mark wakeup
  - Receive data match
- Automatic address matching to reduce ISR overhead:
  - Address mark matching
  - Idle line address matching
  - Address match start, address match end
- Optional 13-bit break character generation / 11-bit break character detection

- Configurable idle length detection supporting 1, 2, 4, 8, 16, 32, 64 or 128 idle characters
- Selectable transmitter output and receiver input polarity
- Hardware flow control support for request to send (RTS) and clear to send (CTS) signals
- Selectable IrDA 1.4 return-to-zero-inverted (RZI) format with programmable pulse width
- Independent FIFO structure for transmit and receive
  - Separate configurable watermark for receive and transmit requests
  - Option for receiver to assert request after a configurable number of idle characters if receive FIFO is not empty

51.2.2 Modes of operation

51.2.2.1 Stop mode

The LPUART will remain functional during Stop mode, provided the CTRL[DOZEEN] bit is clear and the asynchronous transmit and receive clock remain enabled. The LPUART can generate an interrupt or DMA request to cause a wakeup from Stop mode.

If the LPUART is disabled in Stop mode, then it can generate a wakeup via the STAT[RXEDGIF] flag if the receiver detects an active edge.

51.2.2.2 Wait mode

The LPUART can be configured to Stop in Wait modes, when the CTRL[DOZEEN] bit is set. The transmitter and receiver will finish transmitting/receiving the current word.

51.2.2.3 Debug mode

The LPUART remains functional in debug mode.

51.2.3 Signal Descriptions

Signal	Description	I/O
TXD	Transmit data. This pin is normally an output, but is an input (tristated) in single wire mode whenever the transmitter is	I/O

The following figure shows the receiver portion of the LPUART.

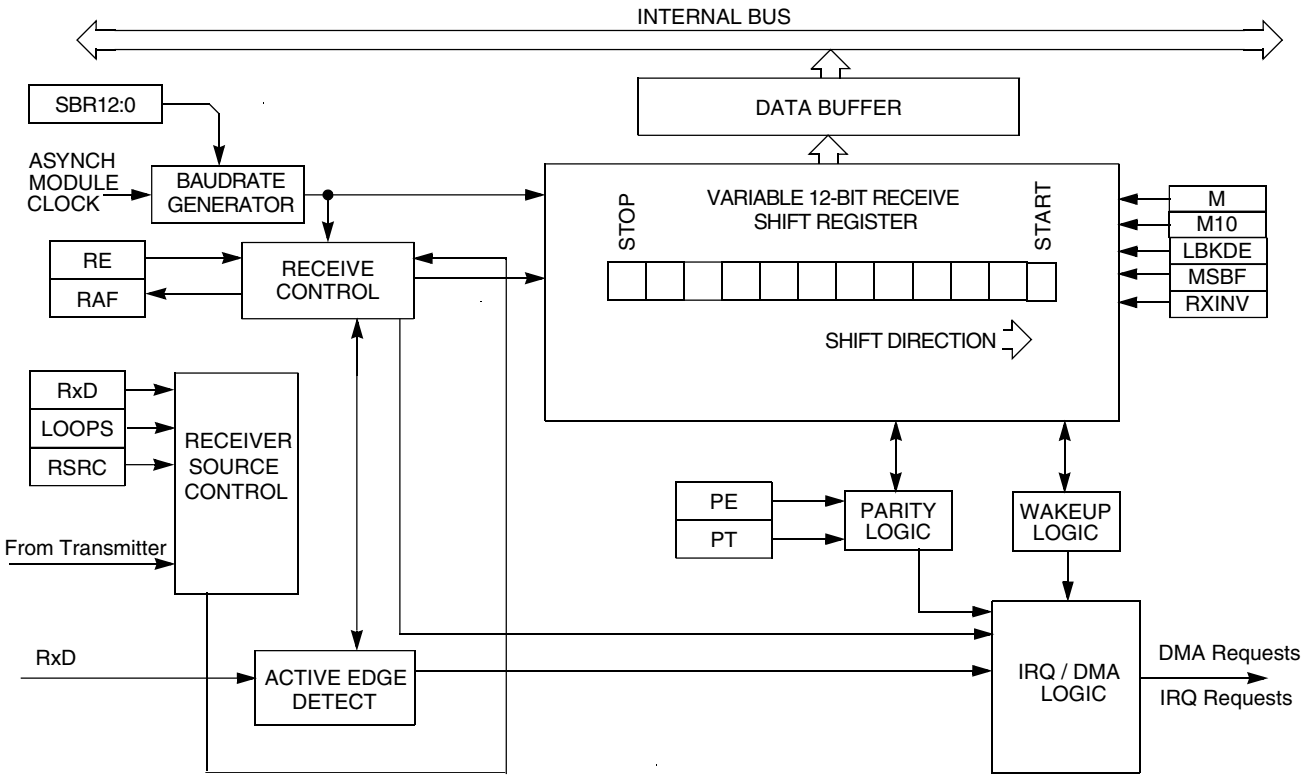

Figure 51-2. LPUART receiver block diagram

51.3 Register definition

The LPUART includes registers to control baud rate, select options, report status, and store transmit/receive data. Access to an address outside the valid memory map will generate a bus error.

NOTE

Writing a Read-Only (RO) register or reading a Write-Only (WO) register can cause bus errors. This module will not check if programmed values in the registers are correct; the application software must ensure that valid programmed values are being written.

51.3.1.6.3 Fields

Field	Function
31 MAEN1	Match Address Mode Enable 1 0b - Normal operation. 1b - Enables automatic address matching or data matching mode for MATCH[MA1].
30 MAEN2	Match Address Mode Enable 2 0b - Normal operation. 1b - Enables automatic address matching or data matching mode for MATCH[MA2].
29 M10	10-bit Mode select The M10 bit causes a tenth bit to be part of the serial transmission. This bit should only be changed when the transmitter and receiver are both disabled. 0b - Receiver and transmitter use 7-bit to 9-bit data characters. 1b - Receiver and transmitter use 10-bit data characters.
28-24 OSR	Oversampling Ratio This field configures the oversampling ratio for the receiver. This field should only be changed when the transmitter and receiver are both disabled. 00000b - Writing 0 to this field will result in an oversampling ratio of 16 00001b - Reserved 00010b - Reserved 00011b - Oversampling ratio of 4, requires BOTHEDGE to be set. 00100b - Oversampling ratio of 5, requires BOTHEDGE to be set. 00101b - Oversampling ratio of 6, requires BOTHEDGE to be set. 00110b - Oversampling ratio of 7, requires BOTHEDGE to be set. 00111b - Oversampling ratio of 8. 01000b - Oversampling ratio of 9. 01001b - Oversampling ratio of 10. 01010b - Oversampling ratio of 11. 01011b - Oversampling ratio of 12. 01100b - Oversampling ratio of 13. 01101b - Oversampling ratio of 14. 01110b - Oversampling ratio of 15. 01111b - Oversampling ratio of 16. 10000b - Oversampling ratio of 17.

Table continues on the next page...

Field	Function
	10001b - Oversampling ratio of 18. 10010b - Oversampling ratio of 19. 10011b - Oversampling ratio of 20. 10100b - Oversampling ratio of 21. 10101b - Oversampling ratio of 22. 10110b - Oversampling ratio of 23. 10111b - Oversampling ratio of 24. 11000b - Oversampling ratio of 25. 11001b - Oversampling ratio of 26. 11010b - Oversampling ratio of 27. 11011b - Oversampling ratio of 28. 11100b - Oversampling ratio of 29. 11101b - Oversampling ratio of 30. 11110b - Oversampling ratio of 31. 11111b - Oversampling ratio of 32.
23 TDMAE	Transmitter DMA Enable TDMAE configures the transmit data register empty flag, STAT[TDRE], to generate a DMA request. 0b - DMA request disabled. 1b - DMA request enabled.
22 —	Reserved
21 RDMAE	Receiver Full DMA Enable RDMAE configures the receiver data register full flag, STAT[RDRF], to generate a DMA request. 0b - DMA request disabled. 1b - DMA request enabled.
20 RIDMAE	Receiver Idle DMA Enable RIDMAE configures the receiver idle flag, STAT[IDLE], to generate a DMA request. When this bit is set, reading the DATA register when either DATA[RXEMPT] or DATA[IDLINE] bit is set, will generate an End Of Packet response until the completion of the existing DMA transfer. During an End of Packet response, reading the DATA register will return 0x0000_33FF and does not pull data from the FIFO. 0b - DMA request disabled. 1b - DMA request enabled.
19-18 MATCFG	Match Configuration Configures the match addressing mode used. This field should only be changed when the transmitter and receiver are both disabled. 00b - Address Match Wakeup 01b - Idle Match Wakeup 10b - Match On and Match Off 11b - Enables RWU on Data Match and Match On/Off for transmitter CTS input
17 BOTHEDGE	Both Edge Sampling Enables sampling of the received data on both edges of the baud rate clock, effectively doubling the number of times the receiver samples the input data for a given oversampling ratio. This bit must be set for oversampling ratios between x4 and x7 and is optional for higher oversampling ratios. This bit should only be changed when the receiver is disabled. 0b - Receiver samples input data using the rising edge of the baud rate clock. 1b - Receiver samples input data using the rising and falling edge of the baud rate clock.
16 RESYNCDIS	Resynchronization Disable When set, disables the resynchronization of the received data word when a data one followed by data zero transition is detected. This bit should only be changed when the receiver is disabled. 0b - Resynchronization during received data word is supported 1b - Resynchronization during received data word is disabled

Table continues on the next page...

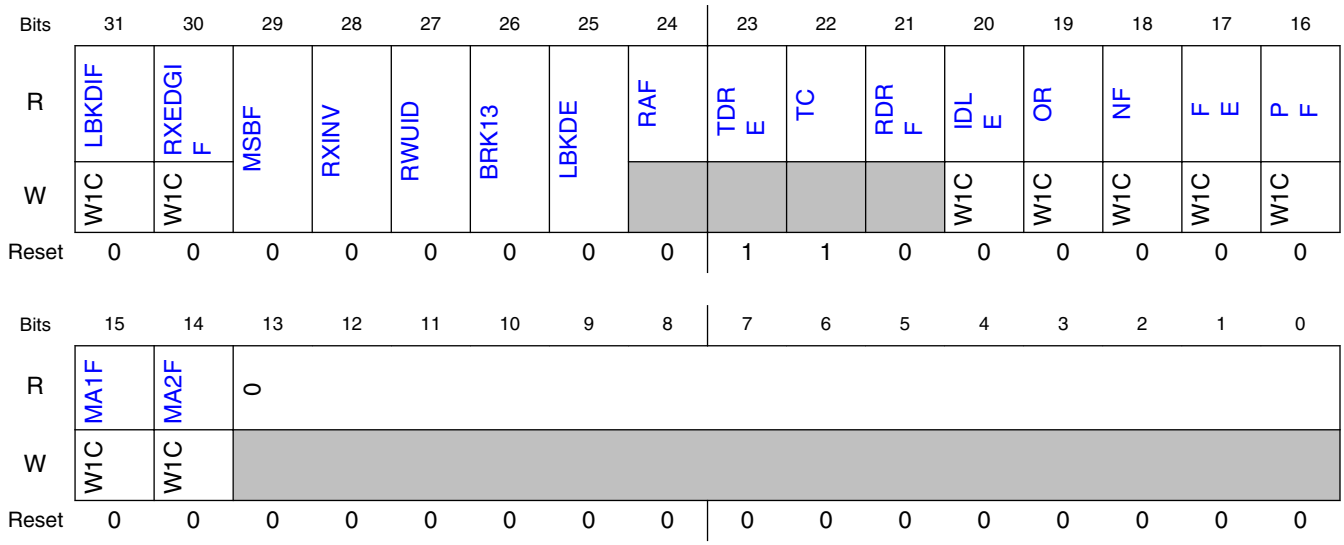
Field	Function
15 LBKDIE	LIN Break Detect Interrupt Enable LBKDIE enables the LIN break detect flag, STAT[LBKDIF], to generate interrupt requests. 0b - Hardware interrupts from STAT[LBKDIF] flag are disabled (use polling). 1b - Hardware interrupt requested when STAT[LBKDIF] flag is 1.
14 RXEDGIE	RX Input Active Edge Interrupt Enable Enables the receive input active edge, STAT[RXEDGIF], to generate interrupt requests. Changing CTRL[LOOP] or CTRL[RSRC] when RXEDGIE is set can cause the STAT[RXEDGIF] flag to set. 0b - Hardware interrupts from STAT[RXEDGIF] are disabled. 1b - Hardware interrupt is requested when STAT[RXEDGIF] flag is 1.
13 SBNS	Stop Bit Number Select SBNS determines whether data characters have one or two stop bits. This bit should only be changed when the transmitter and receiver are both disabled. 0b - One stop bit. 1b - Two stop bits.
12-0 SBR	Baud Rate Modulo Divisor. The 13 bits in SBR[12:0] set the modulo divide rate for the baud rate generator. When SBR is 1 - 8191, the baud rate equals "baud clock / ((OSR+1) × SBR)". The 13-bit baud rate setting [SBR12:SBR0] must be updated only when the transmitter and receiver are both disabled (CTRL[RE] and CTRL[TE] are both 0).

51.3.1.7 LPUART Status Register (STAT)

51.3.1.7.1 Offset

Register	Offset
STAT	14h

51.3.1.7.2 Diagram



51.3.1.7.3 Fields

Field	Function
31 LBKDIF	LIN Break Detect Interrupt Flag LBKDIF is set when the LIN break detect circuitry is enabled and a LIN break character is detected. LBKDIF is cleared by writing a 1 to it. 0b - No LIN break character has been detected. 1b - LIN break character has been detected.
30 RXEDGIF	RXD Pin Active Edge Interrupt Flag RXEDGIF is set whenever the receiver is enabled and an active edge, falling if RXINV = 0, rising if RXINV=1, on the RXD pin occurs. RXEDGIF is cleared by writing a 1 to it. 0b - No active edge on the receive pin has occurred. 1b - An active edge on the receive pin has occurred.
29 MSBF	MSB First Setting this bit reverses the order of the bits that are transmitted and received on the wire. This bit does not affect the polarity of the bits, the location of the parity bit or the location of the start or stop bits. This bit should only be changed when the transmitter and receiver are both disabled. 0b - LSB (bit0) is the first bit that is transmitted following the start bit. Further, the first bit received after the start bit is identified as bit0. 1b - MSB (bit9, bit8, bit7 or bit6) is the first bit that is transmitted following the start bit depending on the setting of CTRL[M], CTRL[PE] and BAUD[M10]. Further, the first bit received after the start bit is identified as bit9, bit8, bit7 or bit6 depending on the setting of CTRL[M] and CTRL[PE].
28 RXINV	Receive Data Inversion Setting this bit reverses the polarity of the received data input. This bit should only be changed when the receiver is disabled. **NOTE:** Setting RXINV inverts the RXD input for all cases: data bits, start and stop bits, break, and idle. 0b - Receive data not inverted. 1b - Receive data inverted.
27	Receive Wake Up Idle Detect

Table continues on the next page...

Field	Function
RWUID	For RWU on idle character, RWUID controls whether the idle character that wakes up the receiver sets the IDLE bit. For address match wakeup, RWUID controls if the IDLE bit is set when the address does not match. This bit should only be changed when the receiver is disabled. 0b - During receive standby state (RWU = 1), the IDLE bit does not get set upon detection of an idle character. During address match wakeup, the IDLE bit does not set when an address does not match. 1b - During receive standby state (RWU = 1), the IDLE bit gets set upon detection of an idle character. During address match wakeup, the IDLE bit does set when an address does not match.
26 BRK13	Break Character Generation Length BRK13 selects a longer transmitted break character length. Detection of a framing error is not affected by the state of this bit. This bit should only be changed when the transmitter is disabled. A break character can be sent by setting CTRL[SBK] or by writing the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] clear. 0b - Break character is transmitted with length of 9 to 13 bit times. 1b - Break character is transmitted with length of 12 to 15 bit times.
25 LBKDE	LIN Break Detection Enable LBKDE selects a longer break character detection length. While LBKDE is set, receive data is not stored in the receive data buffer. 0b - LIN break detect is disabled, normal break character can be detected. 1b - LIN break detect is enabled. LIN break character is detected at length of 11 bit times (if M = 0) or 12 (if M = 1) or 13 (M10 = 1).
24 RAF	Receiver Active Flag RAF is set when the receiver detects the beginning of a valid start bit, and RAF is cleared automatically when the receiver detects an idle line. 0b - LPUART receiver idle waiting for a start bit. 1b - LPUART receiver active (RXD input not idle).
23 TDRE	Transmit Data Register Empty Flag When the transmit FIFO is enabled, TDRE will set when the number of datawords in the transmit FIFO (DATA register) is equal to or less than the number indicated by WATER[TXWATER]). To clear TDRE, write to the DATA register until the number of words in the transmit FIFO is greater than the number indicated by WATER[TXWATER]. When the transmit FIFO is disabled,TDRE will set when the transmit DATA register is empty. To clear TDRE, write to the DATA register. TDRE is not affected by a character that is in the process of being transmitted; it is updated at the start of each transmitted character. 0b - Transmit data buffer full. 1b - Transmit data buffer empty.
22 TC	Transmission Complete Flag TC is cleared when there is a transmission in progress or when a preamble or break character is loaded. TC is set when the transmit buffer is empty and no data, preamble, or break character is being transmitted. When TC is set, the transmit data output signal becomes idle (logic 1). TC is cleared by writing to the DATA register to transmit new data, queuing a preamble by clearing and then setting CTRL[TE], queuing a break character by writing 1 to CTRL[SBK]. 0b - Transmitter active (sending data, a preamble, or a break). 1b - Transmitter idle (transmission activity complete).
21 RDRF	Receive Data Register Full Flag When the receive FIFO is enabled, RDRF is set when the number of datawords in the receive buffer is greater than the number indicated by WATER[RXWATER]. To clear RDRF, read the DATA register until the number of datawords in the receive data buffer is equal to or less than the number indicated by WATER[RXWATER]. When the receive FIFO is disabled, RDRF is set when the receive buffer (the DATA register) is full. To clear RDRF, read the DATA register.

Table continues on the next page...

Field	Function
	A character that is in the process of being received does not cause a change in RDRF until the entire character is received. Even if RDRF is set, the character will continue to be received until an overrun condition occurs once the entire character is received. 0b - Receive data buffer empty. 1b - Receive data buffer full.
20 IDLE	Idle Line Flag IDLE is set when the LPUART receive line becomes idle for a full character time after a period of activity. When CTRL[ILT] is cleared, the receiver starts counting idle bit times after the start bit. If the receive character is all 1s, these bit times and the stop bits time count toward the full character time of logic high, 10 to 13 bit times, needed for the receiver to detect an idle line. When CTRL[ILT] is set, the receiver doesn't start counting idle bit times until after the stop bits. The stop bits and any logic high bit times at the end of the previous character do not count toward the full character time of logic high needed for the receiver to detect an idle line. To clear IDLE, write logic 1 to the IDLE flag. After IDLE has been cleared, it cannot be set again until after a new character has been stored in the receive buffer or a LIN break character has set the LBKDIF flag . IDLE is set only once even if the receive line remains idle for an extended period. 0b - No idle line detected. 1b - Idle line was detected.
19 OR	Receiver Overrun Flag OR is set when software fails to prevent the receive data register from overflowing with data. The OR bit is set immediately after the stop bit has been completely received for the dataword that overflows the buffer and all the other error flags (FE, NF, and PF) are prevented from setting. The data in the shift register is lost, but the data already in the LPUART data registers is not affected. If LBKDE is enabled and a LIN Break is detected, the OR field asserts if LBKDIF is not cleared before the next data character is received. While the OR flag is set, no additional data is stored in the data buffer even if sufficient room exists. To clear OR, write logic 1 to the OR flag. 0b - No overrun. 1b - Receive overrun (new LPUART data lost).
18 NF	Noise Flag The advanced sampling technique used in the receiver takes three samples in each of the received bits. If any of these samples disagrees with the rest of the samples within any bit time in the frame then noise is detected for that character. NF is set whenever the next character to be read from the DATA register was received with noise detected within the character. To clear NF, write logic 1 to the NF field. 0b - No noise detected. 1b - Noise detected in the received character in the DATA register.
17 FE	Framing Error Flag FE is set whenever the next character to be read from the DATA register was received with logic 0 detected where a stop bit was expected. To clear FE, write logic 1 to the FE field. 0b - No framing error detected. This does not guarantee the framing is correct. 1b - Framing error.
16 PF	Parity Error Flag PF is set whenever the next character to be read from the DATA register was received when parity is enabled (PE = 1) and the parity bit in the received character does not agree with the expected parity value. To clear PF, write a logic 1 to the PF field. 0b - No parity error. 1b - Parity error.
15 MA1F	Match 1 Flag

Table continues on the next page...

Field	Function
	MA1F is set whenever the next character to be read from the DATA register matches MA1. To clear MA1F, write a logic 1 to the MA1F field. 0b - Received data is not equal to MA1 1b - Received data is equal to MA1
14 MA2F	Match 2 Flag MA2F is set whenever the next character to be read from the DATA register matches MA2. To clear MA2F, write a logic 1 to the MA2F field. 0b - Received data is not equal to MA2 1b - Received data is equal to MA2
13-0 —	Reserved

51.3.1.8 LPUART Control Register (CTRL)

51.3.1.8.1 Offset

Register	Offset
CTRL	18h

51.3.1.8.2 Function

This read/write register controls various optional features of the LPUART system. This register should only be altered when the transmitter and receiver are both disabled.

51.3.1.8.3 Diagram

51.3.1.8.4 Fields

Field	Function
31 R8T9	Receive Bit 8 / Transmit Bit 9 R8 is the ninth data bit received when the LPUART is configured for 9-bit or 10-bit data formats. When reading 9-bit or 10-bit data, read R8 before reading the DATA register. T9 is the tenth data bit transmitted when the LPUART is configured for 10-bit data formats. When writing 10-bit data, write T9 before writing the DATA register. If T9 does not need to change from its previous value, such as when it is used to generate address mark or parity, they it need not be written each time the DATA register is written. **NOTE:** R8 is a read-only bit and T9 is a write-only bit, the value read is different from the value written.
30 R9T8	Receive Bit 9 / Transmit Bit 8 R9 is the tenth data bit received when the LPUART is configured for 10-bit data formats. When reading 10-bit data, read R9 before reading the DATA register T8 is the ninth data bit transmitted when the LPUART is configured for 9-bit or 10-bit data formats. When writing 9-bit or 10-bit data, write T8 before writing the DATA register. If T8 does not need to change from its previous value, such as when it is used to generate address mark or parity, then it need not be written each time the DATA register is written. **NOTE:** R9 is a read-only bit and T8 is a write-only bit, the value read is different from the value written.
29 TXDIR	TXD Pin Direction in Single-Wire Mode When the LPUART is configured for single-wire half-duplex operation (LOOPS = RSRC = 1), this bit determines the direction of data at the TXD pin. When clearing TXDIR, the transmitter will finish receiving the current character (if any) before the receiver starts receiving data from the TXD pin. 0b - TXD pin is an input in single-wire mode. 1b - TXD pin is an output in single-wire mode.
28 TXINV	Transmit Data Inversion Setting this bit reverses the polarity of the transmitted data output. **NOTE:** Setting TXINV inverts the TXD output for all cases: data bits, start and stop bits, break, and idle. 0b - Transmit data not inverted. 1b - Transmit data inverted.
27 ORIE	Overrun Interrupt Enable This bit enables the overrun flag (OR) to generate hardware interrupt requests. 0b - OR interrupts disabled; use polling. 1b - Hardware interrupt requested when OR is set.
26 NEIE	Noise Error Interrupt Enable This bit enables the noise flag (NF) to generate hardware interrupt requests. 0b - NF interrupts disabled; use polling. 1b - Hardware interrupt requested when NF is set.
25 FEIE	Framing Error Interrupt Enable This bit enables the framing error flag (FE) to generate hardware interrupt requests. 0b - FE interrupts disabled; use polling. 1b - Hardware interrupt requested when FE is set.
24 PEIE	Parity Error Interrupt Enable This bit enables the parity error flag (PF) to generate hardware interrupt requests. 0b - PF interrupts disabled; use polling). 1b - Hardware interrupt requested when PF is set.
23	Transmit Interrupt Enable

Table continues on the next page...

Field	Function
TIE	Enables STAT[TDRE] to generate interrupt requests. 0b - Hardware interrupts from TDRE disabled; use polling. 1b - Hardware interrupt requested when TDRE flag is 1.
22 TCIE	Transmission Complete Interrupt Enable for TCIE enables the transmission complete flag, TC, to generate interrupt requests. 0b - Hardware interrupts from TC disabled; use polling. 1b - Hardware interrupt requested when TC flag is 1.
21 RIE	Receiver Interrupt Enable Enables STAT[RDRF] to generate interrupt requests. 0b - Hardware interrupts from RDRF disabled; use polling. 1b - Hardware interrupt requested when RDRF flag is 1.
20 ILIE	Idle Line Interrupt Enable ILIE enables the idle line flag, STAT[IDLE], to generate interrupt requests. 0b - Hardware interrupts from IDLE disabled; use polling. 1b - Hardware interrupt requested when IDLE flag is 1.
19 TE	Transmitter Enable Enables the LPUART transmitter. TE can also be used to queue an idle preamble by clearing and then setting TE. When TE is cleared, this register bit will read as 1 until the transmitter has completed the current character and the TXD pin is tristated. A single idle character can also be queued by writing to the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] set. 0b - Transmitter disabled. 1b - Transmitter enabled.
18 RE	Receiver Enable Enables the LPUART receiver. When RE is written to 0, this register bit will read as 1 until the receiver finishes receiving the current character (if any). 0b - Receiver disabled. 1b - Receiver enabled.
17 RWU	Receiver Wakeup Control This field can be set to place the LPUART receiver in a standby state. RWU automatically clears when an RWU event occurs, that is, an IDLE event when CTRL[WAKE] is clear or an address match when CTRL[WAKE] is set with STAT[RWUID] is clear. **NOTE:** RWU must be set only with CTRL[WAKE] = 0 (wakeup on idle) if the channel is currently not idle. This can be determined by STAT[RAF]. If the flag is set to wake up an IDLE event and the channel is already idle, it is possible that the LPUART will discard data. This is because the data must be received or a LIN break detected after an IDLE is detected before IDLE is allowed to be reasserted. 0b - Normal receiver operation. 1b - LPUART receiver in standby waiting for wakeup condition.
16 SBK	Send Break Writing a 1 and then a 0 to SBK queues a break character in the transmit data stream. Additional break characters of 9 to 13 bits, or 12 to 15 bits if STAT[BRK13] is set, bit times of logic 0 are queued as long as SBK is set. Depending on the timing of the set and clear of SBK relative to the character currently being transmitted, a second break character may be queued before software clears SBK. A single break character can also be queued by writing to the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] clear. 0b - Normal transmitter operation. 1b - Queue break character(s) to be sent.

Table continues on the next page...

Register definition

Field	Function
15 MA1IE	Match 1 Interrupt Enable 0b - MA1F interrupt disabled 1b - MA1F interrupt enabled
14 MA2IE	Match 2 Interrupt Enable 0b - MA2F interrupt disabled 1b - MA2F interrupt enabled
13-12 —	Reserved
11 M7	7-Bit Mode Select This bit should only be changed when the transmitter and receiver are both disabled. 0b - Receiver and transmitter use 8-bit to 10-bit data characters. 1b - Receiver and transmitter use 7-bit data characters.
10-8 IDLECFG	Idle Configuration Configures the number of idle characters that must be received before the IDLE flag is set. 000b - 1 idle character 001b - 2 idle characters 010b - 4 idle characters 011b - 8 idle characters 100b - 16 idle characters 101b - 32 idle characters 110b - 64 idle characters 111b - 128 idle characters
7 LOOPS	Loop Mode Select When LOOPS is set, the RXD pin is disconnected from the LPUART and the transmitter output is internally connected to the receiver input. The transmitter and the receiver must be enabled to use the loop function. 0b - Normal operation - RXD and TXD use separate pins. 1b - Loop mode or single-wire mode where transmitter outputs are internally connected to receiver input (see RSRC bit).
6 DOZEEN	Doze Enable 0b - LPUART is enabled in Doze mode. 1b - LPUART is disabled in Doze mode.
5 RSRC	Receiver Source Select This field has no meaning or effect unless the LOOPS field is set. When LOOPS is set, the RSRC field determines the source for the receiver shift register input. 0b - Provided LOOPS is set, RSRC is cleared, selects internal loop back mode and the LPUART does not use the RXD pin. 1b - Single-wire LPUART mode where the TXD pin is connected to the transmitter output and receiver input.
4 M	9-Bit or 8-Bit Mode Select 0b - Receiver and transmitter use 8-bit data characters. 1b - Receiver and transmitter use 9-bit data characters.
3 WAKE	Receiver Wakeup Method Select Determines which condition wakes the LPUART when RWU=1: • Address mark in the bit preceding the stop bit (or bit preceding the parity bit when parity is enabled) of the received data character, or • An idle condition on the receive pin input signal. 0b - Configures RWU for idle-line wakeup. 1b - Configures RWU with address-mark wakeup.

Table continues on the next page...

Field	Function
2 ILT	Idle Line Type Select Determines when the receiver starts counting logic 1s as idle character bits. The count begins either after a valid start bit or after the stop bit. If the count begins after the start bit, then a string of logic 1s preceding the stop bit can cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions. **NOTE:** In case the LPUART is programmed with ILT = 1, a logic 0 is automatically shifted after a received stop bit, therefore resetting the idle count. 0b - Idle character bit count starts after start bit. 1b - Idle character bit count starts after stop bit.
1 PE	Parity Enable Enables hardware parity generation and checking. When parity is enabled, the bit immediately before the stop bit is treated as the parity bit. 0b - No hardware parity generation or checking. 1b - Parity enabled.
0 PT	Parity Type Provided parity is enabled (PE = 1), this bit selects even or odd parity. Odd parity means the total number of 1s in the data character, including the parity bit, is odd. Even parity means the total number of 1s in the data character, including the parity bit, is even. 0b - Even parity. 1b - Odd parity.

51.3.1.9 LPUART Data Register (DATA)

51.3.1.9.1 Offset

Register	Offset
DATA	1Ch

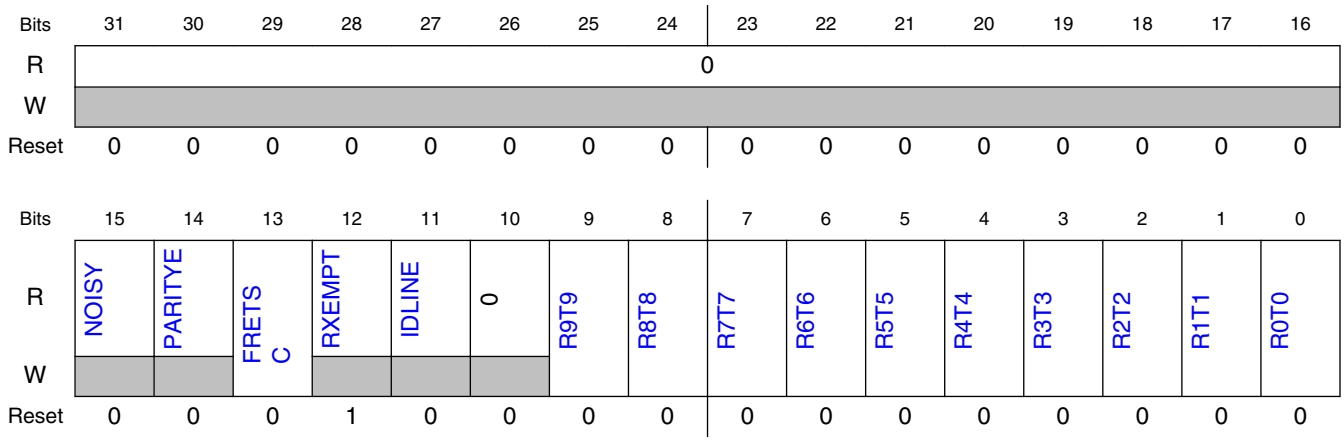
51.3.1.9.2 Function

NOTE

This register is two separate registers. Reads return the contents of the read-only receive data buffer and writes go to the write-only transmit data buffer.

Reads and writes of this register are also involved in the automatic flag clearing mechanisms for some of the LPUART status flags.

51.3.1.9.3 Diagram



51.3.1.9.4 Fields

Field	Function
31-16 —	Reserved
15 NOISY	NOISY The current received dataword contained in DATA[R9:R0] was received with noise. 0b - The dataword was received without noise. 1b - The data was received with noise.
14 PARITYE	PARITYE The current received dataword contained in DATA[R9:R0] was received with a parity error. 0b - The dataword was received without a parity error. 1b - The dataword was received with a parity error.
13 FRETSC	Frame Error / Transmit Special Character For reads, indicates the current received dataword contained in DATA[R9:R0] was received with a frame error. For writes, indicates a break or idle character is to be transmitted instead of the contents in DATA[T9:T0]. T9 is used to indicate a break character when 0 and a idle character when 1, the contents of DATA[T8:T0] should be zero. 0b - The dataword was received without a frame error on read, or transmit a normal character on write. 1b - The dataword was received with a frame error, or transmit an idle or break character on transmit.
12 RXEMPT	Receive Buffer Empty Asserts when there is no data in the receive buffer. This field does not take into account data that is in the receive shift register. 0b - Receive buffer contains valid data. 1b - Receive buffer is empty, data returned on read is not valid.
11 IDLINE	Idle Line Indicates the receiver line was idle before receiving the character in DATA[9:0]. Unlike the IDLE flag, this bit can set for the first character received when the receiver is first enabled. 0b - Receiver was not idle before receiving this character. 1b - Receiver was idle before receiving this character.

Table continues on the next page...

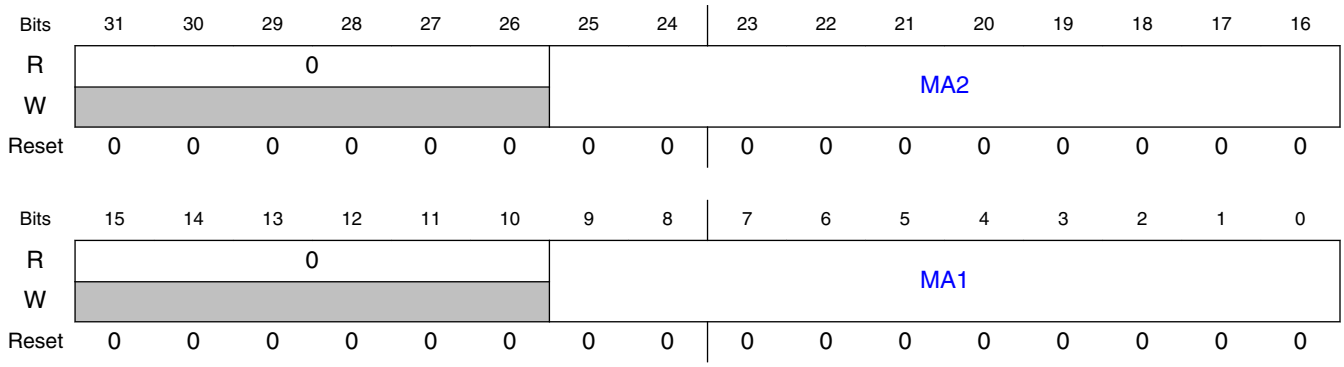
Field	Function
10 —	Reserved
9 R9T9	R9T9 Read receive data buffer 9 or write transmit data buffer 9.
8 R8T8	R8T8 Read receive data buffer 8 or write transmit data buffer 8.
7 R7T7	R7T7 Read receive data buffer 7 or write transmit data buffer 7.
6 R6T6	R6T6 Read receive data buffer 6 or write transmit data buffer 6.
5 R5T5	R5T5 Read receive data buffer 5 or write transmit data buffer 5.
4 R4T4	R4T4 Read receive data buffer 4 or write transmit data buffer 4.
3 R3T3	R3T3 Read receive data buffer 3 or write transmit data buffer 3.
2 R2T2	R2T2 Read receive data buffer 2 or write transmit data buffer 2.
1 R1T1	R1T1 Read receive data buffer 1 or write transmit data buffer 1.
0 R0T0	R0T0 Read receive data buffer 0 or write transmit data buffer 0.

51.3.1.10 LPUART Match Address Register (MATCH)

51.3.1.10.1 Offset

Register	Offset
MATCH	20h

51.3.1.10.2 Diagram



51.3.1.10.3 Fields

Field	Function
31-26 —	Reserved
25-16 MA2	Match Address 2 The MA1 and MA2 fields are compared to input data addresses when the most significant bit is set and the associated BAUD[MAEN] bit is set. If a match occurs, the following data is transferred to the DATA register. If a match fails, the following data is discarded. Software should only write a MAx field when the associated BAUD[MAEN] bit is clear.
15-10 —	Reserved
9-0 MA1	Match Address 1 The MA1 and MA2 fields are compared to input data addresses when the most significant bit is set and the associated BAUD[MAEN] bit is set. If a match occurs, the following data is transferred to the DATA register. If a match fails, the following data is discarded. Software should only write a MAx field when the associated BAUD[MAEN] bit is clear.

51.3.1.11 LPUART Modem IrDA Register (MODIR)

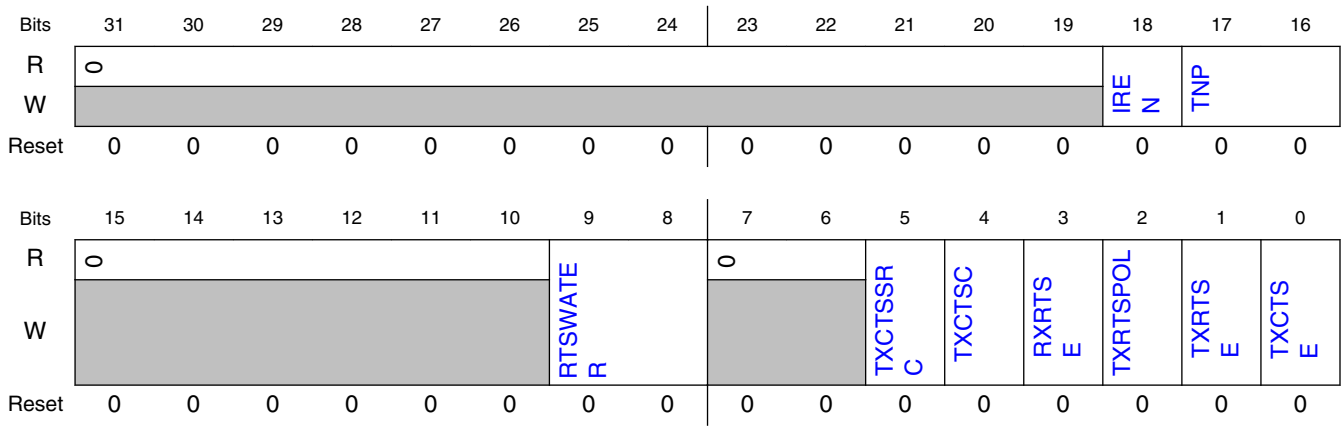
51.3.1.11.1 Offset

Register	Offset
MODIR	24h

51.3.1.11.2 Function

The MODEM register controls options for setting the modem configuration.

51.3.1.11.3 Diagram



51.3.1.11.4 Fields

Field	Function
31-19 —	Reserved
18 IREN	Infrared enable Enables/disables the infrared modulation/demodulation. This bit should only be changed when the transmitter and receiver are both disabled. 0b - IR disabled. 1b - IR enabled.
17-16 TNP	Transmitter narrow pulse Configures whether the LPUART transmits a 1/OSR, 2/OSR, 3/OSR or 4/OSR narrow pulse when IR is enabled. This bit should only be changed when the transmitter and receiver are both disabled. The IR pulse width should be configured to less than half of the oversampling ratio. Common pulse widths are 3/16, 1/16, 1/32 or 1/4 of the bit length. These can be configured by selecting the appropriate oversample ratio and pulse width. 00b - 1/OSR. 01b - 2/OSR. 10b - 3/OSR. 11b - 4/OSR.
15-10 —	Reserved
9-8 RTSWATER	Receive RTS Configuration Configures the assertion and negation of the RX RTS_B output. The RX RTS_B output negates when the number of empty words in the receive FIFO is greater or equal to RTSWATER. If RTSWATER is configured to zero, RTS_B negates when the receive FIFO is full. For the purpose of RX RTS_B generation, the number of words in the receive FIFO updates when a start bit is detected. This supports additional latency between RTS_B negation and the external transmitter ceasing transmission. If both RX RTS_B and address/data matching is enabled, then RTS_B could assert at the end of a character if there is not a match.

Table continues on the next page...

Field	Function
	This field should only be changed when the receiver is disabled.
7-6 —	Reserved
5 TXCTSSRC	Transmit CTS Source Configures the source of the CTS input. 0b - CTS input is the CTS_B pin. 1b - CTS input is the inverted Receiver Match result.
4 TXCTSC	Transmit CTS Configuration Configures if the CTS state is checked at the start of each character or only when the transmitter is idle. 0b - CTS input is sampled at the start of each character. 1b - CTS input is sampled when the transmitter is idle.
3 RXRTSE	Receiver request-to-send enable Allows the RTS output to control the CTS input of the transmitting device to prevent receiver overrun. This bit should only be changed when the receiver is disabled. **NOTE:** Do not set both RXRTSE and TXRTSE. 0b - The receiver has no effect on RTS. 1b - RTS is deasserted if the receiver data register is full or a start bit has been detected that would cause the receiver data register to become full. RTS is asserted if the receiver data register is not full and has not detected a start bit that would cause the receiver data register to become full.
2 TXRTSPOL	Transmitter request-to-send polarity Controls the polarity of the transmitter RTS. TXRTSPOL does not affect the polarity of the receiver RTS. RTS will remain negated in the active low state unless TXRTSE is set. This bit should only be changed when the transmitter is disabled. 0b - Transmitter RTS is active low. 1b - Transmitter RTS is active high.
1 TXRTSE	Transmitter request-to-send enable Controls RTS before and after a transmission. This bit should only be changed when the transmitter is disabled. 0b - The transmitter has no effect on RTS. 1b - When a character is placed into an empty transmitter data buffer , RTS asserts one bit time before the start bit is transmitted. RTS deasserts one bit time after all characters in the transmitter data buffer and shift register are completely sent, including the last stop bit.
0 TXCTSE	Transmitter clear-to-send enable TXCTSE controls the operation of the transmitter. TXCTSE can be set independently from the state of TXRTSE and RXRTSE. 0b - CTS has no effect on the transmitter. 1b - Enables clear-to-send operation. The transmitter checks the state of CTS each time it is ready to send a character. If CTS is asserted, the character is sent. If CTS is deasserted, the signal TXD remains in the mark state and transmission is delayed until CTS is asserted. Changes in CTS as a character is being sent do not affect its transmission.

51.3.1.12 LPUART FIFO Register (FIFO)

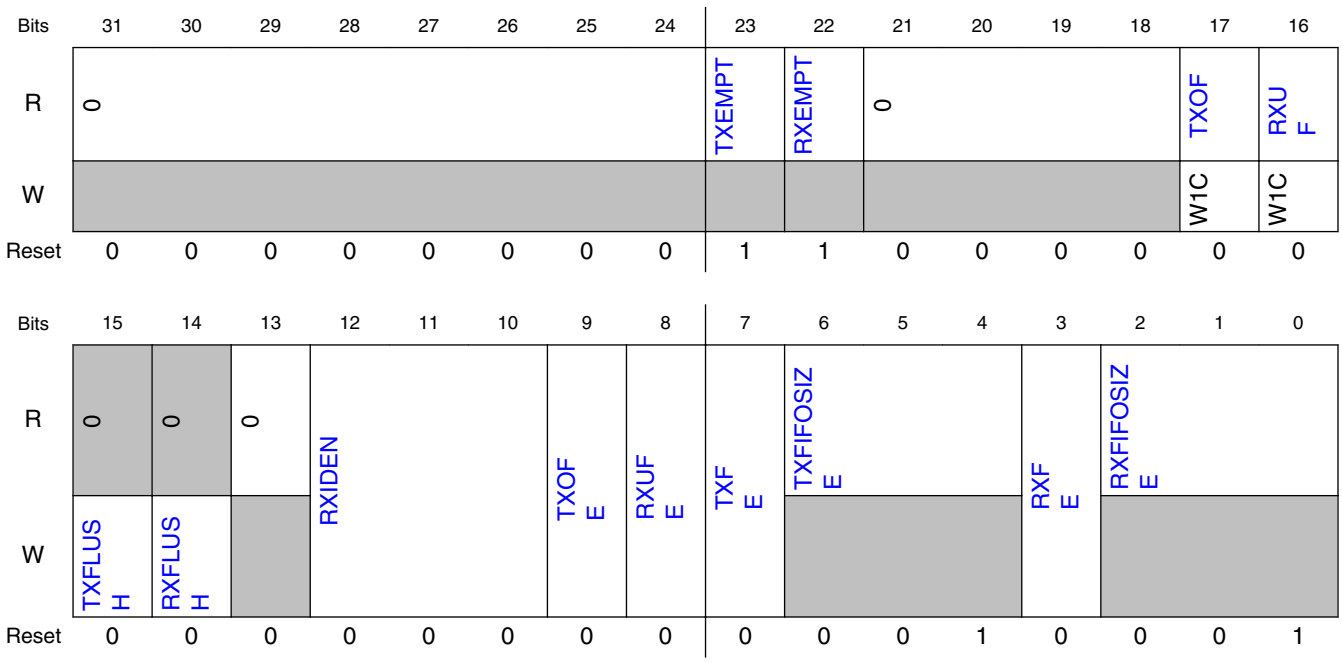
51.3.1.12.1 Offset

Register	Offset
FIFO	28h

51.3.1.12.2 Function

This register provides the ability for the programmer to turn on and off FIFO functionality. It also provides the size of the FIFO that has been implemented. This register may be read at any time. This register must be written only when CTRL[RE] and CTRL[TE] are cleared/not set and when the data buffer/FIFO is empty.

51.3.1.12.3 Diagram



51.3.1.12.4 Fields

Field	Function
31-24 —	Reserved
23 TXEMPT	Transmit Buffer/FIFO Empty Asserts when there is no data in the Transmit FIFO/buffer. This field does not take into account data that is in the transmit shift register. 0b - Transmit buffer is not empty.

Table continues on the next page...

Field	Function
	1b - Transmit buffer is empty.
22 RXEMPT	Receive Buffer/FIFO Empty Asserts when there is no data in the receive FIFO/Buffer. This field does not take into account data that is in the receive shift register. 0b - Receive buffer is not empty. 1b - Receive buffer is empty.
21-18 —	Reserved
17 TXOF	Transmitter Buffer Overflow Flag Indicates that more data has been written to the transmit buffer than it can hold. This field will assert regardless of the value of TXOFE. However, an interrupt will be issued to the host only if TXOFE is set. This flag is cleared by writing a 1. 0b - No transmit buffer overflow has occurred since the last time the flag was cleared. 1b - At least one transmit buffer overflow has occurred since the last time the flag was cleared.
16 RXUF	Receiver Buffer Underflow Flag Indicates that more data has been read from the receive buffer than was present. This field will assert regardless of the value of RXUFE. However, an interrupt will be issued to the host only if RXUFE is set. This flag is cleared by writing a 1. 0b - No receive buffer underflow has occurred since the last time the flag was cleared. 1b - At least one receive buffer underflow has occurred since the last time the flag was cleared.
15 TXFLUSH	Transmit FIFO/Buffer Flush Writing to this field causes all data that is stored in the transmit FIFO/buffer to be flushed. This does not affect data that is in the transmit shift register. 0b - No flush operation occurs. 1b - All data in the transmit FIFO/Buffer is cleared out.
14 RXFLUSH	Receive FIFO/Buffer Flush Writing to this field causes all data that is stored in the receive FIFO/buffer to be flushed. This does not affect data that is in the receive shift register. 0b - No flush operation occurs. 1b - All data in the receive FIFO/buffer is cleared out.
13 —	Reserved
12-10 RXIDEN	Receiver Idle Empty Enable When set, enables the assertion of RDRF when the receiver is idle for a number of idle characters and the FIFO is not empty. 000b - Disable RDRF assertion due to partially filled FIFO when receiver is idle. 001b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 1 character. 010b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 2 characters. 011b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 4 characters. 100b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 8 characters. 101b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 16 characters. 110b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 32 characters. 111b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 64 characters.
9 TXOFE	Transmit FIFO Overflow Interrupt Enable When this field is set, the TXOF flag generates an interrupt to the host. 0b - TXOF flag does not generate an interrupt to the host. 1b - TXOF flag generates an interrupt to the host.
8	Receive FIFO Underflow Interrupt Enable

Table continues on the next page...

Field	Function
RXUFE	When this field is set, the RXUF flag generates an interrupt to the host. 0b - RXUF flag does not generate an interrupt to the host. 1b - RXUF flag generates an interrupt to the host.
7 TXFE	Transmit FIFO Enable When this field is set, the built-in FIFO structure for the transmit buffer is enabled. The size of the FIFO structure is indicated by TXFIFOSIZE. If this field is not set, the transmit buffer operates as a FIFO of depth one dataword regardless of the value in TXFIFOSIZE. Both CTRL[TE] and CTRL[RE] must be cleared prior to changing this field. 0b - Transmit FIFO is not enabled. Buffer is depth 1. 1b - Transmit FIFO is enabled. Buffer is depth indicated by TXFIFOSIZE.
6-4 TXFIFOSIZE	Transmit FIFO Buffer Depth The maximum number of transmit datawords that can be stored in the transmit buffer. This field is read only. 000b - Transmit FIFO/Buffer depth = 1 dataword. 001b - Transmit FIFO/Buffer depth = 4 datawords. 010b - Transmit FIFO/Buffer depth = 8 datawords. 011b - Transmit FIFO/Buffer depth = 16 datawords. 100b - Transmit FIFO/Buffer depth = 32 datawords. 101b - Transmit FIFO/Buffer depth = 64 datawords. 110b - Transmit FIFO/Buffer depth = 128 datawords. 111b - Transmit FIFO/Buffer depth = 256 datawords
3 RXFE	Receive FIFO Enable When this field is set, the built-in FIFO structure for the receive buffer is enabled. The size of the FIFO structure is indicated by the RXFIFOSIZE field. If this field is not set, the receive buffer operates as a FIFO of depth one dataword regardless of the value in RXFIFOSIZE. Both CTRL[TE] and CTRL[RE] must be cleared prior to changing this field. 0b - Receive FIFO is not enabled. Buffer is depth 1. 1b - Receive FIFO is enabled. Buffer is depth indicted by RXFIFOSIZE.
2-0 RXFIFOSIZE	Receive FIFO Buffer Depth The maximum number of receive datawords that can be stored in the receive buffer before an overrun occurs. This field is read only. 000b - Receive FIFO/Buffer depth = 1 dataword. 001b - Receive FIFO/Buffer depth = 4 datawords. 010b - Receive FIFO/Buffer depth = 8 datawords. 011b - Receive FIFO/Buffer depth = 16 datawords. 100b - Receive FIFO/Buffer depth = 32 datawords. 101b - Receive FIFO/Buffer depth = 64 datawords. 110b - Receive FIFO/Buffer depth = 128 datawords. 111b - Receive FIFO/Buffer depth = 256 datawords.

51.3.1.13 LPUART Watermark Register (WATER)

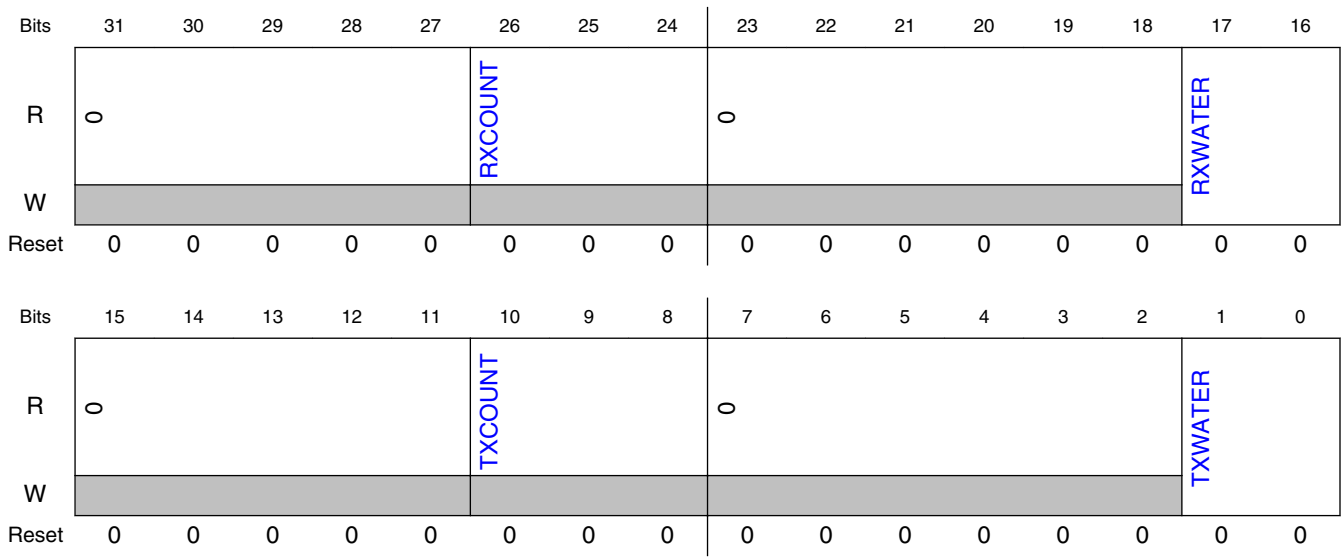
51.3.1.13.1 Offset

Register	Offset
WATER	2Ch

51.3.1.13.2 Function

This register provides the ability to set a programmable threshold for notification of needing additional transmit data. This register may be read at any time but must be written only when CTRL[TE] is not set.

51.3.1.13.3 Diagram



51.3.1.13.4 Fields

Field	Function
31-27 —	Reserved
26-24 RXCOUNT	Receive Counter The value in this register indicates the number of datawords that are in the receive FIFO/buffer. If a dataword is being received, that is, in the receive shift register, it is not included in the count. This value may be used in conjunction with FIFO[RXFIFOSIZE] to calculate how much room is left in the receive FIFO/buffer.
23-18 —	Reserved
17-16 RXWATER	Receive Watermark When the number of datawords in the receive FIFO/buffer is greater than the value in this register field, an interrupt or a DMA request is generated. For proper operation, the value in RXWATER must be set to be less than the receive FIFO/buffer size as indicated by FIFO[RXFIFOSIZE] and FIFO[RXFE] and must be greater than 0.
15-11 —	Reserved

Table continues on the next page...

Field	Function
10-8 TXCOUNT	Transmit Counter The value in this register indicates the number of datawords that are in the transmit FIFO/buffer. If a dataword is being transmitted, that is, in the transmit shift register, it is not included in the count. This value may be used in conjunction with FIFO[TXFIFOSIZE] to calculate how much room is left in the transmit FIFO/buffer.
7-2 —	Reserved
1-0 TXWATER	Transmit Watermark When the number of datawords in the transmit FIFO/buffer is equal to or less than the value in this register field, an interrupt or a DMA request is generated. For proper operation, the value in TXWATER must be set to be less than the size of the transmit buffer/FIFO size as indicated by FIFO[TXFIFOSIZE] and FIFO[TXFE].

51.3.2.5.3 Fields

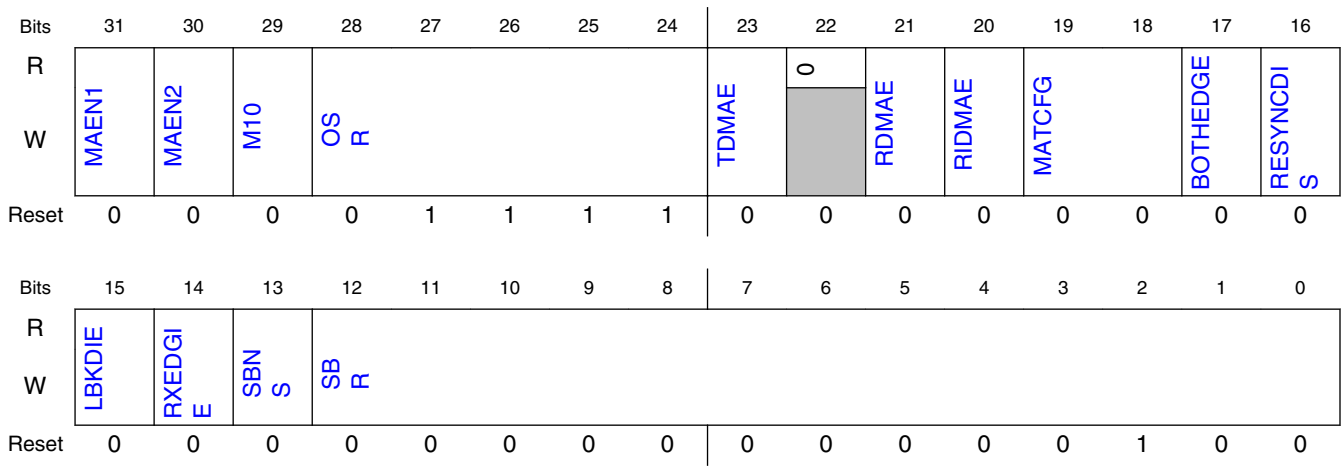
Field	Function
31-2 —	Reserved
1-0 TRGSEL	Trigger Select Configures the input trigger usage. This field should only be changed when the transmitter and receiver are both disabled. 00b - Input trigger is disabled. 01b - Input trigger is used instead of RXD pin input. 10b - Input trigger is used instead of CTS_B pin input. 11b - Input trigger is used to modulate the TXD pin output. The TXD pin output (after TXINV configuration) is ANDed with the input trigger.

51.3.2.6 LPUART Baud Rate Register (BAUD)

51.3.2.6.1 Offset

Register	Offset
BAUD	10h

51.3.2.6.2 Diagram



51.3.2.6.3 Fields

Field	Function
31 MAEN1	Match Address Mode Enable 1 0b - Normal operation. 1b - Enables automatic address matching or data matching mode for MATCH[MA1].
30 MAEN2	Match Address Mode Enable 2 0b - Normal operation. 1b - Enables automatic address matching or data matching mode for MATCH[MA2].
29 M10	10-bit Mode select The M10 bit causes a tenth bit to be part of the serial transmission. This bit should only be changed when the transmitter and receiver are both disabled. 0b - Receiver and transmitter use 7-bit to 9-bit data characters. 1b - Receiver and transmitter use 10-bit data characters.
28-24 OSR	Oversampling Ratio This field configures the oversampling ratio for the receiver. This field should only be changed when the transmitter and receiver are both disabled. 00000b - Writing 0 to this field will result in an oversampling ratio of 16 00001b - Reserved 00010b - Reserved 00011b - Oversampling ratio of 4, requires BOTHEDGE to be set. 00100b - Oversampling ratio of 5, requires BOTHEDGE to be set. 00101b - Oversampling ratio of 6, requires BOTHEDGE to be set. 00110b - Oversampling ratio of 7, requires BOTHEDGE to be set. 00111b - Oversampling ratio of 8.

Table continues on the next page...

Field	Function
	01000b - Oversampling ratio of 9. 01001b - Oversampling ratio of 10. 01010b - Oversampling ratio of 11. 01011b - Oversampling ratio of 12. 01100b - Oversampling ratio of 13. 01101b - Oversampling ratio of 14. 01110b - Oversampling ratio of 15. 01111b - Oversampling ratio of 16. 10000b - Oversampling ratio of 17. 10001b - Oversampling ratio of 18. 10010b - Oversampling ratio of 19. 10011b - Oversampling ratio of 20. 10100b - Oversampling ratio of 21. 10101b - Oversampling ratio of 22. 10110b - Oversampling ratio of 23. 10111b - Oversampling ratio of 24. 11000b - Oversampling ratio of 25. 11001b - Oversampling ratio of 26. 11010b - Oversampling ratio of 27. 11011b - Oversampling ratio of 28. 11100b - Oversampling ratio of 29. 11101b - Oversampling ratio of 30. 11110b - Oversampling ratio of 31. 11111b - Oversampling ratio of 32.
23 TDMAE	Transmitter DMA Enable TDMAE configures the transmit data register empty flag, STAT[TDRE], to generate a DMA request. 0b - DMA request disabled. 1b - DMA request enabled.
22 —	Reserved
21 RDMAE	Receiver Full DMA Enable RDMAE configures the receiver data register full flag, STAT[RDRF], to generate a DMA request. 0b - DMA request disabled. 1b - DMA request enabled.
20 RIDMAE	Receiver Idle DMA Enable RIDMAE configures the receiver idle flag, STAT[IDLE], to generate a DMA request. When this bit is set, reading the DATA register when either DATA[RXEMPT] or DATA[IDLINE] bit is set, will generate an End Of Packet response until the completion of the existing DMA transfer. During an End of Packet response, reading the DATA register will return 0x0000_33FF and does not pull data from the FIFO. 0b - DMA request disabled. 1b - DMA request enabled.
19-18 MATCFG	Match Configuration Configures the match addressing mode used. This field should only be changed when the transmitter and receiver are both disabled. 00b - Address Match Wakeup 01b - Idle Match Wakeup 10b - Match On and Match Off 11b - Enables RWU on Data Match and Match On/Off for transmitter CTS input
17 BOTHEDGE	Both Edge Sampling Enables sampling of the received data on both edges of the baud rate clock, effectively doubling the number of times the receiver samples the input data for a given oversampling ratio. This bit must be set

Table continues on the next page...

Field	Function
	for oversampling ratios between x4 and x7 and is optional for higher oversampling ratios. This bit should only be changed when the receiver is disabled. 0b - Receiver samples input data using the rising edge of the baud rate clock. 1b - Receiver samples input data using the rising and falling edge of the baud rate clock.
16 RESYNCDIS	Resynchronization Disable When set, disables the resynchronization of the received data word when a data one followed by data zero transition is detected. This bit should only be changed when the receiver is disabled. 0b - Resynchronization during received data word is supported 1b - Resynchronization during received data word is disabled
15 LBKDIE	LIN Break Detect Interrupt Enable LBKDIE enables the LIN break detect flag, STAT[LBKDIF], to generate interrupt requests. 0b - Hardware interrupts from STAT[LBKDIF] flag are disabled (use polling). 1b - Hardware interrupt requested when STAT[LBKDIF] flag is 1.
14 RXEDGIE	RX Input Active Edge Interrupt Enable Enables the receive input active edge, STAT[RXEDGIF], to generate interrupt requests. Changing CTRL[LOOP] or CTRL[RSRC] when RXEDGIE is set can cause the STAT[RXEDGIF] flag to set. 0b - Hardware interrupts from STAT[RXEDGIF] are disabled. 1b - Hardware interrupt is requested when STAT[RXEDGIF] flag is 1.
13 SBNS	Stop Bit Number Select SBNS determines whether data characters have one or two stop bits. This bit should only be changed when the transmitter and receiver are both disabled. 0b - One stop bit. 1b - Two stop bits.
12-0 SBR	Baud Rate Modulo Divisor. The 13 bits in SBR[12:0] set the modulo divide rate for the baud rate generator. When SBR is 1 - 8191, the baud rate equals "baud clock / ((OSR+1) × SBR)". The 13-bit baud rate setting [SBR12:SBR0] must be updated only when the transmitter and receiver are both disabled (CTRL[RE] and CTRL[TE] are both 0).

51.3.2.7 LPUART Status Register (STAT)

51.3.2.7.3 Fields

Field	Function
31 LBKDIF	LIN Break Detect Interrupt Flag LBKDIF is set when the LIN break detect circuitry is enabled and a LIN break character is detected. LBKDIF is cleared by writing a 1 to it. 0b - No LIN break character has been detected. 1b - LIN break character has been detected.
30 RXEDGIF	RXD Pin Active Edge Interrupt Flag RXEDGIF is set whenever the receiver is enabled and an active edge, falling if RXINV = 0, rising if RXINV=1, on the RXD pin occurs. RXEDGIF is cleared by writing a 1 to it. 0b - No active edge on the receive pin has occurred. 1b - An active edge on the receive pin has occurred.
29 MSBF	MSB First Setting this bit reverses the order of the bits that are transmitted and received on the wire. This bit does not affect the polarity of the bits, the location of the parity bit or the location of the start or stop bits. This bit should only be changed when the transmitter and receiver are both disabled. 0b - LSB (bit0) is the first bit that is transmitted following the start bit. Further, the first bit received after the start bit is identified as bit0. 1b - MSB (bit9, bit8, bit7 or bit6) is the first bit that is transmitted following the start bit depending on the setting of CTRL[M], CTRL[PE] and BAUD[M10]. Further, the first bit received after the start bit is identified as bit9, bit8, bit7 or bit6 depending on the setting of CTRL[M] and CTRL[PE].
28 RXINV	Receive Data Inversion Setting this bit reverses the polarity of the received data input. This bit should only be changed when the receiver is disabled. **NOTE:** Setting RXINV inverts the RXD input for all cases: data bits, start and stop bits, break, and idle. 0b - Receive data not inverted. 1b - Receive data inverted.
27	Receive Wake Up Idle Detect

Table continues on the next page...

Field	Function
RWUID	For RWU on idle character, RWUID controls whether the idle character that wakes up the receiver sets the IDLE bit. For address match wakeup, RWUID controls if the IDLE bit is set when the address does not match. This bit should only be changed when the receiver is disabled. 0b - During receive standby state (RWU = 1), the IDLE bit does not get set upon detection of an idle character. During address match wakeup, the IDLE bit does not set when an address does not match. 1b - During receive standby state (RWU = 1), the IDLE bit gets set upon detection of an idle character. During address match wakeup, the IDLE bit does set when an address does not match.
26 BRK13	Break Character Generation Length BRK13 selects a longer transmitted break character length. Detection of a framing error is not affected by the state of this bit. This bit should only be changed when the transmitter is disabled. A break character can be sent by setting CTRL[SBK] or by writing the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] clear. 0b - Break character is transmitted with length of 9 to 13 bit times. 1b - Break character is transmitted with length of 12 to 15 bit times.
25 LBKDE	LIN Break Detection Enable LBKDE selects a longer break character detection length. While LBKDE is set, receive data is not stored in the receive data buffer. 0b - LIN break detect is disabled, normal break character can be detected. 1b - LIN break detect is enabled. LIN break character is detected at length of 11 bit times (if M = 0) or 12 (if M = 1) or 13 (M10 = 1).
24 RAF	Receiver Active Flag RAF is set when the receiver detects the beginning of a valid start bit, and RAF is cleared automatically when the receiver detects an idle line. 0b - LPUART receiver idle waiting for a start bit. 1b - LPUART receiver active (RXD input not idle).
23 TDRE	Transmit Data Register Empty Flag When the transmit FIFO is enabled, TDRE will set when the number of datawords in the transmit FIFO (DATA register) is equal to or less than the number indicated by WATER[TXWATER]). To clear TDRE, write to the DATA register until the number of words in the transmit FIFO is greater than the number indicated by WATER[TXWATER]. When the transmit FIFO is disabled,TDRE will set when the transmit DATA register is empty. To clear TDRE, write to the DATA register. TDRE is not affected by a character that is in the process of being transmitted; it is updated at the start of each transmitted character. 0b - Transmit data buffer full. 1b - Transmit data buffer empty.
22 TC	Transmission Complete Flag TC is cleared when there is a transmission in progress or when a preamble or break character is loaded. TC is set when the transmit buffer is empty and no data, preamble, or break character is being transmitted. When TC is set, the transmit data output signal becomes idle (logic 1). TC is cleared by writing to the DATA register to transmit new data, queuing a preamble by clearing and then setting CTRL[TE], queuing a break character by writing 1 to CTRL[SBK]. 0b - Transmitter active (sending data, a preamble, or a break). 1b - Transmitter idle (transmission activity complete).
21 RDRF	Receive Data Register Full Flag When the receive FIFO is enabled, RDRF is set when the number of datawords in the receive buffer is greater than the number indicated by WATER[RXWATER]. To clear RDRF, read the DATA register until the number of datawords in the receive data buffer is equal to or less than the number indicated by WATER[RXWATER]. When the receive FIFO is disabled, RDRF is set when the receive buffer (the DATA register) is full. To clear RDRF, read the DATA register.

Table continues on the next page...

Field	Function
	A character that is in the process of being received does not cause a change in RDRF until the entire character is received. Even if RDRF is set, the character will continue to be received until an overrun condition occurs once the entire character is received. 0b - Receive data buffer empty. 1b - Receive data buffer full.
20 IDLE	Idle Line Flag IDLE is set when the LPUART receive line becomes idle for a full character time after a period of activity. When CTRL[ILT] is cleared, the receiver starts counting idle bit times after the start bit. If the receive character is all 1s, these bit times and the stop bits time count toward the full character time of logic high, 10 to 13 bit times, needed for the receiver to detect an idle line. When CTRL[ILT] is set, the receiver doesn't start counting idle bit times until after the stop bits. The stop bits and any logic high bit times at the end of the previous character do not count toward the full character time of logic high needed for the receiver to detect an idle line. To clear IDLE, write logic 1 to the IDLE flag. After IDLE has been cleared, it cannot be set again until after a new character has been stored in the receive buffer or a LIN break character has set the LBKDIF flag . IDLE is set only once even if the receive line remains idle for an extended period. 0b - No idle line detected. 1b - Idle line was detected.
19 OR	Receiver Overrun Flag OR is set when software fails to prevent the receive data register from overflowing with data. The OR bit is set immediately after the stop bit has been completely received for the dataword that overflows the buffer and all the other error flags (FE, NF, and PF) are prevented from setting. The data in the shift register is lost, but the data already in the LPUART data registers is not affected. If LBKDE is enabled and a LIN Break is detected, the OR field asserts if LBKDIF is not cleared before the next data character is received. While the OR flag is set, no additional data is stored in the data buffer even if sufficient room exists. To clear OR, write logic 1 to the OR flag. 0b - No overrun. 1b - Receive overrun (new LPUART data lost).
18 NF	Noise Flag The advanced sampling technique used in the receiver takes three samples in each of the received bits. If any of these samples disagrees with the rest of the samples within any bit time in the frame then noise is detected for that character. NF is set whenever the next character to be read from the DATA register was received with noise detected within the character. To clear NF, write logic 1 to the NF field. 0b - No noise detected. 1b - Noise detected in the received character in the DATA register.
17 FE	Framing Error Flag FE is set whenever the next character to be read from the DATA register was received with logic 0 detected where a stop bit was expected. To clear FE, write logic 1 to the FE field. 0b - No framing error detected. This does not guarantee the framing is correct. 1b - Framing error.
16 PF	Parity Error Flag PF is set whenever the next character to be read from the DATA register was received when parity is enabled (PE = 1) and the parity bit in the received character does not agree with the expected parity value. To clear PF, write a logic 1 to the PF field. 0b - No parity error. 1b - Parity error.
15 MA1F	Match 1 Flag

Table continues on the next page...

Field	Function
	MA1F is set whenever the next character to be read from the DATA register matches MA1. To clear MA1F, write a logic 1 to the MA1F field. 0b - Received data is not equal to MA1 1b - Received data is equal to MA1
14 MA2F	Match 2 Flag MA2F is set whenever the next character to be read from the DATA register matches MA2. To clear MA2F, write a logic 1 to the MA2F field. 0b - Received data is not equal to MA2 1b - Received data is equal to MA2
13-0 —	Reserved

51.3.2.8 LPUART Control Register (CTRL)

51.3.2.8.1 Offset

Register	Offset
CTRL	18h

51.3.2.8.2 Function

This read/write register controls various optional features of the LPUART system. This register should only be altered when the transmitter and receiver are both disabled.

51.3.2.8.3 Diagram

51.3.2.8.4 Fields

Field	Function
31 R8T9	Receive Bit 8 / Transmit Bit 9 R8 is the ninth data bit received when the LPUART is configured for 9-bit or 10-bit data formats. When reading 9-bit or 10-bit data, read R8 before reading the DATA register. T9 is the tenth data bit transmitted when the LPUART is configured for 10-bit data formats. When writing 10-bit data, write T9 before writing the DATA register. If T9 does not need to change from its previous value, such as when it is used to generate address mark or parity, they it need not be written each time the DATA register is written. **NOTE:** R8 is a read-only bit and T9 is a write-only bit, the value read is different from the value written.
30 R9T8	Receive Bit 9 / Transmit Bit 8 R9 is the tenth data bit received when the LPUART is configured for 10-bit data formats. When reading 10-bit data, read R9 before reading the DATA register T8 is the ninth data bit transmitted when the LPUART is configured for 9-bit or 10-bit data formats. When writing 9-bit or 10-bit data, write T8 before writing the DATA register. If T8 does not need to change from its previous value, such as when it is used to generate address mark or parity, then it need not be written each time the DATA register is written. **NOTE:** R9 is a read-only bit and T8 is a write-only bit, the value read is different from the value written.
29 TXDIR	TXD Pin Direction in Single-Wire Mode When the LPUART is configured for single-wire half-duplex operation (LOOPS = RSRC = 1), this bit determines the direction of data at the TXD pin. When clearing TXDIR, the transmitter will finish receiving the current character (if any) before the receiver starts receiving data from the TXD pin. 0b - TXD pin is an input in single-wire mode. 1b - TXD pin is an output in single-wire mode.
28 TXINV	Transmit Data Inversion Setting this bit reverses the polarity of the transmitted data output. **NOTE:** Setting TXINV inverts the TXD output for all cases: data bits, start and stop bits, break, and idle. 0b - Transmit data not inverted. 1b - Transmit data inverted.
27 ORIE	Overrun Interrupt Enable This bit enables the overrun flag (OR) to generate hardware interrupt requests. 0b - OR interrupts disabled; use polling. 1b - Hardware interrupt requested when OR is set.
26 NEIE	Noise Error Interrupt Enable This bit enables the noise flag (NF) to generate hardware interrupt requests. 0b - NF interrupts disabled; use polling. 1b - Hardware interrupt requested when NF is set.
25 FEIE	Framing Error Interrupt Enable This bit enables the framing error flag (FE) to generate hardware interrupt requests. 0b - FE interrupts disabled; use polling. 1b - Hardware interrupt requested when FE is set.
24 PEIE	Parity Error Interrupt Enable This bit enables the parity error flag (PF) to generate hardware interrupt requests. 0b - PF interrupts disabled; use polling). 1b - Hardware interrupt requested when PF is set.
23	Transmit Interrupt Enable

Table continues on the next page...

Field	Function
TIE	Enables STAT[TDRE] to generate interrupt requests. 0b - Hardware interrupts from TDRE disabled; use polling. 1b - Hardware interrupt requested when TDRE flag is 1.
22 TCIE	Transmission Complete Interrupt Enable for TCIE enables the transmission complete flag, TC, to generate interrupt requests. 0b - Hardware interrupts from TC disabled; use polling. 1b - Hardware interrupt requested when TC flag is 1.
21 RIE	Receiver Interrupt Enable Enables STAT[RDRF] to generate interrupt requests. 0b - Hardware interrupts from RDRF disabled; use polling. 1b - Hardware interrupt requested when RDRF flag is 1.
20 ILIE	Idle Line Interrupt Enable ILIE enables the idle line flag, STAT[IDLE], to generate interrupt requests. 0b - Hardware interrupts from IDLE disabled; use polling. 1b - Hardware interrupt requested when IDLE flag is 1.
19 TE	Transmitter Enable Enables the LPUART transmitter. TE can also be used to queue an idle preamble by clearing and then setting TE. When TE is cleared, this register bit will read as 1 until the transmitter has completed the current character and the TXD pin is tristated. A single idle character can also be queued by writing to the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] set. 0b - Transmitter disabled. 1b - Transmitter enabled.
18 RE	Receiver Enable Enables the LPUART receiver. When RE is written to 0, this register bit will read as 1 until the receiver finishes receiving the current character (if any). 0b - Receiver disabled. 1b - Receiver enabled.
17 RWU	Receiver Wakeup Control This field can be set to place the LPUART receiver in a standby state. RWU automatically clears when an RWU event occurs, that is, an IDLE event when CTRL[WAKE] is clear or an address match when CTRL[WAKE] is set with STAT[RWUID] is clear. **NOTE:** RWU must be set only with CTRL[WAKE] = 0 (wakeup on idle) if the channel is currently not idle. This can be determined by STAT[RAF]. If the flag is set to wake up an IDLE event and the channel is already idle, it is possible that the LPUART will discard data. This is because the data must be received or a LIN break detected after an IDLE is detected before IDLE is allowed to be reasserted. 0b - Normal receiver operation. 1b - LPUART receiver in standby waiting for wakeup condition.
16 SBK	Send Break Writing a 1 and then a 0 to SBK queues a break character in the transmit data stream. Additional break characters of 9 to 13 bits, or 12 to 15 bits if STAT[BRK13] is set, bit times of logic 0 are queued as long as SBK is set. Depending on the timing of the set and clear of SBK relative to the character currently being transmitted, a second break character may be queued before software clears SBK. A single break character can also be queued by writing to the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] clear. 0b - Normal transmitter operation. 1b - Queue break character(s) to be sent.

Table continues on the next page...

Field	Function
15 MA1IE	Match 1 Interrupt Enable 0b - MA1F interrupt disabled 1b - MA1F interrupt enabled
14 MA2IE	Match 2 Interrupt Enable 0b - MA2F interrupt disabled 1b - MA2F interrupt enabled
13-12 —	Reserved
11 M7	7-Bit Mode Select This bit should only be changed when the transmitter and receiver are both disabled. 0b - Receiver and transmitter use 8-bit to 10-bit data characters. 1b - Receiver and transmitter use 7-bit data characters.
10-8 IDLECFG	Idle Configuration Configures the number of idle characters that must be received before the IDLE flag is set. 000b - 1 idle character 001b - 2 idle characters 010b - 4 idle characters 011b - 8 idle characters 100b - 16 idle characters 101b - 32 idle characters 110b - 64 idle characters 111b - 128 idle characters
7 LOOPS	Loop Mode Select When LOOPS is set, the RXD pin is disconnected from the LPUART and the transmitter output is internally connected to the receiver input. The transmitter and the receiver must be enabled to use the loop function. 0b - Normal operation - RXD and TXD use separate pins. 1b - Loop mode or single-wire mode where transmitter outputs are internally connected to receiver input (see RSRC bit).
6 DOZEEN	Doze Enable 0b - LPUART is enabled in Doze mode. 1b - LPUART is disabled in Doze mode.
5 RSRC	Receiver Source Select This field has no meaning or effect unless the LOOPS field is set. When LOOPS is set, the RSRC field determines the source for the receiver shift register input. 0b - Provided LOOPS is set, RSRC is cleared, selects internal loop back mode and the LPUART does not use the RXD pin. 1b - Single-wire LPUART mode where the TXD pin is connected to the transmitter output and receiver input.
4 M	9-Bit or 8-Bit Mode Select 0b - Receiver and transmitter use 8-bit data characters. 1b - Receiver and transmitter use 9-bit data characters.
3 WAKE	Receiver Wakeup Method Select Determines which condition wakes the LPUART when RWU=1: • Address mark in the bit preceding the stop bit (or bit preceding the parity bit when parity is enabled) of the received data character, or • An idle condition on the receive pin input signal. 0b - Configures RWU for idle-line wakeup. 1b - Configures RWU with address-mark wakeup.

Table continues on the next page...

Field	Function
2 ILT	Idle Line Type Select Determines when the receiver starts counting logic 1s as idle character bits. The count begins either after a valid start bit or after the stop bit. If the count begins after the start bit, then a string of logic 1s preceding the stop bit can cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions. **NOTE:** In case the LPUART is programmed with ILT = 1, a logic 0 is automatically shifted after a received stop bit, therefore resetting the idle count. 0b - Idle character bit count starts after start bit. 1b - Idle character bit count starts after stop bit.
1 PE	Parity Enable Enables hardware parity generation and checking. When parity is enabled, the bit immediately before the stop bit is treated as the parity bit. 0b - No hardware parity generation or checking. 1b - Parity enabled.
0 PT	Parity Type Provided parity is enabled (PE = 1), this bit selects even or odd parity. Odd parity means the total number of 1s in the data character, including the parity bit, is odd. Even parity means the total number of 1s in the data character, including the parity bit, is even. 0b - Even parity. 1b - Odd parity.

51.3.2.9 LPUART Data Register (DATA)

51.3.2.9.1 Offset

Register	Offset
DATA	1Ch

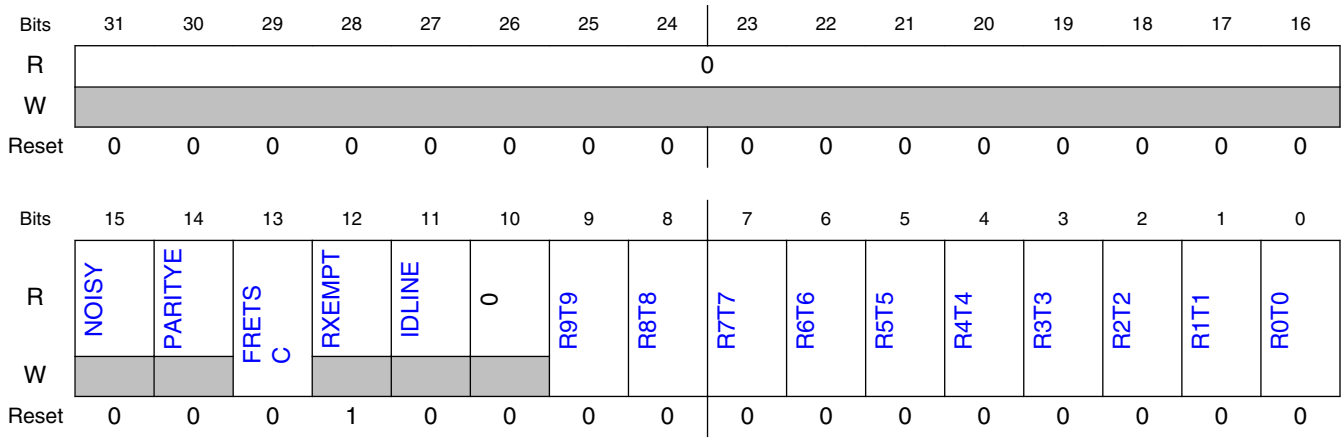
51.3.2.9.2 Function

NOTE

This register is two separate registers. Reads return the contents of the read-only receive data buffer and writes go to the write-only transmit data buffer.

Reads and writes of this register are also involved in the automatic flag clearing mechanisms for some of the LPUART status flags.

51.3.2.9.3 Diagram



51.3.2.9.4 Fields

Field	Function
31-16 —	Reserved
15 NOISY	NOISY The current received dataword contained in DATA[R9:R0] was received with noise. 0b - The dataword was received without noise. 1b - The data was received with noise.
14 PARITYE	PARITYE The current received dataword contained in DATA[R9:R0] was received with a parity error. 0b - The dataword was received without a parity error. 1b - The dataword was received with a parity error.
13 FRETSC	Frame Error / Transmit Special Character For reads, indicates the current received dataword contained in DATA[R9:R0] was received with a frame error. For writes, indicates a break or idle character is to be transmitted instead of the contents in DATA[T9:T0]. T9 is used to indicate a break character when 0 and a idle character when 1, the contents of DATA[T8:T0] should be zero. 0b - The dataword was received without a frame error on read, or transmit a normal character on write. 1b - The dataword was received with a frame error, or transmit an idle or break character on transmit.
12 RXEMPT	Receive Buffer Empty Asserts when there is no data in the receive buffer. This field does not take into account data that is in the receive shift register. 0b - Receive buffer contains valid data. 1b - Receive buffer is empty, data returned on read is not valid.
11 IDLINE	Idle Line Indicates the receiver line was idle before receiving the character in DATA[9:0]. Unlike the IDLE flag, this bit can set for the first character received when the receiver is first enabled. 0b - Receiver was not idle before receiving this character. 1b - Receiver was idle before receiving this character.

Table continues on the next page...

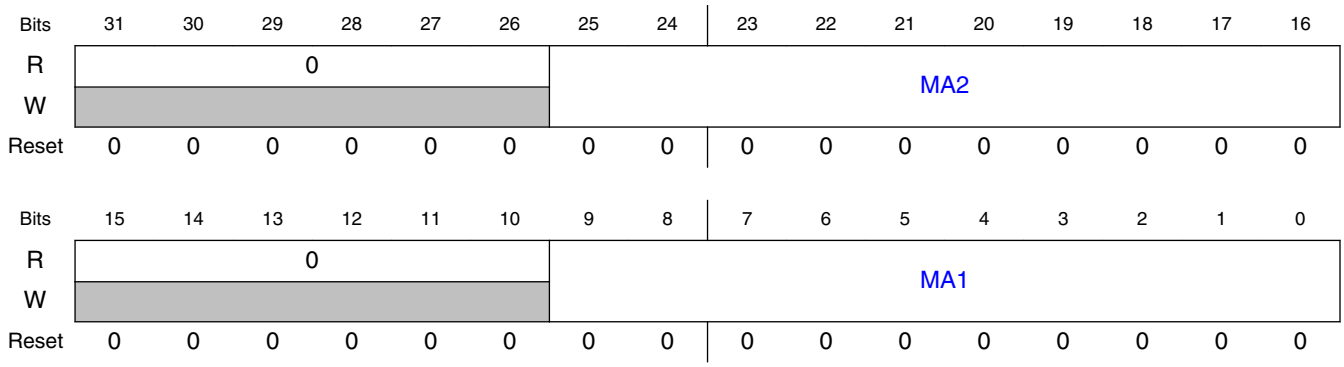
Field	Function
10 —	Reserved
9 R9T9	R9T9 Read receive data buffer 9 or write transmit data buffer 9.
8 R8T8	R8T8 Read receive data buffer 8 or write transmit data buffer 8.
7 R7T7	R7T7 Read receive data buffer 7 or write transmit data buffer 7.
6 R6T6	R6T6 Read receive data buffer 6 or write transmit data buffer 6.
5 R5T5	R5T5 Read receive data buffer 5 or write transmit data buffer 5.
4 R4T4	R4T4 Read receive data buffer 4 or write transmit data buffer 4.
3 R3T3	R3T3 Read receive data buffer 3 or write transmit data buffer 3.
2 R2T2	R2T2 Read receive data buffer 2 or write transmit data buffer 2.
1 R1T1	R1T1 Read receive data buffer 1 or write transmit data buffer 1.
0 R0T0	R0T0 Read receive data buffer 0 or write transmit data buffer 0.

51.3.2.10 LPUART Match Address Register (MATCH)

51.3.2.10.1 Offset

Register	Offset
MATCH	20h

51.3.2.10.2 Diagram



51.3.2.10.3 Fields

Field	Function
31-26 —	Reserved
25-16 MA2	Match Address 2 The MA1 and MA2 fields are compared to input data addresses when the most significant bit is set and the associated BAUD[MAEN] bit is set. If a match occurs, the following data is transferred to the DATA register. If a match fails, the following data is discarded. Software should only write a MAx field when the associated BAUD[MAEN] bit is clear.
15-10 —	Reserved
9-0 MA1	Match Address 1 The MA1 and MA2 fields are compared to input data addresses when the most significant bit is set and the associated BAUD[MAEN] bit is set. If a match occurs, the following data is transferred to the DATA register. If a match fails, the following data is discarded. Software should only write a MAx field when the associated BAUD[MAEN] bit is clear.

51.3.2.11 LPUART Modem IrDA Register (MODIR)

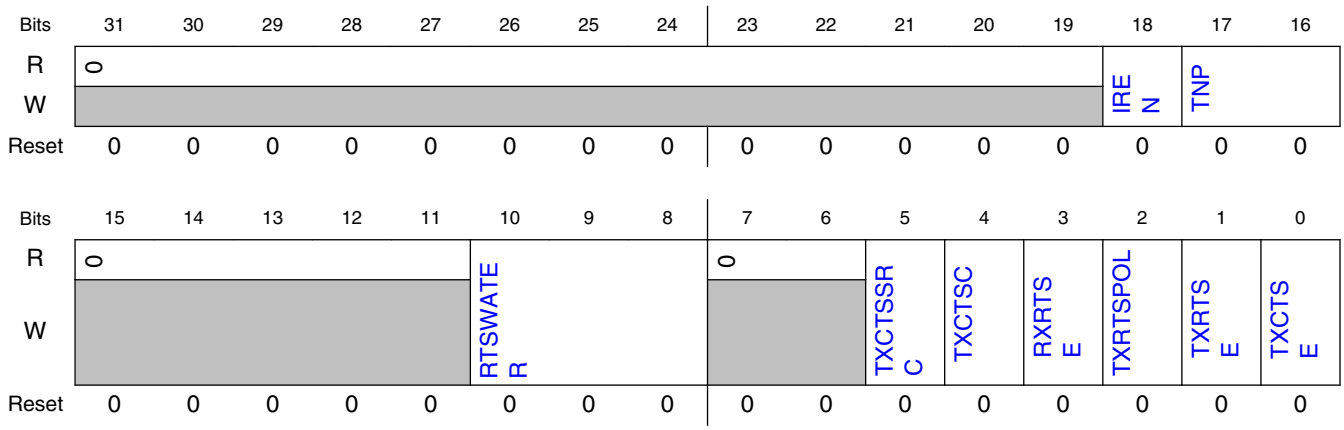
51.3.2.11.1 Offset

Register	Offset
MODIR	24h

51.3.2.11.2 Function

The MODEM register controls options for setting the modem configuration.

51.3.2.11.3 Diagram



51.3.2.11.4 Fields

Field	Function
31-19 —	Reserved
18 IREN	Infrared enable Enables/disables the infrared modulation/demodulation. This bit should only be changed when the transmitter and receiver are both disabled. 0b - IR disabled. 1b - IR enabled.
17-16 TNP	Transmitter narrow pulse Configures whether the LPUART transmits a 1/OSR, 2/OSR, 3/OSR or 4/OSR narrow pulse when IR is enabled. This bit should only be changed when the transmitter and receiver are both disabled. The IR pulse width should be configured to less than half of the oversampling ratio. Common pulse widths are 3/16, 1/16, 1/32 or 1/4 of the bit length. These can be configured by selecting the appropriate oversample ratio and pulse width. 00b - 1/OSR. 01b - 2/OSR. 10b - 3/OSR. 11b - 4/OSR.
15-11 —	Reserved
10-8 RTSWATER	Receive RTS Configuration Configures the assertion and negation of the RX RTS_B output. The RX RTS_B output negates when the number of empty words in the receive FIFO is greater or equal to RTSWATER. If RTSWATER is configured to zero, RTS_B negates when the receive FIFO is full. For the purpose of RX RTS_B generation, the number of words in the receive FIFO updates when a start bit is detected. This supports additional latency between RTS_B negation and the external transmitter ceasing transmission. If both RX RTS_B and address/data matching is enabled, then RTS_B could assert at the end of a character if there is not a match.

Table continues on the next page...

Field	Function
	This field should only be changed when the receiver is disabled.
7-6 —	Reserved
5 TXCTSSRC	Transmit CTS Source Configures the source of the CTS input. 0b - CTS input is the CTS_B pin. 1b - CTS input is the inverted Receiver Match result.
4 TXCTSC	Transmit CTS Configuration Configures if the CTS state is checked at the start of each character or only when the transmitter is idle. 0b - CTS input is sampled at the start of each character. 1b - CTS input is sampled when the transmitter is idle.
3 RXRTSE	Receiver request-to-send enable Allows the RTS output to control the CTS input of the transmitting device to prevent receiver overrun. This bit should only be changed when the receiver is disabled. **NOTE:** Do not set both RXRTSE and TXRTSE. 0b - The receiver has no effect on RTS. 1b - RTS is deasserted if the receiver data register is full or a start bit has been detected that would cause the receiver data register to become full. RTS is asserted if the receiver data register is not full and has not detected a start bit that would cause the receiver data register to become full.
2 TXRTSPOL	Transmitter request-to-send polarity Controls the polarity of the transmitter RTS. TXRTSPOL does not affect the polarity of the receiver RTS. RTS will remain negated in the active low state unless TXRTSE is set. This bit should only be changed when the transmitter is disabled. 0b - Transmitter RTS is active low. 1b - Transmitter RTS is active high.
1 TXRTSE	Transmitter request-to-send enable Controls RTS before and after a transmission. This bit should only be changed when the transmitter is disabled. 0b - The transmitter has no effect on RTS. 1b - When a character is placed into an empty transmitter data buffer , RTS asserts one bit time before the start bit is transmitted. RTS deasserts one bit time after all characters in the transmitter data buffer and shift register are completely sent, including the last stop bit.
0 TXCTSE	Transmitter clear-to-send enable TXCTSE controls the operation of the transmitter. TXCTSE can be set independently from the state of TXRTSE and RXRTSE. 0b - CTS has no effect on the transmitter. 1b - Enables clear-to-send operation. The transmitter checks the state of CTS each time it is ready to send a character. If CTS is asserted, the character is sent. If CTS is deasserted, the signal TXD remains in the mark state and transmission is delayed until CTS is asserted. Changes in CTS as a character is being sent do not affect its transmission.

51.3.2.12 LPUART FIFO Register (FIFO)

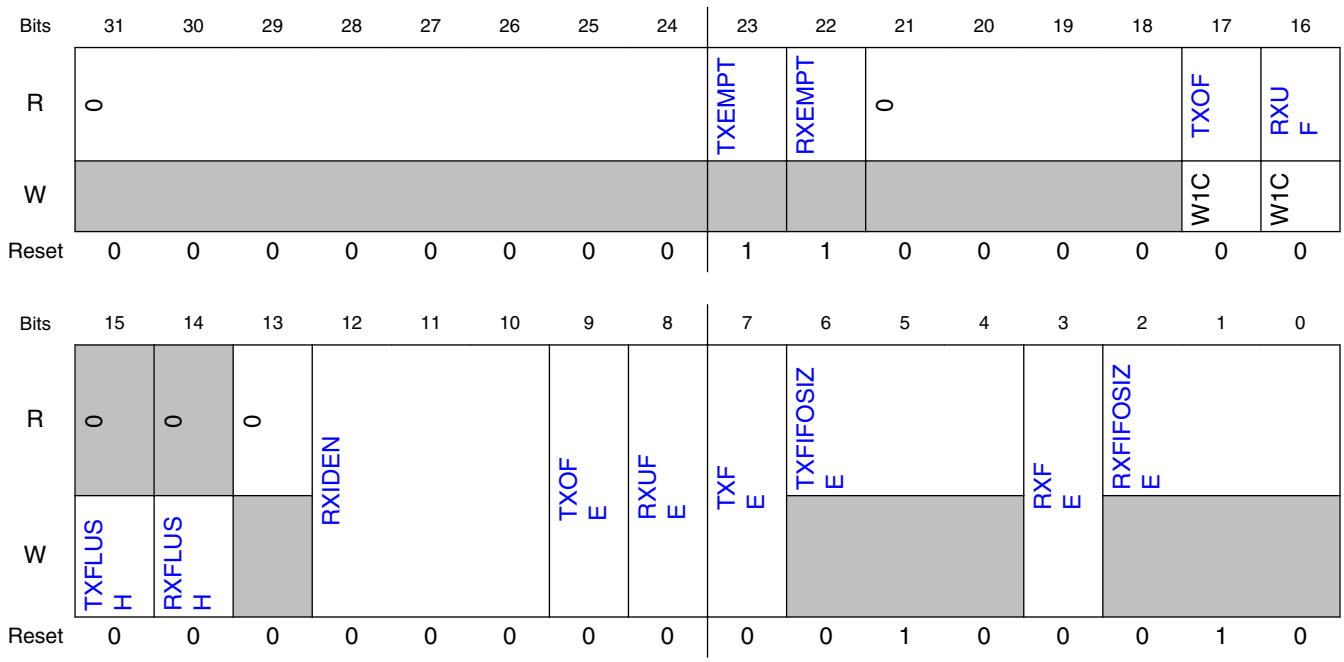
51.3.2.12.1 Offset

Register	Offset
FIFO	28h

51.3.2.12.2 Function

This register provides the ability for the programmer to turn on and off FIFO functionality. It also provides the size of the FIFO that has been implemented. This register may be read at any time. This register must be written only when CTRL[RE] and CTRL[TE] are cleared/not set and when the data buffer/FIFO is empty.

51.3.2.12.3 Diagram



51.3.2.12.4 Fields

Field	Function
31-24 —	Reserved
23 TXEMPT	Transmit Buffer/FIFO Empty Asserts when there is no data in the Transmit FIFO/buffer. This field does not take into account data that is in the transmit shift register. 0b - Transmit buffer is not empty.

Table continues on the next page...

Field	Function
	1b - Transmit buffer is empty.
22 RXEMPT	Receive Buffer/FIFO Empty Asserts when there is no data in the receive FIFO/Buffer. This field does not take into account data that is in the receive shift register. 0b - Receive buffer is not empty. 1b - Receive buffer is empty.
21-18 —	Reserved
17 TXOF	Transmitter Buffer Overflow Flag Indicates that more data has been written to the transmit buffer than it can hold. This field will assert regardless of the value of TXOFE. However, an interrupt will be issued to the host only if TXOFE is set. This flag is cleared by writing a 1. 0b - No transmit buffer overflow has occurred since the last time the flag was cleared. 1b - At least one transmit buffer overflow has occurred since the last time the flag was cleared.
16 RXUF	Receiver Buffer Underflow Flag Indicates that more data has been read from the receive buffer than was present. This field will assert regardless of the value of RXUFE. However, an interrupt will be issued to the host only if RXUFE is set. This flag is cleared by writing a 1. 0b - No receive buffer underflow has occurred since the last time the flag was cleared. 1b - At least one receive buffer underflow has occurred since the last time the flag was cleared.
15 TXFLUSH	Transmit FIFO/Buffer Flush Writing to this field causes all data that is stored in the transmit FIFO/buffer to be flushed. This does not affect data that is in the transmit shift register. 0b - No flush operation occurs. 1b - All data in the transmit FIFO/Buffer is cleared out.
14 RXFLUSH	Receive FIFO/Buffer Flush Writing to this field causes all data that is stored in the receive FIFO/buffer to be flushed. This does not affect data that is in the receive shift register. 0b - No flush operation occurs. 1b - All data in the receive FIFO/buffer is cleared out.
13 —	Reserved
12-10 RXIDEN	Receiver Idle Empty Enable When set, enables the assertion of RDRF when the receiver is idle for a number of idle characters and the FIFO is not empty. 000b - Disable RDRF assertion due to partially filled FIFO when receiver is idle. 001b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 1 character. 010b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 2 characters. 011b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 4 characters. 100b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 8 characters. 101b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 16 characters. 110b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 32 characters. 111b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 64 characters.
9 TXOFE	Transmit FIFO Overflow Interrupt Enable When this field is set, the TXOF flag generates an interrupt to the host. 0b - TXOF flag does not generate an interrupt to the host. 1b - TXOF flag generates an interrupt to the host.
8	Receive FIFO Underflow Interrupt Enable

Table continues on the next page...

Field	Function
RXUFE	When this field is set, the RXUF flag generates an interrupt to the host. 0b - RXUF flag does not generate an interrupt to the host. 1b - RXUF flag generates an interrupt to the host.
7 TXFE	Transmit FIFO Enable When this field is set, the built-in FIFO structure for the transmit buffer is enabled. The size of the FIFO structure is indicated by TXFIFOSIZE. If this field is not set, the transmit buffer operates as a FIFO of depth one dataword regardless of the value in TXFIFOSIZE. Both CTRL[TE] and CTRL[RE] must be cleared prior to changing this field. 0b - Transmit FIFO is not enabled. Buffer is depth 1. 1b - Transmit FIFO is enabled. Buffer is depth indicated by TXFIFOSIZE.
6-4 TXFIFOSIZE	Transmit FIFO Buffer Depth The maximum number of transmit datawords that can be stored in the transmit buffer. This field is read only. 000b - Transmit FIFO/Buffer depth = 1 dataword. 001b - Transmit FIFO/Buffer depth = 4 datawords. 010b - Transmit FIFO/Buffer depth = 8 datawords. 011b - Transmit FIFO/Buffer depth = 16 datawords. 100b - Transmit FIFO/Buffer depth = 32 datawords. 101b - Transmit FIFO/Buffer depth = 64 datawords. 110b - Transmit FIFO/Buffer depth = 128 datawords. 111b - Transmit FIFO/Buffer depth = 256 datawords
3 RXFE	Receive FIFO Enable When this field is set, the built-in FIFO structure for the receive buffer is enabled. The size of the FIFO structure is indicated by the RXFIFOSIZE field. If this field is not set, the receive buffer operates as a FIFO of depth one dataword regardless of the value in RXFIFOSIZE. Both CTRL[TE] and CTRL[RE] must be cleared prior to changing this field. 0b - Receive FIFO is not enabled. Buffer is depth 1. 1b - Receive FIFO is enabled. Buffer is depth indicted by RXFIFOSIZE.
2-0 RXFIFOSIZE	Receive FIFO Buffer Depth The maximum number of receive datawords that can be stored in the receive buffer before an overrun occurs. This field is read only. 000b - Receive FIFO/Buffer depth = 1 dataword. 001b - Receive FIFO/Buffer depth = 4 datawords. 010b - Receive FIFO/Buffer depth = 8 datawords. 011b - Receive FIFO/Buffer depth = 16 datawords. 100b - Receive FIFO/Buffer depth = 32 datawords. 101b - Receive FIFO/Buffer depth = 64 datawords. 110b - Receive FIFO/Buffer depth = 128 datawords. 111b - Receive FIFO/Buffer depth = 256 datawords.

51.3.2.13 LPUART Watermark Register (WATER)

51.3.2.13.1 Offset

Register	Offset
WATER	2Ch

51.3.2.13.2 Function

This register provides the ability to set a programmable threshold for notification of needing additional transmit data. This register may be read at any time but must be written only when CTRL[TE] is not set.

51.3.2.13.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

51.3.2.13.4 Fields

Field	Function
31-28 —	Reserved
27-24 RXCOUNT	Receive Counter The value in this register indicates the number of datawords that are in the receive FIFO/buffer. If a dataword is being received, that is, in the receive shift register, it is not included in the count. This value may be used in conjunction with FIFO[RXFIFOSIZE] to calculate how much room is left in the receive FIFO/buffer.
23-19 —	Reserved
18-16 RXWATER	Receive Watermark When the number of datawords in the receive FIFO/buffer is greater than the value in this register field, an interrupt or a DMA request is generated. For proper operation, the value in RXWATER must be set to be less than the receive FIFO/buffer size as indicated by FIFO[RXFIFOSIZE] and FIFO[RXFE] and must be greater than 0.
15-12 —	Reserved
11-8 TXCOUNT	Transmit Counter The value in this register indicates the number of datawords that are in the transmit FIFO/buffer. If a dataword is being transmitted, that is, in the transmit shift register, it is not included in the count. This value may be used in conjunction with FIFO[TXFIFOSIZE] to calculate how much room is left in the transmit FIFO/buffer.
7-3	Reserved

Table continues on the next page...

Field	Function
—	
2-0 TXWATER	Transmit Watermark When the number of datawords in the transmit FIFO/buffer is equal to or less than the value in this register field, an interrupt or a DMA request is generated. For proper operation, the value in TXWATER must be set to be less than the size of the transmit buffer/FIFO size as indicated by FIFO[TXFIFOSIZE] and FIFO[TXFE].

51.4 Functional description

The LPUART supports full-duplex, asynchronous, NRZ serial communication and comprises a baud rate generator, transmitter, and receiver block. The transmitter and receiver operate independently, although they use the same baud rate generator. The following describes each of the blocks of the LPUART.

51.4.1 Clocking and Resets

Table 51-3. Clocks

LPUART Functional clock	The LPUART functional clock is asynchronous to the bus clock and can remain enabled in low power modes to support transmit and/or receive, including low power wakeups.
Bus clock	The bus clock is only used for bus accesses to the control and configuration registers. The bus clock frequency must be sufficient to support the data bandwidth requirements of the LPUART transmit and receive registers, including the FIFOs.

Table 51-4. Resets

Chip reset	The logic and registers for the LPUART transmitter and receiver are reset to their default state on a chip reset.
Software reset	Resets the LPUART logic and registers to their default state, except for the Global Register. The LPUART software reset is in the Global Register GLOBAL[RST].
FIFO reset	The LPUART implements write-only control bits that reset the transmit FIFO (FIFO[TXFLUSH]) and receive FIFO (FIFO[RXFLUSH]). After a FIFO is reset, that FIFO is empty.

51.4.2 Baud rate generation

A 13-bit modulus counter in the baud rate generator derives the baud rate for both the receiver and the transmitter. The value from 1 to 8191 written to BAUD[SBR] determines the baud clock divisor for the asynchronous LPUART baud clock. The baud

rate clock drives the receiver, while the transmitter is driven by a bit clock which is generated from baud rate clock divided by the over sampling ratio. Depending on the over sampling ratio, the receiver has an acquisition rate of 4 to 32 samples per bit time.

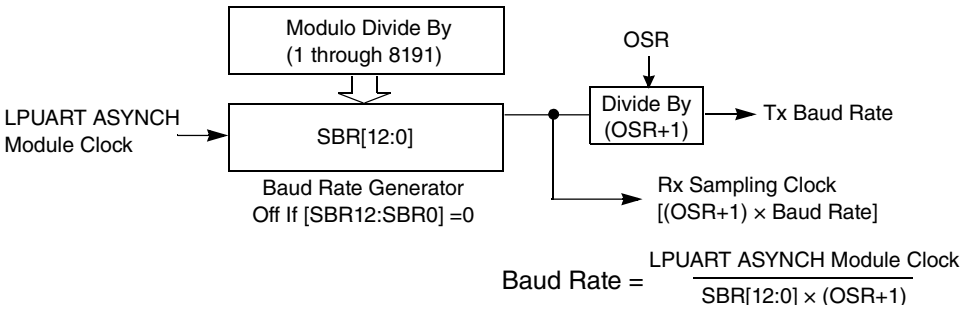

Figure 51-3. LPUART baud rate generation

Baud rate generation is subject to two sources of error:

- Integer division of the asynchronous LPUART baud clock may not give the exact target frequency.
- Synchronization with the asynchronous LPUART baud clock can cause phase shift.

The baud rate generation is a free-running counter that continues whenever the transmitter or receiver is enabled. The transmitter bit clock continues whenever the transmitter is enabled, each transmitted character will align to the next edge of the transmit bit clock.

51.4.3 Transmitter functional description

This section describes the overall block diagram for the LPUART transmitter, as well as specialized functions for sending break and idle characters.

The transmitter output (TXD) idle state defaults to logic high, CTRL[TXINV] is cleared following reset. The transmitter output is inverted by setting CTRL[TXINV]. The transmitter is enabled by setting the CTRL[TE] bit. This queues a preamble character that is one full character frame of the idle state. The transmitter then remains idle until data is available in the transmit data buffer. Programs store data into the transmit data buffer by writing to the DATA register.

The central element of the LPUART transmitter is the transmit shift register that is 9-bit to 13 bits long depending on the setting in the CTRL[M], CTRL[M7], BAUD[M10] and BAUD[SBNS] control bits. For the remainder of this section, assume CTRL[M], CTRL[M7], BAUD[M10] and BAUD[SBNS] are cleared, selecting the normal 8-bit data

mode. In 8-bit data mode, the shift register holds a start bit, eight data bits, and a stop bit. When the transmit shift register is available for a new character, the value waiting in the transmit data register is transferred to the shift register, synchronized with the baud rate clock, and the transmit data register empty (STAT[TDRE]) status flag is set to indicate another character may be written to the transmit data buffer at the DATA register.

If no new character is waiting in the transmit data buffer after a stop bit is shifted out the TXD pin, the transmitter sets the transmit complete flag and enters an idle mode, with TXD high, waiting for more characters to transmit.

Writing 0 to CTRL[TE] does not immediately disable the transmitter. The current transmit activity in progress must first be completed (that could include a data character, idle character or break character), although the transmitter will not start transmitting another character.

51.4.3.1 Send break and queued idle

The CTRL[SBK] bit sends break characters originally used to gain the attention of old teletype receivers. Break characters are a full character time of logic 0, 9-bit to 12-bit times including the start and stop bits. A longer break of 13-bit times can be enabled by setting STAT[BRK13]. Normally, a program would wait for STAT[TDRE] to become set to indicate the last character of a message has moved to the transmit shifter, write 1, and then write 0 to the CTRL[SBK] bit. This action queues a break character to be sent as soon as the shifter is available. If CTRL[SBK] remains 1 when the queued break moves into the shifter, synchronized to the baud rate clock, an additional break character is queued. When the LPUART is the receiving device, a break character is received as 0s in all data bits and a framing error (STAT[FE] = 1) is detected.

A break character can also be transmitted by writing to the DATA register with bit 13 set and the data bits clear. This supports transmitting the break character as part of the normal data stream and also allows the DMA to transmit a break character.

When idle-line wakeup is used, a full character time of idle (logic 1) is needed between messages to wake up any sleeping receivers. Normally, a program would wait for STAT[TDRE] to become set to indicate the last character of a message has moved to the transmit shifter, then write 0 and then write 1 to the CTRL[TE] bit. This action queues an idle character to be sent as soon as the shifter is available. As long as the character in the shifter does not finish while CTRL[TE] is cleared, the LPUART transmitter never actually releases control of the TXD pin.

An idle character can also be transmitted by writing to the DATA register with bit 13 set and the data bits also set. This supports transmitting the idle character as part of the normal data stream and also allows the DMA to transmit a idle character.

The length of the break character is affected by the STAT[BRK13], CTRL[M], CTRL[M7], BAUD[M10] and BAUD[SNBS] bits as shown below.

Table 51-5. Break character length

BRK13	M	M10	M7	SBNS	Break character length
0	0	0	0	0	10 bit times
0	0	0	0	1	11 bit times
0	0	0	1	0	9 bit times
0	0	0	1	1	10 bit times
0	1	0	X	0	11 bit times
0	1	0	X	1	12 bit times
0	X	1	X	0	12 bit times
0	X	1	X	1	13 bit times
1	0	0	0	0	13 bit times
1	0	0	0	1	13 bit times
1	0	0	1	0	12 bit times
1	0	0	1	1	12 bit times
1	1	0	X	0	14 bit times
1	1	0	X	1	14 bit times
1	X	1	X	0	15 bit times
1	X	1	X	1	15 bit times

51.4.3.2 Hardware flow control

The transmitter supports hardware flow control by gating the transmission with the value of CTS_B. If the clear-to-send operation is enabled, the character is transmitted when CTS_B is asserted. If CTS_B is deasserted in the middle of a transmission with characters remaining in the transmitter data buffer, the character in the shift register is sent and TXD remains in the mark state until CTS_B is reasserted. The CTS_B pin must assert for longer than one bit period to guarantee a new transmission is started when the transmitter is idle with data to send.

If the clear-to-send operation is disabled, the transmitter ignores the state of CTS_B.

The transmitter's CTS_B signal can also be enabled even if the same LPUART receiver's RTS_B signal is disabled.

51.4.3.3 Transceiver driver enable

The transmitter can use RTS_B as an enable signal for the driver of an external transceiver. See Transceiver driver enable using RTS_B for details. If the request-to-send operation is enabled, when a character is placed into an empty transmitter data buffer, RTS_B asserts one bit time before the start bit is transmitted. RTS_B remains asserted for the whole time that the transmitter data buffer has any characters. RTS_B deasserts one bit time after all characters in the transmitter data buffer and shift register are completely sent, including the last stop bit. Transmitting a break character also asserts RTS_B, with the same assertion and deassertion timing as having a character in the transmitter data buffer.

The transmitter's RTS_B signal asserts only when the transmitter is enabled. However, the transmitter's RTS_B signal is unaffected by its CTS_B signal. RTS_B will remain asserted until the transfer is completed, even if the transmitter is disabled mid-way through a data transfer.

51.4.3.4 Transceiver driver enable using RTS_B

RS-485 is a multiple drop communication protocol in which the LPUART transceiver's driver is 3-stated unless the LPUART is driving. The RTS_B signal can be used by the transmitter to enable the driver of a transceiver. The polarity of RTS_B can be matched to the polarity of the transceiver's driver enable signal.

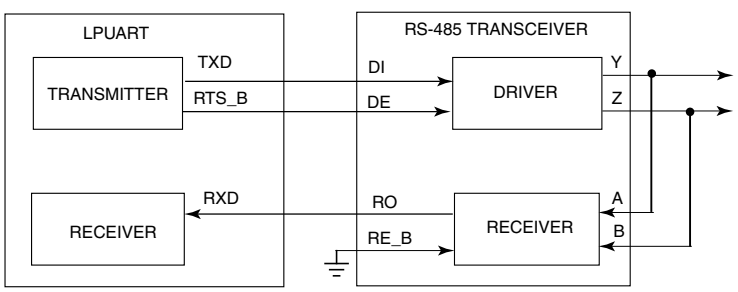

Figure 51-4. Transceiver driver enable using RTS_B

In the figure, the receiver enable signal is asserted. Another option for this connection is to connect RTS_B to both DE and RE_B. The transceiver's receiver is disabled while driving. A pullup can pull RXD to a non-floating value during this time. This option can be refined further by operating the LPUART in single wire mode, freeing the RXD pin for other uses.

51.4.4 Receiver functional description

In this section, the receiver block diagram is a guide for the overall receiver functional description. Next, the data sampling technique used to reconstruct receiver data is described in more detail. Finally, different variations of the receiver wakeup function are explained.

The receiver input is inverted by setting STAT[RXINV]. The receiver is enabled by setting the CTRL[RE] bit. Character frames consist of a start bit of logic 0, seven to ten data bits (msb or lsb first), and one or two stop bits of logic 1. For information about 7-bit, 9-bit or 10-bit data mode, refer to Data Modes. For the remainder of this discussion, assume the LPUART is configured for normal 8-bit data mode.

After receiving the stop bit into the receive shifter, and provided the receive data register is not already full, the data character is transferred to the receive data register and the receive data register full (STAT[RDRF]) status flag is set. If [RDRF] was already set indicating the receive data register (buffer) was already full, the overrun (OR) status flag is set and the new data is lost. Because the LPUART receiver is double-buffered, the program has one full character time after [RDRF] is set before the data in the receive data buffer must be read to avoid a receiver overrun.

When a program detects that the receive data register is full (STAT[RDRF] = 1), it gets the data from the receive data register by reading the DATA register. Refer to Interrupts and status flags for details about flag clearing.

51.4.4.1 Data sampling technique

The LPUART receiver supports a configurable oversampling rate of between 4× and 32× of the baud rate clock for sampling. The receiver starts by taking logic level samples at the oversampling rate times the baud rate to search for a falling edge on the RXD serial data input pin. A falling edge is defined as a logic 0 sample after three consecutive logic 1 samples. The oversampling baud rate clock divides the bit time into 4 to 32 segments from 1 to OSR (where OSR is the configured oversampling ratio). When a falling edge is located, three more samples are taken at (OSR/2), (OSR/2)+1, and (OSR/2)+2 to make sure this was a real start bit and not merely noise. If at least two of these three samples are 0, the receiver assumes it is synchronized to a received character. If another falling edge is detected before the receiver is considered synchronized, the receiver restarts the sampling from the first segment.

The receiver then samples each bit time, including the start and stop bits, at (OSR/2), (OSR/2)+1, and (OSR/2)+2 to determine the logic level for that bit. The logic level is interpreted to be that of the majority of the samples taken during the bit time. If any

sample in any bit time, including the start and stop bits, in a character frame fails to agree with the logic level for that bit, the noise flag (STAT[NF]) is set when the received character is transferred to the receive data buffer.

When the LPUART receiver is configured to sample on both edges of the baud rate clock, the number of segments in each received bit is effectively doubled (from 1 to OSR×2). The start and data bits are then sampled at OSR, OSR+1 and OSR+2. Sampling on both edges of the clock must be enabled for oversampling rates of 4× to 7× and is optional for higher oversampling rates.

The falling edge detection logic continuously looks for falling edges. If an edge is detected, the sample clock is resynchronized to bit times (unless resynchronization has been disabled). This improves the reliability of the receiver in the presence of noise or mismatched baud rates. It does not improve worst case analysis because some characters do not have any extra falling edges anywhere in the character frame.

51.4.4.2 Receiver wakeup operation

Receiver wakeup and receiver address matching is a hardware mechanism that allows an LPUART receiver to ignore the characters in a message intended for a different receiver.

During receiver wakeup, all receivers evaluate the first character(s) of each message, and as soon as they determine the message is intended for a different receiver, they write logic 1 to the receiver wake up control bit (CTRL[RWU]). When CTRL[RWU] and STAT[RWUID] bit are set, the status flags associated with the receiver, with the exception of the idle bit, STAT[IDLE], are inhibited from setting, thus eliminating the software overhead for handling the unimportant message characters. At the end of a message, or at the beginning of the next message, all receivers automatically force CTRL[RWU] to 0 so all receivers wake up in time to look at the first character(s) of the next message.

During receiver address matching, the address matching is performed in hardware and the LPUART receiver will ignore all characters that do not meet the address match requirements.

Table 51-6. Receiver Wakeup Options

RWU	MA1 | MA2	MATCFG	WAKE:RWUID	Receiver Wakeup
0	0	X	X	Normal operation
1	0	00	00	Receiver wakeup on idle line, IDLE flag not set
1	0	00	01	Receiver wakeup on idle line, IDLE flag set

Table continues on the next page...

Table 51-6. Receiver Wakeup Options (continued)

RWU	MA1 | MA2	MATCFG	WAKE:RWUID	Receiver Wakeup
1	0	00	10	Receiver wakeup on address mark
1	1	11	10	Receiver wakeup on data match
0	1	00	X0	Address mark address match, IDLE flag not set for discarded characters
0	1	00	X1	Address mark address match, IDLE flag set for discarded characters
0	1	01	X0	Idle line address match
0	1	10	X0	Address match on and address match off, IDLE flag not set for discarded characters
0	1	10	X1	Address match on and address match off, IDLE flag set for discarded characters

51.4.4.2.1 Idle-line wakeup

When wake is cleared, the receiver is configured for idle-line wakeup. In this mode, CTRL[RWU] is cleared automatically when the receiver detects a full character time of the idle-line level. The CTRL[M], CTRL[M7] and BAUD[M10] control bit selects 7-bit to 10-bit data mode and the BAUD[SBNS] bit selects 1-bit or 2-bit stop bit number that determines how many bit times of idle are needed to constitute a full character time, 9 to 13 bit times because of the start and stop bits.

When CTRL[RWU] is one and STAT[RWUID] is 0, the idle condition that wakes up the receiver does not set the STAT[IDLE] flag. The receiver wakes up and waits for the first data character of the next message that sets the STAT[RDRF] flag and generates an interrupt if enabled. When STAT[RWUID] is 1, any idle condition sets the STAT[IDLE] flag and generates an interrupt if enabled, regardless of whether CTRL[RWU] is 0 or 1.

The idle-line type (CTRL[ILT]) control bit selects one of two ways to detect an idle line. When CTRL[ILT] is cleared, the idle bit counter starts after the start bit so the stop bit and any logic 1s at the end of a character count toward the full character time of idle. When CTRL[ILT] is set, the idle bit counter does not start until after the stop bit time, so the idle detection is not affected by the data in the last character of the previous message.

51.4.4.2.2 Address-mark wakeup

When CTRL[WAKE] is set, the receiver is configured for address-mark wakeup. In this mode, CTRL[RWU] is cleared automatically when the receiver detects a logic 1 in the most significant bit of the received character. When parity is enabled, the second most significant bit is used for address-mark wakeup.

Address-mark wakeup allows messages to contain idle characters, but requires one bit be reserved for use in address frames. The logic 1 in the most significant bit (or second most significant bit when parity is enabled) of an address frame clears the CTRL[RWU] bit and sets the STAT[RDRF] flag. In this case, the character with the address-mark bit is received even though the receiver was sleeping during most of this character time.

51.4.4.2.3 Data match wakeup

When CTRL[RWU] is set, CTRL[WAKE] is set and BAUD[MATCFG] equals 11, the receiver is configured for data match wakeup. In this mode, CTRL[RWU] is cleared automatically when the receiver detects a character that matches MATCH[MA1] field when BAUD[MAEN1] is set, or that matches MATCH[MA2] when BAUD[MAEN2] is set.

51.4.4.2.4 Address Match operation

Address match operation is enabled when the BAUD[MAEN1] or BAUD[MAEN2] bit is set and BAUD[MATCFG] is equal to 00. In this function, a character received by the RXD pin with a logic 1 in the most significant bit (or second most significant bit when parity is enabled) is considered an address and is compared with the associated MATCH[MA1] or MATCH[MA2] field. The character is only transferred to the receive buffer, and STAT[RDRF] is set, if the comparison matches. All subsequent characters received with a logic 0 in the most significant bit (or second most significant bit when parity is enabled) are considered to be data associated with the address and are transferred to the receive data buffer. If no marked address match occurs then no transfer is made to the receive data buffer, and all following characters with logic zero in the most significant bit (or second most significant bit when parity is enabled) are also discarded. If both the BAUD[MAEN1] and BAUD[MAEN2] bits are negated, the receiver operates normally and all data received is transferred to the receive data buffer.

Address match operation functions in the same way for both MATCH[MA1] and MATCH[MA2] fields.

- If only one of BAUD[MAEN1] and BAUD[MAEN2] is asserted, a marked address is compared only with the associated match register field and data is transferred to the receive data buffer only on a match.
- If BAUD[MAEN1] and BAUD[MAEN2] are asserted, a marked address is compared with both match registers and data is transferred only on a match with either of the MATCH[MA1] or MATCH[MA2] fields.

51.4.4.2.5 Idle Match operation

Idle match operation is enabled when the BAUD[MAEN1] or BAUD[MAEN2] bit is set and BAUD[MATCFG] is equal to 01. In this function, the first character received by the RXD pin after an idle line condition is considered an address and is compared with the associated MATCH[MA1] or MATCH[MA2] field. The character is only transferred to the receive buffer, and STAT[RDRF] is set, if the comparison matches. All subsequent characters are considered to be data associated with the address and are transferred to the receive data buffer until the next idle line condition is detected. If no address match occurs then no transfer is made to the receive data buffer, and all following frames until the next idle condition are also discarded. If both the BAUD[MAEN1] and BAUD[MAEN2] bits are negated, the receiver operates normally and all data received is transferred to the receive data buffer.

Idle match operation functions in the same way for both MATCH[MA1] or MATCH[MA2] fields.

- If only one of BAUD[MAEN1] and BAUD[MAEN2] is asserted, the first character after an idle line is compared only with the associated match register and data is transferred to the receive data buffer only on a match.
- If BAUD[MAEN1] and BAUD[MAEN2] are asserted, the first character after an idle line is compared with both MATCH[MA1] or MATCH[MA2] fields and data is transferred only on a match with either of the fields.

51.4.4.2.6 Match On Match Off operation

Match on, match off operation is enabled when both BAUD[MAEN1] and BAUD[MAEN2] are set and BAUD[MATCFG] is equal to 10. In this function, a character received by the RXD pin that matches MATCH[MA1] is received and transferred to the receive buffer, and STAT[RDRF] is set. All subsequent characters are considered to be data and are also transferred to the receive data buffer, until a character is received that matches MATCH[MA2] field. The character that matches MATCH[MA2] and all following characters are discarded; this continues until another

character that matches MATCH[MA1] is received. If both the BAUD[MAEN1] and BAUD[MAEN2] bits are negated, the receiver operates normally and all data received is transferred to the receive data buffer.

NOTE

Match on, match off operation requires both BAUD[MAEN1] and BAUD[MAEN2] to be asserted.

51.4.4.3 Hardware flow control

To support hardware flow control, the receiver can be programmed to automatically deassert and assert RTS_B.

- RTS_B remains asserted until the transfer is complete, even if the transmitter is disabled midway through a data transfer. See Transceiver driver enable using RTS_B for more details.
- If the receiver request-to-send functionality is enabled, the receiver automatically deasserts RTS_B if the number of characters in the receiver data register is full or a start bit is detected that will cause the receiver data register to be full.
- The receiver asserts RTS_B when the number of characters in the receiver data register is not full and has not detected a start bit that will cause the receiver data register to be full. It is not affected if STAT[RDRF] is asserted.
- Even if RTS_B is deasserted, the receiver continues to receive characters until the receiver data buffer is overrun.
- If the receiver request-to-send functionality is disabled, the receiver RTS_B remains deasserted.

51.4.4.4 Infrared decoder

The infrared decoder converts the received character from the IrDA format to the NRZ format used by the receiver. It also has a OSR oversampling baud rate clock counter that filters noise and indicates when a 1 is received.

51.4.4.4.1 Start bit detection

When STAT[RXINV] is cleared, the first falling edge of the received character corresponds to the start bit. The infrared decoder resets its counter. At this time, the receiver also begins its start bit detection process. After the start bit is detected, the receiver synchronizes its bit times to this start bit time. For the rest of the character reception, the infrared decoder's counter and the receiver's bit time counter count independently from each other.

51.4.4.4.2 Noise filtering

Any further rising edges detected during the first half of the infrared decoder counter are ignored by the decoder. Any pulses less than one oversampling baud clock can be undetected by it regardless of whether it is seen in the first or second half of the count.

51.4.4.4.3 Low-bit detection

During the second half of the decoder count, a rising edge is decoded as a 0, which is sent to the receiver. The decoder counter is also reset.

51.4.4.4.4 High-bit detection

At OSR oversampling baud rate clocks after the previous rising edge, if a rising edge is not seen, then the decoder sends a 1 to the receiver.

If the next bit is a 0, which arrives late, then a low-bit is detected according to Low-bit detection. The value sent to the receiver is changed from 1 to a 0. Then, if a noise pulse occurs outside the receiver's bit time sampling period, then the delay of a 0 is not recorded as noise.

51.4.5 Additional LPUART functions

The following sections describe additional LPUART functions.

51.4.5.1 Data Modes

The LPUART transmitter and receiver can be configured to operate in 7-bit data mode by setting CTRL[M7], 9-bit data mode by setting the CTRL[M] or 10-bit data mode by setting BAUD[M10]. In 9-bit mode, there is a ninth data bit and in 10-bit mode, there is a tenth data bit. For the transmit data buffer, these bits are stored in CTRL[T8] and CTRL[T9]. For the receiver, these bits are held in CTRL[R8] and CTRL[R9]. They are also accessible via 16-bit or 32-bit accesses to the DATA register.

For coherent 8-bit writes to the transmit data buffer, write to CTRL[T8] and CTRL[T9] before writing to DATA[7:0]. For 16-bit and 32-bit writes to the DATA register, all 10 transmit bits are written to the transmit data buffer at the same time.

If the bit values to be transmitted as the ninth and tenth bit of a new character are the same as for the previous character, it is not necessary to write to CTRL[T8] and CTRL[T9] again. When data is transferred from the transmit data buffer to the transmit shifter, the value in CTRL[T8] and CTRL[T9] is copied at the same time data is transferred from DATA[7:0] to the shifter.

The 9-bit data mode is typically used with parity to allow eight bits of data plus the parity in the ninth bit, or it is used with address-mark wakeup so the ninth data bit can serve as the wakeup bit. The 10-bit data mode is typically used with parity and address-mark wakeup so the ninth data bit can serve as the wakeup bit and the tenth bit as the parity bit. In custom protocols, the ninth and/or tenth bits can also serve as software-controlled markers.

51.4.5.2 Idle length

An idle character is a character where the start bit, all data bits and stop bits are in the mark position. The CTRL[ILT] bit can be configured to start detecting an idle character from the previous start bit (any data bits and stop bits count towards the idle character detection) or from the previous stop bit.

The number of idle characters that must be received before an idle line condition is detected can also be configured using the CTRL[IDLECFG] field. This field configures the number of idle characters that must be received before the STAT[IDLE] flag is set, the STAT[RAF] flag is cleared and the DATA[IDLINE] flag is set with the next received character.

Idle-line wakeup and idle match operation are also affected by the CTRL[IDLECFG] field. When address match or match on/off operation is enabled, setting the STAT[RWUID] bit will cause any discarded characters to be treated as if they were idle characters.

51.4.5.3 Loop mode

When CTRL[LOOPS] is set, the CTRL[RSRC] bit chooses between loop mode (CTRL[RSRC] = 0) or single-wire mode (CTRL[RSRC] = 1). Loop mode is sometimes used to check software, independent of connections in the external system, to help isolate system problems. In this mode, the transmitter output is internally connected to the receiver input and the RXD pin is not used by the LPUART.

51.4.5.4 Single-wire operation

When CTRL[LOOPS] is set, the CTRL[RSRC] bit chooses between loop mode (CTRL[RSRC] = 0) or single-wire mode (CTRL[RSRC] = 1). Single-wire mode implements a half-duplex serial connection. The receiver is internally connected to the transmitter output and to the TXD pin (the RXD pin is not used).

In single-wire mode, the CTRL[TXDIR] bit controls the direction of serial data on the TXD pin. When CTRL[TXDIR] is cleared, the TXD pin is an input to the receiver and the transmitter is temporarily disconnected from the TXD pin so an external device can send serial data to the receiver. When CTRL[TXDIR] is set, the TXD pin is an output driven by the transmitter, the internal loop back connection is disabled, and as a result the receiver cannot receive characters that are sent out by the transmitter.

51.4.6 Infrared interface

The LPUART provides the capability of transmitting narrow pulses to an IR LED and receiving narrow pulses and transforming them to serial bits, which are sent to the LPUART. The IrDA physical layer specification defines a half-duplex infrared communication link for exchanging data. The full standard includes data rates up to 16 Mbits/s. This module covers data rates only between 2.4 kbits/s and 115.2 kbits/s.

The LPUART has an infrared transmit encoder and receive decoder. The LPUART transmits serial bits of data that are encoded by the infrared submodule to transmit a narrow pulse for every zero bit. No pulse is transmitted for every one bit. When receiving data, the IR pulses are detected using an IR photo diode and transformed to CMOS levels by the IR receive decoder, external from the LPUART. The narrow pulses are then stretched by the infrared receive decoder to get back to a serial bit stream to be received by the LPUART. The polarity of transmitted pulses and expected receive pulses can be inverted so that a direct connection can be made to external IrDA transceiver modules that use active high pulses.

The infrared submodule receives its clock sources from the LPUART. One of these two clocks are selected in the infrared submodule to generate either 1/OSR, 2/OSR, 3/OSR, or 4/OSR narrow pulses during transmission.

51.4.6.1 Infrared transmit encoder

The infrared transmit encoder converts serial bits of data from transmit shift register to the TXD signal. A narrow pulse is transmitted for a 0 bit and no pulse for a 1 bit. The narrow pulse is sent at the start of the bit with a duration of 1/OSR, 2/OSR, 3/OSR, or 4/OSR of a bit time. A narrow low pulse is transmitted for a 0 bit when CTRL[TXINV] is cleared, while a narrow high pulse is transmitted for a 0 bit when CTRL[TXINV] is set.

51.4.6.2 Infrared receive decoder

The infrared receive block converts data from the RXD signal to the receive shift register. A narrow pulse is expected for each 0 received and no pulse is expected for each 1 received. A narrow low pulse is expected for a 0 bit when STAT[RXINV] is cleared, while a narrow high pulse is expected for a 0 bit when STAT[RXINV] is set. This receive decoder meets the edge jitter requirement as defined by the IrDA serial infrared physical layer specification.

51.4.7 Interrupts and status flags

The LPUART transmitter has two status flags that can optionally generate hardware interrupt requests. Transmit data register empty STAT[TDRE]) indicates when there is room in the transmit data buffer to write another transmit character to the DATA register. If the transmit interrupt enable CTRL[TIE]) bit is set, a hardware interrupt is requested when STAT[TDRE] is set. Transmit complete (STAT[TC]) indicates that the transmitter is finished transmitting all data, preamble, and break characters and is idle with TXD at the inactive level. This flag is often used in systems with modems to determine when it is safe to turn off the modem. If the transmit complete interrupt enable (CTRL[TCIE]) bit is set, a hardware interrupt is requested when STAT[TC] is set. Instead of hardware interrupts, software polling may be used to monitor the STAT[TDRE] and STAT[TC] status flags if the corresponding CTRL[TIE] or CTRL[TCIE] local interrupt masks are cleared.

When a program detects that the receive data register is full (STAT[RDRF] = 1), it gets the data from the receive data register by reading the DATA register. The STAT[RDRF] flag is cleared by reading the DATA register.

The IDLE status flag includes logic that prevents it from getting set repeatedly when the RXD line remains idle for an extended period of time. IDLE is cleared by writing 1 to the STAT[IDLE] flag. After STAT[IDLE] has been cleared, it cannot become set again until the receiver has received at least one new character and has set STAT[RDRF].

If the associated error was detected in the received character that caused STAT[RDRF] to be set, the error flags - noise flag (STAT[NF]), framing error (STAT[FE]), and parity error flag (STAT[PF]) - are set at the same time as STAT[RDRF]. These flags are not set in overrun cases.

If STAT[RDRF] was already set when a new character is ready to be transferred from the receive shifter to the receive data buffer, the overrun (STAT[OR]) flag is set instead of the data along with any associated NF, FE, or PF condition is lost.

If the received character matches the contents of MATCH[MA1] and/or MATCH[MA2] then the STAT[MA1F] and/or STAT[MA2F] flags are set at the same time that STAT[RDRF] is set.

At any time, an active edge on the RXD serial data input pin causes the STAT[RXEDGIF] flag to set. The STAT[RXEDGIF] flag is cleared by writing a 1 to it. This function depends on the receiver being enabled (CTRL[RE] = 1).

51.4.8 Peripheral Triggers

The connection of the LPUART peripheral triggers with other peripherals are device specific.

51.4.8.1 Output Triggers

The LPUART generates three output triggers that can be connected to other peripherals on the device.

- The transmit word trigger asserts at the end of each transmitted word, it negates after one bit period.
- The receive word trigger asserts at the end of each received word that is written to the receive FIFO, for one oversampling clock period.
- The receive idle trigger asserts at when the idle flag would set, for one oversampling clock period.

51.4.8.2 Input Trigger

The LPUART supports one peripheral input trigger, that can be configured in one of the following ways.

- The input trigger can be connected in place of the CTS_B pin input. The input trigger must assert for longer than one bit clock period when the transmitter is idle with data to send to guarantee a new transmission.
- The input trigger can modulate the transmit data output (trigger is logically ANDed with the TXD output). The input trigger is expected to be generated from a PWM source with a period that is less than the bit clock frequency.
- The input trigger can be connected in place of the RXD pin input. The input trigger is expected to be generated from a receive data source, such as analog comparator or external pin.

52.1.1 LPSPI

The LPSPI is a low power Serial Peripheral Interface (SPI) module that supports an efficient interface to an SPI bus as a master and/or a slave.

- Can continue operating while the chip is in stop modes, if an appropriate clock is available
- Designed for low CPU overhead, with DMA offloading of FIFO register accesses

The following table shows the LPSPI configuration:

Table 52-2. LPSPI configuration

Parameter	Description
Name	LPSPI
Instances	4
Configurable features	• LPSPI0-1: 4TX/RX FIFO, 4 CS • LPSPI2-3: 16TX/RX FIFO, 4 CS
Interface speed	See the i.MX 7ULP Data Sheet for correct IO specification.
External I/O pins	LPSPI0-3: SIN, SOUT, SCK, PCSx. See the attached IOMUXC spreadsheet for details.

52.1.2 Transmit/command FIFO in master mode

When writing a command to the transmit/command FIFO containing bit TCR[TXMSK]=1 in order to initiate a half-duplex receive transmission with LPSPI in master mode, the user should not write another command into the FIFO before the command containing bit TCR[TXMSK]=1 has finished executing and bit TCR[TXMSK] has been cleared.

52.2 Introduction

The LPSPI is a low power Serial Peripheral Interface (SPI) module that supports an efficient interface to an SPI bus, either as a master and/or as a slave.

- The LPSPI is designed to use little CPU overhead, with DMA offloading of FIFO register accesses.
- The LPSPI can continue operating in stop modes, if an appropriate clock is available.
- The LPSPI supports DMA accesses and generates a DMA request.

The Serial Peripheral Interface bus (SPI) is a synchronous serial communication interface used in embedded systems, typically to perform short distance communications between microcontrollers and peripheral devices, on printed circuit boards. Typical applications include interfacing to Secure Digital cards and LCD displays.

- SPI devices communicate in full duplex mode using a master-slave scheme with a single master. This enables communication in both directions to happen simultaneously.
- Multiple slave devices are selected using individual slave select (SS) lines.
- The master device originates the frame for reading and writing.
- SPI accesses are always synchronous to the external clock.
- Each SPI can only assert one chip select at a time, but technically there can be multiple SPI slaves sharing the same chip select (in the form of a larger shift register). This requires:
  - the SDO of the master to connect to the SDI of the first slave,
  - the SDO of first slave to connect to the SDI of the next slave,
  - and the SDO of last slave to connect to the SDI of the LPSPI master.

  Note that some SPI modules use MISO/MOSI for the input/output data.

52.2.1 Features

The LPSPI supports:

- Word size = 32 bits
- Configurable clock polarity and clock phase
- Master operation supporting multiple peripheral chip selects (see chip-specific information)
- Slave operation
- Command/transmit FIFO of 16 words
- Receive FIFO of 16 words
- Flexible timing parameters in master mode, including SCK frequency and delays between PCS and SCK edges
- Support for full duplex transfers supporting 1-bit transmit and receive on each clock edge
- Support for half duplex transfers supporting 1-bit transmit or receive on each clock edge
- Support for half duplex transfers supporting 2-bit or 4-bit transmit or receive on each clock edge (master only)
- Host request input can be used to control the start time of an SPI bus transfer (master only)
- Receive data match logic supporting wakeup on data match

52.2.2 Block Diagram

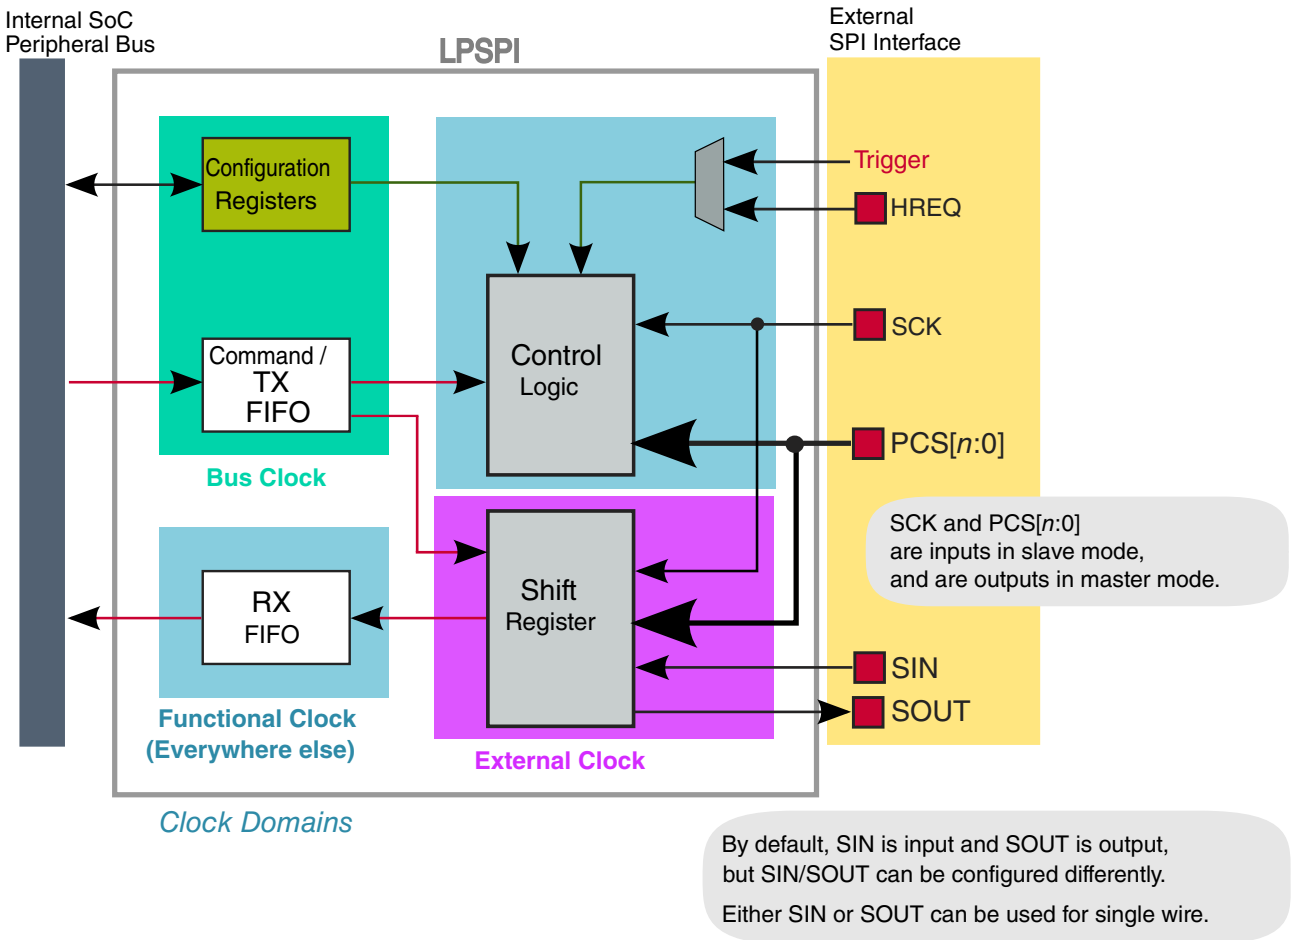

Figure 52-1. Block Diagram

52.2.3 Modes of operation

Table 52-3. Chip modes supported by the LPSPI module

Chip mode	LPSPI Operation
Run	Normal operation
Stop/Wait Stop	Can continue operating in stop mode if the Doze Enable bit (CR[DOZEN]) is clear and the LPSPI is using an external or internal clock source that remains operating during stop/wait modes.stop mode.
Low Power Stop (also called Low Leakage Stop or LLS)	Before entering low power stop mode, the LPSPI will wait for the current transfer to finish any pending operation, temporarily ignoring the Doze Enable (CR[DOZEN]) bit.
Debug (the core is in Debug/Halted mode)	Can continue operating in debug mode, if the Debug Enable bit (CR[DBGEN]) is set.

52.2.4 Signal Descriptions

Table 52-4. Signals

Signal	Name	Description	I/O
SCK	Serial clock	• Input in slave mode • Output in master mode	I/O
PCS[0]	Peripheral Chip Select	• Input in slave mode • Output in master mode	I/O
PCS[1] / HREQ	Peripheral Chip Select or Host Request	Host Request pin is selected when HREN=1 and HRSEL=0 • Input in either slave mode or when used as Host Request • Output in master mode	I/O
PCS[2] / DATA[2]	Peripheral Chip Select or data pin 2 during quad-data transfers	• Input in slave mode • Output in master mode • Input in quad-data receive transfers • Output in quad-data transmit transfers	I/O
PCS[3] / DATA[3]	Peripheral Chip Select or data pin 3 during quad-data transfers	• Input in slave mode • Output in master mode • Input in quad-data receive transfers • Output in quad-data transmit transfers	I/O
SOUT / DATA[0]	Serial Data Output	Can be configured as serial data input signal • Used as data pin 0 in quad-data transfers • Used as data pin 0 in dual-data transfers	I/O
SIN / DATA[1]	Serial Data Input	Can be configured as serial data output signal • Used as data pin 1 in quad-data transfers • Used as data pin 1 in dual-data transfers	I/O

52.3 Functional description

52.3.1 Clocking and resets

For device-specific clocking information, refer to the Clocking chapter.

Table 52-5. Clocks

LPSPI Functional clock	• The LPSPI functional clock is asynchronous to the bus clock. • If the LPSPI functional clock remains enabled in low power modes, then LPSPI can perform SPI bus transfers and low power wakeups, in both master and slave modes. • The LPSPI divides the functional clock by a prescaler; the resulting frequency must be at least 2 times faster than the SPI external clock frequency (LPSPI_SCK).

Table continues on the next page...

Table 52-5. Clocks (continued)

External clock	• The LPSPI shift register is clocked directly by the LPSPI_SCK clock.
	• How the LPSPI_SCK clock is generated or supplied depends upon the mode (master or slave):
	  • in master mode: the LPSPI_SCK clock is generated internally.
	  • in slave mode: the LPSPI_SCK clock is supplied externally.

Bus clock	The bus clock is only used for bus accesses to the LPSPI control and configuration registers. The bus clock frequency must be high enough to support the data bandwidth requirements of the LPSPI registers, including the FIFOs.

Table 52-6. Resets

Chip reset	Resets the LPSPI logic and registers to their default state.
Software reset	• Resets the LPSPI logic and registers to their default state, except for the Control Register. • The LPSPI software reset is in the Control Register CR[RST].
FIFO resets	• Resets the transmit/command FIFO and the receive FIFO. • Control Register CR[RTF](Reset Transmit FIFO) and CR[RRF] (Reset Receive FIFO) are write-only bits. • After being reset,a FIFO is empty.

NOTE

The entire PCSPOL field is not supported in every LPSPI module instance. Refer to the chip-specific information for LPSPI.

Field supported in	Field not supported in
LPSPI0_CFGR1	—
LPSPI1_CFGR1[13–8]	LPSPI1_CFGR1[15–14]
LPSPI2_CFGR1[11–8]	LPSPI2_CFGR1[15–12]

LPSPI4_CFGR1[11–8]	LPSPI4_CFGR1[15–12]
LPSPI5_CFGR1[11–8]	LPSPI5_CFGR1[15–12]
LPSPI6_CFGR1[9–8]	LPSPI6_CFGR1[15–10]
LPSPI7_CFGR1[9–8]	LPSPI7_CFGR1[15–10]
LPSPI8_CFGR1[9–8]	LPSPI8_CFGR1[15–10]
LPSPI9_CFGR1[9–8]	LPSPI9_CFGR1[15–10]

52.3.2 Master Mode

52.3.2.1 Transmit and Command FIFO commands

The transmit and command FIFO is a combined FIFO that includes both transmit data words and command words.

- Transmit data words are stored to the transmit/command FIFO, by writing the Transmit Data Register (TDR).
- Command words are stored to the transmit/command FIFO, by writing the Transmit Command Register (TCR).

When a command word is at the top of the transmit/command FIFO, the actions that can occur depend upon whether the LPSPI module is either busy or between frames, the Continuous Transfer bit (TCR[CONT]), and the Continuing Command bit (TCR[CONTC]).

Table 52-7. Possible actions when a command word is at the top of the transmit/command FIFO

Condition	Action
If the LPSPI is between frames	then the command word is pulled from the FIFO, and that command word controls all subsequent transfers.
If LPSPI is busy and the Continuous Transfer bit (TCR[CONT]) is set or cleared and the Continuing Command bit (TCR[CONTC]) is cleared	then the SPI frame will complete at the end of the existing word, ignoring the FRAMESZ configuration. The command word is then pulled from the FIFO and that command word controls all subsequent transfers (or until the next update to the command word). Note that a command word with CONTC=0 will always terminate (stop) the existing transfer regardless of the previous CONT value.
If the LPSPI is busy and the existing Continuous Transfer bit (TCR[CONT]) is set or cleared and the new Continuing Command bit (TCR[CONTC]) value is set	then the command word must be updated at the frame boundary. The command word is pulled from the FIFO during the last LPSPI_SCK pulse of the existing frame (based on the FRAMESZ configuration), and the frame continues using the new command value for the rest of the frame (or until the next update to the command word). When the Continuing Command bit (TCR[CONTC]) is set, only the lower 24-bits of the command word are updated. If the command word is updated at a word boundary, then the transfer halts (stops) after that word.

NOTE

About the Continuous Transfer bit (CONT) and Continuing Command bit (CONTC):

- Continuous Transfer bit (CONT)=1 is used to keep PCS asserted at end of frame, allowing the transfer to continue.
- Continuing Command bit (CONTC)=1 is used to indicate that this command word should not terminate the existing frame, and the transfer can continue using the new command word.

The Continuing Command bit (CONTC)=1 is restricted in the sense that the new command must load on a frame boundary, and the only way for a transfer to continue from a frame boundary, is when the previous command has the Continuous Transfer bit (CONT)=1.

The current state of the existing command word can be read by reading the Transmit Command Register (TCR). It requires at least 3 LPSPI functional clock cycles for the transmit command register to update after the transmit command register is written (assuming an empty FIFO) and the LPSPI must be enabled (Module Enable CR[MEN] bit is set).

Writing the transmit command register does not initiate a SPI bus transfer, unless the Transmit Data Mask (TCR[TXMSK]) bit is set. When the Transmit Data Mask bit is set, a new command word will not be loaded until the end of the existing frame (based on FRAMESZ configuration); at the end of the transfer, the TXMSK bit will be cleared.

In master mode, the LPSPI command word in the Transmit Command Register (TCR) controls SPI attributes (using bits and fields in registers).

Table 52-8. LPSPI Command Word in Master Mode

Transmit Command Register (TCR)		Description	Can this bit/ field be modified during a data transfer?
Bit/Field	Name		
CPOL	Clock Polarity	Configures the polarity of the LPSPI_SCK pin. Any change of CPOL value will cause a transition on the LPSPI_SCK pin.	N
CPHA	Clock Phase	Configures the clock phase of the transfer.	N
PRESCALE	Prescaler Value	Configures a prescaler used to divide the LPSPI functional clock, to generate the timing parameters of the SPI bus transfer. Changing PRESCALE in conjunction with PCS enables the LPSPI module to connect to different slave devices at different frequencies.	N
PCS	Peripheral Chip Select	Configures which LPSPI_PCS asserts for the transfer; the polarity of LPSPI_PCS is static and configured by PCSPOL. If PCSCFG is set, then PCS[3:2] should not be selected.	N
LSBF	LSB First	Configures if LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted or received first.	Y
BYSW	Byte Swap	Enables byte swap on each 32-bit word when transmitting and receiving data. Byte swapping can be useful when interfacing to devices that organize data as big-endian.	Y
CONT	Continuous Transfer	Configures for a continuous transfer that keeps PCS asserted between frames (as configured by FRAMESZ). A new command word is required to cause PCS to negate. Also supports changing the command word at the frame size boundaries.	Y

Table continues on the next page...

Table 52-8. LPSPI Command Word in Master Mode (continued)

Transmit Command Register (TCR)		Description	Can this bit/ field be modified during a data transfer?
Bit/Field	Name		
CONTC	Continuing Command	Indicates that this is a new command word for the existing continuous transfer. The CONTC bit when set must only be written to the transmit/ command FIFO on a frame bounday.	Y
RXMSK	Receive Data Mask	Masks the receive data and does not store the masked receive data to the receive FIFO or perform receive data matching. Useful for half-duplex transfers or to configure which fields are compared during receive data matching.	Y
TXMSK	Transmit Data Mask	Masks the transmit data, so that masked transmit data is not pulled from transmit FIFO, and the output data pin is tristated (unless configured by Output Config CFGR1[OUTCFG]). Useful for half-duplex transfers.	Y
WIDTH	Transfer Width	Configures the number of bits shifted on each LPSPI_SCK pulse. • 1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats. • 2-bit and 4-bit transfers are useful for interfacing to QuadSPI memory devices, and only support half-duplex data formats, and at least one bit (Transmit Data Mask (TCR[TXMSK] or Receive Data Mask TCR[RXMSK]) must also be set.	Y
FRAMESZ	Frame Size	Configures the frame size in number of bits equal to (FRAMESZ + 1). • The minimum frame size is 8 bits. • The minimum word size is 2 bits; a frame size of 33 bits (or similar) is not supported. • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32-bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO will contain the remainder bits. For example, a 72-bit transfer will consist of 3 words: the 1st and 2nd words are 32-bit, and the 3rd word is 8-bit.	Y

SPI bus transfers:

- The LPSPI initiates a SPI bus transfer when:
  - data is written to the transmit FIFO
  - and the HREQ pin is asserted (or disabled)
  - and the LPSPI is enabled
- To perform the SPI bus transfer, LPSPI uses the attributes configured in the Transmit Command Register (TCR) and uses the timing parameters in the Clock Configuration Register (CCR).

- The SPI bus transfer ends after the FRAMESZ configuration is reached, or at the end of a word when a new transmit command word is at the top of the transmit/command FIFO.
- The HREQ input is only checked on the next time that the LPSPI goes idle (the LPSPI completes the current transfer and the Transmit Command Register (TCR) is empty).

Circular FIFO: The transmit/command FIFO also supports a Circular FIFO feature, which enables the LPSPI master to (periodically) repeat a short data transfer that can fit within the transmit/command FIFO, without requiring additional FIFO accesses. When the circular FIFO is enabled, the current state of the FIFO read pointer is saved and the status flags do not update. After the transmit/command FIFO is considered empty and the LPSPI is idle, the FIFO read pointer is restored with the saved version, so the contents of the transmit/command FIFO are not permanently pulled from the FIFO while circular FIFO mode is enabled.

52.3.2.2 Receive FIFO and Data Match

The receive FIFO is used to store receive data during SPI bus transfers. When the Receive Data Mask TCR[RXMSK] bit is set, the receive data is discarded instead of being stored in the receive FIFO.

- The receive data is written to the receive FIFO at the end of the frame.
- During a multiple word or continuous transfer, the receive data is also written to the receive FIFO at the same time as the new transmit data is read from the transmit FIFO.
- During a continuous transfer, if the transmit FIFO is empty, then the receive data is only written to the receive FIFO after the transmit FIFO is written or after the Transmit Command Register (TCR) is written to end the frame.

Receive data supports a receive data match function that can match received data against one of two words or against a masked data word. The receive data match function can also be configured to compare only the first one or two received data words since the start of the frame.

- Received data that is already discarded due to the Receive Data Mask TCR[RXMSK] bit cannot cause the data match to set, and will delay the receive data match on the first received data word, until all discarded data is received.
- The receiver data match function can also be configured to discard all received data until a data match is detected, using the Receive Data Match Only CFGR0[RDMO] bit.
- After a receive data match, to allow all subsequent data to be received, first clear the Receive Data Match Only CFGR0[RDMO] bit, then clear the Data Match Flag SR[DMF] bit.

52.3.2.3 Timing Parameters

The timing parameters that are used for all SPI bus transfers are relative to the LPSPI functional clock divided by the PRESCALE configuration. Although the Clock Configuration Register (CCR) cannot be changed when the LPSPI module is busy, to support interfacing to different slave devices at different frequencies, the Prescaler Value TCR[PRESCALE] configuration can be changed between SPI bus transfers using the Transmit Command Register (TCR).

Table 52-9. LPSPI Timing Parameters

Clock Configuration Register (CCR)		Description	Min	Max
Bit/Field	Name			
SCKDIV	SCK Divider	Configures the LPSPI_SCK clock period to (SCKDIV +2) cycles. When SCK Divider is configured to an odd number of cycles, the first half of the LPSPI_SCK cycle is one cycle longer than the second half of the LPSPI_SCK cycle.	0 (2 cycles)	255 (257 cycles)
DBT	Delay Between Transfers	Configures the minimum delay between PCS negation and the next PCS assertion to (DBT + 2) cycles. When the command word is updated between transfers, there is a minimum of (DBT/2)+1 cycles between the command word update and any change on LPSPI_PCS pins.	0 (2 cycles)	255 (257 cycles)
DBT	Delay Between Transfers	Configures the delay during a continuous transfer between the last SCK edge of a frame and the first SCK edge of the continuing frame to (DBT + 1) cycles. This is useful when the external slave requires a large delay between different words of an SPI bus transfer.	0 (1 cycle)	255 (256 cycles)
PCSSCK	PCS-to-SCK Delay	Configures the minimum delay between PCS assertion and the first SCK edge to (PCSSCK + 1) cycles.	0 (1 cycle)	255 (256 cycles)
SCKPCS	SCK-to-PCS Delay	Configures the minimum delay between the last SCK edge and the PCS assertion to (SCKPCS + 1) cycles.	0 (1 cycle)	255 (256 cycles)

52.3.2.4 Pin Configuration

- To swap directions or support half-duplex transfers on the same pin, the LPSPI_SIN and LPSPI_SOUT pins can be configured using the Pin Configuration CFGR1[PINCFG].
- To determine if an output data pin (like LPSPI_SOUT) will tristate when the LPSPI_PCS is negated, or if the output data pin will simply retain the last value, use the Output Config CFGR1[OUTCFG].

- When configuring for half-duplex transfers using the same data pin in single-bit transfer mode, or when configuring any transfer in 2-bit and 4-bit transfer modes, the output data pins must be configured to tristate when LPSPI_PCS is negated; use the Output Config CFGR1[OUTCFG].
- When performing quad-data transfers, the Peripheral Chip Select Configuration CFGR1[PCSCFG] must be enabled. The Peripheral Chip Select Configuration CFGR1[PCSCFG] is also used to disable LPSPI_PCS[3:2] functions.

52.3.2.5 Clock Loopback

The LPSPI master can be configured to use 1 of 2 clocks to sample the input data (for example, LPSPI_SIN):

- either the LPSPI_SCK output clock directly
- or a delayed version of the LPSPI_SCK output clock

The delayed version of the LPSPI_SCK is delayed by the LPSPI_SCK pin output delay, plus the LPSPI_SCK pin input delay, and is configured by setting CFGR1[SAMPLE]. Enabling the loopback version of the LPSPI_SCK can improve the setup time of the input data from the slave.

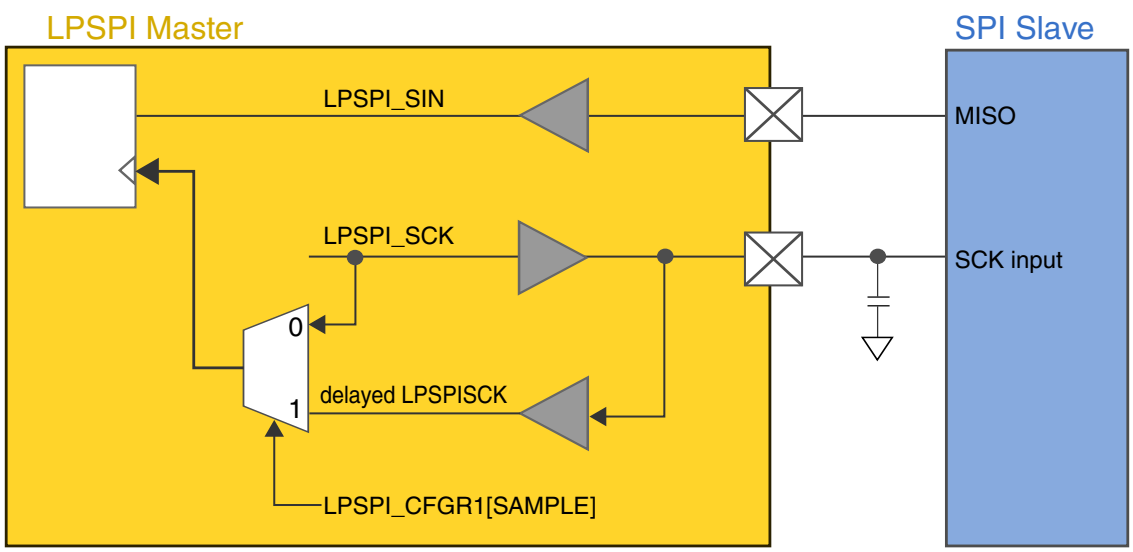

Figure 52-2. Clock Loopback

See the device datasheet for the specific input setup time in master loopback mode.

52.3.3 Slave Mode

LPSPI slave mode:

- uses the same shift register and logic that master mode uses
- does not use the Clock Configuration Register (CCR)
- during SPI bus transfers, requires that the Transmit Command Register (TCR) remain static (unchanging)

52.3.3.1 Transmit and Command FIFO commands

Before enabling the LPSPI in slave mode, the Transmit Command Register (TCR) should be initialized, although the Transmit Command Register register will not update until after the LPSPI is enabled. After being enabled, the Transmit Command Register should only be changed if the LPSPI is idle. In slave mode, the LPSPI command word in the Transmit Command Register (TCR) controls SPI attributes (using bits and fields in registers). Before the LPSPI_PCS input asserts, the transmit FIFO must be filled with transmit data, or the transmit error flag will set.

Table 52-10. LPSPI Command Word in Slave Mode

Transmit Command Register (TCR)		Description
Bit/Field	Name	
CPOL	Clock Polarity	Configures the polarity of the external LPSPI_SCK input.
CPHA	Clock Phase	Configures the clock phase of transfer.
PRESCALE	Prescaler Value	Configures the LPSPI functional clock prescaler.
PCS	Peripheral Chip Select	Configures which LPSPI_PCS is used, the polarity of LPSPI_PCS is static and configured by PCSPOL. If PCSCFG is set, then PCS[3:2] should not be selected.
LSBF	LSB First	Configures if LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted or received first.
BYSW	Byte Swap	Enables byte swap on each 32-bit word when transmitting and receiving data. Byte swapping can be useful when interfacing to devices that organize data as big-endian.
CONT	Continuous Transfer	When Continuous Transfer is set, only the first FRAMSZ bits will be transmitted/ received by the LPSPI module.
CONTC	Continuing Command	CONTC bit is reserved (in slave mode).
RXMSK	Receive Data Mask	Masks the receive data and does not store the masked receive data to the receive FIFO or perform receive data matching. Useful for half-duplex transfers or to configure which fields are compared during receive data matching.
TXMSK	Transmit Data Mask	Masks the transmit data, so that the masked transmit data is not pulled from transmit FIFO, and the output data pin is tristated (unless configured by Output Config CFGR1[OUTCFG]). Useful for half-duplex transfers.
WIDTH	Transfer Width	Configures the number of bits shifted on each LPSPI_SCK pulse. • 1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats. • 2-bit and 4-bit transfers are useful for interfacing to QuadSPI memory devices, and only support half-duplex data formats, and at least one bit (Transmit Data Mask TCR[TXMSK] or Receive Data Mask (TCR[RXMSK]) must also be set.
FRAMESZ	Frame Size	Configures the frame size in number of bits equal to (FRAMESZ + 1). • The minimum frame size is 8 bits.

Table 52-10. LPSPI Command Word in Slave Mode

Transmit Command Register (TCR)		Description
Bit/Field	Name	
		• The minimum word size is 2 bits; a frame size of 33 bits (or similar) is not supported. • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32-bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO will contain the remainder bits. For example, a 72-bit transfer will consist of 3 words: the 1st and 2nd words are 32-bit, and the 3rd word is 8-bit.

52.3.3.2 Receive FIFO and Data Match

The receive FIFO is used to store received data during SPI bus transfers. When the Receive Data Mask TCR[RXMSK] is set, the received data is discarded (instead of storing the received data in the receive FIFO).

Receive data supports a receive data match function that can match received data against one of two words or against a masked data word. The data match function can also be configured to compare only the first one or two received data words since the start of the frame.

- Received data that is already discarded (because the Receive Data Mask TCR[RXMSK] is set) cannot cause the data match to set, and will delay the match on the first received data word, until all discarded data is received.
- The receiver match function can also be configured to discard all received data until a data match is detected, using the Receive Data Match Only CFGR0[RDMO] bit.
- After a receive data match, to allow all subsequent data to be received, first clear the Receive Data Match Only CFGR0[RDMO] bit, then clear the Data Match Flag SR[DMF] bit.

52.3.3.3 Clocked Interface

The LPSPI module supports interfacing to external masters that provide only clock and data pins (LPSPI_PCS is not required). This interface requires:

- using Clock Phase TCR[CPHA] = 1 (data is changed on the leading edge of SCK and captured on the following edge)

- configuring the LPSPI_PCS input to be always asserted (configure the Peripheral Chip Select Polarity CFGR1[PCSPOL[n]] = 1). For example, to configure PCS[0] to be always asserted, set PCSPOL[0] = 1, and don't configure PCS[0] in the pin muxing.
- setting the Automatic PCS CFGR1[AUTOPCS] bit = 1 (Automatic PCS generation is enabled). When Automatic PCS generation (AUTOPCS) is set, a minimum of 4 LPSPI functional clock cycles (divided by PRESCALE configuration) is required between the last LPSPI_SCK edge of one word and the first LPSPI_SCK edge of the next word.

52.3.4 Interrupts and DMA Requests

The next table lists the slave mode sources (status flags) that can generate LPSPI interrupts and LPSPI slave transmit/receive DMA requests.

Table 52-11. LPSPI Interrupts and DMA Requests

Status Register (SR)		Description	Can generate		
Status Flag	Name		Interrupt?	DMA Request?	Low Power Wakeup?
TDF	Transmit Data Flag	Data can be written to transmit FIFO, as configured by the Transmit FIFO Watermark FCR[TXWATER]	Y	TX	Y
RDF	Receive Data Flag	Data can be read from the receive FIFO, as configured by the Receive FIFO Watermark FCR[RXWATER]	Y	RX	Y
WCF	Word Complete Flag	Word is complete, the last bit of the word has been sampled	Y	N	Y
FCF	Frame Complete Flag	Frame is complete, and PCS has negated	Y	RX	Y
TCF	Transfer Complete Flag	Transfer is complete, PCS has negated, and the transmit/command FIFO is empty	Y	N	Y
TEF	Transmit Error Flag	Indicates a transmit/command FIFO underrun. In master mode when the No Stall CFGR1[NOSTALL] bit is clear (0, transfers will stall when transmit FIFO is empty or receive FIFO is full), the Transmit Error Flag bit cannot set.	Y	N	Y
REF	Receive Error Flag	Receive error flag, indicates a receive FIFO overflow. In master mode when the No Stall CFGR1[NOSTALL] bit is clear (0, transfers will stall when transmit FIFO is empty or receive FIFO is full), the Receive Error Flag bit cannot set.	Y	N	Y

Table continues on the next page...

Table 52-11. LPSPI Interrupts and DMA Requests (continued)

Status Register (SR)		Description	Can generate		
Status Flag	Name		Interrupt?	DMA Request?	Low Power Wakeup?
DMF	Data Match Flag	Indicates that the received data has matched the configured data match value	Y	N	Y
MBF	Module Busy Flag	LPSPI is busy performing a SPI bus transfer	N	N	N

52.3.5 Peripheral Triggers

The connection of the LPSPI peripheral triggers to other peripherals depend upon the specific device being used.

Table 52-12. LPSPI Triggers

Trigger	Description	
Frame Output Trigger	The frame output trigger: • asserts at the end of each frame (when PCS negates) • remains asserted until PCS next asserts	The LPSPI generates 2 output triggers that can be connected to other peripherals on the device.
Word Output Trigger	The word output trigger: • asserts at the end of each received word • remains asserted for 1 LPSPI_SCK period	
Input Trigger	To control the start of a LPSPI bus transfer, the LPSPI input trigger can be selected instead of the LPSPI_HREQ input. • The LPSPI input trigger is synchronized, and must assert for at least 2 cycles of the LPSPI functional clock divided by the PRESCALE configuration, so that the input trigger can be detected. • When the LPSPI module is busy, the LPSPI_HREQ input (and therefore the LPSPI input trigger) is ignored .	

52.4 Memory Map and Registers

NOTE

Writing a Read-Only (RO) register or reading a Write-Only (WO) register can cause bus errors. This module will not check if programmed values in the registers are correct; the application software must ensure that valid programmed values are being written.

52.4.1.9.4 Fields

Field	Function
31-28 —	Reserved
27 PCSCFG	Peripheral Chip Select Configuration If performing 4-bit transfers, the Peripheral Chip Select Configuration bit must be set. 0b - PCS[3:2] are enabled 1b - PCS[3:2] are disabled
26 OUTCFG	Output Configuration Configures if the output data is tristated between accesses (LPSPI_PCS is negated). If performing 2-bit or 4-bit transfers, the Output Configuration bit must be set. 0b - Output data retains last value when chip select is negated 1b - Output data is tristated when chip select is negated
25-24 PINCFG	Pin Configuration Configures which pins are used for input and output data during 1-bit transfers. If performing 2-bit or 4-bit transfers, the Pin Configuration field must be 00. 00b - SIN is used for input data and SOUT is used for output data 01b - SIN is used for both input and output data 10b - SOUT is used for both input and output data 11b - SOUT is used for input data and SIN is used for output data
23-19 —	Reserved
18-16 MATCFG	Match Configuration Configures the condition that will cause the DMF to set. **NOTE:** *Syntax:* * is boolean AND, + is boolean OR 000b - Match is disabled 001b - Reserved 010b - 010b - Match is enabled, if 1st data word equals MATCH0 OR MATCH1, i.e., (1st data word = MATCH0 + MATCH1) 011b - 011b - Match is enabled, if any data word equals MATCH0 OR MATCH1, i.e., (any data word = MATCH0 + MATCH1) 100b - 100b - Match is enabled, if 1st data word equals MATCH0 AND 2nd data word equals MATCH1, i.e., [(1st data word = MATCH0) * (2nd data word = MATCH1)] 101b - 101b - Match is enabled, if any data word equals MATCH0 AND the next data word equals MATCH1, i.e., [(any data word = MATCH0) * (next data word = MATCH1)] 110b - 110b - Match is enabled, if (1st data word AND MATCH1) equals (MATCH0 AND MATCH1), i.e., [(1st data word * MATCH1) = (MATCH0 * MATCH1)] 111b - 111b - Match is enabled, if (any data word AND MATCH1) equals (MATCH0 AND MATCH1), i.e., [(any data word * MATCH1) = (MATCH0 * MATCH1)]
15-12 —	Reserved
11-8 PCSPOL	Peripheral Chip Select Polarity Configures the polarity of each Peripheral Chip Select pin. Each PCSPOL bit position (let's call it *n*) corresponds to a PCS[*n*] pin. For example, PCSPOL[0] is chip select 0 (at PCS[0] pin), and PCSPOL[1] is chip select 1 (at PCS[1] pin). If a PCSPOL bit:

Table continues on the next page...

Field	Function
	• =0, then the PCS[*n*] pin is active low. • =1, then the PCS[*n*] pin is active high. **NOTE:** The entire PCSPOL field is not fully supported in every LPSPI module instance. Refer to the chip-specific information for LPSPI.
7-4 —	Reserved
3 NOSTALL	No Stall In master mode, the LPSPI will stall transfers when the transmit FIFO is empty or when the receive FIFO is full, ensuring that no transmit FIFO underrun or receive FIFO overrun can occur. Setting the No Stall bit will disable this functionality. 0b - Transfers will stall when the transmit FIFO is empty or the receive FIFO is full 1b - Transfers will not stall, allowing transmit FIFO underruns or receive FIFO overruns to occur
2 AUTOPCS	Automatic PCS For correct operations, the LPSPI slave normally requires the PCS to negate between frames. Setting the Automatic PCS bit will cause the LPSPI to generate an internal PCS signal at the end of each transfer word when the Clock Phase bit TCR[CPHA] = 1. • When the Automatic PCS bit is set, the SCK must remain idle for at least 4 LPSPI functional clock cycles (divided by the Prescaler Value TCR[PRESCALE] configuration) between each word, to ensure correct operations • In master mode, the Automatic PCS bit is ignored 0b - Automatic PCS generation is disabled 1b - Automatic PCS generation is enabled
1 SAMPLE	Sample Point When set, the LPSPI master will sample the input data on a delayed LPSPI_SCK edge, which improves the setup time when sampling data. • The input data setup time in master mode with delayed LPSPI_SCK edge is equal to the input data setup time in slave mode • In slave mode, the SAMPLE bit is ignored 0b - Input data is sampled on SCK edge 1b - Input data is sampled on delayed SCK edge
0 MASTER	Master Mode Configures the LPSPI in master or slave mode. The Master Mode bit directly controls the direction of the LPSPI_SCK and LPCPI_PCS pins. 0b - Slave mode 1b - Master mode

52.4.1.12.4 Fields

Field	Function
31-24 SCKPCS	SCK-to-PCS Delay In master mode: configures the delay from the last SCK edge to the PCS negation.

Table continues on the next page...

Field	Function
	• The delay is equal to (SCKPCS + 1) cycles of the LPSPI functional clock divided by the Prescaler Value TCR[PRESCALE] configuration. • The minimum delay is 1 cycle.
23-16 PCSSCK	PCS-to-SCK Delay In master mode: configures the delay from the PCS assertion to the first SCK edge. • The delay is equal to (PCSSCK + 1) cycles of the LPSPI functional clock divided by the Prescaler Value TCR[PRESCALE] configuration. • The minimum delay is 1 cycle.

15-8
DBT
	Delay Between Transfers
	In master mode:
	• Configures the delay from the PCS negation to the next PCS assertion.
	  • The delay is equal to (DBT + 2) cycles of the LPSPI functional clock divided by the Prescaler Value TCR[PRESCALE] configuration.
	  • The minimum delay is 2 cycles.
	  • Half of the delay occurs before PCS assertion and the other half of the delay occurs after PCS negation. If the command word is updated between 2 transfers, then the command word is updated half-way between the PCS negation of the last transfer and PCS assertion of the next transfer.
	  • The command word sets which PCS signal is used (of PCS[3:0]}, the polarity/phase of the SCK signal, and the Prescaler Value.
	• Configures the delay from the last SCK edge of a transfer word and the first SCK edge of the next transfer word, in a continuous transfer.
	  • The delay is equal to (DBT + 1) cycles of the LPSPI functional clock divided by the Prescaler Value TCR[PRESCALE] configuration.
	  • The minimum delay is 1 cycle.

7-0 SCKDIV	SCK Divider In master mode, the SCK Divider configures the divide ratio of the SCK pin. • The SCK period is equal to (SCKDIV+2) cycles of the LPSPI functional clock divided by the Prescaler Value TCR[PRESCALE] configuration. • The minimum SCK period is 2 cycles. • If the SCK period is an odd number of cycles, then the 1st half of the SCK period will be 1 cycle longer than the 2nd half of the SCK period.

52.4.1.13 FIFO Control Register (FCR)

52.4.1.13.1 Offset

23-19 —	Reserved
18-16 RXCOUNT	Receive FIFO Count Returns the number of words currently stored in the receive FIFO.
15-8 —	Reserved
7-3 —	Reserved
2-0 TXCOUNT	Transmit FIFO Count Returns the number of words currently stored in the transmit FIFO.

52.4.1.15 Transmit Command Register (TCR)

52.4.1.15.1 Offset

Register	Offset
TCR	60h

52.4.1.15.2 Function

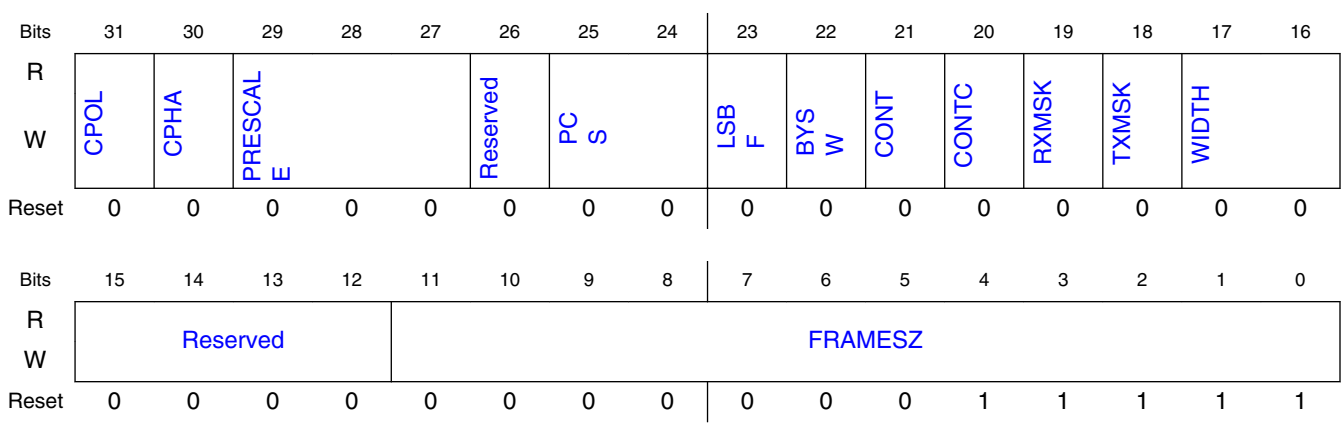
Writes to either the Transmit Command Register or Transmit Data Register will push the data into the transmit FIFO, in the order that the data are written. The Command Register should only be written using 32-bit writes. Command Register writes will be tagged and cause the command register to update, after that entry reaches the top of the FIFO. This allows changes to the command word and the transmit data itself to be interleaved. Changing the command word will cause all subsequent SPI bus transfers to be performed using the new command word.

- **In master mode,** writing a new command word does not initiate a new transfer, unless TXMSK is set. Transfers are initiated by transmit data in the transmit FIFO, or by a new command word (with TXMSK set). Hardware will clear TXMSK when the LPSPI_PCS negates.
- **In master mode,** if the command word is changed before an existing frame has completed, then the existing frame will terminate and the command word will then update. The command word can be changed during a continuous transfer, if CONTC of the new command word is set and the command word is written on a frame size boundary.
- **In slave mode,** the command word should be changed only when the LPSPI is idle and there is no SPI bus transfer.

Avoid register reading problems: Reading the Transmit Command Register will return the current state of the command register. Reading the Transmit Command Register at the same time that the Transmit Command Register is loaded from the transmit FIFO, can return an incorrect Transmit Command Register value. It is recommended:

- to either read the Transmit Command Register when the transmit FIFO is empty,
- or to read the Transmit Command Register more than once and then compare the returned values.

52.4.1.15.3 Diagram



52.4.1.15.4 Fields

Field	Function
31 CPOL	Clock Polarity The Clock Polarity field is only updated between frames. 0b - The inactive state value of SCK is low 1b - The inactive state value of SCK is high
30 CPHA	Clock Phase The Clock Phase field is only updated between frames. 0b - Data is captured on the leading edge of SCK and changed on the following edge of SCK 1b - Data is changed on the leading edge of SCK and captured on the following edge of SCK
29-27 PRESCALE	Prescaler Value For all SPI bus transfers, the Prescaler value applied to the clock configuration register. The Prescaler Value field is only updated between frames. 000b - Divide by 1 001b - Divide by 2 010b - Divide by 4 011b - Divide by 8 100b - Divide by 16 101b - Divide by 32 110b - Divide by 64 111b - Divide by 128
26 —	Reserved
25-24 PCS	Peripheral Chip Select Configures the peripheral chip select used for the transfer. The Peripheral Chip Select field is only updated between frames. **NOTE:** The entire PCS field is not fully supported in every LPSPI module instance. Refer to the chip-specific information for LPSPI. 00b - Transfer using LPSPI_PCS[0] 01b - Transfer using LPSPI_PCS[1] 10b - Transfer using LPSPI_PCS[2] 11b - Transfer using LPSPI_PCS[3]
23 LSBF	LSB First 0b - Data is transferred MSB first 1b - Data is transferred LSB first
22 BYSW	Byte Swap Byte swap will swap the contents of [31:24] with [7:0] and [23:16] with [15:8] for each transmit data word read from the FIFO and for each received data word stored to the FIFO (or compared with match registers). 0b - Byte swap is disabled 1b - Byte swap is enabled
21 CONT	Continuous Transfer • In master mode, continuous transfer will keep the PCS asserted at the end of the frame size, until a command word is received that starts a new frame. • In slave mode, when continuous transfer is enabled, the LPSPI will only transmit the first FRAMESZ bits; after which the LPSPI will transmit received data (assuming a 32-bit shift register). 0b - Continuous transfer is disabled 1b - Continuous transfer is enabled

Table continues on the next page...

Field	Function
20 CONTC	Continuing Command In master mode, the Continuing Command bit allows the command word to be changed within a continuous transfer. • The initial command word must enable continuous transfer (CONT=1), • the continuing command must set this bit (CONTC=1), • and the continuing command word must be loaded on a frame size boundary. For example, if the continuous transfer has a frame size of 64-bits, then a continuing command word must be loaded on a 64-bit boundary. 0b - Command word for start of new transfer 1b - Command word for continuing transfer
19 RXMSK	Receive Data Mask When set, receive data is masked (receive data is not stored in receive FIFO). 0b - Normal transfer 1b - Receive data is masked
18 TXMSK	Transmit Data Mask When set, transmit data is masked (no data is loaded from transmit FIFO and output pin is tristated). In master mode, the Transmit Data Mask bit will initiate a new transfer which cannot be aborted by another command word; the Transmit Data Mask bit will be cleared by hardware at the end of the transfer. 0b - Normal transfer 1b - Mask transmit data
17-16 WIDTH	Transfer Width For 2-bit or 4-bit transfers, either Receive Data Mask (RXMSK) or Transmit Data Mask (TXMSK) must be set. 00b - 1 bit transfer 01b - 2 bit transfer 10b - 4 bit transfer 11b - Reserved
15-12 —	Reserved. Software should only write zero to this field.
11-0 FRAMESZ	Frame Size Configures the frame size in number of bits equal to (FRAMESZ + 1). • The minimum frame size is 8 bits • The minimum word size is 2 bits; a frame size of 33 bits (or similar) is not supported. • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32-bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO will contain the remainder bits. For example, a 72-bit transfer will consist of 3 words: the 1st and 2nd words are 32 bits, and the 3rd word is 8 bits.

52.4.1.16 Transmit Data Register (TDR)

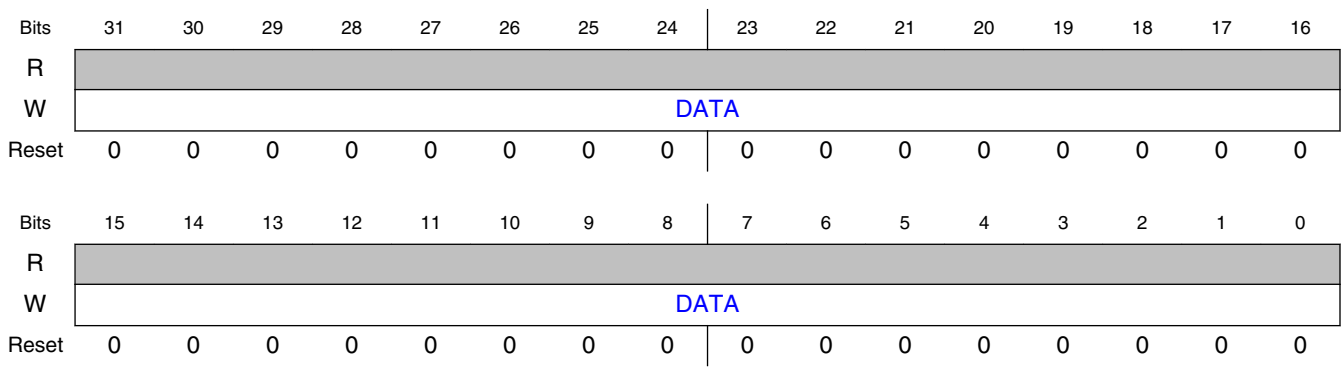
52.4.1.16.1 Offset

Register	Offset
TDR	64h

52.4.1.16.2 Function

Writes to either the Transmit Command Register or Transmit Data Register will push the data into the transmit FIFO, in the order that it (the data) was written. The Data Register can be written using 32-bit, 16-bit or 8-bit writes, but each write will push data into the FIFO with zero pushed in unwritten bytes.

52.4.1.16.3 Diagram



52.4.1.16.4 Fields

Field	Function
31-0 DATA	Transmit Data Both 8-bit and 16-bit writes of transmit data will zero-extend the data written and push the data into the transmit FIFO. To zero-extend 8-bit and 16-bit writes (to 32 bits), means that the higher order (most significant) empty parts of the 8-bit and 16-bit writes are filled with zeroes.

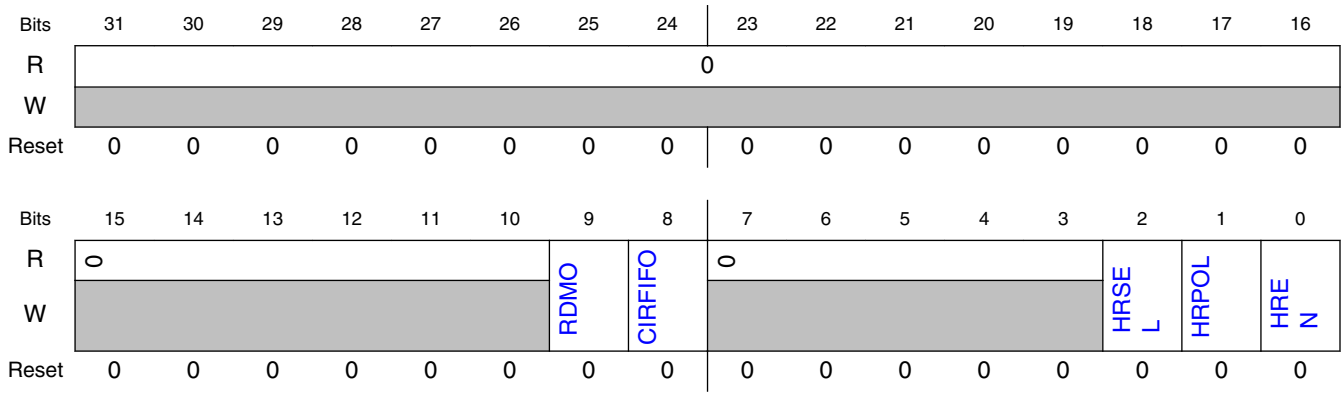
52.4.2.8.1 Offset

Register	Offset
CFGR0	20h

52.4.2.8.2 Diagram



52.4.2.8.3 Fields

Field	Function
31-10 —	Reserved
9 RDMO	Receive Data Match Only When Receive Data Match Only is enabled, all received data that does not cause the Data Match Flag (SR[DMF]) to set is discarded. • Receive Data Match Only bit should be set when the LPSPI is idle and the Data Match Flag is clear • After the Data Match Flag (DMF) is set, the Receive Data Match Only bit configuration is ignored • When disabling RDMO and to ensure that no receive data is lost, before clearing the Data Match Flag, first clear Receive Data Match Only (RDMO) 0b - Received data is stored in the receive FIFO as in normal operations 1b - Received data is discarded unless the Data Match Flag (DMF) is set
8 CIRFIFO	Circular FIFO Enable When enabled, the transmit FIFO read pointer is saved to a temporary register. The transmit FIFO will be emptied as it normally is, but after the LPSPI is idle and the transmit FIFO is empty, then the read pointer value will be restored from the temporary register. This restoring of the read pointer will cause the contents of the transmit FIFO to be cycled through repeatedly. 0b - Circular FIFO is disabled 1b - Circular FIFO is enabled
7-3 —	Reserved
2 HRSEL	Host Request Select Selects the source of the host request input. When the host request function is enabled with the LPSPI_HREQ pin, the LPSPI_PCS[1] function is disabled. 0b - Host request input is the LPSPI_HREQ pin 1b - Host request input is the input trigger
1 HRPOL	Host Request Polarity Configures the polarity of the host request pin. 0b - Active low 1b - Active high

Table continues on the next page...

Field	Function
0 HREN	Host Request Enable When enabled in master mode, the LPSPI will only start a new SPI bus transfer if the host request input is asserted. When the LPSPI is busy, the host request input is ignored. 0b - Host request is disabled 1b - Host request is enabled

52.4.2.9 Configuration Register 1 (CFGR1)

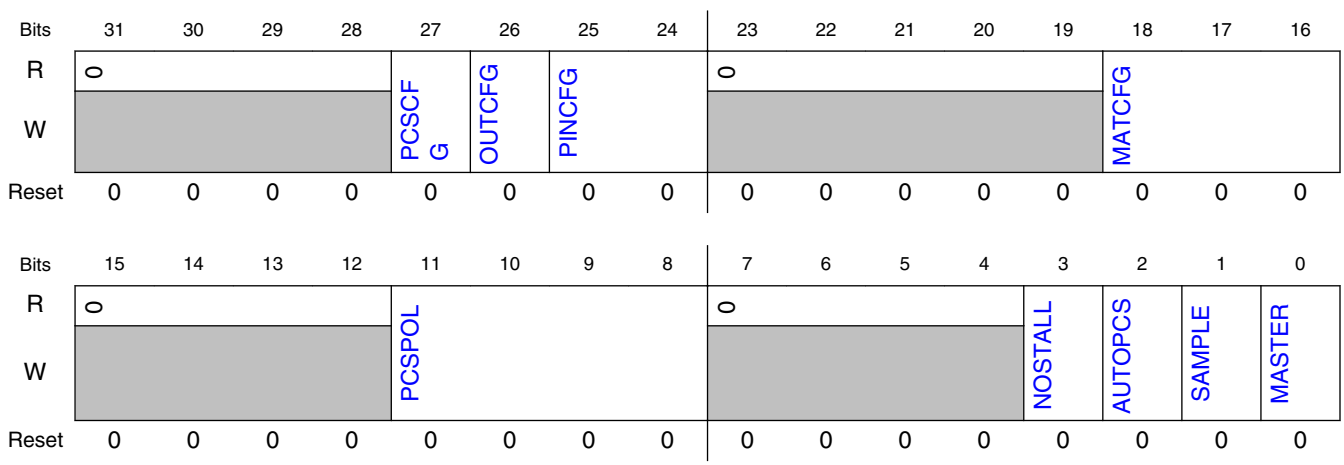
52.4.2.9.1 Offset

Register	Offset
CFGR1	24h

52.4.2.9.2 Function

The CFGR1 should only be written when the LPSPI is disabled.

52.4.2.9.3 Diagram



52.4.2.9.4 Fields

Field	Function
31-28 —	Reserved

Table continues on the next page...

Field	Function
27 PCSCFG	Peripheral Chip Select Configuration If performing 4-bit transfers, the Peripheral Chip Select Configuration bit must be set. 0b - PCS[3:2] are enabled 1b - PCS[3:2] are disabled
26 OUTCFG	Output Configuration Configures if the output data is tristated between accesses (LPSPI_PCS is negated). If performing 2-bit or 4-bit transfers, the Output Configuration bit must be set. 0b - Output data retains last value when chip select is negated 1b - Output data is tristated when chip select is negated
25-24 PINCFG	Pin Configuration Configures which pins are used for input and output data during 1-bit transfers. If performing 2-bit or 4-bit transfers, the Pin Configuration field must be 00. 00b - SIN is used for input data and SOUT is used for output data 01b - SIN is used for both input and output data 10b - SOUT is used for both input and output data 11b - SOUT is used for input data and SIN is used for output data
23-19 —	Reserved
18-16 MATCFG	Match Configuration Configures the condition that will cause the DMF to set. **NOTE:** *Syntax:* * is boolean AND, + is boolean OR 000b - Match is disabled 001b - Reserved 010b - 010b - Match is enabled, if 1st data word equals MATCH0 OR MATCH1, i.e., (1st data word = MATCH0 + MATCH1) 011b - 011b - Match is enabled, if any data word equals MATCH0 OR MATCH1, i.e., (any data word = MATCH0 + MATCH1) 100b - 100b - Match is enabled, if 1st data word equals MATCH0 AND 2nd data word equals MATCH1, i.e., [(1st data word = MATCH0) * (2nd data word = MATCH1)] 101b - 101b - Match is enabled, if any data word equals MATCH0 AND the next data word equals MATCH1, i.e., [(any data word = MATCH0) * (next data word = MATCH1)] 110b - 110b - Match is enabled, if (1st data word AND MATCH1) equals (MATCH0 AND MATCH1), i.e., [(1st data word * MATCH1) = (MATCH0 * MATCH1)] 111b - 111b - Match is enabled, if (any data word AND MATCH1) equals (MATCH0 AND MATCH1), i.e., [(any data word * MATCH1) = (MATCH0 * MATCH1)]
15-12 —	Reserved
11-8 PCSPOL	Peripheral Chip Select Polarity Configures the polarity of each Peripheral Chip Select pin. Each PCSPOL bit position (let's call it *n*) corresponds to a PCS[*n*] pin. For example, PCSPOL[0] is chip select 0 (at PCS[0] pin), and PCSPOL[1] is chip select 1 (at PCS[1] pin). If a PCSPOL bit: • =0, then the PCS[*n*] pin is active low. • =1, then the PCS[*n*] pin is active high. **NOTE:** The entire PCSPOL field is not fully supported in every LPSPI module instance. Refer to the chip-specific information for LPSPI.
7-4 —	Reserved
3	No Stall

Table continues on the next page...

Field	Function
NOSTALL	In master mode, the LPSPI will stall transfers when the transmit FIFO is empty or when the receive FIFO is full, ensuring that no transmit FIFO underrun or receive FIFO overrun can occur. Setting the No Stall bit will disable this functionality. 0b - Transfers will stall when the transmit FIFO is empty or the receive FIFO is full 1b - Transfers will not stall, allowing transmit FIFO underruns or receive FIFO overruns to occur
2 AUTOPCS	Automatic PCS For correct operations, the LPSPI slave normally requires the PCS to negate between frames. Setting the Automatic PCS bit will cause the LPSPI to generate an internal PCS signal at the end of each transfer word when the Clock Phase bit TCR[CPHA] = 1. • When the Automatic PCS bit is set, the SCK must remain idle for at least 4 LPSPI functional clock cycles (divided by the Prescaler Value TCR[PRESCALE] configuration) between each word, to ensure correct operations • In master mode, the Automatic PCS bit is ignored 0b - Automatic PCS generation is disabled 1b - Automatic PCS generation is enabled
1 SAMPLE	Sample Point When set, the LPSPI master will sample the input data on a delayed LPSPI_SCK edge, which improves the setup time when sampling data. • The input data setup time in master mode with delayed LPSPI_SCK edge is equal to the input data setup time in slave mode • In slave mode, the SAMPLE bit is ignored 0b - Input data is sampled on SCK edge 1b - Input data is sampled on delayed SCK edge
0 MASTER	Master Mode Configures the LPSPI in master or slave mode. The Master Mode bit directly controls the direction of the LPSPI_SCK and LPCPI_PCS pins. 0b - Slave mode 1b - Master mode

52.4.2.12.4 Fields

Field	Function
31-24 SCKPCS	SCK-to-PCS Delay In master mode: configures the delay from the last SCK edge to the PCS negation.

Table continues on the next page...

Field	Function
	• The delay is equal to (SCKPCS + 1) cycles of the LPSPI functional clock divided by the Prescaler Value TCR[PRESCALE] configuration. • The minimum delay is 1 cycle.
23-16 PCSSCK	PCS-to-SCK Delay In master mode: configures the delay from the PCS assertion to the first SCK edge. • The delay is equal to (PCSSCK + 1) cycles of the LPSPI functional clock divided by the Prescaler Value TCR[PRESCALE] configuration. • The minimum delay is 1 cycle.

15-8
DBT
	Delay Between Transfers
	In master mode:
	• Configures the delay from the PCS negation to the next PCS assertion.
	  • The delay is equal to (DBT + 2) cycles of the LPSPI functional clock divided by the Prescaler Value TCR[PRESCALE] configuration.
	  • The minimum delay is 2 cycles.
	  • Half of the delay occurs before PCS assertion and the other half of the delay occurs after PCS negation. If the command word is updated between 2 transfers, then the command word is updated half-way between the PCS negation of the last transfer and PCS assertion of the next transfer.
	  • The command word sets which PCS signal is used (of PCS[3:0]}, the polarity/phase of the SCK signal, and the Prescaler Value.
	• Configures the delay from the last SCK edge of a transfer word and the first SCK edge of the next transfer word, in a continuous transfer.
	  • The delay is equal to (DBT + 1) cycles of the LPSPI functional clock divided by the Prescaler Value TCR[PRESCALE] configuration.
	  • The minimum delay is 1 cycle.

7-0 SCKDIV	SCK Divider In master mode, the SCK Divider configures the divide ratio of the SCK pin. • The SCK period is equal to (SCKDIV+2) cycles of the LPSPI functional clock divided by the Prescaler Value TCR[PRESCALE] configuration. • The minimum SCK period is 2 cycles. • If the SCK period is an odd number of cycles, then the 1st half of the SCK period will be 1 cycle longer than the 2nd half of the SCK period.

52.4.2.15 Transmit Command Register (TCR)

52.4.2.15.1 Offset

Register	Offset
TCR	60h

52.4.2.15.2 Function

Writes to either the Transmit Command Register or Transmit Data Register will push the data into the transmit FIFO, in the order that the data are written. The Command Register should only be written using 32-bit writes. Command Register writes will be tagged and cause the command register to update, after that entry reaches the top of the FIFO. This allows changes to the command word and the transmit data itself to be interleaved. Changing the command word will cause all subsequent SPI bus transfers to be performed using the new command word.

- **In master mode,** writing a new command word does not initiate a new transfer, unless TXMSK is set. Transfers are initiated by transmit data in the transmit FIFO, or by a new command word (with TXMSK set). Hardware will clear TXMSK when the LPSPI_PCS negates.
- **In master mode,** if the command word is changed before an existing frame has completed, then the existing frame will terminate and the command word will then update. The command word can be changed during a continuous transfer, if CONTC of the new command word is set and the command word is written on a frame size boundary.
- **In slave mode,** the command word should be changed only when the LPSPI is idle and there is no SPI bus transfer.

Avoid register reading problems: Reading the Transmit Command Register will return the current state of the command register. Reading the Transmit Command Register at the same time that the Transmit Command Register is loaded from the transmit FIFO, can return an incorrect Transmit Command Register value. It is recommended:

- to either read the Transmit Command Register when the transmit FIFO is empty,
- or to read the Transmit Command Register more than once and then compare the returned values.

52.4.2.15.4 Fields

Field	Function
31 CPOL	Clock Polarity The Clock Polarity field is only updated between frames. 0b - The inactive state value of SCK is low 1b - The inactive state value of SCK is high
30 CPHA	Clock Phase The Clock Phase field is only updated between frames. 0b - Data is captured on the leading edge of SCK and changed on the following edge of SCK 1b - Data is changed on the leading edge of SCK and captured on the following edge of SCK
29-27 PRESCALE	Prescaler Value For all SPI bus transfers, the Prescaler value applied to the clock configuration register. The Prescaler Value field is only updated between frames. 000b - Divide by 1 001b - Divide by 2 010b - Divide by 4 011b - Divide by 8 100b - Divide by 16 101b - Divide by 32 110b - Divide by 64 111b - Divide by 128
26 —	Reserved
25-24 PCS	Peripheral Chip Select Configures the peripheral chip select used for the transfer. The Peripheral Chip Select field is only updated between frames. **NOTE:** The entire PCS field is not fully supported in every LPSPI module instance. Refer to the chip-specific information for LPSPI. 00b - Transfer using LPSPI_PCS[0] 01b - Transfer using LPSPI_PCS[1] 10b - Transfer using LPSPI_PCS[2] 11b - Transfer using LPSPI_PCS[3]
23 LSBF	LSB First 0b - Data is transferred MSB first 1b - Data is transferred LSB first
22 BYSW	Byte Swap Byte swap will swap the contents of [31:24] with [7:0] and [23:16] with [15:8] for each transmit data word read from the FIFO and for each received data word stored to the FIFO (or compared with match registers). 0b - Byte swap is disabled 1b - Byte swap is enabled
21 CONT	Continuous Transfer • In master mode, continuous transfer will keep the PCS asserted at the end of the frame size, until a command word is received that starts a new frame. • In slave mode, when continuous transfer is enabled, the LPSPI will only transmit the first FRAMESZ bits; after which the LPSPI will transmit received data (assuming a 32-bit shift register). 0b - Continuous transfer is disabled 1b - Continuous transfer is enabled

Table continues on the next page...

Field	Function
20 CONTC	Continuing Command In master mode, the Continuing Command bit allows the command word to be changed within a continuous transfer. • The initial command word must enable continuous transfer (CONT=1), • the continuing command must set this bit (CONTC=1), • and the continuing command word must be loaded on a frame size boundary. For example, if the continuous transfer has a frame size of 64-bits, then a continuing command word must be loaded on a 64-bit boundary. 0b - Command word for start of new transfer 1b - Command word for continuing transfer
19 RXMSK	Receive Data Mask When set, receive data is masked (receive data is not stored in receive FIFO). 0b - Normal transfer 1b - Receive data is masked
18 TXMSK	Transmit Data Mask When set, transmit data is masked (no data is loaded from transmit FIFO and output pin is tristated). In master mode, the Transmit Data Mask bit will initiate a new transfer which cannot be aborted by another command word; the Transmit Data Mask bit will be cleared by hardware at the end of the transfer. 0b - Normal transfer 1b - Mask transmit data
17-16 WIDTH	Transfer Width For 2-bit or 4-bit transfers, either Receive Data Mask (RXMSK) or Transmit Data Mask (TXMSK) must be set. 00b - 1 bit transfer 01b - 2 bit transfer 10b - 4 bit transfer 11b - Reserved
15-12 —	Reserved. Software should only write zero to this field.
11-0 FRAMESZ	Frame Size Configures the frame size in number of bits equal to (FRAMESZ + 1). • The minimum frame size is 8 bits • The minimum word size is 2 bits; a frame size of 33 bits (or similar) is not supported. • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32-bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO will contain the remainder bits. For example, a 72-bit transfer will consist of 3 words: the 1st and 2nd words are 32 bits, and the 3rd word is 8 bits.

52.4.2.16 Transmit Data Register (TDR)

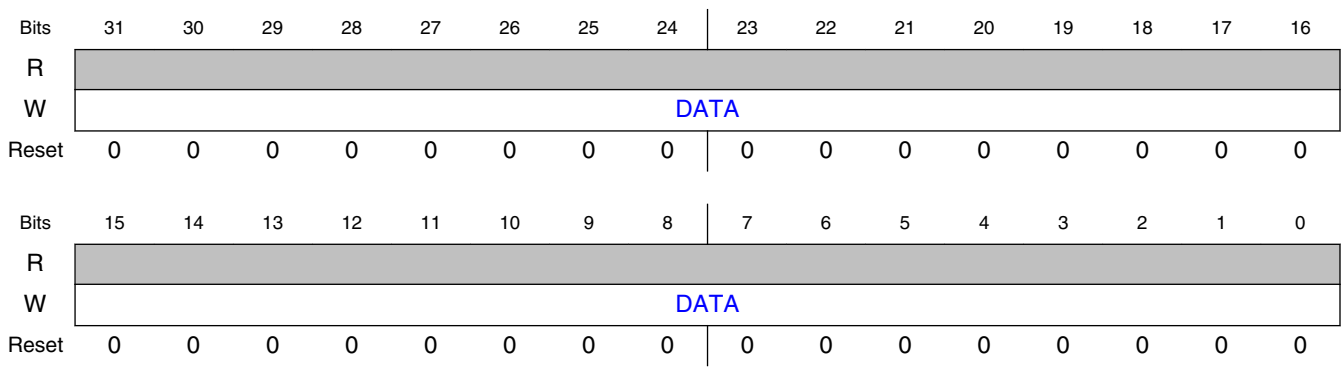
52.4.2.16.1 Offset

Register	Offset
TDR	64h

52.4.2.16.2 Function

Writes to either the Transmit Command Register or Transmit Data Register will push the data into the transmit FIFO, in the order that it (the data) was written. The Data Register can be written using 32-bit, 16-bit or 8-bit writes, but each write will push data into the FIFO with zero pushed in unwritten bytes.

52.4.2.16.3 Diagram



52.4.2.16.4 Fields

Field	Function
31-0 DATA	Transmit Data Both 8-bit and 16-bit writes of transmit data will zero-extend the data written and push the data into the transmit FIFO. To zero-extend 8-bit and 16-bit writes (to 32 bits), means that the higher order (most significant) empty parts of the 8-bit and 16-bit writes are filled with zeroes.

Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port control	Signal multiplexing

53.1.1 LPI2C

The LPI2C is a low power Inter-Integrated Circuit (I2C) module that supports an efficient interface to an I2C bus as a master. The LPI2C can continue operating in stop modes provided an appropriate clock is available and is designed for low CPU overhead with DMA offloading of FIFO register accesses. The LPI2C implements logic support for standard and fast modes of operation.

The following table shows the LPI2C configuration:

Table 53-2. LPI2C configuration

Parameter	Description
Name	LPI2C
Instances	8
Configurable features	LPI2C0-7: SMBUS, 4TX/RX FIFO
Interface speed	LPI2C0-7: 1 Mbps normal mode max
External I/O pins	LPI2C0-7: SDA, SCL. See the attached IOMUXC spreadsheet for pinout details.

53.1.2 Slave mode support

All LPI2C instances in i.MX 7ULP don't support Slave mode. LPI2C module may have been generated including "Slave mode" in order to keep SMBUS feature and all features of Slave mode are not verified. Therefore, HREQ, SCLS and SDAS signals are not required.

53.2 Introduction

The LPI2C is a low power Inter-Integrated Circuit (I2C) module that supports an efficient interface to an I^2C bus as a master and/or as a slave.

- The LPI2C implements logic support for standard-mode, fast-mode, fast-mode plus and ultra-fast modes of operation.
- The LPI2C is designed to use little CPU overhead, with DMA offloading of FIFO register accesses.
- The LPI2C can continue operating in stop modes if an appropriate clock is available.

The LPI2C module also complies with the System Management Bus (SMBus) Specification, version 2. The SMBus is a single-ended simple two-wire bus, which is typically used for low bandwidth communications.

NOTE

The I^2C (Inter-Integrated Circuit) serial bus is multi-master, multi-slave, packet-switched, and single-ended, and is often used to attach microcontroller ICs to lower-speed peripheral ICs.

53.2.1 Features

The LPI2C supports:

- Standard, Fast, Fast+ and Ultra Fast modes are supported
- High speed mode (HS) in slave mode
- High speed mode (HS) in master mode, if SCL pin implements current source pull-up (device-specific)
- Multi-master support, including synchronization and arbitration. Multi-master means any number of master nodes can be present. Additionally, master and slave roles may be changed between messages (after a STOP is sent).
- Clock stretching: Sometimes multiple I2C nodes may be driving the lines at the same time. If any I2C node is driving a line low, then that line will be low. I2C nodes that

are starting to transmit a logical one (by letting the line float high) can detect that the line is low, and thereby know that another I2C node is active at the same time.
    - When node detection is used on the SCL line, it is called *clock stretching*, and clock stretching is used as a I2C flow control mechanism for multiple laves.
    - When node detection is used on the SDA line, it is called *arbitration*, and arbitration ensures that there is only one I2C node transmitter at a time.
- General call, 7-bit and 10-bit addressing
- Software reset, START byte and Device ID (also require software support)

The LPI2C master supports:

- Command/transmit FIFO of 4words.
- Receive FIFO of 4words.
- Command FIFO will wait for idle I2C bus before initiating transfer
- Command FIFO can initiate (repeated) START and STOP conditions and one or more master-receiver transfers
- STOP condition can be generated from command FIFO, or generated automatically when the transmit FIFO is empty
- Host request input to control the start time of an I2C bus transfer
- Flexible receive data match can generate interrupt on data match and/or discard unwanted data
- Flag and optional interrupt to signal Repeated START condition, STOP condition, loss of arbitration, unexpected NACK, and command word errors
- Supports configurable bus idle timeout and pin-stuck-low timeout

The LPI2C slave supports:

- Separate I2C slave registers to minimize software overhead because of master/slave switching
- Support for 7-bit or 10-bit addressing, address range, SMBus alert and general call address
- Transmit data register that supports interrupt or DMA requests
- Receive data register that supports interrupt or DMA requests
- Software-controllable ACK or NACK, with optional clock stretching on ACK/NACK bit
- Configurable clock stretching, to avoid transmit FIFO underrun and receive FIFO overrun errors
- Flag and optional interrupt at end of packet, STOP condition, or bit error detection

53.2.2 Block Diagram

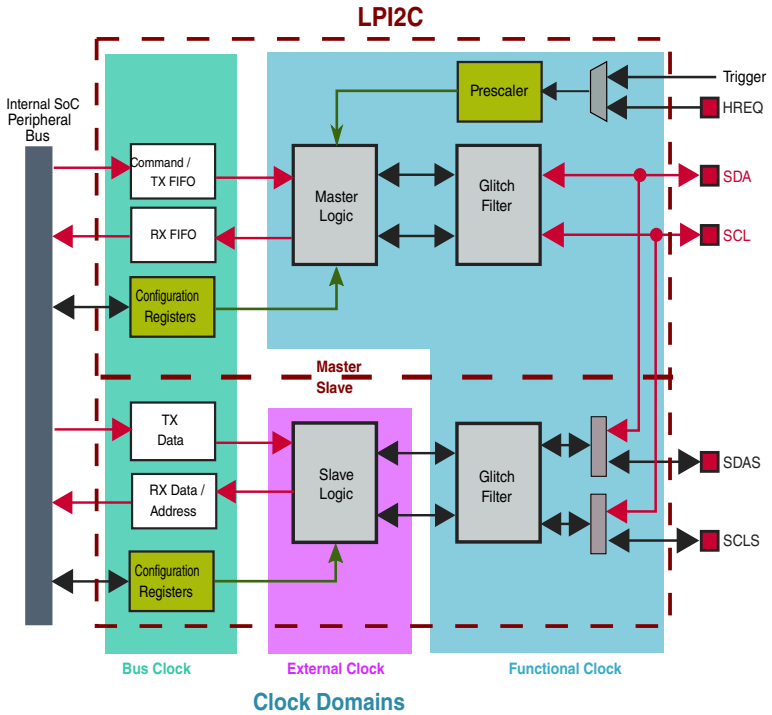

Figure 53-1. LPI2C block diagram

53.2.3 Modes of operation

Table 53-3. Chip modes supported by the LPI2C module

Chip mode	LPI2C Operation
Run	Normal operations
Stop/Wait	Can continue operating in stop/wait modes if the Doze Enable bit (MCR[DOZEN]) is clear and the LPI2C is using an external or internal clock source that remains operating during stop/wait modes.
Low Power Stop (also called Low Leakage Stop or LLS)	Before entering low power stop mode, the LPI2C will wait for the current transfer to finish any pending operation, while temporarily ignoring The Doze Enable (MCR[DOZEN]) bit.
Debug	Can continue operating in debug mode if the Debug Enable bit (MCR[DBGE]) is set.

53.2.4 Signal Descriptions

Table 53-4. Signals

Signal	Name	2-Wire Scheme	4-Wire Scheme	I/O
SCL	LPI2C clock line	SCL	In 4-wire mode, this is the SCL input pin.	I/O
SDA	LPI2C data line	SDA	In 4-wire mode, this is the SDA input pin.	I/O
HREQ	Host request	If host request is asserted and the I2C bus is idle, then it will initiate an LPI2C master transfer.		I
SCLS	Secondary I2C clock line	Not used	In 4-wire mode, this is the SCLS output pin. If LPI2C master/slave are configured to use separate pins, then this the LPI2C slave SCL pin.	I/O
SDAS	Secondary I2C data line	Not used	In 4-wire mode, this is the SDAS output pin. If LPI2C master/slave are configured to use separate pins, then this the LPI2C slave SDA pin.	I/O

53.2.5 Wiring options

LPI2C can be used to implement 2-wire or 4-wire I^{2}C serial busses.

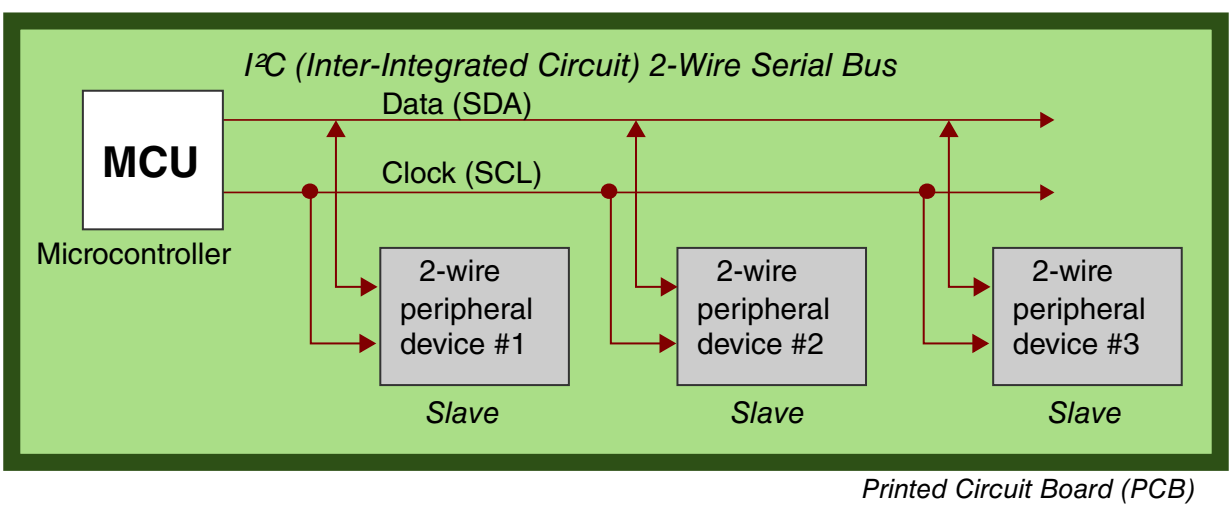

Figure 53-2. 2-Wire scheme

Some applications can provide a lot of load and noise on the I^{2}C bus; to ensure robust I^{2}C operations, a 4-wire interface with the MCU can be used, splitting the 2 lines into inputs and outputs. Using a few transistors, resistors and diodes, designers can make their own inexpensive line drivers.

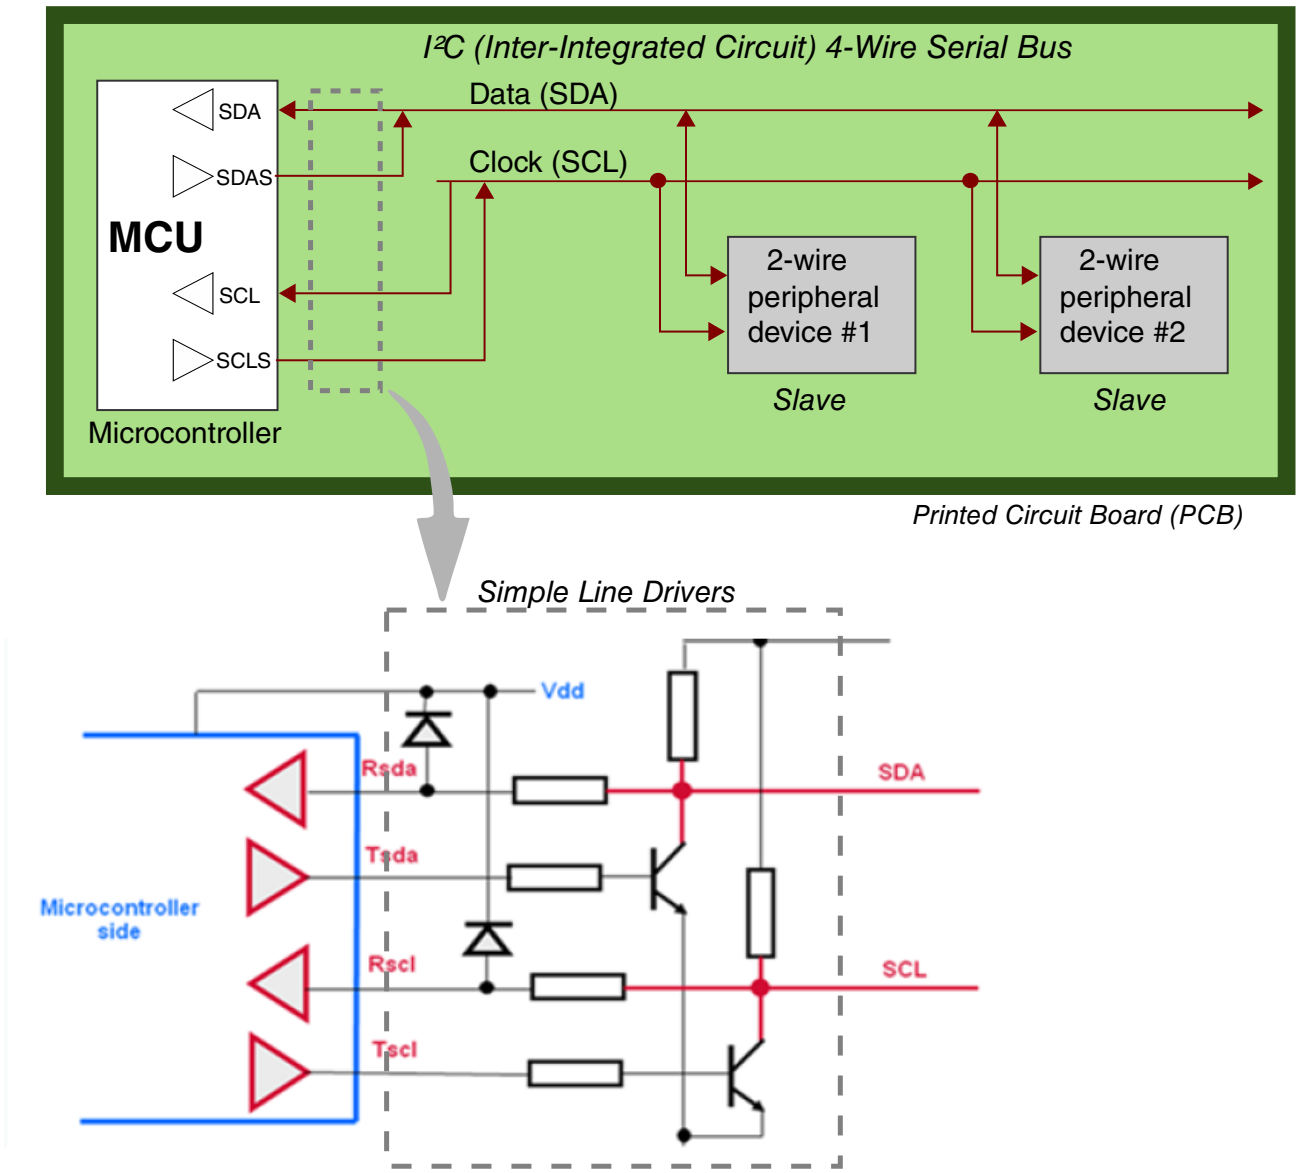

Figure 53-3. 4-Wire scheme

53.3 Memory Map and Registers

NOTE

Writing a Read-Only (RO) register or reading a Write-Only (WO) register can cause bus errors. This module will not check if programmed values in the registers are correct; the application software must ensure that valid programmed values are being written.

7-4 —	Reserved
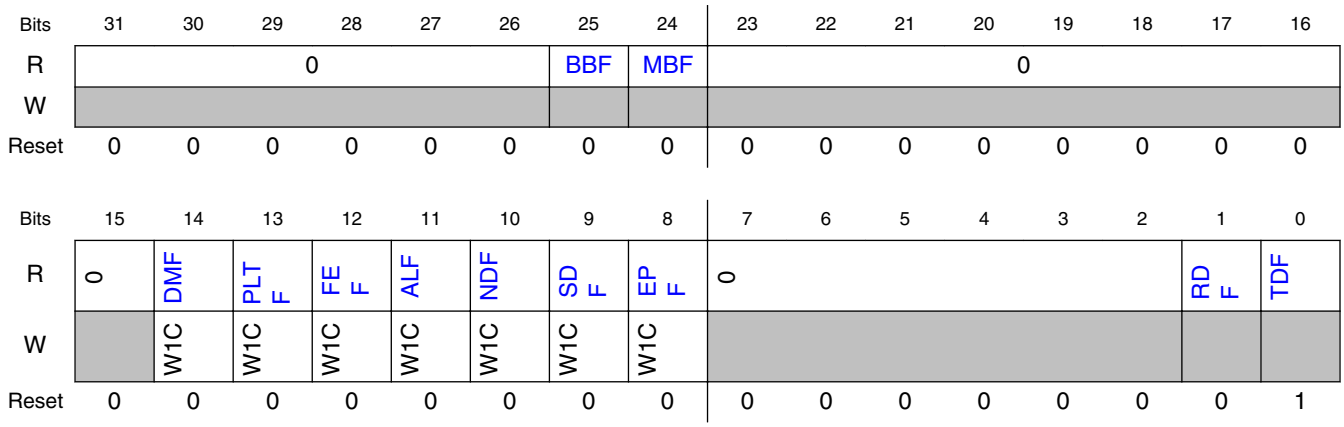
3 DBGEN	Debug Enable 0b - Master is disabled in debug mode 1b - Master is enabled in debug mode
2 DOZEN	Doze mode enable Enables or disables the master in Doze mode 0b - Master is enabled in Doze mode 1b - Master is disabled in Doze mode
1 RST	Software Reset Reset all internal master logic and registers, except the Master Control Register. RST remains set until cleared by software. 0b - Master logic is not reset 1b - Master logic is reset
0 MEN	Master Enable 0b - Master logic is disabled 1b - Master logic is enabled

53.3.1.5 Master Status Register (MSR)

53.3.1.5.1 Offset

Register	Offset
MSR	14h

53.3.1.5.2 Diagram



53.3.1.5.3 Fields

Field	Function
31-26 —	Reserved
25 BBF	Bus Busy Flag 0b - I2C Bus is idle 1b - I2C Bus is busy
24 MBF	Master Busy Flag 0b - I2C Master is idle 1b - I2C Master is busy
23-15 —	Reserved
14 DMF	Data Match Flag Indicates that the received data has matched the MATCH0 and/or MATCH1 fields (as configured by MCFGR1[MATCFG], Match Configuration). Received data *that is discarded due to CMD field* does not cause Data Match Flag to set. 0b - Have not received matching data 1b - Have received matching data
13 PLTF	Pin Low Timeout Flag Will set when the SCL and/or SDA input is low for more than PINLOW cycles (Pin Low Timeout, MCFGR3[PINLOW]), even when the LPI2C master is idle. • Software is responsible for resolving the pin low condition. • Pin Low Timeout Flag cannot be cleared as long as the pin low timeout continues. • Before the LPI2C can initiate a START condition, the Pin Low Timeout Flag must be cleared. 0b - Pin low timeout has not occurred or is disabled 1b - Pin low timeout has occurred
12 FEF	FIFO Error Flag Detects an attempt to send or receive data without first generating a (repeated) START condition. This can occur if the transmit FIFO underflows when the AUTOSTOP bit is set. When FIFO Error Flag is set, the LPI2C master will send a STOP condition (if busy), and will not initiate a new START condition until FIFO Error Flag has been cleared.

Table continues on the next page...

Field	Function
	0b - No error 1b - Master sending or receiving data without a START condition
11 ALF	Arbitration Lost Flag Set: • if the LPI2C master transmits a logic one and detects a logic zero on the I2C bus • or if the LPI2C master detects a START or STOP condition while the LPI2C master is transmitting data When the Arbitration Lost Flag sets, the LPI2C master will release the I2C bus (go idle), and the LPI2C master will not initiate a new START condition until the Arbitration Lost Flag has been cleared. 0b - Master has not lost arbitration 1b - Master has lost arbitration
10 NDF	NACK Detect Flag Set if the LPI2C master detects a NACK when transmitting an address or data. When set, the master will transmit a STOP condition and will not initiate a new START condition until NACK Detect Flag has been cleared. If a NACK is expected for a given address (as configured by the command word), then the NACK Detect Flag will set if a NACK is not generated. 0b - Unexpected NACK was not detected 1b - Unexpected NACK was detected
9 SDF	STOP Detect Flag Set when the LPI2C master generates a STOP condition. 0b - Master has not generated a STOP condition 1b - Master has generated a STOP condition
8 EPF	End Packet Flag Set when the LPI2C master generates either a repeated START condition or a STOP condition. Does not set when the master first generates a START condition. 0b - Master has not generated a STOP or Repeated START condition 1b - Master has generated a STOP or Repeated START condition
7-2 —	Reserved
1 RDF	Receive Data Flag The Receive Data Flag is set whenever the number of words in the receive FIFO is greater than RXWATER. 0b - Receive Data is not ready 1b - Receive data is ready
0 TDF	Transmit Data Flag The Transmit Data Flag is set whenever the number of words in the transmit FIFO is equal or less than TXWATER. 0b - Transmit data is not requested 1b - Transmit data is requested

53.3.1.13.4 Fields

Field	Function
31-30 —	Reserved
29-24 DATAVD	Data Valid Delay Minimum number of cycles (minus one) that is used as the data hold time for SDA. Must be configured less than the minimum SCL low period.
23-22 —	Reserved
21-16 SETHOLD	Setup Hold Delay Minimum number of cycles (minus one) that is used by the master • as the hold time for a START condition • as the setup and hold time for a repeated START condition • as the setup time for a STOP condition The setup time is extended by the time it takes to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) / 2^PRESCALE cycles.
15-14 —	Reserved
13-8 CLKHI	Clock High Period Minimum number of cycles (minus one) that the SCL clock is driven high by the master. The SCL high time is extended by the time it takes to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) / 2^PRESCALE cycles.
7-6 —	Reserved
5-0 CLKLO	Clock Low Period Minimum number of cycles (minus one) that the SCL clock is driven low by the master. The Clock Low Period value is also used for the minimum bus free time between a STOP and a START condition; this is extended by the time it takes to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) / 2^PRESCALE cycles.

53.3.1.14 Master Clock Configuration Register 1 (MCCR1)

53.3.1.14.1 Offset

Register	Offset
MCCR1	50h

53.3.1.14.2 Function

The MCCR1 cannot be changed when the I2C master is enabled and is used for high speed mode transfers. The separate clock configuration for high speed mode allows arbitration to take place in Fast mode (with timing configured by MCCR0), before switching to high speed mode (with timing configured by MCCR1).

53.3.1.14.3 Diagram

25 BBF	Bus Busy Flag Indicates if an I2C bus is idle or busy. 0b - I2C Bus is idle 1b - I2C Bus is busy
24 SBF	Slave Busy Flag Indicates if an I2C slave is idle or busy. 0b - I2C Slave is idle 1b - I2C Slave is busy
23-16 —	Reserved
15 SARF	SMBus Alert Response Flag • SMBus Alert Response Flag is cleared by reading the Address Status Register • SMBus Alert Response Flag cannot generate an asynchronous wakeup 0b - SMBus Alert Response is disabled or not detected 1b - SMBus Alert Response is enabled and detected
14 GCF	General Call Flag Indicates whether a slave has detected the General Call Address. • General Call Flag is cleared by reading the Address Status Register • General Call Flag cannot generate an asynchronous wakeup 0b - Slave has not detected the General Call Address or the General Call Address is disabled 1b - Slave has detected the General Call Address
13 AM1F	Address Match 1 Flag Indicates that the received address has matched the ADDR1 field or ADDR0 to ADDR1 range as configured by ADDRCFG.

Table continues on the next page...

Field	Function
	• Address Match 1 Flag is cleared by reading the Address Status Register • Address Match 1 Flag cannot generate an asynchronous wakeup 0b - Have not received an ADDR1 or ADDR0/ADDR1 range matching address 1b - Have received an ADDR1 or ADDR0/ADDR1 range matching address
12 AM0F	Address Match 0 Flag Indicates that the received address has matched the ADDR0 field as configured by ADDRCFG. • Address Match 0 Flag is cleared by reading the Address Status Register • Address Match 0 Flag cannot generate an asynchronous wakeup 0b - Have not received an ADDR0 matching address 1b - Have received an ADDR0 matching address
11 FEF	FIFO Error Flag FIFO error flag can only be set when clock stretching is disabled. 0b - FIFO underflow or overflow was not detected 1b - FIFO underflow or overflow was detected
10 BEF	Bit Error Flag Bit Error Flag will set if the LPI2C slave transmits a logic one and detects a logic zero on the I2C bus. The slave will ignore the rest of the transfer until the next (repeated) START condition. 0b - Slave has not detected a bit error 1b - Slave has detected a bit error
9 SDF	STOP Detect Flag STOP Detect Flag will set when the LPI2C slave detects a STOP condition and if the LPI2C slave matched the last address byte. 0b - Slave has not detected a STOP condition 1b - Slave has detected a STOP condition
8 RSF	Repeated Start Flag Repeated Start Flag will set when the LPI2C slave detects a repeated START condition and if the LPI2C slave matched the last address byte. The Repeated Start Flag does not set when the slave first detects a START condition. 0b - Slave has not detected a Repeated START condition 1b - Slave has detected a Repeated START condition
7-4 —	Reserved
3 TAF	Transmit ACK Flag Transmit ACK Flag is cleared by writing the Transmit ACK register. 0b - Transmit ACK/NACK is not required 1b - Transmit ACK/NACK is required
2 AVF	Address Valid Flag Address Valid Flag is cleared by reading the address status register. When Receive Data Configuration (SCFGR1[RXCFG]) is set, the Address Valid Flag is also cleared by reading the Receive Data register. 0b - Address Status Register is not valid 1b - Address Status Register is valid
1 RDF	Receive Data Flag Receive Data Flag is cleared by reading the receive data register. When Receive Data Configuration (SCFGR1[RXCFG]) is set, the Receive Data Flag is not cleared when reading the Receive Data register and if AVF is set. 0b - Receive data is not ready 1b - Receive data is ready

Table continues on the next page...

Field	Function
0 TDF	Transmit Data Flag Transmit Data Flag is cleared by writing the Transmit Data register. When Transmit Flag Configuration (TXCFG) is clear, and if a NACK or Repeated START or STOP condition is detected, then Transmit Data Flag is also cleared. 0b - Transmit data not requested 1b - Transmit data is requested

18-16 ADDRCFG	Address Configuration Configures the condition that will cause an address to match. 000b - Address match 0 (7-bit) 001b - Address match 0 (10-bit) 010b - Address match 0 (7-bit) or Address match 1 (7-bit) 011b - Address match 0 (10-bit) or Address match 1 (10-bit) 100b - Address match 0 (7-bit) or Address match 1 (10-bit) 101b - Address match 0 (10-bit) or Address match 1 (7-bit) 110b - From Address match 0 (7-bit) to Address match 1 (7-bit) 111b - From Address match 0 (10-bit) to Address match 1 (10-bit)
15-14 —	Reserved
13 HSMEN	High Speed Mode Enable Enables detection of the High-Speed Mode master code of slave address 0000_1XX, but does not cause an address match on this code. When set and any HS-mode master code is detected, the FILTEN and ACKSTALL bits are ignored until the next STOP condition is detected. 0b - Disables detection of HS-mode master code 1b - Enables detection of HS-mode master code
12 IGNACK	Ignore NACK When Ignore NACK is set, the LPI2C slave will continue transfers after a NACK is detected. Ignore NACK bit is required to be set in Ultra-Fast Mode. 0b - Slave will end transfer when NACK is detected

Table continues on the next page...

Field	Function
	1b - Slave will not end transfer when NACK detected
11 RXCFG	Receive Data Configuration 0b - Reading the Receive Data register will return received data and clear the Receive Data flag (MSR[RDF]). 1b - Reading the Receive Data register when the Address Valid flag (SSR[AVF])is set, will return the Address Status register and clear the Address Valid flag. Reading the Receive Data register when the Address Valid flag is clear, will return received data and clear the Receive Data flag (MSR[RDF]).
10 TXCFG	Transmit Flag Configuration The transmit data flag will always assert before a NACK is detected at the end of a slave-transmit transfer. This can cause an extra word to be written to the transmit data FIFO. • When TXCFG=0, the Transmit Data register is automatically emptied when a slave-transmit transfer is detected. This causes the transmit data flag to assert whenever a slave-transmit transfer is detected, and causes the transmit data flag to negate at the end of the slave-transmit transfer. • When TXCFG=1, the Transmit Data flag will assert whenver the Transmit Data register is empty, and the Transmit Data flag will negate when the Transmit Data register is full. This allows the Transmit Data register to be filled before a slave-transmit transfer is detected, but can cause the Transmit Data register to be written before a NACK is detected on the last byte of a slave transmit transfer. 0b - Transmit Data Flag will only assert during a slave-transmit transfer when the Transmit Data register is empty 1b - Transmit Data Flag will assert whenever the Transmit Data register is empty
9 SAEN	SMBus Alert Enable 0b - Disables match on SMBus Alert 1b - Enables match on SMBus Alert
8 GCEN	General Call Enable 0b - General Call address is disabled 1b - General Call address is enabled
7-4 —	Reserved
3 ACKSTALL	ACK SCL Stall Enables SCL clock stretching during slave-transmit address byte(s) and slave-receiver address and data byte(s), to allow software to write the Transmit ACK Register before the ACK or NACK is transmitted. Clock stretching occurs when transmitting the 9th bit, and is therefore not compatible with high speed mode. When ACKSTALL is enabled, there is no need to set either RX SCL Stall (SCFGR1[RXSTALL]) or Address SCL Stall (SCFGR1[ADRSTALL]). 0b - Clock stretching is disabled 1b - Clock stretching is enabled
2 TXDSTALL	TX Data SCL Stall Enables SCL clock stretching when the Transmit Data flag (SSR[TDF]) is set during a slave-transmit transfer. Clock stretching occurs following the 9th bit, and is therefore compatible with high speed mode. 0b - Clock stretching is disabled 1b - Clock stretching is enabled
1 RXSTALL	RX SCL Stall Enables SCL clock stretching when the Receive Data flag (SSR[RDF]) is set during a slave-receive transfer. Clock stretching occurs following the 9th bit, and is therefore compatible with high speed mode. 0b - Clock stretching is disabled 1b - Clock stretching is enabled

Table continues on the next page...

Field	Function
0 ADRSTALL	Address SCL Stall Enables SCL clock stretching when the Address Valid Flag (SSR[AVF]) is asserted. Clock stretching only occurs following the 9th bit, and is therefore compatible with high speed mode. 0b - Clock stretching is disabled 1b - Clock stretching is enabled

14 ANV	Address Not Valid 0b - Received Address (RADDR) is valid 1b - Received Address (RADDR) is not valid
13-11 —	Reserved
10-0 RADDR	Received Address The Received Address updates whenever the AMF is set; the AMF is cleared by reading the Slave Address Status register. • In 7-bit mode, the address byte is store in RADDR[7:0] • In 10-bit mode, the first address byte is { 11110, RADDR[10:9], RADDR[0] } and the second address byte is RADDR[8:1]. The R/W bit is therefore always stored in RADDR[0]

53.3.1.27 Slave Transmit ACK Register (STAR)

53.3.1.27.1 Offset

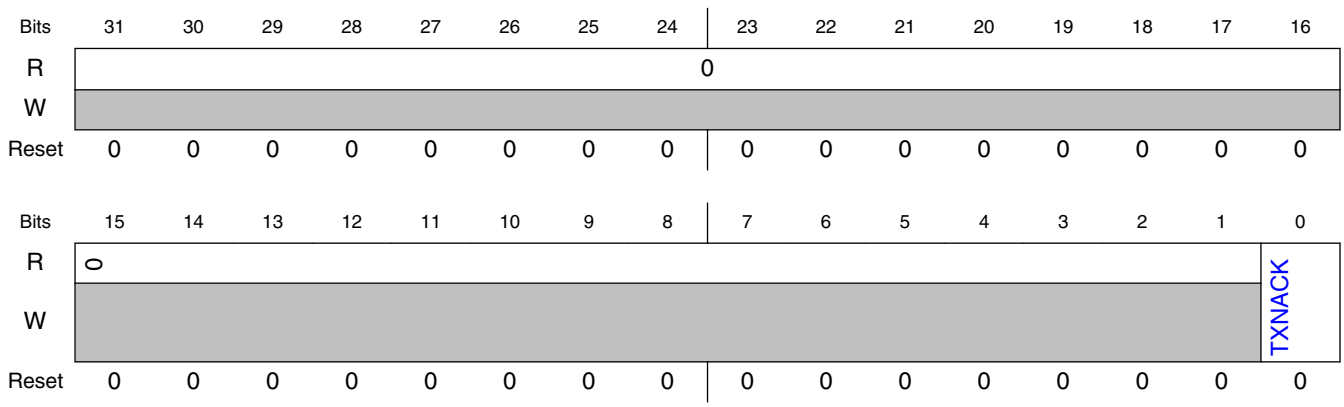
Register	Offset
STAR	154h

53.3.1.27.2 Function

The Slave Transmit ACK Register can only be written when the ACK SCL Stall bit is set in Slave Configuration Register 1 (SCFGR1[ACKSTALL].

- The ACKSTALL bit will enable clock stretching during the ACK/NACK bit slot, and during this time, the STAR register can be written by software.
- The logic ensures that the clock stretching continues for at least 1 bus clock cycle after the STAR register is updated.
- This clock stretching time can be extended more using the Clock Hold Time field (SCFGR2[CLKHOLD], Slave Configuration Register 2).

53.3.1.27.3 Diagram



53.3.1.27.4 Fields

Field	Function
31-1 —	Reserved
0 TXNACK	Transmit NACK After receiving each word, software can transmit either an ACK (logic 0) or a NACK (logic 1); Transmit NACK selects which to use: ACK or NACK. • When ACKSTALL is set, a Transmit NACK must be written once for each matching address byte and each received word. ACKSTALL must be set, because that will stall the data transfer until software reads the received word (and decides whether to respond with an ACK or NACK). • To configure the default ACK/NACK, Transmit NACK can also be written when LPI2C Slave is disabled or idle. 0b - Write a Transmit ACK for each received word 1b - Write a Transmit NACK for each received word

53.3.1.28 Slave Transmit Data Register (STDR)

53.3.1.28.1 Offset

Register	Offset
STDR	160h

53.3.1.28.2 Function

Clock stretching (enabled or disabled) affects when the transmit data is transferred. The TXDSTALL bit will enable clock stretching during the 1st data bit of a slave-transmit transfer.

- **If clock stretching is enabled (TXDSTALL=1)**, then the transmit data transfer is stalled until the Slave Transmit register (STDR) is updated. Clock stretching is extended by at least 1 bus clock cycle after the Slave Transmit Data Register (STDR) is updated, and clock stretching can be delayed even more using the Clock Hold Time field (SCFGR2[CLKHOLD], Slave Configuration Register 2).
- **If clock stretching is disabled (TXDSTALL=0)**, then the transmit data should be written before the start of the slave-transmit transfer; otherwise (i.e., if the transmit data is not written before the start of the slave-transmit transfer), the FIFO Error Flag (SSR[FEF]) will be set.

53.4 Functional description

53.4.1 Clocking and Resets

Table 53-6. Clocks

LPI2C Functional clock	The LPI2C functional clock is asynchronous to the bus clock and can remain enabled in low power modes to support I2C bus transfers by the LPI2C master. The functional clock is also used by the LPI2C slave to support digital filter and data hold time configurations. The LPI2C master divides the functional clock by a prescaler and the resulting frequency must be at least 8 times faster than the I2C bus bandwidth.
External clock	The LPI2C slave logic is clocked directly from the external pins SCL and SDA (or SCLS and SDAS if master and slave are implemented on separate pins). This allows the LPI2C slave to remain operational, even when the LPI2C functional clock is disabled. **NOTE:** The LPI2C slave digital filter must be disabled if the LPI2C functional clock is disabled, and this can affect compliance with some of the timing parameters of the I2C specification, such as the data hold time.
Bus clock	The bus clock is only used for bus accesses to the control and configuration registers. The bus clock frequency must be sufficient to support the data bandwidth requirements of the LPI2C master and slave registers.

Table 53-7. Resets

Chip reset	The logic and registers for the LPI2C master and slave are reset to their default state on a chip reset.
Software reset	• The LPI2C master implements a software reset bit in its Control Register. The MCR[RST] will reset all master logic and registers to their default state, except for the MCR itself. • The LPI2C slave implements a software reset bit in its Control Register. The SCR[RST] will reset all slave logic and registers to their default state, except for the SCR itself.
FIFO reset	• The LPI2C master implements write-only control bits that reset the transmit FIFO (MCR[RTF]) and receive FIFO (MCR[RRF]). After a FIFO is reset, that FIFO is empty. • The LPI2C slave implements write-only control bits that reset the transmit data register (SCR[RTF] and receive data register (SCR[RRF]). After a data register is reset, that data register is empty.

53.4.2 Master Mode

The LPI2C master logic operates independently from the slave logic to perform all master mode transfers on the I2C bus.

53.4.2.1 Transmit and Command FIFO commands

The transmit FIFO stores command data to initiate the various I2C operations. The following operations can be initiated through commands in the transmit FIFO:

- START or Repeated START condition with address byte and expecting ACK or NACK.
- Transmit data (this is the default for zero extended byte writes to the transmit FIFO).
- Receive 1-256 bytes of data (can also be configured to discard receive data and not store in receive FIFO).
- STOP condition (can also be configured to send STOP condition when transmit FIFO is empty).

Multiple transmit and receive commands can be inserted between the START condition and STOP conditon; transmit and receive commands must not be interleaved (to comply with the I2C specification). The receive data command and the receive data and discard commands can be interleaved, to ensure that only the desired received data is stored in the receive FIFO (or compared with the data match logic).

The LPI2C master will automatically transmit a NACK on the last byte of a receive data command unless the next command in the FIFO is also a receive data command. A NACK is also automatically transmitted if the transmit FIFO is empty when a receive data command completes.

The LPI2C master supports 10-bit addressing through a (repeated) START condition, followed by a transmit data byte containing the second address byte, followed by any number of data bytes with the master-transmit data.

A START or Repeated START condition that is expecting a NACK (for example,HS-mode master code) must be followed by a STOP or (repeated) START condition.

53.4.2.2 Master operations

Whenever the LPI2C is enabled, it monitors the I2C bus to detect when the I2C bus is idle (MSR[BBF]). The I2C bus is no longer considered idle if either SCL or SDA are low, and the I2C bus becomes idle if a STOP condition is detected or if a bus idle timeout

is detected (as configured by MCFGR2[BUSIDLE]). After the I2C bus is idle, the transmit FIFO is not empty, and the host request is either asserted or disabled, then the LPI2C master will initiate a transfer on the I2C bus. This involves the following steps:

- Wait the bus idle time equal to (MCCR0[CLKLO] + 1) multiplied by the prescaler (MCFGR1[PRESCALE]).
- Transmit a START condition and address byte using the timing configuration in the Master Clock Configuration Register 0 (MCCR0); if a high speed mode transfer is configured, then the timing configuration from Master Clock Configuration Register 1 (MCCR1) is used instead.
- Perform master-transmit or master-receive transfers, as configured by the transmit FIFO.
- Transmit NACK on the last byte of a master-receive transfer, unless the next command in the transmit FIFO is also a receive data command and the transmit FIFO is not empty.
- Transmit a Repeated START or STOP condition as configured by the transmit FIFO and/or MCFGR1[AUTOSTOP]. A repeated START can change which timing configuration register is used.

When the LPI2C master is disabled (either due to MCR[MEN] being clear or automatically due to mode entry), the LPI2C will continue to empty the transmit FIFO until a STOP condition is transmitted. However, the LPI2C will no longer stall the I2C bus waiting for the transmit or receive FIFO, and after the transmit FIFO is empty, the LPI2C will generate a STOP condition automatically.

The LPI2C master can stall the I2C bus under certain conditions; this will result in SCL pulled low continuously on the first bit of a byte, until the condition is removed:

- LPI2C master is enabled and busy, the transmit FIFO is empty, and MCFGR1[AUTOSTOP] is clear.
- LPI2C master is enabled and receiving data, receive data is not being discarded (due to command or receive data match), and the receive FIFO is full.

53.4.2.3 Receive FIFO and Data Matching

The receive FIFO is used to store receive data during master-receiver transfers. Receive data can also be configured to discard receive data instead of storing in the receive FIFO; this is configured by the command word in the transmit FIFO.

Receive data supports a receive data match function that can match received data against one of two bytes or against a masked data byte. The data match function can also be configured to compare only the first one or two received data words since the last (repeated) START condition. Receive data that is already discarded due to the command

word cannot cause the data match to set, and will delay the match on the first received data word until after the discarded data is received. The receiver match function can also be configured to discard all receive data until a data match is detected, using the MCFGR0[RDMO] control bit. When clearing the MCFGR0[RDMO] control bit following a data match, clear MCFGR0[RDMO] before clearing MSR[DMF], to allow all subsequent data to be received.

53.4.2.4 Timing Parameters

The following timing parameters can be configured by the LPI2C master. Parameters are configured separately for high speed mode (MCCR1) and other modes (MCCR0). This allows the high speed mode master code to be sent using the regular timing parameters, and then switch to the high speed mode timing (following a repeated START) until the next STOP condition.

The LPI2C master timing parameters in LPI2C functional clock cycles are configured as follows. They must be configured to meet the I2C timing specification for the required mode.

Table 53-8. Timing Parameters

I2C Specification Timing Parameter	I2C Specification Timing Symbol	LPI2C Timing Parameter (LPI2C functional clock cycles)
SCL clock period	tSCL	(CLKHI + CLKLO + 2 + SCL_LATENCY) x (2 ^ PRESCALE)
hold time (repeated) START condition	tHD:STA	(SETHOLD +1) x (2 ^ PRESCALE)
LOW period of the SCL clock	tLOW	(CLKLO + 1) x (2 ^ PRESCALE)
HIGH period of the SCL clock	tHIGH	(CLKHI + 1 + SCL_LATENCY) x (2 ^ PRESCALE)
setup time for a repeated START condition or STOP condition	tSU:STA, tSU:STO	(SETHOLD + 1 + SCL_LATENCY) x (2 ^ PRESCALE)
data hold time	tHD:DAT	(DATAVD + 1) x (2 ^ PRESCALE)
data setup time	tSU:DAT	(SDA_LATENCY + 1) x (2 ^ PRESCALE)
bus free time between a STOP and START condition	tBUF	(CLKLO + 1 + SDA_LATENCY) x (2 ^ PRESCALE)
data valid time, data valid acknowledge time	tVD:DAT, tVD:ACK	(DATAVD + 1) x (2 ^ PRESCALE)

The latency parameters are defined in the following table, these parameters assume the risetime is less than one LPI2C functional clock cycle. The risetime depends on a number of factors, including the I/O propagation delay, the I2C bus loading and the external pull-

up resistor sizing. A larger risetime will increase the number of cycles that the signal takes to propagate through the synchronizer (and glitch filter), which increases the latency.

Table 53-9. Synchronization Latency

Timing Parameter	Timing Definition
SCL_LATENCY	ROUNDDOWN ((2 + FILTSCL + SCL_RISETIME) / (2 ^ PRESCALE))
SDA_LATENCY	ROUNDDOWN ((2 + FILTSDA + SDA_RISETIME) / (2 ^ PRESCALE))

The following timing restrictions must be enforced to avoid unexpected START or STOP conditions on the I2C bus, or to avoid unexpected START or STOP conditions detected by the LPI2C master. The timing restrictions can be summarized as **SDA cannot change when SCL is high outside of a transmitted (repeated) START or STOP condition**.

Table 53-10. LPI2C Timing Parameter Restrictions

Timing Parameter	Minimum	Maximum	Comment
CLKLO	0x03	-	Also: CLKLO x (2 ^ PRESCALE) > SCL_LATENCY
CLKHI	0x01	-	Configure CLKHI to meet the duty cycle requirements in the I2C specification
SETHOLD	0x02	-	
DATAVD	0x01	CLKLO - SDA_LATENCY - 1	Configure DATAVD to meet the data hold requirement in the I2C specification
FILTSCL	0x00	[CLKLO x (2 ^ PRESCALE)] - 3	FILTSCL and FILTSDA are the only parameters not multiplied by (2 ^ PRESCALE)
FILTSDA	FILTSCL	[CLKLO x (2 ^ PRESCALE)] - 3	Configuring FILTSDA greater than FILTSCL can delay the SDA input to compensate for board level skew
BUSIDLE	(CLKLO+SETHOLD+2) x 2	-	Must also be greater than (CLKHI+1)

The timing parameters must be configured to meet the requirements of the I2C specification; this will depend on the mode being supported and the LPI2C functional clock frequency. When switching between two modes using the different clock configuration registers (for example, Fast and HS-mode), the PRESCALE factor must remain constant between the modes. Some example timing configurations are provided below.

Table 53-11. LPI2C Example Timing Configurations

I2C Mode	Clock Frequency	Baud Rate	PRESCALE	FILTSCL / FILTSDA	SETHOLD	CLKLO	CLKHI	DATAVD
Fast	8 MHz	400 kbps	0x0	0x0/0x0	0x04	0x0B	0x05	0x02

Table continues on the next page...

Table 53-11. LPI2C Example Timing Configurations (continued)

I2C Mode	Clock Frequency	Baud Rate	PRESCALE	FILTSCL / FILTSDA	SETHOLD	CLKLO	CLKHI	DATAVD
Fast+	8 MHz	1 Mbps	0x0	0x0/0x0	0x02	0x03	0x01	0x01
Fast	48 MHz	400 kbps	0x0	0x1/0x1	0x1D	0x3E	0x35	0x0F
Fast	48 MHz	400 kbps	0x2	0x1/0x1	0x07	0x11	0x0B	0x03
Fast+	48 MHz	1 Mbps	0x2	0x1/0x1	0x03	0x06	0x04	0x04
HS-mode	48 MHz	3.2 Mbps	0x0	0x0/0x0	0x07	0x08	0x03	0x01
Fast	60 MHz	400 kbps	0x1	0x2/0x2	0x11	0x28	0x1F	0x08
Fast+	60 MHz	1 Mbps	0x1	0x2/0x2	0x07	0x0F	0x0B	0x01
HS-mode	60 MHz	3.33 Mbps	0x1	0x0/0x0	0x04	0x04	0x02	0x01

53.4.2.5 Error Conditions

The LPI2C master will monitor for errors while it is active, the following conditions will generate an error flag and block a new START condition from being sent, until the flag is cleared by software:

- A START or STOP condition is detected and is not generated by the LPI2C master (sets MSR[ALF]).
- Transmitting data on SDA and different values are being received (sets MSR[ALF]).
- NACK is detected when transmitting data, and MCFGR1[IGNACK] is clear (sets MSR[NDF]).
- NACK is detected and is expecting ACK for the address byte, and MCFGR1[IGNACK] is clear (sets MSR[NDF]).
- ACK is detected and is expecting NACK for the address byte, and MCFGR1[IGNACK] is clear (sets MSR[NDF]).
- Transmit FIFO is requesting to transmit or receive data without a START condition (sets MSR[FEF]).
- SCL (or SDA if MCFGR1[TIMECFG] is set) is low for (MCFGR2[TIMELOW] * 256) prescaler cycles without a pin transition (sets MSR[PLTF]).

Software must respond to the MSR[PTLF] flag to terminate the existing command either cleanly (by clearing MCR[MEN]), or abruptly (by setting MCR[SWRST]).

The MCFGR2[BUSIDLE] field can be used to force the I2C bus to be considered idle when SCL and SDA remain high for (BUSIDLE+1) prescaler cycles. The I2C bus is normally considered idle when the LPI2C master is first enabled, but when BUSIDLE is configured greater than zero then SCL and/or SDA must be high for (BUSIDLE+1) prescaler cycles before the I2C bus is first considered idle.

53.4.2.6 Pin Configuration

- **Open-drain support:** The LPI2C master defaults to open-drain configuration of the SDA and SCL pins. Support for true open drain depends on the specific device, and requires the pins where LPI2C pins are muxed to support true open drain.
- **High Speed mode support:** Support for high speed mode also depends on the specific device, and requires the SCL pin to support the current source pull-up required in the I2C specification.
- **Ultra-Fast mode support:** The LPI2C master also supports the output-only push-pull function required for I2C ultra-fast mode using the SDA and SCL pins. Support for ultra-fast mode also requires the IGNACK bit to be set.
- **Push-pull 2-wire support:** A push-pull 2-wire configuration is also available to the LPI2C master that may support a partial high speed mode, if the LPI2C is the only master and all I2C pins on the bus are at the same voltage. This will configure the SCL pin as push-pull for every clock except the 9th clock pulse, to allow high speed mode compatible slaves to perform clock stretching. In this mode, the SDA pin is tristated for master-receive data bits and master-transmit ACK/NACK bits, and is configured as push-pull at other times. To avoid the risk of contention when SDA is push-pull, the pin can be configured for open-drain operation, as part of the device-specific configuration.
- **Push-pull 4-wire support:** The push-pull 4-wire configuration separates the SCL input data and output data into separate pins, and separates the SDA input data and output data into separate pins. The SCL/SDA pins are used for input data; the SCLS/SDAS pins are used for output data, with configurable polarity. This simplifies external connections when connecting the LPI2C to the I2C bus through external level shifters or discrete components. When using this 4-wire configuration, the LPI2C master logic and LPI2C slave logic are not able to connect to separate I2C buses.

53.4.3 Slave Mode

To perform all slave mode transfers on the I2C bus, the LPI2C slave logic operates independently from the LPI2C master logic.

53.4.3.1 Address Matching

The LPI2C slave can be configured:

- to match one of two addresses, using either 7-bit or 10-bit addressing modes for each address
- to match a range of addresses in either 7-bit or 10-bit addressing modes

- to match the General Call Address, and generate appropriate flags
- to match the SMBus Alert Address, and generate appropriate flags
- to detect the high speed mode master code, and to disable the digital filters and output valid delay time until the next STOP condition is detected

After a valid address is matched, the LPI2C slave will automatically perform slave-transmit or slave-receive transfers until:

- a NACK is detected (unless IGNACK is set)
- a bit error is detected (the LPI2C slave is driving SDA, but a different value is sampled)
- a (repeated) START or STOP condition is detected

53.4.3.2 Transmit and Receive Data

- The Transmit and Receive Data registers are double-buffered and only update during a slave-transmit and slave-receive transfer, respectively.
- The slave address *that was received* can be configured to be read from either the Receive Data register (for example, when using DMA to transfer data), or from the Address Status register.
- The Transmit Data register can be configured to only request data after a slave-transmit transfer is detected, or to request new data whenever the Transmit Data register is empty.
- The Transmit Data register should only be written when the Transmit Data flag is set.
- The Receive Data register should only be read when the Received Data flag is set (or the Address Valid flag is set and RXCFG=1).
- The Address Status register should only be read when the Address Valid flag is set.

53.4.3.3 Clock Stretching

The LPI2C slave supports many configurable options for when clock stretching is performed. The following conditions can be configured to perform clock stretching:

- During the 9th clock pulse of the address byte and the Address Valid flag is set.
- During the 9th clock pulse of a slave-transmit transfer and the Transmit Data flag is set.
- During the 9th clock pulse of a slave-receive transfer and the Receive Data flag is set.
- During the 8th clock pulse of an address byte or a slave-receive transfer and the Transmit ACK flag is set. In high speed mode, this is disabled.
- Clock stretching can also be extended for CLKHOLD cycles, to allow additional setup time to sample the SDA pin externally. In high speed mode, this is disabled.

Unless extended by the CLKHOLD configuration, clock stretching will extend for one peripheral bus clock cycle after SDA updates when clock stretching is enabled.

53.4.3.4 Timing Parameters

The LPI2C slave can configure the following timing parameters. These parameters are disabled when SCR[FILTEN] is clear, when SCR[FILTDZ] is set in Doze mode, and when LPI2C slave detects high speed mode. When disabled, the LPI2C slave is clocked directly from the I2C bus, and may not satisfy all timing requirements of the I2C specification (such as SDA minimum hold time in Standard/Fast mode).

- SDA data valid time from SCL negation to SDA update
- SCL hold time when clock stretching is enabled to increase setup time when sampling SDA externally
- SCL glitch filter time
- SDA glitch filter time

The LPI2C slave imposes the following restrictions on the timing parameters.

- FILTSDA must be configured to greater than or equal to FILTSCL (unless compensating for board level skew between SDA and SCL).
- DATAVD must be configured less than the minimum SCL low period.

53.4.3.5 Error Conditions

The LPI2C slave can detect the following error conditions:

- Bit error flag will set when the LPI2C slave is driving SDA, but samples a different value than what is expected.
- FIFO error flag will set due to a transmit data underrun or a receive data overrun. To eliminate the possibility of underrun and overrun occurring, enable clock stretching.
- FIFO error flag will also set due to an address overrun when RXCFG is set, otherwise an address overrun is not flagged. To eliminate the possibility of overrun occurring, enable clock stretching.

The LPI2C slave does not implement a timeout due to SCL and/or SDA being stuck low. If this detection is required, then the LPI2C master logic should be used and so software can reset the LPI2C slave when this condition is detected.

53.4.4 Interrupts and DMA Requests

Depending on the specific device, interrupts and DMA requests can be combined in some ways:

- The LPI2C master and slave interrupts may be combined
- The LPI2C master and slave transmit DMA requests may be combined
- The LPI2C master and slave receive DMA requests may be combined

53.4.4.1 Master mode

The next table lists the master mode sources that can generate LPI2C master interrupts and LPI2C master transmit/receive DMA requests.

Table 53-12. Master Interrupts and DMA Requests

Master Status Register (MSR)		Description	Can generate		
Flag	Name		Interrupt?	DMA Request?	Low Power Wakeup?
TDF	Transmit Data Flag	Data can be written to Transmit FIFO, as configured by the Transmit FIFO Watermark MFCR[TXWATER]	Y	TX	Y
RDF	Receive Data Flag	Data can be read from the Receive FIFO, as configured by the Receive FIFO Watermark MFCR[RXWATER]	Y	RX	Y
EPF	End Packet Flag	Master has transmitted a Repeated START or STOP condition	Y	N	Y
SDF	STOP Detect Flag	Master has transmitted a STOP condition	Y	N	Y
NDF	NACK Detect Flag	• During an address byte, the master expected an ACK but detected a NACK • During an address byte, the master expected a NACK but detected an ACK • During a master-transmitter data byte, the master detected a NACK	Y	N	Y
ALF	Arbitration Lost Flag	• The master lost arbitration due to a START/STOP condition detected at the wrong time • Or the master was transmitting data but received different data than the data that was transmitted	Y	N	Y
FEF	FIFO Error Flag	The master is expecting a START condition in the Command FIFO, but the next entry in the Command FIFO is not a START condition	Y	N	Y
PLTF	Pin Low Timeout Flag	Pin low timeout is enabled and SCL (or SDA if configured) is low for longer than the configured timeout	Y	N	Y

Table continues on the next page...

Table 53-12. Master Interrupts and DMA Requests (continued)

Master Status Register (MSR)		Description	Can generate		
Flag	Name		Interrupt?	DMA Request?	Low Power Wakeup?
DMF	Data Match Flag	The received data matches the configured data match, but the received data is not discarded due to a command FIFO entry	Y	N	Y
MBF	Master Busy Flag	LPI2C master is busy transmitting/receiving data	N	N	N
BBF	Bus Busy Flag	LPI2C master is enabled and activity is detected on I2C bus, but a STOP condition has not been detected and a bus idle timeout (if enabled) has not occurred.	N	N	N

53.4.4.2 Slave mode

The next table lists the slave mode sources that can generate LPI2C slave interrupts and the LPI2C slave transmit/receive DMA requests.

Table 53-13. Slave Interrupts and DMA Requests

Slave Status Register (SSR)		Description	Can generate		
Flag	Name		Interrupt?	DMA Request?	Low Power Wakeup?
TDF	Transmit Data Flag	Data can be written to the Slave Transmit Data Register (STDR)	Y	TX	Y
RDF	Receive Data Flag	Data can be read from the Slave Receive Data Register (SRDR)	Y	RX	Y
AVF	Address Valid Flag	Address can be read from the Slave Address Status Register (SASR)	Y	RX	Y
TAF	Transmit ACK Flag	ACK/NACK can be written to the Slave Transmit ACK Register (STAR)	Y	N	Y
RSF	Repeated Start Flag	Slave has detected an address match followed by a Repeated START condition	Y	N	Y
SDF	STOP Detect Flag	Slave has detected an address match followed by a STOP condition	Y	N	Y
BEF	Bit Error Flag	Slave was transmitting data, but received different data than what was transmitted	Y	N	Y
FEF	FIFO Error Flag	• Transmit data underrun • Receive data overrun • Address status overrun (when Receive Data Configuration SCFGR1[RXCFG] = 1,)	Y	N	Y

Table continues on the next page...

Table 53-13. Slave Interrupts and DMA Requests (continued)

Slave Status Register (SSR)		Description	Can generate		
Flag	Name		Interrupt?	DMA Request?	Low Power Wakeup?
		FEF flag can only set when clock stretching is disabled.			
AM0F	Address Match 0 Flag	Slave detected an address match with SAMR[ADDR0] field	Y	N	N
AM1F	Address Match 1 Flag	Slave detected an address match with SAMR[ADDR1] field or using an address range	Y	N	N
GCF	General Call Flag	Slave detected an address match with the General Call address	Y	N	N
SARF	SMBus Alert Response Flag	Slave detected an address match with the SMBus Alert address	Y	N	N
SBF	Slave Busy Flag	LPI2C slave is busy receiving an address byte or is transmitting/receiving data	N	N	N
BBF	Bus Busy Flag	LPI2C slave is enabled and a START condition is detected on I2C bus, but a STOP condition has not been detected	N	N	N

53.4.5 Peripheral Triggers

The connection of the LPI2C peripheral triggers to other peripherals depend upon the specific device being used.

Table 53-14. LPI2C Triggers

Trigger	Description
Master Output Trigger	The LPI2C master generates an output trigger that can be connected to other peripherals on the device. The master output trigger asserts on both a Repeated START or STOP condition, and the master output trigger remains asserted for one cycle of the LPI2C functional clock divided by the prescaler.
Slave Output Trigger	The LPI2C slave generates an output trigger that can be connected to other peripherals on the device. The slave output trigger asserts on both a Repeated START or STOP condition that occurs after a slave address match, and the slave output trigger remains asserted until the next slave SCL pin negation.
Input Trigger	To control the start of a LPI2C bus transfer, the LPI2C input trigger can be selected instead of the HREQ input. The input trigger is synchronized and to be detected, the input trigger must assert for at least 2 cycles of the LPI2C functional clock divided by the PRESCALE configuration. When the LPI2C is busy, the HREQ input (and therefore the input trigger) is ignored.

54.1.1 USB High Speed OTG Controller (USBHS)

The USBHS is a USB 2.0-compliant serial interface engine for implementing a USB interface. The registers and data structures are based on the Enhanced Host Controller Interface Specification for Universal Serial Bus (EHCI). The USBHS module can act as a host, a device or an On-The-Go negotiable host/device on the USB bus. It uses 32-bit AXI bus master and 32-bit IP bus

The USBHS controller interfaces to the processor's core. The controller is programmable to support host or device operation under firmware control.

The following table shows the USBHS configuration:

Table 54-2. USBHS configuration

Parameter	Description
Name	USBHS
Supported standard version	USB2.0 Specification
Instances	2
Configurable features	USBOTG1:

Table continues on the next page...

Table 54-2. USBHS configuration (continued)

Parameter	Description
	• Low-speed/Full-speed/High-speed • Host/Device support • UTMI interface (to on-chip PHY) • 8 bi-directional endpoints • 8x256x36 TX FIFO, 1x256x36 RX FIFO USBOTG2: • Low-speed/Full-speed/High-speed • Host/Device support • Interface to on-chip HSIC PHY (host only) and ULPI interface to off-chip PHY • 8 bi-directional endpoints • 8x256x36 TX FIFO, 1x256x36 RX FIFO
Interface speed	N/A
External I/O pins	• USBOTG1: OC, PWR (other USB0 interface pins are connected to the PHY). See the attached IOMUXC spreadsheet for pin details. • USBOTG2 ULPI interface: DAT[7:0], CLK, DIR, STP, NXT, OC, PWR. See the attached IOMUXC spreadsheet for pin details. • USBOTG2 HSIC Interface: STROBE, DATA. See the attached IOMUXC spreadsheet for pin details.

54.1.2 Overcurrent detection and Power Port features

- Overcurrent condition: If an overcurrent takes place, subsequent operation of USB is not guaranteed. The external device must be able to detect the over-current condition and report it to the part. This signaling is flagged for both OTG1 and OTG2 controllers. The controllers then store this indication so that SW can take corrective action. The overcurrent polarity is chosen via the OVER_CUR_POL bit of the OTG1/2 Control register (USBNC_n_CTRL1[OVER_CUR_POL]). By writing into the OVER_CUR_DIS bit of the same register (USBNC_n_CTRL1[OVER_CUR_DIS]), the overcurrent detection can be disabled.
- Power Port feature: The Power Port feature is used to control power of an external device. This feature is used to drive on or off the VBUS indication of an external device. The Port Power (PP) is configured by writing into the PP bit of the Port Status and Control 1 register (USB_nPORTSC1[PP]). The power polarity is chosen via the PWR_POL bit of the OTG1/2 Control register (USBNC_n_CTRL1[PWR_POL]).

NOTE

For the OTG1, which shares both ULPI and HSIC interfaces, these features are only supported when OTG1 is in ULPI mode. HSIC interface specification does not define such features.

54.1.3 Wake-up from VLLS mode by USB PHY wake-up

USB PHY wake-up sources may be used to wake-up from VLLS mode.

- If VDD_DIG1 is powered off once A7 enters the VLLS mode, then only USBNC_n_CTRL1[WKUP_DPDM_EN] is functional.
- If VDD_DIG1 is not powered off, then all 3 wake-up sources are available.

In A7 VLLS mode, the USB0_ID pin/pad will not be functional because the path from I/O pads to USB PHY is powered off. In that case, USBNC_n_CTRL1[WKUP_ID_EN] bit will be used to enable wake-up on a plugged status change instead of wake-up on ID change. Plugged status is clear if both DP, DM pins are logic high and set otherwise.

54.1.3.1 Both CA7 and CM4 are in VLLS mode

To wake-up from MCU from VLLS mode using USB PHY, it is necessary to configure the feature on SIM_GPR1 and SIM_DGO_GPR11 registers as follows.

1. Set SIM_GPR1[USB_PHY_WAKEUP_ISO_DISABLE]= 1 to disable USB Pins to wake-up logic isolation.
2. Wait at least 100 us before enabling wake-up interrupt to enable proper initialization and avoid an early wake-up. This is required due to the slow clock used by wake-up logic.

NOTE

It is expected that USB interface is unplugged or in suspended state. Any USB activity may result in an early wake-up.

3. Configure one source for USB wake-up at USBNC_n_CTRL1 register as follows:
   - USBNC_n_CTRL1[WKUP_DPDM_EN] (Enabled by default)
   - USBNC_n_CTRL1[WKUP_VBUS_EN]
   - USBNC_n_CTRL1[WKUP_ID_EN])
4. Set SIM_DGO_GPR11[USB_PHY_VLLS_WAKEUP_EN] = 1 (SIM_DGO_GPR11 bit 12) to enable wake-up interrupt. (Follow steps described in SIM DGO Register Protocol)
5. Enable LLWU M6IF interrupt to enable M4 wake-up from VLLS by LLWU_ME[WUME6] = 1.

6. Enter A7 VLLS mode.
7. Enter M4 VLLS mode.

When a wake-up activity is detected, a wake-up will be sent to LLWU. LLWU will wake up M4 and generate IRQ20 (LLWU) to M4. M4 should service the interrupt, may read PF[WUF6] and must clear SIM_DGO_GP11[USB_PHY_VLLS_WAKEUP_EN] (Follow steps described in SIM DGO Register Protocol). M4 should wake up A7 using MU.

54.1.3.2 Only A7 in VLLS mode

Follow steps #1 to 4 described in Both CA7 and CM4 are in VLLS mode, then enter A7 VLLS mode. In this case, the wake-up logic will generate an interrupt IRQ69 to M4. M4 should service interrupt, clear SIM_DGO_GP11[USB_PHY_VLLS_WAKEUP_EN] and use MU to wake up A7 as described in Both CA7 and CM4 are in VLLS mode.

54.1.4 Non VLLS Wake-up by USB PHY wakeup

USBPHY wake-up sources may also be used to generate interrupts when CA7 is not in VLLS mode. In this case, SIM_GPR1[USB_PHY_WAKEUP_ISO_DISABLE] and SIM_DGO_GP11[USB_PHY_VLLS_WAKEUP_EN] should not be set but SIM_GPR1[USB_PHY_NON_VLLS_WAKEUP_EN] should be used in place to enable interrupt.

Wake-up logic will generate interrupt IRQ69 to CM4.

54.2 Overview

The USB controller block provides high performance USB functionality that conforms to the *Universal Serial Bus Specification*, Rev. 2.0 (Compaq, Hewlett-Packard, Intel, Lucent, Microsoft, NEC, Philips; 2000), and the *On-The-Go and Embedded Host Supplement to the USB Revision* 2.0 Specification (Hewlett-Packard Company, Intel Corporation, LSI Corporation, Microsoft Corporation, Renesas Electronics Corporation, ST-Ericsson; 2012).

The USB controller consists of independent USB controller cores: two On-The-Go (OTG) controller cores. Each controller core supports UTMI, or ULPI and HSIC interfaces according to its feature. See Features for more details. controller cores are single-port cores. For the OTG cores, there is only one port. For the HSIC interface, there is also only one port which is used as a downstream port.

The following figure is a block diagram of USB.

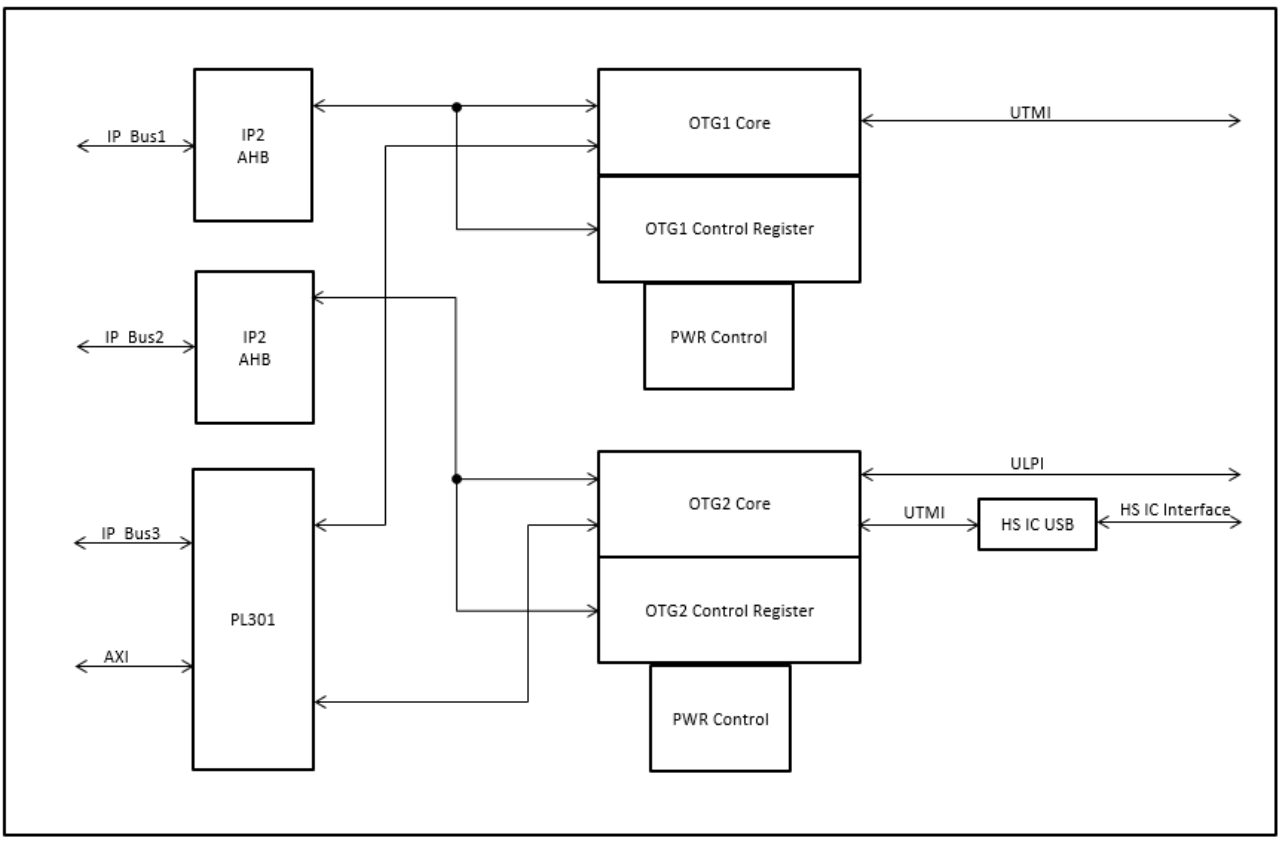

Figure 54-1. USB block diagram

54.2.1 Features

There are USB 2.0 controller cores in this chip:

- Controller Core 0 is also named 'OTG1 Core'; its connected port is named 'OTG1 port'.
- Controller Core 1 is also named 'OTG2 Core'; its connected port is named 'OTG2 port'.

The following list provides features of each of the controller cores.

- USB 2.0 Controller Core 0
  - High-Speed/Full-Speed/Low-Speed OTG core
  - HS/FS/LS UTMI compliant interface
  - High Speed, Full Speed and Low Speed operation in Host mode (with UTMI transceiver)
  - High Speed, and Full Speed operation in Peripheral mode (with UTMI transceiver)

    - Hardware support for OTG signaling, session request protocol, and host negotiation protocol
    - Up to 8 bidirectional endpoints
    - Support charger detection
- USB 2.0 Controller Core 1
    - High-Speed/Full-Speed/Low-Speed OTG core with ULPI interface
    - HS/FS/LS ULPI compliant interface
    - High Speed, Full Speed and Low Speed operation in Host mode (with ULPI transceiver)
    - High Speed, and Full Speed operation in Peripheral mode (with ULPI transceiver)
    - Hardware support for OTG signaling, session request protocol, and host negotiation protocol
    - Up to 8 bidirectional endpoints
    - High-Speed Host-Only core with HSIC interface
    - High Speed Inter-Chip USB compliant interface (HSIC)
- Low-power mode with local and remote wake-up capability
- Embedded DMA controller in each core

54.2.2 Modes of Operation

The USB has two main modes of operation: normal mode and low power mode.

Each USB OTG controller core can operate in High Speed operation (480 Mbps), Full Speed operation (12 Mbps) and Low Speed operation (1.5 Mbps).

This chapter explains the operation modes.

54.2.2.1 Normal Mode

The OTG controller core can operate in Host mode and Device (Peripheral) mode.

Each USB controller core has its corresponding port, which can work in one or more interface modes.

NOTE

Each controller supports only the interface type listed below. Selecting a different interface type in the PORTSC.PTS field results in unpredictable behavior and may cause the system to hang.

- OTG1 port

- This port supports on-chip UTMI transceiver only.

- OTG2 port
  - This port supports on-chip ULPI transceiver.
  - This port supports HSIC interface.

    Interface for on-board HSIC compatible USB peripherals

NOTE

HSIC is an inter-chip interface that is optimized for circuit board layouts.

54.2.2.2 Low-Power Mode

Each USB controller core has a low-power mode (Suspend mode) to save power consumption.

As described in the USB 2.0 specification, the device can go into the Suspend state after it sees a constant Idle state on the upstream facing port. The OTG controller core enters Suspend mode after 3 ms of inactivity on the port when it is in Device Operation mode. Host controllers, including the OTG controller in Host mode, do not suspend automatically but can be placed in Suspend mode by software.

Either the local Arm platform or the remote USB Host/Peripheral can initiate a wake-up sequence to resume USB communication. For details about Suspend/Resume, see USB Power Control.

54.3 External Signals

The table found here describes the external signals of USB.

Table 54-3. USB external signal table

Pin Name	Function		Description
	ALT11	ALT10	
OTG1 Interface

54.4 Functional Description

These sections describe the functionality of the various building blocks of the USB.

54.4.1 USB 2.0 Controller Core 0

The USB 2.0 Controller 0 is an instantiation of an EHCI-compatible core which supports high-, full-, and low-speed operation.

In Host mode, this controller core supports high-, full-, and low-speed operation. In Device mode, it supports high- and full-speed operation.

54.4.1.1 Host Mode

The controller supports direct connection of . a HS/FS/LS device with on-chip UTMI transceiver for USB0 and interface to on-chip HSIC PHY (host only) and ULPI for USB1

Although there is no separate Transaction Translator block in the system, the transaction translator function normally associated with a USB 2.0 high speed hub has been implemented within the DMA and protocol engine blocks to support connection to full and low speed devices.

54.4.1.2 Peripheral (Device) Mode

- Up to eight bidirectional endpoints
- High/full-speed operation
- Support of HNP, and SRP
- Remote wake-up capability

54.4.2 USB 2.0 Controller Core 1

USB 2.0 Controller Core 1 is an instantiation of EHCI-compatible core which supports High Speed / Full Speed / Low Speed operation with ULPI interface. It also supports High Speed operation with HSIC interface.

This USB core's signals connect directly to I/O pins (HSIC interface).

54.4.3 USB Power Control

The USB controller supports suspend and wake-up functionality.

The power control block allows for placing the transceiver in USB low power mode when USB bus is IDLE, and supports local and remote wake-up to bring the transceiver out of USB low power mode when needed. Additionally, the power control block can wake-up the Arm platform from core sleep mode by generating an interrupt.

54.4.3.1 Entering Low Power Suspend Mode

In Host operation mode, low power suspend mode is entered as follows:

1. Clear the ASE and PSE bits in USB_USBCMD, and wait until the AS and PS bits in USB_USBSTS become "0".
2. Set the "SUSPEND" bit in USB_PORTSC1
3. Set the "PHCD" bit in USB_PORTSC1

For device operation mode, low power suspend mode is entered as follows:

1. After Host drive is IDLE for 3ms, an SLI interrupt is issued (the "DCSUSPEND" or "SLI" bit in USB_USBSTS)
2. Set the "PHCD" bit on USB_PORTSC1

54.4.3.2 Wake-Up Events

The power control block monitors the USB bus when the USB core is in the USB suspend state.

Depending on whether the core is on Host or Device mode, a number of wake-up conditions are monitored. Upon detection of a wake-up condition, an interrupt (asynchronous) will be generated to Arm platform if the related wake-up interrupt enable bit is set.

USB wake-up interrupt also re-activates the Arm platform clocks if they were stopped during the suspend.

54.4.3.2.1 Host Mode Events

The host controller wakes up on the following events:

- Remote Wake-up Request

A peripheral can request the host to reactivate the bus by driving wake-up signaling on the DM/DP lines. The power control block sends a wake-up request to the USB core when a J-K transition on DM/DP line is detected.

- Wake-Up On Overcurrent

If Wake-Up On Overcurrent is enabled (WKOC bit in the USB core register PORTSC1 is set '1'), the power control block sends a wake-up request to the USB core when an overcurrent event is detected.

- Wake-Up On Disconnect

If Wake-Up On Disconnect is enabled (WKDC bit in the USB core register PORTSC1 is set '1'), the power control block sends a wake-up request to the USB core when a disconnection event is detected (J-SE0/K-SE0 transition on DM/DP line).

- Wake-Up On Connect

If a Wake-Up On Connect is enabled (WKCN bit in the USB core register PORTSC1 is set '1'), the power control sub-block sends a wake-up request to the USB core when the connection event is detected (SE0-J/SE0-K transition on DM/DP line).

For a detailed description of register bits WKOC, WKDC, WKCN, please see Port Status & Control (USB_*n*PORTSC1).

54.4.4 Interrupts

54.4.4.1 USB Core Interrupts

Each USB core uses one dedicated vector in the Interrupt Table. The vector numbers associated with each of the cores can be found in the Interrupt section.

With the exception of the wake-up interrupts, all of the interrupt sources are controlled in the USB Cores. Refer to the Interrupt Enable Register (USB_*n*USBINTR) for details.

54.4.4.2 USB Wake-Up Interrupts

Each USB Core has an associated wake-up interrupt. The wake-up interrupts are generated outside of the USB controller cores, but using the same vector as the corresponding USB controller cores interrupt.

These interrupts are generated by the Power Control blocks which run on the 32 KHz standby clock. The wake-up interrupt is designed to work even when the USB and Arm platform clocks are disabled, such that a wake-up condition on the USB bus can re-activate the Arm platform clocks.

Because the wake-up interrupt is generated and cleared on a 32 KHz clock, this interrupt request responds very slowly to clear actions. For this reason, the software must disable the wake-up interrupt to clear the request flag. Disabling the interrupt masks the request instantaneously as this is clocked by the Arm platform clock. The software should wait for at least three 32 KHz clock cycles before re-enabling this interrupt to allow sufficient

time for the request flag to clear. Because this interrupt is only used during low power modes of the USB, it is sufficient to enable the wake-up interrupt just prior to entering the USB suspend mode.

54.5 USB Operation Model

This section describes the detailed application knowledge for OTG1 and OTG2 ports.

54.5.1 Register Interface

Configuration, control and status registers are divided into three categories, identification, capability and operational registers.

NOTE

USB controller registers support only DWORD (32-bit) access.

- Identification registers are used to declare the slave interface presence along with the complete set of the hardware configuration parameters.
- Static, read only capability registers define the software limits, restrictions, and capabilities of the host/device controller.
- Operational registers are dynamic control or status registers that may be read only, read/write, or read/write-to-clear. The following sections define the use of these registers.

EHCI registers are listed alongside device registers to show the complementary nature of host and device control.

The following table describes the Interface register sets.

Table 54-4. Interface Register Sets

Offset	Register Set	Explanation
000h-07Ch	Identification Registers	Identification registers are used to declare the slave interface presence and include a table of the hardware configuration parameters.
100h-124h	Capability Registers	Capability registers specify the limits, restrictions, and capabilities of a host/device controller implementation. These values are used as parameters to the host/device controller driver.
080h-0FCh 140h-1FCh	Operational Registers	Operational registers are used by the system software to control and monitor the operational state of the host/device controller.

54.5.1.1 Configuration, Control and Status Register Set

The following table describes the Device/Host capability registers.

NOTE

Depending on implementation, "*x*" can have the following values: UOG1 , UOG2.

Table 54-5. Device/Host Capability Registers

Offset	Size (Bytes)	Mnemonic	Register Name	Device Mode	Host Mode
000h	4	USB_*x*_ID	Identification Register	O	O
004h	4	USB_*x*_HWGENERAL	General Hardware Parameters	O	O

1C0 1C4 ... 1DCh	64	USB_*x*_ENDPTCTRL0 USB_*x*_ENDPTCTRL1 .... USB_*x*_ENDPTCTRL7	Endpoint Control Register 0-7	O	X

NOTE

"O" means the register is available in host/device operation mode;

"X" means the register is reserved in host/device operation mode

54.5.1.2 Identification Registers

Identification registers are used to declare the slave interface presence and include a table of the hardware configuration parameters.

54.5.1.3 OTG Operations

54.5.2 Host Data Structures

This section defines the interface data structures used to communicate control, status, and data between HCD (software) and the Enhanced Host Controller (hardware).

The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of a Periodic Schedule, Periodic Frame List, Asynchronous Schedule, Isochronous Transaction Descriptors, Split-transaction Isochronous Transfer Descriptors, Queue Heads, and Queue Element Transfer Descriptors.

The periodic frame list is the root of all periodic (isochronous and interrupt transfer type) transfers for the host controller. The asynchronous list is the root for all the bulk and control transfers. Isochronous data streams are managed using Isochronous Transaction Descriptors. Isochronous split-transaction data streams are managed with Split-transaction Isochronous Transfer Descriptors. All Interrupt, Control, and Bulk data streams are managed via queue heads and Queue Element Transfer Descriptors. These data structures are optimized to reduce the total memory footprint of the schedule and to reduce (on average) the number of memory accesses needed to execute a USB transaction.

Note that software must ensure that no interface data structure reachable by the EHCI host controller spans a 4 K-page boundary.

The data structures defined in this section are (from the host controller's perspective) a mix of read-only and read/writeable fields. The host controller must preserve the read-only fields on all data structure writes.

54.5.2.1 Periodic Frame List

This schedule is for all periodic transfers (isochronous and interrupt). The periodic schedule is referenced from the operational registers space using the USB_PERIODICLISTBASE address register and the USB_FRINDEX register.

The periodic schedule is based on an array of pointers called the Periodic Frame List.

The USB_PERIODICLISTBASE address register is combined with the USB_FRINDEX register to produce a memory pointer into the frame list. The Periodic Frame List implements a sliding window of work over time.

The following figure shows the organization of periodic schedule.

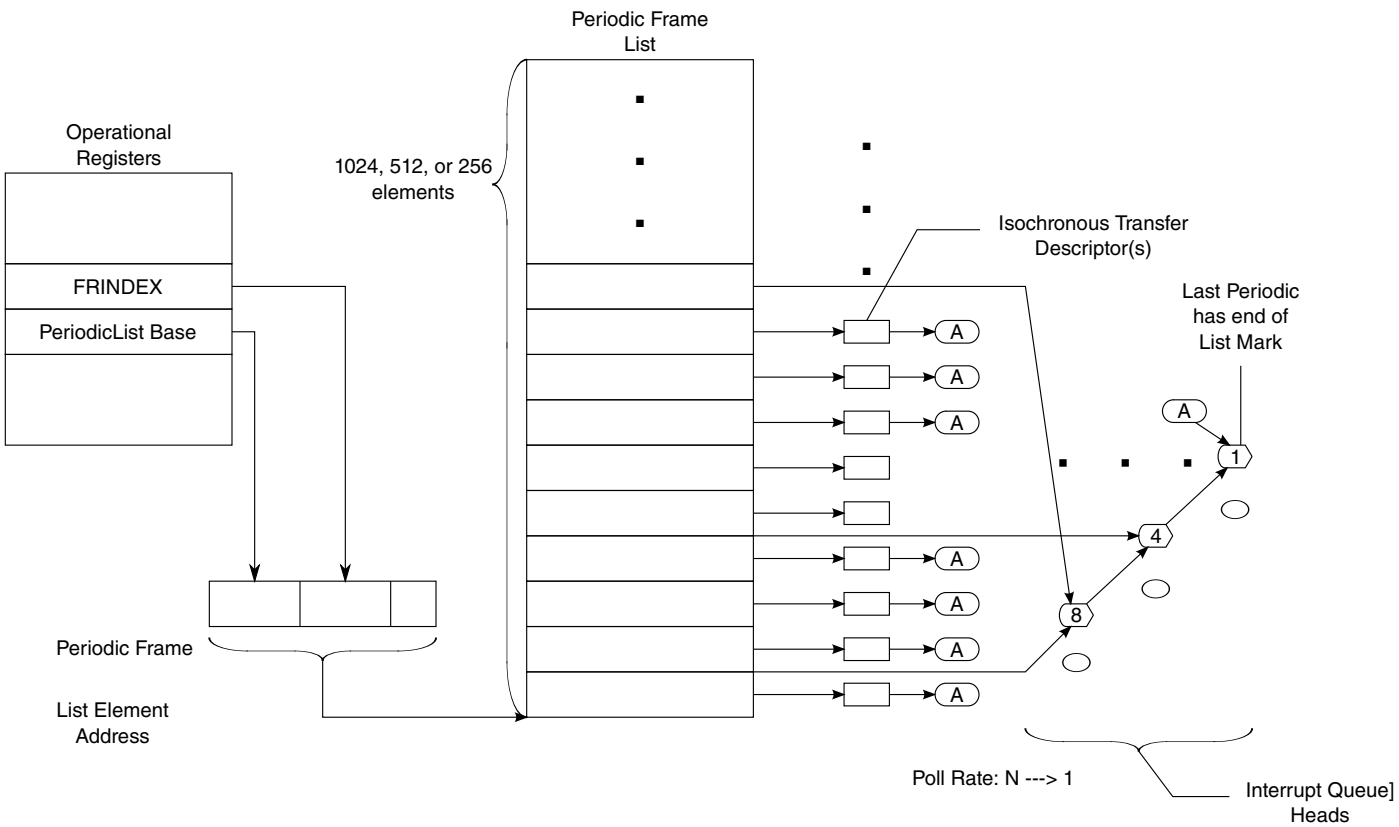

Figure 54-2. Periodic Schedule Organization

Split transaction Interrupt, Bulk and Control are also managed using queue heads and queue element transfer descriptors.

The periodic frame list is a 4 K-page aligned array of Frame List Link pointers. The length of the frame list may be programmable. The programmability of the periodic frame list is exported to system software via the USB_HCCPARAMS register. If non-programmable, the length is 1024 elements. If programmable, the length can be selected by system software as one of 256, 512, or 1024 elements. An implementation must support all three sizes. Programming the size (that is, the number of elements) is accomplished by system software writing the appropriate value into Frame List Size field in the USB_USBCMD register.

Frame List Link pointers direct the host controller to the first work item in the frame's periodic schedule for the current micro-frame. The link pointers are aligned on DWord boundaries within the Frame List.

The table below illustrates the format of the Frame list element pointer.

Table 54-6. Format of Frame List Element Pointer

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Frame List Link Pointer																											0		Typ			03-00H

Frame List Link pointers always reference memory objects that are 32-byte aligned. The referenced object may be an isochronous transfer descriptor for high-speed devices, a split-transaction isochronous transfer descriptor (for full-speed isochronous endpoints), or a queue head (used to support high-, full- and low-speed interrupt). System software should not place non-periodic schedule items into the periodic schedule. The least significant bits in a frame list pointer are used to key the host controller as to the type of object the pointer is referencing.

The least significant bit is the T-Bit (bit 0). When this bit is set to a one, the host controller never uses the value of the frame list pointer as a physical memory pointer. The Typ field is used to indicate the exact type of data structure being referenced by this pointer. The value encodings are.

Table 54-7. Typ Field Value Definitions

Value	Meaning
00b	Isochronous Transfer Descriptor
01b	Queue Head
10b	Split Transaction Isochronous Transfer Descriptor.
11b	Frame Span Traversal Node.

54.5.2.2 Asynchronous List Queue Head Pointer

The Asynchronous Transfer List (based at the USB_ASYNCLISTADDR register) is where all of the control and bulk transfers are managed.

Host controllers use this list only when it reaches the end of the periodic list, the periodic list is disabled, or the periodic list is empty.

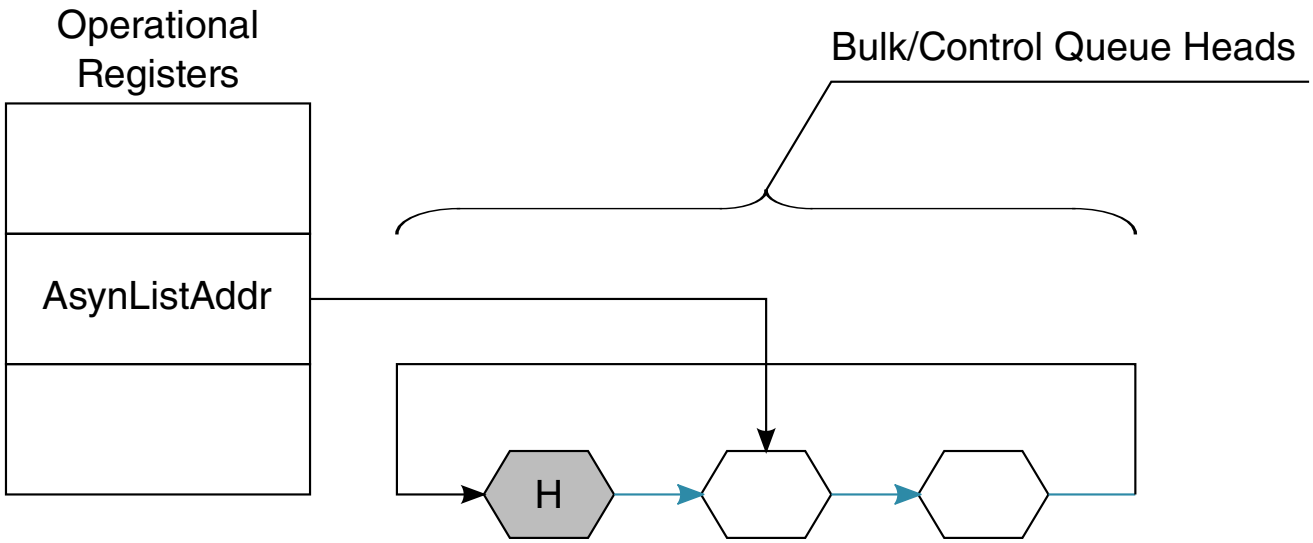

Figure 54-3. Asynchronous Schedule Organization

The Asynchronous list is a simple circular list of queue heads. The USB_ASYNCLISTADDR register is simply a pointer to the next queue head. This implements a pure round-robin service for all queue heads linked into the asynchronous list.

54.5.2.3 Isochronous (High-Speed) Transfer Descriptor (iTD)

The format of an isochronous transfer descriptor is shown in the table below.

This structure is used only for high-speed isochronous endpoints. All other transfer types should use queue structures. Isochronous TDs must be aligned on a 32-byte boundary.

Table 54-8. Isochronous Transaction Descriptor (iTD)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Host Controller Read/Write

Host Controller Read Only

These fields may be modified by the host controller if the I/O field indicates an OUT.

54.5.2.3.1 Next Link Pointer

The first DWord of an iTD is a pointer to the next schedule data structure.

The following table describes the Next Schedule Element pointer field.

Table 54-9. Next Schedule Element Pointer

Bit	Description
31-5 Link Pointer (LP)	These bits correspond to memory address signals [31:5], respectively. This field points to another Isochronous Transaction Descriptor (iTD/siTD) or Queue Head (QH).
4-3	These bits are reserved and their value has no effect on operation. Software should initialize this field to zero.

Table continues on the next page...

Table 54-9. Next Schedule Element Pointer (continued)

Reserved	
2-1 QH/(s)iTD Select (Typ)	This field indicates to the Host Controller whether the item referenced is an iTD, siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor 11b FSTN (frame span traversal node)
0 Terminate (T)	1= Link Pointer field is not valid. 0= Link Pointer field is valid.

54.5.2.3.2 iTD Transaction Status and Control List

DWords 1 through 8 are eight slots of transaction control and status.

Each transaction description includes:

- Status results field
- Transaction length (bytes to send for OUT transactions and bytes received for IN transactions).
- Buffer offset. The PG and Transaction X Offset fields are used with the buffer pointer list to construct the starting buffer address for the transaction.

The host controller uses the information in each transaction description plus the endpoint information contained in the first three DWords of the Buffer Page Pointer list, to execute a transaction on the USB.

The following table describes iTD Transaction Status and Control fields.

Table 54-10. iTD Transaction Status and Control

Bit	Description	
31-28 Status	This field records the status of the transaction executed by the host controller for this slot. This field is a bit vector with the following encoding:	
	Bit	Definition
	31	Active. Set to one by software to enable the execution of an isochronous transaction by the Host Controller. When the transaction associated with this descriptor is completed, the Host Controller sets this bit to zero indicating that a transaction for this element should not be executed when it is next encountered in the schedule.
	30	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). If an overrun condition occurs, no action is necessary.
	29	Babble Detected. Set to one by the Host Controller during status update when" babble" is detected during the transaction generated by this descriptor.

Table continues on the next page...

Table 54-10. iTD Transaction Status and Control (continued)

Bit	Description	
	28	Transaction Error (XactErr). Set to one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). This bit may only be set for isochronous IN transactions.
27-16 Transaction X Length	For an OUT, this field is the number of data bytes the host controller sends during the transaction. The host controller is not required to update this field to reflect the actual number of bytes transferred during the transfer. For an IN, the initial value of the endpoint to deliver. During the status update, the host controller writes back the field is the number of bytes the host expects the number of bytes successfully received. The value in this register is the actual byte count (0‡zero length data, 1‡one byte, 2‡two bytes, etc.). The maximum value this field may contain is 0xC00 (3072).	
15 Interrupt On Complete (IOC)	If this bit is set to one, it specifies that when this transaction completes, the Host Controller should issue an interrupt at the next interrupt threshold.	
14-12 Page Select (PG)	These bits are set by software to indicate which of the buffer page pointers the offset field in this slot should be concatenated to produce the starting memory address for this transaction. The valid range of values for this field is 0 to 6.	
11-0 Transaction X Offset	This field is a value that is an offset, expressed in bytes, from the beginning of a buffer. This field is concatenated onto the buffer page pointer indicated in the adjacent *PG* field to produce the starting buffer address for this transaction.	

54.5.2.3.3 iTD Buffer Page Pointer List (Plus)

DWords 9-15 of an isochronous transaction descriptor are nominally page pointers (4 K aligned) to the data buffer for this transfer descriptor. This data structure requires the associated data buffer to be contiguous (relative to virtual memory), but allows the physical memory pages to be non-contiguous.

Seven page pointers are provided to support the expression of eight isochronous transfers. The seven pointers allow for 3 (transactions) * 1024 (maximum packet size) * 8 (transaction records) (24576 bytes) to be moved with this data structure, regardless of the alignment offset of the first page.

Because each pointer is a 4 K aligned page pointer, the least significant 12 bits in several of the page pointers are used for other purposes.

The tables below illustrate the field descriptions.

Table 54-11. iTD Buffer Pointer Page 0 (Plus)

Bit	Description
31-12 Buffer Pointer (Page 0)	This is a 4 K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11-8 Endpoint Number (Endpt)	This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.

Table continues on the next page...

Table 54-11. iTD Buffer Pointer Page 0 (Plus) (continued)

Bit	Description
7 Reserved	Bit reserved for future use and should be initialized by software to zero.
6-0 Device Address	This field selects the specific device serving as the data source or sink.

Table 54-12. iTD Buffer Pointer Page 1 (Plus)

Bit	Description
31-12 Buffer Pointer (Page 1)	This is a 4K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11 Direction (I/O)	0 = OUT; 1 = IN. This field encodes whether the high-speed transaction should use an IN or OUT PID.
10-0 Maximum Packet Size	This directly corresponds to the maximum packet size of the associated endpoint *(wMaxPacketSize)*. This field is used for high-bandwidth endpoints where more than one transaction is issued per transaction description (per micro-frame). This field is used with the *Multi* field to support high-bandwidth pipes. This field is also used for all IN transfers to detect packet babble. Software should not set a value larger than 1024 (400h). Any value larger yields undefined results.

Table 54-13. iTD Buffer Pointer Page 2 (Plus)

Bit	Description
31-12 Buffer Pointer	This is a 4K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11-2 Reserved	This bit reserved for future use and should be set to zero.
1-0 Multi	This field is used to indicate to the host controller the number of transactions that should be executed per transaction description (per micro-frame). The valid values are: Value Meaning 00b Reserved. A zero in this field yields undefined results. 01b One transaction to be issued for this endpoint per micro- frame. 10b Two transactions to be issued for this endpoint per micro- frame. 11b Three transactions to be issued for this endpoint per micro- frame.

Table 54-14. iTD Buffer Pointer Page 3-6

Bit	Description
31-12 Buffer Pointer	This is a 4 K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11-0 Reserved	These bits reserved for future use and should be set to zero.

54.5.2.4 Split Transaction Isochronous Transfer Descriptor (siTD)

All Full-speed isochronous transfers through the internal transaction translator are managed using the siTD data structure. This data structure satisfies the operational requirements for managing the split transaction protocol.

The following table shows the Split Transaction Isochronous Transfer Descriptor (siTD).

Table 54-15. Split Transaction Isochronous Transfer Descriptor

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Addr

Host Controller Read Only

54.5.2.4.1 Next Link Pointer

DWord0 of a siTD is a pointer to the next schedule data structure.

The following table describes the Next Link Pointer fields.

Table 54-16. Next Link Pointer

Bit	Description
31-5	Next Link Pointer (LP). This field contains the address of the next data object to be processed in the periodic list and corresponds to memory address signals [31:5], respectively.

Table continues on the next page...

Table 54-16. Next Link Pointer (continued)

Bit	Description
4-3	Reserved. These bits must be written as zeros.
2-1	QH/(s)iTD Select (Typ). This field indicates to the Host Controller whether the item referenced is an iTD/siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor 11b FSTN (frame span traversal node)
0	Terminate (T). 1 = Link Pointer field is not valid. 0 = Link Pointer is valid.

54.5.2.4.2 siTD Endpoint Capabilities/Characteristics

DWords 1 and 2 specify static information about the full-speed endpoint, the addressing of the parent Companion Controller, and micro-frame scheduling control.

The tables below describe the Endpoint and transaction translator characteristics and micro-frame schedule control fields.

Table 54-17. Endpoint and Transaction Translator Characteristics

Bit	Description
31	Direction (I/O).0 = OUT; 1 = IN. This field encodes whether the full-speed transaction should be an IN or OUT.
30-24	Port Number. This field is the port number of the recipient Transaction Translator.
23	Reserved. Bit reserved and should be set to zero.
22-16	Hub Address. This field holds the device address of the Companion Controllers' hub.
15-12	Reserved. Field reserved and should be set to zero.
11-8	Endpoint Number (Endpt). This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.
7	Reserved. Bit is reserved for future use. It should be set to zero.
6-0	Device Address. This field selects the specific device serving as the data source or sink.

Table 54-18. Micro-frame Schedule Control

Bit	Description
31-16	Reserved. This field reserved for future use. It should be set to zero.
15-8	Split Completion Mask (mFrame C-Mask). This field (along with the *Active* and *SplitX- state* fields in the *Status* byte) is used to determine during which micro-frames the host controller should execute complete-split transactions. When the criteria for using this field is met, an all zeros value has undefined behavior. The host

Table continues on the next page...

Table 54-18. Micro-frame Schedule Control (continued)

Bit	Description
	controller uses the value of the three low-order bits of the FRINDEX register to index into this bit field. If the FRINDEX register value indexes to a position where the m*Frame C-Mask* field is a one, then this siTD is a candidate for transaction execution. There may be more than one bit in this mask set.
7-0	Split Start Mask (mFrame S-mask). This field (along with the *Active* and *SplitX-state* fields in the *Status* byte) is used to determine during which micro-frames the host controller should execute start-split transactions. The host controller uses the value of the three low-order bits of the FRINDEX register to index into this bit field. If the FRINDEX register value indexes to a position where the m*Frame S-mask* field is a one, then this siTD is a candidate for transaction execution. An all zeros value in this field, in combination with existing periodic frame list has undefined results.

54.5.2.4.3 siTD Transfer State

DWords 3-6 are used to manage the state of the transfer.

The following table describes siTD transfer state fields.

Table 54-19. siTD Transfer Status and Control

Bit	Description
31	Interrupt On Complete (ioc). 0 = Do not interrupt when transaction is complete. 1 = Do interrupt when transaction is complete. When the host controller determines that the split transaction has completed it asserts a hardware interrupt at the next interrupt threshold.
30	Page Select (P). Used to indicate which data page pointer should be concatenated with the *CurrentOffset* field to construct a data buffer pointer (0 selects *Page 0* pointer and 1 selects *Page 1*). The host controller is not required to write this field back when the siTD is retired (*Active* bit transitioned from a one to a zero).
29-26	Reserved. This field reserved for future use and should be set to zero.
25-16	Total Bytes To Transfer. This field is initialized by software to the total number of bytes expected in this transfer. Maximum value is 1023 (3FFh)
15-8	µFrame Complete-split Progress Mask (C-prog-Mask). This field is used by the host controller to record which split-completes has been executed.
7-0: Status—This field records the status of the transaction executed by the host controller for this slot. It is a bit vector with the encoding shown in the following rows.	
7	Active. Set to one by software to enable the execution of an isochronous split transaction by the Host Controller.
6	ERR. Set to a one by the Host Controller when an ERR response is received from the Companion Controller.
5	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). In the case of an under run, the Host Controller transmits an incorrect CRC (thus invalidating the data at the endpoint). If an overrun condition occurs, no action is necessary.
4	Babble Detected. Set to a one by the Host Controller during status update when" babble" is detected during the transaction generated by this descriptor.
3	Transaction Error (XactErr). Set to a one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). This bit is set only for IN transactions.
2	Missed Micro-Frame. The host controller detected that a host-induced hold- off caused the host controller to miss a required complete-split transaction.

Table continues on the next page...

Table 54-19. siTD Transfer Status and Control (continued)

Bit	Description
1	Split Transaction State (SplitXstate). The bit encodings are: Value Meaning 00b Do Start Split. This value directs the host controller to issue a Start split transaction to the endpoint when a match is encountered in the S-mask. 01b Do Complete Split. This value directs the host controller to issue a Complete split transaction to the endpoint when a match is encountered in the C-mask.
0	Reserved. Bit reserved for future use and should be set to zero.

54.5.2.4.4 siTD Buffer Pointer List (plus)

DWords 4 and 5 are the data buffer page pointers for the transfer. This structure supports one physical page cross. The most significant 20 bits of each DWord in this section are the 4 K (page) aligned buffer pointers.

The least significant 12 bits of each DWord are used as additional transfer state. The following table describes the siTD buffer pointer fields.

Table 54-20. Buffer Page Pointer List (plus)

Bit	Description
31-12	Buffer Pointer List. Bits [31:12] of DWords 4 and 5 are 4 K page aligned physical memory addresses. These bits correspond to physical address bits [31:12] respectively. The lower 12 bits in each pointer are defined and used as specified below. The field *P* (see siTD Transfer State) specifies the *current* active pointer.
Bits 11-0 (Page 0)	Current Offset—The 12 least significant bits of the Page 0 pointer are the current byte offset for the current page pointer (as selected with the page indicator bit (*P* field). The host controller is not required to write this field back when the siTD is retired (*Active* bit transitioned from a one to a zero).
Bits 11-0 (Page 1)—The least significant bits of the Page 1 pointer are split into three subfields as shown in the following rows.	
11-5 (Page 1)	Reserved
4-3 (Page 1)	Transaction position (TP). This field is used with T-count to determine whether to send *all*, *first*, *middle*, or *last* with each outbound transaction payload. System software must initialize this field with the appropriate starting value. The host controller must correctly manage this state during the lifetime of the transfer. The bit encodings are: Value Meaning 00b All. The entire full-speed transaction data payload is in this transaction (that is, less than or equal to 188 bytes). 01b Begin. This is the first data payload for a full- speed that is greater than 188 bytes. 10B Mid. This is the *middle* payload for a full-speed OUT transaction that is larger than 188 bytes.

Table continues on the next page...

Table 54-20. Buffer Page Pointer List (plus) (continued)

Bit	Description
	11b End. This is the *last* payload for a full-speed OUT transaction that was larger than 188 bytes.
2-0 (Page 1)	Transaction count (T-Count). Software initializes this field with the number of OUT start-splits this transfer requires. Any value larger than 6 is undefined.

54.5.2.4.5 siTD Back Link Pointer

DWord 6 of a siTD is simply another schedule link pointer. This pointer is always zero, or references a siTD, and it cannot reference any other schedule data structure.

The following table describes the siTD back link pointer fields.

Table 54-21. siTD Back Link Pointer

Bit	Description
31-5	siTD Back Pointer. This field is a physical memory pointer to a siTD.
4-1	Reserved. This field is reserved for future use. It should be set to zero.
0	Terminate (T). 1 = siTD Back Pointer field is not valid. 0 = siTD Back Pointer field is valid.

54.5.2.5 Queue element transfer descriptor (qTD)

This data structure is only used with a queue head. It describes one or more USB transactions to transfer up to 20480 (5*4096) bytes.

The structure contains two structure pointers used for queue advancement, a DWord of transfer state, and a five-element array of data buffer pointers.

It is 32 bytes and must be physically contiguous.

The buffer associated with this transfer must be virtually contiguous. The buffer may start on any byte boundary; however, for optimal utilization of on-chip busses it is recommended to align the buffers on a 32-byte boundary. A separate buffer pointer list element must be used for each physical page in the buffer, regardless of whether the buffer is physically contiguous.

Host controller updates (host controller writes) to stand-alone qTDs only occur during transfer retirement. References in the following bit field definitions of updates to the qTD are to the qTD portion of a queue head.

The following table shows the queue element transfer descriptor data structure.

Table 54-22. Queue element transfer descriptor data structure

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Addr

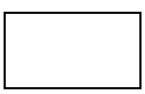
1. 08-0F: Transfer Results

Host Controller Read/Write



Host Controller Read Only

Queue Element Transfer Descriptors must be aligned on 32-byte boundaries.

54.5.2.5.1 Next qTD Pointer

The first DWord of an element transfer descriptor is a pointer to another transfer element descriptor.

The following table describes Next qTD pointer fields.

Table 54-23. qTD Next Element Transfer Pointer (DWord 0)

Bit	Description
31-5	Next Transfer Element Pointer. This field contains the physical memory address of the next qTD to be processed. The field corresponds to memory address signals[31:5], respectively.
4-1	Reserved

Table continues on the next page...

Table 54-23. qTD Next Element Transfer Pointer (DWord 0) (continued)

0	Terminate (T). 1= pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Host Controller that there are no more valid entries in the queue.

54.5.2.5.2 Alternate Next qTD Pointer

The second DWord of a queue element transfer descriptor is used to support hardware-only advance of the data stream to the next transfer descriptor on short packet. To be more explicit the host controller always uses this pointer when the current qTD is retired due to short packet.

The following table describes the TD Alternate Next Element Transfer Pointer field descriptions.

Table 54-24. TD Alternate Next Element Transfer Pointer (DWord 1)

Bit	Description
31-5	Alternate Next Transfer Element Pointer. This field contains the physical memory address of the next qTD to be processed in the event that the current qTD execution encounters a short packet (for an IN transaction). The field corresponds to memory address signals [31:5], respectively.
4-1	Reserved
0	Terminate (T). 1= pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Host Controller that there are no more valid entries in the queue.

54.5.2.5.3 qTD Token

The third DWord of a queue element transfer descriptor contains most of the information the host controller requires to execute a USB transaction (the remaining endpoint-addressing information is specified in the queue head).

NOTE

The field descriptions forward reference fields defined in the queue head. Where necessary, these forward references are preceded with a QH notation.

The following table describes the TD Token fields.

Table 54-25. TD Token (DWord 2)

Bit	Description
31 Data Toggle	This is the data toggle sequence bit. The use of this bit depends on the setting of the *Data Toggle Control* bit in the queue head.

Table continues on the next page...

Table 54-25. TD Token (DWord 2) (continued)

<table>
<tr><th>Bit</th><th>Description</th></tr>
<tr><td>30-16
Total Bytes to Transfer</td><td>This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction, only on the successful completion of the transaction. The maximum value software may store in this field is 5 * 4K (5000H). This is the maximum number of bytes 5 page pointers can access. If the value of this field is zero when the host controller fetches this transfer descriptor (and the active bit is set), the host controller executes a zero-length transaction and retires the transfer descriptor. It is not a requirement for OUT transfers that Total Bytes To Transfer be an even multiple of QHD.Maximum Packet Length. If software builds such a transfer descriptor for an OUT transfer, the last transaction is always less than QHD.Maximum Packet Length.

Although it is possible to create a transfer up to 20K this assumes the 1st offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16K**. Therefore, the maximum recommended transfer is 16 K(4000H).</td></tr>
<tr><td>15
Interrupt On Complete (IOC)</td><td>If this bit is set to a one, it specifies that when this qTD is completed, the Host Controller should issue an interrupt at the next interrupt threshold.</td></tr>
<tr><td>14-12
Current Page (C_Page)</td><td>This field is used as an index into the qTD buffer pointer list. Valid values are in the range 0H to 4H. The host controller is not required to write this field back when the qTD is retired.</td></tr>
<tr><td>11-10
Error Counter (CERR)</td><td>This field is a 2-bit down counter that keeps track of the number of consecutive Errors detected while executing this qTD. If this field is programmed with a non-zero value during set-up, the Host Controller decrements the count and writes it back to the qTD if the transaction fails. If the counter counts from one to zero, the Host Controller marks the qTD inactive, sets the Halted bit to a one, and error status bit for the error that caused CERR to decrement to zero. An interrupt is generated if the USB Error Interrupt Enable bit in the USBINTR register is set to a one. If HCD programs this field to zero during set-up, the Host Controller does not count errors for this qTD and there is no limit on the retries of this qTD. Note that write-backs of intermediate execution state are to the queue head overlay area, not the qTD.

Transaction Error - Decrement

Data Buffer Error - No Decrement[3]

Stalled - No Decrement[1]

Babble Detected - No Decrement[1]

No Error - No Decrement[2]
<table>
<tr><th>Error</th><th>Decrement Counter</th></tr>
<tr><td>1</td><td>Detection of Babble or Stall automatically halts the queue head. Thus, count is not decremented</td></tr>
<tr><td>2</td><td>If the EPS field indicates a HS device or the queue head is in the Asynchronous Schedule (and PIDCode indicates an IN or OUT) and a bus transaction completes and the host controller does not detect a transaction error, then the host controller should reset CERR to extend the total number of errors for this transaction. For example, CERR should be reset with maximum value (3) on each successful completion of a transaction. The host controller must never reset this field if the value at the start of the transaction is 00b.

See Split Transaction Interrupt for CERR adjustment rules when the EPS field indicates a FS or LS device and the queue head is in the Periodic Schedule. See Asynchronous - Do Complete Split for CERR adjustment rules when the EPS field indicates a FS or LS device, the queue head is in the Asynchronous schedule and the PIDCode indicates a SETUP.</td></tr>
</table></td></tr>
</table>

Table continues on the next page...

Table 54-25. TD Token (DWord 2) (continued)

Bit	Description	
	3	Data buffer errors are host problems. They don't count against the device's retries.
	NOTE: Software must not program CERR to a value of zero when the EPS field is programmed with a value indicating a Full- or Low-speed device. This combination could result in undefined behavior.	
9-8 PID Code	This field is an encoding of the token, which should be used for transactions associated with this transfer descriptor. Encodings are:	
	00b	OUT Token generates token (E1H)
	01b	IN Token generates token (69H)
	10b	SETUP Token generates token (2DH) (undefined if endpoint is an interrupt, the queue head is non-zero) transfer type, for example, µ*Frame S-mask* field in.
	11b	Reserved
7-0 Status	This field is used by the Host Controller to communicate individual command execution states back to HCD. This field contains the status of the last transaction performed on this qTD. The bit encodings are:	
	Bit	Status Field Description
	7	Active. Set to one by software to enable the execution of transactions by the Host Controller.
	6	Halted. Set to one by the Host Controller during status updates to indicate that a serious error has occurred at the device/endpoint addressed by this qTD. This can be caused by babble, the error counter counting down to zero, or reception of the STALL handshake from the device during a transaction. Any time that a transaction results in the Halted bit being set to a one, the Active bit is also set to zero.
	5	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). If an overrun condition occurs, the Host Controller forces a timeout condition on the USB, invalidating the transaction at the source. If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
	4	Babble Detected. Set to a one by the Host Controller during status update when" babble" is detected during the transaction. In addition to setting this bit, the Host Controller also sets the *Halted* bit to a one. Because "babble" is considered a fatal error for the transfer, setting the Halted bit to a one insures that no more transactions occur because of this descriptor.
	3	Transaction Error (XactErr). Set to a one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
	2	Missed Micro-Frame. This bit is ignored unless the *QH.EPS* field indicates a full- or low-speed endpoint and the queue head is in the periodic list. This bit is set when the host controller detected that a host-induced hold-off caused the host controller to miss a required complete-split transaction. If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
	1	Split Transaction State (SplitXstate). This bit is ignored by the host controller unless the *QH.EPS* field indicates a full- or low-speed endpoint. When a Full- or Low-speed device, the host controller uses this bit to track the state of the split-

Table continues on the next page...

Table 54-25. TD Token (DWord 2) (continued)

Bit	Description	
		transaction. The functional requirements of the host controller for managing this state bit and the split transaction protocol depends on whether the endpoint is in the periodic or asynchronous schedule. The bit encodings are: Value Meaning 0b Do Start Split. This value directs the host controller to issue a Start split transaction to the endpoint. 1b Do Complete Split. This value directs the host controller to issue a Complete split transaction to the endpoint.
	0	Ping State (P)/ERR. If the *QH.EPS* field indicates a High-speed device and the *PID_Code* indicates an OUT endpoint, then this is the state bit for the Ping protocol. The bit encodings are: Value Meaning 0b Do OUT. This value directs the host controller to issue an OUT PID to the endpoint. 1b Do Ping. This value directs the host controller to issue a PING PID to the endpoint. If the *QH.EPS* field does not indicate a High-speed device, then this field is used as an error indicator bit. It is set to a one by the host controller whenever a periodic split-transaction receives an ERR handshake.

54.5.2.5.4 qTD Buffer Page Pointer List

The last five DWords of a queue element transfer descriptor is an array of physical memory address pointers. These pointers reference the individual pages of a data buffer.

System software initializes Current Offset field to the starting offset into the current page, where current page is selected through the value in the C_Page field.

The following table describes the qTD Buffer Pointer(s) (DWords 3-7) fields.

Table 54-26. qTD Buffer Pointer(s) (DWords 3-7)

Bit	Description
31-12	Buffer Pointer List. Each element in the list is a 4 K page aligned physical memory address. The lower 12 bits in each pointer are reserved (except for the first one), as each memory pointer must reference the start of a 4 K page. The field C_Page specifies the current active pointer. When the transfer element descriptor is fetched, the starting buffer address is selected using C_Page (similar to an array index to select an array element). If a transaction spans a 4K buffer boundary, the host controller must detect the page-span boundary in the data stream, increment C_Page and advance to the next buffer pointer in the list, and conclude the transaction through the new buffer pointer.
11-0	Current Offset (Reserved). This field is reserved in all pointers except the first one (for example Page 0). The host controller should ignore all reserved bits. For the page 0 current offset interpretation, this field is the byte offset into the current page (as selected by C_Page). The host controller is not required to write this field back when the qTD is retired. Software should ensure the Reserved fields are initialized to zero.

54.5.2.6 Queue Head

The table located in this section shows the Queue Head structure layout.

The following table shows the queue head structure layout.

Table 54-27. Queue Head Structure Layout

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Addr
Queue Head Horizontal Link Pointer																											0		Typ		T	03-00
RL				C	Maximum Packet Length											H	dtc	EP		EndPt				I	Device Address							07-04[1]

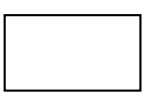
Buffer Pointer (Page 4)																				Reserved												2F-2C[3]

1. 04-0B: Static endpoint state.
2. These fields are used exclusively to support split transactions to USB 2.0 hubs
3. 10-2F: Transfer overlay.
4. 14-27: Transfer results.

Host Controller Read/Write



Host Controller Read Only

54.5.2.6.1 Queue Head Horizontal Link Pointer

The first DWord of a Queue Head contains a link pointer to the next data object to be processed after any required processing in this queue has been completed, as well as the control bits defined below.

This pointer may reference a queue head or one of the isochronous transfer descriptors. It must not reference a queue element transfer descriptor.

The following table describes the Queue head DWord 0 fields.

Table 54-28. Queue Head DWord 0

Bit	Description
31-5	Queue Head Horizontal Link Pointer (QHLP). This field contains the address of the next data object to be processed in the horizontal list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	QH/(s)iTD Select (Typ). This field indicates to the hardware whether the item referenced by the link pointer is an iTD, siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor) 11b FSTN (frame span traversal node)
0	Terminate (T). 1=Last QH (pointer is invalid). 0=Pointer is valid. If the queue head is in the context of the periodic list, a one bit in this field indicates to the host controller that this is the end of the periodic list. This bit is ignored by the host controller when the queue head is in the Asynchronous schedule. Software must ensure that queue heads reachable by the host controller always have valid horizontal link pointers.

54.5.2.6.2 Queue Head Endpoint Capabilities/Characteristics

The second and third DWords of a Queue Head specifies static information about the endpoint. This information does not change over the lifetime of the endpoint.

There are three types of information in this region:

- Endpoint Characteristics. These are the USB endpoint characteristics including addressing, maximum packet size, and endpoint speed.
- Endpoint Capabilities. These are adjustable parameters of the endpoint. They effect how the endpoint data stream is managed by the host controller.
- Split Transaction Characteristics. This data structure is used to manage full- and low-speed data streams for bulk, control, and interrupt via split transactions to USB2.0 Hub Transaction Translator. There are additional fields used for addressing the hub and scheduling the protocol transactions (for periodic).

The host controller must not modify the bits in this region.

The following table describes the Endpoint characteristics: Queue head DWord 1 fields.

Table 54-29. Endpoint Characteristics: Queue Head DWord 1

Bit	Description	
31-28	Nak Count Reload (RL). This field contains a value, which is used by the host controller to reload the Nak Counter field.	
27	Control Endpoint Flag (C). If the *QH.EPS* field indicates the endpoint is not a high-speed device, and the endpoint is a control endpoint, then software must set this bit to a one. Otherwise, it should always set this bit to zero.	
26-16	Maximum Packet Length. This directly corresponds to the maximum packet size of the associated endpoint (*wMaxPacketSize*). The maximum value this field may contain is 0x400 (1024).	
15	Head of Reclamation List Flag (H). This bit is set by System Software to mark a queue head as being the head of the reclamation list.	
14	Data Toggle Control (DTC). This bit specifies where the host controller should get the initial data toggle on an overlay transition. 0b Ignore DT bit from incoming qTD. Host controller preserves DT bit in the queue head. 1b Initial data toggle comes from incoming qTD DT bit. Host controller replaces DT bit in the queue head from the DT bit in the qTD.	
13-12	Endpoint Speed (EPS). This is the speed of the associated endpoint. Bit combinations are:	
	Value	Meaning
	00b	Full-Speed (12 Mbits/sec)
	01b	Low-Speed (1.5 Mbits/sec)
	10b	High-Speed (480 Mbits/sec)
	11b	Reserved
	This field must not be modified by the host controller.	
11-8	Endpoint Number (Endpt). This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.	
7	Inactivate on Next Transaction (I). This bit is used by system software to request that the host controller set the Active bit to zero. See Rebalancing the periodic schedule , for full operational details. This field is only valid when the queue head is in the Periodic Schedule and the *EPS* field indicates a Full or Low-speed endpoint. Setting this bit to one when the queue head is in the Asynchronous Schedule or the *EPS* field indicates a high-speed device yields undefined results.	
6-0	Device Address. This field selects the specific device serving as the data source or sink.	

The table below describes the Endpoint capabilities: Queue head DWord 2 field descriptions.

Table 54-30. Endpoint Capabilities: Queue Head DWord 2

Bit	Description
31-30	High-Bandwidth Pipe Multiplier (Mult). This field is a multiplier used to key the host controller as the number of successive packets the host controller may submit to the endpoint in the current execution. The host controller makes the simplifying assumption that software properly initializes this field (regardless of location of queue head in the schedules or other run time parameters). The valid values are: Value Meaning

Table continues on the next page...

Table 54-30. Endpoint Capabilities: Queue Head DWord 2 (continued)

	00b Reserved. A zero in this field yields undefined results. 01b One transaction to be issued for this endpoint per micro-frame. 10b Two transactions to be issued for this endpoint per micro-frame. 11b Three transactions to be issued for this endpoint per micro-frame.
29-23	Port Number. This field is ignored by the host controller unless the *EPS* field indicates a full- or low-speed device. The value is the port number identifier on the USB 2.0 Hub (for hub at device address *Hub Addr* below), below which the full- or low-speed device associated with this endpoint is attached. This information is used in the split-transaction protocol.
22-16	Hub Addr. This field is ignored by the host controller unless the *EPS* field indicates a full-or low-speed device. The value is the USB device address of the USB 2.0 Hub below which the full- or low-speed device associated with this endpoint is attached. This field is used in the split-transaction protocol.
15-8	Split Completion Mask (µFrame C-Mask). This field is ignored by the host controller unless the *EPS* field indicates this device is a low- or full-speed device and this queue head is in the periodic list. This field (along with the *Active* and *SplitX-state* fields) is used to determine during which micro-frames the host controller should execute a complete-split transaction. When the criteria for using this field are met, a zero value in this field has undefined behavior. This field is used by the host controller to match against the three low-order bits of the FRINDEX register. If the FRINDEX register bits decode to a position where the µ*Frame C- Mask* field is a one, then this queue head is a candidate for transaction execution. There may be more than one bit in this mask set.
7-0	Interrupt Schedule Mask (µFrame S-mask). This field is used for all endpoint speeds. Software should set this field to a zero when the queue head is on the asynchronous schedule. A non-zero value in this field indicates an interrupt endpoint. The host controller uses the value of the three low-order bits of the FRINDEX register as an index into a bit position in this bit vector. If the µ*Frame S-mask* field has a one at the indexed bit position then this queue head is a candidate for transaction execution. If the *EPS* field indicates the endpoint is a high-speed endpoint, then the transaction executed is determined by the *PID_Code* field contained in the execution area. This field is also used to support split transaction types: Interrupt (IN/OUT). This condition is true when this field is non-zero and the *EPS* field indicates this is either a full- or low-speed device. A zero value in this field, in combination with existing in the periodic frame list has undefined results.

54.5.2.6.3 Transfer Overlay-Queue Head

The nine DWords in this area represent a transaction working space for the host controller. The general operational model is that the host controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it follows the Queue Head Horizontal Link Pointer to the next queue head. The host controller will never follow the Next Transfer Queue Element or Alternate Queue Element pointers unless it is actively attempting to advance the queue. For the duration of the transfer, the host controller keeps the incremental status of the transfer in the overlay area. When the transfer is complete, the results are written back to the original queue element.

The DWord3 of a Queue Head contains a pointer to the source qTD currently associated with the overlay. The host controller uses this pointer to write back the overlay area into the source qTD after the transfer is complete.

The following table describes the current qTD link pointer field descriptions.

Table 54-31. Current qTD Link Pointer

Bit	Description
31-5	Current Element Transaction Descriptor Link Pointer. This field contains the address Of the current transaction being processed in this queue and corresponds to memory address signals [31:5], respectively.
4-0	Reserved (R). These bits are ignored by the host controller when using the value as an address to write data. The actual value may vary depending on the usage.

The DWords 4-11 of a queue head are the transaction overlay area. This area has the same base structure as a Queue Element Transfer Descriptor. The queue head utilizes the reserved fields of the page pointers to implement tracking the state of split transactions.

This area is characterized as an overlay because when the queue is advanced to the next queue element, the source queue element is merged onto this area. This area serves as execution cache for the transfer.

The table below describes the Host-controller rules for bits in overlay.

Table 54-32. Host-Controller Rules for Bits in Overlay (DWords 5, 6, 8 and 9)

DWord	Bit	Description
5	4-1	Nak Counter (NakCnt)µRW. This field is a counter the host controller decrements whenever a transaction for the endpoint associated with this queue head results in a Nak or Nyet response. This counter is reloaded from *RL* before a transaction is executed during the first pass of the reclamation list (relative to an Asynchronous List Restart condition). It is also loaded from RL during an overlay.
6	31	Data Toggle. The *Data Toggle Control* controls whether the host controller preserves this bit when an overlay operation is performed.
6	15	Interrupt On Complete (IOC). The IOC control bit is always inherited from the source qTD when the overlay operation is performed.
6	11-10	Error Counter (C_ERR). This two-bit field is copied from the qTD during the overlay and written back during queue advancement.
6	0	Ping State (P)/ERR. If the *EPS* field indicates a high-speed endpoint, then this field should be preserved during the overlay operation.
8	7-0	Split-transaction Complete-split Progress (C-prog-mask). This field is initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.
9	4-0	Split-transaction Frame Tag (Frame Tag). This field is initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.
9	11-5	S-bytes. Software must ensure that the *S-bytes* field in a *qTD* is zero before activating the *qTD*. This field is used to keep track of the number of bytes sent or received during an IN or OUT split transaction.

54.5.2.7 Periodic Frame Span Traversal Node (FSTN)

This data structure is to be used only for managing Full- and Low-speed transactions that span a Host-frame boundary.

See Host Controller Operational Model for FSTNs for full operational details. Software must not use an FSTN in the Asynchronous Schedule. An FSTN in the Asynchronous schedule results in undefined behavior. Software must not use the FSTN feature with a host controller whose USB_HCIVERSION register indicates a revision implementation below 0096h. FSTNs are not defined for implementations before 0.96 and their use yields undefined results.

Table 54-33. Frame Span Traversal Node Structure Layout

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Addr
Normal Path Link Pointer																											0		Typ		T	03-00
Back Path Link Pointer																											0		Typ[1]		T	07-04

1. Must be set to indicate a queue head

Host Controller Read/Write

Host Controller Read Only

54.5.2.7.1 FSTN Normal Path Pointer

The first DWord of an FSTN contains a link pointer to the next schedule object. This object can be of any valid periodic schedule data type.

The following table describes the FSTN normal path pointer fields.

Table 54-34. FSTN Normal Path Pointer Field Descriptions

Bit	Description
31-5	Normal Path Link Pointer (NPLP). This field contains the address of the next data object to be processed in the periodic list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	QH/(s)iTD/FSTN Select (Typ). This field indicates to the Host Controller whether the item referenced is a iTD/siTD, a QH or an FSTN. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor) 11b FSTN (Frame Span Traversal Node)
0	Terminate (T). 1 = Link Pointer field is not valid. 0 = Link Pointer is valid.

54.5.2.7.2 FSTN Back Path Link Pointer

The second DWord of an FTSN node contains a link pointer to a queue head.

If the T-bit in this pointer is zero, then this FSTN is a Save-Place indicator. Its Typ field must be set by software to indicate the target data structure is a queue head. If the T-bit in this pointer is set to one, then this FSTN is the Restore indicator. When the T-bit is one, the host controller ignores the Typ field.

The following table describes the FSTN back path link pointer fields.

Table 54-35. FSTN Back Path Link Pointer Field Descriptions

Bit	Description
31-5	Back Path Link Pointer (BPLP). This field contains the address of a Queue Head. This field corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	Typ. Software must ensure this field is set to indicate the target data structure is a Queue Head. Any other value in this field yields undefined results.
0	Terminate (T). 1=Link Pointer field is not valid (that is the host controller must not use bits [31:5] as a valid memory address). This value also indicates that this FSTN is a Restore indicator. 0=Link Pointer is valid (that is the host controller may use bits [31:5] (in combination with the CTRLDSSEGMENT register if applicable) as a valid memory address). This value also indicates that this FSTN is a Save-Place indicator.

54.5.3 Host Operational Model

The general operational model is for the enhanced interface host controller hardware and enhanced interface host controller driver (generally referred to as system software).

Each significant operational feature of the EHCI host controller is discussed in a separate section. Each section presents the operational model requirements for the host controller hardware. Where appropriate, recommended system software operational models for features are also presented.

54.5.3.1 Host Controller Initialization

After initial power-on or HCReset (hardware or through HCReset bit in the USB_USBCMD register), all of the operational registers are at their default values. After a hardware reset, only the operational registers not contained in the Auxiliary power well are at their default values.

The following table describes the default values of operational registers.

.

Table 54-36. Default Values of Operational Register Space

Operational Register	Default Value (after Reset)
USB_USBCMD	00080000h (00080B00h, if *Asynchronous Schedule Park Capability is one*)
USB_USBSTS	00001000h
USB_USBINTR	00000000h
USB_FRINDEX	00000000h
USB_CTRLDSSEGMENT	00000000h
USB_PERIODICLISTBASE	Undefined
USB_ASYNCLISTADDR	Undefined
USB_CONFIGFLAG	00000000h
USB_PORTSC1	00002000h (w/*PPC* set to one); 00003000h (w/*PPC* set to zero)

To initialize the host controller, software should perform the following steps:

- Write the appropriate value to the USB_USBINTR register to enable the appropriate interrupts.
- Write the base address of the Periodic Frame List to the USB_PERIODICLIST BASE register. If no work items are in the periodic schedule, all elements of the Periodic Frame List should have their T-Bits set to one.
- Write the USB_USBCMD register to set the desired interrupt threshold, frame list size (if applicable) and turn the host controller ON through setting the Run/Stop bit.

At this point, the host controller is up and running and the port registers begin reporting device connects, and so on. System software can enumerate a port through the reset process (where the port is in the enabled state). At this point, the port is active with SOFs occurring down the enabled ports, but the schedules have not enabled. To communicate with devices through the asynchronous schedule, system software must write the USB_ASYNCLISTADDR register with the address of a control or bulk queue head. Software must then enable the asynchronous schedule by writing one to the Asynchronous Schedule Enable bit in the USB_USBCMD register. To communicate with devices through the periodic schedule, system software must enable the periodic schedule by writing one to the Periodic Schedule Enable bit in the USB_USBCMD register.

NOTE

The schedules can be turned on before the first port is reset (and enabled).

When the USB_USBCMD register is written, system software must ensure the appropriate bits are preserved, depending on the intended operation.

54.5.3.2 Port Routing and Control

The EHCI specification defines that a USB 2.0 Host controller is comprised of one high-speed host controller, which implements the EHCI programming interface and 0 to N USB 1.1 companion host controllers.

Companion host controllers (cHCs) may be implementations of either Universal or Open host controller specifications. This configuration is used to deliver the required full USB 2.0-defined port capability; for example, Low-, Full-, and High-speed capability for every port.

NOTE

The USB controllers on do not require nor support companion controllers to support Full and Low Speed device. Full and Low Speed devices are supported within the USB controller by emulating the functionality of a high-speed HUB. Therefore, no port routing is present in the controller. Please refer to Embedded Transaction Translator Function for details.

The following figure illustrates a simple block diagram of the port routing logic and its relationship to the high-speed and companion host controllers within a USB 2.0 host controller.

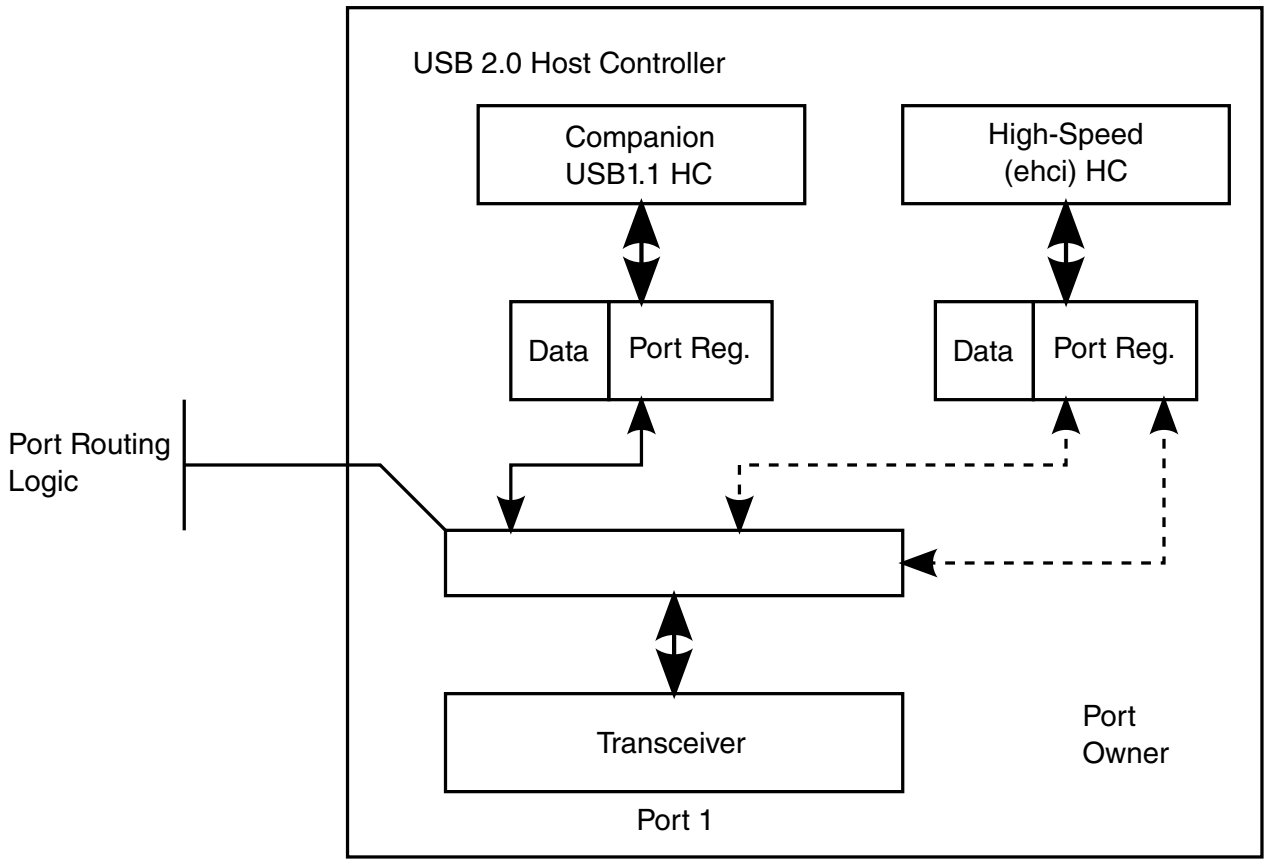


Figure 54-4. Example USB 2.0 Host Controller Port Routing Block Diagram

There exists one transceiver per physical port and each host controller block has its own port status and control registers. The EHCI controller has port status and control registers for every port. Each companion host controller has only the port control and status registers it is required to operate. Either the EHCI host controller or one companion host controller controls each transceiver. Routing logic lies between the transceiver, the port status and control registers.[1]

The port routing logic is controlled from signals originating in the EHCI host controller. The EHCI host controller has a global routing policy control field and per-port ownership control fields. The Configured Flag (CF) bit is the global routing policy control. At power-on or reset, the default routing policy is to the companion controllers (if they exist). If the system does not include a driver for the EHCI host controller and the host controller includes Companion Controllers, then the ports still work in Full- and Low-speed mode (assuming the system includes a driver for the companion controllers). In general, when the EHCI owns the ports, the companion host controllers' port registers do not see a connect indication from the transceiver. Similarly, when a companion host controller owns a port, the EHCI controller's port registers do not see a connect indication

1. The routing logic should not be implemented in the 480 MHz clock domain of the transceiver.

from the transceiver. The details on the rules for the port routing logic are described in the following sections. The USB 2.0 host controller must be implemented as a multi-function PCI device if the implementation includes companion controllers. The companion host controllers' function numbers must be less than the EHCI host controller function number. The EHCI host controller must be a larger function number with respect to the companion host controllers associated with this EHCI host controller. If a PCI device implementation contains only an EHCI controller (that is no companion controllers or other PCI functions), then the EHCI host controller must be function zero, in accordance with the PCI Specification. The N_CC field in the Structural Parameter register (HCSPARAMS) indicates whether the controller implementation includes companion host controllers. When N_CC has a non-zero value there exists companion host controllers. If N_CC has a value of zero, then the host controller implementation does not include companion host controllers. If the host controller root ports are exposed to attachment of full- or low-speed devices, the ports always fails the high-speed chirp during reset and the ports are not enabled. System software can notify the user of the illegal condition. This type of implementation requires a USB 2.0 hub be connected to a root port to provide full and low-speed device connectivity.

System software uses information in the host controller capability registers to determine how the ports are routed to the companion host controllers. See Host Controller Structural Parameters (USB_*n*HCSPARAMS)

54.5.3.2.1 Port Routing Control through EHCI Configured (CF) Bit

Each port in the USB 2.0 host controller are routed either to a single companion host controller or to the EHCI host controller.

The port routing logic is controlled by two mechanisms in the EHCI HC: a host controller global flag and per-port control. The Configured Flag (CF) bit, is used to globally set the policy of the routing logic. Each port register has a Port Owner control bit which allows the EHCI Driver to explicitly control the routing of individual ports. Whenever the CF bit transitions from zero to one (this transition is only available under program control) the port routing unconditionally routes all of the port registers to the EHCI HC (all Port Owner bits go to zero). While the CF-bit is one, the EHCI Driver controls individual ports' routing through the Port Owner control bit. Likewise, whenever the CF bit transitions from one to zero (as a result of Aux power application, HCRESET, or software writing zero to CF-bit), the port routing unconditionally routes all of the port registers to the appropriate companion HC. The default value for the EHCI HC's CF bit (after Aux power application or HCRESET) is zero.

The *view* of the port depends on the current owner. A Universal or Open companion host controller will see port register bits consistent with the appropriate specification. Port bit definitions that are required for EHCI host controllers are not visible to companion host controllers.

The following table summarizes the default routing for all the ports, based on the value of the EHCI HC's CF bit.

Table 54-37. Default Port Routing Depending on EHCI HC CF Bit

HS CF Bit	Default Port Ownership	Explanation
0B	Companion HCs	The companion host controllers own the ports and only Full- and Low-speed devices are supported in the system. The exact port assignments are implementation dependent. The ports behave only as Full- and Low-speed ports in this configuration
1B	EHCI HC	The EHCI host controller has default ownership over all of the ports. The routing logic inhibits device connect events from reaching the companion HCs' port status and control registers when the port owner is the EHCI HC.The EHCI HC has access to the additional port status and control bits defined in this specification (see). The EHCI HC can temporarily release control of the port to a companion HC by setting the *PortOwner* bit in the PORTSC1 register to one.

54.5.3.2.2 Port Routing Control through PortOwner and Disconnect Event

Manipulating the port routing through the CF-bit is an extreme process and not intended to be used during normal operation.

The normal mode of port ownership transferal is on the granularity of individual ports using the Port Owner bit in the EHCI HC's USB_PORTSC1 register (for hand-offs from EHCI to companion host controllers). Individual port ownership is returned to the EHCI controller when the port registers a device disconnect. When the disconnect is detected, the port routing logic immediately returns the port ownership to the EHCI controller. The companion host controller port register detects the device disconnect and operates normally.

Under normal operating conditions (assuming all HC drivers loaded and operational and the EHCI *CF-bit* is set to one), the typical port enumeration sequence proceeds as illustrated below:

- Initial condition is that EHCI is port owner. A device is connected causing the port to detect a connect, set the port connect change bit and issue a port-change interrupt (if enabled).
- EHCI Driver identifies the port with the new connect change bit asserted and sends a change report to the hub driver. Hub driver issues a GetPortStatus() request and

identifies the connect change. It then issues a request to clear the connect change, followed by a request to reset and enable the port.

- When the EHCI Driver receives the request to reset and enable the port, it first checks the value reported by the LineStatus bits in the USB_PORTSC1 register. If they indicate the attached device is a full-speed device (for example, D+ is asserted), then the EHCI Driver sets the PortReset control bit to one (and sets the PortEnable bit to zero) which begins the reset-process. Software times the duration of the reset, then terminates reset signaling by writing zero to the port reset bit. The reset process is actually complete when software reads zero in the PortReset bit. The EHCI Driver checks the PortOwner bit in the USB_PORTSC1 register. If set to one, the connected device is a high-speed device and EHCI Driver (root hub emulator) issues a change report to the hub driver and the hub driver continues to enumerate the attached device.
- At the time the EHCI Driver receives the port reset and enable request the LineStatus bits might indicate a low-speed device. Additionally, when the port reset process is complete, the PortEnable field may indicate that a full-speed device is attached. In either case the EHCI driver sets the PortOwner bit in the USB_PORTSC1 register to one to release port ownership to a companion host controller.
- When the EHCI Driver sets PortOwner bit to one, the port routing logic makes the connection state of the transceiver available to the companion host controller port register and removes the connection state from the EHCI HC port. The EHCI USB_PORTSC1 register observes and reports a disconnect event through the disconnect change bit. The EHCI Driver detects the connection status change (either by polling or by port change interrupt) and then sends a change report to the hub driver. When the hub driver requests that port-state, the EHCI Driver responds with a reset complete change set to one, a connect change set to one and a connect status set to zero. This information is derived directly from the EHCI port register. This allows the hub driver to assume the device was disconnected during reset. It acknowledges the change bits and wait for the next change event. While the EHCI controller does not own the port, it simply remains in a state where the port reports no device connected. The device-connect evaluation circuitry of the companion HC activates and detects the device, the companion Driver detects the connection and enumerates the port.

When a port is routed to a companion HC, it remains under the control of the companion HC until the device is disconnected from the root port (ignoring for now the scenario where EHCI's CF-bit transitions from1b to 0b). When a disconnect occurs, the disconnect event is detected by both the companion HC port control and the EHCI port ownership control. On the event, the port ownership is returned immediately to the EHCI controller. The companion HC stack detects the disconnect and acknowledges as it would in an ordinary standalone implementation. Subsequent connects is detected by the EHCI port register and the process repeats.

54.5.3.2.3 Example Port Routing State Machine

The following figure illustrates an example of how the port ownership should be managed. The following sections describe the entry conditions to each state.

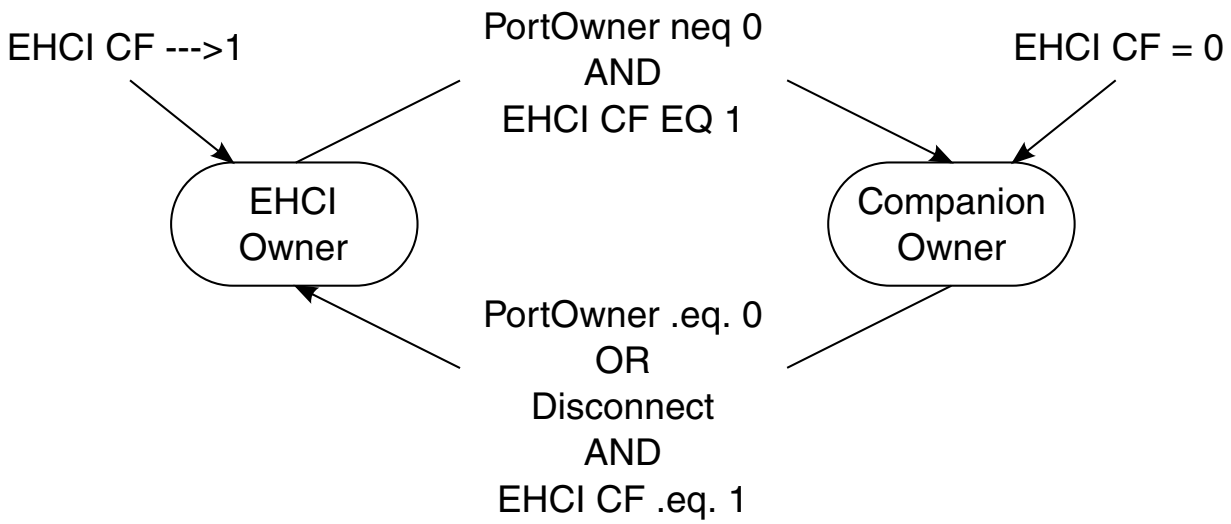

Figure 54-5. Port Owner Handoff State Machine

54.5.3.2.3.1 EHCI HC Owner

Entry to this state occurs when one of the following events occur:

- When the EHCI HC's Configure Flag (CF) bit in the USB_CONFIGFLAG register transitions from zero to one. This signals the fact that the system has a host controller driver for the EHCI HC and that all ports in the USB 2.0 host controller must default route to the EHCI controller.
- When the port is owned by a companion HC and the device is disconnected from the port. The EHCI port routing control logic is notified of the disconnect, and returns port routing to the EHCI controller. The connection state of the companion HC goes immediately to the disconnected state (with appropriate side effect to connect change, enable and enable change). The companion HC driver acknowledges the disconnect by setting the connect status change bit to zero. This allows the companion HC's driver to interact with the port completely through the disconnect process.
- When system software writes zero to the PortOwner bit in the USB_PORTSC1 register. This allows software to take ownership of a port from a companion host controller. When this occurs, the routing logic to the companion HC effectively signals a disconnect to the companion HC's port status and control register.

54.5.3.2.3.2 Companion HC Owner

Entry to this state occurs whenever one of the following events occur:

- When the PortOwner field transitions from zero to one.
- When the HS-mode HC's Configure Flag (CF) is equal to zero.

On entry to this state, the routing logic allows the companion HC port register to detect a device connect. Normal port enumeration proceeds.

54.5.3.2.4 Port Power

The Port Power Control (PPC) bit in the USB_HCSPARAMS register indicates whether the USB 2.0 host controller has port power control (see).

When this bit is zero, then the host controller does not support software control of port power switches. When in this configuration, the port power is always available and the companion host controllers must implement functionality consistent with port power always on. When the *PPC* bit is one, then the host controller implementation includes port power switches. Each available switch has an output enable, which is referred to in this discussion as PortPowerOutputEnable (PPE). PPE is controlled based on the state of the combination bits PPC bit, EHCI Configured (CF)-bit and individual Port Power (PP) bits.

The following table describes the summary behavioral model.

Table 54-38. Port Power Enable Control Rules

CF	CHC[1] (PP)	EHC[2] (PP)	Owner	PPE[3]	Description
0	0	X	CHC	0	When the EHCI controller is not configured, the port is owned by the companion host controller. When the companion HC's port power select is off, then the port power is off.
0	1	X	CHC	1	Similar to previous entry. When the companion HC's port power select is on, then the port power is on.
1	0	0	CHC	0	Port owner has port power turned off, the power to port is off.
1	0	0	EHC	0	Port owner has port power turned off, the power to port is off.
1	0	1	EHC	1	Port owner has port power on, so power to port is on.
1	0	1	CHC	1	If either HC has port power turned on, the power to the port is on.
1	1	0	EHC	1	If either HC has port power turned on, the power to the port is on.

Table continues on the next page...

Table 54-38. Port Power Enable Control Rules (continued)

1	1	0	CHC	1	Port owner has port power on, so power to port is on.
1	1	1	CHC	1	Port owner has port power on, so power to port is on.
1	1	1	EHC	1	Port owner has port power on, so power to port is on.

1. CHC (Companion Host Controller).
2. EHC (EHCI Host Controller).
3. PPE (Port Power Enable). This bit actually turns on the port power switch (if one exists).

54.5.3.2.5 Port Reporting Over-Current

Host controllers are by definition power providers on USB. Whether the ports are considered high- or low-powered is a platform implementation issue. Each EHCI USB_PORTSC1 register has an over-current status and over-current change bit.

The functionality of these bits are specified in the USB Specification Revision 2.0.

The over current detection and limiting logic usually resides outside the host controller logic. This logic may be associated with one or more ports. When this logic detects an over-current condition it is made available to both the companion and EHCI ports. The effect of an over-current status on a companion host controller port is beyond the scope of this document.

The over-current condition effects the following bits in the USB_PORTSC1 register on the EHCI port:

- Over-current Active bits are set to one. When the over-current condition goes away, the Over-current Active bit transitions from one to zero.
- Over-current Change bits are set to one. On every transition of the Over-current Active bit the host controller sets the Over-current Change bit to one. Software sets the Over-current Change bit to zero by writing one to this bit.
- Port Enabled/Disabled bit is set to zero. When this change bit gets set to one, then the Port Change Detect bit in the USB_USBSTS register is set to one.
- Port Power (PP) bits may optionally be set to zero. There is no requirement in USB that a power provider shut off power in an over current condition. It is sufficient to limit the current and leave power applied. When the Over-current Change bit transitions from zero to one, the host controller also sets the Port Change Detect bit in the USB_USBSTS register to one. In addition, if the Port Change Interrupt Enable bit in the USB_USBINTR register is one, then the host controller issues an interrupt to the system. Refer to Table 54-39 for summary behavior for over-current detection when the host controller is halted (suspended from a device component point of view).

54.5.3.3 Suspend/Resume-Host Operational Model

The EHCI host controller provides an equivalent suspend and resume model as that defined for individual ports in a USB 2.0 Hub.

Control mechanisms are provided to allow system software to suspend and resume individual ports. The mechanisms allow the individual ports to be resumed completely through software initiation. Other control mechanisms are provided to parameterize the host controller's response (or sensitivity) to external resume events. In this discussion, host-initiated, or software initiated resumes are called Resume Events/Actions. Bus-initiated resume events are called wake-up events. The classes of wake-up events are:

- Remote-wake-up enabled device asserts resume signaling. In similar kind to USB 2.0 Hubs, EHCI controllers must always respond to explicit device resume signaling and wake-up the system (if necessary).
- Port connect and disconnect and over-current events. Sensitivity to these events can be turned on or off by using the per-port control bits in the USB_PORTSC1 registers.

Selective suspend is a feature supported by every USB_PORTSC1 register. It is used to place specific ports into a suspend mode. This feature is used as a functional component for implementing the appropriate power management policy implemented in a particular operating system. When system software intends to suspend the entire bus, it should selectively suspend all enabled ports, then shut off the host controller by setting the Run/Stop bit in the USB_USBCMD register to zero. The EHCI sub-block can then be placed into a lower device state through the PCI power management interface (see Appendix A, Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November 2000, Intel Corporation. http://www.intel.com).

When a wake event occurs, the system resumes operation and system software eventually set the Run/Stop bit to one and resume the suspended ports. Software must not set the Run/Stop bit to one until it is confirmed that the clock to the host controller is stable. This is usually confirmed in a system implementation in that all of the clocks in the system are stable before the Arm platform is restarted. So, by definition, if software is running, clocks in the system are stable and the Run/Stop bit in the USB_USBCMD register can be set to one. Minimum system software delays are also defined in the PCI Power Management Specification. Refer to PCI Power Management Specification for more information.

54.5.3.3.1 Port Suspend/Resume

System software places individual ports into suspend mode by writing one into the appropriate USB_PORTSC1 Suspend bit. Software must only set the Suspend bit when the port is in the enabled state (Port Enabled bit is one) and the EHCI is the port owner (PortOwner bit is zero).

The host controller may evaluate the Suspend bit immediately or wait until a micro-frame or frame boundary occurs. If evaluated immediately, the port is not suspended until the current transaction (if one is executing) completes. Therefore, there may be several micro-frames of activity on the port until the host controller evaluates the Suspend bit. The host controller must evaluate the Suspend bit at least every frame boundary.

System software can initiate a resume on a selectively suspended port by writing one to the Force Port Resume bit. Software should not attempt to resume a port unless the port reports that it is in the suspended state (see Port Status & Control (USB_*n*PORTSC1)). If system software sets Force Port Resume bit to one when the port is not in the suspended state, the resulting behavior is undefined. In order to assure proper USB device operation, software must wait for at least 10 ms after a port indicates that it is suspended (Suspend bit is one) before initiating a port resume through the Force Port Resume bit. When Force Port Resume bit is one, the host controller sends resume signaling down the port. System software times the duration of the resume (nominally 20 ms) then sets the Force Port Resume bit to zero. When the host controller receives the write to transition Force Port Resume to zero, it completes the resume sequence as defined in the USB specification, and sets both the Force Port Resume and Suspend bits to zero. Software-initiated port resumes do not affect the Port Change Detect bit in the USB_USBSTS register nor do they cause an interrupt if the Port Change Interrupt Enable bit in the USB_USBINTR register is one. An external USB event may also initiate a resume. The wake events are defined above. When a wake event occurs on a suspended port, the resume signaling is detected by the port and the resume is reflected downstream within 100 µsec. The port's Force Port Resume bit is set to one and the Port Change Detect bit in the USB_USBSTS register is set to one. If the Port Change Interrupt Enable bit in the USB_USBINTR register is one the host controller issues a hardware interrupt.

System software observes the resume event on the port, delays a port resume time (nominally 20 ms), then terminates the resume sequence by writing zero to the Force Port Resume bit in the port. The host controller receives the write of zero to Force Port Resume, terminates the resume sequence and sets Force Port Resume and Suspend port bits to zero. Software can determine that the port is enabled (not suspended) by sampling the USB_PORTSC1 register and observing that the Suspend and Force Port Resume bits are zero. Software must ensure that the host controller is running (that is HCHalted bit in the USB_USBSTS register is zero), before terminating a resume by writing zero to a

port's Force Port Resume bit. If HCHalted is one when Force Port Resume is set to zero, then SOFs do not occur down the enabled port and the device returns to suspend mode in a maximum of 10 msec.

The table below summarizes the wake-up events. Whenever a resume event is detected, the Port Change Detect bit in the USB_USBSTS register is set to one. If the Port Change Interrupt Enable bit is one in the USB_USBINTR register, the host controller generates an interrupt on the resume event. Software acknowledges the resume event interrupt by clearing the Port Change Detect status bit in the USB_USBSTS register.

Table 54-39. Behavior During Wake-up Events

Port Status and Signaling Type	Signaled Port Response	Device State	
		D0	Not D0
Port disabled, resume K-State received	No Effect	N/A	N/A
Port suspended, resume K-State received	Resume reflected downstream on signaled port. Force Port Resume status bit in USB_PORTSC1 register is set to one. Port Change Detect bit in USB_USBSTS register set to one.	[1], [2]	[2]
Port is enabled, disabled or suspended, and the port's WKDSCNNT_E bit is one. A disconnect is detected.	Depending in the initial port state, theUSB_ PORTSC1 Connected Enable status bits are set to zero, and the Connect Change status bit is set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [2]	[2]
Port is enabled, disabled or suspended, and the port's WKDSCNNT_E bit is zero. A disconnect is detected.	Depending on the initial port state, the USB_PORTSC1 Connect and Enable status bits are set to zero, and the Connect Change status bit is set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]
Port is not connected and the port's WKCNNT_E bit is one. A connect is detected.	USB_PORTSC1 Connect Status and Connect Status Change bits are set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [2]	[2]
Port is not connected and the port's WKCNNT_E bit is zero. A connect is detected.	USB_PORTSC1 Connect Status and Connect Status Change bits are set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]
Port is connected and the port's WKOC_E bit is one. An over-current condition occurs.	USB_PORTSC1 Over-current Active, Over-current Change bits are set to one. If Port Enable/Disable bit is one, it is set to zero. Port Change Detect bit in the USB_USBSTS register is set to one	[1], [2]	[2]
Port is connected and the port's WKOC_E bit is zero. An over-current condition occurs.	USB_PORTSC1 Over-current Active, Over-current Change bits are set to one. If Port Enable/Disable bit is one, it is set to zero. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]

[1] Hardware interrupt issued if Port Change Interrupt Enable bit in the USB_USBINTR register is one.

[2] PME# asserted if enabled (Note: PME Status must always be set to one).

[3] PME# not asserted.

54.5.3.4 Schedule Traversal Rules

The host controller executes transactions for devices using a simple, shared-memory schedule.

The schedule is comprised of a few data structures, organized into two distinct lists. The data structures are designed to provide the maximum flexibility required by USB, minimize memory traffic and hardware / software complexity.

System software maintains two schedules for the host controller: a periodic schedule and an asynchronous schedule. The root of the periodic schedule is the USB_PERIODICLISTBASE register (see Frame List Base Address (USB_*n*PERIODICLISTBASE))/ Device Address (USB_*n*DEVICEADDR). The USB_PERIODICLISTBASE register is the physical memory base address of the periodic frame list. The periodic frame list is an array of physical memory pointers. The objects referenced from the frame list must be valid schedule data structures as defined in Host Data Structures. In each micro-frame, if the periodic schedule is enabled (see Periodic scheduling threshold) then the host controller must execute from the periodic schedule before executing from the asynchronous schedule. It only executes from the asynchronous schedule after it encounters the end of the periodic schedule. The host controller traverses the periodic schedule by constructing an array offset reference from the USB_PERIODICLISTBASE and the USB_FRINDEX registers (see the following figure). It fetches the element and begins traversing the graph of linked schedule data structures.

The end of the periodic schedule is identified by a next link pointer of a schedule data structure having its T-bit set to one. When the host controller encounters a T-Bit set to one during a horizontal traversal of the periodic list, it interprets this as an End-Of-Periodic-List mark. This causes the host controller to cease working on the periodic schedule and transitions immediately to traversing the asynchronous schedule. After the transition, the host controller executes from the asynchronous schedule until the end of the micro-frame.

The following figure illustrates the derivation of pointer into frame list array.

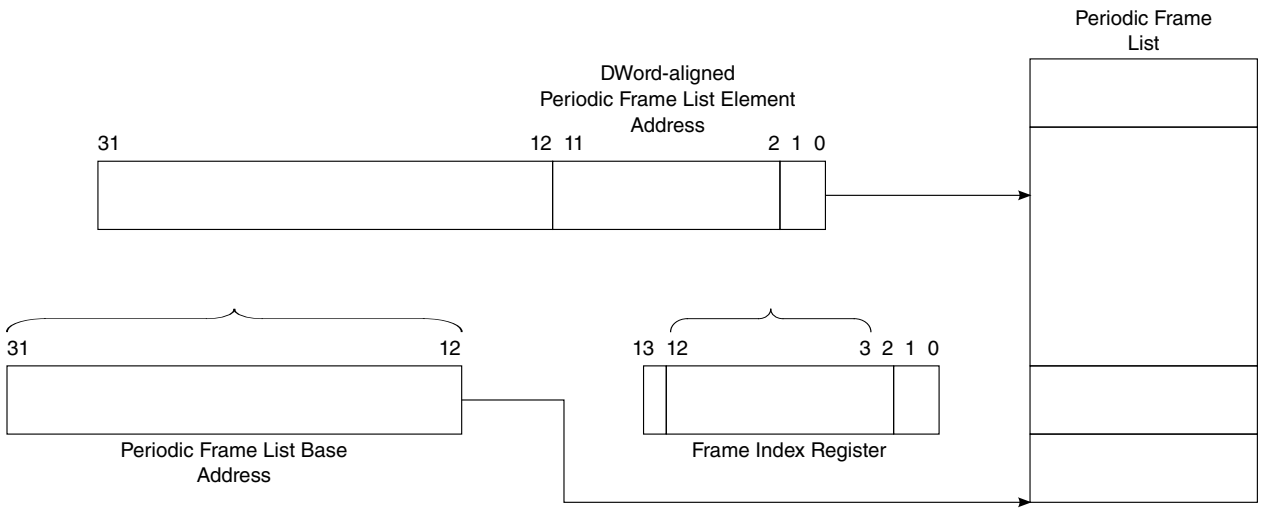

Figure 54-6. Derivation of Pointer into Frame List Array

When the host controller determines that it is the time to execute from the asynchronous list, it uses the operational register USB_ASYNCLISTADDR to access the asynchronous schedule, see the figure below.

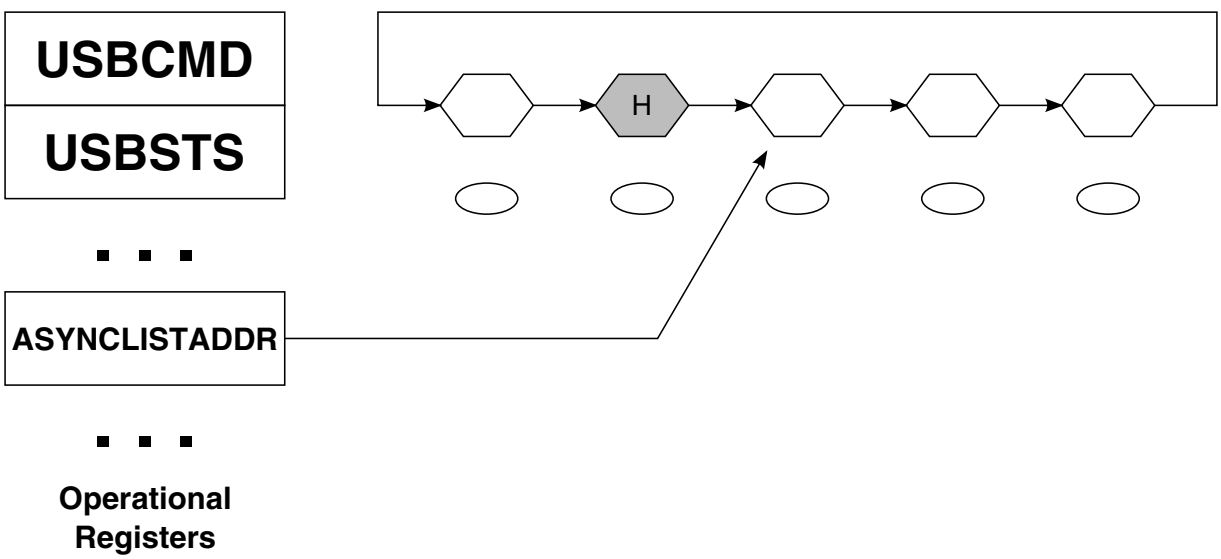

Figure 54-7. General Format of Asynchronous Schedule List

The USB_ASYNCLISTADDR register contains a physical memory pointer to the next queue head. When the host controller makes a transition to executing the asynchronous schedule, it begins by reading the queue head referenced by the USB_ASYNCLISTADDR register. Software must set queue head horizontal pointer T-bits to zero for queue heads in the asynchronous schedule. See Asynchronous Schedule for complete operational details.

54.5.3.4.1 Example - Preserving Micro-Frame Integrity

One of the requirements of a USB host controller is to maintain Frame Integrity. This means that the HC must preserve the micro-frame boundaries.

For example, SOF packets must be generated on time (within the specified allowable jitter), and High-speed EOF1,2 thresholds must be enforced. The end of micro-frame timing points EOF1 and EOF2 are clearly defined in the USB Specification Revision 2.0. One implication of this responsibility is that the HC must ensure that it does not start transactions that do not complete before the end of the micro-frame. More precisely, no transactions should be started by the host controller, which do not complete in their entirety before the EOF1 point. In order to enforce this rule, the host controller must check each transaction before it starts to ensure that it completes before the end of the micro-frame.

So, what exactly needs to be involved in this check? Fundamentally, the transaction data payload, plus bit stuffing, plus transaction overhead must be taken into consideration. It is possible to be extremely accurate on how much time the next transaction takes. Take OUTs for an example. The host controller must fetch all of the OUT data from memory in order to send it onto the USB bus. A host controller implementation could pre-fetch all of the OUT data, and pre-compute the actual number of bits in the token and data packets. In addition, the system knows the depth of the target endpoint, so it could closely estimate turnaround time for handshake. In addition, the host controller knows the size of a handshake packet. Pre-computing effects of bit stuffing and summing up the other overhead numbers can allow the host controller to know exactly whether there is enough bus time, before EOF1 to complete the OUT transaction. To accomplish this particular approach takes an inordinate amount of time and hardware complexity.

The alternative is to make a reasonable guess whether the next transaction can be started. An example approximation algorithm is described below. This example algorithm relies on the EHCI policy that periodic transactions are scheduled first in the micro-frame. It is a reasonable assumption that software never over-commits the micro-frame to periodic transactions greater than the specification allowable 80%. In the available remaining 20% bandwidth, the host controller has some ability (in this example) to decide whether or not to execute a transaction. The result of this algorithm is that sometimes, under some circumstances a transaction is not executed that could have been executed. However, under all circumstances, a transaction is never started unless there is enough time in the frame to complete the transaction.

54.5.3.4.1.1 Transaction Fit - A Best-Fit Approximation Algorithm

A curve is calculated which represents the latest start time for every packet size, at which software schedules the start of a periodic transaction.

This curve is the 80% bandwidth curve. Another curve is calculated which is the absolute, latest permitted start time for every packet size. This curve represents the absolute latest time, that a transaction of each packet size can be started and completed, in the micro-frame. A plot of these two curves are illustrated in Figure 54-8. The plot Y-axis represents the number of byte-times left in a frame.

The space between the 80% and the Last Start plots is bandwidth reclamation area. In this algorithm the host controller may skip transactions during this time if it is prudent.

The Best-Fit Approximation method plots a function ($f(x)$) between the 80% and Last Start curves. The function $f(x)$ adds a constant to every transaction's maximum packet size and the result compared with the number of bytes left in the frame. The constant represents an approximation of the effects of bit stuffing and protocol overhead. The host controller starts transactions whose results land above the function curve. The host controller will not start transactions whose results land below the function curve.

The following figure illustrates the Best-Fit Approximation.

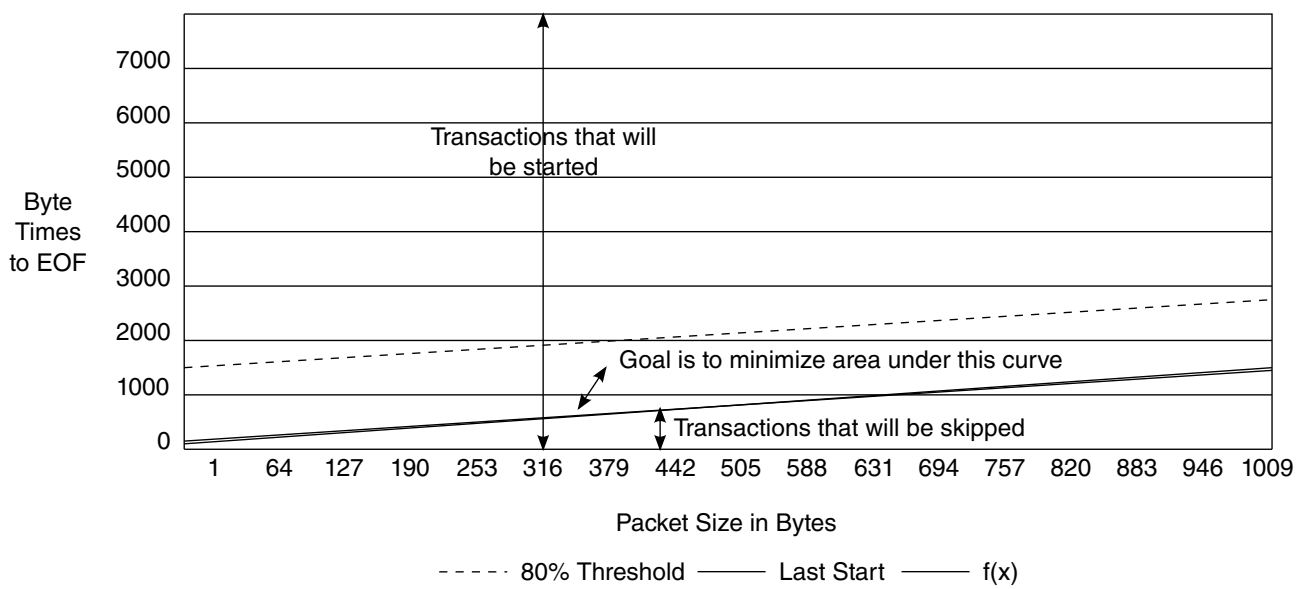

Figure 54-8. Best Fit Approximation

The LastStart line was calculated in this example to assume the absolute worst-case bus overhead per transaction. The particular transaction used is a start-split, zero-length OUT transaction with a handshake. Summaries of the component parts are listed in the table below. The component times were derived from the protocol timings defined in the USB Specification Revision 2.0.

Table 54-40. Example Worse-case Transaction Timing Components

Component	Bit time	Byte Time	Explanation

Table continues on the next page...

Table 54-40. Example Worse-case Transaction Timing Components (continued)

Split Token	76	9.5	Split token as defined in USB core specification. Includes sync, token, eop, and so on.
Host 2 Host IPG	88	11	Number of bit times required between consecutive host packets.
Token	67	8.375	Token as defined in USB core specification. Includes sync, token, eop, and so on.
Host 2 Host IPG	88	11	Token as defined in USB core specification. Includessync, token, eop, and so on.
Data Packet (0 data bytes)	66.7	8.34	Zero-length data packet. Includes sync, PID, crc16, eop, and so on.
Turnaround time	721	90.125	Time for packet initiator (Host) to see the beginning of a response to a transmitted packet.
Handshake packet	48	6	Handshake packet as defined in USB core specification. Includes sync, PID, eop, and so on.
		144	Total

The exact details of the function (f(x)) are up to the particular implementation. However, it should be obvious that the goal is to minimize the area under the curve between the approximation function and the Last Start curve, without dipping below the LastStart line, while at the same time keeping the check as simple as possible for hardware implementation. The f(x) in Figure 54-8 was constructed using the following pseudo-code test on each transaction size data point. This algorithm assumes that the host controller keeps track of the remaining bits in the frame.

```
Alorithm CheckTransactionWillFit (MaximumPacketSize, HC_BytesLeftInFrame)
Begin
Local Temp = MaximumPacketSize + 192
Local rvalue = TRUE
If MaximumPacketSize >= 128 then
     Temp += 128
End If
If Temp > HC_BytesLeftInFrame then
     Rvalue = FALSE
End If
Return rvalue
End
```

This algorithm takes two inputs, the current maximum packet size of the transaction and the hardware counter of the number of bytes left in the current micro-frame. It unconditionally adds a simple constant of 192 to the maximum packet size to account for a first-order effect of transaction overhead and bit stuffing. If the transaction size is greater than or equal to 128 bytes, then an additional constant of 128 is added to the running sum to account for the additional worst-case bit stuffing of payloads larger than 128. An inflection point was inserted at 128 because the $f(x)$ plot was getting close to the LastStart line.

54.5.3.5 Periodic Schedule Frame Boundaries vs Bus Frame Boundaries

The USB Specification Revision 2.0 requires that the frame boundaries (SOF frame number changes) of the high-speed bus and the full- and low-speed bus(s) below USB 2.0 Hubs be strictly aligned.

Super-imposed on this requirement is that USB 2.0 Hubs manage full- and low-speed transactions through a micro-frame pipeline (see start- (SS) and complete- (CS) splits illustrated in the following figure). A simple, direct projection of the frame boundary model into the host controller interface schedule architecture creates tension (complexity for both hardware and software) between the frame boundaries and the scheduling mechanisms required to service the full- and low-speed transaction translator periodic pipelines.

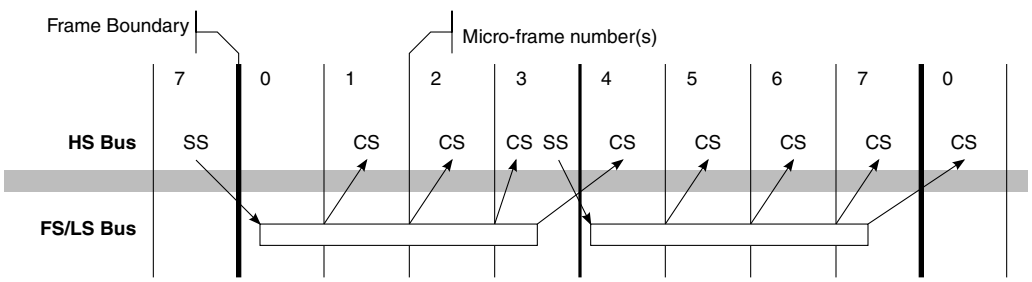

Figure 54-9. Frame Boundary Relationship between HS bus and FS/LS Bus

The simple projection, as the above figure illustrates, introduces frame-boundary wrap conditions for scheduling on both the beginning and end of a frame. In order to reduce the complexity for hardware and software, the host controller is required to implement one micro-frame phase shift for its view of frame boundaries. The phase shift eliminates the beginning of frame and frame-wrap scheduling boundary conditions.

The implementation of this phase shift requires that the host controller use one register value for accessing the periodic frame list and another value for the frame number value included in the SOF token. These two values are separate, but tightly coupled. The periodic frame list is accessed through the Frame List Index Register (USB_FRINDEX) documented in USB Frame Index (USB_*n*FRINDEX) and initially illustrated in Schedule Traversal Rules. Bits FRINDEX[2:0], represent the micro-frame number. The SOF value is coupled to the value of FRINDEX[13:3]. Both FRINDEX[13:3] and the SOF value are increment based on FRINDEX[2:0]. It is required that the SOF value be delayed from the FRINDEX value by one micro-frame. The one micro-frame delay yields host controller periodic schedule and bus frame boundary relationship as illustrated in the following figure. This adjustment allows software to trivially schedule the periodic start and

complete-split transactions for full-and low-speed periodic endpoints, using the natural alignment of the periodic schedule interface. The reasons for selecting this phase-shift are beyond the scope of this specification.

The following figure illustrates how periodic schedule data structures relate to schedule frame boundaries and bus frame boundaries. To aid the presentation, two terms are defined: The host controller's view of the 1 msec boundaries is called H-Frames. The high-speed bus's view of the 1 msec boundaries is called B-Frames.

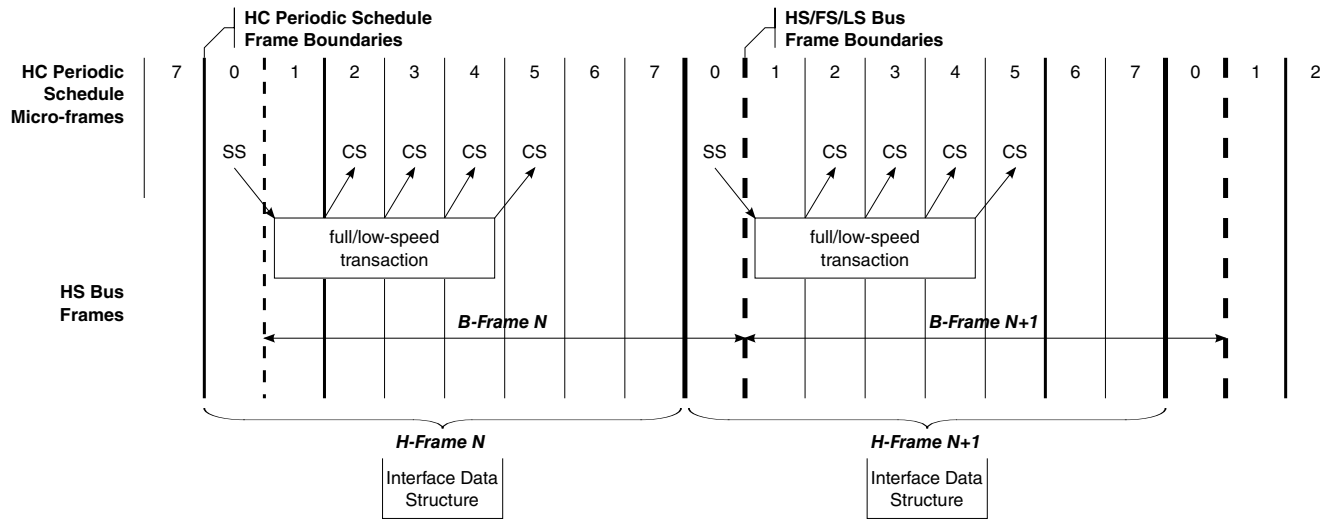

Figure 54-10. Relationship of Periodic Schedule Frame Boundaries to Bus Frame Boundaries

H-Frame boundaries for the host controller correspond to increments of FRINDEX[13:3]. Micro-frame numbers for the H-Frame are tracked by FRINDEX[2:0]. B-Frame boundaries are visible on the high-speed bus through changes in the SOF token's frame number. Micro-frame numbers on the high-speed bus are only derived from the SOF token's frame number (that is the high-speed bus sees eight SOFs with the same frame number value). H-Frames and B-Frames have the fixed relationship (that is B-Frames lag H-Frames by one micro-frame time) illustrated in the figure above. The host controller's periodic schedule is naturally aligned to H-Frames. Software schedules transactions for full- and low-speed periodic endpoints relative the H-Frames. The result is these transactions execute on the high-speed bus at exactly the right time for the USB 2.0 Hub periodic pipeline. As described in USB Frame Index (USB_*n*FRINDEX), the SOF Value can be implemented as a shadow register (in this example, called SOFV), which lags the FRINDEX register bits [13:3] by one micro-frame count. This lag behavior can be accomplished by incrementing FRINDEX[13:3] based on carry-out on the 7 to 0 increment of FRINDEX[2:0] and incrementing SOFV based on the transition of 0 to 1 of FRINDEX[2:0].

Software is allowed to write to FRINDEX. USB Frame Index (USB_*n*FRINDEX) provides the requirements that software should adhere when writing a new value in FRINDEX.

The table below illustrates the required relationship between the value of FRINDEX and the value of SOFV.

Table 54-41. Operation of FRINDEX and SOFV (SOF Value Register)

Current			Next		
FRINDEX[F]	SOFV	FRINDEX[mF]	FRINDEX[F]	SOFV	FRINDEX[mF]
N	N	111b	N+1	N	000b
N+1	N	000b	N+1	N+1	001b
N+1	N+1	001b	N+1	N+1	010b

54.5.3.6 Periodic Schedule

The periodic schedule traversal is enabled or disabled through the Periodic Schedule Enable bit in the USB_USBCMD register. If the Periodic Schedule Enable bit is set to zero, then the host controller simply does not try to access the periodic frame list through the USB_PERIODICLISTBASE register. Likewise, when the Periodic Schedule Enable bit is one, then the host controller does use the USB_PERIODICLISTBASE register to traverse the periodic schedule.

The host controller will not react to modifications to the Periodic Schedule Enable immediately. In order to eliminate conflicts with split transactions, the host controller evaluates the Periodic Schedule Enable bit only when FRINDEX[2:0] is zero. System software must not disable the periodic schedule if the schedule contains an active split transaction work item that spans the 000b micro-frame. These work items must be removed from the schedule before the Periodic Schedule Enable bit is written to zero.

The Periodic Schedule Status bit in the USB_USBSTS register indicates status of the periodic schedule. System software enables (or disables) the periodic schedule by writing one (or zero) to the Periodic Schedule Enable bit in the USB_USBCMD register. Software then can poll the Periodic Schedule Status bit to determine when the periodic

schedule has made the desired transition. Software must not modify the Periodic Schedule Enable bit unless the value of the Periodic Schedule Enable bit equals that of the Periodic Schedule Status bit.

The periodic schedule is used to manage all isochronous and interrupt transfer streams. The base of the periodic schedule is the periodic frame list. Software links schedule data structures to the periodic frame list to produce a graph of scheduled data structures. The graph represents an appropriate sequence of transactions.

The following figure illustrates isochronous transfers (using iTDs and siTDs) with a period of one are linked directly to the periodic frame list. Interrupt transfers (are managed with queue heads) and isochronous streams with periods other than one are linked following the period-one iTD/siTDs. Interrupt queue heads are linked into the frame list ordered by poll rate. Longer poll rates are linked first (for example, closest to the periodic frame list), followed by shorter poll rates, with queue heads with a poll rate of one, on the very end.

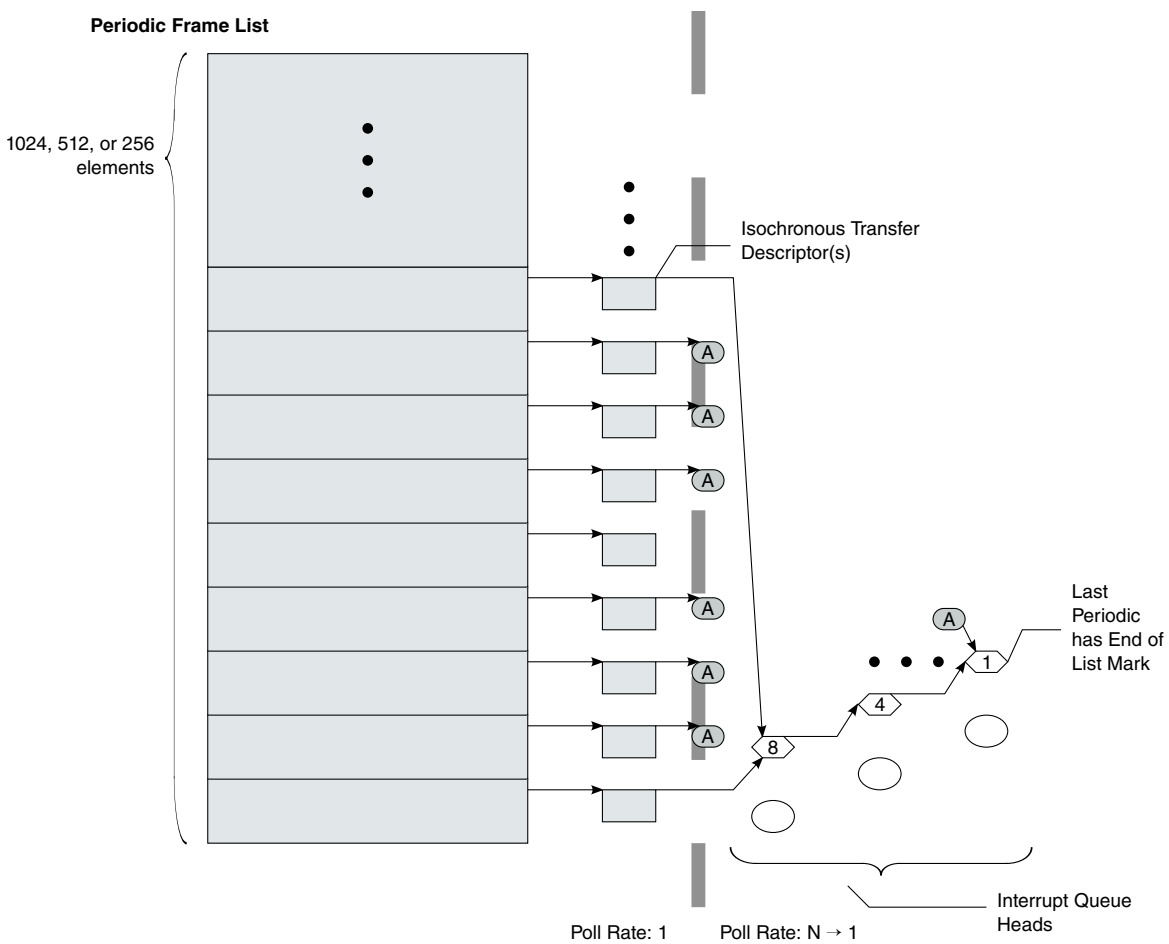

Figure 54-11. Example Periodic Schedule

54.5.3.7 Managing Isochronous Transfers Using iTDs

The structure of an iTD is presented in Isochronous (High-Speed) Transfer Descriptor (iTD). The four distinct sections to an iTD:

- The first field is the Next Link Pointer. This field is for schedule linkage purposes only.
- Transaction description array. This area is an eight-element array. Each element represents control and status information for one micro-frame's worth of transactions for a single high-speed isochronous endpoint.
- The buffer page pointer array is a 7-element array of physical memory pointers to data buffers. These are 4 K aligned pointers to physical memory.
- Endpoint capabilities. This area utilizes the unused low-order 12 bits of the buffer page pointer array. The fields in this area are used across all transactions executed for this iTD, including endpoint addressing, transfer direction, maximum packet size and high-bandwidth multiplier.

54.5.3.7.1 Host Controller Operational Model for iTDs

The host controller uses FRINDEX register bits [12:3] to index into the periodic frame list. This means that the host controller visits each frame list element eight consecutive times before incrementing to the next periodic frame list element. Each iTD contains eight transaction descriptions, which map directly to FRINDEX register bits [2:0]. Therefore, each transaction descriptor corresponds to one micro-frame. Each iTD can span 8 micro-frames worth of transactions.

When the host controller fetches an iTD, it uses FRINDEX register bits [2:0] to index into the transaction description array.

If the active bit in the Status field of the indexed transaction description is set to zero, the host controller ignores the iTD and follows the Next pointer to the next schedule data structure.

When the indexed active bit is one, the host controller continues to parse the iTD. It stores the indexed transaction description and the general endpoint information (device address, endpoint number, maximum packet size, and so on.). It also uses the Page Select (PG) field to index the buffer pointer array, storing the selected buffer pointer and the next sequential buffer pointer. For example, if PG field is 0, then the host controller stores Page 0 and Page 1.

The host controller constructs a physical data buffer address by concatenating the current buffer pointer (as selected using the current transaction description's PG field) and the transaction description's Transaction Offset field. The host controller uses the endpoint addressing information and I/O-bit to execute a transaction to the appropriate endpoint. When the transaction is complete, the host controller clears the active bit and writes back any additional status information to the Status field in the currently selected transaction description.

The data buffer associated with the iTD must be virtually contiguous memory. Seven page pointers are provided to support eight high-bandwidth transactions regardless of the starting packet's offset alignment into the first page. A starting buffer pointer (physical memory address) is constructed by concatenating the page pointer (for example, page 0 pointer) selected by the active transaction descriptions' PG (for example, value: 00B) field with the transaction offset field. As the transaction moves data, the host controller must detect when an increment of the current buffer pointer crosses a page boundary. When this occurs the host controller simply replaces the current buffer pointer's page portion with the next page pointer (for example, page 1 pointer) and continues to move data. The size of each bus transaction is determined by the value in the Maximum Packet Size field. An iTD supports high-bandwidth pipes through the Mult (multiplier) field. When the Mult field is 1, 2, or 3, the host controller executes the specified number of Maximum Packet sized bus transactions for the endpoint in the current micro-frame. In other words, the Mult field represents a transaction count for the endpoint in the current micro-frame. If the Mult field is zero, the operation of the host controller is undefined. The transfer description is used to service all transactions indicated by the Mult field.

For OUT transfers, the value of the Transaction X Length field represents the total bytes to be sent during the micro-frame. The Mult field must be set by software to be consistent with Transaction X Length and Maximum Packet Sixe. The host controller sends the bytes in Maximum Packet Size'd portions. After each transaction, the host controller decrements its local copy of Transaction X Length by Maximum Packet Size. The number of bytes the host controller sends is always Maximum Packet Size or Transaction X Length, whichever is less. The host controller advances the transfer state in the transfer description, updates the appropriate record in the iTD and moves to the next schedule data structure. The maximum sized transaction supported is 3 x 1024 bytes.

For IN transfers, the host controller issues Mult transactions. It is assumed that software has properly initialized the iTD to accommodate all of the possible data. During each IN transaction, the host controller must use Maximum Packet Size to detect packet babble errors. The host controller keeps the sum of bytes received in the Transaction X Length field. After all transactions for the endpoint have completed for the micro-frame, Transaction X Length contains the total bytes received. If the final value of Transaction X Length is less than the value of Maximum Packet Size, then less data than was allowed for was received from the associated endpoint. This short packet condition does not set

the USBINT bit in the USB_USBSTS register to one. The host controller will not detect this condition. If the device sends more than Transaction X Length or Maximum Packet Size bytes (whichever is less), then the host controller sets the Babble Detected bit to one and set the Active bit to zero. Note, that the host controller is not required to update the iTD field Transaction X Length in this error scenario. If the Mult field is greater than one, then the host controller automatically executes the value of Mult transactions. The host controller will not execute all Mult transactions if:

- The endpoint is an OUT and Transaction X Length goes to zero before all the Mult transactions have executed (ran out of data), or
- The endpoint is an IN and the endpoint delivers a short packet, or an error occurs on a transaction before Mult transactions have been executed. The end of micro-frame may occur before all of the transaction opportunities have been executed. When this happens, the transfer state of the transfer description is advanced to reflect the progress that was made, the result written back to the iTD and the host controller proceeds to processing the next micro-frame. Refer to Appendix D for a table summary of the host controller required behavior for all the high-bandwidth transaction cases.

54.5.3.7.2 Software Operational Model for iTDs

A client buffer request to an isochronous endpoint may span 1 to N micro-frames. When N is larger than one, system software may have to use multiple iTDs to read or write data with the buffer (if N is larger than eight, it must use more than one iTD).

The following figure illustrates the simple model of how a client buffer is mapped by system software to the periodic schedule (that is the periodic frame list and a set of iTDs). On the right is the client description of its request. The description includes a buffer base address plus additional annotations to identify which portions of the buffer should be used with each bus transaction. In the middle is the iTD data structures used by the system software to service the client request. Each iTD can be initialized to service up to 24 transactions, organized into eight groups of up to three transactions each. Each group maps to one micro-frame's worth of transactions. The EHCI controller does not provide per-transaction results within a micro-frame. It treats the per-micro-frame transactions as a single logical transfer. On the left is the host controller's frame list. System software establishes references from the appropriate locations in the frame list to each of the appropriate iTDs. If the buffer is large, then system software can use a small set of iTDs to service the entire buffer. System software can activate the transaction description records (contained in each iTD) in any pattern required for the particular data stream.

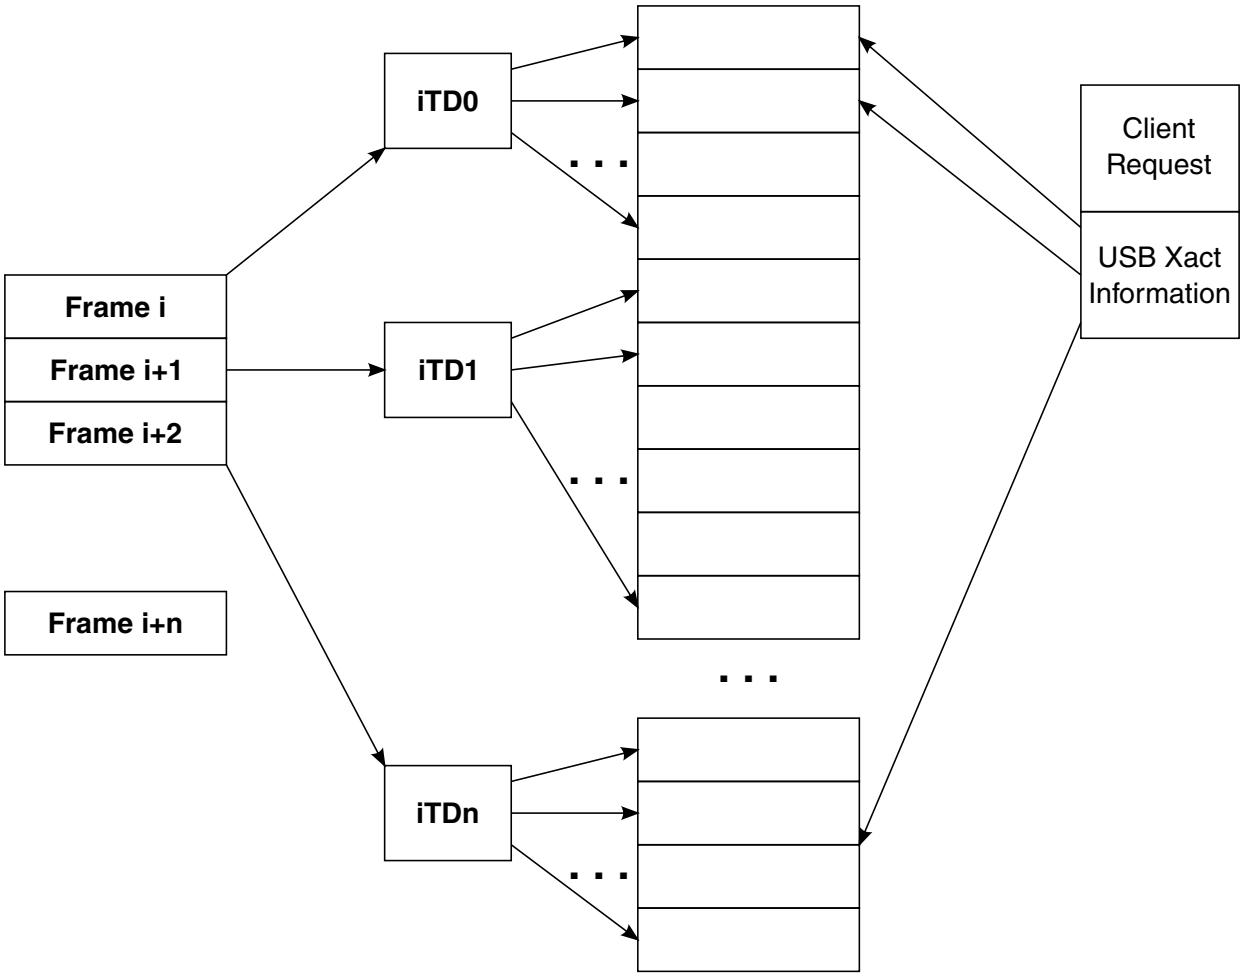

Figure 54-12. Example Association of iTDs to Client Request Buffer

As noted above, the client request includes a pointer to the base of the buffer and offsets into the buffer to annotate which buffer sections are to be used on each bus transaction that occurs on this endpoint. System software must initialize each transaction description in an iTD to ensure it uses the correct portion of the client buffer. For example, for each transaction description, the PG field is set to index the correct physical buffer page pointer and the Transaction Offset field is set relative to the correct buffer pointer page (for example, the same one referenced by the PG field). When the host controller executes a transaction it selects a transaction description record based on FRINDEX[2:0]. It then uses the current Page Buffer Pointer (as selected by the PG field) and concatenates to the transaction offset field. The result is a starting buffer address for the transaction. As the host controller moves data for the transaction, it must watch for a page wrap condition and properly advance to the next available Page Buffer Pointer. System software must not use the Page 6 buffer pointer in a transaction description where the length of the transfer wraps a page boundary. Doing so yields undefined behavior. The host controller hardware is not required to 'alias' the page selector to Page zero. USB 2.0 isochronous

endpoints can specify a period greater than one. Software can achieve the appropriate scheduling by linking iTDs into the appropriate frames (relative to the frame list) and by setting appropriate transaction description elements active bits to one.

54.5.3.7.2.1 Periodic scheduling threshold

The Isochronous Scheduling Threshold field in the USB_HCCPARAMS capability register is an indicator to system software as to how the host controller pre-fetches and effectively caches schedule data structures.

It is used by system software when adding isochronous work items to the periodic schedule. The value of this field indicates to system software the minimum distance it can update isochronous data (relative to the current location of the host controller execution in the periodic list) and still have the host controller process them.

The iTD and siTD data structures each describe 8 micro-frames worth of transactions. The host controller is allowed to cache one (or more) of these data structures in order to reduce memory traffic. Three basic caching models that account for the fact the isochronous data structures span 8 micro-frames. The three caching models are: no caching, micro-frame caching and frame caching.

When software is adding new isochronous transactions to the schedule, it always performs a read of the USB_FRINDEX register to determine the current frame and micro-frame the host controller is currently executing. Of course, there is no information about where in the micro-frame the host controller is, so a constant uncertainty-factor of one micro-frame has to be assumed. Combining the knowledge of where the host controller is executing with the knowledge of the caching model allows the definition of simple algorithms for how closely software can reliably work to the executing host controller.

No caching is indicated with a value of zero in the Isochronous Scheduling Threshold field. The host controller may pre-fetch data structures during a periodic schedule traversal (per micro-frame) but always dumps any accumulated schedule state at the end of the micro-frame. At the appropriate time relative to the beginning of every micro-frame, the host controller always begins schedule traversal from the frame list. Software can use the value of the USB_FRINDEX register (plus the constant 1 uncertainty-factor) to determine the approximate position of the executing host controller. When no caching is selected, software can add an isochronous transaction as near as 2 micro-frames in front of the current executing position of the host controller.

Frame caching is indicated with a non-zero value in bit [7] of the Isochronous Scheduling Threshold field. In the frame-caching model, system software assumes that the host controller caches one (or more) isochronous data structures for an entire frame (8 micro-frames). Software uses the value of the USB_FRINDEX register (plus the constant 1

uncertainty) to determine the current micro-frame/frame (assume modulo 8 arithmetic in adding the constant 1 to the micro-frame number). For any current frame N, if the current micro-frame is 0 to 6, then software can safely add isochronous transactions to Frame N + 1. If the current micro-frame is 7, then software can add isochronous transactions to Frame N + 2.

Micro-frame caching is indicated with a non-zero value in the least-significant 3 bits of the Isochronous Scheduling Threshold field. System software assumes the host controller caches one or more periodic data structures for the number of micro-frames indicated in the Isochronous Scheduling Threshold field. For example, if the count value were 2, then the host controller keeps a window of 2 micro-frames worth of state (current micro-frame, plus the next) on-chip. On each micro-frame boundary, the host controller releases the current micro-frame state and begins accumulating the next micro-frame state.

54.5.3.8 Asynchronous Schedule

The Asynchronous schedule traversal is enabled or disabled through the Asynchronous Schedule Enable bit in the USB_USBCMD register.

If the Asynchronous Schedule Enable bit is set to zero, then the host controller simply does not try to access the asynchronous schedule through the USB_ASYNCLISTADDR register. Likewise, when the Asynchronous Schedule Enable bit is one, then the host controller does use the USB_ASYNCLISTADDR register to traverse the asynchronous schedule. Modifications to the Asynchronous Schedule Enable bit are not necessarily immediate. Rather the new value of the bit is taken into consideration the next time the host controller needs to use the value of the USB_ASYNCLISTADDR register to get the next queue head.

The Asynchronous Schedule Status bit in the USB_USBSTS register indicates status of the asynchronous schedule. System software enables (or disables) the asynchronous schedule by writing one (or zero) to the Asynchronous Schedule Enable bit in the USB_USBCMD register. Software then can poll the Asynchronous Schedule Status bit to determine when the asynchronous schedule has made the desired transition. Software must not modify the Asynchronous Schedule Enable bit unless the value of the Asynchronous Schedule Enable bit equals that of the Asynchronous Schedule Status bit.

The asynchronous schedule is used to manage all Control and Bulk transfers. Control and Bulk transfers are managed using queue head data structures. The asynchronous schedule is based at the USB_ASYNCLISTADDR register. The default value of the USB_ASYNCLISTADDR register after reset is undefined and the schedule is disabled when the Asynchronous Schedule Enable bit is zero.

Software may only write this register with defined results when the schedule is disabled. For example, Asynchronous Schedule Enable bit in the USB_USBCMD and the Asynchronous Schedule Status bit in the USB_USBSTS register are zero. System software enables execution from the asynchronous schedule by writing a valid memory address (of a queue head) into this register. Then software enables the asynchronous schedule by setting the Asynchronous Schedule Enable bit to one. The asynchronous schedule is actually enabled when the Asynchronous Schedule Status bit is one.

When the host controller begins servicing the asynchronous schedule, it begins by using the value of the USB_ASYNCLISTADDR register. It reads the first referenced data structure and begins executing transactions and traversing the linked list as appropriate. When the host controller completes processing the asynchronous schedule, it retains the value of the last accessed queue head's horizontal pointer in the USB_ASYNCLISTADDR register. Next time the asynchronous schedule is accessed, this is the first data structure that is serviced. This provides round-robin fairness for processing the asynchronous schedule.

A host controller completes processing the asynchronous schedule when one of the following events occur:

- The end of a micro-frame occurs.
- The host controller detects an empty list condition (see Empty Asynchronous Schedule Detection)
- The schedule has been disabled through the Asynchronous Schedule Enable bit in the USB_USBCMD register.

The queue heads in the asynchronous list are linked into a simple circular list as shown in Figure 54-7. Queue head data structures are the only valid data structures that may be linked into the asynchronous schedule. An isochronous transfer descriptor (iTD or siTD) in the asynchronous schedule yields undefined results.

The maximum packet size field in a queue head is sized to accommodate the use of this data structure for all non-isochronous transfer types. The USB Specification, Revision 2.0 specifies the maximum packet sizes for all transfer types and transfer speeds. System software should always parameterize the queue head data structures according to the core specification requirements.

54.5.3.8.1 Adding Queue Heads to Asynchronous Schedule

This is a software requirement section.

There are two independent events for adding queue heads to the asynchronous schedule. The first is the initial activation of the asynchronous list. The second is inserting a new queue head into an activated asynchronous list.

Activation of the list is simple. System software writes the physical memory address of a queue head into the USB_ASYNCLISTADDR register, then enables the list by setting the Asynchronous Schedule Enable bit in the USB_USBCMD register to one.

When inserting a queue head into an active list, software must ensure that the schedule is always coherent from the host controllers' point of view. This means that the system software must ensure that all queue head pointer fields are valid. For example, qTD pointers have T-Bits set to one or reference valid qTDs and the Horizontal Pointer references a valid queue head data structure. The following algorithm represents the functional requirements:

```
InsertQueueHead (pQHeadCurrent, pQueueHeadNew)
          --
          -- Requirement: all inputs must be properly initialized.
          --
          -- pQHeadCurrent is a pointer to a queue head that is
          -- already in the active list
          -- pQHeadNew is a pointer to the queue head to be added
          --
          -- This algorithm links a new queue head into a existing
          -- list
          --
          pQueueHeadNew.HorizontalPointer  =  pQueueHeadCurrent.HorizontalPointer
          pQueueHeadCurrent.HorizontalPointer =  physicalAddressOf(pQueueHeadNew)
End InsertQueueHead
```

54.5.3.8.2 Removing Queue Heads from Asynchronous Schedule

This is a software requirement section.

There are two independent events for removing queue heads from the asynchronous schedule. The first is shutting down (deactivating) the asynchronous list. The second is extracting a single queue head from an activated list.

Software deactivates the asynchronous schedule by setting the Asynchronous Schedule Enable bit in the USB_USBCMD register to zero. Software can determine when the list is idle when the Asynchronous Schedule Status bit in the USB_USBSTS register is zero. The normal mode of operation is that software removes queue heads from the asynchronous schedule without shutting it down. Software must not remove an active queue head from the schedule. Software should first deactivate all active qTDs, wait for the queue head to go inactive, then remove the queue head from the asynchronous list. Software removes a queue head from the asynchronous list through the following algorithm. As illustrated, the unlinking is quite easy. Software merely must ensure all of the link pointers reachable by the host controller are kept consistent.

```
UnlinkQueueHead (pQHeadPrevious, pQueueHeadToUnlink, pQHeadNext)
          --
          -- Requirement: all inputs must be properly initialized.
          --
          -- pQHeadPrevious is a pointer to a queue head that
          -- references the queue head to remove
          -- pQHeadToUnlink is a pointer to the queue head to be
```

```
        -- removed
        -- pQheadNext is a pointer to a queue head still in the
        -- schedule. Software provides this pointer with the
        -- following strict rules:
        --          if the host software is one queue head, then
        --          pQHeadNext must be the same as
        --          QueueheadToUnlink.HorizontalPointer. If the host
        --          software is unlinking a consecutive series of
        --          queue heads, QHeadNext must be set by software to
        --          the  queue head remaining in the schedule.
        --
        -- This algorithm unlinks a queue head from a circular list
        --
        pQueueHeadPrevious.HorizontalPointer =  pQueueHeadToUnlink.HorizontalPointer
                          pQueueHeadToUnlink.HorizontalPointer = pQHeadNext
End UnlinkQueueHead
```

If software removes the queue head with the H-bit set to one, it must select another queue head still linked into the schedule and set its H-bit to one. This should be completed before removing the queue head. The requirement is that software keep one queue head in the asynchronous schedule, with its H-bit set to one. At the point software has removed one or more queue heads from the asynchronous schedule, it is unknown whether the host controller has a cached pointer to them. Similarly, it is unknown how long the host controller might retain the cached information, as it is implementation dependent and may be affected by the actual dynamics of the schedule load. Therefore, once software has removed a queue head from the asynchronous list, it must retain the coherency of the queue head (link pointers, and so on). It cannot disturb the removed queue heads until it knows that the host controller does not have a local copy of a pointer to any of the removed data structures.

The method software uses to determine when it is safe to modify a removed queue head is to handshake with the host controller. The handshake mechanism allows software to remove items from the asynchronous schedule, then execute a simple, lightweight handshake that is used by software as a key that it can free (or reuse) the memory associated the data structures it has removed from the asynchronous schedule.

The handshake is implemented with three bits in the host controller. The first bit is a command bit (Interrupt on Async Advance Doorbell bit in the USB_USBCMD register) that allows software to inform the host controller that something has been removed from its asynchronous schedule. The second bit is a status bit (Interrupt on Async Advance bit in the USB_USBSTS register) that the host controller sets after it has released all on-chip state that may potentially reference one of the data structures just removed. When the host controller sets this status bit to one, it also sets the command bit to zero. The third bit is an interrupt enable (Interrupt on Async Advance bit in the USB_USBINTR register) that is matched with the status bit. If the status bit is one and the interrupt enable bit is one, then the host controller asserts a hardware interrupt.

The figure below illustrates a general example. In this example, consecutive queue heads (B and C) are unlinked from the schedule using the algorithm above. Before the unlink operation, the host controller has a copy of queue head A.

The unlink algorithm requires that as software unlinks each queue head, the unlinked queue head is loaded with the address of a queue head that remains in the asynchronous schedule.

When the host controller observes that doorbell bit being set to one, it makes a note of the local reachable schedule information. In this example, the local reachable schedule information includes both queue heads (A and B). It is sufficient that the host controller can set the status bit (and clear the doorbell bit) as soon as it has traversed beyond current reachable schedule information (that is traversed beyond queue head (B) in this example). The following figure illustrates the generic queue head unlink scenario.

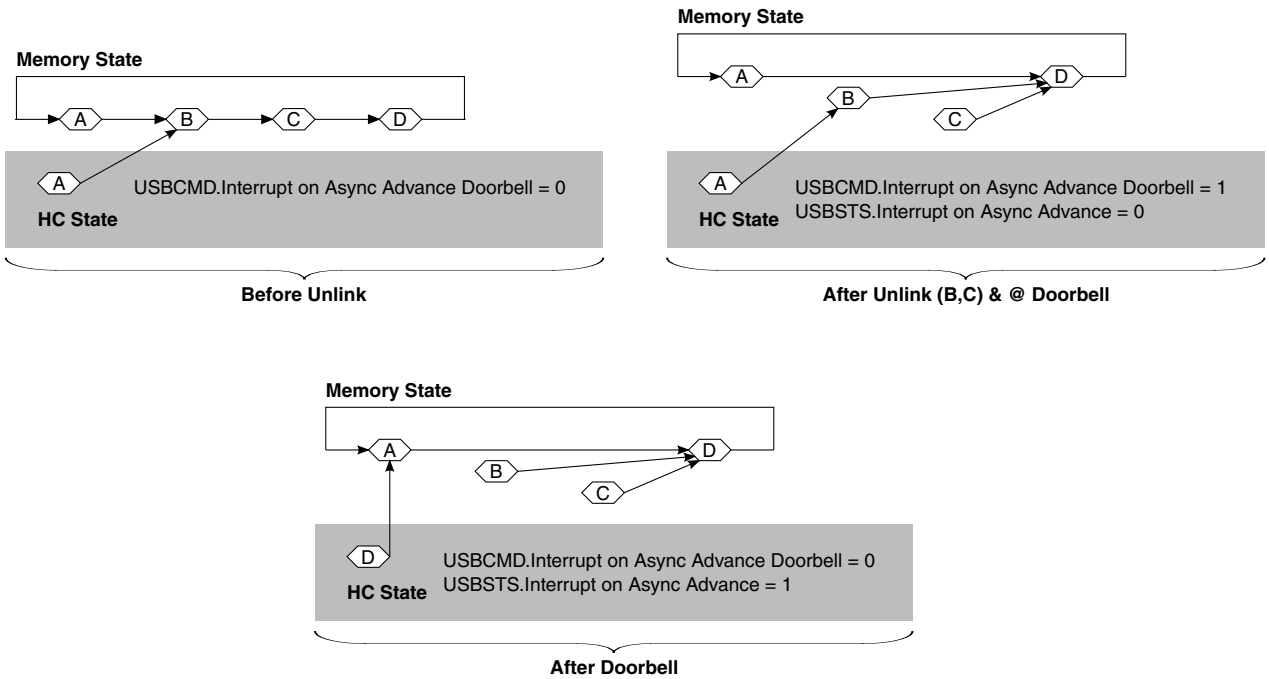

Figure 54-13. Generic Queue Head Unlink Scenario

Alternatively, a host controller implementation is allowed to traverse the entire asynchronous schedule list (for example, observed the head of the queue (twice)) before setting the Advance on Async status bit to one.

Software may re-use the memory associated with the removed queue heads after it observes the Interrupt on Async Advance status bit is set to one, following assertion of the doorbell. Software should acknowledge the Interrupt on Async Advance status as indicated in the USB_USBSTS register, before using the doorbell handshake again.

54.5.3.8.3 Empty Asynchronous Schedule Detection

The Enhanced Host Controller Interface uses two bits to detect when the asynchronous schedule is empty.

The queue head data structure (see Table 54-27) defines an *H-bit* in the queue head, which allows software to mark a queue head as being the *head* of the reclaim list. The Enhanced Host Controller Interface also keeps a 1-bit flag in the USB_USBSTS register (*Reclamation*) that is set to zero when the Enhanced Interface Host Controller observes a queue head with the H-bit set to one. The reclamation flag in the status register is set to one when any USB transaction from the asynchronous schedule is executed (or whenever the asynchronous schedule starts, see Asynchronous schedule traversal: *Start Event*).

If the Enhanced Host Controller Interface ever encounters an *H-bit* of one and a *Reclamation* bit of zero, the EHCI controller simply stops traversal of the asynchronous schedule.

An example illustrating the H-bit in a schedule is shown in the following figure.

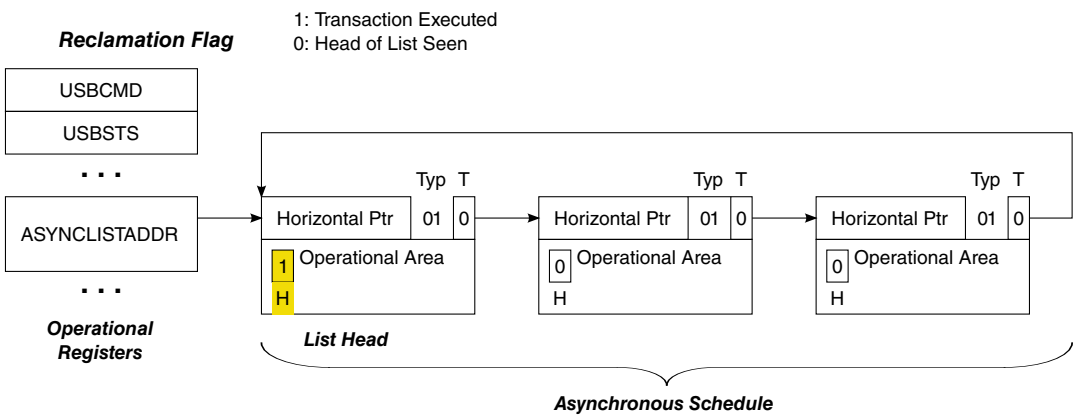

Figure 54-14. Asynchronous Schedule List w/Annotation to Mark Head of List

Software must ensure there is at most one queue head with the *H-bit* set to one, and that it is always coherent with respect to the schedule.

54.5.3.8.4 Restarting Asynchronous Schedule Before EOF

There are many situations where the host controller will detect an empty list *long* before the end of the micro-frame.

It is important to remember that under many circumstances the schedule traversal has stopped due to Nak/Nyet responses from all endpoints.

An example of particular interest is when a start-split for a bulk endpoint occurs early in the micro-frame. Given the EHCI simple traversal rules, the complete-split for that transaction may Nak/Nyet out very quickly. If it is the only item in the schedule, then the host controller ceases traversal of the Asynchronous schedule very early in the micro-frame. In order to provide reasonable service to this endpoint, the host controller should issue the complete-split before the end of the current micro-frame, instead of waiting

until the next micro-frame. When the reason for host controller idling asynchronous schedule traversal is because of empty list detection, it is mandatory the host controller implement a 'waking' method to resume traversal of the asynchronous schedule. An example method is described below.

54.5.3.8.4.1 Example Method for Restarting Asynchronous Schedule Traversal

The reason for idling the host controller when the list is empty is to keep the host controller from unnecessarily occupying too much memory bandwidth. The question is: *how long should the host controller stay idle before restarting*?

The answer in this example is based on deriving a manifest constant, which is the amount of time the host controller will stay idle before restarting traversal. In this example, the manifest constant is called *AsyncSchedSleepTime*, and has a value of 10 µsec. The value is derived based on the analysis in Example Derivation for *AsyncSchedSleepTime*, The traversal algorithm is simple:

- Traverse the Asynchronous schedule until the either an End-Of-micro-Frame event occurs, or an empty list is detected. If the event is an End-of-micro-Frame, go attempt to traverse the Periodic schedule. If the event is an empty list, then set a sleep timer and go to a *schedule sleep* state.
- When the sleep timer expires, set working context to the Asynchronous Schedule start condition and go to *schedule active* state. The start context allows the HC to reload *Nakcnt* fields, and so on. So the HC has a chance to run for more than one iteration through the schedule.

This process simply repeats itself each micro-frame. The figure below illustrates a sample state machine to manage the active and sleep states of the Asynchronous Schedule traversal policy. There are three states: Actively traversing the Asynchronous schedule, Sleeping, and Not Active. The last two are similar in terms of interaction with the Asynchronous schedule, but the Not Active state means that the host controller is busy with the Periodic schedule or the Asynchronous schedule is not enabled. The Sleeping state is specifically a special state where the host controller is just waiting for a period of time before resuming execution of the Asynchronous schedule.

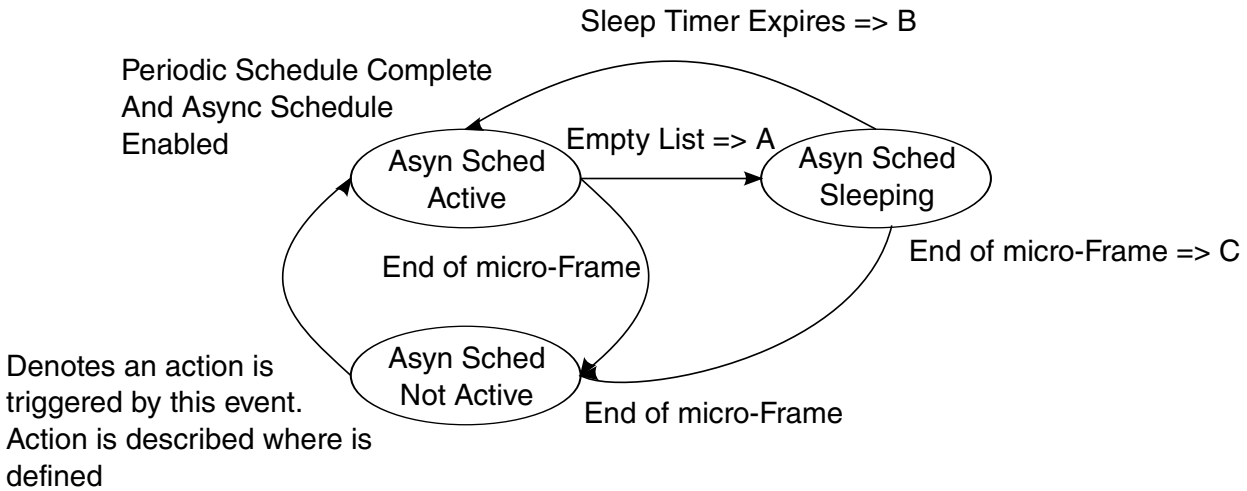

Figure 54-15. Example State Machine for Managing Asynchronous Schedule Traversal

The actions referred to in the figure above are defined in the following table.

Table 54-42. Asynchronous Schedule SM Transition Actions

Action	Action Description Label
A	On detection of the empty list, the host controller sets the *AsynchronousTraversalSleepTimer* to *AsyncSchedSleepTime*.
B	When the *AsynchronousTraversalSleepTimer* expires, the host controller sets the *Reclamation* bit in the USBSTS register to one and moves the Nak Counter reload state machine to WaitForListHead (see Nak Count Reload Control).
C	The host controller cancels the sleep timer (*AsynchronousTraversalSleepTimer*).

54.5.3.8.4.2 Async Sched Not Active

This is the initial state of the traversal state machine after a host controller reset. The traversal state machine does not leave this state when the *Asynchronous Schedule Enable* bit in the USB_USBCMD register is zero.

This state is entered from Async Sched Active or Async Sched Sleeping states when the end-of-micro-frame event is detected.

54.5.3.8.4.3 Async Sched Active

This state is entered from the Async Sched Not Active state when the periodic schedule is not active. It is also entered from the Async Sched Sleeping states when the *AsyncrhonousTraversalSleepTimer* expires. On every transition into this state, the host controller sets the *Reclamation* bit in the USB_USBSTS register to one.

While in this state, the host controller continually traverses the asynchronous schedule until either the end of micro-frame or an empty list condition is detected.

54.5.3.8.4.4 Async Sched Sleeping

The state is entered from the Async Sched Active state when a schedule empty condition is detected. On entry to this state, the host controller sets the *AsynchronousTraversalSleepTimer* to *AsyncSchedSleepTime*.

54.5.3.8.4.5 Example Derivation for *AsyncSchedSleepTime*

The derivation is based on analysis of what work the host controller could be doing next.

It assumes the host controller does not keep any state about what work is possibly pending in the asynchronous schedule. The schedule could contain any mix of the possible combinations of high- full- or low-speed control and bulk requests.

The table below summarizes some of the typical 'next transactions' that could be in the schedule, and the amount of time (for example *footprint*, or *wall clock*) the transaction takes to complete.

Table 54-43. Typical Low-/Full-speed Transaction Times

Transaction Attributes		Footprint (time)	Description
Speed	HS	11.9 ms	Maximum foot print for a worst-case, full-sized bulk data transaction.
Size	512	9.45 ms	Maximum footprint for an approximate best-case, full-sized bulk data transaction.
Type	Bulk		
Speed	FS	~50 ms	Approximate typical for full-sized bulk data. An 8-byte low-speed is about 2x, or between 90 and 100 ms.
Size	64		
Type	Bulk		
Speed	FS	~12 ms	Approximate typical for 8-byte bulk/control (that is setup)
Size	8		
Type	Cntrl		

A *AsyncSchedSleepTime* value of 10 µs provides a reasonable relaxation of the system memory load and still provides a good level of service for the various transfer types and payload sizes. For example, say we detect an empty list after issuing a start-split for a 64-byte full-speed bulk request. Assuming this is the only thing in the list, the host controller gets the results of the full-speed transaction from the hub during the fifth complete-split request. If the full-speed transaction was an IN and it nak'd, the 10 µs sleep period would allow the host controller to get the NAK results on the first complete-split.

54.5.3.8.5 Asynchronous schedule traversal: *Start Event*

Once the HC has *idled* itself through the empty schedule detection (Section 0), it will naturally *activate* and begin processing from the Periodic Schedule at the beginning of each micro-frame.

In addition, it may have idled itself early in a micro-frame. When this occurs (idles early in the micro-frame) the HC must occasionally *re-activate* during the micro-frame and traverse the asynchronous schedule to determine whether any progress can be made. The requirements and method for this restart are described in Restarting Asynchronous Schedule Before EOF . Asynchronous schedule *Start Event*s are defined to be:

- Whenever the host controller transitions from the periodic schedule to the asynchronous schedule. If the periodic schedule is disabled and the asynchronous schedule is enabled, then the beginning of the micro-frame is equivalent to the transition from the periodic schedule, or
- The asynchronous schedule traversal restarts from a sleeping state (see Restarting Asynchronous Schedule Before EOF).

54.5.3.8.6 Reclamation Status Bit (USBSTS Register)

The operation of the empty asynchronous schedule detection feature (see Empty Asynchronous Schedule Detection) depends on the proper management of the *Reclamation* bit in the USB_USBSTS register. The host controller tests for an empty schedule just after it fetches a new queue head while traversing the asynchronous schedule (see Fetch Queue Head).

The host controller is required to set the *Reclamation* bit to one whenever an asynchronous schedule traversal *Start Event*, as documented in Asynchronous schedule traversal: *Start Event*, occurs. The *Reclamation* bit is also set to one whenever the host controller executes a transaction while traversing the asynchronous schedule (see Execute Transaction). The host controller sets the *Reclamation* bit to zero whenever it finds a queue head with its *H-bit* set to one. Software should only set a queue head's *H-bit* if the queue head is in the asynchronous schedule. If software sets the *H-bit* in an interrupt queue head to one, the resulting behavior is undefined. The host controller may set the *Reclamation* bit to zero when executing from the periodic schedule.

54.5.3.9 Operational Model for Nak Counter

This section describes the operational model for the *NakCnt* field defined in a queue head.

See Queue Head Initialization for more information. Software should not use this feature for interrupt queue heads. This rule is not required to be enforced by the host controller.

USB protocol has built-in flow control through the Nak response by a device. There are several scenarios, beyond the Ping feature, where an endpoint may naturally Nak or Nyet the majority of the time. An example is the host controller management of the split transaction protocol for control and bulk endpoints. All bulk endpoints (High- or Full-speed) are serviced through the same asynchronous schedule. The time between the *Start-split* transaction and the first *Complete-split* transaction could be very short (that is like when the endpoint is the only one in the asynchronous schedule). The hub NYETs (effectively Naks) the *Complete-split* transaction until the classic transaction is complete. This could result in the host controller thrashing memory, repeatedly fetching the queue head and executing the transaction to the Hub, which does not complete until after the transaction on the classic bus completes.

The two component fields in a queue head to support the throttling feature: a counter field (*NakCnt*), and a counter reload field (*RL*). *NakCnt* is used by the host controller as one of the criteria to determine whether or not to execute a transaction to the endpoint. The two operational modes associated with this counter:

- Not Used- This mode is set when the *RL* field is zero. The host controller ignores the *NakCnt* field for any execution of transactions through a queue head with an *RL* field of zero. Software must use this selection for interrupt endpoints.
- Nak Throttle Mode- This mode is selected when the *RL* field is non-zero. In this mode, the value in the *NakCnt* field represents the maximum number of Nak or Nyet responses the host controller tolerates on each endpoint. In this mode, the HC decrements the *NakCnt* field based on the token/handshake criteria listed in the table below. The host controller must reload *NakCnt* when the endpoint successfully moves data (for example, policy to reward device for moving data).

The following table describes the NakCnt field adjustment rules.

Table 54-44. NakCnt Field Adjustment Rules

Token	Handshake	
	Handshake NAK	NYET
IN/PING	decrement *NakCnt*	N/A (protocol error)
OUT	decrement *NakCnt*	No Action[1] Start
Split	decrement *NakCnt*	N/A (protocol error)
Complete Split	No Action	Decrement *NakCnt*

1. Recommended behavior on this response is to reload *NakCnt*

In summary, system software enables the counter by setting the reload field (*RL*) to a non-zero value. The host controller may execute a transaction if *NakCnt* is non-zero. The host controller does not execute a transaction if *NakCnt* is zero. The reload mechanism is described in detail in Nak Count Reload Control .

NOTE

When all queue heads in the Asynchronous Schedule either exhausts all transfers or all NakCnt's go to zero, then the host controller detects an empty Asynchronous Schedule and idle schedule traversal (see Empty Asynchronous Schedule Detection).

Any time the host controller begins a new traversal of the Asynchronous Schedule, a *Start Event* is assumed, see Asynchronous schedule traversal: *Start Event*. Every time a Start-Event occurs, the Nak Count reload procedure is enabled.

54.5.3.9.1 Nak Count Reload Control

When the host controller reaches the *Execute Transaction* state for a queue head (meaning that it has an active operational state), it checks to determine whether the *NakCnt* field should be reloaded from *RL* (see Execute Transaction). If the answer is yes, then *RL* is copied into *NakCnt*. After the reload or if the reload is not active, the host controller evaluates whether to execute the transaction.

The host controller must reload nak counters (*NakCnt* see Table 54-27) in queue heads during the first pass through the reclamation list after an asynchronous schedule Start Event (see Asynchronous schedule traversal: *Start Event* for the definition of the Start Event). The Asynchronous Schedule should have at most one queue head marked as the head (see Figure 54-14).

The following figure illustrates an example state machine that satisfies the operational requirements of the host controller detecting the first pass through the Asynchronous Schedule. This state machine is maintained internal to the host controller and is only used to gate reloading of the nak counter during the queue head traversal state: Execute Transaction (see the figure below). The host controller does not perform the nak counter reload operation if the RL field (see Table 54-27) is set to zero.

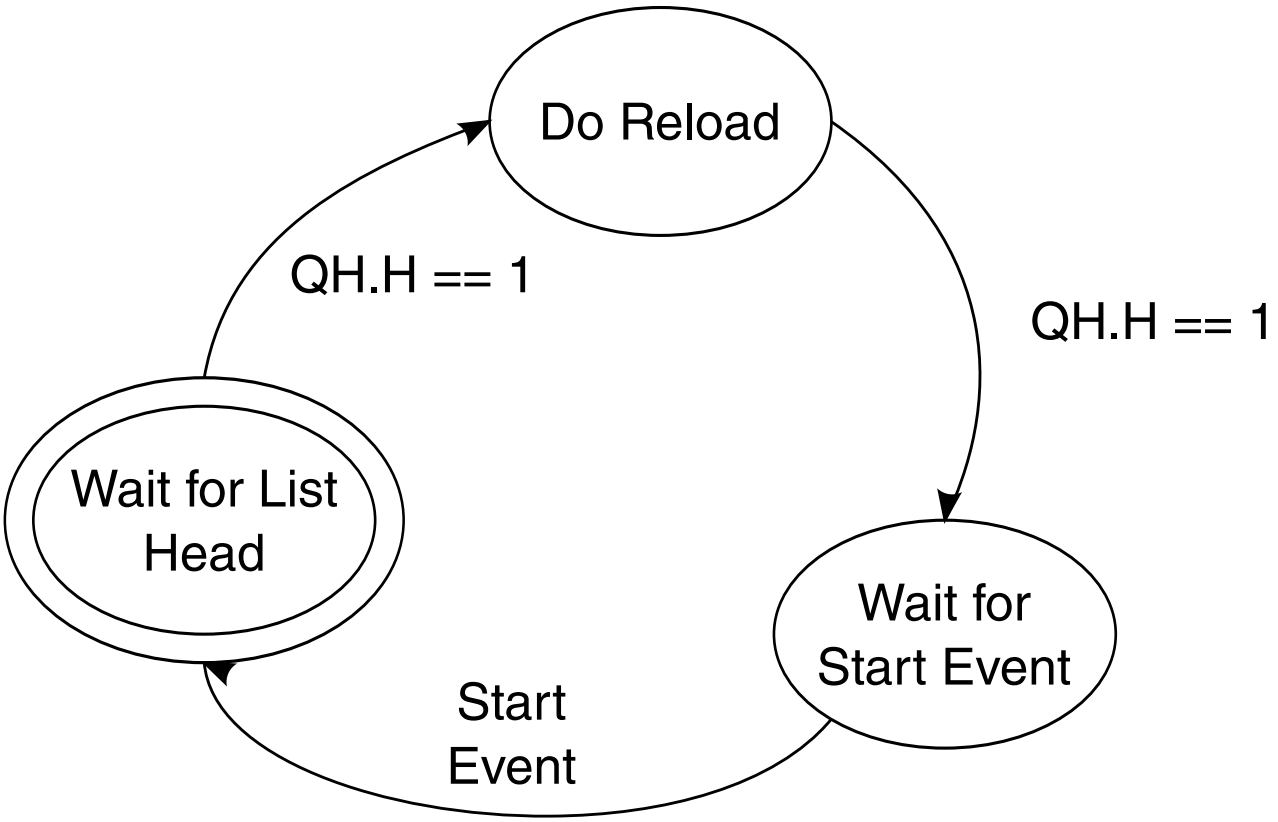

Figure 54-16. Example HC State Machine for Controlling Nak Counter Reloads

54.5.3.9.1.1 Wait for List Head

This is the initial state.

The state machine enters this state from Wait for Start Event when a start event as defined in Asynchronous schedule traversal: *Start Event* occurs.

The purpose of this state is to wait for the first observation of the head of the Asynchronous Schedule.

This occurs when the host controller fetches a queue head whose *H-bit* is set to one.

54.5.3.9.1.2 Do Reload

This state is entered from the Wait for List Head state when the host controller fetches a queue head with the *H-bit* set to one. While in this state, the host controller performs nak counter reloads for every queue head visited that has a non-zero nak reload value (*RL*) field.

54.5.3.9.1.3 Wait for Start Event

This state is entered from the *Do Reload* state when a queue head with the *H-bit* set to one is fetched. While in this state, the host controller does not perform nak counter reloads.

54.5.3.10 Managing Control/Bulk/Interrupt Transfers through Queue Heads

This section presents an overview of how the host controller interacts with queuing data structures.

Queue heads use the Queue Element Transfer Descriptor (qTD) structure. One queue head is used to manage the data stream for one endpoint. The queue head structure contains static endpoint characteristics and capabilities. It also contains a working area from where individual bus transactions for an endpoint are executed (see Overlay area defined in Table 54-27). Each qTD represents one or more bus transactions, which is defined in the context of this specification as a *transfer*.

The general processing model for the host controller's use of a queue head is simple:

- read a queue head,
- execute a transaction from the overlay area,
- write back the results of the transaction to the overlay area,
- move to the next queue head.

If the host controller encounters errors during a transaction, the host controller sets one (or more) of the error reporting bits in the queue head's *Status* field. The *Status* field accumulates all errors encountered during the execution of a qTD (for example, the error bits in the queue head *Status* field are 'sticky' until the transfer (qTD) has completed). This state is always written back to the source qTD when the transfer is complete. On transfer (for example, buffer or halt conditions) boundaries, the host controller must auto-advance (without software intervention) to the next qTD. Additionally, the hardware must be able to halt the queue so no additional bus transactions occurs for the endpoint and the host controller does not advance the queue.

An example host controller operational state machine of a queue head traversal is illustrated in the following figure. This state machine is a model for how a host controller should traverse a queue head. The host controller must be able to advance the queue from the *Fetch QH* state in order to avoid all hardware/software race conditions. This simple mechanism allows software to simply link qTDs to the queue head and *activate* them, then the host controller always *find* them if/when they are reachable. The figure below illustrates the Host Controller Queue Head Traversal State Machine.

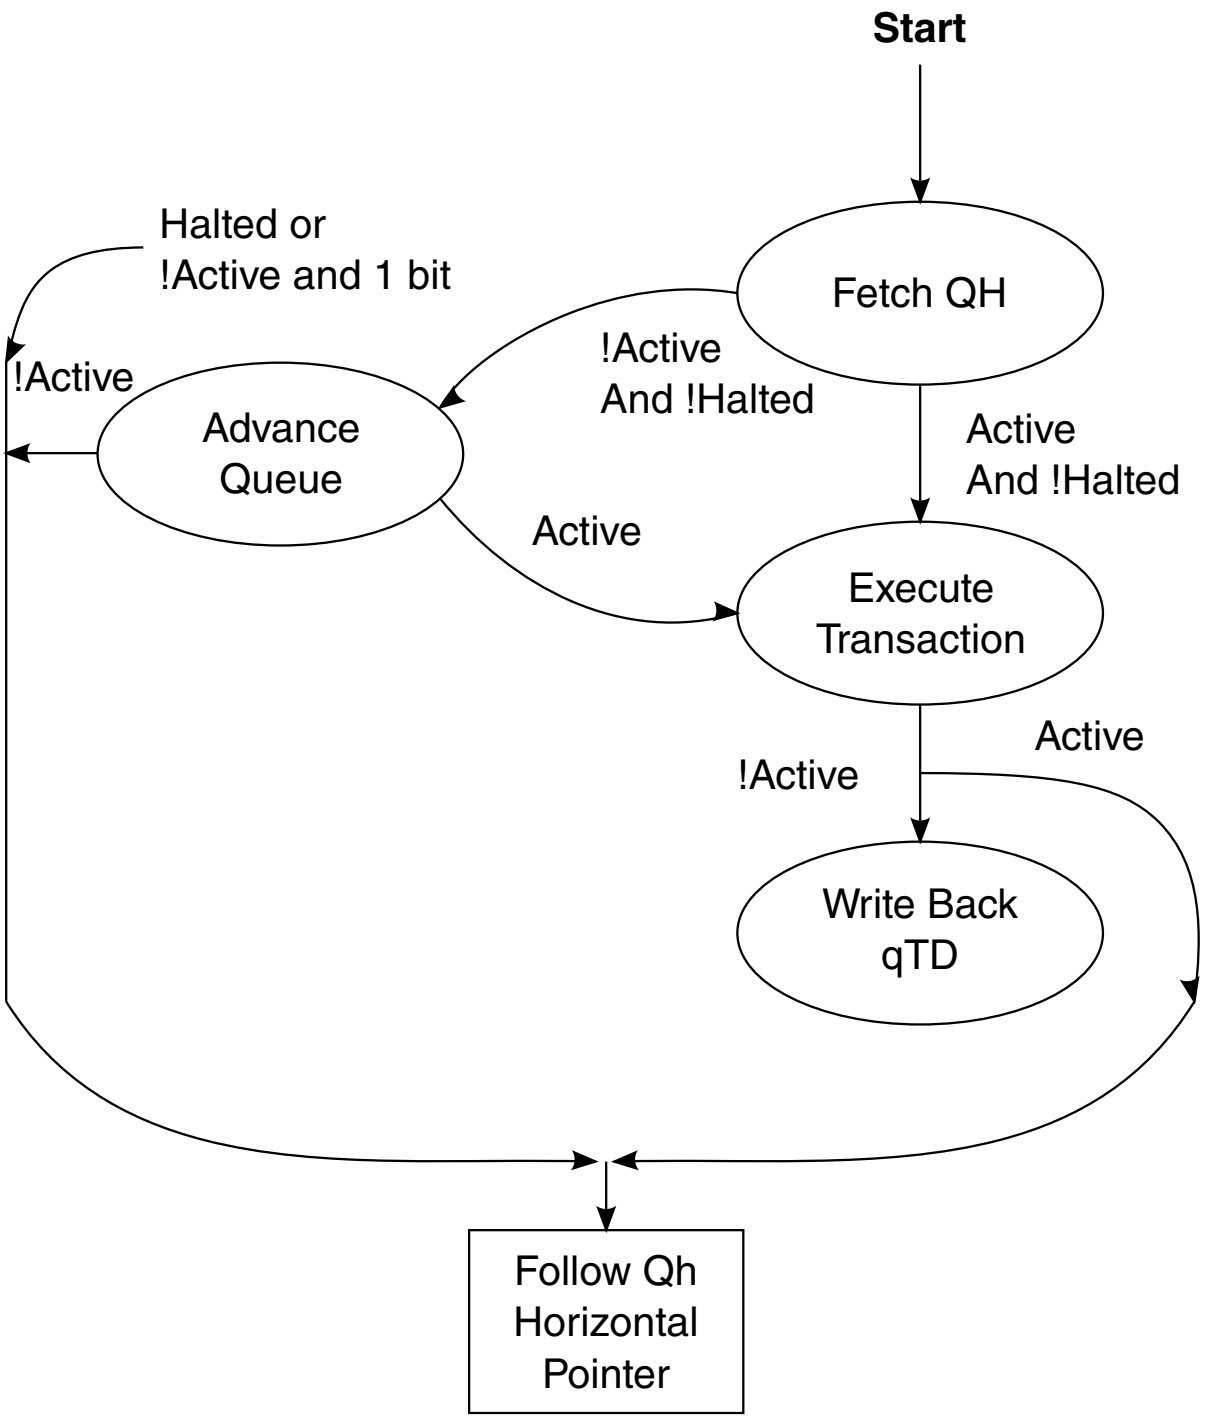

Figure 54-17. Host Controller Queue Head Traversal State Machine

This traversal state machine applies to all queue heads, regardless of transfer type or whether split transactions are required. The following sections describe each state. Each state description describes the entry criteria. The Execute Transaction state (see Execute

Transaction) describes the basic requirements for all endpoints. Split Transactions for Asynchronous Transfers and Split Transaction Interrupt describe details of the required extensions to the Execute Transaction state for endpoints requiring split transactions.

NOTE

Prior to software placing a queue head into either the periodic or asynchronous list, software must ensure the queue head is properly initialized. Minimally, the queue head should be initialized to the following (see Section Queue Head for layout of a queue head):

Valid static endpoint state.

- For the very first use of a queue head, software may zero-out the queue head transfer overlay, then set the *Next qTD Pointer* field value to reference a valid qTD.

54.5.3.10.1 Fetch Queue Head

A queue head can be referenced from the physical address stored in the ASYNCLISTADDR Register (see Next Asynch. Address (USB_*n*ASYNCLISTADDR))/ Endpoint List Address (USB_*n*ENDPTLISTADDR) Additionally, it may be referenced from the *Next LinkPointer* field of an iTD, siTD, FSTN or another Queue Head. If the referencing link pointer has the *Typ* field set to indicate a queue head, it is assumed to reference a queue head structure as defined in Table 54-27.

While in this state, the host controller performs operations to implement empty schedule detection (see Empty Asynchronous Schedule Detection) and Nak Counter reloads (see Operational Model for Nak Counter). After the queue head has been fetched, the host controller conducts the following queries for empty schedule detection:

- If queue head is not an interrupt queue head (that is *S-mask* is zero), and
- The *H-bit* is one, and
- The *Reclamation* bit in the USBSTS register is zero.

When these criteria are met, the host controller stops traversing the asynchronous list (as described in Empty Asynchronous Schedule Detection). When the criteria are not met, the host controller continues schedule traversal. If the queue head is not an interrupt and the *H-bit* is one and the *Reclamation* bit is one, then the host controller sets the *Reclamation* bit in the USBSTS register to zero before completing this state. The operations for reloading of the Nak Counter are described in detail in Operational Model for Nak Counter.

This state is complete when the queue head has been read on-chip.

54.5.3.10.2 Advance Queue

To advance the queue, the host controller must find the next qTD, adjust pointers, perform the overlay and write back the results to the queue head.

This state is entered from the FetchQHD state if the overlay *Active* and *Halt* bits are set to zero. On entry to this state, the host controller determines which next pointer to use to fetch a qTD, fetches a qTD and determines whether or not to perform an overlay.

NOTE

If the *I-bit* is one and the *Active* bit is zero, the host controller immediately skips processing of this queue head, exits this state and uses the horizontal pointer to the next schedule data structure. If the field *Bytes to Transfer* is not zero and the *T-bit* in the *Alternate Next qTD Pointer* is set to zero, then the host controller uses the *Alternate Next qTD Pointer*. Otherwise, the host controller uses the *NextqTD Pointer*. If *NextqTD Pointer's T-bit* is set to one, then the host controller exits this state and uses the horizontal pointer to the next schedule data structure.

Using the selected pointer the host controller fetches the referenced qTD. If the fetched qTD has its *Active* bit set to one, the host controller moves the pointer value used to reach the qTD (*Next* or *Alternate Next*) to the *Current qTD Pointer* field, then performs the overlay. If the fetched qTD has its *Active* bit set to zero, the host controller aborts the queue advance and follows the queue head's horizontal pointer to the next schedule data structure.

The host controller performs the overlay based on the following rules:

- The value of the data toggle (*dt*) field in the overlay area depends on the value of the *data toggle control* (*dtc*) bit (see Table 54-29).
- If the *EPS* field indicates the endpoint is a high-speed endpoint, the *Ping* state field is preserved by the host controller. The value of this field is not changed as a result of the overlay.
- *C-prog-mask* field is set to zero (field from incoming qTD is ignored, as is the current contents of the overlay area).
- *Frame Tag* field is set to zero (field from incoming qTD is ignored, as is the current contents of the overlay area).
- *NakCnt* field in the overlay area is loaded from the *RL* field in the queue head's Static Endpoint State.
- All other areas of the overlay are set by the incoming qTD.

The host controller exits this state when it has committed the write to the queue head.

54.5.3.10.3 Execute Transaction

The host controller enters this state from the Fetch Queue Head state only if the *Active* bit in *Status* field of the queue head is set to one.

On entry to this state, the host controller executes a few pre-operations, then checks some pre-condition criteria before committing to executing a transaction for the queue head.

The pre-operations performed and the pre-condition criteria depend on whether the queue head is an interrupt endpoint. The host controller can determine that a queue head is an interrupt queue head when the queue head's *S-mask* field contains a non-zero value. It is the responsibility of software to ensure the *S-mask* field is appropriately initialized based on the transfer type. There are other criteria that must be met if the *EPS* field indicates that the endpoint is a low- or full-speed endpoint, see Split Transactions for Asynchronous Transfers and Split Transaction Interrupt .

54.5.3.10.3.1 Interrupt Transfer Pre-condition Criteria

If the queue head is for an interrupt endpoint (for example, non-zero *S-mask* field), then the FRINDEX[2:0] field must identify a bit in the *S-mask* field that has one in it.

For example, an *S-mask* value of 00100000b would evaluate to true only when FRINDEX[2:0] is equal to 101b. If this condition is met then the host controller considers this queue head for a transaction.

54.5.3.10.3.2 Asynchronous Transfer Pre-operations and Pre-condition Criteria

If the queue head is not for an interrupt endpoint (for example, zero *S-mask* field), then the host controller performs one pre-operation and then evaluates one pre-condition criteria.

The pre-operation is:

Checks the Nak counter reload state (Operational Model for Nak Counter). It may be necessary for the host controller to reload the Nak Counter field. The reload is performed at this time.

The pre-condition evaluated is:

- Whether or not the *NakCnt* field has been reloaded, the host controller checks the value of the *NakCnt* field in the queue head. If *NakCnt* is non-zero, or if the *Reload Nak Counter* field is zero, then the host controller considers this queue head for a transaction.

54.5.3.10.3.3 Transfer Type Independent Pre-operations

Regardless of the transfer type, the host controller always performs at least one pre-operation and evaluates one pre-condition. The pre-operation is:

- A host controller internal transaction (down) counter *qHTransactionCounter* is loaded from the queue head's *Mult* field. A host controller implementation is allowed to ignore this for queue heads on the asynchronous list. It is mandatory for interrupt queue heads. Software should ensure that the *Mult* field is set appropriately for the transfer type.

The pre-conditions evaluated are:

- The host controller determines whether there is enough time in the micro-frame to complete this transaction (see Transaction Fit - A Best-Fit Approximation Algorithm for an example evaluation method). If there is not enough time to complete the transaction, the host controller exits this state.
- If the value of *qHTransactionCounter* for an interrupt endpoint is zero, then the host controller exits this state.

When the pre-operations are complete and pre-conditions are met, the host controller sets the *Reclamation* bit in the USBSTS register to one and then begins executing one or more transactions using the endpoint information in the queue head. The host controller iterates *qHTransactionCounter* times in this state executing transactions. After each transaction is executed, *qHTransactionCounter* is decremented by one. The host controller exits this state when one of the following events occurs:

- The *qHTransactionCounter* decrements to zero, or
- The endpoint responds to the transaction with any handshake other than an ACK,[4] or
- The transaction experiences a transaction error, or
- The *Active* bit in the queue head goes to zero, or
- There is not enough time in the micro-frame left to execute the next transaction(see Transaction Fit - A Best-Fit Approximation Algorithm) for example method for implementing the frame boundary test).

NOTE

For a high-bandwidth interrupt OUT endpoint, the host controller may optionally immediately retry the transaction if it fails.

The results of each transaction is recorded in the on-chip overlay area. If data was successfully moved during the transaction, the transfer state in the overlay area is advanced. To advance queue head's transfer state, the *Total Bytes to Transfer* field is decremented by the number of bytes moved in the transaction, the data toggle bit (*dt*) is toggled, the current page offset is advanced to the next appropriate value (for example,

advanced by the number of bytes successfully moved), and the *C_Page* field is updated to the appropriate value (if necessary). See Buffer Pointer List Use for Data Streaming with qTDs .

NOTE

The *Total Bytes To Transfer* field may be zero when all the other criteria for executing a transaction are met. When this occurs, the host controller executes zero-length transaction to the endpoint. If the *PID_Code* field indicates an IN transaction and the device delivers data, the host controller detects a packet babble condition, set the *babble* and *halted* bits in the *Status* field, set the *Active* bit to zero, write back the results to the source qTD, then exit this state.

In the event an IN token receives a data PID mismatch response, the host controller must ignore the received data (for example not advance the transfer state for the bytes received). Additionally, if the endpoint is an interrupt IN, then the host controller must record that the transaction occurred (for example, decrement *qHTransactionCounter*). It is recommended (but not required) the host controller continue executing transactions for this endpoint if the resultant value of *qHTransactionCounter* is greater than one.

If the response to the IN bus transaction is a Nak (or Nyet) and *RL* is non-zero, *NakCnt* is decremented by one. If *RL* is zero, then no write-back by the host controller is required (for a transaction receiving a Nak or Nyet response and the value of *CErr* did not change). Software should set the *RL* field to zero if the queue head is an interrupt endpoint. Host controller hardware is not required to enforce this rule or operation.

After the transaction has finished and the host controller has completed the post processing of the results (advancing the transfer state and possibly *NakCnt*, the host controller writes back the results of the transaction to the queue head's overlay area in main memory).

The number of bytes moved during an IN transaction depends on how much data the device endpoint delivers. The maximum number of bytes a device can send is *MaximumPacket Size*. The number of bytes moved during an OUT transaction is either *Maximum Packet Length* bytes or *Total Bytes to Transfer*, whichever is less.

If there was a transaction error during the transaction, the transfer state (as defined above) is not advanced by the host controller. The *CErr* field is decremented by one and the status field is updated to reflect the type of error observed. Transaction errors are summarized in Transaction Error .

The following events causes the host controller to clear the *Active* bit in the queue head's overlay status field. When the *Active* bit transitions from one to zero, the transfer in the overlay is considered complete. The reason for the transfer completion (clearing the *Active* bit) determines the next state.

- *CErr* field decrements to zero. When this occurs the *Halted* bit is set to one and *Active* is set to zero. This results in the hardware not advancing the queue and the pipe halts. Software must intercede to recover.
- The device responds to the transaction with a STALL PID. When this occurs, the *Halted* bit is set to one and the *Active* bit is set to zero. This results in the hardware not advancing the queue and the pipe halts. Software must intercede to recover.
- The *Total Bytes to Transfer* field is zero after the transaction completes.
  - For a zero length transaction, it was zero before the transaction was started. When this condition occurs, the *Active* bit is set to zero.
- The PID code is an IN, and the number of bytes moved during the transaction is less than the *Maximum Packet Length*. When this occurs, the *Active* bit is set to zero and a short packet condition exists. The short-packet condition is detected during the Advance Queue state. Refer to Split Transactions for additional rules for managing low- and full-speed transactions.

With the exception of a NAK response (when *RL* field is zero), the host controller always writes the results of the transaction back to the overlay area in main memory. This includes when the transfer completes. For a high-speed endpoint, the queue head information written back includes minimally the following fields: The *PID Code* field indicates an IN and the device sends more than the expected number of bytes (for example *Maximum Packet Length* or *Total Bytes to Transfer* bytes, whichever is less) (for example a packet babble). This results in the host controller setting the *Halted* bit to one.

- NakCnt, dt, Total Bytes to Transfer, C_Page, Status, CERR, and Current Offset

For a low- or full-speed device the queue head information written back also includes the fields:

- C-prog-mask, FrameTag and S-bytes.

The duration of this state depends on the time it takes to complete the transaction(s) and the status write to the overlay is committed.

54.5.3.10.3.4 Halting a Queue Head

A halted endpoint is defined only for the transfer types that are managed through queue heads (control, bulk and interrupt).

The following events indicate that the endpoint has reached a condition where no more activity can occur without intervention from the driver:

- An endpoint may return a STALL handshake during a transaction,
- A transaction had three consecutive error conditions, or
- A Packet Babble error occurs on the endpoint.

When any of these events occur (for a queue head) the Host Controller halts the queue head and set the USBERRINT status bit in the USB_n_USBSTS register to one. To halt the queue head, the *Active* bit is set to zero and the *Halted* bit is set to one. There may be other error status bits that are set when a queue is halted. The host controller always writes back the overlay area to the source qTD when the transfer is complete, regardless of the reason (normal completion, short packet or halt). The host controller does not advance the transfer state on a transaction that results in a *Halt* condition (for example no updates necessary for *Total Bytes to Transfer*, *C_Page*, *Current Offset,* and *dt*). The host controller must update *CErr* as appropriate. When a queue head is halted, the *USB Error Interrupt* bit in the USB_n_USBSTS register is set to one. If the *USB Error Interrupt Enable* bit in the USB_n_USBINTR register is set to one, a hardware interrupt is generated at the next interrupt threshold.

54.5.3.10.3.5 Asynchronous Schedule Park Mode

Asynchronous Schedule Park mode is a special execution mode that can be enabled by system software, where the host controller is permitted to execute more than one bus transaction from a high-speed queue head in the Asynchronous schedule before continuing horizontal traversal of the Asynchronous schedule.

This feature has no effect on queue heads or other data structures in the Periodic schedule. This feature is similar in intent as the *Mult* feature that is used in the Periodic schedule. Where-as the *Mult* feature is a characteristic that is tunable for each endpoint; park-mode is a policy that is applied to all high-speed queue heads in the asynchronous schedule. It is essentially the specification of an iterator for consecutive bus transactions to the same endpoint. All of the rules for managing bus transactions and the results of those as defined in Execute Transaction apply. This feature merely specifies how many consecutive times the host controller is permitted to execute from the same queue head before moving to the next queue head in the Asynchronous List. This feature should allow the host controller to attain better bus utilization for those devices that are capable of moving data at maximum rate, while at the same time providing a fair service to all endpoints.

A host controller exports its capability to support this feature to system software by setting the *Asynchronous Schedule Park Capability* bit in the USB_n_HCCPARAMs register to one. This information keys system software that the *Asynchronous Schedule Park Mode Enable* and *Asynchronous Schedule Park Mode Count* fields in the USB_n_USBCMD register are modifiable. System software enables the feature by writing a one to the *Asynchronous Schedule Park Mode Enable* bit.

When park-mode is not enabled (for example *Asynchronous Schedule Park Mode Enable* bit in the USB_n_USBCMD register is zero), the host controller must not execute more than one bus transaction per high-speed queue head, per traversal of the asynchronous schedule. When park-mode is enabled, the host controller must not apply the feature to a queue head whose *EPS* field indicates a Low/Full-speed device (for example only one bus transaction is allowed from each Low/Full-speed queue head per traversal of the asynchronous schedule). Park-mode may only be applied to queue heads in the Asynchronous schedule whose *EPS* field indicates that it is a high-speed device.

The host controller must apply park mode to queue heads whose *EPS* field indicates a high-speed endpoint. The maximum number of consecutive bus transactions a host controller may execute on a high-speed queue head is determined by the value in the *Asynchronous Schedule Park Mode Count* field in the USB_n_USBCMD register. Software must not set *Asynchronous Schedule Park Mode Enable* bit to one and also set *Asynchronous Schedule Park Mode Count* field to zero. The resulting behavior is not defined. An example behavioral example describes the operational requirements for the host controller implementing park-mode. This feature does not affect how the host controller handles the bus transaction as defined in Execute Transaction . It only effects how many consecutive bus transactions for the current queue head can be executed. All boundary conditions, error detection and reporting applies as usual. This feature is similar in concept to the use of the *Mult* field for high-bandwidth Interrupt for queue heads in the Periodic Schedule.

The host controller effectively loads an internal down-counter *PM-Count* from *Asynchronous Schedule Park Mode Count* when *Asyncrhonous Schedule Park Mode Enable* bit is one, and a high-speed queue head is first fetched and meets all the criteria for executing a bus transaction. After the bus transaction, *PM-Count* is decremented. The host controller may continue to execute bus transactions from the current queue head until *PM-Count* goes to zero, an error is detected, the buffer for the current transfer is exhausted or the endpoint responds with a flow-control or STALL handshake.

The following table summarizes the responses that effect whether the host controller continues with another bus transaction for the current queue head.

Table 54-45. Actions for Park Mode, based on Endpoint Response and Residual Transfer State

PID	Endpoint Response	Transfer State after Transaction		Action
		PM-Count	Bytes to Transfer	
IN	DATA[0,1] w/Maximum Packet sized data	Not zero	Not Zero	Allowed to perform another bus transaction.[1, 2]
		Not zero	Zero	Retire qTD and move to next QH
		Zero	Don't care	Move to next QH.

Table continues on the next page...

Table 54-45. Actions for Park Mode, based on Endpoint Response and Residual Transfer State (continued)

	DATA[0,1] w/short packet	Don't care	Don't care	Retire qTD and move to next QH.
	NAK	Don't care	Don't care	Move to next QH.
	STALL, XactErr	Don't care	Don't care	Move to next QH.
OUT	ACK	Not zero	Not Zero	Allowed to perform another bus transaction.[2]
		Not zero	Zero	Retire qTD and move to next QH
		Zero	Don't' care	Move to next QH.
	NYET, NAK	Don't care	Don't care	Move to next QH.
	STALL, XactErr	Don't care	Don't care	Move to next QH
PING	ACK	Not Zero	Not Zero	Allowed to perform another bus transaction. [2]
	NAK	Don't care	Don't care	Move to next QH
	STALL, XactErr	Don't care	Don't care	Move to next QH

1. The host controller may continue to execute bus transactions from the current high-speed queue head (if *PM-Count* is not equal to zero), if a PID mismatch is detected (for example expected DATA1 and received DATA0, or visa-versa).
2. This specification does not *require* that the host controller execute another bus transaction when *PM-Count* is non-zero. Implementations are encouraged to make appropriate complexity and performance trade-offs.

54.5.3.10.4 Write Back qTD

This state is entered from the Execute Transaction state when the *Active* bit is set to zero.

The source data for the write-back is the transfer results area of the queue head overlay area (see Table 54-45).

The host controller uses the *Current qTD Pointer* field as the target address for the qTD.

The queue head transfer result area is written back to the transfer result area of the target qTD. This state is also referred to as: qTD retirement. The fields that must be written back to the source qTD include *Total Bytes to Transfer*, *Cerr*, and *Status*.

The duration of this state depends on when the qTD write-back is committed.

54.5.3.10.5 Follow Queue Head Horizontal Pointer

The host controller must use the horizontal pointer in the queue head to the next schedule data structure when any of the following conditions exist:

- If the *Active* bit is one on exit from the Execute Transaction state, or
- When the host controller exits the Write Back qTD state, or
- If the Advance Queue state fails to advance the queue because the target qTD is not active, or
- If the *Halted* bit is one on exit from the Fetch QH state.

There is no functional requirement that the host controller wait until the current transaction is complete before using the horizontal pointer to read the next linked data structure. However, it must wait until the current transaction is complete before executing the next data structure.

54.5.3.10.6 Buffer Pointer List Use for Data Streaming with qTDs

A qTD has an array of buffer pointers, which is used to reference the data buffer for a transfer. This specification requires that the buffer associated with the transfer be *virtually contiguous*.

This means: if the buffer spans more than one physical page, it must obey the following rules (the figure below illustrates an example):

- The first portion of the buffer must begin at some offset in a page and extend through the end of the page.
- The remaining buffer cannot be allocated in small chunks scattered around memory. For each 4 K chunk beyond the first page, each buffer portion matches to a full 4 K page. The final portion, which may only be large enough to occupy a portion of a page, must start at the top of the page and be contiguous within that page.

The buffer pointer list in the qTD is long enough to support a maximum transfer size of 20 K bytes. This case occurs when all five buffer pointers are used and the first offset is zero. A qTD handles a 16 Kbyte buffer with any starting buffer alignment.

The host controller uses the field *C_Page* field as an index value to determine which buffer pointer in the list should be used to start the current transaction. The host controller uses a different buffer pointer for each physical page of the buffer. This is always true, even if the buffer is physically contiguous.

The host controller must detect when the current transaction spans a page boundary and automatically move to the next available buffer pointer in the page pointer list. The next available pointer is reached by incrementing *C_Page* and pulling the next page pointer from the list. Software must ensure there are sufficient buffer pointers to move the amount of data specified in the *Bytes to Transfer* field.

The following figure illustrates a nominal example of how System software would initialize the buffer pointers list and the *C_Page* field for a transfer size of 16383 bytes. *C_Page* is set to zero. The upper 20-bits of Page 0 references the start of the physical page. *Current Offset* (the lower 12-bits of queue head Dword 7) holds the offset in the page for example 2049 (for example 4096-2047). The remaining page pointers are set to reference the beginning of each subsequent 4 K page.

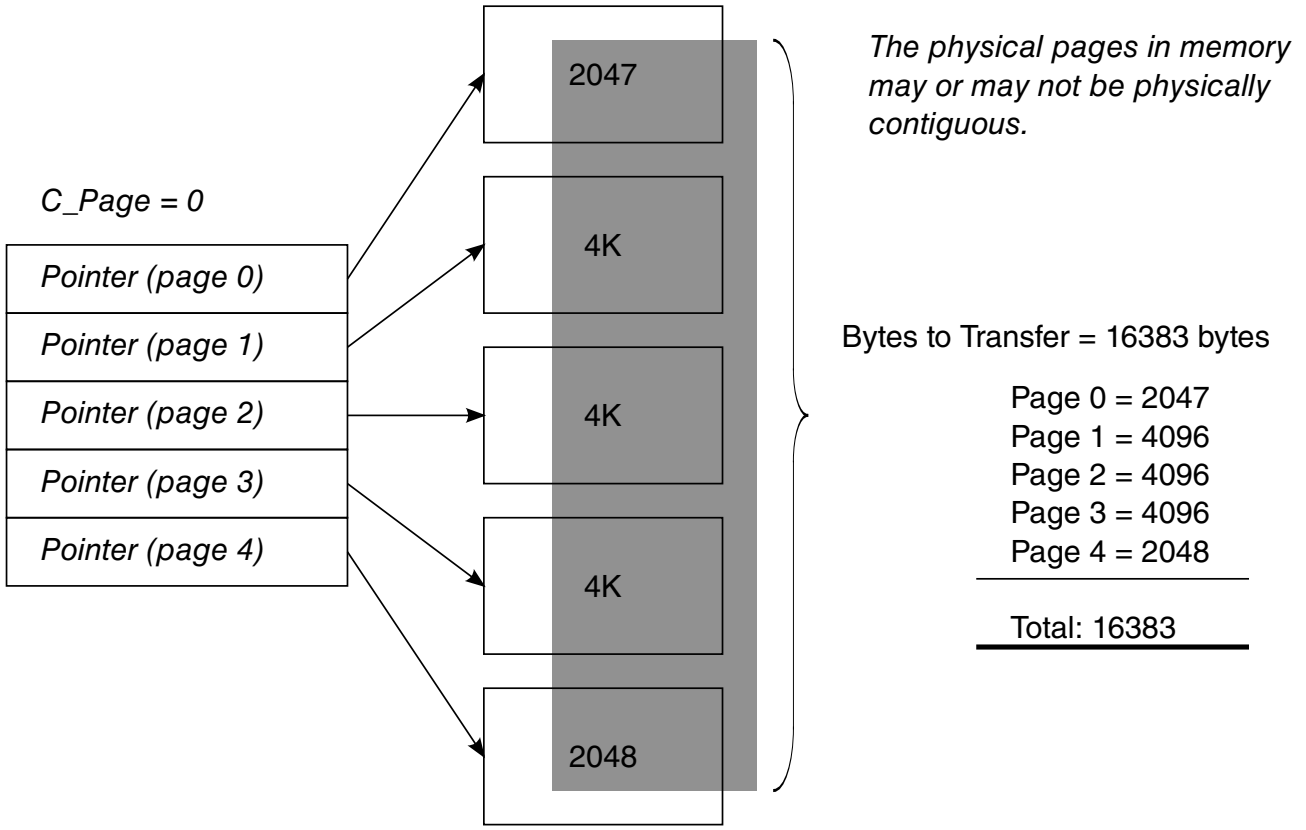

Figure 54-18. Example Mapping of qTD Buffer Pointers to Buffer Pages

For the first transaction on the qTD (assuming a 512-byte transaction), the host controller uses the first buffer pointer (page 0 because *C_Page* is set to zero) and concatenates the *Current Offset* field. The 512 bytes are moved during the transaction, the *Current Offset* and *Total Bytes to Transfer* are adjusted by 512 and written back to the queue head working area.

During the 4th transaction, the host controller needs 511 bytes in page 0 and one byte in page 1. The host controller increments *C_Page* (to 1) and use the page 1 pointer to move the final byte of the transaction. After the 4th transaction, the active page pointer is the page 1 pointer and *Current Offset* has rolled to one, and both are written back to the overlay area. The transactions continue for the rest of the buffer, with the host controller automatically moving to the next page pointer (that is *C_Page*) when necessary. The three conditions for how the host controller handles *C_Page*:

- The current transaction does not span a page boundary. The value of *C_Page* is not adjusted by the host controller.

- The current transaction does span a page boundary. The host controller must detect the page cross condition and advance to the next buffer while streaming data to/from the USB.
- The current transaction completes on a page boundary (that is the last byte moved for the current transaction is the last byte in the page for the current page pointer). The host controller must increment *C_Page* before writing back status for the transaction.

NOTE

The only valid adjustment the host controller may make to *C_Page* is to increment by one.

54.5.3.10.7 Adding Interrupt Queue Heads to the Periodic Schedule

The link path(s) from the periodic frame list to a queue head establishes in which frames a transaction can be executed for the queue head. Queue heads are linked into the periodic schedule so they are polled at the appropriate rate.

System software sets a bit in a queue head's *S-Mask* to indicate which micro-frame within 1 msec period a transaction should be executed for the queue head. Software must ensure that all queue heads in the periodic schedule have *S-Mask* set to a non-zero value. An *S-mask* with zero value in the context of the periodic schedule yields undefined results.

If the desired poll rate is greater than one frame, system software can use a combination of queue head linking and *S-Mask* values to spread interrupts of equal poll rates through the schedule so that the periodic bandwidth is allocated and managed in the most efficient manner possible. Some examples are illustrated in the following table.

Table 54-46. Example Periodic Reference Patterns for Interrupt Transfers with 2ms Poll Rate

Frame # Reference Sequence	Description
0, 2, 4, 6, 8, and so on *S-Mask* = 01h	A queue head for the *bInterval* of 2 msec (16 micro-frames) is linked into the periodic schedule so that it is reachable from the periodic frame list locations indicated in the previous column. In addition, the *S-Mask* field in the queue head is set to 01h, indicating that the transaction for the endpoint should be executed on the bus during micro-frame 0 of the frame.
0, 2, 4, 6, 8, and so on *S-Mask* = 02h	Another example of a queue head with a *bInterval* of 2 msec is linked into the periodic frame list at exactly the same interval as the previous example. However, the *S-Mask* is set to 02h indicating that the transaction for the endpoint should be executed on the bus during micro-frame 1 of the frame.

54.5.3.10.8 Managing Transfer Complete Interrupts from Queue Heads

The host controller sets an interrupt to be signaled at the next interrupt threshold when the completed transfer (qTD) has an *Interrupt on Complete* (*IOC*) bit set to one, or whenever a transfer (qTD) completes with a short packet.

If system software needs multiple qTDs to complete a client request (that is like a control transfer) the intermediate qTDs do not require interrupts. System software may only need a single interrupt to notify it that the complete buffer has been transferred. System software may set IOC's to occur more frequently. A motivation for this may be that it wants early notification so that interface data structures can be re-used in a timely manner.

54.5.3.11 Ping Control

USB 2.0 defines an addition to the protocol for high-speed devices called Ping. Ping is required for all USB 2.0 High-speed bulk and control endpoints.

Ping is not allowed for a split-transaction stream. This extension to the protocol eliminates the bad side-effects of Naking OUT endpoints. The *Status* field has a *Ping State* bit, which the host controller uses to determine the *next* actual PID it uses in the next transaction to the endpoint (see the table below).

The Ping State bit is only managed by the host controller for queue heads that meet the following criteria:

- Queue head is not an interrupt and
- *EPS* field equals High-Speed and
- *PIDCode* field equals OUT

The following table illustrates the state transition table for the host controller's responsibility for maintaining the PING protocol. Refer to Chapter 8 in the USB Specification Revision 2.0 for detailed description on the Ping protocol.

Table 54-47. Ping Control State Transition Table

Event			
Current	Host	Device	Next
Do Ping	PING	Nak	Do Ping
Do Ping	PING	Ack	Do OUT
Do Ping	PING	XactErr [1]	Do Ping
Do Ping	PING	Stall	N/C [2] Do
OUT	OUT	Nak	Do Ping
Do OUT	OUT	Nyet	Do Ping

Table continues on the next page...

Table 54-47. Ping Control State Transition Table (continued)

Do OUT	OUT	Ack	Do OUT
Do OUT	OUT	XactErr[1]	Do Ping
Do OUT	OUT	Stall	N/C [2]

1. Transaction Error (XactErr) is any time the host misses the handshake.
2. No transition change required for the Ping State bit. The Stall handshake results in the endpoint being halted (for example Active set to zero and Halt set to one). Software intervention is required to restart queue. 3 A Nyet response to an OUT means that the device has accepted the data, but cannot receive any more at this time. Host must advance the transfer state and additionally, transition the Ping State bit to Do Ping. The Ping State bit has the following encoding:

Table 54-48. Ping State bit Encoding

Value	Meaning
0B	Do OUT The host controller uses an OUT PID during the next bus transaction to this endpoint.
1B	Do Ping The host controller uses a PING PID during the next bus transaction to this endpoint.

The defined ping protocol (see USB 2.0 Specification, Chapter 8) allows the host to be *imprecise* on the initialization of the ping protocol (that is start in *Do OUT* when we don't know whether there is space on the device or not). The host controller manages the *Ping State* bit. System software sets the initial value in the queue head when it initializes a queue head. The host controller preserves the *Ping State* bit across all queue advancements. This means that when a new qTD is written into the queue head overlay area, the previous value of the *Ping State* bit is preserved.

54.5.3.12 Split Transactions

USB 2.0 defines extensions to the bus protocol for managing USB 1.x data streams through USB 2.0 Hubs.

This section describes how the host controller uses the interface data structures to manage data streams with full- and low-speed devices, connected below USB 2.0 hub, utilizing the split transaction protocol.

Refer to USB 2.0 Specification for the complete definition of the split transaction protocol. Full- and Low-speed devices are enumerated identically as high-speed devices, but the transactions to the Full- and Low-speed endpoints use the split-transaction protocol on the high-speed bus. The split transaction protocol is an encapsulation of (or wrapper around) the Full- or Low-speed transaction. The high-speed wrapper portion of the protocol is addressed to the USB 2.0 Hub and Transaction Translator below which the Full- or Low-speed device is attached.

The EHCI interface uses dedicated data structures for managing full-speed isochronous data streams (see Split Transaction Isochronous Transfer Descriptor (siTD)). Control, Bulk and Interrupt are managed using the queuing data structures (see Queue Head). The interface data structures need to be programmed with the device address and the Transaction Translator number of the USB 2.0 Hub operating as the Low-/Full-speed host controller for this link. The following sections describe the details of how the host controller must process and manage the split transaction protocol.

54.5.3.12.1 Split Transactions for Asynchronous Transfers

A queue head in the asynchronous schedule with an *EPS* field indicating a full-or low-speed device indicates to the host controller that it must use split transactions to stream data for this queue head.

All full-speed bulk and full-, low-speed control are managed through queue heads in the asynchronous schedule.

Software must initialize the queue head with the appropriate device address and port number for the transaction translator that is serving as the full/low-speed host controller for the links connecting the endpoint. Software must also initialize the split transaction state bit (*SplitXState*) to Do-Start-Split. Finally, if the endpoint is a control endpoint, then system software must set the *Control Transfer Type* (*C*) bit in the queue head to one. If this is not a control transfer type endpoint, the *C* bit must be initialized by software to be zero. This information is used by the host controller to properly set the Endpoint Type (ET) field in the split transaction bus token. When the *C* bit is zero, the split transaction token's ET field is set to indicate a bulk endpoint. When the *C* bit is one, the split transaction token's ET field is set to indicate a control endpoint. Refer to Chapter 8 of USB Specification Revision 2.0 for details.

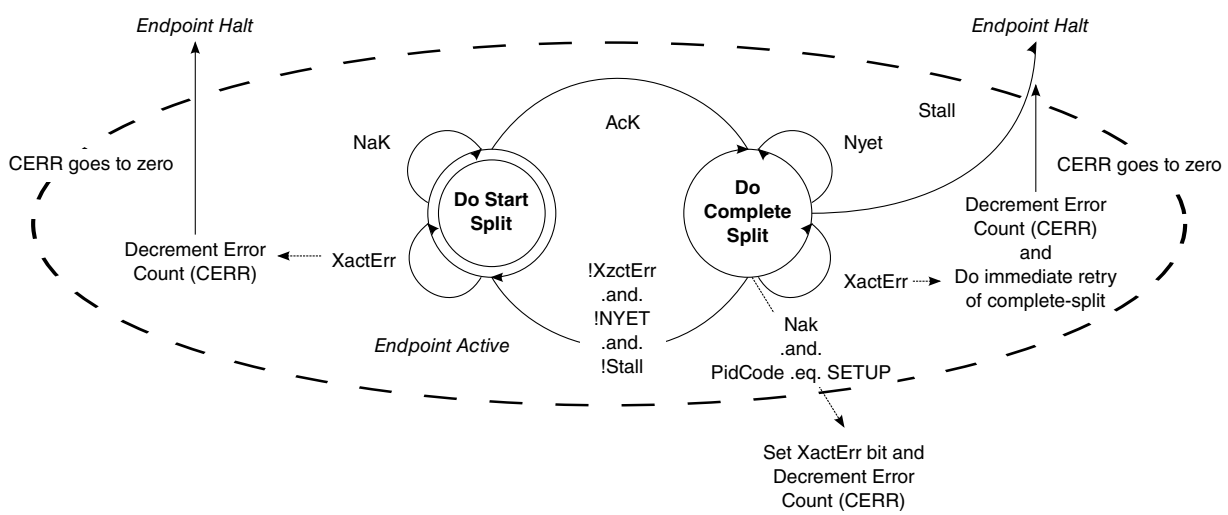

Figure 54-19. Host Controller Asynchronous Schedule Split-Transaction State Machine

54.5.3.12.1.1 Asynchronous - Do Start Split

This is the state which software must initialize a full- or low-speed asynchronous queue head. This state is entered from the Do Complete Split state only after a complete-split transaction receives a valid response from the transaction translator that is not a Nyet handshake.

For queue heads in this state, the host controller executes a start-split transaction to the appropriate transaction translator. If the bus transaction completes without an error and *PidCode* indicates an IN or OUT transaction, then the host controller reloads the error counter (*CErr*). If it is a successful bus transaction and the *PidCode* indicates a SETUP, the host controller does not reload the error counter. If the transaction translator responds with a Nak, the queue head is left in this state, and the host controller proceeds to the next queue head in the asynchronous schedule.

If the host controller times out the transaction (no response, or bad response) the host controller decrements *Cerr* and proceeds to the next queue head in the asynchronous schedule.

54.5.3.12.1.2 Asynchronous - Do Complete Split

This state is entered from the Do Start Split state only after a start-split transaction receives an Ack handshake from the transaction translator.

For queue heads in this state, the host controller executes a complete-split transaction to the appropriate transaction translator. If the transaction translator responds with a Nyet handshake, the queue head is left in this state, the error counter is reset and the host controller proceeds to the next queue head in the asynchronous schedule. When a Nyet handshake is received for a bus transaction where the queue head's *PidCode* indicates an IN or OUT, the host controller reloads the error counter (*CErr*). When a Nyet handshake is received for a complete-split bus transaction where the queue head's *PidCode* indicates a SETUP, the host controller must not adjust the value of *CErr*.

Independent of *PIDCode*, the following responses have the effects:

- Transaction Error (XactErr). Timeout or data CRC failure, and so on. The error counter (*Cerr*) is decremented by one and the complete split transaction is *immediately* retried (if possible). If there is not enough time in the micro-frame to execute the retry, the host controller MUST ensure that the next time the host controller begins executing from the Asynchronous schedule, it must begin executing from this queue head. If another start-split (for some other endpoint) is sent to the transaction translator before the complete-split is really completed, the transaction translator could dump the results (which were never delivered to the host). This is why the core specification states the retries must be immediate. A method to

accomplish this behavior is to not advance the asynchronous schedule. When the host controller returns to the asynchronous schedule in the next micro-frame, the first transaction from the schedule is the retry for this endpoint.

If *Cerr* went to zero, the host controller must halt the queue.

- NAK. The target endpoint Nak'd the full- or low-speed transaction. The state of the transfer is not advanced and the state is exited. If the *PidCode* is a SETUP, then the Nak response is a protocol error. The *XactErr* status bit is set to one and the *CErr* field is decremented.
- STALL. The target endpoint responded with a STALL handshake. The host controller sets the *halt* bit in the status byte, retires the qTD but does not attempt to advance the queue.

If the *PidCode* indicates an IN, then any of following responses are expected:

- DATA0/1. On reception of data, the host controller ensures the PID matches the expected data toggle and checks CRC. If the packet is *good*, the host controller advances the state of the transfer, for example move the data pointer by the number of bytes received, decrement *BytesToTransfer* field by the number of bytes received, and toggle the *dt* bit. The host controller then exit this state. The response and advancement of transfer may trigger other processing events, such as retirement of the qTD and advancement of the queue.

If the data sequence PID does not match the expected, the data is ignored, the transfer state is not advanced and this state is exited. If the *PidCode* indicates an OUT/SETUP, then any of following responses are expected:

- ACK. The target endpoint accepted the data, so the host controller must advance the state of the transfer. The *Current Offset* field is incremented by *Maximum Packet Length* or *Bytes to Transfer*, whichever is less. The field *Bytes To Transfer* is decremented by the same amount and the data toggle bit (*dt*) is toggled. The host controller then exit this state.
- Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue (see Managing Control/Bulk/Interrupt Transfers through Queue Heads).

54.5.3.12.2 Split Transaction Interrupt

Split-transaction Interrupt-IN/OUT endpoints are managed through the same data structures used for high-speed interrupt endpoints. They both co-exist in the periodic schedule.

Queue heads/qTDs offer the set of features required for reliable data delivery, which is characteristic to interrupt transfer types. The split-transaction protocol is managed completely within this defined functional transfer framework. For example, for a high-speed endpoint, the host controller visits a queue head, execute a high-speed transaction (if criteria are met) and advance the transfer state (or not) depending on the results of the entire transaction. For low- and full-speed endpoints, the details of the *execution* phase are different (that is takes more than one bus transaction to complete), but the remainder of the operational framework is intact. This means that the transfer advancement, and so on, occurs as defined in Managing Control/Bulk/Interrupt Transfers through Queue Heads, but only occurs on the completion of a split transaction.

54.5.3.12.2.1 Split Transaction Scheduling Mechanisms for Interrupt

Full- and low-speed Interrupt queue heads have an *EPS* field indicating full- or low-speed and have a non-zero *S-mask* field.

The host controller can detect this combination of parameters and assume the endpoint is a periodic endpoint. Low- and full-speed interrupt queue heads require the use of the split transaction protocol. The host controller sets the Endpoint Type (ET) field in the split token to indicate the transaction is an interrupt. These transactions are managed through a transaction translator's periodic pipeline. Software should not set these fields to indicate the queue head is an interrupt unless the queue head is used in the periodic schedule.

System software manages the per/transaction translator periodic pipeline by budgeting and scheduling exactly during which micro-frames the start-splits and complete-splits for each endpoint occurs. The characteristics of the transaction translator are such that the high-speed transaction protocol must execute during explicit micro-frames, or the data or response information in the pipeline is lost.

The following figure illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule and queue head data structure. The S and ^{C}X labels indicate micro-frames where software can schedule start-splits and complete splits (respectively).

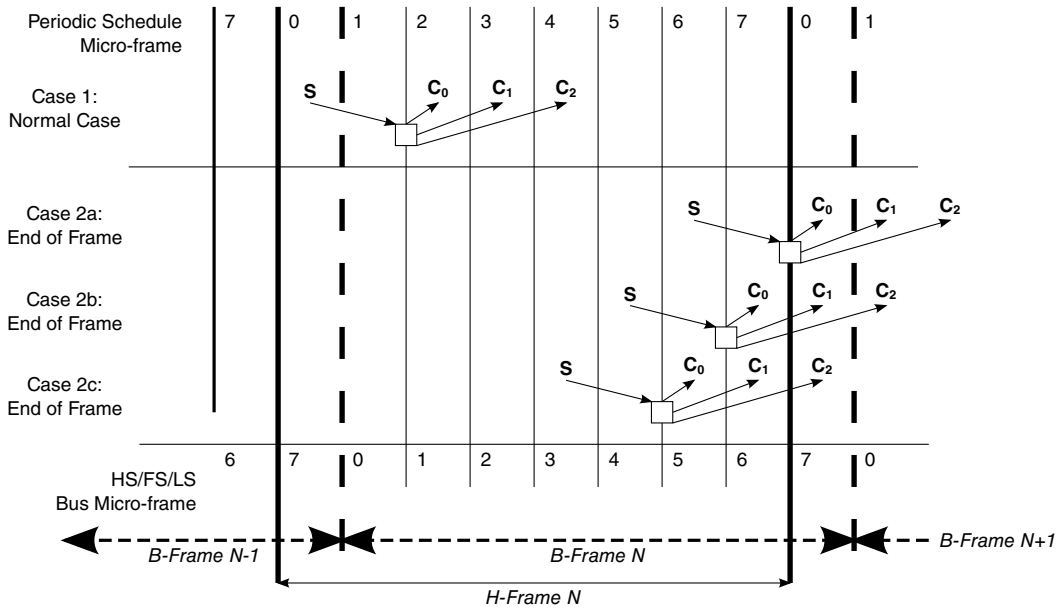

Figure 54-20. Split Transaction, Interrupt Scheduling Boundary Conditions

The scheduling cases are:

- Case 1: The normal scheduling case is where the entire split transaction is completely bounded by a frame (*H-Frame* in this case).
- Case 2a through Case 2c: The USB 2.0 Hub pipeline rules states clearly, when and how many complete-splits must be scheduled to account for earliest to latest execution on the full/low-speed link. The complete-splits may span the *H-Frame* boundary when the start-split is in micro-frame 4 or later. When this occurs, the *H-Frame* to *B-Frame* alignment requires that the queue head be reachable from consecutive periodic frame list locations. System software cannot build an efficient schedule that satisfies this requirement unless it uses FSTNs.

The figure below illustrates the general layout of the periodic schedule.

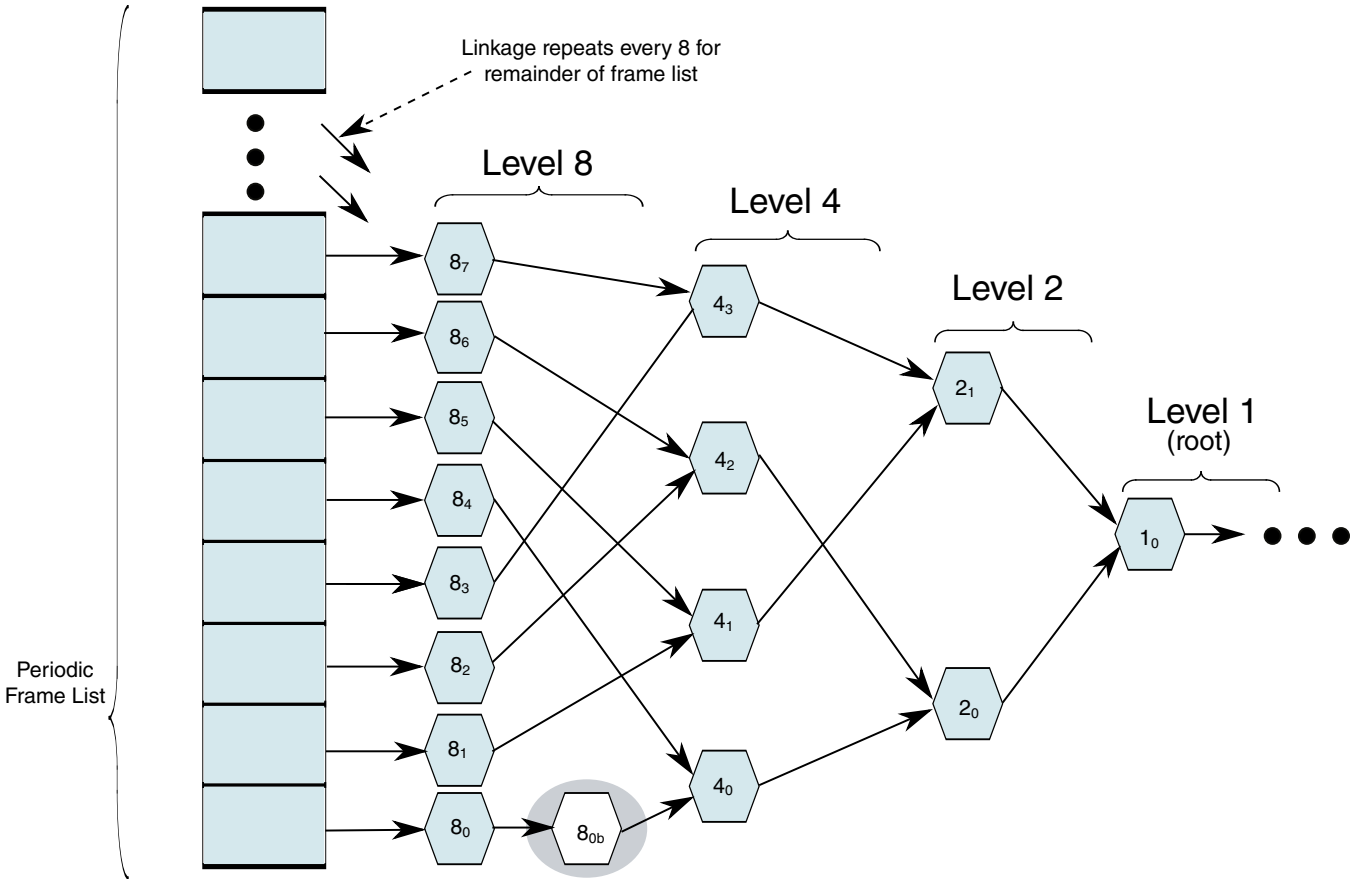

Figure 54-21. General Structure of EHCI Periodic Schedule Utilizing Interrupt Spreading

The periodic frame list is effectively the leaf level a binary tree, which is always traversed leaf to root. Each level in the tree corresponds to a 2^N poll rate. Software can efficiently manage periodic bandwidth on the USB by *spreading* interrupt queue heads that have the same poll rate requirement across all the available paths from the frame list. For example, system software can schedule eight poll rate 8 queue heads and account for them once in the high-speed bus bandwidth allocation.

When an endpoint is allocated an execution footprint that spans a frame boundary, the queue head for the endpoint must be reachable from consecutive locations in the frame list. An example would be if 8_{0b} where such an endpoint. Without additional support on the interface, to get 8_{0b} reachable at the correct time, software would have to link 8_1 to 8_{0b}. It would then have to move 4_1 and everything linked after into the same path as 4_0. This upsets the integrity of the binary tree and disallows the use of the spreading technique.

FSTN data structures are used to preserve the integrity of the binary-tree structure and enable the use of the spreading technique. Host Controller Operational Model for FSTNs defines the hardware and software operational model requirements for using FSTNs.

The following queue head fields are initialized by system software to instruct the host controller when to execute portions of the split-transaction protocol:

- *SplitXState*. This is single bit residing in the *Status* field of a queue head (see Table 54-25). This bit is used to track the current state of the split transaction.
- *Frame S-mask*. This is a bit-field where-in system software sets a bit corresponding to the micro-frame (within an *H-Frame*) that the host controller should execute a start-split transaction. This is always qualified by the value of the *SplitXState* bit in the *Status* field of the queue head. For example, referring to Figure 54-20, case one, the *S-mask* would have a value of 00000001b indicating that if the queue head is traversed by the host controller, and the *SplitXState* indicates Do_Start, and the current micro-frame as indicated by FRINDEX[2:0] is 0, then execute a start-split transaction.
- *Frame C-mask.* This is a bit-field where system software sets one or more bits corresponding to the micro-frames (within an *H-Frame*) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the *SplitXState* bit in the *Status* field of the queue head. For example, referring to Figure 54-20, case one, the *C-mask* would have a value of 00011100b indicating that if the queue head is traversed by the host controller, and the *SplitXState* indicates Do_Complete, and the current micro-frame as indicated by FRINDEX[2:0] is 2, 3, or 4, then execute a complete-split transaction. It is software's responsibility to ensure that the translation between *H-Frames* and *B-Frames* is correctly performed when setting bits in *S-mask* and *C-mask*

54.5.3.12.2.2 Host Controller Operational Model for FSTNs

The FSTN data structure is used to manage Low/Full-speed interrupt queue heads that need to be reached from consecutive frame list locations (that is boundary cases 2a through 2c).

An FSTN is essentially a *back pointer*, similar in intent to the back pointer field in the siTD data structure (see siTD Back Link Pointer).

This feature provides software a simple primitive to save a schedule position, redirect the host controller to traverse the necessary queue heads in the previous frame, then restore the original schedule position and complete normal traversal.

The four components to the use of FSTNs:

- FSTN data structure.
- A *Save Place* indicator. This is always an FSTN with its *Back Path Link Pointer.T-bit* set to zero.

- A *Restore* indicator. This is always an FSTN with its *Back Path Link Pointer.T-bit* set to one.
- Host controller FSTN traversal rules.

When the host controller encounters an FSTN during micro-frames 2 through 7 it simply follows the node's *Normal Path Link Pointer* to access the next schedule data structure.

NOTE

The FSTN's *Normal Path Link Pointer.T-bit* may set to one, which the host controller must interpret as the end of periodic list mark.

When the host controller encounters a *Save-Place* FSTN in micro-frames 0 or 1, it saves the value of the *Normal Path Link Pointer* and set an internal flag indicating that it is executing in *Recovery Path* mode. *Recovery Path* mode modifies the host controller's rules for how it traverses the schedule and limits which data structures is considered for execution of bus transactions. The host controller continues executing in *Recovery Path* mode until it encounters a *Restore* FSTN or it determines that it has reached the end of the micro-frame (see details in the list below).

The rules for schedule traversal and limited execution while in *Recovery Path* mode are:

- Always follow the *Normal Path Link Pointer* when it encounters an FSTN that is a *Save-Place* indicator. The host controller must not recursively follow *Save-Place* FSTNs. Therefore, while executing in *Recovery Path* mode, it must never follow an FSTN's *Back Path Link Pointer*.
- Do not process an siTD or, iTD data structure. Simply follow its *Next Link Pointer*.
- Do not process a QH (Queue Head) whose *EPS* field indicates a high-speed device. Simply follow its *Horizontal Link Pointer*.
- When a QH's *EPS* field indicates a Full/Low-speed device, the host controller considers only it for execution if its *SplitXState* is DoComplete (note: this applies whether the *PID Code* indicates an IN or an OUT). See Execute Transaction and Tracking Split Transaction Progress for Interrupt Transfers for a complete list of additional conditions that must be met in general for the host controller to issue a bus transaction.
  - The host controller must not execute a Start-split transaction while executing in *Recovery Path* mode. See Periodic Isochronous - Do Complete Split for special handling when in *Recovery Path* mode.
- Stop traversing the *recovery path* when it encounters an FSTN that is a *Restore* indicator. The host controller unconditionally uses the saved value of the *Save-Place* FSTN's *Normal Path Link Pointer* when returning to the normal path traversal. The

host controller must clear the context of executing a *Recovery Path* when it restores schedule traversal to the *Save-Place* FSTN's *Normal Path Link Pointer*.

- If the host controller determines that there is not enough time left in the micro-frame to complete processing of the periodic schedule, it abandons traversal of the recovery path, and clears the context of executing a recovery path. The result is that at the start of the next consecutive micro-frame, the host controller starts traversal at the frame list.

An example traversal of a periodic schedule that includes FSTNs is illustrated in the following figure.

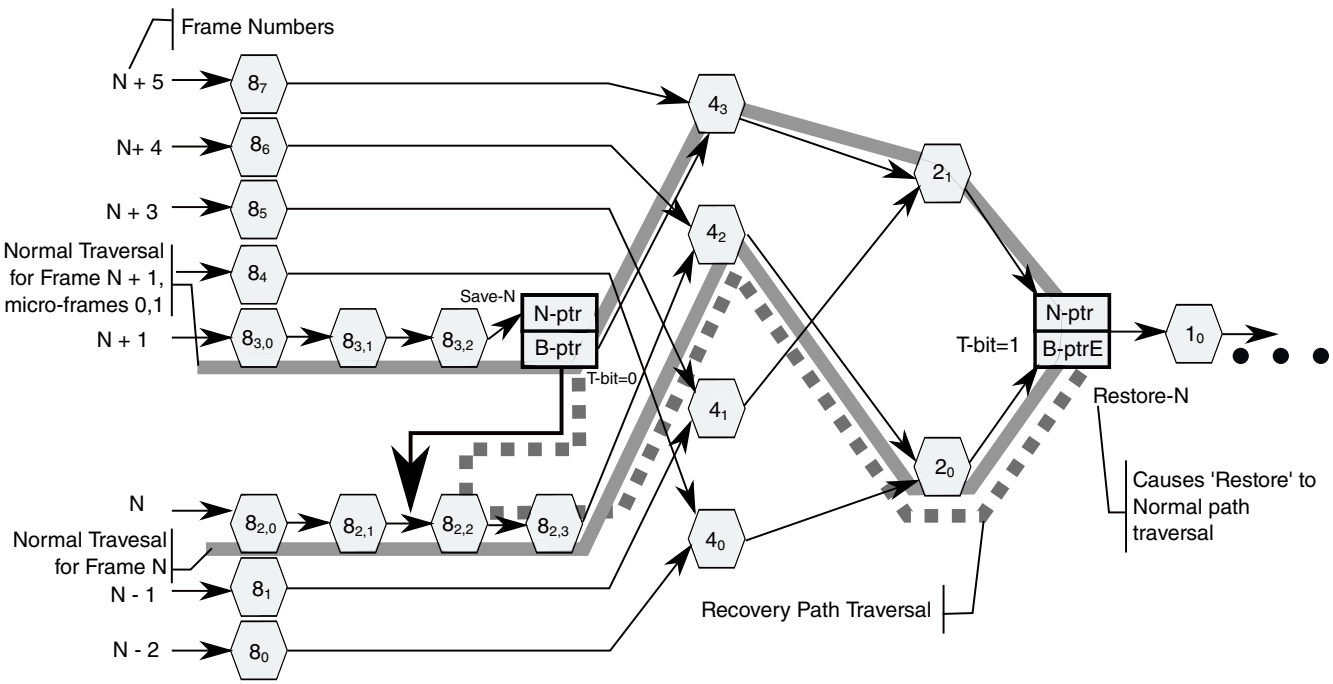

Figure 54-22. Example Host Controller Traversal of Recovery Path via FSTNs

In frame N+1 (micro-frames 0 and 1), when the host controller encounters Save-Path FSTN (Save-N), it observes that Save-N.Back Path Link Pointer.T-bit is zero (definition of a Save-Path indicator). The host controller saves the value of Save-N.Normal Path Link Pointer and follows Save-N.Back Path Link Pointer. At the same time, it sets an internal flag indicating that it is now in *Recovery Path* mode (the recovery path is annotated in the figure above with a large dashed line). The host controller continues traversing data structures on the recovery path and executing only those bus transactions as noted above, on the recovery path until it reaches Restore FSTN (Restore-N). Restore-N.Back Path Link Pointer.T-bit is set to one (definition of a Restore indicator), so the host controller exits *Recovery Path* mode by clearing the internal *Recovery Path* mode flag and commences (restores) schedule traversal using the saved value of the *Save-Place* FSTN's *Normal Path Link Pointer* (for example Save-N.Normal Path Link Pointer). The nodes traversed during these micro-frames include: {$8_{3.0}$, $8_{3.1}$, $8_{3.2}$, Save-A, $8_{2.2}$, $8_{2.3}$, 4_2,

2_0, Restore-N, 4_3, 2_1, Restore-N, 1_0 …}. The nodes on the recovery-path are in bold. In frame N (micro-frames 0-7), for this example, the host controller traverses all of the schedule data structures utilizing the *Normal Path Link Pointers* in any FSTNs it encounters. This is because the host controller has not yet encountered a *Save-Place* FSTN so it not executing in *Recovery Path* mode. When it encounters the *Restore* FSTN, (Restore-N), during micro-frames 0 and 1, it uses Restore-N.Normal Path Link Pointer to traverse to the next data structure (that is normal schedule traversal). This is because the host controller must use a Restore FSTN's *Normal Path Link Pointer* when not executing in a *Recovery-Path* mode. The nodes traversed during frame N include: {$8_{2.0}$, $8_{2.1}$, $8_{2.2}$, $8_{2.3}$, 4_2, 2_0, Restore-N, 1_0 …}.

In frame N+1 (micro-frames 2-7), when the host controller encounters Save-Path FSTN Save-N, it unconditionally follows Save-N.Normal Path Link Pointer. The nodes traversed during these micro-frames include: {$8_{3.0}$, $8_{3.1}$, $8_{3.2}$, Save-A, 4_3, 2_1, Restore-N, 1_0 …}.

54.5.3.12.2.3 Software Operational Model for FSTNs

Software must create a consistent, coherent schedule for the host controller to traverse.

When using FSTNs, system software must adhere to the following rules:

- Each *Save-Place* indicator requires a matching *Restore* indicator.
  - The *Save-Place* indicator is an FSTN with a valid *Back Path Link Pointer and T-bit* equal to zero.
    - *Back Path Link Pointer.Typ* field must be set to indicate the referenced data structure is a queue head. The *Restore* indicator is an FSTN with its *Back Path Link Pointer.T-bit* set to one.
  - A *Restore* FSTN may be matched to one or more *Save-Place* FSTNs. For example, if the schedule includes a poll-rate 1 level, then system software only needs to place a *Restore* FSTN at the beginning of this list in order to match all possible *Save-Place* FSTNs.
- If the schedule does not have elements linked at a poll-rate level of one, and one or more *Save-Place* FSTNs are used, then System Software must ensure the *Restore* FSTN's *Normal Path Link Pointer*'s *T-bit* is set to one, as this is used to mark the end of the periodic list.
- When the schedule does have elements linked at a poll rate level of one, a *Restore* FSTN must be the first data structure on the poll rate one list. All traversal paths from the frame list converge on the poll-rate one list. System software must ensure that *Recovery Path* mode is exited before the host controller is allowed to traverse the poll rate level one list.
- A *Save-Place* FSTN's *Back Path Link Pointer* must reference a queue head data structure. The referenced queue head must be reachable from the previous frame list

location. In other words, if the *Save-Place* FSTN is reachable from frame list offset N, then the FSTN's *Back Path Link Pointer* must reference a queue head that is reachable from frame list offset N-1.

Software should make the schedule as efficient as possible. What this means in this context is that software should have no more than one *Save-Place* FSTN reachable in any single frame. Note there is times when two (or more, depending on the implementation) could exist as full/low-speed footprints change with bandwidth adjustments. This could occur, for example when a bandwidth re-balance causes system software to move the *Save-Place* FSTN from one poll rate level to another. During the transition, software must preserve the integrity of the previous schedule until the new schedule is in place.

54.5.3.12.2.4 Tracking Split Transaction Progress for Interrupt Transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where data is lost.

For interrupt-IN transfers, data is lost when it makes it into the USB 2.0 hub, but the USB 2.0 host system is unable to get it from the USB 2.0 Hub and into the system before it expires from the transaction translator pipeline.

When a lost data condition is detected, the queue must be halted, thus signaling system software to recover from the error. A data-loss condition exists whenever a start-split is issued, accepted and successfully executed by the USB 2.0 Hub, but the complete-splits get unrecoverable errors on the high-speed link, or the complete-splits do not occur at the correct times. One reason complete-splits might not occur at the right time would be due to host-induced system hold-offs that cause the host controller to miss bus transactions because it cannot get timely access to the schedule in system memory.

The same condition can occur for an interrupt-OUT, but the result is not an endpoint halt condition, but rather effects only the progress of the transfer. The queue head has the following fields to track the progress of each split transaction. These fields are used to keep incremental state about which (and when) portions have been executed.

- *C-prog-mask*. This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. *C-prog-mask* is a simple bit-vector that the host controller sets one of the *C-prog*-mask bits for each complete-split executed. The bit position is determined by the micro-frame number in which the complete-split was executed. The host controller always checks *C-prog-mask* before executing a

complete-split transaction. If the previous complete-splits have not been executed then it means one (or more) have been skipped and data has potentially been lost.
- *FrameTag*. This field is used by the host controller during the complete-split portion of the split transaction to tag the queue head with the frame number (*H-Frame* number) when the next complete split must be executed.
- *S-bytes*. This field can be used to store the number of data payload bytes sent during the start-split (if the transaction was an OUT). The *S-bytes* field must be used to accumulate the data payload bytes received during the complete-splits (for an IN).

54.5.3.12.2.5 Split Transaction Execution State Machine for Interrupt

In the following presentation, all references to micro-frame are in the context of a micro-frame within an *H-Frame.*

As with asynchronous Full- and Low-speed endpoints, a split-transaction state machine is used to manage the split transaction sequence.

Aside from the fields defined in the queue head for scheduling and tracking the split transaction, the host controller calculates one internal mechanism that is also used to manage the split transaction. The internal calculated mechanism is:

- *cMicroFrameBit* is a single-bit encoding of the current micro-frame number. It is an eight-bit value calculated by the host controller at the beginning of every micro-frame. It is calculated from the three least significant bits of the *FRINDEX* register (that is, *cMicroFrameBit* = (1 shifted-left(*FRINDEX*[2:0])). The *cMicroFrameBit* has at most one bit asserted, which always corresponds to the current micro-frame number. For example, if the current micro-frame is 0, then *cMicroFrameBit* will equal 00000001b. The variable *cMicroFrameBit* is used to compare against the *S-mask* and *C-mask* fields to determine whether the queue head is marked for a start- or complete-splt transaction for the current micro-frame.

The following figure illustrates the state machine for managing a complete interrupt split transaction. There are two phases to each split transaction. The first is a single start-split transaction, which occurs when the *SplitXState* is at Do_Start and the single bit in *cMicroFrameBit* has a corresponding bit active in *QH.S-mask*. The transaction translator does not acknowledge the receipt of the periodic start-split, so the host controller unconditionally transitions the state to Do_Complete. Due to the available jitter in the transaction translator pipeline, there will be more than one complete-split transaction scheduled by software for the Do_Complete state. This translates simply to the fact that there are multiple bits set to a one in the *QH.C-mask* field.

The host controller keeps the queue head in the Do_Complete state until the split transaction is complete (see definition below), or an error condition triggers the *three-strikes-rule* (for example, after the host tries the same transaction three times, and each

encounters an error, the host controller will stop retrying the bus transaction and halt the endpoint, thus requiring system software to detect the condition and perform system-dependent recovery).

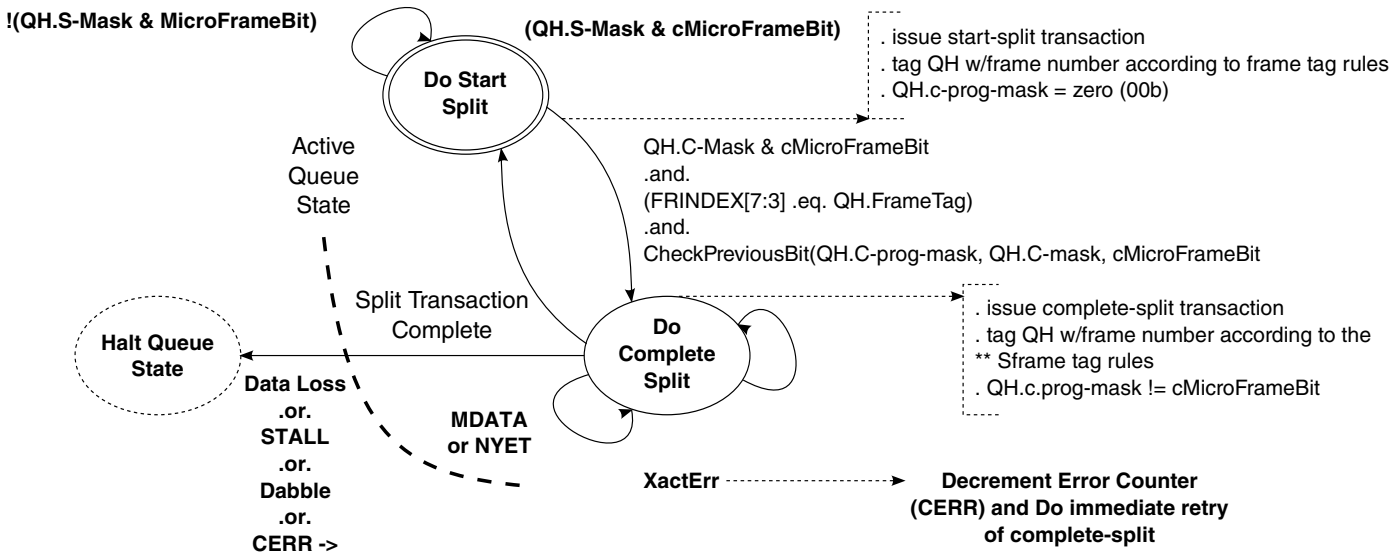

Figure 54-23. Split Transaction State Machine for Interrupt

See Previous Section for the frame tag management rules.

Periodic Interrupt - Do Start Split

This is the state software must initialize a full- or low-speed interrupt queue head *StartXState* bit. This state is entered from the Do_Complete Split state only after the split transaction is complete. This occurs when one of the following events occur: The transaction translator responds to a complete-split transaction with one of the following:

- NAK. A NAK response is a propagation of the full- or low-speed endpoint's NAK response.
- ACK. An ACK response is a propagation of the full- or low-speed endpoint's ACK response. Only occurs on an OUT endpoint.
- DATA 0/1. Only occurs for INs. Indicates that this is the last of the data from the endpoint for this split transaction.
- ERR. The transaction on the low-/full-speed link below the transaction translator had a failure (for example, timeout, bad CRC, etc.).
- NYET (and Last). The host controller issued the last complete-split and the transaction translator responded with a NYET handshake. This means that the start-split was not correctly received by the transaction translator, so it never executed a transaction to the full- or low-speed endpoint, see Section Periodic Isochronous - Do Complete Split for the definition of 'Last'.

Each time the host controller visits a queue head in this state (once within the Execute Transaction state), it performs the following test to determine whether to execute a start-split.

- *QH.S-mask* is bit-wise anded with *cMicroFrameBit*.

If the result is non-zero, then the host controller will issue a start-split transaction. If the *PIDCode* field indicates an IN transaction, the host controller must zero-out the *QH.S-bytes* field. After the split-transaction has been executed, the host controller sets up state in the queue head to track the progress of the complete-split phase of the split transaction. Specifically, it records the expected frame number into *QH.FrameTag* field (see Section), set *C-prog-mask* to zero (00h), and exits this state. Note that the host controller must not adjust the value of *CErr* as a result of completion of a start-split transaction.

Periodic Interrupt - Do Complete Split

This state is entered unconditionally from the Do Start Split state after a start-split transaction is executed on the bus. Each time the host controller visits a queue head in this state (once within the Execute Transaction state), it checks to determine whether a complete-split transaction should be executed now.

There are four tests to determine whether a complete-split transaction should be executed.

- Test A. *cMicroFrameBit* is bit-wise anded with *QH.C-mask* field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this micro-frame.
- Test B. *QH.FrameTag* is compared with the current contents of *FRINDEX*[7:3]. An equal indicates a match.
- Test C. The complete-split progress bit vector is checked to determine whether the previous bit is set, indicating that the previous complete-split was appropriately executed. An example algorithm for this test is provided below:

```
Algorithm Boolean CheckPreviousBit(QH.C-prog-mask, QH.C-mask, cMicroFrameBit)
Begin
-- Return values:
-- TRUE - no error
-- FALSE - error
--
Boolean rvalue = TRUE;
previousBit = cMicroframeBit logical-rotate-right(1)
-- Bit-wise anding previousBit with C-mask indicates
-- whether there was an intent
-- to send a complete split in the previous micro-frame. So,
-- if the
-- 'previous bit' is set in C-mask, check C-prog-mask to
-- make sure it
-- happened.
If (previousBit bitAND QH.C-mask)then
                                If not(previousBit bitAND QH.C-prog-mask) then
                      rvalue = FALSE;
          End if
End If
-- If the C-prog-mask already has a one in this bit position,
```

```
-- then an aliasing
-- error has occurred. It will probably get caught by the
-- FrameTag Test, but
-- at any rate it is an error condition that as detectable here
-- should not allow
-- a transaction to be executed.
If (cMicroFrameBit bitAND QH.C-prog-mask) then
 rvalue = FALSE;
End if
return (rvalue)
End Algorithm
```

- Test D. Check to see if a start-split should be executed in this micro-frame. Note this is the same test performed in the Do Start Split state (see Section Periodic Isochronous - Do Start Split). Whenever it evaluates to TRUE and the controller is NOT processing in the context of a *Recovery Path* mode, it means a start-split should occur in this micro-frame. Test D and Test A evaluating to TRUE at the same time is a system software error. Behavior is undefined.

If (A .and. B .and. C .and. not(D)) then the host controller will execute a complete-split transaction. When the host controller commits to executing the complete-split transaction, it updates *QH.C-prog-mask* by bit-ORing with *cMicroFrameBit*. On completion of the complete-split transaction, the host controller records the result of the transaction in the queue head and sets *QH.FrameTag* to the expected *H-Frame* number (see Section). The effect to the state of the queue head and thus the state of the transfer depends on the response by the transaction translator to the complete-split transaction. The following responses have the effects (note that any responses that result in decrementing of the *CErr* will result in the queue head being halted by the host controller if the result of the decrement is zero):

- NYET (and Last). On each NYET response, the host controller checks to determine whether this is the last complete-split for this split transaction. Last is defined in this context as the condition where all of the scheduled complete-splits have been executed. If it is the last complete-split (with a NYET response), then the transfer state of the queue head is not advanced (never received any data) and this state exited. The transaction translator must have responded to all the clompete-splits with NYETs, meaning that the start-split issued by the host controller was not received. The start-split should be retried at the next poll period.
- The test for whether this is the Last complete split can be performed by XOR *QH.C-mask* with *QH.C-prog-mask*. If the result is all zeros then all complete-splits have been executed. When this condition occurs, the *XactErr* status bit is set to a one and the *CErr* field is decremented.
- NYET (and not Last). See above description for testing for Last. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for *C-prog-mask* and *FrameTag*) and stay in this state. The host controller must not adjust *CErr* on this response.

- Transaction Error (XactErr). Timeout, data CRC failure, etc. The *CErr* field is decremented and the *XactErr* bit in the *Status* field is set to a one. The complete split transaction is *immediately* retried (if *Cerr* is non-zero).If there is not enough time in the micro-frame to complete the retry and the endpoint is an IN, or *CErr* is decremented to a zero from a one, the queue is halted. If there is not enough time in the micro-frame to complete the retry and the endpoint is an OUT and *CErr* is not zero, then this state is exited (that is, return to Do Start Split). This results in a retry of the entire OUT split transaction, at the next poll period. Refer to Chapter 11 Hubs (specifically the section full- and low-speed Interrupts) in the USB Specification Revision 2.0 for detailed requirements on why these errors must be immediately retried.
- ACK. This can only occur if the target endpoint is an OUT. The target endpoint ACK'd the data and this response is a propagation of the endpoint ACK up to the host controller. The host controller must advance the state of the transfer. The *Current Offset* field is incremented by *Maximum Packet Length* or *Bytes to Transfer*, whichever is less. The field *Bytes To Transfer* is decremented by the same amount. And the data toggle bit (*dt*) is toggled. The host controller will then exit this state for this queue head. The host controller must reload *CErr* with maximum value on this response. Advancing the transfer state may cause other process events such as retirement of the qTD and advancement of the queue (see Section Managing Control/Bulk/Interrupt Transfers through Queue Heads).
- MDATA. This response will only occur for an IN endpoint. The transaction translator responded with zero or more bytes of data and an MDATA PID. The incremental number of bytes received is accumulated in *QH.S-bytes*. The host controller must not adjust *CErr* on this response.
- DATA0/1. This response may only occur for an IN endpoint. The number of bytes received is added to the accumulated byte count in *QH.S-bytes*. The state of the transfer is advanced by the result and the host controller will exit this state for this queue head.
- Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue (see Section Managing Control/Bulk/Interrupt Transfers through Queue Heads).
- If the data sequence PID does not match the expected, the entirety of the data received in this split transaction is ignored, the transfer state is not advanced and this state is exited.
- NAK. The target endpoint Nak'd the full- or low-speed transaction. The state of the transfer is not advanced, and this state is exited. The host controller must reload *CErr* with maximum value on this response.

- ERR. There was an error during the full- or low-speed transaction. The ERR status bit is set to a one, *Cerr* is decremented, the state of the transfer is not advanced, and this state is exited.
- STALL. The queue is halted (an exit condition of the Execute Transaction state). The status field bits: *Active* bit is set to zero and the *Halted* bit is set to a one and the qTD is retired. Responses which are not enumerated in the list or which are received out of sequence are illegal and may result in undefined host controller behavior. The other possible combinations of tests A, B, C, and D may indicate that data or response was lost. The table below lists the possible combinations and the appropriate action.

Table 54-49. Interrupt IN/OUT Do Complete Split State Execution Criteria

Condition	Action	Description
not(A) not(D)	Ignore QHD	Neither a start nor complete-split is scheduled for the current micro-frame.Host controller should continue walking the schedule.
A not(C)	If PIDCode = IN Halt QHD If PIDCode = OUT Retry start-split	Progress bit check failed. These means a complete-split has been missed. There is the possibility of lost data. If *PIDCode* is an IN, then the Queue head must be halted. If *PIDCode* is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect *CER*R. In either case, set the *Missed Micro-frame* bit in the status field to a one.
A not(B) C	If PIDCode = IN Halt QHD If PIDCode = OUT Retry start-split	*QH.FrameTag* test failed. This means that exactly one or more *H-Frames* have been skipped. This means complete-splits and have missed. There is the possibility of lost data. If *PIDCode* is an IN, then the Queue head must be halted. If *PIDCode* is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect *CER*R. In either case, set the *Missed Micro-frame* bit in the status field to a one.
A B C not(D)	Execute complete-split	This is the non-error case where the host controller executes a complete-split transaction.
D	If PIDCode = IN Halt QHD If PIDCode = OUT Retry start-split	This is a degenerate case where the start-split was issued, but all of the complete-splits were skipped and all possible intervening opportunities to detect the missed data failed to fire. If *PIDCode* is an IN, then the Queue head must be halted. If *PIDCode* is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect *CER*R. In either case, set the *Missed Micro-frame* bit in the status field to a one. Note: When executing in the context of a *Recovery Path* mode, the host controller is allowed to process the queue head and take the actions indicated above, or it may wait until the queue head is visited in the

Table 54-49. Interrupt IN/OUT Do Complete Split State Execution Criteria

		normal processing mode. Regardless, the host controller must not execute a start-split in the context of a executing in a *Recovery Path* mode.

Managing QH.FrameTag Field

The *QH.FrameTag* field in a queue head is completely managed by the host controller. The rules for setting *QH.FrameTag* are simple:

- Rule 1: If transitioning from Do Start Split to Do Complete Split and the current value of *FRINDEX*[2:0] is 6 *QH.FrameTag* is set to *FRINDEX*[7:3] + 1. This accommodates split transactions whose start-split and complete-splits are in different *H-Frames* (case 2a, see Figure 54-20).
- Rule 2: If the current value of *FRINDEX*[2:0] is 7, *QH.FrameTag* is set to *FRINDEX*[7:3] + 1. This accommodates staying in Do Complete Split for cases 2a, 2b, and 2c (Figure 54-20).
- Rule 3: If transitioning from Do_Start Split to Do Complete Split and the current value of *FRINDEX*[2:0] is not 6, or currently in Do Complete Split and the current value of (*FRINDEX*[2:0]) is not 7, *FrameTag* is set to *FRINDEX*[7:3]. This accommodates all other cases (Figure 54-20).

54.5.3.12.2.6 Rebalancing the periodic schedule

System software must occasionally adjust a periodic queue head's S-mask and C-mask fields during operation.

This need occurs when adjustments to the periodic schedule create a new bandwidth budget and one or more queue head's are assigned new execution footprints (that is, new S-mask and C-mask values).

It is imperative that System software must not update these masks to new values in the midst of a split transaction. In order to avoid any race conditions with the update, the EHCI host controller provides a simple assist to system software. System software sets the *Inactivate-on-next-Transaction* (*I*) bit to a one to signal the host controller that it intends to update the S-mask and C-mask on this queue head. System software will then wait for the host controller to observe the *I-bit* is a one and transition the *Active* bit to a zero. The rules for how and when the host controller sets the *Active* bit to zero are enumerated below:

- If the *Active* bit is a zero, no action is taken. The host controller does not attempt to advance the queue when the *I-bit* is a one.
- If the *Active* bit is a one and the *SplitXState* is DoStart (regardless of the value of *S-mask*), the host controller will simply set *Active* bit to a zero. The host controller is

not required to write the transfer state back to the *current* qTD. Note that if the *S-mask* indicates that a start-split is scheduled for the current micro-frame, the host controller must not issue the start-split bus transaction. It must set the *Active* bit to zero.

System software must save transfer state before setting the *I-bit* to a one. This is required so that it can correctly determine what transfer progress (if any) occurred after the *I-bit* was set to a one and the host controller executed its final bus-transaction and set *Active* to a zero.

After system software has updated the S-mask and C-mask, it must then reactivate the queue head. Because the *Active* bit and the *I-bit* cannot be updated with the same write, system software needs to use the following algorithm to coherently re-activate a queue head that has been stopped via the *I-bit*.

1. Set the *Halted* bit to a one, then
2. Set the *I-bit* to a zero, then
3. Set the *Active* bit to a one and the *Halted* bit to a zero in the same write.

Setting the *Halted* bit to a one inhibits the host controller from attempting to advance the queue between the time the *I-bit* goes to a zero and the *Active* bit goes to a one.

54.5.3.12.3 Split Transaction Isochronous

Full-speed isochronous transfers are managed using the split-transaction protocol through a USB 2.0 transaction translator in a USB2.0 Hub. The EHCI controller utilizes siTD data structure to support the special requirements of isochronous split-transactions.

This data structure uses the scheduling model of isochronous TDs (iTD, Section Isochronous (High-Speed) Transfer Descriptor (iTD)) (see Section Managing Isochronous Transfers Using iTDs for the operational model of iTDs) with the contiguous data feature provided by queue heads. This simple arrangement allows a single isochronous scheduling model and adds the additional feature that all data received from the endpoint (per split transaction) must land into a contiguous buffer.

54.5.3.12.3.1 Split Transaction Scheduling Mechanisms for Isochronous

Full-speed isochronous transactions are managed through a transaction translator's periodic pipeline. As with full- and low-speed interrupt, system software manages each transaction translator's periodic pipeline by budgeting and scheduling exactly during which micro-frames the start-splits and complete-splits for each full-speed isochronous endpoint occur.

The requirements described in Section Split Transaction Scheduling Mechanisms for Interrupt apply. The following figure illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule. The ^{S}X and ^{C}X labels indicate micro-frames where software can schedule start- and complete-splits (respectively). The *H-Frame* boundaries are marked with a large, solid bold vertical line. The *B-Frame* boundaries are marked with a large, bold, dashed line. The bottom of the figure illustrates the relationship of an siTD to the *H-Frame*.

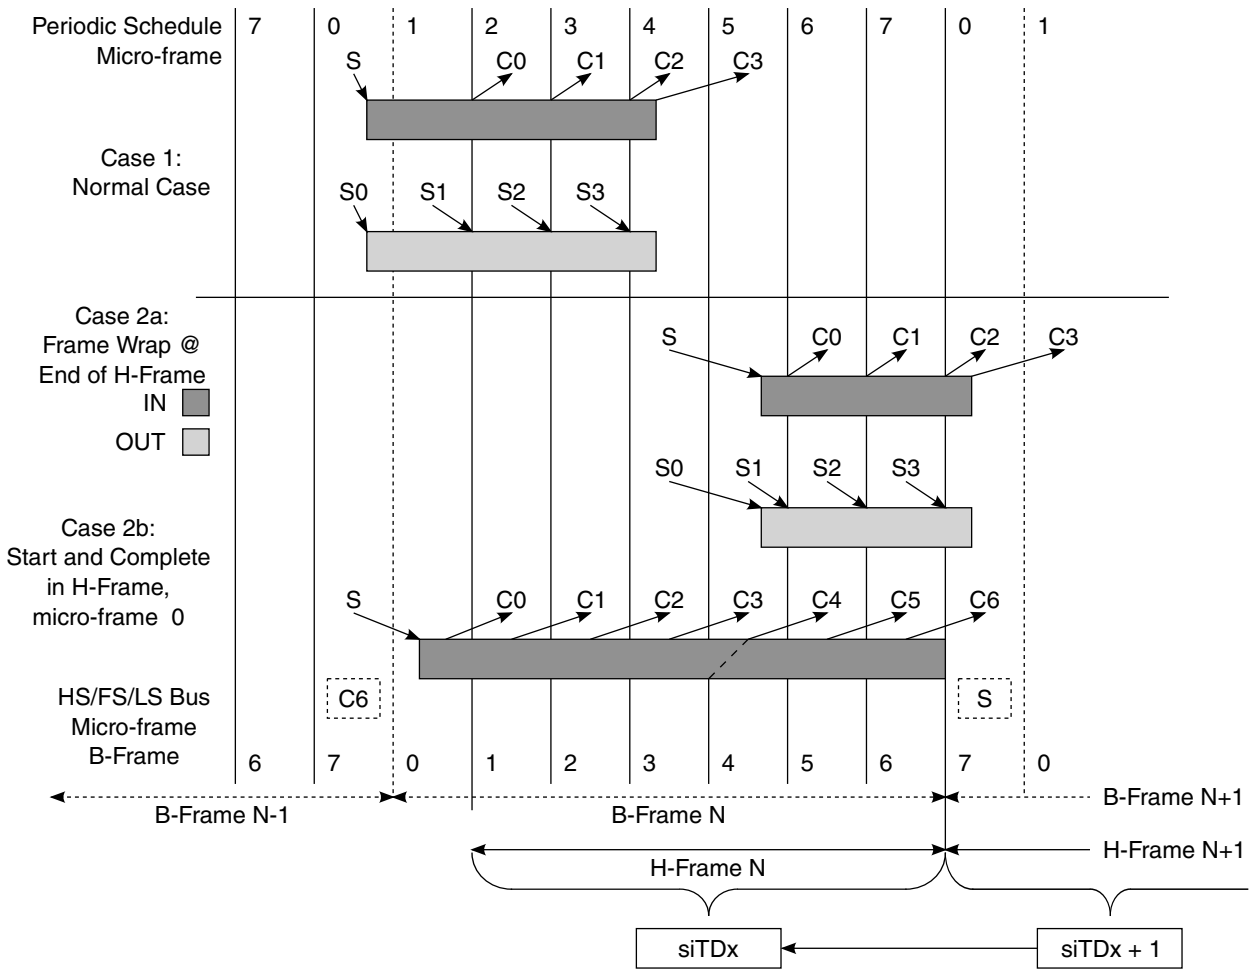

Figure 54-24. Split Transaction, Isochronous Scheduling Boundary Conditions

When the endpoint is an isochronous OUT, there are only start-splits, and no complete-splits. When the endpoint is an isochronous IN, there is at most one start-split and one to *N* complete-splits. The scheduling boundary cases are:

- *Case 1*: The entire split transaction is completely bounded by an *H-Frame*. For example: the start-splits and complete-splits are all scheduled to occur in the same *H-Frame*.

- *Case 2a*: This boundary case is where one or more (at most two) complete-splits of a split transaction IN are scheduled across an *H-Frame* boundary. This can only occur when the split transaction has the possibility of moving data in *B-Frame,* micro-frames 6 or 7 (*H-Frame* micro-frame 7 or 0). When an *H-Frame* boundary wrap condition occurs, the scheduling of the split transaction spans more than one location in the periodic list.(For example, it takes two siTDs in adjacent periodic frame list locations to fully describe the scheduling for the split transaction.)
- Although the scheduling of the split transaction may take two data structures, all of the complete-splits for each full-speed IN isochronous transaction must use only one data pointer. For this reason, siTDs contain a back pointer, the use of which is described below.
- Software must never schedule full-speed isochronous OUTs across an *H-Frame* boundary.
- *Case 2b*: This case can only occur for a very large isochronous IN. It is the only allowed scenario where a start-split and complete-split for the same endpoint can occur in the same micro-frame. Software must enforce this rule by scheduling the large transaction first. Large is defined to be anything larger than 579 byte maximum packet size.

A subset of the same mechanisms employed by full- and low-speed interrupt queue heads are employed in siTDs to schedule and track the portions of isochronous split transactions. The following fields are initialized by system software to instruct the host controller when to execute portions of the split transaction protocol.

- *SplitXState*. This is a single bit residing in the *Status* field of an siTD (see Figure 54-25). This bit is used to track the current state of the split transaction. The rules for managing this bit are described in Section Split Transaction Execution State Machine for Interrupt.
- *Frame S-mask*. This is a bit-field where-in system software sets a bit corresponding to the micro-frame (within an *H-Frame*) that the host controller should execute a start-split transaction. This is always qualified by the value of the *SplitXState* bit. For example, referring to the IN example in Figure 54-24, case one, the *S-mask* would have a value of 00000001b indicating that if the siTD is traversed by the host controller, and the *SplitXState* indicates Do Start Split, and the current micro-frame as indicated by USB_n_FRINDEX[2:0] is 0, then execute a start-split transaction.
- *Frame C-mask.* This is a bit-field where system software sets one or more bits corresponding to the micro-frames (within an *H-Frame*) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the *SplitXState* bit. For example, referring to the IN example in Figure 54-24, case one, the *C-mask* would have a value of 00111100b indicating that if the siTD is traversed by the host controller, and the *SplitXState* indicates Do

Complete Split, and the current micro-frame as indicated by *USB_n_FRINDEX*[2:0] is 2, 3, 4, or 5, then execute a complete-split transaction.

- *Back Pointer*. This field in a siTD is used to complete an IN split-transaction using the previous *H-Frame*'s siTD. This is only used when the scheduling of the complete-splits span an *H-Frame* boundary.

There exists a one-to-one relationship between a high-speed isochronous split transaction (including all start- and complete-splits) and one full-speed isochronous transaction. An siTD contains (amongst other things) buffer state and split transaction scheduling information. An siTD's buffer state always maps to one full-speed isochronous data payload. This means that for any full-speed transaction payload, a single siTD's data buffer must be used. This rule applies to both IN an OUTs. An siTD's scheduling information usually also maps to one high-speed isochronous split transaction. The exception to this rule is the *H-Frame* boundary wrap cases mentioned above.

The siTD data structure describes at most, one frame's worth of high-speed transactions and that description is strictly bounded within a frame boundary. The figure below illustrates some examples. On the top are examples of the full-speed transaction footprints for the boundary scheduling cases described above. In the middle are time-frame references for both the *B-Frames* (HS/FS/LS Bus) and the *H-Frames*. On the bottom is illustrated the relationship between the scope of an siTD description and the time references. Each *H-Frame* corresponds to a single location in the periodic frame list. The implication is that each siTD is reachable from a single periodic frame list location at a time.

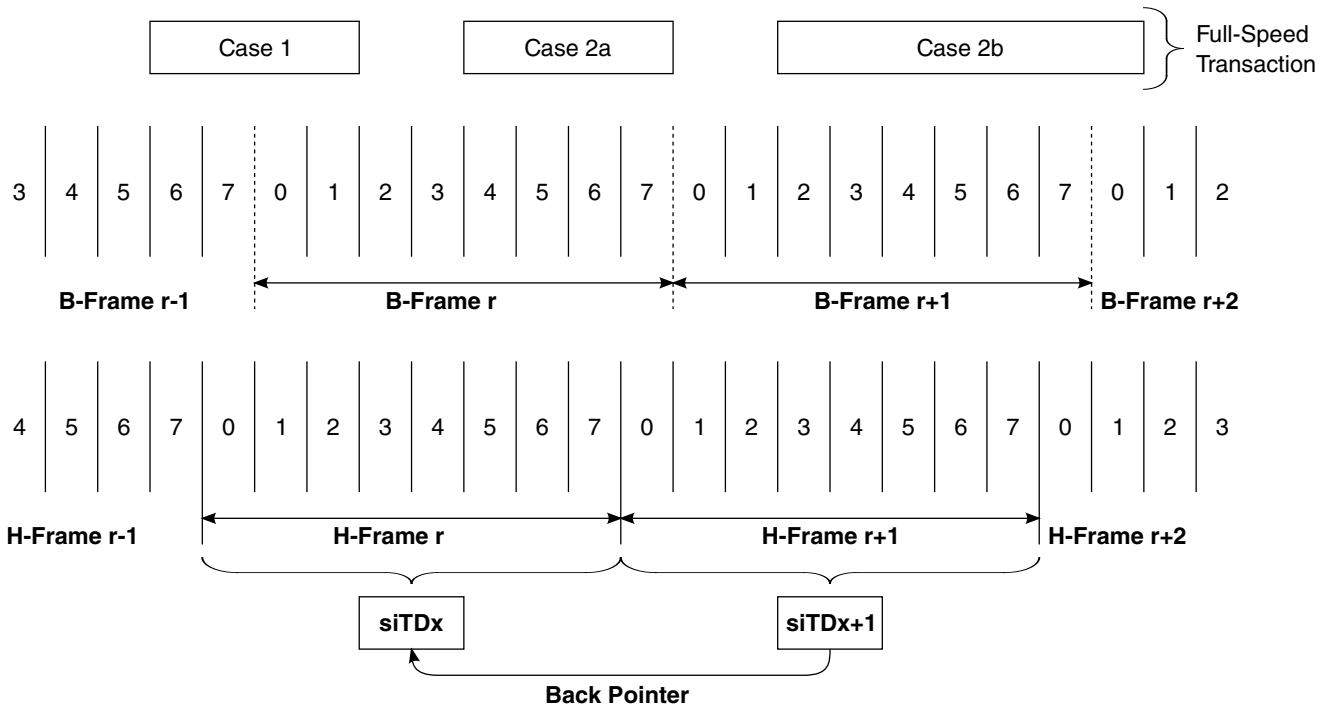

Figure 54-25. siTD Scheduling Boundary Examples

Each case is described below:

- *Case 1*: One siTD is sufficient to describe and complete the isochronous split transaction because the whole isochronous split transaction is tightly contained within a single *H-Frame*.
- *Case 2a, 2b*: Although both INs and OUTs can have these footprints, OUTs always take only one siTD to schedule. However, INs (for these boundary cases) require two siTDs to complete the scheduling of the isochronous split transaction $siTD_X$ is used to always issue the start-split and the first *N* complete-splits. The full-speed transaction (for these cases) can deliver data on the full-speed bus segment during micro-frame 7 of $H\text{-}Frame_{Y+1}$, or micro-frame 0 of $H\text{-}Frame_{Y+2}$. The complete splits are scheduled using $siTD_{X+2}$ (not shown). The complete-splits to extract this data must use the buffer pointer from $siTD_{X+1}$. The only way for the host controller to reach $siTD_{X+1}$ from $H\text{-}Frame_{Y+2}$is to use $siTD_{X+2}$'s back pointer. The host controller rules for when to use the back pointer are described is Section Periodic Isochronous - Do Complete Split .

Software must apply the following rules when calculating the schedule and linking the schedule data structures into the periodic schedule:

- Software must ensure that an isochronous split-transaction is started so that it will complete before the end of the *B-Frame*.
- Software must ensure that for a single full-speed isochronous endpoint, there is never a start-split and complete-split in *H-Frame, micro-frame 1*. This is mandated as a rule so that case 2a and case 2b can be discriminated. According to the core USB specification, the long isochronous transaction illustrated in Case 2b, could be scheduled so that the start-split was in micro-frame 1 of *H-Frame* N and the last complete-split would need to occur in micro-frame 1 of H-Frame N+1. However, it is impossible to discriminate between cases 2a and case 2b, which has significant impact on the complexity of the host controller.

54.5.3.12.3.2 Tracking Split Transaction Progress for Isochronous Transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where device to host data is lost. Isochronous endpoints do not employ the concept of a halt on error, however the host is required to identify and report per-packet errors observed in the data stream. This includes schedule traversal problems (skipped micro-frames), timeouts and corrupted data received.

In similar kind to interrupt split-transactions, the portions of the split transaction protocol must execute in the micro-frames they are scheduled. The queue head data structure used to manage full- and low-speed interrupt has several mechanisms for tracking when portions of a transaction have occurred. Isochronous transfers use siTDs, for their transfers, and the data structures are only reachable via the schedule in the exact micro-frame in which they are required (so all the mechanism employed for tracking in queue heads is not required for siTDs). Software has the option of reusing siTD several times in the complete periodic schedule. However, it must ensure that the results of split transaction N are consumed and the siTD reinitialized (activated) before the host controller gets back to the siTD (in a future micro-frame).

Split-transaction isochronous OUTs utilize a low-level protocol to indicate which portions of the split transaction data have arrived. Control over the low-level protocol is exposed in an siTD via the fields *Transaction Position* (*TP*) and *Transaction Count* (*T-count*). If the entire data payload for the OUT split transaction is larger than 188 bytes, there will be more than one start-split transaction, each of which require proper annotation. If host hold-offs occur, then the sequence of annotations received from the host will not be complete, which is detected and handled by the transaction translator. See Section Periodic Isochronous - Do Start Split for a description on how these fields are used during a sequence of start-split transactions.

The fields *siTD.T-Count* and *siTD.TP* are used by the host controller to drive and sequence the transaction position annotations. It is the responsibility of system software to properly initialize these fields in each siTD. Once the budget for a split-transaction

isochronous endpoint is established, *S-mask*, *T-Count*, and *TP* initialization values for all the siTD associated with the endpoint are constant. They remain constant until the budget for the endpoint is recalculated by software and the periodic schedule adjusted.

For IN-endpoints, the transaction translator simply annotates the response data packets with enough information to allow the host controller to identify the last data. As with split transaction Interrupt, it is the host controller's responsibility to detect when it has missed an opportunity to execute a complete-split. The following field in the siTD is used to track and detect errors in the execution of a split transaction for an IN isochronous endpoint.

- *C-prog-mask*. This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. *C-prog-mask* is a simple bit-vector that the host controller sets a bit for each complete-split executed. The bit position is determined by the micro-frame (USB_n_FRINDEX[2:0]) number in which the complete-split was executed. The host controller always checks *C-prog-mask* before executing a complete-split transaction. If the previous complete-splits have not been executed, then it means one (or more) have been skipped and data has potentially been lost. System software is required to initialize this field to zero before setting an siTD's *Active* bit to a one.

If a transaction translator returns with the final data before all of the complete-splits have been executed, the state of the transfer is advanced so that the remaining complete-splits are not executed. Refer to Section Asynchronous - Do Complete Split for a description on how the state of the transfer is advanced. It is important to note that an IN siTD is retired based solely on the responses from the Transaction Translator to the complete-split transactions. This means, for example, that it is possible for a transaction translator to respond to a complete-split with an MDATA PID. The number of bytes in the MDATA's data payload could cause the siTD field *Total Bytes to Transfer* to decrement to zero. This response can occur, before all of the scheduled complete-splits have been executed. In other interface, data structures (for example, high-speed data streams through queue heads), the transition of *Total Bytes to Transfer* to zero signals the end of the transfer and results in setting of the *Active* bit to zero. However, in this case, the result has not been delivered by the Transaction Translator and the host must continue with the next complete-split transaction to extract the residual transaction state. This scenario occurs because of the pipeline rules for a Transaction Translator (see Chapter 11 of the Universal Serial Bus Revision 2.0). In summary the periodic pipeline rules require that on a micro-frame boundary, the Transaction Translator will hold the final two bytes received (if it has not seen an End Of Packet (EOP)) in the full-speed bus pipe stage and give the

remaining bytes to the high-speed pipeline stage. At the micro-frame boundary, the Transaction Translator could have received the entire packet (including both CRC bytes) but not received the packet EOP. In the next micro-frame, the Transaction Translator will respond with an MDATA and send all of the data bytes (with the two CRC bytes being held in the full-speed pipeline stage). This could cause the siTD to decrement its *Total Bytes to Transfer* field to zero, indicating it has received all expected data. The host must still execute one more (scheduled) complete-split transaction in order to extract the results of the full-speed transaction from the Transaction Translator (for example, the Transaction Translator may have detected a CRC failure, and this result must be forwarded to the host).

If the host experiences hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous OUT, then the protocol to the transaction translator will not be consistent and the transaction translator will detect and react to the problem. Likewise, for host hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous IN, the *C-prog-mask* is used by the host controller to detect errors. However, if the host experiences a hold-off that causes it to skip all of an siTD, or an siTD expires during a host hold off (for example, a hold-off occurs and the siTD is no longer reachable by the host controller in order for it to report the hold-off event), then system software must detect that the siTDs have not been processed by the host controller (that is, state not advanced) and report the appropriate error to the client driver.

54.5.3.12.3.3 Split Transaction Execution State Machine for Isochronous

In the following presentation, all references to micro-frame are in the context of a micro-frame within an *H-Frame.*

If the *Active* bit in the *Status* byte is a zero, the host controller will ignore the siTD and continue traversing the periodic schedule. Otherwise the host controller will process the siTD as specified below. A split transaction state machine is used to manage the split-transaction protocol sequence. The host controller uses the fields defined in Section Tracking Split Transaction Progress for Interrupt Transfers , plus the variable *cMicroFrameBit* defined in Section Split Transaction Execution State Machine for Interrupt to track the progress of an isochronous split transaction. The figure below illustrates the state machine for managing an siTD through an isochronous split transaction. Bold, dotted circles denote the state of the *Active* bit in the *Status* field of a siTD. The Bold, dotted arcs denote the transitions between these states. Solid circles denote the states of the split transaction state machine and the solid arcs denote the transitions between these states. Dotted arcs and boxes reference actions that take place either as a result of a transition or from being in a state.

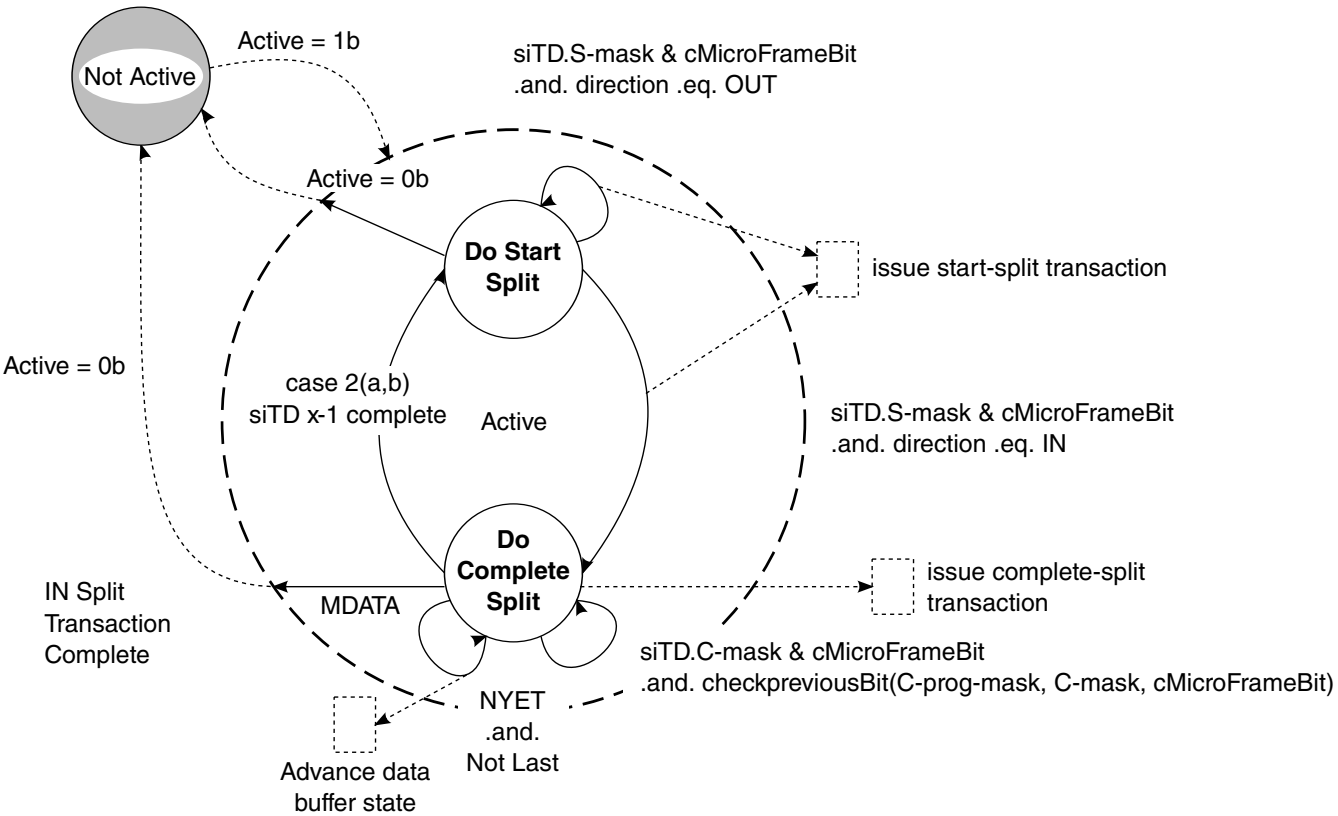

Figure 54-26. Split Transaction State Machine for Isochronous

54.5.3.12.3.4 Periodic Isochronous - Do Start Split

Isochronous split transaction OUTs use only this state.

An siTD for a split-transaction isochronous IN is either initialized to this state, or the siTD transitions to this state from Do Complete Split when a case 2a (IN) or 2b scheduling boundary isochronous split-transaction completes.

Each time the host controller reaches an active siTD in this state, it checks the *siTD.S-mask* against *cMicroFrameBit*. If there is a one in the appropriate position, the siTD will execute a start-split transaction. By definition, the host controller cannot *reach* an siTD at the wrong time. If the *I/O* field indicates an IN, then the start-split transaction includes only the extended token plus the full-speed token. Software must initialize the *siTD.Total Bytes To Transfer* field to the number of bytes expected. This is usually the maximum packet size for the full-speed endpoint. The host controller exits this state when the start-split transaction is complete.

The remainder of this section is specific to an isochronous OUT endpoint (that is, the *I/O* field indicates an OUT). When the host controller executes a start-split transaction for an isochronous OUT it includes a data payload in the start-split transaction. The memory

buffer address for the data payload is constructed by concatenating *siTD.Current Offset* with the page pointer indicated by the page selector field (*siTD.P*). A zero in this field selects Page 0 and a 1 selects Page 1. During the start-split for an OUT, if the data transfer crosses a page boundary during the transaction, the host controller must detect the page cross, update the *siTD.P*-bit from a zero to a one, and begin using the *siTD.Page 1* with *siTD.Current Offset* as the memory address pointer. The field *siTD.TP* is used to annotate each start-split transaction with the indication of which part of the split-transaction data the current payload represents (ALL, BEGIN, MID, END). In all cases the host controller simply uses the value in *siTD.TP* to mark the start-split with the correct transaction position code.

T-Count is always initialized to the number of start-splits for the current frame. *TP* is always initialized to the first required transaction position identifier. The scheduling boundary case (see Figure 54-25) is used to determine the initial value of *TP*. The initial cases are summarized in the following table.

Table 54-50. Initial Conditions for OUT siTD's TP and T-count Fields

Case	T-count	TP	Description
1, 2a	=1	ALL	When the OUT data payload is less than (or equal to) 188 bytes, only one start-split is required to move the data. The one start-split must be marked with an ALL.
1, 2a	!=1	BEGIN	When the OUT data payload is greater than 188 bytes more than one start-split must be used to move the data. The initial start-split must be marked with a BEGIN.

After each start-split transaction is complete, the host controller updates *T-Count* and *TP* appropriately so that the next start-split is correctly annotated.

The table below illustrates all of the *TP* and *T-count* transitions, which must be accomplished by the host controller.

.

Table 54-51. Transaction Position (TP)/Transaction Count (T-Count) Transition Table

TP	T-count next	TP next	Description
ALL	0	N/A	Transition from ALL, to done.
BEGIN	1	END	Transition from BEGIN to END. Occurs when *T-count* starts at 2.
BEGIN	!=1	MID	Transition from BEGIN to MID. Occurs when *T-count* starts at greater than 2.
MID	!=1	MID	*TP* stays at MID while *T-count* is not equal to 1 (that is, greater than 1). This case can occur for any of the scheduling boundary cases where the *T-count* starts greater than 3.
MID	1	END	Transition from MID to END. This case can occur for any of the scheduling boundary cases where the *T-count* starts greater than 2.

The start-split transactions do not receive a handshake from the transaction translator, so the host controller always advances the transfer state in the siTD after the bus transaction is complete. To advance the transfer state the following operations take place:

- The *siTD.Total Bytes To Transfer* and the *siTD.Current Offset* fields are adjusted to reflect the number of bytes transferred.
- The *siTD.P* (page selector) bit is updated appropriately.
- The *siTD.TP* and *siTD.T-count* fields are updated appropriately as defined in Table 54-51.

These fields are then written back to the memory based siTD. The *S-mask* is fixed for the life of the current budget. As mentioned above, *TP* and *T-count* are set specifically in each siTD to reflect the data to be sent from this siTD. Therefore, regardless of the value of *S-mask*, the actual number of start-split transactions depends on *T-count* (or equivalently, *Total Bytes to Transfer*). The host controller must set the *Active* bit to a zero when it detects that all of the schedule data has been sent to the bus. The preferred method is to detect when *T-Count* decrements to zero as a result of a start-split bus transaction. Equivalently, the host controller can detect when *Total Bytes to Transfer* decrements to zero. Either implementation must ensure that if the initial condition is *Total Bytes to Transfer* equal to zero and *T-count* is equal to a one, then the host controller will issue a single start-split, with a zero-length data payload. Software must ensure that *TP*, *T-count* and *Total Bytes to Transfer* are set to deliver the appropriate number of bus transactions from each siTD. An inconsistent combination will yield undefined behavior.

If the host experiences hold-offs that cause the host controller to skip start-split transactions for an OUT transfer, the state of the transfer will not progress appropriately. The transaction translator will observe protocol violations in the arrival of the start-splits for the OUT endpoint (that is, the transaction position annotation will be incorrect as received by the transaction translator).

Example scenarios are described in Section Split Transaction for Isochronous - Processing Examples.

A host controller implementation can optionally track the progress of an OUT split transaction by setting appropriate bits in the *siTD.C-prog-mask* as it executes each scheduled start-split. The *checkPreviousBit*() algorithm defined in Periodic Isochronous - Do Complete Split can be used prior to executing each start-split to determine whether start-splits were skipped. The host controller can use this mechanism to detect missed micro-frames. It can then set the siTD's *Active* bit to zero and stop execution of this siTD. This saves on both memory and high-speed bus bandwidth.

54.5.3.12.3.5 Periodic Isochronous - Do Complete Split

This state is only used by a split-transaction isochronous IN endpoint.

This state is entered unconditionally from the Do Start State after a start-split transaction is executed for an IN endpoint. Each time the host controller visits an siTD in this state, it conducts a number of tests to determine whether it should execute a complete-split transaction. The individual tests are listed below. The sequence they are applied depends on which micro-frame the host controller is currently executing which means that the tests might not be applied until after the siTD referenced from the back pointer has been fetched.

- Test A. *cMicroFrameBit* is bit-wise anded with *siTD.C-mask* field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this micro-frame. This test is always applied to a newly fetched siTD that is in this state.
- Test B. The *siTD.C-prog-mask* bit vector is checked to determine whether the previous complete splits have been executed. An example algorithm is below (this is slightly different than the algorithm used in Section Periodic Isochronous - Do Complete Split). The sequence in which this test is applied depends on the current value of USB_n_FRINDEX[2:0]. If USB_n_FRINDEX[2:0] is 0 or 1, it is not applied until the back pointer has been used. Otherwise it is applied immediately.

```
Algorithm Boolean CheckPreviousBit(siTD.C-prog-mask, siTD.C-mask, cMicroFrameBit)
Begin
          Boolean rvalue = TRUE;
          previousBit = cMicroFrameBit rotate-right(1)
          -- Bit-wise anding previousBit with C-mask indicates whether there was an intent
          -- to send a complete split in the previous micro-frame. So, if the
          -- 'previous bit' is set in C-mask, check C-prog-mask to make sure it
          -- happened.
          if previousBit bitAND siTD.C-mask then
                    if not (previousBit bitAND siTD.C-prog-mask) then
                              rvalue = FALSE
                    End if
          End if
          Return rvalue
End Algorithm
```

If Test A is true and USB_n_FRINDEX[2:0] is zero or one, then this is a case 2a or 2b scheduling boundary (see Figure 54-24). See Section Periodic Isochronous - Do Complete Split for details in handling this condition.

If Test A and Test B evaluate to true, then the host controller will execute a complete-split transaction using the transfer state of the current siTD. When the host controller commits to executing the complete-split transaction, it updates *QH.C-prog-mask* by bit-ORing with *cMicroFrameBit*. The transfer state is advanced based on the completion status of the complete-split transaction. To advance the transfer state of an IN siTD, the host controller must:

- Decrement the number of bytes received from *siTD.Total Bytes To Transfer,*
- Adjust *siTD.Current Offset* by the number of bytes received,

- Adjust *siTD.P* (page selector) field if the transfer caused the host controller to use the next page pointer, and
- Set any appropriate bits in the *siTD.Status* field, depending on the results of the transaction.

Note that if the host controller encounters a condition where *siTD.Total Bytes To Transfer* is zero, and it receives more data, the host controller must not write the additional data to memory. The *siTD.Status.Active* bit must be set to zero and the *siTD.Status.Babble Detected* bit must be set to a one. The fields *siTD.Total Bytes To Transfer*, *siTD.Current Offset*, and *siTD.P* (page selector) are not required to be updated as a result of this transaction attempt.

The host controller must accept (assuming good data packet CRC and sufficient room in the buffer as indicated by the value of *siTD.Total Bytes To Transfer*) MDATA and DATA0/1 data payloads up to and including 192 bytes. A host controller implementation may optionally set *siTD.Status Active* to a zero and *siTD.Status.Babble Detected* to a one when it receives and MDATA or DATA0/1 with a data payload of more than 192 bytes. The following responses have the noted effects:

- ERR. The full-speed transaction completed with a time-out or bad CRC and this is a reflection of that error to the host. The host controller sets the *ERR* bit in the *siTD.Status* field and sets the *Active* bit to a zero.
- Transaction Error (XactErr). The complete-split transaction encounters a Timeout, CRC16 failure, etc. The *siTD.Status* field *XactErr* field is set to a one and the complete-split transaction must be retried immediately. The host controller must use an internal error counter to count the number of retries as a counter field is not provided in the siTD data structure. The host controller will not retry more than two times. If the host controller exhausts the retries or the end of the micro-frame occurs, the *Active* bit is set to zero.
- DATAx (0 or 1). This response signals that the final data for the split transaction has arrived. The transfer state of the siTD is advanced and the *Active* bit is set to a zero. If the *Bytes To Transfer* field has not decremented to zero (including the reception of the data payload in the DATAx response), then less data than was expected, or allowed for was actually received. This *short packet* event does not set the USBINT status bit in the USBSTS register to a one. The host controller will not detect this condition.
- NYET (and Last). On each NYET response, the host controller also checks to determine whether this is the last complete-split for this split transaction. Last was defined in Section Periodic Isochronous - Do Complete Split . If it is the last complete-split (with a NYET response), then the transfer state of the siTD is not advanced (never received any data) and the *Active* bit is set to a zero. No bits are set in the *Status* field because this is essentially a skipped transaction. The transaction translator must have responded to all the scheduled clompete-splits with NYETs,

meaning that the start-split issued by the host controller was not received. This result should be interpreted by system software as if the transaction was completely skipped. The test for whether this is the last complete split can be performed by XORing C-mask with C-prog-mask. A zero result indicates that all complete-splits have been executed.

- MDATA (and Last). See above description for testing for Last. This can only occur when there is an error condition. Either there has been a babble condition on the full-speed link, which delayed the completion of the full-speed transaction, or software set up the *S-mask* and/or *C-mask*s incorrectly. The host controller must set *XactErr* bit to a one and the *Active* bit is set to a zero.
- NYET (and not Last). See above description for testing for Last. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for *C-prog-mask*) and stay in this state.
- MDATA (and not Last). The transaction translator responds with an MDATA when it has partial data for the split transaction. For example, the full-speed transaction data payload spans from micro-frame X to X+1 and during micro-frame X, the transaction translator will respond with an MDATA and the data accumulated up to the end of micro-frame X. The host controller advances the transfer state to reflect the number of bytes received.

If Test A succeeds, but Test B fails, it means that one or more of the complete-splits have been skipped. The host controller sets the *Missed Micro-Frame* status bit and sets the *Active* bit to a zero.

54.5.3.12.3.6 Complete-Split for Scheduling Boundary Cases 2a, 2b

Boundary cases 2a and 2b (INs only) (see Figure 54-24) require that the host controller use the transaction state context of the previous siTD to finish the split transaction. The table below enumerates the transaction state fields.

Table 54-52. Summary siTD Split Transaction State

Buffer State	Status	Execution Progress
Total Bytes To Transfer P (page select) Current Offset TP (transaction position) T-count (transaction count)	All bits in the status field	C-prog-mask

NOTE

TP and *T-count* are used only for Host to Device (OUT) endpoints.

If software has budgeted the schedule of this data stream with a frame wrap case, then it must initialize the *siTD.Back Pointer* field to reference a valid siTD and will have the *siTD.Back Pointer.T-bit* in the *siTD.Back Pointer*

field set to a zero. Otherwise, software must set the *siTD.Back Pointer.T-bit* in the *siTD.Back Pointer* field to a one. The host controller's rules for interpreting when to use the *siTD.Back Pointer* field are listed below. These rules apply only when the siTD's *Active* bit is a one and the *SplitXState* is Do Complete Split.

- When cMicroFrameBit is a 1h and the siTDX.Back Pointer.T-bit is a zero, or
- If cMicroFrameBit is a 2h and siTDX.S-mask[0] is a zero

When either of these conditions apply, then the host controller must use the transaction state from $siTD_{X-1}$.

In order to access $siTD_{X-1}$, the host controller reads on-chip the siTD referenced from $siTD_X$.*Back Pointer*.

The host controller must save the entire state from $siTD_X$ while processing $siTD_{X-1}$. This is to accommodate for case 2b processing. The host controller must not recursively walk the list of *siTD.Back Pointers*.

If $siTD_{X-1}$ is active (*Active* bit is a one and *SplitXStat* is Do Complete Split), then both Test A and Test B are applied as described above. If these criteria to execute a complete-split are met, the host controller executes the complete split and evaluates the results as described above. The transaction state (see Table 54-52) of $siTD_{X-1}$ is appropriately advanced based on the results and written back to memory. If the resultant state of $siTD_{X-1}$'s *Active* bit is a one, then the host controller returns to the context of $siTD_X$, and follows its next pointer to the next schedule item. No updates to $siTD_X$ are necessary.

If $siTD_{X-1}$ is active (*Active* bit is a one and *SplitXStat* is Do Start Split), then the host controller must set *Active* bit to a zero and *Missed Micro-Frame* status bit to a one and the resultant status written back to memory.

If $siTD_{X-1}$*'sActive* bit is a zero, (because it was zero when the host controller first visited $siTD_{X-1}$ via $siTD_X$*'s* back pointer, it transitioned to zero as a result of a detected error, or the results of $siTD_{X-1}$*'s* complete-split transaction transitioned it to zero), then the host controller returns to the context of $siTD_X$ and transitions its *SplitXState* to Do Start Split. The host controller then determines whether the case 2b start split boundary condition exists (that is, if *cMicroframeBit* is a 1b and $siTD_X$.*S-mask*[0] is a 1b). If this criterion is met the host controller immediately executes a start-split transaction and appropriately advances the transaction state of $siTD_X$, then follows $siTD_X$.*Next Pointer* to the next schedule item. If the criterion is not met, the host controller simply follows $siTD_X$.*Next Pointer* to the next schedule item. Note that in the case of a 2b boundary case, the split-transaction of $siTD_{X-1}$ will have its *Active* bit set to zero when the host controller returns

to the context of $siTD_X$. Also, note that software should not initialize an siTD with *C-mask* bits 0 and 1 set to a one and an *S-mask* with bit zero set to a one. This scheduling combination is not supported and the behavior of the host controller is undefined.

54.5.3.12.3.7 Split Transaction for Isochronous - Processing Examples

There is an important difference between how the hardware/software manages the isochronous split transaction state machine and how it manages the asynchronous and interrupt split transaction state machines.

The asynchronous and interrupt split transaction state machines are encapsulated within a single queue head. The progress of the data stream depends on the progress of each split transaction. In some respects, the split-transaction state machine is sequenced via the Execute Transaction queue head traversal state machine (see Figure 54-17).

Isochronous is a pure time-oriented transaction/data stream. The interface data structures are optimized to efficiently describe transactions that need to occur at specific times. The isochronous split-transaction state machine must be managed across these time-oriented data structures. This means that system software must correctly describe the scheduling of split-transactions across more than one data structure.

Then the host controller must make the appropriate state transitions at the appropriate times, in the correct data structures.

For example, the table below illustrates a couple of frames worth of scheduling required to schedule a case 2a full-speed isochronous data stream.

Table 54-53. Example Case 2a - Software Scheduling siTDs for an IN Endpoint

siTDX		Micro-Frames								Initial
#	Masks	0	1	2	3	4	5	6	7	SplitXState
X	S-Mask	-	-	-	-	1	-	-	-	Do Start Split
	C-Mask	1	1	-	-	-	-	1	1	
X+1	S-Mask	-	-	-	-	1	-	-	-	Do Complete Split
	C-Mask	1	1					1	1	
X+2	S-Mask	-	-	-	-	1	-	-	-	Do Complete Split
	C-Mask	1	1					1	1	
X+3	S-Mask	Repeats previous pattern								Do Complete Split
	C-Mask									

This example shows the first three siTDs for the transaction stream. Because this is the case-2a frame-wrap case, *S-masks* of all siTDs for this endpoint have a value of 10h (a one bit in micro-frame 4) and *C-mask* value of C3h (one-bits in micro-frames 0,1, 6 and 7). Additionally, sofware ensures that the *Back Pointer* field of each siTD references the appropriate siTD data structure (and the *Back PointerT-bits* are set to zero).

The initial *SplitXState* of the first siTD is Do Start Split. The host controller will visit the first siTD eight times during frame X. The C-mask bits in micro-frames 0 and 1 are ignored because the state is Do Start Split. During micro-frame 4, the host controller determines that it can run a start-split (and does) and changes *SplitXState* to Do Complete Split. During micro-frames 6 and 7, the host controller executes complete-splits. Notice the siTD for frame X+1 has its *SplitXState* initialized to Do Complete Split. As the host controller continues to traverse the schedule during *H-Frame* X+1, it will visit the second siTD eight times. During micro-frames 0 and 1 it will detect that it must execute complete-splits.

During *H-Frame* X+1, micro-frame 0, the host controller detects that $siTD_{X+1}$'s *Back Pointer.T-bit* is a zero, saves the state of $siTD_{X+1}$ and fetches $siTD_X$. It executes the complete split transaction using the transaction state of $siTD_X$. If the $siTD_X$ split transaction is complete, siTD's *Active* bit is set to zero and results written back to $siTD_X$. The host controller retains the fact that $siTD_X$ is retired and transitions the *SplitXState* in the $siTD_{X+1}$ to Do Start Split. At this point, the host controller is prepared to execute the start-split for $siTD_{X+1}$ when it reaches micro-frame 4. If the split-transaction completes early (transaction-complete is defined in Section Periodic Isochronous - Do Complete Split), that is, before all the scheduled complete-splits have been executed, the host controller will transition $siTD_X$.*SplitXState* to Do Start Split early and naturally skip the remaining scheduled complete-split transactions. For this example, $siTD_{X+1}$ does not receive a DATA0 response until *H-Frame* X+2, micro-frame 1.

During *H-Frame X+2,* micro-frame 0, the host controller detects that $siTD_{X+2}$'s *Back Pointer.T-bit* is a zero, saves the state of $siTD_{X+2}$ and fetches $siTD_{X+1}$. As described above, it executes another split transaction, receives an MDATA response, updates the transfer state, but does not modify the *Active* bit. The host controller returns to the context of $siTD_{X+2}$, and traverses its next pointer without any state change updates to $siTD_{X+2}$. S

During *H-Frame X+2*, micro-frame 1, the host controller detects $siTD_{X+2}$'s *S-mask[0]* is a zero, saves the state of $siTD_{X+2}$ and fetches $siTD_{X+1}$. It executes another complete-split transaction, receives a DATA0 response, updates the transfer state and sets the *Active* bit to a zero. It returns to the state of $siTD_{X+2}$ and changes its *SplitXState* to Do Start Split. At this point, the host controller is prepared to execute start-splits for $siTD_{X+2}$ when it reaches micro-frame 4.

54.5.3.13 Host Controller Pause

When the host controller's *HCHalted* bit in the USBSTS register is a zero, the host controller is sending SOF (Start OF Frame) packets down all enabled ports.

When the schedules are enabled, the EHCI host controller will access the schedules in main memory each micro-frame. This constant pinging of main memory is known to create Arm platform power management problems for mobile systems. Specifically, mobile systems aggressively manage the state of the Arm platform, based on recent history usage. In the more aggressive power saving modes, the Arm platform can disable its caches. Current PC architectures assume that bus-master accesses to main memory must be cache-coherent. So, when bus masters are busy touching memory, the Arm platform power management software can detect this activity over time and inhibit the transition of the Arm platform into its lowest power savings mode. USB controllers are bus-masters and the frequency at which they access their memory-based schedules keeps the Arm platform power management software from placing the Arm platform into its lowest power savings state.

USB Host controllers don't access main memory when they are suspended. However, there are a variety of reasons why placing the USB controllers into suspend won't work, but they are beyond the scope of this document. The base requirement is that the USB controller needs to be kept out of main memory, while at the same time, the USB bus is kept from going into suspend.

EHCI controllers provide a large-grained mechanism that can be manipulated by system software to change the memory access pattern of the host controller. System software can manipulate the schedule enable bits in the USBCMD register to turn on/off the scheduling traversal. A software heuristic can be applied to implement an on/off duty cycle that allows the USB to make reasonable progress and allow the Arm platform power management to get the Arm platform into its lowest power state. This method is not intended to be applied at all times to throttle USB, but should only be applied in very specific configurations and usage loads. For example, when only a keyboard or mouse is attached to the USB, the heuristic could detect times when the USB is attempting to move data only very infrequently and can adjust the duty cycle to allow the Arm platform to reach its low power state for longer periods of time. Similarly, it could detect increases in the USB load and adjust the duty cycle appropriately, even to the point where the schedules are never disabled. The assumption here is that the USB is moving data and the Arm platform will be required to process the data streams.

It is suggested that in order to provide a complete solution for the system, the companion host controllers should also provide a similar method to allow system software to inhibit the companion host controller from accessing its shared memory based data structures (schedule lists or otherwise).

54.5.3.14 Port Test Modes -Host Operational Model

EHCI host controllers must implement the port test modes Test J_State, Test K_State, Test_Packet, Test Force_Enable, and Test SE0_NAK as described in the USB Specification Revision 2.0.

The system is only allowed to test ports that are owned by the EHCI controller (for example, *CF-bit* is a one and *PortOwner* bit is a zero). System software is allowed to have at most one port in test mode at a time. Placing more than one port in test mode will yield undefined results. The required, per port test sequence is (assuming the *CF-bit* in the USB_n_CONFIGFLAG register is a one):

- Disable the periodic and asynchronous schedules by setting the *Asynchronous Schedule Enable* and *Periodic Schedule Enable* bits in the USBCMD register to a zero.
- Place all enabled root ports into the suspended state by setting the *Suspend* bit in each appropriate USB_n_PORTSC register to a one.
- Set the *Run/Stop* bit in the USBCMD register to a zero and wait for the *HCHalted* bit in the USBSTS register, to transition to a one. Note that an EHCI host controller implementation may optionally allow port testing with the *Run/Stop* bit set to a one. However, all host controllers must support port testing with *Run/Stop* set to a zero and *HCHalted* set to a one.
- Set the *Port Test Control* field in the port under test PORTSC register to the value corresponding to the desired test mode. If the selected test is Test_Force_Enable, then the *Run/Stop* bit in the USBCMD register must then be transitioned back to one, in order to enable transmission of SOFs out of the port under test.
- When the test is complete, system software must ensure the host controller is halted (*HCHalted* bit is a one) then it terminates and exits test mode by setting *HCReset* to a one.

54.5.3.15 Interrupts-Host Operational Model

The EHCI Host Controller hardware provides interrupt capability based on a number of sources.

There are several general groups of interrupt sources:

- Interrupts as a result of executing transactions from the schedule (success and error conditions),
- Host controller events (Port change events, etc.), and
- Host Controller error events

All transaction-based sources are maskable through the Host Controller's Interrupt Enable register (USBINTR, see Section). Additionally, individual transfer descriptors can be marked to generate an interrupt on completion. This section describes each interrupt source and the processing that occurs in response to the interrupt.

During normal operation, interrupts may be immediate or deferred until the next interrupt threshold occurs. The interrupt threshold is a tunable parameter via the *Interrupt Threshold Control* field in the USBCMD register. The value of this register controls when the host controller will generate an interrupt on behalf of normal transaction execution. When a transaction completes during an interrupt interval period, the interrupt signaling the completion of the transfer will not occur until the interrupt threshold occurs. For example, the default value is eight micro-frames. This means that the host controller will not generate interrupts any more frequently than once every eight micro-frames.

Section Host System Error details effects of a host system error.

If an interrupt has been scheduled to be generated for the current interrupt threshold interval, the interrupt is not signaled until after the status for the last complete transaction in the interval has been written back to host memory. This may sometimes result in the interrupt not being signaled until the next interrupt threshold.

Initial interrupt processing is the same, regardless of the reason for the interrupt. When an interrupt is signaled by the hardware, Arm platform control is transferred to host controller's USB interrupt handler. The precise mechanism to accomplish the transfer is OS specific. For this discussion it is just assumed that control is received. When the interrupt handler receives control, its first action is to reads the USBSTS (USB Status Register). It then acknowledges the interrupt by clearing all of the interrupt status bits by writing ones to these bit positions. The handler then determines whether the interrupt is due to schedule processing or some other event. After acknowledging the interrupt, the handler (via an OS-specific mechanism), schedules a deferred procedure call (DPC) which will execute later. The DPC routine processes the results of the schedule execution. The precise mechanisms used are beyond the scope of this document.

Note: the host controller is not required to de-assert a currently active interrupt condition when software sets the interrupt enables (in the USBINR register, see Section) to a zero. The only reliable method software should use for acknowledging an interrupt is by transitioning the appropriate status bits in the USBSTS register (Section) from a one to a zero.

54.5.3.15.1 Transfer/Transaction Based Interrupts

These interrupt sources are associated with transfer and transaction progress. They are all dependent on the next interrupt threshold.

54.5.3.15.1.1 Transaction Error

A transaction error is any error that caused the host controller to think that the transfer did not complete successfully.

The table below lists the events/responses that the host can observe as a result of a transaction. The effects of the error counter and interrupt status are summarized in the following paragraphs. Most of these errors set the *XactErr* status bit in the appropriate interface data structure.

There is a small set of protocol errors that relate only when executing a queue head and fit under the umbrella of a WRONG PID error that are significant to explicitly identify. When these errors occur, the *XactErr* status bit in the queue head is set and the *CErr* field is decremented. When the *PIDCode* indicates a SETUP, the following responses are protocol errors and result in *XactErr* bit being set to a one and the *CErr* field being decremented.

- *EPS* field indicates a high-speed device and it returns a Nak handshake to a SETUP.
- *EPS* field indicates a high-speed device and it returns a Nyet handshake to a SETUP.
- *EPS* field indicates a low- or full-speed device and the complete-split receives a Nak handshake.

Table 54-54. Summary of Transaction Errors

Event / Result	Queue Head/qTD/iTD/siTD Side-effects		USB Status Register (USBSTS)
	Cerr	Status Field	USBERRINT
CRC	-1	XactErr set to a one.	1[1]
Timeout	-1	XactErr set to a one.	1[1]
Bad PID[2]	-1	XactErr set to a one.	1[1]
Babble	N/A	Section Serial Bus Babble	1
Buffer Error	N/A	Section Data Buffer Error	

1. If occurs in a queue head, then *USBERRINT* is asserted only when *CErr* counts down from a one to a zero. In addition the queue is halted, see Halting a Queue Head.
2. The host controller received a response from the device, but it could not recognize the PID as a valid PID.

54.5.3.15.1.2 Serial Bus Babble

When a device transmits more data on the USB than the host controller is expecting for this transaction, it is defined to be babbling. In general, this is called a *Packet Babble*.

When a device sends more data than the *Maximum Length* number of bytes, the host controller sets the *Babble Detected* bit to a one and halts the endpoint if it is using a queue head (see Halting a Queue Head). *Maximum Length* is defined as the minimum of *Total Bytes to Transfer* and *Maximum Packet Size*. The *CErr* field is not decremented for a packet babble condition (only applies to queue heads). A babble condition also exists if IN transaction is in progress at High-speed EOF2 point. This is called a frame babble. A frame babble condition is recorded into the appropriate schedule data structure. In addition, the host controller must disable the port to which the frame babble is detected.

The *USBERRINT* bit in the USB_n_USBSTS register is set to a one and if the *USB Error Interrupt Enable* bit in the USB_n_USBINTR register is a one, then a hardware interrupt is signaled to the system at the next interrupt threshold. The host controller must never start an OUT transaction that will babble across a micro-frame EOF.

NOTE

When a host controller detects a data PID mismatch, it must either: disable the packet babble checking for the duration of the bus transaction or do packet babble checking based solely on *Maximum Packet Size*. The USB core specification defines the requirements on a data receiver when it receives a data PID mismatch (for example, expects a DATA0 and gets a DATA1 or visa-versa). In summary, it must ignore the received data and respond with an ACK handshake, in order to advance the transmitter's data sequence.

The EHCI interface allows System software to provide buffers for a Control, Bulk or Interrupt IN endpoint that are not an even multiple of the maximum packet size specified by the device. Whenever a device misses an ACK for an IN endpoint, the host and device are out of synchronization with respect to the progress of the data transfer. The host controller may have advanced the transfer to a buffer that is less than maximum packet size. The device will re-send its maximum packet size data packet, with the original data PID, in response to the next IN token. In order to properly manage the bus protocol, the host controller must disable the packet babble check when it observes the data PID mismatch.

54.5.3.15.1.3 Data Buffer Error

This event indicates that an overrun of incoming data or a underrun of outgoing data has occurred for this transaction.

This would generally be caused by the host controller not being able to access required data buffers in memory within necessary latency requirements. These conditions are not considered transaction errors, and do not effect the error count in the queue head. When these errors do occur, the host controller records the fact the error occurred by setting the *Data Buffer Error* bit in the queue head, iTD or siTD.

If the data buffer error occurs on a non-isochronous IN, the host controller will not issue a handshake to the endpoint. This will force the endpoint to resend the same data (and data toggle) in response to the next IN to the endpoint.

If the data buffer error occurs on an OUT, the host controller must corrupt the end of the packet so that it cannot be interpreted by the device as a good data packet. Simply truncating the packet is not considered acceptable. An acceptable implementation option is to 1's complement the CRC bytes and send them. There are other options suggested in the Transaction Translator section of the USB Specification Revision 2.0.

54.5.3.15.1.4 USB Interrupt (Interrupt on Completion (IOC))

Transfer Descriptors (iTDs, siTDs, and queue heads (qTDs)) contain a bit that can be set to cause an interrupt on their completion. The completion of the transfer associated with that schedule item causes the USB Interrupt (USBINT) bit in the USB_n_USBSTS register to be set to a one.

In addition, if a short packet is encountered on an IN transaction associated with a queue head, then this event also causes USBINT to be set to a one. If the USB Interrupt Enable bit in the USB_n_USBINTR register is set to a one, a hardware interrupt is signaled to the system at the next interrupt threshold. If the completion is because of errors, the *USBERRINT* bit in the USB_n_USBSTS register is also set to a one.

54.5.3.15.1.5 Short Packet

Reception of a data packet that is less than the endpoint's Max Packet size during Control, Bulk or Interrupt transfers signals the completion of the transfer. Whenever a short packet completion occurs during a queue head execution, the *USBINT* bit in the USB_n_USBSTS register is set to a one.

If the *USB Interrupt Enable* bit is set in the USB_n_USBINTR register, a hardware interrupt is signaled to the system at the next interrupt threshold.

54.5.3.15.2 Host Controller Event Interrupts

These interrupt sources are independent of the interrupt threshold (with the one exception being the Interrupt on Async Advance, see Section Interrupt on Async Advance).

54.5.3.15.2.1 Port Change Events

Port registers contain status and status change bits. When the status change bits are set to a one, the host controller sets the *Port Change Detect* bit in the USBSTS register to a one.

If the *Port Change Interrupt Enable* bit in the USB_n_USBINTR register is a one, then the host controller will issue a hardware interrupt. The port status change bits include:

- Connect Status Change
- Port Enable/Disable Change
- Over-current Change
- Force Port Resume

54.5.3.15.2.2 Frame List Rollover

This event indicates that the host controller has wrapped the frame list. The current programmed size of the frame list effects how often this interrupt occurs.

If the frame list size is 1024, then the interrupt will occur every 1024 milliseconds, if it is 512, then it will occur every 512 milliseconds, etc. When a frame list rollover is detected, the host controller sets the *Frame List Rollover* bit in the USB.USBSTS register to a one. If the *Frame List Rollover Enable* bit in the USB.USBINTR register is set to a one, the host controller issues a hardware interrupt. This interrupt is not delayed to the next interrupt threshold.

54.5.3.15.2.3 Interrupt on Async Advance

This event is used for deterministic removal of queue heads from the asynchronous schedule. Whenever the host controller advances the on-chip context of the asynchronous schedule, it evaluates the value of the *Interrupt on Async Advance Doorbell* bit in the USB.USBCMD register.

If it is a one, it sets the *Interrupt on Async Advance* bit in the USB.USBSTS register to a one. If the *Interrupton Async Advance Enable* bit in the USB.USBINTR register is a one, the host controller issues a hardware interrupt at the next interrupt threshold. A detailed explanation of this feature is described in Section Removing Queue Heads from Asynchronous Schedule .

54.5.3.15.2.4 Host System Error

The host controller is a bus master and any interaction between the host controller and the system may experience errors.

The type of host error may be catastrophic to the host controller (such as a Master Abort) making it impossible for the host controller to continue in a coherent fashion.In the presence of non-catastrophic host errors, such as parity errors, the host controller could potentially continue operation. The recommended behavior for these types of errors is to escalate it to a catastrophic error and halt the host controller. Host-based error must result in the following actions:

- The *Run/Stop* bit in the USB.USBCMD register is set to a zero.
- The following bits in the USB.USBSTS register are set:
  - *Host System Error* bit is to a one.
  - *HCHalted* bit is set to a one.
- If the *Host System Error Enable* bit in the USB.USBINTR register is a one, then the host controller will issue a hardware interrupt. This interrupt is not delayed to the next interrupt threshold. The following table summarizes the required actions taken on the various host errors.

Table 54-55. Summary Behavior of EHCI Host Controller on Host System Errors

Cycle Type	Master Abort	Target Abort	Data Phase Parity
Frame list pointer fetch (read)	Fatal	Fatal	Fatal [o]
siTD fetch (read)	Fatal	Fatal	Fatal [o]
siTD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
iTD fetch (read)	Fatal	Fatal	Fatal [o]
iTD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
qTD fetch (read)	Fatal	Fatal	Fatal [o]
qHD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
Data write	Fatal [o]	Fatal [o]	Fatal [o]
Data read	Fatal	Fatal	Fatal [o]

Potentially, a host controller implementation could continue operation without a halt. However, the recommended behavior is to halt the host controller.

NOTE

After a *Host System Error*, Software must reset the host controller through *HCReset* in the USB.USBCMD register before re-initializing and restarting the host controller.

54.5.4 EHCI Deviation

For the purposes a dual-role Host/Device controller with support for On-The-Go applications, it is necessary to deviate from the EHCI specification. Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November

2000, Intel Corporation. http://www.intel.com. Device operation & On-The-Go operation is not specified in the EHCI and thus the implementation supported in this core is proprietary.

The host mode operation of the core is near EHCI compatible with few minor differences documented in this section.

The particulars of the deviations occur in the areas summarized here:

- Embedded Transaction Translator - Allows direct attachment of FS and LS devices in host mode without the need for a companion controller.
- Device operation - In host mode the device operational registers are generally disabled and thus device mode is mostly transparent when in host mode. However, there are a couple exceptions documented in the following sections.
- Embedded design interface - This core does not have a PCI Interface and therefore the PCI configuration registers described in the EHCI specification are not applicable.
- On-The-Go Operation - This design includes an On-The-Go controller for Port #1.

54.5.4.1 Embedded Transaction Translator Function

The OTG controller supports directly connected full and low speed devices without requiring a companion controller by including the capabilities of a USB 2.0 high speed hub transaction translator.

Although there is no separate Transaction Translator block in the system, the transaction translator function normally associated with a high speed hub has been implemented within the DMA and Protocol engine blocks. The embedded transaction translator function is an extension to EHCI interface, but makes use of the standard data structures and operational models that exist in the EHCI specification to support full and low speed devices.

54.5.4.1.1 Capability Registers

The following additions have been added to the capability registers to support the embedded Transaction Translator Function:

- N_TT added to USB.HCSPARAMS - Host Control Structural Parameters
- N_PTT added to USB.HCSPARAMS - Host Control Structural Parameters

54.5.4.1.2 Operational Registers

The following additions have been added to the operational registers to support the embedded TT:

- Addition of two-bit Port Speed (PSPD) to the register.

54.5.4.1.3 Discovery-EHCI Deviation

In a standard EHCI controller design, the EHCI host controller driver detects a Full speed (FS) or Low speed (LS) device by noting if the port enable bit is set after the port reset operation.

The port enable will only be set in a standard EHCI controller implementation after the port reset operation and when the host and device negotiate a High-Speed connection (that is, Chirp completes successfully).

Because this controller has an embedded Transaction Translator, the port enable will always be set after the port reset operation regardless of the result of the host device chirp result and the resulting port speed will be indicated by the PSPD field in USB.PORTSCx.

Therefore, the standard EHCI host controller driver requires an alteration to handle directly connected Full and Low speed devices or hubs.

The change is a fundamental one in that is summarized in the following table.

Table 54-56. Summary of EHCI

Standard EHCI	EHCI with embedded Transaction Translator
After port enable bit is set following a connection and reset sequence, the device/hub is assumed to be HS.	After port enable bit is set following a connection and reset sequence, the device/hub speed is noted from USB.PORTSCx.
FS and LS devices are assumed to be downstream from a HS hub thus, all port-level control is performed through the Hub Class to the nearest Hub.	FS and LS device can be either downstream from a HS hub or directly attached. When the FS/LS device is downstream from a HS hub, then port-level control is done using the Hub Class through the nearest Hub. When a FS/LS device is directly attached, then port-level control is accomplished using USB.PORTSCx.
FS and LS devices are assumed to be downstream from a HS hub with HubAddr=X. [where HubAddr > 0 and HubAddr is the address of the Hub where the bus transitions from HS to FS/LS (ie. Split target hub)]	FS and LS device can be either downstream from a HS hub with HubAddr = X [HubAddr > 0] or directly attached [where HubAddr = 0 and HubAddr is the address of the Root Hub where the bus transitions from HS to FS/LS (ie. Split target hub is the root hub)]

54.5.4.1.4 Data Structures

The same data structures used for FS/LS transactions though a HS hub are also used for transactions through the Root Hub with sm embedded Transaction Translator.

Here it is demonstrated how the Hub Address and Endpoint Speed fields should be set for directly attached FS/LS devices and hubs:

1. QH (for direct attach FS/LS) - Async. (Bulk/Control Endpoints) Periodic (Interrupt)
   - Hub Address = 0
   - Transactions to direct attached device/hub.
     - QH.EPS = Port Speed
   - Transactions to a device downstream from direct attached FS hub.
     - QH.EPS = Downstream Device Speed

NOTE

When QH.EPS = 01 (LS) and PORTSCx.PSPD = 00 (FS), a LS-pre-pid will be sent before the transmitting LS traffic.

Maximum Packet Size must be less than or equal 64 or undefined behaviour may result.

2. siTD (for direct attach FS) - Periodic (ISO Endpoint)
   - All FS ISO transactions:
     - Hub Address = 0
     - siTD.EPS = 00 (full speed)
       - Maximum Packet Size must less than or equal to 1023 or undefined behaviour may result.

54.5.4.1.5 Operational Model

The operational models are well defined for the behavior of the Transaction Translator (see USB 2.0 specification. Universal Serial Bus Specification, Revision 2.0, April 2000, Compaq, Hewlett-Packard, Intel, Lucent, Microsoft, NEC, Philips. http://www.usb.org) and for the EHCI controller moving packets between system memory and a USB-HS hub. Because the embedded Transaction Translator exists within the host controller there is no physical bus between EHCI host controller driver and the USB FS/LS bus. These sections will briefly discuss the operational model for how the EHCI and Transaction Translator operational models are combined without the physical bus between. The following sections assume the reader is familiar with both the EHCI and USB 2.0 Transaction Translator operational models.

54.5.4.1.5.1 Micro- frame Pipeline

The EHCI operational model uses the concept of H-frames and B-frames to describe the pipeline between the Host (H) and the Bus (B). The embedded Transaction Translator shall use the same pipeline algorithms specified in the USB 2.0 specification for a Hub-based Transaction Translator.

All periodic transfers always begin at B-frame 0 (after SOF) and continue until the stored periodic transfers are complete. As an example of the micro-frame pipeline implemented in the embedded Transaction Translator, all periodic transfers that are tagged in EHCI to execute in H-frame 0 will be ready to execute on the bus in B-frame 0.

It is important to note that when programming the S-mask and C-masks in the EHCI data structures to schedule periodic transfers for the embedded Transaction Translator, the EHCI host controller driver must follow the same rules specified in EHCI for programming the S-mask and C-mask for downstream Hub-based Transaction Translators.

Once periodic transfers are exhausted, any stored asynchronous transfer will be moved. Asynchronous transfers are opportunistic in that they shall execute whenever possible and their operation is not tied to H-frame and B-frame boundaries with the exception that an asynchronous transfer can not babble through the SOF (start of B-frame 0.)

54.5.4.1.5.2 Split State Machines

The start and complete split operational model differs from EHCI slightly because there is no bus medium between the EHCI controller and the embedded Transaction Translator.

Where a start or complete-split operation would occur by requesting the split to the HS hub, the start/complete split operation is simple an internal operation to the embedded Transaction Translator. The following table summarizes the conditions where handshakes are emulated from internal state instead of actual handshakes to HS split bus traffic.

Table 54-57. Summary of the Conditons of Handshakes[1]

Condition	Emulate TT Response
Start-Split: All asynchronous buffers full.	NAK
Start-Split: All periodic buffers full.	ERR
Start-Split: Success for start of Async. Transaction.	ACK
Start-Split: Start Periodic Transaction.	No Handshake (Ok)
Complete-Split: Failed to find transaction in queue.	Bus Time Out
Complete-Split: Transaction in Queue is Busy.	NYET
Complete-Split: Transaction in Queue is Complete.	[Actual Handshake from LS/FS device]

1. The un-shaded cells represent Start-Splits and the shaded cells represent Complete-Splits

54.5.4.1.5.3 Asynchronous Transaction Scheduling and Buffer Management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

- Sequencing is provided & a packet length estimator ensures no full-speed/low-speed packet babbles into SOF time.
- Transaction tracking for 2 data pipes.

54.5.4.1.5.3.1 USB 2.0 - 11.17.3

- Sequencing is provided & a packet length estimator ensures no full-speed/low-speed packet babbles into SOF time.

54.5.4.1.5.3.2 USB 2.0 - 11.17.4

- Transaction tracking for 2 data pipes.

54.5.4.1.5.4 Periodic Transaction Scheduling and Buffer Management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

- Abort of pending start-splits
  - EOF (and not started in micro-frames 6)
  - Idle for more than 4 micro-frames
- Abort of pending complete-splits
  - EOF
  - Idle for more than 4 micro-frames
- Transaction tracking for up to 16 data pipes.
- Complete-split transaction searching.

NOTE

There is no data schedule mechanism for these transactions other than the micro-frame pipeline. The embedded TT assumes the number of packets scheduled in a frame does not exceed the frame duration (1 ms) or else undefined behavior may result.

54.5.4.1.5.4.1 USB 2.0 - 11.18.6.[1-2]

- Abort of pending start-splits
  - EOF (and not started in micro-frames 6)
  - Idle for more than 4 micro-frames
- Abort of pending complete-splits
  - EOF
  - Idle for more than 4 micro-frames

54.5.4.1.5.4.2 USB 2.0 - 11.18.[7-8]

- Transaction tracking for up to 16 data pipes.
- Complete-split transaction searching.

NOTE

There is no data schedule mechanism for these transactions other than the micro-frame pipeline. The embedded TT assumes the number of packets scheduled in a frame does not exceed the frame duration (1 ms) or else undefined behavior may result.

54.5.4.1.5.5 Multiple Transaction Translators

The maximum number of embedded Transaction Translators that is currently supported is one as indicated by the N_TT field in the register.

54.5.4.2 Device Operation

The co-existence of a device operational controller within the host controller has little effect on EHCI compatibility for host operation except as noted in this section.

54.5.4.2.1 USB_USBMODE Register

Given that the dual-role controller is initialized in neither host nor device mode, the USB Device Mode (USB_*n*USBMODE) register must be programmed for host operation before the EHCI host controller driver can begin EHCI host operations.

54.5.4.2.2 Non-Zero Fields the Register File

Some of the reserved fields and reserved addresses in the capability registers and operational register have use in device mode, the following must be adhered to:

- Write operations to all EHCI reserved fields (some of which are device fields) with the operation registers should always be written to zero. This is an EHCI requirement of the device controller driver that must be adhered to.
- Read operations by the host controller must properly mask EHCI reserved fields (some of which are device fields) because fields that are used exclusive for device are undefined in host mode .

54.5.4.2.3 SOF Interrupt

This SOF Interrupt used for device mode is shared as a free running 125us interrupt for host mode.

EHCI does not specify this interrupt but it has been added for convenience and as a potential software time base. See USB Status Register (USB_*n*USBSTS) and Interrupt Enable Register (USB_*n*USBINTR) registers.

54.5.4.3 Embedded Design Interface

This is an Embedded USB Host Controller as defined by the EHCI specification and thus does not implement the PCI configuration registers.

54.5.4.3.1 Frame Adjust Register

Given that the optional PCI configuration registers are not included in this implementation, there is no corresponding bit level timing adjustments like is provided by the Frame Adjust register in the PCI configuration registers. Starts of micro-frames are timed precisely to 125 us using the transceiver clock as a reference clock. That is, a 60 Mhz transceiver clock for 8-bit physical interfaces & full-speed serial interfaces or 30 Mhz transceiver clock for 16-bit physical interfaces.

54.5.4.4 Miscellaneous variations from EHCI

54.5.4.4.1 Programmable Physical Interface Behaviour

This design supports multiple Physical interfaces which can operate in differing modes when the core is configured with software programmable Physical Interface Modes. Software programmability allows the selection of the Physical interface part during the board design phase instead of during the chip design phase. The control bits for selecting the Physical Interface operating mode have been added to the Port Status & Control (USB_*n*PORTSC1) register providing a capability that is not defined by EHCI.

54.5.4.4.2 Discovery

54.5.4.4.2.1 Port Reset

The port connect methods specified by EHCI require setting the port reset bit in the Port Status & Control (USB_*n*PORTSC1) register for a duration of 10ms. Due to the complexity required to support the attachment of devices that are not high speed there are counter already present in the design that can count the 10ms reset pulse to alleviate the requirement of the software to measure this duration. Therefore, the basic connection is then summarized as the following:

- [Port Change Interrupt] Port connect change occurs to notify the host controller driver that a device has attached.
- Software shall write a '1' to reset the device.

- Software shall write a '0' to reset the device after 10 ms.
  - This step, which is necessary in a standard EHCI design, may be omitted with this implementation. Should the EHCI host controller driver attempt to write a '0' to the reset bit while a reset is in progress, the write will simple be ignored and the reset will continue until completion.
- [Port Change Interrupt] Port enable change occurs to notify the host controller that the device in now operational and at this point the port speed has been determined.

54.5.4.4.2.2 Port Speed Detection

After the port change interrupt indicates that a port is enabled, the EHCI stack should determine the port speed. Unlike the EHCI implementation, which will re-assign the port owner for any device that does not connect at High-Speed, this host controller supports direct attach of non High-Speed devices.

Therefore, the following differences are important regarding port speed detection:

- Port Owner is read-only and always reads 0.
- A 2-bit Port Speed indicator has been added to PORTSC to provide the current operating speed of the port to the host controller driver.
- A 1-bit High Speed indicator has been added to PORTSC to signify that the port is in High-Speed vs. Full/Low Speed - *This information is redundant with the 2-bit Port Speed indicator above.*

54.5.4.4.3 Port Test Mode

Port Test Control mode behaves fully as described in EHCI. An alternate host controller driver procedure is not necessary or supported.

54.5.5 Device Data Structures

This section defines the interface data structures used to communicate control, status, and data between Device Controller Driver (DCD) Software and the Device Controller.

The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of device Queue Heads and Transfer Descriptors.

NOTE

Software must ensure that no interface data structure reachable by the Device Controller spans a 4K-page boundary.

The data structures defined in the chapter are (from the device controller's perspective) a mix of read-only and read/ writable fields. The device controller must preserve the read-only fields on all data structure writes.

The figure below shows the organization of the EndPoint Queue Head.

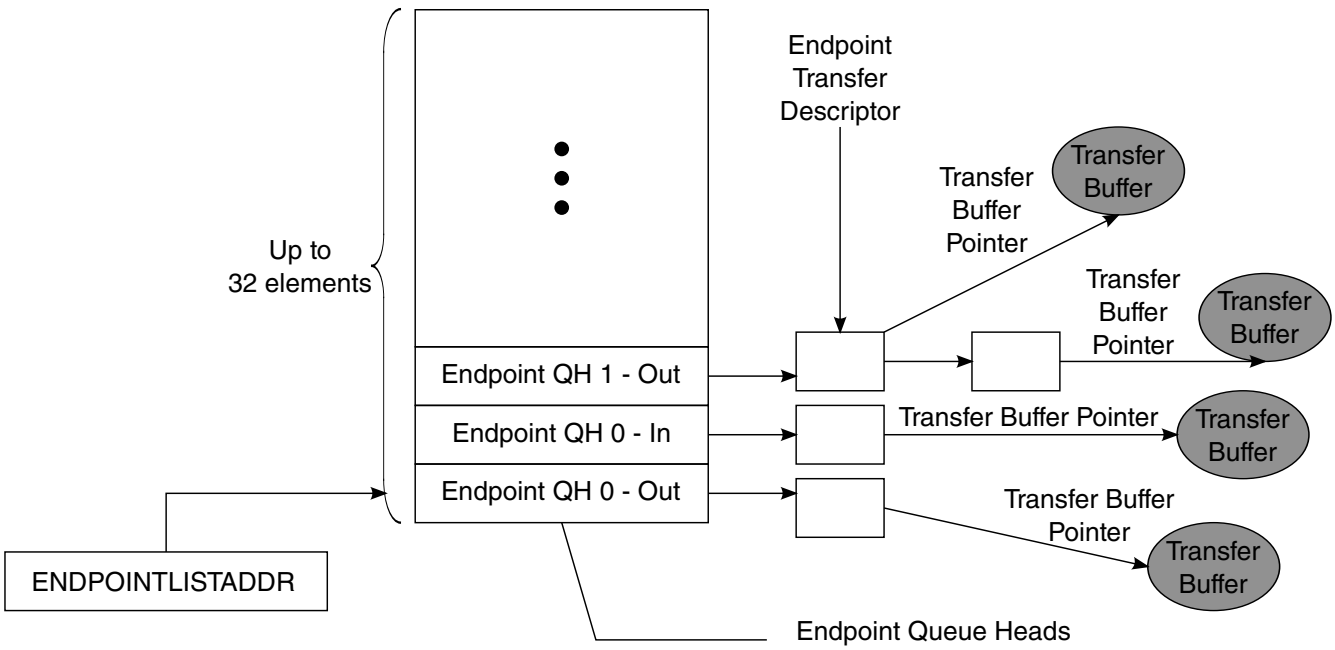

Figure 54-27. EndPoint Queue Head Organization

Endpoint queue heads are arranged in an array in a continuous area of memory pointed to by the USB.ENDPOINTLISTADDR pointer. The even -numbered device queue heads in the list support receive endpoints (OUT/SETUP) and the odd-numbered queue heads in the list are used for transmit endpoints (IN/INTERRUPT). The device controller will index into this array based upon the endpoint number received from the USB bus. All information necessary to respond to transactions for all primed transfers is contained in this list so the Device Controller can readily respond to incoming requests without having to traverse a linked list.

NOTE

The Endpoint Queue Head List must be aligned to a 2k boundary.

54.5.5.1 Endpoint Queue Head (dQH)

The device Endpoint Queue Head (dQH) is where all transfers for a given endpoint are managed. The dQH is a 48-byte data structure, but must be aligned on 64-byte boundaries.

During priming of an endpoint, the dTD (device transfer descriptor) is copied into the overlay area of the dQH, which starts at the nextTD pointer DWord and continues through the end of the buffer pointers DWords. After a transfer is complete, the dTD status DWord is updated in the dTD pointed to by the currentTD pointer. While a packet is in progress, the overlay area of the dQH is used as a staging area for the dTD so that the Device Controller can access needed information with little minimal latency.

Table 54-58. Endpoint Queue Head (dQH)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Host Controller Read/Write

Host Controller Read Only

54.5.5.1.1 Endpoint Capabilities/Characteristics

This DWord specifies static information about the endpoint, in other words, this information does not change over the lifetime of the endpoint. Device Controller software should not attempt to modify this information while the corresponding endpoint is enabled.

Table 54-59 describes the endpoint capabilities.

Table 54-59. Endpoint Capabilities/Characteristics

Bit	Description
31-30	Mult. This field is used to indicate the number of packets executed per transaction description as given by the following: 00 - Execute N Transactions as demonstrated by the USB variable length packet protocol where N is computed using the Maximum Packet Length (dQH) and the Total Bytes field (dTD) 01 Execute 1 Transaction. 10 Execute 2 Transactions. 11 Execute 3 Transactions. **NOTE:** Non-ISO endpoints must set Mult="00". ISO endpoints must set Mult="01", "10", or "11" as needed.
29	Zero Length Termination Select. This bit is used to indicate when a zero length packet is used to terminate transfers where to total transfer length is a multiple . This bit is not relevant for Isochronous 0 - Enable zero length packet to terminate transfers equal to a multiple of the Maximum Packet Length. (default). 1 - Disable the zero length packet on transfers that are equal in length to a multiple Maximum Packet Length.
28-27	Reserved. These bit reserved for future use and should be set to zero.
26-16	Maximum Packet Length. This directly corresponds to the maximum packet size of the associated endpoint (wMaxPacketSize). The maximum value this field may contain is 0x400 (1024).
15	Interrupt On Setup (IOS). This bit is used on control type endpoints to indicate if USBINT is set in response to a setup being received.
14-0	Reserved. Bits reserved for future use and should be set to zero.

54.5.5.1.2 Transfer Overlay-Endpoint Queue Head

The seven DWords in the overlay area represent a transaction working space for the device controller.

The general operational model is that the device controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it will not read the associated endpoint.

After an endpoint is readied, the dTD will be copied into this queue head overlay area by the device controller. Until a transfer is expired, software must not write the queue head overlay area or the associated transfer descriptor. When the transfer is complete, the device controller will write the results back to the original transfer descriptor and advance the queue.

See dTD for a description of the overlay fields.

54.5.5.1.3 Current dTD Pointer

The current dTD pointer is used by the device controller to locate the transfer in progress. This word is for Device Controller (hardware) use only and should not be modified by DCD software.

The following table describes the dTD Pointer.

Table 54-60. Next dTD Pointer

Bit	Description
31-5	Current dTD. This field is a pointer to the dTD that is represented in the transfer overlay area. This field will be modified by the Device Controller to next dTD pointer during endpoint priming or queue advance.
4-0	Reserved. Bit reserved for future use and should be set to zero.

54.5.5.1.4 Set-up Buffer

The set-up buffer is dedicated storage for the 8-byte data that follows a set-up PID.

NOTE

Each endpoint has a TX and an RX dQH associated with it, and only the RX queue head is used for receiving setup data packets.

The following table describes the Multiple Mode Control.

Table 54-61. Multiple Mode Control (HCCPARAMS)

DWord	Bits	Description
1	31-0	Setup Buffer 0. This buffer contains bytes 3 to 0 of an incoming setup buffer packet and is written by the device controller to be read by software.
2	31-0	Setup Buffer 1. This buffer contains bytes 7 to 4 of an incoming setup buffer packet and is written by the device controller to be read by software.

54.5.5.2 Endpoint Transfer Descriptor (dTD)

The dTD describes to the device controller the location and quantity of data to be sent/ received for a given transfer.

The DCD should not attempt to modify any field in an active dTD except the Next Like Pointer, which should only be modified as described in section Managing Transfers with Transfer Descriptors.

Table below shows the Endpoint Transfer Descriptor (dTD).

Table 54-62. Endpoint Transfer Descriptor (dTD)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Next Link Pointer																											0				T
0	Total Bytes															ioc	0			MultO		0		Status							
Buffer Pointer (Page 0)																				Current Offset

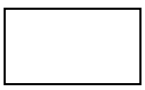
Buffer Pointer (Page 4)	Reserved	

Host Controller Read/Write



Host Controller Read Only

The following table describes the dTD Pointer.

Table 54-63. Next dTD Pointer

Bit	Description
31-5	Next Transfer Element Pointer. This field contains the physical memory address of the next dTD to be processed. The field corresponds to memory address signals [31:5], respectively.
4-1	Reserved. Bits reserved for future use and should be set to zero.
0	Terminate (T). 1=pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Device Controller that there are no more valid entries in the queue.

The following table describes the dTD Token.

Table 54-64. dTD Token

Bit	Description
31	Reserved. Bit reserved for future use and should be set to zero.
30-16	Total Bytes. This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction and only on the successful completion of the transaction. The maximum value software may store in the field is 5*4K (5000H). This is the maximum number of bytes 5 page pointers can access. Although it is possible to create a transfer up to 20K this assumes the 1st offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16K**. Therefore, the maximum recommended transfer is 16K (4000H). If the value of the field is zero when the host controller fetches this transfer descriptor (and the active bit is set), the device controller executes a zero-length transaction and retires the transfer descriptor. It is not a requirement for IN transfers that Total Bytes To Transfer be an even multiple of *Maximum Packet Length*. If software builds such a transfer descriptor for an IN transfer, the last transaction will always be less that *Maximum Packet Length*.
15	Interrupt On Complete (IOC). This bit is used to indicate if USBINT is to be set in response to device controller being finished with this dTD.
14-12	Reserved. Bits reserved for future use and should be set to zero.
11-10	Multiplier Override (MultO). This field can be used for transmit ISO's (ie. ISO-IN) to override the multiplier in the QH. This field must be zero for all packet types that are not transmit-ISO. Example:

Table continues on the next page...

Table 54-64. dTD Token (continued)

	if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultiO = 0 [default] Three packets are sent: {Data2(8); Data1(7); Data0(0)} if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultiO = 2 Two packets are sent: {Data1(8); Data0(7)} For maximal efficiency, software should compute MultO = greatest integer of (Total Bytes / Max. Packet Size) except for the case when Total Bytes = 0; then MultO should be 1. Note: Non-ISO and Non-TX endpoints must set MultO = "00".
9-8	Reserved. Bits reserved for future use and should be set to zero.
7-0	Status. This field is used by the Device Controller to communicate individual command execution states back to the Device Controller software. This field contains the status of the last transaction performed on this qTD. The bit encodings are: Bit Status Field Description 7 Active. 6 Halted. 5 Data Buffer Error. 3 Transaction Error. 4, 2, 0 Reserved.

The table below describes the dTD Buffer Page Pointer List.

Table 54-65. dTD Buffer Page Pointer List

Bit	Description
31-12	Buffer Pointer. Selects the page offset in memory for the packet buffer. Non virtual memory systems will typically set the buffer pointers to a series of incrementing integers.
0,11-0	Current Offset. Offset into the 4kb buffer where the packet is to begin.
1,10-0	Frame Number. Written by the device controller to indicate the frame number in which a packet finishes. This is typically be used to correlate relative completion times of packets on an ISO endpoint.

54.5.6 Device Operational Model

The function of the device operation is to transfer a request in the memory image to and from the Universal Serial Bus.

Using a set of linked list transfer descriptors, pointed to by a queue head, the device controller will perform the data transfers. The following sections explain the use of the device controller from the device controller driver (DCD) point-of-view and further describe how specific USB bus events relate to status changes in the device controller programmer's interface.

54.5.6.1 Device Controller Initialization

After hardware reset, the device is disabled until the Run/Stop bit is set to a '1'. In the disabled state, the pull-up on the USB D+ is not active which prevents an attach event from occurring. At a minimum, it is necessary to have the queue heads setup for endpoint zero before the device attach occurs.

Shortly after the device is enabled, a USB reset will occur followed by setup packet arriving at endpoint 0. A Queue head must be prepared so that the device controller can store the incoming setup packet.

In order to initialize a device, the software should perform the following steps:

- Set Controller Mode in the USB.USBMODE register to device mode.

NOTE

Transitioning from host mode to device mode requires a device controller reset before modifying USB.USBMODE.

- Allocate and Initialize device queue heads in system memory.
  - Minimum: Initialize device queue heads 0 Tx & 0 Rx.

NOTE

All device queue heads for control endpoints must be initialized before the endpoint is enabled. Non-Control device queue heads before the endpoint can be used.

  - For information on device queue heads, refer to section Device Data Structures.
- Configure USB.ENDPOINTLISTADDR Pointer.
  - For additional information on USB.ENDPOINTLISTADDR, refer to the register table.
- Enable the microprocessor interrupt associated with the USB core.
  - Recommended: enable all device interrupts including: USBINT, USBERRINT, Port Change Detect, USB Reset Received, DCSuspend.
  - For a list of available interrupts refer to the Interrupt Enable Register (USB_*n*USBINTR) and the USB Status Register (USB_*n*USBSTS) register tables.
- Set Run/Stop bit to Run Mode.
  - After the Run bit is set and the device is connected to a host, a Bus Reset will be issued by host downstream port. The DCD must monitor the reset event and adjust the software state as described in the Bus Reset section of the Port State and Control section below.

NOTE

Endpoint 0 is designed as a control endpoint only and does not need to be configured using ENDPTCTRL0 register.

It is also not necessary to prime Endpoint 0 initially because the first packet received will always be a setup packet. The contents of the first setup packet will require a response in accordance with USB device framework (Chapter 9) command set.

54.5.6.2 Port State and Control

From a chip or system reset, the device controller enters the *powered* state. A transition from the *powered* state to the *attach* state occurs when the Run/Stop bit is set to a '1'.

After receiving a reset on the bus, the port will enter the *defaultFS or defaultHS* state in accordance with the reset protocol described in Appendix C.2 of the USB Specification Rev. 2.0.

The following state diagram depicts the state of a USB 2.0 device.

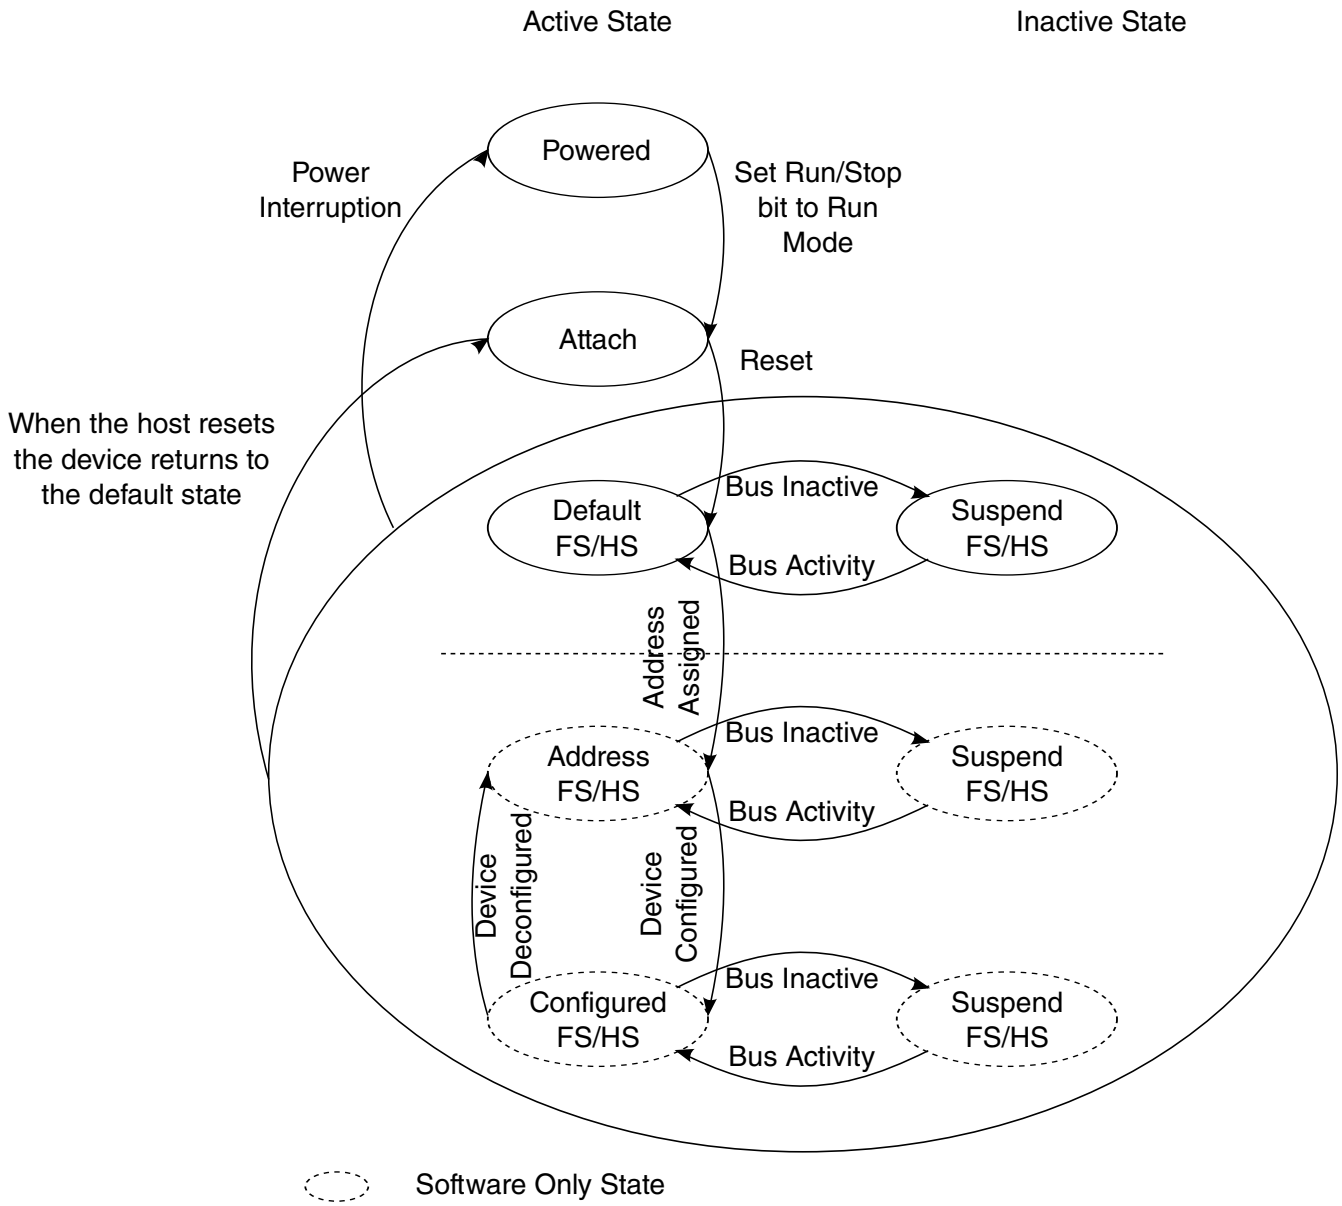


Figure 54-28. Device State Diagram

States *powered, attach, defaultFS/HS, suspendFS/HS* are implemented in the device controller and are communicated to the DCD using the following status bits:

The following table describes the Device Controller State Information Bits.

Table 54-66. Device Controller State Information Bits

Bit	Register
DCSuspend	
USB Reset Received	
Port Change Detect	
High-Speed Port	

It is the responsibility of the DCD to maintain a state variable to differentiate between the *DefaultFS/HS* state and the *Address/Configured* states. Change of state from *Default* to *Address* and the *Configured* states is part of the enumeration process described in the device framework section of the USB 2.0 Specification.

As a result of entering the *Address* state, the device address register (DEVICEADDR) must be programmed by the DCD.

Entry into the *Configured* indicates that all endpoints to be used in the operation of the device have been properly initialized by programming the USB_UOG_ENDPTCTRLx registers and initializing the associated queue heads.

54.5.6.2.1 Bus Reset

A bus reset is used by the host to initialize downstream devices.

When a bus reset is detected, the device controller will renegotiate its attachment speed, reset the device address to 0, and notify the DCD by interrupt (assuming the USB Reset Interrupt Enable is set). After a reset is received, all endpoints (except endpoint 0) are disabled and any primed transactions will be cancelled by the device controller. The concept of priming will be clarified below, but the DCD must perform the following tasks when a reset is received:

Clear all setup token semaphores by reading the Endpoint Status (USB_*n*ENDPTSTAT) register and writing the same value back to the Endpoint Status (USB_*n*ENDPTSTAT) register.

Clear all the endpoint complete status bits by reading the Endpoint Complete (USB_*n*ENDPTCOMPLETE) register and writing the same value back to the Endpoint Complete (USB_*n*ENDPTCOMPLETE) register.

Cancel all primed status by waiting until all bits in the Endpoint Prime (USB_*n*ENDPTPRIME) are 0 and then writing 0xFFFFFFFF to Endpoint Flush (USB_*n*ENDPTFLUSH).

Read the reset bit in the Port Status & Control (USB_*n*PORTSC1) register and make sure that it is still active. A USB reset will occur for a minimum of 3 ms and the DCD must reach this point in the reset cleanup before end of the reset occurs, otherwise a hardware reset of the device controller is recommended (rare.)

- A hardware reset can be performed by writing a one to the device controller reset bit in the USBCMD reset. Note: a hardware reset will cause the device to detach from the bus by clearing the Run/Stop bit. Thus, the DCD must completely re-initialize the device controller after a hardware reset.

Free all allocated dTDs because they will no longer be executed by the device controller. If this is the first time the DCD is processing a USB reset event, then it is likely that no dTDs have been allocated.

At this time, the DCD may release control back to the OS because no further changes to the device controller are permitted until a Port Change Detect is indicated.

After a Port Change Detect, the device has reached the default state and the DCD can read the Port Status & Control (USB_*n*PORTSC1) to determine if the device is operating in FS or HS mode. At this time, the device controller has reached normal operating mode and DCD can begin enumeration according to the USB Chapter 9 - Device Framework.

NOTE

The device DCD may use the FS/HS mode information to determine the bandwidth mode of the device

In some applications, it may not be possible to enable one or more pipes while in FS mode. *Beyond the data rate issue, there is no difference in DCD operation between FS and HS modes.*

54.5.6.2.2 Suspend/Resume

The detials of suspend and resume are explained in these sections.

54.5.6.2.2.1 Suspend

Suspend Description

In order to conserve power, USB devices automatically enter the suspended state when the device has observed no bus traffic for a specified period. When suspended, the USB device maintains any internal status, including its address and configuration. Attached devices must be prepared to suspend at any time they are powered, regardless of if they have been assigned a non-default address, are configured, or neither. Bus activity may cease due to the host entering a suspend mode of its own. In addition, a USB device shall also enter the suspended state when the hub port it is attached to is disabled.

A USB device exits suspend mode when there is bus activity. A USB device may also request the host to exit suspend mode or selective suspend by using electrical signaling to indicate remote wakeup. The ability of a device to signal remote wakeup is optional. If the USB device is capable of remote wakeup signaling, the device must support the ability of the host to enable and disable this capability. When the device is reset, remote wakeup signaling must be disabled.

Suspend Operational Model

The device controller moves into the suspend state when suspend signaling is detected or activity is missing on the upstream port for more than a specific period. After the device controller enters the suspend state, the DCD is notified by an interrupt (assuming *DC Suspend Interrupt* is enabled). When the *DCSuspend* bit in the Port Status & Control (USB_*n*PORTSC1) is set to a '1', the device controller is suspended.

DCD response when the device controller is suspended is application specific and may involve switching to low power operation.

Information on the bus power limits in suspend state can be found in USB 2.0 specification.

NOTE

Review system level clocking issues defined in section (Ref: Signals-Clocking) for the clocking requirements of a suspended device controller.

54.5.6.2.2.2 Resume

If the device controller is suspended, its operation is resumed when any non-idle signaling is received on its upstream facing port. In addition, the device can signal the system to resume operation by forcing resume signaling to the upstream port.

Resume signaling is sent upstream by writing a '1' to the Resume bit in the in the Port Status & Control (USB_*n*PORTSC1) while the device is in suspend state. Sending resume signal to an upstream port should cause the host to issue resume signaling and bring the suspended bus segment (one more devices) back to the active condition.

NOTE

Before resume signaling can be used, the host must enable it by using the Set Feature command defined in device framework (chapter 9) of the USB 2.0 Specification.

54.5.6.3 Managing Endpoints

The USB 2.0 specification defines an endpoint, also called a device endpoint or an address endpoint as a uniquely addressable portion of a USB device that can source or sink data in a communications channel between the host and the device.

The endpoint address is specified by the combination of the endpoint number and the endpoint direction.

The channel between the host and an endpoint at a specific device represents a data pipe. Endpoint 0 for a device is always a *control* type data channel used for device discovery and enumeration. Other types of endpoints support by USB include *bulk, interrupt*, and *isochronous*. Each endpoint type has specific behavior related to packet response and error handling. More detail on endpoint operation can be found in the USB 2.0 specification.

The USB OTG device controller hardware supports up to 8 endpoint numbers.

Each endpoint direction is essentially independent and can be configured with differing behavior in each direction. For example, the DCD can configure endpoint 1-IN to be a bulk endpoint and endpoint 1-OUT to be an isochronous endpoint. This helps to conserve the total number of endpoints required for device operation. The only exception is that control endpoints must use both directions on a single endpoint number to function as a control endpoint. Endpoint 0 is, for example, is always a control endpoint and uses the pair of directions.

Each endpoint direction requires a *queue head* allocated in memory. To support the 8 endpoint numbers, 16 *queue heads* are required. The operation of an endpoint and use of *queue heads* are described later in this document.

54.5.6.3.1 Endpoint Initialization

After hardware reset, all endpoints except endpoint zero are uninitialized and disabled. The DCD must configure and enable each endpoint by writing to configuration bit in the USB_UOG_ENDPTCTRLx register.

Each 32-bit USB_UOG_ENDPTCTRLx is split into an upper and lower half. The lower half of USB_UOG_ENDPTCTRLx is used to configure the receive or OUT endpoint and the upper half is likewise used to configure the corresponding transmit or IN endpoint. Control endpoints must be configured the same in both the upper and lower half of the USB_UOG_ENDPTCTRLx register otherwise the behavior is undefined. The following table shows how to construct a configuration word for endpoint initialization. The following table shows the fields and values for the Device Controller Endpoint initialization.

Table 54-67. Device Controller Endpoint Initialization

Field	Value
Data Toggle Reset	1
Data Toggle Inhibit	0
Endpoint Type	00 Control 01 Isochronous 10 Bulk

Table continues on the next page...

Table 54-67. Device Controller Endpoint Initialization (continued)

	11 Interrupt
Endpoint Stall	0

54.5.6.3.2 Stalling

There are two occasions where the device controller may need to return to the host a STALL.

The first occasion is the functional stall, which is a condition set by the DCD as described in the USB 2.0 device framework. A functional stall is only used on non-control endpoints and can be enabled in the device controller by setting the endpoint stall bit in the USB_UOG_ENDPTCTRLx register associated with the given endpoint and the given direction. In a functional stall condition, the device controller will continue to return STALL responses to all transactions occurring on the respective endpoint and direction until the endpoint stall bit is cleared by the DCD.

A protocol stall, unlike a function stall, is used on control endpoints is automatically cleared by the device controller at the start of a new control transaction (setup phase). When enabling a protocol stall, the DCD should enable the stall bits (both directions) as a pair. A single write to the USB_UOG_ENDPTCTRLx register can ensure that both stall bits are set at the same instant.

NOTE

Any write to the USB_UOG_ENDPTCTRLx register during operational mode must preserve the endpoint type field (that is, perform a read-modify-write).

The following table shows the response matrix for the Device Controller Stall.

Table 54-68. Device Controller Stall Response Matrix

USB Packet	Endpoint Stall Bit.	Effect on STALL bit.	USB Response
SETUP packet received by a non-control endpoint.	N/A	None.	STALL
IN/OUT/PING packet received by a non-control endpoint.	'1'	None.	STALL
IN/OUT/PING packet received by a non-control endpoint.	'0'	None.	ACK/ NAK/ NYET
SETUP packet received by a control endpoint.	N/A	Cleared	ACK
IN/OUT/PING packet received by a control endpoint	'1'	None	STALL

Table continues on the next page...

Table 54-68. Device Controller Stall Response Matrix (continued)

IN/OUT/PING packet received by a control endpoint.	'0'	None.	ACK/ NAK/ NYET

54.5.6.3.3 Data Toggle

Data toggle is a mechanism to maintain data coherency between host and device for any given data pipe.

For more information on data toggle, refer to the USB 2.0 specification.

54.5.6.3.3.1 Data Toggle Reset

The DCD may reset the data toggle state bit and cause the data toggle sequence to reset in the device controller by writing a '1' to the data toggle reset bit in the USB_UOG_ENDPTCTRLx register.

This should only be necessary when configuring/initializing an endpoint or returning from a STALL condition.

54.5.6.3.3.2 Data Toggle Inhibit

NOTE

This feature is for test purposes only and should never be used during normal device controller operation.

Setting the *data toggle Inhibit bit* active ('1') causes the device controller to ignore the data toggle pattern that is normally sent and accept all incoming data packets regardless of the data toggle state.

In normal operation, the device controller checks the DATA0/DATA1 bit against the data toggle to determine if the packet is valid. If Data PID does not match the data toggle state bit maintained by the device controller for that endpoint, the Data toggle is considered not valid. If the data toggle is not valid, the device controller assumes the packet was already received and discards the packet (not reporting it to the DCD). To prevent the host controller from re-sending the same packet, the device controller will respond to the error packet by acknowledging it with either an ACK or NYET response.

54.5.6.3.3.3 Priming Transmit Endpoints

Priming a transmit endpoint will cause the device controller to fetch the device transfer descriptor (dTD) for the transaction pointed to by the device queue head (dQH).

After the dTD is fetched, it will be stored in the dQH until the device controller completes the transfer described by the dTD. Storing the dTD in the dQH allows the device controller to fetch the operating context needed to handle a request from the host without the need to follow the linked list, starting at the dQH when the host request is received.

After the device has loaded the dTD, the leading data in the packet is stored in a FIFO in the device controller. This FIFO is split into virtual channels so that the leading data can be stored for any endpoint up to the maximum number of endpoints configured at device synthesis time.

After a priming request is complete, an endpoint state of primed is indicated in the USB_UOG_ENDPTSTATUS register. For a primed transmit endpoint, the device controller can respond to an IN request from the host and meet the stringent bus turnaround time of High Speed USB.

Because only the leading data is stored in the device controller FIFO, it is necessary for the device controller to begin filling in behind leading data after the transaction starts. The FIFO must be sized to account for the maximum latency that can be incurred by the system memory bus. More information about FIFO sizing is presented in section .

54.5.6.3.3.4 Priming Receive Endpoints

Priming receive endpoints is identical to priming of transmit endpoints from the point of view of the DCD. At the device controller the major difference in the operational model is that there is no data movement of the leading packet data simply because the data is to be received from the host.

Note as part of the architecture, the FIFO for the receive endpoints is not partitioned into multiple channels like the transmit FIFO. Thus, the size of the RX FIFO does not scale with the number of endpoints.

54.5.6.4 Operational Model For Packet Transfers

All transactions on the USB bus are initiated by the host and in turn, the device must respond to any request from the host within the turnaround time stated in the USB 2.0 Specification.

At USB 1.1 Full or Low Speed rates, this turnaround time was significant and the USB 1.1 device controllers were architected so that the device controller could access main memory or interrupt a host protocol processor in order to respond to the USB 1.1

transaction. The architecture of the USB 2.0 device controller must be different because same methods will not meet USB 2.0 High-speed turnaround time requirements by simply increasing clock rate.

A USB host will send requests to the device controller in an order that can not be precisely predicted as a single pipeline, so it is not possible to prepare a single packet for the device controller to execute. However, the order of packet requests is predictable when the endpoint number and direction is considered. For example, if endpoint 3 (transmit direction) is configured as a bulk pipe, then we can expect the host will send IN requests to that endpoint. This device controller is architected in such a way that it can prepare packets for each endpoint/direction in anticipation of the host request. The process of preparing the device controller to send or receive data in response to host initiated transaction on the bus is referred to as "priming" the endpoint. This term will be used throughout the following documentation to describe the device controller operation so the DCD can be architected properly use priming. Further, note that the term "flushing" is used to describe the action of clearing a packet that was queued for execution.

54.5.6.4.1 Interrupt/Bulk Endpoint Operational Model

The behaviors of the device controller for interrupt and bulk endpoints are identical.

All valid IN and OUT transactions to bulk pipes will handshake with a NAK unless the endpoint had been primed. Once the endpoint has been primed, data delivery will commence.

A dTD will be retired by the device controller when the packets described in the transfer descriptor have been completed. Each dTD describes N packets to be transferred according to the USB Variable Length transfer protocol. The formula and table on the following page describe how the device controller computes the number and length of the packets to be sent/received by the USB vary according to the total number of bytes and maximum packet length.

With Zero Length Termination (ZLT) = 0

N = INT(Number Of Bytes/Max. Packet Length) + 1

With Zero Length Termination (ZLT) = 1

N = MAXINT(Number Of Bytes/Max. Packet Length)

Table 54-69. Variable Length Transfer Protocol Example (ZLT = 0)

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	

Table continues on the next page...

Table 54-69. Variable Length Transfer Protocol Example (ZLT = 0) (continued)

512	256	3	256	256	0
512	512	2	512	0	

Table 54-70. Variable Length Transfer Protocol Example (ZLT = 1)

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	
512	256	2	256	256	
512	512	1	512		

NOTE

The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.

TX-dTD is complete when:

- All packets described dTD were successfully transmitted. *** Total bytes in dTD will equal zero when this occurs.

RX-dTD is complete when:

- All packets described in dTD were successfully received. *** Total bytes in dTD will equal zero when this occurs.
- A short packet (number of bytes < maximum packet length) was received. *** This is a successful transfer completion; DCD must check Total Bytes in dTD to determine the number of bytes that are remaining. From the total bytes remaining in the dTD, the DCD can compute the actual bytes received.
- A long packet was received (number of bytes > maximum packet size) OR (total bytes received > total bytes specified). *** This is an error condition. The device controller will discard the remaining packet, and set the Buffer Error bit in the dTD. In addition, the endpoint will be flushed and the USBERR interrupt will become active.

On the successful completion of the packet(s) described by the dTD, the active bit in the dTD will be cleared and the next pointer will be followed when the Terminate bit is clear. When the Terminate bit is set, the device controller will flush the endpoint/direction and cease operations for that endpoint/direction.

On the unsuccessful completion of a packet (see long packet above), the dQH will be left pointing to the dTD that was in error. In order to recover from this error condition, the DCD must properly reinitialize the dQH by clearing the active bit and update the nextTD pointer before attempting to re-prime the endpoint.

NOTE

All packet level errors such as a missing handshake or CRC error will be retried automatically by the device controller.

There is no required interaction with the DCD for handling such errors.

54.5.6.4.1.1 Interrupt/Bulk Endpoint Bus Response Matrix

The table below shows the response matrix for Interrput/Bulk Endpoint Bus.

Table 54-71. Interrupt/Bulk Endpoint Bus Response Matrix

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	Ignore	Ignore	Ignore	N/A	N/A
In	STALL	NAK	Transmit	BS Error	N/A
Out	STALL	NAK	Receive + NYET/ACK	N/A	NAK
Ping	STALL	NAK	ACK	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

NOTE

BS Error = Force Bit Stuff Error

NYET/ACK - NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSERR - System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

54.5.6.4.2 Control Endpoint Operation Model

This section details the setup phase, data phase, status phase, and the control endpoint bus response matrix.

54.5.6.4.2.1 Setup Phase

All requests to a control endpoint begin with a setup phase followed by an optional data phase and a required status phase. The device controller will always accept the setup phase unless the setup lockout is engaged.

The setup lockout will engage so that future setup packets are ignored. Lockout of setup packets ensures that while software is reading the setup packet stored in the queue head, that data is not written as it is being read potentially causing an invalid setup packet.

The setup lockout mechanism can be disabled and a new tripwire type semaphore will ensure that the setup packet payload is extracted from the queue head without being corrupted be an incoming setup packet. This is the preferred behavior because ignoring repeated setup packets due to long software interrupt latency would be a compliance issue.

- Disable Setup Lockout by writing 1 to Setup Lockout Mode (SLOM) in USB Device Mode (USB_*n*USBMODE). (once at initialization). Setup lockout is not necessary when using the tripwire as described below.

NOTE

Leaving the Setup Lockout Mode As 0 will result in pre-2.3 hardware behavior.

- After receiving an interrupt and inspecting Endpoint Setup Status (USB_*n*ENDPTSETUPSTAT) to determine that a setup packet was received on a particular pipe:
  a. Write 1 to clear corresponding bit Endpoint Setup Status (USB_*n*ENDPTSETUPSTAT).
  b. Write 1 to Setup Tripwire (SUTW) in USB Command Register (USB_*n*USBCMD) register.
  c. Duplicate contents of dQH.SetupBuffer into local software byte array.
  d. Read Setup TripWire (SUTW) in USB Command Register (USB_*n*USBCMD) register. (if set - continue; if cleared - goto 2)
  e. Write 0 to clear Setup Tripwire (SUTW) in USB Command Register (USB_*n*USBCMD) register.
  f. Process setup packet using local software byte array copy and execute status/ handshake phases.

NOTE

After receiving a new setup packet the status and/or handshake phases may still be pending from a previous control sequence. These should be flushed & deallocated before linking a new status and/or handshake dTD for the most recent setup packet.

54.5.6.4.2.2 Data Phase

Following the setup phase, the DCD must create a device transfer descriptor for the data phase and prime the transfer.

After priming the packet, the DCD must verify a new setup packet has not been received by reading the USB.ENDPTSETUPSTAT register immediately verifying that the prime had completed. A prime will complete when the associated bit in the Endpoint Prime (USB_*n*ENDPTPRIME) register is zero and the associated bit in the Endpoint Status

(USB_*n*ENDPTSTAT) register is a one. If a prime fails, ie. The Endpoint Prime (USB_*n*ENDPTPRIME) bit goes to zero and the Endpoint Status (USB_*n*ENDPTSTAT) bit is not set, then the prime has failed. This can only be due to improper setup of the dQH, dTD or a setup arriving during the prime operation. If a new setup packet is indicated after the ENDPTPRIME bit is cleared, then the transfer descriptor can be freed and the DCD must reinterpret the setup packet.

Should a setup arrive after the data stage is primed, the device controller will automatically clear the prime status (Endpoint Status (USB_*n*ENDPTSTAT)) to enforce data coherency with the setup packet.

NOTE

- The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is the same as bulk packets described previously.

54.5.6.4.2.3 Status Phase

Similar to the data phase, the DCD must create a transfer descriptor (with byte length equal zero) and prime the endpoint for the status phase.

The DCD must also perform the same checks of the USB.ENDPTSETUPSTAT as described above in the data phase.

NOTE

- The MULT field in the dQH must be set to 00 for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is the same as bulk packets described previously.

54.5.6.4.2.4 Control Endpoint Bus Response Matrix

Shown in the following table is the device controller response to packets on a control endpoint according to the device controller state.

The table below shows the response matrix for the Control Endpoint Bus.

Table 54-72. Control Endpoint Bus Response Matrix

Token Type	Endpoint State					Setup Lockout
	Stall	Not Primed	Primed	Underflow	Overflow	
Setup	ACK	ACK	ACK	N/A	SYSERR	
In	STALL	NAK	Transmit	BS Error	N/A	N/A

Table continues on the next page...

Table 54-72. Control Endpoint Bus Response Matrix (continued)

Out	STALL	NAK	Receive + NYET/ACK	N/A	NAK	N/A
Ping	STALL	NAK	ACK	N/A	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore	Ignore

BS Error = Force Bit Stuff Error

NYET/ACK - NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSERR - System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

54.5.6.4.3 Isochronous Endpoint Operational Model

Isochronous endpoints are used for real-time scheduled delivery of data and their operational model is significantly different than the host throttled Bulk, Interrupt, and Control data pipes.

Real time delivery by the device controller will be accomplished by the following:

- Exactly MULT Packets per (micro) Frame are transmitted/received. Note: MULT is a two-bit field in the device Queue Head. The variable length packet protocol is not used on isochronous endpoints.
- NAK responses are not used. Instead, zero length packets are sent in response to an IN request to an unprimed endpoints. For unprimed RX endpoints, the response to an OUT transaction is to ignore the packet within the device controller.
- Prime requests always schedule the transfer described in the dTD for the next (micro) frame. If the ISO-dTD is still active after that frame, then the ISO-dTD will be held ready until executed or canceled by the DCD.

An EHCI compatible host controller uses the periodic frame list to schedule data exchanges to Isochronous endpoints. The operational model for device mode does not use such a data structure. Instead, the same dTD used for Control/Bulk/Interrupt endpoints is also used for isochronous endpoints. The difference is in the handling of the dTD.

The first difference between bulk and ISO-endpoints is that priming an ISO-endpoint is a delayed operation such that an endpoint will become primed only after a SOF is received. After the DCD writes the prime bit, the prime bit will be cleared as usual to indicate to software that the device controller completed a priming the dTD for transfer. Internal to the design, the device controller hardware masks that prime start until the next frame boundary. This behavior is hidden from the DCD but occurs so that the device controller can match the dTD to a specific (micro)frame.

Another difference with isochronous endpoints is that the transaction must wholly complete in a (micro)frame. Once an ISO transaction is started in a (micro)frame it will retire the corresponding dTD when MULT transactions occur or the device controller finds a fulfillment condition.

The transaction error bit set in the status field indicates a fulfillment error condition. When a fulfillment error occurs, the frame after the transfer failed to complete wholly, the device controller will force retire the ISO-dTD and move to the next ISO-dTD.

It is important to note that fulfillment errors are only caused due to partially completed packets. If no activity occurs to a primed ISO-dTD, the transaction will stay primed indefinitely. This means it is up to software discard transmit ISO-dTDs that pile up from a failure of the host to move the data.

Finally, the last difference with ISO packets is in the data level error handling. When a CRC error occurs on a received packet, the packet is not retried similar to bulk and control endpoints. Instead, the CRC is noted by setting the *Transaction Error* bit and the data is stored as usual for the application software to sort out.

- TX Packet Retired
  - MULT counter reaches zero.
  - Fulfillment Error [*Transaction Error* bit is set]
    - # Packets Occurred > 0 AND # Packets Occurred < MULT

NOTE

For TX-ISO, MULT Counter can be loaded with a lesser value in the dTD Multiplier Override field in hardware versions 2.3 and later. If the Multiplier Override is zero, the MULT Counter is initialized to the Multiplier in the QH.

- RX Packet Retired:
  - MULT counter reaches zero.
  - Non-MDATA Data PID is received**
    - ** Exit criteria only valid in hardware version 2.3 or later. Previous to hardware version 2.3, any PID sequence that did not match the MULT field exactly would be flagged as a transaction error due to PID mismatch or fulfillment error.
  - Overflow Error:
    - Packet received is > maximum packet length. [*Buffer Error* bit is set]
    - Packet received exceeds total bytes allocated in dTD. [*Buffer Error* bit is set]
  - Fulfillment Error [*Transaction Error* bit is set]
    - # Packets Occurred > 0 AND # Packets Occurred < MULT
  - CRC Error [*Transaction Error* bit is set]

NOTE

For ISO, when a dTD is retired, the next dTD is primed for the next frame. For continuous (micro)frame to (micro)frame operation the DCD should ensure that the dTD linked-list is out ahead of the device controller by at least two (micro)frames.

54.5.6.4.3.1 Isochronous Pipe Synchronization

When it is necessary to synchronize an isochronous data pipe to the host, the (micro) frame number (USB_UOG_FRINDEX register) can be used as a marker.

To cause a packet transfer to occur at a specific (micro) frame number [N], the DCD should interrupt on SOF during frame N-1. When the USB_UOG_FRINDEX=N-1, the DCD must write the prime bit. The device controller will prime the isochronous endpoint in (micro) frame N-1 so that the device controller will execute delivery during (micro) frame N.

NOTE

Priming an endpoint towards the end of (micro) frame N-1 will not guarantee delivery in (micro) frame N. The delivery may actually occur in (micro) frame N+1 if device controller does not have enough time to complete the prime before the SOF for packet N is received.

54.5.6.4.3.2 Isochronous Endpoint Bus Response Matrix

The following table shows the response matrix for the Isochronous Endpoint Bus.

Table 54-73. Isochronous Endpoint Bus Response Matrix

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	STALL	STALL	STALL	N/A	N/A
In	NULL Packet	NULL Packet	Transmit	BS Error	N/A
Out	Ignore	Ignore	Receive	N/A	Drop Packet
Ping	Ignore	Ignore	Ignore	Ignore	Ignore
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

1. BS Error = Force Bit Stuff Error

   NULL Packet = Zero Length Packet

54.5.6.5 Managing Queue Heads

The following figure shows the End Point Queue Head.

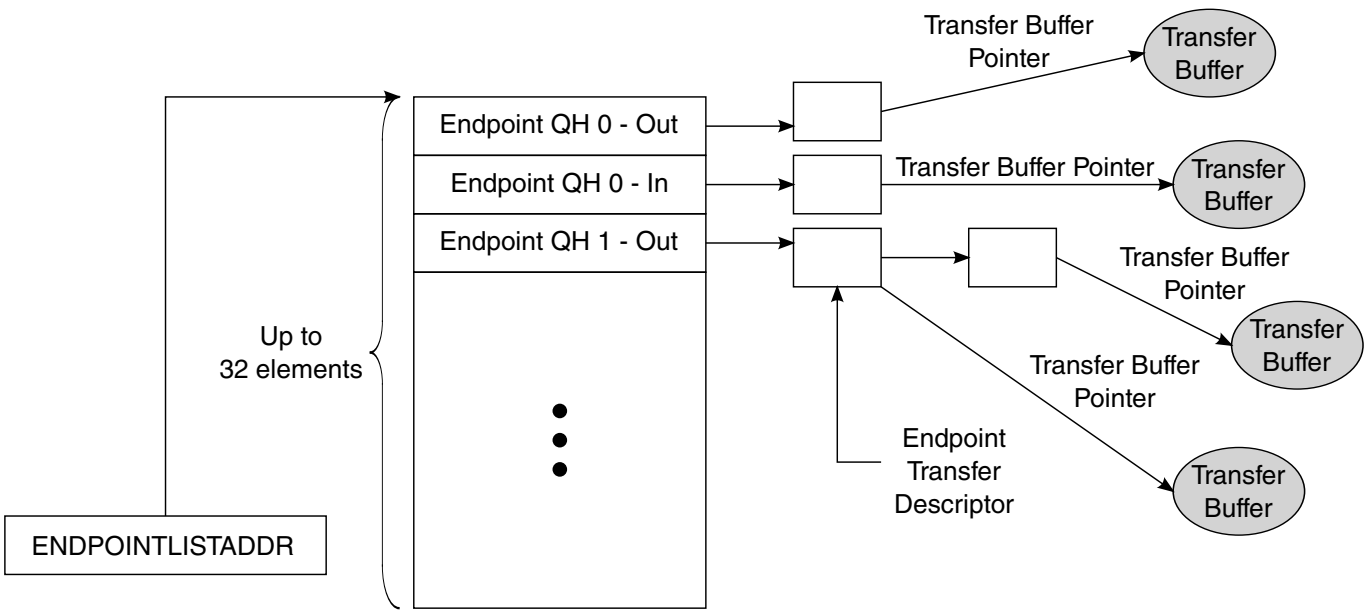

Figure 54-29. End Point Queue Head Diagram

The device queue head (dQH) points to the linked list of transfer tasks, each depicted by the device Transfer Descriptor (dTD). An area of memory pointed to by USB.ENDPOINTLISTADDR contains a group of all dQH's in a sequential list as shown in Figure 54-29. The even elements in the list of dQH's are used for receive endpoints (OUT/SETUP) and the odd elements are used for transmit endpoints (IN/INTERRUPT). Device transfer descriptors are linked head to tail starting at the queue head and ending at a terminate bit. Once the dTD has been retired, it will no longer be part of the linked list from the queue head. Therefore, software is required to track all transfer descriptors because pointers will no longer exist within the queue head once the dTD is retired (see section Software Link Pointers).

In addition to the current and next pointers and the dTD overlay examined in section Operational Model For Packet Transfers, the dQH also contains the following parameters for the associated endpoint: Multipler, Maximum Packet Length, Interrupt On Setup. The complete initialization of the dQH including these fields is demonstrated in the next section.

54.5.6.5.1 Queue Head Initialization

One device queue head must be initialized for each active endpoint.

To initialize a device queue head:

- Write the wMaxPacketSize field as required by the USB Chapter 9 or application specific protocol.
- Write the multiplier field to 0 for control, bulk, and interrupt endpoints. For ISO endpoints, set the multiplier to 1,2, or 3 as required bandwidth and in conjunction with the USB Chapter 9 protocol.

NOTE

In FS mode, the multiplier field can only be 1 for ISO endpoints.

- Write the next dTD Terminate bit field to 1.
- Write the Active bit in the status field to 0.
- Write the Halt bit in the status field to 0.

NOTE

The DCD must only modify dQH if the associated endpoint is not primed and there are no outstanding dTD's.

54.5.6.5.2 Operational Model For Setup Transfers

As discussed in section Control Endpoint Operation Model, setup transfer requires special treatment by the DCD. A setup transfer does not use a dTD but instead stores the incoming data from a setup packet in an 8-byte buffer within the dQH.

Upon receiving notification of the setup packet, the DCD should handle the setup transfer as demonstrated here:

1. Copy setup buffer contents from dQH - RX to software buffer.
2. Acknowledge setup backup by writing a "1" to the corresponding bit in ENDPTSETUPSTAT.

NOTE

- The acknowledge must occur before continuing to process the setup packet.
- After the acknowledge has occurred, the DCD must not attempt to access the setup buffer in the dQH - RX. Only the local software copy should be examined.

3. Check for pending data or status dTD's from previous control transfers and flush if any exist as discussed in section Flushing/De-priming an Endpoint.
4. Decode setup packet and prepare data phase [optional] and status phase transfer as required by the USB Chapter 9 or application specific protocol.

NOTE

It is possible for the device controller to receive setup packets before previous control transfers complete. Existing control packets in progress must be flushed and the new control packet completed.

54.5.6.6 Managing Transfers with Transfer Descriptors

54.5.6.6.1 Software Link Pointers

It is necessary for the DCD software to maintain head and tail pointers to the for the linked list of dTDs for each respective queue head.

This is necessary because the dQH only maintains pointers to the current working dTD and the next dTD to be executed. The operations described in next section for managing dTD will assume the DCD can use reference the head and tail of the dTD linked list. The following figure shows the Software Link Pointers.

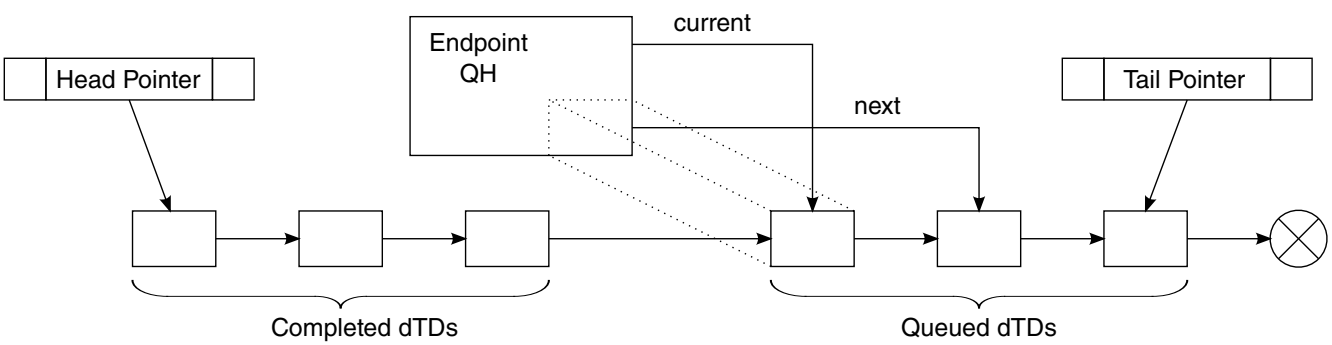

Figure 54-30. Software Link Pointers

NOTE

To conserve memory, the reserved fields at the end of the dQH can be used to store the Head & Tail pointers, but it still remains the responsibility of the DCD to maintain the pointers.

54.5.6.6.2 Building a Transfer Descriptor

Before a transfer can be executed from the linked list, a dTD must be built to describe the transfer.

Use the following procedure for building dTDs.

Allocate 8-DWord dTD block of memory aligned to 8-DWord boundaries. Example: bit address 4:0 would be equal to "00000"

Write the following fields:

1. Initialize first 7 DWords to 0.
2. Set the terminate bit to 1.
3. Fill in total bytes with transfer size.
4. Set the interrupt on complete if desired.
5. Initialize the status field with the active bit set to 1 and all remaining status bits set to 0.
6. Fill in buffer pointer page 0 and the current offset to point to the start of the data buffer.
7. Initialize buffer pointer page 1 through page 4 to be one greater than each of the previous buffer pointer.

54.5.6.6.3 Executing A Transfer Descriptor

To safely add a dTD, the DCD must be follow this procedure which will handle the event where the device controller reaches the end of the dTD list at the same time a new dTD is being added to the end of the list.

Determine whether the link list is empty: Check DCD driver to see if pipe is empty (internal representation of linked-list should indicate if any packets are outstanding).

- Case 1: Link list is empty
  a. Write dQH next pointer AND dQH terminate bit to 0 as a single DWord operation.
  b. Clear active & halt bit in dQH (in case set from a previous error).
  c. Prime endpoint by writing 1 to correct bit position in .
- Case 2: Link list is not empty
  a. Add dTD to end of linked list.
  b. Read correct prime bit in - if 1 DONE.
  c. Set ATDTW bit in USBCMD register to 1.
  d. Read correct status bit in . (store in tmp. variable for later)
  e. Read ATDTW bit in USBCMD register.
     - If 0 goto 3.
     - If 1 continue to 6.
  f. Write ATDTW bit in USBCMD register to 0.
  g. If status bit read in (3) is 1 DONE.
  h. If status bit read in (3) is 0 then Goto Case 1: Step 1.

54.5.6.6.4 Transfer Completion

After a dTD has been initialized and the associated endpoint primed the device controller will execute the transfer upon the host-initiated request. The DCD will be notified with a USB interrupt if the Interrupt On Complete bit was set or alternately, the DCD can poll the endpoint complete register to find when the dTD had been executed. After a dTD has been executed, DCD can check the status bits to determine success or failure.

NOTE

Multiple dTD can be completed in a single endpoint complete notification. After clearing the notification, DCD must search the dTD linked list and retire all dTDs that have finished (Active bit cleared).

By reading the status fields of the completed dTDs, the DCD can determine if the transfers completed successfully. Success is determined with the following combination of status bits:

- Active = 0
- Halted = 0
- Transaction Error = 0
- Data Buffer Error = 0

Should any combination other than the one shown above exist, the DCD must take proper action. Transfer failure mechanisms are indicated in the Device Error Matrix.

In addition to checking the status bit the DCD must read the Transfer Bytes field to determine the actual bytes transferred. When a transfer is complete, the Total Bytes transferred is by decremented by the actual bytes transferred. For Transmit packets, a packet is only complete after the actual bytes reaches zero, but for receive packets, the host may send fewer bytes in the transfer according the USB variable length packet protocol.

54.5.6.6.5 Flushing/De-priming an Endpoint

It is necessary for the DCD to flush to de-prime one more endpoints on a USB device reset or during a broken control transfer.

There may also be application specific requirements to stop transfers in progress. The following procedure can be used by the DCD to stop a transfer in progress:

1. Write a '1' to the corresponding bit(s) in .
2. Wait until all bits in are '0'.

- Software note: this operation may take a large amount of time depending on the USB bus activity. It is not desirable to have this wait loop within an interrupt service routine.

3. Read to ensure that for all endpoints commanded to be flushed, that the corresponding bits are now '0'. If the corresponding bits are '1' after step #2 has finished, then the flush failed as described in the following:
   - Explanation: In very rare cases, a packet is in progress to the particular endpoint when commanded flush using . A safeguard is in place to refuse the flush to ensure that the packet in progress completes successfully. The DCD may need to repeatedly flush any endpoints that fail to flush be repeating steps 1-3 until each endpoint is successfully flushed.

54.5.6.6.6 Device Error Matrix

The following table summarizes packet errors that are not automatically handled by the Device Controller.

Table 54-74. Device Error Matrix

Error	Direction	Packet Type	Data Buffer Error Bit	Transaction Error Bit
Overflow **	RX	Any	1	0
ISO Packet Error	RX	ISO	0	1
ISO Fulfillment Error	Both	ISO	0	1

Notice that the device controller handles all errors on Bulk/Control/Interrupt Endpoints except for a data buffer overflow. However, for ISO endpoints, errors packets are not retried and errors are tagged as indicated. The table below describes the errors.

Table 54-75. Error Descriptions

Error	Description
Overflow	Number of bytes received exceeded max. packet size or total buffer length. ** This error will also set the Halt bit in the dQH and if there are dTDs remaining in the linked list for the endpoint, then those will not be executed.
ISO Packet Error	CRC Error on received ISO packet. Contents not guaranteed to be correct.
ISO Fulfillment Error	Host failed to complete the number of packets defined in the dQH mult field within the given (micro)frame. For scheduled data delivery the DCD may need to readjust the data queue because a fulfillment error will cause Device Controller to cease data transfers on the pipe for one (micro)frame. During the "dead" (micro)frame, the Device Controller reports error on the pipe and primes for the following frame.

54.5.6.7 Servicing Interrupts

The interrupt service routine must consider that there are high-frequency, low-frequency operations, and error operations and order accordingly.

54.5.6.7.1 High-Frequency Interrupts

High frequency interrupts in particular should be handled in the order below. The most important of these is listed first because the DCD must acknowledge a setup buffer in the timeliest manner possible.

The table below describes the High frequency interrupt events.

Table 54-76. High Frequency Interrupt Events

Execution Order	Interrupt	Action
1a	USB Interrupt - USB.ENDPTSETUPSTATUS	Copy contents of setup buffer and acknowledge setup packet (as indicated in Figure 54-29 shows the End Point Queue Head). Process setup packet according to USB 2.0 Chapter 9 or application specific protocol.
1b	USB Interrupt[1] - USB.ENDPTCOMPLETE	Handle completion of dTD as indicated in Figure 54-29 shows the End Point Queue Head.
2	SOF Interrupt	Action as deemed necessary by application. This interrupt may not have a use in all applications.

1. It is likely that multiple interrupts to stack up on any call to the Interrupt Service Routine AND during the Interrupt Service Routine.

54.5.6.7.2 Low-Frequency Interrupts

The low frequency interrupts can be handled in any order because they do not occur often in comparison to the high-frequency interrupts.

The table below shows the Low frequency interrupt events.

Table 54-77. Low Frequency Interrupt Events

Interrupt	Action
Port Change	Change software state information.
Sleep Enable (Suspend)	Change software state information. Low power handling as necessary.
Reset Received	Change software state information. Abort pending transfers.

54.5.6.7.3 Error Interrupts

Error interrupts will be least frequent and should be placed last in the interrupt service routine.

The following table shows the error interrput events.

Table 54-78. Error Interrupt Events

Interrupt	Action
USB Error Interrupt	This error is redundant because it combines USB Interrupt and an error status in the dTD. The DCD will more aptly handle packet-level errors by checking dTD status field upon receipt of USB Interrupt (w/ USB.ENDPTCOMPLETE).
System Error	Unrecoverable error. Immediate Reset of core; free transfers buffers in progress and restart the DCD.

54.6 USB Non-Core Memory Map/Register Definition

There are two kinds of registers in the USB module: USB core registers and USB non-core registers.

USB core registers are used to control USB core functions, and more independent of USB features. Each USB controller core has its own core registers.

USB non-core registera are additional to USB core registers, and more dependent on USB features. i.MX series products vary in non-core registers.

This section describes only the USB non-core registers. For detailed descriptions of USB core registers, please refer to Register Interface .

NOTE

- For reserved bits, please preserve the value when writing (read its reset value, then write this value back)
- "USB_UOG1_", "USB_UOG2_" prefix in register name indicates it is a core register for OTG1/OTG2 controller core respectively.
- USBNC_USB_" prefix in register name indicates it is a USB non-core register.

USBNC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4033_0200	USB OTG Control 1 Register (USBNC_OTG1_CTRL1)	32	R/W	3000_1000h	54.6.1/2461

USBNC_*n*_CTRL1 field descriptions

Field	Description
31 WIR	Wake-up Interrupt Request This bit indicates that a wake-up interrupt request is received on the OTG1 port. This bit is cleared by disabling the wake-up interrupt (clearing bit "OWIE"). 1 Wake-up Interrupt Request received 0 No wake-up interrupt request received
30 Reserved	This field is reserved.
29 WKUP_DPDM_EN	Wake-up on DPDM change enable 1 (Default) DPDM changes wake-up to be enabled, it is for device only. 0 DPDM changes wake-up to be disabled only when VBUS is 0.
28–21 Reserved	This field is reserved.
20 ULPI_PHY_CLK_EN	ULPI PHY clock enable This bit is for ULPI interface only. 1 Enable 0 Disable
19–18 -	This field is reserved. Reserved
17 WKUP_VBUS_EN	Wake-up on VBUS change enable 1 Enable 0 Disable
16 WKUP_ID_EN	Wake-up on ID change enable 1 Enable 0 Disable
15 WKUP_SW	Software Wake-up 1 Force wake-up 0 Inactive
14 WKUP_SW_EN	Software Wake-up Enable 1 Enable 0 Disable
13–11 -	This field is reserved. Reserved
10 WIE	Wake-up Interrupt Enable This bit enables or disables the OTG1 wake-up interrupt. Disabling the interrupt also clears the Interrupt request bit. Wake-up interrupt enable should be turned off after receiving a wake-up interrupt and turned on again prior to going in suspend mode 1 Interrupt Enabled 0 Interrupt Disabled
9 PWR_POL	Power Polarity

Table continues on the next page...

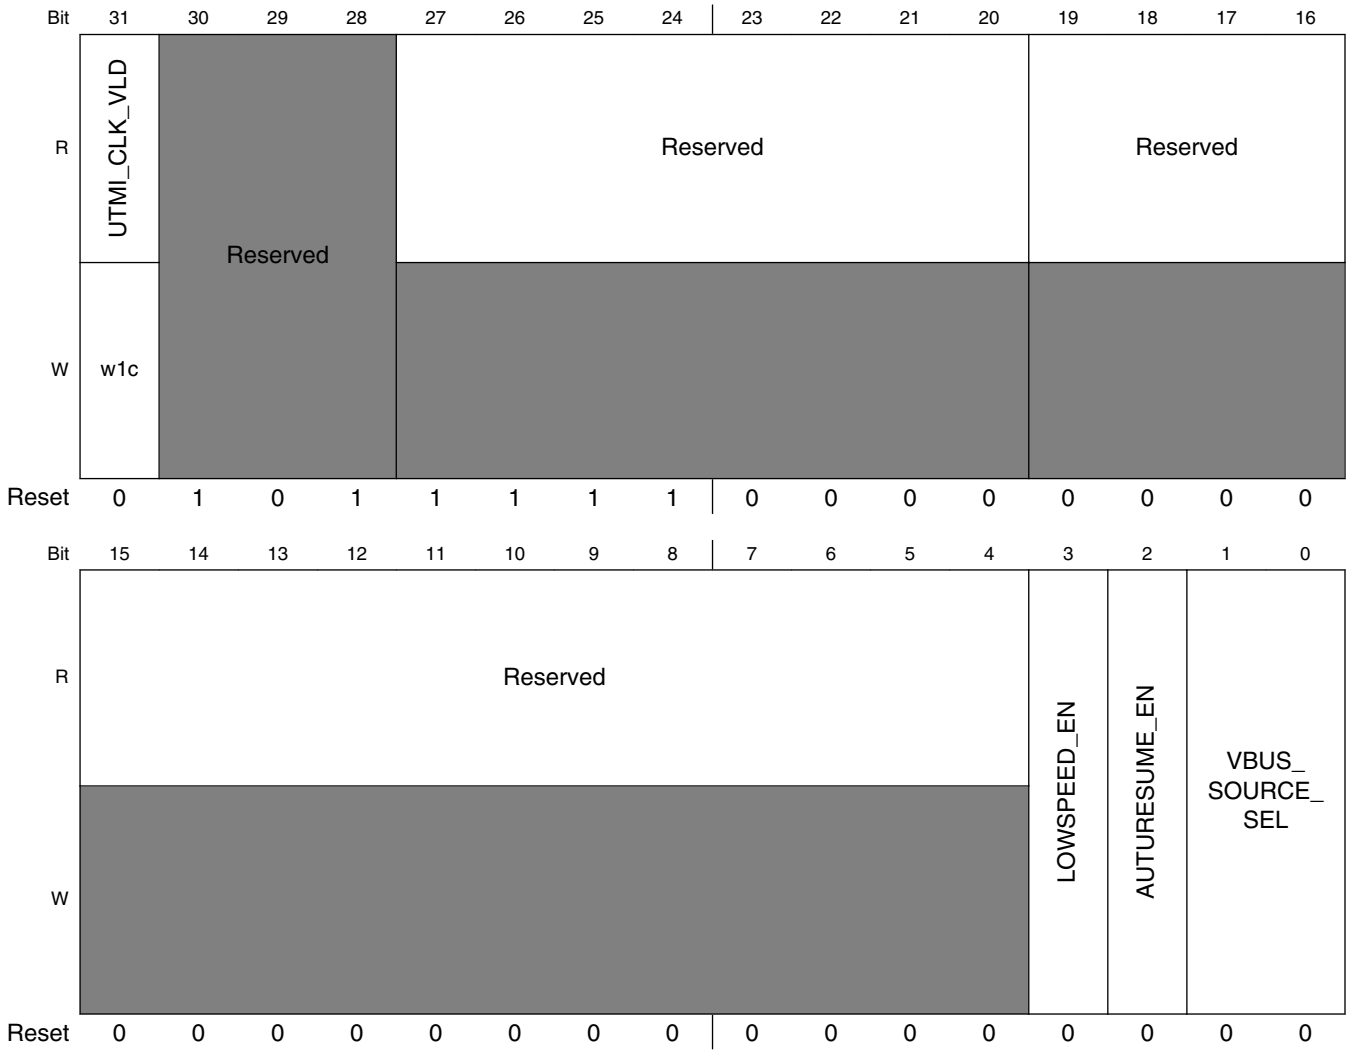
USBNC_*n*_CTRL1 field descriptions (continued)

Field	Description
	This bit should be set according to PMIC Power Pin polarity. 1 PMIC Power Pin is High active. 0 PMIC Power Pin is Low active.
8 OVER_CUR_POL	Polarity of Overcurrent The polarity of OTG1/OTG2 port overcurrent event 1 Low active (low on this signal represents an overcurrent condition) 0 High active (high on this signal represents an overcurrent condition)
7 OVER_CUR_DIS	Disable Overcurrent Detection 1 Disables overcurrent detection 0 Enables overcurrent detection
-	This field is reserved. Reserved

54.6.2 USB OTG Control 2 Register (USBNC_*n*_CTRL2)

The USB Control 2 register controls the integration specific features of the USB module. These features are not directly related to the USB functionality, but control special features, interfacing on the USB ports, as well as power control and wakeup functionality.

Address: 4033_0000h base + 204h offset + (65536d × i), where i=0d to 1d



USBNC_*n*_CTRL2 field descriptions

Field	Description
31 UTMI_CLK_VLD	Indicate whether the UTMI clock to the USB PHY is valid. Write 1 to clear 0 Default

Table continues on the next page...

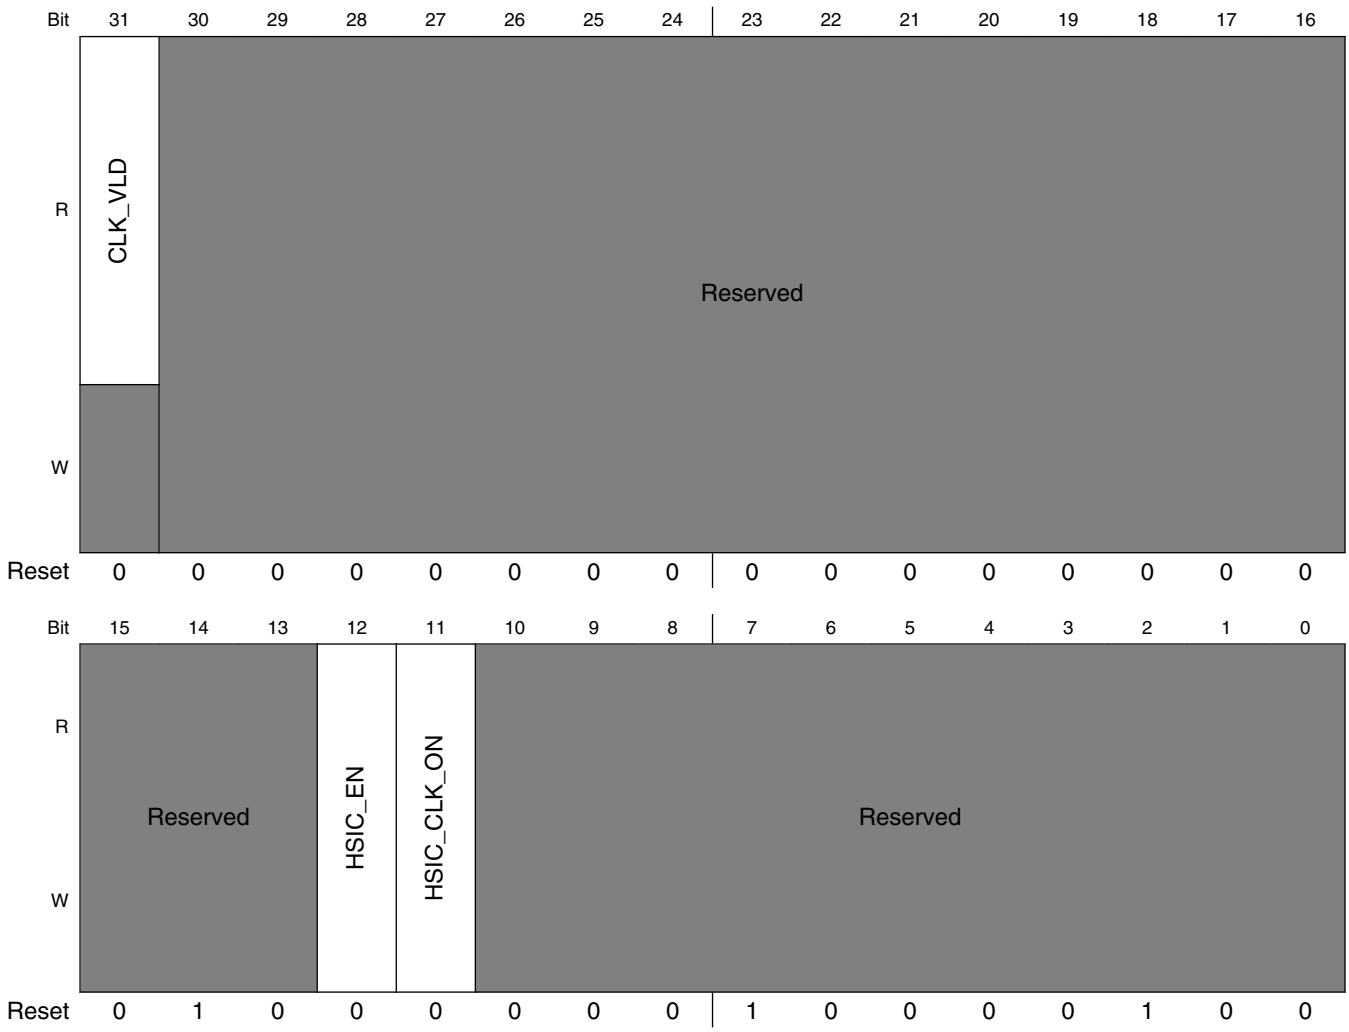
USBNC_*n*_CTRL2 field descriptions (continued)

Field	Description
30–28 Reserved	This field is reserved.
27–20 Reserved	This field is reserved. 0B00011110 Default
19–4 Reserved	This field is reserved.
3 LOWSPEED_EN	Set if AUTURESUME_EN is set and works on low speed. 0 Default
2 AUTURESUME_EN	Auto Resume Enable It is for UTMI PHY host mode only (UH core has no this feature since HSIC PHY does not support auto resume). To set USB, it will send resume with 32 KHz clock when it detects remote wakeup from device. This feature is useful if device drive a very short remote wakeup (minimul value is 1 ms for USB2 spec) and system 24 MHz is off during suspend mode. 0 Default
VBUS_ SOURCE_SEL	VBUS source select when detect VBUS wakeup event, it is for UTMI PHY only (UH core has no such feature). 2'b00 vbus_valid others sess_valid

54.6.3 USB Host HSIC Control Register (USBNC_*n*_HSIC_CTRL)

The USB Host HSIC control register controls Host high speed IC configuration. These features are not directly related to the USB functionality, but control special features, interfacing on the USB ports, as well as power control.

Address: 4033_0000h base + 1_0210h offset + (65536d × i), where i=0d to 0d



USBNC_*n*_HSIC_CTRL field descriptions

Field	Description
31 CLK_VLD	Indicating whether Host HSIC clock is valid. 1 Valid 2 Invalid

Table continues on the next page...

USBNC_*n*_HSIC_CTRL field descriptions (continued)

Field	Description
30–13 -	This field is reserved. Reserved
12 HSIC_EN	Host HSIC enable 1 Enabled 0 Disabled
11 HSIC_CLK_ON	Force Host HSIC module 480M clock on, even when in Host is in suspend mode. 1 Active 0 Inactive
-	This field is reserved. Reserved

USB_*n*HWTXBUF field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
23–16 TXCHANADD	TX FIFO Buffer size is: (2^TXCHANADD) * 4 Bytes. These bits are set to '08h', so buffer size is 256*4 Bytes. For the OTG controller operating in device mode, this is the FIFO buffer size per endpoint. As the OTG controller has 8 TX endpoint, there are 8 of these buffers. For the OTG controller operating in host mode, or for Host-only controller, the entire buffer memory is used as a single TX buffer. Therefore, there is only 1 of this buffer
15–8 -	This field is reserved. Reserved
TXBURST	Default burst size for memory to TX buffer transfer. This is reset value of TXPBURST bits in USB core regsiter USB_n_BURSTSIZE. Please see Programmable Burst Size (USB_*n*BURSTSIZE) .

54.7.6 RX Buffer Hardware Parameters (USB_*n*HWRXBUF)

Address: 4033_0000h base + 14h offset + (65536d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																RXADD								RXBURST							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1	0	0	0

USB_*n*HWRXBUF field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
15–8 RXADD	Buffer total size for all receive endpoints is (2^RXADD). RX Buffer size is: (2^RXADD) * 4 Bytes. These bits are set to '08h', so buffer size is 256*4 Bytes. There is a single Receive FIFO buffer in the USB controller. The buffer is shared for all endpoints for the OTG controller in device mode.
RXBURST	Default burst size for memory to RX buffer transfer. This is reset value of RXPBURST bits in USB core regsiter USB_n_BURSTSIZE. Please see Programmable Burst Size (USB_*n*BURSTSIZE) .

54.7.7 General Purpose Timer #0 Load (USB_*n*GPTIMER0LD)

This register controls load value of the count timer in register n_GPTIMER0CTRL. Please see General Purpose Timer #0 Controller (USB_*n*GPTIMER0CTRL) .

Address: 4033_0000h base + 80h offset + (65536d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

USB_*n*GPTIMER0LD field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
GPTLD	General Purpose Timer Load Value These bit fields are loaded to GPTCNT bits when GPTRST bit is set '1b'. This value represents the time in microseconds minus 1 for the timer duration.

Table continues on the next page...

USB_*n*GPTIMER0LD field descriptions (continued)

Field	Description
	Example: for a one millisecond timer, load 1000-1=999 or 0x0003E7. **NOTE:** Max value is 0xFFFFFF or 16.777215 seconds.

54.7.8 General Purpose Timer #0 Controller (USB_*n*GPTIMER0CTRL)

This register contains the control for this countdown timer and a data field can be queried to determine the running count value. This timer has granularity on 1 us and can be programmed to a little over 16 seconds. There are two counter modes which are described in the register table below. When the timer counter value transitions to zero, an interrupt could be generated if enable.

Interrupt status bit is TI0 bit in n_USBSTS register (See USB Status Register (USB_*n*USBSTS)), interrupt enable bit is TIE0 bit in n_USBINTR register. (See Interrupt Enable Register (USB_*n*USBINTR) .)

Address: 4033_0000h base + 84h offset + (65536d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

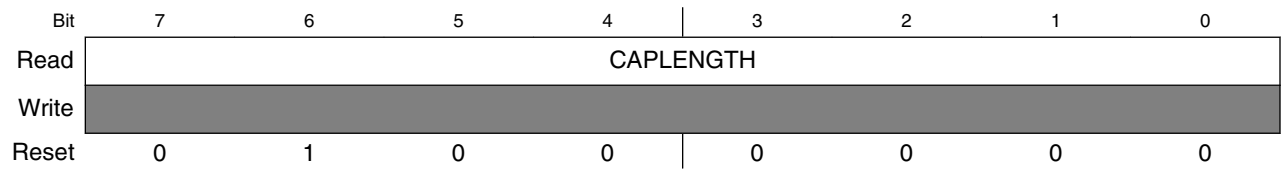
USB_*n*SBUSCFG field descriptions

Field	Description
31–3 -	This field is reserved. Reserved
AHBBRST	AHB master interface Burst configuration These bits control AHB master transfer type sequence (or priority). **NOTE:** This register overrides n_BURSTSIZE register when its value is not zero. 000 Incremental burst of unspecified length only 001 INCR4 burst, then single transfer 010 INCR8 burst, INCR4 burst, then single transfer 011 INCR16 burst, INCR8 burst, INCR4 burst, then single transfer 100 Reserved, don't use 101 INCR4 burst, then incremental burst of unspecified length 110 INCR8 burst, INCR4 burst, then incremental burst of unspecified length 111 INCR16 burst, INCR8 burst, INCR4 burst, then incremental burst of unspecified length

54.7.12 Capability Registers Length (USB_*n*CAPLENGTH)

The Capability Registers Length register contains the address offset to the Operational registers relative to the CAPLENGTH register.

Address: 4033_0000h base + 100h offset + (65536d × i), where i=0d to 1d



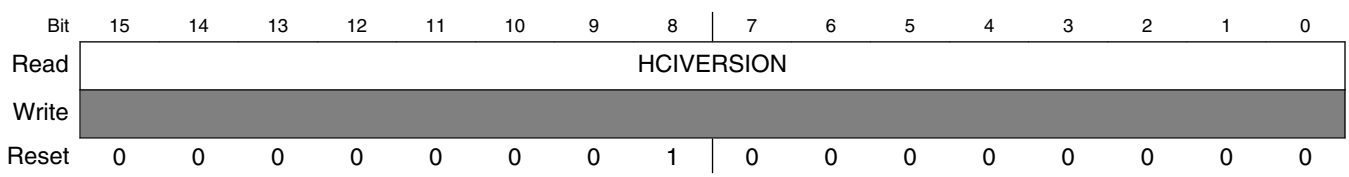
USB_*n*CAPLENGTH field descriptions

Field	Description
CAPLENGTH	These bits are used as an offset to add to register base to find the beginning of the Operational Register. Default value is '40h'.

54.7.13 Host Controller Interface Version (USB_*n*HCIVERSION)

This is a 2-byte register containing a BCD encoding of the EHCI revision number supported by this host controller. The most significant byte of this register represents a major revision and the least significant byte is the minor revision.

Address: 4033_0000h base + 102h offset + (65536d × i), where i=0d to 1d



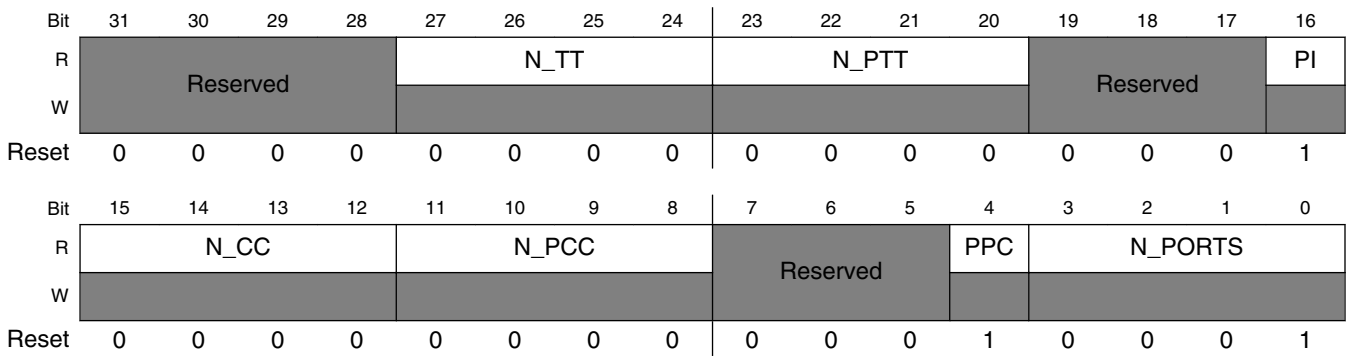
USB_*n*HCIVERSION field descriptions

Field	Description
HCIVERSION	Host Controller Interface Version Number Default value is '10h', which means EHCI rev1.0.

54.7.14 Host Controller Structural Parameters (USB_*n*HCSPARAMS)

The following figure shows the port steering logic capabilities of Host Control Structural Parameters (n_HCSPARAMS).

Address: 4033_0000h base + 104h offset + (65536d × i), where i=0d to 1d



USB_*n*HCSPARAMS field descriptions

Field	Description
31–28 -	This field is reserved. Reserved
27–24 N_TT	Number of Transaction Translators (N_TT). Default value '0000b' This field indicates the number of embedded transaction translators associated with the USB2.0 host controller. These bits would be set to '0001b' for Multi-Port Host, and '0000b' for Single-Port Host.
23–20 N_PTT	Number of Ports per Transaction Translator (N_PTT). Default value '0000b' This field indicates the number of ports assigned to each transaction translator within the USB2.0 host controller. These bits would be set to equal N_PORTS for Multi-Port Host, and '0000b' for Single-Port Host.
19–17 -	This field is reserved. Reserved
16 PI	Port Indicators (P INDICATOR) This bit indicates whether the ports support port indicator control. When set to one, the port status and control registers include a read/writeable field for controlling the state of the port indicator This bit is "1b" in all controller core.
15–12 N_CC	Number of Companion Controller (N_CC). This field indicates the number of companion controllers associated with this USB2.0 host controller. These bits are '0000b' in all controller core. 0 There is no internal Companion Controller and port-ownership hand-off is not supported. 1 There are internal companion controller(s) and port-ownership hand-offs is supported.
11–8 N_PCC	Number of Ports per Companion Controller

Table continues on the next page...

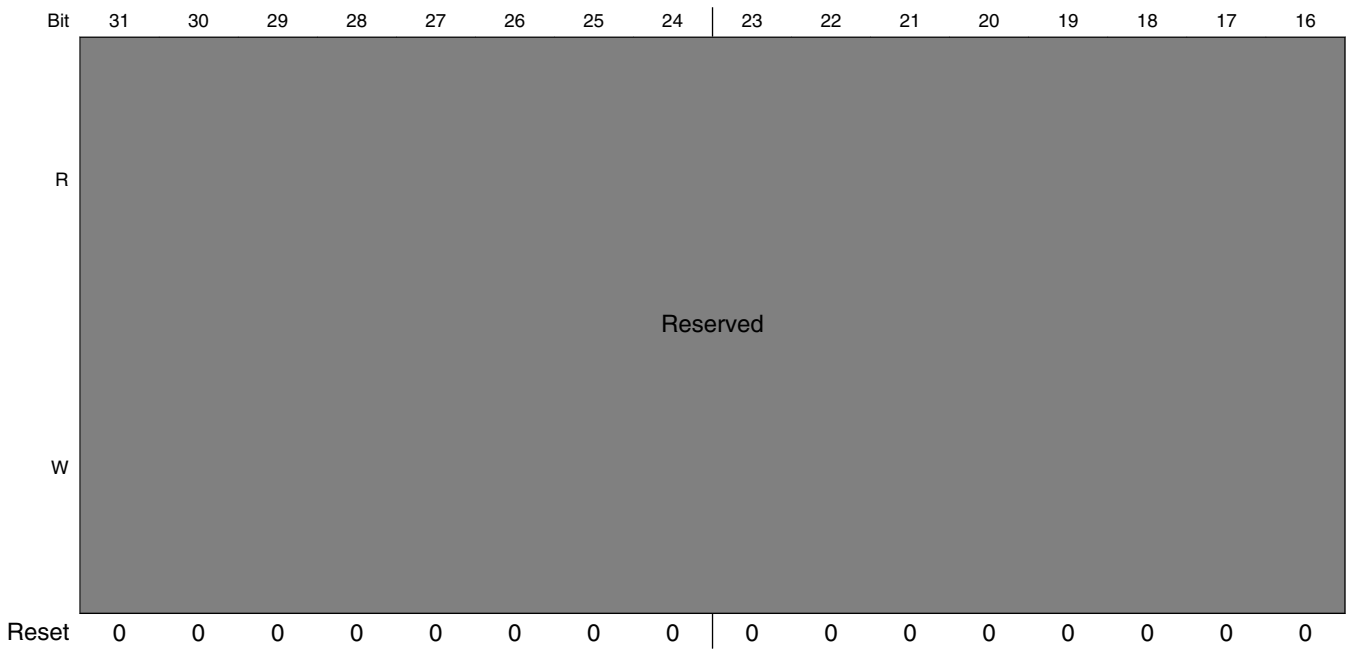
USB_*n*HCSPARAMS field descriptions (continued)

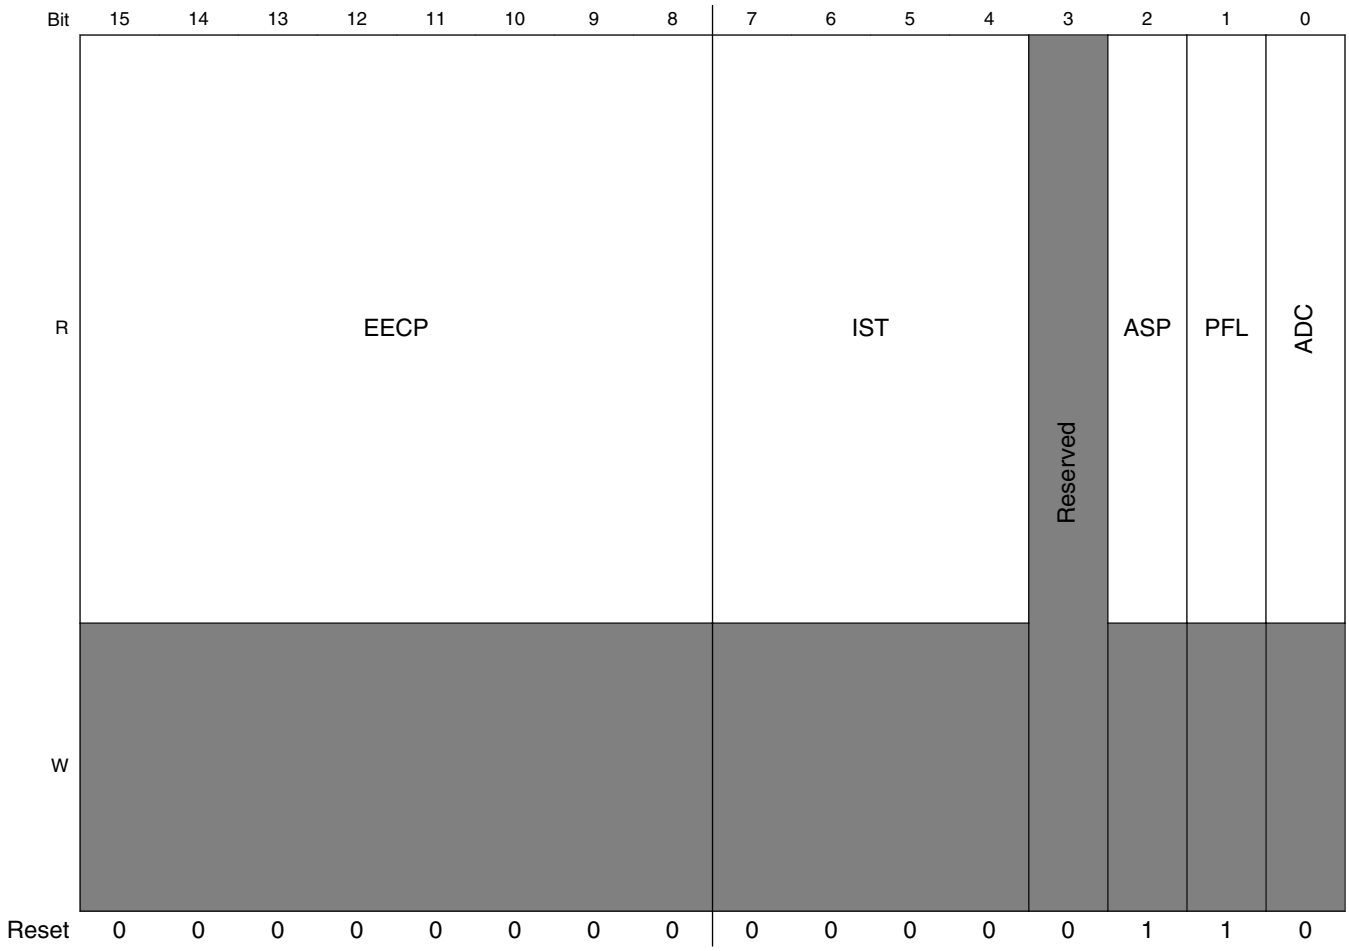
Field	Description
	This field indicates the number of ports supported per internal Companion Controller. It is used to indicate the port routing configuration to the system software. For example, if N_PORTS has a value of 6 and N_CC has a value of 2 then N_PCC could have a value of 3. The convention is that the first N_PCC ports are assumed to be routed to companion controller 1, the next N_PCC ports to companion controller 2, etc. In the previous example, the N_PCC could have been 4, where the first 4 are routed to companion controller 1 and the last two are routed to companion controller 2. The number in this field must be consistent with N_PORTS and N_CC. These bits are '0000b' in all controller core.
7–5 -	This field is reserved. Reserved
4 PPC	Port Power Control This field indicates whether the host controller implementation includes port power control. A one indicates the ports have port power switches. A zero indicates the ports do not have port power switches. The value of this field affects the functionality of the Port Power field in each port status and control register
N_PORTS	Number of downstream ports. This field specifies the number of physical downstream ports implemented on this host controller. The value of this field determines how many port registers are addressable in the Operational Register. Valid values are in the range of 1h to Fh. A zero in this field is undefined. These bits are always set to '0001b' because all controller cores are Single-Port Host.

54.7.15 Host Controller Capability Parameters (USB_*n*HCCPARAMS)

This register identifies multiple mode control (time-base bit functionality), addressing capability.

Address: 4033_0000h base + 108h offset + (65536d × i), where i=0d to 1d





USB_*n*HCCPARAMS field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
15–8 EECP	EHCI Extended Capabilities Pointer. This field indicates the existence of a capabilities list. A value of 00h indicates no extended capabilities are implemented. A non-zero value in this register indicates the offset in PCI configuration space of the first EHCI extended capability. The pointer value must be 40h or greater if implemented to maintain the consistency of the PCI header defined for this class of device. **NOTE:** These bits are set '00h' in all controller core.
7–4 IST	Isochronous Scheduling Threshold. This field indicates, relative to the current position of the executing host controller, where software can reliably update the isochronous schedule. When bit [7] is zero, the value of the least significant 3 bits indicates the number of micro-frames a host controller can hold a set of isochronous data structures (one or more) before flushing the state. When bit [7] is a one, then host software assumes the host controller may cache an isochronous data structure for an entire frame. These bits are set '00h' in all controller core.
3 -	This field is reserved. Reserved

Table continues on the next page...

USB_*n*HCCPARAMS field descriptions (continued)

Field	Description
2 ASP	Asynchronous Schedule Park Capability If this bit is set to a one, then the host controller supports the park feature for high-speed queue heads in the Asynchronous Schedule. The feature can be disabled or enabled and set to a specific level by using the *Asynchronous Schedule Park Mode Enable* and *Asynchronous Schedule Park Mode Count* fields in the USBCMD register. **NOTE:** ASP bit reset value: '00b' for OTG controller core, '11b' for Host-only controller core.
1 PFL	Programmable Frame List Flag If this bit is set to zero, then the system software must use a frame list length of 1024 elements with this host controller. The USBCMD register Frame List Size field is a read-only register and must be set to zero. If set to a one, then the system software can specify and use a smaller frame list and configure the host controller via the USBCMD register Frame List Size field. The frame list must always be aligned on a 4K-page boundary. This requirement ensures that the frame list is always physically contiguous. This bit is set '1b' in all controller core.
0 ADC	64-bit Addressing Capability This bit is set '0b' in all controller core, no 64-bit addressing capability is supported.

54.7.16 Device Controller Interface Version (USB_*n*DCIVERSION)

This register indicates the two-byte BCD encoding of the device controller interface version number.

Address: 4033_0000h base + 120h offset + (65536d × i), where i=0d to 1d

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	DCIVERSION															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

USB_*n*DCIVERSION field descriptions

Field	Description
DCIVERSION	Device Controller Interface Version Number Default value is '01h', which means rev0.1.

54.7.17 Device Controller Capability Parameters (USB_*n*DCCPARAMS)

These fields describe the overall device capability of the controller.

NOTE

This register is only available in OTG controller core.

Address: 4033_0000h base + 124h offset + (65536d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

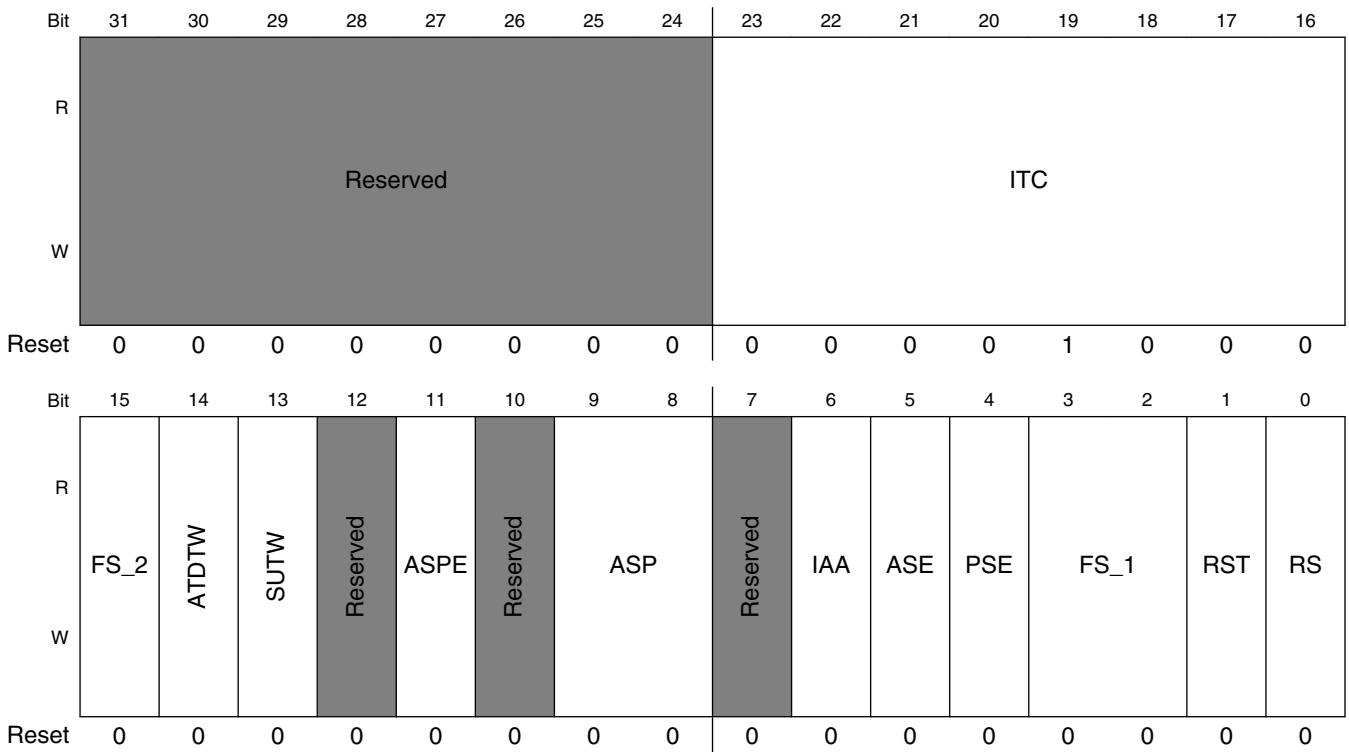
USB_*n*DCCPARAMS field descriptions

Field	Description
31–9 -	This field is reserved. Reserved
8 HC	Host Capable When this bit is 1, this controller is capable of operating as an EHCI compatible USB 2.0 host controller.
7 DC	Device Capable When this bit is 1, this controller is capable of operating as a USB 2.0 device.
6–5 -	This field is reserved. Reserved
DEN	Device Endpoint Number This field indicates the number of endpoints built into the device controller. If this controller is not device capable, then this field will be zero. Valid values are 0 - 15.

54.7.18 USB Command Register (USB_*n*USBCMD)

The Command Register indicates the command to be executed by the serial bus host/device controller. Writing to the register causes a command to be executed.

Address: 4033_0000h base + 140h offset + (65536d × i), where i=0d to 1d



USB_*n*USBCMD field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
23–16 ITC	Interrupt Threshold Control -Read/Write. The system software uses this field to set the maximum rate at which the host/device controller will issue interrupts. ITC contains the maximum interrupt interval measured in micro-frames. Valid values are shown below. Value Maximum Interrupt Interval 0x00 Immediate (no threshold) 0x01 1 micro-frame 0x02 2 micro-frames 0x04 4 micro-frames 0x08 8 micro-frames 0x10 16 micro-frames

Table continues on the next page...

USB_*n*USBCMD field descriptions (continued)

Field	Description
	0x20 32 micro-frames 0x40 64 micro-frames
15 FS_2	Frame List Size - (Read/Write or Read Only). [host mode only] This field is Read/Write only if Programmable Frame List Flag in the HCCPARAMS registers is set to one. This field specifies the size of the frame list that controls which bits in the Frame Index Register should be used for the Frame List Current index. **NOTE:** This field is made up from USBCMD bits 15, 3 and 2. Value Meaning 000 1024 elements (4096 bytes) Default value 001 512 elements (2048 bytes) 010 256 elements (1024 bytes) 011 128 elements (512 bytes) 100 64 elements (256 bytes) 101 32 elements (128 bytes) 110 16 elements (64 bytes) 111 8 elements (32 bytes)
14 ATDTW	Add dTD TripWire - Read/Write. [device mode only] This bit is used as a semaphore to ensure proper addition of a new dTD to an active (primed) endpoint's linked list. This bit is set and cleared by software. This bit would also be cleared by hardware when state machine is hazard region for which adding a dTD to a primed endpoint may go unrecognized.
13 SUTW	Setup TripWire - Read/Write. [device mode only] This bit is used as a semaphore to ensure that the setup data payload of 8 bytes is extracted from a QH by the DCD without being corrupted. If the setup lockout mode is off (SLOM bit in USB core register n_USBMODE, see USB Device Mode (USB_*n*USBMODE)) then there is a hazard when new setup data arrives while the DCD is copying the setup data payload from the QH for a previous setup packet. This bit is set and cleared by software. This bit would also be cleared by hardware when a hazard detected.
12 -	This field is reserved. Reserved
11 ASPE	Asynchronous Schedule Park Mode Enable - Read/Write. If the *Asynchronous Park Capability* bit in the HCCPARAMS register is a one, then this bit defaults to a 1h and is R/W. Otherwise the bit must be a zero and is RO. Software uses this bit to enable or disable Park mode. When this bit is one, Park mode is enabled. When this bit is a zero, Park mode is disabled. **NOTE:** ASPE bit reset value: '0b' for OTG controller core, '1b' for Host-only controller core.
10 -	This field is reserved. Reserved
9–8 ASP	Asynchronous Schedule Park Mode Count - Read/Write. If the *Asynchronous Park Capability* bit in the HCCPARAMS register is a one, then this field defaults to 3h and is R/W. Otherwise it defaults to zero and is Read-Only. It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the

Table continues on the next page...

USB_*n*USBCMD field descriptions (continued)

Field	Description
	Asynchronous schedule before continuing traversal of the Asynchronous schedule. Valid values are 1h to 3h. Software must not write a zero to this bit when *Park Mode Enable* is a one as this will result in undefined behavior. This field is set to 3h in all controller core.
7 -	This field is reserved. Reserved
6 IAA	Interrupt on Async Advance Doorbell - Read/Write. This bit is used as a doorbell by software to tell the host controller to issue an interrupt the next time it advances asynchronous schedule. Software must write a 1 to this bit to ring the doorbell. When the host controller has evicted all appropriate cached schedule states, it sets the Interrupt on Async Advance status bit in the USBSTS register. If the Interrupt on Sync Advance Enable bit in the USBINTR register is one, then the host controller will assert an interrupt at the next interrupt threshold. The host controller sets this bit to zero after it has set the Interrupt on Sync Advance status bit in the USBSTS register to one. Software should not write a one to this bit when the asynchronous schedule is inactive. Doing so will yield undefined results. This bit is only used in host mode. Writing a one to this bit when device mode is selected will have undefined results.
5 ASE	Asynchronous Schedule Enable - Read/Write. Default 0b. This bit controls whether the host controller skips processing the Asynchronous Schedule. Only the host controller uses this bit. Values Meaning 0 Do not process the Asynchronous Schedule. 1 Use the ASYNCLISTADDR register to access the Asynchronous Schedule.
4 PSE	Periodic Schedule Enable- Read/Write. Default 0b. This bit controls whether the host controller skips processing the Periodic Schedule. Only the host controller uses this bit. Values Meaning 0 Do not process the Periodic Schedule 1 Use the PERIODICLISTBASE register to access the Periodic Schedule.
3–2 FS_1	See description at bit 15
1 RST	Controller Reset (RESET) - Read/Write. Software uses this bit to reset the controller. This bit is set to zero by the Host/Device Controller when the reset process is complete. Software cannot terminate the reset process early by writing a zero to this register. Host operation mode: When software writes a one to this bit, the Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. Software should not set this bit to a one when the HCHalted bit in the USBSTS register is a zero. Attempting to reset an actively running host controller will result in undefined behavior. Device operation mode:

Table continues on the next page...

USB_*n*USBCMD field descriptions (continued)

Field	Description
	When software writes a one to this bit, the Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Writing a one to this bit when the device is in the attached state is not recommended, because the effect on an attached host is undefined. In order to ensure that the device is not in an attached state before initiating a device controller reset, all primed endpoints should be flushed and the USBCMD Run/Stop bit should be set to 0.
0 RS	Run/Stop (RS) - Read/Write. Default 0b. 1=Run. 0=Stop. Host operation mode: When set to '1b', the Controller proceeds with the execution of the schedule. The Controller continues execution as long as this bit is set to a one. When this bit is set to 0, the Host Controller completes the current transaction on the USB and then halts. The HC Halted bit in the status register indicates when the Controller has finished the transaction and has entered the stopped state. Software should not write a one to this field unless the controller is in the Halted state (that is, HCHalted in the USBSTS register is a one). Device operation mode: Writing a one to this bit will cause the controller to enable a pull-up on D+ and initiate an attach event. This control bit is not directly connected to the pull-up enable, as the pull-up will become disabled upon transitioning into high-speed mode. Software should use this bit to prevent an attach event before the controller has been properly initialized. Writing a 0 to this will cause a detach event.

54.7.19 USB Status Register (USB_*n*USBSTS)

This register indicates various states of the Host/Device Controller and any pending interrupts. This register does not indicate status resulting from a transaction on the serial bus.

Address: 4033_0000h base + 144h offset + (65536d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved						TI1	TI0	Reserved				UPI	UAI	Reserved	NAKI

Field	Description
31–26 -	This field is reserved. Reserved
25 TI1	General Purpose Timer Interrupt 1(GPTINT1)--R/WC. This bit is set when the counter in the GPTIMER1CTRL register transitions to zero, writing a one to this bit will clear it.
24 TI0	General Purpose Timer Interrupt 0(GPTINT0)--R/WC. This bit is set when the counter in the GPTIMER0CTRL register transitions to zero, writing a one to this bit clears it.
23–20 -	This field is reserved. Reserved
19 UPI	USB Host Periodic Interrupt (USBHSTPERINT) This bit is set by the Host Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set and the TD was from the periodic schedule. This bit is also set by the Host Controller when a short packet is detected AND the packet is on the periodic schedule. A short packet is when the actual number of bytes received was less than the expected number of bytes. This bit is not used by the device controller and will always be 0.
18 UAI	USB Host Asynchronous Interrupt (USBHSTASYNCINT) This bit is set by the Host Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set and the TD was from the asynchronous schedule. This bit is also set by the Host Controller when a short packet is detected AND the packet is on the asynchronous schedule. A short packet is when the actual number of bytes received was less than the expected number of bytes. This bit is not used by the device controller and will always be 0.
17 -	This field is reserved. Reserved

Table continues on the next page...

USB_*n*USBSTS field descriptions (continued)

Field	Description
16 NAKI	NAK Interrupt Bit--RO. This bit is set by hardware when for a particular endpoint both the TX/RX Endpoint NAK bit and corresponding TX/RX Endpoint NAK Enable bit are set. This bit is automatically cleared by hardware when all Enabled TX/RX Endpoint NAK bits are cleared.
15 AS	Asynchronous Schedule Status - Read Only. This bit reports the current real status of the Asynchronous Schedule. When set to zero the asynchronous schedule status is disabled and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Asynchronous Schedule when software transitions the Asynchronous Schedule Enable bit in the USBCMD register. When this bit and the Asynchronous Schedule Enable bit are the same value, the Asynchronous Schedule is either enabled (1) or disabled (0). Only used in the host operation mode.
14 PS	Periodic Schedule Status - Read Only. This bit reports the current real status of the Periodic Schedule. When set to zero the periodic schedule is disabled, and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Periodic Schedule when software transitions the Periodic Schedule Enable bit in the USBCMD register. When this bit and the Periodic Schedule Enable bit are the same value, the Periodic Schedule is either enabled (1) or disabled (0). Only used in the host operation mode.
13 RCL	Reclamation - Read Only. This is a read-only status bit used to detect an empty asynchronous schedule. Only used in the host operation mode.
12 HCH	HCHalted - Read Only. This bit is a zero whenever the Run/Stop bit is a one. The Controller sets this bit to one after it has stopped executing because of the Run/Stop bit being set to 0, either by software or by the Controller hardware (for example, an internal error). Only used in the host operation mode. Default value is '0b' for OTG core, and '1b' for Host1/Host2/Host3 core. This is because OTG core is not operating as host in default. Please see CM bit in USB_n_USBMODE register. **NOTE:** HCH bit reset value: '0b' for OTG controller core, '1b' for Host-only controller core.
11 -	This field is reserved. Reserved
10 ULPII	ULPI Interrupt - R/WC. This bit will be set '1b' by hardware when there is an event completion in ULPI viewport. This bit is usable only if the controller support UPLI interface mode.
9 -	This field is reserved. Reserved
8 SLI	DCSuspend - R/WC. When a controller enters a suspend state from an active state, this bit will be set to a one. The device controller clears the bit upon exiting from a suspend state. Only used in device operation mode.
7 SRI	SOF Received - R/WC.

Table continues on the next page...

USB_*n*USBSTS field descriptions (continued)

Field	Description
	When the device controller detects a Start Of (micro) Frame, this bit will be set to a one. When a SOF is extremely late, the device controller will automatically set this bit to indicate that an SOF was expected. Therefore, this bit will be set roughly every 1ms in device FS mode and every 125ms in HS mode and will be synchronized to the actual SOF that is received. Because the device controller is initialized to FS before connect, this bit will be set at an interval of 1ms during the prelude to connect and chirp. In host mode, this bit will be set every 125us and can be used by host controller driver as a time base. Software writes a 1 to this bit to clear it.
6 URI	USB Reset Received - R/WC. When the device controller detects a USB Reset and enters the default state, this bit will be set to a one. Software can write a 1 to this bit to clear the USB Reset Received status bit. Only used in device operation mode.
5 AAI	Interrupt on Async Advance - R/WC. System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a one to the Interrupt on Async Advance Doorbell bit in the n_USBCMD register. This status bit indicates the assertion of that interrupt source. Only used in host operation mode.
4 SEI	System Error- R/WC. This bit is will be set to '1b' when an Error response is seen to a read on the system interface.
3 FRI	Frame List Rollover - R/WC. The Host Controller sets this bit to a one when the Frame List Index rolls over from its maximum value to zero. The exact value at which the rollover occurs depends on the frame list size. For example. If the frame list size (as programmed in the Frame List Size field of the USB_n_USBCMD register) is 1024, the Frame Index Register rolls over every time FRINDEX [13] toggles. Similarly, if the size is 512, the Host Controller sets this bit to a one every time FHINDEX [12] toggles. Only used in host operation mode.
2 PCI	Port Change Detect - R/WC. The Host Controller sets this bit to a one when on any port a Connect Status occurs, a Port Enable/ Disable Change occurs, or the Force Port Resume bit is set as the result of a J-K transition on the suspended port. The Device Controller sets this bit to a one when the port controller enters the full or high-speed operational state. When the port controller exits the full or high-speed operation states due to Reset or Suspend events, the notification mechanisms are the USB Reset Received bit and the DCSuspend bits respectively.
1 UEI	USB Error Interrupt (USBERRINT) - R/WC. When completion of a USB transaction results in an error condition, this bit is set by the Host/Device Controller. This bit is set along with the USBINT bit, if the TD on which the error interrupt occurred also had its interrupt on complete (IOC) bit set. The device controller detects resume signaling only.
0 UI	USB Interrupt (USBINT) - R/WC. This bit is set by the Host/Device Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set. This bit is also set by the Host/Device Controller when a short packet is detected. A short packet is when the actual number of bytes received was less than the expected number of bytes.

54.7.20 Interrupt Enable Register (USB_*n*USBINTR)

The interrupts to software are enabled with this register. An interrupt is generated when a bit is set and the corresponding interrupt source is active. The USB Status register (n_USBSTS) still shows interrupt sources even if they are disabled by the n_USBINTR register, allowing polling of interrupt events by the software.

Address: 4033_0000h base + 148h offset + (65536d × i), where i=0d to 1d

19 UPIE	USB Host Periodic Interrupt Enable

Table continues on the next page...

USB_*n*USBINTR field descriptions (continued)

Field	Description
	When this bit is one, and the UPI bit in the n_USBSTS register is one, host controller will issue an interrupt at the next interrupt threshold.
18 UAIE	USB Host Asynchronous Interrupt Enable When this bit is one, and the UAI bit in the n_USBSTS register is one, host controller will issue an interrupt at the next interrupt threshold.
17 -	This field is reserved. Reserved
16 NAKE	NAK Interrupt Enable When this bit is one and the NAKI bit in n_USBSTS register is a one the controller will issue an interrupt.
15–11 -	These bits are reserved and should be set to zero.
10 ULPIE	ULPI Interrupt Enable When this bit is one and the UPLII bit in n_USBSTS register is a one the controller will issue an interrupt. This bit is usable only if the controller support UPLI interface mode.
9 -	This field is reserved. Reserved
8 SLE	Sleep Interrupt Enable When this bit is one and the SLI bit in n_n_USBSTS register is a one the controller will issue an interrupt. Only used in device operation mode.
7 SRE	SOF Received Interrupt Enable When this bit is one and the SRI bit in n_USBSTS register is a one the controller will issue an interrupt.
6 URE	USB Reset Interrupt Enable When this bit is one and the URI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in device operation mode.
5 AAE	Async Advance Interrupt Enable When this bit is one and the AAI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.
4 SEE	System Error Interrupt Enable When this bit is one and the SEI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.
3 FRE	Frame List Rollover Interrupt Enable When this bit is one and the FRI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.
2 PCE	Port Change Detect Interrupt Enable When this bit is one and the PCI bit in n_USBSTS register is a one the controller will issue an interrupt.
1 UEE	USB Error Interrupt Enable When this bit is one and the UEI bit in n_USBSTS register is a one the controller will issue an interrupt.
0 UE	USB Interrupt Enable When this bit is one and the UI bit in n_USBSTS register is a one the controller will issue an interrupt.

54.7.21 USB Frame Index (USB_*n*FRINDEX)

This register is used by the host controller to index the periodic frame list. The register updates every 125 microseconds (once each micro-frame). Bits [N: 3] are used to select a particular entry in the Periodic Frame List during periodic schedule execution. The number of bits used for the index depends on the size of the frame list as set by system software in the Frame List Size field in the n_USBCMD register.

This register must be written as a DWord. Byte writes produce undefined results. This register cannot be written unless the Host Controller is in the 'Halted' state as indicated by the HCHalted bit. A write to this register while the Run/Stop hit is set to a one produces undefined results. Writes to this register also affect the SOF value.

In device mode this register is read only and, the device controller updates the FRINDEX [13:3] register from the frame number indicated by the SOF marker. Whenever a SOF is received by the USB bus, FRINDEX [13:3] will be checked against the SOF marker. If FRINDEX [13:3] is different from the SOF marker, FRINDEX [13:3] will be set to the SOF value and FRINDEX [2:0] will be set to zero (that is, SOF for 1 ms frame). If FRINDEX [13:3] is equal to the SOF value, FRINDEX [2:0] will be increment (that is, SOF for 125 us micro-frame.).

Address: 4033_0000h base + 14Ch offset + (65536d × i), where i=0d to 1d

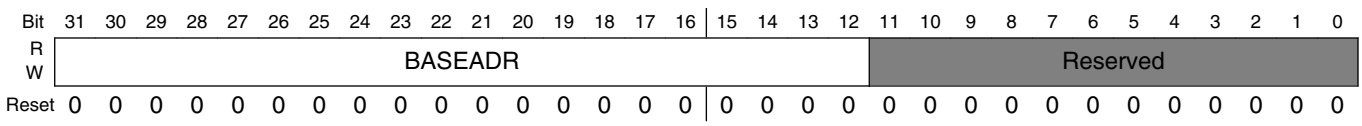
54.7.22 Frame List Base Address (USB_*n*PERIODICLISTBASE)

Host Controller only

This 32-bit register contains the beginning address of the Periodic Frame List in the system memory. HCD loads this register prior to starting the schedule execution by the Host Controller. The memory structure referenced by this physical memory pointer is assumed to be 4-Kbyte aligned. The contents of this register are combined with the Frame Index Register (USB_n_FRINDEX) to enable the Host Controller to step through the Periodic Frame List in sequence.

Address: 4033_0000h base + 154h offset + (65536d × i), where i=0d to 1d



USB_*n*PERIODICLISTBASE field descriptions

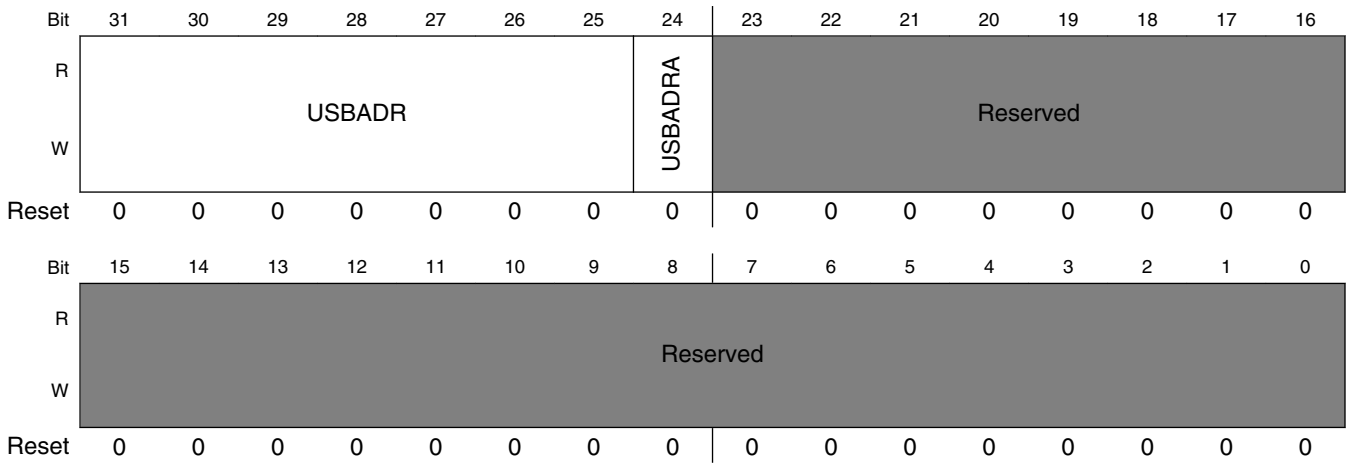
Field	Description
31–12 BASEADR	Base Address (Low). These bits correspond to memory address signals [31:12], respectively. Only used by the host controller.
-	This field is reserved. Reserved

54.7.23 Device Address (USB_*n*DEVICEADDR)

Device Controller only

The upper seven bits of this register represent the device address. After any controller reset or a USB reset, the device address is set to the default address (0). The default address will match all incoming addresses. Software shall reprogram the address after receiving a SET_ADDRESS descriptor.

Address: 4033_0000h base + 154h offset + (65536d × i), where i=0d to 1d



USB_*n*DEVICEADDR field descriptions

Field	Description
31–25 USBADR	Device Address. These bits correspond to the USB device address
24 USBADRA	Device Address Advance. Default=0. When this bit is '0', any writes to USBADR are instantaneous. When this bit is written to a '1' at the same time or before USBADR is written, the write to the USBADR field is staged and held in a hidden register. After an IN occurs on endpoint 0 and is ACKed, USBADR will be loaded from the holding register. Hardware will automatically clear this bit on the following conditions: 1) IN is ACKed to endpoint 0. (USBADR is updated from staging register). 2) OUT/SETUP occur to endpoint 0. (USBADR is not updated). 3) Device Reset occurs (USBADR is reset to 0). **NOTE:** After the status phase of the SET_ADDRESS descriptor, the DCD has 2 ms to program the USBADR field. This mechanism will ensure this specification is met when the DCD can not write of the device address within 2ms from the SET_ADDRESS status phase. If the DCD writes the USBADR with USBADRA=1 after the SET_ADDRESS data phase (before the prime of the status phase), the USBADR will be programmed instantly at the correct time and meet the 2ms USB requirement.
-	This field is reserved. Reserved

54.7.24 Next Asynch. Address (USB_*n*ASYNCLISTADDR)

Host Controller only

This 32-bit register contains the address of the next asynchronous queue head to be executed by the host. Bits [4:0] of this register cannot be modified by the system software and will always return a zero when read.

Address: 4033_0000h base + 158h offset + (65536d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

USB_*n*ENDPTLISTADDR field descriptions

Field	Description
31–11 EPBASE	Endpoint List Pointer(Low). These bits correspond to memory address signals [31:11], respectively. This field will reference a list of up to 32 Queue Head (QH) (that is, one queue head per endpoint & direction).
-	This field is reserved. Reserved

54.7.26 Programmable Burst Size (USB_*n*BURSTSIZE)

This register is used to control the burst size used during data movement on the AHB master interface. This register is ignored if AHBBRST bits in SBUSCFG register is non-zero value.

Address: 4033_0000h base + 160h offset + (65536d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

USB_*n*BURSTSIZE field descriptions

Field	Description
31–17 -	This field is reserved. Reserved
16–8 TXPBURST	Programmable TX Burst Size. Default value is determined by TXBURST bits in n_HWTXBUF. This register represents the maximum length of a the burst in 32-bit words while moving data from system memory to the USB bus.
RXPBURST	Programmable RX Burst Size. Default value is determined by TXBURST bits in n_HWRXBUF. This register represents the maximum length of a the burst in 32-bit words while moving data from the USB bus to system memory.

54.7.27 TX FIFO Fill Tuning (USB_*n*TXFILLTUNING)

The fields in this register control performance tuning associated with how the host controller posts data to the TX latency FIFO before moving the data onto the USB bus. The specific areas of performance include the how much data to post into the FIFO and an estimate for how long that operation should take in the target system.

Definitions:

T_0 = Standard packet overhead

T_1 = Time to send data payload

T_{ff} = Time to fetch packet into TX FIFO up to specified level.

T_s = Total Packet Flight Time (send-only) packet

$T_s = T_0 + T_1$

T_p = Total Packet Time (fetch and send) packet

$T_p = T_{ff} + T_0 + T_1$

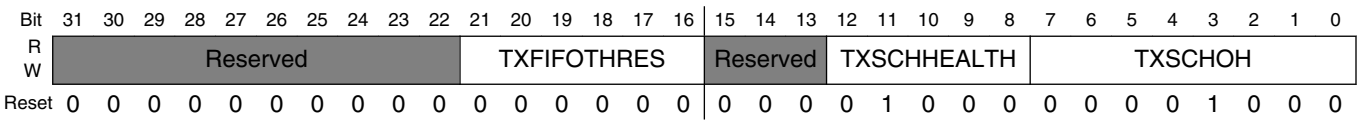
Upon discovery of a transmit (OUT/SETUP) packet in the data structures, host controller checks to ensure T_p remains before the end of the [micro]frame. If so it proceeds to pre-fill the TX FIFO. If at anytime during the pre-fill operation the time remaining the [micro]frame is < T_s then the packet attempt ceases and the packet is tried at a later time. Although this is not an error condition and the host controller will eventually recover, a

mark will be made the scheduler health counter to note the occurrence of a "back-off" event. When a back-off event is detected, the partial packet fetched may need to be discarded from the latency buffer to make room for periodic traffic that will begin after the next SOF. Too many back-off events can waste bandwidth and power on the system bus and thus should be minimized (not necessarily eliminated). Back-offs can be minimized with use of the n_TSCHHEALTH (T_{ff}) described below.

NOTE

The reset value could vary from instance to instance. Please see the detail in bit field description and ignore reset value in summary table in this case!

Address: 4033_0000h base + 164h offset + (65536d × i), where i=0d to 1d



USB_*n*TXFILLTUNING field descriptions

Field	Description
31–22 -	This field is reserved. Reserved
21–16 TXFIFOTHRES	FIFO Burst Threshold. (Read/Write) This register controls the number of data bursts that are posted to the TX latency FIFO in host mode before the packet begins on to the bus. The minimum value is 2 and this value should be a low as possible to maximize USB performance. A higher value can be used in systems with unpredictable latency and/or insufficient bandwidth where the FIFO may underrun because the data transferred from the latency FIFO to USB occurs before it can be replenished from system memory. This value is ignored if the Stream Disable bit in USB_n_USBMODE register is set. Default value is '00h' for OTG controller core, and '02h' for Host-only controller core.
15–13 -	This field is reserved. Reserved
12–8 TXSCHHEALTH	Scheduler Health Counter. (Read/Write To Clear) This register increments when the host controller fails to fill the TX latency FIFO to the level programmed by TXFIFOTHRES before running out of time to send the packet before the next Start-Of-Frame. This health counter measures the number of times this occurs to provide feedback to selecting a proper TXSCHOH. Writing to this register will clear the counter and this counter will max. at 31. Default value is '08h' for OTG controller core, and '00h' for Host-only controller core.
TXSCHOH	Scheduler Overhead. (Read/Write) [Default = 0] This register adds an additional fixed offset to the schedule time estimator described above as Tff. As an approximation, the value chosen for this register should limit the number of back-off events captured in the TXSCHHEALTH to less than 10 per second in a highly utilized bus. Choosing a value that is too high for this register is not desired as it can needlessly reduce USB utilization. The time unit represented in this register is 1.267us when a device is connected in High-Speed Mode. The time unit represented in this register is 6.333us when a device is connected in Low/Full Speed Mode. Default value is '08h' for OTG controller core, and '00h' for Host-only controller core.

54.7.28 Endpoint NAK (USB_*n*ENDPTNAK)

Address: 4033_0000h base + 178h offset + (65536d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

USB_*n*CONFIGFLAG field descriptions

Field	Description
31–1 -	This field is reserved. Reserved
0 CF	Configure Flag Host software sets this bit as the last action in its process of configuring the Host Controller. This bit controls the default port-routing control logic. 0 Port routing control logic default-routes each port to an implementation dependent classic host controller. 1 Port routing control logic default-routes all ports to this host controller.

54.7.31 Port Status & Control (USB_*n*PORTSC1)

Host Controller

A host controller could implement one to eight port status and control registers. The number is determined by N_PORTs bits in HWSPARAMs register (please see Host Controller Structural Parameters (USB_*n*HCSPARAMS)). Software could read this parameter register to determine how many ports need service.

All controller cores on this product are Single-Port, so there is only one port status and control register for each controller core.

This register is only reset by power on reset or controller core reset. The initial conditions of a port are:

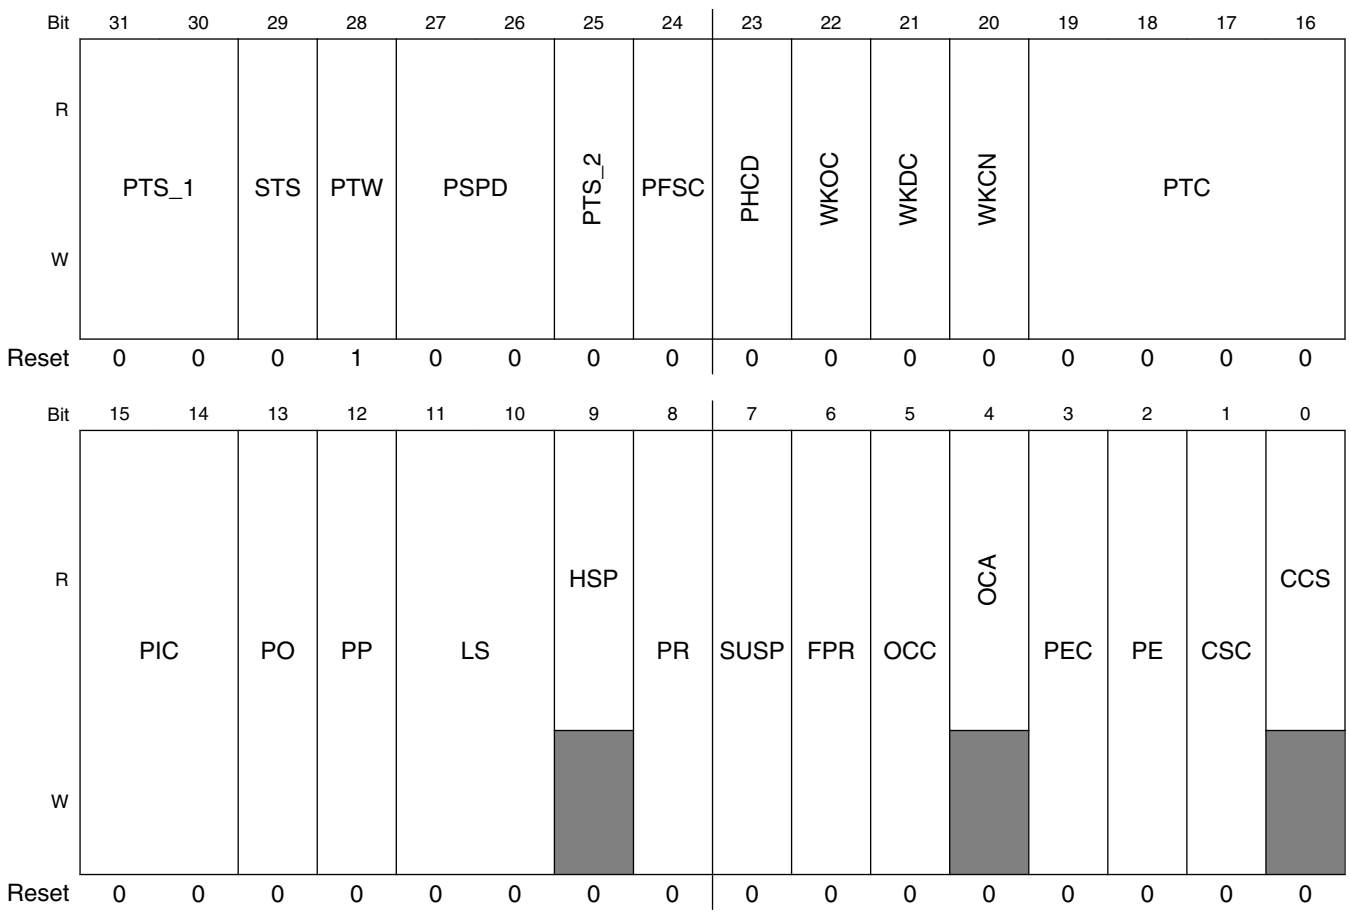
- No device connected
- Port disabled

If the port supports power control, this state remains until port power is supplied (by software).

Device Controller

A controller operating in device mode has only port register one (PORTSC1) and it does not support power control in that mode. Port control in device mode is only used for status port reset, suspend, and current connect status. It is also used to initiate test mode or force signaling and allows software to put the PHY into low power suspend mode and disable the PHY clock.

Address: 4033_0000h base + 184h offset + (65536d × i), where i=0d to 1d



USB_*n*PORTSC1 field descriptions

Field	Description
31–30 PTS_1	Bit field {bit25, bit31, bit30}: "000b" UTMI/UTMI+ "001b" Reserved "010b" ULPI "011b" Serial/USB 1.1 PHY/IC-USB (FS Only) "100b" HSIC **NOTE:** All USB port interface modes are listed in this field description, but not all are supported. For detail feature of each controller core, please see Features . The behaviour is unknown when unsupported interface mode is selected.
29 STS	Serial Transceiver Select - Read Only Serial Transceiver Select 1 Serial Interface Engine is selected 0 Parallel Interface signals is selected Serial Interface Engine can be used in combination with UTMI+/ULPI physical interface to provide FS/LS signaling instead of the parallel interface signals. When this bit is set '1b', serial interface engine will be used instead of parallel interface signals. This bit has no effect unless PTS bits is set to select UTMI+/ULPI interface. The Serial/USB1.1 PHY/IC-USB will use the serial interface engine for FS/LS signaling regardless of this bit value.
28 PTW	Parallel Transceiver Width This bit has no effect if serial interface engine is used. For OTG1/OTG2/Host1 core, it is Read-Only. Reset value is '1b'. 0 Select the 8-bit UTMI interface [60MHz] 1 Select the 16-bit UTMI interface [30MHz]
27–26 PSPD	Port Speed - Read Only. This register field indicates the speed at which the port is operating. 00 Full Speed 01 Low Speed 10 High Speed 11 Undefined
25 PTS_2	See description at bits 31-30
24 PFSC	Port Force Full Speed Connect - Read/Write. Default = 0b. When this bit is set to '1b', the port will be forced to only connect at Full Speed, It disables the chirp sequence that allows the port to identify itself as High Speed. 1 Forced to full speed 0 Normal operation
23 PHCD	PHY Low Power Suspend - Clock Disable (PLPSCD) - Read/Write. Default = 0b. When this bit is set to '1b', the PHY clock is disabled. Reading this bit will indicate the status of the PHY clock.

Table continues on the next page...

USB_*n*PORTSC1 field descriptions (continued)

Field	Description
	NOTE: The PHY clock cannot be disabled if it is being used as the system clock. In device mode, The PHY can be put into Low Power Suspend when the device is not running (USBCMD Run/Stop=0b) or the host has signalled suspend (PORTSC1 SUSPEND=1b). PHY Low power suspend will be cleared automatically when the host initials resume. Before forcing a resume from the device, the device controller driver must clear this bit. In host mode, the PHY can be put into Low Power Suspend when the downstream device has been put into suspend mode or when no downstream device is connected. Low power suspend is completely under the control of software. 1 Disable PHY clock 0 Enable PHY clock
22 WKOC	Wake on Over-current Enable (WKOC_E) - Read/Write. Default = 0b. Writing this bit to a one enables the port to be sensitive to over-current conditions as wake-up events. This field is zero if *Port Power(*Port Status & Control (USB_*n*PORTSC1)*)* is zero.
21 WKDC	Wake on Disconnect Enable (WKDSCNNT_E) - Read/Write. Default=0b. Writing this bit to a one enables the port to be sensitive to device disconnects as wake-up events. This field is zero if *Port Power(*Port Status & Control (USB_*n*PORTSC1)*)* is zero or in device mode.
20 WKCN	Wake on Connect Enable (WKCNNT_E) - Read/Write. Default=0b. Writing this bit to a one enables the port to be sensitive to device connects as wake-up events. This field is zero if *Port Power(*Port Status & Control (USB_*n*PORTSC1)*)* is zero or in device mode.
19–16 PTC	Port Test Control - Read/Write. Default = 0000b. Refer to Port Test Mode for the operational model for using these test modes and the USB Specification Revision 2.0, Chapter 7 for details on each test mode. The FORCE_ENABLE_FS and FORCE ENABLE_LS are extensions to the test mode support specified in the EHCI specification. Writing the PTC field to any of the FORCE_ENABLE_{HS/FS/LS} values will force the port into the connected and enabled state at the selected speed. Writing the PTC field back to TEST_MODE_DISABLE will allow the port state machines to progress normally from that point. **NOTE:** *Low speed operations are not supported as a peripheral device.* Any other value than zero indicates that the port is operating in test mode. Value Specific Test 0000 TEST_MODE_DISABLE 0001 J_STATE 0010 K_STATE 0011 SE0 (host) / NAK (device) 0100 Packet 0101 FORCE_ENABLE_HS 0110 FORCE_ENABLE_FS 0111 FORCE_ENABLE_LS 1000-1111 Reserved
15–14 PIC	Port Indicator Control - Read/Write. Default = Ob. Writing to this field has no effect if the P_INDICATOR bit in the HCSPARAMS register is a zero. Refer to the USB Specification Revision 2.0 for a description on how these bits are to be used. This field is zero if *Port Power* is zero.

Table continues on the next page...

USB_*n*PORTSC1 field descriptions (continued)

Field	Description
	Bit Value Meaning 00 Port indicators are off 01 Amber 10 Green 11 Undefined
13 PO	Port Owner-Read/Write. Default = 0. This bit unconditionally goes to a 0 when the configured bit in the CONFIGFLAG register makes a 0 to 1 transition. This bit unconditionally goes to 1 whenever the Configured bit is zero System software uses this field to release ownership of the port to a selected host controller (in the event that the attached device is not a high-speed device). Software writes a one to this bit when the attached device is not a high-speed device. A one in this bit means that an internal companion controller owns and controls the port. Port owner handoff is not supported in all controller cores, therefore this bit will always be 0.
12 PP	Port Power (PP)-Read/Write or Read Only. The function of this bit depends on the value of the Port Power Switching (PPC) field in the HCSPARAMS register. The behavior is as follows: PPC PP Operation 0 1b *Read Only - Host controller does not have port power control switches. Each port is hard-wired to power.* 1 1b/0b - *Read/Write. Host/OTG controller requires port power control switches. This bit represents the current setting of the switch (0=off, 1=on). When power is not available on a port (that is, PP equals a 0), the port is non-functional and will not report attaches, detaches, etc.* When an over-current condition is detected on a powered port and PPC is a one, the PP bit in each affected port may be transitional by the host controller driver from a one to a zero (removing power from the port). This feature is implemented in all controller cores (PPC = 1).
11–10 LS	Line Status-Read Only. These bits reflect the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines. In host mode, the use of linestate by the host controller driver is not necessary (unlike EHCI), because the port controller state machine and the port routing manage the connection of LS and FS. In device mode, the use of linestate by the device controller driver is not necessary. The encoding of the bits are: Bits [11:10] Meaning 00 SE0 10 J-state 01 K-state 11 Undefined
9 HSP	High-Speed Port - Read Only. Default = 0b. When the bit is one, the host/device connected to the port is in high-speed mode and if set to zero, the host/device connected to the port is not in a high-speed mode.

Table continues on the next page...

USB_*n*PORTSC1 field descriptions (continued)

Field	Description
	NOTE: HSP is redundant with PSPD(bit 27, 26) but remained for compatibility.
8 PR	Port Reset - Read/Write or Read Only. Default = 0b. In Host Mode: Read/Write. 1=Port is in Reset. 0=Port is not in Reset. Default 0. When software writes a one to this bit the bus-reset sequence as defined in the USB Specification Revision 2.0 is started. *This bit will automatically change to zero after the reset sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the reset duration is timed in the driver.* In Device Mode: This bit is a read only status bit. Device reset from the USB bus is also indicated in the USBSTS register. This field is zero if *Port Power(*Port Status & Control (USB_*n*PORTSC1)*)* is zero.
7 SUSP	Suspend - Read/Write or Read Only. Default = 0b. 1=Port in suspend state. 0=Port not in suspend state. In Host Mode: Read/Write. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0x Disable 10 Enable 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction if a transaction was in progress when this bit was written to 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. The host controller will unconditionally set this bit to zero when software sets the *Force Port Resume* bit to zero. The host controller ignores a write of zero to this bit. If host software sets this bit to a one when the port is not enabled (that is, *Port enabled* bit is a zero) the results are undefined. This field is zero if *Port Power(*Port Status & Control (USB_*n*PORTSC1)*)* is zero in host mode. In Device Mode: Read Only. In device mode this bit is a read only status bit.
6 FPR	Force Port Resume -Read/Write. 1= Resume detected/driven on port. 0=No resume (K-state) detected/driven on port. Default = 0. In Host Mode: Software sets this bit to one to drive resume signaling. The Host Controller sets this bit to one if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the *Port Change Detect* bit in the USBSTS register is also set to one. *This bit will automatically change to zero after the resume sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the resume duration is timed in the driver.* Note that when the Host controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. This bit will remain a one until the port has switched to the high-speed idle. Writing a zero has no effect because the port controller will time the resume operation, clear the bit the port control state switches to HS or FS idle.

Table continues on the next page...

USB_*n*PORTSC1 field descriptions (continued)

Field	Description
	This field is zero if *Port Power(*Port Status & Control (USB_*n*PORTSC1)*)* is zero in host mode. This bit is not-EHCI compatible. In Device mode: After the device has been in Suspend State for 5ms or more, software must set this bit to one to drive resume signaling before clearing. The Device Controller will set this bit to one if a J-to-K transition is detected while the port is in the Suspend state. The bit will be cleared when the device returns to normal operation. Also, when this bit wil be cleared because a K-to-J transition detected, the *Port Change Detect* bit in the USBSTS register is also set to one.
5 OCC	Over-current Change-R/WC. Default=0. This bit is set '1b' by hardware when there is a change to Over-current Active. Software can clear this bit by writing a one to this bit position.
4 OCA	Over-current Active-Read Only. Default 0. This bit will automatically transition from one to zero when the over current condition is removed. 1 This port currently has an over-current condition 0 This port does not have an over-current condition.
3 PEC	Port Enable/Disable Change-R/WC. 1=Port enabled/disabled status has changed. 0=No change. Default = 0. In Host Mode: For the root hub, this bit is set to a one only when a port is disabled due to disconnect on the port or due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification). Software clears this by writing a one to it. This field is zero if *Port Power(*Port Status & Control (USB_*n*PORTSC1)*)* is zero. In Device mode: The device port is always enabled, so this bit is always '0b'.
2 PE	Port Enabled/Disabled-Read/Write. 1=Enable. 0=Disable. Default 0. In Host Mode: Ports can only be enabled by the host controller as a part of the reset and enable. Software cannot enable a port by writing a one to this field. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by the host software. Note that the bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host controller and bus events. When the port is disabled, (0b) downstream propagation of data is blocked except for reset. This field is zero if *Port Power(*Port Status & Control (USB_*n*PORTSC1)*)* is zero in host mode. In Device Mode: The device port is always enabled, so this bit is always '1b'.
1 CSC	Connect Status Change-R/WC. 1 =Change in Current Connect Status. 0=No change. Default 0. In Host Mode: Indicates a change has occurred in the port's Current Connect Status. The host/device controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be 'setting' an already-set bit (that is, the bit will remain set). Software clears this bit by writing a one to it.

Table continues on the next page...

USB_*n*PORTSC1 field descriptions (continued)

Field	Description
	This field is zero if *Port Power(*Port Status & Control (USB_*n*PORTSC1)*)* is zero in host mode. In Device Mode: This bit is undefined in device controller mode.
0 CCS	Current Connect Status-Read Only. In Host Mode: 1=Device is present on port. 0=No device is present. Default = 0. This value reflects the current state of the port, and may not correspond directly to the event that caused the *Connect Status Change* bit (Bit 1) to be set. This field is zero if *Port Power(*Port Status & Control (USB_*n*PORTSC1)*)* is zero in host mode. In Device Mode: 1=Attached. 0=Not Attached. Default=0. A one indicates that the device successfully attached and is operating in either high speed or full speed as indicated by the High Speed Port bit in this register. A zero indicates that the device did not attach successfully or was forcibly disconnected by the software writing a zero to the Run bit in the USBCMD register. It does not state the device being disconnected or suspended.

54.7.32 On-The-Go Status & control (USB_*n*OTGSC)

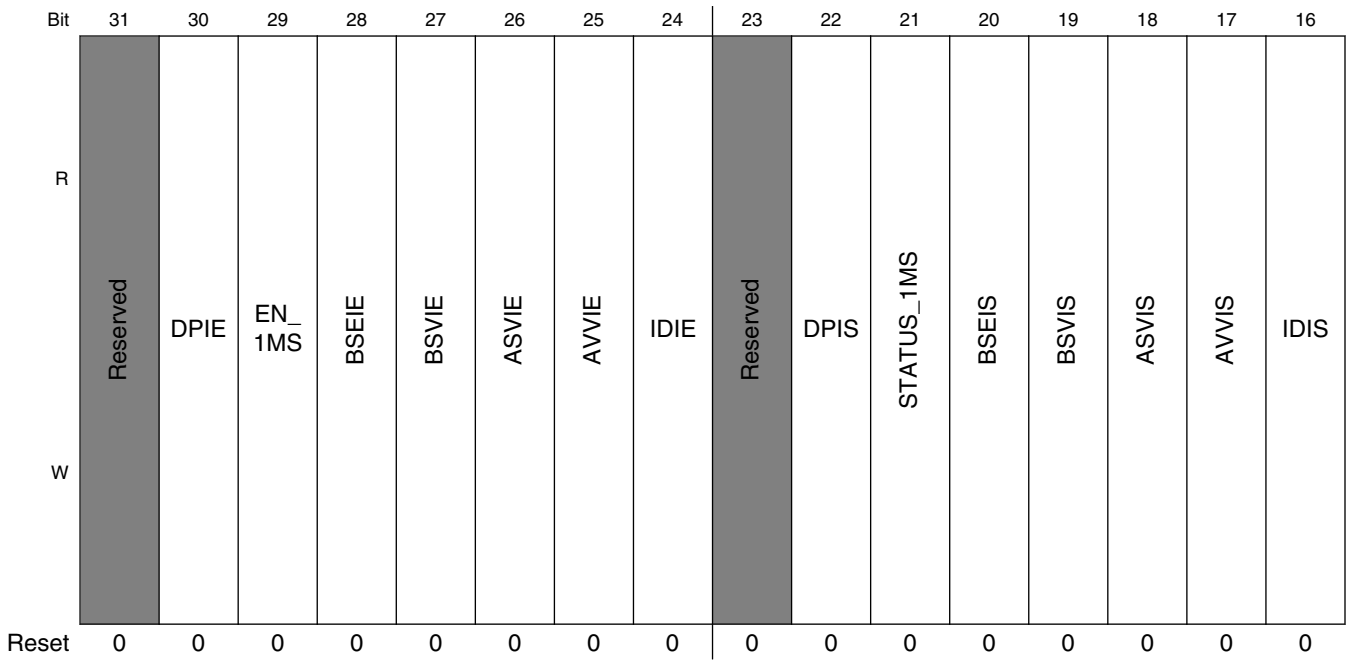
This register is availabe only in OTG controller core. It has four sections:

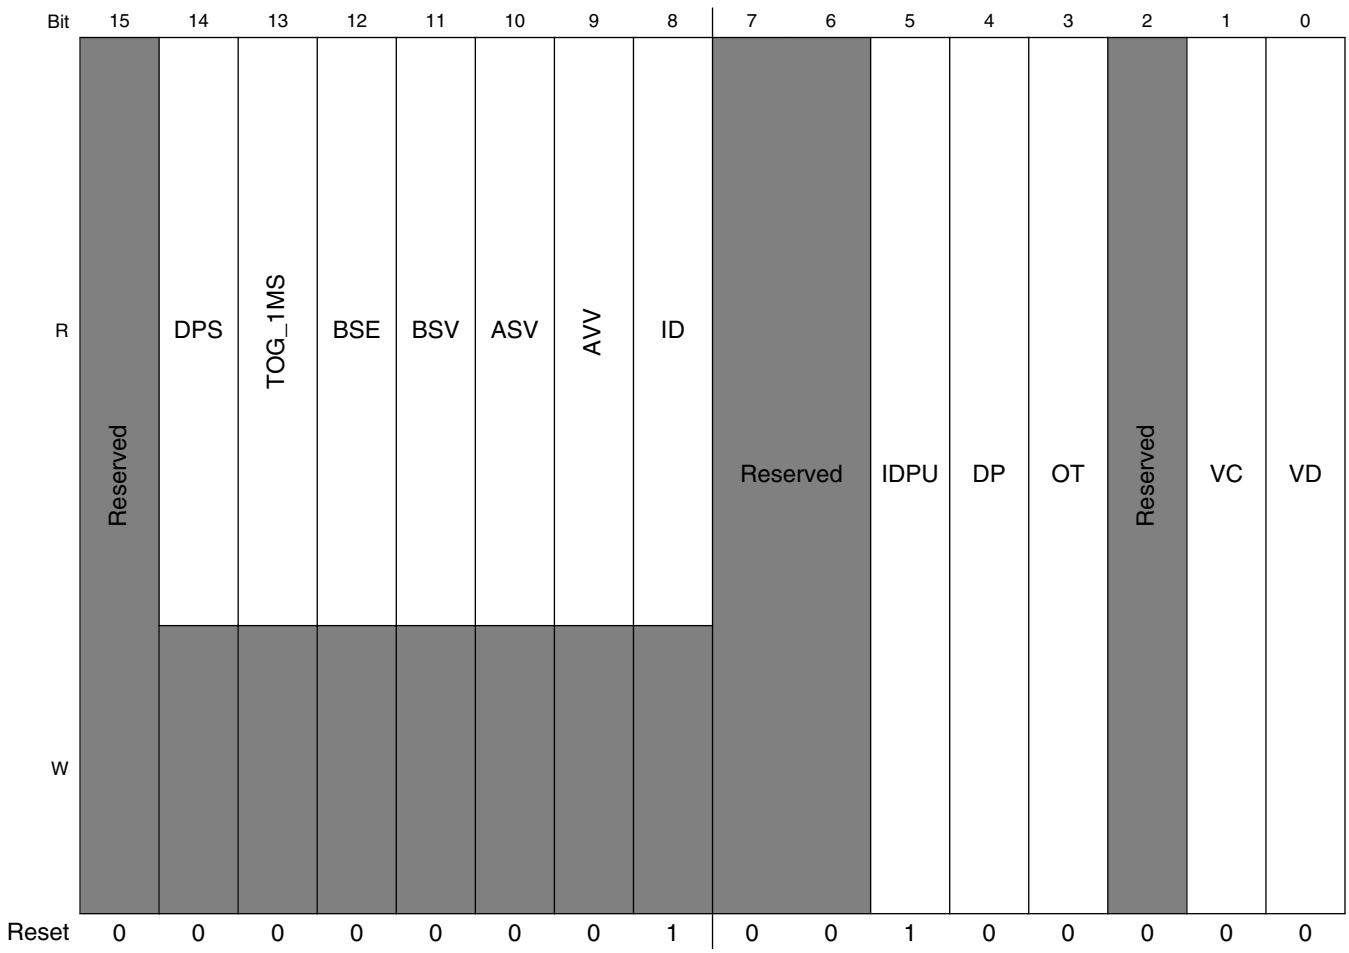
- OTG Interrupt enables (Read/Write)
- OTG Interrupt status (Read/Write to Clear)
- OTG Status inputs (Read Only)
- OTG Controls (Read/Write)

The status inputs are debounced using a 1 ms time constant. Values on the status inputs that do not persist for more than 1 ms does not cause an update of the status input register, or cause an OTG interrupt.

See also USB Device Mode (USB_*n*USBMODE) register.

Address: 4033_0000h base + 1A4h offset + (65536d × i), where i=0d to 1d





USB_*n*OTGSC field descriptions

Field	Description
31 -	This field is reserved. Reserved
30 DPIE	Data Pulse Interrupt Enable
29 EN_1MS	1 millisecond timer Interrupt Enable - Read/Write
28 BSEIE	B Session End Interrupt Enable - Read/Write. Setting this bit enables the B session end interrupt.
27 BSVIE	B Session Valid Interrupt Enable - Read/Write. Setting this bit enables the B session valid interrupt.
26 ASVIE	A Session Valid Interrupt Enable - Read/Write. Setting this bit enables the A session valid interrupt.
25 AVVIE	A VBus Valid Interrupt Enable - Read/Write. Setting this bit enables the A VBus valid interrupt.
24 IDIE	USB ID Interrupt Enable - Read/Write. Setting this bit enables the USB ID interrupt.
23 -	This field is reserved. Reserved
22 DPIS	Data Pulse Interrupt Status - Read/Write to Clear. This bit is set when data bus pulsing occurs on DP or DM. Data bus pulsing is only detected when USBMODE.CM = Host (11) and PORTSC1(0)[PP] = 0. Software must write a one to clear this bit.
21 STATUS_1MS	1 millisecond timer Interrupt Status - Read/Write to Clear. This bit is set once every millisecond. Software must write a one to clear this bit.
20 BSEIS	B Session End Interrupt Status - Read/Write to Clear. This bit is set when VBus has fallen below the B session end threshold. Software must write a one to clear this bit.
19 BSVIS	B Session Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the B session valid threshold. Software must write a one to clear this bit.
18 ASVIS	A Session Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the A session valid threshold. Software must write a one to clear this bit.
17 AVVIS	A VBus Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the VBus valid threshold on an A device. Software must write a one to clear this bit.
16 IDIS	USB ID Interrupt Status - Read/Write. This bit is set when a change on the ID input has been detected. Software must write a one to clear this bit.

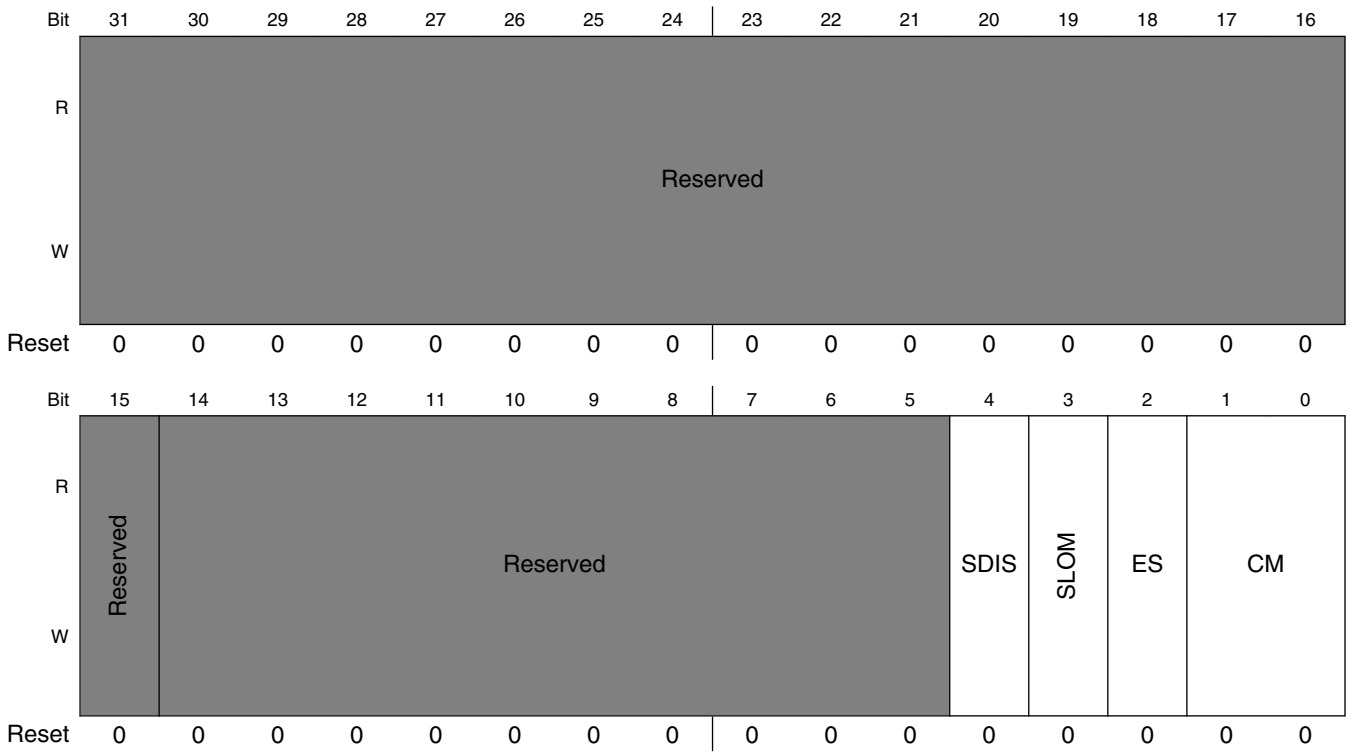
Table continues on the next page...

USB_*n*OTGSC field descriptions (continued)

Field	Description
15 -	This field is reserved. Reserved
14 DPS	Data Bus Pulsing Status - Read Only. A '1' indicates data bus pulsing is being detected on the port.
13 TOG_1MS	1 millisecond timer toggle - Read Only. This bit toggles once per millisecond.
12 BSE	B Session End - Read Only. Indicates VBus is below the B session end threshold.
11 BSV	B Session Valid - Read Only. Indicates VBus is above the B session valid threshold.
10 ASV	A Session Valid - Read Only. Indicates VBus is above the A session valid threshold.
9 AVV	A VBus Valid - Read Only. Indicates VBus is above the A VBus valid threshold.
8 ID	USB ID - Read Only. 0 = A device, 1 = B device
7–6 -	This field is reserved. Reserved
5 IDPU	ID Pullup - Read/Write This bit provide control over the ID pull-up resistor; 0 = off, 1 = on [default]. When this bit is 0, the ID input will not be sampled.
4 DP	Data Pulsing - Read/Write. Setting this bit causes the pullup on DP to be asserted for data pulsing during SRP.
3 OT	OTG Termination - Read/Write. This bit must be set when the OTG device is in device mode, this controls the pulldown on DM.
2 -	This field is reserved. Reserved
1 VC	VBUS Charge - Read/Write. Setting this bit causes the VBus line to be charged. This is used for VBus pulsing during SRP.
0 VD	VBUS_Discharge - Read/Write. Setting this bit causes VBus to discharge through a resistor.

54.7.33 USB Device Mode (USB_*n*USBMODE)

Address: 4033_0000h base + 1A8h offset + (65536d × i), where i=0d to 1d



USB_*n*USBMODE field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
15 -	This field is reserved. Reserved
14–5 -	This field is reserved. Reserved
4 SDIS	Stream Disable Mode. (0 - Inactive [default]; 1 - Active) Device Mode: Setting to a '1' disables double priming on both RX and TX for low bandwidth systems. This mode ensures that when the RX and TX buffers are sufficient to contain an entire packet that the standard double buffering scheme is disabled to prevent overruns/underruns in bandwidth limited systems. Note: In High Speed Mode, all packets received are responded to with a NYET handshake when stream disable is active. Host Mode: Setting to a '1' ensures that overruns/underruns of the latency FIFO are eliminated for low bandwidth systems where the RX and TX buffers are sufficient to contain the entire packet. Enabling stream disable also has the effect of ensuring the TX latency is filled to capacity before the packet is launched onto the USB. **NOTE:** Time duration to pre-fill the FIFO becomes significant when stream disable is active. See TX FIFO Fill Tuning (USB_*n*TXFILLTUNING) and TXTTFILLTUNING [MPH Only] to characterize the adjustments needed for the scheduler when using this feature.

USB_*n*USBMODE field descriptions (continued)

Field	Description
	NOTE: The use of this feature substantially limits of the overall USB performance that can be achieved.
3 SLOM	Setup Lockout Mode. In device mode, this bit controls behavior of the setup lock mechanism. See Control Endpoint Operation Model . 0 Setup Lockouts On (default); 1 Setup Lockouts Off (DCD requires use of Setup Data Buffer Tripwire in USB Command Register (USB_*n*USBCMD) .
2 ES	Endian Select - Read/Write. This bit can change the byte alignment of the transfer buffers to match the host microprocessor. The bit fields in the microprocessor interface and the data structures are unaffected by the value of this bit because they are based upon the 32-bit word. Bit Meaning 0 Little Endian [Default] 1 Big Endian
CM	Controller Mode - R/WO. Controller mode is defaulted to the proper mode for host only and device only implementations. For those designs that contain both host & device capability, the controller defaults to an idle state and needs to be initialized to the desired operating mode after reset. For combination host/device controllers, this register can only be written once after reset. If it is necessary to switch modes, software must reset the controller by writing to the *RESET* bit in the USBCMD register before reprogramming this register. For OTG controller core, reset value is '00b'. For Host-only controller core, reset value is '11b'. 00 Idle [Default for combination host/device] 01 Reserved 10 Device Controller [Default for device only controller] 11 Host Controller [Default for host only controller]

54.7.34 Endpoint Setup Status (USB_*n*ENDPTSETUPSTAT)

Address: 4033_0000h base + 1ACh offset + (65536d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

USB_*n*ENDPTSETUPSTAT field descriptions

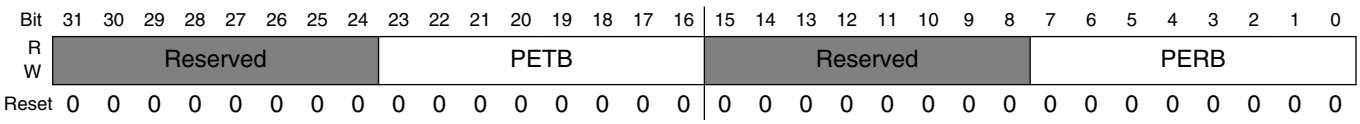
Field	Description
31–16 -	This field is reserved. Reserved
ENDPTSETUPSTAT	Setup Endpoint Status. For every setup transaction that is received, a corresponding bit in this register is set to one. Software must clear or acknowledge the setup transfer by writing a one to a respective bit after it has read the setup data from Queue head. The response to a setup packet as in the order of operations and total response time is crucial to limit bus time outs while the setup lock our mechanism is engaged. See Managing Endpoints in the Device Operational Model. This register is only used in device mode.

54.7.35 Endpoint Prime (USB_*n*ENDPTPRIME)

This register is only used in device mode.

When software sets the prime bit for a given endpoint, the device controller loads the transfer descriptor, pointed to by the queue head, such that the endpoint is ready to transmit or receive when the host sends a request (IN/OUT token). The endpoint will NAK all requests from the host until the endpoint is primed. The controller will automatically re-prime the endpoint with a new transfer descriptor when one is found via the next_dtd pointer of the current transfer descriptor. Hence, the prime bit must only be set by software when a descriptor is added to the queue head.

Address: 4033_0000h base + 1B0h offset + (65536d × i), where i=0d to 1d



USB_*n*ENDPTPRIME field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
23–16 PETB	Prime Endpoint Transmit Buffer - R/WS. For each endpoint a corresponding bit is used to request that a buffer is prepared for a transmit operation in order to respond to a USB IN/INTERRUPT transaction. Software should write a one to the corresponding bit when posting a new transfer descriptor to an endpoint queue head. Hardware automatically uses this bit to begin parsing for a new transfer descriptor from the queue head and prepare a transmit buffer. Hardware clears this bit when the associated endpoint(s) is (are) successfully primed. **NOTE:** These bits are momentarily set by hardware during hardware re-priming operations when a dTD is retired, and the dQH is updated. PETB[N] - Endpoint #N, N is in 0..7
15–8 -	This field is reserved. Reserved
PERB	Prime Endpoint Receive Buffer - R/WS. For each endpoint, a corresponding bit is used to request a buffer prepare for a receive operation for when a USB host initiates a USB OUT transaction. Software should write a one to the corresponding bit whenever posting a new transfer descriptor to an endpoint queue head. Hardware automatically uses this bit to begin parsing for a new transfer descriptor from the queue head and prepare a receive buffer. Hardware clears this bit when the associated endpoint(s) is (are) successfully primed. **NOTE:** These bits are momentarily set by hardware during hardware re-priming operations when a dTD is retired, and the dQH is updated. PERB[N] - Endpoint #N, N is in 0..7

54.7.36 Endpoint Flush (USB_*n*ENDPTFLUSH)

This register is only used in device mode.

Address: 4033_0000h base + 1B4h offset + (65536d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

In most systems, it is unlikely the DCD software will observe this delay. However, should the DCD observe that the stall bit is not set after writing a one to it then follow this procedure: continually write this stall bit until it is set or until a new setup has been received by checking the associated endptsetupstat bit.

54.7.43 Endpoint Control 4 (USB_*n*ENDPTCTRL4)

This is endpoint control register for endpoint 4 in device operation mode.

NOTE

If one endpoint direction is enabled and the paired endpoint of opposite direction is disabled then the unused direction type must be changed from the default control-type to any other type (that is Bulk-type). leaving an unconfigured endpoint control causes undefined behavior for the data pid tracking on the active endpoint/direction.

55.1.1 USB PHY

This device integrates one USB 2.0 PHY macrocells capable of connecting to USB host/device systems at low-speed, full-speed, and high-speed. The USB PHY provides a standard UTMI interface for connection to the USBHS controller. It has the integrated PLL and DCD block, with an IP bus interface for configuration. The USB_DP and USB_DN pins connect directly to the USB connector. The following table shows the configuration of the USB PHY.

Table 55-2. USB PHY configuration

Parameter	Description
Name	USB PHY
Supported standard version	USB2.0 Specification
Instances	1
Configurable features	NA
Interface speed	480 Mbps
External I/O pins	See the IOMUXC spreadsheet attached with this RM.

55.2 USB PHY Overview

The chip contains one integrated USB 2.0 PHY macrocell capable of connecting to USB host/device systems at the USB low-speed (LS) rate of 1.5 Mbits/s, the full-speed (FS) rate of 12 Mbits/s, or the USB 2.0 high-speed (HS) rate of 480 Mbits/s.

See Figure 55-1 for a block diagram of the PHY. The integrated PHY provides a standard UTMI+ interface. It has an integrated 480MHz PLL and DCD (Device Charger Detector) analog circuits, with an IP bus interface for configurations. For this product the Device Charger Detector functions are detailed in the separate USB Device Charger Detection Module (USBDCD) chapter in this Reference Manual. The USB_DP and USB_DM pins connect directly to a USB connector.

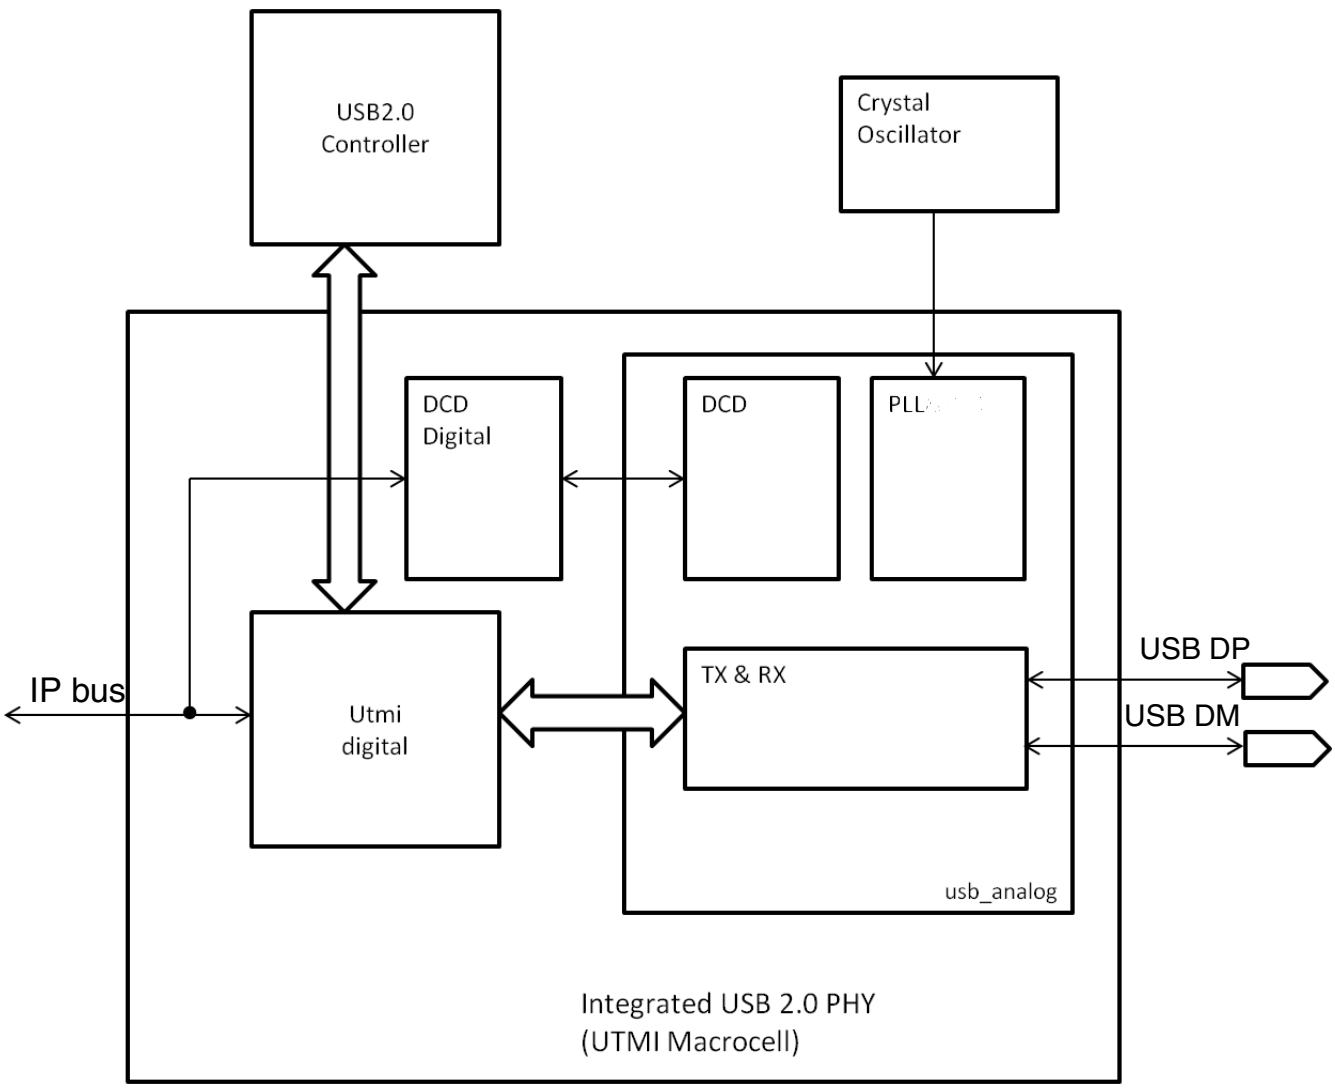

Figure 55-1. USB 2.0 PHY Block Diagram

The following subsections describe the external interfaces, internal interfaces, major blocks, and programmable registers that comprise the integrated USB 2.0 High-Speed PHY.

55.3 Operation

The UTM provides a 16-bit interface to the USB controller. This interface is clocked at 30 MHz.

- The digital portions of the USBPHY block include the UTMI, digital transmitter, digital receiver, and the programmable registers.
- The analog transceiver section comprises an analog receiver and an analog transmitter, as shown in Figure 55-2.

55.3.1 UTMI

The UTMI block handles the line_state bits, reset buffering, suspend distribution, transceiver speed selection, and transceiver termination selection.

The PLL in the USB PHY supplies a 480MHz clock to UTMI digital. The UTMI block will divide the clock to generate the 30MHz clock used in the interface.

55.3.2 Initialization and application information

In order to bring up the internal 480MHz USB PLL clock, four external conditions should be met as shown below.

- The reference clock for USB PLL is the SOSC. So, one needs to enable it via SCG0_SOSCCSR[SOSCEN].
- Enable some settings via the USBPHY_PLL Control/Status Register
  - USBPHY_PLL_SIC[PLL_BYPASS]: Clear this bit to clear bypass feature
  - USBPHY_PLL_SIC[PLL_REG_ENABLE]: Enable USB PLL regulator
  - Delay more than 15 us.
  - USBPHY_PLL_SIC[PLL_BYPASS]: Clear this bit to clear bypass
  - USBPHY_PLL_SIC[PLL_POWER]: Power-up the USB PLL

- USBPHY_PLL_SIC[PLL_EN_USB_CLKS]: Enable the USB clock
- USBPHY_PLL_SIC[PLL_ENABLE]: Enable the clock output from the USB PLL

- The system oscillator ranges from 16 MHz to 32 MHz. USBPHY_PLL_SIC[PLL_DIV_SEL[2:0] should be programmed properly as per the external reference selected.

55.3.3 Digital Transmitter

The digital transmitter receives the 16-bit transmit data from the USB controller and handles the tx_valid, tx_validh and tx_ready handshake.

In addition, it contains the transmit serializer that converts the 16-bit parallel words at 30 MHz to a single bitstream at 480 Mbit for high-speed or 12 Mbit for full-speed or 1.5 Mbit for low-speed. It does this while implementing the bit-stuffing algorithm and the NRZI encoder that are used to remove the DC component from the serial bitstream. The output of this encoder is sent to the low-speed (LS), full-speed (FS) or high-speed (HS) drivers in the analog transceiver section's transmitter block.

55.3.4 Digital Receiver

The digital receiver receives the raw serial bitstream from the low speed (LS) differential transceiver, full speed (FS) differential transceiver, and 480 MHz, 9X oversampled data from the high speed (HS) differential transceiver.

As the phase of the USB host transmitter shifts relative to the local PLL, the receiver section's HS DLL tracks these changes to give a reliable sample of the incoming 480 Mbit/s bitstream. Since this sample point shifts relative to the PLL phase used by the digital logic, a rate-matching elastic buffer is provided to cross this clock domain boundary. Once the bitstream is in the local clock domain, an NRZI decoder and bit unstuffer restore the original payload data bitstream and pass it to a deserializer and holding register. The receive state machine handles the rx_valid, rx_validh, and handshake with the USB controller. The handshake is not interlocked, in that there is no rx_ready signal coming from the controller. The controller must take each 16-bit value as presented by the PHY. The receive state machine provides an rx_active signal to the controller that indicates when it is inside a valid packet (SYNC detected, and so on).

55.3.5 Analog Receiver

The analog receiver comprises five differential receivers, two single-ended receivers, and a 9X, 480 MHz HS data sampling module, as shown in the figure below and described further in this section.

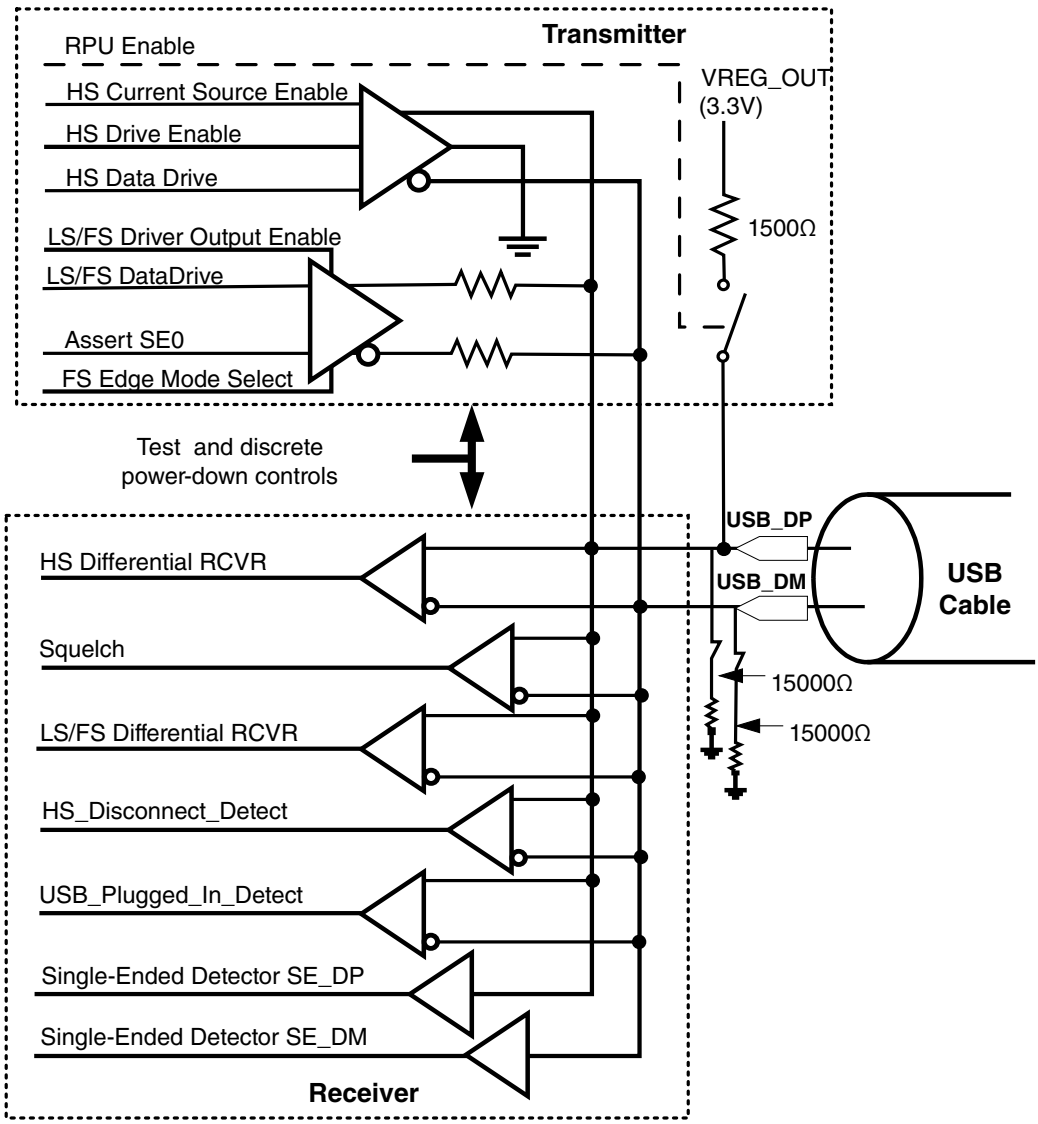

Figure 55-2. USB 2.0 PHY Analog Transceiver Block Diagram

55.3.5.1 HS Differential Receiver

The high-speed differential receiver is both a differential analog receiver and threshold comparator. Its output is high (1'b1) if the differential signal is greater than a 0-V threshold.

Otherwise, its output is low (1'b0). Its purpose is to discriminate the ± 400-mV differential voltage resulting from the high-speed drivers current flow into the dual 45Ω terminations found on each pin of the differential pair. The envelope or squelch detector, described below, ensures that the differential signal has sufficient magnitude to be valid. The HS differential receiver tolerates up to 500 mV of common mode offset.

55.3.5.2 Squelch Detector

The squelch detector is a differential analog receiver and threshold comparator.

Its output is high (1'b1) if the differential magnitude is less than a nominal 100 mV threshold. Otherwise, its output is low (1'b0).

Its purpose is to invalidate the HS differential receiver when the incoming signal is simply too low to receive reliably.

55.3.5.3 LS/FS Differential Receiver

The low-speed/full-speed differential receiver is both a differential analog receiver and threshold comparator.

The crossover voltage falls between 1.3 V and 2.0 V. Its output is 1, when the USB_DP line is above the crossover point and the USB_DM line is below the crossover point. The digital receiver section decodes the receiver data into J or K state according to the speed.

55.3.5.4 HS Disconnect Detector

It is a differential analog receiver and threshold comparator. It outputs high when differential magnitude is greater than a nominal 575-mV threshold. Otherwise, it outputs low.

55.3.5.5 USB Plugged-In (Cable Attach) Detection

The USB HS PHY when operating in device mode provides three different methods for the local USB device to detect the attachment of a cable also attached to a remote USB host or hub. Only one of these methods should be enabled at a time when waiting to identify the cable attachment event, and all of them must be disabled during USB data communication.

The preferred standards-based method is to use the Data Contact Detect function per the *USB Battery Charging Specification, Revision 1.2*. The use of this method is described in the USB Device Charger Detection Module (USBDCD) chapter in this Reference Manual.

The second method, called the USB plugged-in detector, looks for both USB_DP and USB_DM to be high. There is a pair of large on-chip switchable pullup resistors (200 KΩ) that hold both USB_DP and USB_DM high when the USB cable is not attached. The USB plugged-in detector signals a 0 in this case. When operating in device mode, the upstream port in the remote host/hub interface contains a 15 KΩ pulldown resistor which could easily override the 200 KΩ pullup resistor. When the cable attachment event occurs, at least one signal in the pair will be low, which will force the plugged-in detector output high. The USB plugged-in detector is controlled through the USBPHY_CTRL[ENVPLUGINDET] bit field and results are observable through the USBPHY_STATUS[DEVPLUGIN_STATUS] bit field.

The final method is a legacy resistive detection function described in the now-obsolete *USB Battery Charging Specification, Revision 1.0*. This method enables a 125 KΩ pullup resistor on the USB_DP pin and a 375 KΩ pulldown resistor on the USB_DM pin. When no cable is plugged in, the USB_DP pin will be high and the USB_DM pin will be low. If the local device has a cable attached to a remote host or hub, due to the host 15 KΩ pulldowns both the USB_DP and USB_DM pins will be low. If the local device has a cable attached to a dedicated charger with no pullup/pulldown resistors, both the USB_DP and USB_DM pins will be high. This method is enabled through the USBPHY_USB1_VBUS_DETECT[EN_CHARGER_RESISTOR] bit field. Results can be observed using the single ended receiver status in the USBPHY_CHRG_DET_STAT[DP_STATE, DM_STATE] bit fields.

55.3.5.6 Single-Ended USB_DP Receiver

The single-ended USB_DP receiver output is high whenever the USB_DP input is above its nominal 1.8 V threshold.

55.3.5.7 Single-Ended USB_DM Receiver

The single-ended USB_DM receiver output is high whenever the USB_DM input is above its nominal 1.8 V threshold.

55.3.5.8 9X Oversample Module

The 9X oversample module uses nine identically spaced phases of the 480 MHz clock to sample a high speed bit data. The squelch signal is sampled only 1X.

55.3.6 Analog Transmitter

The analog transmitter comprises two differential drivers: one for high-speed signaling and one for full-speed signaling. It also contains the switchable 1.5 KΩ pullup resistor.

See Figure 55-3.

55.3.6.1 Switchable High-Speed 45Ω Termination Resistors

High-speed current mode differential signaling requires good 90 Ω differential termination at each end of the USB cable. This results from switching in 45 Ω terminating resistors from each signal line to ground at each end of the cable.

Because each signal is parallel terminated with 45 Ω at each end, each driver sees a 22.5 Ω load. This load impedance is much too low for full-speed signaling levels—hence the need for switchable high-speed terminating resistors. Switchable trimming resistors are provided to tune the actual termination resistance of each device, as shown in Figure 55-3. The HW_USBPHY_TX_TXCAL45DP bit field, for example, allows one of 16 trimming resistor values to be placed in parallel with the 45Ω terminator on the USB_DP signal.

55.3.6.2 Low-Speed/Full-Speed Differential Driver

The low-speed/full-speed differential drivers are essentially a pair of low-impedance pullup/pulldown devices that are switched in a differential mode for most low-speed or full-speed signaling. One output is driven high while the other output is driven low to signal the "J" state or the "K" state. Both outputs are driven low for the low-speed/full-speed "SE0" state.

55.3.6.3 High-Speed Differential Driver

The high-speed differential driver receives a 17.78 mA current from the constant current source (Iref) and essentially steers it down either the USB_DP signal or the USB_DM signal or alternatively to ground.

This current will produce approximately a 400 mV drop across the 22.5 Ω termination seen by the driver when it is steered onto one of the signal lines. The approximately 17.78 mA current source is referenced back to the integrated voltage-band-gap (Vbg) circuit.

55.3.6.4 Switchable 1.5KΩ USB_DP Pullup Resistor

This product contains a switchable 1.5 KΩ pullup resistor on the USB_DP signal.

This resistor is switched on to indicate to the host/hub controller that a full-speed-capable device is on the USB cable, powered on, and ready. This resistor is switched off at power-on reset so the host does not recognize a USB device until the processor software enables the announcement of a full-speed device.

55.3.6.5 Switchable 15KΩ USB_DP and USB_DM Pulldown Resistors

This product contains switchable 15 KΩ pulldown resistors on both USB_DP and USB_DM signals. They are enabled in host mode to indicate to the device controller on the far end of the USB connection that a host is present. These resistors are also used during certain Battery Charging detector functions.

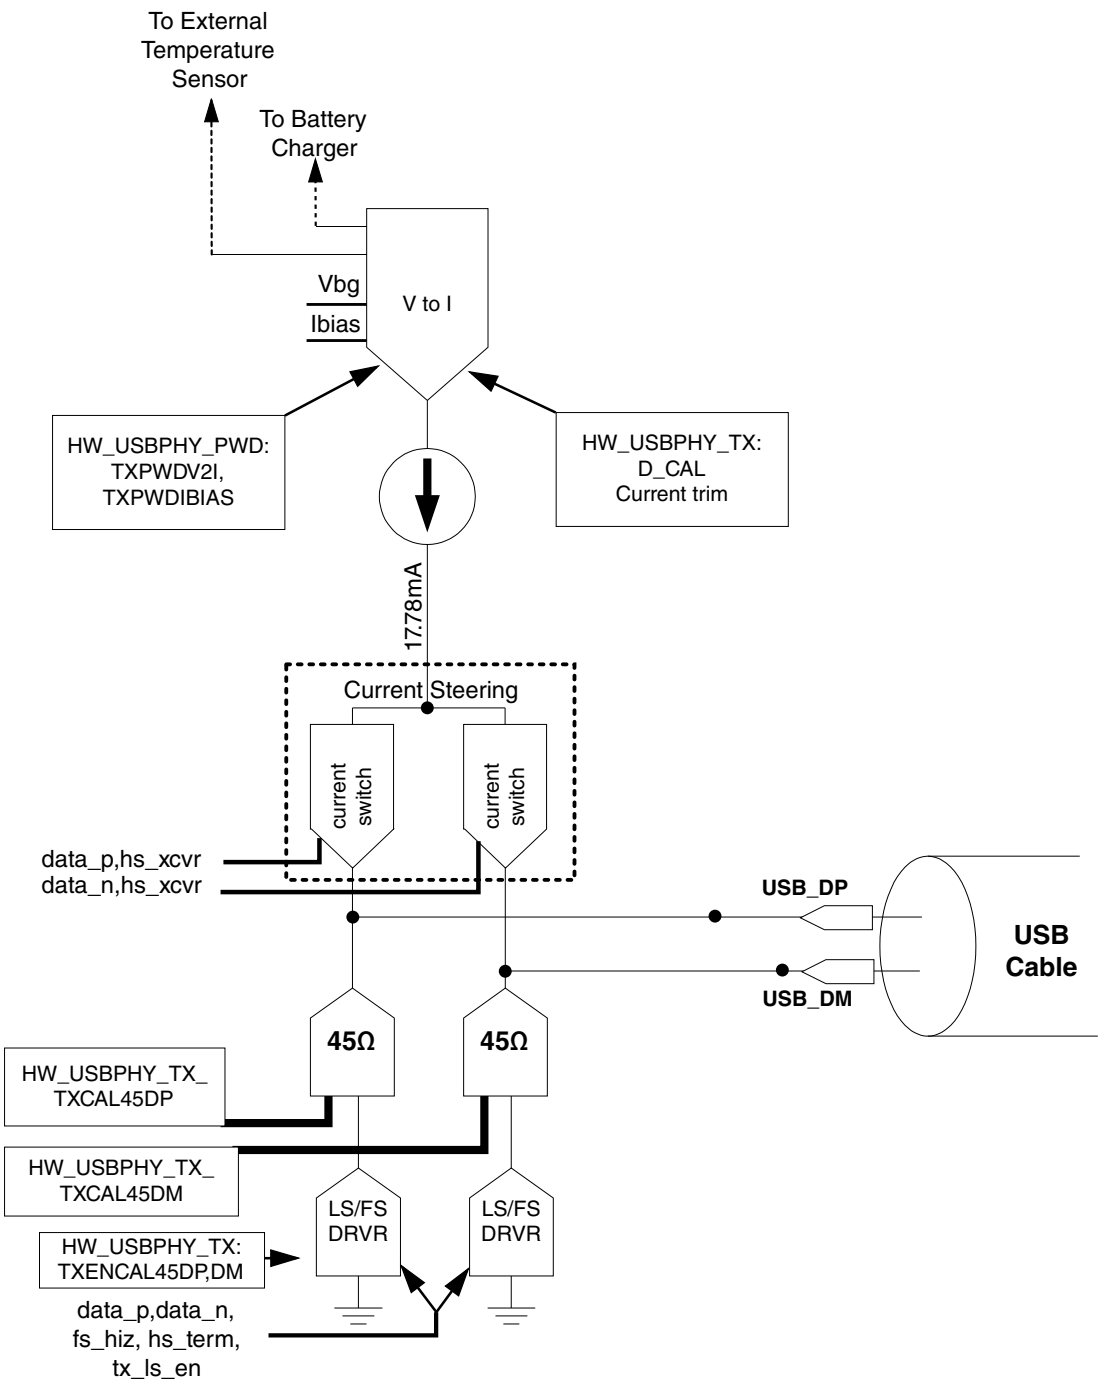

Figure 55-3. USB 2.0 PHY Transmitter Block Diagram

55.3.7 Recommended Register Configuration for USB Certification

The USB HS PHY has programmability to adjust several transceiver parameters.

- The TX HS driver termination impedance/FS driver output impedance and HS driver output currents can be adjusted through bit fields of the USBPHY_TX register. The ability to override the default parametric trim bit fields using the USBPHY_TX register has to be enabled by setting bit fields in the USBPHY_TRIM_OVERRIDE register.
- The HS RX thresholds for the Envelope Detector/Squelch comparator and the Host Disconnect comparator can be adjusted through bit fields of the USBPHY_RX register.

The default values of the bit fields for the transceiver parametric trims are centered with no changes needed for USB Certification testing when the product is used with boards optimized for signal integrity on the HS USB port.

In other cases, such as when external components are inserted between the USB DP/DM pins and the USB connector or other compromises are made on USB DP/DM signal routing, changes to the parametric trim bit fields may be useful.

55.4 USB PHY Memory Map/Register Definition

USBPHY Hardware Register Format Summary

Information for using the Set, Clear, Toggle register features is located in the **Register Macro Usage** section later in this chapter.

USBPHY memory map

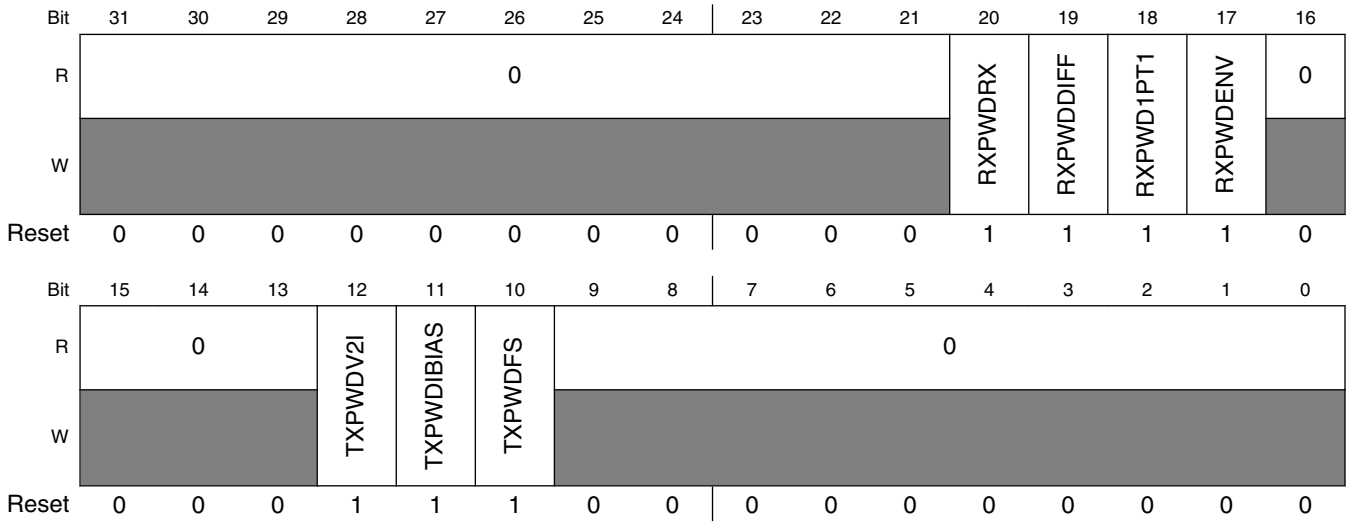
55.4.1 USB PHY Power-Down Register (USBPHY_PWD*n*)

The USB PHY Power-Down Register provides overall control of the PHY power state.

Before programming this register, the PHY clocks must be enabled in the USBPHY_CTRL and USBPHY_PLL_SIC registers.

Address: 4035_0000h base + 0h offset + (4d × i), where i=0d to 3d



USBPHY_PWD*n* field descriptions

Field	Description
31–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 RXPWDRX	This bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHY_CTRL is enabled. 0 Normal operation 1 Power-down the entire USB PHY receiver block except for the full-speed differential receiver
19 RXPWDDIFF	Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHY_CTRL is enabled. 0 Normal operation. 1 Power-down the USB high-speed differential receiver
18 RXPWD1PT1	Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHY_CTRL is enabled. 0 Normal operation 1 Power-down the USB full-speed differential receiver.
17 RXPWDENV	Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHY_CTRL is enabled. 0 Normal operation. 1 Power-down the USB high-speed receiver envelope detector (squelch signal)
16–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 TXPWDV2I	Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHY_CTRL is enabled. Note that these circuits are shared with the battery charge circuit. Setting this to 1 does not power-down these circuits, unless the corresponding bit in the battery charger is also set for power-down.

Table continues on the next page...

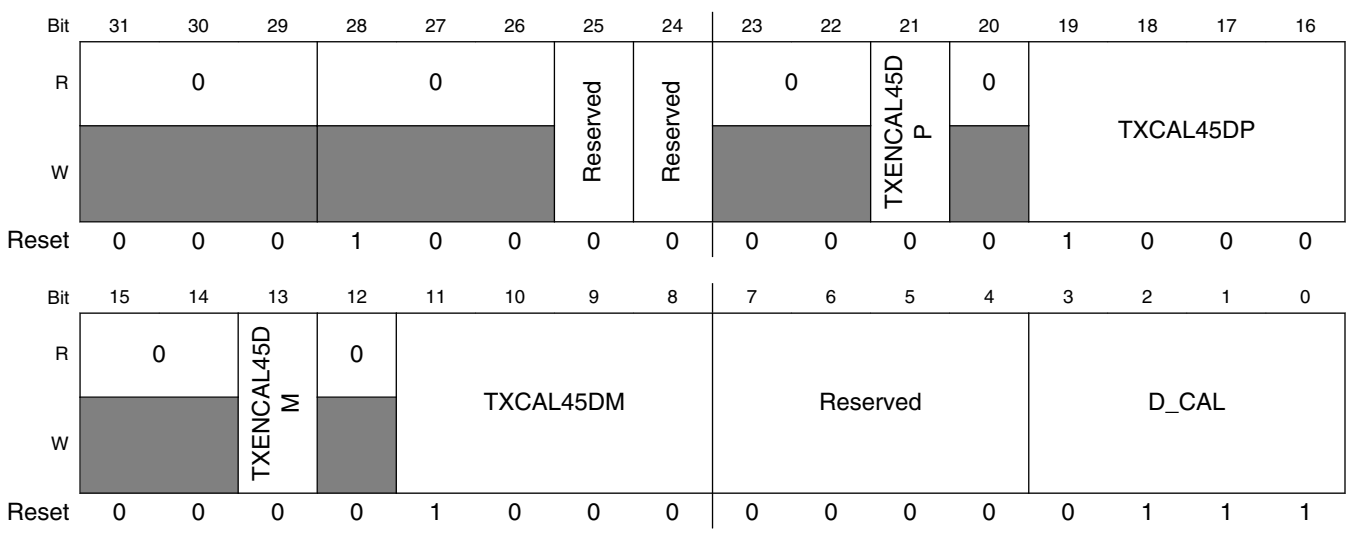
USBPHY_PWD*n* field descriptions (continued)

Field	Description
	0 Normal operation. 1 Power-down the USB PHY transmit V-to-I converter and the current mirror
11 TXPWDIBIAS	Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHY_CTRL is enabled. Note that these circuits are shared with the battery charge circuit. Setting this bit to 1 does not power-down these circuits, unless the corresponding bit in the battery charger is also set for power-down. 0 Normal operation 1 Power-down the USB PHY current bias block for the transmitter. This bit should be set only when the USB is in suspend mode. This effectively powers down the entire USB transmit path
10 TXPWDFS	Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHY_CTRL is enabled. 0 Normal operation. 1 Power-down the USB full-speed drivers. This turns off the current starvation sources and puts the drivers into high-impedance output
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

55.4.2 USB PHY Transmitter Control Register (USBPHY_TX*n*)

The USB PHY Transmitter Control Register handles the transmit controls.

Address: 4035_0000h base + 10h offset + (4d × i), where i=0d to 3d



USBPHY_TX*n* field descriptions

Field	Description
31–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 Reserved	This field is reserved. This bit field must remain at value 1'b0.
24 Reserved	This field is reserved. This bit field must remain at value 1'b0.
23–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 TXENCAL45DP	Enable resistance calibration on DP.
20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–16 TXCAL45DP	Decode to trim the nominal 45Ω series termination resistance to the USB_DP output pin. Maximum resistance = 0000. Resistance is centered by design at 1000. Trimming this resistance will impact both the overshoot/undershoot of the Full Speed TX output and the amplitude of the High Speed TX output. 0000 +19.95% 0001 +17.35% 0010 +14.85% 0011 +12.46% 0100 +9.07% 0101 +5.87% 0110 +2.85% 0111 0% 1000 -2.70% 1001 -5.25% 1010 -7.67% 1011 -9.98% 1100 -12.17% 1101 -14.25% 1110 -18.14% 1111 -21.68%
15–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 TXENCAL45DM	Enable resistance calibration on DM.
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–8 TXCAL45DM	Decode to trim the nominal 45Ω series termination resistance to the USB_DM output pin. Maximum resistance = 0000. Resistance is centered by design at 1000.

Table continues on the next page...

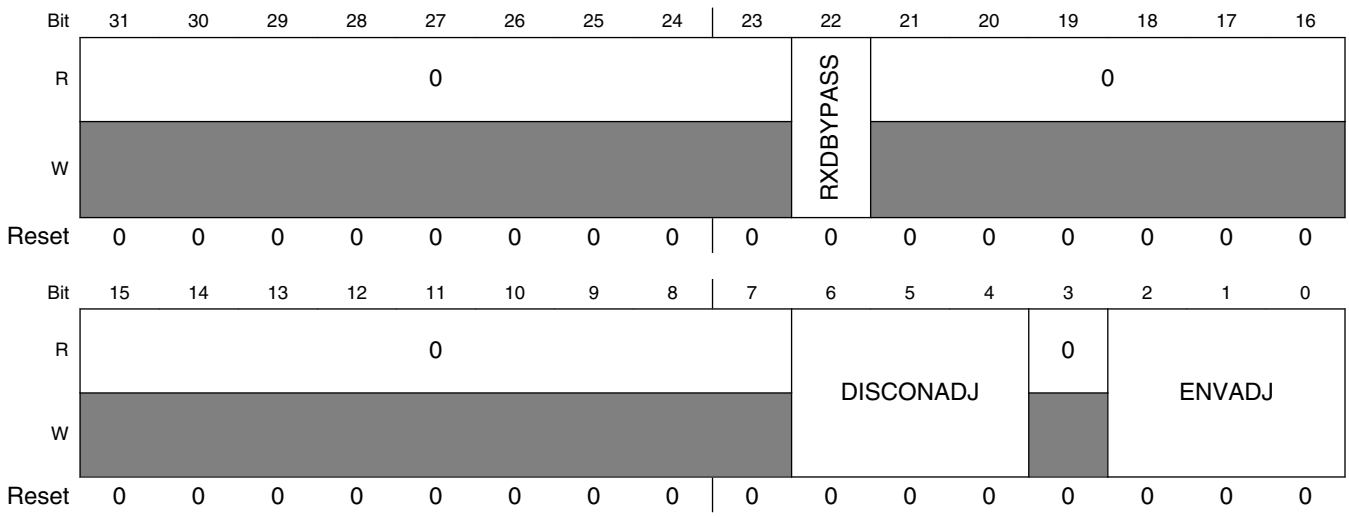
USBPHY_TX*n* field descriptions (continued)

Field	Description
	Trimming this resistance will impact both the overshoot/undershoot of the Full Speed TX output and the amplitude of the High Speed TX output. 0000 +19.95% 0001 +17.35% 0010 +14.85% 0011 +12.46% 0100 +9.07% 0101 +5.87% 0110 +2.85% 0111 0% 1000 -2.70% 1001 -5.25% 1010 -7.67% 1011 -9.98% 1100 -12.17% 1101 -14.25% 1110 -18.14% 1111 -21.68%
7–4 Reserved	This field is reserved. Reserved. **Note:** This bit should remain clear.
D_CAL	Decode to trim the nominal 17.78mA current source for the High Speed TX drivers on USB_DP and USB_DM. This current is directly proportional to the amplitude of the High Speed TX eye diagram. 0000 Maximum current, approximately 19% above nominal. 0111 Nominal 1111 Minimum current, approximately 19% below nominal.

55.4.3 USB PHY Receiver Control Register (USBPHY_RX*n*)

The USB PHY Receiver Control Register handles receive path controls.

Address: 4035_0000h base + 20h offset + (4d × i), where i=0d to 3d



USBPHY_RX*n* field descriptions

Field	Description
31–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 RXDBYPASS	This test mode is intended for lab use only, replace FS differential receiver with DP single ended receiver. 0 Normal operation. 1 Use the output of the USB_DP single-ended receiver in place of the full-speed differential receiver
21–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–4 DISCONADJ	The DISCONADJ field adjusts the trip point for the disconnect detector. 000 Trip-Level Voltage is 0.56875 V 001 Trip-Level Voltage is 0.55000 V 010 Trip-Level Voltage is 0.58125 V 011 Trip-Level Voltage is 0.60000 V 1XX Reserved
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
ENVADJ	The ENVADJ field adjusts the trip point for the envelope detector. Values shown below are nominal DC settings to indicate effect of changing these bits. AC values measured during compliance testing will be somewhat higher. 000 Trip-Level Voltage is 0.1000 V 001 Trip-Level Voltage is 0.1125 V

Table continues on the next page...

USBPHY_RX*n* field descriptions (continued)

Field	Description
	010 Trip-Level Voltage is 0.1250 V 011 Trip-Level Voltage is 0.0875 V 1XX Reserved

55.4.4 USB PHY General Control Register (USBPHY_CTRL*n*)

The USB PHY General Control Register handles OTG and Host controls. This register also includes interrupt enables and connectivity detect enables and results.

Address: 4035_0000h base + 30h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

USBPHY_CTRL*n* field descriptions

Field	Description
31 SFTRST	Writing a 1 to this bit will soft-reset the USBPHY_PWD, USBPHY_TX, USBPHY_RX, and USBPHY_CTRL registers. Set to 0 to release the PHY from reset.
30 CLKGATE	Gate UTMI Clocks. Clear to 0 to run clocks. Set to 1 to gate clocks. Set this to save power while the USB is not actively being used. Configuration state is kept while the clock is gated. Note this bit can be auto-cleared if there is any wakeup event when USB is suspended while ENAUTOCLR_CLKGATE bit of USBPHY_CTRL is enabled.
29 UTMI_SUSPENDM	Used by the PHY to indicate a powered-down state. If all the power-down bits in the USBPHY_PWD are enabled, UTMI_SUSPENDM will be 0, otherwise 1 when USB controller entering into Suspend mode. UTMI_SUSPENDM is negative logic, as required by the UTMI specification.
28 HOST_FORCE_LS_SE0	Forces the next FS packet that is transmitted to have a EOP with low-speed timing. This bit is used in host mode for the resume sequence. After the packet is transferred, this bit is cleared. The design can use this function to force the LS SE0 or use the USBPHY_CTRL_UTMI_SUSPENDM to trigger this event when leaving suspend. This bit is used in conjunction with USBPHY_DEBUG_HOST_RESUME_DEBUG.
27 OTG_ID_VALUE	Indicates the results of USB_ID pin while monitoring the cable plugged into the Micro- or Mini-AB receptacle. False (0) is when ID resistance is less than Ra_Plug_ID, indicating host (A) side. True (1) is when ID resistance is greater than Rb_Plug_ID, indicating device (B) side. Similar to the function of the OTGID_STATUS bit in the USBPHY_STATUS register, but OTG_ID_VALUE has debounce and system clock synchronization logic to filter the glitches on the USB_ID pad.
26 Reserved	Reserved This field is reserved. This bit field has no effect for this module.
25 Reserved	Reserved This field is reserved. This bit field has no effect for this module.
24 FSDLL_RST_EN	Enables the feature to reset the FSDLL lock detection logic at the end of each TX packet.
23 Reserved	This field is reserved. This bit field has no effect for this module. This bit field must remain at value 1'b0.
22 Reserved	This field is reserved. This bit field has no effect for this module. This bit field must remain at value 1'b0.
21 Reserved	This field is reserved. This bit field must remain at value 1'b0.
20 ENAUTOCLR_PHY_PWD	Enables the feature to auto-clear the PWD register bits in USBPHY_PWD if there is wakeup event while USB is suspended. This should be enabled if needed to support auto wakeup without software interaction.
19 ENAUTOCLR_CLKGATE	Enables the feature to auto-clear the CLKGATE bit if there is wakeup event while USB is suspended. This should be enabled if needed to support auto wakeup without software interaction.

Table continues on the next page...

USBPHY_CTRL*n* field descriptions (continued)

Field	Description
18 AUTORESUME_EN	Enable the auto resume feature, when set, HW will use 32KHz clock to send Resume to respond to the device remote wakeup(for host mode only). It's useful when PLL is off and reference clock is also powered down.
17 Reserved	This field is reserved. This bit field has no effect for this module.
16 Reserved	This field is reserved. This bit field has no effect for this module.
15 ENUTMILEVEL3	Enables UTMI+ Level 3 operation for the USB HS PHY. This should be enabled if an Embedded Host use case needs to support an external FS Hub with a LS device connected.
14 ENUTMILEVEL2	Enables UTMI+ Level 2 operation for the USB HS PHY. This should be enabled if an Embedded Host use case needs to support a LS device.
13 Reserved	This field is reserved. This bit field must remain at value 1'b0.
12 DEVPLUGIN_IRQ	Indicates that the device is connected. Reset this bit by writing a 1 to the SCT clear address space and not by a general write.
11 Reserved	This field is reserved. This bit field has no effect for this module.
10 Reserved	This field is reserved. This bit field has no effect for this module.
9 Reserved	This field is reserved. This bit field has no effect for this module.
8 Reserved	This field is reserved. This bit field has no effect for this module.
7 Reserved	This field is reserved. This bit field has no effect for this module. This bit field must remain at value 1'b0.
6 Reserved	This field is reserved. This bit field has no effect for this module.
5 Reserved	This field is reserved. This bit field has no effect for this module.
4 ENDEVPLUGINDET	Enables non-standard resistive plugged-in detection This bit field controls connection of nominal 200kΩ resistors to both the USB_DP and USB_DM pins as one method of detecting when a USB cable is attached in device mode. This bit field must remain at a value of 1'b0 for normal USB data communication, or when using the USBHSDCD module for battery charger detection per the *USB Battery Charger Specification Revision 1.2* or any other detection mechanism for USB cable plugin. The results of this detection method are reported in USBPHY_STATUS[6]. 0 Disables 200kΩ pullup resistors on USB_DP and USB_DM pins (Default) 1 Enables 200kΩ pullup resistors on USB_DP and USB_DM pins
3 HOSTDISCONDETECT_IRQ	Indicates that the device has disconnected in High-Speed mode. Reset this bit by writing a 1 to the SCT clear address space and not by a general write.
2 Reserved	This field is reserved. This bit field has no effect for this module.

Table continues on the next page...

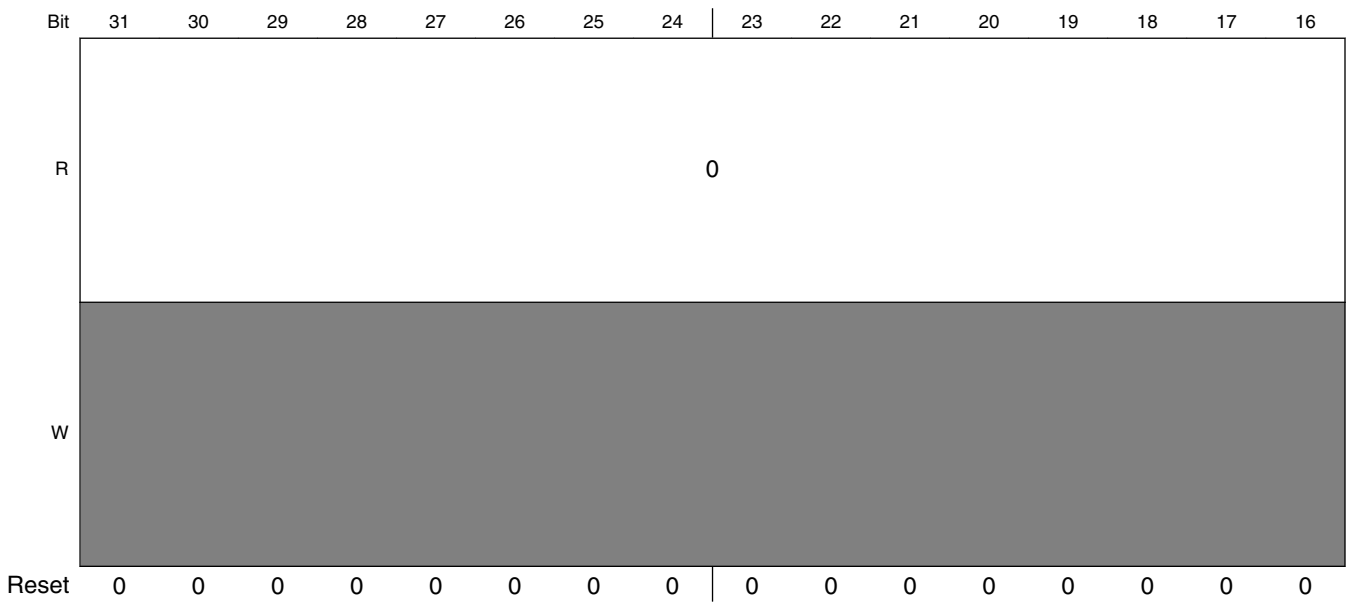
USBPHY_CTRL*n* field descriptions (continued)

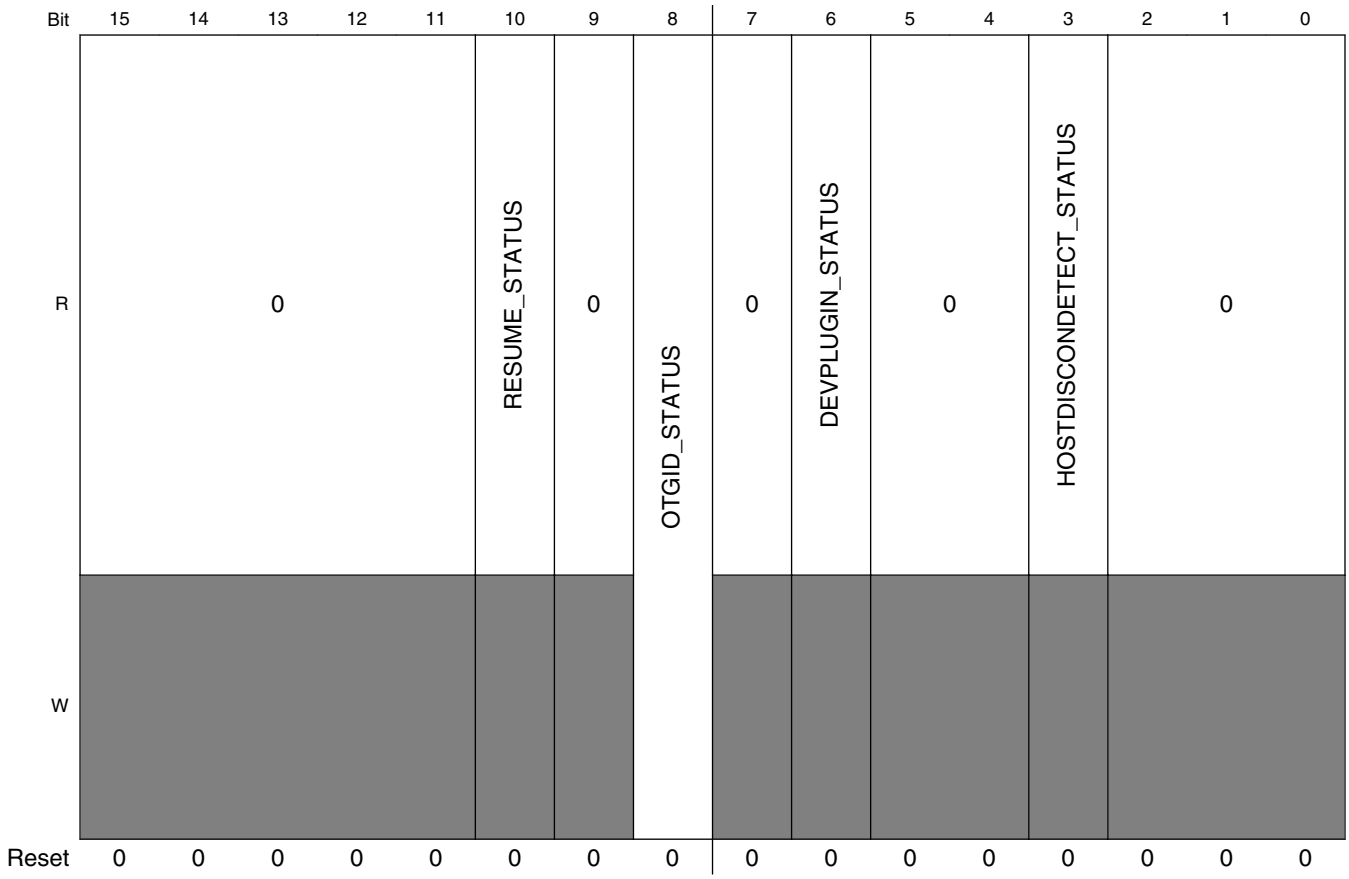
Field	Description
1 ENHOSTDISCONDETECT	For host mode, enables high-speed disconnect detector. This signal allows the override of enabling the detection that is normally done in the UTMI controller. The UTMI controller enables this circuit whenever the host sends a start-of-frame packet. It shall be set after HS device is connected.
0 Reserved	This field is reserved. This bit field has no effect for this module.

55.4.5 USB PHY Status Register (USBPHY_STATUS)

The USB PHY Status Register holds results of IRQ and other detects.

Address: 4035_0000h base + 40h offset = 4035_0040h





USBPHY_STATUS field descriptions

Field	Description
31–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 RESUME_STATUS	Indicates that the host is sending a wake-up after Suspend and has triggered an interrupt.
9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 OTGID_STATUS	Indicates the results of USB_ID pin on the USB cable plugged into the local Micro- or Mini-AB receptacle. False (0) is when ID resistance to ground is less than Ra_Plug_ID, indicating host (A) side. True (1) is when ID resistance is greater than Rb_Plug_ID, indicating device (B) side.
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 DEVPLUGIN_STATUS	Status indicator for non-standard resistive plugged-in detection Indicates that the device has been connected on the USB_DP and USB_DM lines using the non-standard resistive plugged-in detection method controlled by USBPHY_CTRL[4]. When a USB cable attached to a remote host is attached to the local device, the 15kΩ host pulldowns will override the high value resistors used in this detection method.

Table continues on the next page...

USBPHY_STATUS field descriptions (continued)

Field	Description
	0 No attachment to a USB host is detected 1 Cable attachment to a USB host is detected
5–4 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
3 HOSTDISCONDETECT_STATUS	Indicates at the local host (downstream) port that the remote device has disconnected while in High-Speed mode. 0 USB cable disconnect has not been detected at the local host 1 USB cable disconnect has been detected at the local host
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

55.4.6 USB PHY Debug Register 0 (USBPHY_DEBUG0*n*)

This register is used to debug the USB PHY.

Address: 4035_0000h base + 50h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	CLKGATE	HOST_RESUME_DEBUG	SQUELCHRESETLENGTH				ENSQUELCHRESET	0			SQUELCHRESETCOUNT				
W																
Reset	0	1	1	1	1	1	1	1	0	0	0	1	1	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0			ENTX2RXCOUNT	TX2RXCOUNT				0		ENHSTPULLDOWN	HSTPULLDOWN			DEBUG_INTERFACE_HOLD	OTGIDPIOLOCK
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

USBPHY_DEBUG0*n* field descriptions

Field	Description
31 Reserved	Reserved This field is reserved.

Table continues on the next page...

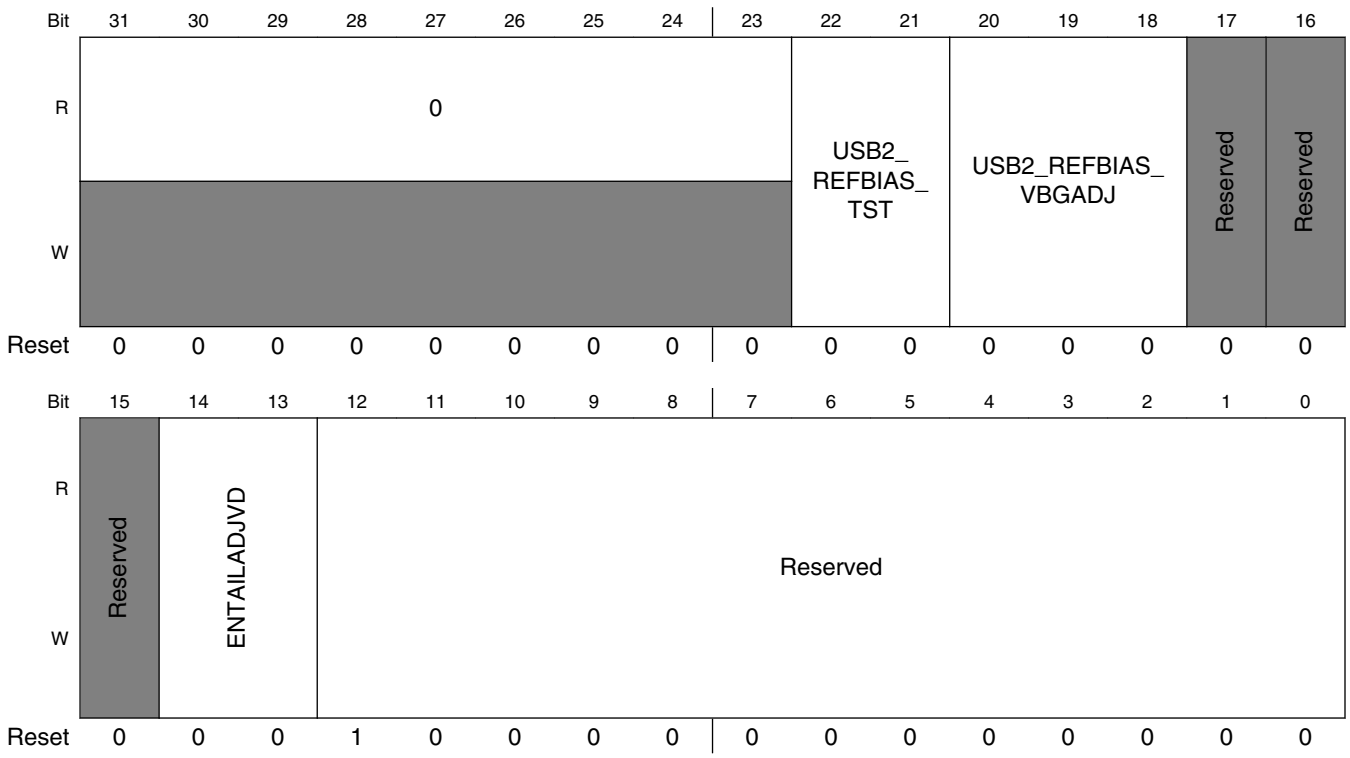
USBPHY_DEBUG0*n* field descriptions (continued)

Field	Description
	This read-only field is reserved and always has the value 0.
30 CLKGATE	Gate Test Clocks. Clear to 0 for running clocks. Set to 1 to gate clocks. Set this to save power while the USB is not actively being used. Configuration state is kept while the clock is gated.
29 HOST_RESUME_DEBUG	Choose to trigger the host resume SE0 with HOST_FORCE_LS_SE0 = 0 or UTMI_SUSPEND = 1.
28–25 SQUELCHRESETLENGTH	Duration of RESET in terms of the number of 480-MHz cycles.
24 ENSQUELCHRESET	Set bit to allow squelch to reset high-speed receive.
23–21 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
20–16 SQUELCHRESETCOUNT	Delay in between the detection of squelch to the reset of high-speed RX.
15–13 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
12 ENTX2RXCOUNT	Set this bit to allow a countdown to transition in between TX and RX.
11–8 TX2RXCOUNT	Delay in between the end of transmit to the beginning of receive. This is a Johnson count value and thus will count to 8.
7–6 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
5–4 ENHSTPULLDOWN	This bit field selects host pulldown overdrive mode. Set bit 5 to value 1'b1 to override the control of the USB_DP 15kΩ pulldown. Set bit 4 to value 1'b1 to override the control of the USB_DM 15Ω pulldown. Clear both bits to value 2'b00 to disable the host pulldown overdrive mode. When in host pulldown overdrive mode, the connection of the individual pulldown resistors is further controlled by the USBPHY_DEBUG[3:2] bit field.
3–2 HSTPULLDOWN	This bit field selects whether to connect pulldown resistors on the USB_DP/USB_DM pins if the corresponding pulldown overdrive mode is enabled through USBPHY_DEBUG[5:4} Set bit 3 to value 1'b1 to connect the 15Ω pulldown on USB_DP line. Set bit 2 to value 1'b1 to connect the 15Ω pulldown on the USB_DM line. Clear both bits to value 2'b00 to disconnect the pulldowns in override mode.
1 DEBUG_INTERFACE_HOLD	Use holding registers to assist in timing for external UTMI interface.
0 OTGIDPIOLOCK	Once OTG ID from USBPHY_STATUS_OTGID_STATUS is sampled, use this to hold the value. This is to save power for the comparators that are used to determine the ID status.

55.4.7 UTMI Debug Status Register 1 (USBPHY_DEBUG1*n*)

Chooses the muxing of the debug register to be shown in USBPHYx_DEBUG0_STATUS.

Address: 4035_0000h base + 70h offset + (4d × i), where i=0d to 3d



USBPHY_DEBUG1*n* field descriptions

Field	Description
31–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–21 USB2_ REFBIAS_TST	Bias current control for usb2_phy
20–18 USB2_ REFBIAS_ VBGADJ	Adjustment bits on bandgap
17 Reserved	This field is reserved. This field is unimplemented and not for use. This bit field must remain at value 1'b0.
16 Reserved	This field is reserved. This field is unimplemented and not for use. This bit field must remain at value 1'b0.

Table continues on the next page...

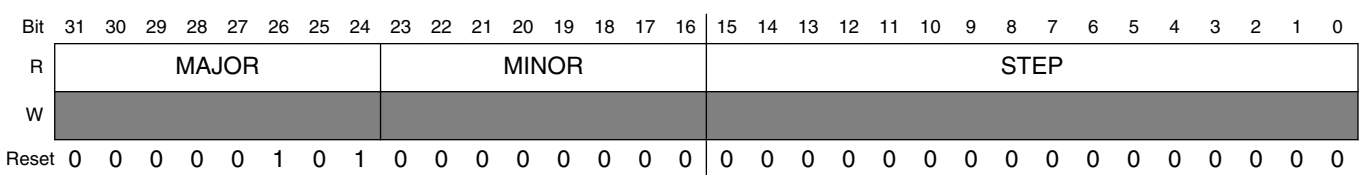
USBPHY_DEBUG1*n* field descriptions (continued)

Field	Description
15 Reserved	This field is reserved. This field is unimplemented and not for use. This bit field must remain at value 1'b0.
14–13 ENTAILADJVD	Delay increment of the rise of squelch: 00 Delay is nominal 01 Delay is +20% 10 Delay is -20% 11 Delay is -40%
Reserved	Reserved This field is reserved. This bit should remain clear.

55.4.8 UTMI RTL Version (USBPHY_VERSION)

Fields for RTL Version.

Address: 4035_0000h base + 80h offset = 4035_0080h



USBPHY_VERSION field descriptions

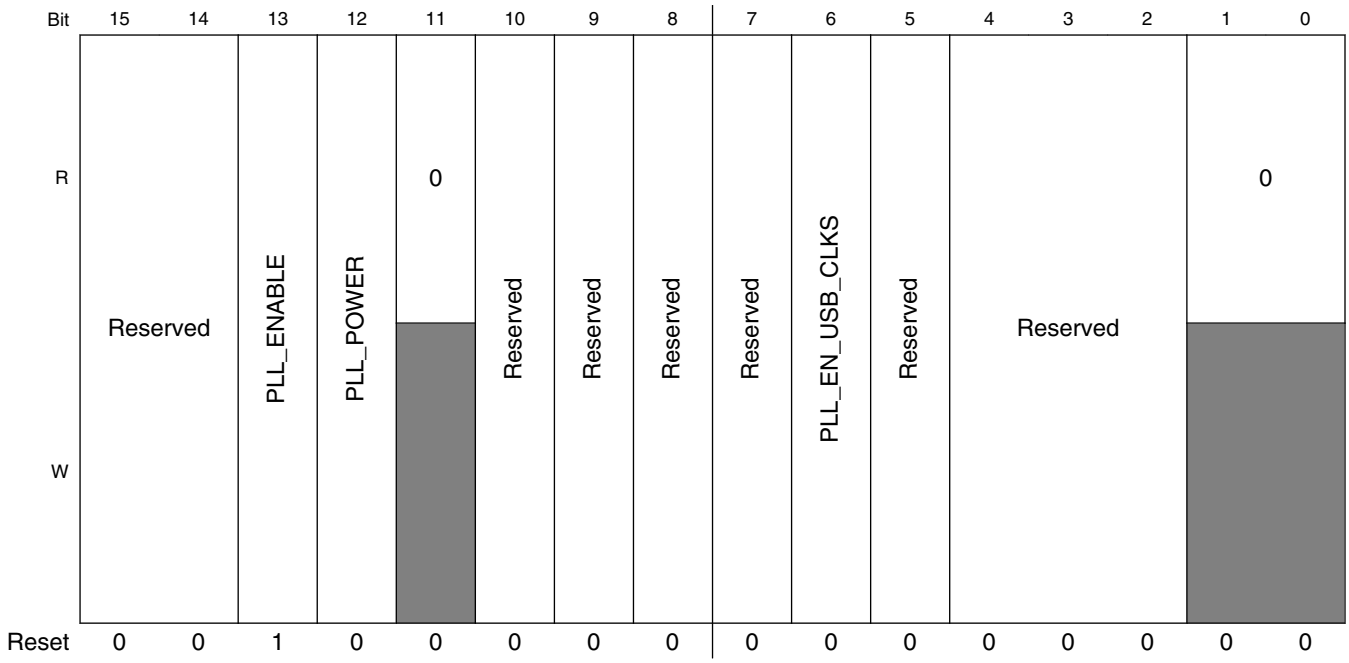
Field	Description
31–24 MAJOR	Fixed read-only value reflecting the MAJOR field of the RTL version
23–16 MINOR	Fixed read-only value reflecting the MINOR field of the RTL version
STEP	Fixed read-only value reflecting the stepping of the RTL version.

55.4.9 USB PHY PLL Control/Status Register (USBPHY_PLL_SIC*n*)

This register configures the 480 MHz USB PHY PLL.

Address: 4035_0000h base + A0h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	PLL_LOCK	0						PLL_DIV_SEL			PLL_REG_ENABLE	REFBIAS_PWD	REFBIAS_PWD_SEL	0	Reserved	PLL_BYPASS
W																
Reset	0	0	0	0	0	0	0	0	1	1	0	1	0	0	0	1



USBPHY_PLL_SIC*n* field descriptions

Field	Description
31 PLL_LOCK	USB PLL lock status indicator 0 PLL is not currently locked 1 PLL is currently locked
30–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–22 PLL_DIV_SEL	This field controls the USB PLL feedback loop divider. Valid range for divider values: 13-240. Fout = Fin * div_select. The USB PLL is designed to produce a 480 MHz output clock. This bit field allows use of different frequency signals for the PLL reference clock input connected to the OSCCLK signal from the system oscillator. When override is enabled through USBPHY_TRIM_OVERRIDE_EN[0], the USB PLL will use this register value. 000 Divide by 13 001 Divide by 15 010 Divide by 16 011 Divide by 20 100 Divide by 22 101 Divide by 25 110 Divide by 30 111 Divide by 240
21 PLL_REG_ENABLE	This field controls the USB PLL regulator, set to enable the regulator. SW must set this bit 15 us before settiing PLL_POWER to avoid glitches on PLL output clock.
20 REFBIAS_PWD	Power down the reference bias This bit is only used when REFBIAS_PWD_SEL is set to 1.

Table continues on the next page...

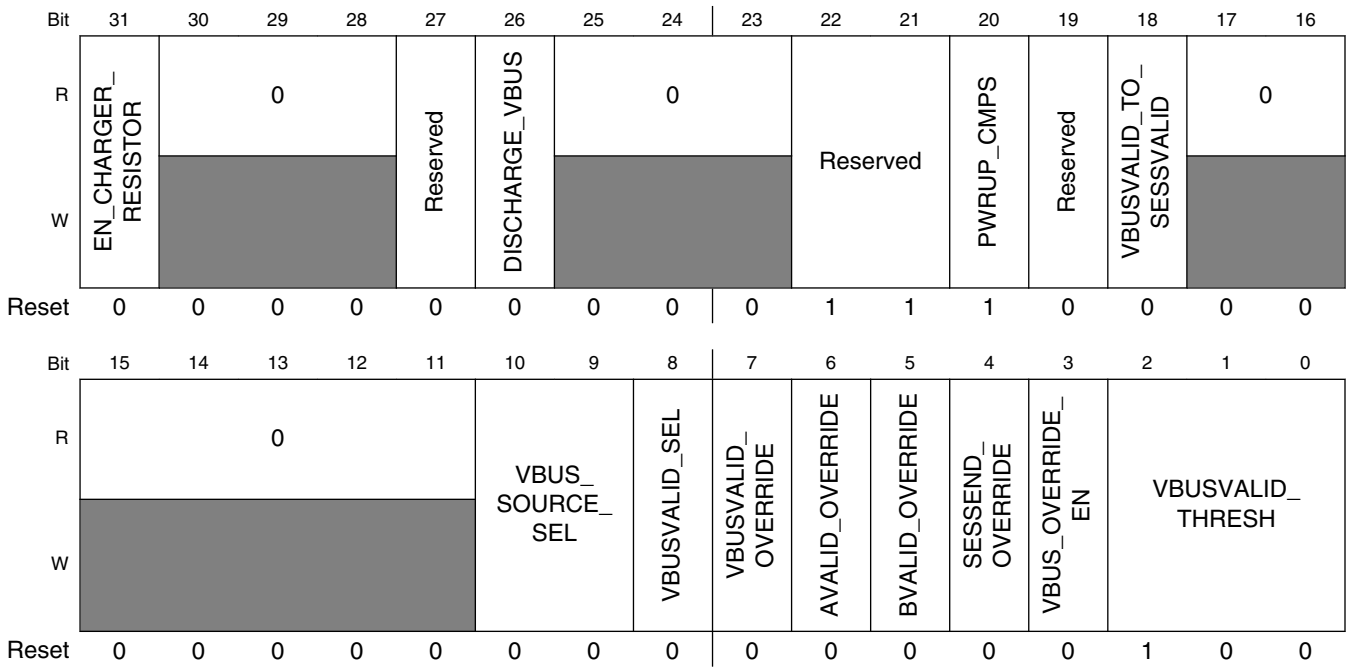
USBPHY_PLL_SIC*n* field descriptions (continued)

Field	Description
19 REFBIAS_PWD_SEL	Reference bias power down select. 0 Selects PLL_POWER to control the reference bias 1 Selects REFBIAS_PWD to control the reference bias.
18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 Reserved	This field is reserved.
16 PLL_BYPASS	Bypass the USB PLL.
15–14 Reserved	This field is reserved. This bit field has no effect for this module.
13 PLL_ENABLE	Enables the clock output from the USB PLL. The real PLL output enable signal is also controlled by PLL power up control. Hardware will disable the PLL output before power down PLL, and enable the PLL output after power up PLL. The software only needs to set it when initializing the PLL.
12 PLL_POWER	Power up the USB PLL. The real PLL power up is also controlled by hardware. Hardware will power down PLL when USB is suspended and the device doesn't use it.
11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 Reserved	This field is reserved. This bit field must remain at value 1'b0.
9 Reserved	This field is reserved. This bit field must remain at value 1'b0.
8 Reserved	This field is reserved. This bit field must remain at value 1'b0.
7 Reserved	This field is reserved. This bit field must remain at value 1'b0.
6 PLL_EN_USB_CLKS	Enables the USB clock from PLL to USB PHY
5 Reserved	This field is reserved. This bit field must remain at value 1'b0.
4–2 Reserved	This field is reserved. This bit field has no effect for this module.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

55.4.10 USB PHY VBUS Detect Control Register (USBPHY_USB1_VBUS_DETECT*n*)

This register defines controls for USB VBUS detect and some additional out of band signaling functions.

Address: 4035_0000h base + C0h offset + (4d × i), where i=0d to 3d



USBPHY_USB1_VBUS_DETECT*n* field descriptions

Field	Description
31 EN_CHARGER_RESISTOR	Enables resistors used for an older method of resistive battery charger detection 0 Disable resistive charger detection resistors on USB_DP and USB_DP 1 Enable resistive charger detection resistors on USB_DP and USB_DP
30–28 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
27 Reserved	This field is reserved. This bit field has no effect for this module.
26 DISCHARGE_VBUS	Controls VBUS discharge resistor This bit field controls a nominal 22kΩ resistor between the USB1_VBUS pin and ground. It can be used to accelerate the fall of the VBUS signal at the end of a session.

Table continues on the next page...

USBPHY_USB1_VBUS_DETECT*n* field descriptions (continued)

Field	Description
	0 VBUS discharge resistor is disabled (Default) 1 VBUS discharge resistor is enabled
25–23 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
22–21 Reserved	This field is reserved. This bit field has no effect for this module.
20 PWRUP_CMPS	Enables the VBUS_VALID comparator Powers up the comparator used for the VBUS_VALID detector. This bit field can be reset to value 1'b0 to save power if the internal VBUS_VALID comparator is not used. 0 Powers down the VBUS_VALID comparator 1 Enables the VBUS_VALID comparator (default)
19 Reserved	Reserved This field is reserved. This bit field has no effect for this module.
18 VBUSVALID_ TO_SESSVALID	Selects the comparator used for VBUS_VALID This bit field controls the comparator used to report the VBUS_VALID results in USBPHY_USB1_VBUS_DETECT[3] between the VBUS_VALID comparator and the Session Valid comparator. The VBUS_VALID comparator is the most accurate and has a programmable threshold set by USBPHY_USB_VBUS_DETECT[2:0]. The Session Valid comparator may be useful in systems using non-standard VBUS voltages. The mux selection in this bit field happens before any VBUS_VALID selection controlled by the USBPHY_USB1_VBUS_DETECT[10:8] bits. 0 Use the VBUS_VALID comparator for VBUS_VALID results 1 Use the Session End comparator for VBUS_VALID results. The Session End threshold is >0.8V and <4.0V.
17–11 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
10–9 VBUS_ SOURCE_SEL	Selects the source of the VBUS_VALID signal reported to the USB controller This is one of the bit fields that selects the source of the VBUS_VALID signal reported to the USB controller. The VBUS_VALID source selections in this bit field only take effect if both USBPHY_USB1_VBUS_DETECT[8] and USBPHY_USB1_VBUS_DETECT[3] each have the value 1'b0. This bit field does not impact the VBUS_VALID value reported in USBPHY_USB1_VBUS_DET_STAT[3]. 00 Use the VBUS_VALID comparator results for signal reported to the USB controller (Default) 01 Use the Session Valid comparator results for signal reported to the USB controller 10 Use the Session Valid comparator results for signal reported to the USB controller 11 Reserved, do not use

Table continues on the next page...

USBPHY_USB1_VBUS_DETECT*n* field descriptions (continued)

Field	Description
8 VBUSVALID_ SEL	Selects the source of the VBUS_VALID signal reported to the USB controller This is one of the bit fields that selects the source of the VBUS_VALID signal reported to the USB controller. The VBUS_VALID source selection in this bit field only takes effect if USBPHY_USB1_VBUS_DETECT[3] has the value 1'b0. This bit field does not impact the VBUS_VALID value reported in USBPHY_USB1_VBUS_DET_STAT[3]. 0 Use the VBUS_VALID comparator results for signal reported to the USB controller (Default) 1 Use the VBUS_VALID_3V detector results for signal reported to the USB controller
7 VBUSVALID_ OVERRIDE	Override value for VBUS_VALID signal sent to USB controller The bit field provides the value for VBUS_VALID reported to the USB controller if the value of USBPHY_USB1_VBUS_DETECT[3] is set to 1'b1. The value of this bit field does not affect the value of USBPHY_USB1_VBUS_DET_STAT[3].
6 AVALID_ OVERRIDE	Override value for A-Device Session Valid The bit field provides the value for USBPHY_USB1_VBUS_DET_STAT[2] if USBPHY_USB_VBUS_DETECT[3] is set to value 1'b1.
5 BVALID_ OVERRIDE	Override value for B-Device Session Valid The bit field provides the value for USBPHY_USB1_VBUS_DET_STAT[1] if USBPHY_USB_VBUS_DETECT[3] is set to value 1'b1.
4 SESSEND_ OVERRIDE	Override value for SESSEND The bit field provides the value for USBPHY_USB1_VBUS_DET_STAT[0] if USBPHY_USB_VBUS_DETECT[3] is set to value 1'b1.
3 VBUS_ OVERRIDE_EN	VBUS detect signal override enable This bit field allows SW to override the results from the VBUS_VALID and Session Valid comparators using the values in USBPHY_USB1_VBUS_DETECT[7:4]. The VBUS_VALID, AVALID, BVALID, and SESSEND signals sent to the USB controller are each affected by these bit selections. The values reported for AVALID, BVALID, and SESSEND in USBPHY_USB1_VBUS_DET_STAT[2:0] are also affected but the value reported for VBUS_VALID in USBPHY_USB1_VBUS_DET_STAT[3] is not affected. This override method may be useful if VBUS detection is not done with the internal VBUS_VALID or Session End comparators. 0 Use the results of the internal VBUS_VALID and Session Valid comparators for VBUS_VALID, AVALID, BVALID, and SESSEND (Default) 1 Use the override values for VBUS_VALID, AVALID, BVALID, and SESSEND
VBUSVALID_ THRESH	Sets the threshold for the VBUSVALID comparator. This comparator is the most accurate method to determine the presence of 5v, and includes hystersis to minimize the need for software debounce of the detection. This comparator has ~50mV of hystersis to prevent chattering at the comparator trip point. 000 4.0 V 001 4.1 V 010 4.2 V 011 4.3 V 100 4.4 V (Default)

Table continues on the next page...

USBPHY_USB1_VBUS_DETECT*n* field descriptions (continued)

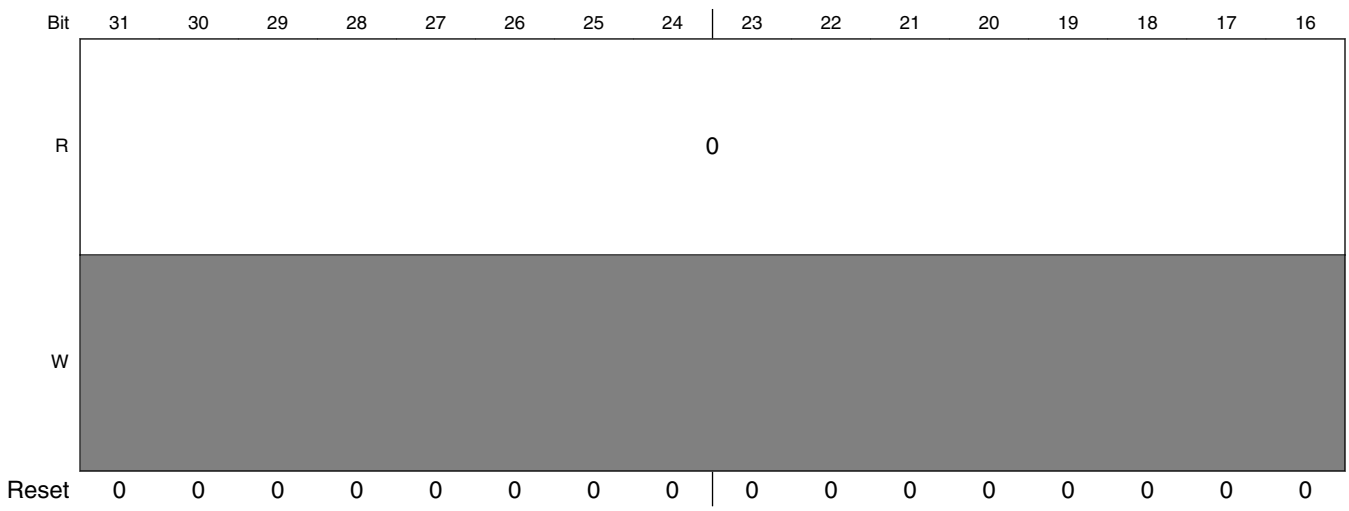
Field	Description
	101 4.5 V 110 4.6 V 111 4.7 V

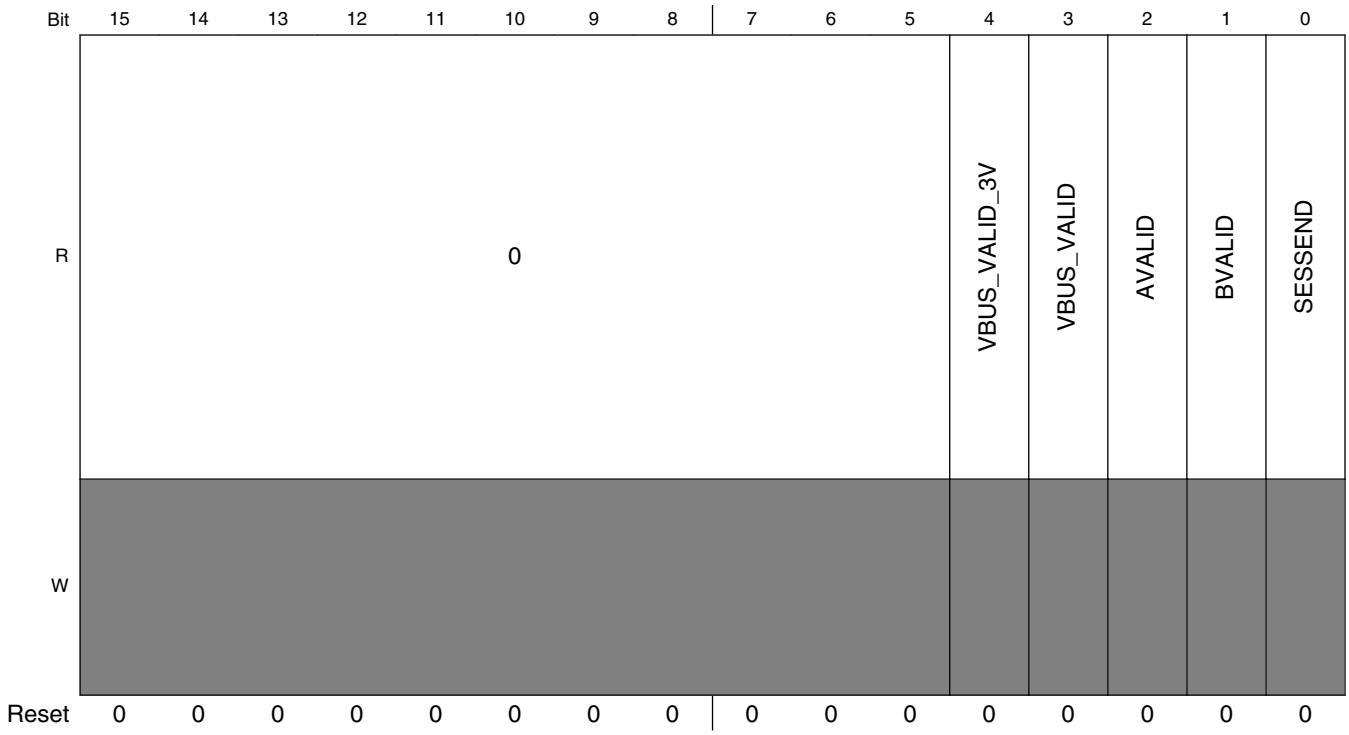
55.4.11 USB PHY VBUS Detector Status Register (USBPHY_USB1_VBUS_DET_STAT)

This register allows observation of status for USB VBUS detect functions.

The values reported in this register are synchronized by the apb_clk.

Address: 4035_0000h base + D0h offset = 4035_00D0h





USBPHY_USB1_VBUS_DET_STAT field descriptions

Field	Description
31–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 VBUS_VALID_3V	VBUS_VALID_3V detector status The VBUS_VALID_3V detector has a lower threshold for the voltage on the USB1_VBUS pin than either the Session Valid or VBUS_VALID comparators. This signal may be useful for applications using a non-standard VBUS voltage. 0 VBUS voltage is below VBUS_VALID_3V threshold 1 VBUS voltage is above VBUS_VALID_3V threshold
3 VBUS_VALID	VBUS voltage status This bit field shows the result of VBUS_VALID detection for the USB1_VBUS pin. The VBUS_VALID comparator used is selected by USBPHY_USB1_VBUS_DETECT[18]. The VBUS_VALID source is not affected by the values of USBPHY_USB1_VBUS_DETECT[7, 3] and cannot be overwritten by SW. 0 VBUS is below the comparator threshold 1 VBUS is above the comparator threshold
2 AVALID	A-Device Session Valid status A-Device Session Valid status, determined by the Session Valid comparator. The default value of this bit is determined by the voltage on the USB1_VBUS pin. This bit can be overwritten by SW using the USBPHY_VBUS_DETECT[6, 3] bit fields.

Table continues on the next page...

USBPHY_USB1_VBUS_DET_STAT field descriptions (continued)

Field	Description
	0 The VBUS voltage is below the Session Valid threshold 1 The VBUS voltage is above the Session Valid threshold
1 BVALID	B-Device Session Valid status B-Device Session Valid status, determined by the Session Valid comparator. The default value of this bit is determined by the voltage on the USB1_VBUS pin. This bit can be overwritten by SW using the USBPHY_VBUS_DETECT[5, 3] bit fields. 0 The VBUS voltage is below the Session Valid threshold 1 The VBUS voltage is above the Session Valid threshold
0 SESSEND	Session End indicator Session End status, value inverted from Session Valid comparator. The default value of this bit is determined by the voltage on the USB1_VBUS pin. This bit can be overwritten by SW using the USBPHY_VBUS_DETECT[4, 3] bit fields. 0 The VBUS voltage is above the Session Valid threshold 1 The VBUS voltage is below the Session Valid threshold

55.4.12 USB PHY Charger Detect Control Register (USBPHY_USB1_CHRG_DETECT*n*)

This register defines controls for USB Battery Charging detection functions.

Address: 4035_0000h base + E0h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0								BGR_ IBIAS	0						
W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0													PULLUP_DP	Reserved	Reserved
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

USBPHY_USB1_CHRG_DETECT*n* field descriptions

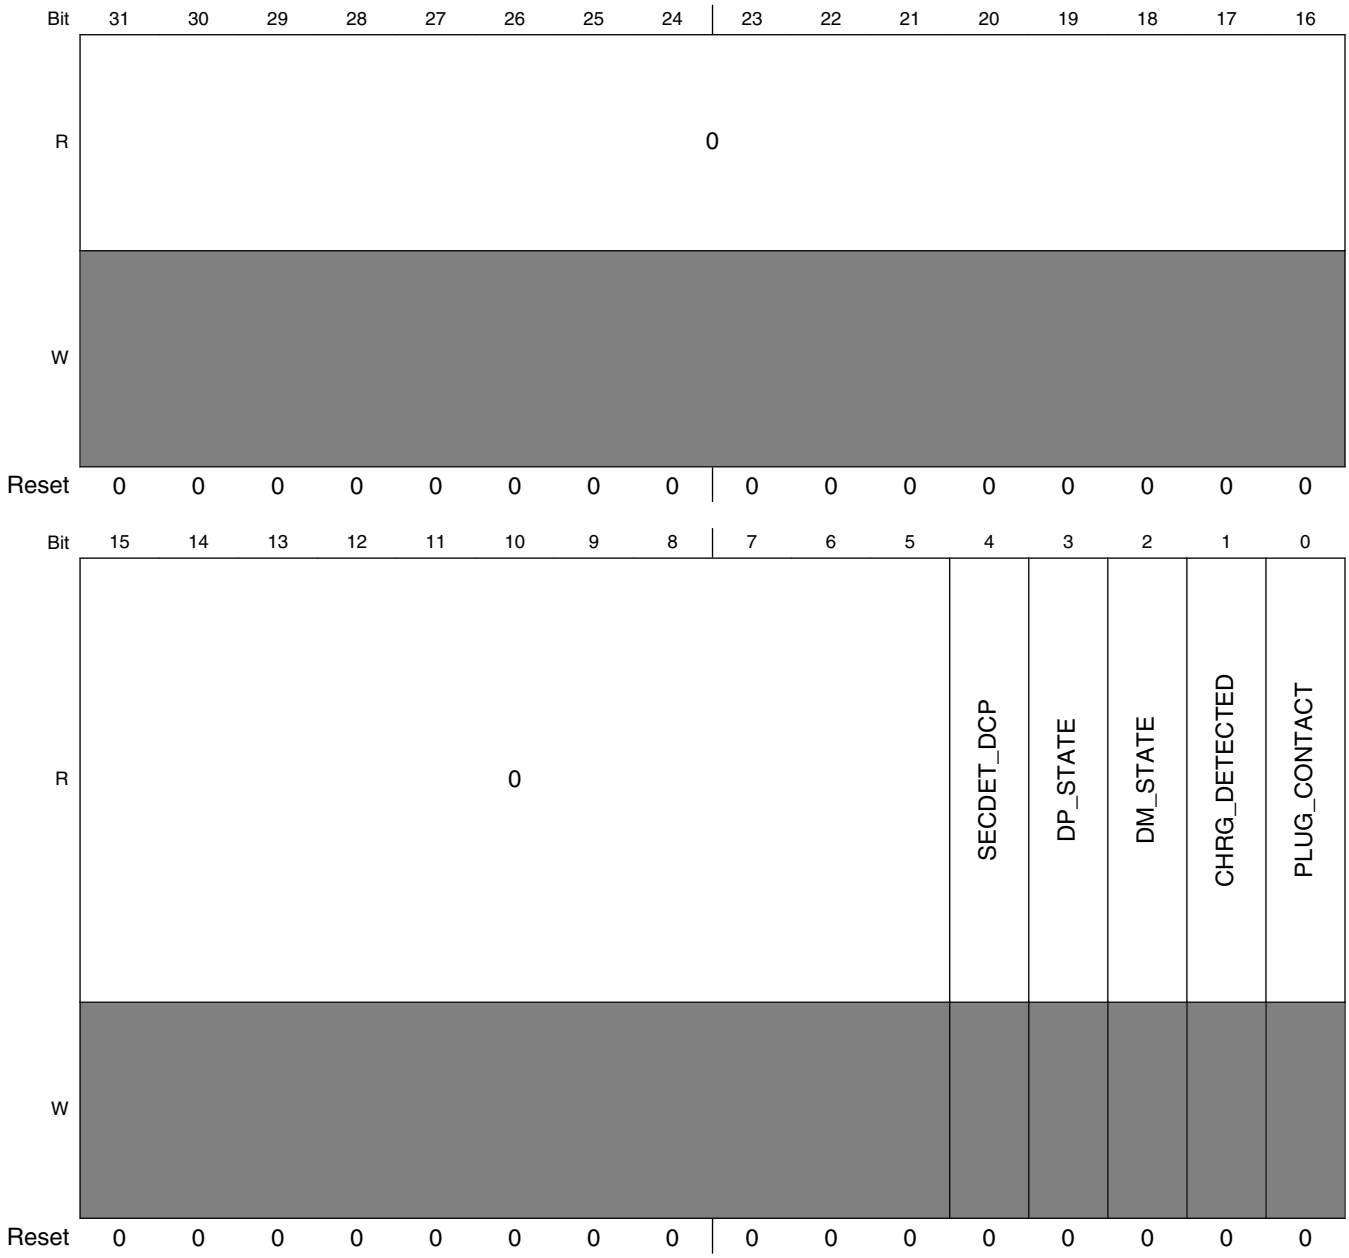
Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 BGR_IBIAS	USB charge detector bias current reference This bit determines the reference for the bias current of the USB charge detector. This bit should always be set to 1. 0 Bias current is derived from the USB PHY internal current generator. 1 Bias current is derived from the reference generator of the bandgap.
22–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 PULLUP_DP	This bit is used to pull up DP, for digital charge detect.
1 Reserved	This field is reserved. This bit field has no effect for this module.
0 Reserved	This field is reserved. This bit field was named FORCE_DETECT on other products. The signal from this bit field has no useful function on this product. The bit field must remain at value 1'b0 to avoid interfering with USB Battery Charging detection.

55.4.13 USB PHY Charger Detect Status Register (USBPHY_USB1_CHRG_DET_STAT)

The control of the USB Battery Charging detection functions has been moved to the USBHSDCD instantiation of the USBDCD module for this product.

For standards-based charger detection purposes, the USBHSDCD registers should be used rather than this register. However, the status values in this register may be useful for debugging or in case other detection methods are used.

Address: 4035_0000h base + F0h offset = 4035_00F0h



USBPHY_USB1_CHRG_DET_STAT field descriptions

Field	Description
31–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 SECDET_DCP	Battery Charging Secondary Detection phase output During the USB Battery Charging Secondary Detection phase using the USBHSDCD module, this bit field indicates which kind of Charging Port was detected. 0 Charging Downstream Port (CDP) has been detected 1 Downstream Charging Port (DCP) has been detected

Table continues on the next page...

USBPHY_USB1_CHRG_DET_STAT field descriptions (continued)

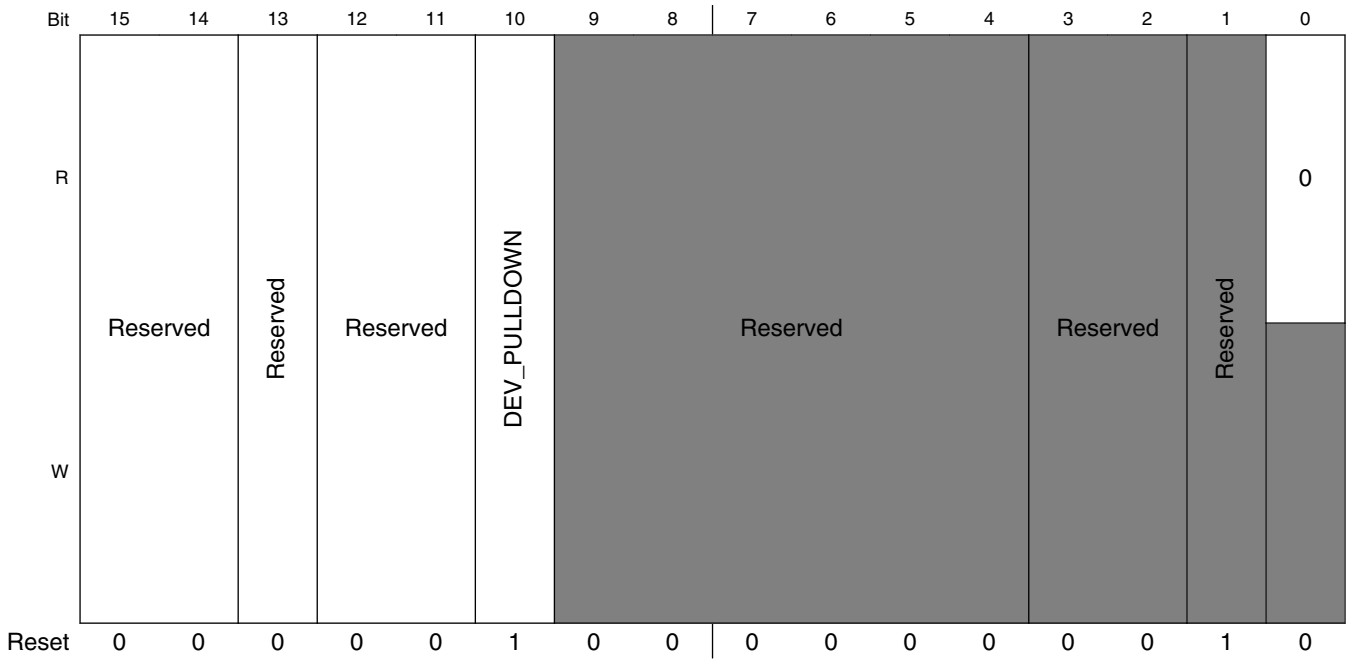
Field	Description
3 DP_STATE	Single ended receiver output for the USB_DP pin, from charger detection circuits. 0 USB_DP pin voltage is < 0.8V 1 USB_DP pin voltage is > 2.0V
2 DM_STATE	Single ended receiver output for the USB_DM pin, from charger detection circuits. 0 USB_DM pin voltage is < 0.8V 1 USB_DM pin voltage is > 2.0V
1 CHRG_ DETECTED	Battery Charging Primary Detection phase output During the USB Battery Charging Primary Detection phase using the USBHSDCD module, this bit field indicates whether a Standard Downstream Port or Charging Port was detected. 0 Standard Downstream Port (SDP) has been detected 1 Charging Port has been detected
0 PLUG_ CONTACT	Battery Charging Data Contact Detection phase output During the Data Contact Detection phase per the *USB Battery Charging Specification Revision 1.2* using the USBHSDCD module, this bit field indicates whether a USB cable has been attached between the remote host and the local device. 0 No USB cable attachment has been detected 1 A USB cable attachment between the device and host has been detected

55.4.14 USB PHY Analog Control Register (USBPHY_ANACTRL*n*)

The USBPHY_ANACTRL register a bit field to allow an additional type of control of 15 kohm pulldown resistors on both USB_DP and USB_DM pins.

Address: 4035_0000h base + 100h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved	Reserved							0							
W																
Reset	0	0	0	0	1	0	1	0	0	0	0	0	0	0	0	0



USBPHY_ANACTRL*n* field descriptions

Field	Description
31 Reserved	This field is reserved.
30–23 Reserved	This field is reserved. This bit is unimplemented and not for use. For normal USB operation this bit field must remain cleared at value 8'h00.
22–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–14 Reserved	This field is reserved. This field is unimplemented and not for use. For normal USB operation, this bit field must remain at value 2'b00.
13 Reserved	This field is reserved. This field is unimplemented and not for use. For normal USB operation, this bit field must remain at value 1'b0.
12–11 Reserved	This field is reserved. This field is unimplemented and not for use. For normal USB operation, this bit field must remain at value 2'b00.
10 DEV_ PULLDOWN	Setting this field to 1'b1 will enable the 15kΩ pulldown resistors on both USB_DP and USB_DM pins. This feature can be used in device mode while the USB cable is disconnected to keep the data pins at known values, avoiding unnecessary interrupts from the single ended receivers. This bit must be reset to 1'b0 during normal USB data communication in device mode, or while battery charger detection using the USBHSDCD module is used. 0 The 15kΩ nominal pulldowns on the USB_DP and USB_DM pinsare disabled in device mode. 1 The 15kΩ nominal pulldowns on the USB_DP and USB_DM pinsare enabled in device mode.
9–4 Reserved	This field is reserved. This field is unimplemented and not for use. For normal USB operation, this bit field must remain at value 6'h00.

Table continues on the next page...

USBPHY_ANACTRL*n* field descriptions (continued)

Field	Description
3–2 Reserved	This field is reserved. This field is unimplemented and not for use. For normal USB operation, this bit field must remain at value 1'b00.
1 Reserved	This field is reserved. This field is unimplemented and not for use. For normal USB operation, this bit field must remain at value 1'b0.
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

55.4.15 USB PHY Loopback Control/Status Register (USBPHY_USB1_LOOPBACK*n*)

This register controls loopback testing of the USB PHY. Loopback mode is for test purposes only; it cannot be used during normal USB data communication.

Address: 4035_0000h base + 110h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0								TSTPKT							
W																
Reset	0	0	0	0	0	0	0	0	0	1	0	1	0	1	0	1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	TSTI_HSFS_MODE_EN	0						UTMO_DIG_TST1	UTMO_DIG_TST0	TSTI_TX_HIZ	TSTI_TX_EN	TSTI_TX_LS_MODE	TSTI_TX_HS_MODE	UTMI_DIG_TST1	UTMI_DIG_TST0	UTMI_TESTSTART
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

USBPHY_USB1_LOOPBACK*n* field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–16 TSTPKT	Selects the packet data byte used for USB loopback testing in Pulse mode. Pulse mode is selected by setting USBPHY_USB1_LOOPBACK[2:1] to a value of 2'b01. Default value produces a data inversion at each unit interval.
15 TSTI_HSFS_ MODE_EN	Setting this bit field to value 1'b1 will enable the loopback test to dynamically change the packet speed. It will send a number of High Speed packets determined by USBPHY_USB1_LOOPBACK_HSFSCNT[TSTI_HS_NUMBER], followed by a number of Full Speed packets determined by USBPHY_USB1_LOOPBACK_HSFSCNT[TSTI_FS_NUMBER].
14–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 UTMO_DIG_ TST1	This read-only bit is a status bit for USB loopback test. Value = 1'b1 indicates a passing result. Test results are only valid while UTMI_TESTSTART is set to value 1'b1.
7 UTMO_DIG_ TST0	This read-only bit is a status bit for USB loopback test results. Value = 1'b0 indicates a passing result. Test results are only valid while UTMI_TESTSTART is set to value 1'b1.
6 TSTI_TX_HIZ	Sets TX Hi-Z for USB loopback test.
5 TSTI_TX_EN	Enable TX for USB loopback test.
4 TSTI_TX_LS_ MODE	Set to value 1'b1 to choose LS for USB loopback testing, set to value 1'b0 to choose HS or FS mode which is defined by TSTI1_TX_HS.
3 TSTI_TX_HS_ MODE	Select HS or FS mode for USB loopback testing. Set to value 1'b1 to choose HS for USB loopback testing, set to value 1'b0 to choose FS mode.
2 UTMI_DIG_TST1	Mode control for USB loopback test. Setting this bit to a value of 1'b1 while UTMI_DIG_TST0 remains at a value of 1'b0 selects Psuedorandom modes for the loopback test.
1 UTMI_DIG_TST0	Mode control for USB loopback test. Setting this bit to a value of 1'b1 while UTMI_DIG_TST1 remains at a value of 1'b0 selects Pulse mode for the loopback test.
0 UTMI_ TESTSTART	This bit enables the USB loopback test.

55.4.16 USB PHY Loopback Packet Number Select Register (USBPHY_USB1_LOOPBACK_HSFSCNT*n*)

Address: 4035_0000h base + 120h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	TSTI_FS_NUMBER																TSTI_HS_NUMBER															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0

USBPHY_USB1_LOOPBACK_HSFSCNT*n* field descriptions

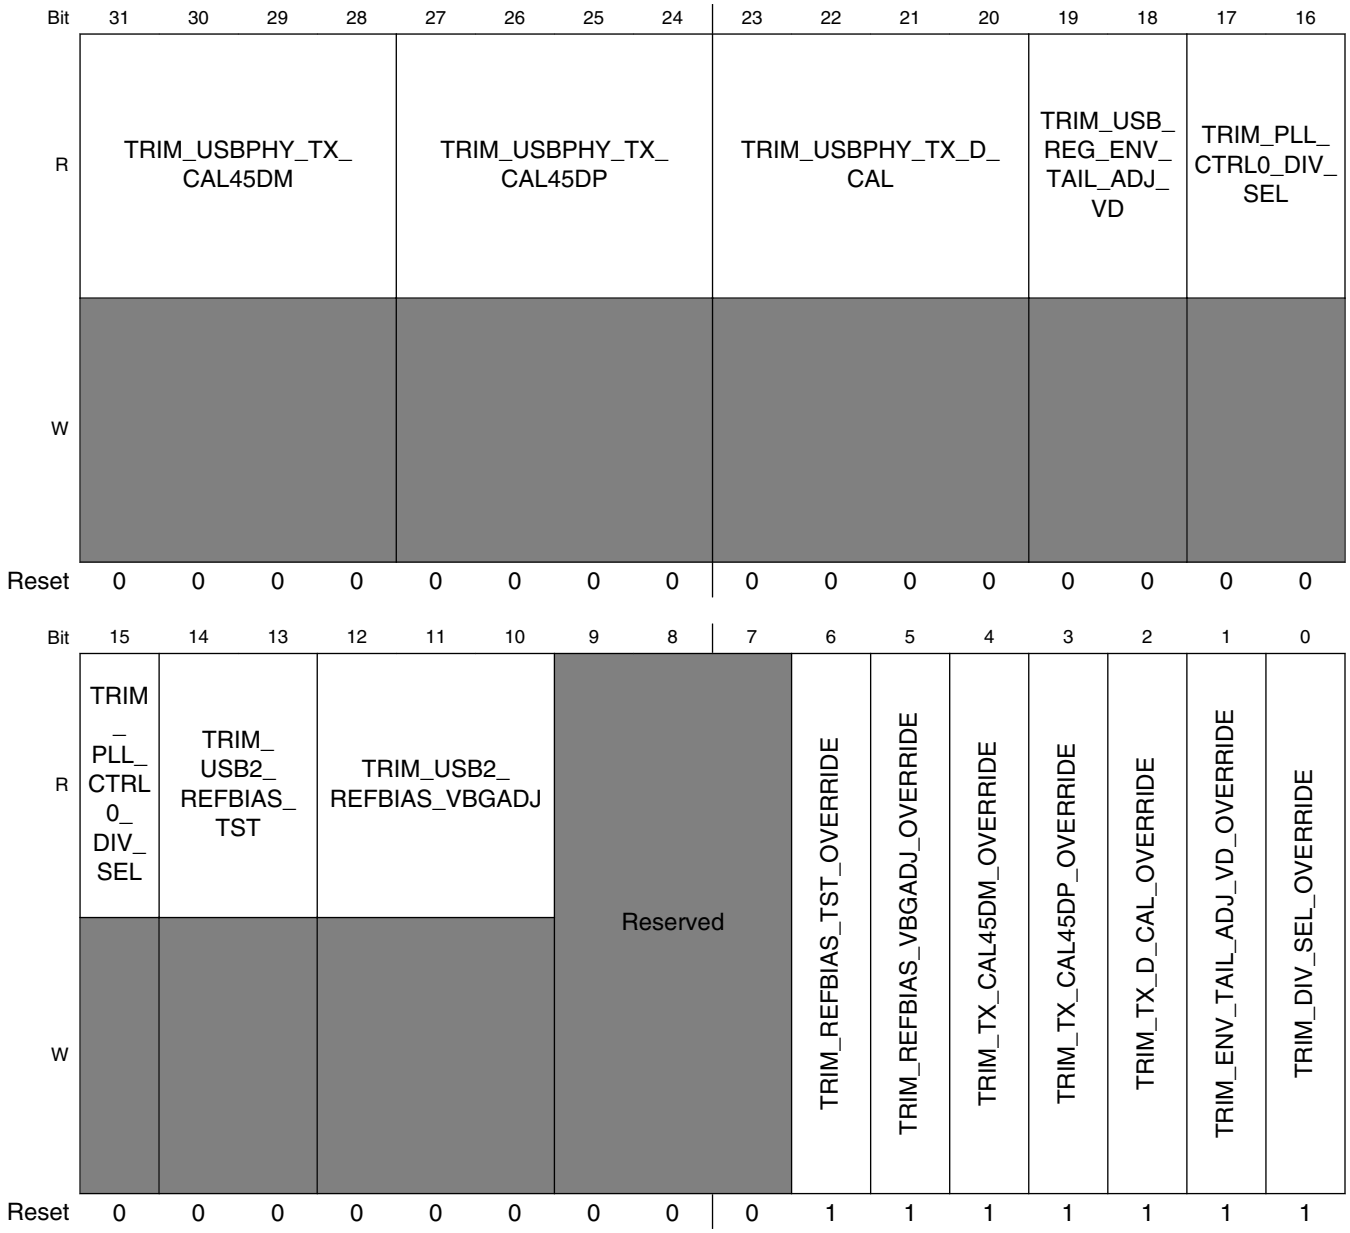
Field	Description
31–16 TSTI_FS_ NUMBER	Full speed packet number, used when USBPHY_USB1_LOOPBACK[TSTI_HSFS_MODE_EN] is set to value 1'b1.
TSTI_HS_ NUMBER	High speed packet number, used when USBPHY_USB1_LOOPBACK[TSTI_HSFS_MODE_EN] is set to value 1'b1.

55.4.17 USB PHY Trim Override Enable Register (USBPHY_TRIM_OVERRIDE_EN*n*)

The bit fields in this register allow observation of the default IFR settings of Phy parameters for TX_CAL45DM, TX_CAL45DP, TX_D_CAL, ENV_TAIL_ADJ, and PLL_DIV_SEL.

Additional bit fields also determine whether those values can be overridden by settings in the USBPHY_TX, USBPHY_DEBUG1, and USBPHY_PLL_SIC registers.

Address: 4035_0000h base + 130h offset + (4d × i), where i=0d to 3d



USBPHY_TRIM_OVERRIDE_EN*n* field descriptions

Field	Description
31–28 TRIM_USBPHY_TX_CAL45DM	IFR value of TX_CAL45DM.
27–24 TRIM_USBPHY_TX_CAL45DP	IFR value of TX_CAL45DP.
23–20 TRIM_USBPHY_TX_D_CAL	IFR value of TX_D_CAL.

Table continues on the next page...

USBPHY_TRIM_OVERRIDE_EN*n* field descriptions (continued)

Field	Description
19–18 TRIM_USB_ REG_ENV_ TAIL_ADJ_VD	IFR value of ENV_TAIL_ADJ.
17–15 TRIM_PLL_ CTRL0_DIV_SEL	IFR value of PLL_DIV_SEL.
14–13 TRIM_USB2_ REFBIAS_TST	Bias current control for usb2_phy
12–10 TRIM_USB2_ REFBIAS_ VBGADJ	Adjustment bits for bandgap
9–7 Reserved	This field is reserved. This field is unimplemented and not for use. This bit field must remain at value 1'b0.
6 TRIM_REFBIAS_ TST_OVERRIDE	Override enable for bias current control When this field is set, the register value in USBPHY_DEBUG1[22:21] will be used.
5 TRIM_REFBIAS_ VBGADJ_ OVERRIDE	Override enable for bandgap adjustment. When this field is set, the register value in USBPHY_DEBUG1[20:18] will be used.
4 TRIM_TX_ CAL45DM_ OVERRIDE	Override enable for TX_CAL45DM, when set, the register value in USBPHY_TX[11:8] will be used.
3 TRIM_TX_ CAL45DP_ OVERRIDE	Override enable for TX_CAL45DP, when set, the register value in USBPHY_TX[19:16] will be used.
2 TRIM_TX_D_ CAL_OVERRIDE	Override enable for TX_D_CAL, when set, the register value in USBPHY_TX[3:0] will be used.
1 TRIM_ENV_ TAIL_ADJ_VD_ OVERRIDE	Override enable for ENV_TAIL_ADJ, when set, the register value in USBPHY_DEBUG1[14:13] will be used.
0 TRIM_DIV_SEL_ OVERRIDE	Override enable for PLL_DIV_SEL, when set, the register value in USBPHY_PLL_SIC[1:0] will be used.

55.5 Register Macro Usage

A common operation is to update one field without disturbing the contents of the remaining fields in the register. Normally, this requires a read-modify-write (RMW) operation, where the CPU reads the register, modifies the target field, then writes the results back to the register. This is an expensive operation in terms of CPU cycles, because of the initial register read.

To address this issue, some hardware registers are implemented as a group, including registers that can be used to either set, clear, or toggle (SCT) individual bits of the primary register. When writing to an SCT register, all bits set to 1 perform the associated operation on the primary register, while all bits set to 0 are not affected. The SCT registers always read back 0, and should be considered write-only. The SCT registers are not implemented if the primary register is read-only.

With this architecture, it is possible to update one or more fields using only register writes. First, all bits of the target fields are cleared by a write to the associated clear register, then the desired value of the target fields is written to the set register. This sequence of two writes is referred to as a clear-set (CS) operation.

A CS operation does have one potential drawback. Whenever a field is modified, the hardware sees a value of 0 before the final value is written. For most fields, passing through the 0 state is not a problem. Nonetheless, this behavior is something to consider when using a CS operation.

Also, a CS operation is not required for fields that are one bit wide. While the CS operation works in this case, it is more efficient to simply set or clear the target bit (that is, one write instead of two). A simple set or clear operation is also atomic, while a CS operation is not.

Note that not all macros for set, clear, or toggle (SCT) are atomic. For registers that do not provide hardware support for this functionality, these macros are implemented as a sequence of read/modify/write operations. When atomic operation is required, the developer should pay attention to this detail, because unexpected behavior might result if an interrupt occurs in the middle of the critical section comprising the update sequence.

Chapter 56
USB DCD

56.1 Chip-specific USBDCD information

Table 56-1. Reference links to related information

Topic	Related module	Reference

56.2.2 Acronyms and abbreviations

The following table contains acronyms and abbreviations used in this document.

Table 56-2. Acronyms and abbreviated terms

Term	Meaning
CDP	Charging Downstream Port, as defined in *USB Battery Charging Specification, Rev. 1.2*
Charging Port	A Charging Port supported by this module is either a CDP or a DCP
DCP	Dedicated Charging Port, as defined in *USB Battery Charging Specification, Rev. 1.2*
FS	Full speed (12 Mbit/s)
HS	High speed (480 Mbit/s)
I_{CFG_MAX}	Current limit for a USB device attached to an SDP, after configuration
I_{DEV_CHG}	Current limit for a USB device attached to a Charging Port
I_{DM_SINK}	Current sink for the D– line
I_{DP_SINK}	Current sink for the D+ line
I_{DP_SRC}	Current source for the D+ line
I_{SUSP}	Current drawn when the USB device is suspended
LDO	Low dropout
LS	Low Speed (1.5 Mbit/s)
N/A	Not applicable
OTG	On-The-Go
R_{DM_DWN}	D– pulldown resistance for data pin contact detect
SDP	Standard Downstream Port, as defined in *USB Battery Charging Specification, Rev 1.2*
V_{DAT_REF}	Data detect reference voltage for the voltage comparator
V_{DP_SRC}	Voltage source for the D+ line
V_{DM_SRC}	Voltage source for the D– line
V_{LGC}	Threshold voltage for logic high

56.2.3 Glossary

The following table shows a glossary of terms used in this document.

Table 56-3. Glossary of terms

Term	Definition
Transceiver	Module that implements the physical layer of the USB standard (FS or LS only).
PHY	Module that implements the physical layer of the USB standard (HS capable).
Attached	Device is physically plugged into USB port, but has *not enabled* either D+ or D– pullup resistor.
Connected	Device is physically plugged into USB port, and has *enabled* either D+ or D– pullup resistor.
Suspended	After 3 ms of no bus activity, the USB device enters suspend mode.
Component	The hardware and software that make up a subsystem.

56.3 Introduction

The USBDCD module works with the USB transceiver to detect whether the USB device is attached to a Charging Port, either a Dedicated Charging Port (DCP) or a Charging Downstream Port (CDP). System software coordinates the detection activites of the module and controls an off-chip integrated circuit that performs the battery charging.

There can be separate instantiations of the USBDCD module for each USB port. The instantiation for the High-Speed capable USB port is named USBHSDCD, so that it can be differentiated from the instantiation for Full-Speed/Low-Speed USB port which retains the name USBDCD. See the chip-specific information for the specific instantiation of your device.

The use of the term "USB transceiver" in this module documentation applies to the USB physical layer instance on the chip, whether it is a FS/LS only transceiver or a HS/FS/LS capable PHY.

56.4 Block diagram

The following figure is a high level block diagram of the module.

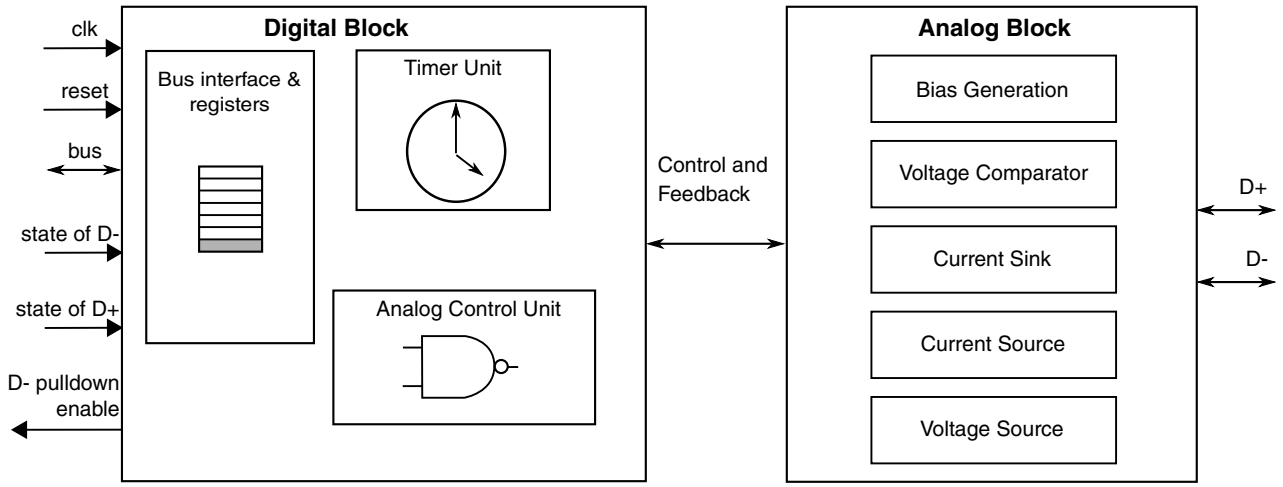

Figure 56-1. Block diagram

The USBDCD module consists of two main blocks:

- A digital block provides the programming interface (memory-mapped registers) and includes the timer unit and the analog control unit.
- An analog block provides the circuitry for the physical detection of the charger, including the bias generation, voltage source, current source, current sink, and voltage comparator circuitry. This block also contains necessary muxes between the source/sink circuits and the D- and D+ pins.

56.5 Features

The USBDCD module offers the following features:

- Compliant with the latest industry standard specification: *USB Battery Charging Specification, Revision 1.1 and 1.2*
- Programmable timing parameters default to values required by the industry standards:
  - Having standard default values allows for easy configuration- simply set the clock frequency before enabling the module.
  - Programmability allows the flexibility to meet future updates of the standards.

56.6 Modes of operation

The operating modes of the USBDCD module are shown in the following table.

Table 56-4. Module modes and their conditions

Module mode	Description	Conditions when used
Enabled	The module performs the charger detection sequence.	System software should enable the module only when *all* of the following conditions are true: • The system uses a rechargeable battery. • The device is being used in an FS USB device application. • The device has detected that it is attached to the USB cable.
Disabled	The module is not active and is held in a low power state.	System software should disable the module when *either* of the following conditions is true: • The charger detect sequence is complete. • The conditions for being enabled are not met.
Powered Off	The digital supply voltage dvdd is removed.	Low system performance requirements allow putting the device into a very low-power stop mode.

Operating mode transitions are shown in the following table.

Table 56-5. Entering and exiting module modes

Module mode	Entering	Exiting	Mode after exiting
Enabled	Set CONTROL[START].	Set CONTROL[SR].[1]	Disabled
Disabled	Take *either* of the following actions: • Set CONTROL[SR].[1] • Reset the module. By default, the module is disabled.	Set CONTROL[START].	Enabled
Powered Off	Perform the following actions: 1. Put the device into very low-power stop mode. 2. Adjust the supply voltages.	Perform the following actions: 1. Restore the supply voltages. 2. Take the device out of very low-power stop mode.	Disabled

1. The effect of setting the SR bit is immediate; that is, the module is disabled even if the sequence has not completed.

56.7 Module signal descriptions

This section describes the module signals. The following table shows a summary of module signals that interface with the pins of the device.

Table 56-6. Signal descriptions

Signal	Description	I/O
USB_DM	USB D– analog data signal. The analog block interfaces directly to the D– signal on the USB bus.	I/O
USB_DP	USB D+ analog data signal. The analog block interfaces directly to the D+ signal on the USB bus.	I/O
avdd33 [1]	3.3 V regulated analog supply	I
vss_bulk	Digital/Analog ground	I
dvdd	Core voltage digital supply	I

1. Voltage must be 3.3 V ± 10% for full functionality of the module. That is, the charger detection function does not work when this voltage is below 3.0 V, and the CONTROL[START] bit should not be set.

NOTE

The transceiver module also interfaces to the USB_DM and USB_DP signals. Both modules and the USB host/hub use these signals as bidirectional, tristate signals.

Information about the signal integrity aspects of the lines including shielding, isolated return paths, input or output impedance, packaging, suggested external components, ESD, and other protections can be found in the USB 2.0 specification and in Application information.

56.8 Memory map/Register definition

This section describes the memory map and registers for the USBHSDCD module.

56.8.1 USBDCD register descriptions

56.8.1.1 USBDCD Memory map

DCD base address: 4035_0800h

Offset	Register	Width (In bits)	Access	Reset value
0h	Control register (CONTROL)	32	RW	0001_0000h
4h	Clock register (CLOCK)	32	RW	0000_00C1h
8h	Status register (STATUS)	32	RO	0000_0000h
Ch	Signal Override Register (SIGNAL_OVERRIDE)	32	RW	0000_0000h
10h	TIMER0 register (TIMER0)	32	RW	0010_0000h
14h	TIMER1 register (TIMER1)	32	RW	000A_0028h
18h	TIMER2_BC11 register (TIMER2_BC11)	32	RW	0028_0001h
18h	TIMER2_BC12 register (TIMER2_BC12)	32	RW	0001_0028h

56.8.1.2 Control register (CONTROL)

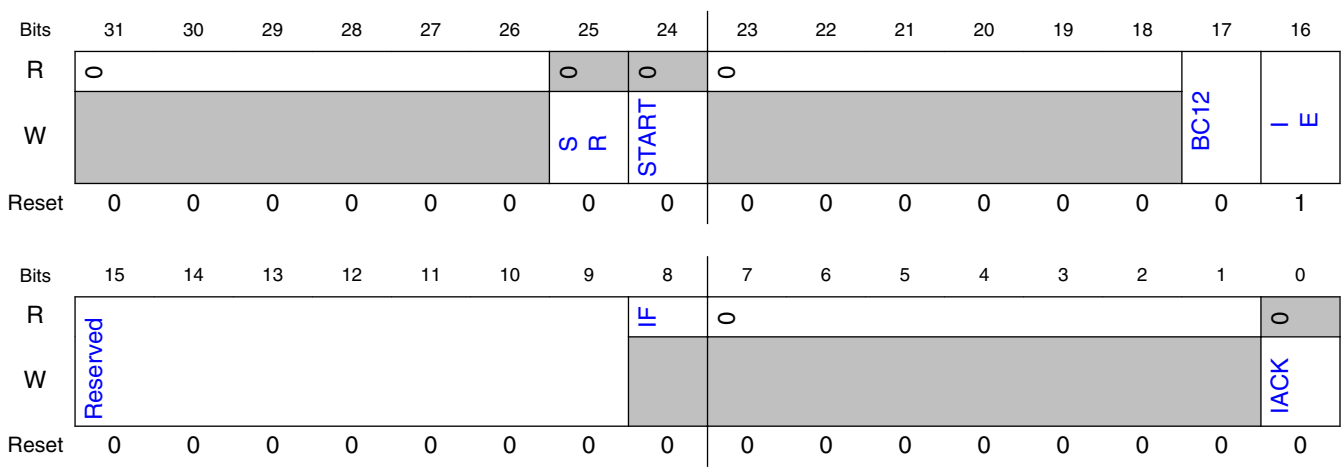
56.8.1.2.1 Offset

Register	Offset
CONTROL	0h

56.8.1.2.2 Function

Contains the control and interrupt bit fields.

56.8.1.2.3 Diagram



56.8.1.2.4 Fields

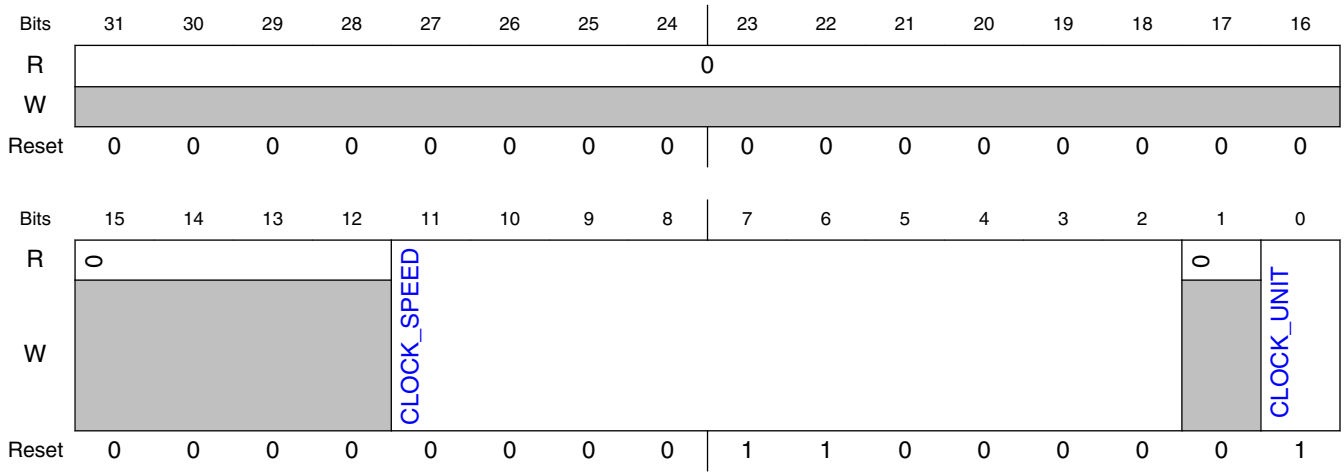
Field	Function
31-26 —	Reserved
25 SR	Software Reset Determines whether a software reset is performed. 0b - Do not perform a software reset. 1b - Perform a software reset.
24 START	Start Change Detection Sequence Determines whether the charger detection sequence is initiated. 0b - Do not start the sequence. Writes of this value have no effect. 1b - Initiate the charger detection sequence. If the sequence is already running, writes of this value have no effect.
23-18 —	Reserved
17 BC12	BC12 BC1.2 compatibility. This bit cannot be changed after start detection. 0b - Compatible with BC1.1 (default) 1b - Compatible with BC1.2
16 IE	Interrupt Enable Enables/disables interrupts to the system. 0b - Disable interrupts to the system. 1b - Enable interrupts to the system.
15-9 —	Reserved
8 IF	Interrupt Flag Determines whether an interrupt is pending. 0b - No interrupt is pending. 1b - An interrupt is pending.
7-1 —	Reserved
0 IACK	Interrupt Acknowledge Determines whether the interrupt is cleared. 0b - Do not clear the interrupt. 1b - Clear the IF bit (interrupt flag).

56.8.1.3 Clock register (CLOCK)

56.8.1.3.1 Offset

Register	Offset
CLOCK	4h

56.8.1.3.2 Diagram



56.8.1.3.3 Fields

Field	Function
31-12 —	Reserved
11-2 CLOCK_SPEED	Numerical Value of Clock Speed in Binary The unit of measure is programmed in CLOCK_UNIT. The valid range is from 1 to 1023 when clock unit is MHz and 4 to 1023 when clock unit is kHz. Examples with CLOCK_UNIT = 1: • For 48 MHz: 0b00_0011_0000 (48) (Default) • For 24 MHz: 0b00_0001_1000 (24) Examples with CLOCK_UNIT = 0: • For 100 kHz: 0b00_0110_0100 (100) • For 500 kHz: 0b01_1111_0100 (500)
1 —	Reserved
0 CLOCK_UNIT	Unit of Measurement Encoding for Clock Speed Specifies the unit of measure for the clock speed. 0b - kHz Speed (between 1 kHz and 1023 kHz) 1b - MHz Speed (between 1 MHz and 1023 MHz)

56.8.1.4 Status register (STATUS)

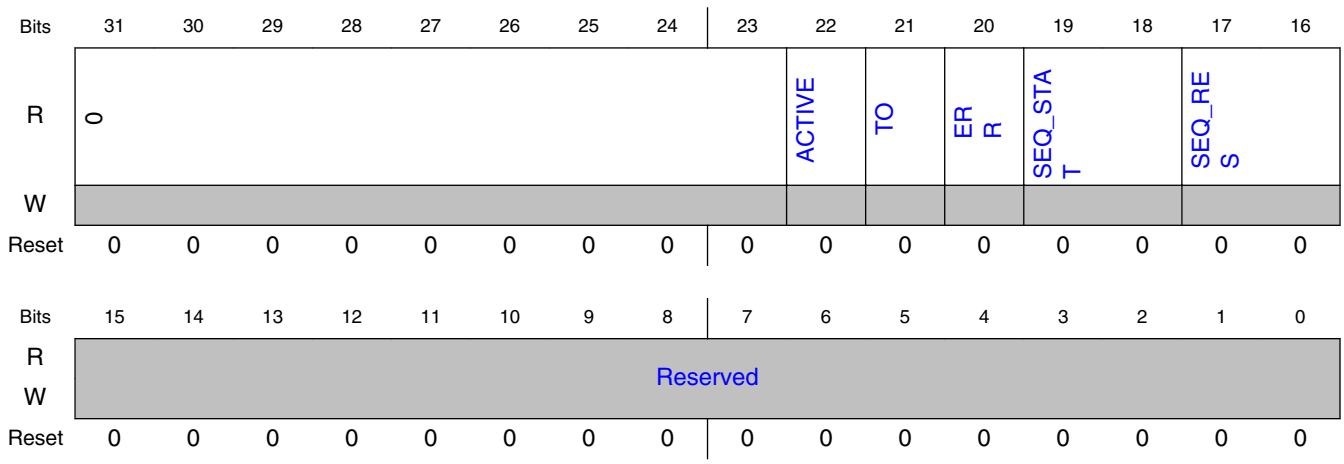
56.8.1.4.1 Offset

Register	Offset
STATUS	8h

56.8.1.4.2 Function

Provides the current state of the module for system software monitoring.

56.8.1.4.3 Diagram



56.8.1.4.4 Fields

Field	Function
31-23 —	Reserved
22 ACTIVE	Active Status Indicator Indicates whether the sequence is running. 0b - The sequence is not running. 1b - The sequence is running.
21 TO	Timeout Flag Indicates whether the detection sequence has passed the timeout threshhold. 0b - The detection sequence has not been running for over 1 s. 1b - It has been over 1 s since the data pin contact was detected and debounced.
20 ERR	Error Flag Indicates whether there is an error in the detection sequence. 0b - No sequence errors. 1b - Error in the detection sequence. See the SEQ_STAT field to determine the phase in which the error occurred.

Table continues on the next page...

Field	Function
19-18 SEQ_STAT	Charger Detection Sequence Status Indicates the status of the charger detection sequence. 00b - The module is either not enabled, or the module is enabled but the data pins have not yet been detected. 01b - Data pin contact detection is complete. 10b - Charging port detection is complete. 11b - Charger type detection is complete.
17-16 SEQ_RES	Charger Detection Sequence Results Reports how the charger detection is attached. 00b - No results to report. 01b - Attached to an SDP. Must comply with USB 2.0 by drawing only 2.5 mA (max) until connected. 10b - Attached to a charging port. The exact meaning depends on bit 18 (value 0: Attached to either a CDP or a DCP. The charger type detection has not completed. value 1: Attached to a CDP. The charger type detection has completed.) 11b - Attached to a DCP.
15-0 —	Reserved **NOTE:** Bits do not always read as 0.

56.8.1.5 Signal Override Register (SIGNAL_OVERRIDE)

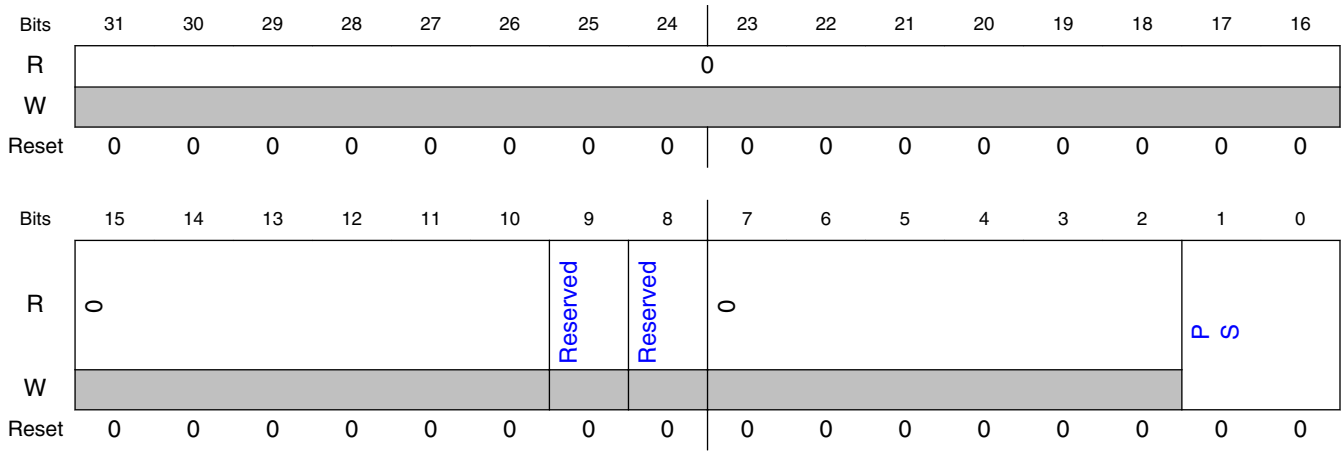
56.8.1.5.1 Offset

Register	Offset
SIGNAL_OVERRIDE	Ch

56.8.1.5.2 Function

The Signal Override register provides a way for the customer to enable signaling required by the USB BC v1.2 specification after the battery charger detection sequences have completed.

56.8.1.5.3 Diagram



56.8.1.5.4 Fields

Field	Function
31-10 —	Reserved
9 —	Reserved Reserved, not for customer use. The value of this bit field may change during module operation.
8 —	Reserved Reserved, not for customer use. The value of this bit field may change during module operation.
7-2 —	Reserved
1-0 PS	Phase Selection Used to enable specified voltage and current source circuits on the USB_DP and USB_DM pins. Customers may set this bit field to 2'b10 for required signaling if attached to a Dedicated Charging Port, or during operation under the Dead Battery Provision. 00b - No overrides. Bit field must remain at this value during normal USB data communication to prevent unexpected conditions on USB_DP and USB_DM pins. (Default) 01b - Reserved, not for customer use. 10b - Enables VDP_SRC voltage source for the USB_DP pin and IDM_SINK current source for the USB_DM pin. 11b - Reserved, not for customer use.

56.8.1.6 TIMER0 register (TIMER0)

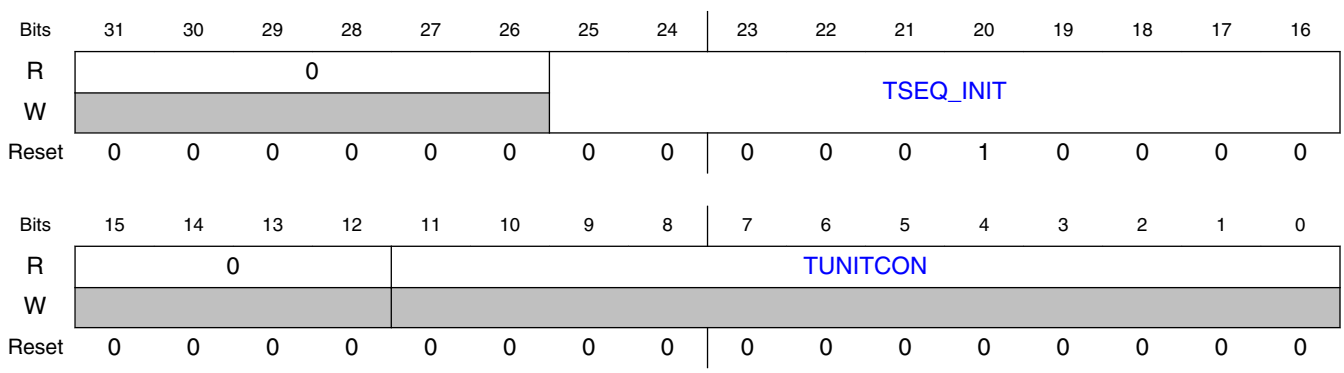
56.8.1.6.1 Offset

Register	Offset
TIMER0	10h

56.8.1.6.2 Function

TIMER0 has an TSEQ_INIT field that represents the system latency in ms. Latency is measured from the time when VBUS goes active until the time system software initiates charger detection sequence in USBDCD module. When software sets the CONTROL[START] bit, the Unit Connection Timer (TUNITCON) is initialized with the value of TSEQ_INIT. Valid values are 0-1023, however the USB Battery Charging Specification requires the entire sequence, including TSEQ_INIT, to be completed in 1s or less.

56.8.1.6.3 Diagram



56.8.1.6.4 Fields

Field	Function
31-26 —	Reserved
25-16 TSEQ_INIT	Sequence Initiation Time TSEQ_INIT represents the system latency (in ms) measured from the time VBUS goes active to the time system software initiates the charger detection sequence in the USBDCD module. When software sets the CONTROL[START] bit, the Unit Connection Timer (TUNITCON) is initialized with the value of TSEQ_INIT. Valid values are 0-1023, but the USB Battery Charging Specification requires the entire sequence, including TSEQ_INIT, to be completed in 1s or less.
15-12 —	Reserved
11-0	Unit Connection Timer Elapse (in ms)

Field	Function
TUNITCON	Displays the amount of elapsed time since the event of setting the START bit plus the value of TSEQ_INIT. The timer is automatically initialized with the value of TSEQ_INIT before starting to count. This timer enables compliance with the maximum time allowed to connect T_{UNIT_CON} under the USB Battery Charging Specification. If the timer reaches the one second limit, the module triggers an interrupt and sets the error flag STATUS[ERR]. The timer continues counting throughout the charger detection sequence, even when control has been passed to software. As long as the module is active, the timer continues to count until it reaches the maximum value of 0xFFF (4095 ms). The timer does not rollover to zero. A software reset clears the timer.

56.8.1.7 TIMER1 register (TIMER1)

56.8.1.7.1 Offset

Register	Offset
TIMER1	14h

56.8.1.7.2 Function

TIMER1 contains timing parameters. Note that register values can be written that are not compliant with the USB Battery Charging Specification, so care should be taken when overwriting the default values.

56.8.1.7.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	1	0	1	0	0	0

56.8.1.7.4 Fields

Field	Function
31-26 —	Reserved
25-16 TDCD_DBNC	Time Period to Debounce D+ Signal Sets the time period (ms) to debounce the D+ signal during the data pin contact detection phase. See "Debouncing the data pin contact" Valid values are 1-1023, but the USB Battery Charging Specification requires a minimum value of 10 ms.
15-10 —	Reserved
9-0 TVDPSRC_ON	Time Period Comparator Enabled This timing parameter is used after detection of the data pin. See "Charging Port Detection". Valid values are 1-1023, but the USB Battery Charging Specification requires a minimum value of 40 ms.

56.8.1.8 TIMER2_BC11 register (TIMER2_BC11)

56.8.1.8.1 Offset

Register	Offset
TIMER2_BC11	18h

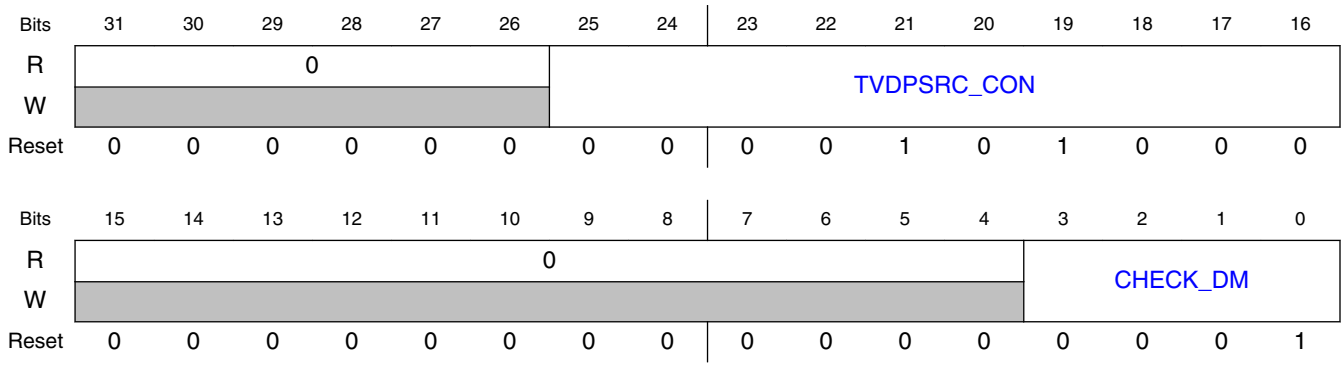
56.8.1.8.2 Function

TIMER2_BC11 contains timing parameters for *USB Battery Charging Specification, Rev 1.1*.

NOTE

Register values can be written that are not compliant with the USB Battery Charging Specification, so care should be taken when overwriting the default values.

56.8.1.8.3 Diagram



56.8.1.8.4 Fields

Field	Function
31-26 —	Reserved
25-16 TVDPSRC_CON	Time Period Before Enabling D+ Pullup Sets the time period (ms) that the module waits after charging port detection before system software must enable the D+ pullup to connect to the USB host. Valid values are 1-1023, but the USB Battery Charging Specification requires a minimum value of 40 ms.
15-4 —	Reserved
3-0 CHECK_DM	Time Before Check of D- Line Sets the amount of time (in ms) that the module waits after the device connects to the USB bus until checking the state of the D- line to determine the type of charging port. See "Charger Type Detection." Valid values are 1-15ms.

56.8.1.9 TIMER2_BC12 register (TIMER2_BC12)

56.8.1.9.1 Offset

Register	Offset
TIMER2_BC12	18h

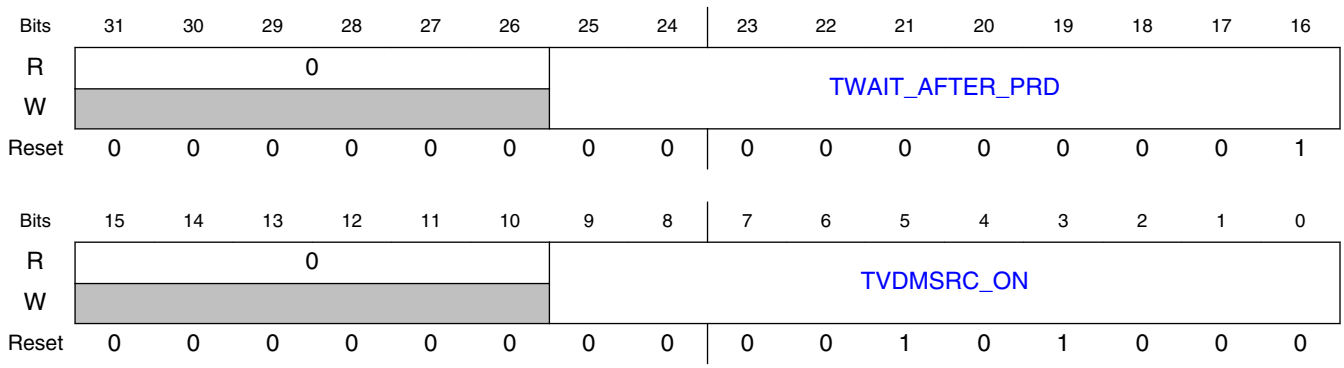
56.8.1.9.2 Function

TIMER2_BC12 contains timing parameters for *USB Battery Charging Specification, Rev 1.2*.

NOTE

Register values can be written that are not compliant with the USB Battery Charging Specification, so care should be taken when overwriting the default values.

56.8.1.9.3 Diagram



56.8.1.9.4 Fields

Field	Function
31-26 —	Reserved
25-16 TWAIT_AFTER_PRD	TWAIT_AFTER_PRD Sets the amount of time (in ms) that the module waits after primary detection before start to secondary detection. Valid values are 1-1023ms. Default is 1ms.
15-10 —	Reserved
9-0 TVDMSRC_ON	TVDMSRC_ON Sets the amount of time (in ms) that the module enables the V_{DM_SRC} . Valid values are 0-40ms.

56.9 Functional description

The sequence of detecting the presence of charging port and type of charging port involves several hardware components, coordinated by system software. This collection of interacting hardware and software is called the USB Battery Charging Subsystem. The following figure shows the USBDCD module as a component of the subsystem. The following table describes the components.

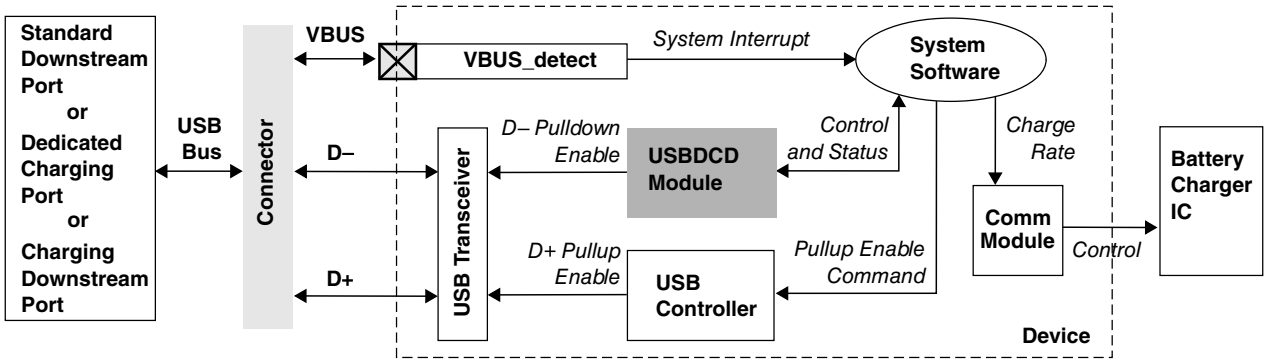


Figure 56-2. USB battery charging subsystem

Table 56-7. USB battery charger subsystem components

Component	Description
Battery Charger IC	The external battery charger IC regulates the charge rate to the rechargable battery. System software is responsible for communicating the appropriate charge rates. **Charger** / **Maximum current drawn** Standard Downstream Port (SDP) / up to 500 mA (I_{CFG_MAX}) Charging Downstream Port (CDP) / up to 1500 mA (I_{DEV_CHG}) Dedicated Charging Port (DCP) / up to 1500 mA (I_{DEV_CHG}) 1. If the USB host has suspended the USB device, system software must configure the system to limit the current drawn from the USB bus to 2.5 mA or less.
Comm Module	A communications module on the device can be used to control the charge rate of the battery charger IC.
System software	Coordinates the detection activities of the subsystem.
USB Controller	The D+ pullup enable control signal plays a role during the charger type detection phase. System software must issue a command to the USB controller to assert this signal. After this pullup is enabled, the device is considered to be connected to the USB bus. The host then attempts to enumerate it. **NOTE:** The USB controller must be used only for USB device applications when using the USBDCD module. For USB host applications, the USBDCD module must be disabled.
USB Transceiver	The USB transceiver contains the pullup resistor for the USB D+ signal and the pulldown resistors for the USB D+ and D– signals. The D+ pullup and the D– pulldown are both used during the charger detection sequence in BC1.1, but it is not used during charger detection in BC1.2. The USB transceiver also outputs the digital state of the D+ and D– signals from the USB bus. The pullup and pulldown enable signals are controlled by other modules during the charger detection sequence in BC1.1: The D+ pullup enable is output from the USB controller and is under software control. The USBDCD module controls the D– pulldown enable.
USBDCD Module	Detects whether the device has been plugged into either an SDP, a CDP, or a DCP.
VBUS_detect	This interrupt pin connected to the USB VBUS signal detects when the device has been plugged into or unplugged from the USB bus. If the system requires waking up from a low power mode on being plugged into the USB port, this interrupt should also be a low power wake up source. If this pin multiplexes other functions, such as GPIO, the pin can be configured as an interrupt so that the USB plug or unplug event can be detected.

1. If the USB host has suspended the USB device, system software must configure the system to limit the current drawn from the USB bus to 2.5 mA or less.

56.9.1 The charger detection sequence

The following figure illustrates the charger detection sequence in a simplified timing diagram based on the *USB Battery Charging Specification, Rev. 1.2*.

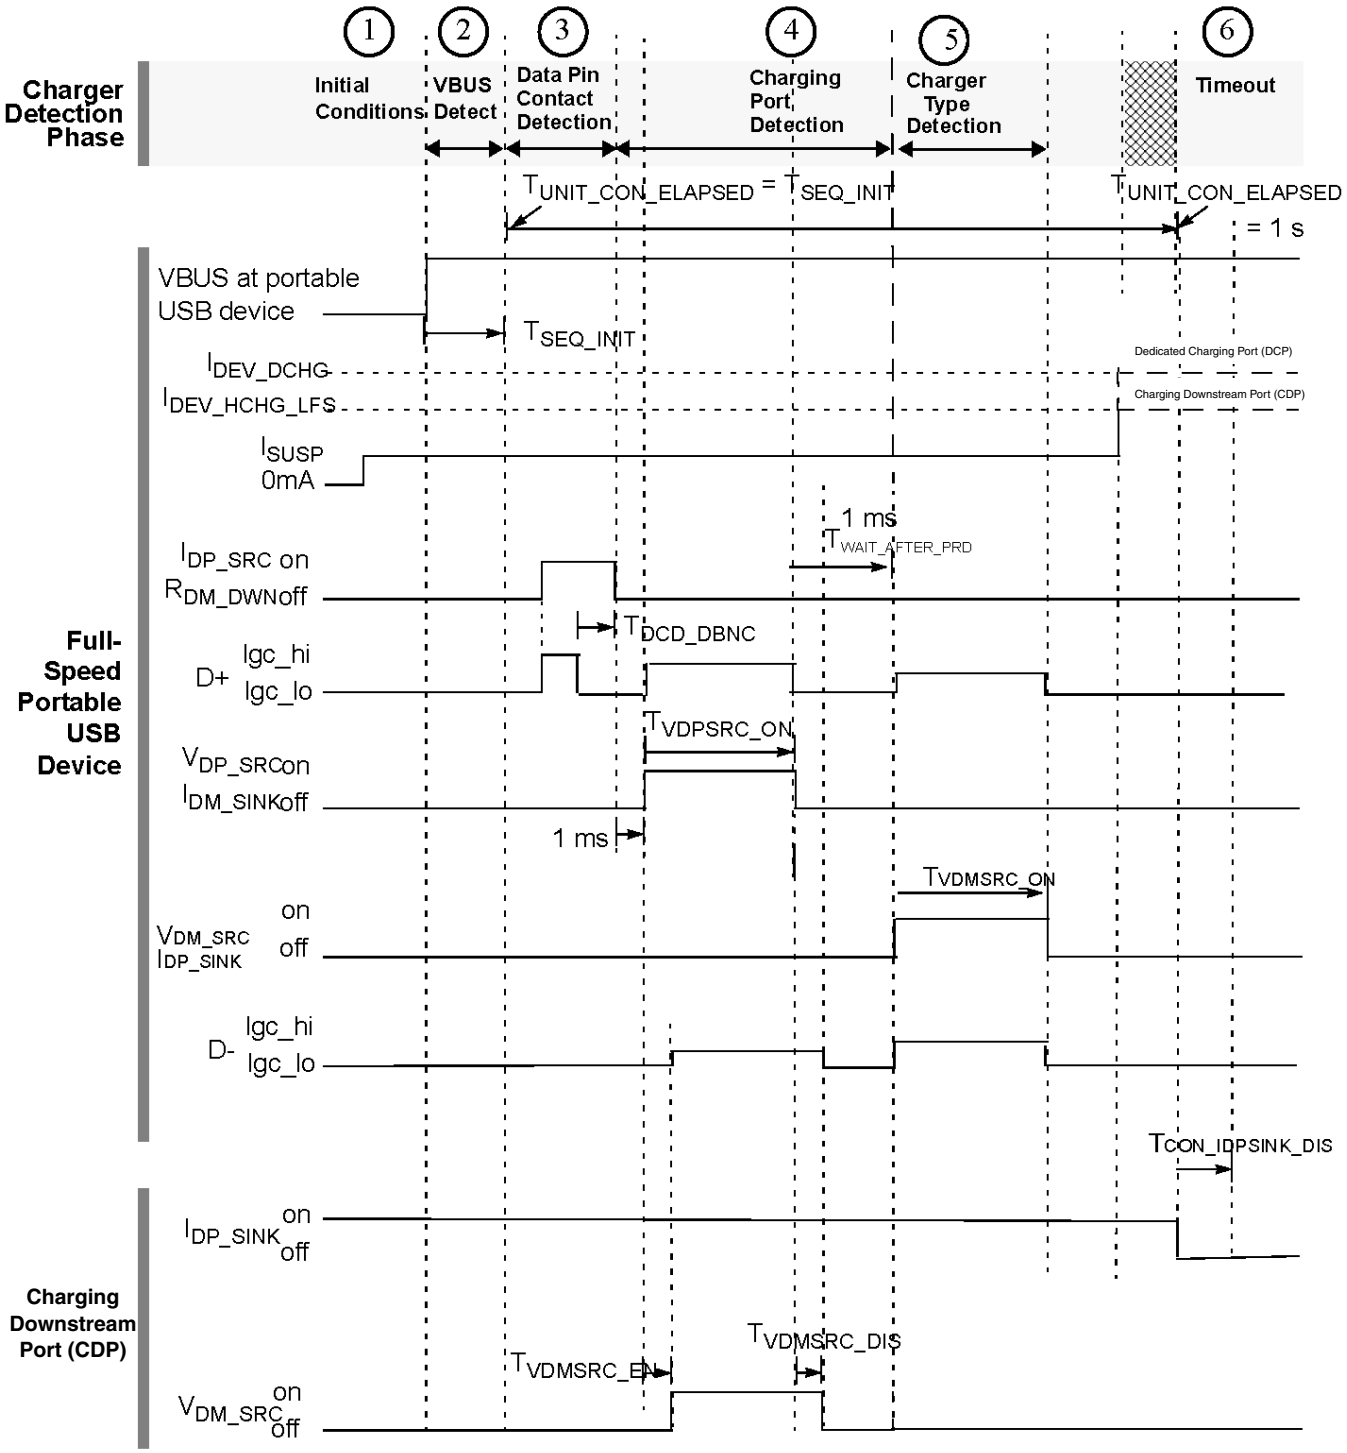

Figure 56-3. Full speed charger detection timing for BC1.2

Timing parameter values used in this module for BC1.2 are listed in the following table.

Table 56-8. Timing parameters for the charger detection sequence for BC1.2

Parameter	USB Battery Charging Spec	Module default	Module programmable range
$T_{DCD\_DBNC'}$ [1]	10 ms min (no max)	10 ms	0– 1023 ms
T_{VDPSRC_ON} [1]	40 ms min (no max)	40 ms	0 –1023 ms
$T_{WAIT\_AFTER\_PRD}$	N/A	1 ms	0– 1023 ms
T_{VDMSRC_ON}	40 ms	40 ms	0 –1023 ms
T_{SEQ_INIT}	N/A	16 ms	0 –1023 ms
T_{UNIT_CON} [1]	1 s	N/A	N/A
T_{VDMSRC_EN} [1]	1– 20 ms	From the USB host	N/A
T_{VDMSRC_DIS} [1]	0 – 20 ms	From the USB host	N/A
$T_{CON\_IDPSINK\_DIS}$ [1]	0 – 10 ms	From the USB host	N/A

1. This parameter is defined by the *USB Battery Charging Specification, Rev. 1.2*.

The following figure illustrates the charger detection sequence in a simplified timing diagram based on the *USB Battery Charging Specification, Rev. 1.1*.

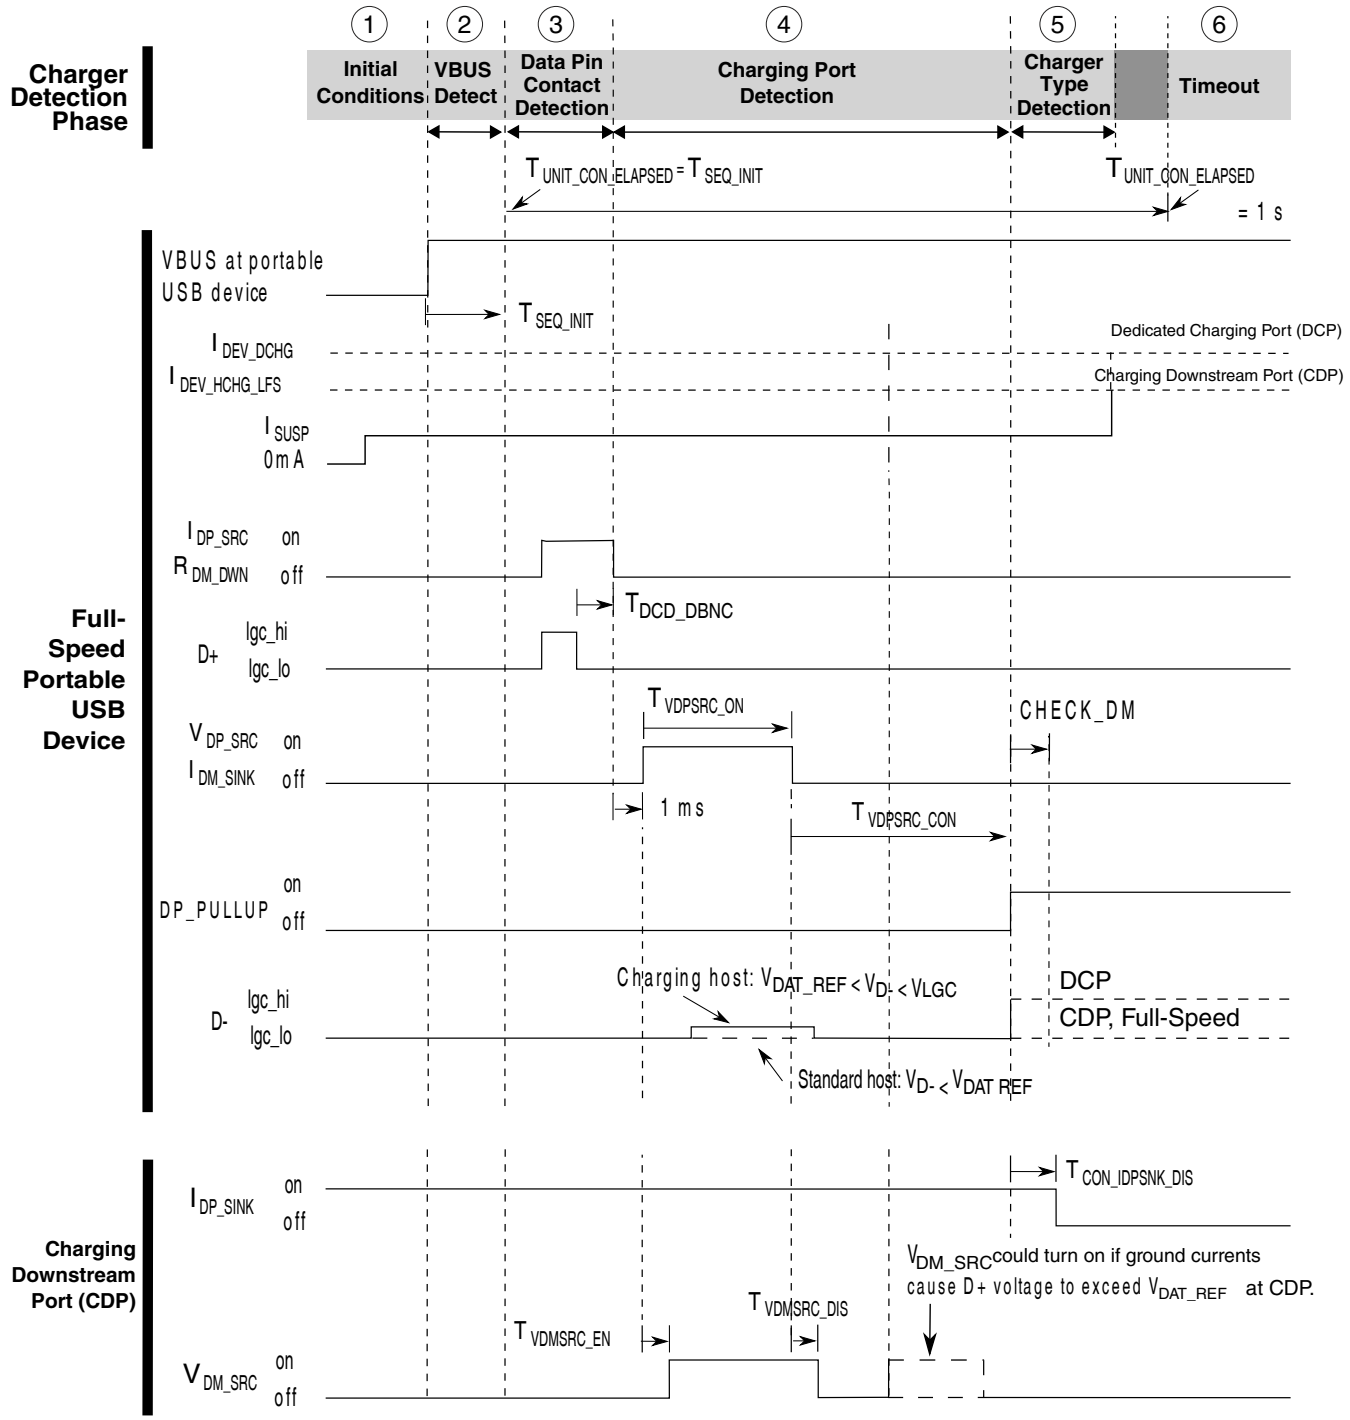

Figure 56-4. Full speed charger detection timing for BC1.1

Timing parameter values used in this module for BC1.1 are listed in the following table.

Table 56-9. Timing parameters for the charger detection sequence for BC1.1

Parameter	USB Battery Charging Spec	Module default	Module programmable range
$T_{DCD\_DBNC'}$ [1]	10 ms min (no max)	10 ms	0– 1023 ms
T_{VDPSRC_ON} [1]	40 ms min (no max)	40 ms	0 –1023 ms
T_{VDPSRC_CON} [1]	40 ms min (no max)	40 ms	0 –1023 ms
CHECK_DM	N/A	1 ms	0– 15 ms
T_{SEQ_INIT}	N/A	16 ms	0 –1023 ms
T_{UNIT_CON} [1]	1 s	N/A	N/A
T_{VDMSRC_EN} [1]	1– 20 ms	From the USB host	N/A
T_{VDMSRC_DIS} [1]	0 –20 ms	From the USB host	N/A
$T_{CON\_IDPSINK\_DIS}$ [1]	0– 20 ms	From the USB host	N/A

1. This parameter is defined by the *USB Battery Charging Specification, Rev. 1.1*.

The following table provides an overview description of the charger detection sequence shown in the preceding figure.

Table 56-10. Overview of the charger detection sequence

Phase		Overview description	Full description
1	Initial Conditions	Initial system conditions that need to be met before the detection sequence is initiated.	Initial System Conditions
2	VBUS Detection	System software detects contact of the VBUS signal with the system interrupt pin VBUS_detect.	VBUS contact detection
3	Data Pin Contact Detection	The USBDCD module detects that the USB data pins D+ and D– have made contact with the USB port.	Data pin contact detection
4	Charging Port Detection	The USBDCD module detects if the port is an SDP or either type of charging port, that is CDP or DCP.	Charging port detection
5	Charger Type Detection	The USBDCD module detects the type of charging port, if applicable.	Charger type detection
6	Sequence Timeout	The USBDCD module did not finish the detection sequence within the timeout interval. The sequence will continue until halted by software.	Charger detection sequence timeout

56.9.1.1 Initial System Conditions

The USBDCD module is intended for use with USB device applications using a rechargable battery. The module does not have support for interfacing with ACA or ACA-Dock equipment as defined in the *USB Battery Charging Specification, Revision 1.2*. It cannot be used with USB applications that are embedded host or OTG.

In addition, before the USBDCD module's charger detection sequence can be initiated, the system must be:

- Powered-up and in run mode. The USBDCD instantiation of this module for the High-Speed port does not directly depend on the VBUS voltage and can operate as long as the avdd33 supply is in a valid range.
- Recently plugged into a USB port.
- Drawing not more than 2.5 mA total system current from the USB bus, except as allowed by the *USB 2.0 Connect Timing Update ECN*.

Examples of allowable precursors to this set of initial conditions include:

- A powered-down device is subsequently powered-up upon being plugged into the USB bus.
- A device in a low power mode subsequently enters run mode upon being plugged into the USB bus.

56.9.1.2 VBUS contact detection

Once the device is plugged into a USB port, the VBUS_detect system interrupt is triggered. System software must do the following to initialize the module and start the charger detection sequence:

1. Restore power if the module is powered-off.
2. Set CONTROL[SR] to initiate a software reset.
3. Configure the USBDCD module by programming the CLOCK register and the timing parameters as needed.
4. Set CONTROL[IE] to enable interrupts, or clear the bit if software polling method is used.
5. Program CONTROL[BC12] based on which revision of the USB Battery Charging Specification is needed.
6. Set CONTROL[START] to start the charger detection sequence.

56.9.1.3 Data pin contact detection

The module must ensure that the data pins have made contact because the detection sequence depends upon the state of the USB D+ and D- signals. USB plugs and receptables are designed such that when the plug is inserted into the receptable, the power pins make contact before the data pins make contact. See the following figure.

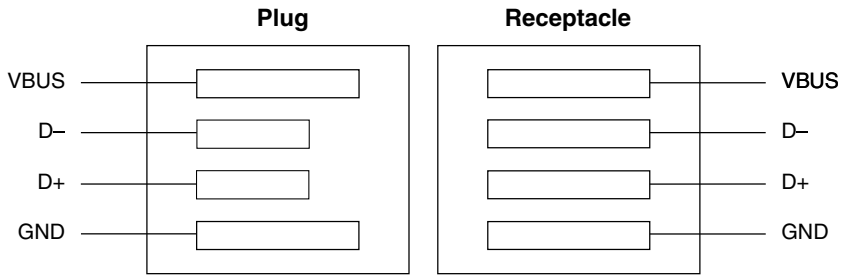

Figure 56-5. Relative pin positions in USB plugs and receptacles

As a result, when a portable USB device is attached to an upstream port, the portable USB device detects VBUS before the data pins have made contact. The time between power pins and data pins making contact depends on how fast the plug is inserted into the receptable. Delays of several hundred milliseconds are possible.

56.9.1.3.1 Debouncing the data pin contact

When system software has initiated the charger detection sequence, as described in Initial System Conditions, the USBDCD module turns on the I_{DP_SRC} current source and enables the R_{DM_DWN} pulldown resistor. If the data pins have not made contact, the D+ line remains high. After the data pins make contact, the D+ line goes low and debouncing begins.

After the D+ line goes low, the module continuously samples the D+ line over the duration of the T_{DCD_DBNC} debounce time interval.By deafult, T_{DCD_DBNC} is 10 ms, but it can be programmed in the TIMER0[TDCD_DBNC] field. See the description of the TIMER0 Register for register information.

When it has remained low for the entire interval, the debouncing is complete. However, if the D+ line returns high during the debounce interval, the module waits until the D+ line goes low again to restart the debouncing. This cycle repeats until either of the following happens:

- The data pin contact has been successfully debounced (see Success in detecting data pin contact (phase completion)).
- A timeout occurs (see Charger detection sequence timeout).

56.9.1.3.2 Success in detecting data pin contact (phase completion)

After successfully debouncing the D+ state, the module does the following:

- Updates the STATUS register to reflect phase completion (See Table 56-14 for field values.)
- Directly proceeds to the next step in the sequence: detection of a charging port (See Charging port detection.)

56.9.1.4 Charging port detection

After it detects that the data pins have made contact, the module waits for a fixed delay of 1 ms, and then attempts to detect whether it is plugged into a charging port. The module connects the following analog units to the USB D+ or D– lines during this phase:

- The voltage source V_{DP_SRC} connects to the D+ line
- The current sink I_{DM_SINK} connects to the D– line
- The voltage comparator connects to the USB D– line, comparing it to the voltage V_{DAT_REF}.

After a time of T_{VDPSRC_ON}, the module samples the D– line. The T_{VDPSRC_ON} parameter is programmable and defaults to 40 ms. After sampling the D– line, the module disconnects the voltage source, current sink, and comparator.

The next steps in the sequence depend on the voltage on the D– line as determined by the voltage comparator. See the following table.

Table 56-11. Sampling D– in the charging port detection phase

If the voltage on D- is...	Then...	See...
Below V_{DAT_REF}	The port is an SDP that does not support using charging currents above I_{CFG_MAX}.	Standard downstream port
Above V_{DAT_REF} but below V_{LGC}	The port is a charging port.	Charging port
Above V_{LGC}	This is an error condition.	Error in charging port detection

56.9.1.4.1 Standard downstream port

As part of the charger detection handshake with a standard USB host, the module does the following without waiting for the interval ($T_{WAIT\_AFTER\_PRD}$ or T_{VDPSRC_CON}) to elapse:

- Updates the STATUS register to reflect that a standard downstream port (SDP) has been detected with SEQ_RES = 01. See Table 56-14 for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE].

At this point, control has been passed to system software via the interrupt. The rest of the sequence, which detects the type of charging port, is not applicable, so software should perform the following steps:

1. Read the STATUS register.
2. Set CONTROL[IACK] to acknowledge the interrupt.
3. Set CONTROL[SR] to issue a software reset to the module.
4. Disable the module.
5. Communicate the appropriate charge rate to the external battery charger IC; see Table 56-7.

56.9.1.4.2 Charging port

As part of the charger detection handshake with any type of USB host, the module waits until the interval ($T_{WAIT\_AFTER\_PRD}$ or T_{VDPSRC_CON}) has elapsed before it does the following:

- Enables V_{DM_SRC} (for *USB Battery Charging Specification, Rev1.2* only).
- Updates the STATUS register to reflect that a charging port has been detected with SEQ_RES = 10. See Table 56-14 for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE].

At this point, control has passed to system software via the interrupt. Software should:

1. Read the STATUS register.
2. Set CONTROL[IACK] to acknowledge the interrupt.
3. Issue a command to the USB controller to pullup the USB D+ line.
4. Wait for the module to complete the final phase of the sequence. See Charger type detection.

56.9.1.4.3 Error in charging port detection

For this error condition, the module does the following:

- Updates the STATUS register to reflect the error with SEQ_RES = 00. See Table 56-14 for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE].

Note that in this case the module does not wait for the interval ($T_{WAIT\_AFTER\_PRD}$ or T_{VDPSRC_CON}) to elapse.

At this point, control has been passed to system software via the interrupt. The rest of the sequence (detecting the type of charging port) is not applicable, so software should:

1. Read the STATUS register.
2. Set CONTROL[IACK] to acknowledge the interrupt.
3. Set CONTROL[SR] to issue a software reset to the module.
4. Disable the module.

56.9.1.5 Charger type detection

For *USB Battery Charging Specification, Rev. 1.2*:

After the USBDCD module enables the V_{DM_SRC}, the module starts the T_{VDMSRC_ON} timer counting down the time interval programmed into the TIMER2[T_{VDMSRC_ON}] field.

Once the T_{VDMSRC_ON} timer has elapsed, the module samples the USB D+ line to determine the type of charger. See the following table.

Table 56-12. Sampling D+ in the charger type detection phase (BC1.2)

If the voltage on D+ is...	Then...	See...
High (D+>V_{DAT_REF})	The port is a DCP. [1]	Dedicated charging port
Low (D+<V_{DAT_REF})	The port is a CDP. [2]	Charging downstream port

1. In a DCP, the D+ and D– lines are shorted together through a small resistor.
2. In a CDP, the D+ and D– lines are not shorted.

For *USB Battery Charging Specification, Rev. 1.1*:

After software enables the D+ pullup resistor, the module is notified automatically (via internal signaling) to start the CHECK_DM timer counting down the time interval programmed in the TIMER2[CHECK_DM] field.

After the CHECK_DM time has elapsed, the module samples the USB D– line to determine the type of charger. See the following table.

Table 56-13. Sampling D– in the charger type detection phase (BC1.1)

If the voltage on D– is...	Then...	See...
High	The port is a DCP. [1]	Dedicated charging port
Low	The port is a CDP. [2]	Charging downstream port

1. In a DCP, the D+ and D– lines are shorted together through a small resistor.
2. In a CDP, the D+ and D– lines are not shorted.

56.9.1.5.1 Dedicated charging port

For a dedicated charging port (DCP), the module does the following:

- Updates the STATUS register to reflect that a dedicated charging port has been detected with SEQ_RES = 11. See Table 56-14 for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE] bit.

The *USB Battery Charging Specification, Rev. 1.2* indicates that additionally if the detection sequence determines an attachment to a DCP, then the USB device should signal on the D+ pin by either enabling the D+ pullup resistor or enabling V_{DP_SRC}.

At this point, control has been passed to system software via the interrupt. Software should:

1. Read the STATUS register.
2. Disable the USB controller to prevent transitions on the USB D+ or D– lines from causing spurious interrupt or wakeup events to the system.
3. Set CONTROL[IACK] to acknowledge the interrupt.
4. Set CONTROL[SR] to issue a software reset to the module.
5. Disable the module.

6. Enable signaling on the D+ pin. This can be done by enabling the Transceiver D+ pullup resistor through configuration of register bit fields in the USB controller instance for this USB port. On this product this signaling can alternatively be done by enabling V_{DP_SRC} through setting the SIGNAL_OVERRIDE[PS] bit field to a value of 2'b10.
7. Communicate the appropriate charge rate to the external battery charger IC; see Table 56-7.

56.9.1.5.2 Charging downstream port

For a charging downstream port (CDP), the module does the following:

- Updates the STATUS register to reflect that a CDP has been detected with SEQ_RES = 10. See Table 56-14 for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE].

At this point, control has been passed to system software via the interrupt. Software should:

1. Read the STATUS register.
2. Set CONTROL[IACK] to acknowledge the interrupt.
3. Set CONTROL[SR] to issue a software reset to the module.
4. Disable the module.
5. Communicate the appropriate charge rate to the external battery charger IC; see Table 56-7.

56.9.1.6 Charger detection sequence timeout

The maximum time allowed to connect according to the *USB Battery Charging Specification* is one second. If the Unit Connection Timer reaches the one second limit and the sequence is still running as indicated by the STATUS[ACTIVE] bit, the module does the following:

- Updates the STATUS register to reflect that a timeout error has occured. See Table 56-14 for field values.

- Sets the CONTROL[IF] bit.
- Generates an interrupt if enabled in CONTROL[IE].
- The detection sequence continues until explicitly halted by software setting the CONTROL[SR] bit.
- The Unit Connection Timer continues counting. See the description of the TIMER0 Register.

At this point, control has been passed to system software via the interrupt, which has two options: ignore the interrupt and allow more time for the sequence to complete, or halt the sequence. To halt the sequence, software should:

1. Read the STATUS register.
2. Set the CONTROL[IACK] bit to acknowledge the interrupt.
3. Set the CONTROL[SR] bit to issue a software reset to the module.
4. Disable the module.

This timeout function is also useful in case software does not realize that the USB device is unplugged from USB port during the charger detection sequence. If the interrupt occurs but the V_{BUS_DETECT} input is low, software can disable and reset the module.

System software might allow the sequence to run past the timeout interrupt under these conditions:

1. The USB Battery Charging Spec is amended to allow more time. In this case, software should poll TIMER0[$T_{UNITCON}$] periodically to track elapsed time after 1s; or
2. For debug purposes.

Note that the $T_{UNITCON}$ register field will stop incrementing when it reaches its maximum value so it will not rollover to zero and start counting up again.

56.9.1.7 Dead Battery Provision signaling

If the system needs to operate under the Dead Battery Provision of the *USB Battery Charging Specification, Revision 1.2*, the USBDCD module must be configured to signal V_{DP_SRC} on the USB_DP pin.

For information on Dead Battery Provision conditions and signaling, see the Dead or weak battery later in this chapter.

56.9.2 Interrupts and events

The USBDCD module has an interrupt to alert system software of certain events, which are listed in the following table. All events except the Phase Complete event for the Data Pin Detection phase can trigger an interrupt.

Table 56-14. Events triggering an interrupt by sequence phase

Sequence phase	Event	Event description	STATUS fields [1]	Phase description
Data Pin Detection	Phase Complete	The module has detected data pin contact. *No interrupt occurs*: CONTROL[IF] = 0.	ERR = 0 SEQ_STAT = 01 SEQ_RES = 00 TO = 0	VBUS contact detection
Charging Port Detection	Phase Complete	The module has completed the process of identifying if the USB port is a charging port or not. **NOTE:** This only applies to *USB Battery Charging Specification, Rev. 1.1*.	ERR = 0 SEQ_STAT = 10 SEQ_RES = 01 or 10 TO = 0	Charging port detection
	Error	The module cannot identify the type of port because the D– line is above the USB's VLGC threshold.	ERR = 1 SEQ_STAT = 10 SEQ_RES = 00 TO = 0	Error in charging port detection
Charger Type Detection	Phase Complete	The module has completed the process of identifying the charger type detection. **Note:** The ERR flag always reads zero because no known error conditions are checked during this phase.	ERR = 0 SEQ_STAT = 11 SEQ_RES = 11 or 10 TO = 0	Charger type detection
Sequence Timeout	Error	The timeout interval from the time the USB device attaches to a USB port until it connects has elapsed.	ERR = 1 SEQ_STAT = last value [2] SEQ_RES = last value [2] TO = 1	Charger detection sequence timeout.

1. See the description of the Status register for register information.
2. The SEQ_STAT and SEQ_RES fields retain the values held at the time of the timeout error.

56.9.2.1 Interrupt Handling

Software can read which event caused the interrupt from the STATUS register during the interrupt service routine.

An interrupt is generated only if CONTROL[IE] is set. The CONTROL[IF] bit is always set under interrupt conditions, even if CONTROL[IE] is cleared. In this case, software can poll CONTROL[IF] to determine if an interrupt condition is pending.

Writes to CONTROL[IF] are ignored. To reset CONTROL[IF], set CONTROL[IACK] to acknowledge the interrupt. Writing to CONTROL[IACK] when CONTROL[IF] is cleared has no effect.

56.9.3 Resets

There are two ways to reset various register contents in this module: hardware resets and a software reset.

56.9.3.1 Hardware resets

Hardware resets originate at the system or device level and propagate down to the individual module level. They include start up reset, low-voltage reset, and all other hardware reset sources.

Hardware resets cause the register contents to be restored to their default state as listed in the register descriptions.

56.9.3.2 Software reset

A software reset re-initializes the module's status information, but leaves configuration information unchanged. The software reset allows software to prepare the module without needing to reprogram the same configuration each time the USB device is plugged into a USB port.

Setting CONTROL[SR] initiates a software reset. The following table shows all register fields that are reset to their default values by a software reset.

Table 56-15. Software reset and register fields affected

Register	Fields affected	Fields not affected
CONTROL[1]	IF	IE, START
STATUS	All	None
CLOCK	None	All
TIMER*n*	TUNITCON	All other

1. CONTROL[SR] and CONTROL[IACK] are self-clearing.

A software reset also returns all internal logic, timers, and counters to their reset states. If the module is already active (STATUS[ACTIVE] = 1), a software reset stops the sequence.

Note

Software must always initiate a software reset before starting the sequence to ensure the module is in a known state.

56.10 Initialization information

This module has been designed for minimal configuration while retaining significant programmability. The CLOCK register needs to be initialized to the actual system clock frequency, unless the default value already matches the system requirements.

The proper operation of the USBHSDCD instantiation of this module requires that the USBPHY_ANACTRL[DEV_PULLDOWN] bit field be reset to value 1'b0 during the period when this module is in use.

The other registers generally do not need to be modified, because they default to values that comply with the USB Battery Charging Specification. However, several timing parameters can be changed for a great deal of flexibility if a particular system requires it.

All module configuration must occur *before* initiating the charger detection sequence. Configuration changes made *after* setting CONTROL[START] result in undefined behavior.

56.11 Application information

This section provides application information.

56.11.1 External pullups

Any external pullups applied to the USB D+ or D- data lines must be capable of being disabled to prevent incorrect pullup values or incorrect operation of the USB subsystem.

56.11.2 Dead or weak battery

According to the *USB Battery Charging Specification, Revision 1.2*, a USB device with a dead or weak battery that is attached to a downstream port can draw charging current from VBUS without connecting for several minutes, until the battery is charged to the point that the USB device can connect. The conditions for this operation are referred to as the Dead Battery Provision.

The *USB Battery Charging Specification, Revision 1.2* limits this charging condition to 100mA for a duration of 45 minutes. The later *USB 2.0 Connect Timing Update ECN* modifies this charging condition to 500mA for a duration of 2 minutes. Customers designing systems to take advantage of the Dead Battery Provision should study both specifications closely.

The USBDCD module is compatible with systems that do not check the strength of the battery. Therefore, this module assumes that the battery is good, so the USB device must immediately connect to the USB bus by pulling the USB_DP pin high after the USBDCD module has determined that the device is attached to an SDP or CDP. (By definition, a DCP does not support connection but still requires a signaling event, see Dedicated charging port.)

The module is also compatible with systems that have other circuitry to check the strength of the battery. In these systems, if it is known that the battery is weak or dead, software can delay connecting to the USB while charging using the Dead Battery Provision. Once the battery is charged to the good battery threshold, software must then connect to the USB host by pulling the USB_DP pin high.

While using the Dead Battery Provision, the USB_DP pin must signal by enabling V_{DP_SRC}. On this product that signaling can be done most simply by setting the USBDCD_SIGNAL_OVERRIDE[PS] bit field to value 2'b10.

56.11.3 Handling unplug events

If the device is unplugged from the USB bus during the charger detection sequence, the contents of the STATUS register must be ignored and the USBDCD module must get a Software Reset, as described in Software reset.

Chapter 57
Cyclic Redundancy Check (CRC)

57.1 Chip-specific CRC information

Table 57-1. Reference links to related information

Topic	Related module	Reference

Power management		Power management
Signal multiplexing	Port control	Signal multiplexing

57.1.1 Cyclic Redundancy Check (CRC)

The CRC module is a hardware CRC generator circuit using 16/32-bit shift register. The CRC module supports error detection for all single, double, odd, and most multi-bits errors, programmable initial seed value, and optional feature to transpose input data and CRC result via transpose register. The following table shows the configuration of the CRC.

Table 57-2. CRC configuration

Parameter	Description
Name	Cyclic Redundancy Check (CRC)
Instances	1
Configurable features	NA
Interface speed	NA
External I/O pins	See the attached IOMUXC spreadsheet for pin details

57.2 Introduction

The cyclic redundancy check (CRC) module generates 16/32-bit CRC code for error detection.

The CRC module provides a programmable polynomial and other parameters required to implement a 16-bit or 32-bit CRC standard.

The 16/32-bit code is calculated for 32 bits of data at a time.

57.2.1 Features

Features of the CRC module include:

- Hardware CRC generator circuit using a 16-bit or 32-bit programmable shift register
- Programmable initial seed value and polynomial
- Option to transpose input data or output data (the CRC result) bitwise or bytewise. This option is required for certain CRC standards. A bytewise transpose operation is not possible when accessing the CRC data register via 8-bit accesses. In this case, the user's software must perform the bytewise transpose function.
- Option for inversion of final CRC result
- 32-bit CPU register programming interface

57.2.2 Block diagram

The following is a block diagram of the CRC.

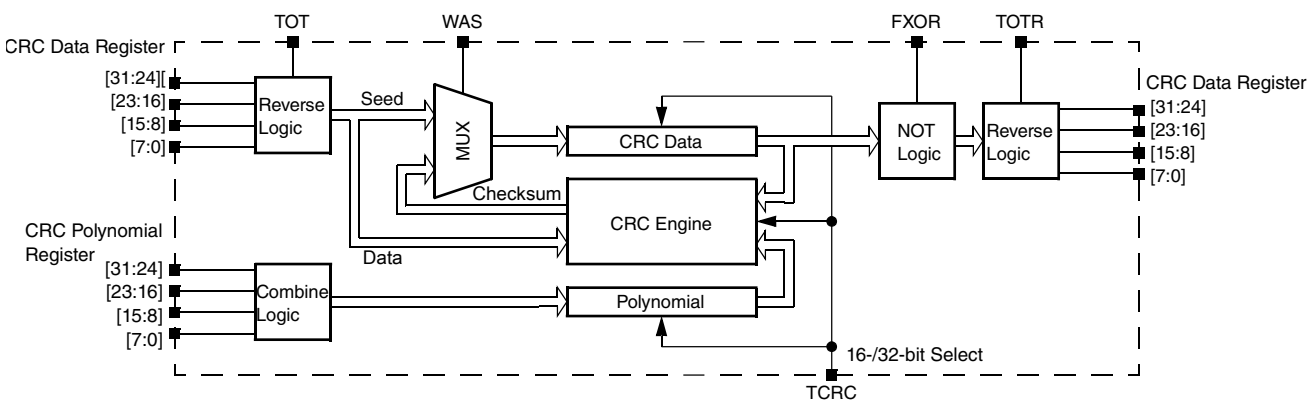

Figure 57-1. Programmable cyclic redundancy check (CRC) block diagram

57.2.3 Modes of operation

Various MCU modes affect the CRC module's functionality.

57.2.3.1 Run mode

This is the basic mode of operation.

57.2.3.2 Low-power modes (Wait or Stop)

Any CRC calculation in progress stops when the MCU enters a low-power mode that disables the module clock. It resumes after the clock is enabled or via the system reset for exiting the low-power mode. Clock gating for this module is dependent on the MCU.

57.3 Memory map and register descriptions

57.3.1 CRC register descriptions

57.3.1.1 CRC Memory map

CRC0 base address: 4102_9000h

Offset	Register	Width (In bits)	Access	Reset value
0h	CRC Data register (DATA)	32	RW	FFFF_FFFFh
4h	CRC Polynomial register (GPOLY)	32	RW	0000_1021h
8h	CRC Control register (CTRL)	32	RW	0000_0000h

57.3.1.2 CRC Data register (DATA)

57.3.1.2.1 Offset

Register	Offset
DATA	0h

57.3.1.2.2 Function

The CRC Data register contains the value of the seed, data, and checksum. When CTRL[WAS] is set, any write to the data register is regarded as the seed value. When CTRL[WAS] is cleared, any write to the data register is regarded as data for general CRC computation.

In 16-bit CRC mode, the HU and HL fields are not used for programming the seed value, and reads of these fields return an indeterminate value. In 32-bit CRC mode, all fields are used for programming the seed value.

When programming data values, the values can be written 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous; with MSB of data value written first.

After all data values are written, the CRC result can be read from this data register. In 16-bit CRC mode, the CRC result is available in the LU and LL fields. In 32-bit CRC mode, all fields contain the result. Reads of this register at any time return the intermediate CRC value, provided the CRC module is configured.

57.3.1.2.4 Fields

Field	Function
31-24 HU	CRC High Upper Byte

Table continues on the next page...

Field	Function
	In 16-bit CRC mode (CTRL[TCRC] is 0), this field is not used for programming a seed value. In 32-bit CRC mode (CTRL[TCRC] is 1), values written to this field are part of the seed value when CTRL[WAS] is 1. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation in both 16-bit and 32-bit CRC modes.
23-16 HL	CRC High Lower Byte In 16-bit CRC mode (CTRL[TCRC] is 0), this field is not used for programming a seed value. In 32-bit CRC mode (CTRL[TCRC] is 1), values written to this field are part of the seed value when CTRL[WAS] is 1. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation in both 16-bit and 32-bit CRC modes.
15-8 LU	CRC Low Upper Byte When CTRL[WAS] is 1, values written to this field are part of the seed value. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation.
7-0 LL	CRC Low Lower Byte When CTRL[WAS] is 1, values written to this field are part of the seed value. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation.

57.3.1.3 CRC Polynomial register (GPOLY)

57.3.1.3.1 Offset

Register	Offset
GPOLY	4h

57.3.1.3.2 Function

This register contains the value of the polynomial for the CRC calculation. The HIGH field contains the upper 16 bits of the CRC polynomial, which are used only in 32-bit CRC mode. Writes to the HIGH field are ignored in 16-bit CRC mode. The LOW field contains the lower 16 bits of the CRC polynomial, which are used in both 16- and 32-bit CRC modes.

57.3.1.3.3 Diagram

57.3.1.3.4 Fields

Field	Function
31-16 HIGH	High Polynominal Half-word Writable and readable in 32-bit CRC mode (CTRL[TCRC] is 1). This field is not writable in 16-bit CRC mode (CTRL[TCRC] is 0).
15-0 LOW	Low Polynominal Half-word Writable and readable in both 32-bit and 16-bit CRC modes.

57.3.1.4 CRC Control register (CTRL)

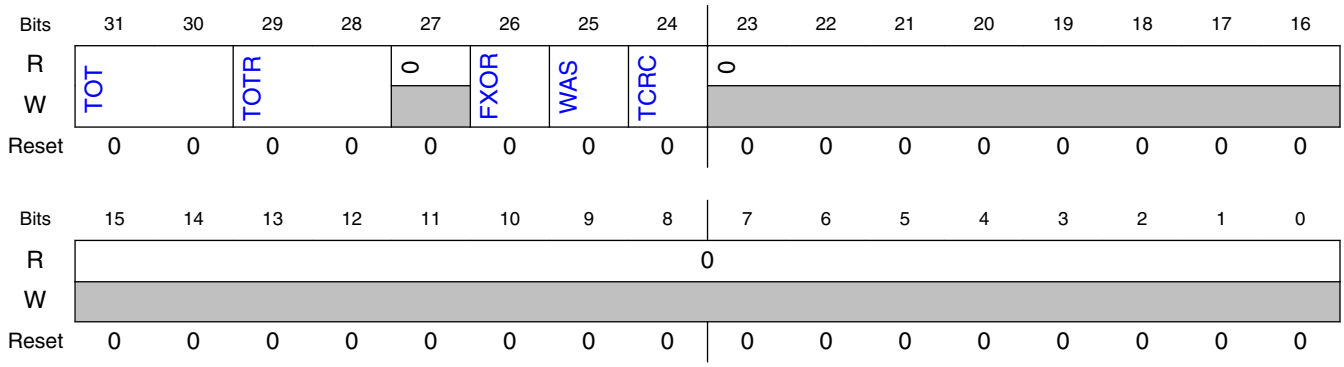
57.3.1.4.1 Offset

Register	Offset
CTRL	8h

57.3.1.4.2 Function

This register controls the configuration and working of the CRC module. Appropriate bits must be set before starting a new CRC calculation. A new CRC calculation is initialized by asserting CTRL[WAS] and then writing the seed into the CRC data register.

57.3.1.4.3 Diagram



57.3.1.4.4 Fields

Field	Function
31-30 TOT	Type Of Transpose For Writes Defines the transpose configuration of the data written to the CRC data register. See the description of the transpose feature for the available transpose options. 00b - No transposition. 01b - Bits in bytes are transposed; bytes are not transposed. 10b - Both bits in bytes and bytes are transposed. 11b - Only bytes are transposed; no bits in a byte are transposed.
29-28 TOTR	Type Of Transpose For Read Identifies the transpose configuration of the value read from the CRC Data register. See the description of the transpose feature for the available transpose options. 00b - No transposition. 01b - Bits in bytes are transposed; bytes are not transposed. 10b - Both bits in bytes and bytes are transposed. 11b - Only bytes are transposed; no bits in a byte are transposed.
27 —	Reserved
26 FXOR	Complement Read Of CRC Data Register Some CRC protocols require the final checksum to be XORed with 0xFFFFFFFF or 0xFFFF. Asserting this bit enables on the fly complementing of read data. 0b - No XOR on reading. 1b - Invert or complement the read value of the CRC Data register.
25 WAS	Write CRC Data Register As Seed When asserted, a value written to the CRC data register is considered a seed value. When deasserted, a value written to the CRC data register is taken as data for CRC computation. 0b - Writes to the CRC data register are data values. 1b - Writes to the CRC data register are seed values.
24 TCRC	TCRC Width of CRC protocol. 0b - 16-bit CRC protocol. 1b - 32-bit CRC protocol.
23-0 —	Reserved

57.4 Functional description

57.4.1 CRC initialization/reinitialization

To enable the CRC calculation, the user must program CRC_CTRL[WAS], CRC_GPOLY,necessary parameters for transposition and CRC result inversion in the applicable registers. Asserting CRC_CTRL[WAS] enables the programming of the seed value into the CRC_DATA register.

After a completed CRC calculation, the module can be reinitialized for a new CRC computation by reasserting CRC_CTRL[WAS] and programming a new, or previously used, seed value. All other parameters must be set before programming the seed value and subsequent data values.

57.4.2 CRC calculations

In 16-bit and 32-bit CRC modes, data values can be programmed 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous. Noncontiguous bytes can lead to an incorrect CRC computation.

57.4.2.1 16-bit CRC

To compute a 16-bit CRC:

1. Clear CRC_CTRL[TCRC] to enable 16-bit CRC mode.
2. Program the transpose and complement options in the CTRL register as required for the CRC calculation. See Transpose feature and CRC result complement for details.
3. Write a 16-bit polynomial to the CRC_GPOLY[LOW] field. The CRC_GPOLY[HIGH] field is not usable in 16-bit CRC mode.
4. Set CRC_CTRL[WAS] to program the seed value.
5. Write a 16-bit seed to CRC_DATA[LU:LL]. CRC_DATA[HU:HL] are not used.
6. Clear CRC_CTRL[WAS] to start writing data values.
7. Write data values into CRC_DATA[HU:HL:LU:LL]. A CRC is computed on every data value write, and the intermediate CRC result is stored back into CRC_DATA[LU:LL].
8. When all values have been written, read the final CRC result from CRC_DATA[LU:LL].

Transpose and complement operations are performed on the fly while reading or writing values. See Transpose feature and CRC result complement for details.

57.4.2.2 32-bit CRC

To compute a 32-bit CRC:

1. Set CRC_CTRL[TCRC] to enable 32-bit CRC mode.
2. Program the transpose and complement options in the CTRL register as required for the CRC calculation. See Transpose feature and CRC result complement for details.
3. Write a 32-bit polynomial to CRC_GPOLY[HIGH:LOW].
4. Set CRC_CTRL[WAS] to program the seed value.
5. Write a 32-bit seed to CRC_DATA[HU:HL:LU:LL].
6. Clear CRC_CTRL[WAS] to start writing data values.
7. Write data values into CRC_DATA[HU:HL:LU:LL]. A CRC is computed on every data value write, and the intermediate CRC result is stored back into CRC_DATA[HU:HL:LU:LL].
8. When all values have been written, read the final CRC result from CRC_DATA[HU:HL:LU:LL]. The CRC is calculated bytewise, and two clocks are required to complete one CRC calculation.

Transpose and complement operations are performed on the fly while reading or writing values. See Transpose feature and CRC result complement for details.

57.4.3 Transpose feature

By default, the transpose feature is not enabled. However, some CRC standards require the input data and/or the final checksum to be transposed. The user software has the option to configure each transpose operation separately, as desired by the CRC standard. The data is transposed on the fly while being read or written.

Some protocols use little endian format for the data stream to calculate a CRC. In this case, the transpose feature usefully flips the bits. This transpose option is one of the types supported by the CRC module.

57.4.3.1 Types of transpose

The CRC module provides several types of transpose functions to flip the bits and/or bytes, for both writing input data and reading the CRC result, separately using the CTRL[TOT] or CTRL[TOTR] fields, according to the CRC calculation being used.

The following types of transpose functions are available for writing to and reading from the CRC data register:

1. CTRL[TOT] or CTRL[TOTR] is 00.

   No transposition occurs.

2. CTRL[TOT] or CTRL[TOTR] is 01

   Bits in a byte are transposed, while bytes are not transposed.

   reg[31:0] becomes {reg[24:31], reg[16:23], reg[8:15], reg[0:7]}

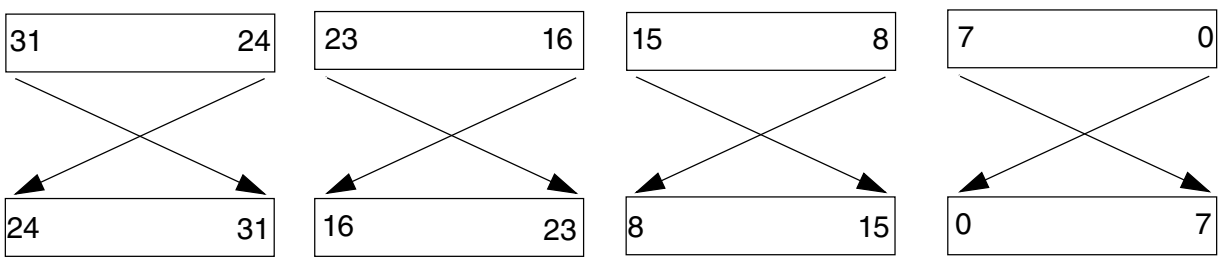


Figure 57-2. Transpose type 01

3. CTRL[TOT] or CTRL[TOTR] is 10.

   Both bits in bytes and bytes are transposed.

   reg[31:0] becomes = {reg[0:7], reg[8:15],reg[16:23], reg[24:31]}

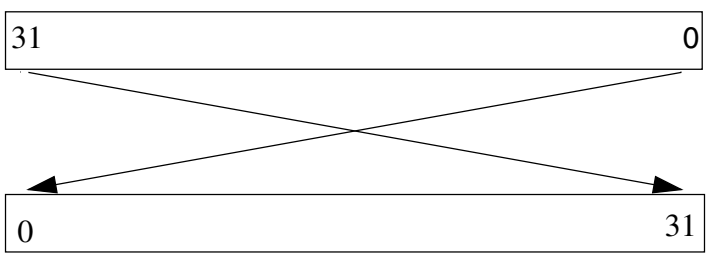

Figure 57-3. Transpose type 10

4. CTRL[TOT] or CTRL[TOTR] is 11.

   Bytes are transposed, but bits are not transposed.

   reg[31:0] becomes {reg[7:0], reg[15:8], reg[23:16], reg[31:24]}

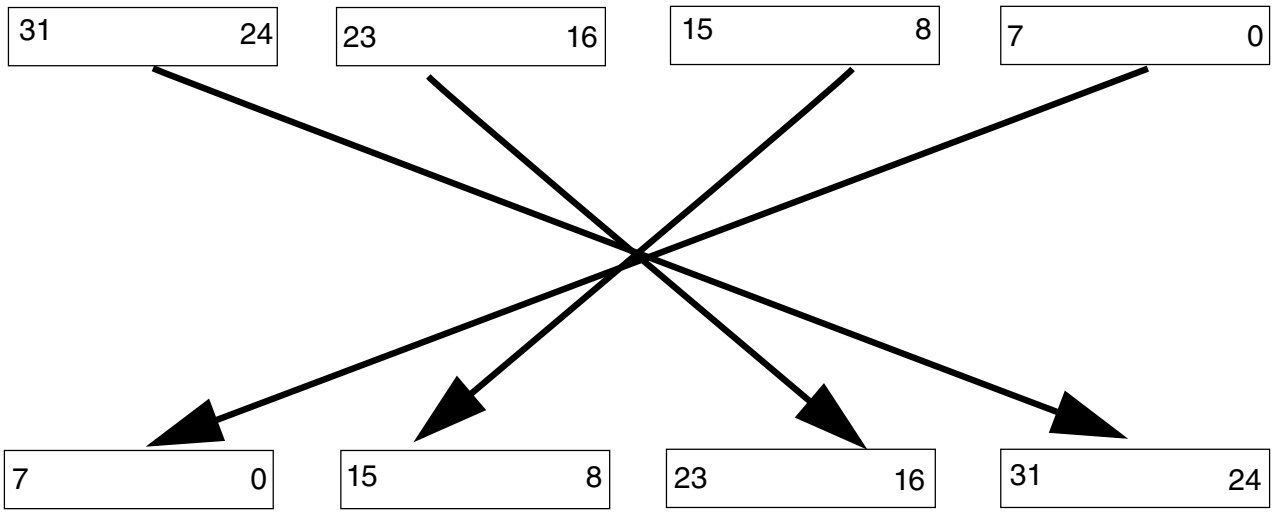

Figure 57-4. Transpose type 11

NOTE

For 8-bit and 16-bit write accesses to the CRC data register, the data is transposed with zeros on the unused byte or bytes (taking 32 bits as a whole), but the CRC is calculated on the valid byte(s) only. When reading the CRC data register for a 16-bit CRC result and using transpose options 10 and 11, the resulting value after transposition resides in the CRC[HU:HL] fields. The user software must account for this situation when reading the 16-bit CRC result, so reading 32 bits is preferred.

57.4.4 CRC result complement

When CTRL[FXOR] is set, the checksum is complemented. The CRC result complement function outputs the complement of the checksum value stored in the CRC data register every time the CRC data register is read. When CTRL[FXOR] is cleared, reading the CRC data register accesses the raw checksum value.

Chapter 58
Low Power Timer (LPTMR)

58.1 Chip-specific LPTMR information

58.1.1 LPTMR

The Low Power Timer (LPTMR) can operate as real-time interrupt or pulse accumulator. It includes a 2^N prescaler (real-time interrupt mode) or glitch filter (pulse accumulator mode). An interrupt is generated when the counter equals the value in the the 16-bit compare register. The counter may reset when the interrupt is generated. This LPTMR module can remain functional when the chip is in low power modes, provided the reference clock to this timer is active.

Table 58-2. LPTMR configuration

Parameter	Description
Name	LPTMR
Instances	2
Configurable features	• LPTMR0-1: 16-bit timer, 1 channel • LPTMR0-1 input sources: See Table 58-3 and Table 58-4
Interface speed	-
External I/O pins	LPTMRx: ALT0-3. See the attached IOMUXC spreadsheet to know the pin details.

58.1.2 LPTMR input sources

The LPTMR_CSR[TPS] bitfield configures the input source used in pulse counter mode. The following tables shows the chip-specific input assignments for this bitfield.

Table 58-3. LPTMR0 pulse counter input options

LPTMR0_CSR[TPS]	Pulse counter input number	Chip input
00	0	CMP0_OUT
01	1	LPTMR0_ALT1 pin
10	2	LPTMR0_ALT2 pin
11	3	LPTMR0_ALT3 pin

Table 58-4. LPTMR1 pulse counter input options

LPTMR1_CSR[TPS]	Pulse counter input number	Chip input
00	0	CMP0_OUT
01	1	LPTMR1 Trigger
10	2	LPTMR1_ALT2 pin
11	3	LPTMR1_ALT3 pin

58.1.3 LPTMR glitch filter/prescaler clocking options

The prescaler and glitch filter of the LPTMR can be clocked from miscellaneous sources determined by LPTMR0_PSR[PCS] and LPTMR0_CSR[TPS] bitfields for LPTMR0 instance (and similarly for LPTMR1). The supported clock sources on this device are shown in LPTMR clocking.

58.2 Introduction

The low-power timer (LPTMR) can be configured to operate as a time counter with optional prescaler, or as a pulse counter with optional glitch filter, across all power modes, including the low-leakage modes. It can also continue operating through most system reset events, allowing it to be used as a time of day counter.

58.2.1 Features

The features of the LPTMR module include:

- 16-bit time counter or pulse counter with compare
  - Optional interrupt can generate asynchronous wakeup from any low-power mode
  - Hardware trigger output
  - Counter supports free-running mode or reset on compare
- Configurable clock source for prescaler/glitch filter
- Configurable input source for pulse counter
  - Rising-edge or falling-edge

58.2.2 Modes of operation

The following table describes the operation of the LPTMR module in various modes.

Table 58-5. Modes of operation

Modes	Description
Run	The LPTMR operates normally.
Wait	The LPTMR continues to operate normally and can be configured to exit the low-power mode by generating an interrupt request.
Stop	The LPTMR continues to operate normally and can be configured to exit the low-power mode by generating an interrupt request.
Low-Leakage	The LPTMR continues to operate normally and can be configured to exit the low-power mode by generating an interrupt request.
Debug	The LPTMR operates normally in Pulse Counter mode, but the counter does not increment in Time Counter mode.

58.3 LPTMR signal descriptions

Table 58-6. LPTMR signal descriptions

Signal	I/O	Description
LPTMR_ALT*n*	I	Pulse Counter Input pin

58.3.1 Detailed signal descriptions

Table 58-7. LPTMR interface—detailed signal descriptions

Signal	I/O	Description	
LPTMR_ALT*n*	I	Pulse Counter Input The LPTMR can select one of the input pins to be used in Pulse Counter mode.	
		State meaning	Assertion—If configured for pulse counter mode with active-high input, then assertion causes the CNR to increment. Deassertion—If configured for pulse counter mode with active-low input, then deassertion causes the CNR to increment.
		Timing	Assertion or deassertion may occur at any time; input may assert asynchronously to the bus clock.

58.4 Memory map and register definition

NOTE

The LPTMR registers are reset only on a POR or LVD event.
See LPTMR power and reset for more details.

15-0 COUNTER	Counter Value The CNR returns the current value of the LPTMR counter at the time this register was last written.

58.5 Functional description

58.5.1 LPTMR power and reset

The LPTMR remains powered in all power modes, including low-leakage modes. If the LPTMR is not required to remain operating during a low-power mode, then it must be disabled before entering the mode.

The LPTMR is reset only on global Power On Reset (POR) or Low Voltage Detect (LVD). When configuring the LPTMR registers, the CSR must be initially written with the timer disabled, before configuring the PSR and CMR. Then, CSR[TIE] must be set as the last step in the initialization. This ensures the LPTMR is configured correctly and the LPTMR counter is reset to zero following a warm reset.

58.5.2 LPTMR clocking

The LPTMR prescaler/glitch filter can be clocked by one of the four clocks. The clock source must be enabled before the LPTMR is enabled.

NOTE

The clock source selected by PSR[PCS] may need to be configured to remain enabled in low-power modes, otherwise the LPTMR will not operate during low-power modes.

In Pulse Counter mode with the prescaler/glitch filter bypassed, the selected input source directly clocks the CNR and no other clock source is required. To minimize power in this case, configure the prescaler clock source for a clock that is not toggling.

NOTE

The clock source or pulse input source selected for the LPTMR should not exceed the frequency f_{LPTMR} defined in the device datasheet.

58.5.3 LPTMR prescaler/glitch filter

The LPTMR prescaler and glitch filter share the same logic which operates as a prescaler in Time Counter mode and as a glitch filter in Pulse Counter mode.

NOTE

The prescaler/glitch filter configuration must not be altered when the LPTMR is enabled.

58.5.3.1 Prescaler enabled

In Time Counter mode, when the prescaler is enabled, the output of the prescaler directly clocks the CNR. When the LPTMR is enabled, the CNR will increment every 2^2 to 2^{16} prescaler clock cycles. After the LPTMR is enabled, the first increment of the CNR will take an additional one or two prescaler clock cycles due to synchronization logic.

58.5.3.2 Prescaler bypassed

In Time Counter mode, when the prescaler is bypassed, the selected prescaler clock increments the CNR on every clock cycle. When the LPTMR is enabled, the first increment will take an additional one or two prescaler clock cycles due to synchronization logic.

58.5.3.3 Glitch filter

In Pulse Counter mode, when the glitch filter is enabled, the output of the glitch filter directly clocks the CNR. When the LPTMR is first enabled, the output of the glitch filter is asserted, that is, logic 1 for active-high and logic 0 for active-low. The following table shows the change in glitch filter output with the selected input source.

If	Then
The selected input source remains deasserted for at least 2^1 to 2^{15} consecutive prescaler clock rising edges	The glitch filter output will also deassert.
The selected input source remains asserted for at least 2^1 to 2^{15} consecutive prescaler clock rising-edges	The glitch filter output will also assert.

NOTE

The input is only sampled on the rising clock edge.

The CNR will increment each time the glitch filter output asserts. In Pulse Counter mode, the maximum rate at which the CNR can increment is once every 2^2 to 2^{16} prescaler clock edges. When first enabled, the glitch filter will wait an additional one or two prescaler clock edges due to synchronization logic.

58.5.3.4 Glitch filter bypassed

In Pulse Counter mode, when the glitch filter is bypassed, the selected input source increments the CNR every time it asserts. Before the LPTMR is first enabled, the selected input source is forced to be asserted. This prevents the CNR from incrementing if the selected input source is already asserted when the LPTMR is first enabled.

58.5.4 LPTMR counter

The CNR increments by one on every:

- Prescaler clock in Time Counter mode with prescaler bypassed
- Prescaler output in Time Counter mode with prescaler enabled
- Input source assertion in Pulse Counter mode with glitch filter bypassed
- Glitch filter output in Pulse Counter mode with glitch filter enabled

The CNR is reset when the LPTMR is disabled or if the counter register overflows. If CSR[TFC] is cleared, then the CNR is also reset whenever CSR[TCF] is set.

When the core is halted in Debug mode:

- If configured for Pulse Counter mode, the CNR continues incrementing.
- If configured for Time Counter mode, the CNR stops incrementing.

The CNR cannot be initialized, but can be read at any time. On each read of the CNR, software must first write to the CNR with any value. This will synchronize and register the current value of the CNR into a temporary register. The contents of the temporary register are returned on each read of the CNR.

When reading the CNR, the bus clock must be at least two times faster than the rate at which the LPTMR counter is incrementing, otherwise incorrect data may be returned.

58.5.5 LPTMR compare

When the CNR equals the value of the CMR and increments, the following events occur:

- CSR[TCF] is set.
- LPTMR interrupt is generated if CSR[TIE] is also set.
- LPTMR hardware trigger is generated.
- CNR is reset if CSR[TFC] is clear.

When the LPTMR is enabled, the CMR can be altered only when CSR[TCF] is set. When updating the CMR, the CMR must be written and CSR[TCF] must be cleared before the LPTMR counter has incremented past the new LPTMR compare value.

NOTE

When the LPTMR is enabled in Time Counter mode, the first increment will take an additional one or two clock cycles due to synchronization logic. This will result in the first compare (and therefore interrupt and hardware trigger) occuring slightly later. A faster prescaler clock or larger prescaler value will minimize this impact.

58.5.6 LPTMR interrupt

The LPTMR interrupt is generated whenever CSR[TIE] and CSR[TCF] are set. CSR[TCF] is cleared by disabling the LPTMR or by writing a logic 1 to it.

CSR[TIE] can be altered and CSR[TCF] can be cleared while the LPTMR is enabled.

The LPTMR interrupt is generated asynchronously to the system clock and can be used to generate a wakeup from any low-power mode, including the low-leakage modes, provided the LPTMR is enabled as a wakeup source.

58.5.7 LPTMR hardware trigger

The LPTMR hardware trigger asserts at the same time the CSR[TCF] is set and can be used to trigger hardware events in other peripherals without software intervention. The hardware trigger is always enabled.

When	Then
The CMR is set to 0 with CSR[TFC] clear	The LPTMR hardware trigger will assert on the first compare and does not deassert.
The CMR is set to a nonzero value, or, if CSR[TFC] is set	The LPTMR hardware trigger will assert on each compare and deassert on the following increment of the CNR.

59.1.1 WDOG (Watchdog Timer)

The Watchdog Timer (WDOG) module keeps a watch on the system functioning and resets it in case of its failure. Reasons for failure include run-away software code and the stoppage of the system clock that in a safety critical system can lead to serious consequences. In such cases, the WDOG brings the system into a safe state of operation. The WDOG monitors the operation of the system by expecting periodic communication from the software, generally known as servicing or refreshing the WDOG. If this periodic refreshing does not occur, the WDOG resets the system. There is a WDOG module associated with each processor, and the third WDOG instance is for security software use.

Table 59-2. WDOG configuration

Parameter	Description
Name	WDOG
Instances	3
Configurable features	NA
Interface speed	NA
External I/O pins	NA

59.1.2 WDOG clock sources

i.MX 7ULP uses the following clock sources to the WDOG module:

- 1 kHz LPO clock from SCG/SIRC
- 32 kHz RTCOSC internal clock from SCG/SNVS
- PCC asyn clk slow peripheral external clock

NOTE

To configure the external reference clock (ext_clk) of the WDG1 (A7) and WDG2 (A7) in the A7 core, first, clear the CGC bit of the PCC_WDOG1 and PCC_WDOG2 registers using the CM4 core, otherwise the WDG does not receive the clock.

59.2 Introduction

The Watchdog Timer (WDOG) module is an independent timer that is available for system use. It provides a safety feature to ensure that software is executing as planned and that the CPU is not stuck in an infinite loop or executing unintended code. If the WDOG module is not serviced (refreshed) within a certain period, it resets the MCU.

59.2.1 Features

Features of the WDOG module include:

- Configurable clock source inputs independent from the bus clock
  - Bus clock
  - LPO clock
  - INTCLK (internal clock)
  - ERCLK (external reference clock)
- Programmable timeout period
  - Programmable 16-bit timeout value
  - Optional fixed 256 clock prescaler when longer timeout periods are needed

- Robust write sequence for counter refresh
  - Refresh sequence of writing 0xA602 and then 0xB480
- Window mode option for the refresh mechanism
  - Programmable 16-bit window value
  - Provides robust check that program flow is faster than expected
  - Early refresh attempts trigger a reset.
- Optional timeout interrupt to allow post-processing diagnostics
  - Interrupt request to CPU with interrupt vector for an interrupt service routine (ISR)
  - Forced reset occurs 128 bus clocks after the interrupt vector fetch.
- Configuration bits are write-once-after-reset to ensure watchdog configuration cannot be mistakenly altered.
- Robust write sequence for unlocking write-once configuration bits
  - Unlock sequence of writing 0xC520 and then 0xD928 for allowing updates to write-once configuration bits
  - Software must make updates within 128 bus clocks after unlocking and before WDOG closing unlock window.

59.2.2 Block diagram

The following figure shows a block diagram of the WDOG module.

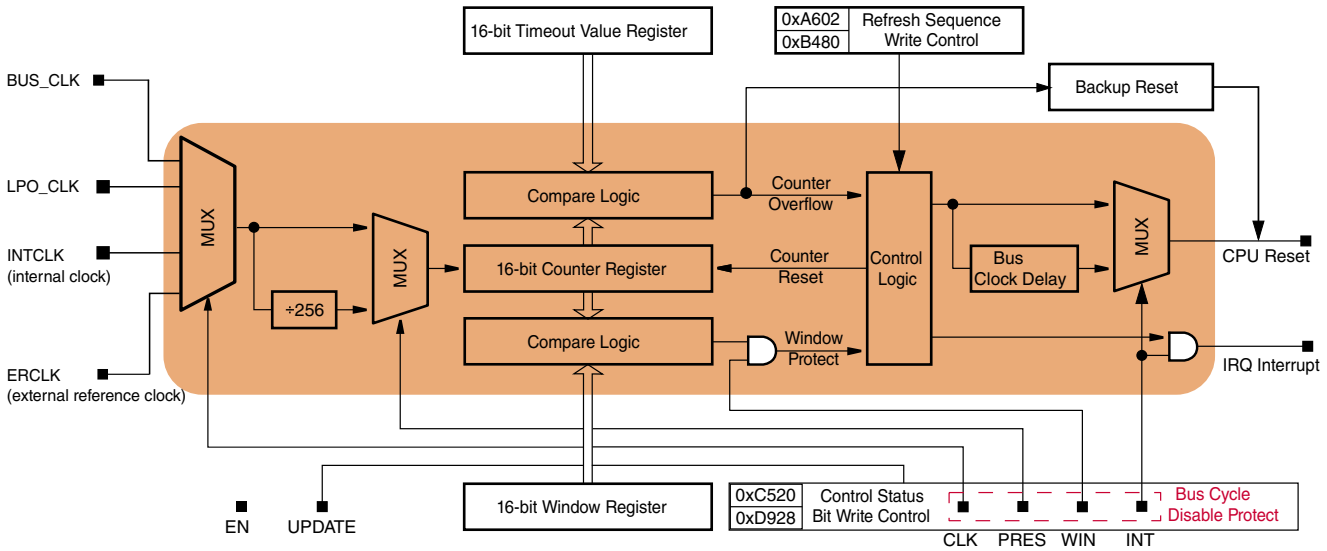

Figure 59-1. WDOG block diagram

59.3.1.2.1 Offset

Register	Offset
CS	0h

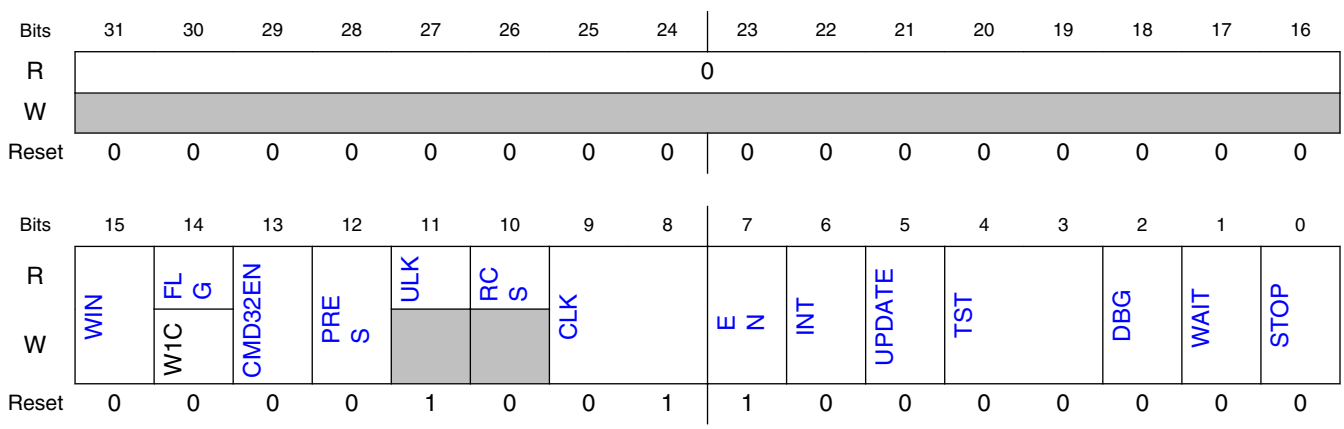
59.3.1.2.2 Function

This section describes the function of Watchdog Control and Status Register.

NOTE

TST is cleared (0:0) on POR only. Any other reset does not affect the value of this field.

59.3.1.2.3 Diagram



59.3.1.2.4 Fields

Field	Function
31-16 —	Reserved
15 WIN	Watchdog Window This write-once bit enables window mode. See the Window mode section. 0b - Window mode disabled. 1b - Window mode enabled.
14 FLG	Watchdog Interrupt Flag This bit is an interrupt indicator when INT is set in control and status register 1. Write 1 to clear it. 0b - No interrupt occurred.

Table continues on the next page...

Field	Function
	1b - An interrupt occurred.
13 CMD32EN	Enables or disables WDOG support for 32-bit (otherwise 16-bit or 8-bit) refresh/unlock command write words This is write-once field, and the user needs to unlock WDOG after writing this field for reconfiguration. 0b - Disables support for 32-bit refresh/unlock command write words. Only 16-bit or 8-bit is supported. 1b - Enables support for 32-bit refresh/unlock command write words. 16-bit or 8-bit is NOT supported.
12 PRES	Watchdog prescaler This write-once bit enables a fixed 256 pre-scaling of watchdog counter reference clock. (The block diagram shows this clock divider option.) 0b - 256 prescaler disabled. 1b - 256 prescaler enabled.
11 ULK	Unlock status This read-only bit indicates whether WDOG is unlocked or not. 0b - WDOG is locked. 1b - WDOG is unlocked.
10 RCS	Reconfiguration Success This read-only bit indicates whether the reconfiguration is successful or not. Default reset value is 0.This bit is set when new configuration takes effect, and is cleared by successful unlock command. 0b - Reconfiguring WDOG. 1b - Reconfiguration is successful.
9-8 CLK	Watchdog Clock This write-once field indicates the clock source that feeds the watchdog counter. See the Clock source section. 00b - Bus clock 01b - LPO clock 10b - INTCLK (internal clock) 11b - ERCLK (external reference clock)
7 EN	Watchdog Enable This write-once bit enables the watchdog counter to start counting. 0b - Watchdog disabled. 1b - Watchdog enabled.
6 INT	Watchdog Interrupt This write-once bit configures the watchdog to immediately generate an interrupt request upon a reset-triggering event (timeout or illegal write to the watchdog), before forcing a reset. After the interrupt vector fetch (which comes after the reset-triggering event), the reset occurs after a delay of 128 bus clocks. 0b - Watchdog interrupts are disabled. Watchdog resets are not delayed. 1b - Watchdog interrupts are enabled. Watchdog resets are delayed by 128 bus clocks from the interrupt vector fetch.
5 UPDATE	Allow updates This write-once bit allows software to reconfigure the watchdog without a reset. 0b - Updates not allowed. After the initial configuration, the watchdog cannot be later modified without forcing a reset. 1b - Updates allowed. Software can modify the watchdog configuration registers within 128 bus clocks after performing the unlock write sequence.
4-3 TST	Watchdog Test Enables the fast test mode. The test mode allows software to exercise all bits of the counter to demonstrate that the watchdog is functioning properly. See the Fast testing of the watchdog section.

Table continues on the next page...

Field	Function
	This write-once field is cleared (0:0) on POR only. Any other reset does not affect the value of this field. 00b - Watchdog test mode disabled. 01b - Watchdog user mode enabled. (Watchdog test mode disabled.) After testing the watchdog, software should use this setting to indicate that the watchdog is functioning normally in user mode. 10b - Watchdog test mode enabled, only the low byte is used. CNT[CNTLOW] is compared with TOVAL[TOVALLOW]. 11b - Watchdog test mode enabled, only the high byte is used. CNT[CNTHIGH] is compared with TOVAL[TOVALHIGH].
2 DBG	Debug Enable This write-once bit enables the watchdog to operate when the chip is in debug mode. 0b - Watchdog disabled in chip debug mode. 1b - Watchdog enabled in chip debug mode.
1 WAIT	Wait Enable This write-once bit enables the watchdog to operate when the chip is in wait mode. 0b - Watchdog disabled in chip wait mode. 1b - Watchdog enabled in chip wait mode.
0 STOP	Stop Enable This write-once bit enables the watchdog to operate when the chip is in stop mode. 0b - Watchdog disabled in chip stop mode. 1b - Watchdog enabled in chip stop mode.

59.3.1.3 Watchdog Counter Register (CNT)

59.3.1.3.1 Offset

Register	Offset
CNT	4h

59.3.1.3.2 Function

This section describes the watchdog counter register.

The watchdog counter register provides access to the value of the free-running watchdog counter. Software can read the counter register at any time.

Software cannot write directly to the watchdog counter; however, two write sequences to these registers have special functions:

1. The *refresh sequence* resets the watchdog counter to 0x0000. See the "Refreshing the Watchdog" section.
2. The *unlock sequence* allows the watchdog to be reconfigured without forcing a reset (when CS[UPDATE] = 1). See the "Configure for reconfigurable" section.

NOTE

All other writes to this register are illegal and force a reset.

59.3.1.3.3 Diagram

59.3.1.4 Watchdog Timeout Value Register (TOVAL)

59.3.1.4.1 Offset

Register	Offset
TOVAL	8h

59.3.1.4.2 Function

This section describes the watchdog timeout value register. TOVAL contains the 16-bit value used to set the timeout period of the watchdog.

The watchdog counter (CNT) is continuously compared with the timeout value (TOVAL). If the counter reaches the timeout value, the watchdog forces a reset triggering event.

NOTE

Do not write 0 to the TOVAL register (if CS[TST]=11b, then TOVALHIGH cannot be written as 0; if CS[TST]=10b, then TOVALLOW cannot be 0); otherwise, the watchdog always generates a reset.

59.3.1.4.3 Diagram

7-0 WINLOW	Low byte of Watchdog Window

59.4 Functional description

The WDOG module provides a fail safe mechanism to ensure the system can be reset to a known state of operation in case of system failure, such as the CPU clock stopping or there being a run away condition in the software code. The watchdog counter runs continuously off a selectable clock source and expects to be serviced (refreshed) periodically. If it is not, it generates a reset triggering event.

59.4.1 Clock source

The watchdog counter has the following clock source options selected by programming CS[CLK]:

- bus clock
- Low-Power Oscillator clock (LPO_CLK)
- internal clock
- external clock

The options allow software to select a clock source independent of the bus clock for applications that need to meet more robust safety requirements. Using a clock source other than the bus clock ensures that the watchdog counter continues to run if the bus clock is somehow halted; see Backup reset.

NOTE

The *default* clock source of WDOG should be enabled after its funcitonal reset is deasserted, for the WDOG module to function properly.

An optional fixed prescaler for all clock sources allows for longer timeout periods. When CS[PRES] is set, the clock source is prescaled by 256 before clocking the watchdog counter.

The following table summarizes the different watchdog timeout periods which could be available, as an example.

Table 59-3. Watchdog timeout availability

Reference clock	Prescaler	Watchdog time-out availability
REF_CLK	Pass through	1×RCP to 65535×RCP [1]
	Enable	256×RCP to 16776960×RCP

1. RCP means Reference Clock Period.

NOTE

When the programmer switches clock sources during reconfiguration, the watchdog hardware holds the counter at zero for 2.5 periods of the previous clock source and 2.5 periods of the new clock source after the configuration time period (128 bus clocks) ends. This delay ensures a smooth transition before restarting the counter with the new configuration.

59.4.2 Watchdog refresh mechanism

The watchdog resets the MCU if the watchdog counter is not refreshed. A robust refresh mechanism makes it very unlikely that the watchdog can be refreshed by runaway code.

To refresh the watchdog counter, software must execute a refresh write sequence before the timeout period expires. In addition, if window mode is used, software must not start the refresh sequence until after the time value set in the WIN register. See the following figure.

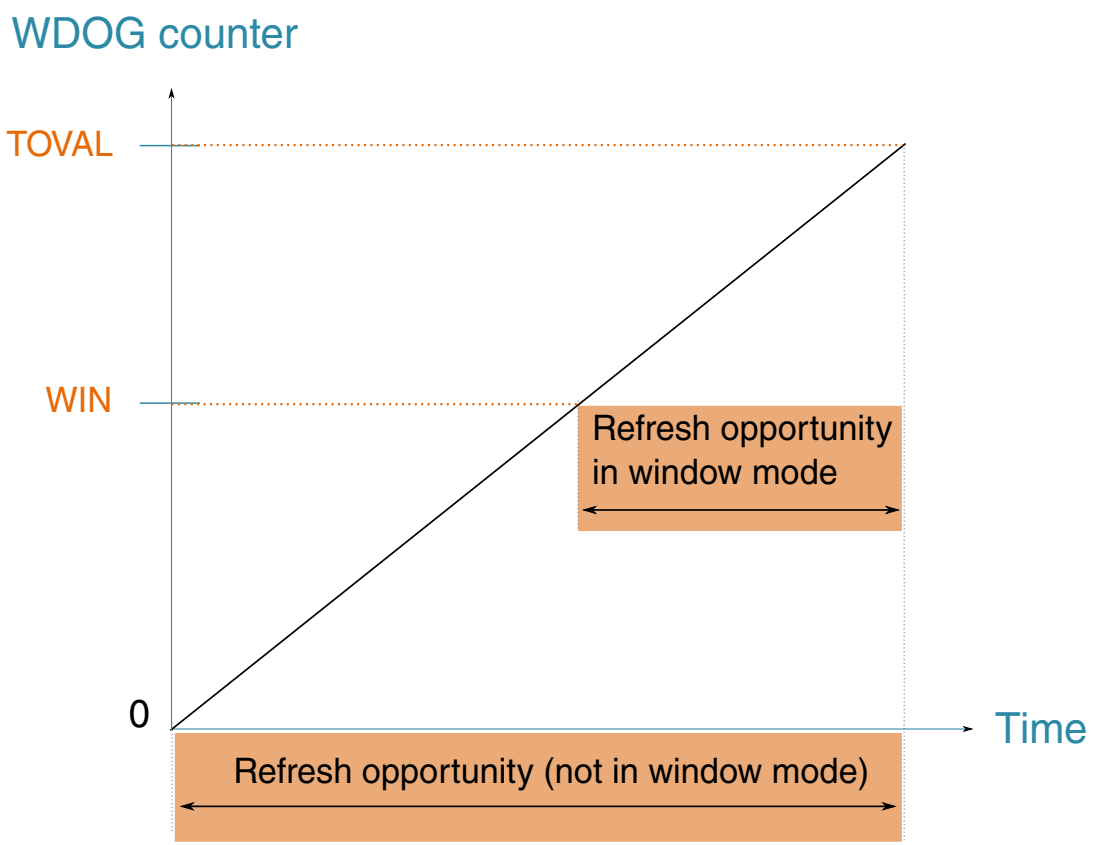

Figure 59-2. Refresh opportunity for the Watchdog counter

59.4.2.1 Window mode

Software finishing its main control loop faster than expected could be an indication of a problem. Depending on the requirements of the application, the WDOG can be programmed to force a reset when refresh attempts are early.

When Window mode is enabled, the watchdog must be refreshed after the counter has reached a minimum expected time value; otherwise, the watchdog resets the MCU. The minimum expected time value is specified in the WIN register. Setting CS[WIN] enables Window mode.

59.4.2.2 Refreshing the Watchdog

The refresh write sequence can be

- either two 16-bit writes (0xA602, 0xB480) or four 8-bit writes (0xA6, 0x02, 0xB4, 0x80) if WDOG_CS[CMD32EN] is 0;
- one 32-bit write (0xB480_A602) if WDOG_CS[CMD32EN] is 1.

to the CNT register. Both methods must occur before the WDG timeout; otherwise, the watchdog resets the MCU.

Note

Before starting the refresh sequence, disable the global interrupts. Otherwise, an interrupt could effectively invalidate the refresh sequence, if the interrupt occurs before the refresh writes finish. After the sequence finishes, restore the global interrupt control state.

The example codes can be found at the end of this chapter.

59.4.3 Configuring the Watchdog

59.4.3.1 Configuring the Watchdog Once

All watchdog control bits, timeout value, and window value are write-once after reset . This means that after a write has occurred they cannot be changed unless a reset occurs. This is guaranteed by the user configuring the window and timeout value first, followed by the other control bits, and ensuring that CS[UPDATE] is also set to 0.

This provides a robust mechanism to configure the watchdog and ensure that a runaway condition cannot mistakenly disable or modify the watchdog configuration after configured.

The new configuration takes effect only after all registers except CNT are written after reset. Otherwise, the WDOG uses the reset values by default. If window mode is not used (CS[WIN] is 0), writing to WIN is not required to make the new configuration take effect.

59.4.3.2 Reconfiguring the Watchdog

In some cases (like when supporting a bootloader function), you may want to reconfigure or disable the watchdog, *without forcing a reset first*.

- By setting CS[UPDATE] to 1 on the initial configuration of the watchdog after a reset, you can reconfigure the watchdog at any time by executing an unlock sequence.
- Conversely, if CS[UPDATE] remains 0, the only way to reconfigure the watchdog is by initiating a reset.

The unlock sequence is similar to the refresh sequence but uses different values.

59.4.3.2.1 Unlocking the Watchdog

The unlock sequence is a write to the CNT register of 0xC520 followed by 0xD928 within 16 bus clocks at any time after the watchdog has been configured. On completing the unlock sequence, the user must reconfigure the watchdog within 128 bus clocks; otherwise, the watchdog closes the unlock window.

NOTE

Due to the 128 bus clocks requirement for reconfiguring the watchdog, some delays must be inserted before executing STOP or WAIT instructions after reconfiguring the watchdog. This ensures that the watchdog's new configuration takes effect before the MCU enters low power mode. Otherwise, the MCU may not be waken up from low power mode.

The example codes can be found at end of this chapter.

59.4.4 Using interrupts to delay resets

- **When interrupts are enabled (CS[INT] = 1):** After a reset-triggering event (like a counter timeout or invalid refresh attempt), the watchdog first generates an interrupt request. Next, the watchdog delays 128 bus clocks (from the interrupt vector fetch, not the reset-triggering event) before forcing a reset, to allow the interrupt service routine (ISR) to perform tasks (like analyzing the stack to debug code).
- **When interrupts are disabled (CS[INT] = 0):** the watchdog does not delay the forcing a reset.

59.4.5 Backup reset

NOTE

A clock source other than the bus clock must be used as the reference clock for the counter; otherwise, the backup reset function is not available.

The backup reset function is a safeguard feature that independently generates a reset in case the main WDOG logic loses its clock (the bus clock) and can no longer monitor the counter. If the watchdog counter overflows twice in succession (without an intervening reset), the backup reset function takes effect and generates a reset.

Backup reset becomes valid when interrupt is enabled and the watchdog clock is from non bus clock. If interrupt is enabled, once the bus clock is cut off before exiting interrupt routine, the normal watchdog reset will be blocked. Under this case, the second overflow will cause backup reset directly.

59.4.6 Functionality in debug and low-power modes

By default, the watchdog is not functional in Debug mode, Wait mode, or Stop mode. However, the watchdog can remain functional in these modes as follows:

- **For Debug mode,** set CS[DBG]. (This way the watchdog is functional in Debug mode even when the CPU is held by the Debug module.)
- **For Wait mode,** set CS[WAIT].
- **For Stop mode,** set CS[STOP], CS[WAIT], and ensure the clock source is active in Stop mode.

NOTE

The watchdog can generate interrupt in Stop mode.

For Debug mode and Stop mode, in addition to the above configurations, a clock source other than the bus clock must be used as the reference clock for the counter; otherwise, the watchdog cannot function.

59.4.7 Fast testing of the watchdog

Before executing application code in safety critical applications, users are required to test that the watchdog works as expected and resets the MCU. Testing every bit of a 16-bit counter by letting it run to the overflow value takes a relatively long time (64 k clocks).

To help minimize the startup delay for application code after reset, the watchdog has a feature to test the watchdog more quickly by splitting the counter into its constituent byte-wide stages. The low and high bytes are run independently and tested for timeout against the corresponding byte of the timeout value register. (For complete coverage when testing the high byte of the counter, the test feature feeds the input clock via the 8th bit of the low byte, thus ensuring that the overflow connection from the low byte to the high byte is tested.)

Using this test feature reduces the test time to 512 clocks (not including overhead, such as user configuration and reset vector fetches). To further speed testing, use a faster clock (such as the bus clock) for the counter reference.

On a power-on reset, the POR bit in the system reset register is set, indicating the user should perform the WDOG fast test.

59.4.7.1 Testing each byte of the counter

The test procedure follows these steps:

1. Program the preferred watchdog timeout value in the TOVAL register during the watchdog configuration time period.
2. Select a byte of the counter to test using the CS[TST] = 10b for the low byte; CS[TST] = 11b for the high byte.
3. Wait for the watchdog to timeout. Optionally, in the idle loop, increment RAM locations as a parallel software counter for later comparison. Because the RAM is not affected by a watchdog reset, the timeout period of the watchdog counter can be compared with the software counter to verify the timeout period has occurred as expected.
4. The watchdog counter times out and forces a reset.
5. Confirm the WDOG flag in the system reset register is set, indicating that the watchdog caused the reset. (The POR flag remains clear.)
6. Confirm that CS[TST] shows a test (10b or 11b) was performed.

If confirmed, the count and compare functions work for the selected byte. Repeat the procedure, selecting the other byte in step 2.

NOTE

CS[TST] is cleared by a POR only and not affected by other resets.

59.4.7.2 Entering user mode

After successfully testing the low and high bytes of the watchdog counter, the user can configure CS[TST] to 01b to indicate the watchdog is ready for use in application user mode. Thus if a reset occurs again, software can recognize the reset trigger as a real watchdog reset caused by runaway or faulty application code.

As an ongoing test when using the default clock source, software can periodically read the CNT register to ensure the counter is being incremented.

59.5 Application Information

The watchdog is enabled by default after reset. To disable or reconfigure the watchdog, it is better to be done before the first watchdog timeout. It is suggested to disable or reconfigure the watchdog at the very beginning of the software code, e.g. beginning of the startup or main function.

NOTE

When the watchdog is configured by user, it needs at least 2.5 periods of watchdog clock to take effect. This means interval between two configures by user must be larger than 2.5 clocks.

NOTE

When Chip startup from BOOT ROM then jump to flash, the watchdog would be disabled in the beginning of bootloader, and enabled when bootloader exits. If there is any code in the flash program want to reconfigure the watchdog, it must be run 2.5 watchdog clocks later after the bootloader exits.

To disable or reconfigure the watchdog without forcing a reset, WDOG_CS[UPDATE] bit must be set during the initial configuration of the WDOG module. Then, the unlock sequence can be used at any time within the timeout limit to reconfigure the watchdog.

59.5.1 Disable Watchdog

To disable the watchdog, first do unlock sequence, then unset the WDOG_CS[EN] bit. The code snippet below shows an example for 32-bit write.

```
DisableInterrupts; // disable global interrupt
WDOG_CNT = 0xD928C520; //unlock watchdog
WDOG_CS &= ~WDOG_CS_EN_MASK; //disable watchdog
EnableInterrupts; //enable global interrupt
```

59.5.2 Disable Watchdog after Reset

All of watchdog registers are unlocked by reset. Therefore, unlock sequence is unnecessary, but it needs to write all of watchdog registers to make the new configuration take effect. The code snippet below shows an example of disabling watchdog after reset.

```
DisableInterrupts; // disable global interrupt
WDOG_CS &= ~WDOG_CS_EN_MASK; // disable watchdog
WDOG_TOVAL= 0xFFFF;
while(WDOG_CS[ULK]);  // waiting for lock
while(~WDOG_CS[RCS]); // waiting for new configuration to take effect
EnableInterrupts; // enable global interrupt
```

59.5.3 Configure Watchdog

The watchdog can be configured once by set the WDOG_CS[UPDATE]=0. After that, the watchdog cannot be reconfigured until a reset. If set WDOG_CS[UPDATE]=1 when configuring the watchdog, the watchdog can be reconfigured without forcing a reset. The following example code shows how to configure the watchdog without window mode, clock source as LPO, interrupt enabled and timeout value to 256 clocks. The code snippet below shows an example for 32-bit write.

Configure once

```
DisableInterrupts; // disable global interrupt
WDOG_CNT = 0xD928C520; //unlock watchdog
while(WDOG_CS[ULK]==0);  //wait until registers are unlocked
WDOG_TOVAL = 256; //set timeout value
WDOG_CS = WDOG_CS_EN(1) | WDOG_CS_CLK(1) | WDOG_CS_INT(1) |
          WDOG_CS_WIN(0) | WDOG_CS_UPDATE(0);
while(WDOG_CS[RCS]==0); //wait until new configuration takes effect
EnableInterrupts; //enable global interrupt
```

Configure for reconfigurable

```
DisableInterrupts; //disable global interrupt
WDOG_CNT = 0xD928C520; //unlock watchdog
while(WDOG_CS[ULK]==0);  //wait until registers are unlocked
WDOG_TOVAL = 256; //set timeout value
WDOG_CS = WDOG_CS_EN(1) | WDOG_CS_CLK(1) | WDOG_CS_INT(1) |
          WDOG_CS_WIN(0) | WDOG_CS_UPDATE(1);
while(WDOG_CS[RCS]==0); //wait until new configuration takes effect
EnableInterrupts; //enable global interrupt
```

59.5.4 Refreshing the Watchdog

To refresh the watchdog and reset the watchdog counter to zero, a refresh sequence is required. The code snippet below shows an example for 32-bit write.

```
DisableInterrupts; // disable global interrupt
WDOG_CNT = 0xB480A602; // refresh watchdog
EnableInterrupts; // enable global interrupt
```

60.1.1 Time stamp timer module (TSTMR)

The TSTMR module is a free running incremental counter that starts running after system reset deassertion and can be read at any time by the software for determining the software ticks. The TSTMR is a 64-bit clock cycle counter. It runs off the 1 MHz clock and resets on every system reset. The counter only stops when the clock to the TSTMR is disabled.

M4 and A7 TSTMRs are instantiated inside SIM module and timer values are mapped in SIM address spaces.

Table 60-2. TSTMR configuration

Parameter	Description
Name	Time Stamp Timer Module (TSTMR)
Instances	2 instances (one in A7 and other in M4)
Configurable features	NA
Interface speed	NA
External I/O pins	NA

60.2 Introduction

The Time Stamp Timer (TSTMR) is a 64-bit clock cycle counter, reset by system reset.

60.2.1 Features

- Free-running Time Stamp Timer

60.3 TSTMR A Memory map and register definition

The TSTMR A Memory Map/Register Definition can be found here.

The TSTMR A registers can be accessed from the A-Side Processor.

NOTE

TSTMR registers can be read with 32-bit accesses only.

60.3.1 TSTMRA register descriptions

This section contains the detailed register descriptions for the TSTMRA registers.

60.3.1.1 TSTMRA Memory map

TSTMRA base address: 410A_3C00h

Offset	Register	Width (In bits)	Access	Reset value
0h	Time Stamp Timer Register Low (LOW)	32	RO	0000_0000h
4h	Time Stamp Timer Register High (HIGH)	32	RO	0000_0000h

60.3.1.2 Time Stamp Timer Register Low (LOW)

60.3.1.2.1 Offset

Register	Offset
LOW	0h

60.3.1.2.2 Function

The Time Stamp Timer is a 64-bit clock cycle counter, reset by system reset. It is readable by way of the TSTMR HIGH and LOW registers. Only 32-bit read accesses are allowed. Any other access will generate a transfer error.

Note the following:

- A complete read operation should include both TSTMR LOW and HIGH reads. If a HIGH read does not follow a LOW read, then any other Time Stamp value read will be locked at a fixed value.
- The TSTMR LOW read should occur first, followed by the TSTMR HIGH read.

60.3.1.2.3 Diagram

Field	Function
31-0 VALUE	Time Stamp Timer High Upper 32 bits of the 64-bit time stamp value. The software must read the LOW first, followed by a read to HIGH to retrieve the complete value. The all-zero reset value may not be readable because the value will increment before it can be read by the software.

60.5 Functional description

The TSTMR module is a free running incrementing counter that starts running after system reset de-assertion and can be read at any time by the software for determining the software ticks. However, the software must follow the read sequence as mentioned in the TSTMR register descriptions for correctly reading the TSTMR value. The TSTMR is a

64-bit counter and hence requires two 32-bit reads to read the full value. The TSTMR runs off the 1 MHz clock and resets on every system reset. The counter only stops when the clock to the TSTMR is disabled.

See the chip-specific TSTMR information for implementation details of this module's instances.

61.1.1 External Watchdog Monitor

The External Watchdog Monitor (EWM) is designed to monitor external circuits, as well as the MCU software flow. This provides a back-up mechanism to the internal WDOG that can reset the system. The EWM has 1 kHz LPO clock source.

The EWM differs from the internal WDOG in that it does not reset the system. The EWM, if allowed to time-out, provides an independent trigger pin that when asserted resets or places an external circuit into a safe mode. The processor resets the EWM counter that is logically ANDed with an external digital input pin. This pin allows an external circuit to influence the reset_out signal.

Table 61-2. EWM configuration

Parameter	Description
Name	EWM

61.1.2 CLKPRESCALER register implementation

The CLKPRESCALER register is used for prescaling the clock frequency of low power clock source (~1 kHz LPO for i.MX 7ULP). Also, the number of bits of this register depends upon clock frequency of this clock source and the desired prescaled value.

61.2 Introduction

For safety, a redundant watchdog system, External Watchdog Monitor (EWM), is designed to monitor external circuits, as well as the MCU software flow. This provides a back-up mechanism to the internal watchdog that resets the MCU's CPU and peripherals.

The watchdog is generally used to monitor the flow and execution of embedded software within an MCU. The watchdog consists of a counter that if allowed to overflow, forces an internal reset (asynchronous) to all on-chip peripherals and optionally assert the RESET_B pin to reset external devices/circuits. The overflow of the watchdog counter must not occur if the software code works well and services the watchdog to re-start the actual counter.

The EWM differs from the internal watchdog in that it does not reset the MCU's CPU and peripherals. The EWM provides an independent EWM_OUT_b signal that when asserted resets or places an external circuit into a safe mode. The EWM_OUT_b signal is asserted upon the EWM counter time-out. An optional external input EWM_in is provided to allow additional control of the assertion of EWM_OUT_b signal.

61.2.1 Features

Features of EWM module include:

- Independent LPO_CLK clock source
- Programmable time-out period specified in terms of number of EWM LPO_CLK clock cycles.
- Windowed refresh option

    - Provides robust check that program flow is faster than expected.
    - Programmable window.
    - Refresh outside window leads to assertion of EWM_OUT_b.
- Robust refresh mechanism
    - Write values of 0xB4 and 0x2C to EWM Refresh Register within 23 peripheral bus clock cycles.
- One output port, EWM_OUT_b, when asserted is used to reset or place the external circuit into safe mode.
- One Input port, EWM_in, allows an external circuit to control the assertion of the EWM_OUT_b signal.

61.2.2 Modes of Operation

This section describes the module's operating modes.

61.2.2.1 Stop Mode

When the EWM is in stop mode, the CPU refreshes to the EWM cannot occur. On entry to stop mode, the EWM's counter freezes.

There are two possible ways to exit from Stop mode:

- On exit from stop mode through a reset, the EWM remains disabled.
- On exit from stop mode by an interrupt, the EWM is re-enabled, and the counter continues to be clocked from the same value prior to entry to stop mode.

Note the following if the EWM enters the stop mode during CPU refresh mechanism: At the exit from stop mode by an interrupt, refresh mechanism state machine starts from the previous state which means, if first refresh command is written correctly and EWM enters the stop mode immediately, the next command has to be written within the next *23* peripheral bus clocks after exiting from stop mode. User must mask all interrupts prior to executing EWM refresh instructions.

61.2.2.2 Debug Mode

Entry to debug mode has no effect on the EWM.

- If the EWM is enabled prior to entry of debug mode, it remains enabled.
- If the EWM is disabled prior to entry of debug mode, it remains disabled.

61.2.3 Block Diagram

This figure shows the EWM block diagram.

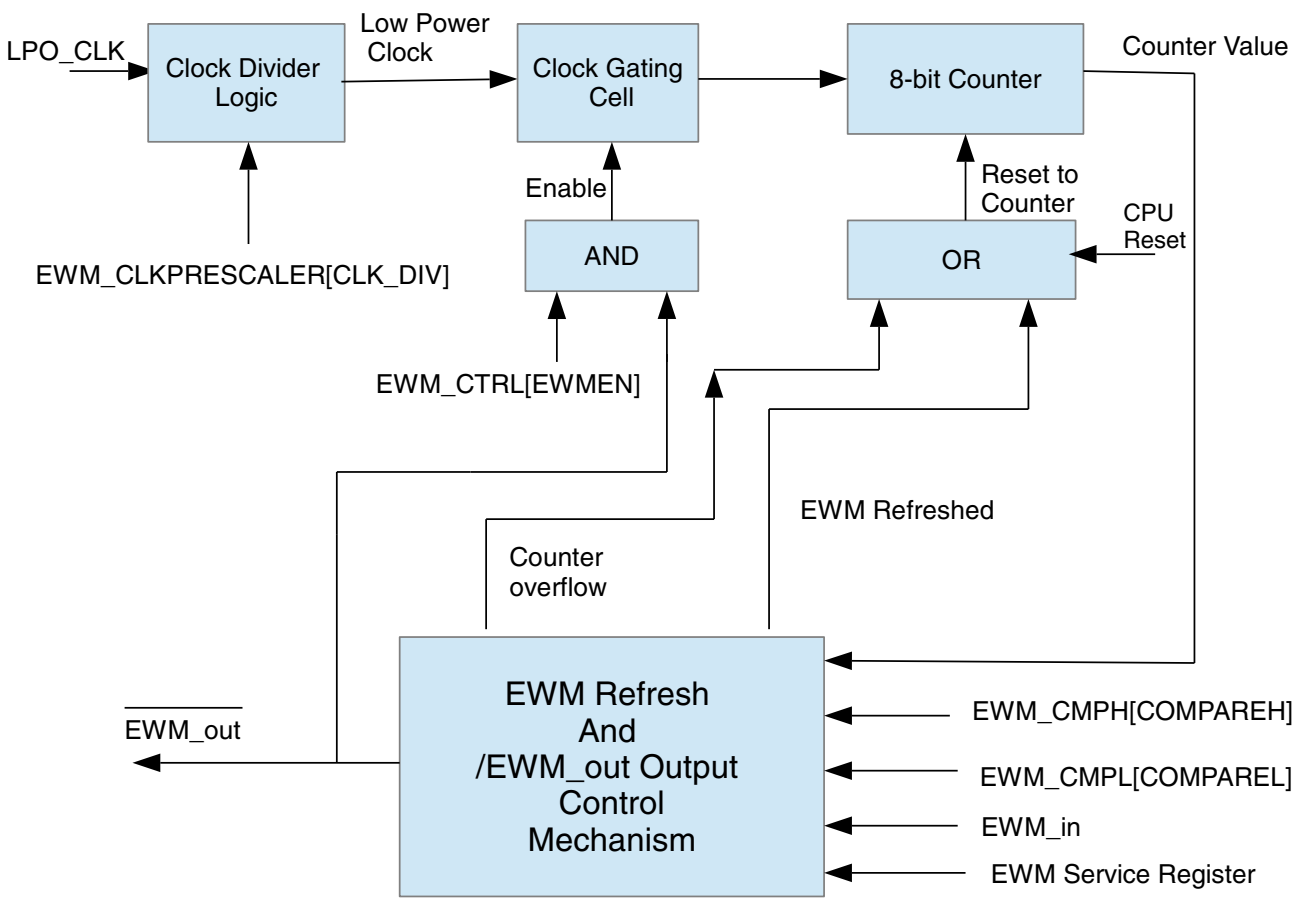

Figure 61-1. EWM Block Diagram

61.3 EWM Signal Descriptions

The EWM has two external signals and internal options for the counter clock sources, as shown in the following table.

NOTE

All active-low signals are now represented with the suffix "_b" throughout the chapter.

Table 61-3. EWM Signal Descriptions

Signal	Description	I/O
EWM_in	EWM input for safety status of external safety circuits. The polarity of EWM_in is programmable using the EWM_CTRL[ASSIN] bit. The default polarity is active low.	I
EWM_OUT_b	EWM reset out signal	O
lpo_clk[3:0]	Low power clock sources for running counter	I

61.4 Memory Map/Register Definition

This section contains the module memory map and registers.

NOTE

EWM only supports 8-bit register access. 16-bit and 32-bit access are not possible.

61.4.1 EWM register descriptions

61.4.1.1 EWM Memory map

EWM base address: 410A_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Control Register (CTRL)	8	RW	00h
1h	Service Register (SERV)	8	WORZ	00h
2h	Compare Low Register (CMPL)	8	RWONCE	00h
3h	Compare High Register (CMPH)	8	RWONCE	FFh
4h	Clock Control Register (CLKCTRL)	8	RWONCE	00h
5h	Clock Prescaler Register (CLKPRESCALER)	8	RWONCE	00h

61.4.1.2 Control Register (CTRL)

61.4.1.2.1 Offset

Register	Offset
CTRL	0h

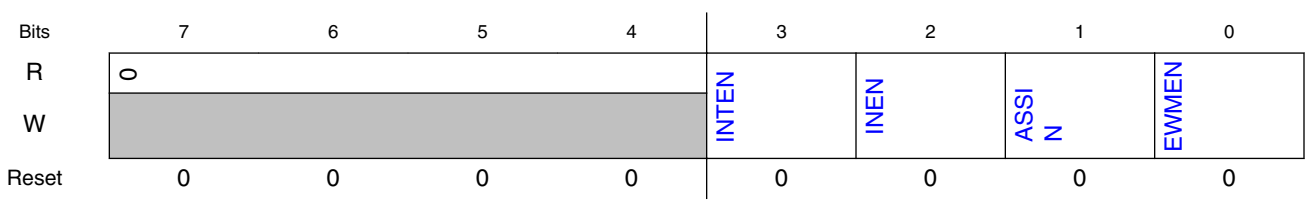
61.4.1.2.2 Function

The CTRL register is cleared by any reset.

NOTE

INEN, ASSIN and EWMEN bits can be written once after a CPU reset. Modifying these bits more than once, generates a bus transfer error.

61.4.1.2.3 Diagram



61.4.1.2.4 Fields

Field	Function
7-4 —	Reserved
3 INTEN	Interrupt Enable. This bit when set and EWM_OUT_b is asserted, an interrupt request is generated. To de-assert interrupt request, user should clear this bit by writing 0.
2 INEN	Input Enable. This bit when set, enables the EWM_in port.
1 ASSIN	EWM_in's Assertion State Select. Default assert state of the EWM_in signal is logic zero. Setting the ASSIN bit inverts the assert state of EWM_in signal to a logic one.
0	EWM enable.

Field	Function
EWMEN	This bit when set, enables the EWM module. This resets the EWM counter to zero and deasserts the EWM_OUT_b signal. This bit when unset, keeps the EWM module disabled. It cannot be re-enabled until a next reset, due to the write-once nature of this bit.

61.4.1.3 Service Register (SERV)

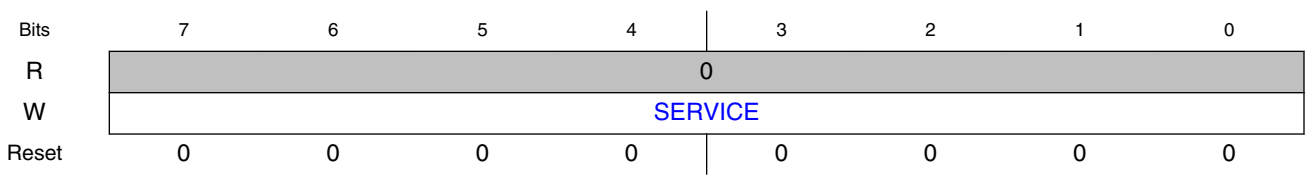
61.4.1.3.1 Offset

Register	Offset
SERV	1h

61.4.1.3.2 Function

The SERV register provides the interface from the CPU to the EWM module. It is write-only and reads of this register return zero.

61.4.1.3.3 Diagram



61.4.1.3.4 Fields

Field	Function
7-0 SERVICE	SERVICE The EWM refresh mechanism requires the CPU to write two values to the SERV register: a first data byte of 0xB4, followed by a second data byte of 0x2C. The EWM refresh is invalid if either of the following conditions is true. • The first or second data byte is not written correctly. • The second data byte is not written within a fixed number of peripheral bus cycles of the first data byte. This fixed number of cycles is called *EWM_refresh_time*. 23 peripheral bus clock cycles are required for *EWM_refresh_time*

61.4.1.4 Compare Low Register (CMPL)

61.4.1.4.1 Offset

Register	Offset
CMPL	2h

61.4.1.4.2 Function

The CMPL register is reset to zero after a CPU reset. This provides no minimum time for the CPU to refresh the EWM counter.

NOTE

This register can be written only once after a CPU reset. Writing this register more than once generates a bus transfer error.

61.4.1.4.3 Diagram

Bits	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0

61.4.1.4.4 Fields

Field	Function
7-0 COMPAREL	COMPAREL To prevent runaway code from changing this field, software should write to this field after a CPU reset even if the (default) minimum refresh time is required.

61.4.1.5 Compare High Register (CMPH)

61.4.1.5.1 Offset

Register	Offset
CMPH	3h

61.4.1.5.2 Function

The CMPH register is reset to 0xFF after a CPU reset. This provides a maximum of 256 clocks time, for the CPU to refresh the EWM counter.

NOTE

This register can be written only once after a CPU reset. Writing this register more than once generates a bus transfer error.

NOTE

The valid values for CMPH are up to 0xFE because the EWM counter never expires when CMPH = 0xFF. The expiration happens only if EWM counter is greater than CMPH.

61.4.1.5.3 Diagram

61.4.1.5.4 Fields

Field	Function
7-0 COMPAREH	COMPAREH To prevent runaway code from changing this field, software should write to this field after a CPU reset even if the (default) maximum refresh time is required.

61.4.1.6 Clock Control Register (CLKCTRL)

61.4.1.6.1 Offset

Register	Offset
CLKCTRL	4h

61.4.1.6.2 Function

This CLKCTRL register is reset to 0x00 after a CPU reset.

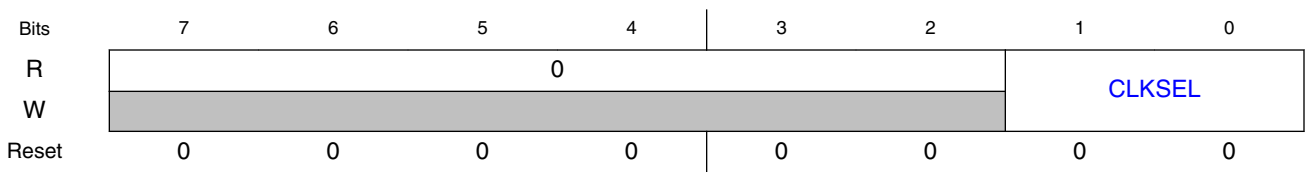
NOTE

This register can be written only once after a CPU reset. Writing this register more than once generates a bus transfer error.

NOTE

User should select the required low power clock before enabling the EWM.

61.4.1.6.3 Diagram



61.4.1.6.4 Fields

Field	Function
7-2 —	reserved
1-0 CLKSEL	CLKSEL EWM has 4 possible low power clock sources for running EWM counter. One of the clock source can be selected by writing into this field. • 00 - lpo_clk[0] will be selected for running EWM counter. • 01 - lpo_clk[1] will be selected for running EWM counter. • 10 - lpo_clk[2] will be selected for running EWM counter. • 11 - lpo_clk[3] will be selected for running EWM counter.

61.4.1.7 Clock Prescaler Register (CLKPRESCALER)

61.4.1.7.1 Offset

Register	Offset
CLKPRESCALER	5h

61.4.1.7.2 Function

This CLKPRESCALER register is reset to 0x00 after a CPU reset.

NOTE

This register can be written only once after a CPU reset. Writing this register more than once generates a bus transfer error.

NOTE

Write the required prescaler value before enabling the EWM.

NOTE

The implementation of this register is chip-specific. See the Chip Configuration details.

61.4.1.7.3 Diagram

Bits	7	6	5	4	3	2	1	0
R W	CLK_DIV							
Reset	0	0	0	0	0	0	0	0

61.4.1.7.4 Fields

Field	Function
7-0 CLK_DIV	CLK_DIV Selected low power clock source for running the EWM counter can be prescaled as below. • Prescaled clock frequency = low power clock source frequency / (1 + CLK_DIV)

61.5 Functional Description

The following sections describe functional details of the EWM module.

NOTE

When the BUS_CLK is lost, then EWM module doesn't generate the EWM_OUT_b signal and no refresh operation is possible

61.5.1 The EWM_OUT_b Signal

The EWM_OUT_b is a digital output signal used to gate an external circuit (application specific) that controls critical safety functions.

The EWM_OUT_b signal remains deasserted when the EWM is being regularly refreshed by the CPU within the programmable refresh window, indicating that the application code is executed as expected.

The EWM_OUT_b signal is asserted in any of the following conditions:

- The EWM refresh occurs when the counter value is less than CMPL value.
- The EWM counter value reaches the CMPH value, and no EWM refresh has occurred.
- If functionality of EWM_in pin is enabled and EWM_in pin is asserted while refreshing the EWM.
- After any reset (by the virtue of the external pull-down mechanism on the EWM_OUT_b pin)

The EWM_OUT_b is asserted after any reset by the virtue of the external pull-down mechanism on the EWM_OUT_b signal. Then, to deassert the EWM_OUT_b signal, set EWMEN bit in the CTRL register to enable the EWM.

If the EWM_OUT_b signal shares its pad with a digital I/O pin, on reset this actual pad defers to being an input signal. The pad state is controlled by the EWM_OUT_b signal only after the EWM is enabled by the EWMEN bit in the CTRL register.

Note

EWM_OUT_b pad must be in pull down state when EWM functionality is used and when EWM is under Reset.

61.5.2 EWM_OUT_b pin state in low power modes

During Wait, Stop and Power Down modes the EWM_OUT_b pin enters a high-impedance state. A user has the option to control the logic state of the pin using an external pull device or by configuring the internal pull device. When the CPU enters a Run mode from Wait or Stop recovery, the pin resumes its previous state before entering Wait or Stop mode. When the CPU enters Run mode from Power Down, the pin returns to its reset state.

61.5.3 The EWM_in Signal

The EWM_in is a digital input signal for safety status of external safety circuits, that allows an external circuit to control the assertion of the EWM_OUT_b signal. For example, in the application, an external circuit monitors a critical safety function, and if there is fault with safety function, the external circuit can then actively initiate the EWM_OUT_b signal that controls the gating circuit.

The EWM_in signal is ignored if the EWM is disabled, or if INEN bit of CTRL register is cleared, as after any reset.

On enabling the EWM (setting the CTRL[EWMEN] bit) and enabling EWM_in functionality (setting the CTRL[INEN] bit), the EWM_in signal must be in the deasserted state prior to the CPU start refreshing the EWM. This ensures that the EWM_OUT_b stays in the deasserted state; otherwise, the EWM_OUT_b output signal is asserted.

Note

The user must update the CMPH and CMPL registers prior to enabling the EWM. After enabling the EWM, the counter resets to zero, therefore the user shall provide a reasonable time after a power-on reset for the external monitoring circuit to stabilize. The user shall also ensure that the EWM_in pin is deasserted.

61.5.4 EWM Counter

It is an 8-bit ripple counter fed from a clock source that is independent of the peripheral bus clock source. As the preferred time-out is between 1 ms and 100 ms the actual clock source should be in the kHz range.

The counter is reset to zero after the CPU reset, or when EWM refresh action completes, or at counter overflow. The counter value is not accessible to the CPU.

61.5.5 EWM Compare Registers

The compare registers CMPL and CMPH are write-once after a CPU reset and cannot be modified until another CPU reset occurs.

The EWM compare registers are used to create a refresh window to refresh the EWM module.

It is illegal to program CMPL and CMPH with same value. In this case, as soon as counter reaches (CMPL + 1), EWM_OUT_b is asserted.

61.5.6 EWM Refresh Mechanism

Other than the initial configuration of the EWM, the CPU can only access the EWM by the EWM Service Register. The CPU must access the EWM service register with correct write of unique data within the windowed time frame as determined by the CMPL and CMPH registers for correct EWM refresh operation. Therefore, three possible conditions can occur:

Table 61-4. EWM Refresh Mechanisms

Condition	Mechanism
An EWM refresh action completes when: CMPL < Counter < CMPH.	The software behaves as expected and the EWM counter is reset to zero. The EWM_OUT_b output signal remains in the deasserted state if, during the EWM refresh action, the EWM_in input has been in deasserted state..
An EWM refresh action completes when Counter < CMPL	The software refreshes the EWM before the windowed time frame, the counter is reset to zero and the EWM_OUT_b output signal is asserted irrespective of the input EWM_in signal.
Counter value reaches CMPH prior to completion of EWM refresh action.	Software has not refreshed the EWM. The EWM counter is reset to zero and the EWM_OUT_b output signal is asserted irrespective of the input EWM_in signal.

61.5.7 EWM Interrupt

When EWM_OUT_b is asserted, an interrupt request is generated to indicate the assertion of the EWM reset out signal. This interrupt is enabled when CTRL[INTEN] is set. Clearing this bit clears the interrupt request but does not affect EWM_OUT_b. The EWM_OUT_b signal can be deasserted only by forcing a system reset.

61.5.8 Selecting the EWM counter clock

There are four possible low power clock sources for the EWM counter. Select one of the available clock sources by programming CLKCTRL[CLKSEL].

61.5.9 Counter clock prescaler

The EWM counter clock source can be prescaled by a clock divider, by programming CLKPRESCALER[CLK_DIV]. This divided clock is used to run the EWM counter.

NOTE

The divided clock used to run the EWM counter must be no more than half the frequency of the bus clock.

Chapter 62
Low Power Timer/Pulse Width Modulation Module (TPM)

62.1.1 TPM

The Timer/PWM Module (TPM) supports input capture, output compare, and the generation of PWM signals to control electric motor and power management applications. The counter, compare and capture registers are clocked by an asynchronous clock that can remain enabled in low power modes. TPM can support global counter bus where one TPM drives the counter bus for the others, provided bit width is the same.

62.1.2 Trigger connections

On i.MX 7ULP, TPM trigger sources get routed through the TRIGMUX module. See the Table 38-2 and Table 38-4 for external/internal trigger connections to this module.

62.2 Introduction

The TPM (Timer/PWM Module) is a 2- to 8-channel timer which supports input capture, output compare, and the generation of PWM signals to control electric motor and power management applications.

The counter, compare and capture registers are clocked by an asynchronous clock that can remain enabled in low power modes. An example of using the TPM with the asynchronous DMA is described in AN4631:Using the Asynchronous DMA features of the Kinetis L Series .

62.2.1 Features

The TPM features include:

- TPM clock mode is selectable
  - Can increment on every edge of the asynchronous counter clock
  - Can increment on rising edge of an external clock input synchronized to the asynchronous counter clock
- Prescaler divide-by 1, 2, 4, 8, 16, 32, 64, or 128
- TPM includes a 16-bit counter

    - It can be a free-running counter or modulo counter
    - The counting can be up or up-down
- Includes 6 channels that can be configured for input capture, output compare, edge-aligned PWM mode, or center-aligned PWM mode
    - In input capture mode the capture can occur on rising edges, falling edges or both edges
    - In output compare mode the output signal can be set, cleared, pulsed, or toggled on match
    - All channels can be configured for edge-aligned PWM mode or center-aligned PWM mode
- Support the generation of an interrupt and/or DMA request per channel
- Support the generation of an interrupt and/or DMA request when the counter overflows
- Support selectable trigger input to optionally reset or cause the counter to start incrementing.
    - The counter can also optionally stop incrementing on counter overflow
- Support the generation of hardware triggers when the counter overflows and per channel

62.2.2 Modes of operation

During debug mode, the TPM can can be configured to temporarily pause all counting until the core returns to normal user operating mode or to operate normally. When the counter is paused, trigger inputs and input capture events are ignored, and PWM outputs are forced to their initial state.

During doze mode, the TPM can be configured to operate normally or to pause all counting for the duration of doze mode. When the counter is paused, trigger inputs and input capture events are ignored, and PWM outputs are forced to their initial state.

During stop mode, the TPM counter clock can remain functional and the TPM can generate an asynchronous interrupt to exit the MCU from stop mode.

62.2.3 Block diagram

The TPM uses one input/output (I/O) pin per channel, CHn (TPM channel (n)) where n is the channel number.

The following figure shows the TPM structure. The central component of the TPM is the 16-bit counter with programmable final value and its counting can be up or up-down.

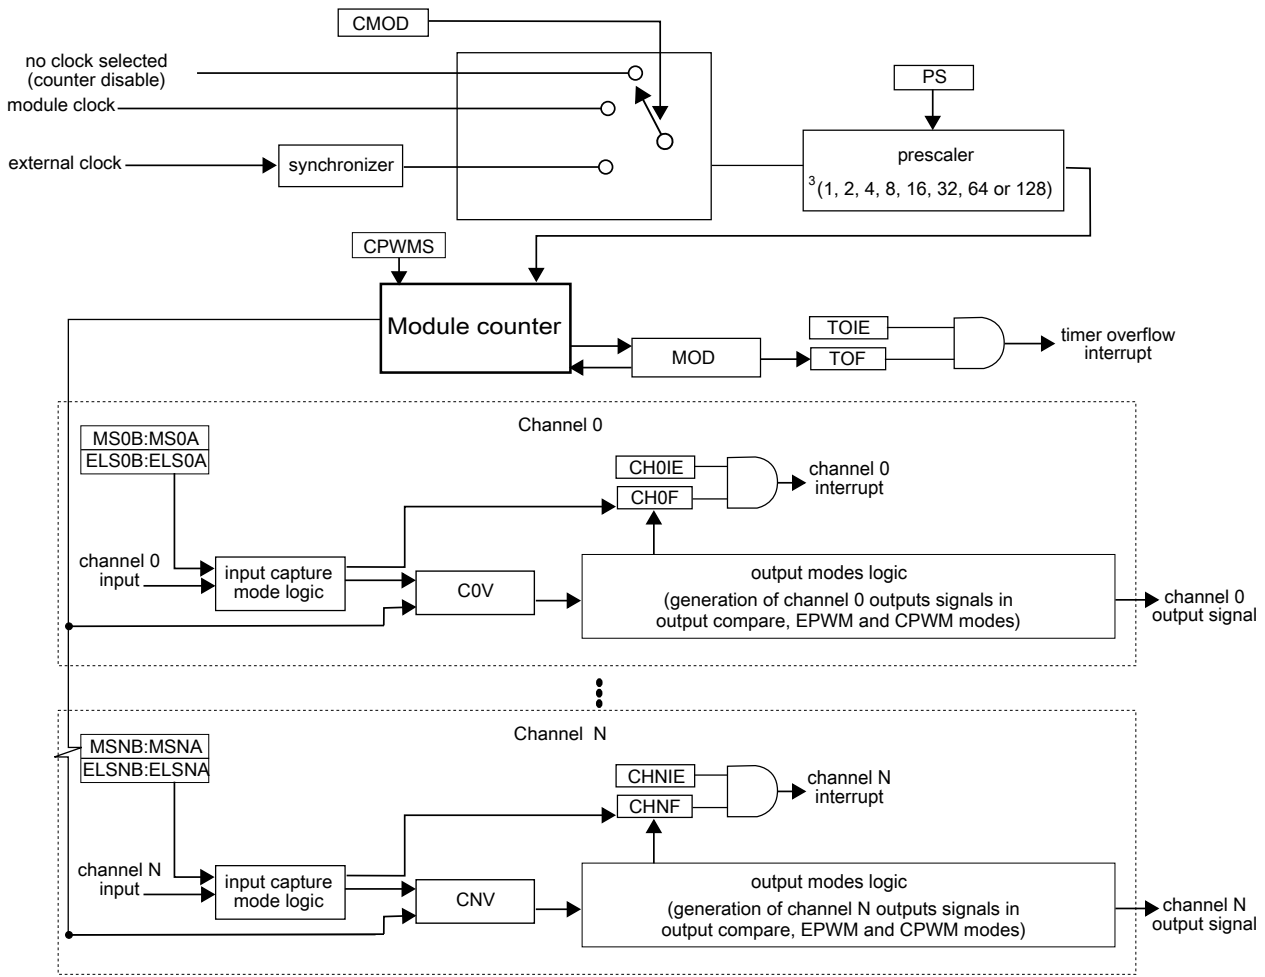

Figure 62-1. TPM block diagram

62.3 TPM Signal Descriptions

Table 62-3 shows the user-accessible signals for the TPM.

Table 62-3. TPM signal descriptions

Signal	Description	I/O
TPM_EXTCLK	External clock. TPM external clock can be selected to increment the counter on every rising edge synchronized to the counter clock.	I

Table continues on the next page...

Table 62-3. TPM signal descriptions (continued)

Signal	Description	I/O
TPM_CHn	TPM channel (n = 5 to 0). A TPM channel pin is configured as output when configured in an output compare or PWM mode and the TPM counter is enabled, otherwise the TPM channel pin is an input.	I/O

62.3.1 TPM_EXTCLK — TPM External Clock

The rising edge of the external input signal is used to increment the TPM counter if selected by CMOD[1:0] bits in the SC register. This input signal must be less than half of the TPM counter clock frequency. The TPM counter prescaler selection and settings are also used when an external input is selected.

62.3.2 TPM_CHn — TPM Channel (n) I/O Pin

Each TPM channel can be configured to operate either as input or output. The direction associated with each channel, input or output, is selected according to the mode assigned for that channel.

62.4 Memory Map and Register Definition

This section provides a detailed description of all TPM registers.

Attempting to access a reserved register location in the TPM memory map will generate a bus error.

62.4.1.5 Status and Control (SC)

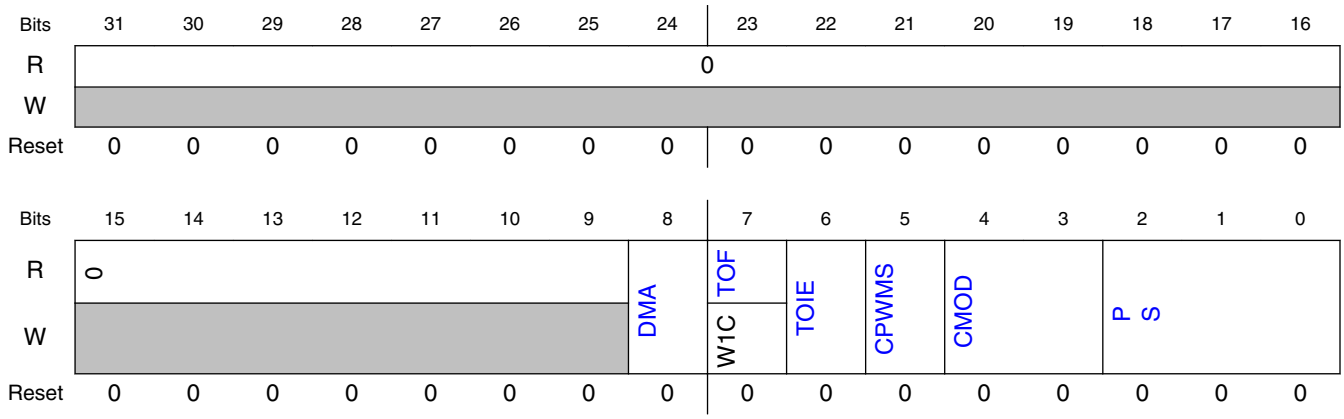
62.4.1.5.1 Offset

Register	Offset
SC	10h

62.4.1.5.2 Function

SC contains the overflow status flag and control bits used to configure the interrupt enable, module configuration and prescaler factor. These controls relate to all channels within this module.

62.4.1.5.3 Diagram



62.4.1.5.4 Fields

Field	Function
31-9 —	Reserved
8 DMA	DMA Enable Enables DMA transfers for the overflow flag. 0b - Disables DMA transfers. 1b - Enables DMA transfers.
7 TOF	Timer Overflow Flag Set by hardware when the TPM counter equals the value in the MOD register and increments. Writing a 1 to TOF clears it. Writing a 0 to TOF has no effect. If another TPM overflow occurs between the flag setting and the flag clearing, the write operation has no effect; therefore, TOF remains set indicating another overflow has occurred. In this case a TOF interrupt request is not lost due to a delay in clearing the previous TOF. 0b - TPM counter has not overflowed. 1b - TPM counter has overflowed.
6 TOIE	Timer Overflow Interrupt Enable Enables TPM overflow interrupts. 0b - Disable TOF interrupts. Use software polling or DMA request. 1b - Enable TOF interrupts. An interrupt is generated when TOF equals one.
5 CPWMS	Center-Aligned PWM Select Selects CPWM mode. This mode configures the TPM to operate in up-down counting mode. This field is write protected. It can be written only when the counter is disabled. 0b - TPM counter operates in up counting mode. 1b - TPM counter operates in up-down counting mode.
4-3 CMOD	Clock Mode Selection Selects the TPM counter clock modes. When disabling the counter, this field remain set until acknolwedged in the TPM clock domain. 00b - TPM counter is disabled

Table continues on the next page...

Field	Function
	01b - TPM counter increments on every TPM counter clock 10b - TPM counter increments on rising edge of TPM_EXTCLK synchronized to the TPM counter clock 11b - TPM counter increments on rising edge of the selected external input trigger.
2-0 PS	Prescale Factor Selection Selects one of 8 division factors for the clock mode selected by CMOD. This field is write protected. It can be written only when the counter is disabled. 000b - Divide by 1 001b - Divide by 2 010b - Divide by 4 011b - Divide by 8 100b - Divide by 16 101b - Divide by 32 110b - Divide by 64 111b - Divide by 128

62.4.1.6 Counter (CNT)

62.4.1.6.1 Offset

Register	Offset
CNT	14h

62.4.1.6.2 Function

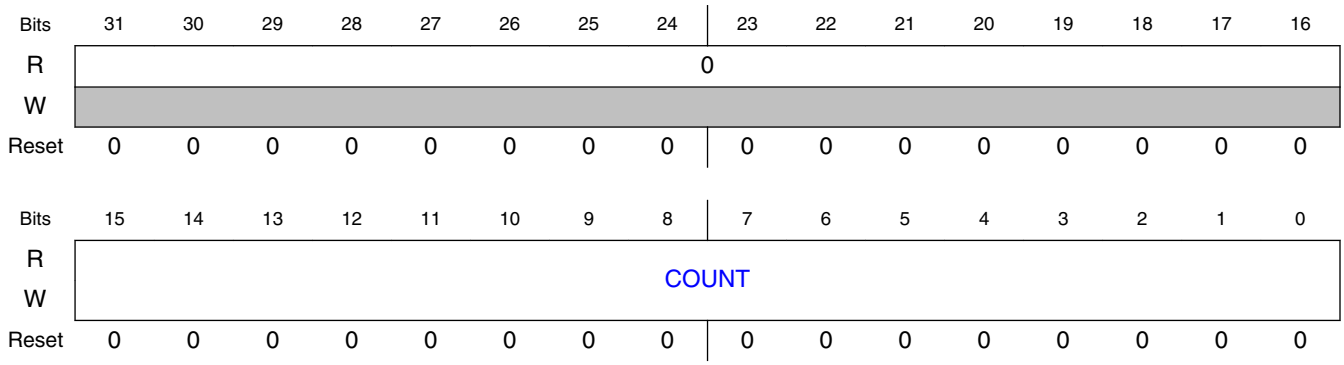
The CNT register contains the TPM counter value.

Reset clears the CNT register. Writing any value to COUNT will trigger a reload of the counter, this will force PWM outputs to their reload state..

When debug is active, the TPM counter does not increment unless configured otherwise.

Reading the CNT register adds two wait states to the register access due to synchronization delays.

62.4.1.6.3 Diagram



62.4.1.6.4 Fields

Field	Function
31-16 —	Reserved
15-0 COUNT	Counter value

62.4.1.7 Modulo (MOD)

62.4.1.7.1 Offset

Register	Offset
MOD	18h

62.4.1.7.2 Function

The Modulo register contains the modulo value for the TPM counter. When the TPM counter reaches the modulo value and increments, the overflow flag (TOF) is set and the next value of TPM counter depends on the selected counting method (see Counter).

Writing to the MOD register latches the value into a buffer. The MOD register is updated with the value of its write buffer according to MOD Register Update . Additional writes to the MOD write buffer are ignored until the register has been updated.

It is recommended to initialize the TPM counter (write to CNT) before writing to the MOD register to avoid confusion about when the first counter overflow will occur.

62.4.1.7.3 Diagram

62.4.1.8 Capture and Compare Status (STATUS)

62.4.1.8.1 Offset

Register	Offset
STATUS	1Ch

62.4.1.8.2 Function

The STATUS register contains a copy of the status flag, CnSC[CHnF] for each TPM channel, as well as SC[TOF], for software convenience.

Each CHnF bit in STATUS is a mirror of CHnF bit in CnSC. All CHnF bits can be checked using only one read of STATUS. All CHnF bits can be cleared by writing all ones to STATUS.

Hardware sets the individual channel flags when an event occurs on the channel. Writing a 1 to CHF clears it. Writing a 0 to CHF has no effect.

If another event occurs between the flag setting and the write operation, the write operation has no effect; therefore, CHF remains set indicating another event has occurred. In this case a CHF interrupt request is not lost due to the clearing sequence for a previous CHF.

16 COMBINE2	Combine Channels 4 and 5 Enables the combine feature for channels 2 and 3. In input capture mode, the combined channels use the even channel input. In software compare modes, the even channel match asserts the output trigger and the odd channel match negates the output trigger. In PWM modes, the even channel match is used for the 1st compare and odd channel match for the 2nd compare. 0b - Channels 4 and 5 are independent. 1b - Channels 4 and 5 are combined.
15-10 —	Reserved
9 COMSWAP1	Combine Channels 2 and 3 Swap When set in combine mode, the odd channel is used for the input capture and 1st compare, the even channel is used for the 2nd compare. 0b - Even channel is used for input capture and 1st compare. 1b - Odd channel is used for input capture and 1st compare.
8 COMBINE1	Combine Channels 2 and 3

Table continues on the next page...

Field	Function
	Enables the combine feature for channels 2 and 3. In input capture mode, the combined channels use the even channel input. In software compare modes, the even channel match asserts the output trigger and the odd channel match negates the output trigger. In PWM modes, the even channel match is used for the 1st compare and odd channel match for the 2nd compare. 0b - Channels 2 and 3 are independent. 1b - Channels 2 and 3 are combined.
7-2 —	Reserved
1 COMSWAP0	Combine Channel 0 and 1 Swap When set in combine mode, the even channel is used for the input capture and 1st compare, the odd channel is used for the 2nd compare. 0b - Even channel is used for input capture and 1st compare. 1b - Odd channel is used for input capture and 1st compare.
0 COMBINE0	Combine Channels 0 and 1 Enables the combine feature for channels 0 and 1. In input capture mode, the combined channels use the even channel input. In software compare modes, the even channel match asserts the output trigger and the odd channel match negates the output trigger. In PWM modes, the even channel match is used for the 1st compare and odd channel match for the 2nd compare. 0b - Channels 0 and 1 are independent. 1b - Channels 0 and 1 are combined.

62.4.1.12 Channel Trigger (TRIG)

62.4.1.12.1 Offset

Register	Offset
TRIG	6Ch

62.4.1.12.2 Function

In input capture mode, configures the trigger input that is used by the channel to capture the counter value. In output compare or PWM mode, configures the trigger input used to modulate the channel output. When modulating the output, the output is forced to zero whenever the trigger is not asserted. Note that the even numbered channels share the first input trigger source and the odd numbered channels share the second input trigger source.

2 POL2	Channel 2 Polarity 0b - The channel polarity is active high. 1b - The channel polarity is active low.
1 POL1	Channel 1 Polarity 0b - The channel polarity is active high. 1b - The channel polarity is active low.
0 POL0	Channel 0 Polarity 0b - The channel polarity is active high. 1b - The channel polarity is active low.

62.4.1.14 Filter Control (FILTER)

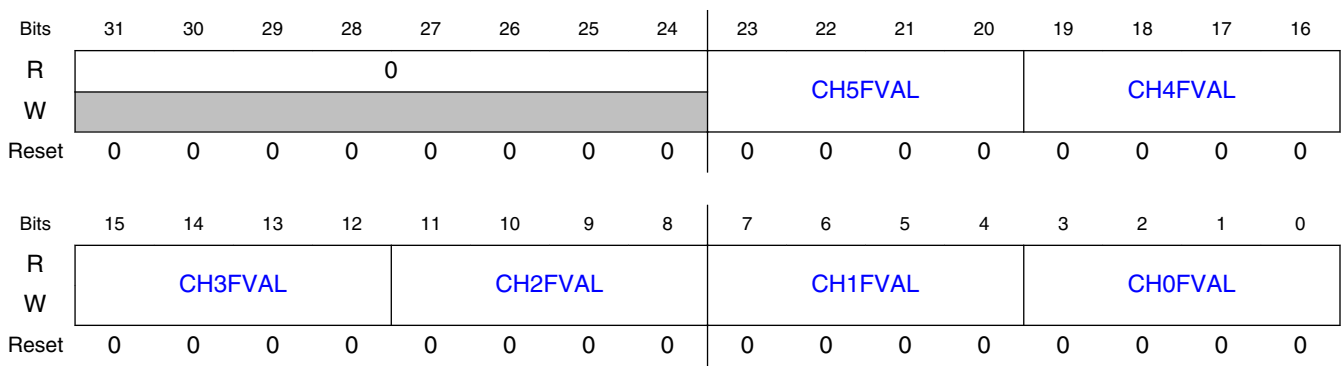
62.4.1.14.1 Offset

Register	Offset
FILTER	78h

62.4.1.14.2 Function

This register selects the filter value of the channel inputs, and an additional output delay value for the channel outputs. In PWM combine modes, the filter can be used to implement deadtime insertion.

62.4.1.14.3 Diagram



62.4.1.14.4 Fields

Field	Function
31-24 —	Reserved
23-20 CH5FVAL	Channel 5 Filter Value Sets the filter value for the channel 5 input when configured for input capture or software compare modes. The filter is disabled when the value is zero, otherwise the filter is configured as (CH5FVAL * 4) clock cycles. Sets the deadtime insertion time for channel 5 in PWM modes. Deadtime insertion is disabled when CH5FVAL is zero, otherwise deadtime insertion for channel 5 is configured as (CH5FVAL * 4) clock cycles.
19-16 CH4FVAL	Channel 4 Filter Value Sets the filter value for the channel 4 input when configured for input capture or software compare modes. The filter is disabled when the value is zero, otherwise the filter is configured as (CH4FVAL * 4) clock cycles.

Table continues on the next page...

Field	Function
	Sets the deadtime insertion time for channel 4 in PWM modes. Deadtime insertion is disabled when CH4FVAL is zero, otherwise deadtime insertion for channel 4 is configured as (CH4FVAL * 4) clock cycles.
15-12 CH3FVAL	Channel 3 Filter Value Sets the filter value for the channel 3 input when configured for input capture or software compare modes. The filter is disabled when the value is zero, otherwise the filter is configured as (CH3FVAL * 4) clock cycles. Sets the deadtime insertion time for channel 3 in PWM modes. Deadtime insertion is disabled when CH3FVAL is zero, otherwise deadtime insertion for channel 3 is configured as (CH3FVAL * 4) clock cycles.
11-8 CH2FVAL	Channel 2 Filter Value Sets the filter value for the channel 2 input when configured for input capture or software compare modes. The filter is disabled when the value is zero, otherwise the filter is configured as (CH2FVAL * 4) clock cycles. Sets the deadtime insertion time for channel 2 in PWM modes. Deadtime insertion is disabled when CH2FVAL is zero, otherwise deadtime insertion for channel 2 is configured as (CH2FVAL * 4) clock cycles.
7-4 CH1FVAL	Channel 1 Filter Value Sets the filter value for the channel 1 input when configured for input capture or software compare modes. The filter is disabled when the value is zero, otherwise the filter is configured as (CH1FVAL * 4) clock cycles. Sets the deadtime insertion time for channel 1 in PWM modes. Deadtime insertion is disabled when CH1FVAL is zero, otherwise deadtime insertion for channel 1 is configured as (CH1FVAL * 4) clock cycles.
3-0 CH0FVAL	Channel 0 Filter Value Sets the filter value for the channel 0 input when configured for input capture or software compare modes. The filter is disabled when the value is zero, otherwise the filter is configured as (CH0FVAL * 4) clock cycles. Sets the deadtime insertion time for channel 0 in PWM modes. Deadtime insertion is disabled when CH0FVAL is zero, otherwise deadtime insertion for channel 0 is configured as (CH0FVAL * 4) clock cycles.

62.4.1.15 Quadrature Decoder Control and Status (QDCTRL)

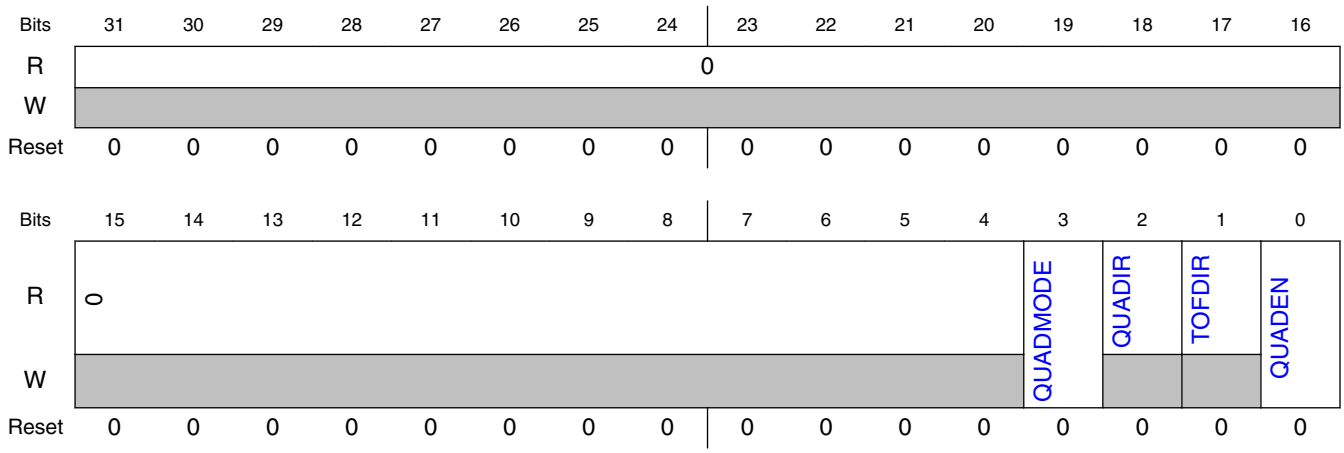
62.4.1.15.1 Offset

Register	Offset
QDCTRL	80h

62.4.1.15.2 Function

This register has the control and status bits for the quadrature decoder mode.

62.4.1.15.3 Diagram



62.4.1.15.4 Fields

Field	Function
31-4 —	Reserved
3 QUADMODE	Quadrature Decoder Mode Selects the encoding mode used in the quadrature decoder mode. 0b - Phase encoding mode. 1b - Count and direction encoding mode.
2 QUADIR	Counter Direction in Quadrature Decode Mode Indicates the counting direction. 0b - Counter direction is decreasing (counter decrement). 1b - Counter direction is increasing (counter increment).
1 TOFDIR	TOFDIR Indicates if the TOF bit was set on the top or the bottom of counting. 0b - TOF bit was set on the bottom of counting. There was an FTM counter decrement and FTM counter changes from its minimum value (zero) to its maximum value (MOD register). 1b - TOF bit was set on the top of counting. There was an FTM counter increment and FTM counter changes from its maximum value (MOD register) to its minimum value (zero).
0 QUADEN	QUADEN Enables the quadrature decoder mode. In this mode, the channel 0 and channel 1 inputs control the TPM counter direction and can only be used for software compare. The quadrature decoder mode has precedence over the other modes. 0b - Quadrature decoder mode is disabled. 1b - Quadrature decoder mode is enabled.

62.4.1.16 Configuration (CONF)

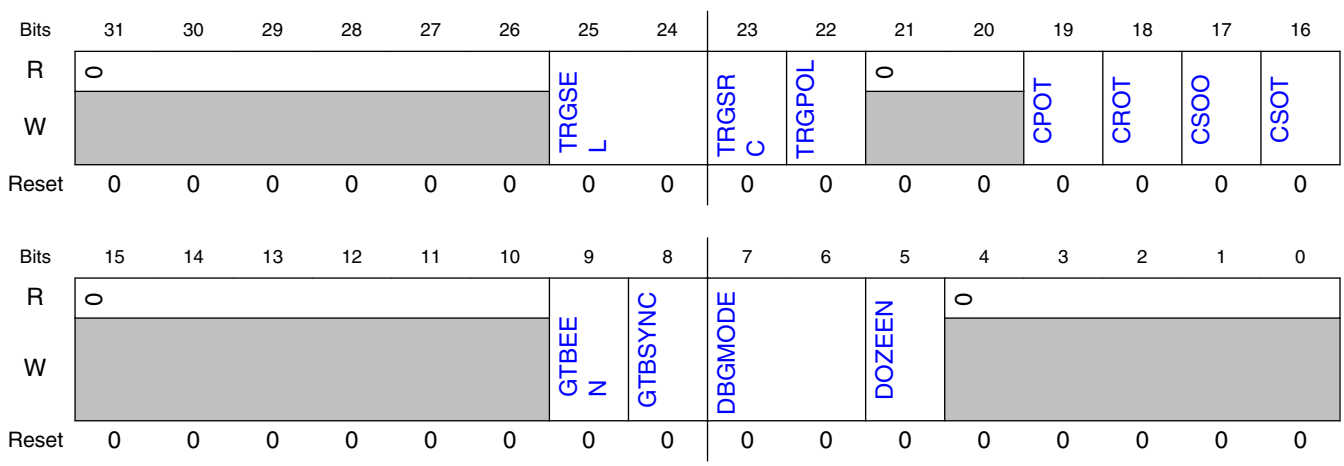
62.4.1.16.1 Offset

Register	Offset
CONF	84h

62.4.1.16.2 Function

This register selects the behavior in debug and wait modes and the use of an external global time base.

62.4.1.16.3 Diagram



62.4.1.16.4 Fields

Field	Function
31-26 —	Reserved
25-24 TRGSEL	Trigger Select Selects the input trigger to use for starting, reloading and/or pausing the counter. The source of the trigger (external or internal to the TPM) is configured by the TRGSRC field. This field should only be changed when the TPM counter is disabled. Refer to chip configuration section for available external trigger options. The available internal trigger sources are listed below. 01b - Channel 0 pin input capture 10b - Channel 1 pin input capture

Table continues on the next page...

Field	Function
	11b - Channel 0 or Channel 1 pin input capture
23 TRGSRC	Trigger Source Selects between internal (channel pin input capture) or external trigger sources. When selecting an internal trigger, the channel selected should be configured for input capture. Only a rising edge input capture can be used to initially start the counter using the CSOT configuration; either rising edge or falling edge input capture can be used to reload the counter using the CROT configuration; and the state of the channel input pin is used to pause the counter using the CPOT configuration. The channel polarity register can be used to invert the polarity of the channel input pins. This field should only be changed when the TPM counter is disabled. 0b - Trigger source selected by TRGSEL is external. 1b - Trigger source selected by TRGSEL is internal (channel pin input capture).
22 TRGPOL	Trigger Polarity Selects the polarity of the external trigger source. This field should only be changed when the TPM counter is disabled. 0b - Trigger is active high. 1b - Trigger is active low.
21-20 —	Reserved
19 CPOT	Counter Pause On Trigger When enabled, the counter will pause incrementing while the trigger remains asserted (level sensitive). While the counter is paused input capture events are ignored, and PWM outputs are forced to their default state. The trigger input is ignored if the TPM counter is paused during debug mode or doze mode. This field should only be changed when the TPM counter is disabled.
18 CROT	Counter Reload On Trigger When set, the TPM counter will reload with zero (and set PWM outputs to their reload state) when a rising edge is detected on the selected trigger input. The trigger input is ignored if the TPM counter is paused during debug mode or doze mode. This field should only be changed when the TPM counter is disabled. 0b - Counter is not reloaded due to a rising edge on the selected input trigger 1b - Counter is reloaded when a rising edge is detected on the selected input trigger
17 CSOO	Counter Stop On Overflow When set, the TPM counter will pause incrementing once the counter equals the MOD value and increments (this also sets the TOF). Reloading the counter with 0 due to writing to the counter register or due to a trigger input does not cause the counter to stop incrementing. Once the counter has stopped incrementing, the counter will not start incrementing unless it is disabled and then enabled again, or a rising edge on the selected trigger input is detected when CSOT is set. While the counter is paused input capture events are ignored, and PWM outputs are forced to their default state. This field should only be changed when the TPM counter is disabled. 0b - TPM counter continues incrementing or decrementing after overflow 1b - TPM counter stops incrementing or decrementing after overflow.
16 CSOT	Counter Start on Trigger When set, the TPM counter will pause incrementing when it is enabled until a rising edge on the selected trigger input is detected. If the TPM counter is paused due to an overflow, a rising edge on the selected trigger input will also cause the TPM counter to start incrementing again. While the counter is paused input capture events are ignored, and PWM outputs are forced to their default state.

Table continues on the next page...

Field	Function
	The trigger input is ignored if the TPM counter is paused during debug mode or doze mode. This field should only be changed when the TPM counter is disabled. 0b - TPM counter starts to increment immediately, once it is enabled. 1b - TPM counter only starts to increment when it a rising edge on the selected input trigger is detected, after it has been enabled or after it has stopped due to overflow.
15-10 —	Reserved
9 GTBEEN	Global time base enable Configures the TPM to use an externally generated global time base counter. When an externally generated timebase is used, the internal TPM counter is not used by the channels but can be used to generate a periodic interruptor DMA request using the Modulo register and timer overflow flag. 0b - All channels use the internally generated TPM counter as their timebase 1b - All channels use an externally generated global timebase as their timebase
8 GTBSYNC	Global Time Base Synchronization When enabled, the TPM counter is synchronized to the global time base. It uses the global timebase enable, trigger, paused state and overflow to ensure the TPM counter starts incrementing at the same time as the global timebase, stops incrementing at the same time as the global timebase and is reset at the same time as the global timebase. This field should only be changed when the TPM counter is disabled. 0b - Global timebase synchronization disabled. 1b - Global timebase synchronization enabled.
7-6 DBGMODE	Debug Mode Configures the TPM behavior in debug mode. All other configurations are reserved. 00b - TPM counter is paused and does not increment during debug mode. Trigger inputs and input capture events are ignored, and PWM outputs are forced to their default state. 11b - TPM counter continues in debug mode.
5 DOZEEN	Doze Enable Configures the TPM behavior in wait mode. 0b - Internal TPM counter continues in Doze mode. 1b - Internal TPM counter is paused and does not increment during Doze mode. Trigger inputs and input capture events are ignored, and PWM outputs are forced to their default state.
4-0 —	Reserved

62.4.2.5 Status and Control (SC)

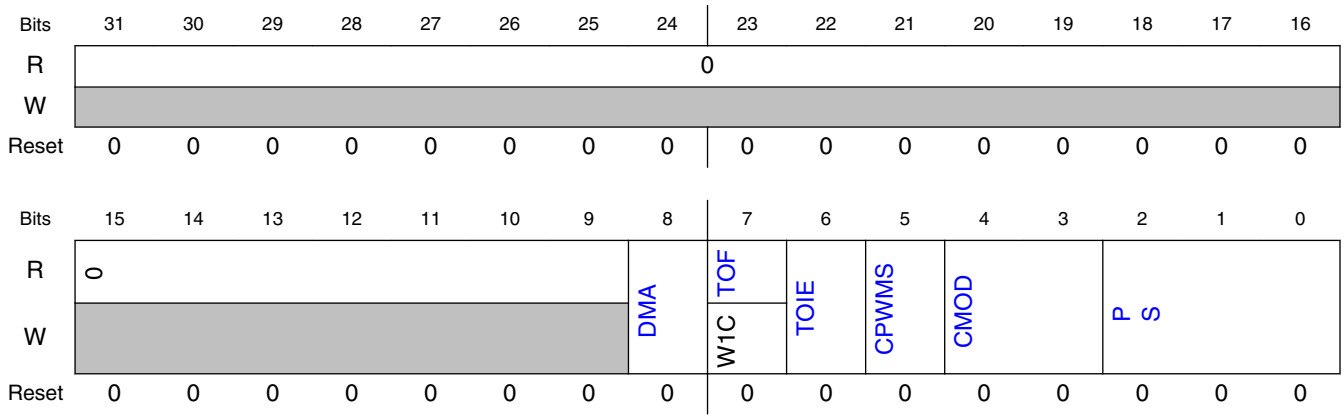
62.4.2.5.1 Offset

Register	Offset
SC	10h

62.4.2.5.2 Function

SC contains the overflow status flag and control bits used to configure the interrupt enable, module configuration and prescaler factor. These controls relate to all channels within this module.

62.4.2.5.3 Diagram



62.4.2.5.4 Fields

Field	Function
31-9 —	Reserved
8 DMA	DMA Enable Enables DMA transfers for the overflow flag. 0b - Disables DMA transfers. 1b - Enables DMA transfers.
7 TOF	Timer Overflow Flag Set by hardware when the TPM counter equals the value in the MOD register and increments. Writing a 1 to TOF clears it. Writing a 0 to TOF has no effect. If another TPM overflow occurs between the flag setting and the flag clearing, the write operation has no effect; therefore, TOF remains set indicating another overflow has occurred. In this case a TOF interrupt request is not lost due to a delay in clearing the previous TOF. 0b - TPM counter has not overflowed. 1b - TPM counter has overflowed.
6 TOIE	Timer Overflow Interrupt Enable Enables TPM overflow interrupts. 0b - Disable TOF interrupts. Use software polling or DMA request. 1b - Enable TOF interrupts. An interrupt is generated when TOF equals one.
5 CPWMS	Center-Aligned PWM Select Selects CPWM mode. This mode configures the TPM to operate in up-down counting mode. This field is write protected. It can be written only when the counter is disabled. 0b - TPM counter operates in up counting mode. 1b - TPM counter operates in up-down counting mode.
4-3 CMOD	Clock Mode Selection Selects the TPM counter clock modes. When disabling the counter, this field remain set until acknolwedged in the TPM clock domain. 00b - TPM counter is disabled

Table continues on the next page...

Field	Function
	01b - TPM counter increments on every TPM counter clock 10b - TPM counter increments on rising edge of TPM_EXTCLK synchronized to the TPM counter clock 11b - TPM counter increments on rising edge of the selected external input trigger.
2-0 PS	Prescale Factor Selection Selects one of 8 division factors for the clock mode selected by CMOD. This field is write protected. It can be written only when the counter is disabled. 000b - Divide by 1 001b - Divide by 2 010b - Divide by 4 011b - Divide by 8 100b - Divide by 16 101b - Divide by 32 110b - Divide by 64 111b - Divide by 128

62.4.2.6 Counter (CNT)

62.4.2.6.1 Offset

Register	Offset
CNT	14h

62.4.2.6.2 Function

The CNT register contains the TPM counter value.

Reset clears the CNT register. Writing any value to COUNT will trigger a reload of the counter, this will force PWM outputs to their reload state..

When debug is active, the TPM counter does not increment unless configured otherwise.

Reading the CNT register adds two wait states to the register access due to synchronization delays.

62.4.2.6.4 Fields

Field	Function
31-0 COUNT	Counter value

62.4.2.7 Modulo (MOD)

62.4.2.7.1 Offset

Register	Offset
MOD	18h

62.4.2.7.2 Function

The Modulo register contains the modulo value for the TPM counter. When the TPM counter reaches the modulo value and increments, the overflow flag (TOF) is set and the next value of TPM counter depends on the selected counting method (see Counter).

Writing to the MOD register latches the value into a buffer. The MOD register is updated with the value of its write buffer according to MOD Register Update . Additional writes to the MOD write buffer are ignored until the register has been updated.

It is recommended to initialize the TPM counter (write to CNT) before writing to the MOD register to avoid confusion about when the first counter overflow will occur.

62.4.2.7.3 Diagram

62.4.2.7.4 Fields

Field	Function
31-0 MOD	Modulo value This field must be written with single 16-bit or 32-bit access.

62.4.2.8 Capture and Compare Status (STATUS)

62.4.2.8.1 Offset

Register	Offset
STATUS	1Ch

62.4.2.8.2 Function

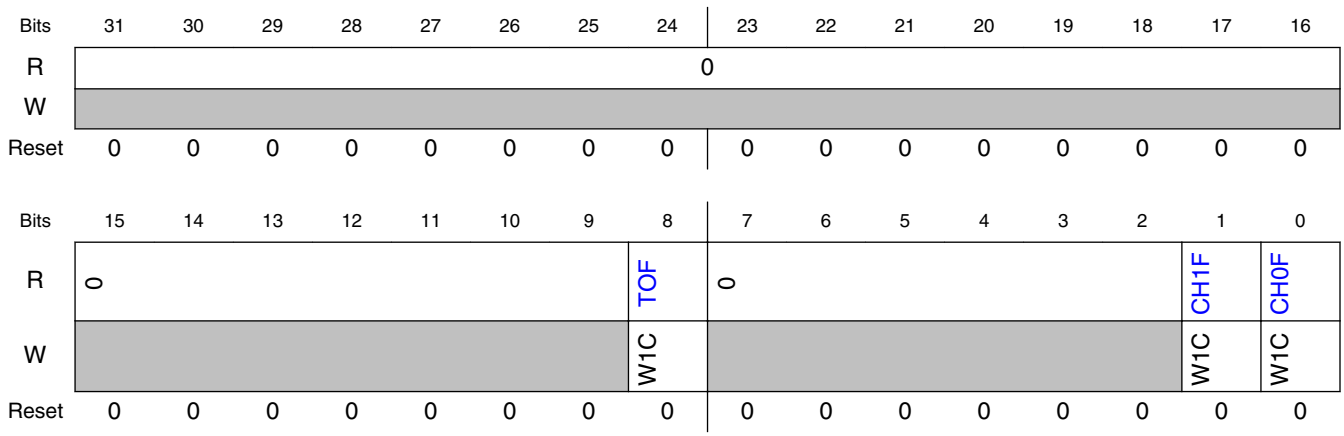
The STATUS register contains a copy of the status flag, CnSC[CHnF] for each TPM channel, as well as SC[TOF], for software convenience.

Each CHnF bit in STATUS is a mirror of CHnF bit in CnSC. All CHnF bits can be checked using only one read of STATUS. All CHnF bits can be cleared by writing all ones to STATUS.

Hardware sets the individual channel flags when an event occurs on the channel. Writing a 1 to CHF clears it. Writing a 0 to CHF has no effect.

If another event occurs between the flag setting and the write operation, the write operation has no effect; therefore, CHF remains set indicating another event has occurred. In this case a CHF interrupt request is not lost due to the clearing sequence for a previous CHF.

62.4.2.8.3 Diagram



62.4.2.8.4 Fields

Field	Function
31-9 —	Reserved
8 TOF	Timer Overflow Flag See register description 0b - TPM counter has not overflowed. 1b - TPM counter has overflowed.
7-2 —	Reserved
1 CH1F	Channel 1 Flag See the register description. 0b - No channel event has occurred. 1b - A channel event has occurred.
0 CH0F	Channel 0 Flag See the register description. 0b - No channel event has occurred. 1b - A channel event has occurred.

62.4.2.9 Channel (n) Status and Control (C0SC - C1SC)

62.4.2.9.1 Offset

Register	Offset
C0SC	20h
C1SC	28h

62.4.2.9.2 Function

CnSC contains the channel-interrupt-status flag and control bits used to configure the interrupt enable, channel configuration, and pin function.

When switching from one channel mode to a different channel mode, the channel must first be disabled and this must be acknowledged in the TPM counter clock domain.

Table 62-5. Mode, Edge, and Level Selection

CPWMS	MSnB:MSnA	ELSnB:ELSnA	Mode	Configuration

Field	Function
31-8 —	Reserved
7	Channel Flag

Table continues on the next page...

Field	Function
CHF	Set by hardware when an event occurs on the channel. CHF is cleared by writing a 1 to the CHF bit. Writing a 0 to CHF has no effect. If another event occurs between the CHF sets and the write operation, the write operation has no effect; therefore, CHF remains set indicating another event has occurred. In this case a CHF interrupt request is not lost due to the delay in clearing the previous CHF. 0b - No channel event has occurred. 1b - A channel event has occurred.
6 CHIE	Channel Interrupt Enable Enables channel interrupts. 0b - Disable channel interrupts. 1b - Enable channel interrupts.
5 MSB	Channel Mode Select Used for further selections in the channel logic. Its functionality is dependent on the channel mode. When a channel is disabled, this field will not change state until acknowledged in the TPM counter clock domain.
4 MSA	Channel Mode Select Used for further selections in the channel logic. Its functionality is dependent on the channel mode. When a channel is disabled, this field will not change state until acknowledged in the TPM counter clock domain.
3 ELSB	Edge or Level Select The functionality of ELSB and ELSA depends on the channel mode. When a channel is disabled, this field will not change state until acknowledged in the TPM counter clock domain.ph>
2 ELSA	Edge or Level Select The functionality of ELSB and ELSA depends on the channel mode. When a channel is disabled, this field will not change state until acknowledged in the TPM counter clock domain.
1 —	Reserved
0 DMA	DMA Enable Enables DMA transfers for the channel. 0b - Disable DMA transfers. 1b - Enable DMA transfers.

62.4.2.10 Channel (n) Value (C0V - C1V)

62.4.2.10.1 Offset

Register	Offset
C0V	24h
C1V	2Ch

62.4.2.10.2 Function

These registers contain the captured TPM counter value for the input modes or the match value for the output modes.

In input capture mode, any write to a CnV register is ignored.

In compare modes, writing to a CnV register latches the value into a buffer. A CnV register is updated with the value of its write buffer according to CnV Register Update . Additional writes to the CnV write buffer are ignored until the register has been updated.

62.4.2.10.3 Diagram

62.4.2.10.4 Fields

Field	Function
31-0 VAL	Channel Value Captured TPM counter value of the input modes or the match value for the output modes. This field must be written with single 16-bit or 32-bit access.

62.4.2.11 Combine Channel Register (COMBINE)

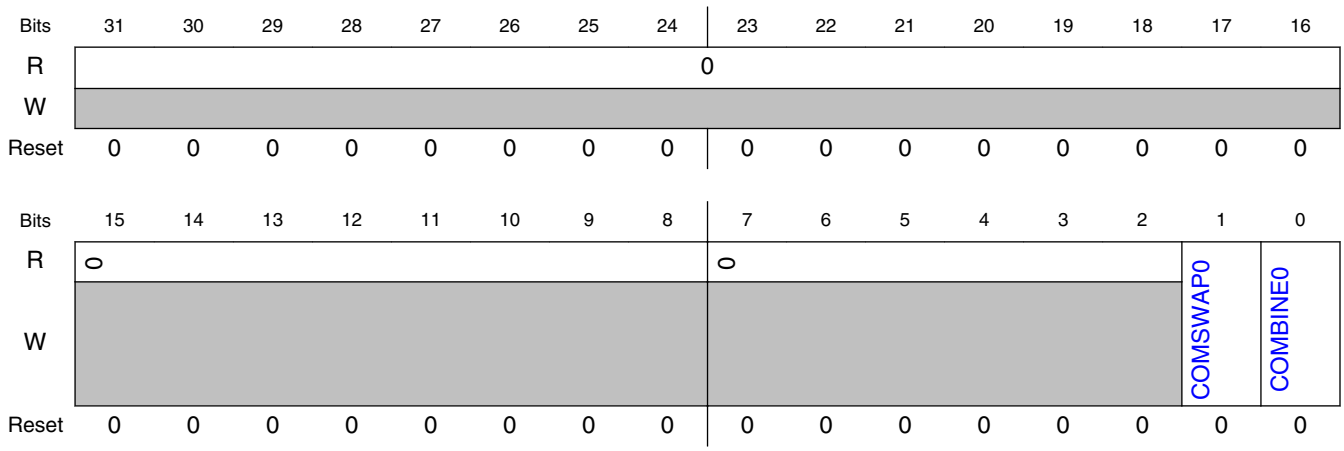
62.4.2.11.1 Offset

Register	Offset
COMBINE	64h

62.4.2.11.2 Function

This register contains the control bits used to configure the combine channel modes for each pair of channels (n) and (n+1), where n is all the even numbered channels.

62.4.2.11.3 Diagram



62.4.2.11.4 Fields

Field	Function
31-8 —	Reserved
7-2 —	Reserved
1 COMSWAP0	Combine Channel 0 and 1 Swap When set in combine mode, the even channel is used for the input capture and 1st compare, the odd channel is used for the 2nd compare. 0b - Even channel is used for input capture and 1st compare. 1b - Odd channel is used for input capture and 1st compare.
0 COMBINE0	Combine Channels 0 and 1 Enables the combine feature for channels 0 and 1. In input capture mode, the combined channels use the even channel input. In software compare modes, the even channel match asserts the output trigger and the odd channel match negates the output trigger. In PWM modes, the even channel match is used for the 1st compare and odd channel match for the 2nd compare. 0b - Channels 0 and 1 are independent. 1b - Channels 0 and 1 are combined.

62.4.2.12 Channel Trigger (TRIG)

62.4.2.12.1 Offset

Register	Offset
TRIG	6Ch

62.4.2.12.2 Function

In input capture mode, configures the trigger input that is used by the channel to capture the counter value. In output compare or PWM mode, configures the trigger input used to modulate the channel output. When modulating the output, the output is forced to zero whenever the trigger is not asserted. Note that the even numbered channels share the first input trigger source and the odd numbered channels share the second input trigger source.

62.4.2.14 Filter Control (FILTER)

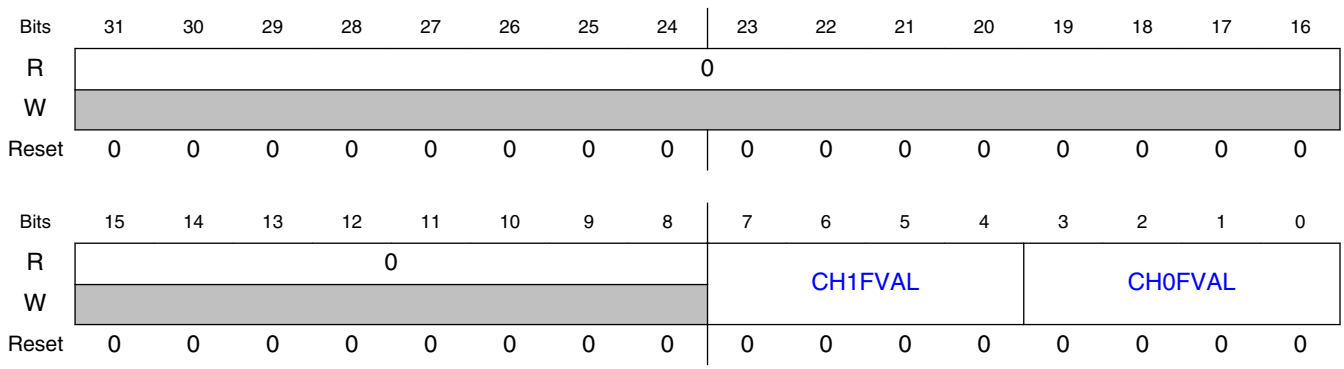
62.4.2.14.1 Offset

Register	Offset
FILTER	78h

62.4.2.14.2 Function

This register selects the filter value of the channel inputs, and an additional output delay value for the channel outputs. In PWM combine modes, the filter can be used to implement deadtime insertion.

62.4.2.14.3 Diagram



62.4.2.14.4 Fields

Field	Function
31-8 —	Reserved
7-4 CH1FVAL	Channel 1 Filter Value Sets the filter value for the channel 1 input when configured for input capture or software compare modes. The filter is disabled when the value is zero, otherwise the filter is configured as (CH1FVAL * 4) clock cycles. Sets the deadtime insertion time for channel 1 in PWM modes. Deadtime insertion is disabled when CH1FVAL is zero, otherwise deadtime insertion for channel 1 is configured as (CH1FVAL * 4) clock cycles.
3-0 CH0FVAL	Channel 0 Filter Value Sets the filter value for the channel 0 input when configured for input capture or software compare modes. The filter is disabled when the value is zero, otherwise the filter is configured as (CH0FVAL * 4) clock cycles. Sets the deadtime insertion time for channel 0 in PWM modes. Deadtime insertion is disabled when CH0FVAL is zero, otherwise deadtime insertion for channel 0 is configured as (CH0FVAL * 4) clock cycles.

62.4.2.15 Quadrature Decoder Control and Status (QDCTRL)

62.4.2.15.1 Offset

Register	Offset
QDCTRL	80h

62.4.2.15.2 Function

This register has the control and status bits for the quadrature decoder mode.

62.4.2.16.4 Fields

Field	Function
31-26 —	Reserved
25-24 TRGSEL	Trigger Select Selects the input trigger to use for starting, reloading and/or pausing the counter. The source of the trigger (external or internal to the TPM) is configured by the TRGSRC field. This field should only be changed when the TPM counter is disabled. Refer to chip configuration section for available external trigger options. The available internal trigger sources are listed below. 01b - Channel 0 pin input capture 10b - Channel 1 pin input capture 11b - Channel 0 or Channel 1 pin input capture
23 TRGSRC	Trigger Source Selects between internal (channel pin input capture) or external trigger sources. When selecting an internal trigger, the channel selected should be configured for input capture. Only a rising edge input capture can be used to initially start the counter using the CSOT configuration; either rising edge or falling edge input capture can be used to reload the counter using the CROT configuration; and the state of the channel input pin is used to pause the counter using the CPOT configuration. The channel polarity register can be used to invert the polarity of the channel input pins. This field should only be changed when the TPM counter is disabled. 0b - Trigger source selected by TRGSEL is external. 1b - Trigger source selected by TRGSEL is internal (channel pin input capture).
22 TRGPOL	Trigger Polarity Selects the polarity of the external trigger source. This field should only be changed when the TPM counter is disabled. 0b - Trigger is active high. 1b - Trigger is active low.
21-20 —	Reserved
19 CPOT	Counter Pause On Trigger When enabled, the counter will pause incrementing while the trigger remains asserted (level sensitive). While the counter is paused input capture events are ignored, and PWM outputs are forced to their default state. The trigger input is ignored if the TPM counter is paused during debug mode or doze mode. This field should only be changed when the TPM counter is disabled.
18 CROT	Counter Reload On Trigger When set, the TPM counter will reload with zero (and set PWM outputs to their reload state) when a rising edge is detected on the selected trigger input. The trigger input is ignored if the TPM counter is paused during debug mode or doze mode. This field should only be changed when the TPM counter is disabled. 0b - Counter is not reloaded due to a rising edge on the selected input trigger 1b - Counter is reloaded when a rising edge is detected on the selected input trigger
17 CSOO	Counter Stop On Overflow

Table continues on the next page...

Field	Function
	When set, the TPM counter will pause incrementing once the counter equals the MOD value and increments (this also sets the TOF). Reloading the counter with 0 due to writing to the counter register or due to a trigger input does not cause the counter to stop incrementing. Once the counter has stopped incrementing, the counter will not start incrementing unless it is disabled and then enabled again, or a rising edge on the selected trigger input is detected when CSOT is set. While the counter is paused input capture events are ignored, and PWM outputs are forced to their default state. This field should only be changed when the TPM counter is disabled. 0b - TPM counter continues incrementing or decrementing after overflow 1b - TPM counter stops incrementing or decrementing after overflow.
16 CSOT	Counter Start on Trigger When set, the TPM counter will pause incrementing when it is enabled until a rising edge on the selected trigger input is detected. If the TPM counter is paused due to an overflow, a rising edge on the selected trigger input will also cause the TPM counter to start incrementing again. While the counter is paused input capture events are ignored, and PWM outputs are forced to their default state. The trigger input is ignored if the TPM counter is paused during debug mode or doze mode. This field should only be changed when the TPM counter is disabled. 0b - TPM counter starts to increment immediately, once it is enabled. 1b - TPM counter only starts to increment when it a rising edge on the selected input trigger is detected, after it has been enabled or after it has stopped due to overflow.
15-10 —	Reserved
9 GTBEEN	Global time base enable Configures the TPM to use an externally generated global time base counter. When an externally generated timebase is used, the internal TPM counter is not used by the channels but can be used to generate a periodic interruptor DMA request using the Modulo register and timer overflow flag. 0b - All channels use the internally generated TPM counter as their timebase 1b - All channels use an externally generated global timebase as their timebase
8 GTBSYNC	Global Time Base Synchronization When enabled, the TPM counter is synchronized to the global time base. It uses the global timebase enable, trigger, paused state and overflow to ensure the TPM counter starts incrementing at the same time as the global timebase, stops incrementing at the same time as the global timebase and is reset at the same time as the global timebase. This field should only be changed when the TPM counter is disabled. 0b - Global timebase synchronization disabled. 1b - Global timebase synchronization enabled.
7-6 DBGMODE	Debug Mode Configures the TPM behavior in debug mode. All other configurations are reserved. 00b - TPM counter is paused and does not increment during debug mode. Trigger inputs and input capture events are ignored, and PWM outputs are forced to their default state. 11b - TPM counter continues in debug mode.
5 DOZEEN	Doze Enable Configures the TPM behavior in wait mode. 0b - Internal TPM counter continues in Doze mode. 1b - Internal TPM counter is paused and does not increment during Doze mode. Trigger inputs and input capture events are ignored, and PWM outputs are forced to their default state.
4-0 —	Reserved

62.5 Functional description

The following sections describe the TPM features.

62.5.1 Clock domains

The TPM module supports two clock domains.

The bus clock domain is used by the register interface and for synchronizing interrupts and DMA requests.

The TPM counter clock domain is used to clock the counter and prescaler along with the output compare and input capture logic. The TPM counter clock is considered asynchronous to the bus clock, can be a higher or lower frequency than the bus clock and can remain operational in Stop mode. Multiple TPM instances are all clocked by the same TPM counter clock in support of the external timebase feature.

62.5.1.1 Counter Clock Mode

The CMOD[1:0] bits in the SC register either disable the TPM counter or select one of three possible clock sources for the TPM counter. After any reset, CMOD[1:0] = 0:0 so the TPM counter is disabled. The CMOD[1:0] can configure one of the following counter clock sources.

- Asynchronous counter clock
- External clock input pin
- External trigger source

The CMOD[1:0] bits may be read or written at any time. Disabling the TPM counter by writing zero to the CMOD[1:0] bits does not affect the TPM counter value or other registers, but must be acknowledged by the TPM counter clock domain before they read as zero.

The external clock input and external trigger source pass through a synchronizer clocked by the TPM counter clock to ensure that counter transitions are properly aligned to counter clock transitions. Therefore, to meet Nyquist criteria considering also jitter, the frequency of the external clock source must be less than half of the counter clock frequency.

62.5.2 Prescaler

The selected counter clock source passes through a prescaler that is a 7-bit counter.

The value of the prescaler is selected by the PS[2:0] bits. The following figure shows an example of the prescaler counter and TPM counter.

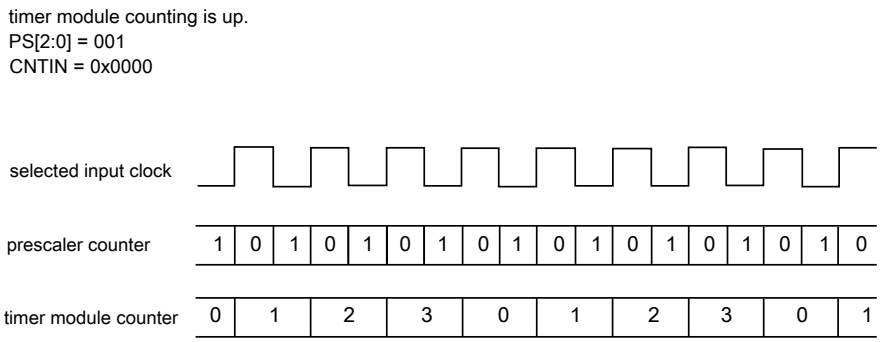

Figure 62-2. Example of the Prescaler Counter

62.5.3 Counter

The TPM has a 16-bit counter that is used by the channels either for input or output modes.

The counter updates from the selected clock divided by the prescaler.

The TPM counter has these modes of operation:

- up counting (see Up counting)
- up-down counting (see Up-down counting)

62.5.3.1 Up counting

Up counting is selected when SC[CPWMS] = 0.

The value of zero is loaded into the TPM counter, and the counter increments until the value of MOD is reached, at which point the counter is reloaded with zero.

The TPM period when using up counting is (MOD + 0x0001) × period of the TPM counter clock.

The TOF bit is set when the TPM counter changes from MOD to zero.

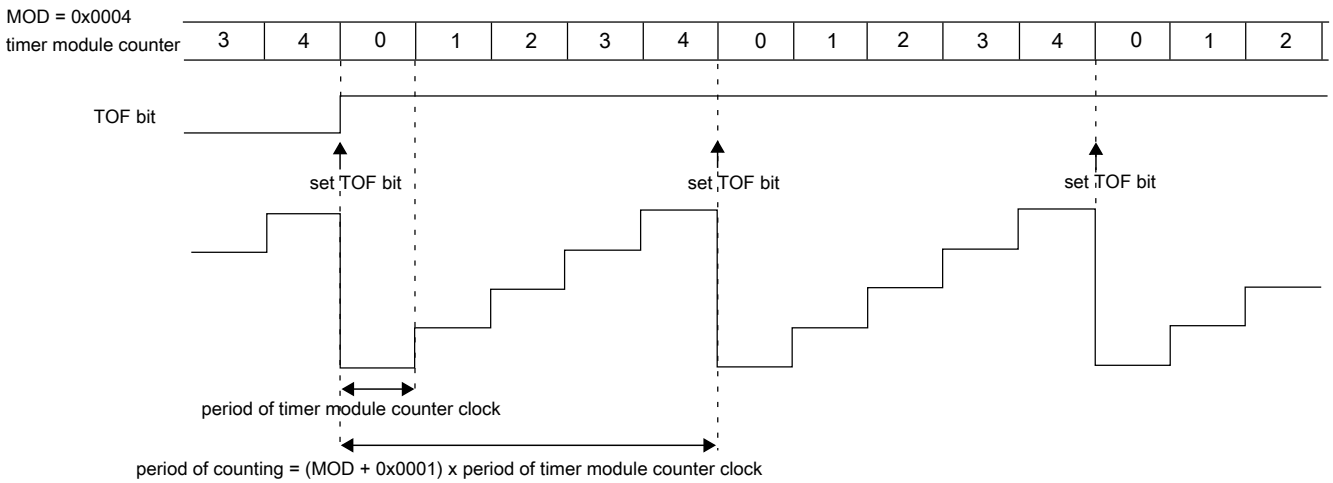

Figure 62-3. Example of TPM Up Counting

Note

- Configuring MOD = 0 is a redundant condition. In this case, the TPM counter is always equal to MOD and the TOF bit is set in each rising edge of the TPM counter clock.
- Configuring MOD = 1 and PS = 0 will attempt to set the TOF bit every second TPM counter clock. Due to synchronization delays between the counter clock and the bus clock, the TOF must be cleared by software two counter clock cycles before TOF can be set again.

62.5.3.2 Up-down counting

Up-down counting is selected when SC[CPWMS] = 1. When configured for up-down counting, configuring CONF[MOD] to less than 2 is not supported.

The value of 0 is loaded into the TPM counter, and the counter increments until the value of MOD is reached, at which point the counter is decremented until it returns to zero and the up-down counting restarts.

The TPM period when using up-down counting is 2 × MOD × period of the TPM counter clock.

The TOF bit is set when the TPM counter changes from MOD to (MOD – 1).

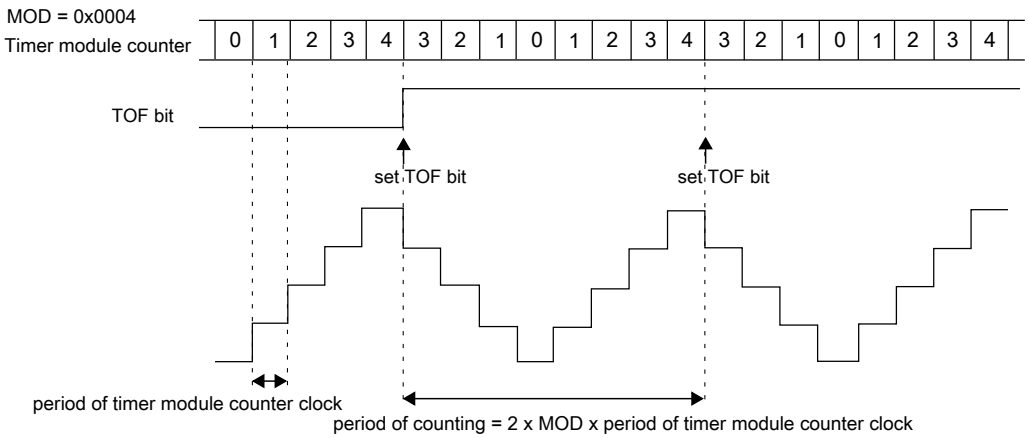

Figure 62-4. Example of up-down counting

62.5.3.3 Counter Reset

Any write to CNT resets the TPM counter and the channel outputs to their initial values (except for channels in output compare mode).

62.5.3.4 Global time base (GTB)

The global time base (GTB) is a TPM function that allows multiple TPM modules to share the same timebase. When the global time base is enabled (CONF[GTBEEN] = 1), the local TPM channels use the counter value, counter enable and overflow indication from the TPM generating the global time base. If the local TPM counter is not generating the global time base, then it can be used as an independent counter or pulse accumulator.

The local TPM counter can also be configured to synchronize to the global time base, by configuring (GTBSYNC = 1). When synchronized to the global time base, the local counter will use the counter enable and counter overflow indication from the TPM generating the global time base. This enables multiple TPM to be configured with the same phase, but with different periods (although the global time base must be configured with the longest period).

62.5.3.5 Counter trigger

The TPM counter can be configured to start, stop or reset in response to a hardware trigger input. The trigger input is synchronized to the asynchronous counter clock, so there is a 3 counter clock delay between the trigger assertion and the counter responding.

- When (CSOT = 1), the counter will not start incrementing until a rising edge is detected on the trigger input.
- When (CSOO= 1), the counter will stop incrementing whenever the TOF flag is set. The counter does not increment again unless it is disabled, or if CSOT = 1 and a rising edge is detected on the trigger input.
- When (CROT= 1), the counter will reset to zero as if an overflow occurred whenever a rising edge is detected on the trigger input. Any PWM channels will update to their reload state.
- When (CPOT = 1), the counter will pause incrementing whenever the trigger input is asserted. The counter will continue incrementing when the trigger input negates. PWM output channels are forced to their default state.

The polarity of the external input trigger can be configured by the TRGPOL register bit.

When an internal trigger source is selected, the trigger input is selected from one or more channel input capture events. The input capture filters are used with the internal trigger sources and the POLn bits can be used to invert the polarity of the input channels. Note that following restrictions apply with input capture channel sources.

- When (CSOT = 1), the counter will only start incrementing on a rising edge on the channel input, provided ELSnA = 1.
- When (CROT= 1), the counter will reset to zero on either edge of the channel input, as configured by ELSnB:ELSnA.
- When (CPOT = 1), the counter will pause incrementing whenever the channel input is asserted. PWM output channels are forced to their default state.

62.5.4 Input Capture Mode

The input capture mode is selected when (CPWMS = 0), (MSnB:MSnA = 0:0), and (ELSnB:ELSnA ≠ 0:0).

When a selected edge occurs on the channel input, the current value of the TPM counter is captured into the CnV register, at the same time the CHnF bit is set and the channel interrupt is generated if enabled by CHnIE = 1 (see the following figure).

When a channel is configured for input capture, the TPM_CHn pin is an edge-sensitive input. ELSnB:ELSnA control bits determine which edge, falling or rising, triggers input-capture event. Note that the maximum frequency for the channel input signal to be detected correctly is counter clock divided by 4, which is required to meet Nyquist criteria for signal sampling.

Writes to the CnV register are ignored in input capture mode.

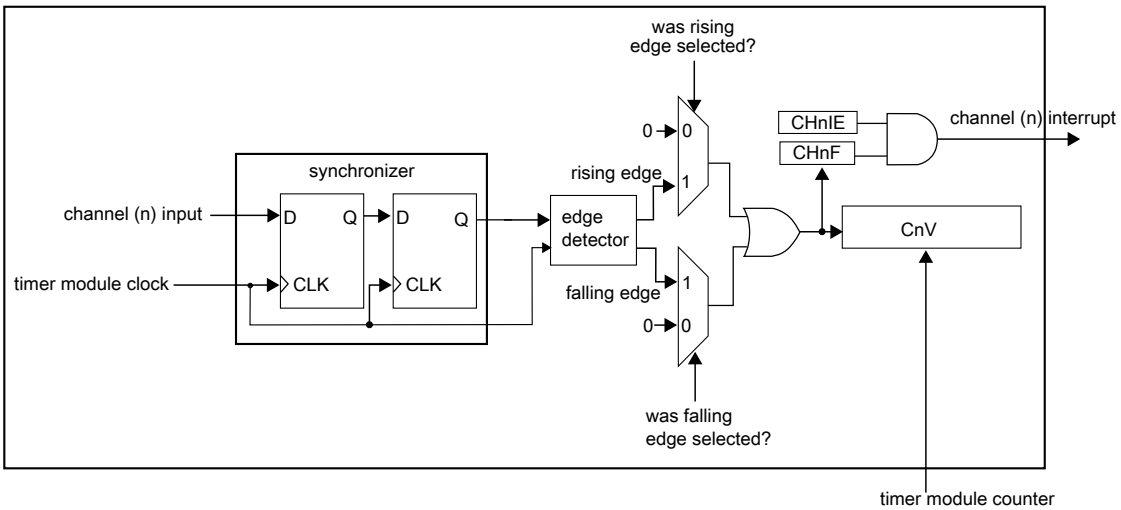

Figure 62-5. Input capture mode

The CHnF bit is set on the third rising edge of the counter clock after a valid edge occurs on the channel input.

62.5.5 Output Compare Mode

The output compare mode is selected when (CPWMS = 0), and (MSnB:MSnA = X:1).

In output compare mode, the TPM can generate timed pulses with programmable position, polarity, duration, and frequency. When the counter matches the value in the CnV register of an output compare channel, the channel (n) output can be set, cleared or toggled if MSnB is clear. If MSnB is set then the channel (n) output is pulsed high or low for as long as the counter matches the value in the CnV register.

When a channel is initially configured to output compare mode, the channel output updates with its negated value (logic 0 for set/toggle/pulse high and logic one for clear/ pulse low).

The CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (TPM counter = CnV).

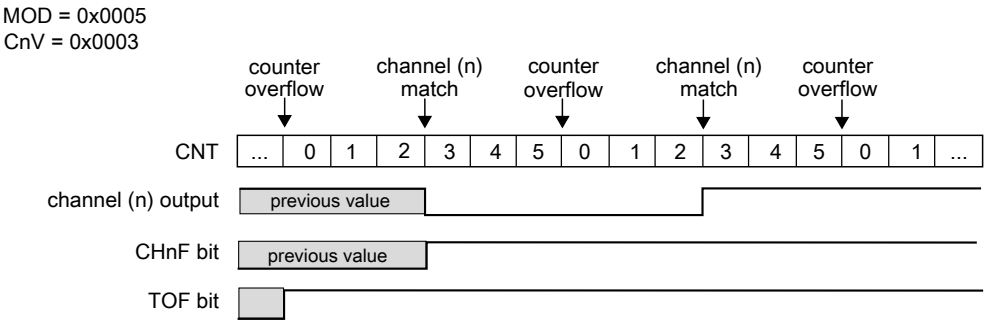

Figure 62-6. Example of the output compare mode when the match toggles the channel output

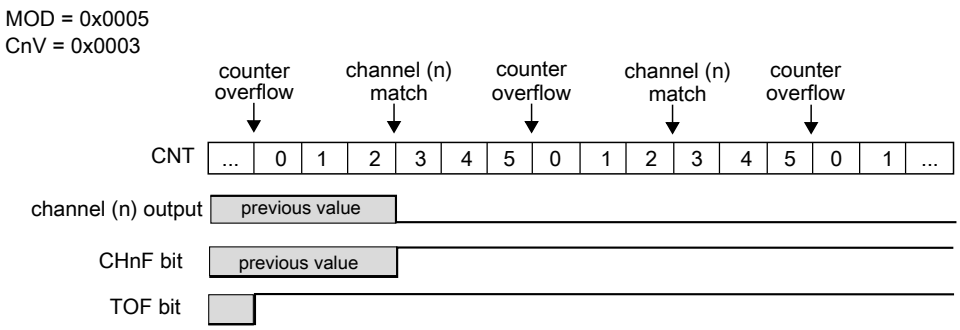

Figure 62-7. Example of the output compare mode when the match clears the channel output

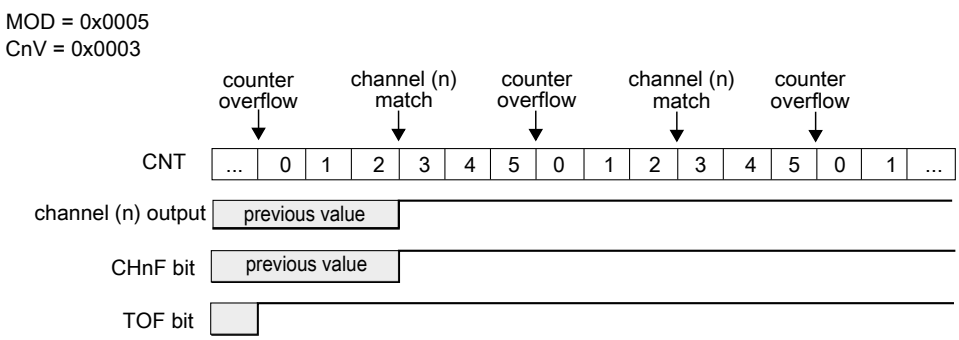

Figure 62-8. Example of the output compare mode when the match sets the channel output

It is possible to use the output compare mode with (MSnB:MSnA = 0:1) and (ELSnB:ELSnA = 0:0). In this case, when the counter reaches the value in the CnV register, the CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1), however the channel (n) output is not modified or controlled by TPM.

62.5.6 Edge-Aligned PWM (EPWM) Mode

The edge-aligned mode is selected when (CPWMS = 0), and (MSnB:MSnA = 1:0).

The EPWM period is determined by (MOD + 0x0001) and the pulse width (duty cycle) is determined by CnV.

The CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (TPM counter = CnV), that is, at the end of the pulse width.

This type of PWM signal is called edge-aligned because the leading edges of all PWM signals are aligned with the beginning of the period, which is the same for all channels within an TPM.

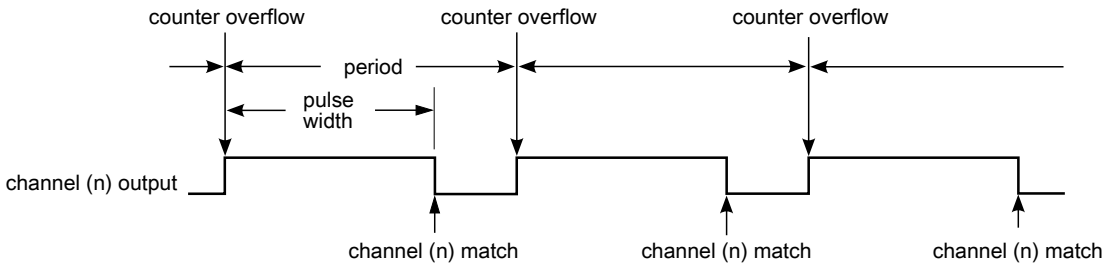

Figure 62-9. EPWM period and pulse width with ELSnB:ELSnA = 1:0

If (ELSnB:ELSnA = 1:0), then the channel (n) output is forced high at the counter overflow or reload (when the zero is loaded into the TPM counter), and it is forced low at the channel (n) match (TPM counter = CnV). When first enabled or whenever the TPM counter is paused, the channel (n) output is forced high.

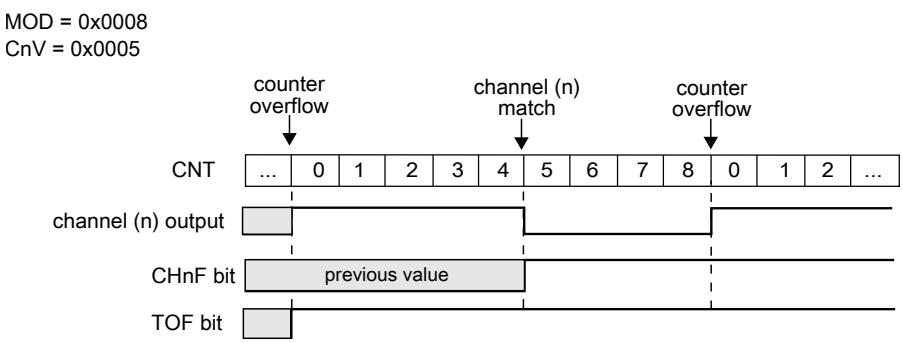

Figure 62-10. EPWM signal with ELSnB:ELSnA = 1:0

If (ELSnB:ELSnA = 0:1), then the channel (n) output is forced low at the counter overflow or reload (when zero is loaded into the TPM counter), and it is forced high at the channel (n) match (TPM counter = CnV). When first enabled or whenever the TPM counter is paused, the channel (n) output is forced low.

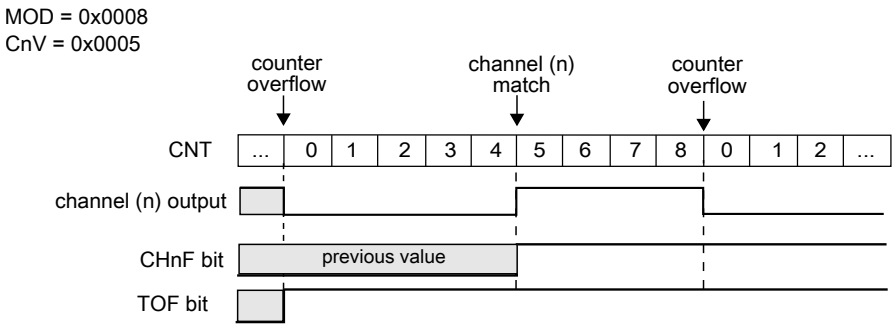

Figure 62-11. EPWM signal with ELSnB:ELSnA = 0:1

If (CnV = 0x0000), then the channel (n) output is a 0% duty cycle EPWM signal. If (CnV > MOD), then the channel (n) output is a 100% duty cycle EPWM signal and CHnF bit is not set since there is never a channel (n) match. Therefore, MOD must be less than 0xFFFF in order to get a 100% duty cycle EPWM signal.

62.5.7 Center-Aligned PWM (CPWM) Mode

The center-aligned mode is selected when (CPWMS = 1) and (MSnB:MSnA = 1:0).

The CPWM pulse width (duty cycle) is determined by 2 × CnV and the period is determined by 2 × MOD (see the following figure). MOD must be kept in the range of 0x0001 to 0x7FFF because values outside this range can produce ambiguous results.

In the CPWM mode, the TPM counter counts up until it reaches MOD and then counts down until it reaches zero.

The CHnF bit is set and channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (TPM counter = CnV) when the TPM counting is down (at the begin of the pulse width) and when the TPM counting is up (at the end of the pulse width).

This type of PWM signal is called center-aligned because the pulse width centers for all channels are when the TPM counter is zero.

The other channel modes are not designed to be used with the up-down counter (CPWMS = 1). Therefore, all TPM channels should be used in CPWM mode when (CPWMS = 1).

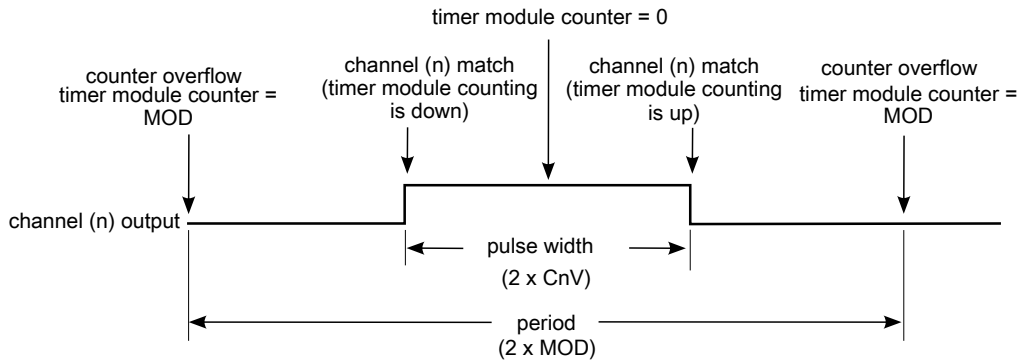

Figure 62-12. CPWM period and pulse width with ELSnB:ELSnA = 1:0

If (ELSnB:ELSnA = 1:0), then the channel (n) output is forced high at the channel (n) match (TPM counter = CnV) when counting down, and it is forced low at the channel (n) match when counting up. When first enabled, when the TPM counter is reloaded, or whenever the TPM counter is paused, the channel (n) output is forced high.

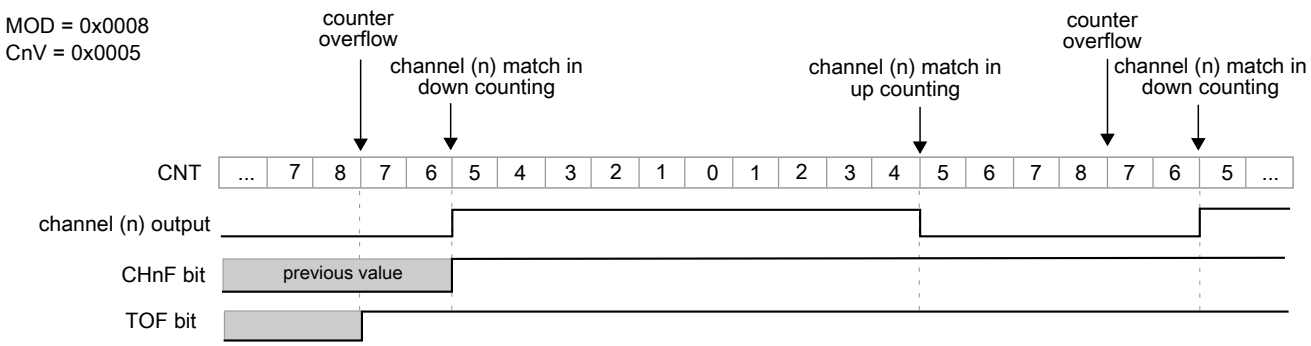

Figure 62-13. CPWM signal with ELSnB:ELSnA = 1:0

If (ELSnB:ELSnA = 0:1), then the channel (n) output is forced low at the channel (n) match (TPM counter = CnV) when counting down, and it is forced high at the channel (n) match when counting up. When first enabled, when the TPM counter is reloaded, or whenever the TPM counter is paused, the channel (n) output is forced low.

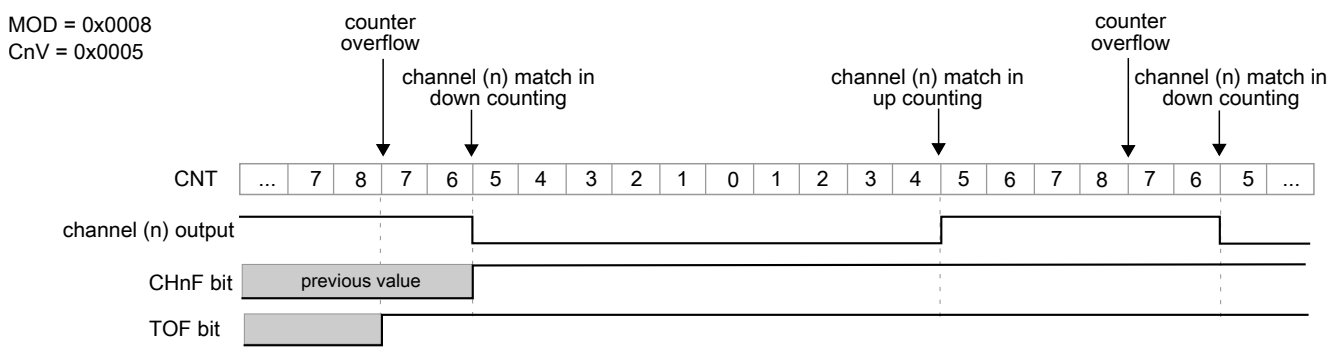

Figure 62-14. CPWM signal with ELSnB:ELSnA = 0:1

If (CnV = 0x0000) then the channel (n) output is a 0% duty cycle CPWM signal.

If (CnV > MOD), then the channel (n) output is a 100% duty cycle CPWM signal, although the CHnF bit is set when the counter changes from incrementing to decrementing. Therefore, MOD must be less than 0xFFFF in order to get a 100% duty cycle CPWM signal.

62.5.8 Combine PWM mode

The Combine PWM mode is selected when:

- MSnB:MSnA = 10
- COMBINEn = 1
- QUADEN = 0, and
- CPWMS = 0

In Combine PWM mode, an even channel (n) and adjacent odd channel (n+1) are combined to generate a PWM signal in the channel (n) output.

In the Combine mode, the PWM period is determined by (MOD + 0x0001) and the PWM pulse width (duty cycle) is determined by (|C(n+1)V − C(n)V|).

The CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (TPM counter = C(n)V). The CH(n+1)F bit is set and the channel (n +1) interrupt is generated, if CH(n+1)IE = 1, at the channel (n+1) match (TPM counter = C(n+1)V).

If channel (n) (ELSnB:ELSnA = 0:1), then the channel (n) output is forced low at the beginning of the period (TPM counter is zero) and at the channel (n+1) match (TPM counter = C(n+1)V). It is forced high at the channel (n) match (TPM counter = C(n)V).

If channel (n) (ELSnB:ELSnA = 1:0), then the channel (n) output is forced high at the beginning of the period (TPM counter is zero) and at the channel (n+1) match (TPM counter = C(n+1)V). It is forced low at the channel (n) match (TPM counter = C(n)V).

When (COMSWAPn = 1), then the channel (n) output is forced low or high at the beginning of the period (TPM counter is zero) and at the channel (n) match (TPM counter = C(n)V). It is forced high or low at the channel (n+1) match (TPM counter = C(n+1)V).

The channel (n+1) output is generated the same as the channel (n) output, but the output polarity is controlled by the channel (n+1) ELSnB:ELSnA configuration.

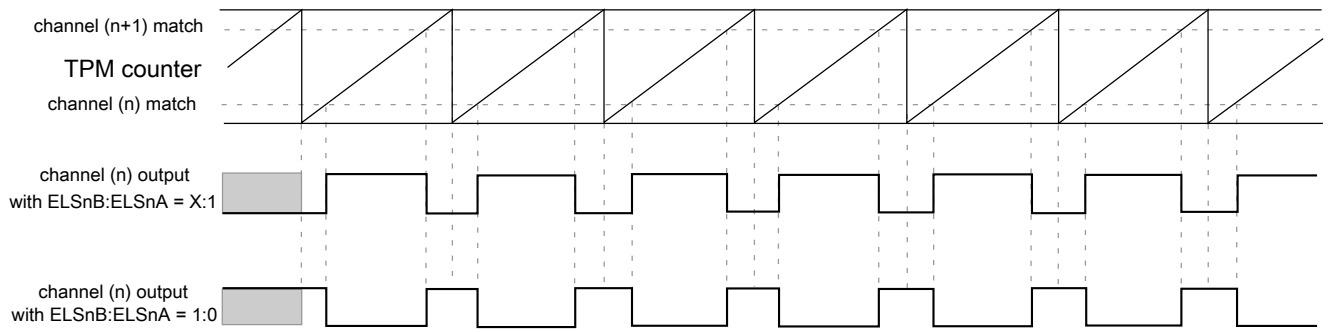

Figure 62-15. Combine mode

The following figures illustrate the PWM signals generation using Combine mode.

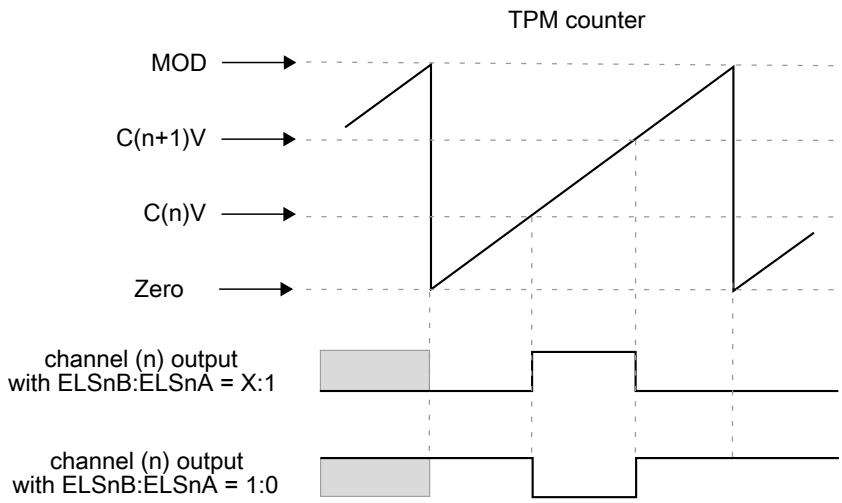

Figure 62-16. Channel (n) output if (C(n)V < MOD) and (C(n+1)V < MOD) and (C(n)V < C(n+1)V)

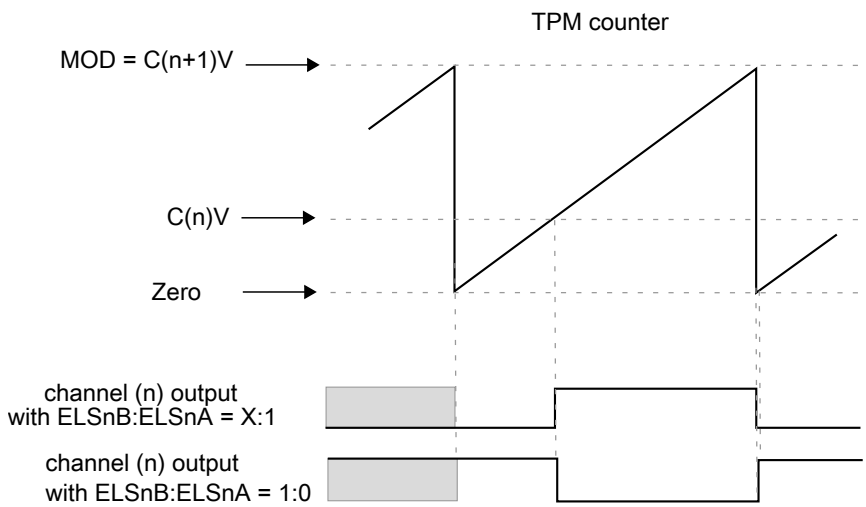

Figure 62-17. Channel (n) output if (C(n)V < MOD) and (C(n+1)V = MOD)

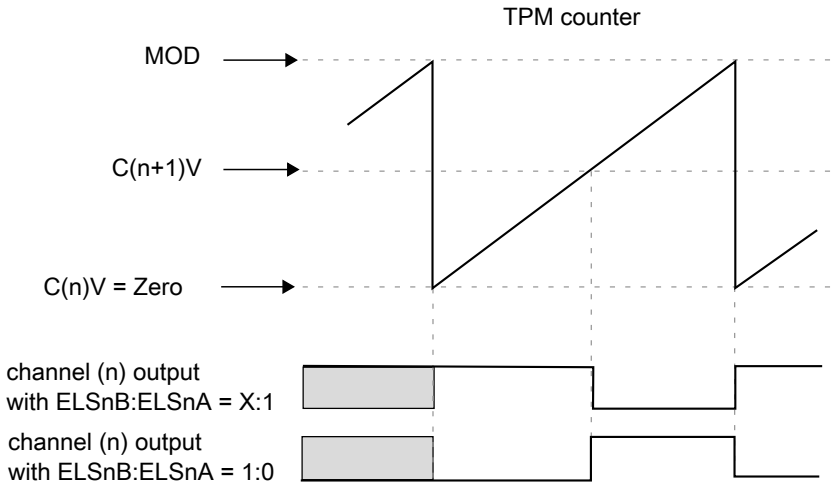

Figure 62-18. Channel (n) output if (C(n)V = zero) and (C(n+1)V < MOD)

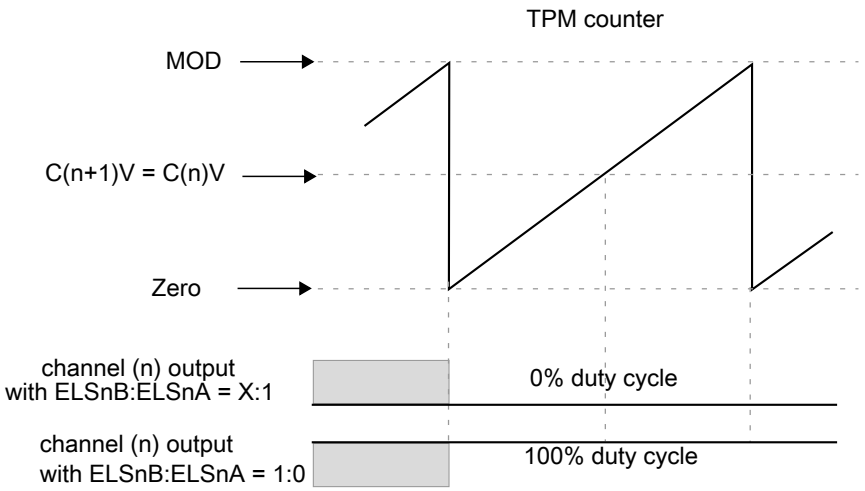

Figure 62-19. Channel (n) output if (C(n)V < MOD) and (C(n+1)V < MOD) and (C(n)V = C(n +1)V)

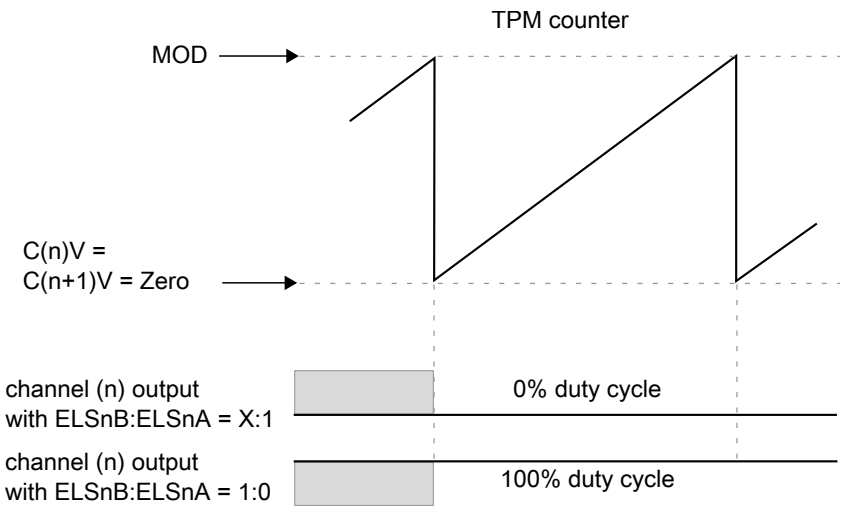

Figure 62-20. Channel (n) output if (C(n)V = C(n+1)V = zero)

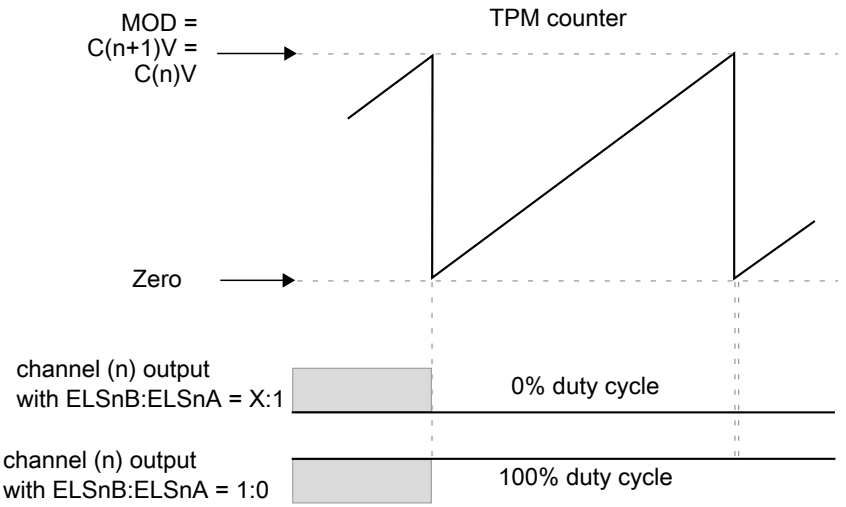

Figure 62-21. Channel (n) output if (C(n)V = C(n+1)V = MOD)

62.5.9 Combine Input Capture mode

The Combine Input Capture mode is selected if COMBINEn= 1 and MSnB:MSnA = 00 and ELSnB:ELSnA != 00. This mode allows to measure a pulse width of the signal on the input of channel (n) of a channel pair. The channel (n) filter can be active in this mode.

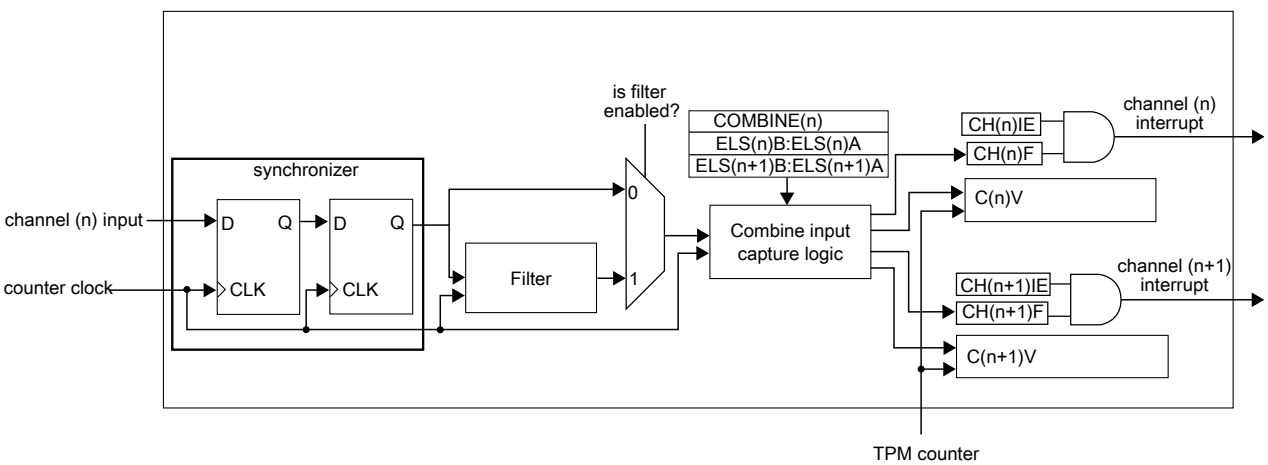

Figure 62-22. Combine Input Capture mode block diagram

The ELS(n)B:ELS(n)A bits select the edge that is captured by channel (n), and ELS(n +1)B:ELS(n+1)A bits select the edge that is captured by channel (n+1).

In the Combine Input Capture mode, only channel (n) input is used and channel (n+1) input is ignored, when COMSWAPn=1 then only channel (n+1) input is used and channel (n) input is ignored.

If the selected edge by channel (n) bits is detected at channel (n) input, then CH(n)F bit is set and the channel (n) interrupt is generated (if CH(n)IE = 1). If the selected edge by channel (n+1) bits is detected at channel (n) input, then CH(n+1)F bit is set and the channel (n+1) interrupt is generated (if CH(n+1)IE = 1).

The C(n)V register stores the value of TPM counter when the selected edge by channel (n) is detected at channel (n) input. The C(n+1)V register stores the value of TPM counter when the selected edge by channel (n+1) is detected at channel (n) input.

Note

- The CH(n)F, CH(n)IE, MS(n)A, ELS(n)B, and ELS(n)A bits are channel (n) bits.
- The CH(n+1)F, CH(n+1)IE, MS(n+1)A, ELS(n+1)B, and ELS(n+1)A bits are channel (n+1) bits.
- The Combine Input Capture mode must be used with ELS(n)B:ELS(n)A = 0:1 or 1:0, ELS(n+1)B:ELS(n+1)A = 0:1 or 1:0.

62.5.10 Input Capture Filter

The input capture filter function is only in input capture mode, or in software compare mode when quadrature decoder mode is enabled.

First, the input signal is synchronized by the counter clock. Following synchronization, the input signal enters the filter block. See the following figure.

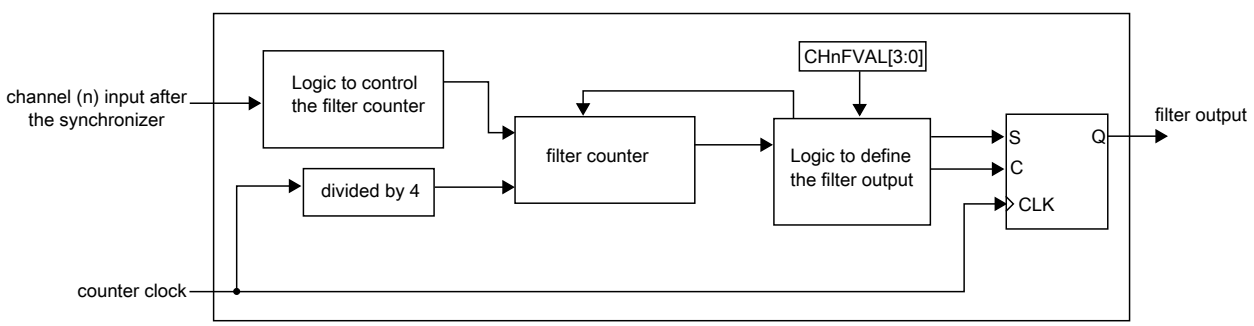

Figure 62-23. Channel input filter

When there is a state change in the input signal, the counter is reset and starts counting up. As long as the new state is stable on the input, the counter continues to increment. When the counter is equal to (CHnFVAL[3:0] × 4), the state change of the input signal is validated.

If the opposite edge appears on the input signal before it can be validated, the counter is reset. At the next input transition, the counter starts counting again. Any pulse that is shorter than the minimum value selected by (CHnFVAL[3:0] × 4 counter clocks) is regarded as a glitch and is not passed through the filter. A timing diagram of the input filter is shown in the following figure.

The filter function is disabled when CHnFVAL[3:0] bits are zero. In this case, the input signal is delayed by 2 rising edges of the counter clock. If (CHnFVAL[3:0] ≠ 0000), then the input signal is delayed by the minimum pulse width (CHnFVAL[3:0] × 4 system clocks) plus a further 3 rising edges of the system clock: two rising edges to the synchronizer, plus one more to the edge detector. In other words, CHnF is set (3 + 4 × CHnFVAL[3:0]) counter clock periods after a valid edge occurs on the channel input.

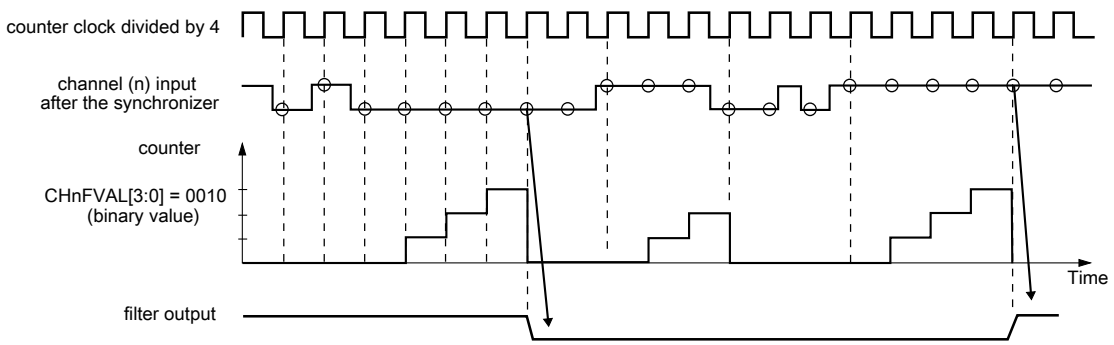

Figure 62-24. Channel input filter example

62.5.11 Deadtime insertion

The deadtime insertion is enabled in PWM combine modes for each pair of channels when CH(n)FVAL and CH(n+1)FVAL are non-zero. The deadtime delay that is used for each TPM channel is defined as (CH(n+1)FVAL[3:0] x 64) + (CH(n)FVAL[3:0] x 4).

The deadtime delay insertion ensures that no two complementary signals (even channel (n) and odd channel (n+1)) drive the active state at the same time.

If ELSnB:ELSnA = 0:1, ELS(n+1)B:ELS(n+1)A = 1:0, COMSWAPn = 0, and the deadtime is enabled, then when the channel (n) match (TPM counter = C(n)V) occurs, the channel (n) output remains at the low value until the end of the deadtime delay when the channel (n) output is set. Similarly, when the channel (n+1) match (TPM counter = C(n +1)V) occurs, the channel (n+1) output remains at the low value until the end of the deadtime delay when the channel (n+1) output is set. See the following figures.

If ELSnB:ELSnA = 1:0, ELS(n+1)B:ELS(n+1)A = 0:1, COMSWAPn = 1,and the deadtime is enabled, then when the channel (n+1) match (TPM counter = C(n+1)V) occurs, the channel (n+1) output remains at the low value until the end of the deadtime

delay when the channel (n+1) output is set. Similarly, when the channel (n) match (TPM counter = CnV) occurs, the channel (n) output remains at the low value until the end of the deadtime delay when the channel (n) output is set.

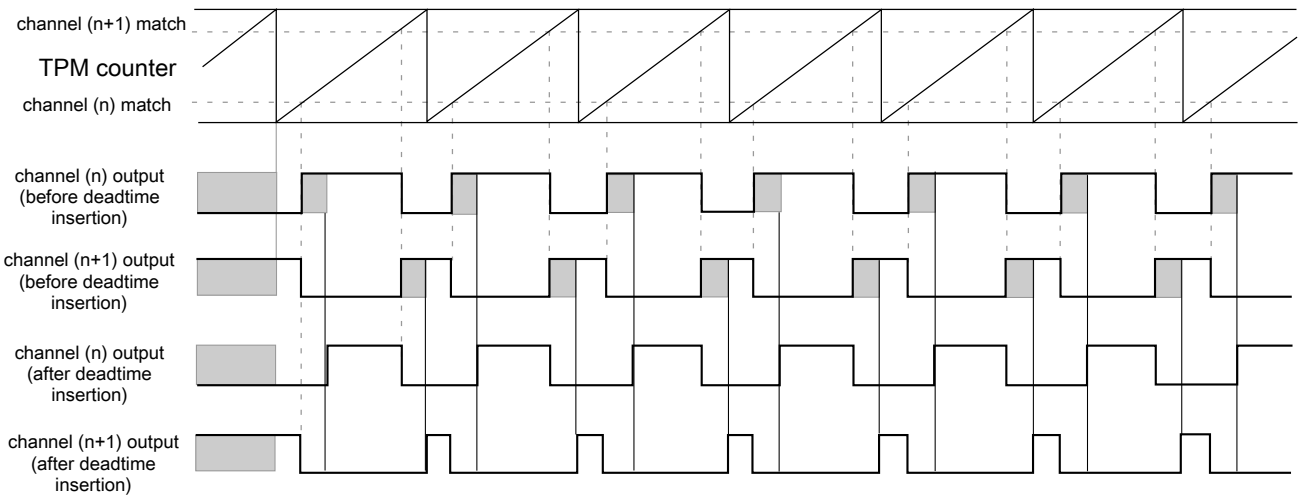

Figure 62-25. Deadtime insertion with ELSnB:ELSnA = 0:1, ELS(n+1)B:ELS(n+1)A = 1:0, COMSWAPn = 0

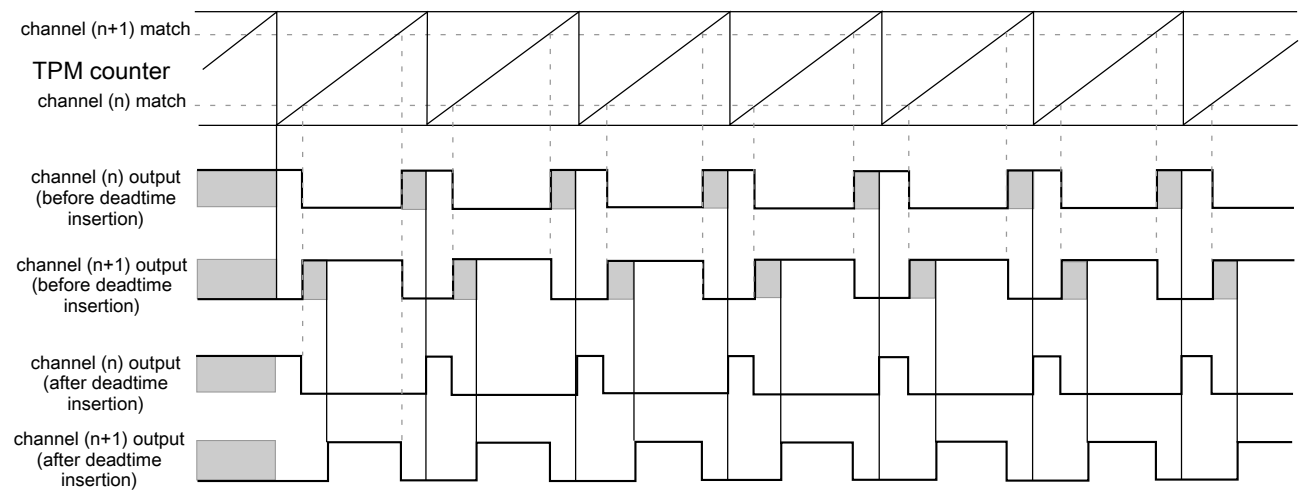

Figure 62-26. Deadtime insertion with ELSnB:ELSnA = 1:0, ELS(n+1)B:ELS(n+1)A = 0:1, COMSWAPn = 1

62.5.12 Quadrature Decoder mode

The Quadrature Decoder mode is selected if (QUADEN = 1). The Quadrature Decoder mode uses the channel 0 (phase A) and channel 1 (phase B) input signals to control the TPM counter increment and decrement. The following figure shows the quadrature decoder block diagram.

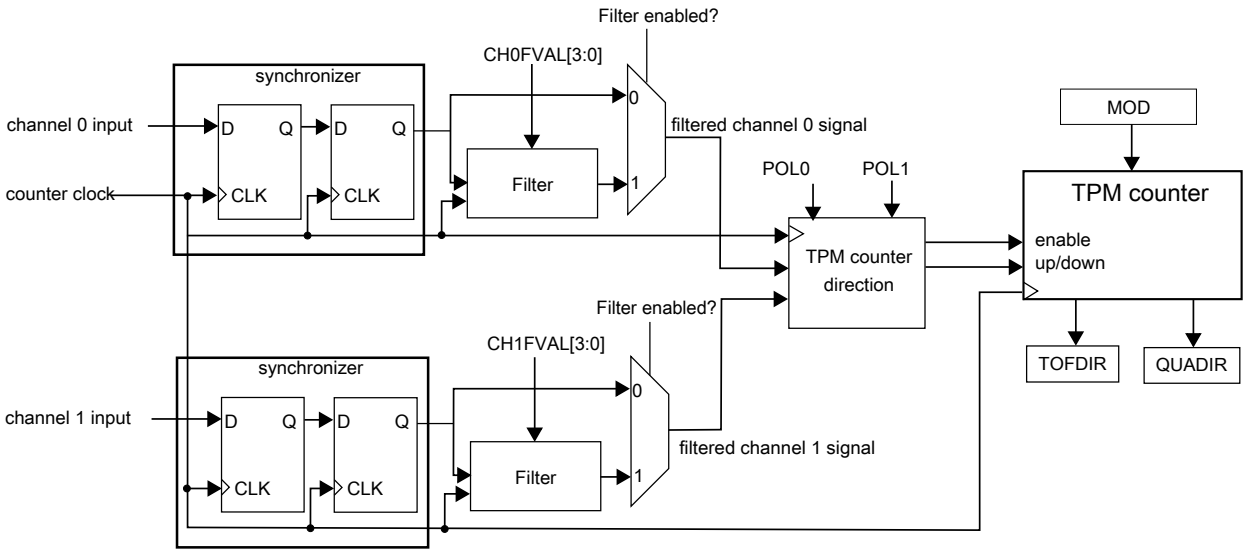

Figure 62-27. Quadrature Decoder block diagram

The input capture filter and channel polarity registers are used to configure the input filter and polarity for the channel 0 and channel 1 inputs in quadrature decode mode.

Note

Notice that the TPM counter is clocked by the channel 0 and channel 1 input signals when quadrature decoder mode is selected. Therefore In quadrature decoder mode, channel 0 and channel 1 can only be used in software compare mode and other TPM channels can only be used in input capture or output compare modes.

The QUADMODE selects the encoding mode used in the Quadrature Decoder mode. If QUADMODE = 1, then the count and direction encoding mode is enabled; see the following figure. In this mode, the channel 1 input value indicates the counting direction, and the channel 0 input defines the counting rate. The TPM counter is updated when there is a rising edge at channel 0 input signal.

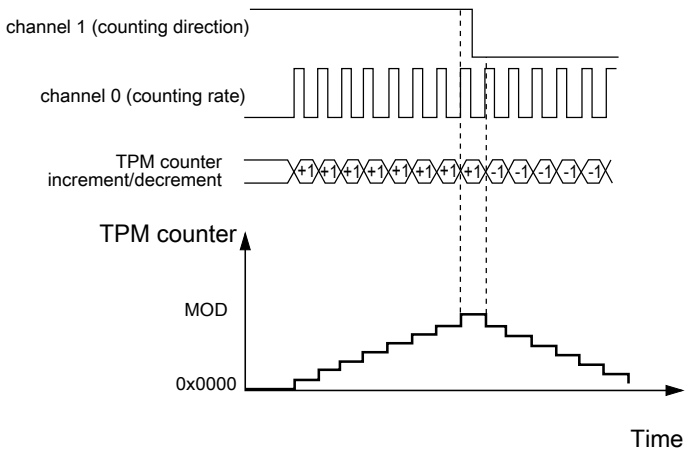

Figure 62-28. Quadrature Decoder – Count and Direction Encoding mode

If QUADMODE = 0, then the Phase Encoding mode is enabled; see the following figure. In this mode, the relationship between channel 0 and channel 1 signals indicates the counting direction, and channel 0 and channel 1 signals define the counting rate. The TPM counter is updated when there is an edge either at the channel 0 or channel 1 signals.

If CH0POL= 0 and CH1POL = 0, then the TPM counter increment happens when:

- there is a rising edge at channel 0 signal and channel 1 signal is at logic zero;
- there is a rising edge at channel 1 signal and channel 0 signal is at logic one;
- there is a falling edge at channel 1 signal and channel 0 signal is at logic zero;
- there is a falling edge at channel 0 signal and channel 1 signal is at logic one;

and the TPM counter decrement happens when:

- there is a falling edge at channel 0 signal and channel 1 signal is at logic zero;
- there is a falling edge at channel 1 signal and channel 0 signal is at logic one;
- there is a rising edge at channel 1 signal and channel 0 signal is at logic zero;
- there is a rising edge at channel 0 signal and channel 1 signal is at logic one.

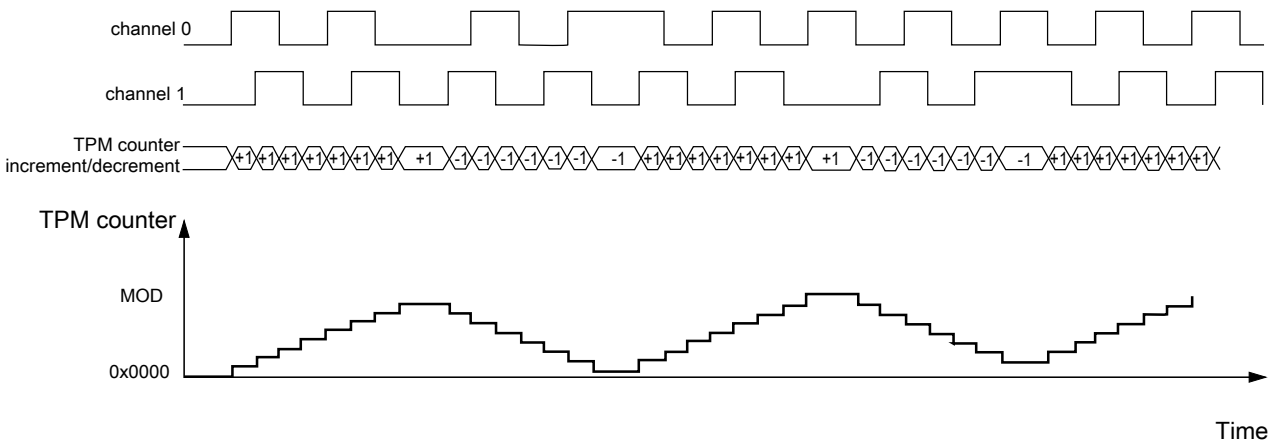

Figure 62-29. Quadrature Decoder – Phase Encoding mode

The following figure shows the TPM counter overflow in up counting. In this case, when the TPM counter changes from MOD to zero, TOF and TOFDIR bits are set. TOF bit indicates the TPM counter overflow occurred. TOFDIR indicates the counting was up when the TPM counter overflow occurred.

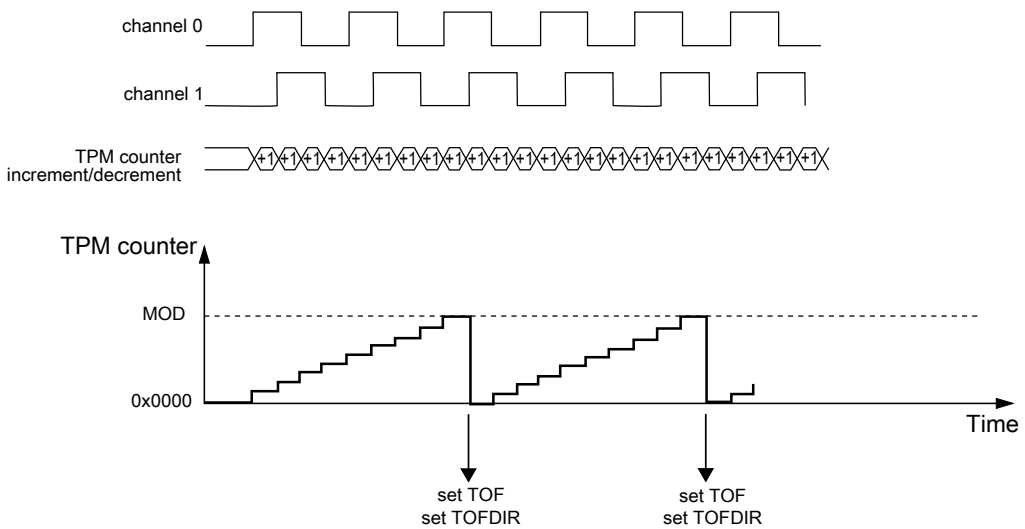

Figure 62-30. TPM Counter overflow in up counting for Quadrature Decoder mode

The following figure shows the TPM counter overflow in down counting. In this case, when the TPM counter changes from zero to MOD, TOF bit is set and TOFDIR bit is cleared. TOF bit indicates the TPM counter overflow occurred. TOFDIR indicates the counting was down when the TPM counter overflow occurred.

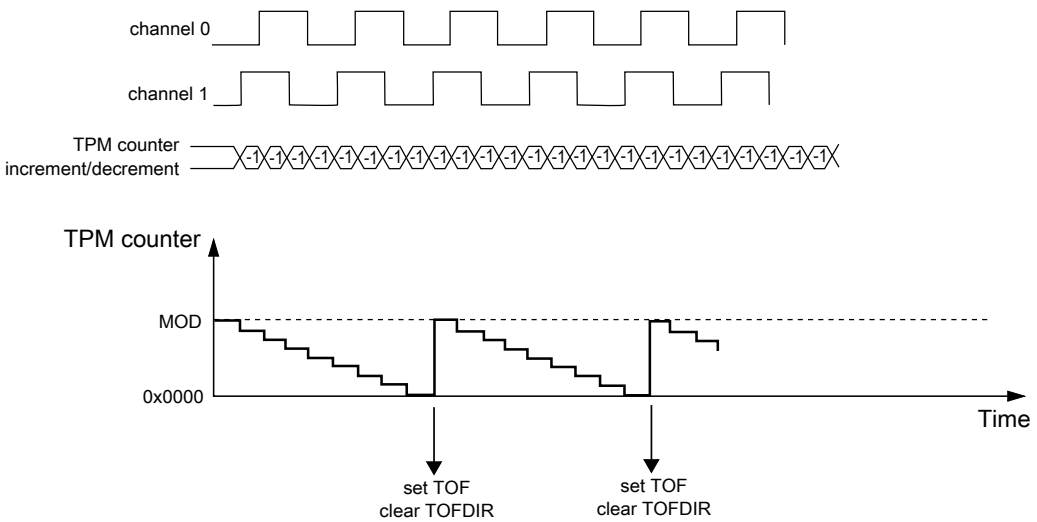

Figure 62-31. TPM counter overflow in down counting for Quadrature Decoder mode

62.5.13 Registers Updated from Write Buffers

62.5.13.1 MOD Register Update

If (CMOD[1:0] = 0:0) then MOD register is updated when MOD register is written.

If (CMOD[1:0] ≠ 0:0), then MOD register is updated according to the CPWMS bit, that is:

- If the selected mode is not CPWM then MOD register is updated after MOD register was written and the TPM counter changes from MOD to zero.
- If the selected mode is CPWM then MOD register is updated after MOD register was written and the TPM counter changes from MOD to (MOD – 1).

62.5.13.2 CnV Register Update

If (CMOD[1:0] = 0:0) then CnV register is updated when CnV register is written.

If (CMOD[1:0] ≠ 0:0), then CnV register is updated according to the selected mode, that is:

- If the selected mode is output compare then CnV register is updated on the next TPM counter increment (end of the prescaler counting) after CnV register was written.

- If the selected mode is EPWM then CnV register is updated after CnV register was written and the TPM counter changes from MOD to zero.
- If the selected mode is CPWM then CnV register is updated after CnV register was written and the TPM counter changes from MOD to (MOD – 1).

62.5.14 DMA

The channel and overflow flags generate a DMA transfer request according to DMA and CHnIE/TOIE bits.

See the following table for more information.

Table 62-6. DMA Transfer Request

DMA	CHnIE/ TOIE	Channel/Overflow DMA Transfer Request	Channel/Overflow Interrupt
0	0	The channel/overflow DMA transfer request is not generated.	The channel/overflow interrupt is not generated.
0	1	The channel/overflow DMA transfer request is not generated.	The channel/overflow interrupt is generated if (CHnF/TOF = 1).
1	0	The channel/overflow DMA transfer request is generated if (CHnF/TOF = 1).	The channel/overflow interrupt is not generated.
1	1	The channel/overflow DMA transfer request is generated if (CHnF/TOF = 1).	The channel/overflow interrupt is generated if (CHnF/TOF = 1).

If DMA = 1, the CHnF/TOF bit can be cleared either by DMA transfer done or writing a one to CHnF/TOF bit (see the following table).

Table 62-7. Clear CHnF/TOF Bit

DMA	How CHnF/TOF Bit Can Be Cleared
0	CHnF/TOF bit is cleared by writing a 1 to CHnF/TOF bit.
1	CHnF/TOF bit is cleared either when the DMA transfer is done or by writing a 1 to CHnF/TOF bit.

62.5.15 Peripheral Triggers

The connection of the TPM peripheral triggers with other peripherals are device specific.

62.5.15.1 Output Triggers

The TPM generates output triggers for the counter and each channel that can be used to trigger events in other peripherals. The counter trigger asserts whenever the TOF is set and remains asserted until the next increment.

Each TPM channel generates both a pre-trigger output and a trigger output. The pre-trigger output asserts whenever the CHnF is set, the trigger output asserts on the first counter increment after the pre-trigger asserts, and then both the trigger and pre-trigger negate on the first counter increment after the trigger asserts.

When (COMBINEn = 1) in output compare modes, the pre-trigger output for both channel (n) and channel (n+1) will assert when CH(n)F is set and will negate when CH(n +1)F is set. The trigger continues to assert on the first counter increment after the pre-trigger asserts and negates at the same time as the pre-trigger negation.

62.5.15.2 Input Trigger

The TPM input trigger can be configured to perform the following operations with configurable polarity:

- Increment the counter on trigger rising edge
- Start incrementing the counter on trigger rising edge
- Reset/reload the counter on trigger rising edge
- Pause the counter while trigger high

The TPM input trigger is synchronized and must assert for at least two counter clock cycles so that the input trigger can be detected.

62.5.16 Reset Overview

The TPM is reset whenever any chip reset occurs.

When the TPM exits from reset:

- the TPM counter and the prescaler counter are zero and are stopped (CMOD[1:0] = 0:0);
- the timer overflow interrupt is zero;
- the channels interrupts are zero;
- the channels are in input capture mode;
- the channels outputs are zero;
- the channels pins are not controlled by TPM (ELS(n)B:ELS(n)A = 0:0).

62.5.17 TPM Interrupts

This section describes TPM interrupts.

62.5.17.1 Timer Overflow Interrupt

The timer overflow interrupt is generated when (TOIE = 1) and (TOF = 1).

62.5.17.2 Channel (n) Interrupt

The channel (n) interrupt is generated when (CHnIE = 1) and (CHnF = 1).

Instances	2
Configurable features	LPIT0-1 • 4 channels, 32-bit timer • LPIT0-1/DMA trigger assignments. See LPIT DMA trigger sources • LPIT0-1/ADC trigger assignments in TRGMUX table. See Table 38-2 and Table 38-3.
Interface speed	NA
External I/O pins	NA

63.1.2 LPIT DMA trigger sources

On this device, LPIT is not directly connected to DMAMUX, it is connected through TRGMUX module. TRGMUX connects a trigger source to LPIT depending on the dedicated TRGMUX register configuration for that module. As described in Table 38-2, Table 38-3, Table 38-4, and Table 38-5, TRGMUX[0/1] outputs 0-7 are connected to DMAMUX[0/1] and LPIT0/1 channels 0-3 can be selected as trigger source.

63.2 Introduction

63.2.1 Overview

LPIT is a low power periodic interrupt timer with multiple timer channels. After a timer reaches a programmed count, the respective timer channel will generate pre-trigger and trigger output signals, and these pre-trigger and trigger outputs can be used to trigger other modules on the device.

- Timers can be configured to be controlled using:
  - external triggers (triggers from outside the LPIT module)
  - or internal triggers (triggers from other timer channels inside the LPIT module).
- The timer channels can be chained together, to form a larger width timer.
- Depending on the timer modes, the timer channels may reload and count again, or stop after reaching the programmed count.

The next figure shows the interface of an LPIT module to the other modules on the SoC.

- The CPU interface provides the clock, reset, register read/write bus interface and handles interrupts from an LPIT.
- The trigger output signals from an LPIT may trigger other modules on the SoC, like the DMA, ADC, and other modules.
- Similarly, other timer modules may provide trigger inputs to an LPIT module, to control when an LPIT timer channel starts.

For the exact module interactions, see the SoC Configuration chapter in your device's hardware Reference Manual (RM).

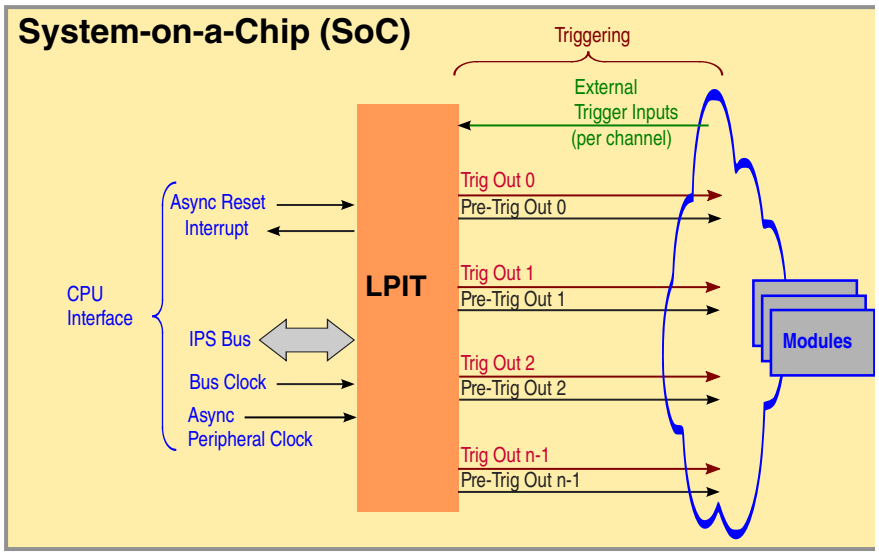

Figure 63-1. LPIT Interface in SoC

Each timer channel in LPIT can be configured to work in either compare modes or capture modes.

- **In compare mode:** the timers decrement when enabled and generate an output pre-trigger and trigger output. The trigger output is 1 clock cycle delayed of the pre-trigger pulse. Each timer channel start, reload and restart can be controlled via control bits. The timer can be configured to always decrement from a programmed start value, or decrement on selected trigger inputs or previous channel timeout (when channels are chained). By chaining timer channels, applications can achieve larger timeout durations.
- **In capture mode:** the timer can be used to perform measurements as the timer value is captured (in the timer value register) when a selected trigger input is asserted. The timer can support once-off or multiple measurements (like frequency measurements).

The timer channels operate on an asynchronous clock, which is independent from the register read/write access clock. Clock synchronization between the clock domains ensures normal operations.

63.2.2 Block Diagram

The next figure shows a detailed block diagram for an LPIT module. The programming model comprises of a global register set (common to all timer channels), and registers for each timer channel (that control their respective timer channels). Access to these registers gets synchronized to the asynchronous peripheral clock, then affects the timer channel registers.

- Each timer channel contains a 32-bit counter that loads the starting value and down counts on every peripheral clock's positive edge.
- After reaching a zero value (a channel timer timeout), a trigger output is generated.
- The counter enable is controlled using a timer enable register control bit, external or internal triggers or via previous channel timeout (when using timer chaining).
- After a channel timer timeout, an interrupt bit is also set, to tell the CPU about the timer timeout.

For more details, see the functional description section.

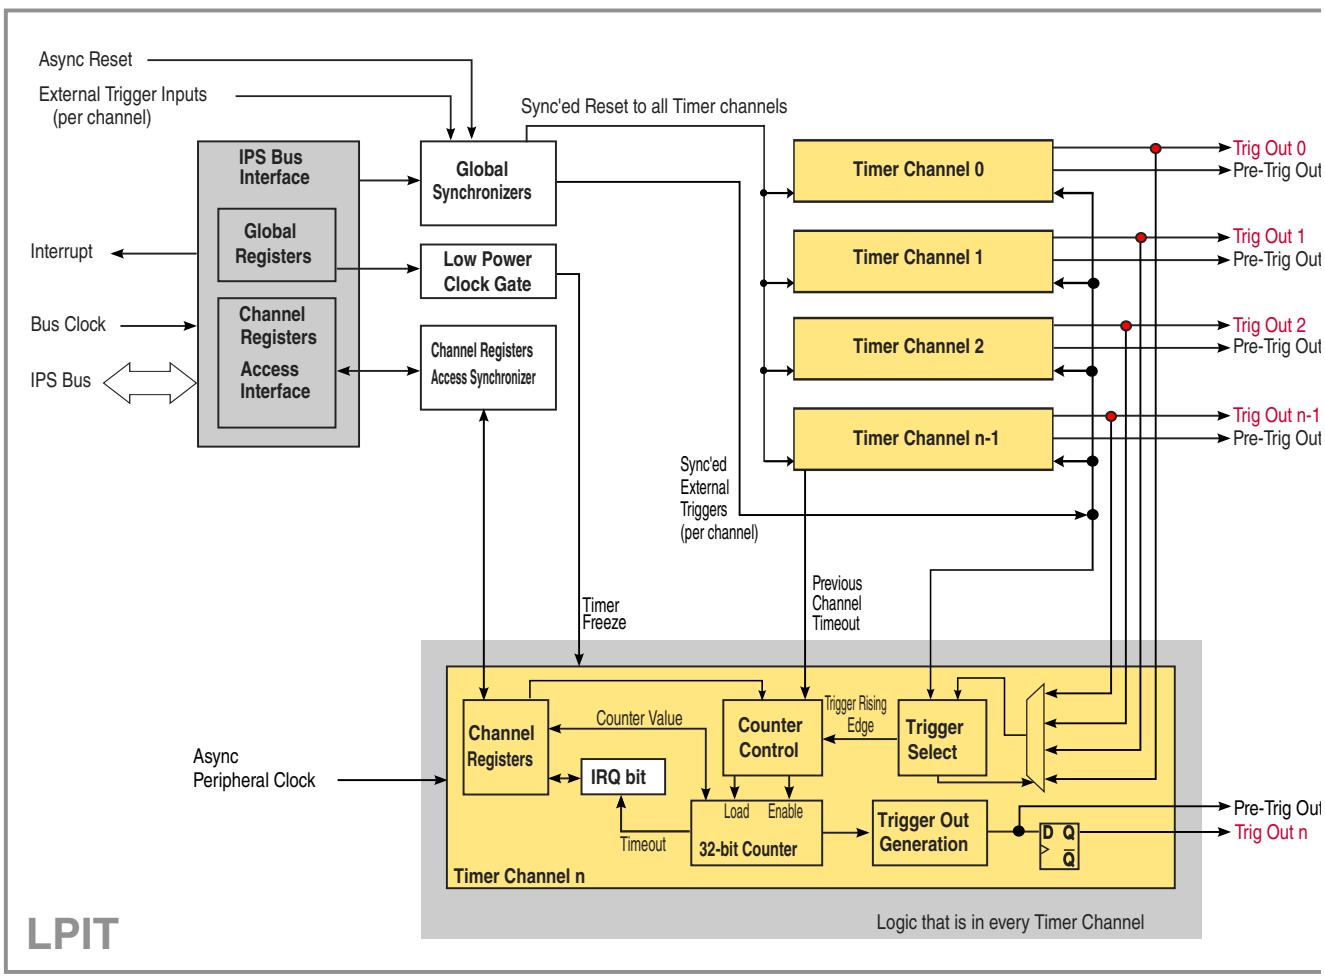

Figure 63-2. Detailed Block Diagram

63.3 Modes of operation

The LPIT module supports the following chip modes.

Table 63-3. Chip modes supported by the LPIT module

Chip mode	LPIT Operation
Run	Normal operation
Stop/Wait	Can continue operating, if the Doze Enable bit (MCR[DOZE_EN]) is set and the LPIT is using an external or internal clock source that remains operating during stop/wait modes.
Low Power Stop (also called Low Leakage Stop or LLS)	The Doze Enable (MCR[DOZE_EN]) bit is ignored and the LPIT will be disabled for the duration of low power mode.
Debug	Can continue operating provided the Debug Enable bit (MCR[DBG_EN]) is set.

63.4 Memory Map and Registers

63.4.1 LPIT register descriptions

The memory map comprises of 32-bit aligned registers, which can be accessed via 8-bit, 16-bit, or 32-bit accesses.

- Write access to reserved locations will generate a transfer error.
- Read access to reserved locations will also generate a transfer error, and the read data bus will show all 0s.

NOTE

- The Memory Map and complete module is in Big Endian format.
- The LPIT module will not check if programmed values in the registers are correct; software must ensure that correct programmed values are being written.

3	Debug Enable Bit

Table continues on the next page...

Field	Function
DBG_EN	Stops the timer channels when the device enters Debug mode 0b - Stop timer channels in Debug mode 1b - Allow timer channels to continue to run in Debug mode
2 DOZE_EN	DOZE Mode Enable Bit Stops the timer channels when the device enters DOZE mode 0b - Stop timer channels in DOZE mode 1b - Allow timer channels to continue to run in DOZE mode
1 SW_RST	Software Reset Bit Resets all channels and registers, except the Module Control Register. The Software Reset bit remains set until cleared by software. **NOTE:** Before clearing the Software Reset bit, software must wait for 4 peripheral clocks (for clock synchronization and reset propagation). 0b - Timer channels and registers are not reset 1b - Reset timer channels and registers

0
M_CEN
	Module Clock Enable
	Enables the peripheral clock to the module timers.
	• The Module Clock Enable bit must be asserted when accessing these registers:
	  • Module Status Register (MSR)
	  • Set Timer Enable Register (SETTEN)
	  • Clear Timer Enable Register (CLRTEN)
	  • Timer Value Registers (TVAL*n*)
	  • Current Timer Value Registers (CVAL*n*)
	  • Timer Control Registers (TCTRL*n*)
	• Both the bus clock and peripheral clock must be enabled to allow for clock synchronization and updating the above registers.
	• Acessing the above mentioned registers while the Module Clock Enable bit (M_CEN) = '0', will assert a transfer error for that bus cycle.
	• Writing to Current Timer Value (CVAL*n*) registers and Reserved registers will always generate a transfer error.
	NOTE: There may be additional clock gating bits in your device that gate the peripheral clock to the LPIT module. Ensure that those additional clock gating bits are configured appropriately, to enable the peripheral clock to the LPIT module.
	0b - Disable peripheral clock to timers
	1b - Enable peripheral clock to timers

Field	Function
3 TIE3	Channel 3 Timer Interrupt Enable Enables interrupt generation when: • the Channel 3 Timer Interrupt Enable bit (TIE3) is set to 1 • and if the corresponding Timer Interrupt Flag (MSR[TIF3]) is asserted (=1, timeout has occurred) 0b - Disabled 1b - Enabled
2 TIE2	Channel 2 Timer Interrupt Enable Enables interrupt generation when: • the Channel 2 Timer Interrupt Enable bit (TIE2) is set to 1 • and if the corresponding Timer Interrupt Flag (MSR[TIF2]) is asserted (=1, timeout has occurred) 0b - Disabled 1b - Enabled
1 TIE1	Channel 1 Timer Interrupt Enable Enables interrupt generation when: • the Channel 1 Timer Interrupt Enable bit (TIE1) is set to 1 • and if the corresponding Timer Interrupt Flag (MSR[TIF1]) is asserted (=1, timeout has occurred) 0b - Disabled 1b - Enabled
0 TIE0	Channel 0 Timer Interrupt Enable Enables interrupt generation when: • the Channel 0 Timer Interrupt Enable bit (TIE0) is set to 1 • and if the corresponding Timer Interrupt Flag (MSR[TIF0]) is asserted (=1, timeout has occurred) 0b - Disabled 1b - Enabled

63.4.1.7 Set Timer Enable Register (SETTEN)

63.4.1.7.1 Offset

Register	Offset
SETTEN	14h

63.4.1.7.2 Function

The Set Timer Enable register allows the simultaneous enabling of timer channels.

- Timer channels can be enabled by
  - either by writing '1' to Timer Enable bit (T_EN) in the respective TCTRLn register,
  - or by setting the corresponding Set Timer Enable bit (SET_T_EN_*n*) in the Set Timer Enable register (SETTEN).

- To disable timer channels simultaneously, use the Clear Timer Enable register (CLRTEN).
- Writing a '0' to the Set Timer Enable register has no effect.

NOTE

Unless the Module Clock Enable bit (MCR[M_CEN]) is set (=1, peripheral clock to timers is enabled)), reading or writing the Set Timer Enable register will generate a transfer error.

31-4 —	This read-only field is reserved and always has the value 0
3 CLR_T_EN_3	Clear Timer 3 Enable • To disable timer channel 3, write '1' to Clear Timer 3 Enable bit. • The Clear Timer 3 Enable bit can be used in addition to Timer Enable bit (T_EN) in TCTRL3 register. • Writing a 1 to Clear Timer 3 Enable bit will not enable the counter. • The Clear Timer 3 Enable bit is self-clearing, which means that the Clear Timer 3 Enable bit will always read 0. 0b - No Action 1b - Clear the Timer Enable bit (TCTRL3[T_EN]) for Timer Channel 3
2 CLR_T_EN_2	Clear Timer 2 Enable • To disable timer channel 2, write '1' to Clear Timer 2 Enable bit. • The Clear Timer 2 Enable bit can be used in addition to Timer Enable bit (T_EN) in TCTRL2 register. • Writing a 1 to Clear Timer 2 Enable bit will not enable the counter. • The Clear Timer 2 Enable bit is self-clearing, which means that the Clear Timer 2 Enable bit will always read 0. 0b - No Action 1b - Clear the Timer Enable bit (TCTRL2[T_EN]) for Timer Channel 2
1 CLR_T_EN_1	Clear Timer 1 Enable • To disable timer channel 1, write '1' to Clear Timer 1 Enable bit. • The Clear Timer 1 Enable bit can be used in addition to Timer Enable bit (T_EN) in TCTRL1 register. • Writing a 1 to Clear Timer 1 Enable bit will not enable the counter. • The Clear Timer 1 Enable bit is self-clearing, which means that the Clear Timer 1 Enable bit will always read 0.

Table continues on the next page...

Field	Function
	0b - No Action 1b - Clear the Timer Enable bit (TCTRL1[T_EN]) for Timer Channel 1
0 CLR_T_EN_0	Clear Timer 0 Enable • To disable timer channel 0, write '1' to Clear Timer 0 Enable bit. • The Clear Timer 0 Enable bit can be used in addition to Timer Enable bit (T_EN) in TCTRL0 register. • Writing a 1 to Clear Timer 0 Enable bit will not enable the counter. • The Clear Timer 0 Enable bit is self-clearing, which means that the Clear Timer 0 Enable bit will always read 0. 0b - No action 1b - Clear the Timer Enable bit (TCTRL0[T_EN]) for Timer Channel 0

63.4.1.9 Timer Value Register (TVAL0 - TVAL3)

63.4.1.9.1 Offset

Register	Offset
TVAL0	20h
TVAL1	30h
TVAL2	40h
TVAL3	50h

63.4.1.9.2 Function

- In compare modes: the Timer Value Registers (TVAL*n*) select the timeout period for the timer channels.
- In capture modes: the Timer Value Registers (TVAL*n*) are loaded with the value of the counter when the trigger asserts.

NOTE

Unless the Module Clock Enable bit (MCR[M_CEN]) is set (=1, peripheral clock to timers is enabled), then reading or writing the TVALn register will generate a transfer error.

63.4.1.9.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

63.4.1.9.4 Fields

Field	Function

31-0
TMR_VAL
	Timer Value
	• In compare mode: Timer Value (TMR_VAL) is the timer channel start value.
	  • The timer will count down until the timer reaches 0, then the timer will generate an interrupt and load the Timer Value register (TVAL*n*) value again.
	  • Writing a new value to the Timer Value register (TVAL*n*) will not restart the timer channel; instead the new value will be loaded *after the timer expires*.
	  • To abort the current timer cycle and start a timer period with a new value, the timer channel must be disabled and enabled *again*.
	• In capture mode: whenever the trigger asserts, the Timer Value register stores the inverse of the counter value.
	
	00000000000000000000000000000000b - Invalid load value in compare mode
	00000000000000000000000000000001b - Invalid load value in compare mode
	00000000000000000000000000000010-11111111111111111111111111111111b - In compare mode: the value to be loaded; in capture mode, the value of the timer

63.4.1.10 Current Timer Value (CVAL0 - CVAL3)

63.4.1.10.1 Offset

Register	Offset
CVAL0	24h
CVAL1	34h
CVAL2	44h
CVAL3	54h

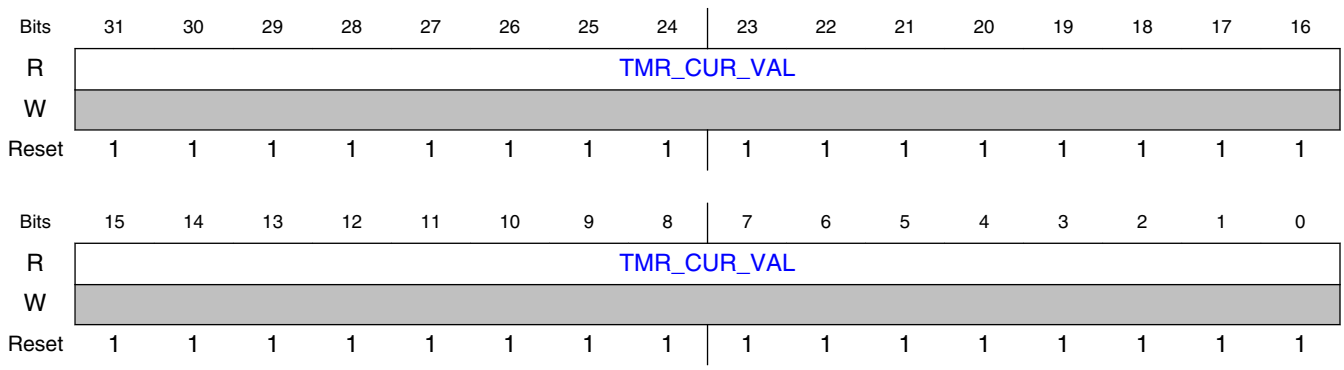
63.4.1.10.2 Function

The Current Timer Value registers indicate the current timer counter value.

NOTE

While the timer is running, CVALn register reads may not return the real value. If the timer value needs to be read, read it during an LPIT interrupt service routine.

63.4.1.10.3 Diagram



63.4.1.10.4 Fields

Field	Function
31-0 TMR_CUR_VAL	Current Timer Value Represents the current timer value, if the timer is enabled.

63.4.1.11 Timer Control Register (TCTRL0 - TCTRL3)

63.4.1.11.1 Offset

Register	Offset
TCTRL0	28h
TCTRL1	38h
TCTRL2	48h
TCTRL3	58h

63.4.1.11.2 Function

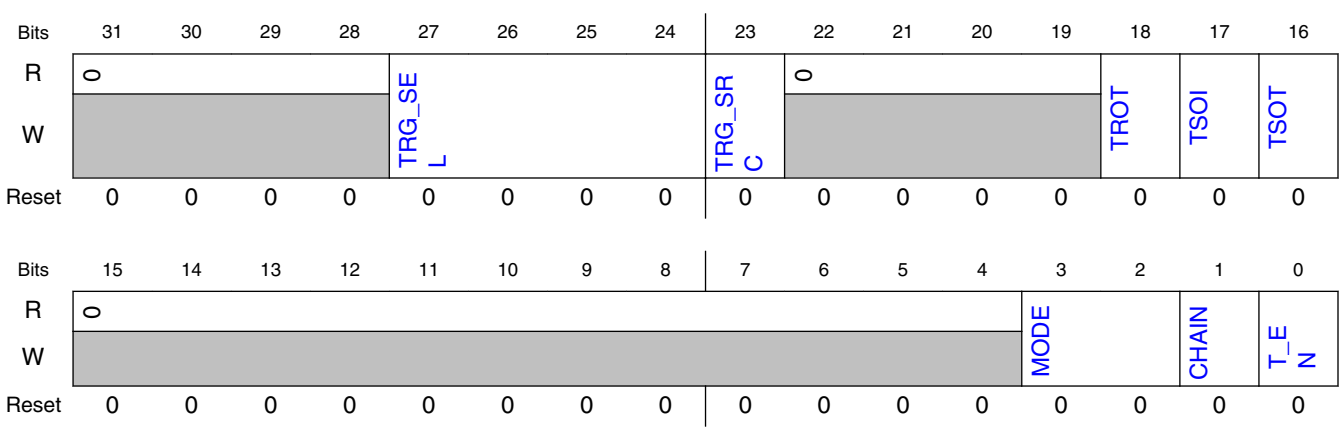
The Timer Control registers contain the control bits for each timer channel.

NOTE

- Unless the peripheral clock to the timers is enabled (Module Clock Enable bit (MCR[M_CEN]) is set (=1)), then reading or writing the Timer Control register will generate a transfer error.
- Timer controls should only be updated when the timer is disabled. In the Timer Control Register TCTRLn, these timer controls include:
  - Trigger Select TRG_SEL
  - Trigger Source TRG_SRC
  - Timer Reload On Trigger TROT
  - Timer Stop On Interrupt TSOI
  - Timer Start On Trigger TSOT
  - Timer Operation Mode MODE
  - Chain Channel CHAIN

  There are 2 ways to disable a timer: write 1 to the specific timer's Clear Timer Enable register bit (CLRTEN[CLR_T_EN_n]) or set the timer enable bit (TCTRLn[T_EN]) = 0 for that channel.

63.4.1.11.3 Diagram



63.4.1.11.4 Fields

Field	Function
31-28	This read-only field is reserved and always has the value 0

Table continues on the next page...

Field	Function
—	
27-24 TRG_SEL	Trigger Select Selects the trigger to use for starting and/or reloading the LPIT timer. • The TRG_SEL field selects one trigger from the set of internal or external triggers that are selected by the Trigger Source bit (TRG_SRC) • Recall that the TRG_SRC bit selects between internal and external trigger signals for each channel **NOTE:** The Trigger Select field should only be changed when the LPIT timer channel is disabled. 0000-0011b - Timer channel 0 - 3 trigger source is selected 0100-1111b - Reserved
23 TRG_SRC	Trigger Source Selects between internal or external trigger sources. The trigger to be used is selected using the TRG_SRC and TRG_SEL bits. Refer to the chip configuration section for available external trigger options. If a channel does not have an associated external trigger, then set the Trigger Source bit (TRG_SRC) = 1. 0b - Selects external triggers 1b - Selects internal triggers
22-19 —	This read-only field is reserved and always has the value 0
18 TROT	Timer Reload On Trigger When set, the LPIT timer will reload when a rising edge is detected on the selected trigger input. The trigger input is ignored if the LPIT is disabled during debug mode (DBGEN = 0) or DOZE mode (DOZE_EN = 0) 0b - Timer will not reload on the selected trigger 1b - Timer will reload on the selected trigger
17 TSOI	Timer Stop On Interrupt Controls whether the channel timer will stop after it (the channel timer) times out or not. 0b - The channel timer does not stop after timeout 1b - The channel timer will stop after a timeout, and the channel timer will restart based on Timer Start On Trigger bit (TSOT). When TSOT = 0, the channel timer will restart after a rising edge on the Timer Enable bit (T_EN) is detected (which means that the timer channel is disabled and then enabled). When TSOT = 1, the channel timer will restart after a rising edge on the selected trigger is detected.
16 TSOT	Timer Start On Trigger Controls when the timer starts decrementing. 0b - Timer starts to decrement immediately based on the restart condition (controlled by the Timer Stop On Interrupt bit (TSOI)) 1b - Timer starts to decrement when a rising edge on a selected trigger is detected
15-4 —	This read-only field is reserved and always has the value 0
3-2 MODE	Timer Operation Mode Configures the channel timer's mode of operation. The MODE bits control how the timer decrements. 00b - 32-bit Periodic Counter 01b - Dual 16-bit Periodic Counter 10b - 32-bit Trigger Accumulator 11b - 32-bit Trigger Input Capture
1 CHAIN	Chain Channel

Table continues on the next page...

Field	Function
	When enabled, the timer channel will decrement when timer channel N-1 trigger asserts. Timer channel 0 cannot be chained. 0b - Channel Chaining is disabled. The channel timer runs independently. 1b - Channel Chaining is enabled. The timer decrements on the previous channel's timeout.
0 T_EN	Timer Enable Enables or disables the Timer Channel 0b - Timer Channel is disabled 1b - Timer Channel is enabled

63.5 Functional description

63.5.1 LPIT programming model

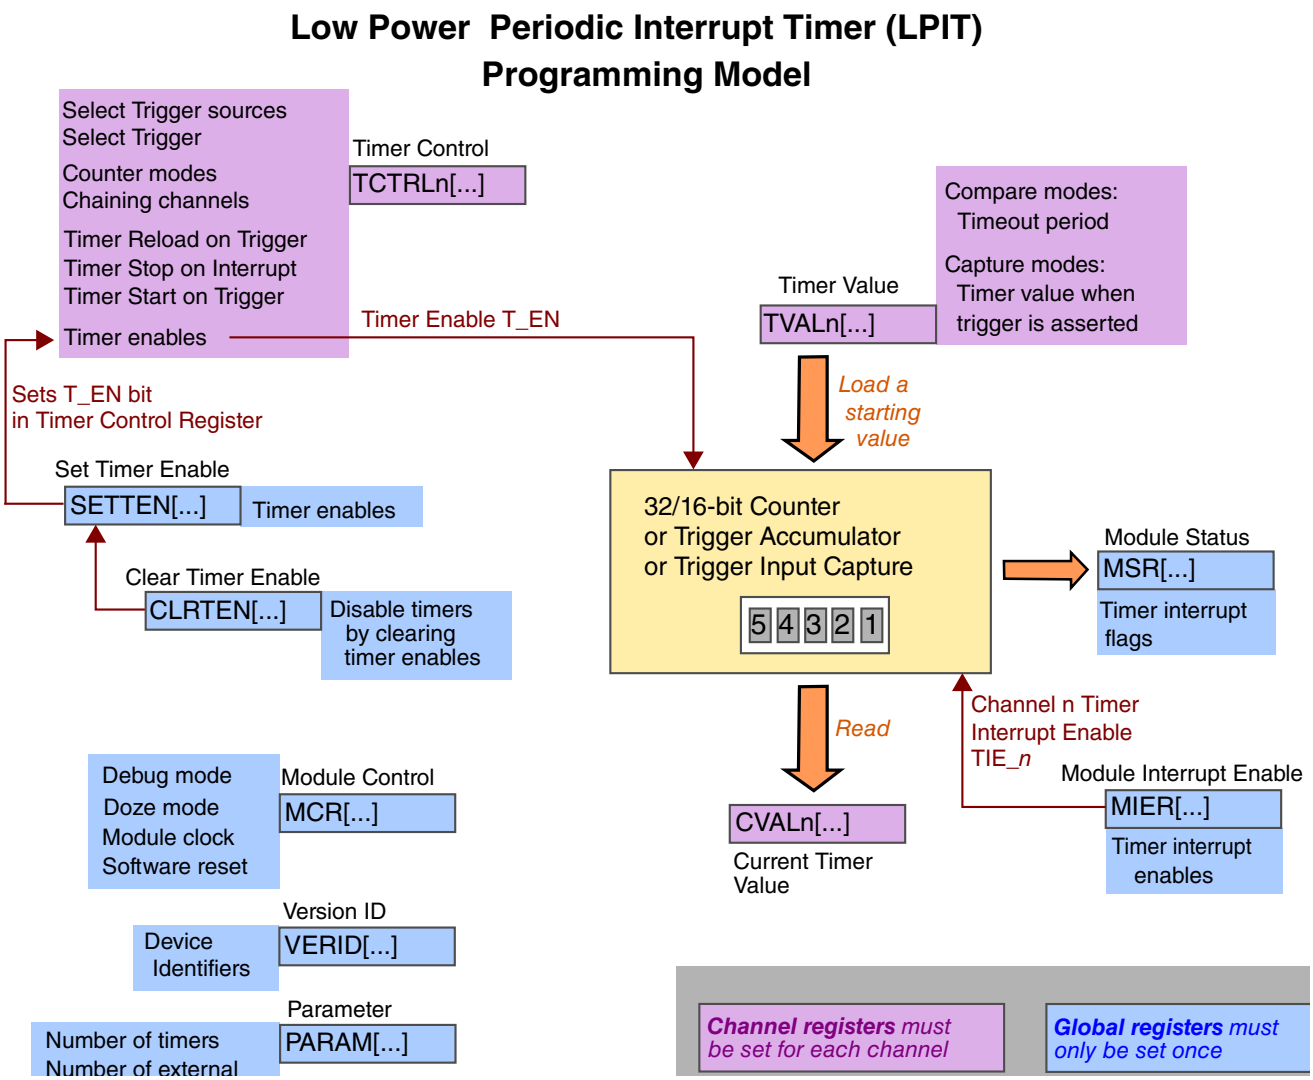


Figure 63-3. Programming Model

Global registers need only be set once:

- Version ID Register (VERID)
- Parameter Register (PARAM)
- Module Control Register (MCR)
- Module Status Register (MSR)
- Module Interrupt Enable Register (MIER)
- Set Timer Enable Register (SETTEN)
- Clear Timer Enable Register (CLRTEN)

Channel registers must be set for each channel:

- Timer Value Register (TVAL0 - TVAL3)

- Current Timer Value (CVAL0 - CVAL3)
- Timer Control Register (TCTRL0 - TCTRL3)

63.5.2 Initialization

Table 63-4. Initializing the LPIT module

Step		How? Why?
1	Enable the peripheral clock	by setting the Module Clock Enable bit (M_CEN) in the Module Control Register (MCR) register. **NOTE:** • Acessing certain registers (MSR, SETTEN, CLRTEN, TVAL, CVAL, and TCTRL) while M_CEN = 0 will lead to assertion of a transfer error for that bus access. • Writing to CVAL and Reserved registers will generate a transfer error. • There might be additional clock gating bits in the device that gate the peripheral clock to this module. When enabling the clock to this module, ensure that software is configuring those additional clock gating bits (in addition to M_CEN bit).
2	Wait for 4 peripheral clock cycles	to allow time for clock synchronization and reset de-assertion.
3	Configure timer control bits	for each timer channel that is to be enabled: • timer mode of operation bits TCTRLn[MODE] • trigger source selection bits TCTRLn[TRG_SEL, TRG_SRC] • trigger control bits TCTRLn[TROT, TSOT, TSOI] **NOTE:** Timer controls should only be updated when the timer is disabled. There are 2 ways to disable a timer: write 1 to the specific timer's Clear Timer Enable register bit (CLRTEN[CLR_T_EN_n]) or set the timer enable bit (TCTRLn[T_EN]) = 0 for that channel.
4	Configure the channels that are to be chained	by setting the CHAIN bit in the corresponding channel's TCTRLn register.
5	Set the timer timeout value	for channels configured in Compare Mode, by programming the appropriate value in TVAL register for those channels.
6	Configure TIEn bits in MIER register	for those channels that are required to generate interrupts on timer timeouts.
7	Configure the low power modes of the module	by setting the DBG_EN and DOZE_EN bits in the MCR register. This is common to all timer channels.
8	Enable the channel timers	by setting the corresponding T_EN bit in the corresponding channel's TCRTLn register.

Also:

- For channels configured in Capture Mode, the timer value can be read from TVALn register when a channel timeout occurs.
- At any time, the current value of the timer for any channel can be read by reading the corresponding channel's CVALn register. The M_CEN bit must be '1' when doing so.
- The timer interrupt flag bits (TIFn) in MSR register get asserted on timer timeout. To clear these timer interrupt flag bits, write '1' to them.

63.5.3 Timer Modes

The timer mode is configured by setting an appropriate value in the MODE bits in TCTRLn register.

Table 63-5. Timer modes that are supported

Timer Mode	Operation
32-bit Periodic Counter	• The counter will load, decrement down to 0 • which will set the timer interrupt flag and assert the output pre-trigger.
Dual 16-bit Periodic Counter	• The counter will load, then the lower 16-bits will decrement down to 0 • which will assert the output pre-trigger. • The upper 16-bits will then decrement down to 0 • which will set the timer interrupt flag and then negate the output pre-trigger.
32-bit Trigger Accumulator	• The counter will load on the 1st trigger rising edge and then decrement down to 0 on each trigger rising edge • which will set the timer interrupt flag and assert the output pre-trigger.

32-bit Trigger Input Capture	• The counter will load with 0xFFFF_FFFF and then decrement down to 0.
	• If a trigger rising edge is detected,
	  • then it will store the inverse of the current counter value in the timer value register
	  • which will set the timer interrupt flag and assert the output pre-trigger.

The timer operation is controlled by Trigger Control bits (TSOT, TSOI, TROT) which control the timer load, reload, start and restart of the timers.

NOTE

- The trigger output is asserted one Peripheral Timer Clock cycle later than pre-trigger output. The trigger output and the pre-trigger output de-assert at the same time.
- The pre-trigger output is asserted for 2 clock cycles and the trigger output is asserted for 1 clock cycle (except in 16-bit Periodic Counter mode, where both pre-trigger and trigger are asserted for many cycles depending on TMR_VAL[31:16]).
- Timer changes *that are based on external triggers* take effect after 4 peripheral clocks after the actual external trigger assertion (due to clock synchronization, rise edge detection and timer update).

63.5.4 Trigger Control for Timers

Various programmable bits control how the trigger inputs and the timer operate. TRG_SEL and TRG_SRC select the timer triggers:

- Trigger Select (TRG_SEL) selects the input trigger for the channel from all of the other channel's trigger outputs.
- Trigger Source (TRG_SRC) selects between the internal trigger and the external trigger inputs to the channel.

The selected trigger affects how the timer operates, using the configuration of the TROT, TSOI and TSOT bits.

Table 63-6. How bits control timer operations

If	=	Then
TSOI *Timer Stop On Interrupt*	1	then the counter stops on a Timer Interrupt flag (MSR[TIFn]) assertion. To reload and decrement, it requires: • a trigger (if TSOT = 1) • a T_EN rising edge (if TSOT = 0)
	0	then the counter does not stop after timeout
TROT *Timer Reload On Trigger*	1	then the counter is loaded on each trigger
	0	then the counter is loaded on every T_EN rising edge or timeout rising edge (timeout not used in Capture modes)
TSOT *Timer Start On Trigger*	1	then the counter will start to decrement on a trigger. Subsequent triggers are ignored until the counter times out.
	0	then the counter decrements immediately on the next clock edge. When channel is Chained or in Capture mode, TSOT has no effect.

In different timer modes, these programmable bits affect the timer operation differently:

Table 63-7. Time modes and programmable bits

Mode	Which programmable bits affect timer operations
32-bit Periodic Counter	All bits (TSOT, TSOI, TROT) affect the timer operation as described previously.
Dual 16-bit Periodic Counter	
32-bit Trigger Accumulator	• Only the TSOI bit controls the timer function. • TROT and TSOT bits have no effect on timer operations.
32-bit Input Trigger Capture	• Only TSOI and TROT bits control the timer function. • TSOT bit has no effect on timer operations.

63.5.5 Channel Chaining

Individual timer channels can be chained together to achieve a larger value of timeout. Chaining the timer channel causes them to work in a *'nested loop'* manner thereby leading to an effective timeout value of $TVAL_{CHn} \times (TVAL_{CHn-1} + 1)$.

The channels are chained by setting the CHAIN bit in corresponding channel's $TCTRL_{CHn}$ register. When a channel is chained, that channel's timer decrements on previous channel's timeout pulse, regardless of the timer mode (MODE bits). The TSOT bit does not have any effect if the channel timer (Channel 'n') is chained to previous channel's timer (Channel 'n-1').

63.5.6 Detailed timing

NOTE

The timing diagrams in these sections are not *cycle-accurate* (i.e., some cycles may not be shown), but the timing diagrams do show the timer channel behavior across several clock cycles.

Table 63-8. Timing diagrams list

Mode		Timing Diagram	TSOT	TROT	TSOI	CHAIN

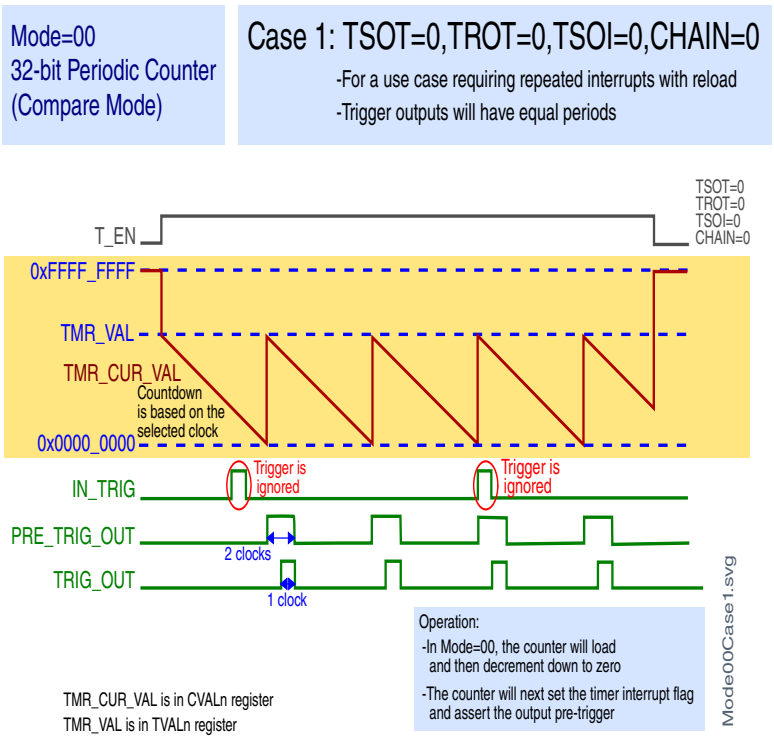

Figure 63-4. Case 1: TSOT = 0, TROT = 0, TSOI = 0, CHAIN = 0

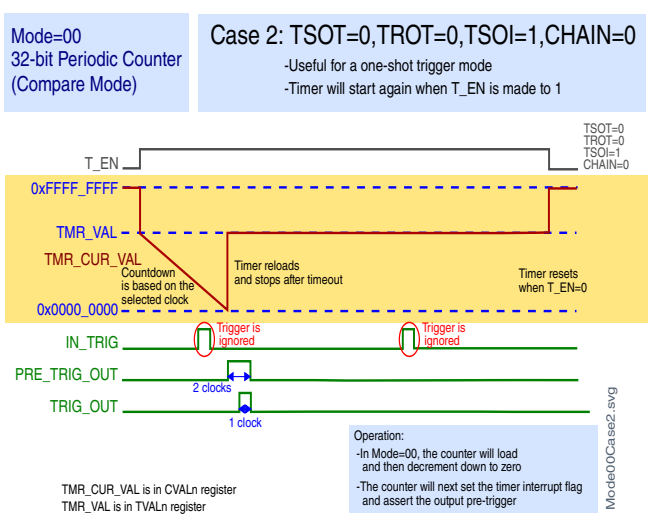

Figure 63-5. Case 2: TSOT = 0, TROT = 0, TSOI = 1, CHAIN = 0

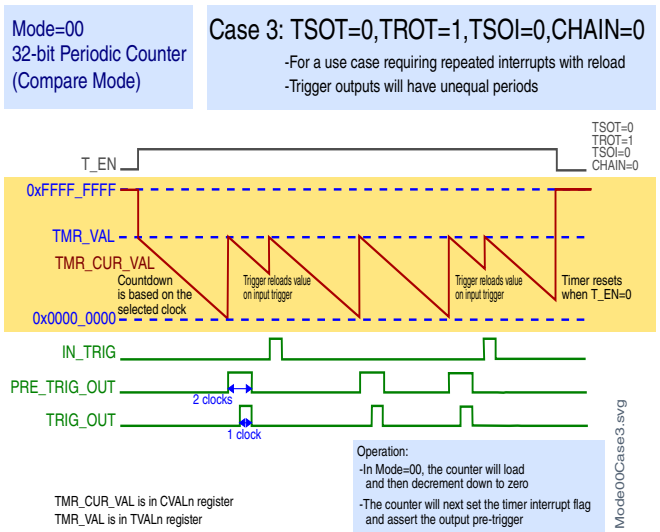

Figure 63-6. Case 3: TSOT = 0, TROT = 1, TSOI = 0, CHAIN = 0

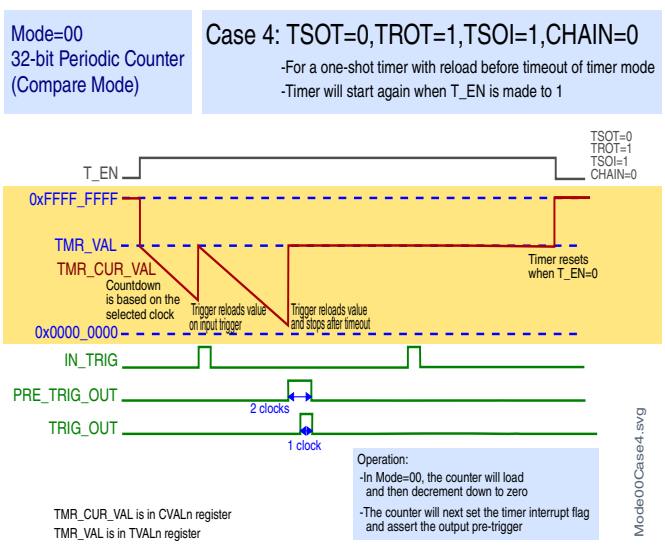

Figure 63-7. Case 4: TSOT = 0, TROT = 1, TSOI = 1, CHAIN = 0

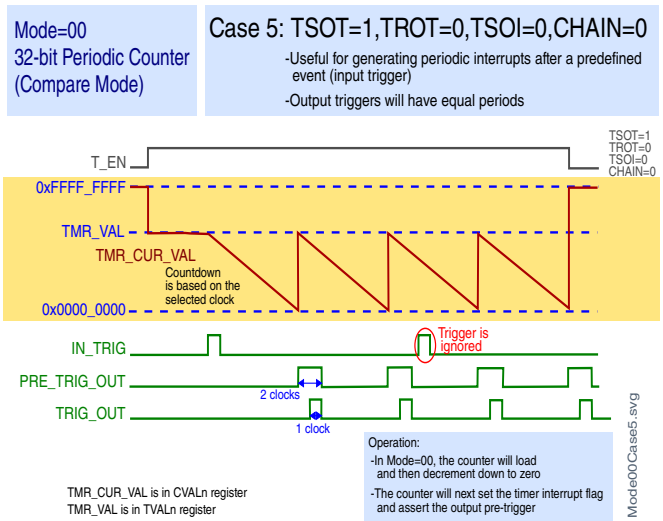

Figure 63-8. Case 5: TSOT = 1, TROT = 0, TSOI = 0, CHAIN = 0

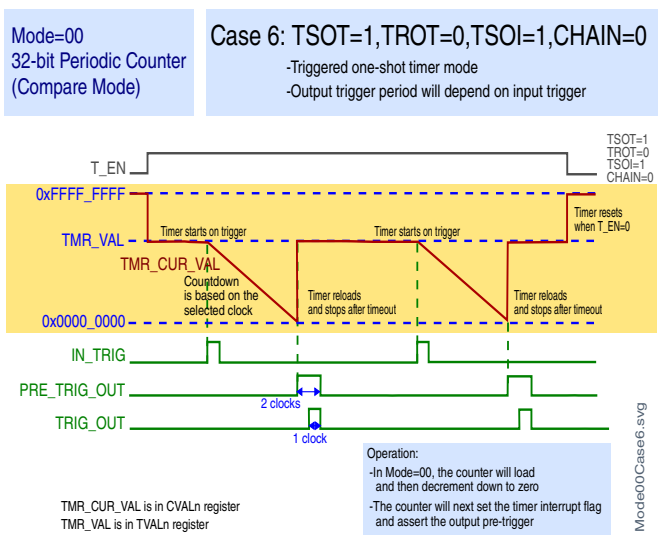

Figure 63-9. Case 6: TSOT = 1, TROT = 0, TSOI = 1, CHAIN = 0

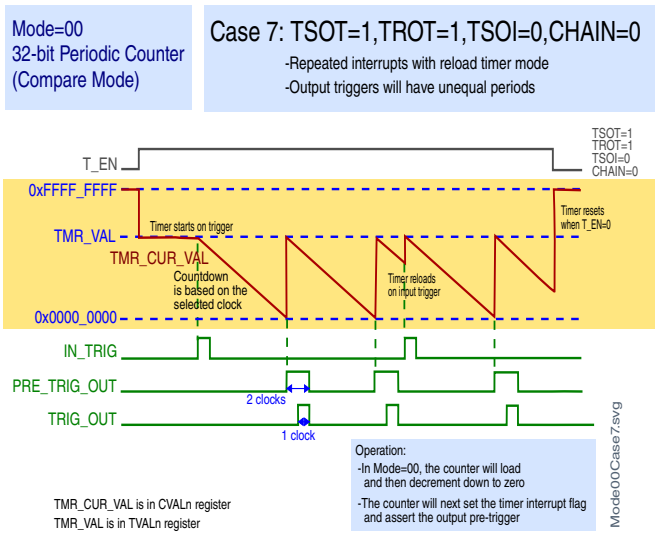

Figure 63-10. Case 7: TSOT = 1, TROT = 1, TSOI = 0, CHAIN = 0

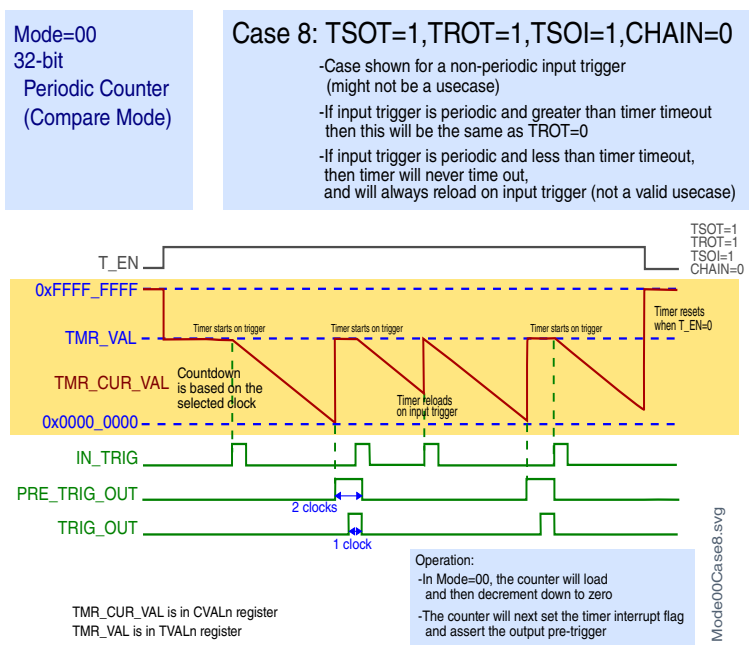

Figure 63-11. Case 8: TSOT = 1, TROT = 1, TSOI = 1, CHAIN = 0

63.5.6.2 Mode=01: 16-bit dual periodic counter (compare mode)

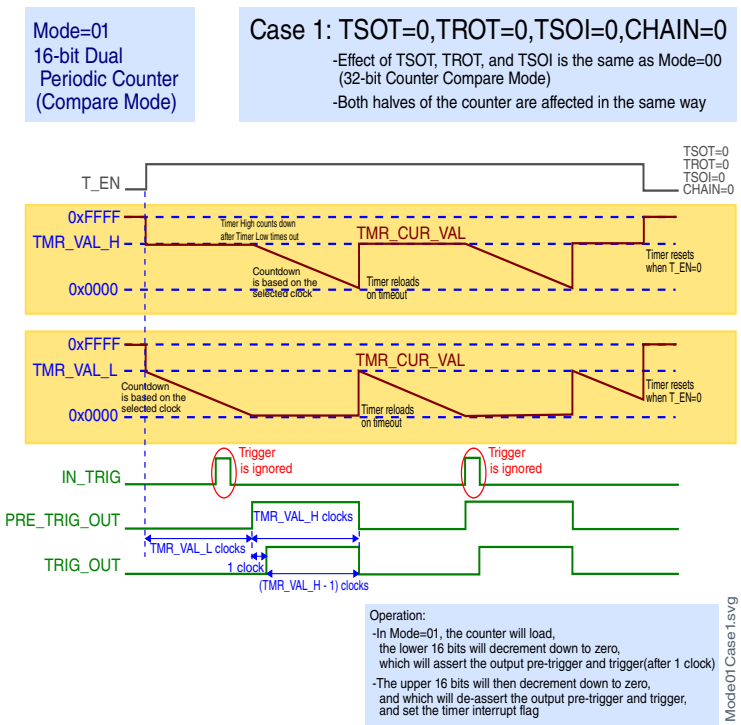

Figure 63-12. Case 1: TSOT = 0, TROT = 0, TSOI = 0, CHAIN = 0

Effect of Timer Control Bits in Mode=01:

- Effect of timer control bits are the same as for Mode=00. Refer to the individual figures of Mode=00.
- The Timer Interrupt (timeout) asserts when {TMR_H,TMR_L} = 0x0000_0000.
- Behavior for Mode = 01 is explained in the next table.

Table 63-9. Mode=01 timer control bits

TSOT	TROT	TSOI	Function	Effect on Timer
0	0	0	• For repeated interrupts with reload • Trigger outputs will have equal periods	Similar to Figure 63-12.
0	0	1	One-shot mode	• Both timers stop after first count down and then time out • Timers will not count again until T_EN is made 1 again • Similar to Figure 63-5.
0	1	0	• For repeated interrupts with reload • Trigger outputs will have unequal periods	• Both timers will reload TMR_VAL on trigger rise edge • Output triggers will clear on reload, if asserted • Similar to Figure 63-6.

Table continues on the next page...

Table 63-9. Mode=01 timer control bits (continued)

TSOT	TROT	TSOI	Function	Effect on Timer
0	1	1	Reloadable one-shot mode	• If a trigger occurs before timeout, then both timers reload and count down (as shown); the timers stop after timeout • A trigger assertion after timeout simply reloads TMR_VAL into the timers • The timers will not count again until T_EN is set to 1 again • Similar to Figure 63-7.
1	0	0	• For generating periodic interrupts after a predefined event (input trigger) • Output triggers will have equal periods	After T_EN rises, the timers do not start until the first trigger's rising edge • Subsequent triggers will have no effect • Similar to Figure 63-8.
1	0	1	• Triggered one-shot timer mode • Output trigger period will depend on input trigger	After T_EN rises, the timers do not start until the first trigger's rising edge. • The timer stops counting after a timeout assertion (a timeout is asserted) • The timer does not start counting again until a new trigger's rising edge is detected • Similar to Figure 63-9.
1	1	0	• For repeated interrupts with reload timer mode • Output triggers will have unequal periods	After T_EN rises, the timers do not start until the first trigger's rising edge • Subsequent triggers will cause the timer to reload TMR_VAL into both counters • The output triggers will clear after a reload, if asserted • Similar to Figure 63-10.
1	1	1	• For a non-periodic input trigger • If input trigger is periodic and greater than timer timeout, then this will be the same as TROT=0 (which is triggered one-shot timer mode; output trigger period will depend on input trigger)	After T_EN rises, the timers do not start until the first trigger's rising edge • The timers stops counting after a timeout assertion (a timeout is asserted) • A trigger's rising edge will cause the timers to reload and then count down • Similar to Figure 63-11.

63.5.6.3 Mode=10: 32-bit trigger accumulator mode

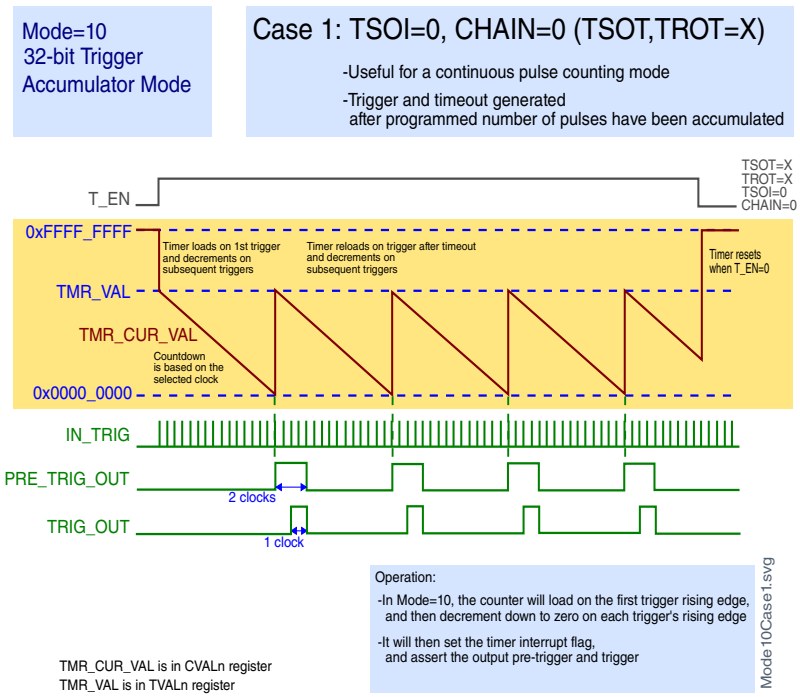

Figure 63-13. Case 1: TSOT = X, TROT = X, TSOI = 0, CHAIN = 0

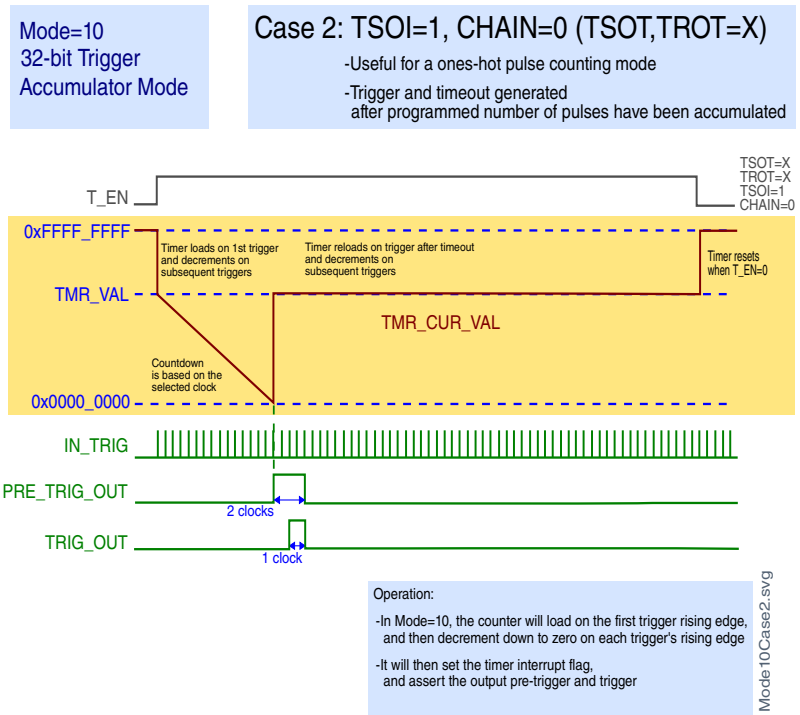

Figure 63-14. Case 2: TSOT = X, TROT = X, TSOI = 1, CHAIN = 0

63.5.6.4 Mode=11: 32-bit trigger capture mode

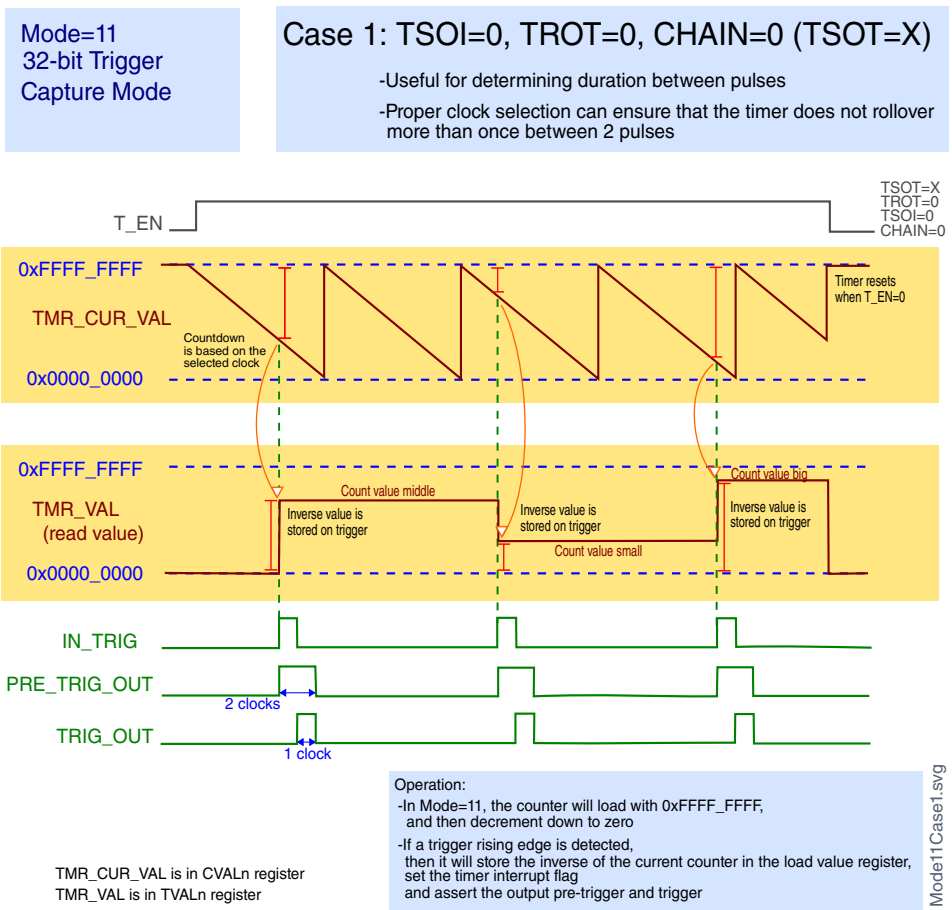

Figure 63-15. Case 1: TSOT = X, TROT = 0, TSOI = 0, CHAIN = 0

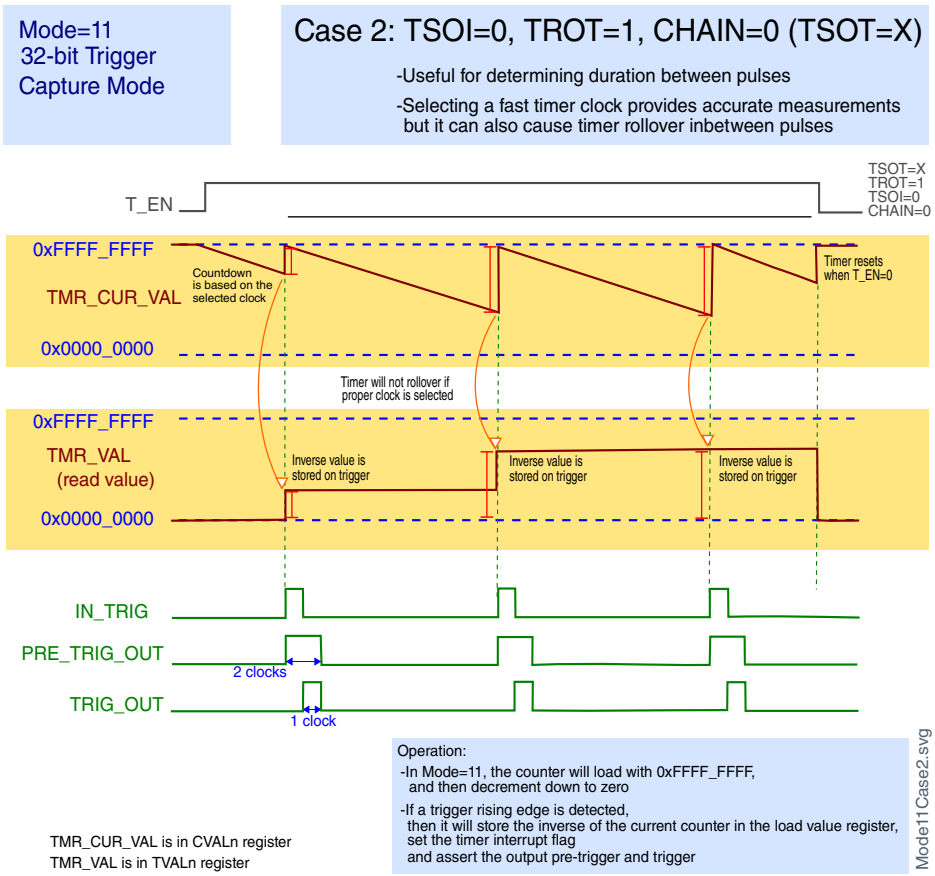

Figure 63-16. Case 2: TSOT = X, TROT = 1, TSOI = 0, CHAIN = 0

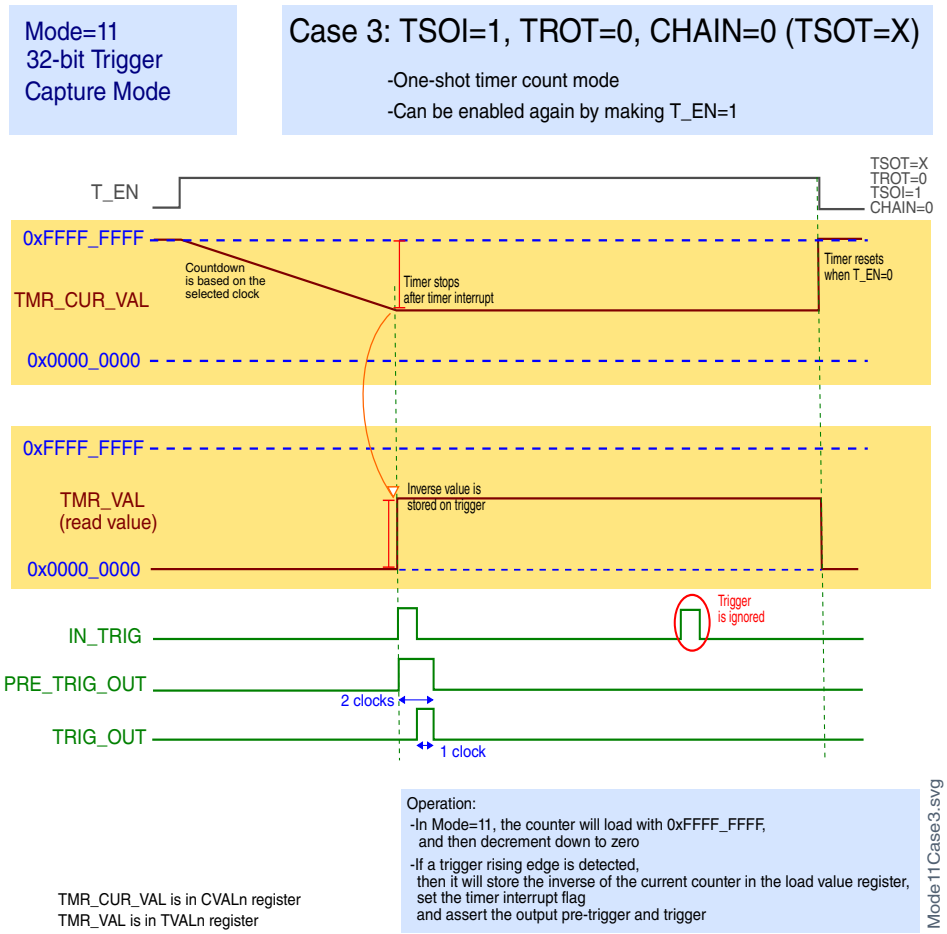

Figure 63-17. Case 3: TSOT = X, TROT = 0, TSOI = 1, CHAIN = 0

Case 4: TSOT = X, TROT = 1, TSOI = 1, CHAIN = 0

Same as previous case (Case 3), except that the timer reloads to 0xFFFF_FFFF and then stops. The timer does not start until T_EN is made 1 again. Case 4 is not a very useful case, because Case 3 covers this.

63.5.6.5 Timer chaining

Effect of Chaining	-Chaining causes Timer “n” to decrement on every timeout pulse (trigger output pulse) from Timer “n – 1”, regardless of what mode is configured in Timer “n” -Timers “n” and “n – 1” effectively form a larger width timer (64-bits) -More than 2 timer channels (or all timer channels) can be chained -It is preferred to have the same trigger source and timer controls configured for chained channels

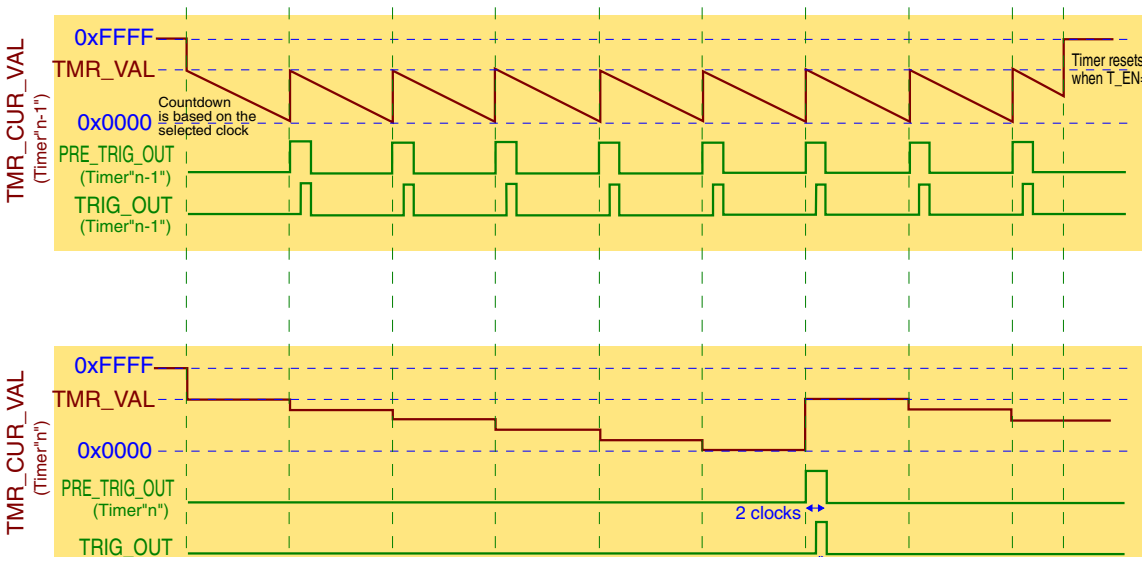

Figure 63-18. Chaining Effects

Signal multiplexing	Port control	Signal multiplexing

64.1.1 Secure Non-Volatile Storage (SNVS)

The SNVS module is designed to safely hold security-related data such as cryptographic key, time counter, monotonic counter, and general purpose security information. A part of the SNVS module belongs to the VBAT domain, that has its own dedicated power supply which is always on. This enables SNVS to keep this data valid and continue to increment the time counter when the power goes down in the rest of the device. The always-powered-up part of the module is isolated from the rest of the logic to ensure that it does not get corrupted when the device is powered down. The following table shows the configuration of the SNVS.

NOTE

The chapter may contain references to security-only topics. For complete SNVS chapter including security details, see the i.MX 7ULP Security Reference Manual

Table 64-2. SNVS configuration

Parameter	Description
Name	Secure Non-Volatile Storage (SNVS)
Instances	1
Features[1]	• Security state • Security violation inputs • Non-secure RTC • Clock monitor • Zeroizable master: 256-bit • General purpose register: 256-bit • Secure RTC • Secure Monotonic Counter • LP voltage monitor input • External tamper detect inputs: 1 • System power fail detector input • Power-on reset • Tamper input glitch filters
Interface speed	NA
External I/O pins	See the IOMUXC spreadsheet attached to i.MX 7ULPRM for pin details. SNVS/RTC Pins (MISC Pins Tab) and SEC_VIO_B Security Violation Input (IO Signal Table).

1. The complete chapter including all security features is available only in i.MX 7ULP Security Reference Manual

64.2 SNVS introduction

SNVS is a companion module to the CAAM module.

SNVS incorporates both security and non-security functionality. The SNVS non-security functionality is described in this document, but the SNVS security functionality is described only in the Security Reference Manual.

SNVS non-security functions:

- Realtime Counter (RTC) - a software accessible realtime counter
  - RTC can be set to the value in the SRTC
- Periodic Interrupt - a hardware-generated interrupt that occurs periodically at software-specified frequency
- General Purpose Register - a set of registers used to hold 256 bits of data specified by software

  - If the SNVS_LP power input is connected to an uninterrupted power supply, e.g. a coin cell battery, the GPR value is maintained when main SoC is powered off
- Chip power-on/power-off - If the SNVS_LP power input is connected to an uninterrupted power supply and the Power On button input signal is connected to a power button external to the chip, logic within SNVS_LP can be used to wake the chip from a power down.

64.2.1 SNVS feature list

The following table summarizes the features of SNVS:

Table 64-3. SNVS feature list

Feature	Description	Links for Further Information
Real time counter (RTC)	• The RTC is driven by a dedicated clock, which is off when the system power is down. • Programmable time alarm interrupt • Periodic interrupt can be generated with software-selected frequency.	SNVS_HP Real Time Counter
General-purpose register	• The general-purpose register is available to software to store 256 bits of data. • The general-purpose register is zeroized when a security violation is detected. • If the SNVS_LP power input is connected to an uninterrupted power supply (see SNVS power domains), the general-purpose register value is retained even if the main chip is powered down.	Using the General-Purpose Register
Register access restrictions	• Some registers/values can be written only once per boot cycle.	privileged and non-privileged registers
Wakeup from power off	• Input signal from off chip requests SNVS_LP to power on the main SoC (Assuming that the SNVS_LP power input is connected to an uninterrupted power supply (see SNVS power domains). • Hardware debounces the input signal using software-specified signal bounce characteristics	LP Wake-Up Interrupt Enable

64.2.2 SNVS functional description

SNVS implements several non-security features that involve software interaction:

- reading or writing the Realtime Counter (RTC) (This is a non-privileged operation.) - software can also instruct SNVS to load the current SRTC value into the RTC
- reading or writing the General Purpose Register (GPR) (Note that there may be a significant delay when reading or writing registers in the LP section if the LP clock is different from the HP clock.)

The following sections describe in more detail the operation of SNVS.

64.3 SNVS Structure

SNVS is organized as two major sub-modules:

- Low-Power Section of SNVS (SNVS_LP)

  The SNVS_LP section provides hardware that enables secure storage and protection of sensitive data. The SNVS module is designed to safely hold security-related data such as cryptographic key, time counter, monotonic counter, and general purpose security information.

  The SNVS_LP block implements the following functional units:
  - Control and Status Registers
  - General Purpose Registers

  When the LP section is powered by a backup battery the state of these registers is maintained even when the main chip power is off. (see SNVS power domains)

- High-Power Section of SNVS (SNVS_HP)

  The SNVS_HP section contains all SNVS status and configuration registers. It implements all features that enable system communication and provisioning of the SNVS_LP section.

  The SNVS_HP provides an interface between SNVS_LP and the rest of the system.

  The SNVS_HP block implements the following functional units:
  - IP Bus Interface
  - SNVS_LP Interface
  - Zeroizable Master Key Programming Mechanism
  - Real Time Counter with Alarm Control and Status Registers
  - Control and status registers

  SNVS_HP is in the chip's power supply domain and thus receives power along with the rest of the chip.

The following figure illustrates the structure of SNVS.

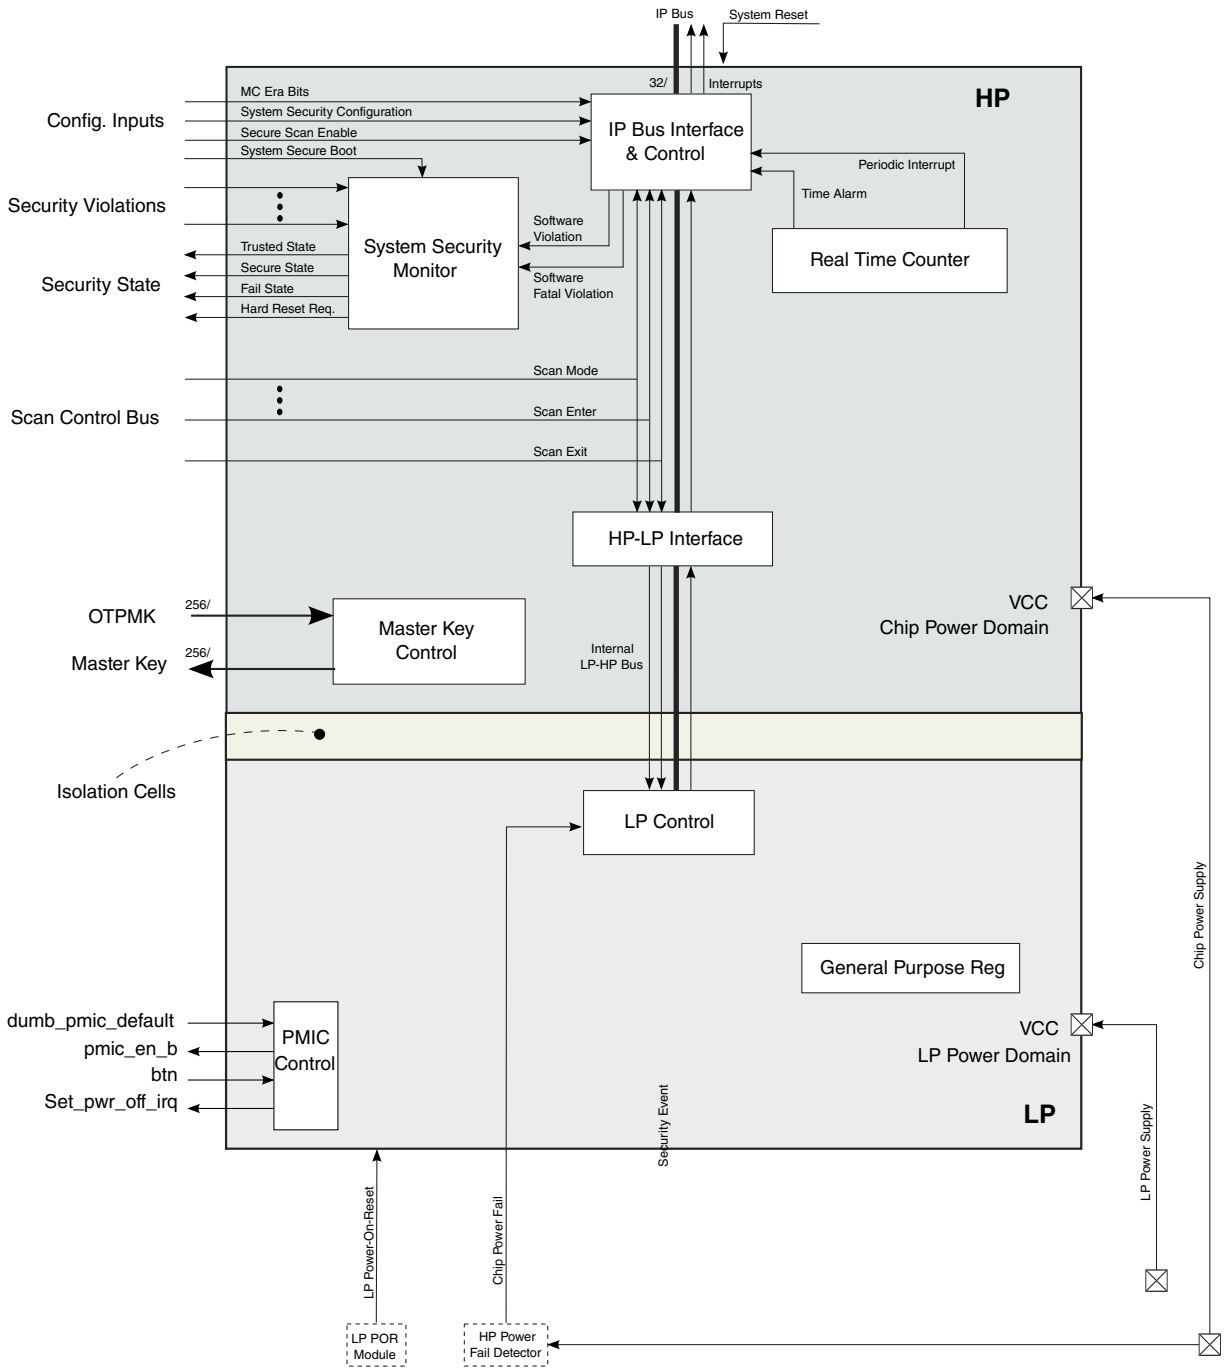

Figure 64-1. SNVS Block Diagram

64.3.1 SNVS power domains

In some versions of SNVS (including this version), the LP (Low Power) section is implemented in an independent power domain from the HP (High Power) section, and most other logic on the chip. Throughout the SNVS documentation whenever mention is

made of "always-on" logic, this assumes a version of SNVS that implements an independent power domain for the LP section, and that the power for this section is supplied by an uninterrupted power supply. The purpose for the independent power domain is so that data can be retained and certain logic can remain functional even when the main chip logic is powered down. But this is possible only if the LP domain remains powered via an uninterrupted power supply when the main chip power domain is powered off. Usually this uninterrupted power supply would be a coin-cell battery, with possibly some power management logic to power the LP section from main power (and perhaps recharge the coin cell battery) when main power is on, and switch to coin-cell power when the main power is off. In versions of SNVS with an independent LP power domain the LP section can be electrically isolated from the rest of the chip logic to ensure that its logic does not get corrupted when the main chip is powered down. If the battery runs down or is removed, an LP POR will occur when the LP section next powers up. Note that some OEMs may choose to connect LP power to HP/main chip power and dispense with a coin cell battery. In that case the SNVS will operate the same as an SNVS without an independent LP power domain. No state will be retained in the LP section when the chip is powered down, and an LP POR will occur whenever there is an HP POR.

64.3.2 Power glitch detector (PGD)

SNVS_LP incorporates a mechanism to detect glitches on the SNVS_LP power supply that might cause the LP control, status, and secure counter values to change. The mechanism works as follows:

1. The PGD register (LPPGDR) is loaded with the known specific value 4173_6166h as part of the SNVS initialization process.
2. Subsequently, this register's value is continuously compared to the hardwired value 4173_6166h.
3. If the comparison indicates that any bit has changed, a power glitch violation is asserted.

Power glitch detection is always enabled and cannot be disabled. At LP POR this register is reset to all 0's, so the hardwired comparison fails and a power glitch violation is reported. Therefore, before programming any feature in the SNVS the power glitch violation should be cleared. The initialization software should write the proper value (4173_6166h) into LPPGDR (see SNVS_LP Power Glitch Detector Register (LPPGDR)) and should then clear the power glitch record in the LP status register (see SNVS_LP Status Register (LPSR)).

The following figure shows the PGD mechanism.

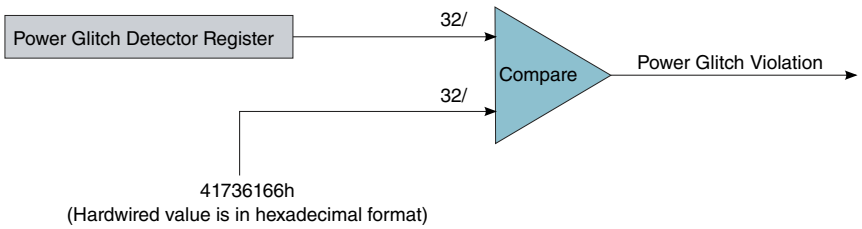

Figure 64-2. Power glitch detector

64.3.3 SNVS clock sources

The SNVS has the following clock sources:

- System peripheral clock input. This clock is used by the SNVS's internal logic, for example, the Security State Machine. This clock can be gated outside of the module when the SNVS indicates that it is not in use.
- HP RTC clock. This clock is used by SNVS_HP real-time counter. This clock does not need to be synchronous with other clocks.

64.4 Runtime Procedures

SNVS implements a number of features that are intended to be accessed by software at runtime (as opposed to accessed at boot time). These features include:

- Real Time Clock (see SNVS_HP Real Time Counter)
- General Purpose Register (see Using the General-Purpose Register)

Procedures for using these features are described in the following sections.

64.4.1 Using SNVS Timer Facilities

SNVS incorporates timer facilities that can optionally generate an interrupt at a specified time. As described in the following sections, SNVS_HP incorporates a Real Time Counter that is available for general use, and SNVS_LP incorporates a Secure Real Time Counter intended for security applications.

64.4.1.1 SNVS_HP Real Time Counter

SNVS_HP implements a real time counter that can be read or written by any application; it has no privileged software access restrictions. When the chip is powered down the RTC is not active and it is reset at chip POR. The RTC can be used to generate a functional interrupt request either at a specific time, or at a specific frequency, or both. To generate an interrupt request at a specific time HPTA_EN is set to 0, the desired time is written to HPTA_MS and HPTA_LS and then HPTA_EN is set to 1. HPTA_EN, HPTA_MS and HPTA_LS can be written by any software that has access to SNVS registers; there are no privileged access restrictions. The counter can be synchronized to the SNVS_LP SRTC by writing to the HP_TS bit of SNVS_HP Control Register. This is particularly useful if the SNVS_LP is powered from an uninterrupted power source (e.g. a coin cell battery) because the RTC can then be set from a chip-internal time source.

64.4.1.2 RTC/SRTC control bits setting

All SNVS registers are programmed from the register bus, consequently any software-initiated changes are synchronized with the IP clock. Several registers can also change synchronously with the RTC/SRTC clock after they are programmed. To avoid IP clock and RTC/SRTC clock synchronization issues, the following values can be changed only when the corresponding function is disabled.

Table 64-4. RTC/SRTC synchronized values list

Function	Value/register	Control bit setting
HP section		
HP Real Time Counter	HPRTCMR and HPRTCLR Registers	RTC_EN = 0 : HPRTCMR/HPRTCLR **can** be programmed RTC_EN = 1 : HPRTCMR/HPRTCLR **cannot** be programmed
HP Time Alarm	HPTAMR and HPTALR Registers	HPTA_EN = 0 : HPTAMR/HPTALR **can** be programmed HPTA_EN = 1 : HPTAMR/HPTALR **cannot** be programmed
LP section		
LP Secure Real Time Counter	LPRTCMR and LPRTCLR Registers	SRTC_ENV = 0 : LPRTCMR/LPRTCLR **can** be programmed SRTC_ENV = 1 : LPRTCMR/LPRTCLR **cannot** be programmed
LP Time Alarm	LPTAR Register	LPTA_EN = 0 : LPTAR **can** be programmed LPTA_EN = 1 : LPTAR **cannot** be programmed

Use the following steps to program synchronized values:

1. Check the enable bit value. If set, clear it.

2. Verify that the enable bit is cleared. There are two reasons to verify the enable bit's setting:

- Enable bit clearing does not happen immediately; it takes three IP clock cycles and two RTC/SRTC clock cycles to change the enable bit's value.
- If the enable bit is locked for programming, it cannot be cleared.

3. Program the desired value.

4. Set the enable bit; it takes three IP clock cycles and two RTC/SRTC clock cycles for the bit to set.

NOTE

Incrementing the value programmed into RTC/SRTC registers by two compensates for the two RTC/SRTC clock cycle delay that is required to enable the counter.

64.4.1.3 Reading RTC and SRTC values

Software should follow the following procedure to ensure that it has read correct data from the RTC (HPRTCMR and HPRTCLR) and SRTC (LPSRTCMR and LPSRTCLR) registers:

- Read the most-significant half and the least-significant half of the RTC/SRTC and then read both halves again. If the values read are the same both times, the value is correct.
- If the two consecutive pairs of reads yield different results, perform two more reads.

The worst case scenario may require three sessions of two consecutive pairs of reads. There are several reasons that the values may be incorrectly read initially:

- Synchronization issues between the RTC/SRTC clock and the system clock
- Since the counter continues to increment, there may be a carry from the least-significant 32-bits to the most-significant bits in between reading the two halves of the counter

64.4.2 Using Other SNVS Registers

The sections below describe how to use the General Purpose Register.Monotonic Counter.The sections below describe how to use the General Purpose Register and the Monotonic Counter.

64.4.2.1 Using the General-Purpose Register

SNVS implements a 256-bit general-purpose register allows software to store a small amount of data. To maintain backward compatibility with versions of SNVS that implement only a 32-bit general purpose register, the most-significant word of the general purpose register is aliased to the original legacy address, and to maintain backward compatibility with versions of snvs_module_name that implement a 128-bit general purpose register, the most-significant half of the general purpose register is aliased to the previous legacy address address. The data in the GPR will be retained during system power-down mode as long as the SNVS_LP remains powered by an uninterrupted power source (e.g. coin cell battery).

64.5 Reset and Initialization of SNVS

SNVS is implemented in two sections (HP and LP) that both must be initialized by software. If the SNVS_LP is powered by an uninterrupted power source that is separate from main SoC power, then SNVS can operate in either of two modes, depending upon whether the main SoC power is on or off. During main SoC power-down SNVS_HP is powered-down, but SNVS_LP is powered from the backup power supply and is electrically isolated from the rest of the chip. In this mode SNVS_LP keeps its registers' values and monitors the SNVS_LP tamper detection inputs, but the LP registers cannot be read or written. During main SoC power-up the isolation of SNVS_LP is disabled and both SNVS_HP and SNVS_LP are powered from the main SoC power. Both LP and HP registers can be read and written (locks and privilege modes permitting). Signals between the SNVS_HP and SNVS_LP sections are enabled and all SNVS functions are operational.

Since the HP and LP sections reside in different power domains, the POR for the two sections can occur at different times. If the SNVS_LP section remains powered by an uninterrupted power source when the main SoC power is off, SNVS_LP is initialized rarely, typically once when the device is first powered on and again whenever the battery is replaced. During main SoC power-up the isolation of SNVS_LP is disabled and both SNVS_HP and SNVS_LP are powered from the main SoC power. Signals between the

SNVS_HP and SNVS_LP sections are enabled and all SNVS functions are operational. The SNVS_HP section is powered from the main SoC power, so it must be initialized after the device is powered on.

- Initializing the LP section
  - The following steps should be completed to properly initialize the SNVS LP section (required at SoC POR):
    - Software should write the proper initialization value (41736166h) into the LP Power Glitch Detector Register and clear the power glitch record in the LP status register. See Power glitch detector (PGD) for more details.
- Initializing the HP section
  - The following steps should be completed to properly initialize the SNVS HP section (required on HP POR, i.e. SoC POR):
    - Perform normal boot to put the SNVS into a functional state (Non-secure, Trusted, Secure) (see HP Command Register, SSM_ST bitfield).
    - Program SNVS general functions/configurations (see HP Control Register).
    - Set lock bits. The MS bit of the HP Lock Register should be set before starting any functional operation. See i.MX 7ULP Security Reference Manual for details.

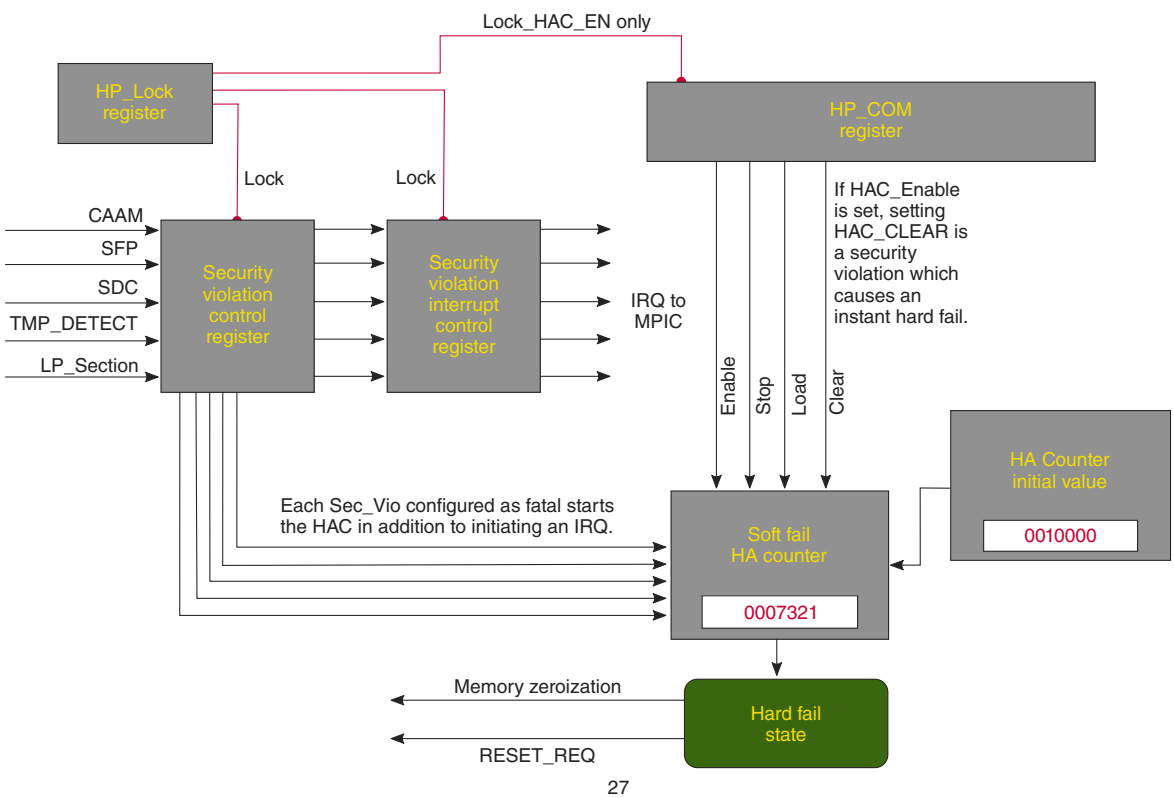

Figure 64-3. Relationship Between the Registers

64.5.1 Initialization Checklists

SNVS is implemented in two sections (HP and LP) that both must be initialized by software. If the SNVS_LP is powered by an uninterrupted power source that is separate from main SoC power, then SNVS can operate in either of two modes, depending upon whether the main SoC power is on or off. During main SoC power-down SNVS_HP is powered-down, but SNVS_LP is powered from the backup power supply and is electrically isolated from the rest of the chip. In this mode SNVS_LP keeps its registers' values and monitors the SNVS_LP tamper detection inputs, but the LP registers cannot be read or written. During main SoC power-up the isolation of SNVS_LP is disabled and both SNVS_HP and SNVS_LP are powered from the main SoC power. Both LP and HP registers can be read and written (locks and privilege modes permitting). Signals between the SNVS_HP and SNVS_LP sections are enabled and all SNVS functions are operational.

Since the HP and LP sections reside in different power domains, the POR for the two sections can occur at different times. If the SNVS_LP section remains powered by an uninterrupted power source when the main SoC power is off, SNVS_LP is initialized rarely, typically once when the device is first powered on and again whenever the battery is replaced. During main SoC power-up the isolation of SNVS_LP is disabled and both SNVS_HP and SNVS_LP are powered from the main SoC power. Signals between the SNVS_HP and SNVS_LP sections are enabled and all SNVS functions are operational. The SNVS_HP section is powered from the main SoC power, so it must be initialized whenever the device is powered on. If the SNVS_LP section is powered from the main SoC power rather than from an uninterrupted power source, the SNVS_LP section must also be initialized at SoC POR.

64.6 SNVS register descriptions

This section contains detailed register descriptions for the SNVS registers. Each description includes a standard register diagram and register table. The register table provides detailed descriptions of the register bit and field functions, in bit order.

SNVS registers consist of two types:

- Privileged read/write accessible
- Non-privileged read/write accessible

Privileged read/write accessible registers can only be accessed for read/write by privileged software. Unauthorized write accesses are ignored, and unauthorized read accesses return zero. Non-privileged software can access privileged access registers when the non-privileged software access enable bit is set in the SNVS_HP Command Register.

- Non-Secure
- Trusted
- Secure

Non-privileged read/write accessible registers are read/write accessible by any software.

The LP register values are set only on LP POR and are unaffected by System (HP) POR. The HP registers are set only on System POR and are unaffected by LP POR.

The following table shows the SNVS main memory map.

NOTE

For more information on security-related bitfields, see the Security Reference Manual.

64.6.1 SNVS Memory map

SNVS base address: 4107_0000

Offset	Register	Width (In bits)	Access	Reset value

Register	Offset
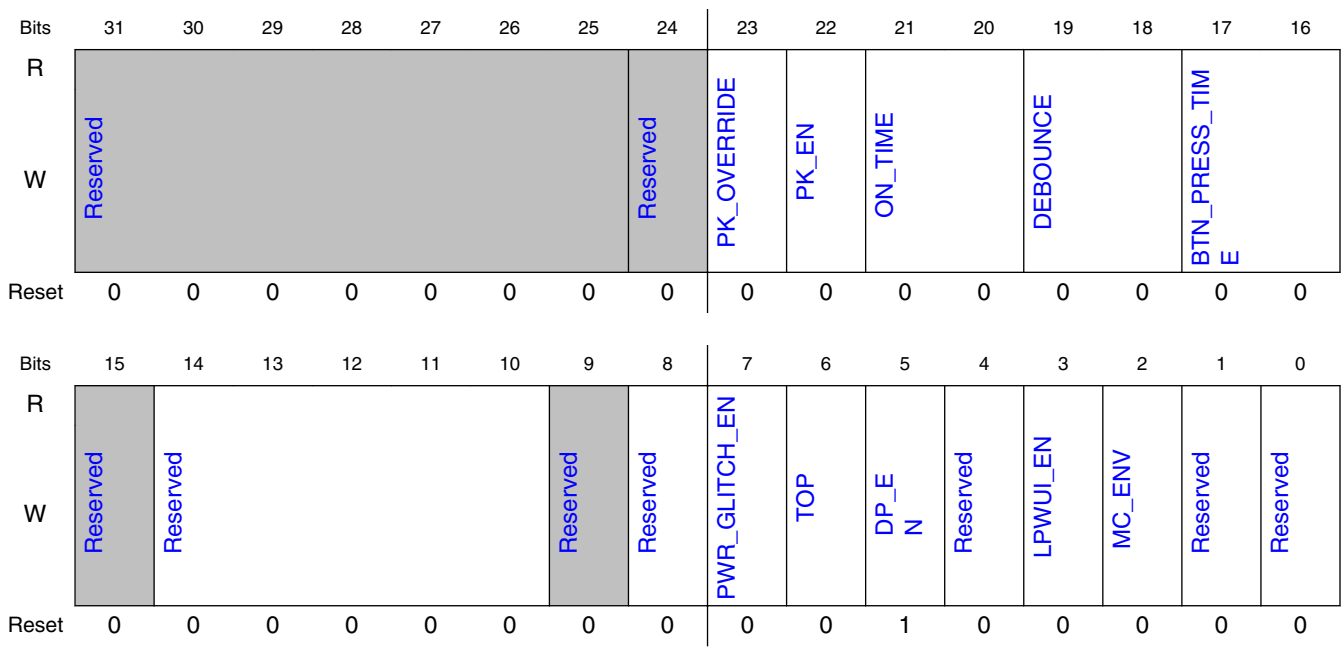
LPCR	38h

64.6.10.2 Function

The SNVS_LP Control Register contains various control bits of the LP section of SNVS. This is a privileged write register.

64.6.10.3 Diagram



64.6.10.4 Fields

Field	Function
31-25 —	Reserved
24 —	Reserved

Table continues on the next page...

Field	Function
23 PK_OVERRIDE	PMIC On Request Override The value written to PK_OVERRIDE will be asserted on output signal snvs_lp_pk_override. That signal is used to override the IOMUX control for the PMIC I/O pad.
22 PK_EN	PMIC On Request Enable The value written to PK_EN will be asserted on output signal snvs_lp_pk_en. That signal is used to turn off the pullup/pulldown circuitry in the PMIC I/O pad.
21-20 ON_TIME	The ON_TIME field is used to configure the period of time after BTN is asserted before pmic_en_b is asserted to turn on the SoC power. 00: 500msec off->on transition time 01: 50msec off->on transition time 10: 100msec off->on transition time 11: 0msec off->on transition time
19-18 DEBOUNCE	This field configures the amount of debounce time for the BTN input signal. 00: 50msec debounce 01: 100msec debounce 10: 500msec debounce 11: 0msec debounce
17-16 BTN_PRESS_TIME	This field configures the button press time out values for the PMIC Logic. 00 : 5 secs 01 : 10 secs 10 : 15 secs 11 : long press disabled (pmic_en_b will not be asserted regardlessof how long BTN is asserted)
15 —	Reserved
14-10 —	Reserved
9 —	Reserved
8 —	Reserved
7 PWR_GLITCH_EN	Power Glitch Enable By default the detection of a power glitch does not cause the pmic_en_b signal to be asserted. Setting the Power Glitch Enable bit to 1 enables the power glitch event for the PMIC. 0 - disabled 1 - enabled
6 TOP	Turn off System Power Asserting this bit causes a signal to be sent to the Power Management IC to turn off the system power. This bit will clear once power is off. This bit is only valid when the Dumb PMIC is enabled. 0b - Leave system power on. 1b - Turn off system power.
5	Dumb PMIC Enabled

Table continues on the next page...

Field	Function
DP_EN	When set, software can control the system power. When cleared, the system requires a Smart PMIC to automatically turn power off. 0b - Smart PMIC enabled. 1b - Dumb PMIC enabled.
4 —	Reserved
3 LPWUI_EN	LP Wake-Up Interrupt Enable This interrupt line should be connected to the external pin and is intended to inform the external chip about an SNVS_LP event (tamper event, MC rollover, SRTC rollover, or time alarm). This wake-up signal can be asserted only when the chip (HP section) is powered down, and the LP section is isolated. 0 LP wake-up interrupt is disabled. 1 LP wake-up interrupt is enabled.
2 MC_ENV	Monotonic Counter Enabled and Valid When set, the MC can be incremented (by write transaction to the LPSMCMR or LPSMCLR). Once MC_SL or MC_HL bit is set this bit can be changed only by LP software reset or LP POR. 0b - MC is disabled or invalid. 1b - MC is enabled and valid.
1 —	Reserved
0 —	Reserved

64.6.11 SNVS_LP Status Register (LPSR)

64.6.11.1 Offset

Register	Offset
LPSR	4Ch

64.6.11.2 Function

The SNVS_LP Status Register reflects the internal state and behavior of the SNVS_LP. This is a privileged write register.

64.6.11.3 Diagram

10 —	Reserved
9 —	Reserved
8-7 —	Reserved
6-4 —	Reserved
3 —	Reserved
2 MCR	Monotonic Counter Rollover 0b - MC has not reached its maximum value. 1b - MC has reached its maximum value.
1-0 —	Reserved

64.6.12 SNVS_LP Secure Monotonic Counter MSB Register (LPSMCMR)

64.6.12.1 Offset

Register	Offset
LPSMCMR	5Ch

64.6.12.2 Function

The SNVS_LP Secure Monotonic Counter MSB Register contains the monotonic counter era bits and the most-significant 16 bits of the monotonic counter. The monotonic counter is incremented by one if there is a write command to the LPSMCMR or LPSMCLR register. This is a non-privileged read-only register.

64.6.12.4 Fields

Field	Function
31-16 MC_ERA_BITS	Monotonic Counter Era Bits These bits are inputs to the module and typically connect to fuses. When the Monotonic Counter is in use (i.e. enabled and valid and powered by an uninterrupted power source, e.g. a coin cell battery), and the boot software detects that the Monotonic Counter most-significant 16 Bits and Monotonic Counter LSB Register have been reset (MC_ENV=0), the boot software can take action to ensure that the value in the monotonic counter remains monotonic (i.e. never decreasing). The action is to blow an additional MC_ERA_BITS fuse. Since the MC_ERA_BITS field forms the most-significant field of the monotonic counter, blowing an additional fuse guarantees that the new monotonic counter value is higher than any previous value. Typically this would be necessary only when the coin cell battery is changed. Since the Monotonic Counter is reset on an LP Software Reset, an excessive number of MC_ERA_BITS fusez may be consumed if LP Software Reset is used repeatedly.
15-0 MON_COUNTER	Monotonic Counter most-significant 16 Bits **Note that writing to this register does *not* change the value of this field to the value that was written.** **The 48-bit monotonic counter value (consisting of LPSMCMR[MON_COUNTER] prepended to LPSMCLR[MON_COUNTER]) is incremented by one when:** • A write transaction to the LPSMCMR or LPSMCLR register is detected. • The MC_ENV bit is set. • MC_SL and MC_HL bits are not set. This value can be reset only by LP software reset or LP POR.

64.6.13 SNVS_LP Secure Monotonic Counter LSB Register (LPSMCLR)

64.6.13.1 Offset

Register	Offset
LPSMCLR	60h

64.6.13.2 Function

The SNVS_LP Secure Monotonic Counter LSB Register contains the 32 least-significant bits of the monotonic counter. The MC is incremented by one if there is a write command to the LPSMCMR or LPSMCLR register. This is a non-privileged read-only register.

64.6.13.3 Diagram

64.6.17.1 Offset

For a = 0 to 7:

Register	Offset
LPGPRa	100h + (a × 4h)

64.6.17.2 Function

The SNVS_LP General Purpose Register is a 256-bit read/write register located in SNVS_LP, which can be used by any application for retaining data during an SoC power-down mode. This is a privileged read/write register. The full GPR register is accessed as 8 32-bit registers located in successive word addresses starting at offset 100h. For backward compatibility with earlier versions of SNVS, LPGPR0..LPGPR3 are aliased at the earlier offset of 90h and LPGPR0 is also aliased at its original offset of 68h. New software should access the GPR register at the preferred offset of 100h. The GPR will be automatically zeroized when an enabled security event occurs, unless GPR zeroization is disabled via the GPR_Z_DIS bit in the LP Control Register.

65.1.1 Analog to Digital Converter (ADC)

The ADC is a 12-bit resolution, successive approximation ADC designed for operation within an integrated microcontroller. The ADC can support up to 16 single-ended external analog inputs. The ADC supports only 12-bit non-differential and 13-bit differential formatting option. The ADC can achieve 1 microsecond conversion rate. The following table shows the configuration of the ADC.

Table 65-2. ADC configuration

Parameter	Description
Name	Analog to Digital Converter (ADC)
Instances	2
Configurable features	• FIFO Size: 16 • Command Buffers: 15 • Compare Values: 4 • Trigger Sources: 2
Interface speed	NA
External I/O pins	ADCx_CHnA, ADCx_CHnB (n = [7:0]). See the attached IOMUX spreadsheet for input sources for all the channels in ADC0 and ADC1.

65.1.2 ADC triggers

On i.MX 7ULP, ADC Trigger sources get routed through Trigger MUX. See the Table 38-2 for ADC0 and ADC1 trigger sources.

This device does not support ADC to ADC, and DAC to ADC type chained conversions but the regular time based conversions should partly cover the ADC Synchronous Operation. The solution consists of a timer based trigger, which can trigger the conversion at regular intervals. The hardware trigger will be associated to a command, so it will switch between ADC 0 and 1 for sampling at every trigger. There are also software triggers in each ADC. So, if multiple ADCs begin sampling with some fixed timing relationship, the user can either connect their hardware trigger sources together, or trigger them in software and program some startup delay on each trigger.

65.1.3 ADC channel input options

To know about the input source options of all the implemented channels (CH0-CH15) of ADC0 and ADC1 and temperature sensor option, see the " ADC Sources" tab in the attached IOMUXC Pinout spreadsheet.

65.1.4 ADC voltage reference sources

The table below shows voltage reference options that can be selected through CFG[REFSEL] field in ADC0 and ADC1.

Table 65-3. ADC0/1 voltage reference sources

ADC instance	Pin name	REFSEL bit value	Voltage reference source
ADC0	vrefh1	REFSEL = 00b	Voltage reference VREFH_ANA18
	vrefh2	REFSEL = 01b	1.8V supply VDD_ANA18
	vrefh3	REFSEL = 10b	1.8V supply VDD_ANA18
	vrefl_1p8		Voltage reference VREFL_ANA
ADC1	vrefh1	REFSEL = 00b	Voltage reference VREFH_ANA18
	vrefh2	REFSEL = 01b	1.8V supply VDD_ANA18
	vrefh3	REFSEL = 10b	1.8V supply VDD_ANA18

Table continues on the next page...

Table 65-3. ADC0/1 voltage reference sources (continued)

ADC instance	Pin name	REFSEL bit value	Voltage reference source
	vrefl_1p8		Voltage reference VREFL_ANA

65.2 Introduction

The 12-bit analog-to-digital converter (ADC) is a successive approximation ADC designed for operation within an integrated microcontroller system-on-chip.

NOTE

For the chip specific modes of operation, see the power management information of the device.

Note

Hexadecimal values are designated by a preceding 0x, binary values designated by a preceding 0b, and decimal values have no preceding character.

65.2.1 Features

Following are the features of the ADC module.

- Linear successive approximation algorithm
  - differential operation with 13-bit resolution
  - single-ended operation with 12-bit resolution
- Channel support for up to 64 analog input channels for conversion of external pins and from internal sources
  - Select external pin inputs paired for conversion as differential channel input
  - Measurement of on-chip analog sources such as DAC, temperature sensor or bandgap
- Channel scaling allows input voltage levels higher than the ADC reference voltage
- Configurable analog input sample time
- Configurable speed options to accommodate operation in low power modes of the device.
- Trigger detect with up to 2 trigger sources with priority level configuration. Software or hardware trigger option for each.
- 15 command buffers allow independent options selection and channel sequence scanning.

- Automatic compare for less-than, greater-than, within range, or out-of-range with "store on true" and "repeat until true" options
- 16-entry conversion result data FIFO with configurable watermark and overflow detection
- Interrupt, DMA or polled operation

65.2.2 Block diagram

The following figure is the ADC module block diagram.

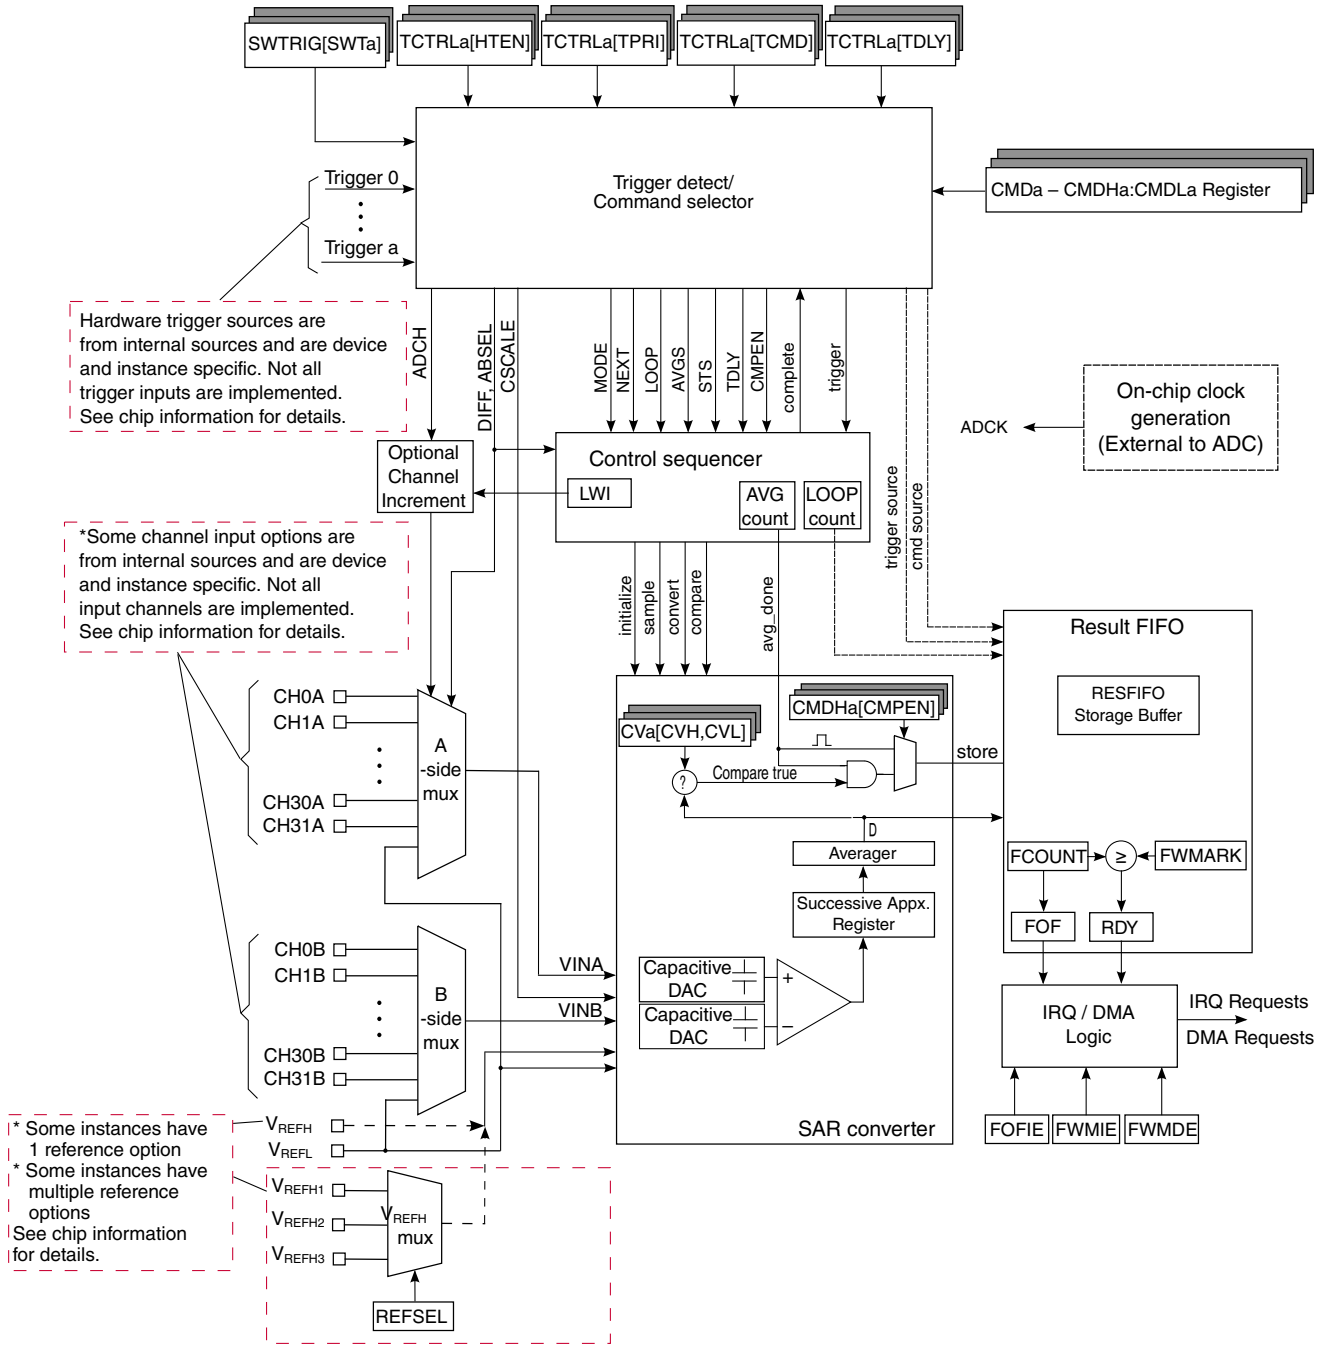

Figure 65-1. ADC block diagram

65.2.3 Modes of operation

The table below shows the operation of ADC module in various chip modes.

Table 65-4. Chip modes supported by the ADC module

Chip mode	ADC Operation
Run	Normal operation
Stop/Wait	Can continue operating provided the Doze Enable bit (CTRL[DOZEN]) is clear and the module is using an external or internal clock source which remains operating during stop/wait modes. When the CTRL[DOZEN] bit is set, the module will wait for the current averaging iteration/FIFO storage to complete before acknowledging stop or wait mode entry.
Low Leakage Stop	The Doze Enable (CTRL[DOZEN]) bit is ignored and the ADC will wait for the current transfer to complete any pending operation before acknowledging low-leakage mode entry.

65.3 Signal descriptions

The ADC module supports up to 64 analog channel inputs with differential and single-ended conversion options for all channels. The module also requires supply and ground connections.

Table 65-5. ADC signal descriptions

Signal	Description	I/O
V_{DDA}	Analog Power Supply	I
V_{SSA}	Analog Ground	I
CH31A–CH0A	A-side Analog Channel Inputs	I
CH31B–CH0B	B-side Analog Channel Inputs	I

NOTE

The voltage reference high (V_{REFH}) used by the ADC is supplied from either an on-chip voltage reference source or from an off-chip source supplied through external pins. V_{REFL} is always from an external pin and must be at the same voltage potential as V_{SSA}. See the chip configuration information on the voltage reference options specific to this packaged device.

NOTE

This block supports a programmable selection of the Voltage Reference High used for ADC conversions (via the CFG[REFSEL] field). See the chip configuration information on the voltage reference options specific to this packaged device.

65.3.1 Analog Power (V_{DDA})

The ADC analog portion uses V_{DDA} as its power connection. In some packages, V_{DDA} is connected internally to V_{DD}. If externally available, connect the V_{DDA} pin to the same voltage potential as V_{DD}. External filtering may be necessary to ensure clean V_{DDA} for good results.

65.3.2 Analog Ground (V_{SSA})

The ADC analog portion uses V_{SSA} as its ground connection. In some packages, V_{SSA} is connected internally to V_{SS}. If externally available, connect the V_{SSA} pin to the same voltage potential as V_{SS}.

65.3.3 Analog Channel Inputs (CH*n*A and CH*n*B)

The CMDL*a*[ADCH], CMDL*a*[DIFF] and CMDL*a*[ABSEL] bitfields control selection of paired or individual input channels. Each ADC command independently makes a channel selection. Each ADCH channel selection has an associated A side and an associated B side input. Each ADCH pair can optionally be converted in a differential mode but only limited pairs are intended to be converted as differential channels (i.e., adjacent pins that have been designed with matched impedance). For the pin pairings available for differential conversions for your device, see the Chip Configuration details.

NOTE

Some of the input channels are from on-chip sources such as temperature sensors and reference voltage sources and may only be connected to individual instances of the ADC module. Some of the input channel options in the bitfield-setting descriptions may not be available for your device. Refer to ADC configuration section in the chip configuration chapter for the channels supported on this device.

65.4 ADC register descriptions

This section describes the ADC registers.

65.4.1 ADC Memory map

ADC0 base address: 4104_1000h

65.4.2 Version ID Register (VERID)

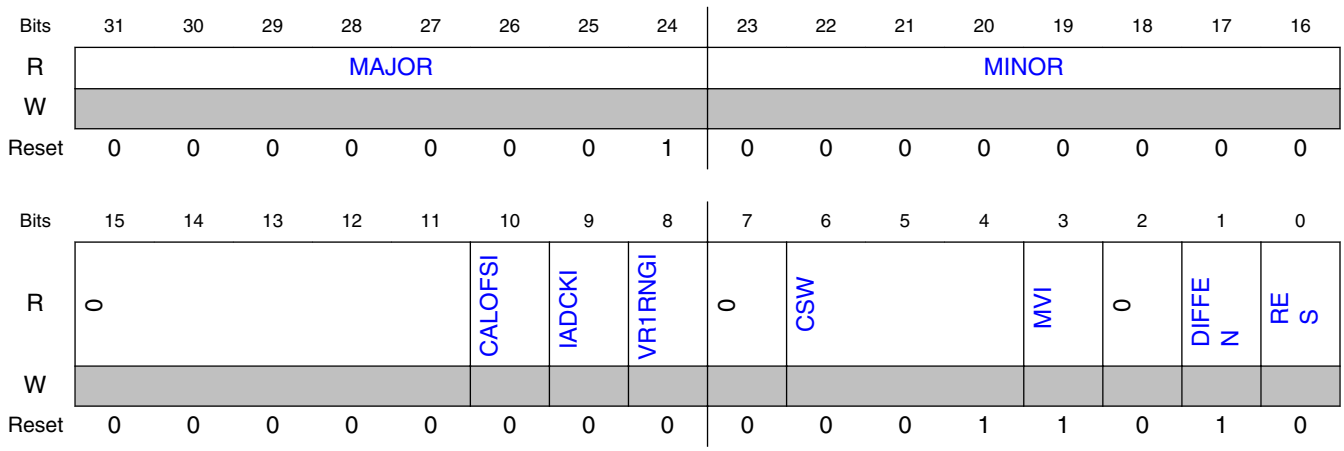
65.4.2.1 Offset

Register	Offset
VERID	0h

65.4.2.2 Function

The Version ID register indicates the version integrated for this instance on the device and also indicates inclusion/exclusion of several optional features.

65.4.2.3 Diagram



65.4.2.4 Fields

Field	Function
31-24 MAJOR	Major Version Number This read-only field returns the major version number for the module specification.
23-16 MINOR	Minor Version Number This read-only field returns the minor version number for the module specification.
15-11 —	Reserved This read-only field is reserved and always has the value 0.
10 CALOFSI	Calibration Offset Function Implemented This read-only field indicates if a calibration function and trimming control register are implemented. When supported, the CFG[CALOFS] and OFSTRIM[OFSTRIM] fields are available in support of this function. 0b - Offset calibration and offset trimming not implemented. 1b - Offset calibration and offset trimming implemented.
9 IADCKI	Internal ADC Clock implemented This read-only field indicates if this implementation of the ADC includes an internal clock source. When supported, the CFG[ADCKEN] field is available and documented for enabling the clock source. When available, this clock source is used in clock selection logic external to the module for use within the system. 0b - Internal clock source not implemented. 1b - Internal clock source (and CFG[ADCKEN]) implemented.
8 VR1RNGI	Voltage Reference 1 Range Control Bit Implemented This read-only field indicates if a control bit is implemented for selecting the input voltage range on Voltage Reference Option 1.When range control is required, the CFG[VREF1RNG] field is available and documented for controlling the Voltage Reference Option 1. 0b - Range control not required. CFG[VREF1RNG] is not implemented. 1b - Range control required. CFG[VREF1RNG] is implemented.
7	Reserved

Table continues on the next page...

Field	Function
—	This read-only field is reserved and always has the value 0.
6-4 CSW	Channel Scale Width This read-only field indicates if channel scaling is supported by this implementation. When supported, each command buffer has a control field (CMDLa[CSCALE]) for setting input scaling. 000b - Channel scaling not supported. 001b - Channel scaling supported. 1-bit CSCALE control field. 110b - Channel scaling supported. 6-bit CSCALE control field.
3 MVI	Multi Vref Implemented This read-only field indicates if multiple Voltage Reference High inputs are supported by this implementation. When multiple voltage references are supported, the CFG[REFSEL] field is available and documented for selecting the Voltage Reference High options. 0b - Single voltage reference high (VREFH) input supported. 1b - Multiple voltage reference high (VREFH) inputs supported.
2 —	Reserved This read-only field is reserved and always has the value 0.
1 DIFFEN	Differential Supported This read-only field indicates if differential operation is supported by this implementation. When supported, each command buffer has control fields (CMDLa[DIFF] and CMDLa[ABSEL]) for configuring for differential operation and expanding the number of supported channels from 32 to 64. 0b - Differential operation not supported. 1b - Differential operation supported. CMDLa[DIFF] and CMDLa[ABSEL] control fields implemented.
0 RES	Resolution This read-only field indicates the maximum accuracy supported by this implementation. When RES=1, each command buffer has a control field (CMDLa[MODE]) for selecting resolution of conversions for the associated command. 0b - Up to 13-bit differential/12-bit single ended resolution supported. 1b - Up to 16-bit differential/15-bit single ended resolution supported.

65.4.3 Parameter Register (PARAM)

65.4.3.1 Offset

Register	Offset
PARAM	4h

65.4.3.2 Function

The Parameter register indicates the size of several variable integration options for this instance on the device.

65.4.3.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	CMD_NUM								CV_NUM							
W																
Reset	0	0	0	0	1	1	1	1	0	0	0	0	0	1	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	FIFOSIZE								TRIG_NUM							
W																
Reset	0	0	0	1	0	0	0	0	0	0	0	0	0	0	1	0

65.4.3.4 Fields

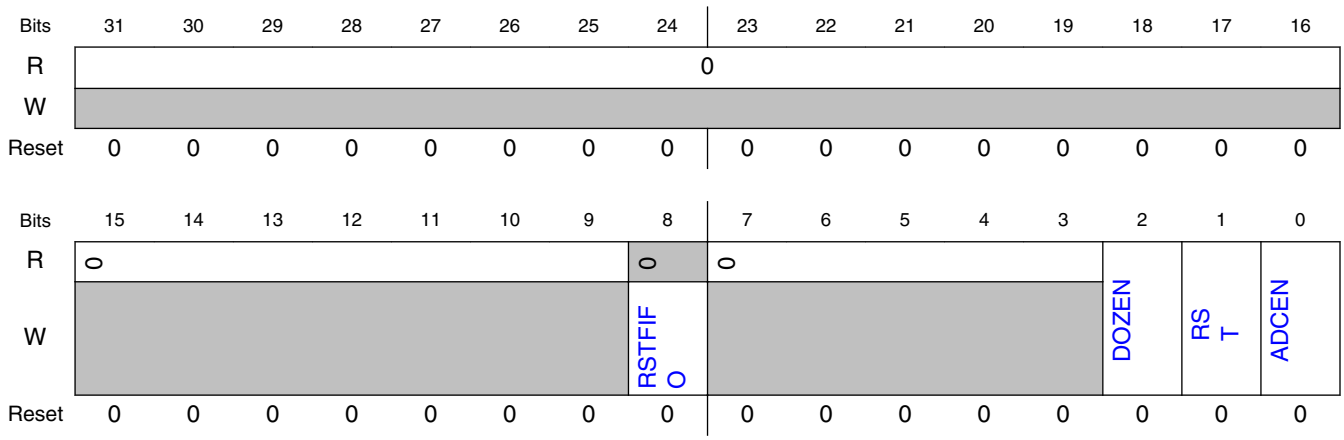
Field	Function
31-24 CMD_NUM	Command Buffer Number Number of command buffers implemented.
23-16 CV_NUM	Compare Value Number Number of compare value registers implemented.
15-8 FIFOSIZE	Result FIFO Depth The maximum number of conversion datawords that can be stored in the result FIFO before an overflow occurs. This field is read-only. 00000001b - Result FIFO depth = 1 dataword. 00000100b - Result FIFO depth = 4 datawords. 00001000b - Result FIFO depth = 8 datawords. 00010000b - Result FIFO depth = 16 datawords. 00100000b - Result FIFO depth = 32 datawords. 01000000b - Result FIFO depth = 64 datawords.
7-0 TRIG_NUM	Trigger Number Number of Triggers implemented.

65.4.4 ADC Control Register (CTRL)

65.4.4.1 Offset

Register	Offset
CTRL	10h

65.4.4.2 Diagram



65.4.4.3 Fields

Field	Function
31-9 —	Reserved This read-only field is reserved and always has the value 0.
8 RSTFIFO	Reset FIFO 0b - No effect. 1b - FIFO is reset.
7-3 —	Reserved This read-only field is reserved and always has the value 0.
2 DOZEN	Doze Enable Controls system transition to Stop and Wait power modes while ADC is converting. When DOZEN is clear, immediate entries to Wait or Stop are allowed. Note that the selected clock source provided from the on-chip clock source must be able to continue operating. When the DOZEN bit is set, the ADC waits for the current averaging iteration/FIFO storage to complete before acknowledging stop or wait mode entry. When the system is entering a Low Leakage Stop mode, the DOZEN bit is ignored and the module waits for the current transfer to complete any pending operation before acknowledging low leakage mode entry. 0b - ADC is enabled in Doze mode. 1b - ADC is disabled in Doze mode.
1 RST	Software Reset Resets all internal logic and registers, except the Control Register. Remains set until cleared by software. 0b - ADC logic is not reset. 1b - ADC logic is reset.
0 ADCEN	ADC Enable 0b - ADC is disabled. 1b - ADC is enabled.

65.4.5 ADC Status Register (STAT)

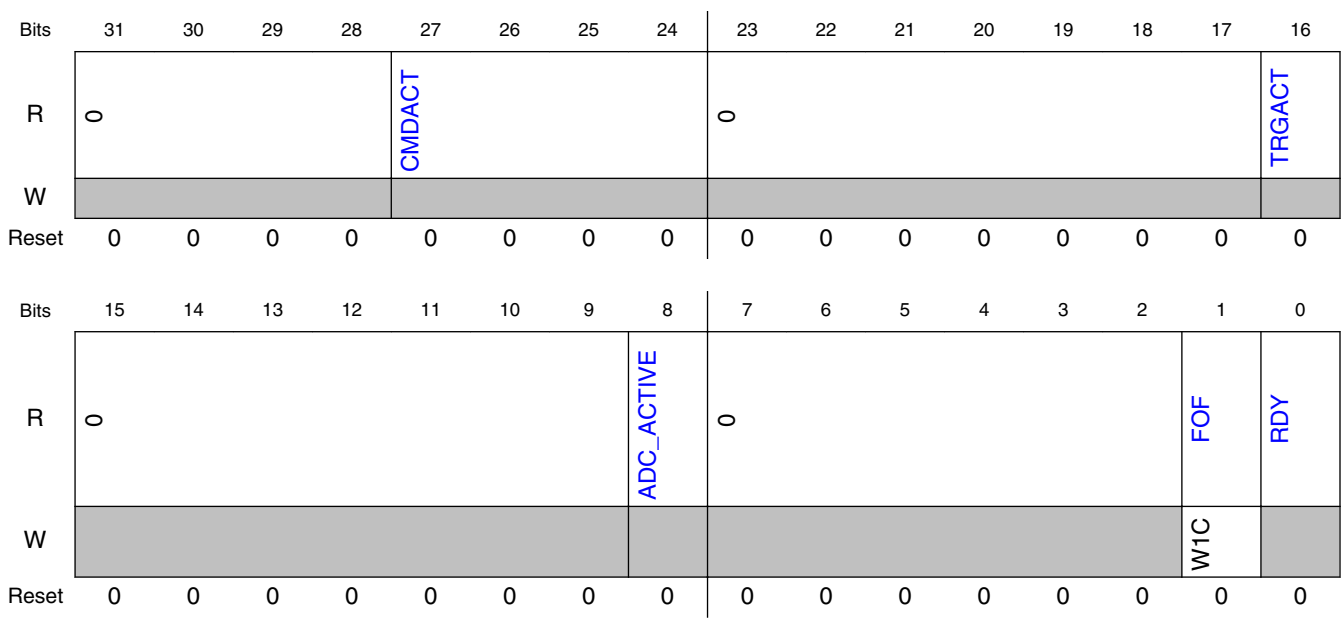
65.4.5.1 Offset

Register	Offset
STAT	14h

65.4.5.2 Function

The Status Register provides the current status of the ADC module.

65.4.5.3 Diagram



65.4.5.4 Fields

Field	Function
31-28 —	Reserved This read-only field is reserved and always has the value 0.

Table continues on the next page...

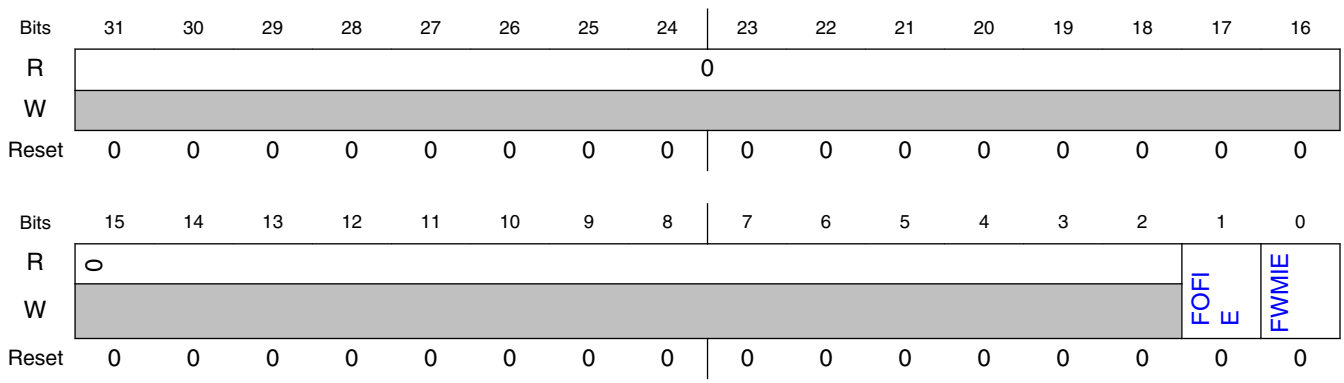
Field	Function
27-24 CMDACT	Command Active CMDACT is a read-only status field indicating the command that is actively being processed. 0000b - No command is currently in progress. 0001b - Command 1 currently being executed. 0010b - Command 2 currently being executed. 0011-1111b - Associated command number is currently being executed.
23-17 —	Reserved This read-only field is reserved and always has the value 0.
16 TRGACT	Trigger Active TRGACT is a read-only status field indicating the trigger associated with the command actively being processed. TRGACT only has meaning when CMDACT is non-zero. 0b - Command (sequence) associated with Trigger 0 currently being executed. 1b - Command (sequence) associated with Trigger 1 currently being executed.
15-9 —	Reserved This read-only field is reserved and always has the value 0.
8 ADC_ACTIVE	ADC Active This flag shows if the module is currently processing a conversion, or has pending triggers to service. When the ADC is IDLE, this bit will be set to 0b0. 0b - The ADC is IDLE. There are no pending triggers to service and no active commands are being processed. 1b - The ADC is processing a conversion, running through the power up delay, or servicing a trigger.
7-2 —	Reserved This read-only field is reserved and always has the value 0.
1 FOF	Result FIFO Overflow Flag Indicates that more data has been written to the Result FIFO than it can hold. The newer data is not stored and the FIFO remains holding the original contents. This field asserts regardless of the value of IE[FOFIE]. However, an interrupt request is issued only if IE[FOFIE] is set. This flag is cleared by writing a 1. 0b - No result FIFO overflow has occurred since the last time the flag was cleared. 1b - At least one result FIFO overflow has occurred since the last time the flag was cleared.
0 RDY	Result FIFO Ready Flag Indicates when the number of valid datawords in the result FIFO is greater than the watermark level set in the FCTRL[FWMARK] bitfield. This field asserts regardless of the value of FWMIE. However, an interrupt request or DMA request occurs only when the associated control bit (IE[FWMIE] and DE[FWMDE]) is set. This flag is cleared when the FCOUNT (which decrements on each read of the RESFIFO register) is less than or equal to the watermark level set in the FCTRL[FWMARK] bitfield. 0b - Result FIFO data level not above watermark level. 1b - Result FIFO holding data above watermark level.

65.4.6 Interrupt Enable Register (IE)

65.4.6.1 Offset

Register	Offset
IE	18h

65.4.6.2 Diagram



65.4.6.3 Fields

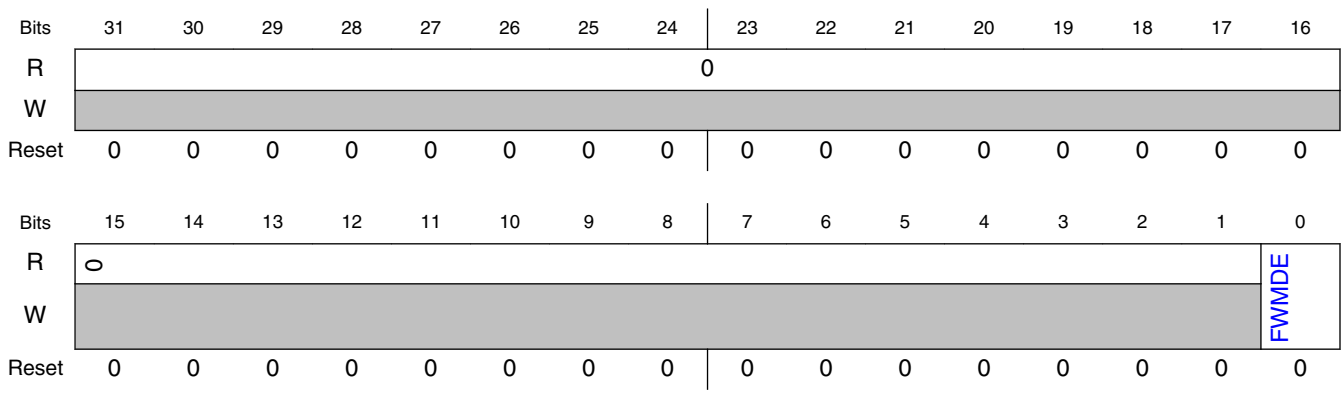
Field	Function
31-2 —	Reserved This read-only field is reserved and always has the value 0.
1 FOFIE	Result FIFO Overflow Interrupt Enable Configures ADC to generate overflow interrupt requests when FOF flag is asserted. 0b - FIFO overflow interrupts are not enabled. 1b - FIFO overflow interrupts are enabled.
0 FWMIE	FIFO Watermark Interrupt Enable Configures the module to generate watermark interrupt requests when RDY flag is asserted. 0b - FIFO watermark interrupts are not enabled. 1b - FIFO watermark interrupts are enabled.

65.4.7 DMA Enable Register (DE)

65.4.7.1 Offset

Register	Offset
DE	1Ch

65.4.7.2 Diagram



65.4.7.3 Fields

Field	Function
31-1 —	Reserved This read-only field is reserved and always has the value 0.
0 FWMDE	FIFO Watermark DMA Enable Configures ADC to generate DMA requests when RDY flag is asserted. 0b - DMA request disabled. 1b - DMA request enabled.

65.4.8 ADC Configuration Register (CFG)

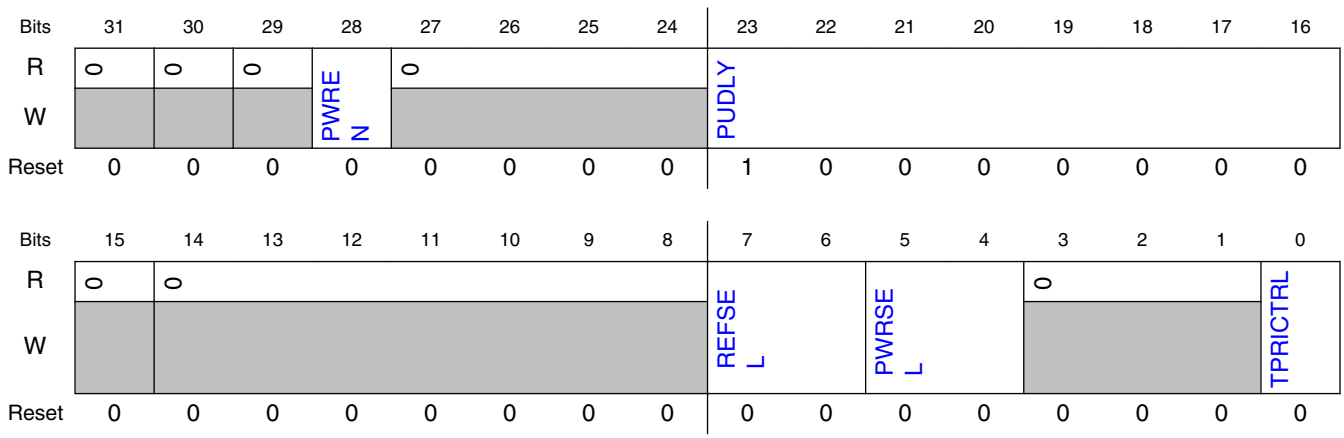
65.4.8.1 Offset

Register	Offset
CFG	20h

65.4.8.2 Function

The Configuration Register controls ADC functions that are common to all commands. The CFG cannot be changed while the CTRL[ADCEN] bit is set. Writes to CFG while CTRL[ADCEN] is set are ignored.

65.4.8.3 Diagram



65.4.8.4 Fields

Field	Function
31	Reserved
—	This read-only field is reserved and always has the value 0.
30	Reserved
—	This read-only field is reserved and always has the value 0.
29	Reserved
—	This read-only field is reserved and always has the value 0.
28 PWREN	ADC Analog Pre-Enable Enables the ADC analog circuits. When setting CFG[PWREN], user code should delay for a period exceeding the analog startup time of $t_{ADCSTUP}$ before enabling the ADC for operation. The module is still operational even when CFG[PWREN] is left clear but command execution start is delayed for a period defined by CFG[PUDLY]. Refer to the device datasheet for ADC idle and ADC active power consumption parameters. 0b - ADC analog circuits are only enabled while conversions are active. Performance is affected due to analog startup delays. 1b - ADC analog circuits are pre-enabled and ready to execute conversions without startup delays (at the cost of higher DC current consumption). When PWREN is set, the power up delay is enforced such that any detected trigger does not begin ADC operation until the power up delay time has passed.

Table continues on the next page...

Field	Function
27-24 —	Reserved This read-only field is reserved and always has the value 0.
23-16 PUDLY	Power Up Delay When CFG[PWREN]=0b0, the ADC analog circuits are only powered while the module is active and there is a counted delay defined by CFG[PUDLY] after an initial trigger transitions the ADC from its Idle state to allow time for the analog circuits to stabilize. The startup delay count of (PUDLY*4) ADCK cycles must result in a longer delay than the analog startup time of $t_{ADCSTUP}$. Accuracy of the initial conversion after activation is degraded if CFG[PUDLY] is set to too small a value. When CFG[PWREN]=0b1 prior to ADC activation, the analog circuits are pre-enabled and the activation delay defined by CFG[PUDLY] is bypassed.
15 —	Reserved This read-only field is reserved and always has the value 0.
14-8 —	Reserved This read-only field is reserved and always has the value 0.
7-6 REFSEL	Voltage Reference Selection Selects the voltage reference high used for conversions. **NOTE:** See the chip configuration information on the voltage reference options specific to this packaged device. 00b - (Default) Option 1 setting. 01b - Option 2 setting. 10b - Option 3 setting. 11b - Reserved
5-4 PWRSEL	Power Configuration Select Configures the module for power and performance. In the highest power setting, the highest conversion rates are possible. Refer to the device datasheet for power and performance capabilities for each setting. The highest power setting corresponds to 0b11 with decreasing power down to 0b00. 00b - Level 1 (Lowest power setting) 01b - Level 2 10b - Level 3 11b - Level 4 (Highest power setting)
3-1 —	Reserved This read-only field is reserved and always has the value 0.
0 TPRICTRL	ADC trigger priority control This bitfield controls how higher priority triggers are handled. See Trigger detect and command execution for a detailed explanation trigger event handling. 0b - If a higher priority trigger is detected during command processing, the current conversion is aborted and the new command specified by the trigger is started. 1b - If a higher priority trigger is received during command processing, the current conversion is completed (including averaging iterations if enabled) and stored to the RESFIFO before the higher priority trigger/command is initiated. Note that compare until true commands can be interrupted prior to resulting in a true conversion.

65.4.9 ADC Pause Register (PAUSE)

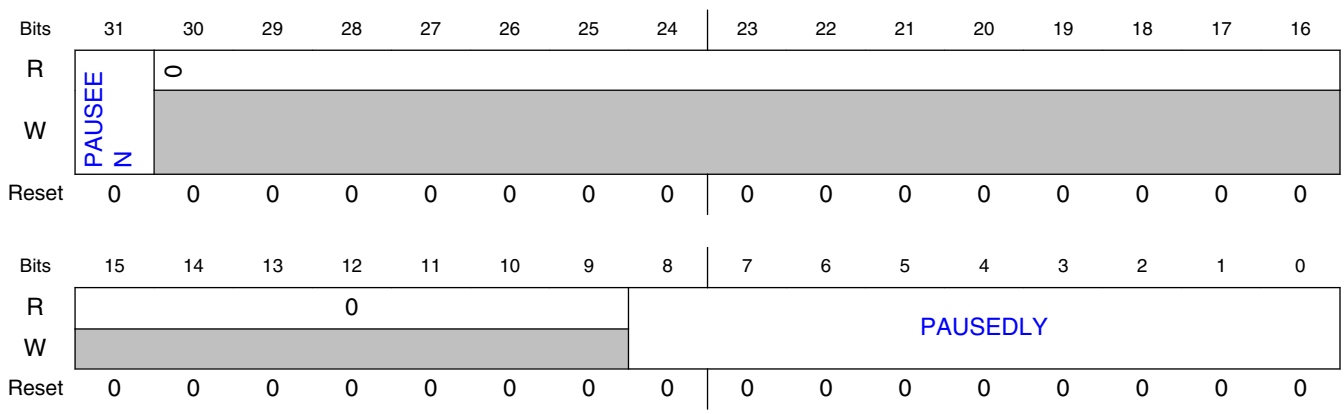
65.4.9.1 Offset

Register	Offset
PAUSE	24h

65.4.9.2 Function

The Pause Register controls an optional inserted delay between conversions. PAUSE cannot be changed while the CTRL[ADCEN] bit is set. Writes to PAUSE while CTRL[ADCEN] is set are ignored.

65.4.9.3 Diagram



65.4.9.4 Fields

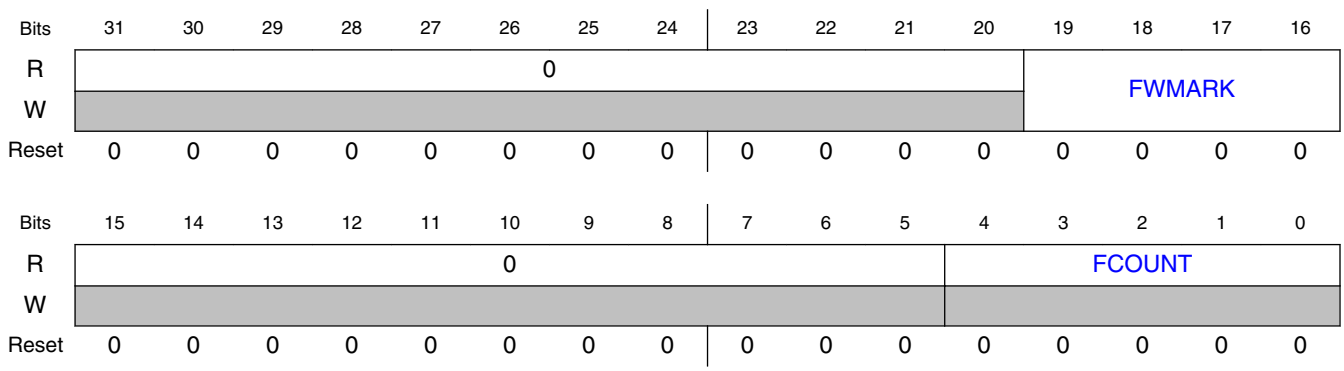
Field	Function
31 PAUSEEN	PAUSE Option Enable Enables the ADC pausing function. When enabled, a programmable delay is inserted during command execution sequencing between LOOP iterations, between commands in a sequence, and between conversions when command is executing in for "Compare Until True" configuration. 0b - Pause operation disabled 1b - Pause operation enabled
30-9 —	Reserved This read-only field is reserved and always has the value 0.
8-0 PAUSEDLY	Pause Delay When PAUSEEN is set, the PAUSEDLY field controls the duration of pausing during command exection sequencing. The pause delay is a count of (PAUSEDLY*4) ADCK cycles.

65.4.10 ADC FIFO Control Register (FCTRL)

65.4.10.1 Offset

Register	Offset
FCTRL	30h

65.4.10.2 Diagram



65.4.10.3 Fields

Field	Function
31-20 —	Reserved This read-only field is reserved and always has the value 0.
19-16 FWMARK	Watermark level selection FWMARK is a programmable threshold setting. When the number of datawords stored in the ADC Result FIFO is greater than the value in this field, the STAT[RDY] flag is asserted to indicate stored data has reached the programmable threshold. When IE[FWMIE] is set, an interrupt request is generated. When DE[FWMDE] is set, a DMA request is generated.
15-5 —	Reserved This read-only field is reserved and always has the value 0.
4-0 FCOUNT	Result FIFO counter This read-only field indicates the number of datawords that are stored in the result FIFO. This value may be used in conjunction with PARAM[FIFOSIZE] to calculate how much room is left in the result FIFO. FCOUNT is incremented with each store of new data to the result FIFO and decrements with each read of the result FIFO. The FIFO is reset by writing to the CTRL[RSTFIFO] bit, resulting in FCTRL[FCOUNT] initialized to 0x0.

65.4.11 Software Trigger Register (SWTRIG)

65.4.11.1 Offset

Register	Offset
SWTRIG	34h

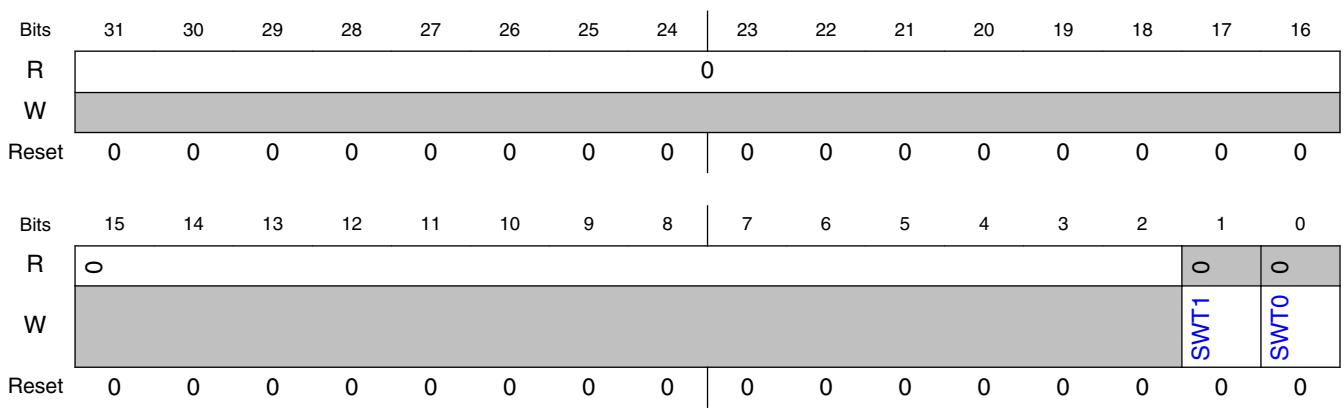
65.4.11.2 Function

The Software Trigger Register (SWTRIG) is written to initiate software triggered conversions. Writes to SWTRIG register are ignored while CTRL[ADCEN] is clear.

NOTE

There is a synchronization delay of 3 ADCK clock cycles when writing to set CTRL[ADCEN]. Writes to SWTRIG will continue to be ignored ultil CTRL[ADCEN] can propagate into the ADCK domain.

65.4.11.3 Diagram



65.4.11.4 Fields

Field	Function
31-2 —	Reserved This read-only field is reserved and always has the value 0.
1 SWT1	Software trigger 1 event Write 1 to SWT1 generates a trigger 1 event. Writing 1 to SWT1 is ignored while the trigger 1 event is being serviced or is pending. 0b - No trigger 1 event generated. 1b - Trigger 1 event generated.
0 SWT0	Software trigger 0 event Write 1 to SWT0 generates a trigger 0 event. Writing 1 to SWT0 is ignored while the trigger 0 event is being serviced or is pending. 0b - No trigger 0 event generated. 1b - Trigger 0 event generated.

65.4.12 Trigger Control Register (TCTRL0 - TCTRL1)

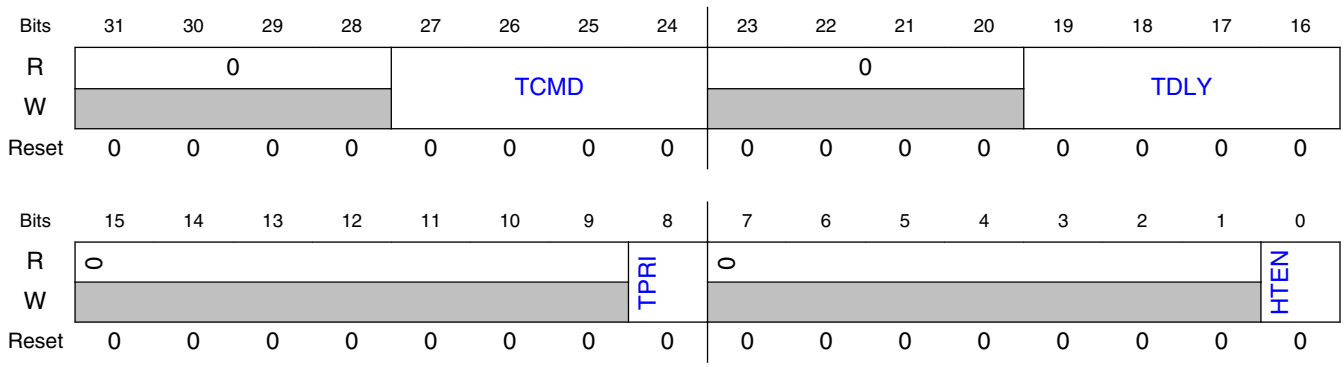
65.4.12.1 Offset

Register	Offset
TCTRL0	C0h
TCTRL1	C4h

65.4.12.2 Function

The Trigger Control (TCTRL*a*) register implements control fields associated with each implemented trigger source. When the ADC is actively executing commands, only one of the TCTRL*a* registers is actively controlling ADC conversions. The actively controlling TCTRL*a* register cannot be updated while the ADC is active. A write to a TCTRL*a* registers while that trigger control register is controlling the ADC operation is ignored.

65.4.12.3 Diagram



65.4.12.4 Fields

Field	Function
31-28 —	Reserved This read-only field is reserved and always has the value 0.
27-24 TCMD	Trigger command select Selects the command from command buffer to execute upon detection of the associated trigger event. When a trigger is received while the ADC is busy converting and the new trigger has higher priority than trigger associated with the current command being executed, the command in this register, associated with the new trigger, is executed under control of CFG[TPRICTRL]. When CFG[TPRICTRL]=0b0, the interruption due to higher priority trigger event is immediate. When CFG[TPRICTRL]=0b1, the current conversion (including any hardware averaging) is allowed to complete and the interruption is at the next loop boundary. 0000b - Not a valid selection from the command buffer. Trigger event is ignored. 0001b - CMD1 is executed 0010-1110b - Corresponding CMD is executed 1111b - CMD15 is executed
23-20 —	Reserved This read-only field is reserved and always has the value 0.
19-16 TDLY	Trigger delay select Selects the trigger delay duration to wait at the start of servicing a trigger event. Each trigger source has an associated programmable delay prior to beginning an initial conversion. When TDLY field is clear, then no delay is incurred. When TDLY is set to a non-zero value, the duration for the delay is 2^{TDLY} ADCK cycles.
15-9 —	Reserved This read-only field is reserved and always has the value 0.
8 TPRI	Trigger priority setting This bitfield sets the priority of the associated trigger source. If two or more triggers have the same priority level setting, the lower order trigger event has the higher priority (e. g., if Trigger 0 and Trigger 1 are both pending triggers and TCTRL0[TPRI] is configured the same as TCTRL1[TPRI], then the command associated with Trigger 0 is serviced first). 0b - Set to highest priority, Level 1

Table continues on the next page...

Field	Function
	1b - Set to lower priority, Level 2
7-1 —	Reserved This read-only field is reserved and always has the value 0.
0 HTEN	Trigger enable Enables hardware trigger source to initiate conversion on the rising-edge of the input trigger source. **NOTE:** Enabling hardware trigger does not disable software triggers. 0b - Hardware trigger source disabled 1b - Hardware trigger source enabled

65.4.13 ADC Command Low Buffer Register (CMDL1 - CMDL15)

65.4.13.1 Offset

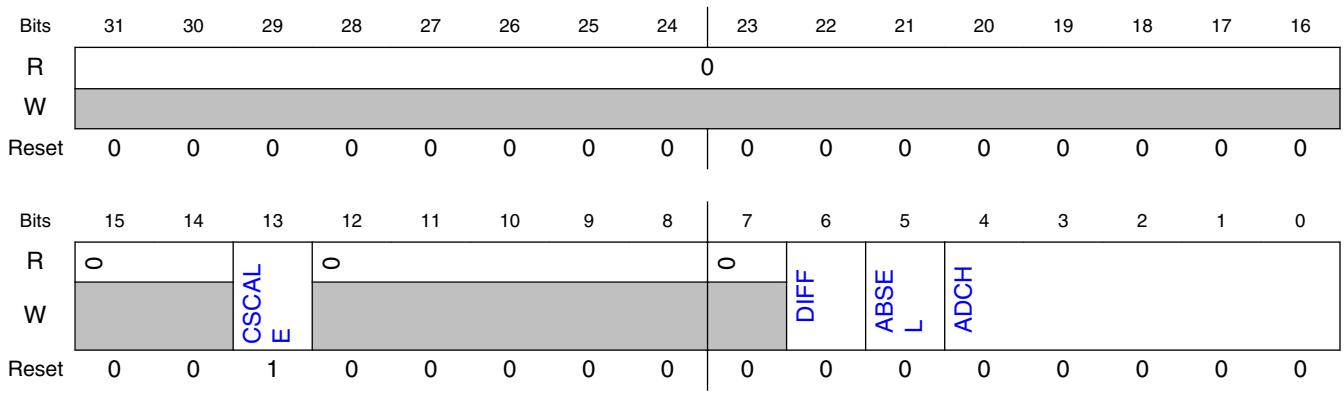
For a = 1 to 15:

Register	Offset
CMDLa	F8h + (a × 8h)

65.4.13.2 Function

There are 15 command buffers (CMD*a*), each constructed from two 32-bit registers (CMDL*a*:CMDH*a*) that can be configured for different channel select and varying conversion options. Any of the command buffers is selected and used as the controlling command by association to a trigger event via configuration of the TCTRL*a*[TCMD] bitfield. When the ADC is actively executing commands, only one of the CMD buffers is actively controlling ADC conversions. The actively controlling CMD buffer cannot be updated while the ADC is active. A write to a CMD buffer while that CMD buffer is controlling the ADC operation is ignored.

65.4.13.3 Diagram



65.4.13.4 Fields

Field	Function
31-14 —	Reserved This read-only field is reserved and always has the value 0.
13 CSCALE	Channel Scale Reduces the selected ADC analog channel input voltage level by a factor. The maximum possible voltage on the ADC channel input should be considered when selecting a CSCALE value to ensure that the reducing factor always results voltage level at or below the VREFH reference. This reducing capability allows conversion of analog inputs higher than VREFH. A-side and B-side channel inputs are both scaled using the CSCALE field. 0b - Scale selected analog channel (Factor of 30/64) 1b - (Default) Full scale (Factor of 1)
12-8 —	Reserved This read-only field is reserved and always has the value 0.
7 —	Reserved This read-only field is reserved and always has the value 0.
6 DIFF	Differential Mode Enable Configures the ADC to operate in differential mode or single-ended mode. 0b - Single-ended mode. 1b - Differential mode.
5 ABSEL	A-side vs. B-side Select When DIFF=0b0, ABSEL selects the channel from either the A-side or B-side channel inputs. When DIFF=0b1, ABSEL configures the ADC result to be (CHnA-CHnB) or (CHnB-CHnA). 0b - When DIFF=0b0, the associated A-side channel is converted as single-ended. When DIFF=0b1, the ADC result is (CHnA-CHnB). 1b - When DIFF=0b0, the associated B-side channel is converted as single-ended. When DIFF=0b1, the ADC result is (CHnB-CHnA).
4-0 ADCH	Input channel select

Field	Function
	Each ADCH channel selection has an associated A side and an associated B side input. The ADCH setting in conjunction with the DIFF and ABSEL bitfield settings selects the input from one of the channel inputs or one of the input pairs. See the DIFF and ABSEL bitfield descriptions. **NOTE:** Not all pairs are intended to be converted as differential channels. For the pin pairings available for differential conversions for your device, see the Chip Configuration details. **NOTE:** Some of the input channels are from internal resources such as temperature sensors and bandgap voltage sources and may only be connected to individual instances of the ADC module. Some of the input channel options in the bitfield-setting descriptions might not be available for your device. For the ADC channel assignments for your device, see the chip-specific information. 00000b - Select CH0A or CH0B or CH0A/CH0B pair. 00001b - Select CH1A or CH1B or CH1A/CH1B pair. 00010b - Select CH2A or CH2B or CH2A/CH2B pair. 00011b - Select CH3A or CH3B or CH3A/CH3B pair. 00100-11101b - Select corresponding channel CHnA or CHnB or CHnA/CHnB pair. 11110b - Select CH30A or CH30B or CH30A/CH30B pair. 11111b - Select CH31A or CH31B or CH31A/CH31B pair.

65.4.14 ADC Command High Buffer Register (CMDH1 - CMDH4)

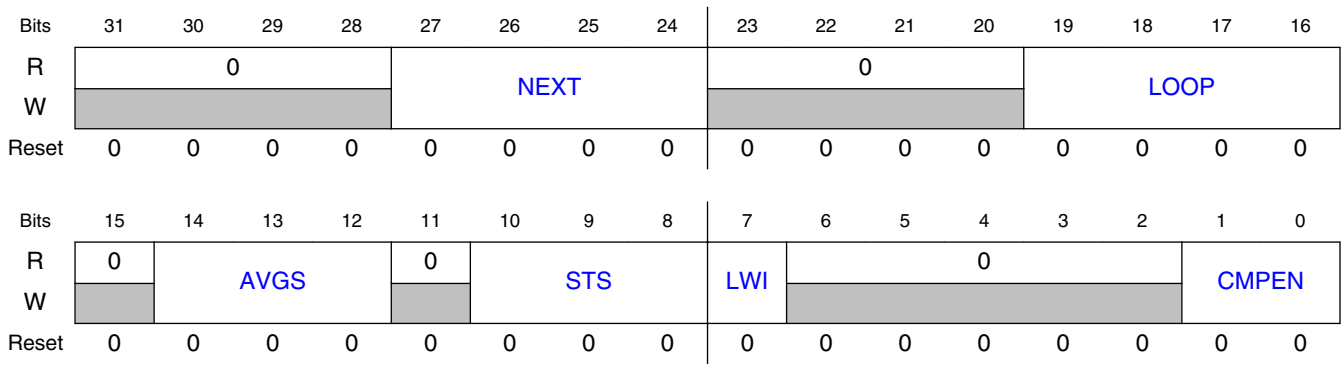
65.4.14.1 Offset

Register	Offset
CMDH1	104h
CMDH2	10Ch
CMDH3	114h
CMDH4	11Ch

65.4.14.2 Function

There are 15 command buffers (CMD*a*), each constructed from two 32-bit registers (CMDL*a*:CMDH*a*) that can be configured for different channel select and varying conversion options. Any of the command buffers is selected and used as the controlling command by association to a trigger event via configuration of the TCTRL*a*[TCMD] bitfield. When the ADC is actively executing commands, only one of the CMD buffers is actively controlling ADC conversions. The actively controlling CMD buffer cannot be updated while the ADC is active. A write to a CMD buffer while that CMD buffer is controlling ADC operation is ignored.

65.4.14.3 Diagram



65.4.14.4 Fields

Field	Function
31-28 —	Reserved This read-only field is reserved and always has the value 0.
27-24 NEXT	Next Command Select Selects the next command to be executed after this command completes. Multiple commands can be configured in a scan configuration by linking the next command in a daisy-chain sequence. The command buffer number is not indicative of any particular order and the order of execution is strictly controlled by the NEXT field (for example, a sequence of commands could be CMD2, CMD1, CMD3). Unending circular command execution is allowed by setting the NEXT field in the last command in a sequence to the first command in the sequence. It is also allowed for a command to set the next command to itself, resulting in a continuous conversion configuration. Setting the next command to 0x0 causes conversions to terminate at the completion of the command. Lower priority trigger events cannot be serviced until a higher priority triggered command (or sequence of commands) completes. 0000b - No next command defined. Terminate conversions at completion of current command. If lower priority trigger pending, begin command associated with lower priority trigger. 0001b - Select CMD1 command buffer register as next command. 0010-1110b - Select corresponding CMD command buffer register as next command 1111b - Select CMD15 command buffer register as next command.
23-20 —	Reserved This read-only field is reserved and always has the value 0.
19-16 LOOP	Loop Count Select Selects how many times this command executes (and stores conversion result to RESFIFO) before finish and transition to the next command or Idle state. LWI field controls whether a single channel is converted on each iteration or auto channel increment results in channel scanning functionality. 0000b - Looping not enabled. Command executes 1 time. 0001b - Loop 1 time. Command executes 2 times. 0010b - Loop 2 times. Command executes 3 times. 0011-1110b - Loop corresponding number of times. Command executes LOOP+1 times. 1111b - Loop 15 times. Command executes 16 times.
15 —	Reserved This read-only field is reserved and always has the value 0.

Table continues on the next page...

Field	Function
14-12 AVGS	Hardware Average Select Selects how many ADC conversions are averaged to create the ADC result (2^{AVGS}). An internal storage buffer is used to capture temporary results while the averaging iterations are executed. Hardware averaging is a nested loop control and does not extend across LOOP boundaries. See Functional description for more detailed description on usage of AVGS, LOOP, and NEXT bitfields in command execution sequencing. 000b - Single conversion. 001b - 2 conversions averaged. 010b - 4 conversions averaged. 011b - 8 conversions averaged. 100b - 16 conversions averaged. 101b - 32 conversions averaged. 110b - 64 conversions averaged. 111b - 128 conversions averaged.
11 —	Reserved This read-only field is reserved and always has the value 0.
10-8 STS	Sample Time Select When programmed to 000 the minimum sample time of 3 ADCK cycles is selected. When STS is programmed to a non-zero value the sample time is ($3 + 2^{STS}$) ADCK cycles. The shortest sample time maximizes conversion speed for lower impedance inputs. Extending sample time allows higher impedance inputs to be accurately sampled. Longer sample times can also be used to lower overall power consumption when command looping and sequencing is configured and high conversion rates are not required. 000b - Minimum sample time of 3 ADCK cycles. 001b - $3 + 2^1$ ADCK cycles; 5 ADCK cycles total sample time. 010b - $3 + 2^2$ ADCK cycles; 7 ADCK cycles total sample time. 011b - $3 + 2^3$ ADCK cycles; 11 ADCK cycles total sample time. 100b - $3 + 2^4$ ADCK cycles; 19 ADCK cycles total sample time. 101b - $3 + 2^5$ ADCK cycles; 35 ADCK cycles total sample time. 110b - $3 + 2^6$ ADCK cycles; 67 ADCK cycles total sample time. 111b - $3 + 2^7$ ADCK cycles; 131 ADCK cycles total sample time.
7 LWI	Loop with Increment When LWI is clear, the LOOP field selects the number of times the selected channel is converted consecutively. When LWI is set, auto channel incrementing is enabled and the LOOP field defines how many consecutive channels are converted as part of the command execution. Example 1: LOOP = 0x8, LWI = 0b0, ABSEL = 0b0, ADCH = 0xD. Convert on channel 13A 8 times. Example 2: LOOP = 0x8, LWI= 0b1, ABSEL = 0b0, ADCH = 0xD. Run channels 13A, 14A, 15A, ... 20A each one time. Maximum channel scanning using a single command buffer then is defined by the maximum value of the LOOP field (16). Note, when LWI is set, the minimum sample length must be extended to CMDHa[STS] = 0x3. 0b - Auto channel increment disabled 1b - Auto channel increment enabled
6-2 —	Reserved This read-only field is reserved and always has the value 0.
1-0 CMPEN	Compare Function Enable After an ADC channel input is sampled and converted and any averaging iterations are performed, the CMDHa[CMPEN] field guides operation of the automatic compare function to optionally only store when the compare operation is true. When compare is enabled, the conversion result is compared to the

Field	Function
	compare value registers (CV*a*[CVH] and CV*a*[CVL]). There are multiple options on command sequencing related to the compare function. See Compare function for a detailed explanation of the compare options. **NOTE:** Not all Command Buffers have implemented the CMPEN field. The CMPEN field is only available in Command Buffers that have a corresponding Compare Value register. 00b - Compare disabled. 01b - Reserved 10b - Compare enabled. Store on true. 11b - Compare enabled. Repeat channel acquisition (sample/convert/compare) until true.

65.4.15 ADC Command High Buffer Register (CMDH5 - CMDH15)

65.4.15.1 Offset

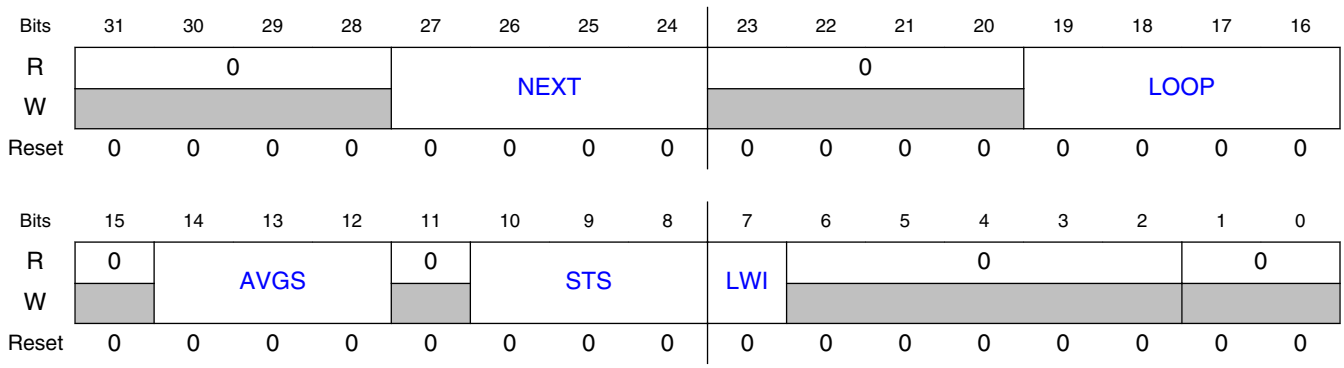
For a = 5 to 15:

Register	Offset
CMDHa	FCh + (a × 8h)

65.4.15.2 Function

There are 15 command buffers (CMD*a*), each constructed from two 32-bit registers (CMDL*a*:CMDH*a*) that can be configured for different channel select and varying conversion options. Any of the command buffers is selected and used as the controlling command by association to a trigger event via configuration of the TCTRL*a*[TCMD] bitfield. When the ADC is actively executing commands, only one of the CMD buffers is actively controlling ADC conversions. The actively controlling CMD buffer cannot be updated while the ADC is active. A write to a CMD buffer while that CMD buffer is controlling ADC operation is ignored.

65.4.15.3 Diagram



65.4.15.4 Fields

Field	Function
31-28 —	Reserved This read-only field is reserved and always has the value 0.
27-24 NEXT	Next Command Select Selects the next command to be executed after this command completes. Multiple commands can be configured in a scan configuration by linking the next command in a daisy-chain sequence. The command buffer number is not indicative of any particular order and the order of execution is strictly controlled by the NEXT field (for example, a sequence of commands could be CMD2, CMD1, CMD3). Unending circular command execution is allowed by setting the NEXT field in the last command in a sequence to the first command in the sequence. It is also allowed for a command to set the next command to itself, resulting in a continuous conversion configuration. Setting the next command to 0x0 causes conversions to terminate at the completion of the command. Lower priority trigger events cannot be serviced until a higher priority triggered command (or sequence of commands) completes. 0000b - No next command defined. Terminate conversions at completion of current command. If lower priority trigger pending, begin command associated with lower priority trigger. 0001b - Select CMD1 command buffer register as next command. 0010-1110b - Select corresponding CMD command buffer register as next command 1111b - Select CMD15 command buffer register as next command.
23-20 —	Reserved This read-only field is reserved and always has the value 0.
19-16 LOOP	Loop Count Select Selects how many times this command executes (and stores conversion result to RESFIFO) before finish and transition to the next command or Idle state. LWI field controls whether a single channel is converted on each iteration or auto channel increment results in channel scanning functionality. 0000b - Looping not enabled. Command executes 1 time. 0001b - Loop 1 time. Command executes 2 times. 0010b - Loop 2 times. Command executes 3 times. 0011-1110b - Loop corresponding number of times. Command executes LOOP+1 times. 1111b - Loop 15 times. Command executes 16 times.
15 —	Reserved This read-only field is reserved and always has the value 0.

Table continues on the next page...

Field	Function
14-12 AVGS	Hardware Average Select Selects how many ADC conversions are averaged to create the ADC result (2^{AVGS}). An internal storage buffer is used to capture temporary results while the averaging iterations are executed. Hardware averaging is a nested loop control and does not extend across LOOP boundaries. See Functional description for more detailed description on usage of AVGS, LOOP, and NEXT bitfields in command execution sequencing. 000b - Single conversion. 001b - 2 conversions averaged. 010b - 4 conversions averaged. 011b - 8 conversions averaged. 100b - 16 conversions averaged. 101b - 32 conversions averaged. 110b - 64 conversions averaged. 111b - 128 conversions averaged.
11 —	Reserved This read-only field is reserved and always has the value 0.
10-8 STS	Sample Time Select When programmed to 000 the minimum sample time of 3 ADCK cycles is selected. When STS is programmed to a non-zero value the sample time is ($3 + 2^{STS}$) ADCK cycles. The shortest sample time maximizes conversion speed for lower impedance inputs. Extending sample time allows higher impedance inputs to be accurately sampled. Longer sample times can also be used to lower overall power consumption when command looping and sequencing is configured and high conversion rates are not required. 000b - Minimum sample time of 3 ADCK cycles. 001b - $3 + 2^1$ ADCK cycles; 5 ADCK cycles total sample time. 010b - $3 + 2^2$ ADCK cycles; 7 ADCK cycles total sample time. 011b - $3 + 2^3$ ADCK cycles; 11 ADCK cycles total sample time. 100b - $3 + 2^4$ ADCK cycles; 19 ADCK cycles total sample time. 101b - $3 + 2^5$ ADCK cycles; 35 ADCK cycles total sample time. 110b - $3 + 2^6$ ADCK cycles; 67 ADCK cycles total sample time. 111b - $3 + 2^7$ ADCK cycles; 131 ADCK cycles total sample time.
7 LWI	Loop with Increment When LWI is clear, the LOOP field selects the number of times the selected channel is converted consecutively. When LWI is set, auto channel incrementing is enabled and the LOOP field defines how many consecutive channels are converted as part of the command execution. Example 1: LOOP = 0x8, LWI = 0b0, ABSEL = 0b0, ADCH = 0xD. Convert on channel 13A 8 times. Example 2: LOOP = 0x8, LWI= 0b1, ABSEL = 0b0, ADCH = 0xD. Run channels 13A, 14A, 15A, ... 20A each one time. Maximum channel scanning using a single command buffer then is defined by the maximum value of the LOOP field (16). Note, when LWI is set, the minimum sample length must be extended to CMDHa[STS] = 0x3. 0b - Auto channel increment disabled 1b - Auto channel increment enabled
6-2 —	Reserved This read-only field is reserved and always has the value 0.
1-0 —	Reserved This read-only field is reserved and always has the value 0.

65.4.16 Compare Value Register (CV1 - CV4)

65.4.16.1 Offset

Register	Offset
CV1	200h
CV2	204h
CV3	208h
CV4	20Ch

65.4.16.2 Function

The compare value registers (CV*a*) contain values used to compare the conversion result when the compare function is enabled. This register is formatted in the same way as the D field in the RESFIFO registers in different modes of operation for both bit position definition and value format using unsigned or signed 2's complement. There is a direct association of each compare value register to a specific command buffer register (i.e., CV1 is only used during execution of CMD1 command).

NOTE

Not all Command Buffers have an associated Compare Value register. The compare function is only available on Command Buffers that have a corresponding Compare Value register.

When the ADC is actively executing commands, the CV*a* register associated with the active command (CMD*a*) cannot be updated and writes to associated CV*a* register during this time are ignored.

65.4.16.3 Diagram

65.4.16.4 Fields

Field	Function
31-16 CVH	Compare Value High. The compare function can be configured to check whether the result is less than, greater than, or if the result falls within or outside a range determined by two compare values. After the input is sampled and converted and any averaging iterations are performed, the compare values in CVL and CVH are optionally used in a compare operation on the result. See Compare function for a description on how CVH is used.
15-0 CVL	Compare Value Low. The compare function can be configured to check whether the result is less than, greater than, or if the result falls within or outside a range determined by two compare values. After the input is sampled and converted and any averaging iterations are performed, the compare values in CVL and CVH are optionally used in a compare operation on the result. See Compare function for a description on how CVL is used.

65.4.17 ADC Data Result FIFO Register (RESFIFO)

65.4.17.1 Offset

Register	Offset
RESFIFO	300h

65.4.17.2 Function

The data result FIFO register (RESFIFO) is a 16 entry FIFO that stores the data result of ADC conversions. In addition, several tag fields of source command and trigger information are stored along with the data. FCTRL[FCOUNT] indicates how many valid datawords are stored in the RESFIFO. Reading RESFIFO provides the oldest unread dataword entry in the FIFO and decrements FCOUNT. The FIFO can be emptied by successive reads of RESFIFO. The FIFO is reset by writing 0b1 to the CTRL[RSTFIFO] bit.

The following table describes the format of data in the result FIFO in the different modes of operation. The sign bit is the (MSB) in signed 2's complement modes. For example, when configured for 12-bit single-ended mode, D[15] and D[2:0] are cleared. When configured for 13-bit differential mode, D[15] is the sign bit and D[2:0] are cleared.

Table 65-6. Data result register format description

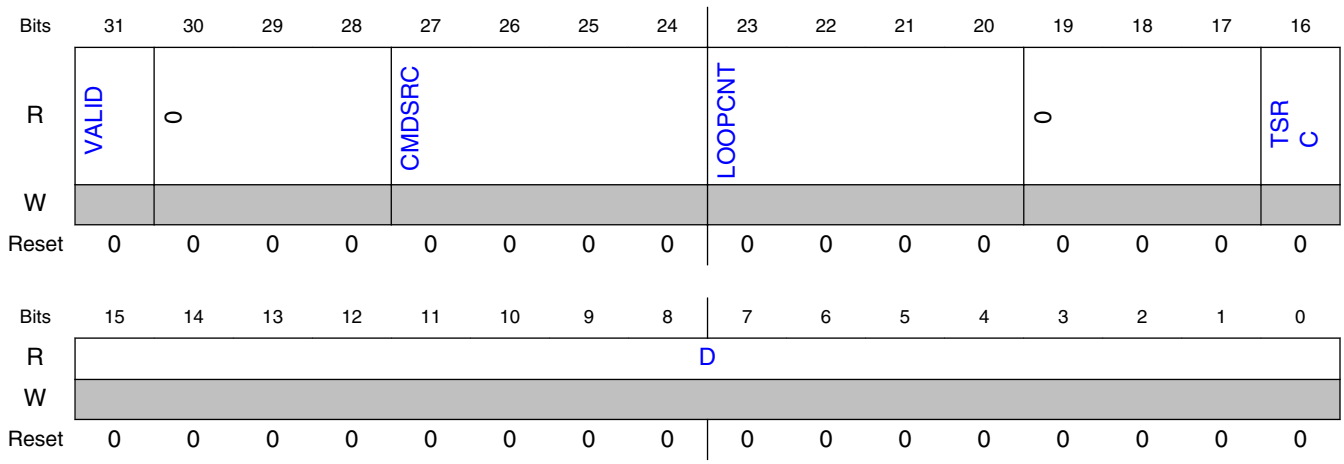
Conversion mode	D15	D14	D13	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0	Format
13-bit differential	S	D	D	D	D	D	D	D	D	D	D	D	D	0	0	0	Signed 2's complement, left-justified, zero extended
12-bit single-ended	0	D	D	D	D	D	D	D	D	D	D	D	D	0	0	0	Unsigned, zero in D[15] and D[2:0]

NOTE

S: Sign bit;

D: Data, which is 2's complement data if indicated

65.4.17.3 Diagram



65.4.17.4 Fields

Field	Function
31 VALID	FIFO entry is valid Indicate the FIFO entry is valid. When the FIFO is holding data the VALID bit is set. When the FIFO is empty the VALID bit is clear. 0b - FIFO is empty. Discard any read from RESFIFO. 1b - FIFO record read from RESFIFO is valid.
30-28 —	Reserved This read-only field is reserved and always has the value 0.
27-24 CMDSRC	Command Buffer Source Indicates the command buffer being executed that generated this result. 0000b - Not a valid value CMDSRC value for a dataword in RESFIFO. 0x0 is only found in initial FIFO state prior to an ADC conversion result dataword being stored to a RESFIFO buffer. 0001b - CMD1 buffer used as control settings for this conversion. 0010-1110b - Corresponding command buffer used as control settings for this conversion. 1111b - CMD15 buffer used as control settings for this conversion.
23-20 LOOPCNT	Loop count value Indicates the loop count value during command execution that generated this result. When CMDHa[LOOP] is non-zero, the command execution stores off a result multiple times during command execution (at the loop boundary). 0000b - Result is from initial conversion in command. 0001b - Result is from second conversion in command. 0010-1110b - Result is from LOOPCNT+1 conversion in command. 1111b - Result is from 16th conversion in command.
19-17 —	Reserved This read-only field is reserved and always has the value 0.
16 TSRC	Trigger Source

Table continues on the next page...

Field	Function
	Indicate the trigger source that initiated a conversion and generated this result. When multiple commands are chained together using the NEXT field, the TSRC field for all datawords stored to the RESFIFO indicate the trigger source that started the sequence of commands. 0b - Trigger source 0 initiated this conversion. 1b - Trigger source 1 initiated this conversion.
15-0 D	Data result The formatting for the data in D is summarized in Table 65-6.

65.5 Functional description

The ADC module performs analog-to-digital conversions on any of the software selectable analog input channels by a successive approximation algorithm. The module initializes to its lowest power state during reset and in Low-Power Stop mode. The ADC analog circuits can optionally be pre-enabled for faster starts to conversions at the expense of higher idle currents. Conversions are initiated by selectable trigger events from software or hardware sources. The trigger detect logic includes a configurable enable and priority scheme for the available trigger sources. The module includes multiple command buffers that provide configurable flexibility for channel scanning and independent channel selections for different trigger sources. Multiple command buffers also allow variable option selection such as input scaling factor,differential vs. single-ended, sample time and averaging on a per-channel basis.

This module optionally averages the result of multiple conversions on a channel before storing the calculated result. The hardware average function is enabled by setting CMDH*a*[AVGS] bitfield to a non-zero value and operates in any of the conversion modes and configurations.

When the conversion and averaging loops are completed, the resulting data is placed in a FIFO data buffer along with other tag information associated with the result. A configurable watermark level supports interrupt or DMA requests when the number of stored datawords exceeds the setting.

The ADC module optionally compares the result of a conversion with the contents of two value registers for less-than, greater-than, inside-range or outside-range detection. The compare function operates in any of the conversion modes and configurations.

The sequencing of an ADC command is summarized in the flow diagram shown below.

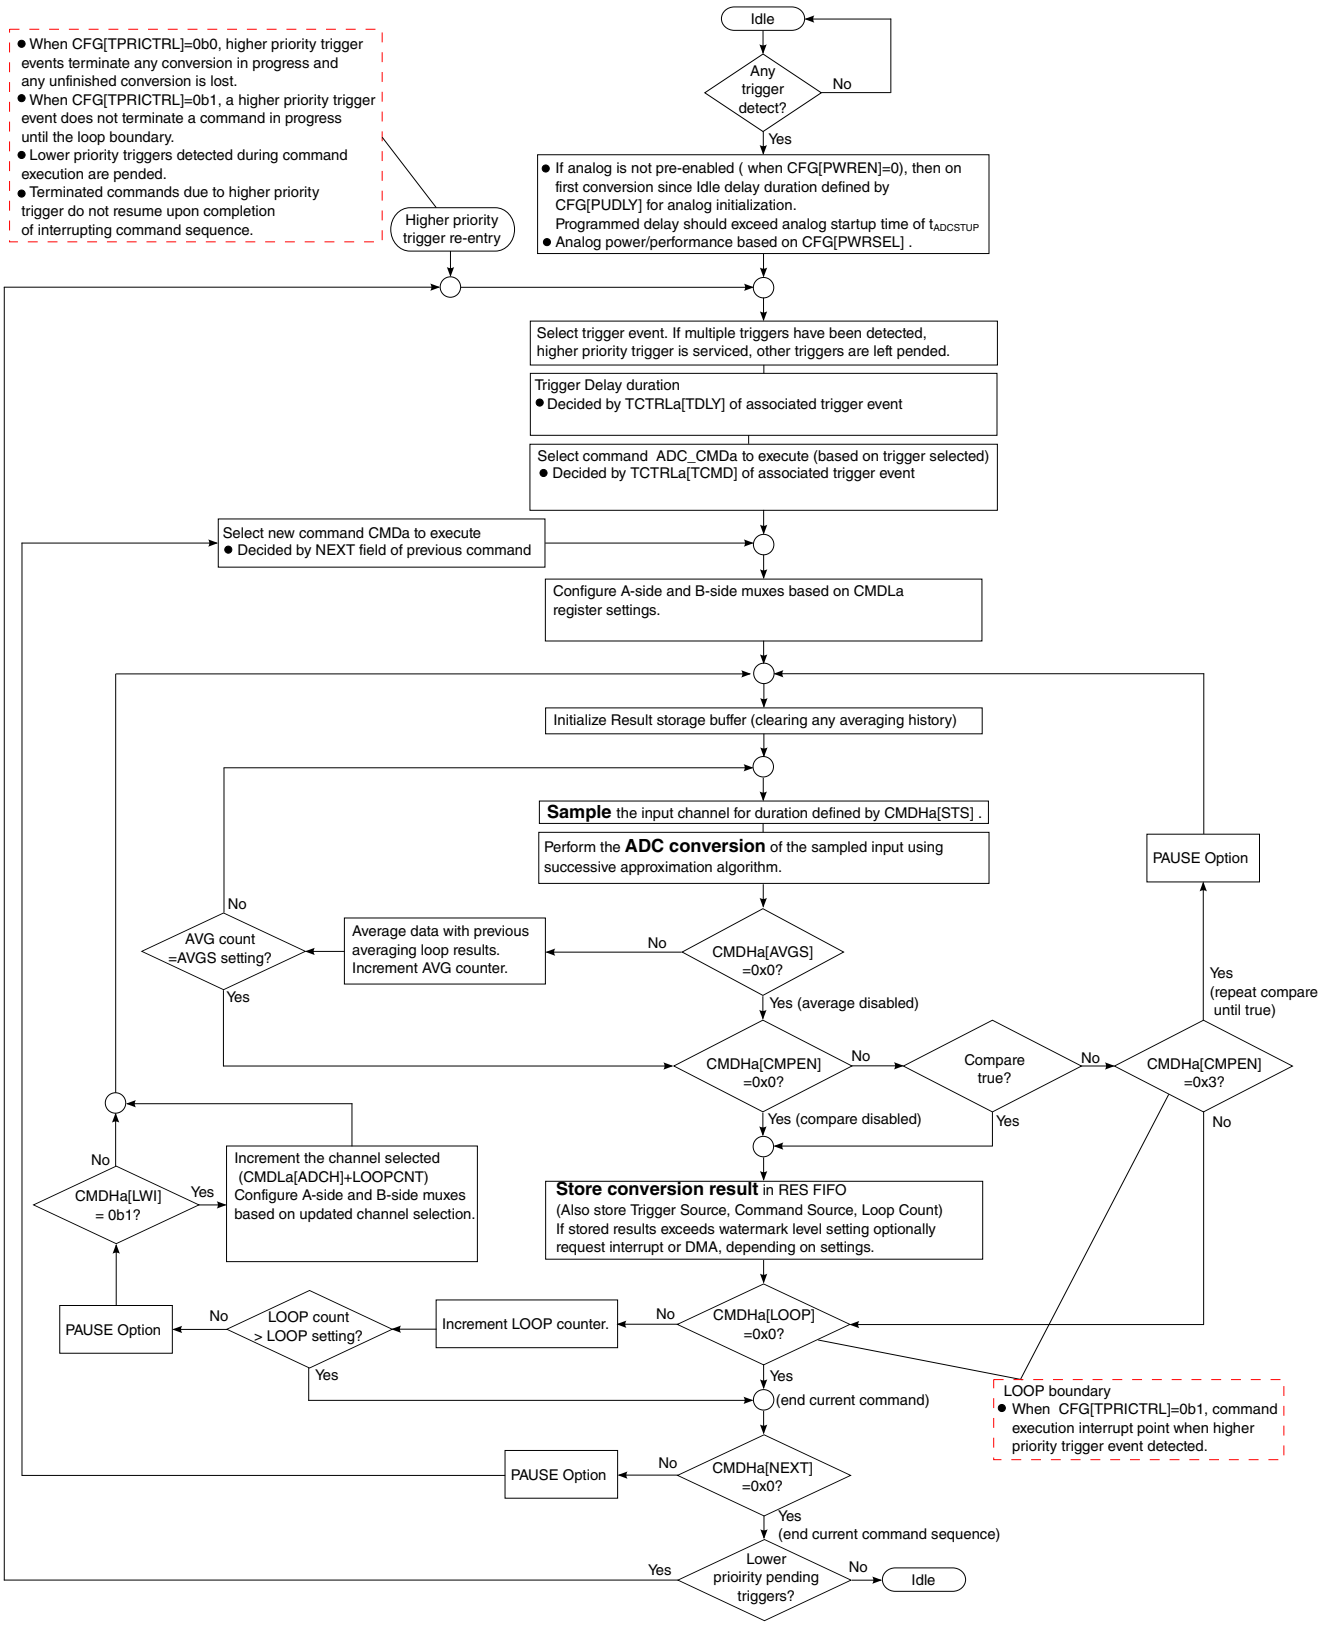


Figure 65-2. ADC command execution flow diagram

65.5.1 Voltage reference

The voltage reference high (V_{REFH}) used by the ADC is supplied from either an on-chip voltage reference source or from an off-chip source supplied through external pins. V_{REFL} is always from an external pin and must be at the same voltage potential as V_{SSA}. See the chip configuration information on the voltage reference options specific to this packaged device.

This block supports a programmable selection of the Voltage Reference High used for ADC conversions (via the CFG[REFSEL] field). See the chip configuration information on the voltage reference options specific to this packaged device.

65.5.2 Power control

The default setting for the ADC analog circuits is disabled while the ADC is in its Idle state. When a trigger is detected and ADC command processing is initiated, the analog circuits are enabled and require a period of initialization before the first conversion cycle. The CFG[PUDLY] should be programmed such that a delay duration longer than $t_{ADCSTUP}$ is incurred. Accuracy of the initial conversion(s) after activation is degraded if CFG[PUDLY] is set to too small a value.

Faster conversion startup times can be achieved by optionally setting the CFG[PWREN] field to pre-enable the analog circuits of the ADC at the expense of power consumption even while the module is in an idle state. When CFG[PWREN] is set, the Power Enable timer is activated and enforces the minimum startup (controlled by the PUDLY register field) before detected triggers are allowed to initiate ADC conversions.

This module also has configuration options for controlling power and performance summarized in the table below. See the device datasheet for specification of the available power modes.

Table 65-7. Power option settings

CFG[PWRSEL]	Description
0b00 (Default)	Level 1. Slowest speed/Lowest power setting.
0b01	Level 2.
0b10	Level 3.
0b11	Level 4. Fastest speed/highest power setting.

In the two highest power mode settings (CFG[PWRSEL]=0x2 or CFG[PWRSEL]=0x3) the ADC will delay start of sampling for 16 ADC clock cycles on the initial conversion since being in its Idle state. This delay is in addition to any configured Power Up delay or trigger delay.

65.5.3 Clock operation

The ADC operates from the ADCK clock input provided from an on-chip clock select block and is used by the SAR conversion control sequencing logic and the FIFO storage buffer. The ADCK frequency must fall within the specified frequency range for ADCK and will vary based on configuration of CFG[PWRSEL]. See the device datasheet for supported frequency ranges.

The ADC continues operating in stop and wait modes provided the Doze Enable bit (CTRL[DOZEN]) is clear and the on-chip clock select block continues to supply an ADCK clock source. When the CTRL[DOZEN] bit is set, the module will wait for the current averaging iteration/FIFO storage to complete before acknowledging stop or wait mode entry.

65.5.4 Trigger detect and command execution

See Figure 65-2 for a flow diagram of command execution sequencing.

ADC command execution is initiated from up to 2 trigger sources. Each trigger can be software generated by writing 0b1 to the corresponding SWTRIG[SWT*n*] bitfield. Alternatively, hardware triggers can be generated from asynchronous input sources at the periphery of the module. The number and sources of hardware triggers implemented is device-specific. See the chip configuration information for description of available hardware trigger sources for this device.

Each hardware trigger source is enabled by setting the associated enable bit (TCTRL*a*[HTEN]). Each trigger source is assigned a priority via the associated priority control field (TCTRL*a*[TPRI]). Each of the trigger sources is configurably associated with a command in the command buffer via the associated command select field (TCTRL*a*[TCMD]).

When a hardware trigger input is enabled, hardware trigger events are detected on the rising-edge of the associated hardware trigger source.

If a trigger event occurs that is configured for a higher priority than the trigger source associated with the currently executing command, the current command is handled in one of two ways depending on the CFG[TPRICTRL] bitfield setting. When

CFG[TPRICTRL]=0b0, a higher priority trigger causes an immediate command abort and the new command specified by the trigger is immediately started. When CFG[TPRICTRL]=0b1, a higher priority triggers allows the current conversion to complete (including averaging and compare functions) before the higher priority command is initiated.

If a lower priority trigger occurs (i.e., a trigger event occurs that is configured for a lower priority than the trigger source associated with the currently executing command), the trigger detect is pended until completion of the current command sequence.

At the completion of a command, the ADC does not resume a previously interrupted command (or series of commands). The module begins command execution associated with the processing of lower priority pending triggers. If no trigger events are pending, the ADC transitions to its idle state.

When a conversion is completed (including hardware averaging when AVGS is non-zero), the result is placed in the RESFIFO buffer. When an ADC command selects looping (when LOOP is non-zero) a command will store multiple conversion results to the FIFO during execution of that command.

At the end of command execution, the NEXT field of the command selects the next command to be executed. Multiple commands can be executed sequentially by configuration of each command's NEXT field. Setting the next command to 0x0 causes conversions to terminate at the completion of the command. Unending circular command execution is allowed by setting the NEXT field in the last command in a sequence to the first command in the sequence. It is also allowed for a command to set the next command to itself, resulting in a continuous conversion configuration. Lower priority trigger events cannot be serviced until a higher priority triggered command (or command sequence) completes.

Disabling the ADC by writing 0b0 to the CTRL[ADCEN] bitfield terminates any active ADC command processing. Writing 0b0 to the CTRL[ADCEN] bitfield causes the current command (or command sequence) to terminate, clears any pending triggers, and sends the module to an Idle state.

65.5.5 Pause option

When the maximum conversion rate is not required by an application the effective conversion rate can be reduced by implementing periodic trigger events to initiate ADC conversions or by selecting a reduced frequency clock as the ADACK source. Both of these options are chip specific and are dependent on ADC triggering and clocking options external to the ADC module. The latency associated with ADC analog power up delays results in a limit on the maximum conversion rate when using periodic triggering.

Another means of reducing conversion rates is by inserting a pause of a programmable duration between LOOP iterations, between commands in a sequence, and between conversions when command is executing in the "Compare Until True" configuration. When PAUSE[PAUSEEN] is set, the PAUSE[PAUSEDLY] field controls the duration of pausing during command exection sequencing. The pause delay is a count of (PAUSEDLY*4) ADCK cycles. The PAUSE register cannot be changed while the CTRL[ADCEN] bit is set. Writes to the PAUSE register while CTRL[ADCEN] is set are ignored.

See Figure 65-2 for the places during command execution sequencing where the pause is optionally inserted.

65.5.6 Result FIFO operation

The ADC includes a 16 entry FIFO in which the result of ADC conversions are stored. In addition, a valid indicator bit, the trigger source, the source command and the loop count are also stored along with the data. FCTRL[FCOUNT] indicates how many valid datawords are stored in the RESFIFO.

A programmable watermark threshold supports configurable notification of data availability. When FCOUNT is greater than FCTRL[FWMARK], the STAT[RDY] flag is asserted. When IE[FWMIE] is set, a watermark interrupt request is issued. When DE[FWMDE] is set, a DMA request is issued. Reading RESFIFO provides the oldest unread dataword entry in the FIFO and decrements FCOUNT. When FCOUNT falls equal to or below FWMARK, the RDY flag is cleared.

The FIFO can be emptied by successive reads of RESFIFO. When the RESFIFO[VALID] bit is 1, the associated FIFO entry is valid. Reading RESFIFO when the FIFO is empty (when RESFIFO[VALID] is clear and FCOUNT=0x0) provides an undefined dataword. The FIFO is reset by writing 0b1 to the CTRL[RSTFIFO] bit.

If the ADC attempts to store a dataword to the FIFO when the FIFO is full, the FIFO overflow flag (FCTRL[FOF]) is set. When IE[FOFIE] is set, an overflow interrupt request is issued. The STAT[FOF] flag is cleared by writing 1 to FOF. On overflow events, no new data is stored and the data associated with the store that triggered the overflow is lost, the current ADC command (sequence) is aborted and all pending trigger events are discarded. No new triggers are detected until the overflow flag is cleared.

65.5.7 Compare function

After the input is sampled and converted and any averaging iterations are performed, the CMDH*a*[CMPEN] field guides operation of the automatic compare function to optionally only store when the compare operation is true. There are multiple options on command sequencing related to the compare function as summarized in the table below.

NOTE

Not all Command Buffers have an associated Compare Value register. The compare function is only available on Command Buffers that have a corresponding Compare Value register.

Table 65-8. Compare modes

CMDH*a*[CMPEN]	Compare Function	Description
0b00	Compare disabled	Do not perform compare operation. Always store the conversion result to the FIFO.
0b01	Reserved	
0b10	Store on true	Perform compare operation. Store conversion result to FIFO at end of averaging only if compare is true. If compare is false, do not store the result to the FIFO. In either the true or false condition, the LOOP setting is considered and increments the LOOP counter before deciding whether the current command has completed or additional LOOP iterations are required.
0b11	Repeat compare until true	Perform compare operation. Store conversion result to FIFO at end of averaging only if compare is true. Once the true condition is found the LOOP setting is considered and increments the LOOP counter before deciding whether the current command has completed or additional LOOP iterations are required. If the compare is false do not store the result to the FIFO. The conversion is repeated without consideration of LOOP setting and does not increment the LOOP counter.

Depending on CV*a*[CVH] and CV*a*[CVL] values programmed, the compare operation checks whether the result is less than, greater than, or if the result falls within or outside a range determined by two compare values. The compare values are used as described in the following table.

Table 65-9. Compare operations

CV*a*[CVL] vs. CV*a*[CVH]	Operation	Description
set CVL < CVH	Outside range (General form)	Compare true if the result is less than CVL value or greater than CVH value.
set CVH to max value set CVL to compare point	Less than	Compare true if the result is less than CVL value.
set CVL to min value set CVH to compare point	Greater than	Compare true if the result is greater than CVH value.

Table continues on the next page...

Table 65-9. Compare operations (continued)

CV*a*[CVL] vs. CV*a*[CVH]	Operation	Description
set CVL > CVH	Inside range	Compare true if the result is less than CVL value and greater than CVH value.

Note

In low power modes where the ADC continues to operate, the compare function can monitor the voltage and only wake the device when the compare condition is met.

Chapter 66
Digital to Analog Converter (DAC)

66.1 Chip-specific DAC information

Table 66-1. Reference links to related information

66.1.1 Digital to Analog Converter (DAC)

The DAC is the 12-bit resolution digital-to-analog converters with programmable reference generator output. The output of the DAC can be placed on an external pin or set as one of the inputs to the analog comparator or ADC. The DAC is capable of achieving 1 microsecond conversion rate for high speed signal and 2 microsecond conversion rate for low speed signal. The following table shows the configuration of the DAC.

Table 66-2. DAC configuration

Parameter	Description
Name	Digital to Analog Converter (DAC)
Instances	2
Configurable features	NA
Interface speed	NA
External I/O pins	DAC_OUT

66.1.2 DAC reference sources

The CR[DACRFS] bit selects the two possible reference sources, DACREF_1 or DACREF_2.

- When DACRFS =0b (DACREF_1), the reference voltage is VREFH_ANA18.
- When DACRFS =1b (DACREF_2), the reference voltage, is VDD_ANA18.

See the register section for details.

NOTE

If DAC is required to have conversion in VLPS or VLLS mode, the bias from PMC 0 needs to be enabled. Bias are enabled from PMC by setting VLPS[FBGHP] bitfield for VLPS mode and VLLS[FBGHP] bitfield for VLLS mode in the PMC 0 register. See PMC register descriptions for details.

66.2 Introduction

The 12-bit digital-to-analog converter (DAC) is a low-power, general-purpose DAC. The output of the DAC can be placed on an external pin or set as one of the inputs to the analog comparator, op-amps, or ADC.

66.3 Features

The features of the DAC module include:

- On-chip programmable reference generator output. The voltage output range is from 1⁄4096 V_{in} to V_{in}, and the step is 1⁄4096 V_{in}, where V_{in} is the input voltage.
- V_{in} can be selected from two reference sources
- 16 -word data buffer supported with configurable watermark and multiple operation modes
- DMA support

66.4 Block diagram

The block diagram of the DAC module is as follows:

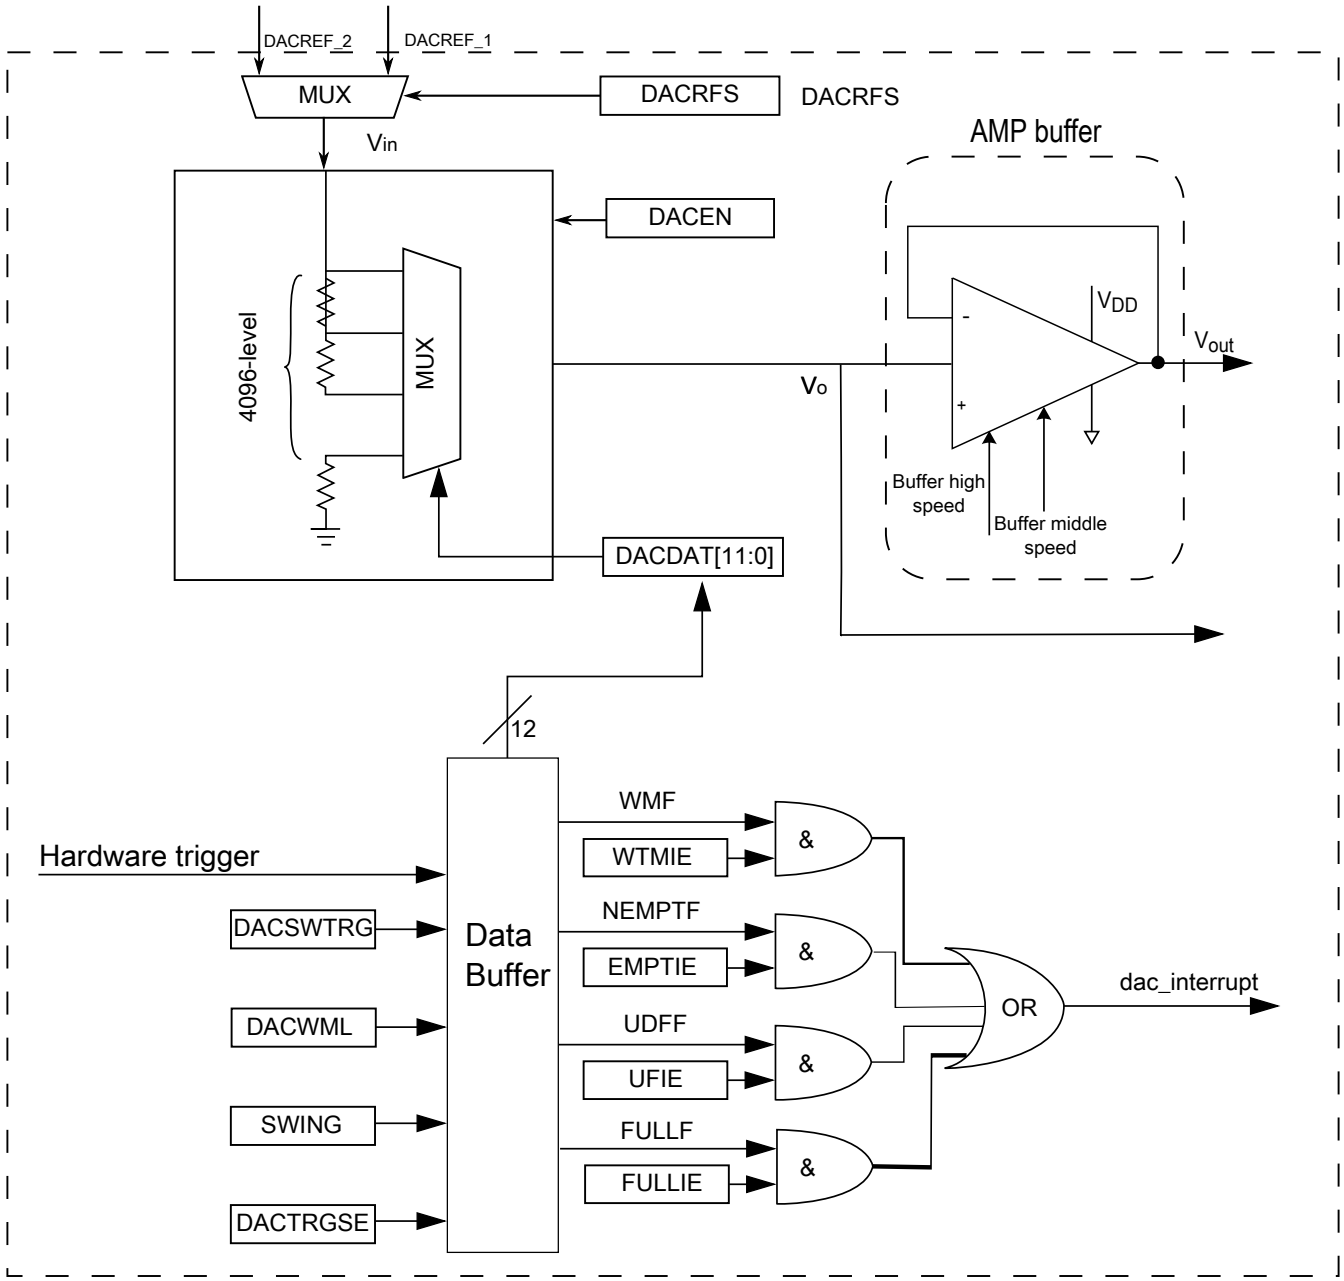

Figure 66-1. DAC block diagram

66.5 Memory map/register definition

The DAC has registers to control analog comparator and programmable voltage divider to perform the digital-to-analog functions.

66.5.1 DAC register descriptions

66.5.1.5.3 Fields

Field	Function
31-24 WML	Watermark Level Select MAX is the FIFO size. **NOTE:** If the FIFO depth is 2, then all settings are treated the same. That is, if the FIFO is not full, the watermark status bit and NEMPTF will be set. One of the status bits maybe needed for DMA or IRQ request.
23 DMAEN	DMA Enable Select 0b - DMA is disabled. 1b - DMA is enabled. When DMA is enabled, the DMA request will be generated by original interrupts. The interrupts will not be presented on this module at the same time.
22 SWRST	Software reset Resets all internal logic and registers, in case of any failure during the Low-power mode. This field is written to only to trigger reset, self clear, or read 0.

Table continues on the next page...

Field	Function
21 FIFORST	FIFO Reset Resets the FIFO pointers. Reading this field will always return zero. FIFO pointers should only be reset when the DAC is disabled. This field can be used to configure both pointers to the same address to reset the FIFO as empty. This field is written to only to trigger reset, self clear, or read zero. 0b - No effect 1b - FIFO reset
20-19 —	Reserved
18 UVIE	Underflow and overflow interrupt enable 0b - Underflow and overflow interrupt is disabled. 1b - Underflow and overflow interrupt is enabled.
17 SWMD	DAC FIFO Mode Select In Swing back mode, the FIFO must be set up such that the FIFO is full. In Swing back mode, a trigger changes the read pointer to make it swing between the FIFO Full and Nearly Empty state. That is, the trigger increases the read pointer till FIFO is nearly empty and decreases the read pointer till the FIFO is full, and so on. 0b - Normal mode 1b - Swing back mode
16 FIFOEN	FIFO Enable 0b - FIFO is disabled and only one level buffer is enabled. Any data written from this buffer goes to conversion. 1b - FIFO is enabled. Data will first read from FIFO to buffer then go to conversion.
15 DACEN	DAC Enable Starts the Programmable Reference Generator operation. 0b - The DAC system is disabled. 1b - The DAC system is enabled.
14 DACRFS	DAC Reference Select 0b - The DAC selects DACREF_1 as the reference voltage. 1b - The DAC selects DACREF_2 as the reference voltage.
13 TRGSEL	DAC Trigger Select 0b - The DAC hardware trigger is selected. 1b - The DAC software trigger is selected.
12 SWTRG	DAC Software Trigger Active high. This is a write-only field, which always reads 0. If DAC software trigger is selected and FIFO is enabled, writing 1 to this field will advance the FIFO read pointer once. **NOTE:** It is not suggested to adopt hardware trigger and software trigger in mixed use, during continuous conversions. 0b - The DAC soft trigger is not valid. 1b - The DAC soft trigger is valid.
11 —	Reserved
10 WTMIE	Watermark Interrupt Enable 0b - Watermark interrupt is disabled. 1b - Watermark interrupt is enabled.
9 EMPTIE	Nearly Empty Interrupt Enable 0b - FIFO Nearly Empty interrupt is disabled. 1b - FIFO Nearly Empty interrupt is enabled.
8	Full Interrupt Enable

Table continues on the next page...

Field	Function
FULLIE	0b - FIFO Full interrupt is disabled. 1b - FIFO Full interrupt is enabled.
7-5 —	Reserved
4 OVFF	Overflow Flag This is the FIFO overflow status flag. This flag indicates that more data has been written into FIFO than it can hold. This field asserts regardless of the value of UVIE. However, an interrupt is issued to the host only if UVIE is set. This flag is cleared by writing a 1 to it. 0b - No overflow has occurred since the last time the flag was cleared. 1b - At least one FIFO overflow has occurred since the last time the flag was cleared.
3 UDFF	Underflow Flag This is the FIFO underflow status flag. If this field is set, it means that there is a new trigger after NEMPTF is set. This field asserts regardless of the value of UVIE. However, an interrupt is issued to the host only if UVIE is set. This flag is cleared by writing a 1 to it. 0b - No underflow has occurred since the last time the flag was cleared. 1b - At least one trigger underflow has occurred since the last time the flag was cleared.
2 WMF	FIFO Watermark Status Flag This field is set if the remaining FIFO data is less than or equal to the watermark setting. It is cleared automatically by writing data into FIFO by DMA or CPU. Write to this bit is ignored in FIFO mode. 0b - The DAC buffer read pointer has not reached the watermark level. 1b - The DAC buffer read pointer has reached the watermark level.
1 NEMPTF	Nearly Empty Flag This is the FIFO nearly empty flag. It is set when only one data remains in FIFO. 0b - More than one data is available in the FIFO. 1b - One data is available in the FIFO.
0 FULLF	Full Flag This is the FIFO Full status bit. This means that the FIFO read pointer equals the write pointer, because of the write pointer increase. This field is cleared if any DAC trigger is making the DAC read pointer increase. Any write to this field is ignored in FIFO mode. 0b - FIFO is not full. 1b - FIFO is full.

66.6 Functional description

The 12-bit DAC module can select one of the two reference inputs—DACREF_1 and DACREF_2 as the DAC reference voltage, V_{in} by STATCTRL [DACRFS]. See the chip-specific DAC information to determine the source options for DACREF_1 and DACREF_2.

When the DAC is enabled, it converts the data in DACDAT0[11:0] or the data from the DAC data buffer to a stepped analog output voltage. The output voltage range is from V_{in} to $V_{in}/4096$, and the step is $V_{in}/4096$.

66.6.1 FIFO mode

In FIFO mode, the buffer is organized as a FIFO. For a valid write to any DATA register, the data is put into the FIFO, and the write pointer is automatically incremented. The module is connected internally to a 32-bit interface. For any 16-bit or 8-bit FIFO access, address bit[1] needs to be 0; otherwise, the write is ignored. A successful 32-bit FIFO write increases the write pointer by one.

For an 8-bit write, the LSB determines which byte lane is written to. Only if both the byte lanes are written to, will the write pointer increase. The user needs to ensure that an 8-bit access is done in pair, and both the upper and lower bytes are written. There is no priority for which byte is written to first.

FIFO mode needs to be enabled with DACCR[FIFOEN].

66.6.2 DAC data buffer operation

When the DAC FIFO is disabled, and the one entry buffer is enabled, the DAC converts the data in the buffer to analog output voltage. Any write to the DATA register will replace the data in the buffer and push data to analog conversion without trigger support.

When the IP interface bus access (IPS) is in write state, the write speed of DATA[DATA0] is high. However, the analog part of the DAC cannot convert data at the same speed. Therefore, the multi write speed limit needs to be defined in the firmware.

66.6.3 DAC interrupts

There are several interrupts and associated flags that can be configured for the DAC buffer.

FIFO request flag

The FIFO request flag is set based on the number of entries in the FIFO and the FIFO watermark configuration. This flag is set when the number of entries in any of the enabled FIFOs is less than or equal to the FIFO watermark configuration and is automatically cleared when the number of entries in FIFO is greater than the FIFO watermark configuration. The FIFO request flag can generate an interrupt or a DMA request.

FIFO warning flag

The FIFO warning flag is set based on the number of entries in the FIFO. The empty flag and full flags are both warning flags. The FIFO warning flag can generate an interrupt (for empty flag only).

FIFO error flag

The FIFO error flag is set when overflow and underflow happens.

66.6.4 DMA operation

When DMA is enabled, DMA requests are generated instead of interrupt requests. The DMA Done signal clears the DMA request.

The status register flags are still set and are cleared automatically when the DMA completes.

66.6.5 Resets

During reset, the DAC is configured in the default mode and is disabled.

66.6.6 Low-Power mode operation

The following table shows the wait mode and the stop mode operation of the DAC module.

Table 66-3. Modes of operation

Modes of operation	Description
Wait mode	The DAC will operate normally, if enabled.
Stop mode	If enabled, the DAC module continues to operate normally, with the hardware trigger initiating the conversion.

NOTE

The assignment of module modes to core modes is chip-specific. For module-to-core mode assignments, see the chapter that describes how modules are configured.

66.6.7 Background Debug Mode Operation

When the microcontroller is in active background debug mode, the CMP continues to operate normally.

Chapter 67
Analog Comparator (ACMP)

67.1.1 Comparator (CMP)

The Comparator module provides a circuit for comparing two analog input voltages. The comparator circuit is designed to operate across the full range of the supply voltage (rail-to-rail operation). The following table shows the configuration of the CMP. The CMP digital wrapper is in the always-on DGO power domain.

Table 67-2. CMP configuration

Parameter	Description
Name	Comparator (CMP)
Instances	2
Configurable features	NA
Interface speed	NA
External I/O pins	See the IOMUXC sheet for pin details

67.1.2 CMP trigger options

On i.MX 7ULP, CMP trigger sources get routed through TRIGMUX module. To know about the input and output trigger options for CMP0 and CMP1, see Table 38-2

67.1.3 CMP voltage reference options

The table below shows supply voltage reference options that can be selected through C1[VRSEL] field in CMP0 and CMP1.

CMP instance	Pin name	VRSEL bit value	Voltage reference source
CMP0	vref1_ana18	VRSEL = 1b	PMC's 1.8V supply VDD_PMC18
	vref0_ana18	VRSEL = 0b	PMC's 1.3V reference
	vrefl_1p8		Global Ground
CMP1	vref1_ana18	VRSEL = 1b	PMC's 1.8V supply VDD_PMC18
	vref0_ana18	VRSEL = 0b	PMC's 1.3V reference
	vrefl_1p8		Global Ground

NOTE

The comparator internal reference needs to be enabled by setting PMC0_ACTRL[BUFEN] bitfield. Before use, in VLPS or VLLS mode, the reference voltage needs to be enabled in PMC 0 by setting VLPS[FBGHP] bitfield for VLPS mode and VLLS[FBGHP] bitfield for VLLS mode. See register description in the PMC chapter.

67.1.4 CMP input connections

To know about the input connections for CMP0 and CMP1, see the "CMP Sources" tab of the IOMUXC spreadsheet attached with this reference manual.

67.2 Introduction

The comparator (CMP) module provides a circuit for comparing two analog input voltages. The comparator circuit is designed to operate across the full range of the supply voltage, known as rail-to-rail operation.

The Analog MUX (ANMUX) provides a circuit for selecting an analog input signal from eight channels. One signal is provided by the 8-bit digital-to-analog converter (DAC). The mux circuit is designed to operate across the full range of the supply voltage.

The DAC is a 256-tap resistor ladder network that provides a selectable voltage reference for applications requiring a voltage reference. The 256-tap resistor ladder network divides the supply reference V_{in} into 256 voltage levels. A 8-bit digital signal input selects the output voltage level, which varies from V_{in} to $V_{in}/256$. V_{in} can be selected from two voltage sources, V_{in1} and V_{in2}.

67.3 Features

The following subsections list the features of the CMP, the DAC, and the ANMUX.

67.3.1 CMP features

The CMP has the following features:

- Operational over the entire supply range
- Inputs may range from rail to rail
- Programmable hysteresis control
- Selectable interrupt on rising-edge, falling-edge, or both rising or falling edges of the comparator output
- Selectable inversion on comparator output
- Capability to produce a wide range of outputs such as:
  - Sampled
  - Windowed, which is ideal for certain PWM zero-crossing-detection applications
  - Digitally filtered:
    - Filter can be bypassed
    - Can be clocked via external SAMPLE signal or scaled bus clock
- External hysteresis can be used at the same time that the output filter is used for internal functions
- Two software selectable performance levels:

    - Shorter propagation delay at the expense of higher power
    - Low power, with longer propagation delay
- DMA transfer support
    - A comparison event can be selected to trigger a DMA transfer
- Functional in all MCU power modes
- The window and filter functions are not available in STOP modes
- The comparator can be triggered by other peripherals to work for only a small fraction of the time

67.3.2 8-bit DAC key features

The 8-bit DAC has the following features:

- 8-bit resolution
- Selectable supply reference source
- Configurable low power mode or high speed mode
- Power Down mode to conserve power when not in use
- Option to route the output to internal comparator input

67.3.3 ANMUX key features

The ANMUX has the following features:

- Two 8-to-1 channel MUXes
- Operational over the entire supply range

67.4 CMP, DAC, and ANMUX diagram

The following figure shows the block diagram for the High-Speed Comparator, DAC, and ANMUX modules.

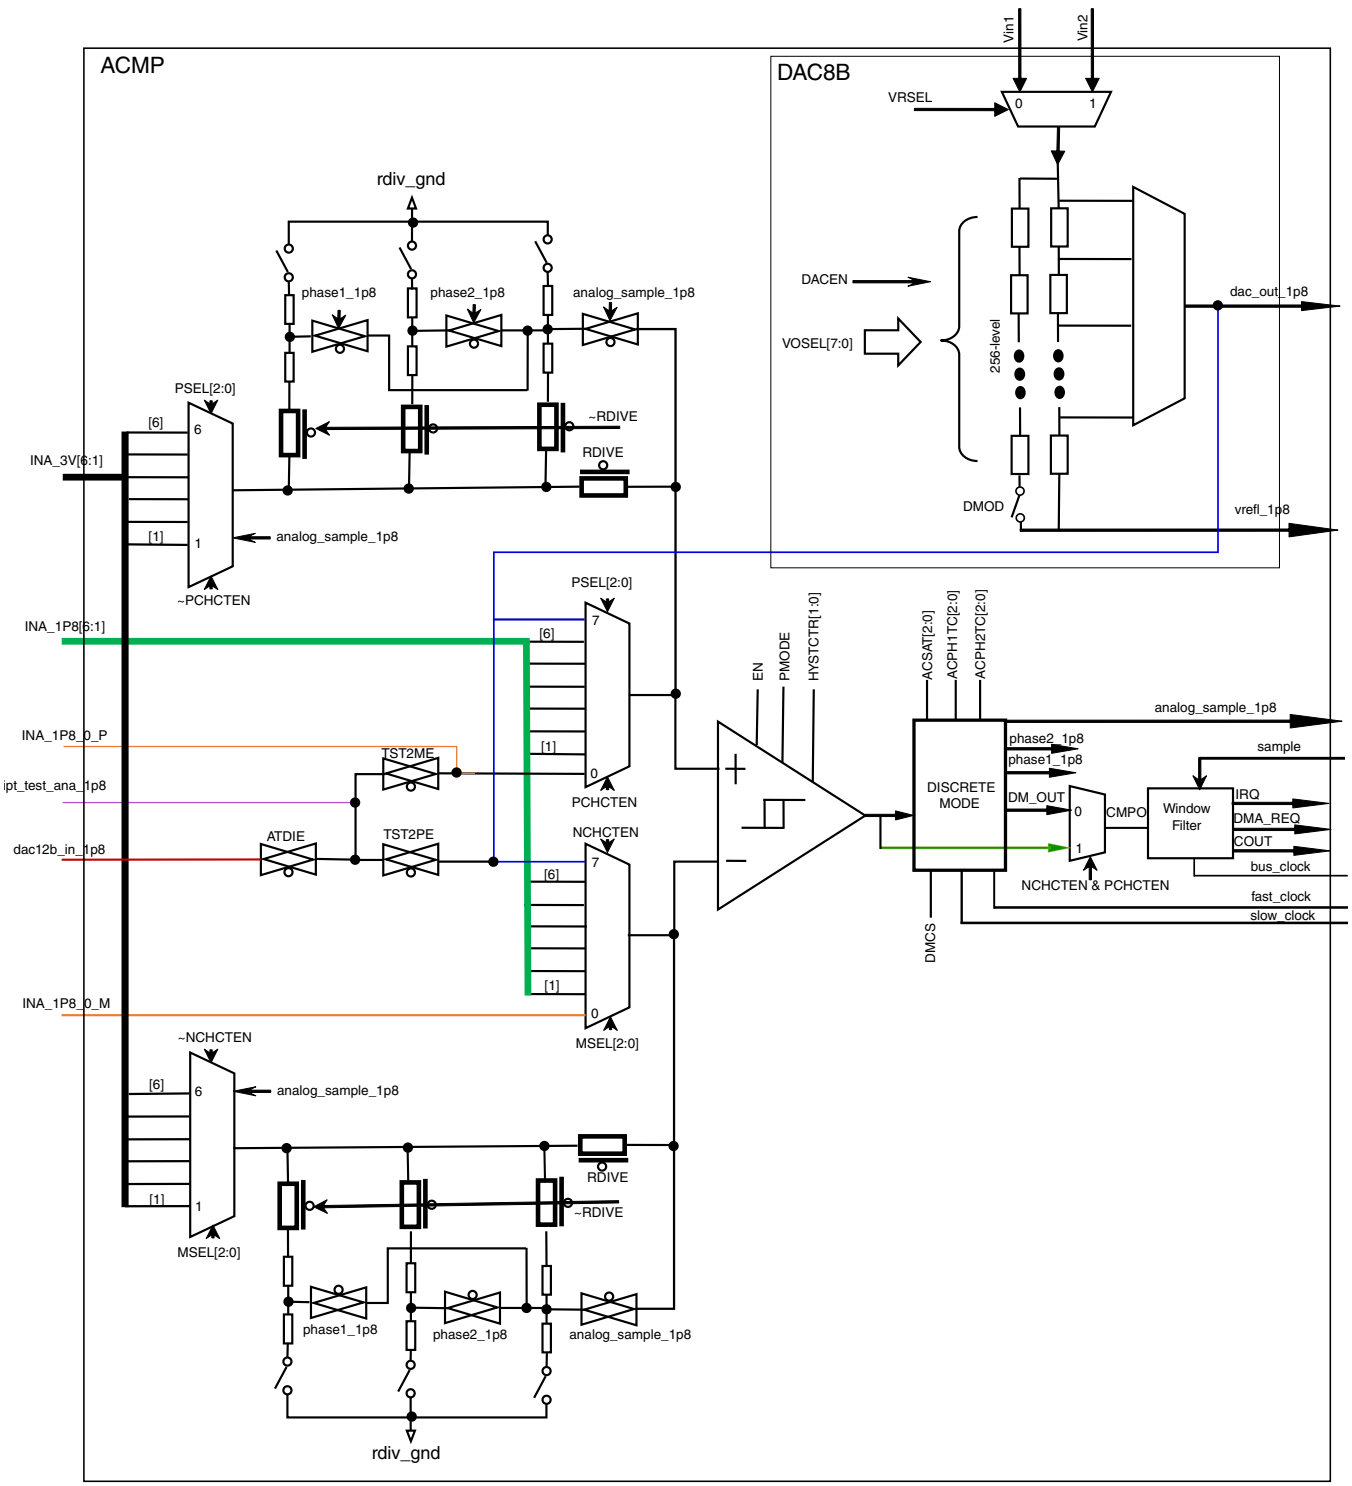

Figure 67-1. CMP high level diagram

67.5 CMP block diagram

The following figure shows the block diagram for the CMP module.

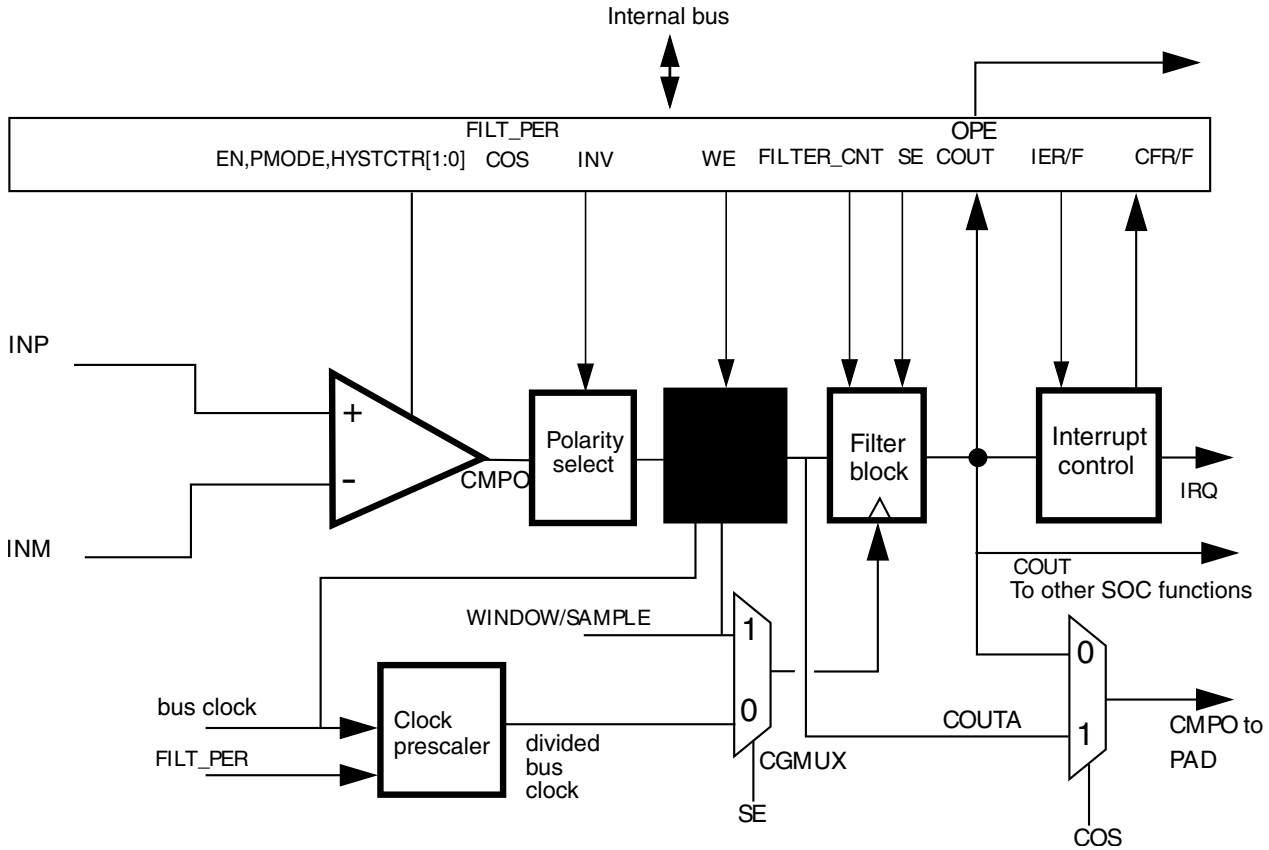

Figure 67-2. Comparator module block diagram

In the CMP block diagram:

- The Window Control block is bypassed when C0[WE] = 0.
- If C0[WE] = 1, the comparator output is sampled on every bus clock when WINDOW=1 to generate COUTA. Sampling does NOT occur when WINDOW = 0.
- The Filter block is bypassed when not in use.

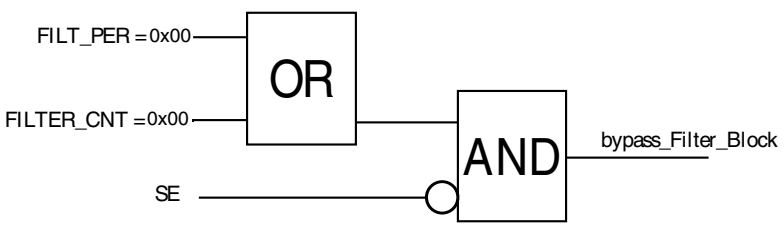

Figure 67-3. Filter block bypass logic

- The Filter block acts as a simple sampler if the filter is bypassed and C0[FILTER_CNT] is set to 0x01.
- The Filter block filters based on multiple samples when the filter is bypassed and C0[FILTER_CNT] is set greater than 0x01.

  - If C0[SE] = 1, the external SAMPLE input is used as the sampling clock.
  - IF C0[SE] = 0, the divided bus clock is used as the sampling clock.
- If enabled, the Filter block will incur up to one bus clock additional latency penalty on COUT due to the fact that COUT, which crosses clock domain boundaries, must be resynchronized to the bus clock.
- C0[WE] and C0[SE] are mutually exclusive.
- If enabled, the filter clock and the sample period must be at least 4 times slower than the system clock to the comparator.

67.6 CMP pin descriptions

This section provides the comparator pin descriptions. The external 3V domain inputs INA_3V[6:1] and 1.8V domain INA_1P8[6:1], INA_1P8_0_P, INA_1P8_0_M are muxed by CMP_C1[PSEL] and CMP_C1[MSEL] before going to the positive and negative ports of the comparator respectively.

Table 67-3. CMP signal descriptions

Signal	Description	I/O
INA_3V[6:1]	The 3V domain analog inputs[6:1]	I
INA_1P8[6:1]	Analog 1.8V input channels [6:1].	I
INA_1P8_0_P	Analog 1.8V input channel 0 positive.	I
INA_1P8_0_m	Analog 1.8V input channel 0 minus.	I

NOTE

It is not recommended to compare 3V domain channel with 1.8V domain channel. If the 3V domain channel's voltage is smaller than 1.8V, in this case, it can be compared with 1.8V domain channel by setting C3[RDIVE] to 0.

67.6.1 External pins

The CMP has two analog inputs: INP and INM. Each of these pins can accept an input voltage that varies across the full operating range of the MCU. If the module is not enabled, each pin can be used as a digital input or output. Consult the specific MCU documentation to determine what functions are shared with these analog inputs.

The user can select either filtered or unfiltered comparator outputs for use on an external I/O pad.

67.7 CMP functional modes

There are three main sub-blocks to the CMP module:

- The comparator itself
- The window function
- The filter function

The filter, CMP_C0[FILTER_CNT], can be clocked from an internal or external clock source. The filter is programmable with respect to the number of samples that must agree before a change in the output is registered. In the simplest case, only one sample must agree. In this case, the filter acts as a simple sampler.

The external sample input is enabled using CMP_C0[SE]. When set, the output of the comparator is sampled only on rising edges of the sample input.

The "windowing mode" is enabled by setting CMP_C0[WE]. When set, the comparator output is sampled only when WINDOW=1. This feature can be used to ignore the comparator output during time periods in which the input voltages are not valid. This is especially useful when implementing zero-crossing-detection for certain PWM applications.

The comparator filter and sampling features can be combined as shown in the following table. Individual modes are discussed below.

Table 67-4. Comparator sample/filter controls

Mode #	CMP_C0[EN]	CMP_C0[WE]	CMP_C0[SE]	CMP_C0[FILTER_CNT]	CMP_C0[FPR]	Operation
1	0	X	X	X	X	**Disabled** See the Disabled mode (# 1).
2A	1	0	0	0x00	X	**Continuous Mode** See the Continuous mode (#s 2A & 2B).
2B	1	0	0	X	0x00	
3A	1	0	1	0x01	X	**Sampled, Non-Filtered mode** See the Sampled, Non-Filtered mode (#s 3A & 3B).
3B	1	0	0	0x01	> 0x00	
4A	1	0	1	> 0x01	X	**Sampled, Filtered mode**

Table continues on the next page...

Table 67-4. Comparator sample/filter controls (continued)

Mode #	CMP_C0[EN]	CMP_C0[WE]	CMP_C0[SE]	CMP_C0[FILTER_CNT]	CMP_C0[FPR]	Operation
4B	1	0	0	> 0x01	> 0x00	See the Sampled, Filtered mode (#s 4A & 4B).
5A	1	1	0	0x00	X	**Windowed mode** Comparator output is sampled on every rising bus clock edge when SAMPLE=1 to generate COUTA. See the Windowed mode (#s 5A & 5B).
5B	1	1	0	X	0x00	
6	1	1	0	0x01	0x01–0xFF	**Windowed/Resampled mode** Comparator output is sampled on every rising bus clock edge when SAMPLE=1 to generate COUTA, which is then resampled on an interval determined by CMP_C0[FPR] to generate COUT. See the Windowed/Resampled mode (# 6).
7	1	1	0	> 0x01	0x01–0xFF	**Windowed/Filtered mode** Comparator output is sampled on every rising bus clock edge when SAMPLE=1 to generate COUTA, which is then resampled and filtered to generate COUT. See the Windowed/Filtered mode (#7).
8	1	1	1	X	X	**Trigger mode** In RUN mode Comparator is configured to the modes same with these Modes #5A, #5B, #6 and #7 as elaborated in above rows depended on the CMP_C0[FILT_CNT] and CMP_C0[FPR] settings. In STOP mode, the comparator and possible the 8bit DAC is triggered work periodically and the active channels follow the round robin cycling scheme. See the Trigger mode.
All other combinations of CMP_C0[EN], CMP_C0[WE], CMP_C0[SE], CMP_C0[FILTER_CNT], and CMP_C0[FPR] are illegal.						

For cases where a comparator is used to drive a fault input, for example, for a motor-control module such as FTM, it must be configured to operate in Continuous mode so that an external fault can immediately pass through the comparator to the target fault circuitry.

Note

Filtering and sampling settings must be changed only after setting CMP_C0[SE]=0, CMP_C0[FPR] =0 and CMP_C0[FILTER_CNT]=0x00. This resets the filter to a known state.

67.7.1 Disabled mode (# 1)

In Disabled mode, the analog comparator is non-functional and consumes no power. CMPO is 0 in this mode.

67.7.2 Continuous mode (#s 2A & 2B)

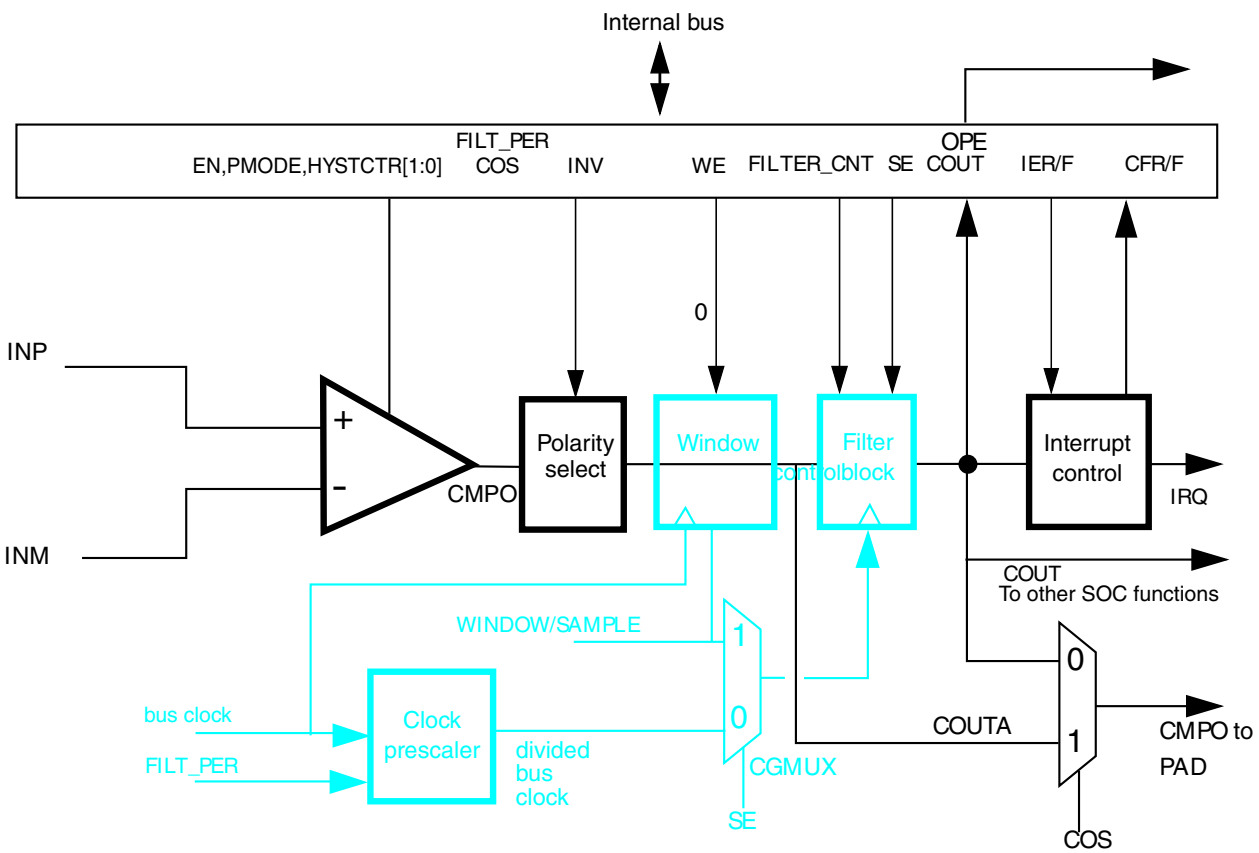

Figure 67-4. Comparator operation in Continuous mode

NOTE

See the chip configuration section for the source of sample/ window input.

The analog comparator block is powered and active. CMPO may be optionally inverted, but is not subject to external sampling or filtering. Both window control and filter blocks are completely bypassed. CMP_C0[COUT] is updated continuously. The path from comparator input pins to output pin is operating in combinational unclocked mode. COUT and COUTA are identical.

For control configurations that result in disabling the filter block, see Figure 67-3.

67.7.3 Sampled, Non-Filtered mode (#s 3A & 3B)

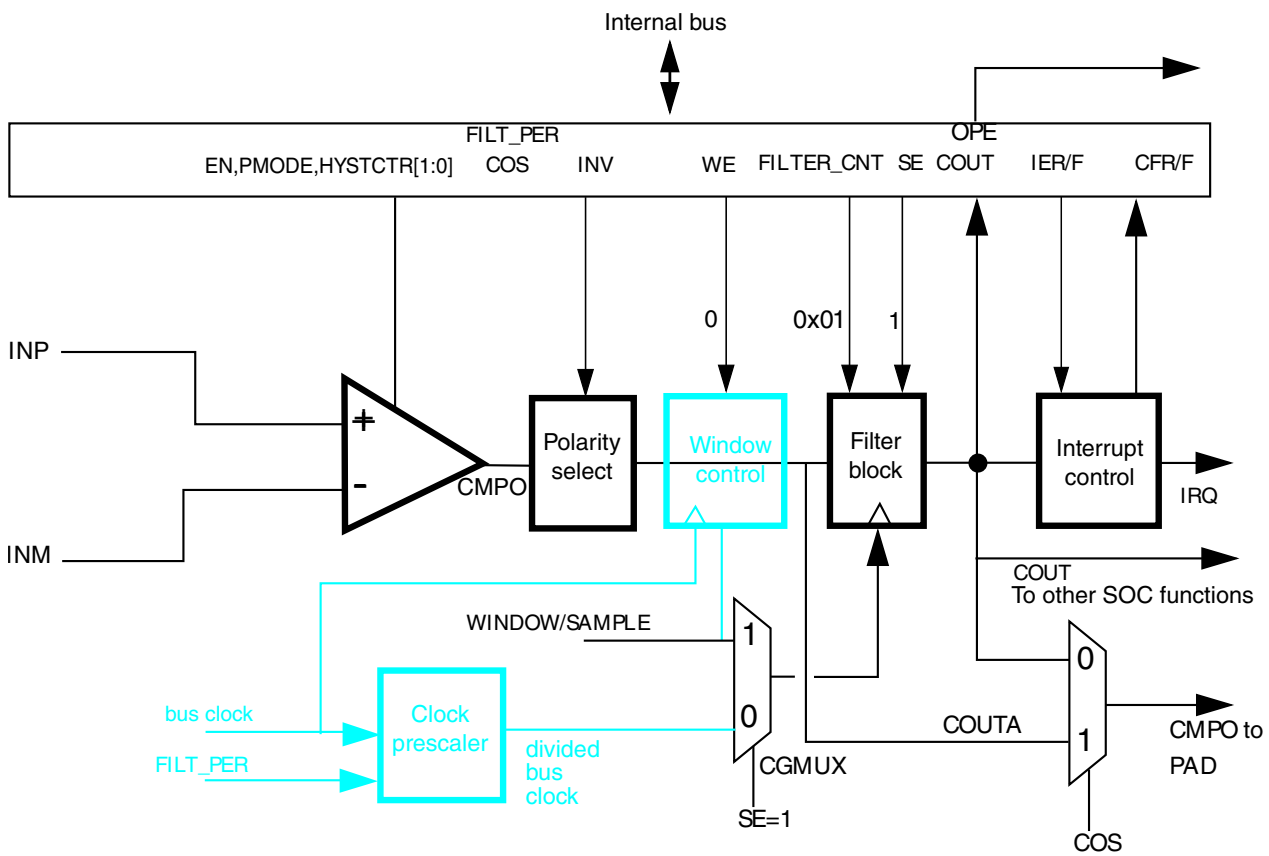

Figure 67-5. Sampled, Non-Filtered (# 3A): sampling point externally driven

In Sampled, Non-Filtered mode, the analog comparator block is powered and active. The path from analog inputs to COUTA is combinational unclocked. Windowing control is completely bypassed. COUTA is sampled whenever a rising edge is detected on the filter block clock input.

The only difference in operation between Sampled, Non-Filtered (# 3A) and Sampled, Non-Filtered (# 3B) is in how the clock to the filter block is derived. In #3A, the clock to filter block is externally derived while in #3B, the clock to filter block is internally derived.

The comparator filter has no other function than sample/hold of the comparator output in this mode (# 3B).

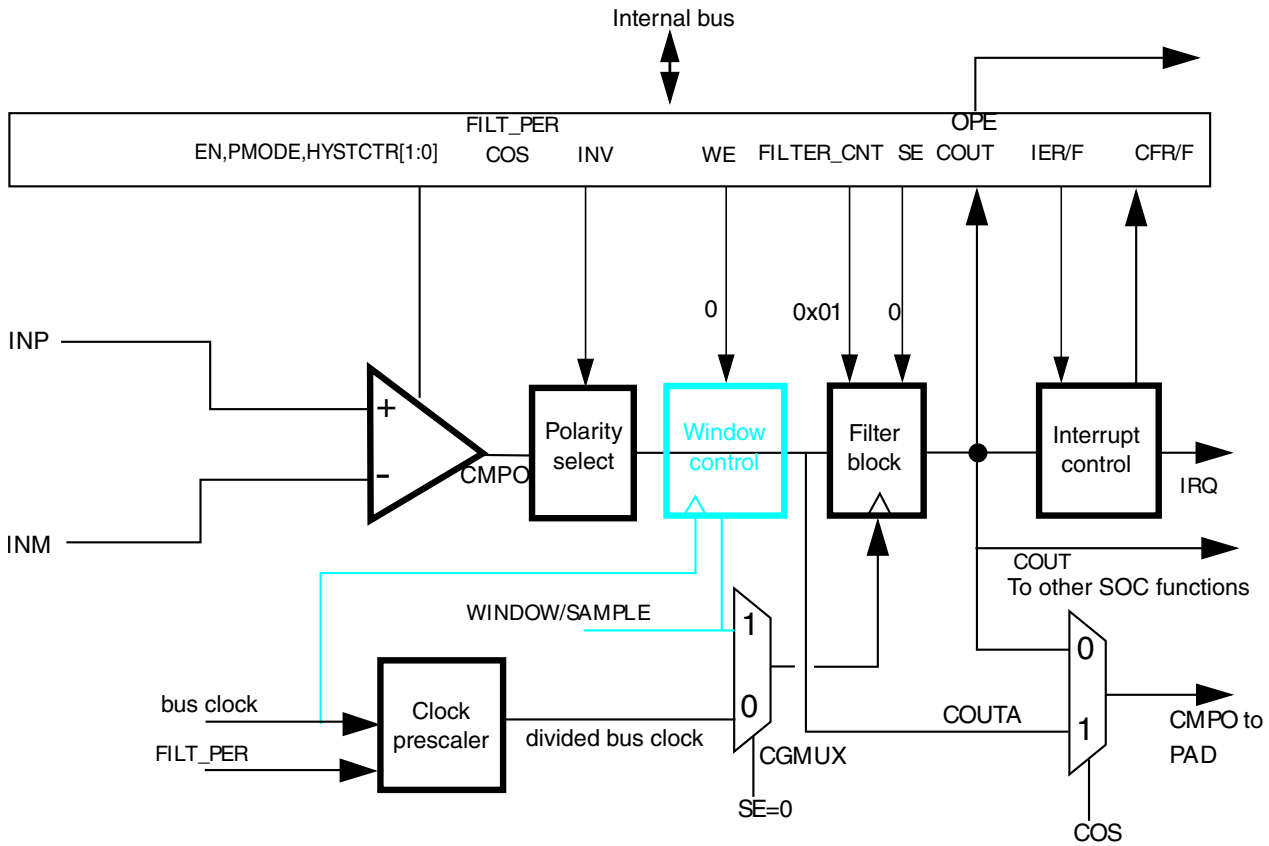

Figure 67-6. Sampled, Non-Filtered (# 3B): sampling interval internally derived

67.7.4 Sampled, Filtered mode (#s 4A & 4B)

In Sampled, Filtered mode, the analog comparator block is powered and active. The path from analog inputs to COUTA is combinational unclocked. Windowing control is completely bypassed. COUTA is sampled whenever a rising edge is detected on the filter block clock input.

The only difference in operation between Sampled, Non-Filtered (# 3A) and Sampled, Filtered (# 4A) is that, now, CMP_C0[FILTER_CNT]>1, which activates filter operation.

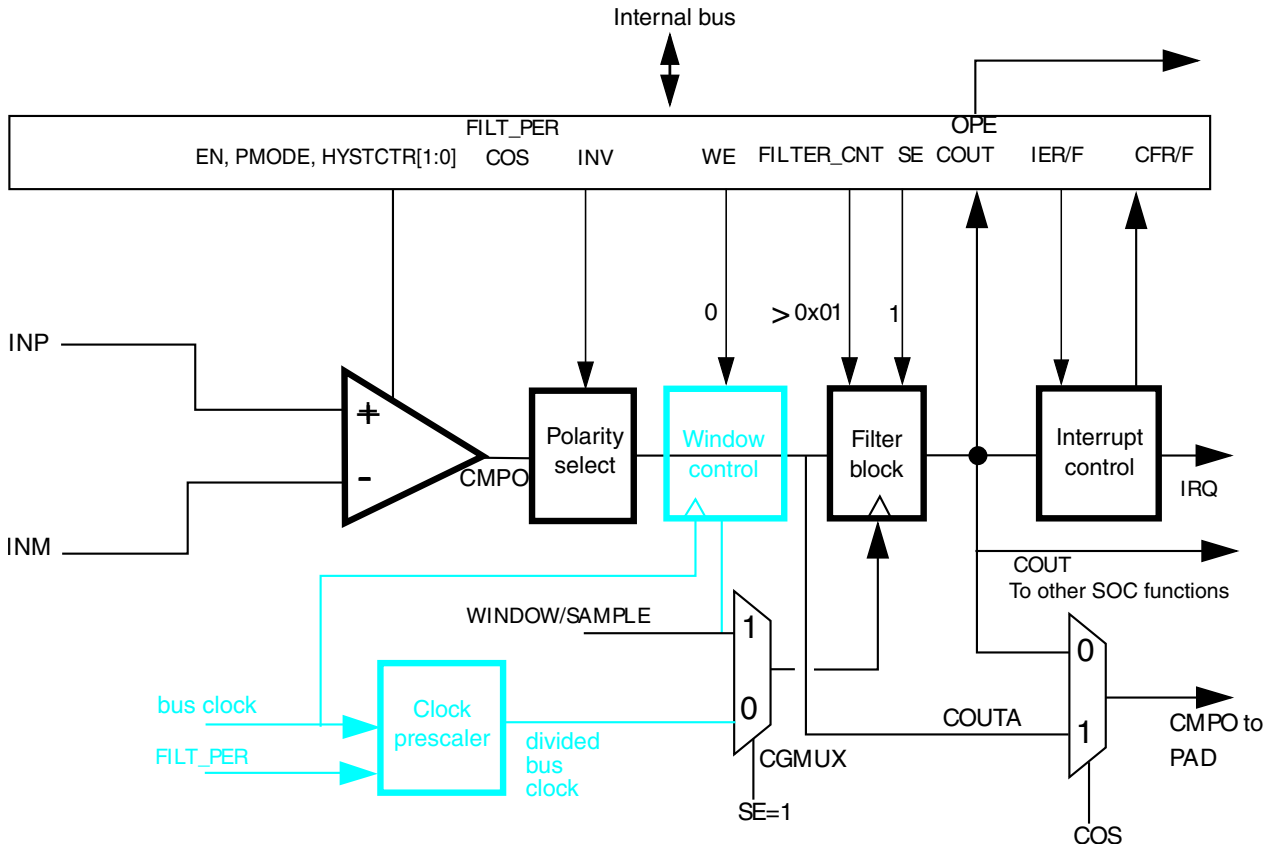

Figure 67-7. Sampled, Filtered (# 4A): sampling point externally driven

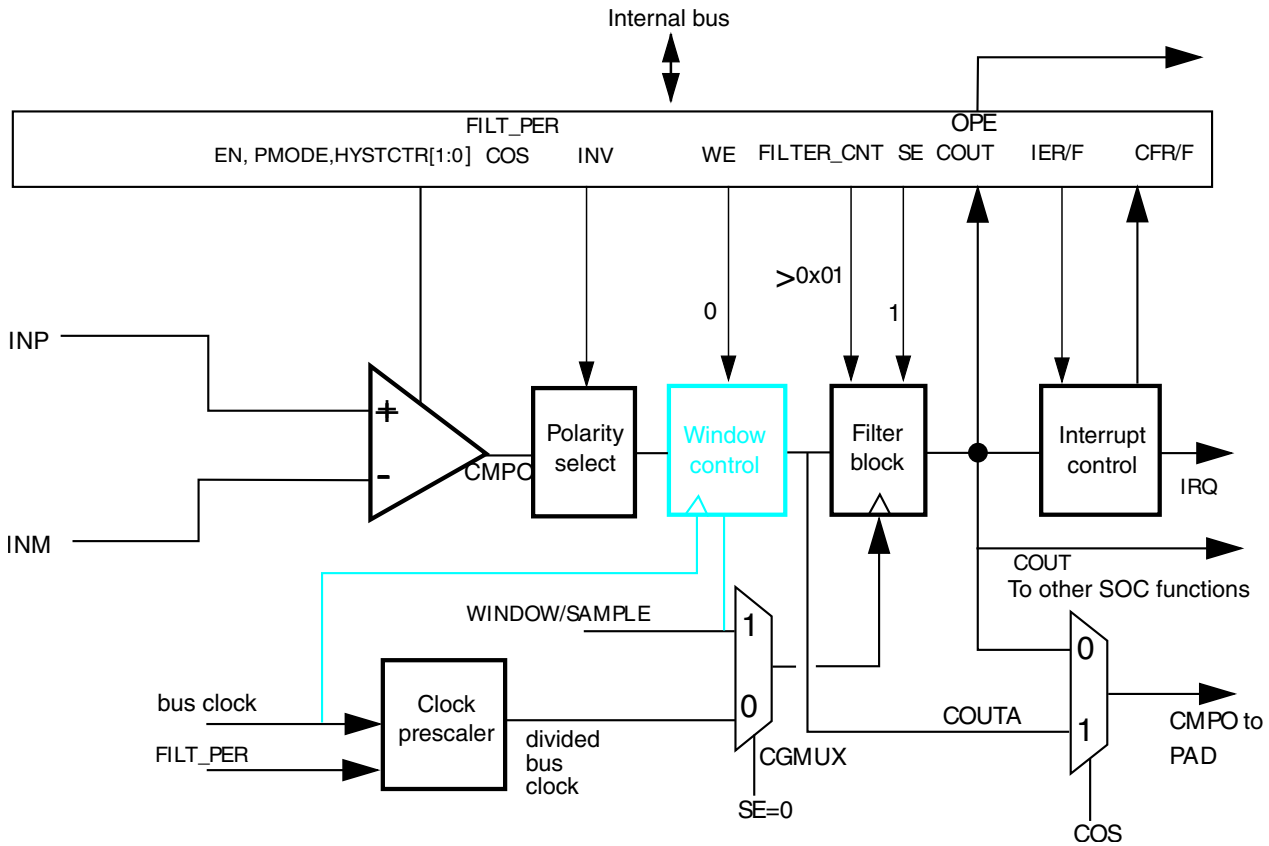

Figure 67-8. Sampled, Filtered (# 4B): sampling point internally derived

The only difference in operation between Sampled, Non-Filtered (# 3B) and Sampled, Filtered (# 4B) is that now, CMP_C0[FILTER_CNT]>1, which activates filter operation.

67.7.5 Windowed mode (#s 5A & 5B)

The following figure illustrates comparator operation in the Windowed mode, ignoring latency of the analog comparator, polarity select, and window control block. It also assumes that the polarity select is set to non-inverting state.

NOTE

The analog comparator output is passed to COUTA only when the WINDOW signal is high.

In actual operation, COUTA may lag the analog inputs by up to one bus clock cycle plus the combinational path delay through the comparator and polarity select logic.

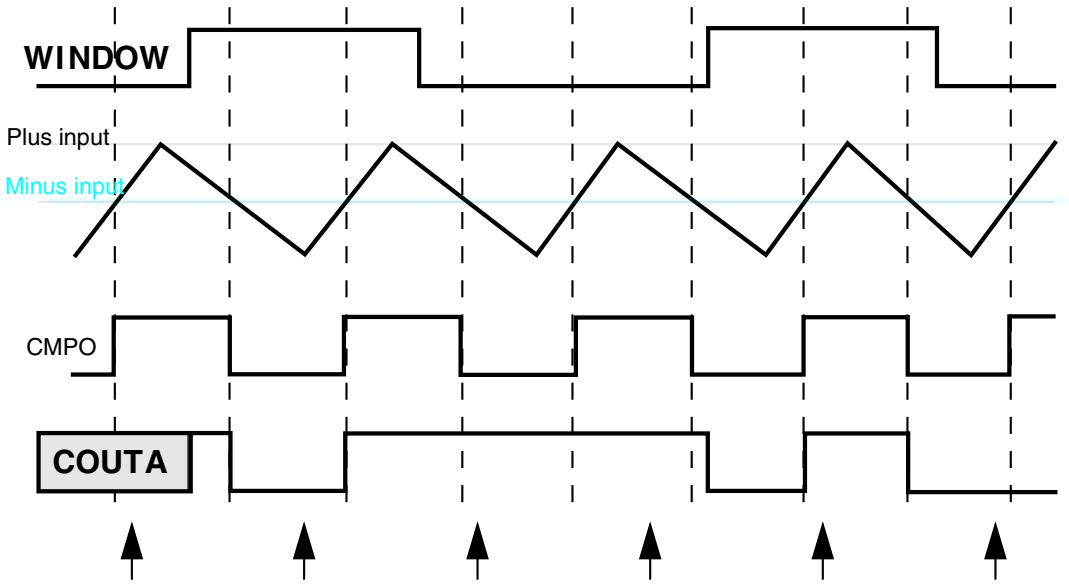

Figure 67-9. Windowed mode timing diagram

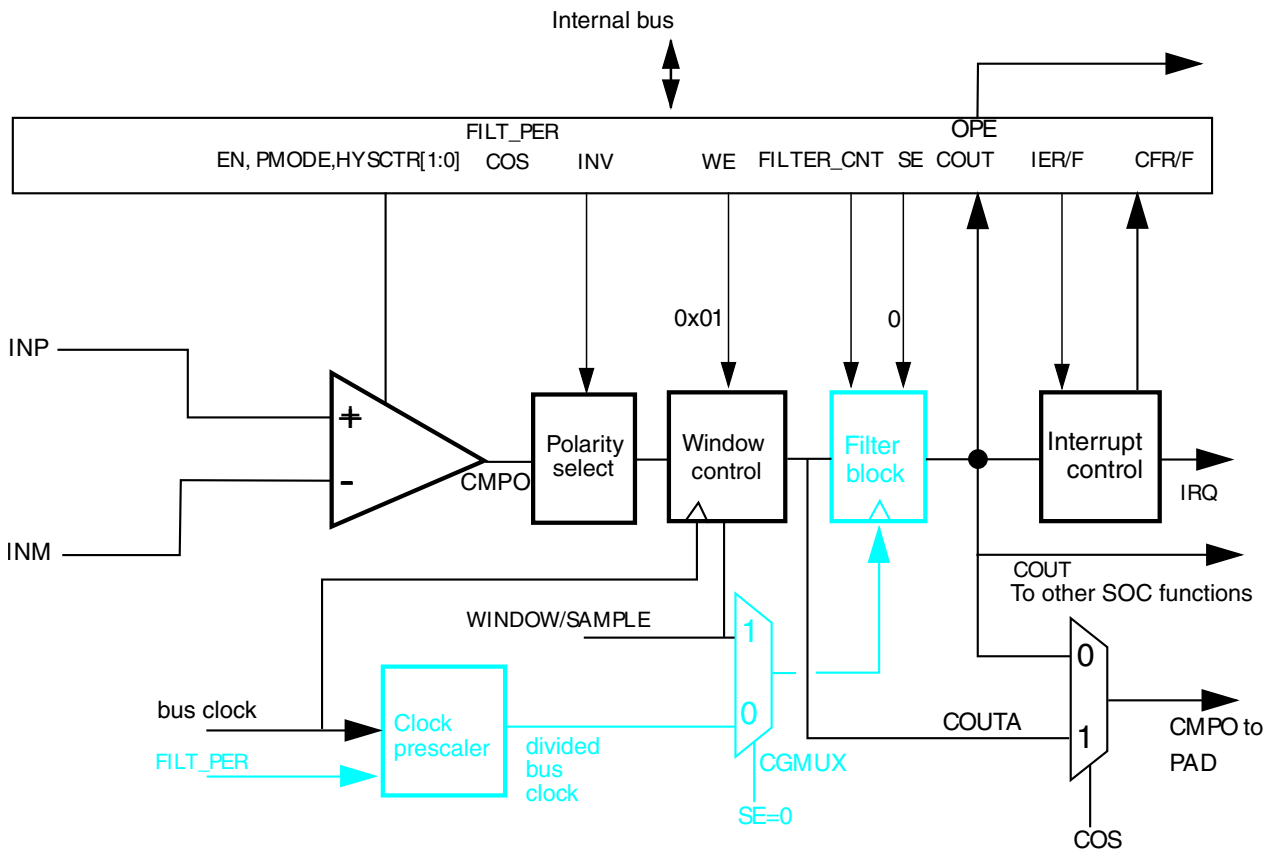

Figure 67-10. Windowed mode

For control configurations which result in disabling the filter block, see Figure 67-3.

When any windowed mode is active, COUTA is clocked by the bus clock whenever WINDOW = 1. The last latched value is held when WINDOW = 0.

67.7.6 Windowed/Resampled mode (# 6)

The following figure uses the same input stimulus shown in Figure 67-9, and adds resampling of COUTA to generate COUT. Samples are taken at the time points indicated by the arrows in the figure. Again, prop delays and latency are ignored for the sake of clarity.

This example was generated solely to demonstrate operation of the comparator in windowed/resampled mode, and does not reflect any specific application. Depending upon the sampling rate and window placement, COUT may not see zero-crossing events detected by the analog comparator. Sampling period and/or window placement must be carefully considered for a given application.

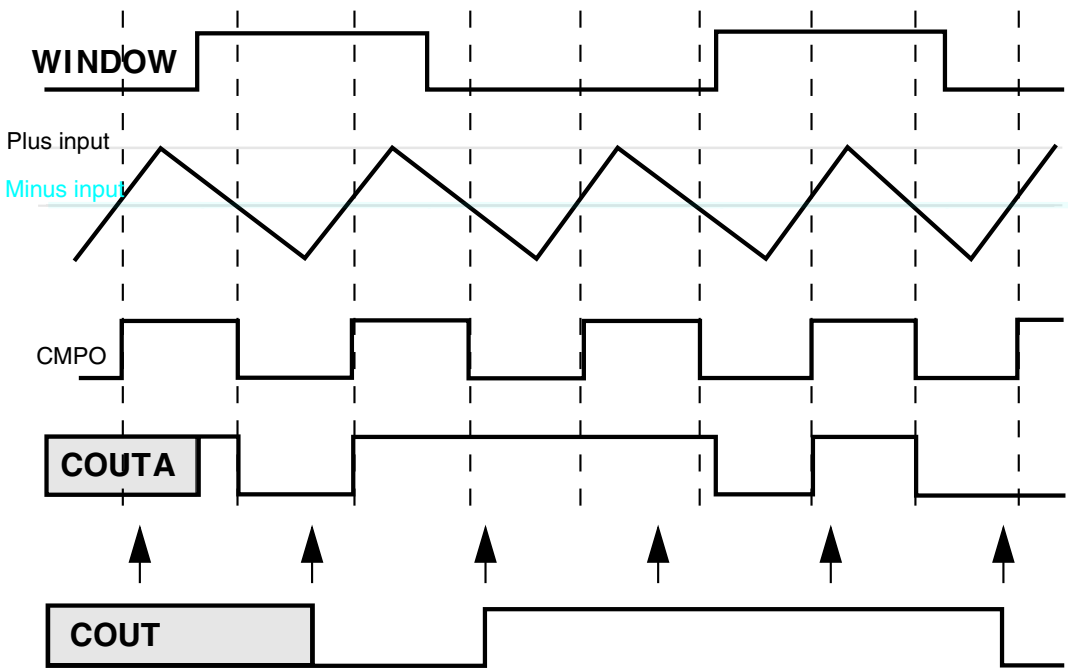

Figure 67-11. Windowed/resampled mode operation

This mode of operation results in an unfiltered string of comparator samples where the interval between the samples is determined by FPR[FILT_PER] and the bus clock rate. Configuration for this mode is virtually identical to that for the Windowed/Filtered Mode shown in the next section. The only difference is that the value of C0[FILTER_CNT] must be 1.

67.7.7 Windowed/Filtered mode (#7)

This is the most complex mode of operation for the comparator block, as it uses both windowing and filtering features. It also has the highest latency of any of the modes. This can be approximated: up to 1 bus clock synchronization in the window function + ((C0[FILTER_CNT] * C0[FPR]) + 1) * bus clock for the filter function.

When any windowed mode is active, COUTA is clocked by the bus clock whenever WINDOW = 1. The last latched value is held when WINDOW = 0.

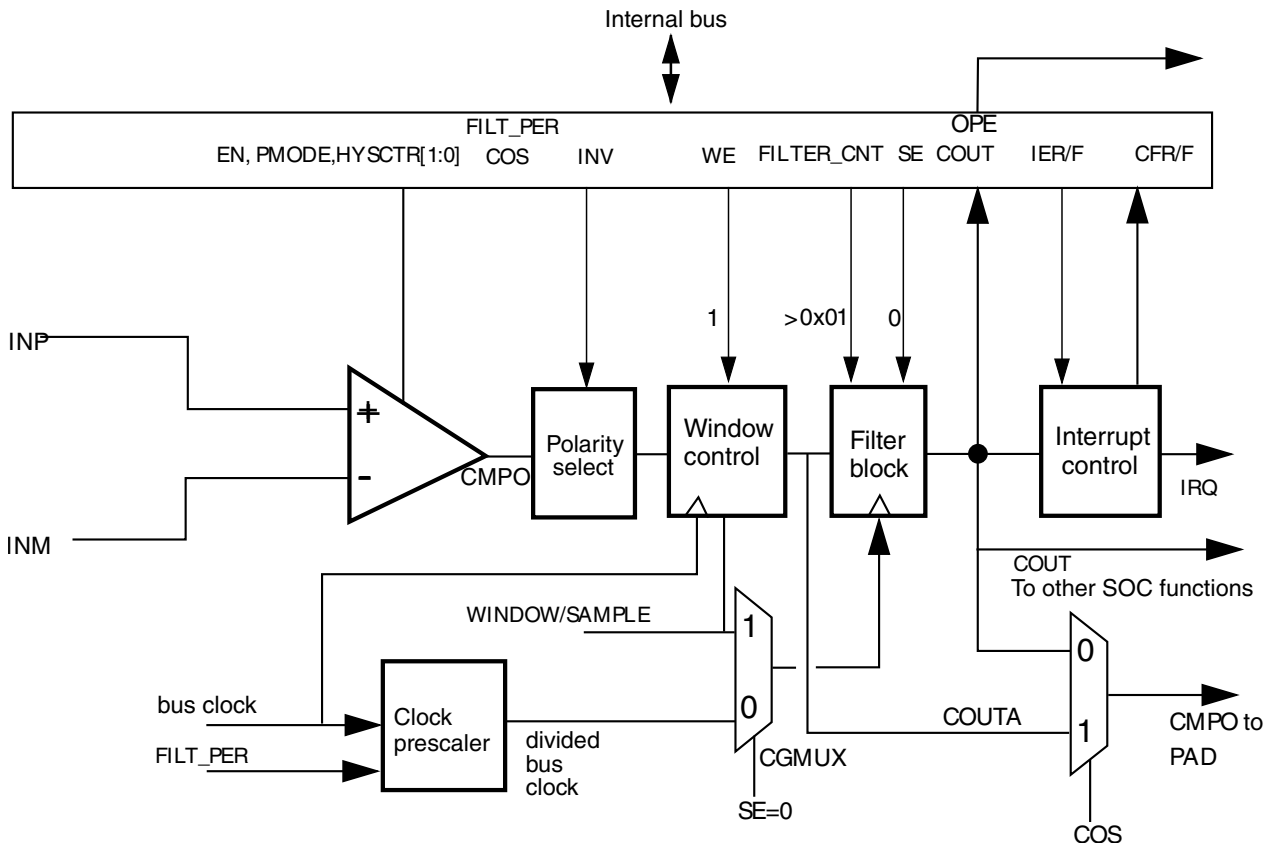

Figure 67-12. Windowed/Filtered mode

67.8.1.4.4 Fields

Field	Function
31 LINKEN	CMP to DAC link enable. This bit is used to enable the link from CMP to DAC enables. When this bit is set, the DAC enable/disable is controlled by CMP_C0[EN] bit instead of CMP_C1[DACEN]. 0b - CMP to DAC link is disabled 1b - CMP to DAC link is enabled.
30 DMAEN	DMA Enable Enables the DMA transfer triggered from the CMP module. When this field and the corresponding interrupt enable bit are set, a DMA request is asserted when CFR or CFF is set. 0b - DMA is disabled. 1b - DMA is enabled.
29 —	Reserved
28 IER	Comparator Interrupt Enable Rising Enables the CFR interrupt from the CMP. When this field is set, an interrupt will be asserted when CFR is set. 0b - Interrupt is disabled. 1b - Interrupt is enabled.
27 IEF	Comparator Interrupt Enable Falling Enables the CFF interrupt from the CMP. When this field is set, an interrupt will be asserted when CFF is set. 0b - Interrupt is disabled. 1b - Interrupt is enabled.
26 CFR	Analog Comparator Flag Rising Detects a rising-edge on COUT, when set, during normal operation. CFR is cleared by writing 1 to it. During Stop modes, CFR is level sensitive 0b - A rising edge has not been detected on COUT. 1b - A rising edge on COUT has occurred.
25 CFF	Analog Comparator Flag Falling Detects a falling-edge on COUT, when set, during normal operation. CFF is cleared by writing 1 to it. During Stop modes, CFF is level senstive . 0b - A falling edge has not been detected on COUT. 1b - A falling edge on COUT has occurred.
24 COUT	Analog Comparator Output Returns the current value of the Analog Comparator output, when read. The field is reset to 0 and will read as C0[INVT] when the Analog Comparator module is disabled, that is, when C0[EN] = 0. Writes to this field are ignored.
23-16 FPR	Filter Sample Period Specifies the sampling period, in bus clock cycles, of the comparator output filter, when C1[SE] = 0. Setting FPR to 0x0 disables the filter. Filter programming and latency details are provided in the CMP functional description. This field has no effect when C0[SE]= 1. In that case, the external SAMPLE signal is used to determine the sampling period.
15 SE	Sample Enable If a write to this register attempts to set both SE and WE, then only Sampling mode is taking effect in MCU Run mode and the Round Robin Cycling(Trigger Mode) is enabled in MCU STOP mode. 0b - Sampling mode is not selected. 1b - Sampling mode is selected.

Table continues on the next page...

Field	Function
14 WE	Windowing Enable If a write to this register attempts to set both SE and WE, then only Sampling mode is taking effect in MCU Run mode and the Round Robin Cycling(Trigger Mode) is enabled in MCU STOP mode. 0b - Windowing mode is not selected. 1b - Windowing mode is selected.
13 —	Reserved
12 PMODE	Power Mode Select 0b - Low Speed (LS) comparison mode is selected. 1b - High Speed (HS) comparison mode is selected.
11 INVT	Comparator invert This bit allows selecting the polarity of the analog comparator function. It is also driven to the COUT output (on both the device pin and as C0[COUT]) when CR1[OPE]=0. 0b - Does not invert the comparator output. 1b - Inverts the comparator output.
10 COS	Comparator Output Select 0b - Set CMPO to equal COUT (filtered comparator output). 1b - Set CMPO to equal COUTA (unfiltered comparator output).
9 OPE	Comparator Output Pin Enable The OPE bit enables the path from the comparator output to a selected pin. 0b - When OPE is 0, the comparator output (after window/filter settings dependent on software configuration) is not available to a packaged pin. 1b - When OPE is 1, and if the software has configured the comparator to own a packaged pin, the comparator is available in a packaged pin.
8 EN	Comparator Module Enable The EN bit enables the Analog Comparator Module. When the module is not enabled, the analog part remains in the off state, and consumes no power. When the same input is selected from analog mux to the positive and negative port, the comparator is disabled automatically. 0b - Analog Comparator is disabled. 1b - Analog Comparator is enabled.
7 —	Reserved
6-4 FILTER_CNT	Filter Sample Count This field specifies the number of consecutive samples that must agree prior to the comparator ouput filter accepting a new output state. For information regarding filter programming and latency, please see the Functional Description. 000b - Filter is disabled. If SE = 1, then COUT is a logic zero (this is not a legal state, and is not recommended). If SE = 0, COUT = COUTA. 001b - 1 consecutive sample must agree (comparator output is simply sampled). 010b - 2 consecutive samples must agree. 011b - 3 consecutive samples must agree. 100b - 4 consecutive samples must agree. 101b - 5 consecutive samples must agree. 110b - 6 consecutive samples must agree. 111b - 7 consecutive samples must agree.
3-2 —	Reserved
1-0 HYSTCTR	Comparator hard block hysteresis control. See chip data sheet to get the actual hystersis value with each level

Field	Function
	00b - The hard block output has level 0 hysteresis internally. 01b - The hard block output has level 1 hysteresis internally. 10b - The hard block output has level 2 hysteresis internally. 11b - The hard block output has level 3 hysteresis internally.

30-28 PSEL	Plus Input MUX Control These bits determines which input is selected for the positive mux. Refer to the chip configuation chapters to get the detailed connections about Reference Input{0,1,2,3,4,5} and Internal Positive Input 0. The 8b DAC output has been connected internally. Note: For the round robin mode of operation, Internal Posivitive input 0 should be excluded from the activie channels and the fixed channel ports, meanwhile, the MSEL and PSEL bitfields in CMP_C1 register must have different values. 000b - Internal Positive Input 0 for Plus Channel -- Internal Plus Input 001b - External Input 1 for Plus Channel -- Reference Input 0 010b - External Input 2 for Plus Channel -- Reference Input 1 011b - External Input 3 for Plus Channel -- Reference Input 2 100b - External Input 4 for Plus Channel -- Reference Input 3 101b - External Input 5 for Plus Channel -- Reference Input 4 110b - External Input 6 for Plus Channel -- Reference Input 5 111b - Internal 8b DAC output
27 —	Reserved
26-24 MSEL	Minus Input MUX Control These bits determine which input is selected for the negative mux. Refer to the chip configuation chapters to get the detailed connections about Reference Input{0,1,2,3,4,5} and Internal Negative Input 0. The 8b DAC output has been connected internally. Note: For the round robin mode of operation, Internal negative input 0 should be excluded from the activie channels and the fixed channel ports, meanwhile, the MSEL and PSEL bitfields in CMP_C1 register must have different values. 000b - Internal Negative Input 0 for Minus Channel -- Internal Minus Input 001b - External Input 1 for Minus Channel -- Reference Input 0 010b - External Input 2 for Minus Channel -- Reference Input 1 011b - External Input 3 for Minus Channel -- Reference Input 2 100b - External Input 4 for Minus Channel -- Reference Input 3 101b - External Input 5 for Minus Channel -- Reference Input 4 110b - External Input 6 for Minus Channel -- Reference Input 5 111b - Internal 8b DAC output
23-22 —	Reserved
21 CHN5	Channel 5 input enable Channel 5 of the input enable for the round-robin checker. If CHN5 is set, then the corresponding channel to the non-fixed mux port is enabled to check its voltage value in the round-robin mode. If the same channel is selected as the reference voltage, this bit has no effect.
20 CHN4	Channel 4 input enable Channel 4 of the input enable for the round-robin checker. If CHN4 is set, then the corresponding channel to the non-fixed mux port is enabled to check its voltage value in the round-robin mode. If the same channel is selected as the reference voltage, this bit has no effect.
19 CHN3	Channel 3 input enable Channel 3 of the input enable for the round-robin checker. If CHN3 is set, then the corresponding channel to the non-fixed mux port is enabled to check its voltage value in the round-robin mode. If the same channel is selected as the reference voltage, this bit has no effect.
18 CHN2	Channel 2 input enable

Table continues on the next page...

Field	Function
	Channel 2 of the input enable for the round-robin checker. If CHN2 is set, then the corresponding channel to the non-fixed mux port is enabled to check its voltage value in the round-robin mode. If the same channel is selected as the reference voltage, this bit has no effect.
17 CHN1	Channel 1 input enable Channel 1 of the input enable for the round-robin checker. If CHN1 is set, then the corresponding channel to the non-fixed mux port is enabled to check its voltage value in the round-robin mode. If the same channel is selected as the reference voltage, this bit has no effect.
16 CHN0	Channel 0 input enable Channel 0 of the input enable for the round-robin checker. If CHN0 is set, then the corresponding channel to the non-fixed mux port is enabled to check its voltage value in the round-robin mode. If the same channel is selected as the reference voltage, this bit has no effect.
15-12 —	Reserved
11 DACOE	DAC Output Enable This bit is used to enable the DAC output. When the DAC output is selected as either the positive input by CMP_C1[PSEL] or negative input by CMP_C1[MSEL], this bit must be set otherwise the behavior will be unpredictable, same applies to round robin mode. 0b - DAC output is enabled 1b - DAC output is disabled
10 DACEN	DAC Enable This bit is used to enable the DAC. When the DAC is disabled, it is powered down to conserve power. 0b - DAC is disabled. 1b - DAC is enabled.
9 VRSEL	Supply Voltage Reference Source Select 0b - Vin1 is selected as resistor ladder network supply reference Vin. Vin1 is from internal PMC. 1b - Vin2 is selected as resistor ladder network supply reference Vin. Vin2 is from PAD.
8 DMODE	DAC Mode Selection 0b - DAC is selected to work in low speed and low power mode. 1b - DAC is selected to work in high speed high power mode.
7-0 VOSEL	DAC Output Voltage Select This bit selects an output voltage from one of 256 distinct levels. DACO = (Vin/256) * (VOSEL[7:0] + 1), so the DACO range is from Vin/256 to Vin.

67.8.1.6.4 Fields

Field	Function
31 —	Reserved
30 RRIE	Round-Robin interrupt enable This bit enables the interrupt/wake-up when the comparison result changes for a given channel. 0b - The round-robin interrupt is disabled. 1b - The round-robin interrupt is enabled when a comparison result changes from the last sample.
29 FXMP	Fixed MUX Port This bit is used to fix the analog mux port for the round-robin mode. 0b - The Plus port is fixed. Only the inputs to the Minus port are swept in each round. 1b - The Minus port is fixed. Only the inputs to the Plus port are swept in each round.
28 —	Reserved
27-25 FXMXCH	Fixed channel selection This field indicates which channel in the mux port is fixed in a given round-robin mode. If FXDACI is set, FXMXCH has no effect. 000b - External Reference Input 0 is selected as the fixed reference input for the fixed mux port. 001b - External Reference Input 1 is selected as the fixed reference input for the fixed mux port. 010b - External Reference Input 2 is selected as the fixed reference input for the fixed mux port. 011b - External Reference Input 3 is selected as the fixed reference input for the fixed mux port. 100b - External Reference Input 4 is selected as the fixed reference input for the fixed mux port.

Table continues on the next page...

Field	Function
	101b - External Reference Input 5 is selected as the fixed reference input for the fixed mux port. 110b - Reserved. 111b - The 8bit DAC is selected as the fixed reference input for the fixed mux port.
24-22 —	Reserved
21 CH5F	CH5F External Channel 5 input changed flag. This bit is set If the channel 5 input changed from the last comparison with the fixed mux port.
20 CH4F	CH4F External Channel 4 input changed flag. This bit is set If the channel 4 input changed from the last comparison with the fixed mux port.
19 CH3F	CH3F External Channel 3 input changed flag. This bit is set If the channel 3 input changed from the last comparison with the fixed mux port.
18 CH2F	CH2F External Channel 2 input changed flag. This bit is set If the channel 2 input changed from the last comparison with the fixed mux port.
17 CH1F	CH1F External Channel 1 input changed flag. This bit is set If the channel 1 input changed from the last comparison with the fixed mux port.
16 CH0F	CH0F External Channel 0 input changed flag. This bit is set If the channel 0 input changed from the last comparison with the fixed mux port.
15-14 NSAM	Number of sample clocks For a given channel, this field specifies how many round-robin clock cycles later the sample takes place. 00b - The comparison result is sampled as soon as the active channel is scanned in one round-robin clock. 01b - The sampling takes place 1 round-robin clock cycle after the next cycle of the round-robin clock. 10b - The sampling takes place 2 round-robin clock cycles after the next cycle of the round-robin clock. 11b - The sampling takes place 3 round-robin clock cycles after the next cycle of the round-robin clock.
13-8 INITMOD	Comparator and DAC initialization delay modulus. These values specify the round robin clock cycles used to determine the comparator and DAC initialization delays specified by the datasheet. For example the initialization delay is 80us and the round robin clock is 100kHz, then INITMOD should be set to 80us/10us = 8. 000000 - The modulus is set to 64(same with 111111). other values - Inilization delay is set to INITMOD * round robin clock period.
7-6 —	Reserved
5-0 ACOn	ACOn The result of the input comparison for channel *n* . This field stores the latest comparison result of the input channel *n* with the fixed mux port. Reading this bit returns the latest comparison result. Writing this field defines the pre-set state of channel *n*.

28 PCHCTEN	Positive Channel Continuous Mode Enable. This bit is used to enable the positive channel working in continuous mode. When this bit is set to 1, it means all the inputs to positive channels are coming from 1.8v domain and no discrete timing is required for the positive channel mux. Otherwise, when it is cleared to 0, positive channel will work in discrete mode, means the positive inputs are coming from 3v domain. 0b - Positive channel is in Discrete Mode and special timing needs to be configured.

Table continues on the next page...

Field	Function
	1b - Positive channel is in Continuous Mode and no special timing is requried.
27-25 —	Reserved
24 NCHCTEN	Negative Channel Continuous Mode Enable. This bit is used to enable the negative channel working in continuous mode. When this bit is set to 1, it means all the inputs to negative channels are coming from 1.8v domain and no discrete timing is required for the positive channel mux. Otherwise, when it is cleared to 0, negative channel will work in discrete mode, means the negative inputs are coming from 3v domain. 0b - Negative channel is in Discrete Mode and special timing needs to be configured. 1b - Negative channel is in Continuous Mode and no special timing is requried.
23-21 —	Reserved
20 RDIVE	Resistor Divider Enable This bit is used to enable the resistor divider for the inputs when they come from 3v domain and their values are above 1.8v. 0b - The resistor is not enabled even when either NCHEN or PCHEN is set to1 but the actual input is in the range of 0 - 1.8v. 1b - The resistor is enabled because the inputs are above 1.8v.
19-17 —	Reserved
16 DMCS	Discrete Mode Clock Selection This bit is used to select the clock source in order to generate the requiried timing for comparator to work in discrete mode. There are generally two kinds of clocks coming from SoC, one is a fast clock(16 - 20MHz) to generate fast prop delay and another one is noramlly 32kHz to work in low power mode. 0b - Slow clock is selected for the timing generation. 1b - Fast clock is selected for the timing generation.
15 —	Reserved
14-12 ACSAT	Analog Comparator Sampling Time control. These values configures the analog comparator sampling timing(speicified by the discrete mode clock period T which is selected by DMCS) in discrete mode. 000b - The sampling time equals to T 001b - The sampling time equasl to 2*T 010b - The sampling time equasl to 4*T 011b - The sampling time equasl to 8*T 100b - The sampling time equasl to 16*T 101b - The sampling time equasl to 32*T 110b - The sampling time equasl to 64*T 111b - The sampling time equasl to 256*T
11 —	Reserved
10-8 ACPH1TC	Analog Comparator Phase1 Timing Control. These values configures the analog comparator phase1 timing when RDIV is set to 1 which means the input volage level is above 1.8v. T means the discrete mode clock period in the table. 000b - Phase1 active time in one sampling period equals to T 001b - Phase1 active time in one sampling period equals to 2*T 010b - Phase1 active time in one sampling period equals to 4*T 011b - Phase1 active time in one sampling period equals to 8*T

Table continues on the next page...

Field	Function
	100b - Phase1 active time in one sampling period equals to T 101b - Phase1 active time in one sampling period equals to T 110b - Phase1 active time in one sampling period equals to T 111b - Phase1 active time in one sampling period equals to 0
7 —	Reserved
6-4 ACPH2TC	Analog Comparator Phase2 Timing Control. These values configures the analog comparator phase2 timing when RDIV is set to 1 which means the input volage level is above 1.8v. T means the discrete mode clock period in the table. 000b - Phase2 active time in one sampling period equals to T 001b - Phase2 active time in one sampling period equals to 2*T 010b - Phase2 active time in one sampling period equals to 4*T 011b - Phase2 active time in one sampling period equals to 8*T 100b - Phase2 active time in one sampling period equals to 16*T 101b - Phase2 active time in one sampling period equals to 32*T 110b - Phase2 active time in one sampling period equals to 64*T 111b - Phase2 active time in one sampling period equals to 16*T
3-0 —	Reserved

67.9 CMP functional description

The CMP module can be used to compare two analog input voltages applied to INP and INM. CMPO is high when the non-inverting input is greater than the inverting input, and is low when the non-inverting input is less than the inverting input. This signal can be selectively inverted by setting CMP_C0[INVT] = 1.

CMP_C0[IER] and CMP_C0[IEF] are used to select the condition that causes the CMP module to assert an interrupt to the processor. CMP_C0[CFF] is set on a falling edge, and CMP_C0[CFR] is set on a rising edge of the comparator output. The optionally filtered CMPO can be read directly through CMP_C0[COUT].

67.9.1 Initialization

A typical startup sequence is as follows.

The time required to stabilize COUT is the power-on delay of the comparators plus the largest propagation delay from a selected analog source through the analog comparator, windowing function, and filter. See the datasheet for power-on delays of the comparators. The windowing function has a maximum of one bus clock period delay. The filter delay is specified in the Low-pass filter section.

During operation, the propagation delay of the selected data paths must always be considered. It may take many bus clock cycles for COUT and CMP_C0[CFR]/ CMP_C0[CFF] to reflect an input change or a configuration change to one of the components involved in the data path.

When programmed for filtering modes, COUT initially equals 0 until sufficient clock cycles have elapsed to fill all stages of the filter. This occurs even if COUTA is at a logic 1.

67.9.2 Low-pass filter

The low-pass filter operates on the unfiltered and unsynchronized and optionally inverted comparator output COUTA and generates the filtered and synchronized output COUT. Both COUTA and COUT can be configured as module outputs and are used for different purposes within the system.

Synchronization and edge detection are always used to determine status register bit values. They also apply to COUT for all sampling and windowed modes. Filtering can be performed using an internal timebase defined by CMP_C0[FPR], or using an external SAMPLE input to determine sample time.

The need for digital filtering and the amount of filtering is dependent on user requirements. Filtering can become more useful in the absence of an external hysteresis circuit. Without external hysteresis, high-frequency oscillations can be generated at COUTA when the selected INM and INP input voltages differ by less than the offset voltage of the differential comparator.

67.9.2.1 Enabling filter modes

Filter modes can be enabled by:

- Setting CMP_C0[FILTER_CNT] > 0x01 and
- Setting CMP_C0[FPR] to a nonzero value or setting C0[SE]=1

If using the divided bus clock to drive the filter, it samples COUTA every CMP_C0[FPR] bus clock cycles.

The filter output is at logic 0 when first initialized, and subsequently changes when all the consecutive CMP_C0[FILTER_CNT] samples agree that the output value has changed. In other words, CMP_C0[COUT] is 0 for some initial period, even when COUTA is at logic 1.

Setting all of CMP_C0[SE], CMP_C0[FPR] and CMP_C0[FILTER_CNT] to 0 disables the filter and eliminates switching current associated with the filtering process.

Note

Always switch to this setting prior to making any changes in filter parameters. This resets the filter to a known state. Switching CMP_C0[FILTER_CNT] on the fly without this intermediate step can result in unexpected behavior.

If CMP_C0[SE]=1, the filter samples COUTA on each positive transition of the sample input. The output state of the filter changes when all the consecutive CMP_C0[FILTER_CNT] samples agree that the output value has changed.

67.9.2.2 Latency issues

The value of CMP_C0[FPR] or SAMPLE period must be set such that the sampling period is just longer than the period of the expected noise. This way a noise spike will corrupt only one sample. The value of CMP_C0[FILTER_CNT] must be chosen to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the power of CMP_C0[FILTER_CNT].

The values of CMP_C0[FPR] or SAMPLE period and CMP_C0[FILTER_CNT] must also be traded off against the desire for minimal latency in recognizing actual comparator output transitions. The probability of detecting an actual output change within the nominal latency is the probability of a correct sample raised to the power of CMP_C0[FILTER_CNT].

The following table summarizes maximum latency values for the various modes of operation *in the absence of noise*. Filtering latency is restarted each time an actual output transition is masked by noise.

Table 67-5. Comparator sample/filter maximum latencies

Mode #	CMP_C0[EN]	CMP_C0[WE]	CMP_C0[SE]	CMP_C0[FILTER_CNT]	Co[FPR]	Operation	Maximum latency[1]
1	0	X	X	X	X	Disabled	N/A
2A	1	0	0	0x00	X	Continuous Mode	T_{PD}
2B	1	0	0	X	0x00		
3A	1	0	1	0x01	X	Sampled, Non-Filtered mode	$T_{PD} + T_{SAMPLE} + T_{per}$
3B	1	0	0	0x01	> 0x00		$T_{PD} + (CMP\_C0[FPR] * T_{per}) + T_{per}$

Table continues on the next page...

Table 67-5. Comparator sample/filter maximum latencies (continued)

Mode #	CMP_C0[EN]	CMP_C0[WE]	CMP_C0[SE]	CMP_C0[FILTER_CNT]	Co[FPR]	Operation	Maximum latency[1]
4A	1	0	1	> 0x01	X	Sampled, Filtered mode	T_{PD} + (CMP_C0[FILTER_CNT] * T_{SAMPLE}) + T_{per}
4B	1	0	0	> 0x01	> 0x00		T_{PD} + (CMP_C0[FILTER_CNT] * CMP_C0[FPR] x T_{per}) + T_{per}
5A	1	1	0	0x00	X	Windowed mode	T_{PD} + T_{per}
5B	1	1	0	X	0x00		T_{PD} + T_{per}
6	1	1	0	0x01	0x01 - 0xFF	Windowed / Resampled mode	T_{PD} + (CMP_C0[FPR] * T_{per}) + 2T_{per}
7	1	1	0	> 0x01	0x01 - 0xFF	Windowed / Filtered mode	T_{PD} + (CMP_C0[FILTER_CNT] * CMP_C0[FPR] x T_{per}) + 2T_{per}

1. T_{PD} represents the intrinsic delay of the analog component plus the polarity select logic. T_{SAMPLE} is the clock period of the external sample clock. T_{per} is the period of the bus clock.

NOTE

The delay in this table does not include the delay caused by the Discrete Mode.

67.9.3 CMP Discrete mode timing sequence

In order to support the 3 V domain input the analog comparator should be configured to work in Discrete Mode since the internal transistors are not 3 V tolerance. This section summarizes the possible configurations depending on the input range.

Note that the sample signal below means that the analog comparator samples the input analog input. It is different from the sample mode that occurs on the digital process to the final comparison result. Also, note that the cross domain round robin cycling (see Trigger mode) is not allowed.

1. When CMP_C3[PCHCTEN] and CMP_C3[NCHCTEN] are set to 1, the CMP is in continuous time operation. No special timing is required.
2. When either CMP_C3[PCHCTEN] or CMP_C3[NCHCTEN] is 0, it means at least one input comes from the 3V PAD.
   a. If CMP_C3[RDIVE] is zero, it means the input signal comes from 3V PAD, but its range still is in the range of 0 to 1.8V, no timing requirement for the generation of Phase1 and Phase2.

In this condition, there are two modes for this comparator, high speed mode and low speed mode. Clock source may come from fast clock(16-20M)

In Figure 67-13, the Analog ready indicates the analog settling time is reached and is ready for comparison. Tc is set by CMP_C3[ACSAT], in high speed mode, it is normally used as 1*T, 2*T, 4*T and 8*T where T is CLOCK period, and in low speed mode (CMP_C0[PMODE] = 0), CMP_C3[ACSAT] is normally used as 16*T, 32*T, 64*T and 256*T.

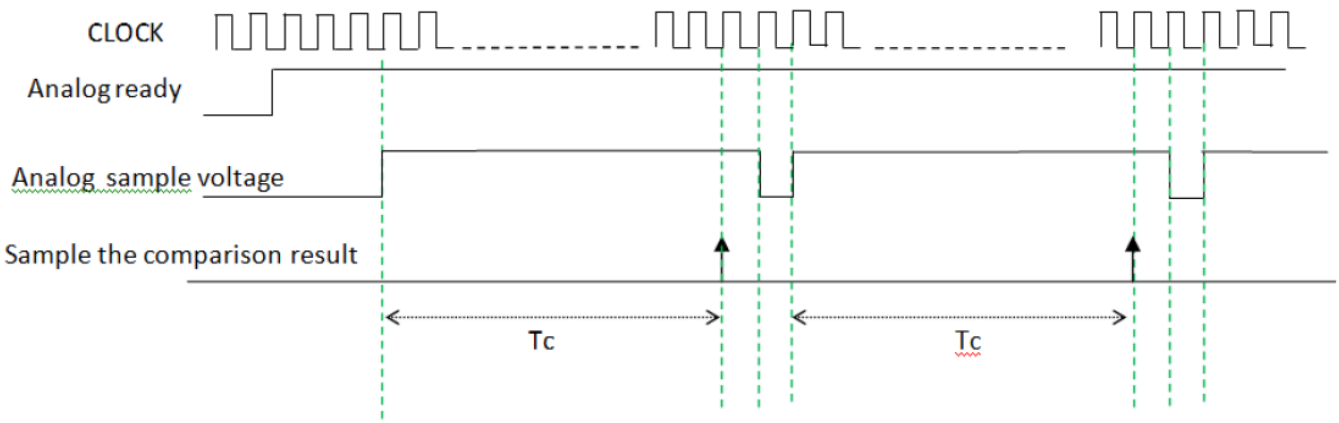

Figure 67-13. CMP_C3[RDIVE] = 0

b. If CMP_C3[RDIVE] == 1, it means the signals come from the 3V PAD and it could over 1.8 V, Phase1, Phase2 will be generated.

If CMP is in high speed mode (CMP_C0[PMODE] = 1) , Tc, Phase1, and Phase2 can be set based on the possible combinations in Table 67-6.

If CMP works in low speed mode, Phase1 is suggested to set to 1*T, Phase2 is suggested to set to 8*T, and Tc is normally set to 16*T, 32*T, 64*T and 256*T.

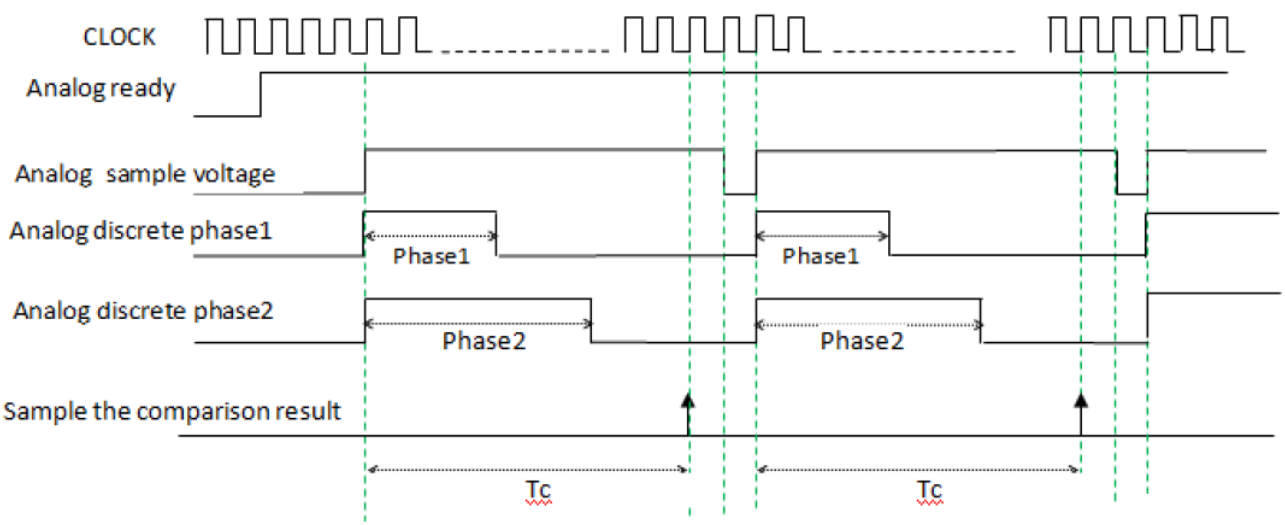

Figure 67-14. CMP_C3[RDIVE] = 1

Table 67-6. Possible Combinations of CMP_C3[ACSAT], CMP_C3[ACPH1TC] and CMP_C3[ACPH2TC]

Tc	Phase1	Phase2
1*T	1*T	1*T
2*T	2*T	2*T
4*T	4*T	4*T
8*T	8*T	8*T
16*T	1*T	16*T
32*T	1*T	32*T
64*T	1*T	64*T
256*T	0	16*T

If the clock comes from 32KHz slow clock(CMP_C3[DMCLKSEL] = 0), both analog phase 1 and phase 2 will be driven to 0 and Tc is limited to T as shown in the figure below.

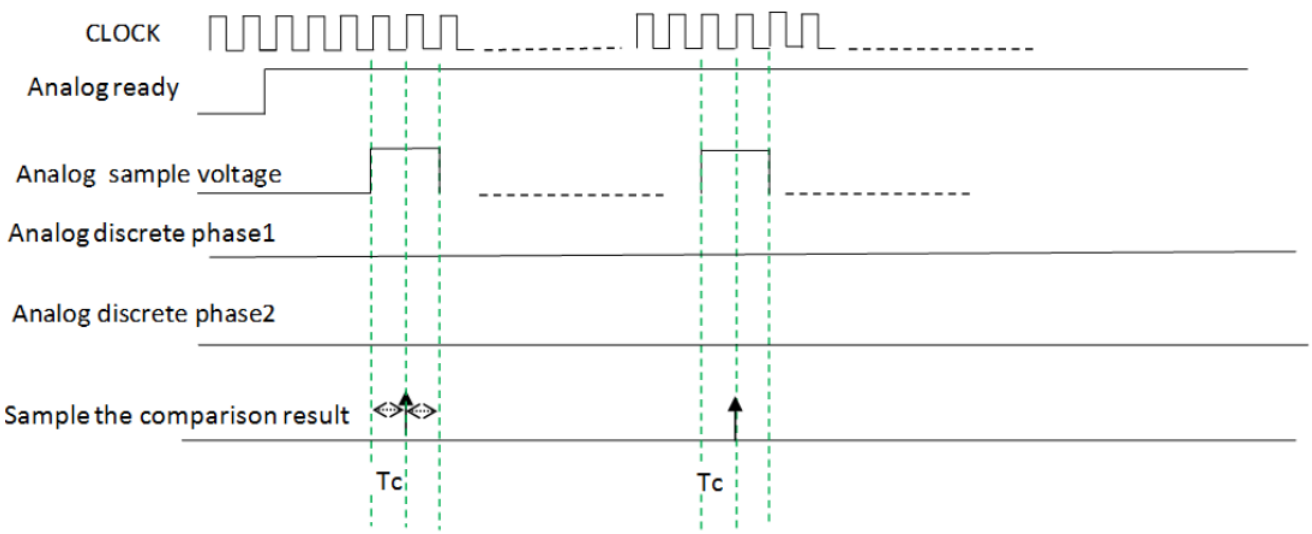

Figure 67-15. Slow (32 kHz) clock timing

67.10 Interrupts

The CMP module is capable of generating an interrupt on either the rising- or falling-edge of the comparator output, or both. Assuming the CMP DMA enable bit is not set, the following table gives the conditions in which the interrupt request is asserted and deasserted.

Table 67-7. CMP interrupt generations

When	Then
CMP_C0[IER] and CMP_C0[CFR] are set	The interrupt request is asserted
CMP_C0[IEF] and CMP_C0[CFF] are set	The interrupt request is asserted
CMP_C0[IER] and CMP_C0[CFR] are cleared for a rising-edge interrupt	The interrupt request is deasserted
CMP_C0[IEF] and CMP_C0[CFF] are cleared for a falling-edge interrupt	The interrupt request is deasserted

67.11 DMA support

Normally, the CMP generates a CPU interrupt if there is a change on the COUT. When DMA support is enabled by setting CMP_C0[DMAEN] and the interrupt is enabled by setting CMP_C0[IER], CMP_C0[IEF], or both, the corresponding change on COUT forces a DMA transfer request rather than a CPU interrupt instead. When the DMA has completed the transfer, it sends a transfer completing indicator signal that deasserts the DMA transfer request and clears the flags (CMP_C0[CFR] and CMP_C0[CFF]) to allow a subsequent change on comparator output to occur and force another DMA request.

The comparator can remain functional in STOP modes. When DMA support is enabled by setting CMP_C0[DMAEN] and the interrupt is enabled by setting CMP_C0[IER], CMP_C0[IEF], or both, the corresponding change on COUT forces a DMA transfer request to wake up the system from STOP modes. After the data transfer has finished, the system will go back to STOP modes. Refer to the DMA chapters in the device reference manual for the asynchronous DMA function for details.

67.12 DAC functional description

This section provides DAC functional description.

67.12.1 Digital-to-analog converter block diagram

The following figure shows the block diagram of the DAC module. It contains a 256-tap resistor ladder network and a 256-to-1 multiplexer, which selects an output voltage from one of 256 distinct levels that outputs from DACO. It is controlled through the control register2(CMP_C1). Its supply reference source can be selected from two sources V_{in1} and V_{in2}. The module can be powered down or disabled when not in use. When in Disabled mode, DACO is connected to the analog ground.

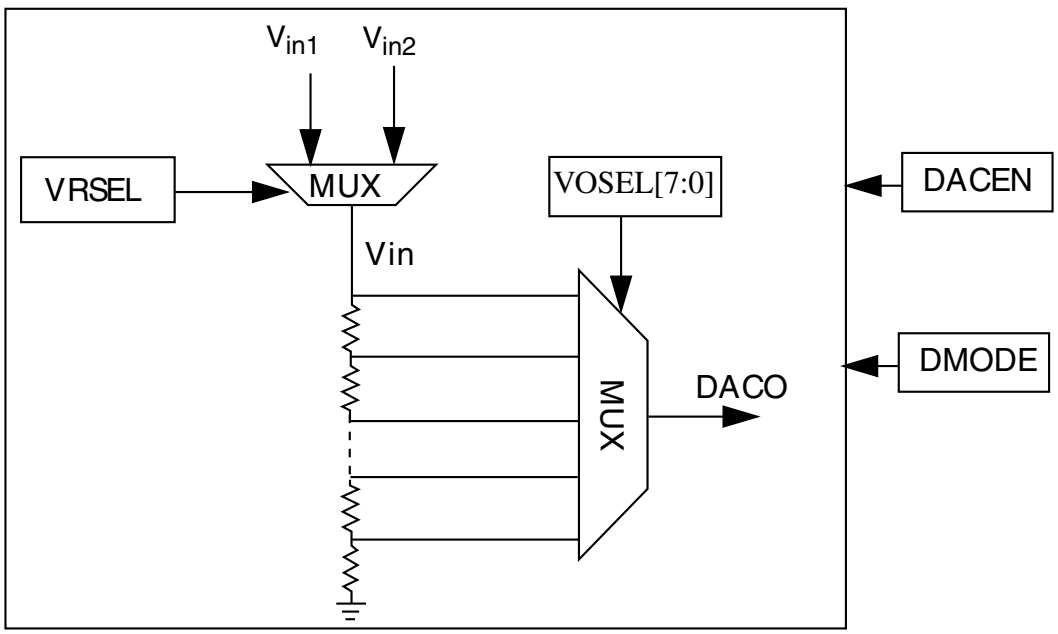

Figure 67-16. 8-bit DAC block diagram

67.12.2 Voltage reference source select

- V_{in1} must be used to connect to the primary voltage source as supply reference of 64 tap resistor ladder
- V_{in2} must be used to connect to an alternate voltage source, or primary source, if an alternate voltage source is not available

67.13 DAC resets

This module has a single reset input, corresponding to the chip-wide peripheral reset.

67.14 DAC clocks

This module has a single clock input, the bus clock.

67.15 DAC interrupts

This module has no interrupts.

67.16 Trigger mode

The CMP and the 8-bit DAC are designed to support the trigger mode operation, which is enabled when the MCU enters STOP modes with CMP_C0[WE], CMP_C0[SE] and CMP_C0[EN] are set.

With this mode enabled, the trigger events that include the operation clock and a trigger start signal will initiate a compare sequence that must first enable the CMP and DAC prior to performing a CMP operation and capturing the output. A fixed channel for either the plus side mux or the minus side mux is selected by software with CMP_C2[FXMP] and CMP_C2[FXMXCH]. It is a mandatory request that the round robin cycling period must be set longer than the time that all the active channels complete the specified comparison cycles specified by CMP_C2[NSAM].

The active channels selected by CMP_C1[CHN*n*] are then routed to the non-fixed channel mux and compared with the reference input in a round-robin manner. In order to meet the comparator stabilization time, after the configurable number of operation clocks defined by CMP_C2[NSAM], the comparison result is sampled for the selected channel. A software pre-programmed state for each channel is configured by writing to CMP_C2[ACO*n*] field. After all the active channels are sampled, if the comparison result changes from its pre-programmed state, the corresponding flag in CMP_C2[CH*n*F] is set. If CMP_C2[RRIE] is set, an asynchronous reset is asserted to bring the MCU out of STOP mode.

Note that these flags do not support generating a DMA transfer event.

This mode is active when the MCU is in STOP mode, so none of the window/filter functions are available. A basic assumption of this mode is that the selected inputs are changing at a much slower rate than the operation clock. It is suggested to configure the comparator in low power comparison mode as well. In programming the

CMP_C2[INITMOD] registers it is need to make sure the INITMOD*round robin clock period must be longer than the initialization delay which can be referred from the chip datasheet.

The following diagram shows the basic flow of this mode. In the diagram, CMP_C1[CHN1], CMP_C1[CHN3], and CMP_C1[CHN4] are set, so channels #1, #3, and #4 are selected for round robin depended on their polarity setting. CMP_C2[NSAM] is set to 2'b01, so one clock later the comparison result of the selected channel is sampled. When channel #3 is compared, the result is sampled, and round robin ends. If any of the comparison results from channel #1, #3, or #4 changed from their programmed value (written to CMP_C2[ACO1], CMP_C2[ACO3], and CMP_C2[ACO4]), an interrupt is generated to wake up the MCU from the STOP mode. Software can then poll the CMP_C2[CH*n*F] to see which channel input(s) changed value during the STOP mode.

NOTE

In round robin mode, it should be ensured that the RTC_CLK period is greater than the comparison time corresponding to the value of CMPx_C0[PMODE].
