Abstract	Technical information for the P89LPC9102, P89LPC9103 and P89LPC9107 devices.

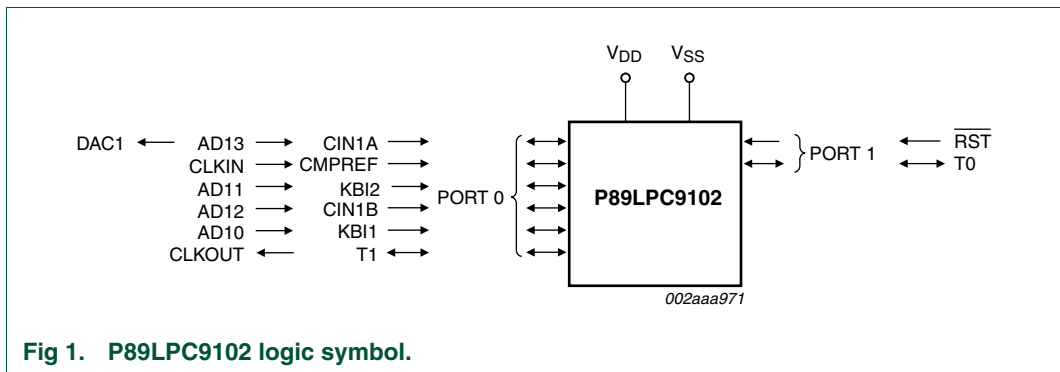

Revision history

Rev	Date	Description
01	20050211	Initial version (9397 750 13919).

1. Introduction

The P89LPC9102/9103/9107 are single-chip microcontrollers designed for applications demanding high-integration, low-cost solutions over a wide range of performance requirements. The P89LPC9102/9103/9107 is based on a high performance processor architecture that executes instructions in two to four clocks, six times the rate of standard 80C51 devices. Many system-level functions have been incorporated into the P89LPC9102/9103/9107 in order to reduce component count, board space, and system cost.

1.1 Logic symbols

1.2 Pin Configuration

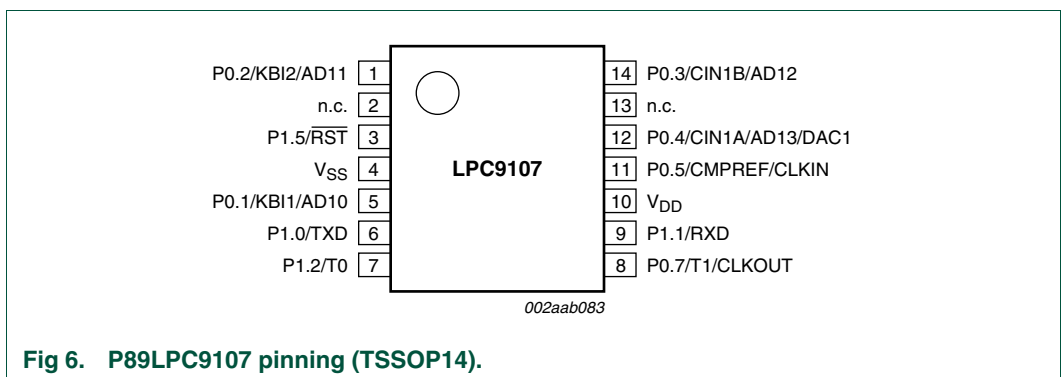

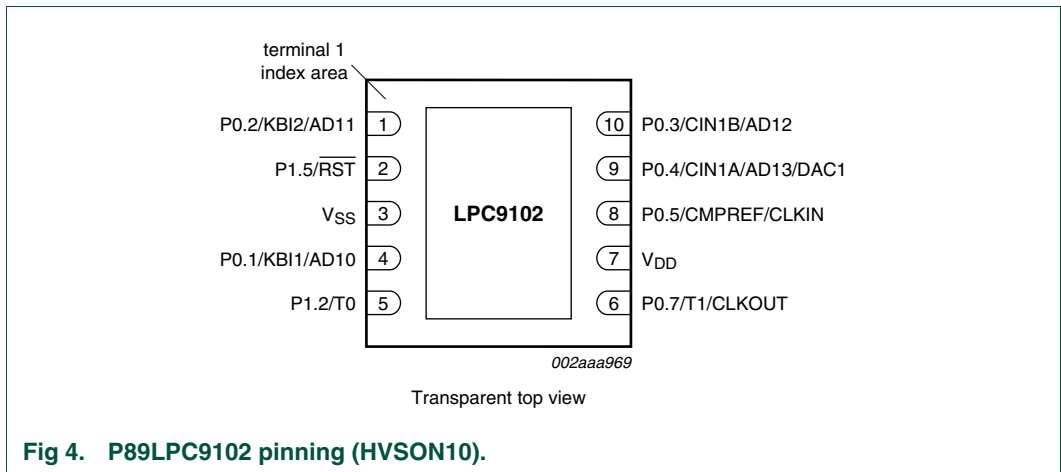

Table 1: P89LPC9102 pin description

Symbol	Pin	Type	Description
P0.1 to P0.5, P0.7		I/O	<p>Port 0: Port 0 is an I/O port with a user-configurable output type. During reset Port 0 latches are configured in the input-only mode with the internal pull-up disabled. The operation of Port 0 pins as inputs and outputs depends upon the port configuration selected. Each port pin is configured independently. Refer to Section 5.1 "Port configurations" for details.</p> <p>The Keypad Interrupt feature operates with Port 0 pins.</p> <p>All pins have Schmitt triggered inputs.</p> <p>Port 0 also provides various special functions as described below:</p>
P0.1/KBI1/ AD10	4	I/O	P0.1 — Port 0 bit 1.
		I	KBI1 — Keyboard input 1.
		I	AD10 — ADC1 channel 0 analog input.
P0.2/KBI2/ AD11	1	I/O	P0.2 — Port 0 bit 2.
		I	KBI2 — Keyboard input 2.
		I	AD11 — ADC1 channel 1 analog input.
P0.3/CIN1B/ AD12	10	I/O	P0.3 — Port 0 bit 3.
		I	CIN1B — Comparator 1 positive input.
		I	AD12 — ADC1 channel 2 analog input.
P0.4/CIN1A/ AD13/DAC1	9	I/O	P0.4 — Port 0 bit 4.
		I	CIN1A — Comparator 1 positive input.
		I	AD13 — ADC1 channel 3 analog input.
		O	DAC1 — Digital to analog converter output.
P0.5/ CMPREF/ CLKIN	8	I/O	P0.5 — Port 0 bit 5.
		I	CMPREF — Comparator reference (negative) input.
		I	CLKIN — External clock input.
P0.7/T1/ CLKOUT	6	I/O	P0.7 — Port 0 bit 7.
		I/O	T1 — Timer/counter 1 external count input or overflow/PWM output.
		I	CLKOUT — Clock output.
P1.2, P1.5		I/O	<p>Port 1: Port 1 is an I/O port with a user-configurable output type. During reset Port 1 latches are configured in the input-only mode with the internal pull-up disabled. The operation of the configurable Port 1 pins as inputs and outputs depends upon the port configuration selected. Each of the configurable port pins are programmed independently. Refer to Section 5.1 "Port configurations" for details. P1.5 is input-only.</p> <p>All pins have Schmitt triggered inputs.</p> <p>Port 1 also provides various special functions as described below:</p>
P1.2/T0	5	I/O	P1.2 — Port 1 bit 2.
		I/O	T0 — Timer/counter 0 external count input or overflow/PWM output.

Table 1: P89LPC9102 pin description ...continued

Symbol	Pin	Type	Description
P1.5/ $\overline{\text{RST}}$	2	I	P1.5 — Port 1 bit 5 (input-only).
		I	$\overline{\text{RST}}$ — External Reset input during power-on or if selected via UCFG1. When functioning as a reset input a LOW on this pin resets the microcontroller, causing I/O ports and peripherals to take on their default states, and the processor begins execution at address 0. Also used during a power-on sequence to force In-System Programming mode. When using an oscillator frequency above 12 MHz, the reset input function of P1.5 must be enabled. An external circuit is required to hold the device in reset at power-up until V_{DD} has reached its specified level. When system power is removed V_{DD} will fall below the minimum specified operating voltage. When using an oscillator frequency above 12 MHz, in some applications, an external brownout detect circuit may be required to hold the device in reset when V_{DD} falls below the minimum specified operating voltage.
V_{SS}	3	I	Ground: 0 V reference.
V_{DD}	7	I	Power supply: This is the power supply voltage for normal operation as well as Idle mode and Power-down mode.

Table 2: P89LPC9103 pin description

Symbol	Pin	Type	Description
P0.1 to P0.5		I/O	Port 0: Port 0 is an I/O port with a user-configurable output type. During reset Port 0 latches are configured in the input-only mode with the internal pull-up disabled. The operation of Port 0 pins as inputs and outputs depends upon the port configuration selected. Each port pin is configured independently. Refer to Section 5.1 "Port configurations" for details. The Keypad Interrupt feature operates with Port 0 pins. All pins have Schmitt triggered inputs. Port 0 also provides various special functions as described below:
P0.1/KBI1/ AD10	4	I/O	P0.1 — Port 0 bit 1.
		I	KBI1 — Keyboard input 1.
		I	AD10 — ADC1 channel 0 analog input.
P0.2/KBI2/ AD11	1	I/O	P0.2 — Port 0 bit 2.
		I	KBI2 — Keyboard input 2.
		I	AD11 — ADC1 channel 1 analog input.
P0.3/CIN1B/ AD12	10	I/O	P0.3 — Port 0 bit 3.
		I	CIN1B — Comparator 1 positive input.
		I	AD12 — ADC1 channel 2 analog input.
P0.4/CIN1A/ AD13/DAC1	9	I/O	P0.4 — Port 0 bit 4.
		I	CIN1A — Comparator 1 positive input.
		I	AD13 — ADC1 channel 3 analog input.
		O	DAC1 — Digital to analog converter output.
P0.5/CMPREF/ CLKIN	6	I/O	P0.5 — Port 0 bit 5.
		I	CMPREF — Comparator reference (negative) input.
		I	CLKIN — External clock input.

Table 2: P89LPC9103 pin description ...continued

Symbol	Pin	Type	Description
P1.0 to P1.5		I/O	<p>Port 1: Port 1 is an I/O port with a user-configurable output type. During reset Port 1 latches are configured in the input-only mode with the internal pull-up disabled. The operation of the configurable Port 1 pins as inputs and outputs depends upon the port configuration selected. Each of the configurable port pins are programmed independently. Refer to Section 5.1 "Port configurations" for details. P1.5 is input-only.</p> <p>All pins have Schmitt triggered inputs.</p> <p>Port 1 also provides various special functions as described below:</p>
P1.0/TXD	5	I/O	P1.0 — Port 1 bit 0.
		O	TXD — Serial port transmitter data.
P1.1/RXD	6	I/O	P1.1 — Port 1 bit 1.
		I	RXD — Serial port receiver data.
P1.5/ $\overline{\text{RST}}$	2	I	P1.5 — Port 1 bit 5 (input-only).
		I	<p>$\overline{\text{RST}}$ — External Reset input during Power-on or if selected via UCFG1. When functioning as a reset input a LOW on this pin resets the microcontroller, causing I/O ports and peripherals to take on their default states, and the processor begins execution at address 0. Also used during a power-on sequence to force In-System Programming mode. When using an oscillator frequency above 12 MHz, the reset input function of P1.5 must be enabled. An external circuit is required to hold the device in reset at power-up until V_{DD} has reached its specified level. When system power is removed V_{DD} will fall below the minimum specified operating voltage. When using an oscillator frequency above 12 MHz, in some applications, an external brownout detect circuit may be required to hold the device in reset when V_{DD} falls below the minimum specified operating voltage.</p>
V_{SS}	3	I	Ground: 0 V reference.
V_{DD}	7	I	Power supply: This is the power supply voltage for normal operation as well as Idle mode and Power-down mode.

Table 3: P89LPC9107 pin description

Symbol	Pin	Type	Description
P0.1 to P0.5, P0.7		I/O	<p>Port 0: Port 0 is an I/O port with a user-configurable output type. During reset Port 0 latches are configured in the input-only mode with the internal pull-up disabled. The operation of Port 0 pins as inputs and outputs depends upon the port configuration selected. Each port pin is configured independently. Refer to Section 5.1 "Port configurations" on page 37 for details.</p> <p>The Keypad Interrupt feature operates with Port 0 pins.</p> <p>All pins have Schmitt triggered inputs.</p> <p>Port 0 also provides various special functions as described below:</p>
P0.1/KBI1/ AD10	5	I/O	P0.1 — Port 0 bit 1.
		I	KBI1 — Keyboard input 1.
		I	AD10 — ADC1 channel 0 analog input.
P0.2/KBI2/ AD11	1	I/O	P0.2 — Port 0 bit 2.
		I	KBI2 — Keyboard input 2.
		I	AD11 — ADC1 channel 1 analog input.
P0.3/CIN1B/ AD12	14	I/O	P0.3 — Port 0 bit 3.
		I	CIN1B — Comparator 1 positive input.
		I	AD12 — ADC1 channel 2 analog input.

Table 3: P89LPC9107 pin description ...continued

Symbol	Pin	Type	Description
P0.4/CIN1A/ AD13/DAC1	12	I/O	P0.4 — Port 0 bit 4.
		I	CIN1A — Comparator 1 positive input.
		I	AD13 — ADC1 channel 3 analog input.
		O	DAC1 — Digital to analog converter output.
P0.5/CMPREF/ CLKIN	11	I/O	P0.5 — Port 0 bit 5.
		I	CMPREF — Comparator reference (negative) input.
		I	CLKIN — External clock input.
P0.7/T1/ CLKOUT	8	I/O	P0.7 — Port 0 bit 7.
		I/O	T1 — Timer/counter 1 external count input or overflow/PWM output.
		I	CLKOUT — Clock output.
P1.0 to P1.2, P1.5		I/O	<p>Port 1: Port 1 is an I/O port with a user-configurable output type. During reset Port 1 latches are configured in the input-only mode with the internal pull-up disabled. The operation of the configurable Port 1 pins as inputs and outputs depends upon the port configuration selected. Each of the configurable port pins are programmed independently. Refer to Section 5.1 “Port configurations” on page 37 for details. P1.5 is input-only.</p> <p>All pins have Schmitt triggered inputs.</p> <p>Port 1 also provides various special functions as described below:</p>
P1.0/TXD	6	I/O	P1.0 — Port 1 bit 0.
		O	TXD — Serial port transmitter data.
P1.1/RXD	9	I/O	P1.1 — Port 1 bit 1.
		I	RXD — Serial port receiver data.
P1.2/T0	7	I/O	P1.2 — Port 1 bit 2.
		I/O	T0 — Timer/counter 0 external count input or overflow/PWM output.
P1.5/ $\overline{\text{RST}}$	3	I	P1.5 — Port 1 bit 5 (input-only).
		I	<p>$\overline{\text{RST}}$ — External Reset input during Power-on or if selected via UCFG1. When functioning as a reset input a LOW on this pin resets the microcontroller, causing I/O ports and peripherals to take on their default states, and the processor begins execution at address 0. Also used during a power-on sequence to force In-System Programming mode. When using an oscillator frequency above 12 MHz, the reset input function of P1.5 must be enabled. An external circuit is required to hold the device in reset at power-up until V_{DD} has reached its specified level. When system power is removed V_{DD} will fall below the minimum specified operating voltage. When using an oscillator frequency above 12 MHz, in some applications, an external brownout detect circuit may be required to hold the device in reset when V_{DD} falls below the minimum specified operating voltage.</p>
V_{SS}	4	I	Ground: 0 V reference.
V_{DD}	10	I	Power supply: This is the power supply voltage for normal operation as well as Idle mode and Power-down mode.

1.3 Special function registers

Remark: Special Function Registers (SFRs) accesses are restricted in the following ways:

- User must **not** attempt to access any SFR locations not defined.
- Accesses to any defined SFR locations must be strictly for the functions for the SFRs.
- SFR bits labeled '-', '0' or '1' can **only** be written and read as follows:
 - '-' Unless otherwise specified, **must** be written with '0', but can return any value when read (even if it was written with '0'). It is a reserved bit and may be used in future derivatives.
 - '0' **must** be written with '0', and will return a '0' when read.
 - '1' **must** be written with '1', and will return a '1' when read.

Table 4: P89LPC9102 special function registers

* indicates SFRs that are bit addressable.

Name	Description	SFR addr.	Bit functions and addresses								Reset value	
			MSB				LSB				Hex	Binary
		Bit address	E7	E6	E5	E4	E3	E2	E1	E0		
ACC*	Accumulator	E0H									00	00000000
ADCON1	A/D control register 1	97H	ENBI1	ENADCI1	TMM1	-	ADC11	ENADC1	ADCS11	ADCS10	00	00000000

TL0	Timer 0 low	8AH									00	00000000
TL1	Timer 1 low	8BH									00	00000000
TMOD	Timer 0 and 1 mode	89H	-	-	T1M1	T1M0	-	-	T0M1	T0M0	00	00000000
TRIM	Internal oscillator trim register	96H	RCCLK	ENCLK	TRIM.5	TRIM.4	TRIM.3	TRIM.2	TRIM.1	TRIM.0	[5] [6]	
WDCON	Watchdog control register	A7H	PRE2	PRE1	PRE0	-	-	WDRUN	WDTOF	WDCLK	[4] [6]	
WDL	Watchdog load	C1H									FF	11111111
WFEED1	Watchdog feed 1	C2H										
WFEED2	Watchdog feed 2	C3H										

- [1] Unimplemented bits in SFRs (labeled '-') are X (unknown) at all times. Unless otherwise specified, ones should not be written to these bits since they may be used for other purposes in future derivatives. The reset values shown for these bits are logic 0s although they are unknown when read.
- [2] All ports are in input-only (high-impedance) state after power-up.
- [3] The RSTSRC register reflects the cause of the UM10112 reset. Upon a power-up reset, all reset source flags are cleared except POF and BOF; the power-on reset value is xx110000.
- [4] After reset, the value is 111001x1, i.e., PRE2 to PRE0 are all logic 1s, WDRUN = 1 and WDCLK = 1. WDTOF bit is logic 1 after watchdog timer reset and is logic 0 after power-on reset. Other resets will not affect WDTOF.
- [5] On power-on reset, the TRIM SFR is initialized with a factory preprogrammed value. Other resets will not cause initialization of the TRIM register.
- [6] The only reset source that affects these SFRs is power-on reset.

Table 5: P89LPC9103 special function registers

* indicates SFRs that are bit addressable.

Name	Description	SFR addr.	Bit functions and addresses								Reset value

1.4 Memory organization

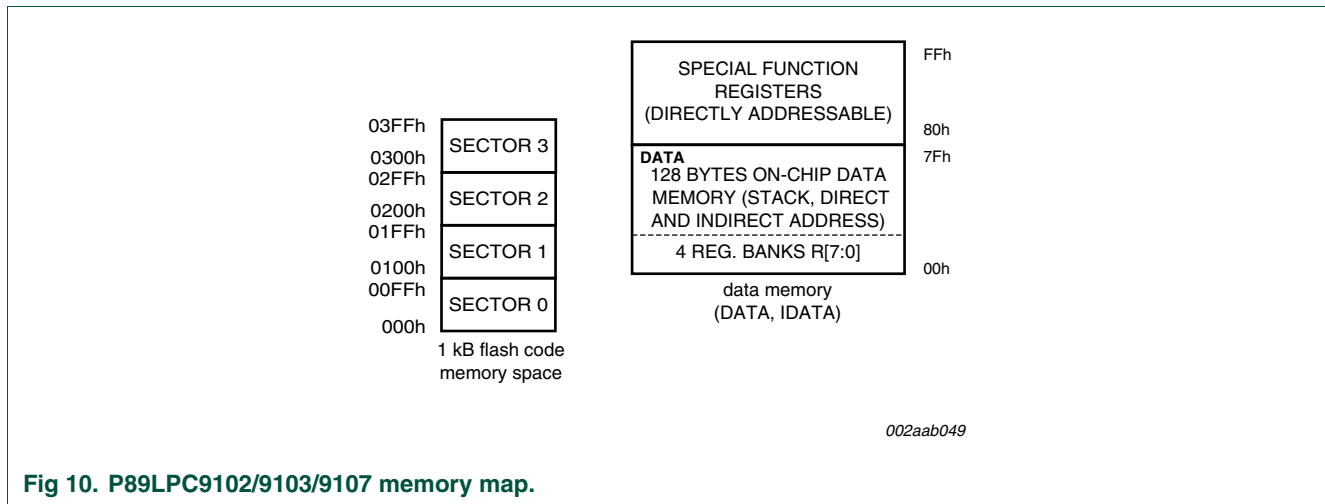

Fig 10. P89LPC9102/9103/9107 memory map.

The various P89LPC9102/9103/9107 memory spaces are as follows:

DATA — 128 bytes of internal data memory space (00h:7Fh) accessed via direct or indirect addressing, using instruction other than MOVX and MOVC. All or part of the Stack may be in this area.

SFR — Special Function Registers. Selected CPU registers and peripheral control and status registers, accessible only via direct addressing.

CODE — 64 kB of Code memory space, accessed as part of program execution and via the MOVC instruction. The P89LPC9102/9103/9107 has 1 kB of on-chip Code memory.

Table 7: Data RAM arrangement

Type	Data RAM	Size (bytes)
DATA	Directly and indirectly addressable memory	128

2. Clocks

2.1 Enhanced CPU

The P89LPC9102/9103/9107 uses an enhanced 80C51 CPU which runs at six times the speed of standard 80C51 devices. A machine cycle consists of two CPU clock cycles, and most instructions execute in one or two machine cycles.

2.2 Clock definitions

The P89LPC9102/9103/9107 device has several internal clocks as defined below:

OSCCLK — Input to the DIVM clock divider. OSCCLK is selected from one of the clock sources and can also be optionally divided to a slower frequency (see [Figure 12](#) and [Section 2.8 “CCLK modification: DIVM register”](#)). **Note:** f_{osc} is defined as the OSCCLK frequency.

CCLK — CPU clock; output of the DIVM clock divider. There are two CCLK cycles per machine cycle, and most instructions are executed in one to two machine cycles (two or four CCLK cycles).

RCCLK — The internal 7.373 MHz RC oscillator output (14.7456 MHz with clock doubler enabled).

PCLK — Clock for the various peripheral devices and is CCLK/2.

2.3 Clock output

The P89LPC9102/9103/9107 supports a user-selectable clock output function on the CLKOUT pin allowing external devices to synchronize to the P89LPC9102/9103/9107. This output is enabled by the ENCLK bit in the TRIM register.

The frequency of this clock output is $\frac{1}{2}$ that of the CCLK. If the clock output is not needed in Idle mode, it may be turned off prior to entering Idle, saving additional power. Note: on reset, the TRIM SFR is initialized with a factory preprogrammed value. Therefore when setting or clearing the ENCLK bit, the user should retain the contents of other bits of the TRIM register. This can be done by reading the contents of the TRIM register (into the ACC for example), modifying bit 6, and writing this result back into the TRIM register. Alternatively, the 'ANL direct' or 'ORL direct' instructions can be used to clear or set bit 6 of the TRIM register.

2.4 On-chip RC oscillator option with clock doubler mode

The P89LPC9102/9103/9107 has a TRIM register that can be used to tune the frequency of the RC oscillator. During reset, the TRIM value is initialized to a factory pre-programmed value to adjust the oscillator frequency to 7.373 MHz, $\pm 1\%$. (Note: the initial value is better than 1%; please refer to the data sheet for behavior over temperature). End user applications can write to the TRIM register to adjust the on-chip RC oscillator to other frequencies. Increasing the TRIM value will decrease the oscillator frequency.

The P89LPC9102/9103/9107 has a clock doubling mode that doubles the frequency provided by the internal RC oscillator to run at 14.7456 MHz. This mode is enabled when the IRCDBL bit (UCFG1.3) is set.

Table 8: On-chip RC oscillator trim register (TRIM - address 96h) bit allocation

Bit	7	6	5	4	3	2	1	0
Symbol	RCCLK	ENCLK	TRIM.5	TRIM.4	TRIM.3	TRIM.2	TRIM.1	TRIM.0
Reset	0	0	Bits 5:0 loaded with factory stored value during reset.					

Table 9: On-chip RC oscillator trim register (TRIM - address 96h) bit description

Bit	Symbol	Description
0	TRIM.0	Trim value. Determines the frequency of the internal RC oscillator. During reset, these bits are loaded with a stored factory calibration value. When writing to either bit 6 or bit 7 of this register, care should be taken to preserve the current TRIM value by reading this register, modifying bits 6 or 7 as required, and writing the result to this register.
1	TRIM.1	
2	TRIM.2	
3	TRIM.3	
4	TRIM.4	
5	TRIM.5	
6	ENCLK	when = 1, CCLK/2 is output on the CLKOUT pin
7	RCCLK	when = 1, selects the RC Oscillator output as the CPU clock (CCLK)

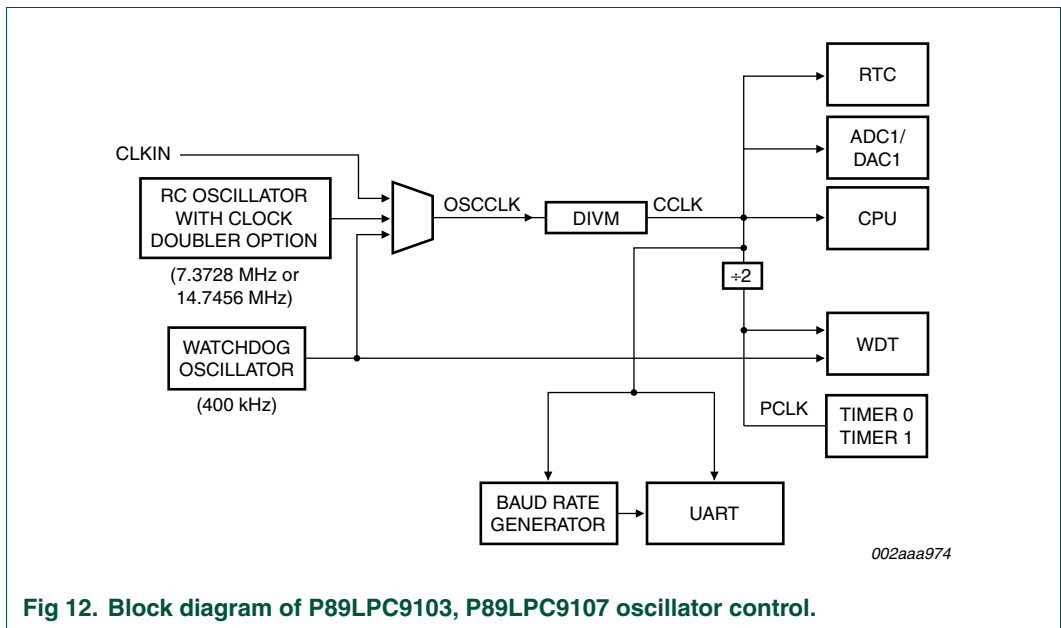

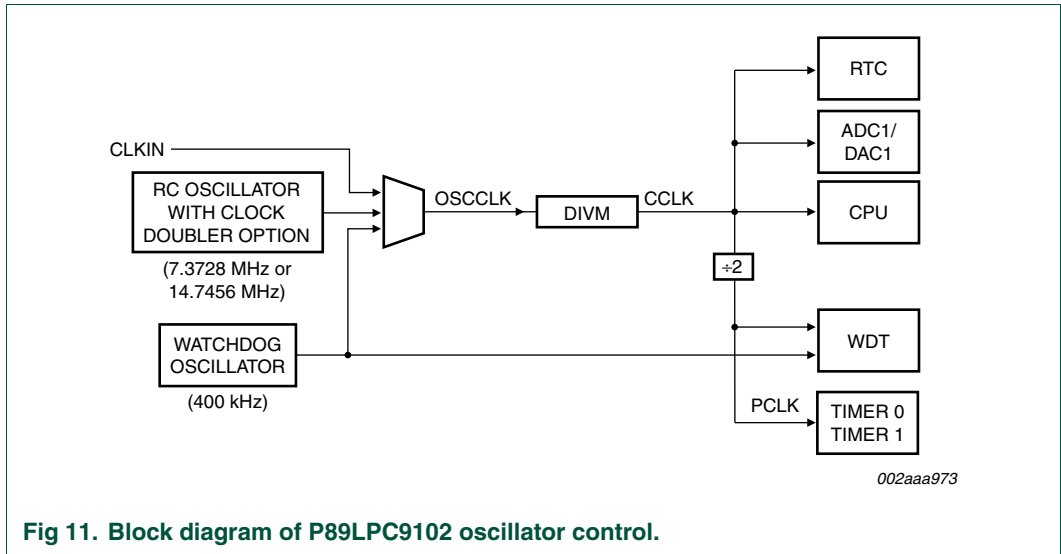

2.5 Watchdog oscillator option

The Watchdog has a separate oscillator which has a frequency of 400 kHz. This oscillator can be used to save power when a high clock frequency is not needed.

2.6 External clock input option

In this configuration, the processor clock is derived from an external source driving the P0.5/CMPREF/CLKIN pin. The rate may be from 0 Hz up to 18 MHz. This pin may also be used as a standard port pin.

When using an external clock input frequency above 12 MHz, the reset input function of P1.5 must be enabled. An external circuit is required to hold the device in reset at power-up until V_{DD} has reached its specified level. When system power is removed V_{DD} will fall below the minimum specified operating voltage. When using an external clock input frequency above 12 MHz, in some applications, an external brownout detect circuit may be required to hold the device in reset when V_{DD} falls below the minimum specified operating voltage. These requirements for clock frequencies above 12 MHz do not apply when using the internal RC oscillator in clock doubler mode.

2.7 CPU Clock (CCLK) wake-up delay

The P89LPC9102/9103/9107 has an internal wake-up timer that delays the clock until it stabilizes depending to the clock source used.

2.8 CCLK modification: DIVM register

The OSCCLK frequency can be divided down, by an integer, up to 510 times by configuring a dividing register, DIVM, to provide CCLK. This produces the CCLK frequency using the following formula:

$$\text{CCLK frequency} = f_{\text{osc}} / (2N)$$

Where: f_{osc} is the frequency of OSCCLK

N is the value of DIVM.

Since N ranges from 0 to 255, the CCLK frequency can be in the range of f_{osc} to $f_{osc}/510$. (for $N = 0$, $CCLK = f_{osc}$).

This feature makes it possible to temporarily run the CPU at a lower rate, reducing power consumption. By dividing the clock, the CPU can retain the ability to respond to events other than those that can cause interrupts (i.e., events that allow exiting the Idle mode) by executing its normal program at a lower rate. This can often result in lower power consumption than in Idle mode. This can allow bypassing the start-up time in cases where Power-down mode would otherwise be used. The value of DIVM may be changed by the program at any time without interrupting code execution.

2.9 Low power select

The P89LPC9102/9103/9107 is designed to run at 18 MHz (CCLK) maximum. However, if CCLK is 8 MHz or slower, the CLKLP SFR bit (AUXR1.7) can be set to a logic 1 to lower the power consumption further. On any reset, CLKLP is logic 0 allowing highest performance. This bit can then be set in software if CCLK is running at 8 MHz or slower.

3. A/D converter

The P89LPC9102/9103/9107 has an 8-bit, 4-channel, multiplexed successive approximation analog-to-digital converter module (ADC1) and one DAC module (DAC1). A block diagram of the A/D converter is shown in [Figure 13](#). The A/D consists of a 4-input multiplexer which feeds a sample and hold circuit providing an input signal to one of two comparator inputs. The control logic in combination with the successive approximation register (SAR) drives a digital-to-analog converter which provides the other input to the comparator. The output of the comparator is fed to the SAR.

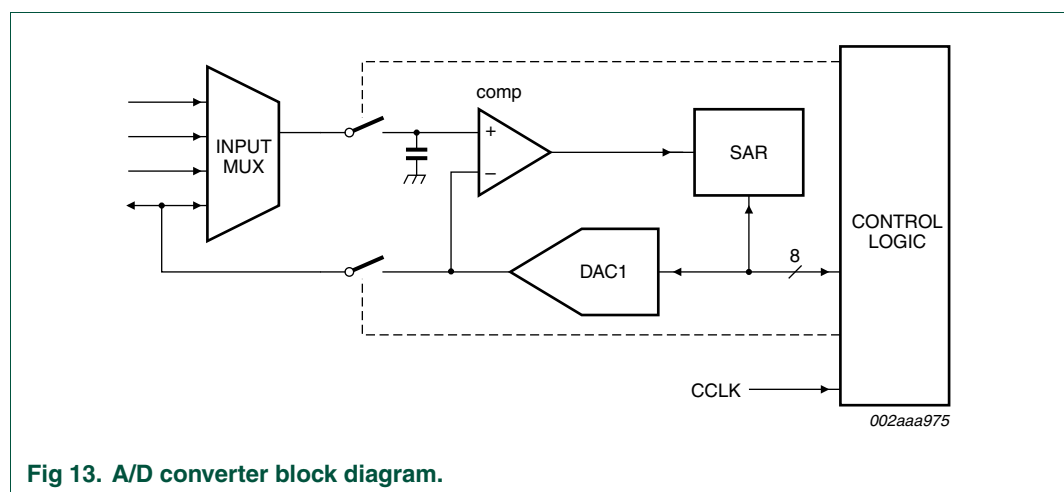

Fig 13. A/D converter block diagram.

3.1 Features

- An 8-bit, 4-channel, multiplexed input, successive approximation A/D converter
- Four A/D result registers
- Six operating modes

- Fixed channel, single conversion mode
- Fixed channel, continuous conversion mode
- Auto scan, single conversion mode
- Auto scan, continuous conversion mode
- Dual channel, continuous conversion mode
- Single step mode
- Three conversion start modes
 - Timer triggered start
 - Start immediately
 - Edge triggered
- 8-bit conversion time of $\geq 3.9 \mu\text{s}$ at an ADC clock of 3.3 MHz
- Interrupt or polled operation
- Boundary limits interrupt
- DAC output to a port pin with high output impedance
- Clock divider
- Power-down mode

3.2 A/D operating modes

3.2.1 Fixed channel, single conversion mode

A single input channel can be selected for conversion. A single conversion will be performed and the result placed in the result register which corresponds to the selected input channel (See [Table 10](#)). An interrupt, if enabled, will be generated after the conversion completes. The input channel is selected in the ADINS register. This mode is selected by setting the SCAN1 bit in the ADMODA register.

Table 10: Input channels and Result registers for fixed channel single, auto scan single, and autoscan continuous conversion modes.

Result register	Input channel	Result register	Input channel
AD1DAT0	AD10	AD1DAT2	AD12
AD1DAT1	AD11	AD1DAT3	AD13

3.2.2 Fixed channel, continuous conversion mode

A single input channel can be selected for continuous conversion. The results of the conversions will be sequentially placed in the four result registers [Table 11](#). An interrupt, if enabled, will be generated after every four conversions. Additional conversion results will again cycle through the four result registers, overwriting the previous results. Continuous conversions continue until terminated by the user. This mode is selected by setting the SCC1 bit in the ADMODA register.

3.2.3 Auto scan, single conversion mode

Any combination of the four input channels can be selected for conversion by setting a channel's respective bit in the ADINS register. The channels are converted from LSB to MSB order (in ADINS). A single conversion of each selected input will be performed and the result placed in the result register which corresponds to the selected input channel

(See [Table 10](#)). An interrupt, if enabled, will be generated after all selected channels have been converted. If only a single channel is selected this is equivalent to single channel, single conversion mode. This mode is selected by setting the SCAN1 bit in the ADMODA register.

Table 11: Result registers and conversion results for fixed channel, continuous conversion mode.

Result register	Contains
AD1DAT0	Selected channel, first conversion result
AD1DAT1	Selected channel, second conversion result
AD1DAT2	Selected channel, third conversion result
AD1DAT3	Selected channel, fourth conversion result

3.2.4 Auto scan, continuous conversion mode

Any combination of the four input channels can be selected for conversion by setting a channel's respective bit in the ADINS register. The channels are converted from LSB to MSB order (in ADINS). A conversion of each selected input will be performed and the result placed in the result register which corresponds to the selected input channel (See [Table 10](#)). An interrupt, if enabled, will be generated after all selected channels have been converted. The process will repeat starting with the first selected channel. Additional conversion results will again cycle through the result registers of the selected channels, overwriting the previous results. Continuous conversions continue until terminated by the user. This mode is selected by setting the BURST1 bit in the ADMODA register.

3.2.5 Dual channel, continuous conversion mode

Any combination of two of the four input channels can be selected for conversion. The result of the conversion of the first channel is placed in the first result register. The result of the conversion of the second channel is placed in the second result register. The first channel is again converted and its result stored in the third result register. The second channel is again converted and its result placed in the fourth result register (See [Table 12](#)). An interrupt is generated, if enabled, after every set of four conversions (two conversions per channel). This mode is selected by setting the SCC1 bit in the ADMODA register.

Table 12: Result registers and conversion results for dual channel, continuous conversion mode.

Result register	Contains
AD1DAT0	First channel, first conversion result
AD1DAT1	Second channel, first conversion result
AD1DAT2	First channel, second conversion result
AD1DAT3	Second channel, second conversion result

3.2.6 Single step

This special mode allows 'single-stepping' in an auto scan conversion mode. Any combination of the four input channels can be selected for conversion. After each channel is converted, an interrupt is generated, if enabled, and the A/D waits for the next start condition. The result of each channel is placed in the result register which corresponds to

the selected input channel (See [Table 10](#)). May be used with any of the start modes. This mode is selected by clearing the BURST1, SCC1, and SCAN1 bits in the ADMODA register.

3.2.7 Conversion mode selection bits

The A/D uses three bits in ADMODA to select the conversion mode. These mode bits are summarized in [Table 13](#), below. Combinations of the three bits, other than the combinations shown, are undefined.

Table 13: Conversion mode bits.

BURST1	SCC1	Scan1	ADC1 conversion mode	BURST0	SCC0	Scan0	ADC0 conversion mode
0	0	0	single step	0	0	0	single step
0	0	1	fixed channel, single auto scan, single	0	0	1	fixed channel, single auto scan, single
0	1	0	fixed channel, continuous dual channel, continuous	0	1	0	fixed channel, continuous dual channel, continuous
1	0	0	auto scan, continuous	1	0	0	auto scan, continuous

3.3 Trigger modes

3.3.1 Timer triggered start

An A/D conversion is started by the overflow of Timer 0. Once a conversion has started, additional Timer 0 triggers are ignored until the conversion has completed. The Timer triggered start mode is available in all A/D operating modes. This mode is selected by the TMM1 bit and the ADCS11 and ADCS10 bits (See [Table 15](#)).

3.3.2 Start immediately

Programming this mode immediately starts a conversion. This start mode is available in all A/D operating modes. This mode is selected by setting the ADCS11 and ADCS10 bits in the ADCON1 register (See [Table 15](#)).

3.3.3 Edge triggered

An A/D conversion is started by rising or falling edge of P1.4. Once a conversion has started, additional edge triggers are ignored until the conversion has completed. The edge triggered start mode is available in all A/D operating modes. This mode is selected by setting the ADCS11 and ADCS10 bits in the ADCON1 register (See [Table 15](#)).

3.3.4 Boundary limits interrupt

The A/D converter has both a HIGH and LOW boundary limit register. After the four MSBs have been converted, these four bits are compared with the four MSBs of the boundary HIGH and LOW registers. If the four MSBs of the conversion are outside the limit an interrupt will be generated, if enabled. If the conversion result is within the limits, the

boundary limits will again be compared after all eight bits have been converted. An interrupt will be generated, if enabled, if the result is outside the boundary limits. The boundary limit may be disabled by clearing the boundary limit interrupt enable.

3.4 DAC output to a port pin with high-impedance

The AD0DAT3 register is used to hold the value fed to the DAC. After a value has been written to AD0DAT3 the DAC output will appear on the DAC0 pin. The DAC output is enabled by the ENDAC0 bit in the ADMODB register (See [Table 19](#)).

3.5 Clock divider

The A/D converter requires that its internal clock source be in the range of 500 kHz to 3.3 MHz to maintain accuracy. A programmable clock divider that divides the clock from 1 to 8 is provided for this purpose (See [Table 19](#)).

3.6 I/O pins used with A/D converter functions

The analog input pins used with for the A/D converter have a digital input and output function. In order to give the best analog performance, pins that are being used with the ADC or DAC should have their digital outputs and inputs disabled and have the 5 V tolerance disconnected. Digital outputs are disabled by putting the port pins into the input-only mode as described in the Port Configurations section (see [Table 25](#)).

Digital inputs will be disconnected automatically from these pins when the pin has been selected by setting its corresponding bit in the ADINS register and the A/D or DAC has been enabled. Pins selected in ADINS will be 3 V tolerant provided that the A/D is enabled and the device is not in power-down, otherwise the pin will remain 5 V tolerant.

3.7 Power-down and idle mode

In idle mode the A/D converter, if enabled, will continue to function and can cause the device to exit idle mode when the conversion is completed if the A/D interrupt is enabled. In Power-down mode or Total Power-down mode, the A/D does not function. If the A/D is enabled, it will consume power. Power can be reduced by disabling the A/D.

Table 14: A/D Control register 1 (ADCON1 - address 97h) bit allocation

7	AIN13	when set, enables the AD13 pin for sampling and conversion

4. Interrupts

The P89LPC9102 supports nine interrupt sources: timers 0 and 1, brownout detect, watchdog timer/RTC, keyboard, comparator 1, and the A/D converter.

The P89LPC9103 supports nine interrupt sources: timers 0 and 1, serial port Tx, serial port Rx, combined serial port Rx/Tx, brownout detect, watchdog timer/RTC, keyboard, comparator, and the A/D converter.

Each interrupt source can be individually enabled or disabled by setting or clearing a bit in the interrupt enable registers IEN0 or IEN1. The IEN0 register also contains a global disable bit, EA, which disables all interrupts.

Each interrupt source can be individually programmed to one of four priority levels by setting or clearing bits in the interrupt priority registers IP0, IPOH, IP1, and IP1H. An interrupt service routine in progress can be interrupted by a higher priority interrupt, but not by another interrupt of the same or lower priority. The highest priority interrupt service cannot be interrupted by any other interrupt source. If two requests of different priority levels are pending at the start of an instruction, the request of higher priority level is serviced.

If requests of the same priority level are pending at the start of an instruction, an internal polling sequence determines which request is serviced. This is called the arbitration ranking. Note that the arbitration ranking is only used to resolve pending requests of the same priority level.

4.1 Interrupt priority structure

Table 22: Interrupt priority level

Priority bits		Interrupt priority level
IPxH	IPx	
0	0	Level 0 (lowest priority)
0	1	Level 1
1	0	Level 2
1	1	Level 3

There are four SFRs associated with the four interrupt levels: IP0, IP0H, IP1, IP1H. Every interrupt has two bits in IPx and IPxH (x = 0,1) and can therefore be assigned to one of four levels, as shown in [Table 22](#).

Table 23: Summary of interrupts

Description	Interrupt flag bit(s)	Vector address	Interrupt enable bit(s)	Interrupt priority	Arbitration ranking	Power-down wake-up
Timer 0 interrupt	TF0	000Bh	ET0 (IEN0.1)	IP0H.1,IP0.1	4	No
Timer 1 interrupt	TF1	001Bh	ET1 (IEN0.3)	IP0H.3,IP0.3	10	No
Serial port Tx and Rx (9103, 9107)	TI and RI	0023h	ES/ESR (IEN0.4)	IP0H.4,IP0.4	13	No
Serial port Rx (9103, 9107)	RI					
Brownout detect	BOF	002Bh	EBO (IEN0.5)	IP0H.5,IP0.5	2	Yes
Watchdog timer/Real-time clock	WDOVF/RTCF	0053h	EWDRT (IEN0.6)	IP0H.6,IP0.6	3	Yes
KBI interrupt	KBIF	003Bh	EKBI (IEN1.1)	IP0H.0,IP0.0	8	Yes
Comparator 1 interrupt	CMF1	0043h	EC (IEN1.2)	IP0H.0,IP0.0	11	Yes
Serial port Tx (9103, 9107)	TI	006Bh	EST (IEN1.6)	IP0H.0,IP0.0	12	No
ADC	ADC11,BNDI1	0073h	EAD (IEN1.7)	IP1H.7,IP1.7	15 (lowest)	No

4.1.1 External interrupt inputs

The P89LPC9102/9103/9107 has a Keypad Interrupt function. This can be used as an external interrupt input.

If enabled when the P89LPC9102/9103/9107 is put into Power-down mode or Idle mode, the interrupt will cause the processor to wake-up and resume operation. Refer to [Section 6.3 "Power reduction modes"](#) for details.

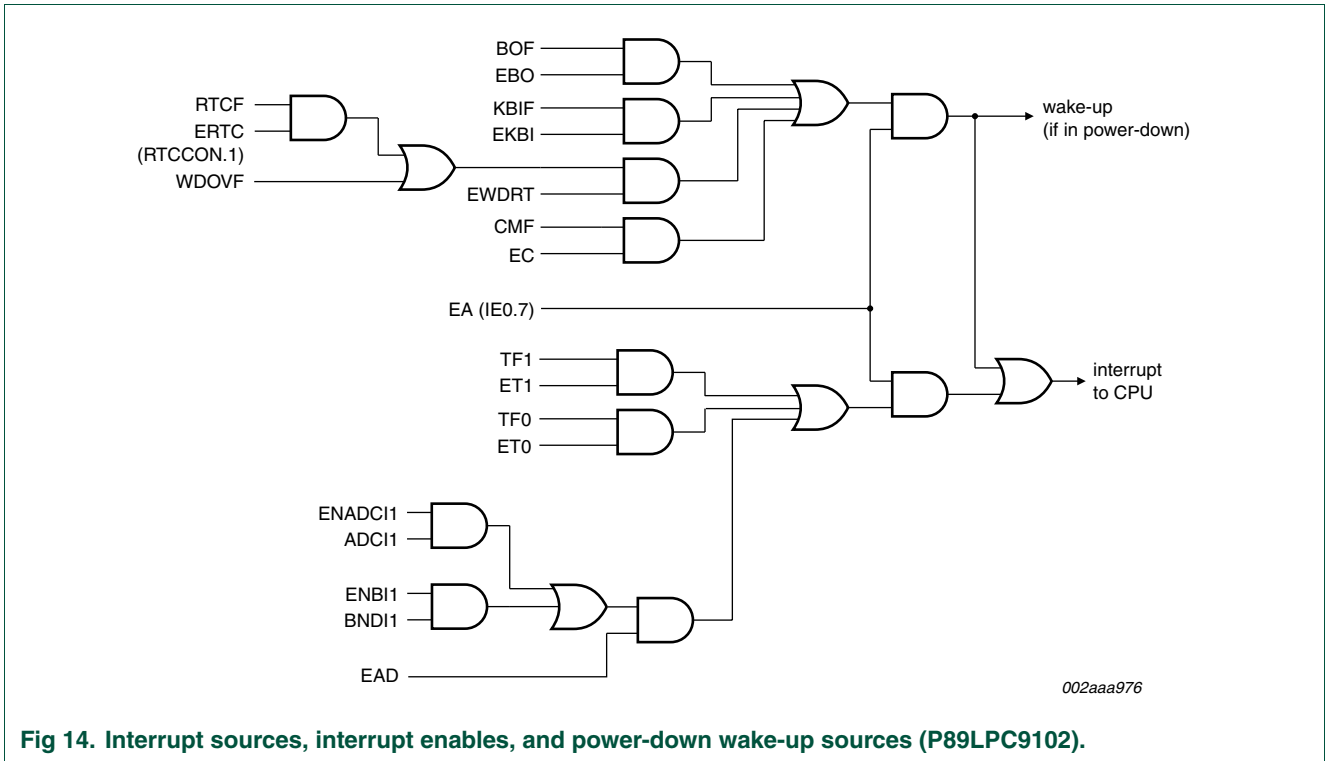

Fig 14. Interrupt sources, interrupt enables, and power-down wake-up sources (P89LPC9102).

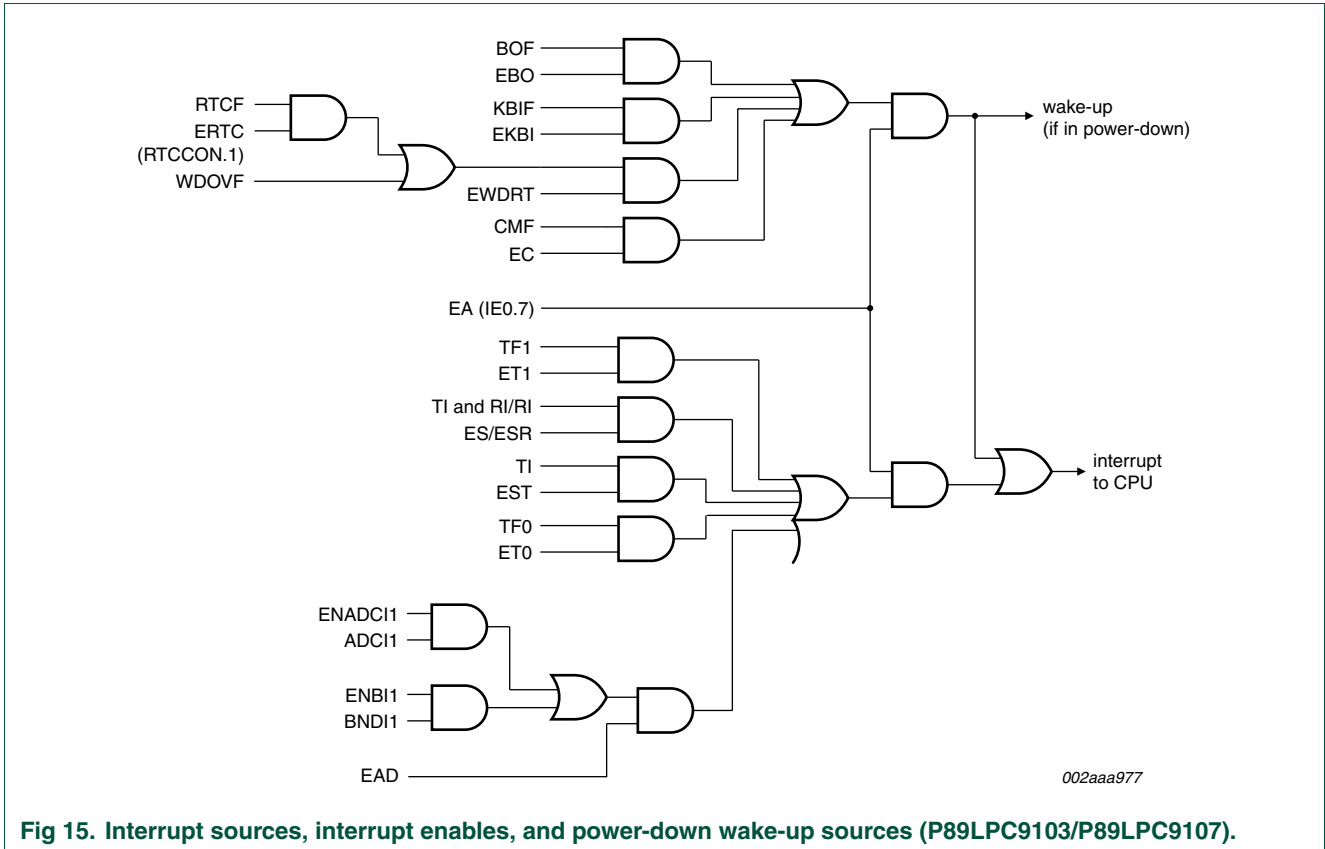

Fig 15. Interrupt sources, interrupt enables, and power-down wake-up sources (P89LPC9103/P89LPC9107).

5. I/O ports

The P89LPC9102/9103/9107 has three I/O ports: Port 0, Port 1, and Port 3. Ports 0 and 1 are 8-bit ports and Port 3 is a 2-bit port. The exact number of I/O pins available depends upon the clock and reset options chosen (see [Table 24](#)).

Table 24: Number of I/O pins available

Clock source	Reset option	Number of I/O pins (8-pin package)
On-chip RC oscillator or watchdog oscillator	No external reset (except during power-up)	8
	External $\overline{\text{RST}}$ pin supported	7
External clock input	No external reset (except during power-up)	7
	External $\overline{\text{RST}}$ pin supported ^[1]	6
Clock source	Reset option	Number of I/O pins (8-pin package)
On-chip oscillator or watchdog oscillator	No external reset (except during power-up)	8

[1] Required for operation with external clock frequency above 12 MHz.

5.1 Port configurations

All but one I/O port pin on the P89LPC9102/9103/9107 may be configured by software to one of four types on a pin-by-pin basis, as shown in [Table 25](#). These are: quasi-bidirectional (standard 80C51 port outputs), push-pull, open drain, and input-only. Two configuration registers for each port select the output type for each port pin.

P1.5 ($\overline{\text{RST}}$) can only be an input and cannot be configured.

Table 25: Port output configuration settings

PxM1.y	PxM2.y	Port output mode
0	0	Quasi-bidirectional
0	1	Push-pull
1	0	Input only (high-impedance)
1	1	Open drain

5.2 Quasi-bidirectional output configuration

Quasi-bidirectional outputs can be used both as an input and output without the need to reconfigure the port. This is possible because when the port outputs a logic HIGH, it is weakly driven, allowing an external device to pull the pin LOW. When the pin is driven LOW, it is driven strongly and able to sink a large current. There are three pull-up transistors in the quasi-bidirectional output that serve different purposes.

One of these pull-ups, called the 'very weak' pull-up, is turned on whenever the port latch for the pin contains a logic 1. This very weak pull-up sources a very small current that will pull the pin HIGH if it is left floating.

A second pull-up, called the 'weak' pull-up, is turned on when the port latch for the pin contains a logic 1 and the pin itself is also at a logic 1 level. This pull-up provides the primary source current for a quasi-bidirectional pin that is outputting a 1. If this pin is pulled LOW by an external device, the weak pull-up turns off, and only the very weak

pull-up remains on. In order to pull the pin LOW under these conditions, the external device has to sink enough current to overpower the weak pull-up and pull the port pin below its input threshold voltage.

The third pull-up is referred to as the 'strong' pull-up. This pull-up is used to speed up LOW-to-HIGH transitions on a quasi-bidirectional port pin when the port latch changes from a logic 0 to a logic 1. When this occurs, the strong pull-up turns on for two CPU clocks quickly pulling the port pin HIGH.

The quasi-bidirectional port configuration is shown in [Figure 16](#).

Although the P89LPC9102/9103/9107 is a 3 V device most of the pins are 5 V-tolerant. If 5 V is applied to a pin configured in quasi-bidirectional mode, there will be a current flowing from the pin to V_{DD} causing extra power consumption. Therefore, applying 5 V to pins configured in quasi-bidirectional mode is discouraged.

A quasi-bidirectional port pin has a Schmitt triggered input that also has a glitch suppression circuit.

(Please refer to the *P89LPC9102/9103/9107 data sheet, Dynamic characteristics* for glitch filter specifications).

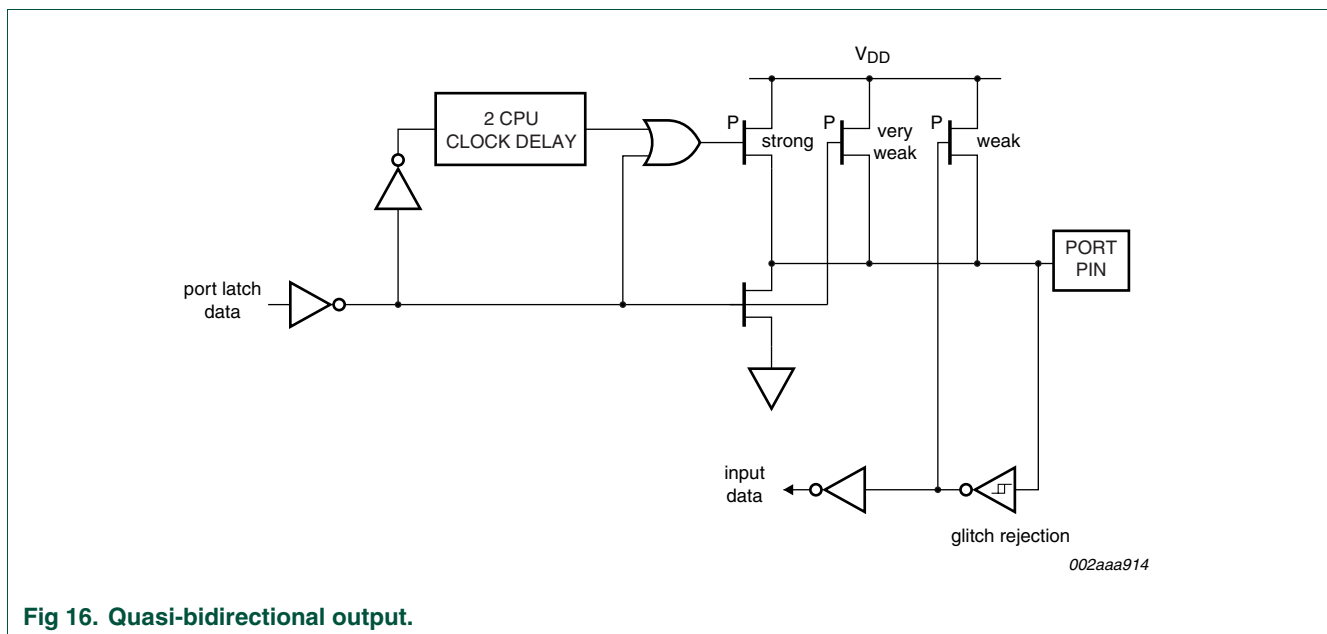

Fig 16. Quasi-bidirectional output.

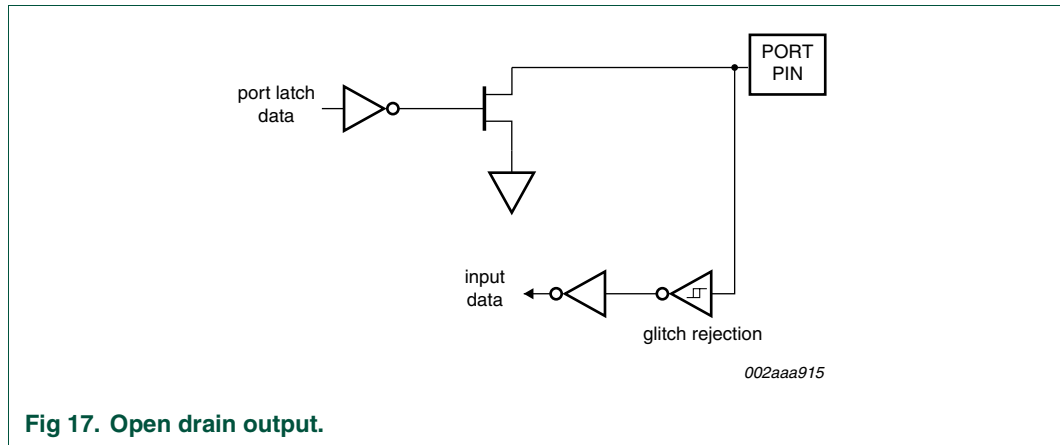

5.3 Open drain output configuration

The open drain output configuration turns off all pull-ups and only drives the pull-down transistor of the port pin when the port latch contains a logic 0. To be used as a logic output, a port configured in this manner must have an external pull-up, typically a resistor tied to V_{DD} . The pull-down for this mode is the same as for the quasi-bidirectional mode.

The open drain port configuration is shown in [Figure 17](#).

An open drain port pin has a Schmitt triggered input that also has a glitch suppression circuit.

Please refer to the *P89LPC9102/9103/9107 data sheet, Dynamic characteristics* for glitch filter specifications.

5.4 Input-only configuration

The input port configuration is shown in [Figure 18](#). It is a Schmitt triggered input that also has a glitch suppression circuit.

(Please refer to the *P89LPC9102/9103/9107 data sheet, Dynamic characteristics* for glitch filter specifications).

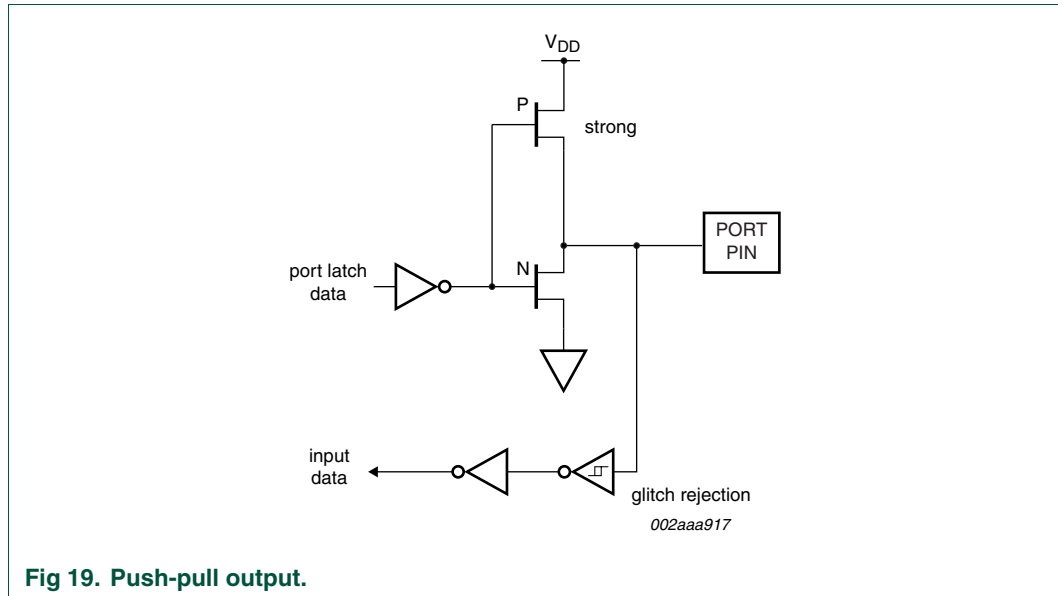

5.5 Push-pull output configuration

The push-pull output configuration has the same pull-down structure as both the open drain and the quasi-bidirectional output modes, but provides a continuous strong pull-up when the port latch contains a logic 1. The push-pull mode may be used when more source current is needed from a port output.

The push-pull port configuration is shown in [Figure 19](#).

A push-pull port pin has a Schmitt triggered input that also has a glitch suppression circuit.

(Please refer to the *P89LPC9102/9103/9107 data sheet, Dynamic characteristics* for glitch filter specifications).

5.6 Port 0 analog functions

The P89LPC9102/9103/9107 incorporates one Analog Comparator. In order to give the best analog performance and minimize power consumption, pins that are being used for analog functions must have both the digital outputs and digital inputs disabled.

Digital outputs are disabled by putting the port pins into the input-only mode as described in the Port Configurations section (see [Figure 18](#)).

Digital inputs on Port 0 may be disabled through the use of the PT0AD register. Bits 1 through 5 in this register correspond to pins P0.1 through P0.5 of Port 0, respectively. Setting the corresponding bit in PT0AD disables that pin's digital input. Port bits that have their digital inputs disabled will be read as logic 0 by any instruction that accesses the port.

On any reset, PT0AD bits 1 through 5 default to logic 0s to enable the digital functions.

5.7 Additional port features

After power-up, all pins are in Input-Only mode. **Please note that this is different from the LPC76x series of devices.**

- After power-up, all I/O pins except P1.5, may be configured by software.
- Pin P1.5 is input only.

Every output on the P89LPC9102/9103/9107 has been designed to sink typical LED drive current. However, there is a maximum total output current for all ports which must not be exceeded. Please refer to the *P89LPC9102/9103/9107 data sheet* for detailed specifications.

All ports pins that can function as an output have slew rate controlled outputs to limit noise generated by quickly switching output signals. The slew rate is factory-set to approximately 10 ns rise and fall times.

Table 26: Port output configuration

Port pin	Configuration SFR bits		Alternate usage	Notes
	PxM1.y	PxM2.y		
P0.1	P0M1.1	P0M2.1	KBI1, AD10	Refer to Section 5.6 “Port 0 analog functions” for usage as analog inputs.
P0.2	P0M1.2	P0M2.2	KBI2, AD11	
P0.3	P0M1.3	P0M2.3	KBI3, CIN1B, AD12

P1.2	P1M1.2	P1M2.2	T0	
P1.5	P1M1.5	P1M2.5	$\overline{\text{RST}}$	

6. Power monitoring functions

The P89LPC9102/9103/9107 incorporates power monitoring functions designed to prevent incorrect operation during initial power-on and power loss or reduction during operation. This is accomplished with two hardware functions: Power-on Detect and Brownout Detect.

6.1 Brownout detection

The Brownout Detect function determines if the power supply voltage drops below a certain level. The default operation for a Brownout Detection is to cause a processor reset. However, it may alternatively be configured to generate an interrupt by setting the BOI (PCON.4) bit and the EBO (IEN0.5) bit.

Enabling and disabling of Brownout Detection is done via the BOPD (PCON.5) bit, bit field PMOD1-0 (PCON.1-0) and user configuration bit BOE (UCFG1.5). If BOE is in an unprogrammed state, brownout is disabled regardless of PMOD1-0 and BOPD. If BOE is in a programmed state, PMOD1-0 and BOPD will be used to determine whether Brownout Detect will be disabled or enabled. PMOD1-0 is used to select the power reduction mode. If PMOD1-0 = '11', the circuitry for the Brownout Detection is disabled for lowest power consumption. BOPD defaults to logic 0, indicating brownout detection is enabled on power-on if BOE is programmed.

If Brownout Detection is enabled, the brownout condition occurs when V_{DD} falls below the Brownout trip voltage, V_{BO} (see *P89LPC9102/9103 Static characteristics*), and is negated when V_{DD} rises above V_{BO} . If Brownout Detection is disabled, the operating voltage range for V_{DD} is 2.4 V to 3.6 V. If the P89LPC9102/9103/9107 device is to operate with a power supply that can be below 2.7 V, BOE should be left in the unprogrammed state so that the device can operate at 2.4 V, otherwise continuous brownout reset may prevent the device from operating.

An application that uses the internal RC oscillator in clock doubler mode and uses Brownout detect should program the BOE bit so that a brownout condition will be detected when V_{DD} falls below 2.7 V.

If Brownout Detect is enabled (BOE programmed, PMOD1-0 \neq '11', BOPD = 0), BOF (RSTSRC.5) will be set when a brownout is detected, regardless of whether a reset or an interrupt is enabled. BOF will stay set until it is cleared in software by writing logic 0 to the bit. Note that if BOE is unprogrammed, BOF is meaningless. If BOE is programmed, and a initial power-on occurs, BOF will be set in addition to the power-on flag (POF - RSTSRC.4).

For correct activation of Brownout Detect, certain V_{DD} rise and fall times must be observed. Please see the P89LPC9102/9103 Data sheet for specifications.

Table 27: Brownout options

BOE (UCFG1.5)	PMOD1-0 (PCON.1-0)	BOPD (PCON.5)	BOI (PCON.4)	EBO (IEN0.5)	EA (IEN0.7)	Description
0 (erased)	XX	X	X	X	X	Brownout disabled. V_{DD} operating range is 2.4 V to 3.6 V.
1 (program med)	11 (total power-down)	X	X	X	X	
	\neq 11 (any mode other than total power-down)	1 (brownout detect powered down)	X	X	X	Brownout disabled. V_{DD} operating range is 2.4 V to 3.6 V. However, BOPD is default to logic 0 upon power-up.
		0 (brownout detect active)	0 (brownout detect generates reset)	X	X	Brownout reset enabled. V_{DD} operating range is 2.7 V to 3.6 V. Upon a brownout reset, BOF (RSTSRC.5) will be set to indicate the reset source. BOF can be cleared by writing logic 0 to the bit.
		1 (brownout detect generates an interrupt)	1 (enable brownout interrupt)	1 (global interrupt enable)	1 (global interrupt enable)	Brownout interrupt enabled. V_{DD} operating range is 2.7 V to 3.6 V. Upon a brownout interrupt, BOF (RSTSRC.5) will be set. BOF can be cleared by writing logic 0 to the bit.
				0	X	Both brownout reset and interrupt disabled. V_{DD} operating range is 2.4 V to 3.6 V. However, BOF (RSTSRC.5) will be set when V_{DD} falls to the Brownout Detection trip point. BOF can be cleared by writing logic 0 to the bit.
				X	0	

6.2 Power-on detection

The Power-On Detect has a function similar to the Brownout Detect, but is designed to work as power initially comes up, before the power supply voltage reaches a level where the Brownout Detect can function. The POF flag (RSTSRC.4) is set to indicate an initial power-on condition. The POF flag will remain set until cleared by software by writing logic 0 to the bit. Note that if BOE (UCFG1.5) is programmed, BOF (RSTSRC.5) will be set when POF is set. If BOE is unprogrammed, BOF is meaningless.

6.3 Power reduction modes

The P89LPC9102/9103/9107 supports three different power reduction modes as determined by SFR bits PCON.1-0 (see [Table 28](#)).

Table 28: Power reduction modes

PMOD1 (PCON.1)	PMOD0 (PCON.0)	Description
0	0	Normal mode (default) - no power reduction.
0	1	Idle mode. The Idle mode leaves peripherals running in order to allow them to activate the processor when an interrupt is generated. Any enabled interrupt source or reset may terminate Idle mode.
1	0	<p>Power-down mode:</p> <p>The Power-down mode stops the oscillator in order to minimize power consumption. The P89LPC9102/9103/9107 exits Power-down mode via any reset, or certain interrupts, brownout Interrupt, or keyboard, Real-time Clock/System Timer), Watchdog, and comparator trips. Waking up by reset is only enabled if the corresponding reset is enabled, and waking up by interrupt is only enabled if the corresponding interrupt is enabled and the EA SFR bit (IEN0.7) is set.</p> <p>In Power-down mode the internal RC oscillator is disabled unless both the RC oscillator has been selected as the system clock AND the RTC is enabled.</p> <p>In Power-down mode, the power supply voltage may be reduced to the RAM keep-alive voltage VRAM. This retains the RAM contents at the point where Power-down mode was entered. SFR contents are not guaranteed after V_{DD} has been lowered to VRAM, therefore it is recommended to wake up the processor via Reset in this situation. V_{DD} must be raised to within the operating range before the Power-down mode is exited.</p> <p>When the processor wakes up from Power-down mode, it will start the oscillator immediately and begin execution when the oscillator is stable. Oscillator stability is determined by counting 256 clocks after start-up for the internal RC or external clock input configurations.</p> <p>Some chip functions continue to operate and draw power during Power-down mode, increasing the total power used during power-down. These include:</p> <ul style="list-style-type: none"> • Brownout Detect • Watchdog timer if WDCLK (WDCON.0) is logic 1 • Comparator (Note: Comparator can be powered down separately with PCONA.5 set to logic 1 and comparator disabled) • Real-time Clock/System Timer (unless RTCPD is logic 1)
1	1	<p>Total Power-down mode: This is the same as Power-down mode except that the Brownout Detection circuitry and the voltage comparator is also disabled to conserve additional power. Note that a brownout reset or interrupt will not occur. Voltage comparator interrupt and Brownout interrupt cannot be used as a wake-up source. The internal RC oscillator is disabled unless both the RC oscillator has been selected as the system clock AND the RTC is enabled.</p> <p>The following are the wake-up options supported:</p> <ul style="list-style-type: none"> • Watchdog timer if WDCLK (WDCON.0) is logic 1. Could generate Interrupt or Reset, either one can wake up the device • Keyboard Interrupt • Real-time Clock/System Timer (unless RTCPD, i.e., PCONA.7 is logic 1) <p>Note: Using the internal RC-oscillator to clock the RTC during power-down may result in relatively high power consumption. Lower power consumption can be achieved by using an external low frequency clock when the Real-time Clock is running during power-down.</p>

Table 29: Power Control register (PCON - address 87h) bit allocation

Bit	7	6	5	4	3	2	1	0
Symbol	SMOD1	SMOD0	BOPD	BOI	GF1	GF0	PMOD1	PMOD0
Reset	0	0	0	0	0	0	0	0

Table 30: Power Control register (PCON - address 87h) bit description

Bit	Symbol	Description
0	PMOD0	Power Reduction Mode (see Section 6.3)
1	PMOD1	
2	GF0	General Purpose Flag 0. May be read or written by user software, but has no effect on operation
3	GF1	General Purpose Flag 1. May be read or written by user software, but has no effect on operation
4	BOI	Brownout Detect Interrupt Enable. When logic 1, Brownout Detection will generate a interrupt. When logic 0, Brownout Detection will cause a reset
5	BOPD	Brownout Detect power-down. When logic 1, Brownout Detect is powered down and therefore disabled. When logic 0, Brownout Detect is enabled. (Note: BOPD must be logic 0 before any programming or erasing commands can be issued. Otherwise these commands will be aborted.)
6	SMOD0	Framing Error Location: <ul style="list-style-type: none"> When logic 0, bit 7 of SCON is accessed as SM0 for the UART When logic 1, bit 7 of SCON is accessed as the framing error status (FE) for the UART (P89LPC9103)
7	SMOD1	Double Baud Rate bit for the serial port (UART) when Timer 1 is used as the baud rate source. When logic 1, the Timer 1 overflow rate is supplied to the UART. When logic 0, the Timer 1 overflow rate is divided by two before being supplied to the UART. (See Section 10) (P89LPC9103)

Table 32: Power Control register A (PCONA - address B5h) bit description

Bit	Symbol	Description
0	-	reserved
1	SPD	Serial Port (UART) power-down: When logic 1, the internal clock to the UART is disabled. Note that in either Power-down mode or Total Power-down mode, the UART clock will be disabled regardless of this bit (P89LPC9103).
2	-	reserved
3	-	reserved
4	ADPD	A/D Converter power-down: When logic 1, turns off the clock to the ADC. To fully power-down the ADC, the user should also set the ENADC1 and ENADC0 bits in registers ADCON1 and ADCON0.

Table 32: Power Control register A (PCONA - address B5h) bit description

Bit	Symbol	Description
5	VCPD	Analog Voltage Comparator power-down: When logic 1, the voltage comparator is powered down. User must disable the voltage comparator prior to setting this bit.
6	-	reserved
7	RTCPD	Real-time Clock power-down: When logic 1, the internal clock to the Real-time Clock is disabled.

7. Reset

The P1.5/ \overline{RST} pin can function as either an active LOW reset input or as a digital input, P1.5. The RPE (Reset Pin Enable) bit in UCFG1, when set to 1, enables the external reset input function on P1.5. When cleared, P1.5 may be used as an input pin.

NOTE: During a power-on sequence, The RPE selection is overridden and this pin will always function as a reset input. An external circuit connected to this pin should not hold this pin LOW during a Power-on sequence as this will keep the device in reset. After power-on this input will function either as an external reset input or as a digital input as defined by the RPE bit. Only a power-on reset will temporarily override the selection defined by RPE bit. Other sources of reset will not override the RPE bit.

NOTE: During a power cycle, V_{DD} must fall below V_{POR} (see *P89LPC9102/9103 Data sheet, Static characteristics*) before power is reapplied, in order to ensure a power-on reset.

Reset can be triggered from the following sources (see [Figure 20](#)):

- External reset pin (during power-on or if user configured via UCFG1. Required for external clock frequency above 12 MHz.)
- Power-on Detect
- Brownout Detect
- Watchdog timer
- Software reset
- UART break detect reset (P89LPC9103,P89LPC9107)

For every reset source, there is a flag in the Reset Register, RSTSRC. The user can read this register to determine the most recent reset source. These flag bits can be cleared in software by writing a logic 0 to the corresponding bit. More than one flag bit may be set:

- During a power-on reset, both POF and BOF are set but the other flag bits are cleared.
- For any other reset, any previously set flag bits that have not been cleared will remain set.

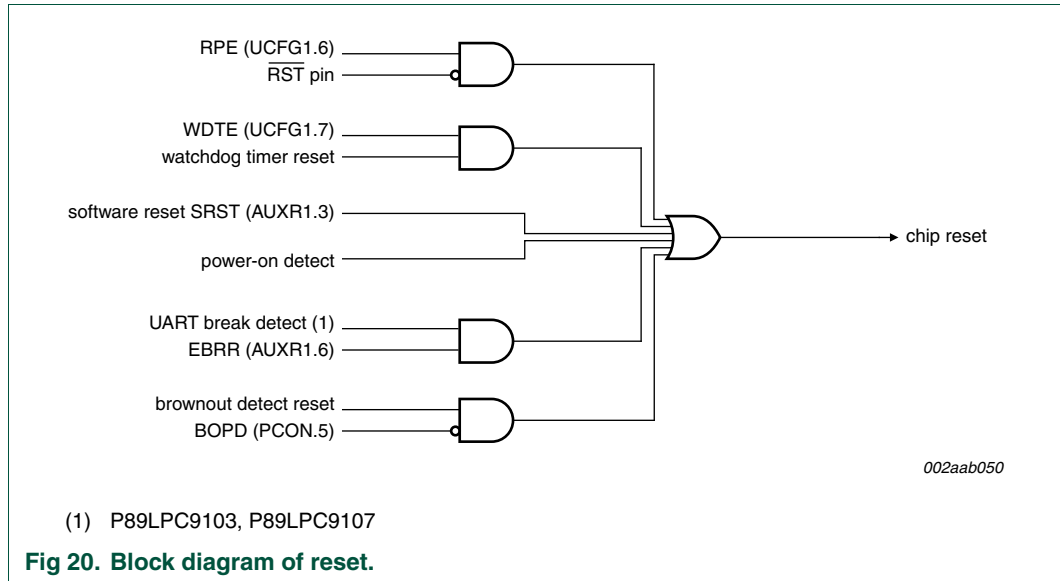

Table 33: Reset Sources register (RSTSRC - address DFh) bit allocation

Bit	7	6	5	4	3	2	1	0
Symbol	-	-	BOF	POF	R_BK	R_WD	R_SF	R_EX
Reset ^[1]	x	x	1	1	0	0	0	0

[1] The value shown is for a power-on reset. Other reset sources will set their corresponding bits.

Table 34: Reset Sources register (RSTSRC - address DFh) bit description

Bit	Symbol	Description
0	R_EX	external reset Flag. When this bit is logic 1, it indicates external pin reset. Cleared by software by writing a logic 0 to the bit or a Power-on reset. If \overline{RST} is still asserted after the Power-on reset is over, R_EX will be set.
1	R_SF	software reset Flag. Cleared by software by writing a logic 0 to the bit or a Power-on reset
2	R_WD	Watchdog timer reset flag. Cleared by software by writing a logic 0 to the bit or a Power-on reset. (NOTE: UCFG1.7 must be = 1)
3	R_BK	break detect reset. If a break detect occurs and EBRR (AUXR1.6) is set to logic 1, a system reset will occur. This bit is set to indicate that the system reset is caused by a break detect. Cleared by software by writing a logic 0 to the bit or on a Power-on reset (P89LPC9103, P89LPC9107).
4	POF	Power-on Detect Flag. When Power-on Detect is activated, the POF flag is set to indicate an initial power-up condition. The POF flag will remain set until cleared by software by writing a logic 0 to the bit. (Note: On a Power-on reset, both BOF and this bit will be set while the other flag bits are cleared.)
5	BOF	Brownout Detect Flag. When Brownout Detect is activated, this bit is set. It will remain set until cleared by software by writing a logic 0 to the bit. (Note: On a Power-on reset, both POF and this bit will be set while the other flag bits are cleared.)
6:7	-	reserved

7.1 Reset vector

Following reset, the P89LPC9102/9103/9107 will fetch instructions from either address 0000h or the Boot address. The Boot address is formed by using the Boot Vector as the HIGH byte of the address and the LOW byte of the address = 00h. The Boot address will

be used if a UART break reset (P89LPC9103, P89LPC9107) occurs or the non-volatile Boot Status bit (BOOTSTAT.0) = 1, or the device has been forced into ISP mode. Otherwise, instructions will be fetched from address 0000H.

8. Timers 0 and 1

The P89LPC9102/9103/9107 has two general-purpose counter/timers which are upward compatible with the 80C51 Timer 0 and Timer 1. Both can be configured to operate either as timers or event counters (see [Table 36](#)). An option to automatically toggle the Tx pin upon timer overflow has been added.

In the 'Timer' function, the timer is incremented every PCLK.

In the 'Counter' function, the register is incremented in response to a 1-to-0 transition on its corresponding external input pin (T0 or T1). The external input is sampled once during every machine cycle. When the pin is HIGH during one cycle and LOW in the next cycle, the count is incremented. The new count value appears in the register during the cycle following the one in which the transition was detected. Since it takes 2 machine cycles (4 CPU clocks) to recognize a 1-to-0 transition, the maximum count rate is $\frac{1}{4}$ of the CPU clock frequency. There are no restrictions on the duty cycle of the external input signal, but to ensure that a given level is sampled at least once before it changes, it should be held for at least one full machine cycle.

The 'Timer' or 'Counter' function is selected by control bits TnC/ \bar{T} (x = 0 and 1 for Timers 0 and 1 respectively) in the Special Function Register TMOD. Timer 0 and Timer 1 have five operating modes (modes 0, 1, 2, 3 and 6), which are selected by bit-pairs (TnM1, TnM0) in TMOD and TnM2 in TAMOD. Modes 0, 1, 2 and 6 are the same for both Timers/Counters. Mode 3 is different. The operating modes are described later in this section.

Table 35: Timer/Counter Mode register (TMOD - address 89h) bit allocation

Table 38: Timer/Counter Auxiliary Mode register (TAMOD - address 8Fh) bit description

Bit	Symbol	Description
0	T0M2	Mode Select for Timer 0. These bits are used with the T0M2 bit in the TAMOD register to determine the Timer 0 mode (see Table 38).
1:3	-	reserved
4	T1M2	Mode Select for Timer 1. These bits are used with the T1M2 bit in the TAMOD register to determine the Timer 1 mode (see Table 38).
The following timer modes are selected by timer mode bits TnM[2:0]:		
000 — 8048 Timer 'TLn' serves as 5-bit prescaler. (Mode 0).		
001 — 16-bit Timer/Counter 'THn' and 'TLn' are cascaded; there is no prescaler. (Mode 1).		
010 — 8-bit auto-reload Timer/Counter. THn holds a value which is loaded into TLn when it overflows. (Mode 2).		
011 — Timer 0 is a dual 8-bit Timer/Counter in this mode. TL0 is an 8-bit Timer/Counter controlled by the standard Timer 0 control bits. TH0 is an 8-bit timer only, controlled by the Timer 1 control bits (see text). Timer 1 in this mode is stopped. (Mode 3).		
100 — Reserved. User must not configure to this mode.		
101 — Reserved. User must not configure to this mode.		
110 — PWM mode (see Section 8.5).		
111 — Reserved. User must not configure to this mode.		
5:7	-	reserved

8.1 Mode 0

Putting either Timer into Mode 0 makes it look like an 8048 Timer, which is an 8-bit Counter with a divide-by-32 prescaler. [Figure 21](#) shows Mode 0 operation.

In this mode, the Timer register is configured as a 13-bit register. As the count rolls over from all logic 1s to all logic 0s, it sets the Timer interrupt flag TF_n. The count input is enabled to the Timer when TR_n = 1. TR_n is a control bit in the Special Function Register TCON ([Table 40](#)).

The 13-bit register consists of all 8 bits of TH_n and the lower 5 bits of TL_n. The upper 3 bits of TL_n are indeterminate and should be ignored. Setting the run flag (TR_n) does not clear the registers.

Mode 0 operation is the same for Timer 0 and Timer 1. See [Figure 21](#).

8.2 Mode 1

Mode 1 is the same as Mode 0, except that all 16 bits of the timer register (TH_n and TL_n) are used. See [Figure 22](#).

8.3 Mode 2

Mode 2 configures the Timer register as an 8-bit Counter (TLn) with automatic reload, as shown in [Figure 23](#). Overflow from TLn not only sets TFn, but also reloads TLn with the contents of THn, which must be preset by software. The reload leaves THn unchanged. Mode 2 operation is the same for Timer 0 and Timer 1.

8.4 Mode 3

When Timer 1 is in Mode 3 it is stopped. The effect is the same as setting TR1 = 0.

Timer 0 in Mode 3 establishes TL0 and TH0 as two separate 8-bit counters. The logic for Mode 3 on Timer 0 is shown in [Figure 24](#). TL0 uses the Timer 0 control bits: T0C/T $\bar{0}$, TR0, and TF0. TH0 is locked into a timer function (counting machine cycles) and takes over the use of TR1 and TF1 from Timer 1. Thus, TH0 now controls the 'Timer 1' interrupt.

Mode 3 is provided for applications that require an extra 8-bit timer. With Timer 0 in Mode 3, an P89LPC9102/9103/9107 device can look like it has three Timer/Counters.

Note: When Timer 0 is in Mode 3, Timer 1 can be turned on and off by switching it into and out of its own Mode 3. It can still be used by the serial port as a baud rate generator, or in any application not requiring an interrupt.

8.5 Mode 6 (P89LPC9102, P89LPC9107)

In this mode, the corresponding timer can be changed to a PWM with a full period of 256 timer clocks (see [Figure 25](#)). Its structure is similar to mode 2, except that:

- TFn (n = 0 and 1 for Timers 0 and 1 respectively) is set and cleared in hardware
- The LOW period of the TFn is in THn, and should be between 1 and 254, and
- The HIGH period of the TFn is always 256 – THn
- Loading THn with 00h will force the Tx pin HIGH, loading THn with FFh will force the Tx pin LOW

Note that interrupt can still be enabled on the LOW to HIGH transition of TFn, and that TFn can still be cleared in software like in any other modes.

Table 39: Timer/Counter Control register (TCON) - address 88h) bit allocation

1	-	reserved
2	-	reserved
3	-	reserved
4	TR0	Timer 0 Run control bit. Set/cleared by software to turn Timer/Counter 0 on/off.

Table 40: Timer/Counter Control register (TCON - address 88h) bit description

Bit	Symbol	Description
5	TF0	Timer 0 overflow flag. Set by hardware on Timer/Counter overflow. Cleared by hardware when the processor vectors to the interrupt routine, or by software. (except in mode 6, where it is cleared in hardware)
6	TR1	Timer 1 Run control bit. Set/cleared by software to turn Timer/Counter 1 on/off
7	TF1	Timer 1 overflow flag. Set by hardware on Timer/Counter overflow. Cleared by hardware when the interrupt is processed, or by software (except in mode 6, see above, when it is cleared in hardware).

8.6 Timer overflow toggle output (P89LPC9102, P89LPC9107)

Timers 0 and 1 can be configured to automatically toggle a port output whenever a timer overflow occurs. The same device pins that are used for the T0 and T1 count inputs and PWM outputs are also used for the timer toggle outputs. This function is enabled by control bits ENT0 and ENT1 in the AUXR1 register, and apply to Timer 0 and Timer 1 respectively. The port outputs will be a logic 1 prior to the first timer overflow when this mode is turned on. In order for this mode to function, the C/\bar{T} bit must be cleared selecting PCLK as the clock source for the timer.

9. Real-time clock system timer

The P89LPC9102/9103/9107 has a simple Real-time Clock/System Timer that allows a user to continue running an accurate timer while the rest of the device is powered down. The Real-time Clock can be an interrupt or a wake-up source (see [Figure 26](#)).

The Real-time Clock is a 23-bit down counter. The clock source for this counter can be either the CPU clock (CCLK) or an external Clock Input (CLKIN). There are three SFRs used for the RTC:

RTCCON — Real-time Clock control.

RTCH — Real-time Clock counter reload HIGH (bits [22:15]).

RTCL — Real-time Clock counter reload LOW (bits [14:7]).

The Real-time clock system timer can be enabled by setting the RTCEN (RTCCON.0) bit. The Real-time Clock is a 23-bit down counter (initialized to all 0's when RTCEN = 0) that is comprised of a 7-bit prescaler and a 16-bit loadable down counter. When RTCEN is written with logic 1, the counter is first loaded with (RTCH, RTCL, '1111111') and will count down. When it reaches all 0's, the counter will be reloaded again with (RTCH, RTCL, '1111111') and a flag - RTCF (RTCCON.7) - will be set.

Fig 26. Real-time clock/system timer block diagram.

9.1 Real-time clock source

RTCS1-0 (RTCCON[6:5]) are used to select either the external clock input or CCLK as the clock source for the RTC, if either the Internal RC oscillator or the internal WD oscillator is used as the CCLK. If CCLK is derived from the external clock input on P0.5 then the RTC can use CCLK (external clock input/DIVM) or the external input as its clock source.

9.2 Changing RTCS1-0

RTCS1-0 cannot be changed if the RTC is currently enabled (RTCCON.0 = 1). Setting RTCEN and updating RTCS1-0 may be done in a single write to RTCCON. However, if RTCEN = 1, this bit must first be cleared before updating RTCS1-0.

9.3 Real-time clock interrupt/wake-up

If ERTC (RTCCON.1), EWDRT (IEN1[6:0]) and EA (IEN0.7) are set to logic 1, RTCF can be used as an interrupt source. This interrupt vector is shared with the watchdog timer. It can also be a source to wake up the device.

9.4 Reset sources affecting the Real-time clock

Only power-on reset will reset the Real-time Clock and its associated SFRs to their default state.

Table 41: Real-time Clock/System Timer clock sources

FOSC2:0	RCCLK	RTCS1:0	RTC clock source	CPU clock source

Reset	0	1	1	x	x	x	0	0

Table 43: Real-time Clock Control register (RTCCON - address D1h) bit description

Bit	Symbol	Description
0	RTCEN	Real-time Clock enable. The Real-time Clock will be enabled if this bit is logic 1. Note that this bit will not power-down the Real-time Clock. The RTCPD bit (PCONA.7) if set, will power-down and disable this block regardless of RTCEN.
1	ERTC	Real-time Clock interrupt enable. The Real-time Clock shares the same interrupt as the watchdog timer. Note that if the user configuration bit WDTE (UCFG1.7) is logic 0, the watchdog timer can be enabled to generate an interrupt. Users can read the RTCF (RTCCON.7) bit to determine whether the Real-time Clock caused the interrupt.
2:4	-	reserved
5	RTCS0	Real-time Clock source select (see Table 41).
6	RTCS1	
7	RTCF	Real-time Clock Flag. This bit is set to logic 1 when the 23-bit Real-time Clock reaches a count of logic 0. It can be cleared in software.

10. UART (P89LPC9103, P89LPC9107)

The P89LPC9103/9107 has an enhanced UART that is compatible with the conventional 80C51 UART except that Timer 2 overflow cannot be used as a baud rate source. The P89LPC9103/9107 does include an independent Baud Rate Generator. The baud rate can be selected from the oscillator (divided by a constant), Timer 1 overflow, or the independent Baud Rate Generator. In addition to the baud rate generation, enhancements over the standard 80C51 UART include Framing Error detection, break detect, automatic address recognition, selectable double buffering and several interrupt options.

The UART can be operated in four modes, as described in the following sections.

10.1 Mode 0

Serial data enters and exits through RXD. TXD outputs the shift clock. 8 bits are transmitted or received, LSB first. The baud rate is fixed at $\frac{1}{16}$ of the CPU clock frequency.

10.2 Mode 1

10 bits are transmitted (through TXD) or received (through RXD): a start bit (logic 0), 8 data bits (LSB first), and a stop bit (logic 1). When data is received, the stop bit is stored in RB8 in Special Function Register SCON. The baud rate is variable and is determined by the Timer 1 overflow rate or the Baud Rate Generator (see [Section 10.6 "Baud Rate generator and selection"](#)).

10.3 Mode 2

11 bits are transmitted (through TXD) or received (through RXD): start bit (logic 0), 8 data bits (LSB first), a programmable 9th data bit, and a stop bit (logic 1). When data is transmitted, the 9th data bit (TB8 in SCON) can be assigned the value of 0 or 1. Or, for example, the parity bit (P, in the PSW) could be moved into TB8. When data is received, the 9th data bit goes into RB8 in Special Function Register SCON and the stop bit is not saved. The baud rate is programmable to either $\frac{1}{16}$ or $\frac{1}{32}$ of the CCLK frequency, as determined by the SMOD1 bit in PCON.

10.4 Mode 3

11 bits are transmitted (through TXD) or received (through RXD): a start bit (logic 0), 8 data bits (LSB first), a programmable 9th data bit, and a stop bit (logic 1). Mode 3 is the same as Mode 2 in all respects except baud rate. The baud rate in Mode 3 is variable and is determined by the Timer 1 overflow rate or the Baud Rate Generator (see [Section 10.6 “Baud Rate generator and selection” on page 55](#)).

In all four modes, transmission is initiated by any instruction that uses SBUF as a destination register. Reception is initiated in Mode 0 by the condition RI = 0 and REN = 1. Reception is initiated in the other modes by the incoming start bit if REN = 1.

10.5 SFR space

The UART SFRs are at the following locations shown in [Table 44](#).

Table 44: UART SFR addresses

Register	Description	SFR location
PCON	Power Control	87H
SCON	Serial Port (UART) Control	98H
SBUF	Serial Port (UART) Data Buffer	99H
SADDR	Serial Port (UART) Address	A9H
SADEN	Serial Port (UART) Address Enable	B9H
SSTAT	Serial Port (UART) Status	BAH
BRGR1	Baud Rate Generator Rate HIGH Byte	BFH
BRGR0	Baud Rate Generator Rate LOW Byte	BEH
BRGCON	Baud Rate Generator Control	BDH

10.6 Baud Rate generator and selection

The P89LPC9103/9107 enhanced UART has an independent Baud Rate Generator. The baud rate is determined by a value programmed into the BRGR1 and BRGR0 SFRs. The UART can use either Timer 1 or the baud rate generator output as determined by BRGCON.2-1 (see [Figure 27](#)). Note that Timer T1 is further divided by 2 if the SMOD1 bit (PCON.7) is set. The independent Baud Rate Generator uses CCLK.

10.7 Updating the BRGR1 and BRGR0 SFRs

The baud rate SFRs, BRGR1 and BRGR0 must only be loaded when the Baud Rate Generator is disabled (the BRGEN bit in the BRGCON register is logic 0). This avoids the loading of an interim value to the baud rate generator. (CAUTION: If either BRGR0 or BRGR1 is written when BRGEN = 1, the result is unpredictable.)

Table 45: UART baud rate generation.

SCON.7 (SM0)	SCON.6 (SM1)	PCON.7 (SMOD1)	BRGCON.1 (SBRGS)	Receive/transmit baud rate for UART
0	0	X	X	CCLK/16
0	1	0	0	CCLK/(256 – TH1)64
		1	0	CCLK/(256 – TH1)32
		X	1	CCLK/((BRGR1, BRGR0) + 16)

Table 45: UART baud rate generation.

SCON.7 (SM0)	SCON.6 (SM1)	PCON.7 (SMOD1)	BRGCON.1 (SBRGS)	Receive/transmit baud rate for UART
1	0	0	X	CCLK/32
		1	X	CCLK/16
1	1	0	0	CCLK/(256 – TH1)64
		1	0	CCLK/(256 – TH1)32
		X	1	CCLK/((BRGR1, BRGR0) + 16)

Table 47: Baud Rate Generator Control register (BRGCON - address BDh) bit description

Bit	Symbol	Description
0	BRGEN	Baud Rate Generator Enable. Enables the baud rate generator. BRGR1 and BRGR0 can only be written when BRGEN = 0.
1	SBRGS	Select Baud Rate Generator as the source for baud rates to UART in modes 1 and 3 (see Table 45 for details)
2:7	-	reserved

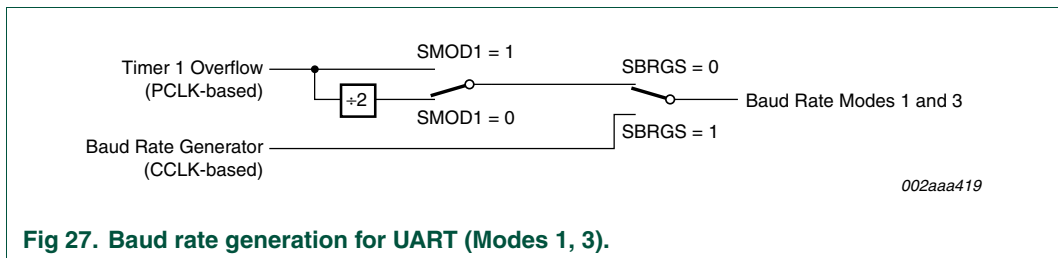

Fig 27. Baud rate generation for UART (Modes 1, 3).

10.8 Framing error

A Framing error occurs when the stop bit is sensed as a logic 0. A Framing error is reported in the status register (SSTAT). In addition, if SMOD0 (PCON.6) is 1, framing errors can be made available in SCON.7. If SMOD0 is 0, SCON.7 is SM0. It is recommended that SM0 and SM1 (SCON.7-6) are programmed when SMOD0 is logic 0.

10.9 Break detect

A break detect is reported in the status register (SSTAT). A break is detected when any 11 consecutive bits are sensed LOW. Since a break condition also satisfies the requirements for a framing error, a break condition will also result in reporting a framing error. Once a break condition has been detected, the UART will go into an idle state and remain in this idle state until a stop bit has been received. The break detect can be used to reset the device and force the device into ISP mode by setting the EBRR bit (AUXR1.6).

Table 48: Serial Port Control register (SCON - address 98h) bit allocation

Bit	7	6	5	4	3	2	1	0
Symbol	SM0/FE	SM1	SM2	REN	TB8	RB8	TI	RI
Reset	x	x	x	x	x	x	0	0

Table 49: Serial Port Control register (SCON - address 98h) bit description

Bit	Symbol	Description
0	RI	Receive interrupt flag. Set by hardware at the end of the 8th bit time in Mode 0, or approximately halfway through the stop bit time in Mode 1. For Mode 2 or Mode 3, if SMOD0, it is set near the middle of the 9th data bit (bit 8). If SMOD0 = 1, it is set near the middle of the stop bit (see SM2 - SCON.5 - for exceptions). Must be cleared by software.
1	TI	Transmit interrupt flag. Set by hardware at the end of the 8th bit time in Mode 0, or at the stop bit (see description of INTLO bit in SSTAT register) in the other modes. Must be cleared by software.
2	RB8	The 9th data bit that was received in Modes 2 and 3. In Mode 1 (SM2 must be 0), RB8 is the stop bit that was received. In Mode 0, RB8 is undefined.
3	TB8	The 9th data bit that will be transmitted in Modes 2 and 3. Set or clear by software as desired.
4	REN	Enables serial reception. Set by software to enable reception. Clear by software to disable reception.
5	SM2	Enables the multiprocessor communication feature in Modes 2 and 3. In Mode 2 or 3, if SM2 is set to 1, then RI will not be activated if the received 9th data bit (RB8) is 0. In Mode 0, SM2 should be 0. In Mode 1, SM2 must be 0.
6	SM1	With SM0 defines the serial port mode, see Table 50 .
7	SM0/FE	The use of this bit is determined by SMOD0 in the PCON register. If SMOD0 = 0, this bit is read and written as SM0, which with SM1, defines the serial port mode. If SMOD0 = 1, this bit is read and written as FE (Framing Error). FE is set by the receiver when an invalid stop bit is detected. Once set, this bit cannot be cleared by valid frames but is cleared by software. (Note: UART mode bits SM0 and SM1 should be programmed when SMOD0 is logic 0 - default mode on any reset.)

Table 50: Serial Port modes

SM0,SM1	UART mode	UART baud rate
00	Mode 0: shift register	CCLK/16 (default mode on any reset)
01	Mode 1: 8-bit UART	Variable (see Table 45)
10	Mode 2: 9-bit UART	CCLK/32 or CCLK/16
11	Mode 3: 9-bit UART	Variable (see Table 45)

Table 51: Serial Port Status register (SSTAT - address BAh) bit allocation

Bit	7	6	5	4	3	2	1	0
Symbol	DBMOD	INTLO	CIDIS	DBISEL	FE	BR	OE	STINT
Reset	x	x	x	x	x	x	0	0

Table 52: Serial Port Status register (SSTAT - address BAh) bit description

Bit	Symbol	Description
0	STINT	Status Interrupt Enable. When set = 1, FE, BR, or OE can cause an interrupt. The interrupt used (vector address 0023h) is shared with RI (CIDIS = 1) or the combined TI/RI (CIDIS = 0). When cleared = 0, FE, BR, OE cannot cause an interrupt. (Note: FE, BR, or OE is often accompanied by a RI, which will generate an interrupt regardless of the state of STINT). Note that BR can cause a break detect reset if EBRR (AUXR1.6) is set to logic 1.
1	OE	Overrun Error flag is set if a new character is received in the receiver buffer while it is still full (before the software has read the previous character from the buffer), i.e., when bit 8 of a new byte is received while RI in SCON is still set. Cleared by software.
2	BR	Break Detect flag. A break is detected when any 11 consecutive bits are sensed LOW. Cleared by software.
3	FE	Framing error flag is set when the receiver fails to see a valid STOP bit at the end of the frame. Cleared by software.
4	DBISEL	Double buffering transmit interrupt select. Used only if double buffering is enabled. This bit controls the number of interrupts that can occur when double buffering is enabled. When set, one transmit interrupt is generated after each character written to SBUF, and there is also one more transmit interrupt generated at the beginning (INTLO = 0) or the end (INTLO = 1) of the STOP bit of the last character sent (i.e., no more data in buffer). This last interrupt can be used to indicate that all transmit operations are over. When cleared = 0, only one transmit interrupt is generated per character written to SBUF. Must be logic 0 when double buffering is disabled. Note that except for the first character written (when buffer is empty), the location of the transmit interrupt is determined by INTLO. When the first character is written, the transmit interrupt is generated immediately after SBUF is written.
5	CIDIS	Combined Interrupt Disable. When set = 1, Rx and Tx interrupts are separate. When cleared = 0, the UART uses a combined Tx/Rx interrupt (like a conventional 80C51 UART). This bit is reset to logic 0 to select combined interrupts.
6	INTLO	Transmit interrupt position. When cleared = 0, the Tx interrupt is issued at the beginning of the stop bit. When set = 1, the Tx interrupt is issued at end of the stop bit. Must be logic 0 for mode 0. Note that in the case of single buffering, if the Tx interrupt occurs at the end of a STOP bit, a gap may exist before the next start bit.
7	DBMOD	Double buffering mode. When set = 1 enables double buffering. Must be logic 0 for UART mode 0. In order to be compatible with existing 80C51 devices, this bit is reset to logic 0 to disable double buffering.

10.10 More about UART Mode 0

In Mode 0, a write to SBUF will initiate a transmission. At the end of the transmission, TI (SCON.1) is set, which must be cleared in software. Double buffering must be disabled in this mode.

Reception is initiated by clearing RI (SCON.0). Synchronous serial transfer occurs and RI will be set again at the end of the transfer. When RI is cleared, the reception of the next character will begin. Refer to [Figure 28](#).

Fig 28. Serial Port Mode 0 (double buffering must be disabled).

10.11 More about UART Mode 1

Reception is initiated by detecting a 1-to-0 transition on RXD. RXD is sampled at a rate 16 times the programmed baud rate. When a transition is detected, the divide-by-16 counter is immediately reset. Each bit time is thus divided into 16 counter states. At the 7th, 8th, and 9th counter states, the bit detector samples the value of RXD. The value accepted is the value that was seen in at least 2 of the 3 samples. This is done for noise rejection. If the value accepted during the first bit time is not 0, the receive circuits are reset and the receiver goes back to looking for another 1-to-0 transition. This provides rejection of false start bits. If the start bit proves valid, it is shifted into the input shift register, and reception of the rest of the frame will proceed.

The signal to load SBUF and RB8, and to set RI, will be generated if, and only if, the following conditions are met at the time the final shift pulse is generated: RI = 0 and either SM2 = 0 or the received stop bit = 1. If either of these two conditions is not met, the received frame is lost. If both conditions are met, the stop bit goes into RB8, the 8 data bits go into SBUF, and RI is activated.

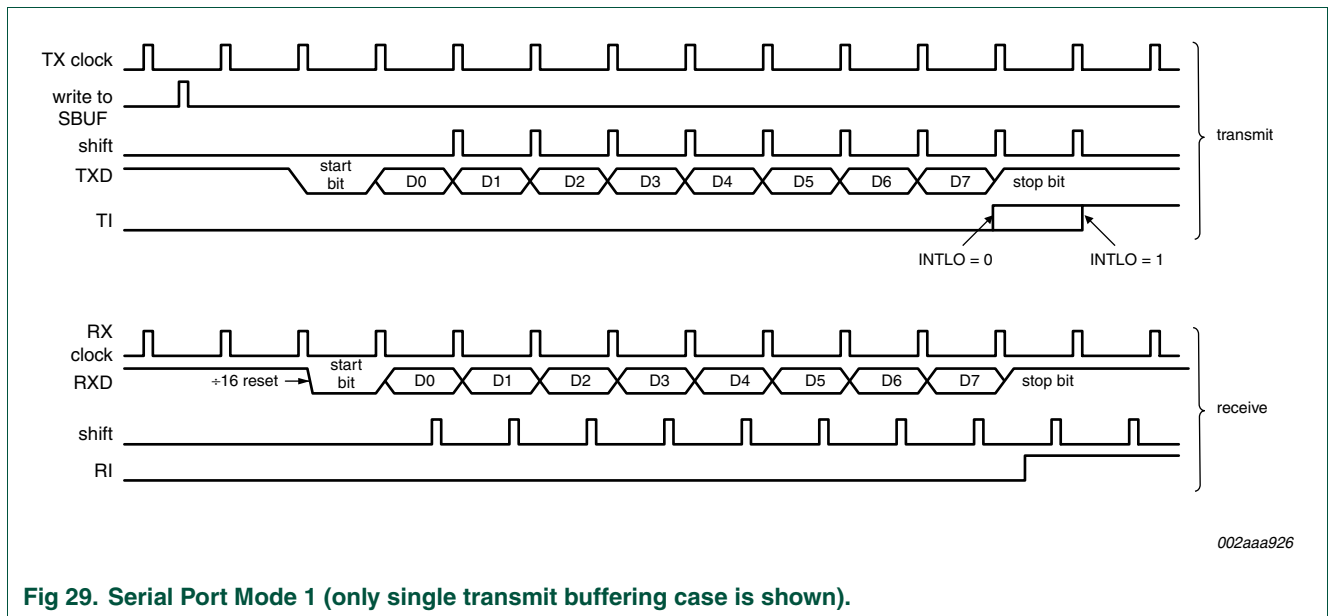

Fig 29. Serial Port Mode 1 (only single transmit buffering case is shown).

10.12 More about UART Modes 2 and 3

Reception is the same as in Mode 1.

The signal to load SBUF and RB8, and to set RI, will be generated if, and only if, the following conditions are met at the time the final shift pulse is generated. (a) RI = 0, and (b) Either SM2 = 0, or the received 9th data bit = 1. If either of these conditions is not met, the received frame is lost, and RI is not set. If both conditions are met, the received 9th data bit goes into RB8, and the first 8 data bits go into SBUF.

Fig 30. Serial Port Mode 2 or 3 (only single transmit buffering case is shown).

10.13 Framing error and RI in Modes 2 and 3 with SM2 = 1

If SM2 = 1 in modes 2 and 3, RI and FE behaves as in the following table.

Table 53: FE and RI when SM2= 1 in Modes 2 and 3.

Mode	PCON.6 (SMOD0)	RB8	RI	FE
2	0	0	No RI when RB8 = 0	Occurs during STOP bit
		1	Similar to Figure 30 , with SMOD0 = 0, RI occurs during RB8, one bit before FE	Occurs during STOP bit
3	1	0	No RI when RB8 = 0	Will NOT occur
		1	Similar to Figure 30 , with SMOD0 = 1, RI occurs during STOP bit	Occurs during STOP bit

10.14 Break detect

A break is detected when 11 consecutive bits are sensed LOW and is reported in the status register (SSTAT). For Mode 1, this consists of the start bit, 8 data bits, and two stop bit times. For Modes 2 and 3, this consists of the start bit, 9 data bits, and one stop bit. The break detect bit is cleared in software or by a reset. The break detect can be used to reset the device and force the device into ISP mode. This occurs if the UART is enabled and the the EBRR bit (AUXR1.6) is set and a break occurs.

10.15 Double buffering

The UART has a transmit double buffer that allows buffering of the next character to be written to SBUF while the first character is being transmitted. Double buffering allows transmission of a string of characters with only one stop bit between any two characters, provided the next character is written between the start bit and the stop bit of the previous character.

Double buffering can be disabled. If disabled (DBMOD, i.e. SSTAT.7 = 0), the UART is compatible with the conventional 80C51 UART. If enabled, the UART allows writing to SnBUF while the previous data is being shifted out.

10.16 Double buffering in different modes

Double buffering is only allowed in Modes 1, 2 and 3. When operated in Mode 0, double buffering must be disabled (DBMOD = 0).

10.17 Transmit interrupts with double buffering enabled (Modes 1,2, and 3)

Unlike the conventional UART, when double buffering is enabled, the Tx interrupt is generated when the double buffer is ready to receive new data. The following occurs during a transmission (assuming eight data bits):

1. The double buffer is empty initially.
2. The CPU writes to SBUF.
3. The SBUF data is loaded to the shift register and a Tx interrupt is generated immediately.
4. If there is more data, go to 6, else continue.
5. If there is no more data, then:
 - If DBISEL is logic 0, no more interrupts will occur.

- If DBISEL is logic 1 and INTLO is logic 0, a Tx interrupt will occur at the beginning of the STOP bit of the data currently in the shifter (which is also the last data).
 - If DBISEL is logic 1 and INTLO is logic 1, a Tx interrupt will occur at the end of the STOP bit of the data currently in the shifter (which is also the last data).
 - Note that if DBISEL is logic 1 and the CPU is writing to SBUF when the STOP bit of the last data is shifted out, there can be an uncertainty of whether a Tx interrupt is generated already with the UART not knowing whether there is any more data following.
6. If there is more data, the CPU writes to SBUF again. Then:
- If INTLO is logic 0, the new data will be loaded and a Tx interrupt will occur at the beginning of the STOP bit of the data currently in the shifter.
 - If INTLO is logic 1, the new data will be loaded and a Tx interrupt will occur at the end of the STOP bit of the data currently in the shifter.
 - Go to 3.

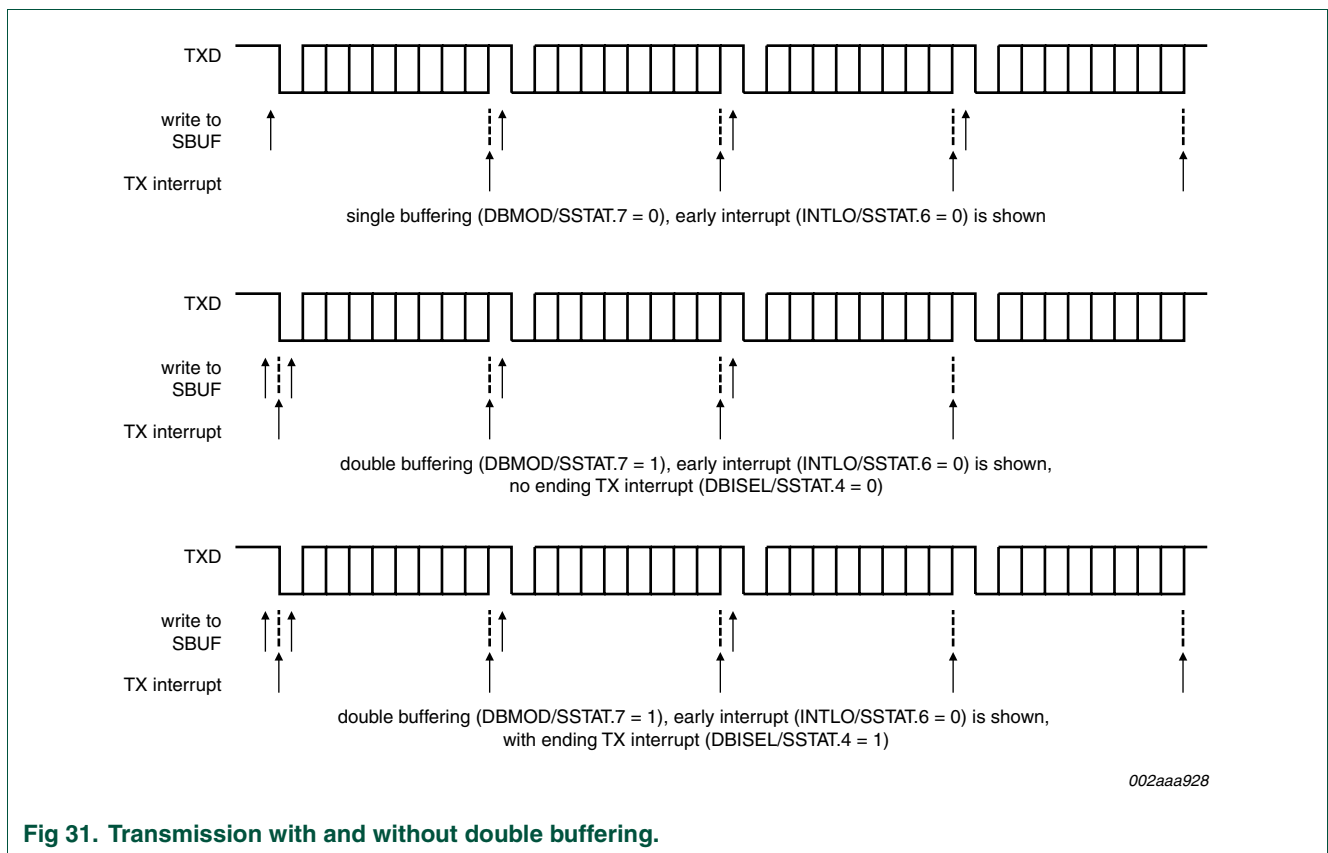

Fig 31. Transmission with and without double buffering.

10.18 The 9th bit (bit 8) in double buffering (Modes 1, 2, and 3)

If double buffering is disabled (DBMOD, i.e. SSTAT.7 = 0), TB8 can be written before or after SBUF is written, provided TB8 is updated before that TB8 is shifted out. TB8 must not be changed again until after TB8 shifting has been completed, as indicated by the Tx interrupt.

If double buffering is enabled, TB8 MUST be updated before SBUF is written, as TB8 will be double-buffered together with SBUF data. The operation described in [Section 10.17](#) becomes as follows:

1. The double buffer is empty initially.
2. The CPU writes to TB8.
3. The CPU writes to SBUF.
4. The SBUF/TB8 data is loaded to the shift register and a Tx interrupt is generated immediately.
5. If there is more data, go to 7, else continue on 6.
6. If there is no more data, then:
 - If DBISEL is logic 0, no more interrupt will occur.
 - If DBISEL is logic 1 and INTLO is logic 0, a Tx interrupt will occur at the beginning of the STOP bit of the data currently in the shifter (which is also the last data).
 - If DBISEL is logic 1 and INTLO is logic 1, a Tx interrupt will occur at the end of the STOP bit of the data currently in the shifter (which is also the last data).
7. If there is more data, the CPU writes to TB8 again.
8. The CPU writes to SBUF again. Then:
 - If INTLO is logic 0, the new data will be loaded and a Tx interrupt will occur at the beginning of the STOP bit of the data currently in the shifter.
 - If INTLO is logic 1, the new data will be loaded and a Tx interrupt will occur at the end of the STOP bit of the data currently in the shifter.
9. Go to 4.
10. Note that if DBISEL is logic 1 and the CPU is writing to SBUF when the STOP bit of the last data is shifted out, there can be an uncertainty of whether a Tx interrupt is generated already with the UART not knowing whether there is any more data following.

10.19 Multiprocessor communications

UART modes 2 and 3 have a special provision for multiprocessor communications. In these modes, 9 data bits are received or transmitted. When data is received, the 9th bit is stored in RB8. The UART can be programmed such that when the stop bit is received, the serial port interrupt will be activated only if RB8 = 1. This feature is enabled by setting bit SM2 in SCON. One way to use this feature in multiprocessor systems is as follows:

When the master processor wants to transmit a block of data to one of several slaves, it first sends out an address byte which identifies the target slave. An address byte differs from a data byte in that the 9th bit is 1 in an address byte and 0 in a data byte. With SM2 = 1, no slave will be interrupted by a data byte. An address byte, however, will interrupt all slaves, so that each slave can examine the received byte and see if it is being addressed. The addressed slave will clear its SM2 bit and prepare to receive the data bytes that follow. The slaves that weren't being addressed leave their SM2 bits set and go on about their business, ignoring the subsequent data bytes.

Note that SM2 has no effect in Mode 0, and must be logic 0 in Mode 1.

10.20 Automatic address recognition

Automatic address recognition is a feature which allows the UART to recognize certain addresses in the serial bit stream by using hardware to make the comparisons. This feature saves a great deal of software overhead by eliminating the need for the software to examine every serial address which passes by the serial port. This feature is enabled by setting the SM2 bit in SCON. In the 9 bit UART modes (mode 2 and mode 3), the Receive Interrupt flag (RI) will be automatically set when the received byte contains either the 'Given' address or the 'Broadcast' address. The 9 bit mode requires that the 9th information bit is a 1 to indicate that the received information is an address and not data.

Using the Automatic Address Recognition feature allows a master to selectively communicate with one or more slaves by invoking the Given slave address or addresses. All of the slaves may be contacted by using the Broadcast address. Two special Function Registers are used to define the slave's address, SADDR, and the address mask, SADEN. SADEN is used to define which bits in the SADDR are to be used and which bits are 'don't care'. The SADEN mask can be logically ANDed with the SADDR to create the 'Given' address which the master will use for addressing each of the slaves. Use of the Given address allows multiple slaves to be recognized while excluding others. The following examples will help to show the versatility of this scheme:

Table 54: Slave 0/1 examples

Example 1		Example 2	
Slave 0	SADDR = 1100 0000	Slave 1	SADDR = 1100 0000
	SADEN = 1111 1101		SADEN = 1111 1110
	Given = 1100 00X0		Given = 1100 000X

In the above example SADDR is the same and the SADEN data is used to differentiate between the two slaves. Slave 0 requires a 0 in bit 0 and it ignores bit 1. Slave 1 requires a 0 in bit 1 and bit 0 is ignored. A unique address for Slave 0 would be 1100 0010 since slave 1 requires a 0 in bit 1. A unique address for slave 1 would be 1100 0001 since a 1 in bit 0 will exclude slave 0. Both slaves can be selected at the same time by an address which has bit 0 = 0 (for slave 0) and bit 1 = 0 (for slave 1). Thus, both could be addressed with 1100 0000.

In a more complex system the following could be used to select slaves 1 and 2 while excluding slave 0:

Table 55: Slave 0/1/2 examples

Example 1		Example 2		Example 3	
Slave 0	SADDR = 1100 0000	Slave 1	SADDR = 1110 0000	Slave 2	SADDR = 1100 0000
	SADEN = 1111 1001		SADEN = 1111 1010		SADEN = 1111 1100
	Given = 1100 00X0		Given = 1110 0X0X		Given = 1110 00XX

In the above example the differentiation among the 3 slaves is in the lower 3 address bits. Slave 0 requires that bit 0 = 0 and it can be uniquely addressed by 1110 0110. Slave 1 requires that bit 1 = 0 and it can be uniquely addressed by 1110 and 0101. Slave 2 requires that bit 2 = 0 and its unique address is 1110 0011. To select Slaves 0 and 1 and exclude Slave 2 use address 1110 0100, since it is necessary to make bit 2 = 1 to exclude slave 2. The Broadcast Address for each slave is created by taking the logical OR of SADDR and SADEN. Zeros in this result are treated as don't-cares. In most cases,

interpreting the don't-cares as ones, the broadcast address will be FF hexadecimal. Upon reset SADDR and SADEN are loaded with 0s. This produces a given address of all 'don't cares' as well as a Broadcast address of all 'don't cares'. This effectively disables the Automatic Addressing mode and allows the microcontroller to use standard UART drivers which do not make use of this feature.

11. Analog comparator

One analog comparator is provided on the P89LPC9102/9103/9107. Input and output options allow use of the comparator in a number of different configurations. Comparator operation is such that the output is a logic 1 (which may be read in a register and/or routed to a pin) when the positive input (one of two selectable pins) is greater than the negative input (selectable from a pin or an internal reference voltage). Otherwise the output is a zero. The comparator may be configured to cause an interrupt when the output value changes.

11.1 Comparator configuration

Each comparator has a control register, CMP1 and is shown in [Table 57](#).

The overall connections to the comparator is shown in [Figure 32](#). There are eight possible configurations for the comparator, as determined by the control bits in the corresponding CMP1 register: CP1, CN1, and OE1. These configurations are shown in [Figure 33](#).

When the comparator is first enabled, the comparator output and interrupt flag are not guaranteed to be stable for 10 microseconds. The corresponding comparator interrupt should not be enabled during that time, and the comparator interrupt flag must be cleared before the interrupt is enabled in order to prevent an immediate interrupt service.

Table 56: Comparator Control register (CMP1 - address ACh) bit allocation

Bit	7	6	5	4	3	2	1	0
Symbol	-	-	CE1	CP1	CN1	-	CO1	CMF1
Reset	x	x	0	0	0	x	0	0

Table 57: Comparator Control register (CMP1 - address ACh, CMP2 - address ADh) bit description

Bit	Symbol	Description
0	CMF1	Comparator interrupt flag. This bit is set by hardware whenever the comparator output CO1 changes state. This bit will cause a hardware interrupt if enabled. Cleared by software.
1	CO1	Comparator output, synchronized to the CPU clock to allow reading by software.
2	-	reserved
3	CN1	Comparator negative input select. When logic 0, the comparator reference pin CMPREF is selected as the negative comparator input. When logic 1, the internal comparator reference, Vref, is selected as the negative comparator input.
4	CP1	Comparator positive input select. When logic 0, CINnA is selected as the positive comparator input. When logic 1, CINnB is selected as the positive comparator input.
5	CE1	Comparator enable. When set, the corresponding comparator function is enabled. Comparator output is stable 10 microseconds after CE1 is set.
6	-	reserved
7	-	reserved

002aaa979

Fig 32. Comparator input and output connections.

11.2 Internal reference voltage

An internal reference voltage, V_{ref} , may supply a default reference when a single comparator input pin is used. Please refer to the *P89LPC9102/9103 Data sheet* for specifications.

11.3 Comparator interrupt

The comparator has an interrupt flag CMF1 contained in its configuration register. This flag is set whenever the comparator output changes state. The flag may be polled by software or may be used to generate an interrupt. The interrupt will be generated when the interrupt enable bit EC in the IEN1 register is set and the interrupt system is enabled via the EA bit in the IEN0 register.

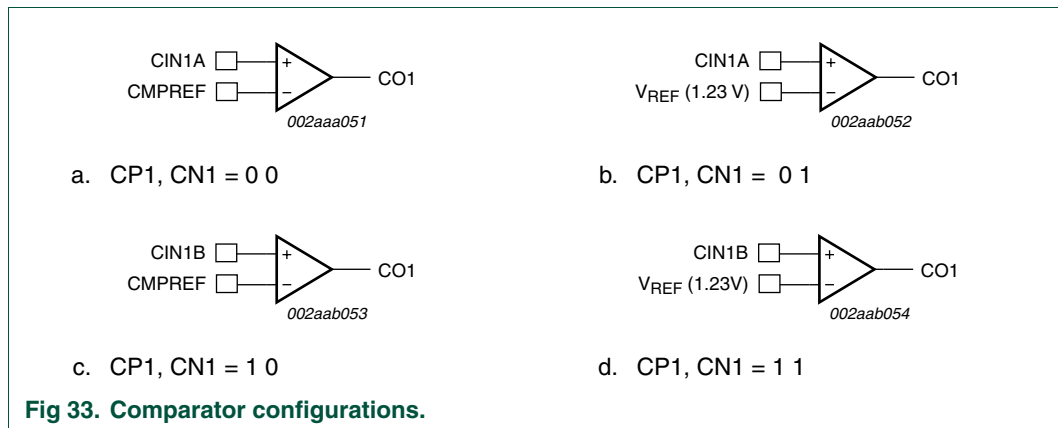

When the comparator is disabled the comparator's output, CO1, goes HIGH. If the comparator output was LOW and then is disabled, the resulting transition of the comparator output from a LOW to HIGH state will set the comparator flag, CMF1. This will cause an interrupt if the comparator interrupt is enabled. The user should therefore disable the comparator interrupt prior to disabling the comparator. Additionally, the user should clear the comparator flag, CMF1, after disabling the comparator.

11.4 Comparator and power reduction modes

The comparator may remain enabled when power-down or Idle mode is activated, but is disabled automatically in Total Power-down mode.

If the comparator interrupt is enabled (except in Total Power-down mode), a change of the comparator output state will generate an interrupt and wake up the processor.

The comparator consumes power in power-down and Idle modes, as well as in the normal operating mode. This should be taken into consideration when system power consumption is an issue. To minimize power consumption, the user can power-down the comparator by disabling the comparator and setting PCONA.5 to logic 1, or simply putting the device in Total Power-down mode.

11.5 Comparator configuration example

The code shown below is an example of initializing the comparator. Comparator 1 is configured to use the CIN1A and CMPREF inputs, and generates an interrupt when the comparator output changes.

```

CMPINIT:
MOV   PTOAD,#030h ;Disable digital INPUTS on pins CIN1A, CMPREF.
ANL   POM2,#0CFh  ;Disable digital OUTPUTS on pins that are used
ORL   POM1,#030h  ;for analog functions: CIN1A, CMPREF.
MOV   CMP1,#020h  ;Turn on comparator 1 and set up for:
                ; - Positive input on CIN1A.
                ; - Negative input from CMPREF pin.
                ; - Output to CMP1 pin enabled.

CALL  delay10us  ;start up for at least 10 microseconds before use.
ANL   CMP1,#0FEh  ;Clear comparator 1 interrupt flag.
SETB  EC         ;Enable the comparator interrupt. The priority is left at
                ; the current value.

SETB  EA         ;Enable the interrupt system (if needed).
RET    ;Return to caller.

```

The interrupt routine used for the comparator must clear the interrupt flag (CMF1) before returning.

12. Keypad interrupt (KBI)

The Keypad Interrupt function is intended primarily to allow a single interrupt to be generated when Port 0 is equal to or not equal to a certain pattern. This function can be used for bus address recognition or keypad recognition. The user can configure the port via SFRs for different tasks.

There are three SFRs used for this function. The Keypad Interrupt Mask Register (KBMASK) is used to define which input pins connected to Port 0 are enabled to trigger the interrupt. The Keypad Pattern Register (KBPATN) is used to define a pattern that is compared to the value of Port 0. The Keypad Interrupt Flag (KBIF) in the Keypad Interrupt Control Register (KBCON) is set when the condition is matched while the Keypad

Interrupt function is active. An interrupt will be generated if it has been enabled by setting the EKBI bit in IEN1 register and EA = 1. The PATN_SEL bit in the Keypad Interrupt Control Register (KBCON) is used to define equal or not-equal for the comparison.

In order to use the Keypad Interrupt as an original KBI function like in the 87LPC76x series, the user needs to set KBPATN = 0FFH and PATN_SEL = 0 (not equal), then any key connected to Port0 which is enabled by KBMASK register is will cause the hardware to set KBIF = 1 and generate an interrupt if it has been enabled. The interrupt may be used to wake up the CPU from Idle or Power-down modes. This feature is particularly useful in handheld, battery powered systems that need to carefully manage power consumption yet also need to be convenient to use.

In order to set the flag and cause an interrupt, the pattern on Port 0 must be held longer than six CCLKs.

[1] The Keypad Interrupt must be enabled in order for the settings of the KBMASK register to be effective.

13. Watchdog Timer (WDT)

The watchdog timer subsystem protects the system from incorrect code execution by causing a system reset when it underflows as a result of a failure of software to feed the timer prior to the timer reaching its terminal count. The watchdog timer can only be reset by a power-on reset.

13.1 Watchdog function

The user has the ability using the WDCON and UCFG1 registers to control the run /stop condition of the WDT, the clock source for the WDT, the prescaler value, and whether the WDT is enabled to reset the device on underflow. In addition, there is a safety mechanism which forces the WDT to be enabled by values programmed into UCFG1 either through IAP or a commercial programmer.

The WDTE bit (UCFG1.7), if set, enables the WDT to reset the device on underflow. Following reset, the WDT will be running regardless of the state of the WDTE bit.

The WDRUN bit (WDCON.2) can be set to start the WDT and cleared to stop the WDT. Following reset this bit will be set and the WDT will be running. All writes to WDCON need to be followed by a feed sequence (see [Section 13.2](#)). Additional bits in WDCON allow the user to select the clock source for the WDT and the prescaler.

When the timer is not enabled to reset the device on underflow, the WDT can be used in 'timer mode' and be enabled to produce an interrupt (IEN0.6) if desired.

The Watchdog Safety Enable bit, WDSE (UCFG1.4) along with WDTE, is designed to force certain operating conditions at power-up. Refer to [Table 64](#) for details.

[Figure 36](#) shows the watchdog timer in Watchdog mode. It consists of a programmable 13-bit prescaler, and an 8-bit down counter. The down counter is clocked (decremented) by a tap taken from the prescaler. The clock source for the prescaler is either PCLK or the Watchdog oscillator selected by the WDCLK bit in the WDCON register. (Note that switching of the clock sources will not take effect immediately - see [Section 13.3](#)).

The Watchdog asserts the watchdog reset when the Watchdog count underflows and the watchdog reset is enabled. When the watchdog reset is enabled, writing to WDL or WDCON must be followed by a feed sequence for the new values to take effect.

If a watchdog reset occurs, the internal reset is active for at least one Watchdog clock cycle (PCLK or the Watchdog oscillator clock). If CCLK is still running, code execution will begin immediately after the reset cycle. If the processor was in Power-down mode, the watchdog reset will start the oscillator and code execution will resume after the oscillator is stable.

Table 64: Watchdog timer configuration

WDTE (UCFG1.7)	WDSE (UCFG1.4)	FUNCTION
0	x	The watchdog reset is disabled. The timer can be used as an internal timer and can be used to generate an interrupt. WDSE has no effect.
1	0	The watchdog reset is enabled. The user can set WDCLK to choose the clock source.
1	1	The watchdog reset is enabled, along with additional safety features: <ol style="list-style-type: none"> 1. WDCLK is forced to 1 (using watchdog oscillator) 2. WDCON and WDL register can only be written once 3. WDRUN is forced to 1 and cannot be cleared by software.

Fig 34. Watchdog prescaler.

13.2 Feed sequence

The watchdog timer control register and the 8-bit down counter (See [Figure 35](#)) are not directly loaded by the user. The user writes to the WDCON and the WDL SFRs. At the end of a feed sequence, the values in the WDCON and WDL SFRs are loaded to the control register and the 8-bit down counter. Before the feed sequence, any new values written to these two SFRs will not take effect. To avoid a watchdog reset, the watchdog timer needs to be fed (via a special sequence of software action called the feed sequence) prior to reaching an underflow.

To feed the Watchdog, two write instructions must be sequentially executed successfully. Between the two write instructions, SFR reads are allowed, but writes are not allowed. The instructions should move A5H to the WFEED1 register and then 5AH to the WFEED2 register. An incorrect feed sequence will cause an immediate watchdog reset. The program sequence to feed the watchdog timer is as follows:

```
CLR EA ;disable interrupt
MOV WFEED1,#0A5h ;do watchdog feed part 1
MOV WFEED2,#05Ah ;do watchdog feed part 2
SETB EA ;enable interrupt
```

This sequence assumes that the P89LPC9102/9103/9107 interrupt system is enabled and there is a possibility of an interrupt request occurring during the feed sequence. If an interrupt was allowed to be serviced and the service routine contained any SFR writes, it would trigger a watchdog reset. If it is known that no interrupt could occur during the feed sequence, the instructions to disable and re-enable interrupts may be removed.

In Watchdog mode (WDTE = 1), writing the WDCON register must be IMMEDIATELY followed by a feed sequence to load the WDL to the 8-bit down counter, and the WDCON to the shadow register. If writing to the WDCON register is not immediately followed by the feed sequence, a watchdog reset will occur.

For example: setting WDRUN = 1:

```
MOV ACC,WDCON ;get WDCON
SETB ACC.2 ;set WD_RUN = 1
MOV WDL,#0FFh ;New count to be loaded to 8-bit down counter
CLR EA ;disable interrupt
MOV WDCON,ACC ;write back to WDCON (after the watchdog is enabled, a feed
                must occur ; immediately)
MOV WFEED1,#0A5h ;do watchdog feed part 1
MOV WFEED2,#05Ah ;do watchdog feed part 2
SETB EA ;enable interrupt
```

In timer mode (WDTE = 0), WDCON is loaded to the control register every CCLK cycle (no feed sequence is required to load the control register), but a feed sequence is required to load from the WDL SFR to the 8-bit down counter before a time-out occurs.

The number of Watchdog clocks before timing out is calculated by the following equations:

$$tclks = (2^{(5+PRE)})(WDL + 1) + 1 \tag{1}$$

where:

PRE is the value of prescaler (PRE2 to PRE0) which can be the range 0 to 7, and;

WDL is the value of Watchdog load register which can be the range of 0 to 255.

The minimum number of tclks is:

$$tclks = (2^{(5+0)})(0 + 1) + 1 = 33 \tag{2}$$

The maximum number of tclks is:

$$tclks = (2^{(5+7)})(255 + 1) + 1 = 1048577 \tag{3}$$

[Table 67](#) shows sample P89LPC9102/9103/9107 timeout values.

Table 65: Watchdog Timer Control register (WDCON - address A7h) bit allocation

Bit	7	6	5	4	3	2	1	0

	255	131,073	327.7 ms	21.8 ms
101	0	1,025	2.56 ms	170.8 μ s
	255	262,145	655.4 ms	43.7 ms
110	0	2,049	5.12 ms	341.5 μ s
	255	524,289	1.31 s	87.4 ms
111	0	4097	10.2 ms	682.8 ms
	255	1,048,577	2.62 s	174.8 ms

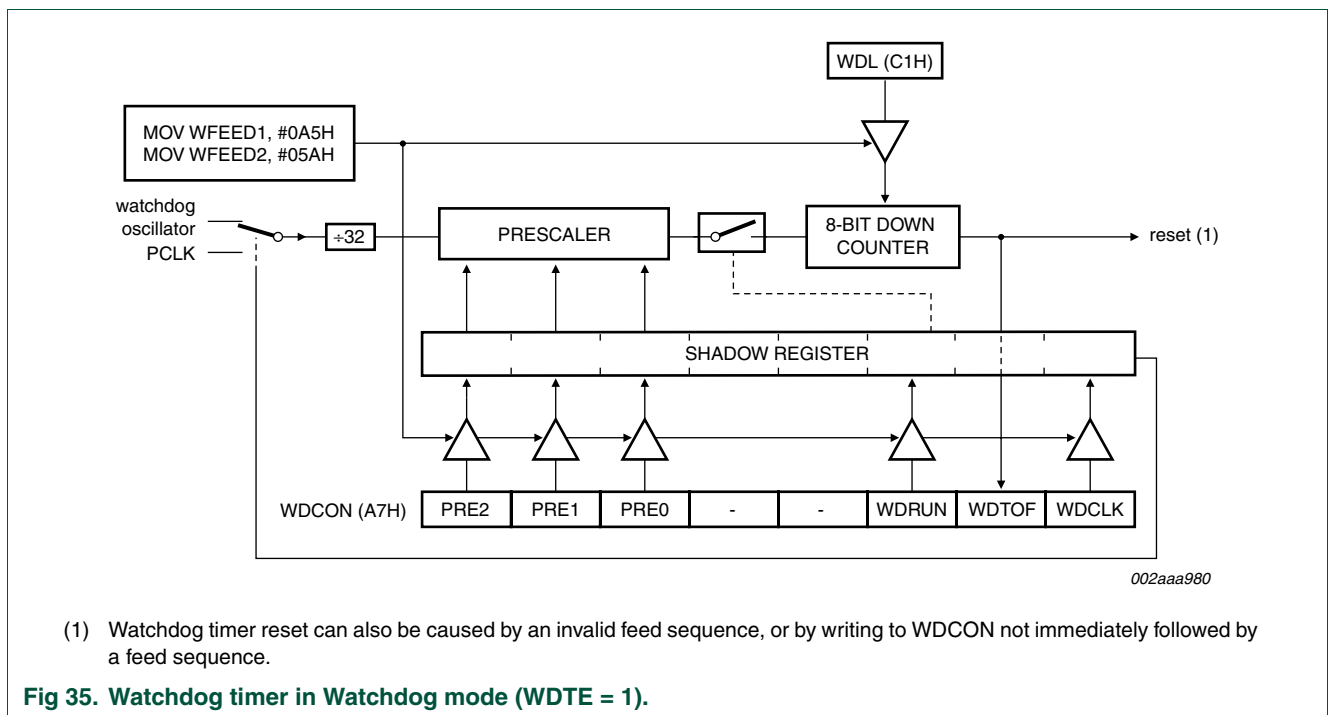

13.3 Watchdog clock source

The watchdog timer system has an on-chip 400 KHz oscillator. The watchdog timer can be clocked from either the Watchdog oscillator or from PCLK (refer to [Figure 34](#)) by configuring the WDCLK bit in the Watchdog Control Register WDCON. When the Watchdog feature is enabled, the timer must be fed regularly by software in order to prevent it from resetting the CPU.

After changing WDCLK (WDCON.0), switching of the clock source will not immediately take effect. As shown in [Figure 36](#), the selection is loaded after a Watchdog feed sequence. In addition, due to clock synchronization logic, it can take two old clock cycles before the old clock source is deselected, and then an additional two new clock cycles before the new clock source is selected.

Since the prescaler starts counting immediately after a feed, switching clocks can cause some inaccuracy in the prescaler count. The inaccuracy could be as much as two old clock source counts plus two new clock cycles.

Note: When switching clocks, it is important that the old clock source is left enabled for two clock cycles after the feed completes. Otherwise, the Watchdog may become disabled when the old clock source is disabled. For example, suppose PCLK (WCLK = 0) is the current clock source. After WCLK is set to logic 1, the program should wait at least two PCLK cycles (4 CCLKs) after the feed completes before going into Power-down mode. Otherwise, the Watchdog could become disabled when CCLK turns off. The Watchdog oscillator will never become selected as the clock source unless CCLK is turned on again first.

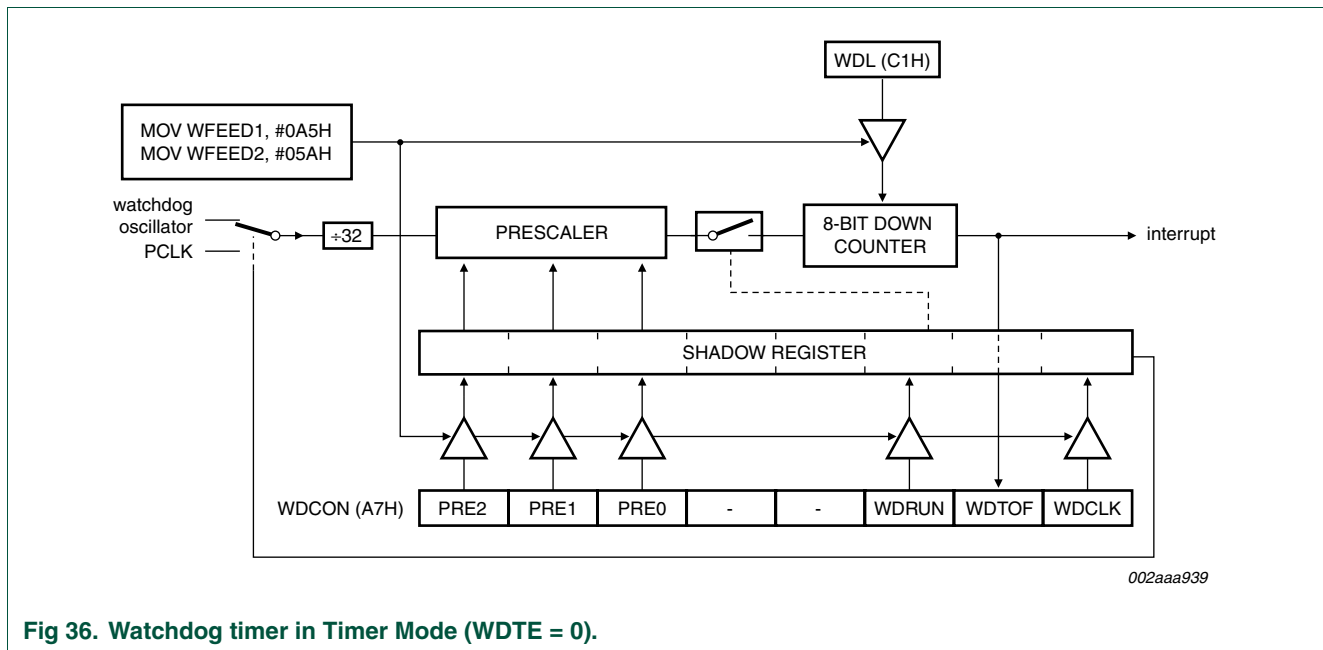

Fig 36. Watchdog timer in Timer Mode (WDTE = 0).

13.4 Watchdog timer in Timer mode

Figure 36 shows the watchdog timer in Timer Mode. In this mode, any changes to WDCON are written to the shadow register after one Watchdog clock cycle. A Watchdog underflow will set the WDTOF bit. If IEN0.6 is set, the Watchdog underflow is enabled to cause an interrupt. WDTOF is cleared by writing a logic 0 to this bit in software. When an underflow occurs, the contents of WDL is reloaded into the down counter and the watchdog timer immediately begins to count down again.

A feed is necessary to cause WDL to be loaded into the down counter before an underflow occurs. Incorrect feeds are ignored in this mode.

13.5 Power-down operation

The WDT oscillator will continue to run in power-down, consuming approximately 50 μA , as long as the WDT oscillator is selected as the clock source for the WDT. Selecting PCLK as the WDT source will result in the WDT oscillator going into power-down with the rest of the device (see Section 13.3). Power-down mode will also prevent PCLK from running and therefore the Watchdog is effectively disabled.

13.6 Periodic wake-up from power-down without an external oscillator

Without using an external oscillator source, the power consumption required in order to have a periodic wake-up is determined by the power consumption of the internal oscillator source used to produce the wake-up. The Real-time clock running from the internal RC oscillator can be used. The power consumption of this oscillator is approximately 300 μA . Instead, if the WDT is used to generate interrupts the current is reduced to approximately 50 μA . Whenever the WDT underflows, the device will wake up.

14. Additional features

The AUXR1 register contains several special purpose control bits that relate to several chip features. AUXR1 is described in [Table 69](#).

Table 68: AUXR1 register (address A2h) bit allocation

Bit	7	6	5	4	3	2	1	0
Symbol	CLKLP	EBRR	ENT1	ENT0	SRST	0	-	DPS
Reset	0	0	0	0	0	0	x	0

Table 69: AUXR1 register (address A2h) bit description

Bit	Symbol	Description
0	DPS	Data Pointer Select. Chooses one of two Data Pointers.
1	-	Not used. Allowable to set to a logic 1.
2	0	This bit contains a hard-wired 0. Allows toggling of the DPS bit by incrementing AUXR1, without interfering with other bits in the register.
3	SRST	Software Reset. When set by software, resets the P89LPC9102/9103/9107 as if a hardware reset occurred.
4	ENT0	When set the P1.2 pin is toggled whenever Timer 0 overflows. The output frequency is therefore one half of the Timer 0 overflow rate. Refer to the Timer/Counters section for details (P89LPC9102).
5	ENT1	When set, the P0.7 pin is toggled whenever Timer 1 overflows. The output frequency is therefore one half of the Timer 1 overflow rate. Refer to the Timer/Counters section for details (P89LPC9102).
6	EBRR	UART Break Detect Reset Enable. If logic 1, UART Break Detect will cause a chip reset and force the device into ISP mode (P89LPC9103).
7	CLKLP	Clock Low Power Select. When set, reduces power consumption in the clock circuits. Can be used when the clock frequency is 8 MHz or less. After reset this bit is cleared to support up to 12 MHz operation.

14.1 Software reset

The SRST bit in AUXR1 gives software the opportunity to reset the processor completely, as if an external reset or watchdog reset had occurred. If a value is written to AUXR1 that contains a logic 1 at bit position 3, all SFRs will be initialized and execution will resume at program address 0000. Care should be taken when writing to AUXR1 to avoid accidental software resets.

14.2 Dual Data Pointers

The dual Data Pointers (DPTR) adds to the ways in which the processor can specify the address used with certain instructions. The DPS bit in the AUXR1 register selects one of the two Data Pointers. The DPTR that is not currently selected is not accessible to software unless the DPS bit is toggled.

Specific instructions affected by the Data Pointer selection are:

INC DPTR — Increments the Data Pointer by 1.

JMP @A+DPTR — Jump indirect relative to DPTR value.

MOV DPTR, #data16 — Load the Data Pointer with a 16-bit constant.

MOVC A, @A+DPTR — Move code byte relative to DPTR to the accumulator.

MOVX A, @DPTR — Move data byte the accumulator to data memory relative to DPTR.

MOVX@DPTR, A — Move data byte from data memory relative to DPTR to the accumulator.

Also, any instruction that reads or manipulates the DPH and DPL registers (the upper and lower bytes of the current DPTR) will be affected by the setting of DPS. The MOVX instructions have limited application for the P89LPC9102/9103/9107 since the part does not have an external data bus. However, they may be used to access Flash configuration information (see Flash Configuration section?) or auxiliary data (XDATA) memory.

Bit 2 of AUXR1 is permanently wired as a logic 0. This is so that the DPS bit may be toggled (thereby switching Data Pointers) simply by incrementing the AUXR1 register, without the possibility of inadvertently altering other bits in the register.

15. Flash memory

The P89LPC9102/9103/9107 Flash memory provides in-circuit electrical erasure and programming. The Flash can be read and written as bytes. The Sector and Page Erase functions can erase any Flash sector (256 bytes) or page (16 bytes). The Chip Erase operation will erase the entire program memory. Two Flash programming methods are available. On-chip erase and write timing generation contribute to a user-friendly programming interface. The **P89LPC9102/9103/9107** Flash reliably stores memory contents even after 100,000 erase and program cycles. The cell is designed to optimize the erase and programming mechanisms. The **P89LPC9102/9103/9107** uses V_{DD} as the supply voltage to perform the Program/Erase algorithms.

15.1 Features

- In-Circuit serial Programming (ICP) with industry-standard commercial programmers.
- IAP-Lite allows individual and multiple bytes of code memory to be used for data storage and programmed under control of the end application.
- Programming and erase over the full operating voltage range
- Read/Programming/Erase using IAP-Lite
- Any flash program operation in 2 ms (4 ms for erase/program)
- Programmable security for the code in the Flash for each sector.
- > 100,000 typical erase/program cycles for each byte.
- 10-year minimum data retention.

15.2 Flash programming and erase

The P89LPC9102/9103/9107 program memory consists 256 byte sectors. Each sector can be further divided into 16-byte pages. In addition to sector erase and page erase, a 16-byte page register is included which allows from 1 byte to 16 bytes of a given page to be programmed at the same time, substantially reducing overall programming time.

15.3 Using Flash as data storage: IAP-Lite

The Flash code memory array of this device supports IAP-Lite operations. Any byte in a non-secured sector of the code memory array may be read using the MOVX instruction and thus is suitable for use as non-volatile data storage. IAP-Lite provides an erase-program function that makes it easy for one or more bytes within a page to be

erased and programmed in a single operation without the need to erase or program any other bytes in the page. IAP-Lite is performed in the application under the control of the microcontroller's firmware using four SFRs and an internal 16-byte 'page register' to facilitate erasing and programming within unsecured sectors. These SFRs are:

- FMCON (Flash Control Register). When read, this is the status register. When written, this is a command register. Note that the status bits are cleared to '0's when the command is written.
- FMDATA (Flash Data Register). Accepts data to be loaded into the page register.
- FMADRL, FMADRH (Flash memory address low, Flash memory address high). Used to specify the byte address within the page register or specify the page within user code memory.

The page register consists of 16 bytes and an update flag for each byte. When a LOAD command is issued to FMCON the page register contents and all of the update flags will be cleared. When FMDATA is written, the value written to FMDATA will be stored in the page register at the location specified by the lower 4 bits of FMADRL. In addition, the update flag for that location will be set. FMADRL will auto-increment to the next location. Auto-increment after writing to the last byte in the page register will 'wrap -around' to the first byte in the page register, but will not affect FMADRL[7:4]. Bytes loaded into the page register do not have to be continuous. Any byte location can be loaded into the page register by changing the contents of FMADRL prior to writing to FMDATA. However, each location in the page register can only be written once following each LOAD command. Attempts to write to a page register location more than once should be avoided.

FMADRH and FMADRL[7:4] are used to select a page of code memory for the erase-program function. When the erase-program command is written to FMCON, the locations within the code memory page that correspond to updated locations in the page register, will have their contents erased and programmed with the contents of their corresponding locations in the page register. Only the bytes that were loaded into the page register will be erased and programmed in the user code array. Other bytes within the user code memory will not be affected.

Writing the erase-program command (68H) to FMCON will start the erase-program process and place the CPU in a program-idle state. The CPU will remain in this idle state until the erase-program cycle is either completed or terminated by an interrupt. When the program-idle state is exited FMCON will contain status information for the cycle.

If an interrupt occurs during an erase/programming cycle, the erase/programming cycle will be aborted and the OI flag (Operation Interrupted) in FMCON will be set. If the application permits interrupts during erasing-programming the user code should check the OI flag (FMCON.0) after each erase-programming operation to see if the operation was aborted. If the operation was aborted, the user's code will need to repeat the process starting with loading the page register.

The erase-program cycle takes 4 ms (2 ms for erase, 2 ms for programming) to complete, regardless of the number of bytes that were loaded into the page register.

Erasing-programming of a single byte (or multiple bytes) in code memory is accomplished using the following steps:

- Write the LOAD command (00H) to FMCON. The LOAD command will clear all locations in the page register and their corresponding update flags.

- Write the address within the page register to FMADRL. Since the loading the page register uses FMADRL[3:0], and since the erase-program command uses FMADRH and FMADRL[7:4], the user can write the byte location within the page register (FMADRL[3:0]) and the code memory page address (FMADRH and FMADRL[7:4]) at this time.
- Write the data to be programmed to FMDATA. This will increment FMADRL pointing to the next byte in the page register.
- Write the address of the next byte to be programmed to FMADRL, if desired. (Not needed for contiguous bytes since FMADRL is auto-incremented). All bytes to be programmed must be within the same page.
- Write the data for the next byte to be programmed to FMDATA.
- Repeat the writing of FMADRL and/or FMDATA until all desired bytes have been loaded into the page register.
- Write the page address in user code memory to FMADRH and FMADRL[7:4], if not previously included when writing the page register address to FMADRL[3:0].
- Write the erase-program command (68H) to FMCON, starting the erase-program cycle.
- Read FMCON to check status. If aborted, repeat starting with the LOAD command.

Table 70: Flash Memory Control register (FMCON - address E4h) bit allocation

    for(i=0;i<16;i=i+1)
    {
        FMDATA = dbytes[i];
    }
    FMCON = EP;//erase & prog page command
    Fm_stat = FMCON;//read the result status
    if ((Fm_stat & 0x0F)!=0) prog_fail=1; else prog_fail=0;
    return(prog_fail);
}

```

15.4 In-circuit programming (ICP)

In-Circuit Programming is a method intended to allow commercial programmers to program and erase these devices without removing the microcontroller from the system. The In-Circuit Programming facility consists of a series of internal hardware resources to facilitate remote programming of the P89LPC9102/9103/9107 through a two-wire serial interface. Philips has made in-circuit programming in an embedded application possible with a minimum of additional expense in components and circuit board area. The ICP function uses five pins (V_{DD} , V_{SS} , P0.5, P0.4, and \overline{RST}). Only a small connector needs to be available to interface your application to an external programmer in order to use this feature.

15.5 Power on reset code execution

The P89LPC9102/9103/9107 contains two special Flash elements: the BOOT VECTOR and the Boot Status Bit. Following reset, the P89LPC9102/9103/9107 examines the contents of the Boot Status Bit. If the Boot Status Bit is set to zero, power-up execution starts at location 0000H, which is the normal start address of the user's application code. When the Boot Status Bit is set to a one, the contents of the Boot Vector is used as the high byte of the execution address and the low byte is set to 00H.

The factory default settings for these devices are shown in [Table 72](#), below.

Table 72: Default Boot vector

Product	Flash size	End address	Signature bytes			Sector size	Page size	Default Boot vector
			Mfg id	Id 1	Id 2			
P89LPC9102/9103/9107	1K × 8	03FFh	15h	DDh	1Bh	256 × 8	16 × 8	00h

15.6 Hardware activation of Boot Vector address

Execution using the Boot Vector can be forced during a power-on sequence (see [Figure 37](#)). This is accomplished by powering up the device with the reset pin initially held low and holding the pin low for a fixed time after V_{DD} rises to its normal operating value. This is followed by three, and only three, properly timed low-going pulses. Fewer or more than three pulses will result in the device not entering this mode. Timing specifications may be found in the data sheet for this device.

This has the same effect as having a non-zero status bit. This allows an application to be built that will normally execute the user code but can be manually forced into executing from an alternate address.

Fig 37. Hardware activation of Boot Vector address.

15.7 Flash write enable

This device has hardware write enable protection. This protection applies during IAP-Lite mode and applies to both the user code memory space and the user configuration bytes (UCFG1, BOOTVEC, and BOOTSTAT). This protection does not apply to the ICP programming mode. If the Activate Write Enable (AWE) bit in BOOTSTAT.7 is a '0', an internal Write Enable (WE) flag is forced set and writes to the flash memory and configuration bytes are enabled. If the Active Write Enable (AWE) bit is a '1' then the state of the internal WE flag can be controlled by the user.

The WE flag is SET by writing the Set Write Enable (08H) command to FMCON followed by a key value (96H) to FMDATA:

```
MOV FMCON,#08H
```

```
MOV FMDATA,#96H
```

The WE flag is CLEARED by writing the Clear Write Enable (0BH) command to FMCON followed by a key value (96H) to FMDATA, or by a reset:

```
MOV FMCON,#0BH
```

```
MOV FMDATA,#96H.
```

15.8 Configuration byte protection

In addition to the hardware write enable protection, described above, the 'configuration bytes' may be separately write protected. These configuration bytes include UCFG1, BOOTVEC, and BOOTSTAT. This protection applies to the IAP-Lite programming mode and does not apply to the ICP or programmer mode.

If the Configuration Write Protect Writ (CWP) bit in BOOTSTAT.6 is a '1' writes to the configuration bytes are disabled. If the Configuration Write Protect Writ (CWP) bit in BOOTSTAT.6 is a '0' writes to the configuration bytes are enabled. The CWP bit is set by programming the BOOTSTAT register. This bit is cleared by using the Clear Configuration Protection command (67h):

```
MOV FMCON,#67H
```

```
MOV FMDATA,#96H
```

The Clear Configuration Protection command can be disabled in IAP-Lite mode by programming to a '1' the Disable Clear Configuration Protection (DCCP) bit in BOOTSTAT.7. When DCCP is set, the CCP command may still be used in ICP mode. This bit is cleared by writing the Clear Configuration Protection command in ICP mode.

15.9 IAP-Lite error status

It is not possible to use the Flash memory as the source of program instructions while programming or erasing this same Flash memory. During an IAP-Lite erase, program, or CRC the CPU enters a program-idle state. The CPU will remain in this program-idle state until the erase, program, or CRC cycle is completed. These cycles are self timed. When the cycle is completed, code execution resumes. If an interrupt occurs during an erase, programming or CRC cycle, the erase, programming, or CRC cycle will be aborted so that the Flash memory can be used as the source of instructions to service the interrupt. An IAP-Lite error condition will be flagged by setting the carry flag and status information returned. The status information returned is shown in [Table 73](#). If the application permits interrupts during erasing, programming, or CRC cycles, the user code should check the carry flag after each erase, programming, or CRC operation to see if an error occurred. If the operation was aborted, the user's code will need to repeat the operation.

Table 73: IAP-Lite error status

Bit	Flag	Description
0	OI	Operation Interrupted. Indicates that an operation was aborted due to an interrupt occurring during a program or erase cycle.
1	SV	Security Violation. Set if program or erase operation fails due to security settings. Cycle is aborted. Memory contents are unchanged. CRC output is invalid.
2	HVE	High Voltage Error. Set if error detected in high voltage generation circuits. Cycle is aborted. Memory contents may be corrupted.
3-7	-	undefined

15.10 User configuration bytes

A number of user-configurable features of the P89LPC9102/9103/9107 must be defined at power-up and therefore cannot be set by the program after start of execution. These features are configured through the use of an Flash byte UCFG1 shown in [Table 75](#)

Table 74: Flash User Configuration Byte (UCFG1) bit allocation

Bit	7	6	5	4	3	2	1	0
Symbol	WDTE	RPE	BOE	WDSE	IRCDBL	FOSC2	FOSC1	FOSC0
Unprogrammed value	0	1	1	0	0	0	1	1

Table 75: Flash User Configuration Byte (UCFG1) bit description

Bit	Symbol	Description
0	FOSC0	CPU oscillator type select. See Section 2 “Clocks” on page 25 for additional information. Combinations other than those shown in Table 76 are reserved for future use and should not be used.
1	FOSC1	
2	FOSC2	
3	IRCDBL	When set =1, this bit doubles the frequency of the internal RC oscillator.
4	WDSE	Watchdog Safety Enable bit. Refer to Table 76 for details.
5	BOE	Brownout Detect Enable (see Section 6.1 “Brownout detection” on page 41)
6	RPE	Reset pin enable. When set =1, enables the reset function of pin P1.5. When cleared, P1.5 may be used as an input pin. NOTE: During a power-up sequence, the RPE selection is overridden and this pin will always function as a reset input. After power-up the pin will function as defined by the RPE bit. Only a power-up reset will temporarily override the selection defined by RPE bit. Other sources of reset will not override the RPE bit.
7	WDTE	Watchdog timer reset enable. When set =1, enables the watchdog timer reset. When cleared = 0, disables the watchdog timer reset. The timer may still be used to generate an interrupt. Refer to Table 76 for details.

Table 76: Oscillator type selection

FOSC[2:0]	Oscillator configuration
000	undefined
001	undefined
010	undefined
011	Internal RC oscillator, 7.373 MHz \pm 2.5 %.
100	Watchdog Oscillator, 400 kHz (+20/ -30 % tolerance).
101	undefined
110	undefined
111	External clock input on CLKIN.

15.11 User security bytes

This device has three security bits associated with each of its eight sectors, as shown in [Table 77](#)

Table 77: Sector Security Bytes (SECx) bit allocation

Bit	7	6	5	4	3	2	1	0
Symbol	-	-	-	-	-	EDISx	SPEDISx	MOVCDISx
Unprogrammed value	0	0	0	0	0	0	0	0

Table 78: Sector Security Bytes (SECx) bit description

Bit	Symbol	Description
0	MOVCDISx	MOVC Disable. Disables the MOVC command for sector x. Any MOVC that attempts to read a byte in a MOVC protected sector will return invalid data. This bit can only be erased when sector x is erased.
1	SPEDISx	Sector Program Erase Disable x. Disables program or erase of all or part of sector x. This bit and sector x are erased by either a sector erase command (ISP, IAP, commercial programmer) or a 'global' erase command (commercial programmer).
2	EDISx	Erase Disable ISP. Disables the ability to perform an erase of sector 'x' in ISP or IAP mode. When programmed, this bit and sector x can only be erased by a 'global' erase command using a commercial programmer. This bit and sector x CANNOT be erased in ISP or IAP modes.
3:7	-	reserved

Table 79: Effects of Security Bits

EDISx	SPEDISx	MOVCDISx	Effects on Programming
0	0	0	None.
0	0	1	Security violation flag set for sector CRC calculation for the specific sector. Security violation flag set for global CRC calculation if any MOVCDISx bit is set. Cycle aborted. Memory contents unchanged. CRC invalid. Program/erase commands will not result in a security violation.
0	1	x	Security violation flag set for program commands or an erase page command. Cycle aborted. Memory contents unchanged. Sector erase and global erase are allowed.
1	x	x	Security violation flag set for program commands or an erase page command. Cycle aborted. Memory contents unchanged. Global erase is allowed.

15.12 Boot Vector register

Table 80: Boot Vector (BOOTVEC) bit allocation

Bit	7	6	5	4	3	2	1	0
Symbol	-	-	-	BOOTV4	BOOTV3	BOOTV2	BOOTV1	BOOTV0
Factory default value	0	0	0	1	1	1	1	1

Table 81: Boot Vector (BOOTVEC) bit description

Bit	Symbol	Description
0:4	BOOTV.0:4	Boot vector. If the Boot Vector is selected as the reset address, the P89LPC9102/9103/9107 will start execution at an address comprised of 00h in the lower eight bits and this BOOTVEC as the upper eight bits after a reset.
5:7	-	reserved

continued >>

15.13 Boot status register

Table 82: Boot Status (BOOTSTAT) bit allocation

Bit	7	6	5	4	3	2	1	0
Symbol	DDCP	CWP	AWP	-	-	-	--	BSB
Factory default value	0	0	0	0	0	0	0	1

Table 83: Boot Status (BOOTSTAT) bit description

Bit	Symbol	Description
0	BSB	Boot Status Bit. If programmed to '1', the P89LPC9102/9103/9107 will always start execution at an address comprised of 00H in the lower eight bits and BOOTVEC as the upper bits after a reset. (See Section 7.1 "Reset vector" on page 46).
1:4	-	reserved
5	AWP	Activate Write Protection bit. When this bit is cleared, the internal Write Enable flag is forced to the set state, thus writes to the flash memory are always enabled. When this bit is set, the Write Enable internal flag can be set or cleared using the Set Write Enable (SWE) or Clear Write Enable (CWE) commands to FMCON.
6	CWP	Configuration Write Protect bit. Protects inadvertent writes to the user programmable configuration bytes (UCFG1, BOOTVEC, and BOOTSTAT). If programmed to '1', the writes to these registers are disabled. If programmed to '0', writes to these registers are enabled. This bit is set by programming the BOOTSTAT register. This bit is cleared by writing the Clear Configuration Protection (CCP) command to FMCON followed by writing 96H to FMDATA.
7	DDCP	Disable Clear Configuration Protection command. If Programmed to '1', the Clear Configuration Protection (CCP) command is disabled in IAP-Lite mode. This command can still be used in ICP mode. If programmed to '0', the CCP command can be used in all programming modes. This bit is set by programming the BOOTSTAT register. This bit is cleared by writing the Clear Configuration Protection (CCP) command in ICP mode.
