Note: A t_{TRIM} delay must be respected between the write to the OTRIMx[4:0] bits and the read of the CAL_FLAGx bit in DAC_SR register in order to get a correct value.This parameter is specified into datasheet electrical characteristics section.

If V_{DDA}, VREF+ and temperature conditions do not change during device operation while it enters more often in standby and VBAT mode, the software may store the OTRIMx[4:0] bits found in the first user calibration in the flash or in back-up registers. then to load/write them directly when the device power is back again thus avoiding to wait for a new calibration time.

When CENx bit is set, it is not allowed to set ENx bit.

28.4.14 Dual DAC channel conversion modes (if dual channels are available)

To efficiently use the bus bandwidth in applications that require the two DAC channels at the same time, three dual registers are implemented: DHR8RD, DHR12RD and DHR12LD. A unique register access is then required to drive both DAC channels at the same time. For the wave generation, no accesses to DHRxxxD registers are required. As a result, two output channels can be used either independently or simultaneously.

15 conversion modes are possible using the two DAC channels and these dual registers. All the conversion modes can nevertheless be obtained using separate DHRx registers if needed.

All modes are described in the paragraphs below.

Independent trigger without wave generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DHR1 register is transferred into DAC_DOR1 (three dac_hclk clock cycles later).

When a DAC channel2 trigger arrives, the DHR2 register is transferred into DAC_DOR2 (three dac_hclk clock cycles later).

Independent trigger with single LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and the same LFSR mask value in the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). Then the LFSR2 counter is updated.

Independent trigger with different LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and set different LFSR masks values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). Then the LFSR2 counter is updated.

Independent trigger with single triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and the same maximum amplitude value in the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The DAC channel2 triangle counter is then updated.

Independent trigger with different triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bits.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The DAC channel2 triangle counter is then updated.

Simultaneous software start

To configure the DAC in this conversion mode, the following sequence is required:

- Load the dual DAC channel data to the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

In this configuration, one dac_hclk clock cycle later, the DHR1 and DHR2 registers are transferred into DAC_DOR1 and DAC_DOR2, respectively.

Simultaneous trigger without wave generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Load the dual DAC channel data to the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DHR1 and DHR2 registers are transferred into DAC_DOR1 and DAC_DOR2, respectively (after three dac_hclk clock cycles).

Simultaneous trigger with single LFSR generation

1. To configure the DAC in this conversion mode, the following sequence is required:
2. Set the two DAC channel trigger enable bits TEN1 and TEN2.
3. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
4. Configure the two DAC channel WAVEx[1:0] bits as 01 and the same LFSR mask value in the MAMPx[3:0] bits.
5. Load the dual DAC channel data to the desired DHR register (DHR12RD, DHR12LD or DHR8RD).

When a trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The LFSR1 counter is then updated. At the same time, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The LFSR2 counter is then updated.

Simultaneous trigger with different LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and set different LFSR mask values using the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The LFSR1 counter is then updated.
At the same time, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The LFSR2 counter is then updated.

Simultaneous trigger with single triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and the same maximum amplitude value using the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The DAC channel1 triangle counter is then updated.

At the same time, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The DAC channel2 triangle counter is then updated.

Simultaneous trigger with different triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three AHB clock cycles later). Then the DAC channel1 triangle counter is updated.

At the same time, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). Then the DAC channel2 triangle counter is updated.

28.5 DAC in low-power modes

Table 271. Effect of low-power modes on DAC

Mode	Description
Sleep	No effect, DAC used with DMA.
Stop(1)	The DAC remains active with a static value. The Sample and hold mode can be selected using LSE/LSI clock.
Standby	The DAC peripheral is powered down and must be reinitialized after exiting Standby mode.

1. Refer to *Section 28.3: DAC implementation* for information on the Stop modes supported by the DAC peripheral.

28.6 DAC interrupts

Table 272. DAC interrupts

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit Sleep mode	Exit Stop mode	Exit Standby mode
DAC	DMA underrun	DMAUDRx	DMAUDRIEx	Write DMAUDRx = 1	Yes	No	No

28.7 DAC registers

Refer to *Section 1 on page 101* for a list of abbreviations used in register descriptions.

The peripheral registers have to be accessed by words (32-bit).

28.7.1 DAC control register (DAC_CR)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	CEN2	DMAUDRIE2	DMAEN2	MAMP2[3:0]				WAVE2[1:0]		TSEL2[3]	TSEL2[2]	TSEL2[1]	TSEL2[0]	TEN2	EN2
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	CEN1	DMAUDRIE1	DMAEN1	MAMP1[3:0]				WAVE1[1:0]		TSEL1[3]	TSEL1[2]	TSEL1[1]	TSEL1[0]	TEN1	EN1
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **CEN2**: DAC channel2 calibration enable

This bit is set and cleared by software to enable/disable DAC channel2 calibration, it can be written only if EN2 bit is set to 0 into DAC_CR (the calibration mode can be entered/exit only when the DAC channel is disabled) Otherwise, the write operation is ignored.

0: DAC channel2 in Normal operating mode

1: DAC channel2 in calibration mode

Note: This bit is available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

Bit 29 **DMAUDRIE2**: DAC channel2 DMA underrun interrupt enable

This bit is set and cleared by software.

0: DAC channel2 DMA underrun interrupt disabled

1: DAC channel2 DMA underrun interrupt enabled

Note: This bit is available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

Bit 28 **DMAEN2**: DAC channel2 DMA enable

This bit is set and cleared by software.

0: DAC channel2 DMA mode disabled

1: DAC channel2 DMA mode enabled

Note: This bit is available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

Bits 27:24 **MAMP2[3:0]**: DAC channel2 mask/amplitude selector

These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.

0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1
0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3
0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7
0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15
0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31
0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63
0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127
0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255
1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511
1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023
1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047
≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

Note: These bits are available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

Bits 23:22 **WAVE2[1:0]**: DAC channel2 noise/triangle wave generation enable

These bits are set/reset by software.

00: wave generation disabled
01: Noise wave generation enabled
1x: Triangle wave generation enabled

Note: Only used if bit TEN2 = 1 (DAC channel2 trigger enabled)
These bits are available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

Bits 21:18 **TSEL2[3:0]**: DAC channel2 trigger selection

These bits select the external event used to trigger DAC channel2

0000: SWTRIG2
0001: dac_ch2_trg1
0010: dac_ch2_trg2
...
1111: dac_ch2_trg15

Refer to the trigger selection tables in *Section 28.4.2: DAC pins and internal signals* for details on trigger configuration and mapping.

Note: Only used if bit TEN2 = 1 (DAC channel2 trigger enabled).
These bits are available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

Bit 17 **TEN2**: DAC channel2 trigger enable

This bit is set and cleared by software to enable/disable DAC channel2 trigger

0: DAC channel2 trigger disabled and data written into the DAC_DHR2 register are transferred one dac_hclk clock cycle later to the DAC_DOR2 register
1: DAC channel2 trigger enabled and data from the DAC_DHR2 register are transferred three dac_hclk clock cycles later to the DAC_DOR2 register

Note: When software trigger is selected, the transfer from the DAC_DHR2 register to the DAC_DOR2 register takes only one dac_hclk clock cycle.
These bits are available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

Bit 16 **EN2**: DAC channel2 enable

This bit is set and cleared by software to enable/disable DAC channel2.

0: DAC channel2 disabled

1: DAC channel2 enabled

Note: These bits are available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **CEN1**: DAC channel1 calibration enable

This bit is set and cleared by software to enable/disable DAC channel1 calibration, it can be written only if bit EN1 = 0 into DAC_CR (the calibration mode can be entered/exit only when the DAC channel is disabled) Otherwise, the write operation is ignored.

0: DAC channel1 in Normal operating mode

1: DAC channel1 in calibration mode

Bit 13 **DMAUDRIE1**: DAC channel1 DMA Underrun Interrupt enable

This bit is set and cleared by software.

0: DAC channel1 DMA Underrun Interrupt disabled

1: DAC channel1 DMA Underrun Interrupt enabled

Bit 12 **DMAEN1**: DAC channel1 DMA enable

This bit is set and cleared by software.

0: DAC channel1 DMA mode disabled

1: DAC channel1 DMA mode enabled

Bits 11:8 **MAMP1[3:0]**: DAC channel1 mask/amplitude selector

These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.

0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1

0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3

0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7

0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15

0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31

0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63

0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127

0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255

1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511

1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023

1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047

≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

Bits 7:6 **WAVE1[1:0]**: DAC channel1 noise/triangle wave generation enable

These bits are set and cleared by software.

00: wave generation disabled

01: Noise wave generation enabled

1x: Triangle wave generation enabled

Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).

Bits 5:2 **TSEL1[3:0]**: DAC channel1 trigger selection
These bits select the external event used to trigger DAC channel1
0000: SWTRIG1
0001: dac_ch1_trg1
0010: dac_ch1_trg2
...
1111: dac_ch1_trg15
Refer to the trigger selection tables in *Section 28.4.2: DAC pins and internal signals* for details on trigger configuration and mapping.
Note: Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).

Bit 1 **TEN1**: DAC channel1 trigger enable
This bit is set and cleared by software to enable/disable DAC channel1 trigger.
0: DAC channel1 trigger disabled and data written into the DAC_DHR1 register are transferred one dac_hclk clock cycle later to the DAC_DOR1 register
1: DAC channel1 trigger enabled and data from the DAC_DHR1 register are transferred three dac_hclk clock cycles later to the DAC_DOR1 register
Note: When software trigger is selected, the transfer from the DAC_DHR1 *register to the DAC_DOR1 register takes only one dac_hclk clock cycle.*

Bit 0 **EN1**: DAC channel1 enable
This bit is set and cleared by software to enable/disable DAC channel1.
0: DAC channel1 disabled
1: DAC channel1 enabled

28.7.2 DAC software trigger register (DAC_SWTRGR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

														w	w

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **SWTRIG2**: DAC channel2 software trigger

This bit is set by software to trigger the DAC in software trigger mode.

0: No trigger

1: Trigger

Note: This bit is cleared by hardware (one dac_hclk clock cycle later) once the DAC_DHR2 register value has been loaded into the DAC_DOR2 register.

This bit is available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

Bit 0 **SWTRIG1**: DAC channel1 software trigger

This bit is set by software to trigger the DAC in software trigger mode.

0: No trigger

1: Trigger

Note: This bit is cleared by hardware (one dac_hclk clock cycle later) once the DAC_DHR1 register value has been loaded into the DAC_DOR1 register.

28.7.3 DAC channel1 12-bit right-aligned data holding register (DAC_DHR12R1)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **DACC1DHRB[11:0]**: DAC channel1 12-bit right-aligned data B

These bits are written by software. They specify 12-bit data for DAC channel1 when the DAC operates in Double data mode.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **DACC1DHR[11:0]**: DAC channel1 12-bit right-aligned data

These bits are written by software. They specify 12-bit data for DAC channel1.

28.7.4 DAC channel1 12-bit left aligned data holding register (DAC_DHR12L1)

Address offset: 0x0C

Reset value: 0x0000 0000

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw				

Bits 31:20 **DACC2DHRB[11:0]**: DAC channel2 12-bit left-aligned data B
These bits are written by software. They specify 12-bit data for DAC channel2 when the DAC operates in Double data mode.

Bits 19:16 Reserved, must be kept at reset value.

Bits 15:4 **DACC2DHR[11:0]**: DAC channel2 12-bit left-aligned data
These bits are written by software which specify 12-bit data for DAC channel2.

Bits 3:0 Reserved, must be kept at reset value.

28.7.8 DAC channel2 8-bit right-aligned data holding register (DAC_DHR8R2)

This register is available only on dual-channel DACs. Refer to *Section 28.3: DAC implementation*.

Address offset: 0x1C

Reset value: 0x0000 0000

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **DACC2DHRB[7:0]**: DAC channel2 8-bit right-aligned data
These bits are written by software. They specify 8-bit data for DAC channel2 when the DAC operates in Double data mode.

Bits 7:0 **DACC2DHR[7:0]**: DAC channel2 8-bit right-aligned data
These bits are written by software which specifies 8-bit data for DAC channel2.

28.7.9 Dual DAC 12-bit right-aligned data holding register (DAC_DHR12RD)

Address offset: 0x20

Reset value: 0x0000 0000

				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **DACC2DHR[11:0]**: DAC channel2 12-bit right-aligned data
These bits are written by software which specifies 12-bit data for DAC channel2.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **DACC1DHR[11:0]**: DAC channel1 12-bit right-aligned data
These bits are written by software which specifies 12-bit data for DAC channel1.

28.7.10 Dual DAC 12-bit left aligned data holding register (DAC_DHR12LD)

Address offset: 0x24

Reset value: 0x0000 0000

Res.	Res.	Res.	Res.	DACC1DOR[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **DACC1DORB[11:0]**: DAC channel1 data output
These bits are read-only. They contain data output for DAC channel1 B.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **DACC1DOR[11:0]**: DAC channel1 data output
These bits are read-only, they contain data output for DAC channel1.

28.7.13 DAC channel2 data output register (DAC_DOR2)

This register is available only on dual-channel DACs. Refer to *Section 28.3: DAC implementation*.

Address offset: 0x30

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	DACC2DOR[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **DACC2DORB[11:0]**: DAC channel2 data output
These bits are read-only. They contain data output for DAC channel2 B.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **DACC2DOR[11:0]**: DAC channel2 data output
These bits are read-only, they contain data output for DAC channel2.

28.7.14 DAC status register (DAC_SR)

Address offset: 0x34

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BWST2	CAL_FLAG2	DMAUDR2	DORSTAT2	DAC2RDY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r	r	rc_w1	r	r

r	r	rc_w1	r	r											

Bit 31 **BWST2**: DAC channel2 busy writing sample time flag

This bit is systematically set just after Sample and hold mode enable. It is set each time the software writes the register DAC_SHSR2, It is cleared by hardware when the write operation of DAC_SHSR2 is complete. (It takes about 3 LSI/LSE periods of synchronization).

0:There is no write operation of DAC_SHSR2 ongoing: DAC_SHSR2 can be written

1:There is a write operation of DAC_SHSR2 ongoing: DAC_SHSR2 cannot be written

Note: This bit is available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

Bit 30 **CAL_FLAG2**: DAC channel2 calibration offset status

This bit is set and cleared by hardware

0: calibration trimming value is lower than the offset correction value

1: calibration trimming value is equal or greater than the offset correction value

Note: This bit is available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

Bit 29 **DMAUDR2**: DAC channel2 DMA underrun flag

This bit is set by hardware and cleared by software (by writing it to 1).

0: No DMA underrun error condition occurred for DAC channel2

1: DMA underrun error condition occurred for DAC channel2 (the currently selected trigger is driving DAC channel2 conversion at a frequency higher than the DMA service capability rate).

Note: This bit is available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

Bit 28 **DORSTAT2**: DAC channel2 output register status bit

This bit is set and cleared by hardware. It is applicable only when the DAC operates in Double data mode.

0: DOR[11:0] is used actual DAC output

1: DORB[11:0] is used actual DAC output

Note: This bit is available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

Bit 27 **DAC2RDY**: DAC channel2 ready status bit

This bit is set and cleared by hardware.

0: DAC channel2 is not yet ready to accept the trigger nor output data

1: DAC channel2 is ready to accept the trigger or output data

Note: This bit is available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

Bits 26:16 Reserved, must be kept at reset value.

Bit 15 **BWST1**: DAC channel1 busy writing sample time flag

This bit is systematically set just after Sample and hold mode enable and is set each time the software writes the register DAC_SHSR1, It is cleared by hardware when the write operation of DAC_SHSR1 is complete. (It takes about 3 LSI/LSE periods of synchronization).

0:There is no write operation of DAC_SHSR1 ongoing: DAC_SHSR1 can be written

1:There is a write operation of DAC_SHSR1 ongoing: DAC_SHSR1 cannot be written

Bit 14 **CAL_FLAG1**: DAC channel1 calibration offset status

This bit is set and cleared by hardware

0: calibration trimming value is lower than the offset correction value

1: calibration trimming value is equal or greater than the offset correction value

Bit 13 **DMAUDR1**: DAC channel1 DMA underrun flag

This bit is set by hardware and cleared by software (by writing it to 1).

0: No DMA underrun error condition occurred for DAC channel1

1: DMA underrun error condition occurred for DAC channel1 (the currently selected trigger is driving DAC channel1 conversion at a frequency higher than the DMA service capability rate)

Bit 12 **DORSTAT1**: DAC channel1 output register status bit

This bit is set and cleared by hardware. It is applicable only when the DAC operates in Double data mode.

0: DOR[11:0] is used actual DAC output

1: DORB[11:0] is used actual DAC output

Bit 11 **DAC1RDY**: DAC channel1 ready status bit

This bit is set and cleared by hardware.

0: DAC channel1 is not yet ready to accept the trigger nor output data

1: DAC channel1 is ready to accept the trigger or output data

Bits 10:0 Reserved, must be kept at reset value.

28.7.15 DAC calibration control register (DAC_CCR)

Address offset: 0x38

Reset value: 0x00XX 00XX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OTRIM2[4:0]				
											rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OTRIM1[4:0]				
											rw	rw	rw	rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **OTRIM2[4:0]**: DAC channel2 offset trimming value

These bits are available only on dual-channel DACs. Refer to *Section 28.3: DAC implementation*.

Bits 15:5 Reserved, must be kept at reset value.

Bits 4:0 **OTRIM1[4:0]**: DAC channel1 offset trimming value

28.7.16 DAC mode control register (DAC_MCR)

Address offset: 0x3C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	SINFORMAT2	DMADOUBLE2	Res.	Res.	Res.	Res.	Res.	MODE2[2:0]		
						rw	rw						rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HFSEL[1]	HFSEL[0]	Res.	Res.	Res.	Res.	SINFORMAT1	DMADOUBLE1	Res.	Res.	Res.	Res.	Res.	MODE1[2:0]		
rw	rw					rw	rw						rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **SINFORMAT2**: Enable signed format for DAC channel2

This bit is set and cleared by software.

0: Input data is in unsigned format

1: Input data is in signed format (2's complement). The MSB bit represents the sign.

Note: This bit is available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

Bit 24 **DMADOUBLE2**: DAC channel2 DMA double data mode

This bit is set and cleared by software.

0: DMA Normal mode selected

1: DMA Double data mode selected

Note: This bit is available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

Bits 23:19 Reserved, must be kept at reset value.

Bits 18:16 **MODE2[2:0]:** DAC channel2 mode

These bits can be written only when the DAC is disabled and not in the calibration mode (when bit EN2 = 0 and bit CEN2 = 0 in the DAC_CR register). If EN2 = 1 or CEN2 = 1 the write operation is ignored.

They can be set and cleared by software to select the DAC channel2 mode:

– DAC channel2 in Normal mode

000: DAC channel2 is connected to external pin with Buffer enabled

001: Reserved

010: DAC channel2 is connected to external pin with buffer disabled

011: Reserved

– DAC channel2 in Sample and hold mode

100: DAC channel2 is connected to external pin with Buffer enabled

101: Reserved

110: DAC channel2 is connected to external pin with Buffer disabled

111: Reserved

Note: This register can be modified only when EN2 = 0.

Refer to Section 28.3: DAC implementation for the availability of DAC channel2.

Bits 15:14 **HFSEL[1:0]**: High frequency interface mode selection
00: High frequency interface mode disabled
01: High frequency interface mode enabled for AHB clock frequency > 80 MHz
10: High frequency interface mode enabled for AHB clock frequency >160 MHz
11: Reserved

Bits 13:10 Reserved, must be kept at reset value.

Bit 9 **SINFORMAT1**: Enable signed format for DAC channel1
This bit is set and cleared by software.
0: Input data is in unsigned format
1: Input data is in signed format (2's complement). The MSB bit represents the sign.

Bit 8 **DMADOUBLE1**: DAC channel1 DMA double data mode
This bit is set and cleared by software.
0: DMA Normal mode selected
1: DMA Double data mode selected

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **MODE1[2:0]:** DAC channel1 mode
These bits can be written only when the DAC is disabled and not in the calibration mode (when bit EN1 = 0 and bit CEN1 = 0 in the DAC_CR register). If EN1 = 1 or CEN1 = 1 the write operation is ignored.
They can be set and cleared by software to select the DAC channel1 mode:
– DAC channel1 in Normal mode
000: DAC channel1 is connected to external pin with Buffer enabled
001: Reserved
010: DAC channel1 is connected to external pin with Buffer disabled
011: Reserved
– DAC channel1 in sample & hold mode
100: DAC channel1 is connected to external pin with Buffer enabled
101: Reserved
110: DAC channel1 is connected to external pin with Buffer disabled
111: Reserved
Note: This register can be modified only when EN1 = 0.

28.7.17 DAC channel1 sample and hold sample time register (DAC_SHSR1)

Address offset: 0x40

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	TSAMPLE1[9:0]									
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **TSAMPLE1[9:0]:** DAC channel1 sample time (only valid in Sample and hold mode)

These bits can be written when the DAC channel1 is disabled or also during normal operation. in the latter case, the write can be done only when BWST1 of DAC_SR register is low, If BWST1 = 1, the write operation is ignored.

*Note: It represents the number of LSI/LSE clocks to perform a sample phase. Sampling time = (*TSAMPLE1[9:0] + 1) x *LSI/LSE clock period.*

28.7.18 DAC channel2 sample and hold sample time register (DAC_SHSR2)

This register is available only on dual-channel DACs. Refer to *Section 28.3: DAC implementation*.

Address offset: 0x44

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	TSAMPLE2[9:0]									
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **TSAMPLE2[9:0]:** DAC channel2 sample time (only valid in Sample and hold mode)
These bits can be written when the DAC channel2 is disabled or also during normal operation. in the latter case, the write can be done only when BWST2 of DAC_SR register is low, if BWST2 = 1, the write operation is ignored.

*Note: It represents the number of LSI/LSE clocks to perform a sample phase. Sampling time = (*TSAMPLE1[9:0] + 1) x *LSI/LSE clock period.*

28.7.19 DAC sample and hold time register (DAC_SHHR)

Address offset: 0x48

Reset value: 0x0001 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	THOLD2[9:0]									
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	THOLD1[9:0]									
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:16 **THOLD2[9:0]:** DAC channel2 hold time (only valid in Sample and hold mode).
Hold time = (THOLD[9:0]) x LSI/LSE clock period
Note: This register can be modified only when EN2 = 0.
These bits are available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:0 **THOLD1[9:0]:** DAC channel1 hold time (only valid in Sample and hold mode)
Hold time = (THOLD[9:0]) x LSI/LSE clock period
Note: This register can be modified only when EN1 = 0.

Note: These bits can be written only when the DAC channel is disabled and in Normal operating mode (when bit ENx = 0 and bit CENx = 0 in the DAC_CR register). If ENx = 1 or CENx = 1 the write operation is ignored.

28.7.20 DAC sample and hold refresh time register (DAC_SHRR)

Address offset: 0x4C

Reset value: 0x0001 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TREFRESH2[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TREFRESH1[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **TREFRESH2[7:0]:** DAC channel2 refresh time (only valid in Sample and hold mode)
Refresh time = (TREFRESH[7:0]) x LSI/LSE clock period
Note: This register can be modified only when EN2 = 0.
These bits are available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **TREFRESH1[7:0]:** DAC channel1 refresh time (only valid in Sample and hold mode)
Refresh time = (TREFRESH[7:0]) x LSI/LSE clock period
Note: This register can be modified only when EN1 = 0.

Note: These bits can be written only when the DAC channel is disabled and in Normal operating mode (when bit ENx = 0 and bit CENx = 0 in the DAC_CR register). If ENx = 1 or CENx = 1 the write operation is ignored.

28.7.21 DAC register map

Table 273 summarizes the DAC registers.

Table 273. DAC register map and reset values

29 Voltage reference buffer (VREFBUF)

29.1 Introduction

The devices embed a voltage reference buffer which can be used as voltage reference for ADCs and also as voltage reference for external components through the VREF+ pin.

29.2 VREFBUF implementation

The table below describes the VREFBUF voltages typical values:

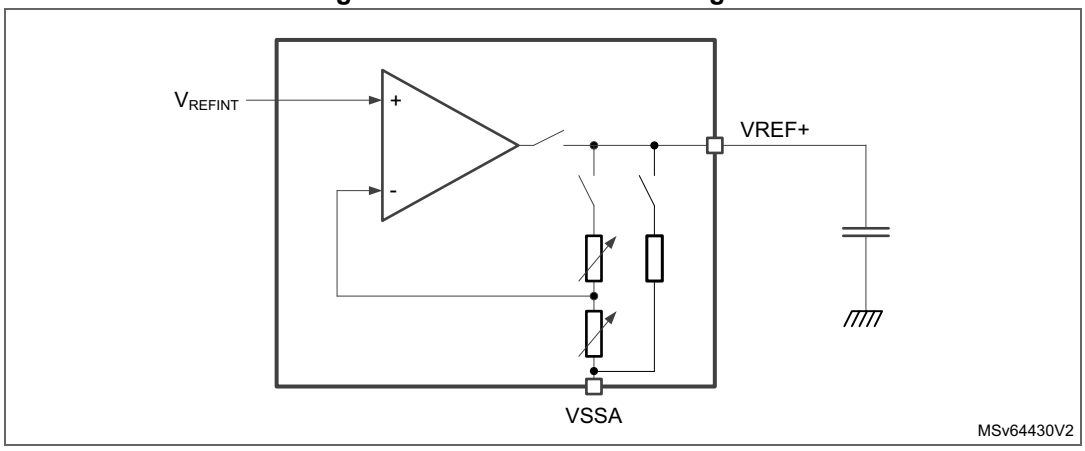
Table 274. VREFBUF typical values

Symbol	Value
VREFBUF0	2.5 V
VREFBUF1	2.048 V
VREFBUF2	1.8 V

Note: Refer to the product datasheet for more details.

29.3 VREFBUF functional description

Figure 272. VREFBUF block diagram



The internal voltage reference buffer is an operational amplifier, with programmable gain. The amplifier input is connected to the internal voltage reference V_{REFINT}. The VREFBUF supports four voltages[(a)], which are configured with VRS bits in the VREFBUF_CSR register:

- VRS = 000: VREFBUF0 voltage selected.
- VRS = 001: VREFBUF1 voltage selected.
- VRS = 010: VREFBUF2 voltage selected.

The internal voltage reference can be configured in four different modes depending on ENVR and HIZ bits configuration. These modes are provided in the table below:

Table 275. VREF buffer modes

ENVR	HIZ	VREF buffer configuration
0	0	VREFBUF buffer off mode: – V_{REF+} pin pulled-down to V_{SSA}
0	1	External voltage reference mode (default value): – VREFBUF buffer off – V_{REF+} pin input mode
1	0	Internal voltage reference mode: – VREFBUF buffer on – V_{REF+} pin connected to VREFBUF buffer output
1	1	Hold mode: – VREF is enable without output buffer, VREF+ pin voltage is hold with the external capacitor – VRR detection disabled and VRR bit keeps last state

After enabling the VREFBUF by setting ENVR bit and clearing HIZ bit in the VREFBUF_CSR register, the user must wait until VRR bit is set, meaning that the voltage reference output has reached its expected value.

29.4 VREFBUF trimming

The VREFBUF output voltage is factory-calibrated by ST. At reset, and each time the VRS setting is changed, the calibration data is automatically loaded to the TRIM register.

Optionally user can trim the output voltage by changing the TRIM register bits directly. In this case, the VRS setting has no more effect on the TRIM register until the device is reset.

29.5 VREFBUF registers

29.5.1 VREFBUF control and status register (VREFBUF_CSR)

Address offset: 0x00

Reset value: 0x0000 0002

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VRS[2:0]			VRR	Res.	HIZ	ENVR
									rw	rw	rw	r		rw	rw

a. The minimum V_{DDA} voltage depends on VRS setting, refer to the product datasheet.

Bits 31:7 Reserved, must be kept at reset value.

Bits 6:4 **VRS[2:0]**: Voltage reference scale

These bits select the value generated by the voltage reference buffer.

VRS = 000: VREFBUF0 voltage selected.
VRS = 001: VREFBUF1 voltage selected.
VRS = 010: VREFBUF2 voltage selected.
Others: Reserved

Note: Refer to the product datasheet for each VREFBUFx voltage setting value.
The software can program this bitfield only when the VREFBUF is disabled (ENVR=0).

Bit 3 **VRR:** Voltage reference buffer ready

0: the voltage reference buffer output is not ready.
1: the voltage reference buffer output reached the requested level.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **HIZ:** High impedance mode

This bit controls the analog switch to connect or not the V_{REF+} pin.
0: V_{REF+} pin is internally connected to the voltage reference buffer output.
1: V_{REF+} pin is high impedance.
Refer to *Table 275: VREF buffer modes* for the mode descriptions depending on ENVR bit configuration.

Bit 0 **ENVR:** Voltage reference buffer mode enable

This bit is used to enable the voltage reference buffer mode.
0: Internal voltage reference mode disable (external voltage reference mode).
1: Internal voltage reference mode (reference buffer enable or hold mode) enable.

29.5.2 VREFBUF calibration control register (VREFBUF_CCR)

Address offset: 0x04

Reset value: 0x0000 00XX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TRIM[5:0]					
										rw	rw	rw	rw	rw	rw

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **TRIM[5:0]**: Trimming code

The TRIM code is a 6-bit unsigned data (minimum 000000, maximum 111111) that is set and updated according the mechanism described below.

Reset:

TRIM[5:0] is automatically initialized with the VRS = 0 trimming value stored in the flash memory during the production test.

VRS change:

TRIM[5:0] is automatically initialized with the trimming value (corresponding to VRS setting) stored in the flash memory during the production test.

Write in TRIM[5:0]:

User can modify the TRIM[5:0] with an arbitrary value. This is permanently disabling the control of the trimming value with VRS (until the device is reset).

Note: If the user application performs the trimming, the trimming code must start from 000000 to 111111 in ascending order.

29.5.3 VREFBUF register map

The following table gives the VREFBUF register map and the reset values.

Table 276. VREFBUF register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3* for the register boundary addresses.

30 Digital camera interface (DCMI)

30.1 Introduction

The digital camera is a synchronous parallel interface able to receive a high-speed data flow from an external 8-, 10-, 12- or 14-bit CMOS camera module. It supports different data formats: YCbCr4:2:2/RGB565 progressive video and compressed data (JPEG).

30.2 DCMI main features

- 8-, 10-, 12- or 14-bit parallel interface
- Embedded/external line and frame synchronization
- Continuous or snapshot mode
- Crop feature
- Supports the following data formats:
  - 8/10/12/14-bit progressive video: either monochrome or raw Bayer
  - YCbCr 4:2:2 progressive video
  - RGB 565 progressive video
  - Compressed data: JPEG

30.3 DCMI functional description

The digital camera interface is a synchronous parallel interface that can receive high-speed data flows. It consists of up to 14 data lines (DCMI_D[13:0]) and a pixel clock line (DCMI_PIXCLK). The pixel clock has a programmable polarity, so that data can be captured on either the rising or the falling edge of the pixel clock.

The data are packed into a 32-bit data register (DCMI_DR) and then transferred through a general-purpose DMA channel. The image buffer is managed by the DMA, not by the camera interface.

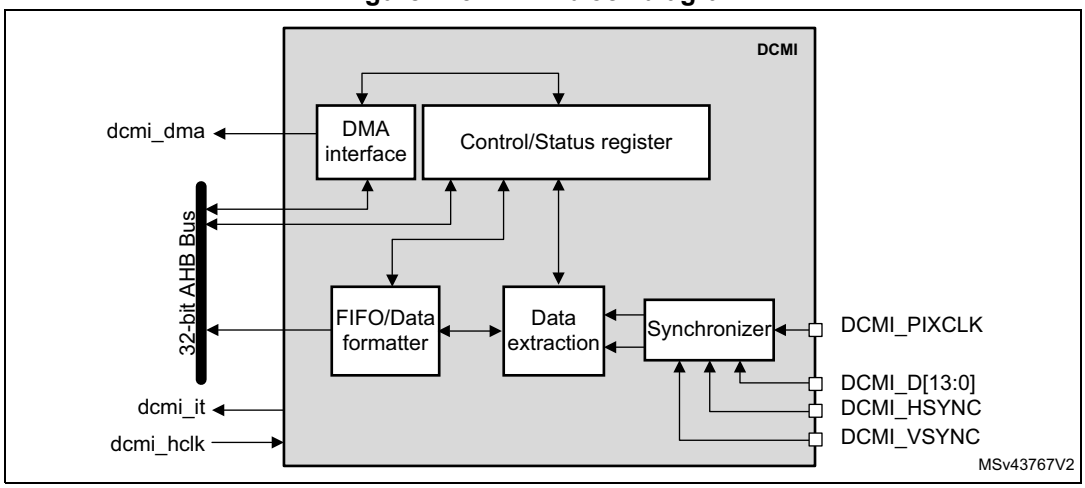
The data received from the camera can be organized in lines/frames (raw YUB/RGB/Bayer modes) or can be a sequence of JPEG images. To enable JPEG image reception, the JPEG bit (bit 3 of DCMI_CR register) must be set.

The data flow is synchronized either by hardware using the optional DCMI_HSYNC (horizontal synchronization) and DCMI_VSYNC (vertical synchronization) signals or by synchronization codes embedded in the data flow.

30.3.1 DCMI block diagram

Figure 273 shows the DCMI block diagram.

Figure 273. DCMI block diagram



30.3.2 DCMI pins and internal signals

The following table shows DCMI pins.

Table 277. DCMI input/output pins

Mode	Pin name	Signal type	Description
8 bits 10 bits 12 bits 14 bits	DCMI_D[7:0] DCMI_D[9:0] DCMI_D[11:0] DCMI_D[13:0]	Inputs	DCMI data
DCMI_PIXCLK		Input	Pixel clock
DCMI_HSYNC		Input	Horizontal synchronization / Data valid
DCMI_VSYNC		Input	Vertical synchronization

The following table shows DCMI internal signals.

Table 278. DCMI internal input/output signals

Internal signal name	Signal type	Description
dcmi_dma	Output	DCMI DMA request
dcmi_it	Output	DCMI interrupt request
dcmi_hclk	Input	DCMI interface clock

30.3.3 DCMI clocks

The digital camera interface uses two clock domains, DCMI_PIXCLK and HCLK. The signals generated with DCMI_PIXCLK are sampled on the rising edge of HCLK once they are stable. An enable signal is generated in the HCLK domain, to indicate that data coming from the camera are stable and can be sampled. The maximum DCMI_PIXCLK period must be higher than 2.5 HCLK periods.

30.3.4 DCMI DMA interface

The DMA interface is active when the CAPTURE bit of the DCMI_CR register is set. A DMA request is generated each time the camera interface receives a complete 32-bit data block in its register.

30.3.5 DCMI physical interface

The interface is composed of 11/13/15/17 inputs. Only the Slave mode is supported.

The camera interface can capture 8-bit, 10-bit, 12-bit or 14-bit data depending on the EDM[1:0] bits of the DCMI_CR register. If less than 14 bits are used, the unused input pins must be connected to ground.

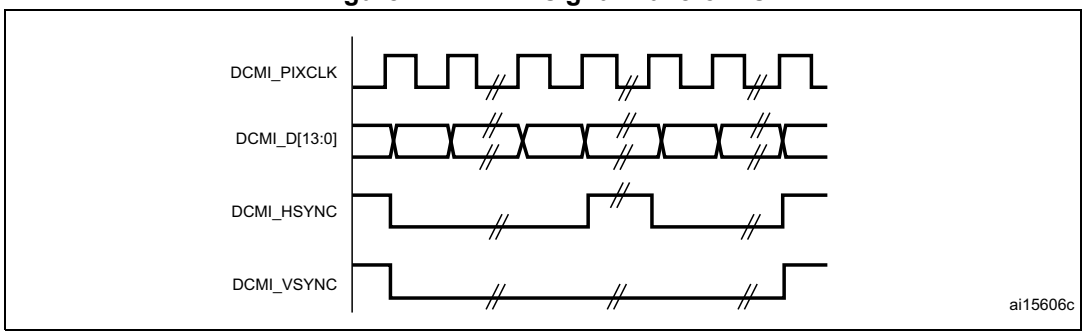
DCMI pins are shown in *Table 277*.

The data are synchronous with DCMI_PIXCLK and change on the rising/falling edge of the pixel clock depending on the polarity.

The DCMI_HSYNC signal indicates the start/end of a line.

The DCMI_VSYNC signal indicates the start/end of a frame

Figure 274. DCMI signal waveforms



1. The capture edge of DCMI_PIXCLK is the falling edge, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

8-bit data

When EDM[1:0] = 00 in DCMI_CR the interface captures 8 LSBs at its input (DCMI_D[7:0]) and stores them as 8-bit data. The DCMI_D[13:8] inputs are ignored. In this case, to capture a 32-bit word, the camera interface takes four pixel clock cycles.

The first captured data byte is placed in the LSB position in the 32-bit word and the 4th captured data byte is placed in the MSB position in the 32-bit word. The table below gives an example of the positioning of captured data bytes in two 32-bit words.

Table 279. Positioning of captured data bytes in 32-bit words (8-bit width)

Byte address	31:24	23:16	15:8	7:0
0	D_{n+3}[7:0]	D_{n+2}[7:0]	D_{n+1}[7:0]	D_n[7:0]
4	D_{n+7}[7:0]	D_{n+6}[7:0]	D_{n+5}[7:0]	D_{n+4}[7:0]

10-bit data

When EDM[1:0] = 01 in DCMI_CR, the camera interface captures 10-bit data at its input DCMI_D[9:0] and stores them as the 10 least significant bits of a 16-bit word. The remaining most significant bits of the DCMI_DR register (bits 11 to 15) are cleared to zero. So, in this case, a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2nd captured data are placed in the MSB position in the 32-bit word as shown in the table below.

Table 280. Positioning of captured data bytes in 32-bit words (10-bit width)

Byte address	31:26	25:16	15:10	9:0
0	0	D_{n+1}[9:0]	0	D_n[9:0]
4	0	D_{n+3}[9:0]	0	D_{n+2}[9:0]

12-bit data

When EDM[1:0] = 10 in DCMI_CR, the camera interface captures the 12-bit data at its input DCMI_D[11:0] and stores them as the 12 least significant bits of a 16-bit word. The remaining most significant bits are cleared to zero. So, in this case a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2nd captured data are placed in the MSB position in the 32-bit word as shown in the table below.

Table 281. Positioning of captured data bytes in 32-bit words (12-bit width)

Byte address	31:28	27:16	15:12	11:0
0	0	D_{n+1}[11:0]	0	D_n[11:0]
4	0	D_{n+3}[11:0]	0	D_{n+2}[11:0]

14-bit data

When EDM[1:0] = 11 in DCMI_CR, the camera interface captures the 14-bit data at its input DCMI_D[13:0] and stores them as the 14 least significant bits of a 16-bit word. The remaining most significant bits are cleared to zero. So, in this case a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2nd captured data are placed in the MSB position in the 32-bit word as shown in the table below.

Table 282. Positioning of captured data bytes in 32-bit words (14-bit width)

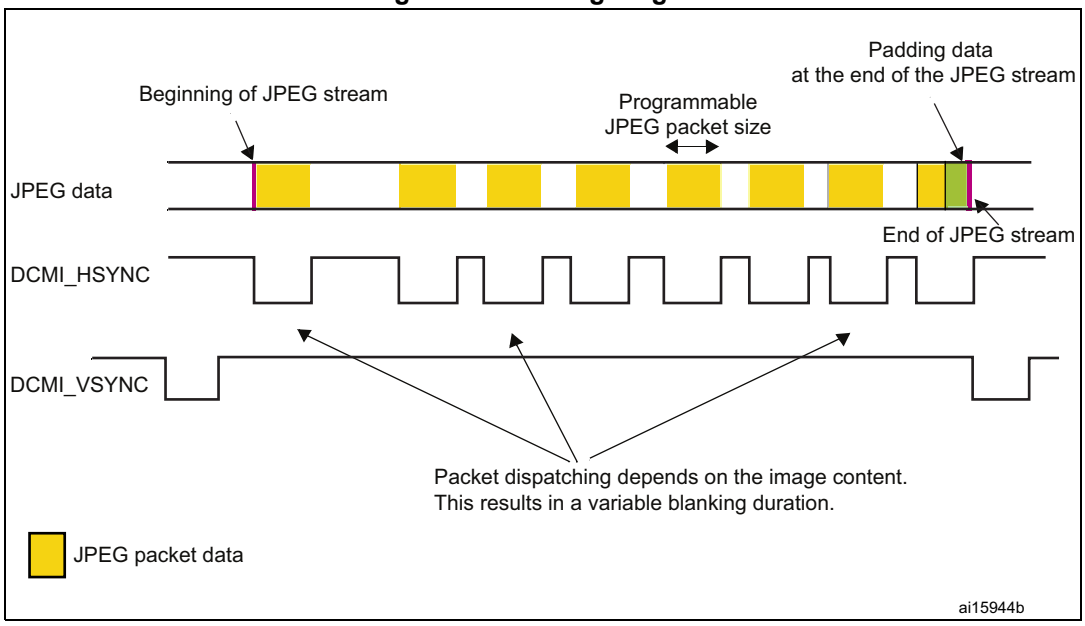
Byte address	31:30	29:16	15:14	13:0
0	0	D_{n+1}[13:0]	0	D_n[13:0]
4	0	D_{n+3}[13:0]	0	D_{n+2}[13:0]

30.3.6 DCMI synchronization

The digital camera interface supports embedded or hardware (DCMI_HSYNC and DCMI_VSYNC) synchronization. When embedded synchronization is used, it is up to the digital camera module to make sure that the 0x00 and 0xFF values are used ONLY for synchronization (not in data). Embedded synchronization codes are supported only for the 8-bit parallel data interface width (that is, in the DCMI_CR register, the EDM[1:0] bits must be cleared).

For compressed data, the DCMI supports only the hardware synchronization mode. In this case, DCMI_VSYNC is used as a start/end of the image, and DCMI_HSYNC is used as a Data Valid signal. *Figure 275* shows the corresponding timing diagram.

Figure 275. Timing diagram



Hardware synchronization mode

In hardware synchronization mode, the two synchronization signals (DCMI_HSYNC/DCMI_VSYNC) are used.

Depending on the camera module/mode, data may be transmitted during horizontal/vertical synchronization periods. The DCMI_HSYNC/DCMI_VSYNC signals act like blanking signals since all the data received during DCMI_HSYNC/DCMI_VSYNC active periods are ignored.

In order to correctly transfer images into the DMA/RAM buffer, data transfer is synchronized with the DCMI_VSYNC signal. When the hardware synchronization mode is selected, and

capture is enabled (CAPTURE bit set in DCMI_CR), data transfer is synchronized with the deactivation of the DCMI_VSYNC signal (next start of frame).

Transfer can then be continuous, with successive frames transferred by DMA to successive buffers or the same/circular buffer. To allow the DMA management of successive frames, a VSIF (Vertical synchronization interrupt flag) is activated at the end of each frame.

Embedded data synchronization mode

In this synchronization mode, the data flow is synchronized using 32-bit codes embedded in the data flow. These codes use the 0x00/0xFF values that are *not* used in data anymore. There are 4 types of codes, all with a 0xFF0000XY format. The embedded synchronization codes are supported only in 8-bit parallel data width capture (in the DCMI_CR register, the EDM[1:0] bits must be cleared). For other data widths, this mode generates unpredictable results and must not be used.

Note: Camera modules can have 8 such codes (in interleaved mode). For this reason, the interleaved mode is not supported by the camera interface (otherwise, every other half-frame would be discarded).

- Mode 2

  Four embedded codes signal the following events
  - Frame start (FS)
  - Frame end (FE)
  - Line start (LS)
  - Line end (LE)

  The XY values in the 0xFF0000XY format of the four codes are programmable (see *Section 30.5.7: DCMI embedded synchronization code register (DCMI_ESCR)*).

  A 0xFF value programmed as a “frame end” means that all the unused codes are interpreted as valid frame end codes.

  In this mode, once the camera interface has been enabled, the frame capture starts after the first occurrence of the frame end (FE) code followed by a frame start (FS) code.
- Mode 1

  An alternative coding is the camera mode 1. This mode is ITU656 compatible.

  The codes signal another set of events:
  - SAV (active line) - line start
  - EAV (active line) - line end
  - SAV (blanking) - end of line during interframe blanking period
  - EAV (blanking) - end of line during interframe blanking period

This mode can be supported by programming the following codes:

- FS $\leq$ 0xFF
- FE ≤ 0xFF
- LS ≤ SAV (active)
- LE ≤ EAV (active)

An embedded unmask code is also implemented for frame/line start and frame/line end codes. Using it, it is possible to compare only the selected unmasked bits with the programmed code. A bit can therefore be selected to compare in the embedded code and

detect a frame/line start or frame/line end. This means that there can be different codes for the frame/line start and frame/line end with the unmasked bit position remaining the same.

Example

FS = 0xA5

Unmask code for FS = 0x10

In this case the frame start code is embedded in the bit 4 of the frame start code.

30.3.7 DCMI capture modes

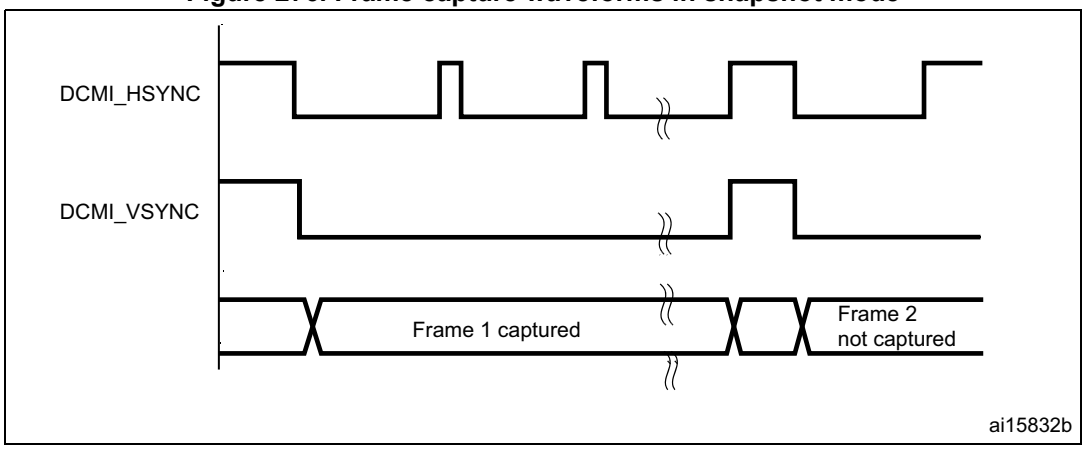
This interface supports two types of capture: snapshot (single frame) and continuous grab.

Snapshot mode (single frame)

In this mode, a single frame is captured (CM = 1 of the DCMI_CR register). After the CAPTURE bit is set in DCMI_CR, the interface waits for the detection of a start of frame before sampling the data. The camera interface is automatically disabled (CAPTURE bit cleared in DCMI_CR) after receiving the first complete frame. An interrupt is generated (IT_FRAME) if it is enabled.

In case of an overrun, the frame is lost and the CAPTURE bit is cleared.

Figure 276. Frame capture waveforms in snapshot mode

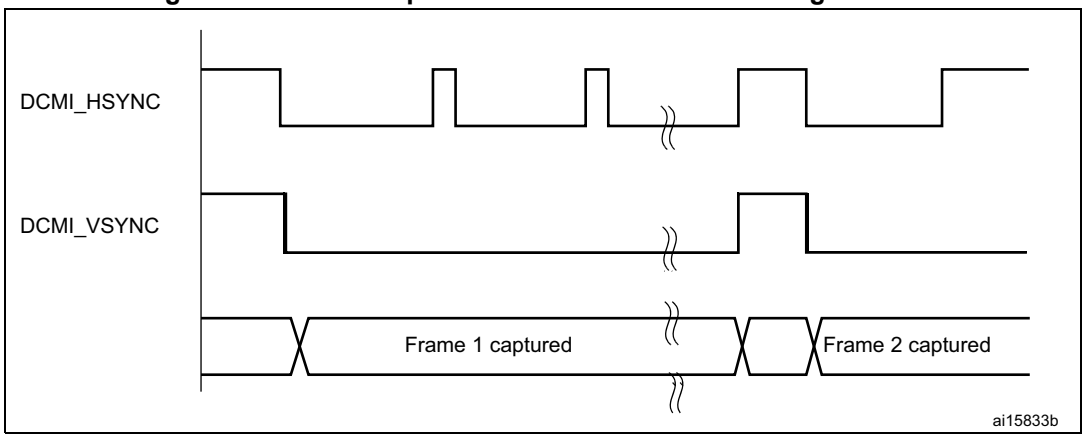


1. Here, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

Continuous grab mode

In this mode (CM bit = 0 in DCMI_CR), once the CAPTURE bit has been set in DCMI_CR, the grabbing process starts on the next DCMI_VSYNC or embedded frame start depending on the mode. The process continues until the CAPTURE bit is cleared in DCMI_CR. Once the CAPTURE bit has been cleared, the grabbing process continues until the end of the current frame.

Figure 277. Frame capture waveforms in continuous grab mode



1. Here, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

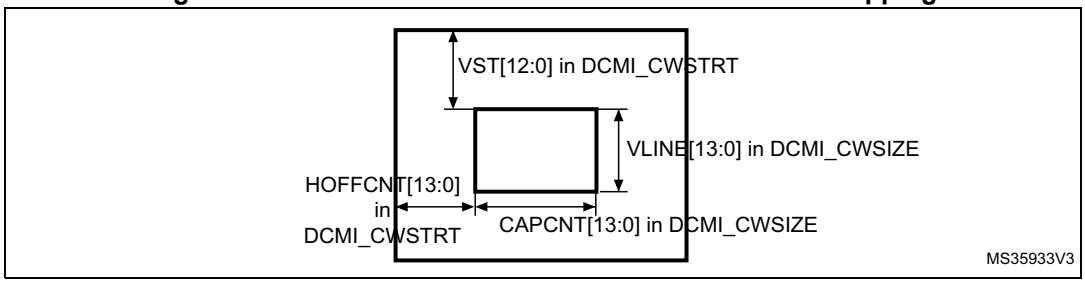
In continuous grab mode, the FCRC[1:0] bits in DCMI_CR can be configured to grab all pictures, every second picture or one out of four pictures to decrease the frame capture rate.

Note: In the hardware synchronization mode (ESS = 0 in DCMI_CR), the IT_VSYNC interrupt is generated (if enabled) even when CAPTURE = 0 in DCMI_CR so, to reduce the frame capture rate even further, the IT_VSYNC interrupt can be used to count the number of frames between 2 captures in conjunction with the Snapshot mode. This is not allowed by embedded data synchronization mode.

30.3.8 DCMI crop feature

With the crop feature, the camera interface can select a rectangular window from the received image. The start (upper left corner) coordinates and size (horizontal dimension in number of pixel clocks and vertical dimension in number of lines) are specified using two 32-bit registers (DCMI_CWSTRT and DCMI_CWSIZE). The size of the window is specified in number of pixel clocks (horizontal dimension) and in number of lines (vertical dimension).

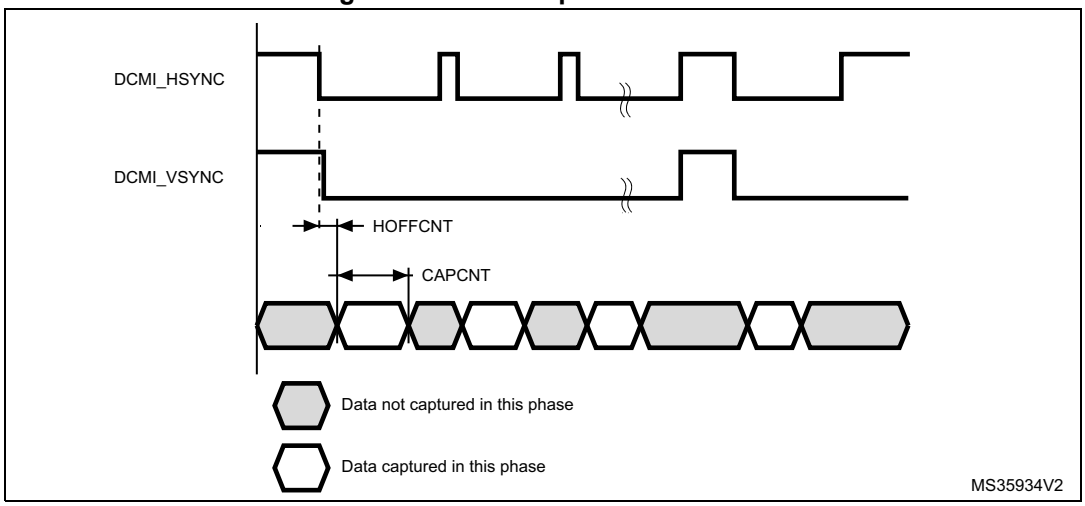
Figure 278. Coordinates and size of the window after cropping



These registers specify the coordinates of the starting point of the capture window as a line number (in the frame, starting from 0) and a number of pixel clocks (on the line, starting from 0), and the size of the window as a line number and a number of pixel clocks. The CAPCNT value can only be a multiple of 4 (two least significant bits are forced to 0) to allow the correct transfer of data through the DMA.

If the DCMI_VSYNC signal goes active before the number of lines is specified in the DCMI_CWSIZE register, then the capture stops and an IT_FRAME interrupt is generated when enabled.

Figure 279. Data capture waveforms



1. Here, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

30.3.9 DCMI JPEG format

To allow JPEG image reception, it is necessary to set the JPEG bit of the DCMI_CR register. JPEG images are not stored as lines and frames, so the DCMI_VSYNC signal is used to start the capture while DCMI_HSYNC serves as a data enable signal. The number of bytes in a line may not be a multiple of 4. This case must be carefully handled since a DMA request is generated each time a complete 32-bit word has been constructed from the captured data. When an end of frame is detected and the 32-bit word to be transferred has not been completely received, the remaining data are padded with zeros and a DMA request is generated.

The crop feature and embedded synchronization codes cannot be used in JPEG format.

30.3.10 DCMI FIFO

A 8-word FIFO is implemented to manage data rate transfers on the AHB. The DCMI features a simple FIFO controller with a read pointer incremented each time the camera interface reads from the AHB, and a write pointer incremented each time the camera interface writes to the FIFO. There is no overrun protection to prevent the data from being overwritten if the AHB interface does not sustain the data transfer rate.

In case of overrun or errors in the synchronization signals, the FIFO is reset and the DCMI interface waits for a new start of frame.

30.3.11 DCMI data format description

Data formats

Three types of data are supported:

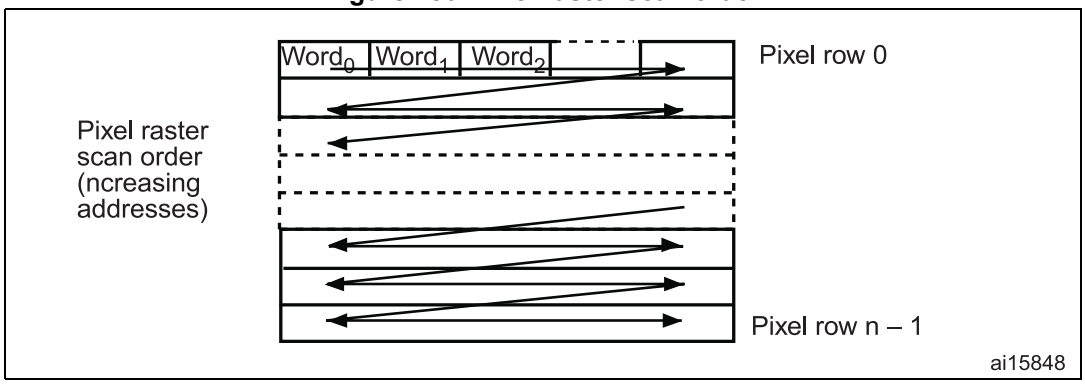
- 8/10/12/14-bit progressive video: either monochrome or raw Bayer format
- YCbCr 4:2:2 progressive video
- RGB565 progressive video. A pixel coded in 16 bits (5 bits for blue, 5 bits for red, 6 bits for green) takes two clock cycles to be transferred.

Compressed data: JPEG

For B&W (black and white), YCbCr or RGB data, the maximum input size is 2048 × 2048 pixels. No limit in JPEG compressed mode.

For monochrome, RGB and YCbCr, the frame buffer is stored in raster mode. 32-bit words are used. Only the little-endian format is supported.

Figure 280. Pixel raster scan order



Monochrome format

Characteristics:

- Raster format
- 8 bits per pixel

The table below shows how the data are stored.

Table 283. Data storage in monochrome progressive video format

Byte address	31:24	23:16	15:8	7:0
0	n + 3	n + 2	n + 1	n
4	n + 7	n + 6	n + 5	n + 4

RGB format

Characteristics:

- Raster format
- RGB
- Interleaved: one buffer: R, G and B interleaved (such as BRGBRGBRG)
- Optimized for display output

The RGB planar format is compatible with standard OS frame buffer display formats.

Only 16 BPP (bits per pixel): RGB565 (2 pixels per 32-bit word) is supported.

The 24 BPP (palletized format) and gray-scale formats are not supported. Pixels are stored in a raster scan order, that is from top to bottom for pixel rows, and from left to right within a pixel row. Pixel components are R (red), G (green) and B (blue). All components have the same spatial resolution (4:4:4 format). A frame is stored in a single part, with the components interleaved on a pixel basis.

The table below shows how the data are stored.

Table 284. Data storage in RGB progressive video format

Byte address	31:27	26:21	20:16	15:11	10:5	4:0
0	Red n + 1	Green n + 1	Blue n + 1	Red n	Green n	Blue n
4	Red n + 4	Green n + 3	Blue n + 3	Red n + 2	Green n + 2	Blue n + 2

YCbCr format

Characteristics:

- Raster format
- YCbCr 4:2:2
- Interleaved: one buffer: Y, Cb and Cr interleaved (such as CbYCrYCbYCr)

Pixel components are Y (luminance or “luma”), Cb and Cr (chrominance or “chroma” blue and red). Each component is encoded in 8 bits. Luma and chroma are stored together (interleaved) as shown in the table below.

Table 285. Data storage in YCbCr progressive video format

Byte address	31:24	23:16	15:8	7:0
0	Y n + 1	Cr n	Y n	Cb n
4	Y n + 3	Cr n + 2	Y n + 2	Cb n + 2

YCbCr format - Y only

Characteristics:

- Raster format
- YCbCr 4:2:2
- The buffer only contains Y information - monochrome image

Pixel components are Y (luminance or “luma”), Cb and Cr (chrominance or “chroma” blue and red). In this mode, the chroma information is dropped. Only the luma component of each pixel, encoded in 8 bits, is stored as shown in *Table 286*.

The result is a monochrome image having the same resolution as the original YCbCr data.

Table 286. Data storage in YCbCr progressive video format - Y extraction mode

Byte address	31:24	23:16	15:8	7:0
0	Y n + 3	Y n + 2	Y n + 1	Y n
4	Y n + 7	Y n + 6	Y n + 5	Y n + 4

Half resolution image extraction

This is a modification of the previous reception modes, being applicable to monochrome, RGB or Y extraction modes.

This mode is used to only store a half resolution image. It is selected through OELS and LSM control bits.

30.4 DCMI interrupts

Five interrupts are generated. All interrupts are maskable by software. The global interrupt (dcmi_it) is the OR of all the individual interrupts. The table below gives the list of all interrupts.

Table 287. DCMI interrupts

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exits Sleep mode	Exists Stop and Standby modes
dcmi_it	End of line	LINE_RIS	LINE_IE	Set LINE_ISC	Yes	No
	End of frame capture	FRAME_RIS	FRAME_IE	Set FRAME_ISC	Yes	No
	Overrun of data reception	OVR_RIS	OVR_IE	Set OVR_ISC	Yes	No
	Synchronization frame	VSYNC_RIS	VSYNC_IE	Set VSYNC_ISC	Yes	No
	Detection of an error in the embedded synchronization frame detection	ERR_RIS	ERR_IE	Set ERR_ISC	Yes	No

30.5 DCMI registers

Refer to *Section 1.2 on page 101* for list of abbreviations used in register descriptions. All DCMI registers must be accessed as 32-bit words, otherwise a bus error occurs.

30.5.1 DCMI control register (DCMI_CR)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OELS	LSM	OEBS	BSM[1:0]	
											rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	ENABLE	Res.	Res.	EDM[1:0]		FCRC[1:0]		VSPOL	HSPOL	PCKPOL	ESS	JPEG	CROP	CM	CAPTURE
	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **OELS:** Odd/Even Line Select (Line Select Start)
This bit works in conjunction with the LSM field (LSM = 1).
0: Interface captures first line after the frame start, second one being dropped.
1: Interface captures second line from the frame start, first one being dropped.

Bit 19 **LSM:** Line Select mode
0: Interface captures all received lines.
1: Interface captures one line out of two.

Bit 18 **OEBS:** Odd/Even Byte Select (Byte Select Start)
This bit works in conjunction with BSM field (BSM $\neq$ 00).
0: Interface captures first data (byte or double byte) from the frame/line start, second one being dropped.
1: Interface captures second data (byte or double byte) from the frame/line start, first one being dropped.

Bits 17:16 **BSM[1:0]:** Byte Select mode
00: Interface captures all received data.
01: Interface captures every other byte from the received data.
10: Interface captures one byte out of four.
11: Interface captures two bytes out of four.
Note: This mode only works for EDM[1:0] = 00. For all other EDM values, this field must be programmed to the reset value.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **ENABLE:** DCMI enable
0: DCMI disabled
1: DCMI enabled
Note: The DCMI configuration registers must be programmed correctly before enabling this bit.

Bits 13:12 Reserved, must be kept at reset value.

Bits 11:10 **EDM[1:0]:** Extended data mode
00: Interface captures 8-bit data on every pixel clock.
01: Interface captures 10-bit data on every pixel clock.
10: Interface captures 12-bit data on every pixel clock.
11: Interface captures 14-bit data on every pixel clock.

Bits 9:8 **FCRC[1:0]:** Frame capture rate control
These bits define the frequency of frame capture. They are meaningful only in Continuous grab mode. They are ignored in snapshot mode.
00: All frames are captured.
01: Every alternate frame captured (50% bandwidth reduction)
10: One frame out of four captured (75% bandwidth reduction)
11: reserved

Bit 7 **VSPOL:** Vertical synchronization polarity
This bit indicates the level on the DCMI_VSYNC pin when the data are not valid on the parallel interface.
0: DCMI_VSYNC active low
1: DCMI_VSYNC active high

Bit 6 **HSPOL:** Horizontal synchronization polarity
This bit indicates the level on the DCMI_HSYNC pin when the data are not valid on the parallel interface.
0: DCMI_HSYNC active low
1: DCMI_HSYNC active high

Bit 5 **PCKPOL:** Pixel clock polarity
This bit configures the capture edge of the pixel clock.
0: Falling edge active
1: Rising edge active

Bit 4 **ESS:** Embedded synchronization select
0: Hardware synchronization data capture (frame/line start/stop) is synchronized with the DCMI_HSYNC/DCMI_VSYNC signals.
1: Embedded synchronization data capture is synchronized with synchronization codes embedded in the data flow.
Note: Valid only for 8-bit parallel data. HSPOL/VSPOL are ignored when the ESS bit is set.
This bit is disabled in JPEG mode.

Bit 3 **JPEG:** JPEG format
0: Uncompressed video format
1: This bit is used for JPEG data transfers. The DCMI_HSYNC signal is used as data enable. The crop and embedded synchronization features (ESS bit) cannot be used in this mode.

Bit 2 **CROP:** Crop feature
0: The full image is captured. In this case the total number of bytes in an image frame must be a multiple of four.
1: Only the data inside the window specified by the crop register is captured. If the size of the crop window exceeds the picture size, then only the picture size is captured.

Bit 1 **CM:** Capture mode
0: Continuous grab mode - The received data are transferred into the destination memory through the DMA. The buffer location and mode (linear or circular buffer) is controlled through the system DMA.
1: Snapshot mode (single frame) - Once activated, the interface waits for the start of frame and then transfers a single frame through the DMA. At the end of the frame, the CAPTURE bit is automatically reset.

Bit 0 **CAPTURE:** Capture enable

0: Capture disabled

1: Capture enabled

The camera interface waits for the first start of frame, then a DMA request is generated to transfer the received data into the destination memory.

In snapshot mode, the CAPTURE bit is automatically cleared at the end of the first frame received.

In continuous grab mode, if the software clears this bit while a capture is ongoing, the bit is effectively cleared after the frame end.

Note: The DMA controller and all DCMI configuration registers must be programmed correctly before enabling this bit.

30.5.2 DCMI status register (DCMI_SR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FNE	VSYNC	HSYNC
													r	r	r

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **FNE**: FIFO not empty

This bit gives the status of the FIFO.

1: FIFO contains valid data.

0: FIFO empty

Bit 1 **VSYNC**: Vertical synchronization

This bit gives the state of the DCMI_VSYNC pin with the correct programmed polarity. When embedded synchronization codes are used, the meaning of this bit is the following:

0: active frame

1: synchronization between frames

In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in DCMI_CR is set.

Bit 0 **HSYNC**: Horizontal synchronization

This bit gives the state of the DCMI_HSYNC pin with the correct programmed polarity. When embedded synchronization codes are used, the meaning of this bit is the following:

0: active line

1: synchronization between lines

In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in DCMI_CR is set.

30.5.3 DCMI raw interrupt status register (DCMI_RIS)

DCMI_RIS gives the raw interrupt status and is accessible in read only. When read, this register returns the status of the corresponding interrupt before masking with the DCMI_IER register value.

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LINE_RIS	VSYNC_RIS	ERR_RIS	OVR_RIS	FRAME_RIS
											r	r	r	r	r

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **LINE_RIS**: Line raw interrupt status

This bit gets set when the DCMI_HSYNC signal changes from the inactive state to the active state. It goes high even if the line is not valid.

In the case of embedded synchronization, this bit is set only if the CAPTURE bit in DCMI_CR is set.

It is cleared by setting the LINE_ISC bit of the DCMI_ICR register.

Bit 3 **VSYNC_RIS**: DCMI_VSYNC raw interrupt status

This bit is set when the DCMI_VSYNC signal changes from the inactive state to the active state.

In the case of embedded synchronization, this bit is set only if the CAPTURE bit is set in DCMI_CR.

It is cleared by setting the VSYNC_ISC bit of the DCMI_ICR register.

Bit 2 **ERR_RIS**: Synchronization error raw interrupt status

0: No synchronization error detected

1: Embedded synchronization characters are not received in the correct order.

This bit is valid only in the embedded synchronization mode. It is cleared by setting the ERR_ISC bit of the DCMI_ICR register.

Note: This bit is available only in embedded synchronization mode.

Bit 1 **OVR_RIS**: Overrun raw interrupt status

0: No data buffer overrun occurred

1: A data buffer overrun occurred and the data FIFO is corrupted.

The bit is cleared by setting the OVR_ISC bit of the DCMI_ICR register.

Bit 0 **FRAME_RIS**: Capture complete raw interrupt status

0: No new capture

1: A frame has been captured.

This bit is set when a frame or window has been captured.

In case of a cropped window, this bit is set at the end of line of the last line in the crop. It is set even if the captured frame is empty (for example window cropped outside the frame).

The bit is cleared by setting the FRAME_ISC bit of the DCMI_ICR register.

30.5.4 DCMI interrupt enable register (DCMI_IER)

The DCMI_IER register is used to enable interrupts. When one of the DCMI_IER bits is set, the corresponding interrupt is enabled. This register is accessible in both read and write.

Address offset: 0x0C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LINE_IE	VSYNC_IE	ERR_IE	OVR_IE	FRAME_IE
											rw	rw	rw	rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **LINE_IE**: Line interrupt enable
0: No interrupt generation when the line is received
1: An Interrupt is generated when a line has been completely received.

Bit 3 **VSYNC_IE**: DCMI_VSYNC interrupt enable
0: No interrupt generation
1: An interrupt is generated on each DCMI_VSYNC transition from the inactive to the active state.
The active state of the DCMI_VSYNC signal is defined by the VSPOL bit.

Bit 2 **ERR_IE**: Synchronization error interrupt enable
0: No interrupt generation
1: An interrupt is generated if the embedded synchronization codes are not received in the correct order.
Note: This bit is available only in embedded synchronization mode.

Bit 1 **OVR_IE**: Overrun interrupt enable
0: No interrupt generation
1: An interrupt is generated if the DMA was not able to transfer the last data before new data (32-bit) are received.

Bit 0 **FRAME_IE**: Capture complete interrupt enable
0: No interrupt generation
1: An interrupt is generated at the end of each received frame/crop window (in crop mode).

30.5.5 DCMI masked interrupt status register (DCMI_MIS)

This DCMI_MIS register is a read-only register. When read, it returns the current masked status value (depending on the value in DCMI_IER) of the corresponding interrupt. A bit in this register is set if the corresponding enable bit in DCMI_IER is set and the corresponding bit in DCMI_RIS is set.

Address offset: 0x10

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LINE_MIS	VSYNC_MIS	ERR_MIS	OVR_MIS	FRAME_MIS
											r	r	r	r	r

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **LINE_MIS**: Line masked interrupt status
This bit gives the status of the masked line interrupt.
0: No interrupt generation when the line is received
1: An Interrupt is generated when a line has been completely received and the LINE_IE bit is set in DCMI_IER.

Bit 3 **VSYNC_MIS**: VSYNC masked interrupt status
This bit gives the status of the masked VSYNC interrupt.
0: No interrupt is generated on DCMI_VSYNC transitions.
1: An interrupt is generated on each DCMI_VSYNC transition from the inactive to the active state and the VSYNC_IE bit is set in DCMI_IER.
The active state of the DCMI_VSYNC signal is defined by the VSPOL bit.

Bit 2 **ERR_MIS**: Synchronization error masked interrupt status
This bit gives the status of the masked synchronization error interrupt.
0: No interrupt is generated on a synchronization error.
1: An interrupt is generated if the embedded synchronization codes are not received in the correct order and the ERR_IE bit in DCMI_IER is set.
Note: This bit is available only in embedded synchronization mode.

Bit 1 **OVR_MIS**: Overrun masked interrupt status
This bit gives the status of the masked overflow interrupt.
0: No interrupt is generated on overrun.
1: An interrupt is generated if the DMA was not able to transfer the last data before new data (32-bit) are received and the OVR_IE bit is set in DCMI_IER.

Bit 0 **FRAME_MIS**: Capture complete masked interrupt status
This bit gives the status of the masked capture complete interrupt
0: No interrupt is generated after a complete capture.
1: An interrupt is generated at the end of each received frame/crop window (in crop mode) and the FRAME_IE bit is set in DCMI_IER.

30.5.6 DCMI interrupt clear register (DCMI_ICR)

The DCMI_ICR register is write-only. Setting a bit of this register clears the corresponding flag in the DCMI_RIS and DCMI_MIS registers. Writing 0 has no effect.

Address offset: 0x14

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LINE_ISC	VSYNC_ISC	ERR_ISC	OVR_ISC	FRAME_ISC
											w	w	w	w	w

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **LINE_ISC**: line interrupt status clear
Setting this bit clears the LINE_RIS flag in the DCMI_RIS register.

Bit 3 **VSYNC_ISC**: Vertical Synchronization interrupt status clear
Setting this bit clears the VSYNC_RIS flag in the DCMI_RIS register.

Bit 2 **ERR_ISC**: Synchronization error interrupt status clear
Setting this bit clears the ERR_RIS flag in the DCMI_RIS register.
Note: This bit is available only in embedded synchronization mode.

Bit 1 **OVR_ISC**: Overrun interrupt status clear
Setting this bit clears the OVR_RIS flag in the DCMI_RIS register.

Bit 0 **FRAME_ISC**: Capture complete interrupt status clear
Setting this bit clears the FRAME_RIS flag in the DCMI_RIS register.

30.5.7 DCMI embedded synchronization code register (DCMI_ESCR)

Address offset: 0x18

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FEC[7:0]								LEC[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LSC[7:0]								FSC[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **FEC[7:0]**: Frame end delimiter code

This byte specifies the code of the frame end delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, FEC.

If FEC is programmed to 0xFF, all the unused codes (0xFF0000XY) are interpreted as frame end delimiters.

Bits 23:16 **LEC[7:0]**: Line end delimiter code

This byte specifies the code of the line end delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, LEC.

Bits 15:8 **LSC[7:0]**: Line start delimiter code

This byte specifies the code of the line start delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, LSC.

Bits 7:0 **FSC[7:0]**: Frame start delimiter code

This byte specifies the code of the frame start delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, FSC.

If FSC is programmed to 0xFF, no frame start delimiter is detected. But, the first occurrence of LSC after an FEC code is interpreted as a start of frame delimiter.

30.5.8 DCMI embedded synchronization unmask register (DCMI_ESUR)

Address offset: 0x1C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FEU[7:0]								LEU[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LSU[7:0]								FSU[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **FEU[7:0]**: Frame end delimiter unmask

This byte specifies the mask to be applied to the code of the frame end delimiter.

0: The corresponding bit in the FEC byte in DCMI_ESCR is masked while comparing the frame end delimiter with the received data.

1: The corresponding bit in the FEC byte in DCMI_ESCR is compared while comparing the frame end delimiter with the received data.

Bits 23:16 **LEU[7:0]**: Line end delimiter unmask

This byte specifies the mask to be applied to the code of the line end delimiter.

0: The corresponding bit in the LEC byte in DCMI_ESCR is masked while comparing the line end delimiter with the received data.

1: The corresponding bit in the LEC byte in DCMI_ESCR is compared while comparing the line end delimiter with the received data.

Bits 15:8 **LSU[7:0]**: Line start delimiter unmask

This byte specifies the mask to be applied to the code of the line start delimiter.

0: The corresponding bit in the LSC byte in DCMI_ESCR is masked while comparing the line start delimiter with the received data.

1: The corresponding bit in the LSC byte in DCMI_ESCR is compared while comparing the line start delimiter with the received data.

Bits 7:0 **FSU[7:0]**: Frame start delimiter unmask

This byte specifies the mask to be applied to the code of the frame start delimiter.
0: The corresponding bit in the FSC byte in DCMI_ESCR is masked while comparing the frame start delimiter with the received data.
1: The corresponding bit in the FSC byte in DCMI_ESCR is compared while comparing the frame start delimiter with the received data.

30.5.9 DCMI crop window start (DCMI_CWSTRT)

Address offset: 0x20

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Refer to *Section 2.3* for the register boundary addresses.

31 Parallel synchronous slave interface (PSSI)

The PSSI peripheral and the DCMI (digital camera interface) use the same circuitry. As a result, these two peripherals cannot be used at the same time: when using the PSSI, the DCMI registers cannot be accessed, and vice-versa.

In addition, the PSSI and the DCMI share the same alternate functions and interrupt vector (see *Section 31.3.2: PSSI pins and internal signals*).

31.1 Introduction

The PSSI is a generic synchronous 8/16-bit parallel data input/output slave interface. It enables the transmitter to send a data valid signal that indicates when the data is valid, and the receiver to output a flow control signal that indicates when it is ready to sample the data.

31.2 PSSI main features

The PSSI peripheral main features are the following:

- Slave mode operation
- 8-bit or 16-bit parallel data input or output
- 8-word (32-byte) FIFO
- Data enable (PSSI_DE) alternate function input and Ready (PSSI_RDY) alternate function output

  When selected, these signals can either enable the transmitter to indicate when the data is valid, allow the receiver to indicate when it is ready to sample the data, or both.

31.3 PSSI functional description

The PSSI is a synchronous parallel slave interface that can send or receive high-speed data flows. It consists of up to 16 data lines (PSSI_D[15:0]) plus a clock line (PSSI_PDCK). The clock polarity can be configured so that data can be captured or transmitted on either the clock rising or falling edge.

Usually, a general-purpose DMA channel is used to pass 32-bit packed data via the data register (PSSI_DR).

The data flow can either be continuous or synchronized by hardware using the optional PSSI_DE (Data enable), and PSSI_RDY (Ready) signals.

Figure 281 shows the PSSI block diagram.

31.3.1 PSSI block diagram

Figure 281. PSSI block diagram

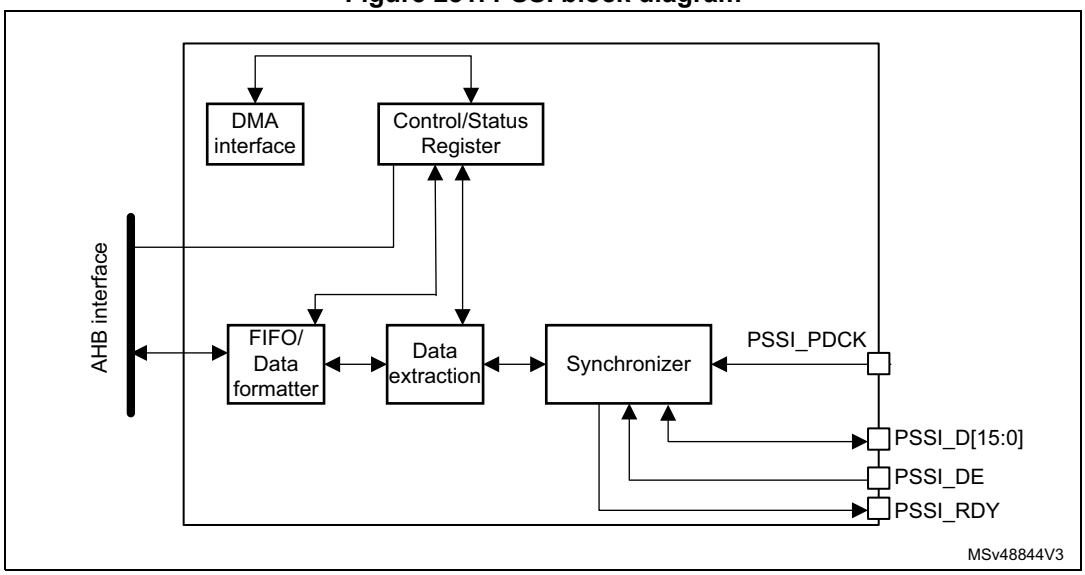

Figure 282. Top-level block diagram

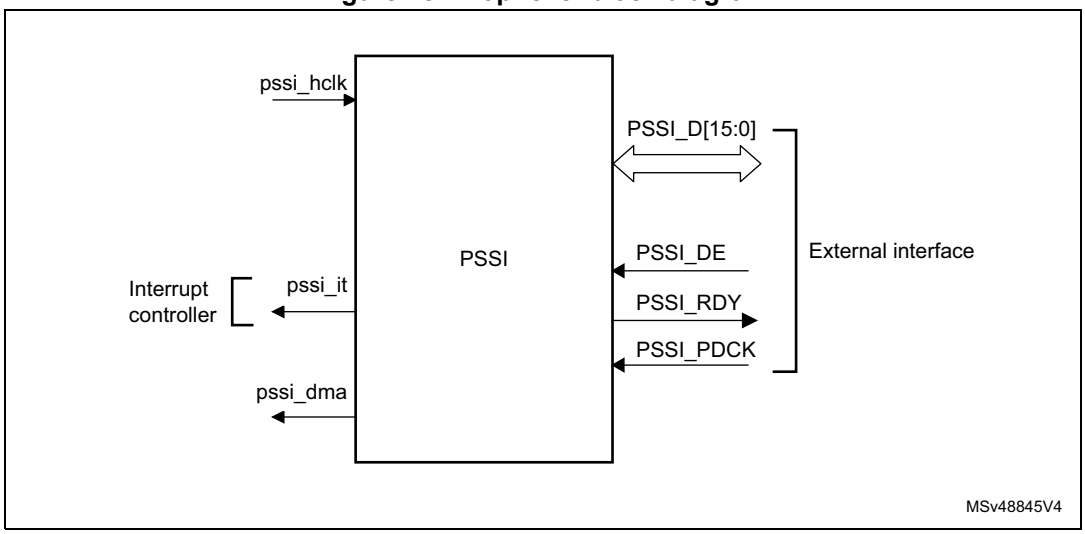


31.3.2 PSSI pins and internal signals

The PSSI interface is composed of 19 pins, though nine signals are enough to transfer parallel data. *Table 289* shows the PSSI pins.

When the PSSI ENABLE bit (bit 14 of PSSI_CR) is set to 1, the alternate functions and the interrupt vector are associated with the PSSI. Otherwise, they are associated with the DCMI. The DCMI ENABLE bit (bit 15 of DCMI_CR) and the PSSI ENABLE bit (bit 14 of PSSI_CR) must not be set to 1 at the same time. As an example, if a GPIO is configured to use the alternate function PSSI_PDCK/DCMI_PIXCK, it is the PSSI_PDCK function which becomes active if PSSI_CR/ENABLE is set to 1.

Table 289. PSSI input/output pins

PSSI signal name	DCMI signal it is shared with	Signal type	Description
PSSI_PDCK	DCMI_PIXCK	Input	Parallel data clock input
PSSI_D[15:0]	DCMI_D[13:0]	Input/output	Data output when transmitting, data input when receiving
PSSI_DE	DCMI_HSYNC	Input	Data enable signal: data valid signal when receiving or flow control signal when transmitting
PSSI_RDY	DCMI_VSYNC	Output	Ready signal: flow control signal when receiving or data valid signal when transmitting

Table 290 shows the PSSI internal input/output signals.

Table 290. PSSI internal input/output signals

Internal signal name	Signal type	Description
pssi_it	Output	Interrupt
pssi_dma	Output	DMA request
pssi_hclk	Input	AHB clock

31.3.3 PSSI clock

The AHB clock frequency must be at least 2.5 times higher than the PSSI_PDCK frequency. At frequency ratios lower than 2.5, data might be corrupted or lost during transfers.

Data transfers are synchronous with PSSI_PDCK. The PSSI_PDCK polarity can be configured as follows, through CKPOL bit (bit 5 of PSSI_CR):

- When CKPOL = 0
  - Input pins are sampled on PSSI_PDCK falling edge
  - Output pins are driven on PSSI_PDCK rising edge
- When CKPOL = 1
  - Input pins are sampled on PSSI_PDCK rising edge
  - Output pins are driven on PSSI_PDCK falling edge

31.3.4 PSSI data management

Data direction

The direction of data transfers is configured through the OUTEN control bit (bit 31 of PSSI_CR):

- When OUTEN is cleared to 0 (default setting), the PSSI operates in receive mode and the data is input on the data pins.
- When OUTEN is set to 1, the peripheral operates in transmit mode and the data is output on the data pins.

OUTEN can be modified only when the ENABLE bit is cleared to 0.

Data register and DMA

Data are transferred from/to the FIFO using the PSSI_DR data register:

- In receive mode, data must be read from the FIFO by reading PSSI_DR.
- In transmit mode, data must be written to the FIFO by writing into PSSI_DR.

Word (32-bit) accesses to PSSI_DR and half-word (16-bit) accesses to PSSI_DR[15:0] are permitted in all modes. Byte (8-bit) accesses to PSSI_DR[7:0] are permitted only when the PSSI is configured to transfer 8 bits at a time (EDM=00 in the PSSI_CR register).

To reduce the load on the CPU, it is recommended to use the DMA to transfer data from/to the PSSI FIFO. When it is used, the DMA must be configured to transfer data via the PSSI_DR register. Using 32-bit transfers optimizes bandwidth and reduces the bus load. However, 8-bit and 16-bit transfers are also permitted.

To use the DMA, set the PSSI DMA enable bit (DMAEN in PSSI_CR) to 1 (default setting). When DMAEN is set to 1, a DMA transfer is initiated when the FIFO is ready for a 32-bit transfer (four valid bytes in receive mode or four empty bytes in transmit mode). As a result, in receive mode, no DMA transfers are initiated if there are three bytes or fewer in the FIFO, even if the DMA is configured to perform 8-bit transfers.

The RTT4B and RTT1B status bits (PSSI_SR) are useful when the CPU directly perform transfers to and from the FIFO. RTT4B set to 1 indicates that the FIFO is ready to transfer four bytes: at least four valid bytes in the FIFO in receive mode or at least four free bytes in transmit mode. RTT1B set to 1 indicates that the FIFO is ready to transfer one byte: at least one valid byte in the FIFO in receive mode or at least one free byte in transmit mode.

8-bit data

The PSSI parallel interface can transfer either 8-bit (using D[7:0]) or 16-bit data (using D[15:0]) depending on the EDM[1:0] control bits (bits 11:10 of PSSI_CR). If the 8-bit configuration is selected (EDM[1:0] set to 00), the unused D[15:0] pins can be used for GPIO or other functions.

When EDM[1:0] in PSSI_CR are programmed to 00, the interface transfers 8 bits using the D[7:0] pins. In this case, D[15:8] are not used and four PSSI_PDCK cycles are required to transfer a 32-bit word.

The least-significant byte (bits 7:0) correspond to the first byte transferred, and the most-significant byte (bits 31:28) corresponds to the forth byte transferred. *Table 291* illustrates the positioning of the data bytes in two 32-bit words.

Table 291. Positioning of captured data bytes in 32-bit words (8-bit width)

Byte address	31:24	23:16	15:8	7:0
0	D_{n+3}[7:0]	D_{n+2}[7:0]	D_{n+1}[7:0]	D_n[7:0]
4	D_{n+7}[7:0]	D_{n+6}[7:0]	D_{n+5}[7:0]	D_{n+4}[7:0]

16-bit data

When EDM[1:0] in PSSI_CR are programmed to 11, the interface transfers 16 bits using the D[15:0] pins. In this case, two PSSI_PDCK cycles are required to transfer a 32-bit word.

The least-significant half word (bits 15:0) correspond to the first half word transferred, and the most-significant half-word (bits 31:16) corresponds to the second half word transferred. *Table 292* illustrates the positioning of the data in two 32-bit words.

Table 292. Positioning of captured data bytes in 32-bit words (16-bit width)

Byte address	31:16	15:0
0	D_{n+1}[15:0]	D_n[15:0]
4	D_{n+3}[15:0]	D_{n+2}[15:0]

FIFO data buffer and error conditions

An eight-word FIFO helps improving performance and avoids overruns and underruns.

If the ready signal (PSSI_RDY) is disabled in receive mode, an overrun error is generated when a clock active edge occurs when the FIFO is full. In this case, the input data is lost.

If the data enable signal (PSSI_DE) is disabled in transmit mode, an underrun error is generated when a clock active edge occurs when the FIFO is empty. In this case, unpredictable data are output.

The OVR_RIS status bit indicates that either an overrun or an underrun occurred. An interrupt can be generated when these events occur.

31.3.5 PSSI optional control signals

Data Enable (PSSI_DE) alternate function input

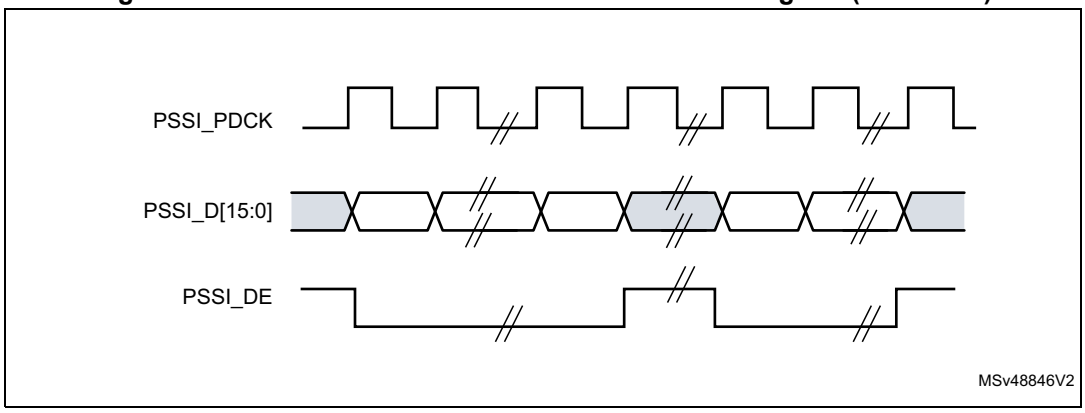
The data enable signal, PSSI_DE, is an optional signal. It is driven by the data source/transmitter in order to indicate that the data is valid to be transferred during the current cycle. When PSSI_DE is inactive, it means that the data must not be sampled by the receiver at the next clock edge.

This alternate function signal can be enabled using the DERDYCFG (bits 20:18 of PSSI_CR) control bits. PSSI_DE polarity is configured through DEPOL control bit (bit 6 of PSSI_CR). PSSI_DE is active low when DEPOL is cleared to 0, and high when DEPOL is et to 1.

The direction of the PSSI_DE signal is defined by the OUTEN value. It is the same as the data direction.

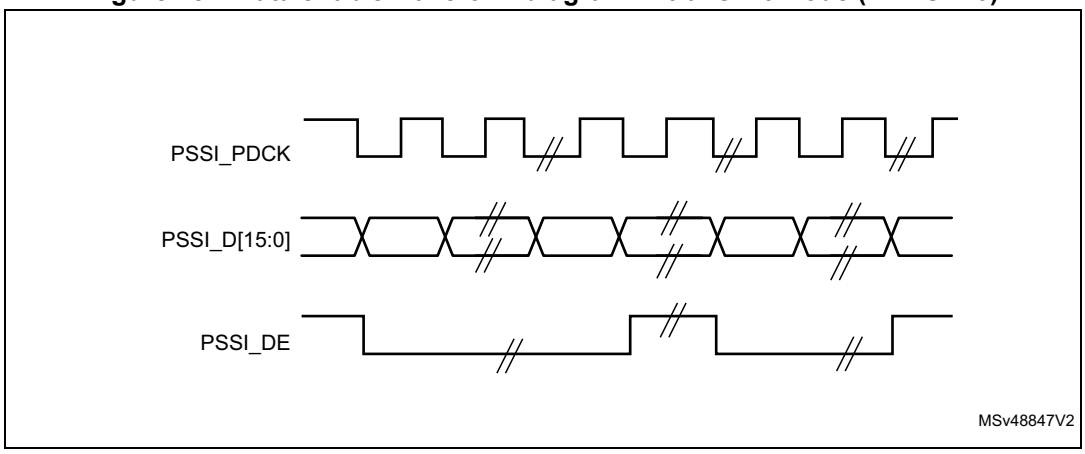
If the PSSI_DE alternate function input is enabled (through DERDYCFG) in receive mode (OUTEN cleared to 0), the PSSI samples PSSI_DE on the same PSSI_PDCK edge as the one used for sampling the data (D[15:0]). If PSSI_DE is active, the sampled data is saved in the FIFO. Otherwise, the sampled data is considered invalid and discarded. The transmitting device can use PSSI_DE as a data valid signal, driving it inactive when the data in the current cycle is not valid. This flow control function allows avoiding underrun errors.

Figure 283. Data enable in receive mode waveform diagram (CKPOL=0)



If the PSSI_DE alternate output function is enabled (through DERDYCFG) in transmit mode (OUTEN=1), the PSSI drives PSSI_DE on the same PSSI_PDCK edge that the one used to drive the data (D[15:0]). If a new 8 or 16-bit data (as programmed in the EDM[1:0] control bits in PSSI_CR) is available for transmission in the internal FIFO, this data is output on the data outputs (D[15:0]) and the PSSI_DE output becomes active on the current PSSI_PDCK edge. Otherwise (if the TX FIFO is empty), the D[15:0] outputs remains unchanged on the next clock edge and the PSSI_DE output becomes inactive.

Figure 284. Data enable waveform diagram in transmit mode (CKPOL=0)



Ready (PSSI_RDY) alternate function output

The ready signal, PSSI_RDY, is an optional signal. It is driven by the receiving device and indicates whether data is being accepted in the current cycle. When PSSI_RDY is inactive, it means that the data must not be sampled by the receiver at the next clock edge.

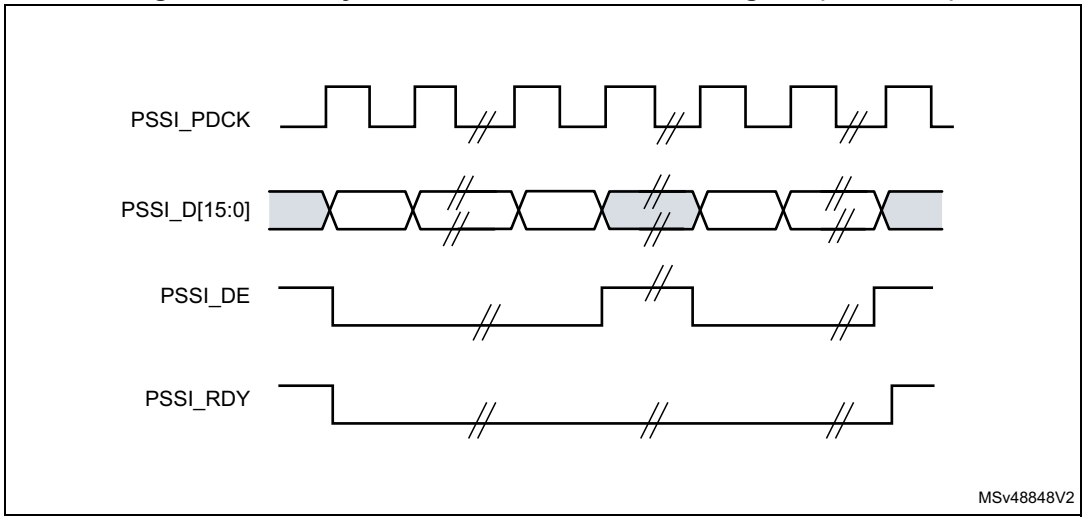
This alternate function signal can be enabled using the DERDYCFG control bits (bits 20:18 of PSSI_CR). PSSI_RDY polarity is configured through the RDYPOL control bit (bit 6 of PSSI_CR). PSSI_RDY is active low when RDYPOL is cleared to 0, and high when RDYPOL set to 1.

The direction of the PSSI_RDY signal is defined by the OUTEN (bit 31 of PSSI_CR). It is set in the opposite direction compared to the PSSI_DE and data signals.

If the PSSI_RDY alternate output function is enabled (through DERDYCFG) in receive mode (OUTEN=0), the PSSI drives PSSI_RDY one PSSI_PDCK half cycle after it samples

the data (D[15:0]). If the FIFO has enough free space to receive more data, the PSSI drives the PSSI_RDY signal active. Otherwise, if the FIFO is full and cannot accept more data, the PSSI drives the PSSI_RDY signal inactive. The transmitting device must repeat the current data in the next cycle when it detects that PSSI_RDY is inactive. This flow control function allows the PSSI to avoid overrun errors when the system (via the DMA) is unable to keep up with the data flow.

Figure 285. Ready in receive mode waveform diagram (CKPOL=0)



If the PSSI_RDY alternate input function is enabled (through DERDYCFG) in transmit mode (OUTEN=1), the PSSI samples the PSSI_RDY signal on the opposite PSSI_PDCK edge to the one at which D[15:0] are driven. If the PSSI_RDY signal is inactive, the PSSI keeps the same data (D[15:0]) and PSSI_DE signals that valid data are available during the next PSSI_PDCK clock cycle. Otherwise, if PSSI_RDY signal is sampled as active, the next data from the TX FIFO (if available) is output on the data outputs (D[15:0]). If no new data are available in the TX FIFO, the PSSI keeps the data output values and outputs the PSSI_DE signal as inactive (if enabled).

The receiving device uses the PSSI_RDY to control the data flow and avoid overrun errors when the system (via the DMA) is unable to keep up with the data flow.

Bidirectional PSSI_DE/PSSI_RDY signal

A single pin can be used for both data enable (PSSI_DE) and ready (PSSI_RDY) functions if DEPOL and RDYPOL are both set to 1 and DERDYCFG is set to 111 or 100 in the PSSI_CR register. In this case, the GPIO corresponding to selected alternate function (PSSI_DE when DERDYCFG=111 or PSSI_RDY when DERDYCFG=100) must be configured as open-drain. The other device must also be configured to drive the line as open-drain, and a weak pull-up must be applied to the line.

The signal thus becomes bidirectional. If either the sender drives the line low (to indicate that the data is not valid) or the receiver drives the line low (to indicate that it is not sampling the current data), then both devices know that the data is not being transferred in the current cycle.

Figure 286. Bidirectional PSSI_DE/PSSI_RDY waveform

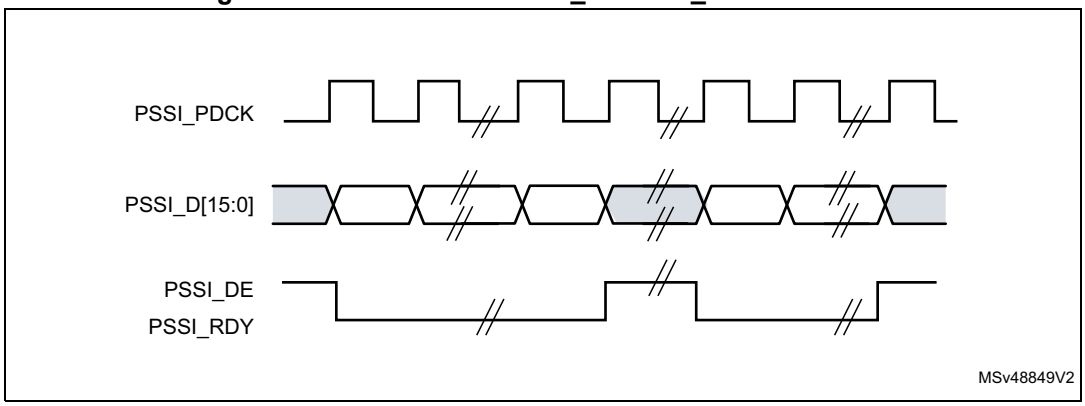


Figure 287. Bidirectional PSSI_DE/PSSI_RDY connection diagram

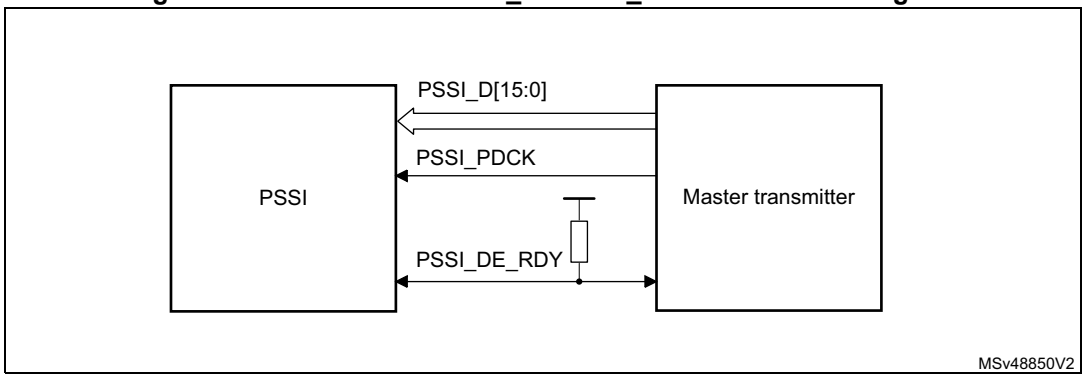

31.4 PSSI interrupts

The PSSI generates only one interrupt (IT_OVR). It is consequently equivalent to the global interrupt (pssi_it). Refer to *Table 293* for the list of interrupts.

The PSSI and the DCMI share the same interrupt vector. When the PSSI ENABLE bit (bit 14 of PSSI_CR) is set to 1, these interrupts are triggered by the PSSI. Otherwise, they are controlled by the DCMI.

The DCMI ENABLE bit (bit 14 of DCMI_CR) and PSSI ENABLE bit must not be set to 1 at the same time.

Table 293. PSSI interrupt requests

Interrupt acronym	Shared with DCMI	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit from low-power mode
IT_OVR	IT_OVR	indicates overrun in receive mode or underrun in transmit mode	OVR_RIS	OVR_IE	OVR_ISC	NA

31.5 PSSI registers

An 8-bit write or a 16-bit write operation to any PSSI register besides PSSI_DR, results in a bus error. 32-bit read and write operations are permitted.

31.5.1 PSSI control register (PSSI_CR)

Address offset: 0x00

Reset value: 0x4000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	ENABLE	Res.	Res.	EDM[1:0]		Res.	RDYPOL	Res.	DEPOL	CKPOL	Res.	Res.	Res.	Res.	Res.
	rw			rw	rw		rw		rw	rw					

Bit 31 **OUTEN:** Data direction selection bit

0: Receive mode: data is input synchronously with PSSI_PDCK

1: Transmit mode: data is output synchronously with PSSI_PDCK

Bit 30 **DMAEN:** DMA enable bit

0: DMA transfers are disabled. The user application can directly access the PSSI_DR register when DMA transfers are disabled.

1: DMA transfers are enabled (default configuration). A DMA channel in the general-purpose DMA controller must be configured to perform transfers from/to PSSI_DR.

Bits 29:21 Reserved, must be kept at reset value.

Bits 20:18 **DERDYCFG[2:0]:** Data enable and ready configuration

000: PSSI_DE and PSSI_RDY both disabled

001: Only PSSI_RDY enabled

010: Only PSSI_DE enabled

011: Both PSSI_RDY and PSSI_DE alternate functions enabled

100: Both PSSI_RDY and PSSI_DE features enabled - bidirectional on PSSI_RDY pin (see *Bidirectional PSSI_DE/PSSI_RDY signal on page 1225*)

101: Only PSSI_RDY function enabled, but mapped to PSSI_DE pin

110: Only PSSI_DE function enabled, but mapped to PSSI_RDY pin

111: Both PSSI_RDY and PSSI_DE features enabled - bidirectional on PSSI_DE pin (see *Bidirectional PSSI_DE/PSSI_RDY signal on page 1225*)

When the PSSI_RDY function is mapped to the PSSI_DE pin (settings 101 or 111), it is still the RDYPOL bit which determines its polarity. Similarly, when the PSSI_DE function is mapped to the PSSI_RDY pin (settings 110 or 111), it is still the DEPOL bit which determines its polarity.

Bits 17:15 Reserved, must be kept at reset value.

Bit 14 **ENABLE:** PSSI enable

0: PSSI disabled

1: PSSI enabled

The contents of the FIFO are flushed when ENABLE is cleared to 0.

Note: When ENABLE=1, the content of PSSI_CR must not be changed, except for the ENABLE bit itself. All configuration bits can change as soon as ENABLE changes from 0 to 1.

The DMA controller and all PSSI configuration registers must be programmed correctly before setting the ENABLE bit to 1.

The ENABLE bit and the DCMI ENABLE bit (bit 15 of DCMI_CR) must not be set to 1 at the same time.

Bits 13:12 Reserved, must be kept at reset value.

Bits 11:10 **EDM[1:0]:** Extended data mode

00: Interface captures 8-bit data on every parallel data clock

01: Reserved, must not be selected

10: Reserved, must not be selected

11: The interface captures 16-bit data on every parallel data clock

Bit 9 Reserved, must be kept at reset value.

Bit 8 **RDYPOL:** Ready (PSSI_RDY) polarity

This bit indicates the level on the PSSI_RDY pin when the data are not valid on the parallel interface.

0: PSSI_RDY active low (0 indicates that the receiver is ready to receive)

1: PSSI_RDY active high (1 indicates that the receiver is ready to receive)

Bit 7 Reserved, must be kept at reset value.

Bit 6 **DEPOL:** Data enable (PSSI_DE) polarity

This bit indicates the level on the PSSI_DE pin when the data are not valid on the parallel interface.

0: PSSI_DE active low (0 indicates that data is valid)

1: PSSI_DE active high (1 indicates that data is valid)

Bit 5 **CKPOL:** Parallel data clock polarity

This bit configures the capture edge of the parallel clock or the edge used for driving outputs, depending on OUTEN.

0: Falling edge active for inputs or rising edge active for outputs

1: Rising edge active for inputs or falling edge active for outputs.

Bits 4:0 Reserved, must be kept at reset value.

31.5.2 PSSI status register (PSSI_SR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RTT1B	RTT4B	Res.	Res.
												r	r		

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **RTT1B:** FIFO is ready to transfer one byte

1: FIFO is ready for a one byte (32-bit) transfer. In receive mode, this means that at least one valid data byte is in the FIFO. In transmit mode, this means that there is at least one byte free in the FIFO.

0: FIFO is not ready for a 1-byte transfer

Bit 2 **RTT4B:** FIFO is ready to transfer four bytes

1: FIFO is ready for a four-byte (32-bit) transfer. In receive mode, this means that at least four valid data bytes are in the FIFO. In transmit mode, this means that there are at least four bytes free in the FIFO.

0: FIFO is not ready for a four-byte transfer

Bits 1:0 Reserved, must be kept at reset value.

31.5.3 PSSI raw interrupt status register (PSSI_RIS)

Address offset: 0x08

Reset value: 0x0000 0000

PSSI_RIS gives the raw interrupt status. This register is read-only. When read, it returns the status of the corresponding interrupt before masking with the PSSI_IER register value.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OVR_RIS	Res.
														r	

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **OVR_RIS:** Data buffer overrun/underrun raw interrupt status

0: No overrun/underrun occurred

1: An overrun/underrun occurred: overrun in receive mode, underrun in transmit mode. This bit is cleared by writing a 1 to the OVR_ISC bit in PSSI_ICR.

Bit 0 Reserved, must be kept at reset value.

31.5.4 PSSI interrupt enable register (PSSI_IER)

Address offset: 0x0C

Reset value: 0x0000 0000

The PSSI_IER register is used to enable interrupts. When one of the PSSI_IER bits is set, the corresponding interrupt is enabled. This register is accessible both in read and write modes.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OVR_IE	Res.
														rw	

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **OVR_IE:** Data buffer overrun/underrun interrupt enable
0: No interrupt generation
1: An interrupt is generated if either an overrun or an underrun error occurred.

Bit 0 Reserved, must be kept at reset value.

31.5.5 PSSI masked interrupt status register (PSSI_MIS)

This PSSI_MIS register is read-only. When read, it returns the current masked status value of the corresponding interrupt (depending on the value in PSSI_IER). A bit in this register is set if the corresponding enable bit in PSSI_IER is set and the corresponding bit in PSSI_RIS is set.

Address offset: 0x10

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OVR_MIS	Res.
														r	

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **OVR_MIS:** Data buffer overrun/underrun masked interrupt status
This bit is set to 1 only when PSSI_IER/OVR_IE and PSSI_RIS/OVR_RIS are both set to 1.
0: No interrupt is generated when an overrun/underrun error occurs
1: An interrupt is generated if there is either an overrun or an underrun error and the OVR_IE bit is set in PSSI_IER.

Bit 0 Reserved, must be kept at reset value.

31.5.6 PSSI interrupt clear register (PSSI_ICR)

Address offset: 0x14

Reset value: 0x0000 0000

The PSSI_ICR register is write-only. Writing a 1 into a bit of this register clears the corresponding bit in the PSSI_RIS and PSSI_MIS registers. Writing a 0 has no effect. Reading this register always gives zeros.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OVR_ISC	Res.
														w	

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **OVR_ISC:** Data buffer overrun/underrun interrupt status clear
Writing this bit to 1 clears the OVR_RIS bit in PSSI_RIS.

Bit 0 Reserved, must be kept at reset value.

31.5.7 PSSI data register (PSSI_DR)

Address offset: 0x28

Reset value: 0x0000 0000

In receive mode (OUTEN = 0), the DMA controller must read the received data from this register. Write operations to PSSI_DR result in an error response. When more bytes than the number of valid bytes are read in the FIFO, the invalid bytes return zeros.

In transmit mode (OUTEN = 1), the DMA controller must write the data to be transmitted into this register. Read operations to PSSI_DR result in an error response.

32-bit, 16-bit, and 8-bit accesses are all supported for PSSI_DR. For instance, 16-bit read/write operations remove/add two bytes from/to the FIFO. However, 8-bit accesses are permitted only when the PSSI is configured to transfer 8 data bits at a time (EDM=00 in PSSI_CR). 8-bit accesses to PSSI_DR when EDM is not set to 0 result in an error response.

All accesses must include byte 0: 8-bit accesses must be performed to bits 7 to 0 and 16-bit accesses from bits 15 to 0. Accesses that do not include byte 0 results in an error response.

Accessing PSSI_DR when ENABLE bit in PSSI_CR is set to 0 results in an error response.

Refer to *Section 2.3* for the register boundary addresses.

32 True random number generator (RNG)

32.1 Introduction

The RNG is a true random number generator that provides full entropy outputs to the application as 32-bit samples. It is composed of a live entropy source (analog) and an internal conditioning component.

The RNG is a NIST SP 800-90B compliant entropy source that can be used to construct a nondeterministic random bit generator (NDRBG).

The RNG true random number generator has been precertified NIST SP800-90B. It has also been tested using the German BSI statistical tests of AIS-31 (T0 to T8).

32.2 RNG main features

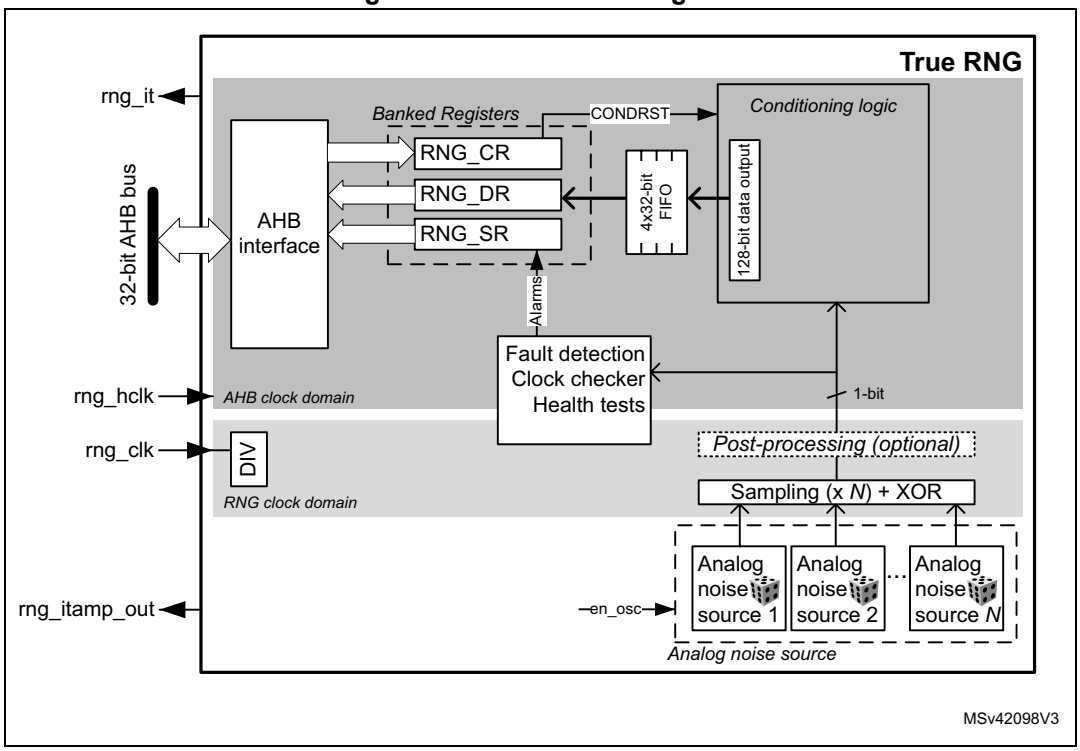
- The RNG delivers 32-bit true random numbers, produced by an analog entropy source conditioned by a NIST SP800-90B approved conditioning stage.
- It can be used as the entropy source to construct a nondeterministic random bit generator (NDRBG).
- In the NIST configuration, it produces four 32-bit random samples every 412 AHB clock cycles if $f_{AHB} < f_{threshold}$ (256 RNG clock cycles otherwise).
- It embeds startup and NIST SP800-90B approved continuous health tests (repetition count and adaptive proportion tests), associated with specific error management
- It can be disabled to reduce power consumption, or enabled with an automatic low power mode (default configuration).
- It has an AMBA® AHB slave peripheral, accessible through 32-bit word single accesses only (else an AHB bus error is generated, and the write accesses are ignored).

32.3 RNG functional description

32.3.1 RNG block diagram

Figure 288 shows the RNG block diagram.

Figure 288. RNG block diagram



32.3.2 RNG internal signals

Table 295 describes a list of useful-to-know internal signals available at the RNG level, not at the STM32 product level (on pads).

Table 295. RNG internal input/output signals

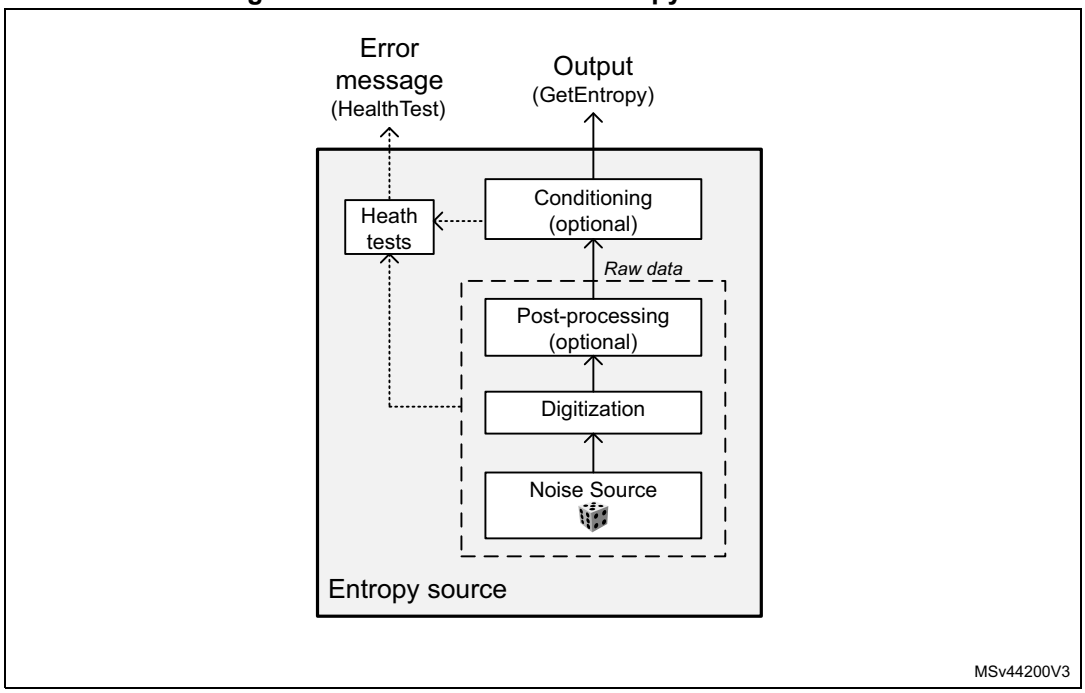
Signal name	Signal type	Description
rng_it	Digital output	RNG global interrupt request
rng_hclk	Digital input	AHB clock
rng_clk	Digital input	RNG dedicated clock, asynchronous to rng_hclk
rng_itamp_out	digital output	RNG internal tamper event signal to TAMP (XORed), triggered when an unexpected hardware fault occurs. When this signal is triggered, RNG stops delivering random samples, requiring a reset and a new initialization to be usable again.

32.3.3 Random number generation

The true random number generator (RNG) delivers truly random data through its AHB interface at deterministic intervals.

Within its boundary RNG integrates all the required NIST components depicted on *Figure 289*. Those components are an analog noise source, a digitization stage, a conditioning algorithm, a health monitoring block and two interfaces that are used to interact with the entropy source: GetEntropy and HealthTest.

Figure 289. NIST SP800-90B entropy source model



The components pictured above are detailed hereafter.

Noise source

The noise source is the component that contains the non-deterministic, entropy-providing activity that is ultimately responsible for the uncertainty associated with the bitstring output by the entropy source. This noise source provides 1-bit samples. It is composed of:

- Multiple analog noise sources (x6), each based on three XORed free-running ring oscillator outputs. It is possible to disable those analog oscillators to save power, as described in *Section 32.3.8: RNG low-power use*.
- The XORing of all the noise sources into a single analog output.
- A sampling stage of this output clocked by a dedicated clock input (rng_clk with integrated divider), delivering a 1-bit raw data output.

This noise source sampling is independent to the AHB interface clock frequency (rng_hclk), with a possibility for the software to decrease the sampling frequency by using the integrated divider.

Note: In Section 32.6: RNG entropy source validation the recommended RNG clock frequencies and associated divider value are given.

Post processing

In the NIST configuration no post-processing is applied to the sampled noise source. In non-NIST configuration B (as defined in *Section 32.6.2*) a normalization debiasing is applied, that is half of the bits are taken from the sampled noise source, half of the bits are taken from the inverted sampled noise source.

Conditioning

The conditioning component in the RNG is a deterministic function that increases the entropy rate of the resulting fixed-length bitstrings output (128-bit). The NIST SP800-90B target is full entropy on the output (128-bit).

The times required between two random number generations, and between the RNG initialization and availability of first sample are described in *Section 32.5: RNG processing time*.

Output buffer

A data output buffer can store up to four 32-bit words that have been output from the conditioning component. When four words have been read from the output FIFO through the RNG_DR register, the content of the 128-bit conditioning output register is pushed into the output FIFO, and a new conditioning round is automatically started. Four new words are added to the conditioning output register after a number of clock cycles specified in *Section 32.5: RNG processing time*.

Whenever a random number is available through the RNG_DR register, the DRDY flag changes from 0 to 1. This flag remains high until the output buffer becomes empty after reading four words from the RNG_DR register.

Note: When interrupts are enabled an interrupt is generated when this data ready flag transitions from 0 to 1. Interrupt is then cleared automatically by the RNG as explained above.

Health checks

This component ensures that the entire entropy source (with its noise source) starts then operates as expected, obtaining assurance that failures are caught quickly and with a high probability and reliability.

The RNG implements the following health check features in accordance with NIST SP800-90B. The described thresholds correspond to the value recommended for register RNG_HTCR (configuration A in *Section 32.6.2*).

1. Startup health tests, performed after reset and before the first use of the RNG as entropy source:
   - Repetition count test, flagging an error when the noise source has provided more than 42 consecutive bits at a constant value (0 or 1).
   - Adaptive proportion test running on a window of 1024 consecutive bits: the RNG verifies that the first bit on the outputs of the noise source is not repeated more than 711 times.
   - Known-answer tests, to verify the conditioning stage.
2. Continuous health tests, running indefinitely on the outputs of the noise source:
   - Repetition count test, similar to the one running in startup tests.
   - Adaptive proportion test, similar to the one running in startup tests.
3. Vendor specific continuous tests
   - Transition count test, flagging an error when the noise source has delivered more than 32 consecutive occurrences of 2-bit patterns (01 or 10).
   - Real-time “too slow” sampling clock detector, flagging an error when one RNG clock cycle (before divider) is smaller than AHB clock cycle divided by 32.
4. On-demand test of digitized noise source (raw data)
   - Supported by restarting the entropy source and rerunning the startup tests (see software reset sequence in *Section 32.3.4: RNG initialization*). Other kinds of on-demand testing (software based) are *not supported*.

The CECS and SECS status bits in the RNG_SR register indicate when an error condition is detected, as detailed in *Section 32.3.7: Error management*.

Note: An interrupt can be generated when an error is detected.

Above the health test thresholds are modified by changing the value in the RNG_HTCR register. See Section 32.6: RNG entropy source validation for details.

32.3.4 RNG initialization

The RNG simplified state machine is pictured on *Figure 290*.

After enabling the RNG (RNGEN = 1 in RNG_CR), the following chain of events occurs:

1. The analog noise source is enabled, and by default the RNG waits 16 cycles of RNG clock cycles (before divider) before starting to sample the analog output and filling the 128-bit conditioning shift register.
2. The conditioning hardware initializes, automatically triggering startup behavior test on the raw data samples and known-answer tests.
3. When startup health tests are completed. During this time, three 128-bit noise source samples are used.
4. The conditioning stage internal input data buffer is filled again with 128-bit and a number of conditioning rounds defined by the RNG configuration (NIST or non-NIST) is performed. The output buffer is then filled with the post processing result.
5. The output buffer is refilled automatically according to the RNG usage.

The associated initialization time can be found in *Section 32.5: RNG processing time*.

Figure 290. RNG initialization overview

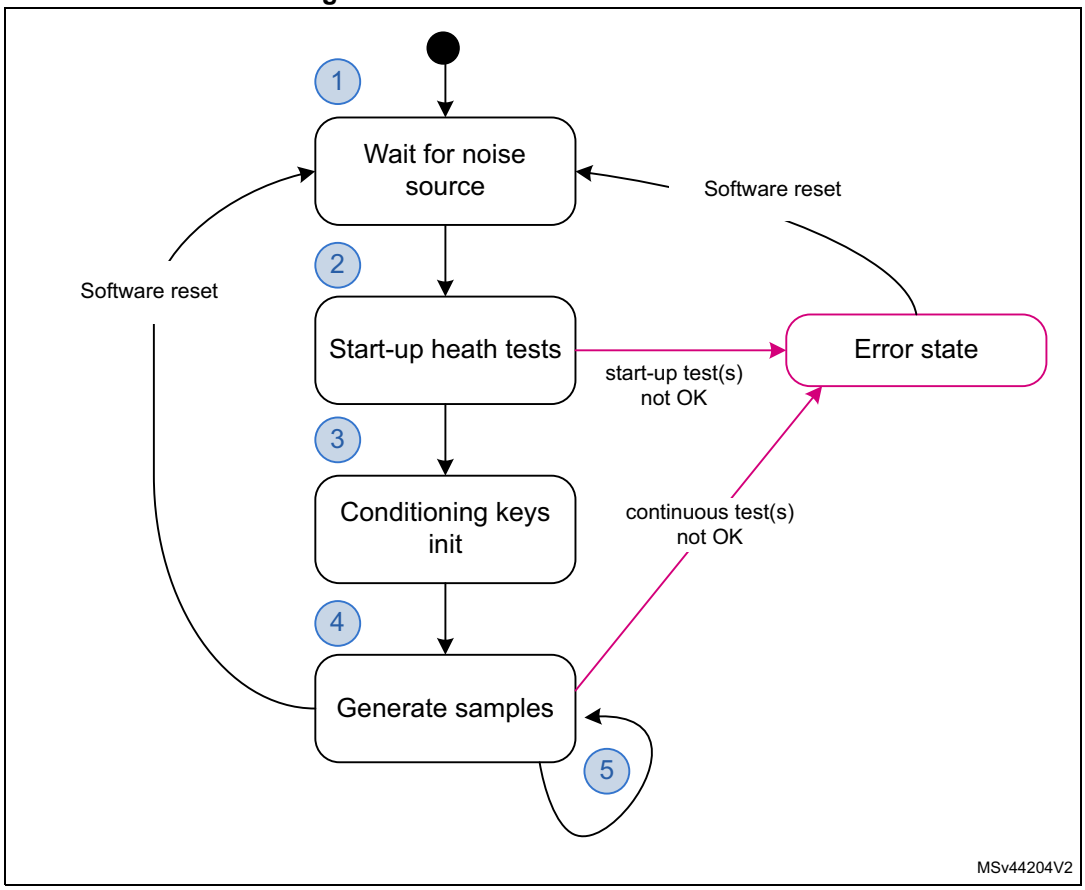


Figure 290 also highlights a possible software reset sequence, implemented by:

1. Writing bits RNGEN = 0 and CONDRST = 1 in the RNG_CR register with the same RNG configuration and a new CLKDIV if needed.
2. Then writing RNGEN = 1 and CONDRST = 0 in the RNG_CR register.
3. Wait for random number to be ready, after initialization completes.

Note: When the RNG peripheral is reset through RCC (hardware reset), the RNG configuration for optimal randomness is lost in the RNG registers. Software reset with CONFIGLOCK set preserves the RNG configuration.

32.3.5 RNG operation

Normal operations

To run the RNG using interrupts, the following steps are recommended:

1. Consult *Section 32.6: RNG entropy source validation* and verify if a specific RNG configuration is required for the application.
   - If it is the case, write in the RNG_CR register the bit CONDRST = 1 together with the correct RNG configuration. Then perform a second write to the RNG_CR register with the bit CONDRST = 0, the interrupt enable bit IE = 1 and the RNG enable bit RNGEN = 1.
   - If it is not the case perform a write to the RNG_CR register with the interrupt enable bit IE = 1 and the RNG enable bit RNGEN = 1.
2. An interrupt is now generated when a random number is ready or when an error occurs. Therefore, at each interrupt, check that:
   - No error occurred. The SEIS and CEIS bits must be set to 0 in the RNG_SR register.
   - A random number is ready. The DRDY bit must be set to 1 in the RNG_SR register.
   - If the above two conditions are true the content of the RNG_DR register can be read up to four consecutive times. If valid data is available in the conditioning output buffer, four additional words can be read by the application (in this case the DRDY bit is still high). If one or both of the above conditions are false, the RNG_DR register must not be read. If an error occurred, the error recovery sequence described in *Section 32.3.7* must be used.

To run the RNG in polling mode following steps are recommended:

1. Consult *Section 32.6: RNG entropy source validation* and verify if a specific RNG configuration is required for the application.
   - If it is the case write in the RNG_CR register the bit CONDRST = 1 together with the correction RNG configuration. Then perform a second write to the RNG_CR register with the bit CONDRST = 0 and the RNG enable bit RNGEN = 1.
   - If it is not the case only enable the RNG by setting the RNGEN bit to 1 in the RNG_CR register.
2. Read the RNG_SR register and check that:
   - No error occurred (the SEIS and CEIS bits must be set to 0)
   - A random number is ready (the DRDY bit must be set to 1)
3. If above conditions are true read the content of the RNG_DR register up to four consecutive times. If valid data is available in the conditioning output buffer four

additional words can be read by the application (in this case the DRDY bit is still high). If one or both of the above conditions are false, the RNG_DR register must not be read. If an error occurred, the error recovery sequence described in *Section 32.3.7* must be used.

Note: When data is not ready (DRDY = 0) RNG_DR returns zero.
It is recommended to always verify that RNG_DR is different from zero. Because when it is the case a seed error occurred between RNG_SR polling and RND_DR output reading (rare event).

If the random number generation period is a concern to the application and if NIST compliance is not required it is possible to select a faster RNG configuration by using the RNG configuration “B”, described in *Section 32.6: RNG entropy source validation*. The gain in random number generation speed is summarized in *Section 32.5: RNG processing time*.

Low-power operations

If the power consumption is a concern to the application, low-power strategies can be used, as described in *Section 32.3.8: RNG low-power use*.

Software post-processing

No specific software post-processing/conditioning is expected to meet the AIS-31 or NIST SP800-90B approvals.

Built-in health check functions are described in *Section 32.3.3: Random number generation*.

32.3.6 RNG clocking

The RNG runs on two different clocks: the AHB bus clock and a dedicated RNG clock.

The AHB clock is used to clock the AHB banked registers and conditioning component. The RNG clock, coupled with a programmable divider (see CLKDIV bitfield in the RNG_CR register) is used for noise source sampling. Recommended clock configurations are detailed in *Section 32.6: RNG entropy source validation*.

*Note: When the CED bit in the RNG_CR register is set to 0, the RNG clock frequency before the internal divider **must be higher** than the AHB clock frequency divided by 32, otherwise the clock checker always flags a clock error (CECS = 1 in the RNG_SR register).*

See *Section 32.3.1: RNG block diagram* for details (AHB and RNG clock domains).

32.3.7 Error management

In parallel to random number generation a health check block verifies the correct noise source behavior and the frequency of the RNG source clock as detailed in this section. Associated error state is also described.

Clock error detection

When the clock error detection is enabled (CED = 0) and if the RNG clock frequency is too low, the RNG sets to 1 both the CEIS and CECS bits to indicate that a clock error occurred. In this case, the application must check that the RNG clock is configured correctly (see *Section 32.3.6: RNG clocking*) and then it must clear the CEIS bit interrupt flag. The CECS bit is automatically cleared when the clocking condition is normal.

Note: The clock error has no impact on generated random numbers that is the application can still read the RNG_DR register.

CEIS is set only when CECS is set to 1 by RNG.

Noise source error detection

When a noise source (or seed) error occurs, the RNG stops generating random numbers and sets to 1 both SEIS and SECS bits to indicate that a seed error occurred. If a value is available in the RNG_DR register, it must not be used as it may not have enough entropy.

The following sequence must be used to fully recover from a seed error:

1. Software reset by writing CONDRST at 1 and at 0 (see bitfield description for details). This step is needed only if SECS is set. Indeed, when SEIS is set and SECS is cleared it means RNG performed the reset automatically (auto-reset). In this case application must clear the SEIS bit interrupt flag.
2. If SECS was set in step 1 (no auto-reset) wait for CONDRST to be cleared in the RNG_CR register, then confirm that SEIS is cleared in the RNG_SR register. Otherwise, just clear the SEIS bit in the RNG_SR register.
3. If SECS was set in step 1 (no auto-reset), wait for SECS to be cleared by RNG. The random number generation is now back to normal.

Note: After a seed error RNG restarts generating random numbers when SECS is cleared.

When the application sets the ARDIS bit in the RNG_CR register, the auto-reset is disabled. CONDRST must be used in step 1.

RNG tamper errors

When an unexpected error is found by the RNG an internal tamper event is triggered in the TAMP peripheral, and the RNG stops delivering random data.

When this event occurs, the secure application needs to reset the RNG peripheral either using the central reset management or the global SoC reset. Then a proper initialization of the RNG is required, again.

32.3.8 RNG low-power use

If power consumption is a concern, the RNG can be disabled as soon as the DRDY bit is set to 1 by setting the RNGEN bit to 0 in the RNG_CR register. As the post-processing logic and the output buffer remain operational while RNGEN = 0 following features are available to the software:

- If there are valid words in the output buffer four random numbers can still be read from the RNG_DR register.
- If there are valid bits in the conditioning output internal register four additional random numbers can be still be read from the RNG_DR register. If it is not the case RNG must be reenabled by the application until the expected new noise source bits threshold is reached (128-bit in NIST mode) and a complete conditioning round is done.
  Four new random words are then available only if the expected number of conditioning round is reached (two if NISTC = 0). The overall time can be found in *Section 32.5: RNG processing time on page 1243*.

When disabling the RNG the user deactivates all the analog seed generators, whose power consumption is given in the datasheet electrical characteristics section. The user also gates

all the logic clocked by the RNG clock. Note that this strategy is adding latency before a random sample is available on the RNG_DR register, because of the RNG initialization time.

If the RNG block is disabled during initialization (that is well before the DRDY bit rises for the first time), the initialization sequence resumes from where it was stopped when RNGEN bit is set to 1, unless the application resets the conditioning logic using CONDRST bit in the RNG_CR register.

When the application wants to gate the RNG clock it is recommended to wait two RNG kernel clock cycles between clearing the RNGEN bit and gating the RNG kernel clock using the RCC.

Also, when application needs to enter a power mode where RNG is de-activated, it is recommended to wait two RNG kernel clock cycles between clearing the RNGEN bit and entering the low power mode using the PWR.

In the two cases above, to avoid unexpected consumption when RNG analog oscillators stay active, application can set the bit 13 in RNG_CR register. Setting this bit adds some marginal power consumption while RNGEN bit is set (RNG activated).

Note: The power modes where RNG is deactivated (that is retained or not available) can be found in the PWR section.

32.4 RNG interrupts

In the RNG an interrupt can be produced on the following events:

- Data ready flag
- Seed error, see *Section 32.3.7: Error management*
- Clock error, see *Section 32.3.7: Error management*

Dedicated interrupt enable control bits are available as shown in *Table 296*.

Table 296. RNG interrupt requests

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method
RNG	Data ready flag	DRDY	IE	None (automatic)
	Seed error flag	SEIS	IE	Write 0 to SEIS or write CONDRST to 1 then to 0
	Clock error flag	CEIS	IE	Write 0 to CEIS

The user can enable or disable the above interrupt sources individually by changing the mask bits or the general interrupt control bit IE in the RNG_CR register. The status of the individual interrupt sources can be read from the RNG_SR register.

Note: Interrupts are generated only when RNG is enabled.

32.5 RNG processing time

In recommended configuration A described in *Table 297*, the time between two sets of four 32-bit data is either:

- 206 x N AHB cycles if $f_{AHB} < f_{threshold}$ (conditioning stage is limiting), or
- 128 x N RNG cycles $f_{AHB} \geq f_{threshold}$ (noise source stage is limiting).

With $f_{threshold} = 1.6 \times f_{RNG}$, for instance 77 MHz if f_{RNG}= 48 MHz.Value N is 2.

Note: When CLKDIV is different from zero, f_{RNG} must take into account the internal divider ratio.

If configuration B is selected the performance figures become:

- 206 AHB cycles if $f_{AHB} < f_{threshold}$ or
- 32 RNG cycles $f_{AHB} \geq f_{threshold}$

with $f_{threshold} = 6.5 \times f_{RNG}$.

32.6 RNG entropy source validation

32.6.1 Introduction

In order to assess the amount of entropy available from the RNG, STMicroelectronics has tested the peripheral using the German BSI AIS-31 statistical tests (T0 to T8), and NIST SP800-90B test suite. The results can be provided on demand or the customer can reproduce the tests.

32.6.2 Validation conditions

STMicroelectronics has tested the RNG true random number generator in the following conditions:

- RNG clock rng_clk= 48 MHz
- RNG configurations described in *Table 297: RNG configurations*. Note that only configuration A can be certified NIST SP800-90B.

Table 297. RNG configurations

RNG Config.	RNG_CR bits						Loop number (N)	RNG_ HTCR register
	NISTC bit	RNG_ CONFIG1 [5:0]	CLKDIV [3:0]	RNG_ CONFIG2 [2:0]	RNG_ CONFIG3 [3:0]	CED bit		
A	0	0x0F	0x0(1)	0x0(2)	0xD	0	2	0x0000 AAC7(3)
B	1	0x18	0x0	0x0	0x0	0	1	0x0000 AAC7

1. For NIST certification the noise source sampling must be 48 MHz or less. Hence, if the RNG clock is different from 48 MHz, this value of CLKDIV must be adapted. See the CLKDIV bitfield description in *Section 32.7.1* for details.
2. 0x1 value is recommended when RNG power consumption is critical. See the end of *Section 32.3.8: RNG low-power use* for details.
3. Corresponds to 42 for repetition tests and 711 for adaptive tests. See *Health checks on page 1237* for details.

32.6.3 Data collection

In order to run statistical tests, it is required to collect samples from the entropy source at the raw data level as well as at the output of the entropy source. For details on data collection and the running of statistical test suites refer to “STM32 microcontrollers random number generation validation using NIST statistical test suite” application note (AN4230) available from *www.st.com*.

Contact STMicroelectronics if the above samples need to be retrieved for the product.

32.7 RNG registers

The RNG is associated with a control register, a data register and a status register.

32.7.1 RNG control register (RNG_CR)

Address offset: 0x000

Reset value: 0x0080 0D00

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CONFIGLOCK	CONDRST	Res.	Res.	Res.	Res.	RNG_CONFIG1[5:0]						CLKDIV[3:0]			
rs	rw					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RNG_CONFIG2[2:0]			NISTC	RNG_CONFIG3[3:0]				ARDIS	Res.	CED	Res.	IE	RNGEN	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw		rw		rw	rw		

Bit 31 **CONFIGLOCK**: RNG Config lock

0: Writes to the RNG_HTCR and RNG_CR configuration bits [29:4] are allowed.

1: Writes to the RNG_HTCR and RNG_CR configuration bits [29:4] are ignored until the next RNG reset.

This bitfield is set once: if this bit is set it can only be reset to 0 if RNG is reset.

Bit 30 **CONDRST**: Conditioning soft reset

Write 1 and then write 0 to reset the conditioning logic, clear all the FIFOs and start a new RNG initialization process, with RNG_SR cleared. Registers RNG_CR and RNG_HTCR are not changed by CONDRST.

This bit must be set to 1 in the same access that set any configuration bits [29:4]. In other words, when CONDRST bit is set to 1 correct configuration in bits [29:4] must also be written.

When CONDRST is set to 0 by the software, its value goes to 0 when the reset process is done. It takes about 2 AHB clock cycles + 2 RNG clock cycles.

Bits 29:26 Reserved, must be kept at reset value.

Bits 25:20 **RNG_CONFIG1[5:0]:** RNG configuration 1

Reserved to the RNG configuration (bitfield 1). Must be initialized using the recommended value documented in *Section 32.6: RNG entropy source validation*.

Writing any bit of RNG_CONFIG1 is taken into account only if the CONDRST bit is set to 1 in the same access, while CONFIGLOCK remains at 0. Writing to this bit is ignored if CONFIGLOCK = 1.

Bits 19:16 **CLKDIV[3:0]**: Clock divider factor

This value used to configure an internal programmable divider (from 1 to 16) acting on the incoming RNG clock. These bits can be written only when the core is disabled (RNGEN = 0).

0x0: internal RNG clock after divider is similar to incoming RNG clock.

0x1: two RNG clock cycles per internal RNG clock.

0x2: 2^2 (= 4) RNG clock cycles per internal RNG clock.

...

0xF: 2^{15} RNG clock cycles per internal clock (for example. an incoming 48 MHz RNG clock becomes a 1.5 kHz internal RNG clock)

Writing these bits is taken into account only if the CONDRST bit is set to 1 in the same access, while CONFIGLOCK remains at 0. Writing to this bit is ignored if CONFIGLOCK = 1.

Bits 15:13 **RNG_CONFIG2[2:0]:** RNG configuration 2

Reserved to the RNG configuration (bitfield 2). Bit 13 can be set when RNG power consumption is critical. See *Section 32.3.8: RNG low-power use*. Refer to the RNG_CONFIG1 bitfield for details.

Bit 12 **NISTC**: NIST custom

0: Hardware default values for NIST compliant RNG. In this configuration per 128-bit output two conditioning loops are performed and 256 bits of noise source are used.

1: Custom values for NIST compliant RNG. See *Section 32.6: RNG entropy source validation* for proposed configuration.

Writing this bit is taken into account only if CONDRST bit is set to 1 in the same access, while CONFIGLOCK remains at 0. Writing to this bit is ignored if CONFIGLOCK = 1.

Bits 11:8 **RNG_CONFIG3[3:0]:** RNG configuration 3

Reserved to the RNG configuration (bitfield 3). Refer to RNG_CONFIG1 bitfield for details.

If the NISTC bit is cleared in this register RNG_CONFIG3 bitfield values are ignored by RNG.

Bit 7 **ARDIS**: Auto reset disable

0: When a noise source error occurs RNG performs an automatic reset to clear the SECS bit.

1: When a noise source error occurs the application must reset RNG by writing CONDRST to 1 then to 0, in order to restart random number generation.

When auto-reset is enabled the application still need to clear the SEIS bit after a noise source error.

Writing this bit is taken into account only if CONDRST bit is set to 1 in the same access, while CONFIGLOCK remains at 0. Writing to this bit is ignored if CONFIGLOCK = 1.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **CED:** Clock error detection

0: Clock error detection enabled

1: Clock error detection is disabled

The clock error detection cannot be enabled nor disabled on-the-fly when the RNG is enabled, that is to enable or disable CED, the RNG must be disabled.

Writing this bit is taken into account only if the CONDRST bit is set to 1 in the same access, while CONFIGLOCK remains at 0. Writing to this bit is ignored if CONFIGLOCK = 1.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **IE:** Interrupt enable

0: RNG interrupt is disabled

1: RNG interrupt is enabled. An interrupt is pending as soon as DRDY = 1, SEIS = 1 or CEIS = 1 in the RNG_SR register.

Bit 2 **RNGEN:** True random number generator enable

0: True random number generator is disabled. Analog noise sources are powered off and logic clocked by the RNG clock is gated.

1: True random number generator is enabled.

Bits 1:0 Reserved, must be kept at reset value.

32.7.2 RNG status register (RNG_SR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SEIS	CEIS	Res.	Res.	SECS	CECS	DRDY
									rc_w0	rc_w0			r	r	r

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **SEIS:** Seed error interrupt status

This bit is set at the same time as SECS. It is cleared by writing 0 (unless CONDRST is used). Writing 1 has no effect.

0: No faulty sequence detected

1: At least one faulty sequence is detected. See SECS bit description for details.

An interrupt is pending if IE = 1 in the RNG_CR register.

Bit 5 **CEIS:** Clock error interrupt status

This bit is set at the same time as CECS. It is cleared by writing 0. Writing 1 has no effect.

0: The RNG clock is correct ($f_{RNGCLK} > f_{HCLK}/32$)

1: The RNG clock before the internal divider is detected too slow ($f_{RNGCLK} < f_{HCLK}/32$)

An interrupt is pending if IE = 1 in the RNG_CR register.

Bits 4:3 Reserved, must be kept at reset value.

Bit 2 **SECS:** Seed error current status

0: No faulty sequence has currently been detected. If the SEIS bit is set, this means that a faulty sequence was detected and the situation has been recovered.

1: At least one of the following faulty sequences has been detected:

- Runtime repetition count test failed (noise source has provided more than 24 consecutive bits at a constant value 0 or 1, or more than 32 consecutive occurrence of two bits patterns 01 or 10)
- Startup or continuous adaptive proportion test on noise source failed.
- Startup post-processing/conditioning sanity check failed.

Bit 1 **CECS:** Clock error current status

0: The RNG clock is correct ($f_{RNGCLK} > f_{HCLK}/32$). If the CEIS bit is set, this means that a slow clock was detected and the situation has been recovered.

1: The RNG clock is too slow ($f_{RNGCLK} < f_{HCLK}/32$).

Note: CECS bit is valid only if the CED bit in the RNG_CR register is set to 0.

Bit 0 **DRDY:** Data ready

0: The RNG_DR register is not yet valid, no random data is available.

1: The RNG_DR register contains valid random data.

Once the output buffer becomes empty (after reading the RNG_DR register), this bit returns to 0 until a new random value is generated.

Note: The DRDY bit can rise when the peripheral is disabled (RNGEN = 0 in the RNG_CR register).

If IE=1 in the RNG_CR register, an interrupt is generated when DRDY = 1.

32.7.3 RNG data register (RNG_DR)

Address offset: 0x008

Reset value: 0x0000 0000

The RNG_DR register is a read-only register that delivers a 32-bit random value when read. The content of this register is valid when the DRDY = 1 and the value is not 0x0, even if RNGEN = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RNDATA[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RNDATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **RNDATA[31:0]:** Random data

32-bit random data, which are valid when DRDY = 1. When DRDY = 0, the RNDATA value is zero.

When DRDY is set, it is recommended to always verify that RNG_DR is different from zero. Because when it is the case a seed error occurred between RNG_SR polling and RND_DR output reading (rare event).

32.7.4 RNG health test control register (RNG_HTCR)

Address offset: 0x010

Reset value: 0x0000 72AC

Writing in RNG_HTCR is taken into account only if the CONDRST bit is set, and the CONFIGLOCK bit is cleared in the RNG_CR. Writing to this register is ignored if CONFIGLOCK=1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
HTCFG[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HTCFG[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **HTCFG[31:0]:** health test configuration

This configuration is used by RNG to configure the health tests. See *Section 32.6: RNG entropy source validation* for the recommended value.

Note: The RNG behavior, including the read to this register, is not guaranteed if a different value from the recommended value is written.

32.7.5 RNG register map

Table 298. RNG register map and reset map

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3* for the register boundary addresses.

33 AES hardware accelerator (AES)

33.1 Introduction

The AES hardware accelerator (AES) encrypts or decrypts data in compliance with the advanced encryption standard (AES) defined by NIST.

AES supports ECB, CBC, CTR, GCM, GMAC, and CCM chaining modes for key sizes of 128 or 256 bits. AES has the possibility to load by hardware the key stored in SAES peripheral, under SAES control.

The peripheral supports DMA single transfers for incoming and outgoing data (two DMA channels are required).

33.2 AES main features

- Compliant with NIST FIPS publication 197 *"Advanced encryption standard (AES)"* (November 2001)
- Encryption and decryption with multiple chaining modes:
  - Electronic codebook (ECB) mode
  - Cipher block chaining (CBC) mode
  - Counter (CTR) mode
  - Galois counter mode (GCM)
  - Galois message authentication code (GMAC) mode
  - Counter with CBC-MAC (CCM) mode
- 128-bit data block processing, supporting cipher key lengths of 128-bit and 256-bit
  - 51 or 75 clock cycle latency in ECB mode for processing one 128-bit block with, respectively, 128-bit or 256-bit key
- Using dedicated key bus, optional key sharing with side-channel resistant SAES peripheral (Shared-key mode), controlled by SAES
- Integrated key scheduler to compute the last round key for ECB/CBC decryption
- 256-bit of write-only registers for storing cryptographic keys (eight 32-bit registers)
- 128-bit of registers for storing initialization vectors (four 32-bit registers)
- 32-bit buffer for data input and output
- Automatic data flow control supporting two direct memory access (DMA) channels, one for incoming data, one for processed data. Only single transfers are supported.
- Data-swapping logic to support 1-, 8-, 16-, or 32-bit data
- AMBA AHB slave peripheral, accessible through 32-bit word single accesses only. Other access types generate an AHB error, and other than 32-bit writes may corrupt the register content.
- Possibility for software to suspend a message if AES needs to process another message with a higher priority, then resume the original message

33.3 AES implementation

The devices have one AES peripheral, implemented as per the following table. It can use the key generated by the SAES peripheral. For comparison, the SAES peripheral is also included in the table.

Table 299. AES versus SAES features

Modes or features(1)	AES	SAES
ECB, CBC chaining	X	X
CTR, CCM, GCM chaining	X	X
AES 128-bit ECB encryption in cycles	51	480
DHUK and BHK key selection	-	X
Resistance to side-channel attacks	-	X
Shared key between SAES and AES	X	
Key sizes in bits	128, 256	128, 256

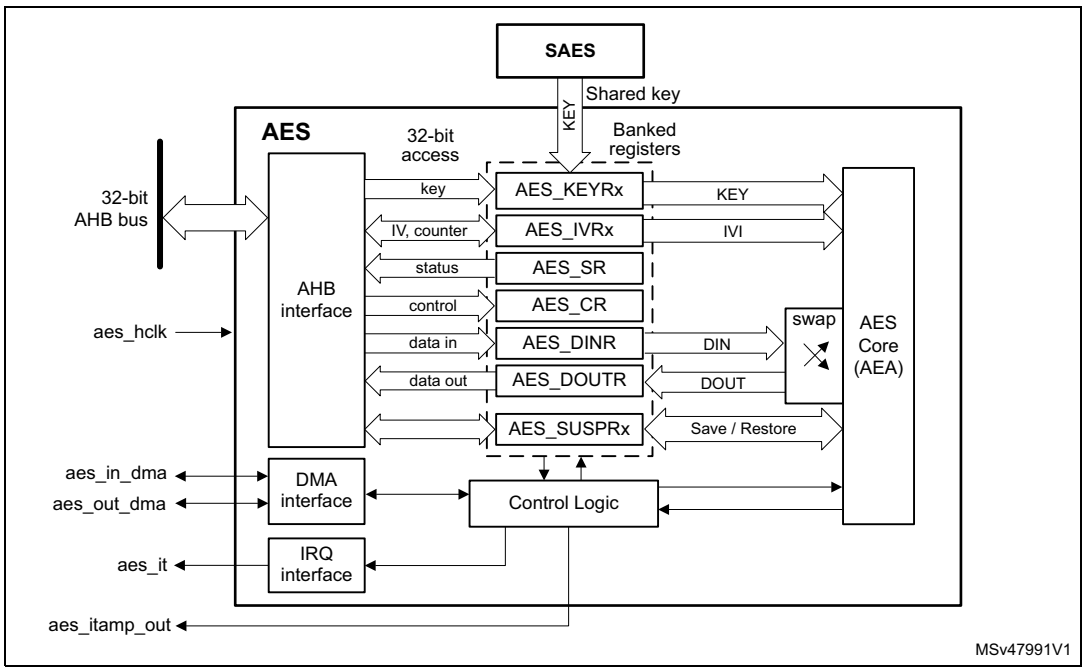
1. X = supported.

33.4 AES functional description

33.4.1 AES block diagram

Figure 291 shows the block diagram of AES.

Figure 291. AES block diagram



33.4.2 AES internal signals

Table 300 describes the user relevant internal signals interfacing the AES peripheral.

Table 300. AES internal input/output signals

Signal name	Signal type	Description
aes_hclk	Input	AHB bus clock
aes_it	Output	AES interrupt request
aes_in_dma	Input/Output	AES incoming data DMA single request/acknowledge
aes_out_dma	Input/Output	AES processed data DMA single request/acknowledge
aes_itamp_out	Output	Tamper event signal to TAMP (XOR-ed), triggered when an unexpected hardware fault occurs. When this signal is triggered, AES automatically clears key registers. A reset is required for AES to be usable again.

33.4.3 AES reset and clocks

The AES peripheral is clocked by the AHB bus clock.

The AES has a dedicated reset bit in the RCC.

33.4.4 AES symmetric cipher implementation

The AES hardware accelerator (AES) is a 32-bit AHB peripheral that encrypts or decrypts 16-byte blocks of data using the advanced encryption standard (AES). It also implements a set of approved AES symmetric key security functions summarized in *Table 301*. Those functions can be certified NIST PUB 140-3.

Table 301. AES approved symmetric key functions

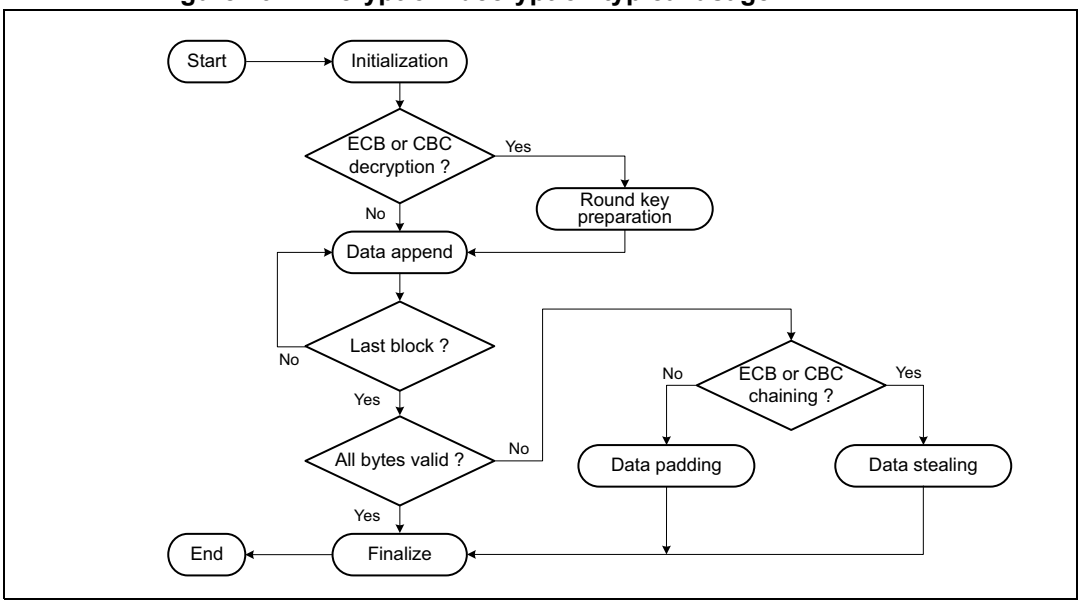
Operations	Algorithm	Specification	Key bit lengths	Chaining modes
Encryption, decryption	AES	FIPS PUB 197 NIST SP800-38A	128, 256	ECB, CBC, CTR
Authenticated encryption or decryption		NIST SP800-38C NIST SP800-38D		GCM, CCM
Cipher-based message authentication code		NIST SP800-38D		GMAC

AES can be used directly by the CPU, or indirectly, using two DMA channels (one for the plaintext, one for the ciphertext).
It is possible to suspend then resume any AES processing, following the sequence described in *Section 33.4.8*.

33.4.5 AES encryption or decryption typical usage

The following figure shows a typical operation for encryption or decryption.

Figure 292. Encryption/ decryption typical usage



Initialization

The AES peripheral is initialized according to the chaining mode. Refer to *Section 33.4.9: AES basic chaining modes (ECB, CBC)* and *Section 33.4.10: AES counter (CTR) mode* for details.

Data append

This section describes different ways of appending data for processing. For ECB or CBC chaining modes, refer to *Section 33.4.7: AES ciphertext stealing and data padding* if the size of data to process is not a multiple of 16 bytes. The last block management in these cases is more complex than what is described in this section.

Appending data using the CPU in polling mode

This method uses flag polling to control the data append through the following sequence:

1. When KEYVALID is set, enable the AES peripheral, by setting the EN bit of the AES_CR register (if not already done).
2. Repeat the following sub-sequence until the payload is entirely processed:
   a) Write four input data words into the AES_DINR register.
   b) Wait until the status flag CCF is set in the AES_ISR register, then read the four data words from the AES_DOUTR register.
   c) Clear the CCF flag, by setting the CCF bit of the AES_ICR register.
   d) If the next processing block is the last block, pad (when applicable) the data with zeros to obtain a complete block, and specify the number of non-valid bytes (using

NPBLB[3:0]) in case of GCM payload encryption or CCM payload decryption (otherwise the tag computation is wrong).

3. As the data block just processed is the last block of the message, optionally discard the data that is not part of the message/payload, then disable the AES peripheral by clearing EN.

Note: Up to three wait cycles are automatically inserted between two consecutive writes to the AES_DINR register, to allow sending the key to the AES processor.

NPBLB[3:0] bitfield is not used in header phase of GCM, GMAC and CCM chaining modes.

Appending data using the CPU in interrupt mode

The method uses interrupt from the AES peripheral to control the data append, through the following sequence:

1. Enable interrupts from AES, by setting the CCFIE bit of the AES_IER register.
2. When KEYVALID is set, enable the AES peripheral, by setting EN (if not already done).
3. Write first four input data words into the AES_DINR register.
4. Handle the data in the AES interrupt service routine. Upon each interrupt:
   a) Read four output data words from the AES_DOUTR register.
   b) Clear the CCF flag and thus the pending interrupt, by setting the CCF bit of the AES_ICR register.
   c) If the next processing block is the last block of the message, pad (when applicable) the data with zeros to obtain a complete block, and specify the number of non-valid bytes (through NPBLB[3:0]) in case of GCM payload encryption or CCM payload decryption (otherwise the tag computation is wrong). Then proceed with point 4e).
   d) If the data block just processed is the last block of the message, optionally discard the data that are not part of the message/payload, then disable the AES peripheral by clearing EN and quit the interrupt service routine.
   e) Write next four input data words into the AES_DINR register and quit the interrupt service routine.

Note: AES is tolerant of delays between consecutive read or write operations, which allows, for example, an interrupt from another peripheral to be served between two AES computations.

The NPBLB[3:0] bitfield is not used in the header phase of GCM, GMAC, and CCM chaining modes.

Appending data using DMA

With this method, all the transfers and processing are managed by DMA and AES. Proceed as follows:

1. If the last block of the message to process is shorter than 16 bytes, prepare the last four-word data block by padding the remainder of the block with zeros.
2. Configure the DMA controller so as to transfer the data to process from the memory to the AES peripheral input and the processed data from the AES peripheral output to the memory, as described in *Section 33.6: AES DMA requests*. Configure the DMA controller so as to generate an interrupt on transfer completion. For GCM payload encryption or CCM payload decryption, the DMA transfer **must not** include the last four-word block if padded with zeros. The sequence described in *Appending data using the CPU in polling mode* must be used instead for this last block, because the

NPBLB[3:0] bitfield must be set up before processing the block, for AES to compute a correct tag.

3. When KEYVALID is set, enable the AES peripheral, by setting EN (if not already done).
4. Enable DMA requests, by setting DMAINEN and DMAOUTEN.
5. Upon DMA interrupt indicating the transfer completion, get the AES-processed data from the memory.

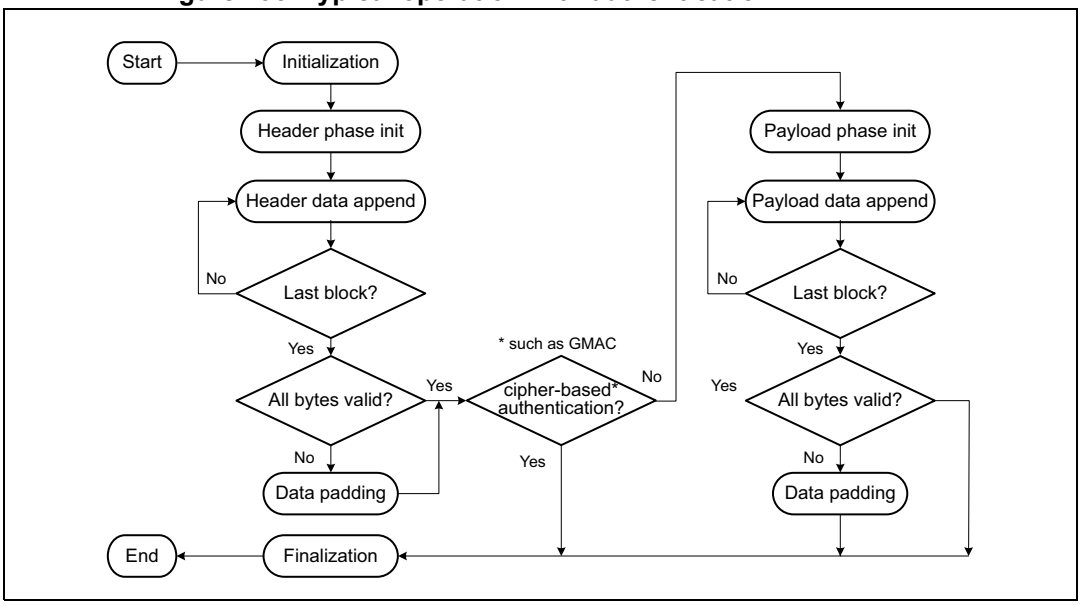
Note: The CCF flag has no use with this method because the reading of the AES_DOUTR register is managed by DMA automatically, without any software action, at the end of the computation phase.

The NPBLB[3:0] bitfield is not used in the header phase of GCM, GMAC, and CCM chaining modes.

33.4.6 AES authenticated encryption, decryption, and cipher-based message authentication

The following figure shows a typical operation for authenticated encryption or decryption, and for cipher-based message authentication.

Figure 293. Typical operation with authentication



Section 33.4.11: AES Galois/counter mode (GCM) and *Section 33.4.13: AES counter with CBC-MAC (CCM)* describe detailed sequences supported by AES.

Cipher-based message authentication flow omits the payload phase, as shown in the figure. Detailed sequence supported by AES is described in *Section 33.4.12: AES Galois message authentication code (GMAC)*.

33.4.7 AES ciphertext stealing and data padding

When using AES in ECB or CBC modes to manage messages the size of which is not a multiple of the block size (16 bytes), the application must use ciphertext stealing techniques such as those described in NIST *Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation: Three Variants of Ciphertext Stealing for CBC Mode*. Since

AES does not implement such techniques, the application must complete the *last block* of input data using data from the *second last* block.

Note: Ciphertext stealing techniques are not documented in this reference manual.

Similarly, in modes other than ECB or CBC, an incomplete input data block (that is, a block with input data shorter than 16 bytes) must be padded with zeros prior to encryption. That is, extra bits must be appended to the trailing end of the data string. After decryption, the extra bits must be discarded. Since AES does not implement automatic data padding operation to the *last block*, the application must follow the recommendation given in this document to manage messages the size of which is not a multiple of 16 bytes.

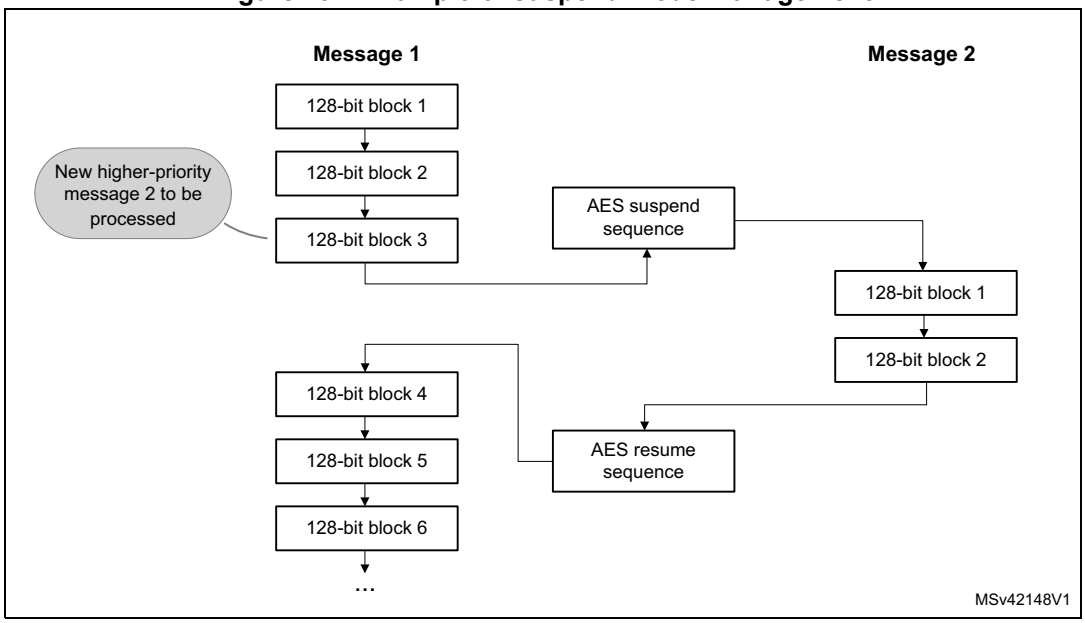
33.4.8 AES suspend and resume operations

A message can be suspended to process another message with a higher priority. When the higher-priority message is sent, the suspended message can resume. This applies to both encryption and decryption mode.

Suspend and resume operations do not break the chaining operation. The message processing can resume as soon as AES is enabled again, to receive a next data block.

Figure 294 gives an example of suspend and resume operations: Message 1 is suspended in order to send a shorter and higher-priority Message 2.

Figure 294. Example of suspend mode management



A detailed description of suspend and resume operations is in the sections dedicated to each chaining mode.

33.4.9 AES basic chaining modes (ECB, CBC)

ECB is the simplest mode of operation. There are no chaining operations, and no special initialization stage. The message is divided into blocks and each block is encrypted or decrypted separately. When decrypting in ECB, a special key scheduling is required before processing the first block.

Figure 295 and *Figure 296* describe the electronic codebook (ECB) chaining implementation in encryption and in decryption, respectively. To select ECB chaining mode, write CHMOD[2:0] with 0x0.

Figure 295. ECB encryption

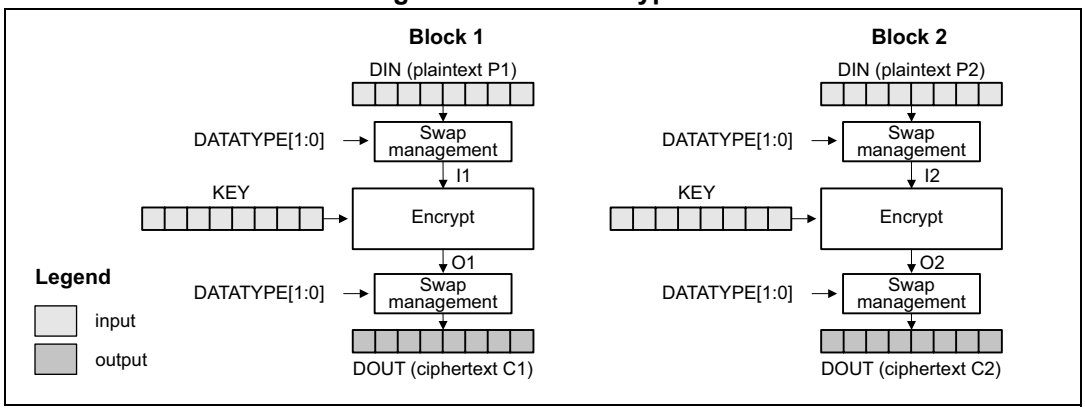


Figure 296. ECB decryption

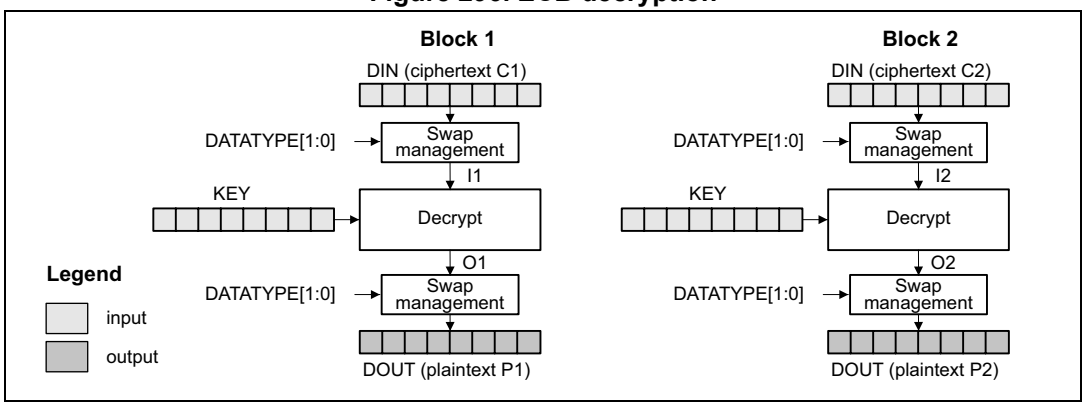

In CBC encryption mode the output of each block chains with the input of the following block. To make each message unique, an initialization vector is used during the first block processing. When decrypting in CBC, a special key scheduling is required before processing the first block.

Figure 297 and *Figure 298* describe the cipher block chaining (CBC) implementation in encryption and in decryption, respectively. To select this chaining mode, write CHMOD[2:0] with 0x1.

Figure 297. CBC encryption

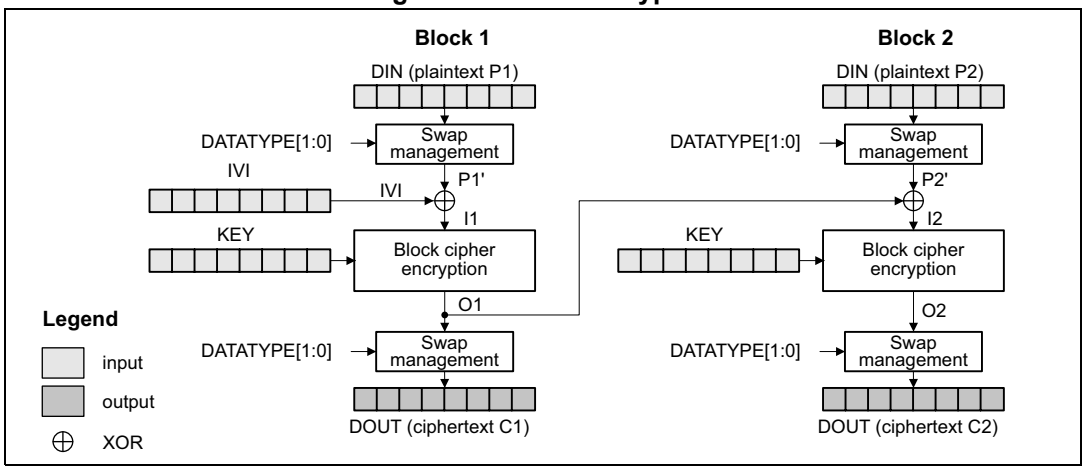

Figure 298. CBC decryption

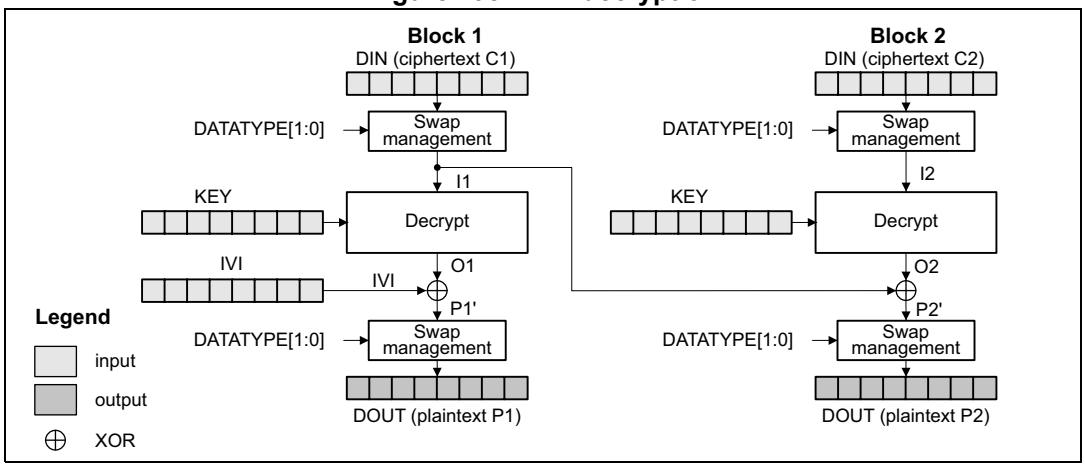


For more details, refer to NIST *Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation.*

ECB and CBC encryption process

This process is described in *Section 33.4.5*, with the following sequence of events:

1. Disable the AES peripheral, by clearing EN.
2. Initialize the AES_CR register as follows:
   - Select ECB or CBC chaining mode (write CHMOD[2:0] with 0x0 or 0x1) in *encryption* mode (write MODE[1:0] with 0x0).
   - Configure the data type, through DATATYPE[1:0].
   - Configure the key size, through KEYSIZE.
   - Select the key mode, using KMOD[1:0]. If the key comes from the SAES peripheral, write KMOD[1:0] with 0x2, otherwise keep it at 0x0.

3. Write the initialization vector into the AES_IVRx registers if CBC mode is selected in the previous step.
4. Write the key into the AES_KEYRx registers if KMOD[1:0] is at 0x0. If KMOD[1:0] is at 0x2, the key is transferred from the SAES peripheral (see *Section 33.4.14*).
5. Wait until KEYVALID is set (the key loading completed).
6. Enable the AES peripheral, by setting EN.
7. Append cleartext data:
   a) If it is the second-last or the last block and the plaintext size of the message is not a multiple of 16 bytes, follow the guidance in *Section 33.4.7*.
   b) Append the cleartext block into AES as described in *Section 33.4.5*, then read the AES_DOUTR register four times to save the ciphertext block.
   c) Repeat the step *b)* until the third-last plaintext block is encrypted. For the last two blocks, follow the steps *a)* and *b)*.
8. Finalize the sequence: disable the AES peripheral, by clearing EN.

ECB/CBC decryption process

This process is described in *Section 33.4.5*, with the following sequence of events:

1. Disable the AES peripheral, by clearing EN.
2. Initialize the AES_CR register as follows:
   – Select the *key derivation* mode (write MODE[1:0] with 0x1). The CHMOD[2:0] bitfield is not significant during this operation.
   – Configure the data type, through DATATYPE[1:0].
   – Configure the key size, through KEYSIZE.
   – Select the key mode, using KMOD[1:0]. If the key comes from the SAES peripheral, write KMOD[1:0] with 0x2, otherwise keep it at 0x0.
3. Write the key into the AES_KEYRx registers if KMOD[1:0] is at 0x0. If KMOD[1:0] is at 0x2, the key is transferred from the SAES peripheral (see *Section 33.4.14*).
4. Wait until KEYVALID is set (the key loading completed).
5. Enable the AES peripheral, by setting EN. The peripheral immediately starts an AES round for key preparation.
6. Wait until the CCF flag in the AES_ISR register is set.
7. Clear the CCF flag, by setting the CCF bit of the AES_ICR register. The decryption key is available in the AES core and AES is disabled automatically.
8. Select ECB or CBC chaining mode (write CHMOD[2:0] with 0x0 or 0x1) in *decryption* mode (write MODE[1:0] with 0x2). Do not change other parameters.
9. Write the initialization vector into the AES_IVRx registers if CBC mode is selected in the previous step.
10. Enable the AES peripheral, by setting EN.

11. Append encrypted data:
    a) If it is the second-last or the last block and the ciphertext size of the message is not a multiple of 16 bytes, follow the guidance in *Section 33.4.7*.
    b) Append the ciphertext block into AES as described in *Section 33.4.5*, then read the AES_DOUTR register four times to save the cleartext block (MSB first).
    c) Repeat the step *b)* until the third-last ciphertext block is decrypted. For the last two blocks, follow the steps *a)* and *b)*.
12. Finalize the sequence: disable the AES peripheral, by clearing EN.

Suspend/resume operations in ECB/CBC modes

To suspend the processing of a message, proceed as follows:

1. If DMA is used, stop the AES DMA transfers to the input FIFO, by clearing the DMAINEN bit of the AES_CR register.
2. If DMA is not used, read four times the AES_DOUTR register to save the last processed block. If DMA is used, wait until the CCF flag is set in the AES_ISR register then stop the DMA transfers from the output FIFO, by clearing the DMAOUTEN bit of the AES_CR register.
3. If DMA is not used, wait until the CCF flag in the AES_ISR register is set (computation completed).
4. Clear the CCF flag, by setting the CCF bit of the AES_ICR register.
5. Save initialization vector registers (only required in CBC mode as the AES_IVRx registers are altered during the data processing).
6. Disable the AES peripheral, by clearing EN.
7. Save the AES_CR register and clear the key registers if they are not needed, to process the higher-priority message.
8. If DMA is used, save the DMA controller status (pointers for AES input and output data transfers, number of remaining bytes, and so on).

To resume the processing of a message, proceed as follows:

1. If DMA is used, configure the DMA controller so as to complete the remaining input FIFO and output FIFO transfers.
2. Disable the AES peripheral, by clearing EN.
3. Restore the AES_CR register (with correct KEYSIZE) then restore the AES_KEYRx registers. If KMOD[1:0] is at 0x2, the key must be transferred again from the SAES peripheral (see *Section 33.4.14*).
4. Prepare the decryption key, as described in *ECB/CBC decryption process* (only required for ECB or CBC decryption).
5. Restore the AES_IVRx registers, using the saved configuration (only required in CBC mode).
6. Enable the AES peripheral, by setting EN.
7. If DMA is used, enable AES DMA transfers, by setting DMAINEN and DMAOUTEN.

Note: It is not required to save the key registers as the application knows the original key.

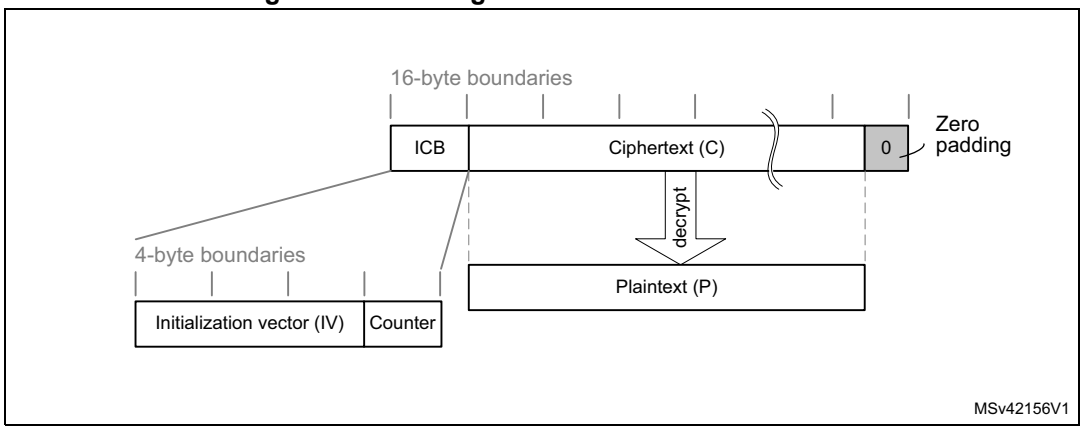
33.4.10 AES counter (CTR) mode

The CTR mode uses the AES core to generate a key stream. The keys are then XOR-ed with the plaintext to obtain the ciphertext. Unlike with ECB and CBC modes, no key

scheduling is required for the CTR decryption since the AES core is always used in encryption mode.

A typical message construction in CTR mode is given in *Figure 299*.

Figure 299. Message construction in CTR mode



The structure of this message is:

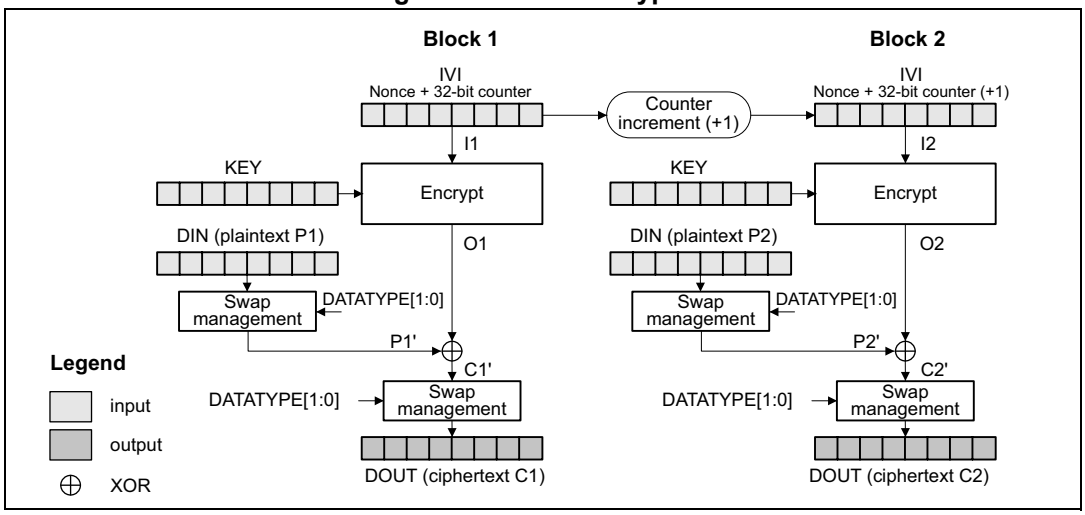
- A 16-byte initial counter block (ICB), composed of two distinct fields:
  - **Initialization vector** (IV): a 96-bit value that must be unique for each encryption cycle with a given key.
  - **Counter**: a 32-bit big-endian integer that is incremented each time a block processing is completed. The initial value of the counter must be set to 1.
- The plaintext P is encrypted as ciphertext C, with a known length. This length can be non-multiple of 16 bytes, in which case a plaintext padding is required.

For more details, refer to NIST *Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation.*

CTR encryption and decryption

Figure 300 describes the counter (CTR) chaining implementation in the AES peripheral (encryption). To select this chaining mode, write CHMOD[2:0] with 0x2.

Figure 300. CTR encryption



Initialization vectors in AES must be initialized as shown in *Table 302*.

Table 302. Counter mode initialization vector definition

AES_IVR3[31:0]	AES_IVR2[31:0]	AES_IVR1[31:0]	AES_IVR0[31:0]
IVI[127:96]	IVI[95:64]	IVI[63:32]	IVI[31:0] 32-bit counter = 0x0001

CTR encryption and decryption process

This process is described in *Section 33.4.5*, with the following sequence of events:

1. Disable the AES peripheral, by clearing EN.
2. Initialize the AES_CR register:
   - Select CTR chaining mode (write CHMOD[2:0] with 0x2) in encryption or decryption mode (write MODE[1:0] with 0x0 or 0x2).
   - Configure the data type, through DATATYPE[1:0].
   - Configure the key size, through KEYSIZE.
   - Select the key mode, using KMOD[1:0]. If the key comes from the SAES peripheral, write KMOD[1:0] with 0x2, otherwise keep it at 0x0.
3. Write the initialization vector into the AES_IVRx registers according to *Table 302*.
4. Write the key into the AES_KEYRx registers if KMOD[1:0] is at 0x0. If KMOD[1:0] is at 0x2, the key is transferred from the SAES peripheral (see *Section 33.4.14*).
5. Wait until KEYVALID is set (the key loading completed).
6. Enable the AES peripheral, by setting EN.
7. Append data:
   a) If it is the last block and the plaintext (encryption) or ciphertext (decryption) size in the block is less than 16 bytes, pad the remainder of the block with zeros.
   b) Append the data block into AES as described in *Section 33.4.5*, then read the AES_DOUTR register four times to save the resulting block (MSB first).
   c) Repeat the step *b)* until the second-last block is processed. For the last block of plaintext (encryption only), follow the steps *a)* and *b)*. For the last block, discard

the bits that are not part of the message when the last block is smaller than 16 bytes.

8. Finalize the sequence: disable the AES peripheral, by clearing EN.

Suspend/resume operations in CTR mode

Like for the CBC mode, it is possible to interrupt a message to send a higher-priority message, then resume the interrupted message. Detailed CBC suspend and resume sequence is described in *Section 33.4.9: AES basic chaining modes (ECB, CBC)*.

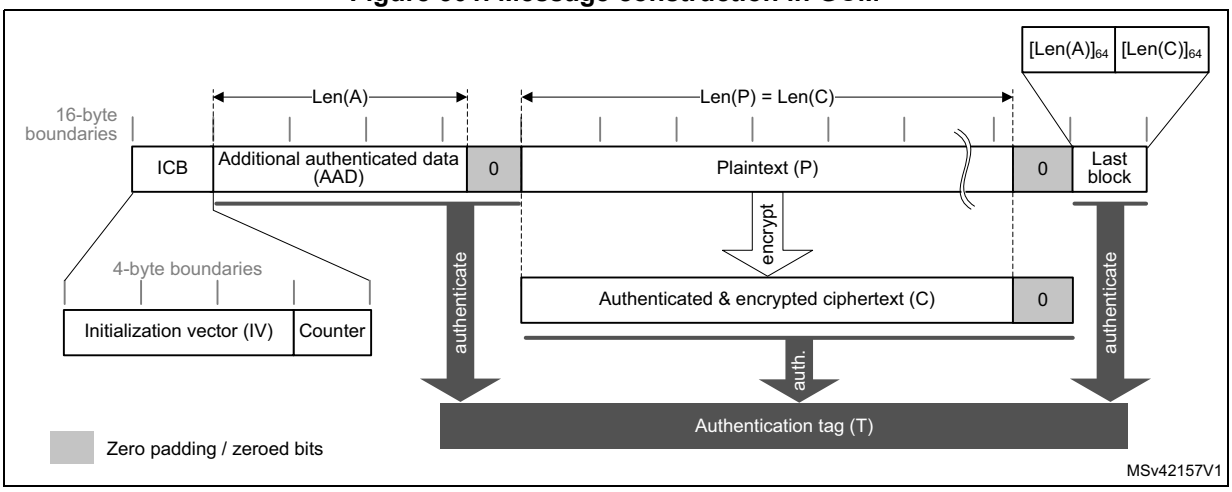
Note: Like for CBC mode, the IV registers must be reloaded during the resume operation.

33.4.11 AES Galois/counter mode (GCM)

The AES Galois/counter mode (GCM) allows encrypting and authenticating a plaintext message into the corresponding ciphertext and tag (also known as message authentication code).

GCM mode is based on AES in counter mode for confidentiality. It uses a multiplier over a fixed finite field for computing the message authentication code. The following figure shows a typical message construction in GCM mode.

Figure 301. Message construction in GCM



The message has the following structure:

- **16-byte initial counter block (ICB)**, composed of two distinct fields:
  - **Initialization vector (IV):** a 96-bit value that must be unique for each encryption cycle with a given key. The GCM standard supports IVs with less than 96 bits, but in this case strict rules apply.
  - **Counter:** a 32-bit big-endian integer that is incremented each time a block processing is completed. According to NIST specification, the counter value is 0x2 when processing the first block of payload.
- **Authenticated header AAD** (also knows as additional authentication data) has a known length Len(A) that may be a non-multiple of 16 bytes, and must not exceed $2^{64} – 1$ bits. This part of the message is only authenticated, not encrypted.

- **Plaintext message P** is both authenticated and encrypted as ciphertext C, with a known length Len(P) that may be non-multiple of 16 bytes, and cannot exceed 2^{32} - 2 16-byte blocks.
- **Last block** contains the AAD header length (bits [32:63]) and the payload length (bits [96:127]) information, as shown in *Table 304*.

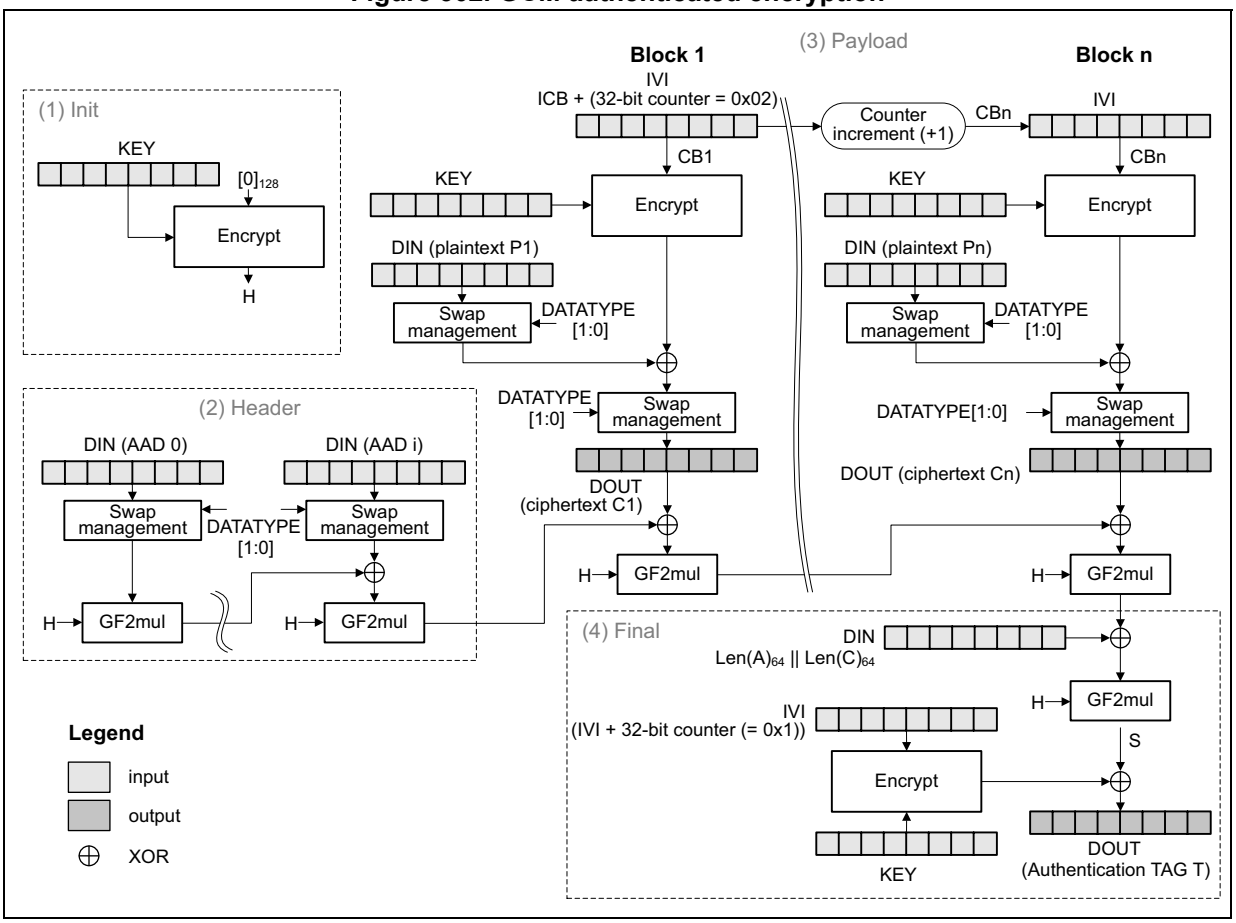
The GCM standard specifies that ciphertext C has the same bit length as the plaintext P.

When a part of the message (AAD or P) has a length that is a non-multiple of 16-bytes a special padding scheme is required.

For more details, refer to NIST *Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.*

Figure 302 describes the GCM chaining implementation in the AES peripheral (encryption). To select this chaining mode, write CHMOD[2:0] with 0x3.

Figure 302. GCM authenticated encryption



The first counter block (CB1) is derived from the initial counter block ICB by the application software, as defined in *Table 303*.

Table 303. Initialization of IV registers in GCM mode

AES_IVR3[31:0]	AES_IVR2[31:0]	AES_IVR1[31:0]	AES_IVR0[31:0]
ICB[127:96]	ICB[95:64]	ICB[63:32]	ICB[31:0] 32-bit counter = 0x0002

The last block of a GCM message contains the AAD header length and the payload length information, as shown in *Table 304*.

Table 304. GCM last block definition

Word order to AES_DINR	First word	Second word	Third word	Fourth word
Input data	AAD length[63:32]	AAD length[31:0]	Payload length[63:32]	Payload length[31:0]

GCM encryption and decryption process

This process is described in *Section 33.4.6*, with the following sequence of events:

GCM initialize

1. Disable the AES peripheral, by clearing EN.
2. Initialize the AES_CR register:
   - Select GCM chaining mode (write CHMOD[2:0] with 0x3) in encryption or decryption mode (write MODE[1:0] with 0x0 or 0x2). Do not write MODE[1:0] with 0x1.
   - Configure the data type, through DATATYPE[1:0]
   - Configure the key size, through KEYSIZE.
   - Select the key mode, using KMOD[1:0]. If the key comes from the SAES peripheral, write KMOD[1:0] with 0x2, otherwise keep it at 0x0.
   - Select the GCM initialization phase, by writing GCMPH[1:0] with 0x0.
3. Write the initialization vector in AES_IVRx registers according to *Table 303*.
4. Write the key into the AES_KEYRx registers if KMOD[1:0] is at 0x0. If KMOD[1:0] is at 0x2, the key is transferred from the SAES peripheral (see *Section 33.4.14*).
5. Wait until KEYVALID is set (the key loading completed).
6. Set EN to start the calculation of the hash key. EN is automatically cleared when the calculation is completed.
7. Wait until the CCF flag is set in the AES_ISR register, indicating that the GCM hash subkey (H) computation is completed.
8. Clear the CCF flag by setting the CCF bit of the AES_ICR register.

GCM header phase

9. Initialize header phase:
   a) Select the GCM header phase, by writing 0x1 to GCMPH[1:0]. Do not change the other configurations written during GCM initialization.
   b) Enable the AES peripheral, by setting EN.

10. Append header data:
    a) If it is the last block and the AAD in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
    b) Append the data block into AES as described in *Section 33.4.5*.
    c) Repeat the step *b)* until the second-last AAD data block is processed. For the last block, follow the steps *a)* and *b)*.

Note: This phase can be skipped if there is no AAD, that is, Len(A) = 0.

No data are read during header phase.

GCM payload phase

11. Initialize payload phase:
    a) Select the GCM payload phase, by writing GCMPH[1:0] with 0x2. Do not change the other configurations written during GCM initialization.
    b) If the header phase is skipped, enable the AES peripheral by setting EN.
12. Append payload data:
    a) If it is the last block and the message in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
    b) Append the data block into AES as described in *Section 33.4.5*, then read the AES_DOUTR register four times to save the resulting block
    c) Repeat the step *b)* until the second-last plaintext block is encrypted or until the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), follow the steps *a)* and *b)*. For the last block, discard the bits that are not part of the payload when the last block is smaller than 16 bytes.

Note: This phase can be skipped if there is no payload, that is, Len(C)=0 (see GMAC mode).

GCM finalization

13. Select the GCM final phase, by writing GCMPH[1:0] with 0x3. Do not change the other configurations written during GCM initialization.
14. Write the final GCM block into the AES_DINR register. It is the concatenated AAD bit and payload bit lengths, as shown in *Table 304*.
15. Wait until the CCF flag in the AES_ISR register is set.
16. Get the GCM authentication tag, by reading the AES_DOUTR register four times.
17. Clear the CCF flag, by setting the CCF bit in AES_ICR register.
18. Disable the AES peripheral, by clearing EN. If it is an authenticated decryption, compare the generated tag with the expected tag passed with the message.

Note: In the final phase, data are written to AES_DINR normally (no swapping), while swapping is applied to tag data read from AES_DOUTR.

When transiting from the header or the payload phase to the final phase, the AES peripheral must not be disabled, otherwise the result is wrong.

Suspend/resume operations in GCM mode

To suspend the processing of a message, proceed as follows:

1. If DMA is used, stop the AES DMA transfers to the input FIFO, by clearing DMAINEN. If DMA is not used, wait until the CCF flag in the AES_ISR register is set (computation completed).
2. In the payload phase, if DMA is not used, read four times the AES_DOUTR register to save the last-processed block. If DMA is used, wait until the CCF flag in the AES_ISR register is set then stop the DMA transfers from the output FIFO, by clearing DMAOUTEN.
3. Clear the CCF flag of the AES_ISR register, by setting the CCF bit of the AES_ICR register.
4. Save the AES_SUSPRx registers in the memory.
5. In the payload phase, save the AES_IVRx registers as, during the data processing, they changed from their initial values. In the header phase, this step is not required.
6. Disable the AES peripheral, by clearing EN.
7. Save the current AES_CR configuration in the memory. Key registers do not need to be saved as the original key value is known by the application.
8. If DMA is used, save the DMA controller status (pointer for AES input data transfers, number of remaining bytes, and so on). In the payload phase, also save the pointer for AES output data transfers.

To resume the processing of a message, proceed as follows:

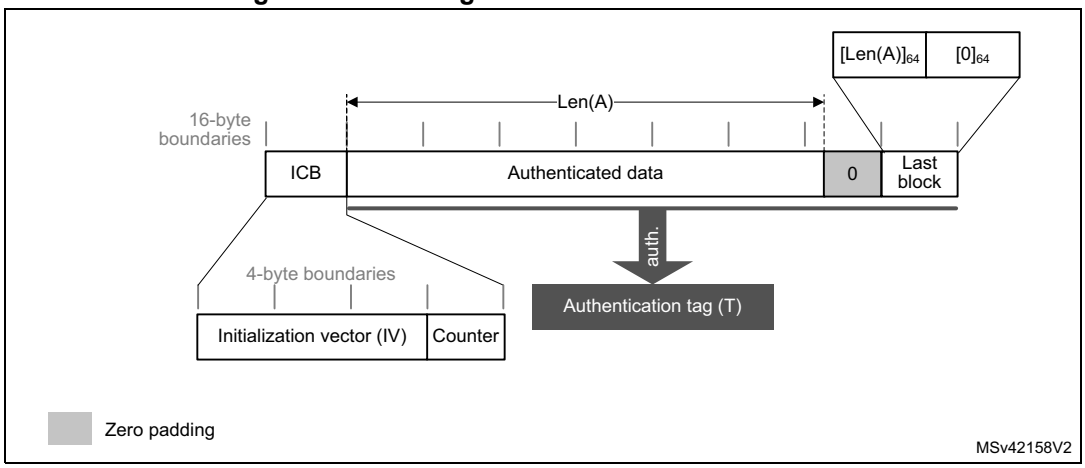
1. If DMA is used, configure the DMA controller in order to complete the remaining input FIFO transfers. In the payload phase, also configure the DMA controller for the remaining output FIFO transfers.
2. Disable the AES peripheral, by clearing EN.
3. Write the suspend register values, previously saved in the memory, back into their corresponding AES_SUSPRx registers.
4. In the payload phase, write the initialization vector register values, previously saved in the memory, back into their corresponding AES_IVRx registers. In the header phase, write initial setting values back into the AES_IVRx registers.
5. Restore the initial setting values in the AES_CR and AES_KEYRx registers if KMOD[1:0] is at 0x0. If KMOD[1:0] is at 0x2, the key is transferred from the SAES peripheral (see *Section 33.4.14*).
6. Enable the AES peripheral, by setting EN.
7. If DMA is used, enable AES DMA requests, by setting DMAINEN (and DMAOUTEN if in payload phase).

33.4.12 AES Galois message authentication code (GMAC)

The Galois message authentication code (GMAC) allows the authentication of a plaintext, generating the corresponding tag information (also known as message authentication code).

GMAC is similar to GCM, except that it is applied on a message composed only by plaintext authenticated data (that is, only header, no payload). The following figure shows typical message construction for GMAC.

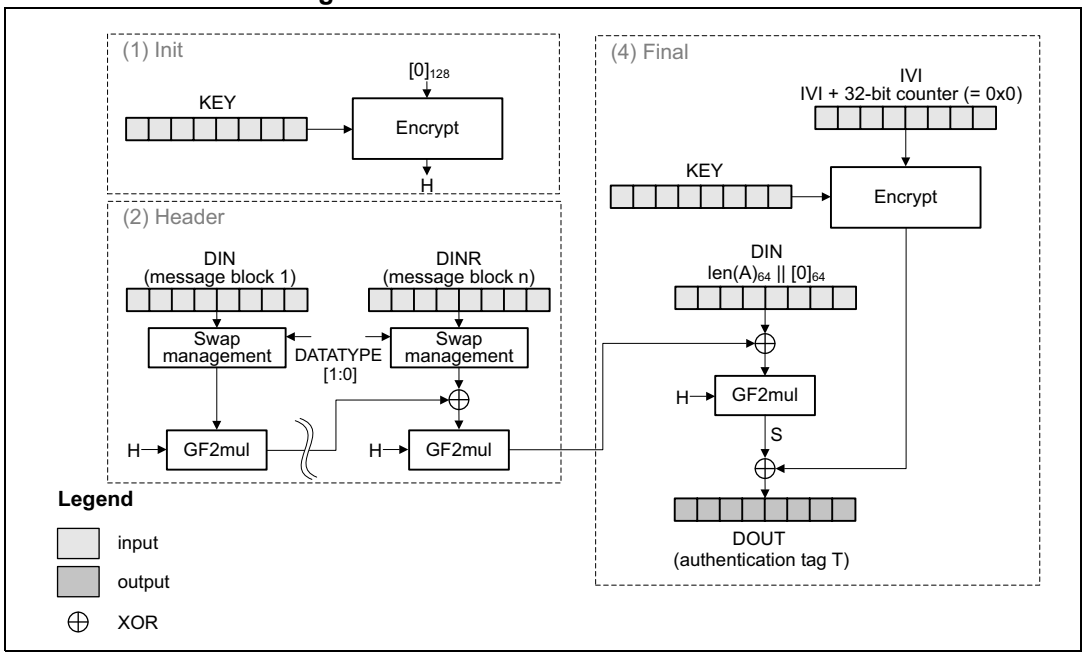
Figure 303. Message construction in GMAC mode



For more details, refer to NIST *Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.*

Figure 304 describes the GMAC chaining implementation in the AES peripheral. To select this chaining mode, write CHMOD[2:0] with 0x3.

Figure 304. GMAC authentication mode



The GMAC algorithm corresponds to the GCM algorithm applied on a message that only contains a header. As a consequence, all steps and settings are the same as with the GCM, except that the payload phase is omitted.

Suspend/resume operations in GMAC

In GMAC mode, the sequence described for the GCM applies except that only the header phase can be interrupted.

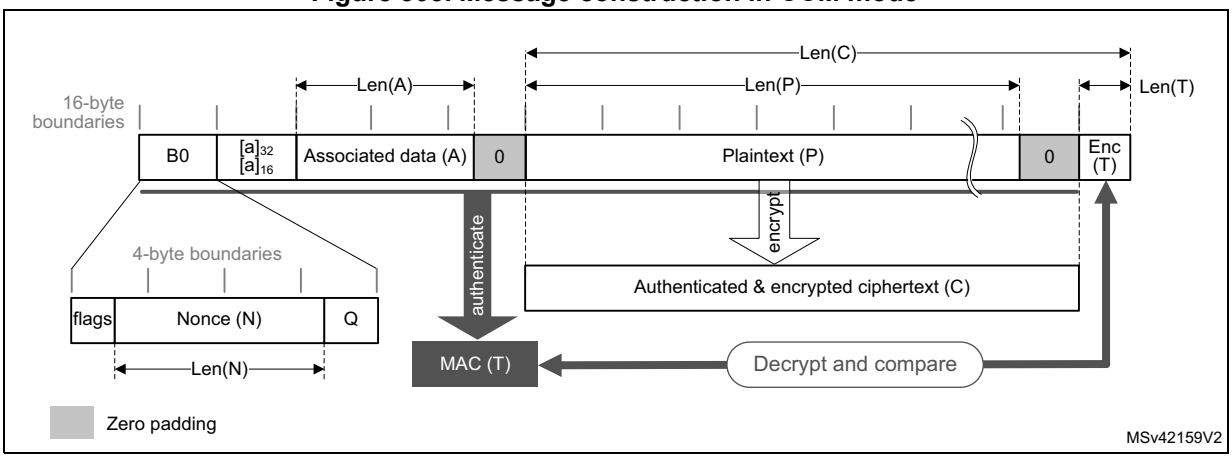
33.4.13 AES counter with CBC-MAC (CCM)

The AES counter with cipher block chaining-message authentication code (CCM) algorithm allows encryption and authentication of plaintext, generating the corresponding ciphertext and tag (also known as message authentication code). To ensure confidentiality, the CCM algorithm is based on AES counter mode processing. It uses cipher block chaining technique to generate the message authentication code. This is commonly called CBC-MAC.

Note: NIST does not approve CBC-MAC as an authentication mode outside the context of the CCM specification.

The following figure shows typical message construction for CCM.

Figure 305. Message construction in CCM mode



The structure of the message is:

- **16-byte first authentication block (B0)**, composed of three distinct fields:
  - **Q:** a bit string representation of the octet length of P (Len(P))
  - **Nonce (N):** a single-use value (that is, a new nonce must be assigned to each new communication) of Len(N) size. The sum Len(N) + Len(P) must be equal to 15 bytes.
  - **Flags:** most significant octet containing four flags for control information, as specified by the standard. It contains two 3-bit strings to encode the values **t** (MAC length expressed in bytes) and **Q** (plaintext length such that Len(P) < 2^{8Q} bytes). The counter blocks range associated to **Q** is equal to 2^{8Q-4}, that is, if the maximum value of **Q** is 8, the counter blocks used in cipher must be on 60 bits.
- **16-byte blocks (B)** associated to the associated data (A).
  This part of the message is only authenticated, not encrypted. This section has a known length Len(A) that can be a non-multiple of 16 bytes (see *Figure 305*). The standard also states that, on MSB bits of the first message block (B1), the associated data length expressed in bytes (a) must be encoded as follows:
  - If $0 < a < 2^{16} - 2^8$, then it is encoded as $[a]_{16}$, that is, on two bytes.
  - If $2^{16} - 2^8 < a < 2^{32}$, then it is encoded as 0xff || 0xfe || $[a]_{32}$, that is, on six bytes.
  - If $2^{32} < a < 2^{64}$, then it is encoded as 0xff || 0xff || $[a]_{64}$, that is, on ten bytes.

- **16-byte blocks (B)** associated to the plaintext message P, which is both authenticated and encrypted as ciphertext C, with a known length Len(P). This length can be a non-multiple of 16 bytes (see *Figure 305*).
- **Encrypted MAC (T)** of length Len(T) appended to the ciphertext C of overall length Len(C).

When a part of the message (A or P) has a length that is a non-multiple of 16-bytes, a special padding scheme is required.

Note: CCM chaining mode can also be used with associated data only (that is, no payload).

As an example, the C.1 section in NIST Special Publication 800-38C gives the following values (hexadecimal numbers):

N: 10111213 141516 (Len(N) = 56 bits or 7 bytes)

A: 00010203 04050607 (Len(A) = 64 bits or 8 bytes)

P: 20212223 (Len(P) = 32 bits or 4 bytes)

T: 6084341B (Len(T) = 32 bits or t = 4)

B0: 4F101112 13141516 00000000 00000004
B1: 00080001 02030405 06070000 00000000
B2: 20212223 00000000 00000000 00000000

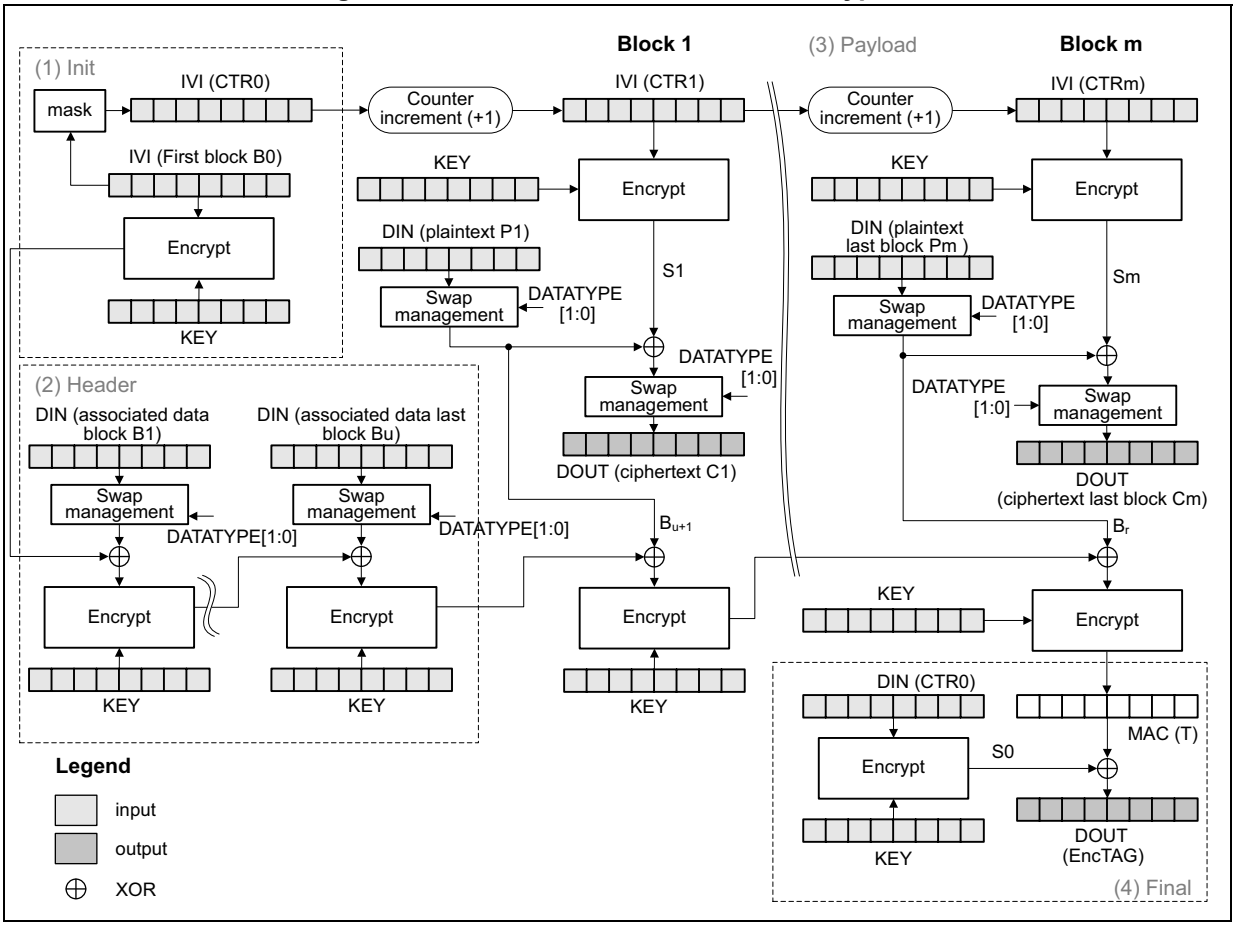
CTR0: 0710111213 141516 00000000 00000000

CTR1: 0710111213 141516 00000000 00000001

For more details, refer to NIST *Special Publication 800-38C, Recommendation for Block Cipher Modes of Operation - The CCM Mode for Authentication and Confidentiality*.

Figure 306 describes the CCM chaining implementation in the AES peripheral (encryption). To select this chaining mode, write CHMOD[2:0] with 0x4.

Figure 306. CCM mode authenticated encryption



The first block of a CCM message (B0) must be prepared by the application as defined in *Table 305*.

Table 305. Initialization of IV registers in CCM mode

AES_IVR3[31:0]	AES_IVR2[31:0]	AES_IVR1[31:0]	AES_IVR0[31:0]
B0[127:96](1)	B0[95:64]	B0[63:32]	B0[31:0](2)

1. The 5 most significant bits are cleared (flag bits).
2. Q length bits are cleared, except for the bit 0 that is set.

AES supports counters up to 64 bits, as specified by NIST.

CCM encryption and decryption process

This process is described in *Section 33.4.6*, with the following sequence of events:

CCM initialize

1. Disable the AES peripheral, by clearing EN.
2. Initialize the AES_CR register:
   - Select CCM chaining mode (write CHMOD[2:0] with 0x4) in encryption or decryption mode (write MODE[1:0] with 0x0 or 0x2). Do not write MODE[1:0] with 0x1.
   - Configure the data type, through DATATYPE[1:0]
   - Configure the key size, through KEYSIZE.
   - Select the key mode, using KMOD[1:0]. If the key comes from the SAES peripheral, write KMOD[1:0] with 0x2, otherwise keep it at 0x0.
   - Select the CCM initialization phase, by writing GCMPH[1:0] with 0x0.
3. Write the B0 data in AES_IVRx registers according to *Table 305*.
4. Write the key into the AES_KEYRx registers if KMOD[1:0] is at 0x0. If KMOD[1:0] is at 0x2, the key is transferred from the SAES peripheral (see *Section 33.4.14*).
5. Wait until KEYVALID is set (the key loading completed).
6. Set EN to start the first mask calculation. The EN bit is automatically cleared when the calculation is completed.
7. Wait until the CCF flag in the AES_ISR register is set.
8. Clear the CCF flag, by setting the CCF bit of the AES_ICR register.

CCM header phase

9. Initialize header phase:
   a) Prepare the first block of the (B1) data associated with the message, in accordance with CCM chaining rules.
   b) Select the CCM header phase, by writing GCMPH[1:0] with 0x1. Do not change the other configurations written during the CCM initialization.
   c) Enable the AES peripheral, by setting EN.
10. Append header data:
    a) If it is the last block and the associated data in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
    b) Append the data block into AES as described in *Section 33.4.5*.
    c) Repeat the step *b)* until the second-last associated data block is processed. For the last block, follow the steps *a)* and *b)*.

Note: This phase can be skipped if there is no associated data, that is, Len(A) = 0

No data are read during the header phase.

CCM payload phase

11. Initialize payload phase:
    a) Select the CCM payload phase, by writing GCMPH[1:0] with 0x2. Do not change the other configurations written during the CCM initialization.
    b) If the header phase is skipped, enable the AES peripheral, by setting EN.

12. Append payload data:
    a) In encryption only, if it is the last block and the plaintext in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
    b) Append the data block into AES as described in *Section 33.4.5*, then read the AES_DOUTR register four times to save the resulting block.
    c) Repeat the step *b)* until the second-last plaintext block is encrypted or until the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), follow the steps *a)* and *b)*. For the last block, discard the bits that are not part of the payload when the last block is smaller than 16 bytes.

Note: This phase can be skipped if there is no payload, that is, Len(P) = 0 or Len(C) = Len(T).

Remove $LSB_{Len(T)}(C)$ encrypted tag information when decrypting ciphertext C.

CCM finalization

13. Select the CCM final phase, by writing GCMPH[1:0] with 0x3. Do not change the other configurations written during the CCM initialization.
14. Wait until CCF flag in the AES_ISR register is set.
15. Get the CCM authentication tag, by reading the AES_DOUTR register four times.
16. Clear the CCF flag, by setting the CCF bit of the AES_ICR register.
17. Disable the AES peripheral, by clearing EN. If it is an authenticated decryption, compare the generated tag with the expected tag passed with the message. Mask the authentication tag output with tag length to obtain a valid tag.

Note: In the final phase, swapping is applied to tag data read from AES_DOUTR register.

When transiting from the header or the payload phase to the final phase, the AES peripheral must not be disabled, otherwise the result is wrong.

Suspend and resume operations in CCM mode

To suspend the processing of a message in header or payload phase, proceed as follows:

1. If DMA is used, stop the AES DMA transfers to the input FIFO, by clearing DMAINEN. If DMA is not used, wait until the CCF flag of the AES_ISR register is set (computation completed).
2. In the payload phase, if DMA is not used, read four times the AES_DOUTR register to save the last-processed block. If DMA is used, wait until the CCF flag in the AES_ISR register is set, then stop the DMA transfers from the output FIFO, by clearing DMAOUTEN.
3. Clear the CCF flag in the AES_ISR register, by setting the CCF bit of the AES_ICR register.
4. Save the AES_SUSPRx registers in the memory.
5. Save the IV registers as they are altered during the data processing.
6. Disable the AES peripheral, by clearing EN.
7. Save the current AES_CR configuration in the memory. Key registers do not need to be saved as the original key value is known by the application.
8. If DMA is used, save the DMA controller status (pointer for AES input data transfers, number of remaining bytes, and so on). In the payload phase, also save pointer for AES output data transfers.

To resume the processing of a message, proceed as follows:

1. If DMA is used, configure the DMA controller in order to complete the remaining input FIFO transfers. In the payload phase, also configure the DMA controller for the remaining output FIFO transfers.
2. Disable the AES peripheral, by clearing EN.
3. Write the suspend register values, previously saved in the memory, back into their corresponding AES_SUSPRx registers.
4. Restore AES_IVRx registers using the saved configuration.
5. Restore the initial setting values in the AES_CR and AES_KEYRx registers if KMOD[1:0] is at 0x0. If KMOD[1:0] is at 0x2, the key must be transferred again from the SAES peripheral (see *Section 33.4.14*).
6. Enable the AES peripheral, by setting EN.
7. If DMA is used, enable AES DMA requests, by setting DMAINEN (and DMAOUTEN if in payload phase).

33.4.14 AES key sharing with secure AES co-processor

The AES peripheral can use the SAES peripheral as security co-processor. The secure application prepares the key in the robust SAES peripheral and when it is ready, the AES application can load this prepared key through a dedicated hardware key bus.

The recommended sequence is described hereafter and in the section *SAES operations with shared keys* in the *SAES* section of this document.

1. In SAES peripheral, the application encrypts (wraps) the key to share in Shared-key mode (KMOD[1:0] at 0x2).
2. Each time the shared key is required in AES peripheral, the application decrypts it in the SAES peripheral in Shared-key mode (KMOD[1:0] at 0x2).
3. Once the shared key is decrypted (unwrapped) and loaded in SAES_KEYRx registers it can be shared with AES. To load the shared key in AES, the application sets KEYSIZE as appropriate and writes KMOD[1:0] with 0x2. When KEYVALID is cleared, the key is automatically transfered by hardware into the AES_KEYRx registers and the BUSY flag in the AES_SR register set.
4. Once the key transfer is completed, the BUSY flag is cleared and the KEYVALID flag set in the AES_SR register. If KEYVALID is not set when BUSY bit is cleared, or if the KEIF flag is set in the AES_ISR register, either the KEYSIZE value is incorrect or an unexpected event occurred during the transfer (such as DPA error, tamper event or KEYVALID cleared before the end of the transfer). When such errors occur, reset both peripherals through their IPRST bits and restart the whole key sharing process.

When the key sharing sequence is completed, the AES is initialized with a valid, shared key. The application can then process data in normal key mode, by writing KMOD[1:0] with 0x0.

Note: This sequence in AES peripheral can be run multiple times (for example, to manage a suspend/resume situation), as long as SAES peripheral is unused and duly remains in key sharing state.

33.4.15 AES data registers and data swapping

Data input and output

A 16-byte data block enters the AES peripheral with four successive 32-bit word writes into the AES_DINR register (bitfield DIN[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

A 16-byte data block is retrieved from the AES peripheral with four successive 32-bit word reads of the AES_DOUTR register (bitfield DOUT[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

The four 32-bit words of a 16-byte data block must be stored in the memory consecutively and in big-endian order, that is, with the most significant word on the lowest address. See *Table 306* “no swapping” option for details.

Data swapping

The AES peripheral can be configured to perform a bit-, a byte-, a half-word-, or no swapping on the input data word in the AES_DINR register, before loading it to the AES processing core, and on the data output from the AES processing core, before sending it to the AES_DOUTR register. The choice depends on the type of data. For example, a byte swapping is used for an ASCII text stream.

The data swap type is selected through DATATYPE[1:0]. The selection applies to both AES input and output.

Note: The data in AES key registers (AES_KEYRx) and initialization vector registers (AES_IVRx) are not sensitive to the swap mode selection.

The AES data swapping feature is summarized in *Table 306* and *Figure 307*.

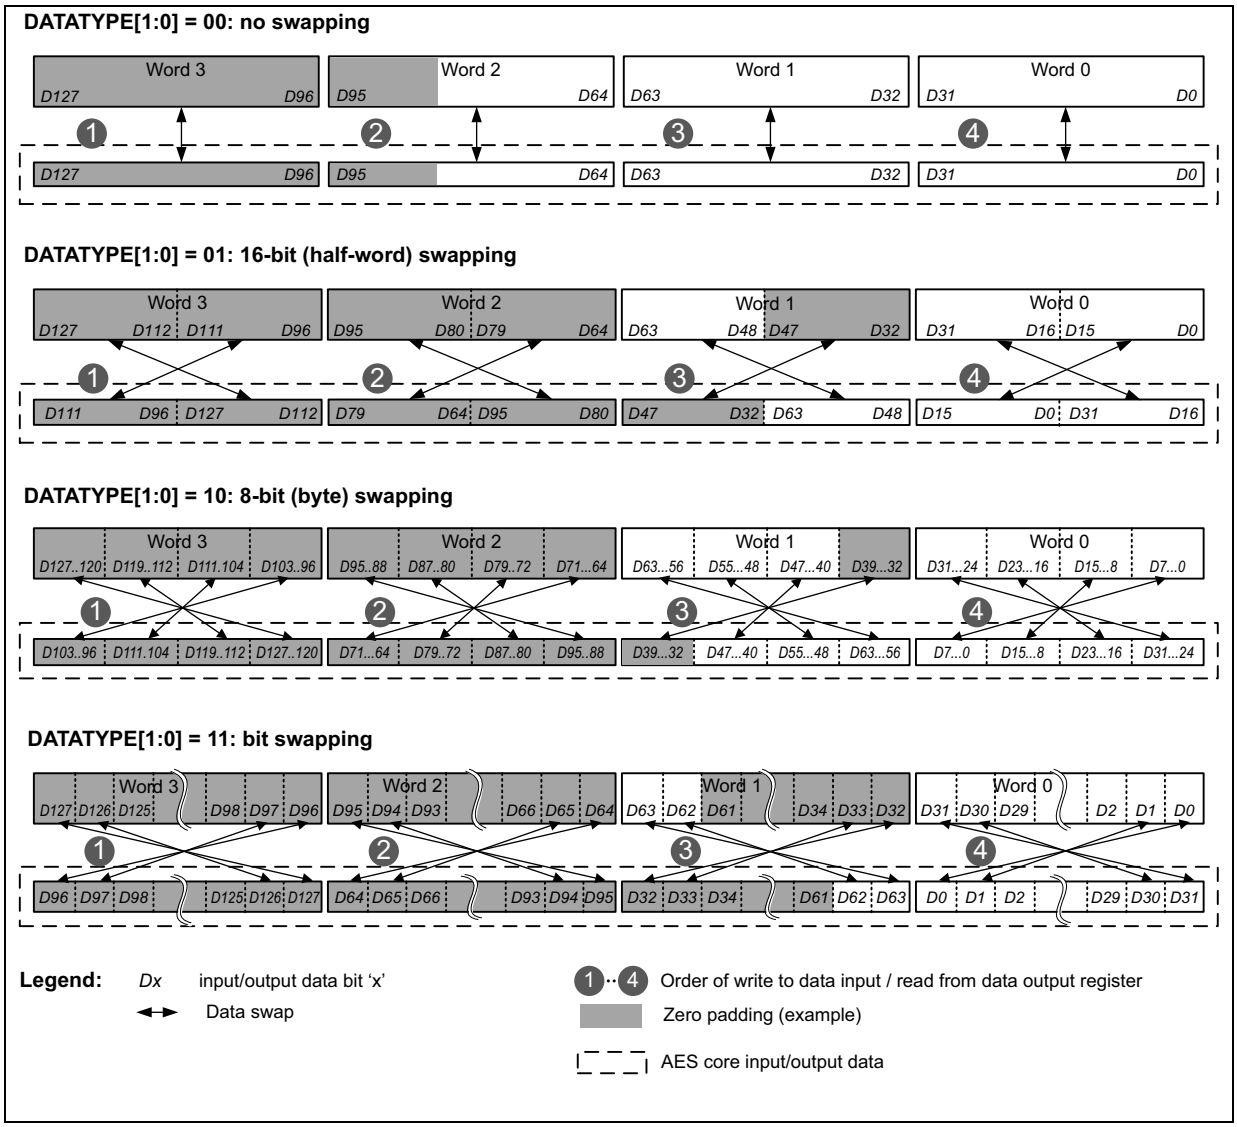
Table 306. AES data swapping example

DATATYPE[1:0]	Swapping performed	Data block
		System memory data (big-endian)
0x0	No swapping	Block[127..64]: 0x04EEF672 2E04CE96 Block[63..0]: 0x4E6F7720 69732074
		Address @, word[127..96]: 0x04EEF672 Address @ + 0x4, word[95..64]: 0x2E04CE96 Address @ + 0x8, word[63..32]: 0x4E6F7720 Address @ + 0xC, word[31..0]: 0x69732074
0x1	Half-word (16-bit) swapping	Block[63..0]: 0x**4E6F** 7720 **6973** 2074
		Address @, word[63..32]: 0x7720 **4E6F** Address @ + 0x4, word[31..0]: 0x2074 **6973**
0x2	Byte (8-bit) swapping	Block[63..0]: 0x**4E** 6F **77** 20 **69** 73 **20** 74
		Address @, word[63..32]: 0x20**77** 6F**4E** Address @ + 0x4, word[31..0]: 0x74**20** 73**69**

Table 306. AES data swapping example (continued)

DATATYPE[1:0]	Swapping performed	Data block
		System memory data (big-endian)
0x3	Bit swapping	Block[63..32]: 0x4E6F7720 0100 1110 0110 1111 0111 0111 0010 0000 Block[31..0]: 0x69732074 0110 1001 0111 0011 0010 0000 0111 0100
		Address @, word[63..32]: 0x04EE F672 0000 0100 1110 1110 1111 0110 0111 0010 Address @ + 0x4, word[31..0]: 0x2E04 CE96 0010 1110 0000 0100 1100 1110 1001 0110

Figure 307. 128-bit block construction according to the data type



Data padding

Figure 307 also gives an example of memory data block padding with zeros such that the zeroed bits after the data swap form a contiguous zone at the MSB end of the AES core input buffer. The example shows the padding of an input data block containing:

- 84 message bits, with DATATYPE[1:0] = 0x0
- 48 message bits, with DATATYPE[1:0] = 0x1
- 56 message bits, with DATATYPE[1:0] = 0x2
- 34 message bits, with DATATYPE[1:0] = 0x3

33.4.16 AES key registers

The eight AES_KEYRx write-only registers store the encryption or decryption key information, as shown on *Table 307*. Reads are not allowed for security reason.

Note: In memory and in AES *key registers, keys are stored in little-endian format, with most significant byte on the highest address.*

Table 307. Key endianness in AES_KEYRx registers (128/256-bit keys)

AES_KEYR7 [31:0]	AES_KEYR6 [31:0]	AES_KEYR5 [31:0]	AES_KEYR4 [31:0]	AES_KEYR3 [31:0]	AES_KEYR2 [31:0]	AES_KEYR1 [31:0]	AES_KEYR0 [31:0]
-	-	-	-	KEY[127:96]	KEY[95:64]	KEY[63:32]	KEY[31:0]
KEY[255:224]	KEY[223:192]	KEY[191:160]	KEY[159:128]	KEY[127:96]	KEY[95:64]	KEY[63:32]	KEY[31:0]

The key registers are not affected by the data swapping feature controlled by the DATATYPE[1:0] bitfield.

Write operations to the AES_KEYRx registers are ignored when AES peripheral is enabled (EN bit set). The application must check this before modifying key registers.

The entire key must be written before starting an AES computation. In normal key mode (KMOD[1:0] at 0x0), the key registers must always be written in either ascending or descending order. The write sequence becomes:

- AES_KEYRx (x = 0 to 3 or x=3 to 0) for KEYSIZE cleared
- AES_KEYRx (x = 0 to 7 or x=7 to 0) for KEYSIZE set

Note: KEYSIZE must be written before the key.

As soon as the first key register is written, the KEYVALID flag is cleared. Once the key registers writing sequence is completed, KEYVALID is set and EN becomes writable. If an error occurs, KEYVALID is cleared and KEIF set (see *Section 33.4.18*).

33.4.17 AES initialization vector registers

The four AES_IVRx registers store the initialization vector (IV) information, as shown in *Table 308*. They can only be written if the AES peripheral is disabled (EN cleared).

Note: In memory and in AES IV registers, initialization vectors are stored in little-endian format, with most significant byte on the highest address.

Table 308. IVI bitfield spread over AES_IVRx registers

AES_IVR3[31:0]	AES_IVR2[31:0]	AES_IVR1[31:0]	AES_IVR0[31:0]
IVI[127:96]	IVI[95:64]	IVI[63:32]	IVI[31:0]

Initialization vector information depends on the chaining mode selected. When used, AES_IVRx registers are updated upon each AES computation cycle (useful for managing suspend mode).

The initialization vector registers are not affected by the data swapping feature controlled through DATATYPE[1:0].

33.4.18 AES error management

The AES peripheral manages the errors described in this section.

Read error flag (RDERRF)

Unexpected read attempt of the AES_DOUTR register returns zero, setting the RDERRF flag and the RWEIF flag. RDERRF is triggered during the computation phase or during the input phase.

Note: AES is not disabled when RDERRF rises and it continues processing.

An interrupt is generated if the RWEIE bit is set. For more details, refer to *Section 33.5: AES interrupts*.

The RDERRF and RWEIF flags are cleared by setting the RWEIF bit of the AES_ICR register.

Write error flag (WDERR)

Unexpected write attempt of the AES_DINR register is ignored, setting the WRERRF and the RWEIF flags. WRERRF is triggered during the computation phase or during the output phase.

Note: AES is not disabled when WRERRF rises and it continues processing.

An interrupt is generated if the RWEIE bit is set. For more details, refer to *Section 33.5: AES interrupts*.

The WRERRF and RWEIF flags are cleared by setting the RWEIF bit of the AES_ICR register.

Key error interrupt flag (KEIF)

There are multiple sources of errors that set the KEIF flag of the AES_ISR register and clear the KEYVALID bit of the AES_SR register:

- **Key writing sequence error:** triggered upon detecting an incorrect sequence of writing key registers. See *Section 33.4.16: AES key registers* for details.
- **Key sharing size mismatch error:** triggered when KMOD[1:0] is at 0x2 and KEYSIZE in AES peripheral does not match KEYSIZE in SAES peripheral.

- **Key sharing error:** triggered upon failing transfer of SAES shared key to AES peripheral. See *Section 33.4.14: AES key sharing with secure AES co-processor* for details.

The KEIF flag is cleared with corresponding bit of the AES_ICR register. An interrupt is generated if the KEIE bit of the AES_IER register is set. For more details, refer to *Section 33.5: AES interrupts*.

Upon a key sharing error, reset both AES and SAES peripherals through the IPRST bit of their corresponding control register, then restart the key sharing sequence.

Note: For any key error, clear KEIF flag prior to disabling and re-configuring AES.

33.5 AES interrupts

There are multiple individual maskable interrupt sources generated by the AES peripheral to signal the following events:

- computation completed (CCF)
- read error (RDERRF)
- write error (WRERRF)
- key error (KEIF)

See *Section 33.4.18: AES error management* for details on AES errors.

These sources are combined into a common interrupt signal from the AES peripheral that connects to the Cortex® CPU interrupt controller. Application can enable or disable AES interrupt sources individually by setting/clearing the corresponding enable bit of the AES_IER register.

The status of the individual maskable interrupt sources can be read from the AES_ISR register. They are cleared by setting the corresponding bit of the AES_ICR register.

Table 309 gives a summary of the available features.

Table 309. AES interrupt requests

Interrupt acronym	Interrupt event	Event flag	Enable bit	Interrupt clear method
AES	computation completed flag	CCF	CCFIE	set CCF(1)
	read error flag	RDERRF(2)	RWEIE	set RWEIF(1)
	write error flag	WRERRF(2)		
	key error flag	KEIF	KEIE	set KEIF(1)

1. Bit of the AES_ICR register.
2. Flag of the AES_SR register, mirrored by the flag RWEIF of the AES_ISR register.

33.6 AES DMA requests

The AES peripheral provides an interface to connect to the DMA (direct memory access) controller. The DMA operation is controlled through the DMAINEN and DMAOUTEN bits of the AES_CR register. When key derivation is selected (MODE[1:0] is at 0x1), setting those bits has no effect.

AES only supports single DMA requests.

Detailed usage of DMA with AES can be found in *Appending data using DMA* subsection of *Section 33.4.5: AES encryption or decryption typical usage*.

Data input using DMA

Setting DMAINEN enables DMA writing into AES. AES then initiates, during the input phase, a set of single DMA requests for each 16-byte data block to write to the AES_DINR register (quadruple 32-bit word, MSB first).

Note: According to the algorithm and the mode selected, special padding / ciphertext stealing might be required (see Section 33.4.7).

Data output using DMA

Setting DMAOUTEN enables DMA reading from AES. AES then initiates, during the output phase, a set of single DMA requests for each 16-byte data block to read from the AES_DOUTR register (quadruple 32-bit word, MSB first).

After the output phase, at the end of processing of a 16-byte data block, AES switches automatically to a new input phase for the next data block, if any.

In DMA mode, the CCF flag has no use because the reading of the AES_DOUTR register is managed by DMA automatically at the end of the computation phase. The CCF flag must only be cleared when transiting back to managing the data transfers by software.

Note: According to the message size, extra bytes might need to be discarded by application in the last block.

Stopping DMA transfers

All DMA request signals are de-asserted when AES is disabled (EN cleared) or the DMA enable bit (DMAINEN for input data, DMAOUTEN for output data) is cleared.

33.7 AES processing latency

The following tables provide the 16-byte data block processing latency per operating mode.

Table 310. Processing latency for ECB, CBC and CTR

Key size	Mode of operation	Chaining algorithm	Clock cycles
128-bit	Encryption or decryption(1)	ECB, CBC, CTR	51
	Key preparation	-	59
256-bit	Encryption or decryption(1)	ECB, CBC, CTR	75
	Key preparation	-	82

1. Excluding key preparation time (ECB and CBC only).

Table 311. Processing latency for GCM and CCM (in clock cycles)

Key size	Mode of operation	Chaining algorithm	Initialization phase	Header phase(1)	Payload phase(1)	Final phase(1)
128-bit	Encryption/ Decryption	GCM	64	35	51	59
		CCM	63	55	114	58

Table 311. Processing latency for GCM and CCM (in clock cycles) (continued)

Key size	Mode of operation	Chaining algorithm	Initialization phase	Header phase(1)	Payload phase(1)	Final phase(1)
256-bit	Encryption/ Decryption	GCM	88	35	75	75
		CCM	87	79	162	82

1. Data insertion can include wait states forced by AES on the AHB bus (maximum 3 cycles, typical 1 cycle).

33.8 AES registers

The registers are accessible through 32-bit word single accesses only. Other access types generate an AHB error, and other than 32-bit writes may corrupt the register content.

33.8.1 AES control register (AES_CR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IPRST	Res.	Res.	Res.	Res.	Res.	KMOD[1:0]		NPBLB[3:0]				Res.	KEYSIZE	Res.	CHMOD[2]
rw						rw	rw	rw	rw	rw	rw		rw		rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	GCMPH[1:0]		DMAOUTEN	DMAINEN	Res.	Res.	Res.	Res.	CHMOD[1:0]		MODE[1:0]		DATATYPE[1:0]		EN
	rw	rw	rw	rw					rw	rw	rw	rw	rw	rw	rw

Bit 31 **IPRST**: AES peripheral software reset

Setting the bit resets the AES peripheral, putting all registers to their default values, except the IPRST bit itself. Hence, any key-relative data are lost. For this reason, it is recommended to set the bit before handing over the AES to a less secure application.

The bit must be kept low while writing any configuration registers.

Bits 30:26 Reserved, must be kept at reset value.

Bits 25:24 **KMOD[1:0]**: Key mode selection

The bitfield defines how the AES key can be used by the application. KEYSIZE must be correctly initialized when setting KMOD[1:0] different from zero.

0x0: Normal key mode. Key registers are freely usable.

0x2: Shared key mode. If shared key mode is properly initialized in SAES peripheral, the AES peripheral automatically loads its key registers with the data stored in the SAES key registers. The key value is available in AES key registers when BUSY bit is cleared and KEYVALID is set in the AES_SR register. Key error flag KEIF is set otherwise in the AES_ISR register.

Others: Reserved

Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bits 23:20 **NPBLB[3:0]:** Number of padding bytes in last block

This padding information must be filled by software before processing the last block of GCM payload encryption or CCM payload decryption, otherwise authentication tag computation is incorrect.

0x0: All bytes are valid (no padding)

0x1: Padding for the last LSB byte

...

0xF: Padding for the 15 LSB bytes of last block.

Bit 19 Reserved, must be kept at reset value.

Bit 18 **KEYSIZE:** Key size selection
This bitfield defines the key length in bits of the key used by AES.
0: 128-bit
1: 256-bit
Attempts to write the bit are ignored when BUSY is set, as well as when the EN is set before the write access and it is not cleared by that write access.

Bit 17 Reserved, must be kept at reset value.

Bit 15 Reserved, must be kept at reset value.

Bits 14:13 **GCMPH[1:0]:** GCM or CCM phase selection
This bitfield selects the phase, applicable only with GCM, GMAC or CCM chaining modes.
0x0: Initialization phase
0x1: Header phase
0x2: Payload phase
0x3: Final phase

Bit 12 **DMAOUTEN**: DMA output enable
This bit enables automatic generation of DMA requests during the data phase, for outgoing data transfers from AES via DMA.
0: Disable
1: Enable
Setting this bit is ignored when MODE[1:0] is at 0x1 (key derivation).

Bit 11 **DMAINEN**: DMA input enable
This bit enables automatic generation of DMA requests during the data phase, for incoming data transfers to AES via DMA.
0: Disable
1: Enable
Setting this bit is ignored when MODE[1:0] is at 0x1 (key derivation).

Bits 10:7 Reserved, must be kept at reset value.

Bits 16, 6:5 **CHMOD[2:0]**: Chaining mode
This bitfield selects the AES chaining mode:
0x0: Electronic codebook (ECB)
0x1: Cipher-block chaining (CBC)
0x2: Counter mode (CTR)
0x3: Galois counter mode (GCM) and Galois message authentication code (GMAC)
0x4: Counter with CBC-MAC (CCM)
others: Reserved
Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bits 4:3 **MODE[1:0]**: Operating mode
This bitfield selects the AES operating mode:
0x0: Encryption
0x1: Key derivation (or key preparation), for ECB/CBC decryption only
0x2: Decryption
0x3: Reserved
Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bits 2:1 **DATATYPE[1:0]**: Data type

This bitfield defines the format of data written in the AES_DINR register or read from the AES_DOUTR register, through selecting the mode of data swapping. This swapping is defined in *Section 33.4.15: AES data registers and data swapping*.

0x0: No swapping (32-bit data).

0x1: Half-word swapping (16-bit data)

0x2: Byte swapping (8-bit data)

0x3: Bit-level swapping

Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bit 0 **EN**: Enable

This bit enables/disables the AES peripheral.

0: Disable

1: Enable

At any moment, clearing then setting the bit re-initializes the AES peripheral.

This bit is automatically cleared by hardware upon the completion of the key preparation (MODE[1:0] at 0x1) and upon the completion of GCM/GMAC/CCM initialization phase.

– The bit cannot be set as long as KEYVALID is cleared

33.8.2 AES status register (AES_SR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	KEYVALID	Res.	Res.	Res.	BUSY	WRERRF	RDERRF	Res.
								r				r	r	r	

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **KEYVALID**: Key valid flag

This bit is set by hardware when the key of size defined by KEYSIZE is loaded in AES_KEYRx key registers.

0: Key not valid

1: Key valid

The EN bit can only be set when KEYVALID is set.

In normal mode when KMOD[1:0] is at zero, the key must be written in the key registers in the correct sequence, otherwise the KEIF flag is set and KEYVALID remains cleared.

When KMOD[1:0] is different from zero, the BUSY flag is automatically set by AES. When the key is loaded successfully, BUSY is cleared and KEYVALID set. Upon an error, KEIF is usually set, BUSY cleared and KEYVALID remains cleared.

If set, KEIF must be cleared through the AES_ICR register, otherwise KEYVALID cannot be set. See the KEIF flag description for more details.

For further information on key loading, refer to *Section 33.4.16: AES key registers*.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **BUSY:** Busy

This flag indicates whether AES is idle or busy.

0: Idle

1: Busy

AES is flagged as idle when disabled (when EN is low) or when the last processing is completed.

AES is flagged as busy when processing a block data, preparing a key (ECB or CBC decryption only), or transferring a shared key from the SAES peripheral.

When GCM encryption is selected, this flag must be at zero before suspending current process to manage a higher-priority message.

Bit 2 **WRERRF**: Write error flag

This bit is set when an unexpected write to the AES_DINR register occurred. When set WRERRF bit has no impact on the AES operations.

0: No error

1: Unexpected write to AES_DINR register occurred during computation or data output phase.

The flag setting generates an interrupt if the RWEIE bit of the AES_IER register is set.

The flag is cleared by setting the RWEIF bit of the AES_ICR register.

Bit 1 **RDERRF**: Read error flag

This bit is set when an unexpected read to the AES_DOUTR register occurred. When set RDERRF bit has no impact on the AES operations.

0: No error

1: Unexpected read to AES_DOUTR register occurred during computation or data input phase.

The flag setting generates an interrupt if the RWEIE bit of the AES_IER register is set.

The flag is cleared by setting the RWEIF bit of the AES_ICR register.

Bit 0 Reserved, must be kept at reset value.

33.8.3 AES data input register (AES_DINR)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DIN[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DIN[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **DIN[31:0]**: Data input

A four-fold sequential write to this bitfield during the Input phase results in writing a complete 16-bytes block of input data to the AES peripheral. From the first to the fourth write, the corresponding data weights are [127:96], [95:64], [63:32], and [31:0]. Upon each write, the data from the 32-bit input buffer are handled by the data swap block according to the DATATYPE[1:0] bitfield, then written into the AES core 16-bytes input buffer.

Reads return zero.

33.8.4 AES data output register (AES_DOUTR)

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DOUT[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DOUT[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **DOUT[31:0]**: Data output

This read-only bitfield fetches a 32-bit output buffer. A four-fold sequential read of this bitfield, upon the computation completion (CCF flag set), virtually reads a complete 16-byte block of output data from the AES peripheral. Before reaching the output buffer, the data produced by the AES core are handled by the data swap block according to the DATATYPE[1:0] bitfield.

Data weights from the first to the fourth read operation are: [127:96], [95:64], [63:32], and [31:0].

33.8.5 AES key register 0 (AES_KEYR0)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
KEY[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
KEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **KEY[31:0]**: Cryptographic key, bits [31:0]

These are bits [31:0] of the write-only bitfield KEY[255:0] AES encryption or decryption key, depending on the MODE[1:0] bitfield of the AES_CR register.

Writes to AES_KEYRx registers are ignored when AES is enabled (EN bit set). When the key comes from the SAES peripheral (KMOD[1:0] at 0x2), writes to key registers are also ignored and they result in setting the KEIF bit of the AES_ISR register.

With KMOD[1:0] at 0x0, a special writing sequence is required. In this sequence, any valid write to AES_KEYRx register clears the KEYVALID flag except for the sequence-completing write that sets it. Also refer to the description of the KEYVALID flag in the AES_SR register.

33.8.6 AES key register 1 (AES_KEYR1)

Address offset: 0x014

Reset value: 0x0000 0000

IVI[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **IVI[31:0]**: Initialization vector input, bits [31:0]

AES_IVRx registers store the 128-bit initialization vector or the nonce, depending on the chaining mode selected. This value is updated by hardware after each computation round (when applicable). Write to this register is ignored when EN bit is set in AES_SR register

33.8.10 AES initialization vector register 1 (AES_IVR1)

Address offset: 0x024

Reset value: 0x0000 0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
KEY[239:224]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **KEY[255:224]**: Cryptographic key, bits [255:224]

Refer to the AES_KEYR0 register for description of the KEY[255:0] bitfield and for information relative to writing AES_KEYRx registers.

33.8.17 AES suspend registers (AES_SUSPRx)

Address offset: 0x040 + x * 0x4, (x = 0 to 7)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SUSP[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SUSP[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SUSP[31:0]**: Suspend data

AES_SUSPRx registers contain the complete internal register states of the AES when the GCM, GMAC or CCM processing of the current task is suspended to process a higher-priority task. Refer to *Section 33.4.8: AES suspend and resume operations* for more details.

Read to this register returns zero when EN bit is cleared in AES_SR register.

AES_SUSPRx registers are not used in other chaining modes than GCM, GMAC or CCM.

33.8.18 AES interrupt enable register (AES_IER)

Address offset: 0x300

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	KEIE	RWEIE	CCFIE
													rw	rw	rw

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **KEIE:** Key error interrupt enable

This bit enables or disables (masks) the AES interrupt generation when KEIF (key error flag) is set.

0: Disabled (masked)

1: Enabled (not masked)

Bit 1 **RWEIE:** Read or write error interrupt enable

This bit enables or disables (masks) the AES interrupt generation when RWEIF (read and/or write error flag) is set.

0: Disabled (masked)

1: Enabled (not masked)

Bit 0 **CCFIE:** Computation complete flag interrupt enable

This bit enables or disables (masks) the AES interrupt generation when CCF (computation complete flag) is set.

0: Disabled (masked)

1: Enabled (not masked)

33.8.19 AES interrupt status register (AES_ISR)

Address offset: 0x304

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	KEIF	RWEIF	CCF
													r	r	r

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **KEIF:** Key error interrupt flag

This read-only bit is set by hardware when the key information fails to load into key registers.

0: No key error detected

1: Key information failed to load into key registers

The flag setting generates an interrupt if the KEIE bit of the AES_IER register is set.

The flag is cleared by setting the corresponding bit of the AES_ICR register.

KEIF is raised upon any of the following events:

–AES_KEYRx register write does not respect the correct order. (For KEYSIZE cleared, AES_KEYR0 then AES_KEYR1 then AES_KEYR2 then AES_KEYR3 register, or reverse. For KEYSIZE set, AES_KEYR0 then AES_KEYR1 then AES_KEYR2 then AES_KEYR3 then AES_KEYR4 then AES_KEYR5 then AES_KEYR6 then AES_KEYR7, or reverse).

–AES fails to load the key shared by the SAES peripheral (KMOD[1:0] = 0x2).

KEIF must be cleared by the application software, otherwise KEYVALID cannot be set.

Bit 1 **RWEIF:** Read or write error interrupt flag

This read-only bit is set by hardware when a RDERRF or a WRERRF error flag is set in the AES_SR register.

0: No read or write error detected

1: Read or write error detected

The flag setting generates an interrupt if the RWEIE bit of the AES_IER register is set.

The flag is cleared by setting the corresponding bit of the AES_ICR register.

The flags has no meaning when key derivation mode is selected.

See the AES_SR register for details.

Bit 0 **CCF:** Computation complete flag

This flag indicates whether the computation is completed. It is significant only when the DMAOUTEN bit is cleared, and it may stay high when DMAOUTEN is set.

0: Not completed

1: Completed

The flag setting generates an interrupt if the CCFIE bit of the AES_IER register is set.

The flag is cleared by setting the corresponding bit of the AES_ICR register.

33.8.20 AES interrupt clear register (AES_ICR)

Address offset: 0x308

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	KEIF	RWEIF	CCF
													w	w	w

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **KEIF:** Key error interrupt flag clear
Setting this bit clears the KEIF status bit of the AES_ISR register.

Bit 1 **RWEIF:** Read or write error interrupt flag clear
Setting this bit clears the RWEIF status bit of the AES_ISR register, and clears both RDERRF and WRERRF flags in the AES_SR register.

Bit 0 **CCF:** Computation complete flag clear
Setting this bit clears the CCF status bit of the AES_ISR register.

33.8.21 AES register map

Table 312. AES register map and reset values

Refer to *Section 2.3 on page 111* for the register boundary addresses.

34 Secure AES coprocessor (SAES)

34.1 Introduction

The secure AES coprocessor (SAES) encrypts or decrypts data in compliance with the advanced encryption standard (AES) defined by NIST. It incorporates a protection against side-channel attacks (SCA), including differential power analysis (DPA), certified SESIP and PSA security assurance level 3.

SAES supports ECB, CBC, CTR, GCM, GMAC, and CCM chaining modes for key sizes of 128 or 256 bits, as well as special modes such as hardware secret key encryption/ decryption (Wrapped-key mode) and key sharing with faster AES peripheral (Shared-key mode).

SAES has the possibility to load by hardware STM32 hardware secret master keys (boot hardware key BHK and derived hardware unique key DHUK), usable but not readable by application.

The peripheral supports DMA single transfers for incoming and outgoing data (two DMA channels are required). It is hardware-linked with the true random number generator (TRNG) and with the AES peripheral.

34.2 SAES main features

- Compliant with NIST FIPS publication 197 *"Advanced encryption standard (AES)"* (November 2001)
- Encryption and decryption with multiple chaining modes:
  - Electronic codebook (ECB) mode
  - Cipher block chaining (CBC) mode
  - Counter (CTR) mode
  - Galois counter mode (GCM)
  - Galois message authentication code (GMAC) mode
  - Counter with CBC-MAC (CCM) mode
- Protection against side-channel attacks (SCA), incl. differential power analysis (DPA), certified SESIP and PSA security assurance level 3
- 128-bit data block processing, supporting cipher key lengths of 128-bit and 256-bit
  - 480 or 680 clock cycle latency in ECB mode for processing one 128-bit block with, respectively, 128-bit or 256-bit key
- Hardware secret key encryption/ decryption (Wrapped-key mode)
- Using dedicated key bus, optional key sharing with faster AES peripheral (Shared-key mode), controlled by SAES
- Integrated key scheduler to compute the last round key for ECB/CBC decryption
- 256-bit of write-only registers for storing cryptographic keys (eight 32-bit registers)
  - Optional 128-bit or 256-bit hardware loading of two hardware secret keys (BHK, DHUK) that can be XOR-ed together
- Security context enforcement for keys
- 128-bit of registers for storing initialization vectors (four 32-bit registers)
- 32-bit buffer for data input and output
- Automatic data flow control supporting two direct memory access (DMA) channels, one for incoming data, one for processed data. Only single transfers are supported.
- Data-swapping logic to support 1-, 8-, 16-, or 32-bit data
- AMBA AHB slave peripheral, accessible through 32-bit word single accesses only. Other access types generate an AHB error, and other than 32-bit writes may corrupt the register content.
- Possibility for software to suspend a message if SAES needs to process another message with a higher priority, then resume the original message

34.3 SAES implementation

The devices have one SAES peripheral, implemented as per the following table. It shares the key with the AES peripheral. For comparison, the AES peripheral is also included in the table.

Table 313. AES versus SAES features

Modes or features(1)	AES	SAES
ECB, CBC chaining	X	X
CTR, CCM, GCM chaining	X	X
AES 128-bit ECB encryption in cycles	51	480
DHUK and BHK key selection		X
Resistance to side-channel attacks	-	X
Shared key between SAES and AES	X	
Key sizes in bits	128, 256	128, 256

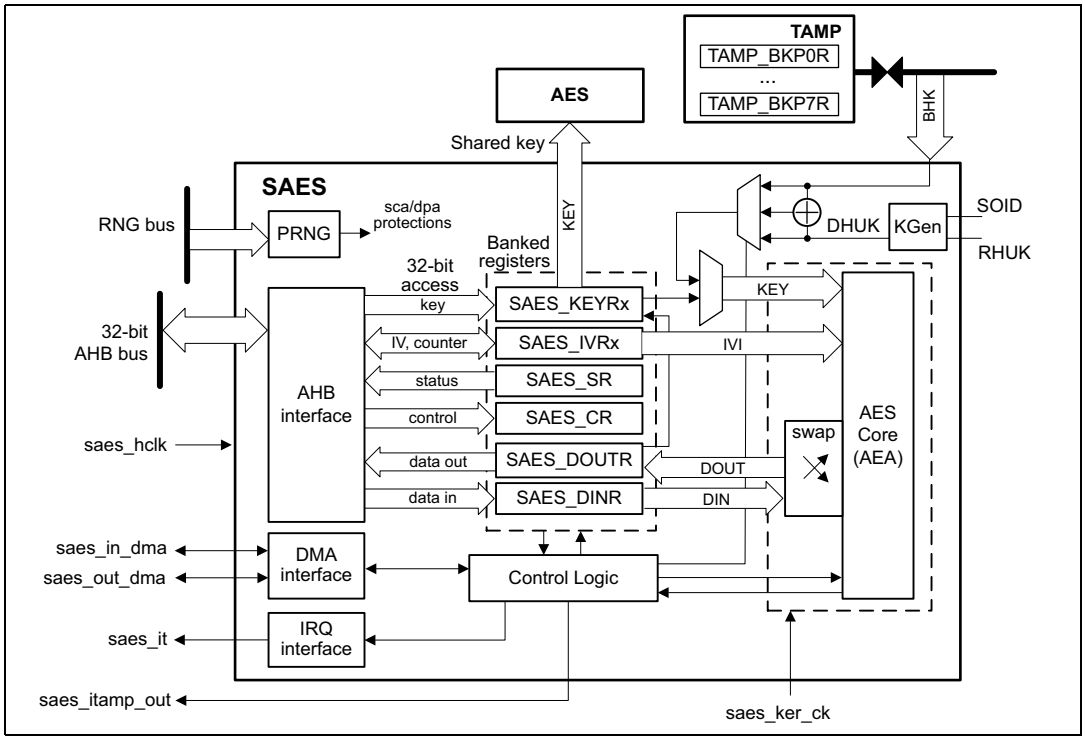
1. X = supported.

34.4 SAES functional description

34.4.1 SAES block diagram

Figure 308 shows the block diagram of SAES.

Figure 308. SAES block diagram



Note: AES represents the AES peripheral.

34.4.2 SAES internal signals

Table 314 describes the user relevant internal signals interfacing the SAES peripheral.

Table 314. SAES internal input/output signals

Signal name	Signal type	Description
saes_hclk	Input	AHB bus clock
saes_ker_ck	Input	SAES kernel clock.
saes_it	Output	SAES interrupt request
saes_in_dma	Input/Output	SAES incoming data DMA single request/acknowledge
saes_out_dma	Input/Output	SAES processed data DMA single request/acknowledge
saes_itamp_out	Output	Tamper event signal to TAMP (XOR-ed), triggered when an unexpected hardware fault occurs. When this signal is triggered, SAES automatically clears key registers. A reset is required for SAES to be usable again.
RHUK	Input	256-bit root hardware unique key (non-volatile, unique per device and secret to software), used to internally compute the derived hardware unique key (DHUK)
BHK(1)	Input	256-bit boot hardware key (BHK) stored in tamper-resistant secure backup registers and written by a secure code during boot. Once written, this key cannot be read nor written by any application until the next product reset.
SOID	Input	Static operating ID hardware input used during each DHUK computation. Its change causes the erasure of key registers and sets the KEIF flag.

1. Connected to a set of backup registers in TAMP peripheral that are written, then read/write locked, by the application software (see *Section 34.4.17* for details).

34.4.3 SAES reset and clocks

The SAES peripheral is clocked by the AHB bus clock. The SAES instance has also a dedicated kernel clock programmed in the RCC.

The SAES has a dedicated reset bit in the RCC.

34.4.4 SAES symmetric cipher implementation

The secure AES coprocessor (SAES) is a 32-bit AHB peripheral that encrypts or decrypts 16-byte blocks of data using the advanced encryption standard (AES). It also implements a set of approved AES symmetric key security functions summarized in *Table 315*. Those functions can be certified NIST PUB 140-3.

Table 315. SAES approved symmetric key functions

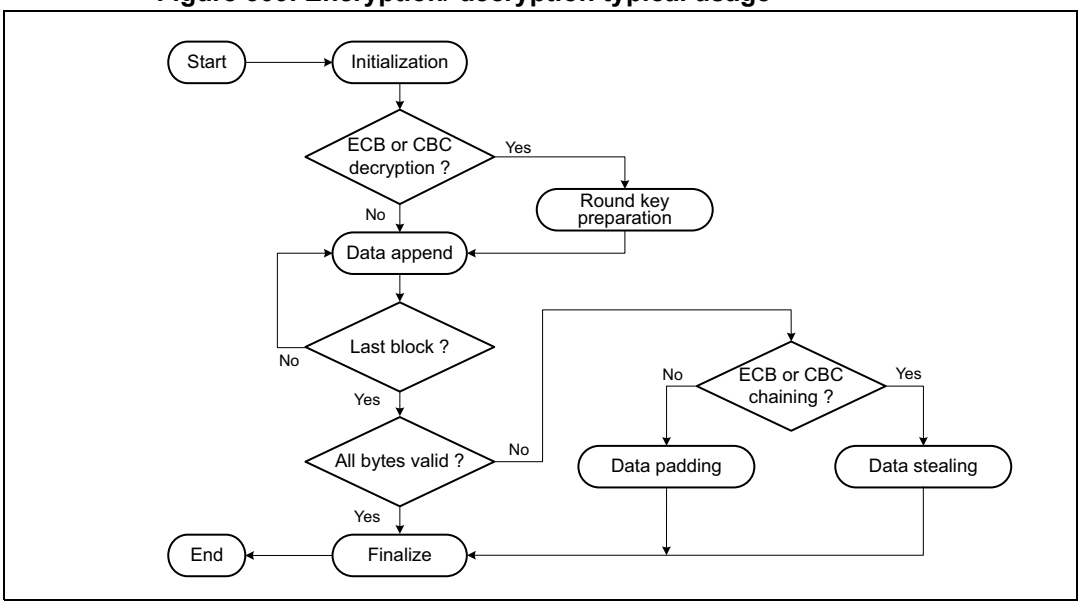
Operations	Algorithm	Specification	Key bit lengths	Chaining modes
Encryption, decryption	AES	FIPS PUB 197 NIST SP800-38A	128, 256	ECB, CBC, CTR
Authenticated encryption or decryption		NIST SP800-38C NIST SP800-38D		GCM, CCM
Cipher-based message authentication code		NIST SP800-38D		GMAC

SAES can be used directly by the CPU, or indirectly, using two DMA channels (one for the plaintext, one for the ciphertext).
It is possible to suspend then resume any SAES processing, following the sequence described in *Section 34.4.8*.

34.4.5 SAES encryption or decryption typical usage

The following figure shows a typical operation for encryption or decryption.

Figure 309. Encryption/ decryption typical usage



Initialization

The SAES peripheral is initialized according to the chaining mode. Refer to *Section 34.4.9: SAES basic chaining modes (ECB, CBC)* and *Section 34.4.10: SAES counter (CTR) mode* for details.

Data append

This section describes different ways of appending data for processing. For ECB or CBC chaining modes, refer to *Section 34.4.7: SAES ciphertext stealing and data padding* if the size of data to process is not a multiple of 16 bytes. The last block management in these cases is more complex than what is described in this section.

Appending data using the CPU in polling mode

This method uses flag polling to control the data append through the following sequence:

1. When KEYVALID is set, enable the SAES peripheral, by setting the EN bit of the SAES_CR register (if not already done).
2. Repeat the following sub-sequence until the payload is entirely processed:
   a) Write four input data words into the SAES_DINR register.
   b) Wait until the status flag CCF is set in the SAES_ISR register, then read the four data words from the SAES_DOUTR register.
   c) Clear the CCF flag, by setting the CCF bit of the SAES_ICR register.
   d) If the next processing block is the last block, pad (when applicable) the data with zeros to obtain a complete block, and specify the number of non-valid bytes (using NPBLB[3:0]) in case of GCM payload encryption or CCM payload decryption (otherwise the tag computation is wrong).
3. As the data block just processed is the last block of the message, optionally discard the data that is not part of the message/payload, then disable the SAES peripheral by clearing EN.

Note: Up to three wait cycles are automatically inserted between two consecutive writes to the SAES_DINR register, to allow sending the key to the AES co-processor.

NPBLB[3:0] bitfield is not used in header phase of GCM, GMAC and CCM chaining modes.

Appending data using the CPU in interrupt mode

The method uses interrupt from the SAES peripheral to control the data append, through the following sequence:

1. Enable interrupts from SAES, by setting the CCFIE bit of the SAES_IER register.
2. When KEYVALID is set, enable the SAES peripheral, by setting EN (if not already done).
3. Write first four input data words into the SAES_DINR register.
4. Handle the data in the SAES interrupt service routine. Upon each interrupt:
   a) Read four output data words from the SAES_DOUTR register.
   b) Clear the CCF flag and thus the pending interrupt, by setting the CCF bit of the SAES_ICR register.
   c) If the next processing block is the last block of the message, pad (when applicable) the data with zeros to obtain a complete block, and specify the number of non-valid bytes (through NPBLB[3:0]) in case of GCM payload encryption or CCM payload decryption (otherwise the tag computation is wrong). Then proceed with point 4e).
   d) If the data block just processed is the last block of the message, optionally discard the data that are not part of the message/payload, then disable the SAES peripheral by clearing EN and quit the interrupt service routine.
   e) Write next four input data words into the SAES_DINR register and quit the interrupt service routine.

Note: SAES is tolerant of delays between consecutive read or write operations, which allows, for example, an interrupt from another peripheral to be served between two SAES computations.

The NPBLB[3:0] bitfield is not used in the header phase of GCM, GMAC, and CCM chaining modes.

Appending data using DMA

With this method, all the transfers and processing are managed by DMA and SAES. Proceed as follows:

1. If the last block of the message to process is shorter than 16 bytes, prepare the last four-word data block by padding the remainder of the block with zeros.
2. Configure the DMA controller so as to transfer the data to process from the memory to the SAES peripheral input and the processed data from the SAES peripheral output to the memory, as described in *Section 34.6: SAES DMA requests*. Configure the DMA controller so as to generate an interrupt on transfer completion. For GCM payload encryption or CCM payload decryption, the DMA transfer **must not** include the last four-word block if padded with zeros. The sequence described in *Appending data using the CPU in polling mode* must be used instead for this last block, because the NPBLB[3:0] bitfield must be set up before processing the block, for SAES to compute a correct tag.
3. When KEYVALID is set, enable the SAES peripheral, by setting EN (if not already done).
4. Enable DMA requests, by setting DMAINEN and DMAOUTEN.
5. Upon DMA interrupt indicating the transfer completion, get the SAES-processed data from the memory.

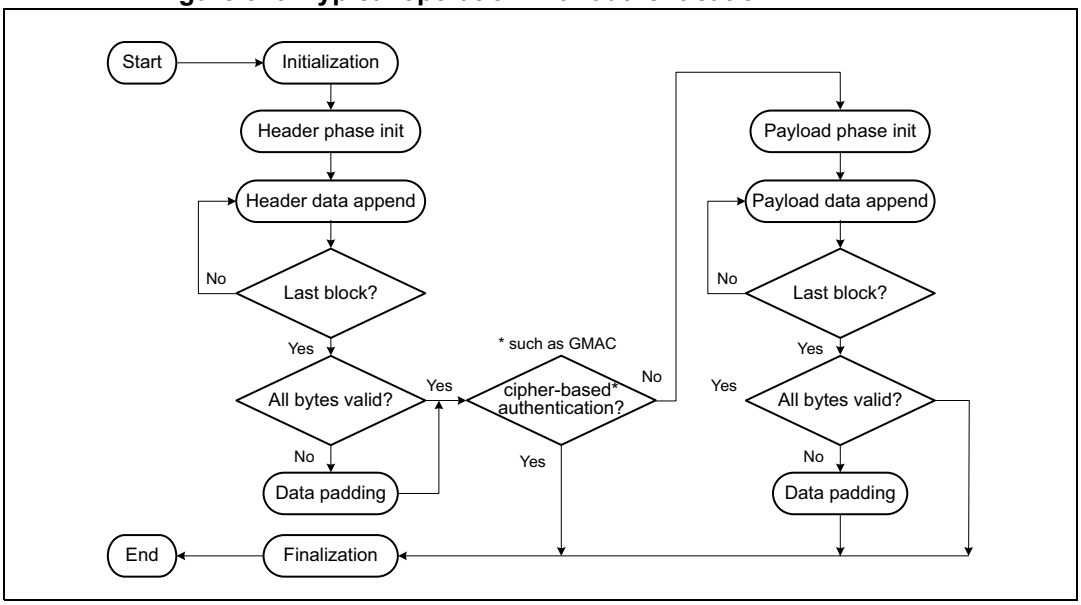
Note: The CCF flag has no use with this method because the reading of the SAES_DOUTR register is managed by DMA automatically, without any software action, at the end of the computation phase.

The NPBLB[3:0] bitfield is not used in the header phase of GCM, GMAC, and CCM chaining modes.

34.4.6 SAES authenticated encryption, decryption, and cipher-based message authentication

The following figure shows a typical operation for authenticated encryption or decryption, and for cipher-based message authentication.

Figure 310. Typical operation with authentication



Section 34.4.11: SAES Galois/counter mode (GCM) and *Section 34.4.13: SAES counter with CBC-MAC (CCM)* describe detailed sequences supported by SAES.

Cipher-based message authentication flow omits the payload phase, as shown in the figure. Detailed sequence supported by SAES is described in *Section 34.4.12: SAES Galois message authentication code (GMAC)*.

34.4.7 SAES ciphertext stealing and data padding

When using SAES in ECB or CBC modes to manage messages the size of which is not a multiple of the block size (16 bytes), the application must use ciphertext stealing techniques such as those described in NIST *Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation: Three Variants of Ciphertext Stealing for CBC Mode*. Since SAES does not implement such techniques, the application must complete the *last block* of input data using data from the *second last* block.

Note: Ciphertext stealing techniques are not documented in this reference manual.

Similarly, in modes other than ECB or CBC, an incomplete input data block (that is, a block with input data shorter than 16 bytes) must be padded with zeros prior to encryption. That is, extra bits must be appended to the trailing end of the data string. After decryption, the extra bits must be discarded. Since SAES does not implement automatic data padding operation to the *last block*, the application must follow the recommendation given in this document to manage messages the size of which is not a multiple of 16 bytes.

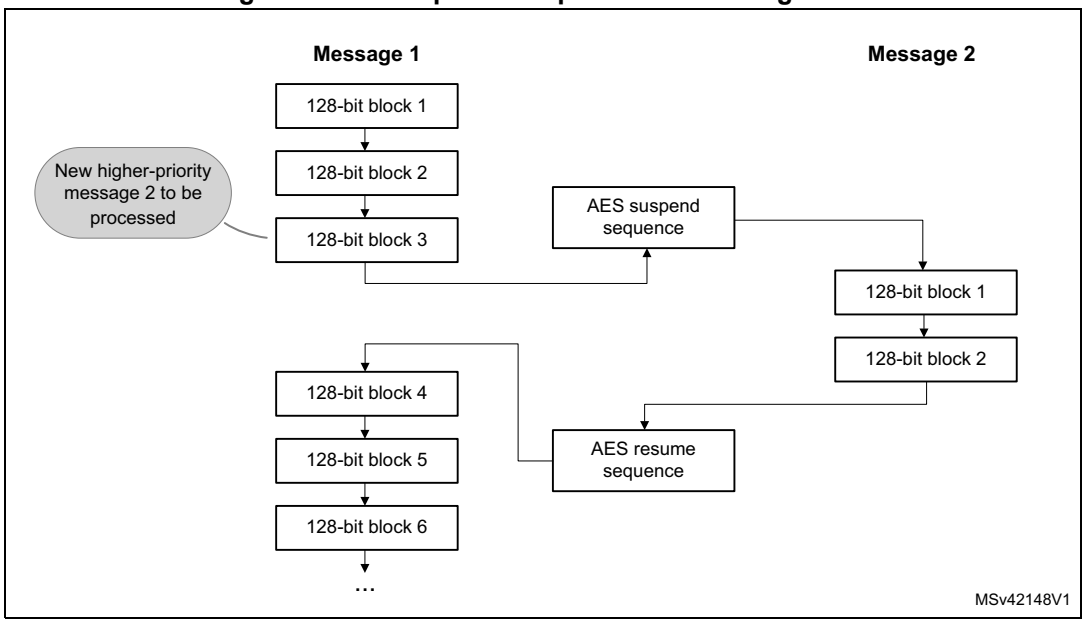
34.4.8 SAES suspend and resume operations

A message can be suspended to process another message with a higher priority. When the higher-priority message is sent, the suspended message can resume. This applies to both encryption and decryption mode.

Suspend and resume operations do not break the chaining operation. The message processing can resume as soon as SAES is enabled again, to receive a next data block.

Figure 311 gives an example of suspend and resume operations: Message 1 is suspended in order to send a shorter and higher-priority Message 2.

Figure 311. Example of suspend mode management



A detailed description of suspend and resume operations is in the sections dedicated to each chaining mode.

34.4.9 SAES basic chaining modes (ECB, CBC)

ECB is the simplest mode of operation. There are no chaining operations, and no special initialization stage. The message is divided into blocks and each block is encrypted or decrypted separately. When decrypting in ECB, a special key scheduling is required before processing the first block.

Figure 312 and *Figure 313* describe the electronic codebook (ECB) chaining implementation in encryption and in decryption, respectively. To select ECB chaining mode, write CHMOD[2:0] with 0x0.

Figure 312. ECB encryption

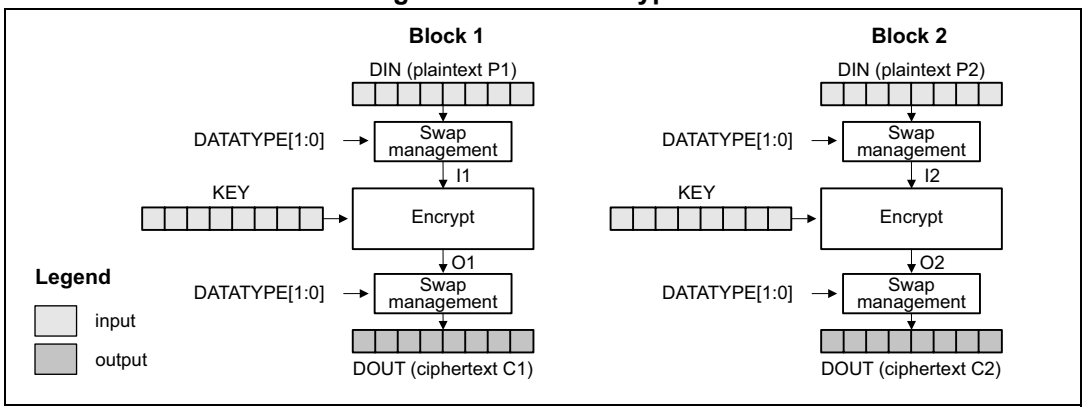


Figure 313. ECB decryption

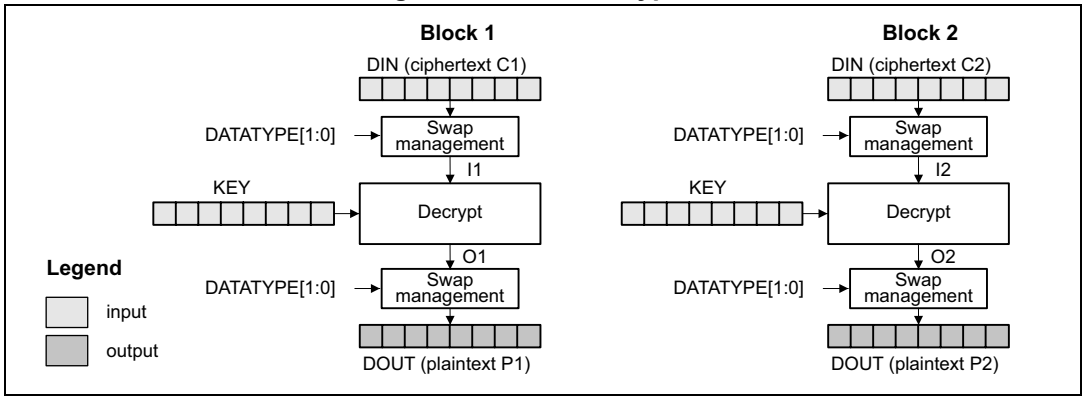

In CBC encryption mode the output of each block chains with the input of the following block. To make each message unique, an initialization vector is used during the first block processing. When decrypting in CBC, a special key scheduling is required before processing the first block.

Figure 314 and *Figure 315* describe the cipher block chaining (CBC) implementation in encryption and in decryption, respectively. To select this chaining mode, write CHMOD[2:0] with 0x1.

Figure 314. CBC encryption

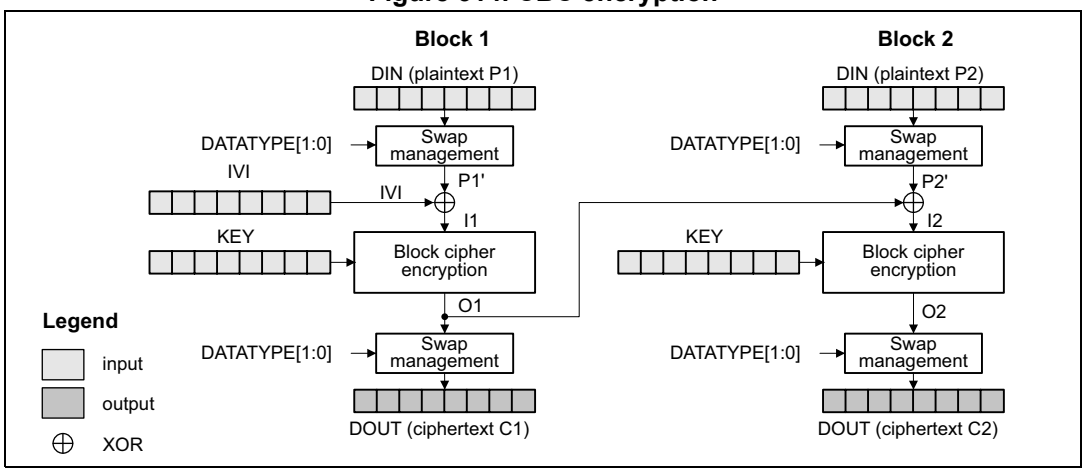

Figure 315. CBC decryption

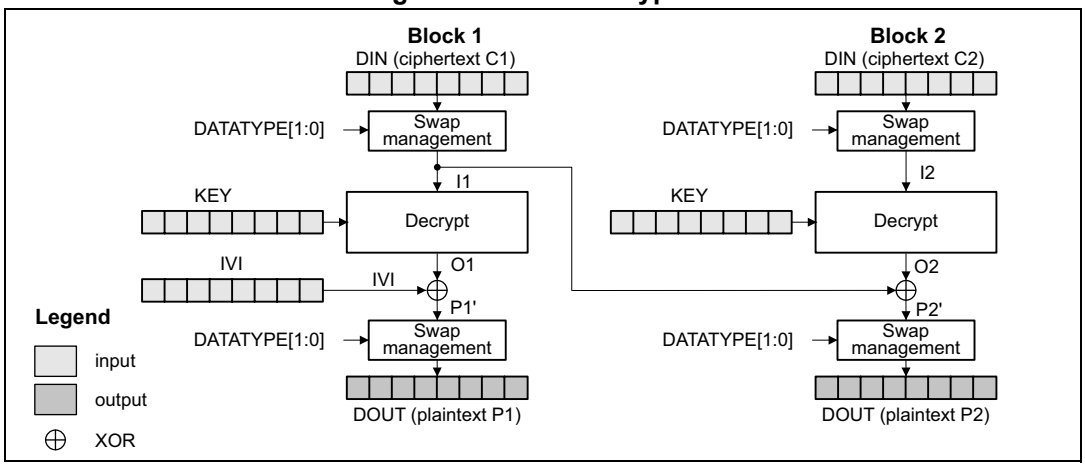


For more details, refer to NIST *Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation.*

ECB and CBC encryption process

This process is described in *Section 34.4.5*, with the following sequence of events:

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register as follows:
   - Select ECB or CBC chaining mode (write CHMOD[2:0] with 0x0 or 0x1) in *encryption* mode (write MODE[1:0] with 0x0).
   - Configure the data type, through DATATYPE[1:0].
   - Configure the key size, through KEYSIZE. If the key must not be shared with a different security context (different secure attribute), the KEYPROT bit must also be set.
   - Select normal key mode by writing KMOD[1:0] with 0x0. For the other KMOD[1:0] values, refer to *Section 34.4.14* (wrapped keys) and *Section 34.4.15* (shared keys).
4. Write the initialization vector into the SAES_IVRx registers if CBC mode is selected in the previous step.
5. Write the key into the SAES_KEYRx registers. Alternatively, select a key source different from the key registers by writing KEYSEL[2:0] with a value different from 0x0. Refer to *Section 34.4.17: SAES key registers* for details.
6. Wait until KEYVALID is set (the key loading completed).
7. Enable the SAES peripheral, by setting EN.
8. Append cleartext data:
   a) If it is the second-last or the last block and the plaintext size of the message is not a multiple of 16 bytes, follow the guidance in *Section 34.4.7*.
   b) Append the cleartext block into SAES as described in *Section 34.4.5*, then read the SAES_DOUTR register four times to save the ciphertext block.
   c) Repeat the step *b)* until the third-last plaintext block is encrypted. For the last two blocks, follow the steps *a)* and *b)*.
9. Finalize the sequence: disable the SAES peripheral, by clearing EN.

ECB/CBC decryption process

This process is described in *Section 34.4.5*, with the following sequence of events:

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register as follows:
   - Select the *key derivation* mode (write MODE[1:0] with 0x1). The CHMOD[2:0] bitfield is not significant during this operation.
   - Configure the data type, through DATATYPE[1:0].
   - Configure the key size, through KEYSIZE. If the key must not be shared with a different security context (different secure attribute), the KEYPROT bit must also be set.
   - Select normal key mode by writing KMOD[1:0] with 0x0. For the other KMOD[1:0] values, refer to *Section 34.4.14* (wrapped keys) and *Section 34.4.15* (shared keys).
4. Write the key into the SAES_KEYRx registers. Alternatively, select a key source different from the key registers by writing KEYSEL[2:0] with a value different from 0x0. Refer to *Section 34.4.17: SAES key registers* for details.
5. Wait until KEYVALID is set (the key loading completed).
6. Enable the SAES peripheral, by setting EN. The peripheral immediately starts an AES round for key preparation.
7. Wait until the CCF flag in the SAES_ISR register is set.
8. Clear the CCF flag, by setting the CCF bit of the SAES_ICR register. The decryption key is available in the AES core and SAES is disabled automatically.
9. Select ECB or CBC chaining mode (write CHMOD[2:0] with 0x0 or 0x1) in *decryption* mode (write MODE[1:0] with 0x2). Do not change other parameters.
10. Write the initialization vector into the SAES_IVRx registers if CBC mode is selected in the previous step.
11. Enable the SAES peripheral, by setting EN.
12. Append encrypted data:
    a) If it is the second-last or the last block and the ciphertext size of the message is not a multiple of 16 bytes, follow the guidance in *Section 34.4.7*.
    b) Append the ciphertext block into SAES as described in *Section 34.4.5*, then read the SAES_DOUTR register four times to save the cleartext block (MSB first).
    c) Repeat the step *b)* until the third-last ciphertext block is decrypted. For the last two blocks, follow the steps *a)* and *b)*.
13. Finalize the sequence: disable the SAES peripheral, by clearing EN.

Suspend/resume operations in ECB/CBC modes

The following sequences are valid for normal key mode (KMOD[1:0] at 0x0).

To suspend the processing of a message, proceed as follows:

1. If DMA is used, stop the SAES DMA transfers to the input FIFO, by clearing the DMAINEN bit of the SAES_CR register.
2. If DMA is not used, read four times the SAES_DOUTR register to save the last processed block. If DMA is used, wait until the CCF flag is set in the SAES_ISR

register then stop the DMA transfers from the output FIFO, by clearing the DMAOUTEN bit of the SAES_CR register.

3. If DMA is not used, wait until the CCF flag in the SAES_ISR register is set (computation completed).
4. Clear the CCF flag, by setting the CCF bit of the SAES_ICR register.
5. Save initialization vector registers (only required in CBC mode as the SAES_IVRx registers are altered during the data processing).
6. Disable the SAES peripheral, by clearing EN.
7. Save the SAES_CR register and clear the key registers if they are not needed, to process the higher-priority message.
8. If DMA is used, save the DMA controller status (pointers for SAES input and output data transfers, number of remaining bytes, and so on).

To resume the processing of a message, proceed as follows:

1. If DMA is used, configure the DMA controller so as to complete the remaining input FIFO and output FIFO transfers.
2. Disable the SAES peripheral, by clearing EN.
3. Restore the SAES_CR register (with correct KEYSIZE) then restore the SAES_KEYRx registers. Alternatively, select a key source different from key registers, using KEYSEL[2:0]. Refer to *Section 34.4.17: SAES key registers* for details.
4. Prepare the decryption key, as described in *ECB/CBC decryption process* (only required for ECB or CBC decryption).
5. Restore the SAES_IVRx registers, using the saved configuration (only required in CBC mode).
6. Enable the SAES peripheral, by setting EN.
7. If DMA is used, enable SAES DMA transfers, by setting DMAINEN and DMAOUTEN.

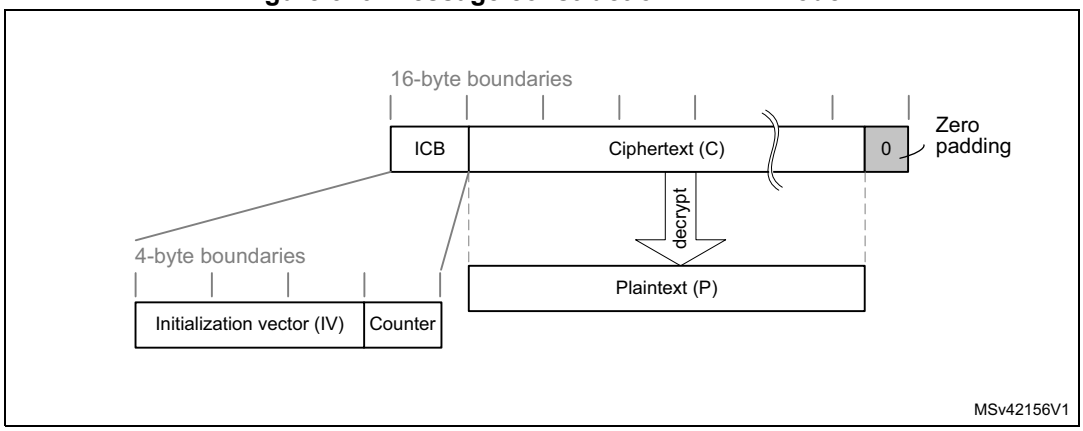
Note: It is not required to save the key registers as the application knows the original key.

34.4.10 SAES counter (CTR) mode

The CTR mode uses the AES core to generate a key stream. The keys are then XOR-ed with the plaintext to obtain the ciphertext. Unlike with ECB and CBC modes, no key scheduling is required for the CTR decryption since the AES core is always used in encryption mode.

A typical message construction in CTR mode is given in *Figure 316*.

Figure 316. Message construction in CTR mode



The structure of this message is:

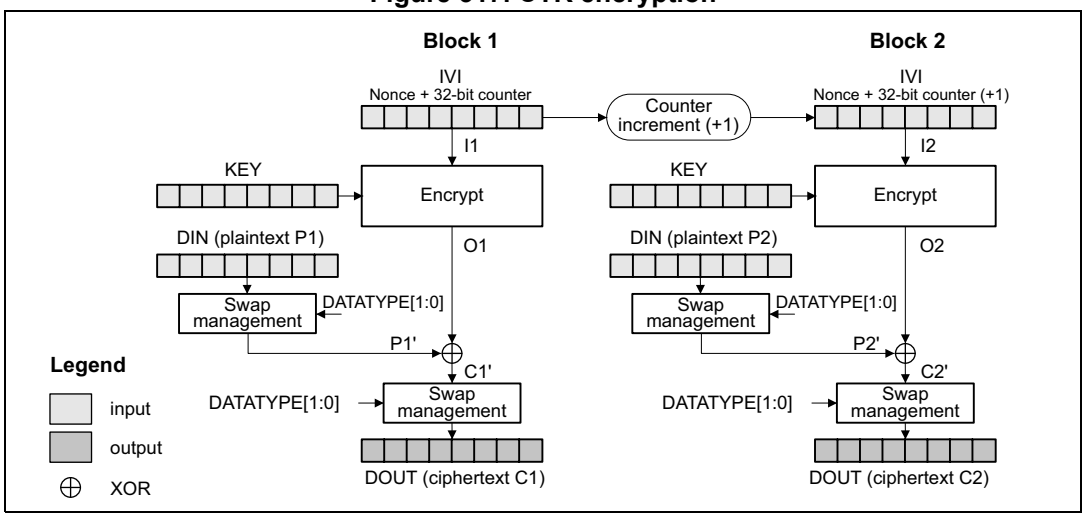
- A 16-byte initial counter block (ICB), composed of two distinct fields:
  - **Initialization vector** (IV): a 96-bit value that must be unique for each encryption cycle with a given key.
  - **Counter**: a 32-bit big-endian integer that is incremented each time a block processing is completed. The initial value of the counter must be set to 1.
- The plaintext P is encrypted as ciphertext C, with a known length. This length can be non-multiple of 16 bytes, in which case a plaintext padding is required.

For more details, refer to NIST *Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation.*

CTR encryption and decryption

Figure 317 describes the counter (CTR) chaining implementation in the SAES peripheral (encryption). To select this chaining mode, write CHMOD[2:0] with 0x2.

Figure 317. CTR encryption



Initialization vectors in SAES must be initialized as shown in *Table 316*.

Table 316. Counter mode initialization vector definition

SAES_IVR3[31:0]	SAES_IVR2[31:0]	SAES_IVR1[31:0]	SAES_IVR0[31:0]
IVI[127:96]	IVI[95:64]	IVI[63:32]	IVI[31:0] 32-bit counter = 0x0001

CTR encryption and decryption process

This process is described in *Section 34.4.5*, with the following sequence of events:

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register:
   - Select CTR chaining mode (write CHMOD[2:0] with 0x2) in encryption or decryption mode (write MODE[1:0] with 0x0 or 0x2).
   - Configure the data type, through DATATYPE[1:0].
   - Configure the key size, through KEYSIZE. If the key must not be shared with a different security context (different secure attribute), the KEYPROT bit must also be set.
   - Select normal key mode, by writing KMOD[1:0] with 0x0. For the other KMOD[1:0] values, refer to *Section 34.4.14* (wrapped keys) and *Section 34.4.15* (shared keys).
4. Write the initialization vector into the SAES_IVRx registers according to *Table 316*.
5. Write the key into the SAES_KEYRx registers. Alternatively, select a key source different from the key registers by writing KEYSEL[2:0] with a value different from 0x0. Refer to *Section 34.4.17: SAES key registers* for details.
6. Wait until KEYVALID is set (the key loading completed).
7. Enable the SAES peripheral, by setting EN.
8. Append data:
   a) If it is the last block and the plaintext (encryption) or ciphertext (decryption) size in the block is less than 16 bytes, pad the remainder of the block with zeros.
   b) Append the data block into SAES as described in *Section 34.4.5*, then read the SAES_DOUTR register four times to save the resulting block (MSB first).
   c) Repeat the step *b)* until the second-last block is processed. For the last block of plaintext (encryption only), follow the steps *a)* and *b)*. For the last block, discard the bits that are not part of the message when the last block is smaller than 16 bytes.
9. Finalize the sequence: disable the SAES peripheral, by clearing EN.

Suspend/resume operations in CTR mode

Like for the CBC mode, it is possible to interrupt a message to send a higher-priority message, then resume the interrupted message. Detailed CBC suspend and resume sequence is described in *Section 34.4.9: SAES basic chaining modes (ECB, CBC)*.

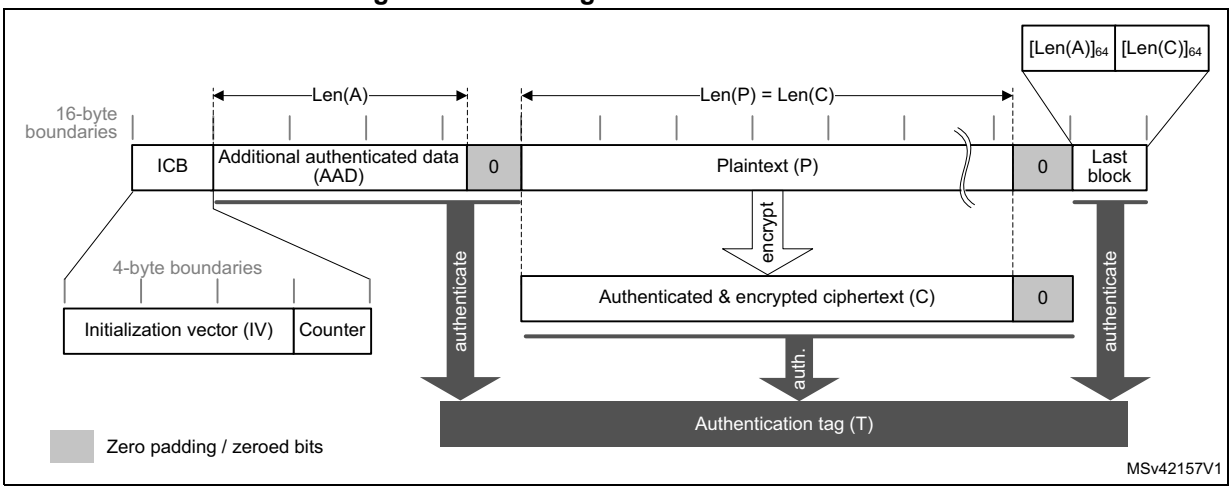
Note: Like for CBC mode, the IV registers must be reloaded during the resume operation.

34.4.11 SAES Galois/counter mode (GCM)

The AES Galois/counter mode (GCM) allows encrypting and authenticating a plaintext message into the corresponding ciphertext and tag (also known as message authentication code).

GCM mode is based on AES in counter mode for confidentiality. It uses a multiplier over a fixed finite field for computing the message authentication code. The following figure shows a typical message construction in GCM mode.

Figure 318. Message construction in GCM



The message has the following structure:

- **16-byte initial counter block (ICB)**, composed of two distinct fields:
  - **Initialization vector (IV):** a 96-bit value that must be unique for each encryption cycle with a given key. The GCM standard supports IVs with less than 96 bits, but in this case strict rules apply.
  - **Counter:** a 32-bit big-endian integer that is incremented each time a block processing is completed. According to NIST specification, the counter value is 0x2 when processing the first block of payload.
- **Authenticated header AAD** (also knows as additional authentication data) has a known length Len(A) that may be a non-multiple of 16 bytes, and must not exceed $2^{64} – 1$ bits. This part of the message is only authenticated, not encrypted.
- **Plaintext message P** is both authenticated and encrypted as ciphertext C, with a known length Len(P) that may be non-multiple of 16 bytes, and cannot exceed 2^{32} - 2 16-byte blocks.
- **Last block** contains the AAD header length (bits [32:63]) and the payload length (bits [96:127]) information, as shown in *Table 318*.

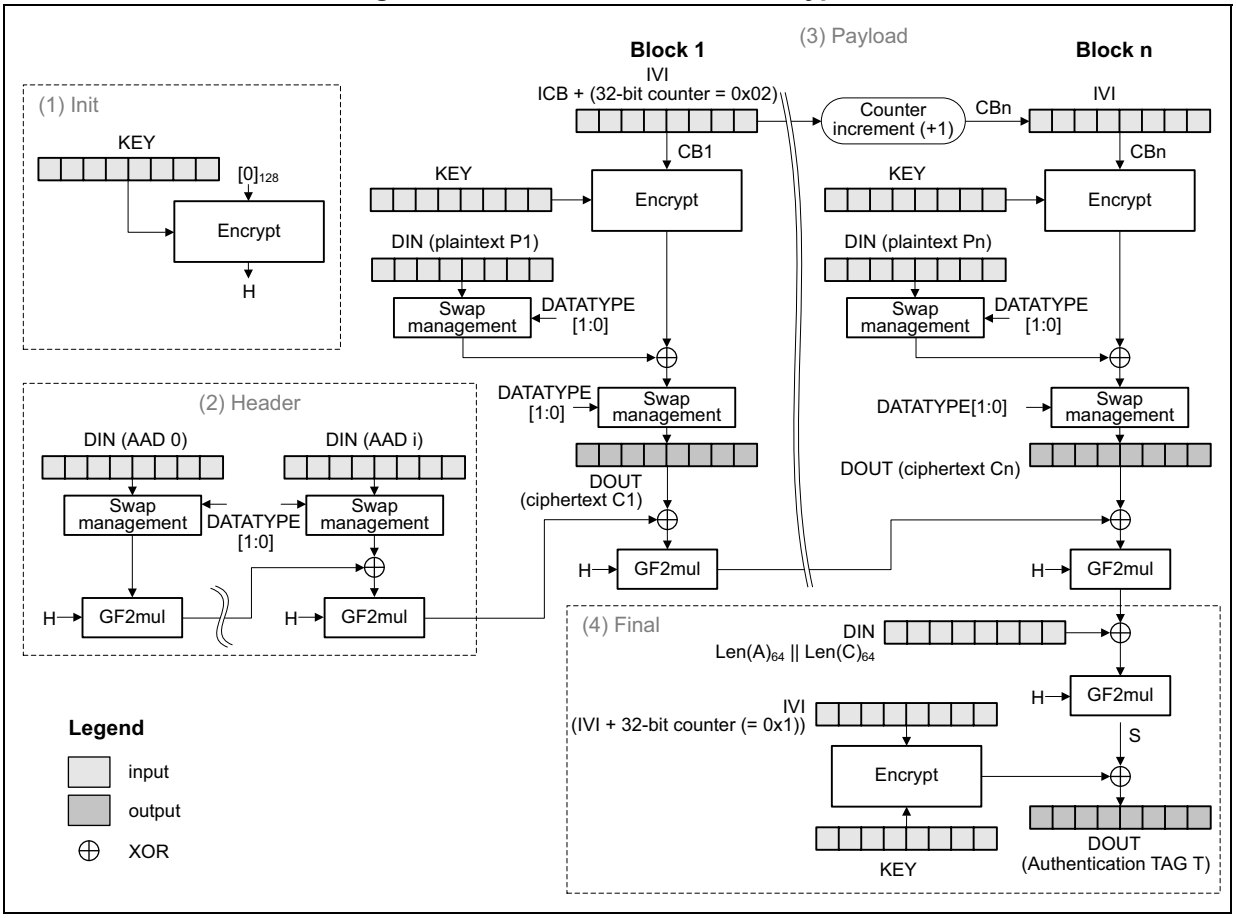
The GCM standard specifies that ciphertext C has the same bit length as the plaintext P.

When a part of the message (AAD or P) has a length that is a non-multiple of 16-bytes a special padding scheme is required.

For more details, refer to NIST *Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.*

Figure 319 describes the GCM chaining implementation in the SAES peripheral (encryption). To select this chaining mode, write CHMOD[2:0] with 0x3.

Figure 319. GCM authenticated encryption



The first counter block (CB1) is derived from the initial counter block ICB by the application software, as defined in *Table 317*.

Table 317. Initialization of IV registers in GCM mode

SAES_IVR3[31:0]	SAES_IVR2[31:0]	SAES_IVR1[31:0]	SAES_IVR0[31:0]
ICB[127:96]	ICB[95:64]	ICB[63:32]	ICB[31:0] 32-bit counter = 0x0002

The last block of a GCM message contains the AAD header length and the payload length information, as shown in *Table 318*.

Table 318. GCM last block definition

Word order to SAES_DINR	First word	Second word	Third word	Fourth word
Input data	AAD length[63:32]	AAD length[31:0]	Payload length[63:32]	Payload length[31:0]

GCM encryption and decryption process

This process is described in *Section 34.4.6*, with the following sequence of events:

GCM initialize

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register:
   - Select GCM chaining mode (write CHMOD[2:0] with 0x3) in encryption or decryption mode (write MODE[1:0] with 0x0 or 0x2). Do not write MODE[1:0] with 0x1.
   - Configure the data type, through DATATYPE[1:0]
   - Configure the key size, through KEYSIZE. If the key must not be shared with a different security context (such as secure, non-secure, specific CPU), also set KEYPROT.
   - Select normal key mode, by writing KMOD[1:0] with 0x0. For the other KMOD[1:0] values, refer to *Section 34.4.14* (wrapped keys) and *Section 34.4.15* (shared keys).
   - Select the GCM initialization phase, by writing GCMPH[1:0] with 0x0.
4. Write the initialization vector in SAES_IVRx registers according to *Table 317*.
5. Write the key into the SAES_KEYRx registers. Alternatively, select a key source different from the key registers by writing KEYSEL[2:0] with a value different from 0x0. Refer to *Section 34.4.17: SAES key registers* for details.
6. Wait until KEYVALID is set (the key loading completed).
7. Set EN to start the calculation of the hash key. EN is automatically cleared when the calculation is completed.
8. Wait until the CCF flag is set in the SAES_ISR register, indicating that the GCM hash subkey (H) computation is completed.
9. Clear the CCF flag by setting the CCF bit of the SAES_ICR register.

GCM header phase

10. Initialize header phase:
    a) Select the GCM header phase, by writing 0x1 to GCMPH[1:0]. Do not change the other configurations written during GCM initialization.
    b) Enable the SAES peripheral, by setting EN.
11. Append header data:
    a) If it is the last block and the AAD in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
    b) Append the data block into SAES as described in *Section 34.4.5*.
    c) Repeat the step *b)* until the second-last AAD data block is processed. For the last block, follow the steps *a)* and *b)*.

Note: This phase can be skipped if there is no AAD, that is, Len(A) = 0.

No data are read during header phase.

GCM payload phase

12. Initialize payload phase:
    a) Select the GCM payload phase, by writing GCMPH[1:0] with 0x2. Do not change the other configurations written during GCM initialization.
    b) If the header phase is skipped, enable the SAES peripheral by setting EN.
13. Append payload data:
    a) If it is the last block and the message in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
    b) Append the data block into SAES as described in *Section 34.4.5*, then read the SAES_DOUTR register four times to save the resulting block
    c) Repeat the step *b)* until the second-last plaintext block is encrypted or until the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), follow the steps *a)* and *b)*. For the last block, discard the bits that are not part of the payload when the last block is smaller than 16 bytes.

Note: This phase can be skipped if there is no payload, that is, Len(C)=0 (see GMAC mode).

GCM finalization

14. Encryption only: wait until the BUSY flag in the SAES_SR register is cleared.
15. Select the GCM final phase, by writing GCMPH[1:0] with 0x3. Do not change the other configurations written during GCM initialization.
16. Write the final GCM block into the SAES_DINR register. It is the concatenated AAD bit and payload bit lengths, as shown in *Table 318*.
17. Wait until the CCF flag in the SAES_ISR register is set.
18. Get the GCM authentication tag, by reading the SAES_DOUTR register four times.
19. Clear the CCF flag, by setting the CCF bit in SAES_ICR register.
20. Disable the SAES peripheral, by clearing EN. If it is an authenticated decryption, compare the generated tag with the expected tag passed with the message.

Note: In the final phase, data are written to SAES_DINR normally (no swapping), while swapping is applied to tag data read from SAES_DOUTR.

When transiting from the header or the payload phase to the final phase, the SAES peripheral must not be disabled, otherwise the result is wrong.

Suspend/resume operations in GCM mode

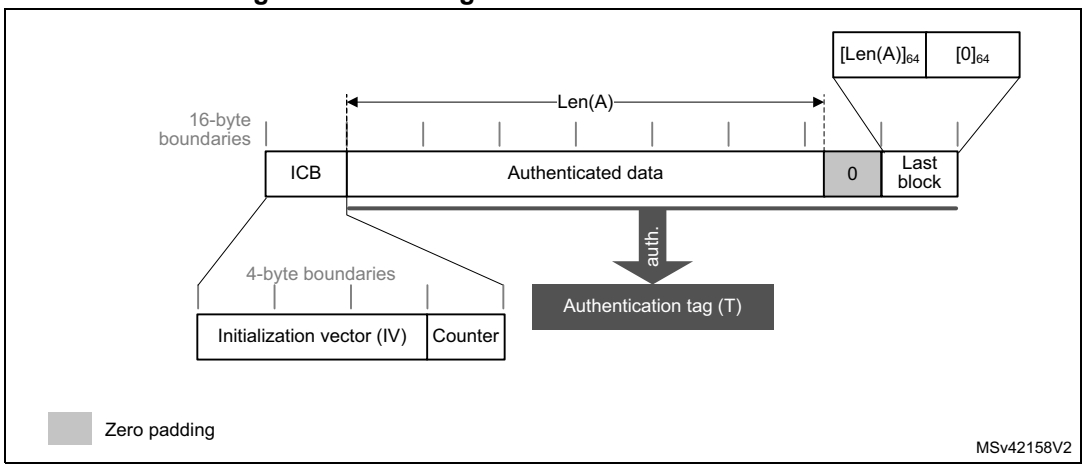
Suspend/resume operations are not supported in GCM mode.

34.4.12 SAES Galois message authentication code (GMAC)

The Galois message authentication code (GMAC) allows the authentication of a plaintext, generating the corresponding tag information (also known as message authentication code).

GMAC is similar to GCM, except that it is applied on a message composed only by plaintext authenticated data (that is, only header, no payload). The following figure shows typical message construction for GMAC.

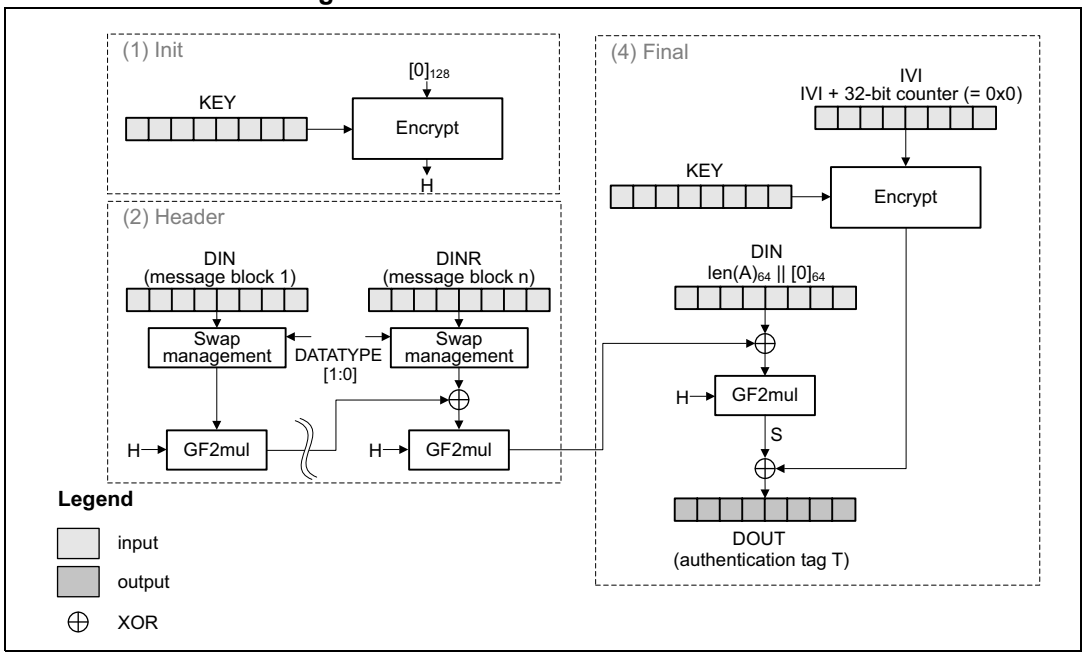
Figure 320. Message construction in GMAC mode



For more details, refer to NIST *Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.*

Figure 321 describes the GMAC chaining implementation in the SAES peripheral. To select this chaining mode, write CHMOD[2:0] with 0x3.

Figure 321. GMAC authentication mode



The GMAC algorithm corresponds to the GCM algorithm applied on a message that only contains a header. As a consequence, all steps and settings are the same as with the GCM, except that the payload phase is omitted.

Suspend/resume operations in GMAC

Suspend/resume operations are not supported in GMAC mode.

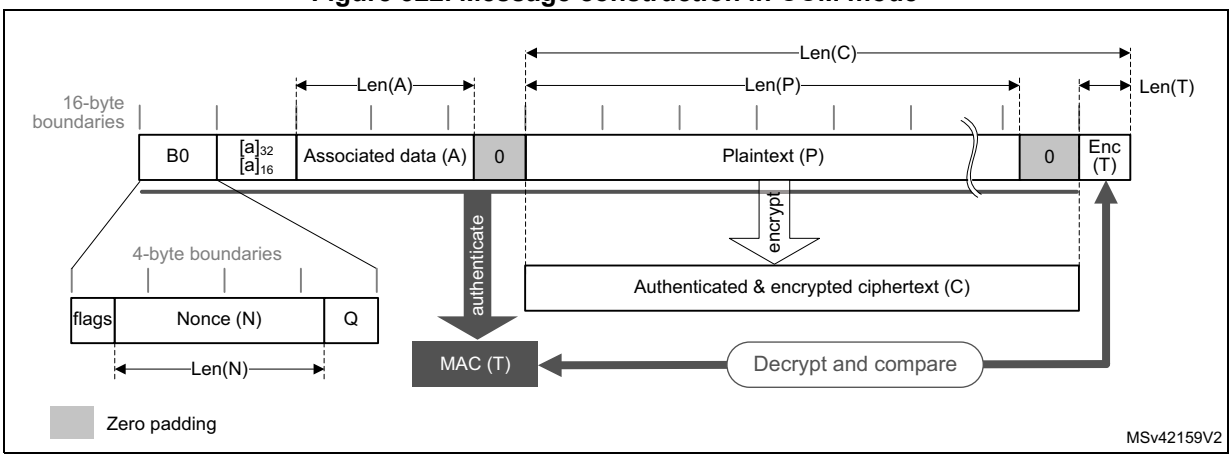
34.4.13 SAES counter with CBC-MAC (CCM)

The AES counter with cipher block chaining-message authentication code (CCM) algorithm allows encryption and authentication of plaintext, generating the corresponding ciphertext and tag (also known as message authentication code). To ensure confidentiality, the CCM algorithm is based on AES counter mode processing. It uses cipher block chaining technique to generate the message authentication code. This is commonly called CBC-MAC.

Note: NIST does not approve CBC-MAC as an authentication mode outside the context of the CCM specification.

The following figure shows typical message construction for CCM.

Figure 322. Message construction in CCM mode



The structure of the message is:

- **16-byte first authentication block (B0)**, composed of three distinct fields:
  - **Q:** a bit string representation of the octet length of P (Len(P))
  - **Nonce (N):** a single-use value (that is, a new nonce must be assigned to each new communication) of Len(N) size. The sum Len(N) + Len(P) must be equal to 15 bytes.
  - **Flags:** most significant octet containing four flags for control information, as specified by the standard. It contains two 3-bit strings to encode the values **t** (MAC length expressed in bytes) and **Q** (plaintext length such that Len(P) < 2^{8Q} bytes). The counter blocks range associated to **Q** is equal to 2^{8Q-4}, that is, if the maximum value of **Q** is 8, the counter blocks used in cipher must be on 60 bits.
- **16-byte blocks (B)** associated to the associated data (A).
  This part of the message is only authenticated, not encrypted. This section has a known length Len(A) that can be a non-multiple of 16 bytes (see *Figure 322*). The standard also states that, on MSB bits of the first message block (B1), the associated data length expressed in bytes (a) must be encoded as follows:
  - If $0 < a < 2^{16} - 2^8$, then it is encoded as $[a]_{16}$, that is, on two bytes.
  - If $2^{16} - 2^8 < a < 2^{32}$, then it is encoded as 0xff || 0xfe || $[a]_{32}$, that is, on six bytes.
  - If $2^{32} < a < 2^{64}$, then it is encoded as 0xff || 0xff || $[a]_{64}$, that is, on ten bytes.

- **16-byte blocks (B)** associated to the plaintext message P, which is both authenticated and encrypted as ciphertext C, with a known length Len(P). This length can be a non-multiple of 16 bytes (see *Figure 322*).
- **Encrypted MAC (T)** of length Len(T) appended to the ciphertext C of overall length Len(C).

When a part of the message (A or P) has a length that is a non-multiple of 16-bytes, a special padding scheme is required.

Note: CCM chaining mode can also be used with associated data only (that is, no payload).

As an example, the C.1 section in NIST Special Publication 800-38C gives the following values (hexadecimal numbers):

N: 10111213 141516 (Len(N) = 56 bits or 7 bytes)

A: 00010203 04050607 (Len(A) = 64 bits or 8 bytes)

P: 20212223 (Len(P) = 32 bits or 4 bytes)

T: 6084341B (Len(T) = 32 bits or t = 4)

B0: 4F101112 13141516 00000000 00000004
B1: 00080001 02030405 06070000 00000000
B2: 20212223 00000000 00000000 00000000

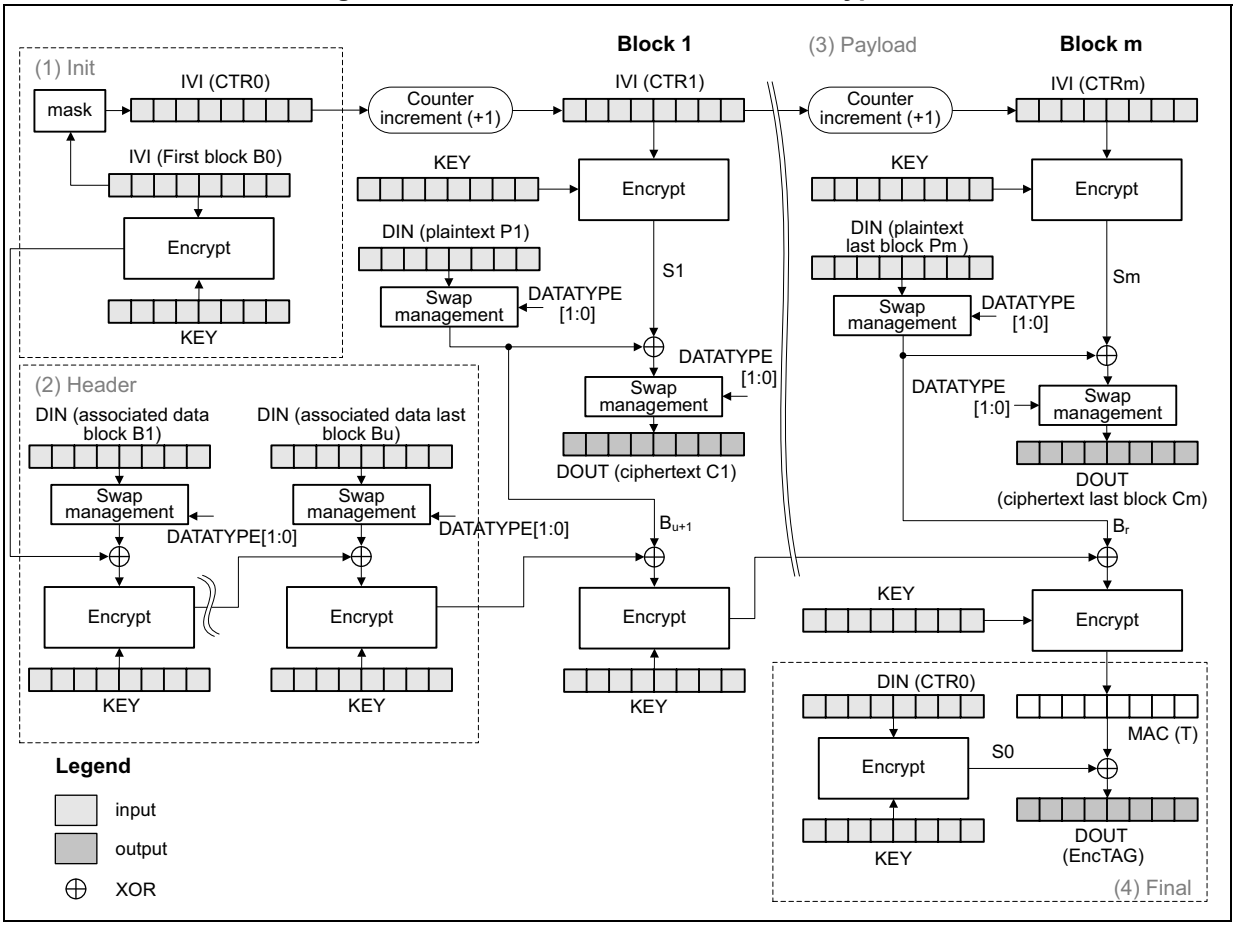
CTR0: 0710111213 141516 00000000 00000000

CTR1: 0710111213 141516 00000000 00000001

For more details, refer to NIST *Special Publication 800-38C, Recommendation for Block Cipher Modes of Operation - The CCM Mode for Authentication and Confidentiality*.

Figure 323 describes the CCM chaining implementation in the SAES peripheral (encryption). To select this chaining mode, write CHMOD[2:0] with 0x4.

Figure 323. CCM mode authenticated encryption



The first block of a CCM message (B0) must be prepared by the application as defined in *Table 319*.

Table 319. Initialization of IV registers in CCM mode

SAES_IVR3[31:0]	SAES_IVR2[31:0]	SAES_IVR1[31:0]	SAES_IVR0[31:0]
B0[127:96](1)	B0[95:64]	B0[63:32]	B0[31:0](2)

1. The 5 most significant bits are cleared (flag bits).
2. Q length bits are cleared, except for the bit 0 that is set.

SAES supports counters up to 64 bits, as specified by NIST.

CCM encryption and decryption process

This process is described in *Section 34.4.6*, with the following sequence of events:

CCM initialize

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register:
   - Select CCM chaining mode (write CHMOD[2:0] with 0x4) in encryption or decryption mode (write MODE[1:0] with 0x0 or 0x2). Do not write MODE[1:0] with 0x1.
   - Configure the data type, through DATATYPE[1:0]
   - Configure the key size, through KEYSIZE. If the key must not be shared with a different security context, also set the KEYPROT bit.
   - Select normal key mode, by writing KMOD[1:0] with 0x0. For the other KMOD[1:0] values, refer to *Section 34.4.14* (wrapped keys) and *Section 34.4.15* (shared keys).
   - Select the CCM initialization phase, by writing GCMPH[1:0] with 0x0.
4. Write the B0 data in SAES_IVRx registers according to *Table 319*.
5. Write the key into the SAES_KEYRx registers. Alternatively, select a key source different from the key registers by writing KEYSEL[2:0] with a value different from 0x0. Refer to *Section 34.4.17: SAES key registers* for details.
6. Wait until KEYVALID is set (the key loading completed).
7. Set EN to start the first mask calculation. The EN bit is automatically cleared when the calculation is completed.
8. Wait until the CCF flag in the SAES_ISR register is set.
9. Clear the CCF flag, by setting the CCF bit of the SAES_ICR register.

CCM header phase

10. Initialize header phase:
    a) Prepare the first block of the (B1) data associated with the message, in accordance with CCM chaining rules.
    b) Select the CCM header phase, by writing GCMPH[1:0] with 0x1. Do not change the other configurations written during the CCM initialization.
    c) Enable the SAES peripheral, by setting EN.
11. Append header data:
    a) If it is the last block and the associated data in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
    b) Append the data block into SAES as described in *Section 34.4.5*.
    c) Repeat the step *b)* until the second-last associated data block is processed. For the last block, follow the steps *a)* and *b)*.

Note: This phase can be skipped if there is no associated data, that is, Len(A) = 0

No data are read during the header phase.

CCM payload phase

12. Initialize payload phase:
    a) Select the CCM payload phase, by writing GCMPH[1:0] with 0x2. Do not change the other configurations written during the CCM initialization.
    b) If the header phase is skipped, enable the SAES peripheral, by setting EN.
13. Append payload data:
    a) In encryption only, if it is the last block and the plaintext in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
    b) Append the data block into SAES as described in *Section 34.4.5*, then read the SAES_DOUTR register four times to save the resulting block.
    c) Repeat the step *b)* until the second-last plaintext block is encrypted or until the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), follow the steps *a)* and *b)*. For the last block, discard the bits that are not part of the payload when the last block is smaller than 16 bytes.

Note: This phase can be skipped if there is no payload, that is, Len(P) = 0 or Len(C) = Len(T).

Remove $LSB_{Len(T)}(C)$ encrypted tag information when decrypting ciphertext C.

CCM finalization

14. Select the CCM final phase, by writing GCMPH[1:0] with 0x3. Do not change the other configurations written during the CCM initialization.
15. Wait until CCF flag in the SAES_ISR register is set.
16. Get the CCM authentication tag, by reading the SAES_DOUTR register four times.
17. Clear the CCF flag, by setting the CCF bit of the SAES_ICR register.
18. Disable the SAES peripheral, by clearing EN. If it is an authenticated decryption, compare the generated tag with the expected tag passed with the message. Mask the authentication tag output with tag length to obtain a valid tag.

Note: In the final phase, swapping is applied to tag data read from SAES_DOUTR register.

When transiting from the header or the payload phase to the final phase, the SAES peripheral must not be disabled, otherwise the result is wrong.

Suspend and resume operations in CCM mode

To suspend the processing of a message in header or payload phase, proceed as follows:

1. If DMA is used, stop the SAES DMA transfers to the input FIFO, by clearing DMAINEN. If DMA is not used, wait until the CCF flag of the SAES_ISR register is set (computation completed).
2. In the payload phase, if DMA is not used, read four times the SAES_DOUTR register to save the last-processed block. If DMA is used, wait until the CCF flag in the SAES_ISR register is set, then stop the DMA transfers from the output FIFO, by clearing DMAOUTEN.
3. Clear the CCF flag in the SAES_ISR register, by setting the CCF bit of the SAES_ICR register.
4. Save the SAES_SUSPRx registers in the memory.
5. Save the IV registers as they are altered during the data processing.
6. Disable the SAES peripheral, by clearing EN.

7. Save the current SAES_CR configuration in the memory. Key registers do not need to be saved as the original key value is known by the application.
8. If DMA is used, save the DMA controller status (pointer for SAES input data transfers, number of remaining bytes, and so on). In the payload phase, also save pointer for SAES output data transfers.

To resume the processing of a message, proceed as follows:

1. If DMA is used, configure the DMA controller in order to complete the remaining input FIFO transfers. In the payload phase, also configure the DMA controller for the remaining output FIFO transfers.
2. Disable the SAES peripheral, by clearing EN.
3. Write the suspend register values, previously saved in the memory, back into their corresponding SAES_SUSPRx registers.
4. Restore SAES_IVRx registers using the saved configuration.
5. Restore the initial setting values in the SAES_CR and SAES_KEYRx registers. Alternatively, select a key source different from the key registers, by setting KEYSEL[2:0] to a value different from 0x0. Refer to *Section 34.4.17: SAES key registers* for details.
6. Enable the SAES peripheral, by setting EN.
7. If DMA is used, enable SAES DMA requests, by setting DMAINEN (and DMAOUTEN if in payload phase).

34.4.14 SAES operation with wrapped keys

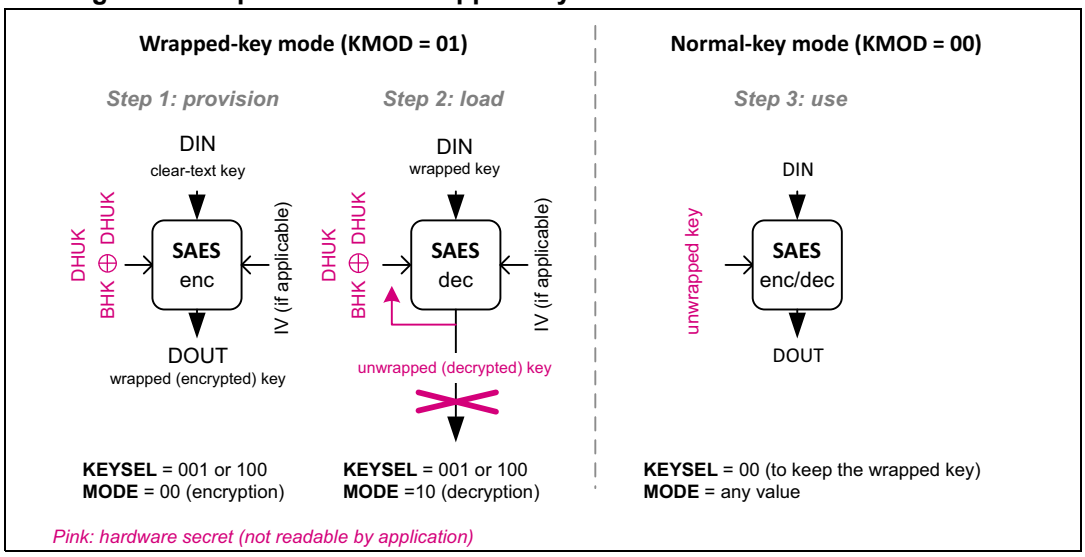
SAES peripheral can wrap (encrypt) and unwrap (decrypt) application keys using hardware-secret key DHUK, XOR-ed or not with application key BHK. With this feature, AES keys can be made usable by application software without being exposed in clear-text (unencrypted).

Wrapped key sequences are too small to be suspended/resumed. SAES cannot unwrap a key using an unwrapped key.

Operation with wrapped keys for SAES in ECB and CBC modes

Figure 324 summarizes how to wrap or unwrap keys for SAES in ECB and CBC modes. To protect the wrapped key, select DHUK by writing KEYSEL[2:0] with 0x1 or 0x4. Alternatively, select BHK by writing KEYSEL[2:0] with 0x2 if the corresponding registers are read/write-locked in the TAMP peripheral.

Figure 324. Operation with wrapped keys for SAES in ECB and CBC modes



Note: DHUK value depends on privilege, KMOD[1:0], KEYSEL[2:0], CHMOD[2:0], and on whether SAES peripheral is secure or non-secure.

Key wrapping for SAES

The recommended sequence to wrap (that is, encrypt) a key is as follows:

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register as follow:
   - Select ECB or CBC chaining mode (write CHMOD[2:0] with 0x0 or 0x1) in *encryption* mode (MODE[1:0] at 0x0)
   - Select 32-bit data type (DATATYPE[1:0] at 0x0)
   - Configure the key size with KEYSIZE. This information is used both for the encryption key and for the key to be encrypt.
   - Select wrapped key mode by writing KMOD[1:0] with 0x1
4. Write the initialization vector in SAES_IVRx registers if CBC mode has been selected in previous step.
5. Select the DHUK key source by writing KEYSEL[2:0] with 0x1 or 0x4. Refer to *Section 34.4.17* for details on the use of KEYSEL[2:0] at 0x4.
6. Wait until KEYVALID is set (DHUK loading completed).
7. Enable the SAES peripheral, by setting EN.
8. Write the SAES_DINR register four times to input the key to encrypt (MSB first, see *Table 321 on page 1329*).
9. Wait until CCF flag is set in the SAES_ISR register.
10. Get the encrypted key (MSB first) by reading the SAES_DOUTR register four times. Then clear the CCF flag, by setting the CCF bit in SAES_ICR register.
11. Repeat steps *8.* to *10.* if KEYSIZE is set.
12. Disable the SAES peripheral, by clearing EN.

Note: Encryption in Wrapped-key mode is only supported when ECB or CBC is selected.

Key unwrapping for SAES

The recommended sequence to unwrap (or decrypt) a wrapped (encrypted) key using ECB/CBC is as follows:

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register as follow:
   - Select the chaining mode used during the wrapping process (CHMOD[2:0] at 0x0 or 0x1) in *key derivation* mode (MODE[1:0] at 0x1)
   - Select 32-bit data type (DATATYPE[1:0] at 0x0)
   - Configure the key size used during the wrapping process, with KEYSIZE. This information is used both for the decryption key and for the key to decrypt.
   - Select wrapped key mode, by writing KMOD[1:0] with 0x1.
4. Select the DHUK key source, by writing KEYSEL[2:0] with 0x1 or 0x4. Refer to *Section 34.4.17* for details on the use of KEYSEL[2:0] at 0x4.
5. Wait until KEYVALID is set (the key loading completed).
6. Set EN bit in SAES_CR to enable the peripheral
7. Wait until CCF flag is set in the SAES_ISR register.
8. Clear the CCF flag, by setting the CCF bit in SAES_ICR register. The decryption key is available in the AES core, and SAES is disabled automatically.
9. Select the *decryption* mode (MODE[1:0] at 0x2). Other parameters are unchanged.
10. Write the initialization vector in SAES_IVRx registers if CBC mode has been selected in previous step.
11. Enable the SAES peripheral, by setting EN.
12. Write the SAES_DINR register four times to input the key to decrypt (MSB first, see *Table 321 on page 1329*).
13. Wait until CCF flag is set in the SAES_ISR register. Then clear the CCF flag by setting the CCF bit in SAES_ICR register. Reading SAES_DOUTR returns zero and triggers a read error (RDERR).
14. Repeat steps *12.* and *13.* if KEYSIZE is set.
15. Disable the SAES peripheral, by clearing EN.

At the end of this sequence, the decrypted wrapped key is immediately usable by the application for any AES operation (normal key mode). Decrypted wrapped key can be shared with an application running in a different security context (different security or Compartment ID attribute) if KEYPROT bit was cleared during step 3.

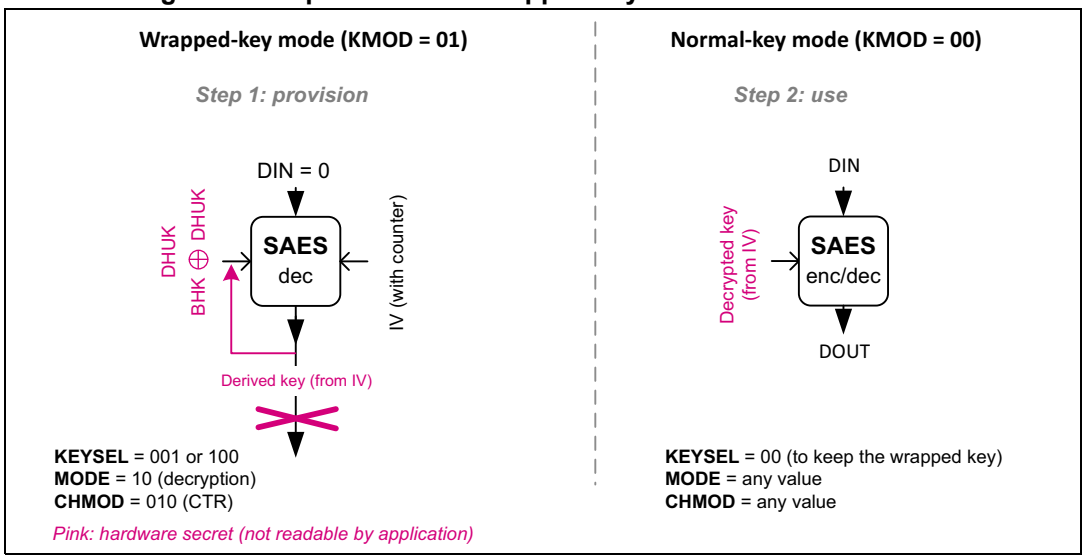
Note: When KMOD[1:0] = 0x1 (wrapped key) and MODE[1:0] = 0x2 (decryption) a read access to SAES_DOUTR register triggers a read error (RDERR).

When KEYSEL[2:0] is at 0x1 (DHUK) or 0x4 (DHUK XOR BHK), the application software must use the same privilege, security, KMOD[1:0], CHMOD[2:0] and KEYSIZE context for encryption and decryption. Otherwise, the result is incorrect.

Operation with wrapped keys for SAES in CTR mode

Figure 325 summarizes how to unwrap keys for SAES in CTR mode. To protect the derived key, select DHUK by writing KEYSEL[2:0] with 0x1 or 0x4. Alternatively, select BHK by writing KEYSEL[2:0] with 0x2 if the corresponding registers are read/write-locked in the TAMP peripheral.

Figure 325. Operation with wrapped keys for SAES in CTR mode



Note: DHUK value depends on privilege, KMOD[1:0], KEYSEL[2:0], CHMOD[2:0], and on whether SAES peripheral is secure or non-secure.

The recommended sequence for SAES wrapped key mode using CTR is as follows:

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register as follow:
   - Select the CTR chaining mode (CHMOD[2:0] at 0x2) in decryption mode (MODE[1:0] at 0x2). Other MODE[1:0] values are not supported.
   - Select 32-bit data type (DATATYPE[1:0] at 0x0)
   - Configure the key size with KEYSIZE. It is used for encryption key and for the key to share.
   - Select wrapped key mode, by writing KMOD[1:0] with 0x1.
4. Write the initialization vector in SAES_IVRx registers, keeping the two least significant bits of SAES_IVR0 at zero.
5. Select the DHUK key source by writing KEYSEL[2:0] with 0x1 or 0x4. Refer to *Section 34.4.17* for details on the use of KEYSEL[2:0] at 0x4.
6. Wait until KEYVALID is set (the key loading completed).
7. Enable the SAES peripheral, by setting EN.
8. Wait until CCF flag is set in the SAES_ISR register.
9. Clear the CCF flag, by setting the CCF bit in SAES_ICR register. The derived hardware secret key is available in SAES_KEYRx registers.
10. Repeat steps *8.* and *9.* if KEYSIZE is set.
11. Disable the SAES peripheral, by clearing EN.

At the end of this sequence, the hardware secret key derived from the public data in the SAES_IVRx registers is then immediately usable by the application for any AES operation (normal key mode).

Note: The configuration KMOD[1:0] at 0x1 (wrapped key), CHMOD[2:0] at 0x2 (CTR chaining), and MODE at 0x0 (encryption) disables the peripheral, by automatically clearing the EN bit of the SAES_*CR register.*

34.4.15 SAES operation with shared keys

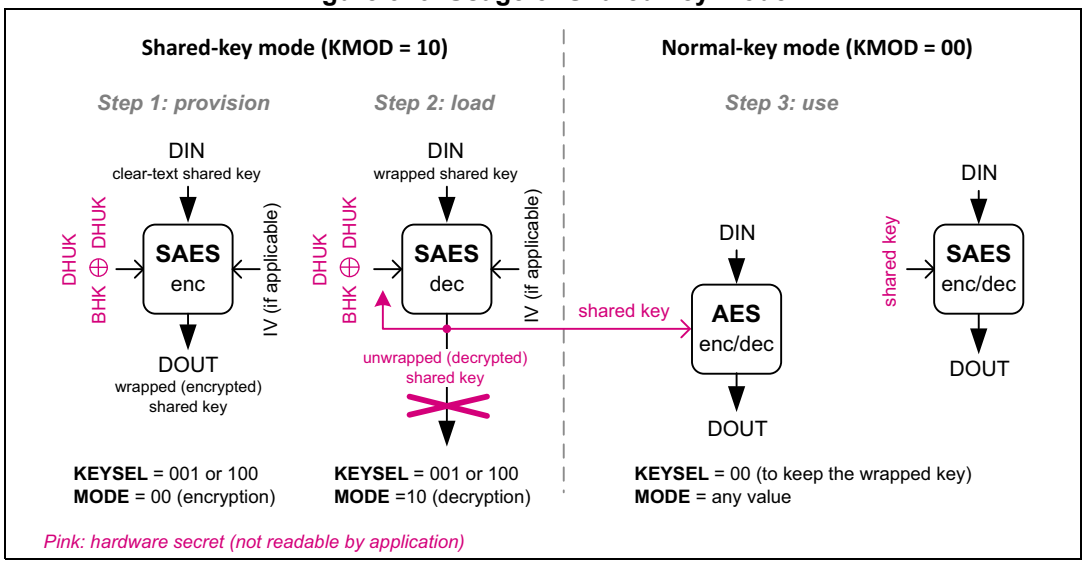
SAES peripheral can share application keys wrapped with hardware-secret key DHUK, XOR-ed or not with application key BHK. With this feature, the application software can make the AES keys available to the AES peripheral, without exposing them in clear-text (unencrypted).

Shared key sequences are too small to be suspended/resumed. SAES cannot unwrap a shared key using an unwrapped key.

Note: When a key stored in SAES is shared with AES, the protection given by KEYPROT bit is lost. The protection is detailed in Section 34.4.17: SAES key registers.

Figure 326 summarizes how to wrap or unwrap keys to share with *AES* peripheral. To protect the shared key, DHUK must be selected, by writing KEYSEL[2:0] with 0x1 or 0x4. Alternatively, select BHK by writing KEYSEL[2:0] with 0x2 if the corresponding registers are read/write-locked in the TAMP peripheral.

Figure 326. Usage of Shared-key mode



Note: DHUK value depends on privilege, KMOD[1:0], KSHAREID, KEYSEL[2:0], CHMOD[2:0], and on whether SAES peripheral is secure or non-secure.

In the step 3, AES represents the AES peripheral.

Key wrapping for AES peripheral

Before SAES can share a key with the AES peripheral, the key must be encrypted (wrapped) once. The encryption sequence of a shared key is the same as for a wrapped key, with KMOD[1:0] at 0x2 (shared key) and KSHAREID[1:0] kept at 0x0 in the step 3 in *Figure 326*. See *Key wrapping for SAES* for details.

Note: Encryption in Shared-key mode is only supported when ECB or CBC is selected.

Key unwrapping for AES peripheral (shared key)

Each time SAES needs to share a key with the AES peripheral, shared encrypted key must be decrypted (unwrapped) in SAES, then loaded by AES. The overall sequence is described next.

Sequence in the SAES peripheral

The decryption sequence of a shared key is the same as for a wrapped key, with KMOD[1:0] at 0x2 (shared key) and KSHAREID[1:0] kept at 0x0 in the step 3 in *Figure 326*. See *Key unwrapping for SAES* for details.

In shared key mode when decryption mode is selected (MODE[1:0] at 0x2), a read access to the SAES_DOUTR register triggers a read error (RDERR).

Note: Instead of being shared, a decrypted shared key can be used directly in SAES as the KEYSEL[2:0] bitfield is automatically cleared. In this case, KMOD[1:0] must be written with 0x0 (normal key mode).

Sequence in the AES peripheral

Once the shared key is decrypted in SAES key registers, it can be shared with the AES peripheral, while SAES peripheral remains in key sharing state, that is, with KMOD[1:0] at 0x2 and KEYVALID set. The sequence in the AES key share target peripheral is described in *AES key sharing with secure AES co-processor* of the corresponding section in this document. It can be run multiple times (for example, to manage a suspend/resume situation) as long as SAES is unused and duly remains in key sharing state.

Note: When KMOD[1:0] is at 0x2 and BUSY set in the AES peripheral, and KEYSIZE value of AES and SAES differs, the key sharing fails and the KEIF flag is raised in both peripherals.

When KEYSEL[2:0] is at 0x1 (DHUK) or 0x4 (DHUK XOR BHK), the application software must use the same privilege, security, KMOD[1:0] / KSHAREID[1:0], CHMOD[2:0], and KEYSIZE context for encryption and decryption. Otherwise, the result is incorrect.

34.4.16 SAES data registers and data swapping

Data input and output

A 16-byte data block enters the SAES peripheral with four successive 32-bit word writes into the SAES_DINR register (bitfield DIN[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

A 16-byte data block is retrieved from the SAES peripheral with four successive 32-bit word reads of the SAES_DOUTR register (bitfield DOUT[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

The four 32-bit words of a 16-byte data block must be stored in the memory consecutively and in big-endian order, that is, with the most significant word on the lowest address. See *Table 320* “no swapping” option for details.

Data swapping

The SAES peripheral can be configured to perform a bit-, a byte-, a half-word-, or no swapping on the input data word in the SAES_DINR register, before loading it to the AES processing core, and on the data output from the AES processing core, before sending it to the SAES_DOUTR register. The choice depends on the type of data. For example, a byte swapping is used for an ASCII text stream.

The data swap type is selected through DATATYPE[1:0]. The selection applies to both SAES input and output.

Note: The data in SAES key registers (SAES_KEYRx) and initialization vector registers (SAES_IVRx) are not sensitive to the swap mode selection.

The SAES data swapping feature is summarized in *Table 320* and *Figure 327*.

Table 320. AES data swapping example

DATATYPE[1:0]	Swapping performed	Data block
		System memory data (big-endian)
0x0	No swapping	Block[127..64]: 0x04EEF672 2E04CE96 Block[63..0]: 0x4E6F7720 69732074
		Address @, word[127..96]: 0x04EEF672 Address @ + 0x4, word[95..64]: 0x2E04CE96 Address @ + 0x8, word[63..32]: 0x4E6F7720 Address @ + 0xC, word[31..0]: 0x69732074
0x1	Half-word (16-bit) swapping	Block[63..0]: 0x**4E6F** 7720 **6973** 2074
		Address @, word[63..32]: 0x7720 **4E6F** Address @ + 0x4, word[31..0]: 0x2074 **6973**
0x2	Byte (8-bit) swapping	Block[63..0]: 0x**4E** 6F **77** 20 **69** 73 **20** 74
		Address @, word[63..32]: 0x20**77** 6F**4E** Address @ + 0x4, word[31..0]: 0x74**20** 73**69**
0x3	Bit swapping	Block[63..32]: 0x4E6F7720 0100 1110 0110 1111 0111 0111 0010 0000 Block[31..0]: 0x69732074 0110 1001 0111 0011 0010 0000 0111 0100

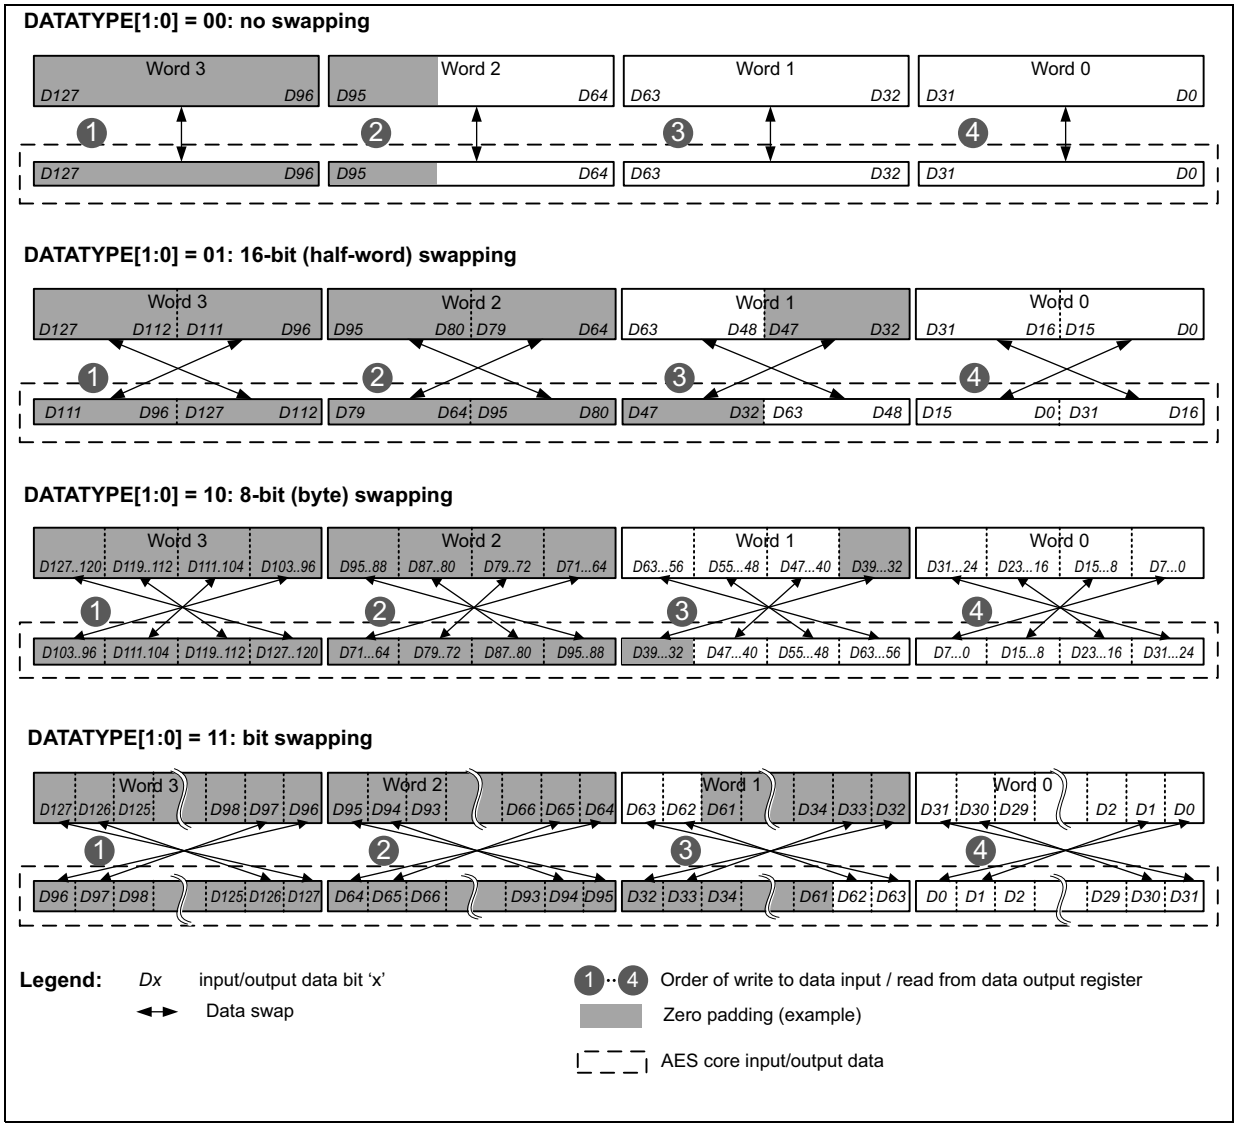
Figure 327. 128-bit block construction according to the data type



Data padding

Figure 327 also gives an example of memory data block padding with zeros such that the zeroed bits after the data swap form a contiguous zone at the MSB end of the AES core input buffer. The example shows the padding of an input data block containing:

- 84 message bits, with DATATYPE[1:0] = 0x0
- 48 message bits, with DATATYPE[1:0] = 0x1
- 56 message bits, with DATATYPE[1:0] = 0x2
- 34 message bits, with DATATYPE[1:0] = 0x3

34.4.17 SAES key registers

The eight SAES_KEYRx write-only registers store the encryption or decryption key information, as shown on *Table 321*. Reads are not allowed for security reason.

Note: In memory and in SAES *key registers, keys are stored in little-endian format, with most significant byte on the highest address.*

Table 321. Key endianness in SAES_KEYRx registers (128/256-bit keys)

SAES_KEYR7 [31:0]	SAES_KEYR6 [31:0]	SAES_KEYR5 [31:0]	SAES_KEYR4 [31:0]	SAES_KEYR3 [31:0]	SAES_KEYR2 [31:0]	SAES_KEYR1 [31:0]	SAES_KEYR0 [31:0]
-	-	-	-	KEY[127:96]	KEY[95:64]	KEY[63:32]	KEY[31:0]
KEY[255:224]	KEY[223:192]	KEY[191:160]	KEY[159:128]	KEY[127:96]	KEY[95:64]	KEY[63:32]	KEY[31:0]
TAMP_BKP7R [31:0]	TAMP_BKP6R [31:0]	TAMP_BKP5R [31:0]	TAMP_BKP4R [31:0]	TAMP_BKP3R [31:0]	TAMP_BKP2R [31:0]	TAMP_BKP1R [31:0]	TAMP_BKP0R [31:0]

The key registers are not affected by the data swapping feature controlled by the DATATYPE[1:0] bitfield.

Write operations to the SAES_KEYRx registers are ignored when SAES peripheral is enabled (EN bit set) and KEYSEL[2:0] is different from zero. The application must check this before modifying key registers.

The entire key must be written before starting an AES computation. In normal key mode (KMOD[1:0] at 0x0), with KEYSEL[2:0] at 0x0, the key registers must always be written in either ascending or descending order. The write sequence becomes:

- SAES_KEYRx (x = 0 to 3 or x=3 to 0) for KEYSIZE cleared
- SAES_KEYRx (x = 0 to 7 or x=7 to 0) for KEYSIZE set

Note: KEYSIZE must be written before the key.

As soon as the first key register is written, the KEYVALID flag is cleared. Once the key registers writing sequence is completed, KEYVALID is set and EN becomes writable. If an error occurs, KEYVALID is cleared and KEIF set (see *Section 34.4.19*).

Key selection

With KEYSEL[2:0] at 0x0, the application must write the key in the SAES_KEYRx registers.

With KEYSEL[2:0] at 0x1, a derived hardware unique key (DHUK), computed inside SAES from a non-volatile and secret root hardware unique key, is loaded directly into key registers, based on KEYSIZE information. Thanks to the key derivation function, a secure SAES uses a secure DHUK, while a non-secure SAES uses a non-secure DHUK.

With KEYSEL[2:0] at 0x2, the boot hardware key (BHK), stored in tamper-resistant secure backup registers, is entirely transferred into key registers upon a secure application performing a single read of all TAMP_BKPxR registers (x = 0 to 3 for KEYSIZE cleared, x = 0 to 7 for KEYSIZE set) in either ascending or descending order. Refer to *Table 321*.

With KEYSEL[2:0] at 0x4, the XOR combination of DHUK and BHK is entirely transferred into key registers upon a secure application performing a single read of all TAMP_BKPxR registers (x = 0 to 3 for KEYSIZE cleared, x = 0 to 7 for KEYSIZE set) in either ascending or descending order. Refer to *Table 321*.

Repeated writing of KEYSEL[2:0] with the same non-zero value only triggers the loading of DHUK or BHK if KEYVALID is set. The recommended method to clear KEYVALID is to set IPRST. Such method is required for example when switching from ECB decryption to ECB encryption, selecting the same BHK (KEYSEL[2:0] at 0x2).

For all KEYSEL[2:0] values, initiating the key-loading sequence sets the BUSY flag and clears the KEYVALID flag. Once the amount of bits defined by KEYSIZE is transfered to the SAES_KEYRx registers, BUSY is cleared, KEYVALID set and the EN bit becomes writable. If an error occurs, BUSY and KEYVALID are cleared and KEIF set (see *Section 34.4.19*).

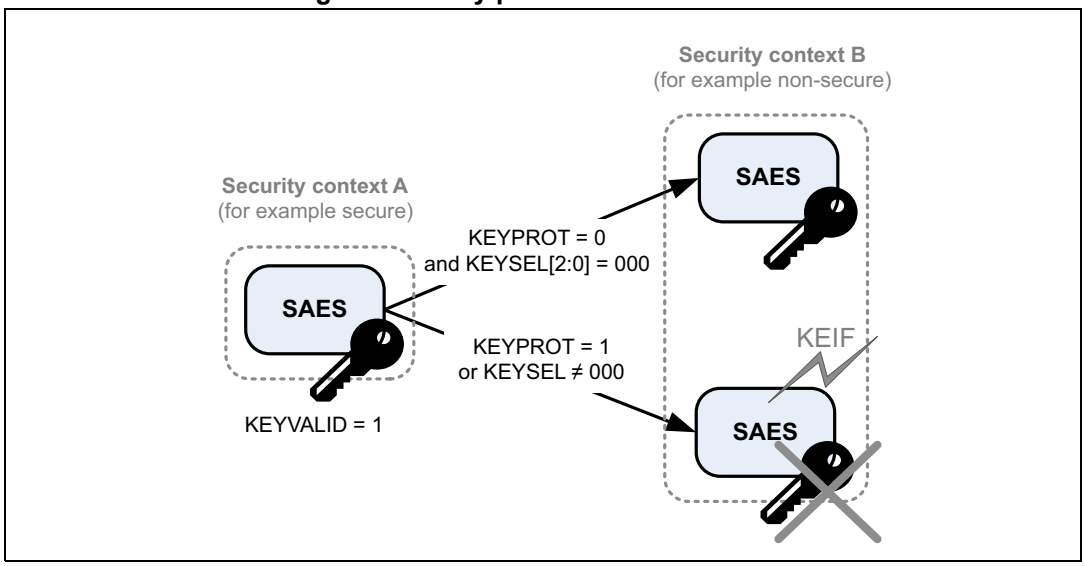
Note: DHUK, BHK and their XOR combination are not readable by any software (even secure).

Key protection

As depicted in *Figure 328*, when an application sets the KEYPROT bit before writing a key in SAES_KEYRx, any application executing in a different security context (that is, different security attribute) triggers a KEIF error flag upon access to any SAES register when KEYVALID is set.

Note: KEYSEL[2:0] values different from zero (normal key) automatically protect the key registers.

Figure 328. Key protection mechanisms



34.4.18 SAES initialization vector registers

The four SAES_IVRx registers store the initialization vector (IV) information, as shown in *Table 322*. They can only be written if the SAES peripheral is disabled (EN cleared).

Note: In memory and in SAES IV registers, initialization vectors are stored in little-endian format, with most significant byte on the highest address.

Table 322. IVI bitfield spread over SAES_IVRx registers

SAES_IVR3[31:0]	SAES_IVR2[31:0]	SAES_IVR1[31:0]	SAES_IVR0[31:0]
IVI[127:96]	IVI[95:64]	IVI[63:32]	IVI[31:0]

Initialization vector information depends on the chaining mode selected. When used, SAES_IVRx registers are updated upon each AES computation cycle (useful for managing suspend mode).

The initialization vector registers are not affected by the data swapping feature controlled through DATATYPE[1:0].

34.4.19 SAES error management

The SAES peripheral manages the errors described in this section.

Read error flag (RDERRF)

Unexpected read attempt of the SAES_DOUTR register returns zero, setting the RDERRF flag and the RWEIF flag. RDERRF is triggered during the computation phase or during the input phase.

Note: Unless otherwise indicated, SAES is not disabled when RDERRF rises and it continues processing.

An interrupt is generated if the RWEIE bit is set. For more details, refer to *Section 34.5: SAES interrupts*.

The RDERRF and RWEIF flags are cleared by setting the RWEIF bit of the SAES_ICR register.

Write error flag (WDERR)

Unexpected write attempt of the SAES_DINR register is ignored, setting the WRERRF and the RWEIF flags. WRERRF is triggered during the computation phase or during the output phase.

Note: Unless otherwise indicated, SAES is not disabled when WRERRF rises and it continues processing.

An interrupt is generated if the RWEIE bit is set. For more details, refer to *Section 34.5: SAES interrupts*.

The WRERRF and RWEIF flags are cleared by setting the RWEIF bit of the SAES_ICR register.

Key error interrupt flag (KEIF)

There are multiple sources of errors that set the KEIF flag of the SAES_ISR register and clear the KEYVALID bit of the SAES_SR register:

- **Key protection error:** while KEYVALID is set, then if KEYPROT is set or KEYSEL[2:0] is different from zero, this error is triggered when an application executing in a security context different from the one used to load the key (that is, different security attribute) accesses SAES.
- **Key writing sequence error:** triggered upon detecting an incorrect sequence of writing key registers. See *Section 34.4.17: SAES key registers* for details.
- **Key sharing size mismatch error:** triggered when KMOD[1:0] is at 0x2 and KEYSIZE in AES peripheral does not match KEYSIZE in SAES peripheral.

- **Key sharing error:** triggered upon failing transfer of SAES shared key to AES peripheral. See *Section 34.4.15: SAES operation with shared keys* for details.
- **Hardware secret key loading error:** triggered upon failing load of DHUK or BHK into SAES. KEYSEL[2:0] at 0x1 (DHUK), 0x2 (BHK) or 0x4 (DHUK XOR BHK) is not functional.

The KEIF flag is cleared with corresponding bit of the SAES_ICR register. An interrupt is generated if the KEIE bit of the SAES_IER register is set. For more details, refer to *Section 34.5: SAES interrupts*.

Upon a key selection error, clearing the KEIF flag automatically restarts the key selection process. Persisting problems (for example, RHUK load failing) may require a power-on reset.

Upon a key sharing error, reset both AES and SAES peripherals through the IPRST bit of their corresponding control register, then restart the key sharing sequence.

Note: For any key error, clear KEIF flag prior to disabling and re-configuring SAES.

RNG error interrupt flag (RNGEIF)

SAES fetches random numbers from the RNG peripheral automatically after an IP reset triggered in the RCC. SAES cannot be used when RNGEIF is set.

An error detected while fetching a random number from RNG peripheral (due to, for example, bad entropy) sets the RNGEIF flag of the SAES_ISR register. The flag is cleared by setting the corresponding bit of the SAES_ICR register. An interrupt is generated if the RNGEIE bit of the SAES_IER register is set. For more details, refer to *Section 34.5: SAES interrupts*.

Upon an RNG error:

- Verify that the RNG peripheral AHB clock is enabled and no noise source (or seed) error is pending in this peripheral.
- Clear RNGEIF or reset the peripheral by setting IPRST. The clearance of the BUSY flag then indicates the completion of the random number fetch from RNG.

Note: To avoid RNGEIF errors, it is recommended to activate the RNG AHB clock each time SAES AHB clock is activated.

About DPA errors

An unexpected error triggers an SAES internal tamper event in the TAMP peripheral, and stops any SAES co-processor processing.

To resume normal operation, reset the SAES peripheral through RCC or global reset.

34.5 SAES interrupts

There are multiple individual maskable interrupt sources generated by the SAES peripheral to signal the following events:

- computation completed (CCF)
- read error (RDERRF)
- write error (WRERRF)
- key error (KEIF)
- RNG error (RNGEIF)

See *Section 34.4.19: SAES error management* for details on SAES errors.

These sources are combined into a common interrupt signal from the SAES peripheral that connects to the Cortex® CPU interrupt controller. Application can enable or disable SAES interrupt sources individually by setting/clearing the corresponding enable bit of the SAES_IER register.

The status of the individual maskable interrupt sources can be read from the SAES_ISR register. They are cleared by setting the corresponding bit of the SAES_ICR register.

Table 323 gives a summary of the available features.

Table 323. SAES interrupt requests

Interrupt acronym	Interrupt event	Event flag	Enable bit	Interrupt clear method
SAES	computation completed flag	CCF	CCFIE	set CCF(1)
	read error flag	RDERRF(2)	RWEIE	set RWEIF(1)
	write error flag	WRERRF(2)		
	key error flag	KEIF	KEIE	set KEIF(1)
	RNG error flag	RNGEIF	RNGEIE	set RNGEIF(1)

1. Bit of the SAES_ICR register.
2. Flag of the SAES_SR register, mirrored by the flag RWEIF of the SAES_ISR register.

34.6 SAES DMA requests

The SAES peripheral provides an interface to connect to the DMA (direct memory access) controller. The DMA operation is controlled through the DMAINEN and DMAOUTEN bits of the SAES_CR register. When key derivation is selected (MODE[1:0] is at 0x1), setting those bits has no effect.

SAES only supports single DMA requests.

Detailed usage of DMA with SAES can be found in *Appending data using DMA* subsection of *Section 34.4.5: SAES encryption or decryption typical usage*.

Data input using DMA

Setting DMAINEN enables DMA writing into SAES. SAES then initiates, during the input phase, a set of single DMA requests for each 16-byte data block to write to the SAES_DINR register (quadruple 32-bit word, MSB first).

Note: According to the algorithm and the mode selected, special padding / ciphertext stealing might be required (see Section 34.4.7).

Data output using DMA

Setting DMAOUTEN enables DMA reading from SAES. SAES then initiates, during the output phase, a set of single DMA requests for each 16-byte data block to read from the SAES_DOUTR register (quadruple 32-bit word, MSB first).

After the output phase, at the end of processing of a 16-byte data block, SAES switches automatically to a new input phase for the next data block, if any.

In DMA mode, the CCF flag has no use because the reading of the SAES_DOUTR register is managed by DMA automatically at the end of the computation phase. The CCF flag must only be cleared when transiting back to managing the data transfers by software.

Note: According to the message size, extra bytes might need to be discarded by application in the last block.

Stopping DMA transfers

All DMA request signals are de-asserted when SAES is disabled (EN cleared) or the DMA enable bit (DMAINEN for input data, DMAOUTEN for output data) is cleared.

34.7 SAES processing latency

The following tables provide the 16-byte data block processing latency per operating mode.

Table 324. Processing latency for ECB, CBC and CTR

Key size	Mode of operation	Chaining algorithm	Clock cycles(1)
128-bit	Encryption or decryption(2)	ECB, CBC, CTR	**480**
	Key preparation	-	**145**
256-bit	Encryption or decryption(2)	ECB, CBC, CTR	**680**
	Key preparation	-	**230**

1. SAES kernel clock
2. Excluding key preparation time (ECB and CBC only).

Table 325. Processing latency for GCM and CCM (in SAES kernel clock cycles)

Key size	Mode of operation	Chaining algorithm	Initialization phase	Header phase(1)	Payload phase(1)	Final phase(1)
128-bit	Mode 1: Encryption/ Mode 3: Decryption	GCM	490	72(2)	480(3)	490
		CCM	490	490	800	490
256-bit	Mode 1: Encryption/ Mode 3: Decryption	GCM	650	72(2)	690(3)	650
		CCM	650	680	1350	650

1. Data insertion can include wait states forced by SAES on the AHB bus (maximum 3 cycles, typical 1 cycle).
2. SAES AHB clock cycles instead of kernel clock cycle (Galois multiplier only).
3. As a worst case in encryption mode, add extra 72 AHB clock cycles for the last block computation.

34.8 SAES registers

The registers are accessible through 32-bit word single accesses only. Other access types generate an AHB error, and other than 32-bit writes may corrupt the register content.

34.8.1 SAES control register (SAES_CR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IPRST	KEYSEL[2:0]			KSHAREID[1:0]		KMOD[1:0]		NPBLB[3:0]				KEYPROT	KEYSIZE	Res.	CHMOD[2]
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	GCMPH[1:0]		DMAOUTEN	DMAINEN	Res.	Res.	Res.	Res.	CHMOD[1:0]		MODE[1:0]		DATATYPE[1:0]		EN
	rw	rw	rw	rw					rw	rw	rw	rw	rw	rw	rw

Bit 31 **IPRST**: SAES peripheral software reset

Setting the bit resets the SAES peripheral, putting all registers to their default values, except the IPRST bit itself. Hence, any key-relative data are lost. For this reason, it is recommended to set the bit before handing over the SAES to a less secure application.

The bit must be kept low while writing any configuration registers.

Bits 30:28 **KEYSEL[2:0]**: Key selection

The bitfield defines the source of the key information to use in the AES cryptographic core.

0x0: Software key, loaded in key registers SAES_KEYx

0x1: Derived hardware unique key (DHUK)

0x2: Boot hardware key (BHK)

0x4: XOR of DHUK and BHK

Others: Reserved (if used, unfreeze SAES with IPRST)

When KEYSEL[2:0] is different from zero, selected key value is available in key registers when BUSY bit is cleared and KEYVALID is set in the SAES_SR register. Otherwise, the key error flag KEIF is set. Repeated writing of KEYSEL[2:0] with the same non-zero value only triggers the loading of DHUK or BHK when KEYVALID is cleared.

When the application software changes the key selection by writing the KEYSEL[2:0] bitfield, the key registers are immediately erased and the KEYVALID flag cleared.

At the end of the decryption process, if KMOD[1:0] is other than zero, KEYSEL[2:0] is cleared.

With the bitfield value other than zero and KEYVALID set, the application cannot transfer the ownership of SAES with a loaded key to an application running in another security context (such as secure, non-secure). More specifically, when security of an access to any register does not match the information recorded by SAES, the KEIF flag is set.

Attempts to write the bitfield are ignored when the BUSY flag of SAES_SR register is set, as well as when the EN bit of the SAES_CR register is set before the write access and it is not cleared by that write access.

Bits 27:26 **KSHAREID[1:0]**: Key share identification

This bitfield defines, at the end of a decryption process with KMOD[1:0] at 0x2 (shared key), which target can read the SAES key registers using a dedicated hardware bus.

0x0: AES peripheral

Others: Reserved

Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bits 25:24 **KMOD[1:0]**: Key mode selection

The bitfield defines how the SAES key can be used by the application. KEYSIZE must be correctly initialized when setting KMOD[1:0] different from zero.

0x0: Normal key mode. Key registers are freely usable and no specific use or protection applies to SAES_DINR and SAES_DOUTR registers.

0x1: Wrapped key for SAES mode. Key loaded in key registers can only be used to encrypt or decrypt AES keys. Hence, when a decryption is selected, read-as-zero SAES_DOUTR register is automatically loaded into SAES key registers after a successful decryption process.

0x2: Shared key mode. After a successful decryption process (unwrapping), SAES key registers are shared with the peripheral described in KSHAREID[1:0] bitfield. This sharing is valid only while KMOD[1:0] at 0x2 and KEYVALID=1. When a decryption is selected, read-as-zero SAES_DOUTR register is automatically loaded into SAES key registers after a successful decryption process.

Others: Reserved

With KMOD[1:0] other than zero, any attempt to configure the SAES peripheral for use by an application belonging to a different security domain (such as secure or non-secure) results in automatic key erasure and setting of the KEIF flag.

Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bits 23:20 **NPBLB[3:0]:** Number of padding bytes in last block

This padding information must be filled by software before processing the last block of GCM payload encryption or CCM payload decryption, otherwise authentication tag computation is incorrect.

0x0: All bytes are valid (no padding)

0x1: Padding for the last LSB byte

...

0xF: Padding for the 15 LSB bytes of last block.

Bit 19 **KEYPROT**: Key protection

When set, hardware-based key protection is enabled.

0: When KEYVALID is set and KEYSEL[2:0] = 0 application can transfer the ownership of the SAES, with its loaded key, to an application running in another security context (such as non-secure, secure).

1: When KEYVALID is set, key error flag (KEIF) is set when an access to any registers is detected, this access having a security context (for example, secure, non-secure) that does not match the one of the application that loaded the key.

Attempts to write the bit are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bit 18 **KEYSIZE:** Key size selection

This bitfield defines the key length in bits of the key used by SAES.

0: 128-bit

1: 256-bit

When KMOD[1:0] is at 0x1 or 0x2, KEYSIZE also defines the length of the key to encrypt or decrypt.

Attempts to write the bit are ignored when BUSY is set, as well as when the EN is set before the write access and it is not cleared by that write access.

Bit 17 Reserved, must be kept at reset value.

Bit 15 Reserved, must be kept at reset value.

Bits 14:13 **GCMPH[1:0]:** GCM or CCM phase selection

This bitfield selects the phase, applicable only with GCM, GMAC or CCM chaining modes.
0x0: Initialization phase
0x1: Header phase
0x2: Payload phase
0x3: Final phase

Bit 12 **DMAOUTEN**: DMA output enable

This bit enables automatic generation of DMA requests during the data phase, for outgoing data transfers from SAES via DMA.
0: Disable
1: Enable
Setting this bit is ignored when MODE[1:0] is at 0x1 (key derivation).

Bit 11 **DMAINEN**: DMA input enable

This bit enables automatic generation of DMA requests during the data phase, for incoming data transfers to SAES via DMA.
0: Disable
1: Enable
Setting this bit is ignored when MODE[1:0] is at 0x1 (key derivation).

Bits 10:7 Reserved, must be kept at reset value.

Bits 16, 6:5 **CHMOD[2:0]**: Chaining mode

This bitfield selects the AES chaining mode:
0x0: Electronic codebook (ECB)
0x1: Cipher-block chaining (CBC)
0x2: Counter mode (CTR)
0x3: Galois counter mode (GCM) and Galois message authentication code (GMAC)
0x4: Counter with CBC-MAC (CCM)
others: Reserved
Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bits 4:3 **MODE[1:0]**: Operating mode

This bitfield selects the SAES operating mode:
0x0: Encryption
0x1: Key derivation (or key preparation), for ECB/CBC decryption only
0x2: Decryption
0x3: Reserved
Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bits 2:1 **DATATYPE[1:0]**: Data type

This bitfield defines the format of data written in the SAES_DINR register or read from the SAES_DOUTR register, through selecting the mode of data swapping. This swapping is defined in *Section 34.4.16: SAES data registers and data swapping*.
0x0: No swapping (32-bit data).
0x1: Half-word swapping (16-bit data)
0x2: Byte swapping (8-bit data)
0x3: Bit-level swapping
Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bit 0 **EN**: Enable

This bit enables/disables the SAES peripheral.

0: Disable

1: Enable

At any moment, clearing then setting the bit re-initializes the SAES peripheral. When KMOD[1:0] is different from 0x0, using IPRST bit is recommended instead.

This bit is automatically cleared by hardware upon the completion of the key preparation (MODE[1:0] at 0x1) and upon the completion of GCM/GMAC/CCM initialization phase.

The bit cannot be set as long as KEYVALID is cleared, or when SAES is in one of the following configurations:

– KMOD[1:0] at 0x1 (wrap), CHMOD[2:0] at 0x3 (GCM)

– KMOD[1:0] at 0x1 (wrap), CHMOD[2:0] at 0x2 (CTR), MODE[1:0] at 0x0 (encryption).

34.8.2 SAES status register (SAES_SR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	KEYVALID	Res.	Res.	Res.	BUSY	WRERRF	RDERRF	Res.
								r				r	r	r	

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **KEYVALID**: Key valid flag

This bit is set by hardware when the key of size defined by KEYSIZE is loaded in SAES_KEYRx key registers.

0: Key not valid

1: Key valid

The EN bit can only be set when KEYVALID is set.

In normal mode when KEYSEL[2:0] is at zero, the key must be written in the key registers in the correct sequence, otherwise the KEIF flag is set and KEYVALID remains cleared.

When KEYSEL[2:0] is different from zero, the BUSY flag is automatically set by SAES. When the key is loaded successfully, BUSY is cleared and KEYVALID set. Upon an error, KEIF is set, BUSY cleared and KEYVALID remains cleared.

If set, KEIF must be cleared through the SAES_ICR register, otherwise KEYVALID cannot be set. See the KEIF flag description for more details.

For further information on key loading, refer to *Section 34.4.17: SAES key registers*.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **BUSY:** Busy

This flag indicates whether SAES is idle or busy.

0: Idle

1: Busy

SAES is flagged as idle when disabled (when EN is low) or when the last processing is completed.

SAES is flagged as busy when processing a block data, preparing a key (ECB or CBC decryption only), fetching random number from the RNG, or transferring a shared key to the target peripheral.

When GCM encryption is selected, this flag must be at zero before suspending current process to manage a higher-priority message. BUSY must also be cleared before selecting the GCM final phase.

Bit 2 **WRERRF**: Write error flag

This bit is set when an unexpected write to the SAES_DINR register occurred. When set WRERRF bit has no impact on the SAES operations.

0: No error

1: Unexpected write to SAES_DINR register occurred during computation or data output phase.

The flag setting generates an interrupt if the RWEIE bit of the SAES_IER register is set.

The flag is cleared by setting the RWEIF bit of the SAES_ICR register.

Bit 1 **RDERRF**: Read error flag

This bit is set when an unexpected read to the SAES_DOUTR register occurred. When set RDERRF bit has no impact on the SAES operations.

0: No error

1: Unexpected read to SAES_DOUTR register occurred during computation or data input phase.

The flag setting generates an interrupt if the RWEIE bit of the SAES_IER register is set.

The flag is cleared by setting the RWEIF bit of the SAES_ICR register.

Bit 0 Reserved, must be kept at reset value.

34.8.3 SAES data input register (SAES_DINR)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DIN[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DIN[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **DIN[31:0]**: Data input

A four-fold sequential write to this bitfield during the Input phase results in writing a complete 16-bytes block of input data to the SAES peripheral. From the first to the fourth write, the corresponding data weights are [127:96], [95:64], [63:32], and [31:0]. Upon each write, the data from the 32-bit input buffer are handled by the data swap block according to the DATATYPE[1:0] bitfield, then written into the AES core 16-bytes input buffer.

Reads return zero.

34.8.4 SAES data output register (SAES_DOUTR)

Address offset: 0x00C

Reset value: 0x0000 0000

Read when KMOD[1:0] is at 0x1 or 0x2 while MODE[1:0] is at 0x2 and EN is set triggers a read error.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DOUT[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DOUT[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **DOUT[31:0]**: Data output

This read-only bitfield fetches a 32-bit output buffer. A four-fold sequential read of this bitfield, upon the computation completion (CCF flag set), virtually reads a complete 16-byte block of output data from the SAES peripheral. Before reaching the output buffer, the data produced by the AES core are handled by the data swap block according to the DATATYPE[1:0] bitfield.

Data weights from the first to the fourth read operation are: [127:96], [95:64], [63:32], and [31:0].

34.8.5 SAES key register 0 (SAES_KEYR0)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
KEY[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
KEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **KEY[31:0]**: Cryptographic key, bits [31:0]

These are bits [31:0] of the write-only bitfield KEY[255:0] AES encryption or decryption key, depending on the MODE[1:0] bitfield of the SAES_CR register.

Writes to SAES_KEYRx registers are ignored when SAES is enabled (EN bit set). When KEYSEL[2:0] is different from 0 and KEYVALID is 0, writes to key registers are also ignored and they result in setting the KEIF bit of the SAES_ISR register.

With KMOD[1:0] at 0x0, a special writing sequence is required. In this sequence, any valid write to AES_KEYRx register clears the KEYVALID flag except for the sequence-completing write that sets it. Also refer to the description of the KEYVALID flag in the AES_SR register.

34.8.6 SAES key register 1 (SAES_KEYR1)

Address offset: 0x014

Reset value: 0x0000 0000

IVI[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **IVI[31:0]**: Initialization vector input, bits [31:0]

SAES_IVRx registers store the 128-bit initialization vector or the nonce, depending on the chaining mode selected. This value is updated by hardware after each computation round (when applicable). Write to this register is ignored when EN bit is set in SAES_SR register

34.8.10 SAES initialization vector register 1 (SAES_IVR1)

Address offset: 0x024

Reset value: 0x0000 0000

KEY[239:224]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **KEY[255:224]**: Cryptographic key, bits [255:224]

Refer to the SAES_KEYR0 register for description of the KEY[255:0] bitfield and for information relative to writing SAES_KEYRx registers.

34.8.17 SAES suspend registers (SAES_SUSPRx)

Address offset: 0x040 + x * 0x4, (x = 0 to 7)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SUSP[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SUSP[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SUSP[31:0]**: Suspend data

SAES_SUSPRx registers contain the complete internal register states of the SAES when the CCM processing of the current task is suspended to process a higher-priority task. Refer to *Section 34.4.8: SAES suspend and resume operations* for more details.

Read to this register returns zero when EN bit is cleared in SAES_SR register.

SAES_SUSPRx registers are not used in other chaining modes than CCM.

34.8.18 SAES interrupt enable register (SAES_IER)

Address offset: 0x300

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RNGEIE	KEIE	RWEIE	CCFIE
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **RNGEIE:** RNG error interrupt enable

This bit enables or disables (masks) the SAES interrupt generation when RNGEIF (RNG error flag) is set.

0: Disabled (masked)

1: Enabled (not masked)

Bit 2 **KEIE:** Key error interrupt enable

This bit enables or disables (masks) the SAES interrupt generation when KEIF (key error flag) is set.

0: Disabled (masked)

1: Enabled (not masked)

Bit 1 **RWEIE:** Read or write error interrupt enable

This bit enables or disables (masks) the SAES interrupt generation when RWEIF (read and/or write error flag) is set.

0: Disabled (masked)

1: Enabled (not masked)

Bit 0 **CCFIE:** Computation complete flag interrupt enable

This bit enables or disables (masks) the SAES interrupt generation when CCF (computation complete flag) is set.

0: Disabled (masked)

1: Enabled (not masked)

34.8.19 SAES interrupt status register (SAES_ISR)

Address offset: 0x304

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RNGEIF	KEIF	RWEIF	CCF
												r	r	r	r

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **RNGEIF:** RNG error interrupt flag

This read-only bit is set by hardware when an error is detected on RNG bus interface (for example bad entropy).

0: RNG bus is functional

1: Error detected on RNG bus interface (random seed fetching error)

The flag setting generates an interrupt if the RNGEIE bit of the SAES_IER register is set.

The flag is cleared by setting the corresponding bit of the SAES_ICR register. The clear action triggers the reload of a new random number from the RNG peripheral.

Bit 2 **KEIF:** Key error interrupt flag

This read-only bit is set by hardware when the key information fails to load into key registers or when the key register use is forbidden.

0: No key error detected

1: Key information failed to load into key registers or the key register use is forbidden

The flag setting generates an interrupt if the KEIE bit of the SAES_IER register is set.

The flag is cleared by setting the corresponding bit of the SAES_ICR register.

KEIF is raised upon any of the following events:

–SAES fails to load the DHUK (KEYSEL[2:0] = 0x1 or 0x4).

–SAES fails to load the BHK (KEYSEL[2:0] = 0x2 or 0x4).

–AES fails to load the key shared by SAES peripheral (KMOD[1:0] = 0x2).

–KEYVALID is set and either KEYPROT is set or KEYSEL[2:0] is other than 0x0. The security context of the application that loads the key (secure or non-secure) does not match the security attribute of the access to SAES_CR or SAES_DOUT. In this case, KEYVALID and EN bits are cleared.

–SAES_KEYRx register write does not respect the correct order. (For KEYSIZE cleared, SAES_KEYR0 then SAES_KEYR1 then SAES_KEYR2 then SAES_KEYR3 register, or reverse. For KEYSIZE set, SAES_KEYR0 then SAES_KEYR1 then SAES_KEYR2 then SAES_KEYR3 then SAES_KEYR4 then SAES_KEYR5 then SAES_KEYR6 then SAES_KEYR7, or reverse).

KEIF must be cleared by the application software, otherwise KEYVALID cannot be set.

Bit 1 **RWEIF:** Read or write error interrupt flag

This read-only bit is set by hardware when a RDERRF or a WRERRF error flag is set in the SAES_SR register.

0: No read or write error detected

1: Read or write error detected

The flag setting generates an interrupt if the RWEIE bit of the SAES_IER register is set.

The flag is cleared by setting the corresponding bit of the SAES_ICR register.

The flags has no meaning when key derivation mode is selected.

See the SAES_SR register for details.

Bit 0 **CCF:** Computation complete flag

This flag indicates whether the computation is completed. It is significant only when the DMAOUTEN bit is cleared, and it may stay high when DMAOUTEN is set.

0: Not completed

1: Completed

The flag setting generates an interrupt if the CCFIE bit of the SAES_IER register is set.

The flag is cleared by setting the corresponding bit of the SAES_ICR register.

34.8.20 SAES interrupt clear register (SAES_ICR)

Address offset: 0x308

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RNGEIF	KEIF	RWEIF	CCF
												w	w	w	w

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **RNGEIF:** RNG error interrupt flag clear

Application must set this bit to clear the RNGEIF status bit in SAES_ISR register.

Bit 2 **KEIF:** Key error interrupt flag clear

Setting this bit clears the KEIF status bit of the SAES_ISR register.

Bit 1 **RWEIF:** Read or write error interrupt flag clear

Setting this bit clears the RWEIF status bit of the SAES_ISR register, and clears both RDERRF and WRERRF flags in the SAES_SR register.

Bit 0 **CCF:** Computation complete flag clear

Setting this bit clears the CCF status bit of the SAES_ISR register.

Refer to *Section 2.3 on page 111* for the register boundary addresses.

35 Hash processor (HASH)

35.1 Introduction

The hash processor is a fully compliant implementation of the secure hash algorithm (SHA-1, SHA-2 family) and the HMAC (keyed-hash message authentication code) algorithm. HMAC is suitable for applications requiring message authentication.

The hash processor computes FIPS (Federal Information Processing Standards) approved digests of length of 160, 224, 256 bits, for messages of any length less than 2^{64} bits (for SHA-1, SHA-224 and SHA-256) or less than 2^{128} bits (for SHA-384, SHA-512).

35.2 HASH main features

- Suitable for data authentication applications, compliant with:
  - Federal Information Processing Standards Publication FIPS PUB 180-4, *Secure Hash Standard* (SHA-1 and SHA-2 family)
  - Federal Information Processing Standards Publication FIPS PUB 186-4, *Digital Signature Standard (DSS)*
  - Internet Engineering Task Force (IETF) Request For Comments RFC 2104, *HMAC: Keyed-Hashing for Message Authentication* and Federal Information Processing Standards Publication FIPS PUB 198-1, *The Keyed-Hash Message Authentication Code (HMAC)*
- Fast computation of SHA-1, SHA2-224, SHA2-256, SHA2-384, and SHA2-512
  - 82 (respectively 66) clock cycles for processing one 512-bit block of data using SHA-1 (respectively SHA-256) algorithm
  - 98 clock cycles for processing one 1024-bit block of data using either SHA2-384 or SHA2-512 algorithm
  - Support for SHA-2 truncated outputs (SHA2-512/224, SHA2-512/256)
- Support for HMAC mode with all supported algorithm
- Corresponding 32-bit words of the digest from consecutive message blocks are added to each other to form the digest of the whole message
  - Automatic 32-bit words swapping to comply with the internal little-endian representation of the input bit-string
  - Supported word swapping format: bits, bytes, half-words and 32-bit words
- Single 32-bit, write-only, input register associated to an internal input FIFO, corresponding to a 64-byte block size (16 x 32 bits)
- Automatic padding to complete the input bit string to fit digest minimum block size
- AHB slave peripheral, accessible by 32-bit words only (else an AHB error is generated)
- 8 × 32-bit words (H0 to H15) for output message digest
- Automatic data flow control supporting direct memory access (DMA) using one channel.
- Support for both single and fixed DMA burst transfers of four words.
- Interruptible message digest computation, on a per-block basis
  - Re-loadable digest registers
  - Hashing computation suspend/resume mechanism, including DMA

35.3 HASH implementation

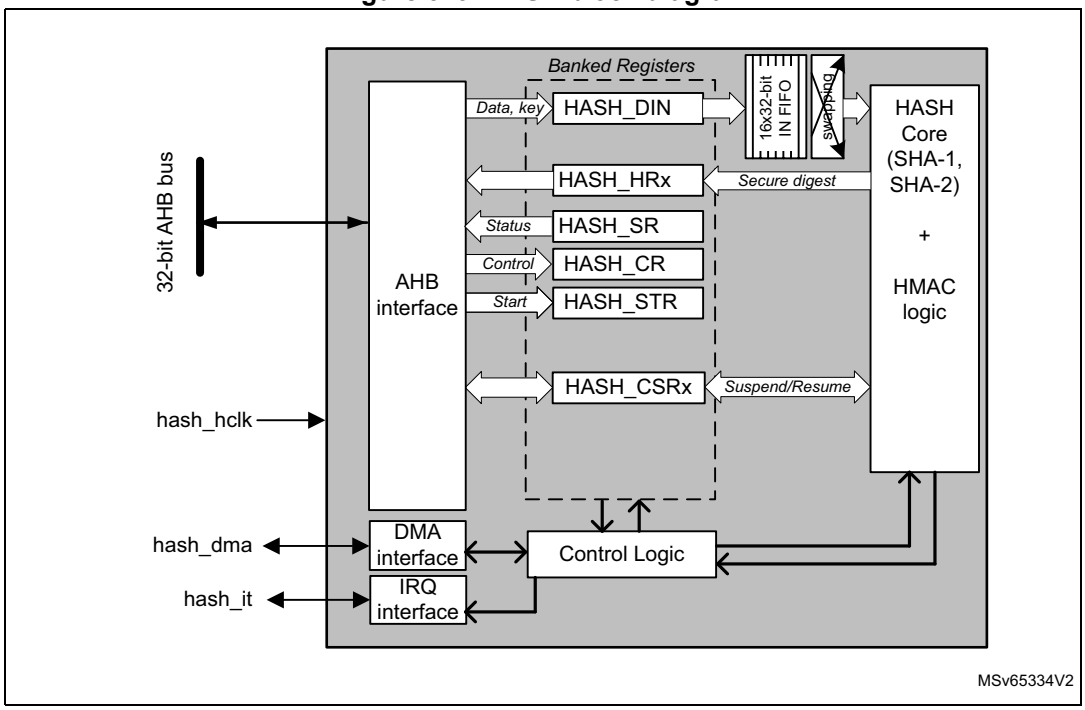
The devices have a single instance of HASH peripheral.

35.4 HASH functional description

35.4.1 HASH block diagram

Figure 329 shows the block diagram of the hash processor.

Figure 329. HASH block diagram



35.4.2 HASH internal signals

Table 327 describes a list of useful to know internal signals available at HASH level, not at product level (on pads).

Table 327. HASH internal input/output signals

Signal name	Signal type	Description
hash_hclk	digital input	AHB bus clock
hash_it	digital output	Hash processor global interrupt request
hash_dma	digital input/output	DMA burst request/ acknowledge

35.4.3 About secure hash algorithms

The hash processor is a fully compliant implementation of the secure hash algorithm defined by FIPS PUB 180-4 standard.

With each algorithm, the HASH computes a condensed representation of a message or data file. More specifically, when a message is presented on the input, the HASH processing core produces a fixed-length output string called a message digest (see *Table 328*).

Table 328. Information on supported hash algorithms

Algorithm	Message digest size (in bits)	Block size (in bytes)(1)	Message length	Bit string message
SHA-1	160	64	$< 2^{64}$ bits	Yes
SHA2-224	224			
SHA2-256	256			
SHA2-384	384	128	$< 2^{128}$ bits	Yes
SHA2-512	512(2)			

1. Block size = (NBWE-1) * 4 bytes. NBWE[4:0] bitfield can be read from the HASH_SR register after ALGO and INIT bits are written in the HASH_CR register.
2. Digest size is 224 bits for SHA2-512/224 and 256 bits for SHA2-512/256 (truncated modes).

The message digest can then be processed with a digital signature algorithm in order to generate or verify the signature for the message.

Signing the message digest rather than the message often improves the efficiency of the process since the message digest is usually much smaller in size than the message. The verifier of a digital signature has to use the same hash algorithm as the one used by the creator of the digital signature.

The SHA-2 functions supported by the hash processor are qualified as “secure” by NIST because it is computationally infeasible to find a message that corresponds to a given message digest, or to find two different messages that produce the same message digest (SHA-1 does not qualify as secure since February 2017). Any change to a message in transit results, with very high probability, in a different message digest, and the signature fails to verify.

35.4.4 Message data feeding

The message (or data file) to be processed by the HASH must be considered as a bit string. Per FIPS PUB 180-4 standard this message bit string grows from left to right, with hexadecimal words expressed in “big-endian” convention, so that within each word, the most significant bit is stored in the left-most bit position. For example message string “abc” with a bit string representation of “**01100001 01100010 01100011**” is represented by a 32-bit word **0x00636261**, and 8-bit words **0x61626300**.

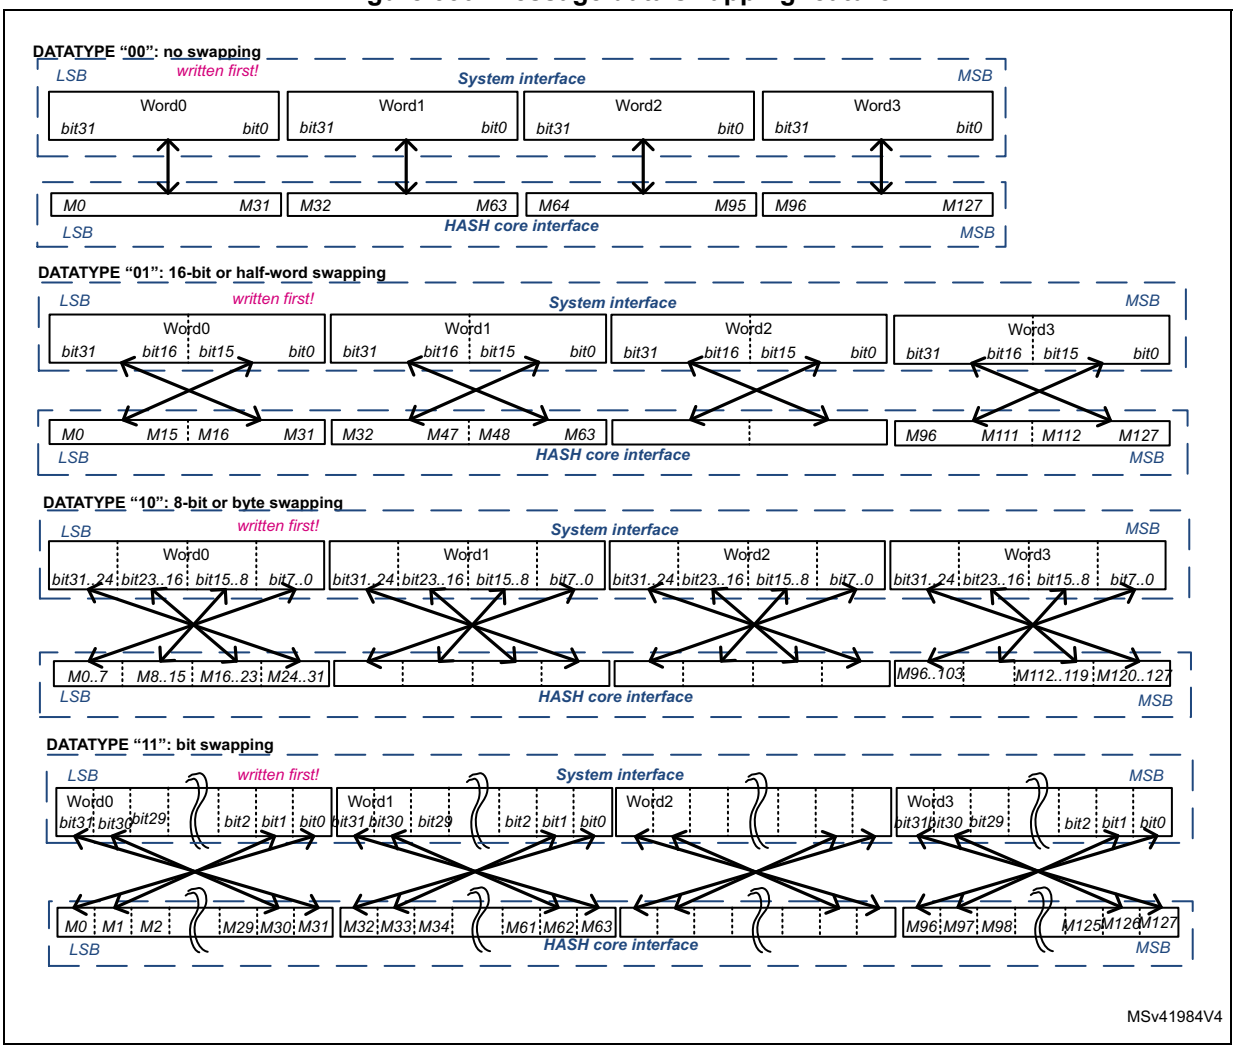
Data are entered into the HASH one 32-bit word at a time, by writing them into the HASH_DIN register. The current contents of the HASH_DIN register are transferred to the 16 words input FIFO each time the register is written with new data. Hence HASH_DIN and the FIFO form a seventeen 32-bit words length FIFO (named the IN buffer).

In accordance to the kind of data to be processed (for example byte swapping when data are ASCII text stream) there must be a bit, byte, half-word or no swapping operation to be

performed on data from the input FIFO before entering the little-endian hash processing core. *Figure 330* shows how the hash processing core 32-bit data block M0...31 is constructed from one 32-bit words popped into input FIFO by the driver, according to the DATATYPE bitfield in the HASH control register (HASH_CR)

HASH_DIN data endianness when bit swapping is disabled (DATATYPE = 00) can be described as following: the least significant bit of the message has to be at MSB position in the first word entered into the hash processor, the 32nd bit of the bit string has to be at MSB position in the second word entered into the hash processor and so on.

Figure 330. Message data swapping feature



35.4.5 Message digest computing

The hash processor sequentially processes several blocks when computing the message digest. Block sizes can be found in *Table 328: Information on supported hash algorithms*.

Each time the DMA or the CPU writes a block to the hash processor, the HASH automatically starts computing the message digest. This operation is known as partial digest computation.

As described in *Section 35.4.4: Message data feeding*, the message to be processed is entered into the HASH 32-bit word at a time, writing to the HASH_DIN register to fill the input FIFO. In order to perform the hash computation on this data the application must follow below sequence.

1. Initialize the hash processor using the HASH_CR register:
   - Write to the HASH_CR register to select the right algorithm using the ALGO bitfield, and set the INIT bit (other bits are kept at zero). Then read the NBWE bitfield from the HASH_SR register to deduce the algorithm block size, which equals `(NBWE-1) * 4`. This step is not required if the block size is already known (see *Table 328* for details).
   - Select the right algorithm using the ALGO[3:0] field. If needed, program the correct swapping operation on the message input words using the DATATYPE[1:0] bitfield.
   - When HMAC mode is required, set the MODE bit as well as the LKEY bit if the HMAC key size is greater than the known block size of the algorithm (otherwise keep LKEY cleared). Refer to *Section 35.4.7: HMAC operation* for details.
   - Update NBLW[4:0] in the HASH_STR register to define the number of valid bits in the last word of the message if it is different from 32 bits. NBLW information are used to correctly perform the automatic message padding before the final message digest computation.
2. Complete the initialization by setting the INIT bit in HASH_CR register. Also set the DMAE bit if data are transferred via DMA.

Caution: When programming step 2, it is important that the correct configuration values (ALGO, DATATYPE, HMAC mode, key length, NBLW) are set up before or at the same time.

3. Start filling data by writing to the HASH_DIN register, unless data are automatically transferred via DMA. Note that the processing of a block can start only once the last value of the block has entered the input FIFO. The way the partial or final digest computation is managed depends on the way data are fed into the processor:
   - Data are filled by software:

     Partial digest computations are triggered each time the application writes the first word of the next block, the block size being defined by NBWE bits in HASH_SR. Once the processor is ready again (DINIS = 1 in HASH_SR), the software can write new data to HASH_DIN. This mechanism avoids the introduction of wait states by the HASH.

     The final digest computation is triggered when the last block is entered and the software sets the DCAL bit. If the message length is not an exact multiple of the

block size, the NBLW field in HASH_STR register must be written prior to writing DCAL bit (see *Section 35.4.6* for details).

– Data are filled as a single DMA transfer (MDMAT = 0):

  Partial digest computations are triggered automatically each time the FIFO is full.

  The final digest computation is triggered automatically when the last block has been transferred to the HASH_DIN register by DMA (DCAL bit is set by hardware). If the message length is not an exact multiple of the block size, the NBLW field in HASH_STR register must be written prior to enabling the DMA (see *Section 35.4.6* for details).

– Data are filled using multiple DMA transfers (MDMAT = 1):

  Partial digest computations are triggered as for single DMA transfers (refer to the above description). However the final digest computation is not triggered automatically when the last block has been transferred by DMA to the HASH_DIN register (DCAL bit is not set by hardware). It enables the hash processor to receive a new DMA transfer as part of this digest computation. To launch the final digest computation, the software must clear MDMAT bit before the last DMA transfer in order to trigger the final digest computation as it is done for single DMA transfers.

4. Once the digest calculation is completed (DCIS = 1), the resulting digest can be read from the output registers, as described in *Table 329*.

Table 329. Hash processor outputs

Algorithm	Valid output registers	Most significant bit	Digest size (in bits)
SHA-1	HASH_H0 to HASH_H4	HASH_H0[31]	160
SHA2-224	HASH_H0 to HASH_H6	HASH_H0[31]	224
SHA2-256	HASH_H0 to HASH_H7		256
SHA2-384	HASH_H0 to HASH_H11	HASH_H0[31]	384
SHA2-512	HASH_H0 to HASH_H15		512(1)

1. Digest size is 224 bits for SHA2-512/224 and 256 bits for SHA2-512/256 (truncated modes)

For more information about HMAC detailed instructions, refer to *Section 35.4.7: HMAC operation*.

35.4.6 Message padding

Overview

When computing a condensed representation of a message, the process of feeding data into the hash processor (with automatic partial digest computation every block size transfer) loops until the last bits of the original message are written to the HASH_DIN register.

As the length (number of bits) of a message can be any integer value, the last word written to the hash processor may have a valid number of bits between 1 and 32. This number of valid bits in the last word, NBLW, has to be written to the HASH_STR register, so that message padding is correctly performed before the final message digest computation.

Padding processing

Detailed padding sequences, with DMA enabled or disabled, are described in *Section 35.4.5: Message digest computing*.

Padding example

As specified by Federal Information Processing Standards PUB 180-4, message padding consists in appending a “1” followed by *k* “0”s, itself followed by a 64-bit integer that is equal to the length *L* in bits of the message. These three padding operations generate a padded message of length *L* + 1 + *k* + 64, which by construction is a multiple of 512 bits.

For the hash processor, the “1” is added to the last word written to the HASH_DIN register at the bit position defined by the NBLW bitfield, and the remaining upper bits are cleared (“0”s).

Example from FIPS PUB180-4

Let us assume that the original message is the ASCII binary-coded form of “abc”, of length L = 24:

```
byte 0    byte 1   byte 2   byte 3
01100001 01100010 01100011 UUUUUUUU
<-- 1st word written to HASH_DIN -->
```

NBLW has to be loaded with the value 24: a “**1**” is appended at bit location 24 in the bit string (starting counting from left to right in the above bit string), which corresponds to bit 31 in the HASH_DIN register (little-endian convention):

```
01100001 01100010 01100011 1UUUUUUU
```

Since L = 24, the number of bits in the above bit string is 25, and 423 “0” bits are appended, making now 448 bits.

This gives in hexadecimal (byte words in big-endian format):

```
61626380 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000
```

The message length value, **L**, in two-word format (that is 00000000 00000018) is appended. Hence the final padded message in hexadecimal (byte words in big-endian format):

```
61626380 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000018
```

If the hash processor is programmed to swap byte within HASH_DIN input register (DATATYPE = 10 in HASH_CR), the above message has to be entered using following sequence:

1. **0xUU636261** is written to the HASH_DIN register (where '**U**' means don't care)
2. **0x18** is written to the HASH_STR register (the number of valid bits in the last word written to the HASH_DIN register is 24, as the original message length is 24 bits)
3. **0x10** is written to the HASH_STR register to start the message padding (described above) and then perform the digest computation.
4. The hash computing is complete with the message digest available in the HASH_HRx registers (x = 0...4) for the SHA-1 algorithm. For this FIPS example, the expected value is as follows:

```
HASH_HR0 = 0xA9993E36
HASH_HR1 = 0x4706816A
HASH_HR2 = 0xBA3E2571
HASH_HR3 = 0x7850C26C
HASH_HR4 = 0x9CD0D89D
```

35.4.7 HMAC operation

Overview

As specified by Internet Engineering Task Force RFC2104 and NIST FIPS PUB 198-1, the HMAC algorithm is used for message authentication by irreversibly binding the message being processed to a key chosen by the user. The algorithm consists of two nested hash operations:

```
HMAC(message)= Hash((Key | pad) XOR opad |
               Hash((Key | pad) XOR ipad | message))
```

where:

- **opad** = $[0x5C]_n$ (outer pad) and **ipad** = $[0x36]_n$ (inner pad)
- $[X]_n$ represents a repetition of X *n* times, where *n* equal to the byte size of the underlying hash function data block (n = 64 when block size is 512 bits).
- **pad** is a sequence of zeroes needed to extend the key to the length *n* defined above. If the key length is greater than *n*, the application must first hash the key using Hash() function and then use the resultant byte string as the actual key to HMAC.
- | represents the concatenation operator.

Note: HMAC mode of the hash processor can be used with all supported algorithms.

HMAC processing

Four different steps are required to compute the HMAC:

1. The software sets the INIT bit, with the MODE bit set and the ALGO bits selecting the desired algorithm. The LKEY bit must also be set if the key being used is longer than the block size. In this case, as required by HMAC specifications, the hash processor uses the hash of the key instead of the real key.
2. The software provides the key to be used for the inner hash function, using the same mechanism as the message string loading, that is by writing the key data into

HASH_DIN register and then completing the transfer by setting DCAL bit and the correct NBLW to HASH_STR register.

3. Once the processor is ready again (DINIS = 1 in HASH_SR), the software can write the message string to HASH_DIN. When the last word of the last block is entered and the software sets DCAL bit in HASH_STR register, the NBLW bitfield must be programmed at the same time to a value different from zero if the message length is not an exact multiple of the block size. Note that the DMA can also be used to feed the message string, as described in *Section 35.4.5: Message digest computing*.
4. Once the processor is ready again (DINIS = 1 in HASH_SR), the software provides the key to be used for the outer hash function, writing the key data into HASH_DIN register, and then completing the transfer by setting DCAL bit and programming the correct NBLW to HASH_STR register. The HMAC result can be found in the valid output registers (HASH_HRx) as soon as DCIS bit is set.

Note: The computation latency of the HMAC primitive depends on the lengths of the keys and message, as described in Section 35.6: HASH processing time.

Endianness management details can be found in Section 35.4.4: Message data feeding.

HMAC example

Below is an example of HMAC SHA-1 algorithm (ALGO = 00 and MODE = 1 in HASH_CR) as specified by NIST. SHA-1 block size is 64 bytes.

Let us assume that the original message is the ASCII binary-coded form of "**`Sample message for keylen = blocklen`**", of length L = 34 bytes. If the HASH is programmed in no swapping mode (DATATYPE = 00 in HASH_CR), the following data must be loaded sequentially into HASH_DIN register:

1. **Inner hash key** input (length = 64, i.e. no padding), specified by NIST. As key length = 64, LKEY bit is cleared in HASH_CR register

   `00010203 04050607 08090A0B 0C0D0E0F 10111213 14151617`
   `18191A1B 1C1D1E1F 20212223 24252627 28292A2B 2C2D2E2F`
   `30313233 34353637 38393A3B 3C3D3E3F`
2. **Message** input (length = 34, i.e. padding required). HASH_STR must be set to **`0x20`** to start message padding and inner hash computation (see **'U**' as don't care)

   `53616D70 6C65206D 65737361 67652066 6F72206B 65796C65`
   `6E3D626C 6F636B6C 656EUUUU`
3. **Outer hash key** input (length = 64, i.e. no padding). A key identical to the inner hash key is entered here.
4. **Final outer hash computing** is then performed by the HASH. The HMAC-SHA1 digest result is available in the HASH_HRx registers, as shown below:

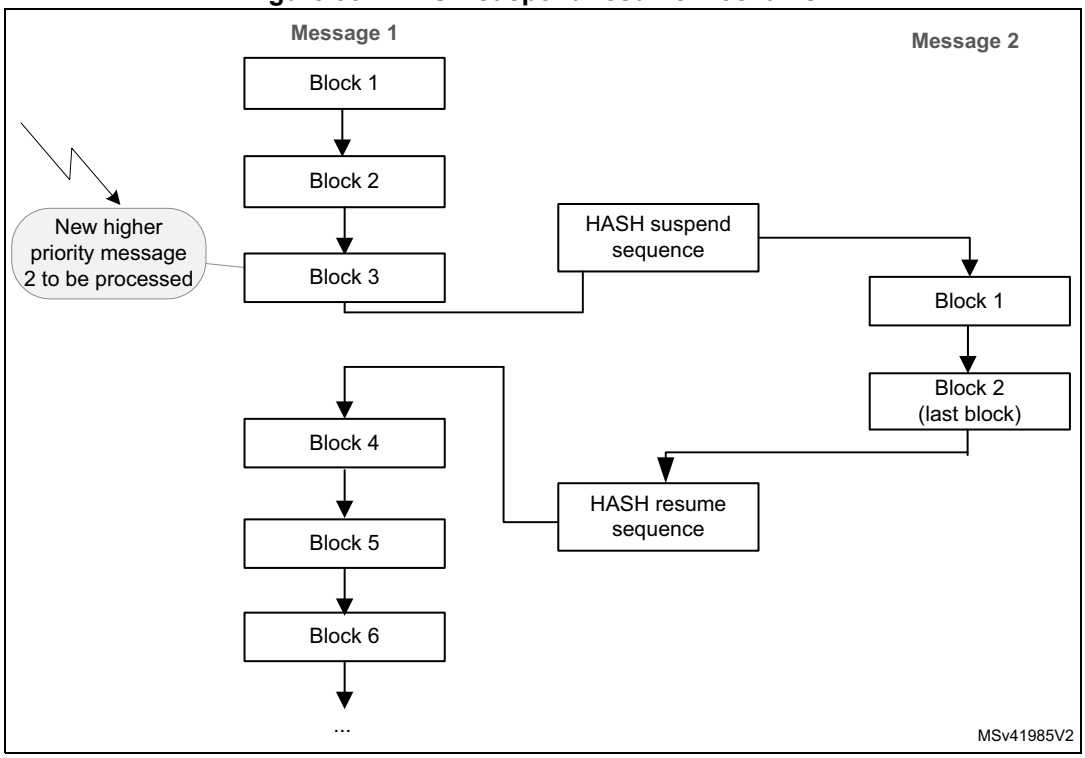
   `HASH_HR0 = 0x5FD596EE`
   `HASH_HR1 = 0x78D5553C`
   `HASH_HR2 = 0x8FF4E72D`
   `HASH_HR3 = 0x266DFD19`
   `HASH_HR4 = 0x2366DA29`

35.4.8 HASH suspend/resume operations

Overview

It is possible to interrupt a hash/HMAC operation to perform another processing with a higher priority. The interrupted process completes later when the higher-priority task has been processed, as shown in *Figure 331*.

Figure 331. HASH suspend/resume mechanism



To do so, the context of the interrupted task must be saved from the HASH registers to memory, and then be restored from memory to the HASH registers.

The procedures where the data flow is controlled by software or by DMA are described hereafter.

Data loaded by software

When the DMA is not used to load the message into the hash processor, the context can be saved only when no block processing is ongoing.

To suspend the processing of a message, proceed as follows after writing the number of words defined in NBWE:

1. In Polling mode, wait for BUSY = 0 then poll if the DINIS status bit is set.
   In Interrupt mode, implement the next step in DINIS interrupt handler (recommended).
2. Store the contents of the following registers into memory:
   - HASH_IMR
   - HASH_STR
   - HASH_CR
   - HASH_CSR0 to HASH_CSR37, when SHA-1 or SHA2-256 is selected, plus HASH_CSR38 to HASH_CSR53 if an HMAC operation was ongoing
   - HASH_CSR0 to HASH_CSR90, when SHA2-384 or SHA2-512 (truncated or not) is selected, plus HASH_CSR91 to HASH_CSR102 if an HMAC operation was ongoing.

To resume the processing of a message, proceed as follows:

1. Write the following registers with the values saved in memory: HASH_IMR, HASH_STR, HASH_CR.
2. Initialize the hash processor by setting the INIT bit in the HASH_CR register
3. Write the HASH_CSRx registers with the values saved in memory.
4. Restart the processing from the point where it has been interrupted.

Data loaded by DMA

When the DMA is used to load the message into the hash processor, it is recommended to suspend and then restore a secure digest computing as described below.

In this sequence the DMA channel allocated to the hash peripheral remains allocated to the processing of message 1 (see *Figure 331*).

To suspend the processing of a message using DMA, proceed as follows:

1. Clear the DMAE bit to disable the DMA interface. The hash peripheral automatically fetches enough data via the DMA to complete the current burst transfer.
2. Wait until the last DMA transfer is complete (DMAS = 0 in HASH_SR).
3. Disable the DMA channel.
4. In Polling or Interrupt mode (recommended), wait until the hash processor is ready (no block is being processed), that is wait for DINIS = 1 in HASH_SR. If DCIS is also set in HASH_SR, the hash result is available and the context swapping is useless. Else go to step 5.
5. Save HASH_IMR, HASH_STR and HASH_CR registers. Also save a number of HASH_CSRx registers depending on the SHA algorithm that is used:
   - When SHA-1 or SHA2-256 is selected, save HASH_CSR0 to HASH_CSR37, plus HASH_CSR38 to HASH_CSR53 if an HMAC operation was ongoing.
   - When SHA2-384 or SHA2-512 is selected, save HASH_CSR0 to HASH_CSR90, plus HASH_CSR91 to HASH_CSR102 if an HMAC operation was ongoing.

To resume the processing of a message using DMA, proceed as follows:

1. Reconfigure the DMA controller so that it proceeds with the transfer of the message up to the end if it is not interrupted again.
2. Program the values saved in memory to HASH_IMR, HASH_STR and HASH_CR registers.
3. Initialize the hash processor by setting the INIT bit in the HASH_CR register.
4. Program the values saved in memory to the HASH_CSRx registers.
5. Restart the processing from the point where it was interrupted by setting the DMAE bit.

35.4.9 HASH DMA interface

The HASH supports both single and fixed DMA burst transfers of four words.

The hash processor provides an interface to connect to the DMA controller. This DMA can be used to write data to the HASH by setting the DMAE bit in the HASH_CR register. When this bit is set, the HASH initiates a DMA request each time a block has to be written to the HASH_DIN register.

Once four 32-bit words have been received, the HASH automatically triggers a new request to the DMA. For more information refer to *Section 35.4.5: Message digest computing*.

Before starting the DMA transfer, the software must program the number of valid bits in the last word that is copied into HASH_DIN register. This is done by writing in HASH_STR register the following value:

`NBLW = Len(Message)% 32` where "**`x%32`**" gives the remainder of x divided by 32.

The DMAS bit of the HASH_SR register provides information on the DMA interface activity. This bit is set with DMAE and cleared when DMAE is cleared and no DMA transfer is ongoing.

Note: No interrupt is associated to DMAS bit.

When MDMAT is set, the size of the transfer must be a multiple of four words.

35.4.10 HASH error management

No error flags are generated by the hash processor.

35.5 HASH interrupts

Two individual maskable interrupt sources are generated by the hash processor to signal the following events:

- Digest calculation completion (DCIS)
- Data input buffer ready (DINIS)

Both interrupt sources are connected to the same global interrupt request signal (hash_it), which is in turn connected to the device interrupt controller. Each interrupt source can individually be enabled or disabled by changing the mask bits in the HASH_IMR register. Setting the appropriate mask bit enables the interrupt.

The status of each maskable interrupt sources can be read from the HASH_SR register. *Table 330* gives a summary of the available features.

Table 330. HASH interrupt requests

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method
HASH	Digest computation completed	DCIS	DCIE	Clear DCIS or set INIT
	Data input buffer ready to get a new block	DINIS	DINIE	Clear DINIS or write to HASH_DIN

35.6 HASH processing time

Table 331 summarizes the time required to process an intermediate block for each mode of operation.

Table 331. Processing time (in clock cycle)

Mode of operation	Block size (in bytes)	FIFO load(1)	Computation phase	Total
SHA-1	64	16	66	**82**
SHA2-224		16	50	**66**
SHA2-256				
SHA2-384	128	32	66	**98**
SHA2-512(2)				

1. Add the time required to load the block into the processor.
2. SHA2-512 includes SHA2-512/224 and SHA2-512/256 modes.

The time required to process the last block of a message (or of a key in HMAC) can be longer. This time depends on the length of the last block and the size of the key (in HMAC mode).

Compared to the processing of an intermediate block, it can be increased by the factor below:

- **1 to 2.5** for a hash message
- **~2.5** for an HMAC input-key
- **1 to 2.5** for an HMAC message
- **~2.5** for an HMAC output key in case of a short key
- **3.5 to 5** for an HMAC output key in case of a long key

35.7 HASH registers

The hash core is associated with several control and status registers and several message digest registers. All these registers are accessible through 32-bit word accesses only, else an AHB error is generated.

35.7.1 HASH control register (HASH_CR)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ALGO[3:0]				LKEY
											rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	MDMAT	DINNE	NBW[3:0]				Res.	MODE	DATATYPE[1:0]		DMAE	INIT	Res.	Res.
		rw	r	r	r	r	r		rw	rw	rw	rw	rw		

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:17 **ALGO[3:0]**: Algorithm selection

These bits select the hash algorithm:
0000: SHA-1
0001: reserved
0010: SHA2-224
0011: SHA2-256
1100: SHA2-384
1101: SHA2-512/224
1110: SHA2-512/256
1111: SHA2-512
This selection is only taken into account when the INIT bit is set. Changing this bitfield during a computation has no effect.
When the ALGO bitfield is updated and INIT bit is set, NBWE in HASH_SR is automatically updated to 0x11.

Bit 16 **LKEY**: Long key selection

The application must set this bit if the HMAC key is greater than the block size corresponding to the hash algorithm (see *Table 328: Information on supported hash algorithms* for details). For example the block size is 64 bytes for SHA2-256.
0: HMAC key is shorter or equal to the block size (short key). The actual key value written in HASH_DIN is used during the HMAC computation.
1: HMAC key is longer than the block size (long key). The hash of the key is used instead of the real key during the HMAC computation.
This selection is only taken into account when the INIT and MODE bits are set (HMAC mode selected). Changing this bit during a computation has no effect.

Bit 15 Reserved, must be kept at reset value.

Bit 14 Reserved, must be kept at reset value.

Bit 13 **MDMAT**: Multiple DMA transfers

This bit is set when hashing large files when multiple DMA transfers are needed.
0: DCAL is automatically set at the end of a DMA transfer.
1: DCAL is not automatically set at the end of a DMA transfer.

Bit 12 **DINNE**: DIN not empty

Refer to DINNE bit of HASH_SR for a description of DINNE bit.
This bit is read-only.

Bits 11:8 **NBW[3:0]:** Number of words already pushed

Refer to NBWP[3:0] bitfield of HASH_SR for a description of NBW[3:0] bitfield.
This bit is read-only.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **MODE:** Mode selection

This bit selects the normal or the keyed HMAC mode for the selected algorithm:
0: Hash mode selected
1: HMAC mode selected. LKEY bit must be set if the key being used is longer than the algorithm block size.
This selection is only taken into account when the INIT bit is set. Changing this bit during a computation has no effect.

Bits 5:4 **DATATYPE[1:0]:** Data type selection

This bitfield defines the format of the data entered into the HASH_DIN register:
00: 32-bit data. The data written into HASH_DIN are directly used by the HASH processing, without reordering.
01: 16-bit data or half-word. The data written into HASH_DIN are considered as two half-words, and are swapped before being used by the HASH processing.
10: 8-bit data or bytes. The data written into HASH_DIN are considered as four bytes, and are swapped before being used by the HASH processing.
11: bit data or bit string. The data written into HASH_DIN are considered as 32 bits (1st bit of the string at position 0), and are swapped before being used by the HASH processing (1st bit of the string at position 31).

Bit 3 **DMAE:** DMA enable

0: DMA transfers disabled
1: DMA transfers enabled. A DMA request is sent as soon as the hash core is ready to receive data.
After this bit is set, it is cleared by hardware while the last data of the message is written into the hash processor.
Clearing this bit while a DMA transfer is ongoing does not abort the current transfer. Instead, the DMA interface of the HASH remains internally enabled until the transfer is complete or INIT is set.
Setting INIT bit does not clear DMAE bit.

Bit 2 **INIT:** Initialize message digest calculation

Setting this bit resets the hash processor core, so that the HASH is ready to compute the message digest of a new message.
Clearing this bit has no effect. Reading this bit always returns 0.

Bits 1:0 Reserved, must be kept at reset value.

35.7.2 HASH data input register (HASH_DIN)

Address offset: 0x04

Reset value: 0x0000 0000

HASH_DIN is the data input register. It is 32-bit wide. This register is used to enter the message by blocks defined by the hash algorithm (see *Table 328: Information on supported hash algorithms* for details). For example the block size is 64 bytes for SHA2-256.

When the HASH_DIN register is programmed, the value presented on the AHB bus is ‘pushed’ into the hash core and the register takes the new value presented on the AHB bus. To get a correct message format, the DATATYPE bits must have been previously configured in the HASH_CR register.

When a complete block has been written to the HASH_DIN register, an intermediate digest calculation is launched:

- by writing first data of the next block into the HASH_DIN register, if the DMA is not used
- automatically, if the DMA is used

When the last block has been written to the HASH_DIN register, the final digest calculation (including padding) is launched by setting the DCAL bit in the HASH_STR register (final digest calculation). This operation is automatic if the DMA is used and MDMAT bit is cleared.

Reading the HASH_DIN register returns zeros.

Note: When the HASH is busy, a write access to the HASH_DIN register might stall the AHB bus if the digest calculation (intermediate or final) is not complete.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DATAIN[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATAIN[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **DATAIN[31:0]:** Data input

Writing this register pushes the current register content into the FIFO, and the register takes the new value presented on the AHB bus.

Reading this register returns zeros.

35.7.3 HASH start register (HASH_STR)

Address offset: 0x08

Reset value: 0x0000 0000

The HASH_STR register has two functions:

- It is used to define the number of valid bits in the last word of the message entered in the hash processor (that is the number of valid least significant bits in the last data written to the HASH_DIN register)
- It is used to start the processing of the last block in the message by setting the DCAL bit.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	DCAL	Res.	Res.	Res.	NBLW[4:0]				
							rw				rw	rw	rw	rw	rw

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **DCAL:** Digest calculation

Setting this bit starts the message padding using the previously written value of NBLW, and starts the calculation of the final message digest with all the data words written to the input FIFO since the INIT bit was last set.

Reading this bit returns 0.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **NBLW[4:0]:** Number of valid bits in the last word

When the last word of the message bit string is written to HASH_DIN register, the hash processor takes only the valid bits, specified as below, after internal data swapping:

0x00: All the 32 bits of the last data written are valid message bits, that is M[31:0]

0x01: Only one bit of the last data written (after swapping) is valid, that is M[0]

0x02: Only two bits of the last data written (after swapping) are valid, that is M[1:0]

0x03: Only three bits of the last data written (after swapping) are valid that is M[2:0]

...

0x1F: Only 31 bits of the last data written (after swapping) are valid that is M[30:0]

The above mechanism is valid only if DCAL = 0. If NBLW bits are written while DCAL is set , the NBLW bitfield remains unchanged. In other words it is not possible to configure NBLW and set DCAL at the same time.

Reading NBLW bits returns the last value written to NBLW.

35.7.4 HASH digest registers

These registers contain the message digest result defined as follows:

- HASH_HR0, HASH_HR1, HASH_HR2, HASH_HR3 and HASH_HR4 registers return the SHA-1 digest result.
- HASH_HR0 to HASH_HR6 registers return the SHA2-224, SHA2-512/224 digest result.
- HASH_HR0 to HASH_HR7 registers return the SHA2-256, SHA2-512/256 digest result.
- HASH_HR0 to HASH_HR11 registers return the SHA2-384 digest result.
- HASH_HR0 to HASH_HR15 registers return the SHA2-512 digest result

In all cases, the digest most significant bit is stored in HASH_HR0[31], and unused HASH_HRx registers reads as zero.

If a read access to one of these registers is performed while the hash core is calculating an intermediate digest or a final message digest (DCIS bit equals 0), then the read operation returns zeros.

Note: When starting a digest computation for a new message (by setting the INIT bit), HASH_HRx registers are forced to their reset values.

HASH_HR0 to HASH_HR4 registers can be accessed through two different addresses (register aliasing).

HASH aliased digest register x (HASH_HRAx)

Address offset: 0x0C + x * 0x4, (x = 0 to 4)

Reset value: 0x0000 0000

The content of the HASH_HRAx registers is identical to the one of the HASH_HRx registers located at address offset 0x310.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DCIE	DINIE
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **DCIE:** Digest calculation completion interrupt enable
0: Digest calculation completion interrupt disabled
1: Digest calculation completion interrupt enabled.

Bit 0 **DINIE:** Data input interrupt enable
0: Data input interrupt disabled
1: Data input interrupt enabled

35.7.6 HASH status register (HASH_SR)

Address offset: 0x24

Reset value: 0x0011 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	NBWE[4:0]				
											r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DINNE	Res.	NBWP[4:0]					Res.	Res.	Res.	Res.	Res.	BUSY	DMAS	DCIS	DINIS
r		r	r	r	r	r						r	r	rc_w0	rc_w0

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **NBWE[4:0]:** Number of words expected
This bitfield reflects the number of words in the message that must be pushed into the FIFO to trigger a partial computation. NBWE is decremented by 1 when a write access is performed to the HASH_DIN register.
NBWE is set to the expected block size +1 in words (0x11) when INIT bit is set in HASH_CR. It is set to the expected block size (0x10) when the partial digest calculation ends.

Bit 15 **DINNE:** DIN not empty
This bit is set when the HASH_DIN register holds valid data (that is after being written at least once). It is cleared when either the INIT bit (initialization) or the DCAL bit (completion of the previous message processing) is set.
0: No data are present in the data input buffer
1: The input buffer contains at least one word of data

Bit 14 Reserved, must be kept at reset value.

Bits 13:9 **NBWP[4:0]:** Number of words already pushed

This bitfield is the exact number of words in the message that have already been pushed into the FIFO. NBWP is incremented by 1 when a write access is performed to the HASH_DIN register.

When a digest calculation starts, NBWP is updated to NBWP- block size (in words), and NBWP goes to zero when the INIT bit is set.

Bits 8:4 Reserved, must be kept at reset value.

Bit 3 **BUSY:** Busy bit

0: No block is currently being processed
1: The hash core is processing a block of data

Bit 2 **DMAS:** DMA Status

This bit provides information on the DMA interface activity. It is set with DMAE and cleared when DMAE = 0 and no DMA transfer is ongoing. No interrupt is associated with this bit.

0: DMA interface is disabled (DMAE = 0) and no transfer is ongoing
1: DMA interface is enabled (DMAE = 1) or a transfer is ongoing

Bit 1 **DCIS:** Digest calculation completion interrupt status

This bit is set by hardware when a digest becomes ready (the whole message has been processed). It is cleared by writing it to 0 or by setting the INIT bit in the HASH_CR register.

0: No digest available in the HASH_HRx registers (zeros are returned)
1: Digest calculation complete, a digest is available in the HASH_HRx registers. An interrupt is generated if the DCIE bit is set in the HASH_IMR register.

Bit 0 **DINIS:** Data input interrupt status

This bit is set by hardware when the FIFO is ready to get a new block (16 locations are free). It is cleared by writing it to 0 or by writing the HASH_DIN register.

0: Less than 16 locations are free in the input buffer
1: A new block can be entered into the input buffer. An interrupt is generated if the DINIE bit is set in the HASH_IMR register.

When DINIS = 0, HASH_CSRx registers reads as zero.

35.7.7 HASH context swap registers

These registers contain the complete internal register states of the hash processor. They are useful when a suspend/resume operation has to be performed because a high-priority task needs to use the hash processor while it is already used by another task.

When such an event occurs, the HASH_CSRx registers have to be read and the read values have to be saved in the system memory space. Then the hash processor can be used by the preemptive task. When the hash computation is complete, the saved context can be read from memory and written back into the HASH_CSRx registers.

HASH_CSRx registers can be read only when DINIS equals to 1, otherwise zeros are returned.

HASH context swap register x (HASH_CSRx)

Address offset: 0x0F8 + x * 0x4, (x = 0 to 102)

Reset value: 0x0022 0002 (HASH_CSR0)

Reset value: 0x0020 0000 (HASH_CSR2)

Reset value: 0x0000 0000 (others)

36 Public key accelerator (PKA)

36.1 Introduction

PKA (public key accelerator) is intended for the computation of cryptographic public key primitives, specifically those related to RSA, Diffie-Hellmann or ECC (elliptic curve cryptography) over GF(p) (Galois fields). To achieve high performance at a reasonable cost, these operations are executed in the Montgomery domain.

For a given operation, all needed computations are performed within the accelerator, so no further hardware/software elaboration is needed to process the inputs or the outputs.

When manipulating secrets, the PKA incorporates a protection against side-channel attacks (SCA), including differential power analysis (DPA), certified SESIP and PSA security assurance level 3.

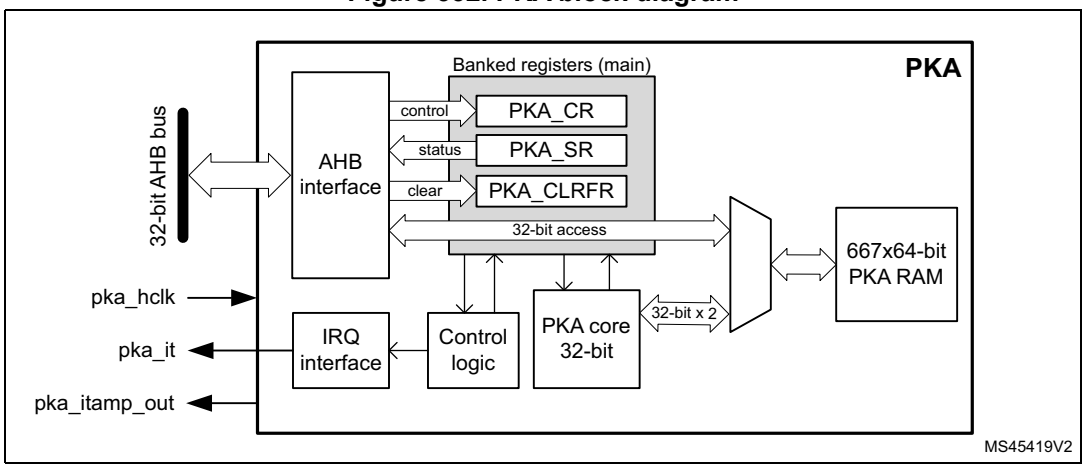
36.2 PKA main features

- Acceleration of RSA, DH and ECC over GF(p) operations, based on the Montgomery method for fast modular multiplications. More specifically:
  - RSA modular exponentiation, RSA chinese remainder theorem (CRT) exponentiation
  - ECC scalar multiplication, point on curve check, complete addition, double base ladder, projective to affine
  - ECDSA signature generation and verification
- Capability to handle operands up to 4160 bits for RSA/DH and 640 bits for ECC
- When manipulating secrets: protection against side-channel attacks (SCA), including differential power analysis (DPA), certified SESIP and PSA security assurance level 3
  - Applicable to modular exponentiation, ECC scalar multiplication and ECDSA signature generation
- Arithmetic and modular operations such as addition, subtraction, multiplication, modular reduction, modular inversion, comparison, and Montgomery multiplication
- Built-in Montgomery domain inward and outward transformations
- AMBA AHB slave peripheral, accessible through 32-bit word single accesses only (otherwise an AHB bus error is generated, and write accesses are ignored)

36.3 PKA functional description

36.3.1 PKA block diagram

Figure 332. PKA block diagram



36.3.2 PKA internal signals

Table 333 lists the internal signals available at the PKA level, not necessarily available on product bonding pads.

Table 333. Internal input/output signals

Signal name	Signal type	Description
pka_hclk	Digital input	AHB bus clock
pka_it	Digital output	Public key accelerator IP global interrupt request
pka_itamp_out	Digital output	PKA internal tamper event signal to TAMP (XOR-ed), triggered when an unexpected fault occurs while PKA manipulates secrets, or when the programmed input point is not found on the input curve (ECDSA signature and ECC scalar multiplication only). This signal is asserted as soon as a fault is detected. When asserted, read access to PKA registers are reset to 0 and writes are ignored. The signal is de-asserted when PKA memory is cleared.

36.3.3 PKA reset and clocks

PKA is clocked on the AHB bus clock. When the PKA peripheral reset signal is released PKA_RAM is cleared automatically, taking 667 clock cycles. During this time the setting of bit EN in PKA_CR register is ignored.

According to the security policy applied to the device, PKA RAM can also be reset following a tamper event. Refer to *Tamper detection and response* in the System security section (if applicable to this product).

36.3.4 PKA public key acceleration

Overview

Public key accelerator (PKA) is used to accelerate Rivest, Shamir and Adleman (RSA), Diffie-Hellman (DH) as well as ECC over prime field operations. Supported operand sizes is up to 4160 bits for RSA and DH, and up to 640 bits for ECC.

The PKA supports all non-singular elliptic curves defined over prime fields, that can be described with a short Weierstrass equation $y^2 = x^3 + ax + b$ (mod p). More information can be found in *Section 36.5.1: Supported elliptic curves*.

Note: Binary curves, Edwards curves and Curve25519 are not supported by the PKA.

A memory of 5336 bytes (667 words of 64 bits) called PKA RAM is used to provide initial data to the PKA, and to hold the results after computation is completed. Access is done though the PKA AHB interface.

PKA operating modes

The list of operations the PKA can perform is detailed in *Table 334* and *Table 335*, respectively, for integer arithmetic functions and prime field (Fp) elliptic curve functions.

Table 334. PKA integer arithmetic functions list

PKA_CR.MODE[5:0]		Performed operation	Reference

0x0C	001100	Arithmetic comparison (A=B, A>B, A<B)	*Section 36.4.12*
0x07	000111	RSA CRT exponentiation	*Section 36.4.13*

Table 335. PKA prime field (Fp) elliptic curve functions list

PKA_CR.MODE[5:0]		Performed operation	Reference
Hex	Binary		
0x28	101000	Point on elliptic curve Fp check	*Section 36.4.14*
0x20	100000	ECC scalar multiplication kP (protected)	*Section 36.4.15*
0x23	100011	ECC complete addition	*Section 36.4.18*
0x24	100100	ECDSA sign (protected)	*Section 36.4.16*
0x26	100110	ECDSA verification	*Section 36.4.17*
0x27	100111	ECC double base ladder	*Section 36.4.19*
0x2F	101111	ECC projective to affine	*Section 36.4.20*

Each of these operating modes has an associated code that has to be written to the MODE field in the PKA_CR register. If the application selects any value that is not documented below the write to MODE bitfield is ignored, and an operation error (OPERRF) is triggered. When this happens, a new operation must be selected after the error is cleared.

Some operations in *Table 334* and *Table 335* are indicated as protected. Those operations are used when manipulating secret keys (modular exponentiation for RSA decryption, scalar multiplication and signature for ECC). Those secrets (protected against side channel attacks) are automatically erased from PKA RAM at the end of the protected operations (BUSY goes low). They are also protected against side channel attacks.

Caution: For security reason it is very important to select protected modular exponentiation (MODE = 0x3) when performing RSA decryption.

Montgomery space and fast mode operations

For efficiency reason the PKA internally performs modular multiply operations in the Montgomery domain, automatically performing inward and outward transformations.

As Montgomery parameter computation is time consuming the application can decide to use a faster mode of operation, during which the precomputed Montgomery parameter is supplied before starting the operation. Performance improvement is detailed in *Section 36.5.2: Computation times*.

The only operation using fast mode is modular exponentiation (MODE = 0x02).

36.3.5 Typical applications for PKA

Introduction

The PKA can be used to accelerate a number of public key cryptographic functions. In particular:

- RSA encryption and decryption
- RSA key finalization
- CRT-RSA decryption
- DSA and ECDSA signature generation and verification
- DH and ECDH key agreement

Specifications of the above functions are given in following publications:

- FIPS PUB 186-4, Digital Signature Standard (DSS), July 2013 by NIST
- PKCS #1, RSA Cryptography Standard, v1.5, v2.1 and v2.2. by RSA Laboratories
- IEEE1363-2000, IEEE Standard Specifications for Public-Key Cryptography, January 2000
- ANSI X9.62-2005, Public Key Cryptography for the Financial Services Industry, The Elliptic Curve Digital Signature Algorithm (ECDSA), November 2005

The principles of the main functions are described in this section, for a more detailed description refer to the above cited documents.

RSA key pair

For the following RSA operations a public key and a private key information are defined as below:

- Alice transmits her public key (*n*, *e*) to Bob. Numbers *n* and *e* are very large positive integers.
- Alice keeps secret her private key d, also a very large positive integer. Alternatively this private key can also be represented by a quintuple (p, q, dp, dq, qInv).

For more information on the above representations refer to the RSA specification.

RSA encryption/decryption principle

As recommended by the PKCS#1 specification, Bob, to encrypt message M using Alice's public key (*n*, *e*) must go through the following steps:

1. Compute the encoded message EM = ENCODE(M), where ENCODE is an encoding method.
2. Turn EM into an integer *m*, with $0 \leq m < n$ and (*m*, *n*) being coprimes.
3. Compute ciphertext $c = m^e \bmod n$.
4. Convert the integer c into a string ciphertext C.

Alice, to decrypt ciphertext c using her private key *d*, follows the steps indicated below:

1. Convert the ciphertext C to an integer ciphertext representative c.
2. If necessary, retrieve the prime factors (p, q) using (n, e, d) information, then compute phi = (p - 1) * (q - 1). Refer to NIST SP800-56B Appendix C for details.
3. Recover plaintext $m = c^d \bmod n = (m^e)^d \bmod n$. If the private key is the quintuple (p, q, dp, dq, qInv), then plaintext *m* is obtained by performing the operations:
   a) $m_1 = c^{dp} \bmod p$
   b) $m_2 = c^{dq} \bmod q$
   c) $h = qInv\ (m_1 - m_2) \bmod p$
   d) $m = m_2 + h\ q$
4. Convert the integer message representative *m* to an encoded message EM.
5. Recover message M = DECODE(EM), where DECODE is a decoding method.

Above operations can be accelerated by PKA using *Modular exponentiation* $A^e \bmod n$ if the private key is *d*, or *RSA CRT exponentiation* if the private key is the quintuple (p, q, dp, dq, qInv).

Note: The decoding operation and the conversion operations between message and integers are specified in PKCS#1 standard.

Note: For the decryption process protected version of modular exponentiation (MODE = 0x3) is strongly recommended for security reason. For encryption process MODE = 0x3 cannot be used, as it requires the knowledge of the private key.

Elliptic curve selection

For following ECC operations curve parameters are defined as below:

- Curve corresponds to the elliptic curve field agreed among actors (Alice and Bob). Supported curves parameters are summarized in *Section 36.5.1: Supported elliptic curves*.
- G is the chosen elliptic curve base point (also known as generator), with a large prime order n (i.e. *n* x G = identity element O).

ECDSA message signature generation

ECDSA (elliptic curve digital signature algorithm) signature generation function principle is the following: Alice, to sign a message *m* using her private key integer d_A, goes through the following steps.

1. Calculate e = HASH(*m*), where HASH is a cryptographic hash function.
2. Let z be the L_n leftmost bits of e, where L_n is the bit length of the group order *n*.
3. Select a cryptographically secure random integer k where $0 < k < n$.
4. Calculate the curve point $(x_1, y_1) = k \times G$.
5. Calculate $r = x_1 \bmod n$. If $r = 0$ go back to step 3.
6. Calculate $s = k^{-1} (z + rd_A) \bmod n$. If $s = 0$ go back to step 3.
7. The signature is the pair (*r*, *s*).

Steps 4 to 7 are accelerated by PKA using:

- *ECDSA sign* or
- All of the operations below:
  - *ECC Fp scalar multiplication* k x P
  - *Modular reduction* A mod *n*
  - *Modular inversion* A^{-1} mod *n*
  - *Modular addition* and *Modular and Montgomery multiplication*

ECDSA signature verification

ECDSA (elliptic curve digital signature algorithm) signature verification function principle is the following: Bob, to authenticate Alice's signature, must have a copy of her public key curve point Q_A.

Bob can verify that Q_A is a valid curve point going through the following steps:

1. check that Q_A is not equal to the identity element O
2. check that Q_A is on the agreed curve
3. check that n x Q_A = O.

Then Bob follows the procedure detailed below:

1. verify that r and s are integer in [1, n-1]
2. calculate e = HASH(m), where HASH is the agreed cryptographic hash function
3. let z be the L_n leftmost bits of e
4. calculate w = s^{-1} mod n
5. calculate u_1 = zw mod n and u_2 = rw mod n
6. calculate the curve point $(x_1, y_1) = u_1 \times G + u_2 \times Q_A$
7. the signature is valid if $r = x_1$ (mod n), it is invalid otherwise.

Steps 4 to 7 are accelerated by PKA using *ECDSA verification*.

36.3.6 PKA procedure to perform an operation

Enabling/disabling PKA

Setting the EN bit to 1 in PKA_CR register enables the PKA peripheral. The PKA becomes available when INITOK bit is set in PKA_SR. When EN = 0, the PKA peripheral is kept under reset, with PKA memory still accessible by the application through the AHB interface.

Note: When PKA is in the process of clearing its memory EN bit cannot be set.

Note: When setting EN bit in PKA_CR make sure that the value of MODE bitfield corresponds to an authorized PKA operation (see OPERRF in Section 36.3.7).

Clearing EN bit to 0 while a calculation is in progress causes the operation to be aborted. In this case, the content of the PKA memory is not guaranteed, with the exception of the PKA modes 0x03, 0x20 and 0x24. For these operations, the PKA memory is cleared after abort, making the memory unavailable for 667 cycles. During this clearing time only PKA registers can be accessed, with writes to EN bits ignored.

If INITOK bit stays at 0, make sure that the RNG peripheral is clocked and properly initialized, then try to enable PKA again.

Data formats

The format of the input data and the results in the PKA RAM are specified, for each operation, in *Section 36.4*.

Executing a PKA operation

Each of the supported PKA operation is executed using the following procedure:

1. Load initial data into the PKA internal RAM, which is located at address offset 0x400.
2. Write in the MODE field of PKA_CR register, specifying the operation which is to be executed and then assert the START bit, also in PKA_CR register.
3. Wait until the PROCENDF bit in the PKA_SR register is set to 1, indicating that the computation is complete.
4. Read the result data from the PKA internal RAM, then clear PROCENDF bit by setting PROCENDFC bit in PKA_CLRFR.

Note: When PKA is busy (BUSY = 1) any access by the application to PKA RAM is ignored, and the flag RAMERRF is set in PKA_SR.

Selecting an illegal or unknown operation in step *2* triggers an OPERRF error, and step *3* (PROCENDF = 1) never happens. See *Section 36.3.7* for details.

Using precomputed Montgomery parameters (PKA Fast mode)

As explained in *Section 36.3.4*, when computing many operations with the same modulus it can be beneficial for the application to compute only once the corresponding Montgomery parameter (see, for example, *Section 36.4.5*). This is know as “Fast mode”.

To manage the usage of Fast mode it is recommended to follow the procedure described below:

1. Load in PKA RAM the modulus size and value information. Such information is compiled in *Section 36.5.1*.
2. Program in PKA_CR register the PKA in *Montgomery parameter computation* mode (MODE=”0x1”) then assert the START bit.
3. Wait until the PROCENDF bit in the PKA_SR register is set to 1, then read back from PKA memory the corresponding Montgomery parameter, and then clear PROCENDF bit by setting PROCENDFC bit in PKA_CLRFR.
4. Proceed with the required PKA operation, loading on top of regular input data the Montgomery information R2 mod m. All addresses are indicated in *Section 36.4*.

36.3.7 PKA error management

When PKA is used some errors can occur:

- The access to PKA RAM falls outside the expected range. In this case the Address Error flag (ADDRERRF) is set in the PKA_SR register.
- An AHB access to the PKA RAM occurred while the PKA core was using it. In this case the RAM Error Flag (RAMERRF) is set in the PKA_SR register, reads to PKA RAM return zero, while writes are ignored.
- The selected operating mode using MODE bitfield is not listed in PKA operating modes (or in bitfield description), or PKA is running in limited mode (see LMF bit in PKA_SR). In this case the operation error flag (OPERRF) is set in the PKA_SR register, and write to MODE bitfield is ignored.

For each error flag above PKA generates an interrupt if the application sets the corresponding bit in PKA_CR register (see *Section 36.6* for details).

ADDRERRF, OPERRF and RAMERRF errors are cleared by setting the corresponding bit in PKA_CLRFR.

The PKA can be re-initialized at any moment by resetting the EN bit in the PKA_CR register.

OPERRF error must be cleared using OPERRFC bit in PKA_CLRFR before a new operation is written in PKA_CR register.

36.4 PKA operating modes

36.4.1 Introduction

The various operations supported by PKA are described in the following subsections, defining the format of the input data and of the results, both stored in the PKA RAM.

Warning: The validity of all input parameters to the PKA must be checked before starting any operation, as PKA assumes that all of them are valid and consistent with each other. Input parameters must not exceed the operand size specified in the operation tables.

The following information applies to all PKA operations.

- PKA core processes 64-bit words in its RAM. Hence hereafter all word size is 64-bit
- When an element is written as input in the PKA RAM, an additional word with all bits equal to zero has to be added after the most significant input word. This rule does not apply if the operand has a fixed size of 1.
- All reported RAM storage addresses refer to the least significant word of the data, and to obtain the actual address to use application must add to the indicated offset the base address of the PKA.
- Supported operand “Size” are:
  - ROS (RSA operand Size): data size is (*rsa_size* / 64 + 1) words, with *rsa_size* equal to the chosen modulus length in bits. For example, when computing RSA with an operand size of 1024 bits, ROS is equal to 17 words, or 1088 bits.
  - EOS (ECC operand Size): data size is (*ecc_size* / 64 + 1) words, with *ecc_size* equal to the chosen prime modulus length in bits. For example, when computing ECC with an operand size of 192 bits, EOS is equal to 4 words, or 256 bits.
  - ROS and EOS values include the required additional all 0 word.
- Unless indicated otherwise, all operands in the tables are integers.

Note: Fractional results for above formulas must be rounded up to the nearest integer since PKA core processes 64-bit words.

Note: The maximum ROS is 66 words (4160-bit max exponent size), while the maximum EOS is 11 words (640-bit max operand size).

As a first example (and to better understand the endianess in PKA memory), to prepare the operation *ECC Fp scalar multiplication*, when the application writes the x coordinate of point P for an ECC P256 curve (EOS = 5 words), the least significant bit must be placed in bit 0 at address offset 0x578, and the most significant bit in bit 63 at address offset 0x590. Then, as mentioned above, the application must write the empty word 0x0000000000000000 at address offset 0x598.

As a second example, still to prepare the operation ECC Fp scalar multiplication, when the application need to write the information a = -3, on a curve with a modulus length of 224 bits (i.e. four 64-bit words, rounded up, plus one) following data must be written in PKA memory:

```
@RAM+410   0x0000000000000001  /* curve coefficient 'a' sign without extra word */
@RAM+418   0x0000000000000011  /* value of |a| LSB
@RAM+420   0x0000000000000000  ...
@RAM+428   0x0000000000000000  ...
```

```
@RAM+430    0x0000000000000000  value of |a| MSB */
@RAM+438    0x0000000000000000  /* additional all 0 word */
```

36.4.2 Montgomery parameter computation

This function is used to compute the Montgomery parameter (R^2 mod *n*) used by PKA to convert operands into the Montgomery residue system representation. This operation can be very useful when fast mode operation is used, because in this case the Montgomery parameter is passed as input, saving the time for its computation.

Note: This operation can also be used with ECC curves. In this case prime modulus length and EOS size must be used.

Operation instructions for Montgomery parameter computation are summarized in *Table 336*.

Table 336. Montgomery parameter computation

Parameters with direction		Value (note)	Storage	Size
IN	MODE	0x01	PKA_CR	6 bits
	Modulus length	(in bits, 0 ≤ value < 4160)	RAM@0x408	64 bits
	Modulus value n	(odd integer only, n < 2^{4160})	RAM@0x1088	ROS
OUT	Result: R^2 mod n	-	RAM@0x620	

36.4.3 Modular addition

Modular addition operation consists in the computation of A + B mod *n*. Operation instructions are summarized in *Table 337*.

Table 337. Modular addition

Parameters with direction		Value (note)	Storage	Size
IN	MODE	0x0E	PKA_CR	6 bits
	Operand length	(in bits, not null)	RAM@0x408	64 bits
	Operand A	(0 ≤ A < n)	RAM@0xA50	ROS
	Operand B	(0 ≤ B < n)	RAM@0xC68	
	Modulus value n	(n < 2^{4160})	RAM@0x1088	
OUT	Result: A+B mod n	(0 ≤ result < n)	RAM@0xE78	

36.4.4 Modular subtraction

Modular subtraction operation consists in the following computations:

- If A ≥ B result equals A - B mod *n*
- If A < B result equals A + n - B mod *n*

Operation instructions are summarized in *Table 338*.

Table 338. Modular subtraction

Parameters with direction		Value (note)	Storage	Size
IN	MODE	0x0F	PKA_CR	6 bits
	Operand length	(in bits, not null)	RAM@0x408	64 bits
	Operand A	(0 ≤ A < n)	RAM@0xA50	ROS
	Operand B	(0 ≤ B < n)	RAM@0xC68	
	Modulus value n	(n < 2^{4160})	RAM@0x1088	
OUT	Result: A-B mod n	(0 ≤ result < n)	RAM@0xE78	

36.4.5 Modular and Montgomery multiplication

To be more efficient when performing a sequence of multiplications the PKA accelerates multiplication which has at least one input in the Montgomery domain. The two main uses of this operation are:

- Map a value from natural domain to Montgomery domain and vice-versa
- Perform a modular multiplication A x B mod *n*

The method to perform above operations are described below. Note that “x” function is this operation, and A, B, C operands are in the natural domain.

1. Inward (or outward) conversion into (or from) Montgomery domain
   a) Assuming that A is an integer in the natural domain:
      – Compute *r2modn* using *Montgomery parameter computation*.
      – Result AR= A x *r2modn* mod *n* is A in the Montgomery domain.
   b) Assuming that BR is an integer in the Montgomery domain:
      – Result B = BR x 1 mod *n* is B in the natural domain.
      – Similarly, above value AR computed in a) can be converted into the natural domain by computing A = AR x 1 mod *n.*
2. Simple modular multiplication A x B mod *n*
   a) Compute *r2modn* using *Montgomery parameter computation*.
   b) Compute AR = A x *r2modn* mod *n*. Output is in the Montgomery domain.
   c) Compute AB= AR x B mod *n*. Output is in natural domain.
3. Multiple modular multiplication A x B x C mod *n*
   a) Compute *r2modn* using *Montgomery parameter computation*.
   b) Compute AR = A x *r2modn* mod *n*. Output is in the Montgomery domain.
   c) Compute BR = B x *r2modn* mod *n*. Output is in the Montgomery domain.
   d) Compute ABR= AR x BR mod *n*. Output is in the Montgomery domain.
   e) Compute CR = C x *r2modn* mod *n*. Output is in the Montgomery domain.
   f) Compute ABCR= ABR x CR mod *n*. Output is in the Montgomery domain.
   g) (optional) Repeat the two steps above if more operands need to be multiplied.
   h) Compute ABC= ABCR x 1 mod *n* to retrieve the result in natural domain.

Operation instructions for Montgomery multiplication are summarized in *Table 339*.

Table 339. Montgomery multiplication

Parameters with direction		Value (note)	Storage	Size
IN	MODE	0x10	PKA_CR	6 bits
	Operand length	(in bits, not null)	RAM@0x408	64 bits
	Operand A	(0 ≤ A < n)	RAM@0xA50	ROS
	Operand B	(0 ≤ B < n)	RAM@0xC68	
	Modulus value n	(odd integer only, n < 2^{4160})	RAM@0x1088	
OUT	Result: AxB mod n(1)	-	RAM@0xE78	

1. Result in Montgomery domain or in natural domain, depending upon the inputs nature (see examples *2* and *3*).

36.4.6 Modular exponentiation

Modular exponentiation operation is commonly used to perform a single-step RSA operation. It consists in the computation of A^e mod *n*.

RSA operation involving public information (RSA encryption) can use the normal or fast mode detailed on *Table 340* and *Table 341*. RSA operation involving secret information (RSA decryption) must use the protected mode detailed on *Table 342*, for security reason.

Note: Once this operation is started PKA control register and PKA memory is no more available. Access is restored once BUSY bit is set to 0 by the PKA.

When this operation completes with errors due to unexpected hardware events a PKA tamper event is triggered to TAMP peripheral, and access to PKA RAM becomes blocked until erased by hardware.

Note: When MODE = 0x03, if the error output is different from 0xD60D all the memory content is cleared by PKA to avoid leaking information about the private key.

Operation instructions for modular exponentiation are summarized in *Table 340* (normal mode), *Table 341* (fast mode) and in *Table 342* (protected mode). Fast mode usage is explained in *Section 36.3.6*.

Table 340. Modular exponentiation (normal mode)

Parameters with direction		Value (note)	Storage	Size
IN	MODE	0x00	PKA_CR	6 bits
IN	Exponent length	(in bits, not null)	RAM@0x400	64 bits
	Operand length	(in bits, not null)	RAM@0x408	
IN/OUT	Operand A (base of exponentiation)	(0 ≤ A < n)	RAM@0xC68	ROS
IN	Exponent e	(0 ≤ e < n)	RAM@0xE78	
	Modulus value n	(odd integer only, n < 2^{4160})	RAM@0x1088	
OUT	Result: A^e mod n	(0 ≤ result < n)	RAM@0x838	

Table 341. Modular exponentiation (fast mode)

Parameters with direction		Value (note)	Storage	Size
IN	MODE	0x02	PKA_CR	6 bits
IN	Exponent length	(in bits, not null)	RAM@0x400	64 bits
	Operand length	(in bits, not null)	RAM@0x408	
IN/OUT	Operand A (base of exponentiation)	(0 ≤ A < n)	RAM@0xC68	ROS
IN	Exponent e	(0 ≤ e < n)	RAM@0xE78	
	Modulus value n	(odd integer only, n < 2^{4160})	RAM@0x1088	
IN/OUT	Montgomery parameter R2 mod n	(mandatory)	RAM@0x620	
OUT	Result: A^e mod n	(0 ≤ result < n)	RAM@0x838	

Table 342. Modular exponentiation (protected mode)

Parameters with direction		Value (note)	Storage	Size
IN	MODE	0x03	PKA_CR	6 bits
	Exponent e length	(in bits, not null)	RAM@0x400	64 bits
	Modulus or operand length	(in bits, not null)	RAM@0x408	
	Operand A (base of exponentiation)	(0 ≤ A < n)	RAM@0x16C8	ROS
	Exponent e	(0 ≤ e < n)	RAM@0x14B8	
	Modulus value n	(odd integer only, n < 2^{4096})	RAM@0x0838	
	Phi value(1)	-	RAM@0x0C68	
OUT	Result: A^e mod n	(0 ≤ result < n)	RAM@0x838	
ERROR	Error A^e mod n	– No errors: 0xD60D – Errors: 0xCBC9	RAM@0x1298	64 bits

1. Euler totient function of n^1 with phi = (p - 1) * (q - 1), where p and q are prime factors of modulus n (see NIST SP800-56B Appendix C or *RSA encryption/decryption principle* for details). As optimization it is recommended to keep phi information as part of the key pair generation. Alternative is to store the key as (*p*, *q*, *e*, *d*) instead of (*N*, *e*, *d*, *phi*), in this case, to derive *N* and *phi* using PKA arithmetic multiplier: *N* = *p* * *q*, and *phi* = (*p* - 1) * (*q* - 1).

36.4.7 Modular inversion

Modular inversion operation consists in the computation of multiplicative inverse A^{-1} mod *n*. If the modulus *n* is prime, for all values of A (1 ≤ A < *n*) modular inversion output is valid. If the modulus *n* is not prime, A has an inverse only if the greatest common divisor between A and *n* is 1.

If the operand A is a divisor of the modulus *n* the result is a multiple of a factor of *n*.

Operation instructions for modular inversion are summarized in *Table 343*.

Table 343. Modular inversion

Parameters with direction		Value (note)	Storage	Size
IN	MODE	0x08	PKA_CR	6 bits
	Operand length	(in bits, not null)	RAM@0x408	64 bits
	Operand A	(0 ≤ A < n)	RAM@0xA50	ROS
	Modulus value n	(odd integer only, n < 2^{4160})	RAM@0xC68	
OUT	Result: A^{-1} mod n	0 < result < n	RAM@0xE78	

36.4.8 Modular reduction

Modular reduction operation consists in the computation of the remainder of A divided by n. Operation instructions are summarized in *Table 344*.

Table 344. Modular reduction

Parameters with direction		Value (note)	Storage	Size
IN	MODE	0x0D	PKA_CR	6 bits
	Operand length	(in bits, not null)	RAM@0x400	64 bits
	Modulus length	(in bits, 8 < value < 4160)	RAM@0x408	
	Operand A	(0 ≤ A < 2n < 2^{4160})	RAM@0xA50	ROS
	Modulus value n	(odd integer only, n < 2^{4160})	RAM@0xC68	
OUT	Result A mod n	(0 < result < n)	RAM@0xE78	

36.4.9 Arithmetic addition

Arithmetic addition operation consists in the computation of A + B. Operation instructions are summarized in *Table 345*.

Table 345. Arithmetic addition

Parameters with direction		Value (note)	Storage	Size
IN	MODE	0x09	PKA_CR	6 bits
	Operand length M	(in bits, not null)	RAM@0x408	64 bits
	Operand A	(0 ≤ A < 2^M)	RAM@0xA50	ROS
	Operand B	(0 ≤ B < 2^M)	RAM@0xC68	
OUT	Result: A+B	(0 ≤ result < 2^{M+1})	RAM@0xE78	ROS + 1

36.4.10 Arithmetic subtraction

Arithmetic subtraction operation consists in the following computations:

- If A ≥ B result equals A - B
- If A < B and M/32 residue is > 0 result equals A + $2^{int(M/32)*32+1}$ - B
- If A < B and M/32 residue is 0 result equals A + $2^{int(M/32)*32}$ - B

For the last two bullets the 32-bit word following the most significant word of the output equals 0xFFFF FFFF, as result is negative.

Operation instructions are summarized in *Table 346*.

Table 346. Arithmetic subtraction

Parameters with direction		Value (note)	Storage	Size
IN	MODE	0x0A	PKA_CR	6 bits
	Operand length M	(in bits, not null)	RAM@0x408	64 bits
	Operand A	($0 \leq < A < 2^M$)	RAM@0xA50	ROS
	Operand B	($0 \leq < B < 2^M$)	RAM@0xC68	
OUT	Result: A-B	($0 \leq$ result $< 2^M$)	RAM@0xE78	

36.4.11 Arithmetic multiplication

Arithmetic multiplication operation consists in the computation of AxB. Operation instructions are summarized in *Table 347*.

Table 347. Arithmetic multiplication

Parameters with direction		Value (note)	Storage	Size
IN	MODE	0x0B	PKA_CR	6 bits
	Operand length M	(in bits, not null)	RAM@0x408	64 bits
	Operand A	($0 \leq A < 2^M$)	RAM@0xA50	ROS
	Operand B	($0 \leq B < 2^M$)	RAM@0xC68	
OUT	Result: AxB	($0 \leq$ result $< 2^M$)	RAM@0xE78	2xROS

36.4.12 Arithmetic comparison

Arithmetic comparison operation consists in the following computation:

- If A = B then result = 0xED2C
- If A > B then result = 0x7AF8
- If A < B then result = 0x916A

Operation instructions for arithmetic comparison are summarized in *Table 348*.

Table 348. Arithmetic comparison

Parameters with direction		Value (note)	Storage	Size
IN	MODE	0x0C	PKA_CR	6 bits
	Operand length M	(in bits, not null)	RAM@0x408	64 bits
	Operand A	($0 \leq A < 2^M$)	RAM@0xA50	ROS
	Operand B	($0 \leq B < 2^M$)	RAM@0xC68	
OUT	Result A?B	0xED2C, 0x7AF8 or 0x916A	RAM@0xE78	64 bits

36.4.13 RSA CRT exponentiation

For efficiency many popular crypto libraries such as OpenSSL RSA use the following optimization for decryption and signing based on the chinese remainder theorem (CRT):

- *p* and *q* are precomputed primes, stored as part of the private key
- d_P= d mod (*p* -1)
- d_Q= d mod (*q* -1) and
- q_{inv}= q^{-1} mod *p*

These values allow the recipient to compute the exponentiation m = A^d (mod pq) more efficiently as follows:

- m_1 = A^{dP} mod *p*
- m_2 = A^{dQ} mod *q*
- h = q_{inv} (m_1 - m_2) mod *p*, with m_1> m_2
- m = m_2 + hq mod *pq*

Operation instructions for computing CRT exponentiation A^d mod pq are summarized in *Table 349*.

Table 349. CRT exponentiation

Parameters with direction		Value (note)	Storage	Size
IN	MODE	0x07	PKA_CR	6 bits
IN	Operand length	(in bits, not null)	RAM@0x408	64 bits
IN	Operand d_P	(0 < d_P < $2^{M/2}$)	RAM@0x730	ROS / 2
	Operand d_Q	(0 < d_Q < $2^{M/2}$)	RAM@0xE78	
	Operand q_{inv}	(0 < q_{inv} < $2^{M/2}$)	RAM@0x948	
	Prime *p*(1)	(0 < p < $2^{M/2}$)	RAM@0xB60	
	Prime *q*(1)	(0 < q< $2^{M/2}$)	RAM@0x1088	
IN	Operand A	(0 < A< 2^M)	RAM@0x12A0	ROS
OUT	Result: A^d mod *pq*	(0 ≤ result < *pq*)	RAM@0x838	

1. Must be different from 2.

36.4.14 Point on elliptic curve Fp check

This operation consists in checking whether a given point P (x, y) satisfies or not the curves over prime fields equation y^2 = (x^3 + *ax* + *b*) mod *p,* where *a* and *b* are elements of the curve.

Operation instructions for point on elliptic curve Fp check are summarized in *Table 350*.

Table 350. Point on elliptic curve Fp check

Parameters with direction		Value (note)	Storage	Size
IN	MODE	0x28	PKA_CR	6 bits
	Modulus length	(in bits, not null, 8 < value < 640)	RAM@0x408	64 bits
	Curve coefficient *a* sign	0x0: positive 0x1: negative	RAM@0x410	
	Curve coefficient |a|	(absolute value, |a| < p)	RAM@0x418	EOS
	Curve coefficient *b*	(|b| < p)	RAM@0x520	
	Curve modulus value *p*	(odd integer prime, 0 < p < 2640)	RAM@0x470	
	Point P coordinate *x*	(x < *p*)	RAM@0x578	
	Point P coordinate *y*	(y < *p*)	RAM@0x5D0	
	Montgomery parameter R2 mod n	-	RAM@0x4C8	
OUT	Result: point P on curve	– 0xD60D: point on curve – 0xA3B7: point not on curve – 0xF946: x or y coordinate is not smaller than modulus p	RAM@0x680	64 bits

36.4.15 ECC Fp scalar multiplication

This operation consists in the computation of a k x P (x_P, y_P), where P is a point on a curve over prime fields and “x” is the elliptic curve scalar point multiplication. Result of the computation is a point that belongs to the same curve or a point at infinity.

Operation instructions for ECC Fp scalar multiplication are summarized in *Table 351*.

Note: Once this operation is started PKA control register and PKA memory is no more available. Access is restored once BUSY bit is set to 0 by the PKA.

When this operation completes with errors due to unexpected hardware events, a PKA tamper event is triggered to TAMP peripheral, and access to PKA RAM becomes blocked until erased by hardware. PKA tamper is also triggered when the programmed input point is not found on the input ECC curve. PKA operation "Point on elliptic curve" can be used to avoid this.

Table 351. ECC Fp scalar multiplication

Parameters with direction		Value (note)	Storage	Size
IN	MODE	0x20	PKA_CR	6 bits
IN	Curve prime order *n* length	(in bits, not null,)	RAM@0x400	64 bits
	Curve modulus *p* length	(in bits, not null, 8 < value < 640)	RAM@0x408	
	Curve coefficient *a* sign	– 0x0: positive – 0x1: negative	RAM@0x410	

Table 351. ECC Fp scalar multiplication (continued)

Parameters with direction		Value (note)	Storage	Size
IN	Curve coefficient |*a*|	(absolute value, |a| < p)	RAM@0x418	EOS
	Curve coefficient *b*	(positive integer)	RAM@0x520	
	Curve modulus value *p*	(odd integer prime, $0 < p < 2^{640}$)	RAM@0x1088	
	Scalar multiplier k	($0 \leq k < 2^{640}$)	RAM@0x12A0	
	Point P coordinate x_P	($x < p$)	RAM@0x578	
	Point P coordinate y_P	($y < p$)	RAM@0x470	
	Curve prime order *n*	(integer prime)	RAM@0xF88	
OUT	Result: k x P coordinate *x'*	(result < *p*)	RAM@0x578	
	Result: k x P coordinate *y'*	(result < *p*)	RAM@0x5D0	
ERROR	Error k x P	– No errors: 0xD60D – Errors: 0xCBC9	RAM@0x680	64 bits

When performing this operation the following special cases must be noted:

- For k = 0 this function returns a point at infinity (0, 0) if curve parameter b is nonzero, (0, 1) otherwise. For k different from 0 it might happen that a point at infinity is returned. When the application detects this behavior a new computation must be carried out.
- For k < 0 (i.e. a negative scalar multiplication is required) the multiplier absolute value k = |-k| must be provided to the PKA. After the computation completion, the formula -P = (x, -y) can be used to compute the y coordinate of the effective final result (the x coordinate remains the same).

Note: If the error output is different from 0xD60D all the memory content is cleared by PKA to avoid leaking information about the private key.

36.4.16 ECDSA sign

ECDSA signing operation (outlined in *Section 36.3.5*) is summarized in *Table 352* (input parameters) and in *Table 353* (output parameters).

The application has to check if the output error is equal to 0xD60D, if it is different a new k must be generated and the ECDSA sign operation must be repeated.

Note: Once this operation is started PKA control register and PKA memory is no more available. Access is restored once BUSY bit is set to 0 by the PKA.

When this operation completes with errors due to unexpected hardware events a PKA tamper event is triggered to TAMP peripheral, and access to PKA RAM becomes blocked until erased by hardware. PKA tamper is also triggered when the programmed input point is not found on the input ECC curve. PKA operation "Point on elliptic curve" can be used to avoid this.

Table 352. ECDSA sign - Inputs

Parameters with direction		Value (note)	Storage	Size
IN	MODE	0x24	PKA_CR	6 bits
	Curve prime order n length (*nlen*)	(in bits, not null)	RAM@0x400	64 bits
	Curve modulus p length	(in bits, 8 < value < 640)	RAM@0x408	
	Curve coefficient a sign	0x0: positive 0x1: negative	RAM@0x410	
	Curve coefficient |a|	(absolute value, |a| < p)	RAM@0x418	EOS
	Curve coefficient b	(positive integer)	RAM@0x520	
	Curve modulus value *p*	(odd integer prime, $0 < p < 2^{640}$)	RAM@0x1088	
	Integer k(1)	($0 \leq k < 2^{640}$)	RAM@0x12A0	
	Curve base point G coordinate x	(x < *p*)	RAM@0x578	
	Curve base point G coordinate y	(y < *p*)	RAM@0x470	
	Hash of message z	(hash size equal to *nlen*)(2)	RAM@0xFE8	
	Private key d	(0 < d)	RAM@0xF28	
	Curve prime order n	(integer prime)	RAM@0xF88	

1. This integer is usually a cryptographically secure random number, but in some cases k can be deterministically generated.
2. Padding with zeroes or hash truncation must be used to have the hash parameter size equal to the curve prime order n length.

Table 353. ECDSA sign - Outputs

Parameters with direction		Value (note)	Storage	Size
OUT	Signature part *r*	(0 < *r* < n)	RAM@0x730	EOS
	Signature part *s*	(0 < *s* < n)	RAM@0x788	
ERROR	Result of signature	– 0xD60D: successful computation, no error – 0xCBC9: failed computation – 0xA3B7: signature part r is equal to 0 – 0xF946: signature part s is equal to 0	RAM@0xFE0	64 bits

Note: If the error output equals 0xD60D or 0xCBC9 all the memory content is cleared by PKA to avoid leaking information about the private key. If error output equals 0xA3B7 or 0xF946 PKA memory content is partially erased, keeping the error code readable.

Extended ECDSA support

PKA also supports extended ECDSA signature, for which the inputs and the outputs are the same as ECDSA signature (*Table 352* and *Table 353*, respectively), with the addition of the coordinates of the point kG. This extra output is defined in *Table 354*.

Table 354. Extended ECDSA sign - Extra outputs

Parameters with direction		Value (note)	Storage	Size
OUT	Curve point kG coordinate x_1	($0 \le x_1 < p$)	RAM@0x1400	EOS
	Curve point kG coordinate y_1	($0 \le y_1 < p$)	RAM@0x1458	

36.4.17 ECDSA verification

ECDSA verification operation (outlined in *Section 36.3.5*) is summarized in *Table 355* (input parameters) and *Table 356* (output parameters).

The application has to check if the output error is equal to 0xD60D, if different the signature is not verified.

Table 355. ECDSA verification - Inputs

Parameters with direction		Value (note)	Storage	Size
IN	MODE	0x26	PKA_CR	6 bits
	Curve prime order n length (*nlen*)	(in bits, not null)	RAM@0x408	64 bits
	Curve modulus p length	(in bits, not null, 8 < value < 640)	RAM@0x4C8	
	Curve coefficient a sign	0x0: positive 0x1: negative	RAM@0x468	
	Curve coefficient |a|	(absolute value, |a| < p)	RAM@0x470	EOS
	Curve modulus value *p*	(odd integer prime, $0< p < 2^{640}$)	RAM@0x4D0	
	Curve base point G coordinate x	($x < p$)	RAM@0x678	
	Curve base point G coordinate y	($y < p$)	RAM@0x6D0	
	Public-key curve point Q coordinate x_Q	($x_Q < p$)	RAM@0x12F8	
	Public-key curve point Q coordinate y_Q	($y_Q < p$)	RAM@0x1350	
	Signature part *r*	($0 < r < n$)	RAM@0x10E0	
	Signature part *s*	($0 < s < n$)	RAM@0xC68	
	Hash of message *z*	(hash size equal to *nlen*)(1)	RAM@0x13A8	
	Curve prime order *n*	(integer prime)	RAM@0x1088	

1. Padding with zeroes or hash truncation must be used to have the hash parameter size equal to the curve prime order n length.

Table 356. ECDSA verification - Outputs

Parameters with direction		Value (note)	Storage	Size
OUT	Result: ECDSA verify	– 0xD60D: valid signature – 0xA3B7: invalid signature	RAM@0x5D0	64 bits
	Computed signature part *r*	– (0 < *r* < n)	RAM@0x578	EOS

36.4.18 ECC complete addition

ECC complete addition computes the addition of two given points on an elliptic curve.

Operation instructions are summarized in *Table 357*.

Note: The two input points and the resulting point are represented in Jacobian coordinates (X,Y,Z). To input a point in affine coordinates (x,y) conversion (X,Y,Z) = (x,y,1) can be used. To convert resulting point to Jacobian coordinates conversion (x,y)= (X/Z^2,Y/Z^3) can be used.

Table 357. ECC complete addition

Parameters with direction		Value (note)	Storage	Size
IN	MODE	0x23	PKA_CR	6 bits
	Curve modulus *p* length	(in bits, not null, 8 < value < 640)	RAM@0x408	64 bits
	Curve coefficient *a* sign	– 0x0: positive 0x1: negative	RAM@0x410	
	Curve modulus value *p*	(odd integer prime, $0 < p < 2^{640}$)	RAM@0x470	EOS
	Curve coefficient |*a*|	(absolute value, |a| < p)	RAM@0x418	
	First point P coordinate X	(x < *p*)	RAM@0x628	
	First point P coordinate Y	(y < *p*)	RAM@0x680	
	First point P coordinate Z	(z < *p*)	RAM@0x6D8	
	Second point Q coordinate X	(x < *p*)	RAM@0x730	
	Second point Q coordinate Y	(y < *p*)	RAM@0x788	
	Second point Q coordinate Z	(z < *p*)	RAM@0x7E0	
OUT	Result coordinate X	(x < *p*)	RAM@0xD60	
	Result coordinate Y	(y < *p*)	RAM@0xDB8	
	Result coordinate Z	(z < *p*)	RAM@0xE10	

36.4.19 ECC double base ladder

ECC double base ladder operation consists in the computation of k*P+m*Q, where (P,Q) are two points on an elliptic curve and (k,m) are two scalars. Operation instructions are summarized in *Table 358*.

If the resulting point is the point at infinity (error code 0xA3B7), resulting coordinate equals (0, 0).

Note: The two input points are represented in Jacobian coordinates (X, Y , Z). To input a point in affine coordinates (x, y) conversion (X, Y, Z) = (x, y, 1) can be used. The result is represented in affine coordinates (x ,y)

Table 358. ECC double base ladder

Parameters with direction		Value (note)	Storage	Size
IN	MODE	0x27	PKA_CR	6 bits
	Curve prime order *n* length	(in bits, not null)	RAM@0x400	64 bits
	Curve modulus *p* length	(in bits, not null, 8 < value < 640)	RAM@0x408	
	Curve coefficient *a* sign	– 0x0: positive – 0x1: negative	RAM@0x410	EOS
	Curve coefficient |*a*|	(absolute value, |a| < p)	RAM@0x418	
	Curve modulus value *p*	(odd integer prime, $0 < p < 2^{640}$)	RAM@0x470	
	Integer k	($0 < k < 2^{640}$)	RAM@0x520	
	Integer m	($0 < m < 2^{640}$)	RAM@0x578	
	First point P coordinate X	(x < *p*)	RAM@0x628	
	First point P coordinate Y	(y < *p*)	RAM@0x680	
	First point P coordinate Z	(z < *p*)	RAM@0x6D8	
	Second point Q coordinate X	(x < *p*)	RAM@0x730	
	Second point Q coordinate Y	(y < *p*)	RAM@0x788	
	Second point Q coordinate Z	(z < *p*)	RAM@0x7E0	
OUT	Result coordinate x	(x < *p*)	RAM@0x578	EOS
	Result coordinate y	(y < *p*)	RAM@0x5D0	
	Error code	– Point not at infinity: 0xD60D – Point at infinity: 0xA3B7	RAM@0x520	64 bits

36.4.20 ECC projective to affine

ECC projective to affine operation computes the conversion between the representation of a point P in homogeneous projective coordinates and the representation of the point P in affine coordinates. Namely, if the point is represented by the triple (X, Y, Z), it computes the affine coordinates (x, y) = (X/Z, Y/Z).

All the operations are performed modulo the modulus p of the curve, which the point belongs to. If the resulting point is the point at infinity (error code 0xA3B7), resulting coordinate equals (0,0).

Operation instructions are summarized in *Table 359*.

Table 359. ECC projective to affine

Parameters with direction		Value (note)	Storage	Size
IN	MODE	0x2F	PKA_CR	6 bits
	Curve modulus *p* length	(in bits, 8 < value < 640)	RAM@0x408	64 bits
	Curve modulus value p	(odd integer prime, $0 < p < 2^{640}$)	RAM@0x470	EOS
	Point P coordinate X (projective)	(x < *p*)	RAM@0xD60	
	Point P coordinate Y (projective)	(y < *p*)	RAM@0xDB8	
	Point P coordinate Z (projective)	(z < *p*)	RAM@0xE10	
	Montgomery parameter R2 mod n	-	RAM@0x4C8	
OUT	Point P coordinate x (affine)	(x < *p*)	RAM@0x578	
	Point P coordinate y (affine)	(y < *p*)	RAM@0x5D0	
ERROR	Error code	– Point not at infinity: 0xD60D – Point at infinity: 0xA3B7	RAM@0x680	64 bits

36.5 Example of configurations and processing times

36.5.1 Supported elliptic curves

The PKA supports all non-singular elliptic curves defined over prime fields. Those curves can be described with a short Weierstrass equation, $y^2 = x^3 + ax + b \pmod{p}$.

Note: Binary curves, Edwards curves and Curve25519 are not supported by the PKA.
The maximum supported operand size for ECC operations is 640 bits.

When publishing the ECC domain parameters of those elliptic curves, standard bodies define the following parameters:

- the prime integer *p*, used as the modulus for all point arithmetic in the finite field GF(*p*)
- the (usually prime) integer *n*, the order of the group generated by G, defined below
- the base point of the curve G, defined by its coordinates (*Gx*, *Gy*)
- the integers *a* and *b*, coefficients of the short Weierstrass equation.

For the last bullet, when standard bodies define *a* as negative, PKA supports two representations:

1. **a defined as *p*-|*a*|** in the finite field GF(*p*), for example **p-3**:
   Curve coefficient p = 0xFFFFFFFE FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF 00000000 FFFFFFFF FFFFFFF**F**
   Curve coefficient a sign= 0x0 (positive)
   Curve coefficient a = 0xFFFFFFFE FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF 00000000 FFFFFFFF FFFFFFF**C**
2. ***a* defined as negative**, for example **-3**:
   Curve coefficient p = 0xFFFFFFFE FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF 00000000 FFFFFFFF FFFFFFFF
   Curve coefficient a sign= 0x**1** (negative)
   Curve coefficient a = 0x00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 0000000**3**

Table 360 summarizes the family of curves supported by PKA for ECC operations.

36.5.2 Computation times

The following tables summarize the PKA computation times, expressed in AHB clock cycles.

Table 361. Modular exponentiation

Exponent length (in bits)	Mode	Modulus length (in bits)			
		1024	2048	3072	4096
3	Normal	124600	491000	684000	1133200
	Fast	22700	82000	178000	311000
17	Normal	135700	531400	772400	1288000
	Fast	33800	122500	266500	465800
2^{16} + 1	Normal	180000	693700	1126200	1907200
	Fast	78200	284700	620400	1085000
1024	Protected	9958000	-	-	-
	Normal	5850000	-	-	-
	Fast	5748000	-	-	-
	CRT(1)	1775000	-	-	-
2048	Protected	-	63886000	-	-
	Normal	-	42240000	-	-
	Fast	-	41832000	-	-
	CRT(1)	-	11670000	-	-
3072	Protected	-	-	199403000	-
	Normal	-	-	136830000	-
	Fast	-	-	136325000	-
	CRT(1)	-	-	36886000	-
4096	Protected	-	-	-	454318000
	Normal	-	-	-	316000000
	Fast	-	-	-	315226000
	CRT(1)	-	-	-	84577000

1. CRT stands for chinese remainder theorem optimization (MODE bitfield= 0x07).

Table 362. ECC scalar multiplication(1)

Modulus length (in bits)							
160	192	256	320	384	512	521	640
-	1590000	3083000	5339000	8518000	17818000	21053000	31826000

1. These times depend on the number of 1s included in the scalar parameter, and include the computation of Montgomery parameter R2.

Table 363. ECDSA signature average computation time(1) (2)

Modulus length (in bits)							
160	**192**	**256**	**320**	**384**	**512**	**521**	**640**
-	1500000	2744000	4579000	7184000	14455000	16685000	24965000

1. These values are average execution times of random moduli of given length, as they depend upon the length and the value of the modulus.
2. The execution time for the moduli that define the finite field of NIST elliptic curves is shorter than that needed for the moduli used for Brainpool elliptic curves or for random moduli of the same size.

Table 364. ECDSA verification average computation times

Modulus length (in bits)							
160	**192**	**256**	**320**	**384**	**512**	**521**	**640**
1011000	1495000	2938000	5014000	7979000	16804000	19254000	29582000

Table 365. ECC double base ladder average computation times

Modulus length (in bits)							
160	**192**	**256**	**320**	**384**	**512**	**521**	**640**
967000	1419000	2768000	4784000	7547000	15854000	18257000	28257000

Table 366. ECC projective to affine average computation times

Modulus length (in bits)						
160	**192**	**256**	**320**	**384**	**512**	**640**
47600	78000	148300	253000	419000	838400	1049300

Table 367. ECC complete addition average computation times

Modulus length (in bits)						
160	**192**	**256**	**320**	**384**	**512**	**640**
10000	12000	18000	26000	39000	53000	89000

Table 368. Point on elliptic curve Fp check average computation times

Modulus length (in bits)							
160	**192**	**256**	**320**	**384**	**512**	**521**	**640**
3400	4200	6100	8300	10900	17200	-	-

Table 369. Montgomery parameters average computation times(1)

Modulus length (in bits)							
192	**256**	**320**	**512**	**1024**	**2048**	**3072**	**4096**
8600	8710	11870	17000	102000	410000	506000	822000

1. The computation times depend upon the length and the value of the modulus, hence these values are average execution times of random moduli of given length.

36.6 PKA interrupts

There are four individual maskable interrupt sources generated by the public key accelerator, signaling the following events:

1. PKA unsupported operation error (OPERRF), see *Section 36.3.7*
2. Access to unmapped address (ADDRERRF), see *Section 36.3.7*
3. PKA RAM access while PKA operation is in progress (RAMERRF), see *Section 36.3.7*
4. PKA end of operation (PROCENDF)

The interrupt sources are connected to the same global interrupt request signal pka_it.

The user can enable or disable above interrupt sources individually by changing the mask bits in the *PKA control register (PKA_CR)*. Setting the appropriate mask bit to 1 enables the interrupt. The status of the individual interrupt events can be read from the PKA status register (PKA_SR), and it is cleared in PKA_CLRFR register.

Table 370 gives a summary of the available features.

Table 370. PKA interrupt requests

Acronym	Event	Event flag	Enable control bit	Clear method
PKA	Unsupported operation	OPERRF	OPERRIE	Set OPERRFC bit
	Access to unmapped address error	ADDRERRF	ADDRERRIE	Set ADDRERRFC bit
	PKA RAM access error	RAMERRF	RAMERRIE	Set RAMERRFC bit
	PKA end of operation	PROCENDF	PROCENDIE	Set PROCENDFC bit

36.7 PKA registers

36.7.1 PKA control register (PKA_CR)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OP ERRIE	ADDR ERRIE	RAM ERRIE	Res.	PROC ENDIE	Res.
										rw	rw	rw		rw	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	MODE[5:0]						Res.	Res.	Res.	Res.	Res.	Res.	START	EN
		rw	rw	rw	rw	rw	rw							rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **OPERRIE**: Operation error interrupt enable
0: No interrupt is generated when OPERRF flag is set in PKA_SR.
1: An interrupt is generated when OPERRF flag is set in PKA_SR.

Bit 20 **ADDRERRIE**: Address error interrupt enable
0: No interrupt is generated when ADDRERRF flag is set in PKA_SR.
1: An interrupt is generated when ADDRERRF flag is set in PKA_SR.

Bit 19 **RAMERRIE**: RAM error interrupt enable
0: No interrupt is generated when RAMERRF flag is set in PKA_SR.
1: An interrupt is generated when RAMERRF flag is set in PKA_SR.

Bit 18 Reserved, must be kept at reset value.

Bit 17 **PROCENDIE**: End of operation interrupt enable
0: No interrupt is generated when PROCENDF flag is set in PKA_SR.
1: An interrupt is generated when PROCENDF flag is set in PKA_SR.

Bits 16:14 Reserved, must be kept at reset value.

Bits 13:8 **MODE[5:0]**: PKA operation code

000000: Montgomery parameter computation then modular exponentiation
000001: Montgomery parameter computation only
000010: Modular exponentiation only (Montgomery parameter must be loaded first)
000011: Modular exponentiation (protected, used when manipulating secrets)
100000: Montgomery parameter computation then ECC scalar multiplication (protected)
100100: ECDSA sign (protected)
100110: ECDSA verification
101000: Point on elliptic curve Fp check
000111: RSA CRT exponentiation
001000: Modular inversion
001001: Arithmetic addition
001010: Arithmetic subtraction
001011: Arithmetic multiplication
001100: Arithmetic comparison
001101: Modular reduction
001110: Modular addition
001111: Modular subtraction
010000: Montgomery multiplication
100011: ECC complete addition
100111: ECC double base ladder
101111: ECC projective to affine

When an operation not listed here is written by the application with EN bit set, OPERRF bit is set in PKA_SR register, and the write to MODE bitfield is ignored. When PKA is configured in limited mode (LMF = 1 in PKA_SR), writing a MODE different from 0x26 with EN bit to 1 triggers OPERRF bit to be set and write to MODE bit is ignored.

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **START**: start the operation

Writing 1 to this bit starts the operation which is selected by MODE[5:0], using the operands and data already written to the PKA RAM. This bit is always read as 0.

When an illegal operation is selected while START bit is set no operation is started, and OPERRF bit is set in PKA_SR.

Note: START is ignored if PKA is busy.

Bit 0 **EN**: PKA enable

0: Disable PKA

1: Enable PKA. PKA becomes functional when INITOK is set by hardware in PKA_SR. When an illegal operation is selected while EN = 1, OPERRF bit is set in PKA_SR. See PKA_CR.MODE bitfield for details.

Note: When EN = 0, PKA RAM can still be accessed by the application.

36.7.2 PKA status register (PKA_SR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OP ERRF	ADDR ERRF	RAM ERRF	Res.	PROC ENDF	BUSY
										r	r	r		r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LMF	INITOK
														r	r

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **OPERRF**: Operation error flag

0: No event error

1: An illegal or unknown operation has been selected in PKA_CR register

This bit is cleared using OPERRFC bit in PKA_CLRFR.

Bit 20 **ADDRERRF**: Address error flag

0: No address error

1: Address access is out of range (unmapped address)

This bit is cleared using ADDRERRFC bit in PKA_CLRFR.

Bit 19 **RAMERRF**: PKA RAM error flag

0: No PKA RAM access error

1: An AHB access to the PKA RAM occurred while the PKA core was computing and using its internal RAM (AHB PKA_RAM access are not allowed while PKA operation is in progress).

This bit is cleared using RAMERRFC bit in PKA_CLRFR.

Bit 18 Reserved, must be kept at reset value.

Bit 17 **PROCENDF**: PKA end of operation flag

0: Operation in progress

1: PKA operation is completed. This flag is set when the BUSY bit is deasserted.

Bit 16 **BUSY**: Busy flag

This bit is set whenever a PKA operation is in progress (START = 1 in PKA_CR). It is automatically cleared when the computation is complete, making PKA RAM accessible again.

0: No operation is in progress (default)

1: An operation is in progress

If PKA is started with a wrong opcode, it stays busy for a couple of cycles, then it aborts automatically the operation and goes back to ready (BUSY = 0).

Bits 15:2 Reserved, must be kept at reset value.

Bit 1 **LMF**: Limited mode flag

This bit is updated when EN bit in PKA_CR is set

0: All values documented in MODE bitfield can be used.

1: Only ECDSA verification (MODE = 0x26) is supported by the PKA.

Bit 0 **INITOK**: PKA initialization OK
This bit is asserted when PKA initialization is complete. When RNG is not able to output proper random numbers INITOK stays at 0.
0: PKA is not initialized correctly. START bit cannot be set.
1: PKA is initialized correctly and can be used normally.

36.7.3 PKA clear flag register (PKA_CLRFR)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OP ERRFC	ADDR ERRFC	RAM ERRFC	Res.	PROC ENDFC	Res.
										w	w	w		w	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **OPERRFC**: Clear operation error flag
0: No action
1: Clear the OPERRF flag in PKA_SR

Bit 20 **ADDRERRFC**: Clear address error flag
0: No action
1: Clear the ADDRERRF flag in PKA_SR

Bit 19 **RAMERRFC**: Clear PKA RAM error flag
0: No action
1: Clear the RAMERRF flag in PKA_SR

Bit 18 Reserved, must be kept at reset value.

Bit 17 **PROCENDFC**: Clear PKA end of operation flag
0: No action
1: Clear the PROCENDF flag in PKA_SR

Bits 16:0 Reserved, must be kept at reset value.

Note: Reading PKA_CLRFR returns all 0s.

36.7.4 PKA RAM

The PKA RAM is mapped at the offset address of 0x0400 compared to the PKA base address. Only 32-bit word single accesses are supported, through PKA.AHB interface.

RAM size is 5336 bytes (max word offset: 0x14D0)

Note: PKA RAM cannot be used just after a PKA reset or a product reset, as described in Section 36.3.3: PKA reset and clocks.

36.7.5 PKA register map

Table 371. PKA register map and reset values

Refer to *Section 2.3 on page 111* for the register boundary addresses.

37 On-the-fly decryption engine (OTFDEC)

37.1 Introduction

OTFDEC allows on-the-fly decryption of the AHB traffic based on the read request address information. Four independent and non-overlapping encrypted regions can be defined in OTFDEC.

OTFDEC uses AES-128 in counter mode to achieve the lowest possible latency. As a consequence, each time the content of one encrypted region is changed, the entire region must be re-encrypted with a different cryptographic context (key or initialization vector). This constraint makes OTFDEC suitable to decrypt read-only data or code, stored in external NOR flash.

Note: When OTFDEC is used in conjunction with OCTOSPI, it is mandatory to access the flash memory using the memory-mapped mode of the flash memory controller.

When security is enabled in the product, OTFDEC can be programmed only by a secure host.

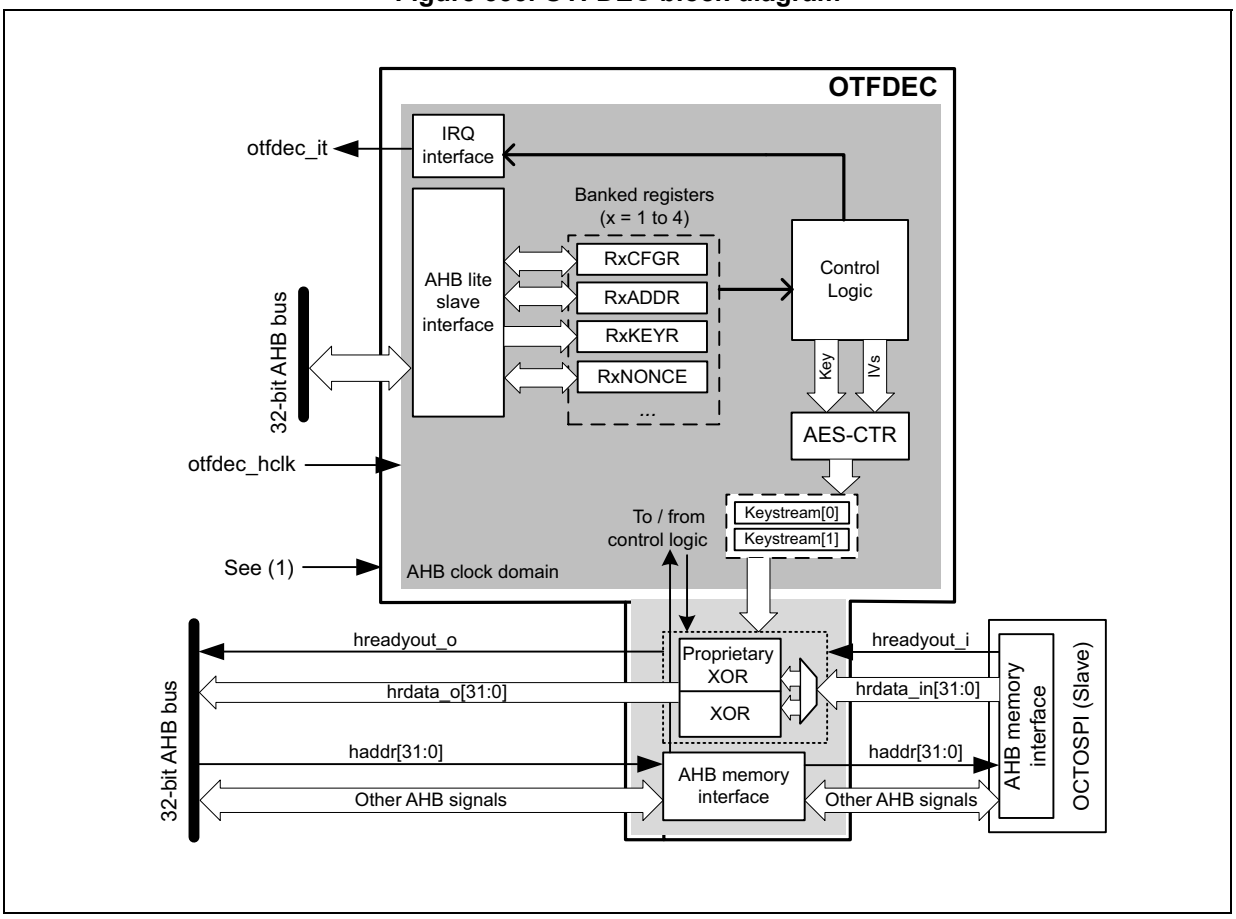
37.2 OTFDEC main features

- On-the-fly 128-bit decryption during the OCTOSPI Memory-mapped read operations (single or multiple).
  - Use of AES in counter (CTR) mode, with two 128-bit keystream buffers
  - Support for any read size
  - Physical address of the reads used for the encryption/decryption
- Up to four independent encrypted regions
  - Granularity of the region definition: 4096 bytes
  - Region configuration write-locking mechanism
  - Each region has its own 128-bit key, two bytes firmware version, and eight bytes application-defined nonce. At least one of those must be changed each time an encryption is performed by the application.
- Encryption keys confidentiality and integrity protection
  - Write-only registers, with software locking mechanism
  - Availability of 8-bit CRC as public key information
- Support for OCTOSPI pre-fetching mechanism
- Possibility to select an enhanced encryption mode to add a proprietary layer of protection on top of AES stream cipher (execute only)
- Privileged-aware AMBA AHB slave peripheral, accessible through 32-bit word single accesses only (otherwise an AHB bus error is generated, and write accesses are ignored)
- Secure only programming if TrustZone security is enabled in the product
- Encryption mode

37.3 OTFDEC functional description

37.3.1 OTFDEC block diagram

Figure 333. OTFDEC block diagram



1. otfdec_tzen

37.3.2 OTFDEC internal signals

Table 372 describes a list of useful to know internal signals available at OTFDEC level, not at the product level (on pads).

Table 372. OTFDEC internal input/output signals

Signal name	Signal type	Description
otfdec_hclk	Digital input	AHB bus clock
otfdec_it	Digital output	OTFDEC global interrupt request
otfdec_tzen	Digital input	OTFDEC TrustZone enable, controlling TrustZone features of the peripheral (TZEN)

The TZEN option bit in FLASH is used to activate TrustZone in the device.

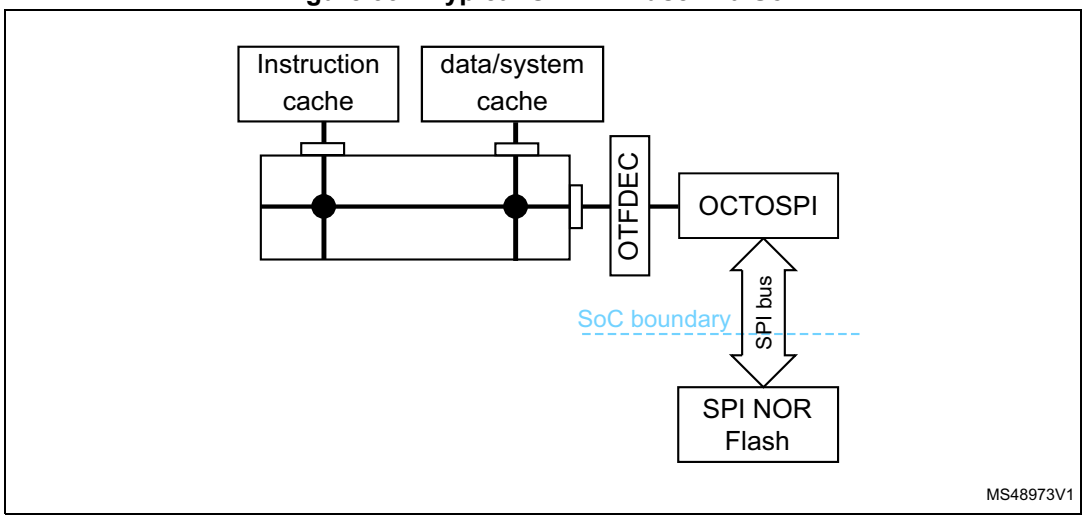
- TZEN = 1: TrustZone security is enabled in the product.
- TZEN = 0: TrustZone security is disabled in the product.

37.3.3 OTFDEC on-the-fly decryption

Introduction

Typical usage for OTFDEC is shown on *Figure 334*.

Figure 334. Typical OTFDEC use in a SoC



Original purpose of OTFDEC is to protect the confidentiality of read-only firmware libraries stored in external SPI NOR flash devices.

A special locking scheme is available in OTFDEC in order to protect the integrity of the decryption keys and also to protect the other configurations against software denial of services attacks. OTFDEC access to most registers can be made privileged-only by setting PRIV bit in OTFDEC_PRIVCFGR register. OTFDEC is only writeable by TrustZone CPU, when TrustZone security is activated.

When OTFDEC is used in conjunction with OCTOSPI, it is mandatory to read the flash memory using the Memory-mapped mode of the flash controller.

On top of decrypting on-the-fly, OTFDEC can also encrypt 32-bit word at a time (see *Section 37.5.3: Encrypting for OTFDEC* for more details).

OTFDEC architecture

OTFDEC analyzes all AHB read transfers on the associated AHB bus. If the read request is within one of the four regions programmed in OTFDEC, the control logic triggers a keystream computation based on AES algorithm in counter mode. This keystream is then used to decrypt on-the-fly the data present in the read transfer from the OCTOSPI AHB master, tying low the HREADYOUT signal of this master while the keystream information is being computed (this takes up to 11 cycles). Any accesses outside the enabled OTFDEC regions belong to a non-encrypted region.

Each OTFDEC region is programmed through OTFDEC_RxCFGR, OTFDEC_RxSTARTADDR, OTFDEC_RxENDADDR, OTFDEC_RxNONCER and

OTFDEC_RxKEYR registers, where x = 1 to 4. In OTFDEC_RxCFGR, the MODE bits define the OTFDEC operating mode (standard or enhanced encryption).

Granularity for the region determination is 4096 bytes.

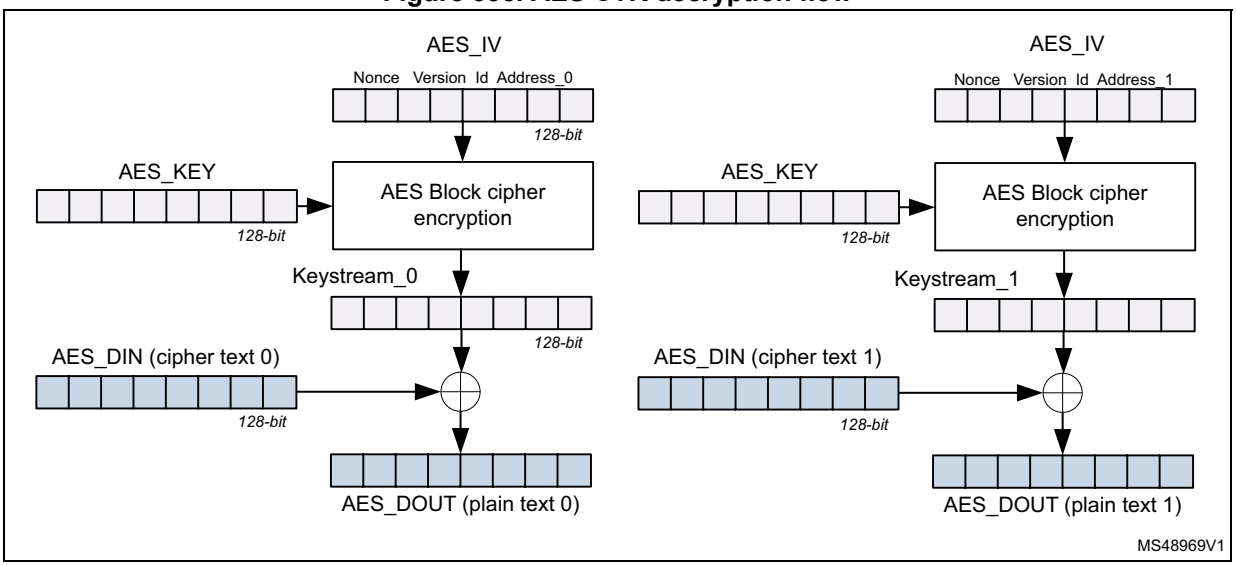
Note: Although OTFDEC does not prevent region overlapping, it is not a valid programming and it must be avoided by application software.

OTFDEC can decrypt incremental or wrap bursts only if they do not cross the 4096-byte aligned address boundaries.

37.3.4 OTFDEC usage of AES in counter mode decryption

Figure 335 shows how OTFDEC uses industry standard Advanced Encryption Standard (AES) algorithm in counter chaining mode. This mode is specified by NIST in *Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation*.

Figure 335. AES CTR decryption flow



Every 128-bit data block, a special keystream information is computed using AES block cipher, as defined below:

- initialization vector AES_IV[127:0] = RxNONCER1[31:0] || RxNONCER0[31:0] || 0b0000 0000 0000 0000 || RxCFGR[31:16] || 0b00 || (x-1) || ReadAddress[31:4]
- key material AES_KEY[127:0] = R*x*KEYR3[31:0] || R*x*KEYR2[31:0] || R*x*KEYR1[31:0] || R*x*KEYR0[31:0]

Note: Above x is the RegionID of the selected encrypted region (x=1 to 4).
ReadAddress is the AHB address of the encrypted data block, modulo 128-bit.

Resulting 128-bit keystream is XORed with 128-bit cipher text data to produce the 128-bit clear text data.

- AES_DIN and AES_DOUT data blocks are constructed following the rule below (“|” represents a binary concatenation):
  AES_Dx[127:0]= AHB_word(@ | 0xC)[31:0] | AHB_word(@ | 0x8)[31:0] | AHB_word(@ | 0x4)[31:0] || AHB_word(@ | 0x0)[31:0], where @ is the hexadecimal address used to compute the keystream (ReadAddress[31:4] above).

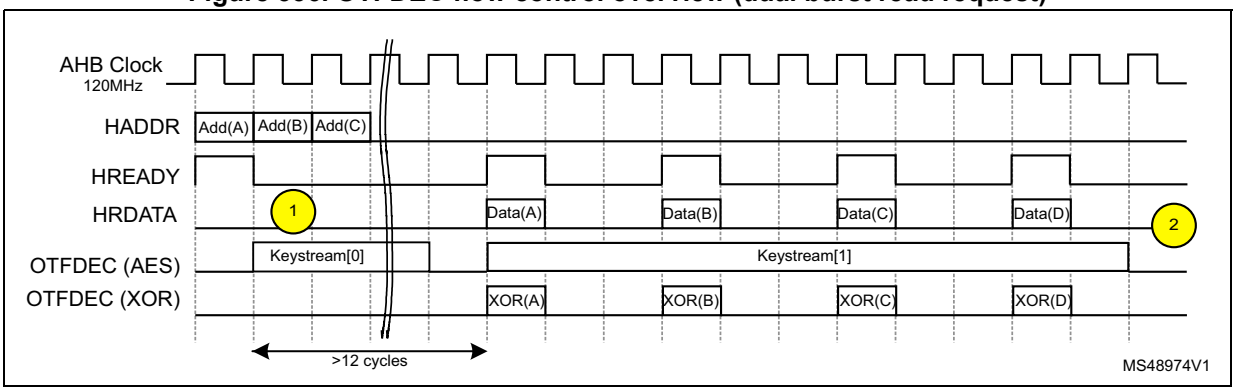
When the read request is not within an encrypted region, or the decryption is not enabled in this region, the AHB data is not changed.

Note: When the application sets the MODE bitfield to 11 in OTFDEC_RxCFGR, an additional layer of protection is added on top of the AES stream cipher. This enhanced encryption mode can only be used with instructions (execute-only region).

37.3.5 Flow control management

Figure 336 shows how OTFDEC manages one INCR4 AHB burst that corresponds to one 128-bit AES data block.

Figure 336. OTFDEC flow control overview (dual burst read request)



with the following notes:

1. OTFDEC enforces HREADY signal from the AHB master low as it is not ready to decrypt data (keystream computation).
2. Thanks to the keystream buffer, OTFDEC can be ready to process a new batch of data within 12 cycles in this configuration (120 MHz AHB clock, 104 MHz SPI bus delivering 2 bytes per SPI clock).

37.3.6 OTFDEC error management

OTFDEC automatically manages errors defined as below:

- Illegal read to OTFDEC_RxKEYR registers
- Illegal write to OTFDEC_RxKEYR registers while CONFIGLOCK or KEYLOCK = 1 in OTFDEC_RxCFGR, while the access is secure. If the security is disabled in the product, the same error occurs when the access is nonsecure.
- Illegal write to OTFDEC_RxCFGR, OTFDEC_RxSTARTADDR, OTFDEC_RxENDADDR or OTFDEC_RxNONCER registers while CONFIGLOCK = 1 in OTFDEC_RxCFGR (x = 1 to 4), while the access is secure. If the security is disabled in the product the same error occurs when the access is nonsecure.
- Illegal read to an execute-only region (MODE[1:0] = 11). Such illegal request returns 0x0, without bus error.
- Execution request to a region while encryption is enabled (ENC = 1). The request returns 0x0, without bus error.
- Key error: read request to an encrypted region while its key registers are null or not properly initialized (KEYCRC = 0x0). Source of the error can be an incorrect key loading sequence (see KEYCRC in OTFDEC_RxCFGR) or it can be an abort event

(tamper detection, unauthorized debug connection, untrusted boot, RDP level regression). Such read request returns 0x0, without bus error.

- Write to any registers while the access is nonsecure, if TrustZone security is enabled in the product.

  This last error is managed and cleared through TrustZone interrupt controller, as described in the GTZC section of the product reference manual.

For these errors (except the last one), an interrupt can be generated if the SEIE, XONEIE or KEIE bit is set in OTFDEC_IER register (see *Section 37.4*).

Note: After a key error, OTFDEC keys must be properly initialized again, and a reset of OTFDEC may be needed if registers are locked.

37.4 OTFDEC interrupts

There are three independent maskable interrupt sources generated by the OTFDEC, signaling following security events:

- Illegal read or write access to keys (SEIF flag), see *Section 37.3.6*
- Illegal write to a region configuration while CONFIGLOCK = 1 (SEIF flag), see *Section 37.3.6*
- Read access to an execute-only region (MODE[1:0] = 11), triggering the XONEIF flag
- Executing while encryption is enabled (XONEIF flag)
- Key error (encrypted regions read as zero) triggering the KEIF flag, see *Section 37.3.6*.

Interrupt sources are connected to the same global interrupt request signal.

OTFDEC interrupt sources can be enabled/disabled by setting the corresponding SEIE, XONEIE or KEIE bit in OTFDEC_IER, as described in *Table 373*. Status of the interrupt event is found in OTFDEC_ISR, and this event can be cleared using OTFDEC_ICR.

Table 373. OTFDEC interrupt requests

Interrupt acronym	Interrupt event	Event flag(1)	Enable control bit	Interrupt clear method
OTFDEC	Security error	SEIF	SEIE	Set SEIF in OTFDEC_ICR
	Execute-only Execute while encryption	XONEIF	XONEIE	Set XONEIF in OTFDEC_ICR
	Key error	KEIF	KEIE	Set KEIF in OTFDEC_ICR

1. The event flags are found in the OTFDEC_ISR register.

37.5 OTFDEC application information

37.5.1 OTFDEC initialization process

Introduction

One key aspect of OTFDEC is the trusted initialization of its registers, as it involves secret keys. Two trusted initialization schemes are recommended here below.

Note: Those sequences are for production code, as during firmware development, it is not always recommended to lock the key or the region configuration.

Writes to configuration registers are effective when the configuration locks allow it, even if the region is enabled.

Initialization scheme 1: one key for all regions

In this scheme, one entity owns the secret key used to decrypt the four protected regions. The recommended OTFDEC configuration sequence is described below:

1. For *x* = 1 to 4, write the correct MODE[1:0] value in OTFDEC_RxCFGR.
2. For *x* = 1 to 4, program OTFDEC_RxKEYR registers using the sequence described in KEYCRC (to have a valid CRC). Warning as key registers are write only.
3. For *x* = 1 to 4, check the key CRC. If OK, set KEYLOCK bit in OTFDEC_R*x*CFGR. This bit cannot be cleared (key registers in this region *x* are no more writable).
4. To do to decrypt a region x (task that does not necessarily have to be performed by the entity that owns the decryption keys):
   a) Verify if the key CRC corresponds to the encrypted binary stored in the region.
   b) Fill the detailed information corresponding to this binary (nonce, start address, end address, version number).
   c) Enable decryption of this region using REG_EN.
   d) Set CONFIGLOCK bit in OTFDEC_R*x*CFGR. This bit cannot be cleared (the region configuration is no more writable).

Caution: For a given region, when MODE bits are changed, the key registers and associated CRC are cleared by hardware. As a consequence, step 1 above must be done before step 2, and MODE bits must not be modified after step 2.

Initialization scheme 2: one key per region

In this scheme, one entity can own the secret used to decrypt one (or more) protected region. The recommended OTFDEC configuration sequence is described below:

1. To do to decrypt a region x (this task **must** be performed by the entity that owns the corresponding key):
   a) Write the correct MODE[1:0] value in OTFDEC_R*x*CFGR.
   b) Program OTFDEC_RxKEYR registers using the sequence described in KEYCRC (to have a valid CRC). Warning as key registers are write only.
   c) Check the key CRC. If OK, set KEYLOCK bit in OTFDEC_R*x*CFGR. This bit cannot be cleared (key registers are no more writable).
   d) Fill the detailed information corresponding to the protected firmware (nonce, start address, end address, version number).
   e) Enable decryption of this region using REG_EN.
   f) Set CONFIGLOCK bit in OTFDEC_R*x*CFGR. This bit cannot be cleared (the region configuration is no more writable).

Caution: For a given region, when MODE bits are changed, the key registers and associated CRC are cleared by hardware. As a consequence step a) above must be done before step b), and MODE bits must not be modified after step b).

37.5.2 OTFDEC and power management

Each time OTFDEC is reset, the correct key loading sequence described in *Section 37.5.1* must be performed (in this case KEYCRC = 0 in OTFDEC_RxCFGR).

It is recommended for application software to verify this point each time OTFDEC is reset by hardware.

37.5.3 Encrypting for OTFDEC

Code and data standard encryption

OTFDEC uses standard AES in counter mode when processing a binary stored in a protected region with MODE[1:0] = 10. When this mode is selected, any AES compatible hardware accelerator or library can be used to encrypt those protected libraries. OTFDEC can be used as well, as described in enhanced encryption section below (with MODE[1:0] = 10).

Definition and endianness of the AES inputs and outputs are defined in *Section 37.3.4: OTFDEC usage of AES in counter mode decryption*.

Enhanced encryption with OTFDEC

OTFDEC uses a proprietary layer of protection on top of the standard AES in counter mode when processing a code stored in a protected region with MODE[1:0] = 11.

Enhanced encryption mode can be used to increase the robustness against tampering.

Recommended sequence to encrypt using OTFDEC is described below:

1. The application in charge of the encryption sets the ENC bit in OTFDEC_CR. This application must run in TrustZone secure mode when TrustZone security is enabled in the product. If PRIV bit is set in OTFDEC_PRIVCFGR, this application must be privileged.
2. Encryption application initializes OTFDEC as described in *Section 37.5.1: OTFDEC initialization process*. OCTOSPI must also be properly clocked, so that OTFDEC is fully functional in encryption mode. This step can also be done before step 1.
3. Encryption application writes 32-bit of clear-text data at the expected protected address, then reads it back encrypted at the same address to store it in RAM. Note that this data stays inside the device, as it is intercepted by OTFDEC in encryption mode.
4. Encryption application goes back to previous step (changing the address) until the whole binary is processed.
5. Encryption application clears the ENC bit in OTFDEC_CR. Another application can then take the encrypted binary and flash it to the correct address in external flash.

There are few important notes about this procedure:

- Encryption granularity is 32-bit (single 32-bit access is mandatory).
- While ENC bit is set, reads to non-encrypted regions return normal data (such as no encryption nor decryption). While in encryption mode, no access to OCTOSPI (including registers) must be done. This is because the OTFDEC cuts the communication with OCTOPSI while ENC bit is set.
- OTFDEC does not support execution while ENC = 1 (only encrypted data reads). Upon illegal execution detection a XONEIF flag is raised and zero is returned.

37.5.4 OTFDEC key CRC source code

Below is the CRC source code that can be used to compare with the result of the computation provided by OTFDEC in KEYCRC bitfield after loading the keys in OTFDEC_RxKEYR registers.

```
uint8_t getCRC(uint32_t * keyin)
{
  const uint8_t CRC7_POLY = 0x7;
  const uint32_t key_strobe[4] = {0xAA55AA55, 0x3, 0x18, 0xC0};
  uint8_t  i, j, k, crc = 0x0;
  uint32_t  keyval;

  for (j = 0; j < 4; j++)
  {
    keyval = *(keyin+j);
    if (j == 0)
    {
      keyval ^= key_strobe[0];
    }
    else
    {
      keyval ^= (key_strobe[j] << 24) | (crc << 16) | (key_strobe[j] << 8)
| crc;
    }

    for (i = 0, crc = 0; i < 32; i++)
    {
      k = (((crc >> 7) ^ (keyval >> (31-i))&0xF)) & 1;
      crc <<= 1;
      if (k)
      {
        crc ^= CRC7_POLY;
       }
    }
    crc^=0x55;
  }
  return crc;
}
```

37.6 OTFDEC registers

37.6.1 OTFDEC control register (OTFDEC_CR)

Address offset: 0x0

Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ENC
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **ENC**: Encryption mode bit

When this bit is set, OTFDEC is used in encryption mode, during which application can write clear text data then read back encrypted data. When this bit is cleared (default), OTFDEC is used in decryption mode, during which application only read back decrypted data. For both modes, cryptographic context (keys, nonces, firmware versions) must be properly initialized. When this bit is set, only data accesses are allowed (zeros are returned otherwise, and XONEIF is set). When MODE = 11, enhanced encryption mode is automatically selected.

0: OTFDEC working in decryption mode

1: OTFDEC working in encryption mode

Note: When ENC bit is set, no access to OCTOSPI must be done (registers and Memory-mapped region).

37.6.2 OTFDEC privileged access control configuration register (OTFDEC_PRIVCFGR)

Address offset: 0x10

Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRIV
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **PRIV:** Privileged access protection.

0: No additional protection is added on OTFDEC register accesses.

1: An additional protection is added when accessing all registers except OTFDEC_PRIVCFGR:

– Unprivileged read accesses to registers return zeros

– Unprivileged write accesses to registers are ignored.

Note: This bit can only be written in privileged mode. There is no limitations on reads.

37.6.3 OTFDEC region x configuration register (OTFDEC_RxCFGR)

Address offset: 0x20 + 0x30 * (x - 1), (x = 1 to 4)

Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

Writes are ignored if CONFIGLOCK bit is set to 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
REG_VERSION[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
KEYCRC[7:0]								Res.	Res.	MODE[1:0]		Res.	KEYLOCK	CONFIGLOCK	REG_EN
r	r	r	r	r	r	r	r			rw	rw		rs	rs	rw

Bits 31:16 **REG_VERSION[15:0]**: region firmware version

This 16-bit bitfield must be correctly initialized before the region corresponding REG_EN bit is set in OTFDEC_RxCFGR.

Bits 15:8 **KEYCRC[7:0]**: region key 8-bit CRC

When KEYLOCK = 0, KEYCRC bitfield is automatically computed by hardware while loading the key of this region in this exact sequence: KEYR0 then KEYR1 then KEYR2 then finally KEYR3 (all written once). A new computation starts as soon as a new valid sequence is initiated, and KEYCRC is read as zero until a valid sequence is completed.

When KEYLOCK = 1, KEYCRC remains unchanged until the next reset.

CRC computation is an 8-bit checksum using the standard CRC-8-CCITT algorithm $X^8 + X^2 + X + 1$ (according the convention). Source code is available in *Section 37.5.4*.

This field is read only.

Note: CRC information is updated only after the last bit of the key has been written.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **MODE[1:0]**: operating mode

This bitfield selects the OTFDEC operating mode for this region:

10: All read accesses are decrypted (instruction or data).

11: Enhanced encryption mode is activated, and only instruction accesses are decrypted

Others: Reserved

When MODE ≠ 11, the standard AES encryption mode is activated.

When either of the MODE bits are changed, the region key and associated CRC are zeroed.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **KEYLOCK**: region key lock

0: Writes to this region KEYRx registers are allowed.

1: Writes to this region KEYRx registers are ignored until next OTFDEC reset. KEYCRC bitfield is locked.

Note: This bit is set once: if this bit is set, it can only be reset to 0 if the OTFDEC is reset.

Bit 1 **CONFIGLOCK**: region config lock

0: Writes to this region OTFDEC_RxCFGR, OTFDEC_RxSTARTADDR, OTFDEC_RxENDADDR and OTFDEC_RxNONCERy registers are allowed.

1: Writes to this region OTFDEC_RxCFGR, OTFDEC_RxSTARTADDR, OTFDEC_RxENDADDR and OTFDEC_RxNONCERy registers are ignored until next OTFDEC reset.

Note: This bit is set once. If this bit is set, it can only be reset to 0 if OTFDEC is reset. Setting this bit forces KEYLOCK bit to 1.

Bit 0 **REG_EN**: region on-the-fly decryption enable

0: On-the-fly decryption is disabled for this region.

1: On-the-fly decryption is enabled for this region. Data are XORed with the corresponding keystream.

Note: Garbage is decrypted if region context (version, key, nonce) is not valid when this bit is set.

37.6.4 OTFDEC region x start address register (OTFDEC_RxSTARTADDR)

Address offset: 0x24 + 0x30 * (x - 1), (x = 1 to 4)

Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
REG_START_ADDR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REG_START_ADDR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **REG_START_ADDR[31:0]**: Region AHB start address

This register must be written before the region corresponding REG_EN bit in the OTFDEC_RxCFGR register is set.

Writing to this register is discarded if performed while the region CONFIGLOCK bit in the OTFDEC_RxCFGR register is set.

Note: When determining the region the first 12 bits (LSB) and the last 4 bits (MSB) are ignored.

When this register is accessed in read the 4 MSB bits and the 12 LSB bits return zeros .

37.6.5 OTFDEC region x end address register (OTFDEC_RxENDADDR)

Address offset: 0x28 + 0x30 * (x - 1), (x = 1 to 4)

Reset value: 0x0000 0FFF

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
REG_END_ADDR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REG_END_ADDR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **REG_END_ADDR[31:0]**: Region AHB end address

This register must be written before the region corresponding REG_EN bit in the OTFDEC_RxCFGR register is set, and OTFDEC_RxENDADDR must be strictly greater than OTFDEC_RxSTARTADDR to be valid.

Writing to this register is discarded if performed while the region CONFIGLOCK bit in OTFDEC_RxCFGR is set.

Note: When determining the region the first 12 bits (LSB) and the last 4 bits (MSB) are ignored.

When this register is accessed in read the 4 MSB bits return zeros and the 12 LSB bits return ones.

37.6.6 OTFDEC region x nonce register 0 (OTFDEC_RxNONCER0)

Address offset: 0x2C + 0x30 * (x - 1), (x = 1 to 4)

Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

REG_NONCE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **REG_NONCE[31:0]**: Region nonce, bits [31:0]

This register must be written before the region corresponding REG_EN bit in OTFDEC_RxCFGR is set.

Writing is discarded in this register if performed while the region CONFIGLOCK bit in the OTFDEC_RxCFGR is set.

37.6.7 OTFDEC region x nonce register 1 (OTFDEC_RxNONCER1)

Address offset: 0x30 + 0x30 * (x - 1), (x = 1 to 4)

Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

REG_NONCE[47:32]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **REG_NONCE[63:32]**: Region nonce, bits [63:32]

Refer to the OTFDEC_RxNONCER0 register for description of the NONCE[63:0] bitfield.

37.6.8 OTFDEC region x key register 0 (OTFDEC_RxKEYR0)

Address offset: 0x34 + 0x30 * (x - 1), (x = 1 to 4)

Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

REG_KEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **REG_KEY[31:0]**: Region key, bits [31:0]

This register must be written before the region corresponding REG_EN bit in OTFDEC_RxCFGR is set.

Reading this register returns a zero value. Writing to this register is discarded if performed while the region CONFIGLOCK or KEYLOCK bit is set in the OTFDEC_RxCFGR.

Note: When application successfully changes MODE bits in OTFDEC*_RxCFGR and* OTFDEC*_RxKEYR, and associated KEYCRC are erased.*

37.6.9 OTFDEC region x key register 1 (OTFDEC_RxKEYR1)

Address offset: 0x38 + 0x30 * (x - 1), (x = 1 to 4)

Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

REG_KEY[47:32]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **REG_KEY[63:32]**: Region key, bits [63:32]
Refer to the OTFDEC_RxKEYR0 register for description of the KEY[127:0] bitfield.

37.6.10 OTFDEC region x key register 2 (OTFDEC_RxKEYR2)

Address offset: 0x3C + 0x30 * (x - 1), (x = 1 to 4)

Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

REG_KEY[79:64]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **REG_KEY[95:64]**: Region key, bits [95:64]
Refer to the OTFDEC_RxKEYR0 register for description of the KEY[127:0] bitfield.

37.6.11 OTFDEC region x key register 3 (OTFDEC_RxKEYR3)

Address offset: 0x40 + 0x30 * (x - 1), (x = 1 to 4)

Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

REG_KEY[111:96]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **REG_KEY[127:96]**: Region key, bits [127:96]

Refer to the OTFDEC_RxKEYR0 register for description of the KEY[127:0] bitfield.

37.6.12 OTFDEC interrupt status register (OTFDEC_ISR)

Address offset: 0x300

Reset value: 0x0000 0000

Unprivileged reads return zero if PRIV bit is set in OTFDEC_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	KEIF	XONEIF	SEIF
													r	r	r

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **KEIF:** Key error interrupt flag status

This bit is set by hardware and read only by application. The bit is set when a read access occurs on an encrypted region, while its key registers is null or not properly initialized (KEYCRC = 0x0).

This bit is cleared when the application sets in OTFDEC_ICR the corresponding bit to 1.

0: OTFDEC operates properly.

1: Read access detected on an enabled encrypted region with its key registers null or not properly initialized (KEYCRC = 0x0). OTFDEC returns a zeroed value for the read, and an optional interrupt is generated if bit KEIE is set to 1 in OTFDEC_IER.

After KEIF is set any subsequent read to the region with bad key registers returns a zeroed value. This state remains until those key registers are properly initialized (KEYCRC not zero).

Bit 1 **XONEIF:** Execute-only execute-never error interrupt flag status

This bit is set by hardware and read only by application. This bit is set when a read access and not an instruction fetch is detected on any encrypted region with MODE bits set to 11. Lastly, XONEIF is also set when an execute access is detected while encryption mode is enabled.

This bit is cleared when application sets in OTFDEC_ICR the corresponding bit to 1.

0: No execute-only error status. No interrupt pending.

1: Read access detected on one region with MODE bits set to 11 or execute access detected while ENC = 1. OTFDEC returns a zeroed value for the illegal access, and an optional interrupt is generated if bit XONEIE is set to 1 in OTFDEC_IER.

Bit 0 **SEIF:** Security error interrupt flag status

This bit is set by hardware and read only by application. This bit is set when at least one security error has been detected.

This bit is cleared when application sets in OTFDEC_ICR the corresponding bit to 1.

0: No security error status. No interrupt pending.

1: Security error flag status, with interrupt pending. Actual interrupt generation is dependent on OTFDEC_IER corresponding bit SEIE.

37.6.13 OTFDEC interrupt clear register (OTFDEC_ICR)

Address offset: 0x304

Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	KEIF	XONEIF	SEIF
													w	w	w

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **KEIF:** Key error interrupt flag clear
This bit is written by application, and always read as 0.
0: KEIF flag status is not affected.
1: KEIF flag status is cleared in OTFDEC_ISR.
Note: Clearing KEIF does not solve the source of the problem (bad key registers). To be able to access again any encrypted region, OTFDEC key registers must be properly initialized again.

Bit 1 **XONEIF:** Execute-only execute-never error interrupt flag clear
This bit is written by application, and always read as 0.
0: XONEIF flag status is not affected.
1: XONEIF flag status is cleared in OTFDEC_ISR.

Bit 0 **SEIF:** Security error interrupt flag clear
This bit is written by application, and always read as 0.
0: SEIF flag status is not affected.
1: SEIF flag status is cleared in OTFDEC_ISR.

37.6.14 OTFDEC interrupt enable register (OTFDEC_IER)

Address offset: 0x308

Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	KEIE	XONEIE	SEIE
													rw	rw	rw

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **KEIE:** Key error interrupt enable

This bit is read and written by application. It controls the OTFDEC interrupt generation when KEIF flag status is set.

0: Interrupt generation on key error flag KEIF is disabled (masked).

1: Interrupt generation on key error flag KEIF is enabled (not masked).

Bit 1 **XONEIE:** Execute-only execute-never error interrupt enable

This bit is read and written by application. It controls the OTFDEC interrupt generation when XONEIF flag status is set.

0: Interrupt generation on execute-only error XONEIF is disabled (masked).

1: Interrupt generation on execute-only error XONEIF is enabled (not masked).

Bit 0 **SEIE:** Security error interrupt enable

This bit is read and written by application. It controls the OTFDEC interrupt generation when SEIF flag status is set.

0: Interrupt generation on security error SEIF is disabled (masked).

1: Interrupt generation on security error SEIF is enabled (not masked).

38 Advanced-control timers (TIM1/TIM8)

38.1 TIM1/TIM8 introduction

The advanced-control timers (TIM1/TIM8) consist of a 16-bit auto-reload counter driven by a programmable prescaler.

It may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM, complementary PWM with dead-time insertion).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The advanced-control (TIM1/TIM8) and general-purpose (TIMy) timers are completely independent, and do not share any resources. They can be synchronized together as described in *Section 38.3.30: Timer synchronization*.

38.2 TIM1/TIM8 main features

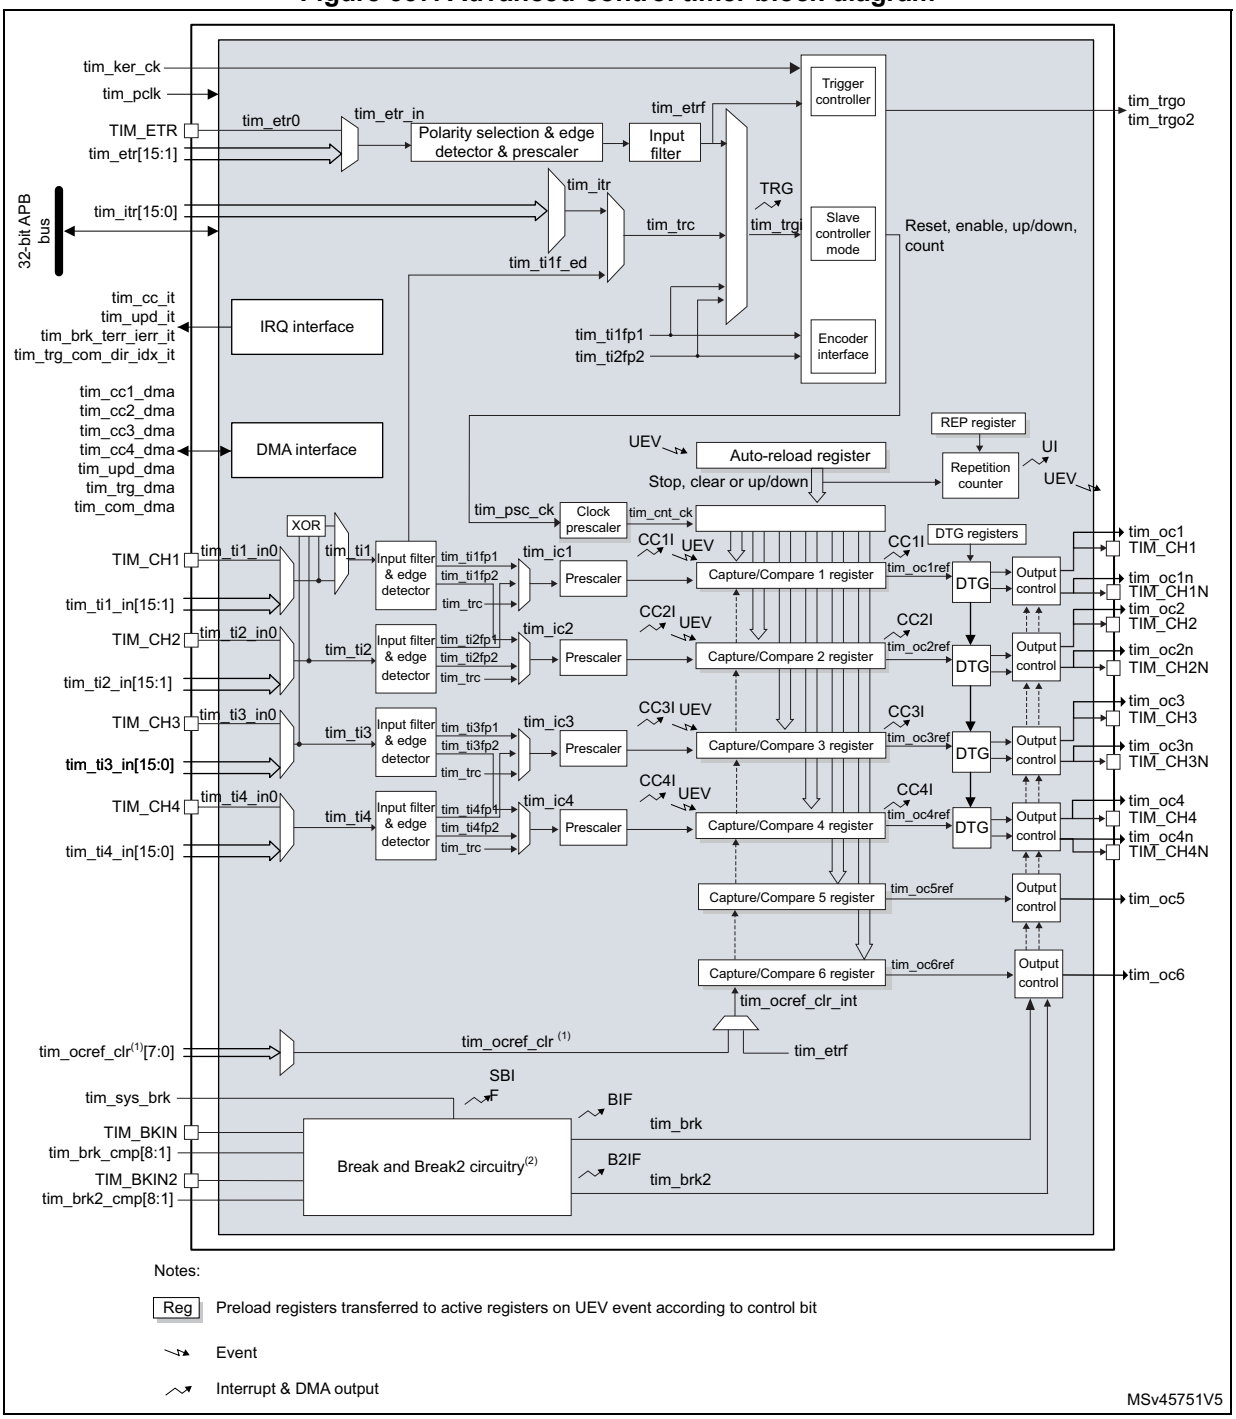
TIM1/TIM8 timer features include:

- 16-bit up, down, up/down auto-reload counter.
- 16-bit programmable prescaler allowing dividing (also “on the fly”) the counter clock frequency either by any factor between 1 and 65536.
- Up to 6 independent channels for:
  - Input capture (but channels 5 and 6)
  - Output compare
  - PWM generation (Edge and Center-aligned Mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time
- Synchronization circuit to control the timer with external signals and to interconnect several timers together.
- Repetition counter to update the timer registers only after a given number of cycles of the counter.
- 2 break inputs to put the timer’s output signals in a safe user selectable configuration.
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
- Supports incremental (quadrature) encoder and Hall-sensor circuitry for positioning purposes
- Trigger input for external clock or cycle-by-cycle current management

38.3 TIM1/TIM8 functional description

38.3.1 Block diagram

Figure 337. Advanced-control timer block diagram



1. This feature is not available on all timers, refer to *Section 38.3.2: TIM1/TIM8 pins and internal signals*.
2. See *Figure 384: Break and Break2 circuitry overview* for details.

38.3.2 TIM1/TIM8 pins and internal signals

The tables in this section summarize the TIM inputs and outputs

Table 375. TIM input/output pins

Pin name	Signal type	Description
TIM_CH1 TIM_CH2 TIM_CH3 TIM_CH4	Input/Output	Timer multi-purpose channels. Each channel can be used for capture, compare or PWM. TIM_CH1 and TIM_CH2 can also be used as external clock (below 1/4 of the tim_ker_ck clock), external trigger and quadrature encoder inputs. TIM_CH1, TIM_CH2 and TIM_CH3 can be used to interface with digital hall effect sensors.
TIM_CH1N TIM_CH2N TIM_CH3N TIM_CH4N	Output	Timer complementary outputs, derived from TIM_CHx outputs with the possibility to have deadtime insertion.
TIM_ETR	Input	External trigger input. This input can be used as external trigger or as external clock source. This input can receive a clock with a frequency higher than the tim_ker_ck if the tim_etr_in prescaler is used.
TIM_BKIN TIM_BKIN2	Input / Output	Break and Break2 inputs. These inputs can also be configured in bidirectional mode.

Table 376. TIM internal input/output signals

Internal signal name	Signal type	Description
tim_ti1_in[15:0] tim_ti2_in[15:0] tim_ti3_in[15:0] tim_ti4_in[15:0]	Input	Internal timer inputs bus. The tim_ti1_in[15:0] and tim_ti2_in[15:0] inputs can be used for capture or as external clock (below 1/4 of the tim_ker_ck clock) and for quadrature encoder signals.
tim_etr[15:0]	Input	External trigger internal input bus. These inputs can be used as trigger, external clock or for hardware cycle-by-cycle pulsewidth control. These inputs can receive clock with a frequency higher than the tim_ker_ck if the tim_etr_in prescaler is used.
tim_itr[15:0]	Input	Internal trigger input bus. These inputs can be used for the slave mode controller or as a input clock (below 1/4 of the tim_ker_ck clock).
tim_trgo/tim_trgo2	Output	Internal trigger outputs. These triggers are used by other timers and /or other peripherals.

Table 376. TIM internal input/output signals (continued)

Internal signal name	Signal type	Description
tim_ocref_clr[7:0]	Input	Timer tim_ocref_clr input bus. These inputs can be used to clear the tim ocxref signals, typically for hardware cycle-by-cycle pulsewidth control.
tim_brk_cmp[8:1]	Input	Break input for internal signals
tim_brk2_cmp[8:1]	Input	Break2 input for internal signals
tim_sys_brk[n:0]	Input	System break input. This input gathers the MCU's system level errors.
tim_pclk	Input	Timer APB clock
tim_ker_ck	Input	Timer kernel clock
tim_cc_it	Output	Timer capture/compare interrupt
tim_upd_it	Output	Timer update event interrupt
tim_brk_terr_ierr_it	Output	Timer break, break2, transition error and index error interrupt
tim_trg_com_dir_idx_it	Output	Timer trigger, commutation, direction and index interrupt
tim_cc1_dma tim_cc2_dma tim_cc3_dma tim_cc4_dma	Output	Timer capture / compare 1..4 dma requests
tim_upd_dma	Output	Timer update dma request
tim_trg_dma	Output	Timer trigger dma request
tim_com_dma	Output	Timer commutation dma request

38.3.3 Time-base unit

The main block of the programmable advanced-control timer is a 16-bit counter with its related auto-reload register. The counter can count up, down or both up and down. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software, even when the counter is running.

The time-base unit includes:

- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Auto-reload register (TIMx_ARR)
- Repetition counter register (TIMx_RCR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detailed for each configuration.

The counter is clocked by the prescaler output tim_cnt_ck, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note: The counter starts counting 1 clock cycle after setting the CEN bit in the TIMx_CR1 register.

Prescaler description

The prescaler divides the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

Figure 338 and *Figure 339* give some examples of the counter behavior when the prescaler ratio is changed on the fly.

Figure 338. Counter timing diagram with prescaler division change from 1 to 2

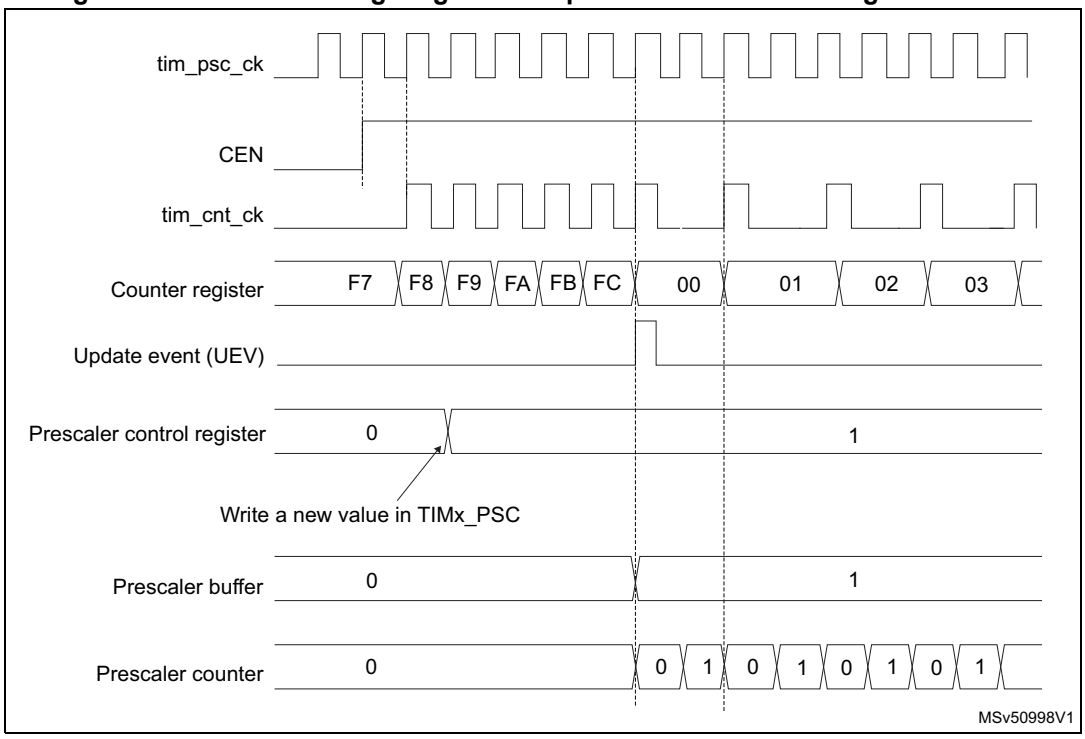

Figure 339. Counter timing diagram with prescaler division change from 1 to 4

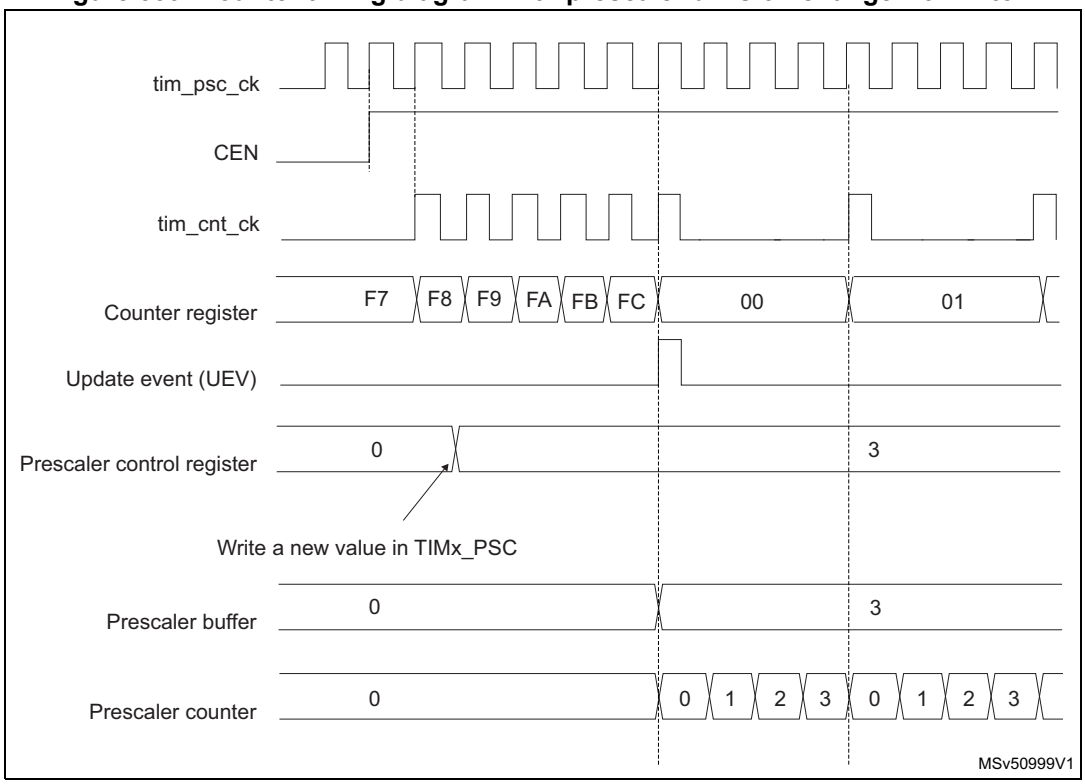

38.3.4 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

If the repetition counter is used, the update event (UEV) is generated after upcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR) + 1. Else the update event is generated at each counter overflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register,
- The auto-reload shadow register is updated with the preload value (TIMx_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

Figure 340. Counter timing diagram, internal clock divided by 1

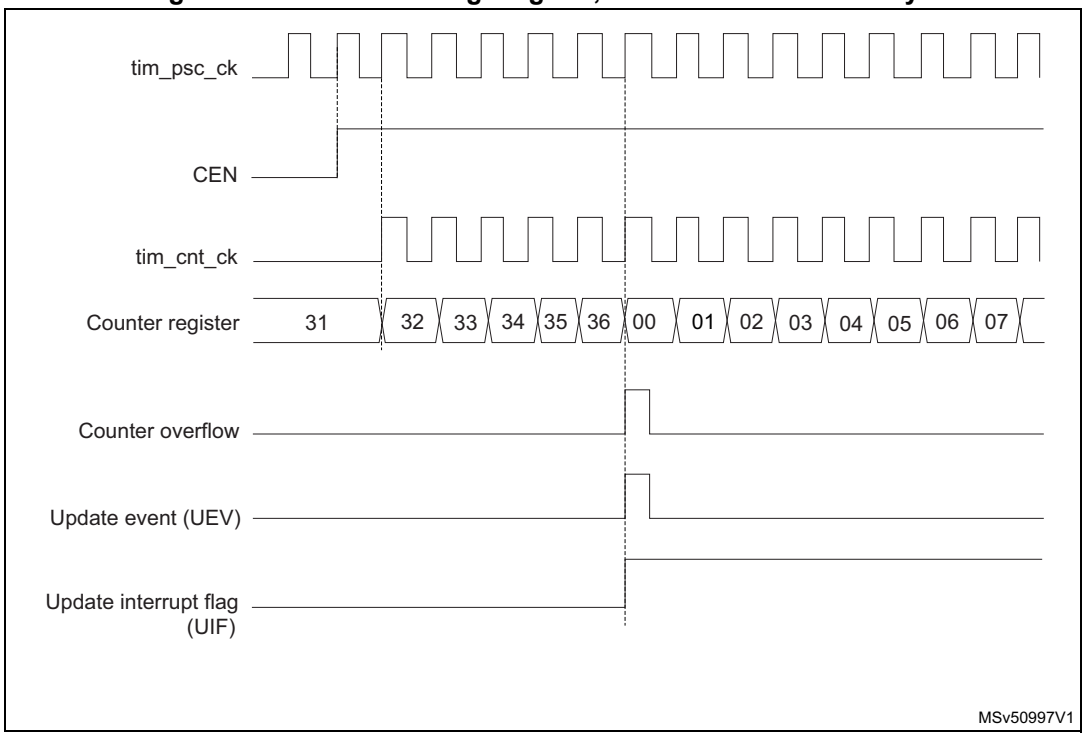

Figure 341. Counter timing diagram, internal clock divided by 2

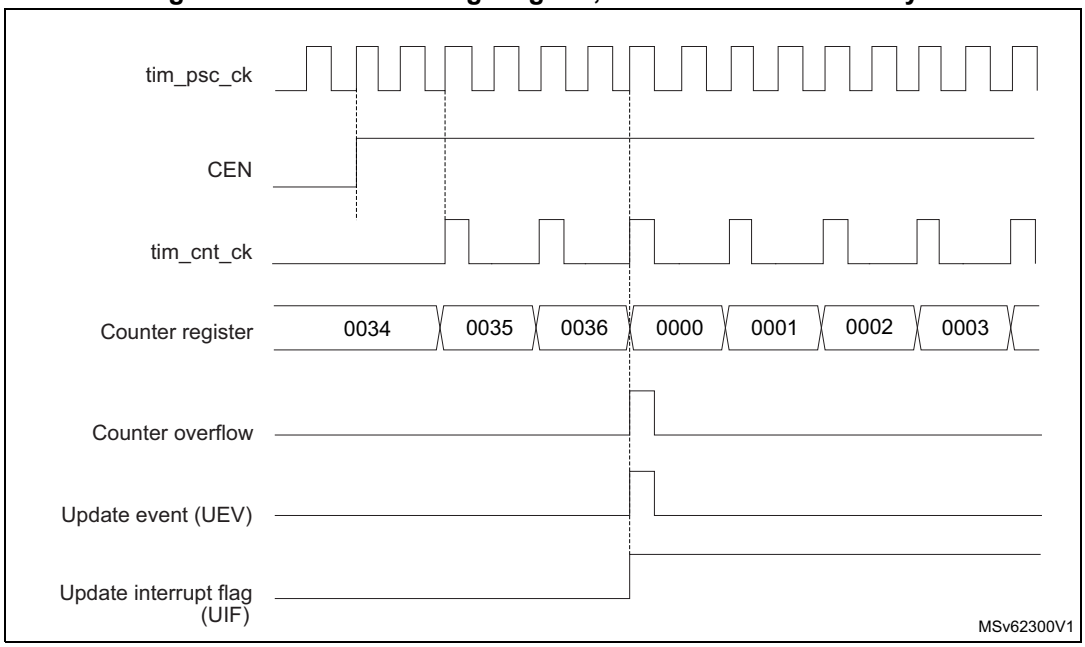

Figure 342. Counter timing diagram, internal clock divided by 4

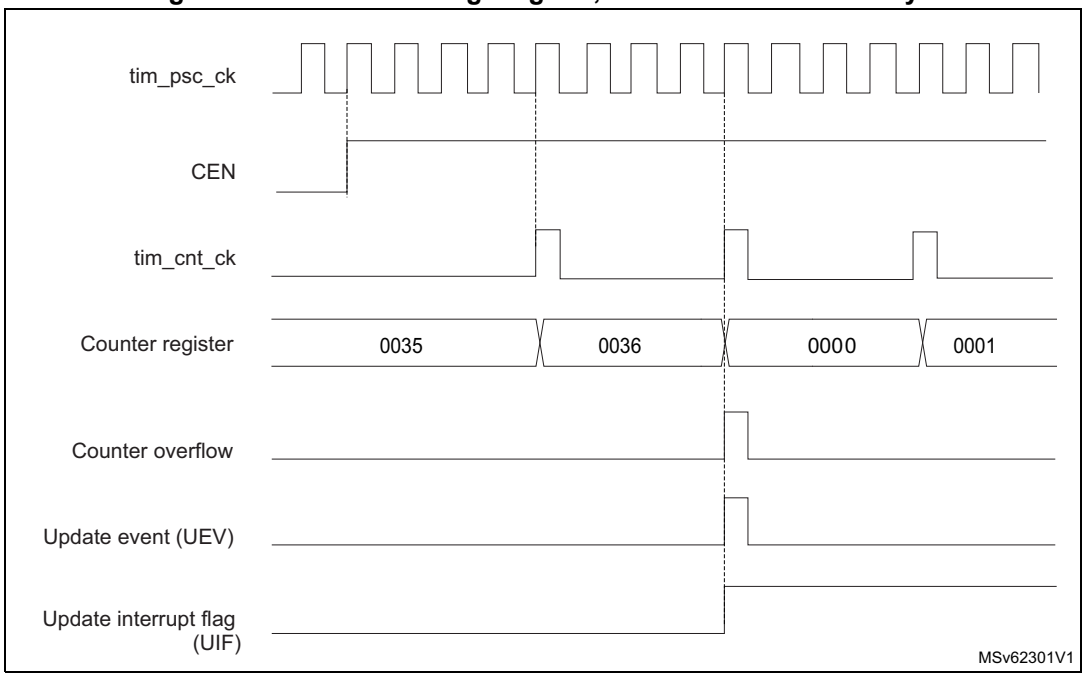

Figure 343. Counter timing diagram, internal clock divided by N

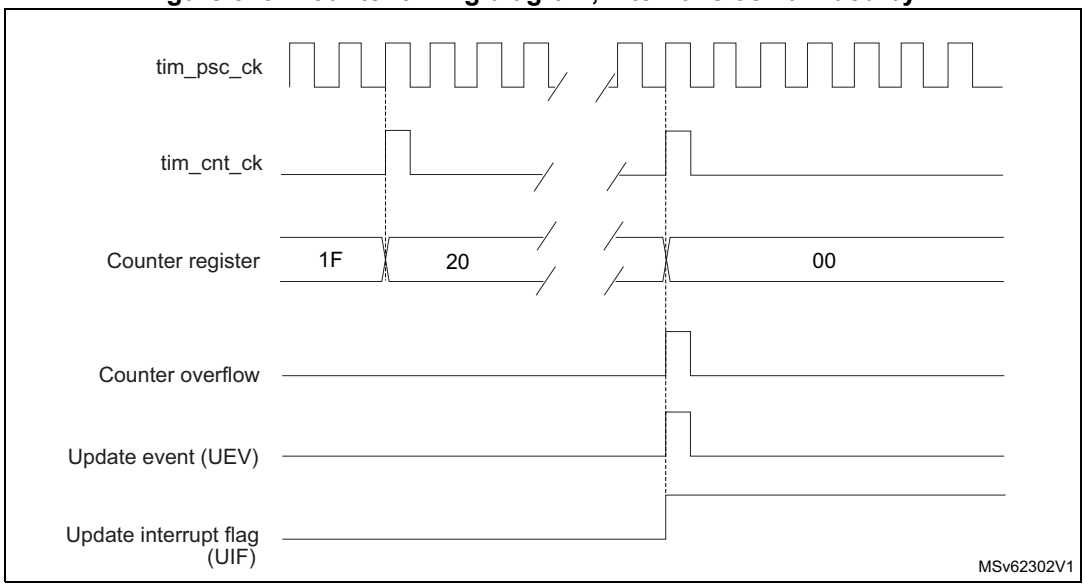

Figure 344. Counter timing diagram, update event when ARPE=0 (TIMx_ARR not preloaded)

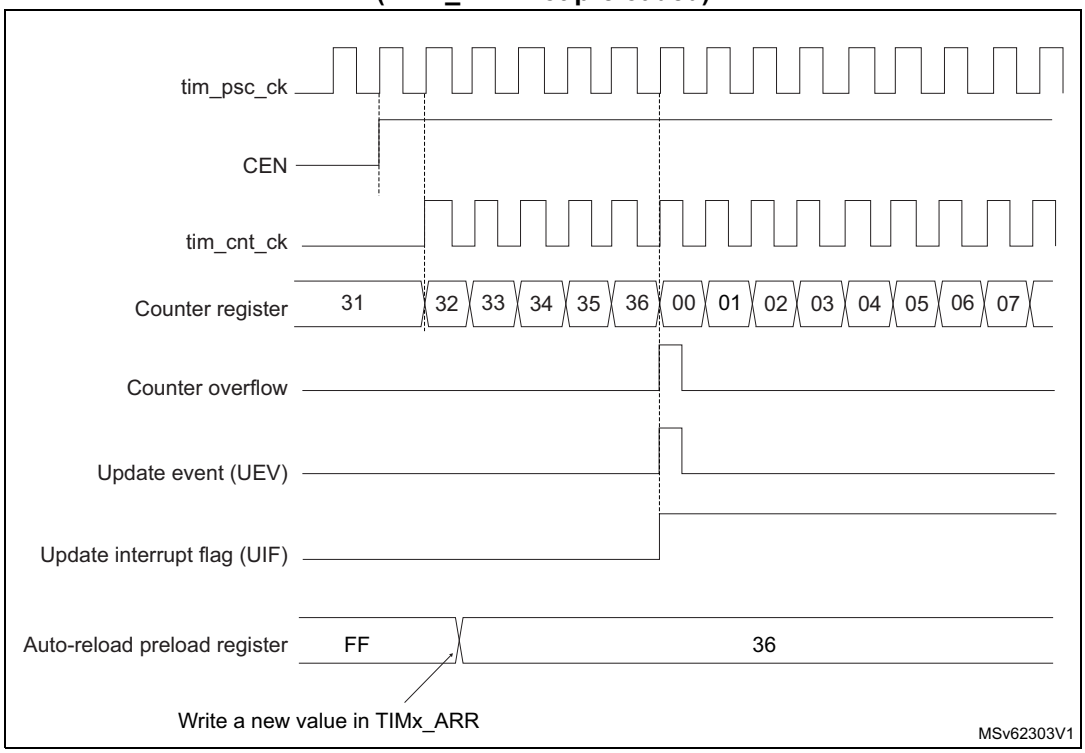

Figure 345. Counter timing diagram, update event when ARPE=1 (TIMx_ARR preloaded)

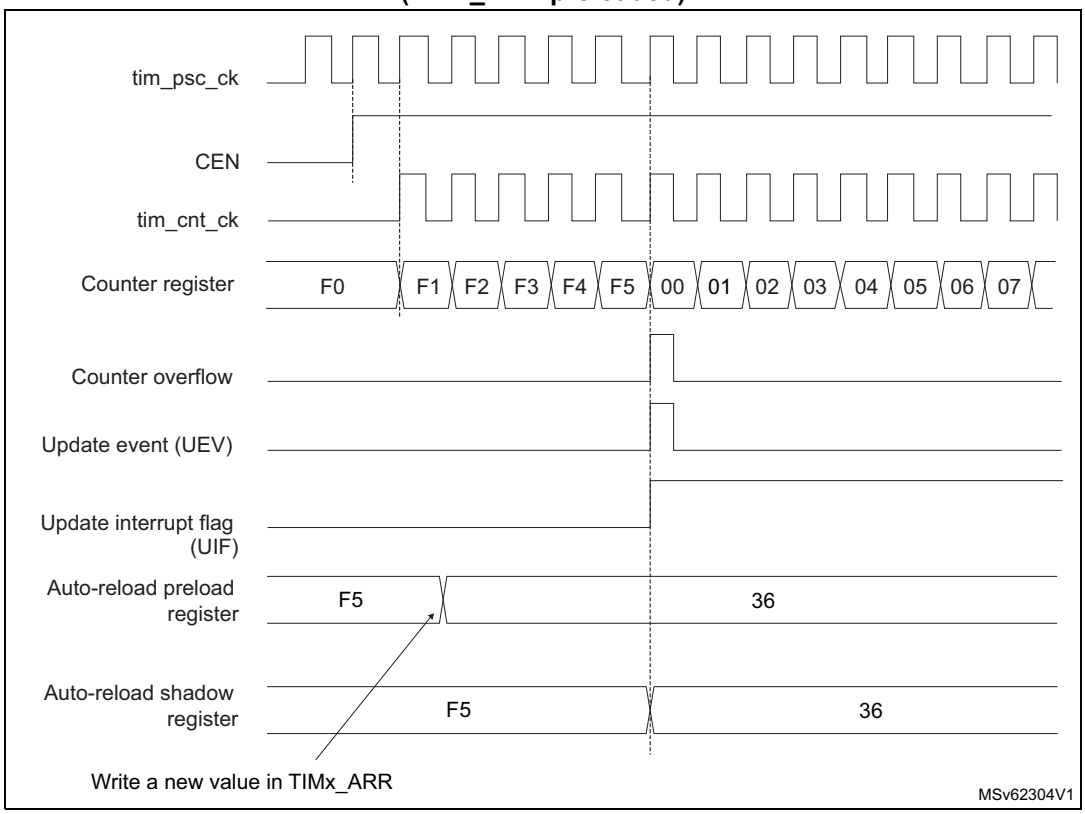

Downcounting mode

In downcounting mode, the counter counts from the auto-reload value (content of the TIMx_ARR register) down to 0, then restarts from the auto-reload value and generates a counter underflow event.

If the repetition counter is used, the update event (UEV) is generated after downcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR) + 1. Else the update event is generated at each counter underflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current auto-reload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn't change).

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register.
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that the auto-reload is updated before the counter is reloaded, so that the next period is the expected one.

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

Figure 346. Counter timing diagram, internal clock divided by 1

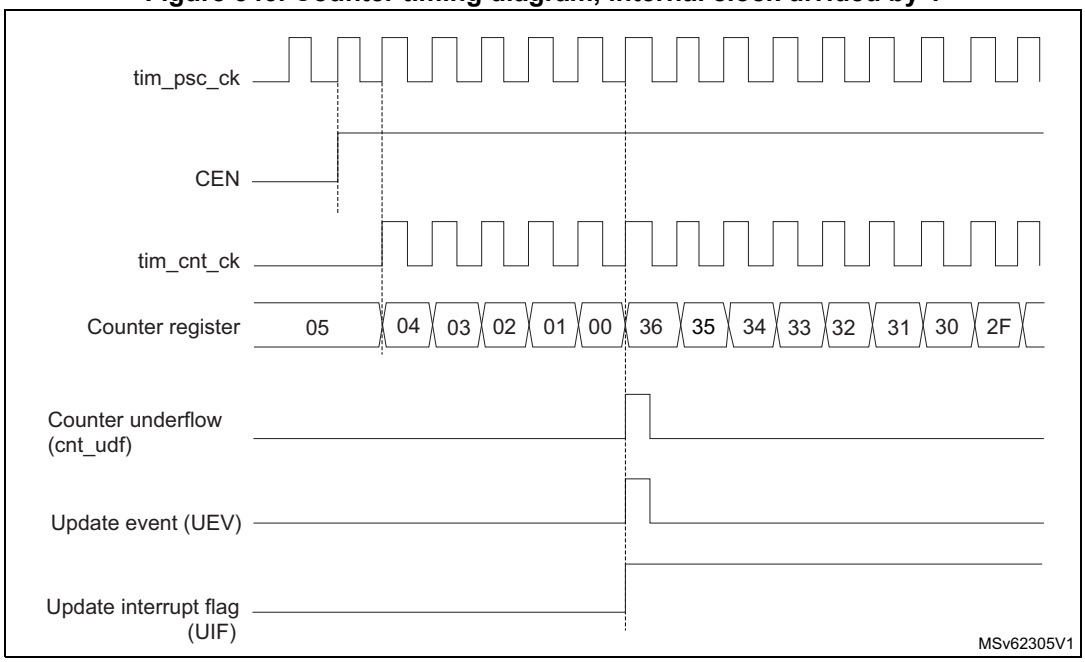

Figure 347. Counter timing diagram, internal clock divided by 2

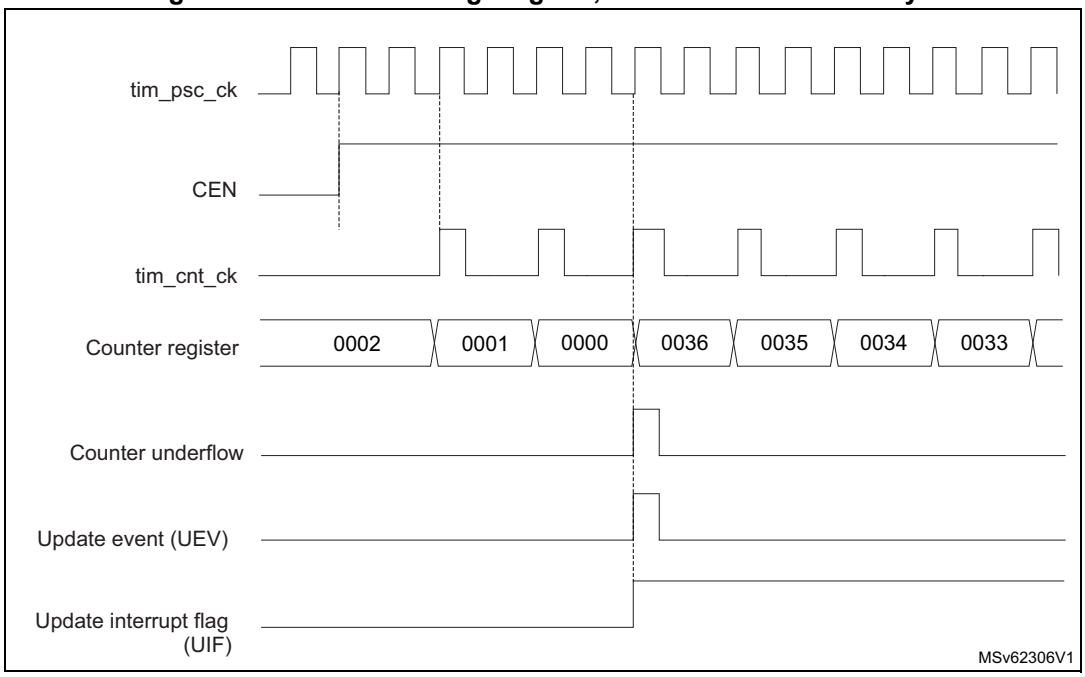

Figure 348. Counter timing diagram, internal clock divided by 4

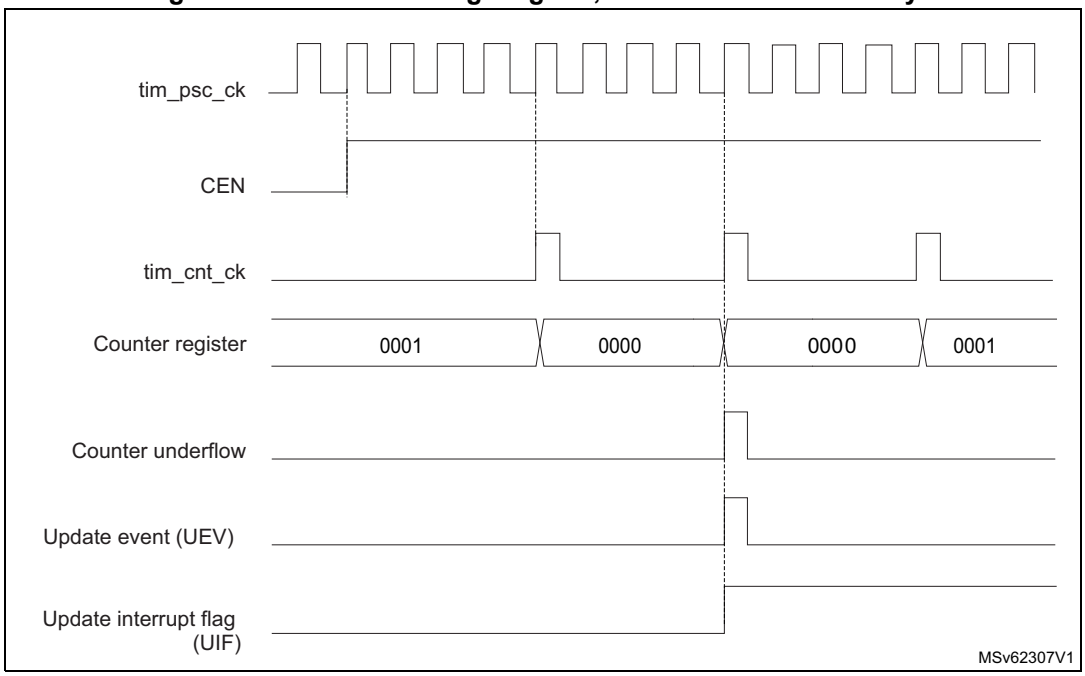

Figure 349. Counter timing diagram, internal clock divided by N

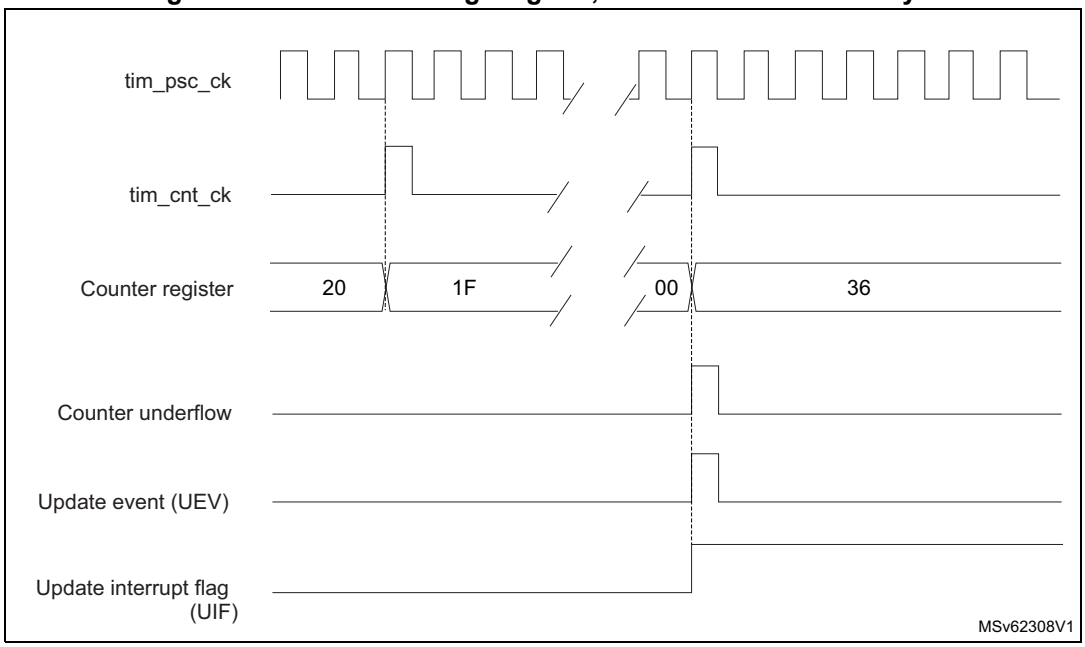

Figure 350. Counter timing diagram, update event when repetition counter is not used

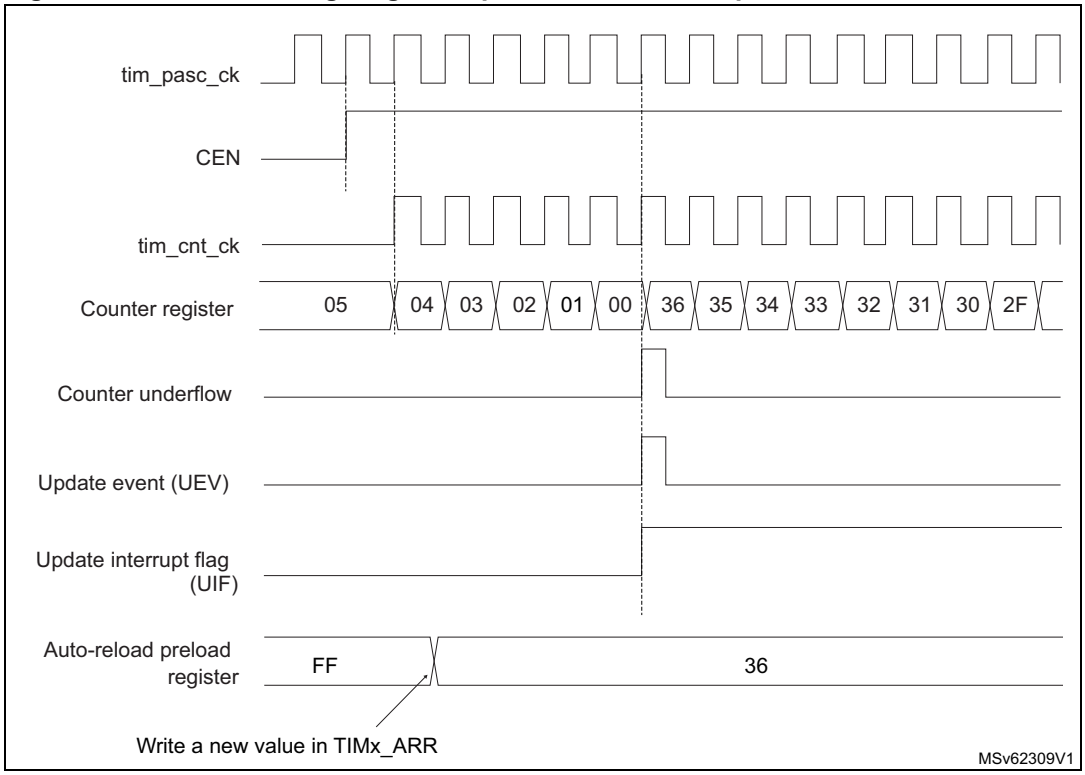


Center-aligned mode (up/down counting)

In center-aligned mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register) – 1, generates a counter overflow event, then counts from the auto-

reload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are not equal to '00'. The Output compare interrupt flag of channels configured in output is set when: the counter counts down (Center aligned mode 1, CMS = "01"), the counter counts up (Center aligned mode 2, CMS = "10") the counter counts up and down (Center aligned mode 3, CMS = "11").

In this mode, the DIR direction bit in the TIMx_CR1 register cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current auto-reload value.

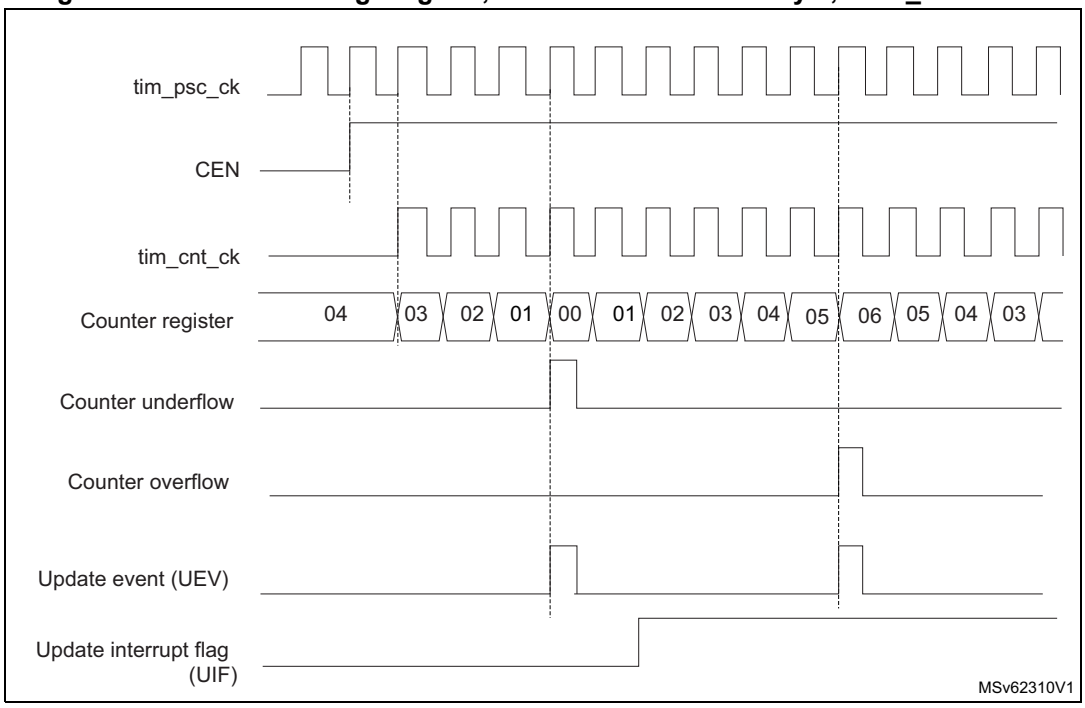
In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an UEV update event but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register)
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that if the update source is a counter overflow, the auto-reload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.

Figure 351. Counter timing diagram, internal clock divided by 1, TIMx_ARR = 0x6



1. Here, center-aligned mode 1 is used (for more details refer to *Section 38.6: TIM1/TIM8 registers*).

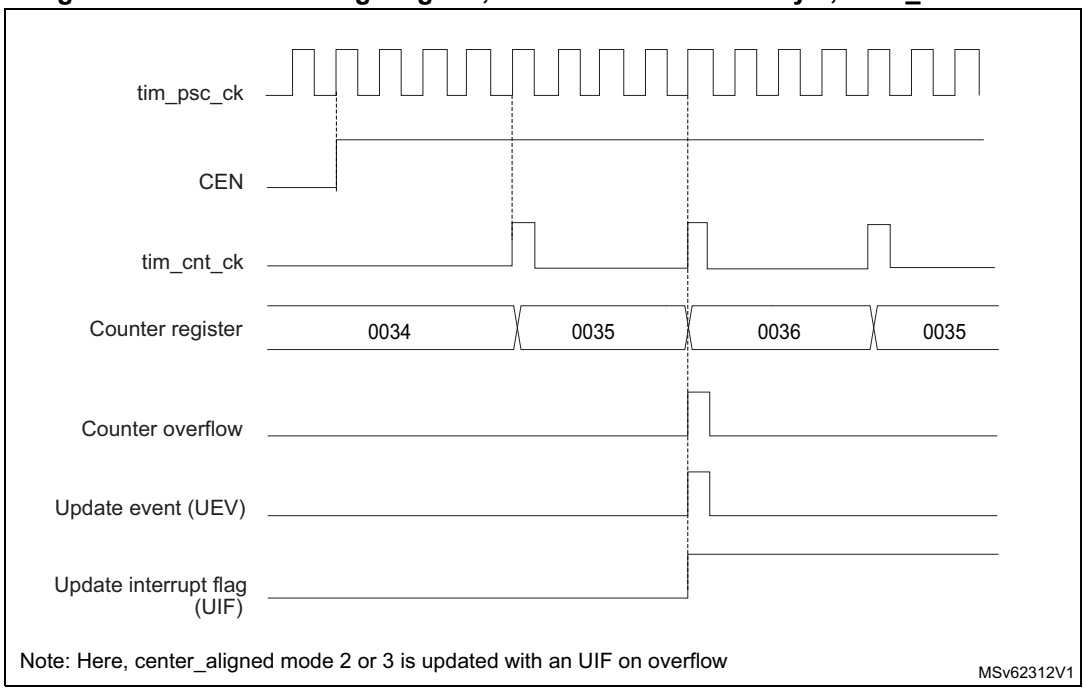

Figure 354. Counter timing diagram, internal clock divided by N

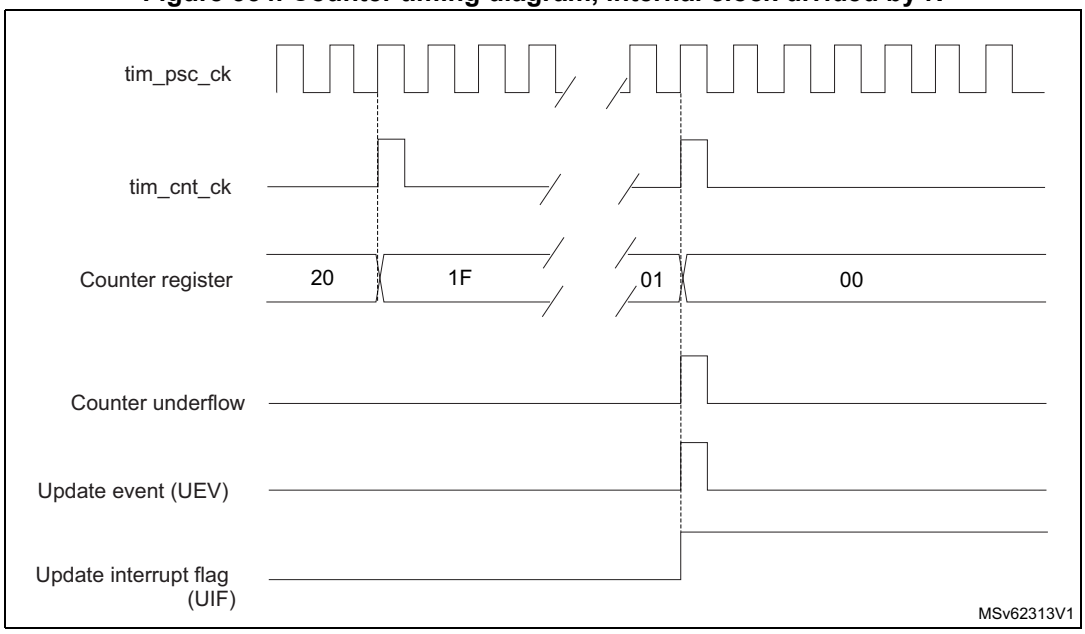

Figure 355. Counter timing diagram, update event with ARPE=1 (counter underflow)

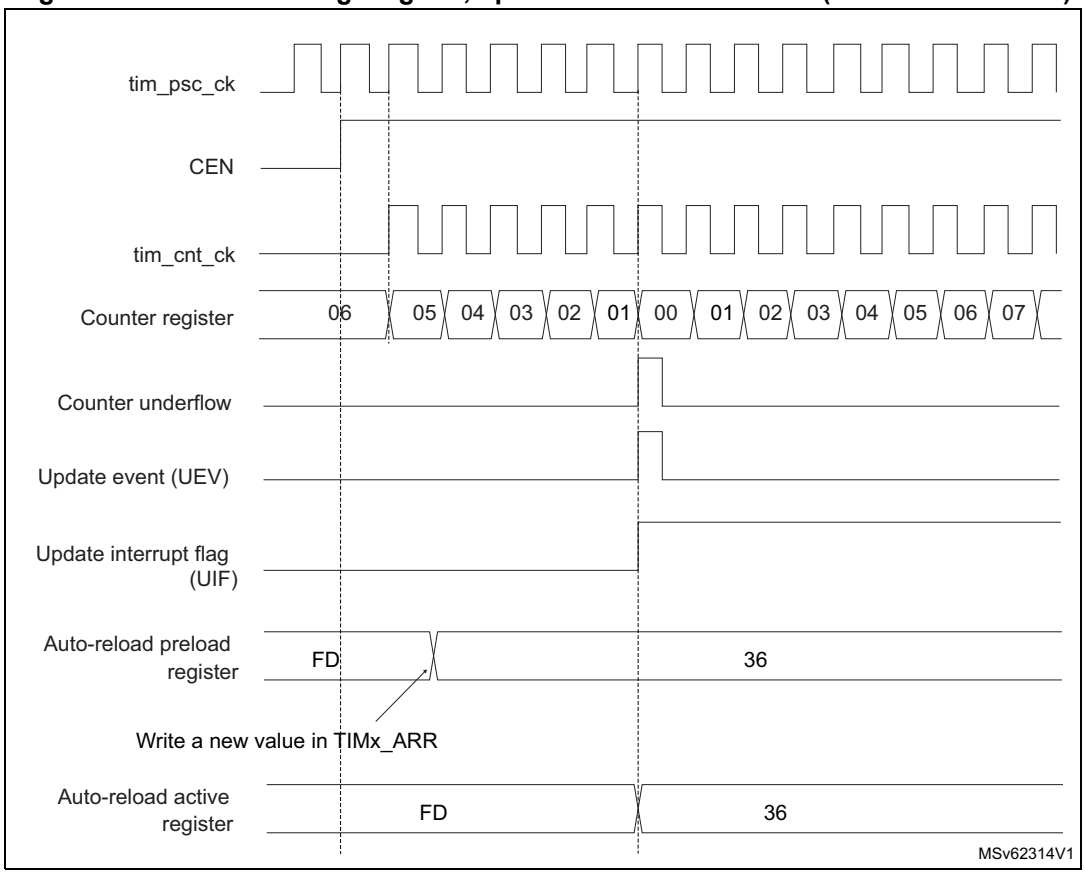

Figure 356. Counter timing diagram, Update event with ARPE=1 (counter overflow)

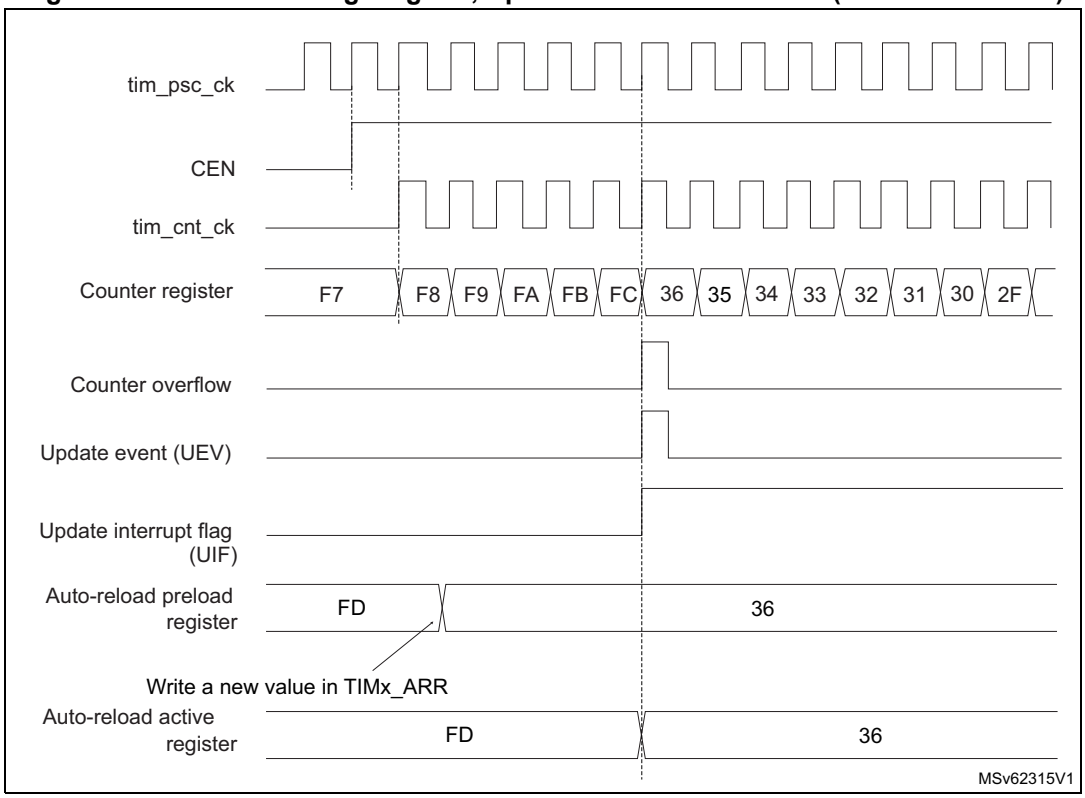


38.3.5 Repetition counter

Section 38.3.3: Time-base unit describes how the update event (UEV) is generated with respect to the counter overflows/underflows. It is actually generated only when the repetition counter has reached zero. This can be useful when generating PWM signals.

This means that data are transferred from the preload registers to the shadow registers (TIMx_ARR auto-reload register, TIMx_PSC prescaler register, but also TIMx_CCRx capture/compare registers in compare mode) every N+1 counter overflows or underflows, where N is the value in the TIMx_RCR repetition counter register.

The repetition counter is decremented:

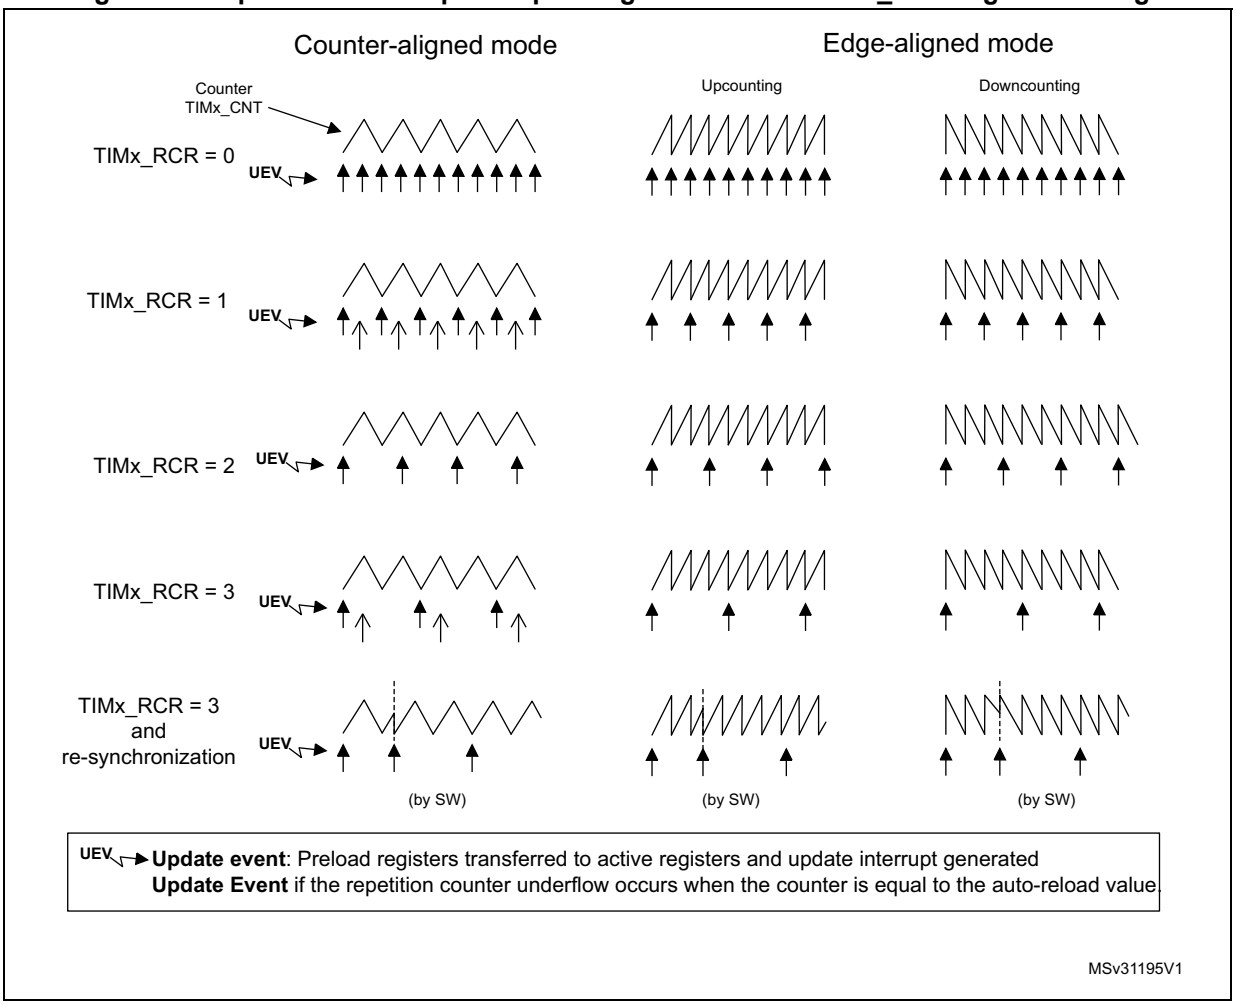
- At each counter overflow in upcounting mode,
- At each counter underflow in downcounting mode,
- At each counter overflow and at each counter underflow in center-aligned mode. Although this limits the maximum number of repetition to 32768 PWM cycles, it makes it possible to update the duty cycle twice per PWM period. When refreshing compare registers only once per PWM period in center-aligned mode, maximum resolution is $2xT_{ck}$, due to the symmetry of the pattern.

The repetition counter is an auto-reload type; the repetition rate is maintained as defined by the TIMx_RCR register value (refer to *Figure 357*). When the update event is generated by software (by setting the UG bit in TIMx_EGR register) or by hardware through the slave mode controller, it occurs immediately whatever the value of the repetition counter is and the repetition counter is reloaded with the content of the TIMx_RCR register.

In Center aligned mode, for odd values of RCR, the update event occurs either on the overflow or on the underflow depending on when the RCR register was written and when the counter was launched: if the RCR was written before launching the counter, the UEV occurs on the underflow. If the RCR was written after launching the counter, the UEV occurs on the overflow.

For example, for RCR = 3, the UEV is generated each 4th overflow or underflow event depending on when the RCR was written.

Figure 357. Update rate examples depending on mode and TIMx_RCR register settings



38.3.6 External trigger input

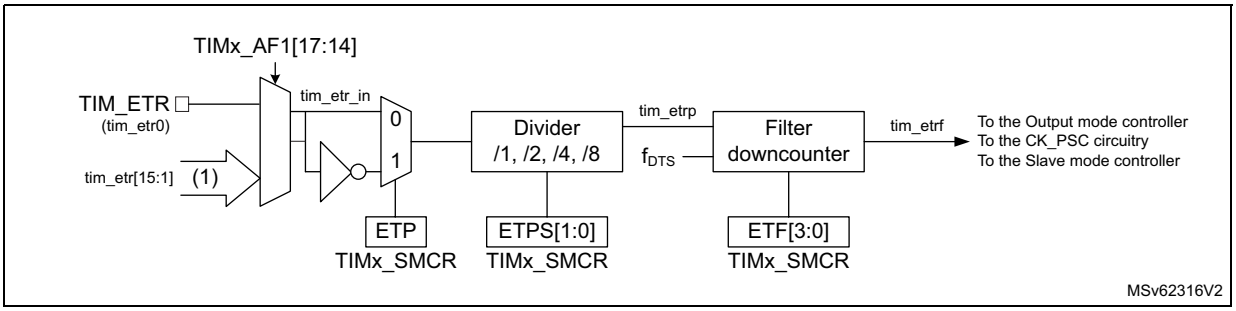
The timer features an external trigger input tim_etr_in. It can be used as:

- external clock (external clock mode 2, see *Section 38.3.7*)
- trigger for the slave mode (see *Section 38.3.30*)
- PWM reset input for cycle-by-cycle current regulation (see *Section 38.3.9*)

Figure 358 below describes the tim_etr_in input conditioning. The input polarity is defined with the ETP bit in TIMxSMCR register. The trigger can be prescaled with the divider programmed by the ETPS[1:0] bitfield and digitally filtered with the ETF[3:0] bitfield. The resulting signal (tim_etrf) is available for three purposes: as an external clock, to condition

the output (typically to reset a PWM output for a current limitation), and as a trigger for the Slave mode controller.

Figure 358. External trigger input block



The tim_etr_in input comes from multiple sources: input pins (default configuration), or internal sources. The selection is done with the ETRSEL[3:0] bitfield in the TIMx_AF1 register.

Refer to *Section 38.3.2: TIM1/TIM8 pins and internal signals* for the list of sources connected to the etr_in input in the product.

38.3.7 Clock selection

The counter clock can be provided by the following clock sources:

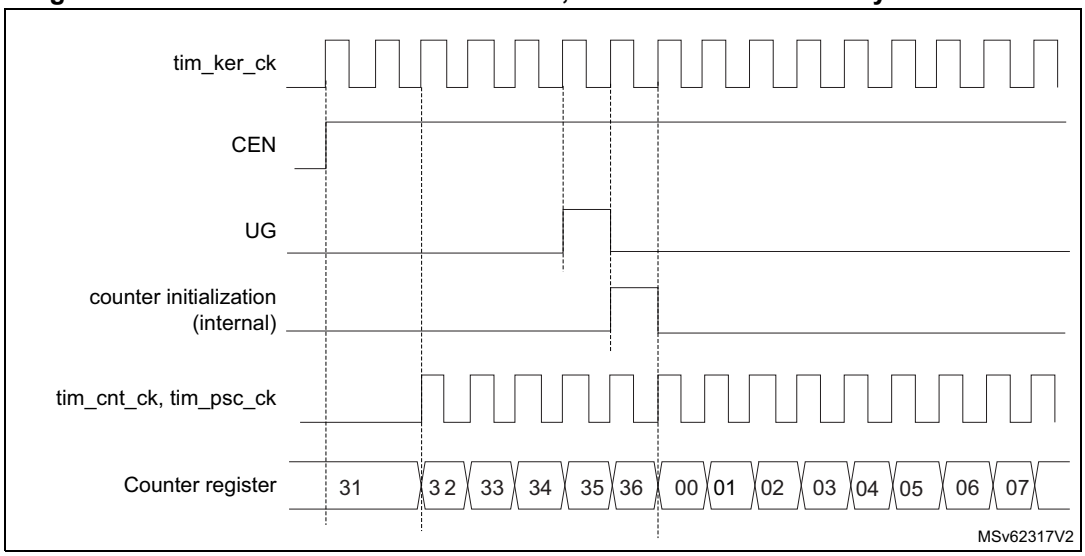
- Internal clock (tim_ker_ck)
- External clock mode1: external input pin (tim_ti1 or tim_ti2)
- External clock mode2: external trigger input (tim_etr_in)
- Encoder mode

Internal clock source (tim_ker_ck)

If the slave mode controller is disabled (SMS=000), then the CEN, DIR (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock tim_ker_ck.

Figure 359 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

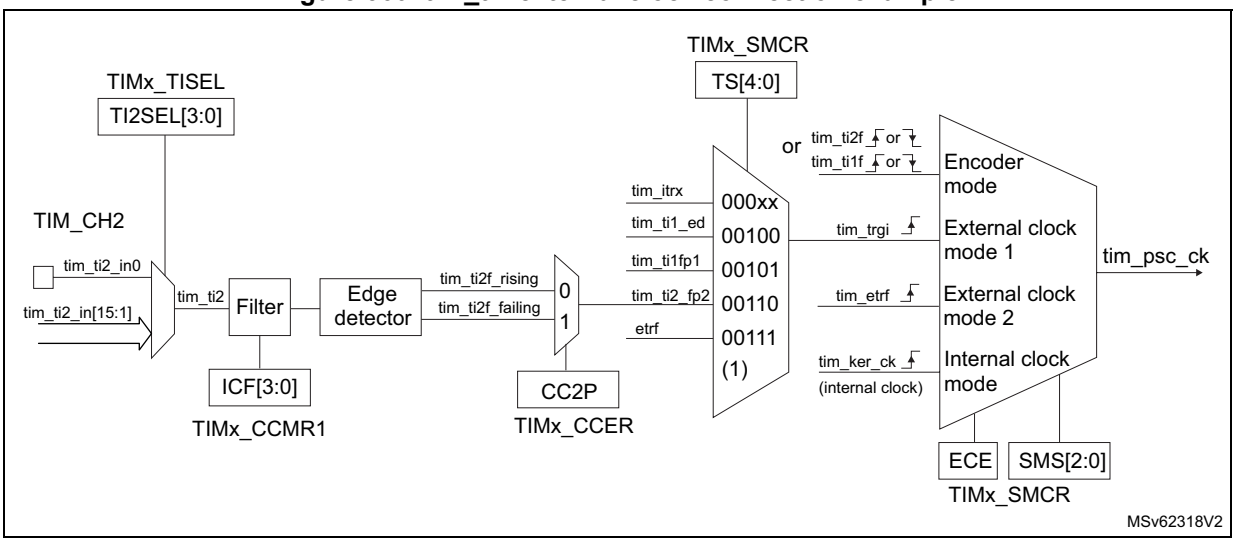
Figure 359. Control circuit in normal mode, internal clock divided by 1



External clock source mode 1

This mode is selected when SMS=111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

Figure 360. tim_ti2 external clock connection example



1. Codes ranging from 01000 to 11111 are reserved.

For example, to configure the upcounter to count in response to a rising edge on the tim_ti2 input, use the following procedure:

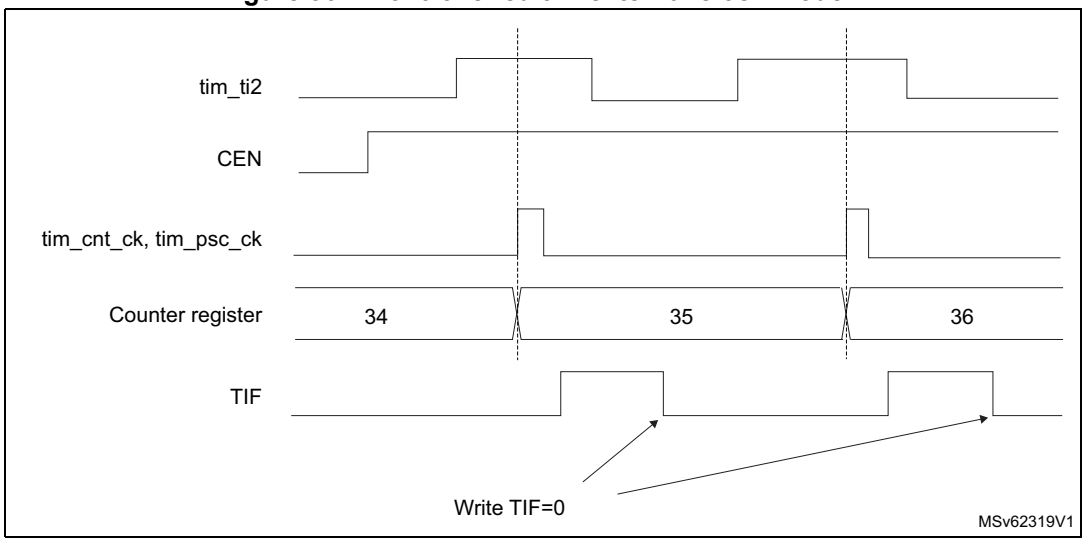
1. Configure channel 2 to detect rising edges on the tim_ti2 input by writing CC2S = ‘01’ in the TIMx_CCMR1 register.
2. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 register (if no filter is needed, keep IC2F=0000).
3. Select rising edge polarity by writing CC2P=0 and CC2NP=0 in the TIMx_CCER register.
4. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx_SMCR register.
5. Select tim_ti2 as the trigger input source by writing TS=00110 in the TIMx_SMCR register.
6. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

Note: The capture prescaler is not used for triggering, it is not necessary to configure it.

When a rising edge occurs on tim_ti2, the counter counts once and the TIF flag is set.

The delay between the rising edge on tim_ti2 and the actual clock of the counter is due to the resynchronization circuit on tim_ti2 input.

Figure 361. Control circuit in external clock mode 1



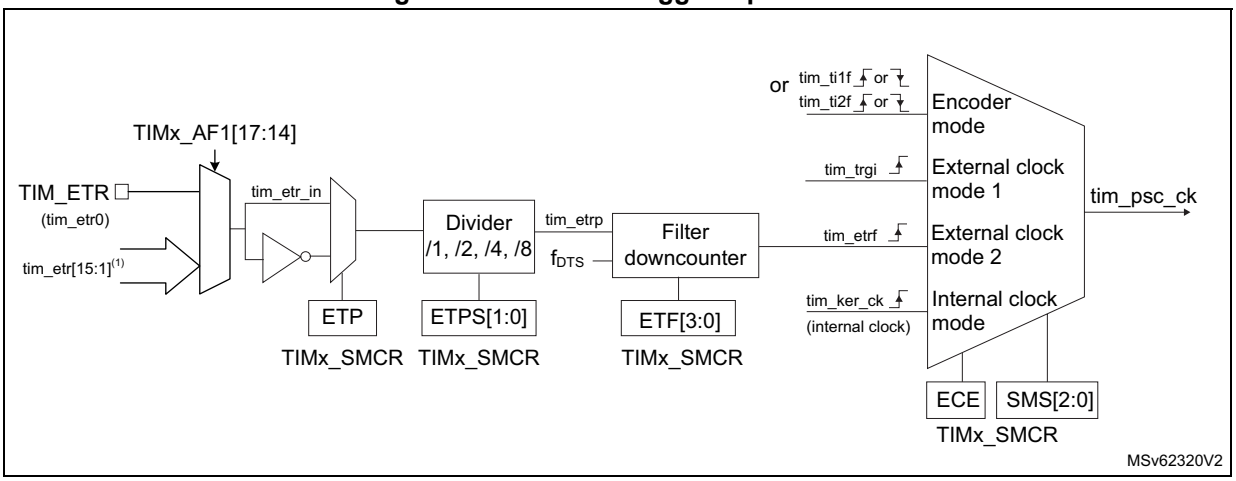
External clock source mode 2

This mode is selected by writing ECE=1 in the TIMx_SMCR register.

The counter counts at each rising or falling edge on the external trigger input tim_etr_in.

The *Figure 362* gives an overview of the external trigger input block.

Figure 362. External trigger input block



1. Refer to *Section 38.3.2: TIM1/TIM8 pins and internal signals*.

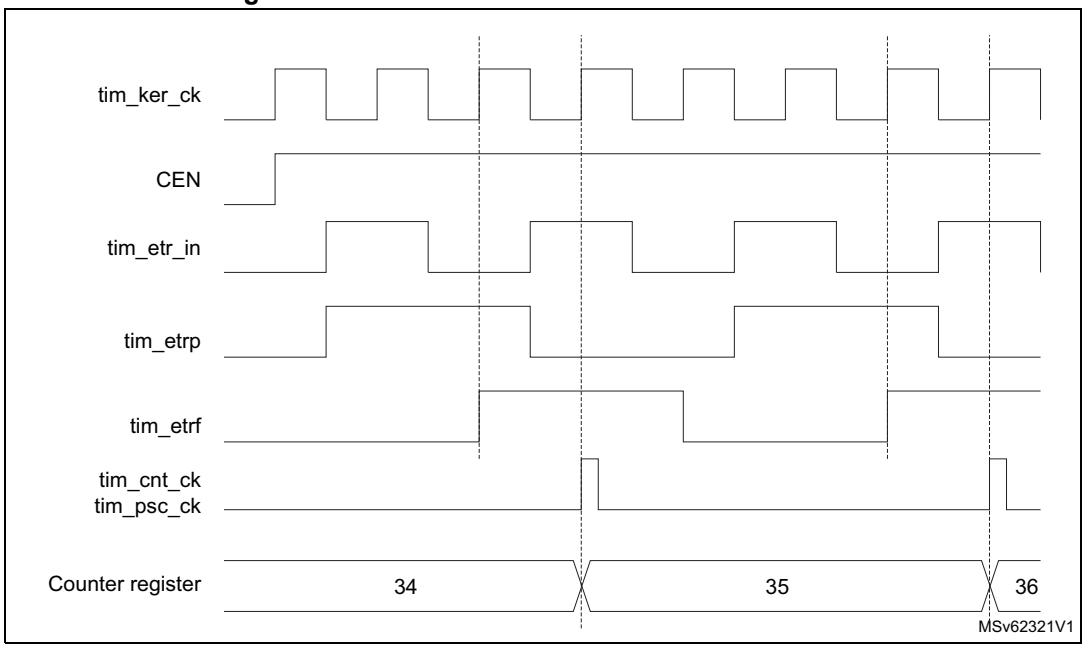
For example, to configure the upcounter to count each 2 rising edges on tim_etr_in, use the following procedure:

1. As no filter is needed in this example, write ETF[3:0]=0000 in the TIMx_SMCR register.
2. Set the prescaler by writing ETPS[1:0]=01 in the TIMx_SMCR register
3. Select rising edge detection on the tim_etr_in input by writing ETP=0 in the TIMx_SMCR register
4. Enable external clock mode 2 by writing ECE=1 in the TIMx_SMCR register.
5. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

The counter counts once each 2 tim_etr_in rising edges.

The delay between the rising edge on tim_etr_in and the actual clock of the counter is due to the resynchronization circuit on the tim_etrp signal. As a consequence, the maximum frequency which can be correctly captured by the counter is at most ¼ of tim_ker_ck frequency. When the ETRP signal is faster, the user must apply a division of the external signal by a proper ETPS prescaler setting.

Figure 363. Control circuit in external clock mode 2



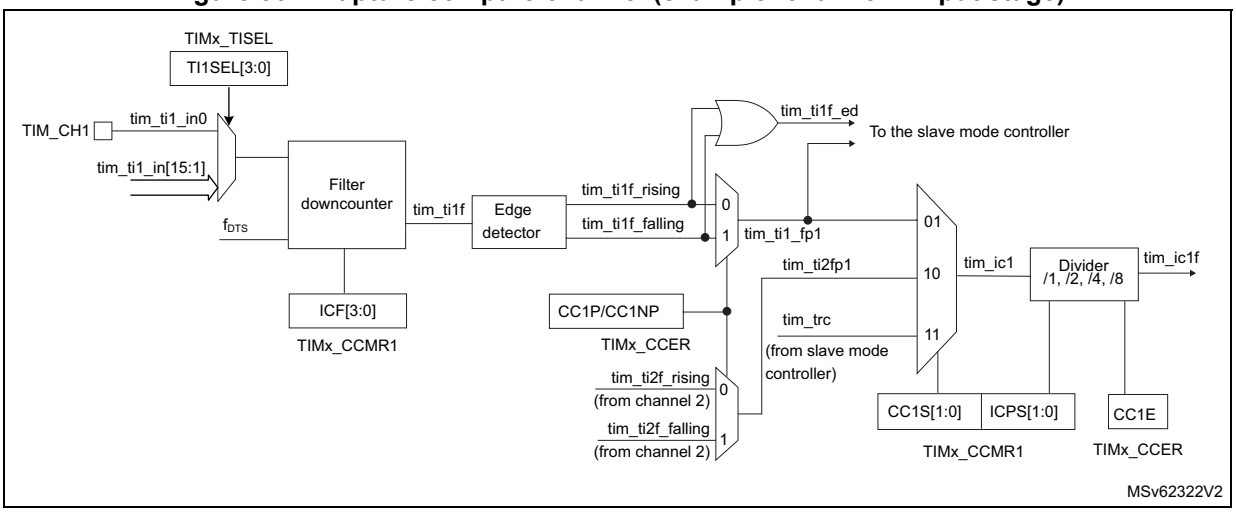
38.3.8 Capture/compare channels

Each capture/compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing, and prescaler, except for channels 5 and 6) and an output stage (with comparator and output control).

Figure 364 to *Figure 367* give an overview of one capture/compare channel.

The input stage samples the corresponding tim_tix input to generate a filtered signal tim_tixf. Then, an edge detector with polarity selection generates a signal (tim_tixfpy) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

Figure 364. Capture/compare channel (example: channel 1 input stage)



The output stage generates an intermediate waveform which is then used for reference: tim_ocxref (active high). The polarity acts at the end of the chain.

Figure 365. Capture/compare channel 1 main circuit

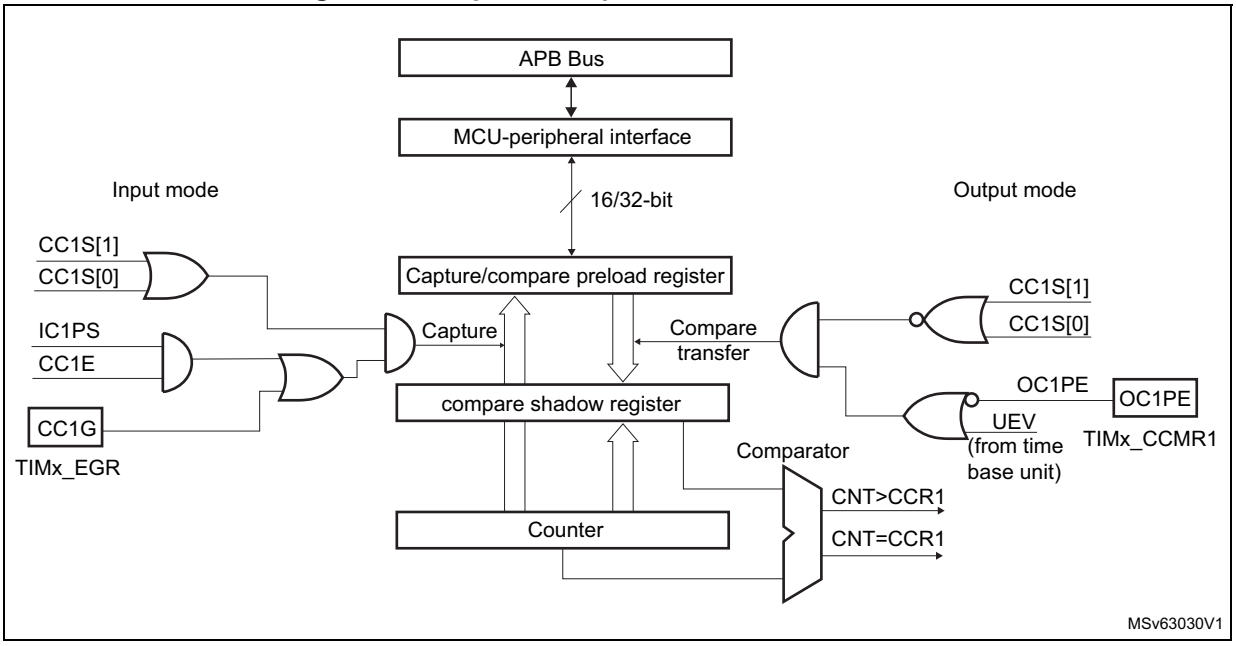


Figure 366. Output stage of capture/compare channel (channel 1, idem ch. 2, 3 and 4)

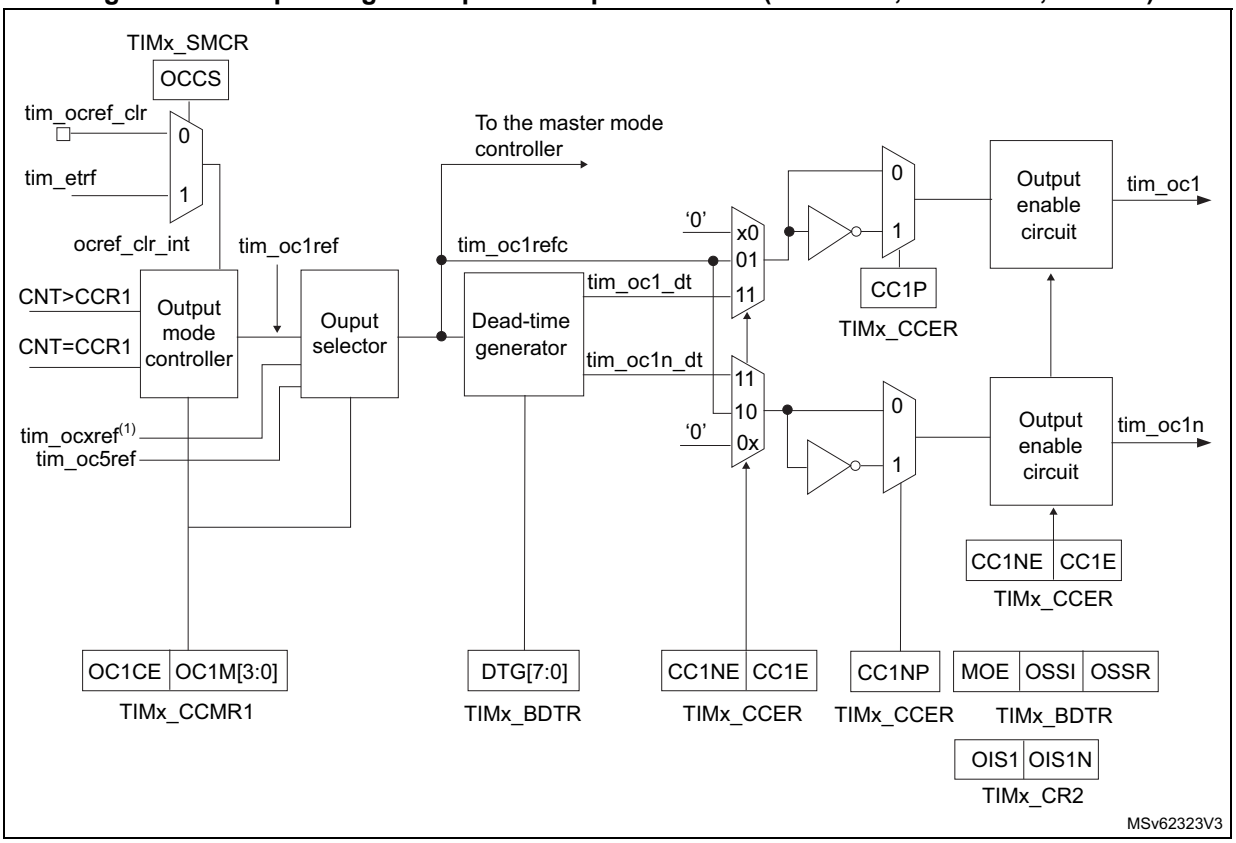
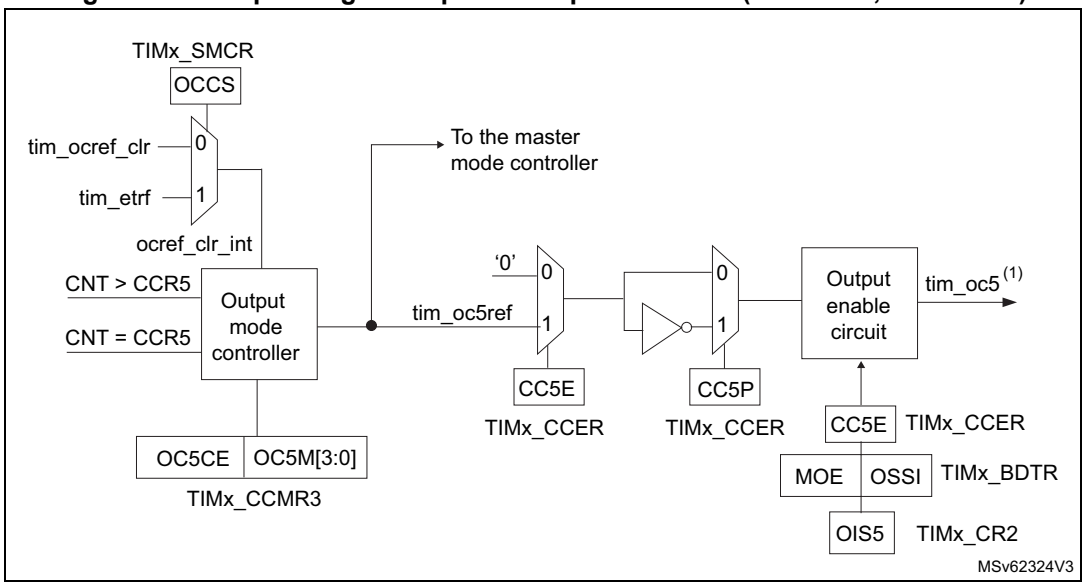


1. tim_ocxref, where x is the rank of the complementary channel

Figure 367. Output stage of capture/compare channel (channel 5, idem ch. 6)



1. Not available externally.

The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

38.3.9 Input capture mode

In Input capture mode, the capture/compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCXIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to '0' or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when tim_ti1 input rises. To do this, use the following procedure:

- Select the active input: TIMx_CCR1 must be linked to the tim_ti1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.
- Program the appropriate input filter duration in relation with the signal connected to the timer (when the input is one of the tim_tix (ICxF bits in the TIMx_CCMRx register). Let's imagine that, when toggling, the input signal is not stable during at must 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on tim_ti1 when 8 consecutive samples with the new level have been detected (sampled at f_{DTS} frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.
- Select the edge of the active transition on the tim_ti1 channel by writing CC1P and CC1NP bits to 0 in the TIMx_CCER register (rising edge in this case).
- Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to '00' in the TIMx_CCMR1 register).
- Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.
- If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:

- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which may happen after reading the flag and before reading the data.

Note: IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.

38.3.10 PWM input mode

This mode is used to measure both the period and the duty cycle of a PWM signal connected to single tim_tix input:

- The TIMx_CCR1 register holds the period value (interval between two consecutive rising edges)
- The TIM_CCR2 register holds the pulsewidth (interval between two consecutive rising and falling edges

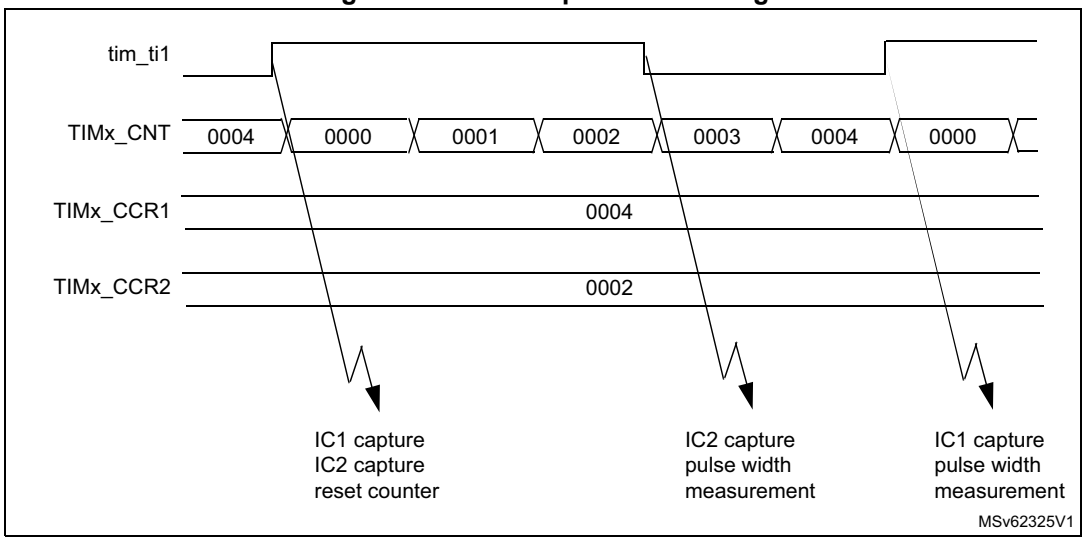
This mode is a particular case of input capture mode. The set-up procedure is similar with the following differences:

- Two ICx signals are mapped on the same tim_tixfp1 input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two tim_tixfp signals is selected as trigger input and the slave mode controller is configured in reset mode.

The period and the pulsewidth of a PWM signal applied on tim_ti1 can be measured using the following procedure:

- Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (tim_ti1 selected).
- Select the active polarity for tim_ti1fp1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P and CC1NP bits to ‘0’ (active on rising edge).
- Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (tim_ti1 selected).
- Select the active polarity for tim_ti1fp2 (used for capture in TIMx_CCR2): write the CC2P and CC2NP bits to CC2P/CC2NP=’10’ (active on falling edge).
- Select the valid trigger input: write the TS bits to 00101 in the TIMx_SMCR register (tim_ti1fp1 selected).
- Configure the slave mode controller in reset mode: write the SMS bits to 0100 in the TIMx_SMCR register.
- Enable the captures: write the CC1E and CC2E bits to ‘1’ in the TIMx_CCER register.

Figure 368. PWM input mode timing



38.3.11 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (tim_ocxref and then tim_ocx/tim_ocxn) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (tim_ocxref/tim_ocx) to its active level, user just needs to write 0101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus tim_ocxref is forced high (tim_ocxref is always active high) and tim_ocx get opposite value to CCxP polarity bit.

For example: CCxP=0 (tim_ocx active high) => tim_ocx is forced to high level.

The tim_ocxref signal can be forced low by writing the OCxM bits to 0100 in the TIMx_CCMRx register.

Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.

38.3.12 Output compare mode

This function is used to control an output waveform or indicate when a period of time has elapsed. Channels 1 to 4 can be output, while channel 5 and 6 are only available inside the microcontroller (for instance, for compound waveform generation or for ADC triggering).

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCER register). The output pin can keep its level (OCXM=0000), be set

active (OCxM=0001), be set inactive (OCxM=0010) or can toggle (OCxM=0011) on match.

- Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

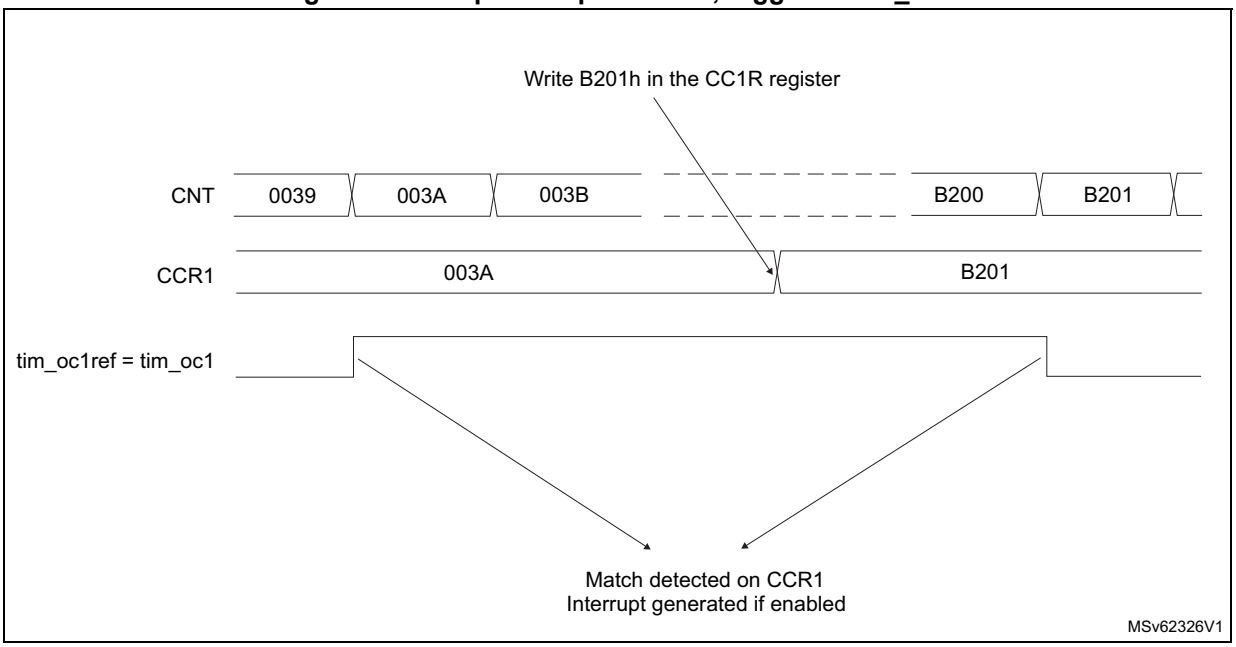
In output compare mode, the update event UEV has no effect on tim_ocxref and tim_ocx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
   - Write OCxM = 0011 to toggle tim_ocx output pin when CNT matches CCRx
   - Write OCxPE = 0 to disable preload register
   - Write CCxP = 0 to select active high polarity
   - Write CCxE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE='0', else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in *Figure 369*.

Figure 369. Output compare mode, toggle on tim_oc1



38.3.13 PWM mode

Pulse width modulation mode is used to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per tim_ocx output) by writing ‘0110’ (PWM mode 1) or ‘0111’ (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

tim_ocx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. tim_ocx output is enabled by a combination of the CCxE, CCxNE, MOE, OSSI and OSSR bits (TIMx_CCER and TIMx_BDTR registers). Refer to the TIMx_CCER register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx ≤ TIMx_CNT or TIMx_CNT ≤ TIMx_CCRx (depending on the direction of the counter).

The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx_CR1 register.

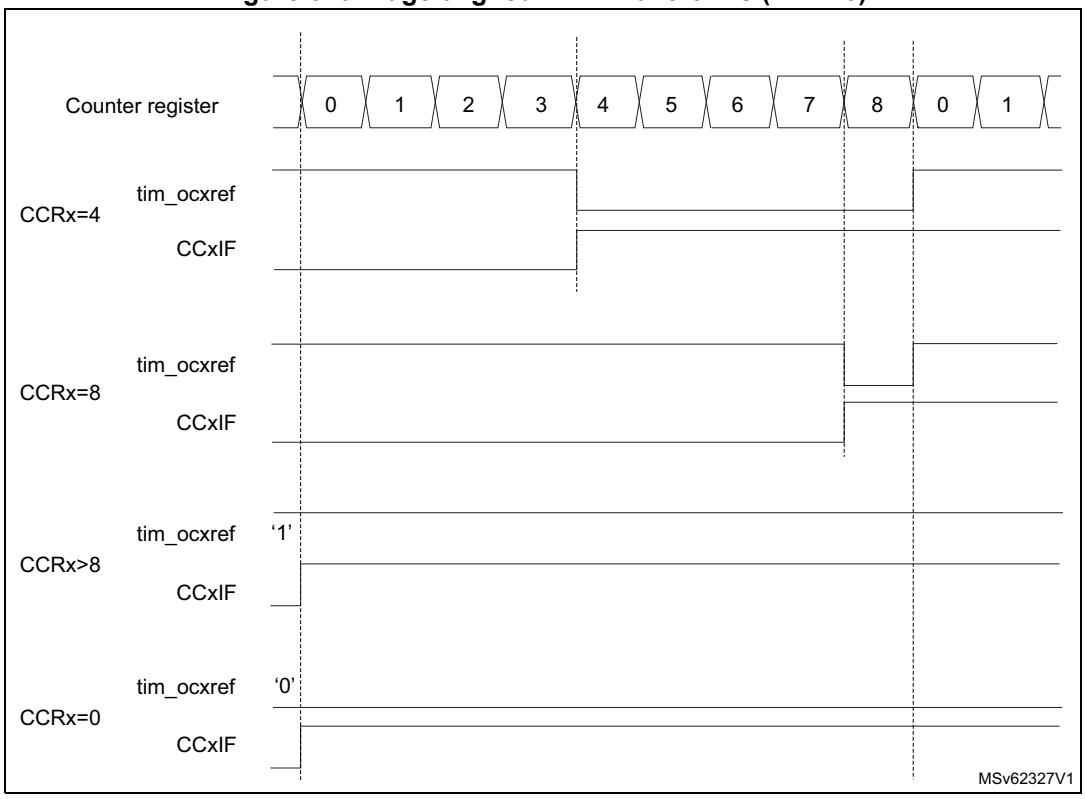
PWM edge-aligned mode

- Upcounting configuration

  Upcounting is active when the DIR bit in the TIMx_CR1 register is low. Refer to the *Upcounting mode on page 1435*.

  In the following example, we consider PWM mode 1. The reference PWM signal tim_ocxref is high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then tim_ocxref is held at ‘1’. If the compare value is 0 then tim_ocxref is held at ‘0’. *Figure 370* shows some edge-aligned PWM waveforms in an example where TIMx_ARR=8.

Figure 370. Edge-aligned PWM waveforms (ARR=8)



- Downcounting configuration

  Downcounting is active when DIR bit in TIMx_CR1 register is high. Refer to the *Downcounting mode on page 1439*

  In PWM mode 1, the reference signal tim_ocxref is low as long as TIMx_CNT > TIMx_CCRx else it becomes high. If the compare value in TIMx_CCRx is greater than the auto-reload value in TIMx_ARR, then tim_ocxref is held at ‘1’. 0% PWM is not possible in this mode.

PWM center-aligned mode

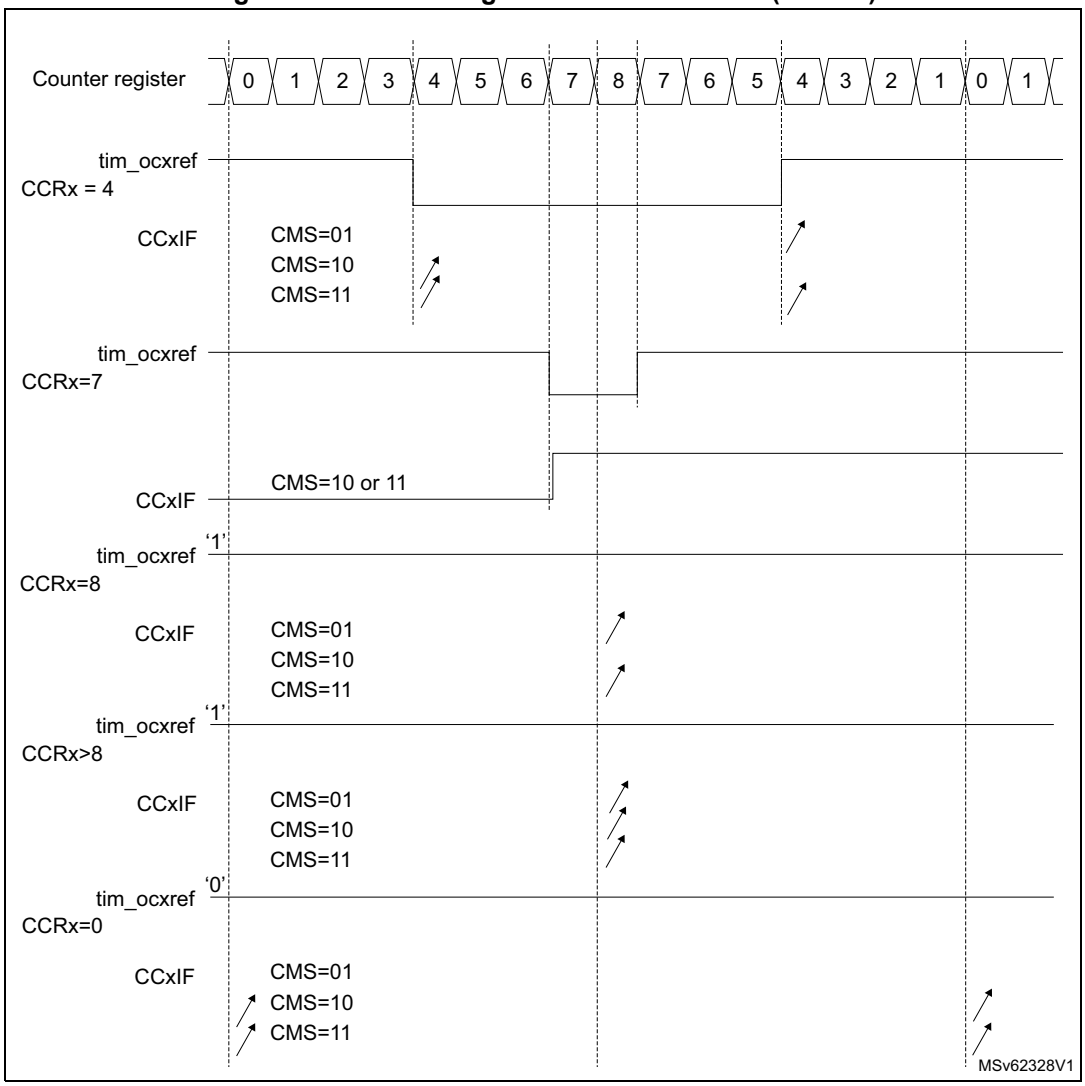
Center-aligned mode is active when the CMS bits in TIMx_CR1 register are different from ‘00’ (all the remaining configurations having the same effect on the tim_ocxref/tim_ocx signals). The compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit

(DIR) in the TIMx_CR1 register is updated by hardware and must not be changed by software. Refer to the *Center-aligned mode (up/down counting) on page 1442*.

Figure 371 shows some center-aligned PWM waveforms in an example where:

- TIMx_ARR=8,
- PWM mode is the PWM mode 1,
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS=01 in TIMx_CR1 register.

Figure 371. Center-aligned PWM waveforms (ARR=8)



Hints on using center-aligned mode:

- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit

in the TIMx_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.

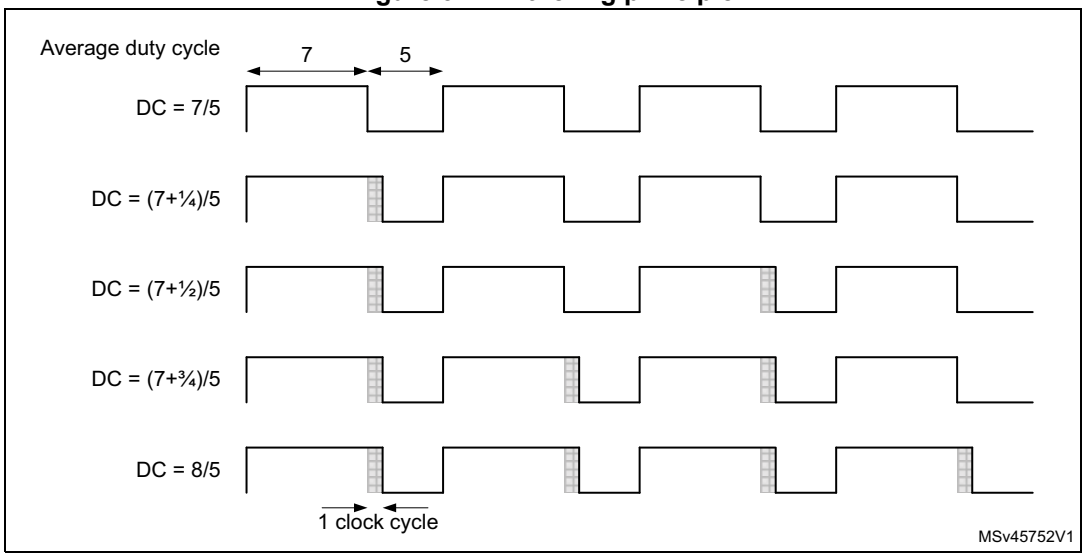
- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  - The direction is not updated if a value greater than the auto-reload value is written in the counter (TIMx_CNT > TIMx_ARR). For example, if the counter was counting up, it continues to count up.
  - The direction is updated if 0 or the TIMx_ARR value is written in the counter but no Update Event UEV is generated.
- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx_EGR register) just before starting the counter and not to write the counter while it is running.

Dithering mode

The PWM mode effective resolution can be increased by enabling the dithering mode, using the DITHEN bit in the TIMx_CR1 register. This applies to both the CCR (for duty cycle resolution increase) and ARR (for PWM frequency resolution increase).

The operating principle is to have the actual CCR (or ARR) value slightly changed (adding or not one timer clock period) over 16 consecutive PWM periods, with predefined patterns. This allows a 16-fold resolution increase, considering the average duty cycle or PWM period. The *Figure 372* below presents the dithering principle applied to 4 consecutive PWM cycles.

Figure 372. Dithering principle

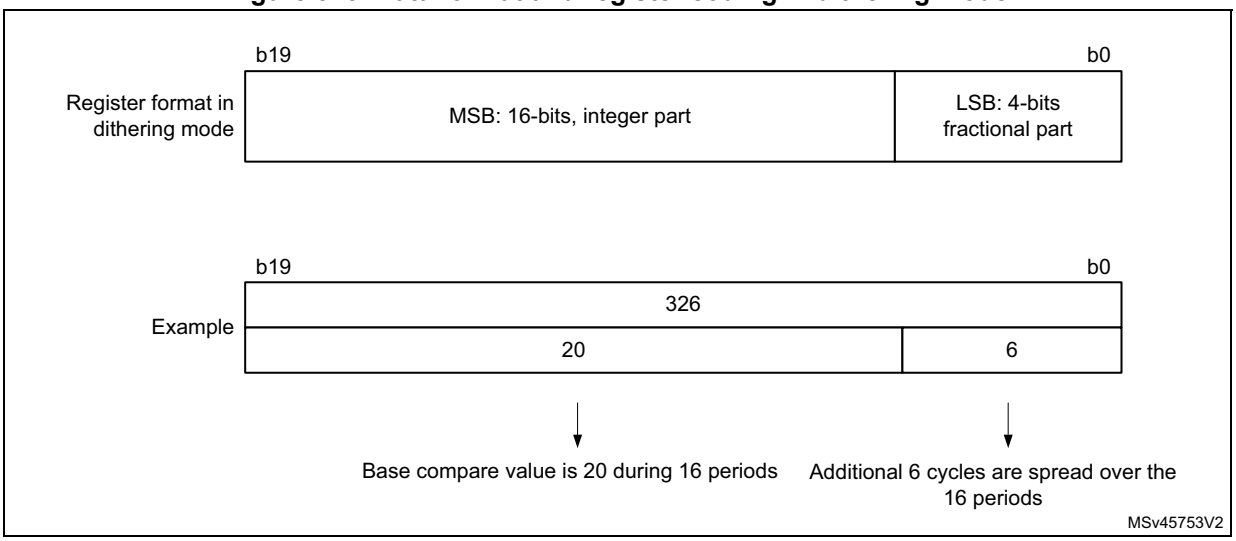


When the dithering mode is enabled, the register coding is changed as follows (see *Figure 373* for example):

- the 4 LSBs are coding for the enhanced resolution part (fractional part)
- The MSBs are left-shifted to the bits 19:4 and are coding for the base value

Note: The following sequence must be followed when resetting the DITHEN bit:
1. CEN and ARPE bits must be reset
2. The DITHEN bit must be reset
3. The CCIF flags must be cleared
4. The CEN bit can be set (eventually with ARPE = 1).

Figure 373. Data format and register coding in dithering mode



The minimum frequency is given by the following formula:

$$\text{Resolution} = \frac{F_{Tim}}{F_{pwm}} \Rightarrow F_{pwmMin} = \frac{F_{Tim}}{Max_{Resolution}}$$

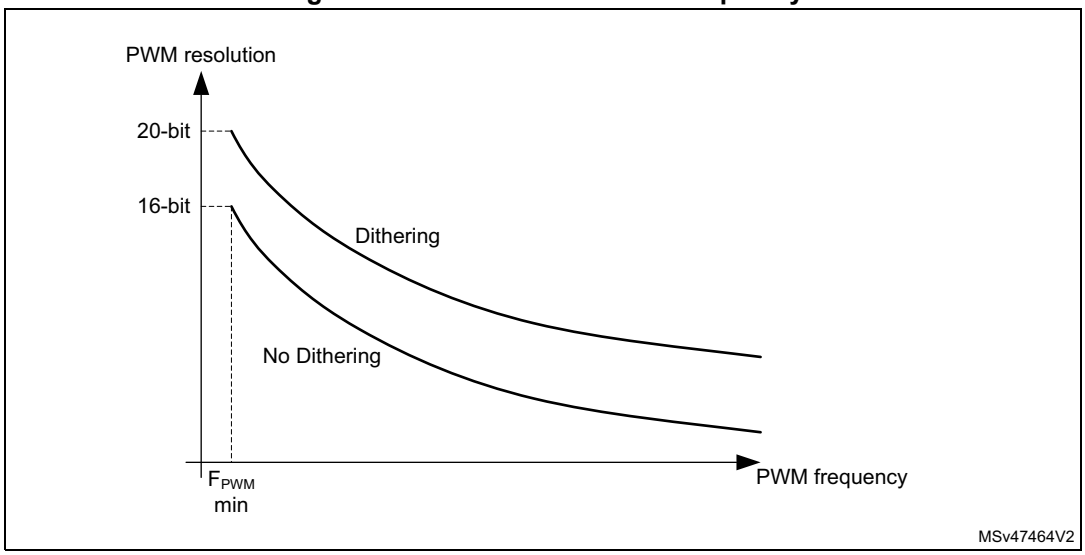
$$\text{Dithering mode disabled: } F_{pwmMin} = \frac{F_{Tim}}{65536}$$

$$\text{Dithering mode enabled: } F_{pwmMin} = \frac{F_{Tim}}{65535 + \frac{15}{16}}$$

Note: The maximum TIMx_ARR and TIMxCCRy values are limited to 0xFFFEF in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part).

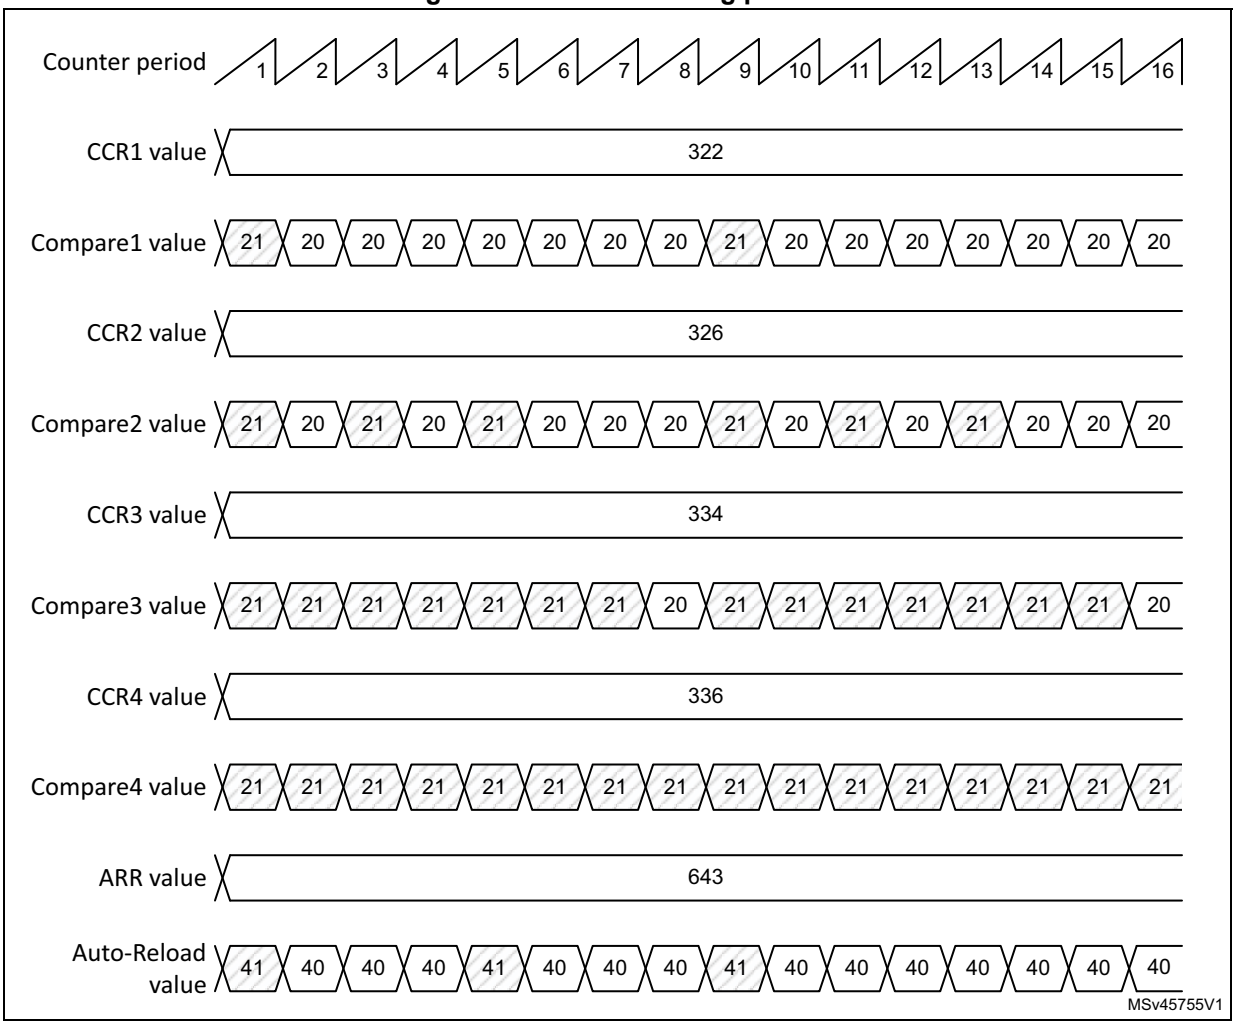
As shown on the *Figure 374* below, the dithering mode is used to increase the PWM resolution whatever the PWM frequency.

Figure 374. PWM resolution vs frequency



The duty cycle and / or period changes are spread over 16 consecutive periods, as described in the *Figure 375* below.

Figure 375. PWM dithering pattern



The auto-reload and compare values increments are spread following specific patterns described in the *Table 386* below. The dithering sequence is done to have increments distributed as evenly as possible and minimize the overall ripple.

Table 386. CCR and ARR register change dithering pattern

LSB value	PWM period															
	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
0000	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

1010	+1	+1	+1	-	+1	-	+1	-	+1	+1	+1	-	+1	-	+1	-
1011	+1	+1	+1	-	+1	+1	+1	-	+1	+1	+1	-	+1	-	+1	-
1100	+1	+1	+1	-	+1	+1	+1	-	+1	+1	+1	-	+1	+1	+1	-
1101	+1	+1	+1	+1	+1	+1	+1	-	+1	+1	+1	-	+1	+1	+1	-
1110	+1	+1	+1	+1	+1	+1	+1	-	+1	+1	+1	+1	+1	+1	+1	-
1111	+1	+1	+1	+1	+1	+1	+1	+1	+1	+1	+1	+1	+1	+1	+1	-

The dithering mode is also available in center-aligned PWM mode (CMS bits in TIMx_CR1 register are not equal to '00'). In this case, the dithering pattern is applied over 8 consecutive PWM periods, considering the up and down counting phases as shown in the *Figure 376* below.

Figure 376. Dithering effect on duty cycle in center-aligned PWM mode

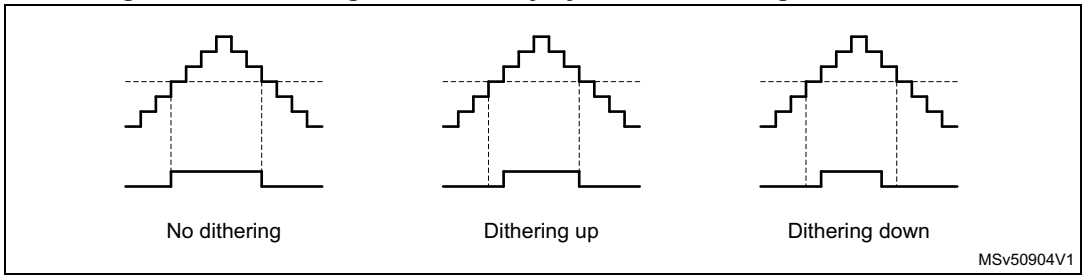

Table 387 below shows how the dithering pattern is added in center-aligned PWM mode.

Table 387. CCR register change dithering pattern in center-aligned PWM mode

LSB value	PWM period

38.3.14 Asymmetric PWM mode

Asymmetric mode allows two center-aligned PWM signals to be generated with a programmable phase shift. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and the phase-shift are determined by a pair of TIMx_CCRx register. One register controls the PWM during up-counting, the second during down counting, so that PWM is adjusted every half PWM cycle:

- tim_oc1refc (or tim_oc2refc) is controlled by TIMx_CCR1 and TIMx_CCR2
- tim_oc3refc (or tim_oc4refc) is controlled by TIMx_CCR3 and TIMx_CCR4

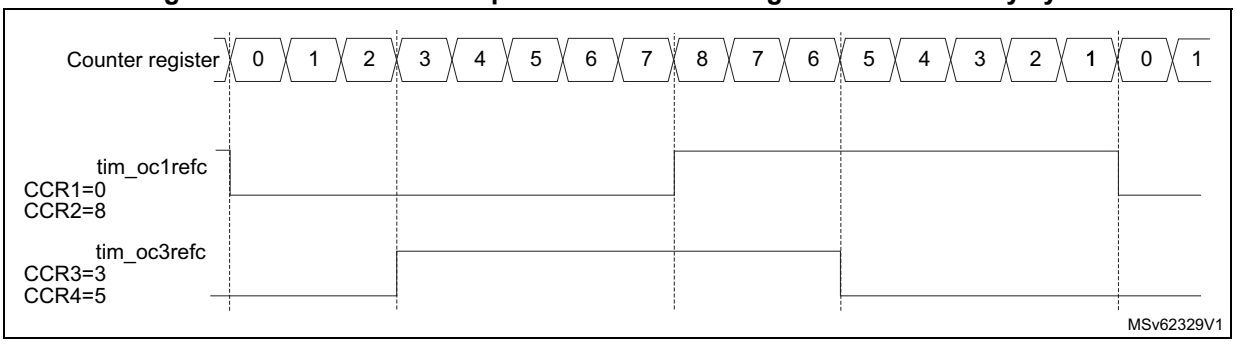
Asymmetric PWM mode can be selected independently on two channel (one tim_ocx output per pair of CCR registers) by writing ‘1110’ (Asymmetric PWM mode 1) or ‘1111’ (Asymmetric PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

Note: The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

When a given channel is used as asymmetric PWM channel, its complementary channel can also be used. For instance, if an tim_oc1refc signal is generated on channel 1 (Asymmetric PWM mode 1), it is possible to output either the tim_oc2ref signal on channel 2, or an tim_oc2refc signal resulting from asymmetric PWM mode 1.

Figure 377 represents an example of signals that can be generated using Asymmetric PWM mode (channels 1 to 4 are configured in Asymmetric PWM mode 2). Together with the deadtime generator, this allows a full-bridge phase-shifted DC to DC converter to be controlled.

Figure 377. Generation of 2 phase-shifted PWM signals with 50% duty cycle



38.3.15 Combined PWM mode

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, tim_ocxrefc, are made of an OR or AND logical combination of two reference PWMs:

- tim_oc1refc (or tim_oc2refc) is controlled by TIMx_CCR1 and TIMx_CCR2
- tim_oc3refc (or tim_oc4refc) is controlled by TIMx_CCR3 and TIMx_CCR4

Combined PWM mode can be selected independently on two channels (one tim_ocx output per pair of CCR registers) by writing ‘1100’ (Combined PWM mode 1) or ‘1101’ (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

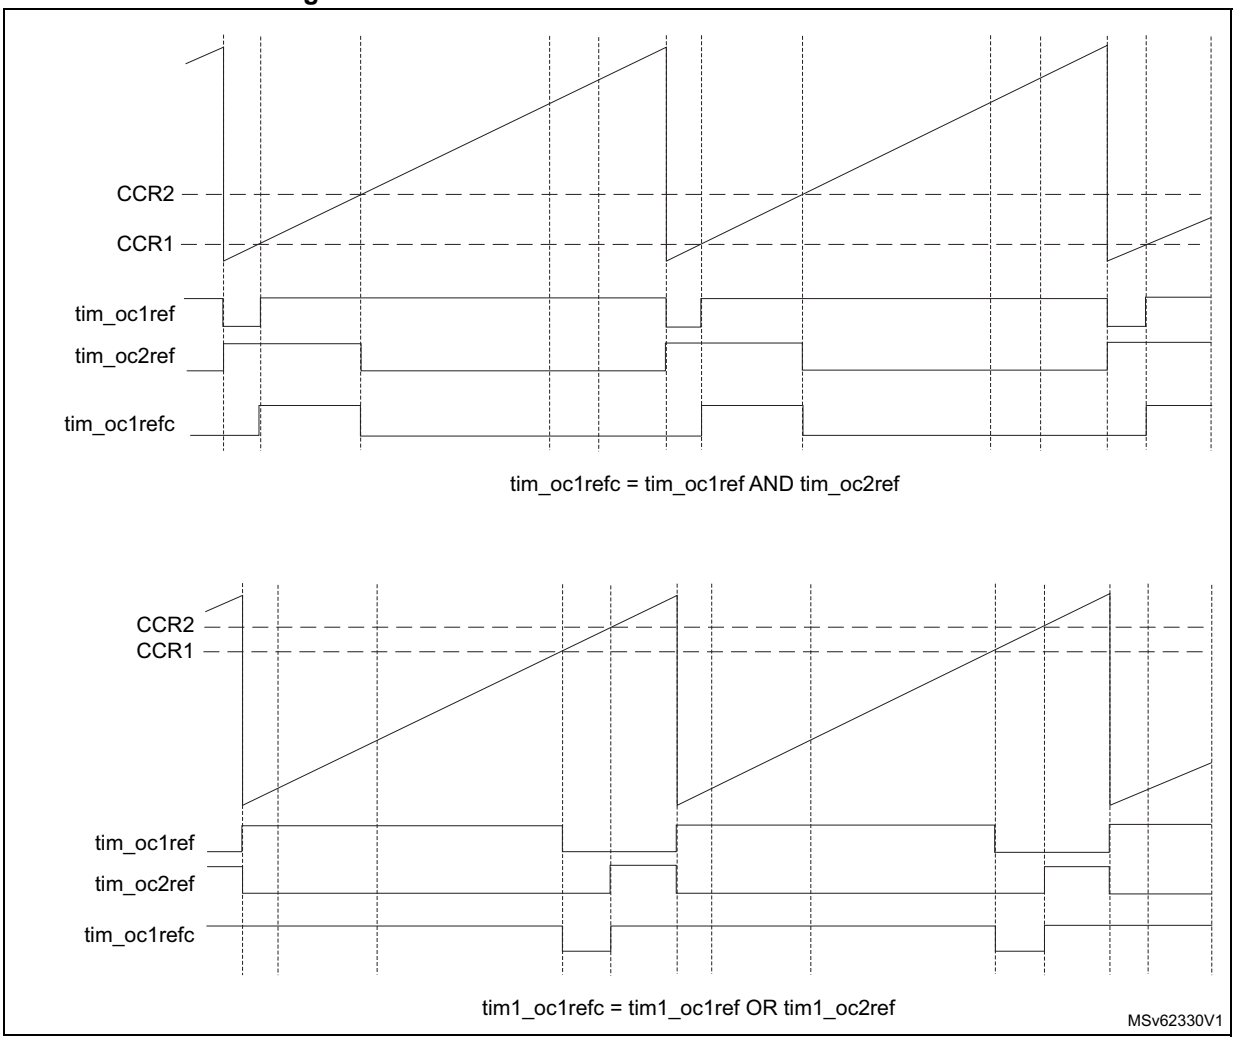
When a given channel is used as combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

Note: The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

Figure 378 represents an example of signals that can be generated using combined PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,
- Channel 3 is configured in Combined PWM mode 2,
- Channel 4 is configured in PWM mode 1.

Figure 378. Combined PWM mode on channel 1 and 3



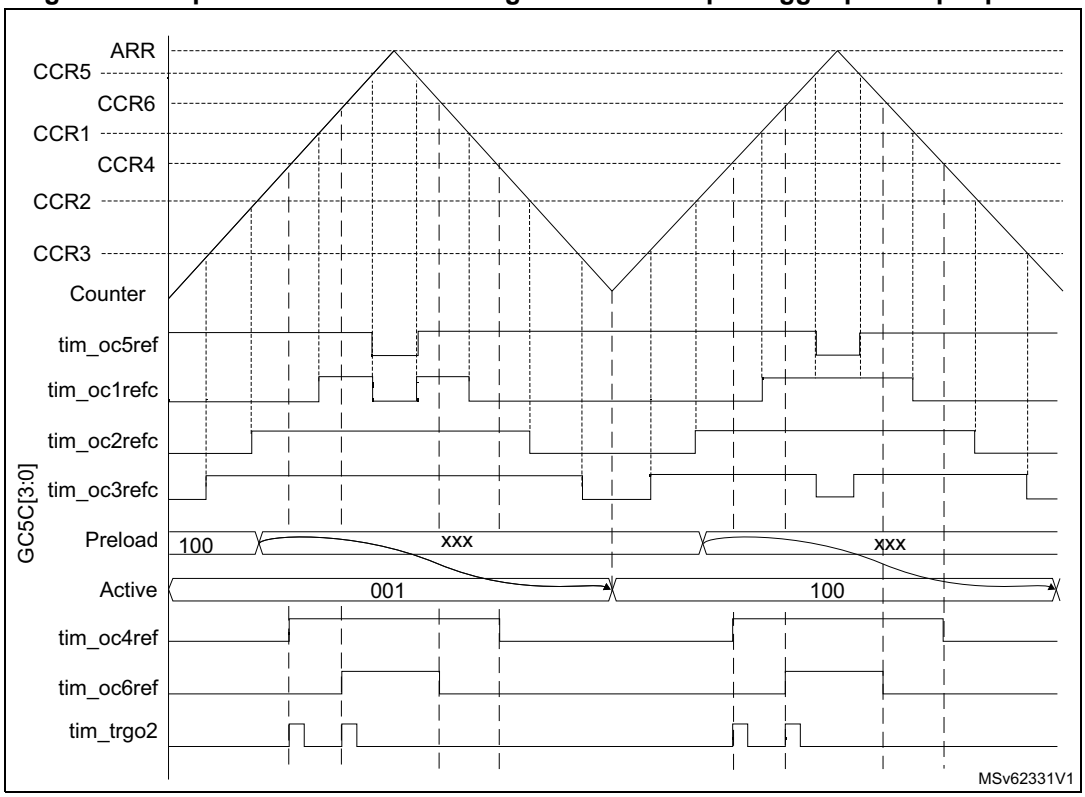
38.3.16 Combined 3-phase PWM mode

Combined 3-phase PWM mode allows one to three center-aligned PWM signals to be generated with a single programmable signal ANDed in the middle of the pulses. The tim_oc5ref signal is used to define the resulting combined signal. The 3-bits GC5C[3:1] in the TIMx_CCR5 allow selection on which reference signal the tim_oc5ref is combined. The resulting signals, tim_ocxrefc, are made of an AND logical combination of two reference PWMs:

- If GC5C1 is set, tim_oc1refc is controlled by TIMx_CCR1 and TIMx_CCR5
- If GC5C2 is set, tim_oc2refc is controlled by TIMx_CCR2 and TIMx_CCR5
- If GC5C3 is set, tim_oc3refc is controlled by TIMx_CCR3 and TIMx_CCR5

Combined 3-phase PWM mode can be selected independently on channels 1 to 3 by setting at least one of the 3-bits GC5C[3:1].

Figure 379. 3-phase combined PWM signals with multiple trigger pulses per period



The tim_trgo2 waveform shows how the ADC can be synchronized on given 3-phase PWM signals. Refer to *Section 38.3.31: ADC triggers* for more details.

38.3.17 Complementary outputs and dead-time insertion

The advanced-control timers (TIM1/TIM8) can output two complementary signals and manage the switching-off and the switching-on instants of the outputs.

This time is generally known as dead-time and it has to be adjusted depending on the devices that are connected to the outputs and their characteristics (intrinsic delays of level-shifters, delays due to power switches...).

The polarity of the outputs (main output tim_ocx or complementary tim_ocxn) can be selected independently for each output. This is done by writing to the CCxP and CCxNP bits in the TIMx_CCER register.

The complementary signals tim_ocx and tim_ocxn are activated by a combination of several control bits: the CCxE and CCxNE bits in the TIMx_CCER register and the MOE, OISx, OISxN, OSSI and OSSR bits in the TIMx_BDTR and TIMx_CR2 registers. Refer to *Table 395: Output control bits for complementary tim_ocx and tim_ocxn channels with break feature on page 1544* for more details. In particular, the dead-time is activated when switching to the idle state (MOE falling down to 0).

Dead-time insertion is enabled by setting both CCxE and CCxNE bits, and the MOE bit if the break circuit is present. There is one 10-bit dead-time generator for each channel. From a

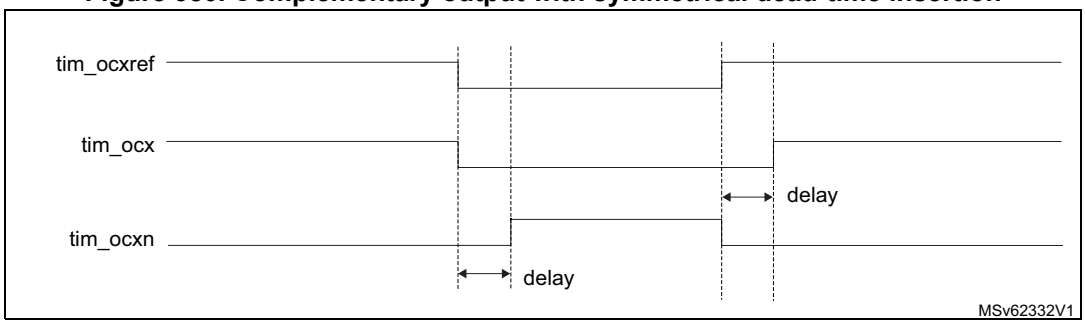
reference waveform tim_ocxref, it generates 2 outputs tim_ocx and tim_ocxn. If tim_ocx and tim_ocxn are active high:

- The tim_ocx output signal is the same as the reference signal except for the rising edge, which is delayed relative to the reference rising edge.
- The tim_ocxn output signal is the opposite of the reference signal except for the rising edge, which is delayed relative to the reference falling edge.

If the delay is greater than the width of the active output (tim_ocx or tim_ocxn) then the corresponding pulse is not generated.

The following figures show the relationships between the output signals of the dead-time generator and the reference signal tim_ocxref. (we suppose CCxP=0, CCxNP=0, MOE=1, CCxE=1 and CCxNE=1 in these examples)

Figure 380. Complementary output with symmetrical dead-time insertion



The DTAE bit in the TIMx_DTR2 is used to differentiate the deadtime values for rising and falling edges of the reference signal, as shown on *Figure 381*.

In asymmetrical mode (DTAE = 1), the rising edge-referred deadtime is defined by the DTG[7:0] bitfield in the TIMx_BDTR register, while the falling edge-referred is defined by the DTGF[7:0] bitfield in the TIMx_DTR2 register. The DTAE bit must be written before enabling the counter and must not be modified while CEN=1.

It is possible to have the deadtime value updated on-the-fly during pwm operation, using a preload mechanism. The deadtime bitfield DTG[7:0] and DTGF[7:0] are preloaded when the DTPE bit is set, in the TIMX_DTR2 register. The preload value is loaded in the active register on the next update event.

Note: If the DTPE bit is enabled while the counter is enabled, any new value written since last update is discarded and previous value is used.

Figure 381. Asymmetrical deadtime

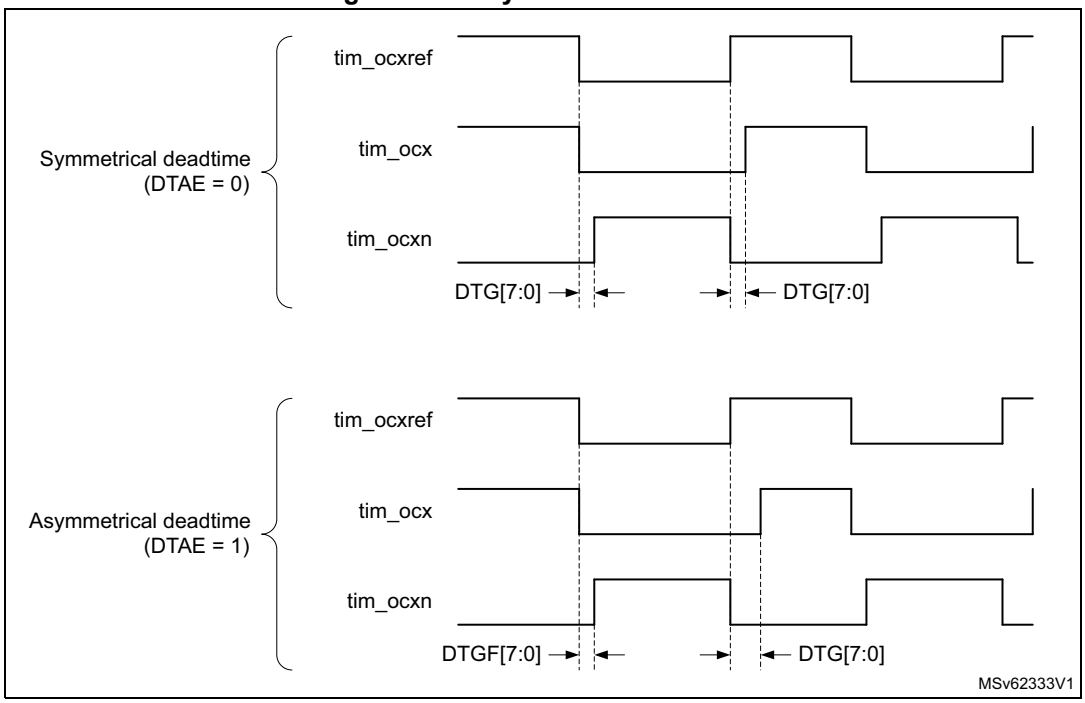


Figure 382. Dead-time waveforms with delay greater than the negative pulse

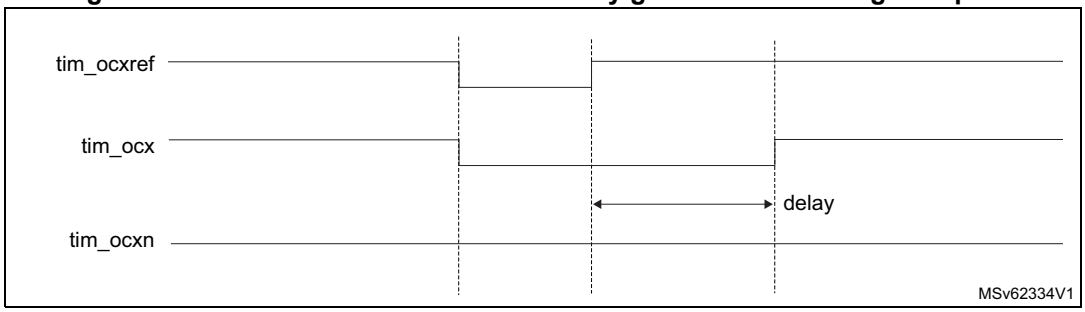

Figure 383. Dead-time waveforms with delay greater than the positive pulse

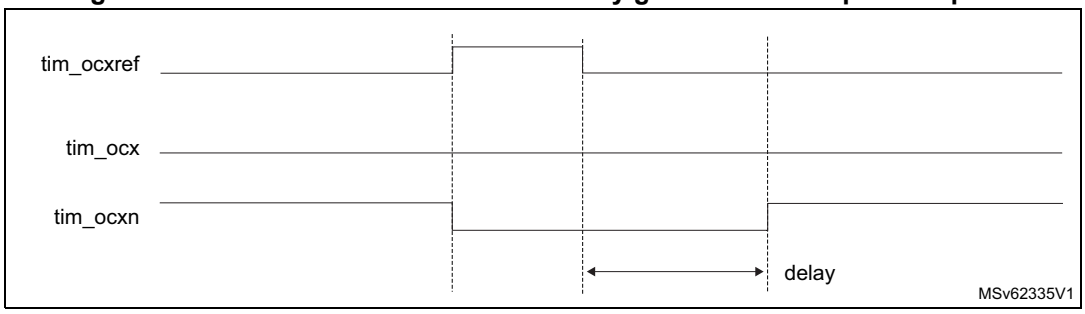


The dead-time delay is the same for each of the channels and is programmable with the DTG bits in the TIMx_BDTR register. Refer to *Section 38.6.20: TIMx break and dead-time register (TIMx_BDTR)(x = 1, 8)* for delay calculation.

Re-directing tim_ocxref to tim_ocx or tim_ocxn

In output mode (forced, output compare or PWM), tim_ocxref can be re-directed to the tim_ocx output or to tim_ocxn output by configuring the CCxE and CCxNE bits in the TIMx_CCER register.

This is used to send a specific waveform (such as PWM or static active level) on one output while the complementary remains at its inactive level. Other alternative possibilities are to have both outputs at inactive level or both outputs active and complementary with dead-time.

Note: When only tim_ocxn is enabled (CCxE=0, CCxNE=1), it is not complemented and becomes active as soon as tim_ocxref is high. For example, if CCxNP=0 then tim_ocxn=tim_ocxref. On the other hand, when both tim_ocx and tim_ocxn are enabled (CCxE=CCxNE=1) tim_ocx becomes active when tim_ocxref is high whereas tim_ocxn is complemented and becomes active when tim_ocxref is low.

38.3.18 Using the break function

The purpose of the break function is to protect power switches driven by PWM signals generated with the timers. The two break inputs are usually connected to fault outputs of power stages and 3-phase inverters. When activated, the break circuitry shuts down the PWM outputs and forces them to a predefined safe state. A number of internal MCU events can also be selected to trigger an output shut-down.

The break features two channels. A break channel which gathers both system-level fault (clock failure, ECC / parity errors,...) and application fault (from input pins and built-in comparator), and can force the outputs to a predefined level (either active or inactive) after a deadtime duration. A break2 channel which only includes application faults and is able to force the outputs to an inactive state.

The output enable signal and output levels during break are depending on several control bits:

- the MOE bit in TIMx_BDTR register is used to enable /disable the outputs by software and is reset in case of break or break2 event.
- the OSSI bit in the TIMx_BDTR register defines whether the timer controls the output in inactive state or releases the control to the GPIO controller (typically to have it in Hi-Z mode)
- the OISx and OISxN bits in the TIMx_CR2 register which are setting the output shut-down level, either active or inactive. The tim_ocx and tim_ocxn outputs cannot be set both to active level at a given time, whatever the OISx and OISxN values. Refer to *Table 395: Output control bits for complementary tim_ocx and tim_ocxn channels with break feature on page 1544* for more details.

When exiting from reset, the break circuit is disabled and the MOE bit is low. The break functions can be enabled by setting the BKE and BK2E bits in the TIMx_BDTR register. The break input polarities can be selected by configuring the BKP and BK2P bits in the same register. BKEx and BKPx can be modified at the same time. When the BKEx and BKPx bits are written, a delay of 1 APB clock cycle is applied before the writing is effective. Consequently, it is necessary to wait 1 APB clock period to correctly read back the bit after the write operation.

Because MOE falling edge can be asynchronous, a resynchronization circuit has been inserted between the actual signal (acting on the outputs) and the synchronous control bit (accessed in the TIMx_BDTR register). It results in some delays between the asynchronous

and the synchronous signals. In particular, if MOE is set to 1 whereas it was low, a delay must be inserted (dummy instruction) before reading it correctly. This is because the write acts on the asynchronous signal whereas the read reflects the synchronous signal.

The sources for break (tim_brk) channel are:

- External sources connected to one of the TIMx_BKIN pin (as per selection done in the GPIO alternate function selection registers), with polarity selection and optional digital filtering
- Internal sources:
  - coming from a tim_brk_cmpx input (refer to *Section 38.3.2: TIM1/TIM8 pins and internal signals* for product specific implementation)
  - coming from a system break request (refer to *Section 38.3.2: TIM1/TIM8 pins and internal signals* for product specific implementation)

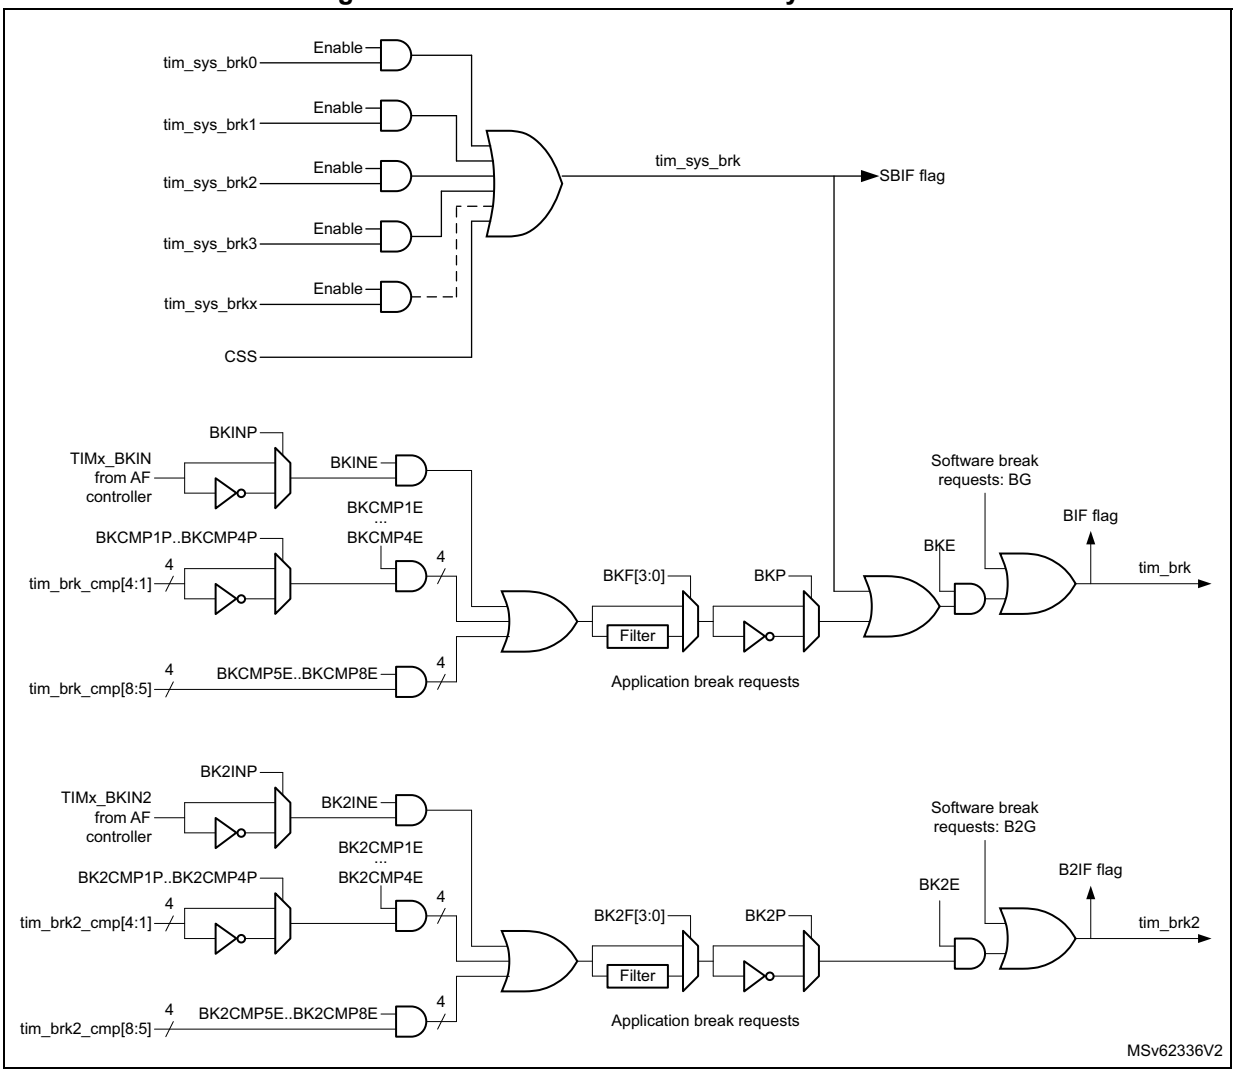
The sources for break2 (tim_brk2) are:

- External sources connected to one of the TIMx_BKIN2 pin (as per selection done in the GPIO alternate function selection registers), with polarity selection and optional digital filtering
- Internal sources coming from a tim_brk2_cmpx input (refer to *Section 38.3.2: TIM1/TIM8 pins and internal signals* for product specific implementation)

Break events can also be generated by software using BG and B2G bits in the TIMx_EGR register.

All sources are ORed before entering the timer tim_brk or tim_brk2 inputs, as per *Figure 384* below.

Figure 384. Break and Break2 circuitry overview



Note: An asynchronous (clockless) operation is only guaranteed when the programmable filter is disabled. If it is enabled, a fail safe clock mode (for example by using the internal PLL and/or the CSS) must be used to guarantee that break events are handled.

When one of the breaks occurs (selected level on one of the break inputs):

- The MOE bit is cleared asynchronously, putting the outputs in inactive state, idle state or even releasing the control to the GPIO controller (selected by the OSSI bit). This feature is enabled even if the MCU oscillator is off.
- Each output channel is driven with the level programmed in the OISx bit in the TIMx_CR2 register as soon as MOE=0. If OSSI=0, the timer releases the output control (taken over by the GPIO controller), otherwise the enable output remains high.
- When complementary outputs are used:
  - The outputs are first put in inactive state (depending on the polarity). This is done asynchronously so that it works even if no clock is provided to the timer.
  - If the timer clock is still present, then the dead-time generator is reactivated in order to drive the outputs with the level programmed in the OISx and OISxN bits after a dead-time. Even in this case, tim_ocx and tim_ocxn cannot be driven to

their active level together. Note that because of the resynchronization on MOE, the dead-time duration is slightly longer than usual (around 2 tim_ker_ck clock cycles).

  - If OSSI=0, the timer releases the output control (taken over by the GPIO controller which forces a Hi-Z state), otherwise the enable outputs remain or become high as soon as one of the CCxE or CCxNE bits is high.

- The break status flag (SBIF, BIF and B2IF bits in the TIMx_SR register) is set. An interrupt is generated if the BIE bit in the TIMx_DIER register is set. A DMA request can be sent if the BDE bit in the TIMx_DIER register is set.
- If the AOE bit in the TIMx_BDTR register is set, the MOE bit is automatically set again at the next update event (UEV). As an example, this can be used to perform a regulation. Otherwise, MOE remains low until the application sets it to '1' again. In this case, it can be used for security and the break input can be connected to an alarm from power drivers, thermal sensors or any security components.

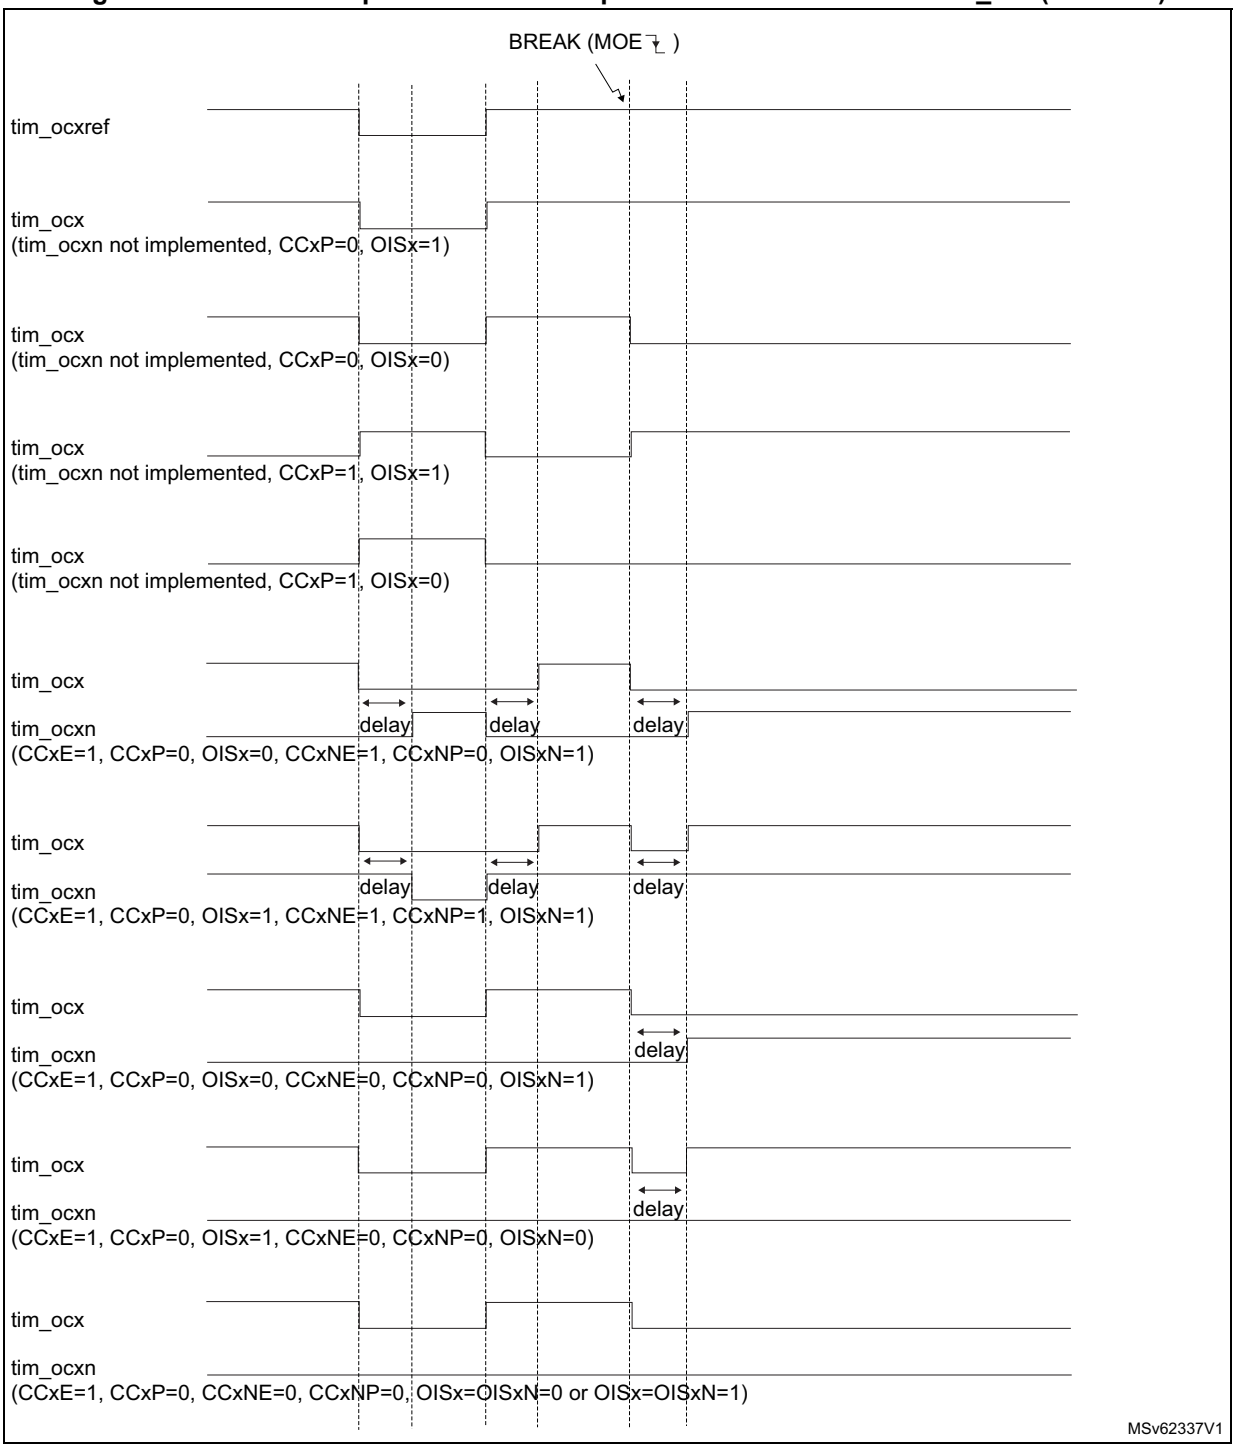
Note: If the MOE is reset by the CPU while the AOE bit is set, the outputs are in idle state and forced to inactive level or Hi-Z depending on OSSI value. If both the MOE and AOE bits are reset by the CPU, the outputs are in disabled state and driven with the level programmed in the OISx bit in the TIMx_CR2 register.

Note: The break inputs are active on level. Thus, the MOE cannot be set while the break input is active (neither automatically nor by software). In the meantime, the status flag BIF and B2IF cannot be cleared.

In addition to the break input and the output management, a write protection has been implemented inside the break circuit to safeguard the application. It is used to freeze the configuration of several parameters (dead-time duration, tim_ocx/tim_ocxn polarities and state when disabled, OCxM configurations, break enable and polarity). The application can choose from 3 levels of protection selected by the LOCK bits in the TIMx_BDTR register. Refer to *Section 38.6.20: TIMx break and dead-time register (TIMx_BDTR)(x = 1, 8)*. The LOCK bits can be written only once after an MCU reset.

Figure 385 shows an example of behavior of the outputs in response to a break.

Figure 385. Various output behavior in response to a break event on tim_brk (OSSI = 1)



The two break inputs have different behaviors on timer outputs:

- The tim_brk input can either disable (inactive state) or force the PWM outputs to a predefined safe state.
- tim_brk2 can only disable (inactive state) the PWM outputs.

The tim_brk has a higher priority than tim_brk2 input, as described in *Table 388*.

Note: tim_brk2 must only be used with OSSR = OSSI = 1.

Table 388. Behavior of timer outputs versus tim_brk/tim_brk2 inputs

tim_brk	tim_brk2	Timer outputs state	Typical use case	
			tim_ocxn output (low side switches)	tim_ocx output (high side switches)
Active	X	– Inactive then forced output state (after a deadtime) – Outputs disabled if OSSI = 0 (control taken over by GPIO logic)	ON after deadtime insertion	OFF
Inactive	Active	Inactive	OFF	OFF

Figure 386 gives an example of tim_ocx and tim_ocxn output behavior in case of active signals on tim_brk and tim_brk2 inputs. In this case, both outputs have active high polarities (CCxP = CCxNP = 0 in TIMx_CCER register).

Figure 386. PWM output state following tim_brk and tim_brk2 assertion (OSSI=1)

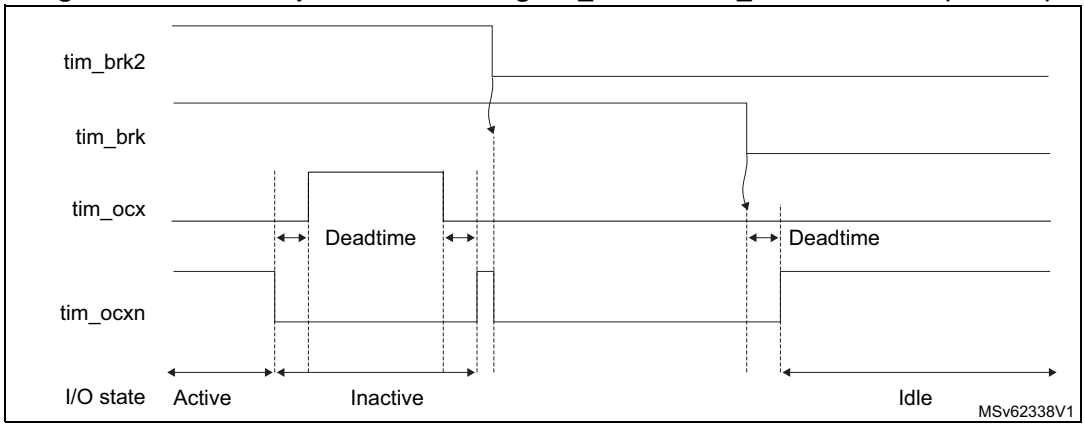


Figure 387. PWM output state following tim_brk assertion (OSSI=0)

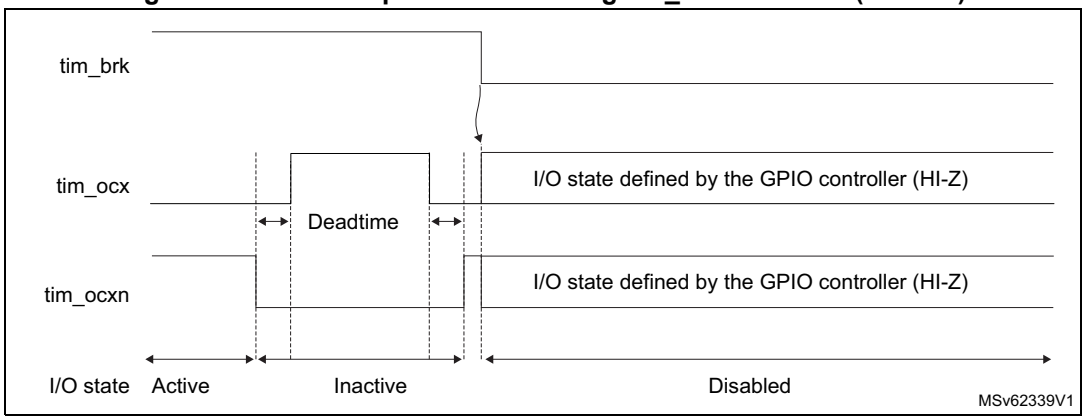


38.3.19 Bidirectional break inputs

The TIM1/TIM8 are featuring bidirectional break I/Os, as represented on *Figure 388*.

This provides support for:

- A board-level global break signal available for signaling faults to external MCUs or gate drivers, with a unique pin being both an input and an output status pin
- Internal break sources and multiple external open drain sources ORed together to trigger a unique break event, when multiple internal and external break sources must be merged

The tim_brk and tim_brk2 inputs are configured in bidirectional mode using the BKBID and BK2BID bits in the TIMxBDTR register. The BKBID programming bits can be locked in read-only mode using the LOCK bits in the TIMxBDTR register (in LOCK level 1 or above).

The bidirectional mode is available for both the tim_brk and tim_brk2 inputs, and require the I/O to be configured in open-drain mode with active low polarity (using BKINP, BKP, BK2INP and BK2P bits). Any break request coming either from system (for example CSS), from on-chip peripherals or from break inputs forces a low level on the break input to signal the fault event. The bidirectional mode is inhibited if the polarity bits are not correctly set (active high polarity), for safety purposes.

The break software events (BG and B2G) also cause the break I/O to be forced to '0' to indicate to the external components that the timer is entered in break state. However, this is valid only if the break is enabled (BKE or B2KE = 1). When a software break event is generated with BKE or B2KE = 0), the outputs are put in safe state and the break flag is set, but there is no effect on the TIMx_BKIN and TIMx_BKIN2 I/Os.

A safe disarming mechanism prevents the system to be definitively locked-up (a low level on the break input triggers a break which enforces a low level on the same input).

When the BKDSRM (BK2DSRM) bit is set to 1, this releases the break output to clear a fault signal and to give the possibility to re-arm the system.

At no point the break protection circuitry can be disabled:

- The break input path is always active: a break event is active even if the BKDSRM (BK2DSRM) bit is set and the open drain control is released. This prevents the PWM output to be re-started as long as the break condition is present.
- The BKDSRM (BK2DSRM) bit cannot disarm the break protection as long as the outputs are enabled (MOE bit is set) (see *Table 389*).

Table 389. Break protection disarming conditions

MOE	BKBID (BK2BID)	BKDSRM (BK2DSRM)	Break protection state
0	0	X	Armed
0	1	0	Armed
0	1	1	Disarmed
1	X	X	Armed

Arming and re-arming break circuitry

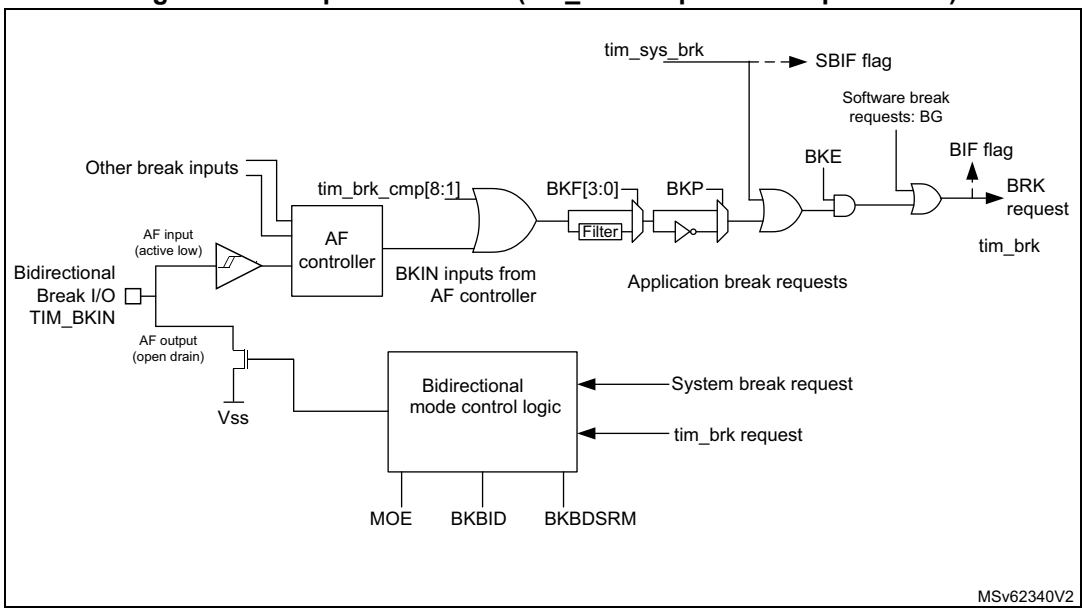
The break circuitry (in input or bidirectional mode) is armed by default (peripheral reset configuration).

The following procedure must be followed to re-arm the protection after a break (break2) event:

- The BKDSRM (BK2DSRM) bit must be set to release the output control
- The software must wait until the system break condition disappears (if any) and clear the SBIF status flag (or clear it systematically before re-arming)
- The software must poll the BKDSRM (BK2DSRM) bit until it is cleared by hardware (when the application break condition disappears)

From this point, the break circuitry is armed and active, and the MOE bit can be set to re-enable the PWM outputs.

Figure 388. Output redirection (tim_brk2 request not represented)



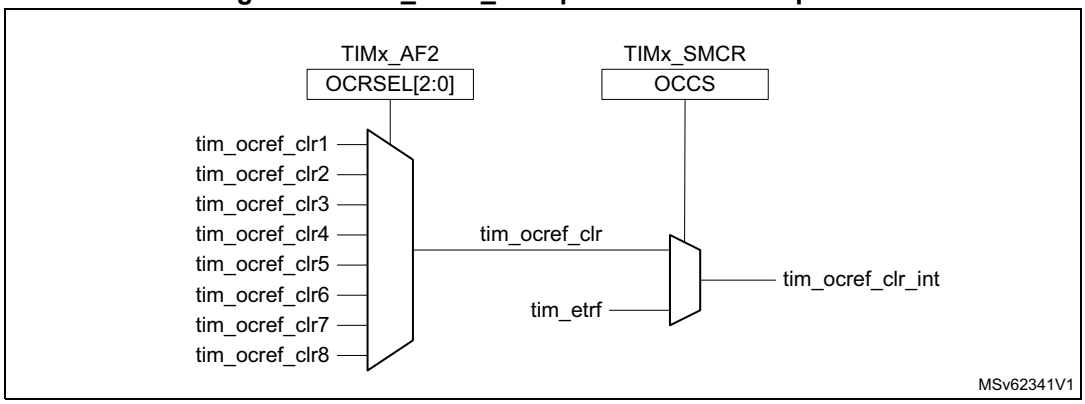
38.3.20 Clearing the tim_ocxref signal on an external event

The tim_ocxref signal of a given channel can be cleared when a high level is applied on the tim_ocref_clr_int input (OCxCE enable bit in the corresponding TIMx_CCMRx register set to 1). tim_ocxref remains low until the next transition to the active state, on the following PWM

cycle. This function can only be used in Output compare and PWM modes. It does not work in Forced mode. tim_ocref_clr_int input can be selected between the tim_ocref_clr input and tim_etrf (tim_etr_in after the filter) by configuring the OCCS bit in the TIMx_SMCR register.

The tim_ocref_clr input can be selected among several inputs, using the OCRSEL[2:0] bitfield in the TIMx_AF2 register, as shown on the *Figure 389* below. Refer to *Section 38.3.2: TIM1/TIM8 pins and internal signals* for a list of sources available in the product.

Figure 389. tim_ocref_clr input selection multiplexer

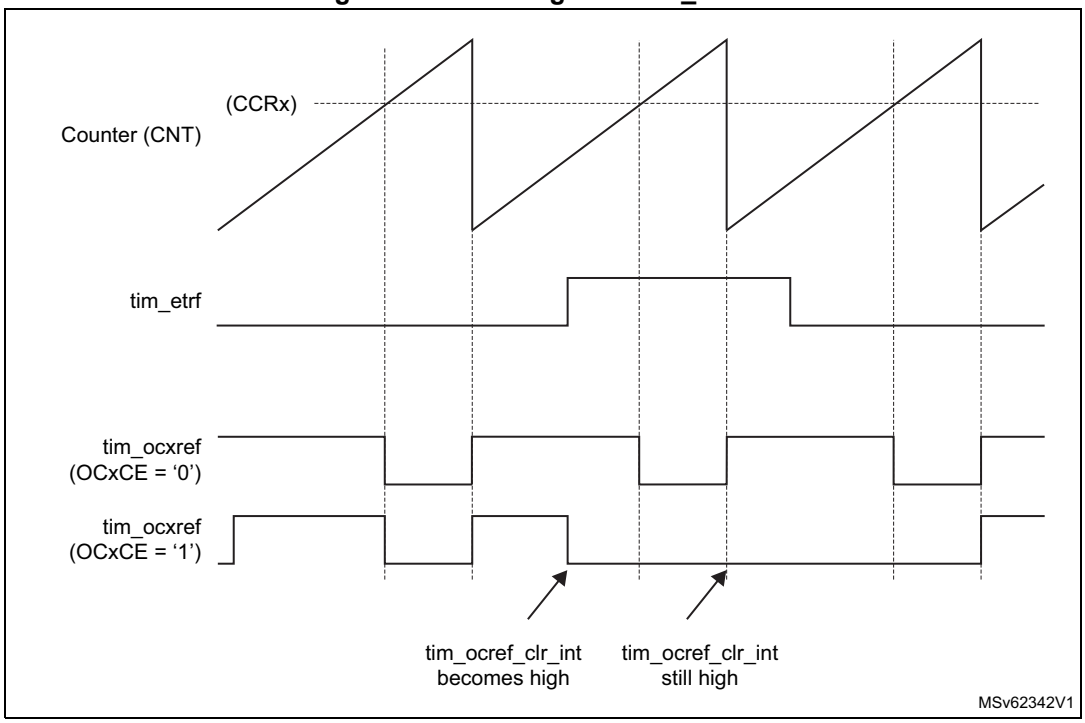


When tim_etrf is chosen, tim_etr_in must be configured as follows:

1. The External Trigger Prescaler must be kept off: bits ETPS[1:0] of the TIMx_SMCR register set to ‘00’.
2. The external clock mode 2 must be disabled: bit ECE of the TIMx_SMCR register set to ‘0’.
3. The External Trigger Polarity (ETP) and the External Trigger Filter (ETF) can be configured according to application needs (as per polarity of the source connected to the trigger and eventual need to remove noise using the filter).

Figure 390 shows the behavior of the tim_ocxref signal when the tim_etrf Input becomes High, for both values of the enable bit OCxCE. In this example, the timer TIMx is programmed in PWM mode.

Figure 390. Clearing TIMx tim_ocxref



Note: In case of a PWM with a 100% duty cycle (if CCRx>ARR), then tim_ocxref is enabled again at the next counter overflow.

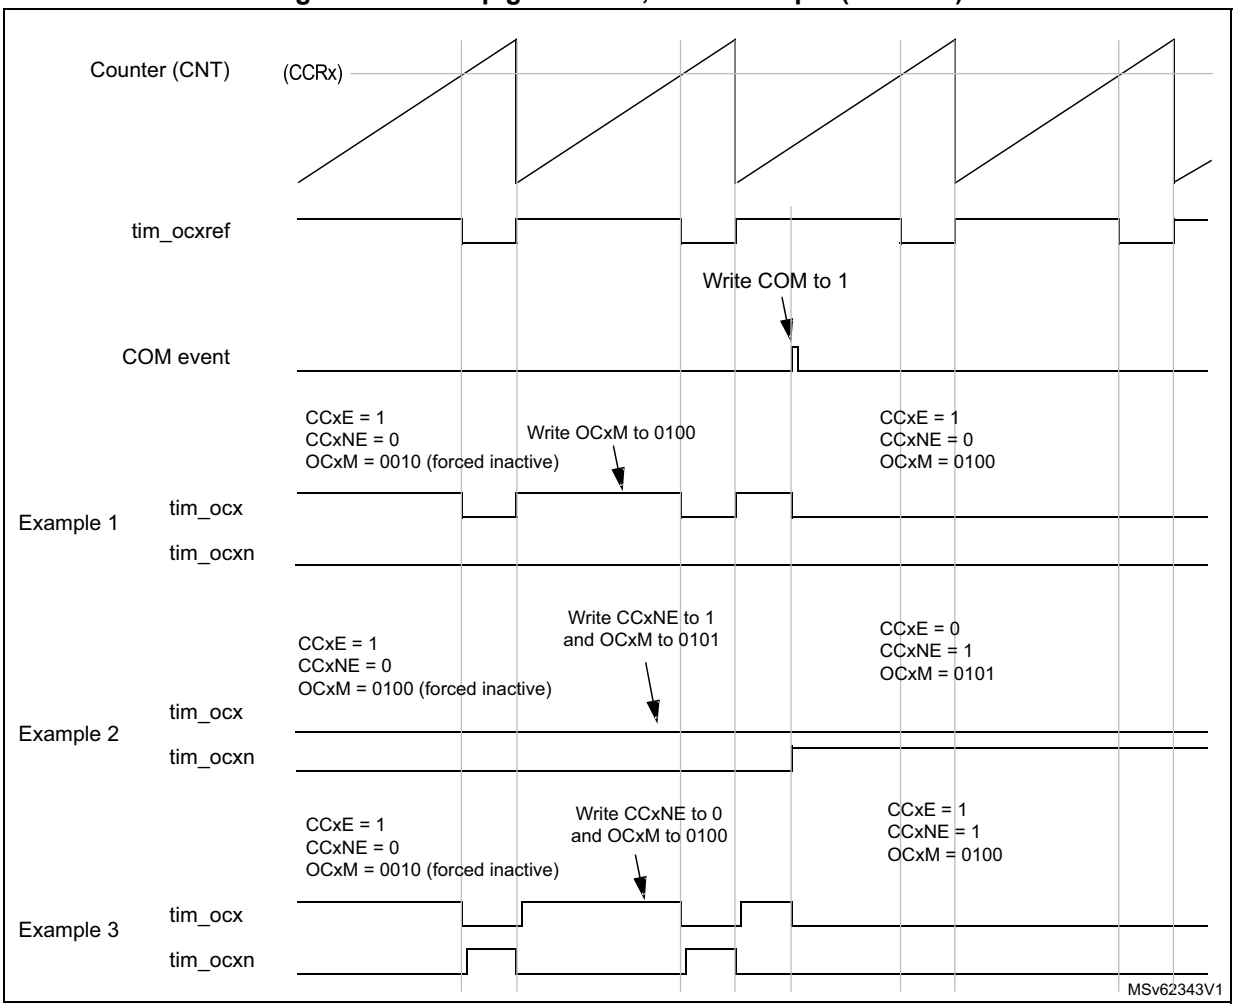
38.3.21 6-step PWM generation

When complementary outputs are used on a channel, preload bits are available on the OCxM, CCxE and CCxNE bits. The preload bits are transferred to the shadow bits at the COM commutation event. Thus one can program in advance the configuration for the next step and change the configuration of all the channels at the same time. COM can be generated by software by setting the COM bit in the TIMx_EGR register or by hardware (on tim_trgi rising edge).

A flag is set when the COM event occurs (COMIF bit in the TIMx_SR register), which can generate an interrupt (if the COMIE bit is set in the TIMx_DIER register) or a DMA request (if the COMDE bit is set in the TIMx_DIER register).

The *Figure 391* describes the behavior of the tim_ocx and tim_ocxn outputs when a COM event occurs, in 3 different examples of programmed configurations.

Figure 391. 6-step generation, COM example (OSSR=1)



38.3.22 One-pulse mode

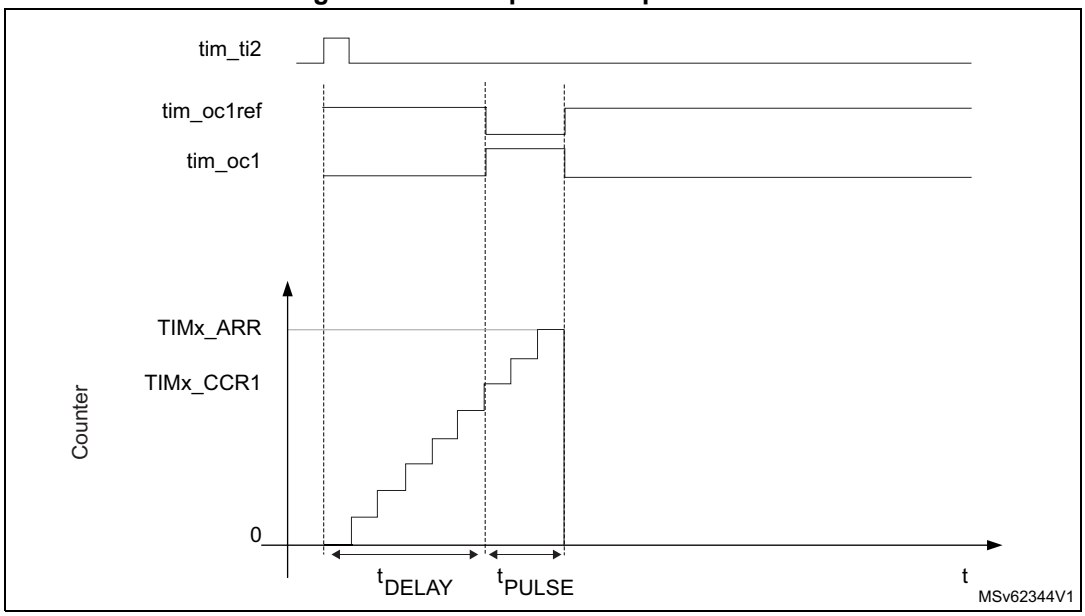
One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- In upcounting: CNT < CCRx ≤ ARR (in particular, 0 < CCRx)
- In downcounting: CNT > CCRx

Figure 392. Example of one pulse mode.



For example one may want to generate a positive pulse on tim_oc1 with a length of t_{PULSE} and after a delay of t_{DELAY} as soon as a positive edge is detected on the tim_ti2 input pin.

Let's use tim_ti2fp2 as trigger 1:

- Map tim_ti2fp2 to tim_ti2 by writing CC2S='01' in the TIMx_CCMR1 register.
- tim_ti2fp2 must detect a rising edge, write CC2P='0' and CC2NP='0' in the TIMx_CCER register.
- Configure tim_ti2fp2 as trigger for the slave mode controller (tim_trgi) by writing TS=00110 in the TIMx_SMCR register.
- tim_ti2fp2 is used to start the counter by writing SMS to '110' in the TIMx_SMCR register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The t_{DELAY} is defined by the value written in the TIMx_CCR1 register.
- The t_{PULSE} is defined by the difference between the auto-reload value and the compare value (TIMx_ARR - TIMx_CCR1).
- Let's say one want to build a waveform with a transition from '0' to '1' when a compare match occurs and a transition from '1' to '0' when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing OC1M=111 in the TIMx_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE='1' in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case one has to write the compare value in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on tim_ti2. CC1P is written to '0' in this example.

In our example, the DIR and CMS bits in the TIMx_CR1 register must be low.

Since only 1 pulse (Single mode) is needed, a 1 must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). When OPM bit in the TIMx_CR1 register is set to '0', so the Repetitive Mode is selected.

Particular case: tim_ocx fast enable:

In One-pulse mode, the edge detection on tim_tix input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay t_{DELAY} min we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then tim_ocxref (and tim_ocx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

38.3.23 Retriggerable One-pulse mode

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with Non-retriggerable one-pulse mode described in *Section 38.3.22*:

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

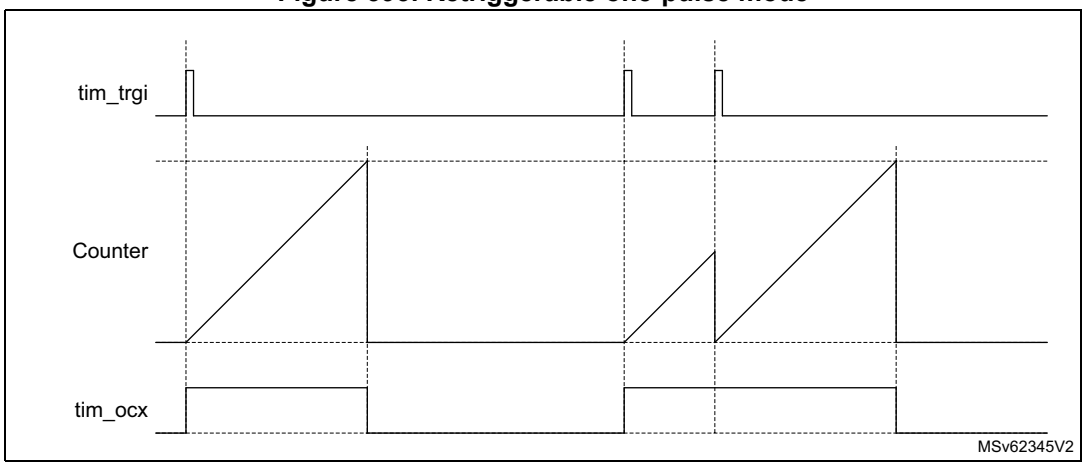
The timer must be in Slave mode, with the bits SMS[3:0] = ‘1000’ (Combined Reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to ‘1000’ or ‘1001’ for retriggerable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode, CCRx must be above or equal to ARR.

Note: The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit are not contiguous with the 3 least significant ones.

This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.

Figure 393. Retriggerable one-pulse mode

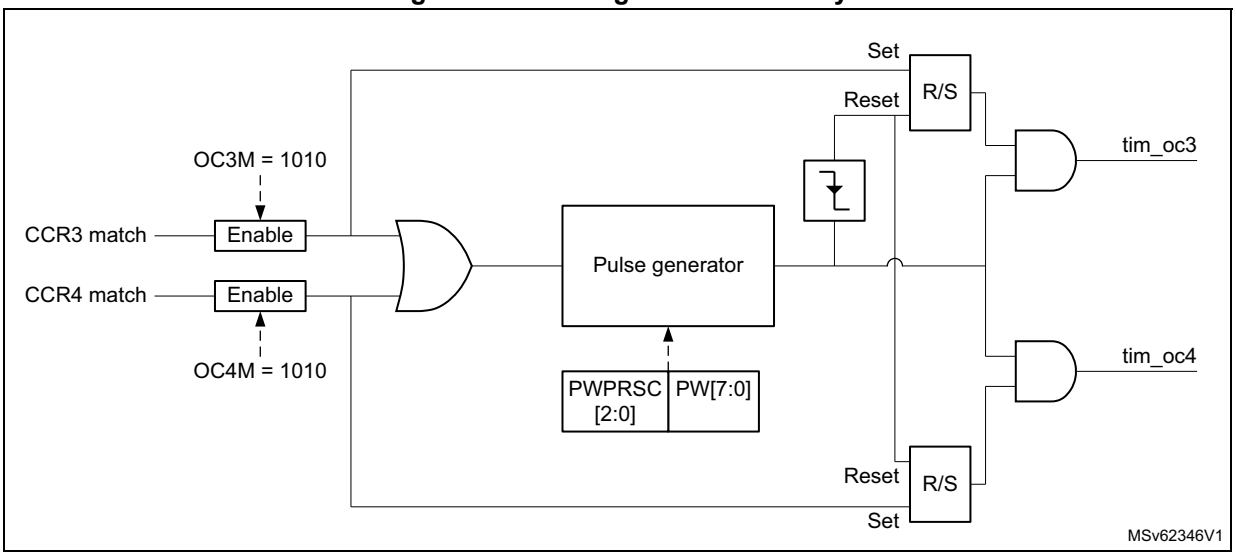


38.3.24 Pulse on compare mode

A pulse can be generated upon compare match event. A signal with a programmable pulsewidth generated when the counter value equals a given compare value, for debugging or synchronization purposes.

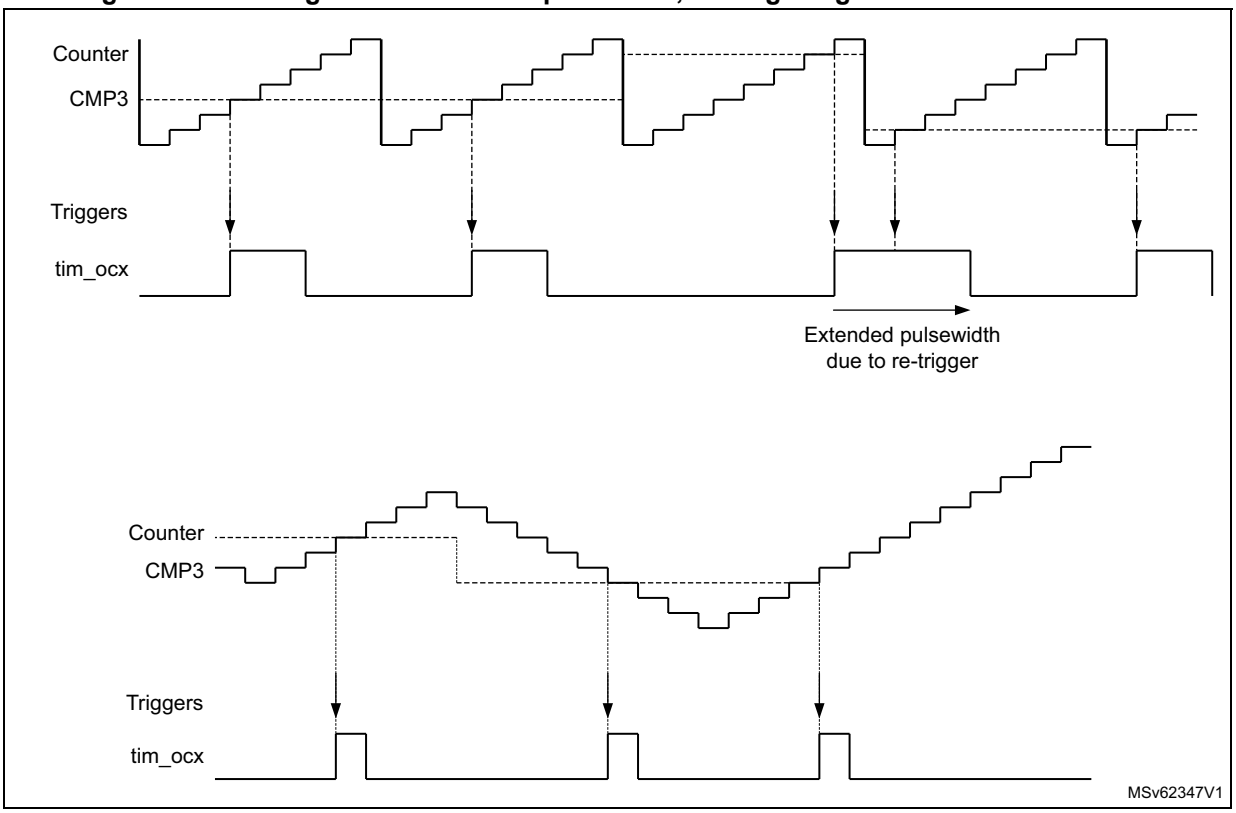
This mode is available for any slave mode selection, including encoder modes, in edge and center aligned counting modes. It is solely available for channel 3 and channel 4. The pulse generator is unique and is shared by the two channels, as shown on the *Figure 394* below.

Figure 394. Pulse generator circuitry



The *Figure 395* below shows how the pulse is generated for edge-aligned and encoder operating modes.

Figure 395. Pulse generation on compare event, for edge-aligned and encoder modes



This output compare mode is selected using the OC3M[3:0] and OC4M[3:0] bit fields in TIMx_CCMR2 register.

The pulsewidth is programmed using the PW[7:0] bitfield in the register, using a specific clock prescaled according to PWPRSC[2:0] bits, as follows:

$t_{PW} = PW[7:0] \times t_{PWG}$

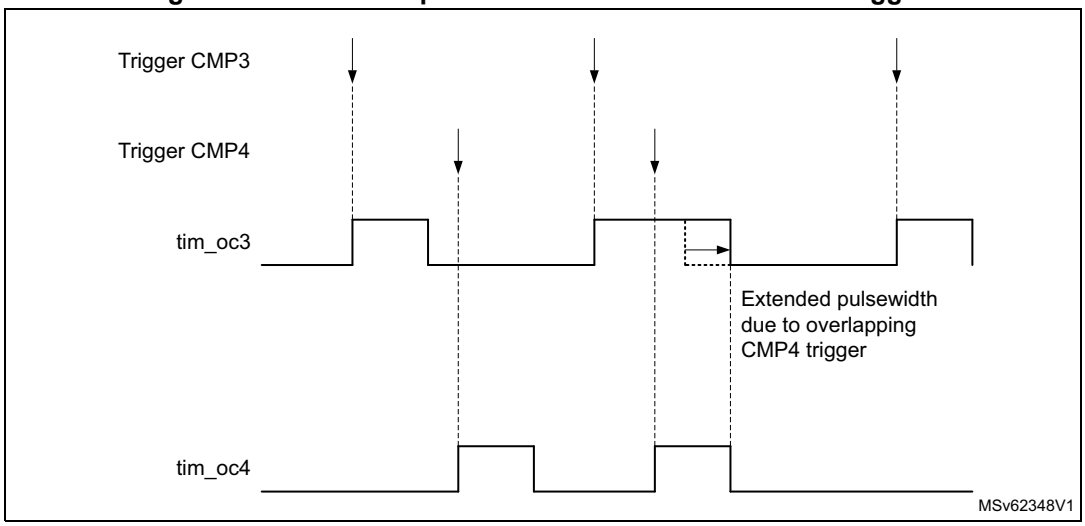
where $t_{PWG} = (2^{(PWPRSC[2:0])}) \times t_{tim\_ker\_ck}$.

gives the resolution and maximum values depending on the prescaler value.

The pulse is retriggerable: a new trigger while the pulse is ongoing, causes the pulse to be extended.

Note: If the two channels are enabled simultaneously, the pulses are issued independently as long as the trigger on one channel is not overlapping the pulse generated on the concurrent output. On the opposite, if the two triggers are overlapping, the pulse width related to the 1st arriving trigger is extended (because of the re-trigger), while the pulse width of the last arriving trigger is correct (as shown on the Figure 396 below).

Figure 396. Extended pulsewidth in case of concurrent triggers



38.3.25 Encoder interface mode

Quadrature encoder

To select Encoder Interface mode write SMS='0001' in the TIMx_SMCR register if the counter is counting on tim_ti1 edges only, SMS='0010' if it is counting on tim_ti2 edges only and SMS='0011' if it is counting on both tim_ti1 and tim_ti2 edges.

Select the tim_ti1 and tim_ti2 polarity by programming the CC1P and CC2P bits in the TIMx_CCER register. When needed, the input filter can be programmed as well. CC1NP and CC2NP must be kept low.

The two inputs tim_ti1 and tim_ti2 are used to interface to an quadrature encoder. Refer to *Table 390*. The counter is clocked by each valid transition on tim_ti1fp1 or tim_ti2fp2 (tim_ti1 and tim_ti2 after input filter and polarity selection, tim_ti1fp1=tim_ti1 if not filtered and not inverted, tim_ti2fp2=tim_ti2 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIMx_CR1 register written to '1'). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (tim_ti1 or tim_ti2), whatever the counter is counting on tim_ti1 only, tim_ti2 only or both tim_ti1 and tim_ti2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the TIMx_ARR register (0 to ARR or ARR down to 0 depending on the direction). So the TIMx_ARR must be configured before starting. In the same way, the capture, compare, prescaler, repetition counter, trigger output features continue to work as normal. Encoder mode and External clock mode 2 are not compatible and must not be selected together.

In this mode, the counter is modified automatically following the speed and the direction of the quadrature encoder and its content, therefore, always represents the encoder's position. The count direction correspond to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming tim_ti1 and tim_ti2 do not switch at the same time.

Table 390. Counting direction versus encoder signals (CC1P = CC2P = 0)

Active edge	SMS[3:0]	Level on opposite signal (tim_ti1fp1 for tim_ti2, tim_ti2fp2 for tim_ti1)	tim_ti1fp1 signal		tim_ti2fp2 signal	
			Rising	Falling	Rising	Falling
Counting on tim_ti1 only x1 mode	1110	High	Down	Up	No count	No count
		Low	No count	No count	No count	No count
Counting on tim_ti2 only x1 mode	1111	High	No count	No count	Up	Down
		Low	No count	No count	No count	No count
Counting on tim_ti1 only x2 mode	0001	High	Down	Up	No count	No count
		Low	Up	Down	No count	No count
Counting on tim_ti2 only x2 mode	0010	High	No count	No count	Up	Down
		Low	No count	No count	Down	Up
Counting on tim_ti1 and tim_ti2 x4 mode	0011	High	Down	Up	Up	Down
		Low	Up	Down	Down	Up

A quadrature encoder can be connected directly to the MCU without external interface logic. However, comparators are normally be used to convert the encoder's differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicate the mechanical zero position, may be connected to the external trigger input and trigger a counter reset.

The *Figure 397* gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example we assume that the configuration is the following:

- CC1S='01' (TIMx_CCMR1 register, tim_ti1fp1 mapped on tim_ti1).
- CC2S='01' (TIMx_CCMR2 register, tim_ti1fp2 mapped on tim_ti2).
- CC1P='0' and CC1NP='0' (TIMx_CCER register, tim_ti1fp1 non-inverted, tim_ti1fp1=tim_ti1).
- CC2P='0' and CC2NP='0' (TIMx_CCER register, tim_ti1fp2 non-inverted, tim_ti1fp2= tim_ti2).
- SMS='0011' (TIMx_SMCR register, both inputs are active on both rising and falling edges).
- CEN='1' (TIMx_CR1 register, Counter enabled).

Figure 397. Example of counter operation in encoder interface mode.

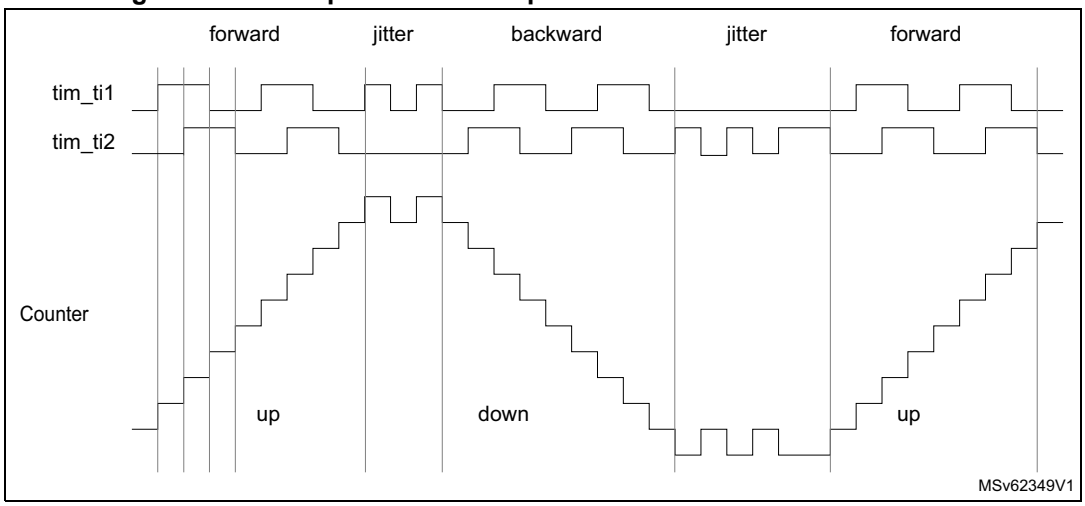


Figure 398 gives an example of counter behavior when tim_ti1fp1 polarity is inverted (same configuration as above except CC1P='1').

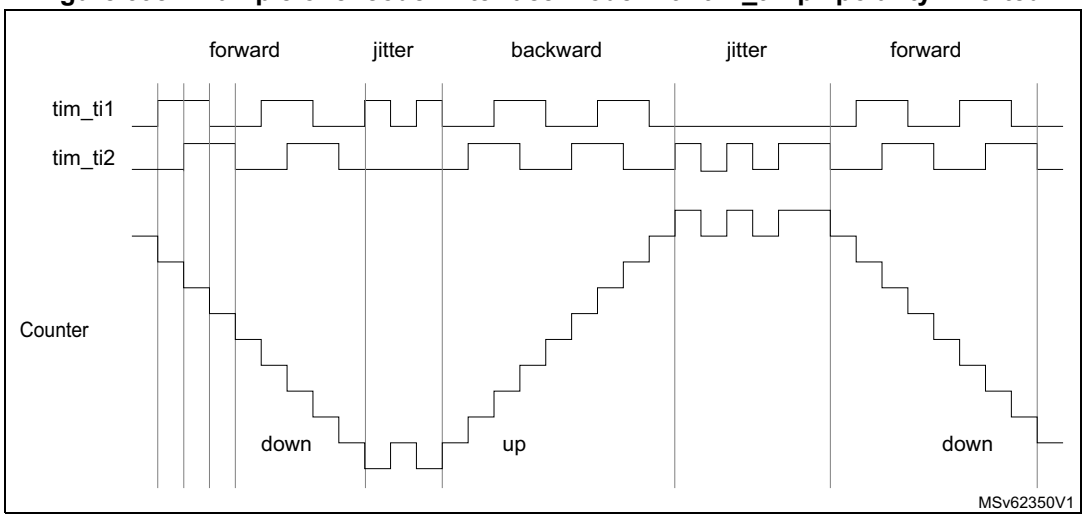
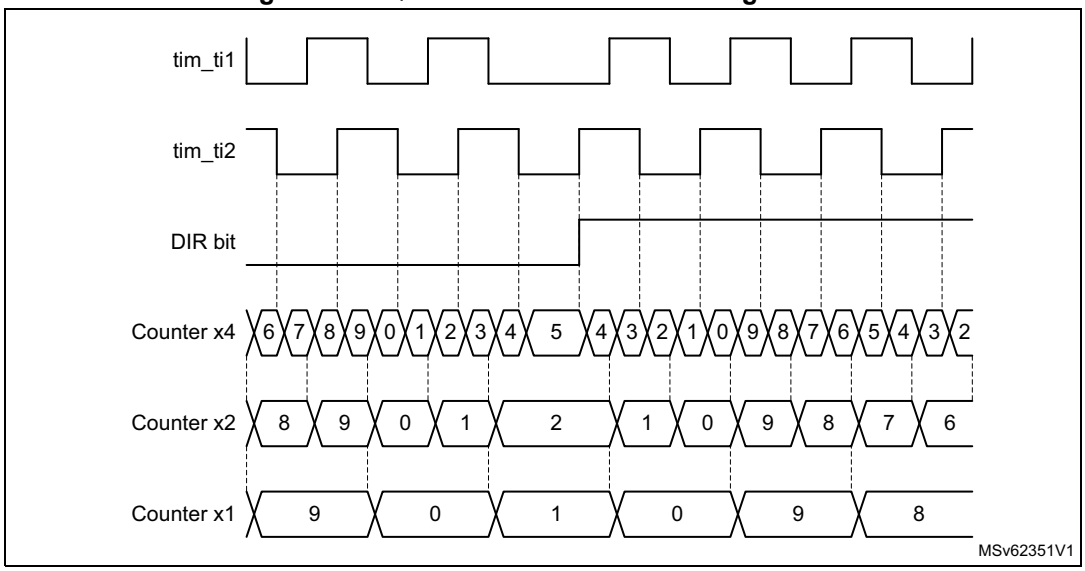
Figure 398. Example of encoder interface mode with tim_ti1fp1 polarity inverted.



The *Figure 399* below shows the timer counter value during a speed reversal, for various counting modes.

Figure 399. Quadrature encoder counting modes



The timer, when configured in Encoder Interface mode provides information on the sensor's current position. Dynamic information can be obtained (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. This can be done by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). when available, it is also possible to read its value through a DMA request.

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the update interrupt flag (UIF) into the timer counter register's bit 31 (TIMxCNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter's most significant bit is only accessible in write mode).

Clock plus direction encoder mode

In addition to the quadrature encoder mode, the timer offers support other types of encoders.

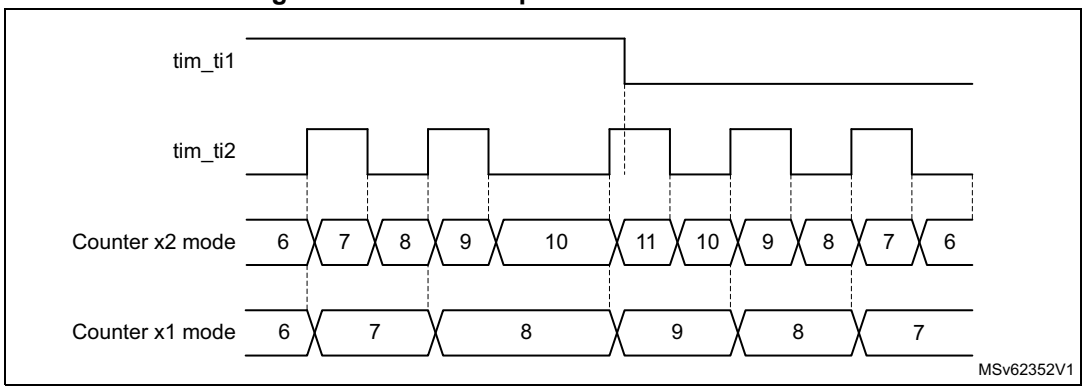
In the "clock plus direction" mode shown on *Figure 400*, the clock is provided on a single line, on tim_ti2, while the direction is forced using the tim_ti1 input.

This mode is enabled with the SMS[3:0] bitfield in the TIMx_SMCR register, as following:

- 1010: x2 mode, the counter is updated on both rising and falling edges of the clock
- 1011: x1 mode, the counter is updated on a single clock edge, as per CC2P bit value: CC2P = 0 corresponds to rising edge sensitivity and CC2P = 1 corresponds to falling edge sensitivity

The polarity of the direction signal on tim_ti1 is set with the CC1P bit: 0 corresponds to positive polarity (up-counting when tim_ti1 is high and down-counting when tim_ti1 is low) and CC1P = 1 corresponds to negative polarity (up-counting when tim_ti1 is low).

Figure 400. Direction plus clock encoder mode



Directional Clock encoder mode

In the “directional clock” mode on *Figure 401*, the clocks are provided on two lines, with a single one at once, depending on the direction, so as to have one up-counting clock line and one down-counting clock line.

This mode is enabled with the SMS[3:0] bitfield in the TIMx_SMCR register, as following:

- 1100: x2 mode, the counter is updated on both rising and falling edges of any of the two clock line. The CC1P and CC2P bits are coding for the clock idle state. CCxP = 0 corresponds to high-level idle state (refer to *Figure 401* below) and CCxP = 1 corresponds to low-level idle state (refer to *Figure 402* below).
- 1101: x1 mode, the counter is updated on a single clock edge, as per CC1P and CC2P bit value. CCxP = 0 corresponds to falling edge sensitivity and high-level idle state (refer to *Figure 401* below), CCxP = 1 corresponds to rising edge sensitivity and low-level idle state (refer to *Figure 402* below).

Figure 401. Directional clock encoder mode (CC1P = CC2P = 0)

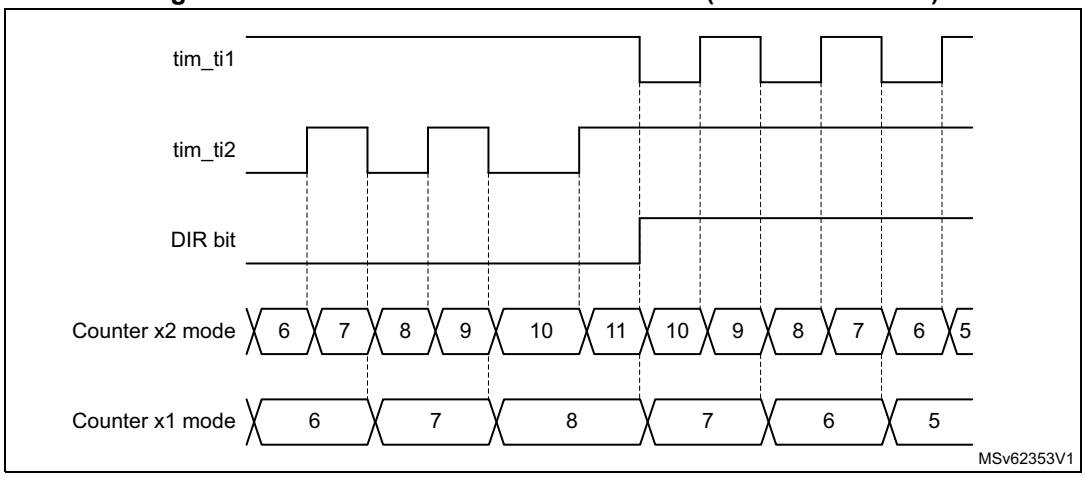


Figure 402. Directional clock encoder mode (CC1P = CC2P = 1)

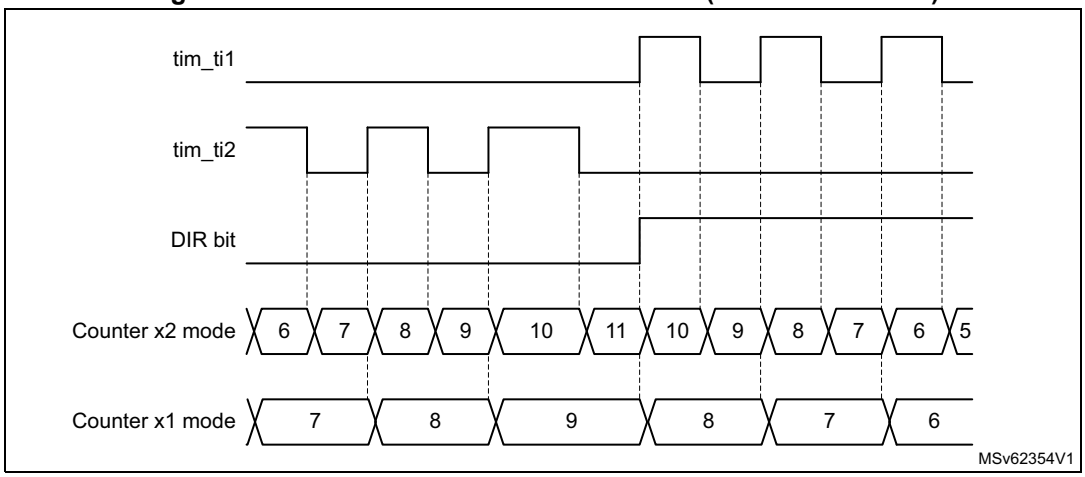


The *Table 391* here-below details how the directional clock mode operates, for any input transition.

Table 391. Counting direction versus encoder signals and polarity settings

Directional clock mode	SMS[3:0]	Level on opposite signal (tim_ti1fp1 for tim_ti2, tim_ti2fp2 for tim_ti1)	tim_ti1fp1 signal		tim_ti2fp2 signal	
			Rising	Falling	Rising	Falling
x2 mode CCxP=0	1100	High	Down	Down	Up	Up
		Low	No count	No count	No count	No count
x2 mode CCxP=1	1100	High	No count	No count	No count	No count
		Low	Down	Down	Up	Up
x1 mode CCxP=0	1101	High	No count	Down	No count	Up
		Low	No count	No count	No count	No count
x1 mode CCxP=1	1101	High	No count	No count	No count	No count
		Low	Down	No count	Up	No count

Index Input

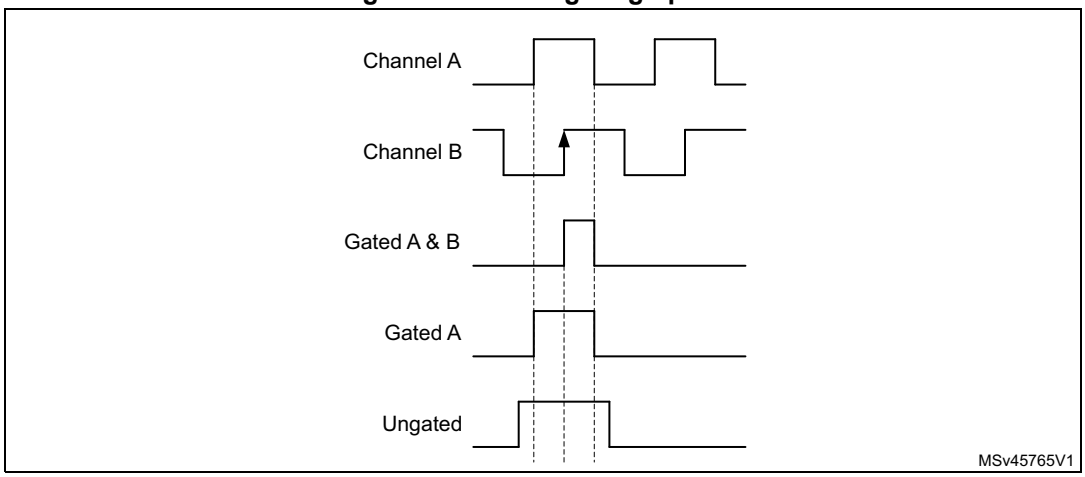
The counter can be reset by an index signal coming from the encoder, indicating an absolute reference position. The Index signal must be connected to the tim_etr_in input. It can be filtered using the digital input filter.

The index functionality is enabled with the IE bit in the TIMX_ECR register. The IE bit must be set only in encoder mode, when the SMS[3:0] bitfield has the following values: 0001, 0010, 011, 1010, 1011, 1100, 1101, 1110, 1111.

Commercially available encoders are proposed with several options for index pulse conditioning, as per the *Figure 403* below:

- gated with A and B: the pulsewidth is 1/4 of one channel period, aligned with both A and B edges
- gated with A (or gated with B): the pulsewidth is 1/2 of one channel period, aligned with the two edges on channel A (resp. channel B)
- ungated: the pulsewidth is up to one channel period, without any alignment to the edges

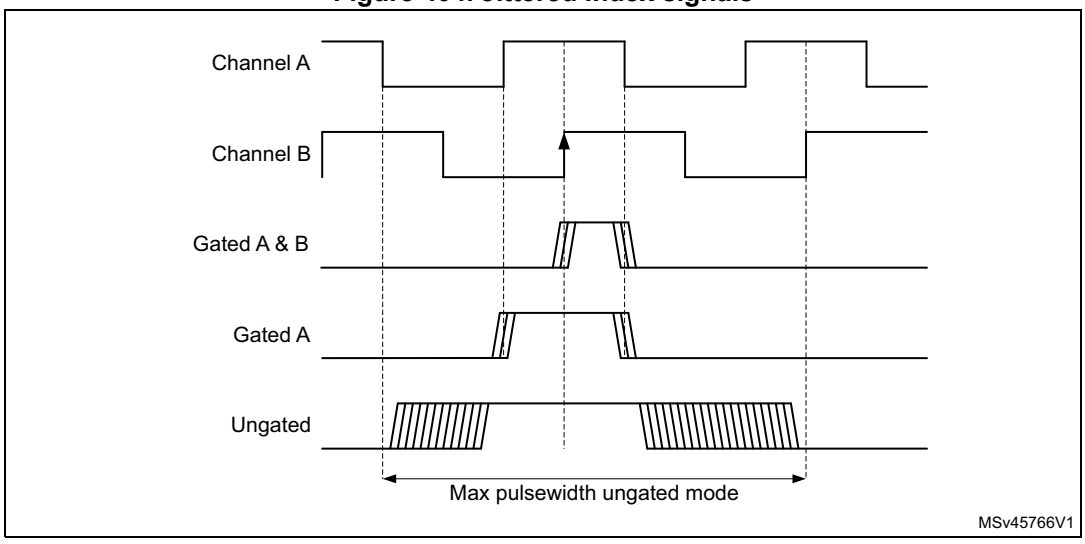
Figure 403. Index gating options



The circuitry tolerates jitter on index signal, whatever the gating mode, as show on *Figure 404* below.

In ungated mode, the signal must be strictly below 2 encoder periods. If the pulsewidth is greater or equal to 2 encoder period, the counter is reset multiple times.

Figure 404. Jittered Index signals



The timer supports the 3 gating options identically, without any specific programming needed. It is only necessary to define on which encoder state (i.e. channel A and channel B

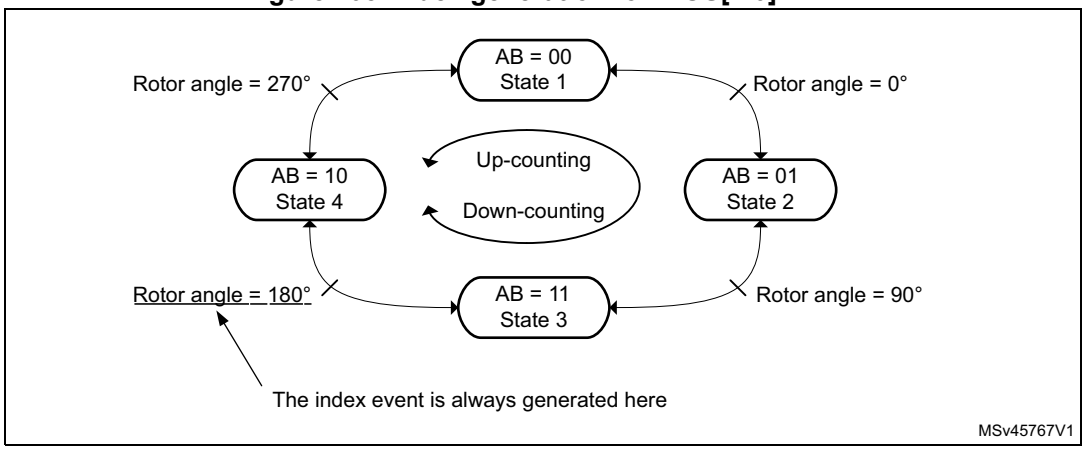
state combination) the index must be synchronized, using the IPOS[1:0] bitfield in the TIMx_ECR register.

The Index detection event acts differently depending on counting direction to ensure symmetrical operation during speed reversal:

- The counter is reset during up-counting (DIR bit = 0).
- The counter is set to TIMx_ARR when down counting.

This allows the index to be generated on the very same mechanical angular position whatever the counting direction. The *Figure 405* below shows at which position is the index generated, for a simplistic example (an encoder providing 4 edges par mechanical rotation).

Figure 405. Index generation for IPOS[1:0] = 11



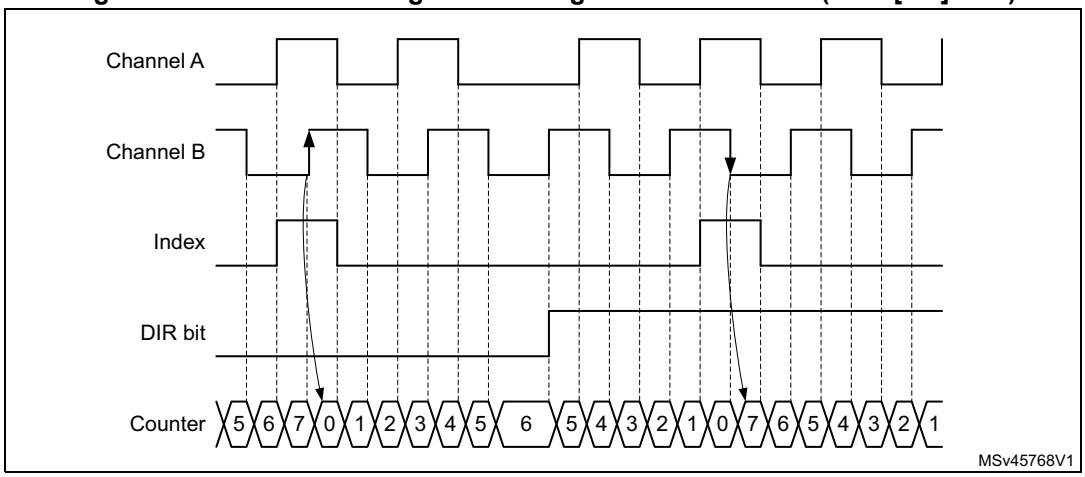
The *Figure 406* below presents waveforms and corresponding values for IPOS[1:0] = 11. It shows that the instant at which the counter value is forced is automatically adjusted depending on the counting direction:

- Counter set to 0 when encoder state is '11' (ChA=1, ChB=1), when up-counting (DIR bit = 0).
- Counter set to TIMx_ARR when exiting the '11' state, when down-counting (DIR bit = 1).

An interrupt can be issued upon index detection event.

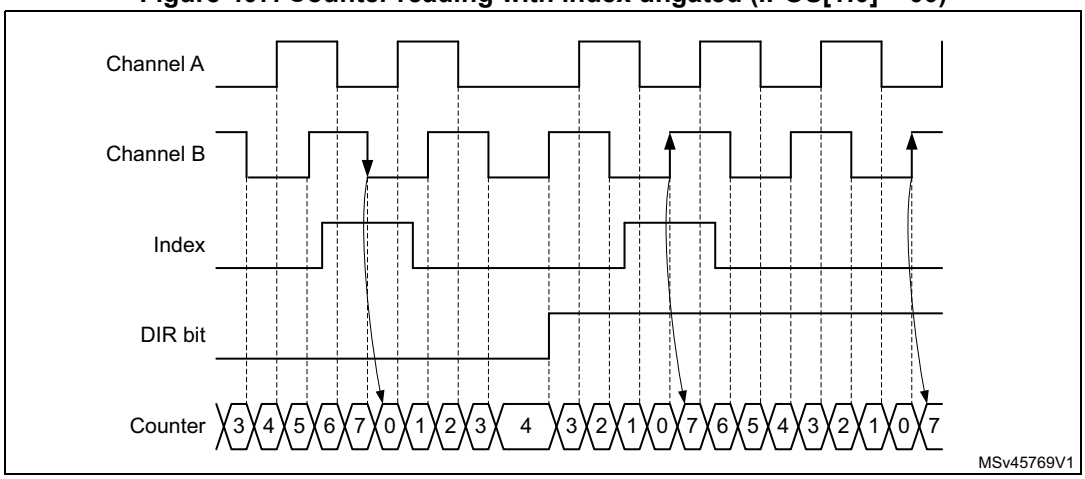
The arrows are indicating on which transition is the index event interrupt generated.

Figure 406. Counter reading with index gated on channel A (IPOS[1:0] = 11)



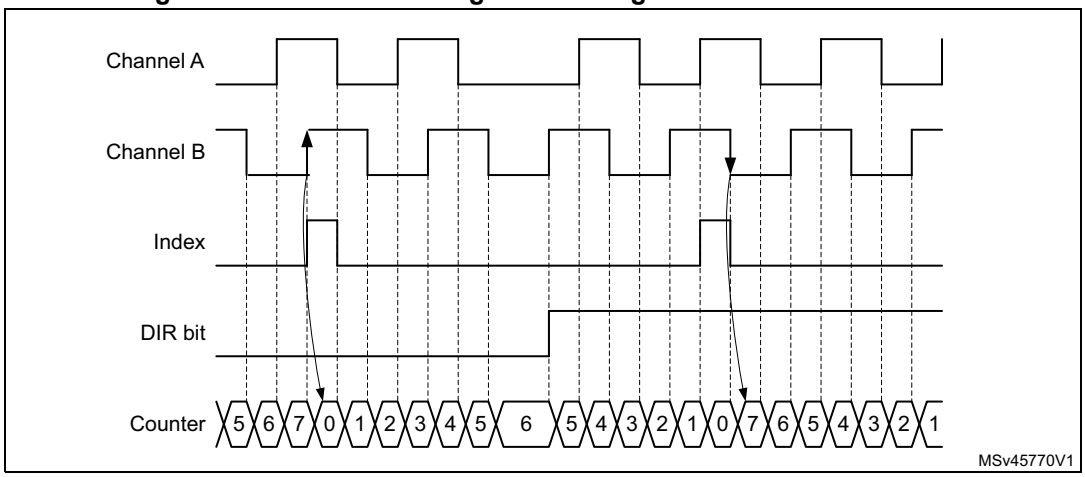
The *Figure 407.* below presents waveforms and corresponding values for the ungated mode. The arrows are indicating on which transition is the index event generated.

Figure 407. Counter reading with index ungated (IPOS[1:0] = 00)



The *Figure 408.* below shows how the ‘gated on A & B’ mode is handled, for various pulse alignment scenario. The arrows are indicating on which transition is the index event generated.

Figure 408. Counter reading with index gated on channel A and B



The *Figure 409* and *Figure 410* detail the case where the subsequent index pulse may be narrower than one quarter of the encoder clock period.

Figure 409. Encoder mode behavior in case of narrow index pulse (IPOS[1:0] = 11)

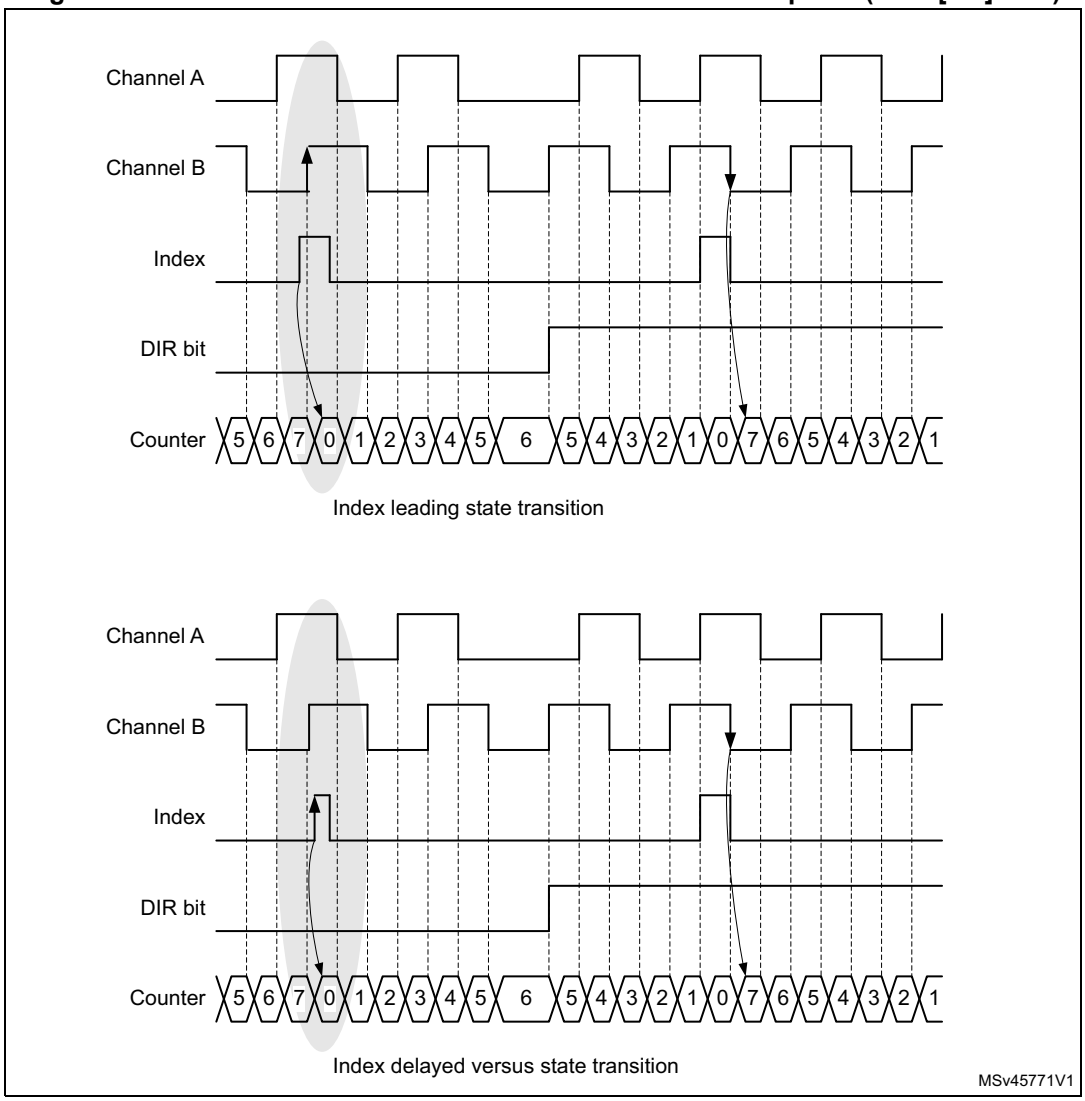


Figure 410. Counter reset Narrow index pulse (closer view, ARR = 0x07)

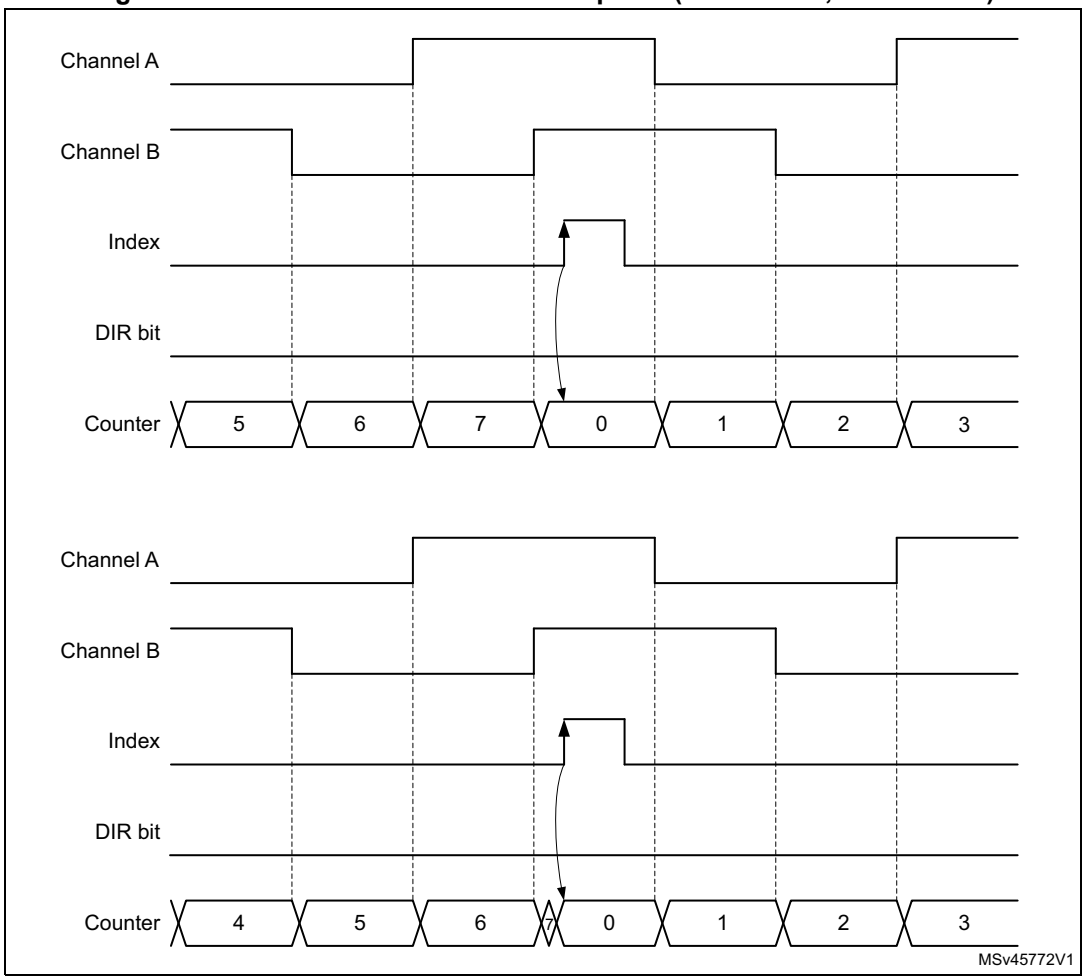
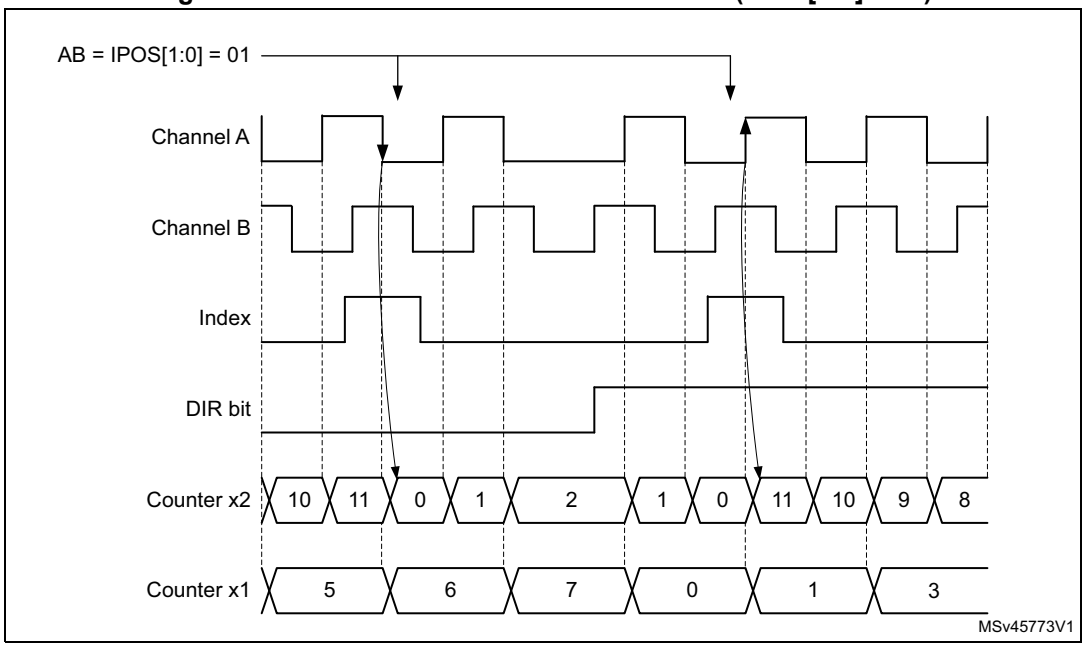


The *Figure 411* below shows how the index is managed in x1 and x2 modes.

Figure 411. Index behavior in x1 and x2 mode (IPOS[1:0] = 01)

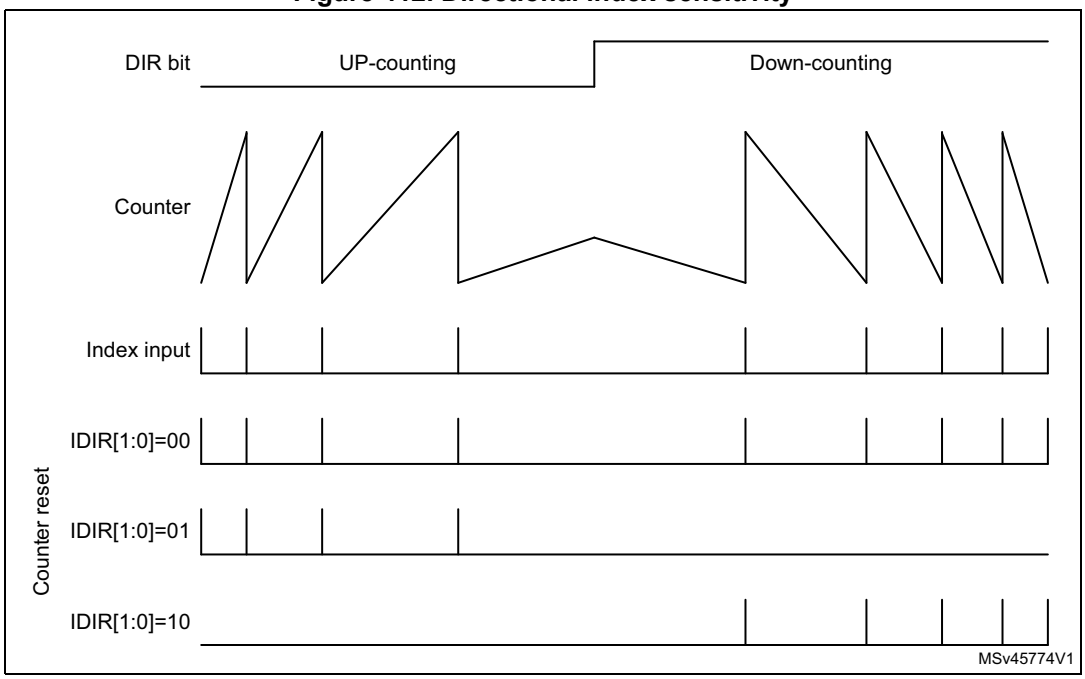


Directional index sensitivity

The IDIR[1:0] bitfield in the TIMx_ECR register allows the index to be active only in a selected counting direction.

The *Figure 412* below shows the relationship between index and counter reset events, depending on IDIR[1:0] value.

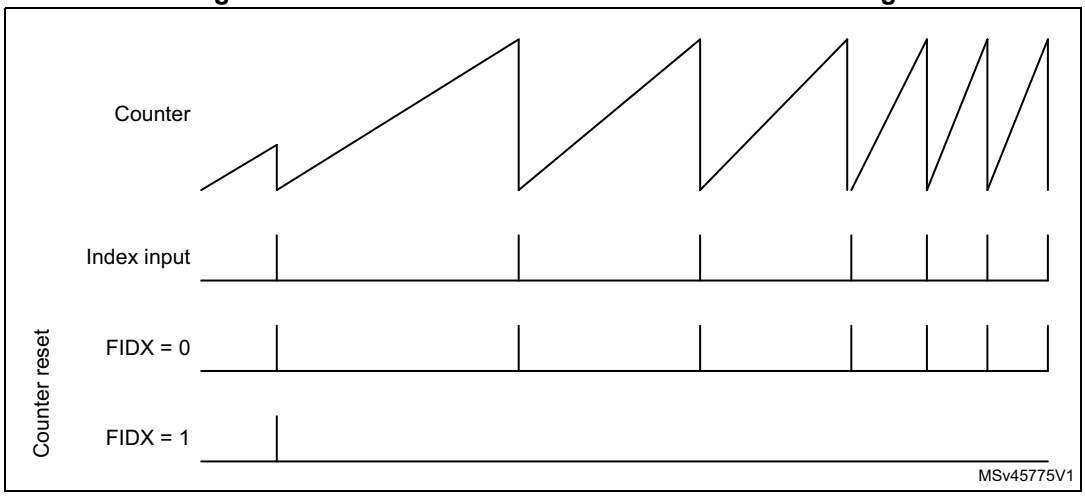
Figure 412. Directional index sensitivity



Special first index event management

The FIDX bit in the TIMx_ECR register allows the Index to be taken only once, as shown on the *Figure 413* below. Once the first index has arrived, any subsequent index is ignored. If needed, the circuitry can be re-armed by writing the FIDX bit to 0 and setting it again to 1.

Figure 413. Counter reset as function of FIDX bit setting



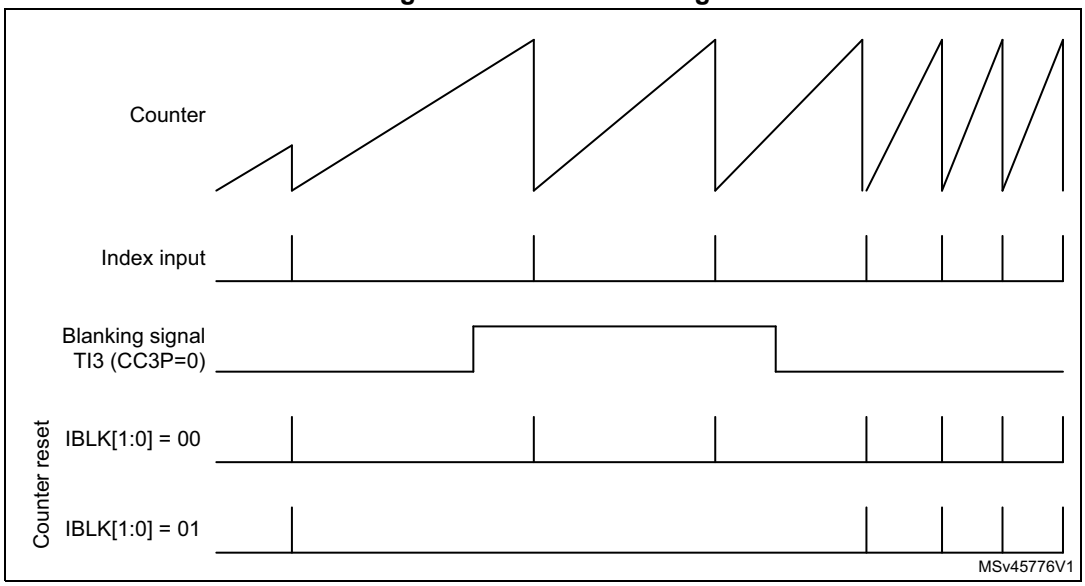
Index blanking

The Index event can be blanked using the tim_ti3 or tim_ti4 inputs. During the blanking window, the index events are no longer resetting the counter, as shown on the *Figure 414* below.

This mode is enabled using the IBLK[1:0] bitfield in the TIMx_ECR register, as following:

- IBLK[1:0] = 00: Index signal always active
- IBLK[1:0] = 01: Index signal blanking on tim_ti3 input
- IBLK[1:0] = 10: Index signal blanking on tim_ti4 input

Figure 414. Index blanking



Index management in non-quadrature mode

The *Figure 415* and *Figure 416* below detail how the index is managed in directional clock mode and clock plus direction mode, when the SMS[3:0] bitfield is equal to 1010, 1011, 1100, 1101.

For both of these modes, the index sensitivity is set with the IPOS[0] bit as following:

- IPOS[0] = 0: Index is detected on clock low level
- IPOS[0] = 1: Index is detected on clock high level

The IPOS[1] bit is not-significant.

Figure 415. Index behavior in clock + direction mode, IPOS[0] = 1

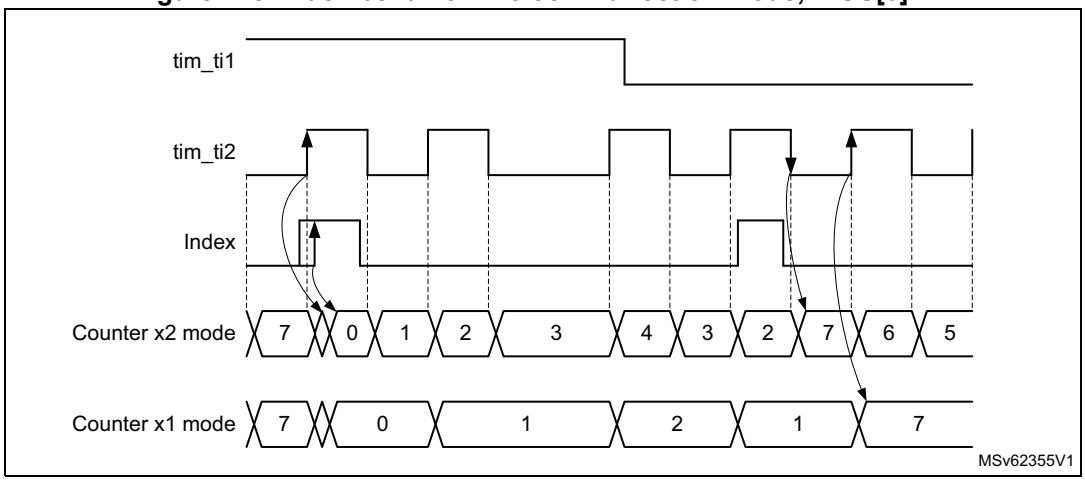


Figure 416. Index behavior in directional clock mode, IPOS[0] = 1

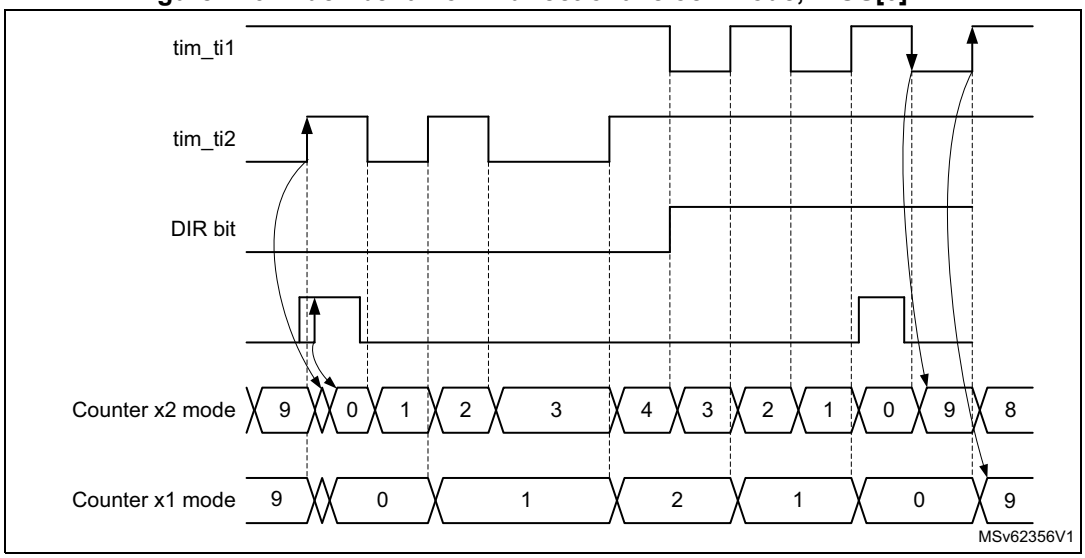
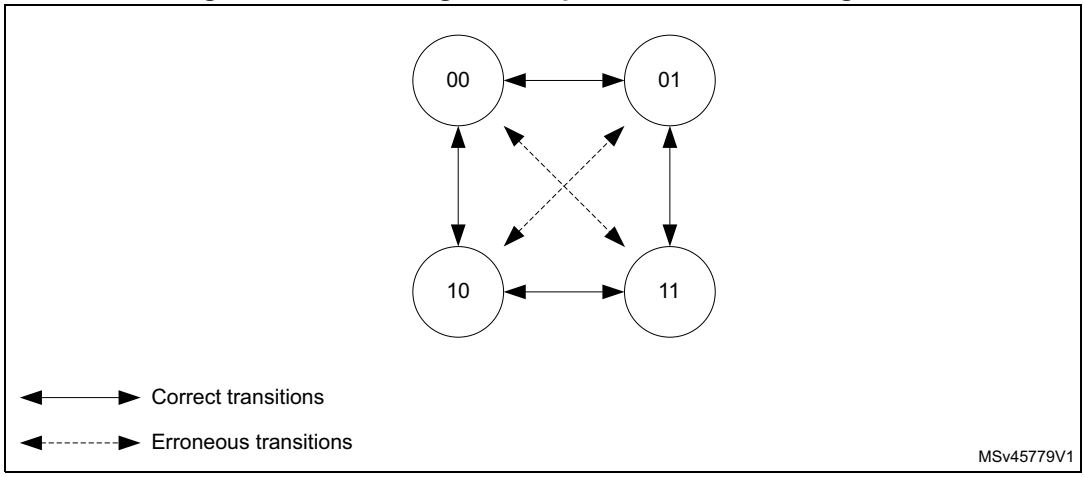


Encoder error management

For encoder configurations where 2 quadrature signals are available, it is possible to detect transition errors. The reading on the 2 inputs corresponds to a 2-bit gray code which can be represented as a state diagram, on the *Figure 417.* below. A single bit is expected to change at once. An erroneous transition sets the TERRF interrupt flag in the TIMx_SR status

register. A transition error interrupt is generated if the TERRIE bit is set in the TIMx_DIER register.

Figure 417. State diagram for quadrature encoded signals



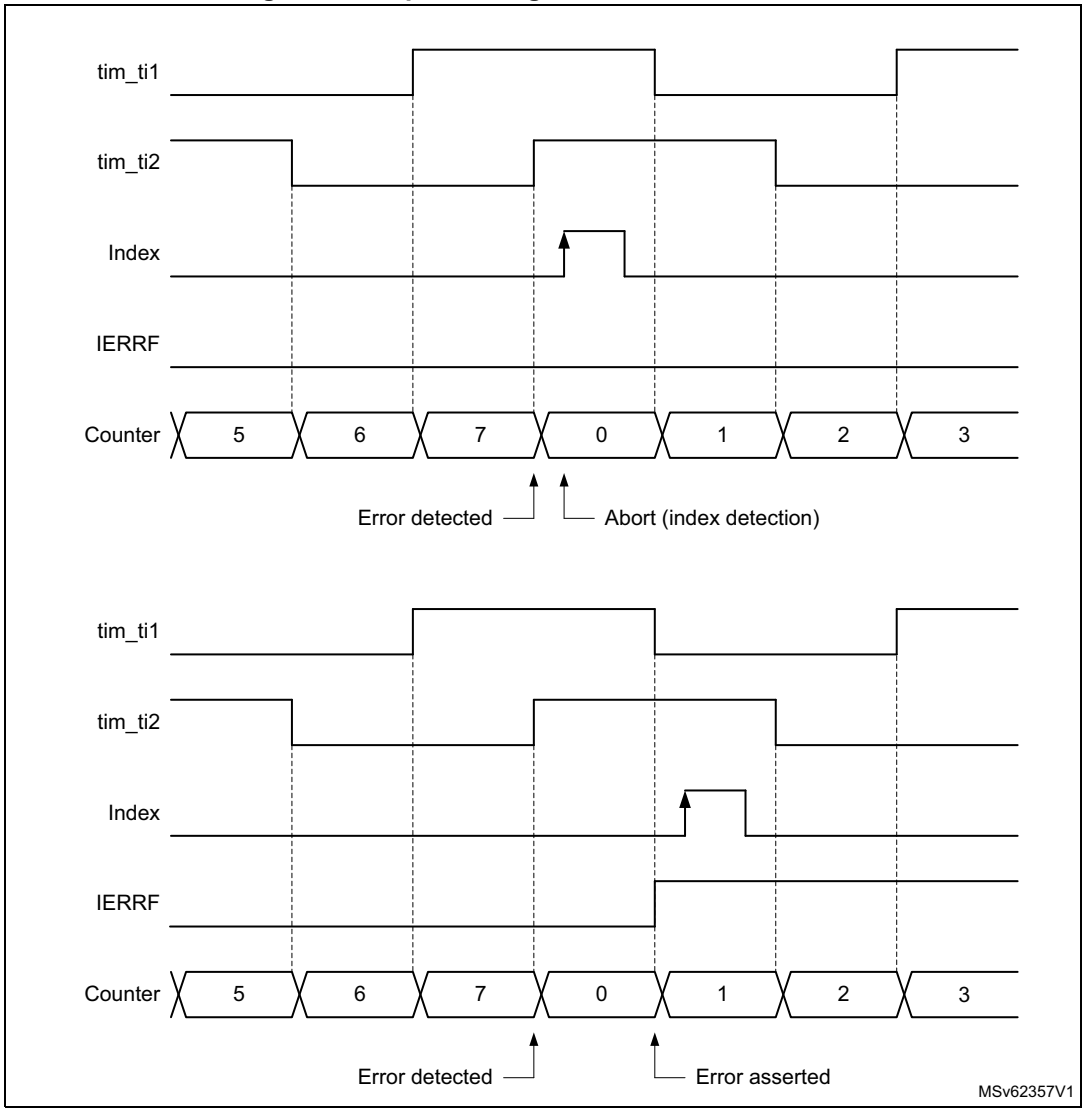
For encoder having an Index signal, it is possible to detect abnormal operation resulting in an excess of pulses per revolution. An encoder with N pulses per revolution provides 4xN counts per revolution. The Index signal resets the counter every 4xN clock periods.

If the counter value is incremented from TIMx_ARR to 0 or decremented from 0 to TIMxARR value without any index event, this is reported as an Index position error.

The overflow threshold is programmed using the TIMx_ARR register. A 1000 lines encoder results in a counter value being between 0 and 3999 (in 4x reading mode). The overflow detection threshold must be programmed by setting TIMx_ARR = 3999 + 1 = 4000.

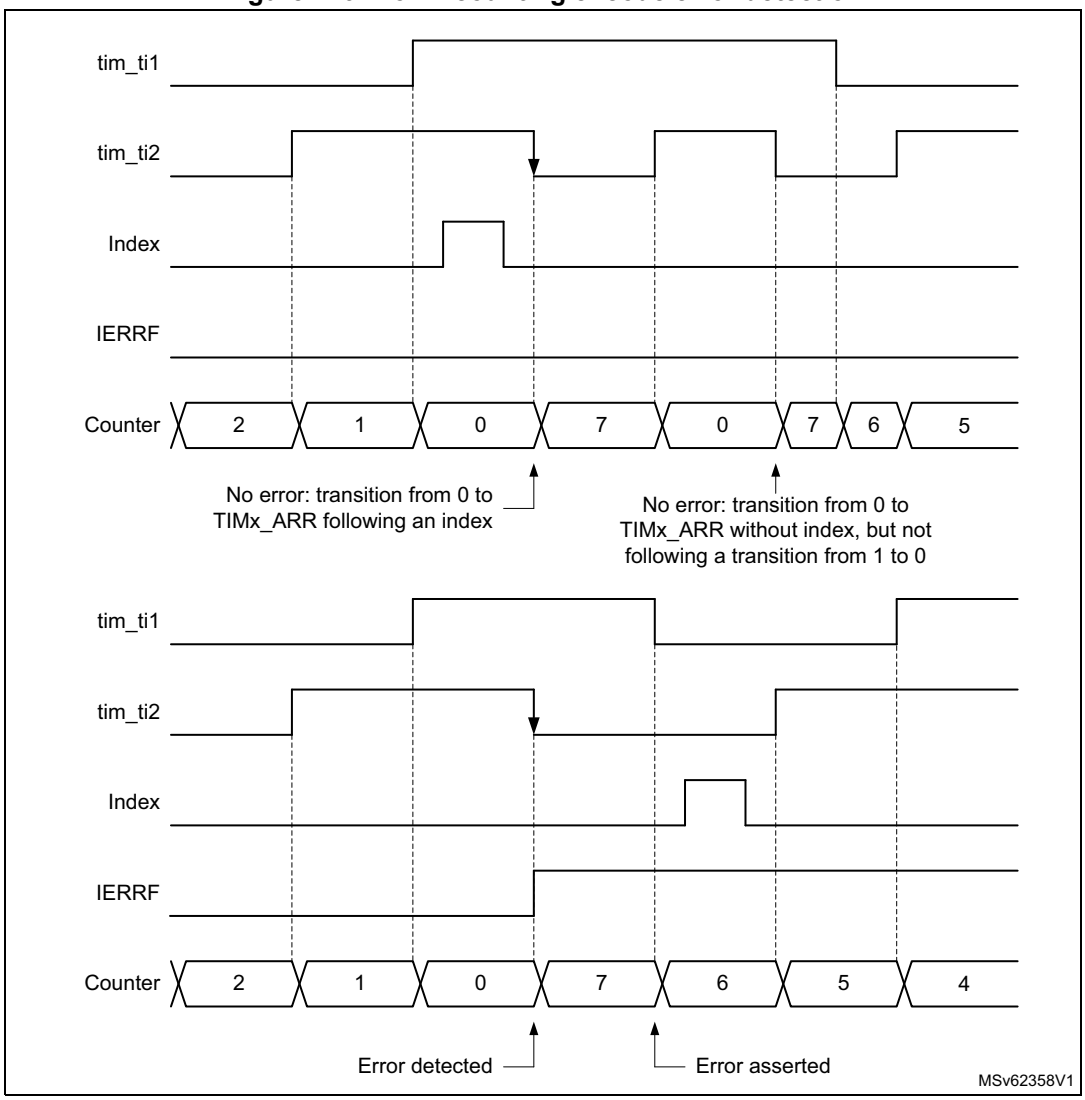
The error assertion is delayed to the transition 0 to 1 when in up-counting. This is cope with narrow index pulses in gated A and B mode, as shown on *Figure 418* below.

Figure 418. Up-counting encoder error detection



In down-counting mode, the detection is conditioned by a preliminary transition from 1 to 0. This is to cope with narrow index pulses in gated A and B mode, as shown on *Figure 419* below, to avoid any false error detection in case the encoder dithers between TIMx_ARR and 0 immediately after the index detection.

Figure 419. Down-counting encode error detection



An index error sets the IERRF interrupt flag in the TIMx_SR status register. An index error interrupt is generated if the IERRIE bit is set in the TIMx_DIER register.

Functional encoder Interrupts

The following interrupts are also available in encoder mode

- Direction change: any change of the counting direction in encoder mode causes the DIR bit in the TIMx_CR1 register to toggle. The direction change sets the DIRF interrupt flag in the TIMx_SR status register. A direction change interrupt is generated if the DIRIE bit is set in the TIMx_DIER register.
- Index event: the Index event sets the IDXF interrupt flag in the TIMx_SR status register. An Index interrupt is generated if the IDXIE bit is set in the TIMx_DIER register.

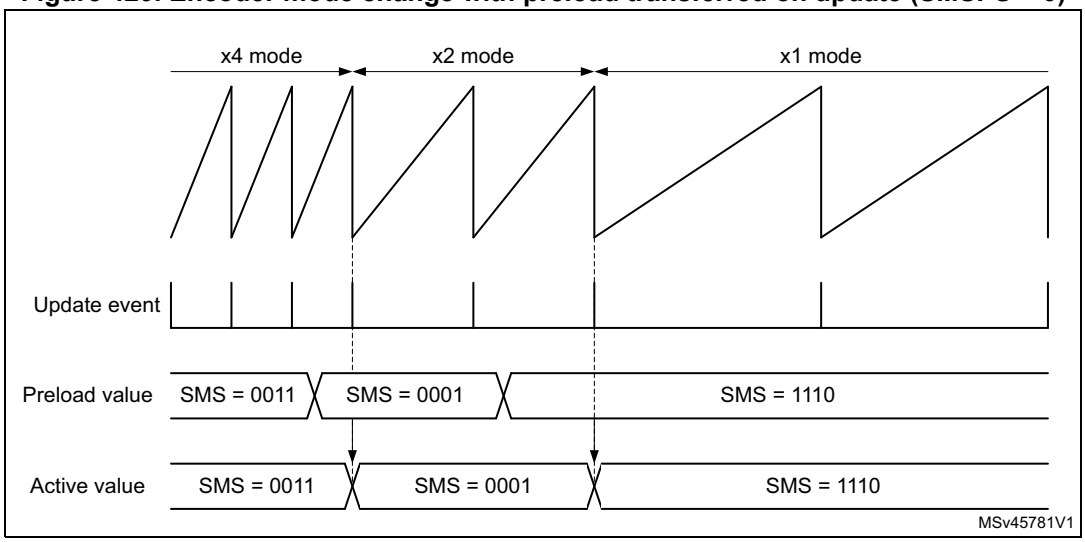
Slave mode selection preload for run-time encoder mode update

It may be necessary to switch from one encoder mode to another during run-time. This is typically done at high-speed to decrease the Update interrupt rate, by switching from x4 to x2 to x1 mode, as show on the *Figure 420* below.

For this purpose, the SMS[3:0] bit can be preloaded. This is enabled by setting the SMSPE enable bit in the TIMx_SMCR register. The trigger for the transfer from SMS[3:0] preload to active value can be selected with the SMSPS bit in the TIMx_SMCR register.

- SMSPS = 0: the transfer is triggered by the update event (UEV) occurring when the counter overflows when upcounting, and underflows when downcounting.
- SMSPS = 1: the transfer is triggered by the Index event.

Figure 420. Encoder mode change with preload transferred on update (SMSPS = 0)



Encoder clock output

The encoder mode operating principle is not perfectly suited for high-resolution velocity measurements, at low speed, as it requires a relatively long integration time to have a sufficient number of clock edges and a precise measurement.

At low speed, a better solution is to do an edge-to-edge clock period measurement. This can be achieved using a slave timer. The timer can output the encoder clock information on the tim_trgo output. The slave timer can then perform a period measurement and provide velocity information for each and every encoder clock edge.

This mode is enabled by setting the MMS[3:0] bitfield to 1000, in the TIMx_CR2 register.It is valid for the following SMS[3:0] values: 0001, 0010, 0011, 1010, 1011, 1100, 1101, 1110, 1111. Any other SMS[3:0] code is not allowed and may lead to unexpected behavior.

38.3.26 Direction bit output

Its is possible to output a direction signal out of the timer, on the tim_oc3n and tim_oc4 output signals (copy of the DIR bit in the TIMx_CR1 register). This is achieved by setting the OC3M[3:0] or the OC4M[3:0] bit field to 1011 in the TIMx_CCMR2 register.

This feature can be used for monitoring the counting direction (or rotation direction) in encoder mode, or to have a signal indicating the up/down phases in center-aligned PWM mode.

38.3.27 UIF bit remapping

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into the timer counter register's bit 31 (TIMxCNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. In particular cases, it can ease the calculations by avoiding race conditions, caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

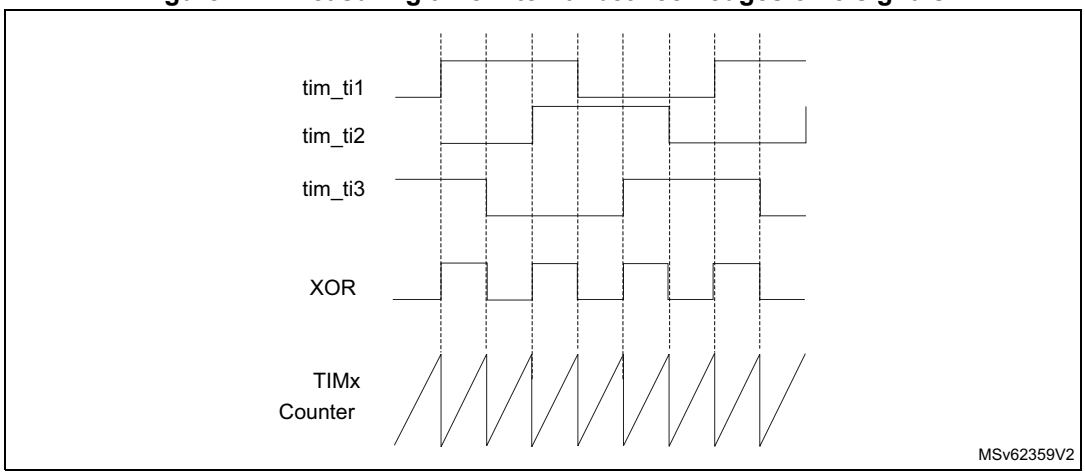
There is no latency between the UIF and UIFCPY flags assertion.

38.3.28 Timer input XOR function

The TI1S bit in the TIMx_CR2 register, allows the input filter of channel 1 to be connected to the output of an XOR gate, combining the three input pins tim_ti1, tim_ti2 and tim_ti3.

The XOR output can be used with all the timer input functions such as trigger or input capture. It is convenient to measure the interval between edges on two input signals, as per *Figure 421* below.

Figure 421. Measuring time interval between edges on 3 signals



38.3.29 Interfacing with Hall sensors

This is done using the advanced-control timers to generate PWM signals to drive the motor and another timer TIMx referred to as "interfacing timer" in *Figure 422*. The "interfacing timer" captures the 3 timer input pins (tim_ti1, tim_ti2 and tim_ti3) connected through a XOR to the tim_ti1 input channel (selected by setting the TI1S bit in the TIMx_CR2 register).

The slave mode controller is configured in reset mode; the slave input is tim_ti1f_ed. Thus, each time one of the 3 inputs toggles, the counter restarts counting from 0. This creates a time base triggered by any change on the Hall inputs.

On the "interfacing timer", capture/compare channel 1 is configured in capture mode, capture signal is tim_trc (See *Figure 364: Capture/compare channel (example: channel 1*

input stage) on page 1453). The captured value, which corresponds to the time elapsed between 2 changes on the inputs, gives information about motor speed.

The “interfacing timer” can be used in output mode to generate a pulse which changes the configuration of the channels of the advanced-control timer (by triggering a COM event). The advanced-control timer is used to generate PWM signals to drive the motor. To do this, the interfacing timer channel must be programmed so that a positive pulse is generated after a programmed delay (in output compare or PWM mode). This pulse is sent to the advanced-control timer through the tim_trgo output.

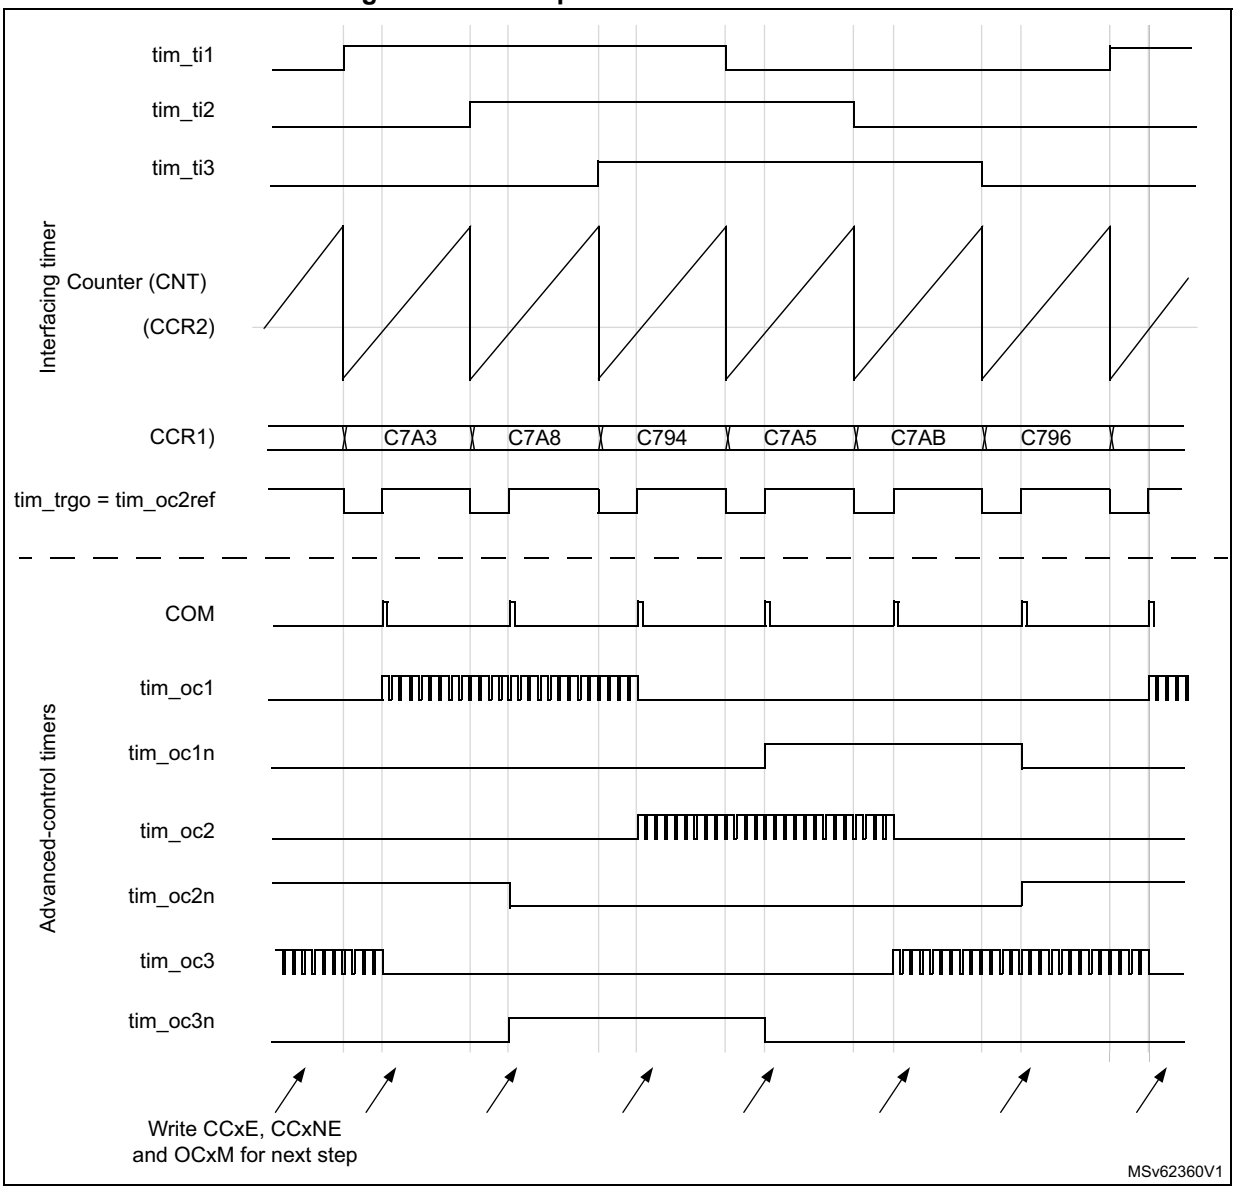
Example: one wants to change the PWM configuration of the advanced-control timer after a programmed delay each time a change occurs on the Hall inputs connected to one of the TIMx timers.

- Configure 3 timer inputs ORed to the tim_ti1 input channel by writing the TI1S bit in the TIMx_CR2 register to ‘1’,
- Program the time base: write the TIMx_ARR to the max value (the counter must be cleared by the tim_ti1 change. Set the prescaler to get a maximum counter period longer than the time between 2 changes on the sensors,
- Program the channel 1 in capture mode (tim_trc selected): write the CC1S bits in the TIMx_CCMR1 register to ‘01’. The digital filter can also be programmed if needed,
- Program the channel 2 in PWM 2 mode with the desired delay: write the OC2M bits to ‘111’ and the CC2S bits to ‘00’ in the TIMx_CCMR1 register,
- Select tim_oc2ref as trigger output on tim_trgo: write the MMS bits in the TIMx_CR2 register to ‘101’,

In the advanced-control timer, the right tim_itrx input must be selected as trigger input, the timer is programmed to generate PWM signals, the capture/compare control signals are preloaded (CCPC=1 in the TIMx_CR2 register) and the COM event is controlled by the trigger input (CCUS=1 in the TIMx_CR2 register). The PWM control bits (CCxE, OCxM) are written after a COM event for the next step (this can be done in an interrupt subroutine generated by the rising edge of tim_oc2ref).

The *Figure 422* describes this example.

Figure 422. Example of Hall sensor interface



38.3.30 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. Refer to *Section 39.4.23: Timer synchronization* for details. They can be synchronized in several modes: Reset mode, Gated mode, Trigger mode, Reset + trigger and gated + reset modes.

Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

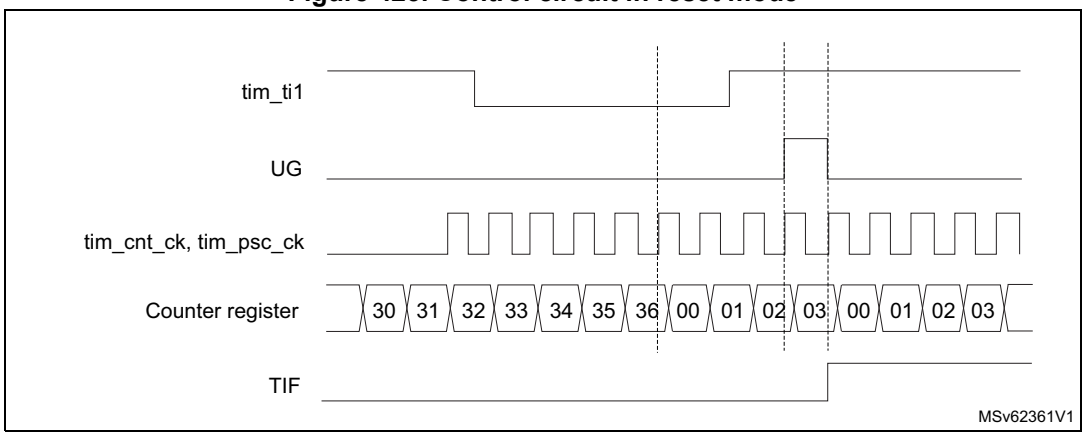
In the following example, the upcounter is cleared in response to a rising edge on tim_ti1 input:

- Configure the channel 1 to detect rising edges on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P=0 and CC1NP='0' in TIMx_CCER register to validate the polarity (and detect rising edges only).
- Configure the timer in reset mode by writing SMS=100 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.
- Start the counter by writing CEN=1 in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until tim_ti1 rising edge. When tim_ti1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on tim_ti1 and the actual reset of the counter is due to the resynchronization circuit on tim_ti1 input.

Figure 423. Control circuit in reset mode



Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

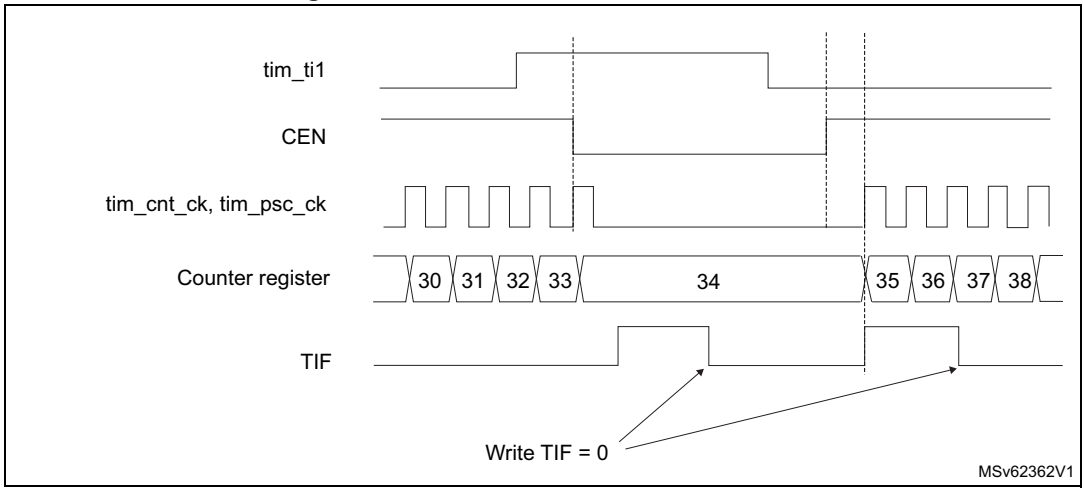
In the following example, the upcounter counts only when tim_ti1 input is low:

- Configure the channel 1 to detect low levels on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx_CCMR1 register. Write CC1P=1 and CC1NP='0' in TIMx_CCER register to validate the polarity (and detect low level only).
- Configure the timer in gated mode by writing SMS=101 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.
- Enable the counter by writing CEN=1 in the TIMx_CR1 register (in gated mode, the counter doesn't start if CEN=0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as tim_ti1 is low and stops as soon as tim_ti1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on tim_ti1 and the actual stop of the counter is due to the resynchronization circuit on tim_ti1 input.

Figure 424. Control circuit in Gated mode



Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

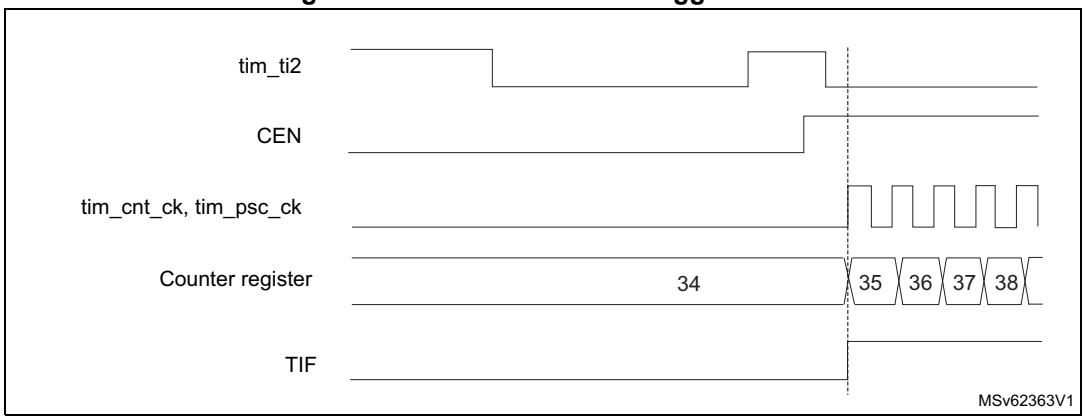
In the following example, the upcounter starts in response to a rising edge on tim_ti2 input:

- Configure the channel 2 to detect rising edges on tim_ti2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, CC2S=01 in TIMx_CCMR1 register. Write CC2P=1 and CC2NP=0 in TIMx_CCER register to validate the polarity (and detect low level only).
- Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select tim_ti2 as the input source by writing TS=00110 in TIMx_SMCR register.

When a rising edge occurs on tim_ti2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on tim_ti2 and the actual start of the counter is due to the resynchronization circuit on tim_ti2 input.

Figure 425. Control circuit in trigger mode



Slave mode: Combined reset + trigger mode

In this case, a rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for One-pulse mode.

Slave mode: Combined gated + reset mode

The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

This mode is used to detect out-of-range PWM signal (duty cycle exceeding a maximum expected value).

Slave mode: external clock mode 2 + trigger mode

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the tim_etr_in signal is used as external clock input, and another input can be selected as trigger input (in reset mode, gated mode or trigger mode). It is recommended not to select tim_etr_in as tim_trgi through the TS bits of TIMx_SMCR register.

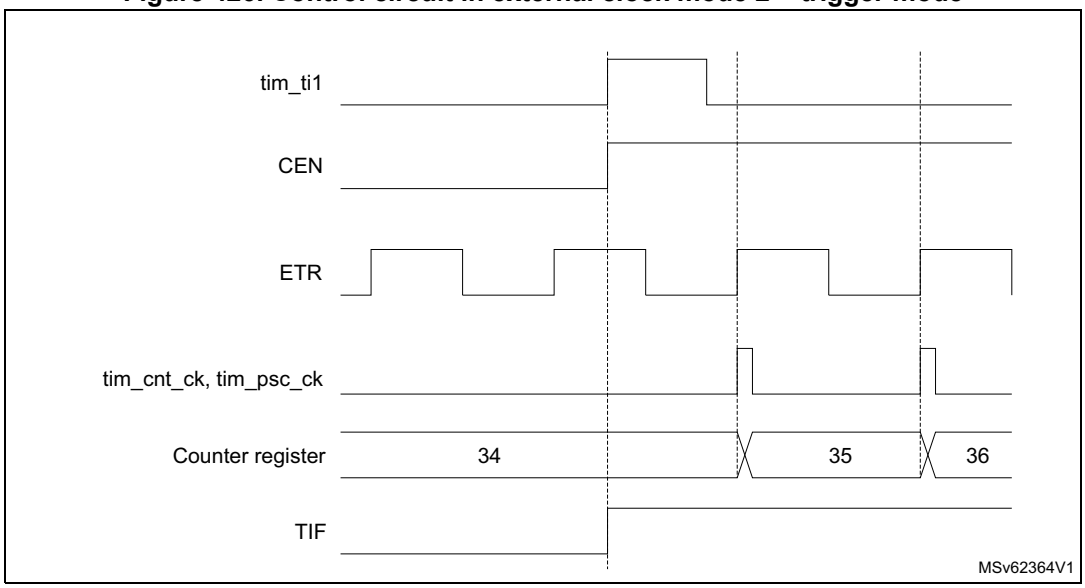
In the following example, the upcounter is incremented at each rising edge of the tim_etr_in signal as soon as a rising edge of tim_ti1 occurs:

1. Configure the external trigger input circuit by programming the TIMx_SMCR register as follows:
   - ETF = 0000: no filter
   - ETPS=00: prescaler disabled
   - ETP=0: detection of rising edges on tim_etr_in and ECE=1 to enable the external clock mode 2.
2. Configure the channel 1 as follows, to detect rising edges on TI:
   - IC1F=0000: no filter.
   - The capture prescaler is not used for triggering and does not need to be configured.
   - CC1S=01in TIMx_CCMR1 register to select only the input capture source
   - CC1P=0 and CC1NP='0' in TIMx_CCER register to validate the polarity (and detect rising edge only).
3. Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.

A rising edge on tim_ti1 enables the counter and sets the TIF flag. The counter then counts on tim_etr_in rising edges.

The delay between the rising edge of the tim_etr_in signal and the actual reset of the counter is due to the resynchronization circuit on tim_etrp input.

Figure 426. Control circuit in external clock mode 2 + trigger mode



Note: The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo or the tim_trgo2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

38.3.31 ADC triggers

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events. It is also possible to generate a pulse issued by internal edge detectors, such as:

- Rising and falling edges of OC4ref
- Rising edge on OC5ref or falling edge on OC6ref

The triggers are issued on the tim_trgo2 internal line which is redirected to the ADC. There is a total of 16 possible events, which can be selected using the MMS2[3:0] bits in the TIMx_CR2 register.

An example of an application for 3-phase motor drives is given in *Figure 379 on page 1471*.

Note: The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo or the tim_trgo2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

Note: The clock of the ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the timer.

38.3.32 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests upon a single event. The main purpose is to be able to re-program part of the timer multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIMx_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx_DMAR register is actually redirected to one of the timer registers.

The DBL[4:0] bits in the TIMx_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx_DCR register define the DMA base address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register:

Example:

00000: TIMx_CR1

00001: TIMx_CR2

00010: TIMx_SMCR

The DBSS[3:0] bits in the TIMx_DCR register defines the interrupt source that triggers the DMA burst transfers (see *Section 38.6.29: TIMx DMA control register (TIMx_DCR)(x = 1, 8)* for details).

As an example, the timer DMA burst feature is used to update the contents of the CCRx registers (x = 2, 3, 4) upon an update event, with the DMA transferring half words into the CCRx registers.

This is done in the following steps:

1. Configure the corresponding DMA channel as follows:
   – DMA channel peripheral address is the DMAR register address.
   – DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into CCRx registers.
   – Number of data to transfer = 3 (see note below).
   – Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bit fields as follows: DBL = 3 transfers, DBA = 0xE and DBSS = 1.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx.
5. Enable the DMA channel.

This example is for the case where every CCRx register to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer must be 6. Let's take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3 and data6 is transferred to CCR4.

Note: A null value can be written to the reserved registers.

38.3.33 TIM1/TIM8 DMA requests

The TIM1/TIM8 can generate a DMA request, as shown in the table below.

Table 392. DMA request

DMA request signal	DMA request	Enable control bit
tim_upd_dma	Update	UDE
tim_cc1_dma	Capture/compare 1	CC1DE
tim_cc2_dma	Capture/compare 2	CC2DE
tim_cc3_dma	Capture/compare 3	CC3DE
tim_cc4_dma	Capture/compare 4	CC4DE
tim_com_dma	Commutation (COM)	COMDE
tim_trg_dma	Trigger	TDE

38.3.34 Debug mode

When the microcontroller enters debug mode (Cortex-M33 core halted), the TIMx counter can either continue to work normally or stop, depending on DBG_TIMx_STOP configuration bit in DBG module.

The behavior in debug mode can be programmed with a dedicated configuration bit per timer in the Debug support (DBG) module.

For safety purposes, when the counter is stopped, the outputs are disabled (as if the MOE bit was reset). The outputs can either be forced to an inactive state (OSSI bit = 1), or have their control taken over by the GPIO controller (OSSI bit = 0), typically to force a Hi-Z.

For more details, refer to section Debug support (DBG).

38.4 TIM1/TIM8 low-power modes

Table 393. Effect of low-power modes on TIM1/TIM8

Mode	Description
Sleep	No effect, peripheral is active. The interrupts can cause the device to exit from Sleep mode.
Stop	The timer operation is stopped and the register content is kept. No interrupt can be generated.
Standby	The timer is powered-down and must be reinitialized after exiting the Standby mode.

38.5 TIM1/TIM8 interrupts

The TIM1/TIM8 can generate multiple interrupts, as shown in *Table 394*.

Table 394. Interrupt requests

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit from Sleep mode	Exit from Stop and Standby mode
TIM_UP	Update	UIF	UIE	write 0 in UIF	Yes	No
TIM_CC	Capture/compare 1	CC1IF	CC1IE	write 0 in CC1IF	Yes	No
	Capture/compare 2	CC2IF	CC2IE	write 0 in CC2IF	Yes	No

38.6 TIM1/TIM8 registers

Refer to *Section 1.2* for a list of abbreviations used in register descriptions.

38.6.1 TIMx control register 1 (TIMx_CR1)(x = 1, 8)

Address offset: 0x000

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	DITHEN	UIFREMAP	Res.	CKD[1:0]		ARPE	CMS[1:0]		DIR	OPM	URS	UDIS	CEN
			rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **DITHEN**: Dithering enable

0: Dithering disabled
1: Dithering enabled

Note: The DITHEN bit can only be modified when CEN bit is reset.

Bit 11 **UIFREMAP**: UIF status bit remapping

0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division

This bit-field indicates the division ratio between the timer clock (tim_ker_ck) frequency and the dead-time and sampling clock (t_{DTS})used by the dead-time generators and the digital filters (tim_etr_in, tim_tix),

00: $t_{DTS}=t_{tim\_ker\_ck}$
01: $t_{DTS}=2*t_{tim\_ker\_ck}$
10: $t_{DTS}=4*t_{tim\_ker\_ck}$
11: Reserved, do not program this value

Bit 7 **ARPE**: Auto-reload preload enable

0: TIMx_ARR register is not buffered
1: TIMx_ARR register is buffered

Bits 6:5 **CMS[1:0]**: Center-aligned mode selection

00: Edge-aligned mode. The counter counts up or down depending on the direction bit (DIR).
01: Center-aligned mode 1. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set only when the counter is counting down.
10: Center-aligned mode 2. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set only when the counter is counting up.
11: Center-aligned mode 3. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set both when the counter is counting up or down.

Note: It is not allowed to switch from edge-aligned mode to center-aligned mode as long as the counter is enabled (CEN=1)

Bit 4 **DIR**: Direction
0: Counter used as upcounter
1: Counter used as downcounter
Note: This bit is read only when the timer is configured in Center-aligned mode or Encoder mode.

Bit 3 **OPM**: One-pulse mode
0: Counter is not stopped at update event
1: Counter stops counting at the next update event (clearing the bit CEN)

Bit 2 **URS**: Update request source
This bit is set and cleared by software to select the UEV event sources.
0: Any of the following events generate an update interrupt or DMA request if enabled. These events can be:
– Counter overflow/underflow
– Setting the UG bit
– Update generation through the slave mode controller
1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS**: Update disable
This bit is set and cleared by software to enable/disable UEV event generation.
0: UEV enabled. The Update (UEV) event is generated by one of the following events:
– Counter overflow/underflow
– Setting the UG bit
– Update generation through the slave mode controller
Buffered registers are then loaded with their preload values.
1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable
0: Counter disabled
1: Counter enabled
Note: External clock, gated mode and encoder mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.

38.6.2 TIMx control register 2 (TIMx_CR2)(x = 1, 8)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	MMS[3]	Res.	MMS2[3:0]				Res.	OIS6	Res.	OIS5
						rw		rw	rw	rw	rw		rw		rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OIS4N	OIS4	OIS3N	OIS3	OIS2N	OIS2	OIS1N	OIS1	TI1S	MMS[2:0]			CCDS	CCUS	Res.	CCPC
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw

Bits 31:26 Reserved, must be kept at reset value.

Bit 24 Reserved, must be kept at reset value.

Bits 23:20 **MMS2[3:0]**: Master mode selection 2

These bits allow the information to be sent to ADC for synchronization (tim_trgo2) to be selected. The combination is as follows:

0000: **Reset** - the UG bit from the TIMx_EGR register is used as trigger output (tim_trgo2). If the reset is generated by the trigger input (slave mode controller configured in reset mode), the signal on tim_trgo2 is delayed compared to the actual reset.

0001: **Enable** - the Counter Enable signal CNT_EN is used as trigger output (tim_trgo2). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between the CEN control bit and the trigger input when configured in Gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on tim_trgo2, except if the Master/Slave mode is selected (see the MSM bit description in TIMx_SMCR register).

0010: **Update** - the update event is selected as trigger output (tim_trgo2). For instance, a master timer can then be used as a prescaler for a slave timer.

0011: **Compare pulse** - the trigger output sends a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or compare match occurs (tim_trgo2).

0100: **Compare** - tim_oc1refc signal is used as trigger output (tim_trgo2)

0101: **Compare** - tim_oc2refc signal is used as trigger output (tim_trgo2)

0110: **Compare** - tim_oc3refc signal is used as trigger output (tim_trgo2)

0111: **Compare** - tim_oc4refc signal is used as trigger output (tim_trgo2)

1000: **Compare** - tim_oc5refc signal is used as trigger output (tim_trgo2)

1001: **Compare** - tim_oc6refc signal is used as trigger output (tim_trgo2)

1010: **Compare Pulse** - tim_oc4refc rising or falling edges generate pulses on tim_trgo2

1011: **Compare pulse** - tim_oc6refc rising or falling edges generate pulses on tim_trgo2

1100: **Compare pulse** - tim_oc4refc or tim_oc6refc rising edges generate pulses on tim_trgo2

1101: **Compare pulse** - tim_oc4refc rising or tim_oc6refc falling edges generate pulses on tim_trgo2

1110: **Compare pulse** - tim_oc5refc or tim_oc6refc rising edges generate pulses on tim_trgo2

1111: **Compare pulse** - tim_oc5refc rising or tim_oc6refc falling edges generate pulses on tim_trgo2

Note: The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

Bit 19 Reserved, must be kept at reset value.

Bit 18 **OIS6**: Output idle state 6 (tim_oc6 output)
Refer to OIS1 bit

Bit 17 Reserved, must be kept at reset value.

Bit 16 **OIS5**: Output idle state 5 (tim_oc5 output)
Refer to OIS1 bit

Bit 15 **OIS4N**: Output idle state 4 (tim_oc4n output)
Refer to OIS1N bit

Bit 14 **OIS4**: Output idle state 4 (tim_oc4 output)
Refer to OIS1 bit

Bit 13 **OIS3N**: Output idle state 3 (tim_oc3n output)
Refer to OIS1N bit

Bit 12 **OIS3**: Output idle state 3 (tim_oc3n output)
Refer to OIS1 bit

Bit 11 **OIS2N**: Output idle state 2 (tim_oc2n output)
Refer to OIS1N bit

Bit 10 **OIS2**: Output idle state 2 (tim_oc2 output)
Refer to OIS1 bit

Bit 9 **OIS1N**: Output idle state 1 (tim_oc1n output)
0: tim_oc1n=0 after a dead-time when MOE=0
1: tim_oc1n=1 after a dead-time when MOE=0
Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 8 **OIS1**: Output idle state 1 (tim_oc1 output)
0: tim_oc1=0 (after a dead-time) when MOE=0
1: tim_oc1=1 (after a dead-time) when MOE=0
Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 7 **TI1S**: tim_ti1 selection
0: The tim_ti1_in[15:0] multiplexer output is connected to tim_ti1 input
1: tim_ti1_in[15:0], tim_ti2_in[15:0] and tim_ti3_in[15:0] multiplexers outputs are XORed and connected to the tim_ti1 input

Bits 25, 6:4 **MMS[3:0]**: Master mode selection

These bits select the information to be sent in master mode to slave timers for synchronization (tim_trgo). The combination is as follows:

0000: **Reset** - the UG bit from the TIMx_EGR register is used as trigger output (tim_trgo). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on tim_trgo is delayed compared to the actual reset.

0001: **Enable** - the Counter Enable signal CNT_EN is used as trigger output (tim_trgo). It is useful to start several timers at the same time or to control a window in which a slave timer is enable. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on tim_trgo, except if the master/slave mode is selected (see the MSM bit description in TIMx_SMCR register).

0010: **Update** - The update event is selected as trigger output (tim_trgo). For instance a master timer can then be used as a prescaler for a slave timer.

0011: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred. (tim_trgo).

0100: **Compare** - tim_oc1refc signal is used as trigger output (tim_trgo)

0101: **Compare** - tim_oc2refc signal is used as trigger output (tim_trgo)

0110: **Compare** - tim_oc3refc signal is used as trigger output (tim_trgo)

0111: **Compare** - tim_oc4refc signal is used as trigger output (tim_trgo)

1000: **Encoder Clock output** - The encoder clock signal is used as trigger output (tim_trgo). This code is valid for the following SMS[3:0] values: 0001, 0010, 0011, 1010, 1011, 1100, 1101, 1110, 1111. Any other SMS[3:0] code is not allowed and may lead to unexpected behavior.

Other codes reserved

Note: The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

Bit 3 **CCDS**: Capture/compare DMA selection

0: CCx DMA request sent when CCx event occurs

1: CCx DMA requests sent when update event occurs

Bit 2 **CCUS**: Capture/compare control update selection

0: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit only

1: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit or when an rising edge occurs on tim_trgi

Note: This bit acts only on channels that have a complementary output.

Bit 1 Reserved, must be kept at reset value.

Bit 0 **CCPC**: Capture/compare preloaded control

0: CCxE, CCxNE and OCxM bits are not preloaded

1: CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated only when a commutation event (COM) occurs (COMG bit set or rising edge detected on tim_trgi, depending on the CCUS bit).

Note: This bit acts only on channels that have a complementary output.

38.6.3 TIMx slave mode control register (TIMx_SMCR)(x = 1, 8)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	SMSPS	SMSPE	Res.	Res.	TS[4:3]		Res.	Res.	Res.	SMS[3]
						rw	rw			rw	rw				rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ETP	ECE	ETPS[1:0]		ETF[3:0]				MSM	TS[2:0]			OCCS	SMS[2:0]		
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **SMSPS**: SMS preload source

This bit selects whether the events that triggers the SMS[3:0] bitfield transfer from preload to active

0: The transfer is triggered by the Timer's Update event

1: The transfer is triggered by the Index event

Bit 24 **SMSPE**: SMS preload enable

This bit selects whether the SMS[3:0] bitfield is preloaded

0: SMS[3:0] bitfield is not preloaded

1: SMS[3:0] preload is enabled

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **TS[4:3]**: Trigger selection - bit 4:3

Refer to TS[2:0] description - bits 6:4

Bits 19:17 Reserved, must be kept at reset value.

Bit 15 **ETP**: External trigger polarity

This bit selects whether tim_etr_in or tim_$\overline{\text{etr_in}}$ is used for trigger operations

0: tim_etr_in is non-inverted, active at high level or rising edge.

1: tim_etr_in is inverted, active at low level or falling edge.

Bit 14 **ECE**: External clock enable

This bit enables External clock mode 2.

0: External clock mode 2 disabled

1: External clock mode 2 enabled. The counter is clocked by any active edge on the tim_etrf signal.

Note: Setting the ECE bit has the same effect as selecting external clock mode 1 with tim_trgi connected to tim_etrf (SMS=111 and TS=00111).

It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, tim_trgi must not be connected to tim_etrf in this case (TS bits must not be 00111).

If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is tim_etrf.

Bits 13:12 **ETPS[1:0]**: External trigger prescaler

External trigger signal tim_etrp frequency must be at most 1/4 of TIMxCLK frequency. A prescaler can be enabled to reduce tim_etrp frequency. It is useful when inputting fast external clocks on tim_etr_in.

00: Prescaler OFF
01: tim_etr_in frequency divided by 2
10: tim_etr_in frequency divided by 4
11: tim_etr_in frequency divided by 8

Bits 11:8 **ETF[3:0]**: External trigger filter

This bit-field then defines the frequency used to sample tim_etrp signal and the length of the digital filter applied to tim_etrp. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at f_{DTS}
0001: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=2
0010: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=4
0011: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=8
0100: $f_{SAMPLING}=f_{DTS}/2$, N=6
0101: $f_{SAMPLING}=f_{DTS}/2$, N=8
0110: $f_{SAMPLING}=f_{DTS}/4$, N=6
0111: $f_{SAMPLING}=f_{DTS}/4$, N=8
1000: $f_{SAMPLING}=f_{DTS}/8$, N=6
1001: $f_{SAMPLING}=f_{DTS}/8$, N=8
1010: $f_{SAMPLING}=f_{DTS}/16$, N=5
1011: $f_{SAMPLING}=f_{DTS}/16$, N=6
1100: $f_{SAMPLING}=f_{DTS}/16$, N=8
1101: $f_{SAMPLING}=f_{DTS}/32$, N=5
1110: $f_{SAMPLING}=f_{DTS}/32$, N=6
1111: $f_{SAMPLING}=f_{DTS}/32$, N=8

Bit 7 **MSM:** Master/slave mode

0: No action
1: The effect of an event on the trigger input (tim_trgi) is delayed to allow a perfect synchronization between the current timer and its slaves (through tim_trgo). It is useful if we want to synchronize several timers on a single external event.

Bits 6:4 **TS[2:0]:** Trigger selection

This bitfield is combined with TS[4:3] bits.

This bit-field selects the trigger input to be used to synchronize the counter.

00000: Internal Trigger 0 (tim_itr0)
00001: Internal Trigger 1 (tim_itr1)
00010: Internal Trigger 2 (tim_itr2)
00011: Internal Trigger 3 (tim_itr3)
00100: tim_ti1 Edge Detector (tim_ti1f_ed)
00101: Filtered Timer Input 1 (tim_ti1fp1)
00110: Filtered Timer Input 2 (tim_ti2fp2)
00111: External Trigger input (tim_etrf)
01000: Internal Trigger 4 (tim_itr4)
01001: Internal Trigger 5 (tim_itr5)
01010: Internal Trigger 6 (tim_itr6)
01011: Internal Trigger 7 (tim_itr7)
01100: Internal Trigger 8 (tim_itr8)
01101: Internal Trigger 9 (tim_itr9)
01110: Internal Trigger 10 (tim_itr10)
01111: Internal trigger 11 (tim_itr11)
10000: Internal trigger 12 (tim_itr12)
10001: Internal trigger 13 (tim_itr13)
10010: Internal trigger 14 (tim_itr14)
10011: Internal trigger 15 (tim_itr15)
Others: Reserved

See *Table 381: Internal trigger connection* for more details on tim_itrx meaning for each Timer.

Note: These bits must be changed only when they are not used (for example when SMS = 000) to avoid wrong edge detections at the transition.

Bit 3 **OCCS:** OCREF clear selection

This bit is used to select the OCREF clear source.

0: tim_ocref_clr_int is connected to the tim_ocref_clr input
1: tim_ocref_clr_int is connected to tim_etrf

Bits 16, 2:0 **SMS[3:0]:** Slave mode selection

When external signals are selected the active edge of the trigger signal (tim_trgi) is linked to the polarity selected on the external input (see Input Control register and Control Register description.

0000: Slave mode disabled - if CEN = ‘1’ then the prescaler is clocked directly by the internal clock.

0001: Quadrature encoder mode 1, x2 mode- Counter counts up/down on tim_ti1fp1 edge depending on tim_ti2fp2 level.

0010: Quadrature encoder mode 2, x2 mode - Counter counts up/down on tim_ti2fp2 edge depending on tim_ti1fp1 level.

0011: Quadrature encoder mode 3, x4 mode - Counter counts up/down on both tim_ti1fp1 and tim_ti2fp2 edges depending on the level of the other input.

0100: Reset Mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter and generates an update of the registers.

0101: Gated Mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

0110: Trigger Mode - The counter starts at a rising edge of the trigger tim_trgi (but it is not reset). Only the start of the counter is controlled.

0111: External Clock Mode 1 - Rising edges of the selected trigger (tim_trgi) clock the counter.

1000: Combined reset + trigger mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers and starts the counter.

1001: Combined gated + reset mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

1010: Encoder mode: Clock plus direction, x2 mode.

1011: Encoder mode: Clock plus direction, x1 mode, tim_ti2fp2 edge sensitivity is set by CC2P

1100: Encoder mode: Directional Clock, x2 mode.

1101: Encoder mode: Directional Clock, x1 mode, tim_ti1fp1 and tim_ti2fp2 edge sensitivity is set by CC1P and CC2P.

1110: Quadrature encoder mode: x1 mode, counting on tim_ti1fp1 edges only, edge sensitivity is set by CC1P.

1111: Quadrature encoder mode: x1 mode, counting on tim_ti2fp2 edges only, edge sensitivity is set by CC2P.

Note: The gated mode must not be used if tim_ti1f_ed is selected as the trigger input (TS=00100). Indeed, tim_ti1f_ed outputs 1 pulse for each transition on TI1F, whereas the gated mode checks the level of the trigger signal.

Note: The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo or the tim_trgo2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

38.6.4 TIMx DMA/interrupt enable register (TIMx_DIER)(x = 1, 8)

Address offset: 0x00C

Reset value: 0x0000 0000

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **TERRF**: Transition error interrupt flag
This flag is set by hardware when a transition error is detected in encoder mode. It is cleared by software by writing it to ‘0’.
0: No encoder transition error has been detected.
1: An encoder transition error has been detected

Bit 22 **IERRF**: Index error interrupt flag
This flag is set by hardware when an index error is detected. It is cleared by software by writing it to ‘0’.
0: No index error has been detected.
1: An index error has been detected

Bit 21 **DIRF**: Direction change interrupt flag
This flag is set by hardware when the direction changes in encoder mode (DIR bit value in TIMx_CR is changing). It is cleared by software by writing it to ‘0’.
0: No direction change
1: Direction change

Bit 20 **IDXF**: Index interrupt flag
This flag is set by hardware when an index event is detected. It is cleared by software by writing it to ‘0’.
0: No index event occurred.
1: An index event has occurred

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **CC6IF**: Compare 6 interrupt flag
Refer to CC1IF description
Note: Channel 6 can only be configured as output.

Bit 16 **CC5IF**: Compare 5 interrupt flag
Refer to CC1IF description
Note: Channel 5 can only be configured as output.

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **SBIF**: System break interrupt flag
This flag is set by hardware as soon as the system break input goes active. It can be cleared by software if the system break input is not active.
This flag must be reset to re-start PWM operation.
0: No break event occurred.
1: An active level has been detected on the system break input. An interrupt is generated if BIE=1 in the TIMx_DIER register.

Bit 12 **CC4OF**: Capture/compare 4 overcapture flag
Refer to CC1OF description

Bit 11 **CC3OF**: Capture/compare 3 overcapture flag
Refer to CC1OF description

Bit 10 **CC2OF**: Capture/compare 2 overcapture flag
Refer to CC1OF description

Bit 9 **CC1OF**: Capture/compare 1 overcapture flag

This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to ‘0’.

0: No overcapture has been detected.

1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set

Bit 8 **B2IF**: Break 2 interrupt flag

This flag is set by hardware as soon as the break 2 input goes active. It can be cleared by software if the break 2 input is not active.

0: No break event occurred.

1: An active level has been detected on the break 2 input. An interrupt is generated if BIE=1 in the TIMx_DIER register.

Bit 7 **BIF**: Break interrupt flag

This flag is set by hardware as soon as the break input goes active. It can be cleared by software if the break input is not active.

0: No break event occurred.

1: An active level has been detected on the break input. An interrupt is generated if BIE=1 in the TIMx_DIER register.

Bit 6 **TIF**: Trigger interrupt flag

This flag is set by hardware on the TRG trigger event (active edge detected on tim_trgi input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.

0: No trigger event occurred.

1: Trigger interrupt pending.

Bit 5 **COMIF**: COM interrupt flag

This flag is set by hardware on COM event (when capture/compare Control bits - CCxE, CCxNE, OCxM - have been updated). It is cleared by software.

0: No COM event occurred.

1: COM interrupt pending.

Bit 4 **CC4IF**: Capture/compare 4 interrupt flag

Refer to CC1IF description

Bit 3 **CC3IF**: Capture/compare 3 interrupt flag

Refer to CC1IF description

Bit 2 **CC2IF**: Capture/compare 2 interrupt flag
Refer to CC1IF description

Bit 1 **CC1IF**: Capture/compare 1 interrupt flag
This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx_CCR1 register (input capture mode only).
0: No compare match / No input capture occurred
1: A compare match or an input capture occurred
If channel CC1 is configured as output: this flag is set when the content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in downcounting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx_CR1 register for the full description.
If channel CC1 is configured as input: this bit is set when counter value has been captured in TIMx_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCER).

Bit 0 **UIF**: Update interrupt flag
This bit is set by hardware on an update event. It is cleared by software.
0: No update occurred.
1: Update interrupt pending. This bit is set by hardware when the registers are updated:
–At overflow or underflow regarding the repetition counter value (update if repetition counter = 0) and if the UDIS=0 in the TIMx_CR1 register.
–When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS=0 and UDIS=0 in the TIMx_CR1 register.
–When CNT is reinitialized by a trigger event (refer to *Section 38.6.3: TIMx slave mode control register (TIMx_SMCR)(x = 1, 8)*), if URS=0 and UDIS=0 in the TIMx_CR1 register.

38.6.6 TIMx event generation register (TIMx_EGR)(x = 1, 8)

Address offset: 0x014

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	B2G	BG	TG	COMG	CC4G	CC3G	CC2G	CC1G	UG
							w	w	w	w	w	w	w	w	w

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **B2G**: Break 2 generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: A break 2 event is generated. MOE bit is cleared and B2IF flag is set. Related interrupt can occur if enabled.

Bit 7 **BG**: Break generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or DMA transfer can occur if enabled.

Bit 6 **TG**: Trigger generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: The TIF flag is set in TIMx_SR register. Related interrupt or DMA transfer can occur if enabled.

Bit 5 **COMG**: Capture/compare control update generation
This bit can be set by software, it is automatically cleared by hardware
0: No action
1: CCxE, CCxNE and OCxM bits update (providing CCPC bit is set)
Note: This bit acts only on channels having a complementary output.

Bit 4 **CC4G**: Capture/compare 4 generation
Refer to CC1G description

Bit 3 **CC3G**: Capture/compare 3 generation
Refer to CC1G description

Bit 2 **CC2G**: Capture/compare 2 generation
Refer to CC1G description

Bit 1 **CC1G**: Capture/compare 1 generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: A capture/compare event is generated on channel 1:
If channel CC1 is configured as output:
CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.
If channel CC1 is configured as input:
The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation
This bit can be set by software, it is automatically cleared by hardware.
0: No action
1: Reinitialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared if the center-aligned mode is selected or if DIR=0 (upcounting), else it takes the auto-reload value (TIMx_ARR) if DIR=1 (downcounting).

38.6.7 TIMx capture/compare mode register 1 (TIMx_CCMR1) (x = 1, 8)

Address offset: 0x018

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

IC2F[3:0]				IC2PSC[1:0]		CC2S[1:0]		IC1F[3:0]				IC1PSC[1:0]		CC1S[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Input capture mode:

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **IC2F[3:0]**: Input capture 2 filter

Bits 11:10 **IC2PSC[1:0]**: Input capture 2 prescaler

Bits 9:8 **CC2S[1:0]**: Capture/compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output

01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2

10: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1

11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

Note: CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIMx_CCER).

Bits 7:4 **IC1F[3:0]**: Input capture 1 filter

This bit-field defines the frequency used to sample tim_ti1 input and the length of the digital filter applied to tim_ti1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at f_{DTS}
0001: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=2
0010: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=4
0011: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=8
0100: $f_{SAMPLING}=f_{DTS}/2$, N=6
0101: $f_{SAMPLING}=f_{DTS}/2$, N=8
0110: $f_{SAMPLING}=f_{DTS}/4$, N=6
0111: $f_{SAMPLING}=f_{DTS}/4$, N=8
1000: $f_{SAMPLING}=f_{DTS}/8$, N=6
1001: $f_{SAMPLING}=f_{DTS}/8$, N=8
1010: $f_{SAMPLING}=f_{DTS}/16$, N=5
1011: $f_{SAMPLING}=f_{DTS}/16$, N=6
1100: $f_{SAMPLING}=f_{DTS}/16$, N=8
1101: $f_{SAMPLING}=f_{DTS}/32$, N=5
1110: $f_{SAMPLING}=f_{DTS}/32$, N=6
1111: $f_{SAMPLING}=f_{DTS}/32$, N=8

Bits 3:2 **IC1PSC[1:0]**: Input capture 1 prescaler

This bit-field defines the ratio of the prescaler acting on CC1 input (tim_ic1). The prescaler is reset as soon as CC1E='0' (TIMx_CCER register).

00: no prescaler, capture is done each time an edge is detected on the capture input
01: capture is done once every 2 events
10: capture is done once every 4 events
11: capture is done once every 8 events

Bits 1:0 **CC1S[1:0]**: Capture/compare 1 Selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output
01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1
10: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2
11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx_CCER).

38.6.8 TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1)(x = 1, 8)

Address offset: 0x018

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

OC2 CE	OC2M[2:0]			OC2 PE	OC2 FE	CC2S[1:0]		OC1 CE	OC1M[2:0]			OC1 PE	OC1 FE	CC1S[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Output compare mode:

Bits 31:25 Reserved, must be kept at reset value.

Bits 23:17 Reserved, must be kept at reset value.

Bit 15 **OC2CE:** Output compare 2 clear enable

Bits 24, 14:12 **OC2M[3:0]**: Output compare 2 mode

Bit 11 **OC2PE**: Output compare 2 preload enable

Bit 10 **OC2FE**: Output compare 2 fast enable

Bits 9:8 **CC2S[1:0]**: Capture/compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output

01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2

10: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1

11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)

Note: CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIMx_CCER).

Bit 7 **OC1CE:** Output compare 1 clear enable

0: tim_oc1ref is not affected by the tim_ocref_clr_int signal

1: tim_oc1ref is cleared as soon as a High level is detected on tim_ocref_clr_int signal (tim_ocref_clr input or tim_etrf input)

Bits 16, 6:4 **OC1M[3:0]**: Output compare 1 mode

These bits define the behavior of the output reference signal tim_oc1ref from which tim_oc1 and tim_oc1n are derived. tim_oc1ref is active high whereas tim_oc1 and tim_oc1n active level depends on CC1P and CC1NP bits.

0000: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs.This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the ouput keeps the state (active or inactive) it had before entering the frozen state.

0001: Set channel 1 to active level on match. tim_oc1ref signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0010: Set channel 1 to inactive level on match. tim_oc1ref signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0011: Toggle - tim_oc1ref toggles when TIMx_CNT=TIMx_CCR1.

0100: Force inactive level - tim_oc1ref is forced low.

0101: Force active level - tim_oc1ref is forced high.

0110: PWM mode 1 - In upcounting, channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else inactive. In downcounting, channel 1 is inactive (tim_oc1ref=‘0’) as long as TIMx_CNT>TIMx_CCR1 else active (tim_oc1ref=’1’).

0111: PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else active. In downcounting, channel 1 is active as long as TIMx_CNT>TIMx_CCR1 else inactive.

1000: Retrigerrable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1001: Retrigerrable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1010: Reserved,

1011: Reserved,

1100: Combined PWM mode 1 - tim_oc1ref has the same behavior as in PWM mode 1. tim_oc1refc is the logical OR between tim_oc1ref and tim_oc2ref.

1101: Combined PWM mode 2 - tim_oc1ref has the same behavior as in PWM mode 2. tim_oc1refc is the logical AND between tim_oc1ref and tim_oc2ref.

1110: Asymmetric PWM mode 1 - tim_oc1ref has the same behavior as in PWM mode 1. tim_oc1refc outputs tim_oc1ref when the counter is counting up, tim_oc2ref when it is counting down.

1111: Asymmetric PWM mode 2 - tim_oc1ref has the same behavior as in PWM mode 2. tim_oc1refc outputs tim_oc1ref when the counter is counting up, tim_oc2ref when it is counting down.

Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S=’00’ (the channel is configured in output).

Note: In PWM mode, the OCREF level changes when the result of the comparison changes, when the output compare mode switches from “frozen” mode to “PWM” mode and when the output compare mode switches from “force active/inactive” mode to “PWM” mode.

Note: On channels having a complementary output, this bit field is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the OC1M active bits take the new value from the preloaded bits only when a COM event is generated.

Bit 3 **OC1PE**: Output compare 1 preload enable

0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken in account immediately.

1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded in the active register at each update event.

Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00' (the channel is configured in output).

Bit 2 **OC1FE**: Output compare 1 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIMx_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.

0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.

1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1

10: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2

11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx_CCER).

38.6.9 TIMx capture/compare mode register 2 (TIMx_CCMR2) (x = 1, 8)

Address offset: 0x01C

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 3 in input capture mode and channel 4 in output compare mode).

Input capture mode

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **IC4F[3:0]**: Input capture 4 filter

Bits 11:10 **IC4PSC[1:0]**: Input capture 4 prescaler

Bits 9:8 **CC4S[1:0]**: Capture/compare 4 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.
00: CC4 channel is configured as output
01: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti4
10: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti3
11: CC4 channel is configured as input, tim_ic4 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

Note: CC4S bits are writable only when the channel is OFF (CC4E = '0' in TIMx_CCER).

Bits 7:4 **IC3F[3:0]**: Input capture 3 filter

Bits 3:2 **IC3PSC[1:0]**: Input capture 3 prescaler

Bits 1:0 **CC3S[1:0]**: Capture/compare 3 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.
00: CC3 channel is configured as output
01: CC3 channel is configured as input, tim_ic3 is mapped on tim_ti3
10: CC3 channel is configured as input, tim_ic3 is mapped on tim_ti4
11: CC3 channel is configured as input, tim_ic3 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

Note: CC3S bits are writable only when the channel is OFF (CC3E = '0' in TIMx_CCER).

38.6.10 TIMx capture/compare mode register 2 [alternate] (TIMx_CCMR2)(x = 1, 8)

Address offset: 0x01C

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 3 in input capture mode and channel 4 in output compare mode).

Output compare mode

Bits 31:25 Reserved, must be kept at reset value.

Bits 23:17 Reserved, must be kept at reset value.

Bit 15 **OC4CE**: Output compare 4 clear enable

Bits 24, 14:12 **OC4M[3:0]**: Output compare 4 mode
Refer to OC3M[3:0] bit description

Bit 11 **OC4PE**: Output compare 4 preload enable

Bit 10 **OC4FE**: Output compare 4 fast enable

Bits 9:8 **CC4S[1:0]**: Capture/compare 4 selection
This bit-field defines the direction of the channel (input/output) as well as the used input.
00: CC4 channel is configured as output
01: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti4
10: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti3
11: CC4 channel is configured as input, tim_ic4 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)
Note: CC4S bits are writable only when the channel is OFF (CC4E = '0' in TIMx_CCER).

Bit 7 **OC3CE:** Output compare 3 clear enable

Bits 16, 6:4 **OC3M[3:0]**: Output compare 3 mode

These bits define the behavior of the output reference signal tim_oc3ref from which tim_oc3 and tim_oc3n are derived. tim_oc3ref is active high whereas tim_oc3 and tim_oc3n active level depends on CC3P and CC3NP bits.

0000: Frozen - The comparison between the output compare register TIMx_CCR3 and the counter TIMx_CNT has no effect on the outputs.(this mode is used to generate a timing base).

0001: Set channel 3 to active level on match. tim_oc3ref signal is forced high when the counter TIMx_CNT matches the capture/compare register 3 (TIMx_CCR3).

0010: Set channel 3 to inactive level on match. tim_oc3ref signal is forced low when the counter TIMx_CNT matches the capture/compare register 3 (TIMx_CCR3).

0011: Toggle - tim_oc3ref toggles when TIMx_CNT=TIMx_CCR3.

0100: Force inactive level - tim_oc3ref is forced low.

0101: Force active level - tim_oc3ref is forced high.

0110: PWM mode 1 - In upcounting, channel 3 is active as long as TIMx_CNT<TIMx_CCR3 else inactive. In downcounting, channel 3 is inactive (tim_oc3ref=‘0’) as long as TIMx_CNT>TIMx_CCR3 else active (tim_oc3ref=’1’).

0111: PWM mode 2 - In upcounting, channel 3 is inactive as long as TIMx_CNT<TIMx_CCR3 else active. In downcounting, channel 3 is active as long as TIMx_CNT>TIMx_CCR3 else inactive.

1000: Retrigerrable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1001: Retrigerrable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1010: Pulse on compare: a pulse is generated on tim_oc3ref upon CCR3 match event, as per PWPRSC[2:0] and PW[7:0] bitfields programming in TIMxECR.

1011: Direction output. The tim_oc3ref signal is overridden by a copy of the DIR bit.

1100: Combined PWM mode 1 - tim_oc3ref has the same behavior as in PWM mode 1. tim_oc3refc is the logical OR between tim_oc3ref and tim_oc4ref.

1101: Combined PWM mode 2 - tim_oc3ref has the same behavior as in PWM mode 2. tim_oc3refc is the logical AND between tim_oc3ref and tim_oc4ref.

1110: Asymmetric PWM mode 1 - tim_oc3ref has the same behavior as in PWM mode 1. tim_oc3refc outputs tim_oc3ref when the counter is counting up, tim_oc4ref when it is counting down.

1111: Asymmetric PWM mode 2 - tim_oc3ref has the same behavior as in PWM mode 2. tim_oc3refc outputs tim_oc3ref when the counter is counting up, tim_oc4ref when it is counting down.

Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S=’00’ (the channel is configured in output).

Note: In PWM mode, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.

On channels having a complementary output, this bit field is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the OC3M active bits take the new value from the preloaded bits only when a COM event is generated.

Bit 3 **OC3PE**: Output compare 3 preload enable

Bit 2 **OC3FE**: Output compare 3 fast enable

Bits 1:0 **CC3S[1:0]**: Capture/compare 3 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC3 channel is configured as output

01: CC3 channel is configured as input, tim_ic3 is mapped on tim_ti3

10: CC3 channel is configured as input, tim_ic3 is mapped on tim_ti4

11: CC3 channel is configured as input, tim_ic3 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

Note: CC3S bits are writable only when the channel is OFF (CC3E = '0' in TIMx_CCER).

38.6.11 TIMx capture/compare enable register (TIMx_CCER)(x = 1, 8)

Address offset: 0x020

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **CC6P**: Capture/compare 6 output polarity
Refer to CC1P description

Bit 20 **CC6E**: Capture/compare 6 output enable
Refer to CC1E description

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **CC5P**: Capture/compare 5 output polarity
Refer to CC1P description

Bit 16 **CC5E**: Capture/compare 5 output enable
Refer to CC1E description

Bit 15 **CC4NP**: Capture/compare 4 complementary output polarity
Refer to CC1NP description

Bit 14 **CC4NE**: Capture/compare 4 complementary output enable
Refer to CC1NE description

Bit 13 **CC4P**: Capture/compare 4 output polarity
Refer to CC1P description

Bit 12 **CC4E**: Capture/compare 4 output enable
Refer to CC1E description

Bit 11 **CC3NP**: Capture/compare 3 complementary output polarity
Refer to CC1NP description

Bit 10 **CC3NE**: Capture/compare 3 complementary output enable
Refer to CC1NE description

Bit 9 **CC3P**: Capture/compare 3 output polarity
Refer to CC1P description

Bit 8 **CC3E**: Capture/compare 3 output enable
Refer to CC1E description

Bit 7 **CC2NP**: Capture/compare 2 complementary output polarity
Refer to CC1NP description

Bit 6 **CC2NE**: Capture/compare 2 complementary output enable
Refer to CC1NE description

Bit 5 **CC2P**: Capture/compare 2 output polarity
Refer to CC1P description

Bit 4 **CC2E**: Capture/compare 2 output enable
Refer to CC1E description

Bit 3 **CC1NP**: Capture/compare 1 complementary output polarity
CC1 channel configured as output:
0: tim_oc1n active high.
1: tim_oc1n active low.
CC1 channel configured as input:
This bit is used in conjunction with CC1P to define the polarity of tim_ti1fp1 and tim_ti2fp1.
Refer to CC1P description.

Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S="00" (channel configured as output).

Note: On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1NP active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 2 **CC1NE**: Capture/compare 1 complementary output enable
0: Off - tim_oc1n is not active. tim_oc1n level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.
1: On - tim_oc1n signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.

Note: On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1NE active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 1 **CC1P**: Capture/compare 1 output polarity

0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)

1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

When CC1 channel is configured as input, both CC1NP/CC1P bits select the active polarity of TI1FP1 and TI2FP1 for trigger or capture operations.

CC1NP=0, CC1P=0: non-inverted/rising edge. The circuit is sensitive to TIxFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode or encoder mode).

CC1NP=0, CC1P=1: inverted/falling edge. The circuit is sensitive to TIxFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is inverted (trigger operation in gated mode or encoder mode).

CC1NP=1, CC1P=1: non-inverted/both edges/ The circuit is sensitive to both TIxFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), TIxFP1is not inverted (trigger operation in gated mode). This configuration must not be used in encoder mode.

CC1NP=1, CC1P=0: the configuration is reserved, it must not be used.

Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

Note: On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1P active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 0 **CC1E**: Capture/compare 1 output enable

0: Capture mode disabled / OC1 is not active (see below)

1: Capture mode enabled / OC1 signal is output on the corresponding output pin

When CC1 channel is configured as output, the OC1 level depends on MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits, regardless of the CC1E bits state. Refer to *Table 395* for details.

Note: On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1E active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Table 395. Output control bits for complementary tim_ocx and tim_ocxn channels with break feature

Control bits					Output states[1]	
MOE bit	OSSI bit	OSSR bit	CCxE bit	CCxNE bit	tim_ocx output state	tim_ocxn output state
1	X	X	0	0	Output disabled (not driven by the timer: Hi-Z) tim_ocx=0, tim_ocxn=0	
		0	0	1	Output disabled (not driven by the timer: Hi-Z) tim_ocx=0	tim_ocxref + Polarity tim_ocxn = tim_ocxref xor CCxNP
		0	1	0	tim_ocxref + Polarity tim_ocx=tim_ocxref xor CCxP	Output Disabled (not driven by the timer: Hi-Z) tim_ocxn=0
		X	1	1	OCREF + Polarity + dead-time	Complementary to OCREF (not OCREF) + Polarity + dead-time
		1	0	1	Off-State (output enabled with inactive state) tim_ocx=CCxP	tim_ocxref + Polarity tim_ocxn = tim_ocxref x or CCxNP
		1	1	0	tim_ocxref + Polarity tim_ocx=tim_ocxref xor CCxP	Off-State (output enabled with inactive state) tim_ocxn=CCxNP
0	0	X	X	X	Output disabled (not driven by the timer: Hi-Z).	
	1		0	0		
			0	1	Off-State (output enabled with inactive state) Asynchronously: tim_ocx=CCxP, tim_ocxn=CCxNP (if tim_brk or tim_brk2 is triggered). Then (this is valid only if tim_brk is triggered), if the clock is present: tim_ocx=OISx and tim_ocxn=OISxN after a dead-time, assuming that OISx and OISxN do not correspond to OCX and tim_ocxn both in active state (may cause a short circuit when driving switches in half-bridge configuration). *Note: tim_brk2 can only be used if OSSI = OSSR = 1.*	
			1	0		
			1	1		

1. When both outputs of a channel are not used (control taken over by GPIO), the OISx, OISxN, CCxP and CCxNP bits must be kept cleared.

Note: The state of the external I/O pins connected to the complementary tim_ocx and tim_ocxn channels depends on the tim_ocx and tim_ocxn channel state and the GPIO registers.

38.6.12 TIMx counter (TIMx_CNT)(x = 1, 8)

Address offset: 0x024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
UIF CPY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CNT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **UIFCPY**: UIF copy

This bit is a read-only copy of the UIF bit of the TIMx_ISR register. If the UIFREMAP bit in the TIMxCR1 is reset, bit 31 is reserved and read at 0.

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:0 **CNT[15:0]**: Counter value

Non-dithering mode (DITHEN = 0)

The register holds the counter value.

Dithering mode (DITHEN = 1)

The register only holds the non-dithered part in CNT[15:0]. The fractional part is not available.

38.6.13 TIMx prescaler (TIMx_PSC)(x = 1, 8)

Address offset: 0x028

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PSC[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0 **PSC[15:0]**: Prescaler value

The counter clock frequency ($f_{tim\_cnt\_ck}$) is equal to $f_{tim\_psc\_ck}$ / (PSC[15:0] + 1).
PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in “reset mode”).

38.6.14 TIMx auto-reload register (TIMx_ARR)(x = 1, 8)

Address offset: 0x02C

Reset value: 0x0000 FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ARR[19:16]			
												rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ARR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **ARR[19:0]**: Auto-reload value

ARR is the value to be loaded in the actual auto-reload register.

Refer to the *Section 38.3.3: Time-base unit on page 1433* for more details about ARR update and behavior.

The counter is blocked while the auto-reload value is null.

Non-dithering mode (DITHEN = 0)

The register holds the auto-reload value.

Dithering mode (DITHEN = 1)

The register holds the integer part in ARR[19:4]. The ARR[3:0] bitfield contains the dithered part.

38.6.15 TIMx repetition counter register (TIMx_RCR)(x = 1, 8)

Address offset: 0x030

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REP[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0 **REP[15:0]**: Repetition counter reload value

This bitfield defines the update rate of the compare registers (i.e. periodic transfers from preload to active registers) when preload registers are enable. It also defines the update interrupt generation rate, if this interrupt is enable.

When the repetition down-counter reaches zero, an update event is generated and it restarts counting from REP value. As the repetition counter is reloaded with REP value only at the repetition update event UEV, any write to the TIMx_RCR register is not taken in account until the next repetition update event.

It means in PWM mode (REP+1) corresponds to:

– the number of PWM periods in edge-aligned mode

– the number of half PWM period in center-aligned mode.

38.6.16 TIMx capture/compare register 1 (TIMx_CCR1)(x = 1, 8)

Address offset: 0x034

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CCR1[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **CCR1[19:0]**: Capture/compare 1 value

If channel CC1 is configured as output: CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc1 output.

Non-dithering mode (DITHEN = 0)

The register holds the compare value in CCR1[15:0]. The CCR1[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the integer part in CCR1[19:4]. The CCR1[3:0] bitfield contains the dithered part.

If channel CC1 is configured as input: CR1 is the counter value transferred by the last input capture 1 event (tim_ic1). The TIMx_CCR1 register is read-only and cannot be programmed.

Non-dithering mode (DITHEN = 0)

The register holds the capture value in CCR1[15:0]. The CCR1[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the capture in CCR1[19:4]. The CCR1[3:0] bits are reset.

38.6.17 TIMx capture/compare register 2 (TIMx_CCR2)(x = 1, 8)

Address offset: 0x038

Reset value: 0x0000 0000

CCR2[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **CCR2[19:0]**: Capture/compare 2 value

If channel CC2 is configured as output: CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc2 output.

Non-dithering mode (DITHEN = 0)

The register holds the compare value in CCR2[15:0]. The CCR2[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the integer part in CCR2[19:4]. The CCR2[3:0] bitfield contains the dithered part.

If channel CC2 is configured as input: CCR2 is the counter value transferred by the last input capture 2 event (tim_ic2). The TIMx_CCR2 register is read-only and cannot be programmed.

Non-dithering mode (DITHEN = 0)

The register holds the capture value in CCR2[15:0]. The CCR2[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the capture in CCR2[19:4]. The CCR2[3:0] bits are reset.

38.6.18 TIMx capture/compare register 3 (TIMx_CCR3)(x = 1, 8)

Address offset: 0x03C

Reset value: 0x0000 0000

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **CCR3[19:0]**: Capture/compare value

If channel CC3 is configured as output: CCR3 is the value to be loaded in the actual capture/compare 3 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2 register (bit OC3PE). Else the preload value is copied in the active capture/compare 3 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc3 output.
Non-dithering mode (DITHEN = 0)
The register holds the compare value in CCR3[15:0]. The CCR3[19:16] bits are reset.
Dithering mode (DITHEN = 1)
The register holds the integer part in CCR3[19:4]. The CCR3[3:0] bitfield contains the dithered part.
If channel CC3 is configured as input: CCR3 is the counter value transferred by the last input capture 3 event (tim_ic3). The TIMx_CCR3 register is read-only and cannot be programmed.
Non-dithering mode (DITHEN = 0)
The register holds the capture value in CCR3[15:0]. The CCR3[19:16] bits are reset.
Dithering mode (DITHEN = 1)
The register holds the capture in CCR3[19:4]. The CCR3[3:0] bits are reset.

38.6.19 TIMx capture/compare register 4 (TIMx_CCR4)(x = 1, 8)

Address offset: 0x040

Reset value: 0x0000 0000

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **CCR4[19:0]**: Capture/compare value

If channel CC4 is configured as output: CCR4 is the value to be loaded in the actual capture/compare 4 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2 register (bit OC4PE). Else the preload value is copied in the active capture/compare 4 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signalled on tim_oc4 output.

Non-dithering mode (DITHEN = 0)

The register holds the compare value in CCR4[15:0]. The CCR4[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the integer part in CCR4[19:4]. The CCR4[3:0] bitfield contains the dithered part.

If channel CC4 is configured as input: CCR4 is the counter value transferred by the last input capture 4 event (tim_ic4). The TIMx_CCR4 register is read-only and cannot be programmed.

Non-dithering mode (DITHEN = 0)

The register holds the capture value in CCR4[15:0]. The CCR4[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the capture in CCR4[19:4]. The CCR4[3:0] bits are reset.

38.6.20 TIMx break and dead-time register (TIMx_BDTR)(x = 1, 8)

Address offset: 0x044

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	BK2BID	BKBID	BK2 DSRM	BK DSRM	BK2P	BK2E	BK2F[3:0]				BKF[3:0]

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **BK2BID**: Break2 bidirectional

Refer to BKBID description

Bit 28 **BKBID**: Break bidirectional

0: Break input tim_brk in input mode

1: Break input tim_brk in bidirectional mode

In the bidirectional mode (BKBID bit set to 1), the break input is configured both in input mode and in open drain output mode. Any active break event asserts a low logic level on the Break input to indicate an internal break event to external devices.

Note: This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 27 **BK2DSRM**: Break2 disarm

Refer to BKDSRM description

Bit 26 **BKDSRM**: Break disarm

0: Break input tim_brk is armed

1: Break input tim_brk is disarmed

This bit is cleared by hardware when no break source is active.

The BKDSRM bit must be set by software to release the bidirectional output control (open-drain output in Hi-Z state) and then be polled it until it is reset by hardware, indicating that the fault condition has disappeared.

Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 25 **BK2P**: Break 2 polarity

0: Break input tim_brk2 is active low

1: Break input tim_brk2 is active high

Note: This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 24 **BK2E**: Break 2 enable

This bit enables the complete break 2 protection (including all sources connected to bk_acth and BKIN sources, as per *Figure 384: Break and Break2 circuitry overview*).

0: Break2 function disabled

1: Break2 function enabled

Note: The BRKIN2 must only be used with OSSR = OSSI = 1.

Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bits 23:20 **BK2F[3:0]**: Break 2 filter

This bit-field defines the frequency used to sample tim_brk2 input and the length of the digital filter applied to tim_brk2. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, tim_brk2 acts asynchronously
0001: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=2
0010: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=4
0011: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=8
0100: $f_{SAMPLING}=f_{DTS}/2$, N=6
0101: $f_{SAMPLING}=f_{DTS}/2$, N=8
0110: $f_{SAMPLING}=f_{DTS}/4$, N=6
0111: $f_{SAMPLING}=f_{DTS}/4$, N=8
1000: $f_{SAMPLING}=f_{DTS}/8$, N=6
1001: $f_{SAMPLING}=f_{DTS}/8$, N=8
1010: $f_{SAMPLING}=f_{DTS}/16$, N=5
1011: $f_{SAMPLING}=f_{DTS}/16$, N=6
1100: $f_{SAMPLING}=f_{DTS}/16$, N=8
1101: $f_{SAMPLING}=f_{DTS}/32$, N=5
1110: $f_{SAMPLING}=f_{DTS}/32$, N=6
1111: $f_{SAMPLING}=f_{DTS}/32$, N=8

Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 19:16 **BKF[3:0]**: Break filter

This bit-field defines the frequency used to sample tim_brk input and the length of the digital filter applied to tim_brk. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, tim_brk acts asynchronously
0001: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=2
0010: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=4
0011: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=8
0100: $f_{SAMPLING}=f_{DTS}/2$, N=6
0101: $f_{SAMPLING}=f_{DTS}/2$, N=8
0110: $f_{SAMPLING}=f_{DTS}/4$, N=6
0111: $f_{SAMPLING}=f_{DTS}/4$, N=8
1000: $f_{SAMPLING}=f_{DTS}/8$, N=6
1001: $f_{SAMPLING}=f_{DTS}/8$, N=8
1010: $f_{SAMPLING}=f_{DTS}/16$, N=5
1011: $f_{SAMPLING}=f_{DTS}/16$, N=6
1100: $f_{SAMPLING}=f_{DTS}/16$, N=8
1101: $f_{SAMPLING}=f_{DTS}/32$, N=5
1110: $f_{SAMPLING}=f_{DTS}/32$, N=6
1111: $f_{SAMPLING}=f_{DTS}/32$, N=8

Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 15 **MOE**: Main output enable

This bit is cleared asynchronously by hardware as soon as one of the break inputs is active (tim_brk or tim_brk2). It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.

0: In response to a break 2 event. OC and OCN outputs are disabled
In response to a break event or if MOE is written to 0: OC and OCN outputs are disabled or forced to idle state depending on the OSSI bit.

1: OC and OCN outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIMx_CCER register).
See OC/OCN enable description for more details (*Section 38.6.11: TIMx capture/compare enable register (TIMx_CCER)(x = 1, 8)*).

Bit 14 **AOE**: Automatic output enable

0: MOE can be set only by software

1: MOE can be set by software or automatically at the next update event (if none of the break inputs tim_brk and tim_brk2 is active)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 13 **BKP**: Break polarity

0: Break input tim_brk is active low

1: Break input tim_brk is active high

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 12 **BKE**: Break enable

This bit enables the complete break protection (including all sources connected to bk_acth and BKIN sources, as per *Figure 384: Break and Break2 circuitry overview*).

0: Break function disabled

1: Break function enabled

Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 11 **OSSR**: Off-state selection for Run mode

This bit is used when MOE=1 on channels having a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.

See OC/OCN enable description for more details (*Section 38.6.11: TIMx capture/compare enable register (TIMx_CCER)(x = 1, 8)*).

0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO logic, which forces a Hi-Z state).

1: When inactive, OC/OCN outputs are enabled with their inactive level as soon as CCxE=1 or CCxNE=1 (the output is still controlled by the timer).

Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 10 **OSSI**: Off-state selection for idle mode

This bit is used when MOE=0 due to a break event or by a software write, on channels configured as outputs.
See OC/OCN enable description for more details (*Section 38.6.11: TIMx capture/compare enable register (TIMx_CCER)(x = 1, 8)*).

0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO logic and which imposes a Hi-Z state).

1: When inactive, OC/OCN outputs are first forced with their inactive level then forced to their idle level after the deadtime. The timer maintains its control over the output.

Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 9:8 **LOCK[1:0]**: Lock configuration

These bits offer a write protection against software errors.

00: LOCK OFF - No bit is write protected.

01: LOCK Level 1 = DTG bits in TIMx_BDTR register, OISx and OISxN bits in TIMx_CR2 register and BKBID/BK2BID/BKE/BKP/AOE bits in TIMx_BDTR register can no longer be written.

10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIMx_CCER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written.

11: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIMx_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written.

Note: The LOCK bits can be written only once after the reset. Once the TIMx_BDTR register has been written, their content is frozen until the next reset.

Bits 7:0 **DTG[7:0]**: Dead-time generator setup

This bit-field defines the duration of the dead-time inserted between the complementary outputs. DT correspond to this duration.
DTG[7:5]=0xx => DT=DTG[7:0]x t_{dtg} with $t_{dtg}=t_{DTS}$.
DTG[7:5]=10x => DT=(64+DTG[5:0])xt_{dtg} with $T_{dtg}=2xt_{DTS}$.
DTG[7:5]=110 => DT=(32+DTG[4:0])xt_{dtg} with $T_{dtg}=8xt_{DTS}$.
DTG[7:5]=111 => DT=(32+DTG[4:0])xt_{dtg} with $T_{dtg}=16xt_{DTS}$.
Example if T_{DTS}=125ns (8MHz), dead-time possible values are:
0 to 15875 ns by 125 ns steps,
16 us to 31750 ns by 250 ns steps,
32 us to 63us by 1 us steps,
64 us to 126 us by 2 us steps

Note: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

38.6.21 TIMx capture/compare register 5 (TIMx_CCR5)(x = 1, 8)

Address offset: 0x048

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CCR5[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **GC5C3**: Group channel 5 and channel 3
Distortion on channel 3 output:
0: No effect of tim_oc5ref on tim_oc3refc
1: tim_oc3refc is the logical AND of tim_oc3ref and tim_oc5ref
This bit can either have immediate effect or be preloaded and taken into account after an update event (if preload feature is selected in TIMxCCMR2).
Note: it is also possible to apply this distortion on combined PWM signals.

Bit 30 **GC5C2**: Group channel 5 and channel 2
Distortion on channel 2 output:
0: No effect of tim_oc5ref on tim_oc2refc
1: tim_oc2refc is the logical AND of tim_oc2ref and tim_oc5ref
This bit can either have immediate effect or be preloaded and taken into account after an update event (if preload feature is selected in TIMxCCMR1).
Note: it is also possible to apply this distortion on combined PWM signals.

Bit 29 **GC5C1**: Group channel 5 and channel 1
Distortion on channel 1 output:
0: No effect of oc5ref on oc1refc
1: oc1refc is the logical AND of oc1ref and oc5ref
This bit can either have immediate effect or be preloaded and taken into account after an update event (if preload feature is selected in TIMxCCMR1).
Note: it is also possible to apply this distortion on combined PWM signals.

Bits 28:20 Reserved, must be kept at reset value.

Bits 19:0 **CCR5[19:0]**: Capture/compare 5 value
CCR5 is the value to be loaded in the actual capture/compare 5 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR3 register (bit OC5PE). Else the preload value is copied in the active capture/compare 5 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc5 output.
Non-dithering mode (DITHEN = 0)
The register holds the compare value in CCR5[15:0]. The CCR5[19:16] bits are reset.
Dithering mode (DITHEN = 1)
The register holds the integer part in CCR5[19:4]. The CCR5[3:0] bitfield contains the dithered part.

38.6.22 TIMx capture/compare register 6 (TIMx_CCR6)(x = 1, 8)

Address offset: 0x04C

Reset value: 0x0000 0000

CCR6[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **CCR6[19:0]**: Capture/compare 6 value

CCR6 is the value to be loaded in the actual capture/compare 6 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR3 register (bit OC6PE). Else the preload value is copied in the active capture/compare 6 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc6 output.
Non-dithering mode (DITHEN = 0)
The register holds the compare value in CCR6[15:0]. The CCR6[19:16] bits are reset.
Dithering mode (DITHEN = 1)
The register holds the integer part in CCR6[19:4]. The CCR6[3:0] bitfield contains the dithered part.

38.6.23 TIMx capture/compare mode register 3 (TIMx_CCMR3) (x = 1, 8)

Address offset: 0x050

Reset value: 0x0000 0000

Refer to the above CCMR1 register description. Channels 5 and 6 can only be configured in output.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DTGF[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **DTPE**: Deadtime preload enable

0: Deadtime value is not preloaded

1: Deadtime value preload is enabled

Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 16 **DTAE**: Deadtime asymmetric enable

0: Deadtime on rising and falling edges are identical, and defined with DTG[7:0] register

1: Deadtime on rising edge is defined with DTG[7:0] register and deadtime on falling edge is defined with DTGF[7:0] bits.

Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **DTGF[7:0]**: Dead-time falling edge generator setup

This bit-field defines the duration of the dead-time inserted between the complementary outputs, on the falling edge.

DTGF[7:5]=0xx => DTF=DTGF[7:0]x t_{dtg} with $t_{dtg}=t_{DTS}$.

DTGF[7:5]=10x => DTF=(64+DTGF[5:0])xt_{dtg} with $T_{dtg}=2xt_{DTS}$.

DTGF[7:5]=110 => DTF=(32+DTGF[4:0])xt_{dtg} with $T_{dtg}=8xt_{DTS}$.

DTGF[7:5]=111 => DTF=(32+DTGF[4:0])xt_{dtg} with $T_{dtg}=16xt_{DTS}$.

Example if T_{DTS}=125ns (8MHz), dead-time possible values are:

0 to 15875 ns by 125 ns steps,

16 us to 31750 ns by 250 ns steps,

32 us to 63us by 1 us steps,

64 us to 126 us by 2 us steps

Note: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

38.6.25 TIMx timer encoder control register (TIMx_ECR)(x = 1, 8)

Address offset: 0x058

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	PWPRSC[2:0]			PW[7:0]							
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IPOS[1:0]		FIDX	IBLK[1:0]		IDIR[1:0]		IE
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:24 **PWPRSC[2:0]**: Pulse width prescaler

This bitfield sets the clock prescaler for the pulse generator, as following:

$t_{PWG} = (2^{(PWPRSC[2:0])}) \times t_{tim\_ker\_ck}$

Bits 23:16 **PW[7:0]**: Pulse width

This bitfield defines the pulse duration, as following:

$t_{PW} = PW[7:0] \times t_{PWG}$

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:6 **IPOS[1:0]**: Index positioning

In quadrature encoder mode (SMS[3:0] = 0001, 0010, 0011, 1110, 1111), this bit indicates in which AB input configuration the Index event resets the counter.

00: Index resets the counter when AB = 00
01: Index resets the counter when AB = 01
10: Index resets the counter when AB = 10
11: Index resets the counter when AB = 11

In directional clock mode or clock plus direction mode (SMS[3:0] = 1010, 1011, 1100, 1101), these bits indicates on which level the Index event resets the counter. In bidirectional clock mode, this applies for both clock inputs.

x0: Index resets the counter when clock is 0
x1: Index resets the counter when clock is 1

Note: IPOS[1] bit is not significant

Bit 5 **FIDX**: First index

This bit indicates if the first index only is taken into account

0: Index is always active
1: the first Index only resets the counter

Bits 4:3 **IBLK[1:0]**: Index blanking
This bit indicates if the Index event is conditioned by the tim_ti3 or tim_ti4 input
00: Index always active
01: Index disabled when tim_ti3 input is active, as per CC3P bitfield
10: Index disabled when tim_ti4 input is active, as per CC4P bitfield
11: Reserved

Bits 2:1 **IDIR[1:0]**: Index direction
This bit indicates in which direction the Index event resets the counter.
00: Index resets the counter whatever the direction
01: Index resets the counter when up-counting only
10: Index resets the counter when down-counting only
11: Reserved

Bit 0 **IE**: Index enable
This bit indicates if the Index event resets the counter.
0: Index disabled
1: Index enabled

38.6.26 TIMx timer input selection register (TIMx_TISEL)(x = 1, 8)

Address offset: 0x05C

Reset value: 0x0000 0000

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:18 Reserved, must be kept at reset value.

Bits 17:14 **ETRSEL[3:0]**: etr_in source selection
These bits select the etr_in input source.
0000: tim_etr0: TIMx_ETR input
0001: tim_etr1
...
1111: tim_etr15
Refer to *Section 38.3.2: TIM1/TIM8 pins and internal signals* for product specific implementation.

Note: These bits can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 13 **BKCMP4P**: tim_brk_cmp4 input polarity
This bit selects the tim_brk_cmp4 input sensitivity. It must be programmed together with the BKP polarity bit.
0: tim_brk_cmp4 input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)
1: tim_brk_cmp4 input polarity is inverted (active high if BKP = 0, active low if BKP = 1)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 12 **BKCMP3P**: tim_brk_cmp3 input polarity

This bit selects the tim_brk_cmp3 input sensitivity. It must be programmed together with the BKP polarity bit.

0: tim_brk_cmp3 input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)

1: tim_brk_cmp3 input polarity is inverted (active high if BKP = 0, active low if BKP = 1)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 11 **BKCMP2P**: tim_brk_cmp2 input polarity

This bit selects the tim_brk_cmp2 input sensitivity. It must be programmed together with the BKP polarity bit.

0: tim_brk_cmp2 input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)

1: tim_brk_cmp2 input polarity is inverted (active high if BKP = 0, active low if BKP = 1)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 10 **BKCMP1P**: tim_brk_cmp1 input polarity

This bit selects the tim_brk_cmp1 input sensitivity. It must be programmed together with the BKP polarity bit.

0: tim_brk_cmp1 input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)

1: tim_brk_cmp1 input polarity is inverted (active high if BKP = 0, active low if BKP = 1)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 9 **BKINP**: TIMx_BKIN input polarity

This bit selects the TIMx_BKIN alternate function input sensitivity. It must be programmed together with the BKP polarity bit.

0: TIMx_BKIN input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)

1: TIMx_BKIN input polarity is inverted (active high if BKP = 0, active low if BKP = 1)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 8 **BKCMP8E**: tim_brk_cmp8 enable

This bit enables the tim_brk_cmp8 for the timer's tim_brk input. tim_brk_cmp8 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp8 input disabled

1: tim_brk_cmp8 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 7 **BKCMP7E**: tim_brk_cmp7 enable

This bit enables the tim_brk_cmp7 for the timer's tim_brk input. tim_brk_cmp7 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp7 input disabled

1: tim_brk_cmp7 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 6 **BKCMP6E**: tim_brk_cmp6 enable

This bit enables the tim_brk_cmp6 for the timer's tim_brk input. tim_brk_cmp6 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp6 input disabled

1: tim_brk_cmp6 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 5 **BKCMP5E**: tim_brk_cmp5 enable

This bit enables the tim_brk_cmp5 for the timer's tim_brk input. tim_brk_cmp5 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp5 input disabled

1: tim_brk_cmp5 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 4 **BKCMP4E**: tim_brk_cmp4 enable

This bit enables the tim_brk_cmp4 for the timer's tim_brk input. tim_brk_cmp4 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp4 input disabled

1: tim_brk_cmp4 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 3 **BKCMP3E**: tim_brk_cmp3 enable

This bit enables the tim_brk_cmp3 for the timer's tim_brk input. tim_brk_cmp3 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp3 input disabled

1: tim_brk_cmp3 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 2 **BKCMP2E**: tim_brk_cmp2 enable

This bit enables the tim_brk_cmp2 for the timer's tim_brk input. tim_brk_cmp2 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp2 input disabled

1: tim_brk_cmp2 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 1 **BKCMP1E**: tim_brk_cmp1 enable

This bit enables the tim_brk_cmp1 for the timer's tim_brk input. tim_brk_cmp1 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp1 input disabled

1: tim_brk_cmp1 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 0 **BKINE**: TIMx_BKIN input enable

This bit enables the TIMx_BKIN alternate function input for the timer's tim_brk input. TIMx_BKIN input is 'ORed' with the other tim_brk sources.

0: TIMx_BKIN input disabled

1: TIMx_BKIN input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Note: Refer to Section 38.3.2: TIM1/TIM8 pins and internal signals for product specific implementation.

38.6.28 TIMx alternate function register 2 (TIMx_AF2)(x = 1, 8)

Address offset: 0x064

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	BK2CMP4P	BK2CMP3P	BK2CMP2P	BK2CMP1P	BK2INP	BK2CMP8E	BK2CMP7E	BK2CMP6E	BK2CMP5E	BK2CMP4E	BK2CMP3E	BK2CMP2E	BK2CMP1E	BK2INE
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **OCRSEL[2:0]**: ocref_clr source selection

These bits select the ocref_clr input source.

000: tim_ocref_clr0

001: tim_ocref_clr1

...

111: tim_ocref_clr7

Refer to *Section 38.3.2: TIM1/TIM8 pins and internal signals* for product specific information.

Note: These bits can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **BK2CMP4P**: tim_brk2_cmp4 input polarity

This bit selects the tim_brk2_cmp4 input sensitivity. It must be programmed together with the BK2P polarity bit.

0: tim_brk2_cmp4 input polarity is not inverted (active low if BK2P = 0, active high if BK2P = 1)

1: tim_brk2_cmp4 input polarity is inverted (active high if BK2P = 0, active low if BK2P = 1)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 12 **BK2CMP3P**: tim_brk2_cmp3 input polarity

This bit selects the tim_brk2_cmp3 input sensitivity. It must be programmed together with the BK2P polarity bit.

0: tim_brk2_cmp3 input polarity is not inverted (active low if BK2P = 0, active high if BK2P = 1)

1: tim_brk2_cmp3 input polarity is inverted (active high if BK2P = 0, active low if BK2P = 1)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 11 **BK2CMP2P**: tim_brk2_cmp2 input polarity

This bit selects the tim_brk2_cmp2 input sensitivity. It must be programmed together with the BK2P polarity bit.

0: tim_brk2_cmp2 input polarity is not inverted (active low if BK2P = 0, active high if BK2P = 1)

1: tim_brk2_cmp2 input polarity is inverted (active high if BK2P = 0, active low if BK2P = 1)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 10 **BK2CMP1P**: tim_brk2_cmp1 input polarity

This bit selects the tim_brk2_cmp1 input sensitivity. It must be programmed together with the BK2P polarity bit.

0: tim_brk2_cmp1 input polarity is not inverted (active low if BK2P = 0, active high if BK2P = 1)

1: tim_brk2_cmp1 input polarity is inverted (active high if BK2P = 0, active low if BK2P = 1)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 9 **BK2INP**: TIMx_BKIN2 input polarity

This bit selects the TIMx_BKIN2 alternate function input sensitivity. It must be programmed together with the BK2P polarity bit.

0: TIMx_BKIN2 input polarity is not inverted (active low if BK2P = 0, active high if BK2P = 1)

1: TIMx_BKIN2 input polarity is inverted (active high if BK2P = 0, active low if BK2P = 1)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 8 **BK2CMP8E**: tim_brk2_cmp8 enable

This bit enables the tim_brk2_cmp8 for the timer's tim_brk2 input. tim_brk2_cmp8 output is 'ORed' with the other tim_brk2 sources.

0: tim_brk2_cmp8 input disabled

1: tim_brk2_cmp8 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 7 **BK2CMP7E**: tim_brk2_cmp7 enable

This bit enables the tim_brk2_cmp7 for the timer's tim_brk2 input. tim_brk2_cmp7 output is 'ORed' with the other tim_brk2 sources.

0: tim_brk2_cmp7 input disabled

1: tim_brk2_cmp7 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 6 **BK2CMP6E**: tim_brk2_cmp6 enable

This bit enables the tim_brk2_cmp6 for the timer's tim_brk2 input. tim_brk2_cmp6 output is 'ORed' with the other tim_brk2 sources.

0: tim_brk2_cmp6 input disabled

1: tim_brk2_cmp6 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 5 **BK2CMP5E**: tim_brk2_cmp5 enable

This bit enables the tim_brk2_cmp5 for the timer's tim_brk2 input. tim_brk2_cmp5 output is 'ORed' with the other tim_brk2 sources.

0: tim_brk2_cmp5 input disabled

1: tim_brk2_cmp5 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 4 **BK2CMP4E**: tim_brk2_cmp4 enable

This bit enables the tim_brk2_cmp4 for the timer's tim_brk2 input. tim_brk2_cmp4 output is 'ORed' with the other tim_brk2 sources.

0: tim_brk2_cmp4 input disabled

1: tim_brk2_cmp4 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 3 **BK2CMP3E**: tim_brk2_cmp3 enable

This bit enables the tim_brk2_cmp3 for the timer's tim_brk2 input. tim_brk2_cmp3 output is 'ORed' with the other tim_brk2 sources.

0: tim_brk2_cmp3 input disabled

1: tim_brk2_cmp3 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 2 **BK2CMP2E**: tim_brk2_cmp2 enable

This bit enables the tim_brk2_cmp2 for the timer's tim_brk2 input. tim_brk2_cmp2 output is 'ORed' with the other tim_brk2 sources.

0: tim_brk2_cmp2 input disabled

1: tim_brk2_cmp2 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 1 **BK2CMP1E**: tim_brk2_cmp1 enable

This bit enables the tim_brk2_cmp1 for the timer's tim_brk2 input. tim_brk2_cmp1 output is 'ORed' with the other tim_brk2 sources.

0: tim_brk2_cmp1 input disabled

1: tim_brk2_cmp1 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 0 **BK2INE**: TIMx_BKIN2 input enable

This bit enables the TIMx_BKIN2 alternate function input for the timer's tim_brk2 input. TIMx_BKIN2 input is 'ORed' with the other tim_brk2 sources.

0: TIMx_BKIN2 input disabled

1: TIMx_BKIN2 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Note: Refer to Section 38.3.2: TIM1/TIM8 pins and internal signals for product specific implementation.

38.6.29 TIMx DMA control register (TIMx_DCR)(x = 1, 8)

Address offset: 0x3DC

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DBSS[3:0]			
												rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	DBL[4:0]					Res.	Res.	Res.	DBA[4:0]				
			rw	rw	rw	rw	rw				rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:16 **DBSS[3:0]**: DMA burst source selection

This bitfield defines the interrupt source that triggers the DMA burst transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address).

0000: Reserved
0001: Update
0010: CC1
0011: CC2
0100: CC3
0101: CC4
0110: COM
0111: Trigger
Others: reserved

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **DBL[4:0]**: DMA burst length

This 5-bit vector defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e. the number of transfers. Transfers can be in half-words or in bytes (see example below).

00000: 1 transfer
00001: 2 transfers
00010: 3 transfers
...
11010: 26 transfers

Example: Let us consider the following transfer: DBL = 7 bytes & DBA = TIM2_CR1.

–If DBL = 7 bytes and DBA = TIM2_CR1 represents the address of the byte to be transferred, the address of the transfer is given by the following equation:

(TIMx_CR1 address) + DBA + (DMA index), where DMA index = DBL

In this example, 7 bytes are added to (TIMx_CR1 address) + DBA, which gives us the address from/to which the data are copied. In this case, the transfer is done to 7 registers starting from the following address: (TIMx_CR1 address) + DBA

According to the configuration of the DMA Data Size, several cases may occur:

–If the DMA Data Size is configured in half-words, 16-bit data are transferred to each of the 7 registers.

–If the DMA Data Size is configured in bytes, the data are also transferred to 7 registers: the first register contains the first MSB byte, the second register, the first LSB byte and so on. So with the transfer Timer, one also has to specify the size of data transferred by DMA.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DBA[4:0]**: DMA base address

This 5-bits vector defines the base-address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.

Example:

00000: TIMx_CR1
00001: TIMx_CR2
00010: TIMx_SMCR
...

38.6.30 TIMx DMA address for full transfer (TIMx_DMAR)(x = 1, 8)

Address offset: 0x3E0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DMAB[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DMAB[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DMAB[31:0]**: DMA register for burst accesses

A read or write operation to the DMAR register accesses the register located at the address (TIMx_CR1 address) + (DBA + DMA index) x 4

where TIMx_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIMx_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx_DCR).

38.6.31 TIMx register map

TIMx registers are mapped as 16-bit addressable registers as described in the table below:

Table 396. TIMx register map and reset values

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

39 General-purpose timers (TIM2/TIM3/TIM4/TIM5)

39.1 TIM2/TIM3/TIM4/TIM5 introduction

The general-purpose timers consist of a 16-bit or 32-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (*input capture*) or generating output waveforms (*output compare and PWM*).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The timers are completely independent, and do not share any resources. They can be synchronized together as described in *Section 39.4.23: Timer synchronization*.

39.2 TIM2/TIM3/TIM4/TIM5 main features

General-purpose TIMx timer features include:

- 16-bit or 32-bit up, down, up/down auto-reload counter.
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535.
- Up to 4 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (Edge- and Center-aligned modes)
  - One-pulse mode output
- Synchronization circuit to control the timer with external signals and to interconnect several timers.
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
- Supports incremental (quadrature) encoder and hall-sensor circuitry for positioning purposes
- Trigger input for external clock or cycle-by-cycle current management

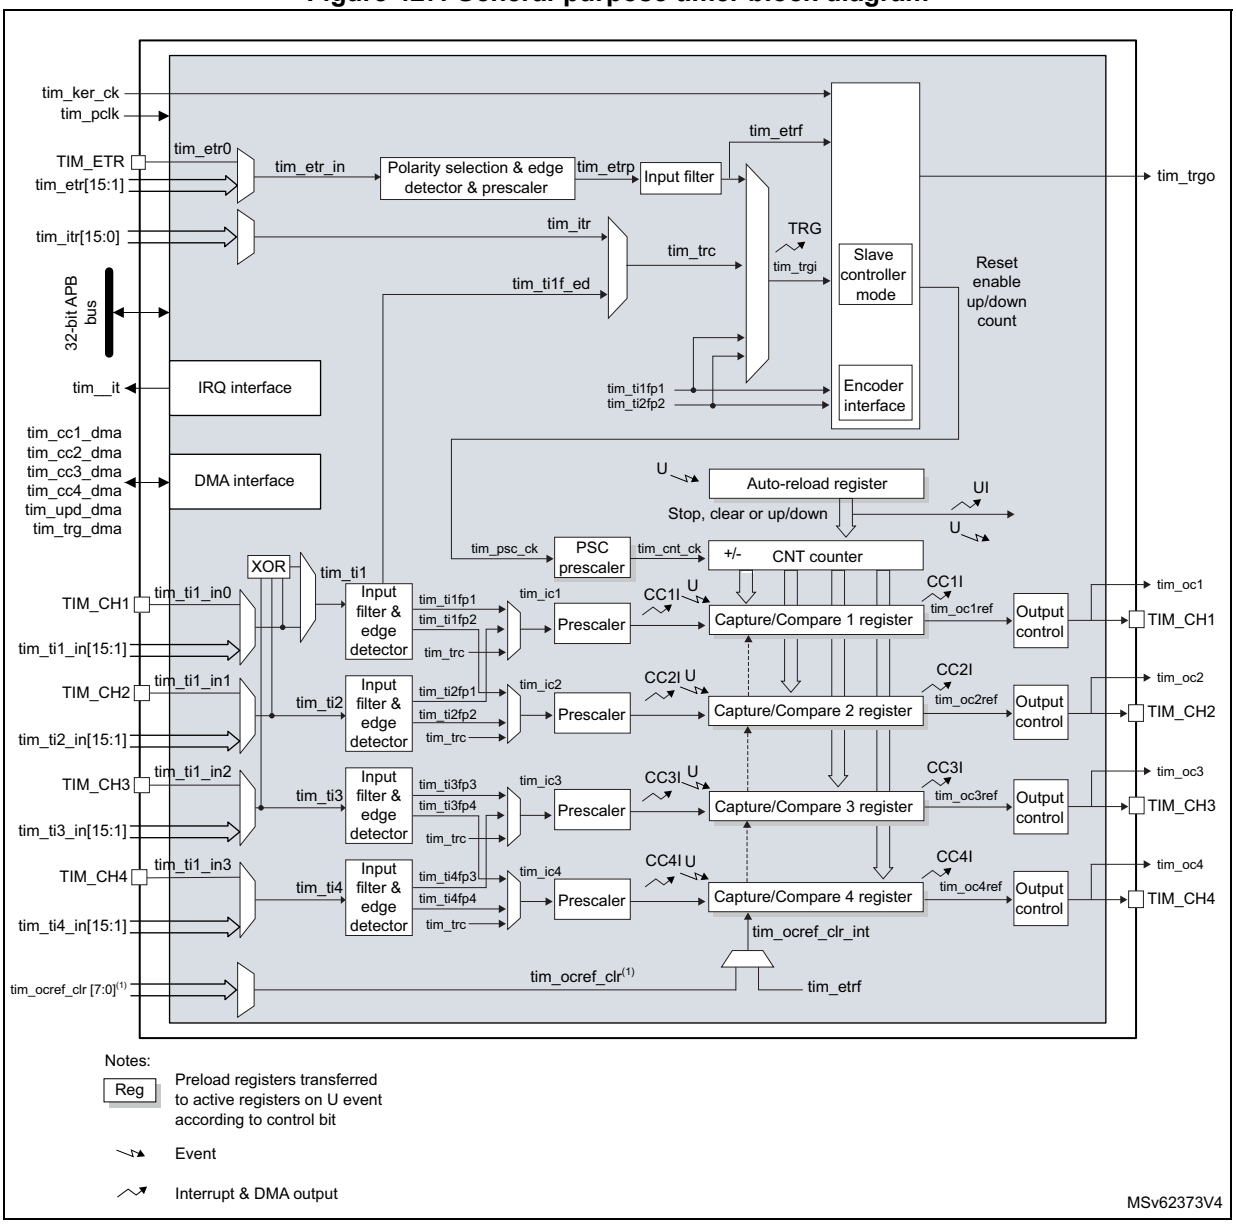
39.4.1 Block diagram

Figure 427. General-purpose timer block diagram



1. This feature is not available on all timers, refer to the *Section 39.3: TIM2/TIM3/TIM4/TIM5 implementation*.

39.4.2 TIM2/TIM3/TIM4/TIM5 pins and internal signals

Table 398 and *Table 399* in this section summarize the TIM inputs and outputs.

Table 398. TIM input/output pins

Pin name	Signal type	Description
TIM_CH1 TIM_CH2 TIM_CH3 TIM_CH4	Input/Output	Timer multi-purpose channels. Each channel be used for capture, compare, or PWM. TIM_CH1 and TIM_CH2 can also be used as external clock (below 1/4 of the tim_ker_ck clock) , external trigger and quadrature encoder inputs. TIM_CH1, TIM_CH2 and TIM_CH3 can be used to interface with digital hall effect sensors.
TIM_ETR	Input	External trigger input. This input can be used as external trigger or as external clock source. This input can receive a clock with a frequency higher than the tim_ker_ck if the tim_etr_in prescaler is used.

Table 399. TIM internal input/output signals

Internal signal name	Signal type	Description
tim_ti1_in[15:0] tim_ti2_in[15:0] tim_ti3_in[15:0] tim_ti4_in[15:0]	Input	Internal timer inputs bus. The tim_ti1_in[15:0] and tim_ti2_in[15:0] inputs can be used for capture or as external clock (below 1/4 of the tim_ker_ck clock) and for quadrature encoder signals.
tim_etr[15:0]	Input	External trigger internal input bus. These inputs can be used as trigger, external clock or for hardware cycle-by-cycle pulse width control. These inputs can receive clock with a frequency higher than the tim_ker_ck if the tim_etr_in prescaler is used.
tim_itr[15:0]	Input	Internal trigger input bus. These inputs can be used for the slave mode controller or as a input clock (below 1/4 of the tim_ker_ck clock).
tim_trgo	Output	Internal trigger output. This trigger can trigger other on-chip peripherals.
tim_ocref_clr[7:0]	Input	Timer tim_ocref_clr input bus. These inputs can be used to clear the tim_ocxref signals, typically for hardware cycle-by-cycle pulse width control.
tim_pclk	Input	Timer APB clock.
tim_ker_ck	Input	Timer kernel clock

Table 399. TIM internal input/output signals (continued)

Internal signal name	Signal type	Description
tim_it	Output	Global Timer interrupt, gathering capture/compare, update and break trigger requests.
tim_cc1_dma tim_cc2_dma tim_cc3_dma tim_cc4_dma	Output	Timer capture / compare 1..4 dma requests.
tim_upd_dma	Output	Timer update dma request.
tim_trg_dma	Output	Timer trigger dma request.

Table 400, *Table 401*, *Table 402* and *Table 403* are listing the sources connected to the tim_ti[4:1] input multiplexers.

39.4.3 Time-base unit

The main block of the programmable timer is a 16-bit/32-bit counter with its related auto-reload register. The counter can count up, down or both up and down. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter Register (TIMx_CNT)
- Prescaler Register (TIMx_PSC):
- Auto-Reload Register (TIMx_ARR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.

The counter is clocked by the prescaler output tim_cnt_ck, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the actual counter enable signal CNT_EN is set 1 clock cycle after CEN.

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit/32-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

Figure 428 and *Figure 429* give some examples of the counter behavior when the prescaler ratio is changed on the fly:

Figure 428. Counter timing diagram with prescaler division change from 1 to 2

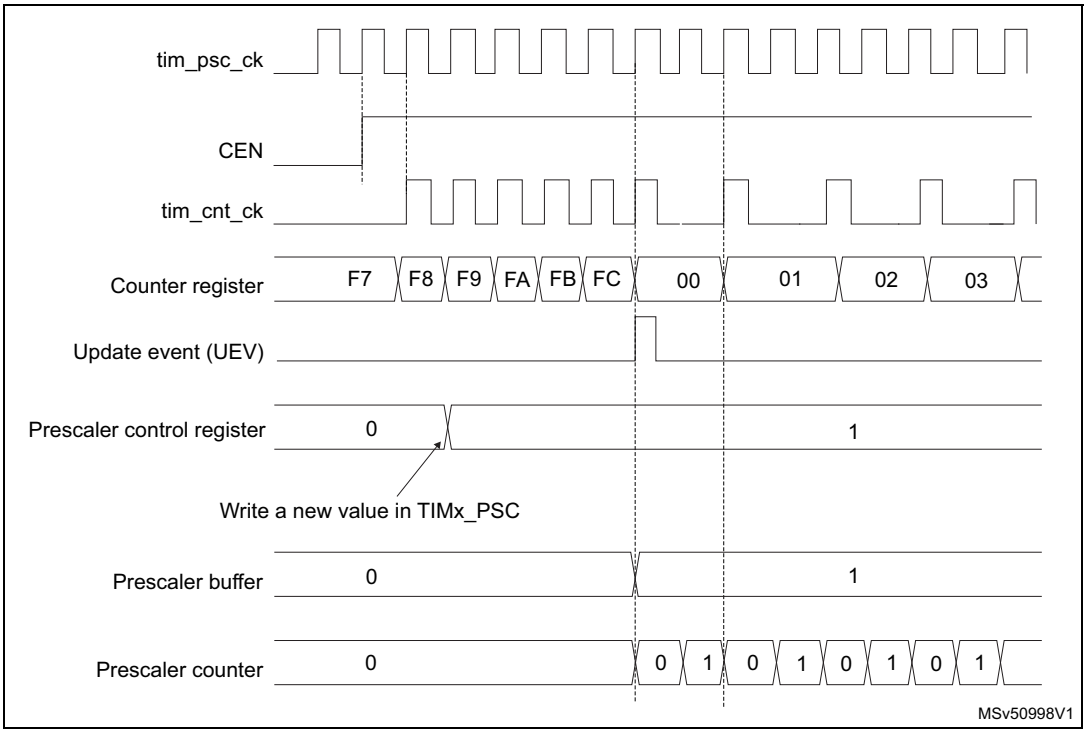

Figure 429. Counter timing diagram with prescaler division change from 1 to 4

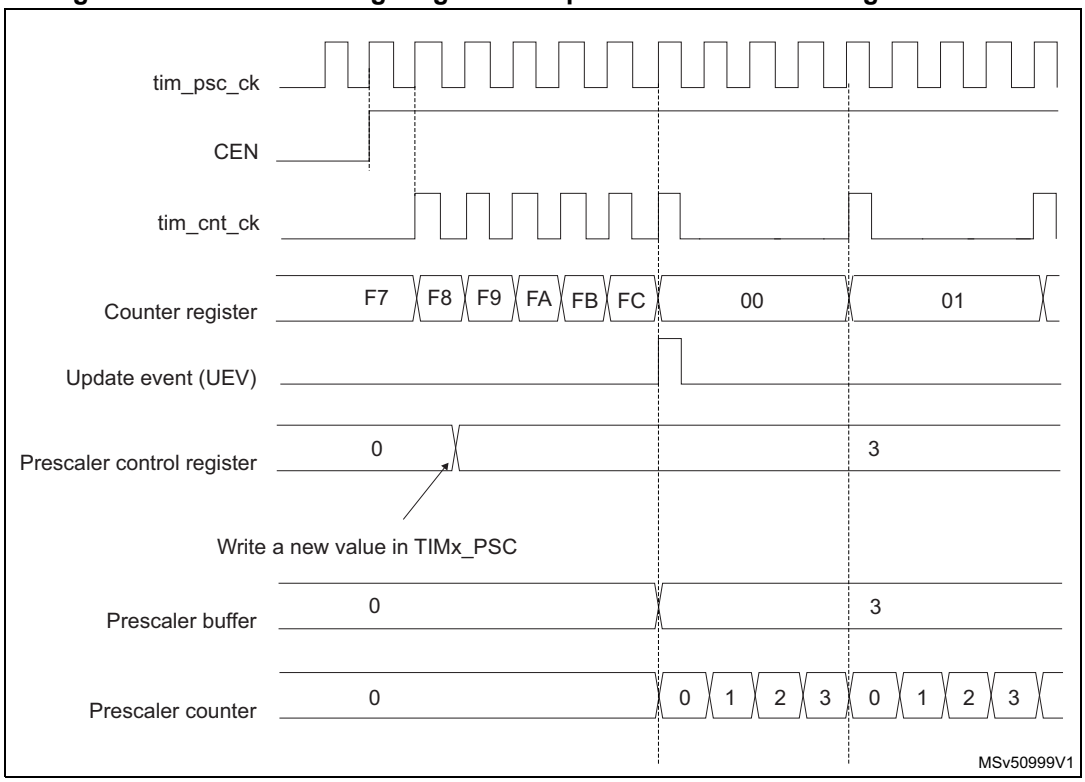

39.4.4 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

An Update event can be generated at each counter overflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register)
- The auto-reload shadow register is updated with the preload value (TIMx_ARR)

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

Figure 430. Counter timing diagram, internal clock divided by 1

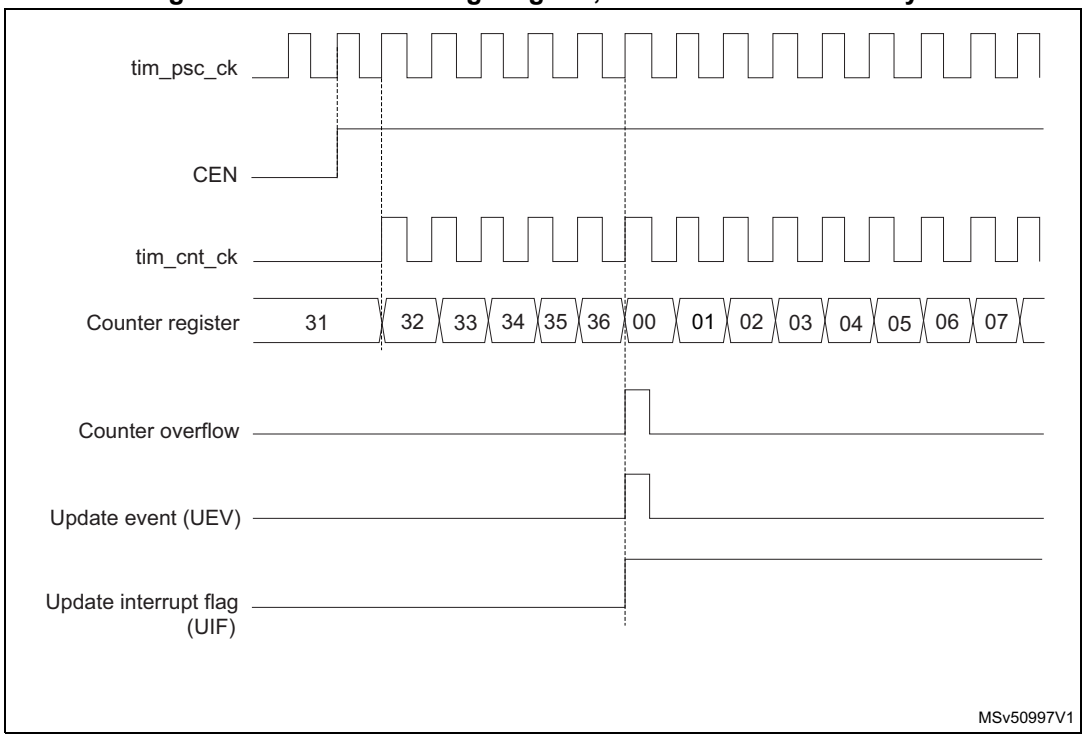

Figure 431. Counter timing diagram, internal clock divided by 2

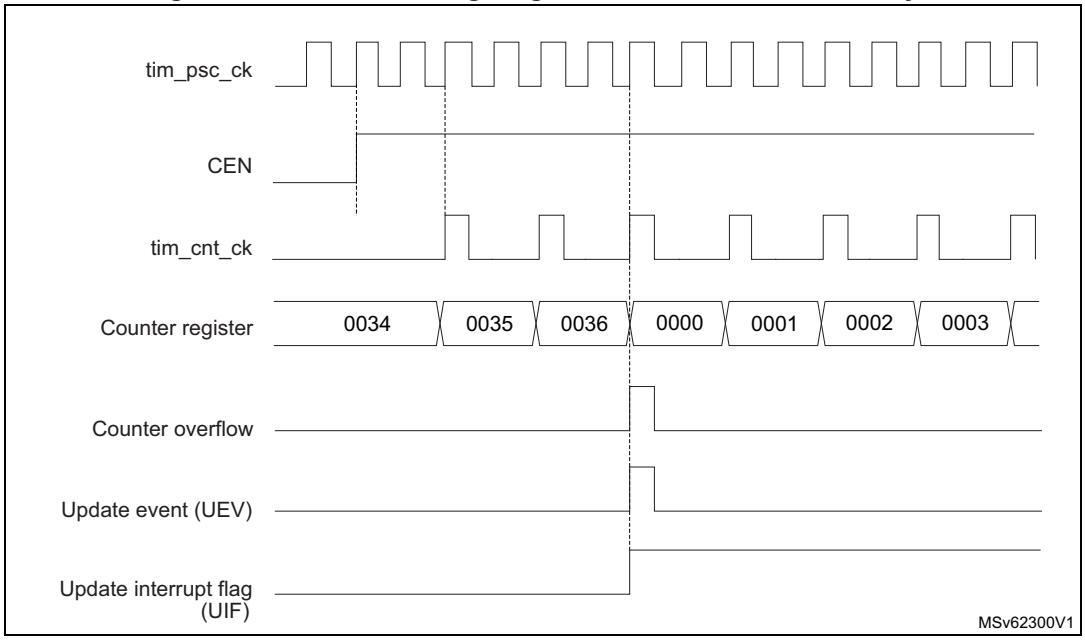

Figure 432. Counter timing diagram, internal clock divided by 4

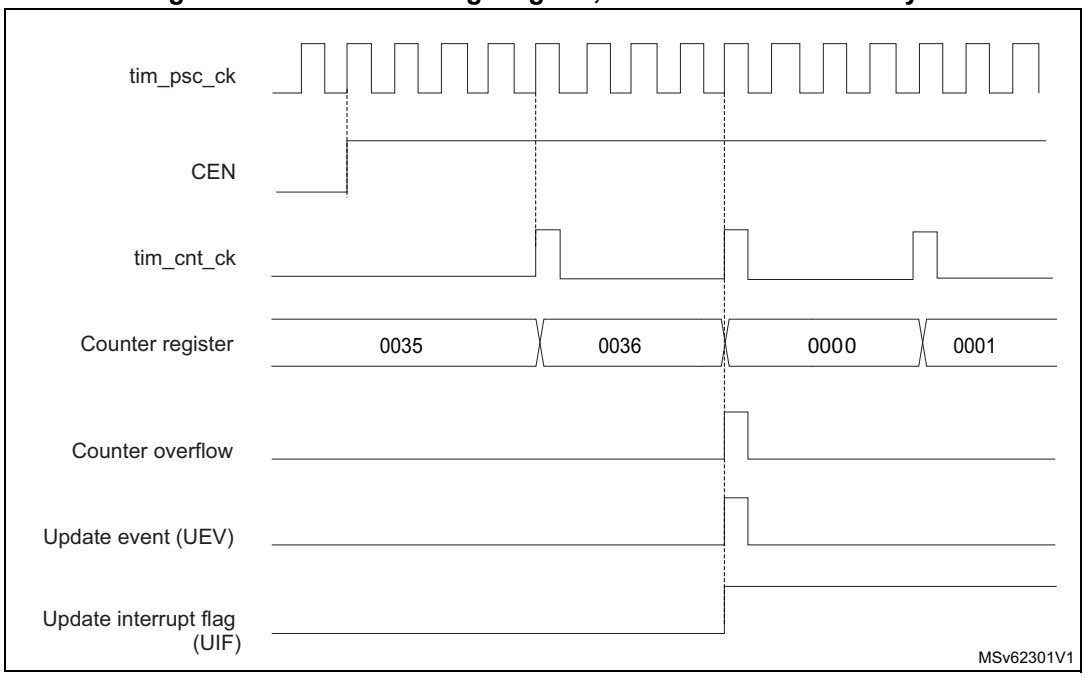

Figure 433. Counter timing diagram, internal clock divided by N

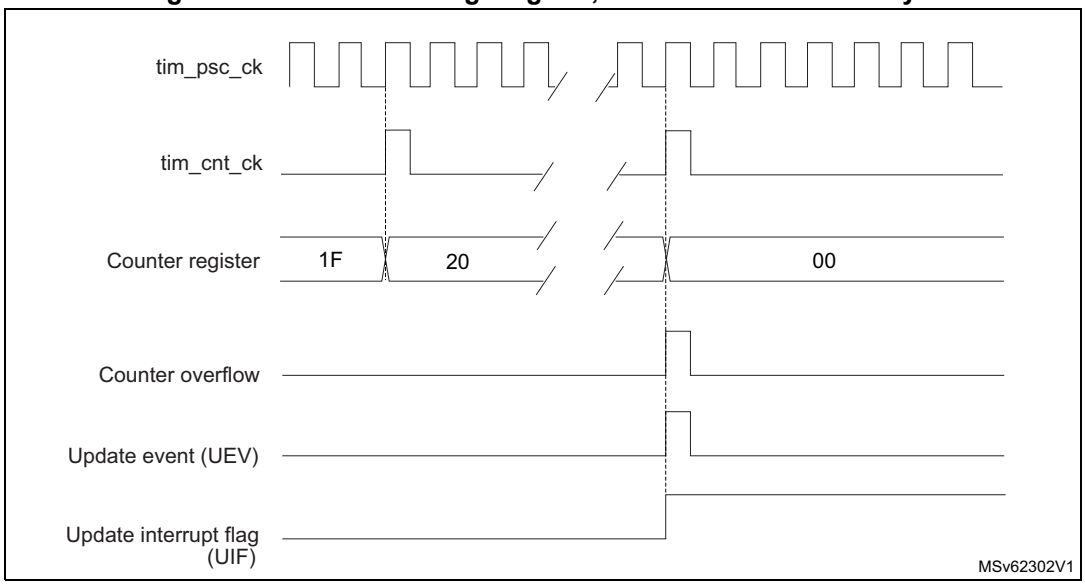

Figure 434. Counter timing diagram, Update event when ARPE=0 (TIMx_ARR not preloaded)

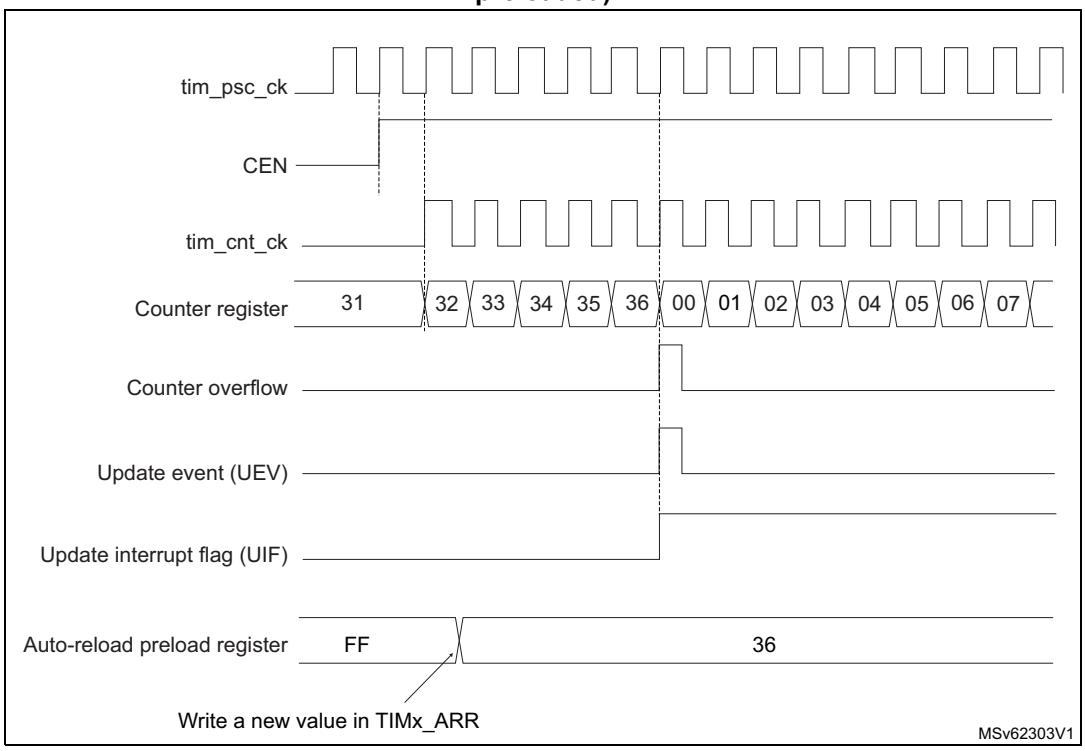

Figure 435. Counter timing diagram, Update event when ARPE=1 (TIMx_ARR preloaded)

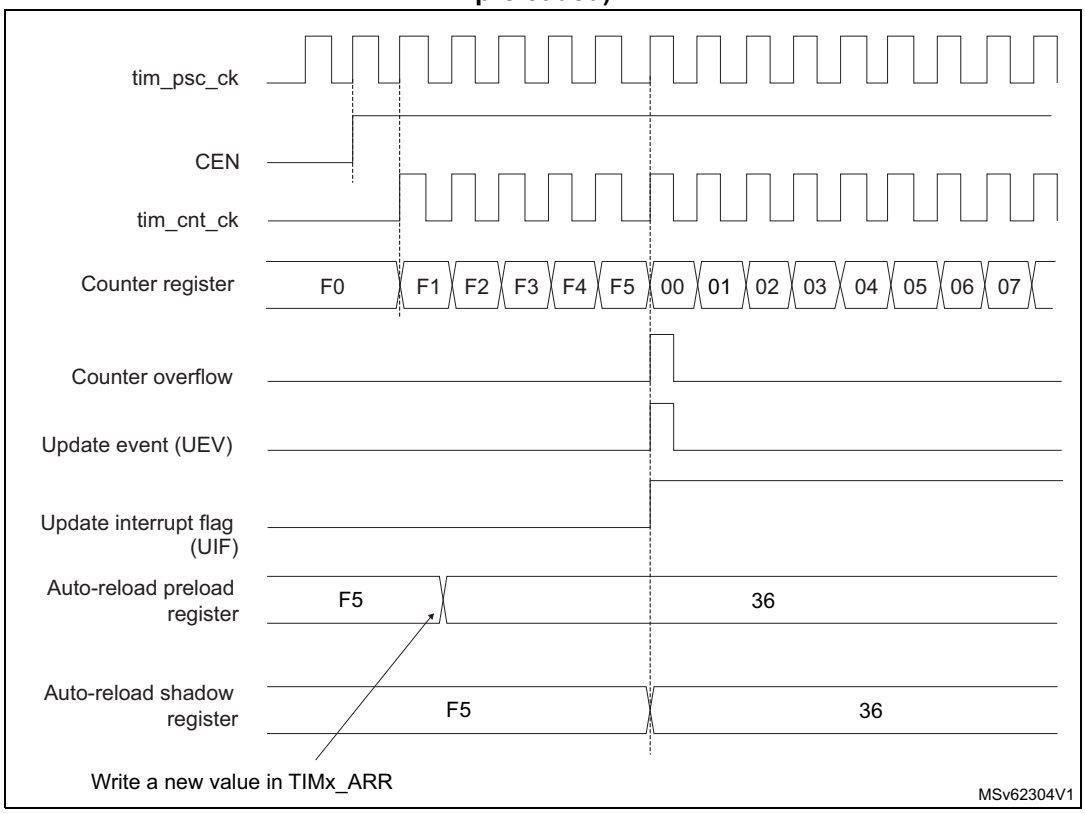

Downcounting mode

In downcounting mode, the counter counts from the auto-reload value (content of the TIMx_ARR register) down to 0, then restarts from the auto-reload value and generates a counter underflow event.

An Update event can be generate at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller)

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current auto-reload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn't change).

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that the auto-reload is updated before the counter is reloaded, so that the next period is the expected one.

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

Figure 436. Counter timing diagram, internal clock divided by 1

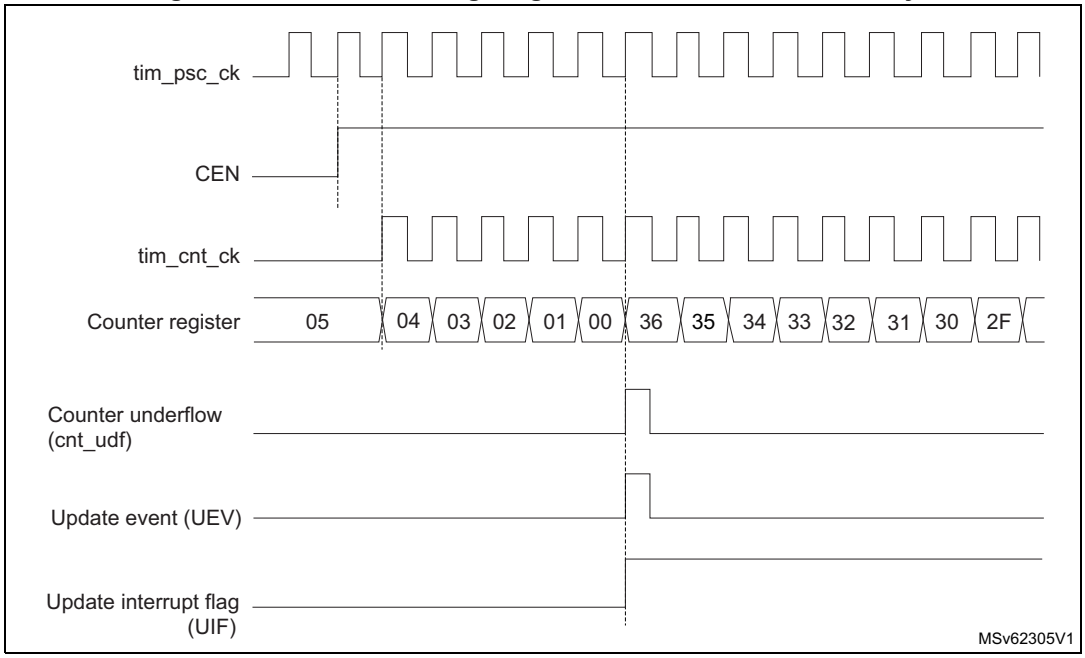

Figure 437. Counter timing diagram, internal clock divided by 2

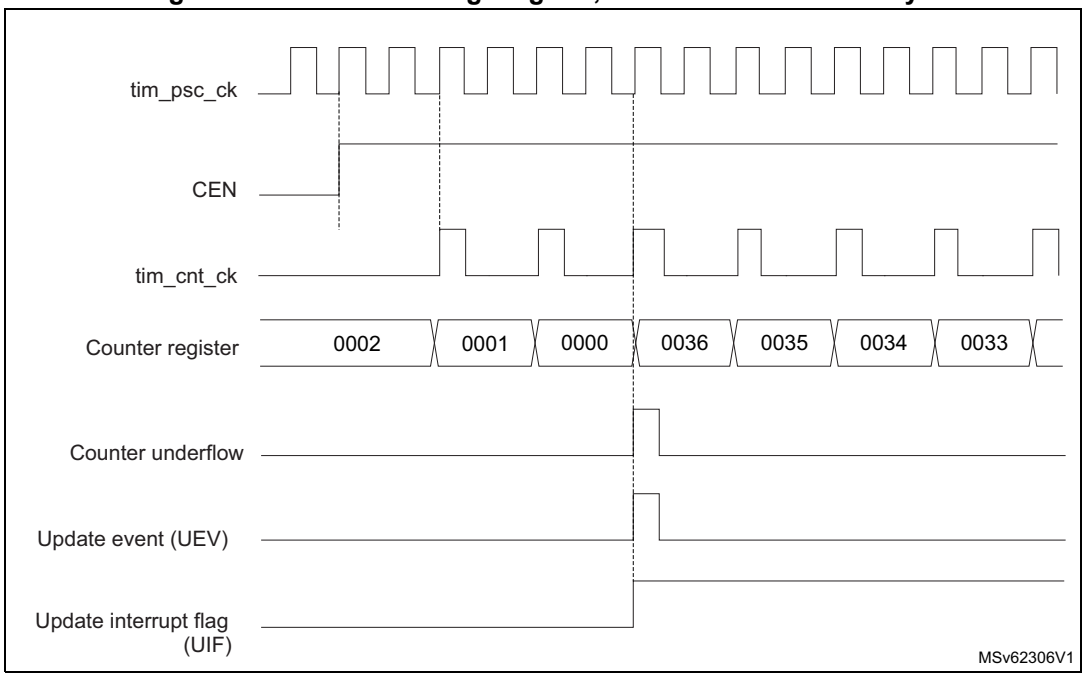

Figure 438. Counter timing diagram, internal clock divided by 4

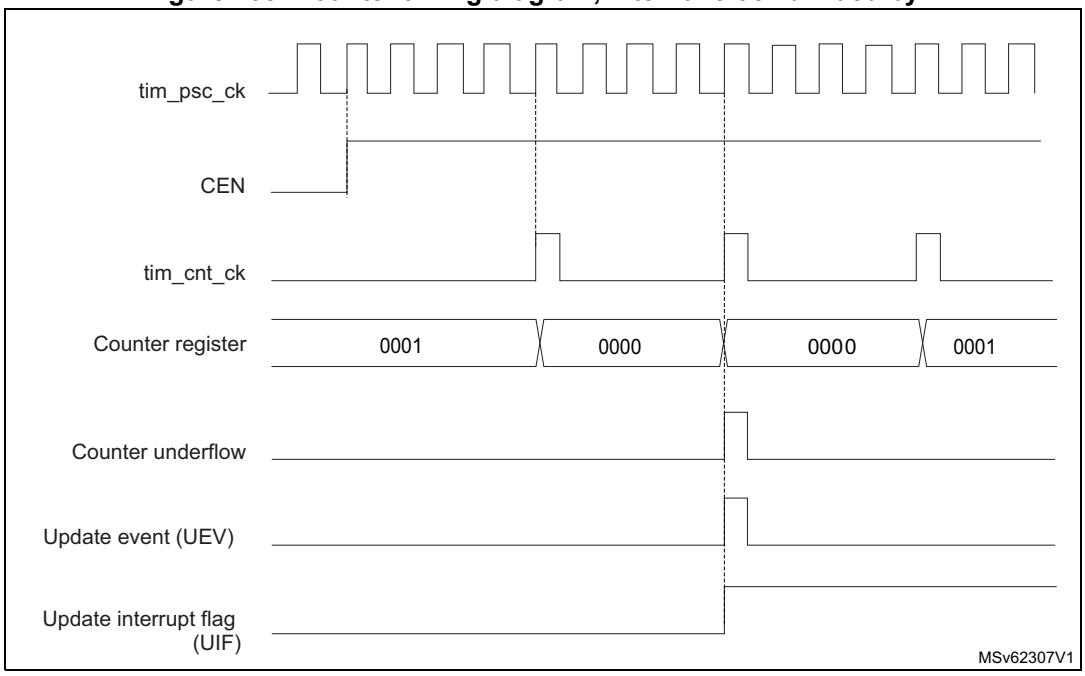

Figure 439. Counter timing diagram, internal clock divided by N

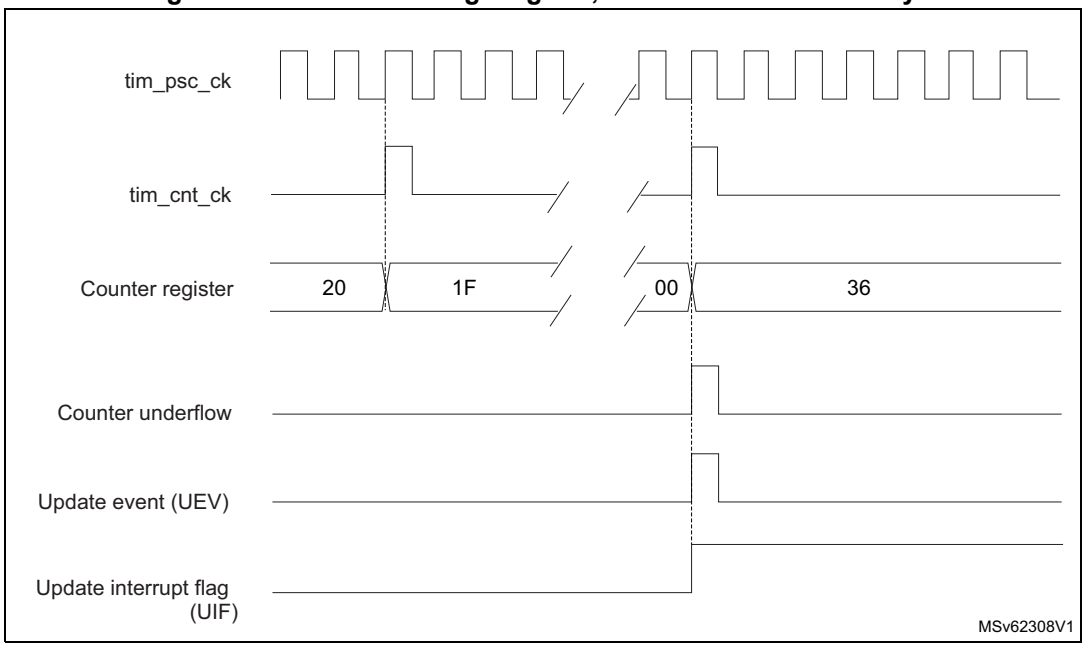

Figure 440. Counter timing diagram, Update event

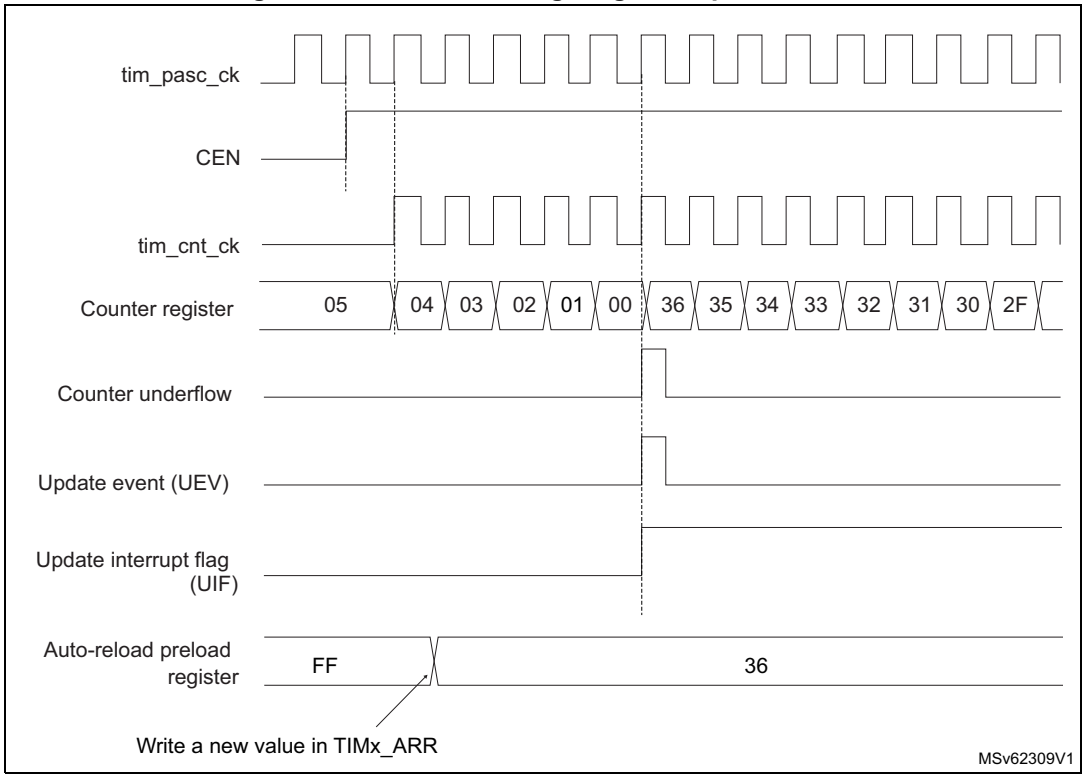


Center-aligned mode (up/down counting)

In center-aligned mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register) – 1, generates a counter overflow event, then counts from the auto-

reload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are not equal to '00'. The Output compare interrupt flag of channels configured in output is set when: the counter counts down (Center aligned mode 1, CMS = "01"), the counter counts up (Center aligned mode 2, CMS = "10") the counter counts up and down (Center aligned mode 3, CMS = "11").

In this mode, the direction bit (DIR from TIMx_CR1 register) cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current auto-reload value.

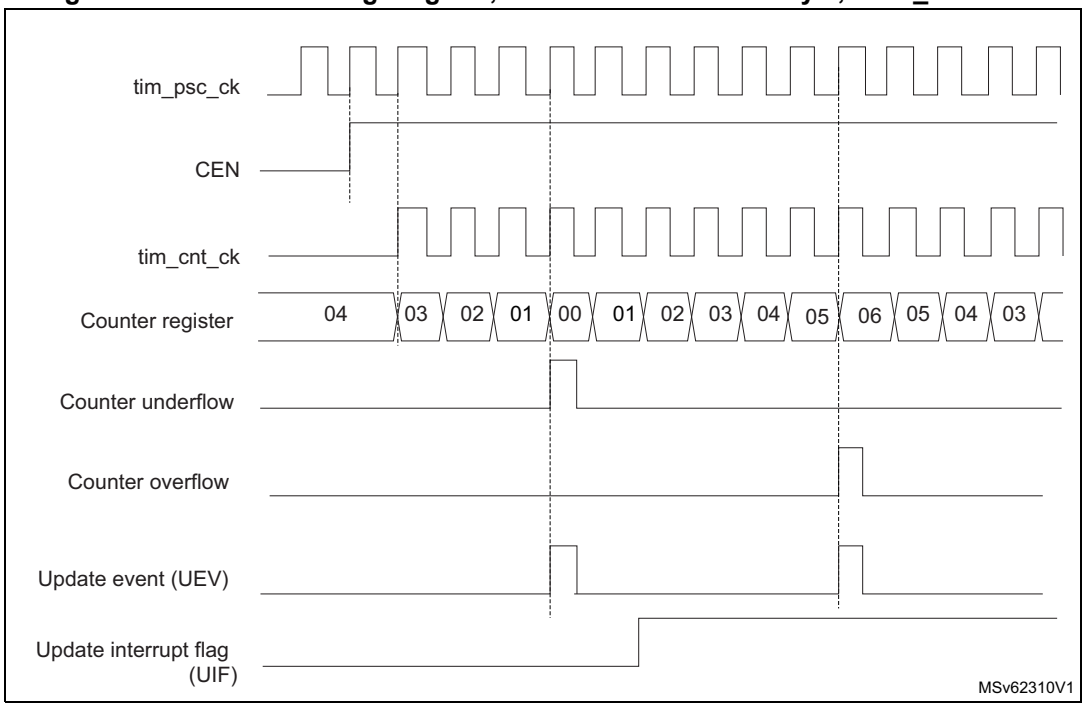
In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupt when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that if the update source is a counter overflow, the auto-reload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.

Figure 441. Counter timing diagram, internal clock divided by 1, TIMx_ARR=0x6



1. Here, center-aligned mode 1 is used (for more details refer to *Section 39.5.1: TIMx control register 1 (TIMx_CR1)(x = 2 to 5) on page 1648*).

Figure 442. Counter timing diagram, internal clock divided by 2

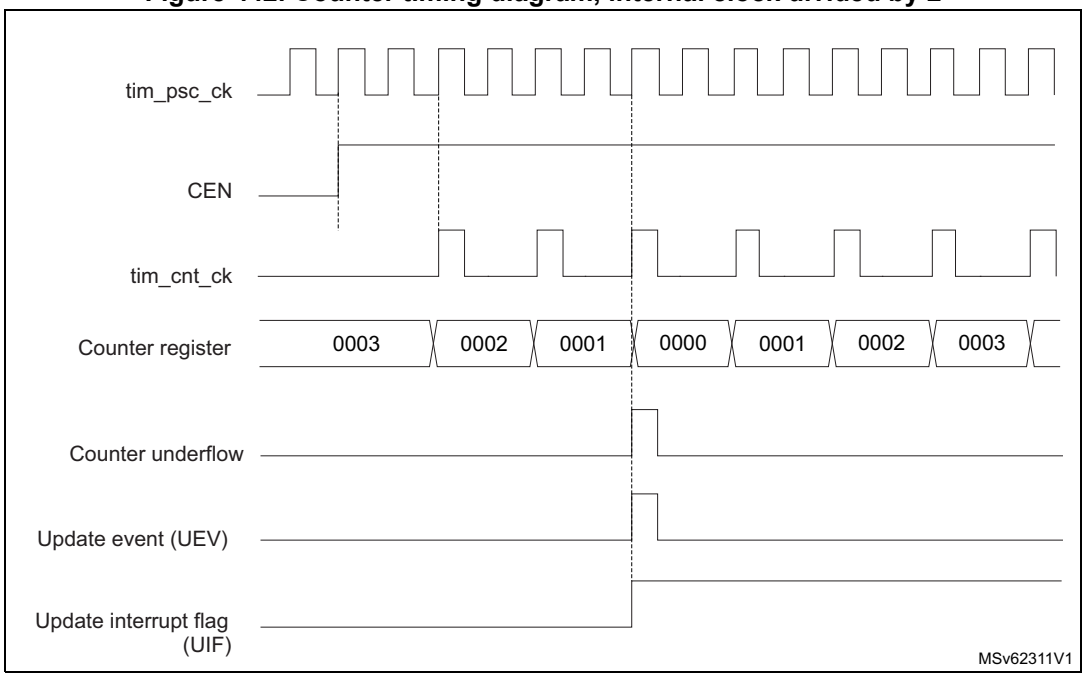


Figure 443. Counter timing diagram, internal clock divided by 4, TIMx_ARR=0x36

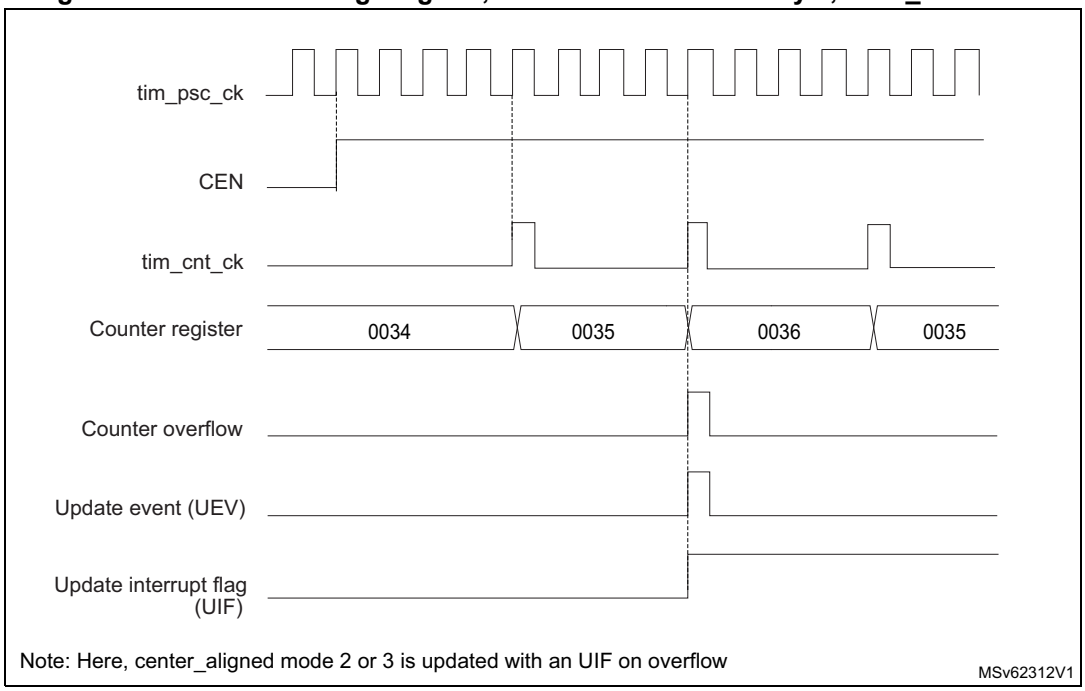

1. Center-aligned mode 2 or 3 is used with an UIF on overflow.

Figure 444. Counter timing diagram, internal clock divided by N

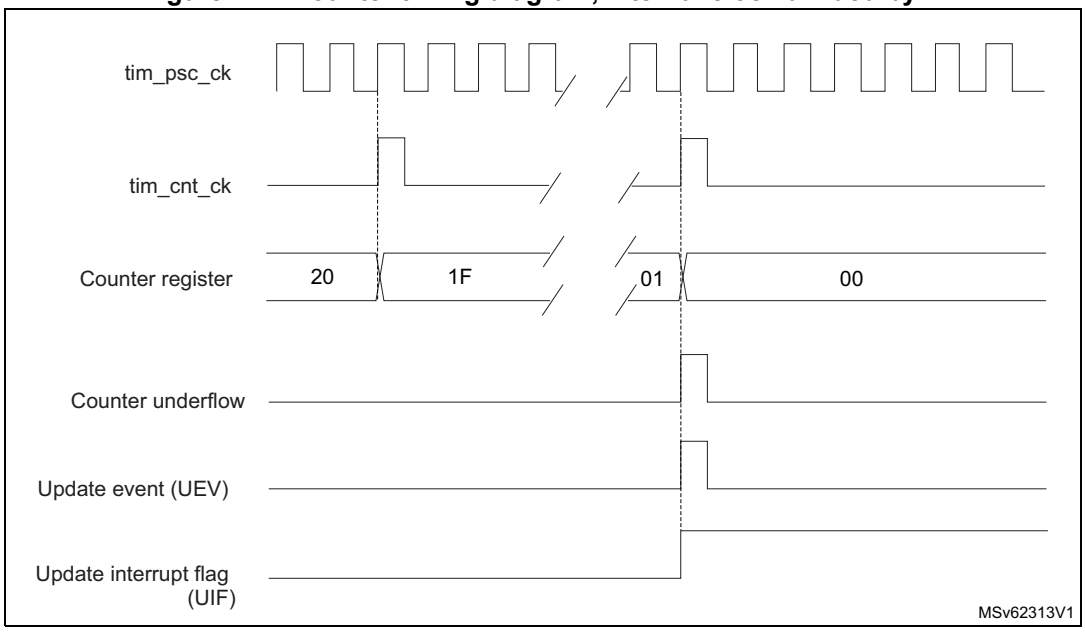

Figure 445. Counter timing diagram, Update event with ARPE=1 (counter underflow)

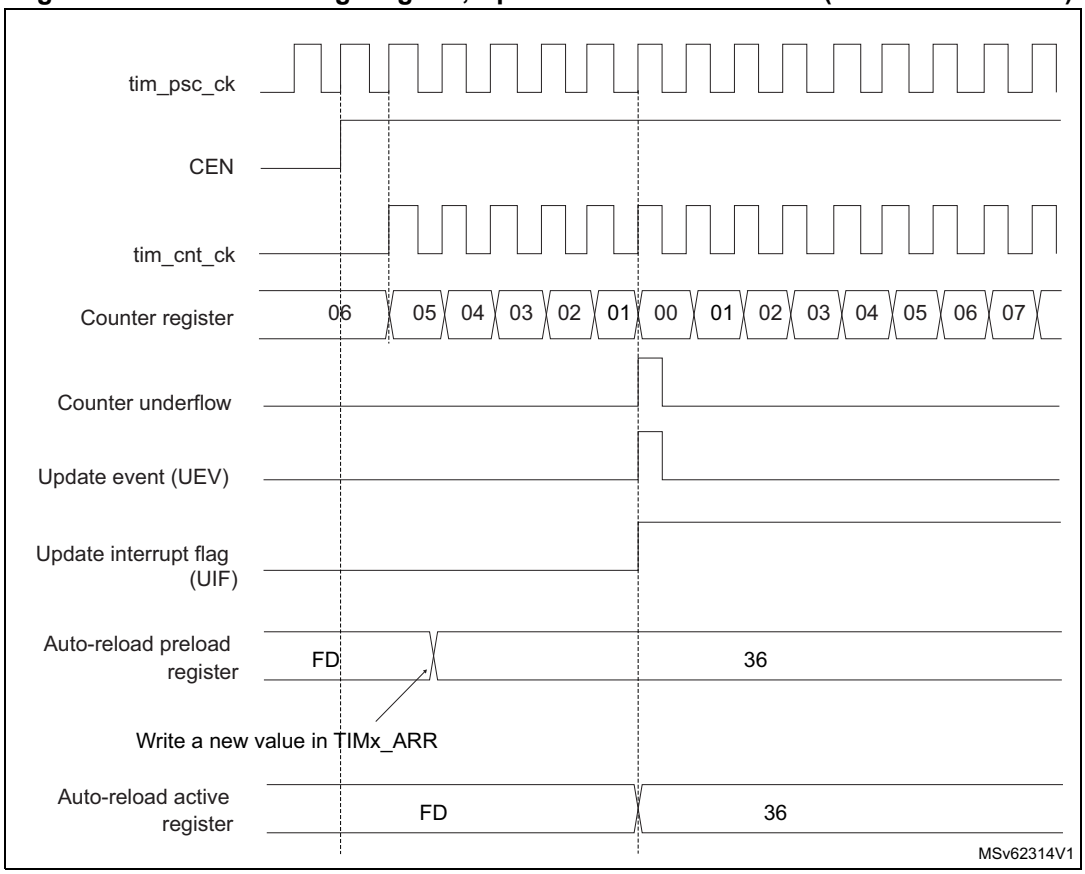

Figure 446. Counter timing diagram, Update event with ARPE=1 (counter overflow)

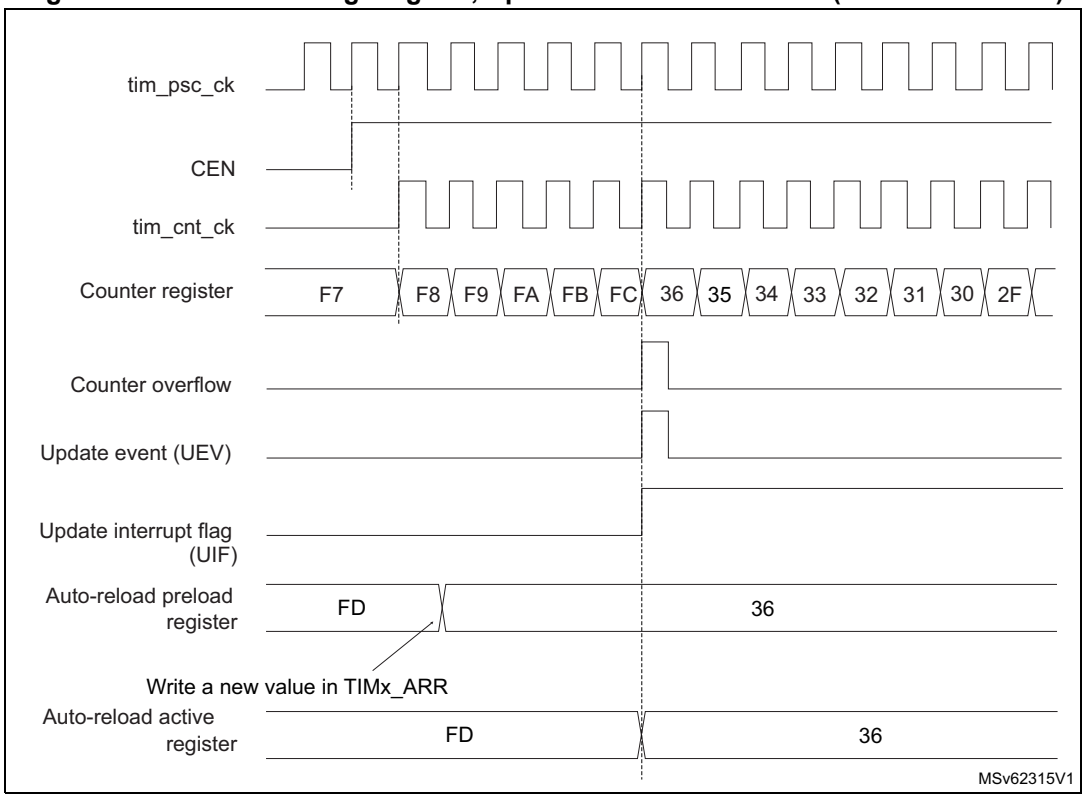


39.4.5 Clock selection

The counter clock can be provided by the following clock sources:

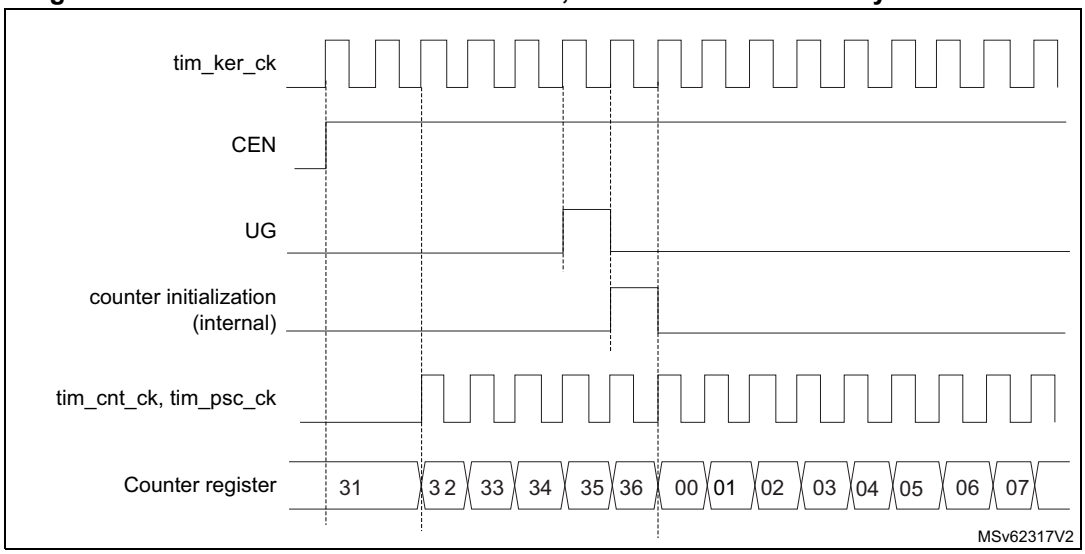
- Internal clock (tim_ker_ck)
- External clock mode1: external input pin (tim_ti1 or tim_ti2)
- External clock mode2: external trigger input (tim_etr_in)
- Internal trigger inputs (tim_itr): using one timer as prescaler for another timer, for example, Timer 1 can be configured to act as a prescaler for Timer 2. Refer to *: Using one timer as prescaler for another timer on page 1640* for more details.

Internal clock source (tim_ker_ck)

If the slave mode controller is disabled (SMS=000 in the TIMx_SMCR register), then the CEN, DIR (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock tim_ker_ck.

Figure 447 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

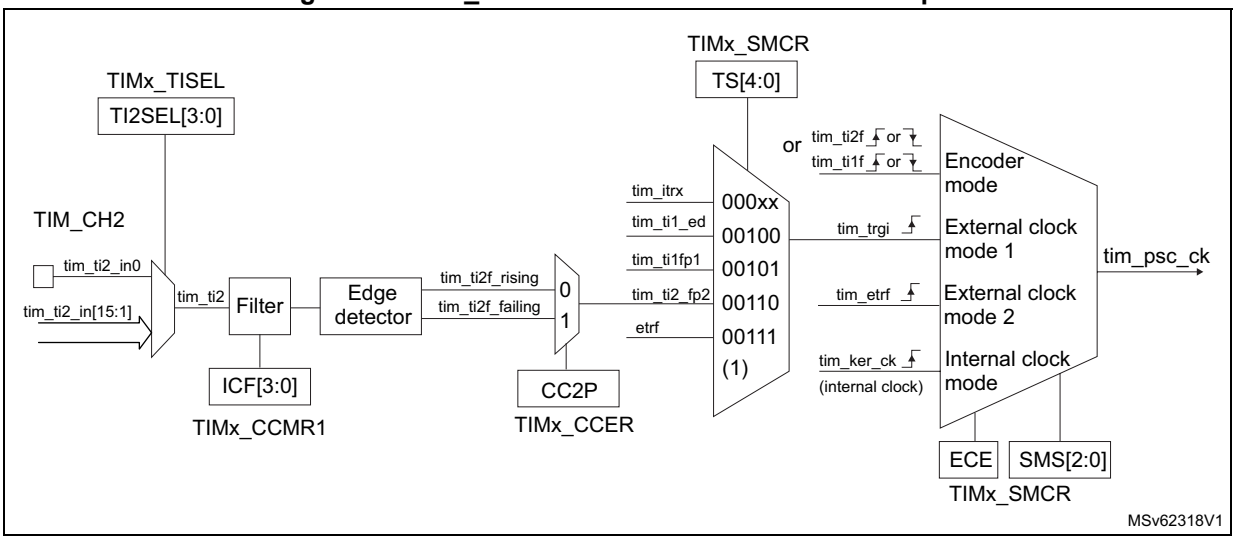
Figure 447. Control circuit in normal mode, internal clock divided by 1



External clock source mode 1

This mode is selected when SMS=111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

Figure 448. tim_ti2 external clock connection example



1. Codes ranging from 01000 to 11111: tim_itr[15:0].

For example, to configure the upcounter to count in response to a rising edge on the tim_ti2 input, use the following procedure:

For example, to configure the upcounter to count in response to a rising edge on the tim_ti2 input, use the following procedure:

1. Select the proper tim_ti2_in[15:0] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Configure channel 2 to detect rising edges on the tim_ti2 input by writing CC2S= ‘01 in the TIMx_CCMR1 register.
3. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 register (if no filter is needed, keep IC2F=0000).

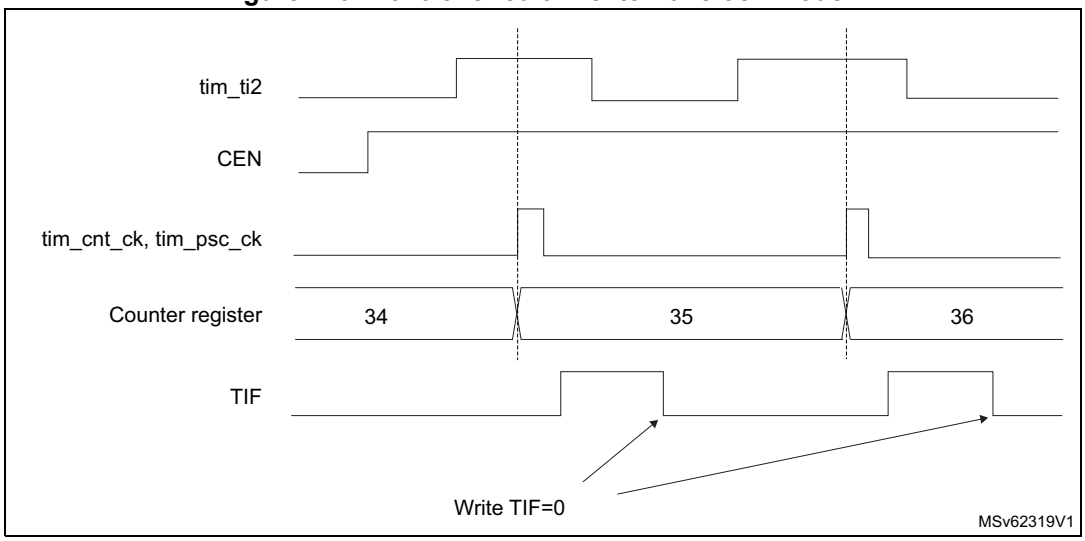
Note: The capture prescaler is not used for triggering, so it does not need to be configured.

4. Select rising edge polarity by writing CC2P=0 and CC2NP=0 and CC2NP=0 in the TIMx_CCER register.
5. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx_SMCR register.
6. Select tim_ti2 as the input source by writing TS=00110 in the TIMx_SMCR register.
7. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

When a rising edge occurs on tim_ti2, the counter counts once and the TIF flag is set.

The delay between the rising edge on tim_ti2 and the actual clock of the counter is due to the resynchronization circuit on tim_ti2 input.

Figure 449. Control circuit in external clock mode 1



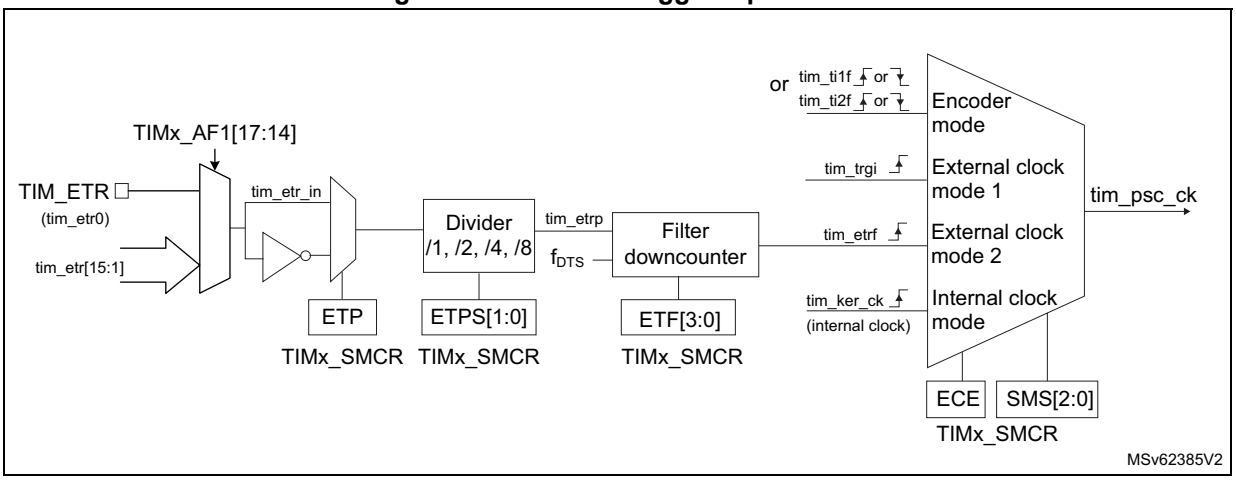
External clock source mode 2

This mode is selected by writing ECE=1 in the TIMx_SMCR register.

The counter can count at each rising or falling edge on the external trigger input tim_etr_in.

Figure 450 gives an overview of the external trigger input block.

Figure 450. External trigger input block



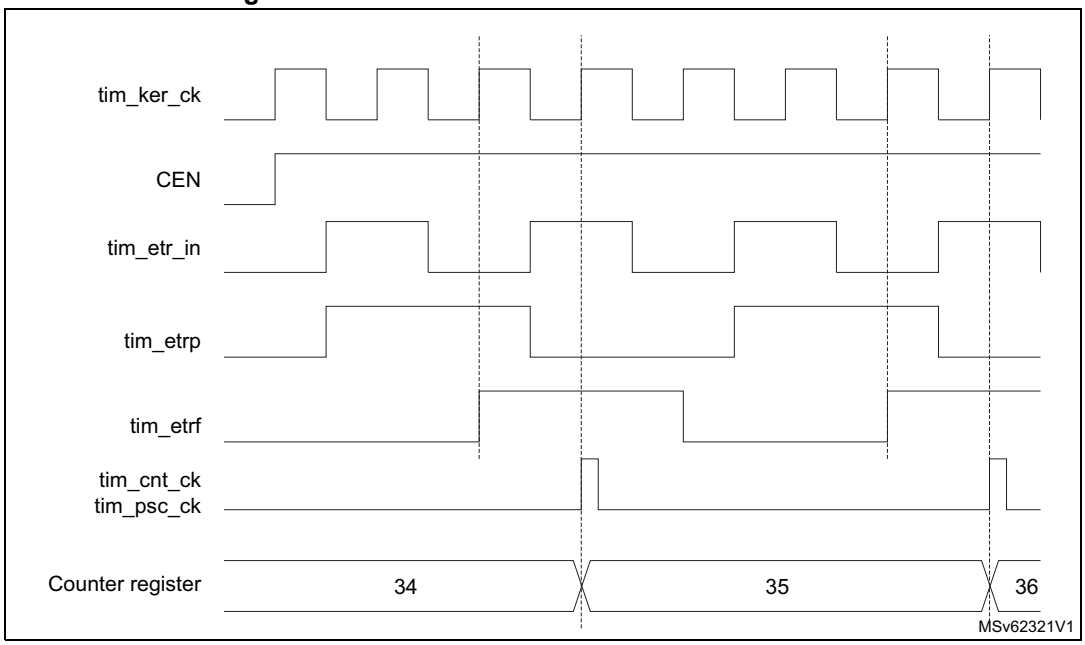
For example, to configure the upcounter to count each 2 rising edges on tim_etr_in, use the following procedure:

1. Select the proper tim_etr_in source (internal or external) with the ETRSEL[3:0] bits in the TIMx_AF1 register.
2. As no filter is needed in this example, write ETF[3:0]=0000 in the TIMx_SMCR register.
3. Set the prescaler by writing ETPS[1:0]=01 in the TIMx_SMCR register
4. Select rising edge detection on the tim_etr_in by writing ETP=0 in the TIMx_SMCR register
5. Enable external clock mode 2 by writing ECE=1 in the TIMx_SMCR register.
6. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

The counter counts once each 2 tim_etr_in rising edges.

The delay between the rising edge on tim_etr_in and the actual clock of the counter is due to the resynchronization circuit on the tim_etrp signal. As a consequence, the maximum frequency that can be correctly captured by the counter is at most ¼ of TIMxCLK frequency. When the ETRP signal is faster, the user must apply a division of the external signal by a proper ETPS prescaler setting.

Figure 451. Control circuit in external clock mode 2



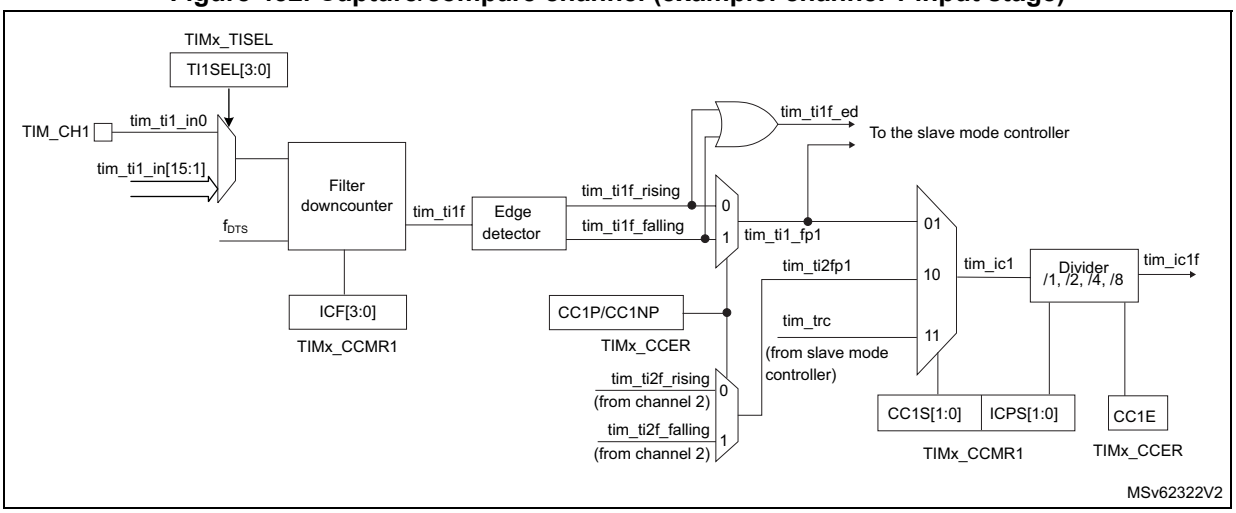
39.4.6 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), a input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

The following figure gives an overview of one Capture/Compare channel.

The input stage samples the corresponding tim_tix input to generate a filtered signal tim_tixf. Then, an edge detector with polarity selection generates a signal (tim_tixfpy) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

Figure 452. Capture/compare channel (example: channel 1 input stage)



The output stage generates an intermediate waveform which is then used for reference: tim_ocxref (active high). The polarity acts at the end of the chain.

Figure 453. Capture/compare channel 1 main circuit

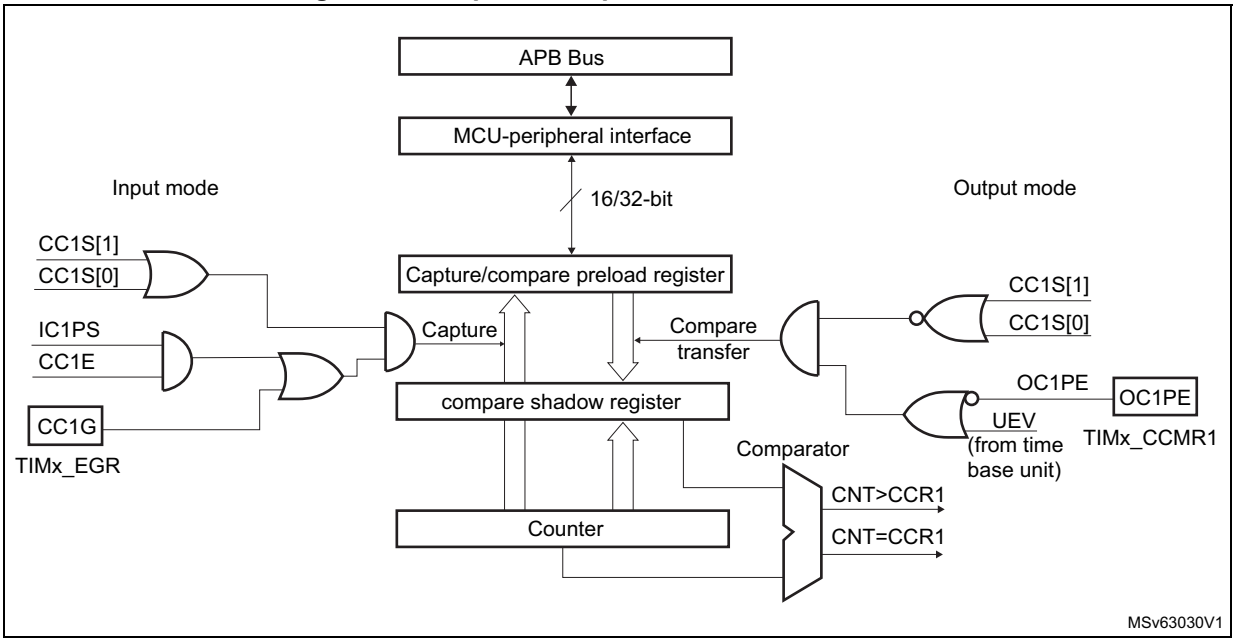


Figure 454. Output stage of capture/compare channel (channel 1, idem ch.2, 3 and 4)

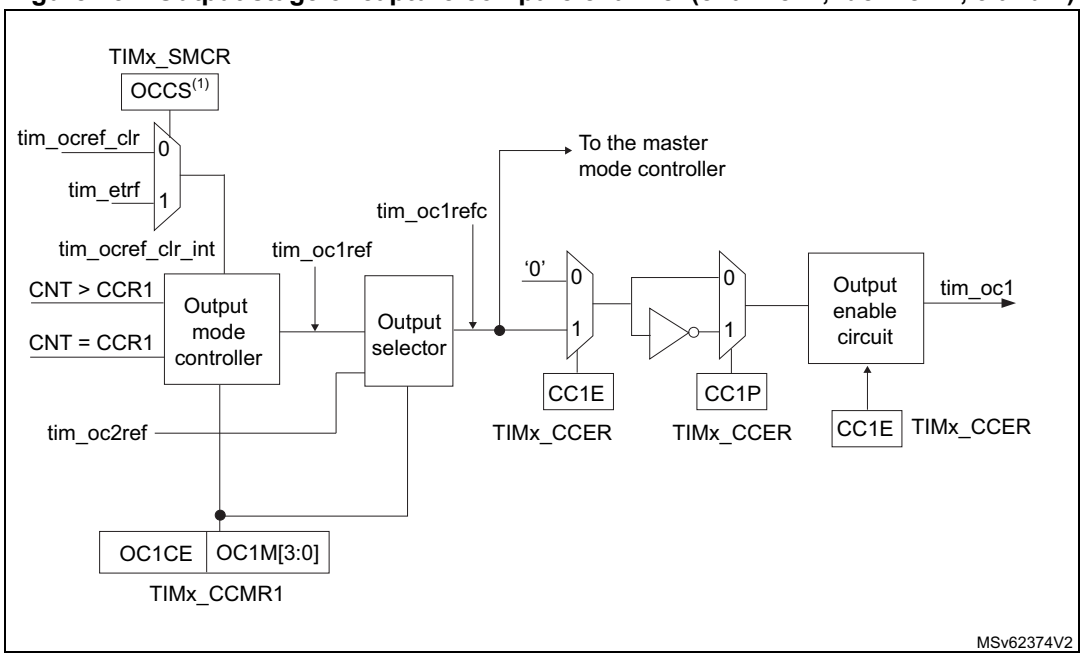


1. Available on some instances only. If not available, tim_etrf is directly connected to tim_ocref_clr_int.

The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

39.4.7 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCXIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to 0 or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when tim_ti1 input rises. To do this, use the following procedure:

1. Select the proper tim_tix_in[15:0] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input: TIMx_CCR1 must be linked to the tim_ti1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.
3. Program the needed input filter duration in relation with the signal connected to the timer (when the input is one of the tim_tix (ICxF bits in the TIMx_CCMRx register). Let's imagine that, when toggling, the input signal is not stable during at must 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on tim_ti1 when 8 consecutive samples with the new level have been detected (sampled at f_{DTS} frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.
4. Select the edge of the active transition on the tim_ti1 channel by writing the CC1P and CC1NP and CC1NP bits to 000 in the TIMx_CCER register (rising edge in this case).
5. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to 00 in the TIMx_CCMR1 register).
6. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.
7. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:

- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which may happen after reading the flag and before reading the data.

Note: IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.

39.4.8 PWM input mode

This mode is used to measure both the period and the duty cycle of a PWM signal connected to single tim_tix input:

- The TIMx_CCR1 register holds the period value (interval between two consecutive rising edges)
- The TIM_CCR2 register holds the pulse width (interval between two consecutive rising and falling edges

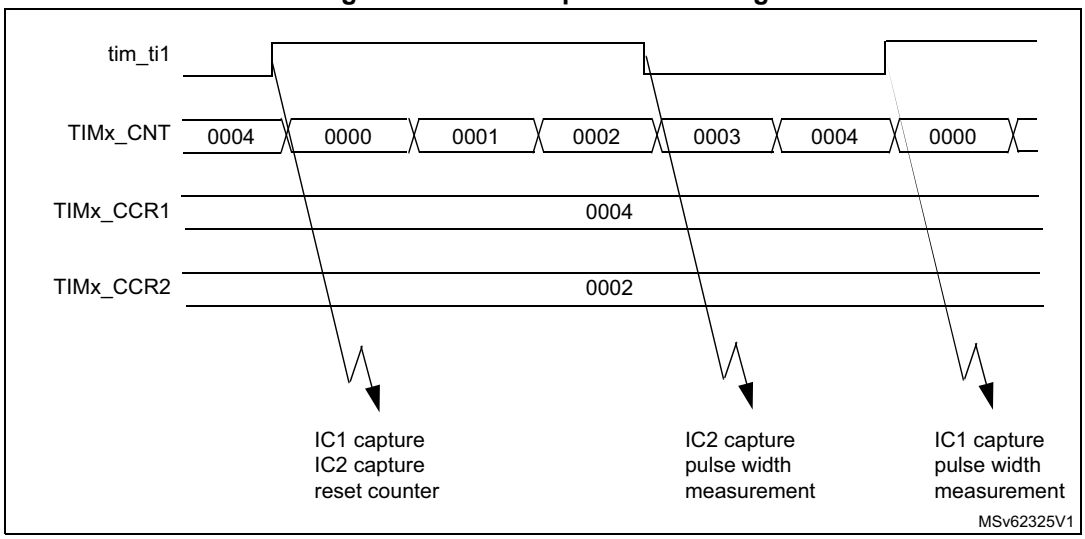
This mode is a particular case of input capture mode. The set-up procedure is similar wit hthe following differences:

- Two ICx signals are mapped on the same tim_tix input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.

The period and the pulse width of a PWM signal applied on tim_ti1 can be measured using the following procedure:

1. Select the proper tim_tix_in[15:0] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (tim_ti1 selected).
3. Select the active polarity for tim_ti1fp1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P to ‘0’ and the CC1NP bit to ‘0’ (active on rising edge).
4. Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (tim_ti1 selected).
5. Select the active polarity for tim_ti1fp2 (used for capture in TIMx_CCR2): write the CC2P bit to ‘1’ and the CC2NP bit to ’0’ (active on falling edge).
6. Select the valid trigger input: write the TS bits to 00101 in the TIMx_SMCR register (tim_ti1fp1 selected).
7. Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx_SMCR register.
8. Enable the captures: write the CC1E and CC2E bits to ‘1 in the TIMx_CCER register.

Figure 455. PWM input mode timing



1. The PWM input mode can be used only with the TIMx_CH1/TIMx_CH2 signals due to the fact that only tim_ti1fp1 and tim_ti2fp2 are connected to the slave mode controller.

39.4.9 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (tim_ocxref and then tim_ocx) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (tim_ocxref/tim_ocx) to its active level, one just needs to write 101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus tim_ocxref is forced high (tim_ocxref is always active high) and tim_ocx get opposite value to CCxP polarity bit.

For example: CCxP=0 (tim_ocx active high) => tim_ocx is forced to high level.

tim_ocxref signal can be forced low by writing the OCxM bits to 100 in the TIMx_CCMRx register.

Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the Output Compare Mode section.

39.4.10 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP

bit in the TIMx_CCER register). The output pin can keep its level (OCXM=000), be set active (OCxM=001), be set inactive (OCxM=010) or can toggle (OCxM=011) on match.

- Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

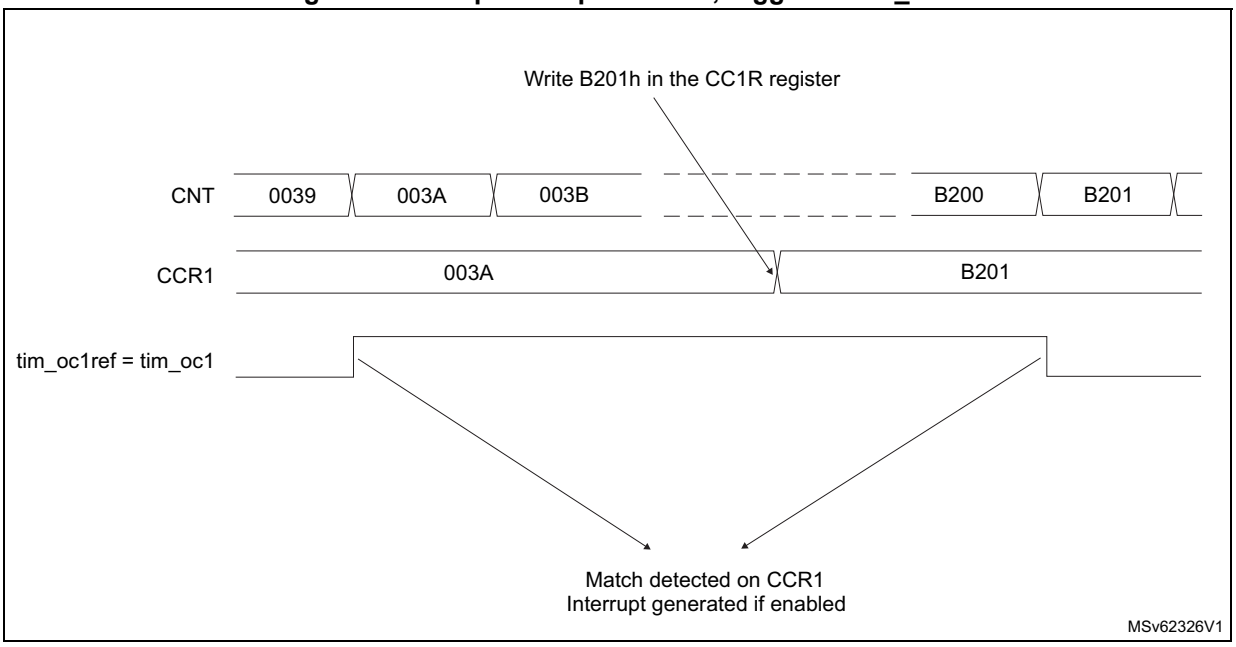
In output compare mode, the update event UEV has no effect on tim_ocxref and tim_ocx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE and/or CCxDE bits if an interrupt and/or a DMA request is to be generated.
4. Select the output mode. For example:
   a) Write OCxM = 0011 to toggle tim_ocx output pin when CNT matches CCRx
   b) Write OCxPE = 0 to disable preload register
   c) Write CCxP = 0 to select active high polarity
   d) Write CCxE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE=0, else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in *Figure 456*.

Figure 456. Output compare mode, toggle on tim_oc1



39.4.11 PWM mode

Pulse width modulation mode is used to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per tim_ocx output) by writing 110 (PWM mode 1) or ‘111 (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

tim_ocx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. tim_ocx output is enabled by the CCxE bit in the TIMx_CCER register. Refer to the TIMx_CCERx register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx ≤ TIMx_CNT or TIMx_CNT ≤ TIMx_CCRx (depending on the direction of the counter). The tim_ocref_clr can be cleared by an external event through the tim_etr_in or the tim_oceref_clr signals. In this case the tim_ocref_clr signal is asserted only:

- After a compare match event
- When the output compare mode (OCxM bits in TIMx_CCMRx register) switches from the “frozen” configuration (no comparison, OCxM=‘000) to one of the PWM modes (OCxM=‘110 or ‘111). This forces the PWM by software while the timer is running.

The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx_CR1 register.

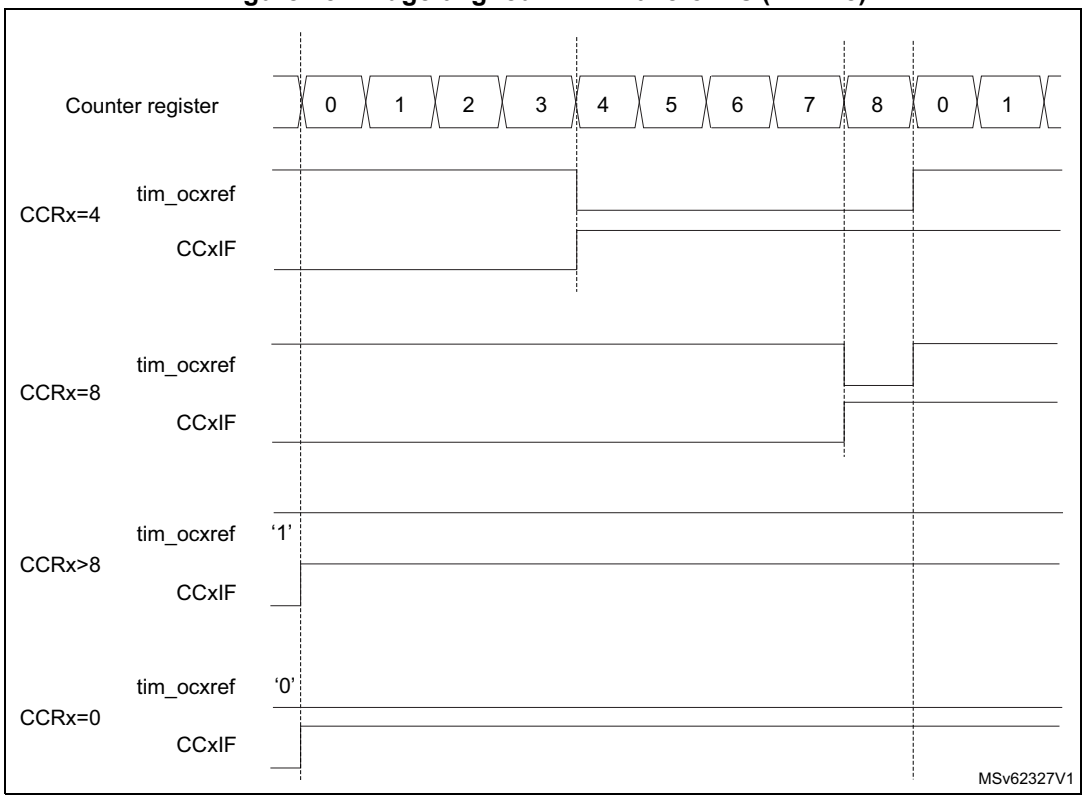
PWM edge-aligned mode

Upcounting configuration

Upcounting is active when the DIR bit in the TIMx_CR1 register is low. Refer to *Upcounting mode on page 1578*.

In the following example, we consider PWM mode 1. The reference PWM signal tim_ocxref is high as long as TIMx_CNT <TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then tim_ocxref is held at ‘1. If the compare value is 0 then tim_ocxref is held at ‘0. *Figure 457* shows some edge-aligned PWM waveforms in an example where TIMx_ARR=8.

Figure 457. Edge-aligned PWM waveforms (ARR=8)



Downcounting configuration

Downcounting is active when DIR bit in TIMx_CR1 register is high. Refer to *Downcounting mode on page 1582*.

In PWM mode 1, the reference signal tim_ocxref is low as long as TIMx_CNT>TIMx_CCRx else it becomes high. If the compare value in TIMx_CCRx is greater than the auto-reload value in TIMx_ARR, then tim_ocxref is held at 100%. PWM is not possible in this mode.

PWM center-aligned mode

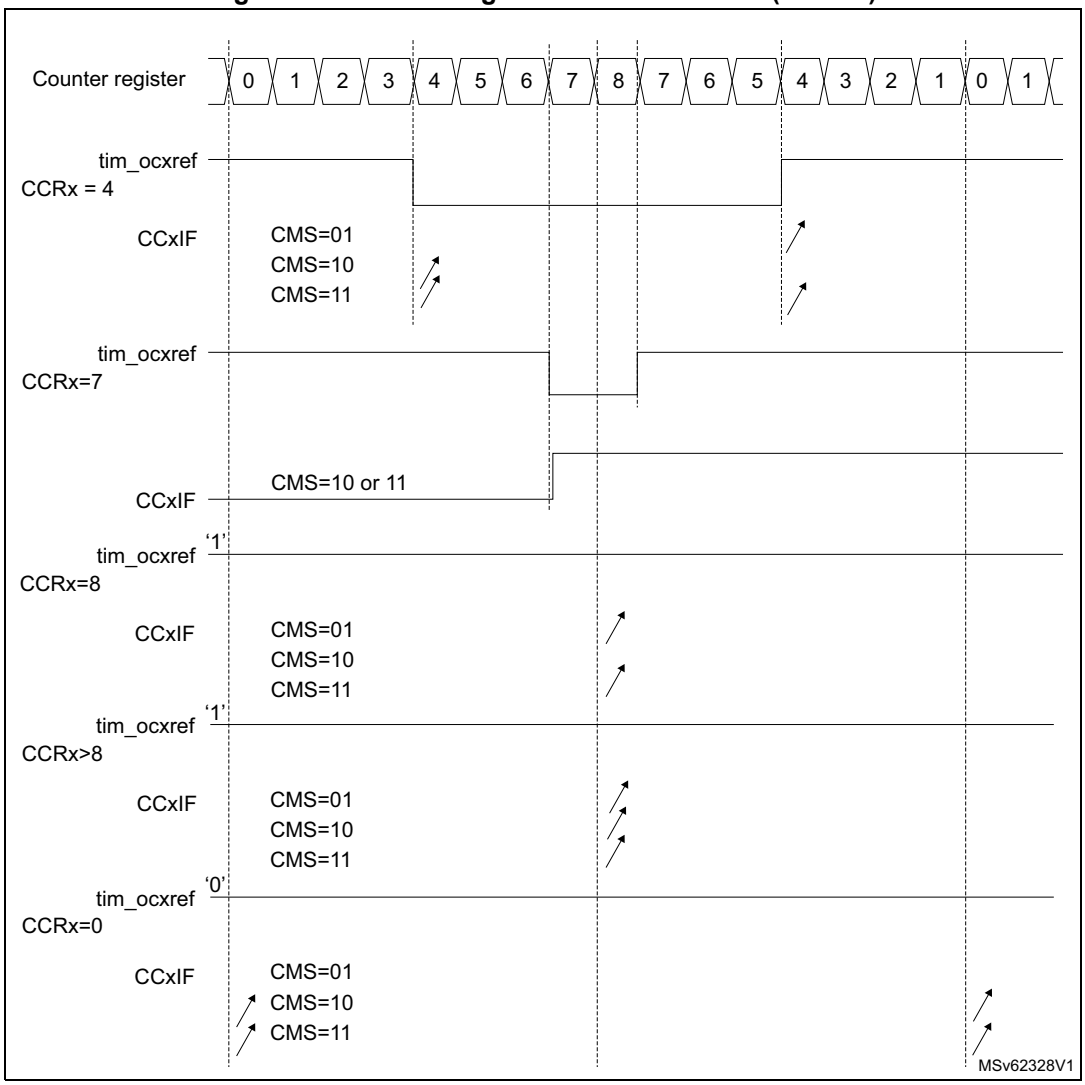
Center-aligned mode is active when the CMS bits in TIMx_CR1 register are different from ‘00 (all the remaining configurations having the same effect on the tim_ocxref/tim_ocx signals). The compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit

(DIR) in the TIMx_CR1 register is updated by hardware and must not be changed by software. Refer to *Center-aligned mode (up/down counting) on page 1585*.

Figure 458 shows some center-aligned PWM waveforms in an example where:

- TIMx_ARR=8,
- PWM mode is the PWM mode 1,
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS=01 in TIMx_CR1 register.

Figure 458. Center-aligned PWM waveforms (ARR=8)



Hints on using center-aligned mode:

- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit

in the TIMx_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.

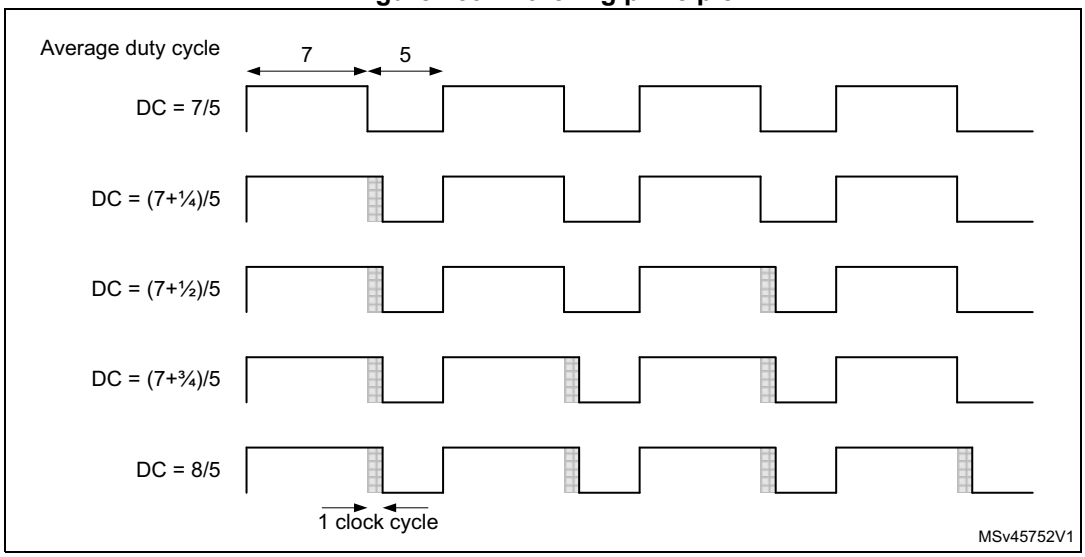
- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  - The direction is not updated if a value greater than the auto-reload value is written in the counter (TIMx_CNT>TIMx_ARR). For example, if the counter was counting up, it continues to count up.
  - The direction is updated if 0 or the TIMx_ARR value is written in the counter but no Update Event UEV is generated.
- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx_EGR register) just before starting the counter and not to write the counter while it is running.

Dithering mode

The PWM mode effective resolution can be increased by enabling the dithering mode, using the DITHEN bit in the TIMx_CR1 register. This applies to both the CCR (for duty cycle resolution increase) and ARR (for PWM frequency resolution increase).

The operating principle is to have the actual CCR (or ARR) value slightly changed (adding or not one timer clock period) over 16 consecutive PWM periods, with predefined patterns. This allows a 16-fold resolution increase, considering the average duty cycle or PWM period. The *Figure 459* below presents the dithering principle applied to 4 consecutive PWM cycles.

Figure 459. Dithering principle



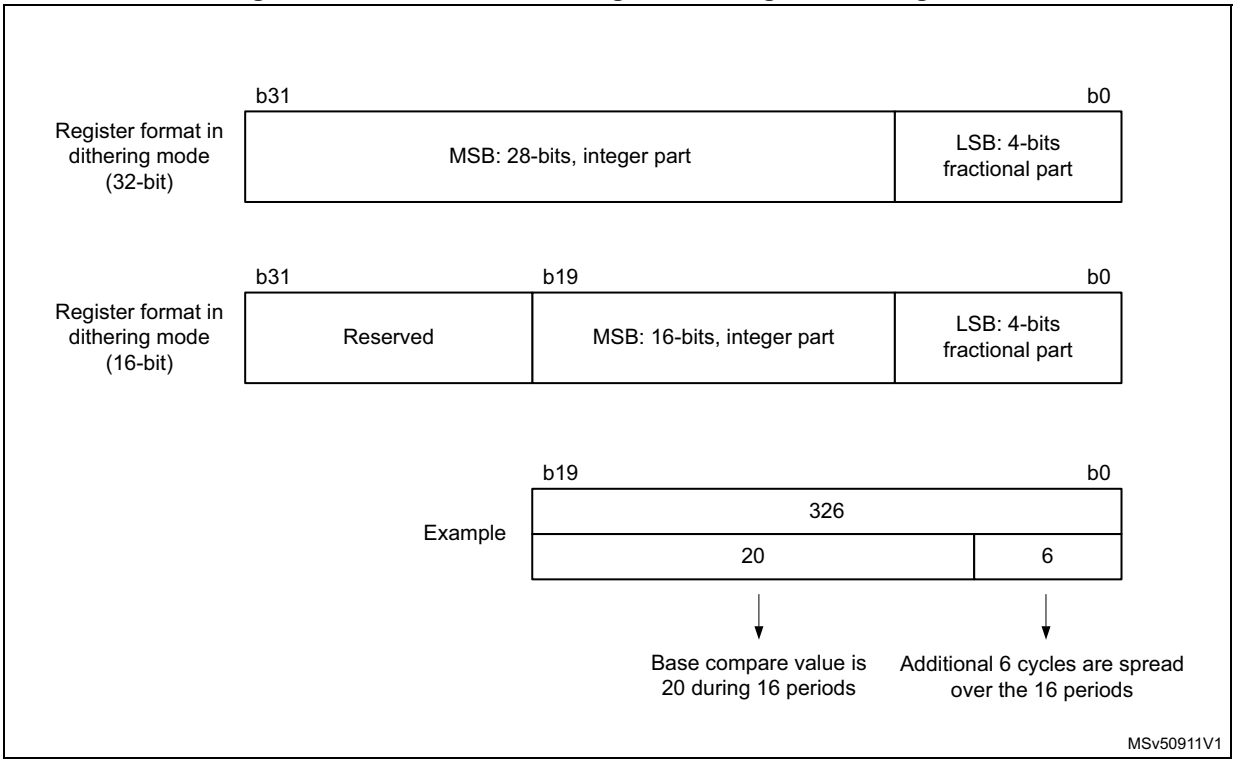
When the dithering mode is enabled, the register coding is changed as following (see *Figure 460* for example):

- The 4 LSBs are coding for the enhanced resolution part (fractional part).
- The MSBs are left-shifted by 4 places and are coding for the base value. In 16-bit mode, the 16-bit format is maintained.

Note: The following sequence must be followed when resetting the DITHEN bit:

1. *CEN and ARPE bits must be reset.*
2. *The DITHEN bit must be reset.*
3. *The CCIF flags must be cleared.*
4. *The CEN bit can be set (eventually with ARPE = 1).*

Figure 460. Data format and register coding in dithering mode



The minimum frequency is given by the following formula:

$$\text{Resolution} = \frac{F_{Tim}}{F_{pwm}} \Rightarrow F_{pwmMin} = \frac{F_{Tim}}{Max_{Resolution}}$$

$$\text{Dithering mode disabled: } F_{pwmMin} = \frac{F_{Tim}}{65536}$$

$$\text{Dithering mode (16-bit timer): } F_{pwmMin} = \frac{F_{Tim}}{65535 + \frac{15}{16}}$$

$$\text{Dithering mode (32-bit timer): } F_{pwmMin} = \frac{F_{Tim}}{268435454 + \frac{15}{16}}$$

Note: For 16-bit timers, the maximum TIMx_ARR and TIMxCCRy values are limited to 0xFFFEF in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part). For 32-bit timers, the maximum TIMx_ARR and TIMxCCRy values are limited to

0xFFFFFFEF in dithering mode (corresponds to 264435454 for the integer part and 15 for the dithered part).

As shown on the *Figure 461* and *Figure 462* below, the dithering mode is used to increase the PWM resolution.

Figure 461. PWM resolution vs frequency (16-bit mode)

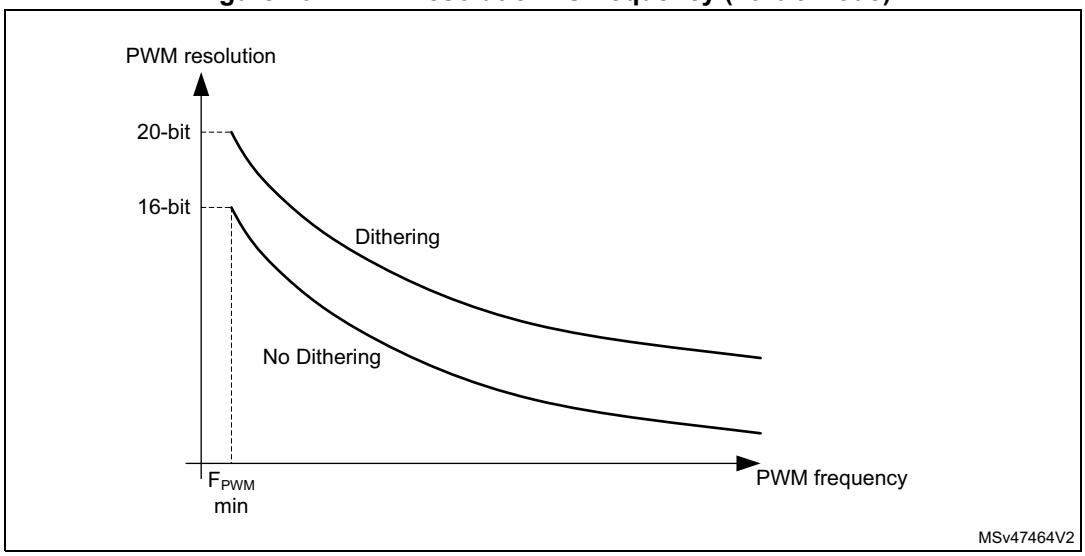


Figure 462. PWM resolution vs frequency (32-bit mode)

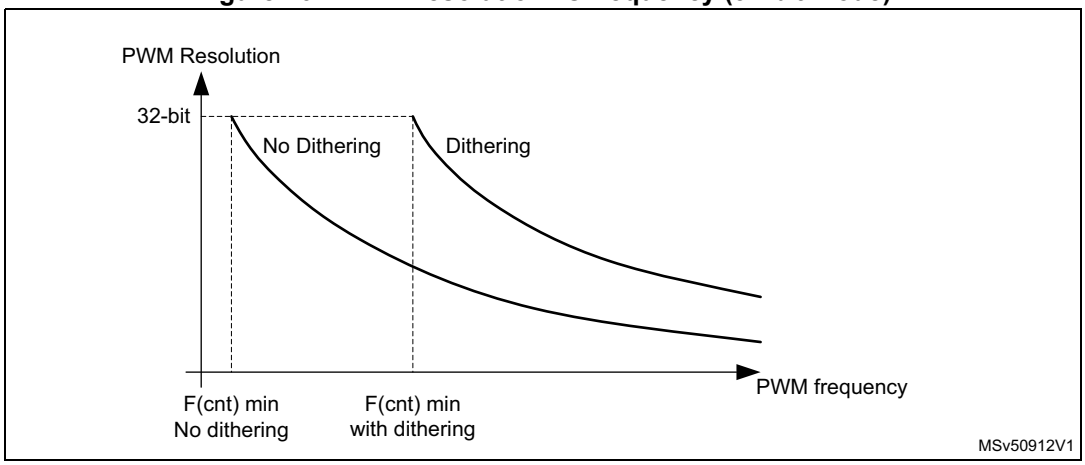
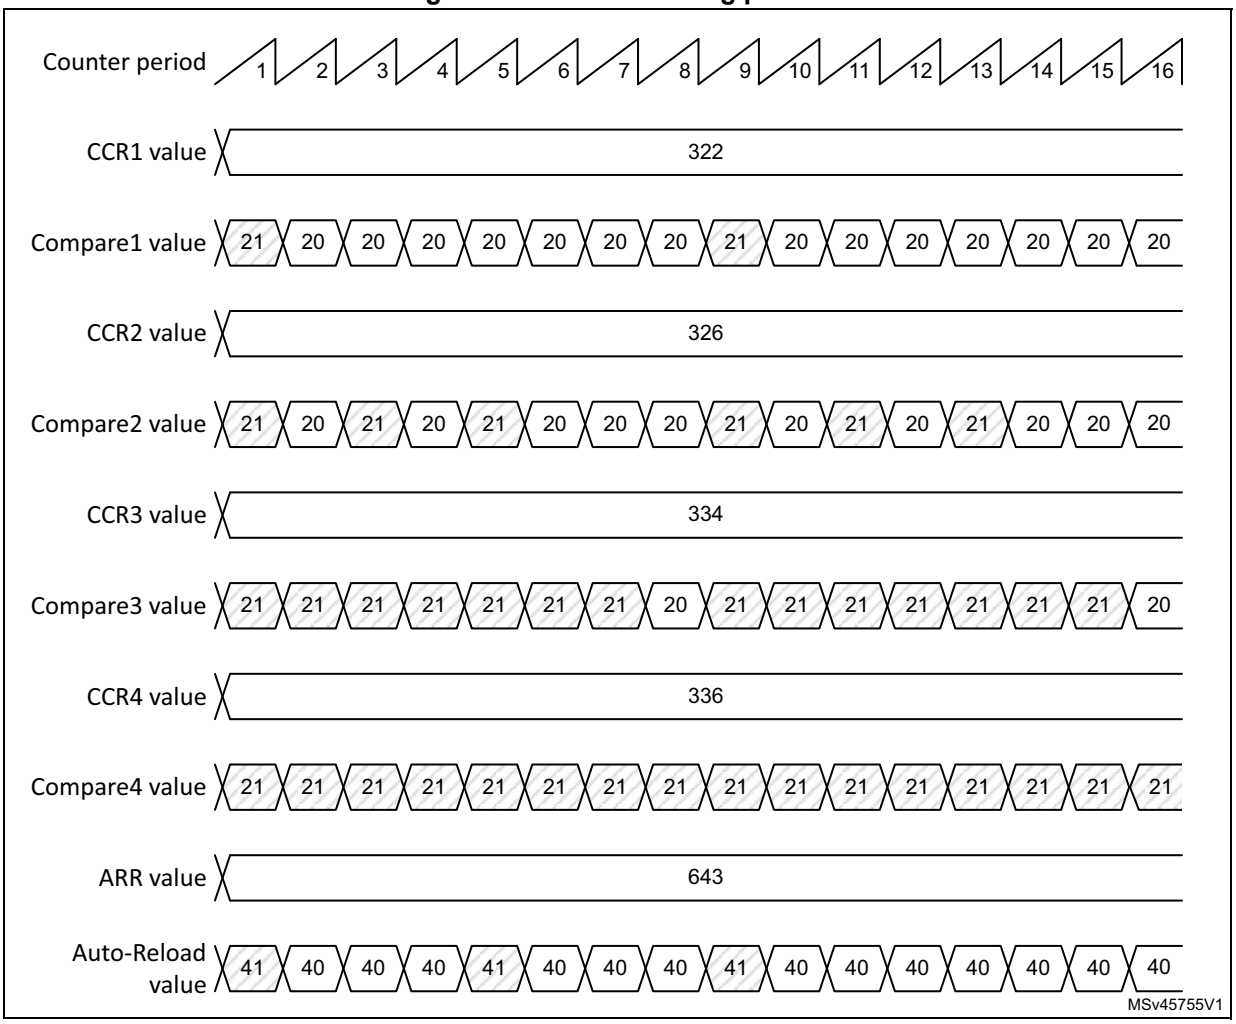


The duty cycle and / or period changes are spread over 16 consecutive periods, as described in the *Figure 463* below.

Figure 463. PWM dithering pattern



The auto-reload and compare values increments are spread following specific patterns described in the *Table 406* below. The dithering sequence is done to have increments distributed as evenly as possible and minimize the overall ripple.

Table 406. CCR and ARR register change dithering pattern

LSB value	PWM period															
	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
0000	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
0001	+1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

39.4.12 Asymmetric PWM mode

Asymmetric mode allows two center-aligned PWM signals to be generated with a programmable phase shift. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and the phase-shift are determined by a pair of TIMx_CCRx registers. One register controls the PWM during up-counting, the second during down counting, so that PWM is adjusted every half PWM cycle:

- tim_oc1refc (or tim_oc2refc) is controlled by TIMx_CCR1 and TIMx_CCR2
- tim_oc3refc (or tim_oc4refc) is controlled by TIMx_CCR3 and TIMx_CCR4

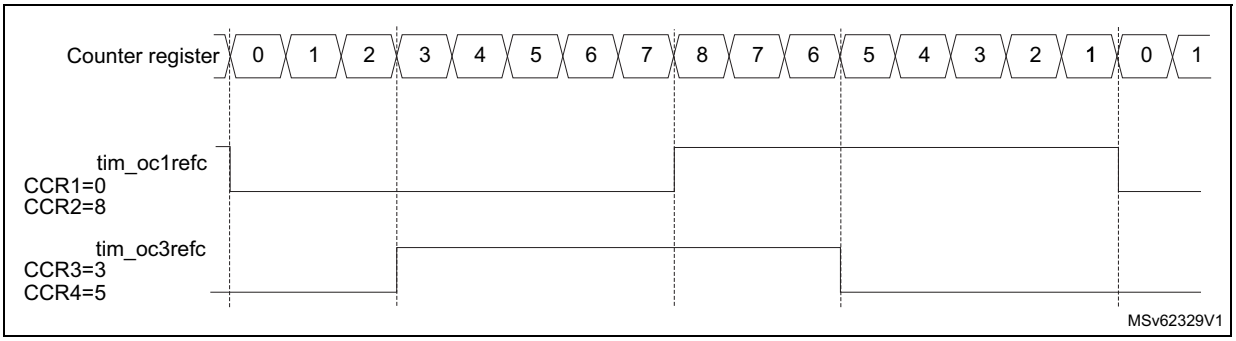
Asymmetric PWM mode can be selected independently on two channels (one tim_ocx output per pair of CCR registers) by writing ‘1110’ (Asymmetric PWM mode 1) or ‘1111’ (Asymmetric PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

Note: The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

When a given channel is used as asymmetric PWM channel, its secondary channel can also be used. For instance, if an tim_oc1refc signal is generated on channel 1 (Asymmetric PWM mode 1), it is possible to output either the tim_oc2ref signal on channel 2, or an tim_oc2refc signal resulting from asymmetric PWM mode 2.

Figure 465 shows an example of signals that can be generated using Asymmetric PWM mode (channels 1 to 4 are configured in Asymmetric PWM mode 2).

Figure 465. Generation of 2 phase-shifted PWM signals with 50% duty cycle



39.4.13 Combined PWM mode

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, tim_ocxrefc, are made of an OR or AND logical combination of two reference PWMs:

– tim_oc1refc (or tim_oc2refc) is controlled by TIMx_CCR1 and TIMx_CCR2

– tim_oc3refc (or tim_oc4refc) is controlled by TIMx_CCR3 and TIMx_CCR4

Combined PWM mode can be selected independently on two channels (one tim_ocx output per pair of CCR registers) by writing ‘1100’ (Combined PWM mode 1) or ‘1101’ (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

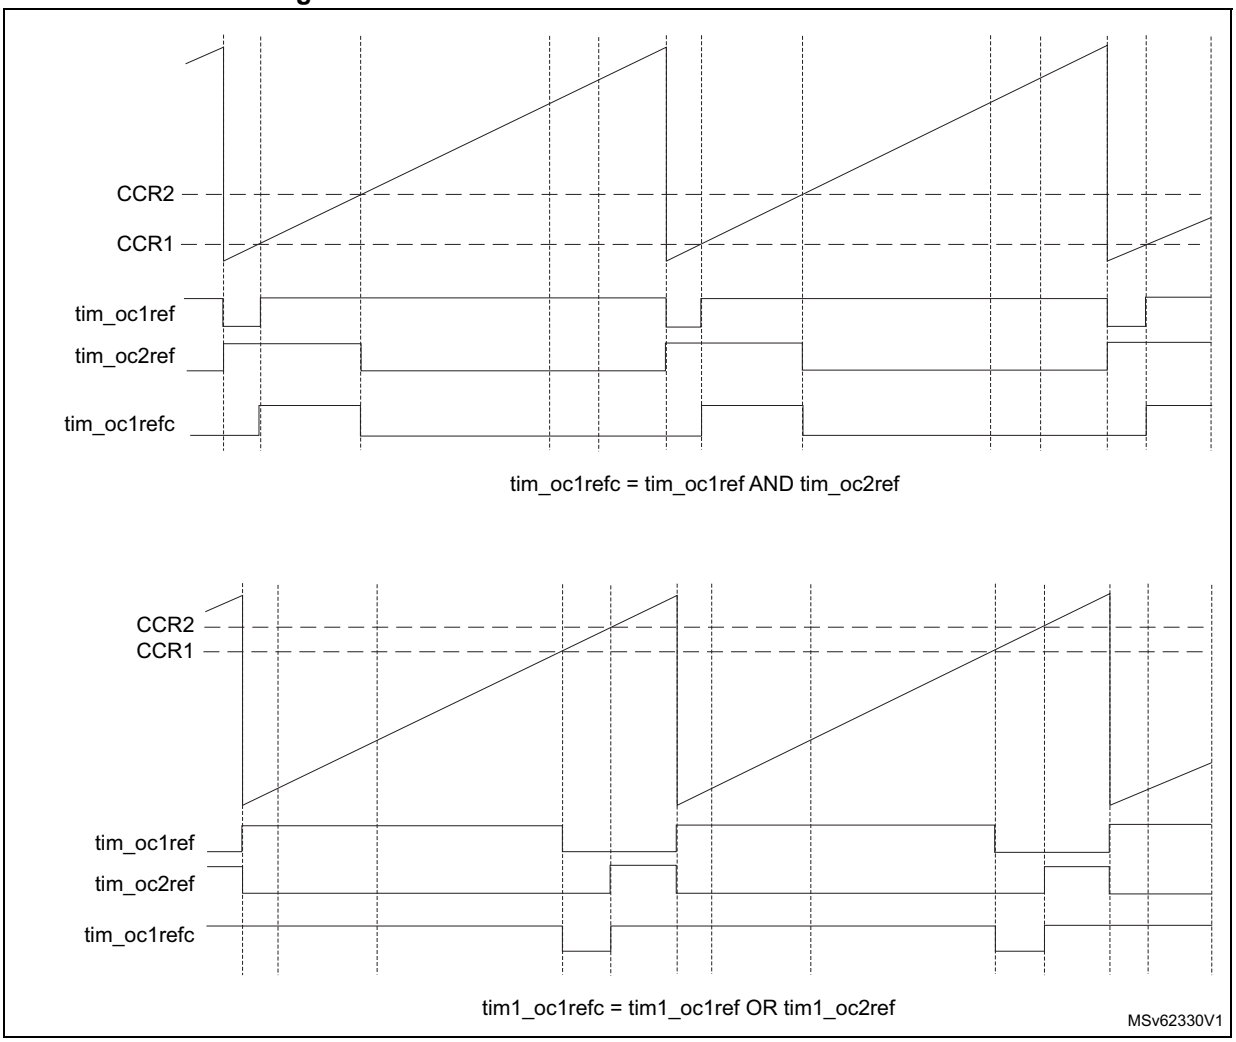
When a given channel is used as combined PWM channel, its secondary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

Note: The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

Figure 466 shows an example of signals that can be generated using combined PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,
- Channel 3 is configured in Combined PWM mode 2,
- Channel 4 is configured in PWM mode 1

Figure 466. Combined PWM mode on channels 1 and 3



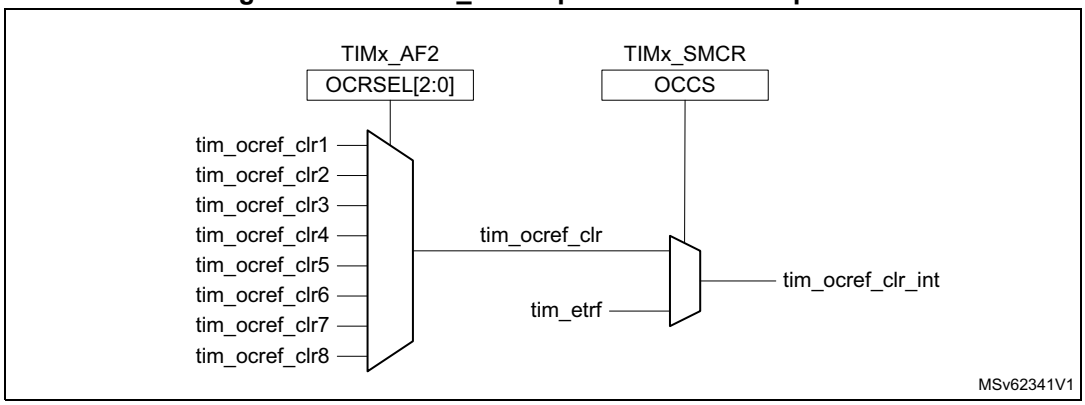
39.4.14 Clearing the tim_ocxref signal on an external event

The tim_ocxref signal of a given channel can be cleared when a high level is applied on the tim_ocref_clr_int input (OCxCE enable bit in the corresponding TIMx_CCMRx register set to 1). tim_ocxref remains low until the next transition to the active state, on the following PWM cycle. This function can only be used in Output compare and PWM modes. It does not work in Forced mode.

The tim_ocref_clr_int source depends on the OCREF clear selection feature implementation, refer to *Section 39.3: TIM2/TIM3/TIM4/TIM5 implementation*.

If the OCREF clear selection feature is implemented, the tim_ocref_clr_int can be selected between the tim_ocref_clr input and the tim_etrf input (tim_etr_in after the filter) by configuring the OCCS bit in the TIMx_SMCR register. The tim_ocref_clr input can be selected among several tim_ocref_clr[7:0] inputs, using the OCRSEL[2:0] bitfield in the TIMx_AF2 register, as shown in *Figure 467* below.

Figure 467. OCREF_CLR input selection multiplexer



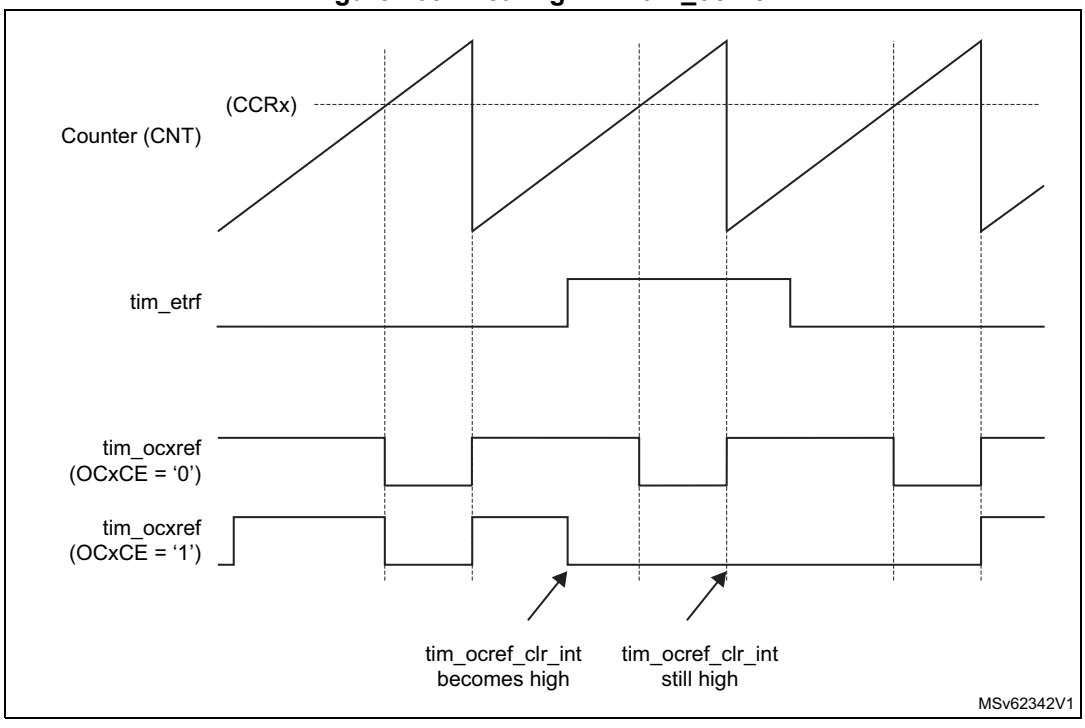
If the OCREF clear selection feature is not implemented, the tim_ocref_clr_int input is directly connected to the tim_etrf input.

For example, the tim_ocref_clr_int signal can be connected to the output of a comparator to be used for current handling. In this case, tim_etr_in must be configured as follows:

1. The external trigger prescaler must be kept off: bits ETPS[1:0] in the TIMx_SMCR register are cleared to 00.
2. The external clock mode 2 must be disabled: bit ECE in the TIM1_SMCR register is cleared to 0.
3. The external trigger polarity (ETP) and the external trigger filter (ETF) can be configured according to the application's needs.

Figure 468 shows the behavior of the tim_ocxref signal when the tim_etrf input becomes high, for both values of the OCxCE enable bit. In this example, the timer TIMx is programmed in PWM mode.

Figure 468. Clearing TIMx tim_ocxref



Note: In case of a PWM with a 100% duty cycle (if CCRx>ARR), tim_ocxref is enabled again at the next counter overflow.

39.4.15 One-pulse mode

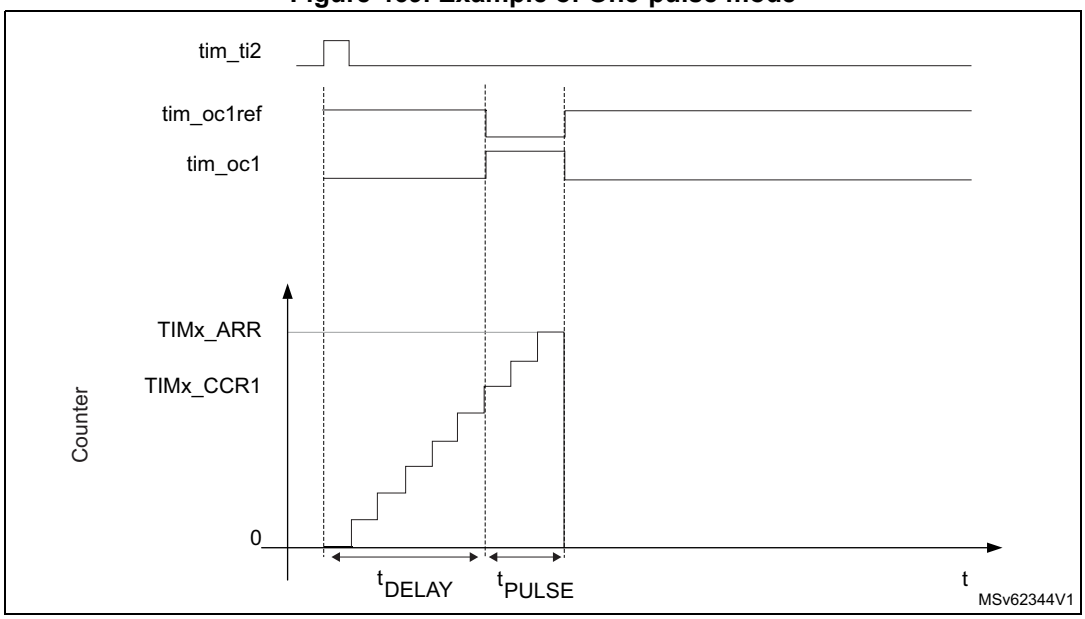
One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- CNT<CCRx ≤ ARR (in particular, 0<CCRx),

Figure 469. Example of One-pulse mode



For example one may want to generate a positive pulse on tim_oc1 with a length of t_{PULSE} and after a delay of t_{DELAY} as soon as a positive edge is detected on the tim_ti2 input pin.

Let's use tim_ti2fp2 as trigger 1:

1. Select the proper tim_ti2_in[15:0] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Map tim_ti2fp2 on tim_ti2 by writing CC2S=01 in the TIMx_CCMR1 register.
3. tim_ti2fp2 must detect a rising edge, write CC2P=0 and CC2NP='0' in the TIMx_CCER register.
4. Configure tim_ti2fp2 as trigger for the slave mode controller (tim_trgi) by writing TS=00110 in the TIMx_SMCR register.
5. tim_ti2fp2 is used to start the counter by writing SMS to '110 in the TIMx_SMCR register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The t_{DELAY} is defined by the value written in the TIMx_CCR1 register.
- The t_{PULSE} is defined by the difference between the auto-reload value and the compare value (TIMx_ARR - TIMx_CCR1).
- Let's say one want to build a waveform with a transition from '0 to '1 when a compare match occurs and a transition from '1 to '0 when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing OC1M=111 in the TIMx_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE=1 in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case one has to write the compare value in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on tim_ti2. CC1P is written to '0 in this example.

In our example, the DIR and CMS bits in the TIMx_CR1 register must be low.

Since only 1 pulse (Single mode) is needed, a 1 must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). When OPM bit in the TIMx_CR1 register is set to '0', so the Repetitive Mode is selected.

Particular case: tim_ocx fast enable:

In One-pulse mode, the edge detection on tim_tix input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay t_{DELAY} min we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then tim_ocxref (and tim_ocx) is forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

39.4.16 Retriggerable one-pulse mode

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with Non-retriggerable one-pulse mode described in *Section 39.4.15*:

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = '1000' (Combined Reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to '1000' or '1001' for Retriggerable OPM mode 1 or 2.

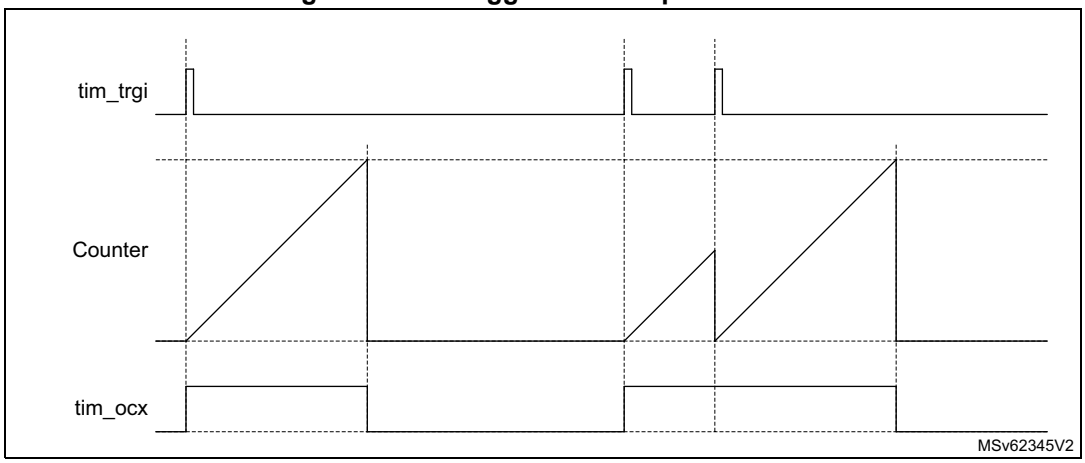
If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode CCRx must be above or equal to ARR.

Note: In Retriggerable one-pulse mode, the CCxIF flag is not significant.

The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.

Figure 470. Retriggerable one-pulse mode

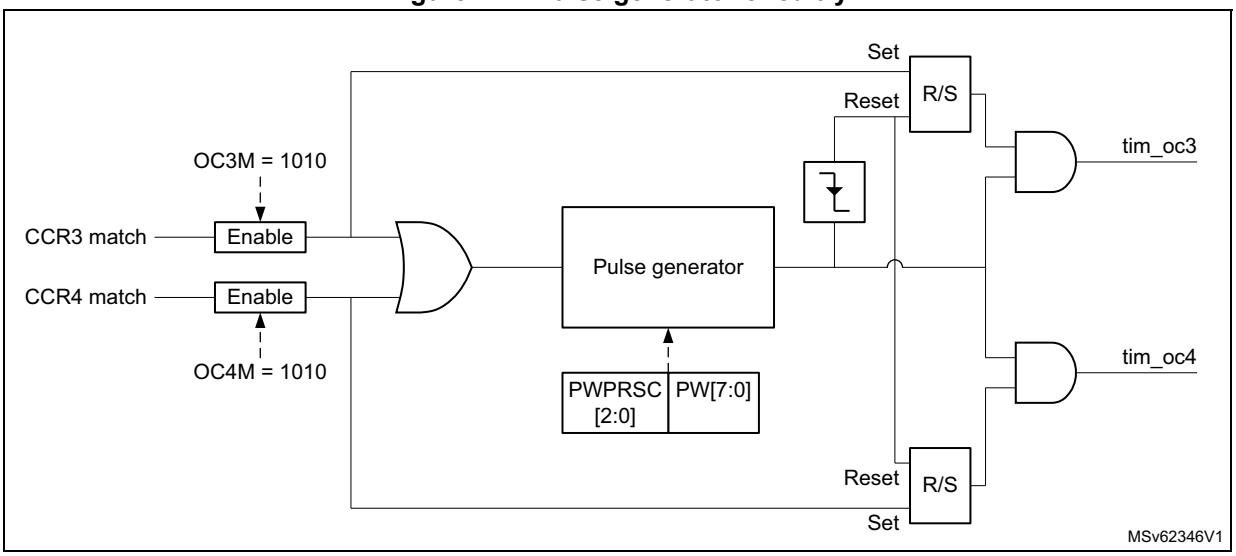


39.4.17 Pulse on compare mode

A pulse can be generated upon compare match event. A signal with a programmable pulse width generated when the counter value equals a given compare value, for debugging or synchronization purposes.

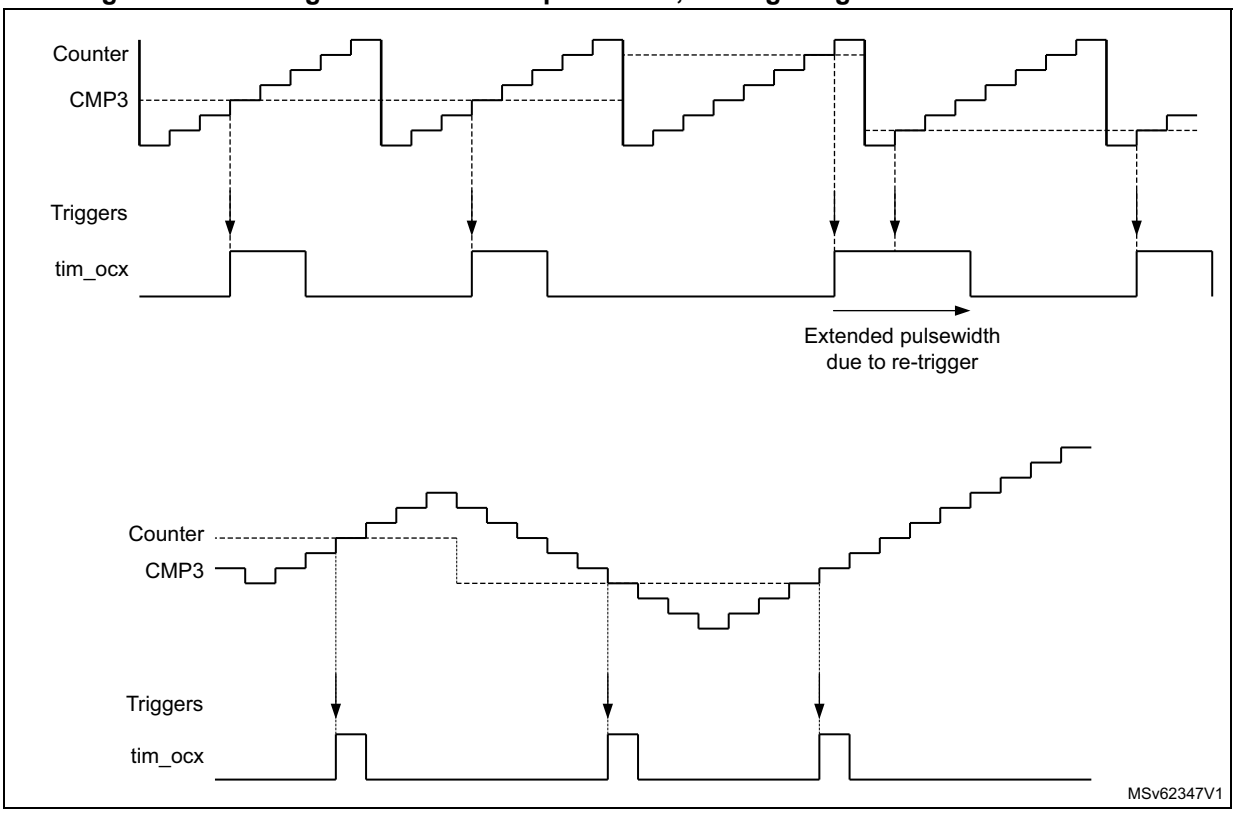
This mode is available for any slave mode selection, including encoder modes, in edge and center aligned counting modes. It is solely available for channel 3 and channel 4. The pulse generator is unique and is shared by the two channels, as shown on the *Figure 471* below.

Figure 471. Pulse generator circuitry



The *Figure 472* below shows how the pulse is generated for edge-aligned and encoder operating modes.

Figure 472. Pulse generation on compare event, for edge-aligned and encoder modes



This output compare mode is selected using the OC3M[3:0] and OC4M[3:0] bit fields in TIMx_CCMR2 register.

The pulse width is programmed using the PW[7:0] bitfield in the register, using a specific clock prescaled according to PWPRSC[2:0] bits, as follows:

$t_{PW} = PW[7:0] \times t_{PWG}$

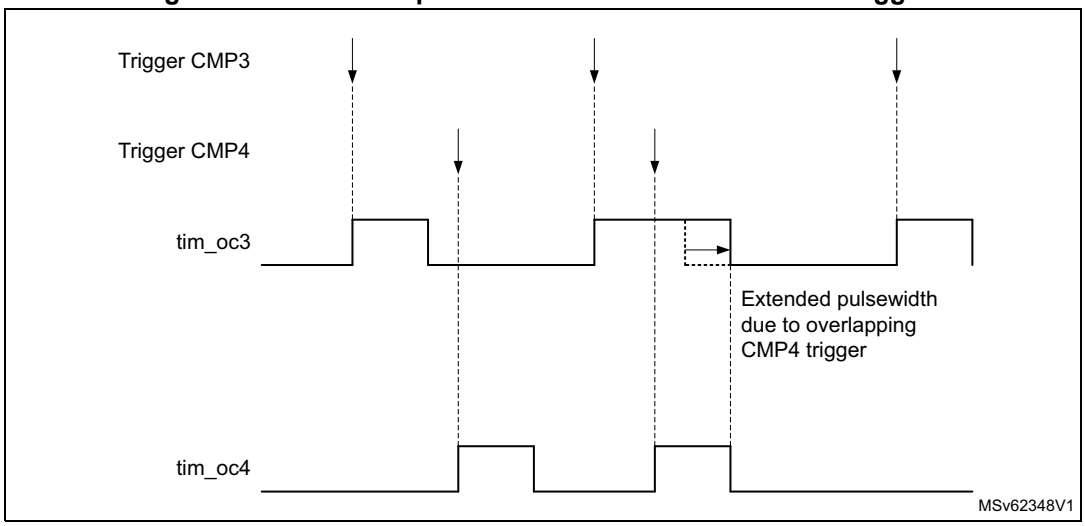
where $t_{PWG} = (2^{(PWPRSC[2:0])}) \times t_{tim\_ker\_ck}$.

gives the resolution and maximum values depending on the prescaler value.

The pulse is retriggerable: a new trigger while the pulse is ongoing, causes the pulse to be extended.

Note: If the two channels are enabled simultaneously, the pulses are issued independently as long as the trigger on one channel is not overlapping the pulse generated on the concurrent output. On the opposite, if the two triggers are overlapping, the pulse width related to the 1st arriving trigger is extended (because of the re-trigger), while the pulse width of the last arriving trigger is correct (as shown on the Figure 473 below).

Figure 473. Extended pulse width in case of concurrent triggers



39.4.18 Encoder interface mode

Quadrature encoder

To select Encoder Interface mode write SMS='0001 in the TIMx_SMCR register if the counter is counting on tim_ti1 edges only, SMS=0010 if it is counting on tim_ti2 edges only and SMS=0011 if it is counting on both tim_ti1 and tim_ti2 edges.

Select the tim_ti1 and tim_ti2 polarity by programming the CC1P and CC2P bits in the TIMx_CCER register. CC1NP and CC2NP must be kept cleared. When needed, the input filter can be programmed as well.

The two inputs tim_ti1 and tim_ti2 are used to interface to an incremental encoder. Refer to *Table 408*. The counter is clocked by each valid transition on tim_ti1fp1 or tim_ti2fp2 (tim_ti1 and tim_ti2 after input filter and polarity selection, tim_ti1fp1=tim_ti1 if not filtered and not inverted, tim_ti2fp2=tim_ti2 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIMx_CR1 register written to '1). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (tim_ti1 or tim_ti2), whatever the counter is counting on tim_ti1 only, tim_ti2 only or both tim_ti1 and tim_ti2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the TIMx_ARR register (0 to ARR or ARR down to 0 depending on the direction). So the TIMx_ARR must be configured before starting. In the same way, the capture, compare, prescaler, trigger output features continue to work as normal. Encoder mode and External clock mode 2 are not compatible and must not be selected together.

In this mode, the counter is modified automatically following the speed and the direction of the quadrature encoder and its content, therefore, always represents the encoder's position. The count direction correspond to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming tim_ti1 and tim_ti2 do not switch at the same time.

Table 408. Counting direction versus encoder signals(CC1P = CC2P = 0)

Active edge	SMS[3:0]	Level on opposite signal (tim_ti1fp1 for tim_ti2, tim_ti2fp2 for tim_ti1)	tim_ti1fp1 signal		tim_ti2fp2 signal	
			Rising	Falling	Rising	Falling
Counting on tim_ti1 only x1 mode	1110	High	Down	Up	No count	No count
		Low	No count	No count	No count	No count
Counting on tim_ti2 only x1 mode	1111	High	No count	No count	Up	Down
		Low	No count	No count	No count	No count
Counting on tim_ti1 only x2 mode	0001	High	Down	Up	No count	No count
		Low	Up	Down	No count	Down
Counting on tim_ti2 only x2 mode	0010	High	No count	No count	Up	Down
		Low	No count	No count	Down	Up
Counting on tim_ti1 and tim_ti2 x4 mode	0011	High	Down	Up	Up	Down
		Low	Up	Down	Down	Up

A quadrature encoder can be connected directly to the MCU without external interface logic. However, comparators are normally be used to convert the encoder's differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicate the mechanical zero position, may be connected to the external trigger input and trigger a counter reset.

Figure 474 gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example we assume that the configuration is the following:

- CC1S= 01 (TIMx_CCMR1 register, tim_ti1fp1 mapped on tim_ti1)
- CC2S= 01 (TIMx_CCMR2 register, tim_ti2fp2 mapped on tim_ti2)
- CC1P and CC1NP = '0' (TIMx_CCER register, tim_ti1fp1 noninverted, tim_ti1fp1=tim_ti1)
- CC2P and CC2NP = '0' (TIMx_CCER register, tim_ti2fp2 noninverted, tim_ti2fp2=tim_ti2)
- SMS= 0011 (TIMx_SMCR register, both inputs are active on both rising and falling edges)
- CEN= 1 (TIMx_CR1 register, Counter is enabled)

Figure 474. Example of counter operation in encoder interface mode

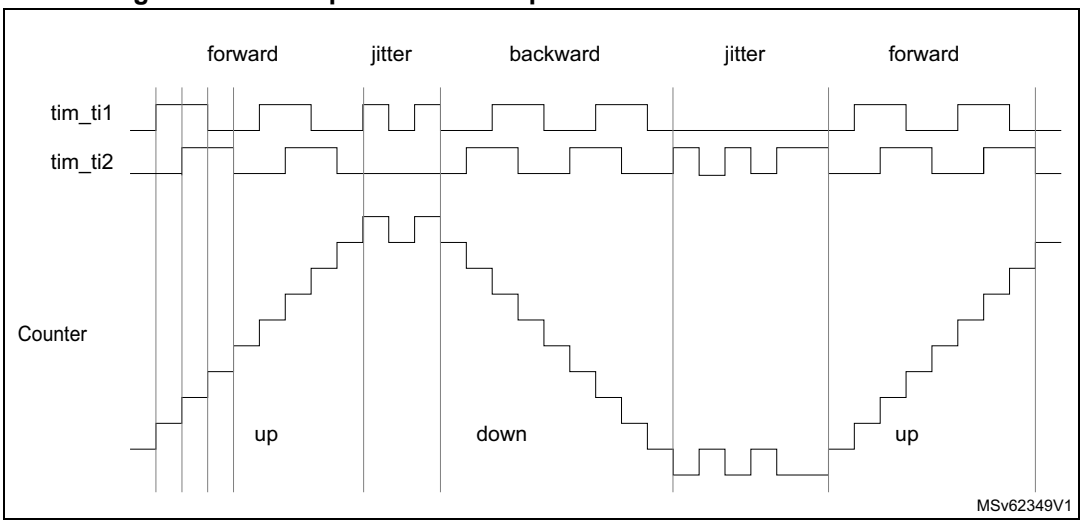


Figure 475 gives an example of counter behavior when tim_ti1fp1 polarity is inverted (same configuration as above except CC1P=1).

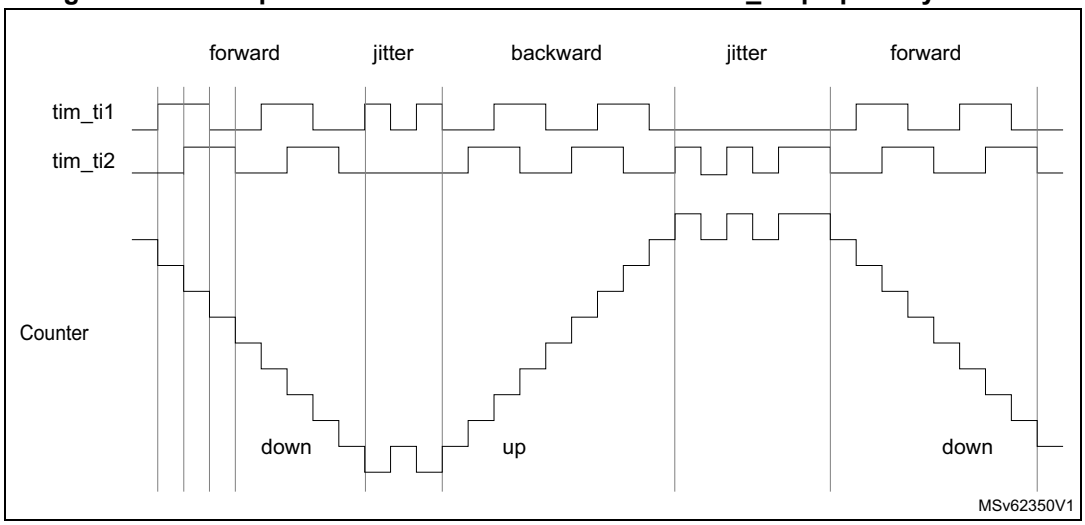
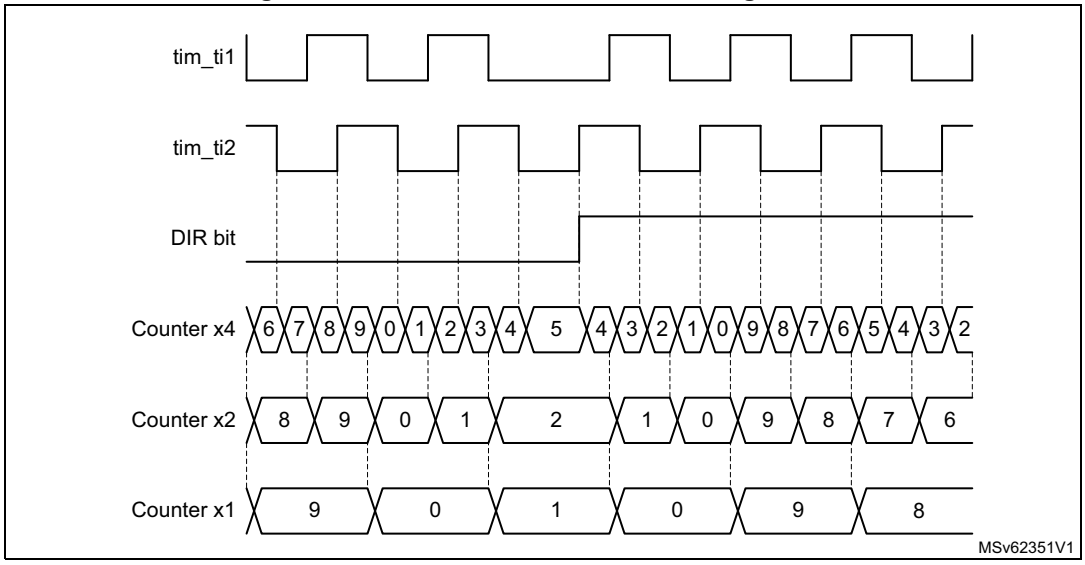
Figure 475. Example of encoder interface mode with tim_ti1fp1 polarity inverted



The *Figure 476* below shows the timer counter value during a speed reversal, for various counting modes.

Figure 476. Quadrature encoder counting modes



The timer, when configured in Encoder Interface mode provides information on the sensor's current position. Dynamic information can be obtained (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. This can be done by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). when available, it is also possible to read its value through a DMA request.

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the update interrupt flag (UIF) into the timer counter register's bit 31 (TIMxCNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter's most significant bit is only accessible in write mode).

Clock plus direction encoder mode

In addition to the quadrature encoder mode, the timer offers support other types of encoders.

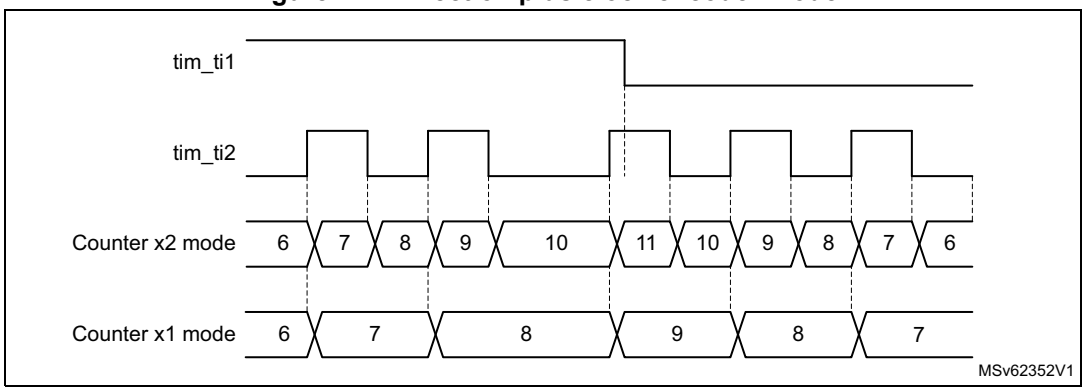
In the "clock plus direction" mode shown on *Figure 477*, the clock is provided on a single line, on tim_ti2, while the direction is forced using the tim_ti1 input.

This mode is enabled with the SMS[3:0] bitfield in the TIMx_SMCR register, as following:

- 1010: x2 mode, the counter is updated on both rising and falling edges of the clock
- 1011: x1 mode, the counter is updated on a single clock edge, as per CC2P bit value: CC2P = 0 corresponds to rising edge sensitivity and CC2P = 1 corresponds to falling edge sensitivity

The polarity of the direction signal on tim_ti1 is set with the CC1P bit: 0 corresponds to positive polarity (up-counting when tim_ti1 is high and down-counting when tim_ti1 is low) and CC1P = 1 corresponds to negative polarity (up-counting when tim_ti1 is low).

Figure 477. Direction plus clock encoder mode



Directional Clock encoder mode

In the “directional clock” mode on *Figure 478*, the clocks are provided on two lines, with a single one at once, depending on the direction, so as to have one up-counting clock line and one down-counting clock line.

This mode is enabled with the SMS[3:0] bitfield in the TIMx_SMCR register, as following:

- 1100: x2 mode, the counter is updated on both rising and falling edges of any of the two clock line. The CC1P and CC2P bits are coding for the clock idle state. CCxP = 0 corresponds to high-level idle state (refer to *Figure 478* below) and CCxP = 1 corresponds to low-level idle state (refer to *Figure 479* below).
- 1101: x1 mode, the counter is updated on a single clock edge, as per CC1P and CC2P bit value. CCxP = 0 corresponds to falling edge sensitivity and high-level idle state (refer to *Figure 478* below), CCxP = 1 corresponds to rising edge sensitivity and low-level idle state (refer to *Figure 479* below).

Figure 478. Directional clock encoder mode (CC1P = CC2P = 0)

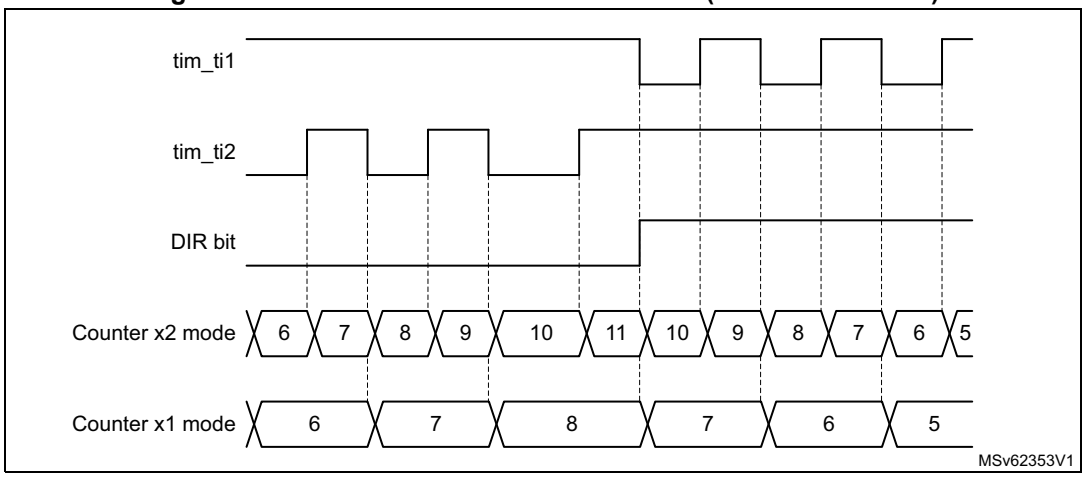


Figure 479. Directional clock encoder mode (CC1P = CC2P = 1)

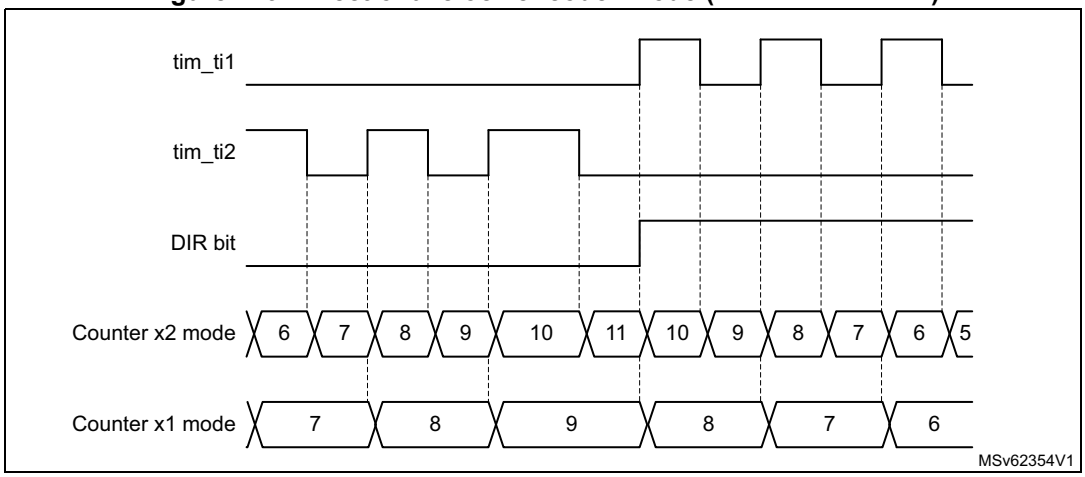


The *Table 409* here-below details how the directional clock mode operates, for any input transition.

Table 409. Counting direction versus encoder signals and polarity settings

Directional clock mode	SMS[3:0]	Level on opposite signal (tim_ti1fp1 for tim_ti2, tim_ti2fp2 for tim_ti1)	tim_ti1fp1 signal		tim_ti2fp2 signal	
			Rising	Falling	Rising	Falling
x2 mode CCxP=0	1100	High	Down	Down	Up	Up
		Low	No count	No count	No count	No count
x2 mode CCxP=1	1100	High	No count	No count	No count	No count
		Low	Down	Down	Up	Up
x1 mode CCxP=0	1101	High	No count	Down	No count	Up
		Low	No count	No count	No count	No count
x1 mode CCxP=1	1101	High	No count	No count	No count	No count
		Low	Down	No count	Up	No count

Index Input

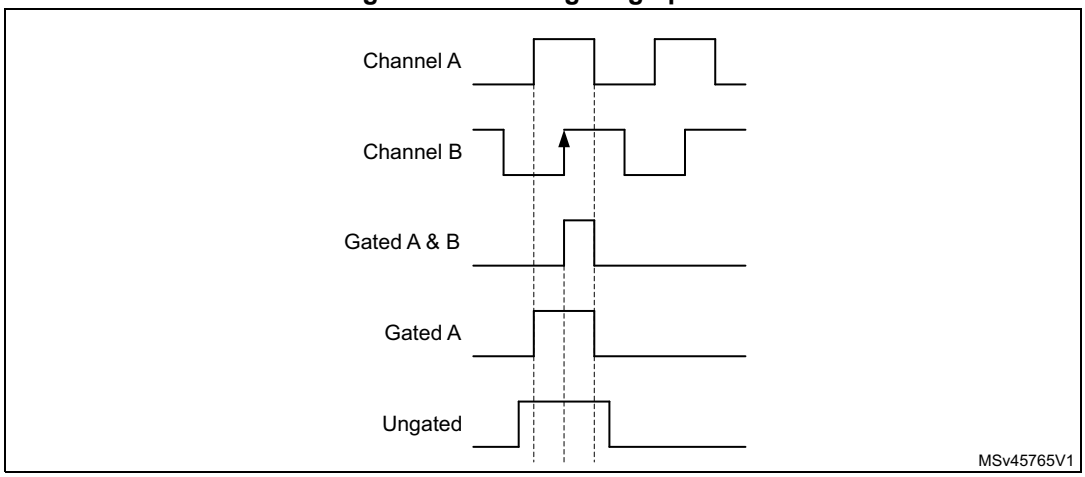
The counter can be reset by an Index signal coming from the encoder, indicating an absolute reference position. The Index signal must be connected to the tim_etr_in input. It can be filtered using the digital input filter.

The index functionality is enabled with the IE bit in the TIMx_ECR register. The IE bit must be set only in encoder mode, when the SMS[3:0] bitfield has the following values: 0001, 0010, 011, 1010, 1011, 1100, 1101, 1110, 1111.

Commercially available encoders are proposed with several options for index pulse conditioning, as per the *Figure 480* below:

- gated with A and B: the pulse width is 1/4 of one channel period, aligned with both A and B edges
- gated with A (or gated with B): the pulse width is 1/2 of one channel period, aligned with the two edges on channel A (resp. channel B)
- ungated: the pulse width is up to one channel period, without any alignment to the edges

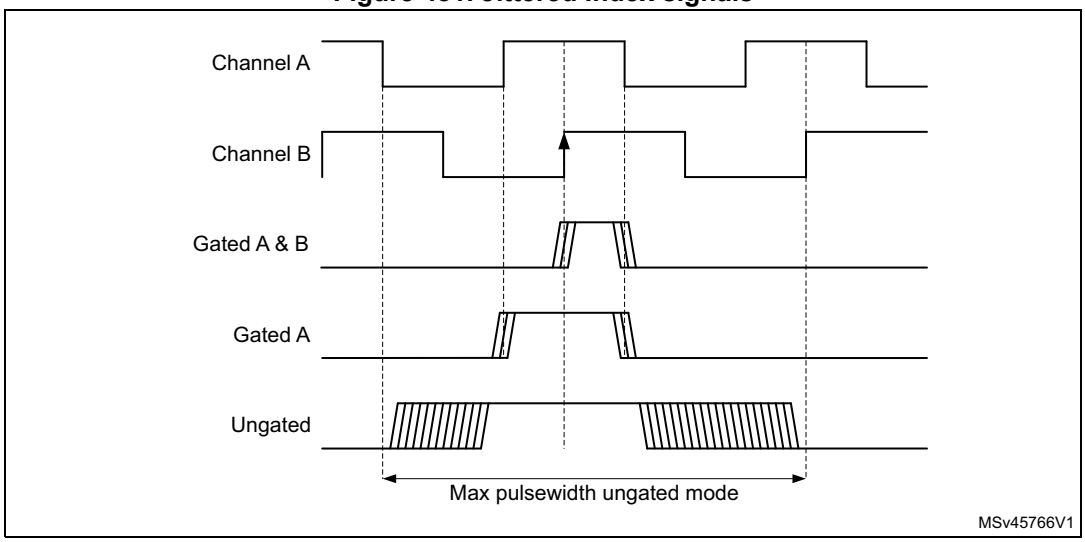
Figure 480. Index gating options



The circuitry tolerates jitter on index signal, whatever the gating mode, as show on *Figure 481* below.

In ungated mode, the signal must be strictly below 2 encoder periods. If the pulse width is greater or equal to 2 encoder period, the counter is reset multiple times.

Figure 481. Jittered Index signals



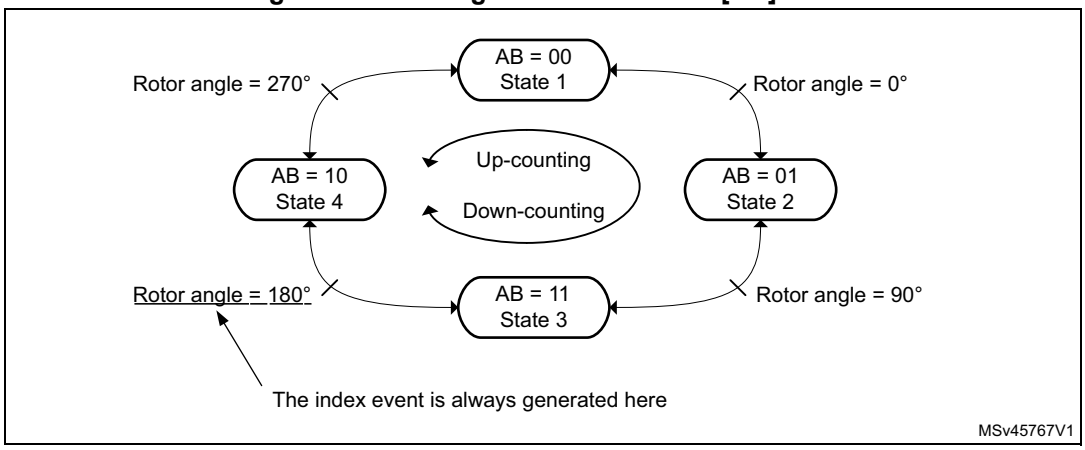
The timer supports the 3 gating options identically, without any specific programming needed. It is only necessary to define on which encoder state (i.e. channel A and channel B state combination) the index must be synchronized, using the IPOS[1:0] bitfield in the TIMx_ECR register.

The Index detection event acts differently depending on counting direction to ensure symmetrical operation during speed reversal:

- The counter is reset during up-counting (DIR bit = 0)
- The counter is set to TIMx_ARR when down counting

This allows the index to be generated on the very same mechanical angular position whatever the counting direction. The *Figure 482* below shows at which position is the index generated, for a simplistic example (an encoder providing 4 edges par mechanical rotation).

Figure 482. Index generation for IPOS[1:0] = 11



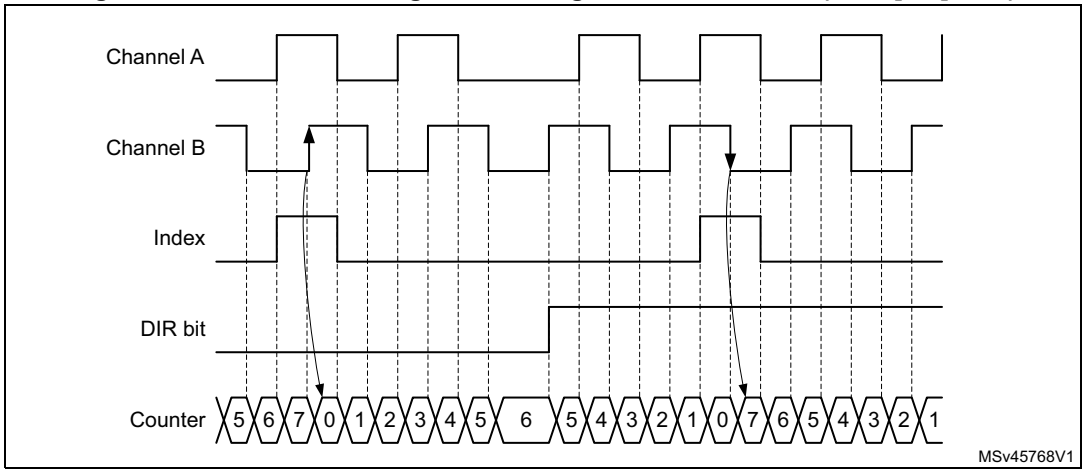
The *Figure 483* below presents waveforms and corresponding values for IPOS[1:0] = 11. It shows that the instant at which the counter value is forced is automatically adjusted depending on the counting direction:

- Counter set to 0 when encoder state is '11' (ChA=1, ChB=1), when up-counting (DIR bit = 0).
- Counter set to TIMx_ARR when exiting the '11' state, when down-counting (DIR bit = 1).

An interrupt can be issued upon index detection event.

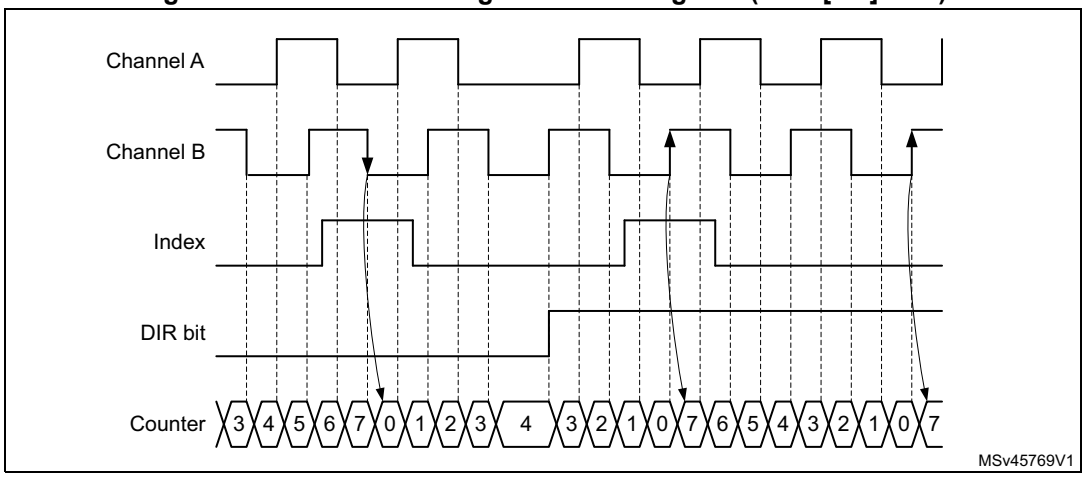
The arrows are indicating on which transition is the index event interrupt generated.

Figure 483. Counter reading with index gated on channel A (IPOS[1:0] = 11)



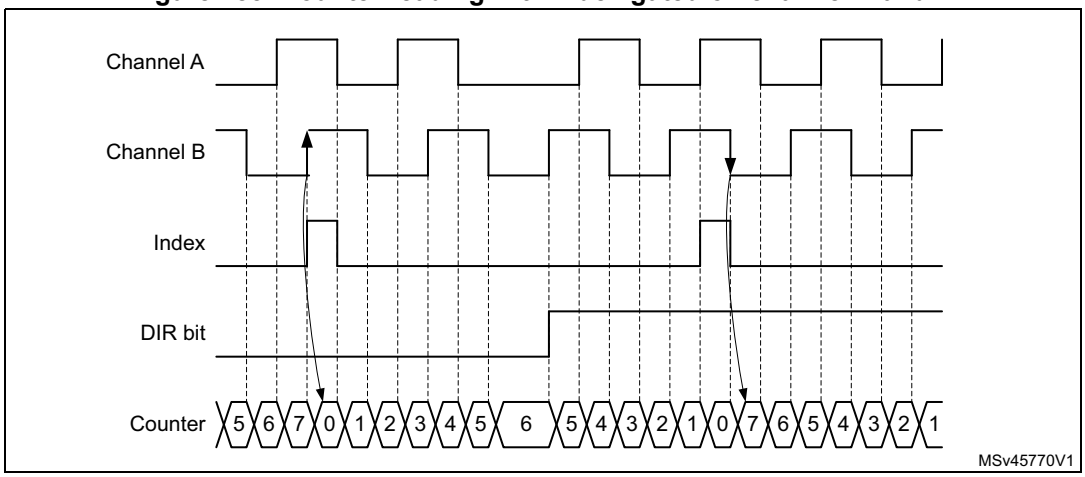
The *Figure 484* below presents waveforms and corresponding values for the ungated mode. The arrows are indicating on which transition is the index event generated.

Figure 484. Counter reading with index ungated (IPOS[1:0] = 00)



The *Figure 485* below shows how the 'gated on A & B' mode is handled, for various pulse alignment scenario. The arrows are indicating on which transition is the index event generated.

Figure 485. Counter reading with index gated on channel A and B



The *Figure 486* and *Figure 487* detail the case where the subsequent index pulse may be narrower than one quarter of the encoder clock period.

Figure 486. Encoder mode behavior in case of narrow index pulse (IPOS[1:0] = 11)

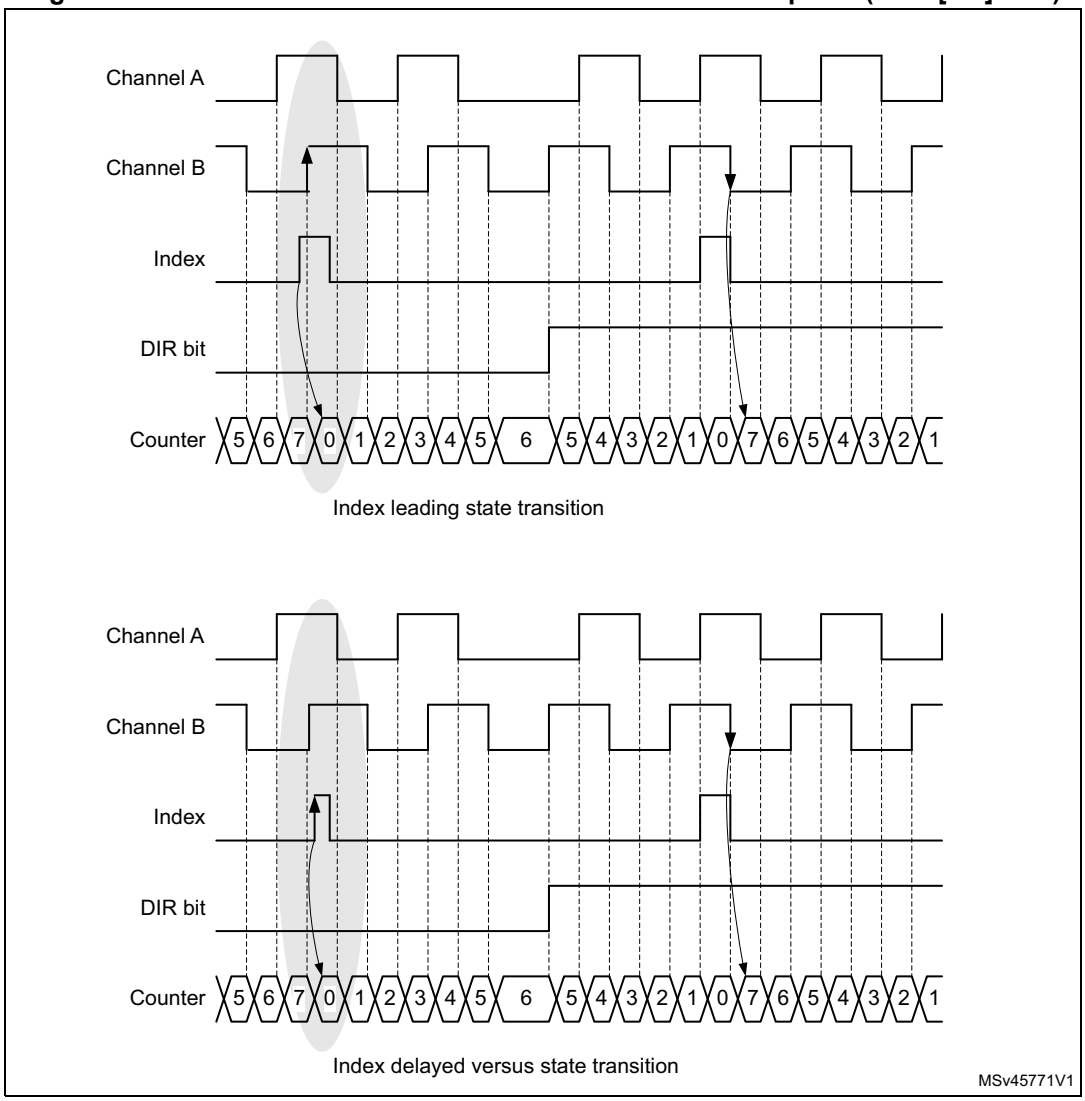


Figure 487. Counter reset Narrow index pulse (closer view, ARR = 0x07)

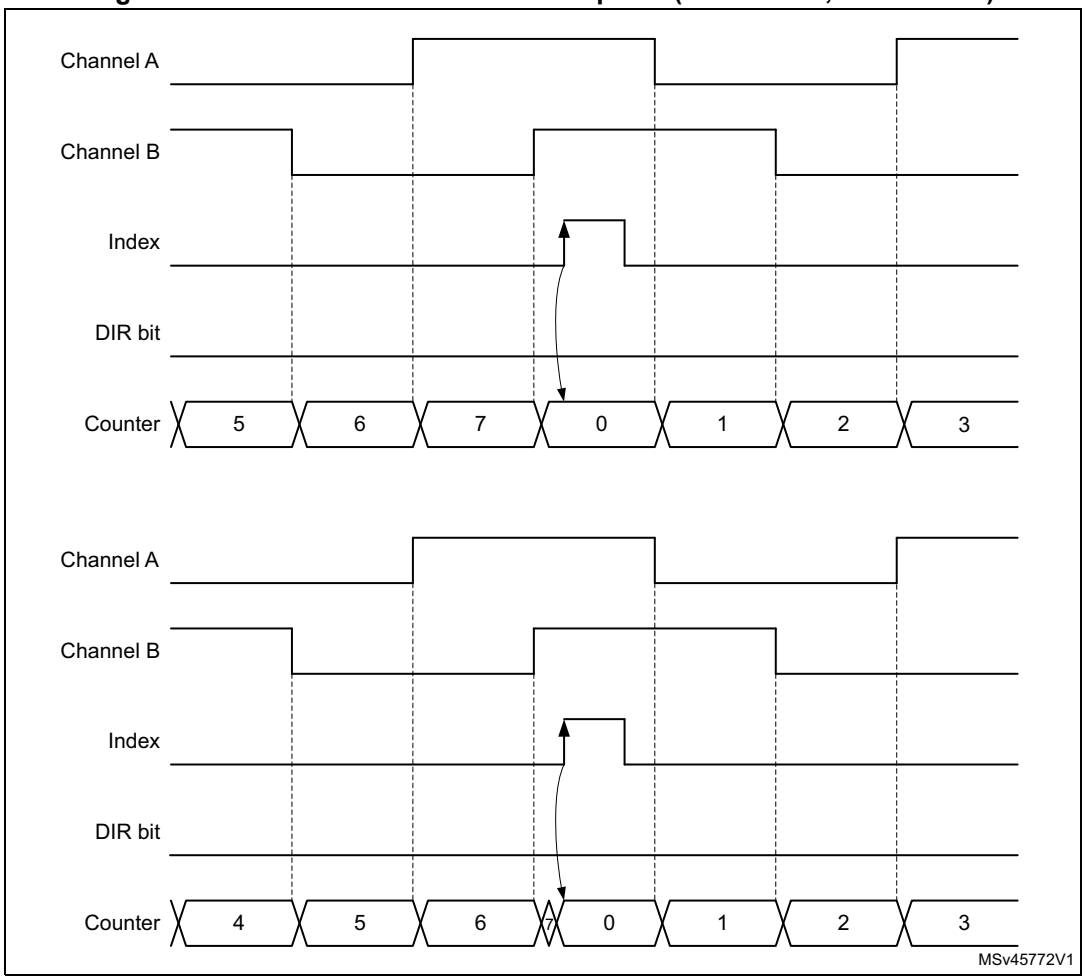
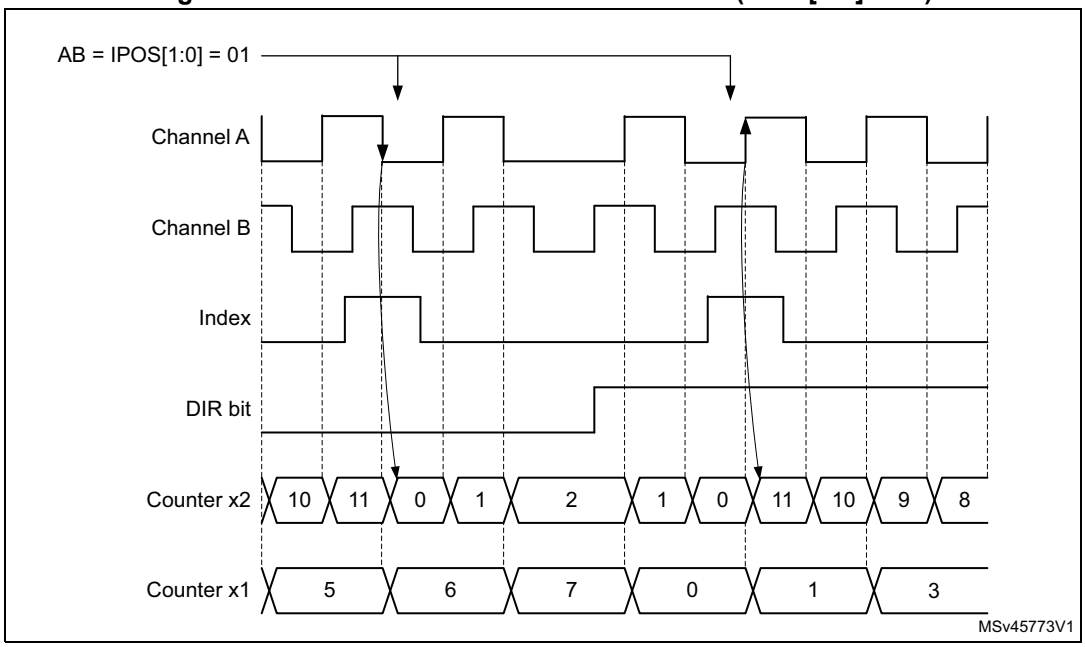


The *Figure 488* below shows how the index is managed in x1 and x2 modes.

Figure 488. Index behavior in x1 and x2 mode (IPOS[1:0] = 01)

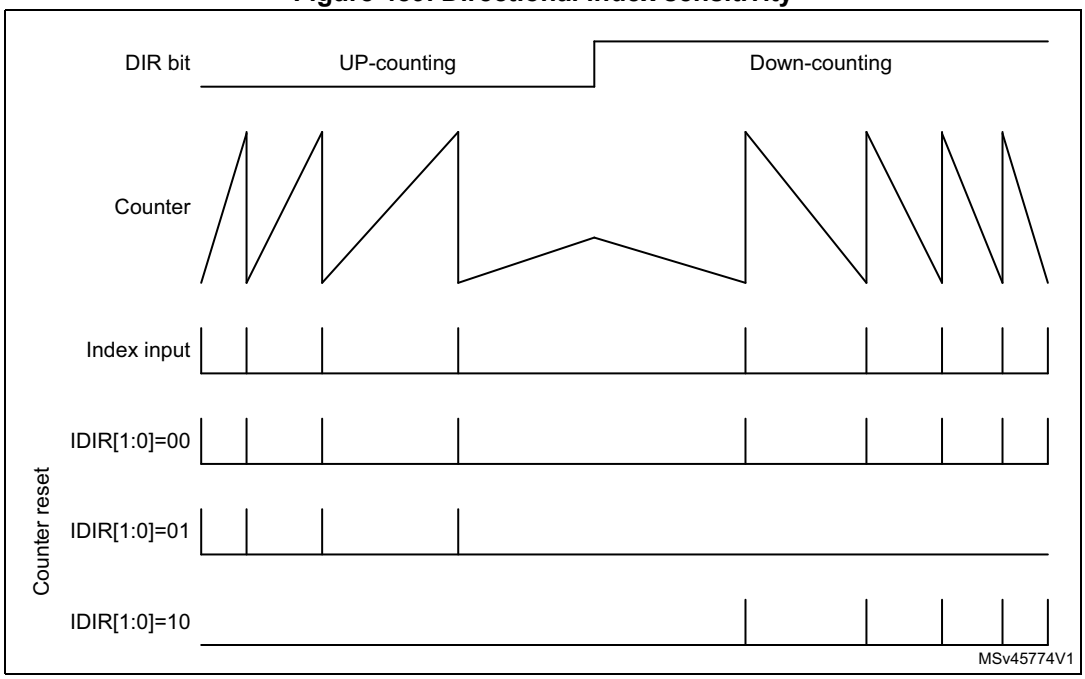


Directional index sensitivity

The IDIR[1:0] bitfield in the TIMx_ECR register allows the index to be active only in a selected counting direction.

The *Figure 489* below shows the relationship between index and counter reset events, depending on IDIR[1:0] value.

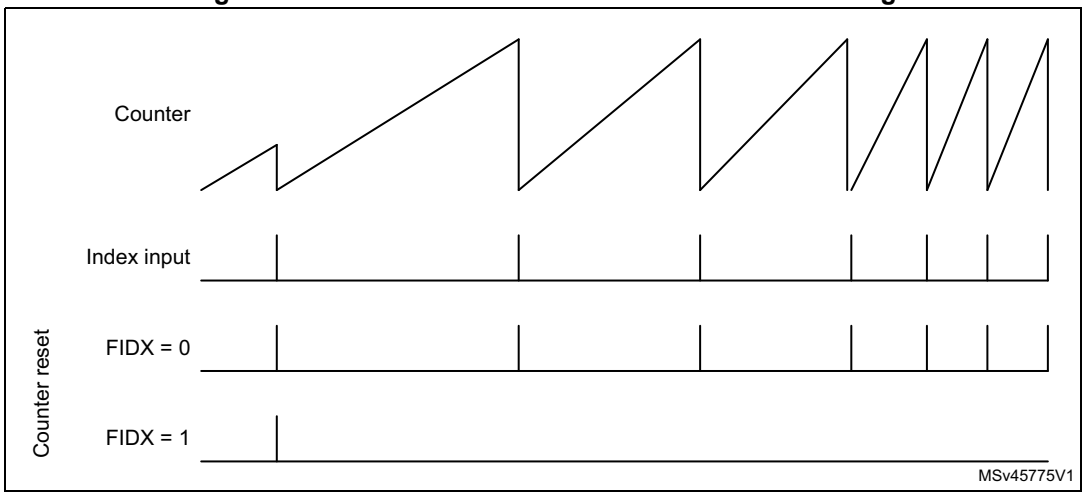
Figure 489. Directional index sensitivity



Special first index event management

The FIDX bit in the TIMx_ECR register allows the Index to be taken only once, as shown on the *Figure 490* below. Once the first index has arrived, any subsequent index is ignored. If needed, the circuitry can be re-armed by writing the FIDX bit to 0 and setting it again to 1.

Figure 490. Counter reset as function of FIDX bit setting



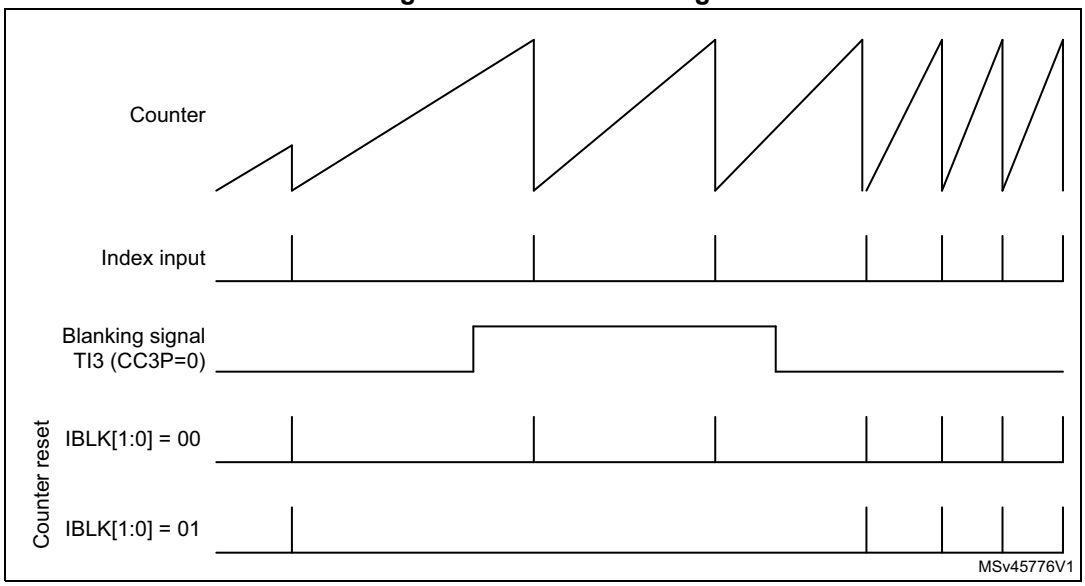
Index blanking

The Index event can be blanked using the tim_ti3 or tim_ti4 inputs. During the blanking window, the index events are no longer resetting the counter, as shown on the *Figure 491* below.

This mode is enabled using the IBLK[1:0] bitfield in the TIMx_ECR register, as following:

- IBLK[1:0] = 00: Index signal always active
- IBLK[1:0] = 01: Index signal blanking on tim_ti3 input
- IBLK[1:0] = 10: Index signal blanking on tim_ti4 input

Figure 491. Index blanking



Index management in non-quadrature mode

The *Figure 492* and *Figure 493* below detail how the index is managed in directional clock mode and clock plus direction mode, when the SMS[3:0] bitfield is equal to 1010, 1011, 1100, 1101.

For both of these modes, the index sensitivity is set with the IPOS[0] bit as following:

- IPOS[0] = 0: Index is detected on clock low level
- IPOS[0] = 1: Index is detected on clock high level

The IPOS[1] bit is not-significant.

Figure 492. Index behavior in clock + direction mode, IPOS[0] = 1

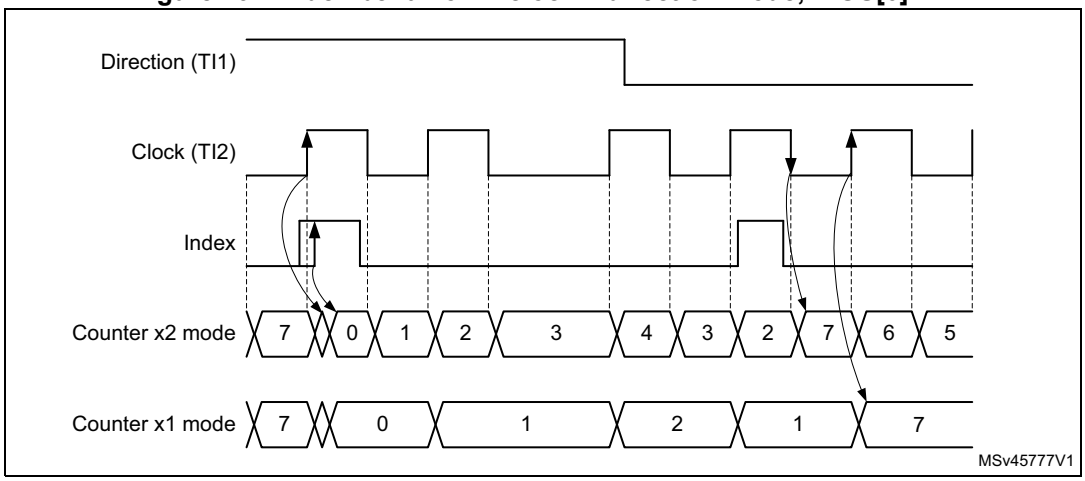


Figure 493. Index behavior in directional clock mode, IPOS[0] = 1

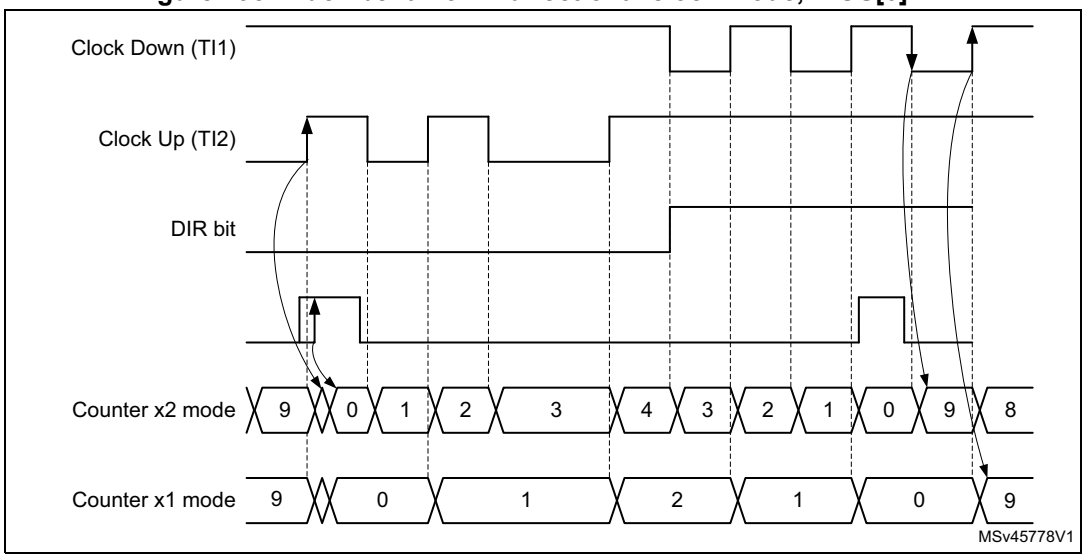
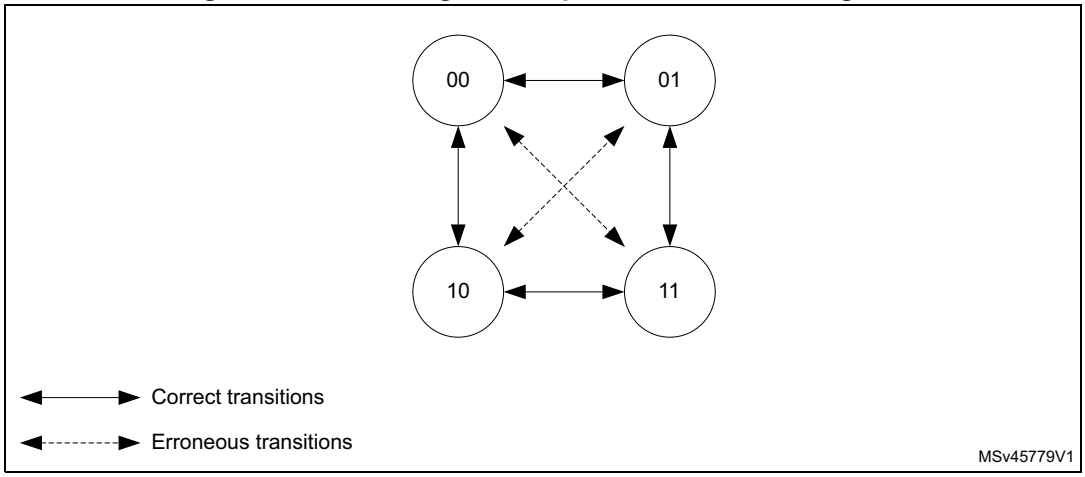


Encoder error management

For encoder configurations where 2 quadrature signals are available, it is possible to detect transition errors. The reading on the 2 inputs corresponds to a 2-bit gray code which can be represented as a state diagram, on the *Figure 494.* below. A single bit is expected to change at once. An erroneous transition sets the TERRF interrupt flag in the TIMx_SR status

register. A transition error interrupt is generated if the TERRIE bit is set in the TIMx_DIER register.

Figure 494. State diagram for quadrature encoded signals



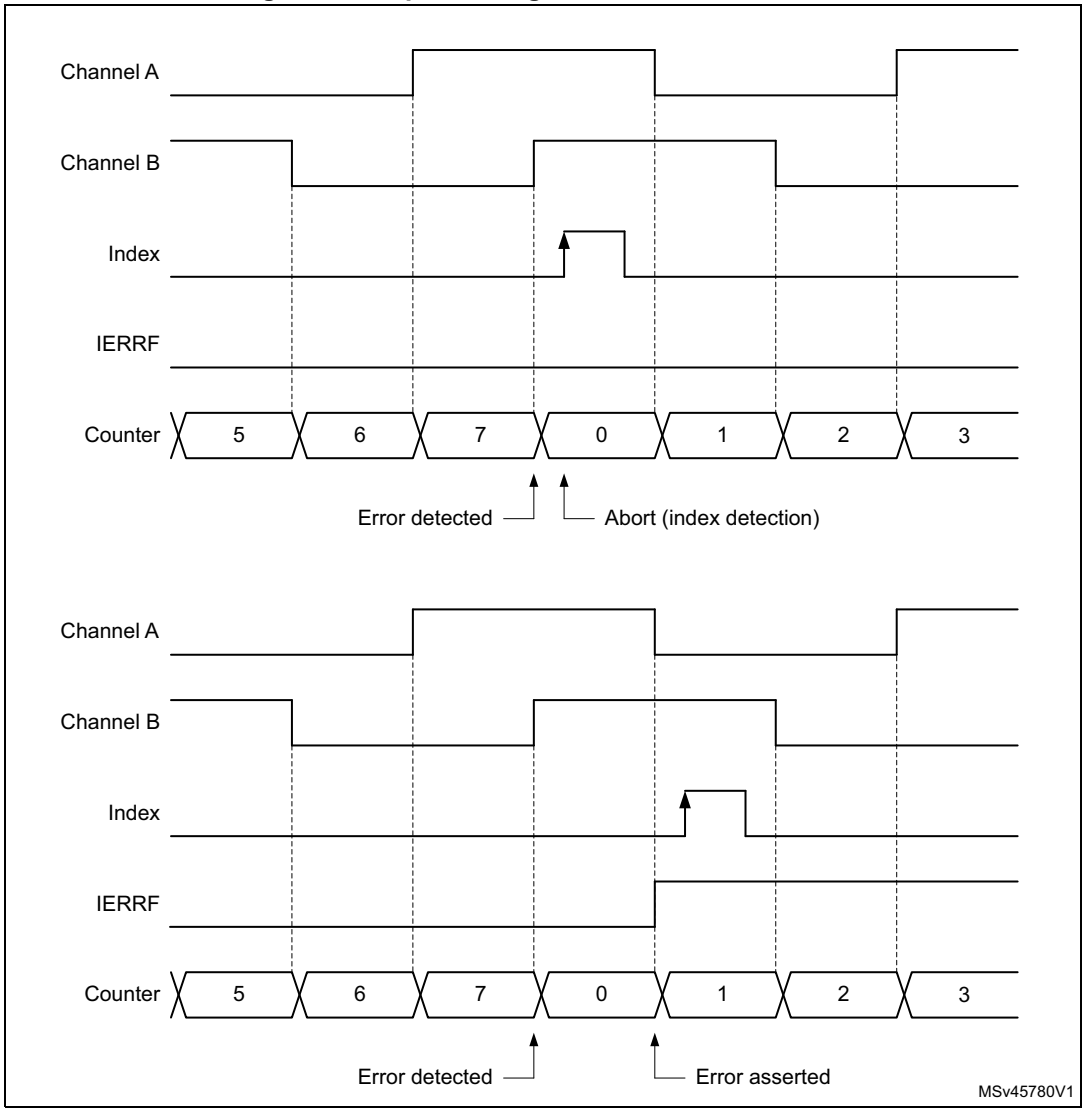
For encoder having an Index signal, it is possible to detect abnormal operation resulting in an excess of pulses per revolution. An encoder with N pulses per revolution provides 4xN counts per revolution. The Index signal resets the counter every 4xN clock periods.

If the counter value is incremented from TIMx_ARR to 0 or decremented from 0 to TIMxARR value without any index event, this is reported as an Index position error.

The overflow threshold is programmed using the TIMx_ARR register. A 1000 lines encoder results in a counter value being between 0 and 3999 (in 4x reading mode). The overflow detection threshold must be programmed by setting TIMx_ARR = 3999 + 1 = 4000.

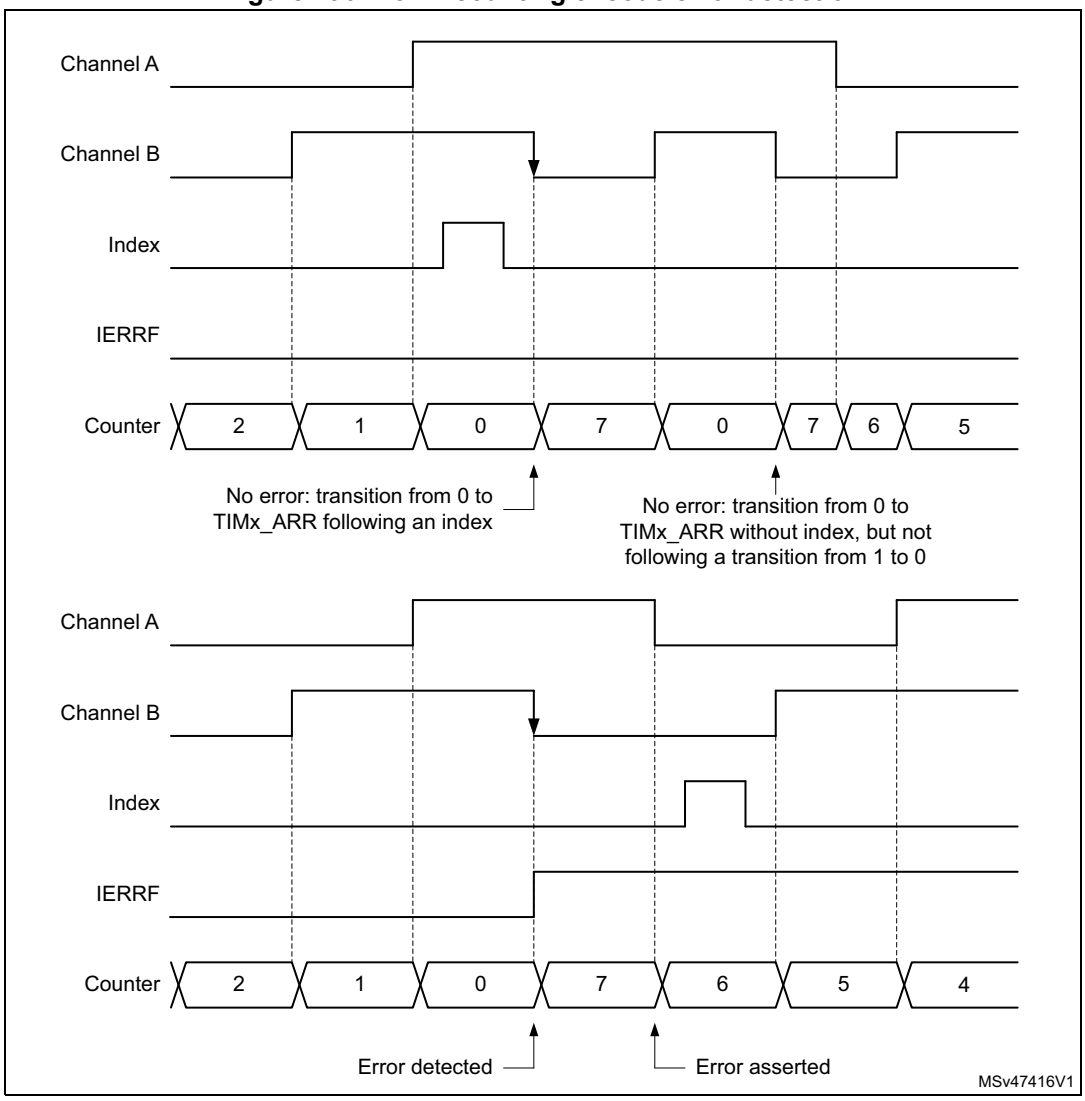
The error assertion is delayed to the transition 0 to 1 when in up-counting. This is cope with narrow index pulses in gated A and B mode, as shown on *Figure 495* below.

Figure 495. Up-counting encoder error detection



In down-counting mode, the detection is conditioned by a preliminary transition from 1 to 0. This is to cope with narrow index pulses in gated A and B mode, as shown on *Figure 496* below, to avoid any false error detection in case the encoder dithers between TIMx_ARR and 0 immediately after the index detection.

Figure 496. Down-counting encode error detection



An index error sets the IERRF interrupt flag in the TIMx_SR status register. An index error interrupt is generated if the IERRIE bit is set in the TIMx_DIER register.

Functional encoder Interrupts

The following interrupts are also available in encoder mode

- Direction change: any change of the counting direction in encoder mode causes the DIR bit in the TIMx_CR1 register to toggle. The direction change sets the DIRF interrupt flag in the TIMx_SR status register. A direction change interrupt is generated if the DIRIE bit is set in the TIMx_DIER register.
- Index event: the Index event sets the IDXF interrupt flag in the TIMx_SR status register. An Index interrupt is generated if the IDXIE bit is set in the TIMx_DIER register.

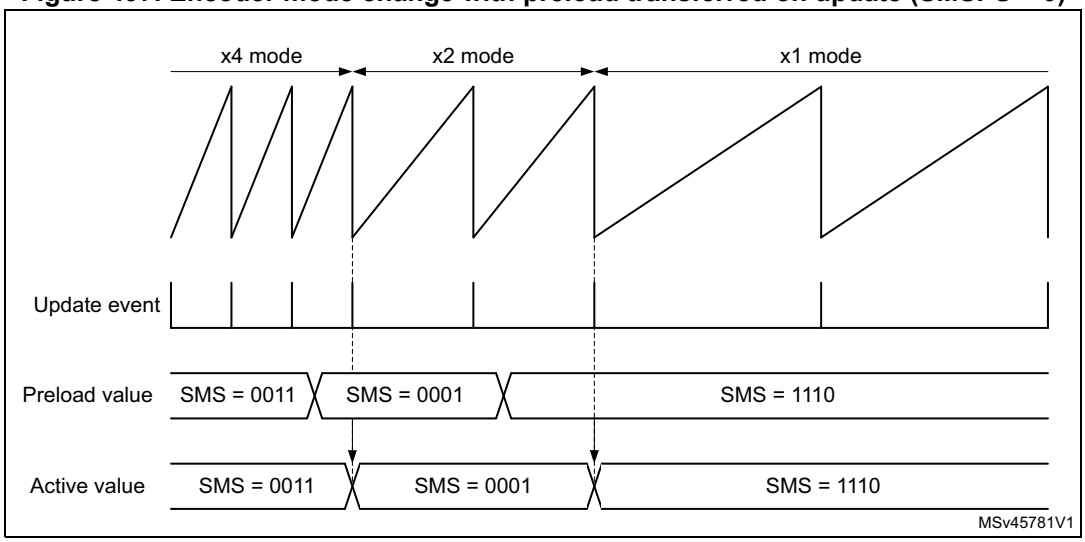
Slave mode selection preload for run-time encoder mode update

It may be necessary to switch from one encoder mode to another during run-time. This is typically done at high-speed to decrease the Update interrupt rate, by switching from x4 to x2 to x1 mode, as show on the *Figure 497* below.

For this purpose, the SMS[3:0] bit can be preloaded. This is enabled by setting the SMSPE enable bit in the TIMx_SMCR register. The trigger for the transfer from SMS[3:0] preload to active value can be selected with the SMSPS bit in the TIMx_SMCR register.

- SMSPS = 0: the transfer is triggered by the update event (UEV) occurring when the counter overflows when upcounting, and underflows when downcounting.
- SMSPS = 1: the transfer is triggered by the Index event.

Figure 497. Encoder mode change with preload transferred on update (SMSPS = 0)



Encoder clock output

The encoder mode operating principle is not perfectly suited for high-resolution velocity measurements, at low speed, as it requires a relatively long integration time to have a sufficient number of clock edges and a precise measurement.

At low speed, a better solution is to do an edge-to-edge clock period measurement. This can be achieved using a slave timer. The timer can output the encoder clock information on the tim_trgo output. The slave timer can then perform a period measurement and provide velocity information for each and every encoder clock edge.

This mode is enabled by setting the MMS[3:0] bitfield to 1000, in the TIMx_CR2 register.It is valid for the following SMS[3:0] values: 0001, 0010, 0011, 1010, 1011, 1100, 1101, 1110, 1111. Any other SMS[3:0] code is not allowed and may lead to unexpected behavior.

39.4.19 Direction bit output

Its is possible to output a direction signal out of the timer, on the tim_oc3 and tim_oc4 output signals (copy of the DIR bit in the TIMx_CR1 register). This is achieved by setting the OC3M[3:0] or the OC4M[3:0] bit field to 1011 in the TIMx_CCMR2 register.

This feature can be used for monitoring the counting direction (or rotation direction) in encoder mode, or to have a signal indicating the up/down phases in center-aligned PWM mode.

39.4.20 UIF bit remapping

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the update interrupt flag (UIF) into bit 31 of the timer counter register's bit 31 (TIMxCNT[31]). This is used to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter's most significant bit is only accessible in write mode).

39.4.21 Timer input XOR function

The TI1S bit in the TIM1xx_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the three input pins tim_ti1, tim_ti2 and tim_ti3.

The XOR output can be used with all the timer input functions such as trigger or input capture.

An example of this feature used to interface Hall sensors is given in *Section 38.3.29: Interfacing with Hall sensors on page 1508*.

39.4.22 Timers and external trigger synchronization

The TIMx Timers can be synchronized with an external trigger in several modes: Reset mode, Gated mode, Trigger mode, Reset + trigger and gated + reset modes.

Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on tim_ti1 input:

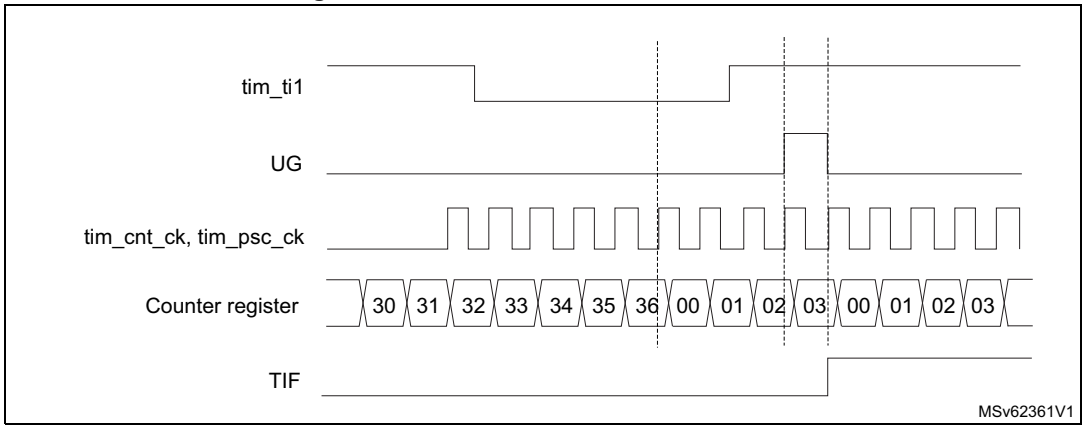
1. Configure the channel 1 to detect rising edges on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P=0 and CC1NP=0 in TIMx_CCER register to validate the polarity (and detect rising edges only).
2. Configure the timer in reset mode by writing SMS=100 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.
3. Start the counter by writing CEN=1 in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until tim_ti1 rising edge. When tim_ti1 rises, the counter is cleared and restarts from 0. In the meantime, the

trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on tim_ti1 and the actual reset of the counter is due to the resynchronization circuit on tim_ti1 input.

Figure 498. Control circuit in reset mode



Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

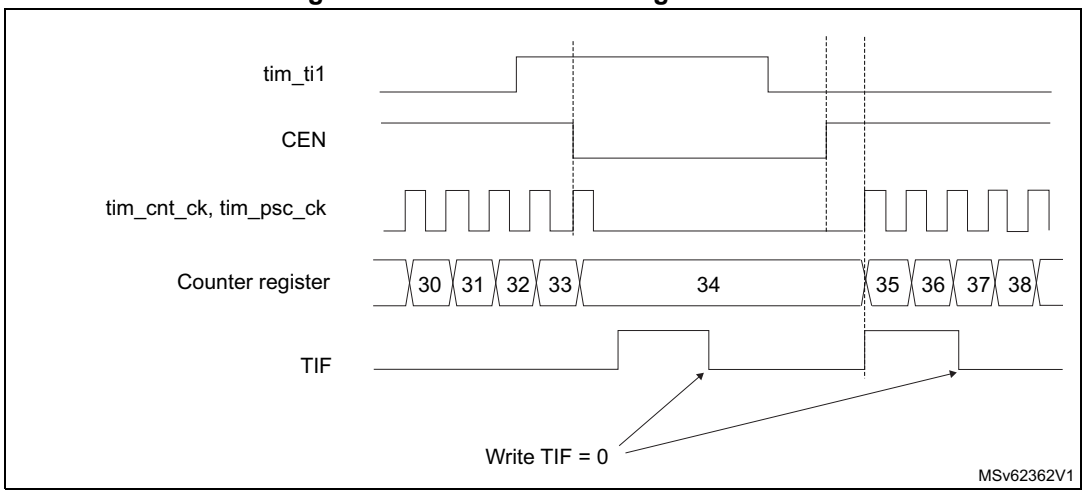
In the following example, the upcounter counts only when tim_ti1 input is low:

1. Configure the channel 1 to detect low levels on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx_CCMR1 register. Write CC1P=1 and CC1NP=0 in TIMx_CCER register to validate the polarity (and detect low level only).
2. Configure the timer in gated mode by writing SMS=101 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.
3. Enable the counter by writing CEN=1 in the TIMx_CR1 register (in gated mode, the counter doesn't start if CEN=0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as tim_ti1 is low and stops as soon as tim_ti1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on tim_ti1 and the actual stop of the counter is due to the resynchronization circuit on tim_ti1 input.

Figure 499. Control circuit in gated mode



Note: The configuration "CCxP=CCxNP=1" (detection of both rising and falling edges) does not have any effect in gated mode because gated mode acts on a level and not on an edge.

Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

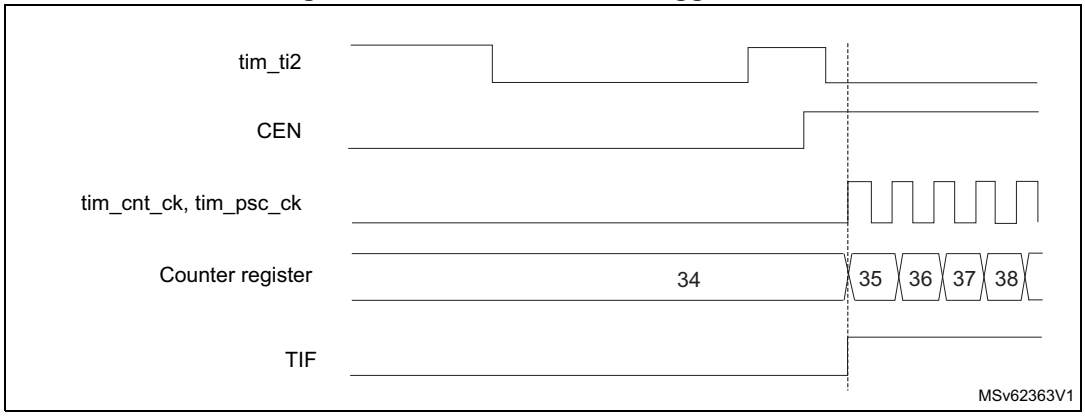
In the following example, the upcounter starts in response to a rising edge on tim_ti2 input:

1. Configure the channel 2 to detect rising edges on tim_ti2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. CC2S bits are selecting the input capture source only, CC2S=01 in TIMx_CCMR1 register. Write CC2P=1 and CC2NP=0 in TIMx_CCER register to validate the polarity (and detect low level only).
2. Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select tim_ti2 as the input source by writing TS=00110 in TIMx_SMCR register.

When a rising edge occurs on tim_ti2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on tim_ti2 and the actual start of the counter is due to the resynchronization circuit on tim_ti2 input.

Figure 500. Control circuit in trigger mode



Slave mode selection preload for run-time encoder mode update

The SMS[3:0] bit can be preloaded. This is enabled by setting the SMSPE enable bit in the TIMx_SMCR register. The trigger for the transfer from SMS[3:0] preload to active value is the update event (UEV) occurring when the counter overflows.

Slave mode – combined reset + trigger mode

In this case, a rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for one-pulse mode.

Slave mode – combined gated + reset mode

The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

This mode is used to detect out-of-range PWM signal (duty cycle exceeding a maximum expected value).

Slave mode – external clock mode 2 + trigger mode

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the tim_etr_in signal is used as external clock input, and another input can be selected as trigger input when operating in reset mode, gated mode or trigger mode. It is recommended not to select tim_etr_in as tim_trgi through the TS bits of TIMx_SMCR register.

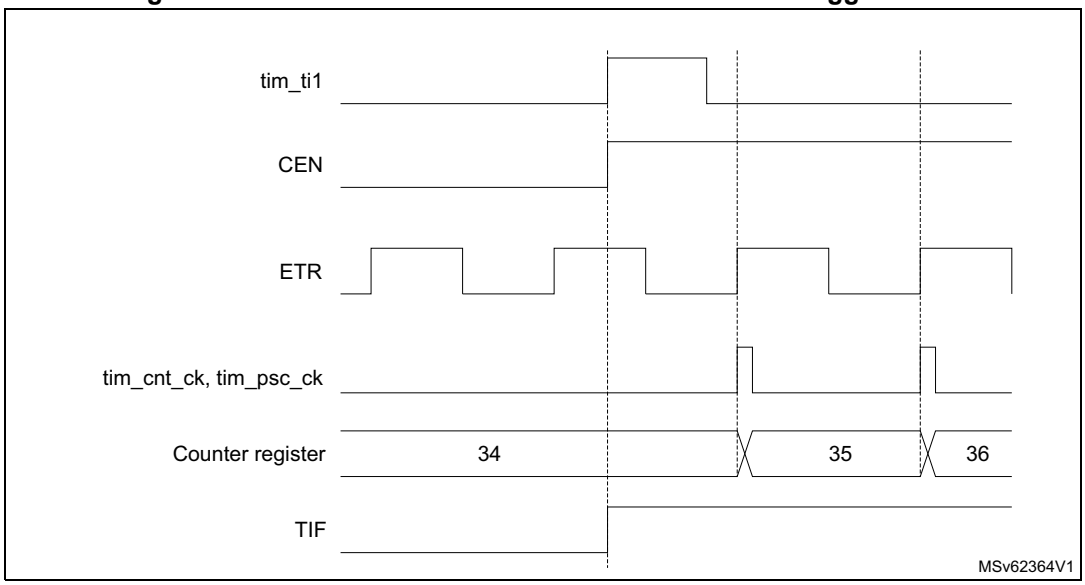
In the following example, the upcounter is incremented at each rising edge of the tim_etr_in signal as soon as a rising edge of tim_ti1 occurs:

1. Configure the external trigger input circuit by programming the TIMx_SMCR register as follows:
   - ETF = 0000: no filter
   - ETPS=00: prescaler disabled
   - ETP=0: detection of rising edges on tim_etr_in and ECE=1 to enable the external clock mode 2.
2. Configure the channel 1 as follows, to detect rising edges on TI:
   - IC1F=0000: no filter.
   - The capture prescaler is not used for triggering and does not need to be configured.
   - CC1S=01in TIMx_CCMR1 register to select only the input capture source
   - CC1P=0 and CC1NP=0 in TIMx_CCER register to validate the polarity (and detect rising edge only).
3. Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.

A rising edge on tim_ti1 enables the counter and sets the TIF flag. The counter then counts on tim_etr_in rising edges.

The delay between the rising edge of the tim_etr_in signal and the actual reset of the counter is due to the resynchronization circuit on tim_etrp input.

Figure 501. Control circuit in external clock mode 2 + trigger mode



39.4.23 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. When one Timer is configured in Master Mode, it can reset, start, stop or clock the counter of another Timer configured in Slave Mode.

Figure 502 and *Figure 503* show examples of master/slave timer connections.

Figure 502. Master/Slave timer example

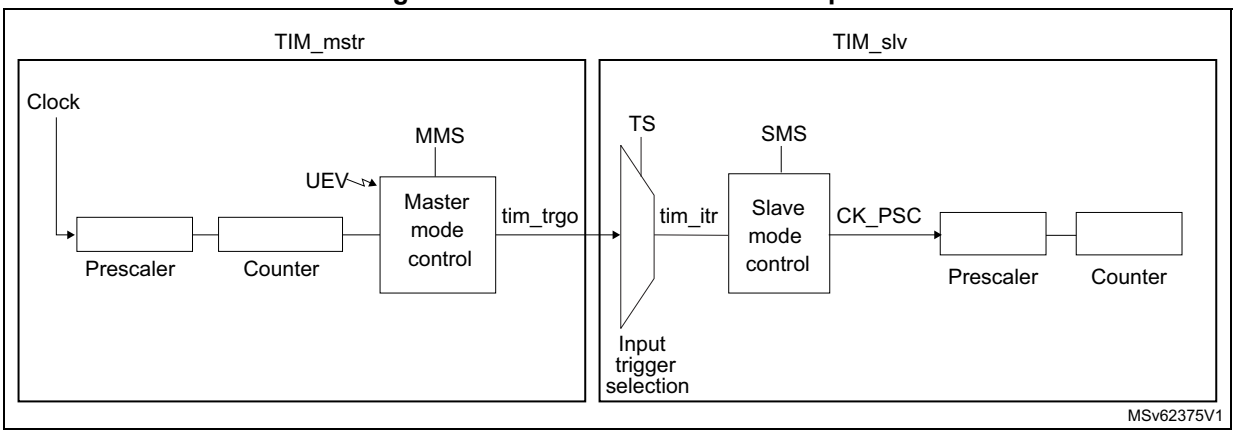


Figure 503. Master/slave connection example with 1 channel only timers

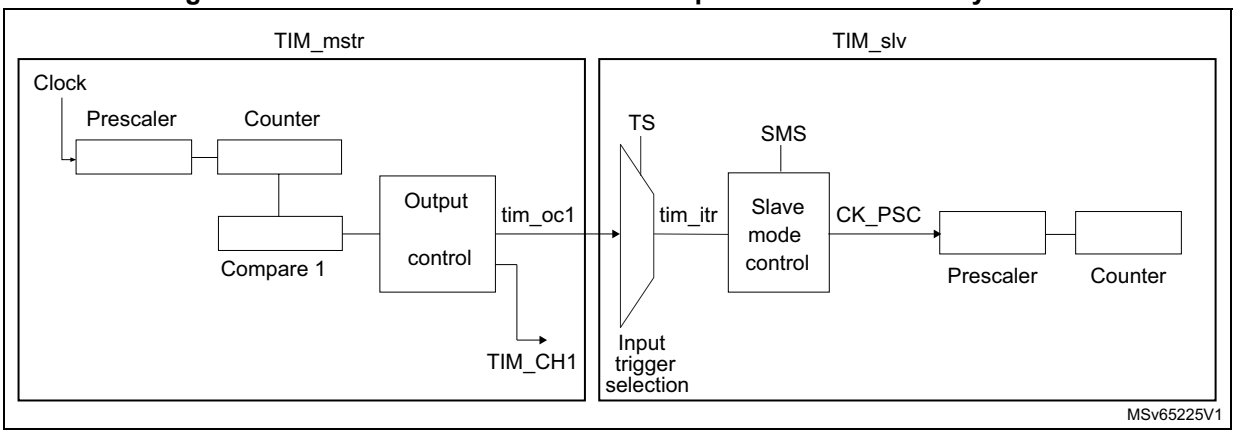


Note: The timers with one channel only (see Figure 503) do not feature a master mode. However, the tim_oc1 output signal can serve as trigger for slave timer (see TIMx internal trigger connection table in Section 39.4.2: TIM2/TIM3/TIM4/TIM5 pins and internal signals). The tim_oc1 signal pulse width must be programmed to be at least 2 clock cycles of the destination timer, to make sure the slave timer detects the trigger. For instance, if the destination timer tim_ker_ck clock is 4 times slower than the source timer, the OC1 pulse width must be 8 clock cycles.

Using one timer as prescaler for another timer

For example, TIM_mstr can be configured to act as a prescaler for TIM_slv. Refer to *Figure 502*. To do this:

1. Configure TIM_mstr in master mode so that it outputs a periodic trigger signal on each update event UEV. If MMS=010 is written in the TIM_mstr_CR2 register, a rising edge is output on tim_trgo each time an update event is generated.
2. To connect the tim_trgo output of TIM_mstr to TIM_slv, TIM_slv must be configured in slave mode using ITR2 as internal trigger. This is selected through the TS bits in the TIM_slv_SMCR register (writing TS=00010).
3. Then the slave mode controller must be put in external clock mode 1 (write SMS=111 in the TIM_slv_SMCR register). This causes TIM_slv to be clocked by the rising edge of the periodic TIM_mstr trigger signal (which correspond to the TIM_mstr counter overflow).
4. Finally both timers must be enabled by setting their respective CEN bits (TIMx_CR1 register).

Note: If tim_ocx is selected on TIM_mstr as the trigger output (MMS=1xx), its rising edge is used to clock the counter of TIM_slv.

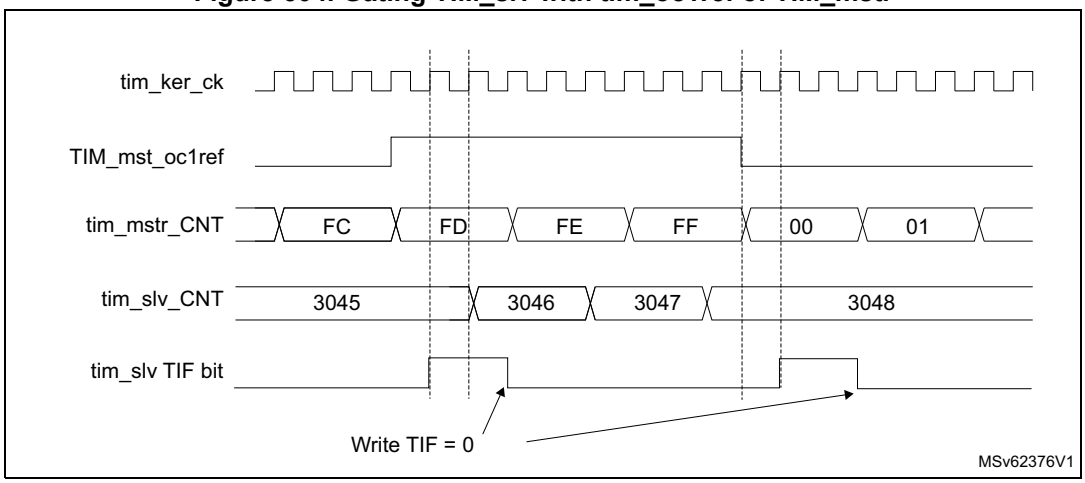
Using one timer to enable another timer

In this example, we control the enable of TIM_slv with the output compare 1 of TIM_mstr. Refer to *Figure 502* for connections. TIM_slv counts on the divided internal clock only when tim_oc1ref of TIM_mstr is high. Both counter clock frequencies are divided by 3 by the prescaler compared to tim_ker_ck ($f_{tim\_cnt\_ck} = f_{tim\_ker\_ck}/3$).

1. Configure TIM_mstr master mode to send its Output Compare 1 Reference (tim_oc1ref) signal as trigger output (MMS=100 in the TIM_mstr_CR2 register).
2. Configure the TIM_mstr tim_oc1ref waveform (TIM_mstr_CCMR1 register).
3. Configure TIM_slv to get the input trigger from TIM_mstr (TS=00010 in the TIM_slv_SMCR register).
4. Configure TIM_slv in gated mode (SMS=101 in TIM_slv_SMCR register).
5. Enable TIM_slv by writing ‘1 in the CEN bit (TIM_slv_CR1 register).
6. Start TIM_mstr by writing ‘1 in the CEN bit (TIM_mstr_CR1 register).

Note: The slave timer counter clock is not synchronized with the master timer counter clock, this mode only affects the TIM_slv counter enable signal.

Figure 504. Gating TIM_slv with tim_oc1ref of TIM_mstr

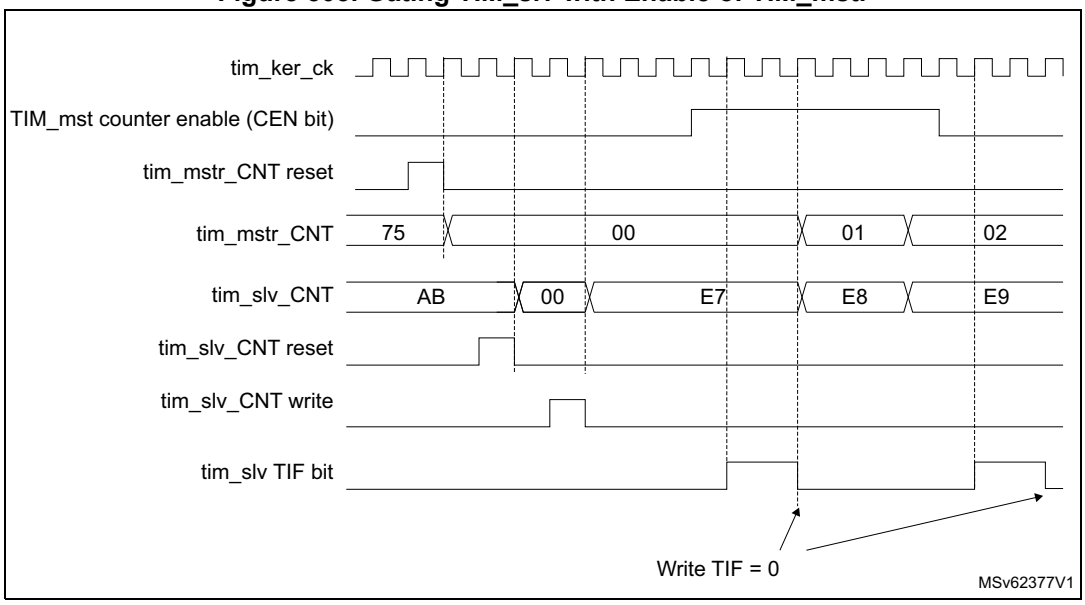


In the example in *Figure 504*, the TIM_slv counter and prescaler are not initialized before being started. So they start counting from their current value. It is possible to start from a given value by resetting both timers before starting TIM_mstr. Then any value can be written in the timer counters. The timers can easily be reset by software using the UG bit in the TIMx_EGR registers.

In the next example (refer to *Figure 505*), we synchronize TIM_mstr and TIM_slv. TIM_mstr is the master and starts from 0. TIM_slv is the slave and starts from 0xE7. The prescaler ratio is the same for both timers. TIM_slv stops when TIM_mstr is disabled by writing ‘0 to the CEN bit in the TIM_mstr_CR1 register:

1. Configure TIM_mstr master mode to send its Output Compare 1 Reference (tim_oc1ref) signal as trigger output (MMS=100 in the TIM_mstr_CR2 register).
2. Configure the TIM_mstr tim_oc1ref waveform (TIM_mstr_CCMR1 register).
3. Configure TIM_slv to get the input trigger from TIM_mstr (TS=00010 in the TIM_slv_SMCR register).
4. Configure TIM_slv in gated mode (SMS=101 in TIM_slv_SMCR register).
5. Reset TIM_mstr by writing ‘1 in UG bit (TIM_mstr_EGR register).
6. Reset TIM_slv by writing ‘1 in UG bit (TIM_slv_EGR register).
7. Initialize TIM_slv to 0xE7 by writing ‘0xE7’ in the TIM_slv counter (TIM_slv_CNT).
8. Enable TIM_slv by writing ‘1 in the CEN bit (TIM_slv_CR1 register).
9. Start TIM_mstr by writing ‘1 in the CEN bit (TIM_mstr_CR1 register).
10. Stop TIM_mstr by writing ‘0 in the CEN bit (TIM_mstr_CR1 register).

Figure 505. Gating TIM_slv with Enable of TIM_mstr

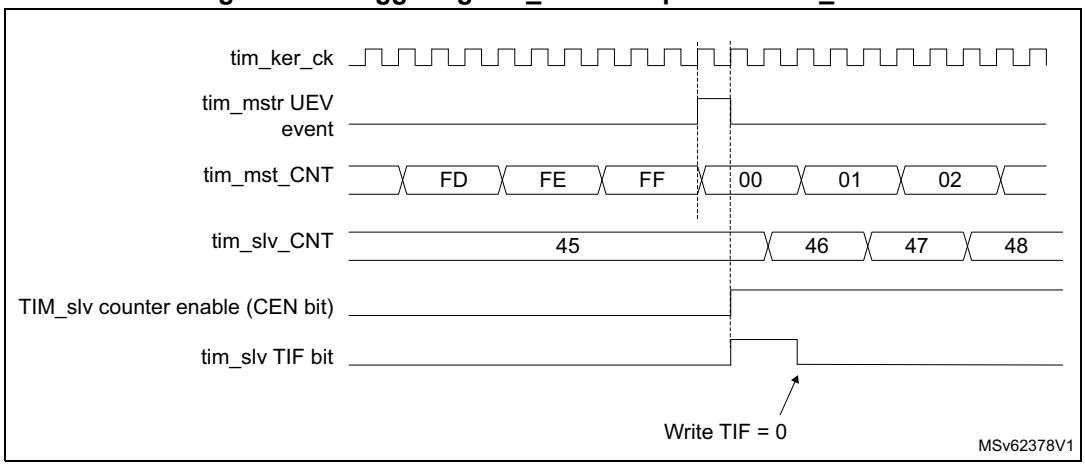


Using one timer to start another timer

In this example, we set the enable of TIM_slv with the update event of TIM_mstr. Refer to *Figure 502* for connections. TIM_slv starts counting from its current value (which can be non-zero) on the divided internal clock as soon as the update event is generated by TIM_mstr. When TIM_slv receives the trigger signal its CEN bit is automatically set and the counter counts until we write ‘0 to the CEN bit in the TIM_slv_CR1 register. Both counter clock frequencies are divided by 3 by the prescaler compared to tim_ker_ck ($f_{tim\_cnt\_ck} = f_{tim\_ker\_ck}/3$).

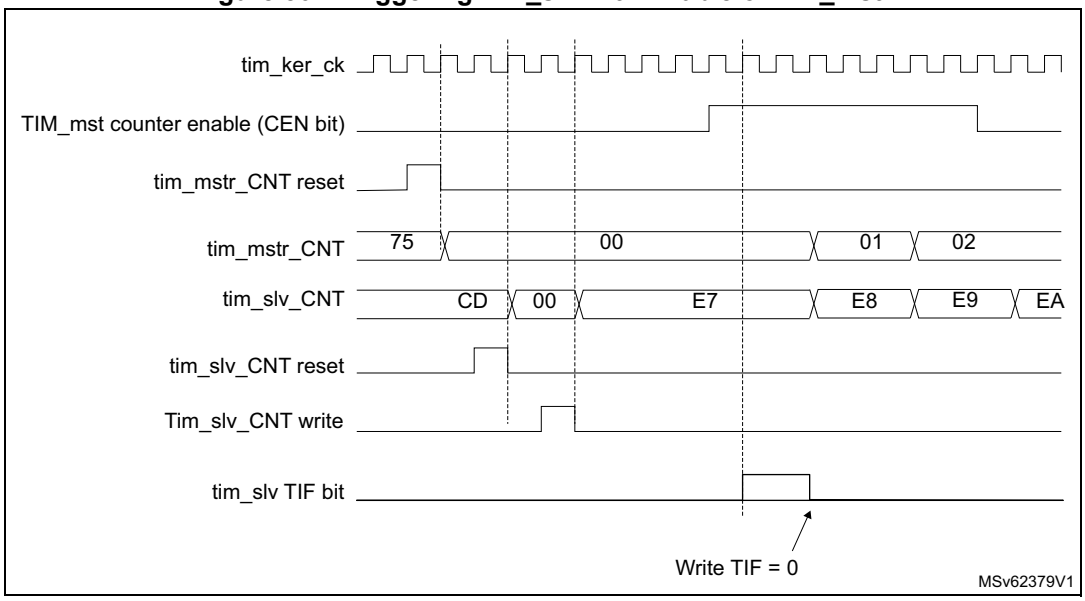
1. Configure TIM_mstr master mode to send its Update Event (UEV) as trigger output (MMS=010 in the TIM_mstr_CR2 register).
2. Configure the TIM_mstr period (TIM_mstr_ARR registers).
3. Configure TIM_slv to get the input trigger from TIM_mstr (TS=00010 in the TIM_slv_SMCR register).
4. Configure TIM_slv in trigger mode (SMS=110 in TIM_slv_SMCR register).
5. Start TIM_mstr by writing ‘1 in the CEN bit (TIM_mstr_CR1 register).

Figure 506. Triggering TIM_slv with update of TIM_mstr



As in the previous example, both counters can be initialized before starting counting. *Figure 507* shows the behavior with the same configuration as in *Figure 506* but in trigger mode instead of gated mode (SMS=110 in the TIM_slv_SMCR register).

Figure 507. Triggering TIM_slv with Enable of TIM_mstr



Starting 2 timers synchronously in response to an external trigger

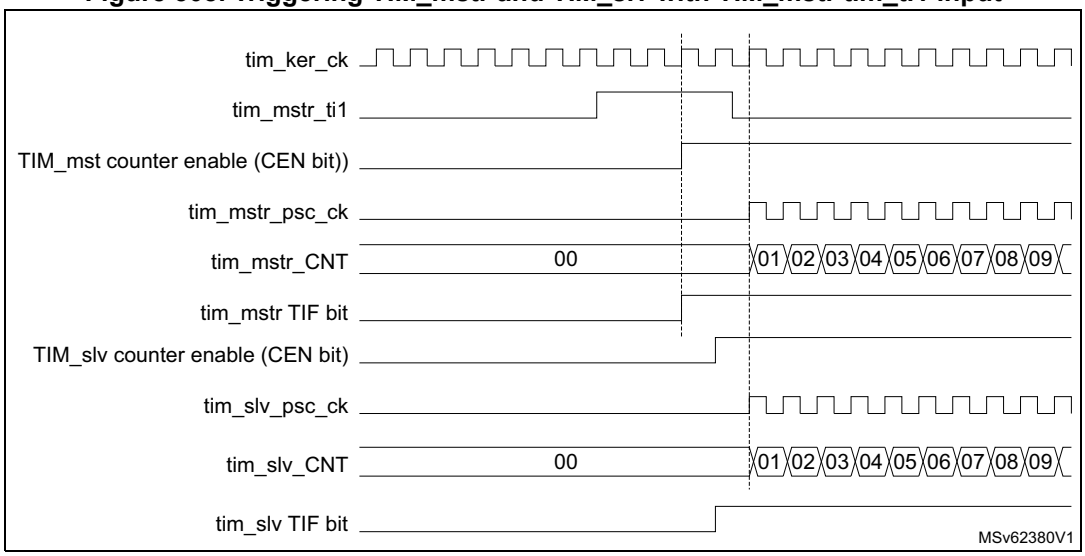
In this example, we set the enable of TIM_mstr when its tim_ti1 input rises, and the enable of TIM_slv with the enable of TIM_mstr. Refer to *Figure 502* for connections. To ensure the counters are aligned, TIM_mstr must be configured in Master/Slave mode (slave with respect to tim_ti1, master with respect to TIM_slv):

1. Configure TIM_mstr master mode to send its Enable as trigger output (MMS=001 in the TIM_mstr_CR2 register).
2. Configure TIM_mstr slave mode to get the input trigger from tim_ti1 (TS=00100 in the TIM_mstr_SMCR register).
3. Configure TIM_mstr in trigger mode (SMS=110 in the TIM_mstr_SMCR register).
4. Configure the TIM_mstr in Master/Slave mode by writing MSM=1 (TIM_mstr_SMCR register).
5. Configure TIM_slv to get the input trigger from TIM_mstr (TS=00000 in the TIM_slv_SMCR register).
6. Configure TIM_slv in trigger mode (SMS=110 in the TIM_slv_SMCR register).

When a rising edge occurs on tim_ti1 (TIM_mstr), both counters starts counting synchronously on the internal clock and both TIF flags are set.

Note: In this example both timers are initialized before starting (by setting their respective UG bits). Both counters starts from 0, but an offset can easily be inserted between them by writing any of the counter registers (TIMx_CNT). One can see that the master/slave mode insert a delay between CNT_EN and CK_PSC on TIM_mstr.

Figure 508. Triggering TIM_mstr and TIM_slv with TIM_mstr tim_ti1 input



Note: The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

39.4.24 ADC triggers

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events.

Note: The clock of the slave peripherals (such as timer, ADC) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

39.4.25 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests upon a single event. The main purpose is to be able to re-program part of the timer multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIMx_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx_DMAR register is actually redirected to one of the timer registers.

The DBL[4:0] bits in the TIMx_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx_DCR registers define the DMA base address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register:

Example:

00000: TIMx_CR1

00001: TIMx_CR2

00010: TIMx_SMCR

The DBSS[3:0] bits in the TIMx_DCR register defines the interrupt source that triggers the DMA burst transfers (see *Section 39.5.29: TIMx DMA control register (TIMx_DCR)(x = 2 to 5)* for details).

As an example, the timer DMA burst feature is used to update the contents of the CCRx registers (x = 2, 3, 4) upon an update event, with the DMA transferring half words into the CCRx registers.

This is done in the following steps:

1. Configure the corresponding DMA channel as follows:
   - DMA channel peripheral address is the DMAR register address
   - DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into CCRx registers.
   - Number of data to transfer = 3 (See note below).
   - Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bit fields as follows: DBL = 3 transfers, DBA = 0xE and DBSS = 1.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx
5. Enable the DMA channel

This example is for the case where every CCRx register has to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer must be 6. Let's take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3 and data6 is transferred to CCR4.

Note: A null value can be written to the reserved registers.

39.4.26 TIM2/TIM3/TIM4/TIM5 DMA requests

The TIM2/TIM3/TIM4/TIM5 can generate a DMA requests, as shown in *Table 410*.

Table 410. DMA request

DMA request signal	DMA request	Enable control bit
tim_upd_dma	Update	UDE
tim_cc1_dma	Capture/compare 1	CC1DE
tim_cc2_dma	Capture/compare 2	CC2DE
tim_cc3_dma	Capture/compare 3	CC3DE
tim_cc4_dma	Capture/compare 4	CC4DE
tim_trg_dma	Trigger	TDE

Note: Some timer's DMA requests may not be connected to the DMA controller. Refer to the DMA section(s) for more details.

39.4.27 Debug mode

When the microcontroller enters debug mode (Cortex-M33 core halted), the TIMx counter can either continues to work normally or stops.

The behavior in debug mode can be programmed with a dedicated configuration bit per timer in the Debug support (DBG) module.

For more details, refer to section Debug support (DBG).

39.4.28 TIM2/TIM3/TIM4/TIM5 low-power modes

Table 411. Effect of low-power modes on TIM2/TIM3/TIM4/TIM5

Mode	Description
Sleep	No effect, peripheral is active. The interrupts can cause the device to exit from Sleep mode.
Stop	The timer operation is stopped and the register content is kept. No interrupt can be generated.
Standby	The timer is powered-down and must be reinitialized after exiting the Standby mode.

39.4.29 TIM2/TIM3/TIM4/TIM5 interrupts

The TIM2/TIM3/TIM4/TIM5 can generate multiple interrupts, as shown in *Table 412*.

Table 412. Interrupt requests

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit from Sleep mode	Exit from Stop and Standby mode
TIM_UP	Update	UIF	UIE	write 0 in UIF	Yes	No
TIM_CC	Capture/compare 1	CC1IF	CC1IE	write 0 in CC1IF	Yes	No
	Capture/compare 2	CC2IF	CC2IE	write 0 in CC2IF	Yes	No
	Capture/compare 3	CC3IF	CC3IE	write 0 in CC3IF	Yes	No
	Capture/compare 4	CC4IF	CC4IE	write 0 in CC4IF	Yes	No
TIM_TRG	Trigger	TIF	TIE	write 0 in TIF	Yes	No
TIM_DIR_IDX	Index	IDXF	IDXIE	write 0 in IDXF	Yes	No
	Direction	DIRF	DIRIE	write 0 in DIRF	Yes	No
TIM_IERR	Index Error	IERRF	IERRIE	write 0 in IERRF	Yes	No
TIM_TER	Transition Error	TERRF	TERRIE	write 0 in TERRF	Yes	No

39.5 TIM2/TIM3/TIM4/TIM5 registers

Refer to *Section 1.2* for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

39.5.1 TIMx control register 1 (TIMx_CR1)(x = 2 to 5)

Address offset: 0x000

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	DITHEN	UIFREMAP	Res.	CKD[1:0]		ARPE	CMS[1:0]		DIR	OPM	URS	UDIS	CEN
			rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **DITHEN**: Dithering Enable

0: Dithering disabled

1: Dithering enabled

Note: The DITHEN bit can only be modified when CEN bit is reset.

Bit 11 **UIFREMAP**: UIF status bit remapping

0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.

1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division

This bit-field indicates the division ratio between the timer clock (tim_ker_ck) frequency and sampling clock used by the digital filters (tim_etr_in, tim_tix),

00: $t_{DTS} = t_{tim\_ker\_ck}$

01: $t_{DTS} = 2 \times t_{tim\_ker\_ck}$

10: $t_{DTS} = 4 \times t_{tim\_ker\_ck}$

11: Reserved

Bit 7 **ARPE**: Auto-reload preload enable

0: TIMx_ARR register is not buffered

1: TIMx_ARR register is buffered

Bits 6:5 **CMS[1:0]**: Center-aligned mode selection

00: Edge-aligned mode. The counter counts up or down depending on the direction bit (DIR).

01: Center-aligned mode 1. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set only when the counter is counting down.

10: Center-aligned mode 2. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set only when the counter is counting up.

11: Center-aligned mode 3. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set both when the counter is counting up or down.

Note: It is not allowed to switch from edge-aligned mode to center-aligned mode as long as the counter is enabled (CEN=1)

Bit 4 **DIR**: Direction

0: Counter used as upcounter

1: Counter used as downcounter

Note: This bit is read only when the timer is configured in Center-aligned mode or Encoder mode.

Bit 3 **OPM**: One-pulse mode

0: Counter is not stopped at update event

1: Counter stops counting at the next update event (clearing the bit CEN)

Bit 2 **URS**: Update request source

This bit is set and cleared by software to select the UEV event sources.

0: Any of the following events generate an update interrupt or DMA request if enabled. These events can be:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS**: Update disable

This bit is set and cleared by software to enable/disable UEV event generation.

0: UEV enabled. The Update (UEV) event is generated by one of the following events:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

Buffered registers are then loaded with their preload values.

1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable

0: Counter disabled

1: Counter enabled

Note: External clock, gated mode and encoder mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.

CEN is cleared automatically in one-pulse mode, when an update event occurs.

39.5.2 TIMx control register 2 (TIMx_CR2)(x = 2 to 5)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	MMS[3]	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
						rw									
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TI1S	MMS[2:0]			CCDS	Res.	Res.	Res.
								rw	rw	rw	rw	rw			

Bits 31:26 Reserved, must be kept at reset value.

Bits 24:8 Reserved, must be kept at reset value.

Bit 7 **TI1S**: tim_ti1 selection

0: The tim_ti1_in[15:0] multiplexer output is to tim_ti1 input
1: The tim_ti1_in[15:0], tim_ti2_in[15:0] and tim_ti3_in[15:0] multiplexers outputs are XORed and connected to the tim_ti1 input. See also *Section 38.3.29: Interfacing with Hall sensors on page 1508*.

Bits 25, 6, 5, 4 **MMS[3:0]**: Master mode selection

These bits are used to select the information to be sent in master mode to slave timers for synchronization (tim_trgo). The combination is as follows:

0000: **Reset** - the UG bit from the TIMx_EGR register is used as trigger output (tim_trgo). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on tim_trgo is delayed compared to the actual reset.

0001: **Enable** - the Counter enable signal, CNT_EN, is used as trigger output (tim_trgo). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode.
When the Counter Enable signal is controlled by the trigger input, there is a delay on tim_trgo, except if the master/slave mode is selected (see the MSM bit description in TIMx_SMCR register).

0010: **Update** - The update event is selected as trigger output (tim_trgo). For instance a master timer can then be used as a prescaler for a slave timer.

0011: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred (tim_trgo).

0100: **Compare** - tim_oc1refc signal is used as trigger output (tim_trgo)

0101: **Compare** - tim_oc2refc signal is used as trigger output (tim_trgo)

0110: **Compare** - tim_oc3refc signal is used as trigger output (tim_trgo)

0111: **Compare** - tim_oc4refc signal is used as trigger output (tim_trgo)

1000: **Encoder Clock output** - The encoder clock signal is used as trigger output (tim_trgo). This code is valid for the following SMS[3:0] values: 0001, 0010, 0011, 1010, 1011, 1100, 1101, 1110, 1111. Any other SMS[3:0] code is not allowed and may lead to unexpected behavior.

Others: Reserved

Note: The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

Bit 3 **CCDS**: Capture/compare DMA selection

0: CCx DMA request sent when CCx event occurs
1: CCx DMA requests sent when update event occurs

Bits 2:0 Reserved, must be kept at reset value.

39.5.3 TIMx slave mode control register (TIMx_SMCR)(x = 2 to 5)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	SMSPS	SMSPE	Res.	Res.	TS[4:3]		Res.	Res.	Res.	SMS[3]
						rw	rw			rw	rw				rw

ETP	ECE	ETPS[1:0]		ETF[3:0]				MSM	TS[2:0]			OCCS	SMS[2:0]		
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **SMSPS**: SMS preload source

This bit selects whether the events that triggers the SMS[3:0] bitfield transfer from preload to active

0: The transfer is triggered by the Timer's Update event

1: The transfer is triggered by the Index event

Bit 24 **SMSPE**: SMS preload enable

This bit selects whether the SMS[3:0] bitfield is preloaded

0: SMS[3:0] bitfield is not preloaded

1: SMS[3:0] preload is enabled

Bits 23:22 Reserved, must be kept at reset value.

Bits 19:17 Reserved, must be kept at reset value.

Bit 15 **ETP**: External trigger polarity

This bit selects whether tim_etr_in or $\overline{\text{tim\_etr\_in}}$ is used for trigger operations

0: tim_etr_in is non-inverted, active at high level or rising edge

1: tim_etr_in is inverted, active at low level or falling edge

Bit 14 **ECE**: External clock enable

This bit enables External clock mode 2.

0: External clock mode 2 disabled

1: External clock mode 2 enabled. The counter is clocked by any active edge on the tim_etrf signal.

Note: Setting the ECE bit has the same effect as selecting external clock mode 1 with tim_trgi connected to tim_etrf (SMS=111 and TS=00111).
It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, tim_trgi must not be connected to tim_etrf in this case (TS bits must not be 00111).
If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is tim_etrf.

Bits 13:12 **ETPS[1:0]**: External trigger prescaler

External trigger signal tim_etrp frequency must be at most 1/4 of tim_ker_ck frequency. A prescaler can be enabled to reduce tim_etrp frequency. It is useful when inputting fast external clocks on tim_etr_in.

00: Prescaler OFF

01: tim_etrp frequency divided by 2

10: tim_etrp frequency divided by 4

11: tim_etrp frequency divided by 8

Bits 11:8 **ETF[3:0]**: External trigger filter

This bit-field then defines the frequency used to sample tim_etrp signal and the length of the digital filter applied to tim_etrp. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at f_{DTS}
0001: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=2
0010: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=4
0011: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=8
0100: $f_{SAMPLING}=f_{DTS}/2$, N=6
0101: $f_{SAMPLING}=f_{DTS}/2$, N=8
0110: $f_{SAMPLING}=f_{DTS}/4$, N=6
0111: $f_{SAMPLING}=f_{DTS}/4$, N=8
1000: $f_{SAMPLING}=f_{DTS}/8$, N=6
1001: $f_{SAMPLING}=f_{DTS}/8$, N=8
1010: $f_{SAMPLING}=f_{DTS}/16$, N=5
1011: $f_{SAMPLING}=f_{DTS}/16$, N=6
1100: $f_{SAMPLING}=f_{DTS}/16$, N=8
1101: $f_{SAMPLING}=f_{DTS}/32$, N=5
1110: $f_{SAMPLING}=f_{DTS}/32$, N=6
1111: $f_{SAMPLING}=f_{DTS}/32$, N=8

Bit 7 **MSM**: Master/Slave mode

0: No action
1: The effect of an event on the trigger input (tim_trgi) is delayed to allow a perfect synchronization between the current timer and its slaves (through tim_trgo). It is useful if we want to synchronize several timers on a single external event.

Bits 21, 20, 6, 5, 4 **TS[4:0]**: Trigger selection

This bit-field selects the trigger input to be used to synchronize the counter.

00000: Internal trigger 0 (tim_itr0)
00001: Internal trigger 1 (tim_itr1)
00010: Internal trigger 2 (tim_itr2)
00011: Internal trigger 3 (tim_itr3)
00100: tim_ti1 edge detector (tim_ti1f_ed)
00101: Filtered timer input 1 (tim_ti1fp1)
00110: Filtered timer input 2 (tim_ti2fp2)
00111: External trigger input (tim_etrf)
01000: Internal trigger 4 (tim_itr4)
01001: Internal trigger 5 (tim_itr5)
01010: Internal trigger 6 (tim_itr6)
01011: Internal trigger 7 (tim_itr7)
01100: Internal trigger 8 (tim_itr8)
01101: Internal trigger 9 (tim_itr9)
01110: Internal trigger 10 (tim_itr10)
01111: Internal trigger 11 (tim_itr11)
10000: Internal trigger 12 (tim_itr12)
10001: Internal trigger 13 (tim_itr13)
10010: Internal trigger 14 (tim_itr14)
10011: Internal trigger 15 (tim_itr15)
Others: Reserved

See *Section 39.4.2: TIM2/TIM3/TIM4/TIM5 pins and internal signals* for product specific implementation details.

Note: These bits must be changed only when they are not used (for example when SMS = 000) to avoid wrong edge detections at the transition.

Bit 3 **OCCS**: OCREF clear selection

This bit is used to select the OCREF clear source
0: tim_ocref_clr_int is connected to the tim_ocref_clr input
1: tim_ocref_clr_int is connected to tim_etrf

Note: If the OCREF clear selection feature is not supported, this bit is reserved and forced by hardware to '0'. Section 39.3: TIM2/TIM3/TIM4/TIM5 implementation.

Bits 16, 2, 1, 0 **SMS[3:0]**: Slave mode selection

When external signals are selected the active edge of the trigger signal (tim_trgi) is linked to the polarity selected on the external input (see Input Control register and Control Register description.

0000: Slave mode disabled - if CEN = ‘1 then the prescaler is clocked directly by the internal clock.

0001: Encoder mode 1 - Counter counts up/down on tim_ti1fp1 edge depending on tim_ti2fp2 level.

0010: Encoder mode 2 - Counter counts up/down on tim_ti2fp2 edge depending on tim_ti1fp1 level.

0011: Encoder mode 3 - Counter counts up/down on both tim_ti1fp1 and tim_ti2fp2 edges depending on the level of the other input.

0100: Reset Mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter and generates an update of the registers.

0101: Gated Mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

0110: Trigger Mode - The counter starts at a rising edge of the trigger tim_trgi (but it is not reset). Only the start of the counter is controlled.

0111: External Clock Mode 1 - Rising edges of the selected trigger (tim_trgi) clock the counter.

1000: Combined reset + trigger mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers and starts the counter.

1001: Combined gated + reset mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

1010: Encoder mode: Clock plus direction, x2 mode.

1011: Encoder mode: Clock plus direction, x1 mode, tim_ti2fp2 edge sensitivity is set by CC2P.

1100: Encoder mode: Directional Clock, x2 mode.

1101: Encoder mode: Directional Clock, x1 mode, tim_ti1fp1 and tim_ti2fp2 edge sensitivity is set by CC1P and CC2P.

1110: Quadrature encoder mode: x1 mode, counting on tim_ti1fp1 edges only, edge sensitivity is set by CC1P.

1111: Quadrature encoder mode: x1 mode, counting on tim_ti2fp2 edges only, edge sensitivity is set by CC2P.

Note: The gated mode must not be used if tim_ti1f_ed is selected as the trigger input (TS=00100). Indeed, tim_ti1f_ed outputs 1 pulse for each transition on tim_ti1f, whereas the gated mode checks the level of the trigger signal.

Note: The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

39.5.4 TIMx DMA/Interrupt enable register (TIMx_DIER)(x = 2 to 5)

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **TERRIE**: Transition error interrupt enable
0: Transition error interrupt disabled
1: Transition error interrupt enabled

Bit 22 **IERRIE**: Index error interrupt enable
0: Index error interrupt disabled
1: Index error interrupt enabled

Bit 21 **DIRIE**: Direction change interrupt enable
0: Direction change interrupt disabled
1: Direction change interrupt enabled

Bit 20 **IDXIE**: Index interrupt enable
0: Index interrupt disabled
1: Index interrupt enabled

Bits 19:15 Reserved, must be kept at reset value.

Bit 14 **TDE**: Trigger DMA request enable
0: Trigger DMA request disabled.
1: Trigger DMA request enabled.

Bit 13 Reserved, must be kept at reset value.

Bit 12 **CC4DE**: Capture/Compare 4 DMA request enable
0: CC4 DMA request disabled.
1: CC4 DMA request enabled.

Bit 11 **CC3DE**: Capture/Compare 3 DMA request enable
0: CC3 DMA request disabled.
1: CC3 DMA request enabled.

Bit 10 **CC2DE**: Capture/Compare 2 DMA request enable
0: CC2 DMA request disabled.
1: CC2 DMA request enabled.

Bit 9 **CC1DE**: Capture/Compare 1 DMA request enable
0: CC1 DMA request disabled.
1: CC1 DMA request enabled.

Bit 8 **UDE**: Update DMA request enable
0: Update DMA request disabled.
1: Update DMA request enabled.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **TIE**: Trigger interrupt enable
0: Trigger interrupt disabled.
1: Trigger interrupt enabled.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **CC4IE**: Capture/Compare 4 interrupt enable
0: CC4 interrupt disabled.
1: CC4 interrupt enabled.

Bit 3 **CC3IE**: Capture/Compare 3 interrupt enable
0: CC3 interrupt disabled.
1: CC3 interrupt enabled.

Bit 2 **CC2IE**: Capture/Compare 2 interrupt enable
0: CC2 interrupt disabled.
1: CC2 interrupt enabled.

Bit 1 **CC1IE**: Capture/Compare 1 interrupt enable
0: CC1 interrupt disabled.
1: CC1 interrupt enabled.

Bit 0 **UIE**: Update interrupt enable
0: Update interrupt disabled.
1: Update interrupt enabled.

39.5.5 TIMx status register (TIMx_SR)(x = 2 to 5)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TERRF	IERRF	DIRF	IDXF	Res.	Res.	Res.	Res.

			rc_w0	rc_w0	rc_w0	rc_w0			rc_w0		rc_w0	rc_w0	rc_w0	rc_w0	rc_w0

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **TERRF**: Transition error interrupt flag
This flag is set by hardware when a transition error is detected in encoder mode. It is cleared by software by writing it to ‘0’.
0: No encoder transition error has been detected.
1: An encoder transition error has been detected

Bit 22 **IERRF**: Index error interrupt flag
This flag is set by hardware when an index error is detected. It is cleared by software by writing it to ‘0’.
0: No index error has been detected.
1: An index error has been detected

Bit 21 **DIRF**: Direction change interrupt flag
This flag is set by hardware when the direction changes in encoder mode (DIR bit value in TIMx_CR is changing). It is cleared by software by writing it to ‘0’.
0: No direction change
1: Direction change

Bit 20 **IDXF**: Index interrupt flag
This flag is set by hardware when an index event is detected. It is cleared by software by writing it to ‘0’.
0: No index event occurred.
1: An index event has occurred

Bits 19:13 Reserved, must be kept at reset value.

Bit 12 **CC4OF**: Capture/Compare 4 overcapture flag
refer to CC1OF description

Bit 11 **CC3OF**: Capture/Compare 3 overcapture flag
refer to CC1OF description

Bit 10 **CC2OF**: Capture/compare 2 overcapture flag
refer to CC1OF description

Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag
This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to ‘0’.
0: No overcapture has been detected.
1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **TIF**: Trigger interrupt flag
This flag is set by hardware on the TRG trigger event (active edge detected on tim_trgi input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.
0: No trigger event occurred.
1: Trigger interrupt pending.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **CC4IF**: Capture/Compare 4 interrupt flag
Refer to CC1IF description

Bit 3 **CC3IF**: Capture/Compare 3 interrupt flag
Refer to CC1IF description

Bit 2 **CC2IF**: Capture/Compare 2 interrupt flag
Refer to CC1IF description

Bit 1 **CC1IF**: Capture/compare 1 interrupt flag
This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx_CCR1 register (input capture mode only).
0: No compare match / No input capture occurred
1: A compare match or an input capture occurred
If channel CC1 is configured as output: this flag is set when the content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in downcounting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx_CR1 register for the full description.
If channel CC1 is configured as input: this bit is set when counter value has been captured in TIMx_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCER).

Bit 0 **UIF**: Update interrupt flag
This bit is set by hardware on an update event. It is cleared by software.
0: No update occurred
1: Update interrupt pending. This bit is set by hardware when the registers are updated:
At overflow or underflow and if UDIS=0 in the TIMx_CR1 register.
When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS=0 and UDIS=0 in the TIMx_CR1 register.
When CNT is reinitialized by a trigger event (refer to the synchro control register description), if URS=0 and UDIS=0 in the TIMx_CR1 register.

39.5.6 TIMx event generation register (TIMx_EGR)(x = 2 to 5)

Address offset: 0x014

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TG	Res.	CC4G	CC3G	CC2G	CC1G	UG
									w		w	w	w	w	w

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **TG**: Trigger generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: The TIF flag is set in TIMx_SR register. Related interrupt or DMA transfer can occur if enabled.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **CC4G**: Capture/compare 4 generation
Refer to CC1G description

Bit 3 **CC3G**: Capture/compare 3 generation
Refer to CC1G description

Bit 2 **CC2G**: Capture/compare 2 generation
Refer to CC1G description

Bit 1 **CC1G**: Capture/compare 1 generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: A capture/compare event is generated on channel 1:
If channel CC1 is configured as output:
CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.
If channel CC1 is configured as input:
The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation
This bit can be set by software, it is automatically cleared by hardware.
0: No action
1: Re-initialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared if the center-aligned mode is selected or if DIR=0 (upcounting), else it takes the auto-reload value (TIMx_ARR) if DIR=1 (downcounting).

39.5.7 TIMx capture/compare mode register 1 (TIMx_CCMR1)(x = 2 to 5)

Address offset: 0x018

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

IC2F[3:0]				IC2PSC[1:0]		CC2S[1:0]		IC1F[3:0]				IC1PSC[1:0]		CC1S[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Input capture mode

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **IC2F[3:0]**: Input capture 2 filter

Bits 11:10 **IC2PSC[1:0]**: Input capture 2 prescaler

Bits 9:8 **CC2S[1:0]**: Capture/compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output.

01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2.

10: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1.

11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

Note: CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCER).

Bits 7:4 **IC1F[3:0]**: Input capture 1 filter

This bit-field defines the frequency used to sample tim_ti1 input and the length of the digital filter applied to tim_ti1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at f_{DTS}

0001: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=2

0010: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=4

0011: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=8

0100: $f_{SAMPLING}=f_{DTS}/2$, N=6

0101: $f_{SAMPLING}=f_{DTS}/2$, N=8

0110: $f_{SAMPLING}=f_{DTS}/4$, N=6

0111: $f_{SAMPLING}=f_{DTS}/4$, N=8

1000: $f_{SAMPLING}=f_{DTS}/8$, N=6

1001: $f_{SAMPLING}=f_{DTS}/8$, N=8

1010: $f_{SAMPLING}=f_{DTS}/16$, N=5

1011: $f_{SAMPLING}=f_{DTS}/16$, N=6

1100: $f_{SAMPLING}=f_{DTS}/16$, N=8

1101: $f_{SAMPLING}=f_{DTS}/32$, N=5

1110: $f_{SAMPLING}=f_{DTS}/32$, N=6

1111: $f_{SAMPLING}=f_{DTS}/32$, N=8

Bits 3:2 **IC1PSC[1:0]**: Input capture 1 prescaler

This bit-field defines the ratio of the prescaler acting on CC1 input (tim_ic1). The prescaler is reset as soon as CC1E=0 (TIMx_CCER register).

00: no prescaler, capture is done each time an edge is detected on the capture input

01: capture is done once every 2 events

10: capture is done once every 4 events

11: capture is done once every 8 events

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1

10: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2

11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).

39.5.8 TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1)(x = 2 to 5)

Address offset: 0x018

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

Output compare mode

Bits 31:25 Reserved, must be kept at reset value.

Bits 23:17 Reserved, must be kept at reset value.

Bit 15 **OC2CE**: Output compare 2 clear enable

Bits 24, 14:12 **OC2M[3:0]**: Output compare 2 mode
refer to OC1M description on bits 6:4

Bit 11 **OC2PE**: Output compare 2 preload enable

Bit 10 **OC2FE**: Output compare 2 fast enable

Bits 9:8 **CC2S[1:0]**: Capture/Compare 2 selection
This bit-field defines the direction of the channel (input/output) as well as the used input.
00: CC2 channel is configured as output
01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2
10: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1
11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)
Note: CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCER).

Bit 7 **OC1CE**: Output compare 1 clear enable
0: tim_oc1ref is not affected by the tim_ocref_clr_int input
1: tim_oc1ref is cleared as soon as a High level is detected on tim_ocref_clr_int input

Bits 16, 6:4 **OC1M[3:0]**: Output compare 1 mode

These bits define the behavior of the output reference signal tim_oc1ref from which tim_oc1 is derived. tim_oc1ref is active high whereas tim_oc1 active level depends on CC1P bit.

0000: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the ouput keeps the state (active or inactive) it had before entering the frozen state.

0001: Set channel 1 to active level on match. tim_oc1ref signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0010: Set channel 1 to inactive level on match. tim_oc1ref signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0011: Toggle - tim_oc1ref toggles when TIMx_CNT=TIMx_CCR1.

0100: Force inactive level - tim_oc1ref is forced low.

0101: Force active level - tim_oc1ref is forced high.

0110: PWM mode 1 - In upcounting, channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else inactive. In downcounting, channel 1 is inactive (tim_oc1ref=0) as long as TIMx_CNT>TIMx_CCR1 else active (tim_oc1ref=1).

0111: PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else active. In downcounting, channel 1 is active as long as TIMx_CNT>TIMx_CCR1 else inactive.

1000: Retriggerable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1001: Retriggerable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1010: Reserved.

1011: Reserved.

1100: Combined PWM mode 1 - tim_oc1ref has the same behavior as in PWM mode 1. tim_oc1refc is the logical OR between tim_oc1ref and tim_oc2ref.

1101: Combined PWM mode 2 - tim_oc1ref has the same behavior as in PWM mode 2. tim_oc1refc is the logical AND between tim_oc1ref and tim_oc2ref.

1110: Asymmetric PWM mode 1 - tim_oc1ref has the same behavior as in PWM mode 1. tim_oc1refc outputs tim_oc1ref when the counter is counting up, tim_oc2ref when it is counting down.

1111: Asymmetric PWM mode 2 - tim_oc1ref has the same behavior as in PWM mode 2. tim_oc1refc outputs tim_oc1ref when the counter is counting up, tim_oc2ref when it is counting down.

Note: In PWM mode, the OCREF level changes when the result of the comparison changes, when the output compare mode switches from “frozen” mode to “PWM” mode and when the output compare mode switches from “force active/inactive” mode to “PWM” mode.

Bit 3 **OC1PE**: Output compare 1 preload enable

0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken in account immediately.
1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded in the active register at each update event.

Bit 2 **OC1FE**: Output compare 1 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIMx_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.
0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.
1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.
00: CC1 channel is configured as output.
01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1.
10: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2.
11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).

39.5.9 TIMx capture/compare mode register 2 (TIMx_CCMR2)(x = 2 to 5)

Address offset: 0x01C

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

Input capture mode

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **IC4F[3:0]**: Input capture 4 filter

Bits 11:10 **IC4PSC[1:0]**: Input capture 4 prescaler

Bits 9:8 **CC4S[1:0]**: Capture/Compare 4 selection
This bit-field defines the direction of the channel (input/output) as well as the used input.
00: CC4 channel is configured as output
01: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti4
10: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti3
11: CC4 channel is configured as input, tim_ic4 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)
Note: CC4S bits are writable only when the channel is OFF (CC4E = 0 in TIMx_CCER).

Bits 7:4 **IC3F[3:0]**: Input capture 3 filter

Bits 3:2 **IC3PSC[1:0]**: Input capture 3 prescaler

Bits 1:0 **CC3S[1:0]**: Capture/Compare 3 selection
This bit-field defines the direction of the channel (input/output) as well as the used input.
00: CC3 channel is configured as output
01: CC3 channel is configured as input, tim_ic3 is mapped on tim_ti3
10: CC3 channel is configured as input, tim_ic3 is mapped on tim_ti4
11: CC3 channel is configured as input, tim_ic3 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)
Note: CC3S bits are writable only when the channel is OFF (CC3E = 0 in TIMx_CCER).

39.5.10 TIMx capture/compare mode register 2 [alternate] (TIMx_CCMR2)(x = 2 to 5)

Address offset: 0x01C

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

Output compare mode

Bits 31:25 Reserved, must be kept at reset value.

Bits 23:17 Reserved, must be kept at reset value.

Bit 15 **OC4CE**: Output compare 4 clear enable

Bits 24, 14:12 **OC4M[3:0]**: Output compare 4 mode
Refer to OC1M description (bits 6:4 in TIMx_CCMR1 register)

Bit 11 **OC4PE**: Output compare 4 preload enable

Bit 10 **OC4FE**: Output compare 4 fast enable

Bits 9:8 **CC4S[1:0]**: Capture/Compare 4 selection
This bit-field defines the direction of the channel (input/output) as well as the used input.
00: CC4 channel is configured as output
01: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti4
10: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti3
11: CC4 channel is configured as input, tim_ic4 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)
Note: CC4S bits are writable only when the channel is OFF (CC4E = 0 in TIMx_CCER).

Bit 7 **OC3CE**: Output compare 3 clear enable

Bits 16, 6:4 **OC3M[3:0]**: Output compare 3 mode
Refer to OC1M description (bits 6:4 in TIMx_CCMR1 register)

Bit 3 **OC3PE**: Output compare 3 preload enable

Bit 2 **OC3FE**: Output compare 3 fast enable

Bits 1:0 **CC3S[1:0]**: Capture/Compare 3 selection
This bit-field defines the direction of the channel (input/output) as well as the used input.
00: CC3 channel is configured as output
01: CC3 channel is configured as input, tim_ic3 is mapped on tim_ti3
10: CC3 channel is configured as input, tim_ic3 is mapped on tim_ti4
11: CC3 channel is configured as input, tim_ic3 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)
Note: CC3S bits are writable only when the channel is OFF (CC3E = 0 in TIMx_CCER).

39.5.11 TIMx capture/compare enable register (TIMx_CCER)(x = 2 to 5)

Address offset: 0x020

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CC4NP	Res.	CC4P	CC4E	CC3NP	Res.	CC3P	CC3E	CC2NP	Res.	CC2P	CC2E	CC1NP	Res.	CC1P	CC1E
rw		rw	rw	rw		rw	rw	rw		rw	rw	rw		rw	rw

Bit 15 **CC4NP**: *Capture/Compare 4 output Polarity.*
Refer to CC1NP description

Bit 14 Reserved, must be kept at reset value.

Bit 13 **CC4P**: *Capture/Compare 4 output Polarity.*
Refer to CC1P description

Bit 12 **CC4E**: *Capture/Compare 4 output enable.*
refer to CC1E description

Bit 11 **CC3NP**: *Capture/Compare 3 output Polarity.*
Refer to CC1NP description

Bit 10 Reserved, must be kept at reset value.

Bit 9 **CC3P**: *Capture/Compare 3 output Polarity.*
Refer to CC1P description

Bit 8 **CC3E**: *Capture/Compare 3 output enable.*
Refer to CC1E description

Bit 7 **CC2NP**: *Capture/Compare 2 output Polarity.*
Refer to CC1NP description

Bit 6 Reserved, must be kept at reset value.

Bit 5 **CC2P**: *Capture/Compare 2 output Polarity.*
refer to CC1P description

Bit 4 **CC2E**: *Capture/Compare 2 output enable.*
Refer to CC1E description

Bit 3 **CC1NP**: *Capture/Compare 1 output Polarity.*
CC1 channel configured as output: CC1NP must be kept cleared in this case.
CC1 channel configured as input: This bit is used in conjunction with CC1P to define tim_ti1fp1/tim_ti2fp1 polarity. refer to CC1P description.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CC1P**: *Capture/Compare 1 output Polarity.*
0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)
1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)
When CC1 channel is configured as input, both CC1NP/CC1P bits select the active polarity of TI1FP1 and TI2FP1 for trigger or capture operations.
CC1NP=0, CC1P=0: non-inverted/rising edge. The circuit is sensitive to TIxFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode or encoder mode).
CC1NP=0, CC1P=1: inverted/falling edge. The circuit is sensitive to TIxFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is inverted (trigger operation in gated mode or encoder mode).
CC1NP=1, CC1P=1: non-inverted/both edges. The circuit is sensitive to both TIxFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), TIxFP1is not inverted (trigger operation in gated mode). This configuration must not be used in encoder mode.
CC1NP=1, CC1P=0: this configuration is reserved, it must not be used.

Bit 0 **CC1E**: *Capture/Compare 1 output enable.*
0: Capture mode disabled / OC1 is not active
1: Capture mode enabled / OC1 signal is output on the corresponding output pin

Table 413. Output control bit for standard tim_ocx channels

CCxE bit	tim_ocx output state
0	Output disabled (not driven by the timer: Hi-Z)
1	Output enabled (tim_ocx = tim_ocxref + Polarity)

Note: The state of the external IO pins connected to the standard tim_ocx channels depends only on the GPIO registers when CCxE=0.

39.5.12 TIMx counter (TIMx_CNT)(x = 3, 4)

Address offset: 0x024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31 **UIFCPY**: Value depends on IUFREMAP in TIMx_CR1.
If UIFREMAP = 0
Reserved
If UIFREMAP = 1
UIFCPY: UIF Copy
This bit is a read-only copy of the UIF bit of the TIMx_ISR register

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:0 **CNT[15:0]**: Counter value‘
Non-dithering mode (DITHEN = 0)
The register holds the counter value.
Dithering mode (DITHEN = 1)
The register holds the non-dithered part in CNT[15:0]. The fractional part is not available.

39.5.13 TIMx counter (TIMx_CNT)(x = 2, 5)

Address offset: 0x024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CNT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **UIFCPY_CNT[31]**: Value depends on IUFREMAP in TIMx_CR1.
If UIFREMAP = 0
CNT[31]: Most significant bit of counter value
If UIFREMAP = 1
UIFCPY: UIF Copy
This bit is a read-only copy of the UIF bit of the TIMx_ISR register

Bits 30:0 **CNT[30:0]**: Least significant part of counter value
Non-dithering mode (DITHEN = 0)
The register holds the counter value.
Dithering mode (DITHEN = 1)
The register holds the non-dithered part in CNT[30:0]. The fractional part is not available.

39.5.14 TIMx prescaler (TIMx_PSC)(x = 2 to 5)

Address offset: 0x028

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PSC[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0 **PSC[15:0]**: Prescaler value
The counter clock frequency tim_cnt_ck is equal to $f_{tim\_psc\_ck}$ / (PSC[15:0] + 1).
PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in “reset mode”).

39.5.15 TIMx auto-reload register (TIMx_ARR)(x = 3, 4)

Address offset: 0x02C

Reset value: 0x0000 FFFF

ARR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **ARR[19:0]**: Low Auto-reload value

ARR is the value to be loaded in the actual auto-reload register.
Refer to the *Section 39.4.3: Time-base unit on page 1576* for more details about ARR update and behavior.
The counter is blocked while the auto-reload value is null.
Non-dithering mode (DITHEN = 0)
The register holds the auto-reload value.
Dithering mode (DITHEN = 1)
The register holds the integer part in ARR[19:4]. The ARR[3:0] bitfield contains the dithered part.

39.5.16 TIMx auto-reload register (TIMx_ARR)(x = 2, 5)

Address offset: 0x02C

Reset value: 0xFFFF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ARR[31:16]

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ARR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ARR[31:0]**: Auto-reload value

ARR is the value to be loaded in the actual auto-reload register.
Refer to the *Section 39.4.3: Time-base unit on page 1576* for more details about ARR update and behavior.
The counter is blocked while the auto-reload value is null.
Non-dithering mode (DITHEN = 0)
The register holds the auto-reload value.
Dithering mode (DITHEN = 1)
The register holds the integer part in ARR[31:4]. The ARR[3:0] bitfield contains the dithered part.

39.5.17 TIMx capture/compare register 1 (TIMx_CCR1)(x = 3, 4)

Address offset: 0x034

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CCR1[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **CCR1[19:0]**: Capture/compare 1 value

If channel CC1 is configured as output:

CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc1 output.

Non-dithering mode (DITHEN = 0)

The register holds the compare value in CCR1[15:0]. The CCR1[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the integer part in CCR1[19:4]. The CCR1[3:0] bitfield contains the dithered part.

If channel CC1 is configured as input:

CCR1 is the counter value transferred by the last input capture 1 event (tim_ic1). The TIMx_CCR1 register is read-only and cannot be programmed.

Non-dithering mode (DITHEN = 0)

The CCR1[15:0] bits hold the capture value. The CCR1[19:16] bits are reserved.

Dithering mode (DITHEN = 1)

The register holds the capture in CCR1[19:0]. The CCR1[3:0] bits are reset.

39.5.18 TIMx capture/compare register 1 (TIMx_CCR1)(x = 2, 5)

Address offset: 0x034

Reset value: 0x0000 0000

CCR1[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **CCR1[31:0]**: Capture/compare 1 value

If channel CC1 is configured as output:

CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc1 output.

Non-dithering mode (DITHEN = 0)

The register holds the compare value.

Dithering mode (DITHEN = 1)

The register holds the integer part in CCR1[31:4]. The CCR1[3:0] bitfield contains the dithered part.

If channel CC1 is configured as input:

CCR1 is the counter value transferred by the last input capture 1 event (tim_ic1). The TIMx_CCR1 register is read-only and cannot be programmed.

Non-dithering mode (DITHEN = 0)

The register holds the capture value.

Dithering mode (DITHEN = 1)

The register holds the capture in CCR1[31:0]. The CCR1[3:0] bits are reset.

39.5.19 TIMx capture/compare register 2 (TIMx_CCR2)(x = 3, 4)

Address offset: 0x038

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **CCR2[19:0]**: Capture/compare 1 value

If channel CC2 is configured as output:

CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc2 output.

Non-dithering mode (DITHEN = 0)

The register holds the compare value in CCR2[15:0]. The CCR2[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the integer part in CCR2[19:4]. The CCR2[3:0] bitfield contains the dithered part.

If channel CC2 is configured as input:

CCR2 is the counter value transferred by the last input capture 2 event (tim_ic2). The TIMx_CCR2 register is read-only and cannot be programmed.

Non-dithering mode (DITHEN = 0)

The CCR2[15:0] bits hold the capture value. The CCR2[19:16] bits are reserved.

Dithering mode (DITHEN = 1)

The register holds the capture in CCR2[19:0]. The CCR2[3:0] bits are reset.

39.5.20 TIMx capture/compare register 2 (TIMx_CCR2)(x = 2, 5)

Address offset: 0x038

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CCR2[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **CCR2[31:0]**: Capture/compare 2 value

If channel CC2 is configured as output:

CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc2 output.

Non-dithering mode (DITHEN = 0)

The register holds the compare value.

Dithering mode (DITHEN = 1)

The register holds the integer part in CCR2[31:4]. The CCR2[3:0] bitfield contains the dithered part.

If channel CC2 is configured as input:

CCR2 is the counter value transferred by the last input capture 2 event (tim_ic2). The TIMx_CCR2 register is read-only and cannot be programmed.

Non-dithering mode (DITHEN = 0)

The register holds the capture value.

Dithering mode (DITHEN = 1)

The register holds the capture in CCR2[31:0]. The CCR2[3:0] bits are reset.

39.5.21 TIMx capture/compare register 3 (TIMx_CCR3)(x = 3, 4)

Address offset: 0x03C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CCR3[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **CCR3[19:0]**: Capture/compare 3 value

If channel CC3 is configured as output:

CCR3 is the value to be loaded in the actual capture/compare 3 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR3 register (bit OC3PE). Else the preload value is copied in the active capture/compare 3 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc3 output.

Non-dithering mode (DITHEN = 0)

The register holds the compare value in CCR3[15:0]. The CCR3[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the integer part in CCR3[19:4]. The CCR3[3:0] bitfield contains the dithered part.

If channel CC3 is configured as input:

CCR3 is the counter value transferred by the last input capture 3 event (tim_ic3). The TIMx_CCR3 register is read-only and cannot be programmed.

Non-dithering mode (DITHEN = 0)

The CCR3[15:0] bits hold the capture value. The CCR3[19:16] bits are reserved.

Dithering mode (DITHEN = 1)

The register holds the capture in CCR3[19:0]. The CCR3[3:0] bits are reset.

39.5.22 TIMx capture/compare register 3 (TIMx_CCR3)(x = 2, 5)

Address offset: 0x03C

Reset value: 0x0000 0000

CCR3[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **CCR3[31:0]**: Capture/compare 3 value

If channel CC3 is configured as output:

CCR3 is the value to be loaded in the actual capture/compare 3 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR3 register (bit OC3PE). Else the preload value is copied in the active capture/compare 3 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc3 output.

Non-dithering mode (DITHEN = 0)

The register holds the compare value.

Dithering mode (DITHEN = 1)

The register holds the integer part in CCR3[31:4]. The CCR3[3:0] bitfield contains the dithered part.

If channel CC3 is configured as input:

CCR3 is the counter value transferred by the last input capture 3 event (tim_ic3). The TIMx_CCR3 register is read-only and cannot be programmed.

Non-dithering mode (DITHEN = 0)

The register holds the capture value.

Dithering mode (DITHEN = 1)

The register holds the capture in CCR3[31:0]. The CCR3[3:0] bits are reset.

39.5.23 TIMx capture/compare register 4 (TIMx_CCR4)(x = 3, 4)

Address offset: 0x040

Reset value: 0x0000 0000

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **CCR4[19:0]**: Capture/compare 4 value

If channel CC4 is configured as output:

CCR4 is the value to be loaded in the actual capture/compare 4 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR4 register (bit OC4PE). Else the preload value is copied in the active capture/compare 4 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc4 output.

Non-dithering mode (DITHEN = 0)

The register holds the compare value in CCR4[15:0]. The CCR4[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the integer part in CCR4[19:4]. The CCR4[3:0] bitfield contains the dithered part.

If channel CC4 is configured as input:

CCR4 is the counter value transferred by the last input capture 4 event (tim_ic4). The TIMx_CCR4 register is read-only and cannot be programmed.

Non-dithering mode (DITHEN = 0)

The CCR4[15:0] bits hold the capture value. The CCR4[19:16] bits are reserved.

Dithering mode (DITHEN = 1)

The register holds the capture in CCR4[19:0]. The CCR4[3:0] bits are reset.

39.5.24 TIMx capture/compare register 4 (TIMx_CCR4)(x = 2, 5)

Address offset: 0x040

Reset value: 0x0000 0000

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **CCR4[31:0]**: Capture/compare 4 value

If channel CC4 is configured as output:

CCR4 is the value to be loaded in the actual capture/compare 4 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR4 register (bit OC4PE). Else the preload value is copied in the active capture/compare 4 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc4 output.

Non-dithering mode (DITHEN = 0)

The register holds the compare value.

Dithering mode (DITHEN = 1)

The register holds the integer part in CCR4[31:4]. The CCR4[3:0] bitfield contains the dithered part.

If channel CC4 is configured as input:

CCR4 is the counter value transferred by the last input capture 4 event (tim_ic4). The TIMx_CCR4 register is read-only and cannot be programmed.

Non-dithering mode (DITHEN = 0)

The register holds the capture value.

Dithering mode (DITHEN = 1)

The register holds the capture in CCR4[31:0]. The CCR4[3:0] bits are reset.

39.5.25 TIMx timer encoder control register (TIMx_ECR)(x = 2 to 5)

Address offset: 0x058

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	PWPRSC[2:0]			PW[7:0]							
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IPOS[1:0]		FIDX	IBLK[1:0]		IDIR[1:0]		IE
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:24 **PWPRSC[2:0]**: Pulse width prescaler

This bitfield sets the clock prescaler for the pulse generator, as following:

$t_{PWG} = (2^{(PWPRSC[2:0])}) \times t_{tim\_ker\_ck}$

Bits 23:16 **PW[7:0]**: Pulse width

This bitfield defines the pulse duration, as following:

$t_{PW} = PW[7:0] \times t_{PWG}$

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:6 **IPOS[1:0]**: Index positioning

In quadrature encoder mode (SMS[3:0] = 0001, 0010, 0011, 1110, 1111), this bit indicates in which AB input configuration the Index event resets the counter.

00: Index resets the counter when AB = 00
01: Index resets the counter when AB = 01
10: Index resets the counter when AB = 10
11: Index resets the counter when AB = 11

In directional clock mode or clock plus direction mode (SMS[3:0] = 1010, 1011, 1100, 1101), these bits indicates on which level the Index event resets the counter. In bidirectional clock mode, this applies for both clock inputs.

x0: Index resets the counter when clock is 0
x1: Index resets the counter when clock is 1

Note: IPOS[1] bit is not significant

Bit 5 **FIDX**: First index

This bit indicates if the first index only is taken into account

0: Index is always active
1: the first Index only resets the counter

Bits 4:3 **IBLK[1:0]**: Index blanking

This bit indicates if the Index event is conditioned by the tim_ti3 input

00: Index always active
01: Index disabled hen tim_ti3 input is active, as per CC3P bitfield
10: Index disabled when tim_ti4 input is active, as per CC4P bitfield
11: Reserved

Bits 2:1 **IDIR[1:0]**: Index direction

This bit indicates in which direction the Index event resets the counter.

00: Index resets the counter whatever the direction
01: Index resets the counter when up-counting only
10: Index resets the counter when down-counting only
11: Reserved

Bit 0 **IE**: Index enable

This bit indicates if the Index event resets the counter.

0: Index disabled
1: Index enabled

39.5.26 TIMx timer input selection register (TIMx_TISEL)(x = 2 to 5)

Address offset: 0x05C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	DBL[4:0]					Res.	Res.	Res.	DBA[4:0]				
			rw	rw	rw	rw	rw				rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:16 **DBSS[3:0]**: DMA burst source selection

This bitfield defines the interrupt source that triggers the DMA burst transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address).

0000: Reserved
0001: Update
0010: CC1
0011: CC2
0100: CC3
0101: CC4
0110: COM
0111: Trigger
Others: reserved

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **DBL[4:0]**: DMA burst length

This 5-bit vector defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e. the number of transfers. Transfers can be in half-words or in bytes (see example below).

00000: 1 transfer
00001: 2 transfers
00010: 3 transfers
...
11010: 26 transfers

Example: Let us consider the following transfer: DBL = 7 bytes & DBA = TIM2_CR1.

–If DBL = 7 bytes and DBA = TIM2_CR1 represents the address of the byte to be transferred, the address of the transfer is given by the following equation:

(TIMx_CR1 address) + DBA + (DMA index), where DMA index = DBL

In this example, 7 bytes are added to (TIMx_CR1 address) + DBA, which gives us the address from/to which the data are copied. In this case, the transfer is done to 7 registers starting from the following address: (TIMx_CR1 address) + DBA

According to the configuration of the DMA Data Size, several cases may occur:

–If the DMA Data Size is configured in half-words, 16-bit data are transferred to each of the 7 registers.

–If the DMA Data Size is configured in bytes, the data are also transferred to 7 registers: the first register contains the first MSB byte, the second register, the first LSB byte and so on. So with the transfer Timer, one also has to specify the size of data transferred by DMA.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DBA[4:0]**: DMA base address

This 5-bits vector defines the base-address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.

Example:
00000: TIMx_CR1,
00001: TIMx_CR2,
00010: TIMx_SMCR,
...

39.5.30 TIMx DMA address for full transfer (TIMx_DMAR)(x = 2 to 5)

Address offset: 0x3E0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DMAB[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DMAB[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DMAB[31:0]**: DMA register for burst accesses

A read or write operation to the DMAR register accesses the register located at the address

(TIMx_CR1 address) + (DBA + DMA index) x 4

where TIMx_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIMx_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx_DCR).

39.5.31 TIMx register map

TIMx registers are mapped as described in the table below.

Table 414. TIM2/TIM3/TIM4/TIM5 register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3 on page 111* for the register boundary addresses.

40 Basic timers (TIM6/TIM7)

40.1 TIM6/TIM7 introduction

The basic timers TIM6/TIM7 consist in a 16-bit auto-reload counter driven by a programmable prescaler.

They may be used as generic timers for time-base generation.

The basic timer can also be used for triggering the digital-to-analog converter. This is done with the trigger output of the timer.

The timers are completely independent, and do not share any resources.

40.2 TIM6/TIM7 main features

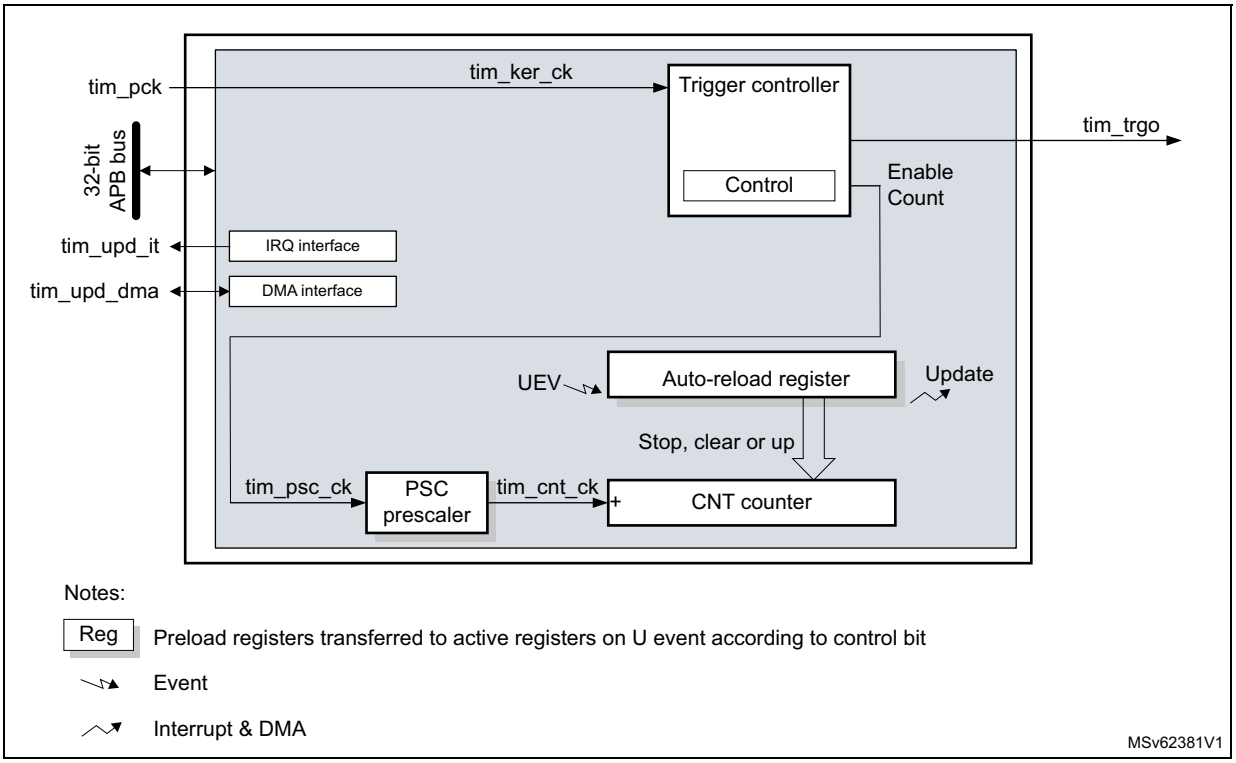
Basic timer (TIM6/TIM7) features include:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535
- Synchronization circuit to trigger the DAC
- Interrupt/DMA generation on the update event: counter overflow

40.3 TIM6/TIM7 functional description

40.3.1 TIM6/TIM7 block diagram

Figure 509. Basic timer block diagram



40.3.2 TIM6/TIM7 internal signals

The table in this section summarizes the TIM inputs and outputs.

Table 415. TIM internal input/output signals

Internal signal name	Signal type	Description
tim_pclk	Input	Timer APB clock
tim_ker_ck	Input	Timer kernel clock. This clock must be synchronous with tim_pclk (derived from the same source). The clock ratio tim_ker_ck/tim_pclk must be an integer:1, 2, 3,..., 16 (maximum value)
tim_trgo	Output	Internal trigger output. This trigger can trigger other on-chip peripherals (DAC).
tim_upd_it	Output	Timer update event interrupt
tim_upd_dma	Output	Timer update dma request

40.3.3 TIM6/TIM7 clocks

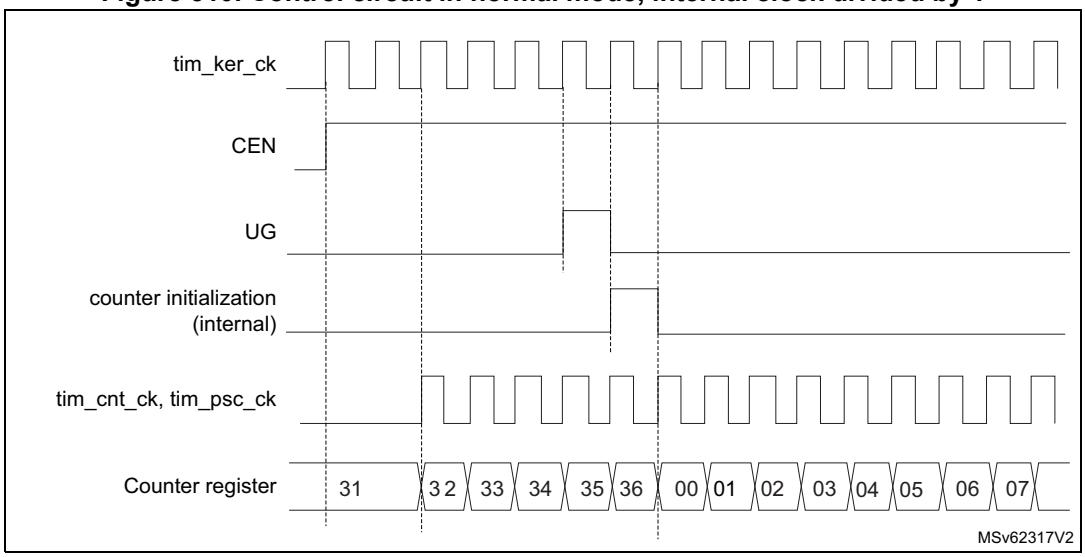
The timer bus interface is clocked by the tim_pclk APB clock.

The counter clock tim_ker_ck is connected to the tim_pclk input.

The CEN (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except for UG that remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock tim_ker_ck.

Figure 510 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

Figure 510. Control circuit in normal mode, internal clock divided by 1



40.3.4 Time-base unit

The main block of the programmable timer is a 16-bit upcounter with its related auto-reload register. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter Register (TIMx_CNT)
- Prescaler Register (TIMx_PSC)
- Auto-Reload Register (TIMx_ARR)

The auto-reload register is preloaded. The preload register is accessed each time an attempt is made to write or read the auto-reload register. The contents of the preload register are transferred into the shadow register permanently or at each update event UEV, depending on the auto-reload preload enable bit (ARPE) in the TIMx_CR1 register. The update event is sent when the counter reaches the overflow value and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.

The counter is clocked by the prescaler output tim_cnt_ck, which is enabled only when the counter enable bit (CEN) in the TIMx_CR1 register is set.

Note that the actual counter enable signal tim_cnt_en is set 1 clock cycle after CEN bit set.

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as the TIMx_PSC control register is buffered. The new prescaler ratio is taken into account at the next update event.

Figure 511 and *Figure 512* give some examples of the counter behavior when the prescaler ratio is changed on the fly.

Figure 511. Counter timing diagram with prescaler division change from 1 to 2

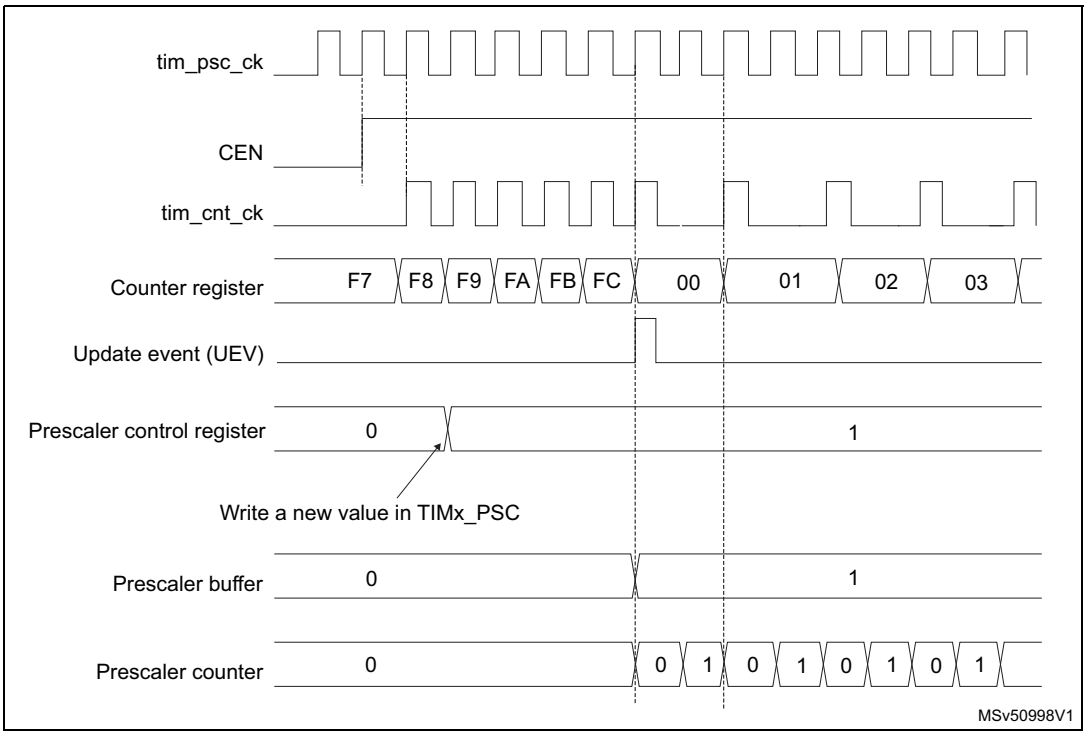


Figure 512. Counter timing diagram with prescaler division change from 1 to 4

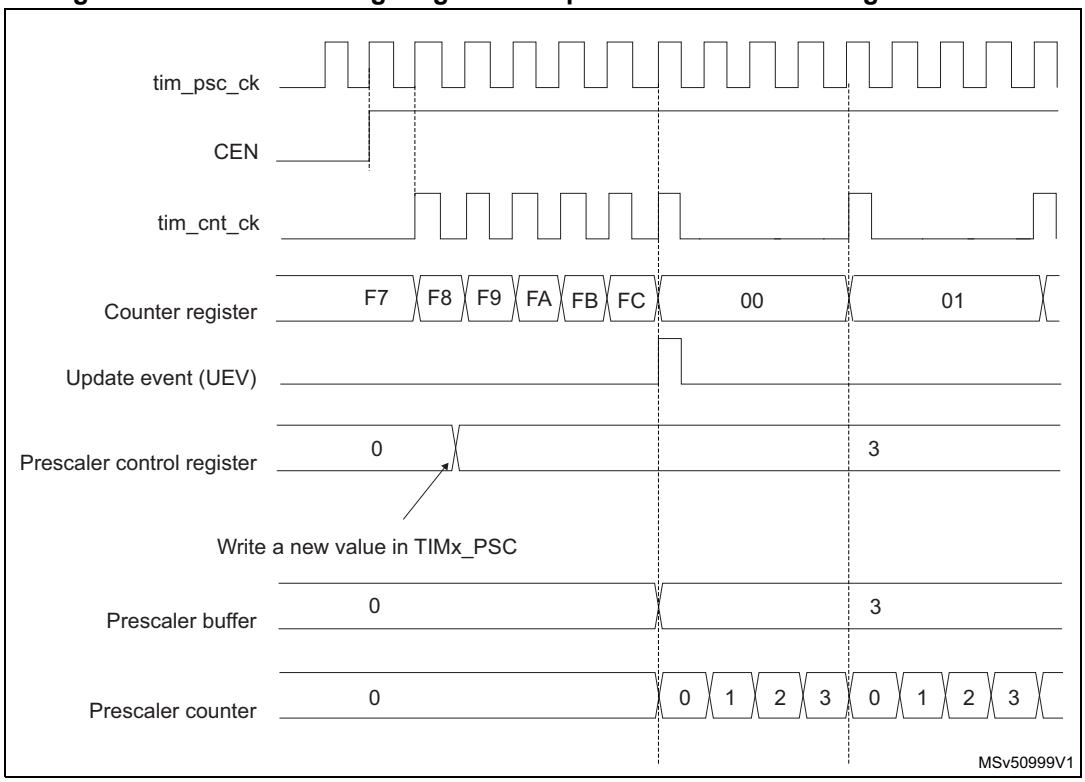

40.3.5 Counting mode

The counter counts from 0 to the auto-reload value (contents of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

An update event can be generate at each counter overflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This avoids updating the shadow registers while writing new values into the preload registers. In this way, no update event occurs until the UDIS bit has been written to 0, however, the counter and the prescaler counter both restart from 0 (but the prescale rate does not change). In addition, if the URS (update request selection) bit in the TIMx_CR1 register is set, setting the UG bit generates an update event UEV, but the UIF flag is not set (so no interrupt or DMA request is sent).

When an update event occurs, all the registers are updated and the update flag (UIF bit in the TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (contents of the TIMx_PSC register)
- The auto-reload shadow register is updated with the preload value (TIMx_ARR)

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR = 0x36.

Figure 513. Counter timing diagram, internal clock divided by 1

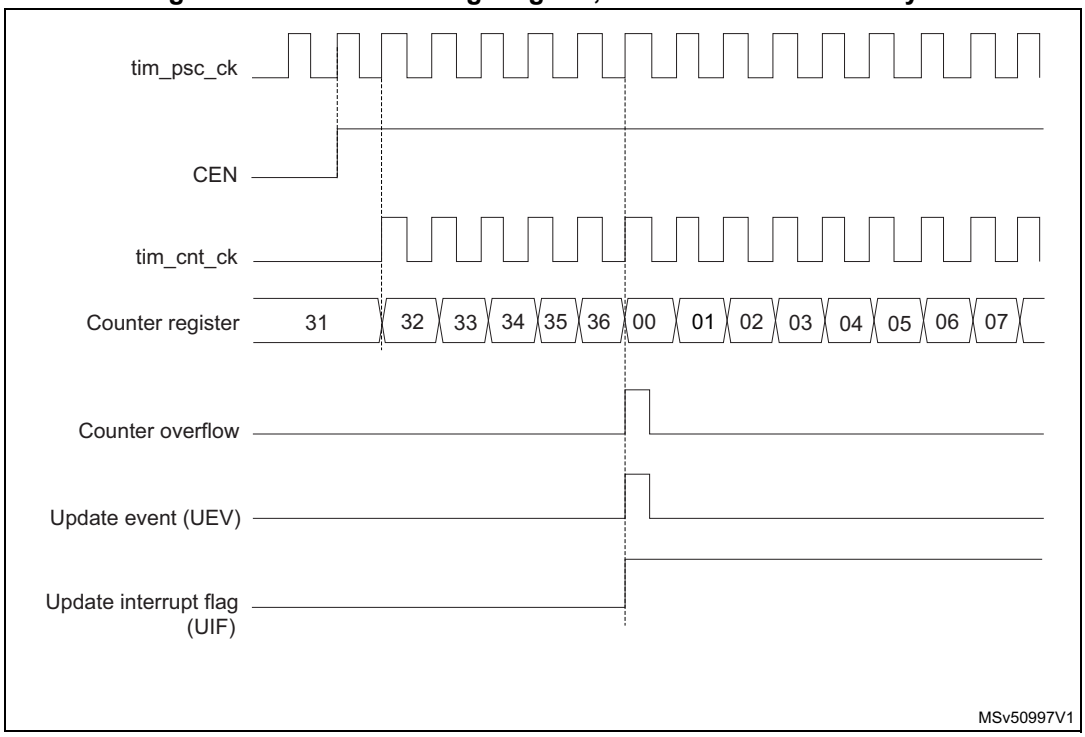

Figure 514. Counter timing diagram, internal clock divided by 2

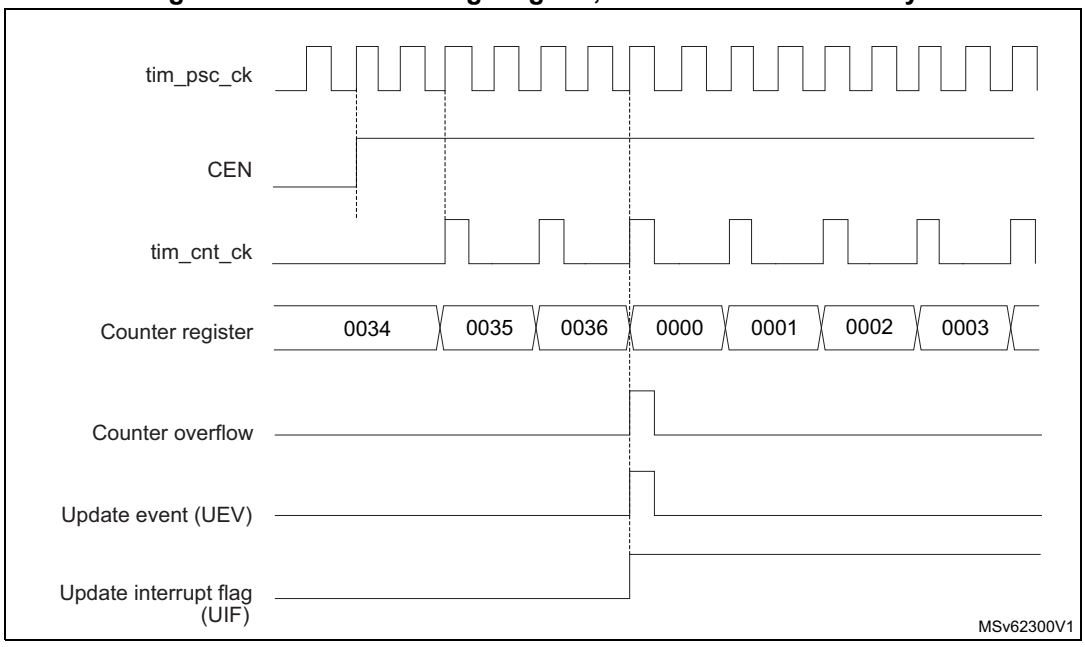

Figure 515. Counter timing diagram, internal clock divided by 4

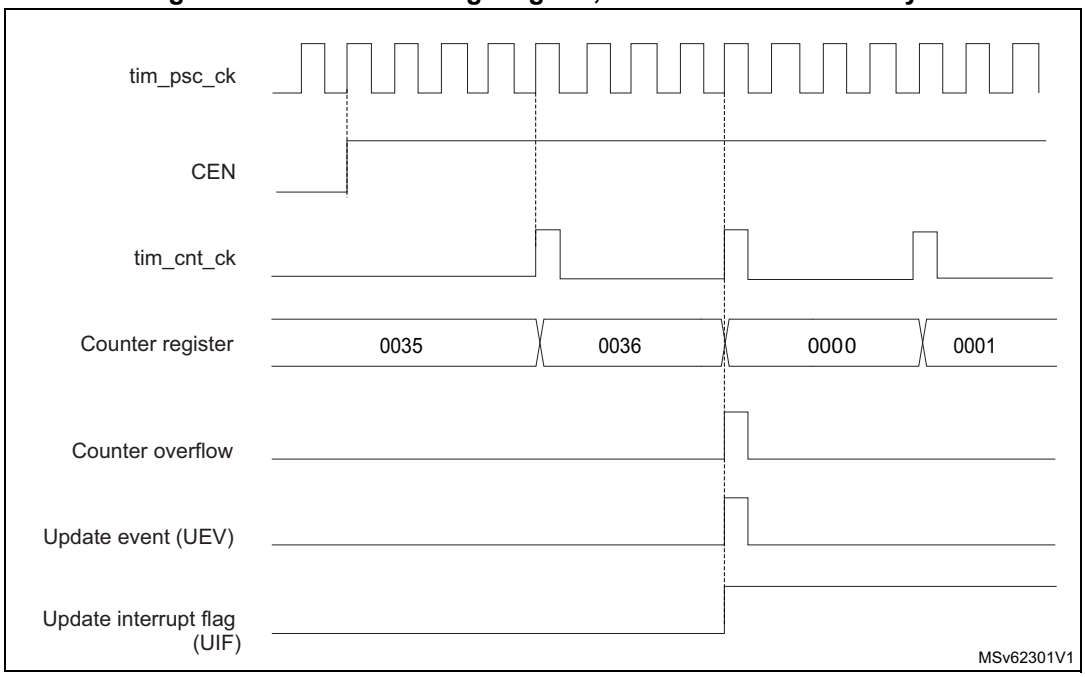

Figure 516. Counter timing diagram, internal clock divided by N

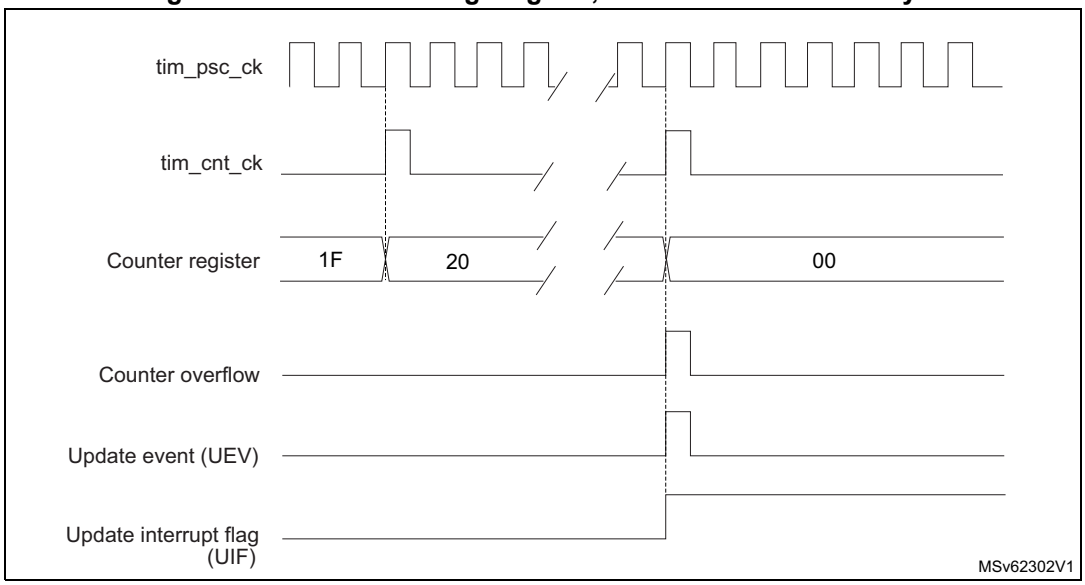

Figure 517. Counter timing diagram, update event when ARPE = 0 (TIMx_ARR not preloaded)

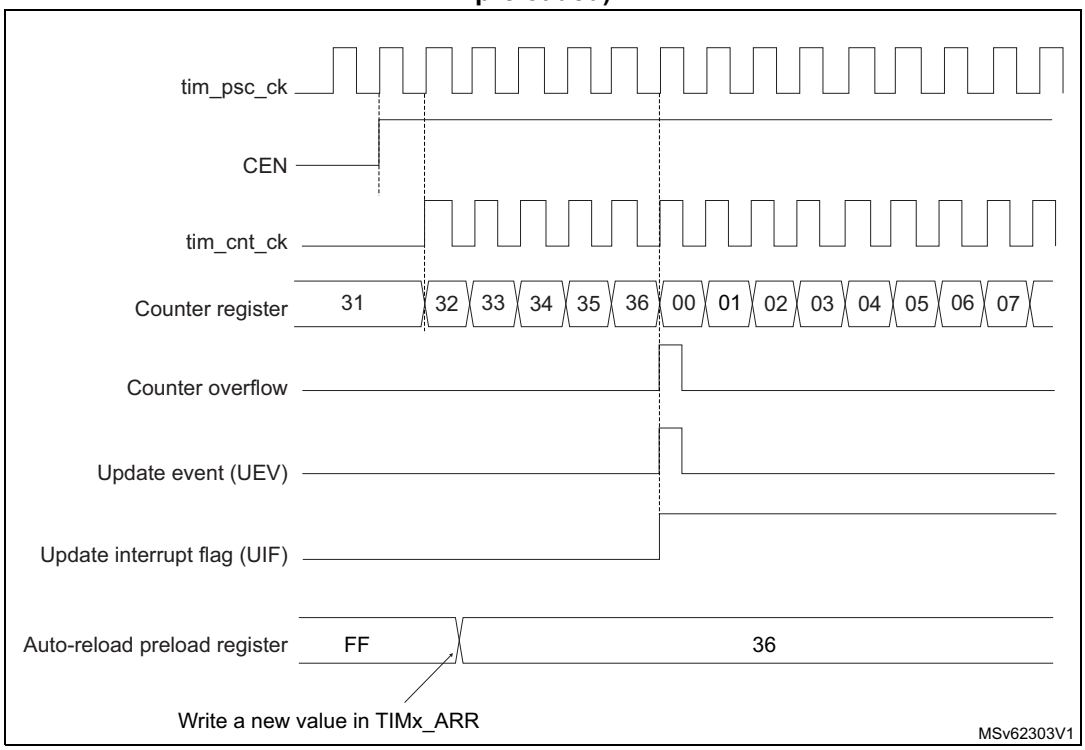

Figure 518. Counter timing diagram, update event when ARPE=1 (TIMx_ARR preloaded)

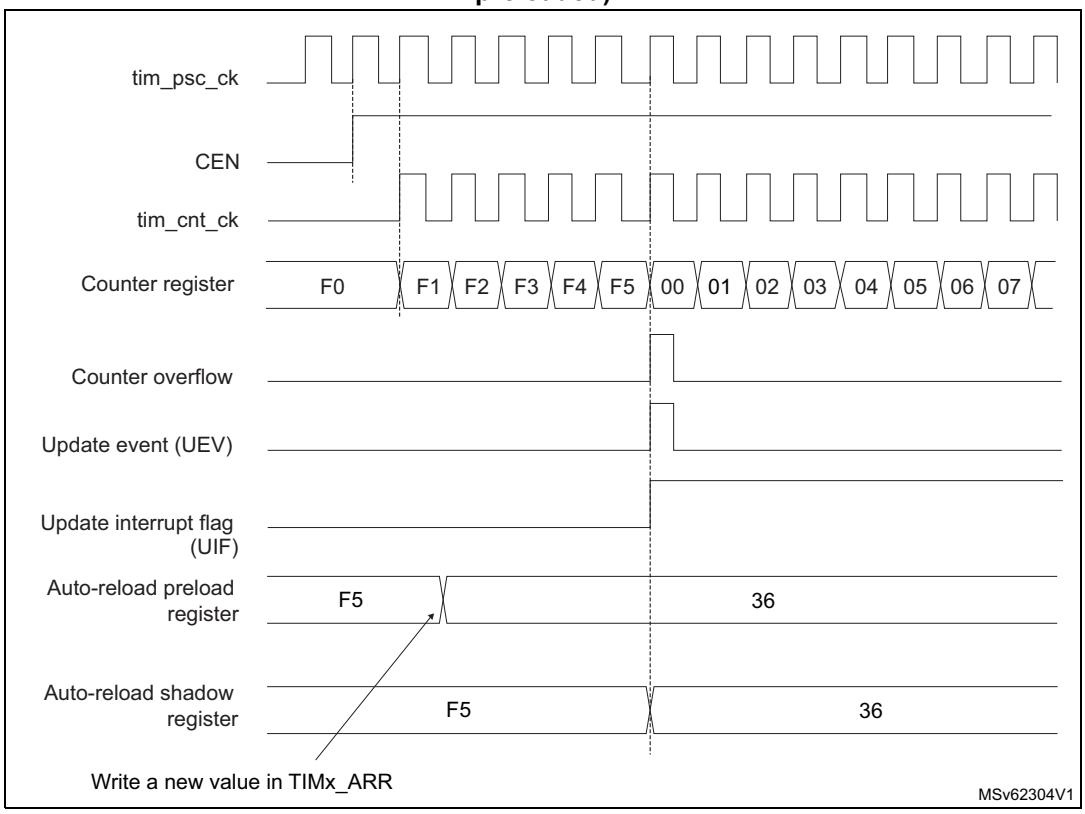


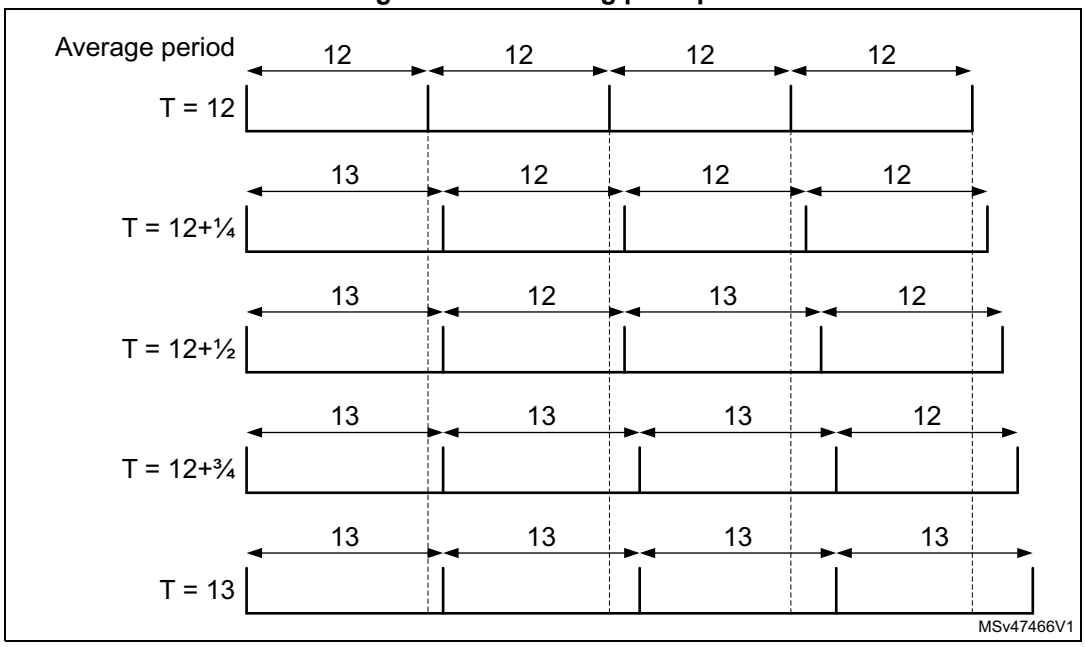
Dithering mode

The time base effective resolution can be increased by enabling the dithering mode, using the DITHEN bit in the TIMx_CR1 register. This affects the way the TIMx_ARR is behaving, and is useful for adjusting the average counter period when the timer is used as a trigger (typically for a DAC).

The operating principle is to have the actual ARR value slightly changed (adding or not one timer clock period) over 16 consecutive counting periods, with predefined patterns. This allows a 16-fold resolution increase, considering the average counting period.

The *Figure 519* below presents the dithering principle applied to 4 consecutive counting periods.

Figure 519. Dithering principle

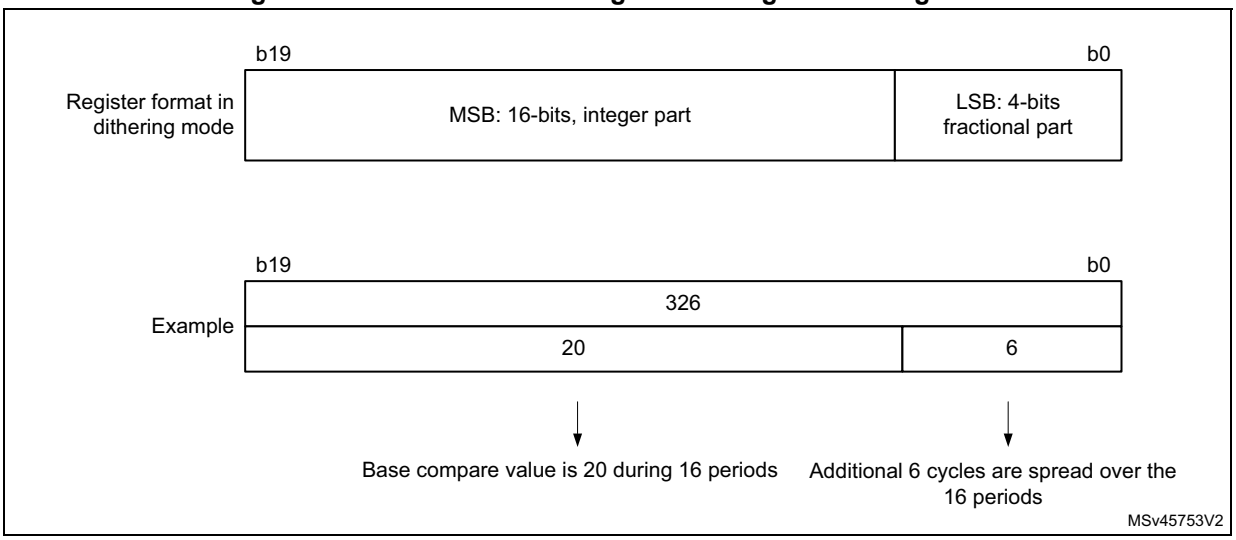


When the dithering mode is enabled, the register coding is changed as following (see *Figure 520* for example):

- the 4 LSBs are coding for the enhanced resolution part (fractional part)
- The MSBs are left-shifted to the bits 19:4 and are coding for the base value

Note: The following sequence must be followed when resetting the DITHEN bit:
1. CEN and ARPE bits must be reset
2. The DITHEN bit must be reset
3. The CEN bit can be set (eventually with ARPE = 1).

Figure 520. Data format and register coding in dithering mode



The minimum frequency is given by the following formula:

$$\text{Resolution} = \frac{F_{Tim}}{F_{pwm}} \Rightarrow F_{pwmMin} = \frac{F_{Tim}}{Max_{Resolution}}$$

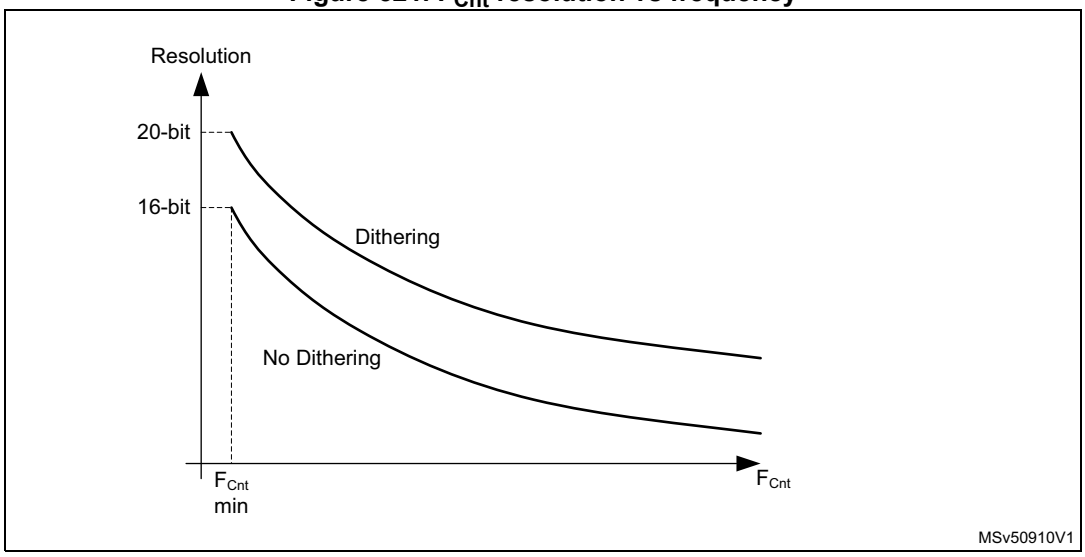
$$\text{Dithering mode disabled: } F_{pwmMin} = \frac{F_{Tim}}{65536}$$

$$\text{Dithering mode enabled: } F_{pwmMin} = \frac{F_{Tim}}{65535 + \frac{15}{16}}$$

Note: The maximum TIMx_ARR value is limited to 0xFFFEF in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part).

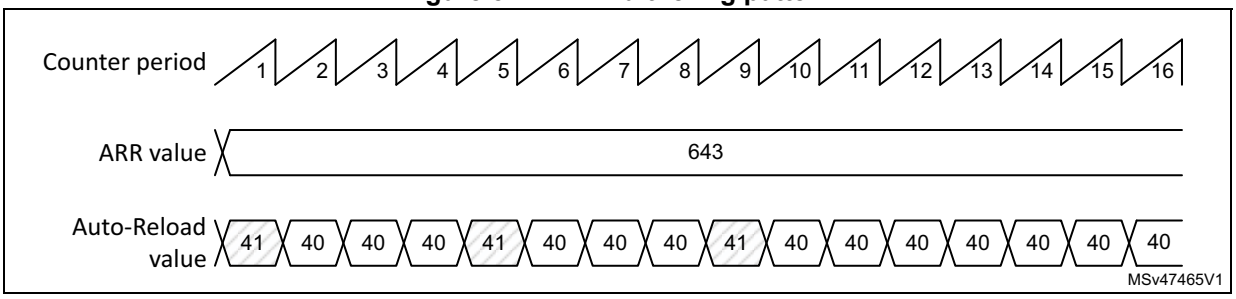
As shown on the *Figure 521* below, the dithering mode is used to increase the PWM resolution whatever the PWM frequency.

Figure 521. F_{Cnt} resolution vs frequency



The period changes are spread over 16 consecutive periods, as described in the *Figure 522* below.

Figure 522. PWM dithering pattern



The auto-reload and compare values increments are spread following specific patterns described in the *Table 416* below. The dithering sequence is done to have increments distributed as evenly as possible and minimize the overall ripple.

Table 416. TIMx_ARR register change dithering pattern

40.3.6 UIF bit remapping

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into the timer counter register's bit 31 (TIMxCNT[31]). This is used to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. In particular cases, it can ease the calculations by avoiding race conditions caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the assertions of the UIF and UIFCPY flags.

40.3.7 ADC triggers

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events.

Note: The clock of the slave peripherals (such as timer, ADC) receiving the tim_trgo signal must be enabled prior to receiving events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

40.3.8 TIM6/TIM7 DMA requests

The TIM6/TIM7 can generate a single DMA request, as shown in *Table 417*.

Table 417. DMA request

DMA acronym	DMA request	Enable control bit
tim_upd_dma	Update	UDE

40.3.9 Debug mode

When the microcontroller enters debug mode (Cortex-M33 core halted), the TIMx counter can either continue to work normally or be stopped.

The behavior in debug mode can be programmed with a dedicated configuration bit per timer in the Debug support (DBG) module.

For more details, refer to section Debug support (DBG).

40.3.10 TIM6/TIM7 low-power modes

Table 418. Effect of low-power modes on TIM6/TIM7

Mode	Description
Sleep	No effect, peripheral is active. The interrupts can cause the device to exit from Sleep mode.
Stop	The timer operation is stopped and the register content is kept. No interrupt can be generated.
Standby	The timer is powered-down and must be reinitialized after exiting the Standby mode.

40.3.11 TIM6/TIM7 interrupts

The TIM6/TIM7 can generate a single interrupt, as shown in *Table 419*.

Table 419. Interrupt request

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit from Sleep mode	Exit from Stop and Standby mode
TIM6 TIM7	Update	UIF	UIE	write 0 in UIF	Yes	No

40.4 TIM6/TIM7 registers

Refer to *Section 1.2 on page 101* for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

40.4.1 TIMx control register 1 (TIMx_CR1)(x = 6 to 7)

Address offset: 0x00

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	DITHEN	UIFREMAP	Res.	Res.	Res.	ARPE	Res.	Res.	Res.	OPM	URS	UDIS	CEN
			rw	rw				rw				rw	rw	rw	rw

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **DITHEN**: Dithering enable
0: Dithering disabled
1: Dithering enabled
Note: The DITHEN bit can only be modified when CEN bit is reset.

Bit 11 **UIFREMAP**: UIF status bit remapping
0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bits 10:8 Reserved, must be kept at reset value.

Bit 7 **ARPE**: Auto-reload preload enable
0: TIMx_ARR register is not buffered.
1: TIMx_ARR register is buffered.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One-pulse mode
0: Counter is not stopped at update event
1: Counter stops counting at the next update event (clearing the CEN bit).

Bit 2 **URS**: Update request source

This bit is set and cleared by software to select the UEV event sources.

0: Any of the following events generates an update interrupt or DMA request if enabled. These events can be:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS**: Update disable

This bit is set and cleared by software to enable/disable UEV event generation.

0: UEV enabled. The Update (UEV) event is generated by one of the following events:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

Buffered registers are then loaded with their preload values.

1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable

0: Counter disabled

1: Counter enabled

CEN is cleared automatically in one-pulse mode, when an update event occurs.

40.4.2 TIMx control register 2 (TIMx_CR2)(x = 6 to 7)

Address offset: 0x04

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MMS[2:0]			Res.	Res.	Res.	Res.
									rw	rw	rw				

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:4 **MMS[2:0]**: Master mode selection

These bits are used to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:

000: **Reset** - the UG bit from the TIMx_EGR register is used as a trigger output (tim_trgo).

001: **Enable** - the Counter enable signal, tim_cnt_en, is used as a trigger output (tim_trgo). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated when the CEN control bit is written.

010: **Update** - The update event is selected as a trigger output (tim_trgo). For instance a master timer can then be used as a prescaler for a slave timer.

Note: The clock of the slave timer or he peripheral receiving the tim_trgo must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

Bits 3:0 Reserved, must be kept at reset value.

40.4.3 TIMx DMA/Interrupt enable register (TIMx_DIER)(x = 6 to 7)

Address offset: 0x0C

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	UDE	Res.	Res.	Res.	Res.	Res.	Res.	Res.	UIE
							rw								rw

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **UDE**: Update DMA request enable

0: Update DMA request disabled.
1: Update DMA request enabled.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **UIE**: Update interrupt enable

0: Update interrupt disabled.
1: Update interrupt enabled.

40.4.4 TIMx status register (TIMx_SR)(x = 6 to 7)

Address offset: 0x10

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	UIF
															rc_w0

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **UIF**: Update interrupt flag

This bit is set by hardware on an update event. It is cleared by software.

0: No update occurred.

1: Update interrupt pending. This bit is set by hardware when the registers are updated:

– On counter overflow if UDIS = 0 in the TIMx_CR1 register.

– When CNT is reinitialized by software using the UG bit in the TIMx_EGR register, if URS = 0 and UDIS = 0 in the TIMx_CR1 register.

40.4.5 TIMx event generation register (TIMx_EGR)(x = 6 to 7)

Address offset: 0x14

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	UG
															w

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **UG**: Update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action.

1: Re-initializes the timer counter and generates an update of the registers. Note that the prescaler counter is cleared too (but the prescaler ratio is not affected).

40.4.6 TIMx counter (TIMx_CNT)(x = 6 to 7)

Address offset: 0x24

Reset value: 0x0000 0000

CNT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **UIFCPY**: UIF copy

This bit is a read-only copy of the UIF bit of the TIMx_ISR register. If the UIFREMAP bit in TIMx_CR1 is reset, bit 31 is reserved and read as 0.

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:0 **CNT[15:0]**: Counter value

Non-dithering mode (DITHEN = 0)

The register holds the counter value.

Dithering mode (DITHEN = 1)

The register only holds the non-dithered part in CNT[15:0]. The fractional part is not available.

40.4.7 TIMx prescaler (TIMx_PSC)(x = 6 to 7)

Address offset: 0x28

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PSC[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0 **PSC[15:0]**: Prescaler value

The counter clock frequency $f_{tim\_cnt\_ck}$ is equal to $f_{tim\_psc\_ck}$ / (PSC[15:0] + 1).

PSC contains the value to be loaded into the active prescaler register at each update event. (including when the counter is cleared through UG bit of TIMx_EGR register.

40.4.8 TIMx auto-reload register (TIMx_ARR)(x = 6 to 7)

Address offset: 0x2C

Reset value: 0x0000 FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ARR[19:16]			
												rw	rw	rw	rw

ARR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **ARR[19:0]**: Auto-reload value

ARR is the value to be loaded into the actual auto-reload register.

Refer to *Section 40.3.4: Time-base unit on page 1689* for more details about ARR update and behavior.

The counter is blocked while the auto-reload value is null.

Non-dithering mode (DITHEN = 0)

The register holds the auto-reload value in ARR[15:0]. The ARR[19:16] bits are reserved.

Dithering mode (DITHEN = 1)

The register holds the integer part in ARR[19:4]. The ARR[3:0] bitfield contains the dithered part.

40.4.9 TIMx register map

TIMx registers are mapped as 16-bit addressable registers as described in the table below:

Table 420. TIMx register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

41 General-purpose timers (TIM12/TIM13/TIM14)

41.1 TIM12/TIM13/TIM14 introduction

The TIM12/TIM13/TIM14 general-purpose timers consist in a 16-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The TIM12/TIM13/TIM14 timers are completely independent, and do not share any resources. They can be synchronized together as described in *Section 41.4.20: Timer synchronization (TIM12 only)*.

41.2 TIM12 main features

The features of the TIM12 general-purpose timer include:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide the counter clock frequency by any factor between 1 and 65536 (can be changed “on the fly”)
- Up to 2 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Synchronization circuit to control the timer with external signals and to interconnect several timers together
- Interrupt generation on the following events:
  - Update: counter overflow, counter initialization (by software or internal trigger)
  - Trigger event (counter start, stop, initialization or count by internal trigger)
  - Input capture
  - Output compare

41.3 TIM13/TIM14 main features

The features of general-purpose timers TIM13/TIM14 include:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide the counter clock frequency by any factor between 1 and 65536 (can be changed “on the fly”)
- independent channel for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Interrupt generation on the following events:
  - Update: counter overflow, counter initialization (by software)
  - Input capture
  - Output compare

41.4 TIM12/TIM13/TIM14 functional description

41.4.1 Block diagram

Figure 523. General-purpose timer block diagram (TIM12)

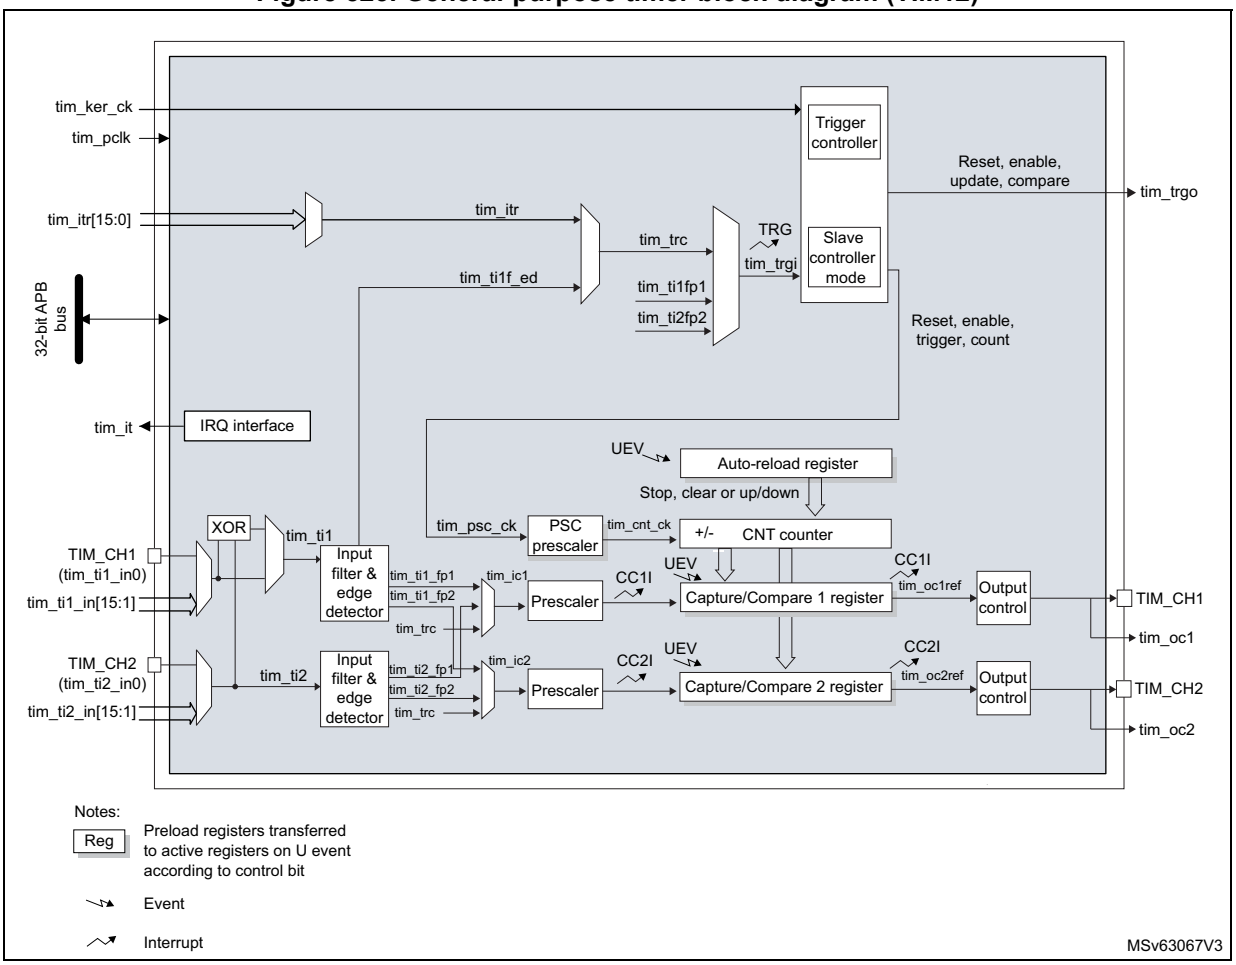

Figure 524. General-purpose timer block diagram (TIM13/TIM14)

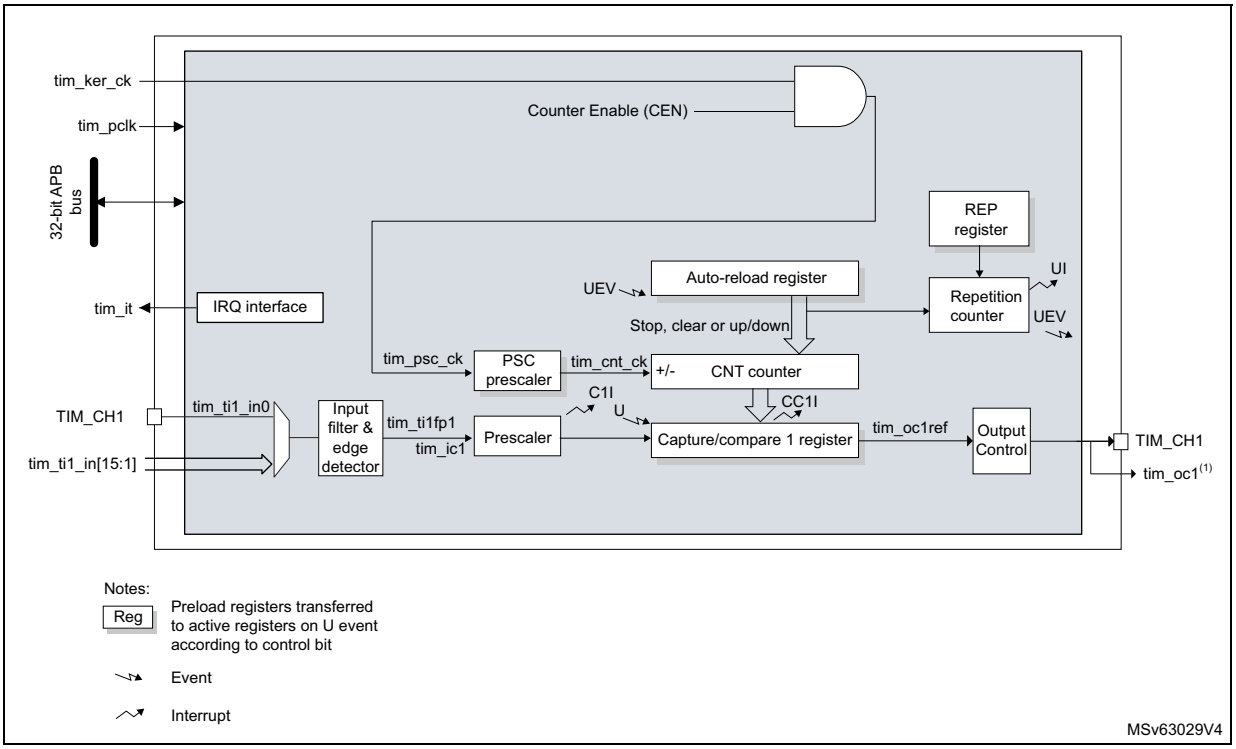

1. This signal can be used as trigger for some slave timer (see internal trigger connection table in next section). See *Section 41.4.21: Using timer output as trigger for other timers (TIM13/TIM14 only)* for details.

41.4.2 TIM12/TIM13/TIM14 pins and internal signals

Table 421 and *Table 422* in this section summarize the TIM inputs and outputs.

Table 421. TIM input/output pins

Pin name	Signal type	Description
TIM_CH1 TIM_CH2(1)	Input/Output	Timer multi-purpose channels. Each channel be used for capture, compare, or PWM. TIM_CH1 and TIM_CH2 can also be used as external clock (below 1/4 of the tim_ker_ck clock) and external trigger inputs.

1. Available for TIM12 only.

Table 422. TIM internal input/output signals

Internal signal name	Signal type	Description
tim_ti1_in[15:0] tim_ti2_in[15:0](1)	Input	Internal timer inputs bus. These inputs can be used for capture or as external clock (below 1/4 of the tim_ker_ck clock).
tim_itr[15:0](1)	Input	Internal trigger input bus. These inputs can be used for the slave mode controller or as a input clock (below 1/4 of the tim_ker_ck clock).
tim_oc1 tim_oc2(1)	Output	Internal timer output. Can be used for triggering other timers or the ADC(s).

Table 422. TIM internal input/output signals (continued)

Internal signal name	Signal type	Description
tim_trgo(1)	Output	Internal trigger output. This trigger can trigger other on-chip peripherals.
tim_pclk	Input	Timer APB clock
tim_ker_ck	Input	Timer kernel clock. This clock must be synchronous with tim_pclk (derived from the same source). The clock ratio tim_ker_ck/tim_pclk must be an integer:1, 2, 3,..., 16 (maximum value)
tim_it	Output	Global Timer interrupt, gathering capture/compare, update, break trigger and commutation requests

1. Available for TIM12 only.

Table 423 and *Table 424* list the sources connected to the tim_ti[2:1] input multiplexers.

41.4.3 Time-base unit

The main block of the timer is a 16-bit up-counter with its related auto-reload register. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Auto-reload register (TIMx_ARR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in details for each configuration.

The counter is clocked by the prescaler output tim_cnt_ck, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the counter starts counting 1 clock cycle after setting the CEN bit in the TIMx_CR1 register.

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

Figure 525 and *Figure 526* give some examples of the counter behavior when the prescaler ratio is changed on the fly.

Figure 525. Counter timing diagram with prescaler division change from 1 to 2

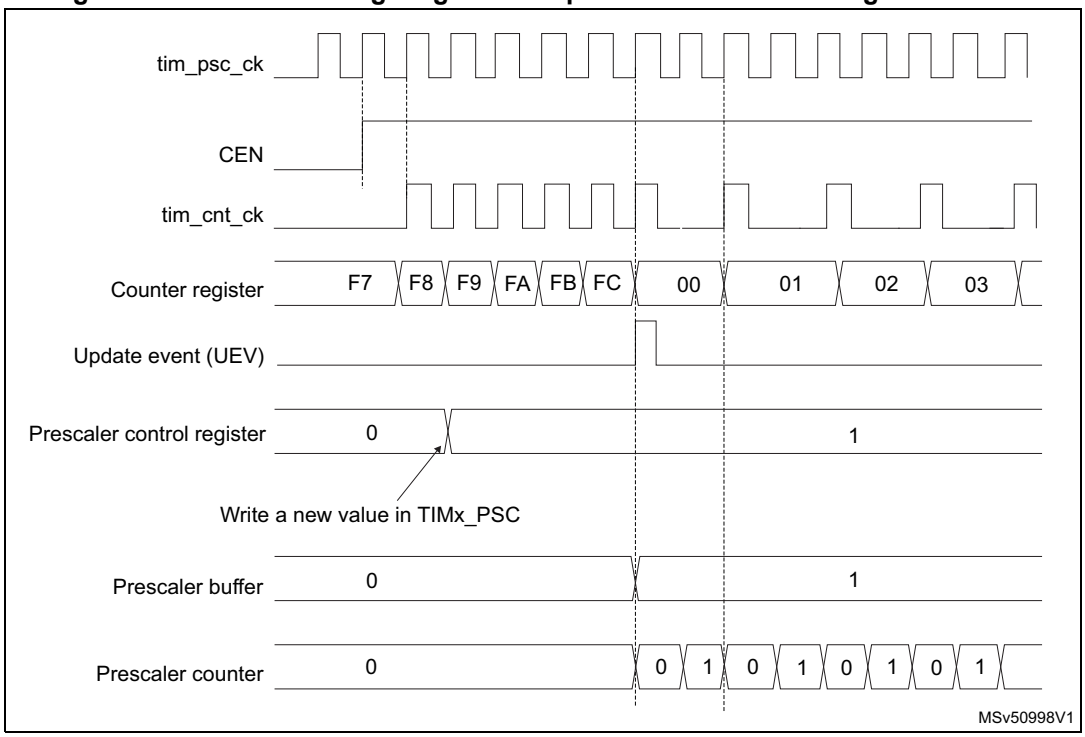

Figure 526. Counter timing diagram with prescaler division change from 1 to 4

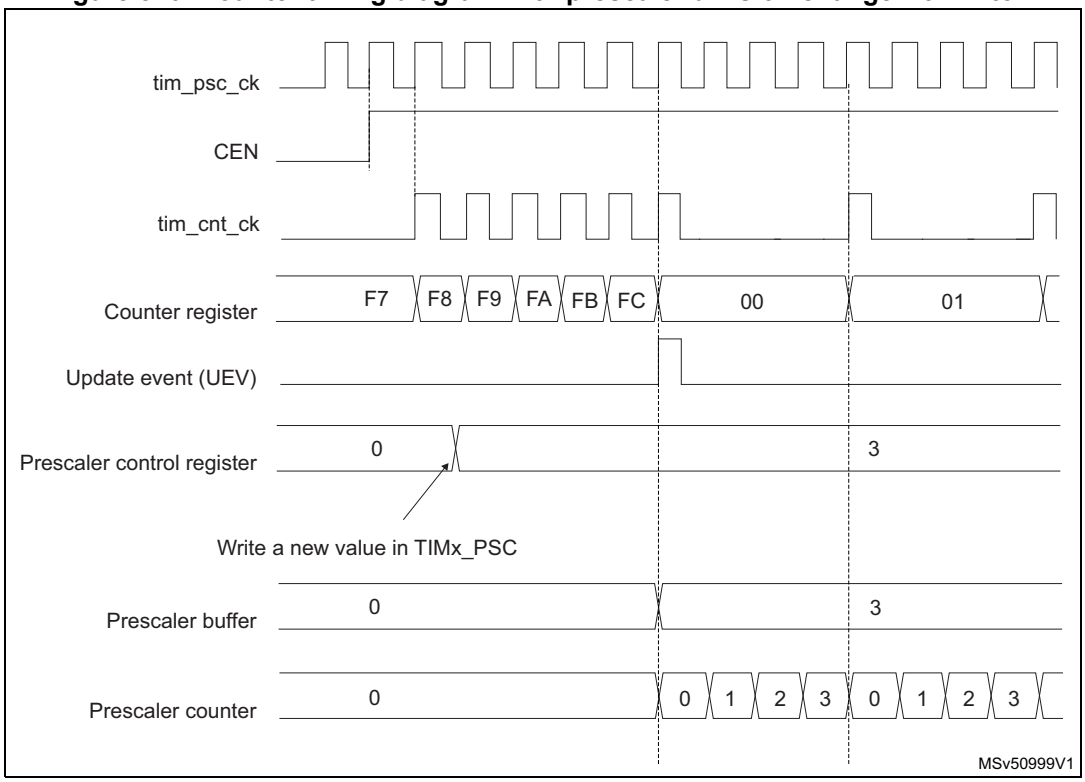

41.4.4 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller on TIM12) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The auto-reload shadow register is updated with the preload value (TIMx_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

Figure 527. Counter timing diagram, internal clock divided by 1

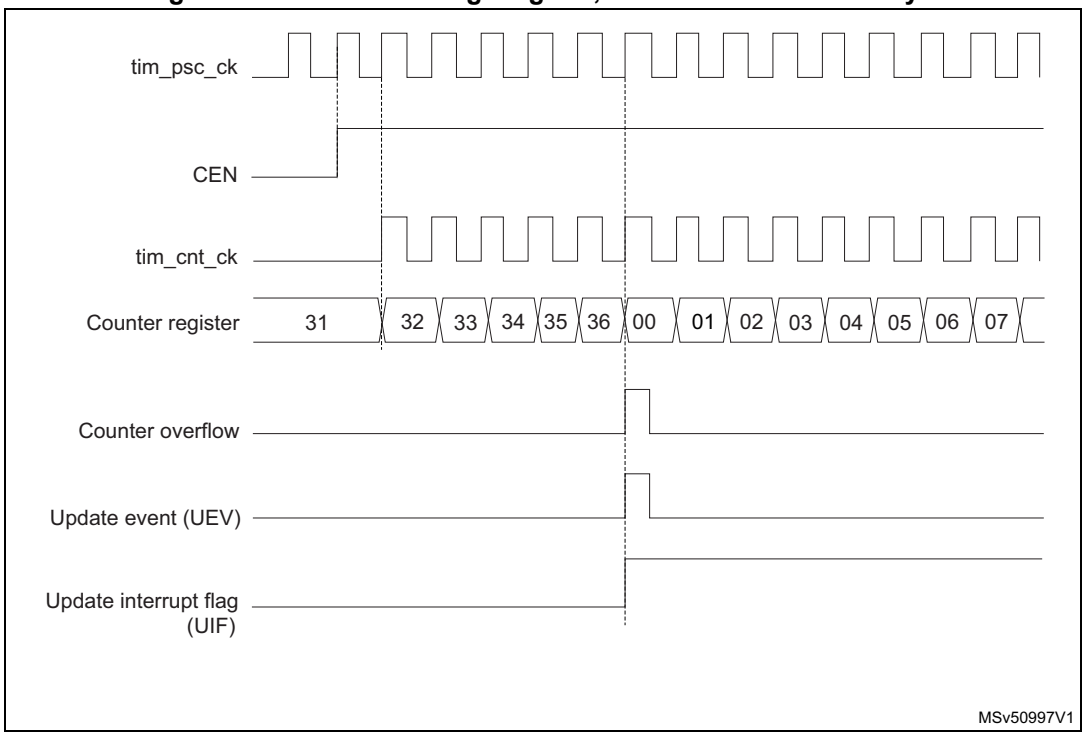

Figure 528. Counter timing diagram, internal clock divided by 2

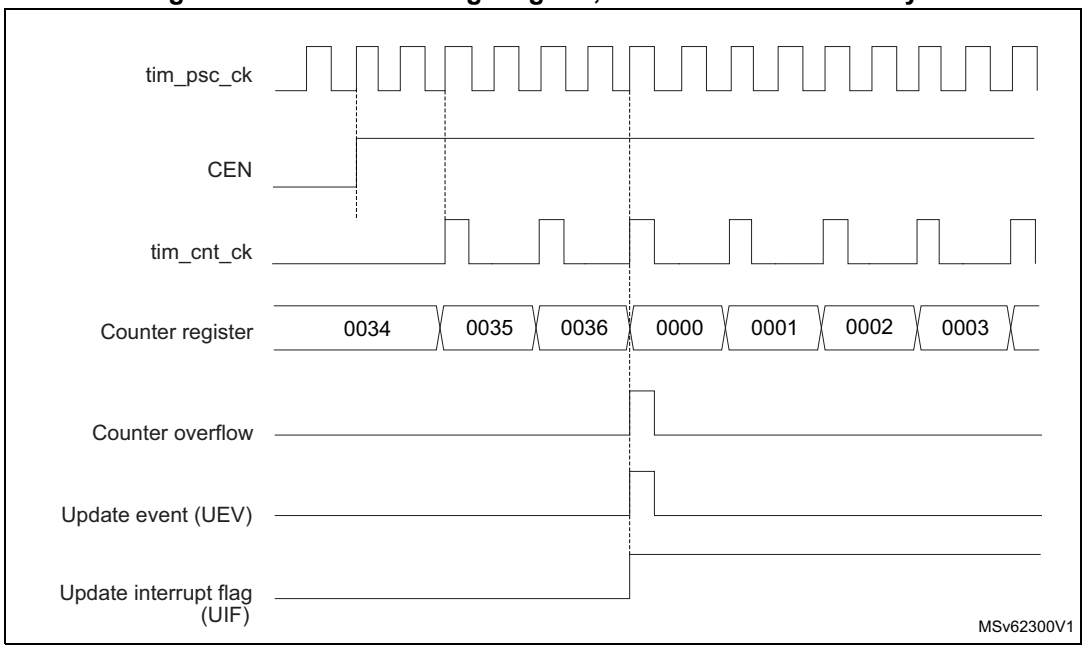

Figure 529. Counter timing diagram, internal clock divided by 4

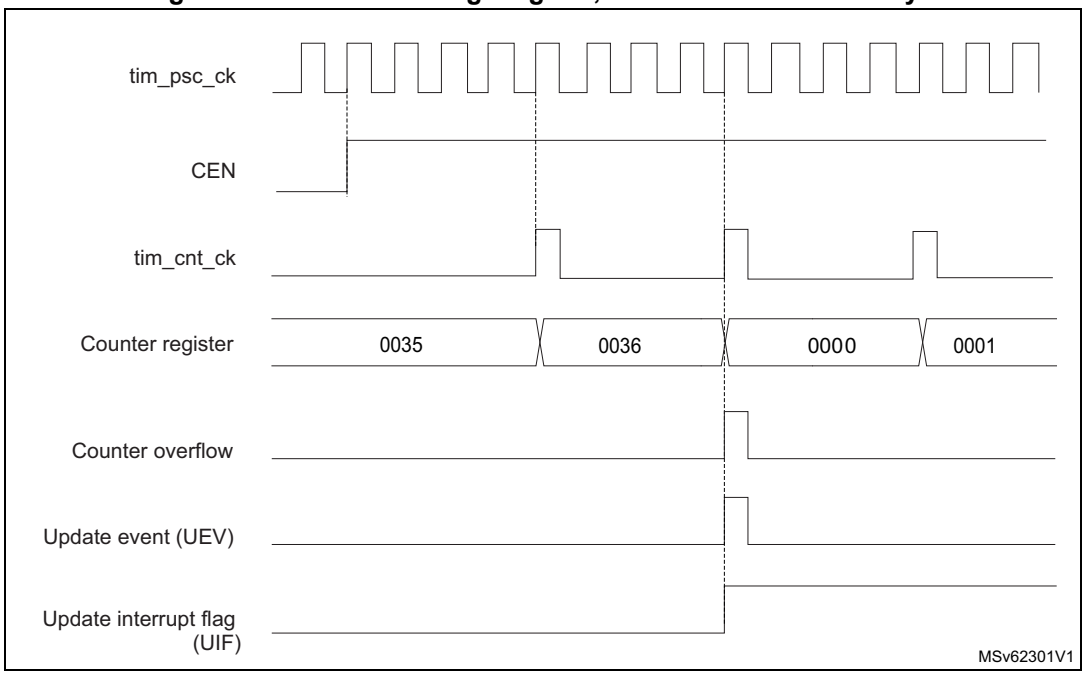

Figure 530. Counter timing diagram, internal clock divided by N

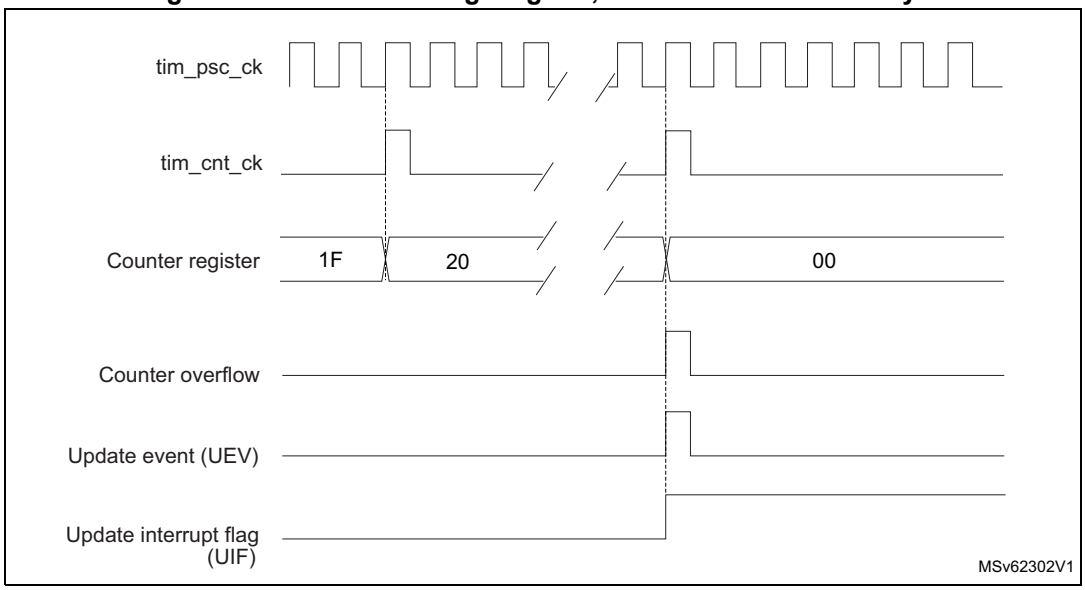

Figure 531. Counter timing diagram, update event when ARPE=0 (TIMx_ARR not preloaded)

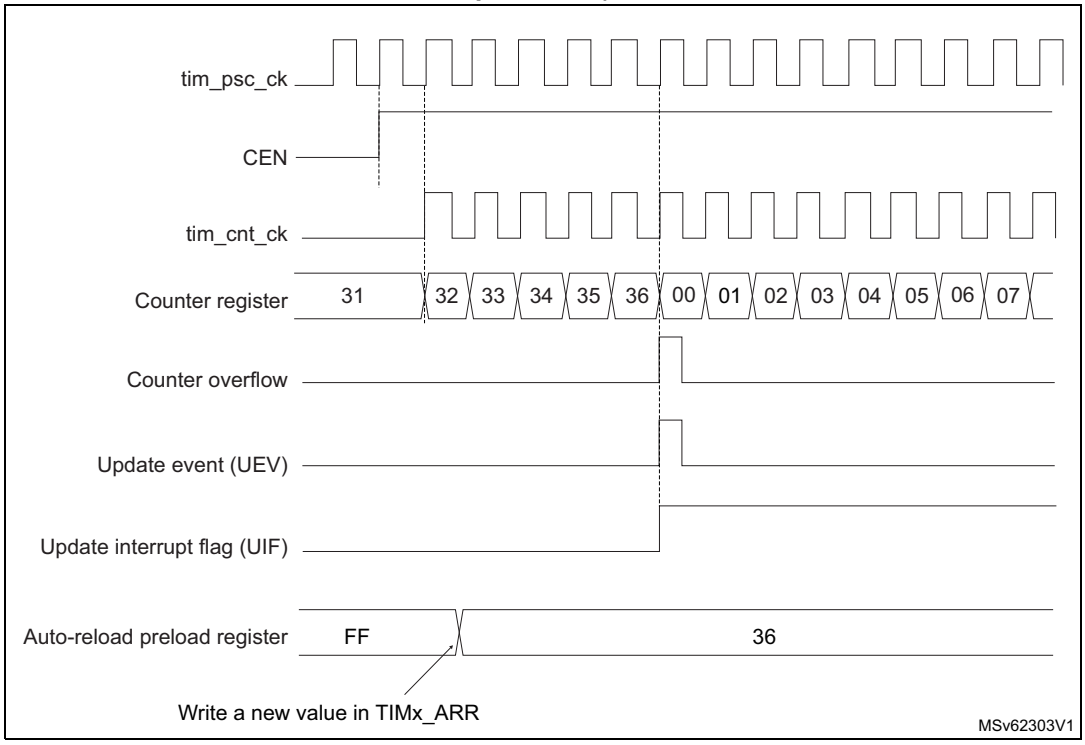

Figure 532. Counter timing diagram, update event when ARPE=1 (TIMx_ARR preloaded)

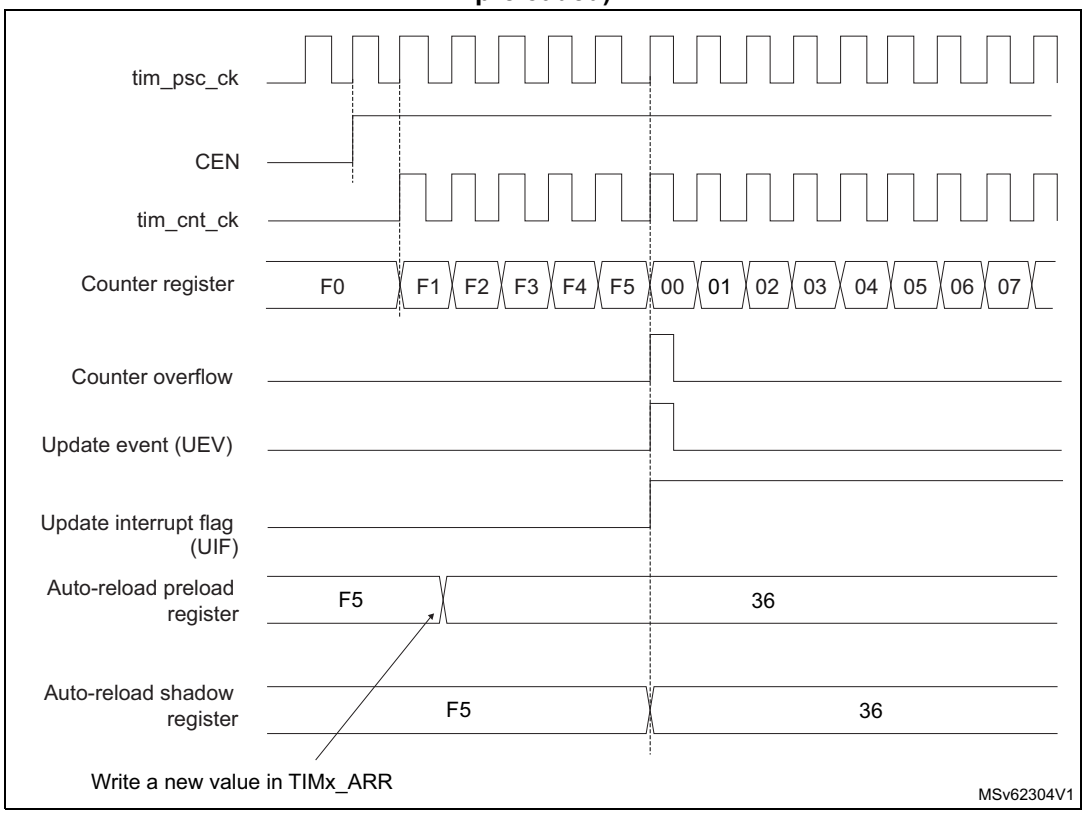


41.4.5 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (tim_ker_ck)
- External clock mode1 (for TIM12): external input pin (tim_ti1 or tim_ti2, if available)
- Internal trigger inputs (tim_itrx) (for TIM12): connecting the trigger output from another timer. For instance, another timer can be configured as a prescaler for TIM12. Refer to *Section : Using one timer as prescaler for another timer* for more details.

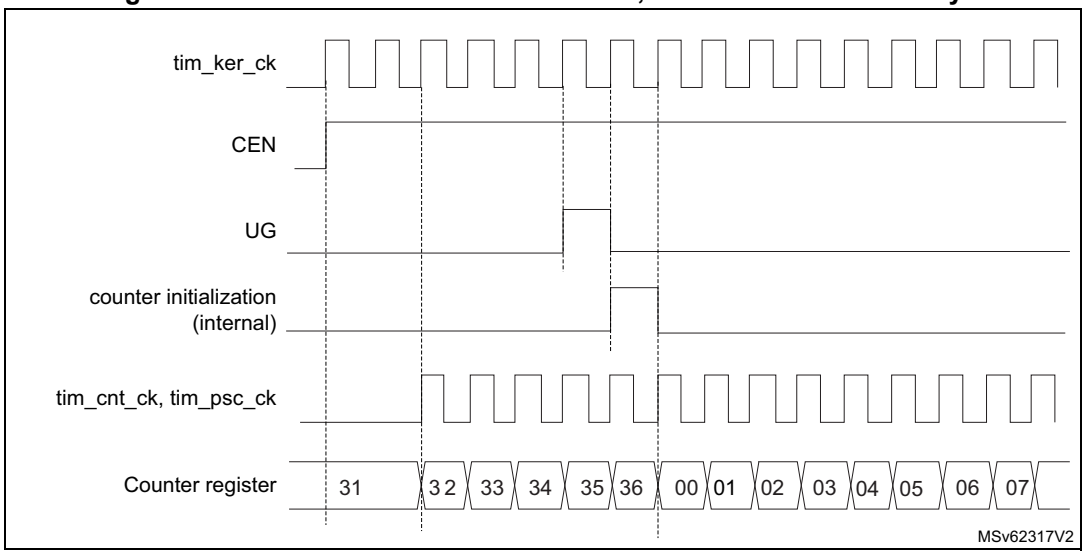
Internal clock source (tim_ker_ck)

The internal clock source is the default clock source for TIM13/TIM14.

For TIM12, the internal clock source is selected when the slave mode controller is disabled (SMS='000'). The CEN bit in the TIMx_CR1 register and the UG bit in the TIMx_EGR register are then used as control bits and can be changed only by software (except for UG which remains cleared). As soon as the CEN bit is programmed to 1, the prescaler is clocked by the internal clock tim_ker_ck.

Figure 533 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

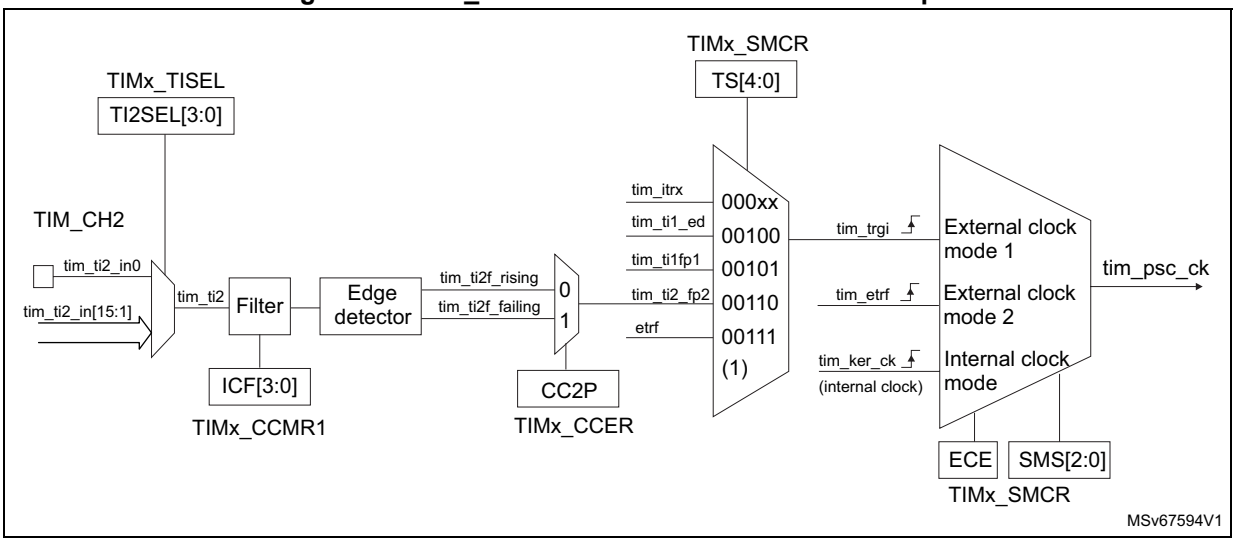
Figure 533. Control circuit in normal mode, internal clock divided by 1



External clock source mode 1

This mode is selected when SMS='111' in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

Figure 534. tim_ti2 external clock connection example



For example, to configure the upcounter to count in response to a rising edge on the tim_ti2 input, use the following procedure:

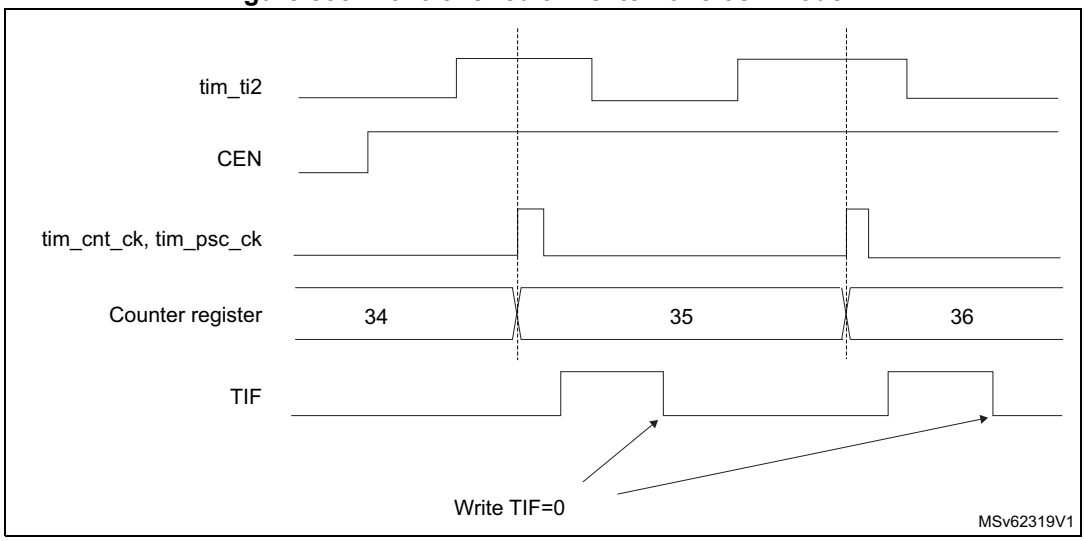
1. Select the proper tim_ti2_in[15:0] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Configure channel 2 to detect rising edges on the tim_ti2 input by writing CC2S = ‘01’ in the TIMx_CCMR1 register.
3. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 register (if no filter is needed, keep IC2F=’0000’).
4. Select the rising edge polarity by writing CC2P=’0’ and CC2NP=’0’ in the TIMx_CCER register.
5. Configure the timer in external clock mode 1 by writing SMS=’111’ in the TIMx_SMCR register.
6. Select tim_ti2 as the trigger input source by writing TS=’110’ in the TIMx_SMCR register.
7. Enable the counter by writing CEN=’1’ in the TIMx_CR1 register.

Note: The capture prescaler is not used for triggering, it is not necessary to configure it.

When a rising edge occurs on tim_ti2, the counter counts once and the TIF flag is set.

The delay between the rising edge on tim_ti2 and the actual clock of the counter is due to the resynchronization circuit on tim_ti2 input.

Figure 535. Control circuit in external clock mode 1



41.4.6 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), a input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

Figure 536, *Figure 537*, *Figure 538* and *Figure 539* give an overview of a capture/compare channel.

The input stage samples the corresponding tim_tix input to generate a filtered signal tim_tixf. Then, an edge detector with polarity selection generates a signal (tim_tixfpy) which

can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

Figure 536. Capture/compare channel 1 input stage (TIM13/TIM14)

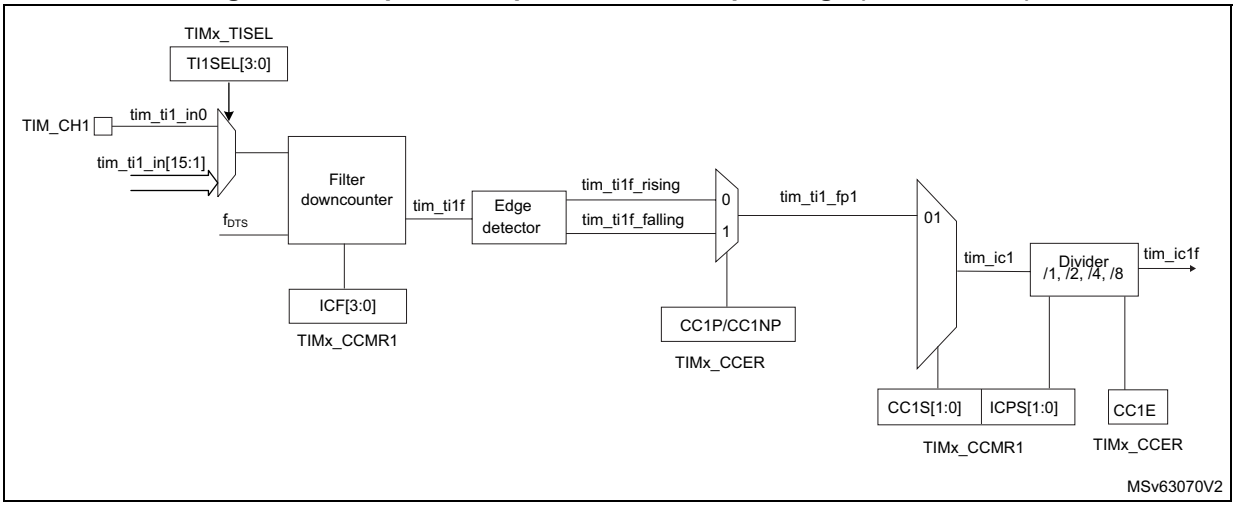


Figure 537. Capture/compare channel 1 input stage (TIM12)

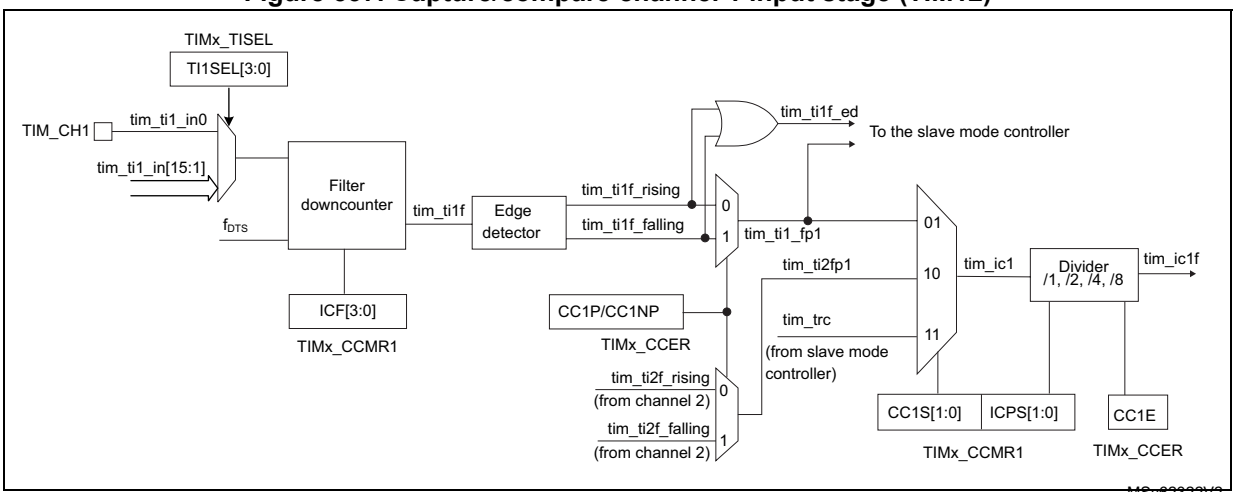

The output stage generates an intermediate waveform which is then used for reference: tim_ocxref (active high). The polarity acts at the end of the chain.

Figure 538. Capture/compare channel 1 main circuit

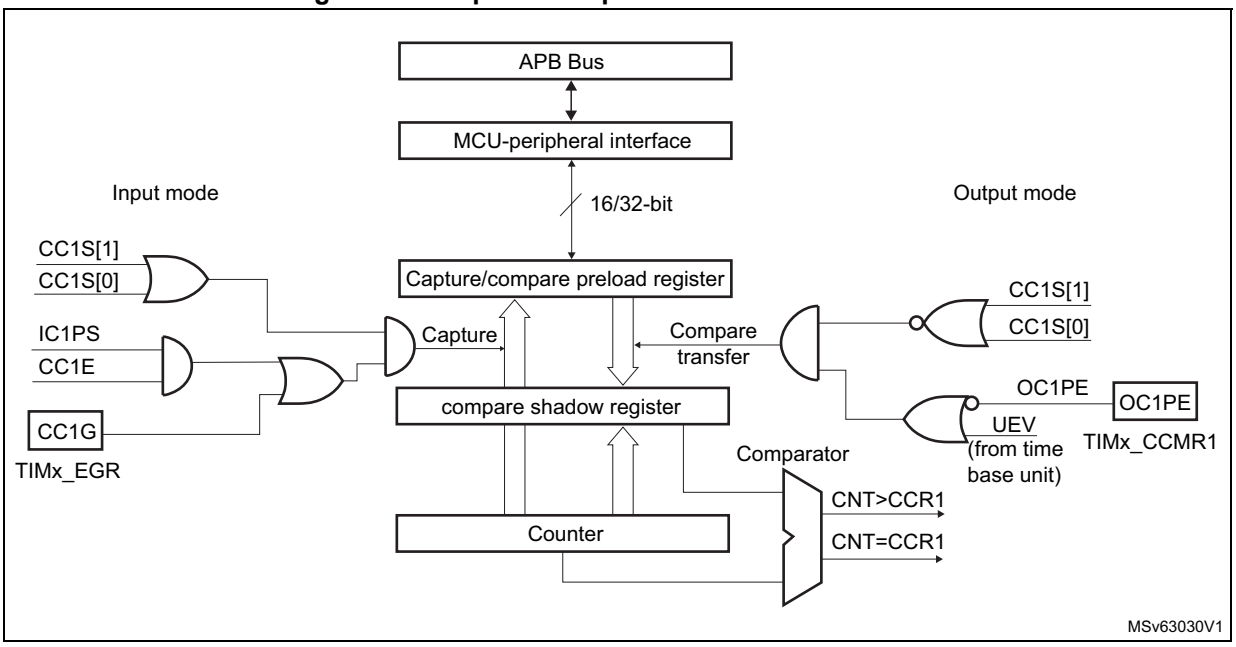

Figure 539. Output stage of capture/compare channel 1

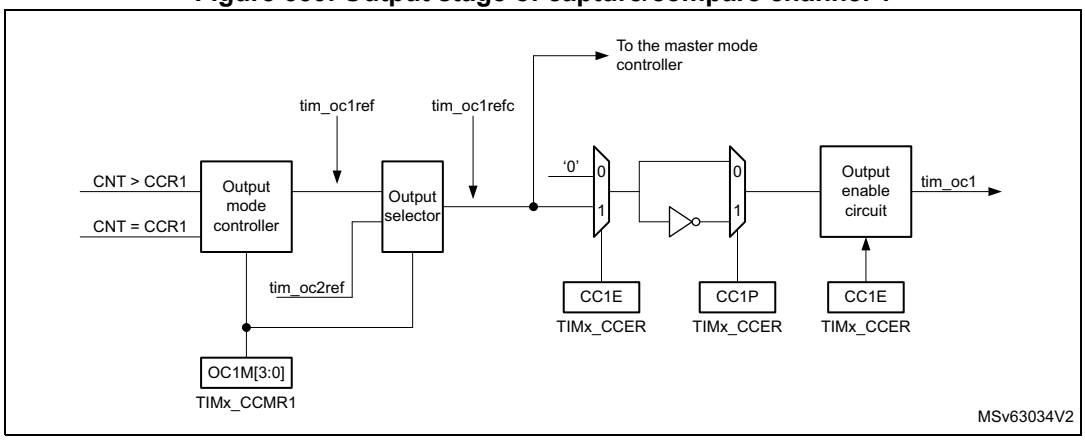


The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

41.4.7 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding tim_icx signal. When a capture occurs, the corresponding CCXIF flag (TIMx_SR register) is set and an interrupt request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be

cleared by software by writing it to ‘0’ or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when tim_ti1 input rises. To do this, use the following procedure:

1. Select the proper tim_ti1_in[15:0] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input: TIMx_CCR1 must be linked to the tim_ti1 input, so write the CC1S bits to ‘01’ in the TIMx_CCMR1 register. As soon as CC1S becomes different from ‘00’, the channel is configured in input mode and the TIMx_CCR1 register becomes read-only.
3. Program the appropriate input filter duration in relation with the signal connected to the timer (by programming the ICxF bits in the TIMx_CCMRx register if the input is one of the tim_tix inputs). Let’s imagine that, when toggling, the input signal is not stable during at must 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on tim_ti1 when 8 consecutive samples with the new level have been detected (sampled at f_{DTS} frequency). Then write IC1F bits to ‘0011’ in the TIMx_CCMR1 register.
4. Select the edge of the active transition on the tim_ti1 channel by programming CC1P and CC1NP bits to ‘00’ in the TIMx_CCER register (rising edge in this case).
5. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to ‘00’ in the TIMx_CCMR1 register).
6. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.
7. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register.

When an input capture occurs:

- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which may happen after reading the flag and before reading the data.

Note: IC interrupt requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.

41.4.8 PWM input mode (TIM12 only)

This mode allows to measure both the period and the duty cycle of a PWM signal connected to single tim_tix input:

- The TIMx_CCR1 register holds the period value (interval between two consecutive rising edges)
- The TIM_CCR2 register holds the pulsewidth (interval between two consecutive rising and falling edges

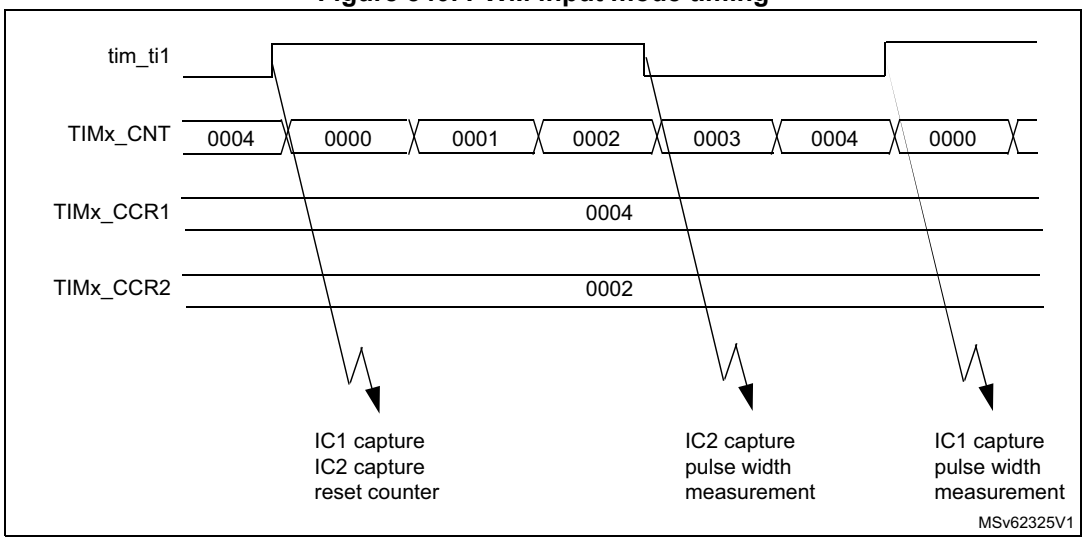
This mode is a particular case of input capture mode. The set-up procedure is similar with the following differences:

- Two tim_icx signals are mapped on the same tim_tix input.
- These 2 tim_icx signals are active on edges with opposite polarity.
- One of the two tim_tixfpy signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, one can measure the period (in TIMx_CCR1 register) and the duty cycle (in TIMx_CCR2 register) of the PWM applied on tim_ti1 using the following procedure (depending on tim_ker_ck frequency and prescaler value):

1. Select the proper tim_ti1_in[15:0] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input for TIMx_CCR1: write the CC1S bits to ‘01’ in the TIMx_CCMR1 register (tim_ti1 selected).
3. Select the active polarity for tim_ti1fp1 (used both for capture in TIMx_CCR1 and counter clear): program the CC1P and CC1NP bits to ‘00’ (active on rising edge).
4. Select the active input for TIMx_CCR2: write the CC2S bits to ‘10’ in the TIMx_CCMR1 register (tim_ti1 selected).
5. Select the active polarity for tim_ti1fp2 (used for capture in TIMx_CCR2): program the CC2P and CC2NP bits to ‘10’ (active on falling edge).
6. Select the valid trigger input: write the TS bits to ‘00101’ in the TIMx_SMCR register (tim_ti1fp1 selected).
7. Configure the slave mode controller in reset mode: write the SMS bits to ‘100’ in the TIMx_SMCR register.
8. Enable the captures: write the CC1E and CC2E bits to ‘1’ in the TIMx_CCER register.

Figure 540. PWM input mode timing



41.4.9 Forced output mode

In output mode (CCxS bits = ‘00’ in the TIMx_CCMRx register), each output compare signal (tim_ocxref and then tim_ocx) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (tim_ocxref/tim_ocx) to its active level, one just needs to write ‘0101’ in the OCxM bits in the corresponding TIMx_CCMRx register. Thus tim_ocxref is forced high (tim_ocxref is always active high) and tim_ocx get opposite value to CCxP polarity bit.

For example: CCxP=’0’ (tim_ocx active high) => tim_ocx is forced to high level.

The tim_ocxref signal can be forced low by writing the OCxM bits to ‘0100’ in the TIMx_CCMRx register.

Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt requests can be sent accordingly. This is described in the output compare mode section below.

41.4.10 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

1. Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCER register). The output pin can keep its level (OCxM=’0000’), be set active (OCxM=’0001’), be set inactive (OCxM=’0010’) or can toggle (OCxM=’0011’) on match.
2. Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
3. Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIMx_DIER register).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

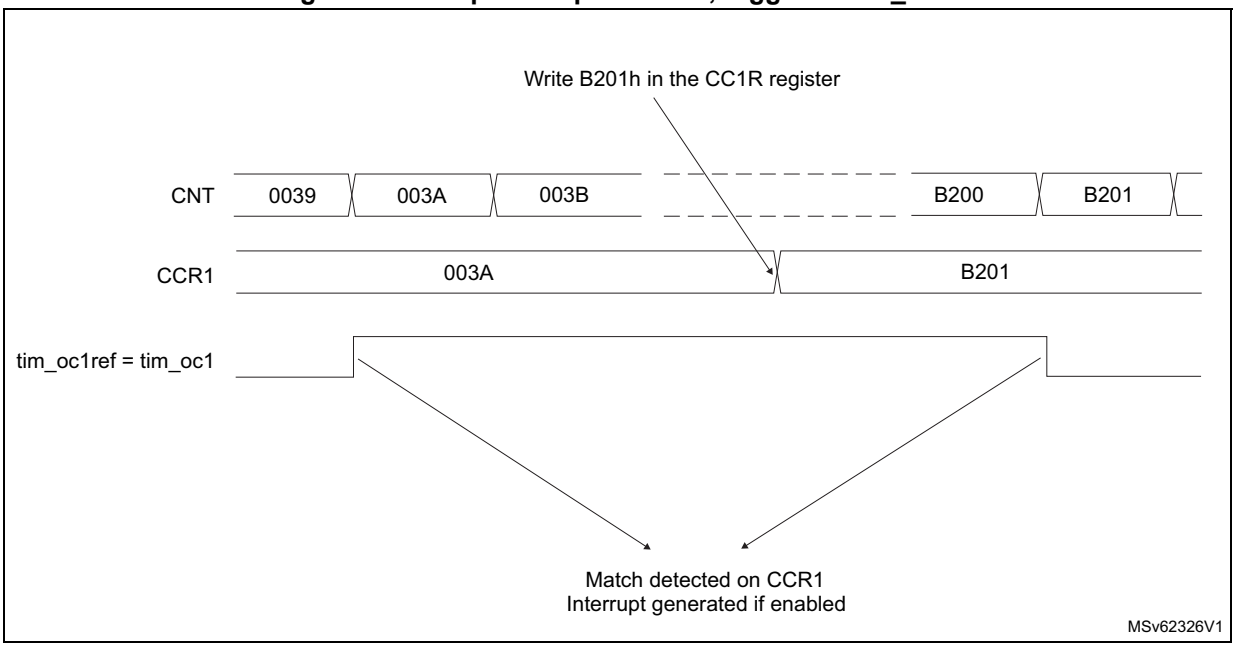
In output compare mode, the update event UEV has no effect on tim_ocxref and tim_ocx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure:

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
   - Write OCxM = ‘0011’ to toggle tim_ocx output pin when CNT matches CCRx
   - Write OCxPE = ‘0’ to disable preload register
   - Write CCxP = ‘0’ to select active high polarity
   - Write CCxE = ‘1’ to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE=’0’, else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in *Figure 541*.

Figure 541. Output compare mode, toggle on tim_oc1.



41.4.11 PWM mode

Pulse Width Modulation mode allows to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per tim_ocx output) by writing ‘0110’ (PWM mode 1) or ‘0111’ (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

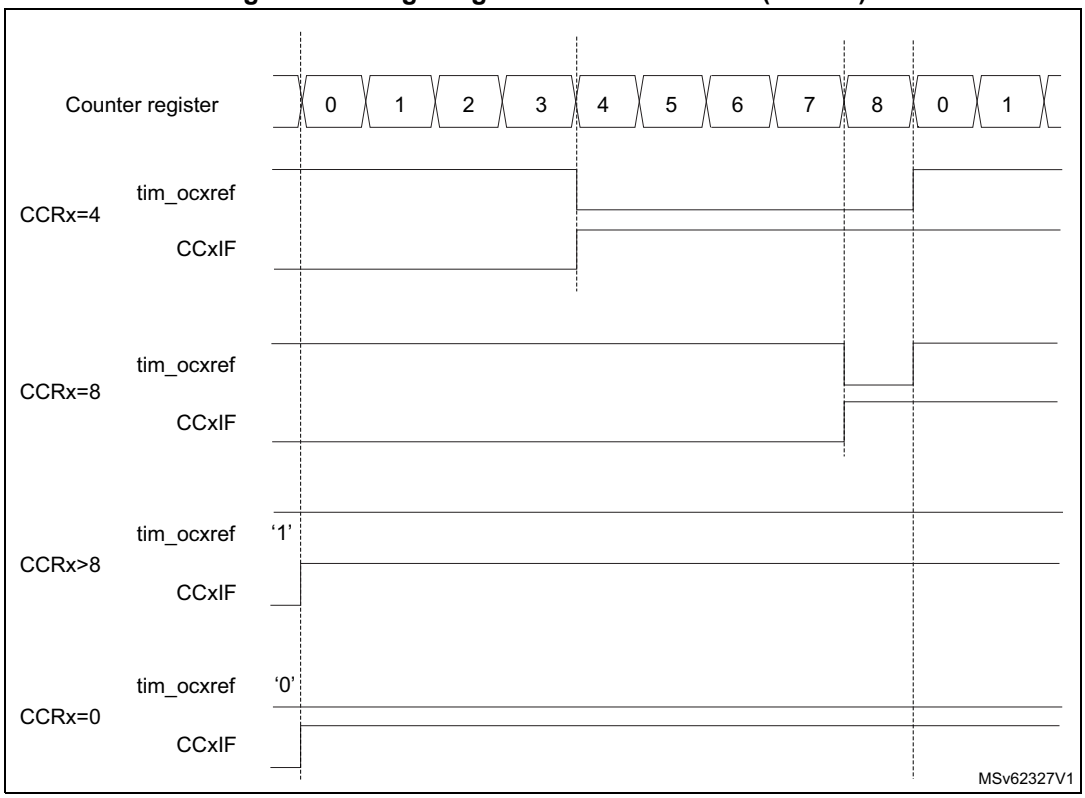
The tim_ocx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. The tim_ocx output is enabled by the CCxE bit in the TIMx_CCER register. Refer to the TIMx_CCERx register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CNT ≤ TIMx_CCRx.

The timer is able to generate PWM in edge-aligned mode only since the counter is upcounting.

In the following example, we consider PWM mode 1. The reference PWM signal tim_ocxref is high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then tim_ocxref is held at ‘1’. If the compare value is 0 then tim_ocxref is held at ‘0’. *Figure 542* shows some edge-aligned PWM waveforms in an example where TIMx_ARR=8.

Figure 542. Edge-aligned PWM waveforms (ARR=8)

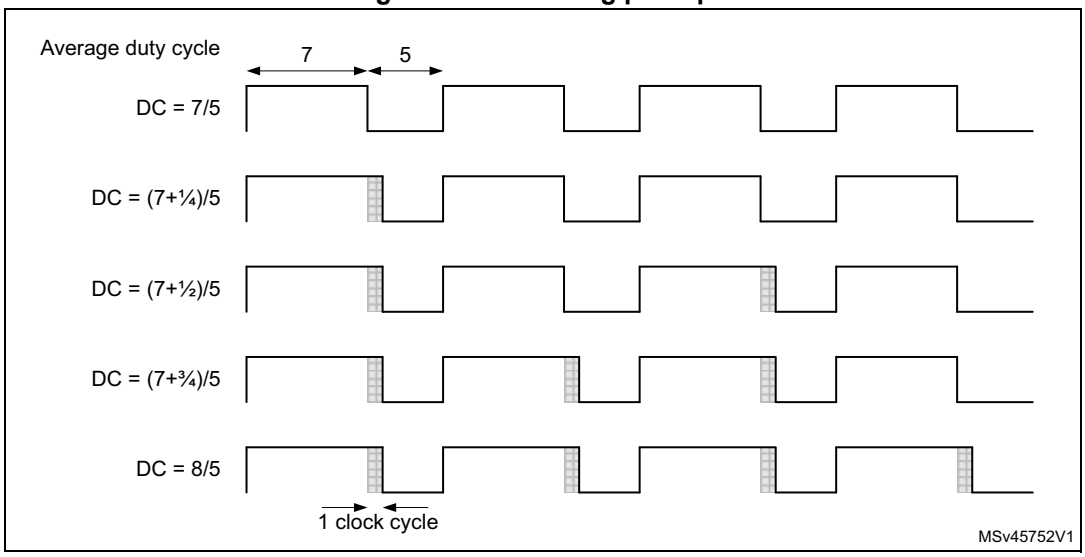


Dithering mode

The PWM mode effective resolution can be increased by enabling the dithering mode, using the DITHEN bit in the TIMx_CR1 register. This applies to both the CCR (for duty cycle resolution increase) and ARR (for PWM frequency resolution increase).

The operating principle is to have the actual CCR (or ARR) value slightly changed (adding or not one timer clock period) over 16 consecutive PWM periods, with predefined patterns. This allows a 16-fold resolution increase, considering the average duty cycle or PWM period. The *Figure 543* below presents the dithering principle applied to 4 consecutive PWM cycles.

Figure 543. Dithering principle

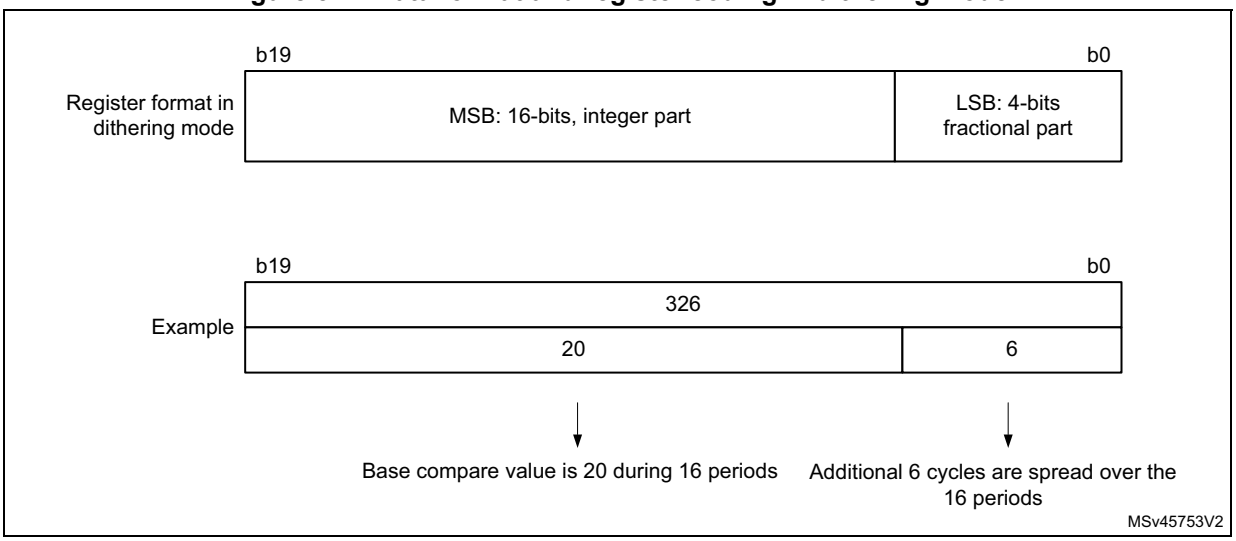


When the dithering mode is enabled, the register coding is changed as following (see *Figure 544* for example):

- the 4 LSBs are coding for the enhanced resolution part (fractional part)
- the MSBs are left-shifted to the bits 19:4 and are coding for the base value.

Note: The following sequence must be followed when resetting the DITHEN bit:
4. CEN and ARPE bits must be reset
5. The DITHEN bit must be reset
6. The CCIF flags must be cleared
7. The CEN bit can be set (eventually with ARPE = 1).

Figure 544. Data format and register coding in dithering mode



The minimum frequency is given by the following formula:

$$\text{Resolution} = \frac{F_{Tim}}{F_{pwm}} \Rightarrow F_{pwmMin} = \frac{F_{Tim}}{Max_{Resolution}}$$

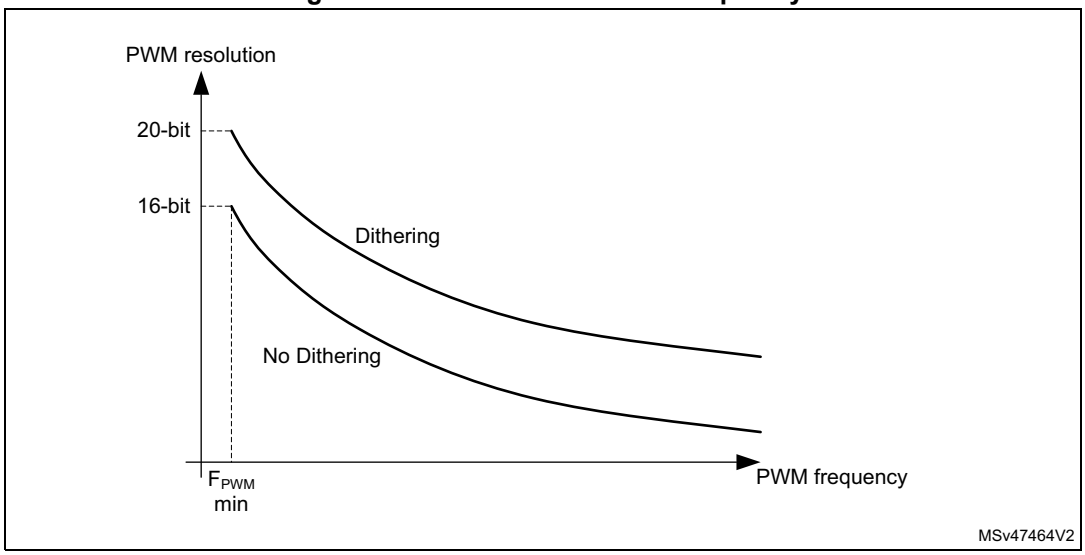
$$\text{Dithering mode disabled: } F_{pwmMin} = \frac{F_{Tim}}{65536}$$

$$\text{Dithering mode enabled: } F_{pwmMin} = \frac{F_{Tim}}{65535 + \frac{15}{16}}$$

Note: The maximum TIMx_ARR and TIMxCCRy values are limited to 0xFFFEF in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part).

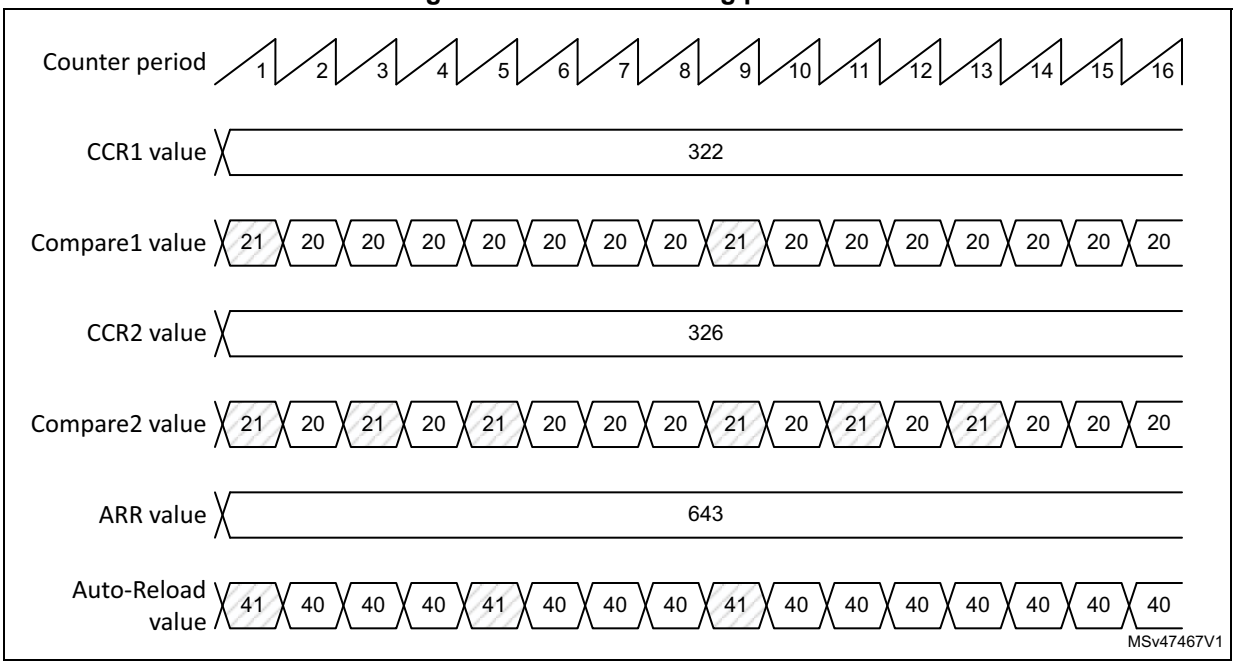
As shown on the *Figure 545* below, the dithering mode allows to increase the PWM resolution whatever the PWM frequency.

Figure 545. PWM resolution vs frequency



The duty cycle and / or period changes are spread over 16 consecutive periods, as described in the *Figure 546* below.

Figure 546. PWM dithering pattern



The auto-reload and compare values increments are spread following specific patterns described in the *Table 426* below. The dithering sequence is done to have increments distributed as evenly as possible and minimize the overall ripple.

Table 426. CCR and ARR register change dithering pattern

41.4.12 Combined PWM mode (TIM12 only)

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, tim_ocxrefc, are made of an OR or AND logical combination of two reference PWMs:

- tim_oc1refc (or tim_oc2refc) is controlled by the TIMx_CCR1 and TIMx_CCR2 registers

Combined PWM mode can be selected independently on two channels (one tim_ocx output per pair of CCR registers) by writing ‘1100’ (Combined PWM mode 1) or ‘1101’ (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

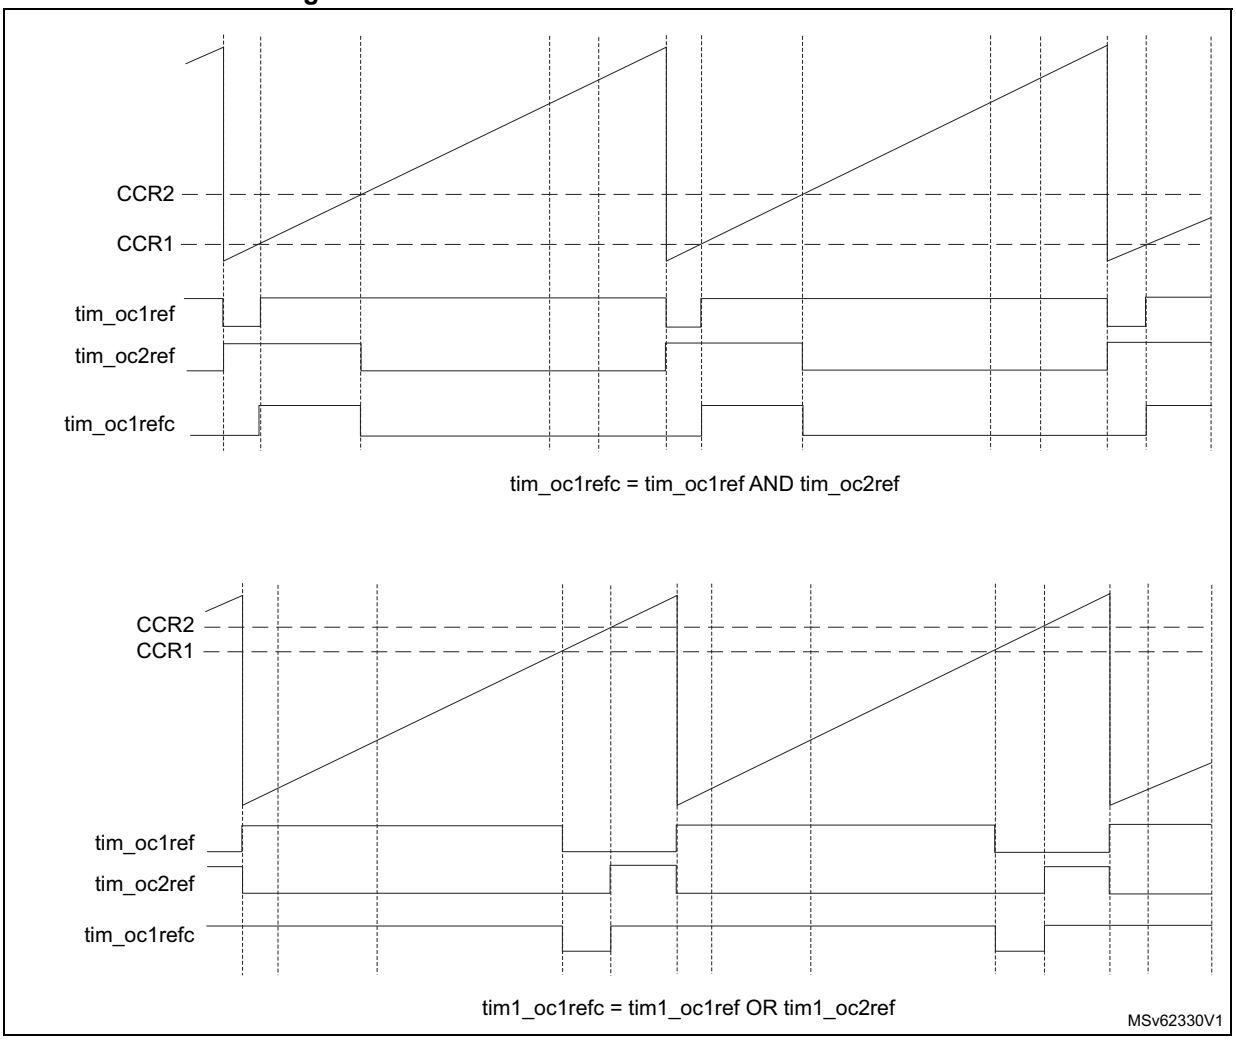
When a given channel is used as a combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

Note: The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

Figure 547 represents an example of signals that can be generated using combined PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2
- Channel 2 is configured in PWM mode 1

Figure 547. Combined PWM mode on channel 1 and 2



41.4.13 One-pulse mode

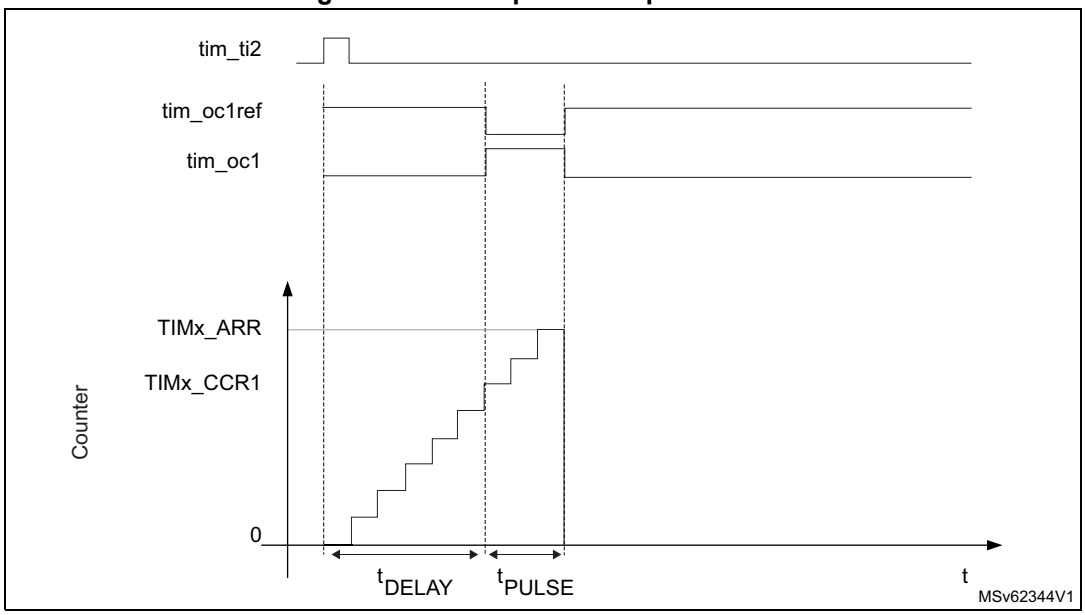
One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be as follows:

CNT < CCRx ≤ ARR (in particular, 0 < CCRx)

Figure 548. Example of one pulse mode



For example one may want to generate a positive pulse on tim_oc1 with a length of tPULSE and after a delay of tDELAY as soon as a positive edge is detected on the tim_ti2 input pin.

Use tim_ti2fp2 as trigger 1:

1. Select the proper tim_ti2_in[15:0] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Map tim_ti2fp2 to tim_ti2 by writing CC2S='01' in the TIMx_CCMR1 register.
3. tim_ti2fp2 must detect a rising edge, write CC2P='0' and CC2NP='0' in the TIMx_CCER register.
4. Configure tim_ti2fp2 as trigger for the slave mode controller (tim_trgi) by writing TS='00110' in the TIMx_SMCR register.
5. tim_ti2fp2 is used to start the counter by writing SMS to '110' in the TIMx_SMCR register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The t_{DELAY} is defined by the value written in the TIMx_CCR1 register.
- The t_{PULSE} is defined by the difference between the auto-reload value and the compare value (TIMx_ARR - TIMx_CCR1).
- Let's say one want to build a waveform with a transition from '0' to '1' when a compare match occurs and a transition from '1' to '0' when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing OC1M='0111' in the TIMx_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE='1' in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case one has to write the compare value in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on tim_ti2. CC1P is written to '0' in this example.

Since only 1 pulse (Single mode) is needed, a 1 must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over

from the auto-reload value back to 0). When OPM bit in the TIMx_CR1 register is set to '0', so the Repetitive Mode is selected.

Particular case: tim_ocx fast enable

In One-pulse mode, the edge detection on tim_tix input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay t_{DELAY} min we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then tim_ocxref (and tim_ocx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

41.4.14 Retriggerable one pulse mode (TIM12 only)

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with non-retriggerable one pulse mode described in *Section 41.4.13: One-pulse mode*:

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

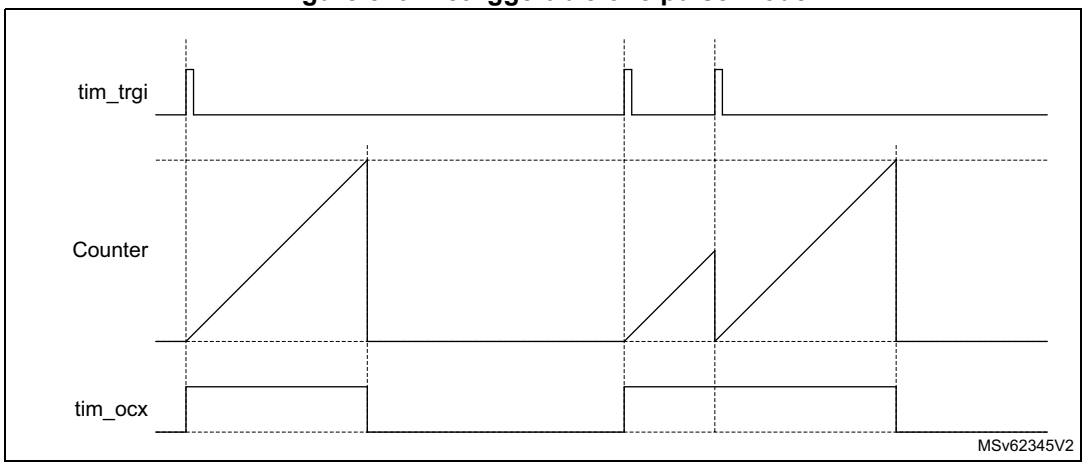
The timer must be in Slave mode, with the bits SMS[3:0] = ‘1000’ (Combined Reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to ‘1000’ or ‘1001’ for retrigerrable OPM mode 1 or 2.

If the timer is configured in up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in down-counting mode, CCRx must be above or equal to ARR.

Note: The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit are not contiguous with the 3 least significant ones.

This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.

Figure 549. Retriggerable one pulse mode



41.4.15 UIF bit remapping

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into bit 31 of the timer counter register (TIMxCNT[31]). This allows to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. In particular cases, it can ease the calculations by avoiding race conditions caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

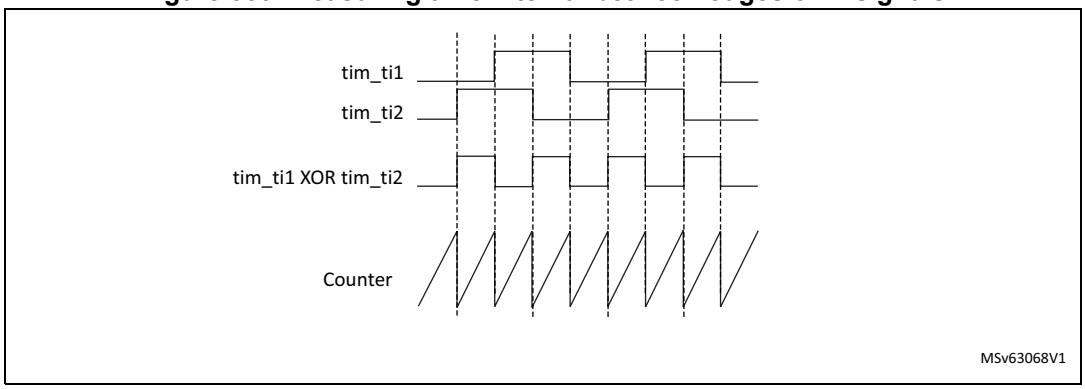
There is no latency between the assertions of the UIF and UIFCPY flags.

41.4.16 Timer input XOR function

The TI1S bit in the TIMx_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the two input pins tim_ti1 and tim_ti2.

The XOR output can be used with all the timer input functions such as trigger or input capture. It is useful for measuring the interval between the edges on two input signals, as shown in *Figure 550*.

Figure 550. Measuring time interval between edges on 2 signals



41.4.17 TIM12 external trigger synchronization

The TIM12 timer can be synchronized with an external trigger in several modes: Reset mode, Gated mode, Trigger mode, Reset + trigger and gated + reset mode.

Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on tim_ti1 input:

1. Configure the channel 1 to detect rising edges on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=’0000’). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = ‘01’ in the TIMx_CCMR1

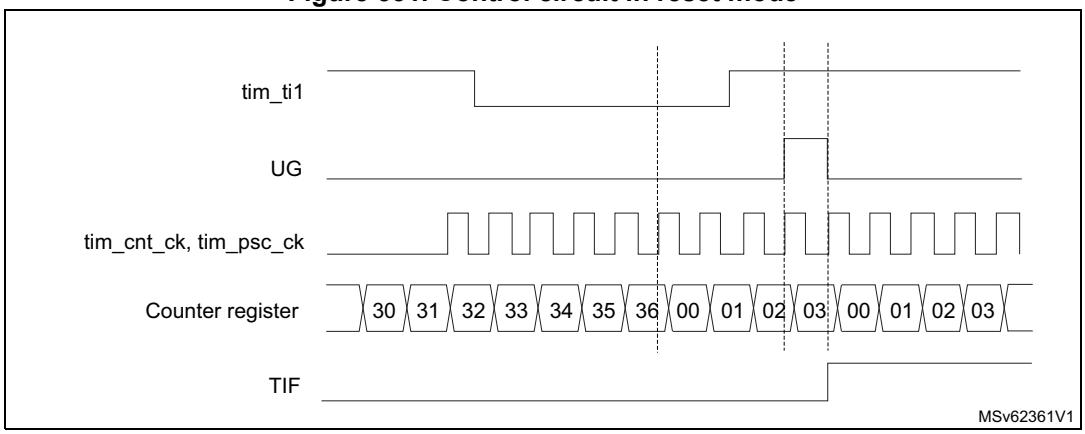
register. Program CC1P and CC1NP to ‘00’ in TIMx_CCER register to validate the polarity (and detect rising edges only).

2. Configure the timer in reset mode by writing SMS=’100’ in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=’00101’ in TIMx_SMCR register.
3. Start the counter by writing CEN=’1’ in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until tim_ti1 rising edge. When tim_ti1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request can be sent if enabled (depending on the TIE bit in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on tim_ti1 and the actual reset of the counter is due to the resynchronization circuit on tim_ti1 input.

Figure 551. Control circuit in reset mode



Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

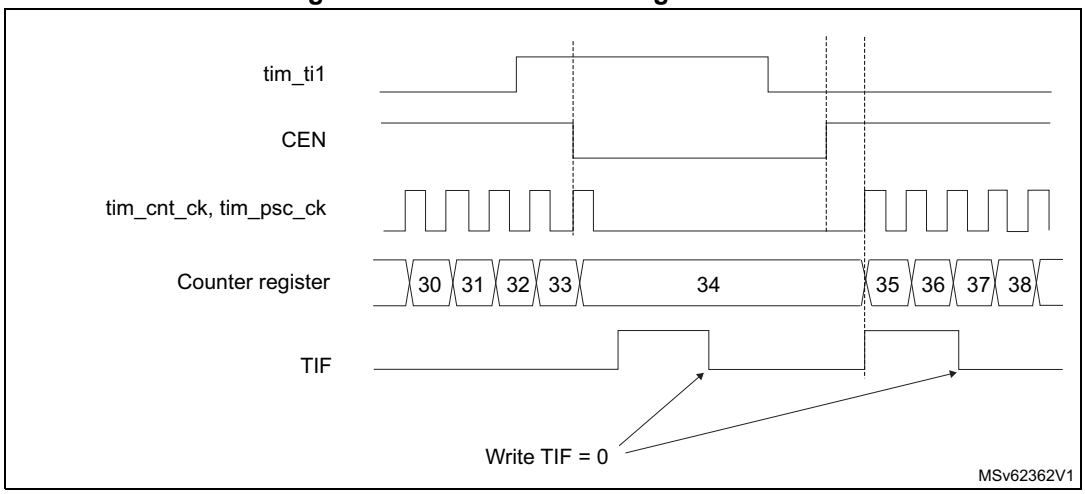
In the following example, the upcounter counts only when tim_ti1 input is low:

1. Configure the channel 1 to detect low levels on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=’0000’). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=’01’ in TIMx_CCMR1 register. Program CC1P=’1’ and CC1NP=’0’ in TIMx_CCER register to validate the polarity (and detect low level only).
2. Configure the timer in gated mode by writing SMS=’101’ in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=’00101’ in TIMx_SMCR register.
3. Enable the counter by writing CEN=’1’ in the TIMx_CR1 register (in gated mode, the counter doesn’t start if CEN=’0’, whatever is the trigger input level).

The counter starts counting on the internal clock as long as tim_ti1 is low and stops as soon as tim_ti1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on tim_ti1 and the actual stop of the counter is due to the resynchronization circuit on tim_ti1 input.

Figure 552. Control circuit in gated mode



Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

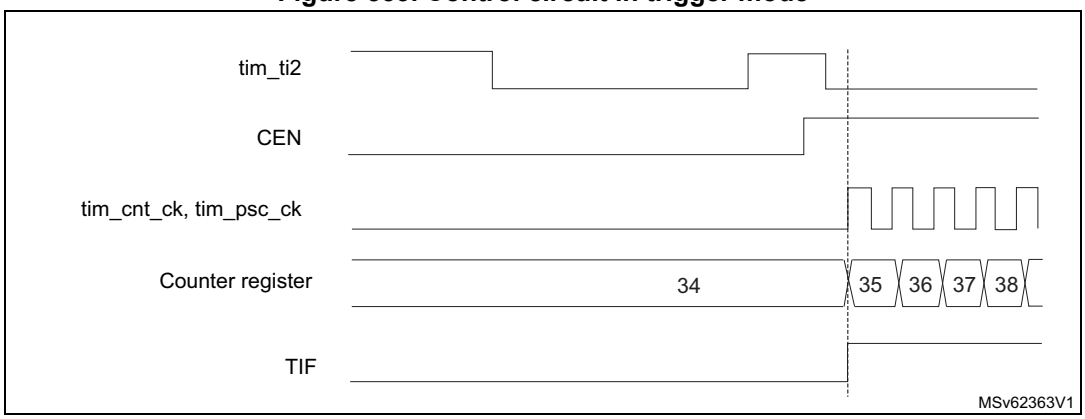
In the following example, the upcounter starts in response to a rising edge on tim_ti2 input:

1. Configure the channel 2 to detect rising edges on tim_ti2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=’0000’). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, CC2S=’01’ in TIMx_CCMR1 register. Program CC2P=’1’ and CC2NP=’0’ in TIMx_CCER register to validate the polarity (and detect low level only).
2. Configure the timer in trigger mode by writing SMS=’110’ in TIMx_SMCR register. Select tim_ti2 as the input source by writing TS=’00110’ in TIMx_SMCR register.

When a rising edge occurs on tim_ti2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on tim_ti2 and the actual start of the counter is due to the resynchronization circuit on tim_ti2 input.

Figure 553. Control circuit in trigger mode



41.4.18 Slave mode – combined reset + trigger mode

In this case, a rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for one-pulse mode.

41.4.19 Slave mode – combined reset + gated mode

The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

41.4.20 Timer synchronization (TIM12 only)

The TIMx timers are linked together internally for timer synchronization or chaining. Refer to *Section 39.4.23: Timer synchronization* for details.

Note: The clock of the slave timer must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

41.4.21 Using timer output as trigger for other timers (TIM13/TIM14 only)

The timers with one channel only do not feature a master mode. However, the OC1 output signal can be used to trigger some other timers (including timers described in other sections of this document). Check the “TIMx internal trigger connection” table of any timer on the device to identify which timers can be targeted as slave.

The OC1 signal pulse width must be programmed to be at least 2 clock cycles of the destination timer, to make sure the slave timer detects the trigger.

For instance, if the destination's timer CK_INT clock is 4 times slower than the source timer, the OC1 pulse width must be 8 clock cycles.

41.4.22 ADC triggers (TIM12 only)

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events.

Note: The clock of the slave peripherals (such as timer, ADC) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

41.4.23 Debug mode

When the microcontroller enters debug mode (Cortex-M33 core halted), the TIMx counter can either continue to work normally or stop.

The behavior in debug mode can be programmed with a dedicated configuration bit per timer in the Debug support (DBG) module.

For more details, refer to the debug section.

41.5 TIM12/TIM13/TIM14 low-power modes

Table 427. Effect of low-power modes on TIM12/TIM13/TIM14

Mode	Description
Sleep	No effect, peripheral is active. The interrupts can cause the device to exit from Sleep mode.
Stop	The timer operation is stopped and the register content is kept. No interrupt can be generated.
Standby	The timer is powered-down and must be reinitialized after exiting the Standby mode.

41.6 TIM12/TIM13/TIM14 interrupts

The TIM12/TIM13/TIM14 can generate multiple interrupts, as shown in *Table 428*.

Table 428. Interrupt requests

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit from Sleep mode	Exit from Stop and Standby mode
TIM	Update	UIF	UIE	write 0 in UIF	Yes	No
	Capture/compare 1	CC1IF	CC1IE	write 0 in CC1IF	Yes	No
TIM	Capture/compare 2(1)	CC2IF	CC2IE	write 0 in CC2IF	Yes	No
	Trigger(1)	TIF	TIE	write 0 in TIF	Yes	No

1. Available for TIM12 only.

41.7 TIM12 registers

Refer to *Section 1.2* for a list of abbreviations used in register descriptions.

The peripheral registers have to be written by half-words (16 bits) or words (32 bits). Read accesses can be done by bytes (8 bits), half-words (16 bits) or words (32 bits).

41.7.1 TIM12 control register 1 (TIM12_CR1)

Address offset: 0x000

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	DITHEN	UIFREMAP	Res.	CKD[1:0]		ARPE	Res.	Res.	Res.	OPM	URS	UDIS	CEN
			rw	rw		rw	rw	rw				rw	rw	rw	rw

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **DITHEN**: Dithering enable
0: Dithering disabled
1: Dithering enabled
Note: The DITHEN bit can only be modified when CEN bit is reset.

Bit 11 **UIFREMAP**: UIF status bit remapping
0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division
This bit-field indicates the division ratio between the timer clock (tim_ker_ck) frequency and sampling clock used by the digital filters (tim_tix),
00: $t_{DTS} = t_{tim\_ker\_ck}$
01: $t_{DTS} = 2 \times t_{tim\_ker\_ck}$
10: $t_{DTS} = 4 \times t_{tim\_ker\_ck}$
11: Reserved

Bit 7 **ARPE**: Auto-reload preload enable
0: TIMx_ARR register is not buffered.
1: TIMx_ARR register is buffered.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One-pulse mode
0: Counter is not stopped on the update event
1: Counter stops counting on the next update event (clearing the CEN bit).

Bit 2 **URS**: Update request source

This bit is set and cleared by software to select the UEV event sources.

0: Any of the following events generates an update interrupt if enabled. These events can be:

– Counter overflow

– Setting the UG bit

– Update generation through the slave mode controller

1: Only counter overflow generates an update interrupt if enabled.

Bit 1 **UDIS**: Update disable

This bit is set and cleared by software to enable/disable update event (UEV) generation.

0: UEV enabled. An UEV is generated by one of the following events:

– Counter overflow

– Setting the UG bit

Buffered registers are then loaded with their preload values.

1: UEV disabled. No UEV is generated, shadow registers keep their value (ARR, PSC, CCRx). The counter and the prescaler are reinitialized if the UG bit is set.

Bit 0 **CEN**: Counter enable

0: Counter disabled

1: Counter enabled

CEN is cleared automatically in one-pulse mode, when an update event occurs.

Note: External clock and gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.

41.7.2 TIM12 control register 2 (TIM12_CR2)

Address offset: 0x004

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TI1S	MMS[2:0]			Res.	Res.	Res.	Res.
								rw	rw	rw	rw				

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **TI1S**: tim_ti1 selection

0: The tim_ti1_in[15:0] multiplexer output is connected to tim_ti1 input

1: The tim_ti1_in[15:0] and tim_ti2_in[15:0] multiplexers output are connected to the tim_ti1 input (XOR combination)

Bits 6:4 **MMS[2:0]**: Master mode selection

These bits allow to select the information to be sent in master mode to slave timers for synchronization (tim_trgo). The combination is as follows:

000: Reset - the UG bit from the TIMx_EGR register is used as trigger output (tim_trgo). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on tim_trgo is delayed compared to the actual reset.

001: Enable - the Counter Enable signal CNT_EN is used as trigger output (tim_trgo). It is useful to start several timers at the same time or to control a window in which a slave timer is enable. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on tim_trgo, except if the master/slave mode is selected (see the MSM bit description in TIMx_SMCR register).

010: Update - The update event is selected as trigger output (tim_trgo). For instance a master timer can then be used as a prescaler for a slave timer.

011: Compare Pulse - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred (tim_trgo).

100: Compare - tim_oc1refc signal is used as trigger output (tim_trgo).

101: Compare - tim_oc2refc signal is used as trigger output (tim_trgo).

Bits 3:0 Reserved, must be kept at reset value.

41.7.3 TIM12 slave mode control register (TIM12_SMCR)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TS[4:3]		Res.	Res.	Res.	SMS[3]
										rw	rw				rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MSM	TS[2:0]			Res.	SMS[2:0]		
								rw	rw	rw	rw		rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 19:17 Reserved, must be kept at reset value.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **MSM:** Master/Slave mode

0: No action

1: The effect of an event on the trigger input (tim_trgi) is delayed to allow a perfect synchronization between the current timer and its slaves (through tim_trgo). It is useful in order to synchronize several timers on a single external event.

Bits 21, 20, 6, 5, 4 **TS[4:0]:** Trigger selection

This TS[4:0] bitfield selects the trigger input to be used to synchronize the counter.

00000: Internal Trigger 0 (tim_itr0)
00001: Internal Trigger 1 (tim_itr1)
00010: Internal Trigger 2 (tim_itr2)
00011: Internal Trigger 3 (tim_itr3)
00100: tim_ti1 Edge Detector (tim_ti1f_ed)
00101: Filtered Timer Input 1 (tim_ti1fp1)
00110: Filtered Timer Input 2 (tim_ti2fp2)
01000: Internal Trigger 4 (tim_itr4)
01001: Internal Trigger 5 (tim_itr5)
01010: Internal Trigger 6 (tim_itr6)
01011: Internal Trigger 7 (tim_itr7)
01100: Internal Trigger 8 (tim_itr8)
01101: Internal Trigger 9 (tim_itr9)
01110: Internal Trigger 10 (tim_itr10)
01111: Internal Trigger 10 (tim_itr11)
10000: Internal Trigger 10 (tim_itr12)
10001: Internal Trigger 10 (tim_itr13)
10010: Internal Trigger 10 (tim_itr14)
10011: Internal Trigger 10 (tim_itr15)
Others: Reserved

See *Table 425: TIMx internal trigger connection* for more details on the meaning of tim_itrx for each timer.

Note: These bits must be changed only when they are not used (for example when SMS='000') to avoid wrong edge detections at the transition.

Bit 3 Reserved, must be kept at reset value.

Bits 16, 2, 1, 0 **SMS[3:0]:** Slave mode selection

When external signals are selected the active edge of the trigger signal (tim_trgi) is linked to the polarity selected on the external input (see Input Control register and Control Register description.

0000: Slave mode disabled - if CEN = '1' then the prescaler is clocked directly by the internal clock.

0001: Reserved

0010: Reserved

0011: Reserved

0100: Reset Mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter and generates an update of the registers.

0101: Gated Mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

0110: Trigger Mode - The counter starts at a rising edge of the trigger tim_trgi (but it is not reset). Only the start of the counter is controlled.

0111: External Clock Mode 1 - Rising edges of the selected trigger (tim_trgi) clock the counter.

1000: Combined reset + trigger mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers and starts the counter.

1001: Combined gated + reset mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

Other codes: reserved.

Note: The gated mode (including gated + reset mode) must not be used if tim_ti1f_ed is selected as the trigger input (TS='00100'). Indeed, tim_ti1f_ed outputs 1 pulse for each transition on tim_ti1f, whereas the gated mode checks the level of the trigger signal.

Note: The clock of the slave peripherals (timer, ADC,...) receiving the tim_trgo signals must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

41.7.4 TIM12 Interrupt enable register (TIM12_DIER)

Address offset: 0x00C

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TIE	Res.	Res.	Res.	CC2IE	CC1IE	UIE
									rw				rw	rw	rw

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **TIE**: Trigger interrupt enable

0: Trigger interrupt disabled.

1: Trigger interrupt enabled.

Bits 5:3 Reserved, must be kept at reset value.

Bit 2 **CC2IE**: Capture/Compare 2 interrupt enable
0: CC2 interrupt disabled.
1: CC2 interrupt enabled.

Bit 1 **CC1IE**: Capture/Compare 1 interrupt enable
0: CC1 interrupt disabled.
1: CC1 interrupt enabled.

Bit 0 **UIE**: Update interrupt enable
0: Update interrupt disabled.
1: Update interrupt enabled.

41.7.5 TIM12 status register (TIM12_SR)

Address offset: 0x010

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	CC2OF	CC1OF	Res.	Res.	TIF	Res.	Res.	Res.	CC2IF	CC1IF	UIF
					rc_w0	rc_w0			rc_w0				rc_w0	rc_w0	rc_w0

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **CC2OF**: Capture/compare 2 overcapture flag
refer to CC1OF description

Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag
This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to ‘0’.
0: No overcapture has been detected.
1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **TIF**: Trigger interrupt flag
This flag is set by hardware on the TRG trigger event (active edge detected on tim_trgi input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.
0: No trigger event occurred.
1: Trigger interrupt pending.

Bits 5:3 Reserved, must be kept at reset value.

Bit 2 **CC2IF**: Capture/Compare 2 interrupt flag
refer to CC1IF description

Bit 1 **CC1IF**: Capture/compare 1 interrupt flag
This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx_CCR1 register (input capture mode only).
0: No compare match / No input capture occurred
1: A compare match or an input capture occurred.
If channel CC1 is configured as output: this flag is set when he content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in down-counting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx_CR1 register for the full description.
If channel CC1 is configured as input: this bit is set when counter value has been captured in TIMx_CCR1 register (an edge has been detected on tim_ic1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCER).

Bit 0 **UIF**: Update interrupt flag
This bit is set by hardware on an update event. It is cleared by software.
0: No update occurred.
1: Update interrupt pending. This bit is set by hardware when the registers are updated:
– At overflow and if UDIS='0' in the TIMx_CR1 register.
– When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS='0' and UDIS='0' in the TIMx_CR1 register.
– When CNT is reinitialized by a trigger event (refer to*Section 41.7.3: TIM12 slave mode control register (TIM12_SMCR)*), if URS='0' and UDIS='0' in the TIMx_CR1 register.

41.7.6 TIM12 event generation register (TIM12_EGR)

Address offset: 0x014

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TG	Res.	Res.	Res.	CC2G	CC1G	UG
									w				w	w	w

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **TG**: Trigger generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: The TIF flag is set in the TIMx_SR register. Related interrupt can occur if enabled

Bits 5:3 Reserved, must be kept at reset value.

Bit 2 **CC2G**: Capture/compare 2 generation
refer to CC1G description

Bit 1 **CC1G**: Capture/compare 1 generation
This bit is set by software to generate an event, it is automatically cleared by hardware.
0: No action
1: A capture/compare event is generated on channel 1:
If channel CC1 is configured as output:
the CC1IF flag is set, the corresponding interrupt is sent if enabled.
If channel CC1 is configured as input:
The current counter value is captured in the TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation
This bit can be set by software, it is automatically cleared by hardware.
0: No action
1: Re-initializes the counter and generates an update of the registers. The prescaler counter is also cleared and the prescaler ratio is not affected. The counter is cleared.

41.7.7 TIM12 capture/compare mode register 1 (TIM12_CCMR1)

Address offset: 0x018

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits in this register have different functions in input and output modes.

Input capture mode:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IC2F[3:0]				IC2PSC[1:0]		CC2S[1:0]		IC1F[3:0]				IC1PSC[1:0]		CC1S[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **IC2F[3:0]**: Input capture 2 filter

Bits 11:10 **IC2PSC[1:0]**: Input capture 2 prescaler

Bits 9:8 **CC2S[1:0]**: Capture/compare 2 selection
This bitfield defines the direction of the channel (input/output) as well as the used input.
00: CC2 channel is configured as output
01: CC2 channel is configured as input, IC2 is mapped on tim_ti2
10: CC2 channel is configured as input, IC2 is mapped on tim_ti1
11: CC2 channel is configured as input, IC2 is mapped on tim_trc. This mode works only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)
Note: The CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCER).

Bits 7:4 **IC1F[3:0]**: Input capture 1 filter

This bitfield defines the frequency used to sample the tim_ti1 input and the length of the digital filter applied to tim_ti1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at f_{DTS}
0001: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=2
0010: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=4
0011: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=8
0100: $f_{SAMPLING}=f_{DTS}/2$, N=6
0101: $f_{SAMPLING}=f_{DTS}/2$, N=8
0110: $f_{SAMPLING}=f_{DTS}/4$, N=6
0111: $f_{SAMPLING}=f_{DTS}/4$, N=8
1000: $f_{SAMPLING}=f_{DTS}/8$, N=6
1001: $f_{SAMPLING}=f_{DTS}/8$, N=8
1010: $f_{SAMPLING}=f_{DTS}/16$, N=5
1011: $f_{SAMPLING}=f_{DTS}/16$, N=6
1100: $f_{SAMPLING}=f_{DTS}/16$, N=8
1101: $f_{SAMPLING}=f_{DTS}/32$, N=5
1110: $f_{SAMPLING}=f_{DTS}/32$, N=6
1111: $f_{SAMPLING}=f_{DTS}/32$, N=8

Bits 3:2 **IC1PSC[1:0]**: Input capture 1 prescaler

This bitfield defines the ratio of the prescaler acting on the CC1 input (tim_ic1).
The prescaler is reset as soon as CC1E='0' (TIMx_CCER register).
00: no prescaler, capture is done each time an edge is detected on the capture input
01: capture is done once every 2 events
10: capture is done once every 4 events
11: capture is done once every 8 events

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.
00: CC1 channel is configured as output
01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1
10: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2
11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

Note: The CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).

41.7.8 TIM12 capture/compare mode register 1 [alternate] (TIM12_CCMR1)

Address offset: 0x018

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits in this register have different functions in input and output modes.

Output compare mode:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	OC2M [3]	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OC1M [3]
							rw								rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	OC2M[2:0]			OC2PE	OC2FE	CC2S[1:0]		Res.	OC1M[2:0]			OC1PE	OC1FE	CC1S[1:0]	
	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bits 23:17 Reserved, must be kept at reset value.

Bit 15 Reserved, must be kept at reset value.

Bits 24, 14:12 **OC2M[3:0]**: Output compare 2 mode
Refer to OC1M[3:0] for bit description.

Bit 11 **OC2PE**: Output compare 2 preload enable

Bit 10 **OC2FE**: Output compare 2 fast enable

Bits 9:8 **CC2S[1:0]**: Capture/Compare 2 selection
This bitfield defines the direction of the channel (input/output) as well as the used input.
00: CC2 channel is configured as output
01: CC2 channel is configured as input, IC2 is mapped on tim_ti2
10: CC2 channel is configured as input, IC2 is mapped on tim_ti1
11: CC2 channel is configured as input, IC2 is mapped on tim_trc. This mode works only if an internal trigger input is selected through the TS bit (TIMx_SMCR register
Note: The CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCER).

Bit 7 Reserved, must be kept at reset value.

Bits 16, 6:4 **OC1M[3:0]**: Output compare 1 mode (refer to bit 16 for OC1M[3])

These bits define the behavior of the output reference signal tim_oc1ref from which tim_oc1 is derived. tim_oc1ref is active high whereas the active level of tim_oc1 depends on the CC1P.

0000: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the ouput keeps the state (active or inactive) it had before entering the frozen state.

0001: Set channel 1 to active level on match. The tim_oc1ref signal is forced high when the TIMx_CNT counter matches the capture/compare register 1 (TIMx_CCR1).

0010: Set channel 1 to inactive level on match. The tim_oc1ref signal is forced low when the TIMx_CNT counter matches the capture/compare register 1 (TIMx_CCR1).

0011: Toggle - tim_oc1ref toggles when TIMx_CNT=TIMx_CCR1

0100: Force inactive level - tim_oc1ref is forced low

0101: Force active level - tim_oc1ref is forced high

0110: PWM mode 1 - channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else it is inactive

0111: PWM mode 2 - channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else it is active

1000: Retrigerrable OPM mode 1 - The channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1001: Retrigerrable OPM mode 2 - The channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update.

1010: Reserved,

1011: Reserved,

1100: Combined PWM mode 1 - tim_oc1ref has the same behavior as in PWM mode 1. tim_oc1refc is the logical OR between tim_oc1ref and tim_oc2ref.

1101: Combined PWM mode 2 - tim_oc1ref has the same behavior as in PWM mode 2. tim_oc1refc is the logical AND between tim_oc1ref and tim_oc2ref.

1110: Reserved,

1111: Reserved

Note: In PWM mode, the OCREF level changes when the result of the comparison changes, when the output compare mode switches from “frozen” mode to “PWM” mode and when the output compare mode switches from “force active/inactive” mode to “PWM” mode.

Bit 3 **OC1PE**: Output compare 1 preload enable

0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken into account immediately

1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded into the active register at each update event

Bit 2 **OC1FE**: Output compare 1 fast enable

This bit is used to accelerate the effect of an event on the trigger in input on the CC output.

0: CC1 behaves normally depending on the counter and CCR1 values even when the trigger is ON. The minimum delay to activate the CC1 output when an edge occurs on the trigger input is 5 clock cycles

1: An active edge on the trigger input acts like a compare match on the CC1 output. Then, OC is set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OC1FE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

00:CC1 channel is configured as output

01:CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1

10:CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2

11:CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode works only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)

Note: The CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).

41.7.9 TIM12 capture/compare enable register (TIM12_CCER)

Address offset: 0x020

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CC2NP	Res.	CC2P	CC2E	CC1NP	Res.	CC1P	CC1E
								rw		rw	rw	rw		rw	rw

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **CC2NP**: Capture/Compare 2 output Polarity

Refer to CC1NP description

Bit 6 Reserved, must be kept at reset value.

Bit 5 **CC2P**: Capture/Compare 2 output Polarity

Refer to CC1P description

Bit 4 **CC2E**: Capture/Compare 2 output enable

Refer to CC1E description

Bit 3 **CC1NP**: Capture/Compare 1 complementary output Polarity

CC1 channel configured as output: CC1NP must be kept cleared

CC1 channel configured as input: CC1NP is used in conjunction with CC1P to define tim_ti1fp1/tim_ti2fp1 polarity (refer to CC1P description).

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CC1P**: Capture/Compare 1 output Polarity.

0: tim_oc1 active high (output mode) / Edge sensitivity selection (input mode, see below)

1: tim_oc1 active low (output mode) / Edge sensitivity selection (input mode, see below)

When CC1 channel is configured as input, both CC1NP/CC1P bits select the active polarity of tim_ti1fp1 and tim_ti2fp1 for trigger or capture operations.

CC1NP=0, CC1P=0: non-inverted/rising edge. The circuit is sensitive to tim_tixfp1 rising edge (capture or trigger operations in reset, external clock or trigger mode), tim_tixfp1 is not inverted (trigger operation in gated mode).

CC1NP=0, CC1P=1: inverted/falling edge. The circuit is sensitive to tim_tixfp1 falling edge (capture or trigger operations in reset, external clock or trigger mode), tim_tixfp1 is inverted (trigger operation in gated mode).

CC1NP=1, CC1P=1: non-inverted/both edges/ The circuit is sensitive to both tim_tixfp1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), tim_tixfp1 is not inverted (trigger operation in gated mode).

CC1NP=1, CC1P=0: This configuration is reserved, it must not be used.

Bit 0 **CC1E**: Capture/Compare 1 output enable.

0: Capture mode disabled / tim_oc1 is not active

1: Capture mode enabled / tim_oc1 signal is output on the corresponding output pin

Table 429. Output control bit for standard tim_ocx channels

CCxE bit	tim_ocx output state
0	Output disabled (not driven by the timer: Hi-Z)
1	Output enabled (tim_ocx = tim_ocxref + Polarity)

Note: The states of the external I/O pins connected to the standard tim_ocx *channels depend on the state of the* tim_ocx *channel and on the GPIO registers.*

41.7.10 TIM12 counter (TIM12_CNT)

Address offset: 0x024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
UIF CPY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CNT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **UIFCPY**: UIF Copy
This bit is a read-only copy of the UIF bit in the TIMx_ISR register.

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:0 **CNT[15:0]**: Counter value
Non-dithering mode (DITHEN = 0)
The register holds the counter value.
Dithering mode (DITHEN = 1)
The register only holds the non-dithered part in CNT[15:0]. The fractional part is not available.

41.7.11 TIM12 prescaler (TIM12_PSC)

Address offset: 0x028

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PSC[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0 **PSC[15:0]**: Prescaler value
The counter clock frequency tim_cnt_ck is equal to $f_{tim\_psc\_ck}$ / (PSC[15:0] + 1).
PSC contains the value to be loaded into the active prescaler register at each update event. (including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in “reset mode”).

41.7.12 TIM12 auto-reload register (TIM12_ARR)

Address offset: 0x02C

Reset value: 0x0000 FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ARR[19:16]			
												rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ARR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **ARR[19:0]**: Auto-reload value
ARR is the value to be loaded in the actual auto-reload register.
Refer to the *Section 41.4.3: Time-base unit on page 1712* for more details about ARR update and behavior.
The counter is blocked while the auto-reload value is null.
Non-dithering mode (DITHEN = 0)
The register holds the auto-reload value in ARR[15:0]. The ARR[19:16] bits are reset.
Dithering mode (DITHEN = 1)
The register holds the integer part in ARR[19:4]. The ARR[3:0] bitfield contains the dithered part.

41.7.13 TIM12 capture/compare register 1 (TIM12_CCR1)

Address offset: 0x034

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CCR1[19:16]			
												rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCR1[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **CCR1[19:0]**: Capture/compare 1 value

If channel CC1 is configured as output:

CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc1 output.

Non-dithering mode (DITHEN = 0)

The register holds the compare value in CCR1[15:0]. The CCR1[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the integer part in CCR1[19:4]. The CCR1[3:0] bitfield contains the dithered part.

If channel CC1 is configured as input:

CR1 is the counter value transferred by the last input capture 1 event (tim_ic1). The TIMx_CCR1 register is read-only and cannot be programmed.

Non-dithering mode (DITHEN = 0)

The register holds the capture value in CCR1[15:0]. The CCR1[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the capture in CCR1[19:4]. The CCR1[3:0] bits are reset.

41.7.14 TIM12 capture/compare register 2 (TIM12_CCR2)

Address offset: 0x038

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CCR2[19:16]			
												rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCR2[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **CCR2[19:0]**: Capture/compare 2 value

If channel CC2 is configured as output:

CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signalled on tim_oc2 output.

Non-dithering mode (DITHEN = 0)

The register holds the compare value in CCR2[15:0]. The CCR2[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the integer part in CCR2[19:4]. The CCR2[3:0] bitfield contains the dithered part.

If channel CC2 is configured as input:

CCR2 is the counter value transferred by the last input capture 1 event (tim_ic2). The TIMx_CCR2 register is read-only and cannot be programmed.

Non-dithering mode (DITHEN = 0)

The register holds the capture value in CCR2[15:0]. The CCR2[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the capture in CCR2[19:4]. The CCR2[3:0] bits are reset.

41.7.15 TIM12 timer input selection register (TIM12_TISEL)

Address offset: 0x05C

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	TI2SEL[3:0]				Res.	Res.	Res.	Res.	TI1SEL[3:0]			
				rw	rw	rw	rw					rw	rw	rw	rw

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **TI2SEL[3:0]**: selects tim_ti2_in[15:0] input

0000: TIMx_CH2 input (tim_ti2_in0)

0001: tim_ti2_in1

...

0100: tim_ti2_in15

Refer to *Table 424: Interconnect to the tim_ti2 input multiplexer* for interconnects list.

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **TI1SEL[3:0]**: selects tim_ti1_in[15:0] input

0000: TIMx_CH1 input (tim_ti1_in0)

0001: tim_ti1_in1

...

1111: tim_ti1_in15

Refer to *Table 423: Interconnect to the tim_ti1 input multiplexer* for interconnects list.

41.7.16 TIM12 register map

TIM12 registers are mapped as 16-bit addressable registers as described below:

Table 430. TIM12 register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3 on page 111* for the register boundary addresses.

41.8 TIM13/TIM14 registers

The peripheral registers have to be written by half-words (16 bits) or words (32 bits). Read accesses can be done by bytes (8 bits), half-words (16 bits) or words (32 bits).

41.8.1 TIMx control register 1 (TIMx_CR1)(x = 13, 14)

Address offset: 0x000

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	DITHEN	UIFREMAP	Res.	CKD[1:0]		ARPE	Res.	Res.	Res.	OPM	URS	UDIS	CEN
			rw	rw		rw	rw	rw				rw	rw	rw	rw

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **DITHEN**: Dithering enable
0: Dithering disabled
1: Dithering enabled
Note: The DITHEN bit can only be modified when CEN bit is reset.

Bit 11 **UIFREMAP**: UIF status bit remapping
0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division
This bit-field indicates the division ratio between the timer clock (tim_ker_ck) frequency and sampling clock used by the digital filters (tim_tix),
00: $t_{DTS} = t_{tim\_ker\_ck}$
01: $t_{DTS} = 2 \times t_{tim\_ker\_ck}$
10: $t_{DTS} = 4 \times t_{tim\_ker\_ck}$
11: Reserved

Bit 7 **ARPE**: Auto-reload preload enable
0: TIMx_ARR register is not buffered
1: TIMx_ARR register is buffered

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One-pulse mode
0: Counter is not stopped on the update event
1: Counter stops counting on the next update event (clearing the CEN bit).

Bit 2 **URS**: Update request source

This bit is set and cleared by software to select the update interrupt (UEV) sources.

0: Any of the following events generate an UEV if enabled:

– Counter overflow

– Setting the UG bit

1: Only counter overflow generates an UEV if enabled.

Bit 1 **UDIS**: Update disable

This bit is set and cleared by software to enable/disable update interrupt (UEV) event generation.

0: UEV enabled. An UEV is generated by one of the following events:

– Counter overflow

– Setting the UG bit.

Buffered registers are then loaded with their preload values.

1: UEV disabled. No UEV is generated, shadow registers keep their value (ARR, PSC, CCRx). The counter and the prescaler are reinitialized if the UG bit is set.

Bit 0 **CEN**: Counter enable

0: Counter disabled

1: Counter enabled

Note: External clock and gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.

41.8.2 TIMx Interrupt enable register (TIMx_DIER)(x = 13, 14)

Address offset: 0x00C

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CC1IE	UIE
														rw	rw

Bits 15:2 Reserved, must be kept at reset value.

Bit 1 **CC1IE**: Capture/Compare 1 interrupt enable

0: CC1 interrupt disabled

1: CC1 interrupt enabled

Bit 0 **UIE**: Update interrupt enable

0: Update interrupt disabled

1: Update interrupt enabled

41.8.3 TIMx status register (TIMx_SR)(x = 13, 14)

Address offset: 0x010

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	CC1OF	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CC1IF	UIF
						rc_w0								rc_w0	rc_w0

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag

This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to ‘0’.

0: No overcapture has been detected.

1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set

Bits 8:2 Reserved, must be kept at reset value.

Bit 1 **CC1IF**: Capture/compare 1 interrupt flag

This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx_CCR1 register (input capture mode only).

0: No compare match / No input capture occurred

1: A compare match or an input capture occurred.

If channel CC1 is configured as output: this flag is set when he content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in down-counting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx_CR1 register for the full description.

If channel CC1 is configured as input: this bit is set when counter value has been captured in TIMx_CCR1 register (an edge has been detected on tim_ic1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCER).

Bit 0 **UIF**: Update interrupt flag

This bit is set by hardware on an update event. It is cleared by software.

0: No update occurred.

1: Update interrupt pending. This bit is set by hardware when the registers are updated:

– At overflow and if UDIS=’0’ in the TIMx_CR1 register.

– When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS=’0’ and UDIS=’0’ in the TIMx_CR1 register.

41.8.4 TIMx event generation register (TIMx_EGR)(x = 13, 14)

Address offset: 0x014

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CC1G	UG
														w	w

Bits 15:2 Reserved, must be kept at reset value.

Bit 1 **CC1G**: Capture/compare 1 generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: A capture/compare event is generated on channel 1:
If channel CC1 is configured as output:
CC1IF flag is set, Corresponding interrupt or is sent if enabled.
If channel CC1 is configured as input:
The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation

This bit can be set by software, it is automatically cleared by hardware.
0: No action
1: Re-initialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared.

41.8.5 TIMx capture/compare mode register 1 (TIMx_CCMR1)(x = 13, 14)

Address offset: 0x018

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

Input capture mode:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IC1F[3:0]				IC1PSC[1:0]		CC1S[1:0]	
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **IC1F[3:0]**: Input capture 1 filter

This bit-field defines the frequency used to sample tim_ti1 input and the length of the digital filter applied to tim_ti1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at f_{DTS}
0001: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=2
0010: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=4
0011: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=8
0100: $f_{SAMPLING}=f_{DTS}/2$, N=6
0101: $f_{SAMPLING}=f_{DTS}/2$, N=8
0110: $f_{SAMPLING}=f_{DTS}/4$, N=6
0111: $f_{SAMPLING}=f_{DTS}/4$, N=8
1000: $f_{SAMPLING}=f_{DTS}/8$, N=6
1001: $f_{SAMPLING}=f_{DTS}/8$, N=8
1010: $f_{SAMPLING}=f_{DTS}/16$, N=5
1011: $f_{SAMPLING}=f_{DTS}/16$, N=6
1100: $f_{SAMPLING}=f_{DTS}/16$, N=8
1101: $f_{SAMPLING}=f_{DTS}/32$, N=5
1110: $f_{SAMPLING}=f_{DTS}/32$, N=6
1111: $f_{SAMPLING}=f_{DTS}/32$, N=8

Bits 3:2 **IC1PSC[1:0]**: Input capture 1 prescaler

This bit-field defines the ratio of the prescaler acting on CC1 input (tim_ic1).
The prescaler is reset as soon as CC1E='0' (TIMx_CCER register).
00: no prescaler, capture is done each time an edge is detected on the capture input
01: capture is done once every 2 events
10: capture is done once every 4 events
11: capture is done once every 8 events

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.
00: CC1 channel is configured as output
01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1
10: Reserved
11: Reserved

Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).

41.8.6 TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1)(x = 13, 14)

Address offset: 0x018

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

Output compare mode:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OC1M [3]
															rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OC1M[2:0]			OC1PE	OC1FE	CC1S[1:0]	
									rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bits 15:7 Reserved, must be kept at reset value.

Bits 16, 6:4 **OC1M[3:0]**: Output compare 1 mode (refer to bit 16 for OC1M[3])

These bits define the behavior of the output reference signal tim_oc1ref from which tim_oc1 is derived. tim_oc1ref is active high whereas tim_oc1 active level depends on CC1P bit.

0000: Frozen. The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the output keeps the state (active or inactive) it had before entering the frozen state.

0001: Set channel 1 to active level on match. tim_oc1ref signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0010: Set channel 1 to inactive level on match. tim_oc1ref signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0011: Toggle - tim_oc1ref toggles when TIMx_CNT = TIMx_CCR1.

0100: Force inactive level - tim_oc1ref is forced low.

0101: Force active level - tim_oc1ref is forced high.

0110: PWM mode 1 - Channel 1 is active as long as TIMx_CNT < TIMx_CCR1 else inactive.

0111: PWM mode 2 - Channel 1 is inactive as long as TIMx_CNT < TIMx_CCR1 else active

Others: Reserved

Note: In PWM mode, the OCREF level changes when the result of the comparison changes, when the output compare mode switches from “frozen” mode to “PWM” mode and when the output compare mode switches from “force active/inactive” mode to “PWM” mode.

Bit 3 **OC1PE**: Output compare 1 preload enable

0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken in account immediately.

1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded in the active register at each update event.

Bit 2 **OC1FE**: Output compare 1 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIMx_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.

0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.

1: An active edge on the trigger input acts like a compare match on CC1 output. OC is then set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OC1FE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output.

01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1.

10: Reserved.

11: Reserved.

Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).

41.8.7 TIMx capture/compare enable register (TIMx_CCER)(x = 13, 14)

Address offset: 0x020

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CC1NP	Res.	CC1P	CC1E
												rw		rw	rw

Bits 15:4 Reserved, must be kept at reset value.

Bit 3 **CC1NP**: Capture/Compare 1 complementary output Polarity.

CC1 channel configured as output: CC1NP must be kept cleared.

CC1 channel configured as input: CC1NP bit is used in conjunction with CC1P to define tim_ti1fp1 polarity (refer to CC1P description).

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CC1P**: Capture/Compare 1 output Polarity.

0: tim_oc1 active high (output mode) / Edge sensitivity selection (input mode, see below)

1: tim_oc1 active low (output mode) / Edge sensitivity selection (input mode, see below)

When CC1 channel is configured as input, both CC1NP/CC1P bits select the active polarity of tim_ti1fp1 for capture operations.

CC1NP=0, CC1P=0: non-inverted/rising edge. The circuit is sensitive to tim_ti1fp1 rising edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode).

CC1NP=0, CC1P=1: inverted/falling edge. The circuit is sensitive to tim_ti1fp1 falling edge (capture or trigger operations in reset, external clock or trigger mode), tim_ti1fp1 is inverted (trigger operation in gated mode).

CC1NP=1, CC1P=1: non-inverted/both edges/ The circuit is sensitive to both tim_ti1fp1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), tim_ti1fp1 not inverted (trigger operation in gated mode).

CC1NP=1, CC1P=0:This configuration is reserved, it must not be used.

Bit 0 **CC1E**: Capture/Compare 1 output enable.

0: Capture mode disabled / tim_oc1 is not active

1: Capture mode enabled / tim_oc1 signal is output on the corresponding output pin

Table 431. Output control bit for standard tim_ocx channels

CCxE bit	tim_ocx output state
0	Output Disabled (tim_ocx='0')
1	tim_ocx=tim_ocxref + Polarity

Note: The state of the external I/O pins connected to the standard tim_ocx channels depends on the tim_ocx channel state and the GPIO registers.

41.8.8 TIMx counter (TIMx_CNT)(x = 13, 14)

Address offset: 0x024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
UIF CPY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CNT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **UIFCPY**: UIF Copy

This bit is a read-only copy of the UIF bit in the TIMx_ISR register.

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:0 **CNT[15:0]**: Counter value

Non-dithering mode (DITHEN = 0)

The register holds the counter value.

Dithering mode (DITHEN = 1)

The register only holds the non-dithered part in CNT[15:0]. The fractional part is not available.

41.8.9 TIMx prescaler (TIMx_PSC)(x = 13, 14)

Address offset: 0x028

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PSC[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0 **PSC[15:0]**: Prescaler value

The counter clock frequency tim_cnt_ck is equal to $f_{tim\_psc\_ck}$ / (PSC[15:0] + 1).

PSC contains the value to be loaded in the active prescaler register at each update event.

(including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in “reset mode”).

41.8.10 TIMx auto-reload register (TIMx_ARR)(x = 13, 14)

Address offset: 0x02C

Reset value: 0x0000 FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ARR[19:16]			
												rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ARR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **ARR[19:0]**: Auto-reload value

ARR is the value to be loaded in the actual auto-reload register.

Refer to the *Section 41.4.3: Time-base unit on page 1712* for more details about ARR update and behavior.

The counter is blocked while the auto-reload value is null.

Non-dithering mode (DITHEN = 0)

The register holds the auto-reload value in ARR[15:0]. The ARR[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the integer part in ARR[19:4]. The ARR[3:0] bitfield contains the dithered part.

41.8.11 TIMx capture/compare register 1 (TIMx_CCR1)(x = 13, 14)

Address offset: 0x034

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CCR1[19:16]			
												rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCR1[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **CCR1[19:0]**: Capture/compare 1 value

If channel CC1 is configured as output:

CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc1 output.

Non-dithering mode (DITHEN = 0)

The register holds the compare value in CCR1[15:0]. The CCR1[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the integer part in CCR1[19:4]. The CCR1[3:0] bitfield contains the dithered part.

If channel CC1 is configured as input:

CR1 is the counter value transferred by the last input capture 1 event (tim_ic1). The TIMx_CCR1 register is read-only and cannot be programmed.

Non-dithering mode (DITHEN = 0)

The register holds the capture value in CCR1[15:0]. The CCR1[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the capture in CCR1[19:4]. The CCR1[3:0] bits are reset.

41.8.12 TIMx timer input selection register (TIMx_TISEL)(x = 13, 14)

Address offset: 0x05C

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TI1SEL[3:0]			
												rw	rw	rw	rw

Bits 15:4 Reserved, must be kept at reset value.

Bits 3:0 **TI1SEL[3:0]**: selects tim_ti1_in[15:0] input
0000: TIMx_CH1 input (tim_ti1_in0)
0001: tim_ti1_in1
...
1111: tim_ti1_in15
Refer to *Table 423: Interconnect to the tim_ti1 input multiplexer* for interconnects list.

41.8.13 TIM13/TIM14 register map

TIMx registers are mapped as 16-bit addressable registers as described in the tables below:

Table 432. TIM13/TIM14 register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

42 General purpose timers (TIM15/TIM16/TIM17)

42.1 TIM15/TIM16/TIM17 introduction

The TIM15/TIM16/TIM17 timers consist of a 16-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM, complementary PWM with dead-time insertion).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The TIM15/TIM16/TIM17 timers are completely independent, and do not share any resources. TIM15 can be synchronized as described in *Section 42.4.26: Timer synchronization (TIM15 only)*.

42.2 TIM15 main features

TIM15 includes the following features:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535
- Up to 2 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (edge mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time (for channel 1 only)
- Synchronization circuit to control the timer with external signals and to interconnect several timers together
- Repetition counter to update the timer registers only after a given number of cycles of the counter
- Break input to put the timer’s output signals in the reset state or a known state
- Interrupt/DMA generation on the following events:
  - Update: counter overflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
  - Break input (interrupt request)

42.3 TIM16/TIM17 main features

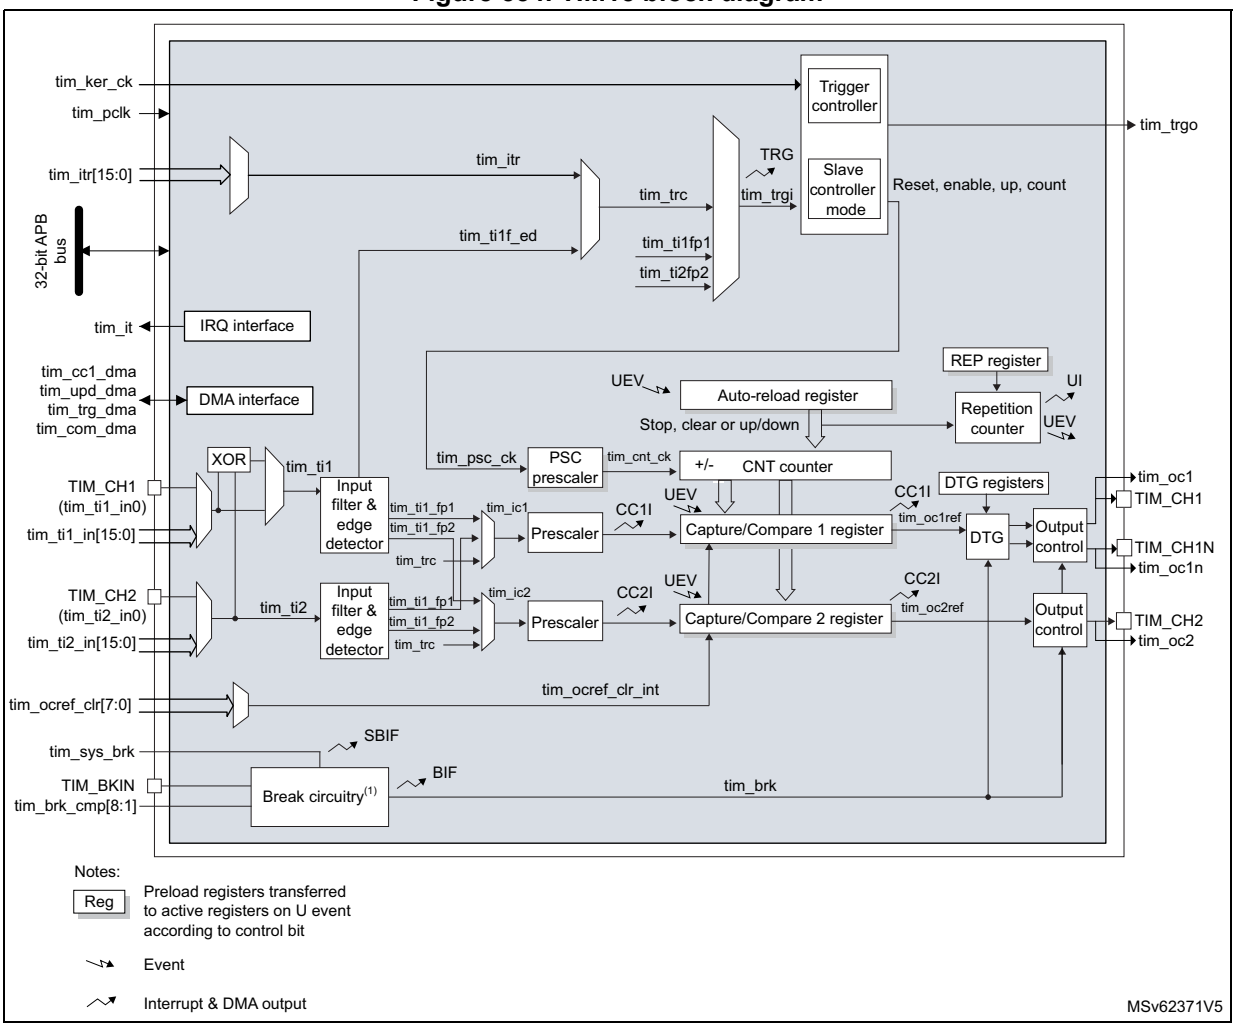
The TIM16/TIM17 timers include the following features:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535
- One channel for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time
- Repetition counter to update the timer registers only after a given number of cycles of the counter
- Break input to put the timer’s output signals in the reset state or a known state
- Interrupt/DMA generation on the following events:
  - Update: counter overflow
  - Input capture
  - Output compare
  - Break input

42.4 TIM15/TIM16/TIM17 functional description

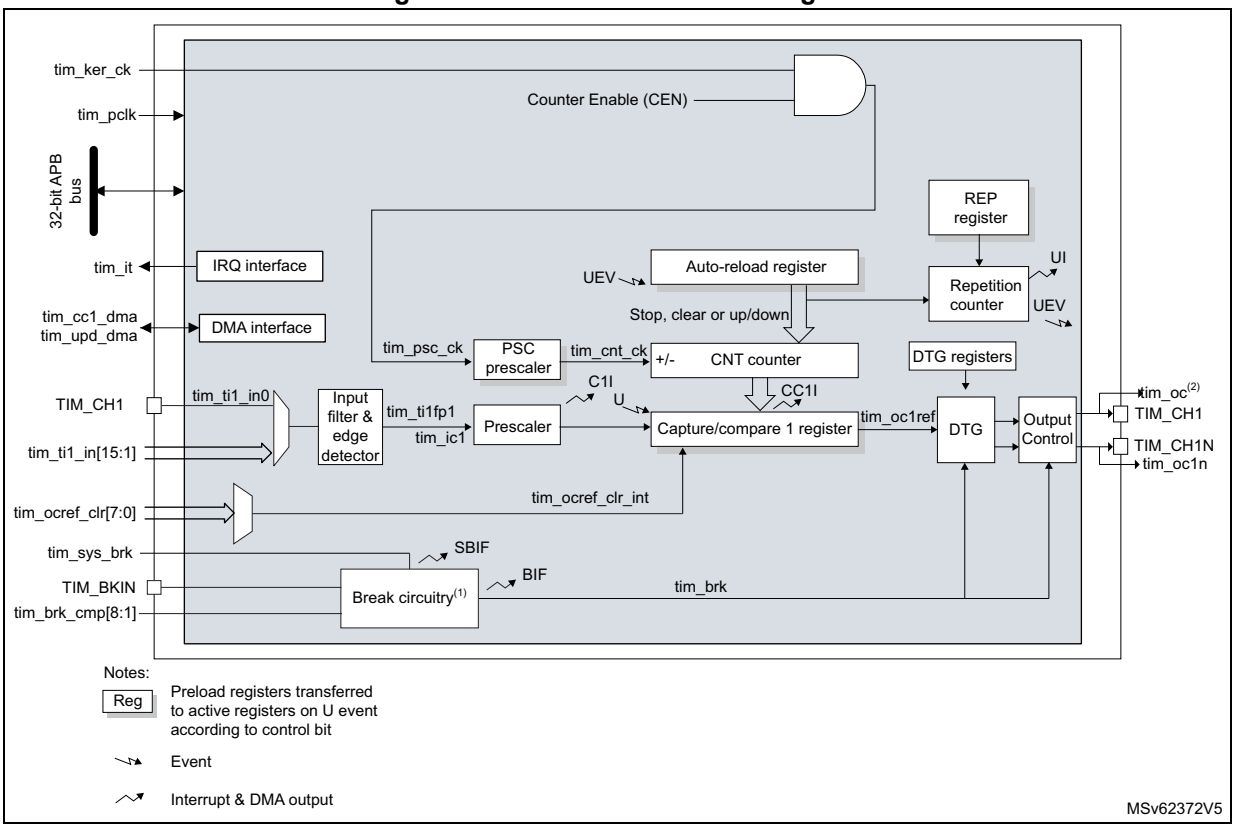
42.4.1 Block diagram

Figure 554. TIM15 block diagram



1. Refer to *Section 42.4.15: Using the break function* for details.

Figure 555. TIM16/TIM17 block diagram



1. Refer to *Section 42.4.15: Using the break function* for details.
2. This signal can be used as trigger for some slave timer (see internal trigger connection table in next section). See *Section 42.4.27: Using timer output as trigger for other timers (TIM16/TIM17 only)* for details.

42.4.2 TIM15/TIM16/TIM17 pins and internal signals

Table 433 and *Table 434* in this section summarize the TIM inputs and outputs.

Table 433. TIM input/output pins

Pin name	Signal type	Description
TIM_CH1 TIM_CH2(1)	Input/Output	Timer multi-purpose channels. Each channel be used for capture, compare, or PWM. TIM_CH1 and TIM_CH2 can also be used as external clock (below 1/4 of the tim_ker_ck clock) and external trigger inputs.
TIM_CH1N	Output	Timer complementary outputs, derived from TIM_CH1 output with the possibility to have deadtime insertion.
TIM_BKIN	Input / Output	Break input. This input can also be configured in bidirectional mode.

1. Available for TIM15 only.

Table 434. TIM internal input/output signals

Internal signal name	Signal type	Description
tim_ti1_in[15:0] tim_ti2_in[15:0](1)	Input	Internal timer inputs bus. These inputs can be used for capture or as external clock (below 1/4 of the tim_ker_ck clock).
tim_itr[15:0](1)	Input	Internal trigger input bus. These inputs can be used for the slave mode controller or as a input clock (below 1/4 of the tim_ker_ck clock).
tim_trgo(1)	Output	Internal trigger output. This trigger can trigger other on-chip peripherals.
tim_ocref_clr[7:0]	Input	Timer tim_ocref_clr input bus. These inputs can be used to clear the tim_ocxref signals, typically for hardware cycle-by-cycle pulsewidth control.
tim_brk_cmp[8:1]	Input	Break input for internal signals
tim_sys_brk[n:0]	Input	System break input. This input gathers the MCU's system level errors.
tim_pclk	Input	Timer APB clock
tim_ker_ck	Input	Timer kernel clock. This clock must be synchronous with tim_pclk (derived from the same source). The clock ratio tim_ker_ck/tim_pclk must be an integer:1, 2, 3,..., 16 (maximum value)
tim_it	Output	Global Timer interrupt, gathering capture/compare, update, break trigger and commutation requests
tim_cc1_dma	Output	Timer capture / compare 1 dma request
tim_upd_dma	Output	Timer update dma request
tim_trg_dma	Output	Timer trigger dma request
tim_com_dma	Output	Timer commutation dma request

1. Available for TIM15 only.

Table 435 and *Table 436* list the sources connected to the tim_ti[2:1] input multiplexers.

Table 435. Interconnect to the tim_ti1 input multiplexer

CSS	Clock Security System	None (always enabled)

42.4.3 Time-base unit

The main block of the programmable advanced-control timer is a 16-bit upcounter with its related auto-reload register. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Auto-reload register (TIMx_ARR)
- Repetition counter register (TIMx_RCR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detailed for each configuration.

The counter is clocked by the prescaler output tim_cnt_ck, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the counter starts counting 1 clock cycle after setting the CEN bit in the TIMx_CR1 register.

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

Figure 556 and *Figure 557* give some examples of the counter behavior when the prescaler ratio is changed on the fly:

Figure 556. Counter timing diagram with prescaler division change from 1 to 2

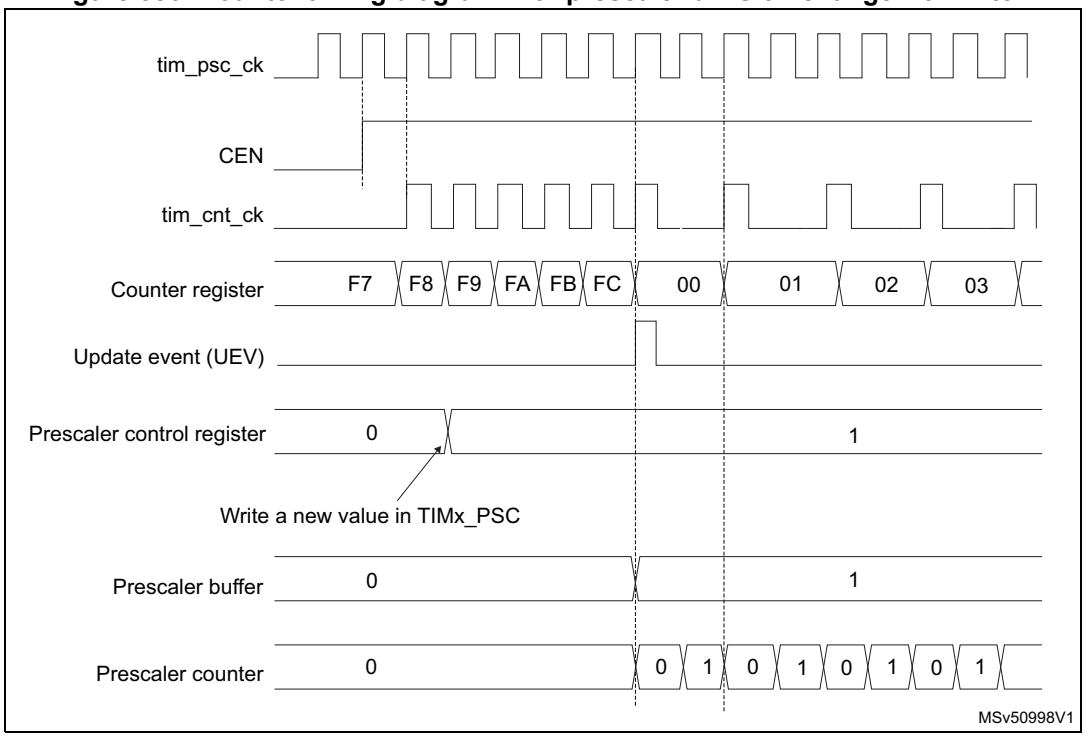

Figure 557. Counter timing diagram with prescaler division change from 1 to 4

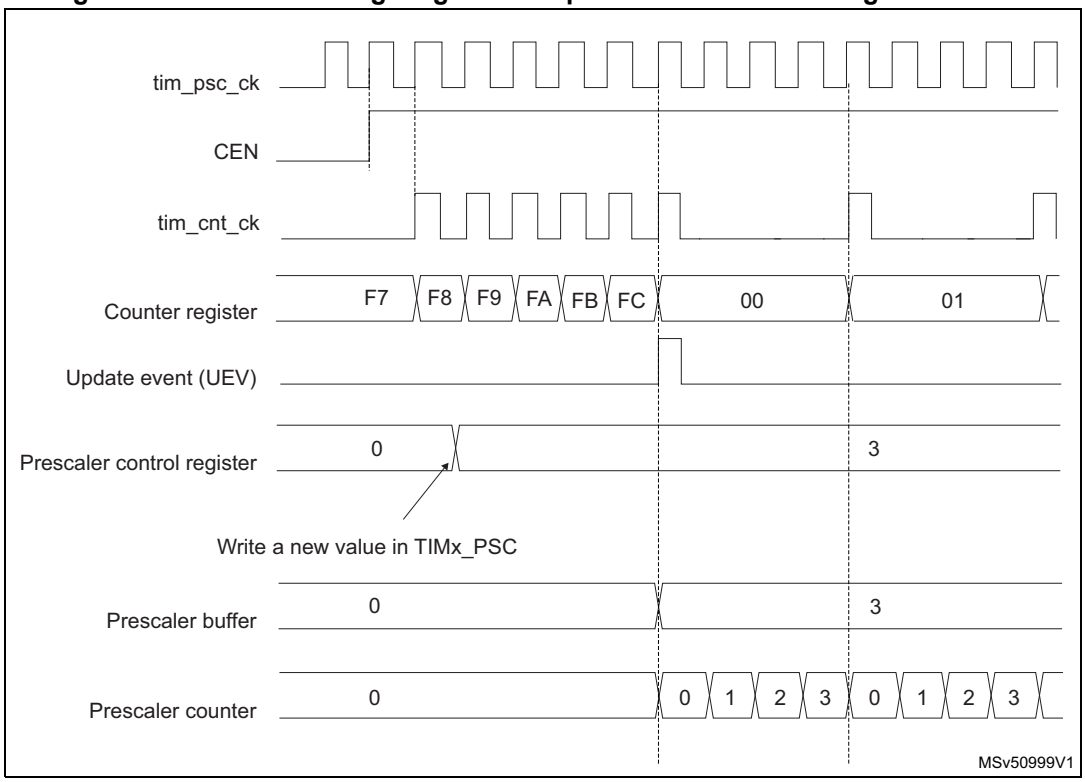

42.4.4 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

If the repetition counter is used, the update event (UEV) is generated after upcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR). Else the update event is generated at each counter overflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register,
- The auto-reload shadow register is updated with the preload value (TIMx_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

Figure 558. Counter timing diagram, internal clock divided by 1

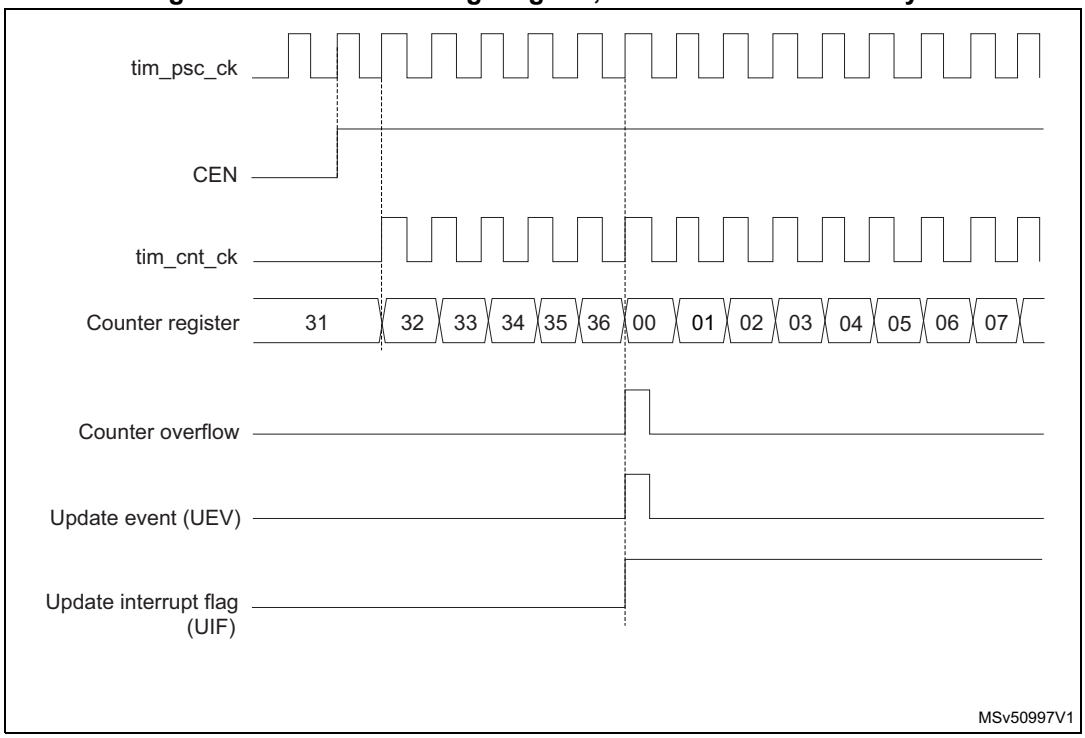

Figure 559. Counter timing diagram, internal clock divided by 2

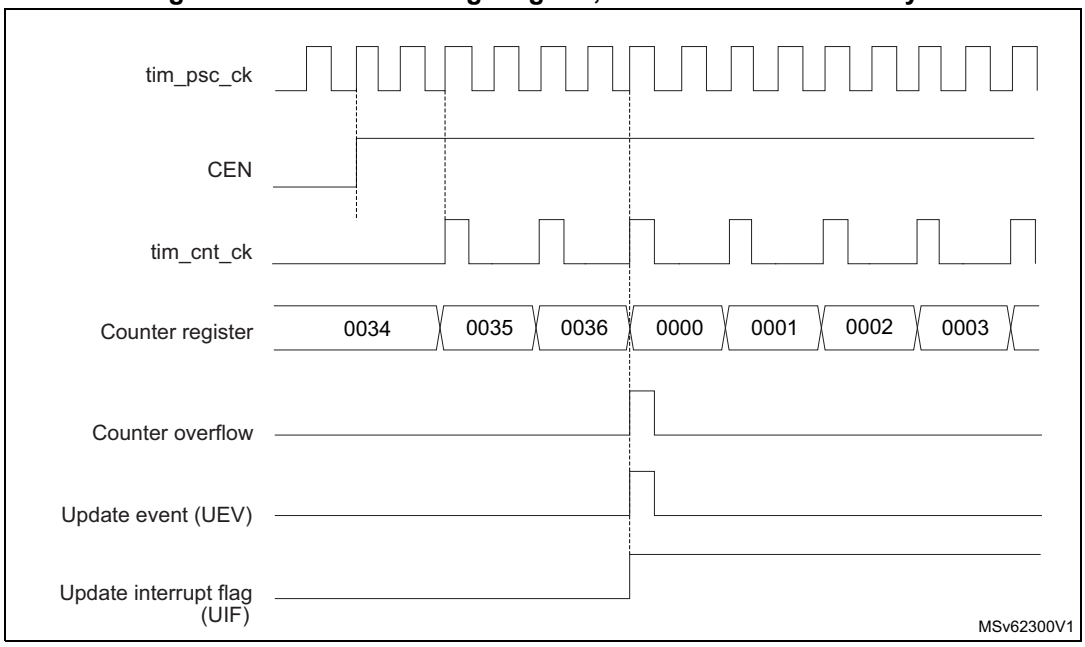

Figure 560. Counter timing diagram, internal clock divided by 4

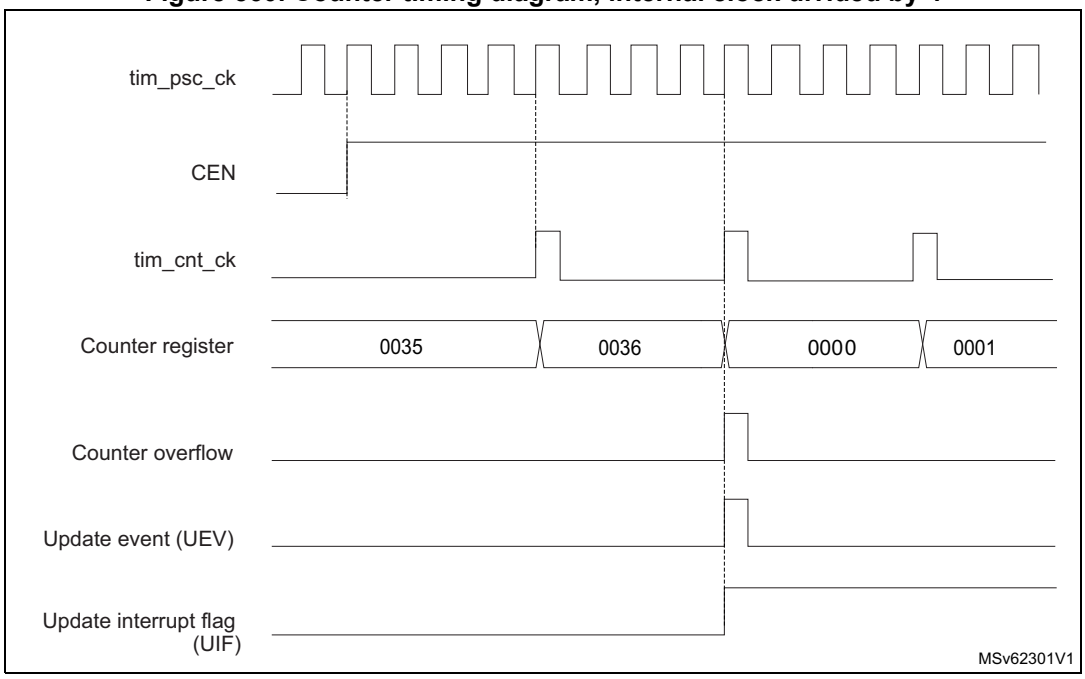

Figure 561. Counter timing diagram, internal clock divided by N

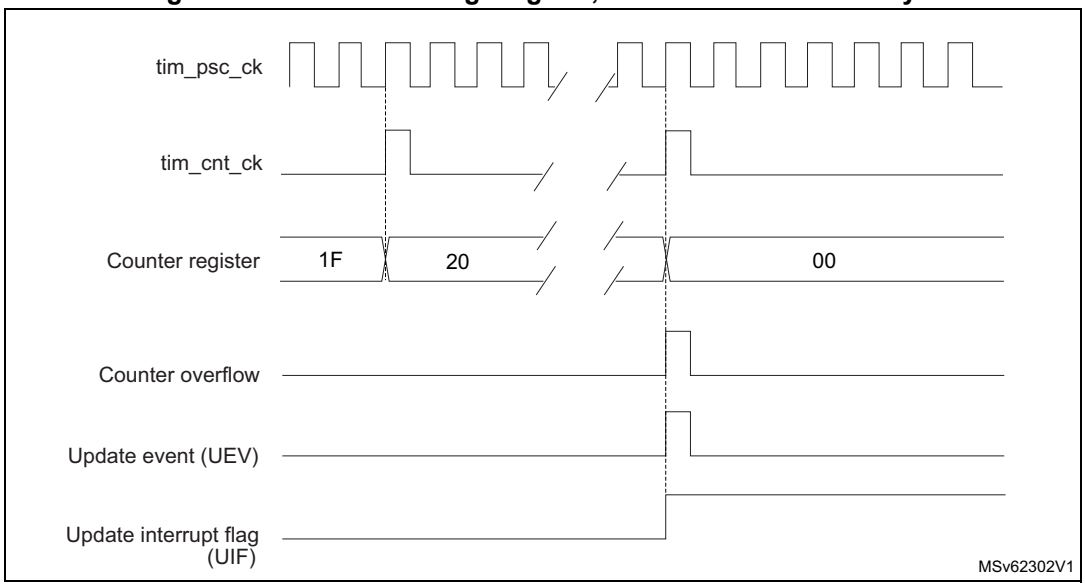

Figure 562. Counter timing diagram, update event when ARPE=0 (TIMx_ARR not preloaded)

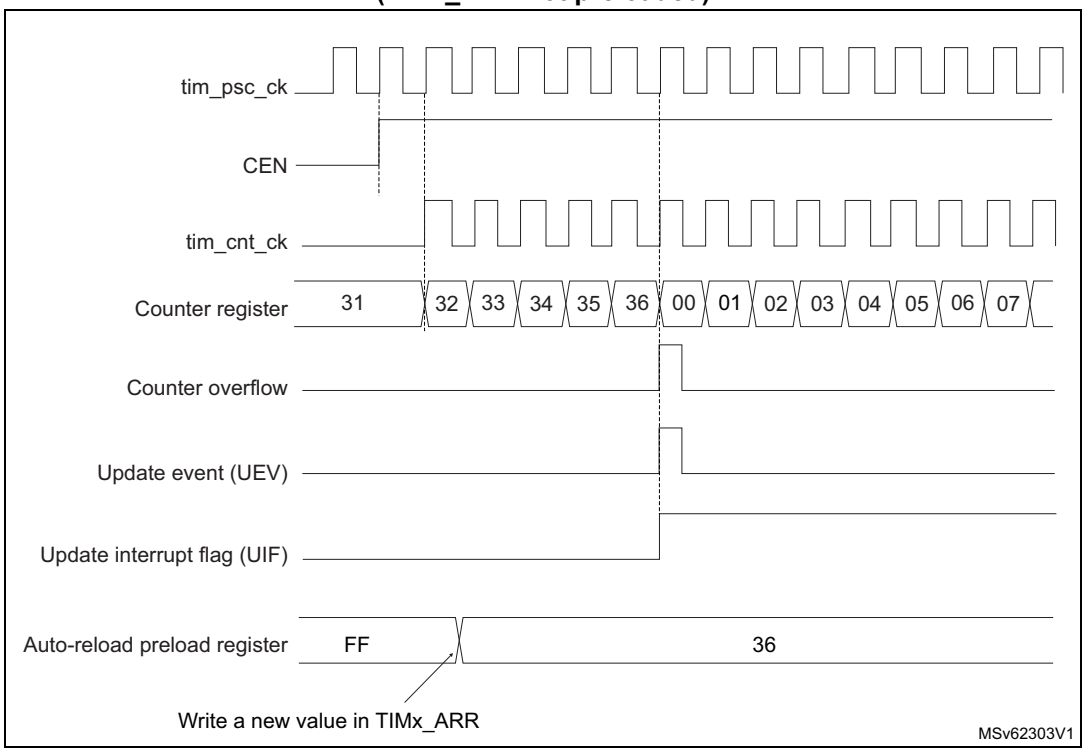

Figure 563. Counter timing diagram, update event when ARPE=1 (TIMx_ARR preloaded)

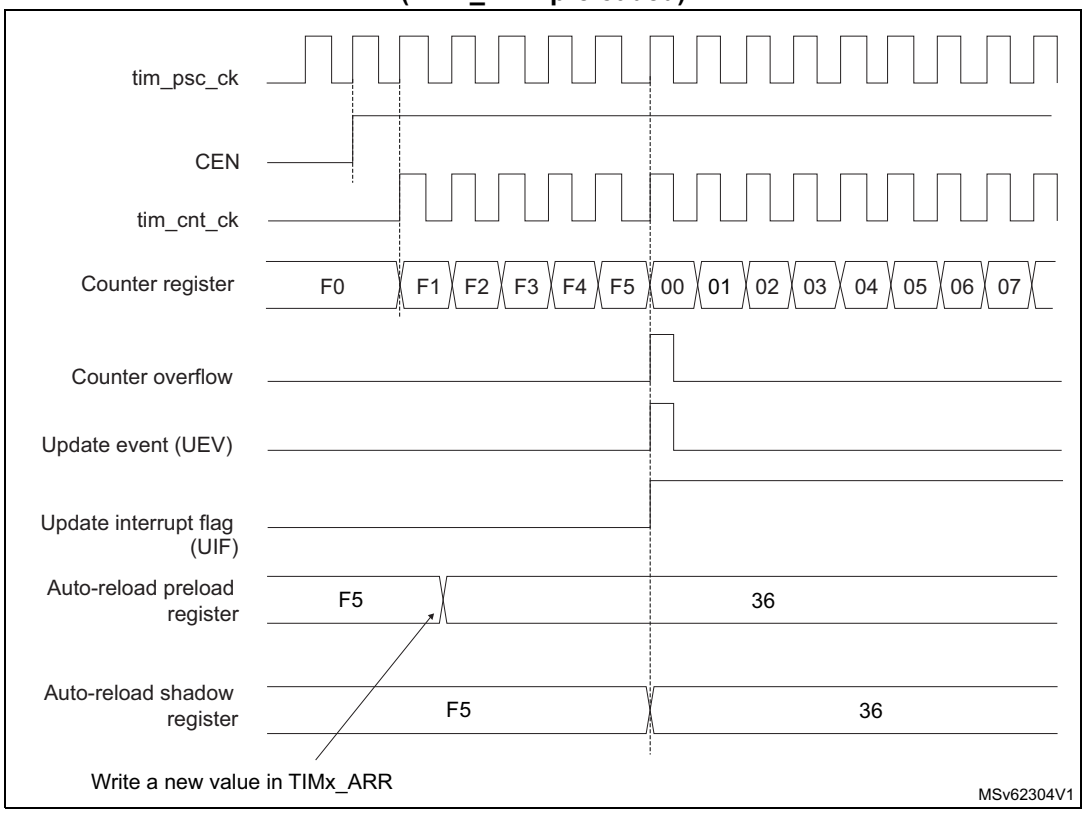


42.4.5 Repetition counter

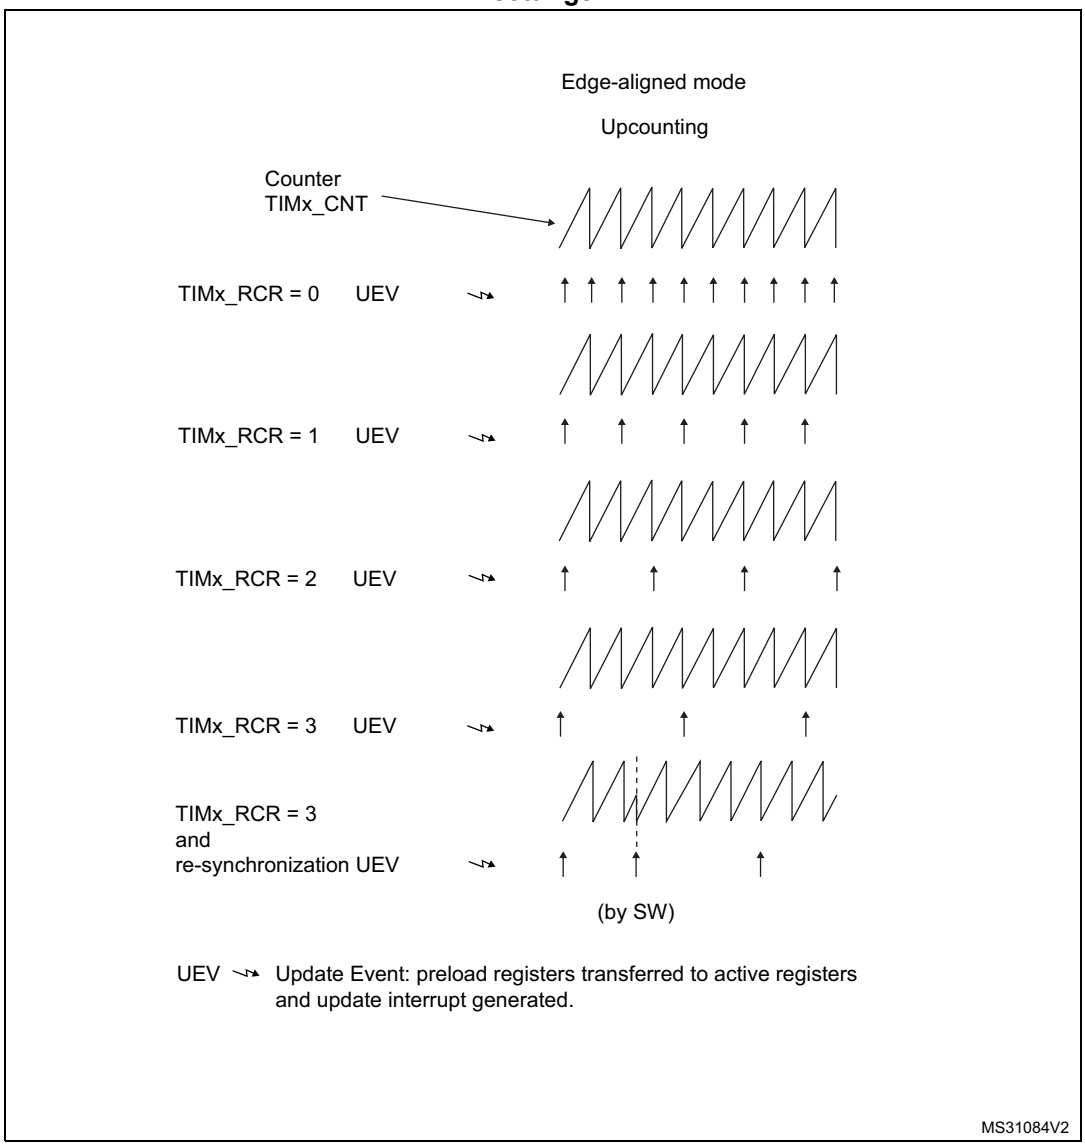
Section 42.4.3: Time-base unit describes how the update event (UEV) is generated with respect to the counter overflows. It is actually generated only when the repetition counter has reached zero. This can be useful when generating PWM signals.

This means that data are transferred from the preload registers to the shadow registers (TIMx_ARR auto-reload register, TIMx_PSC prescaler register, but also TIMx_CCRx capture/compare registers in compare mode) every N counter overflows, where N is the value in the TIMx_RCR repetition counter register.

The repetition counter is decremented at each counter overflow.

The repetition counter is an auto-reload type; the repetition rate is maintained as defined by the TIMx_RCR register value (refer to *Figure 564*). When the update event is generated by software (by setting the UG bit in TIMx_EGR register) or by hardware through the slave mode controller, it occurs immediately whatever the value of the repetition counter is and the repetition counter is reloaded with the content of the TIMx_RCR register.

Figure 564. Update rate examples depending on mode and TIMx_RCR register settings



42.4.6 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (tim_ker_ck)
- External clock mode1: external input pin (tim_ti1 or tim_ti2, if available)
- Internal trigger inputs (tim_itrx) (only for TIM15): using one timer as the prescaler for another timer, for example, TIM1 can be configured to act as a prescaler for TIM15. Refer to *Using one timer to enable another timer* for more details.

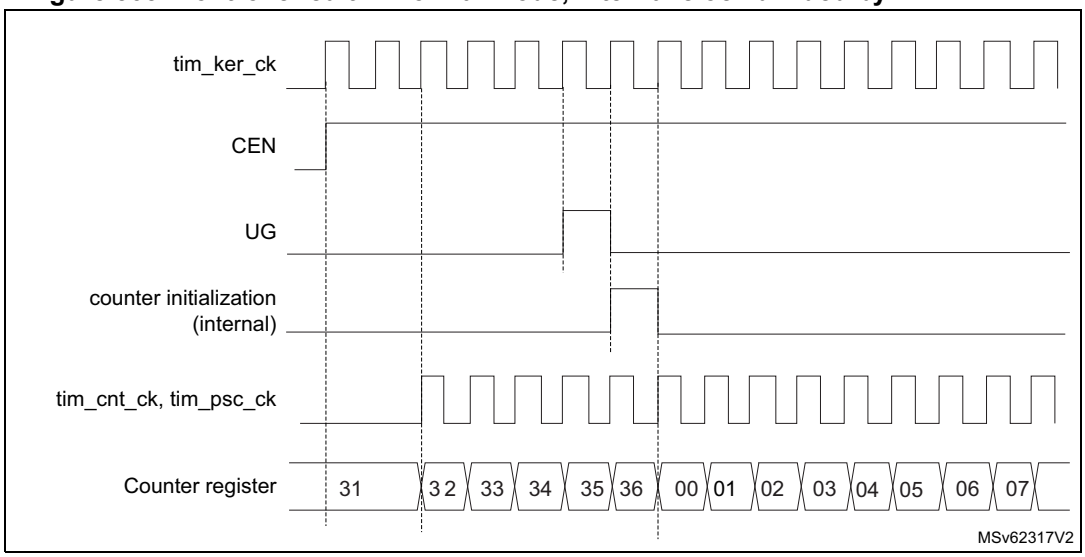
Internal clock source (tim_ker_ck)

If the slave mode controller is disabled (SMS=000), then the CEN (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed

only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock tim_ker_ck.

Figure 565 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

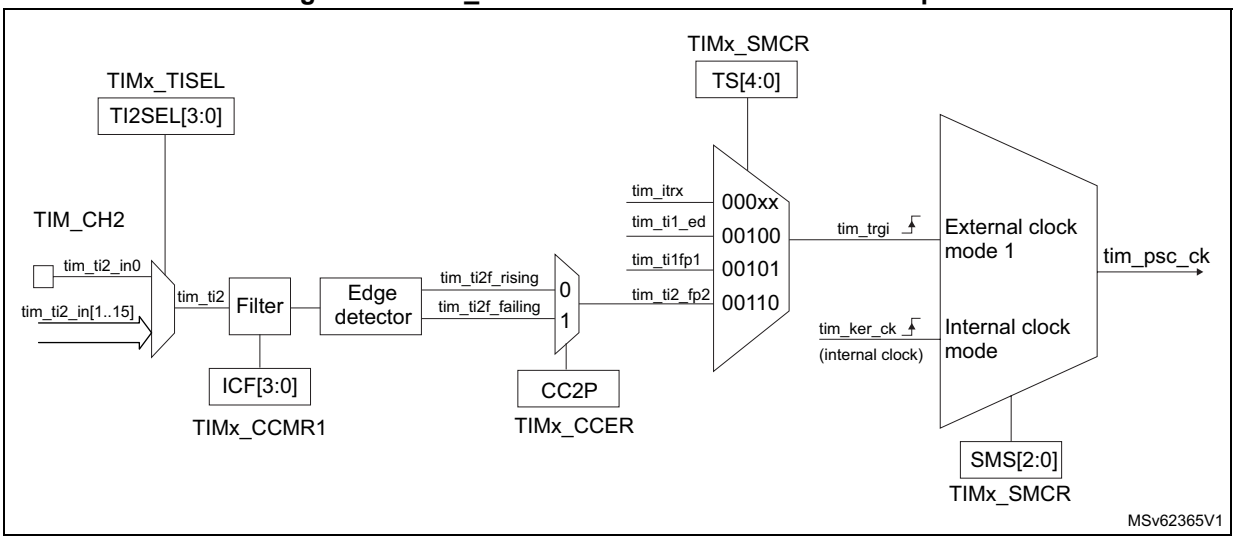
Figure 565. Control circuit in normal mode, internal clock divided by 1



External clock source mode 1

This mode is selected when SMS=111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

Figure 566. tim_ti2 external clock connection example



For example, to configure the upcounter to count in response to a rising edge on the tim_ti2 input, use the following procedure:

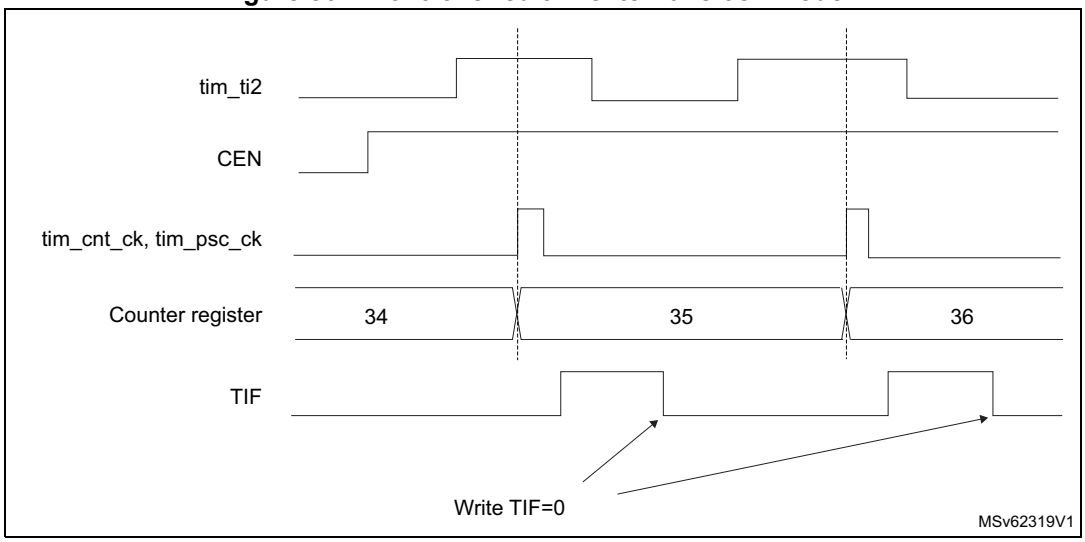
1. Select the proper tim_ti2_in[15:0] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Configure channel 2 to detect rising edges on the tim_ti2 input by writing CC2S = ‘01’ in the TIMx_CCMR1 register.
3. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 register (if no filter is needed, keep IC2F=0000).
4. Select rising edge polarity by writing CC2P=0 in the TIMx_CCER register.
5. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx_SMCR register.
6. Select tim_ti2 as the trigger input source by writing TS=00110 in the TIMx_SMCR register.
7. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

Note: The capture prescaler is not used for triggering, it is not necessary to configure it.

When a rising edge occurs on tim_ti2, the counter counts once and the TIF flag is set.

The delay between the rising edge on tim_ti2 and the actual clock of the counter is due to the resynchronization circuit on tim_ti2 input.

Figure 567. Control circuit in external clock mode 1



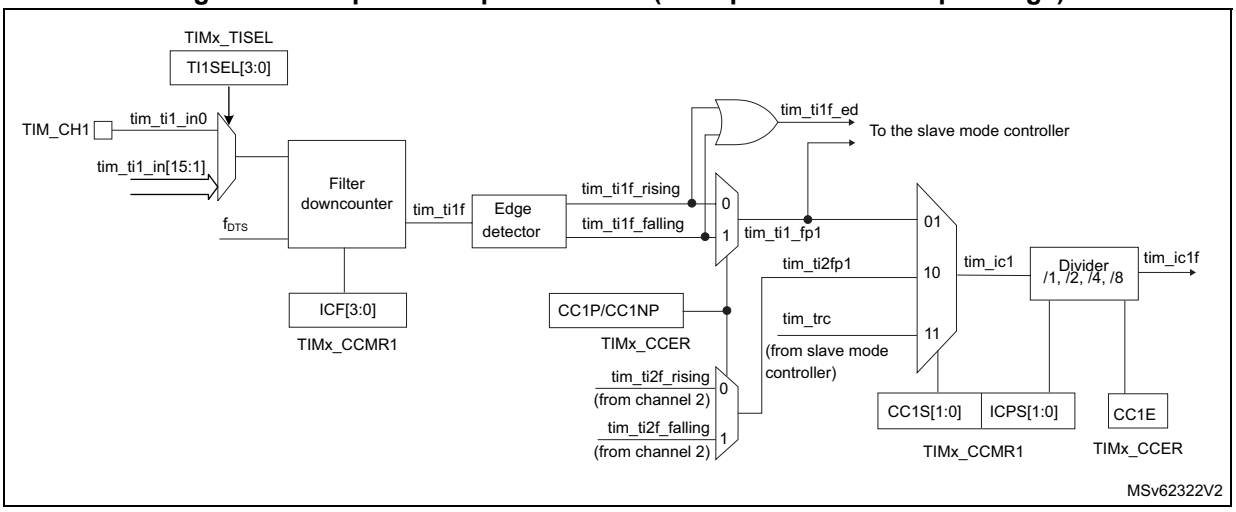
42.4.7 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), a input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

Figure 568 to *Figure 571* give an overview of one Capture/Compare channel.

The input stage samples the corresponding tim_tix input to generate a filtered signal tim_tixf. Then, an edge detector with polarity selection generates a signal (tim_tixfpy) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

Figure 568. Capture/compare channel (example: channel 1 input stage)



The output stage generates an intermediate waveform which is then used for reference: tim_ocxref (active high). The polarity acts at the end of the chain.

Figure 569. Capture/compare channel 1 main circuit

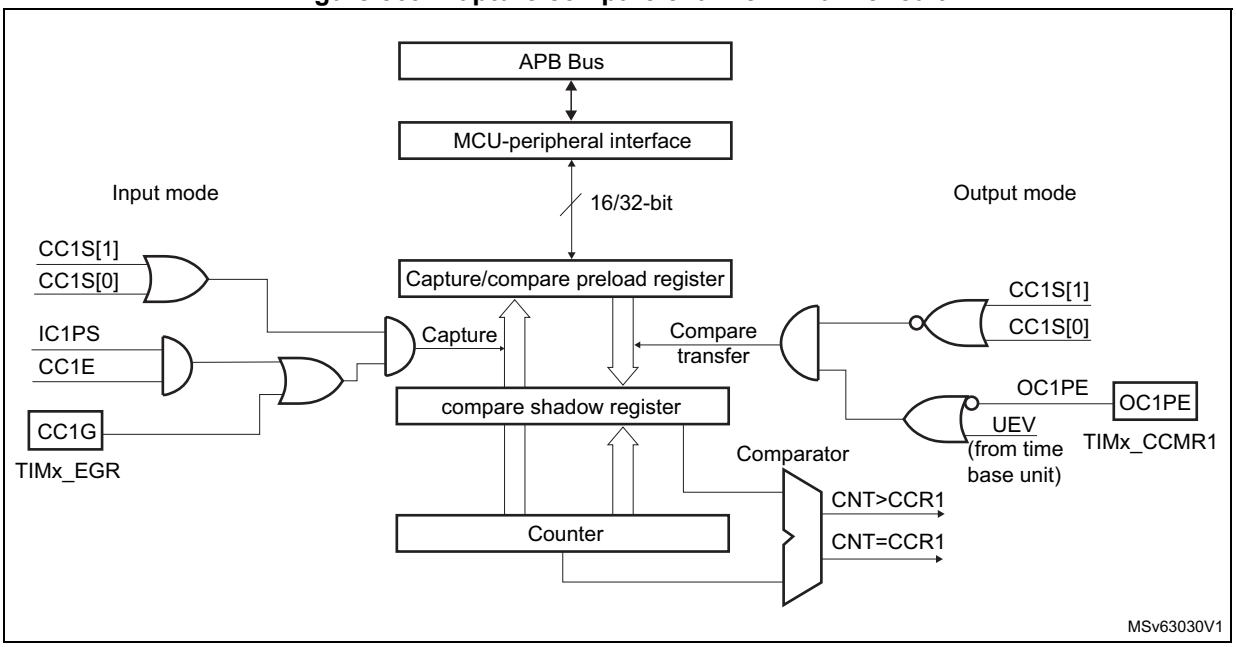


Figure 570. Output stage of capture/compare channel (channel 1)

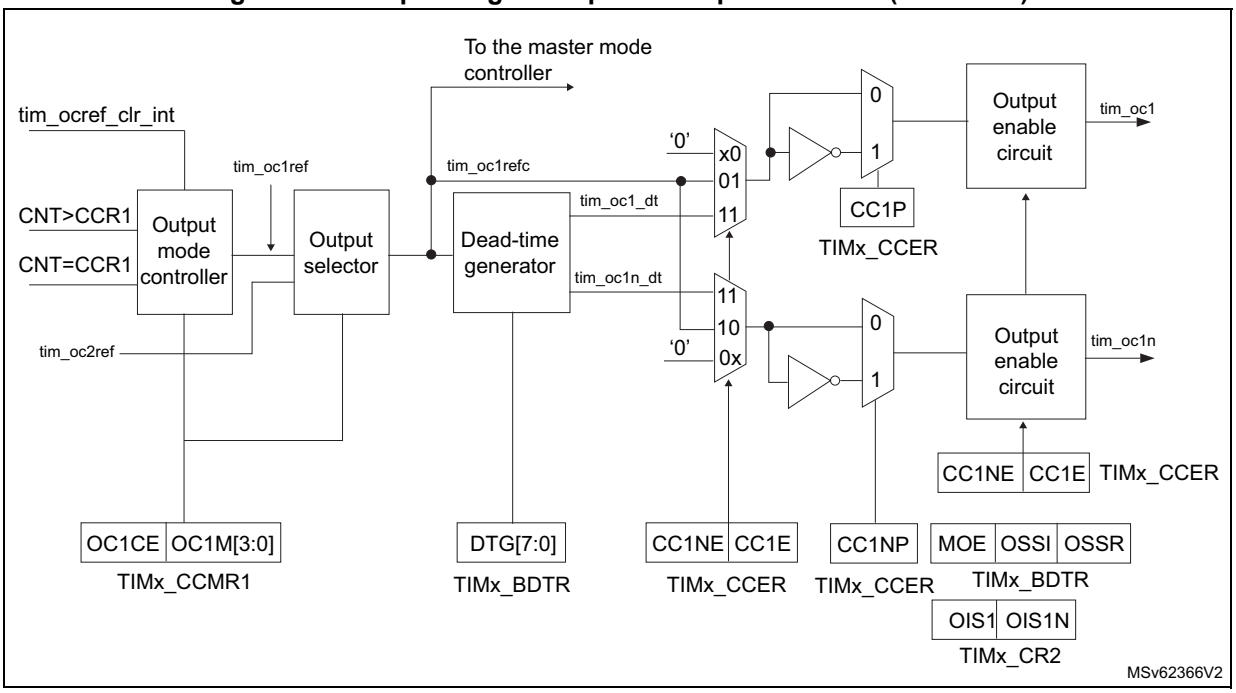

Figure 571. Output stage of capture/compare channel (channel 2 for TIM15)

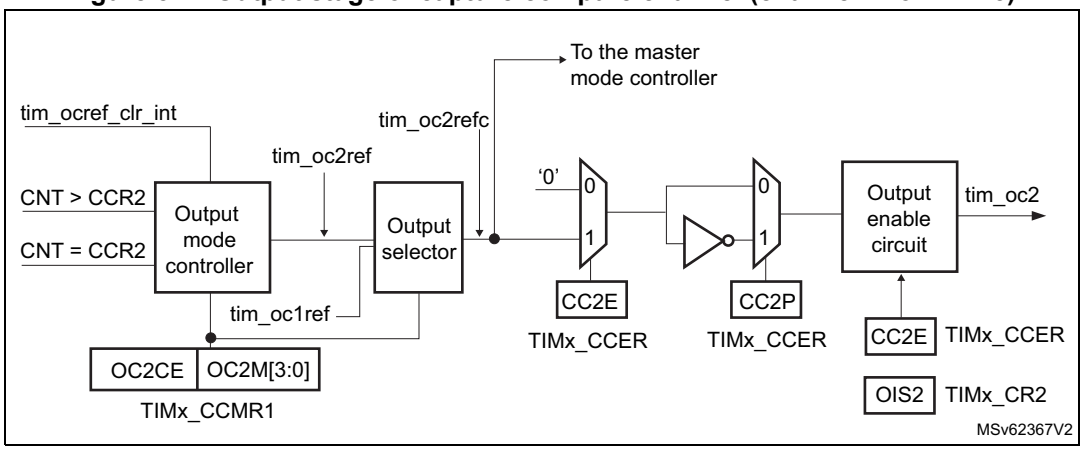


The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

42.4.8 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding tim_icx signal. When a capture occurs, the corresponding CCXIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was

already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to ‘0’ or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when tim_ti1 input rises. To do this, use the following procedure:

1. Select the proper tim_ti1_in[15:1] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input: TIMx_CCR1 must be linked to the tim_ti1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.
3. Program the appropriate input filter duration in relation with the signal connected to the timer (when the input is one of the tim_tix (ICxF bits in the TIMx_CCMRx register). Let’s imagine that, when toggling, the input signal is not stable during at least 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on tim_ti1 when 8 consecutive samples with the new level have been detected (sampled at f_{DTS} frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.
4. Select the edge of the active transition on the tim_ti1 channel by writing CC1P bit to 0 in the TIMx_CCER register (rising edge in this case).
5. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to ‘00’ in the TIMx_CCMR1 register).
6. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.
7. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:

- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which may happen after reading the flag and before reading the data.

Note: IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.

42.4.9 PWM input mode (only for TIM15)

This mode is used to measure both the period and the duty cycle of a PWM signal connected to single tim_tix input:

- The TIMx_CCR1 register holds the period value (interval between two consecutive rising edges)
- The TIMx_CCR2 register holds the pulsewidth (interval between two consecutive rising and falling edges

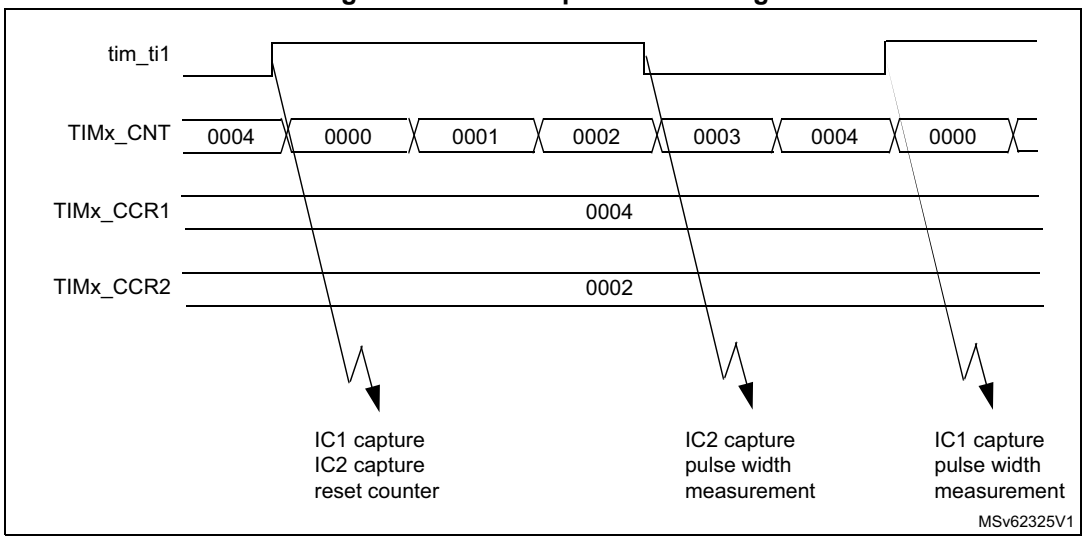
This mode is a particular case of input capture mode. The set-up procedure is similar with the following differences:

- Two tim_icx signals are mapped on the same tim_tix input.
- These 2 tim_icx signals are active on edges with opposite polarity.
- One of the two tim_tixfpy signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, one can measure the period (in TIMx_CCR1 register) and the duty cycle (in TIMx_CCR2 register) of the PWM applied on tim_ti1 using the following procedure (depending on tim_ker_ck frequency and prescaler value):

1. Select the proper tim_ti1_in[15:0] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (tim_ti1 selected).
3. Select the active polarity for tim_ti1fp1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P and CC1NP bits to ‘0’ (active on rising edge).
4. Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (tim_ti1 selected).
5. Select the active polarity for tim_ti1fp2 (used for capture in TIMx_CCR2): write the CC2P and CC2NP bits to ‘10’ (active on falling edge).
6. Select the valid trigger input: write the TS bits to 00101 in the TIMx_SMCR register (tim_ti1fp1 selected).
7. Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx_SMCR register.
8. Enable the captures: write the CC1E and CC2E bits to ‘1’ in the TIMx_CCER register.

Figure 572. PWM input mode timing



1. The PWM input mode can be used only with the TIMx_CH1/TIMx_CH2 signals due to the fact that only tim_ti1fp1 and tim_ti2fp2 are connected to the slave mode controller.

42.4.10 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (tim_ocxref and then tim_ocx/tim_ocxn) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (tim_ocxref/tim_ocx) to its active level, one just needs to write 101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus tim_ocxref is forced high (tim_ocxref is always active high) and tim_ocx get opposite value to CCxP polarity bit.

For example: CCxP=0 (tim_ocx active high) => tim_ocx is forced to high level.

The tim_ocxref signal can be forced low by writing the OCxM bits to 100 in the TIMx_CCMRx register.

Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.

42.4.11 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP

bit in the TIMx_CCER register). The output pin can keep its level (OCXM=000), be set active (OCxM=001), be set inactive (OCxM=010) or can toggle (OCxM=011) on match.

- Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

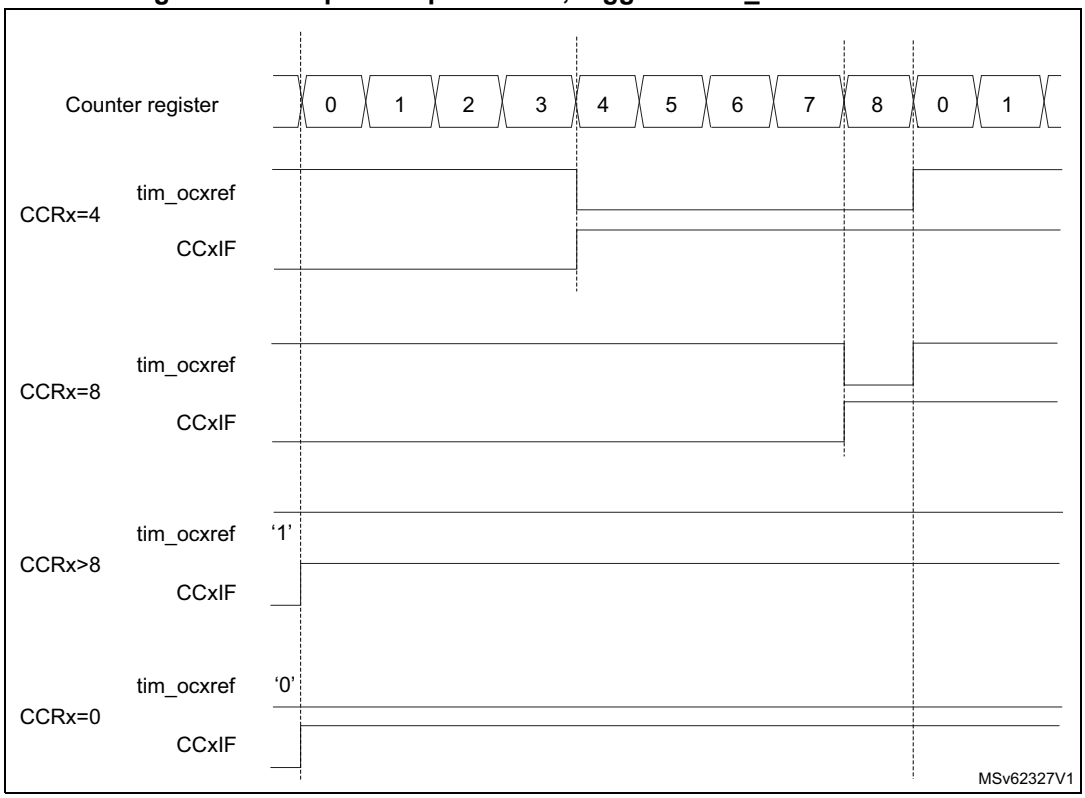
In output compare mode, the update event UEV has no effect on tim_ocxref and tim_ocx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
   - Write OCxM = 011 to toggle tim_ocx output pin when CNT matches CCRx
   - Write OCxPE = 0 to disable preload register
   - Write CCxP = 0 to select active high polarity
   - Write CCxE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE='0', else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in *Figure 573*.

Figure 573. Output compare mode, toggle on tim_oc1



42.4.12 PWM mode

Pulse width modulation mode is used to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per tim_ocx output) by writing '110' (PWM mode 1) or '111' (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

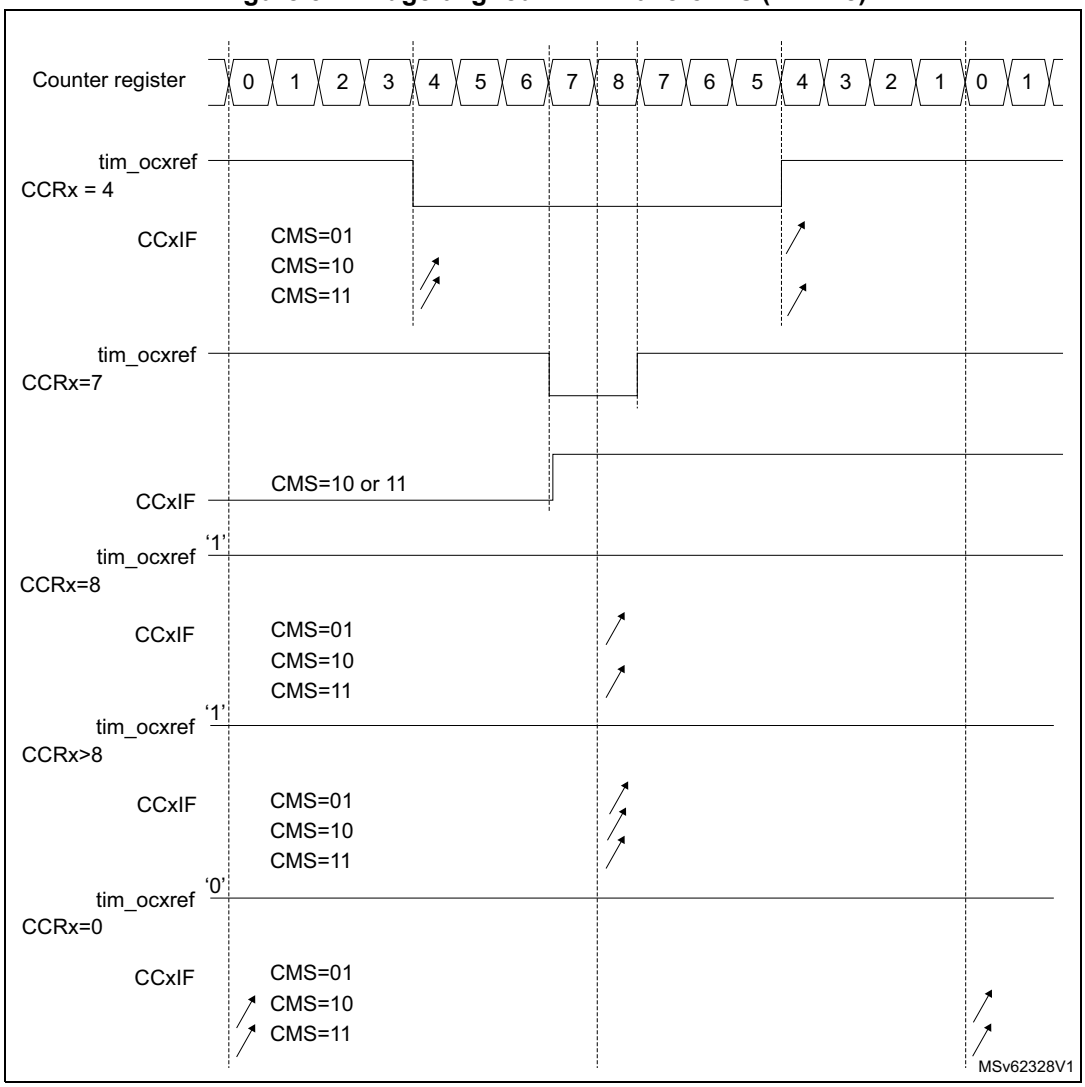
tim_ocx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. tim_ocx output is enabled by a combination of the CCxE, CCxNE, MOE, OSSI and OSSR bits (TIMx_CCER and TIMx_BDTR registers). Refer to the TIMx_CCER register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx ≤ TIMx_CNT or TIMx_CNT ≤ TIMx_CCRx (depending on the direction of the counter).

The TIM15/TIM16/TIM17 are capable of upcounting only. Refer to *Upcounting mode on page 1778*.

In the following example, we consider PWM mode 1. The reference PWM signal tim_ocxref is high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then tim_ocxref is held at ‘1’. If the compare value is 0 then tim_ocxref is held at ‘0’. *Figure 574* shows some edge-aligned PWM waveforms in an example where TIMx_ARR=8.

Figure 574. Edge-aligned PWM waveforms (ARR=8)

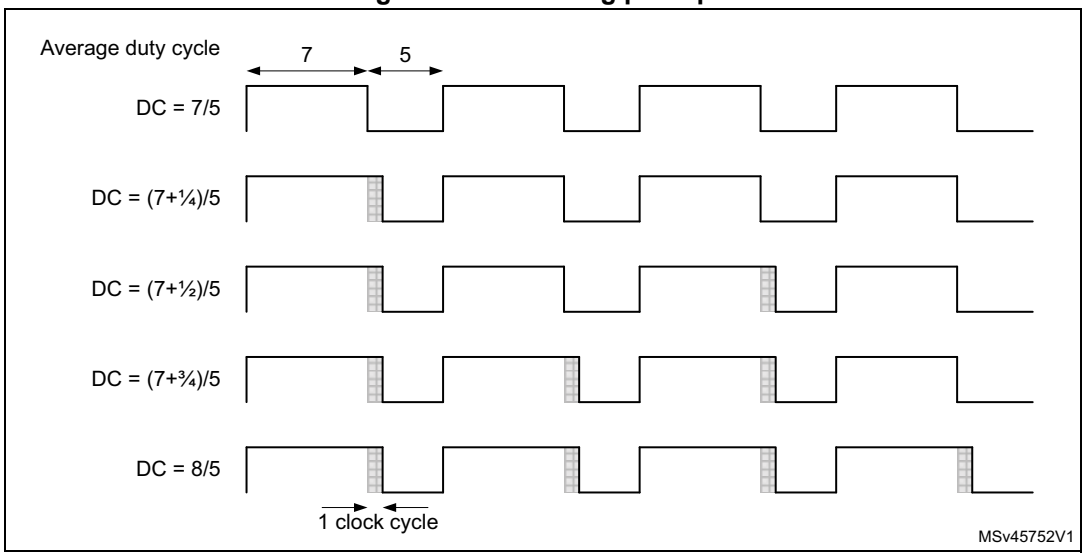


Dithering mode

The PWM mode effective resolution can be increased by enabling the dithering mode, using the DITHEN bit in the TIMx_CR1 register. This applies to both the CCR (for duty cycle resolution increase) and ARR (for PWM frequency resolution increase).

The operating principle is to have the actual CCR (or ARR) value slightly changed (adding or not one timer clock period) over 16 consecutive PWM periods, with predefined patterns. This allows a 16-fold resolution increase, considering the average duty cycle or PWM period. The *Figure 575* below presents the dithering principle applied to 4 consecutive PWM cycles.

Figure 575. Dithering principle

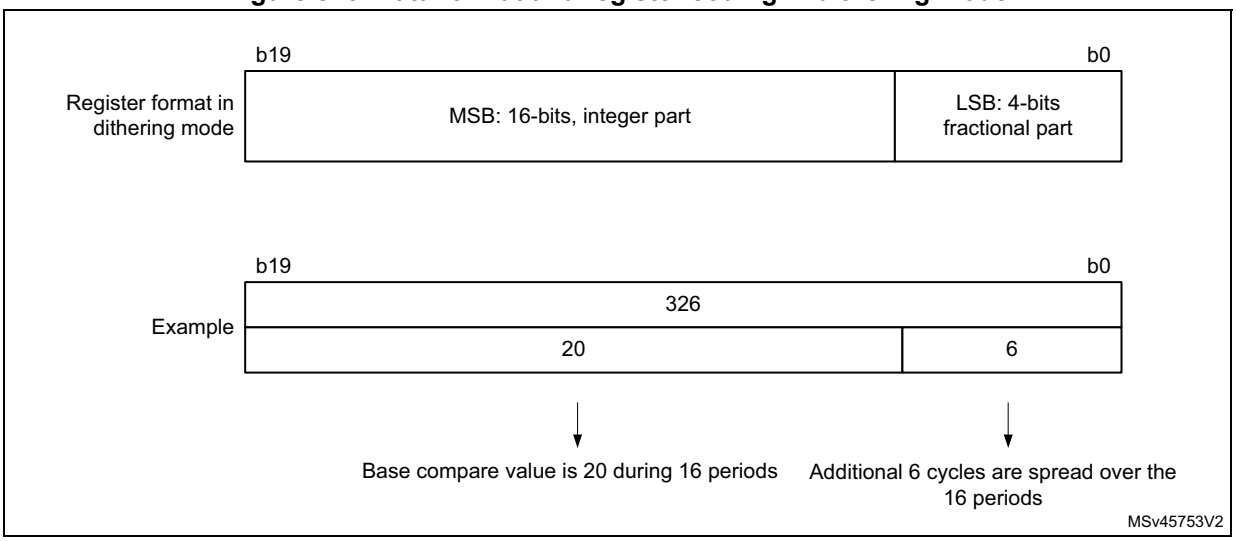


When the dithering mode is enabled, the register coding is changed as following (see *Figure 576* for example):

- the 4 LSBs are coding for the enhanced resolution part (fractional part)
- the MSBs are left-shifted to the bits 19:4 and are coding for the base value.

Note: The following sequence must be followed when resetting the DITHEN bit:
1. CEN and ARPE bits must be reset
2. The ARR[3:0] bits must be reset
3. The CCIF flags must be cleared
4. The CEN bit can be set (eventually with ARPE = 1).

Figure 576. Data format and register coding in dithering mode



The minimum frequency is given by the following formula:

$$\text{Resolution} = \frac{F_{Tim}}{F_{pwm}} \Rightarrow F_{pwmMin} = \frac{F_{Tim}}{Max_{Resolution}}$$

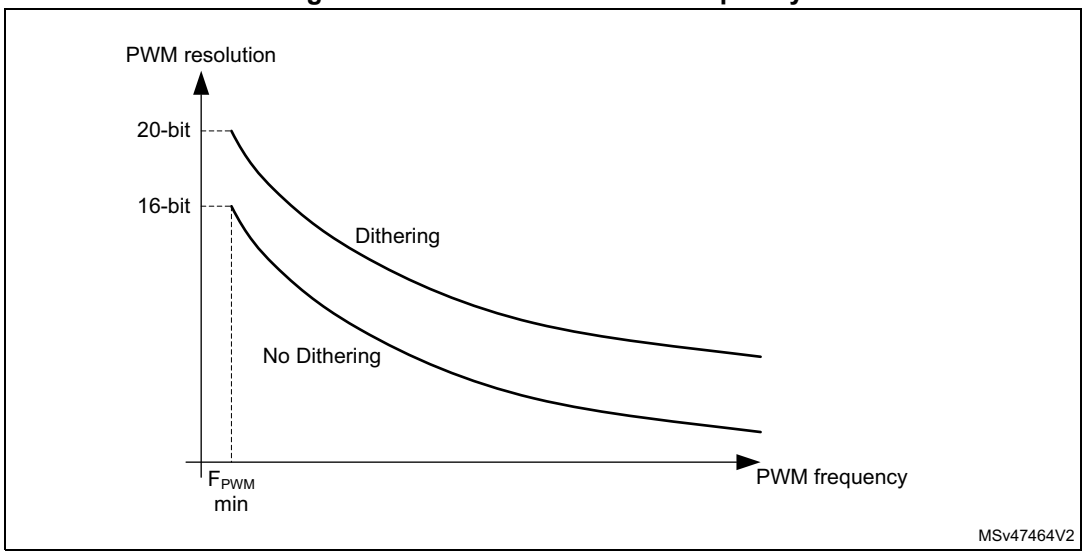
$$\text{Dithering mode disabled: } F_{pwmMin} = \frac{F_{Tim}}{65536}$$

$$\text{Dithering mode enabled: } F_{pwmMin} = \frac{F_{Tim}}{65535 + \frac{15}{16}}$$

Note: The maximum TIMx_ARR and TIMxCCRy values are limited to 0xFFFEF in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part).

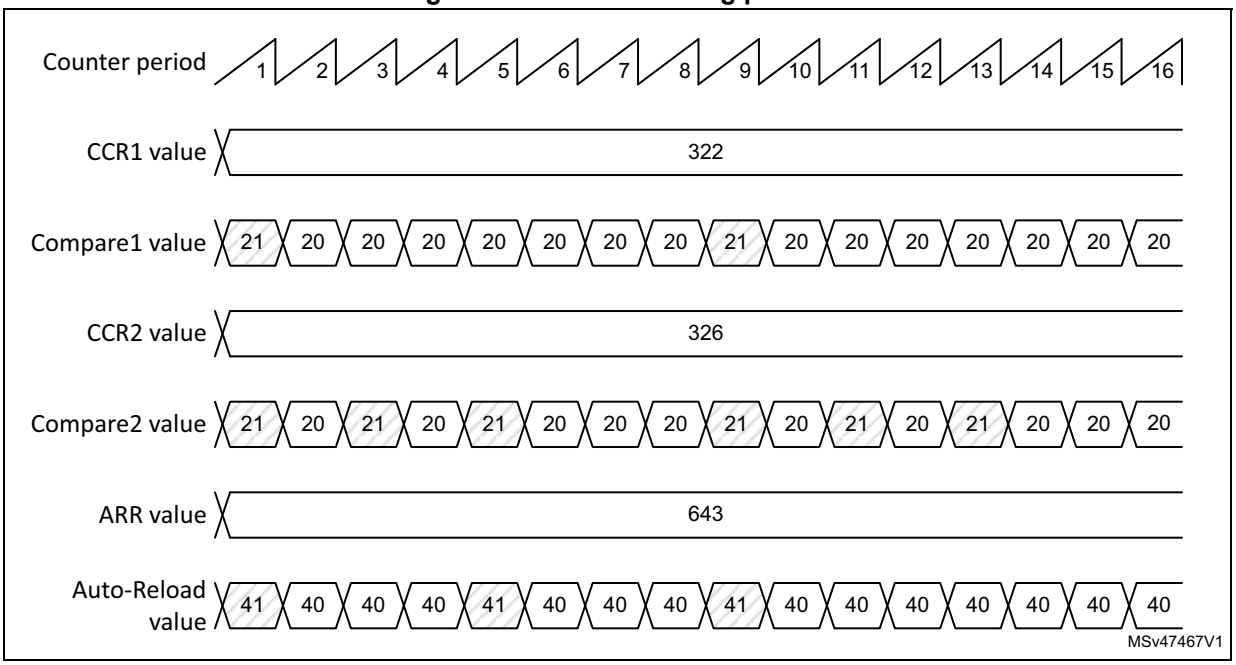
As shown on the *Figure 577* below, the dithering mode is used to increase the PWM resolution whatever the PWM frequency.

Figure 577. PWM resolution vs frequency



The duty cycle and / or period changes are spread over 16 consecutive periods, as described in the *Figure 578* below.

Figure 578. PWM dithering pattern



The auto-reload and compare values increments are spread following specific patterns described in the *Table 440* below. The dithering sequence is done to have increments distributed as evenly as possible and minimize the overall ripple.

Table 440. CCR and ARR register change dithering pattern

42.4.13 Combined PWM mode (TIM15 only)

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, tim_ocxrefc, are made of an OR or AND logical combination of two reference PWMs:

- tim_oc1refc (or tim_oc2refc) is controlled by the TIMx_CCR1 and TIMx_CCR2 registers

Combined PWM mode can be selected independently on two channels (one tim_ocx output per pair of CCR registers) by writing ‘1100’ (Combined PWM mode 1) or ‘1101’ (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

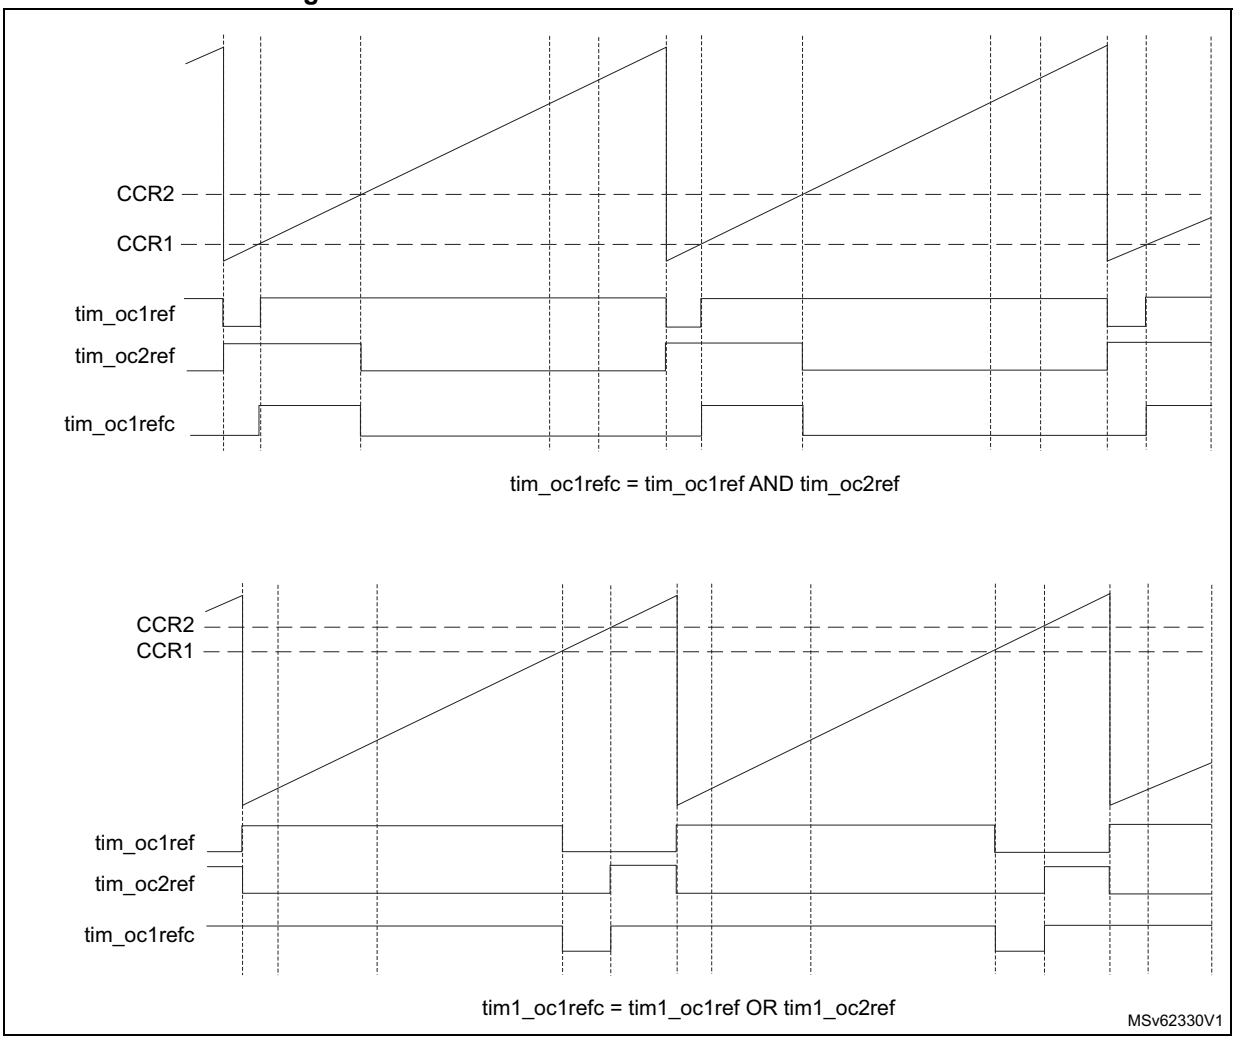
When a given channel is used as a combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

Note: The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

Figure 579 represents an example of signals that can be generated using combined PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,

Figure 579. Combined PWM mode on channel 1 and 2



42.4.14 Complementary outputs and dead-time insertion

The TIM15/TIM16/TIM17 general-purpose timers can output one complementary signal and manage the switching-off and switching-on of the outputs.

This time is generally known as dead-time and it has to be adjusted depending on the devices that are connected to the outputs and their characteristics (intrinsic delays of level-shifters, delays due to power switches...)

The polarity of the outputs (main output tim_ocx or complementary tim_ocxn) can be selected independently for each output. This is done by writing to the CCxP and CCxNP bits in the TIMx_CCER register.

The complementary signals tim_ocx and tim_ocxn are activated by a combination of several control bits: the CCxE and CCxNE bits in the TIMx_CCER register and the MOE, OISx, OISxN, OSSI and OSSR bits in the TIMx_BDTR and TIMx_CR2 registers. Refer to *Table 447: Output control bits for complementary tim_oc1 and tim_oc1n channels with break feature (TIM16/TIM17) on page 1859* for more details. In particular, the dead-time is activated when switching to the idle state (MOE falling down to 0).

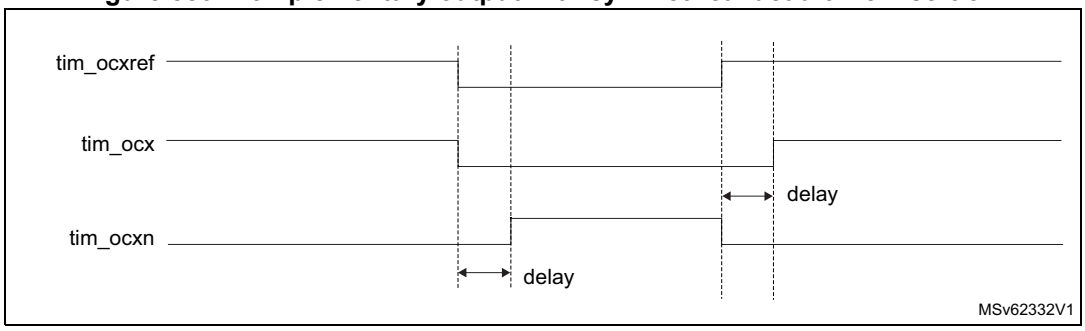
Dead-time insertion is enabled by setting both CCxE and CCxNE bits, and the MOE bit if the break circuit is present. There is one 10-bit dead-time generator for each channel. From a reference waveform tim_ocxref, it generates 2 outputs tim_ocx and tim_ocxn. If tim_ocx and tim_ocxn are active high:

- The tim_ocx output signal is the same as the reference signal except for the rising edge, which is delayed relative to the reference rising edge.
- The tim_ocxn output signal is the opposite of the reference signal except for the rising edge, which is delayed relative to the reference falling edge.

If the delay is greater than the width of the active output (tim_ocx or tim_ocxn) then the corresponding pulse is not generated.

The following figures show the relationships between the output signals of the dead-time generator and the reference signal tim_ocxref. (we suppose CCxP=0, CCxNP=0, MOE=1, CCxE=1 and CCxNE=1 in these examples)

Figure 580. Complementary output with symmetrical dead-time insertion.



The DTAE bit in the TIMx_DTR2 is used to differentiate the deadtime values for rising and falling edges of the reference signal, as shown on *Figure 581*.

In asymmetrical mode (DTAE = 1), the rising edge-referred deadtime is defined by the DTG[7:0] bitfield in the TIMx_BDTR register, while the falling edge-referred is defined by the DTGF[7:0] bitfield in the TIMx_DTR2 register. The DTAE bit must be written before enabling the counter and must be not modified while CEN = 1.

It is possible to have the deadtime value updated on-the-fly during pwm operation, using a preload mechanism. The deadtime bitfield DTG[7:0] and DTGF[7:0] are preloaded when the DTPE bit is set, in the TIMX_DTR2 register. The preload value is loaded in the active register on the next update event.

Note: If the DTPE bit is enabled while the counter is enabled, any new value written since last update is discarded and previous value is used.

Figure 581. Asymmetrical deadtime

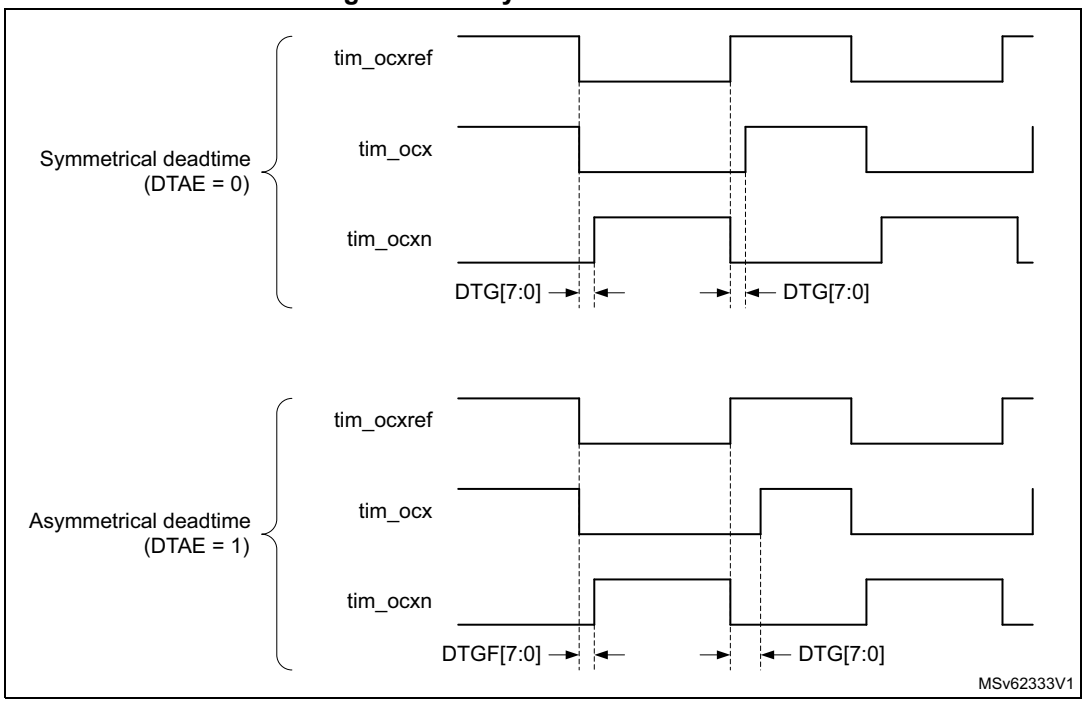


Figure 582. Dead-time waveforms with delay greater than the negative pulse.

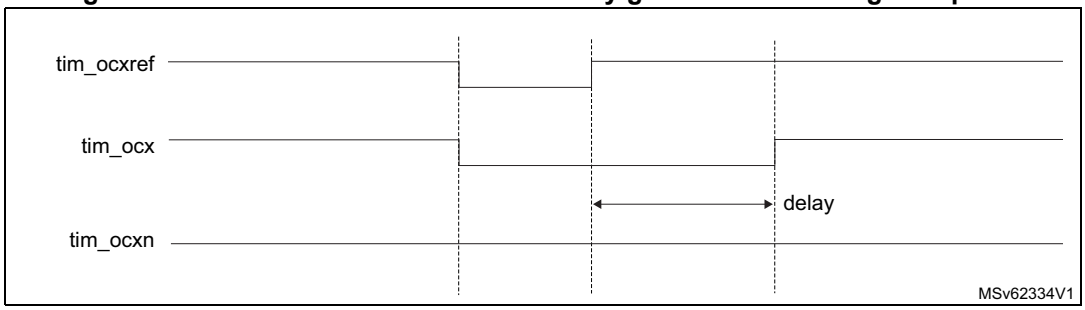

Figure 583. Dead-time waveforms with delay greater than the positive pulse.

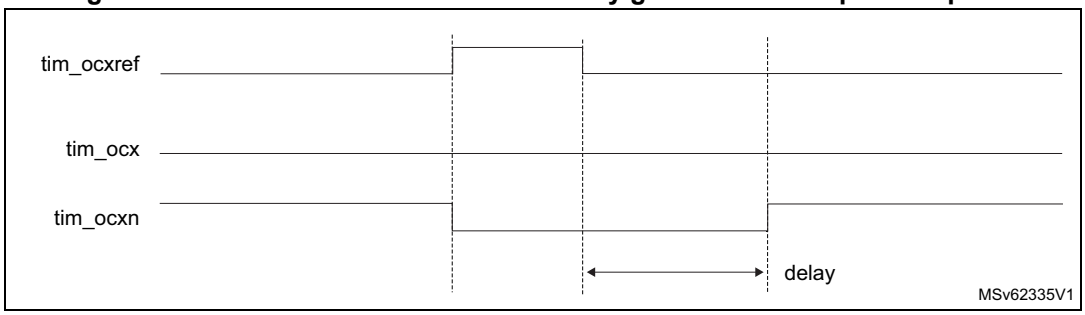


The dead-time delay is the same for each of the channels and is programmable with the DTG bits in the TIMx_BDTR register. Refer to *Section 42.8.14: TIMx break and dead-time register (TIMx_BDTR)(x = 16 to 17) on page 1863* for delay calculation.

Re-directing tim_ocxref to tim_ocx or tim_ocxn

In output mode (forced, output compare or PWM), tim_ocxref can be re-directed to the tim_ocx output or to tim_ocxn output by configuring the CCxE and CCxNE bits in the TIMx_CCER register.

This is used to send a specific waveform (such as PWM or static active level) on one output while the complementary remains at its inactive level. Other alternative possibilities are to have both outputs at inactive level or both outputs active and complementary with dead-time.

Note: When only tim_ocxn is enabled (CCxE=0, CCxNE=1), it is not complemented and becomes active as soon as tim_ocxref is high. For example, if CCxNP=0 then tim_ocxn=tim_ocxref. On the other hand, when both tim_ocx and tim_ocxn are enabled (CCxE=CCxNE=1) tim_ocx becomes active when tim_ocxref is high whereas tim_ocxn is complemented and becomes active when tim_ocxref is low.

42.4.15 Using the break function

The purpose of the break function is to protect power switches driven by PWM signals generated with the timers. The break input is usually connected to fault outputs of power stages and 3-phase inverters. When activated, the break circuitry shuts down the PWM outputs and forces them to a predefined safe state.

The break channel gathers both system-level fault (clock failure, ECC / parity errors,...) and application fault (from input pins and built-in comparator), and can force the outputs to a predefined level (either active or inactive) after a deadtime duration.

The output enable signal and output levels during break are depending on several control bits:

- the MOE bit in TIMx_BDTR register is used to enable /disable the outputs by software and is reset in case of break or break2 event.
- the OSSI bit in the TIMx_BDTR register defines whether the timer controls the output in inactive state or releases the control to the GPIO controller (typically to have it in Hi-Z mode)
- the OISx and OISxN bits in the TIMx_CR2 register which are setting the output shut-down level, either active or inactive. The tim_ocx and tim_ocxn outputs cannot be set both to active level at a given time, whatever the OISx and OISxN values. Refer to *Table 447: Output control bits for complementary tim_oc1 and tim_oc1n channels with break feature (TIM16/TIM17) on page 1859* for more details.

When exiting from reset, the break circuit is disabled and the MOE bit is low. The break function is enabled by setting the BKE bit in the TIMx_BDTR register. The break input polarity can be selected by configuring the BKP bit in the same register. BKE and BKP can be modified at the same time. When the BKE and BKP bits are written, a delay of 1 APB clock cycle is applied before the writing is effective. Consequently, it is necessary to wait 1 APB clock period to correctly read back the bit after the write operation.

Because MOE falling edge can be asynchronous, a resynchronization circuit has been inserted between the actual signal (acting on the outputs) and the synchronous control bit (accessed in the TIMx_BDTR register). It results in some delays between the asynchronous and the synchronous signals. In particular, if MOE is set to 1 whereas it was low, a delay must be inserted (dummy instruction) before reading it correctly. This is because the write acts on the asynchronous signal whereas the read reflects the synchronous signal.

The break is generated by the tim_brk inputs which has:

- Programmable polarity (BKP bit in the TIMx_BDTR register)
- Programmable enable bit (BKE bit in the TIMx_BDTR register)
- Programmable filter (BKF[3:0] bits in the TIMx_BDTR register) to avoid spurious events.

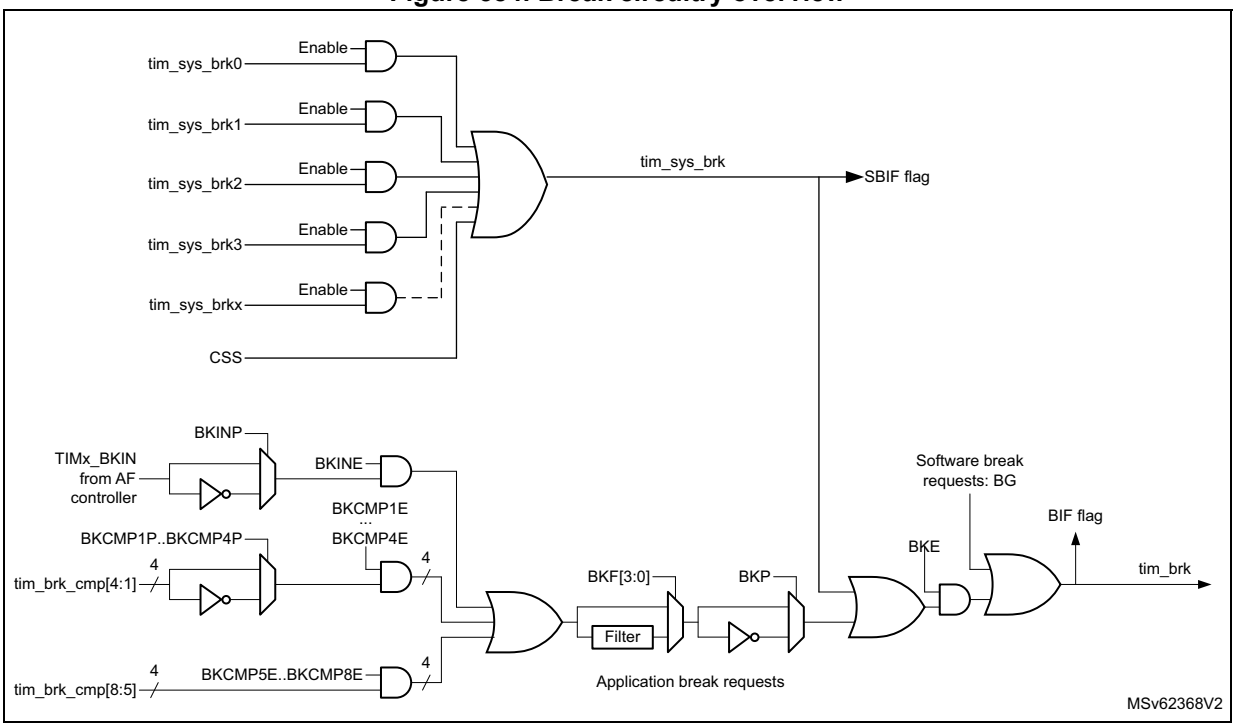
The break can be generated from multiple sources which can be individually enabled and with programmable edge sensitivity, using the TIMx_AF1 register.

The sources for break (tim_brk) channel are:

- External sources connected to one of the TIM_BKIN pin (as per selection done in the GPIO alternate function selection registers), with polarity selection and optional digital filtering
- Internal sources:
  - coming from a tim_brk_cmpx input (refer to *Section 42.4.2: TIM15/TIM16/TIM17 pins and internal signals* for product specific implementation)
  - coming from a system break request on the tim_sys_brk inputs (refer to *Section 42.4.2: TIM15/TIM16/TIM17 pins and internal signals* for product specific implementation)

Break events can also be generated by software using BG bit in the TIMx_EGR register. All sources are ORed before entering the timer tim_brk inputs, as per *Figure 584* below.

Figure 584. Break circuitry overview



Caution: An asynchronous (clockless) operation is only guaranteed when the programmable filter is disabled. If it is enabled, a fail safe clock mode (for example, using the internal PLL and/or the CSS) must be used to guarantee that break events are handled.

When a break occurs (selected level on the break input):

- The MOE bit is cleared asynchronously, putting the outputs in inactive state, idle state or even releasing the control to the GPIO (selected by the OSSI bit). This feature functions even if the MCU oscillator is off.
- Each output channel is driven with the level programmed in the OISx bit in the TIMx_CR2 register as soon as MOE=0. If OSSI=0, the timer releases the output control (taken over by the GPIO) else the enable output remains high.
- When complementary outputs are used:
  - The outputs are first put in reset state inactive state (depending on the polarity). This is done asynchronously so that it works even if no clock is provided to the timer.
  - If the timer clock is still present, then the dead-time generator is reactivated in order to drive the outputs with the level programmed in the OISx and OISxN bits after a dead-time. Even in this case, tim_ocx and tim_ocxn cannot be driven to their active level together. Note that because of the resynchronization on MOE, the dead-time duration is a bit longer than usual (around 2 tim_ker_ck clock cycles).
  - If OSSI=0 then the timer releases the enable outputs (taken over by the GPIO which forces a Hi-Z state) else the enable outputs remain or become high as soon as one of the CCxE or CCxNE bits is high.
- The break status flag (BIF bit in the TIMx_SR register) is set. An interrupt can be generated if the BIE bit in the TIMx_DIER register is set. A DMA request can be sent if the BDE bit in the TIMx_DIER register is set.
- If the AOE bit in the TIMx_BDTR register is set, the MOE bit is automatically set again at the next update event UEV. This can be used to perform a regulation, for instance. Else, MOE remains low until it is written with 1 again. In this case, it can be used for security and the break input can be connected to an alarm from power drivers, thermal sensors or any security components.

Note: If the MOE is reset by the CPU while the AOE bit is set, the outputs are in idle state and forced to inactive level or Hi-Z depending on OSSI value. If both the MOE and AOE bits are reset by the CPU, the outputs are in disabled state and driven with the level programmed in the OISx bit in the TIMx_CR2 register.

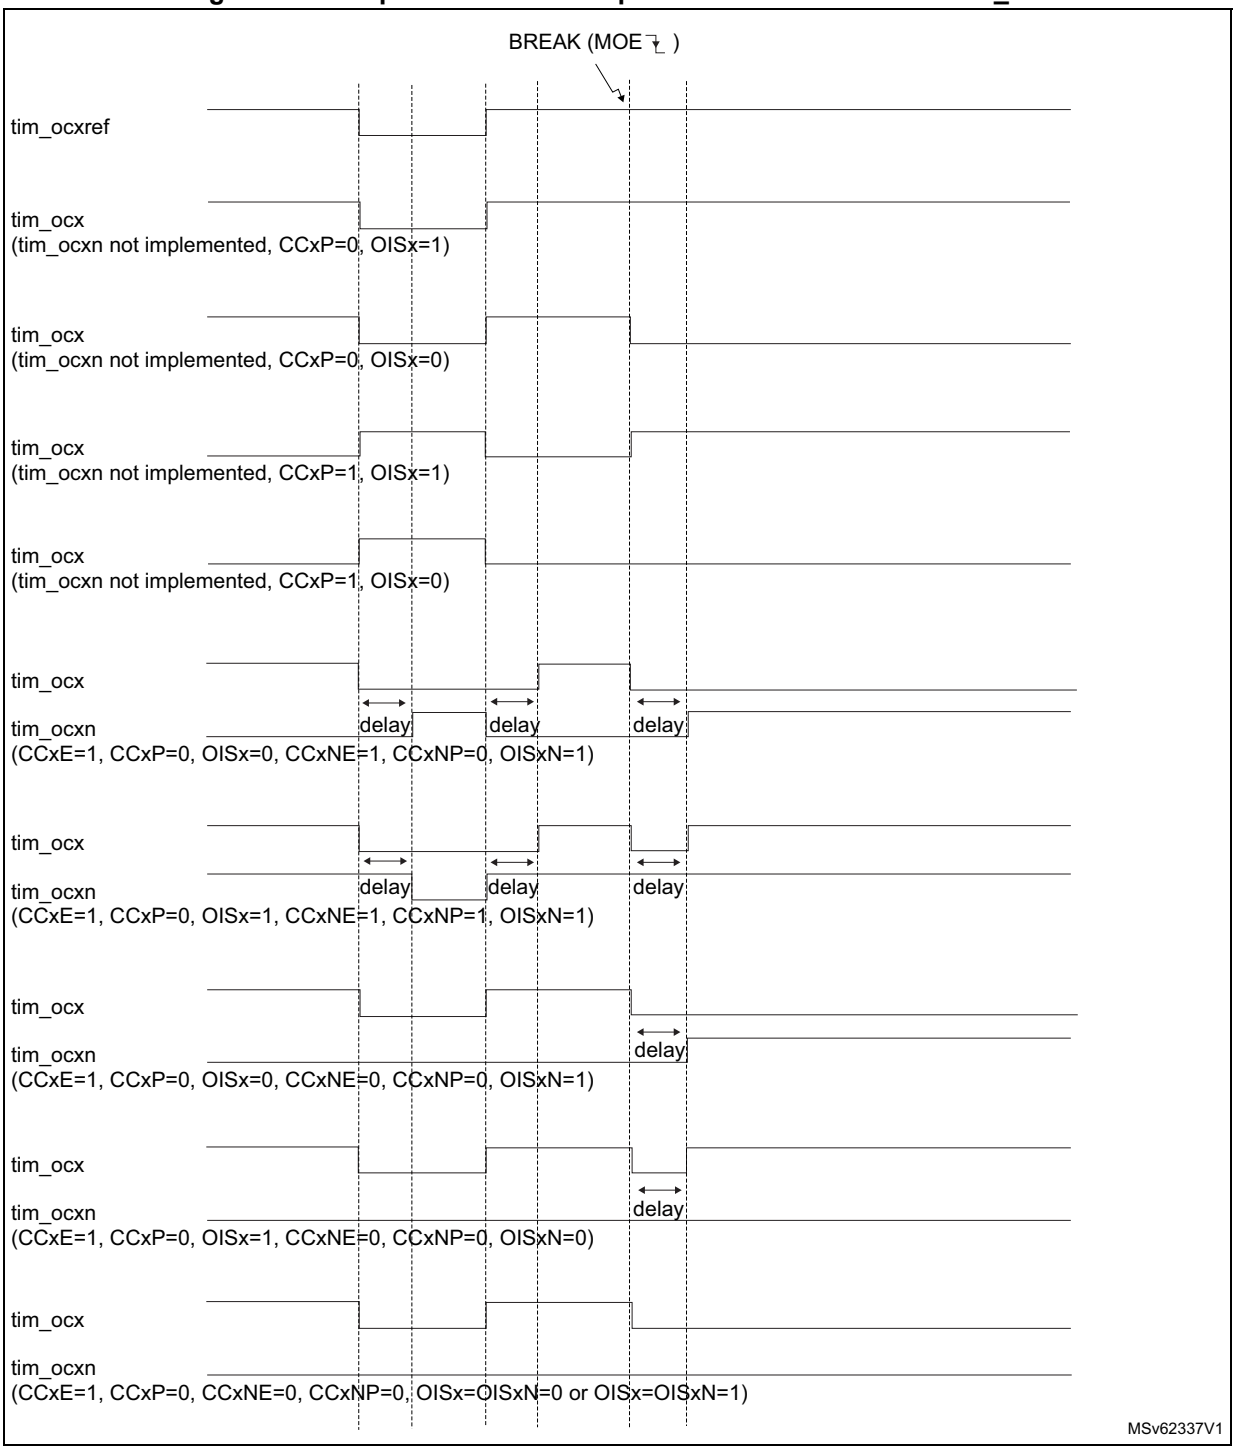
Note: The break inputs is acting on level. Thus, the MOE cannot be set while the break input is active (neither automatically nor by software). In the meantime, the status flag BIF cannot be cleared.

The break can be generated by the tim_brk input which has a programmable polarity and an enable bit BKE in the TIMx_BDTR Register.

In addition to the break input and the output management, a write protection has been implemented inside the break circuit to safeguard the application. It is used to freeze the configuration of several parameters (dead-time duration, tim_ocx/tim_ocxn polarities and state when disabled, OCxM configurations, break enable and polarity). The protection can be selected among 3 levels with the LOCK bits in the TIMx_BDTR register. Refer to *Section 42.8.14: TIMx break and dead-time register (TIMx_BDTR)(x = 16 to 17)*. The LOCK bits can be written only once after an MCU reset.

The *Figure 585* shows an example of behavior of the outputs in response to a break.

Figure 585. Output behavior in response to a break event on tim_brk



42.4.16 Bidirectional break input

The TIM15/TIM16/TIM17 are featuring bidirectional break I/Os, as represented on *Figure 586*.

They are used to have:

- A board-level global break signal available for signaling faults to external MCUs or gate drivers, with a unique pin being both an input and an output status pin
- Internal break sources and multiple external open drain sources ORed together to trigger a unique break event, when multiple internal and external break sources must be merged

The tim_brk input is configured in bidirectional mode using the BKBID bit in the TIMxBDTR register. The BKBID programming bit can be locked in read-only mode using the LOCK bits in the TIMxBDTR register (in LOCK level 1 or above).

The bidirectional mode requires the I/O to be configured in open-drain mode with active low polarity (using BKINP and BKP bits). Any break request coming either from system (for example CSS), from on-chip peripherals or from break inputs forces a low level on the break input to signal the fault event. The bidirectional mode is inhibited if the polarity bits are not correctly set (active high polarity), for safety purposes.

The break software event (triggered by setting the BG bit) also causes the break I/O to be forced to '0' to indicate to the external components that the timer has entered in break state. However, this is valid only if the break is enabled (BKE = 1). When a software break event is generated with BKE = 0, the outputs are put in safe state and the break flag is set, but there is no effect on the TIM_BKIN I/O.

A safe disarming mechanism prevents the system to be definitively locked-up (a low level on the break input triggers a break which enforces a low level on the same input).

When the BKDSRM bit is set to 1, this releases the break output to clear a fault signal and to give the possibility to re-arm the system.

At no point the break protection circuitry can be disabled:

- The break input path is always active: a break event is active even if the BKDSRM bit is set and the open drain control is released. This prevents the PWM output to be re-started as long as the break condition is present.
- The BKDSRM bit cannot disarm the break protection as long as the outputs are enabled (MOE bit is set) (see *Table 441*)

Table 441. Break protection disarming conditions

MOE	BKBID	BKDSRM	Break protection state
0	0	X	Armed
0	1	0	Armed
0	1	1	Disarmed
1	X	X	Armed

Arming and re-arming break circuitry

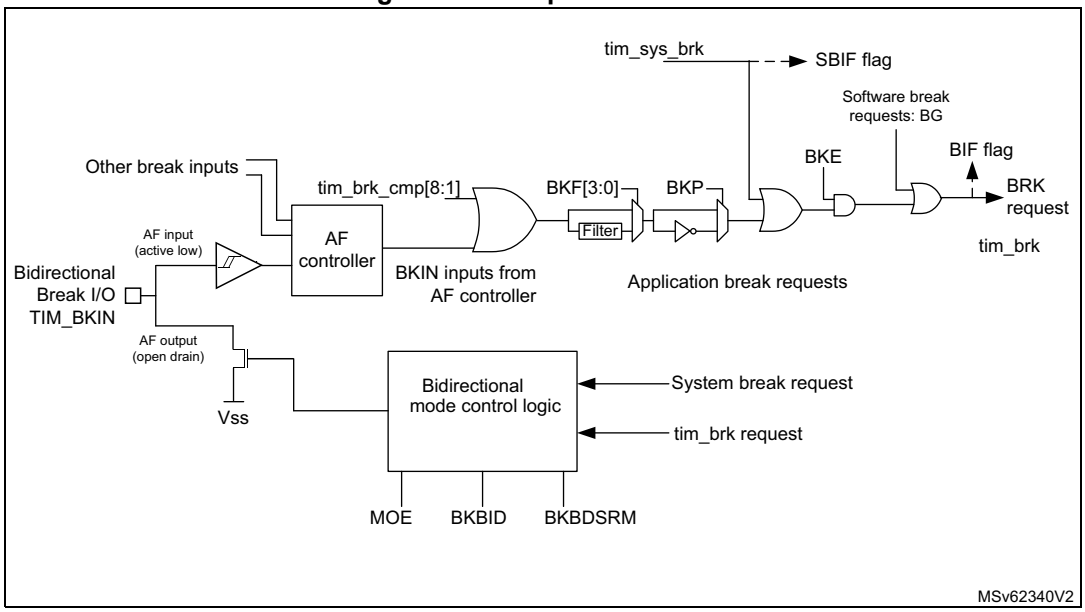
The break circuitry (in input or bidirectional mode) is armed by default (peripheral reset configuration).

The following procedure must be followed to re-arm the protection after a break event:

- The BKDSRM bit must be set to release the output control
- The software must wait until the system break condition disappears (if any) and clear the SBIF status flag (or clear it systematically before re-arming)
- The software must poll the BKDSRM bit until it is cleared by hardware (when the application break condition disappears)

From this point, the break circuitry is armed and active, and the MOE bit can be set to re-enable the PWM outputs.

Figure 586. Output redirection

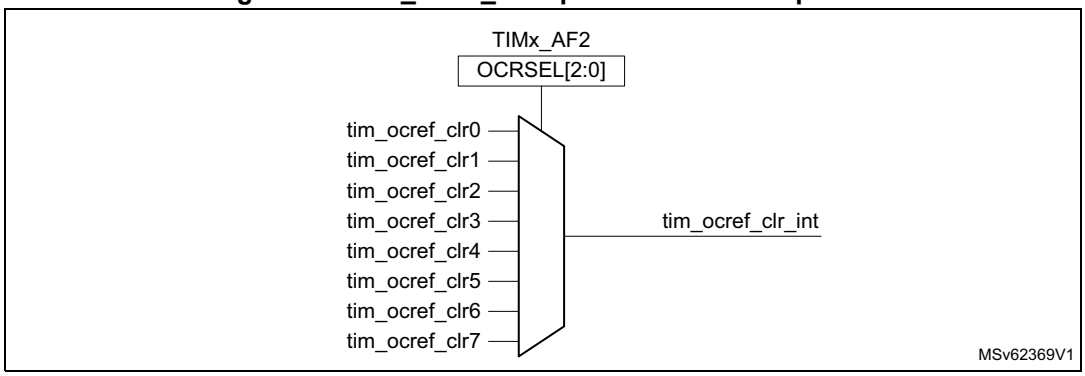


42.4.17 Clearing the tim_ocxref signal on an external event

The tim_ocxref signal of a given channel can be cleared when a high level is applied on the tim_ocref_clr_int input (OCxCE enable bit in the corresponding TIMx_CCMRx register set to 1). tim_ocxref remains low until the next transition to the active state, on the following PWM cycle. This function can only be used in Output compare and PWM modes. It does not work in Forced mode.

The tim_ocref_clr_int input can be selected among several inputs, as shown on *Figure 587* below.

Figure 587. tim_ocref_clr input selection multiplexer



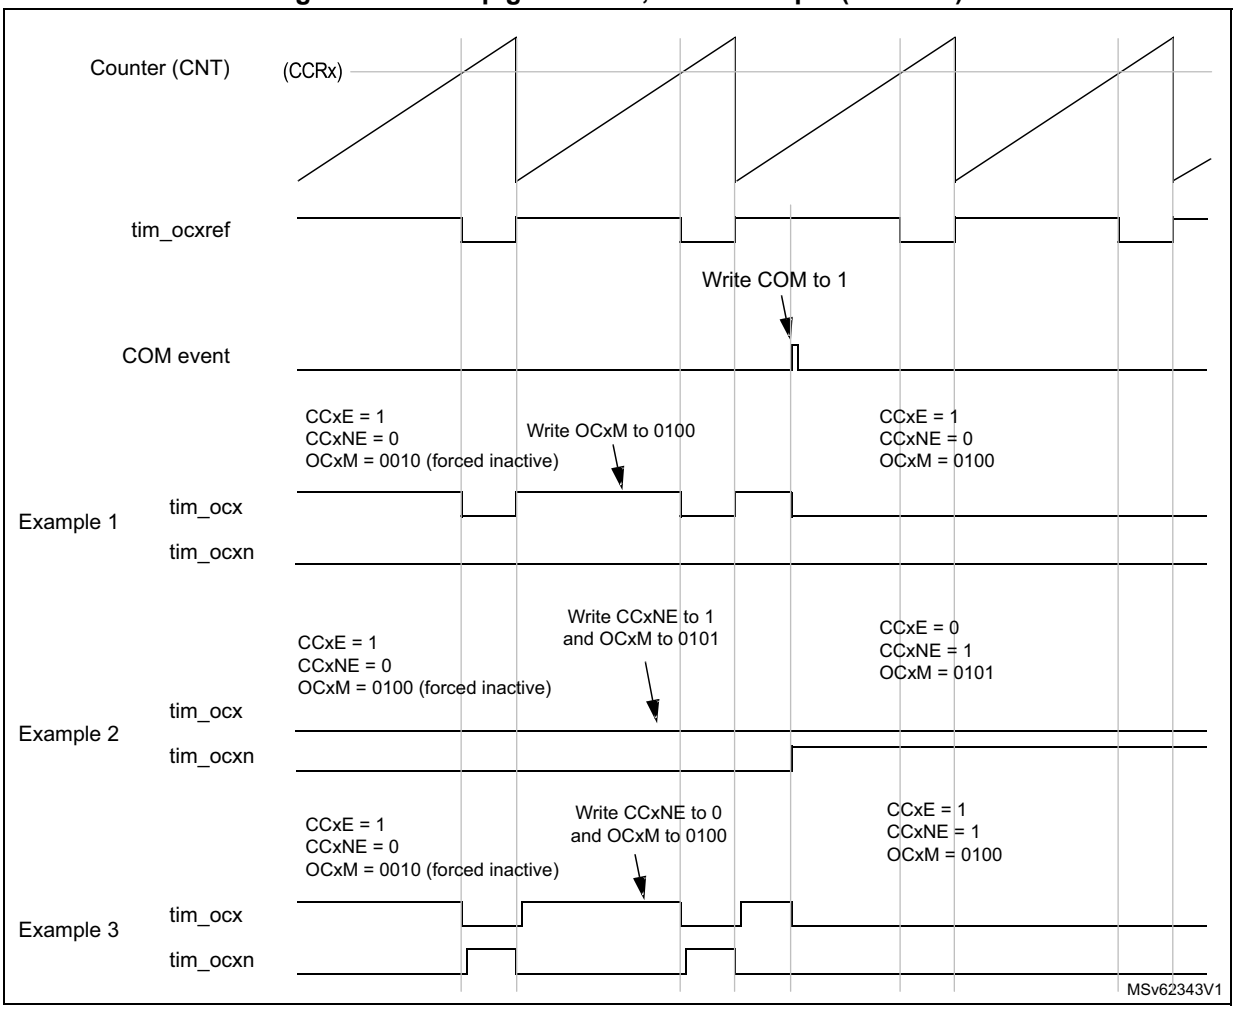
42.4.18 6-step PWM generation

When complementary outputs are used on a channel, preload bits are available on the OCxM, CCxE and CCxNE bits. The preload bits are transferred to the shadow bits at the COM commutation event. Thus one can program in advance the configuration for the next step and change the configuration of all the channels at the same time. COM can be generated by software by setting the COM bit in the TIMx_EGR register or by hardware (on tim_trgi rising edge).

A flag is set when the COM event occurs (COMIF bit in the TIMx_SR register), which can generate an interrupt (if the COMIE bit is set in the TIMx_DIER register) or a DMA request (if the COMDE bit is set in the TIMx_DIER register).

The *Figure 588* describes the behavior of the tim_ocx and tim_ocxn outputs when a COM event occurs, in 3 different examples of programmed configurations.

Figure 588. 6-step generation, COM example (OSSR=1)



42.4.19 One-pulse mode

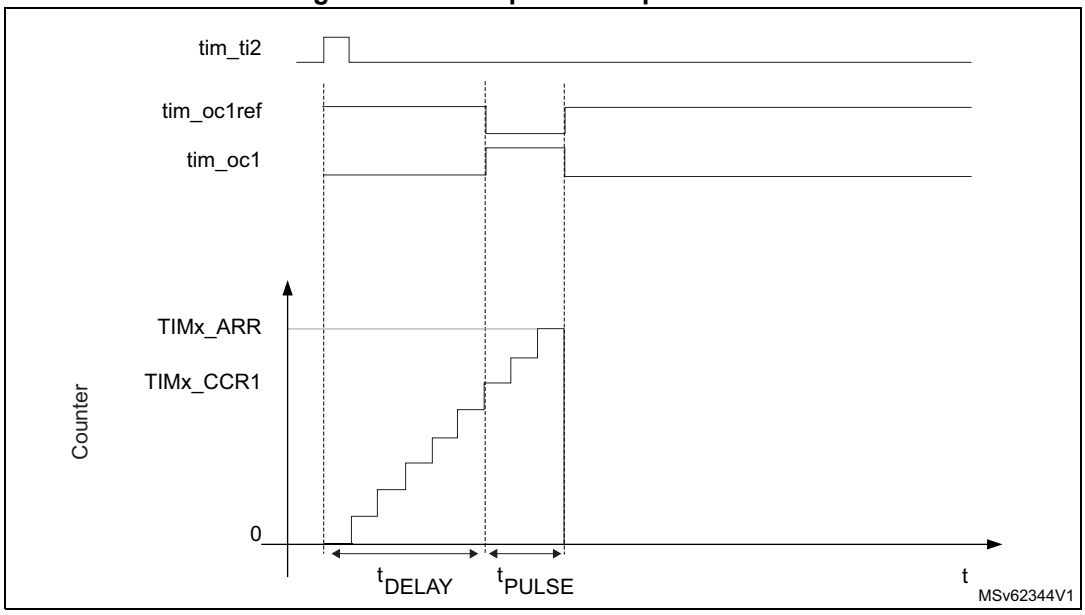
One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- CNT < CCRx ≤ ARR (in particular, 0 < CCRx)

Figure 589. Example of one pulse mode.



For example one may want to generate a positive pulse on tim_oc1 with a length of t_{PULSE} and after a delay of t_{DELAY} as soon as a positive edge is detected on the tim_ti2 input pin.

Let's use tim_ti2fp2 as trigger 1:

1. Select the proper tim_ti2_in[15:1] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Map tim_ti2fp2 to tim_ti2 by writing CC2S='01' in the TIMx_CCMR1 register.
3. tim_ti2fp2 must detect a rising edge, write CC2P='0' and CC2NP='0' in the TIMx_CCER register.
4. Configure tim_ti2fp2 as trigger for the slave mode controller (tim_trgi) by writing TS='00110' in the TIMx_SMCR register.
5. tim_ti2fp2 is used to start the counter by writing SMS to '110' in the TIMx_SMCR register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The t_{DELAY} is defined by the value written in the TIMx_CCR1 register.
- The t_{PULSE} is defined by the difference between the auto-reload value and the compare value (TIMx_ARR - TIMx_CCR1).
- Let's say one want to build a waveform with a transition from '0' to '1' when a compare match occurs and a transition from '1' to '0' when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing OC1M=111 in the TIMx_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE='1' in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case one has to write the compare value in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on tim_ti2. CC1P is written to '0' in this example.

Since only 1 pulse is needed, a 1 must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0).

Particular case: tim_ocx fast enable

In One-pulse mode, the edge detection on tim_tix input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay t_{DELAY} min we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then tim_ocxref (and tim_ocx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

42.4.20 Retriggerable one pulse mode (TIM15 only)

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with Non-retriggerable one pulse mode described in *Section 42.4.19*:

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

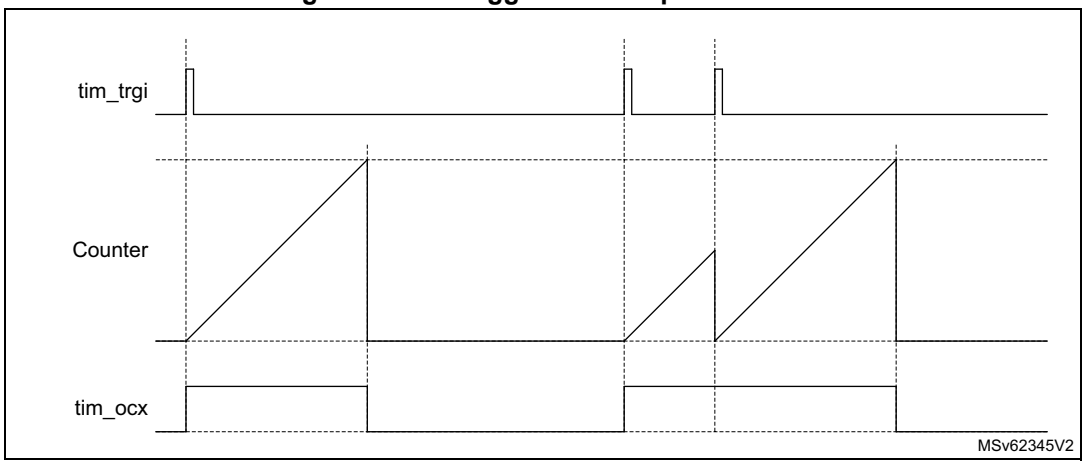
The timer must be in Slave mode, with the bits SMS[3:0] = '1000' (Combined Reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to '1000' or '1001' for Retrigerrable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode, CCRx must be above or equal to ARR.

Note: The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit are not contiguous with the 3 least significant ones.

This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.

Figure 590. Retriggerable one pulse mode



42.4.21 UIF bit remapping

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into bit 31 of the timer counter register (TIMxCNT[31]). This is used to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. In particular cases, it can ease the calculations by avoiding race conditions caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

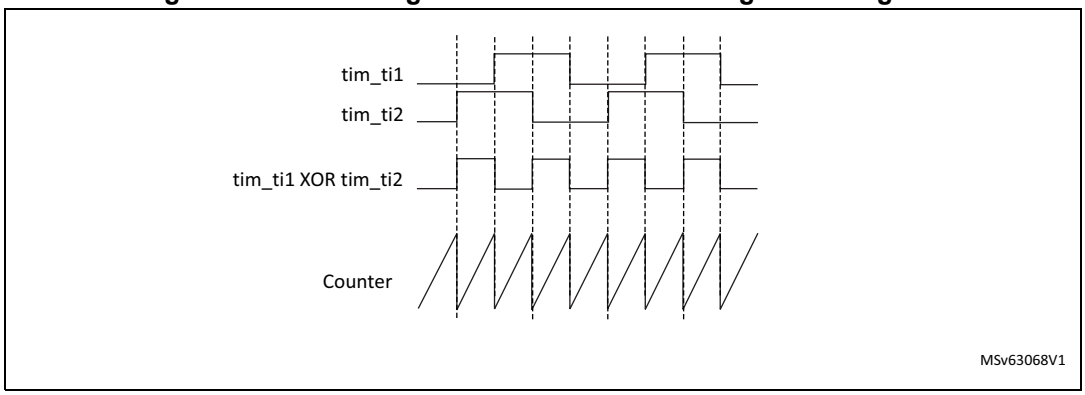
There is no latency between the assertions of the UIF and UIFCPY flags.

42.4.22 Timer input XOR function (TIM15 only)

The TI1S bit in the TIMx_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the two input pins tim_ti1 and tim_ti2.

The XOR output can be used with all the timer input functions such as trigger or input capture. It is useful for measuring the interval between the edges on two input signals, as shown in *Figure 591*.

Figure 591. Measuring time interval between edges on 2 signals



42.4.23 External trigger synchronization (TIM15 only)

The TIM timers are linked together internally for timer synchronization or chaining.

The TIM15 timer can be synchronized with an external trigger in several modes: Reset mode, Gated mode, Trigger mode, Reset + trigger and gated + reset modes.

Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

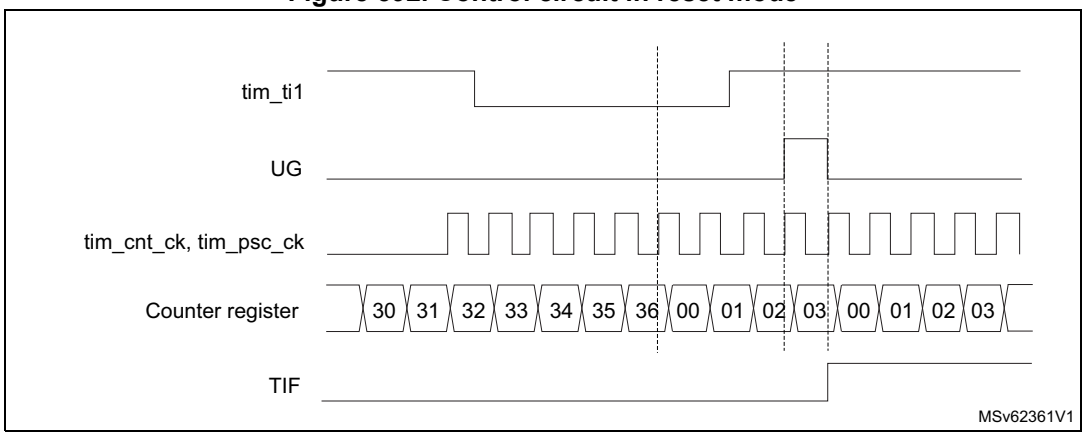
In the following example, the upcounter is cleared in response to a rising edge on tim_ti1 input:

1. Configure the channel 1 to detect rising edges on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P='0' and CC1NP='0' in the TIMx_CCER register to validate the polarity (and detect rising edges only).
2. Configure the timer in reset mode by writing SMS=100 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.
3. Start the counter by writing CEN=1 in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until tim_ti1 rising edge. When tim_ti1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on tim_ti1 and the actual reset of the counter is due to the resynchronization circuit on tim_ti1 input.

Figure 592. Control circuit in reset mode



Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

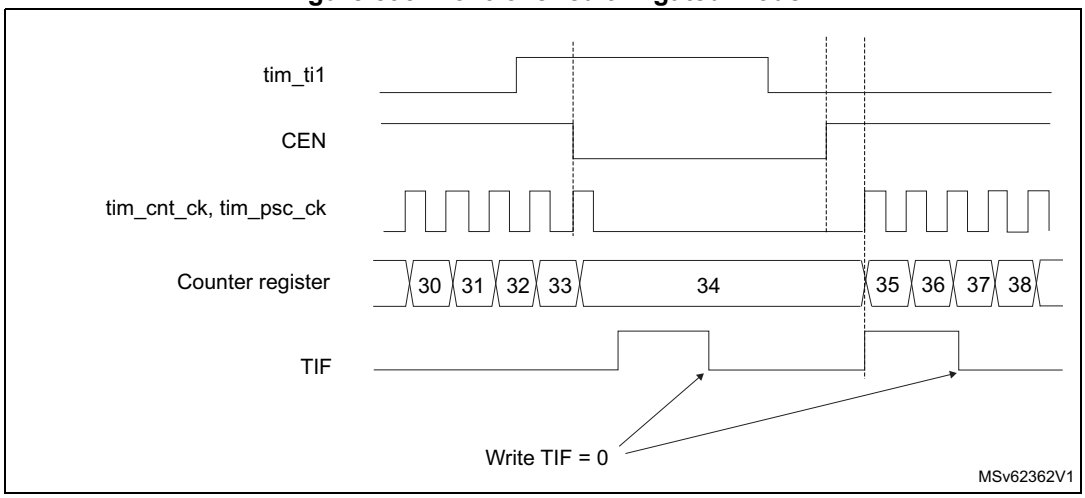
In the following example, the upcounter counts only when tim_ti1 input is low:

1. Configure the channel 1 to detect low levels on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx_CCMR1 register. Write CC1P=1 and CC1NP = '0' in the TIMx_CCER register to validate the polarity (and detect low level only).
2. Configure the timer in gated mode by writing SMS=101 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.
3. Enable the counter by writing CEN=1 in the TIMx_CR1 register (in gated mode, the counter doesn't start if CEN=0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as tim_ti1 is low and stops as soon as tim_ti1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on tim_ti1 and the actual stop of the counter is due to the resynchronization circuit on tim_ti1 input.

Figure 593. Control circuit in gated mode



Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

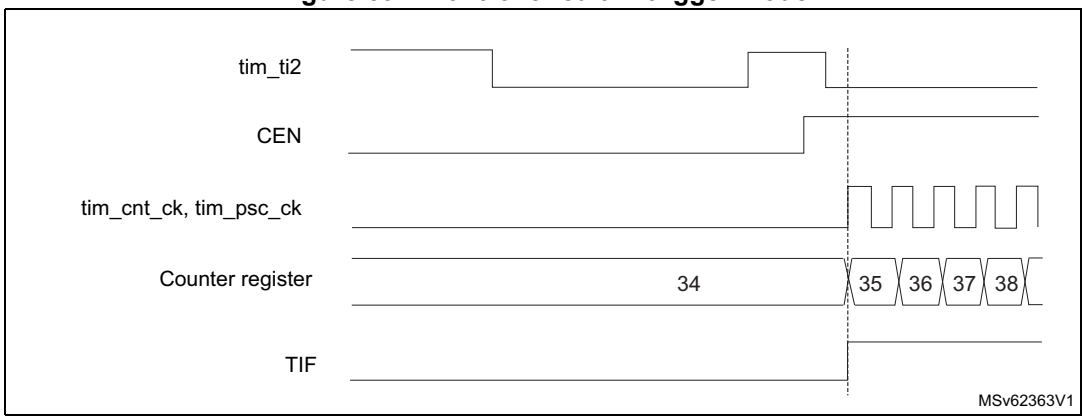
In the following example, the upcounter starts in response to a rising edge on tim_ti2 input:

1. Configure the channel 2 to detect rising edges on tim_ti2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, CC2S=01 in TIMx_CCMR1 register. Write CC2P='1' and CC2NP='0' in the TIMx_CCER register to validate the polarity (and detect low level only).
2. Configure the timer in trigger mode by writing SMS=110 in the TIMx_SMCR register. Select tim_ti2 as the input source by writing TS=00110 in the TIMx_SMCR register.

When a rising edge occurs on tim_ti2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on tim_ti2 and the actual start of the counter is due to the resynchronization circuit on tim_ti2 input.

Figure 594. Control circuit in trigger mode



Slave mode selection preload for run-time update

The SMS[3:0] bit can be preloaded. This is enabled by setting the SMSPE enable bit in the TIMx_SMCR register. The trigger for the transfer from SMS[3:0] preload to active value is the update event (UEV) occurring when the counter overflows.

42.4.24 Slave mode – combined reset + trigger mode (TIM15 only)

In this case, a rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for one-pulse mode.

42.4.25 Slave mode – combined reset + gated mode (TIM15 only)

The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

This mode is used to detect out-of-range PWM signal (duty cycle exceeding a maximum expected value).

42.4.26 Timer synchronization (TIM15 only)

The TIMx timers are linked together internally for timer synchronization or chaining. Refer to *Section 39.4.23: Timer synchronization* for details.

Note: The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

42.4.27 Using timer output as trigger for other timers (TIM16/TIM17 only)

The timers with one channel only do not feature a master mode. However, the OC1 output signal can be used to trigger some other timers (including timers described in other sections of this document). Check the “TIMx internal trigger connection” table of any timer on the device to identify which timers can be targeted as slave.

The OC1 signal pulse width must be programmed to be at least 2 clock cycles of the destination timer, to make sure the slave timer detects the trigger.

For instance, if the destination's timer CK_INT clock is 4 times slower than the source timer, the OC1 pulse width must be 8 clock cycles.

42.4.28 ADC triggers (TIM15 only)

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events.

Note: The clock of the slave peripherals (such as timer, ADC) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

42.4.29 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests on a single event. The main purpose is to be able to re-program several timer registers multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIMx_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx_DMAR register is actually redirected to one of the timer registers.

The DBL[4:0] bits in the TIMx_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx_DCR registers define the DMA base address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.

Example:

00000: TIMx_CR1,

00001: TIMx_CR2,

00010: TIMx_SMCR,

The DBSS[3:0] bits in the TIMx_DCR register defines the interrupt source that triggers the DMA burst transfers (see *Section 42.8.19: TIMx DMA control register (TIMx_DCR)(x = 16 to 17)* for details).

For example, the timer DMA burst feature can be used to update the contents of the CCRx registers (x = 2, 3, 4) on an update event, with the DMA transferring half words into the CCRx registers.

This is done in the following steps:

1. Configure the corresponding DMA channel as follows:
   - DMA channel peripheral address is the DMAR register address
   - DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into the CCRx registers.
   - Number of data to transfer = 3 (See note below).
   - Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bit fields as follows: DBL = 3 transfers, DBA = 0xE and DBSS = 1.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx
5. Enable the DMA channel

This example is for the case where every CCRx register is to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer must be 6. Let's take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3 and data6 is transferred to CCR4.

Note: A null value can be written to the reserved registers.

42.4.30 TIM15/TIM16/TIM17 DMA requests

The TIM15/TIM16/TIM17 can generate a DMA requests, as shown in *Table 442*.

Table 442. DMA request

DMA request signal	DMA request	Enable control bit
tim_upd_dma	Update	UDE
tim_cc1_dma	Capture/compare 1	CC1DE
tim_com_dma(1)	Commutation (COM)	COMDE
tim_trg_dma(1)	Trigger	TDE

1. Available for TIM15 only.

42.4.31 Debug mode

When the microcontroller enters debug mode (Cortex-M33 core halted), the TIMx counter can either continue to work normally or stop.

The behavior in debug mode can be programmed with a dedicated configuration bit per timer in the Debug support (DBG) module.

For safety purposes, when the counter is stopped, the outputs are disabled (as if the MOE bit was reset). The outputs can either be forced to an inactive state (OSSI bit = 1), or have their control taken over by the GPIO controller (OSSI bit = 0) to force them to Hi-Z.

For more details, refer to the debug section.

42.5 TIM15/TIM16/TIM17 low-power modes

Table 443. Effect of low-power modes on TIM15/TIM16/TIM17

Mode	Description
Sleep	No effect, peripheral is active. The interrupts can cause the device to exit from Sleep mode.
Stop	The timer operation is stopped and the register content is kept. No interrupt can be generated.
Standby	The timer is powered-down and must be reinitialized after exiting the Standby mode.

42.6 TIM15/TIM16/TIM17 interrupts

The TIM15/TIM16/TIM17 can generate multiple interrupts, as shown in *Table 444*.

Table 444. Interrupt requests

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit from Sleep mode	Exit from Stop and Standby mode
TIM	Update	UIF	UIE	write 0 in UIF	Yes	No
	Capture/compare 1	CC1IF	CC1IE	write 0 in CC1IF	Yes	No
	Capture/compare 2(1)	CC2IF	CC2IE	write 0 in CC2IF	Yes	No
	Commutation (COM)	COMIF	COMIE	write 0 in COMIF	Yes	No
	Trigger(1)	TIF	TIE	write 0 in TIF	Yes	No
	Break	BIF	BIE	write 0 in BIF	Yes	No

1. Available for TIM15 only.

42.7 TIM15 registers

Refer to *Section 1.2* for a list of abbreviations used in register descriptions.

42.7.1 TIM15 control register 1 (TIM15_CR1)

Address offset: 0x00

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	DITHEN	UIFREMAP	Res.	CKD[1:0]		ARPE	Res.	Res.	Res.	OPM	URS	UDIS	CEN
			rw	rw		rw	rw	rw				rw	rw	rw	rw

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 DITHEN: Dithering enable
0: Dithering disabled
1: Dithering enabled
Note: The DITHEN bit can only be modified when CEN bit is reset.

Bit 11 **UIFREMAP**: UIF status bit remapping
0: No remapping. UIF status bit is not copied to TIM15_CNT register bit 31.
1: Remapping enabled. UIF status bit is copied to TIM15_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division
This bitfield indicates the division ratio between the timer clock (tim_ker_ck) frequency and the dead-time and sampling clock (t_{DTS}) used by the dead-time generators and the digital filters (tim_tix)
00: $t_{DTS} = t_{tim\_ker\_ck}$
01: $t_{DTS} = 2*t_{tim\_ker\_ck}$
10: $t_{DTS} = 4*t_{tim\_ker\_ck}$
11: Reserved

Bit 7 **ARPE**: Auto-reload preload enable
0: TIM15_ARR register is not buffered
1: TIM15_ARR register is buffered

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One-pulse mode
0: Counter is not stopped at update event
1: Counter stops counting at the next update event (clearing the bit CEN)

Bit 2 **URS**: Update request source

This bit is set and cleared by software to select the UEV event sources.

0: Any of the following events generate an update interrupt if enabled. These events can be:

– Counter overflow/underflow

– Setting the UG bit

– Update generation through the slave mode controller

1: Only counter overflow/underflow generates an update interrupt if enabled

Bit 1 **UDIS**: Update disable

This bit is set and cleared by software to enable/disable UEV event generation.

0: UEV enabled. The Update (UEV) event is generated by one of the following events:

– Counter overflow/underflow

– Setting the UG bit

– Update generation through the slave mode controller

Buffered registers are then loaded with their preload values.

1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable

0: Counter disabled

1: Counter enabled

Note: External clock and gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.

42.7.2 TIM15 control register 2 (TIM15_CR2)

Address offset: 0x04

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	OIS2	OIS1N	OIS1	TI1S	MMS[2:0]			CCDS	CCUS	Res.	CCPC
					rw	rw	rw	rw	rw	rw	rw	rw	rw		rw

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **OIS2:** Output idle state 2 (tim_oc2 output)

0: tim_oc2=0 when MOE=0

1: tim_oc2=1 when MOE=0

Note: This bit cannot be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in the TIM15_BKR register).

Bit 9 **OIS1N**: Output Idle state 1 (tim_oc1n output)

0: tim_oc1n=0 after a dead-time when MOE=0

1: tim_oc1n=1 after a dead-time when MOE=0

Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM15_BKR register).

Bit 8 **OIS1**: Output Idle state 1 (tim_oc1 output)

0: tim_oc1=0 after a dead-time when MOE=0

1: tim_oc1=1 after a dead-time when MOE=0

Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM15_BKR register).

Bit 7 **TI1S**: tim_ti1 selection

0: The tim_ti1_in[15:0] multiplexer output is connected to tim_ti1 input

1: The tim_ti1_in[15:0] and tim_ti2_in[15:0] multiplexers output are connected to the tim_ti1 input (XOR combination)

Bits 6:4 **MMS[2:0]**: Master mode selection

These bits are used to select the information to be sent in master mode to slave timers for synchronization (tim_trgo). The combination is as follows:

000: **Reset** - the UG bit from the TIM15_EGR register is used as trigger output (tim_trgo). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on tim_trgo is delayed compared to the actual reset.

001: **Enable** - the Counter Enable signal CNT_EN is used as trigger output (tim_trgo). It is useful to start several timers at the same time or to control a window in which a slave timer is enable. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on tim_trgo, except if the master/slave mode is selected (see the MSM bit description in TIM15_SMCR register).

010: **Update** - The update event is selected as trigger output (tim_trgo). For instance a master timer can then be used as a prescaler for a slave timer.

011: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred (tim_trgo).

100: **Compare** - tim_oc1refc signal is used as trigger output (tim_trgo).

101: **Compare** - tim_oc2refc signal is used as trigger output (tim_trgo).

Bit 3 **CCDS**: Capture/compare DMA selection

0: CCx DMA request sent when CCx event occurs

1: CCx DMA requests sent when update event occurs

Bit 2 **CCUS**: Capture/compare control update selection

0: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit only.

1: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit or when an rising edge occurs on tim_trgi.

Note: This bit acts only on channels that have a complementary output.

Bit 1 Reserved, must be kept at reset value.

Bit 0 **CCPC**: Capture/compare preloaded control

0: CCxE, CCxNE and OCxM bits are not preloaded

1: CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated only when a commutation event (COM) occurs (COMG bit set or rising edge detected on tim_trgi, depending on the CCUS bit).

Note: This bit acts only on channels that have a complementary output.

42.7.3 TIM15 slave mode control register (TIM15_SMCR)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	SMSPE	Res.	Res.	TS[4:3]		Res.	Res.	Res.	SMS[3]
							rw			rw	rw				rw

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MSM	TS[2:0]			Res.	SMS[2:0]		
								rw	rw	rw	rw		rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **SMSPE:** SMS preload enable

This bit selects whether the SMS[3:0] bitfield is preloaded.

0: SMS[3:0] bitfield is not preloaded

1: SMS[3:0] preload is enabled

Bits 23:22 Reserved, must be kept at reset value.

Bits 19:17 Reserved, must be kept at reset value.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **MSM:** Master/slave mode

0: No action

1: The effect of an event on the trigger input (tim_trgi) is delayed to allow a perfect synchronization between the current timer and its slaves (through tim_trgo). It is useful if we want to synchronize several timers on a single external event.

Bits 21, 20, 6, 5, 4 **TS[4:0]:** Trigger selection

This bit field selects the trigger input to be used to synchronize the counter.

00000: Internal Trigger 0 (tim_itr0)
00001: Internal Trigger 1 (tim_itr1)
00010: Internal Trigger 2 (tim_itr2)
00011: Internal Trigger 3 (tim_itr3)
00100: tim_ti1 Edge Detector (tim_ti1f_ed)
00101: Filtered Timer Input 1 (tim_ti1fp1)
00110: Filtered Timer Input 2 (tim_ti2fp2)
00111: Reserved
01000: Internal Trigger 4 (tim_itr4)
01001: Internal Trigger 5 (tim_itr5)
01010: Internal Trigger 6 (tim_itr6)
01011: Internal Trigger 7 (tim_itr7)
01100: Internal Trigger 8 (tim_itr8)
01101: Internal Trigger 9 (tim_itr9)
01110: Internal Trigger 10 (tim_itr10)
10000: Internal trigger 12 (tim_itr12)
10001: Internal trigger 13 (tim_itr13)
10010: Internal trigger 14 (tim_itr14)
10011: Internal trigger 15 (tim_itr15)
Others: Reserved

See *Section 42.4.2: TIM15/TIM16/TIM17 pins and internal signals* for more details on tim_itrx meaning for each timer.

Note: These bits must be changed only when they are not used (for example when SMS=000) to avoid wrong edge detections at the transition.

Bit 3 Reserved, must be kept at reset value.

Bits 16, 2, 1, 0 **SMS[3:0]:** Slave mode selection

When external signals are selected the active edge of the trigger signal (tim_trgi) is linked to the polarity selected on the external input (see Input Control register and Control Register description.

0000: Slave mode disabled - if CEN = ‘1’ then the prescaler is clocked directly by the internal clock.

0001: Reserved

0010: Reserved

0011: Reserved

0100: Reset Mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter and generates an update of the registers.

0101: Gated Mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

0110: Trigger Mode - The counter starts at a rising edge of the trigger tim_trgi (but it is not reset). Only the start of the counter is controlled.

0111: External Clock Mode 1 - Rising edges of the selected trigger (tim_trgi) clock the counter.

1000: Combined reset + trigger mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers and starts the counter.

1001: Combined gated + reset mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

Others: Reserved.

Note: The gated mode must not be used if tim_ti1f_ed is selected as the trigger input (TS=’00100’). Indeed, tim_ti1f_ed outputs 1 pulse for each transition on tim_ti1f, whereas the gated mode checks the level of the trigger signal.

Note: The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

42.7.4 TIM15 DMA/interrupt enable register (TIM15_DIER)

Address offset: 0x0C

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

0: Update interrupt disabled
1: Update interrupt enabled

42.7.5 TIM15 status register (TIM15_SR)

Address offset: 0x10

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	CC2OF	CC1OF	Res.	BIF	TIF	COMIF	Res.	Res.	CC2IF	CC1IF	UIF
					rc_w0	rc_w0		rc_w0	rc_w0	rc_w0			rc_w0	rc_w0	rc_w0

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **CC2OF**: Capture/Compare 2 overcapture flag
Refer to CC1OF description

Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag
This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to ‘0’.
0: No overcapture has been detected
1: The counter value has been captured in TIM15_CCR1 register while CC1IF flag was already set

Bit 8 Reserved, must be kept at reset value.

Bit 7 **BIF**: Break interrupt flag

This flag is set by hardware as soon as the break input goes active. It can be cleared by software if the break input is not active.

0: No break event occurred

1: An active level has been detected on the break input

Bit 6 **TIF**: Trigger interrupt flag

This flag is set by hardware on the TRG trigger event (active edge detected on tim_trgi input when the slave mode controller is enabled in all modes but gated mode, both edges in case gated mode is selected). It is set when the counter starts or stops when gated mode is selected. It is cleared by software.

0: No trigger event occurred

1: Trigger interrupt pending

Bit 5 **COMIF:** COM interrupt flag

This flag is set by hardware on a COM event (once the capture/compare control bits –CCxE, CCxNE, OCxM– have been updated). It is cleared by software.

0: No COM event occurred

1: COM interrupt pending

Bits 4:3 Reserved, must be kept at reset value.

Bit 2 **CC2IF**: Capture/Compare 2 interrupt flag

refer to CC1IF description

Bit 1 **CC1IF**: Capture/Compare 1 interrupt flag

This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx_CCR1 register (input capture mode only).

0: No compare match / No input capture occurred

1: A compare match or an input capture occurred

If channel CC1 is configured as output: this flag is set when the content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in downcounting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx_CR1 register for the full description.

If channel CC1 is configured as input: this bit is set when counter value has been captured in TIMx_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCER).

Bit 0 **UIF**: Update interrupt flag

This bit is set by hardware on an update event. It is cleared by software.

0: No update occurred.

1: Update interrupt pending. This bit is set by hardware when the registers are updated:

– At overflow regarding the repetition counter value (update if repetition counter = 0) and if the UDIS=0 in the TIM15_CR1 register.

– When CNT is reinitialized by software using the UG bit in TIM15_EGR register, if URS=0 and UDIS=0 in the TIM15_CR1 register.

– When CNT is reinitialized by a trigger event (refer to *Section 42.7.3: TIM15 slave mode control register (TIM15_SMCR)*), if URS=0 and UDIS=0 in the TIM15_CR1 register.

42.7.6 TIM15 event generation register (TIM15_EGR)

Address offset: 0x14

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BG	TG	COMG	Res.	Res.	CC2G	CC1G	UG
								w	w	rw			w	w	w

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **BG**: Break generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or DMA transfer can occur if enabled.

Bit 6 **TG**: Trigger generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: The TIF flag is set in TIM15_SR register. Related interrupt or DMA transfer can occur if enabled

Bit 5 **COMG:** Capture/Compare control update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action

1: When the CCPC bit is set, it is possible to update the CCxE, CCxNE and OCxM bits

Note: This bit acts only on channels that have a complementary output.

Bits 4:3 Reserved, must be kept at reset value.

Bit 2 **CC2G**: Capture/Compare 2 generation

Refer to CC1G description

Bit 1 **CC1G**: Capture/Compare 1 generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1 A capture/compare event is generated on channel 1:

If channel CC1 is configured as output:

CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.

If channel CC1 is configured as input:

The current value of the counter is captured in TIM15_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action

1: Reinitialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected).

42.7.7 TIM15 capture/compare mode register 1 (TIM15_CCMR1)

Address offset: 0x18

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IC2F[3:0]				IC2PSC[1:0]		CC2S[1:0]		IC1F[3:0]				IC1PSC[1:0]		CC1S[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Input capture mode

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **IC2F[3:0]**: Input capture 2 filter

Bits 11:10 **IC2PSC[1:0]**: Input capture 2 prescaler

Bits 9:8 **CC2S[1:0]**: Capture/Compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output

01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2

10: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1

11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIM15_SMCR register)

Note: CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIM15_CCER).

Bits 7:4 **IC1F[3:0]**: Input capture 1 filter

This bit-field defines the frequency used to sample tim_ti1 input and the length of the digital filter applied to tim_ti1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at f_{DTS}
0001: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=2
0010: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=4
0011: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=8
0100: $f_{SAMPLING}=f_{DTS}/2$, N=6
0101: $f_{SAMPLING}=f_{DTS}/2$, N=8
0110: $f_{SAMPLING}=f_{DTS}/4$, N=6
0111: $f_{SAMPLING}=f_{DTS}/4$, N=8
1000: $f_{SAMPLING}=f_{DTS}/8$, N=6
1001: $f_{SAMPLING}=f_{DTS}/8$, N=8
1010: $f_{SAMPLING}=f_{DTS}/16$, N=5
1011: $f_{SAMPLING}=f_{DTS}/16$, N=6
1100: $f_{SAMPLING}=f_{DTS}/16$, N=8
1101: $f_{SAMPLING}=f_{DTS}/32$, N=5
1110: $f_{SAMPLING}=f_{DTS}/32$, N=6
1111: $f_{SAMPLING}=f_{DTS}/32$, N=8

Bits 3:2 **IC1PSC[1:0]**: Input capture 1 prescaler

This bit-field defines the ratio of the prescaler acting on CC1 input (tim_ic1). The prescaler is reset as soon as CC1E='0' (TIM15_CCER register).

00: no prescaler, capture is done each time an edge is detected on the capture input
01: capture is done once every 2 events
10: capture is done once every 4 events
11: capture is done once every 8 events

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output
01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1
10: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2
11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIM15_SMCR register)

Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIM15_CCER).

42.7.8 TIM15 capture/compare mode register 1 [alternate] (TIM15_CCMR1)

Address offset: 0x18

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Output compare mode:

Bits 31:25 Reserved, must be kept at reset value.

Bits 23:17 Reserved, must be kept at reset value.

Bit 15 **OC2CE**: Output compare 2 clear enable

Bits 24, 14:12 **OC2M[3:0]**: Output compare 2 mode

Bit 11 **OC2PE**: Output compare 2 preload enable

Bit 10 **OC2FE**: Output compare 2 fast enable

Bits 9:8 **CC2S[1:0]**: Capture/Compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output.

01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2.

10: C2 channel is configured as input, tim_ic2 is mapped on tim_ti1.

11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through the TS bit (TIM15_SMCR register)

Note: CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIM15_CCER).

Bit 7 **OC1CE**: Output compare 1 clear enable

0: tim_oc1ref is not affected by the tim_ocref_clr_int input.

1: tim_oc1ref is cleared as soon as a High level is detected on tim_ocref_clr_int input.

Bits 16, 6:4 **OC1M[3:0]**: Output compare 1 mode

These bits define the behavior of the output reference signal tim_oc1ref from which tim_oc1 and tim_oc1n are derived. tim_oc1ref is active high whereas tim_oc1 and tim_oc1n active level depends on CC1P and CC1NP bits.

0000: Frozen - The comparison between the output compare register TIM15_CCR1 and the counter TIM15_CNT has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the output keeps the state (active or inactive) it had before entering the frozen state.

0001: Set channel 1 to active level on match. tim_oc1ref signal is forced high when the counter TIM15_CNT matches the capture/compare register 1 (TIM15_CCR1).

0010: Set channel 1 to inactive level on match. tim_oc1ref signal is forced low when the counter TIM15_CNT matches the capture/compare register 1 (TIM15_CCR1).

0011: Toggle - tim_oc1ref toggles when TIM15_CNT=TIM15_CCR1.

0100: Force inactive level - tim_oc1ref is forced low.

0101: Force active level - tim_oc1ref is forced high.

0110: PWM mode 1 - Channel 1 is active as long as TIM15_CNT<TIM15_CCR1 else inactive.

0111: PWM mode 2 - Channel 1 is inactive as long as TIM15_CNT<TIM15_CCR1 else active.

1000: Retrigerrable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1001: Retrigerrable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1010: Reserved

1011: Reserved

1100: Combined PWM mode 1 - tim_oc1ref has the same behavior as in PWM mode 1. tim_oc1refc is the logical OR between tim_oc1ref and tim_oc2ref.

1101: Combined PWM mode 2 - tim_oc1ref has the same behavior as in PWM mode 2. tim_oc1refc is the logical AND between tim_oc1ref and tim_oc2ref.

1110: Reserved,

1111: Reserved,

Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIM15_BDTR register) and CC1S='00' (the channel is configured in output).

In PWM mode, the OCREF level changes when the result of the comparison changes, when the output compare mode switches from "frozen" mode to "PWM" mode and when the output compare mode switches from "force active/inactive" mode to "PWM" mode.

On channels that have a complementary output, this bit field is preloaded. If the CCPC bit is set in the TIM15_CR2 register then the OC1M active bits take the new value from the preloaded bits only when a COM event is generated.

Bit 3 **OC1PE**: Output Compare 1 preload enable

0: Preload register on TIM15_CCR1 disabled. TIM15_CCR1 can be written at anytime, the new value is taken in account immediately.

1: Preload register on TIM15_CCR1 enabled. Read/Write operations access the preload register. TIM15_CCR1 preload value is loaded in the active register at each update event.

Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIM15_BDTR register) and CC1S='00' (the channel is configured in output).

Bit 2 **OC1FE**: Output Compare 1 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIMx_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.

0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.

1: An active edge on the trigger input acts like a compare match on CC1 output. Then, tim_ocx is set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output.

01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1.

10: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2.

11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIM15_SMCR register)

Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIM15_CCER).

42.7.9 TIM15 capture/compare enable register (TIM15_CCER)

Address offset: 0x20

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CC2NP	Res.	CC2P	CC2E	CC1NP	CC1NE	CC1P	CC1E
								rw		rw	rw	rw	rw	rw	rw

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **CC2NP**: Capture/Compare 2 complementary output polarity
Refer to CC1NP description

Bit 6 Reserved, must be kept at reset value.

Bit 5 **CC2P**: Capture/Compare 2 output polarity
Refer to CC1P description

Bit 4 **CC2E**: Capture/Compare 2 output enable
Refer to CC1E description

Bit 3 **CC1NP**: Capture/Compare 1 complementary output polarity

CC1 channel configured as output:

0: tim_oc1n active high

1: tim_oc1n active low

CC1 channel configured as input:

This bit is used in conjunction with CC1P to define the polarity of tim_ti1fp1 and tim_ti2fp1. Refer to CC1P description.

Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIM15_BDTR register) and CC1S="00" (the channel is configured in output).

On channels that have a complementary output, this bit is preloaded. If the CCPC bit is set in the TIM15_CR2 register then the CC1NP active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 2 **CC1NE**: Capture/Compare 1 complementary output enable

0: Off - tim_oc1n is not active. tim_oc1n level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.

1: On - tim_oc1n signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.

Bit 1 **CC1P**: Capture/Compare 1 output polarity

CC1 channel configured as output:

0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)

1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

When CC1 channel is configured as input, both CC1NP/CC1P bits select the active polarity of TI1FP1 and TI2FP1 for trigger or capture operations.

CC1NP=0, CC1P=0: non-inverted/rising edge. The circuit is sensitive to TIxFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode).

CC1NP=0, CC1P=1: inverted/falling edge. The circuit is sensitive to TIxFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is inverted (trigger operation in gated mode).

CC1NP=1, CC1P=1: non-inverted/both edges/ The circuit is sensitive to both TIxFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), TIxFP1is not inverted (trigger operation in gated mode).

CC1NP=1, CC1P=0: this configuration is reserved, it must not be used.

Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIM15_BDTR register).

On channels that have a complementary output, this bit is preloaded. If the CCPC bit is set in the TIM15_CR2 register then the CC1P active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 0 **CC1E**: Capture/Compare 1 output enable

0: Capture mode disabled / OC1 is not active (see below)

1: Capture mode enabled / OC1 signal is output on the corresponding output pin

When CC1 channel is configured as output, the OC1 level depends on MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits, regardless of the CC1E bits state. Refer to *Table 445* for details.

Table 445. Output control bits for complementary tim_ocx and tim_ocxn channels with break feature (TIM15)

Control bits					Output states(1)	
MOE bit	OSSI bit	OSSR bit	CCxE bit	CCxNE bit	tim_ocx output state	tim_ocxn output state
1	X	X	0	0	Output Disabled (not driven by the timer: Hi-Z) tim_ocx=0 tim_ocxn=0	
		0	0	1	Output Disabled (not driven by the timer: Hi-Z) tim_ocx=0	tim_ocxref + Polarity tim_ocxn=tim_ocxref XOR CCxNP
		0	1	0	tim_ocxref + Polarity tim_ocx=tim_ocxref XOR CCxP	Output Disabled (not driven by the timer: Hi-Z) tim_ocxn=0
		X	1	1	tim_ocxref + Polarity + dead-time	Complementary to tim_ocxref (not OCREF) + Polarity + dead-time
		1	0	1	Off-State (output enabled with inactive state) tim_ocx=CCxP	tim_ocxref + Polarity tim_ocxn=tim_ocxref XOR CCxNP
		1	1	0	tim_ocxref + Polarity tim_ocx=tim_ocxref xor CCxP	Off-State (output enabled with inactive state) tim_ocxn=CCxNP
0	0	X	X	X	Output disabled (not driven by the timer: Hi-Z)	
	1		0	0		
			0	1	Off-State (output enabled with inactive state) Asynchronously: tim_ocx=CCxP, tim_ocxn=CCxNP Then if the clock is present: tim_ocx=OISx and tim_ocxn=OISxN after a dead-time, assuming that OISx and OISxN do not correspond to tim_ocx and tim_ocxn both in active state	
			1	0		
			1	1		

1. When both outputs of a channel are not used (control taken over by GPIO controller), the OISx, OISxN, CCxP and CCxNP bits must be kept cleared.

Note: The state of the external I/O pins connected to the complementary tim_ocx and tim_ocxn channels depends on the tim_ocx and tim_ocxn channel state and GPIO control and alternate function selection registers.

42.7.10 TIM15 counter (TIM15_CNT)

Address offset: 0x24

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
UIF CPY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CNT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **UIFCPY**: UIF Copy
This bit is a read-only copy of the UIF bit in the TIM15_ISR register.

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:0 **CNT[15:0]**: Counter value
Non-dithering mode (DITHEN = 0)
The register holds the counter value.
Dithering mode (DITHEN = 1)
The register only holds the non-dithered part in CNT[15:0]. The fractional part is not available.

42.7.11 TIM15 prescaler (TIM15_PSC)

Address offset: 0x28

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PSC[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0 **PSC[15:0]**: Prescaler value
The counter clock frequency ($f_{tim\_cnt\_ck}$) is equal to $f_{tim\_psc\_ck}$ / (PSC[15:0] + 1).
PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIM15_EGR register or through trigger controller when configured in “reset mode”).

42.7.12 TIM15 auto-reload register (TIM15_ARR)

Address offset: 0x2C

Reset value: 0x0000 FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ARR[19:16]			
												rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ARR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **ARR[19:0]**: Auto-reload value

ARR is the value to be loaded in the actual auto-reload register.

Refer to the *Section 42.4.3: Time-base unit on page 1776* for more details about ARR update and behavior.

The counter is blocked while the auto-reload value is null.

Non-dithering mode (DITHEN = 0)

The register holds the auto-reload value in ARR[15:0]. The ARR[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the integer part in ARR[19:4]. The ARR[3:0] bitfield contains the dithered part.

42.7.13 TIM15 repetition counter register (TIM15_RCR)

Address offset: 0x30

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	REP[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **REP[7:0]**: Repetition counter reload value

This bitfield defines the update rate of the compare registers (i.e. periodic transfers from preload to active registers) when preload registers are enable. It also defines the update interrupt generation rate, if this interrupt is enable.

When the repetition down-counter reaches zero, an update event is generated and it restarts counting from REP value. As the reptition counter is reloaded with REP value only at the repetition update event UEV, any write to the TIM15_RCR register is not taken in account until the next repetition update event.

It means in PWM mode (REP+1) corresponds to the number of PWM periods in edge-aligned mode:

- the number of PWM periods in edge-aligned mode
- the number of half PWM period in center-aligned mode

42.7.14 TIM15 capture/compare register 1 (TIM15_CCR1)

Address offset: 0x34

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CCR1[19:16]			
												rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCR1[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **CCR1[19:0]**: Capture/compare 1 value

If channel CC1 is configured as output:

CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIM15_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIM15_CNT and signaled on tim_oc1 output.

Non-dithering mode (DITHEN = 0)

The register holds the compare value in CCR1[15:0]. The CCR1[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the integer part in CCR1[19:4]. The CCR1[3:0] bitfield contains the dithered part.

If channel CC1 is configured as input:

CR1 is the counter value transferred by the last input capture 1 event (tim_ic1). The TIMx_CCR1 register is read-only and cannot be programmed.

Non-dithering mode (DITHEN = 0)

The register holds the capture value in CCR1[15:0]. The CCR1[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the capture in CCR1[19:4]. The CCR1[3:0] bits are reset.

42.7.15 TIM15 capture/compare register 2 (TIM15_CCR2)

Address offset: 0x38

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CCR2[19:16]			
												rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCR2[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **CCR2[19:0]**: Capture/compare 2 value

If channel CC2 is configured as output:

CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIM15_CCMR2 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIM15_CNT and signalled on tim_oc2 output.

Non-dithering mode (DITHEN = 0)

The register holds the compare value in CCR2[15:0]. The CCR2[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the integer part in CCR2[19:4]. The CCR2[3:0] bitfield contains the dithered part.

If channel CC2 is configured as input:

CCR2 is the counter value transferred by the last input capture 1 event (tim_ic2). The TIMx_CCR2 register is read-only and cannot be programmed.

Non-dithering mode (DITHEN = 0)

The register holds the capture value in CCR2[15:0]. The CCR2[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the capture in CCR2[19:4]. The CCR2[3:0] bits are reset.

42.7.16 TIM15 break and dead-time register (TIM15_BDTR)

Address offset: 0x44

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	BKBID	Res.	BK DSRM	Res.	Res.	Res.	Res.	Res.	Res.	BKF[3:0]			
			rw		rw							rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MOE	AOE	BKP	BKE	OSSR	OSSI	LOCK[1:0]		DTG[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Note: As the BKBID, BKDSRM, BKF[3:0], AOE, BKP, BKE, OSSI, OSSR and DTG[7:0] bits may be write-locked depending on the LOCK configuration, it may be necessary to configure all of them during the first write access to the TIM15_BDTR register.

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **BKBID**: Break bidirectional

0: Break input tim_brk in input mode
1: Break input tim_brk in bidirectional mode
In the bidirectional mode (BKBID bit set to 1), the break input is configured both in input mode and in open drain output mode. Any active break event asserts a low logic level on the Break input to indicate an internal break event to external devices.

Note: This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 27 Reserved, must be kept at reset value.

Bit 26 **BKDSRM**: Break disarm

0: Break input tim_brk is armed
1: Break input tim_brk is disarmed
This bit is cleared by hardware when no break source is active.
The BKDSRM bit must be set by software to release the bidirectional output control (open-drain output in Hi-Z state) and then be polled until it is reset by hardware, indicating that the fault condition has disappeared.

Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bits 25:20 Reserved, must be kept at reset value.

Bits 19:16 **BKF[3:0]**: Break filter

This bit-field defines the frequency used to sample the tim_brk input signal and the length of the digital filter applied to tim_brk. The digital filter is made of an event counter in which N events are needed to validate a transition on the output:
0000: No filter, tim_brk acts asynchronously
0001: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=2
0010: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=4
0011: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=8
0100: $f_{SAMPLING}=f_{DTS}/2$, N=6
0101: $f_{SAMPLING}=f_{DTS}/2$, N=8
0110: $f_{SAMPLING}=f_{DTS}/4$, N=6
0111: $f_{SAMPLING}=f_{DTS}/4$, N=8
1000: $f_{SAMPLING}=f_{DTS}/8$, N=6
1001: $f_{SAMPLING}=f_{DTS}/8$, N=8
1010: $f_{SAMPLING}=f_{DTS}/16$, N=5
1011: $f_{SAMPLING}=f_{DTS}/16$, N=6
1100: $f_{SAMPLING}=f_{DTS}/16$, N=8
1101: $f_{SAMPLING}=f_{DTS}/32$, N=5
1110: $f_{SAMPLING}=f_{DTS}/32$, N=6
1111: $f_{SAMPLING}=f_{DTS}/32$, N=8

Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 15 **MOE**: Main output enable

This bit is cleared asynchronously by hardware as soon as the tim_brk input is active. It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.

0: tim_ocx and tim_ocxn outputs are disabled or forced to idle state depending on the OSSI bit.

1: tim_ocx and tim_ocxn outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIM15_CCER register)

See tim_ocx/tim_ocxn enable description for more details (*Section 42.7.9: TIM15 capture/compare enable register (TIM15_CCER) on page 1831*).

Bit 14 **AOE**: Automatic output enable

0: MOE can be set only by software

1: MOE can be set by software or automatically at the next update event (if the break input is not be active)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 13 **BKP**: Break polarity

0: Break input tim_brk is active low

1: Break input tim_brk is active high

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 12 **BKE**: Break enable

0: Break inputs (tim_brk and tim_sys_brk clock failure event) disabled

1; Break inputs (tim_brk and tim_sys_brk clock failure event) enabled

This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 11 **OSSR**: Off-state selection for Run mode

This bit is used when MOE=1 on channels that have a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.

See tim_ocx/tim_ocxn enable description for more details (*Section 42.7.9: TIM15 capture/compare enable register (TIM15_CCER) on page 1831*).

0: When inactive, tim_ocx/tim_ocxn outputs are disabled (the timer releases the output control which is taken over by the GPIO, which forces a Hi-Z state)

1: When inactive, tim_ocx/tim_ocxn outputs are enabled with their inactive level as soon as CCxE=1 or CCxNE=1 (the output is still controlled by the timer).

Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 10 **OSSI**: Off-state selection for Idle mode

This bit is used when MOE=0 on channels configured as outputs.

See tim_ocx/tim_ocxn enable description for more details (*Section 42.7.9: TIM15 capture/compare enable register (TIM15_CCER) on page 1831*).

0: When inactive, tim_ocx/tim_ocxn outputs are disabled (tim_ocx/tim_ocxn enable output signal=0)

1: When inactive, tim_ocx/tim_ocxn outputs are forced first with their idle level as soon as CCxE=1 or CCxNE=1. tim_ocx/tim_ocxn enable output signal=1)

Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIM15_BDTR register).

Bits 9:8 **LOCK[1:0]**: Lock configuration

These bits offer a write protection against software errors.

00: LOCK OFF - No bit is write protected

01: LOCK Level 1 = DTG bits in TIM15_BDTR register, OISx and OISxN bits in TIM15_CR2 register and BKBID/BKE/BKP/AOE bits in TIM15_BDTR register can no longer be written

10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIM15_CCER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written.

11: OCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIM15_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written.

Note: The LOCK bits can be written only once after the reset. Once the TIM15_BDTR register has been written, their content is frozen until the next reset.

Bits 7:0 **DTG[7:0]**: Dead-time generator setup

This bit-field defines the duration of the dead-time inserted between the complementary outputs. DT correspond to this duration.

DTG[7:5]=0xx => DT=DTG[7:0]x t_{dtg} with $t_{dtg}=t_{DTS}$

DTG[7:5]=10x => DT=(64+DTG[5:0])xt_{dtg} with $T_{dtg}=2xt_{DTS}$

DTG[7:5]=110 => DT=(32+DTG[4:0])xt_{dtg} with $T_{dtg}=8xt_{DTS}$

DTG[7:5]=111 => DT=(32+DTG[4:0])xt_{dtg} with $T_{dtg}=16xt_{DTS}$

Example if T_{DTS}=125ns (8MHz), dead-time possible values are:

0 to 15875 ns by 125 ns steps,

16 µs to 31750 ns by 250 ns steps,

32 µs to 63 µs by 1 µs steps,

64 µs to 126 µs by 2 µs steps

Note: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM15_BDTR register).

42.7.17 TIM15 timer deadtime register 2 (TIM15_DTR2)

Address offset: 0x054

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DTPE	DTAE
														rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DTGF[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **DTPE**: Deadtime preload enable

0: Deadtime value is not preloaded

1: Deadtime value preload is enabled

Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 16 **DTAE**: Deadtime asymmetric enable
0: Deadtime on rising and falling edges are identical, and defined with DTG[7:0] register
1: Deadtime on rising edge is defined with DTG[7:0] register and deadtime on falling edge is defined with DTGF[7:0] bits.
Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM15_BDTR register).

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **DTGF[7:0]**: Dead-time falling edge generator setup
This bit-field defines the duration of the dead-time inserted between the complementary outputs, on the falling edge.
DTGF[7:5]=0xx => DTF=DTGF[7:0]x t_{dtg} with $t_{dtg}=t_{DTS}$.
DTGF[7:5]=10x => DTF=(64+DTGF[5:0])xt_{dtg} with $T_{dtg}=2xt_{DTS}$.
DTGF[7:5]=110 => DTF=(32+DTGF[4:0])xt_{dtg} with $T_{dtg}=8xt_{DTS}$.
DTGF[7:5]=111 => DTF=(32+DTGF[4:0])xt_{dtg} with $T_{dtg}=16xt_{DTS}$.
Example if T_{DTS}=125ns (8MHz), dead-time possible values are:
0 to 15875 ns by 125 ns steps,
16 us to 31750 ns by 250 ns steps,
32 us to 63us by 1 us steps,
64 us to 126 us by 2 us steps
Note: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM15_BDTR register).

42.7.18 TIM15 input selection register (TIM15_TISEL)

Address offset: 0x5C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	TI2SEL[3:0]				Res.	Res.	Res.	Res.	TI1SEL[3:0]			
				rw	rw	rw	rw					rw	rw	rw	rw

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:8 **TI2SEL[3:0]**: selects tim_ti2_in[15:0] input
0000: TIM15_CH2 input (tim_ti2_in0)
0001: tim_ti2_in1
...
1111: tim_ti2_in15
Refer to *Section 42.4.2: TIM15/TIM16/TIM17 pins and internal signals* for interconnects list.

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **TI1SEL[3:0]**: selects tim_ti1_in[15:0] input
0000: TIM15_CH1 input (tim_ti1_in0)
0001: tim_ti1_in1
...
1111: tim_ti1_in15
Refer to *Section 42.4.2: TIM15/TIM16/TIM17 pins and internal signals* for interconnects list.

42.7.19 TIM15 alternate function register 1 (TIM15_AF1)

Address offset: 0x060

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	BK CMP4P	BK CMP3P	BK CMP2P	BK CMP1P	BKINP	BK CMP8E	BK CMP7E	BK CMP6E	BK CMP5E	BK CMP4E	BK CMP3E	BK CMP2E	BK CMP1E	BKINE
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Refer to *Section 42.4.2: TIM15/TIM16/TIM17 pins and internal signals* for product specific implementation.

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **BKCMP4P**: tim_brk_cmp4 input polarity

This bit selects the tim_brk_cmp4 input sensitivity. It must be programmed together with the BKP polarity bit.

0: tim_brk_cmp4 input is active high

1: tim_brk_cmp4 input is active low

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 12 **BKCMP3P**: tim_brk_cmp3 input polarity

This bit selects the tim_brk_cmp3 input sensitivity. It must be programmed together with the BKP polarity bit.

0: tim_brk_cmp3 input is active high

1: tim_brk_cmp3 input is active low

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 11 **BKCMP2P**: tim_brk_cmp2 input polarity

This bit selects the tim_brk_cmp2 input sensitivity. It must be programmed together with the BKP polarity bit.

0: tim_brk_cmp2 input is active high

1: tim_brk_cmp2 input is active low

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 10 **BKCMP1P**: tim_brk_cmp1 input polarity

This bit selects the tim_brk_cmp1 input sensitivity. It must be programmed together with the BKP polarity bit.

0: tim_brk_cmp1 input is active high

1: tim_brk_cmp1 input is active low

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 9 **BKINP**: TIMx_BKIN input polarity

This bit selects the TIMx_BKIN alternate function input sensitivity. It must be programmed together with the BKP polarity bit.

0: TIMx_BKIN input is active high

1: TIMx_BKIN input is active low

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 8 **BKCMP8E**: tim_brk_cmp8 enable

This bit enables the tim_brk_cmp8 for the timer's tim_brk input. mdf_brkx output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp8 input disabled

1: tim_brk_cmp8 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 7 **BKCMP7E**: tim_brk_cmp7 enable

This bit enables the tim_brk_cmp7 for the timer's tim_brk input. COMP7 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp7 input disabled

1: tim_brk_cmp7 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 6 **BKCMP6E**: tim_brk_cmp6 enable

This bit enables the tim_brk_cmp6 for the timer's tim_brk input. tim_brk_cmp6 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp6 input disabled

1: tim_brk_cmp6 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 5 **BKCMP5E**: tim_brk_cmp5 enable

This bit enables the tim_brk_cmp5 for the timer's tim_brk input. tim_brk_cmp5 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp5 input disabled

1: tim_brk_cmp5 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 4 **BKCMP4E**: tim_brk_cmp4 enable

This bit enables the tim_brk_cmp4 for the timer's tim_brk input. tim_brk_cmp4 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp4 input disabled

1: tim_brk_cmp4 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 3 **BKCMP3E**: tim_brk_cmp3 enable

This bit enables the tim_brk_cmp3 for the timer's tim_brk input. tim_brk_cmp3 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp3 input disabled

1: tim_brk_cmp3 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 2 **BKCMP2E**: tim_brk_cmp2 enable

This bit enables the tim_brk_cmp2 for the timer's tim_brk input. tim_brk_cmp2 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp2 input disabled

1: tim_brk_cmp2 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 1 **BKCMP1E**: tim_brk_cmp1 enable

This bit enables the tim_brk_cmp1 for the timer's tim_brk input. tim_brk_cmp1 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp1 input disabled

1: tim_brk_cmp1 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 0 **BKINE**: TIMx_BKIN input enable

This bit enables the TIMx_BKIN alternate function input for the timer's tim_brk input. TIMx_BKIN input is 'ORed' with the other tim_brk sources.

0: TIMx_BKIN input disabled

1: TIMx_BKIN input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

42.7.20 TIM15 alternate function register 2 (TIM15_AF2)

Address offset: 0x064

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OCRSEL[2:0]		
													rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **OCRSEL[2:0]**: ocref_clr source selection

These bits select the ocref_clr input source.

000: tim_ocref_clr0

001: tim_ocref_clr1

010: tim_ocref_clr2

011: tim_ocref_clr3

100: tim_ocref_clr4

101: tim_ocref_clr5

110: tim_ocref_clr6

111: tim_ocref_clr7

Refer to *Section 42.4.2: TIM15/TIM16/TIM17 pins and internal signals* for product specific implementation.

Note: These bits can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Bits 15:0 Reserved, must be kept at reset value.

42.7.21 TIM15 DMA control register (TIM15_DCR)

Address offset: 0x3DC

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DBSS[3:0]			
												rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	DBL[4:0]					Res.	Res.	Res.	DBA[4:0]				
			rw	rw	rw	rw	rw				rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:16 **DBSS[3:0]**: DMA burst source selection

This bitfield defines the interrupt source that triggers the DMA burst transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address).

0000: Reserved

0001: Update

0010: CC1

0110: COM

0111: Trigger

Other: reserved

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **DBL[4:0]**: DMA burst length

This 5-bit field defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIM15_DMAR address).

00000: 1 transfer,
00001: 2 transfers,
00010: 3 transfers,
...
10001: 18 transfers.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DBA[4:0]**: DMA base address

This 5-bit field defines the base-address for DMA transfers (when read/write access are done through the TIM15_DMAR address). DBA is defined as an offset starting from the address of the TIM15_CR1 register.

Example:

00000: TIM15_CR1,
00001: TIM15_CR2,
00010: TIM15_SMCR,
...

42.7.22 TIM15 DMA address for full transfer (TIM15_DMAR)

Address offset: 0x3E0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DMAB[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DMAB[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DMAB[31:0]**: DMA register for burst accesses

A read or write operation to the DMAR register accesses the register located at the address

(TIM15_CR1 address) + (DBA + DMA index) x 4

where TIM15_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIM15_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIM15_DCR).

42.7.23 TIM15 register map

TIM15 registers are mapped as 16-bit addressable registers as described in the table below:

Table 446. TIM15 register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3 on page 111* for the register boundary addresses.

42.8 TIM16/TIM17 registers

Refer to *Section 1.2* for a list of abbreviations used in register descriptions.

42.8.1 TIMx control register 1 (TIMx_CR1)(x = 16 to 17)

Address offset: 0x00

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	DITHEN	UIFREMAP	Res.	CKD[1:0]		ARPE	Res.	Res.	Res.	OPM	URS	UDIS	CEN
			rw	rw		rw	rw	rw				rw	rw	rw	rw

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **DITHEN**: Dithering enable
0: Dithering disabled
1: Dithering enabled
Note: The DITHEN bit can only be modified when CEN bit is reset.

Bit 11 **UIFREMAP**: UIF status bit remapping
0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division
This bit-field indicates the division ratio between the timer clock (tim_ker_ck) frequency and the dead-time and sampling clock (t_{DTS})used by the dead-time generators and the digital filters (tim_tix),
00: $t_{DTS}=t_{tim\_ker\_ck}$
01: $t_{DTS}=2*t_{tim\_ker\_ck}$
10: $t_{DTS}=4*t_{tim\_ker\_ck}$
11: Reserved

Bit 7 **ARPE**: Auto-reload preload enable
0: TIMx_ARR register is not buffered
1: TIMx_ARR register is buffered

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One pulse mode
0: Counter is not stopped at update event
1: Counter stops counting at the next update event (clearing the bit CEN)

Bit 2 **URS**: Update request source
This bit is set and cleared by software to select the UEV event sources.
0: Any of the following events generate an update interrupt or DMA request if enabled. These events can be:
– Counter overflow/underflow
– Setting the UG bit
– Update generation through the slave mode controller
1: nly counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS**: Update disable

This bit is set and cleared by software to enable/disable UEV event generation.

0: UEV enabled. The Update (UEV) event is generated by one of the following events:

– Counter overflow/underflow

– Setting the UG bit

– Update generation through the slave mode controller

Buffered registers are then loaded with their preload values.

1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable

0: Counter disabled

1: Counter enabled

Note: External clock and gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.

42.8.2 TIMx control register 2 (TIMx_CR2)(x = 16 to 17)

Address offset: 0x04

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	OIS1N	OIS1	Res.	Res.	Res.	Res.	CCDS	CCUS	Res.	CCPC
						rw	rw					rw	rw		rw

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **OIS1N**: Output Idle state 1 (tim_oc1n output)

0: tim_oc1n=0 after a dead-time when MOE=0

1: tim_oc1n=1 after a dead-time when MOE=0

Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BKR register).

Bit 8 **OIS1**: Output Idle state 1 (tim_oc1 output)

0: tim_oc1=0 after a dead-time when MOE=0

1: tim_oc1=1 after a dead-time when MOE=0

Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BKR register).

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **CCDS**: Capture/compare DMA selection

0: CCx DMA request sent when CCx event occurs

1: CCx DMA requests sent when update event occurs

Bit 2 **CCUS**: Capture/compare control update selection

0: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit only.

1: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit or when a rising edge occurs on tim_trgi (if available).

Note: This bit acts only on channels that have a complementary output.

Bit 1 Reserved, must be kept at reset value.

Bit 0 **CCPC**: Capture/compare preloaded control
0: CCxE, CCxNE and OCxM bits are not preloaded
1: CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated only when COM bit is set.
Note: This bit acts only on channels that have a complementary output.

42.8.3 TIMx DMA/interrupt enable register (TIMx_DIER)(x = 16 to 17)

Address offset: 0x0C

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	CC1DE	UDE	BIE	Res.	COMIE	Res.	Res.	Res.	CC1IE	UIE
						rw	rw	rw		rw				rw	rw

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **CC1DE**: Capture/Compare 1 DMA request enable
0: CC1 DMA request disabled
1: CC1 DMA request enabled

Bit 8 **UDE**: Update DMA request enable
0: Update DMA request disabled
1: Update DMA request enabled

Bit 7 **BIE**: Break interrupt enable
0: Break interrupt disabled
1: Break interrupt enabled

Bit 6 Reserved, must be kept at reset value.

Bit 5 **COMIE:** COM interrupt enable
0: COM interrupt disabled
1: COM interrupt enabled

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **CC1IE**: Capture/Compare 1 interrupt enable
0: CC1 interrupt disabled
1: CC1 interrupt enabled

Bit 0 **UIE**: Update interrupt enable
0: Update interrupt disabled
1: Update interrupt enabled

42.8.4 TIMx status register (TIMx_SR)(x = 16 to 17)

Address offset: 0x10

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	CC1OF	Res.	BIF	Res.	COMIF	Res.	Res.	Res.	CC1IF	UIF
						rc_w0		rc_w0		rc_w0				rc_w0	rc_w0

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag

This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to ‘0’.

0: No overcapture has been detected

1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set

Bit 8 Reserved, must be kept at reset value.

Bit 7 **BIF**: Break interrupt flag

This flag is set by hardware as soon as the tim_brk input goes active. It can be cleared by software if the break input is not active.

0: No break event occurred

1: An active level has been detected on the break input

Bit 6 Reserved, must be kept at reset value.

Bit 5 **COMIF:** COM interrupt flag

This flag is set by hardware on a COM event (once the capture/compare control bits –CCxE, CCxNE, OCxM– have been updated). It is cleared by software.

0: No COM event occurred

1: COM interrupt pending

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **CC1IF**: Capture/Compare 1 interrupt flag

This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx_CCR1 register (input capture mode only).

0: No compare match / No input capture occurred

1: A compare match or an input capture occurred

If channel CC1 is configured as output: this flag is set when the content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in down-counting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx_CR1 register for the full description.

If channel CC1 is configured as input: this bit is set when counter value has been captured in TIMx_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCER).

Bit 0 **UIF**: Update interrupt flag

This bit is set by hardware on an update event. It is cleared by software.

0: No update occurred.

1: Update interrupt pending. This bit is set by hardware when the registers are updated:

– At overflow regarding the repetition counter value (update if repetition counter = 0) and if the UDIS=0 in the TIMx_CR1 register.

– When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS=0 and UDIS=0 in the TIMx_CR1 register.

42.8.5 TIMx event generation register (TIMx_EGR)(x = 16 to 17)

Address offset: 0x14

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BG	Res.	COMG	Res.	Res.	Res.	CC1G	UG
								w		w				w	w

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **BG**: Break generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action.

1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or DMA transfer can occur if enabled.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **COMG:** Capture/Compare control update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action

1: When the CCPC bit is set, it is possible to update the CCxE, CCxNE and OCxM bits

Note: This bit acts only on channels that have a complementary output.

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **CC1G**: Capture/Compare 1 generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action.

1: A capture/compare event is generated on channel 1:

If channel CC1 is configured as output:

CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.

If channel CC1 is configured as input:

The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action.

1: Reinitialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected).

42.8.6 TIMx capture/compare mode register 1 (TIMx_CCMR1) (x = 16 to 17)

Address offset: 0x18

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IC1F[3:0]				IC1PSC[1:0]		CC1S[1:0]	
								rw	rw	rw	rw	rw	rw	rw	rw

Input capture mode

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **IC1F[3:0]**: Input capture 1 filter

This bit-field defines the frequency used to sample tim_ti1 input and the length of the digital filter applied to tim_ti1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at f_{DTS}
0001: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=2
0010: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=4
0011: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=8
0100: $f_{SAMPLING}=f_{DTS}/2$, N=
0101: $f_{SAMPLING}=f_{DTS}/2$, N=8
0110: $f_{SAMPLING}=f_{DTS}/4$, N=6
0111: $f_{SAMPLING}=f_{DTS}/4$, N=8
1000: $f_{SAMPLING}=f_{DTS}/8$, N=6
1001: $f_{SAMPLING}=f_{DTS}/8$, N=8
1010: $f_{SAMPLING}=f_{DTS}/16$, N=5
1011: $f_{SAMPLING}=f_{DTS}/16$, N=6
1100: $f_{SAMPLING}=f_{DTS}/16$, N=8
1101: $f_{SAMPLING}=f_{DTS}/32$, N=5
1110: $f_{SAMPLING}=f_{DTS}/32$, N=6
1111: $f_{SAMPLING}=f_{DTS}/32$, N=8

Bits 3:2 **IC1PSC[1:0]**: Input capture 1 prescaler

This bit-field defines the ratio of the prescaler acting on CC1 input (tim_ic1).
The prescaler is reset as soon as CC1E='0' (TIMx_CCER register).
00: no prescaler, capture is done each time an edge is detected on the capture input.
01: capture is done once every 2 events
10: capture is done once every 4 events
11: capture is done once every 8 events

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1

Others: Reserved

Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx_CCER).

42.8.7 TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1)(x = 16 to 17)

Address offset: 0x18

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OC1M[3]
															rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OC1CE	OC1M[2:0]			OC1PE	OC1FE	CC1S[1:0]	
								rw	rw	rw	rw	rw	rw	rw	rw

Output compare mode:

Bits 31:17 Reserved, must be kept at reset value.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **OC1CE**: Output Compare 1 clear enable

0: tim_oc1ref is not affected by the tim_ocref_clr input.

1: tim_oc1ref is cleared as soon as a High level is detected on tim_ocref_clr input.

Bits 16, 6:4 **OC1M[3:0]**: Output Compare 1 mode

These bits define the behavior of the output reference signal tim_oc1ref from which tim_oc1 and tim_oc1n are derived. tim_oc1ref is active high whereas tim_oc1 and tim_oc1n active level depends on CC1P and CC1NP bits.

0000: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the output keeps the state (active or inactive) it had before entering the frozen state.

0001: Set channel 1 to active level on match. tim_oc1ref signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0010: Set channel 1 to inactive level on match. tim_oc1ref signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0011: Toggle - tim_oc1ref toggles when TIMx_CNT=TIMx_CCR1.

0100: Force inactive level - tim_oc1ref is forced low.

0101: Force active level - tim_oc1ref is forced high.

0110: PWM mode 1 - Channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else inactive.

0111: PWM mode 2 - Channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else active.

Others: Reserved

Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00' (the channel is configured in output).

In PWM mode, the OCREF level changes when the result of the comparison changes, when the output compare mode switches from "frozen" mode to "PWM" mode and when the output compare mode switches from "force active/inactive" mode to "PWM" mode.

Bit 3 **OC1PE**: Output Compare 1 preload enable

0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken in account immediately.

1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded in the active register at each update event.

Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00' (the channel is configured in output).

Bit 2 **OC1FE**: Output Compare 1 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIMx_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.

0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.

1: An active edge on the trigger input acts like a compare match on CC1 output. Then, tim_ocx is set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OC1FE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1

Others: Reserved

Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx_CCER).

42.8.8 TIMx capture/compare enable register (TIMx_CCER)(x = 16 to 17)

Address offset: 0x20

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CC1NP	CC1NE	CC1P	CC1E
												rw	rw	rw	rw

Bits 15:4 Reserved, must be kept at reset value.

Bit 3 **CC1NP**: Capture/Compare 1 complementary output polarity

CC1 channel configured as output:

0: tim_oc1n active high

1: tim_oc1n active low

CC1 channel configured as input:

This bit is used in conjunction with CC1P to define the polarity of tim_ti1fp1. Refer to the description of CC1P.

Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S=”00” (the channel is configured in output).

On channels that have a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1NP active bit takes the new value from the preloaded bit only when a commutation event is generated.

Bit 2 **CC1NE**: Capture/Compare 1 complementary output enable

0: Off - tim_oc1n is not active. tim_oc1n level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.

1: On - tim_oc1n signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.

Bit 1 **CC1P**: Capture/Compare 1 output polarity

0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)

1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

When CC1 channel is configured as input, both CC1NP/CC1P bits select the active polarity of TI1FP1 and TI2FP1 for trigger or capture operations.

CC1NP=0, CC1P=0: non-inverted/rising edge. The circuit is sensitive to TIxFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode).

CC1NP=0, CC1P=1: inverted/falling edge. The circuit is sensitive to TIxFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is inverted (trigger operation in gated mode).

CC1NP=1, CC1P=1: non-inverted/both edges/ The circuit is sensitive to both TIxFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), TIxFP1is not inverted (trigger operation in gated mode).

CC1NP=1, CC1P=0: this configuration is reserved, it must not be used.

Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

On channels that have a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1P active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 0 **CC1E**: Capture/Compare 1 output enable

0: Capture mode disabled / OC1 is not active (see below)

1: Capture mode enabled / OC1 signal is output on the corresponding output pin

When CC1 channel is configured as output, the OC1 level depends on MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits, regardless of the CC1E bits state. Refer to *Table 447* for details.

Table 447. Output control bits for complementary tim_oc1 and tim_oc1n channels with break feature (TIM16/TIM17)

Control bits					Output states(1)	
MOE bit	OSSI bit	OSSR bit	CC1E bit	CC1NE bit	tim_oc1 output state	tim_oc1n output state
1	X	X	0	0	Output Disabled (not driven by the timer: Hi-Z) tim_oc1=0 tim_oc1n=0	
		0	0	1	Output Disabled (not driven by the timer: Hi-Z) tim_oc1=0	tim_oc1ref + Polarity tim_oc1n=tim_oc1ref XOR CC1NP
		0	1	0	tim_oc1ref + Polarity tim_oc1=tim_oc1ref XOR CC1P	Output Disabled (not driven by the timer: Hi-Z) tim_oc1n=0
		X	1	1	tim_oc1ref + Polarity + dead-time	Complementary to tim_oc1ref (not tim_oc1ref) + Polarity + dead-time
		1	0	1	Off-State (output enabled with inactive state) tim_oc1=CC1P	tim_oc1ref + Polarity tim_oc1n=tim_oc1ref XOR CC1NP
		1	1	0	tim_oc1ref + Polarity tim_oc1=tim_oc1ref XOR CC1P	Off-State (output enabled with inactive state) tim_oc1n=CC1NP
0	0	X	X	X	Output disabled (not driven by the timer: Hi-Z)	
	1		0	0		
			0	1	Off-State (output enabled with inactive state) Asynchronously: tim_oc1=CC1P, tim_oc1n=CC1NP Then if the clock is present: tim_oc1=OIS1 and tim_oc1n=OIS1N after a dead-time, assuming that OIS1 and OIS1N do not correspond to tim_oc1 and tim_oc1n both in active state	
			1	0		
			1	1		

1. When both outputs of a channel are not used (control taken over by GPIO controller), the OIS1, OIS1N, CC1P and CC1NP bits must be kept cleared.

Note: The state of the external I/O pins connected to the complementary tim_oc1 and tim_oc1n channels depends on the tim_oc1 and tim_oc1n channel state and GPIO control and alternate function selection registers.

42.8.9 TIMx counter (TIMx_CNT)(x = 16 to 17)

Address offset: 0x24

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CNT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **UIFCPY**: UIF Copy

This bit is a read-only copy of the UIF bit of the TIMx_ISR register. If the UIFREMAP bit in TIMx_CR1 is reset, bit 31 is reserved.

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:0 **CNT[15:0]**: Counter value

Non-dithering mode (DITHEN = 0)

The register holds the counter value.

Dithering mode (DITHEN = 1)

The register only holds the non-dithered part in CNT[15:0]. The fractional part is not available.

42.8.10 TIMx prescaler (TIMx_PSC)(x = 16 to 17)

Address offset: 0x28

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PSC[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0 **PSC[15:0]**: Prescaler value

The counter clock frequency (tim_cnt_ck) is equal to $f_{tim\_psc\_ck}$ / (PSC[15:0] + 1).

PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in “reset mode”).

42.8.11 TIMx auto-reload register (TIMx_ARR)(x = 16 to 17)

Address offset: 0x2C

Reset value: 0x0000 FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ARR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **ARR[19:0]**: Auto-reload value

ARR is the value to be loaded in the actual auto-reload register.

Refer to the *Section 42.4.3: Time-base unit on page 1776* for more details about ARR update and behavior.

The counter is blocked while the auto-reload value is null.

Non-dithering mode (DITHEN = 0)

The register holds the auto-reload value in ARR[15:0]. The ARR[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the integer part in ARR[19:4]. The ARR[3:0] bitfield contains the dithered part.

42.8.12 TIMx repetition counter register (TIMx_RCR)(x = 16 to 17)

Address offset: 0x30

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	REP[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **REP[7:0]**: Repetition counter reload value

This bitfield defines the update rate of the compare registers (i.e. periodic transfers from preload to active registers) when preload registers are enable. It also defines the update interrupt generation rate, if this interrupt is enable.

When the repetition down-counter reaches zero, an update event is generated and it restarts counting from REP value. As the repetition counter is reloaded with REP value only at the repetition update event UEV, any write to the TIMx_RCR register is not taken in account until the next repetition update event.

It means in PWM mode (REP+1) corresponds to the number of PWM periods in edge-aligned mode:

- the number of PWM periods in edge-aligned mode
- the number of half PWM period in center-aligned mode

42.8.13 TIMx capture/compare register 1 (TIMx_CCR1)(x = 16 to 17)

Address offset: 0x34

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CCR1[19:16]			
												rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCR1[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **CCR1[19:0]**: Capture/Compare 1 value

If channel CC1 is configured as output:
CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc1 output.
Non-dithering mode (DITHEN = 0)
The register holds the compare value in CCR1[15:0]. The CCR1[19:16] bits are reset.
Dithering mode (DITHEN = 1)
The register holds the integer part in CCR1[19:4]. The CCR1[3:0] bitfield contains the dithered part.
If channel CC1 is configured as input:
CCR1 is the counter value transferred by the last input capture 1 event (tim_ic1).
Non-dithering mode (DITHEN = 0)
The register holds the capture value in CCR1[15:0]. The CCR1[19:16] bits are reset.
Dithering mode (DITHEN = 1)
The register holds the capture in CCR1[19:4]. The CCR1[3:0] bits are reset.

42.8.14 TIMx break and dead-time register (TIMx_BDTR)(x = 16 to 17)

Address offset: 0x44

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	BKBID	Res.	BK DSRM	Res.	Res.	Res.	Res.	Res.	Res.	BKF[3:0]			
			rw		rw							rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MOE	AOE	BKP	BKE	OSSR	OSSI	LOCK[1:0]		DTG[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Note: As the BKBID, BKDSRM, BKF[3:0], AOE, BKP, BKE, OSSI, OSSR and DTG[7:0] bits may be write-locked depending on the LOCK configuration, it may be necessary to configure all of them during the first write access to the TIMx_BDTR register.

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **BKBID**: Break Bidirectional

0: Break input tim_brk in input mode
1: Break input tim_brk in bidirectional mode
In the bidirectional mode (BKBID bit set to 1), the break input is configured both in input mode and in open drain output mode. Any active break event asserts a low logic level on the Break input to indicate an internal break event to external devices.

Note: This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 27 Reserved, must be kept at reset value.

Bit 26 **BKDSRM**: Break Disarm

0: Break input tim_brk is armed
1: Break input tim_brk is disarmed
This bit is cleared by hardware when no break source is active.
The BKDSRM bit must be set by software to release the bidirectional output control (open-drain output in Hi-Z state) and then be polled it until it is reset by hardware, indicating that the fault condition has disappeared.

Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bits 25:20 Reserved, must be kept at reset value.

Bits 19:16 **BKF[3:0]**: Break filter

This bit-field defines the frequency used to sample tim_brk input and the length of the digital filter applied to tim_brk. The digital filter is made of an event counter in which N events are needed to validate a transition on the output:

0000: No filter, tim_brk acts asynchronously
0001: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=2
0010: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=4
0011: $f_{SAMPLING}=f_{tim\_ker\_ck}$, N=8
0100: $f_{SAMPLING}=f_{DTS}/2$, N=6
0101: $f_{SAMPLING}=f_{DTS}/2$, N=8
0110: $f_{SAMPLING}=f_{DTS}/4$, N=6
0111: $f_{SAMPLING}=f_{DTS}/4$, N=8
1000: $f_{SAMPLING}=f_{DTS}/8$, N=6
1001: $f_{SAMPLING}=f_{DTS}/8$, N=8
1010: $f_{SAMPLING}=f_{DTS}/16$, N=5
1011: $f_{SAMPLING}=f_{DTS}/16$, N=6
1100: $f_{SAMPLING}=f_{DTS}/16$, N=8
1101: $f_{SAMPLING}=f_{DTS}/32$, N=5
1110: $f_{SAMPLING}=f_{DTS}/32$, N=6
1111: $f_{SAMPLING}=f_{DTS}/32$, N=8

This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 15 **MOE**: Main output enable

This bit is cleared asynchronously by hardware as soon as the tim_brk input is active. It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.

0: tim_oc1 and tim_oc1n outputs are disabled or forced to idle state depending on the OSSI bit.

1: tim_oc1 and tim_oc1n outputs are enabled if their respective enable bits are set (CC1E, CC1NE in TIMx_CCER register)

See tim_oc1/tim_oc1n enable description for more details (*Section 42.8.8: TIMx capture/compare enable register (TIMx_CCER)(x = 16 to 17) on page 1857*).

Bit 14 **AOE**: Automatic output enable

0: MOE can be set only by software

1: MOE can be set by software or automatically at the next update event (if the tim_brk input is not active)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 13 **BKP**: Break polarity

0: Break input tim_brk is active low
1: Break input tim_brk is active high

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 12 **BKE**: Break enable

0: Break inputs (tim_brk and tim_sys_brk event) disabled
1; Break inputs (tim_brk and tim_sys_brk event) enabled

Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 11 **OSSR**: Off-state selection for Run mode

This bit is used when MOE=1 on channels that have a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.

See tim_oc1/tim_oc1n enable description for more details (*Section 42.8.8: TIMx capture/compare enable register (TIMx_CCER)(x = 16 to 17) on page 1857*).

0: When inactive, tim_oc1/tim_oc1n outputs are disabled (the timer releases the output control which is taken over by the GPIO, which forces a Hi-Z state)

1: When inactive, tim_oc1/tim_oc1n outputs are enabled with their inactive level as soon as CC1E=1 or CC1NE=1 (the output is still controlled by the timer).

Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 10 **OSSI**: Off-state selection for Idle mode

This bit is used when MOE=0 on channels configured as outputs.

See tim_oc1/tim_oc1n enable description for more details (*Section 42.8.8: TIMx capture/compare enable register (TIMx_CCER)(x = 16 to 17) on page 1857*).

0: When inactive, tim_oc1/tim_oc1n outputs are disabled (tim_oc1/tim_oc1n enable output signal=0)

1: When inactive, tim_oc1/tim_oc1n outputs are forced first with their idle level as soon as CC1E=1 or CC1NE=1. tim_oc1/tim_oc1n enable output signal=1)

Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 9:8 **LOCK[1:0]**: Lock configuration

These bits offer a write protection against software errors.

00: LOCK OFF - No bit is write protected

01: LOCK Level 1 = DTG bits in TIMx_BDTR register, OISx and OISxN bits in TIMx_CR2 register and BKBID/BKE/BKP/AOE bits in TIMx_BDTR register can no longer be written.

10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIMx_CCER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written.

11: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIMx_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written.

Note: The LOCK bits can be written only once after the reset. Once the TIMx_BDTR register has been written, their content is frozen until the next reset.

Bits 7:0 **DTG[7:0]**: Dead-time generator setup

This bit-field defines the duration of the dead-time inserted between the complementary outputs. DT correspond to this duration.

DTG[7:5]=0xx => DT=DTG[7:0]x t_{dtg} with $t_{dtg}=t_{DTS}$

DTG[7:5]=10x => DT=(64+DTG[5:0])xt_{dtg} with $T_{dtg}=2xt_{DTS}$

DTG[7:5]=110 => DT=(32+DTG[4:0])xt_{dtg} with $T_{dtg}=8xt_{DTS}$

DTG[7:5]=111 => DT=(32+DTG[4:0])xt_{dtg} with $T_{dtg}=16xt_{DTS}$

Example if T_{DTS}=125ns (8MHz), dead-time possible values are:

0 to 15875 ns by 125 ns steps,

16 µs to 31750 ns by 250 ns steps,

32 µs to 63 µs by 1 µs steps,

64 µs to 126 µs by 2 µs steps

Note: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

42.8.15 TIMx timer deadtime register 2 (TIMx_DTR2)(x = 16 to 17)

Address offset: 0x054

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DTPE	DTAE
														rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DTGF[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **DTPE**: Deadtime preload enable

0: Deadtime value is not preloaded

1: Deadtime value preload is enabled

Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 16 **DTAE**: Deadtime asymmetric enable

0: Deadtime on rising and falling edges are identical, and defined with DTG[7:0] register

1: Deadtime on rising edge is defined with DTG[7:0] register and deadtime on falling edge is defined with DTGF[7:0] bits.

Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **DTGF[7:0]**: Dead-time falling edge generator setup

This bit-field defines the duration of the dead-time inserted between the complementary outputs, on the falling edge.

DTGF[7:5]=0xx => DTF=DTGF[7:0]x t_{dtg} with $t_{dtg}=t_{DTS}$.

DTGF[7:5]=10x => DTF=(64+DTGF[5:0])xt_{dtg} with $T_{dtg}=2xt_{DTS}$.

DTGF[7:5]=110 => DTF=(32+DTGF[4:0])xt_{dtg} with $T_{dtg}=8xt_{DTS}$.

DTGF[7:5]=111 => DTF=(32+DTGF[4:0])xt_{dtg} with $T_{dtg}=16xt_{DTS}$.

Example if T_{DTS}=125ns (8MHz), dead-time possible values are:

0 to 15875 ns by 125 ns steps,

16 us to 31750 ns by 250 ns steps,

32 us to 63us by 1 us steps,

64 us to 126 us by 2 us steps

Note: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

42.8.16 TIMx input selection register (TIMx_TISEL)(x = 16 to 17)

Address offset: 0x5C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Refer to *Section 42.4.2: TIM15/TIM16/TIM17 pins and internal signals* for product specific implementation.

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **BKCMP4P**: tim_brk_cmp4 input polarity
This bit selects the tim_brk_cmp4 input sensitivity. It must be programmed together with the BKP polarity bit.
0: tim_brk_cmp4 input is active high
1: tim_brk_cmp4 input is active low

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 12 **BKCMP3P**: tim_brk_cmp3 input polarity

This bit selects the tim_brk_cmp3 input sensitivity. It must be programmed together with the BKP polarity bit.

0: tim_brk_cmp3 input is active high

1: tim_brk_cmp3 input is active low

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 11 **BKCMP2P**: tim_brk_cmp2 input polarity

This bit selects the tim_brk_cmp2 input sensitivity. It must be programmed together with the BKP polarity bit.

0: tim_brk_cmp2 input is active high

1: tim_brk_cmp2 input is active low

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 10 **BKCMP1P**: tim_brk_cmp1 input polarity

This bit selects the tim_brk_cmp1 input sensitivity. It must be programmed together with the BKP polarity bit.

0: tim_brk_cmp1 input is active high

1: tim_brk_cmp1 input is active low

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 9 **BKINP**: TIMx_BKIN input polarity

This bit selects the TIMx_BKIN alternate function input sensitivity. It must be programmed together with the BKP polarity bit.

0: TIMx_BKIN input is active high

1: TIMx_BKIN input is active low

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 8 **BKCMP8E**: tim_brk_cmp8 enable

This bit enables the tim_brk_cmp8 for the timer's tim_brk input. mdf_brkx output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp8 input disabled

1: tim_brk_cmp8 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 7 **BKCMP7E**: tim_brk_cmp7 enable

This bit enables the tim_brk_cmp7 for the timer's tim_brk input. tim_brk_cmp7 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp7 input disabled

1: tim_brk_cmp7 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 6 **BKCMP6E**: tim_brk_cmp6 enable

This bit enables the tim_brk_cmp6 for the timer's tim_brk input. tim_brk_cmp6 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp6 input disabled

1: tim_brk_cmp6 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 5 **BKCMP5E**: tim_brk_cmp5 enable

This bit enables the tim_brk_cmp5 for the timer's tim_brk input. tim_brk_cmp5 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp5 input disabled

1: tim_brk_cmp5 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 4 **BKCMP4E**: tim_brk_cmp4 enable

This bit enables the tim_brk_cmp4 for the timer's tim_brk input. tim_brk_cmp4 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp4 input disabled

1: tim_brk_cmp4 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 3 **BKCMP3E**: tim_brk_cmp3 enable

This bit enables the tim_brk_cmp3 for the timer's tim_brk input. tim_brk_cmp3 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp3 input disabled

1: tim_brk_cmp3 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 2 **BKCMP2E**: tim_brk_cmp2 enable

This bit enables the tim_brk_cmp2 for the timer's tim_brk input. tim_brk_cmp2 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp2 input disabled

1: tim_brk_cmp2 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 1 **BKCMP1E**: tim_brk_cmp1 enable

This bit enables the tim_brk_cmp1 for the timer's tim_brk input. tim_brk_cmp1 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp1 input disabled

1: tim_brk_cmp1 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 0 **BKINE**: TIMx_BKIN input enable

This bit enables the TIMx_BKIN alternate function input for the timer's tim_brk input. TIMx_BKIN input is 'ORed' with the other tim_brk sources.

0: TIMx_BKIN input disabled

1: TIMx_BKIN input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

42.8.18 TIMx alternate function register 2 (TIMx_AF2)(x = 16 to 17)

Address offset: 0x064

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OCRSEL[2:0]

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **OCRSEL[2:0]**: tim_ocref_clr source selection

These bits select the tim_ocref_clr input source.

000: tim_ocref_clr0

001: tim_ocref_clr1

010: tim_ocref_clr2

011: tim_ocref_clr3

100: tim_ocref_clr4

101: tim_ocref_clr5

110: tim_ocref_clr6

111: tim_ocref_clr7

Refer to *Section 42.4.2: TIM15/TIM16/TIM17 pins and internal signals* for product specific implementation.

Note: These bits can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 15:0 Reserved, must be kept at reset value.

42.8.19 TIMx DMA control register (TIMx_DCR)(x = 16 to 17)

Address offset: 0x3DC

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DBSS[3:0]			
												rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	DBL[4:0]					Res.	Res.	Res.	DBA[4:0]				
			rw	rw	rw	rw	rw				rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:16 **DBSS[3:0]**: DMA burst source selection

This bitfield defines the interrupt source that triggers the DMA burst transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address).

0000: Reserved

0001: Update

0010: CC1

Other: reserved

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **DBL[4:0]**: DMA burst length

This 5-bit field defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e. the number of transfers. Transfers can be in half-words or in bytes (see example below).

00000: 1 transfer,
00001: 2 transfers,
00010: 3 transfers,
...
10001: 18 transfers.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DBA[4:0]**: DMA base address

This 5-bit field defines the base-address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.

Example:
00000: TIMx_CR1,
00001: TIMx_CR2,
00010: TIMx_SMCR,
...

Example: Let us consider the following transfer: DBL = 7 transfers and DBA = TIMx_CR1. In this case the transfer is done to/from 7 registers starting from the TIMx_CR1 address.

42.8.20 TIM16/TIM17 DMA address for full transfer (TIMx_DMAR)(x = 16 to 17)

Address offset: 0x3E0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DMAB[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DMAB[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DMAB[31:0]**: DMA register for burst accesses

A read or write operation to the DMAR register accesses the register located at the address

(TIMx_CR1 address) + (DBA + DMA index) x 4

where TIMx_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIMx_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx_DCR).

42.8.21 TIM16/TIM17 register map

TIM16/TIM17 registers are mapped as 16-bit addressable registers as described in the table below:

Table 448. TIM16/TIM17 register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3* for the register boundary addresses.

43 Low-power timer (LPTIM)

43.1 Introduction

The LPTIM is a 16-bit timer that benefits from the ultimate developments in power consumption reduction. Thanks to its diversity of clock sources, the LPTIM is able to keep running in all power modes except for Standby mode. Given its capability to run even with no internal clock source, the LPTIM can be used as a “Pulse Counter” which can be useful in some applications. Also, the LPTIM capability to wake up the system from low-power modes, makes it suitable to realize “Timeout functions” with extremely low power consumption.

The LPTIM introduces a flexible clock scheme that provides the needed functionalities and performance, while minimizing the power consumption.

43.2 LPTIM main features

- 16 bit upcounter
- 3-bit prescaler with 8 possible dividing factors (1,2,4,8,16,32,64,128)
- Selectable clock
  - Internal clock sources: configurable internal clock source (see RCC section)
  - External clock source over LPTIM input (working with no LP oscillator running, used by Pulse Counter application)
- 16 bit ARR autoreload register
- 16 bit capture/compare register
- Continuous/One-shot mode
- Selectable software/hardware input trigger
- Programmable Digital Glitch filter
- Configurable output: Pulse, PWM
- Configurable I/O polarity
- Encoder mode
- Repetition counter
- Up to 2 independent channels for:
  - Input capture
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Interrupt generation on 10 events
- DMA request generation on the following events:
  - Update event
  - Input capture

43.3 LPTIM implementation

Table 449 describes LPTIM implementation on STM32H563/H573 and STM32H562 devices. The full set of features is implemented in LPTIM1, 2, 3, 5 and 6. LPTIM4 supports a smaller set of features.

Table 449. STM32H563/H573 and STM32H562 LPTIM features

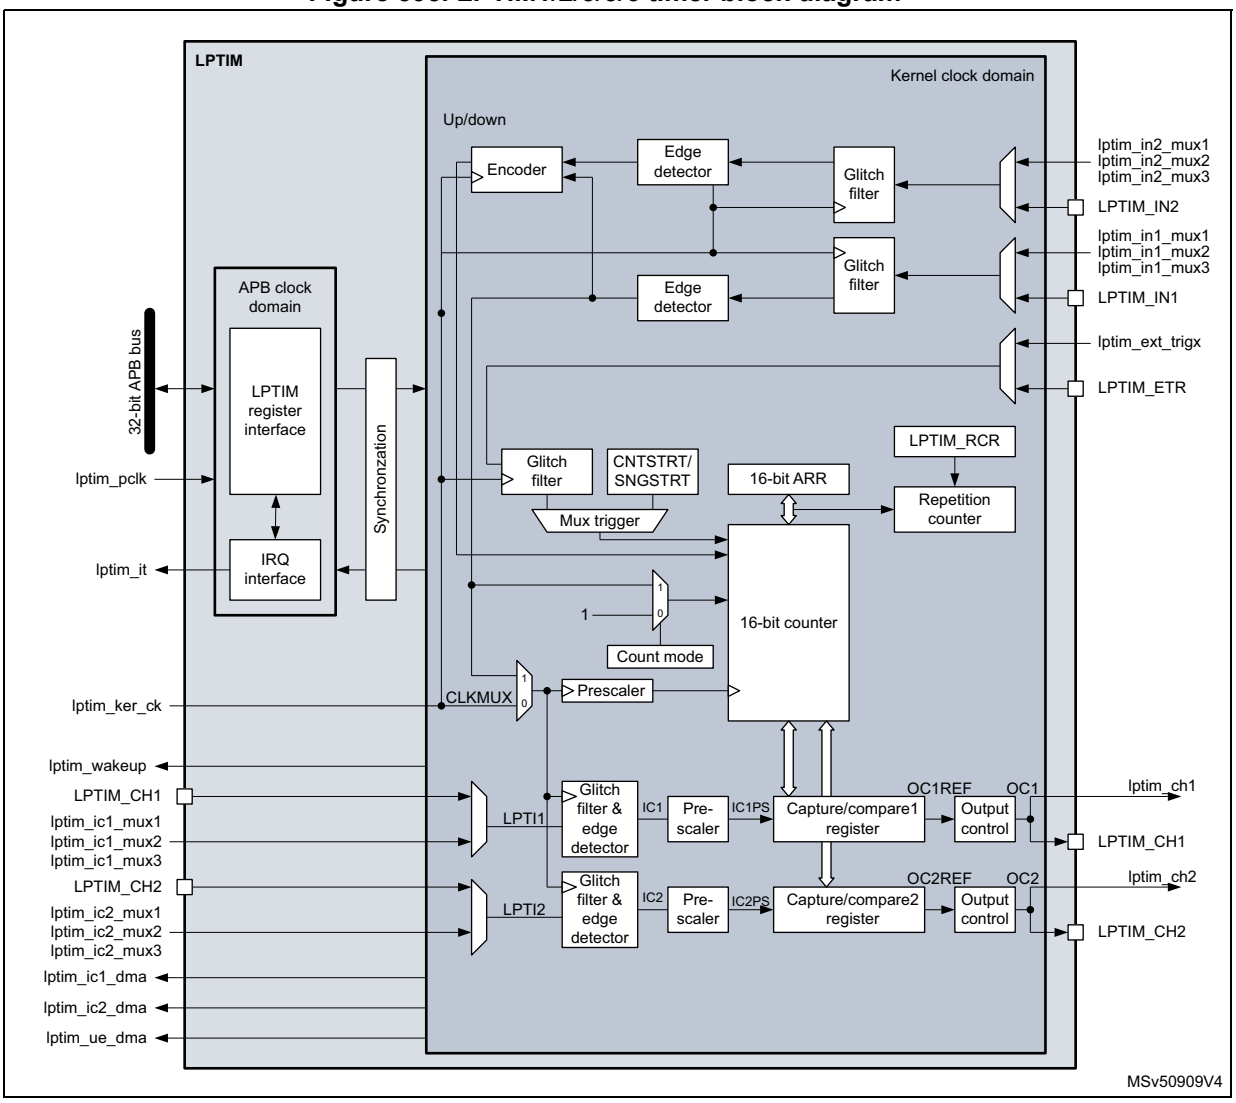
LPTIM modes/features(1)	LPTIM1	LPTIM2	LPTIM3	LPTIM4	LPTIM5	LPTIM6
Encoder mode	X	X	X	-	X	X
PWM mode	X	X	X	X	X	X
Input Capture	X	X	X	-	X	X
Number of channels	2	2	2	0	2	2
Number of DMA requests	3	3	3	0	3	3
Wake-up from Stop mode	X	X	X	X	X	X
Autonomous mode	-	-	-	-	-	-

1. X = supported.

43.4 LPTIM functional description

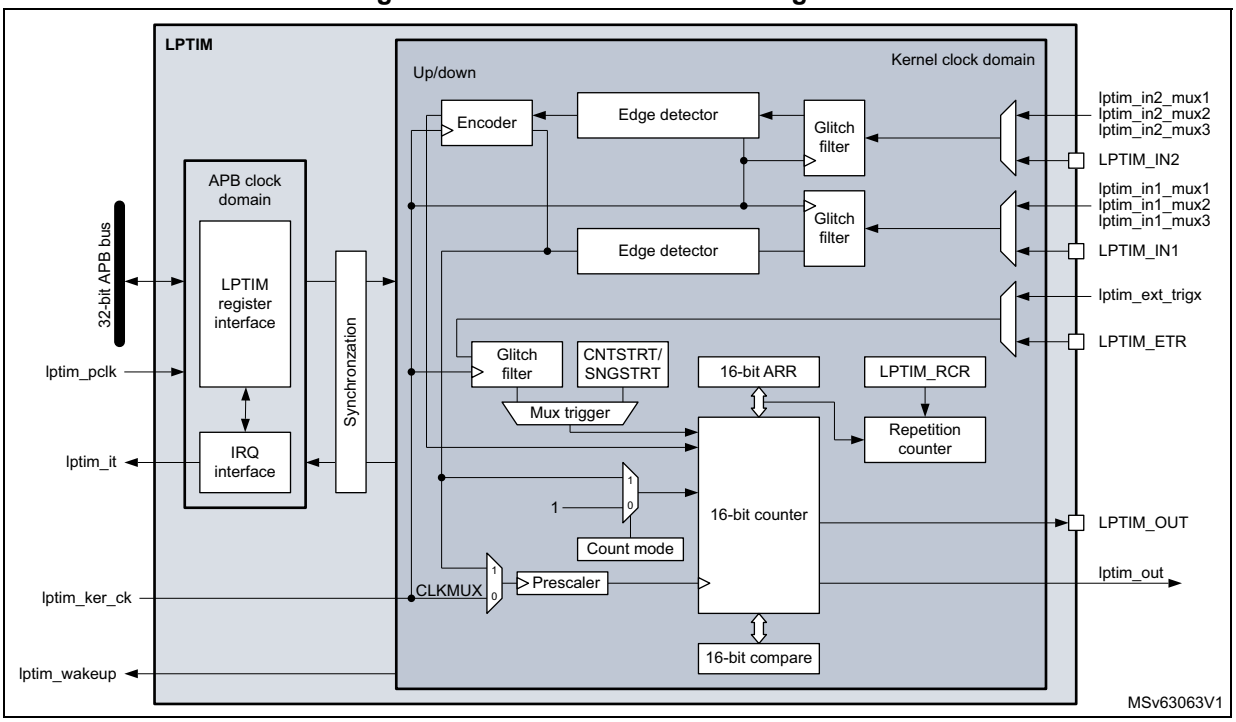
43.4.1 LPTIM block diagram

Figure 595. LPTIM1/2/3/5/6 timer block diagram(1)



1. Some IOs may not be available, refer to *Section 43.4.2: LPTIM pins and internal signals*.

Figure 596. LPTIM4 timer block diagram(1)



1. Some IOs may not be available, refer to *Section 43.4.2: LPTIM pins and internal signals*.

43.4.2 LPTIM pins and internal signals

The following tables provide the list of LPTIM pins and internal signals, respectively.

Table 450. LPTIM1/2/3/5/6 input/output pins

Names	Signal type	Description
LPTIM_IN1	Digital input	LPTIM Input 1 from GPIO pin on mux input 0
LPTIM_IN2	Digital input	LPTIM Input 2 from GPIO pin on mux input 0
LPTIM_ETR	Digital input	LPTIM external trigger GPIO pin
LPTIM_CH1	Digital input/output	LPTIM channel 1 Input/Output GPIO pin
LPTIM_CH2	Digital input/output	LPTIM channel 2 Input/Output GPIO pin

Table 451. LPTIM4 input/output pins

Names	Signal type	Description
LPTIM_IN1	Digital input	LPTIM Input 1 from GPIO pin on mux input 0
LPTIM_ETR	Digital input	LPTIM external trigger GPIO pin
LPTIM_OUT	Digital output	LPTIM Output GPIO pin

Table 452. LPTIM1/2/3/5/6 internal signals

Names	Signal type	Description
lptim_pclk	Digital input	LPTIM APB clock domain
lptim_ker_ck	Digital input	LPTIM kernel clock
lptim_in1_mux1	Digital input	Internal LPTIM input 1 connected to mux input 1
lptim_in1_mux2	Digital input	Internal LPTIM input 1 connected to mux input 2
lptim_in1_mux3	Digital input	Internal LPTIM input 1 connected to mux input 3
lptim_in2_mux1	Digital input	Internal LPTIM input 2 connected to mux input 1
lptim_in2_mux2	Digital input	Internal LPTIM input 2 connected to mux input 2
lptim_in2_mux3	Digital input	Internal LPTIM input 2 connected to mux input 3
lptim_ic1_mux1	Digital input	Internal LPTIM input capture 1 connected to mux input 1
lptim_ic1_mux2	Digital input	Internal LPTIM input capture 1 connected to mux input 2
lptim_ic1_mux3	Digital input	Internal LPTIM input capture 1 connected to mux input 3
lptim_ic2_mux1	Digital input	Internal LPTIM input capture 2 connected to mux input 1
lptim_ic2_mux2	Digital input	Internal LPTIM input capture 2 connected to mux input 2
lptim_ic2_mux3	Digital input	Internal LPTIM input capture 2 connected to mux input 3
lptim_ext_trigx	Digital input	LPTIM external trigger input x
lptim_it	Digital output	LPTIM global interrupt
lptim_wakeup	Digital output	LPTIM wake-up event
lptim_ic1_dma	Digital output	LPTIM input capture 1 DMA request
lptim_ic2_dma	Digital output	LPTIM input capture 2 DMA request
lptim_ue_dma	Digital output	LPTIM update event DMA request

Table 453. LPTIM4 internal signals

Names	Signal type	Description
lptim_pclk	Digital input	LPTIM APB clock domain
lptim_ker_ck	Digital input	LPTIM kernel clock
lptim_in1_mux1	Digital input	Internal LPTIM input 1 connected to mux input 1
lptim_in1_mux2	Digital input	Internal LPTIM input 1 connected to mux input 2
lptim_in1_mux3	Digital input	Internal LPTIM input 1 connected to mux input 3
lptim_ext_trigx	Digital input	LPTIM external trigger input x
lptim_out	Digital output	LPTIM counter output
lptim_it	Digital output	LPTIM global interrupt
lptim_wakeup	Digital output	LPTIM wake-up event

43.4.3 LPTIM input and trigger mapping

The LPTIM external trigger and input connections are detailed hereafter.

Table 454. LPTIM1/2/3/4/5/6 external trigger connection

TRIGSEL	External trigger					
	LPTIM1	LPTIM2	LPTIM3	LPTIM4	LPTIM5	LPTIM6

43.4.4 LPTIM reset and clocks

The LPTIM can be clocked using several clock sources. It can be clocked using an internal clock signal which can be any configurable internal clock source selectable through the RCC (see RCC section for more details). Also, the LPTIM can be clocked using an external clock signal injected on its external Input1. When clocked with an external clock source, the LPTIM may run in one of these two possible configurations:

- The first configuration is when the LPTIM is clocked by an external signal but in the same time an internal clock signal is provided to the LPTIM from configurable internal clock source (see RCC section).
- The second configuration is when the LPTIM is solely clocked by an external clock source through its external Input1. This configuration is the one used to realize Timeout function or Pulse counter function when all the embedded oscillators are turned off after entering a low-power mode.

Programming the CKSEL and COUNTMODE bits allows controlling whether the LPTIM uses an external clock source or an internal one.

When configured to use an external clock source, the CKPOL bits are used to select the external clock signal active edge. If both edges are configured to be active ones, an internal clock signal must also be provided (first configuration). In this case, the internal clock signal frequency must be at least four times higher than the external clock signal frequency.

43.4.5 Glitch filter

The LPTIM inputs, either external (mapped to GPIOs) or internal (mapped on the chip-level to other embedded peripherals), are protected with digital filters that prevent any glitches and noise perturbations to propagate inside the LPTIM. This is in order to prevent spurious counts or triggers.

Before activating the digital filters, an internal clock source must first be provided to the LPTIM. This is necessary to guarantee the proper operation of the filters.

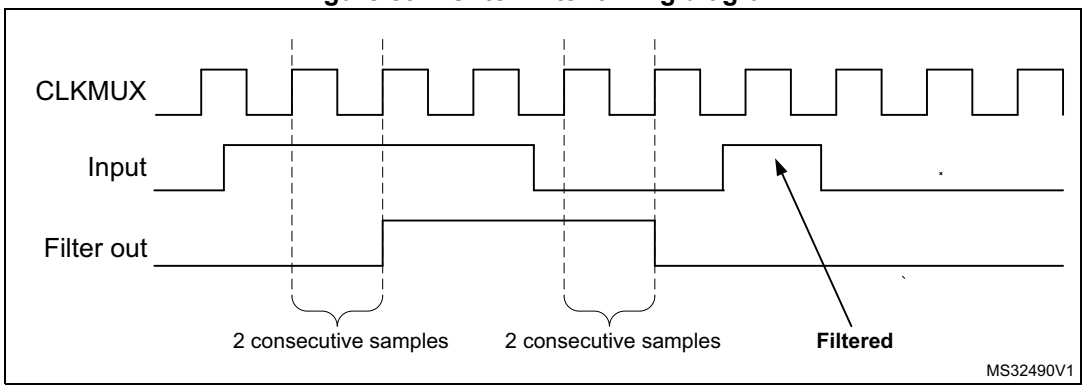
The digital filters are divided into three groups:

- The first group of digital filters protects the LPTIM internal or external inputs. The digital filters sensitivity is controlled by the CKFLT bits
- The second group of digital filters protects the LPTIM internal or external trigger inputs. The digital filters sensitivity is controlled by the TRGFLT bits.
- The third group of digital filters protects the LPTIM internal or external input captures. The digital filters sensitivity is controlled by the ICxF bits.

Note: The digital filters sensitivity is controlled by groups. It is not possible to configure each digital filter sensitivity separately inside the same group.

The filter sensitivity acts on the number of consecutive equal samples that is detected on one of the LPTIM inputs to consider a signal level change as a valid transition. *Figure 597* shows an example of glitch filter behavior in case of a 2 consecutive samples programmed.

Figure 597. Glitch filter timing diagram



Note: In case no internal clock signal is provided, the digital filter must be deactivated by setting the CKFLT, ICxF and TRGFLT bits to '0'. In that case, an external analog filter may be used to protect the LPTIM external inputs against glitches.

43.4.6 Prescaler

The LPTIM 16-bit counter is preceded by a configurable power-of-2 prescaler. The prescaler division ratio is controlled by the PRESC[2:0] 3-bit field. The table below lists all the possible division ratios:

Table 461. Prescaler division ratios

programming	dividing factor
000	/1
001	/2

Table 461. Prescaler division ratios (continued)

programming	dividing factor
010	/4
011	/8
100	/16
101	/32
110	/64
111	/128

43.4.7 Trigger multiplexer

The LPTIM counter may be started either by software or after the detection of an active edge on one of the 8 trigger inputs.

TRIGEN[1:0] is used to determine the LPTIM trigger source:

- When TRIGEN[1:0] equals ‘00’, The LPTIM counter is started as soon as one of the CNTSTRT or the SNGSTRT bits is set by software. The three remaining possible values for the TRIGEN[1:0] are used to configure the active edge used by the trigger inputs. The LPTIM counter starts as soon as an active edge is detected.
- When TRIGEN[1:0] is different than ‘00’, TRIGSEL[2:0] is used to select which of the 8 trigger inputs is used to start the counter.

The external triggers are considered asynchronous signals for the LPTIM. So after a trigger detection, a two-counter-clock period latency is needed before the timer starts running due to the synchronization.

If a new trigger event occurs when the timer is already started it is ignored (unless timeout function is enabled).

Note: The timer must be enabled before setting the SNGSTRT/CNTSTRT bits. Any write on these bits when the timer is disabled is discarded by hardware.

Note: When starting the counter by software (TRIGEN[1:0] = 00), there is a delay of 3 kernel clock cycles between the LPTIM_CR register update (set one of SNGSTRT or CNTSTRT bits) and the effective start of the counter.

43.4.8 Operating mode

The LPTIM features two operating modes:

- The Continuous mode: the timer is free running, the timer is started from a trigger event and never stops until the timer is disabled
- One-shot mode: the timer is started from a trigger event and stops when an LPTIM update event is generated.

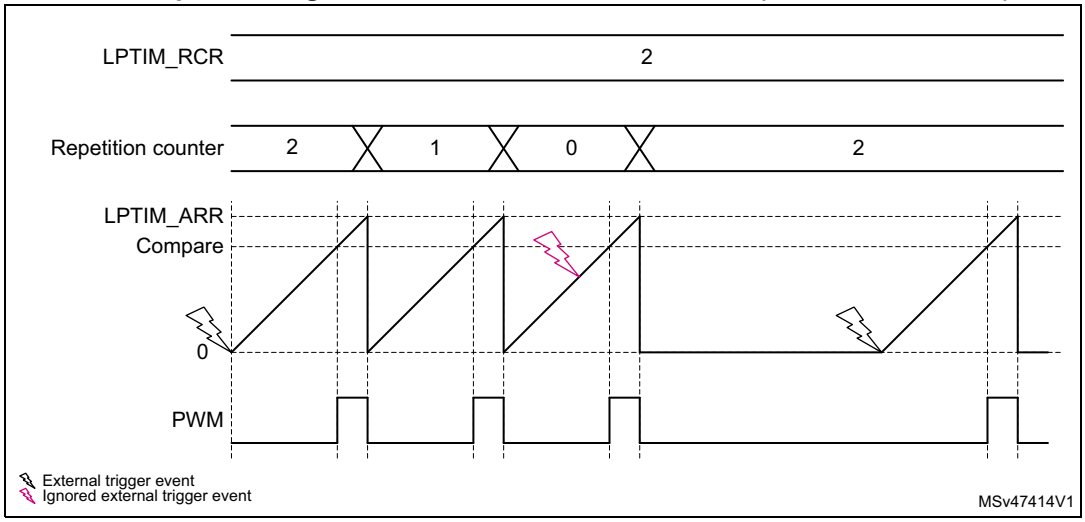
One-shot mode

To enable the one-shot counting, the SNGSTRT bit must be set.

A new trigger event re-starts the timer. Any trigger event occurring after the counter starts and before the next LPTIM update event, is discarded.

In case an external trigger is selected, each external trigger event arriving after the SNGSTRT bit is set, and after the repetition counter has stopped (after the update event), and if the repetition register content is different from zero, the repetition counter gets reloaded with the value already contained by the repetition register and a new one-shot counting cycle is started as shown in *Figure 598*.

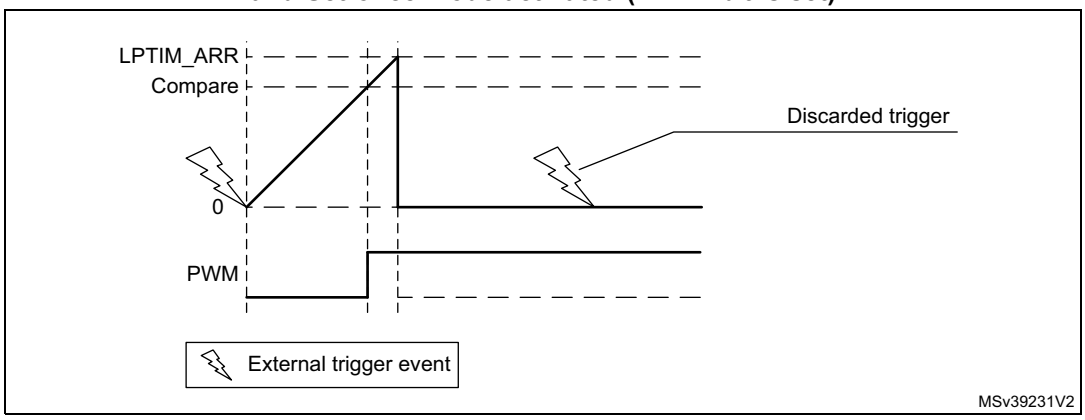
Figure 598. LPTIM output waveform, single counting mode configuration when repetition register content is different than zero (with PRELOAD = 1)



- Set-once mode activated:

Note that when the WAVE bitfield in the LPTIM_CFGR register is set, the Set-once mode is activated. In this case, the counter is only started once following the first trigger, and any subsequent trigger event is discarded as shown in *Figure 599*.

Figure 599. LPTIM output waveform, Single counting mode configuration and Set-once mode activated (WAVE bit is set)



In case of software start (TRIGEN[1:0] = ‘00’), the SNGSTRT setting starts the counter for one-shot counting.

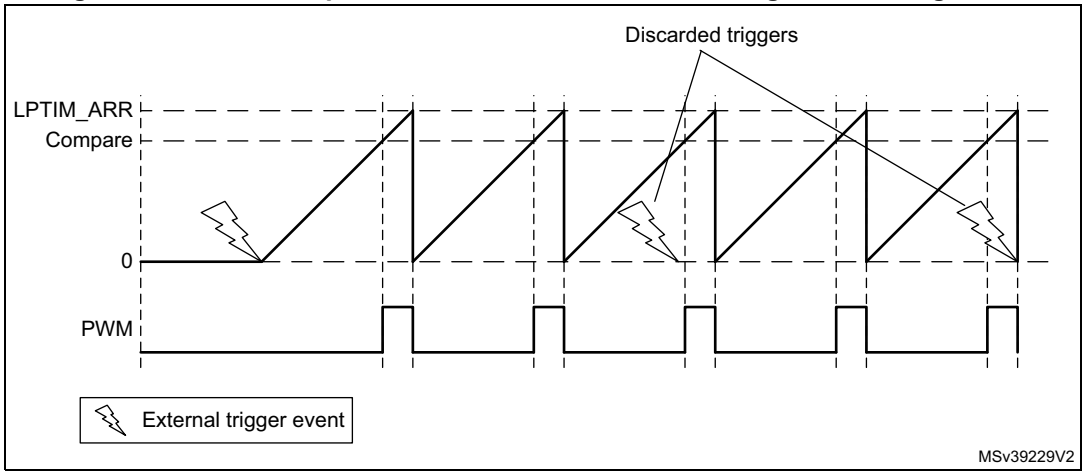
Continuous mode

To enable the continuous counting, the CNTSTRT bit must be set.

In case an external trigger is selected, an external trigger event arriving after CNTSTRT is set, starts the counter for continuous counting. Any subsequent external trigger event is discarded as shown in *Figure 600*.

In case of software start (TRIGEN[1:0] = ‘00’), setting CNTSTRT starts the counter for continuous counting.

Figure 600. LPTIM output waveform, Continuous counting mode configuration



SNGSTRT and CNTSTRT bits can only be set when the timer is enabled (The ENABLE bit is set to ‘1’). It is possible to change “on the fly” from One-shot mode to Continuous mode.

If the Continuous mode was previously selected, setting SNGSTRT switches the LPTIM to the One-shot mode. The counter (if active) stops as soon as an LPTIM update event is generated.

If the One-shot mode was previously selected, setting CNTSTRT switches the LPTIM to the Continuous mode. The counter (if active) restarts as soon as it reaches ARR.

43.4.9 Timeout function

The detection of an active edge on one selected trigger input can be used to reset the LPTIM counter. This feature is controlled through the TIMOUT bit.

The first trigger event starts the timer, any successive trigger event resets the LPTIM counter and the repetition counter and the timer restarts.

A low-power timeout function can be realized. The timeout value corresponds to the compare value; if no trigger occurs within the expected time frame, the MCU is waked-up by the compare match event.

43.4.10 Waveform generation

Two 16-bit registers, the LPTIM_ARR (autoreload register) and LPTIM_CCRx (capture/compare register), are used to generate several different waveforms on LPTIM output

The timer can generate the following waveforms:

- The PWM mode: the LPTIM output is set as soon as the counter value in LPTIM_CNT exceeds the compare value in LPTIM_CCRx. The LPTIM output is reset as soon as a

match occurs between the LPTIM_ARR and the LPTIM_CNT register. For more details see *Section 43.4.19: PWM mode*.

- The One-pulse mode: the output waveform is similar to the one of the PWM mode for the first pulse, then the output is permanently reset
- The Set-once mode: the output waveform is similar to the One-pulse mode except that the output is kept to the last signal level (depends on the output configured polarity).

The above described modes require that the LPTIM_ARR register value be strictly greater than the LPTIM_CCRx register value.

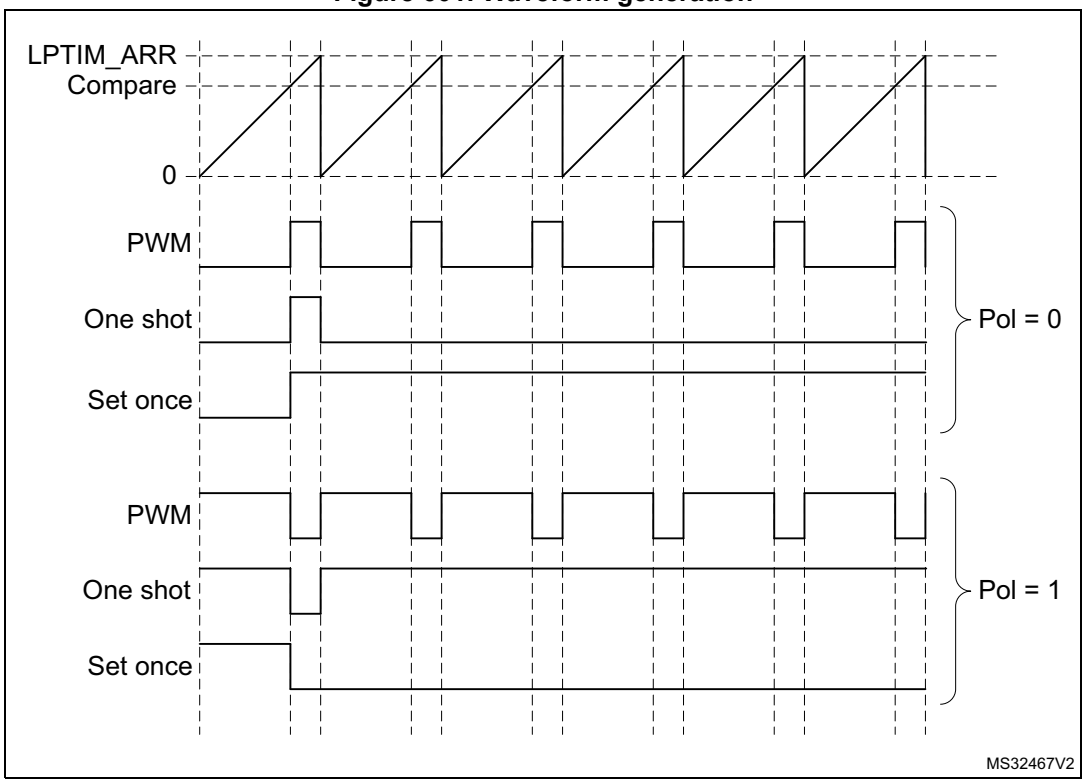
The LPTIM output waveform can be configured through the WAVE bit as follow:

- Resetting the WAVE bit to '0' forces the LPTIM to generate either a PWM waveform or a One pulse waveform depending on which bit is set: CNTSTRT or SNGSTRT.
- Setting the WAVE bit to '1' forces the LPTIM to generate a Set-once mode waveform.

The WAVPOL/CCxP bit controls the LPTIM output polarity. The change takes effect immediately, so the output default value changes immediately after the polarity is re-configured, even before the timer is enabled.

Signals with frequencies up to the LPTIM clock frequency divided by 2 can be generated. *Figure 601* below shows the three possible waveforms that can be generated on the LPTIM output. Also, it shows the effect of the polarity change using the WAVPOL/CCxP bit.

Figure 601. Waveform generation



43.4.11 Register update

The LPTIM_ARR register, the LPTIM_RCR register and the LPTIM_CCRx register are updated immediately after the APB bus write operation or in synchronization with the next LPTIM update event if the timer is already started.

The PRELOAD bit controls how the LPTIM_ARR, the LPTIM_RCR and the LPTIM_CCRx registers are updated:

- When the PRELOAD bit is reset to ‘0’, the LPTIM_ARR, the LPTIM_RCR and the LPTIM_CCRx registers are immediately updated after any write access.
- When the PRELOAD bit is set to ‘1’, the LPTIM_ARR, the LPTIM_RCR and the LPTIM_CCRx registers are updated at next LPTIM update event, if the timer has been already started.

The LPTIM APB interface and the LPTIM kernel logic use different clocks, so there is some latency between the APB write and the moment when these values are available to the counter comparator. Within this latency period, any additional write into these registers must be avoided.

The ARROK flag, the REPOK flag and the CMPxOK flag in the LPTIM_ISR register indicate when the write operation is completed to respectively the LPTIM_ARR register, the LPTIM_RCR register and the LPTIM_CCRx register.

After a write to the LPTIM_ARR, the LPTIM_RCR or the LPTIM_CCRx register, a new write operation to the same register can only be performed when the previous write operation is completed. Any successive write before respectively the ARROK flag, the REPOK flag or the CMPxOK flag be set, leads to unpredictable results.

43.4.12 Counter mode

The LPTIM counter can be used to count external events on the LPTIM Input1 or it can be used to count internal clock cycles. The CKSEL and COUNTMODE bits control which source is used for updating the counter.

In case the LPTIM is configured to count external events on Input1, the counter can be updated following a rising edge, falling edge or both edges depending on the value written to the CKPOL[1:0] bits.

The count modes below can be selected, depending on CKSEL and COUNTMODE values:

- CKSEL = 0: the LPTIM is clocked by an internal clock source
  - COUNTMODE = 0

    The LPTIM is configured to be clocked by an internal clock source and the LPTIM counter is configured to be updated following each internal clock pulse.
  - COUNTMODE = 1

    The LPTIM external Input1 is sampled with the internal clock provided to the LPTIM.

    Consequently, in order not to miss any event, the frequency of the changes on the external Input1 signal must never exceed the frequency of the internal clock

provided to the LPTIM. Also, the internal clock provided to the LPTIM must not be prescaled (PRESC[2:0] = 000).

- CKSEL = 1: the LPTIM is clocked by an external clock source

  COUNTMODE value is don't care.

  In this configuration, the LPTIM has no need for an internal clock source (except if the glitch filters are enabled). The signal injected on the LPTIM external Input1 is used as system clock for the LPTIM. This configuration is suitable for operation modes where no embedded oscillator is enabled.

  For this configuration, the LPTIM counter can be updated either on rising edges or falling edges of the input1 clock signal but not on both rising and falling edges.

  Since the signal injected on the LPTIM external Input1 is also used to clock the LPTIM kernel logic, there is some initial latency (after the LPTIM is enabled) before the counter is incremented. More precisely, the first five active edges on the LPTIM external Input1 (after LPTIM is enable) are lost.

43.4.13 Timer enable

The ENABLE bit located in the LPTIM_CR register is used to enable/disable the LPTIM kernel logic. After setting the ENABLE bit, a delay of two counter clock is needed before the LPTIM is actually enabled.

The LPTIM_CFGR register must be modified only when the LPTIM is disabled.

43.4.14 Timer counter reset

In order to reset the content of LPTIM_CNT register to zero, two reset mechanisms are implemented:

- The synchronous reset mechanism: the synchronous reset is controlled by the COUNTRST bit in the LPTIM_CR register. After setting the COUNTRST bitfield to '1', the reset signal is propagated in the LPTIM kernel clock domain. So it is important to note that a few clock pulses of the LPTIM kernel logic elapse before the reset is taken into account. This makes the LPTIM counter count few extra pluses between the time when the reset is trigger and it become effective. Since the COUNTRST bit is located in the APB clock domain and the LPTIM counter is located in the LPTIM kernel clock domain, a delay of 3 clock cycles of the kernel clock is needed to synchronize the reset signal issued by the APB clock domain when writing '1' to the COUNTRST bit.
- The asynchronous reset mechanism: the asynchronous reset is controlled by the RSTARE bit located in the LPTIM_CR register. When this bit is set to '1', any read access to the LPTIM_CNT register resets its content to zero. Asynchronous reset must be triggered within a timeframe in which no LPTIM core clock is provided. For example when LPTIM Input1 is used as external clock source, the asynchronous reset must be applied only when there is enough insurance that no toggle occurs on the LPTIM Input1.
  Note that to read reliably the content of the LPTIM_CNT register two successive read accesses must be performed and compared. A read access can be considered reliable when the value of the two read accesses is equal. Unfortunately when asynchronous reset is enabled there is no possibility to read twice the LPTIM_CNT register.

Warning: There is no mechanism inside the LPTIM that prevents the two reset mechanisms from being used simultaneously. So

developer must make sure that these two mechanisms are used exclusively.

43.4.15 Encoder mode

This mode allows handling signals from quadrature encoders used to detect angular position of rotary elements. Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value programmed into the LPTIM_ARR register (0 up to ARR or ARR down to 0 depending on the direction). Therefore LPTIM_ARR must be configured before starting the counter. From the two external input signals, Input1 and Input2, a clock signal is generated to clock the LPTIM counter. The phase between those two signals determines the counting direction.

The Encoder mode is only available when the LPTIM is clocked by an internal clock source. The signals frequency on both Input1 and Input2 inputs must not exceed the LPTIM internal clock frequency divided by 4. This is mandatory in order to guarantee a proper operation of the LPTIM.

Direction change is signalized by the two Down and Up flags in the LPTIM_ISR register. Also, an interrupt can be generated for both direction change events if enabled through the DOWNIE bit.

To activate the Encoder mode the ENC bit has to be set to ‘1’. The LPTIM must first be configured in Continuous mode.

When Encoder mode is active, the LPTIM counter is modified automatically following the speed and the direction of the incremental encoder. Therefore, its content always represents the encoder’s position. The count direction, signaled by the Up and Down flags, correspond to the rotation direction of the encoder rotor.

According to the edge sensitivity configured using the CKPOL[1:0] bits, different counting scenarios are possible. The following table summarizes the possible combinations, assuming that Input1 and Input2 do not switch at the same time.

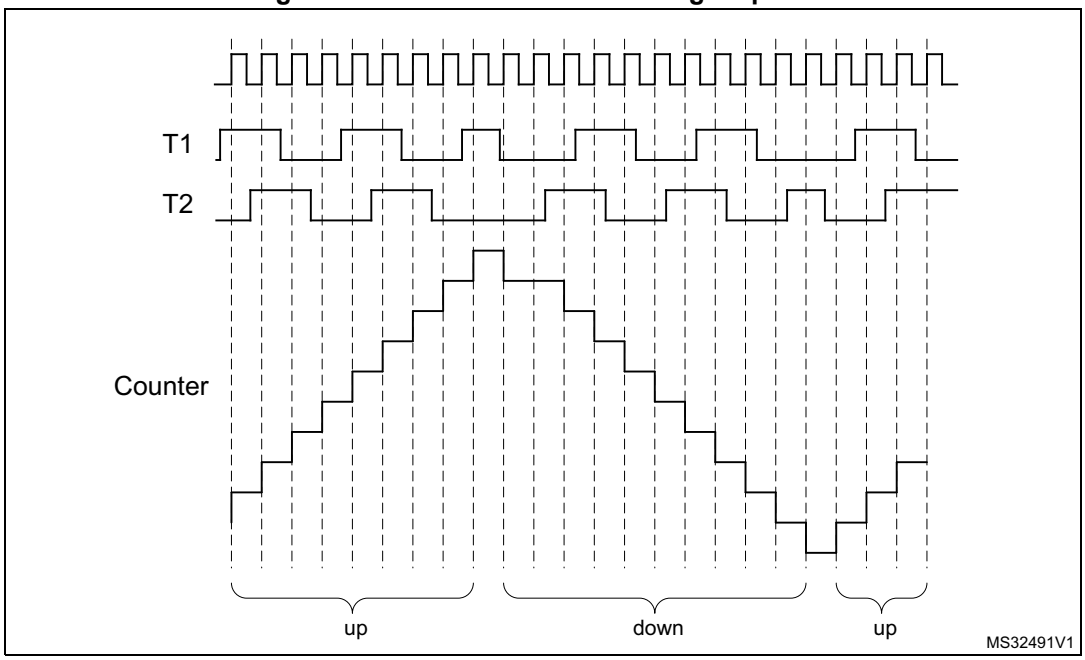
Table 462. Encoder counting scenarios

Active edge	Level on opposite signal (Input1 for Input2, Input2 for Input1)	Input1 signal		Input2 signal	
		Rising	Falling	Rising	Falling
Rising Edge	High	Down	No count	Up	No count
	Low	Up	No count	Down	No count
Falling Edge	High	No count	Up	No count	Down
	Low	No count	Down	No count	Up
Both Edges	High	Down	Up	Up	Down
	Low	Up	Down	Down	Up

The following figure shows a counting sequence for Encoder mode where both-edge sensitivity is configured.

Caution: In this mode the LPTIM must be clocked by an internal clock source, so the CKSEL bit must be maintained to its reset value which is equal to ‘0’. Also, the prescaler division ratio must be equal to its reset value which is 1 (PRESC[2:0] bits must be ‘000’).

Figure 602. Encoder mode counting sequence



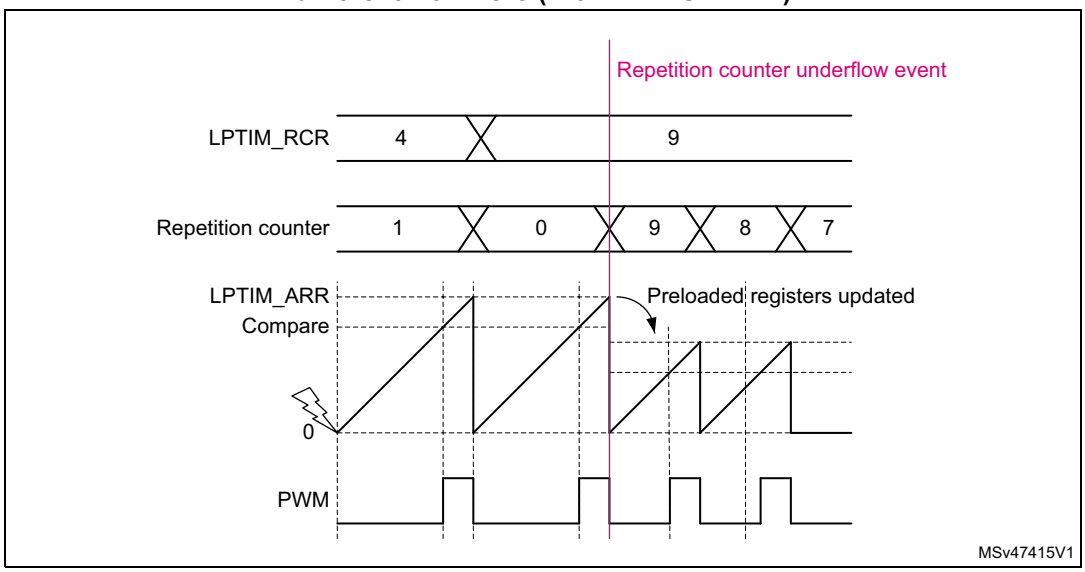
43.4.16 Repetition Counter

The LPTIM features a repetition counter that decrements by 1 each time an LPTIM counter overflow event occurs. A repetition counter underflow event is generated when the repetition counter contains zero and the LPTIM counter overflows. Next to each repetition counter underflow event, the repetition counter gets loaded with the content of the REP[7:0] bitfield which belongs to the repetition register LPTIM_RCR.

A repetition underflow event is generated on each and every LPTIM counter overflow when the REP[7:0] register is set to 0.

When PRELOAD = 1, writing to the REP[7:0] bitfield has no effect on the content of the repetition counter until the next repetition underflow event occurs. The repetition counter continues to decrement each LPTIM counter overflow event and only when a repetition underflow event is generated, the new value written into REP[7:0] is loaded into the repetition counter. This behavior is depicted in *Figure 603*.

Figure 603. Continuous counting mode when repetition register LPTIM_RCR different from zero (with PRELOAD = 1)



A repetition counter underflow event is systematically associated with LPTIM preloaded registers update (refer to section "Register update" for more information).

Repetition counter underflow event is signaled to the software through the update event (UE) flag mapped into the LPTIM_ISR register. When set, the UE flag can trigger an LPTIM interrupt if its respective update event interrupt enable (UEIE) control bit, mapped to the LPTIM_DIER register, is set.

The repetition register LPTIM_RCR is located in the APB bus interface clock domain where the repetition counter itself is located in the LPTIM kernel clock domain. Each time a new value is written to the LPTIM_RCR register, that new content is propagated from the APB bus interface clock domain to the LPTIM kernel clock domain so that the new written value is loaded to the repetition counter immediately after a repetition counter underflow event. The synchronization delay for the new written content is four APB clock cycles plus three LPTIM kernel clock cycles and it is signaled by the REPOK flag located in the LPTIM_ISR register when it is elapsed. When the LPTIM kernel clock cycle is relatively slow, for instance when the LPTIM kernel is being clocked by the LSI clock source, it can be lengthy to keep polling on the REPOK flag by software to detect that the synchronization of the LPTIM_RCR register content is finished. For that reason, the REPOK flag, when set, can generate an interrupt if its associated REPOKIE control bit in the LPTIM_DIER register is set.

Note: After a write to the LPTIM_RCR register, a new write operation to the same register can only be performed when the previous write operation is completed. Any successive write before the REPOK flag is set, leads to unpredictable results.

Caution: When using repetition counter with PRELOAD = 0, LPTIM_RCR register must be changed at least five counter cycles before the autoreload match event, otherwise an unpredictable behavior may occur.

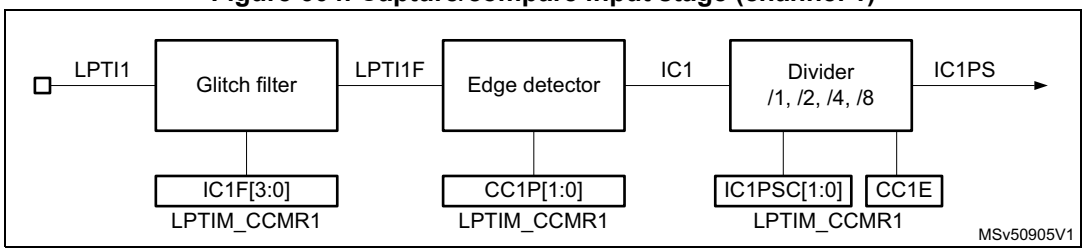
43.4.17 Capture/compare channels

Each capture/compare channel is built around a capture/compare register, an input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control) for PWM.

Input stage

The input stage samples the corresponding LPTIx input to generate a filtered signal LPTIxF. Then, an edge detector with polarity selection generates ICx signal used as the capture command. It is prescaled to generate the capture command signal (ICxPS).

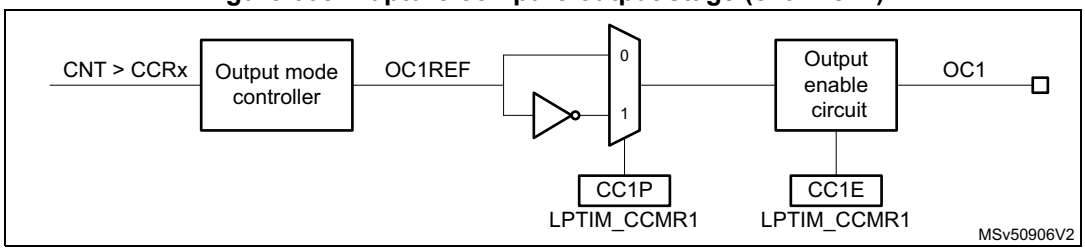
Figure 604. Capture/compare input stage (channel 1)



Output stage

The output stage generates an intermediate waveform which is then used for reference: OCxREF (active high). The polarity acts at the end of the chain.

Figure 605. Capture/compare output stage (channel 1)



43.4.18 Input capture mode

In Input capture mode, the capture/compare registers (LPTIM_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. Assuming input capture is enabled on a channel x (CCxE set) and when a capture occurs, the corresponding CCxIF flag (LPTIM_ISR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (LPTIM_ISR register) is set. CCxIF can be cleared by software by writing the CCxICF to 1 or by reading the captured data stored in the LPTIM_CCRx register. CCxOF is cleared by writing CCxOCF to 1.

Note: In DMA mode, the input capture channel have to be enabled (set CCxE bit) the last, after enabling the IC DMA request and after starting the counter. This is in order to prevent generating an input capture DMA request when the counter is not started yet.

Input capture Glitch filter latency

When a trigger event arrives on channel x input (LPTIx) and depending on the configured glitch filter (ICxF[1:0] field in CCMRx register) and on the kernel clock prescaler value

(PRESC[2:0] field in CFGR register), there is a variable latency that leads to a systematic offset (see *Table 463*) between the captured value stored in the CCRx register and the real value corresponding to the capture trigger.

This offset has no impact on pulse width measurement as it is systematic and compensated between two captures.

The real capture value corresponding to the input capture trigger can be calculated using the below formula:

Real capture value = captured(LPTIM_CCRx) - offset

The relevant offset must be used depending on the glitch filter and on the kernel clock prescaler value (PRESC field in CFGR register)

Example: determining the real capture value when PRESC[2:0] = 0x2 and ICxF = 0x3.

For this configuration (PRESC[2:0] = 0x2 and ICxF = 0x3) and according to the *Table 463*, the offset is 5.

Assuming that the captured value in CCRx is 9 (LPTIM_CNT = 9), this means that the capture trigger occurred when the LPTIM_CNT was equal to 9 - 5 = 4.

Table 463. Input capture Glitch filter latency (in counter step unit)

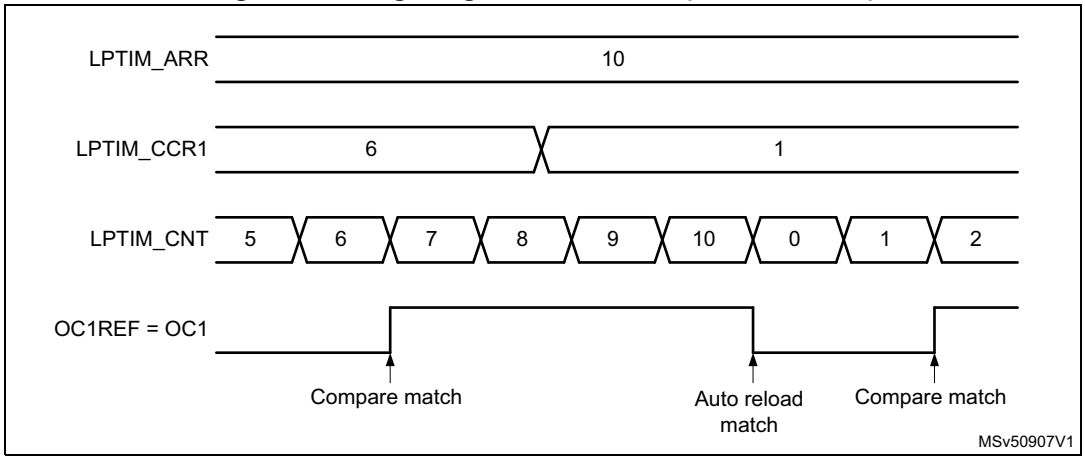
43.4.19 PWM mode

The PWM mode enables to generate a signal with a frequency determined by the value of the LPTIM_ARR register and a duty cycle determined by the value of the LPTIM_CCRx register. The LPTIM is able to generate PWM in edge-aligned mode.

OCx polarity is software programmable using the CCxP bit in the LPTIM_CCMRx register. It can be programmed as active high or active low. OCx output is enabled by the CCxE bit in the LPTIM_CCMRx register. Refer to the LPTIM_CCMRx register description for more details.

Figure 606 gives an example where the LPTIM channel 1 is configured in PWM mode with LPTIM_CCR1 = 6 then 1 and LPTIM_ARR=10.

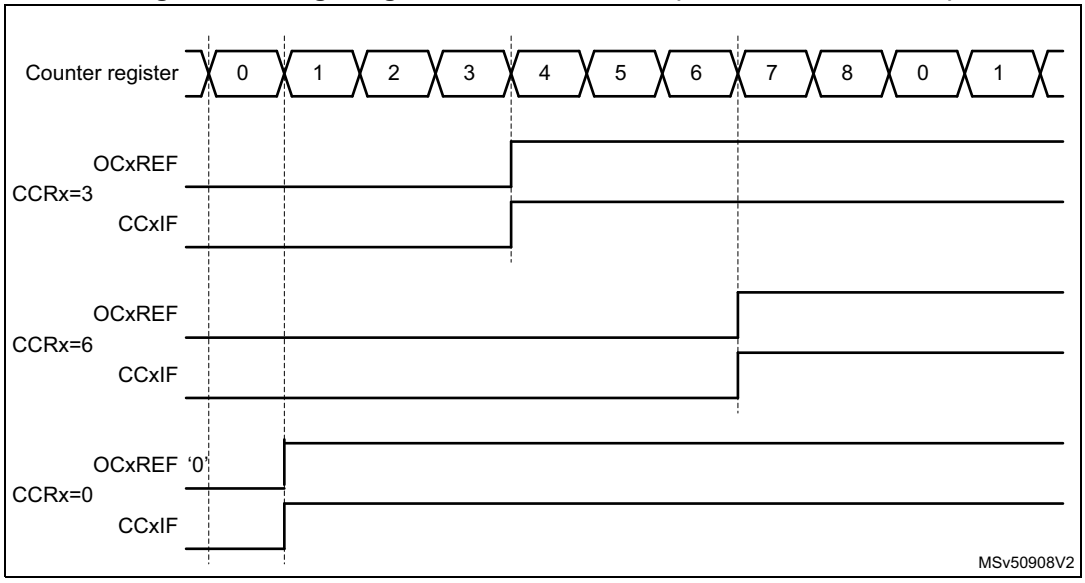
Figure 606. Edge-aligned PWM mode (PRELOAD = 1)



In the following example the reference PWM signal OCxREF is low as long as LPTIM_CNT ≤ LPTIM_CCRx else it becomes high.

Figure 607 shows some edge-aligned PWM waveforms in an example where LPTIM_ARR = 8.

Figure 607. Edge-aligned PWM waveforms (ARR=8 and CCxP = 0)



PWM mode with immediate update PRELOAD = 0

The PWM mode with PRELOAD = 0 enables the early change of the output level within the current PWM cycle. Based on the immediate update (PRELOAD = 0) of the LPTIM_CCRx register and on the continuous comparison of LPTIM_CNT and LPTIM_CCRx registers, it permits to have a new duty cycle value applied as soon as possible within the current PWM cycle, without having to wait for the completion of the current PWM period.

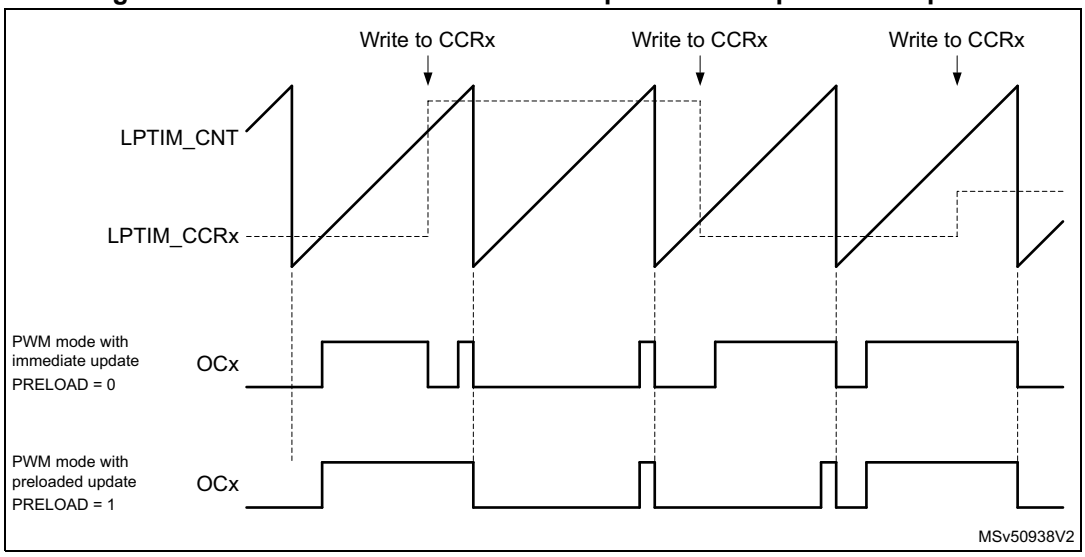
When the (PRELOAD = 0), the OCxREF signal level can be changed on-the-fly by software (or DMA) by updating the compare value in the LPTIM_CCRx register.

Depending on the written compare value and on the current counter and compare values, the OCxREF level is re-assigned as illustrated below:

- If the new compare value does not exceed the current counter value and the current compare value exceeds the counter, OCxREF level is re-assigned high as soon as the new compare value is written.
- If the new compare value exceeds the counter value and the current compare value does not exceed the counter, OCxREF level is re-assigned low as soon as the new compare value is written.

The output reference signal OCxREF level is left unchanged when none of the new compare value and the current compare value exceed the counter. *Figure 608* illustrates the behavior of the OCxREF signal level when PRELOAD = 0 and PRELOAD = 1.

Figure 608. PWM mode with immediate update versus preloaded update



Note: For both PWM modes, the compare match, auto-reload match and the update event flags are set one LPTIM counter cycle later after the corresponding event, the OCxREF level is also changed one LPTIM counter cycle later after the corresponding event. For instance when the LPTIM_CCRx is set to 3 the CCxIF is set when the LPTIM_CNT = 4. Figure 606 illustrates this behavior.

43.4.20 DMA requests

The LPTIM has the capability to generate two categories of DMA requests:

- DMA requests used to retrieve the input-capture counter values
- DMA update requests are used to re-program part of the LPTIMER, multiple times, at regular intervals, without software overhead.

Input capture DMA request

Each LPTIM channel has its dedicated input capture DMA request. A DMA request is generated (if CCxDE bit is set in LPTIM_DIER) and CCxIF is set each time a capture is ready in the CCRx register. The captured values in CCRx can then be transferred regularly by DMA to the desired memory destination. The CCxIF is automatically cleared by hardware when the captured value in CCRx register is read.

Note: The ICx DMA request signal lptim_icx_dma is reset in the following conditions:

- *if the corresponding DMA request is disabled (clear CCxDE bit in the LPTIM_DIER register)*
- *or if the channel x is disabled (clear CCxE bit)*
- *or if the LPTIM is disabled (clear the ENABLE bit in the LPTIM_CR register)*

Update event DMA request

A DMA request is generated (if UEDE is set in LPTIM_DIER) and the UE flag is set at each update event. DMA request can be used to regularly update the LPTIM_ARR, the LPTIM_RCR or the LPTIM_CCRx registers permitting to generate custom PWM waveforms.

The UE is automatically cleared by hardware upon any bus master (like CPU or DMA) write access to the LPTIM_ARR register.

Note: The UE DMA request signal lptim_ue_dma is reset in the following conditions:

- if the corresponding DMA request is disabled (clear UEDE bit in the LPTIM_DIER register)

- or if the LPTIM is disabled (clear the ENABLE bit in the LPTIM_CR register)

43.4.21 Debug mode

When the microcontroller enters debug mode (core halted), the LPTIM counter either continues to work normally or stops, depending on the DBG_LPTIM_STOP configuration bit in the DBG module.

43.5 LPTIM low-power modes

Table 464. Effect of low-power modes on the LPTIM

Mode	Description
Sleep	No effect. LPTIM interrupts cause the device to exit Sleep mode.
Stop	If the LPTIM is clocked by an oscillator available in Stop mode, LPTIM is functional and the interrupts cause the device to exit the Stop mode.
Standby	The LPTIM peripheral is powered down and must be reinitialized after exiting Standby mode.

Note: All DMA requests must be disabled (reset UEDE and CCxDE bits) before entering Sleep, Stop and Standby modes.

43.6 LPTIM interrupts

The following events generate an interrupt/wake-up event, if they are enabled through the LPTIM_DIER register:

- Compare match
- Auto-reload match (whatever the direction if encoder mode)
- External trigger event
- Autoreload register write completed
- Compare register write completed
- Direction change (encoder mode), programmable (up / down / both).
- Update Event
- Repetition register update OK
- Input capture occurred
- Over-capture occurred
- Interrupt enable register update OK

Note: If any bit in the LPTIM_DIER register is set after that its corresponding flag in the LPTIM_ISR register (Status Register) is set, the interrupt is not asserted.

Table 465. Interrupt events

Interrupt vector	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit from Sleep mode	Exit from Stop mode(1)
LPTIMx	Compare match	CCxIF	CCxIE	Write 1 to CCxCF	Yes	Yes
	Input capture(2)	CCxIF	CCxIE	Write 1 to CCxCF	Yes	Yes
	Over-capture(2)	CCxOF	CCxOIE	Write 1 to CCxOCF	Yes	Yes
	Auto-reload match	ARRM	ARRMIE	Write 1 to ARRMCF	Yes	Yes
	External trigger event	EXTTRIG	EXTTRIGIE	Write 1 to EXTTRIGCF	Yes	Yes
	Auto-reload register update OK	ARROK	ARROKIE	Write 1 to ARROKCF	Yes	Yes
	Capture/compare register update OK	CMPxOK	CMPxOKIE	Write 1 to CMPxOKCF	Yes	Yes
	Direction change to up(3)	UP	UPIE	Write 1 to UPCF	Yes	Yes
	Direction change to down(3)	DOWN	DOWNIE	Write 1 to DOWNCF	Yes	Yes
	Update Event	UE	UEIE	Write 1 to UECF	Yes	Yes
	Repetition register update OK	REPOK	REPOKIE	Write 1 to REPOKCF	Yes	Yes

1. Each LPTIM event can wake up the device from Stop mode only if the LPTIM instance supports the wake-up from Stop mode feature. Refer to *Section 43.3: LPTIM implementation*.
2. If LPTIM does not implement any channel this event does not exist. Refer to *Section 43.3: LPTIM implementation*.
3. If LPTIM does not support encoder mode feature, this event does not exist. Refer to *Section 43.3: LPTIM implementation*.

43.7 LPTIM registers

Refer to *Section 1.2: List of abbreviations for registers on page 101* for a list of abbreviations used in register descriptions.

The peripheral registers can only be accessed by words (32-bit).

43.7.1 LPTIM4 interrupt and status register (LPTIM4_ISR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

							r	r	r	r	r	r	r	r	r

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **DIEROK:** Interrupt enable register update OK

DIEROK is set by hardware to inform application that the APB bus write operation to the LPTIM_DIER register has been successfully completed. DIEROK flag can be cleared by writing 1 to the DIEROKCF bit in the LPTIM_ICR register.

Bits 23:9 Reserved, must be kept at reset value.

Bit 8 **REPOK**: Repetition register update OK

REPOK is set by hardware to inform application that the APB bus write operation to the LPTIM_RCR register has been successfully completed. REPOK flag can be cleared by writing 1 to the REPOKCF bit in the LPTIM_ICR register.

Bit 7 **UE**: LPTIM update event occurred

UE is set by hardware to inform application that an update event was generated. UE flag can be cleared by writing 1 to the UECF bit in the LPTIM_ICR register.

Bit 6 **DOWN**: Counter direction change up to down

In Encoder mode, DOWN bit is set by hardware to inform application that the counter direction has changed from up to down. DOWN flag can be cleared by writing 1 to the DOWNCF bit in the LPTIM_ICR register.

Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3: LPTIM implementation.

Bit 5 **UP**: Counter direction change down to up

In Encoder mode, UP bit is set by hardware to inform application that the counter direction has changed from down to up. UP flag can be cleared by writing 1 to the UPCF bit in the LPTIM_ICR register.

Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3: LPTIM implementation.

Bit 4 **ARROK**: Autoreload register update OK

ARROK is set by hardware to inform application that the APB bus write operation to the LPTIM_ARR register has been successfully completed. ARROK flag can be cleared by writing 1 to the ARROKCF bit in the LPTIM_ICR register.

Bit 3 **CMP1OK**: Compare register 1 update OK

CMP1OK is set by hardware to inform application that the APB bus write operation to the LPTIM_CCR1 register has been successfully completed. CMP1OK flag can be cleared by writing 1 to the CMP1OKCF bit in the LPTIM_ICR register.

Bit 2 **EXTTRIG**: External trigger edge event

EXTTRIG is set by hardware to inform application that a valid edge on the selected external trigger input has occurred. If the trigger is ignored because the timer has already started, then this flag is not set. EXTTRIG flag can be cleared by writing 1 to the EXTTRIGCF bit in the LPTIM_ICR register.

Bit 1 **ARRM**: Autoreload match

ARRM is set by hardware to inform application that LPTIM_CNT register's value reached the LPTIM_ARR register's value. ARRM flag can be cleared by writing 1 to the ARRMCF bit in the LPTIM_ICR register.

Bit 0 **CC1IF**: Compare 1 interrupt flag

The CC1IF flag is set by hardware to inform application that LPTIM_CNT register value matches the compare register's value. The CC1IF flag can be cleared by writing 1 to the CC1CF bit in the LPTIM_ICR register.

0: No match

1: The content of the counter LPTIM_CNT register value has matched the LPTIM_CCR1 register's value

43.7.2 LPTIMx interrupt and status register [alternate] (LPTIMx_ISR) (x = 1 to 3, 5, 6)

This description of the register can only be used for output compare mode. See next section for input capture mode.

Address offset: 0x000

Reset value: 0x0000 0000

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **DIEROK:** Interrupt enable register update OK

DIEROK is set by hardware to inform application that the APB bus write operation to the LPTIM_DIER register has been successfully completed. DIEROK flag can be cleared by writing 1 to the DIEROKCF bit in the LPTIM_ICR register.

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 Reserved, must be kept at reset value.

Bit 20 Reserved, must be kept at reset value.

Bit 19 **CMP2OK**: Compare register 2 update OK

CMP2OK is set by hardware to inform application that the APB bus write operation to the LPTIM_CCR2 register has been successfully completed. CMP2OK flag can be cleared by writing 1 to the CMP2OKCF bit in the LPTIM_ICR register.

Note: If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 43.3.

Bits 18:12 Reserved, must be kept at reset value.

Bit 11 Reserved, must be kept at reset value.

Bit 10 Reserved, must be kept at reset value.

Bit 9 **CC2IF**: Compare 2 interrupt flag

If channel CC2 is configured as output:

The CC2IF flag is set by hardware to inform application that LPTIM_CNT register value matches the compare register's value. CC2IF flag can be cleared by writing 1 to the CC2CF bit in the LPTIM_ICR register.

0: No match

1: The content of the counter LPTIM_CNT register value has matched the LPTIM_CCR2 register's value

Note: If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 43.3.

Bit 8 **REPOK**: Repetition register update OK

REPOK is set by hardware to inform application that the APB bus write operation to the LPTIM_RCR register has been successfully completed. REPOK flag can be cleared by writing 1 to the REPOKCF bit in the LPTIM_ICR register.

Bit 7 **UE**: LPTIM update event occurred

UE is set by hardware to inform application that an update event was generated. The corresponding interrupt or DMA request is generated if enabled. UE flag can be cleared by writing 1 to the UECF bit in the LPTIM_ICR register. The UE flag is automatically cleared by hardware once the LPTIM_ARR register is written by any bus master like CPU or DMA.

Bit 6 **DOWN**: Counter direction change up to down

In Encoder mode, DOWN bit is set by hardware to inform application that the counter direction has changed from up to down. DOWN flag can be cleared by writing 1 to the DOWNCF bit in the LPTIM_ICR register.

Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.

Bit 5 **UP**: Counter direction change down to up

In Encoder mode, UP bit is set by hardware to inform application that the counter direction has changed from down to up. UP flag can be cleared by writing 1 to the UPCF bit in the LPTIM_ICR register.

Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.

Bit 4 **ARROK**: Autoreload register update OK

ARROK is set by hardware to inform application that the APB bus write operation to the LPTIM_ARR register has been successfully completed. ARROK flag can be cleared by writing 1 to the ARROKCF bit in the LPTIM_ICR register.

Bit 3 **CMP1OK**: Compare register 1 update OK

CMP1OK is set by hardware to inform application that the APB bus write operation to the LPTIM_CCR1 register has been successfully completed. CMP1OK flag can be cleared by writing 1 to the CMP1OKCF bit in the LPTIM_ICR register.

Bit 2 **EXTTRIG**: External trigger edge event

EXTTRIG is set by hardware to inform application that a valid edge on the selected external trigger input has occurred. If the trigger is ignored because the timer has already started, then this flag is not set. EXTTRIG flag can be cleared by writing 1 to the EXTTRIGCF bit in the LPTIM_ICR register.

Bit 1 **ARRM**: Autoreload match

ARRM is set by hardware to inform application that LPTIM_CNT register's value reached the LPTIM_ARR register's value. ARRM flag can be cleared by writing 1 to the ARRMCF bit in the LPTIM_ICR register.

Bit 0 **CC1IF**: Compare 1 interrupt flag

If channel CC1 is configured as output:

The CC1IF flag is set by hardware to inform application that LPTIM_CNT register value matches the compare register's value. CC1IF flag can be cleared by writing 1 to the CC1CF bit in the LPTIM_ICR register.

0: No match

1: The content of the counter LPTIM_CNT register value has matched the LPTIM_CCR1 register's value

43.7.3 LPTIMx interrupt and status register [alternate] (LPTIMx_ISR) (x = 1 to 3, 5, 6)

This description of the register can only be used for input capture mode. See previous section for output compare mode.

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

		r	r			r	r	r	r	r	r		r	r	r

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **DIEROK:** Interrupt enable register update OK

DIEROK is set by hardware to inform application that the APB bus write operation to the LPTIM_DIER register has been successfully completed. DIEROK flag can be cleared by writing 1 to the DIEROKCF bit in the LPTIM_ICR register.

Bits 23:16 Reserved, must be kept at reset value.

Bit 15 Reserved, must be kept at reset value.

Bit 14 Reserved, must be kept at reset value.

Bit 13 **CC2OF**: Capture 2 over-capture flag

This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing 1 to the CC2OCF bit in the LPTIM_ICR register.

0: No over-capture has been detected.

1: The counter value has been captured in LPTIM_CCR2 register while CC2IF flag was already set.

Note: If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 43.3.

Bit 12 **CC1OF**: Capture 1 over-capture flag

This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing 1 to the CC1OCF bit in the LPTIM_ICR register.

0: No over-capture has been detected.

1: The counter value has been captured in LPTIM_CCR1 register while CC1IF flag was already set.

Note: If LPTIM does not implement at least 1 channel this bit is reserved. Refer to Section 43.3.

Bit 11 Reserved, must be kept at reset value.

Bit 10 Reserved, must be kept at reset value.

Bit 9 **CC2IF**: Capture 2 interrupt flag

If channel CC2 is configured as input:

CC2IF is set by hardware to inform application that the current value of the counter is captured in LPTIM_CCR2 register. The corresponding interrupt or DMA request is generated if enabled. The CC2OF flag is set if the CC2IF flag was already high.

0: No input capture occurred

1: The counter value has been captured in the LPTIM_CCR2 register. (An edge has been detected on IC2 which matches the selected polarity). The CC2IF flag is automatically cleared by hardware once the captured value is read (CPU or DMA). The CC2IF flag can be cleared by writing 1 to the CC2CF bit in the LPTIM_ICR register.

Note: If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 43.3.

Bit 8 **REPOK**: Repetition register update OK

REPOK is set by hardware to inform application that the APB bus write operation to the LPTIM_RCR register has been successfully completed. REPOK flag can be cleared by writing 1 to the REPOKCF bit in the LPTIM_ICR register.

Bit 7 **UE**: LPTIM update event occurred

UE is set by hardware to inform application that an update event was generated. UE flag can be cleared by writing 1 to the UECF bit in the LPTIM_ICR register.

Bit 6 **DOWN**: Counter direction change up to down

In Encoder mode, DOWN bit is set by hardware to inform application that the counter direction has changed from up to down. DOWN flag can be cleared by writing 1 to the DOWNCF bit in the LPTIM_ICR register.

Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.

Bit 5 **UP**: Counter direction change down to up

In Encoder mode, UP bit is set by hardware to inform application that the counter direction has changed from down to up. UP flag can be cleared by writing 1 to the UPCF bit in the LPTIM_ICR register.

Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.

Bit 4 **ARROK**: Autoreload register update OK

ARROK is set by hardware to inform application that the APB bus write operation to the LPTIM_ARR register has been successfully completed. ARROK flag can be cleared by writing 1 to the ARROKCF bit in the LPTIM_ICR register.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **EXTTRIG**: External trigger edge event

EXTTRIG is set by hardware to inform application that a valid edge on the selected external trigger input has occurred. If the trigger is ignored because the timer has already started, then this flag is not set. EXTTRIG flag can be cleared by writing 1 to the EXTTRIGCF bit in the LPTIM_ICR register.

Bit 1 **ARRM**: Autoreload match

ARRM is set by hardware to inform application that LPTIM_CNT register's value reached the LPTIM_ARR register's value. ARRM flag can be cleared by writing 1 to the ARRMCF bit in the LPTIM_ICR register.

Bit 0 **CC1IF**: capture 1 interrupt flag

If channel CC1 is configured as input:

CC1IF is set by hardware to inform application that the current value of the counter is captured in LPTIM_CCR1 register. The corresponding interrupt or DMA request is generated if enabled. The CC1OF flag is set if the CC1IF flag was already high.

0:No input capture occurred

1:The counter value has been captured in the LPTIM_CCR1 register. (An edge has been detected on IC1 which matches the selected polarity). The CC1IF flag is automatically cleared by hardware once the captured value is read (CPU or DMA).CC1IF flag can be cleared by writing 1 to the CC1CF bit in the LPTIM_ICR register.

43.7.4 LPTIM4 interrupt clear register (LPTIM4_ICR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

							w	w	w	w	w	w	w	w	w

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **DIEROKCF:** Interrupt enable register update OK clear flag

Writing 1 to this bit clears the DIEROK flag in the LPTIM_ISR register.

Bits 23:9 Reserved, must be kept at reset value.

Bit 8 **REPOKCF**: Repetition register update OK clear flag

Writing 1 to this bit clears the REPOK flag in the LPTIM_ISR register.

Bit 7 **UECF**: Update event clear flag

Writing 1 to this bit clear the UE flag in the LPTIM_ISR register.

Bit 6 **DOWNCF**: Direction change to down clear flag

Writing 1 to this bit clear the DOWN flag in the LPTIM_ISR register.

Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.

Bit 5 **UPCF**: Direction change to UP clear flag

Writing 1 to this bit clear the UP flag in the LPTIM_ISR register.

Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.

Bit 4 **ARROKCF**: Autoreload register update OK clear flag
Writing 1 to this bit clears the ARROK flag in the LPTIM_ISR register

Bit 3 **CMP1OKCF**: Compare register 1 update OK clear flag
Writing 1 to this bit clears the CMP1OK flag in the LPTIM_ISR register.

Bit 2 **EXTTRIGCF**: External trigger valid edge clear flag
Writing 1 to this bit clears the EXTTRIG flag in the LPTIM_ISR register

Bit 1 **ARRMCF**: Autoreload match clear flag
Writing 1 to this bit clears the ARRM flag in the LPTIM_ISR register

Bit 0 **CC1CF**: Capture/compare 1 clear flag
Writing 1 to this bit clears the CC1IF flag in the LPTIM_ISR register.

43.7.5 LPTIMx interrupt clear register [alternate] (LPTIMx_ICR) (x = 1 to 3, 5, 6)

This description of the register can only be used for output compare mode. See next section for input capture compare mode.

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **DIEROKCF:** Interrupt enable register update OK clear flag
Writing 1 to this bit clears the DIEROK flag in the LPTIM_ISR register.

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 Reserved, must be kept at reset value.

Bit 20 Reserved, must be kept at reset value.

Bit 19 **CMP2OKCF**: Compare register 2 update OK clear flag
Writing 1 to this bit clears the CMP2OK flag in the LPTIM_ISR register.
Note: If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 43.3.

Bits 18:12 Reserved, must be kept at reset value.

Bit 11 Reserved, must be kept at reset value.

Bit 10 Reserved, must be kept at reset value.

Bit 9 **CC2CF**: Capture/compare 2 clear flag
Writing 1 to this bit clears the CC2IF flag in the LPTIM_ISR register.
Note: If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 43.3.

Bit 8 **REPOKCF**: Repetition register update OK clear flag
Writing 1 to this bit clears the REPOK flag in the LPTIM_ISR register.

Bit 7 **UECF**: Update event clear flag
Writing 1 to this bit clear the UE flag in the LPTIM_ISR register.

Bit 6 **DOWNCF**: Direction change to down clear flag
Writing 1 to this bit clear the DOWN flag in the LPTIM_ISR register.
Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.

Bit 5 **UPCF**: Direction change to UP clear flag
Writing 1 to this bit clear the UP flag in the LPTIM_ISR register.
Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.

Bit 4 **ARROKCF**: Autoreload register update OK clear flag
Writing 1 to this bit clears the ARROK flag in the LPTIM_ISR register

Bit 3 **CMP1OKCF**: Compare register 1 update OK clear flag
Writing 1 to this bit clears the CMP1OK flag in the LPTIM_ISR register.

Bit 2 **EXTTRIGCF**: External trigger valid edge clear flag
Writing 1 to this bit clears the EXTTRIG flag in the LPTIM_ISR register

Bit 1 **ARRMCF**: Autoreload match clear flag
Writing 1 to this bit clears the ARRM flag in the LPTIM_ISR register

Bit 0 **CC1CF**: Capture/compare 1 clear flag
Writing 1 to this bit clears the CC1IF flag in the LPTIM_ISR register.

43.7.6 LPTIMx interrupt clear register [alternate] (LPTIMx_ICR) (x = 1 to 3, 5, 6)

This description of the register can only be used for input capture mode. See previous section for output compare mode.

Address offset: 0x004

Reset value: 0x0000 0000

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **DIEROKCF:** Interrupt enable register update OK clear flag
Writing 1 to this bit clears the DIEROK flag in the LPTIM_ISR register.

Bits 23:16 Reserved, must be kept at reset value.

Bit 15 Reserved, must be kept at reset value.

Bit 14 Reserved, must be kept at reset value.

Bit 13 **CC2OCF**: Capture/compare 2 over-capture clear flag
Writing 1 to this bit clears the CC2OF flag in the LPTIM_ISR register.
Note: If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 43.3.

Bit 12 **CC1OCF**: Capture/compare 1 over-capture clear flag
Writing 1 to this bit clears the CC1OF flag in the LPTIM_ISR register.
Note: If LPTIM does not implement at least 1 channel this bit is reserved. Refer to Section 43.3.

Bit 11 Reserved, must be kept at reset value.

Bit 10 Reserved, must be kept at reset value.

Bit 9 **CC2CF**: Capture/compare 2 clear flag
Writing 1 to this bit clears the CC2IF flag in the LPTIM_ISR register.
Note: If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 43.3.

Bit 8 **REPOKCF**: Repetition register update OK clear flag
Writing 1 to this bit clears the REPOK flag in the LPTIM_ISR register.

Bit 7 **UECF**: Update event clear flag
Writing 1 to this bit clear the UE flag in the LPTIM_ISR register.

Bit 6 **DOWNCF**: Direction change to down clear flag
Writing 1 to this bit clear the DOWN flag in the LPTIM_ISR register.
Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.

Bit 5 **UPCF**: Direction change to UP clear flag
Writing 1 to this bit clear the UP flag in the LPTIM_ISR register.
Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.

Bit 4 **ARROKCF**: Autoreload register update OK clear flag
Writing 1 to this bit clears the ARROK flag in the LPTIM_ISR register

Bit 3 Reserved, must be kept at reset value.

Bit 2 **EXTTRIGCF**: External trigger valid edge clear flag
Writing 1 to this bit clears the EXTTRIG flag in the LPTIM_ISR register

Bit 1 **ARRMCF**: Autoreload match clear flag
Writing 1 to this bit clears the ARRM flag in the LPTIM_ISR register

Bit 0 **CC1CF**: Capture/compare 1 clear flag
Writing 1 to this bit clears the CC1IF flag in the LPTIM_ISR register.

43.7.7 LPTIM4 interrupt enable register (LPTIM4_DIER)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	REPOKIE	UEIE	DOWNIE	UPIE	ARROKIE	CMP1OKIE	EXTTRIGIE	ARRMIE	CC1IE
							rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **REPOKIE**: Repetition register update OK interrupt Enable
0: Repetition register update OK interrupt disabled
1: Repetition register update OK interrupt enabled

Bit 7 **UEIE**: Update event interrupt enable
0: Update event interrupt disabled
1: Update event interrupt enabled

Bit 6 **DOWNIE**: Direction change to down Interrupt Enable
0: DOWN interrupt disabled
1: DOWN interrupt enabled
Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.

Bit 5 **UPIE**: Direction change to UP Interrupt Enable
0: UP interrupt disabled
1: UP interrupt enabled
Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.

Bit 4 **ARROKIE**: Autoreload register update OK Interrupt Enable
0: ARROK interrupt disabled
1: ARROK interrupt enabled

Bit 3 **CMP1OKIE**: Compare register 1 update OK interrupt enable
0: CMPOK register 1 interrupt disabled
1: CMPOK register 1 interrupt enabled

Bit 2 **EXTTRIGIE**: External trigger valid edge Interrupt Enable
0: EXTTRIG interrupt disabled
1: EXTTRIG interrupt enabled

Bit 1 **ARRMIE**: Autoreload match Interrupt Enable
0: ARRM interrupt disabled
1: ARRM interrupt enabled

Bit 0 **CC1IE**: Capture/compare 1 interrupt enable
0: Capture/compare 1 interrupt disabled
1: Capture/compare 1 interrupt enabled

Caution: The LPTIMx_DIER register must only be modified when the LPTIM is enabled (ENABLE bit set to 1). After a write to the LPTIMx_DIER register, a new write operation to the same register can only be performed when the previous write operation is completed. Any successive write before the DIEROK flag is set, leads to unpredictable results.

43.7.8 LPTIMx interrupt enable register [alternate] (LPTIMx_DIER) (x = 1 to 3, 5, 6)

This description of the register can only be used for output compare mode. See next section for input capture compare mode.

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **UEDE**: Update event DMA request enable
- 0: UE DMA request disabled. Writing '0' to the UEDE bit resets the associated ue_dma_req signal.
- 1: UE DMA request enabled

Note: If LPTIM does not implement at least 1 channel this bit is reserved. Refer to Section 43.3.

Bit 22 Reserved, must be kept at reset value.

Bit 21 Reserved, must be kept at reset value.

Bit 20 Reserved, must be kept at reset value.

Bit 19 **CMP2OKIE**: Compare register 2 update OK interrupt enable
- 0: CMPOK register 2 interrupt disabled
- 1: CMPOK register 2 interrupt enabled

Note: If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 43.3.

Bits 18:12 Reserved, must be kept at reset value.

Bit 11 Reserved, must be kept at reset value.

Bit 10 Reserved, must be kept at reset value.

Bit 9 **CC2IE**: Capture/compare 2 interrupt enable
- 0: Capture/compare 2 interrupt disabled
- 1: Capture/compare 2 interrupt enabled

Note: If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 43.3.

Bit 8 **REPOKIE**: Repetition register update OK interrupt Enable
- 0: Repetition register update OK interrupt disabled
- 1: Repetition register update OK interrupt enabled

Bit 7 **UEIE**: Update event interrupt enable
- 0: Update event interrupt disabled
- 1: Update event interrupt enabled

Bit 6 **DOWNIE**: Direction change to down Interrupt Enable
0: DOWN interrupt disabled
1: DOWN interrupt enabled
Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.

Bit 5 **UPIE**: Direction change to UP Interrupt Enable
0: UP interrupt disabled
1: UP interrupt enabled
Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.

Bit 4 **ARROKIE**: Autoreload register update OK Interrupt Enable
0: ARROK interrupt disabled
1: ARROK interrupt enabled

Bit 3 **CMP1OKIE**: Compare register 1 update OK interrupt enable
0: CMPOK register 1 interrupt disabled
1: CMPOK register 1 interrupt enabled

Bit 2 **EXTTRIGIE**: External trigger valid edge Interrupt Enable
0: EXTTRIG interrupt disabled
1: EXTTRIG interrupt enabled

Bit 1 **ARRMIE**: Autoreload match Interrupt Enable
0: ARRM interrupt disabled
1: ARRM interrupt enabled

Bit 0 **CC1IE**: Capture/compare 1 interrupt enable
0: Capture/compare 1 interrupt disabled
1: Capture/compare 1 interrupt enabled

Caution: The LPTIMx_DIER register must only be modified when the LPTIM is enabled (ENABLE bit set to 1). After a write to the LPTIMx_DIER register, a new write operation to the same register can only be performed when the previous write operation is completed. Any successive write before the DIEROK flag is set, leads to unpredictable results.

43.7.9 LPTIMx interrupt enable register [alternate] (LPTIMx_DIER) (x = 1 to 3, 5, 6)

This description of the register can only be used for input capture mode. See previous section for output compare mode.

Address offset: 0x008

Reset value: 0x0000 0000

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 Reserved, must be kept at reset value.

Bit 26 Reserved, must be kept at reset value.

Bit 25 **CC2DE**: Capture/compare 2 DMA request enable
0: CC2 DMA request disabled. Writing '0' to the CC2DE bit resets the associated ic2_dma_req signal.
1: CC2 DMA request enabled
Note: If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 43.3.

Bit 24 Reserved, must be kept at reset value.

Bit 23 **UEDE**: Update event DMA request enable
0: UE DMA request disabled. Writing '0' to the UEDE bit resets the associated ue_dma_req signal.
1: UE DMA request enabled
Note: If LPTIM does not implement at least 1 channel this bit is reserved. Refer to Section 43.3.

Bits 22:17 Reserved, must be kept at reset value.

Bit 16 **CC1DE**: Capture/compare 1 DMA request enable
0: CC1 DMA request disabled. Writing '0' to the CC1DE bit resets the associated ic1_dma_req signal.
1: CC1 DMA request enabled
Note: If LPTIM does not implement at least 1 channel this bit is reserved. Refer to Section 43.3.

Bit 15 Reserved, must be kept at reset value.

Bit 14 Reserved, must be kept at reset value.

Bit 13 **CC2OIE**: Capture/compare 2 over-capture interrupt enable
0: CC2 over-capture interrupt disabled
1: CC2 over-capture interrupt enabled
Note: If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 43.3.

Bit 12 **CC1OIE**: Capture/compare 1 over-capture interrupt enable
0: CC1 over-capture interrupt disabled
1: CC1 over-capture interrupt enabled
Note: If LPTIM does not implement at least 1 channel this bit is reserved. Refer to Section 43.3.

Bit 11 Reserved, must be kept at reset value.

Bit 10 Reserved, must be kept at reset value.

Bit 9 **CC2IE**: Capture/compare 2 interrupt enable
0: Capture/compare 2 interrupt disabled
1: Capture/compare 2 interrupt enabled
Note: If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 43.3.

Bit 8 **REPOKIE**: Repetition register update OK interrupt Enable
0: Repetition register update OK interrupt disabled
1: Repetition register update OK interrupt enabled

Bit 7 **UEIE**: Update event interrupt enable
0: Update event interrupt disabled
1: Update event interrupt enabled

Bit 6 **DOWNIE**: Direction change to down Interrupt Enable
0: DOWN interrupt disabled
1: DOWN interrupt enabled
Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.

Bit 5 **UPIE**: Direction change to UP Interrupt Enable
0: UP interrupt disabled
1: UP interrupt enabled
Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.

Bit 4 **ARROKIE**: Autoreload register update OK Interrupt Enable
0: ARROK interrupt disabled
1: ARROK interrupt enabled

Bit 3 Reserved, must be kept at reset value.

Bit 2 **EXTTRIGIE**: External trigger valid edge Interrupt Enable
0: EXTTRIG interrupt disabled
1: EXTTRIG interrupt enabled

Bit 1 **ARRMIE**: Autoreload match Interrupt Enable
0: ARRM interrupt disabled
1: ARRM interrupt enabled

Bit 0 **CC1IE**: Capture/compare 1 interrupt enable
0: Capture/compare 1 interrupt disabled
1: Capture/compare 1 interrupt enabled

Caution: The LPTIMx_DIER register must only be modified when the LPTIM is enabled (ENABLE bit set to 1). After a write to the LPTIMx_DIER register, a new write operation to the same register can only be performed when the previous write operation is completed. Any successive write before the DIEROK flag is set, leads to unpredictable results.

43.7.10 LPTIM configuration register (LPTIM_CFGR)

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	ENC	COUNT MODE	PRE LOAD	WAV POL	WAVE	TIMOUT	TRIGEN[1:0]		Res.
							rw	rw	rw	rw	rw	rw	rw	rw	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TRIGSEL[2:0]			Res.	PRESC[2:0]			Res.	TRGFLT[1:0]		Res.	CKFLT[1:0]		CKPOL[1:0]		CKSEL
rw	rw	rw		rw	rw	rw		rw	rw		rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 Reserved, must be kept at reset value.

Bits 28:25 Reserved, must be kept at reset value.

Bit 24 **ENC**: Encoder mode enable

The ENC bit controls the Encoder mode

0: Encoder mode disabled

1: Encoder mode enabled

Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.

Bit 23 **COUNTMODE**: counter mode enabled

The COUNTMODE bit selects which clock source is used by the LPTIM to clock the counter:

0: the counter is incremented following each internal clock pulse

1: the counter is incremented following each valid clock pulse on the LPTIM external Input1

Bit 22 **PRELOAD**: Registers update mode

The PRELOAD bit controls the LPTIM_ARR, LPTIM_RCR and the LPTIM_CCRx registers update modality

0: Registers are updated after each APB bus write access

1: Registers are updated at the end of the current LPTIM period

Bit 21 **WAVPOL**: Waveform shape polarity

The WAVPOL bit controls the output polarity

0: The LPTIM output reflects the compare results between LPTIM_CNT and LPTIM_CCRx registers

1: The LPTIM output reflects the inverse of the compare results between LPTIM_CNT and LPTIM_CCRx registers

Note: If the LPTIM implements at least one capture/compare channel, this bit is reserved. Refer to Section 43.3.

Bit 20 **WAVE**: Waveform shape

The WAVE bit controls the output shape

0: Deactivate Set-once mode

1: Activate the Set-once mode

Bit 19 **TIMOUT**: Timeout enable

The TIMOUT bit controls the Timeout feature

0: A trigger event arriving when the timer is already started is ignored

1: A trigger event arriving when the timer is already started resets and restarts the LPTIM counter and the repetition counter

Bits 18:17 **TRIGEN[1:0]**: Trigger enable and polarity

The TRIGEN bits controls whether the LPTIM counter is started by an external trigger or not. If the external trigger option is selected, three configurations are possible for the trigger active edge:

00: software trigger (counting start is initiated by software)

01: rising edge is the active edge

10: falling edge is the active edge

11: both edges are active edges

Bit 16 Reserved, must be kept at reset value.

Bits 15:13 **TRIGSEL[2:0]**: Trigger selector

The TRIGSEL bits select the trigger source that serves as a trigger event for the LPTIM among the below 8 available sources:

000: lptim_ext_trig0
001: lptim_ext_trig1
010: lptim_ext_trig2
011: lptim_ext_trig3
100: lptim_ext_trig4
101: lptim_ext_trig5
110: lptim_ext_trig6
111: lptim_ext_trig7

See *Section 43.4.3: LPTIM input and trigger mapping* for details.

Bit 12 Reserved, must be kept at reset value.

Bits 11:9 **PRESC[2:0]:** Clock prescaler

The PRESC bits configure the prescaler division factor. It can be one among the following division factors:

000: /1
001: /2
010: /4
011: /8
100: /16
101: /32
110: /64
111: /128

Bit 8 Reserved, must be kept at reset value.

Bits 7:6 **TRGFLT[1:0]:** Configurable digital filter for trigger

The TRGFLT value sets the number of consecutive equal samples that are detected when a level change occurs on an internal trigger before it is considered as a valid level transition. An internal clock source must be present to use this feature

00: any trigger active level change is considered as a valid trigger
01: trigger active level change must be stable for at least 2 clock periods before it is considered as valid trigger.
10: trigger active level change must be stable for at least 4 clock periods before it is considered as valid trigger.
11: trigger active level change must be stable for at least 8 clock periods before it is considered as valid trigger.

Bit 5 Reserved, must be kept at reset value.

Bits 4:3 **CKFLT[1:0]:** Configurable digital filter for external clock

The CKFLT value sets the number of consecutive equal samples that are detected when a level change occurs on an external clock signal before it is considered as a valid level transition. An internal clock source must be present to use this feature

00: any external clock signal level change is considered as a valid transition
01: external clock signal level change must be stable for at least 2 clock periods before it is considered as valid transition.
10: external clock signal level change must be stable for at least 4 clock periods before it is considered as valid transition.
11: external clock signal level change must be stable for at least 8 clock periods before it is considered as valid transition.

Bits 2:1 **CKPOL[1:0]:** Clock Polarity

When the LPTIM is clocked by an external clock source, CKPOL bits is used to configure the active edge or edges used by the counter:

00: the rising edge is the active edge used for counting.
If the LPTIM is configured in Encoder mode (ENC bit is set), the encoder sub-mode 1 is active.

01: the falling edge is the active edge used for counting.
If the LPTIM is configured in Encoder mode (ENC bit is set), the encoder sub-mode 2 is active.

10: both edges are active edges. When both external clock signal edges are considered active ones, the LPTIM must also be clocked by an internal clock source with a frequency equal to at least four times the external clock frequency.
If the LPTIM is configured in Encoder mode (ENC bit is set), the encoder sub-mode 3 is active.

11: not allowed

Refer to *Section 43.4.15: Encoder mode* for more details about Encoder mode sub-modes.

Bit 0 **CKSEL:** Clock selector

The CKSEL bit selects which clock source the LPTIM uses:

0: LPTIM is clocked by internal clock source (APB clock or any of the embedded oscillators)

1: LPTIM is clocked by an external clock source through the LPTIM external Input1

Caution: The LPTIM_CFGR register must only be modified when the LPTIM is disabled (ENABLE bit reset to ‘0’).

43.7.11 LPTIM control register (LPTIM_CR)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RSTARE	COUNTRST	CNTSTRT	SNGSTRT	ENABLE
											rw	rs	rw	rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **RSTARE:** Reset after read enable

This bit is set and cleared by software. When RSTARE is set to '1', any read access to LPTIM_CNT register asynchronously resets LPTIM_CNT register content.
This bit can be set only when the LPTIM is enabled.

Bit 3 **COUNTRST:** Counter reset

This bit is set by software and cleared by hardware. When set to '1' this bit triggers a synchronous reset of the LPTIM_CNT counter register. Due to the synchronous nature of this reset, it only takes place after a synchronization delay of 3 LPTimer core clock cycles (LPTimer core clock may be different from APB clock).
This bit can be set only when the LPTIM is enabled. It is automatically reset by hardware.

Caution: COUNTRST must never be set to '1' by software before it is already cleared to '0' by hardware. Software must consequently check that COUNTRST bit is already cleared to '0' before attempting to set it to '1'.

Bit 2 **CNTSTRT:** Timer start in Continuous mode

This bit is set by software and cleared by hardware.

In case of software start (TRIGEN[1:0] = ‘00’), setting this bit starts the LPTIM in Continuous mode.

If the software start is disabled (TRIGEN[1:0] different than ‘00’), setting this bit starts the timer in Continuous mode as soon as an external trigger is detected.

If this bit is set when a single pulse mode counting is ongoing, then the timer does not stop at the next match between the LPTIM_ARR and LPTIM_CNT registers and the LPTIM counter keeps counting in Continuous mode.

This bit can be set only when the LPTIM is enabled. It is automatically reset by hardware.

Bit 1 **SNGSTRT:** LPTIM start in Single mode

This bit is set by software and cleared by hardware.

In case of software start (TRIGEN[1:0] = ‘00’), setting this bit starts the LPTIM in single pulse mode.

If the software start is disabled (TRIGEN[1:0] different than ‘00’), setting this bit starts the LPTIM in single pulse mode as soon as an external trigger is detected.

If this bit is set when the LPTIM is in continuous counting mode, then the LPTIM stops at the following match between LPTIM_ARR and LPTIM_CNT registers.

This bit can only be set when the LPTIM is enabled. It is automatically reset by hardware.

Bit 0 **ENABLE:** LPTIM enable

The ENABLE bit is set and cleared by software.

0: LPTIM is disabled. Writing '0' to the ENABLE bit resets all the DMA request signals (input capture and update event DMA requests).

1: LPTIM is enabled

43.7.12 LPTIM compare register 1 (LPTIM_CCR1)

Address offset: 0x014

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCR1[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **CCR1[15:0]**: Capture/compare 1 value

If channel CC1 is configured as output:

CCR1 is the value to be loaded in the capture/compare 1 register.

Depending on the PRELOAD option, the CCR1 register is immediately updated if the PRELOAD bit is reset and updated at next LPTIM update event if PREOAD bit is reset.

The capture/compare register 1 contains the value to be compared to the counter LPTIM_CNT and signaled on OC1 output.

If channel CC1 is configured as input:

CCR1 becomes read-only, it contains the counter value transferred by the last input capture 1 event. The LPTIM_CCR1 register is read-only and cannot be programmed.

If LPTIM does not implement any channel:

The compare register 1 contains the value to be compared to the counter LPTIM_CNT and signaled on LPTIM output.

Caution: The LPTIM_CCR1 register must only be modified when the LPTIM is enabled (ENABLE bit set to ‘1’).

43.7.13 LPTIM autoreload register (LPTIM_ARR)

Address offset: 0x018

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ARR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **ARR[15:0]:** Auto reload value

ARR is the autoreload value for the LPTIM.

This value must be strictly greater than the CCRx[15:0] value.

Caution: The LPTIM_ARR register must only be modified when the LPTIM is enabled (ENABLE bit set to ‘1’).

43.7.14 LPTIM counter register (LPTIM_CNT)

Address offset: 0x01C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CNT[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **CNT[15:0]:** Counter value

When the LPTIM is running with an asynchronous clock, reading the LPTIM_CNT register may return unreliable values. So in this case it is necessary to perform two consecutive read accesses and verify that the two returned values are identical.

43.7.15 LPTIM configuration register 2 (LPTIM_CFGR2)

Address offset: 0x024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IC2SEL[1:0]		Res.	Res.	IC1SEL[1:0]	
										rw	rw			rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IN2SEL[1:0]		Res.	Res.	IN1SEL[1:0]	
										rw	rw			rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:20 **IC2SEL[1:0]**: LPTIM input capture 2 selection

The IC2SEL bits control the LPTIM Input capture 2 multiplexer, which connects LPTIM Input capture 2 to one of the available inputs.
00: lptim_ic2_mux0
01: lptim_ic2_mux1
10: lptim_ic2_mux2
11: lptim_ic2_mux3
For connection details refer to *Section 43.4.3: LPTIM input and trigger mapping*.

Bits 19:18 Reserved, must be kept at reset value.

Bits 17:16 **IC1SEL[1:0]**: LPTIM input capture 1 selection

The IC1SEL bits control the LPTIM Input capture 1 multiplexer, which connects LPTIM Input capture 1 to one of the available inputs.
00: lptim_ic1_mux0
01: lptim_ic1_mux1
10: lptim_ic1_mux2
11: lptim_ic1_mux3
For connection details refer to *Section 43.4.3: LPTIM input and trigger mapping*.

Bits 15:6 Reserved, must be kept at reset value.

Bits 5:4 **IN2SEL[1:0]**: LPTIM input 2 selection

The IN2SEL bits control the LPTIM input 2 multiplexer, which connects LPTIM input 2 to one of the available inputs.
00: lptim_in2_mux0
01: lptim_in2_mux1
10: lptim_in2_mux2
11: lptim_in2_mux3
For connection details refer to *Section 43.4.3: LPTIM input and trigger mapping*.

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **IN1SEL[1:0]**: LPTIM input 1 selection

The IN1SEL bits control the LPTIM input 1 multiplexer, which connects LPTIM input 1 to one of the available inputs.
00: lptim_in1_mux0
01: lptim_in1_mux1
10: lptim_in1_mux2
11: lptim_in1_mux3
For connection details refer to *Section 43.4.3: LPTIM input and trigger mapping*.

43.7.16 LPTIM repetition register (LPTIM_RCR)

Address offset: 0x028

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	REP[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **REP[7:0]**: Repetition register value
REP is the repetition value for the LPTIM.

Caution: The LPTIM_RCR register must only be modified when the LPTIM is enabled (ENABLE bit set to ‘1’). When using repetition counter with PRELOAD = 0, LPTIM_RCR register must be changed at least five counter cycles before the auto reload match event, otherwise an unpredictable behavior may occur.

43.7.17 LPTIM capture/compare mode register 1 (LPTIM_CCMR1)

Address offset: 0x02C

Reset value: 0x0000 0000

The channels can be used in input (capture mode) or in output (PWM mode). The direction of a channel is defined by configuring the corresponding CCxSEL bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	IC2F[1:0]		Res.	Res.	IC2PSC[1:0]		Res.	Res.	Res.	Res.	CC2P[1:0]		CC2E	CC2 SEL
		rw	rw			rw	rw					rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	IC1F[1:0]		Res.	Res.	IC1PSC[1:0]		Res.	Res.	Res.	Res.	CC1P[1:0]		CC1E	CC1 SEL
		rw	rw			rw	rw					rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **IC2F[1:0]**: Input capture 2 filter

This bitfield defines the number of consecutive equal samples that are detected when a level change occurs on an external input capture signal before it is considered as a valid level transition. An internal clock source must be present to use this feature.

00: any external input capture signal level change is considered as a valid transition

01: external input capture signal level change must be stable for at least 2 clock periods before it is considered as valid transition.

10: external input capture signal level change must be stable for at least 4 clock periods before it is considered as valid transition.

11: external input capture signal level change must be stable for at least 8 clock periods before it is considered as valid transition.

Bits 27:26 Reserved, must be kept at reset value.

Bits 25:24 **IC2PSC[1:0]**: Input capture 2 prescaler

This bitfield defines the ratio of the prescaler acting on the CC2 input (IC2).

00: no prescaler, capture is done each time an edge is detected on the capture input

01: capture is done once every 2 events

10: capture is done once every 4 events

11: capture is done once every 8 events

Bits 23:20 Reserved, must be kept at reset value.

Bits 19:18 **CC2P[1:0]**: Capture/compare 2 output polarity.

Condition: CC2 as output

Only bit2 is used to set polarity when output mode is enabled, bit3 is don't care.

0: OC2 active high

1: OC2 active low

Condition: CC2 as input

This field is used to select the IC2 polarity for capture operations.

00: rising edge, circuit is sensitive to IC2 rising edge

01: falling edge, circuit is sensitive to IC2 falling edge

10: reserved, do not use this configuration.

11: both edges, circuit is sensitive to both IC2 rising and falling edges.

Bit 17 **CC2E**: Capture/compare 2 output enable.

Condition: CC2 as output

0: Off - OC2 is not active. Writing '0' to the CC2E bit resets the ue_dma_req signal only if all the other LPTIM channels are disabled.

1: On - OC2 signal is output on the corresponding output pin

Condition: CC2 as input

This bit determines if a capture of the counter value can actually be done into the input capture/compare register 2 (LPTIM_CCR2) or not.

0: Capture disabled. Writing '0' to the CC2E bit resets the associated ic2_dma_req signal.

1: Capture enabled.

Bit 16 **CC2SEL**: Capture/compare 2 selection

This bitfield defines the direction of the channel, input (capture) or output mode.

0: CC2 channel is configured in output PWM mode

1: CC2 channel is configured in input capture mode

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **IC1F[1:0]**: Input capture 1 filter

This bitfield defines the number of consecutive equal samples that are detected when a level change occurs on an external input capture signal before it is considered as a valid level transition. An internal clock source must be present to use this feature.

00: any external input capture signal level change is considered as a valid transition

01: external input capture signal level change must be stable for at least 2 clock periods before it is considered as valid transition.

10: external input capture signal level change must be stable for at least 4 clock periods before it is considered as valid transition.

11: external input capture signal level change must be stable for at least 8 clock periods before it is considered as valid transition.

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:8 **IC1PSC[1:0]**: Input capture 1 prescaler

This bitfield defines the ratio of the prescaler acting on the CC1 input (IC1).

00: no prescaler, capture is done each time an edge is detected on the capture input

01: capture is done once every 2 events

10: capture is done once every 4 events

11: capture is done once every 8 events

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:2 **CC1P[1:0]**: Capture/compare 1 output polarity.

Condition: CC1 as output

Only bit2 is used to set polarity when output mode is enabled, bit3 is don't care.

0: OC1 active high, the LPTIM output reflects the compare results between LPTIM_ARR and LPTIM_CCRx registers

1: OC1 active low, the LPTIM output reflects the inverse of the compare results between LPTIM_ARR and LPTIM_CCRx registers

Condition: CC1 as input

This field is used to select the IC1 polarity for capture operations.

00: rising edge, circuit is sensitive to IC1 rising edge

01: falling edge, circuit is sensitive to IC1 falling edge

10: reserved, do not use this configuration.

11: both edges, circuit is sensitive to both IC1 rising and falling edges.

Bit 1 **CC1E**: Capture/compare 1 output enable.

Condition: CC1 as output

0: Off - OC1 is not active. Writing '0' to the CC1E bit resets the ue_dma_req signal only if all the other LPTIM channels are disabled.

1: On - OC1 signal is output on the corresponding output pin

Condition: CC1 as input

This bit determines if a capture of the counter value can actually be done into the input capture/compare register 1 (LPTIM_CCR1) or not.

0: Capture disabled. Writing '0' to the CC1E bit resets the associated ic1_dma_req signal.

1: Capture enabled.

Bit 0 **CC1SEL**: Capture/compare 1 selection

This bitfield defines the direction of the channel input (capture) or output mode.

0: CC1 channel is configured in output PWM mode

1: CC1 channel is configured in input capture mode

Caution: After a write to the LPTIM_CCMRx register, a new write operation to the same register can only be performed after a delay that must be equal or greater than the value of (PRESC × 3)

kernel clock cycles, PRESC[2:0] being the clock decimal division factor (1, 2, 4,..128). Any successive write violating this delay, leads to unpredictable results.

Caution: The CCxSEL, ICxF[1:0], CCxP[1:0] and ICxPSC[1:0] fields must only be modified when the channel x is disabled (CCxE bit reset to 0).

If LPTIM does not implement any channel this register is reserved. Refer to Section 43.3.

43.7.18 LPTIM compare register 2 (LPTIM_CCR2)

Address offset: 0x034

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **CCR2[15:0]**: Capture/compare 2 value

If channel CC2 is configured as output:

CCR2 is the value to be loaded in the capture/compare 2 register.

Depending on the PRELOAD option, the CCR2 register is immediately updated if the PRELOAD bit is reset and updated at next LPTIM update event if PREOAD bit is reset.

The capture/compare register 2 contains the value to be compared to the counter LPTIM_CNT and signaled on OC2 output.

If channel CC2 is configured as input:

CCR2 becomes read-only, it contains the counter value transferred by the last input capture 2 event. The LPTIM_CCR2 register is read-only and cannot be programmed.

Caution: The LPTIM_CCR2 register must only be modified when the LPTIM is enabled (ENABLE bit set to '1').

Note: If the LPTIM implements less than 2 channels this register is reserved. Refer to *Section 43.3: LPTIM implementation*.

43.7.19 LPTIM register map

The following table summarizes the LPTIM registers.

Table 466. LPTIM register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

1. If LPTIM does not implement at least 2 channels this bit is reserved. Refer to *Section 43.3: LPTIM implementation*.
2. If LPTIM does not support encoder mode feature, this bit is reserved. Refer to *Section 43.3: LPTIM implementation*.
3. If the LPTIM implements at least one capture/compare channel, this bit is reserved. Refer to *Section 43.3: LPTIM implementation*.
4. If LPTIM does not implement any channel this register is reserved. Refer to *Section 43.3: LPTIM implementation*.
5. If the LPTIM implements less than 2 channels this register is reserved. Refer to *Section 43.3: LPTIM implementation*.

Refer to *Section 2.3 on page 111* for the register boundary addresses.

44 Independent watchdog (IWDG)

44.1 Introduction

The independent watchdog (IWDG) peripheral offers a high safety level, thanks to its capability to detect malfunctions due to software or hardware failures.

The IWDG is clocked by an independent clock, and stays active even if the main clock fails.

In addition, the watchdog function is performed in the V_{DD} voltage domain, allowing the IWDG to remain functional even in low-power modes. Refer to *Section 44.3* to check the capability of the IWDG in this product.

The IWDG is best suited for applications that require the watchdog to run as a totally independent process outside the main application, making it very reliable to detect any unexpected behavior.

44.2 IWDG main features

- 12-bit down-counter
- Dual voltage domain, thus enabling operation in low-power modes
- Independent clock
- Early wake-up interrupt generation
- Reset generation
  - In case of timeout
  - In case of refresh outside the expected window

44.3 IWDG implementation

Table 467. IWDG features (1)

IWDG modes/features	IWDG
LSI used as IWDG kernel clock (iwdg_ker_ck)	X
Window function	X
Early wake-up interrupt generation	X
System reset generation (2)	X
Capability to work in system Stop	X
Capability to work in system Standby	X
Capability to generate an interrupt in system Stop	X
Capability to generate an interrupt in system Standby	-
Capability to be frozen when the microcontroller enters in Debug mode (3)	X
Option bytes to control the activity in Stop mode (4)	X
Option bytes to control the activity in Standby mode (5)	X
Option bytes to control the Hardware mode (6)	X

1. 'X' = supported, '-' = not supported.
2. Refer to the RCC section for additional information.
3. Controlled via DBG_IWDG_STOP in DBG section.

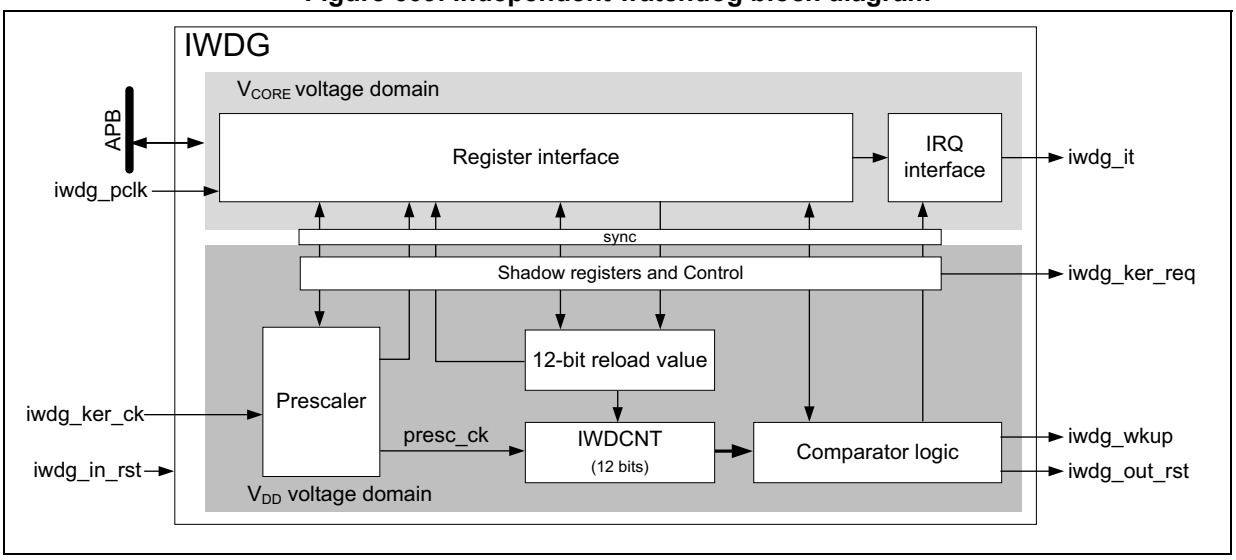
4. Controlled via the option byte IWDG_STOP in FLASH section.
5. Controlled via the option byte IWDG_STDBY in FLASH section.
6. Controlled via the option byte IWDG_SW in FLASH section.

44.4 IWDG functional description

44.4.1 IWDG block diagram

Figure 609 shows the functional blocks of the independent watchdog module.

Figure 609. Independent watchdog block diagram



The register and IRQ interfaces are located into the V_{CORE} voltage domain. The watchdog function itself is located into the V_{DD} voltage domain to remain functional in low-power modes. See *Section 44.3* for IWDG capabilities.

The register and IRQ interfaces are mainly clocked by the APB clock (iwdg_pclk), while the watchdog function is clocked by a dedicated kernel clock (iwdg_ker_ck). A synchronization mechanism makes the data exchange between the two domains possible. Note that most of the registers located in the register interface are shadowed into the V_{DD} voltage domain.

The IWDG down-counter (IWDCNT) is clocked by the prescaled clock (presc_ck). The prescaled clock is generated from the kernel clock iwdg_ker_ck divided by the prescaler, according to PR[3:0] bitfield.

44.4.2 IWDG internal signals

The list of IWDG internal signals is detailed in *Table 468*.

Table 468. IWDG internal input/output signals

Signal name	Signal type	Description
iwdg_ker_ck	Input	IWDG kernel clock
iwdg_ker_req	Input	IWDG kernel clock request
iwdg_pclk	Input	IWDG APB clock
iwdg_out_rst	Output	IWDG reset output
iwdg_in_rst	Input	IWDG reset input
iwdg_wkup	Output	IWDG wake-up event
iwdg_it	Output	IWDG early wake-up interrupt

44.4.3 Software and hardware watchdog modes

The watchdog modes allow the application to select the way the IWDG is enabled, either by software commands (Software watchdog mode), or automatically (Hardware watchdog mode). All other functions work similarly for both Software and Hardware modes.

The Software watchdog mode is the default working mode. The independent watchdog is started by writing the value 0x0000 CCCC into the *IWDG key register (IWDG_KR)*, and the IWDCNT starts counting down from the reset value (0xFFF).

In the Hardware watchdog mode the independent watchdog is started automatically at power-on, or every time it is reset (via iwdg_in_rst). The IWDCNT down-counter starts counting down from the reset value 0xFFF. The hardware watchdog mode feature is enabled through the device option bits, see *Section 44.3* for details.

When the IWDG is enabled the ONF flag is set to 1.

When the IWDCNT reaches 0x000, a reset signal is generated (iwdg_out_rst asserted).

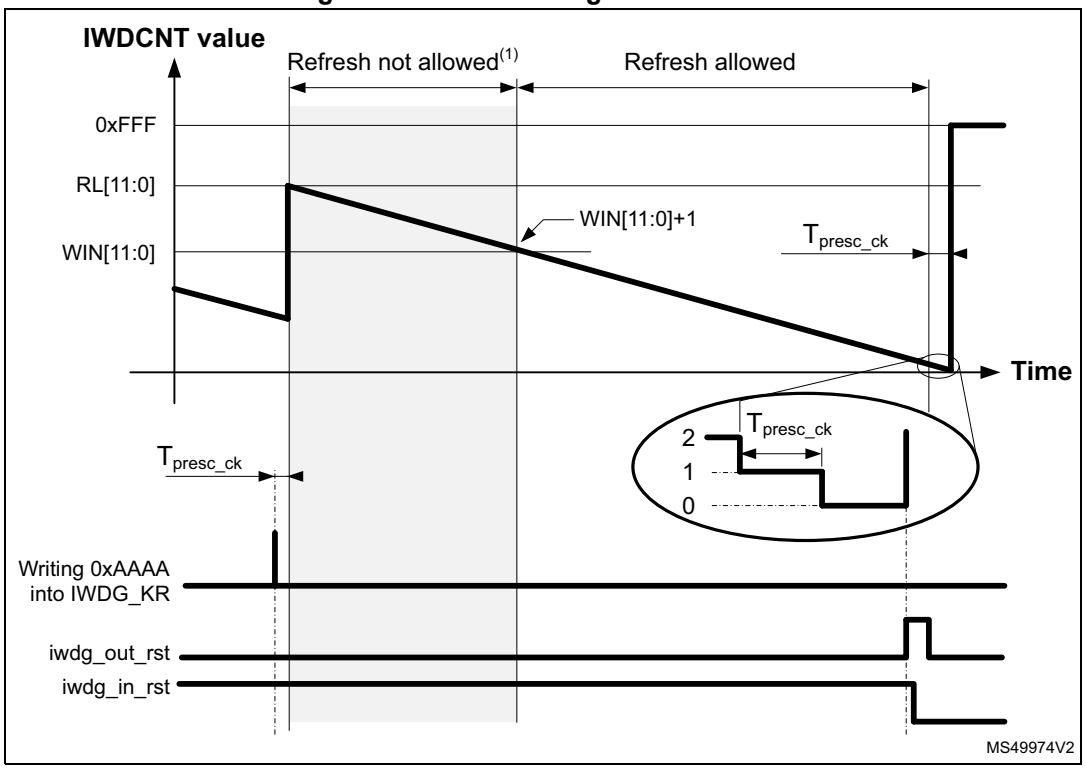
Whenever the key value 0x0000 AAAA is written in the *IWDG key register (IWDG_KR)*, the IWDG_RLR value is reloaded into the IWDCNT, and the watchdog reset is prevented.

Due to re-synchronization delays, the IWDG must be refreshed before the IWDCNT down-counter reaches 1.

Once started, the IWDG can be stopped only when it is reset (iwdg_in_rst asserted).

As shown in *Figure 610*, when the refresh command is executed, one period of presc_ck later, the IWDCNT is reloaded with the content of RL[11:0].

Figure 610. Reset timing due to timeout



1. If window option activated.

If the IWDG is not refreshed before the IWDCNT reaches 1, then the IWDG generates a reset (i.e. iwdg_out_rst asserted). In return, the RCC resets the IWDG (assertion of iwdg_in_rst) to clear the reset source.

44.4.4 Window option

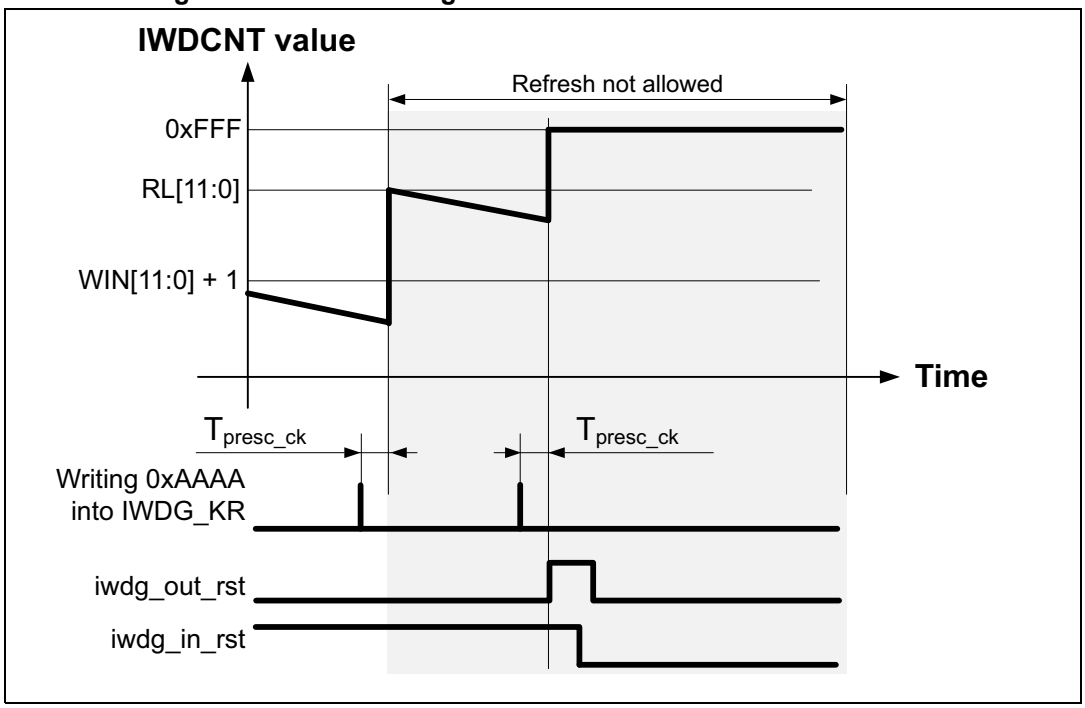
The IWDG can also work as a window watchdog by setting the appropriate window in the *IWDG window register (IWDG_WINR)*.

If the reload operation is performed while the counter is greater than WIN[11:0] + 1 a reset is generated. WIN[11:0] is located in the *IWDG window register (IWDG_WINR)*. As shown in *Figure 611*, the reset is generated one period of presc_ck after the unexpected refresh command.

The default value of the *IWDG window register (IWDG_WINR)* is 0x0000 0FFF, so, if not updated, the window option is disabled.

As soon as the window value changes, the down-counter (IWDCNT) is reloaded with the RL[11:0] value to ease the estimation for where the next refresh must take place.

Figure 611. Reset timing due to refresh in the not allowed area



Configuring the IWDG when the window option is enabled

1. Enable the IWDG by writing 0x0000 CCCC in the *IWDG key register (IWDG_KR)*.
2. Enable register access by writing 0x0000 5555 in the *IWDG key register (IWDG_KR)*.
3. Write the IWDG prescaler by programming *IWDG prescaler register (IWDG_PR)*.
4. Write the *IWDG reload register (IWDG_RLR)*.
5. If needed, enable the early wake-up interrupt, and program the early wake-up comparator, by writing the proper values into the *IWDG early wake-up interrupt register (IWDG_EWCR)*.
6. Write to the *IWDG window register (IWDG_WINR)*. This automatically reloads the IWDCNT down-counter with the RL[11:0] value.
7. Wait for the registers to be updated (IWDG_SR = 0x0000 0000).
8. Write 0x0000 0000 into *IWDG key register (IWDG_KR)* to write-protect registers.

Note: Step 7 can be skipped if the application does not intend to disable the APB clock after the completion of this sequence.

Configuring the IWDG when the window option is disabled

When the window option it is not used, the IWDG can be configured as follows:

1. Enable the IWDG by writing 0x0000 CCCC in the *IWDG key register (IWDG_KR)*.
2. Enable register access by writing 0x0000 5555 in the *IWDG key register (IWDG_KR)*.
3. Write the prescaler by programming the *IWDG prescaler register (IWDG_PR)*.
4. Write the *IWDG reload register (IWDG_RLR)*.
5. If needed, enable the early wake-up interrupt, and program the early wake-up comparator, by writing the proper values into the *IWDG early wake-up interrupt register (IWDG_EWCR)*.
6. Wait for the registers to be updated (IWDG_SR = 0x0000 0000).
7. Refresh the counter with RL[11:0] value, and write-protect registers by writing 0x0000 AAAA into *IWDG key register (IWDG_KR)*.

Updating the window comparator

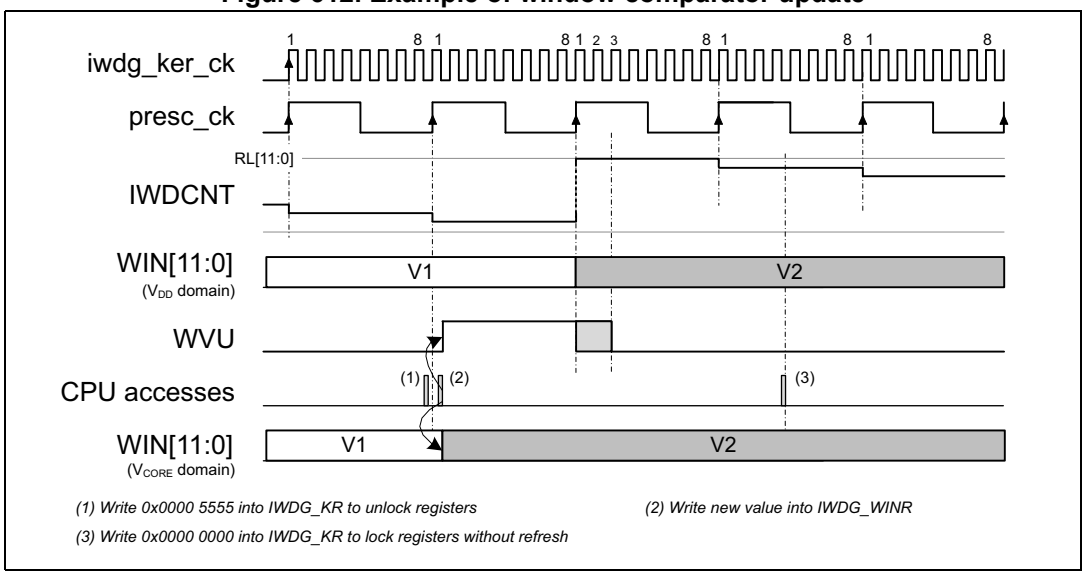
It is possible to update the window comparator when the IWDG is already running. The IWDCNT is reloaded as well. The following sequence can be performed to update the window comparator:

1. Enable register access by writing 0x0000 5555 in the IWDG key register (IWDG_KR).
2. Write to the IWDG window register (IWDG_WINR). This automatically reloads the IWDCNT down-counter with RL[11:0] value.
3. Wait for WVU = 0
4. Lock registers by writing IWDG_KR to 0x0000 0000

Step *3* can be skipped if the application does not intend to disable the APB clock after the completion of this sequence.

Figure 612 shows this sequence. As soon as the IWDG_WINR register is written, the WVU flag goes high. The new window value and the reload of IWDCNT with RL[11:0] are effective on the next rising edge of presc_ck. The WVU flag goes back to 0, in the worst case, two kernel clock periods later. So WVU remains high at most one period of presc_ck, plus two periods of the kernel clock.

Figure 612. Example of window comparator update



44.4.5 Debug

When the processor enters into Debug mode (core halted), the IWDCNT down-counter either continues to work normally or stops, depending on debug capability of the product. Refer to *Section 44.3* for details on the capabilities of this product.

44.4.6 Register access protection

Write accesses to *IWDG prescaler register (IWDG_PR)*, *IWDG reload register (IWDG_RLR)*, *IWDG early wake-up interrupt register (IWDG_EWCR)* and *IWDG window register (IWDG_WINR)* are protected. To modify them, first write 0x0000 5555 in the *IWDG key register (IWDG_KR)*. A write access to this register with a different value breaks the sequence and register access is protected again. This is the case of the reload operation (writing 0x0000 AAAA).

A status register is available to indicate that an update of the prescaler or the down-counter reload value or the window value is ongoing.

44.5 IWDG low-power modes

Depending on option bytes configuration, the IWDG can continue counting or not during the low-power modes. Refer to *Section 44.3* for details.

Table 469. Effect of low-power modes on IWDG

Mode	Description
Sleep	No effect. IWDG interrupts cause the device to exit the Sleep mode.
Stop	The IWDG remains active or not, depending on option bytes configuration. Refer to *Section 44.3* for details. IWDG interrupts cause the device exit the Stop mode.
Standby	The IWDG remains active or not, depending on option bytes configuration. Refer to *Section 44.3* for details. IWDG interrupts do not make the device to exit from Standby mode.

44.6 IWDG interrupts

The IWDG offers the possibility to generate an early interrupt depending on the value of the down-counter. The early interrupt is enabled by setting the EWIE bit of the *IWDG early wake-up interrupt register (IWDG_EWCR)* to 1.

A comparator value (EWIT[11:0]) allows the application to define at which position the early interrupt must be generated.

When the IWDCNT down-counter reaches the value of EWIT[11:0] - 1, the iwdg_wkup is activated, making it possible for the system to exit from low-power mode if needed.

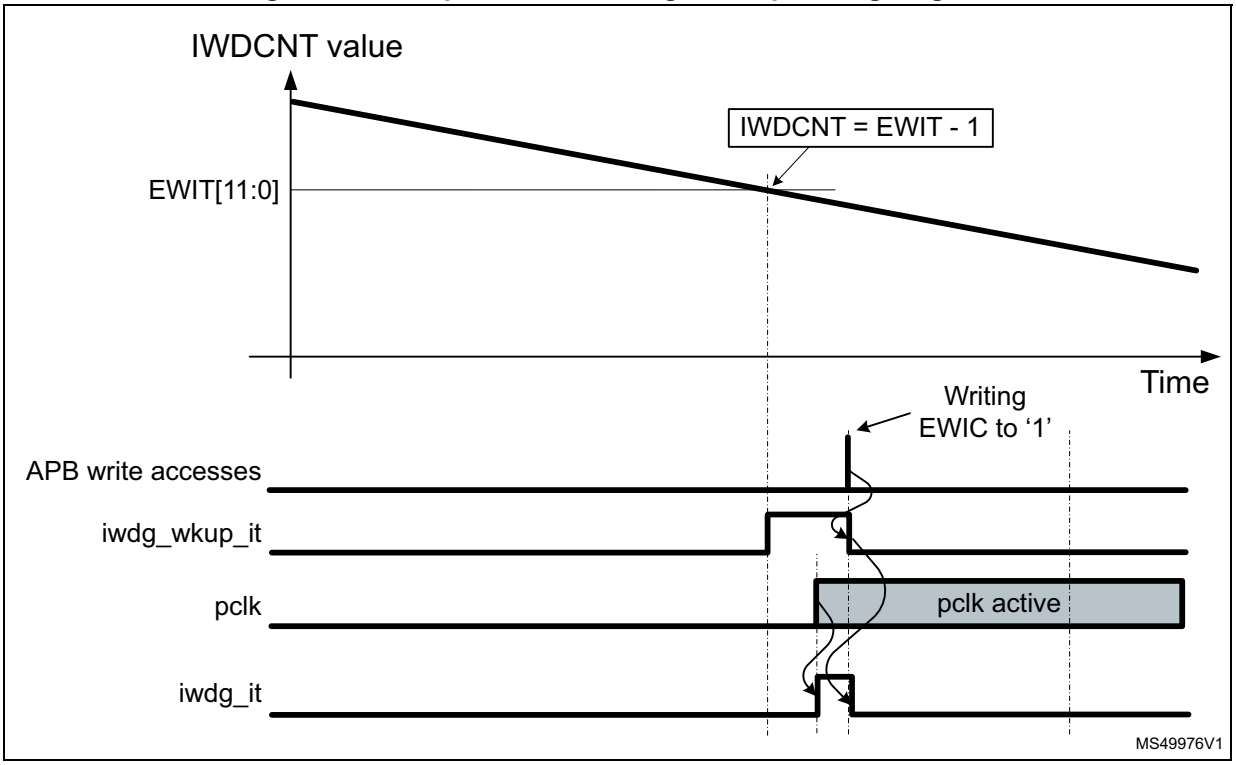
When the APB clock is available, the iwdg_it is activated as well.

In addition the flag EWIF of the *IWDG status register (IWDG_SR)* is set to 1.

The EWI interrupt is acknowledged by writing '1' to the EWIC bit in the *IWDG early wake-up interrupt register (IWDG_EWCR)*.

Writing into the IWDG_EWCR register also triggers a refresh of the down-counter (IWDCNT) with the reload value RL[11:0].

Figure 613. Independent watchdog interrupt timing diagram



The early wake-up interrupt (EWI) can be used if specific safety operations or data logging must be performed before the watchdog reset is generated.

Changing the early wake-up comparator value

It is possible to change the early wake-up comparator value or to enable/disable the interrupt generation at any time, by performing the following sequence:

1. Enable register access by writing 0x0000 5555 in the *IWDG key register (IWDG_KR)*.
2. Enable or disable the early wake-up interrupt, and/or program the early wake-up comparator, by writing the proper values into the *IWDG early wake-up interrupt register (IWDG_EWCR)*.
3. Wait for EWU = '0', EWU is located into the *IWDG status register (IWDG_SR)*.
4. Write-protect registers by writing 0x0000 0000 to *IWDG key register (IWDG_KR)*.

Step *3* can be skipped if the application does not intend to disable the APB clock after the completion of this sequence.

Figure 613 shows this sequence. As soon as the IWDG_EWCR register is written, the EWU flag goes high. The new comparator value and the reload of IWDCNT with RL[11:0] are effective on the next rising edge of presc_ck. The EWU flag goes back to 0, in the worst case, two kernel clock periods later. So, EWU remains high at most one period of presc_ck, plus two periods of the kernel clock.

Figure 614. Example of early wake-up comparator update

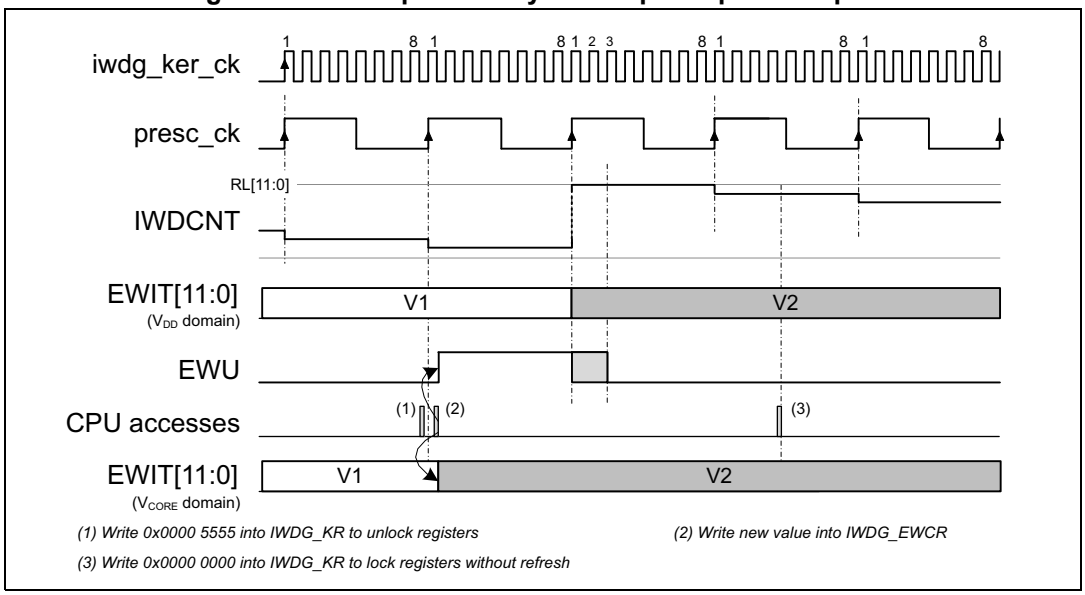


Table 470 summarizes the IWDG interrupt request.

Table 470. IWDG interrupt request

Interrupt event	Event flag	Interrupt clear method	Interrupt enable control bit	Activated interrupt	
				iwdg_it	iwdg_wkup_it
IWDCNT reaches EWIT value	EWIF	Writing EWIC to '1'	EWIE	Y(1)	Y(2)

1. Generated when a clock is present on iwdg_pclk input.
2. Generated when a clock is present on iwdg_ker_ck input.

44.7 IWDG registers

Refer to *Section 1.2 on page 101* for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

Most of the registers located into the register interface are shadowed into the V_{DD} voltage domain. When the iwdg_in_rst is asserted, the watchdog logic and the shadow registers located into the V_{DD} voltage domain are reset.

When the application reads back a watchdog register, the hardware transfers the value of the corresponding shadow register to the register interface.

When the application writes a watchdog register, the hardware updates the corresponding shadow register.

44.7.1 IWDG key register (IWDG_KR)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
KEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **KEY[15:0]:** Key value (write only, read 0x0000)

These bits can be used for several functions, depending upon the value written by the application:

- 0xAAAA: reloads the RL[11:0] value into the IWDCNT down-counter (watchdog refresh), and write-protects registers. This value must be written by software at regular intervals, otherwise the watchdog generates a reset when the counter reaches 0.
- 0x5555: enables write-accesses to the registers.
- 0xCCCC: enables the watchdog (except if the hardware watchdog option is selected) and write-protects registers.
- values different from 0x5555: write-protects registers.

Note that only IWDG_PR, IWDG_RLR, IWDG_EWCR and IWDG_WINR registers have a write-protection mechanism.

44.7.2 IWDG prescaler register (IWDG_PR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PR[3:0]			
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **PR[3:0]:** Prescaler divider

These bits are write access protected, see *Section 44.4.6*. They are written by software to select the prescaler divider feeding the counter clock. PVU bit of the *IWDG status register (IWDG_SR)* must be reset to be able to change the prescaler divider.

0000: divider / 4
0001: divider / 8
0010: divider / 16
0011: divider / 32
0100: divider / 64
0101: divider / 128
0110: divider / 256
0111: divider / 512
Others: divider / 1024

Note: Reading this register returns the prescaler value from the V_{DD} voltage domain. This value may not be up to date/valid if a write operation to this register is ongoing. For this reason the value read from this register is valid only when the PVU bit in the IWDG status register (IWDG_SR) is reset.

44.7.3 IWDG reload register (IWDG_RLR)

Address offset: 0x08

Reset value: 0x0000 0FFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	RL[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **RL[11:0]:** Watchdog counter reload value

These bits are write access protected, see *Section 44.4.6*. They are written by software to define the value to be loaded in the watchdog counter each time the value 0xAAAA is written in the *IWDG key register (IWDG_KR)*. The watchdog counter counts down from this value. The timeout period is a function of this value and the prescaler.clock. It is not recommended to set RL[11:0] to a value lower than 2.

The RVU bit in the *IWDG status register (IWDG_SR)* must be reset to be able to change the reload value.

Note: Reading this register returns the reload value from the V_{DD} voltage domain. This value may not be up to date/valid if a write operation to this register is ongoing, hence the value read from this register is valid only when the RVU bit in the IWDG status register (IWDG_SR) is reset.

44.7.4 IWDG status register (IWDG_SR)

Address offset: 0x0C

Reset value: 0x0000 0000 (0xFFFF FEFF)

This register contains various status flags. Note that the mask value between parenthesis means that the reset value of ONF bit is not defined. When the IWDG is configured in

software mode, the reset value of ONF bit is 0, when the IWDG is configured in hardware mode, the reset value of ONF bit is 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	EWIF	Res.	Res.	Res.	Res.	Res.	ONF	Res.	Res.	Res.	Res.	EWU	WVU	RVU	PVU
	r						r					r	r	r	r

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **EWIF**: Watchdog early interrupt flag

This bit is set to ‘1’ by hardware in order to indicate that an early interrupt is pending. This bit must be cleared by the software by writing the bit EWIC of IWDG_EWCR register to ‘1’.

Bits 13:9 Reserved, must be kept at reset value.

Bit 8 **ONF**: Watchdog enable status bit

Set to ‘1’ by hardware as soon as the IWDG is started. In software mode, it remains to '1' until the IWDG is reset. In hardware mode, this bit is always set to '1'.

0: The IWDG is not activated

1: The IWDG is activated and needs to be refreshed regularly by the application

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **EWU**: Watchdog interrupt comparator value update

This bit is set by hardware to indicate that an update of the interrupt comparator value (EWIT[11:0]) or an update of the EWIE is ongoing. It is reset by hardware when the update operation is completed in the V_{DD} voltage domain (takes up to one period of presc_ck and two periods of the IWDG kernel clock iwdg_ker_ck).

The EWIT[11:0] and EWIE fields can be updated only when EWU bit is reset.

Bit 2 **WVU:** Watchdog counter window value update

This bit is set by hardware to indicate that an update of the window value is ongoing. It is reset by hardware when the reload value update operation is completed in the V_{DD} voltage domain (takes up to one period of presc_ck and two periods of the IWDG kernel clock iwdg_ker_ck).

The window value can be updated only when WVU bit is reset.

This bit is generated only if generic “window” = 1.

Bit 1 **RVU:** Watchdog counter reload value update

This bit is set by hardware to indicate that an update of the reload value is ongoing. It is reset by hardware when the reload value update operation is completed in the V_{DD} voltage domain (takes up to six periods of the IWDG kernel clock iwdg_ker_ck).

The reload value can be updated only when RVU bit is reset.

Bit 0 **PVU:** Watchdog prescaler value update

This bit is set by hardware to indicate that an update of the prescaler value is ongoing. It is reset by hardware when the prescaler update operation is completed in the V_{DD} voltage domain (takes up to six periods of the IWDG kernel clock iwdg_ker_ck).

The prescaler value can be updated only when PVU bit is reset.

Note: If several reload, prescaler, early interrupt position or window values are used by the application, it is mandatory to wait until RVU bit is reset before changing the reload value, to wait until PVU bit is reset before changing the prescaler value, to wait until WVU bit is reset

before changing the window value, and to wait until EWU bit is reset before changing the early interrupt position value. After updating the prescaler and/or the reload/window/early interrupt value, it is not necessary to wait until RVU or PVU or WVU or EWU is reset before continuing code execution, except in case of low-power mode entry.

44.7.5 IWDG window register (IWDG_WINR)

Address offset: 0x10

Reset value: 0x0000 0FFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	WIN[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **WIN[11:0]:** Watchdog counter window value

These bits are write access protected, see *Section 44.4.6*.They contain the high limit of the window value to be compared with the downcounter.

To prevent a reset, the IWDCNT downcounter must be reloaded when its value is lower than WIN[11:0] + 1 and greater than 1.

The WVU bit in the *IWDG status register (IWDG_SR)* must be reset to be able to change the reload value.

Note: Reading this register returns the reload value from the V_{DD} voltage domain. This value may not be valid if a write operation to this register is ongoing. For this reason the value read from this register is valid only when the WVU bit in the IWDG status register (IWDG_SR) is reset.

44.7.6 IWDG early wake-up interrupt register (IWDG_EWCR)

Address offset: 0x14

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EWIE	EWIC	Res.	Res.	EWIT[11:0]											
rw	w			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **EWIE**: Watchdog early interrupt enable

Set and reset by software.

0: The early interrupt interface is disabled.

1: The early interrupt interface is enabled.

The EWU bit in the *IWDG status register (IWDG_SR)* must be reset to be able to change the value of this bit.

Bit 14 **EWIC**: Watchdog early interrupt acknowledge

The software must write a 1 into this bit in order to acknowledge the early wake-up interrupt and to clear the EWIF flag. Writing 0 has not effect, reading this flag returns a 0.

Bits 13:12 Reserved, must be kept at reset value.

Bits 11:0 **EWIT[11:0]:** Watchdog counter window value

These bits are write access protected (see *Section 44.4.6*). They are written by software to define at which position of the IWDCNT down-counter the early wake-up interrupt must be generated. The early interrupt is generated when the IWDCNT is lower or equal to EWIT[11:0] - 1.

EWIT[11:0] must be bigger than 1.

An interrupt is generated only if EWIE = 1.

The EWU bit in the *IWDG status register (IWDG_SR)* must be reset to be able to change the reload value.

Note: Reading this register returns the Early wake-up comparator value and the Interrupt enable bit from the V_{DD} voltage domain. This value may not be up to date/valid if a write operation to this register is ongoing, hence the value read from this register is valid only when the EWU bit in the IWDG status register (IWDG_SR) is reset.

44.7.7 IWDG register map

Table 471. IWDG register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3 on page 111* for the register boundary addresses.

45 System window watchdog (WWDG)

45.1 Introduction

The system window watchdog (WWDG) is used to detect the occurrence of a software fault, usually generated by external interference or by unforeseen logical conditions, which causes the application program to abandon its normal sequence.

The watchdog circuit generates a reset on expiry of a programmed time period, unless the program refreshes the contents of the down-counter before the T6 bit is cleared. A reset is also generated if the 7-bit down-counter value (in the control register) is refreshed before the down-counter reaches the window register value. This implies that the counter must be refreshed in a limited window.

The WWDG clock is prescaled from the APB clock and has a configurable time-window that can be programmed to detect abnormally late or early application behavior.

The WWDG is best suited for applications requiring the watchdog to react within an accurate timing window.

45.2 WWDG main features

- Programmable free-running down-counter
- Conditional reset
  - Reset (if watchdog activated) when the down-counter value becomes lower than 0x40
  - Reset (if watchdog activated) if the down-counter is reloaded outside the window (see *Figure 616*)
- Early wake-up interrupt (EWI): triggered (if enabled and the watchdog activated) when the down-counter is equal to 0x40

45.3 WWDG implementation

Table 472. WWDG features(1)

WWDG mode / feature	WWDG
Window function	X
Early wake-up interrupt generation	X
System reset generation(2)	X
Capability to work in system Stop	-
Capability to work in system Standby	-
Capability to be frozen when the microcontroller enters in Debug mode(3)	X
Option bytes to control the Hardware mode(4)	X

1. “X” = supported, “-” = not supported.
2. Refer to the RCC section for additional information.
3. Controlled via DBG_WWDG_STOP in DBG block.

4. Controlled via the option byte WWDG_SW. When WWDG_SW is set in HW mode the WWDG is running as soon as the CPU is in Run or Sleep modes.

45.4 WWDG functional description

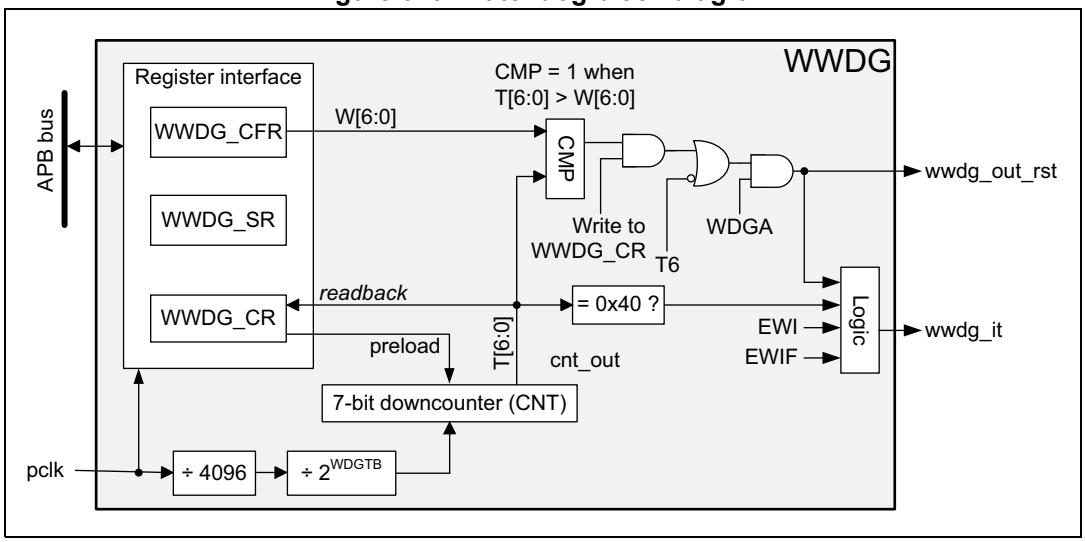
If the watchdog is activated (the WDGA bit is set in the WWDG_CR register), and when the 7-bit down-counter (T[6:0] bits) is decremented from 0x40 to 0x3F (T6 becomes cleared), it initiates a reset. If the software reloads the counter while the counter is greater than the value stored in the window register, then a reset is generated.

The application program must write in the WWDG_CR register at regular intervals during normal operation to prevent a reset. This operation can take place only when the counter value is lower than or equal to the window register value, and higher than 0x3F. The value to be stored in the WWDG_CR register must be between 0xFF and 0xC0.

Refer to *Figure 615* for the WWDG block diagram.

45.4.1 WWDG block diagram

Figure 615. Watchdog block diagram



45.4.2 WWDG internal signals

Table 473 gives the list of WWDG internal signals.

Table 473. WWDG internal input/output signals

Signal name	Signal type	Description
pclk	Digital input	APB bus clock
wwdg_out_rst	Digital output	WWDG reset signal output
wwdg_it	Digital output	WWDG early interrupt output

45.4.3 Enabling the watchdog

When the user option WWDG_SW selects “Software window watchdog”, the watchdog is always disabled after a reset. It is enabled by setting the WDGA bit in the WWDG_CR register, then it cannot be disabled again, except by a reset.

When the user option WWDG_SW selects “Hardware window watchdog”, the watchdog is always enabled after a reset, it cannot be disabled.

45.4.4 Controlling the down-counter

This down-counter is free-running, counting down even if the watchdog is disabled. When the watchdog is enabled, the T6 bit must be set to prevent generating an immediate reset.

The T[5:0] bits contain the number of increments that represent the time delay before the watchdog produces a reset. The timing varies between a minimum and a maximum value, due to the unknown status of the prescaler when writing to the WWDG_CR register (see *Figure 616*). The *WWDG configuration register (WWDG_CFR)* contains the high limit of the window: to prevent a reset, the down-counter must be reloaded when its value is lower than or equal to the window register value, and greater than 0x3F. *Figure 616* describes the window watchdog process.

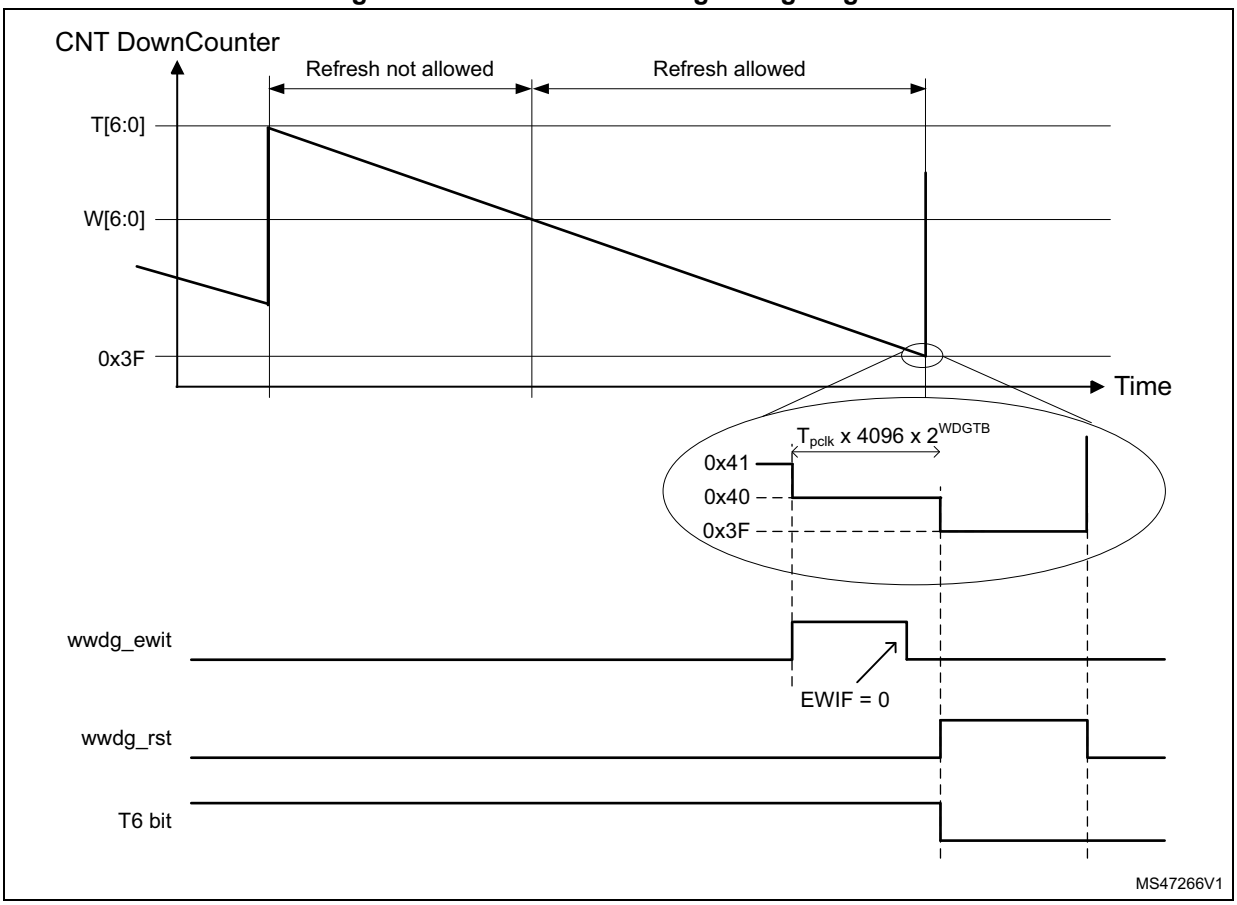
Note: The T6 bit can be used to generate a software reset (the WDGA bit is set and the T6 bit is cleared).

45.4.5 How to program the watchdog timeout

Use the formula in *Figure 616* to calculate the WWDG timeout.

Warning: When writing to the WWDG_CR register, always write 1 in the T6 bit to avoid generating an immediate reset.

Figure 616. Window watchdog timing diagram



The formula to calculate the timeout value is given by:

$$t_{WWDG} = t_{PCLK} \times 4096 \times 2^{WDGTB[2:0]} \times (T[5:0] + 1) \quad (ms)$$

where:

t_{WWDG}: WWDG timeout

t_{PCLK}: APB clock period measured in ms

4096: value corresponding to internal divider

As an example, if APB frequency is 48 MHz, WDGTB[2:0] is set to 3 and T[5:0] is set to 63:

$$t_{WWDG} = (1/\ 48000) \times 4096 \times 2^{3} \times (63 + 1) = 43.69ms$$

Refer to the datasheet for the minimum and maximum values of t_{WWDG}.

45.4.6 Debug mode

When the device enters debug mode (processor halted), the WWDG counter either continues to work normally or stops, depending on the configuration bit in DBG module. For more details, refer to *Section 58: Debug support (DBG)*.

45.5 WWDG interrupts

The early wake-up interrupt (EWI) can be used if specific safety operations or data logging must be performed before the reset is generated. To enable the early wake-up interrupt, the application must:

- Write EWIF bit of WWDG_SR register to 0, to clear unwanted pending interrupt
- Write EWI bit of WWDG_CFR register to 1, to enable interrupt

When the down-counter reaches the value 0x40, a watchdog interrupt is generated, and the corresponding interrupt service routine (ISR) can be used to trigger specific actions (such as communications or data logging), before resetting the device.

In some applications, the EWI interrupt can be used to manage a software system check and/or system recovery/graceful degradation, without generating a WWDG reset. In this case the corresponding ISR must reload the WWDG counter to avoid the WWDG reset, then trigger the required actions.

The watchdog interrupt is cleared by writing '0' to the EWIF bit in the WWDG_SR register.

Note: When the watchdog interrupt cannot be served (for example due to a system lock in a higher priority task), the WWDG reset is eventually generated.

Table 474. WWDG interrupt requests

Interrupt		Event flag	Enable control bit	Interrupt clearing method	Exit from mode		
Vector	Event				Sleep	Stop(1)	Standby(1)
WWDG(2)	Early wake-up interrupt	EWIF	EWI	Write EWIF flag to 0	Yes	No	No

1. The WWDG interrupt can have additional capabilities, refer to *Section 45.3* for details.
2. WWDG vector corresponds to the assertion of the wwdg_it signal.

45.6 WWDG registers

Refer to *Section 1.2 on page 101* for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by halfwords (16-bit) or words (32-bit).

45.6.1 WWDG control register (WWDG_CR)

Address offset: 0x000

Reset value: 0x0000 007F

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WDGA	T[6:0]						
								rs	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **WDGA:** Activation bit

This bit is set by software and only cleared by hardware after a reset. When WDGA = 1, the watchdog can generate a reset.

0: Watchdog disabled

1: Watchdog enabled

Bits 6:0 **T[6:0]:** 7-bit counter (MSB to LSB)

These bits contain the value of the watchdog counter, decremented every (4096 x $2^{WDGTB[2:0]}$) PCLK cycles. A reset is produced when it is decremented from 0x40 to 0x3F (T6 becomes cleared).

45.6.2 WWDG configuration register (WWDG_CFR)

Address offset: 0x004

Reset value: 0x0000 007F

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	WDGTB[2:0]			Res.	EWI	Res.	Res.	W[6:0]						
		rw	rw	rw		rs			rw	rw	rw	rw	rw	rw	rw

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:11 **WDGTB[2:0]:** Timer base

The timebase of the prescaler can be modified as follows:

000: CK counter clock (PCLK div 4096) div 1

001: CK counter clock (PCLK div 4096) div 2

010: CK counter clock (PCLK div 4096) div 4

011: CK counter clock (PCLK div 4096) div 8

100: CK counter clock (PCLK div 4096) div 16

101: CK counter clock (PCLK div 4096) div 32

110: CK counter clock (PCLK div 4096) div 64

111: CK counter clock (PCLK div 4096) div 128

Bit 10 Reserved, must be kept at reset value.

Bit 9 **EWI:** Early wake-up interrupt enable

Set by software and cleared by hardware after a reset. When set, an interrupt occurs whenever the counter reaches the value 0x40.

Bits 8:7 Reserved, must be kept at reset value.

Bits 6:0 **W[6:0]:** 7-bit window value

These bits contain the window value to be compared with the down-counter.

45.6.3 WWDG status register (WWDG_SR)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	EWIF
															rc_w0

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **EWIF:** Early wake-up interrupt flag

This bit is set by hardware when the counter has reached the value 0x40. It must be cleared by software by writing 0. Writing 1 has no effect. This bit is also set if the interrupt is not enabled.

45.6.4 WWDG register map

The following table gives the WWDG register map and reset values.

Table 475. WWDG register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3 on page 111* for the register boundary addresses.

46 Real-time clock (RTC)

46.1 Introduction

The RTC provides an automatic wake-up to manage all low-power modes.

The real-time clock (RTC) is an independent BCD timer/counter. The RTC provides a time-of-day clock/calendar with programmable alarm interrupts.

As long as the supply voltage remains in the operating range, the RTC never stops, regardless of the device status (Run mode, low-power mode or under reset).

The RTC is functional in V_{BAT} mode.

46.2 RTC main features

The RTC supports the following features (see *Figure 617: RTC block diagram*):

- Calendar with subseconds, seconds, minutes, hours (12 or 24 format), week day, date, month, year, in BCD (binary-coded decimal) format.
- Binary mode with 32-bit free-running counter.
- Automatic correction for 28, 29 (leap year), 30, and 31 days of the month.
- Two programmable alarms.
- On-the-fly correction from 1 to 32767 RTC clock pulses. This can be used to synchronize it with a master clock.
- Reference clock detection: a more precise second source clock (50 or 60 Hz) can be used to enhance the calendar precision.
- Digital calibration circuit with 0.95 ppm resolution, to compensate for quartz crystal inaccuracy.
- Timestamp feature which can be used to save the calendar content. This function can be triggered by an event on the timestamp pin, or by a tamper event, or by a switch to V_{BAT} mode.
- 17-bit auto-reload wake-up timer (WUT) for periodic events with programmable resolution and period.
- TrustZone support:
  - RTC fully securable
  - Alarm A, alarm B, wake-up Timer and timestamp individual secure or nonsecure configuration
- Alarm A, alarm B, wake-up Timer and timestamp individual privilege protection

The RTC is supplied through a switch that takes power either from the V_{DD} supply when present or from the VBAT pin.

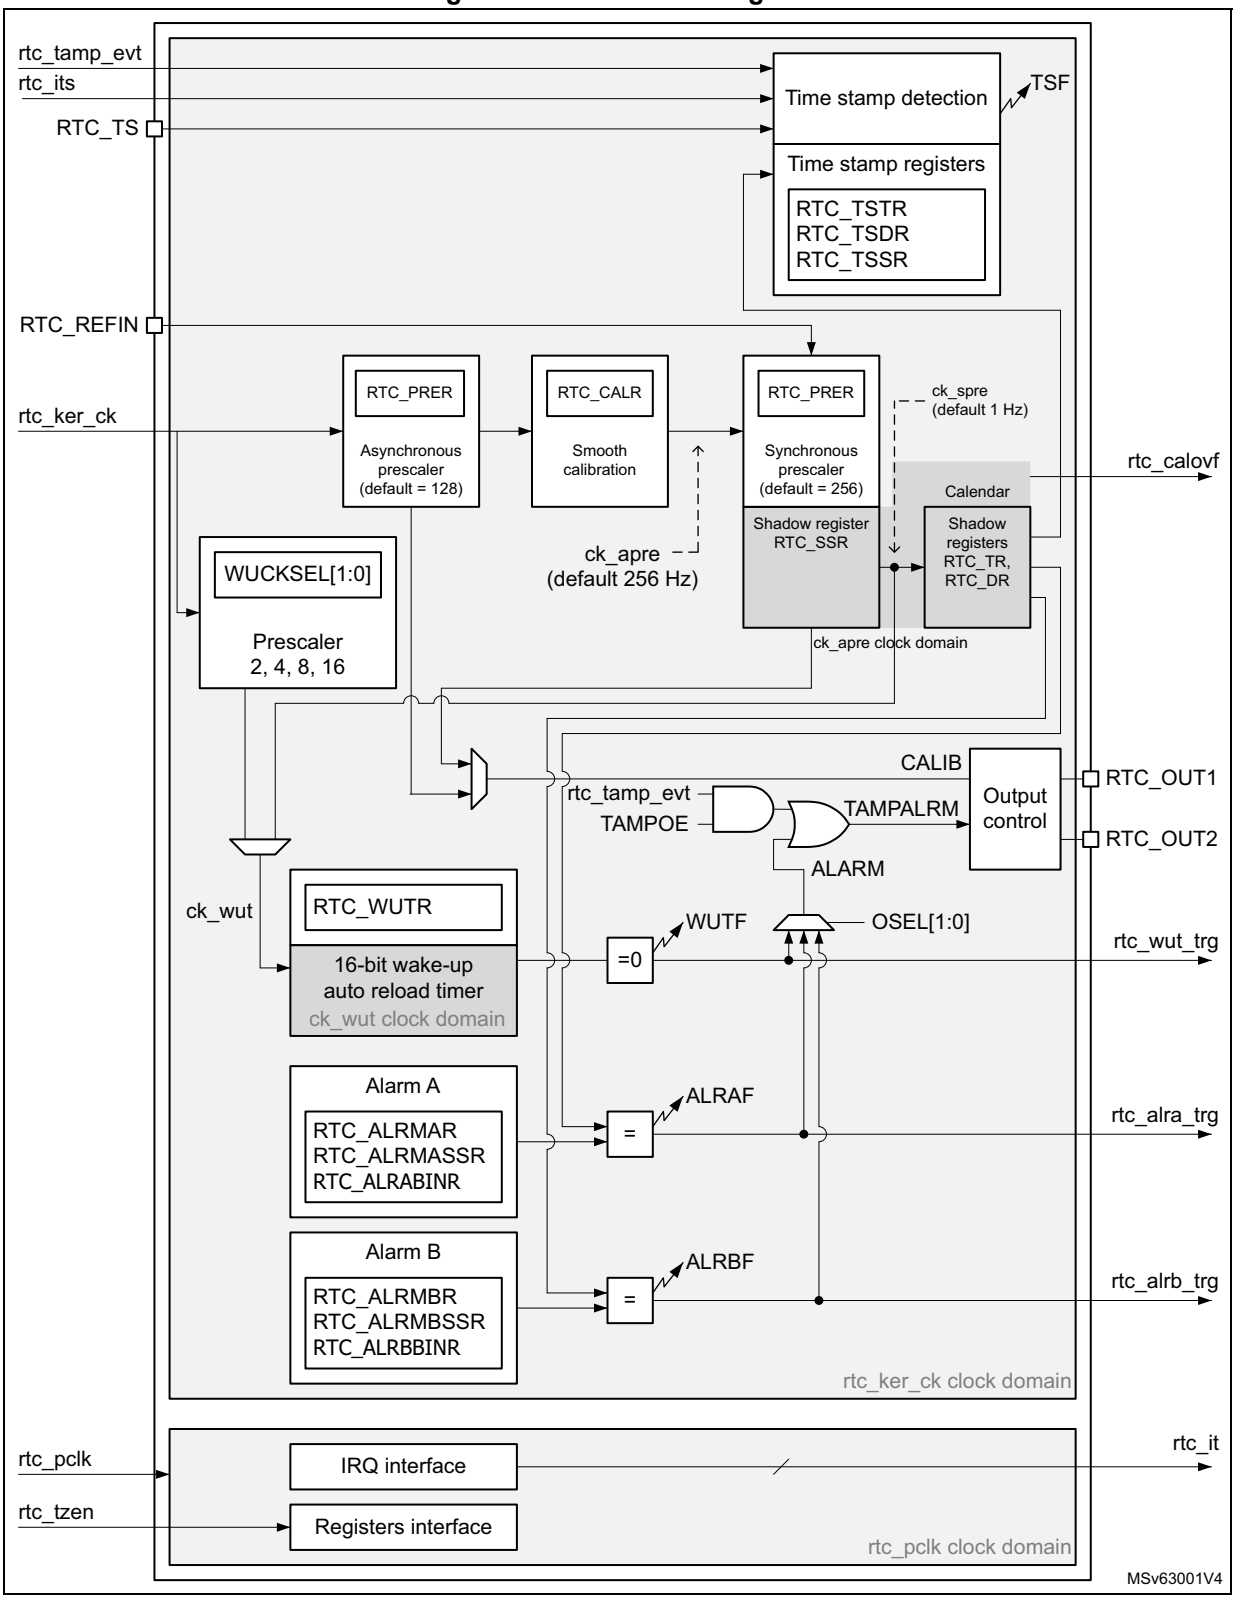
The RTC is functional in V_{BAT} mode and in all low-power modes when it is clocked by the LSE.

All RTC events (Alarm, wake-up Timer, Timestamp) can generate an interrupt and wake-up the device from the low-power modes.

46.3 RTC functional description

46.3.1 RTC block diagram

Figure 617. RTC block diagram



46.3.2 RTC pins and internal signals

Table 476. RTC input/output pins

Pin name	Signal type	Description
RTC_TS	Input	RTC timestamp input
RTC_REFIN	Input	RTC 50 or 60 Hz reference clock input
RTC_OUT1	Output	RTC output 1
RTC_OUT2	Output	RTC output 2

RTC_OUT1 and RTC_OUT2 which select one of the following two outputs:

- CALIB: 512 Hz or 1 Hz clock output (with an LSE frequency of 32.768 kHz). This output is enabled by setting the COE bit in the RTC_CR register.
- TAMPALRM: This output is the OR between rtc_tamp_evt and ALARM signals.

ALARM is enabled by configuring the OSEL[1:0] bits in the RTC_CR register which select the alarm A, alarm B or wake-up outputs. rtc_tamp_evt is enabled by setting the TAMPOE bit in the RTC_CR register which selects the tamper event outputs.

Table 477. RTC internal input/output signals

Internal signal name	Signal type	Description
rtc_ker_ck	Input	RTC kernel clock, also named RTCCLK in this document
rtc_pclk	Input	RTC APB clock
rtc_its	Input	RTC internal timestamp event
rtc_tamp_evt	Input	Tamper event (internal or external) detected in TAMP peripheral
rtc_tzen	Input	RTC TrustZone enabled
rtc_it	Output	RTC interrupts (refer to *Section 46.5: RTC interrupts* for details)
rtc_alra_trg	Output	RTC alarm A event detection trigger
rtc_alrb_trg	Output	RTC alarm B event detection trigger
rtc_wut_trg	Output	RTC wake-up timer event detection trigger
rtc_calovf	Output	RTC calendar overflow: this signal is generated when the RTC calendar reaches its maximum value, on the 31st of December 99, at 23:59:59. The calendar is then frozen and cannot overflow.

The RTC kernel clock is usually the LSE at 32.768 kHz although it is possible to select other clock sources in the RCC (refer to RCC for more details). Some functions are not available in some low-power modes or V_{BAT} when the selected clock is not LSE. Refer to *Section 46.4: RTC low-power modes* for more details.

Table 478. RTC interconnection

Signal name	Source/destination
rtc_its	From power controller (PWR): main power loss/switch to V_{BAT} detection output
rtc_tamp_evt	From TAMP peripheral: tamp_evt
rtc_tzen	From FLASH option bytes: TZEN
rtc_calovf	To TAMP peripheral: tamp_itamp5

The TZEN option bit is used to activate TrustZone in the device.

TZEN = 1: TrustZone activated.

TZEN = 0: TrustZone disabled.

When TrustZone is disabled, the APB access to the RTC registers are nonsecure.

The triggers outputs can be used as triggers for other peripherals.

46.3.3 GPIOs controlled by the RTC and TAMP

The GPIOs included in the Battery Backup Domain (V_{BAT}) are directly controlled by the peripherals providing functions on these I/Os, whatever the GPIO configuration.

RTC_OUT1, RTC_TS, TAMP_IN1, TAMP_OUT2 and TAMP_OUT3 are mapped on the same pin (PC13). The RTC and TAMP functions mapped on PC13 are available in all low-power modes and in V_{BAT} mode.

The output mechanism follows the priority order shown in *Table 479*.

Table 479. RTC pin PC13 configuration(1)

PC13 Pin function		OSEL[1:0] (ALARM output enable)	TAMPOE (TAMPER output enable)	COE (CALIB output enable)	OUT2EN	TAMPALRM_TYPE	TAMPALRM_PU	TAMP2E=TAMP2AM=1 with ATOSHARE=0, or TAMPxE=TAMPxAM=1 with ATOSHARE=1 and ATOSELx=1	TAMP3E=TAMP3AM=1 with ATOSHARE=0 and OUT3_RMP=00, or TAMPxE=TAMPxAM=1 with ATOSHARE=1, ATOSELx=2 and OUT3_RMP=00	TAMP1E (TAMP_IN1 input enable)	TSE (RTC_TS input enable)

	Don't care	Don't care	0				0	0		

1. OD: open drain; PP: push-pull.
2. In this configuration the GPIO must be configured in input.

RTC_OUT2, TAMP_IN2 and TAMP_OUT3 are mapped on the same pin (PI8). PI8 configuration is controlled by the RTC, whatever the PI8 GPIO configuration. The RTC or TAMP functions mapped on PI8 are available in all low-power modes and in VBAT mode.

The output mechanism follows the priority order shown in *Table 480*.

Table 480. PI8 configuration

PI1 Pin function		OSEL[1:0] (ALARM output enable)	TAMPOE (TAMPER output enable)	COE (CALIB output enable)	OUT2EN &OUT2_RMP	TAMPALRM_TYPE	TAMPALRM_PU	TAMP3E=TAMP3AM=1 with ATOSHARE=0 and OUT3_RMP=01, or TAMPxE=TAMPxAM=1 with ATOSHARE=1, ATOSELx=2 and OUT3_RMP=01	TAMP2E & IN2_RMP
TAMPALRM output Push-Pull		01 or 10 or 11	0	Don't care	1	0	0	Don't care	Don't care
		00	1						
		01 or 10 or 11	1

Standard GPIO		00	0	0	0	Don't care	Don't care	0	0

In addition, it is possible to output RTC_OUT2 on PB2 or PI8 pin thanks to OUT2EN and OUT2_RMP bits. The different functions are mapped on RTC_OUT1 or on RTC_OUT2 depending on OSEL, COE and OUT2EN configuration, as shown in table *Table 481*.

Table 481. RTC_OUT mapping

OSEL[1:0] bits ALARM output enable)	COE bit (CALIB output enable)	OUT2EN bit	RTC_OUT1 on PC13	RTC_OUT2 on PB2 or PI8
00	0	0	-	-
00	1		CALIB	-
01 or 10 or 11	Don't care		TAMPALRM	-
00	0	1	-	-
00	1		-	CALIB
01 or 10 or 11	0		-	TAMPALRM
01 or 10 or 11	1		TAMPALRM	CALIB

46.3.4 RTC secure protection modes

By default after a backup domain power-on reset, all RTC registers can be read or written in both secure and nonsecure modes, except for the RTC secure configuration register (RTC_SECCFGR) which can be written in secure mode only. The RTC protection configuration is not affected by a system reset.

When the SEC bit is set in the RTC_SECCFGR register:

- Writing the RTC registers is possible only in secure mode.
- Reading RTC_SECCFGR, RTC_PRIVCFGR, RTC_MISR, RTC_TR, RTC_DR, RTC_SSR, RTC_PRER and RTC_CALR is always possible in secure and nonsecure modes. All the other RTC registers can be read only in secure mode.

When the SEC bit is cleared, it is still possible to protect some of the registers by setting dedicated INITSEC, CALSEC, TSSEC, WUTSEC, ALRASEC or ALRBSEC control bits. If all these bits are also set, all the RTC registers can be read and written in secure and nonsecure mode.

- When INITSEC is set:
  - RTC_TR, RTC_DR, RTC_PRER registers, plus INIT, BIN and BCDU in RTC_ICSR, FMT control bits in RTC_CR and INITPRIV in the RTC_PRIVCFGR can be written only in secure mode.
  - These registers and control bits can be read in secure and nonsecure mode.
- When CALSEC is set:
  - RTC_SHIFTR and RTC_CALR registers, plus ADD1H, SUB1H and REFCKON control bits in the RTC_CR and CALPRIV in the RTC_PRIVCFGR can be written only in secure mode.
  - These registers and control bits can be read in secure and nonsecure mode.
- When ALRASEC is set:
  - RTC_ALRMAR, RTC_ALRMASSR and RTC_ALRABINR registers, plus ALRAE, ALRAFCLR, ALRAIE and SSRUIE in the RTC_CR, CALRAF and CSSRUF in the

RTC_SCR, ALRAF and SSRUF in RTC_SR, and ALRAMF and SSRUMF in RTC_SMISR can be read and written only in secure mode.

  - ALRAPRIV in the RTC_PRIVCFGR can be written only in secure mode
- When ALRBSEC is set:
  - RTC_ALRMBR, RTC_ALRMBSSR and RTC_ALRBBINR registers, plus ALRBE ALRBFCLR, ALRBIE in the RTC_CR, CALRBF in the RTC_SCR, ALRBF in RTC_SR, and ALRBMF in RTC_SMISR can be read and written only in secure mode.
  - ALRBPRIV in the RTC_PRIVCFGR can be written only in secure mode.
- When WUTSEC is set:
  - RTC_WUTR register, plus WUTE, WUTIE and WUCKSEL control bits in the RTC_CR, CWUTF in the RTC_SCR, WUTF in RTC_SR, and WUTMF in RTC_SMISR can be read and written only in secure mode.
  - WUTPRIV in the RTC_PRIVCFGR can be written only in secure mode
- When TSSEC is set:
  - RTC_TSTR, RTC_TSDR and RTC_TSSSR registers, plus TAMPTS, ITSE, TSE, TSIE, TSEDGE control bits in the RTC_CR, CITSF, CTSOVF and CTSF bits in the RTC_SCR, TSF, TSOVF and ITSF in RTC_SR, and TSMF, TSOVMF and ITSMF in RTC_SMISR can be read and written only in secure mode.
  - TSPRIV in the RTC_PRIVCFGR can be written only in secure mode

A nonsecure access to a secure-protected register is denied:

- There is no bus error generated.
- In case the register has a global protection: a notification is generated through a flag/interrupt in the TZIC (TrustZone illegal access controller). In case only a few bits of the register are protected (for registers with mixed features such as RTC_CR...), no notification is generated.
- When write protected, the bits are not written.
- When read protected they are read as 0.

As soon as at least one function is configured to be secured, the RTC reset and clock control is also secured in the RCC.

46.3.5 RTC privilege protection modes

By default after a backup domain power-on reset, all RTC registers can be read or written in both privileged and non-privileged modes, except for the RTC privilege mode control register (RTC_PRIVCFGR) which can be written in privilege mode only. The RTC protection configuration is not affected by a system reset.

When the PRIV bit is set in the RTC_PRIVCFGR register:

- Writing the RTC registers is possible only in privileged mode.
- Reading the RTC_SECCFGR, RTC_PRIVCFGR, RTC_TR, RTC_DR, RTC_SSR, RTC_PRER and RTC_CALR is always possible in privilege and non-privilege modes. All the other RTC registers can be read only in privilege mode.

When the PRIV bit is cleared, it is still possible to protect some of the registers by setting dedicated INITPRIV, CALPRIV, TSPRIV, WUTPRIV, ALRAPRV or ALRBPRIV control bits. If

all these bits are also cleared, all the RTC registers can be read or written in privilege and non-privilege modes.

- When INITPRIV is set:
  - RTC_TR, RTC_DR, RTC_PRER registers, plus INIT, BIN and BCDU in RTC_ICSR and FMT control bits in RTC_CR, plus INITSEC in the RTC_SECCFGR can be written only in privilege mode.
  - These registers and control bits can be read in privilege and non-privilege mode.
- When CALPRIV is set:
  - RTC_SHIFTR and RTC_CALR registers, plus ADD1H, SUB1H and REFCKON control bits in the RTC_CR, plus CALDSEC in the RTC_SECCFGR can be written only in privilege mode.
  - These registers and control bits can be read in privilege and non-privilege mode.
- When ALRAPRIV is set:
  - RTC_ALRMAR, RTC_ALRMASSR and RTC_ALRABINR registers, plus ALRAE ALRAFCLR, ALRAIE and SSRUIE in the RTC_CR, and CALRAF and CSSRUF in the RTC_SCR, ALRAF and SSRUF in RTC_SR, and ALRAMF and SSRUMF in RTC_MISR and RTC_SMISR can be read and written only in privilege mode.
  - ALRASEC in the RTC_SECCFGR can be written only in privilege mode.
- When ALRBPRIV is set:
  - RTC_ALRMBR, RTC_ALRMBSSR and RTC_ALRBBINR registers, plus ALRBE ALRBFCLR, ALRBIE in the RTC_CR, and CALRBF in the RTC_SCR, ALRBF in RTC_SR, and ALRBMF in RTC_MISR and RTC_SMISR can be read and written only in privilege mode.
  - ALRBSEC in the RTC_SECCFGR can be written only in privilege mode.
- When WUTPRIV is set:
  - RTC_WUTR register, plus WUTE, WUTIE and WUCKSEL control bits in the RTC_CR, and CWUTF in the RTC_SCR, WUTF in RTC_SR, and WUTMF in RTC_MISR and RTC_SMISR can be read and written only in privilege mode.
  - WUTSEC in the RTC_SECCFGR can be written only in privilege mode.
- When TSPRIV is set:
  - RTC_TSTR, RTC_TSDR and RTC_TSSSR registers, plus TAMPTS, ITSE, TSE, TSIE, TSEDGE control bits in the RTC_CR, CITSF, CTSOVF and CTSF bits in the RTC_SCR, TSF, TSOVF and ITSF in RTC_SR, and TSMF, TSOVMF and ITSMF in RTC_MISR and RTC_SMISR can be read and written only in privilege mode.
  - TSSEC in the RTC_SECCFGR can be written only in privilege mode.

A non-privileged access to a privileged-protected register is denied:

- There is no bus error generated.
- When write protected, the bits are not written.
- When read protected they are read as 0.

46.3.6 Clock and prescalers

For more information on the RTC clock (RTCCLK) source configuration, refer to “Reset and clock control (RCC)”.

BCD mode (BIN=00)

A programmable prescaler stage generates a 1 Hz clock which is used to update the calendar. To minimize power consumption, the prescaler is split into 2 programmable prescalers (see *Figure 617: RTC block diagram*):

- A 7-bit asynchronous prescaler configured through the PREDIV_A bits of the RTC_PRER register.
- A 15-bit synchronous prescaler configured through the PREDIV_S bits of the RTC_PRER register.

Note: When both prescalers are used, it is recommended to configure the asynchronous prescaler to a high value to minimize consumption.

The asynchronous prescaler division factor is set to 128, and the synchronous division factor to 256, to obtain an internal clock frequency of 1 Hz (ck_spre) with an LSE frequency of 32.768 kHz.

The minimum division factor is 1 and the maximum division factor is 2^{22}.

This corresponds to a maximum input frequency of around 4 MHz.

f_{ck_apre} is given by the following formula:

$$f_{CK\_APRE} = \frac{f_{RTCCLK}}{PREDIV\_A + 1}$$

The ck_apre clock is used to clock the binary RTC_SSR subsecond downcounter. When it reaches 0, RTC_SSR is reloaded with the content of PREDIV_S.

f_{ck_spre} is given by the following formula:

$$f_{CK\_SPRE} = \frac{f_{RTCCLK}}{(PREDIV\_S + 1) \times (PREDIV\_A + 1)}$$

The ck_spre clock can be used either to update the calendar or as timebase for the 16-bit wake-up auto-reload timer. To obtain short timeout periods, the 16-bit wake-up auto-reload timer can also run with the RTCCLK divided by the programmable 4-bit asynchronous prescaler (see *Section 46.3.10: Periodic auto-wake-up* for details).

Binary mode (BIN=01)

The SSR binary down-counter is extended to 32-bit length and is free running. The time and date calendar BCD registers are not functional.

This down-counter is clocked by ck_apre: the output of the 7-bit asynchronous prescaler configured through the PREDIV_A bits of the RTC_PRER register.

PREDIV_S value is don't care.

Mixed mode (BIN=10 or 11)

The SSR binary down-counter is extended to 32-bit length and is free running. The time and date calendar BCD registers are also available.

This down-counter is clocked by ck_apre: the output of the 7-bit asynchronous prescaler configured through the PREDIV_A bits of the RTC_PRER register. The bits BCDU[2:0] are

used to define when the calendar is incremented by 1 second, using the SSR least significant bits.

46.3.7 Real-time clock and calendar

The RTC calendar time and date registers are accessed through shadow registers which are synchronized with PCLK (APB clock). They can also be accessed directly in order to avoid waiting for the synchronization duration.

- RTC_SSR for the subseconds
- RTC_TR for the time
- RTC_DR for the date

Every RTCCLK periods, the current calendar value is copied into the shadow registers, and the RSF bit of RTC_ICSR register is set (see *Section 46.6.12: RTC shift control register (RTC_SHIFTR)*). The copy is not performed in Stop and Standby mode. When exiting these modes, the shadow registers are updated after up to 4 RTCCLK periods.

When the application reads the calendar registers, it accesses the content of the shadow registers. It is possible to make a direct access to the calendar registers by setting the BYPSHAD control bit in the RTC_CR register. By default, this bit is cleared, and the user accesses the shadow registers.

When reading the RTC_SSR, RTC_TR or RTC_DR registers in BYPSHAD = 0 mode, the frequency of the APB clock (f_{APB}) must be at least 7 times the frequency of the RTC clock (f_{RTCCLK}).

The shadow registers are reset by system reset.

46.3.8 Calendar ultra-low power mode

It is possible to reduce drastically the RTC power consumption by setting the LPCAL bit in the RTC_CALR register. In this configuration, the whole RTC is clocked by ck_apre only instead of both RTCCLK and ck_apre. Consequently, some flags delays are longer, and the calibration window is longer (refer to *Section : RTC ultra-low-power mode*).

The LPCAL bit is ignored (assumed to be 0) when asynchronous prescaler division factor (PREDIV_A+1) is not a power of 2.

Switching from LPCAL=0 to LPCAL=1 or from LPCAL=1 to LPCAL=0 is not immediate and requires a few ck_apre periods to complete.

46.3.9 Programmable alarms

The RTC unit provides programmable alarm: alarm A and alarm B. The description below is given for alarm A, but can be translated in the same way for alarm B.

The programmable alarm function is enabled through the ALRAE bit in the RTC_CR register.

The ALRAF is set to 1 if the calendar subseconds, seconds, minutes, hours, date or day match the values programmed in the alarm registers RTC_ALRMASSR and RTC_ALRMAR. Each calendar field can be independently selected through the MSKx bits of the RTC_ALRMAR register, and through the MASKSSx bits of the RTC_ALRMASSR register.

When the binary mode is used, the subsecond field can be programmed in the alarm binary register RTC_ALRABINR.

The alarm interrupt is enabled through the ALRAIE bit in the RTC_CR register.

In case the Alarm is used to generate a trigger event for another peripheral, the ALRAF can be automatically cleared by hardware by configuring the ALRAFCLR bit at 1 in the RTC_CR register. In this configuration there is no need for software intervention if the only purpose is clearing the ALRAF flag.

Caution: If the seconds field is selected (MSK1 bit reset in RTC_ALRMAR), the synchronous prescaler division factor set in the RTC_PRER register must be at least 3 to ensure correct behavior.

Alarm A and alarm B (if enabled by bits OSEL[1:0] in RTC_CR register) can be routed to the TAMPALRM output. TAMPALRM output polarity can be configured through bit POL the RTC_CR register.

46.3.10 Periodic auto-wake-up

The periodic wake-up flag is generated by a 16-bit programmable auto-reload down-counter. The wake-up timer range can be extended to 17 bits.

The wake-up function is enabled through the WUTE bit in the RTC_CR register.

The wake-up timer clock input ck_wut can be:

- RTC clock (RTCCLK) divided by 2, 4, 8, or 16.

  When RTCCLK is LSE (32.768 kHz), this permits the wake-up interrupt period to be configured from 122 µs to 32 s, with a resolution down to 61 µs.
- ck_spre (usually 1 Hz internal clock) in BCD mode, or the clock used to update the calendar as defined by BCDU in binary or mixed (BCD-binary) modes.

  When ck_spre frequency is 1 Hz, a wake-up time from 1 s to around 36 hours can be achieved with one-second resolution. This large programmable time range is divided in 2 parts:
  - from 1 s to 18 hours when WUCKSEL [2:1] = 10
  - and from around 18 h to 36 h when WUCKSEL[2:1] = 11. In this last case 2^{16} is added to the 16-bit counter current value. When the initialization sequence is complete (see *Programming the wake-up timer on page 1963*), the timer starts counting down. When the wake-up function is enabled, the down-counting remains active in low-power modes. In addition, when it reaches 0, the WUTF flag is set in the RTC_SR register, and the wake-up counter is automatically reloaded with its reload value (RTC_WUTR register value).

Depending on WUTOCLR in the RTC_WUTR register, the WUTF flag must either be cleared by software (WUTOCLR = 0x0000), or the WUTF is automatically cleared by hardware when the auto-reload down counter reaches WUTOCLR value (0x0000 < WUTOCLR ≤ WUT).

The wake-up flag is output on an internal signal rtc_wut that can be used by other peripherals (refer to section *Section 46.3.1: RTC block diagram*).

When the periodic wake-up interrupt is enabled by setting the WUTIE bit in the RTC_CR register, it can exit the device from low-power modes.

The periodic wake-up flag can be routed to the TAMPALRM output provided it has been enabled through bits OSEL[1:0] of RTC_CR register. TAMPALRM output polarity can be configured through the POL bit in the RTC_CR register.

System reset, as well as low-power modes (Sleep, Stop, and Standby) have no influence on the wake-up timer.

46.3.11 RTC initialization and configuration

RTC Binary, BCD or Mixed mode

By default the RTC is in BCD mode (BIN = 00 in the RTC_ICSR register): the RTC_SSR register contains the subsecond field SS[15:0], clocked by ck_apre, allowing to generate a 1 Hz clock to update the calendar registers in BCD format (RTC_TR and RTC_DR).

When the RTC is configured in binary mode (BIN = 01 in the RTC_ICSR register): the RTC_SSR register contains the binary counter SS[31:0], clocked by ck_apre. The calendar registers in BCD format (RTC_TR and RTC_DR) are not used.

When the RTC is configured in mixed mode (BIN = 10 or 11 in the RTC_ICSR register): the RTC_SSR register contains the binary counter SS[31:0], clocked by ck_apre. The calendar is updated (1 second increment) each time the SSR[BCDU+7:0] reaches 0.

RTC register write protection

After system reset, the RTC registers are protected against parasitic write access by the DBP bit in the power control peripheral (refer to the PWR power control section). DBP bit must be set in order to enable RTC registers write access.

After Backup domain reset, some of the RTC registers are write-protected: RTC_TR, RTC_DR, RTC_PRER, RTC_CALR, RTC_SHIFTR, the bits INIT, BIN and BCDU in RTC_ICSR and the bits FMT, SUB1H, ADD1H, REFCKON in RTC_CR.

The following steps are required to unlock the write protection on the protected RTC registers.

1. Write 0xCA into the RTC_WPR register.
2. Write 0x53 into the RTC_WPR register.

Writing a wrong key reactivates the write protection.

The protection mechanism is not affected by system reset.

The registers protected by INITPRIV are write-protected by the INIT KEY.

The registers protected by CALDPRIV are write-protected by the CAL KEY.

In case PRIV or INITPRIV is set in the RTC_PRIVCFGR, and/or SEC or INITSEC is set in the RTC_SECCFGR: the INIT KEY is unlocked and locked only if the write accesses into the RTC_WPR register are done in the privilege and security mode defined by PRIV, INITPRIV, SEC, INITSEC configuration.

In case PRIV or CALPRIV is set in the RTC_PRIVCFGR, and/or SEC or CALSEC is set in the RTC_SECCFGR: the CAL KEY is unlocked and locked only if the write accesses into the RTC_WPR register are done in the privilege and security mode defined by PRIV, CALPRIV, SEC, CALSEC configuration.

Calendar initialization and configuration

To program the initial time and date calendar values, including the time format and the prescaler configuration, the following sequence is required:

1. Set INIT bit to 1 in the RTC_ICSR register to enter initialization mode. In this mode, the calendar counter is stopped and its value can be updated.
2. Poll INITF bit of in the RTC_ICSR register. The initialization phase mode is entered when INITF is set to 1.
   – If LPCAL=0: INITF is set around 2 RTCCLK cycles after INIT bit is set.
   – If LPCAL=1: INITF is set up to 2 ck_apre cycle after INIT bit is set.
3. To generate a 1 Hz clock for the calendar counter, program both the prescaler factors in RTC_PRER register, plus BIN and BCDU in the RTC_ICSR register.
4. Load the initial time and date values in the shadow registers (RTC_TR and RTC_DR), and configure the time format (12 or 24 hours) through the FMT bit in the RTC_CR register.
5. Exit the initialization mode by clearing the INIT bit. The actual calendar counter value is then automatically loaded.
   – If LPCAL=0: the counting restarts after 4 RTCCLK clock cycles.
   – If LPCAL=1: the counting restarts after up to 2 RTCCLK + 1 ck_apre.

When the initialization sequence is complete, the calendar starts counting. The RTC_SSR content is initialized with:

- PREDIV_S in BCD mode (BIN=00)
- 0xFFFF FFFF in binary or mixed (BCD-binary) modes (BIN=01, 10 or 11).

In BCD mode, RTC_SSR contains the value of the synchronous prescaler counter. This enables one to calculate the exact time being maintained by the RTC down to a resolution of 1 / (PREDIV_S + 1) seconds. As a consequence, the resolution can be improved by increasing the synchronous prescaler value (PREDIV_S[14:0]). The maximum resolution allowed (30.52 µs with a 32768 Hz clock) is obtained with PREDIV_S set to 0x7FFF.

However, increasing PREDIV_S means that PREDIV_A must be decreased in order to maintain the synchronous prescaler output at 1 Hz. In this way, the frequency of the asynchronous prescaler output increases, which may increase the RTC dynamic consumption. The RTC dynamic consumption is optimized for PREDIV_A+1 being a power of 2.

Note: After a system reset, the application can read the INITS flag in the RTC_ICSR register to check if the calendar has been initialized or not. If this flag equals 0, the calendar has not been initialized since the year field is set at its Backup domain reset default value (0x00).

Note: To read the calendar after initialization, the software must first check that the RSF flag is set in the RTC_ICSR register.

Daylight saving time

The daylight saving time management is performed through bits SUB1H, ADD1H, and BKP of the RTC_CR register.

Using SUB1H or ADD1H, the software can subtract or add one hour to the calendar in one single operation without going through the initialization procedure.

In addition, the software can use the BKP bit to memorize this operation.

Programming the alarm

A similar procedure must be followed to program or update the programmable alarms. The procedure below is given for alarm A but can be translated in the same way for alarm B.

1. Clear ALRAE in RTC_CR to disable alarm A.
2. Program the alarm A registers (RTC_ALRMASSR/RTC_ALRMAR or RTC_ALRABINR).
3. Set ALRAE in the RTC_CR register to enable alarm A again.

Note: Each change of the RTC_CR register is taken into account after around 2 RTCCLK clock cycles due to clock synchronization.

Programming the wake-up timer

The following sequence is required to configure or change the wake-up timer auto-reload value (WUT[15:0] in RTC_WUTR):

1. Clear WUTE in RTC_CR to disable the wake-up timer.
2. Poll WUTWF until it is set in RTC_ICSR to make sure the access to wake-up auto-reload counter and to WUCKSEL[2:0] bits is allowed. This step must be skipped in calendar initialization mode.
   - If WUCKSEL[2] = 0: WUTWF is set around 1 ck_wut + 1 RTCCLK cycles after WUTE bit is cleared.
   - If WUCKSEL[2] = 1: WUTWF is set up to 1 ck_apre + 1 RTCCLK cycles after WUTE bit is cleared.
3. Program the wake-up auto-reload value WUT[15:0], WUTOCLR[15:0] and the wake-up clock selection (WUCKSEL[2:0] bits in RTC_CR). Set WUTE in RTC_CR to enable the timer again. The wake-up timer restarts down-counting.
   - If WUCKSEL[2] = 0: WUTWF is cleared around 1 ck_wut + 1 RTCCLK cycles after WUTE bit is set.
   - If WUCKSEL[2] = 1: WUTWF is cleared up to 1 ck_apre + 1 RTCCLK cycles after WUTE bit is set.

46.3.12 Reading the calendar

When BYPSHAD control bit is cleared in the RTC_CR register

To read the RTC calendar registers (RTC_SSR, RTC_TR and RTC_DR) properly, the APB clock frequency (f_{PCLK}) must be equal to or greater than seven times the RTC clock frequency (f_{RTCCLK}). This ensures a secure behavior of the synchronization mechanism.

If the APB clock frequency is less than seven times the RTC clock frequency, the software must read the calendar time and date registers twice. If the second read of the RTC_TR gives the same result as the first read, this ensures that the data is correct. Otherwise a third read access must be done. In any case the APB clock frequency must never be lower than the RTC clock frequency.

The RSF bit is set in RTC_ICSR register each time the calendar registers are copied into the RTC_SSR, RTC_TR and RTC_DR shadow registers. The copy is performed every RTCCLK cycle. To ensure consistency between the 3 values, reading either RTC_SSR or RTC_TR locks the values in the higher-order calendar shadow registers until RTC_DR is read. In case the software makes read accesses to the calendar in a time interval smaller than 1 RTCCLK periods: RSF must be cleared by software after the first calendar read, and

then the software must wait until RSF is set before reading again the RTC_SSR, RTC_TR and RTC_DR registers.

After waking up from low-power mode (Stop or Standby), RSF must be cleared by software. The software must then wait until it is set again before reading the RTC_SSR, RTC_TR and RTC_DR registers.

The RSF bit must be cleared after wake-up and not before entering low-power mode.

After a system reset, the software must wait until RSF is set before reading the RTC_SSR, RTC_TR and RTC_DR registers. Indeed, a system reset resets the shadow registers to their default values.

After an initialization (refer to *Calendar initialization and configuration on page 1962*): the software must wait until RSF is set before reading the RTC_SSR, RTC_TR and RTC_DR registers.

After synchronization (refer to *Section 46.3.14: RTC synchronization*): the software must wait until RSF is set before reading the RTC_SSR, RTC_TR and RTC_DR registers.

When the BYPSHAD control bit is set in the RTC_CR register (bypass shadow registers)

Reading the calendar registers gives the values from the calendar counters directly, thus eliminating the need to wait for the RSF bit to be set. This is especially useful after exiting from low-power modes (Stop or Standby), since the shadow registers are not updated during these modes.

When the BYPSHAD bit is set to 1, the results of the different registers might not be coherent with each other if an RTCCLK edge occurs between two read accesses to the registers. Additionally, the value of one of the registers may be incorrect if an RTCCLK edge occurs during the read operation. The software must read all the registers twice, and then compare the results to confirm that the data is coherent and correct. Alternatively, the software can just compare the two results of the least-significant calendar register.

Note: While BYPSHAD = 1, instructions which read the calendar registers require one extra APB cycle to complete.

46.3.13 Resetting the RTC

The calendar shadow registers (RTC_SSR, RTC_TR and RTC_DR) and some bits of the RTC status register (RTC_ICSR) are reset to their default values by all available system reset sources.

On the contrary, the following registers are reset to their default values by a Backup domain reset and are not affected by a system reset: the RTC current calendar registers, the RTC control register (RTC_CR), the prescaler register (RTC_PRER), the RTC calibration register (RTC_CALR), the RTC shift register (RTC_SHIFTR), the RTC timestamp registers (RTC_TSSSR, RTC_TSTR and RTC_TSDR), the wake-up timer register (RTC_WUTR), the alarm A and alarm B registers (RTC_ALRMASSR/RTC_ALRMAR/RTC_ALRABINR and RTC_ALRMBSSR/RTC_ALRMBR/RTC_ALRBBINR).

In addition, when clocked by LSE, the RTC keeps on running under system reset if the reset source is different from the Backup domain reset one (refer to RCC for details about RTC clock sources not affected by system reset). When a Backup domain reset occurs, the RTC is stopped and all the RTC registers are set to their reset values.

46.3.14 RTC synchronization

The RTC can be synchronized to a remote clock with a high degree of precision. After reading the subsecond field (RTC_SSR or RTC_TSSSR), a calculation can be made of the precise offset between the times being maintained by the remote clock and the RTC. The RTC can then be adjusted to eliminate this offset by “shifting” its clock by a fraction of a second using RTC_SHIFTR.

The RTC can be finely adjusted using the RTC shift control register (RTC_SHIFTR). Writing to RTC_SHIFTR can shift (either delay or advance) the clock with a resolution of 1 ck_apre period.

The shift operation consists in adding the SUBFS[14:0] value to the synchronous prescaler counter SS[15:0]: this delays the clock.

If at the same time the ADD1S bit is set in BCD or mixed mode, this results in adding one second and at the same time subtracting a fraction of second, so this advances the clock. ADD1S has no effect in binary mode.

As soon as a shift operation is initiated by a write to the RTC_SHIFTR register, the SHPF flag is set by hardware to indicate that a shift operation is pending. This bit is cleared by hardware as soon as the shift operation has completed.

Caution: In mixed mode (BIN=10 or 11), the SUBFS[14:BCDU+8] must be written with 0.

Caution: Before initiating a shift operation in BCD mode, the user must check that SS[15] = 0 in order to ensure that no overflow occurs. In mixed mode, the user must check that the bit SS[BCDU+8] = 0.

Caution: This synchronization feature is not compatible with the reference clock detection feature: firmware must not write to RTC_SHIFTR when REFCKON = 1.

46.3.15 RTC reference clock detection

This feature is available only in BCD mode (BIN=00).

The update of the RTC calendar can be synchronized to a reference clock, RTC_REFIN, which is usually the mains frequency (50 or 60 Hz). The precision of the RTC_REFIN reference clock should be higher than the 32.768 kHz LSE clock. When the RTC_REFIN detection is enabled (REFCKON bit of RTC_CR set to 1), the calendar is still clocked by the LSE, and RTC_REFIN is used to compensate for the imprecision of the calendar update frequency (1 Hz).

Each 1 Hz clock edge is compared to the nearest RTC_REFIN clock edge (if one is found within a given time window). In most cases, the two clock edges are properly aligned. When the 1 Hz clock becomes misaligned due to the imprecision of the LSE clock, the RTC shifts the 1 Hz clock a bit so that future 1 Hz clock edges are aligned. Thanks to this mechanism, the calendar becomes as precise as the reference clock.

The RTC detects if the reference clock source is present by using the 256 Hz clock (ck_apre) generated from the 32.768 kHz quartz. The detection is performed during a time window around each of the calendar updates (every 1 s). The window equals 7 ck_apre periods when detecting the first reference clock edge. A smaller window of 3 ck_apre periods is used for subsequent calendar updates.

Each time the reference clock is detected in the window, the asynchronous prescaler which outputs the ck_spre clock is forced to reload. This has no effect when the reference clock and the 1 Hz clock are aligned because the prescaler is being reloaded at the same

moment. When the clocks are not aligned, the reload shifts future 1 Hz clock edges a little for them to be aligned with the reference clock.

If the reference clock halts (no reference clock edge occurred during the 3 ck_apre window), the calendar is updated continuously based solely on the LSE clock. The RTC then waits for the reference clock using a large 7 ck_apre period detection window centered on the ck_spre edge.

When the RTC_REFIN detection is enabled, PREDIV_A and PREDIV_S must be set to their default values:

- PREDIV_A = 0x007F
- PREVID_S = 0x00FF

Note: RTC_REFIN clock detection is not available in Standby mode.

46.3.16 RTC smooth digital calibration

The RTC frequency can be digitally calibrated with a resolution of about 0.954 ppm with a range from -487.1 ppm to +488.5 ppm. The correction of the frequency is performed using series of small adjustments (adding and/or subtracting individual ck_cal pulses).

If LPCAL=0: ck_cal = RTCCLK

If LPCAL=1: ck_cal = ck_apre

These adjustments are fairly well distributed so that the RTC is well calibrated even when observed over short durations of time.

RTC ultra-low-power mode

The RTC consumption can be reduced by setting the LPCAL bit in the RTC calibration register (RTC_CALR). In this case, the calibration mechanism is applied on ck_apre instead of RTCCLK. The resulting accuracy is the same, but the calibration is performed during a calibration cycle of about 2^{20} x PREDIV_A x RTCCLK pulses instead of 2^{20} RTCCLK pulses when LPCAL=0.

Smooth calibration mechanism

The smooth calibration register (RTC_CALR) specifies the number of ck_cal clock cycles to be masked during the calibration cycle:

- Setting the bit CALM[0] to 1 causes exactly one pulse to be masked during the calibration cycle.
- Setting CALM[1] to 1 causes two additional cycles to be masked
- Setting CALM[2] to 1 causes four additional cycles to be masked
- and so on up to CALM[8] set to 1 which causes 256 clocks to be masked.

Note: CALM[8:0] (RTC_CALR) specifies the number of ck_cal pulses to be masked during the calibration cycle. Setting the bit CALM[0] to 1 causes exactly one pulse to be masked during the calibration cycle at the moment when cal_cnt[19:0] is 0x80000; CALM[1] = 1 causes two other cycles to be masked (when cal_cnt is 0x40000 and 0xC0000); CALM[2] = 1 causes four other cycles to be masked (cal_cnt = 0x20000/0x60000/0xA0000/ 0xE0000); and so on up to CALM[8] = 1 which causes 256 clocks to be masked (cal_cnt = 0xXX800).

While CALM permits the RTC frequency to be reduced by up to 487.1 ppm with fine resolution, the bit CALP can be used to increase the frequency by 488.5 ppm. Setting CALP

to 1 effectively inserts an extra ck_cal pulse every 2^{11} ck_cal cycles, which means that 512 clocks are added during every calibration cycle.

Using CALM together with CALP, an offset ranging from -511 to +512 ck_cal cycles can be added during the calibration cycle, which translates to a calibration range of -487.1 ppm to +488.5 ppm with a resolution of about 0.954 ppm.

The formula to calculate the effective calibrated frequency (F_{CAL}) given the input frequency (F_{RTCCLK}) is as follows:

$$F_{CAL} = F_{RTCCLK} \times [1 + (CALP \times 512 - CALM) / (2^{20} + CALM - CALP \times 512)]$$

Caution: PREDIV_A must be greater or equal to 3.

Calibration when PREDIV_A < 3

The CALP bit can not be set to 1 when the asynchronous prescaler value (PREDIV_A bits in RTC_PRER register) is less than 3. If CALP was already set to 1 and PREDIV_A bits are set to a value less than 3, CALP is ignored and the calibration operates as if CALP was equal to 0.

It is however possible to perform a calibration with PREDIV_A less than 3 in BCD mode, the synchronous prescaler value (PREDIV_S) should be reduced so that each second is accelerated by 8 ck_cal clock cycles, which is equivalent to adding 256 clock cycles every calibration cycle. As a result, between 255 and 256 clock pulses (corresponding to a calibration range from 243.3 to 244.1 ppm) can effectively be added during each calibration cycle using only the CALM bits.

With a nominal RTCCLK frequency of 32768 Hz, when PREDIV_A equals 1 (division factor of 2), PREDIV_S should be set to 16379 rather than 16383 (4 less). The only other interesting case is when PREDIV_A equals 0, PREDIV_S should be set to 32759 rather than 32767 (8 less).

If PREDIV_S is reduced in this way, the formula given the effective frequency of the calibrated input clock is as follows:

$$F_{CAL} = F_{RTCCLK} \times [1 + (256 - CALM) / (2^{20} + CALM - 256)]$$

In this case, CALM[7:0] equals 0x100 (the midpoint of the CALM range) is the correct setting if RTCCLK is exactly 32768.00 Hz.

Verifying the RTC calibration

It is recommended to verify the RTC calibration with LPCAL = 0, in order to have a 32-second calibration cycle.

RTC precision is ensured by measuring the precise frequency of RTCCLK and calculating the correct CALM value and CALP values. An optional 1 Hz output is provided to allow applications to measure and verify the RTC precision.

Measuring the precise frequency of the RTC over a limited interval can result in a measurement error of up to 2 RTCCLK clock cycles over the measurement period, depending on how the digital calibration cycle is aligned with the measurement period.

However, this measurement error can be eliminated if the measurement period is the same length as the calibration cycle period. In this case, the only error observed is the error due to the resolution of the digital calibration.

- By default, the calibration cycle period is 32 seconds.

  Using this mode and measuring the accuracy of the 1 Hz output over exactly 32 seconds guarantees that the measure is within 0.477 ppm (0.5 RTCCLK cycles over 32 seconds, due to the limitation of the calibration resolution).
- CALW16 bit of the RTC_CALR register can be set to 1 to force a 16- second calibration cycle period.

  In this case, the RTC precision can be measured during 16 seconds with a maximum error of 0.954 ppm (0.5 RTCCLK cycles over 16 seconds). However, since the calibration resolution is reduced, the long term RTC precision is also reduced to 0.954 ppm: CALM[0] bit is stuck at 0 when CALW16 is set to 1.
- CALW8 bit of the RTC_CALR register can be set to 1 to force a 8-second calibration cycle period.

  In this case, the RTC precision can be measured during 8 seconds with a maximum error of 1.907 ppm (0.5 RTCCLK cycles over 8 s). The long term RTC precision is also reduced to 1.907 ppm: CALM[1:0] bits are stuck at 00 when CALW8 is set to 1.

Re-calibration on-the-fly

The calibration register (RTC_CALR) can be updated on-the-fly while RTC_ICSR/INITF = 0, by using the follow process:

1. Poll the RTC_ICSR/RECALPF (re-calibration pending flag).
2. If it is set to 0, write a new value to RTC_CALR, if necessary. RECALPF is then automatically set to 1
3. Within three ck_apre cycles after the write operation to RTC_CALR, the new calibration settings take effect.

46.3.17 Timestamp function

Timestamp is enabled by setting the TSE or ITSE bits of RTC_CR register to 1.

When TSE is set:

The calendar is saved in the timestamp registers (RTC_TSSSR, RTC_TSTR, RTC_TSDR) when a timestamp event is detected on the RTC_TS pin.

When TAMPTS is set:

The calendar is saved in the timestamp registers (RTC_TSSSR, RTC_TSTR, RTC_TSDR) when an internal or external tamper event is detected. Refer to *RTC control register (RTC_CR)* and refer to *Section : Timestamp on tamper event*.

When ITSE is set:

The calendar is saved in the timestamp registers (RTC_TSSSR, RTC_TSTR, RTC_TSDR) when an internal timestamp event is detected. The internal timestamp event is generated by the switch to the V_{BAT} supply.

When a timestamp event occurs, due to internal or external event, the timestamp flag bit (TSF) in RTC_SR register is set. In case the event is internal, the ITSF flag is also set in RTC_SR register.

By setting the TSIE bit in the RTC_CR register, an interrupt is generated when a timestamp event occurs.

If a new timestamp event is detected while the timestamp flag (TSF) is already set, the timestamp overflow flag (TSOVF) flag is set and the timestamp registers (RTC_TSTR and RTC_TSDR) maintain the results of the previous event.

Note: TSF is set up to 2 ck_apre cycles after the timestamp event from RTC_TS pin or from rtc_its internal signal occurs due to synchronization process. TSF is set up to 3 ck_apre cycles after tamper flags.

TSOVF is set up to only 1 ck_apre cycle after the event occurs. This means that if two timestamp events are close together, TSOVF can be seen as '1' while TSF is still '0'. As a consequence, it is recommended to poll TSOVF only after TSF has been set.

Caution: If a timestamp event occurs immediately after the TSF bit is supposed to be cleared, then both TSF and TSOVF bits are set. To avoid masking a timestamp event occurring at the same moment, the application must not write 0 into TSF bit unless it has already read it to 1.

46.3.18 Calibration clock output

When the COE bit is set to 1 in the RTC_CR register, a reference clock is provided on the CALIB device output.

If the COSEL bit in the RTC_CR register is reset and PREDIV_A = 0x7F, the CALIB frequency is $f_{RTCCLK/64}$. This corresponds to a calibration output at 512 Hz for an RTCCLK frequency at 32.768 kHz. The CALIB duty cycle is irregular: there is a light jitter on falling edges. It is therefore recommended to use rising edges.

When COSEL is set and “PREDIV_S+1” is a non-zero multiple of 256 (i.e: PREDIV_S[7:0] = 0xFF), the CALIB frequency is $f_{RTCCLK}/(256 * (PREDIV\_A+1))$. This corresponds to a calibration output at 1 Hz for prescaler default values (PREDIV_A = Ox7F, PREDIV_S = 0xFF), with an RTCCLK frequency at 32.768 kHz.

Note: When COSEL is cleared, the CALIB output is the output of the 6^{th} stage of the asynchronous prescaler. If LPCAL is changed from 0 to 1, the output can be irregular (glitch...) during the LPCAL switch. If LPCAL = 1 this output is always available. If LPCAL = 0, no output is present if PREDIV_A is < 0x20.

When COSEL is set, the CALIB output is the output of the 8^{th} stage of the synchronous prescaler.

46.3.19 Tamper and alarm output

The OSEL[1:0] control bits in the RTC_CR register are used to activate the alarm output TAMPALRM, and to select the function which is output. These functions reflect the contents of the corresponding flags in the RTC_SR register.

When the TAMPOE control bit is set in the RTC_CR, all external and internal tamper flags are ORed and routed to the TAMPALRM output. If OSEL = 00 the TAMPALRM output reflects only the tampers flags. If OSEL ≠ 00, the signal on TAMPALRM provides both tamper flags and alarm A, B, or wake-up flag.

The polarity of the TAMPALRM output is determined by the POL control bit in RTC_CR so that the opposite of the selected flags bit is output when POL is set to 1.

TAMPALRM output

The TAMPALRM pin can be configured in output open drain or output push-pull using the control bit TAMPALRM_TYPE in the RTC_CR register. It is possible to apply the internal pull-up in output mode thanks to TAMPALRM_PU in the RTC_CR.

Note: Once the TAMPALRM *output is enabled, it has priority over CALIB on RTC_OUT1.*

In case the TAMPALRM is configured open-drain in the RTC, the RTC_OUT1 GPIO must be configured as input.

46.4 RTC low-power modes

Table 482. Effect of low-power modes on RTC

Mode	Description
Sleep	No effect RTC interrupts cause the device to exit the Sleep mode.
Stop	The RTC remains active when the RTC clock source is LSE or LSI. RTC interrupts cause the device to exit the Stop mode.
Standby	The RTC remains active when the RTC clock source is LSE or LSI. RTC interrupts cause the device to exit the Standby mode.

The table below summarizes the RTC pins and functions capability in all modes.

Table 483. RTC pins functionality over modes

Functions	Functional in all low-power modes except Standby mode	Functional in Standby mode	Functional in V_{BAT} mode
RTC_TS	Yes	Yes	Yes
RTC_REFIN	Yes	No	No
RTC_OUT1	Yes	Yes	Yes
RTC_OUT2	Yes	Yes	Yes

46.5 RTC interrupts

The interrupt channel is set in the masked interrupt status register or in the secure masked interrupt status register depending on its security mode configuration. The nonsecure interrupt output or the secure interrupt output is also activated.

Table 484. Nonsecure interrupt requests

Interrupt acronym	Interrupt event	Event flag(1)	Enable control bit(2)	Interrupt clear method	Exit from low-power modes
RTC	Alarm A	ALRAF	ALRAIE and (ALRASEC=0 and SEC=0)	write 1 in CALRAF	Yes(3)
	Alarm B	ALRBF	ALRBIE and (ALRBSEC=0 and SEC=0)	write 1 in CALRBF	Yes(3)
	Timestamp	TSF	TSIE and (TSSEC=0 and SEC=0)	write 1 in CTSF	Yes(3)
	Wake-up timer	WUTF	WUTIE and (WUTSEC=0 and SEC=0)	write 1 in CWUTF	Yes(3)
	SSR underflow	SSRUF	SSRUIE and (ALRASEC=0 and SEC=0)	write 1 in CSSRUF	Yes(3)

1. The event flags are in the RTC_SR register.
2. The interrupt masked flags (resulting from event flags AND enable control bits) are in the RTC_MISR register.
3. When the RTC is clocked by an oscillator functional in the low-power mode.

Table 485. Secure interrupt requests

Interrupt acronym	Interrupt event	Event flag(1)	Enable control bit(2)	Interrupt clear method	Exit from low-power modes
RTC_S	Alarm A	ALRAF	ALRAIE and (ALRASEC=1 or SEC=1)	write 1 in CALRAF	Yes(3)
	Alarm B	ALRBF	ALRBIE and (ALRBSEC=1 or SEC=1)	write 1 in CALRBF	Yes(3)
	Timestamp	TSF	TSIE and (TSSEC=1 or SEC=1)	write 1 in CTSF	Yes(3)
	Wake-up timer	WUTF	WUTIE and (WUTSEC=1 or SEC=1)	write 1 in CWUTF	Yes(3)
	SSR underflow	SSRUF	SSRUIE and (ALRASEC=1 or SEC=1)	write 1 in CSSRUF	Yes(3)

1. The event flags are in the RTC_SR register.
2. The interrupt masked flags (resulting from event flags AND enable control bits) are in the RTC_SMISR register.
3. When the RTC is clocked by an oscillator functional in the low-power mode.

46.6 RTC registers

Refer to *Section 1.2* of the reference manual for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by words (32-bit).

46.6.1 RTC time register (RTC_TR)

The RTC_TR is the calendar time shadow register. This register must be written in initialization mode only. Refer to *Calendar initialization and configuration on page 1962* and *Reading the calendar on page 1963*.

This register is write protected. The write access procedure is described in *RTC register write protection on page 1961*.

This register can be write-protected against nonsecure access. Refer to *Section 46.3.4: RTC secure protection modes*.

This register can be write-protected against non-privileged access. Refer to *Section 46.3.5: RTC privilege protection modes*.

Address offset: 0x00

Backup domain reset value: 0x0000 0000

System reset value: 0x0000 0000 (when BYPSHAD = 0, not affected when BYPSHAD = 1)

0: AM or 24-hour format
1: PM

Bits 21:20 **HT[1:0]**: Hour tens in BCD format

Bits 19:16 **HU[3:0]**: Hour units in BCD format

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **MNT[2:0]**: Minute tens in BCD format

Bits 11:8 **MNU[3:0]**: Minute units in BCD format

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **ST[2:0]**: Second tens in BCD format

Bits 3:0 **SU[3:0]**: Second units in BCD format

46.6.2 RTC date register (RTC_DR)

The RTC_DR is the calendar date shadow register. This register must be written in initialization mode only. Refer to *Calendar initialization and configuration on page 1962* and *Reading the calendar on page 1963*.

This register is write protected. The write access procedure is described in *RTC register write protection on page 1961*.

This register can be write-protected against nonsecure access. Refer to *Section 46.3.4: RTC secure protection modes*.

This register can be write-protected against non-privileged access. Refer to *Section 46.3.5: RTC privilege protection modes*.

Address offset: 0x04

Backup domain reset value: 0x0000 2101

System reset value: 0x0000 2101 (when BYPSHAD = 0, not affected when BYPSHAD = 1)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:20 **YT[3:0]**: Year tens in BCD format

Bits 19:16 **YU[3:0]**: Year units in BCD format

Bits 15:13 **WDU[2:0]**: Week day units
000: forbidden
001: Monday
...
111: Sunday

Bit 12 **MT**: Month tens in BCD format

Bits 11:8 **MU[3:0]**: Month units in BCD format

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **DT[1:0]**: Date tens in BCD format

Bits 3:0 **DU[3:0]**: Date units in BCD format

Note: The calendar is frozen when reaching the maximum value, and can't roll over.

46.6.3 RTC subsecond register (RTC_SSR)

Address offset: 0x08

Backup domain reset value: 0x0000 0000

System reset value: 0x0000 0000 (when BYPSHAD = 0, not affected when BYPSHAD = 1)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SS[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SS[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **SS[31:0]**: Synchronous binary counter

SS[31:16]: Synchronous binary counter MSB values

When Binary or Mixed mode is selected (BIN = 01 or 10 or 11):

SS[31:16] are the 16 MSB of the SS[31:0] free-running down-counter.

When BCD mode is selected (BIN=00):

SS[31:16] are forced by hardware to 0x0000.

SS[15:0]: Subsecond value/synchronous binary counter LSB values

When Binary mode is selected (BIN = 01 or 10 or 11):

SS[15:0] are the 16 LSB of the SS[31:0] free-running down-counter.

When BCD mode is selected (BIN=00):

SS[15:0] is the value in the synchronous prescaler counter. The fraction of a second is given by the formula below:

Second fraction = (PREDIV_S - SS) / (PREDIV_S + 1)

SS can be larger than PREDIV_S only after a shift operation. In that case, the correct time/date is one second less than as indicated by RTC_TR/RTC_DR.

46.6.4 RTC initialization control and status register (RTC_ICSR)

This register is write protected. The write access procedure is described in *RTC register write protection on page 1961*.

This register can be globally protected, or each bit of this register can be individually protected against nonsecure access. Refer to *Section 46.3.4: RTC secure protection modes*.

This register can be globally protected, or each bit of this register can be individually protected against non-privileged access. Refer to *Section 46.3.5: RTC privilege protection modes*.

Address offset: 0x0C

Backup domain reset value: 0x0000 0007

System reset: not affected except INIT, INITF, and RSF bits which are cleared to 0

			rw	rw	rw	rw	rw	rw	r	rc_w0	r	r	r		

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **RECALPF**: Recalibration pending Flag

The RECALPF status flag is automatically set to 1 when software writes to the RTC_CALR register, indicating that the RTC_CALR register is blocked. When the new calibration settings are taken into account, this bit returns to 0. Refer to *Re-calibration on-the-fly*.

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:10 **BCDU[2:0]**: BCD update (BIN = 10 or 11)

In mixed mode when both BCD calendar and binary extended counter are used (BIN = 10 or 11), the calendar second is incremented using the SSR Least Significant Bits.

0x0: 1s calendar increment is generated each time SS[7:0] = 0
0x1: 1s calendar increment is generated each time SS[8:0] = 0
0x2: 1s calendar increment is generated each time SS[9:0] = 0
0x3: 1s calendar increment is generated each time SS[10:0] = 0
0x4: 1s calendar increment is generated each time SS[11:0] = 0
0x5: 1s calendar increment is generated each time SS[12:0] = 0
0x6: 1s calendar increment is generated each time SS[13:0] = 0
0x7: 1s calendar increment is generated each time SS[14:0] = 0

Bits 9:8 **BIN[1:0]**: Binary mode

00: Free running BCD calendar mode (Binary mode disabled).
01: Free running Binary mode (BCD mode disabled)
10: Free running BCD calendar and Binary modes
11: Free running BCD calendar and Binary modes

Bit 7 **INIT**: Initialization mode

0: Free running mode

1: Initialization mode used to program time and date register (RTC_TR and RTC_DR), and prescaler register (RTC_PRER), plus BIN and BCDU fields. Counters are stopped and start counting from the new value when INIT is reset.

Bit 6 **INITF**: Initialization flag

When this bit is set to 1, the RTC is in initialization state, and the time, date and prescaler registers can be updated.

0: Calendar registers update is not allowed

1: Calendar registers update is allowed

Bit 5 **RSF**: Registers synchronization flag

This bit is set by hardware each time the calendar registers are copied into the shadow registers (RTC_SSR, RTC_TR and RTC_DR). This bit is cleared by hardware in initialization mode, while a shift operation is pending (SHPF = 1), or when in bypass shadow register mode (BYPSHAD = 1). This bit can also be cleared by software.

It is cleared either by software or by hardware in initialization mode.

0: Calendar shadow registers not yet synchronized

1: Calendar shadow registers synchronized

Bit 4 **INITS**: Initialization status flag

This bit is set by hardware when the calendar year field is different from 0 (Backup domain reset state).

0: Calendar has not been initialized

1: Calendar has been initialized

Bit 3 **SHPF**: Shift operation pending

This flag is set by hardware as soon as a shift operation is initiated by a write to the RTC_SHIFTR register. It is cleared by hardware when the corresponding shift operation has been executed. Writing to the SHPF bit has no effect.

0: No shift operation is pending

1: A shift operation is pending

Bit 2 **WUTWF**: Wake-up timer write flag

This bit is set by hardware when WUT value can be changed, after the WUTE bit has been set to 0 in RTC_CR.

It is cleared by hardware in initialization mode.

0: Wake-up timer configuration update not allowed except in initialization mode

1: Wake-up timer configuration update allowed

Bits 1:0 Reserved, must be kept at reset value.

46.6.5 RTC prescaler register (RTC_PRER)

This register must be written in initialization mode only. The initialization must be performed in two separate write accesses. Refer to *Calendar initialization and configuration on page 1962*.

This register is write protected. The write access procedure is described in *RTC register write protection on page 1961*.

This register can be write-protected against nonsecure access. Refer to *Section 46.3.4: RTC secure protection modes*.

This register can be write-protected against non-privileged access. Refer to *Section 46.3.5: RTC privilege protection modes*.

Address offset: 0x10

Backup domain reset value: 0x007F 00FF

System reset: not affected

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PREDIV_A[6:0]

Res.	PREDIV_S[14:0]														
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:16 **PREDIV_A[6:0]**: Asynchronous prescaler factor

This is the asynchronous division factor:
ck_apre frequency = RTCCLK frequency/(PREDIV_A+1)

Bit 15 Reserved, must be kept at reset value.

Bits 14:0 **PREDIV_S[14:0]**: Synchronous prescaler factor

This is the synchronous division factor:
ck_spre frequency = ck_apre frequency/(PREDIV_S+1)

46.6.6 RTC wake-up timer register (RTC_WUTR)

This register can be written only when WUTWF is set to 1 in RTC_ICSR.

This register can be protected against nonsecure access. Refer to *Section 46.3.4: RTC secure protection modes*.

This register can be protected against non-privileged access. Refer to *Section 46.3.5: RTC privilege protection modes*.

Address offset: 0x14

Backup domain reset value: 0x0000 FFFF

System reset: not affected

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
WUTOCLR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WUT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **WUTOCLR[15:0]**: Wake-up auto-reload output clear value

When WUTOCLR[15:0] is different from 0x0000, WUTF is set by hardware when the auto-reload down-counter reaches 0 and is cleared by hardware when the auto-reload downcounter reaches WUTOCLR[15:0].

When WUTOCLR[15:0] = 0x0000, WUTF is set by hardware when the WUT down-counter reaches 0 and is cleared by software.

Bits 15:0 **WUT[15:0]**: Wake-up auto-reload value bits

When the wake-up timer is enabled (WUTE set to 1), the WUTF flag is set every (WUT[15:0] + 1) ck_wut cycles. The ck_wut period is selected through WUCKSEL[2:0] bits of the RTC_CR register.

When WUCKSEL[2] = 1, the wake-up timer becomes 17-bits and WUCKSEL[1] effectively becomes WUT[16] the most-significant bit to be reloaded into the timer.

The first assertion of WUTF occurs between WUT and (WUT + 2) ck_wut cycles after WUTE is set. Setting WUT[15:0] to 0x0000 with WUCKSEL[2:0] = 011 (RTCCLK/2) is forbidden.

46.6.7 RTC control register (RTC_CR)

This register is write protected. The write access procedure is described in RTC register write protection on page 1961.

This register can be globally protected, or each bit of this register can be individually protected against nonsecure access. Refer to *Section 46.3.4: RTC secure protection modes*.

This register can be globally protected, or each bit of this register can be individually protected against non-privileged access. Refer to *Section 46.3.5: RTC privilege protection modes*.

Address offset: 0x18

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **OUT2EN**: RTC_OUT2 output enable

With this bit set, the RTC outputs can be remapped on RTC_OUT2 as follows:
OUT2EN = 0: RTC output 2 disable
If OSEL ≠ 00 or TAMPOE = 1: TAMPALRM is output on RTC_OUT1
If OSEL = 00 and TAMPOE = 0 and COE = 1: CALIB is output on RTC_OUT1
OUT2EN = 1: RTC output 2 enable
If (OSEL ≠ 00 or TAMPOE = 1) and COE = 0: TAMPALRM is output on RTC_OUT2
If OSEL = 00 and TAMPOE = 0 and COE = 1: CALIB is output on RTC_OUT2
If (OSEL ≠ 00 or TAMPOE = 1) and COE = 1: CALIB is output on RTC_OUT2 and TAMPALRM is output on RTC_OUT1.

Bit 30 **TAMPALRM_TYPE**: TAMPALRM output type

0: TAMPALRM is push-pull output
1: TAMPALRM is open-drain output

Bit 29 **TAMPALRM_PU**: TAMPALRM pull-up enable

0: No pull-up is applied on TAMPALRM output
1: A pull-up is applied on TAMPALRM output

Bit 28 **ALRBFCLR**: Alarm B flag automatic clear

0: Alarm B event generates a trigger event and ALRBF must be cleared by software to allow next alarm event.
1: Alarm B event generates a trigger event. ALRBF is automatically cleared by hardware after 1 ck_apre cycle.

Bit 27 **ALRAFCLR**: Alarm A flag automatic clear

0: Alarm A event generates a trigger event and ALRAF must be cleared by software to allow next alarm event.
1: Alarm A event generates a trigger event. ALRAF is automatically cleared by hardware after 1 ck_apre cycle.

Bit 26 **TAMPOE**: Tamper detection output enable on TAMPALRM
0: The tamper flag is not routed on TAMPALRM
1: The tamper flag is routed on TAMPALRM, combined with the signal provided by OSEL and with the polarity provided by POL.

Bit 25 **TAMPTS**: Activate timestamp on tamper detection event
0: Tamper detection event does not cause a RTC timestamp to be saved
1: Save RTC timestamp on tamper detection event
TAMPTS is valid even if TSE = 0 in the RTC_CR register. Timestamp flag is set up to 3 ck_apre cycles after the tamper flags.
Note: TAMPTS must be cleared before entering RTC initialization mode.

Bit 24 **ITSE**: timestamp on internal event enable
0: internal event timestamp disabled
1: internal event timestamp enabled

Bit 23 **COE**: Calibration output enable
This bit enables the CALIB output
0: Calibration output disabled
1: Calibration output enabled

Bits 22:21 **OSEL[1:0]**: Output selection
These bits are used to select the flag to be routed to TAMPALRM output.
00: Output disabled
01: Alarm A output enabled
10: Alarm B output enabled
11: Wake-up output enabled

Bit 20 **POL**: Output polarity
This bit is used to configure the polarity of TAMPALRM output.
0: The pin is high when ALRAF/ALRBF/WUTF is asserted (depending on OSEL[1:0]), or when a TAMPxF/ITAMPxF is asserted (if TAMPOE = 1).
1: The pin is low when ALRAF/ALRBF/WUTF is asserted (depending on OSEL[1:0]), or when a TAMPxF/ITAMPxF is asserted (if TAMPOE = 1).

Bit 19 **COSEL**: Calibration output selection
When COE = 1, this bit selects which signal is output on CALIB.
0: Calibration output is 512 Hz
1: Calibration output is 1 Hz
These frequencies are valid for RTCCLK at 32.768 kHz and prescalers at their default values (PREDIV_A = 127 and PREDIV_S = 255). Refer to *Section 46.3.18: Calibration clock output*.

Bit 18 **BKP**: Backup
This bit can be written by the user to memorize whether the daylight saving time change has been performed or not.

Bit 17 **SUB1H**: Subtract 1 hour (winter time change)
When this bit is set outside initialization mode, 1 hour is subtracted to the calendar time if the current hour is not 0. This bit is always read as 0.
Setting this bit has no effect when current hour is 0.
0: No effect
1: Subtracts 1 hour to the current time. This can be used for winter time change.

Bit 16 **ADD1H**: Add 1 hour (summer time change)

When this bit is set outside initialization mode, 1 hour is added to the calendar time. This bit is always read as 0.

0: No effect

1: Adds 1 hour to the current time. This can be used for summer time change

Bit 15 **TSIE**: Timestamp interrupt enable

0: Timestamp interrupt disable

1: Timestamp interrupt enable

Bit 14 **WUTIE**: Wake-up timer interrupt enable

0: Wake-up timer interrupt disabled

1: Wake-up timer interrupt enabled

Bit 13 **ALRBIE**: Alarm B interrupt enable

0: Alarm B interrupt disable

1: Alarm B interrupt enable

Bit 12 **ALRAIE**: Alarm A interrupt enable

0: Alarm A interrupt disabled

1: Alarm A interrupt enabled

Bit 11 **TSE**: timestamp enable

0: timestamp disable

1: timestamp enable

Bit 10 **WUTE**: Wake-up timer enable

0: Wake-up timer disabled

1: Wake-up timer enabled

Note: When the wake-up timer is disabled, wait for WUTWF = 1 before enabling it again.

Bit 9 **ALRBE**: Alarm B enable

0: Alarm B disabled

1: Alarm B enabled

Bit 8 **ALRAE**: Alarm A enable

0: Alarm A disabled

1: Alarm A enabled

Bit 7 **SSRUIE**: SSR underflow interrupt enable

0: SSR underflow interrupt disabled

1: SSR underflow interrupt enabled

Bit 6 **FMT**: Hour format

0: 24 hour/day format

1: AM/PM hour format

Bit 5 **BYPSHAD**: Bypass the shadow registers

0: Calendar values (when reading from RTC_SSR, RTC_TR, and RTC_DR) are taken from the shadow registers, which are updated once every two RTCCLK cycles.

1: Calendar values (when reading from RTC_SSR, RTC_TR, and RTC_DR) are taken directly from the calendar counters.

Note: If the frequency of the APB clock is less than seven times the frequency of RTCCLK, BYPSHAD must be set to 1.

Bit 4 **REFCKON**: RTC_REFIN reference clock detection enable (50 or 60 Hz)
0: RTC_REFIN detection disabled
1: RTC_REFIN detection enabled
Note: BIN must be 0x00 and PREDIV_S must be 0x00FF.

Bit 3 **TSEDGE**: Timestamp event active edge
0: RTC_TS input rising edge generates a timestamp event
1: RTC_TS input falling edge generates a timestamp event
TSE must be reset when TSEDGE is changed to avoid unwanted TSF setting.

Bits 2:0 **WUCKSEL[2:0]**: ck_wut wake-up clock selection
000: RTC/16 clock is selected
001: RTC/8 clock is selected
010: RTC/4 clock is selected
011: RTC/2 clock is selected
10x: ck_spre (usually 1 Hz) clock is selected in BCD mode. In binary or mixed mode, this is the clock selected by BCDU.
11x: ck_spre (usually 1 Hz) clock is selected in BCD mode. In binary or mixed mode, this is the clock selected by BCDU. Furthermore, 2^{16} is added to the WUT counter value.

Note: Bits 6 and 4 of this register can be written in initialization mode only (RTC_ICSR/INITF = 1).

WUT = wake-up unit counter value. WUT = (0x0000 to 0xFFFF) + 0x10000 added when WUCKSEL[2:1 = 11].

Bits 2 to 0 of this register can be written only when RTC_CR WUTE bit = 0 and RTC_ICSR WUTWF bit = 1.

It is recommended not to change the hour during the calendar hour increment as it may mask the incrementation of the calendar hour.

ADD1H and SUB1H changes are effective in the next second.

46.6.8 RTC privilege mode control register (RTC_PRIVCFGR)

This register can be written only when the APB access is privileged. This register can be write-protected, or each bit of this register can be individually write-protected against nonsecure access depending on the RTC_SECCFGR configuration (refer to *Section 46.3.5: RTC privilege protection modes*).

Address offset: 0x1C

Backup domain reset value: 0x0000 0000

System reset: not affected

rw	rw	rw										rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **PRIV**: RTC privilege protection

0: All RTC registers can be written when the APB access is privileged or non-privileged, except the registers protected by other privilege protection bits.

1: All RTC registers can be written only when the APB access is privileged.

Bit 14 **INITPRIV**: Initialization privilege protection

0: RTC Initialization mode, calendar and prescalers registers can be written when the APB access is privileged or non-privileged.

1: RTC Initialization mode, calendar and prescalers registers can be written only when the APB access is privileged.

Bit 13 **CALPRIV**: Shift register, Delight saving, calibration and reference clock privilege protection

0: Shift register, Delight saving, calibration and reference clock can be written when the APB access is privileged or non-privileged.

1: Shift register, Delight saving, calibration and reference clock can be written only when the APB access is privileged.

Bits 12:4 Reserved, must be kept at reset value.

Bit 3 **TSPRIV**: Timestamp privilege protection

0: RTC Timestamp configuration and interrupt clear can be written when the APB access is privileged or non-privileged.

1: RTC Timestamp configuration and interrupt clear can be written only when the APB access is privileged.

Bit 2 **WUTPRIV**: Wake-up timer privilege protection

0: RTC wake-up timer configuration and interrupt clear can be written when the APB access is privileged or non-privileged.

1: RTC wake-up timer configuration and interrupt clear can be written only when the APB access is privileged.

Bit 1 **ALRBPRIV**: Alarm B privilege protection

0: RTC Alarm B configuration and interrupt clear can be written when the APB access is privileged or non-privileged.

1: RTC Alarm B configuration and interrupt clear can be written only when the APB access is privileged.

Bit 0 **ALRAPRIV**: Alarm A and SSR underflow privilege protection

0: RTC Alarm A and SSR underflow configuration and interrupt clear can be written when the APB access is privileged or non-privileged.

1: RTC Alarm A and SSR underflow configuration and interrupt clear can be written only when the APB access is privileged.

Note: Refer to Section 46.3.5: RTC privilege protection modes for details on the read protection.

46.6.9 RTC secure configuration register (RTC_SECCFGR)

This register can be written only when the APB access is secure.

This register can be globally write-protected, or each bit of this register can be individually write-protected against non-privileged access depending on the RTC_PRIVCFGR configuration (refer to *Section 46.3.5: RTC privilege protection modes*).

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **SEC**: RTC global protection

0: All RTC registers can be written when the APB access is secure or non-secure, except the registers protected by other secure protection bits.

1: All RTC registers can be written only when the APB access is secure.

Bit 14 **INITSEC**: Initialization protection

0: RTC Initialization mode, calendar and prescalers registers can be written when the APB access is secure or nonsecure.

1: RTC Initialization mode, calendar and prescalers registers can be written only when the APB access is secure.

Bit 13 **CALSEC**: Shift register, daylight saving, calibration and reference clock protection

0: Shift register, daylight saving, calibration and reference clock can be written when the APB access is secure or nonsecure.

1: Shift register, daylight saving, calibration and reference clock can be written only when the APB access is secure.

Bits 12:4 Reserved, must be kept at reset value.

Bit 3 **TSSEC**: Timestamp protection

0: RTC timestamp configuration and interrupt clear can be written when the APB access is secure or nonsecure.

1: RTC timestamp configuration and interrupt clear can be written only when the APB access is secure.

Bit 2 **WUTSEC**: Wake-up timer protection

0: RTC wake-up timer configuration and interrupt clear can be written when the APB access is secure or nonsecure.

1: RTC wake-up timer configuration and interrupt clear can be written only when the APB access is secure.

Bit 1 **ALRBSEC**: Alarm B protection

0: RTC alarm B configuration and interrupt clear can be written when the APB access is secure or nonsecure.

1: RTC alarm B configuration and interrupt clear can be written only when the APB access is secure.

Bit 0 **ALRASEC**: Alarm A and SSR underflow protection

0: RTC alarm A and SSR underflow configuration and interrupt clear can be written when the APB access is secure or nonsecure.

1: RTC alarm A and SSR underflow configuration and interrupt clear can be written only when the APB access is secure.

Note: Refer to Section 46.3.4: RTC secure protection modes for details on the read protection.

46.6.10 RTC write protection register (RTC_WPR)

Address offset: 0x24

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	KEY[7:0]							
								w	w	w	w	w	w	w	w

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **KEY[7:0]**: Write protection key

This byte is written by software.

Reading this byte always returns 0x00.

Refer to *RTC register write protection* for a description of how to unlock RTC register write protection.

46.6.11 RTC calibration register (RTC_CALR)

This register is write protected. The write access procedure is described in *RTC register write protection on page 1961*.

This register can be write-protected against nonsecure access. Refer to *Section 46.3.4: RTC secure protection modes*.

This register can be write-protected against non-privileged access. Refer to *Section 46.3.5: RTC privilege protection modes*.

Address offset: 0x28

Backup domain reset value: 0x0000 0000

System reset: not affected

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CALP	CALW8	CALW 16	LPCAL	Res.	Res.	Res.	CALM[8:0]								
rw	rw	rw	rw				rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **CALP**: Increase frequency of RTC by 488.5 ppm
0: No RTCCLK pulses are added.
1: One RTCCLK pulse is effectively inserted every 2^{11} pulses (frequency increased by 488.5 ppm).
This feature is intended to be used in conjunction with CALM, which lowers the frequency of the calendar with a fine resolution. if the input frequency is 32768 Hz, the number of RTCCLK pulses added during a 32-second window is calculated as follows:
(512 × CALP) - CALM.
Refer to *Section 46.3.16: RTC smooth digital calibration*.

Bit 14 **CALW8**: Use an 8-second calibration cycle period
When CALW8 is set to 1, the 8-second calibration cycle period is selected.
Note: CALM[1:0] are stuck at 00 when CALW8 = 1. Refer to Section 46.3.16: RTC smooth digital calibration.

Bit 13 **CALW16**: Use a 16-second calibration cycle period
When CALW16 is set to 1, the 16-second calibration cycle period is selected. This bit must not be set to 1 if CALW8 = 1.
Note: CALM[0] is stuck at 0 when CALW16 = 1. Refer to Section 46.3.16: RTC smooth digital calibration.

Bit 12 **LPCAL**: RTC low-power mode

0: Calibration window is 2^{20} RTCCLK, which is a high-consumption mode. This mode must be set only when less than 32s calibration window is required.

1: Calibration window is 2^{20} ck_apre, which is the required configuration for ultra-low consumption mode.

Bits 11:9 Reserved, must be kept at reset value.

Bits 8:0 **CALM[8:0]**: Calibration minus

The frequency of the calendar is reduced by masking CALM out of 2^{20} RTCCLK pulses (32 seconds if the input frequency is 32768 Hz). This decreases the frequency of the calendar with a resolution of 0.9537 ppm.

To increase the frequency of the calendar, this feature should be used in conjunction with CALP. See *Section 46.3.16: RTC smooth digital calibration on page 1966*.

46.6.12 RTC shift control register (RTC_SHIFTR)

This register is write protected. The write access procedure is described in *RTC register write protection on page 1961*.

This register can be protected against nonsecure access. Refer to *Section 46.3.4: RTC secure protection modes*.

This register can be protected against non-privileged access. Refer to *Section 46.3.5: RTC privilege protection modes*.

Address offset: 0x2C

Backup domain reset value: 0x0000 0000

System reset: not affected

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADD1S	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
w															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	SUBFS[14:0]														
	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bit 31 **ADD1S**: Add one second

0: No effect

1: Add one second to the clock/calendar

This bit is write only and is always read as zero. Writing to this bit has no effect when a shift operation is pending (when SHPF = 1, in RTC_ICSR).

This function is intended to be used with SUBFS (see description below) in order to effectively add a fraction of a second to the clock in an atomic operation.

Bits 30:15 Reserved, must be kept at reset value.

Bits 14:0 **SUBFS[14:0]**: Subtract a fraction of a second

These bits are write only and is always read as zero. Writing to this bit has no effect when a shift operation is pending (when SHPF = 1, in RTC_ICSR).

The value which is written to SUBFS is added to the synchronous prescaler counter. Since this counter counts down, this operation effectively subtracts from (delays) the clock by:

Delay (seconds) = SUBFS / (PREDIV_S + 1)

A fraction of a second can effectively be added to the clock (advancing the clock) when the ADD1S function is used in conjunction with SUBFS, effectively advancing the clock by:

Advance (seconds) = (1 - (SUBFS / (PREDIV_S + 1))).

In mixed BCD-binary mode (BIN=10 or 11), the SUBFS[14:BCDU+8] must be written with 0.

Note: Writing to SUBFS causes RSF to be cleared. Software can then wait until RSF = 1 to be sure that the shadow registers have been updated with the shifted time.

46.6.13 RTC timestamp time register (RTC_TSTR)

The content of this register is valid only when TSF is set to 1 in RTC_SR. It is cleared when TSF bit is reset.

This register can be protected against nonsecure access. Refer to *Section 46.3.4: RTC secure protection modes*.

This register can be protected against non-privileged access. Refer to *Section 46.3.5: RTC privilege protection modes*.

Address offset: 0x30

Res.	SS[14:0]														
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	w	rw	rw

Bit 31 **SSCLR**: Clear synchronous counter on alarm (Binary mode only)

0: The synchronous binary counter (SS[31:0] in RTC_SSR) is free-running.

1: The synchronous binary counter (SS[31:0] in RTC_SSR) is running from 0xFFFF FFFF to RTC_ALRABINR.SS[31:0] value and is automatically reloaded with 0xFFFF FFFF one ck_apre cycle after reaching RTC_ALRABINR.SS[31:0].

Note: SSCLR must be kept to 0 when BCD or mixed mode is used (BIN = 00, 10 or 11).

Bit 30 Reserved, must be kept at reset value.

Bits 29:24 **MASKSS[5:0]**: Mask the most-significant bits starting at this bit

0: No comparison on subseconds for Alarm A. The alarm is set when the seconds unit is incremented (assuming that the rest of the fields match).

1: SS[31:1] are don't care in Alarm A comparison. Only SS[0] is compared.

2: SS[31:2] are don't care in Alarm A comparison. Only SS[1:0] are compared.

...

31: SS[31] is don't care in Alarm A comparison. Only SS[30:0] are compared.

From 32 to 63: All 32 SS bits are compared and must match to activate alarm.

Note: In BCD mode (BIN=00) the overflow bits of the synchronous counter (bits 31:15) are never compared. These bits can be different from 0 only after a shift operation.

Bits 23:15 Reserved, must be kept at reset value.

Bits 14:0 **SS[14:0]**: Subseconds value

This value is compared with the contents of the synchronous prescaler counter to determine if alarm A is to be activated. Only bits 0 up MASKSS-1 are compared.

This field is the mirror of SS[14:0] in the RTC_ALRABINR, and so can also be read or written through RTC_ALRABINR.

Note: SS[3:0] must be 0000 when SSCLR is set with ATCKSEL[3] = 1 in TAMP_ATCR1.

46.6.18 RTC alarm B register (RTC_ALRMBR)

This register can be written only when ALRBE is reset in RTC_CR register, or in initialization mode.

This register can be protected against nonsecure access. Refer to *Section 46.3.4: RTC secure protection modes*.

This register can be protected against non-privileged access. Refer to *Section 46.3.5: RTC privilege protection modes*.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SSRUF	ITSF	TSOVF	TSF	WUTF	ALRBF	ALRAF
									r	r	r	r	r	r	r

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **SSRUF**: SSR underflow flag
This flag is set by hardware when the SSR rolls under 0. SSRUF is not set when SSCLR=1.

Bit 5 **ITSF**: Internal timestamp flag
This flag is set by hardware when a timestamp on the internal event occurs.

Bit 4 **TSOVF**: Timestamp overflow flag

This flag is set by hardware when a timestamp event occurs while TSF is already set.

It is recommended to check and then clear TSOVF only after clearing the TSF bit. Otherwise, an overflow might not be noticed if a timestamp event occurs immediately before the TSF bit is cleared.

Bit 3 **TSF**: Timestamp flag

This flag is set by hardware when a timestamp event occurs.

If ITSF flag is set, TSF must be cleared together with ITSF.

Note: TSF is not set if TAMPTS = 1 and the tamper flag is read during the 3 ck_apre cycles following tamper event. Refer to Timestamp on tamper event for more details.

Bit 2 **WUTF**: Wake-up timer flag

This flag is set by hardware when the wake-up auto-reload counter reaches 0.

If WUTOCLR[15:0] is different from 0x0000, WUTF is cleared by hardware when the wake-up auto-reload counter reaches WUTOCLR value.

If WUTOCLR[15:0] is 0x0000, WUTF must be cleared by software.

This flag must be cleared by software at least 1.5 RTCCLK periods before WUTF is set to 1 again.

Bit 1 **ALRBF**: Alarm B flag

This flag is set by hardware when the time/date registers (RTC_TR and RTC_DR) match the alarm B register (RTC_ALRMBR).

Bit 0 **ALRAF**: Alarm A flag

This flag is set by hardware when the time/date registers (RTC_TR and RTC_DR) match the alarm A register (RTC_ALRMAR).

Note: The bits of this register are cleared 2 APB clock cycles after setting their corresponding clear bit in the RTC_SCR register.

46.6.21 RTC nonsecure masked interrupt status register (RTC_MISR)

This register can be globally protected, or each bit of this register can be individually protected against non-privileged access. Refer to *Section 46.3.5: RTC privilege protection modes*.

									r	r	r	r	r	r	r

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **SSRUMF**: SSR underflow nonsecure masked flag
This flag is set by hardware when the SSR underflow nonsecure interrupt occurs.

Bit 5 **ITSMF**: Internal timestamp nonsecure masked flag
This flag is set by hardware when a timestamp on the internal event occurs and timestamp nonsecure interrupt is raised.

Bit 4 **TSOVMF**: Timestamp overflow nonsecure masked flag
This flag is set by hardware when a timestamp interrupt occurs while TSMF is already set.
It is recommended to check and then clear TSOVF only after clearing the TSF bit. Otherwise, an overflow might not be noticed if a timestamp event occurs immediately before the TSF bit is cleared.

Bit 3 **TSMF**: Timestamp nonsecure masked flag
This flag is set by hardware when a timestamp nonsecure interrupt occurs.
If ITSF flag is set, TSF must be cleared together with ITSF.

Bit 2 **WUTMF**: Wake-up timer nonsecure masked flag
This flag is set by hardware when the wake-up timer nonsecure interrupt occurs.
This flag must be cleared by software at least 1.5 RTCCLK periods before WUTF is set to 1 again.

Bit 1 **ALRBMF**: Alarm B nonsecure masked flag
This flag is set by hardware when the alarm B nonsecure interrupt occurs.

Bit 0 **ALRAMF**: Alarm A masked flag
This flag is set by hardware when the alarm A nonsecure interrupt occurs.

46.6.22 RTC secure masked interrupt status register (RTC_SMISR)

This register can be globally protected, or each bit of this register can be individually protected against nonsecure access. Refer to *Section 46.3.4: RTC secure protection modes*.

This register can be globally protected, or each bit of this register can be individually protected against non-privileged access. Refer to *Section 46.3.5: RTC privilege protection modes*.

Address offset: 0x58

Backup domain reset value: 0x0000 0000

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **SSRUMF**: SSR underflow secure masked flag
This flag is set by hardware when the SSR underflow secure interrupt occurs.

Bit 5 **ITSMF**: Internal timestamp interrupt secure masked flag
This flag is set by hardware when a timestamp on the internal event occurs and timestamp secure interrupt is raised.

Bit 4 **TSOVMF**: Timestamp overflow interrupt secure masked flag
This flag is set by hardware when a timestamp secure interrupt occurs while TSMF is already set.
It is recommended to check and then clear TSOVF only after clearing the TSF bit. Otherwise, an overflow might not be noticed if a timestamp event occurs immediately before the TSF bit is cleared.

Bit 3 **TSMF**: Timestamp interrupt secure masked flag
This flag is set by hardware when a timestamp secure interrupt occurs.
If ITSF flag is set, TSF must be cleared together with ITSF.

Bit 2 **WUTMF**: Wake-up timer interrupt secure masked flag
This flag is set by hardware when the wake-up timer secure interrupt occurs.
This flag must be cleared by software at least 1.5 RTCCLK periods before WUTF is set to 1 again.

Bit 1 **ALRBMF**: Alarm B interrupt secure masked flag
This flag is set by hardware when the alarm B secure interrupt occurs.

Bit 0 **ALRAMF**: Alarm A interrupt secure masked flag
This flag is set by hardware when the alarm A secure interrupt occurs.

46.6.23 RTC status clear register (RTC_SCR)

This register can be globally protected, or each bit of this register can be individually protected against nonsecure access. Refer to *Section 46.3.4: RTC secure protection modes*.

This register can be globally protected, or each bit of this register can be individually protected against non-privileged access. Refer to *Section 46.3.5: RTC privilege protection modes*.

Address offset: 0x5C

Backup domain reset value: 0x0000 0000

System reset: not affected

									w	w	w	w	w	w	w

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **CSSRUF**: Clear SSR underflow flag
Writing ‘1’ in this bit clears the SSRUF in the RTC_SR register.

Bit 5 **CITSF**: Clear internal timestamp flag
Writing 1 in this bit clears the ITSF bit in the RTC_SR register.

Bit 4 **CTSOVF**: Clear timestamp overflow flag
Writing 1 in this bit clears the TSOVF bit in the RTC_SR register.
It is recommended to check and then clear TSOVF only after clearing the TSF bit. Otherwise, an overflow might not be noticed if a timestamp event occurs immediately before the TSF bit is cleared.

Bit 3 **CTSF**: Clear timestamp flag
Writing 1 in this bit clears the TSF bit in the RTC_SR register.
If ITSF flag is set, TSF must be cleared together with ITSF by setting CRSF and CITSF.

Bit 2 **CWUTF**: Clear wake-up timer flag
Writing 1 in this bit clears the WUTF bit in the RTC_SR register.

Bit 1 **CALRBF**: Clear alarm B flag
Writing 1 in this bit clears the ALRBF bit in the RTC_SR register.

Bit 0 **CALRAF**: Clear alarm A flag
Writing 1 in this bit clears the ALRAF bit in the RTC_SR register.

46.6.24 RTC option register (RTC_OR)

Address offset: 0x60

Backup domain reset value: 0x0000 0000

System reset: not affected

47 Tamper and backup registers (TAMP)

47.1 Introduction

The anti-tamper detection circuit is used to protect sensitive data from external attacks. 32 32-bit backup registers are retained in all low-power modes and also in V_{BAT} mode. The backup registers, as well as other secrets in the device, are protected by this anti-tamper detection circuit with 11 tamper pins and 13 internal tampers. The external tamper pins can be configured for edge detection, or level detection with or without filtering, or active tamper which increases the security level by auto checking that the tamper pins are not externally opened or shorted.

47.2 TAMP main features

- A tamper detection can optionally erase the backup registers, backup SRAM, SRAM2, caches and cryptographic peripherals. The device resources protected by tamper are named “device secrets”.
- 32 32-bit backup registers:
  - The backup registers (TAMP_BKPxR) are implemented in the backup domain that remains powered-on by V_{BAT} when the V_{DD} power is switched off.
- Up to 11 tamper pins for 8 external tamper detection events:
  - Active tamper mode: continuous comparison between tamper output and input to protect from physical open-short attacks.
  - Flexible active tamper I/O management: from 5 meshes (each input associated to its own exclusive output) to 8 meshes (single output shared for up to 8 tamper inputs)
  - Passive tampers: ultra-low power edge or level detection with internal pull-up hardware management.
  - Configurable digital filter.
- 13 internal tamper events to protect against transient or environmental perturbation attacks
- Each tamper can be configured in two modes:
  - Confirmed mode: immediate erase of secrets on tamper detection, including backup registers erase
  - Potential mode: most of the secrets erase following a tamper detection are launched by software
- Any tamper detection can generate a RTC timestamp event.
- TrustZone support:
  - Tamper secure or nonsecure configuration.
  - Backup registers configuration in 3 configurable-size areas:

    1 read/write secure area.

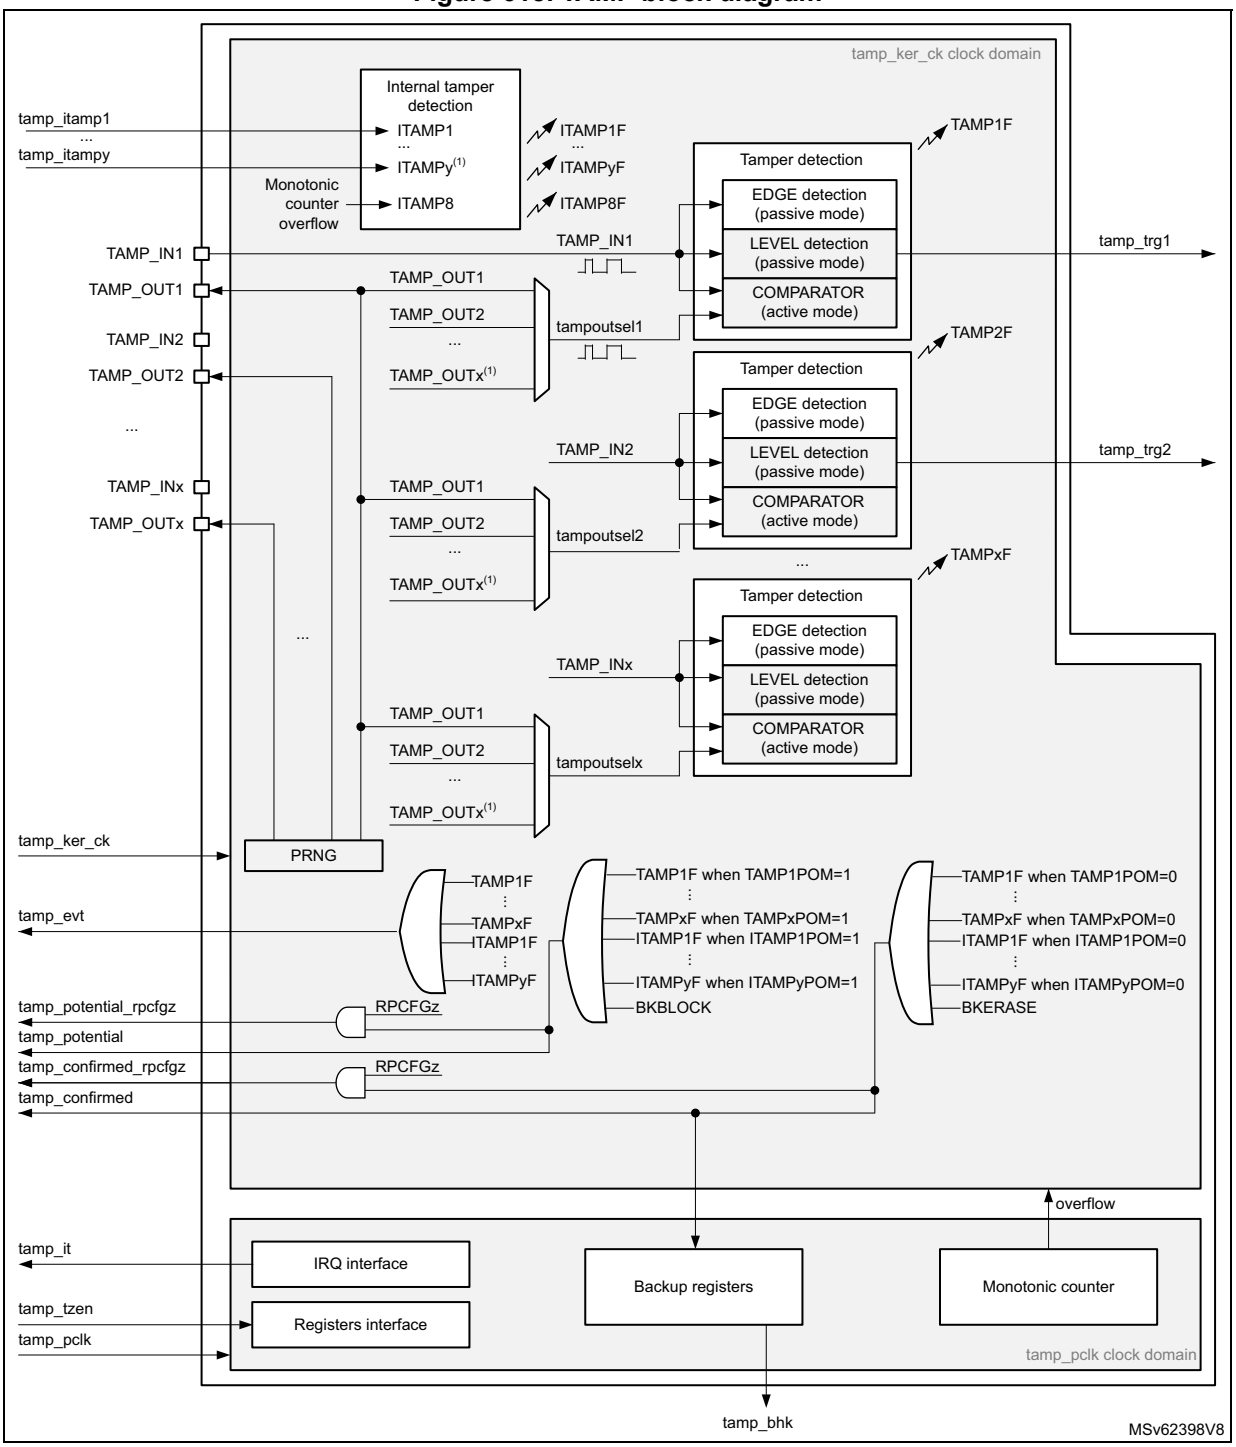
    1 write secure/read nonsecure area.

    1 read/write nonsecure area.
  - Boot hardware key for secure AES, stored in backup registers, protected against read and write access.
- Tamper configuration and backup registers privilege protection
- Monotonic counter.

47.3 TAMP functional description

47.3.1 TAMP block diagram

Figure 618. TAMP block diagram



1. The number of external and internal tampers depends on products.

47.3.2 TAMP pins and internal signals

Table 487. TAMP input/output pins

Pin name	Signal type	Description
TAMP_INx (x = pin index)	Input	Tamper input pin
TAMP_OUTx (x = pin index)	Output	Tamper output pin (active mode only)

Table 488. TAMP internal input/output signals

Internal signal name	Signal type	Description
tamp_ker_ck	Input	TAMP kernel clock, connected to rtc_ker_ck and also named RTCCLK in this document
tamp_pclk	Input	TAMP APB clock, connected to rtc_pclk
tamp_itamp[y] (y = signal index)	Inputs	Internal tamper event sources
tamp_tzen	Input	TAMP TrustZone enabled
tamp_evt	Output	Tamper event detection flag (internal or external tamper), whatever confirmed or potential mode configuration.
tamp_potential	Output	Potential tamper detection signal, used for device secrets(1) protection. This signal is active when: – a tamper event detection flag (internal or external tamper), is generated in potential mode. – or a software request is done by writing BKBLOCK to 1
tamp_confirmed	Output	Confirmed tamper detection signal, used for device secrets(1) protection. This signal is active when: – a tamper event detection flag (internal or external tamper), is generated in confirmed mode. – or a software request is done by writing BKERASE to 1
tamp_potential_rpcfgz (z = signal index)	Output	Potential tamper detection signal generated only when RPCFGz = 1. This signal is active when: – a tamper event detection flag (internal or external tamper), is generated in potential mode. – or a software request is done by writing BKBLOCK to 1

Table 488. TAMP internal input/output signals (continued)

Internal signal name	Signal type	Description
tamp_confirmed_rpcfgz (z = signal index)	Output	Confirmed tamper detection signal generated only when RPCFGz = 1. This signal is active when: – a tamper event detection flag (internal or external tamper), is generated in confirmed mode. – or a software request is done by writing BKERASE to 1
tamp_it	Output	TAMP interrupt (refer to *Section 47.5: TAMP interrupts* for details)
tamp_trg[x] (x = signal index)	Output	Tamper detection trigger
tamp_bhk	Output	Tamper boot hardware key bus

1. Refer to *Table 489: TAMP interconnection*.

The TAMP kernel clock is usually the LSE at 32.768 kHz although it is possible to select other clock sources in the RCC (refer to RCC for more details). Some detections modes are not available in some low-power modes or V_{BAT} depending on the selected clock (refer to *Section 47.4: TAMP low-power modes* for more details.

Table 489. TAMP interconnection

Signal name	Source/Destination
tamp_tzen	From FLASH option bytes: TZEN
tamp_evt	rtc_tamp_evt used to generate a timestamp event
tamp_potential	The tamp_potential signal is used to block the read and write accesses to the device secrets listed hereafter: – backup registers – SRAM2 RHUK (root hardware unique key) in system Flash memory and BHK (boot hardware key) hardware buses to SAES are blocked. The tamp_potential signal is used to erase the device secrets listed hereafter: – ICACHE content – SAES, AES, HASH peripherals – PKA SRAM The device secrets access is blocked when erase is ongoing.

Table 489. TAMP interconnection (continued)

Signal name	Source/Destination
tamp_confirmed	The tamp_confirmed signal is used to erase the device secrets listed hereafter: – backup registers – SRAM2 – ICACHE/DCACHE content – OTFDEC keys and CRC registers – SAES, AES, HASH peripherals – PKA SRAM The device secrets access is blocked when erase is ongoing. RHUK in system Flash memory (root hardware unique key) hardware bus to SAES is blocked.
tamp_potential_rpcfg0	When the bit RPCFG0 is set in the TAMP_RPCFGR, the tamp_potential_rpcfg0 signal is used to block the read and write accesses to the device secrets listed hereafter: – Backup SRAM
tamp_confirmed_rpcfg0	When the bit RPCFG0 is set in the TAMP_RPCFGR, the tamp_confirmed_rpcfg0 signal is used to erase the device secrets listed hereafter: – Backup SRAM The device secrets access is blocked when erase is on-going.
tamp_itamp1	Backup domain voltage threshold monitoring(1)
tamp_itamp2	Temperature monitoring(1)
tamp_itamp3	LSE monitoring (LSECSS)(2)
tamp_itamp4	HSE monitoring (rcc_hsecss_fail)
tamp_itamp5	RTC calendar overflow (rtc_calovf)
tamp_itamp6	JTAG/SWD access when NVSTATE ≠ OPEN
tamp_itamp7	ADC2 watchdog monitoring 1
tamp_itamp8(3)	Monotonic counter 1 overflow
tamp_itamp9	Cryptographic peripherals fault (SAES or AES or PKA or TRNG)
tamp_itamp11	IWDG reset when tamper flag is set (potential tamper timeout)
tamp_itamp12	ADC2 analog watchdog monitoring 2
tamp_itamp13	ADC2 analog watchdog monitoring 3
tamp_itamp15	System fault
tamp_bhk	saes_bhk. This bus is used to load the boot hardware key in the secure AES co-processor.

1. This monitoring must be enabled by setting MONEN in *PWR backup domain control register (PWR_BDCR)*.
2. This monitoring must be enabled by setting LSEON in *PWR backup domain control register (PWR_BDCR)*.
3. This signal is generated in the TAMP peripheral.

The TZEN option bit is used to activate TrustZone in the device.

TZEN = 1: TrustZone activated.

TZEN = 0: TrustZone disabled.

When TrustZone is disabled, the APB access to the TAMP registers are nonsecure.

47.3.3 GPIOs controlled by the RTC and TAMP

Refer to *Section 46.3.3: GPIOs controlled by the RTC and TAMP*.

47.3.4 TAMP register write protection

After system reset, the TAMP registers (including backup registers) are protected against parasitic write access by the DBP bit in the power control peripheral (refer to the PWR power control section). DBP bit must be set in order to enable TAMP registers write access.

47.3.5 TAMP secure protection modes

By default after a backup domain power-on reset, all TAMP registers can be read or written in both secure and nonsecure modes, except for the TAMP secure configuration register (TAMP_SECCFGR) which can be written in secure mode only. The TAMP protection configuration is not affected by a system reset.

- When the TAMPSEC bit is set in the TAMP_SECCFGR register:
  - Writing the TAMP registers is possible only in secure mode, except for the backup registers which have their own protection setting.
  - Reading TAMP_SECCFGR, TAMP_PRIVCFGR and TAMP_MISR is always possible in secure and nonsecure modes. All the other TAMP registers can be read only in secure mode, except for the backup registers and monotonic counters which have their own protection setting.
- When the CNT1SEC bit is set in the TAMP_SECCFGR register: the TAMP_COUNT1R can be read and written only in secure mode.

A nonsecure access to a secure-protected register is denied:

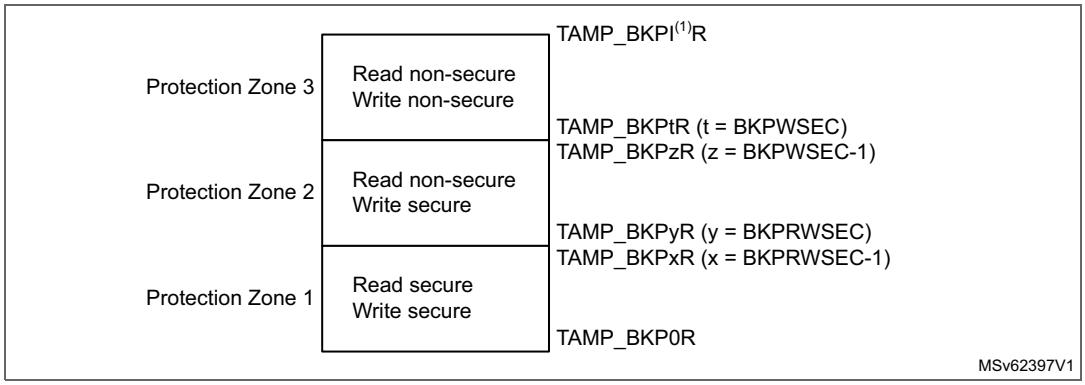
- There is no bus error generated.
- A notification is generated through a flag/interrupt in the TZIC (TrustZone illegal access controller).
- When write protected, the bits are not written.
- When read protected they are read as 0.

As soon as at least one function is configured to be secured, the TAMP reset and clock control is also secured in the RCC.

47.3.6 Backup registers protection zones

The backup registers protection is configured thanks to BKPRWSEC[7:0] and BKPWSEC[7:0] (refer to the figure below):

Figure 619. Backup registers protection zones



1. I = last backup register index

In case TZEN =1, the bits BKPWPRIV and BKPRWPRIV in the TAMP_PRIVCFGR can be written only in secure mode.

47.3.7 TAMP privilege protection modes

By default after a backup domain power-on reset, all TAMP registers can be read or written in both privileged and non-privileged modes, except for the TAMP privilege configuration register (TAMP_PRIVCFGR) which can be written in privilege mode only. The TAMP protection configuration is not affected by a system reset.

When the TAMPPRIV bit is set in the TAMP_PRIVCFGR register:

- Writing the TAMP registers is possible only in privilege mode, except for the backup registers and the monotonic counters which have their own protection setting.
- When the CNT1PRIV bit is set in the TAMP_PRIVCFGR register: the TAMP_COUNT1R can be read and written only in privilege mode.
- Reading TAMP_SECCFGR, TAMP_PRIVCFGR is always possible in privilege and non-privilege modes. All the other TAMP registers can be read only in privileged mode, except for the backup registers and the monotonic counters which have their own protection setting.

The backup registers protection is configured thanks to BKPRWSEC[7:0] and BKPRWPRIV for the protection zone 1, and thanks to BKPRWSEC[7:0], BKPWSEC[7:0] and BKPWPRIV for the protection zone 2 (refer to *Figure 619*). The BHKLOCK bit can be written only in privileged mode when the BKPRWPRIV bit is set.

A non-privileged access to a privileged-protected register is denied:

- There is no bus error generated.
- When write protected, the bits are not written.
- When read protected they are read as 0.

47.3.8 Boot hardware key (BHK)

The eight first backup registers from TAMP_BKP0R to TAMP_BKP7R can be used to store a boot hardware key for the secure AES.

For this purpose, these registers must belong to the Protection Zone 1: BKPRWSEC must be greater or equal to 8.

Once the backup registers are written with the boot hardware key, the BHKLOCK bit must be set in the TAMP_SECCFGR register. Once BHKLOCK is set, the 8 backup registers cannot be accessed anymore by software: they are read as 0 and write to these registers is ignored. BHKLOCK cannot be cleared by software, and is cleared by hardware following a tamper event or when the readout protection (RDP) is disabled. It is also cleared with BKERASE command (in all cases the backup registers are also erased).

Refer to section secure AES co-processor (SAES) for details on procedure to download the boot hardware key in the SAES.

47.3.9 Tamper detection

The tamper detection main purpose is to protect the device secrets from device external attacks. The detection is made on events on TAMP_INx (x = pin index) I/Os, or on internal monitors detecting out-of-range device conditions.

The tamper detection can be configured for the following purposes:

- erase the backup registers and other device secrets stored in SRAMs or peripherals listed in *Table 489: TAMP interconnection*. The device secrets list is configurable thanks to *TAMP resources protection configuration register (TAMP_RPCFGR)*.
- block the read/write access to the backup registers and other device secrets stored in SRAMs or peripherals listed in *Table 489: TAMP interconnection*. The device secrets list is configurable thanks to TAMP_RPCFGR.
- generate an interrupt, capable to wake-up from low-power modes
- generate a hardware trigger for the low-power timers, or a RTC timestamp event

The external I/Os tamper detection supports 2 main configurations:

- Passive mode: TAMP_INx I/Os are monitored and a tamper is detected either on edge or on level.
- Active mode: TAMP_INx (x = pin index) is continuously compared with TAMP_OUTy (y = pin index) allowing open-short detection.

A digital filter can be applied on external tamper detection to avoid false detection. In addition, it is possible to configure each tamper source in potential mode, so that the secrets erase is not launched by hardware on tamper detection. The secrets erase can then be launched by software after software checks.

47.3.10 TAMP backup registers and other device secrets erase

The backup registers (TAMP_BKPxR) are not reset by system reset or when the device wakes up from Standby mode.

The backup registers and the other device secrets are not reset when the corresponding mask is set (TAMPxMSK=1 in the TAMP_CR2 register).

Note: The backup registers are also erased when the readout protection of the flash is changed from level 1 to level 0.

Tamper detection – confirmed mode

The confirmed mode is selected for TAMPx (external tamper x) when TAMPxPOM = 0 in the TAMP_CR2 register. The confirmed mode is selected for ITAMPx (internal tamper x) when ITAMPxPOM = 0 in the TAMP_CR3 register. The effects of a tamper detection in confirmed mode are described with tamp_confirmed and tamp_confirmed_rpcfgx signals in the *Table 489: TAMP interconnection*.

This mode is selected to erase automatically the device secrets when the tamper is detected.

Tamper detection – potential mode

The potential mode is selected for TAMPx (external tamper x) when TAMPxPOM = 1 in the TAMP_CR2 register. The potential tamper mode is selected for ITAMPx (internal tamper x) when ITAMPxPOM = 1 in the TAMP_CR3 register. The effects of a tamper detection in potential mode are described with tamp_potential and tamp_potential_rpcfgx signals in the *Table 489: TAMP interconnection*.

This mode is selected to avoid irreversible erasure of some device secrets when the tamper is detected. In this mode, some device secrets are not erased when the corresponding tamper event is detected. In addition, the read and write accesses to these device secrets are blocked as soon as the tamper detection flag is set in potential mode, until this flag is cleared by setting the corresponding clear flag in the TAMP_SCR register. Therefore the software can perform some checks to discriminate false from true tampers, and decide to launch secrets erase only in case of the potential tamper is confirmed to be a true tamper. The device secrets are erased by software by setting the BKERASE bit in the TAMP_CR2 register.

Potential tamper to confirmed tamper timeout

Some internal tampers generate a tamper event if the independent watchdog reset occurs when another tamper flag is set (refer to *Table 489: TAMP interconnection*). The IWDG tamper must be configured with ITAMPxPOM = 0. This permits the erasure of device secrets to be forced by hardware after a timeout, in case the previous tamper event was in potential mode. This is equivalent to change the “potential tamper” into “confirmed tamper” if a watchdog reset occurs before any software decision following the potential tamper event.

Device resources protection configuration

Some device resources can be configured in order to be included to the list of the device secrets protected by tamper detection.

When RPCFGz = 0 in the TAMP_RPCFGR, the device resource associated to RPCFGz is not protected by the TAMP peripheral:

- It is not affected by tamper detection (whatever confirmed or potential mode)
- It is not affected by BKERASE software command
- It is not affected by BKBLOCK software command

When RPCFGz = 1 in the TAMP_RPCFGR, the device resource associated to RPCFGz is protected by the TAMP peripheral:

- It is affected by confirmed tamper detection and BKERASE software command, as described with tamp_confirmed_rpcfgz signal in *Table 489: TAMP interconnection*
- It is affected by potential tamper detection and BKBLOCK software command, as described with tamp_potential_rpcfgz signal in *Table 489: TAMP interconnection*

Table 490. Device resource x tamper protection

-	Potential tamper or BKBLOCK	Confirmed tamper or BKERASE
RPCFGx = 0	No effect on device resource x	No effect on device resource x
RPCFGx = 1	Device secret x protected as described by tamp_potential_rpcfgx(1)	Device secret x protected as described by tamp_confirmed_rpcfgx(1)

1. Refer to *Table 489: TAMP interconnection*.

Device secrets access blocked by software

By default, the device secrets can be accessed by the application, except if a tamper event flag is detected: the device secrets access is not possible as long as a tamper flag is set.

It is possible to block the access to the device secrets by software, by setting the BKBLOCK bit of the TAMP_CR2 register. The device secrets access is possible only when BKBLOCK = 0 and no tamper flag is set.

47.3.11 Tamper detection configuration and initialization

Each input can be enabled by setting the corresponding TAMPxE bits to 1 in the TAMP_CR register.

Each TAMP_INx tamper detection input is associated with a flag TAMPxF in the TAMP_SR register.

By setting the TAMPxIE bit in the TAMP_IER register, an interrupt is generated when a tamper detection event occurs (when TAMPxF is set). Setting TAMPxIE is not allowed when the corresponding TAMPxMSK is set.

Trigger output generation on tamper event

The tamper event detection can be used as trigger input by the low-power timers.

When TAMPxMSK bit is cleared in TAMP_CR register, the TAMPxF flag must be cleared by software in order to allow a new tamper detection on the same pin.

When TAMPxMSK bit is set, the TAMPxF flag is masked, and kept cleared in TAMP_SR register. This configuration permits the low-power timers to be triggered automatically in Stop mode, without requiring the system wake-up to perform the TAMPxF clearing. In this case, the backup registers are not cleared.

This feature is available only when the tamper is configured in the *Level detection with filtering on tamper inputs (passive mode)* mode (TAMPFLT ≠ 00 and active mode is not selected).

Timestamp on tamper event

With TAMPTS set to 1 in the RTC_CR, any internal or external tamper event causes a timestamp to occur. In case a timestamp occurs due to tamper event, either the TSF bit or the TSOVF bit is set in RTC_SR, in the same manner as if a normal timestamp event occurs.

Note: TSF is set up to 3 ck_apre cycles after TAMPxF flags. TSF is not set if RTCCLK is stopped (it is set when RTCCLK restarts).

Note: If TAMPxF is cleared before the expected rise of TSF, TSF is not set. Consequently, in case TAMPTS = 1, the software should either wait for timestamp flag before clearing the tamper flag, or should read the RTC counters values in the TAMP interrupt routine.

Edge detection on tamper inputs (passive mode)

If the TAMPFLT bits are 00, the TAMP_INx pins generate tamper detection events when either a rising edge or a falling edge is observed depending on the corresponding TAMPxTRG bit. The internal pull-up resistors on the TAMP_INx inputs are deactivated when edge detection is selected.

Caution: When TAMPFLT = 00 and TAMPxTRG = 0 (rising edge detection), a tamper event may be detected by hardware if the tamper input is already at high level before enabling the tamper detection.

After a tamper event has been detected and cleared, the TAMP_INx should be disabled and then re-enabled (TAMPxE set to 1) before re-programming the backup registers (TAMP_BKPxR). This prevents the application from writing to the backup registers while the TAMP_INx input value still indicates a tamper detection. This is equivalent to a level detection on the TAMP_INx input.

Note: Tamper detection is still active when V_{DD} power is switched off. To avoid unwanted resetting of the backup registers, the pin to which the TAMPx is mapped should be externally tied to the correct level.

Level detection with filtering on tamper inputs (passive mode)

Level detection with filtering is performed by setting TAMPFLT to a non-zero value. A tamper detection event is generated when either 2, 4, or 8 (depending on TAMPFLT) consecutive samples are observed at the level designated by the TAMPxTRG bits.

The TAMP_INx inputs are precharged through the I/O internal pull-up resistance before its state is sampled, unless disabled by setting TAMPPUDIS to 1. The duration of the precharge is determined by the TAMPPRCH bits, allowing for larger capacitances on the TAMP_INx inputs.

The trade-off between tamper detection latency and power consumption through the pull-up can be optimized by using TAMPFREQ to determine the frequency of the sampling for level detection.

Note: Refer to the microcontroller datasheet for the electrical characteristics of the pull-up resistors.

Active tamper detection

When the TAMPxAM bit is set in the TAMP_ATCR, the tamper events are configured in active mode, which is based on a comparison between a TAMP_OUTy pin and a TAMP_INx pin. By default (ATOSHARE = 0) the comparison is made between TAMP_INx and TAMP_OUTx (y = x). When ATOSHARE bit is set, the same output can be used for several tamper inputs. The TAMP_OUTy function is enabled on the I/O as soon as it is selected for comparison with an active tamper input TAMP_INx (TAMPxEN = TAMPxAM = 1), thanks to ATOSHARE and ATOSELx bits. Refer to ATOSHARE and ATOSEL bits descriptions in the TAMP_ATCRx (x = 1, 2) registers.

Every two CK_ATPER cycles (CK_ATPER = 2^{ATPER} × CK_ATPRE), TAMP_OUTy output pin provides a value provided by a pseudo random number generator (PRNG). After outputting this value, the TAMP_OUTy pin outputs its opposite value one CK_ATPER cycle after.

Table 491. Active tamper output change period

ATCKSEL[3:0]	CK_ATPRE frequency	ATPER[2:0]	Tamper output change (CK_ATPER) frequency	Tamper output change period(1) (ms)
0x0	f_{RTCCLK}	0x0	f_{RTCCLK}	0.030
		0x1	$f_{RTCCLK}/2$	0.061
		0x2	$f_{RTCCLK}/4$	0.122
		0x3	$f_{RTCCLK}/8$	0.244
		0x4	$f_{RTCCLK}/16$	0.488
		0x5	$f_{RTCCLK}/32$	0.977
		0x6	$f_{RTCCLK}/64$	1.953
		0x7	$f_{RTCCLK}/128$	3.906
…	…	…	…	…
0x7	$f_{RTCCLK}/128$	0x0	$f_{RTCCLK}/128$	3.906
		0x1	$f_{RTCCLK}/256$	7.8125
		0x2	$f_{RTCCLK}/512$	15.625
		0x3	$f_{RTCCLK}/1024$	31.250
		0x4	$f_{RTCCLK}/2048$	62.5
		0x5	$f_{RTCCLK}/4096$	125
		0x6	$f_{RTCCLK}/8192$	250
		0x7	$f_{RTCCLK}/16384$	500
0xB	$f_{RTCCLK}/2048$(2)	0x0	$f_{RTCCLK}/2048$	62.5
		0x1	$f_{RTCCLK}/4096$	125
		0x2	$f_{RTCCLK}/8192$	250
		0x3	$f_{RTCCLK}/16384$	500
		0x4	$f_{RTCCLK}/32768$	1000
		0x5	$f_{RTCCLK}/65536$	2000
		0x6	$f_{RTCCLK}/131072$	4000
		0x7	$f_{RTCCLK}/262144$	8000

1. Assuming f_{RTCCLK} = 32768 Hz.
2. This setting requires that (PREDIV_A+1) = 128 and (PREDIV_S+1) is a multiple of 16.

PRNG is consumed by the selected tamper outputs at a different frequency depending on the number of selected tamper outputs. The number of selected outputs depends on TAMPxAM, TAMPxE, ATOSEL and ATOSHARE.

- When only 1 output is selected: PRNG is consumed every 16 CK_ATPER periods.
- When 2 outputs are selected: PRNG is consumed every 8 CK_ATPER periods.
- When 3 or 4 outputs are selected: PRNG is consumed every 4 CK_ATPER periods.

- When 5 or more outputs are selected: PRNG is consumed every 2 CK_ATPER periods

The PRNG needs minimum 9 CK_ATPRE cycles to output a new value. Consequently the minimum ATPER values for correct functionality are provided in the table below:

Table 492. Minimum ATPER value

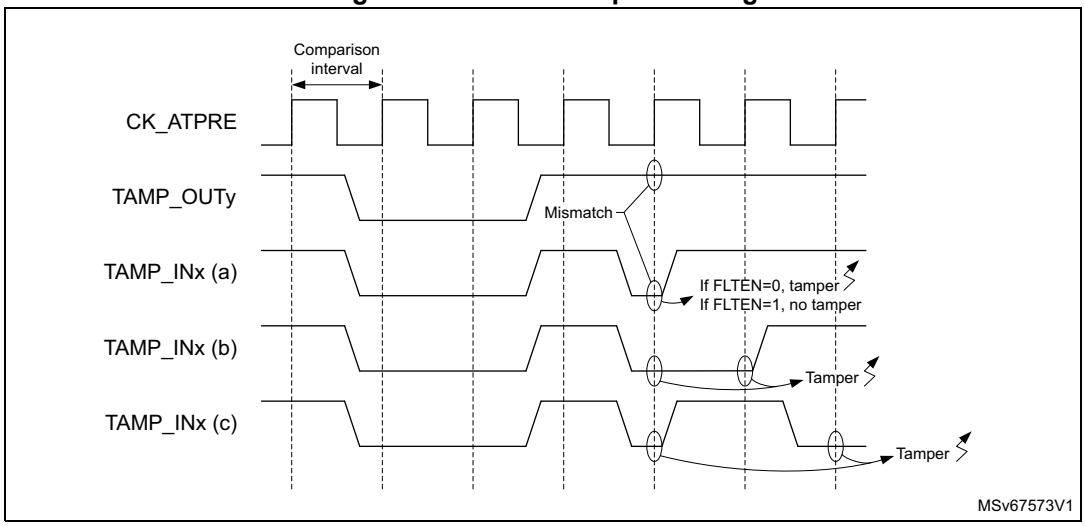
Number of selected outputs	Minimum ATPER
1	0
2	1
3 or 4	2
5 or more	3

The TAMP_INx pin is externally connected to TAMP_OUTy pin. The comparison is made between TAMP_OUTy output value and TAMP_INx received value, every CK_ATPRE cycle. In case a comparison mismatch occurs, the TAMPxF bit is set in the TAMP_SR register.

As an example, TAMP_OUT1 can be used for comparison with TAMP_IN1 and TAMP_IN2 by configuring and enabling both TAMP1 and TAMP2 in active mode, with ATOSHARE = 1, ATOSEL1 = 000 and ATOSEL2 = 000.

The active tamper can be combined with input filtering when FLTEN = 1. In this case, the tamper is detected only when 2 comparisons are false, in 4 consecutive comparison samples.

Figure 620. Active tamper filtering



As illustrated in *Figure 620*, if FLTEN = 0, any mismatch between the TAMP_OUTy output and the associated TAMP_INx input when the latter is sampled generates a tamper. This is the case in all three examples (a), (b) and (c).

If FLTEN = 1, example (a) does not generate a tamper, since only one mismatch is detected in four consecutive comparisons. In example (b), a tamper is generated since two successive mismatches are detected. Example (c) also generates a tamper, since two mismatches occur in four consecutive comparisons, even though the mismatches do not occur on successive samples.

Setting FLTEN = 1 avoids unwanted detection of tampers due to glitches, bounce or transitory states on the TAMP_INx inputs, by ignoring single pulses which are shorter than one period of CK_ATPRE, programmed in the ATCKSEL field of the TAMP_ATCR1 register. The minimum filtered pulse width is listed in *Table 493* for each possible setting of ATCKSEL, assuming f_{RTCCLK} = 32.768 kHz.

Table 493. Active tamper filtered pulse duration

ATCKSEL[3:0]	CK_ATPRE frequency	Minimum filtered pulse width (ms)
0x0	f_{RTCCLK}	0.030
0x1	$f_{RTCCLK}/2$	0.061
0x2	$f_{RTCCLK}/4$	0.122
0x3	$f_{RTCCLK}/8$	0.244
0x4	$f_{RTCCLK}/16$	0.488
0x5	$f_{RTCCLK}/32$	0.977
0x6	$f_{RTCCLK}/64$	1.953
0x7	$f_{RTCCLK}/128$	3.906
0xB	$f_{RTCCLK}/2048$	62.500(1)

1. This setting requires that (PREDIV_A+1) = 128 and (PREDIV_S+1) is a multiple of 16.

Note: Multiple pulses which are shorter than one CK_ATPRE period may nevertheless cause a tamper if they result in two mismatches in four consecutive comparisons.

Caution: Entering RTC initialization mode stops CK_ATPRE and CK_ATPER clocks when ATCKSEL[3] = 1. Therefore, TAMP_OUTy pin stops toggling until INIT mode exit.

Refer to section *Section : Calendar initialization and configuration*.

Refer also to *RTC alarm A subsecond register (RTC_ALRMASSR)*, *RTC alarm B subsecond register (RTC_ALRMBSSR)*, *RTC alarm A binary mode register (RTC_ALRABINR)* and *RTC alarm B binary mode register (RTC_ALRBBINR)* in case RTC binary mode is used in conjunction with ATCKSEL[3] = 1.

Caution: Caution: The active tamper detection is no more functional in case of calendar overflow when ATCKSEL[3] = 1. It is mandatory to enable the internal tamper 5 on calendar overflow to ensure tamper protection.

The pseudo-random generator must be initialized with a seed. This is done by writing consecutively four 32-bit random values in the TAMP_ATSEEDR register. Programming the seed automatically sends it to the PRNG. As long as the new seed is transferred and elaborated by the PRNG, the SEEDF bit is set in the TAMP_ATOR and it is not allowed to switch off the TAMP APB clock. The duration of the elaboration is up to 184 APB clock cycles after the forth seed is written. Consequently, after writing a new seed, the user must wait until SEEDF is cleared before entering low-power modes.

The active tamper outputs are activated only after the first seed is written and the elaboration is completed. Then new seeds can be written and elaborated during active tamper activity.

Active tamper initialization

Here is the software procedure to initialize the active tampers after system reset:

Read INITS in TAMP_ATOR register.

- If INITS = 0x0 (initialization was not done):
  a) Write TAMP_ATCR to configure Active tamper clock, filter and output sharing if any, and active mode.
  b) Write TAMP_CR1 to enable tampers (all the needed tampers must be enabled in the same write access).
  c) Write SEED by writing four times in the TAMP_ATSEEDR.
  d) Wait until SEEDF = 0 in TAMP_ATOR. Backup registers are then protected by active tamper.
- If INITS = 0x1 (initialization already done):
  No initialization. To increase randomness a new SEED should be provided regularly. When a new SEED is provided, wait until SEEDF = 0 before entering a low-power mode which switches off the TAMP APB clock.
- In case the tampers are disabled by software, and re-enabled afterwards, the SEED must be written after enabling tampers:
  a) Write TAMP_CR1 to enable tampers (all the needed tampers must be enabled in the same write access).
  b) Write SEED by writing four times in the TAMP_ATSEEDR.
  c) Wait until SEEDF = 0 in TAMP_ATOR. Backup registers are then protected by active tamper.

47.4 TAMP low-power modes

Table 494. Effect of low-power modes on TAMP

Mode	Description
Sleep	No effect. TAMP interrupts cause the device to exit the Sleep mode.
Stop	No effect on all features, except for level detection with filtering and active tamper modes which remain active only when the clock source is LSE or LSI. Tamper events cause the device to exit the Stop mode.
Standby	No effect on all features, except for level detection with filtering and active tamper modes which remain active only when the clock source is LSE or LSI. Tamper events cause the device to exit the Standby mode.

Table 495. TAMP pins functionality over modes

Pin name	Functional in all low-power modes	Functional in V_{BAT} mode
TAMP_IN[8:1]	Yes(1)	Yes(1)
TAMP_OUT[8:1]	Yes(2)	Yes(3)

1. Only PC13, PI8, PA0, PA1 and PA2 are functional in Standby and V_{BAT} modes.
2. Only PC13, PA1 and PI8 are functional in Standby mode.
3. Only PC13, PA1 and PI8 are functional in V_{BAT} mode.

47.5 TAMP interrupts

The interrupt channel is set in the masked interrupt status register or in the secure masked interrupt status register depending on its security mode configuration (TAMPSEC).

Table 496. Interrupt requests

Interrupt acronym	Interrupt event	Event flag(1)	Enable control bit	Interrupt clear method	Exit from low-power modes
TAMP	Tamper x(2)	TAMPxF	TAMPxIE	Write 1 in CTAMPxF	Yes(3)
	Internal tamper y(2)	ITAMPyF	ITAMPyIE	Write 1 in CITAMPyF	Yes(3)

1. The event flags are in the TAMP_SR register.
2. The number of tampers and internal tampers events depend on products.
3. Refer to *Table 494: Effect of low-power modes on TAMP* for more details about available features in the low-power modes.

47.6 TAMP registers

Refer to *Section 1.2* of the reference manual for a list of abbreviations used in register descriptions. The peripheral registers can be accessed by words (32-bit).

47.6.1 TAMP control register 1 (TAMP_CR1)

This register can be protected against nonsecure access. Refer to *Section 47.3.5: TAMP secure protection modes*.

This register can be protected against non-privileged access. Refer to *Section 47.3.7: TAMP privilege protection modes*.

1: Internal tamper 8 enabled.

Bit 22 **ITAMP7E**: Internal tamper 7 enable
0: Internal tamper 7 disabled.
1: Internal tamper 7 enabled

Bit 21 **ITAMP6E**: Internal tamper 6 enable
0: Internal tamper 6 disabled.
1: Internal tamper 6 enabled.

Bit 20 **ITAMP5E**: Internal tamper 5 enable
0: Internal tamper 5 disabled.
1: Internal tamper 5 enabled.

Bit 19 **ITAMP4E**: Internal tamper 4 enable
0: Internal tamper 4 disabled.
1: Internal tamper 4 enabled.

Bit 18 **ITAMP3E**: Internal tamper 3 enable
0: Internal tamper 3 disabled.
1: Internal tamper 3 enabled.

Bit 17 **ITAMP2E**: Internal tamper 2 enable
0: Internal tamper 2 disabled.
1: Internal tamper 2 enabled.

Bit 16 **ITAMP1E**: Internal tamper 1 enable
0: Internal tamper 1 disabled.
1: Internal tamper 1 enabled.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **TAMP8E**: Tamper detection on TAMP_IN8 enable(1)
0: Tamper detection on TAMP_IN8 is disabled.
1: Tamper detection on TAMP_IN8 is enabled.

Bit 6 **TAMP7E**: Tamper detection on TAMP_IN7 enable(1)
0: Tamper detection on TAMP_IN7 is disabled.
1: Tamper detection on TAMP_IN7 is enabled.

Bit 5 **TAMP6E**: Tamper detection on TAMP_IN6 enable(1)
0: Tamper detection on TAMP_IN6 is disabled.
1: Tamper detection on TAMP_IN6 is enabled.

Bit 4 **TAMP5E**: Tamper detection on TAMP_IN5 enable(1)
0: Tamper detection on TAMP_IN5 is disabled.
1: Tamper detection on TAMP_IN5 is enabled.

Bit 3 **TAMP4E**: Tamper detection on TAMP_IN4 enable(1)
0: Tamper detection on TAMP_IN4 is disabled.
1: Tamper detection on TAMP_IN4 is enabled.

Bit 2 **TAMP3E**: Tamper detection on TAMP_IN3 enable(1)
0: Tamper detection on TAMP_IN3 is disabled.
1: Tamper detection on TAMP_IN3 is enabled.

Bit 1 **TAMP2E**: Tamper detection on TAMP_IN2 enable(1)
0: Tamper detection on TAMP_IN2 is disabled.
1: Tamper detection on TAMP_IN2 is enabled.

Bit 0 **TAMP1E**: Tamper detection on TAMP_IN1 enable(1)
0: Tamper detection on TAMP_IN1 is disabled.
1: Tamper detection on TAMP_IN1 is enabled.

1. Tamper detection mode (selected with TAMP_FLTCR, TAMP_ATCR1, TAMP_ATCR2 registers and TAMPxTRG bits in TAMP_CR2), must be configured before enabling the tamper detection.

47.6.2 TAMP control register 2 (TAMP_CR2)

This register can be protected against nonsecure access. Refer to *Section 47.3.5: TAMP secure protection modes*.

This register can be protected against non-privileged access. Refer to *Section 47.3.7: TAMP privilege protection modes*.

Address offset: 0x04

Bit 31 **TAMP8TRG**: Active level for tamper 8 input (active mode disabled)
0: If TAMPFLT ≠ 00 tamper 8 input staying low triggers a tamper detection event.
If TAMPFLT = 00 tamper 8 input rising edge triggers a tamper detection event.
1: If TAMPFLT ≠ 00 tamper 8 input staying high triggers a tamper detection event.
If TAMPFLT = 00 tamper 8 input falling edge triggers a tamper detection event.

Bit 30 **TAMP7TRG**: Active level for tamper 7 input (active mode disabled)
0: If TAMPFLT ≠ 00 tamper 7 input staying low triggers a tamper detection event.
If TAMPFLT = 00 tamper 7 input rising edge triggers a tamper detection event.
1: If TAMPFLT ≠ 00 tamper 7 input staying high triggers a tamper detection event.
If TAMPFLT = 00 tamper 7 input falling edge triggers a tamper detection event.

Bit 29 **TAMP6TRG**: Active level for tamper 6 input (active mode disabled)
0: If TAMPFLT ≠ 00 tamper 6 input staying low triggers a tamper detection event.
If TAMPFLT = 00 tamper 6 input rising edge triggers a tamper detection event.
1: If TAMPFLT ≠ 00 tamper 6 input staying high triggers a tamper detection event.
If TAMPFLT = 00 tamper 6 input falling edge triggers a tamper detection event.

Bit 28 **TAMP5TRG**: Active level for tamper 5 input (active mode disabled)
0: If TAMPFLT ≠ 00 tamper 5 input staying low triggers a tamper detection event.
If TAMPFLT = 00 tamper 5 input rising edge triggers a tamper detection event.
1: If TAMPFLT ≠ 00 tamper 5 input staying high triggers a tamper detection event.
If TAMPFLT = 00 tamper 5 input falling edge triggers a tamper detection event.

Bit 27 **TAMP4TRG**: Active level for tamper 4 input (active mode disabled)
0: If TAMPFLT ≠ 00 tamper 4 input staying low triggers a tamper detection event.
If TAMPFLT = 00 tamper 4 input rising edge triggers a tamper detection event.
1: If TAMPFLT ≠ 00 tamper 4 input staying high triggers a tamper detection event.
If TAMPFLT = 00 tamper 4 input falling edge triggers a tamper detection event.

Bit 26 **TAMP3TRG**: Active level for tamper 3 input
0: If TAMPFLT ≠ 00 tamper 3 input staying low triggers a tamper detection event.
If TAMPFLT = 00 tamper 3 input rising edge triggers a tamper detection event.
1: If TAMPFLT ≠ 00 tamper 3 input staying high triggers a tamper detection event.
If TAMPFLT = 00 tamper 3 input falling edge triggers a tamper detection event.

Bit 25 **TAMP2TRG**: Active level for tamper 2 input
0: If TAMPFLT ≠ 00 tamper 2 input staying low triggers a tamper detection event.
If TAMPFLT = 00 tamper 2 input rising edge triggers a tamper detection event.
1: If TAMPFLT ≠ 00 tamper 2 input staying high triggers a tamper detection event.
If TAMPFLT = 00 tamper 2 input falling edge triggers a tamper detection event.

Bit 24 **TAMP1TRG**: Active level for tamper 1 input
0: If TAMPFLT ≠ 00 tamper 1 input staying low triggers a tamper detection event.
If TAMPFLT = 00 tamper 1 input rising edge triggers a tamper detection event.
1: If TAMPFLT ≠ 00 tamper 1 input staying high triggers a tamper detection event.
If TAMPFLT = 00 tamper 1 input falling edge triggers a tamper detection event.

Bit 23 **BKERASE**: Backup registers and device secrets(1) erase
Writing ‘1’ to this bit reset the backup registers and device secrets(1). Writing 0 has no effect. This bit is always read as 0.

Bit 22 **BKBLOCK**: Backup registers and device secrets(1) access blocked
0: backup registers and device secrets(1) can be accessed if no tamper flag is set
1: backup registers and device secrets(1) cannot be accessed

Bits 21:19 Reserved, must be kept at reset value.

Bit 18 **TAMP3MSK**: Tamper 3 mask

0: Tamper 3 event generates a trigger event and TAMP3F must be cleared by software to allow next tamper event detection.

1: Tamper 3 event generates a trigger event. TAMP3F is masked and internally cleared by hardware. The backup registers and device secrets(1) are not erased.

The tamper 3 interrupt must not be enabled when TAMP3MSK is set.

Bit 17 **TAMP2MSK**: Tamper 2 mask

0: Tamper 2 event generates a trigger event and TAMP2F must be cleared by software to allow next tamper event detection.

1: Tamper 2 event generates a trigger event. TAMP2F is masked and internally cleared by hardware. The backup registers and device secrets(1) are not erased.

The tamper 2 interrupt must not be enabled when TAMP2MSK is set.

Bit 16 **TAMP1MSK**: Tamper 1 mask

0: Tamper 1 event generates a trigger event and TAMP1F must be cleared by software to allow next tamper event detection.

1: Tamper 1 event generates a trigger event. TAMP1F is masked and internally cleared by hardware. The backup registers and device secrets(1) are not erased.

The tamper 1 interrupt must not be enabled when TAMP1MSK is set.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **TAMP8POM**: Tamper 8 potential mode

0: Tamper 8 event detection is in confirmed mode(1).

1: Tamper 8 event detection is in potential mode(2).

Bit 6 **TAMP7POM**: Tamper 7 potential mode

0: Tamper 7 event detection is in confirmed mode(1).

1: Tamper 7 event detection is in potential mode(2).

Bit 5 **TAMP6POM**: Tamper 6 potential mode

0: Tamper 6 event detection is in confirmed mode(1).

1: Tamper 6 event detection is in potential mode(2).

Bit 4 **TAMP5POM**: Tamper 5 potential mode

0: Tamper 5 event detection is in confirmed mode(1).

1: Tamper 5 event detection is in potential mode(2).

Bit 3 **TAMP4POM**: Tamper 4 potential mode

0: Tamper 4 event detection is in confirmed mode(1).

1: Tamper 4 event detection is in potential mode(2).

Bit 2 **TAMP3POM**: Tamper 3 potential mode

0: Tamper 3 event detection is in confirmed mode(1).

1: Tamper 3 event detection is in potential mode(2).

Bit 1 **TAMP2POM**: Tamper 2 potential mode

0: Tamper 2 event detection is in confirmed mode(1).

1: Tamper 2 event detection is in potential mode(2).

Bit 0 **TAMP1POM**: Tamper 1 potential mode

0: Tamper 1 event detection is in confirmed mode(1).

1: Tamper 1 event detection is in potential mode(2).

1. The effects of tamper detection in confirmed mode is described with tamp_confirmed and tamp_confirmed_rpcfgx signals in *Table 489: TAMP interconnection*.
2. The effects of tamper detection in potential mode is described with tamp_potential and tamp_potential_rpcfgx signals in *Table 489: TAMP interconnection*.

47.6.3 TAMP control register 3 (TAMP_CR3)

This register can be protected against nonsecure access. Refer to *Section 47.3.5: TAMP secure protection modes*.

This register can be protected against non-privileged access. Refer to *Section 47.3.7: TAMP privilege protection modes*.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TAMP PUDIS	TAMPPRCH [1:0]		TAMPFLT [1:0]		TAMPFREQ [2:0]		
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **TAMPPUDIS**: TAMP_INx pull-up disable

This bit determines if each of the TAMPx pins are precharged before each sample.

0: Precharge TAMP_INx pins before sampling (enable internal pull-up)

1: Disable precharge of TAMP_INx pins.

Bits 6:5 **TAMPPRCH[1:0]**: TAMP_INx precharge duration

These bit determines the duration of time during which the pull-up/is activated before each sample. TAMPPRCH is valid for each of the TAMP_INx inputs.

0x0: 1 RTCCLK cycle

0x1: 2 RTCCLK cycles

0x2: 4 RTCCLK cycles

0x3: 8 RTCCLK cycles

Bits 4:3 **TAMPFLT[1:0]**: TAMP_INx filter count

These bits determines the number of consecutive samples at the specified level (TAMP*TRG) needed to activate a tamper event. TAMPFLT is valid for each of the TAMP_INx inputs.

0x0: Tamper event is activated on edge of TAMP_INx input transitions to the active level (no internal pull-up on TAMP_INx input).

0x1: Tamper event is activated after 2 consecutive samples at the active level.

0x2: Tamper event is activated after 4 consecutive samples at the active level.

0x3: Tamper event is activated after 8 consecutive samples at the active level.

Bits 2:0 **TAMPFREQ[2:0]**: Tamper sampling frequency

Determines the frequency at which each of the TAMP_INx inputs are sampled.

0x0: RTCCLK / 32768 (1 Hz when RTCCLK = 32768 Hz)

0x1: RTCCLK / 16384 (2 Hz when RTCCLK = 32768 Hz)

0x2: RTCCLK / 8192 (4 Hz when RTCCLK = 32768 Hz)

0x3: RTCCLK / 4096 (8 Hz when RTCCLK = 32768 Hz)

0x4: RTCCLK / 2048 (16 Hz when RTCCLK = 32768 Hz)

0x5: RTCCLK / 1024 (32 Hz when RTCCLK = 32768 Hz)

0x6: RTCCLK / 512 (64 Hz when RTCCLK = 32768 Hz)

0x7: RTCCLK / 256 (128 Hz when RTCCLK = 32768 Hz)

Note: This register concerns only the tamper inputs in passive mode.

47.6.5 TAMP active tamper control register 1 (TAMP_ATCR1)

This register can be protected against nonsecure access. Refer to *Section 47.3.5: TAMP secure protection modes*.

This register can be protected against non-privileged access. Refer to *Section 47.3.7: TAMP privilege protection modes*.

Address offset: 0x10

Backup domain reset value: 0x0007 0000

System reset: not affected

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FLTEN	ATO SHARE	Res.	Res.	Res.	ATPER[2:0]			Res.	Res.	Res.	Res.	ATCKSEL[3:0]			
rw	rw				rw	rw	rw					rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ATOSEL4[1:0]		ATOSEL3[1:0]		ATOSEL2[1:0]		ATOSEL1[1:0]		TAMP8 AM	TAMP7 AM	TAMP6 AM	TAMP5 AM	TAMP4 AM	TAMP3 AM	TAMP2 AM	TAMP1 AM
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **FLTEN**: Active tamper filter enable

0: Active tamper filtering disable

1: Active tamper filtering enable: a tamper event is detected when 2 comparison mismatches occur out of 4 consecutive samples.

Bit 30 **ATOSHARE**: Active tamper output sharing

0: Each active tamper input TAMP_INi is compared with its dedicated output TAMP_OUTi

1: Each active tamper input TAMP_INi is compared with TAMPOUTSELi defined by ATOSELi bits.

Bits 29:27 Reserved, must be kept at reset value.

Bits 26:24 **ATPER[2:0]**: Active tamper output change period

The tamper output is changed every CK_ATPER = (2^{ATPER} x CK_ATPRE) cycles. Refer to *Table 492: Minimum ATPER value*.

Bits 23:20 Reserved, must be kept at reset value.

Bits 19:16 **ATCKSEL[3:0]**: Active tamper RTC asynchronous prescaler clock selection

These bits selects the RTC asynchronous prescaler stage output. The selected clock is CK_ATPRE.

0000: RTCCLK is selected
0001: RTCCLK/2 is selected
0010: RTCCLK/4 is selected
0011: RTCCLK/8 is selected
0100: RTCCLK/16 is selected
0101: RTCCLK/32 is selected
0110: RTCCLK/64 is selected
0111: RTCCLK/128 is selected
1011: RTCCLK/2048 is selected when (PREDIV_A+1) = 128 and (PREDIV_S+1) is a multiple of 16.
Others: Reserved

Note: These bits can be written only when all active tampers are disabled. The write protection remains for up to 1.5 CK_ATPRE cycles after all the active tampers are disable.

Bits 15:14 **ATOSEL4[1:0]**: Active tamper shared output 4 selection
00: TAMPOUTSEL4 = TAMP_OUT1
01: TAMPOUTSEL4 = TAMP_OUT2
10: TAMPOUTSEL4 = TAMP_OUT3
11: TAMPOUTSEL4 = TAMP_OUT4
If the TAMP_OUTx output is not available in the package pinout, the ouput selection value is reserved and must not be used.

Bits 13:12 **ATOSEL3[1:0]**: Active tamper shared output 3 selection
00: TAMPOUTSEL3 = TAMP_OUT1
01: TAMPOUTSEL3 = TAMP_OUT2
10: TAMPOUTSEL3 = TAMP_OUT3
11: TAMPOUTSEL3 = TAMP_OUT4
If the TAMP_OUTx output is not available in the package pinout, the ouput selection value is reserved and must not be used.

Bits 11:10 **ATOSEL2[1:0]**: Active tamper shared output 2 selection
00: TAMPOUTSEL2 = TAMP_OUT1
01: TAMPOUTSEL2 = TAMP_OUT2
10: TAMPOUTSEL2 = TAMP_OUT3
11: TAMPOUTSEL2 = TAMP_OUT4
If the TAMP_OUTx output is not available in the package pinout, the ouput selection value is reserved and must not be used.

Bits 9:8 **ATOSEL1[1:0]**: Active tamper shared output 1 selection
00: TAMPOUTSEL1 = TAMP_OUT1
01: TAMPOUTSEL1 = TAMP_OUT2
10: TAMPOUTSEL1 = TAMP_OUT3
11: TAMPOUTSEL1 = TAMP_OUT4
If the TAMP_OUTx output is not available in the package pinout, the ouput selection value is reserved and must not be used.

Bit 7 **TAMP8AM**: Tamper 8 active mode
0: Tamper 8 detection mode is passive.
1: Tamper 8 detection mode is active.

Bit 6 **TAMP7AM**: Tamper 7 active mode
0: Tamper 7 detection mode is passive.
1: Tamper 7 detection mode is active.

Bit 5 **TAMP6AM**: Tamper 6 active mode
0: Tamper 6 detection mode is passive.
1: Tamper 6 detection mode is active.

Bit 4 **TAMP5AM**: Tamper 5 active mode
0: Tamper 5 detection mode is passive.
1: Tamper 5 detection mode is active.

Bit 3 **TAMP4AM**: Tamper 4 active mode
0: Tamper 4 detection mode is passive.
1: Tamper 4 detection mode is active.

Bit 2 **TAMP3AM**: Tamper 3 active mode
0: Tamper 3 detection mode is passive.
1: Tamper 3 detection mode is active.

Bit 1 **TAMP2AM**: Tamper 2 active mode
0: Tamper 2 detection mode is passive.
1: Tamper 2 detection mode is active.

Bit 0 **TAMP1AM**: Tamper 1 active mode
0: Tamper 1 detection mode is passive.
1: Tamper 1 detection mode is active.

Note: Changing the active tampers configuration in this register is not allowed when a TAMPxAM bit is set, unless the corresponding TAMPxE bits are all cleared in the TAMP_CR1 register.

All tampers configured in active mode must be enabled at the same time (by setting all related TAMPxE in the same TAMP_CR1 write).

All tampers configured in active mode must be disabled at the same time (by clearing all related TAMPxE in the same TAMP_CR1 write).

A minimum duration of 1 CK_ATPRE period must be waited for after disabling the active tampers and before re-enabling them.

47.6.6 TAMP active tamper seed register (TAMP_ATSEEDR)

This register can be protected against nonsecure access. Refer to *Section 47.3.5: TAMP secure protection modes*.

This register can be protected against non-privileged access. Refer to *Section 47.3.7: TAMP privilege protection modes*.

Address offset: 0x14

Backup domain reset value: 0x0000 0000

System reset: not affected

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SEED[31:16]

SEED[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **SEED[31:0]**: Pseudo-random generator seed value
This register must be written four times with 32-bit values to provide the 128-bit seed to the PRNG. Writing to this register automatically sends the seed value to the PRNG.

47.6.7 TAMP active tamper output register (TAMP_ATOR)

This register can be protected against nonsecure access. Refer to *Section 47.3.5: TAMP secure protection modes*.

This register can be protected against non-privileged access. Refer to *Section 47.3.7: TAMP privilege protection modes*.

Address offset: 0x18

Backup domain reset value: 0x0000 0000

System reset: not affected, except for SEEDF which is reset to 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
INITS	SEEDF	Res.	Res.	Res.	Res.	Res.	Res.	PRNG[7:0]							
r	r							r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **INITS**: Active tamper initialization status

This flag is set by hardware when the PRNG has absorbed the first 128-bit seed, meaning that the enabled active tampers are functional. This flag is cleared when the active tampers are disabled.

Bit 14 **SEEDF**: Seed running flag

This flag is set by hardware when a new seed is written in the TAMP_ATSEEDR. It is cleared by hardware when the PRNG has absorbed this new seed, and by system reset. The TAMP APB clock must not be switched off as long as SEEDF is set.

Bits 13:8 Reserved, must be kept at reset value.

Bits 7:0 **PRNG[7:0]**: Pseudo-random generator value

This field provides the values of the PRNG output. Because of potential inconsistencies due to synchronization delays, PRNG must be read at least twice. The read value is correct if it is equal to previous read value.

This field can only be read when the APB is in secure mode.

47.6.8 TAMP active tamper control register 2 (TAMP_ATCR2)

This register can be protected against nonsecure access. Refer to *Section 47.3.5: TAMP secure protection modes*.

This register can be protected against non-privileged access. Refer to *Section 47.3.7: TAMP privilege protection modes*.

Address offset: 0x1C

Bits 31:29 **ATOSEL8[2:0]**: Active tamper shared output 8 selection
000: TAMPOUTSEL8 = TAMP_OUT1
001: TAMPOUTSEL8 = TAMP_OUT2
010: TAMPOUTSEL8 = TAMP_OUT3
011: TAMPOUTSEL8 = TAMP_OUT4
100: TAMPOUTSEL8 = TAMP_OUT5
101: TAMPOUTSEL8 = TAMP_OUT6
110: TAMPOUTSEL8 = TAMP_OUT7
111: TAMPOUTSEL8 = TAMP_OUT8
If the TAMP_OUTx output is not available in the package pinout, the ouput selection value is reserved and must not be used.

Bits 28:26 **ATOSEL7[2:0]**: Active tamper shared output 7 selection
000: TAMPOUTSEL7 = TAMP_OUT1
001: TAMPOUTSEL7 = TAMP_OUT2
010: TAMPOUTSEL7 = TAMP_OUT3
011: TAMPOUTSEL7 = TAMP_OUT4
100: TAMPOUTSEL7 = TAMP_OUT5
101: TAMPOUTSEL7 = TAMP_OUT6
110: TAMPOUTSEL7 = TAMP_OUT7
111: TAMPOUTSEL7 = TAMP_OUT8
If the TAMP_OUTx output is not available in the package pinout, the ouput selection value is reserved and must not be used.

Bits 25:23 **ATOSEL6[2:0]**: Active tamper shared output 6 selection
000: TAMPOUTSEL6 = TAMP_OUT1
001: TAMPOUTSEL6 = TAMP_OUT2
010: TAMPOUTSEL6 = TAMP_OUT3
011: TAMPOUTSEL6 = TAMP_OUT4
100: TAMPOUTSEL6 = TAMP_OUT5
101: TAMPOUTSEL6 = TAMP_OUT6
110: TAMPOUTSEL6 = TAMP_OUT7
111: TAMPOUTSEL6 = TAMP_OUT8
If the TAMP_OUTx output is not available in the package pinout, the ouput selection value is reserved and must not be used.

Bits 22:20 **ATOSEL5[2:0]**: Active tamper shared output 5 selection
000: TAMPOUTSEL5 = TAMP_OUT1
001: TAMPOUTSEL5 = TAMP_OUT2
010: TAMPOUTSEL5 = TAMP_OUT3
011: TAMPOUTSEL5 = TAMP_OUT4
100: TAMPOUTSEL5 = TAMP_OUT5
101: TAMPOUTSEL5 = TAMP_OUT6
110: TAMPOUTSEL5 = TAMP_OUT7
111: TAMPOUTSEL5 = TAMP_OUT8
If the TAMP_OUTx output is not available in the package pinout, the ouput selection value is reserved and must not be used.

Bits 19:17 **ATOSEL4[2:0]**: Active tamper shared output 4 selection
000: TAMPOUTSEL4 = TAMP_OUT1
001: TAMPOUTSEL4 = TAMP_OUT2
010: TAMPOUTSEL4 = TAMP_OUT3
011: TAMPOUTSEL4 = TAMP_OUT4
100: TAMPOUTSEL4 = TAMP_OUT5
101: TAMPOUTSEL4 = TAMP_OUT6
110: TAMPOUTSEL4 = TAMP_OUT7
111: TAMPOUTSEL4 = TAMP_OUT8
If the TAMP_OUTx output is not available in the package pinout, the ouput selection value is reserved and must not be used.
Bits 18:17 are the mirror of ATOSEL2[1:0] in the TAMP_ATCR1, and so can also be read or written through TAMP_ATCR1.

Bits 16:14 **ATOSEL3[2:0]**: Active tamper shared output 3 selection
000: TAMPOUTSEL3 = TAMP_OUT1
001: TAMPOUTSEL3 = TAMP_OUT2
010: TAMPOUTSEL3 = TAMP_OUT3
011: TAMPOUTSEL3 = TAMP_OUT4
100: TAMPOUTSEL3 = TAMP_OUT5
101: TAMPOUTSEL3 = TAMP_OUT6
110: TAMPOUTSEL3 = TAMP_OUT7
111: TAMPOUTSEL3 = TAMP_OUT8
If the TAMP_OUTx output is not available in the package pinout, the ouput selection value is reserved and must not be used.
Bits 15:14 are the mirror of ATOSEL3[1:0] in the TAMP_ATCR1, and so can also be read or written through TAMP_ATCR1.

Bits 13:11 **ATOSEL2[2:0]**: Active tamper shared output 2 selection
000: TAMPOUTSEL2 = TAMP_OUT1
001: TAMPOUTSEL2 = TAMP_OUT2
010: TAMPOUTSEL2 = TAMP_OUT3
011: TAMPOUTSEL2 = TAMP_OUT4
100: TAMPOUTSEL2 = TAMP_OUT5
101: TAMPOUTSEL2 = TAMP_OUT6
110: TAMPOUTSEL2 = TAMP_OUT7
111: TAMPOUTSEL2 = TAMP_OUT8
If the TAMP_OUTx output is not available in the package pinout, the ouput selection value is reserved and must not be used.
Bits 12:11 are the mirror of ATOSEL2[1:0] in the TAMP_ATCR1, and so can also be read or written through TAMP_ATCR1.

Bits 10:8 **ATOSEL1[2:0]**: Active tamper shared output 1 selection
000: TAMPOUTSEL1 = TAMP_OUT1
001: TAMPOUTSEL1 = TAMP_OUT2
010: TAMPOUTSEL1 = TAMP_OUT3
011: TAMPOUTSEL1 = TAMP_OUT4
100: TAMPOUTSEL1 = TAMP_OUT5
101: TAMPOUTSEL1 = TAMP_OUT6
110: TAMPOUTSEL1 = TAMP_OUT7
111: TAMPOUTSEL1 = TAMP_OUT8
If the TAMP_OUTx output is not available in the package pinout, the ouput selection value is reserved and must not be used.
Bits 9:8 are the mirror of ATOSEL1[1:0] in the TAMP_ATCR1, and so can also be read or written through TAMP_ATCR1.

Bits 7:0 Reserved, must be kept at reset value.

Note: Changing the active tampers configuration in this register is not allowed when a TAMPxAM bit is set, unless the corresponding TAMPxE bits are all cleared in the TAMP_CR1 register.

All tampers configured in active mode must be enabled at the same time (by setting all related TAMPxE in the same TAMP_CR1 write).

All tampers configured in active mode must be disabled at the same time (by clearing all related TAMPxE in the same TAMP_CR1 write).

A minimum duration of 1 CK_ATPRE period must be waited for after disabling the active tampers and before re-enabling them.

47.6.9 TAMP secure configuration register (TAMP_SECCFGR)

If TZEN = 1, this register can be written only when the APB access is secure. If TZEN = 0, BKPRWSEC[7:0], BKPWSEC[7:0] and BHKLOCK can be written with nonsecure APB access, and TAMPSEC, CNT1SEC cannot be written.

This register can be globally write-protected, or each bit of this register can be individually write-protected against non-privileged access depending on the TAMP_PRIVCFGR configuration (refer to *Section 47.3.7: TAMP privilege protection modes*).

Address offset: 0x20

Backup domain reset value: 0x0000 0000

System reset: not affected

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TAMPSEC	BHKLOCK	Res.	Res.	Res.	Res.	Res.	Res.	BKPWSEC[7:0]							
rw	rs							rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CNT1SEC	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BKPRWSEC[7:0]							
rw								rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **TAMPSEC**: Tamper protection (excluding monotonic counters and backup registers)

0: Tamper configuration and interrupt can be written when the APB access is secure or nonsecure.

1: Tamper configuration and interrupt can be written only when the APB access is secure.

Note: Refer to Section 47.3.5: TAMP secure protection modes for details on the read protection.

Bit 30 **BHKLOCK**: Boot hardware key lock

This bit can be read and can only be written to 1 by software. It is cleared by hardware together with the backup registers following a tamper detection event or when the readout protection (RDP) is disabled.

0: The Backup registers from TAMP_BKP0R to TAMP_BKP7R can be accessed according to the Protection zone they belong to.

1: The backup registers from TAMP_BKP0R to TAMP_BKP7R cannot be accessed neither in read nor in write (they are read as 0 and write ignore).

Bits 29:24 Reserved, must be kept at reset value.

Bits 23:16 **BKPWSEC[7:0]**: Backup registers write protection offset

BKPWSEC value must be from 0 to 32.

Protection zone 2 is defined for backup registers from TAMP_BKPyR (y = BKPRWSEC) to TAMP_BKPzR (z = BKPWSEC-1, with BKPWSEC > BKPRWSEC):

- if TZEN=1, these backup registers can be written only with secure access.
- They can be read with secure or nonsecure access.

If BKPWSEC = 0 or if BKPWSEC ≤ BKPRWSEC: there is no protection zone 2.

Protection zone 3 is defined for backup registers from TAMP_BKPtR (t = BKPWSEC if BKPWSEC ≥ BKPRWSEC, else t = BKPRWSEC).

- They can be read or written with secure or nonsecure access.

If BKPWSEC = 32: there is no protection zone 3.

Refer to *Figure 619: Backup registers protection zones*.

Note: If TZEN=0: the protection zone 2 can be read and written with nonsecure access.

Note: If BKPWPRIV is set, BKPRWSEC[7:0] can be written only in privileged mode.

Bit 15 **CNT1SEC**: Monotonic counter 1 secure protection
0: Monotonic counter 1 (TAMP_COUNT1R) can be read and written when the APB access is secure or nonsecure.
1: Monotonic counter 1 (TAMP_COUNT1R) can be read and written only when the APB access is secure.

Bits 14:8 Reserved, must be kept at reset value.

Bits 7:0 **BKPRWSEC[7:0]**: Backup registers read/write protection offset
BKPRWSEC value must be from 0 to 32.

Protection zone 1 is defined for backup registers from TAMP_BKP0R to TAMP_BKPxR (x = BKPRWSEC-1, with BKPRWSEC ≥ 1).
– if TZEN=1, these backup registers can be read and written only with secure access.
If BKPRWSEC = 0: there is no protection zone 1.

Refer to *Figure 619: Backup registers protection zones*.

Note: If TZEN=0: the protection zone 1 can be read and written with nonsecure access.
Note: If BKPRWPRIV is set, BKPRWSEC[7:0] can be written only in privileged mode.

47.6.10 TAMP privilege configuration register (TAMP_PRIVCFGR)

This register can be written only when the APB access is privileged.

When TZEN = 1, this register can be write-protected, or each bit of this register can be individually write-protected against nonsecure access depending on the TAMP_SECCFGR configuration (refer to *Section 47.3.5: TAMP secure protection modes*).

Address offset: 0x24

Backup domain reset value: 0x0000 0000

System reset: not affected

rw															

Bit 31 **TAMPPRIV**: Tamper privilege protection (excluding backup registers)
0: Tamper configuration and interrupt can be written with privileged or unprivileged access.
1: Tamper configuration and interrupt can be written only with privileged access.
Note: Refer to Section 47.3.7: TAMP privilege protection modes for details on the read protection.

Bit 30 **BKPWPRIV**: Backup registers zone 2 privilege protection
0: Backup registers zone 2 can be written with privileged or unprivileged access.
1: Backup registers zone 2 can be written only with privileged access.

Bit 29 **BKPRWPRIV**: Backup registers zone 1 privilege protection
0: Backup registers zone 1 can be read and written with privileged or unprivileged access.
1: Backup registers zone 1 can be read and written only with privileged access

Bits 28:16 Reserved, must be kept at reset value.

Bit 15 **CNT1PRIV**: Monotonic counter 1 privilege protection
0: Monotonic counter 1 (TAMP_COUNT1R) can be read and written when the APB access is privileged or non-privileged.
1: Monotonic counter 1 (TAMP_COUNT1R) can be read and written only when the APB access is privileged.

Bits 14:0 Reserved, must be kept at reset value.

47.6.11 TAMP interrupt enable register (TAMP_IER)

This register can be protected against nonsecure access. Refer to *Section 47.3.5: TAMP secure protection modes*.

This register can be protected against non-privileged access. Refer to *Section 47.3.7: TAMP privilege protection modes*.

Bit 31 Reserved, must be kept at reset value.

Bit 30 **ITAMP15F**: Internal tamper 15 flag
This flag is set by hardware when a tamper detection event is detected on the internal tamper 15.

Bit 29 Reserved, must be kept at reset value.

Bit 28 **ITAMP13F**: Internal tamper 13 flag
This flag is set by hardware when a tamper detection event is detected on the internal tamper 13.

Bit 27 **ITAMP12F**: Internal tamper 12 flag
This flag is set by hardware when a tamper detection event is detected on the internal tamper 12.

Bit 26 **ITAMP11F**: Internal tamper 11 flag
This flag is set by hardware when a tamper detection event is detected on the internal tamper 11.

Bit 25 Reserved, must be kept at reset value.

Bit 24 **ITAMP9F**: Internal tamper 9 flag
This flag is set by hardware when a tamper detection event is detected on the internal tamper 9.

Bit 23 **ITAMP8F**: Internal tamper 8 flag
This flag is set by hardware when a tamper detection event is detected on the internal tamper 8.

Bit 22 **ITAMP7F**: Internal tamper 7 flag
This flag is set by hardware when a tamper detection event is detected on the internal tamper 7.

Bit 21 **ITAMP6F**: Internal tamper 6 flag
This flag is set by hardware when a tamper detection event is detected on the internal tamper 6.

Bit 20 **ITAMP5F**: Internal tamper 5 flag
This flag is set by hardware when a tamper detection event is detected on the internal tamper 5.

Bit 19 **ITAMP4F**: Internal tamper 4 flag
This flag is set by hardware when a tamper detection event is detected on the internal tamper 4.

Bit 18 **ITAMP3F**: Internal tamper 3 flag
This flag is set by hardware when a tamper detection event is detected on the internal tamper 3.

Bit 17 **ITAMP2F**: Internal tamper 2 flag
This flag is set by hardware when a tamper detection event is detected on the internal tamper 2.

Bit 16 **ITAMP1F**: Internal tamper 1 flag
This flag is set by hardware when a tamper detection event is detected on the internal tamper 1.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **TAMP8F**: TAMP8 detection flag
This flag is set by hardware when a tamper detection event is detected on the TAMP8 input

Bit 6 **TAMP7F**: TAMP7 detection flag
This flag is set by hardware when a tamper detection event is detected on the TAMP7 input.

Bit 5 **TAMP6F**: TAMP6 detection flag
This flag is set by hardware when a tamper detection event is detected on the TAMP6 input.

Bit 4 **TAMP5F**: TAMP5 detection flag
This flag is set by hardware when a tamper detection event is detected on the TAMP5 input.

Bit 3 **TAMP4F**: TAMP4 detection flag
This flag is set by hardware when a tamper detection event is detected on the TAMP4 input.

Bit 2 **TAMP3F**: TAMP3 detection flag
This flag is set by hardware when a tamper detection event is detected on the TAMP3 input.

Bit 1 **TAMP2F**: TAMP2 detection flag
This flag is set by hardware when a tamper detection event is detected on the TAMP2 input.

Bit 0 **TAMP1F**: TAMP1 detection flag
This flag is set by hardware when a tamper detection event is detected on the TAMP1 input.

47.6.13 TAMP nonsecure masked interrupt status register (TAMP_MISR)

This register can be protected against non-privileged access. Refer to *Section 47.3.7: TAMP privilege protection modes*.

Address offset: 0x34

Backup domain reset value: 0x0000 0000

Bit 31 Reserved, must be kept at reset value.

Bit 30 **ITAMP15MF**: internal tamper 15 nonsecure interrupt masked flag
This flag is set by hardware when the internal tamper 15 nonsecure interrupt is raised.

Bit 29 Reserved, must be kept at reset value.

Bit 28 **ITAMP13MF**: internal tamper 13 nonsecure interrupt masked flag
This flag is set by hardware when the internal tamper 13 nonsecure interrupt is raised.

Bit 27 **ITAMP12MF**: internal tamper 12 nonsecure interrupt masked flag
This flag is set by hardware when the internal tamper 12 nonsecure interrupt is raised.

Bit 26 **ITAMP11MF**: internal tamper 11 nonsecure interrupt masked flag
This flag is set by hardware when the internal tamper 11 nonsecure interrupt is raised.

Bit 25 Reserved, must be kept at reset value.

Bit 24 **ITAMP9MF**: internal tamper 9 nonsecure interrupt masked flag
This flag is set by hardware when the internal tamper 9 nonsecure interrupt is raised.

Bit 23 **ITAMP8MF**: Internal tamper 8 nonsecure interrupt masked flag
This flag is set by hardware when the internal tamper 8 nonsecure interrupt is raised.

Bit 22 **ITAMP7MF**: Internal tamper 7 tamper nonsecure interrupt masked flag
This flag is set by hardware when the internal tamper 7 nonsecure interrupt is raised.

Bit 21 **ITAMP6MF**: Internal tamper 6 nonsecure interrupt masked flag
This flag is set by hardware when the internal tamper 6 nonsecure interrupt is raised.

Bit 20 **ITAMP5MF**: Internal tamper 5 nonsecure interrupt masked flag
This flag is set by hardware when the internal tamper 5 nonsecure interrupt is raised.

Bit 19 **ITAMP4MF**: Internal tamper 4 nonsecure interrupt masked flag
This flag is set by hardware when the internal tamper 4 nonsecure interrupt is raised.

Bit 18 **ITAMP3MF**: Internal tamper 3 nonsecure interrupt masked flag
This flag is set by hardware when the internal tamper 3 nonsecure interrupt is raised.

Bit 17 **ITAMP2MF**: Internal tamper 2 nonsecure interrupt masked flag
This flag is set by hardware when the internal tamper 2 nonsecure interrupt is raised.

Bit 16 **ITAMP1MF**:Internal tamper 1 nonsecure interrupt masked flag
This flag is set by hardware when the internal tamper 1 nonsecure interrupt is raised.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **TAMP8MF**: TAMP8 nonsecure interrupt masked flag
This flag is set by hardware when the tamper 8 nonsecure interrupt is raised.

Bit 6 **TAMP7MF**: TAMP7 nonsecure interrupt masked flag
This flag is set by hardware when the tamper 7 nonsecure interrupt is raised.

Bit 5 **TAMP6MF**: TAMP6 nonsecure interrupt masked flag
This flag is set by hardware when the tamper 6 nonsecure interrupt is raised.

Bit 4 **TAMP5MF**: TAMP5 nonsecure interrupt masked flag
This flag is set by hardware when the tamper 5 nonsecure interrupt is raised.

Bit 3 **TAMP4MF**: TAMP4 nonsecure interrupt masked flag
This flag is set by hardware when the tamper 4 nonsecure interrupt is raised.

Bit 2 **TAMP3MF**: TAMP3 nonsecure interrupt masked flag
This flag is set by hardware when the tamper 3 nonsecure interrupt is raised.

Bit 1 **TAMP2MF**: TAMP2 nonsecure interrupt masked flag
This flag is set by hardware when the tamper 2 nonsecure interrupt is raised.

Bit 0 **TAMP1MF**: TAMP1 nonsecure interrupt masked flag
This flag is set by hardware when the tamper 1 nonsecure interrupt is raised.

47.6.14 TAMP secure masked interrupt status register (TAMP_SMISR)

This register can be protected against nonsecure access. Refer to *Section 47.3.5: TAMP secure protection modes*.

This register can be protected against non-privileged access. Refer to *Section 47.3.7: TAMP privilege protection modes*.

Bit 31 Reserved, must be kept at reset value.

Bit 30 **ITAMP15MF**: internal tamper 15 secure interrupt masked flag
This flag is set by hardware when the internal tamper 15 secure interrupt is raised.

Bit 29 Reserved, must be kept at reset value.

Bit 28 **ITAMP13MF**: internal tamper 13 secure interrupt masked flag
This flag is set by hardware when the internal tamper 13 secure interrupt is raised.

Bit 27 **ITAMP12MF**: internal tamper 12 secure interrupt masked flag
This flag is set by hardware when the internal tamper 12 secure interrupt is raised.

Bit 26 **ITAMP11MF**: internal tamper 11 secure interrupt masked flag
This flag is set by hardware when the internal tamper 11 secure interrupt is raised.

Bit 25 Reserved, must be kept at reset value.

Bit 24 **ITAMP9MF**: internal tamper 9 secure interrupt masked flag
This flag is set by hardware when the internal tamper 9 secure interrupt is raised.

Bit 23 **ITAMP8MF**: Internal tamper 8 secure interrupt masked flag
This flag is set by hardware when the internal tamper 8 secure interrupt is raised.

Bit 22 **ITAMP7MF**: Internal tamper 7 secure interrupt masked flag
This flag is set by hardware when the internal tamper 7 secure interrupt is raised.

Bit 21 **ITAMP6MF**: Internal tamper 6 secure interrupt masked flag
This flag is set by hardware when the internal tamper 6 secure interrupt is raised.

Bit 20 **ITAMP5MF**: Internal tamper 5 secure interrupt masked flag
This flag is set by hardware when the internal tamper 5 secure interrupt is raised.

Bit 19 **ITAMP4MF**: Internal tamper 4 secure interrupt masked flag
This flag is set by hardware when the internal tamper 4 secure interrupt is raised.

Bit 18 **ITAMP3MF**: Internal tamper 3 secure interrupt masked flag
This flag is set by hardware when the internal tamper 3 secure interrupt is raised.

Bit 17 **ITAMP2MF**: Internal tamper 2 secure interrupt masked flag
This flag is set by hardware when the internal tamper 2 secure interrupt is raised.

Bit 16 **ITAMP1MF**: Internal tamper 1 secure interrupt masked flag
This flag is set by hardware when the internal tamper 1 secure interrupt is raised.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **TAMP8MF**: TAMP8 secure interrupt masked flag
This flag is set by hardware when the tamper 8 secure interrupt is raised.

Bit 6 **TAMP7MF**: TAMP7 secure interrupt masked flag
This flag is set by hardware when the tamper 7 secure interrupt is raised.

Bit 5 **TAMP6MF**: TAMP6 secure interrupt masked flag
This flag is set by hardware when the tamper 6 secure interrupt is raised.

Bit 4 **TAMP5MF**: TAMP5 secure interrupt masked flag
This flag is set by hardware when the tamper 5 secure interrupt is raised.

Bit 3 **TAMP4MF**: TAMP4 secure interrupt masked flag
This flag is set by hardware when the tamper 4 secure interrupt is raised.

Bit 2 **TAMP3MF**: TAMP3 secure interrupt masked flag
This flag is set by hardware when the tamper 3 secure interrupt is raised.

Bit 1 **TAMP2MF**: TAMP2 secure interrupt masked flag
This flag is set by hardware when the tamper 2 secure interrupt is raised.

Bit 0 **TAMP1MF**: TAMP1 secure interrupt masked flag
This flag is set by hardware when the tamper 1 secure interrupt is raised.

47.6.15 TAMP status clear register (TAMP_SCR)

This register can be protected against nonsecure access. Refer to *Section 47.3.5: TAMP secure protection modes*.

This register can be protected against non-privileged access. Refer to *Section 47.3.7: TAMP privilege protection modes*.

Address offset: 0x3C

Bit 31 Reserved, must be kept at reset value.

Bit 30 **CITAMP15F**: Clear ITAMP15 detection flag
Writing 1 in this bit clears the ITAMP15F bit in the TAMP_SR register.

Bit 29 Reserved, must be kept at reset value.

Bit 28 **CITAMP13F**: Clear ITAMP13 detection flag
Writing 1 in this bit clears the ITAMP13F bit in the TAMP_SR register.

Bit 27 **CITAMP12F**: Clear ITAMP12 detection flag
Writing 1 in this bit clears the ITAMP12F bit in the TAMP_SR register.

Bit 26 **CITAMP11F**: Clear ITAMP11 detection flag
Writing 1 in this bit clears the ITAMP11F bit in the TAMP_SR register.

Bit 25 Reserved, must be kept at reset value.

Bit 24 **CITAMP9F**: Clear ITAMP9 detection flag
Writing 1 in this bit clears the ITAMP9F bit in the TAMP_SR register.

Bit 23 **CITAMP8F**: Clear ITAMP8 detection flag
Writing 1 in this bit clears the ITAMP8F bit in the TAMP_SR register.

Bit 22 **CITAMP7F**: Clear ITAMP7 detection flag
Writing 1 in this bit clears the ITAMP7F bit in the TAMP_SR register.

Bit 21 **CITAMP6F**: Clear ITAMP6 detection flag
Writing 1 in this bit clears the ITAMP6F bit in the TAMP_SR register.

Bit 20 **CITAMP5F**: Clear ITAMP5 detection flag
Writing 1 in this bit clears the ITAMP5F bit in the TAMP_SR register.

Bit 19 **CITAMP4F**: Clear ITAMP4 detection flag
Writing 1 in this bit clears the ITAMP4F bit in the TAMP_SR register.

Bit 18 **CITAMP3F**: Clear ITAMP3 detection flag
Writing 1 in this bit clears the ITAMP3F bit in the TAMP_SR register.

Bit 17 **CITAMP2F**: Clear ITAMP2 detection flag
Writing 1 in this bit clears the ITAMP2F bit in the TAMP_SR register.

Bit 16 **CITAMP1F**: Clear ITAMP1 detection flag
Writing 1 in this bit clears the ITAMP1F bit in the TAMP_SR register.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **CTAMP8F**: Clear TAMP8 detection flag
Writing 1 in this bit clears the TAMP8F bit in the TAMP_SR register.

Bit 6 **CTAMP7F**: Clear TAMP7 detection flag
Writing 1 in this bit clears the TAMP7F bit in the TAMP_SR register.

Bit 5 **CTAMP6F**: Clear TAMP6 detection flag
Writing 1 in this bit clears the TAMP6F bit in the TAMP_SR register.

Bit 4 **CTAMP5F**: Clear TAMP5 detection flag
Writing 1 in this bit clears the TAMP5F bit in the TAMP_SR register.

Bit 3 **CTAMP4F**: Clear TAMP4 detection flag
Writing 1 in this bit clears the TAMP4F bit in the TAMP_SR register.

Bit 2 **CTAMP3F**: Clear TAMP3 detection flag
Writing 1 in this bit clears the TAMP3F bit in the TAMP_SR register.

Bit 1 **CTAMP2F**: Clear TAMP2 detection flag
Writing 1 in this bit clears the TAMP2F bit in the TAMP_SR register.

Bit 0 **CTAMP1F**: Clear TAMP1 detection flag
Writing 1 in this bit clears the TAMP1F bit in the TAMP_SR register.

47.6.16 TAMP monotonic counter 1 register (TAMP_COUNT1R)

This register can be protected against nonsecure access. Refer to *Section 47.3.5: TAMP secure protection modes*.

This register can be protected against non-privileged access. Refer to *Section 47.3.7: TAMP privilege protection modes*.

Address offset: 0x040

48 Inter-integrated circuit (I2C) interface

48.1 Introduction

The I^2C (inter-integrated circuit) bus interface handles communications between the microcontroller and the serial I^2C bus. It provides multimaster capability, and controls all I^2C bus-specific sequencing, protocol, arbitration and timing. It supports Standard-mode (Sm), Fast-mode (Fm) and Fast-mode Plus (Fm+).

The I^2C bus interface is also SMBus (system management bus) and PMBus® (power management bus) compatible.

DMA can be used to reduce CPU overload.

48.2 I2C main features

- I^2C bus specification rev03 compatibility:
  - Slave and master modes
  - Multimaster capability
  - Standard-mode (up to 100 kHz)
  - Fast-mode (up to 400 kHz)
  - Fast-mode Plus (up to 1 MHz)
  - 7-bit and 10-bit addressing mode
  - Multiple 7-bit slave addresses (2 addresses, 1 with configurable mask)
  - All 7-bit addresses acknowledge mode
  - General call
  - Programmable setup and hold times
  - Easy to use event management
  - Optional clock stretching
  - Software reset
- 1-byte buffer with DMA capability
- Programmable analog and digital noise filters

The following features are also available, depending upon product implementation (see *Section 48.3*):

- SMBus specification rev 3.0 compatibility:
  - Hardware PEC (packet error checking) generation and verification with ACK control
  - Command and data acknowledge control
  - Address resolution protocol (ARP) support
  - Host and device support
  - SMBus alert
  - Timeouts and idle condition detection
- PMBus rev 1.3 standard compatibility
- Independent clock: a choice of independent clock sources allowing the I2C communication speed to be independent from the i2c_pclk reprogramming

- Wake-up from Stop mode on address match

48.3 I2C implementation

Table 498. STM32H563/H573 and STM32H562 I2C implementation

I2C features(1)	I2C1	I2C2	I2C3	I2C4
7-bit addressing mode	X	X	X	X
10-bit addressing mode	X	X	X	X
Standard-mode (up to 100 kbit/s)	X	X	X	X
Fast-mode (up to 400 kbit/s)	X	X	X	X
Fast-mode Plus with 20 mA output drive I/Os (up to 1 Mbit/s)	X	X	X	X
Independent clock	X	X	X	X
Wake-up from stop mode only (no autonomous mode)	X	X	X	X
SMBus/PMBus	X	X	X	X

1. X = supported.

48.4 I2C functional description

In addition to receiving and transmitting data, this interface converts them from serial to parallel format and vice versa. The interrupts are enabled or disabled by software. The interface is connected to the I^2C bus by a data pin (SDA) and by a clock pin (SCL). It can be connected with a standard (up to 100 kHz), Fast-mode (up to 400 kHz) or Fast-mode Plus (up to 1 MHz) I^2C bus.

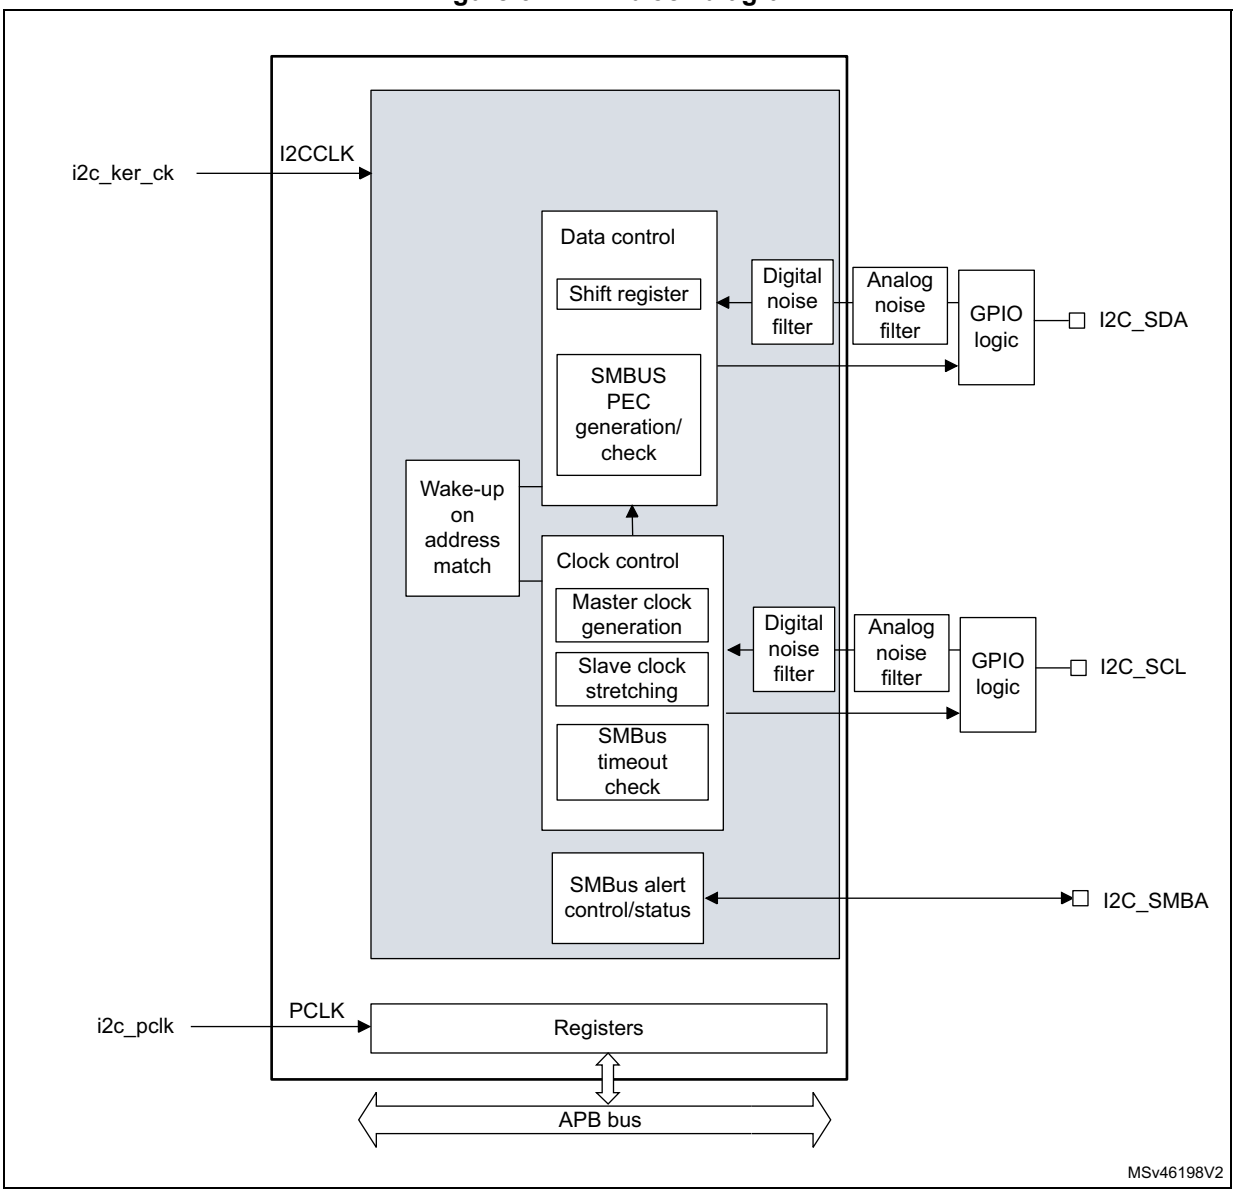
This interface can also be connected to an SMBus with data (SDA) and clock (SCL) pins.

If the SMBus feature is supported, the optional SMBus Alert pin (SMBA) is also available.

48.4.1 I2C block diagram

The block diagram of the I2C interface is shown in *Figure 621*.

Figure 621. I2C block diagram



The I2C is clocked by an independent clock source, which allows the I2C to operate independently from the i2c_pclk frequency.

48.4.2 I2C pins and internal signals

Table 499. I2C input/output pins

Pin name	Signal type	Description
I2C_SDA	Bidirectional	I2C data
I2C_SCL	Bidirectional	I2C clock
I2C_SMBA	Bidirectional	SMBus alert

Table 500. I2C internal input/output signals

Internal signal name	Signal type	Description
i2c_ker_ck	Input	I2C kernel clock, also named I2CCLK in this document
i2c_pclk	Input	I2C APB clock
i2c_it	Output	I2C interrupts, refer to *Table 513* for the list of interrupt sources
i2c_rx_dma	Output	I2C receive data DMA request (I2C_RX)
i2c_tx_dma	Output	I2C transmit data DMA request (I2C_TX)

48.4.3 I2C clock requirements

The I2C kernel is clocked by i2c_ker_ck.

The i2c_ker_ck period t_{I2CCLK} must respect the following conditions:

- $t_{I2CCLK} < (t_{LOW} - t_{filters}) / 4$
- $t_{I2CCLK} < t_{HIGH}$

with:

t_{LOW}: SCL low time and t_{HIGH}: SCL high time

$t_{filters}$: when enabled, sum of the delays brought by the analog and by the digital filters.

The digital filter delay is DNF x t_{I2CCLK}.

The i2c_pclk clock period t_{PCLK} must respect the condition:

- $t_{PCLK} < 4 / 3\ t_{SCL}$ (t_{SCL}: SCL period)

Caution: When the I2C kernel is clocked by i2c_pclk, this clock must respect the conditions for t_{I2CCLK}.

48.4.4 Mode selection

The interface can operate in one of the four following modes:

- Slave transmitter
- Slave receiver
- Master transmitter
- Master receiver

By default, it operates in slave mode. The interface automatically switches from slave to master when it generates a START condition, and from master to slave if an arbitration loss or a STOP generation occurs, allowing multimaster capability.

Communication flow

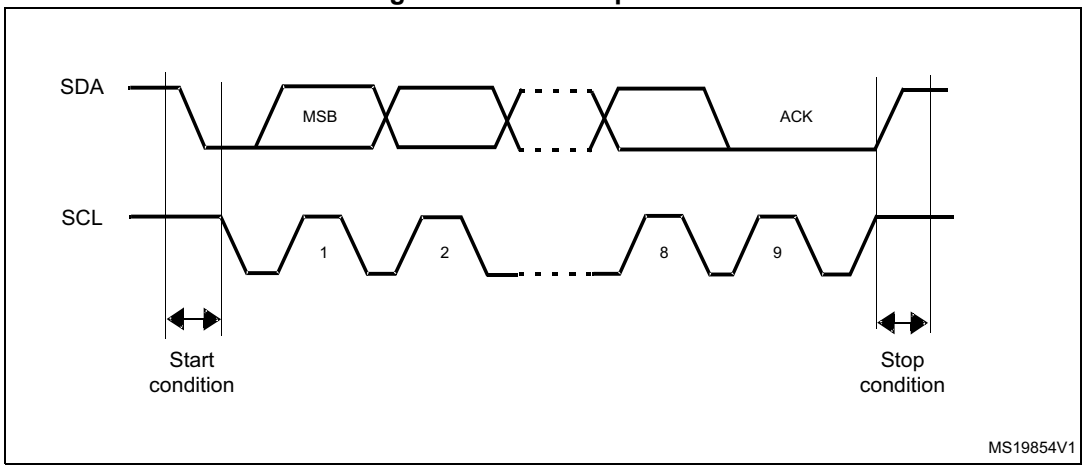
In master mode, the I2C interface initiates a data transfer and generates the clock signal. A serial data transfer always begins with a START condition, and ends with a STOP condition. Both START and STOP conditions are generated in master mode by software.

In slave mode, the interface is capable of recognizing its own addresses (7- or 10-bit), and the general call address. The general call address detection can be enabled or disabled by software. The reserved SMBus addresses can also be enabled by software.

Data and addresses are transferred as 8-bit bytes, MSB first. The first byte(s) following the START condition contains the address (one in 7-bit mode, two in 10-bit mode). The address is always transmitted in master mode.

A ninth clock pulse follows the eight clock cycles of a byte transfer, during which the receiver must send an acknowledge bit to the transmitter (see *Figure 622*).

Figure 622. I²C bus protocol



Acknowledge can be enabled or disabled by software. The I2C interface addresses can be selected by software.

48.4.5 I2C initialization

Enabling and disabling the peripheral

The I2C peripheral clock must be configured and enabled in the clock controller, then the I2C can be enabled by setting the PE bit in the I2C_CR1 register.

When the I2C is disabled (PE = 0), the I²C performs a software reset. Refer to *Section 48.4.6* for more details.

Noise filters

Before enabling the I2C peripheral by setting the PE bit in I2C_CR1 register, the user must configure the noise filters, if needed. By default, an analog noise filter is present on the SDA and SCL inputs. This filter is compliant with the I²C specification, which requires the suppression of spikes with pulse width up to 50 ns in Fast-mode and Fast-mode Plus. The

user can disable this analog filter by setting the ANFOFF bit, and/or select a digital filter by configuring the DNF[3:0] bit in the I2C_CR1 register.

When the digital filter is enabled, the level of the SCL or the SDA line is internally changed only if it remains stable for more than DNF x i2c_ker_ck periods. This allows spikes with a programmable length of 1 to 15 i2c_ker_ck periods to be suppressed.

Table 501. Comparison of analog vs. digital filters

-	Analog filter	Digital filter
Pulse width of suppressed spikes	≥ 50 ns	Programmable length, from one to fifteen I2C peripheral clocks
Benefits	Available in Stop mode	– Programmable length: extra filtering capability versus standard requirements – Stable length
Drawbacks	Variation vs. temperature, voltage, process	Wake-up from Stop mode on address match is not available when digital filter is enabled

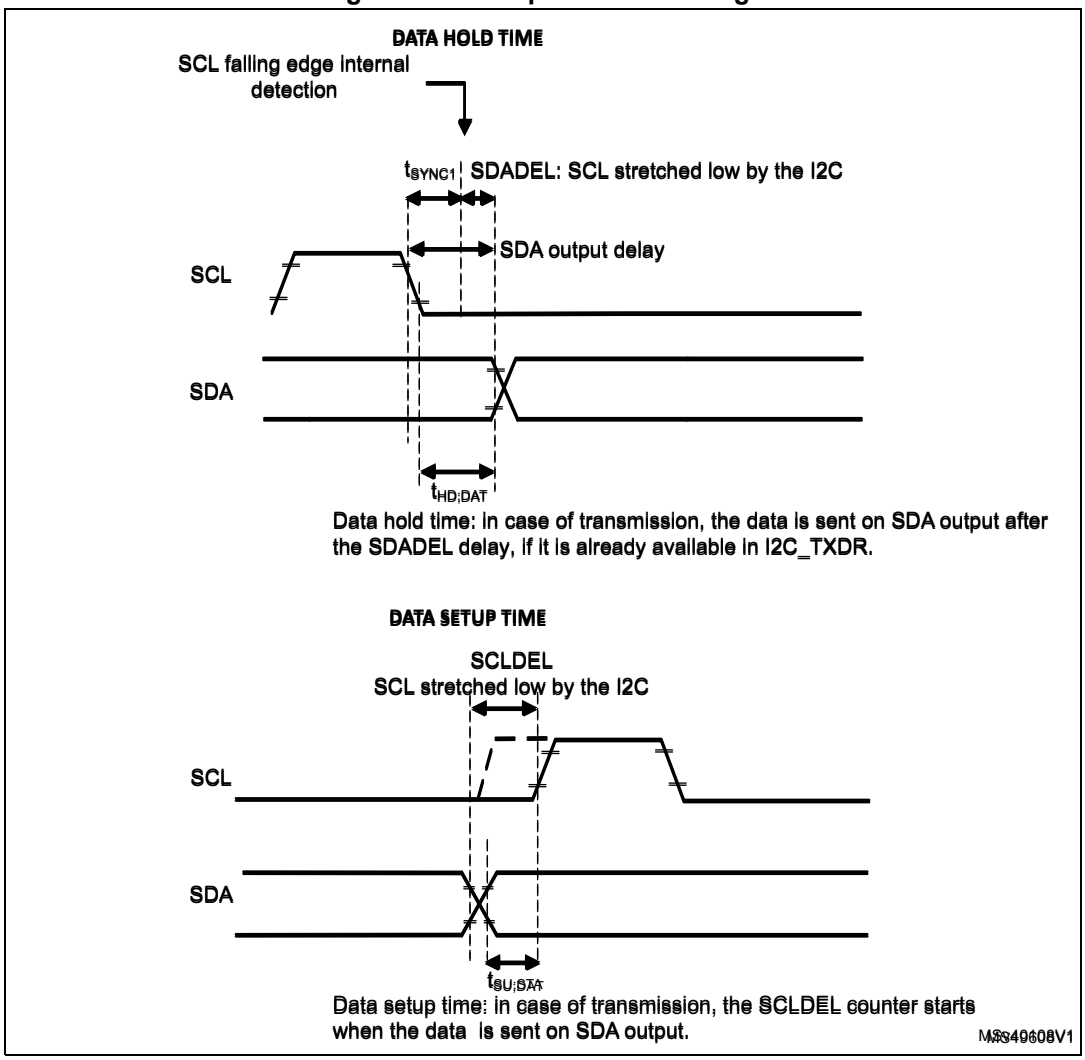
Caution: The filter configuration cannot be changed when the I2C is enabled.

I2C timings

The timings must be configured to guarantee correct data hold and setup times, in master and slave modes. This is done by programming the PRESC[3:0], SCLDEL[3:0] and SDADEL[3:0] bits in the I2C_TIMINGR register.

The STM32CubeMX tool calculates and provides the I2C_TIMINGR content in the I2C configuration window.

Figure 623. Setup and hold timings



When the SCL falling edge is internally detected, a delay (t_{SDADEL}, impacting the hold time $t_{HD;DAT}$) is inserted before sending SDA output: t_{SDADEL} = SDADEL x t_{PRESC} + t_{I2CCLK}, where t_{PRESC} = (PRESC + 1) x t_{I2CCLK}.

The total SDA output delay is:

t_{SYNC1} + {[SDADEL x (PRESC + 1) + 1] x t_{I2CCLK}}

t_{SYNC1} duration depends upon:

- SCL falling slope
- When enabled, input delay brought by the analog filter: $t_{AF(min)} < t_{AF} < t_{AF(max)}$
- When enabled, input delay brought by the digital filter: t_{DNF} = DNF x t_{I2CCLK}
- Delay due to SCL synchronization to i2c_ker_ck clock (two to three i2c_ker_ck periods)

To bridge the undefined region of the SCL falling edge, the user must program SDADEL in such a way that:

{$t_{f\ (max)}$ + $t_{HD;DAT\ (min)}$ - $t_{AF(min)}$ - [(DNF + 3) x t_{I2CCLK}]} / {(PRESC + 1) x t_{I2CCLK}} ≤ SDADEL

$SDADEL \leq \{t_{HD;DAT\ (max)} - t_{AF(max)} - [(DNF + 4) \times t_{I2CCLK}]\} / \{(PRESC + 1) \times t_{I2CCLK}\}$

Note: $t_{AF(min)}$ / $t_{AF(max)}$ *are part of the equation only when the analog filter is enabled. Refer to the device datasheet for* t_{AF} *values.*

The maximum $t_{HD;DAT}$ can be 3.45 µs for Standard-mode, 0.9 µs for Fast-mode, 0.45 µs for Fast-mode Plus. It must be lower than the maximum of $t_{VD;DAT}$ by a transition time. This maximum must only be met if the device does not stretch the LOW period (t_{LOW}) of the SCL signal. If the clock stretches the SCL, the data must be valid by the set-up time before it releases the clock.

The SDA rising edge is usually the worst case. In this case the previous equation becomes:

$SDADEL \leq \{t_{VD;DAT\ (max)} - t_{r\ (max)} - t_{AF\ (max)} - [(DNF + 4) \times t_{I2CCLK}]\} / \{(PRESC + 1) \times t_{I2CCLK}\}$.

Note: *This condition can be violated when NOSTRETCH = 0, because the device stretches SCL low to guarantee the set-up time, according to the SCLDEL value.*

Refer to *Table 502* for t_f, t_r, $t_{HD;DAT}$, and $t_{VD;DAT}$ standard values.

- After t_{SDADEL}, or after sending SDA output when the slave had to stretch the clock because the data was not yet written in I2C_TXDR register, SCL line is kept at low level during the setup time. This setup time is $t_{SCLDEL} = (SCLDEL + 1) \times t_{PRESC}$, where $t_{PRESC} = (PRESC + 1) \times t_{I2CCLK}$. t_{SCLDEL} impacts the setup time $t_{SU;DAT}$.

To bridge the undefined region of the SDA transition (rising edge usually worst case), the user must program SCLDEL in such a way that:

$\{[t_{r\ (max)} + t_{SU;DAT\ (min)}] / [(PRESC + 1)] \times t_{I2CCLK}]\} - 1 \leq SCLDEL$

Refer to *Table 502* for t_r and $t_{SU;DAT}$ standard values.

The SDA and SCL transition time values to use are the ones in the application. Using the maximum values from the standard increases the constraints for the SDADEL and SCLDEL calculation, but ensures the feature, whatever the application.

Note: *At every clock pulse, after SCL falling edge detection, the I2C master or slave stretches SCL low during at least [(SDADEL + SCLDEL + 1) x (PRESC + 1) + 1] x* t_{I2CCLK}*, in both transmission and reception modes. In transmission mode, if the data is not yet written in I2C_TXDR when SDADEL counter is finished, the I2C keeps on stretching SCL low until the next data is written. Then new data MSB is sent on SDA output, and SCLDEL counter starts, continuing stretching SCL low to guarantee the data setup time.*

If NOSTRETCH = 1 in slave mode, the SCL is not stretched. Consequently, the SDADEL must be programmed so that it guarantees a sufficient setup time.

Table 502. I²C-SMBus specification data setup and hold times

Symbol	Parameter	Standard-mode (Sm)		Fast-mode (Fm)		Fast-mode Plus (Fm+)		SMBus		Unit
		Min.	Max	Min.	Max	Min.	Max	Min.	Max	
$t_{HD;DAT}$	Data hold time	0	-	0	-	0	-	0.3	-	µs
$t_{VD;DAT}$	Data valid time	-	3.45	-	0.9	-	0.45	-	-	

Table 502. I²C-SMBus specification data setup and hold times (continued)

Symbol	Parameter	Standard-mode (Sm)		Fast-mode (Fm)		Fast-mode Plus (Fm+)		SMBus		Unit
		Min.	Max	Min.	Max	Min.	Max	Min.	Max	
$t_{SU;DAT}$	Data setup time	250	-	100	-	50	-	250	-	ns
t_r	Rise time of both SDA and SCL signals	-	1000	-	300	-	120	-	1000	
t_f	Fall time of both SDA and SCL signals	-	300	-	300	-	120	-	300	

Additionally, in master mode, the SCL clock high and low levels must be configured by programming the PRESC[3:0], SCLH[7:0] and SCLL[7:0] bit fields in the I2C_TIMINGR register.

- When the SCL falling edge is internally detected, a delay is inserted before releasing the SCL output.
  This delay is $t_{SCLL} = (SCLL + 1) \times t_{PRESC}$ where $t_{PRESC} = (PRESC + 1) \times t_{I2CCLK}$.
  t_{SCLL} impacts the SCL low time t_{LOW}.
- When the SCL rising edge is internally detected, a delay is inserted before forcing the SCL output to low level. This delay is $t_{SCLH} = (SCLH + 1) \times t_{PRESC}$, where $t_{PRESC} = (PRESC+ 1) \times t_{I2CCLK}$. t_{SCLH} impacts the SCL high time t_{HIGH}.

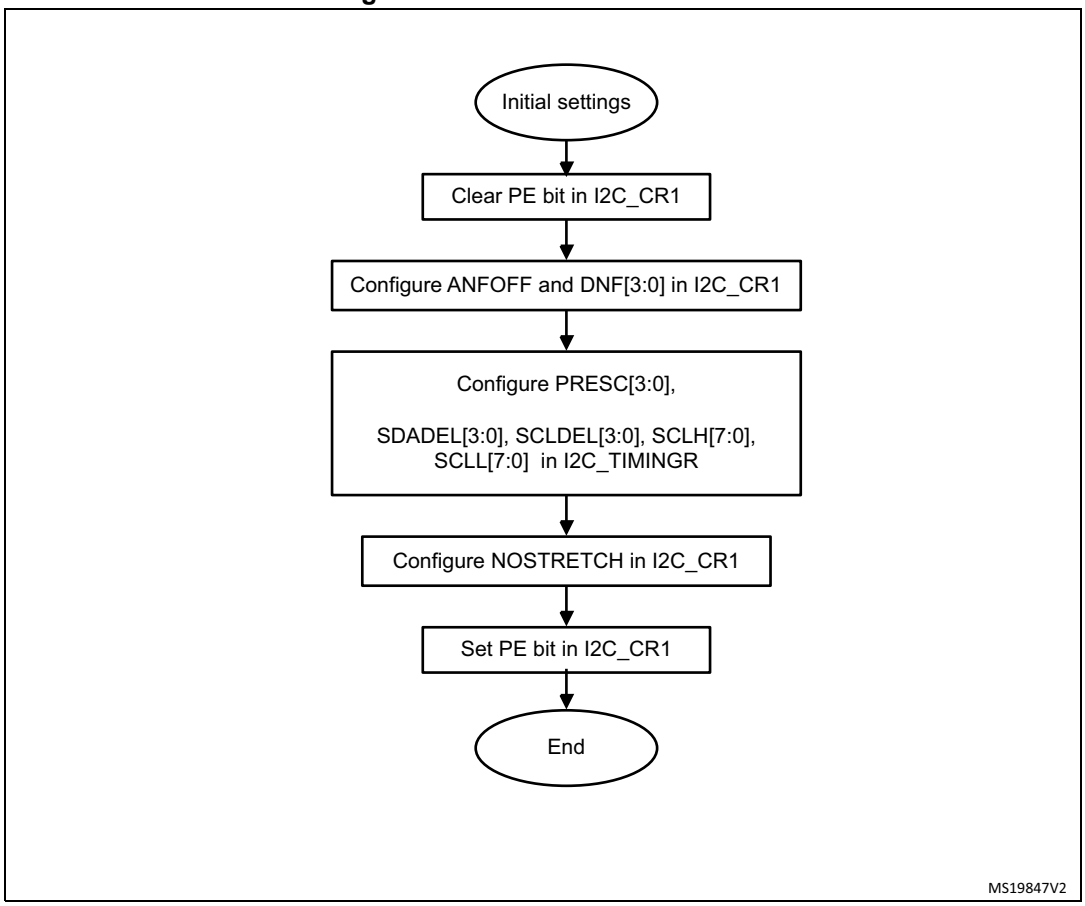
Refer to *I2C master initialization* for more details.

Caution: Changing the timing configuration is not allowed when the I2C is enabled.

The I2C slave NOSTRETCH mode must also be configured before enabling the peripheral. Refer to *I2C slave initialization* for more details.

Caution: Changing the NOSTRETCH configuration is not allowed when the I2C is enabled.

Figure 624. I2C initialization flow



48.4.6 Software reset

A software reset can be performed by clearing the PE bit in the I2C_CR1 register. In that case I2C lines SCL and SDA are released. Internal states machines are reset and communication control bits, as well as status bits, come back to their reset value. The configuration registers are not impacted.

Impacted register bits:

1. I2C_CR2 register: START, STOP, NACK
2. I2C_ISR register: BUSY, TXE, TXIS, RXNE, ADDR, NACKF, TCR, TC, STOPF, BERR, ARLO, OVR

In addition when the SMBus feature is supported:

1. I2C_CR2 register: PECBYTE
2. I2C_ISR register: PECERR, TIMEOUT, ALERT

PE must be kept low during at least three APB clock cycles to perform the software reset. This is ensured by the following software sequence:

1. Write PE = 0
2. Check PE = 0
3. Write PE = 1

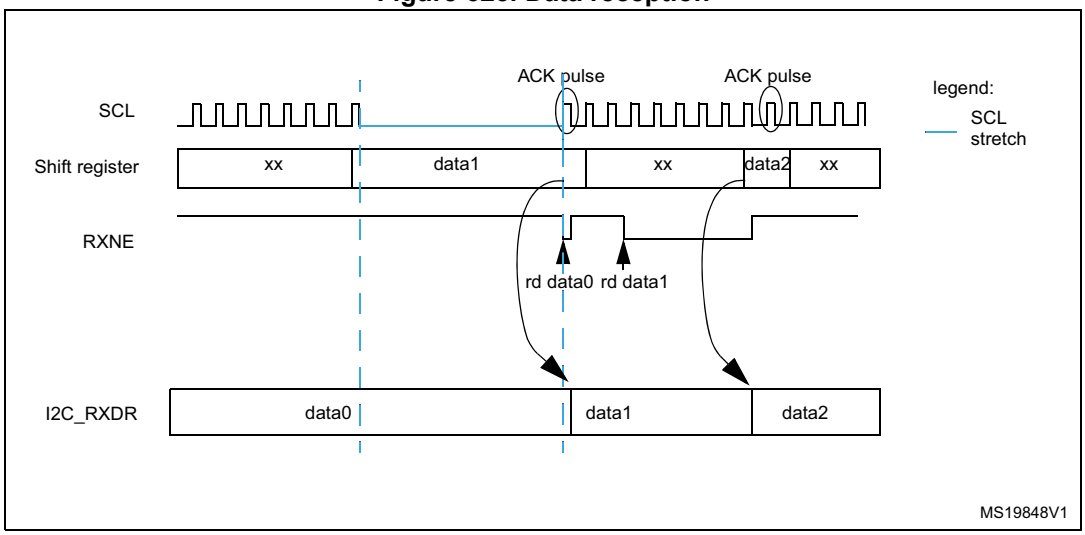
48.4.7 Data transfer

The data transfer is managed through transmit and receive data registers and a shift register.

Reception

The SDA input fills the shift register. After the eighth SCL pulse (when the complete data byte is received), the shift register is copied into I2C_RXDR register if it is empty (RXNE = 0). If RXNE = 1, meaning that the previous received data byte has not yet been read, the SCL line is stretched low until I2C_RXDR is read. The stretch is inserted between the eighth and ninth SCL pulse (before the acknowledge pulse).

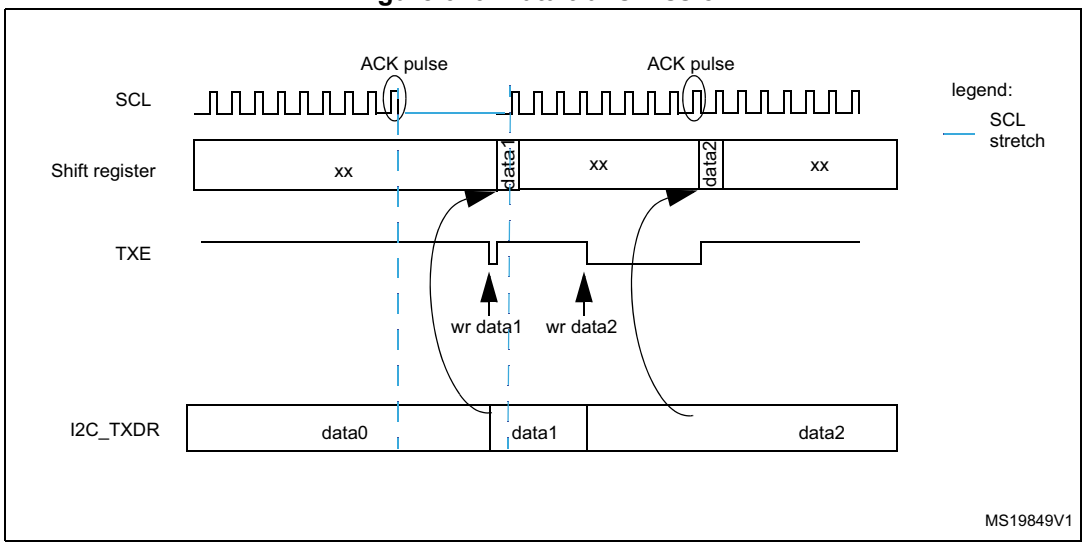
Figure 625. Data reception



Transmission

If the I2C_TXDR register is not empty (TXE = 0), its content is copied into the shift register after the ninth SCL pulse (the acknowledge pulse). Then the shift register content is shifted out on SDA line. If TXE = 1, meaning that no data is written yet in I2C_TXDR, SCL line is stretched low until I2C_TXDR is written. The stretch is done after the ninth SCL pulse.

Figure 626. Data transmission



Hardware transfer management

The I2C features an embedded byte counter to manage byte transfer and to close the communication in various modes, such as:

- NACK, STOP and ReSTART generation in master mode
- ACK control in slave receiver mode
- PEC generation/checking when SMBus feature is supported

The byte counter is always used in master mode. By default, it is disabled in slave mode.It can be enabled by software by setting the SBC (slave byte control) bit in the I2C_CR1 register.

The number of bytes to be transferred is programmed in the NBYTES[7:0] bit field in the I2C_CR2 register. If the number of bytes to be transferred (NBYTES) is greater than 255, or if a receiver wants to control the acknowledge value of a received data byte, the reload mode must be selected by setting the RELOAD bit in the I2C_CR2 register. In this mode, the TCR flag is set when the number of bytes programmed in NBYTES is transferred, and an interrupt is generated if TCIE is set. SCL is stretched as long as TCR flag is set. TCR is cleared by software when NBYTES is written to a non-zero value.

When the NBYTES counter is reloaded with the last number of bytes, RELOAD bit must be cleared.

When RELOAD = 0 in master mode, the counter can be used in two modes:

- **Automatic end mode** (AUTOEND = 1 in the I2C_CR2 register). In this mode, the master automatically sends a STOP condition once the number of bytes programmed in the NBYTES[7:0] bit field is transferred.
- **Software end mode** (AUTOEND = 0 in the I2C_CR2 register). In this mode, software action is expected once the number of bytes programmed in the NBYTES[7:0] bit field is transferred; the TC flag is set and an interrupt is generated if the TCIE bit is set. The SCL signal is stretched as long as the TC flag is set. The TC flag is cleared by software when the START or STOP bit is set in the I2C_CR2 register. This mode must be used when the master wants to send a RESTART condition.

Caution: The AUTOEND bit has no effect when the RELOAD bit is set.

Table 503. I2C configuration

Function	SBC bit	RELOAD bit	AUTOEND bit
Master Tx/Rx NBYTES + STOP	x	0	1
Master Tx/Rx + NBYTES + RESTART	x	0	0
Slave Tx/Rx, all received bytes ACKed	0	x	x
Slave Rx with ACK control	1	1	x

48.4.8 I2C slave mode

I2C slave initialization

To work in slave mode, the user must enable at least one slave address. Registers I2C_OAR1 and I2C_OAR2 are available to program the slave own addresses OA1 and OA2.

- OA1 can be configured either in 7-bit mode (by default), or in 10-bit addressing mode by setting the OA1MODE bit in the I2C_OAR1 register.

  OA1 is enabled by setting the OA1EN bit in the I2C_OAR1 register.
- If additional slave addresses are required, the second slave address OA2 can be configured. Up to seven OA2 LSB can be masked by configuring the OA2MSK[2:0] bits in the I2C_OAR2 register. Therefore for OA2MSK configured from 1 to 6, only OA2[7:2], OA2[7:3], OA2[7:4], OA2[7:5], OA2[7:6] or OA2[7] are compared with the received address. As soon as OA2MSK is not equal to 0, the address comparator for OA2 excludes the I2C reserved addresses (0000 XXX and 1111 XXX), which are not acknowledged. If OA2MSK = 7, all received 7-bit addresses are acknowledged (except reserved addresses). OA2 is always a 7-bit address.

  These reserved addresses can be acknowledged if they are enabled by the specific enable bit, if they are programmed in the I2C_OAR1 or I2C_OAR2 register with OA2MSK = 0.

  OA2 is enabled by setting the OA2EN bit in the I2C_OAR2 register.
- The general call address is enabled by setting the GCEN bit in the I2C_CR1 register.

When the I2C is selected by one of its enabled addresses, the ADDR interrupt status flag is set, and an interrupt is generated if the ADDRIE bit is set.

By default, the slave uses its clock stretching capability, which means that it stretches the SCL signal at low level when needed, to perform software actions. If the master does not

support clock stretching, the I2C must be configured with NOSTRETCH = 1 in the I2C_CR1 register.

After receiving an ADDR interrupt, if several addresses are enabled, the user must read the ADDCODE[6:0] bits in the I2C_ISR register to check which address matched. DIR flag must also be checked to know the transfer direction.

Slave clock stretching (NOSTRETCH = 0)

In default mode, the I2C slave stretches the SCL clock in the following situations:

- When the ADDR flag is set: the received address matches with one of the enabled slave addresses. This stretch is released when the ADDR flag is cleared by software setting the ADDRCF bit.
- In transmission, if the previous data transmission is completed and no new data is written in I2C_TXDR register, or if the first data byte is not written when the ADDR flag is cleared (TXE = 1). This stretch is released when the data is written to the I2C_TXDR register.
- In reception when the I2C_RXDR register is not read yet and a new data reception is completed. This stretch is released when I2C_RXDR is read.
- When TCR = 1 in Slave Byte Control mode, reload mode (SBC = 1 and RELOAD = 1), meaning that the last data byte has been transferred. This stretch is released when then TCR is cleared by writing a non-zero value in the NBYTES[7:0] field.
- After SCL falling edge detection, the I2C stretches SCL low during [(SDADEL + SCLDEL + 1) x (PRESC+ 1) + 1] x t_{I2CCLK}.

Slave without clock stretching (NOSTRETCH = 1)

When NOSTRETCH = 1 in the I2C_CR1 register, the I2C slave does not stretch the SCL signal.

- The SCL clock is not stretched while the ADDR flag is set.
- In transmission, the data must be written in the I2C_TXDR register before the first SCL pulse corresponding to its transfer occurs. If not, an underrun occurs, the OVR flag is set in the I2C_ISR register and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register. The OVR flag is also set when the first data transmission starts and the STOPF bit is still set (has not been cleared). Therefore, if the user clears the STOPF flag of the previous transfer only after writing the first data to be transmitted in the next transfer, it ensures that the OVR status is provided, even for the first data to be transmitted.
- In reception, the data must be read from the I2C_RXDR register before the ninth SCL pulse (ACK pulse) of the next data byte occurs. If not, an overrun occurs, the OVR flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

Slave byte control mode

To allow byte ACK control in slave reception mode, the Slave byte control mode must be enabled by setting the SBC bit in the I2C_CR1 register. This is required to be compliant with SMBus standards.

The Reload mode must be selected to allow byte ACK control in slave reception mode (RELOAD = 1). To get control of each byte, NBYTES must be initialized to 0x1 in the ADDR interrupt subroutine, and reloaded to 0x1 after each received byte. When the byte is received, the TCR bit is set, stretching the SCL signal low between the eighth and ninth SCL pulses. The user can read the data from the I2C_RXDR register, and then decide to acknowledge it or not by configuring the ACK bit in the I2C_CR2 register. The SCL stretch is released by programming NBYTES to a non-zero value: the acknowledge or not-acknowledge is sent, and the next byte can be received.

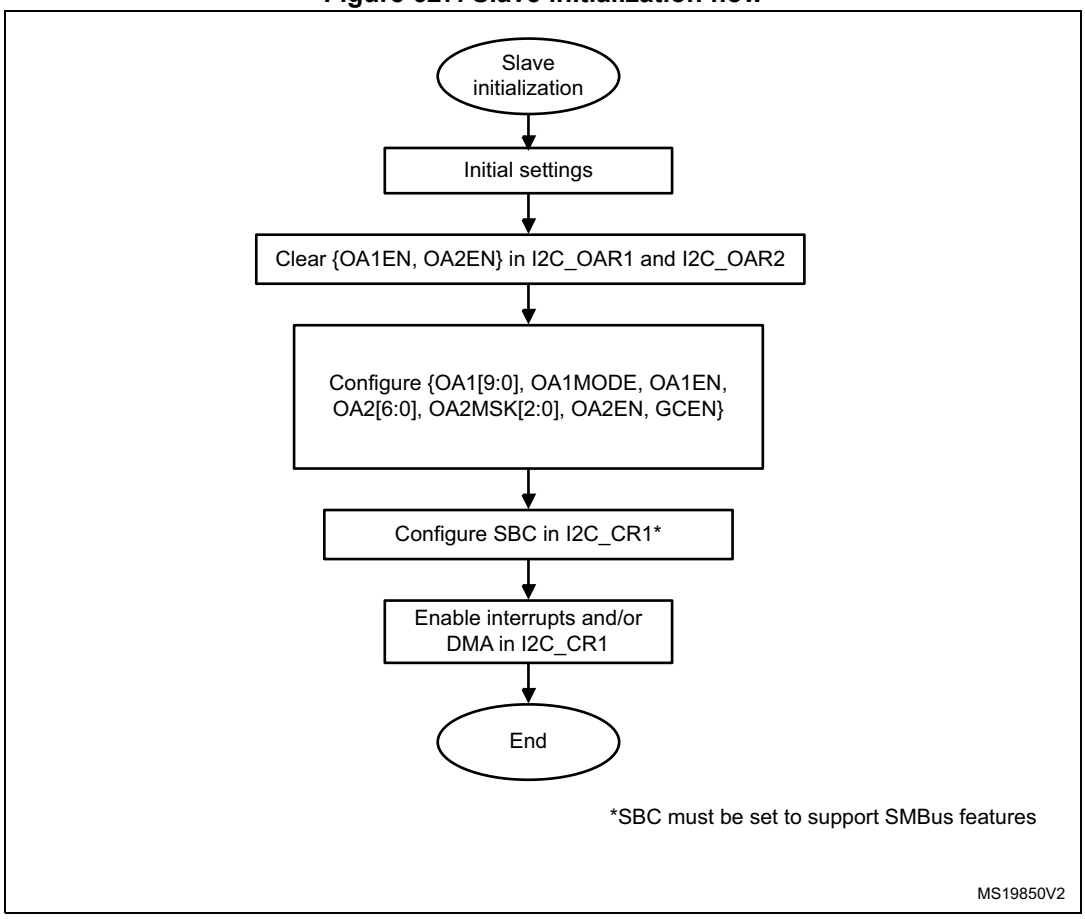
NBYTES can be loaded with a value greater than 0x1, and in this case, the reception flow is continuous during NBYTES data reception.

Note: The SBC bit must be configured when the I2C is disabled, or when the slave is not addressed, or when ADDR = 1.

The RELOAD bit value can be changed when ADDR = 1, or when TCR = 1.

Caution: The Slave byte control mode is not compatible with NOSTRETCH mode. Setting SBC when NOSTRETCH = 1 is not allowed.

Figure 627. Slave initialization flow



Slave transmitter

A transmit interrupt status (TXIS) is generated when the I2C_TXDR register becomes empty. An interrupt is generated if the TXIE bit is set in the I2C_CR1 register.

The TXIS bit is cleared when the I2C_TXDR register is written with the next data byte to be transmitted.

When a NACK is received, the NACKF bit is set in the I2C_ISR register and an interrupt is generated if the NACKIE bit is set in the I2C_CR1 register. The slave automatically releases the SCL and SDA lines in order to let the master perform a STOP or a RESTART condition. The TXIS bit is not set when a NACK is received.

When a STOP is received and the STOPIE bit is set in the I2C_CR1 register, the STOPF flag is set in the I2C_ISR register and an interrupt is generated. In most applications, the SBC bit is usually programmed to 0. In this case, If TXE = 0 when the slave address is received (ADDR = 1), the user can choose either to send the content of the I2C_TXDR register as the first data byte, or to flush the I2C_TXDR register by setting the TXE bit in order to program a new data byte.

In Slave byte control mode (SBC = 1), the number of bytes to be transmitted must be programmed in NBYTES in the address match interrupt subroutine (ADDR = 1). In this case, the number of TXIS events during the transfer corresponds to the value programmed in NBYTES.

Caution: When NOSTRETCH = 1, the SCL clock is not stretched while the ADDR flag is set, so the user cannot flush the I2C_TXDR register content in the ADDR subroutine, in order to program the first data byte. The first data byte to be sent must be previously programmed in the I2C_TXDR register:

- This data can be the data written in the last TXIS event of the previous transmission message.
- If this data byte is not the one to be sent, the I2C_TXDR register can be flushed by setting the TXE bit in order to program a new data byte. The STOPF bit must be cleared only after these actions, in order to guarantee that they are executed before the first data transmission starts, following the address acknowledge.

  If STOPF is still set when the first data transmission starts, an underrun error is generated (the OVR flag is set).

  If a TXIS event is needed, (transmit interrupt or transmit DMA request), the user must set the TXIS bit in addition to the TXE bit, in order to generate a TXIS event.

Figure 628. Transfer sequence flow for I2C slave transmitter, NOSTRETCH = 0

EV3: TXIS ISR: wr data3
EV4: TXIS ISR: wr data4 (not sent)
EV5: STOPF ISR: (optional: set TXE and TXIS), set STOPCF

MS19853V2

Slave receiver

RXNE is set in I2C_ISR when the I2C_RXDR is full, and generates an interrupt if RXIE is set in I2C_CR1. RXNE is cleared when I2C_RXDR is read.

When a STOP is received and STOPIE is set in I2C_CR1, STOPF is set in I2C_ISR and an interrupt is generated.

48.4.9 I2C master mode

I2C master initialization

Before enabling the peripheral, the I2C master clock must be configured by setting the SCLH and SCLL bits in the I2C_TIMINGR register.

The STM32CubeMX tool calculates and provides the I2C_TIMINGR content in the I2C Configuration window.

A clock synchronization mechanism is implemented in order to support multi-master environment and slave clock stretching.

In order to allow clock synchronization:

- The low level of the clock is counted using the SCLL counter, starting from the SCL low level internal detection.
- The high level of the clock is counted using the SCLH counter, starting from the SCL high level internal detection.

The I2C detects its own SCL low level after a t_{SYNC1} delay depending on the SCL falling edge, SCL input noise filters (analog + digital) and SCL synchronization to the I2CxCLK clock. The I2C releases SCL to high level once the SCLL counter reaches the value programmed in the SCLL[7:0] bits in the I2C_TIMINGR register.

The I2C detects its own SCL high level after a t_{SYNC2} delay depending on the SCL rising edge, SCL input noise filters (analog + digital) and SCL synchronization to I2CxCLK clock. The I2C ties SCL to low level once the SCLH counter reaches the value programmed in the SCLH[7:0] bits in the I2C_TIMINGR register.

Consequently the master clock period is:

$t_{SCL} = t_{SYNC1} + t_{SYNC2} + \{[(SCLH+ 1) + (SCLL+ 1)] \times (PRESC+ 1) \times t_{I2CCLK}\}$

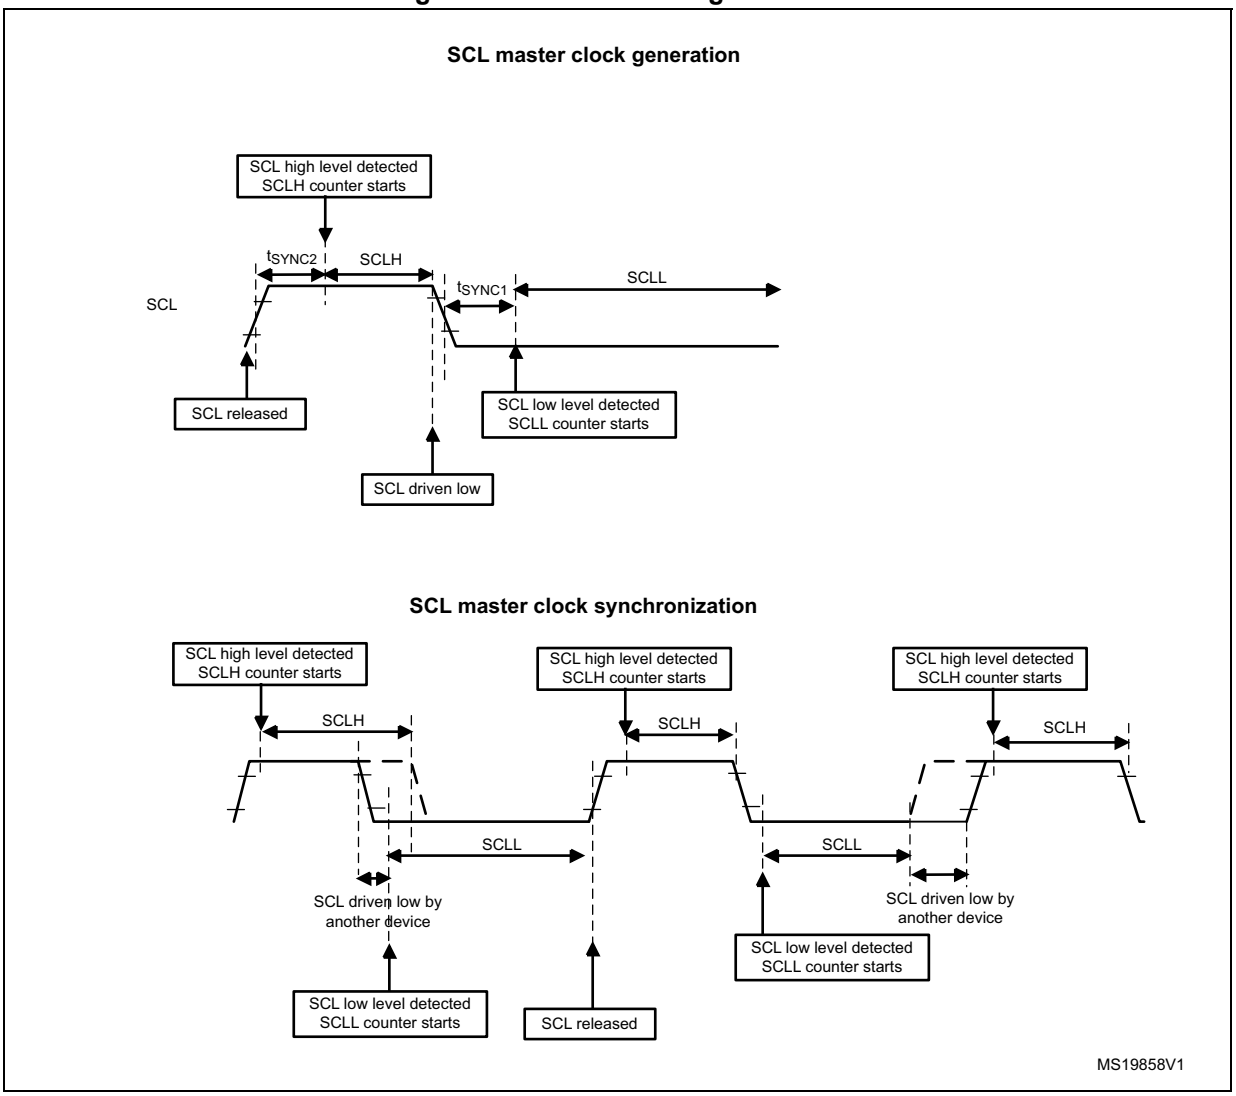
The duration of t_{SYNC1} depends upon:

- SCL falling slope
- When enabled, input delay induced by the analog filter
- When enabled, input delay induced by the digital filter: DNF x t_{I2CCLK}
- Delay due to SCL synchronization with i2c_ker_ck clock (two to three i2c_ker_ck periods)

The duration of t_{SYNC2} depends upon:

- SCL rising slope
- When enabled, input delay induced by the analog filter
- When enabled, input delay induced by the digital filter: DNF x t_{I2CCLK}
- Delay due to SCL synchronization with i2c_ker_ck clock (two to three i2c_ker_ck periods)

Figure 634. Master clock generation



Caution: To be I^2C or SMBus compliant, the master clock must respect the timings given in the following table.

Table 504. I^2C-SMBus specification clock timings

Symbol	Parameter	Standard-mode (Sm)		Fast-mode (Fm)		Fast-mode Plus (Fm+)		SMBus		Unit
		Min	Max	Min	Max	Min	Max	Min	Max	
f_{SCL}	SCL clock frequency	-	100	-	400	-	1000	-	100	kHz
$t_{HD:STA}$	Hold time (repeated) START condition	4.0	-	0.6	-	0.26	-	4.0	-	µs
$t_{SU:STA}$	Set-up time for a repeated START condition	4.7	-	0.6	-	0.26	-	4.7	-	
$t_{SU:STO}$	Set-up time for STOP condition	4.0	-	0.6	-	0.26	-	4.0	-	
t_{BUF}	Bus free time between a STOP and START condition	4.7	-	1.3	-	0.5	-	4.7	-	
t_{LOW}	Low period of the SCL clock	4.7	-	1.3	-	0.5	-	4.7	-	
t_{HIGH}	Period of the SCL clock	4.0	-	0.6	-	0.26	-	4.0	50	
t_r	Rise time of both SDA and SCL signals	-	1000	-	300	-	120	-	1000	ns
t_f	Fall time of both SDA and SCL signals	-	300	-	300	-	120	-	300	

Note: SCLL is also used to generate the t_{BUF} and $t_{SU:STA}$ timings, and SCLH is also used to generate the $t_{HD:STA}$ and $t_{SU:STO}$ timings.

Refer to *Section 48.4.10* for examples of I2C_TIMINGR settings vs. i2c_ker_ck frequency.

Master communication initialization (address phase)

In order to initiate the communication, the user must program the following parameters for the addressed slave in the I2C_CR2 register:

- Addressing mode (7-bit or 10-bit): ADD10
- Slave address to be sent: SADD[9:0]
- Transfer direction: RD_WRN
- In case of 10-bit address read: HEAD10R bit. HEAD10R must be configure to indicate if the complete address sequence must be sent, or only the header in case of a direction change.
- The number of bytes to be transferred: NBYTES[7:0]. If the number of bytes is equal to or greater than 255 bytes, NBYTES[7:0] must initially be filled with 0xFF.

The user must then set the START bit in I2C_CR2 register. Changing all the above bits is not allowed when START bit is set.

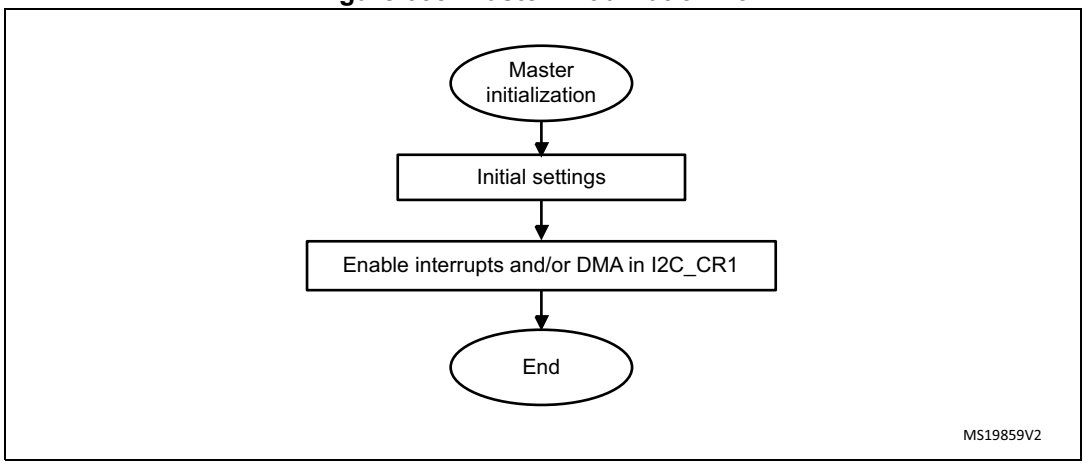
Then the master automatically sends the START condition followed by the slave address as soon as it detects that the bus is free (BUSY = 0) and after a delay of t_{BUF}.

In case of an arbitration loss, the master automatically switches back to slave mode and can acknowledge its own address if it is addressed as a slave.

Note: The START bit is reset by hardware when the slave address is sent on the bus, whatever the received acknowledge value. The START bit is also reset by hardware if an arbitration loss occurs.
In 10-bit addressing mode, when the slave address first seven bits are NACKed by the slave, the master relaunches automatically the slave address transmission until ACK is received. In this case ADDRCF must be set if a NACK is received from the slave, to stop sending the slave address.
If the I2C is addressed as a slave (ADDR = 1) while the START bit is set, the I2C switches to slave mode and the START bit is cleared.

Note: The same procedure is applied for a repeated start condition. In this case BUSY = 1.

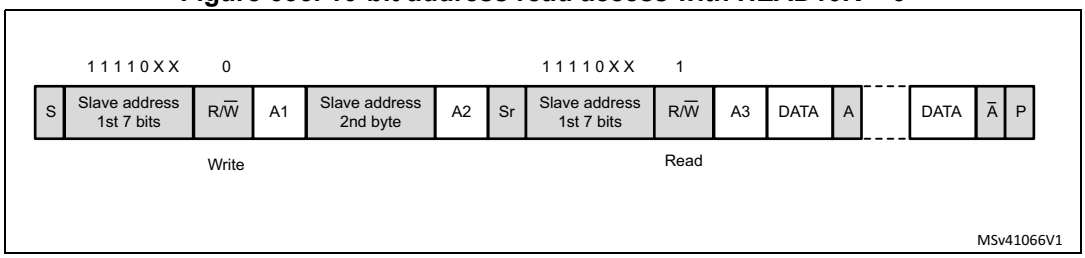
Figure 635. Master initialization flow



Initialization of a master receiver addressing a 10-bit address slave

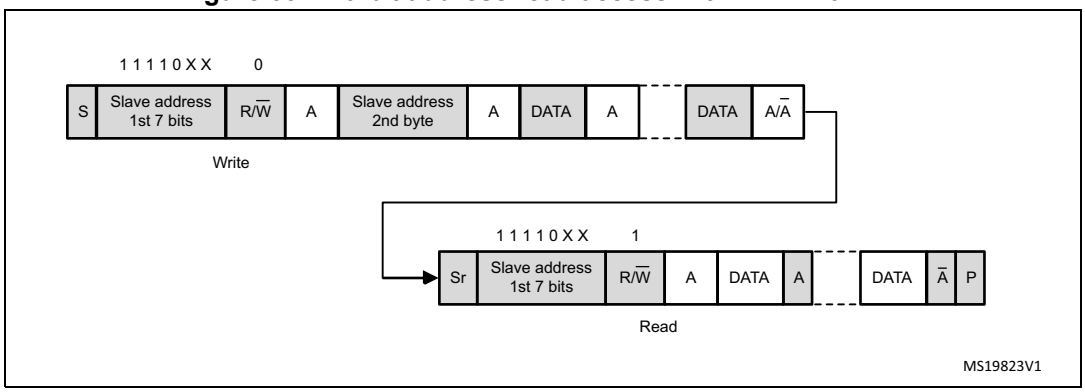
- If the slave address is in 10-bit format, the user can choose to send the complete read sequence by clearing the HEAD10R bit in the I2C_CR2 register. In this case the master automatically sends the following complete sequence after the START bit is set: (Re)Start + Slave address 10-bit header Write + Slave address second byte + REStart + Slave address 10-bit header Read

Figure 636. 10-bit address read access with HEAD10R = 0



- If the master addresses a 10-bit address slave, transmits data to this slave and then reads data from the same slave, a master transmission flow must be done first. Then a repeated start is set with the 10-bit slave address configured with HEAD10R = 1. In this case the master sends this sequence: ReStart + Slave address 10-bit header Read.

Figure 637. 10-bit address read access with HEAD10R = 1



Master transmitter

In the case of a write transfer, the TXIS flag is set after each byte transmission, after the ninth SCL pulse when an ACK is received.

A TXIS event generates an interrupt if the TXIE bit is set in the I2C_CR1 register. The flag is cleared when the I2C_TXDR register is written with the next data byte to be transmitted.

The number of TXIS events during the transfer corresponds to the value programmed in NBYTES[7:0]. If the total number of data bytes to be sent is greater than 255, reload mode must be selected by setting the RELOAD bit in the I2C_CR2 register. In this case, when NBYTES data have been transferred, the TCR flag is set and the SCL line is stretched low until NBYTES[7:0] is written to a non-zero value.

The TXIS flag is not set when a NACK is received.

- When RELOAD = 0 and NBYTES data have been transferred:
  - In automatic end mode (AUTOEND = 1), a STOP is automatically sent.
  - In software end mode (AUTOEND = 0), the TC flag is set and the SCL line is stretched low in order to perform software actions:

    A RESTART condition can be requested by setting the START bit in the I2C_CR2 register with the proper slave address configuration, and number of bytes to be transferred. Setting the START bit clears the TC flag and the START condition is sent on the bus.

    A STOP condition can be requested by setting the STOP bit in the I2C_CR2 register. Setting the STOP bit clears the TC flag and the STOP condition is sent on the bus.
- If a NACK is received: the TXIS flag is not set, and a STOP condition is automatically sent after the NACK reception. the NACKF flag is set in the I2C_ISR register, and an interrupt is generated if the NACKIE bit is set.

Figure 638. Transfer sequence flow for I2C master transmitter for N ≤ 255 bytes

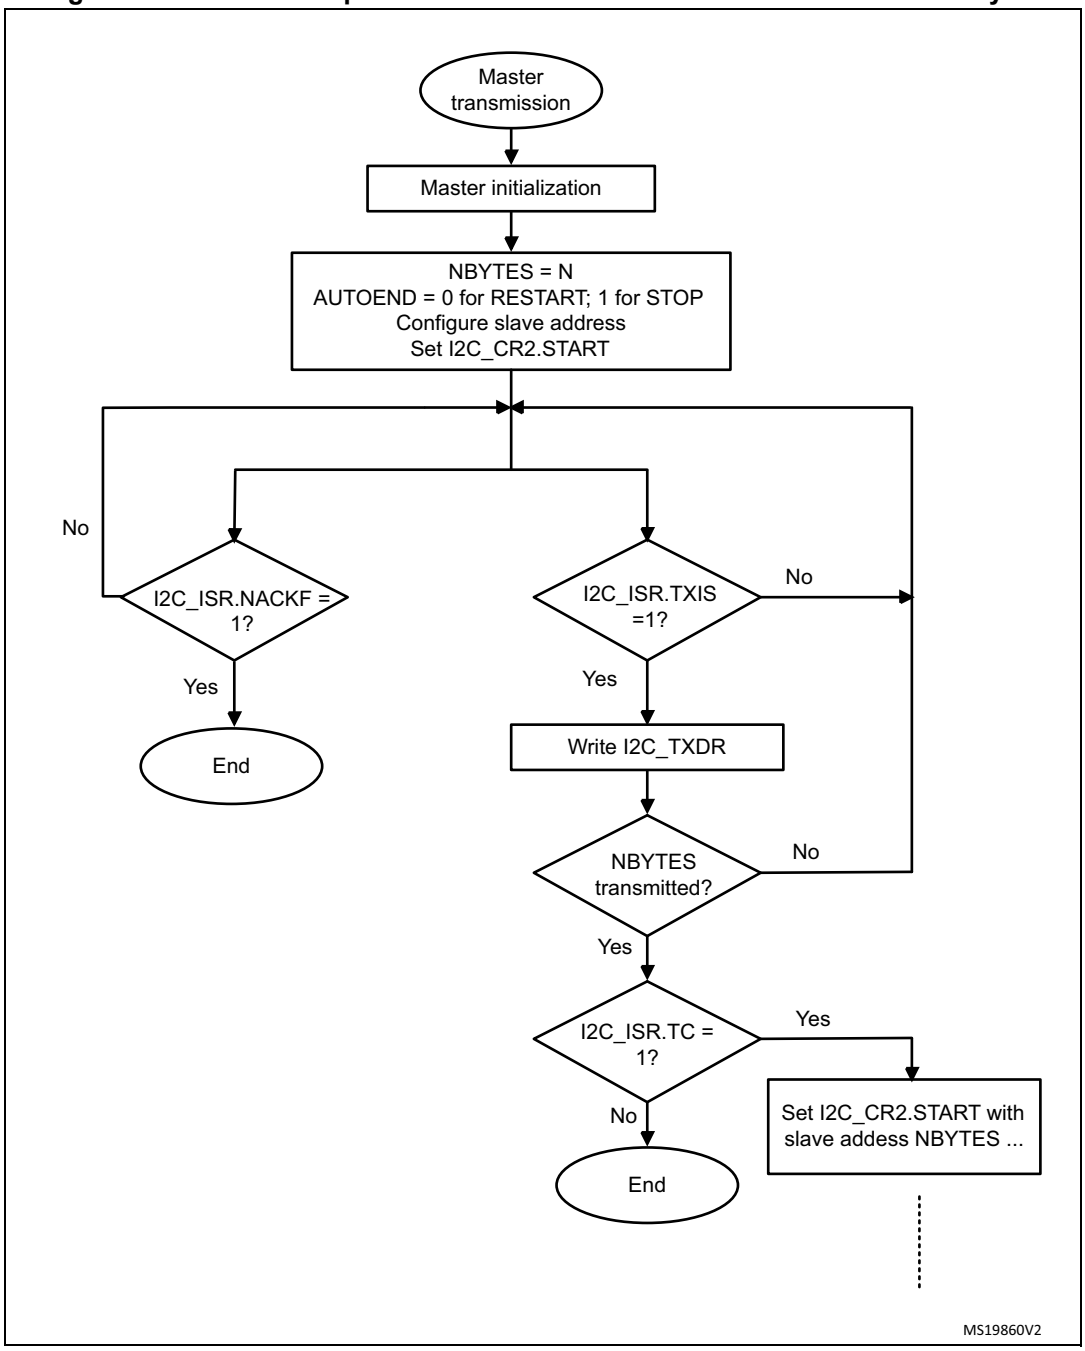


Figure 639. Transfer sequence flow for I2C master transmitter for N > 255 bytes

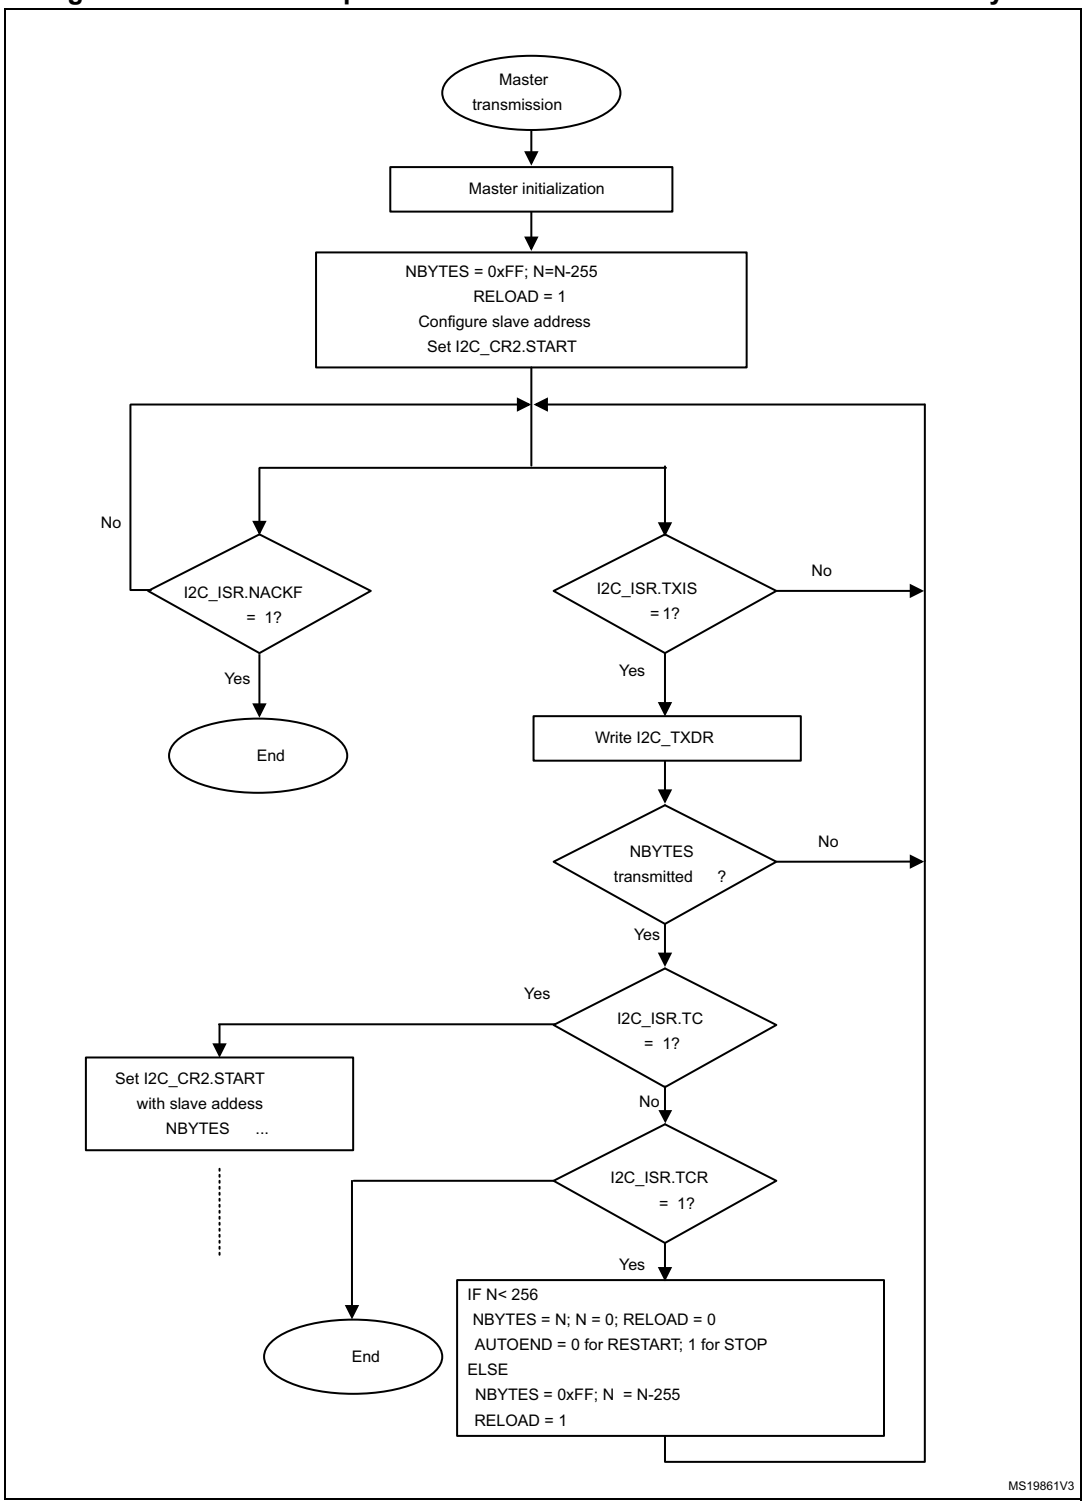

Figure 640. Transfer bus diagrams for I2C master transmitter (mandatory events only)

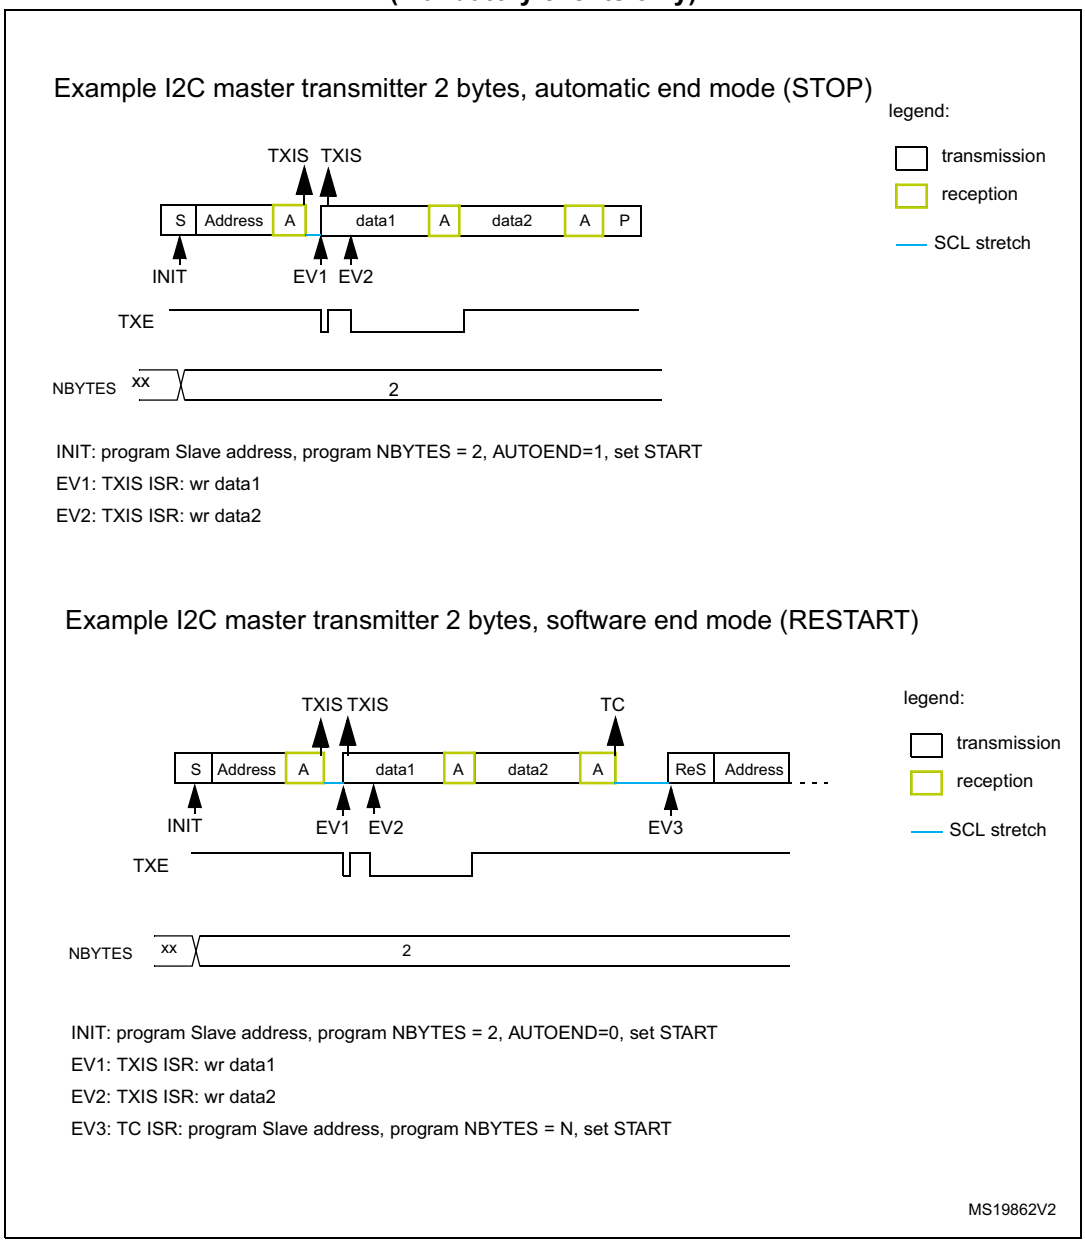

Master receiver

In the case of a read transfer, the RXNE flag is set after each byte reception, after the eighth SCL pulse. An RXNE event generates an interrupt if the RXIE bit is set in the I2C_CR1 register. The flag is cleared when I2C_RXDR is read.

If the total number of data bytes to be received is greater than 255, reload mode must be selected by setting the RELOAD bit in the I2C_CR2 register. In this case, when NBYTES[7:0] data have been transferred, the TCR flag is set and the SCL line is stretched low until NBYTES[7:0] is written to a non-zero value.

- When RELOAD = 0 and NBYTES[7:0] data have been transferred:
  - In automatic end mode (AUTOEND = 1), a NACK and a STOP are automatically sent after the last received byte.
  - In software end mode (AUTOEND = 0), a NACK is automatically sent after the last received byte, the TC flag is set and the SCL line is stretched low in order to allow software actions:

    A RESTART condition can be requested by setting the START bit in the I2C_CR2 register with the proper slave address configuration, and number of bytes to be transferred. Setting the START bit clears the TC flag and the START condition, followed by slave address, are sent on the bus.

    A STOP condition can be requested by setting the STOP bit in the I2C_CR2 register. Setting the STOP bit clears the TC flag and the STOP condition is sent on the bus.

Figure 641. Transfer sequence flow for I2C master receiver for N ≤ 255 bytes

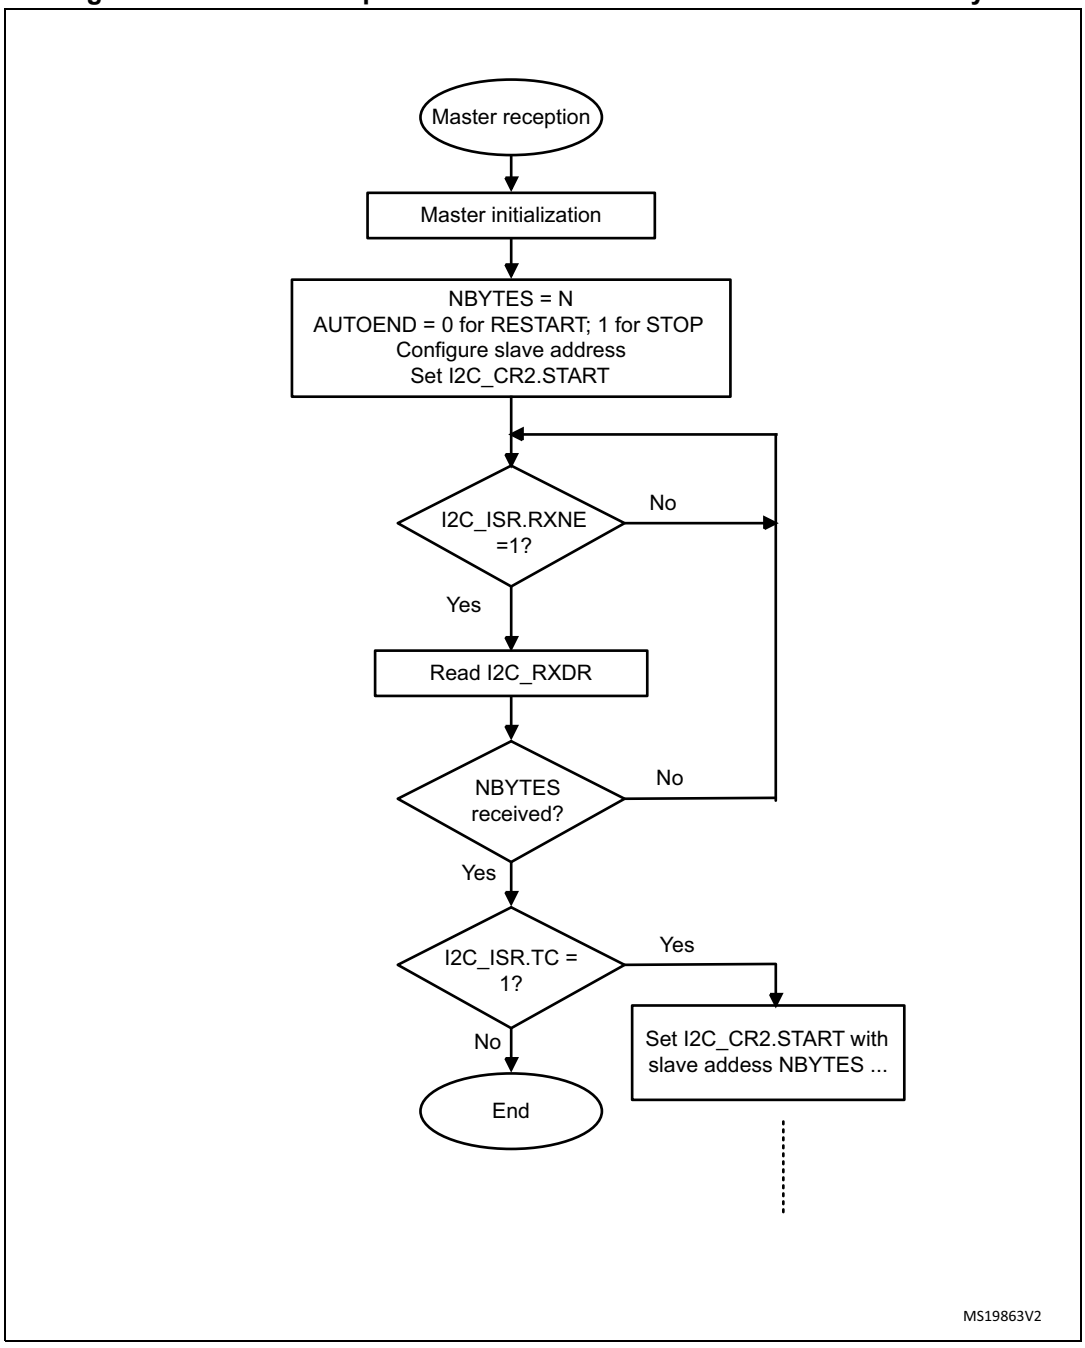

Figure 642. Transfer sequence flow for I2C master receiver for N > 255 bytes

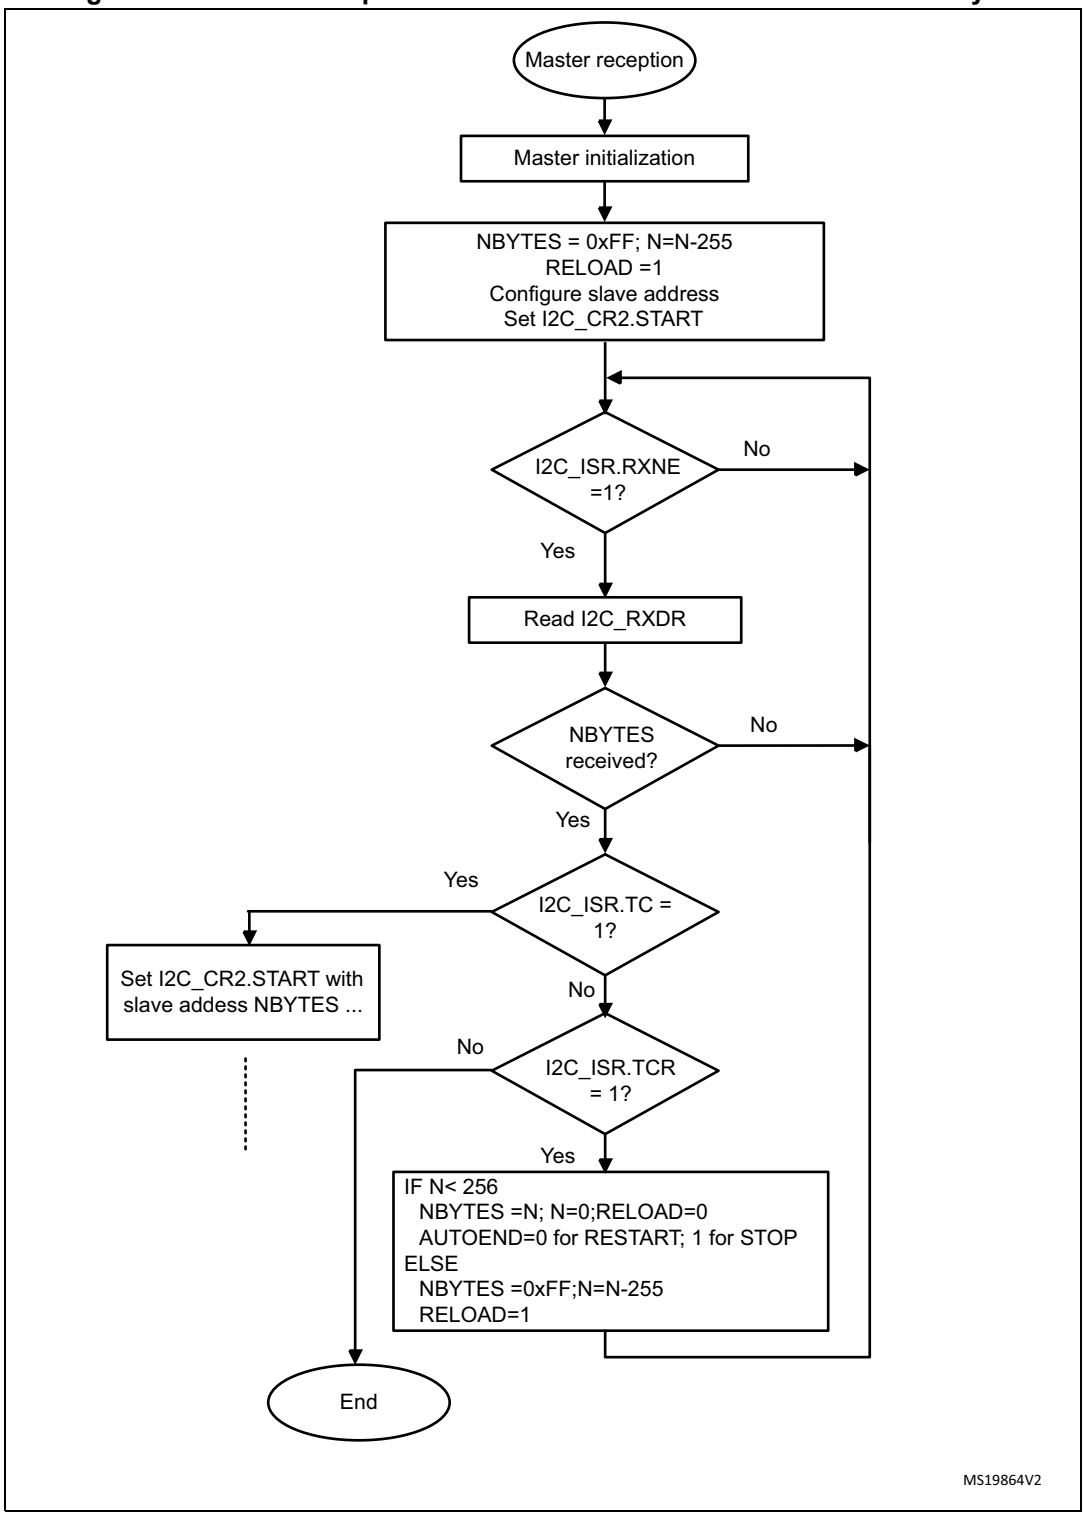

Figure 643. Transfer bus diagrams for I2C master receiver (mandatory events only)

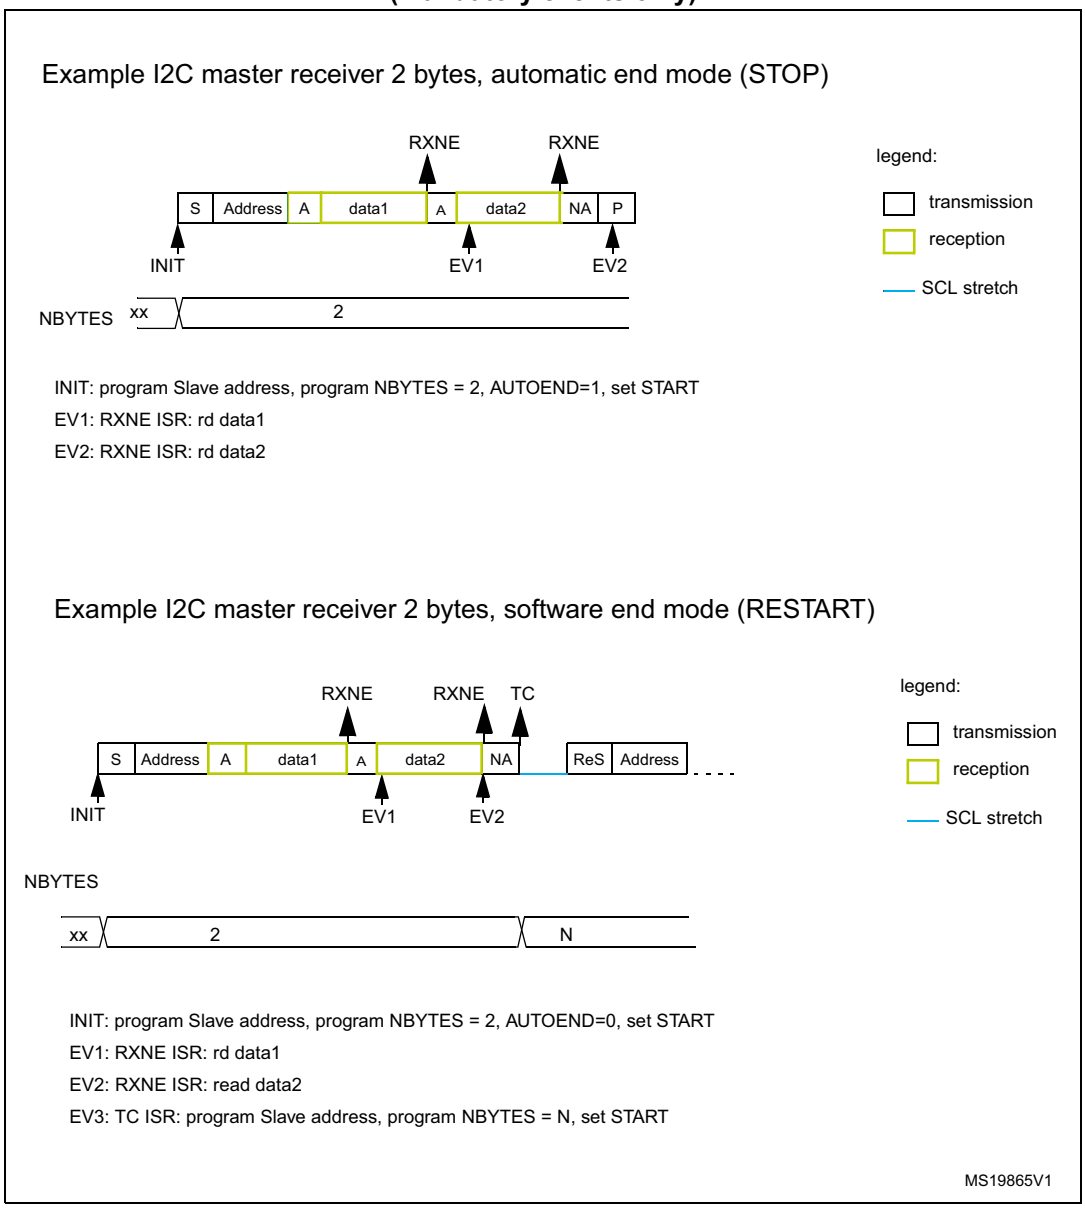


48.4.10 I2C_TIMINGR register configuration examples

The following tables provide examples of how to program the I2C_TIMINGR to obtain timings compliant with the I^2C specification. To get more accurate configuration values, use the STM32CubeMX tool (I2C Configuration window).

Table 505. Examples of timing settings for f_{I2CCLK} = 8 MHz

Parameter	Standard-mode (Sm)		Fast-mode (Fm)	Fast-mode Plus (Fm+)
	10 kHz	100 kHz	400 kHz	500 kHz
PRESC	0x1	0x1	0x0	0x0
SCLL	0xC7	0x13	0x9	0x6
t_{SCLL}	200 x 250 ns = 50 µs	20 x 250 ns = 5.0 µs	10 x 125 ns = 1250 ns	7 x 125 ns = 875 ns
SCLH	0xC3	0xF	0x3	0x3
t_{SCLH}	196 x 250 ns = 49 µs	16 x 250 ns = 4.0µs	4 x 125 ns = 500 ns	4 x 125 ns = 500 ns
t_{SCL}(1)	~100 µs(2)	~10 µs(2)	~2.5 µs(3)	~2.0 µs(4)
SDADEL	0x2	0x2	0x1	0x0
t_{SDADEL}	2 x 250 ns = 500 ns	2 x 250 ns = 500 ns	1 x 125 ns = 125 ns	0 ns
SCLDEL	0x4	0x4	0x3	0x1
t_{SCLDEL}	5 x 250 ns = 1250 ns	5 x 250 ns = 1250 ns	4 x 125 ns = 500 ns	2 x 125 ns = 250 ns

1. t_{SCL} is greater than t_{SCLL} + t_{SCLH} due to SCL internal detection delay. Values provided for t_{SCL} are examples only.
2. t_{SYNC1} + t_{SYNC2} minimum value is 4 x t_{I2CCLK} = 500 ns. Example with t_{SYNC1} + t_{SYNC2} = 1000 ns.
3. t_{SYNC1} + t_{SYNC2} minimum value is 4 x t_{I2CCLK} = 500 ns. Example with t_{SYNC1} + t_{SYNC2} = 750 ns.
4. t_{SYNC1} + t_{SYNC2} minimum value is 4 x t_{I2CCLK} = 500 ns. Example with t_{SYNC1} + t_{SYNC2} = 655 ns.

Table 506. Examples of timing settings for f_{I2CCLK} = 16 MHz

Parameter	Standard-mode (Sm)		Fast-mode (Fm)	Fast-mode Plus (Fm+)
	10 kHz	100 kHz	400 kHz	1000 kHz
PRESC	0x3	0x3	0x1	0x0
SCLL	0xC7	0x13	0x9	0x4
t_{SCLL}	200 x 250 ns = 50 µs	20 x 250 ns = 5.0 µs	10 x 125 ns = 1250 ns	5 x 62.5 ns = 312.5 ns
SCLH	0xC3	0xF	0x3	0x2
t_{SCLH}	196 x 250 ns = 49 µs	16 x 250 ns = 4.0 µs	4 x 125 ns = 500 ns	3 x 62.5 ns = 187.5 ns
t_{SCL}(1)	~100 µs(2)	~10 µs(2)	~2.5 µs(3)	~1.0 µs(4)
SDADEL	0x2	0x2	0x2	0x0
t_{SDADEL}	2 x 250 ns = 500 ns	2 x 250 ns = 500 ns	2 x 125 ns = 250 ns	0 ns
SCLDEL	0x4	0x4	0x3	0x2
t_{SCLDEL}	5 x 250 ns = 1250 ns	5 x 250 ns = 1250 ns	4 x 125 ns = 500 ns	3 x 62.5 ns = 187.5 ns

1. t_{SCL} is greater than t_{SCLL} + t_{SCLH} due to SCL internal detection delay. Values provided for t_{SCL} are examples only.
2. t_{SYNC1} + t_{SYNC2} minimum value is 4 x t_{I2CCLK} = 250 ns. Example with t_{SYNC1} + t_{SYNC2} = 1000 ns.
3. t_{SYNC1} + t_{SYNC2} minimum value is 4 x t_{I2CCLK} = 250 ns. Example with t_{SYNC1} + t_{SYNC2} = 750 ns.
4. t_{SYNC1} + t_{SYNC2} minimum value is 4 x t_{I2CCLK} = 250 ns. Example with t_{SYNC1} + t_{SYNC2} = 500 ns.

48.4.11 SMBus specific features

This section is relevant only when the SMBus feature is supported (refer to *Section 48.3*).

Introduction

The system management bus (SMBus) is a two-wire interface through which various devices can communicate with each other and with the rest of the system. It is based on I^2C principles of operation. The SMBus provides a control bus for system and power management related tasks.

This peripheral is compatible with the SMBus specification (http://smbus.org).

The system management bus specification refers to three types of devices

- A slave is a device that receives or responds to a command.
- A master is a device that issues commands, generates the clocks, and terminates the transfer.
- A host is a specialized master that provides the main interface to the system's CPU. A host must be a master-slave and must support the SMBus host notify protocol. Only one host is allowed in a system.

This peripheral can be configured as master or slave device, and also as a host.

Bus protocols

There are eleven possible command protocols for any given device. A device can use any or all of them to communicate. The protocols are Quick Command, Send Byte, Receive Byte, Write Byte, Write Word, Read Byte, Read Word, Process Call, Block Read, Block Write, and Block Write-Block Read Process Call. These protocols must be implemented by the user software.

For more details on these protocols, refer to SMBus specification (http://smbus.org).

Address resolution protocol (ARP)

SMBus slave address conflicts can be resolved by dynamically assigning a new unique address to each slave device. To provide a mechanism to isolate each device for the purpose of address assignment, each device must implement a unique device identifier (UDID). This 128-bit number is implemented by software.

This peripheral supports the Address Resolution Protocol (ARP). The SMBus Device Default Address (0b1100 001) is enabled by setting SMBDEN bit in I2C_CR1 register. The ARP commands must be implemented by the user software.

Arbitration is also performed in slave mode for ARP support.

For more details of the SMBus address resolution protocol, refer to SMBus specification (http://smbus.org).

Received command and data acknowledge control

A SMBus receiver must be able to NACK each received command or data. In order to allow the ACK control in slave mode, the Slave Byte Control mode must be enabled by setting SBC bit in I2C_CR1 register. Refer to *Slave byte control mode* for more details.

Host notify protocol

This peripheral supports the host notify protocol by setting the SMBHEN bit in the I2C_CR1 register. In this case the host acknowledges the SMBus host address (0b0001 000).

When this protocol is used, the device acts as a master and the host as a slave.

SMBus alert

The SMBus ALERT optional signal is supported. A slave-only device can signal the host through the SMBALERT# pin that it wants to talk. The host processes the interrupt and simultaneously accesses all SMBALERT# devices through the alert response address (0b0001 100). Only the device(s) which pulled SMBALERT# low acknowledges the alert response address.

When configured as a slave device(SMBHEN = 0), the SMBA pin is pulled low by setting the ALERTEN bit in the I2C_CR1 register. The Alert Response Address is enabled at the same time.

When configured as a host (SMBHEN = 1), the ALERT flag is set in the I2C_ISR register when a falling edge is detected on the SMBA pin and ALERTEN = 1. An interrupt is generated if the ERRIE bit is set in the I2C_CR1 register. When ALERTEN = 0, the ALERT line is considered high even if the external SMBA pin is low.

If the SMBus ALERT pin is not needed, the SMBA pin can be used as a standard GPIO if ALERTEN = 0*.*

Packet error checking

A packet error checking mechanism has been introduced in the SMBus specification to improve reliability and communication robustness. The packet error checking is implemented by appending a packet error code (PEC) at the end of each message transfer. The PEC is calculated by using the $C(x) = x^8 + x^2 + x + 1$ CRC-8 polynomial on all the message bytes (including addresses and read/write bits).

The peripheral embeds a hardware PEC calculator and allows a not acknowledge to be sent automatically when the received byte does not match with the hardware calculated PEC.

Timeouts

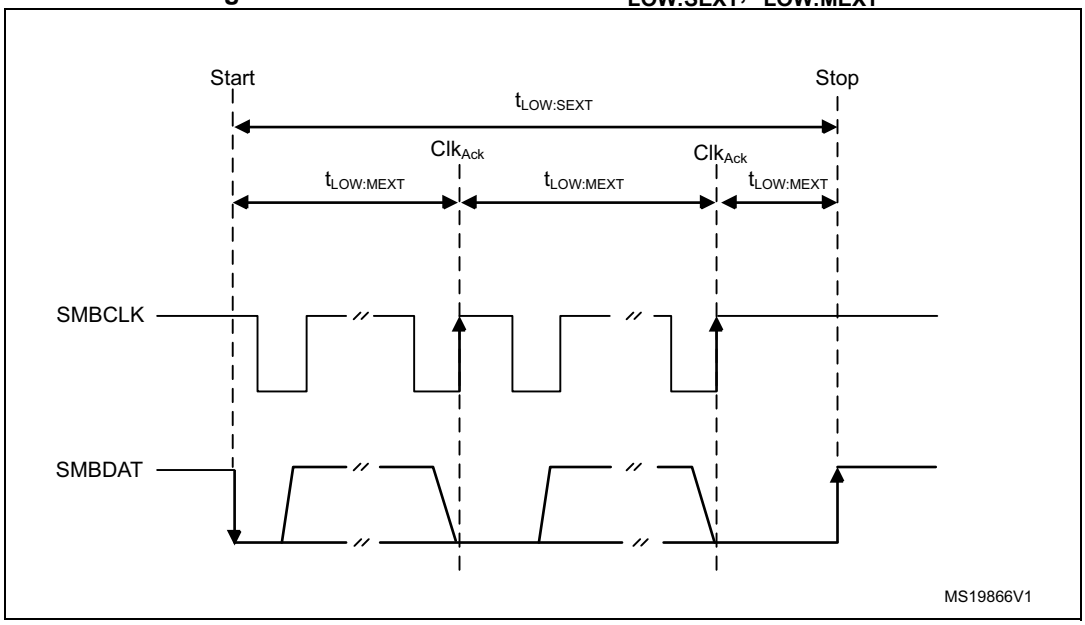
This peripheral embeds hardware timers in order to be compliant with the three timeouts defined in SMBus specification.

Table 507. SMBus timeout specifications

Symbol	Parameter	Limits		Unit
		Min	Max	
$t_{TIMEOUT}$	Detect clock low timeout	25	35	ms
$t_{LOW:SEXT}$(1)	Cumulative clock low extend time (slave device)	-	25	
$t_{LOW:MEXT}$(2)	Cumulative clock low extend time (master device)	-	10	

1. $t_{LOW:SEXT}$ is the cumulative time a given slave device is allowed to extend the clock cycles in one message from the initial START to the STOP. It is possible that another slave device or the master also extends the clock causing the combined clock low extend time to be greater than $t_{LOW:SEXT}$. Therefore, this parameter is measured with the slave device as the sole target of a full-speed master.
2. $t_{LOW:MEXT}$ is the cumulative time a master device is allowed to extend its clock cycles within each byte of a message as defined from START-to-ACK, ACK-to-ACK, or ACK-to-STOP. It is possible that a slave device or another master also extends the clock, causing the combined clock low time to be greater than $t_{LOW:MEXT}$ on a given byte. Therefore, this parameter is measured with a full speed slave device as the sole target of the master.

Figure 644. Timeout intervals for $t_{LOW:SEXT}$, $t_{LOW:MEXT}$



Bus idle detection

A master can assume that the bus is free if it detects that the clock and data signals have been high for $t_{IDLE} > t_{HIGH,MAX}$ (refer to *I2C timings*).

This timing parameter covers the condition where a master has been dynamically added to the bus, and may not have detected a state transition on the SMBCLK or SMBDAT lines. In this case, the master must wait long enough to ensure that a transfer is not currently in progress. The peripheral supports a hardware bus idle detection.

48.4.12 SMBus initialization

This section is relevant only when SMBus feature is supported (see *Section 48.3*).

In addition to I2C initialization, some other specific initialization must be done to perform SMBus communication.

Received command and data acknowledge control (slave mode)

A SMBus receiver must be able to NACK each received command or data. To allow ACK control in slave mode, the Slave byte control mode must be enabled by setting the SBC bit in the I2C_CR1 register. Refer to *Slave byte control mode* for more details.

Specific address (slave mode)

The specific SMBus addresses must be enabled if needed. Refer to *Bus idle detection* for more details.

- The SMBus device default address (0b1100 001) is enabled by setting the SMBDEN bit in the I2C_CR1 register.
- The SMBus host address (0b0001 000) is enabled by setting the SMBHEN bit in the I2C_CR1 register.
- The alert response address (0b0001100) is enabled by setting the ALERTEN bit in the I2C_CR1 register.

Packet error checking

PEC calculation is enabled by setting the PECEN bit in the I2C_CR1 register. Then the PEC transfer is managed with the help of the hardware byte counter NBYTES[7:0] in the I2C_CR2 register. The PECEN bit must be configured before enabling the I2C.

The PEC transfer is managed with the hardware byte counter, so the SBC bit must be set when interfacing the SMBus in slave mode. The PEC is transferred after NBYTES - 1 data have been transferred when the PECBYTE bit is set and the RELOAD bit is cleared. If RELOAD is set, PECBYTE has no effect.

Caution: Changing the PECEN configuration is not allowed when the I2C is enabled.

Table 508. SMBus with PEC configuration

Mode	SBC bit	RELOAD bit	AUTOEND bit	PECBYTE bit
Master Tx/Rx NBYTES + PEC+ STOP	x	0	1	1
Master Tx/Rx NBYTES + PEC + ReSTART	x	0	0	1
Slave Tx/Rx with PEC	1	0	x	1

Timeout detection

The timeout detection is enabled by setting the TIMOUTEN and TEXTEN bits in the I2C_TIMEOUTR register. The timers must be programmed in such a way that they detect a timeout before the maximum time given in the SMBus specification.

- $t_{TIMEOUT}$ check

  To enable the $t_{TIMEOUT}$ check, the 12-bit TIMEOUTA[11:0] bits must be programmed with the timer reload value, to check the $t_{TIMEOUT}$ parameter. The TIDLE bit must be configured to 0 to detect the SCL low level timeout.

  Then the timer is enabled by setting the TIMOUTEN in the I2C_TIMEOUTR register.

  If SCL is tied low for a time greater than (TIMEOUTA + 1) x 2048 x t_{I2CCLK}, the TIMEOUT flag is set in the I2C_ISR register.

  Refer to *Table 509*.

Caution: Changing the TIMEOUTA[11:0] bits and TIDLE bit configuration is not allowed when the TIMEOUTEN bit is set.

- $t_{LOW:SEXT}$ and $t_{LOW:MEXT}$ check

  Depending on if the peripheral is configured as a master or as a slave, the 12-bit TIMEOUTB timer must be configured to check $t_{LOW:SEXT}$ for a slave, and $t_{LOW:MEXT}$ for a master. As the standard specifies only a maximum, the user can choose the same value for both. The timer is then enabled by setting the TEXTEN bit in the I2C_TIMEOUTR register.

  If the SMBus peripheral performs a cumulative SCL stretch for a time greater than (TIMEOUTB + 1) x 2048 x t_{I2CCLK}, and in the timeout interval described in *Bus idle detection* section, the TIMEOUT flag is set in the I2C_ISR register.

  Refer to *Table 510*

Caution: Changing the TIMEOUTB configuration is not allowed when the TEXTEN bit is set.

Bus idle detection

To enable the t_{IDLE} check, the 12-bit TIMEOUTA[11:0] field must be programmed with the timer reload value, to obtain the t_{IDLE} parameter. The TIDLE bit must be configured to ‘1 to detect both SCL and SDA high level timeout. The timer is then enabled by setting the TIMOUTEN bit in the I2C_TIMEOUTR register.

If both the SCL and SDA lines remain high for a time greater than (TIMEOUTA + 1) x 4 x t_{I2CCLK}, the TIMEOUT flag is set in the I2C_ISR register.

Refer to *Table 511*.

Caution: Changing TIMEOUTA and TIDLE configuration is not allowed when TIMEOUTEN is set.

48.4.13 SMBus: I2C_TIMEOUTR register configuration examples

This section is relevant only when SMBus feature is supported. Refer to *Section 48.3*.

- Configuring the maximum duration of $t_{TIMEOUT}$ to 25 ms:

Table 509. Examples of TIMEOUTA settings (max $t_{TIMEOUT}$ = 25 ms)

f_{I2CCLK}	TIMEOUTA[11:0] bits	TIDLE bit	TIMEOUTEN bit	$t_{TIMEOUT}$
8 MHz	0x61	0	1	98 x 2048 x 125 ns = 25 ms
16 MHz	0xC3	0	1	196 x 2048 x 62.5 ns = 25 ms

- Configuring the maximum duration of $t_{LOW:SEXT}$ and $t_{LOW:MEXT}$ to 8 ms:

Table 510. Examples of TIMEOUTB settings

f_{I2CCLK}	TIMEOUTB[11:0] bits	TEXTEN bit	$t_{LOW:EXT}$
8 MHz	0x1F	1	32 x 2048 x 125 ns = 8 ms
16 MHz	0x3F	1	64 x 2048 x 62.5 ns = 8 ms

- Configuring the maximum duration of t_{IDLE} to 50 µs

Table 511. Examples of TIMEOUTA settings (max t_{IDLE} = 50 µs)

f_{I2CCLK}	TIMEOUTA[11:0] bits	TIDLE bit	TIMEOUTEN bit	t_{TIDLE}
8 MHz	0x63	1	1	100 x 4 x 125 ns = 50 µs
16 MHz	0xC7	1	1	200 x 4 x 62.5 ns = 50 µs

48.4.14 SMBus slave mode

This section is relevant only when the SMBus feature is supported (refer to *Section 48.3*).

In addition to I2C slave transfer management (refer to *Section 48.4.8*), additional software flows are provided to support the SMBus.

SMBus slave transmitter

When the IP is used in SMBus, SBC must be programmed to 1 to enable the PEC transmission at the end of the programmed number of data bytes. When the PECBYTE bit

is set, the number of bytes programmed in NBYTES[7:0] includes the PEC transmission. In that case the total number of TXIS interrupts is NBYTES - 1, and the content of the I2C_PECR register is automatically transmitted if the master requests an extra byte after the NBYTES - 1 data transfer.

Caution: The PECBYTE bit has no effect when the RELOAD bit is set.

Figure 645. Transfer sequence flow for SMBus slave transmitter N bytes + PEC

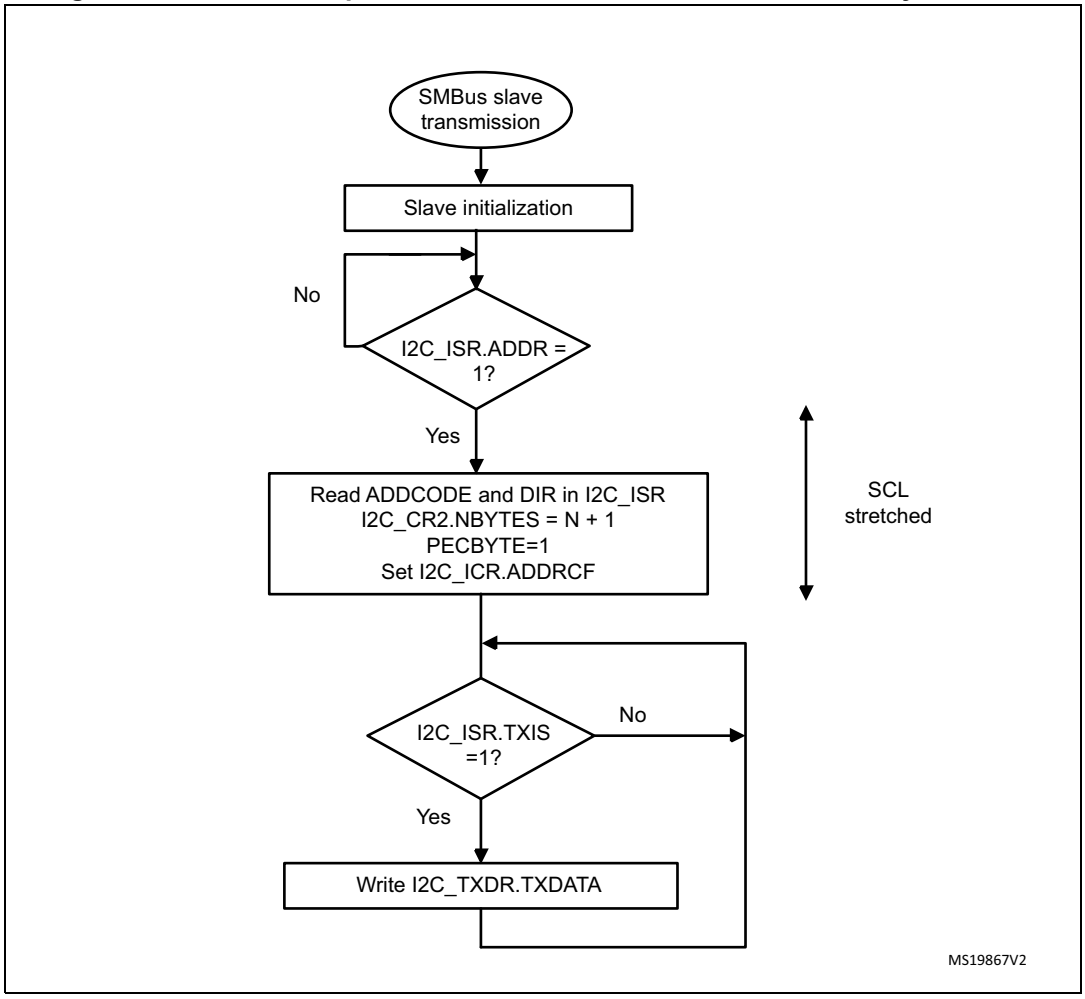


Figure 646. Transfer bus diagrams for SMBus slave transmitter (SBC = 1)

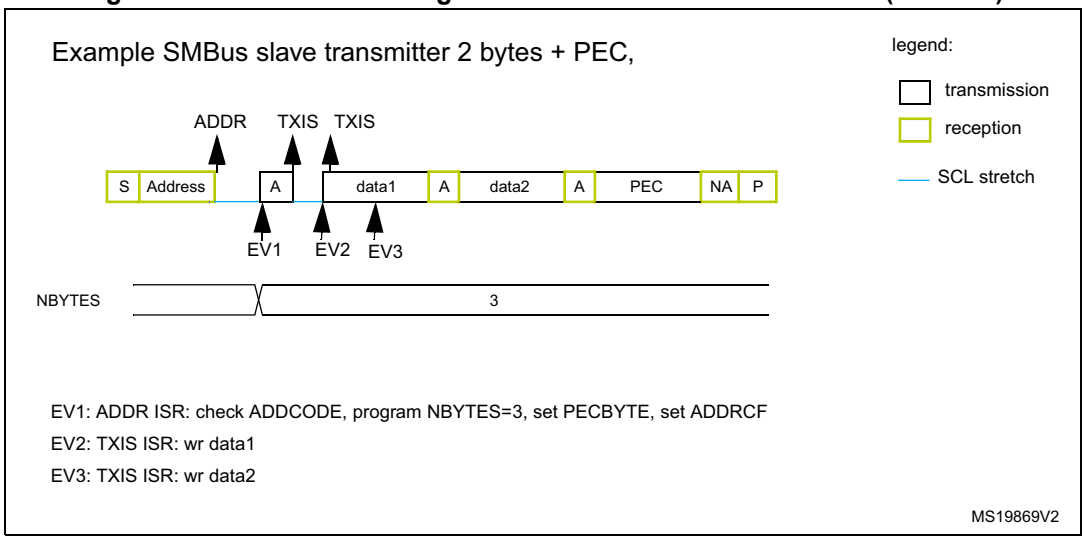

SMBus slave receiver

When the I2C is used in SMBus mode, SBC must be programmed to 1 to allow the PEC checking at the end of the programmed number of data bytes. In order to allow the ACK control of each byte, the reload mode must be selected (RELOAD = 1). Refer to *Slave byte control mode* for more details.

To check the PEC byte, the RELOAD bit must be cleared and the PECBYTE bit must be set. In this case, after NBYTES - 1 data have been received, the next received byte is compared with the internal I2C_PECR register content. A NACK is automatically generated if the comparison does not match, and an ACK is automatically generated if the comparison matches, whatever the ACK bit value. Once the PEC byte is received, it is copied into the I2C_RXDR register like any other data, and the RXNE flag is set.

In the case of a PEC mismatch, the PECERR flag is set and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

If no ACK software control is needed, the user can program PECBYTE = 1 and, in the same write operation, program NBYTES with the number of bytes to be received in a continuous flow. After NBYTES - 1 are received, the next received byte is checked as being the PEC.

Caution: The PECBYTE bit has no effect when the RELOAD bit is set.

Figure 647. Transfer sequence flow for SMBus slave receiver N bytes + PEC

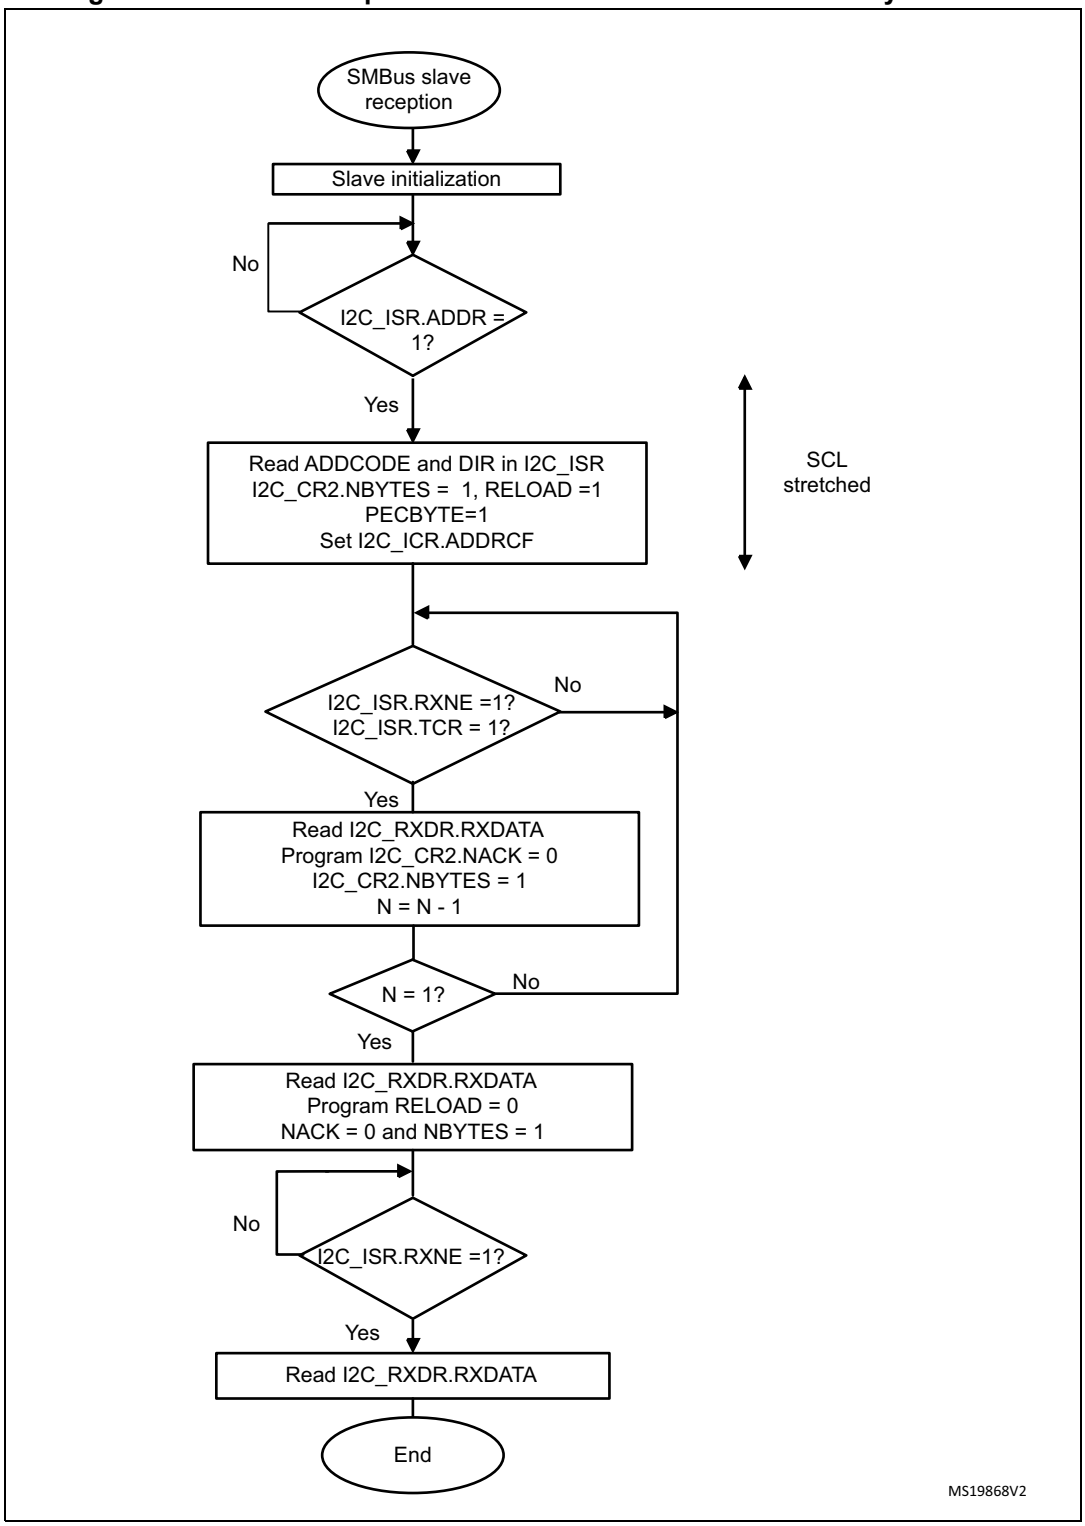

Figure 648. Bus transfer diagrams for SMBus slave receiver (SBC = 1)

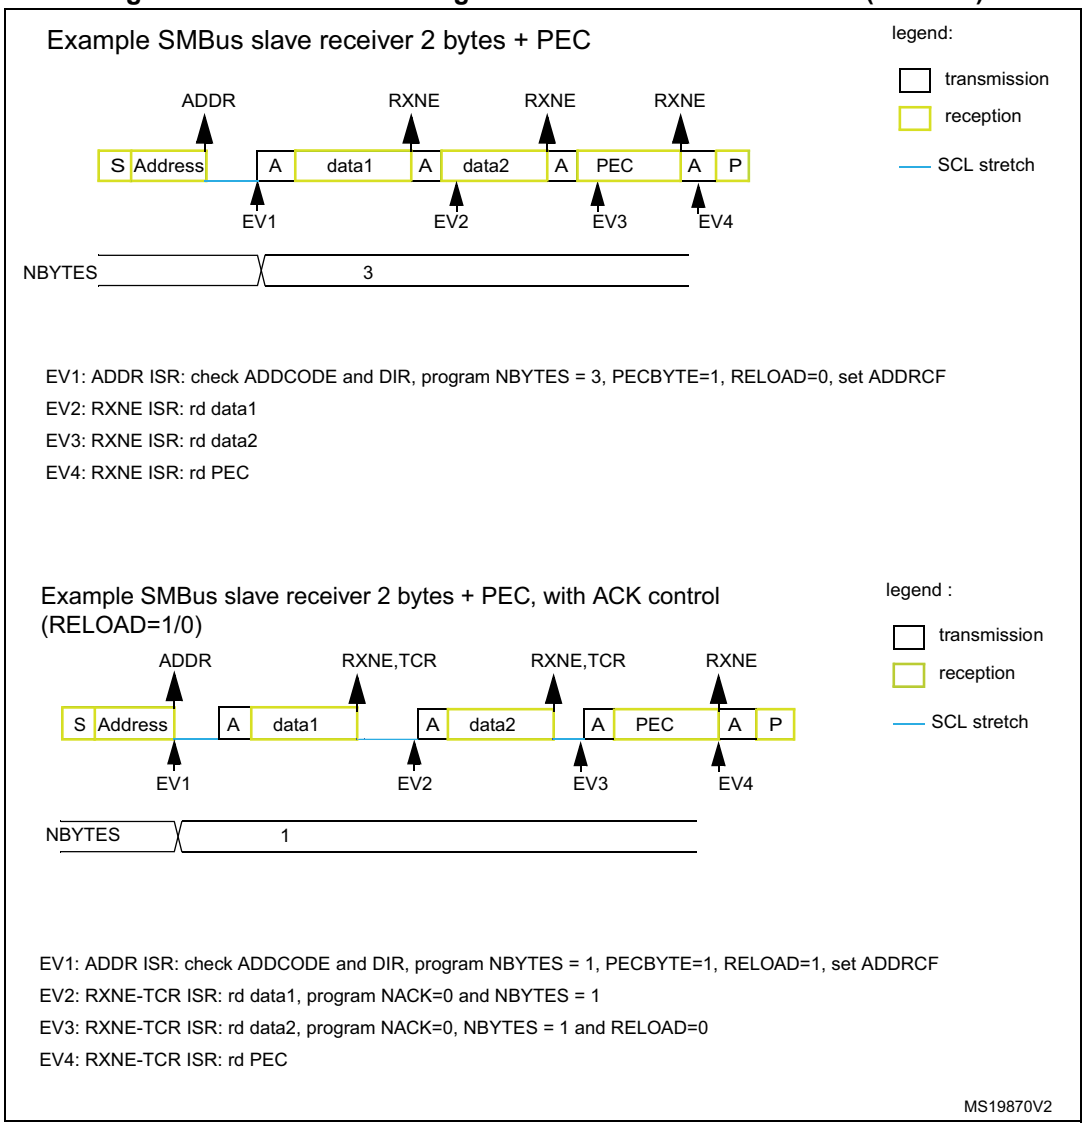


This section is relevant only when the SMBus feature is supported (refer to *Section 48.3*).

In addition to I2C master transfer management (refer to *Section 48.4.9*), additional software flows are provided to support the SMBus.

SMBus master transmitter

When the SMBus master wants to transmit the PEC, the PECBYTE bit must be set and the number of bytes must be programmed in the NBYTES[7:0] field, before setting the START bit. In this case the total number of TXIS interrupts is NBYTES - 1. So if the PECBYTE bit is set when NBYTES = 0x1, the content of the I2C_PECR register is automatically transmitted.

If the SMBus master wants to send a STOP condition after the PEC, automatic end mode must be selected (AUTOEND = 1). In this case, the STOP condition automatically follows the PEC transmission.

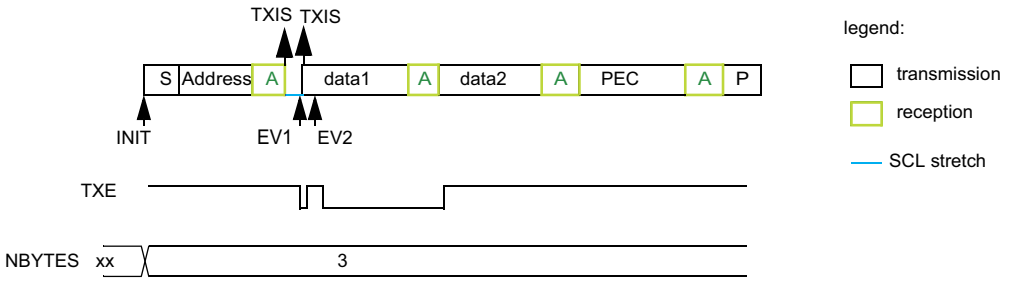
When the SMBus master wants to send a RESTART condition after the PEC, software mode must be selected (AUTOEND = 0). In this case, once NBYTES - 1 have been

transmitted, the I2C_PECR register content is transmitted and the TC flag is set after the PEC transmission, stretching the SCL line low. The RESTART condition must be programmed in the TC interrupt subroutine.

Caution: The PECBYTE bit has no effect when the RELOAD bit is set.

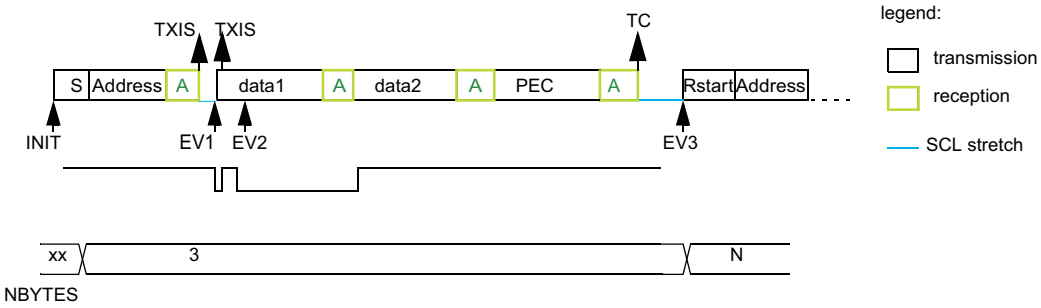
Figure 649. Bus transfer diagrams for SMBus master transmitter

Example SMBus master transmitter 2 bytes + PEC, automatic end mode (STOP)



INIT: program Slave address, program NBYTES = 3, AUTOEND=1, set PECBYTE, set START
EV1: TXIS ISR: wr data1
EV2: TXIS ISR: wr data2

Example SMBus master transmitter 2 bytes + PEC, software end mode (RESTART)



INIT: program Slave address, program NBYTES = 3, AUTOEND=0, set PECBYTE, set START
EV1: TXIS ISR: wr data1
EV2: TXIS ISR: wr data2
EV3: TC ISR: program Slave address, program NBYTES = N, set START

MS19871V2

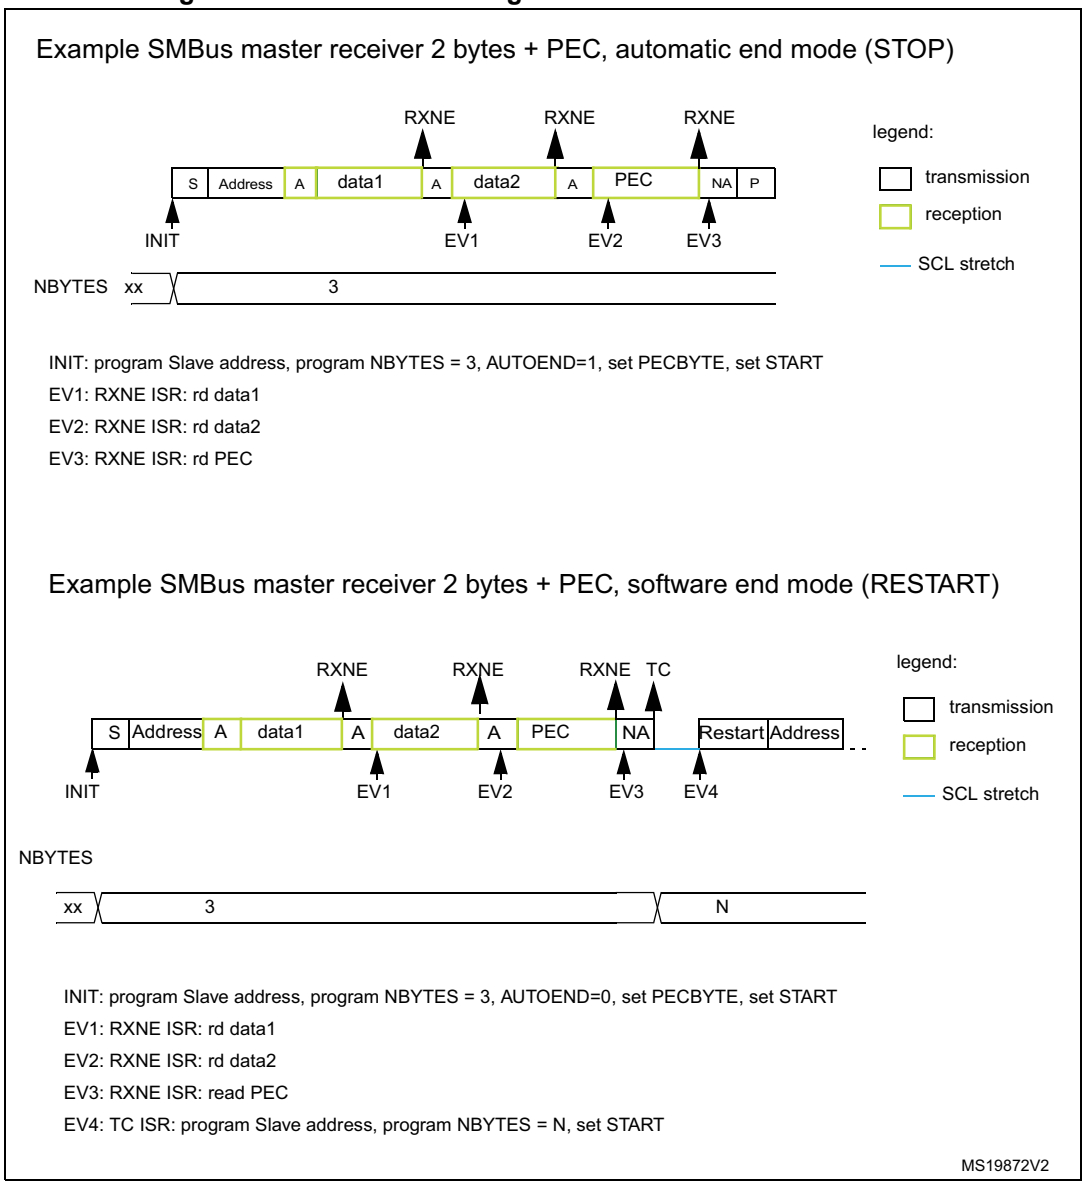
SMBus master receiver

When the SMBus master wants to receive the PEC followed by a STOP at the end of the transfer, automatic end mode can be selected (AUTOEND = 1). The PECBYTE bit must be set and the slave address must be programmed, before setting the START bit. In this case, after NBYTES - 1 data have been received, the next received byte is automatically checked versus the I2C_PECR register content. A NACK response is given to the PEC byte, followed by a STOP condition.

When the SMBus master receiver wants to receive the PEC byte followed by a RESTART condition at the end of the transfer, software mode must be selected (AUTOEND = 0). The PECBYTE bit must be set and the slave address must be programmed, before setting the START bit. In this case, after NBYTES - 1 data have been received, the next received byte is automatically checked versus the I2C_PECR register content. The TC flag is set after the PEC byte reception, stretching the SCL line low. The RESTART condition can be programmed in the TC interrupt subroutine.

Caution: The PECBYTE bit has no effect when the RELOAD bit is set.

Figure 650. Bus transfer diagrams for SMBus master receiver



48.4.15 Wake-up from Stop mode on address match

This section is relevant only when wake-up from Stop mode feature is supported (refer to *Section 48.3*).

The I2C is able to wake-up the MCU from Stop mode (APB clock is off), when it is addressed. All addressing modes are supported.

Wake-up from Stop mode is enabled by setting the WUPEN bit in the I2C_CR1 register. The HSI and CSI only oscillator must be selected as the clock source for I2CCLK in order to allow wake-up from Stop mode.

During Stop mode, the HSI and CSI only is switched off. When a START is detected, the I2C interface switches the HSI and CSI only on, and stretches SCL low until HSI and CSI only is woken up.

HSI and CSI only is then used for the address reception.

In case of an address match, the I2C stretches SCL low during MCU wake-up time. The stretch is released when ADDR flag is cleared by software, and the transfer goes on normally.

If the address does not match, the HSI and CSI only is switched off again and the MCU is not woken up.

Note: If the I2C clock is the system clock, or if WUPEN = 0, the HSI and CSI only *is not switched on after a START is received.*

Only an ADDR interrupt can wake-up the MCU. Therefore do not enter Stop mode when the I2C is performing a transfer as a master, or as an addressed slave after the ADDR flag is set. This can be managed by clearing SLEEPDEEP bit in the ADDR interrupt routine and setting it again only after the STOPF flag is set.

Caution: The digital filter is not compatible with the wake-up from Stop mode feature. If the DNF bit is not equal to 0, setting the WUPEN bit has no effect.

Caution: This feature is available only when the I2C clock source is the HSI and CSI only oscillator.

Caution: Clock stretching must be enabled (NOSTRETCH = 0) to ensure proper operation of the wake-up from Stop mode feature.

Caution: If wake-up from Stop mode is disabled (WUPEN = 0), the I2C peripheral must be disabled before entering Stop mode (PE = 0).

48.4.16 Error conditions

The following errors are the conditions that can cause a communication fail.

Bus error (BERR)

A bus error is detected when a START or a STOP condition is detected and is not located after a multiple of nine SCL clock pulses. A START or a STOP condition is detected when an SDA edge occurs while SCL is high.

The bus error flag is set only if the I2C is involved in the transfer as master or addressed slave (i.e not during the address phase in slave mode).

In case of a misplaced START or RESTART detection in slave mode, the I2C enters address recognition state like for a correct START condition.

When a bus error is detected, the BERR flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

Arbitration lost (ARLO)

An arbitration loss is detected when a high level is sent on the SDA line, but a low level is sampled on the SCL rising edge.

- In master mode, arbitration loss is detected during the address phase, data phase and data acknowledge phase. In this case, the SDA and SCL lines are released, the START control bit is cleared by hardware and the master switches automatically to slave mode.
- In slave mode, arbitration loss is detected during data phase and data acknowledge phase. In this case, the transfer is stopped, and the SCL and SDA lines are released.

When an arbitration loss is detected, the ARLO flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

Overrun/underrun error (OVR)

An overrun or underrun error is detected in slave mode when NOSTRETCH = 1 and:

- In reception when a new byte is received and the RXDR register has not been read yet. The new received byte is lost, and a NACK is automatically sent as a response to the new byte.
- In transmission:
  - When STOPF = 1 and the first data byte must be sent. The content of the I2C_TXDR register is sent if TXE = 0, 0xFF if not.
  - When a new byte must be sent and the I2C_TXDR register has not been written yet, 0xFF is sent.

When an overrun or underrun error is detected, the OVR flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

Packet error checking error (PECERR)

This section is relevant only when the SMBus feature is supported (refer to *Section 48.3*).

A PEC error is detected when the received PEC byte does not match with the I2C_PECR register content. A NACK is automatically sent after the wrong PEC reception.

When a PEC error is detected, the PECERR flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

Timeout error (TIMEOUT)

This section is relevant only when the SMBus feature is supported (refer to *Section 48.3*).

A timeout error occurs for any of these conditions:

- TIDLE = 0 and SCL remained low for the time defined in the TIMEOUTA[11:0] bits: this is used to detect an SMBus timeout.
- TIDLE = 1 and both SDA and SCL remained high for the time defined in the TIMEOUTA [11:0] bits: this is used to detect a bus idle condition.
- Master cumulative clock low extend time reached the time defined in the TIMEOUTB[11:0] bits (SMBus $t_{LOW:MEXT}$ parameter).
- Slave cumulative clock low extend time reached the time defined in TIMEOUTB[11:0] bits (SMBus $t_{LOW:SEXT}$ parameter).

When a timeout violation is detected in master mode, a STOP condition is automatically sent.

When a timeout violation is detected in slave mode, SDA and SCL lines are automatically released.

When a timeout error is detected, the TIMEOUT flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

Alert (ALERT)

This section is relevant only when the SMBus feature is supported (refer to *Section 48.3*).

The ALERT flag is set when the I2C interface is configured as a Host (SMBHEN = 1), the alert pin detection is enabled (ALERTEN = 1) and a falling edge is detected on the SMBA pin. An interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

48.4.17 DMA requests

Transmission using DMA

DMA (direct memory access) can be enabled for transmission by setting the TXDMAEN bit in the I2C_CR1 register. Data is loaded from an SRAM area configured using the DMA peripheral (see *Section 11: Direct memory access controller (DMA) on page 359*) to the I2C_TXDR register whenever the TXIS bit is set.

Only the data are transferred with DMA.

- In master mode: the initialization, the slave address, direction, number of bytes and START bit are programmed by software (the transmitted slave address cannot be transferred with DMA). When all data are transferred using DMA, the DMA must be initialized before setting the START bit. The end of transfer is managed with the NBYTES counter. Refer to *Master transmitter*.
- In slave mode:
  - With NOSTRETCH = 0, when all data are transferred using DMA, the DMA must be initialized before the address match event, or in ADDR interrupt subroutine, before clearing ADDR.
  - With NOSTRETCH = 1, the DMA must be initialized before the address match event.
- For instances supporting SMBus: the PEC transfer is managed with NBYTES counter. Refer to *SMBus slave transmitter* and *SMBus master transmitter*.

Note: If DMA is used for transmission, the TXIE bit does not need to be enabled.

Reception using DMA

DMA (direct memory access) can be enabled for reception by setting the RXDMAEN bit in the I2C_CR1 register. Data is loaded from the I2C_RXDR register to an SRAM area configured using the DMA peripheral (refer to *Section 11: Direct memory access controller (DMA) on page 359*) whenever the RXNE bit is set. Only the data (including PEC) are transferred with DMA.

- In master mode, the initialization, the slave address, direction, number of bytes and START bit are programmed by software. When all data are transferred using DMA, the DMA must be initialized before setting the START bit. The end of transfer is managed with the NBYTES counter.
- In slave mode with NOSTRETCH = 0, when all data are transferred using DMA, the DMA must be initialized before the address match event, or in the ADDR interrupt subroutine, before clearing the ADDR flag.
- If SMBus is supported (see *Section 48.3*) the PEC transfer is managed with the NBYTES counter. Refer to *SMBus slave receiver* and *SMBus master receiver*.

Note: If DMA is used for reception, the RXIE bit does not need to be enabled.

48.4.18 Debug mode

When the microcontroller enters debug mode (core halted), the SMBus timeout either continues to work normally or stops, depending on the DBG_I2Cx_ configuration bits in the DBG module.

48.5 I2C low-power modes

Table 512. Effect of low-power modes on the I2C

Mode	Description
Sleep	No effect. I2C interrupts cause the device to exit the Sleep mode.
Stop(1)	The I2C registers content is kept. – WUPEN = 1 and I2C is clocked by an internal oscillator (HSI and CSI only): the address recognition is functional. The I2C address match condition causes the device to exit the Stop mode. – WUPEN = 0: the I2C must be disabled before entering Stop mode.
Standby	The I2C peripheral is powered down and must be reinitialized after exiting Standby mode.

1. Refer to *Section 48.3* for information about the Stop modes supported by each instance. If wake-up from a specific Stop mode is not supported, the instance must be disabled before entering this Stop mode.

48.6 I2C interrupts

The following table gives the list of I2C interrupt requests.

Table 513. I2C interrupt requests

Interrupt acronym		Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit Sleep mode	Exit Stop modes	Exit Standby modes
I2C	I2C_EV	Receive buffer not empty	RXNE	RXIE	Read I2C_RXDR register	Yes	No	No
		Transmit buffer interrupt status	TXIS	TXIE	Write I2C_TXDR register			
		Stop detection interrupt flag	STOPF	STOPIE	Write STOPCF = 1			
		Transfer complete reload	TCR	TCIE	Write I2C_CR2 with NBYTES[7:0] ≠ 0			
		Transfer complete	TC		Write START = 1 or STOP = 1			
		Address matched	ADDR	ADDRIE	Write ADDRCF = 1		Yes(1)	
		NACK reception	NACKF	NACKIE	Write NACKCF = 1		No	
	I2C_ER	Bus error	BERR	ERRIE	Write BERRCF = 1	Yes	No	No
		Arbitration loss	ARLO		Write ARLOCF = 1			
		Overrun/ Underrun	OVR		Write OVRCF = 1			
		PEC error	PECERR		Write PECERRCF = 1			
		Timeout/ t_{LOW} error	TIMEOUT		Write TIMEOUTCF = 1			
		SMBus alert	ALERT		Write ALERTCF = 1			

1. The ADDR match event can wake up the device from Stop mode only if the I2C instance supports the Wake-up from Stop mode feature. Refer to *Section 48.3*.

48.7 I2C registers

Refer to *Section 1.2 on page 101* for a list of abbreviations used in register descriptions.

The peripheral registers are accessed by words (32-bit).

48.7.1 I2C control register 1 (I2C_CR1)

Address offset: 0x00

Reset value: 0x0000 0000

Access: no wait states, except if a write access occurs while a write access is ongoing. In this case, wait states are inserted in the second write access, until the previous one is completed. The latency of the second write access can be up to 2 x i2c_pclk + 6 x i2c_ker_ck.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
STOPFACLR	ADDRACLR	Res.	Res.	Res.	Res.	Res.	FMP	PECEN	ALERTEN	SMBDEN	SMBHEN	GCEN	WUPEN	NOSTRETCH	SBC
rw	rw						rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RXDMAEN	TXDMAEN	Res.	ANFOFF	DNF[3:0]				ERRIE	TCIE	STOPIE	NACKIE	ADDRIE	RXIE	TXIE	PE
rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **STOPFACLR**: STOP detection flag (STOPF) automatic clear

0: STOPF flag is set by hardware, cleared by software by setting STOPCF bit.

1: STOPF flag remains cleared by hardware. This mode can be used in NOSTRETCH slave mode, to avoid the overrun error if the STOPF flag is not cleared before next data transmission. This allows a slave data management by DMA only, without any interrupt from peripheral.

Bit 30 **ADDRACLR**: Address match flag (ADDR) automatic clear

0: ADDR flag is set by hardware, cleared by software by setting ADDRCF bit.

1: ADDR flag remains cleared by hardware. This mode can be used in slave mode, to avoid the ADDR clock stretching if the I2C enables only one slave address. This allows a slave data management by DMA only, without any interrupt from peripheral.

Bits 29:25 Reserved, must be kept at reset value.

Bit 24 **FMP**: Fast-mode Plus 20 mA drive enable

0: 20 mA I/O drive disabled

1: 20 mA I/O drive enabled

Bit 23 **PECEN:** PEC enable

0: PEC calculation disabled

1: PEC calculation enabled

Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 48.3.

Bit 22 **ALERTEN**: SMBus alert enable

0: The SMBus alert pin (SMBA) is not supported in host mode (SMBHEN = 1). In device mode (SMBHEN = 0), the SMBA pin is released and the Alert Response Address header is disabled (0001100x followed by NACK).
1: The SMBus alert pin is supported in host mode (SMBHEN = 1). In device mode (SMBHEN = 0), the SMBA pin is driven low and the Alert Response Address header is enabled (0001100x followed by ACK).

Note: When ALERTEN = 0, the SMBA pin can be used as a standard GPIO.
If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 48.3.

Bit 21 **SMBDEN**: SMBus device default address enable

0: Device default address disabled. Address 0b1100001x is NACKed.
1: Device default address enabled. Address 0b1100001x is ACKed.

Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 48.3.

Bit 20 **SMBHEN**: SMBus host address enable

0: Host address disabled. Address 0b0001000x is NACKed.
1: Host address enabled. Address 0b0001000x is ACKed.

Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 48.3.

Bit 19 **GCEN**: General call enable

0: General call disabled. Address 0b00000000 is NACKed.
1: General call enabled. Address 0b00000000 is ACKed.

Bit 18 **WUPEN**: Wake-up from Stop mode enable

0: Wake-up from Stop mode disable.
1: Wake-up from Stop mode enable.

Note: If the wake-up from Stop mode feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 48.3.

Note: WUPEN can be set only when DNF = '0000'

Bit 17 **NOSTRETCH**: Clock stretching disable

This bit is used to disable clock stretching in slave mode. It must be kept cleared in master mode.
0: Clock stretching enabled
1: Clock stretching disabled

Note: This bit can be programmed only when the I2C is disabled (PE = 0).

Bit 16 **SBC**: Slave byte control

This bit is used to enable hardware byte control in slave mode.
0: Slave byte control disabled
1: Slave byte control enabled

Bit 15 **RXDMAEN**: DMA reception requests enable

0: DMA mode disabled for reception
1: DMA mode enabled for reception

Bit 14 **TXDMAEN**: DMA transmission requests enable

0: DMA mode disabled for transmission
1: DMA mode enabled for transmission

Bit 13 Reserved, must be kept at reset value.

Bit 12 **ANFOFF:** Analog noise filter OFF
0: Analog noise filter enabled
1: Analog noise filter disabled
Note: This bit can be programmed only when the I2C is disabled (PE = 0).

Bits 11:8 **DNF[3:0]**: Digital noise filter
These bits are used to configure the digital noise filter on SDA and SCL input. The digital filter, filters spikes with a length of up to DNF[3:0] * t_{I2CCLK}
0000: Digital filter disabled
0001: Digital filter enabled and filtering capability up to 1 t_{I2CCLK}
...
1111: digital filter enabled and filtering capability up to15 t_{I2CCLK}
Note: If the analog filter is enabled, the digital filter is added to it.
This filter can be programmed only when the I2C is disabled (PE = 0).

Bit 7 **ERRIE**: Error interrupts enable
0: Error detection interrupts disabled
1: Error detection interrupts enabled
Note: Any of these errors generate an interrupt:
Arbitration loss (ARLO)
Bus error detection (BERR)
Overrun/Underrun (OVR)
Timeout detection (TIMEOUT)
PEC error detection (PECERR)
Alert pin event detection (ALERT)

Bit 6 **TCIE**: Transfer complete interrupt enable
0: Transfer complete interrupt disabled
1: Transfer complete interrupt enabled
Note: Any of these events generate an interrupt:
Transfer complete (TC)
Transfer complete reload (TCR)

Bit 5 **STOPIE**: Stop detection interrupt enable
0: Stop detection (STOPF) interrupt disabled
1: Stop detection (STOPF) interrupt enabled

Bit 4 **NACKIE**: Not acknowledge received interrupt enable
0: Not acknowledge (NACKF) received interrupts disabled
1: Not acknowledge (NACKF) received interrupts enabled

Bit 3 **ADDRIE**: Address match interrupt enable (slave only)
0: Address match (ADDR) interrupts disabled
1: Address match (ADDR) interrupts enabled

Bit 2 **RXIE**: RX interrupt enable
0: Receive (RXNE) interrupt disabled
1: Receive (RXNE) interrupt enabled

Bit 1 **TXIE**: TX interrupt enable
0: Transmit (TXIS) interrupt disabled
1: Transmit (TXIS) interrupt enabled

Bit 0 **PE**: Peripheral enable
0: Peripheral disable
1: Peripheral enable
Note: When PE = 0, the I2C SCL and SDA lines are released. Internal state machines and status bits are put back to their reset value. When cleared, PE must be kept low for at least three APB clock cycles.

48.7.2 I2C control register 2 (I2C_CR2)

Address offset: 0x04

Reset value: 0x0000 0000

Access: no wait states, except if a write access occurs while a write access is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to 2 x i2c_pclk + 6 x i2c_ker_ck.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	PEC BYTE	AUTO END	RE LOAD	NBYTES[7:0]							
					rs	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NACK	STOP	START	HEAD10R	ADD10	RD_WRN	SADD[9:0]									
rs	rs	rs	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **PECBYTE**: Packet error checking byte
This bit is set by software, and cleared by hardware when the PEC is transferred, or when a STOP condition or an Address matched is received, also when PE = 0.
0: No PEC transfer.
1: PEC transmission/reception is requested
Note: Writing 0 to this bit has no effect.
This bit has no effect when RELOAD is set.
This bit has no effect is slave mode when SBC = 0.
If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 48.3.

Bit 25 **AUTOEND**: Automatic end mode (master mode)
This bit is set and cleared by software.
0: software end mode: TC flag is set when NBYTES data are transferred, stretching SCL low.
1: Automatic end mode: a STOP condition is automatically sent when NBYTES data are transferred.
Note: This bit has no effect in slave mode or when the RELOAD bit is set.

Bit 24 **RELOAD**: NBYTES reload mode
This bit is set and cleared by software.
0: The transfer is completed after the NBYTES data transfer (STOP or RESTART follows).
1: The transfer is not completed after the NBYTES data transfer (NBYTES is reloaded). TCR flag is set when NBYTES data are transferred, stretching SCL low.

Bits 23:16 **NBYTES[7:0]**: Number of bytes

The number of bytes to be transmitted/received is programmed there. This field is don't care in slave mode with SBC = 0.

Note: Changing these bits when the START bit is set is not allowed.

Bit 15 **NACK**: NACK generation (slave mode)

The bit is set by software, cleared by hardware when the NACK is sent, or when a STOP condition or an Address matched is received, or when PE = 0.

0: an ACK is sent after current received byte.

1: a NACK is sent after current received byte.

Note: Writing 0 to this bit has no effect.

This bit is used in slave mode only: in master receiver mode, NACK is automatically generated after last byte preceding STOP or RESTART condition, whatever the NACK bit value.

When an overrun occurs in slave receiver NOSTRETCH mode, a NACK is automatically generated, whatever the NACK bit value.

When hardware PEC checking is enabled (PECBYTE = 1), the PEC acknowledge value does not depend on the NACK value.

Bit 14 **STOP**: Stop generation (master mode)

The bit is set by software, cleared by hardware when a STOP condition is detected, or when PE = 0.

In master mode:

0: No Stop generation.

1: Stop generation after current byte transfer.

Note: Writing 0 to this bit has no effect.

Bit 13 **START**: Start generation

This bit is set by software, and cleared by hardware after the Start followed by the address sequence is sent, by an arbitration loss, by an address matched in slave mode, by a timeout error detection, or when PE = 0.

0: No Start generation.

1: Restart/Start generation:

If the I2C is already in master mode with AUTOEND = 0, setting this bit generates a Repeated start condition when RELOAD = 0, after the end of the NBYTES transfer.

Otherwise setting this bit generates a START condition once the bus is free.

Note: Writing 0 to this bit has no effect.

The START bit can be set even if the bus is BUSY or I2C is in slave mode.

This bit has no effect when RELOAD is set.

Bit 12 **HEAD10R**: 10-bit address header only read direction (master receiver mode)

0: The master sends the complete 10-bit slave address read sequence: Start + 2 bytes 10-bit address in write direction + Restart + first seven bits of the 10-bit address in read direction.

1: The master only sends the first seven bits of the 10-bit address, followed by Read direction.

Note: Changing this bit when the START bit is set is not allowed.

Bit 11 **ADD10**: 10-bit addressing mode (master mode)

0: The master operates in 7-bit addressing mode,

1: The master operates in 10-bit addressing mode

Note: Changing this bit when the START bit is set is not allowed.

Bit 10 **RD_WRN**: Transfer direction (master mode)
0: Master requests a write transfer.
1: Master requests a read transfer.
Note: Changing this bit when the START bit is set is not allowed.

Bits 9:0 **SADD[9:0]**: Slave address (master mode)
In 7-bit addressing mode (ADD10 = 0):
SADD[7:1] must be written with the 7-bit slave address to be sent. The bits SADD[9], SADD[8] and SADD[0] are don't care.
In 10-bit addressing mode (ADD10 = 1):
SADD[9:0] must be written with the 10-bit slave address to be sent.
Note: Changing these bits when the START bit is set is not allowed.

48.7.3 I2C own address 1 register (I2C_OAR1)

Address offset: 0x08

Reset value: 0x0000 0000

Access: no wait states, except if a write access occurs while a write access is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to 2 x i2c_pclk + 6 x i2c_ker_ck.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

OA1EN	Res.	Res.	Res.	Res.	OA1 MODE	OA1[9:0]									
rw					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **OA1EN**: Own address 1 enable
0: Own address 1 disabled. The received slave address OA1 is NACKed.
1: Own address 1 enabled. The received slave address OA1 is ACKed.

Bits 14:11 Reserved, must be kept at reset value.

Bit 10 **OA1MODE**: Own address 1 10-bit mode
0: Own address 1 is a 7-bit address.
1: Own address 1 is a 10-bit address.
Note: This bit can be written only when OA1EN = 0.

Bits 9:0 **OA1[9:0]**: Interface own slave address
7-bit addressing mode: OA1[7:1] contains the 7-bit own slave address. The bits OA1[9], OA1[8] and OA1[0] are don't care.
10-bit addressing mode: OA1[9:0] contains the 10-bit own slave address.
Note: These bits can be written only when OA1EN = 0.

48.7.4 I2C own address 2 register (I2C_OAR2)

Address offset: 0x0C

Reset value: 0x0000 0000

Access: no wait states, except if a write access occurs while a write access is ongoing. In this case, wait states are inserted in the second write access, until the previous one is completed. The latency of the second write access can be up to 2x i2c_pclk + 6 x i2c_ker_ck.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OA2EN	Res.	Res.	Res.	Res.	OA2MSK[2:0]			OA2[7:1]							Res.
rw					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **OA2EN**: Own address 2 enable
0: Own address 2 disabled. The received slave address OA2 is NACKed.
1: Own address 2 enabled. The received slave address OA2 is ACKed.

Bits 14:11 Reserved, must be kept at reset value.

Bits 10:8 **OA2MSK[2:0]**: Own address 2 masks
000: No mask
001: OA2[1] is masked and don't care. Only OA2[7:2] are compared.
010: OA2[2:1] are masked and don't care. Only OA2[7:3] are compared.
011: OA2[3:1] are masked and don't care. Only OA2[7:4] are compared.
100: OA2[4:1] are masked and don't care. Only OA2[7:5] are compared.
101: OA2[5:1] are masked and don't care. Only OA2[7:6] are compared.
110: OA2[6:1] are masked and don't care. Only OA2[7] is compared.
111: OA2[7:1] are masked and don't care. No comparison is done, and all (except reserved) 7-bit received addresses are acknowledged.

Note: These bits can be written only when OA2EN = 0.

As soon as OA2MSK is not equal to 0, the reserved I2C addresses (0b0000xxx and 0b1111xxx) are not acknowledged even if the comparison matches.

Bits 7:1 **OA2[7:1]**: Interface address
7-bit addressing mode: 7-bit address

Note: These bits can be written only when OA2EN = 0.

Bit 0 Reserved, must be kept at reset value.

48.7.5 I2C timing register (I2C_TIMINGR)

Address offset: 0x10

Reset value: 0x0000 0000

Access: no wait states

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PRESC[3:0]				Res.	Res.	Res.	Res.	SCLDEL[3:0]				SDADEL[3:0]			
rw	rw	rw	rw					rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SCLH[7:0]								SCLL[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 **PRESC[3:0]**: Timing prescaler

This field is used to prescale i2c_ker_ck in order to generate the clock period t_{PRESC} used for data setup and hold counters (refer to *I2C timings*) and for SCL high and low level counters (refer to *I2C master initialization*).

t_{PRESC} = (PRESC + 1) x t_{I2CCLK}

Bits 27:24 Reserved, must be kept at reset value.

Bits 23:20 **SCLDEL[3:0]**: Data setup time

This field is used to generate a delay t_{SCLDEL} between SDA edge and SCL rising edge. In master mode and in slave mode with NOSTRETCH = 0, the SCL line is stretched low during t_{SCLDEL}.

t_{SCLDEL} = (SCLDEL + 1) x t_{PRESC}

Note: t_{SCLDEL} is used to generate $t_{SU:DAT}$ timing.

Bits 19:16 **SDADEL[3:0]**: Data hold time

This field is used to generate the delay t_{SDADEL} between SCL falling edge and SDA edge. In master mode and in slave mode with NOSTRETCH = 0, the SCL line is stretched low during t_{SDADEL}.

t_{SDADEL}= SDADEL x t_{PRESC}

Note: SDADEL is used to generate $t_{HD:DAT}$ timing.

Bits 15:8 **SCLH[7:0]**: SCL high period (master mode)

This field is used to generate the SCL high period in master mode.

t_{SCLH} = (SCLH + 1) x t_{PRESC}

Note: SCLH is also used to generate $t_{SU:STO}$ and $t_{HD:STA}$ timing.

Bits 7:0 **SCLL[7:0]**: SCL low period (master mode)

This field is used to generate the SCL low period in master mode.

t_{SCLL} = (SCLL + 1) x t_{PRESC}

Note: SCLL is also used to generate t_{BUF} and $t_{SU:STA}$ timings.

Note: This register must be configured when the I2C is disabled (PE = 0).

Note: The STM32CubeMX tool calculates and provides the I2C_TIMINGR content in the I2C Configuration window.

48.7.6 I2C timeout register (I2C_TIMEOUTR)

Address offset: 0x14

Reset value: 0x0000 0000

Access: no wait states, except if a write access occurs while a write access is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to 2 x i2c_pclk + 6 x i2c_ker_ck.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TEXTEN	Res.	Res.	Res.	TIMEOUTB[11:0]											
rw				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TIMOUTEN	Res.	Res.	TIDLE	TIMEOUTA[11:0]											
rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **TEXTEN**: Extended clock timeout enable
0: Extended clock timeout detection is disabled
1: Extended clock timeout detection is enabled. When a cumulative SCL stretch for more than $t_{LOW:EXT}$ is done by the I2C interface, a timeout error is detected (TIMEOUT = 1).

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 **TIMEOUTB[11:0]**: Bus timeout B
This field is used to configure the cumulative clock extension timeout:
In master mode, the master cumulative clock low extend time ($t_{LOW:MEXT}$) is detected
In slave mode, the slave cumulative clock low extend time ($t_{LOW:SEXT}$) is detected
$t_{LOW:EXT}$ = (TIMEOUTB + TIDLE = 01) x 2048 x t_{I2CCLK}
Note: These bits can be written only when TEXTEN = 0.

Bit 15 **TIMOUTEN**: Clock timeout enable
0: SCL timeout detection is disabled
1: SCL timeout detection is enabled: when SCL is low for more than $t_{TIMEOUT}$ (TIDLE = 0) or high for more than t_{IDLE} (TIDLE = 1), a timeout error is detected (TIMEOUT = 1).

Bits 14:13 Reserved, must be kept at reset value.

Bit 12 **TIDLE**: Idle clock timeout detection
0: TIMEOUTA is used to detect SCL low timeout
1: TIMEOUTA is used to detect both SCL and SDA high timeout (bus idle condition)
Note: This bit can be written only when TIMOUTEN = 0.

Bits 11:0 **TIMEOUTA[11:0]**: Bus Timeout A
This field is used to configure:
The SCL low timeout condition $t_{TIMEOUT}$ when TIDLE = 0
$t_{TIMEOUT}$= (TIMEOUTA + 1) x 2048 x t_{I2CCLK}
The bus idle condition (both SCL and SDA high) when TIDLE = 1
t_{IDLE}= (TIMEOUTA + 1) x 4 x t_{I2CCLK}
Note: These bits can be written only when TIMOUTEN = 0.

Note: If the SMBus feature is not supported, this register is reserved and forced by hardware to "0x00000000". Refer to Section 48.3.

48.7.7 I2C interrupt and status register (I2C_ISR)

Address offset: 0x18

Reset value: 0x0000 0001

Access: no wait states

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ADDCODE[6:0]							DIR
								r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BUSY	Res.	ALERT	TIME OUT	PEC ERR	OVR	ARLO	BERR	TCR	TC	STOPF	NACKF	ADDR	RXNE	TXIS	TXE
r		r	r	r	r	r	r	r	r	r	r	r	r	rs	rs

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:17 **ADDCODE[6:0]**: Address match code (slave mode)

These bits are updated with the received address when an address match event occurs (ADDR = 1).

In the case of a 10-bit address, ADDCODE provides the 10-bit header followed by the two MSBs of the address.

Bit 16 **DIR**: Transfer direction (slave mode)

This flag is updated when an address match event occurs (ADDR = 1).

0: Write transfer, slave enters receiver mode.

1: Read transfer, slave enters transmitter mode.

Bit 15 **BUSY**: Bus busy

This flag indicates that a communication is in progress on the bus. It is set by hardware when a START condition is detected. It is cleared by hardware when a STOP condition is detected, or when PE = 0.

Bit 14 Reserved, must be kept at reset value.

Bit 13 **ALERT**: SMBus alert

This flag is set by hardware when SMBHEN = 1 (SMBus host configuration), ALERTEN = 1 and an SMBALERT event (falling edge) is detected on SMBA pin. It is cleared by software by setting the ALERTCF bit.

Note: This bit is cleared by hardware when PE = 0.

If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 48.3.

Bit 12 **TIMEOUT**: Timeout or t_{LOW} detection flag

This flag is set by hardware when a timeout or extended clock timeout occurred. It is cleared by software by setting the TIMEOUTCF bit.

Note: This bit is cleared by hardware when PE = 0.

If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 48.3.

Bit 11 **PECERR**: PEC Error in reception

This flag is set by hardware when the received PEC does not match with the PEC register content. A NACK is automatically sent after the wrong PEC reception. It is cleared by software by setting the PECCF bit.

Note: This bit is cleared by hardware when PE = 0.

If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 48.3.

Bit 10 **OVR**: Overrun/Underrun (slave mode)

This flag is set by hardware in slave mode with NOSTRETCH = 1, when an overrun/underrun error occurs. It is cleared by software by setting the OVRCF bit.

Note: This bit is cleared by hardware when PE = 0.

Bit 9 **ARLO**: Arbitration lost

This flag is set by hardware in case of arbitration loss. It is cleared by software by setting the ARLOCF bit.

Note: This bit is cleared by hardware when PE = 0.

Bit 8 **BERR**: Bus error

This flag is set by hardware when a misplaced Start or STOP condition is detected whereas the peripheral is involved in the transfer. The flag is not set during the address phase in slave mode. It is cleared by software by setting *BERRCF bit.*

Note: This bit is cleared by hardware when PE = 0.

Bit 7 **TCR**: Transfer Complete Reload

This flag is set by hardware when RELOAD = 1 and NBYTES data have been transferred. It is cleared by software when NBYTES is written to a non-zero value.

Note: This bit is cleared by hardware when PE = 0.

This flag is only for master mode, or for slave mode when the SBC bit is set.

Bit 6 **TC**: Transfer Complete (master mode)

This flag is set by hardware when RELOAD = 0, AUTOEND = 0 and NBYTES data have been transferred. It is cleared by software when START bit or STOP bit is set.

Note: This bit is cleared by hardware when PE = 0.

Bit 5 **STOPF**: Stop detection flag

This flag is set by hardware when a STOP condition is detected on the bus and the peripheral is involved in this transfer:

- either as a master, provided that the STOP condition is generated by the peripheral.
- or as a slave, provided that the peripheral has been addressed previously during this transfer.

It is cleared by software by setting the STOPCF bit.

Note: This bit is cleared by hardware when PE = 0.

Bit 4 **NACKF**: Not Acknowledge received flag

This flag is set by hardware when a NACK is received after a byte transmission. It is cleared by software by setting the NACKCF bit.

Note: This bit is cleared by hardware when PE = 0.

Bit 3 **ADDR**: Address matched (slave mode)

This bit is set by hardware as soon as the received slave address matched with one of the enabled slave addresses. It is cleared by software by setting *ADDRCF bit.*

Note: This bit is cleared by hardware when PE = 0.

Bit 2 **RXNE**: Receive data register not empty (receivers)

This bit is set by hardware when the received data is copied into the I2C_RXDR register, and is ready to be read. It is cleared when I2C_RXDR is read.

Note: This bit is cleared by hardware when PE = 0.

Bit 1 **TXIS**: Transmit interrupt status (transmitters)

This bit is set by hardware when the I2C_TXDR register is empty and the data to be transmitted must be written in the I2C_TXDR register. It is cleared when the next data to be sent is written in the I2C_TXDR register.

This bit can be written to 1 by software only when NOSTRETCH = 1, to generate a TXIS event (interrupt if TXIE = 1 or DMA request if TXDMAEN = 1).

Note: This bit is cleared by hardware when PE = 0.

Bit 0 **TXE**: Transmit data register empty (transmitters)

This bit is set by hardware when the I2C_TXDR register is empty. It is cleared when the next data to be sent is written in the I2C_TXDR register.

This bit can be written to 1 by software in order to flush the transmit data register I2C_TXDR.

Note: This bit is set by hardware when PE = 0.

48.7.8 I2C interrupt clear register (I2C_ICR)

Address offset: 0x1C

Reset value: 0x0000 0000

Access: no wait states

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

		w	w	w	w	w	w			w	w	w			

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **ALERTCF**: Alert flag clear

Writing 1 to this bit clears the ALERT flag in the I2C_ISR register.

Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 48.3.

Bit 12 **TIMOUTCF**: Timeout detection flag clear

Writing 1 to this bit clears the TIMEOUT flag in the I2C_ISR register.

Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 48.3.

Bit 11 **PECCF**: PEC Error flag clear

Writing 1 to this bit clears the PECERR flag in the I2C_ISR register.

Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 48.3.

Bit 10 **OVRCF**: Overrun/Underrun flag clear

Writing 1 to this bit clears the OVR flag in the I2C_ISR register.

Bit 9 **ARLOCF**: Arbitration lost flag clear
Writing 1 to this bit clears the ARLO flag in the I2C_ISR register.

Bit 8 **BERRCF**: Bus error flag clear
Writing 1 to this bit clears the BERRF flag in the I2C_ISR register.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **STOPCF**: STOP detection flag clear
Writing 1 to this bit clears the STOPF flag in the I2C_ISR register.

Bit 4 **NACKCF**: Not Acknowledge flag clear
Writing 1 to this bit clears the NACKF flag in I2C_ISR register.

Bit 3 **ADDRCF**: Address matched flag clear
Writing 1 to this bit clears the ADDR flag in the I2C_ISR register. Writing 1 to this bit also clears the START bit in the I2C_CR2 register.

Bits 2:0 Reserved, must be kept at reset value.

48.7.9 I2C PEC register (I2C_PECR)

Address offset: 0x20

Reset value: 0x0000 0000

Access: no wait states

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PEC[7:0]							
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **PEC[7:0]:** Packet error checking register
This field contains the internal PEC when PECEN=1.
The PEC is cleared by hardware when PE = 0.

Note: If the SMBus feature is not supported, this register is reserved and forced by hardware to "0x00000000". Refer to Section 48.3.

48.7.10 I2C receive data register (I2C_RXDR)

Address offset: 0x24

Reset value: 0x0000 0000

Access: no wait states

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **TXDATA[7:0]:** 8-bit transmit data
Data byte to be transmitted to the I^2C bus
Note: These bits can be written only when TXE = 1.

48.7.12 I2C register map

The table below provides the I2C register map and reset values.

Table 514. I2C register map and reset values

49 Improved inter-integrated circuit (I3C)

49.1 Introduction

The I3C interface handles communication between this device and others, such as sensors and host processor, connected on an I3C bus.

An I3C bus is a two-wire, serial single-ended, multidrop bus, intended to improve a legacy I^2C bus.

The I3C SDR-only peripheral implements all the features required by the MIPI® I3C specification v1.1. It can control all I3C bus-specific sequencing, protocol, arbitration, and timing, and can act as controller (formerly known as master), or as target (formerly known as slave).

When acting as controller, the I3C peripheral improves the features of the I^2C interface preserving some backward compatibility: it allows an I^2C target to operate on an I3C bus in legacy I^2C fast-mode (Fm) or legacy I^2C fast-mode plus (Fm+), provided that the latter does not perform clock stretching.

The I3C peripheral can be used with DMA, to off-load the CPU.

49.2 I3C main features

The I3C peripheral supports:

- MIPI® I3C specification v1.1 (see details in *Table 518*), as:
  - I3C SDR-only primary controller
  - I3C SDR-only secondary controller
  - I3C SDR-only target
- I3C SCL bus clock frequency up to 12.5 MHz
- Registers configuration from the host application via the APB slave port
- Queued data transfers:
  - Transmit FIFO (TX-FIFO) for data bytes/words to be transmitted on the I3C bus
  - Receive FIFO (RX-FIFO) for received data bytes/words on the I3C bus
  - For each FIFO, optional DMA mode with a dedicated DMA channel
- Queued control/status transfers, when controller:
  - Control FIFO (C-FIFO) for control words to be sent on the I3C bus
  - Optional status FIFO (S-FIFO) for status words as received on the I3C bus
  - For each FIFO, optional DMA mode with a dedicated DMA channel
- Messages:
  - Legacy I^2C read/write messages to legacy I^2C targets in Fm/Fm+
  - I3C SDR read/write private messages
  - I3C SDR broadcast CCC messages (see details in *Table 524*)
  - I3C SDR read/write direct CCC messages (see details in *Table 524*)

- Frame-level management, when controller:
  - Optional C-FIFO and TX-FIFO preload
  - Multiple messages encapsulation
  - Optional arbitrable header generation on the I3C bus
  - HDR exit pattern generation on the I3C bus for error recovery
- Programmable bus timing, when controller:
  - SCL high and low period
  - SDA hold time
  - Bus free (minimum) time
  - Bus available/idle condition time
  - Clock stall time
- Target-initiated requests management:
  - Simultaneous support up to four targets, when controller
  - In-band interrupts, with programmable IBI payload (up to 4 bytes), with pending read notification support
  - Bus control request, with recovery flow support and hand-off delay
  - Hot-join mechanism
- HDR exit pattern detection, when target
- Bus error management:
  - CEx with x = 0, 1, 2, 3 when controller
  - TEx with x = 0, 1, ..., 6 when target
  - Bus control switch error and recovery
  - Target reset
- Individual programmable event-based management:
  - Per-event identification with flag reporting and clear control
  - Host application notification via flag polling, and/or via interrupt with a per-event programmable enable
  - Error type identification
- Wake-up from Stop mode(s), as controller (see *Section 49.3.2*):
  - On an in-band interrupt without payload
  - On a hot-join request
  - On a controller-role request
- Wakeup from Stop mode(s), as target (see *Section 49.3.2*):
  - On a reset pattern
  - On a missed start
- Multiclock domain management:
  - Separate APB clock and kernel clock, driven from independently programmed clock sources via the RCC, in addition to SCL clock
  - Minimum operating frequency for the kernel clock and the APB clock vs. the application-driven SCL clock (see clocks constraints in *Section 49.6.2*)

49.3 I3C implementation

49.3.1 I3C instantiation

There is a single I3C instance in the device.

49.3.2 I3C wake-up from low-power mode(s)

The peripheral can wake up the device from a low-power mode, as detailed in *Table 515*. For more details about the wake-up capabilities, refer to *Section 49.13*.

Table 515. I3C wake-up

Wake-up
From Stop mode with SVOS3

49.3.3 I3C FIFOs

The FIFOs are implemented as defined in *Table 516*.

Table 516. I3C FIFOs implementation

FIFO	Content	Unit	Size (in unit)	Used as controller/target (rationale)
C-FIFO	(32-bit) Control words	Word	2	Controller (a frame can be based on multiple control words; this is not the case as target)
S-FIFO	(32-bit) Status words			Controller (target: status only in register mode)
TX-FIFO	Transmitted data	Byte	8	Controller and target
RX-FIFO	Received data			

49.3.4 I3C triggers

This feature is not available in this product: no hardware trigger signal is connected as an input to the I3C peripheral.

49.3.5 I3C interrupt(s)

The interrupt mapping is implemented as detailed in *Table 517*.

Table 517. I3C interrupt(s)

Signal name	Signal type	Description
i3c_err_it	O	Error interrupt line
i3c_evt_it	O	Event interrupt line

49.3.6 I3C MIPI® support

The I3C peripheral supports the MIPI specification v1.1, as defined in *Table 518*.

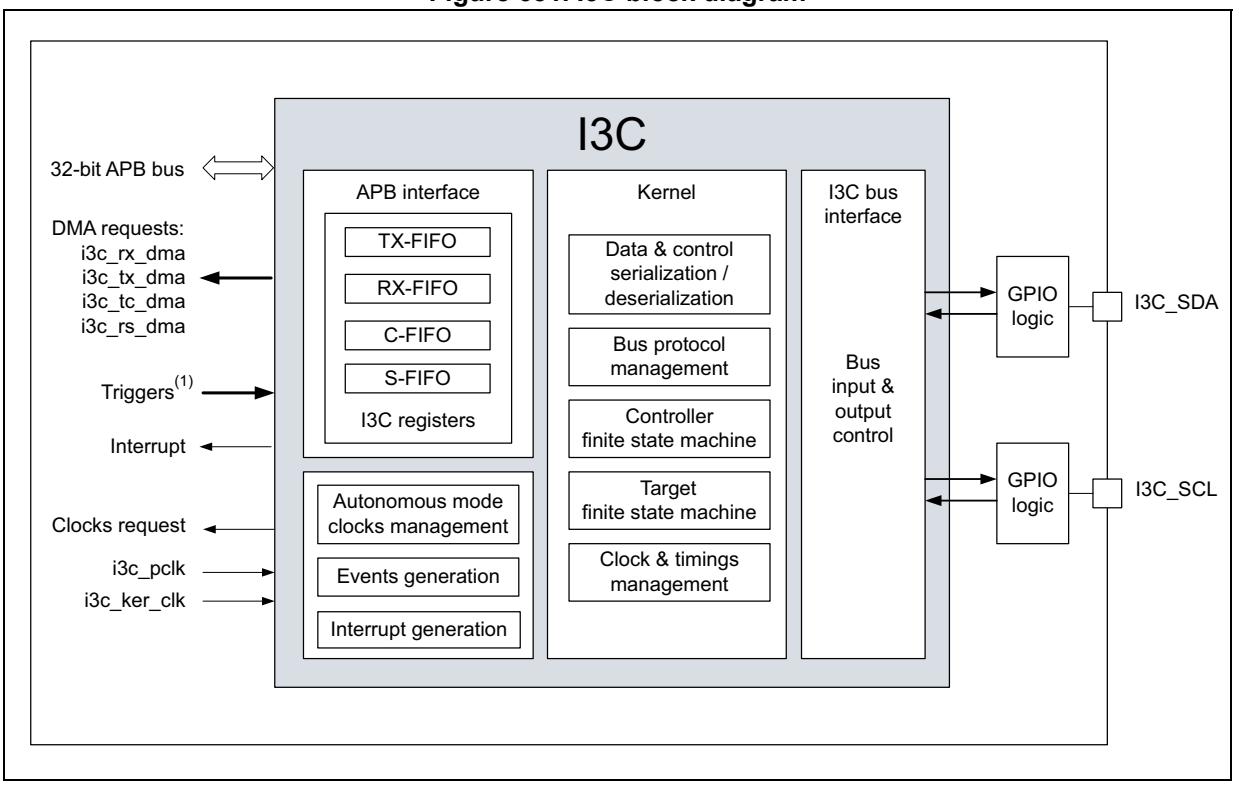
Table 518. I3C peripheral controller/target features versus MIPI v1.1

Feature	MIPI I3C v1.1	I3C peripheral		Comments
		When controller	When target	
I3C SDR message	X	X	X	-
Legacy I^2C message (Fm/Fm+)	X	X	-	Mandatory when controller, and the I3C bus is mixed with (external) legacy I^2C target(s). Optional in MIPI v1.1 when target.
HDR DDR message	X	-	-	Optional in MIPI v1.1
HDR-TSL/TSP, HDR-BT	X	-	-	Optional in MIPI v1.1
Dynamic address assignment	X	X	X	-
Static address	X	X	-	No (intended) support of the peripheral as a target on an I^2C bus.
Grouped addressing	X	X	-	Optional in MIPI v1.1
CCCs	X	X	X	Mandatory and some optional CCCs supported (refer to *Table 524* when controller/target).
Error detection and recovery	X	X	X	-
In-band interrupt (with MDB)	X	X	X	-
Secondary controller	X	X	X	-
Hot-join mechanism	X	X	X	-
Target reset	X	X	X	-
Synchronous timing control	X	X	-	Optional in MIPI v1.1
Asynchronous timing control 0	X	X	-	Mandatory in MIPI v1.1 when controller. Optional in MIPI v1.1 when target.
Asynchronous timing control 1, 2, 3	X	-	-	Optional in MIPI v1.1
Device to device tunneling	X	X	-	Optional in MIPI v1.1
Multi-lane data transfer	X	-	-	Optional in MIPI v1.1
Monitoring device early termination	X	-	-	Optional in MIPI v1.1

49.4 I3C block diagram

The I3C block diagram is illustrated in *Figure 651*.

Figure 651. I3C block diagram



1. This feature is implementation-dependent, and can be unavailable. Refer to *Section 49.3.4: I3C triggers*.

49.5 I3C pins and internal signals

Table 519. I3C input/output pins

Pin name	Signal type	Description
I3C_SDA	Bidirectional	I3C bus serial data line
I3C_SCL	Bidirectional	I3C bus serial clock line

Table 520. I3C internal input/output signals

Signal name	Signal type	Description
i3c_pclk	I	APB clock
i3c_ker_clk	I	Kernel clock (also named as I3CCLK)
i3c_pclk_req	O	APB clock request
i3c_ker_clk_req	O	Kernel clock request
i3c_it(1)	O	Global interrupt line

Table 520. I3C internal input/output signals (continued)

Signal name	Signal type	Description
i3c_err_it(1)	O	Error interrupt line
i3c_evt_it(1)	O	Event interrupt line
i3c_rx_dma	O	DMA request for reading received bytes/words from RX-FIFO.
i3c_tx_dma	O	DMA request for writing to be transmitted bytes/words to TX-FIFO.
i3c_tc_dma	O	DMA request for writing to be transmitted control words to C-FIFO, when peripheral acts as controller.
i3c_rs_dma	O	DMA request for reading status words from S-FIFO, when peripheral acts as controller.

1. This signal is implementation-dependent. Refer to *Section 49.3.5*.

49.6 I3C reset and clocks

49.6.1 I3C reset

On a system reset, the I3C peripheral is reset.

Alternatively, the software can reset specifically the peripheral by writing the corresponding reset control bit (I3CxRST) of the reset and clock controller (RCC). Refer to the RCC section of this document for more details.

Additionally, when acting as target, the enabled peripheral (EN = 1 in the I3C_CFGR register) can receive an in-band reset pattern on the I3C bus from the controller. The software is then notified (when RSTF = 1 in the I3C_EVR register and/or the corresponding interrupt is enabled) to perform the requested action, as registered in RSTACT[1:0] of the I3C_DEVR0 register, on the former reception of the broadcast or direct RSTACT CCC. Refer to *Table 524* and *Section 49.16.16* for more details.

This reset interrupt notification can be used to wake up from a low power mode, where the I3C peripheral (typically in the V_{CORE} domain) is active.

For more details about the corresponding low-power mode(s), refer to the power management in the PWR section.

49.6.2 I3C clocks and requirements

As indicated in the *Figure 651*, the I3C peripheral is implemented with several clock domains:

- SCL bus clock: for the I3C bus interface
  - When controller: the user must set and can adjust SCL/SDA timings by programming *I3C timing register 0 (I3C_TIMINGR0)*, *I3C timing register 1 (I3C_TIMINGR1)* and *I3C timing register 2 (I3C_TIMINGR2)*, as summarized in *Controller initialization* and *Updating the configuration for a transfer, as controller*.
  - When target: the user must set and comply with the bus available condition (t_{AVAL} for an in-band interrupt or controller-role request), and the bus idle condition (t_{IDLE} for a hot-join request), by programming *I3C timing register 1 (I3C_TIMINGR1)*, as summarized in *Target initialization*.

- I3CCLK kernel clock: for the I3C protocol management, data and control serialization/deserialization, controller and target finite state machines, bus clock and timings management
- APB clock: for the APB interface, DMA interface, events, and interrupt generation

APB clock and kernel clocks are driven from independently programmed clock sources via the RCC (refer to *Section 11: Reset and clock control (RCC)*).

I3C kernel clock requirement, as controller

According to the intended value of the SCL clock on the bus, the application must guarantee that the frequency of the I3CCLK kernel clock be at least 2x the frequency of the SCL clock

Note: Sustaining $F_{SCL\ max}$ = 12.9 MHz means a frequency of the I3CCLK kernel clock > 25.8 MHz.

I3C kernel clock requirements, as target

According to the intended value of the SCL clock on the bus, the application must guarantee a minimum operating frequency for the I3CCLK kernel clock, meeting the following constraints:

1. Period of the I3CCLK kernel clock < t_{HIGH} (SCL clock high period)
   - $t_{HIGH\ min}$ = 24 ns. A frequency higher than 41.7 MHz guarantees this constraint, which can be relaxed, depending on the I3C bus/controller
2. Period of the I3CCLK kernel clock < t_{CASr} (clock after repeated start condition)
   - $t_{CASr\ min} = t_{CAS\ min} / 2$ = 19.2 ns. A frequency higher than 52 MHz guarantees this constraint, which can be relaxed, depending on the I3C bus/controller
3. Two periods of the I3CCLK kernel clock < t_{LOW_OD} (SCL clock low period in open drain)
   - $t_{LOW\_OD\ min}$ = 200 ns. A frequency higher than 10 MHz guarantees this constraint, which can be relaxed, depending on the I3C bus/controller
4. Frequency of the I3CCLK kernel clock > 2.5x frequency of the SCL clock
   - $F_{SCL\ max}$ = 12.9 MHz. A frequency higher than 32.3 MHz guarantees this constraint, which can be relaxed, depending on the I3C controller

APB clock requirement

According to the intended value of the SCL clock on the bus, the application must guarantee a minimum operating frequency for the APB clock:

APB clock period < 3x (SCL clock period) - I3CCLK kernel clock period

This means that $F_{APB} > [F_{SCL} \times F_{I3CCLK} / (3x\ F_{I3CCLK} - F_{SCL})]$

Note: This equation can be simplified to a minimum value of 5 MHz for the APB frequency.

49.7 I3C peripheral state and programming

49.7.1 I3C peripheral state

The I3C peripheral plays the role of I3C bus controller, or the role of an I3C target. In any case (see*Figure 652* and *Figure 653*) the peripheral is in one of the following states:

- Disabled state:
  - After an I3C reset (system reset or I3C reset from RCC), the peripheral is in disabled state.
  - When the software sets to 1 bit EN in the I3C_CFGR register, the peripheral takes into account the value of the different configuration registers, and switches to the (enabled and) idle state.
- Idle state:
  - After being enabled (EN = 1), the peripheral activates its I3CCLK and SCL clock domains, and is able to communicate on the I3C bus.
  - The software can partly update the I3C peripheral configuration, see *Updating the configuration for a transfer, as controller* and *Updating the configuration of the I3C peripheral, as target* for more details.
  - The peripheral switches to the (enabled and) active state, either:

  a) Once the software initiates a transfer (as controller: when the software initiates a frame transfer; as target: when the software initiates an IBI/CR/HJ request)

  b) Or once the hardware receives a request from another I3C device on the bus (as controller: after a start request from a target and a maximum T_{CAS} time; as target: when receiving a broadcast/direct CCC or a private read/write).
- Active state:
  - The peripheral executes the transfer(s) on the bus
  - When the requested transfer(s) is(are) completed, the software is notified by an event from the *I3C event register (I3C_EVR)*, and the corresponding interrupt is enabled by *I3C interrupt enable register (I3C_IER)*. The peripheral switches to idle state, is still able to communicate on the bus, and can be (partly) reconfigured.

  a) As controller: the raised event/flag can be frame completed (FCF), IBI/controller-role/hot-join request completed (IBIF/CRF/HJF), or transfer error (ERRF)

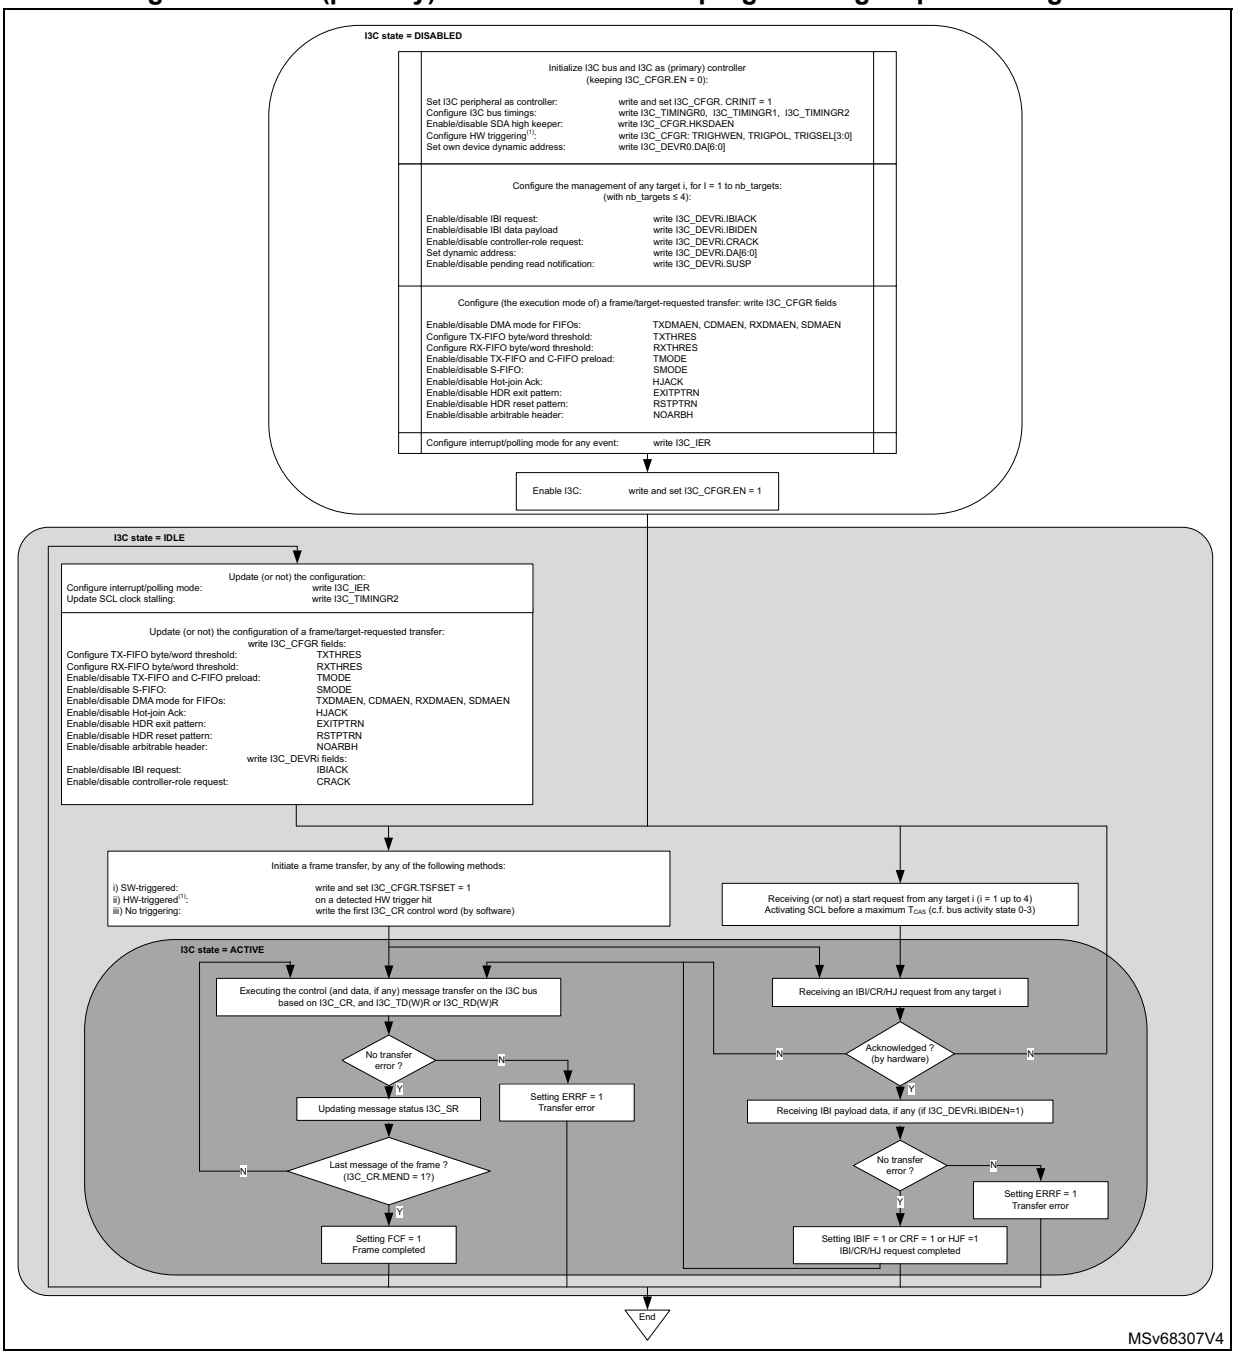
  b) As target: the raised event/flag can be dynamic address assignment completed (DAUPDF), IBI completed (IBIENDF), controller-role gaining completed (CRUPDF), broadcast/direct CCC completed (xxUPDF/RSTF/GETF/STAF), private read/write completed (FCF), or transfer error (ERRF)

Note: The software can disable the peripheral (write EN = 0), partially resetting it (subparts within the SCL clock domain and the I3CCLK kernel clock domain). Event, interrupt, and clock request generation are also impacted. The previously written configuration of the APB registers is kept and not modified.

49.7.2 I3C controller state and programming sequence

Figure 652 illustrates the overall programming sequence of the I3C peripheral acting as (primary) controller, including state transitions, main subtasks, and conditions, as explained in this section.

Figure 652. I3C (primary) controller state and programming sequence diagram



1. This feature is implementation-dependent and can be unavailable. Refer to *Section 49.3.4: I3C triggers*.

Controller initialization

When the controller is in disabled state (EN = 0 in the I3C_CFGR register), the software must initialize as follows:

- Configure *I3C configuration register (I3C_CFGR)* with the following fields:
  - CRINIT = 1: as I3C bus controller
  - HKSDAEN: high keeper on SDA enable/disable
- Configure I3C bus timings:
  a) *I3C timing register 0 (I3C_TIMINGR0)*:
  - SCL clock high time period (t_{DIG_H}, $t_{DIG\_H\_MIXED}$) in legacy I^2C and I3C open-drain/push-pull
  - SCL clock low time period (t_{DIG_L}, $t_{DIG\_OD\_L}$) in legacy I^2C and I3C open-drain/push-pull

  b) *I3C timing register 1 (I3C_TIMINGR1)*:
  - SDA hold time in push-pull (t_{HD_PP})
  - bus free condition time (I3C $t_{CAS,}$ legacy I^2C t_{BUF})
  - I3C repeated start timing (t_{CASr}, t_{CBSr})
  - I3C stop timing (t_{CBP})
  - SCL clock low maximum stalling on the ENTDAA CCC ($t_{STALLDAA}$), or on the ACK/NACK of a legacy I^2C or address phase of an I3C transfer, or the parity bit of a write data transfer, or on the ACK/NACK data phase of a legacy I^2C write, or on the transition bit of an I3C read transfer, or on the ACK/NACK phase of a legacy I^2C write (t_{STALL}), to adjust SCL clock low stalling, if needed by the peripheral itself, when used as controller
  - $t_{NEWCRLock}$ for controller-role hand-off procedure (after GETACCCR CCC)

  c) *I3C timing register 2 (I3C_TIMINGR2)*:
  - SCL clock low stalling time, with separated enable/disable for each phase, to adjust SCL clock low stalling, if needed on the SDA hand-off with the addressed I3C target or legacy I^2C target
- Configure its own dynamic address: DA [6:0] field of the *I3C own device characteristics register (I3C_DEVR0)*
- Configure the management of any device target x: *I3C device x characteristics register (I3C_DEVRx)*, for x = 1 to x ≤ 4
- Configure the execution mode of a frame transfer or a target-requested transfer: *I3C configuration register (I3C_CFGR)*, with the following fields:
  - TXDMAEN, CDMAEN, RXDMAEN, SDMAEN: DMA mode enable/disable for respectively, TX-FIFO, C-FIFO, RX-FIFO, S-FIFO
  - TXTHRES, RXTHRES: respectively TX-FIFO and RX-FIFO byte/world threshold
  - TMODE: transmit mode (enable/disable for both TX-FIFO and C-FIFO preload)
  - SMODE: S-FIFO enable/disable
  - EXITPTRN, RSTPTRN: exit, reset pattern enable/disable
  - HJACK: hot-join acknowledge enable/disable
  - NOARBH: arbitrable header disable/enable
- Configure interrupt generation or polling mode from any event: *I3C interrupt enable register (I3C_IER)*

Then, the software can enable the I3C peripheral (set EN = 1)

Note: The software can write once all the fields of the I3C_CFGR while enabling it.

Start a controller-initiated frame transfer

When the controller is in enabled state (EN = 1 in the I3C_CFGR register), the software can initiate a frame transfer by any of the following configuration methods:

1. Software-triggering: on a write and set TSFSET = 1 in the I3C_CFGR register
   - This causes the hardware to raise the flag CFNFF = 1 in the I3C_EVR register, to request a first control word I3C_CR to be written.
2. No triggering: on a write of the first control word I3C_CR by software.

Then, regardless of the frame starting method, the I3C peripheral switches to active state. While the control word is not the last message of the I3C frame (while MEND = 0 in the I3C_CR register), and while there is no transfer error (while ERRF = 1 in the I3C_EVR register), the hardware keeps requesting a next control word, and continuing the frame transfer:

a) If the C-FIFO in not configured in DMA mode (CDMAEN = 0 in the I3C_CFGR register), the software writes a next control word following the flag CFNFF = 1 in the I3C_EVR register, or the corresponding interrupt if enabled (if CFNFIE = 1 in I3C_IER register)

b) If the C-FIFO in configured in DMA mode (CDMAEN = 1), a next control word is automatically pushed and written by the allocated DMA channel consequently to the asserted I3C DMA request (i3c_tc_dma).

Start and receiving a target-initiated transfer

When the controller is in enabled state (EN = 1 in the I3C_CFGR register), concurrently to a possible controller-initiated transfer, a target can initiate a transfer by issuing a start request (drive SDA low), provided the controller has allowed a hot-join request, an IBI request, or a controller-role request via the I3C_DEVR0 register.

In this case, even though the controller software has no intent to start a frame transfer, the hardware switches to active state (activates the SCL clock before a maximum t_{CAS} time defined as 1 µs, 100 µs, 2 ms or 50 ms, depending on, respectively, the bus activity state 0, 1, 2 or 3) to receive the hot-join/in-band interrupt/controller-role request from the target.

For more information about the execution of target-initiated I3C bus transfer and its related programming as a controller, refer to the relevant figures in *Section 49.9*:

- *Figure 664: IBI transfer, as controller/target*
- *Figure 665: Hot-join request transfer, as controller/target*
- *Figure 666: Controller-role request transfer, as controller/target*

Executing a (controller-initiated) frame transfer

The controller executes on the bus the frame transfer until the completion of the last message (FCF = 1 in the I3C_EVR register), or a transfer error (ERRF = 1 in the I3C_EVR register), and the corresponding interrupt, if enabled. This is based on I3C_CR and I3C_TD(W)R registers, written explicitly by software or pushed by the allocated DMA channel, and based on the I3C_RD(W)R, read explicitly by the software or by the allocated DMA channel. Then the I3C controller switches back to idle state.

For more information about the execution of controller-initiated I3C bus transfer and its related programming as a controller, refer to figures in *Section 49.9*:

- *Figure 654: I3C CCC messages, as controller*
- *Figure 655: I3C broadcast ENTDAA CCC, as controller*
- *Figure 656: I3C broadcast, direct read and direct write RSTACT CCC, as controller*
- *Figure 661: I3C private read/write messages, as controller*
- *Figure 663: Legacy I2C read/write messages, as controller*

Figure 652 does not include the management of the FIFOs (TX-FIFO, RX-FIFO, C-FIFO, and S-FIFO). This is detailed in *Section 49.10*.

For each completed message without transfer error, the hardware reports the exchanged transfer on the I3C bus by updating *I3C status register (I3C_SR)*, which can be read or not by the software when the S-FIFO is disabled (SMODE = 0 in the I3C_CFGR register).

- In the case of a direct CCC read or a private read transfer, in addition to the completion of the last message (FCF = 1 in the I3C_EVR register) or a transfer error (ERRF = 1 in the I3C_EVR register) and the corresponding interrupt if enabled, and provided that the S-FIFO is disabled for the status register I3C_SR (SMODE = 0 in the I3C_CFGR register), the software is notified if the read transfer is ended prematurely by the target by RXTGTENDF = 1 in the I3C_EVR register, and the corresponding interrupt, if enabled. The software can then read I3C_SR, to get more information about the executed transfer.

Alternatively, if the S-FIFO is enabled (SMODE = 1 in the I3C_CFGR register), the status register I3C_SR must be read for each executed message, either directly by the software (notified by SFNEF = 1 in the I3C_EVR register and the corresponding interrupt, if enabled), or via the DMA (if SDMAEN = 1 in the I3C_CFGR register), no matter if a read is prematurely ended by the target or not. Frame completion (FCF = 1 in the I3C_EVR register) occurs only after reading the status of the last message (S-FIFO is empty). For more information, refer to *Section 49.10.4*.

Updating the configuration for a transfer, as controller

Back in idle state, the software can update the configuration of the I3C peripheral before the next transfer:

- Modify SCL clock stalling via *I3C timing register 2 (I3C_TIMINGR2)*
- Modify the interrupt/polling mode policy via *I3C interrupt enable register (I3C_IER)*
- Modify the following fields of the *I3C configuration register (I3C_CFGR)*:
  - TXTHRES, RXTHRES
  - TMODE, SMODE
  - TXDMAEN, CDMAEN, RXDMAEN, SDMAEN
  - EXITPTRN, RSTPTRN
  - NOARBH

- Modify/prepare the control words, status words, read/write data of the next frame transfer to be executed, by software and/or DMA
  - *I3C message control register (I3C_CR)*, *I3C message control register [alternate] (I3C_CR)*
  - *I3C status register (I3C_SR)*
  - *I3C transmit data byte register (I3C_TDR)*, *I3C transmit data word register (I3C_TDWR)*
  - *I3C receive data byte register (I3C_RDR)*, *I3C receive data word register (I3C_RDWR)*
- Typically after having issued and completed a broadcast/direct DISEC/ENEC CCC:
  - Modify the hot-join acknowledge policy via bit HJACK in the I3C_CFGR register
  - Modify IBI/CR acknowledge policy to any target x, via *I3C device x characteristics register (I3C_DEVRx)*

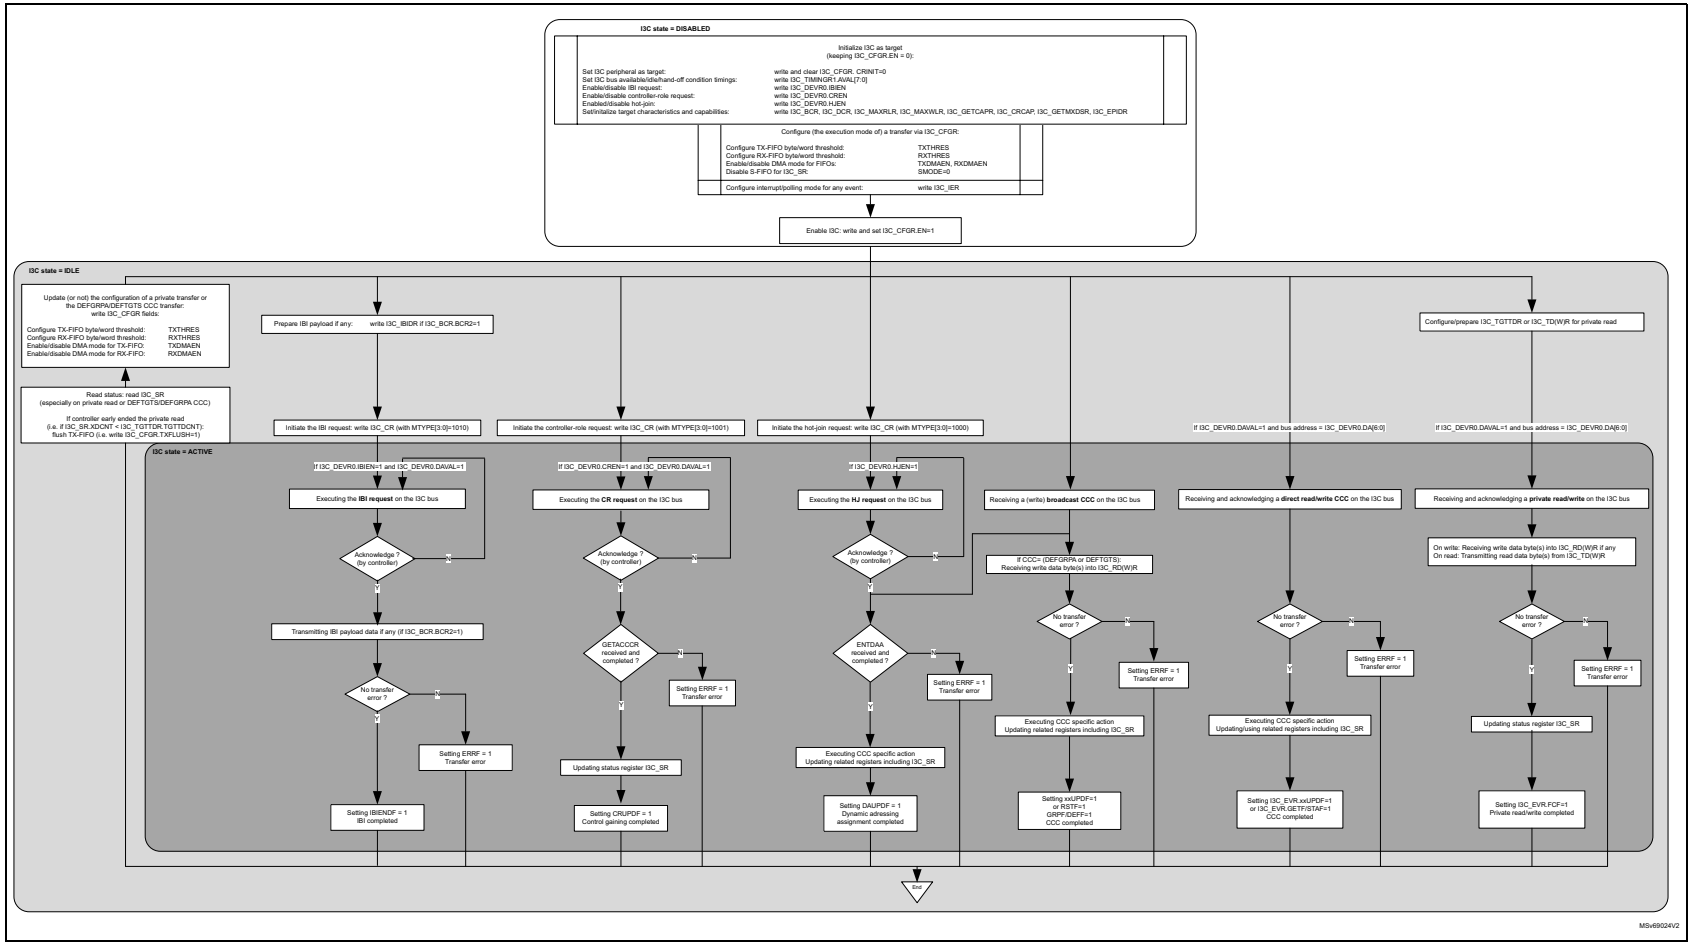
The registers usage vs. the I3C peripheral role as controller is summarized in *Section 49.8.1*.

The static/dynamic registers fields usage when acting as controller is summarized in *Table 522*.

49.7.3 I3C target state and programming sequence

Figure 653 illustrates the overall programming sequence of the peripheral acting as target, including state transitions, main subtasks, and conditions as explained in this section.

Figure 653. I3C target state and programing sequence diagram



Target initialization

When the target is in disabled state (EN = 0 in the I3C_CFGR register), the software must initialize as follows:

- Set I3C peripheral as target: write and clear CRINIT = 0 in the I3C_CFGR register
- Set I3C bus timings via *I3C timing register 1 (I3C_TIMINGR1)*: write AVAL[7:0] for:
  - Bus available condition time (t_{AVAL}) for IBI or controller-role request
  - Bus idle condition time (t_{IDLE}) for hot-join request
  - $t_{NEWCRLock}$ for controller-role hand-off procedure (after GETACCCR CCC)
- Configure target-initiated requests: write *I3C own device characteristics register (I3C_DEVR0)* with
  - IBIEN: in-band interrupt (also known as IBI) request enable/disable
  - CREN: controller-role request enable/disable
  - HJEN: hot-join request enable/disable
- Initialize target characteristics and capabilities: write
  - *I3C bus characteristics register (I3C_BCR)*
  - *I3C device characteristics register (I3C_DCR)*
  - *I3C maximum read length register (I3C_MAXRLR)*
  - *I3C maximum write length register (I3C_MAXWLR)*
  - *I3C get capability register (I3C_GETCAPR)*
  - *I3C controller-role capability register (I3C_CRCAPR)*
  - *I3C get max data speed register (I3C_GETMXDSR)*
  - *I3C extended provisioned ID register (I3C_EPIDR)*
- Configure the execution mode of a transfer: *I3C configuration register (I3C_CFGR)*, with the following fields:
  - TXDMAEN, RXDMAEN: DMA mode enable/disable for, respectively, TX-FIFO and RX-FIFO
  - TXTHRES, RXTHRES: respectively TX-FIFO and RX-FIFO byte/world threshold
  - Disable S-FIFO: SMODE = 0 (default/reset value)
- Configure interrupt generation or polling mode from any event: *I3C interrupt enable register (I3C_IER)*

Then, the software can enable the I3C peripheral (write and set EN = 1).

Note: The software can write once all the fields of the I3C_CFGR register while enabling it.

Receiving a (broadcast CCC, direct read/write CCC or private read/write) message from the controller

When the target is in idle state (EN = 1 in the I3C_CFGR register), the target is ready to receive a communication message on the I3C bus from the controller, and is ready to switch to the active state.

Typically, first, the active target is receiving a broadcast ENTDAA CCC, possibly after optional received broadcast ENEC/DISEC CCC(s), and is then assigned a dynamic address. The event DAUPF in the I3C_EVR register is raised to 1, the related interrupt is generated if enabled, and the target goes back to idle state.

After that, the idle target is ready to receive any other broadcast CCC message, or direct read/write CCC, or private read/write message from the controller.

For more information about the execution of controller-initiated I3C bus transfers and its related programming as a target, including the updated I3C registers and fields, refer to figures in *Section 49.9*:

- *Figure 657: I3C CCC messages, as target*
- *Figure 658: I3C broadcast ENTDAA CCC, as target*
- *Figure 659: I3C broadcast DEFTGTS CCC, as target*
- *Figure 660: I3C broadcast DEFGRPA CCC, as target*
- *Figure 662: I3C private read/write messages, as target*

Figure 653 does not include the FIFOs management (TX-FIFO, RX-FIFO). This is detailed in *Section 49.10*.

Read the message status register

For each received and completed message without transfer error, the hardware reports the exchanged transfer on the I3C bus by updating the *I3C status register (I3C_SR)*, which can be read by the software after being notified by the corresponding flag in the *I3C event register (I3C_EVR)*, or by the corresponding interrupt if enabled in the *I3C interrupt enable register (I3C_IER)*.

I3C status register (I3C_SR) must be read by the software after the following messages:

- A private read: to get the number of exchanged data bytes, as the controller can have ended the transfer earlier than expected by the target (if XDCNT[15:0] in the I3C_SR register is lower than TGTTDCNT[15:0] in the I3C_TGTTDR register). If so, software must flush the TX-FIFO (write TXFLUSH = 1 in the I3C_CFGR register).
- A DEFTGTS CCC or a DEFGRPA CCC: to get the number of received data bytes in the RX-FIFO

Start a (target-initiated) transfer

When the target goes first from disabled to idle state (software writes EN = 1 in the I3C_CFGR register), concurrently to be able to receive a broadcast CCC from the controller, the software can initiate a hot-join request (the software writes MTYPE[3:0] = 1000 in the I3C_CR register) to be eligible to participate to a next ENTDAA CCC, provided it is allowed to do so (HJEN = 1 in the I3C_DEVR0 register).

Once a dynamic address is assigned (DAUPF = 1 in the I3C_EVR register), more generally and possibly concurrently to a frame transfer emitted by the controller, the software can initiate an IBI (in-band interrupt request) to the controller, or a controller-role request by writing the related control word into the I3C_CR register.

For more information about the execution of target-initiated I3C bus transfer, and its related programming as a target, refer to figures in *Section 49.9*:

- *Figure 664: IBI transfer, as controller/target*
- *Figure 665: Hot-join request transfer, as controller/target*
- *Figure 666: Controller-role request transfer, as controller/target*

Updating the configuration of the I3C peripheral, as target

Back in idle state, the software can update the configuration of the I3C target before a next transfer:

- Modify the interrupt/polling mode policy via *I3C interrupt enable register (I3C_IER)*
- Modify following fields of the *I3C configuration register (I3C_CFGR)*:
  - TXTHRES, RXTHRES
  - TXDMAEN, RXDMAEN
- Modify/prepare the *I3C IBI payload data register (I3C_IBIDR)*, if any payload (if BCR2 = 1 in the I3C_BCR register), before initiating an IBI transfer (write *I3C message control register [alternate] (I3C_CR)* with MTYPE[3:0] = 1010)
- Modify/prepare *I3C target transmit configuration register (I3C_TGTTDR)*, to disable or enable the TX-FIFO to be preloaded with a defined number of data bytes to be transmitted, before receiving a private read or a direct CCC read (out of the GETSTATUS CCC) from the controller

The registers usage vs. the I3C peripheral role as target is summarized in *Section 49.8.1*.

The static/dynamic registers fields usage, when acting as target, is summarized in *Table 523*.

49.8 I3C registers and programming

49.8.1 I3C register set, as controller/target

Table 521 lists the registers and their usage versus the I3C peripheral role.

Table 521. I3C register usage

Register	Used as controller	Used as target
I3C_CR	X	X
I3C_CFGR	X	X
I3C_RDR	X	X
I3C_RDWR	X	X
I3C_TDR	X	X
I3C_TDWR	X	X
I3C_IBIDR	X	X
I3C_TGTTDR	-	X
I3C_SR	X	X
I3C_SER	X	X
I3C_RMR	X	X
I3C_EVR	X	X
I3C_IER	X	X
I3C_CEVR	X	X
I3C_DEVR0	X	X

Table 521. I3C register usage (continued)

Register	Used as controller	Used as target
I3C_DEVRx x = 1..4	X	-
I3C_MAXRLR	-	X
I3C_MAXWLR	-	X
I3C_TIMINGR0	X	-
I3C_TIMINGR1	X	X
I3C_TIMINGR2	X	-
I3C_BCR	-	X
I3C_DCR	-	X
I3C_GETCAPR	-	X
I3C_CRCAPR	-	X
I3C_GETMXDSR	-	X
I3C_EPIDR	-	X

49.8.2 I3C registers and fields use vs. peripheral state, as controller

When the I3C peripheral acts as controller, *Table 522* lists the registers and their usage versus the controller state (disabled, idle, and active).

Table 522. I3C registers/fields usage versus controller state

Register	Used as controller	Writable only in disabled state	Typically written/read in idle state	Typically written/read in idle or active state
I3C_CR	X	-	-	X

Table 522. I3C registers/fields usage versus controller state (continued)

Register	Used as controller	Writable only in disabled state	Typically written/read in idle state	Typically written/read in idle or active state
I3C_CFGR	X	CRINIT HKSDAEN EN(1)	Write: any used field except {CRINIT, HKSDAEN}, namely {CDMAEN SDMAEN TXDMAEN RXDMAEN TMODE SMODE TXTHRES RXTHRES HJACK EXITPTRN RSTPTRN NOARBH}(2) CFLUSH SFLUSH TXFLUSH RXFLUSH TSFSET	-
I3C_RDR	X	-	-	Read
I3C_RDWR	X	-	-	Read
I3C_TDR	X	-	-	Write
I3C_TDWR	X	-	-	Write
I3C_IBIDR	X	-	-	Read
I3C_TGTTDR	-			
I3C_SR	X	-	-	Read
I3C_SER	X	-	Read	-
I3C_RMR	X	-	-	Read RADD[6:0] IBIRDCNT[2:0]

Table 522. I3C registers/fields usage versus controller state (continued)

Register	Used as controller	Writable only in disabled state	Typically written/read in idle state	Typically written/read in idle or active state
I3C_EVR	X	-	-	Read (controller-role fields): HJF CRF IBIF FCF ERRF RXTGTENDF RXFNEF TXFNFF SFNEF CFNFF RXLASTF TXLASTF TXFEF CFEF
I3C_IER	X	Write xIE with x = HJ, CR, IBI, FC, ERR, RXTGTEND, RXFNE, TXFNF, SFNE, CFNF(2)		
I3C_CEVR	X	-	-	Write (controller-role fields, refer to I3C_EVR)
I3C_DEVR0	X	Write DA[6:0](2)		-
I3C_DEVRx x = 1..4	X	Write SUSP, IBIDEN, IBIACK, CRACK, DA[6:0](2)		-

Table 523. I3C registers/fields usage versus target state (continued)

Register	Used as target	Writable only in disabled state	Typically written/read in idle state	Typically written/read in idle or active state
I3C_GETMXDSR	X	X	-	-
I3C_EPIDR	X	X	-	-

1. Bit EN in the I3C_CFGR register is written and set in disabled state (when the same bit is 0). This field can be also written and de-asserted in idle state.
2. These fields are typically written and initialized in disabled state during I3C bus configuration. They are not write-protected when EN = 0.

49.9 I3C bus transfers and programming

49.9.1 I3C command set (CCCs), as controller/target

The list of the supported I3C command set (for example, list of CCCs, common command codes) and the overview of how they are handled by the peripheral acting as controller or target, is specified in *Table 524*.

Table 524. List of supported I3C CCCs, as controller/target

CCC name	CCC value	Read /write	With/without defining byte With/without sub-command byte	With/without optional data byte(s)	Use as controller	Use as target, raised I3C_EVR event	When target: specific action
Broadcast CCCs							
ENEC	0x00	Write	No defining/sub-command byte	With one data byte (enable target events byte)	X	X, INTUPDF	Update and enable I3C_DEVR0: HJEN, CREN, IBIEN if any
DISEC	0x01			With one data byte (disable target events byte)	X	X, INTUPDF	Update and disable I3C_DEVR0: HJEN, CREN, IBIEN if any
ENTASx x = 0...3	0x02 ... 0x05			No data byte	X	X, ASUPDF	Update I3C_DEVR0.AS[1:0]
RSTDAA	0x06			-	X	X, DAUPDF	Clear I3C_DEVR0.DAVAL = 0
ENTDAA	0x07			-	X	X, DAUPDF	Update I3C_DEVR0: DA[6:0] and set DAVAL = 1
DEFTGTS	0x08			With [1+ 4x (1+ number_of_targets)] x data bytes	X	X, DEFF	Update I3C_RDR/ I3C_RDWR. Refer to *Figure 659*.
SETMWL	0x09			With two data byte	X	X, MWLUPDF	Update I3C_MAXWLR
SETMRL	0x0A			With 2 or 3 data bytes	X	X, MRLUPDF	Update I3C_MAXRLR
ENTTM	0x0B			With one data byte	X	-	
SETXTIME	0x28		With sub-command byte	Without or with one or more data bytes	X		
SETAASA	0x29		No defining/sub-command byte	No data byte	X		
RSTACT	0x2A		With defining byte (0x00, 0x01 or 0x02)		X	X, RSTF after detected reset pattern	Update I3C_DEVR0: RSTACT[1:0] and set RSTVAL = 1
DEFGRPA	0x2B		No defining/sub-command byte	With several data bytes	X	X, GRPF	Update I3C_RDR/ RDWR. Refer to *Figure 660*.
RSTGRPA	0x2C			No data byte	X	-	-

Table 524. List of supported I3C CCCs, as controller/target (continued)

CCC name	CCC value	Read /write	With/without defining byte With/without sub-command byte	With/without optional data byte(s)	Use as controller	Use as target, raised I3C_EVR event	When target: specific action
Direct CCCs							Action if ACK (if I3C target Address = I3C_DEVR0.DA[6:0] and I3C_DEVR0.DAVAL = 1) (else NACK)
ENEC	0x80	Write	No defining/sub-command byte	With one data byte (enable target events byte)	X	X, INTUPDF	Update and enable I3C_DEVR0: HJEN, CREN, IBIEN if any
DISEC	0x81			With one data byte (disable target events byte)	X	X, INTUPDF	Update and disable I3C_DEVR0: HJEN, CREN, IBIEN if any
ENTASx x = 0...3	0x82...0x85			No data byte	X	X, ASUPDF	Update I3C_DEVR0.AS[1:0]
SETDASA	0x87			No data byte	X	-	-
SETNEWDA	0x88			With one data byte	X	X, DAUPDF	Update I3C_DEVR0: DA[6:0] (and set DAVAL = 1)
SETMWL	0x89			With two data bytes	X	X, MWLUPDF	Update I3C_MAXWLR
SETMRL	0x8A			With two or three data bytes	X	X, MRLUPDF	Update I3C_MAXRLR
GETMWL	0x8B	Read	No defining/sub-command byte	With two data bytes	X	X, GETF	Return data bytes from I3C_MAXWLR[15:0]. Refer to *Section 49.16.19*.
GETMRL	0x8C			With two or three data bytes	X	X, GETF	Return data bytes from I3C_MAXRLR[15:0] and if I3C_BCR.BCR2 = 1 return third byte from I3C_MAXRLR.IBIP[2:0]. Refer to *Section 49.16.18*.

Table 524. List of supported I3C CCCs, as controller/target (continued)

CCC name	CCC value	Read /write	With/without defining byte With/without sub-command byte	With/without optional data byte(s)	Use as controller	Use as target, raised I3C_EVR event	When target: specific action
GETPID	0x8D	Read	No defining/sub-command byte	With six data bytes	X	X, GETF	Return data bytes from I3C_EPIDR. Refer to *Section 49.16.28*.
GETBCR	0x8E			With one data byte	X	X, GETF	Return data byte from I3C_BCR[7:0]. Refer to *Section 49.16.23*.
GETDCR	0x8F				X	X, GETF	Return I3C_DCR[7:0]. Refer to *Section 49.16.24*.
GETSTATUS	0x90		With or without defining byte (TGTSTAT, PRECR)	With two data bytes (format 1 or format 2 with PRECR)	X	X, STAF if format 1 X, GETF if format 2	Return 2 data bytes, as detailed in *Section 49.9.9*.
GETACCCR	0x91		No defining/sub-command byte	With one data byte	X	X, CRUPDF	Return data byte from I3C_DEVR0.DA[6:0] with parity bit
GETMXDS	0x94		With or without defining byte (WRRDTURN, CRHDLY)	With two data bytes (format 1) or 5 data bytes (format 2 or format 3 with WRRDTURN) or 1 data byte (format 3 with CRHDLY)	X	X, GETF	Return data byte(s) from I3C_GETMXDSR. Refer to *Section 49.16.27*.
GETCAPS	0x95		With or without defining byte (TGTSTAT, CRCAPS)	With 3 data bytes (format 1 or format 2 with TGTSTAT) or two data bytes (format 2 with CRCAPS)	X	X, GETF	Return 3 GETCAPx data bytes from I3C_GETCAPR (refer to *Section 49.16.25*) or Return 2 CRCAPx data bytes from I3C_CRCAPR (refer to *Section 49.16.26*)
D2DXFER	0x97	Write	With defining byte	With defining byte	X	-	-
SETXTIME	0x98		With sub-command byte	With sub-command byte	X		
GETXTIME	0x99	Read	No defining/sub-command byte	No defining/sub-command byte	X		

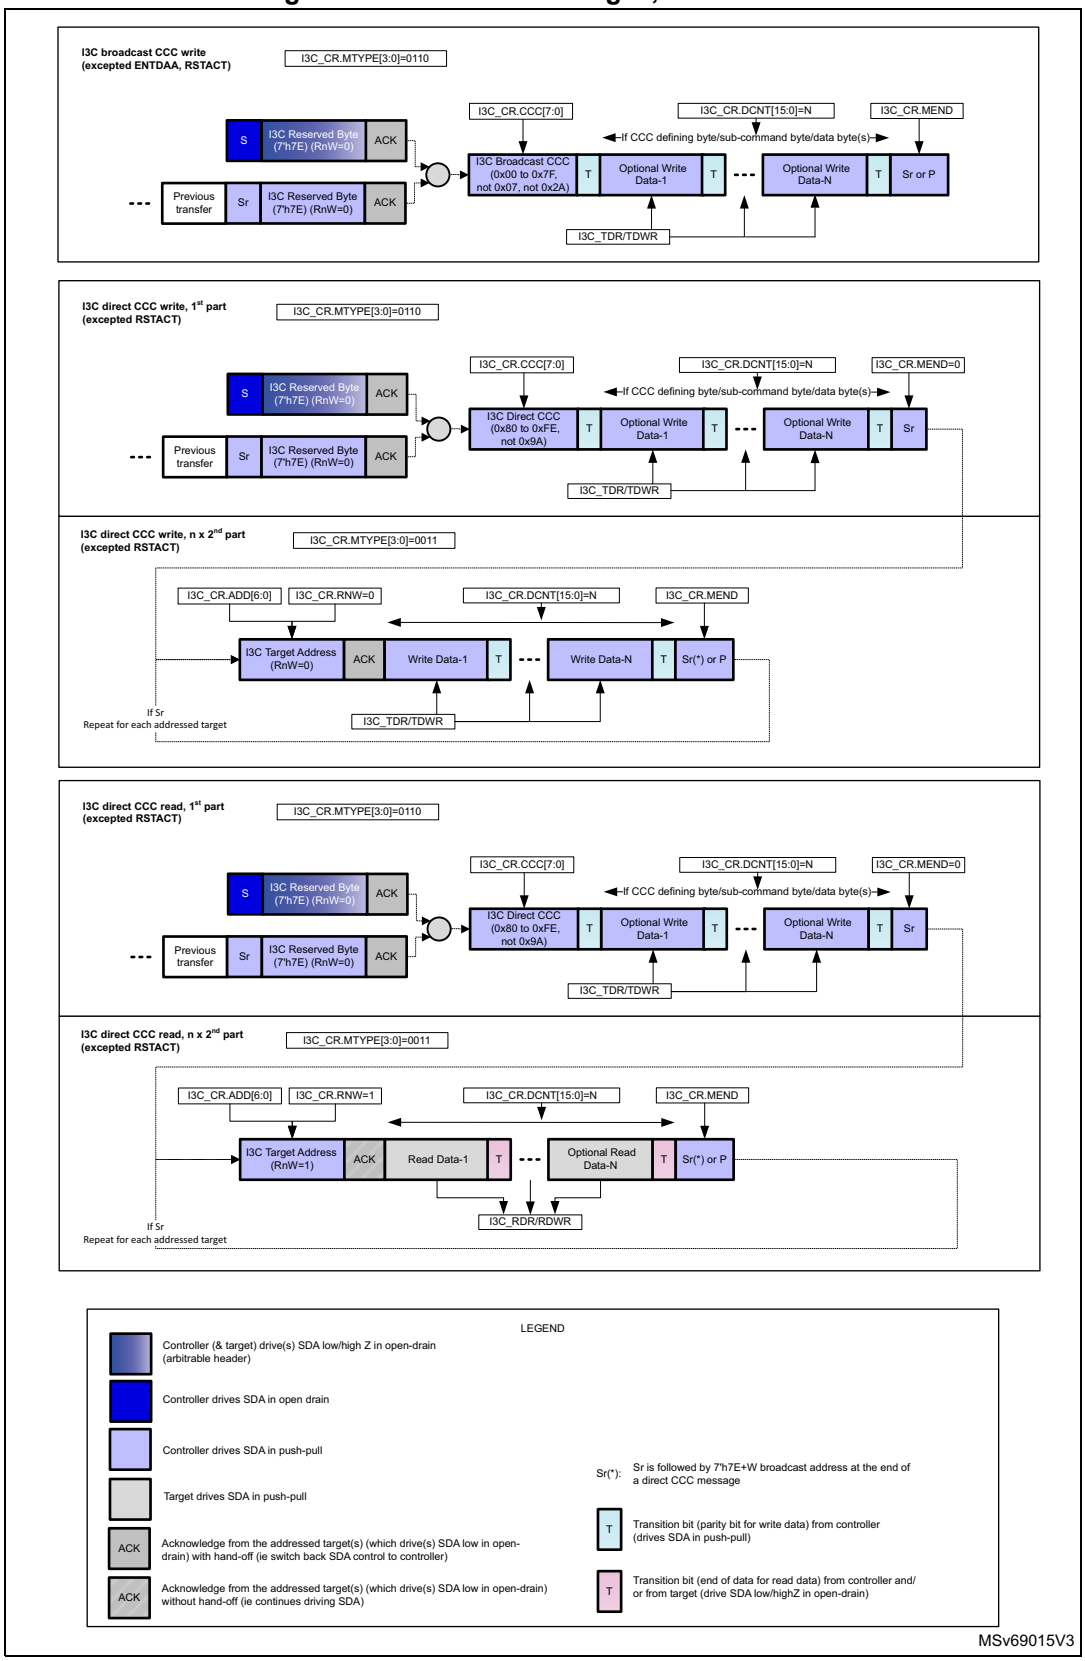
Table 524. List of supported I3C CCCs, as controller/target (continued)

CCC name	CCC value	Read /write	With/without defining byte With/without sub-command byte	With/without optional data byte(s)	Use as controller	Use as target, raised I3C_EVR event	When target: specific action
RSTACT	0x9A	Read/ Write	With defining byte (0x00, 0x01, or 0x02)	With defining byte (0x00, 0x01, or 0x02)	X	X, RSTF if detected reset pattern	Read: return data byte from RSTACT[1:0] in the I3C_DEVR0 register. Write: update I3C_DEVR0: RSTACT[1:0] and set RSTVAL = 1
SETGRPA	0x9B	Write	No defining/sub-command byte	No defining/sub-command byte	X	-	-
RSTGRPA	0x9C				X		

49.9.2 I3C broadcast/direct CCC transfer (except ENTDAA, RSTACT), as controller

Figure 654 illustrates I3C broadcast CCC write transfer (except ENTDAA, RSTACT), and direct CCC read/write transfer, as communicated on the I3C bus, and as programmed when acting as controller.

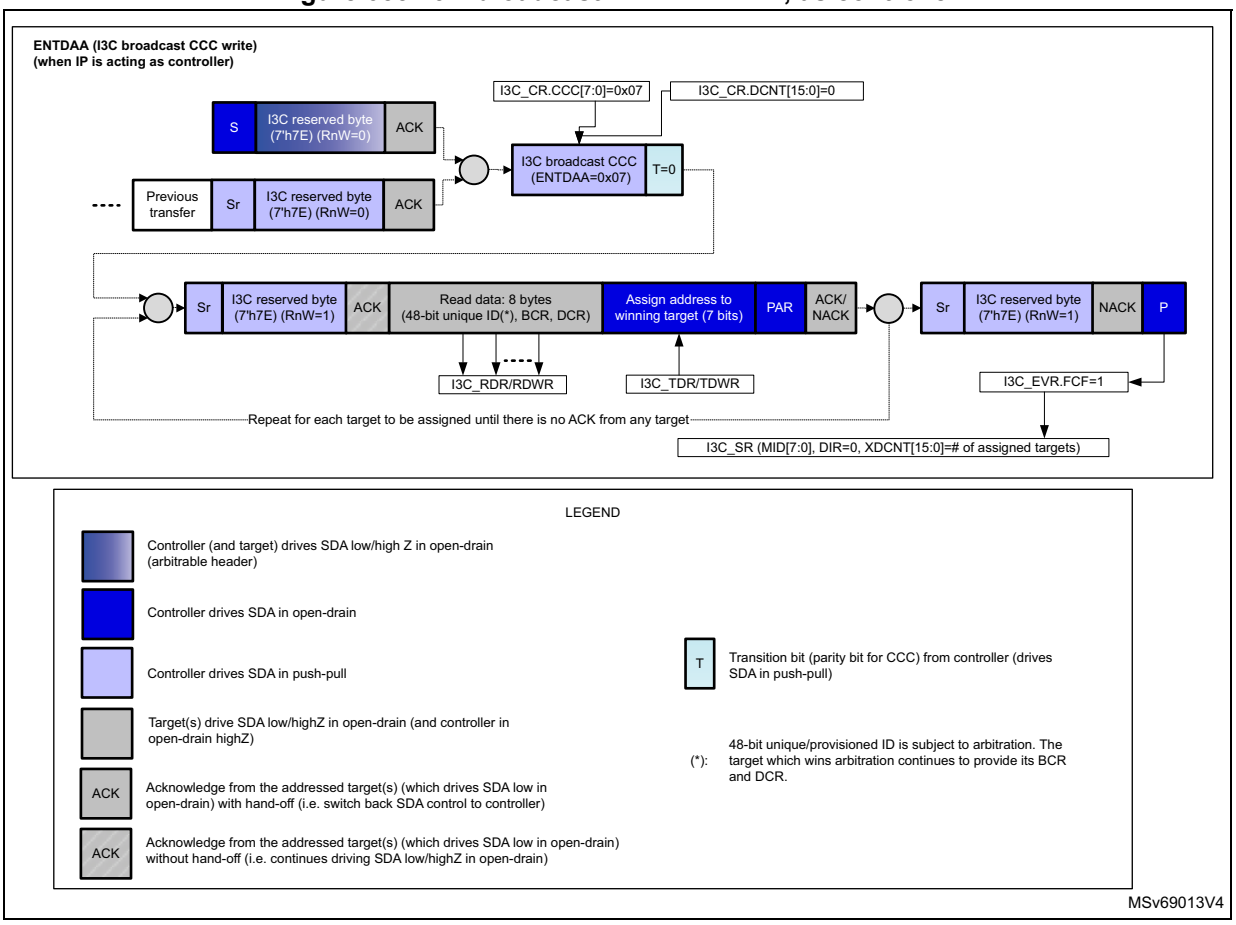
Figure 654. I3C CCC messages, as controller



49.9.3 I3C broadcast ENTDAA CCC transfer, as controller

Figure 655 illustrates I3C broadcast ENTDAA CCC, as communicated on the I3C bus, and as programmed when acting as controller.

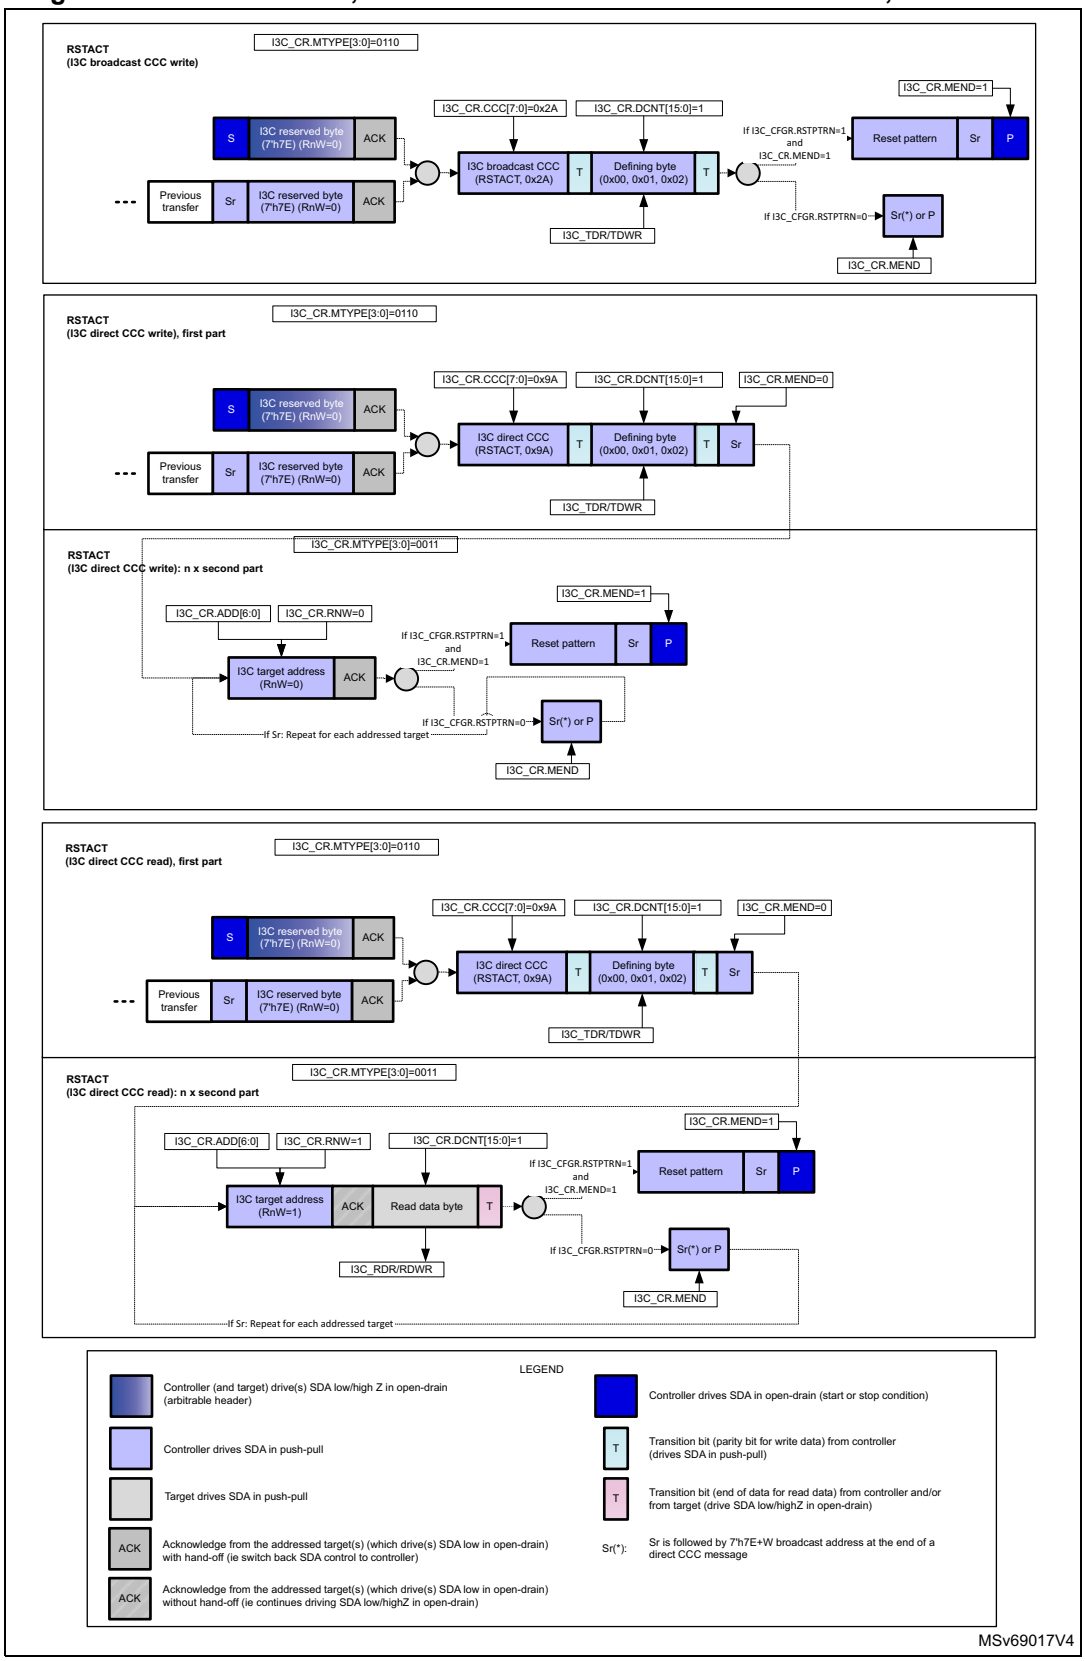
Figure 655. I3C broadcast ENTDAA CCC, as controller



49.9.4 I3C broadcast/direct RSTACT CCC transfer, as controller

Figure 656 illustrates I3C broadcast (write), direct write and read RSTACT CCC, as communicated on the I3C bus, and as programmed when acting as controller.

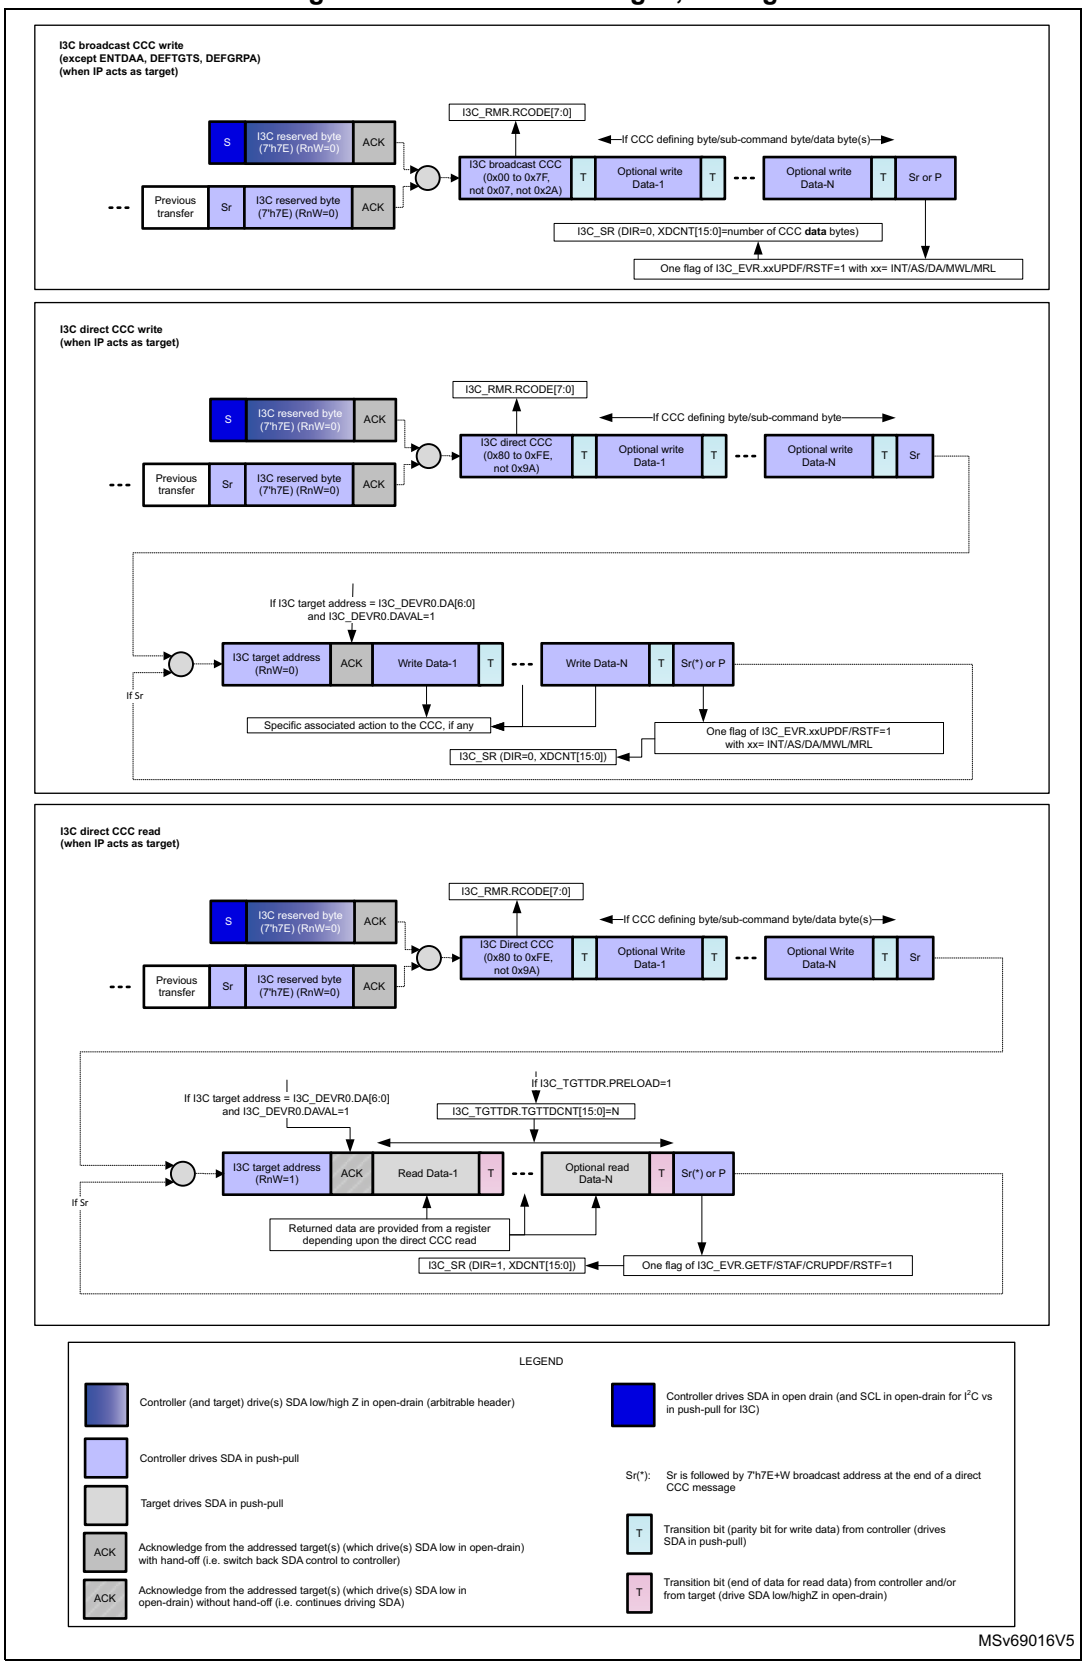
Figure 656. I3C broadcast, direct read and direct write RSTACT CCC, as controller



49.9.5 I3C broadcast/direct CCC transfer (except ENTDAA, DEFTGTS, DEFGRPA), as target

Figure 657 illustrates I3C broadcast CCC write transfer (except ENTDAA, DEFTGTS, DEFGRPA), direct CCC read/write transfer, as communicated on the I3C bus, and as programmed when acting as target.

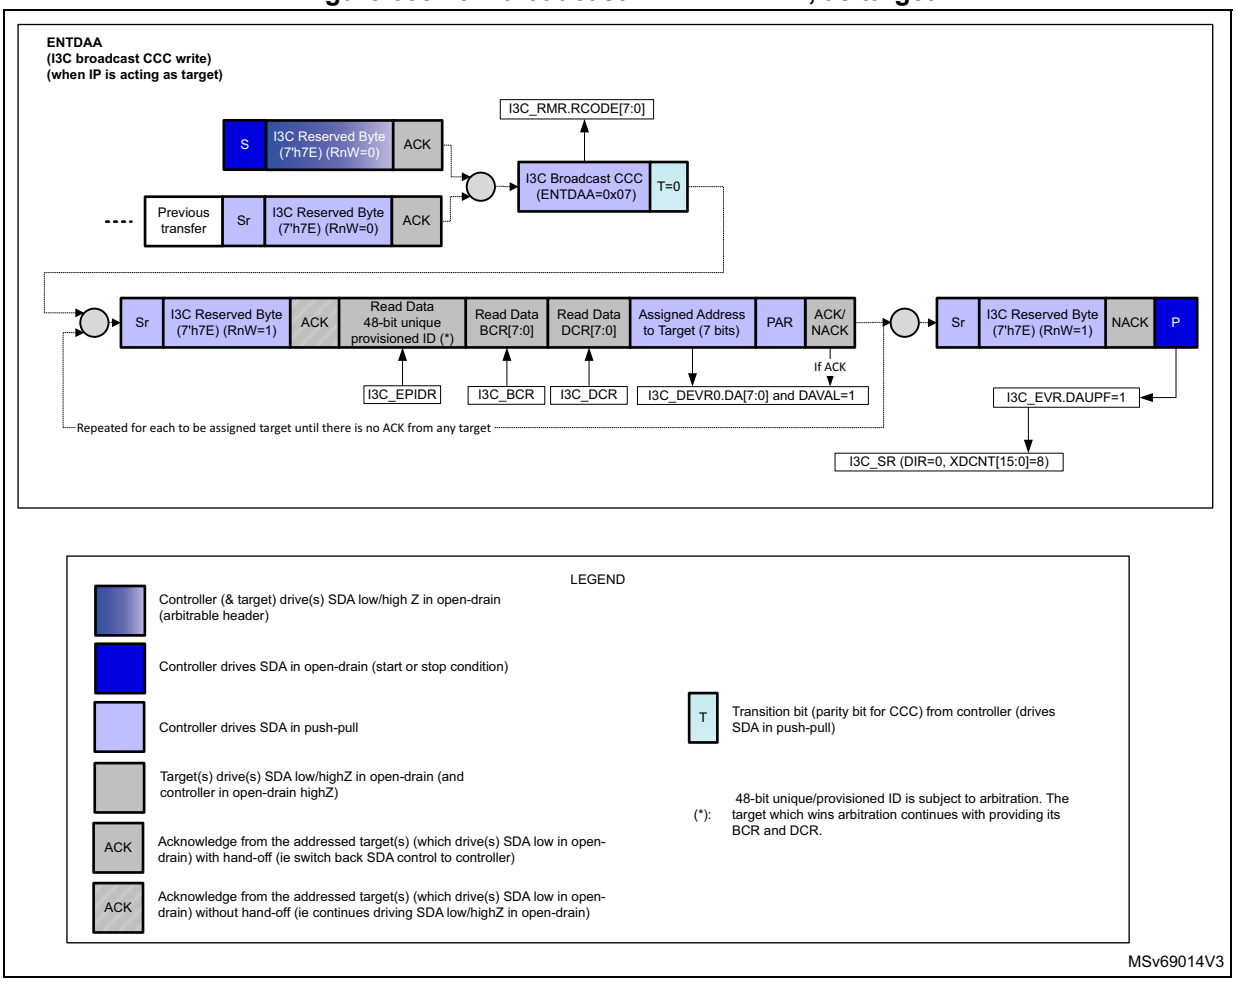
Figure 657. I3C CCC messages, as target



49.9.6 I3C broadcast ENTDAA CCC transfer, as target

Figure 658 illustrates I3C broadcast ENTDAA CCC, as communicated on the I3C bus, and as programmed when acting as target.

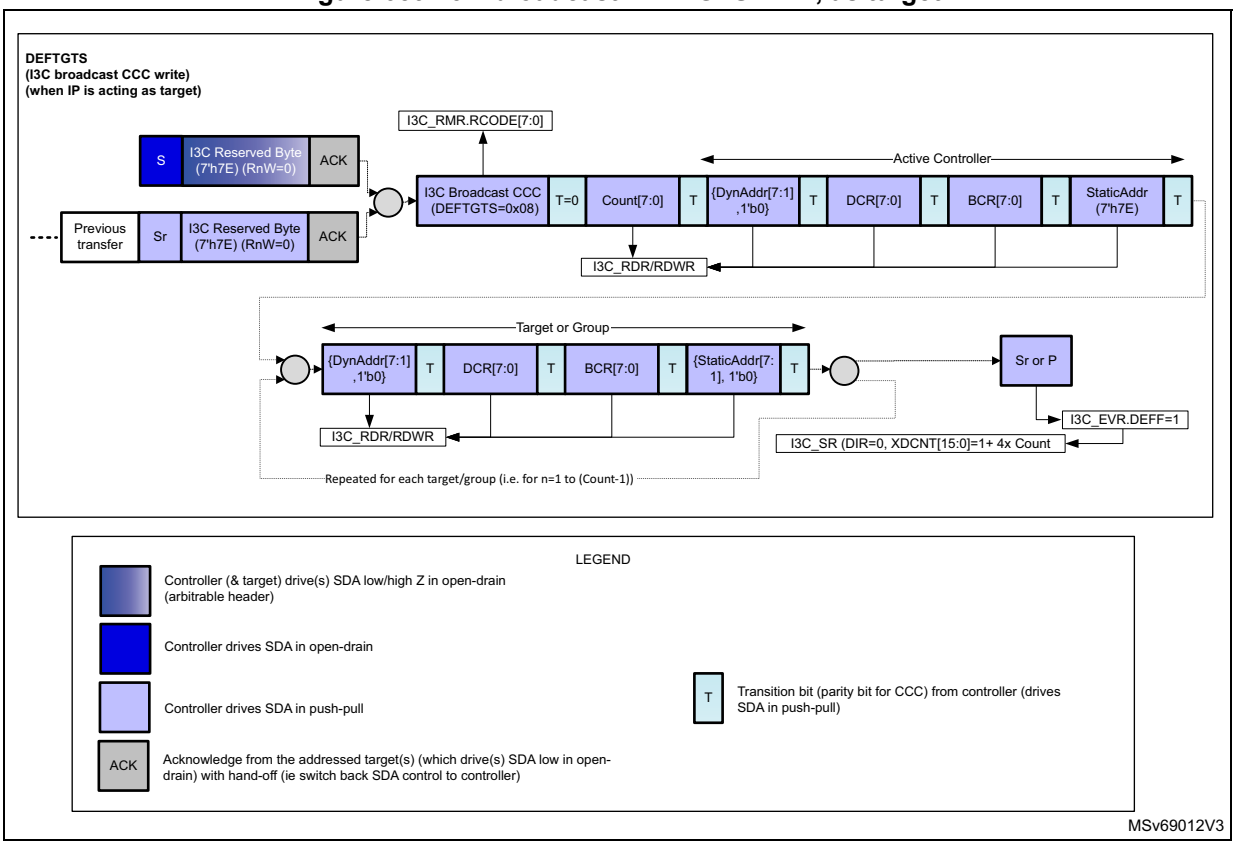
Figure 658. I3C broadcast ENTDAA CCC, as target



49.9.7 I3C broadcast DEFTGTS CCC transfer, as target

Figure 659 illustrates I3C broadcast DEFTGTS CCC, as communicated on the I3C bus, and as programmed when acting as target.

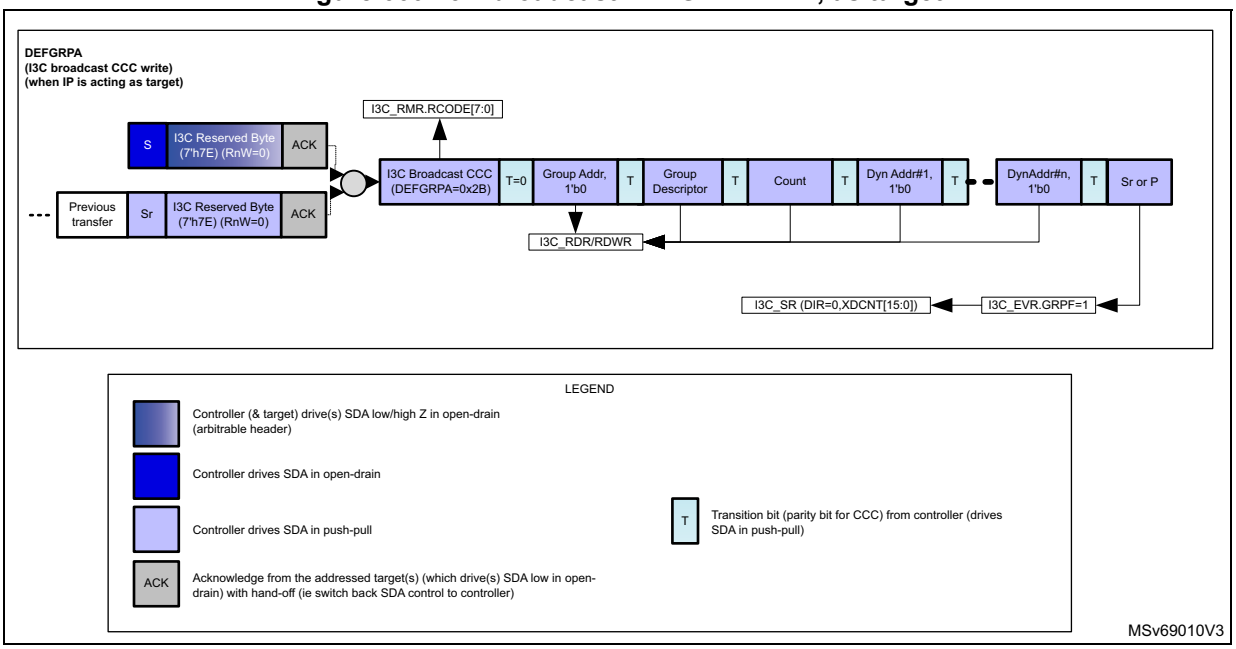
Figure 659. I3C broadcast DEFTGTS CCC, as target



49.9.8 I3C broadcast DEFGRPA CCC transfer, as target

Figure 660 illustrates I3C broadcast DEFGRPA CCC, as communicated on the I3C bus, and as programmed when acting as target.

Figure 660. I3C broadcast DEFGRPA CCC, as target



49.9.9 I3C direct GETSTATUS CCC response, as target

When the I3C acts as target, the hardware returns two data bytes on reception of GETSTATUS CCC, with format 1 (without defining byte or with defining byte TGTSTAT = 0x00), or format 2 (with defining byte PRECR = 0x91).

The returned 2-byte STATUS[15:0] with format 1 on the I3C bus is then as follows:

- STATUS[15:14] = 00 (unused)
- STATUS[13] = 1 if a missed start was detected since the former GETSTATUS CCC, else 0
- STATUS[12] = 1 if an overrun/underrun error was detected since the former GETSTATUS CCC, else 0
- STATUS[11] = 1 if an SCL stable for more than 125 µs was detected during an SDR read since the former GETSTATUS CCC, else 0
- STATUS[10:8] = 000 to 110: encoded value x = 0 to 6, corresponding to a target error TEx if a protocol error was detected since the former GETSTATUS CCC (if STATUS[5] = 1), else 000
- STATUS[7:6] = 00 (ready to prepare for hand-off procedure)
- STATUS[5] = 1 if a protocol error was detected since the former GETSTATUS CCC, else 0
- STATUS[4] = 0 (reserved)
- STATUS[3:1] = 000 (unused)

- STATUS[0] = 1 if there is a pending interrupt (if an IBI is configured in the I3C_CR register, and IBIEN = 1 and DAVAL = 1 in the I3C_DEVR0.register, and the IBI is not yet acknowledged by the controller neither disabled via DISEC), else 0

The returned 2-byte STATUS[15:0] with format 2 on the I3C bus is then as follows:

- STATUS[15:8] = 0000 0000 (unused)
- STATUS[7:2] = 00000 (unused)
- STATUS[1] = 1 if a received DEFTGTS or a received DEFGRPA CCC is still under software processing, and the related event is not yet cleared by software (DEFF = 1 or GRPF = 1 in the I3C_EVR register); the controller must wait before issuing a GETACCR CCC (else it is not acknowledged)
- STATUS[0] = 1 if a DEFTGTS or DEFGRPA CCC may have been missed. This bit is asserted if a missed start is detected (WKPF = 1 in the I3C_EVR register), de-asserted if DEFF = 1 or GRPF = 1 in the I3C_EVR register.

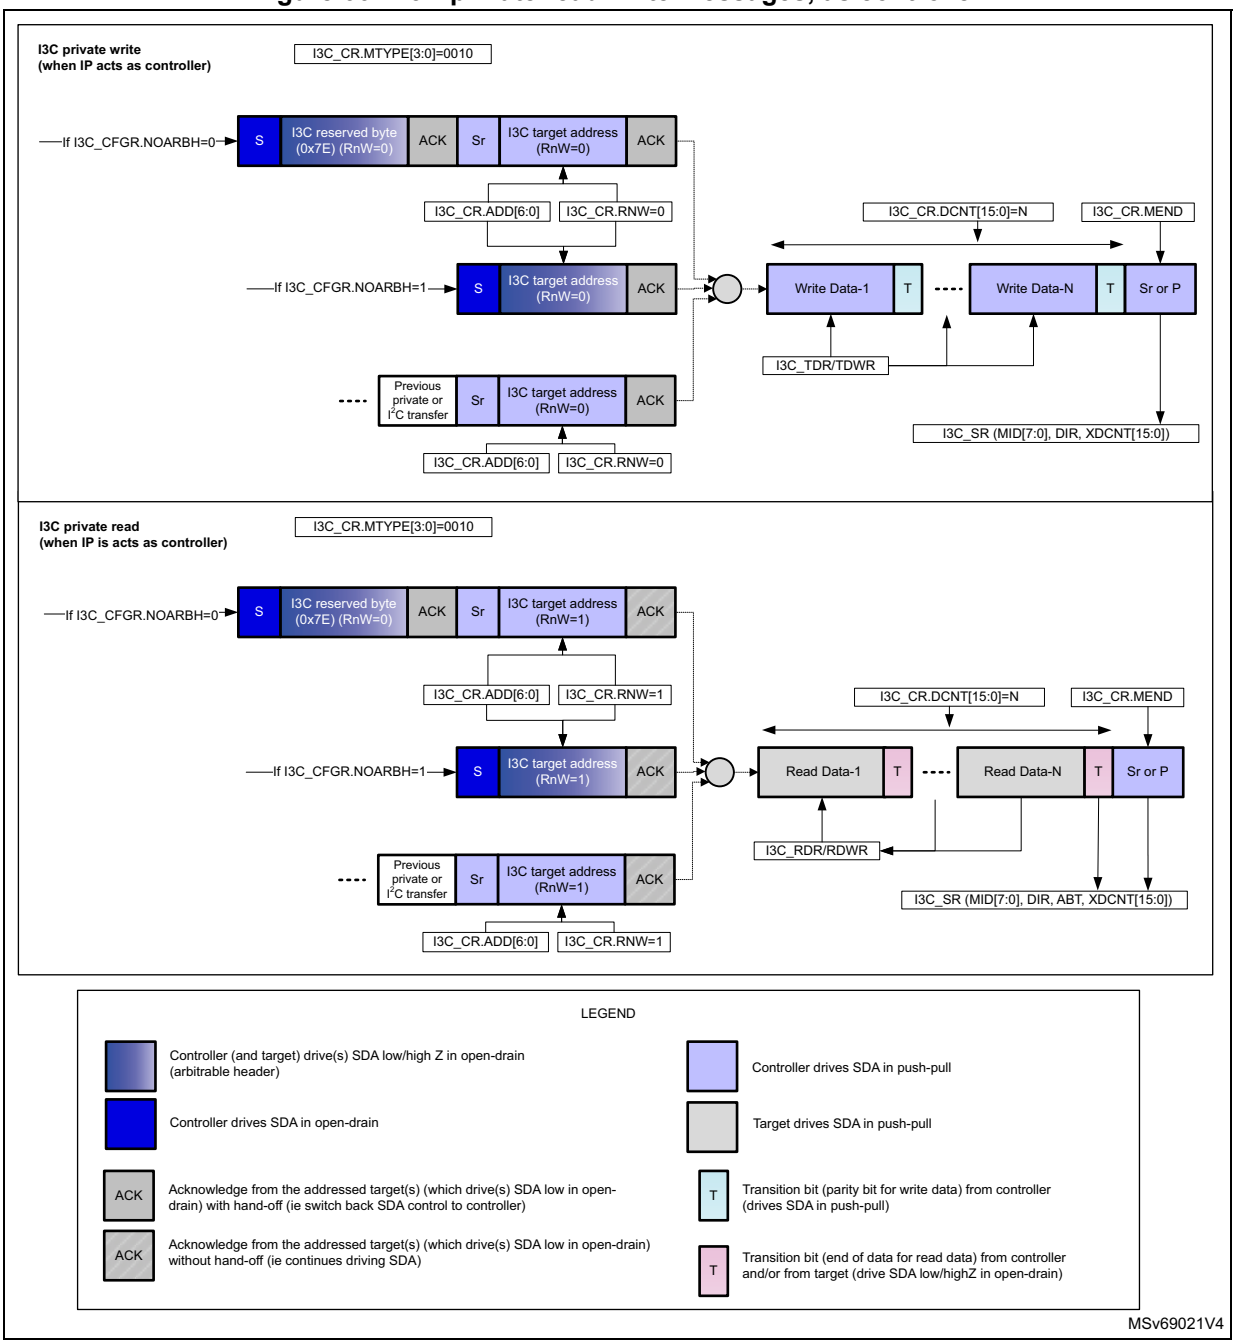
Completion of a GETSTATUS CCC of format 1 is reported by STAF = 1 in the I3C_EVR register, and the corresponding interrupt if enabled (if STAIE = 1 in the I3C_IER register).

Completion of a GETSTATUS CCC of format 2 is reported by GETF = 1 in the I3C_EVR register, and the corresponding interrupt if enabled (if GETIE = 1 in the I3C_IER register).

49.9.10 I3C private read/write transfer, as controller

Figure 661 illustrates private read/write transfer, as communicated on the I3C bus, and as programmed when acting as controller.

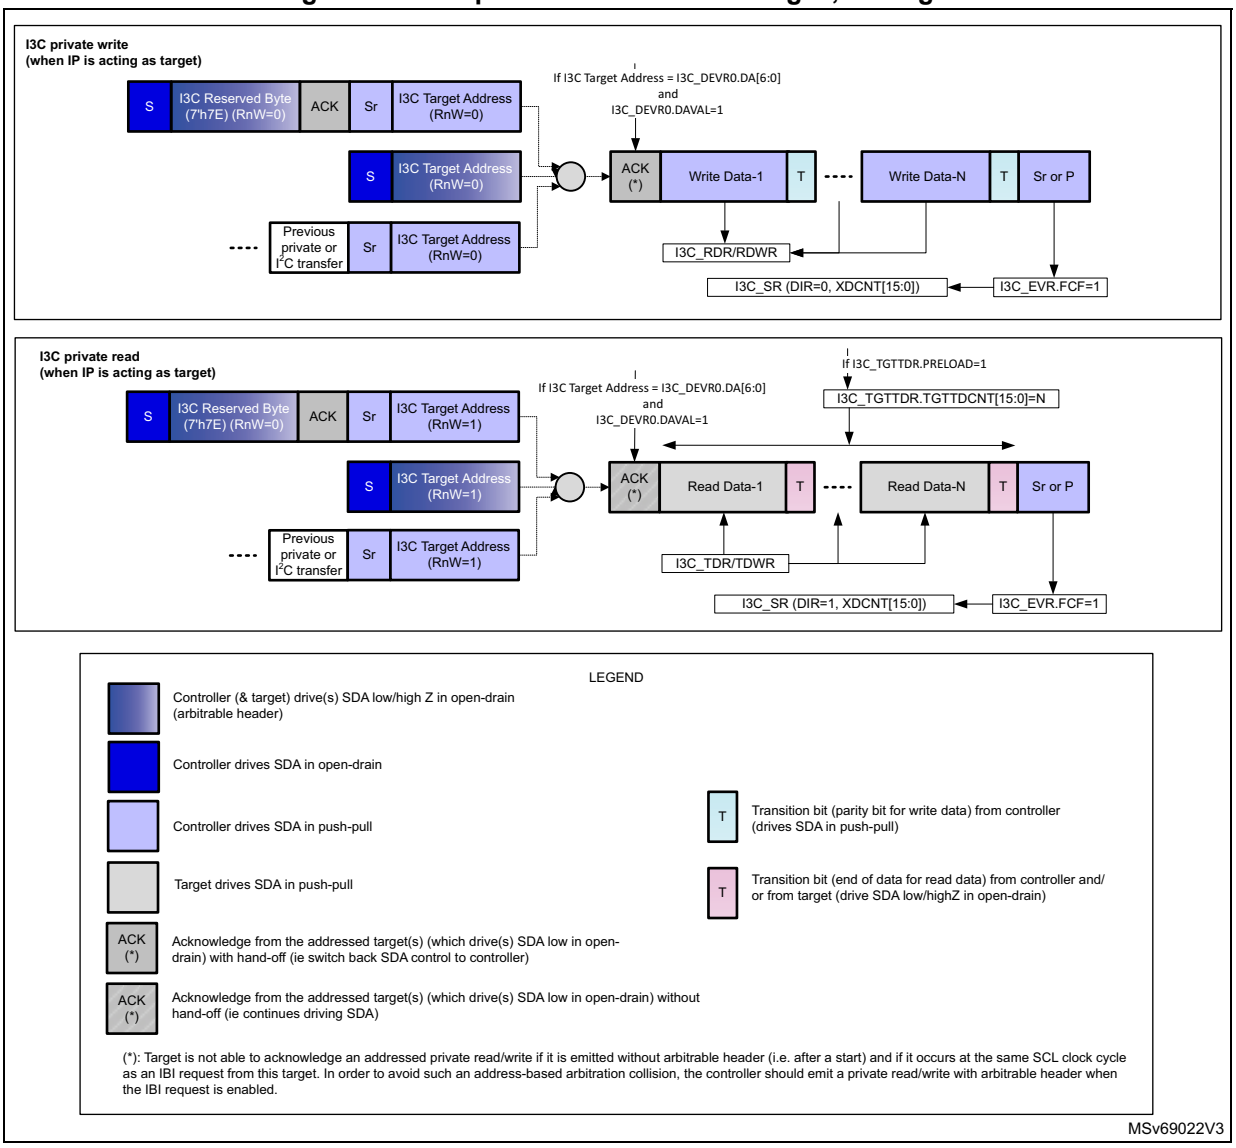
Figure 661. I3C private read/write messages, as controller



49.9.11 I3C private read/write transfer, as target

Figure 662 illustrates I3C private read/write transfer, as communicated on the I3C bus, and as programmed when acting as target.

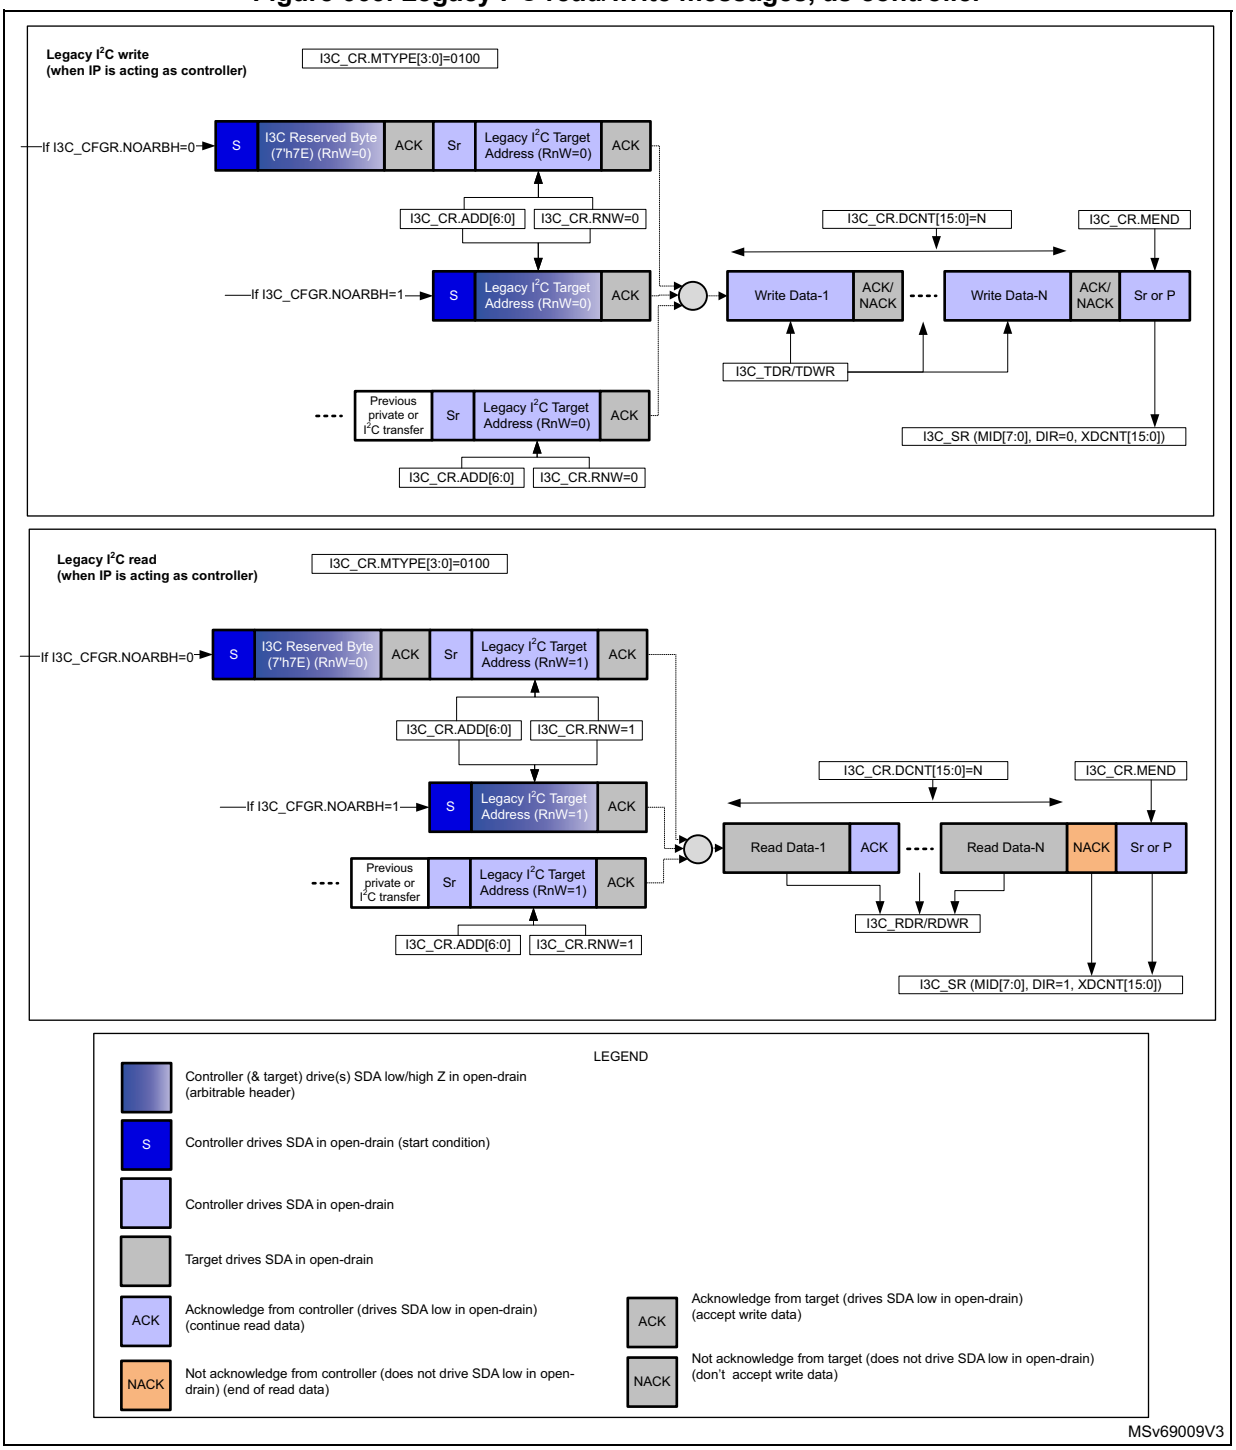
Figure 662. I3C private read/write messages, as target



49.9.12 Legacy I²C read/write transfer, as controller

Figure 663 illustrates legacy I²C read/write transfer, as communicated on the I3C bus, and as programmed when acting as controller.

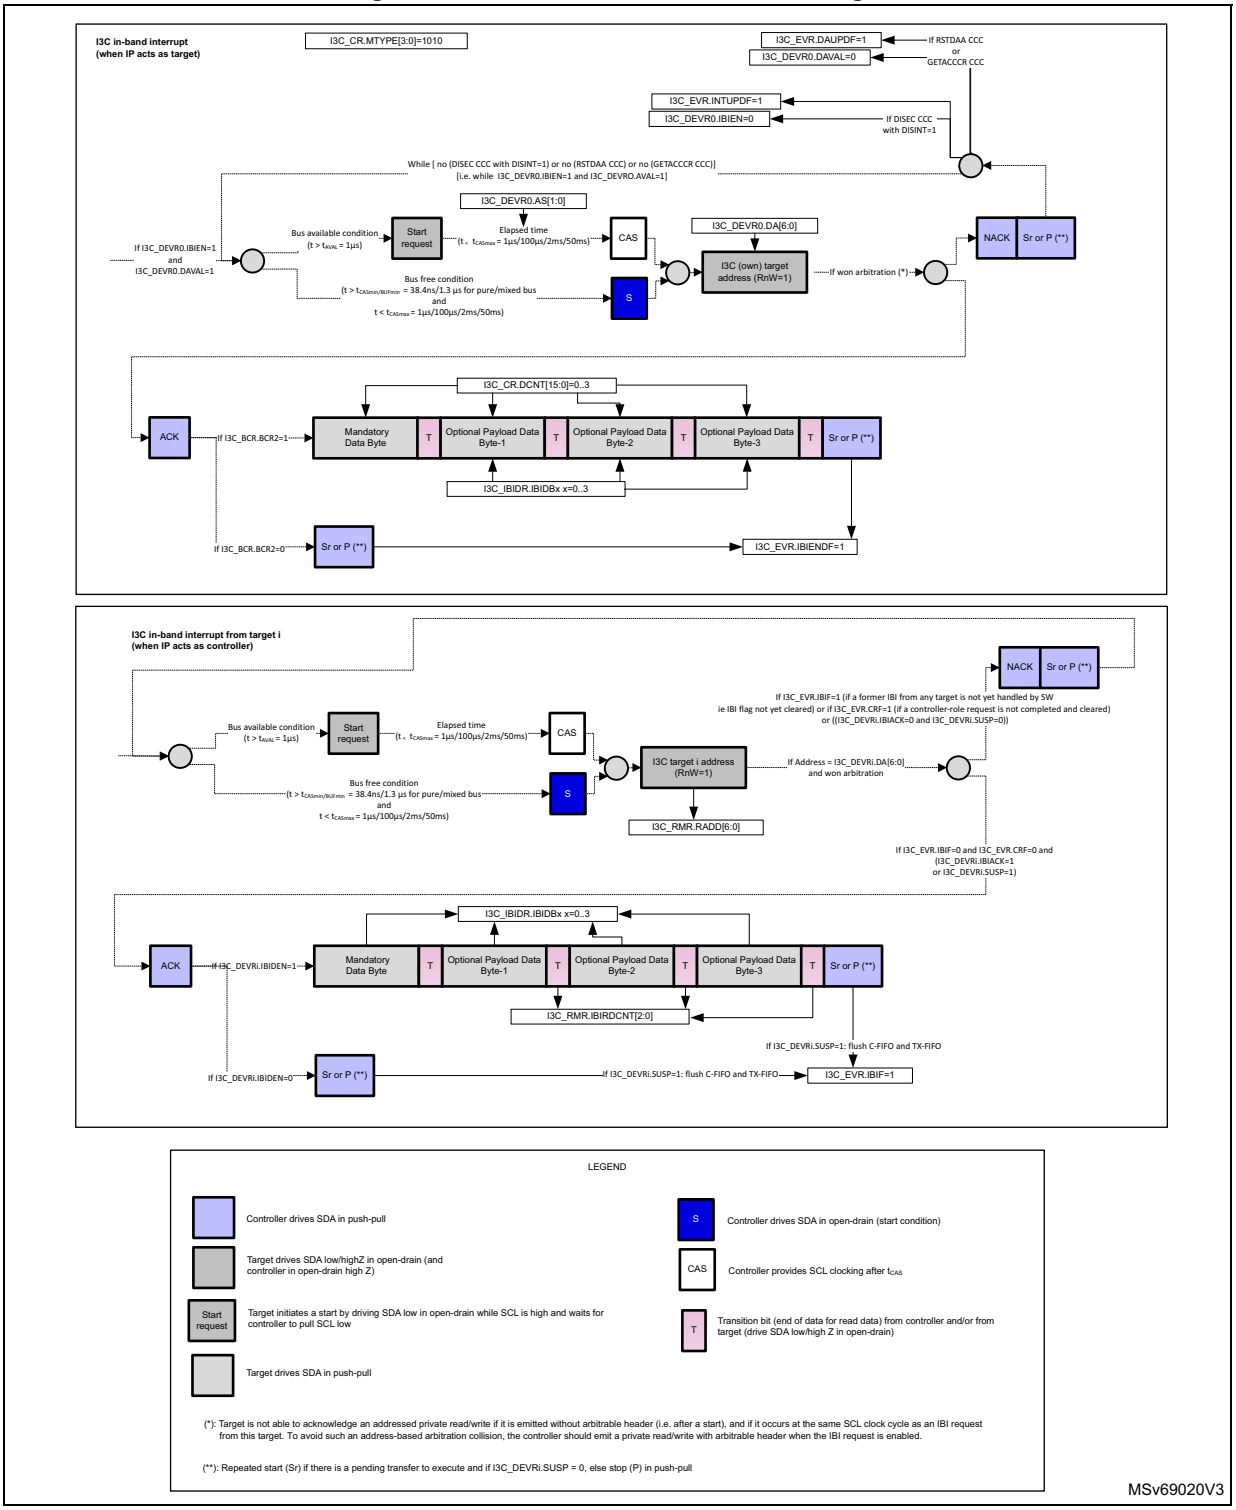
Figure 663. Legacy I²C read/write messages, as controller



49.9.13 I3C IBI transfer, as controller/target

Figure 664 illustrates IBI (in-band interrupt) transfer, as communicated on the I3C bus, and as programmed when acting as target or received as controller.

Figure 664. IBI transfer, as controller/target

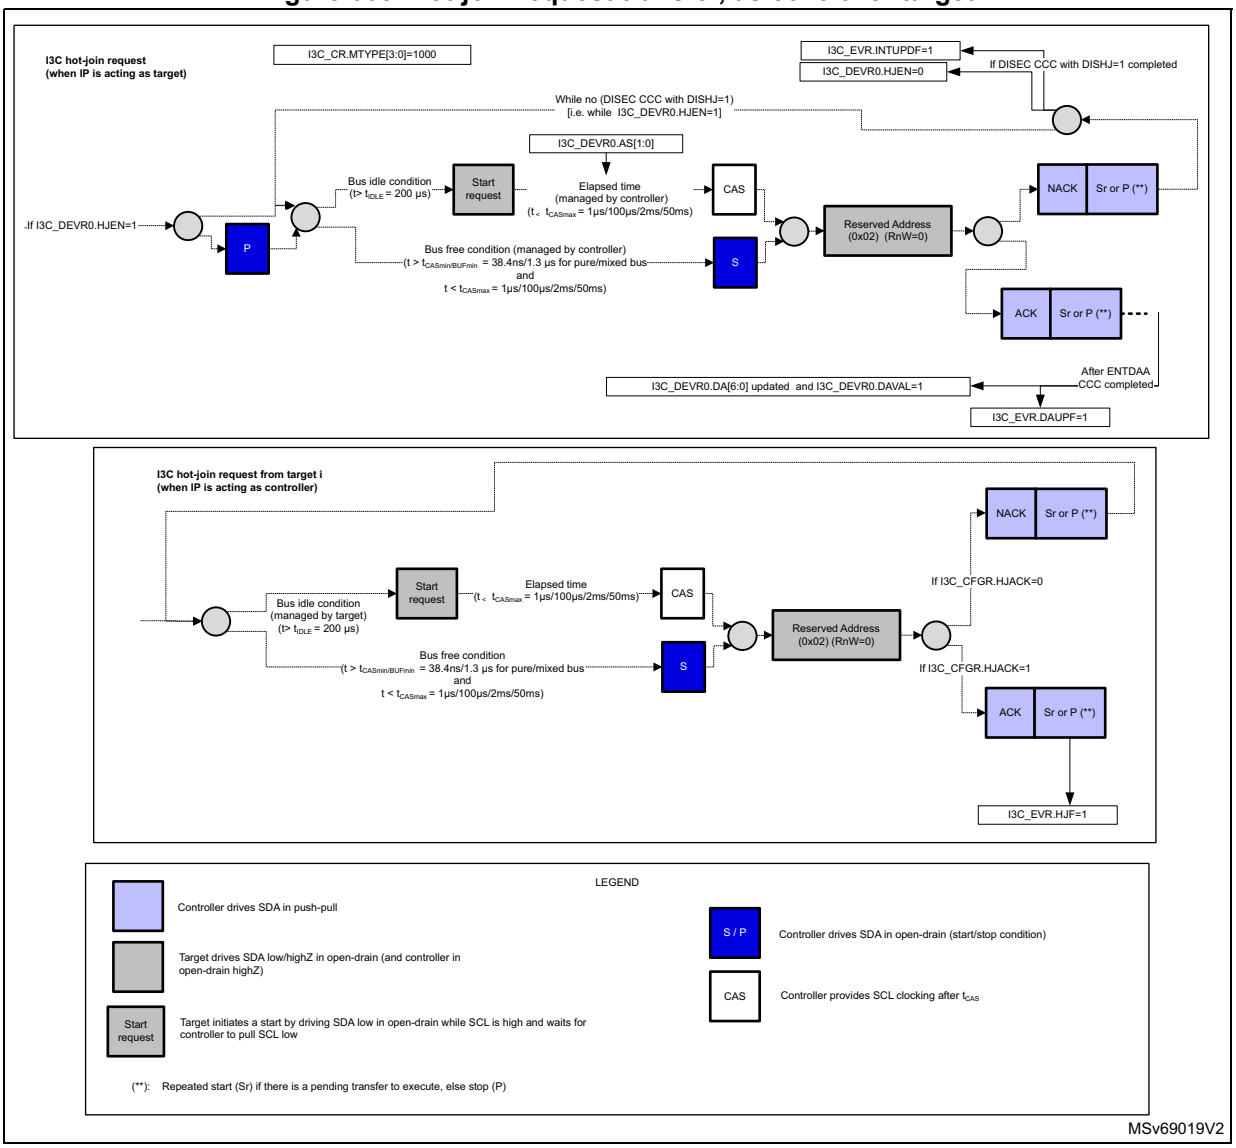


When the peripheral acts as controller, the I3C_IBIDR register is used to receive the IBI data payload. Consequently, the IBI request from the target must not exceed a 4-byte data payload. If there is more information to be exchanged in the context of this in-band interrupt, the controller software must issue a private read.

49.9.14 I3C hot-join request transfer, as controller/target

Figure 665 illustrates hot-join request transfer, as communicated on the I3C bus, and as programmed when acting as target or received as controller.

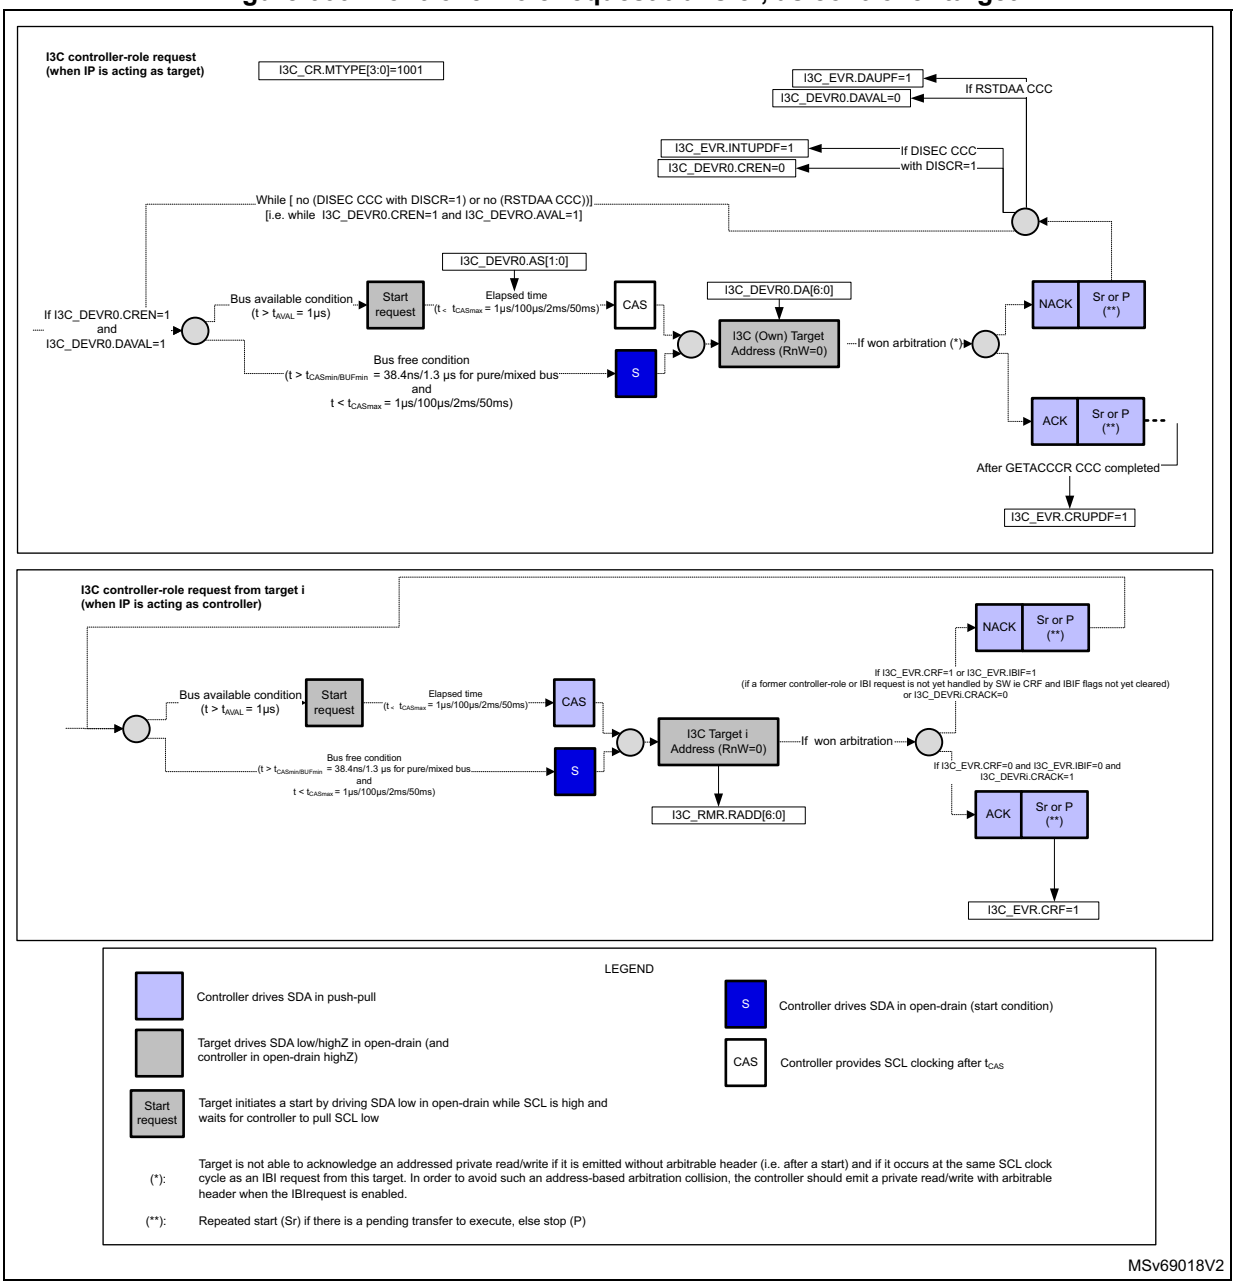
Figure 665. Hot-join request transfer, as controller/target



49.9.15 I3C controller-role request transfer, as controller/target

Figure 666 illustrates controller-role request transfer, as communicated on the I3C bus, and as programmed when acting as target or received as controller.

Figure 666. Controller-role request transfer, as controller/target



49.10 I3C FIFOs management, as controller

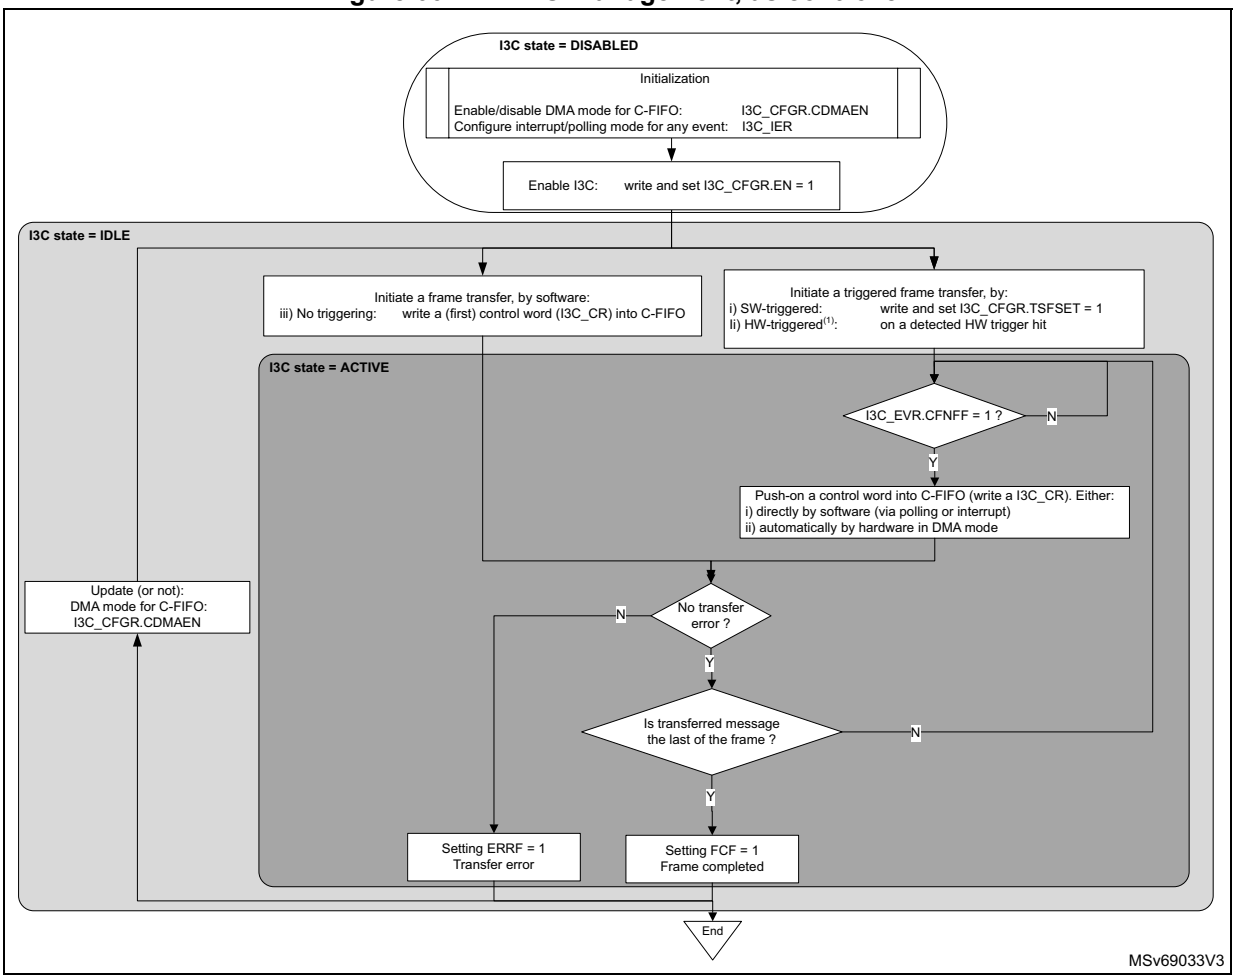
49.10.1 C-FIFO management, as controller

When controller, as illustrated in figures of *Section 49.9*, C-FIFO can be used during any of the following transfers:

- broadcast CCC (*Figure 654*, *Figure 655*, *Figure 656*)
- direct read/write CCC (*Figure 656*)
  - command part, first message
  - data part, next message(s)
- private read/write (*Figure 661*)
- legacy I2C read/write (*Figure 663*)
- software-initiated error recovery (SCL forced to be stopped until next header message followed by HDR exit pattern)

Figure 667 illustrates the management of the C-FIFO for queuing control word(s) on the I3C bus, when the I3C peripheral acts as controller.

Figure 667. C-FIFO management, as controller



1. This feature is implementation-dependent and can be unavailable. Refer to *Section 49.3.4*.

First, the software must initialize the C-FIFO management via CDMAEN in the I3C_CFGR register, to be written either:

- directly by the software (if CDMAEN = 0) at the control word level:
  - via polling mode (CFNFIE = 0 in the I3C_IER register): waiting for a next control word is requested by the hardware (CFNFF = 1 in the I3C_IER register) before an explicit write to the I3C_CR register
  - via enabled interrupt notification if CFNFIE = 1
- by the allocated DMA channel (if CDMAEN = 1) to the corresponding DMA request from the I3C peripheral (i3c_tc_dma):
  - as configured at block level, the DMA is automatically pushing-on/writing control word(s) into the I3C_CR register from its memory source buffer, until the frame completion (a stop is emitted on the I3C bus after the last message of the frame), unless a transfer error occurs.

In any case, if C-FIFO is empty and a restart must be emitted with a new control word, a C-FIFO underrun is reported (ERRF = 1 in the I3C_EVR register and COVR = 1 in the I3C_SER register). If enabled by ERRIE = 1 in the I3C_IER register, an interrupt is generated.

The DMA mode for the C-FIFO management can be modified when the I3C peripheral is not in active state.

When controller, if a transfer error occurs (ERRF = 1 in the I3C_EVR register), the C-FIFO is flushed automatically by the hardware.

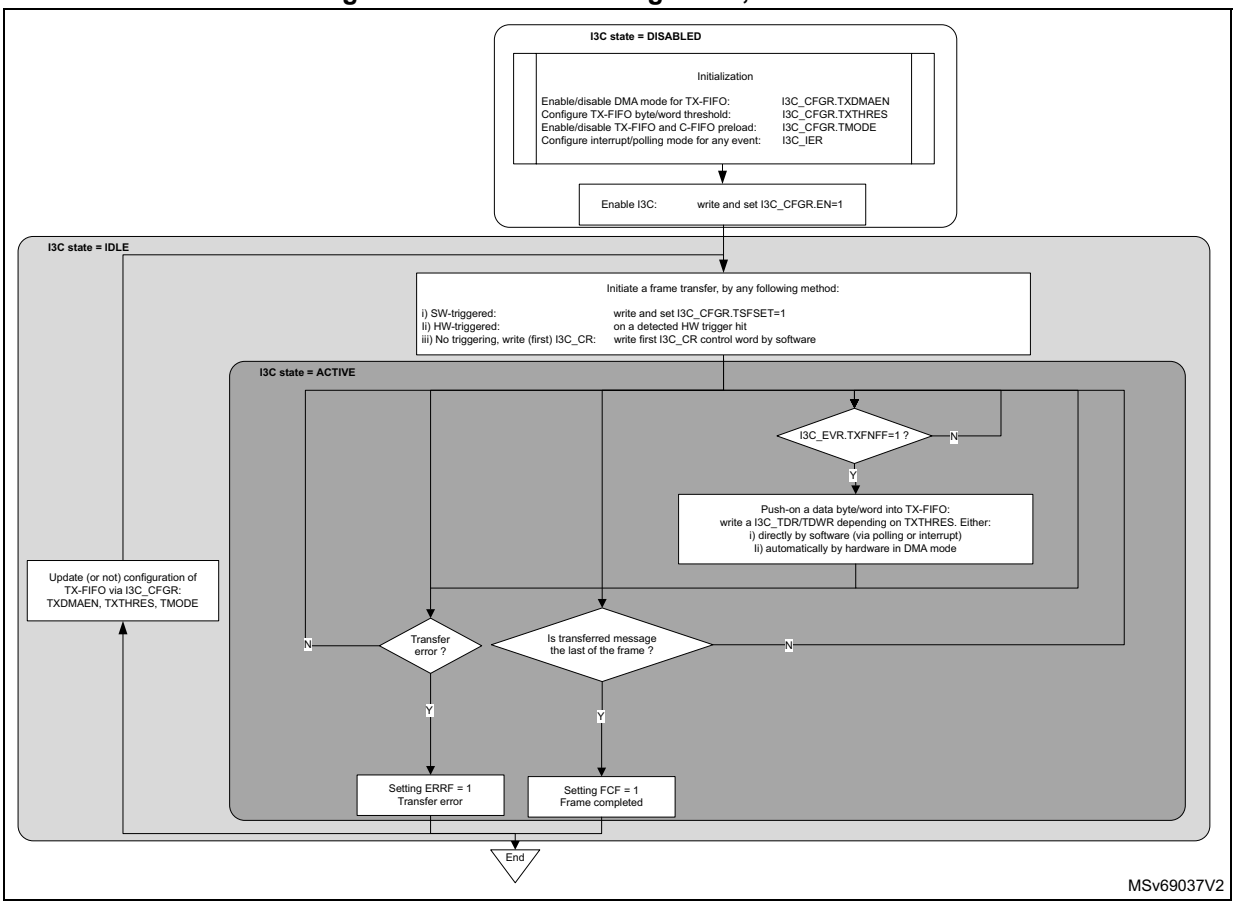
49.10.2 TX-FIFO management, as controller

When controller, as shown in figures of *Section 49.9*, TX-FIFO can be used during any of the following transfers:

- broadcast or direct CCC (including ENTDAA and RSTACT), if a defining/sub-command byte or if data byte(s) are present (*Figure 654*, *Figure 655*, *Figure 656*)
- private write (*Figure 661*)
- legacy I2C write (*Figure 663*)

Figure 668 illustrates the management of the TX-FIFO for queuing data bytes or word(s) to be transmitted on the I3C bus, when the I3C peripheral acts as controller.

Figure 668. TX-FIFO management, as controller



First, the software must initialize the TX-FIFO management via the following fields in the I3C_CFGR register:

- TXDMAEN: enable/disable DMA mode for TX-FIFO
- TXTHRES: push-on data byte(s) or word(s) into TX-FIFO
- TMODE: enable/disable TX-FIFO and C-FIFO preload

Then, depending upon bit TXDMAEN in the I3C_CFGR register, the TX-FIFO is written either:

- directly by the software (if TXDMAEN = 0) at the byte/word level:
  - via polling mode (TXFNFIE = 0 in the I3C_IER register): waiting for a next data byte/word is requested by the hardware (TXFNFF = 1 in the I3C_IER register) before an explicit write to the I3C_TDR or I3C_TDWR register, depending upon bit TXTHRES in the I3C_CGFR register
  - via enabled interrupt notification if TXFNFIE = 1
- by the allocated DMA channel (if TXDMAEN = 1) to the corresponding DMA request from the I3C peripheral (i3c_tx_dma):
  - as configured at DMA block level, the DMA is automatically pushing-on/writing data bytes/words to the I3C_TDR or I3C_TDWR register (depending upon bit TXTHRES in the I3C_CGFR. register) from its memory source buffer, until the frame completion (a stop is emitted on the I3C bus after the last message of the frame), unless a transfer error occurs.

An I3C message begins from a start or a repeated start, and ends with a stop or a repeated start. At message level, the last data byte/word to be transmitted is flagged by TXLASTF = 1 in the I3C_EVR register. When an I3C frame is described with multiple messages (separated by a repeated start), this event can be used by the software to update the pointer to the buffer where the byte(s)/word(s) of the next message is/are stored.

When frame completion is reported (FCF = 1 in the I3C_EVR register, and the corresponding interrupt is enabled), the TX-FIFO is empty.

If the TX-FIFO is empty and a data byte must be transmitted on the I3C bus, a TX-FIFO underrun is reported (ERRF = 1 in the I3C_EVR register and DOVR = 1 in the I3C_SER register). If enabled by ERRIE = 1 in the I3C_IER register, an interrupt is generated.

The configuration for the TX-FIFO management can be modified when the I3C peripheral is not in active state.

When controller, if a transfer error occurs (ERRF = 1), the TX-FIFO is automatically flushed by the hardware.

No C-FIFO/TX-FIFO preload

As defined in *Table 516*, C-FIFO size is two words, TX-FIFO size is 8 bytes.

When no C-FIFO/TX-FIFO preload is configured (TMODE = 0 in the I3C_CFGR register), the I3C peripheral emits a start on the I3C bus as soon as the first control word is written into the C-FIFO. Then, it decodes the I3C_CR register, and requires a next data byte/word to be written, if needed within this message. As soon as a next control word is detected as required by the hardware to be transmitted on the I3C bus (if a repeated start must be emitted on the I3C bus or if the C-FIFO gets available room), this control word is requested to be written into the C-FIFO until the last message (MEND = 1 in the I3C_CR register).

Similarly, as soon as another data byte/word is detected as required by the hardware to be transmitted on the I3C bus (if a repeated start must be emitted on the I3C bus, and if TX-FIFO is not full, and if data byte(s)/word(s) must be transmitted during this I3C message), this data byte/word must be written in the TX-FIFO.

C-FIFO and TX-FIFO preload

When C-FIFO/TX-FIFO preload is configured (TMODE = 1 in the I3C_CFGR register), before emitting a start on the bus, the I3C peripheral waits for loading as much as possible both the C-FIFO and the TX-FIFO, as follows:

- wait for a first control word to be written into the C-FIFO
- wait for data byte(s)/word(s) to be written in the TX-FIFO, if any, as defined by the first control word (if RNW = 0 and DCNT[15:0] = 0 in the I3C_CR register), and up to the TX-FIFO size
- If TX-FIFO is not full and if the first control word is not the last of the frame (MEND = 0 in the I3C_CR register):
  - Wait for a second control word to be written into the C-FIFO, then C-FIFO is full.
  - If TX-FIFO is not full, wait for data byte(s)/word(s) to be written in the TX-FIFO, if any, as defined by the second control word (RNW = 0 and DCNT[15:0] = 0 in the I3C_CR register), and up to the TX-FIFO size.

Then, as soon as a next control word is detected as required by the hardware to be transmitted on the I3C bus (if a repeated start must be emitted on the I3C bus), this control

word is requested to be written into the C-FIFO until the last message (MEND = 1 in the I3C_CR register).

Similarly, as soon as a next data byte/word is detected as required by the hardware to be transmitted on the I3C bus (if a repeated start must be emitted on the I3C bus and if TX-FIFO is not full and if data byte(s)/word(s) are to be transmitted during this I3C message), this data byte/word must be written in the TX-FIFO.

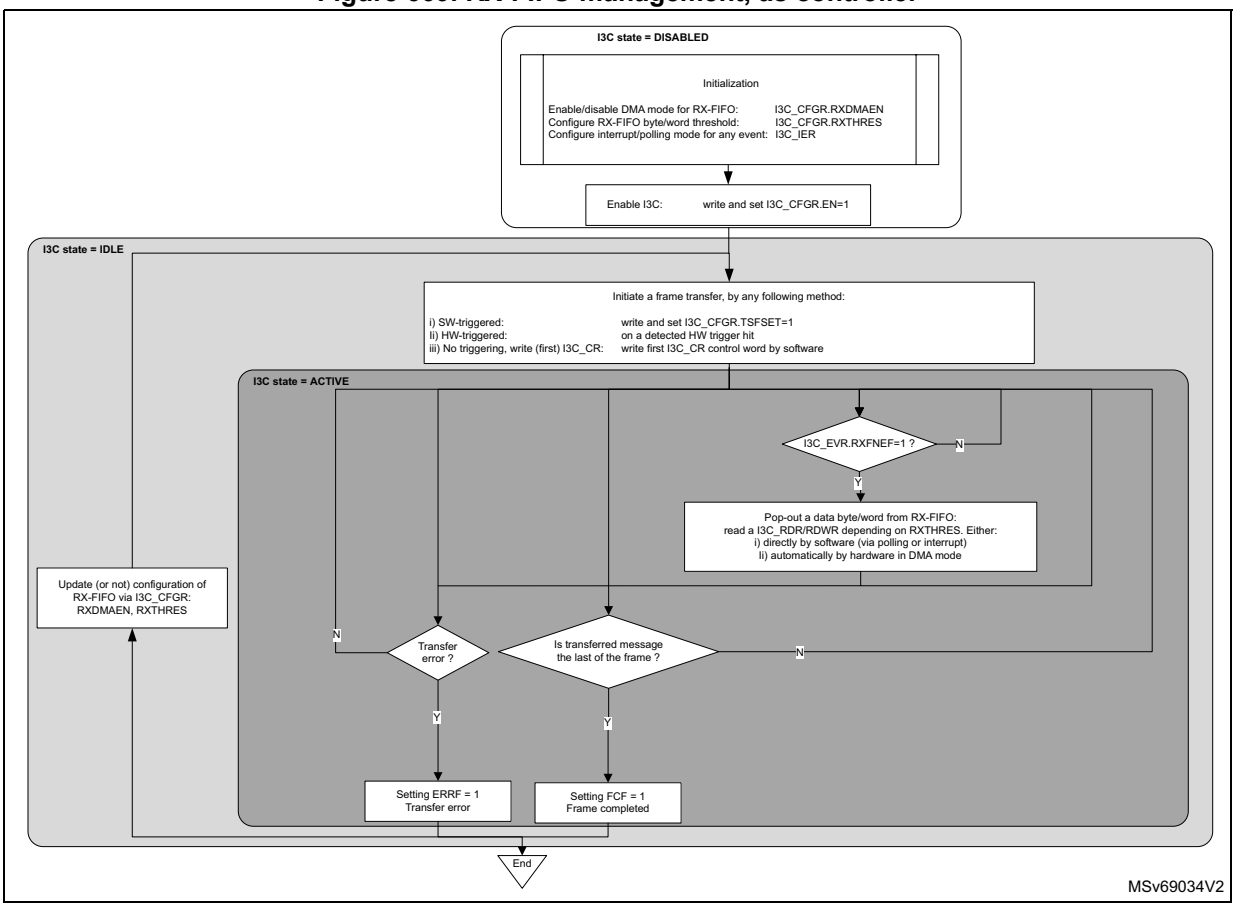
49.10.3 RX-FIFO management, as controller

When controller, as shown in figures of *Section 49.9*, RX-FIFO is used during any of the following transfers:

- broadcast ENTDAA CCC (*Figure 655*)
- direct CCC read (*Figure 654*), including direct RSTACT CCC read (*Figure 656*)
- private read (*Figure 661*)
- legacy I2C read (*Figure 663*)

Figure 669 illustrates the management of the RX-FIFO for queuing and popping-out data bytes or word(s) as received from the I3C bus, when the I3C peripheral acts as controller.

Figure 669. RX-FIFO management, as controller



First, the software must initialize the RX-FIFO management via the following fields of the I3C_CFGR register:

- RXDMAEN: enable/disable DMA mode for RX-FIFO
- RXTHRES: pop-out data byte(s) or word(s) from RX-FIFO

Then, depending on RXDMAEN, the RX-FIFO is read either:

- directly by the software (RXDMAEN = 0) at the byte/word level:
  - via polling mode (RXFNEIE = 0 in the I3C_IER register): waiting for a next data byte/word is requested by the hardware (RXFNEF = 1 in the I3C_IER register) before an explicit read to the I3C_RDR or I3C_RDWR register, depending upon bit RXTHRES in the I3C_CGFR register
  - via enabled interrupt notification if RXFNEIE = 1 in the I3C_IER register
- by the allocated DMA channel (if RXDMAEN = 1) to the corresponding DMA request from the I3C peripheral (i3c_rx_dma):
  - as configured at DMA block level, the DMA automatically pops-out/reads data bytes/words from the I3C_RDR or I3C_RDWR register (depending upon bit RXTHRES), and writes them into its memory destination buffer, until the frame completion (a stop is emitted on the I3C bus after the last message of the frame), unless a transfer error occurs.

An I3C message begins from a start or a repeated start, and ends with a stop or a repeated start. At message level, the last received data byte/word from the I3C bus is flagged by IRXLASTF = 1 in the I3C_EVR register. When an I3C frame is described with multiple messages (separated by a repeated start), this event can be used by the software for updating the pointer to the buffer where is/are stored the data byte(s)/word(s) of the next message.

If RX-FIFO is full and a data byte is received on the I3C bus, an RX-FIFO overrun is reported (ERRF = 1 in the I3C_EVR register and DOVR = 1 in the I3C_SER register). If enabled by ERRIE = 1 in the I3C_IER register, an interrupt is generated.

The configuration for the RX-FIFO management can be modified when the I3C peripheral is not in active state.

Early read termination from the target

A private read message can be early completed (also known as prematurely ended) by the addressed target.

- If RXDMAEN = 1:
  - the software must allocate, for the DMA request i3c_rx_dma, a DMA channel x, capable of peripheral early termination (refer to DMA implementation section).
  - The software must configure the DMA channel x to enable the DMA peripheral-flow control mode via PFREQ = 1 in the DMA_CxTR2 register, to be able to perform a(n) (early or not) DMA block completion.
  - Then, on block completion, the software can read BR1.BNDT[15:0] in DMA_Cx and/or DMA_CxSAR register(s), to get the effective number of DMA transferred bytes.
- If RXDMAEN = 0:
  - at message level, the last received data byte/word from the I3C bus is flagged by RXFNEF = 1 and RXLASTF = 1 in the I3C_EVR register.

In any case, if the S-FIFO is disabled (if SMODE = 0 in the I3C_CFGR register), the software is notified that an early read termination occurs by RXTGTENDF = 1 in the I3C_EVR register, and the corresponding interrupt if enabled. Then, software can read the status register I3C_SR to check information related to the last message ,and get the number of received data bytes on the prematurely ended read transfer (XDCNT[15:0] in the I3C_SR register).

In any case, if the S-FIFO is enabled (SMODE = 1 in the I3C_CFGR register), the software or the DMA (depending upon SDMAEN in the I3C_CFGR register) must read for each message the status register I3C_SR. The number of effective received data bytes on the prematurely ended read message is reported by XDCNT[15:0] (and then ABT = 1) in the I3C_SR register.

For more information, refer to *I3C status register (I3C_SR)* and *Section 49.10.4*.

49.10.4 S-FIFO management, as controller

When controller, S-FIFO can be used by the software to be able to read the *I3C status register (I3C_SR)* for each transferred message.

Reading status register with disabled S-FIFO

If SMODE = 0 in the I3C_CFGR register, the S-FIFO is disabled and the status register can be read as a usual register:

- the register content is overwritten by hardware when is transferee a new message
- I3C_SR contains the status of the last transferred message
- SCL clock is not stalled if status register is not read.

If SMODE = 0, for the specific case of a private read prematurely ended by the target:

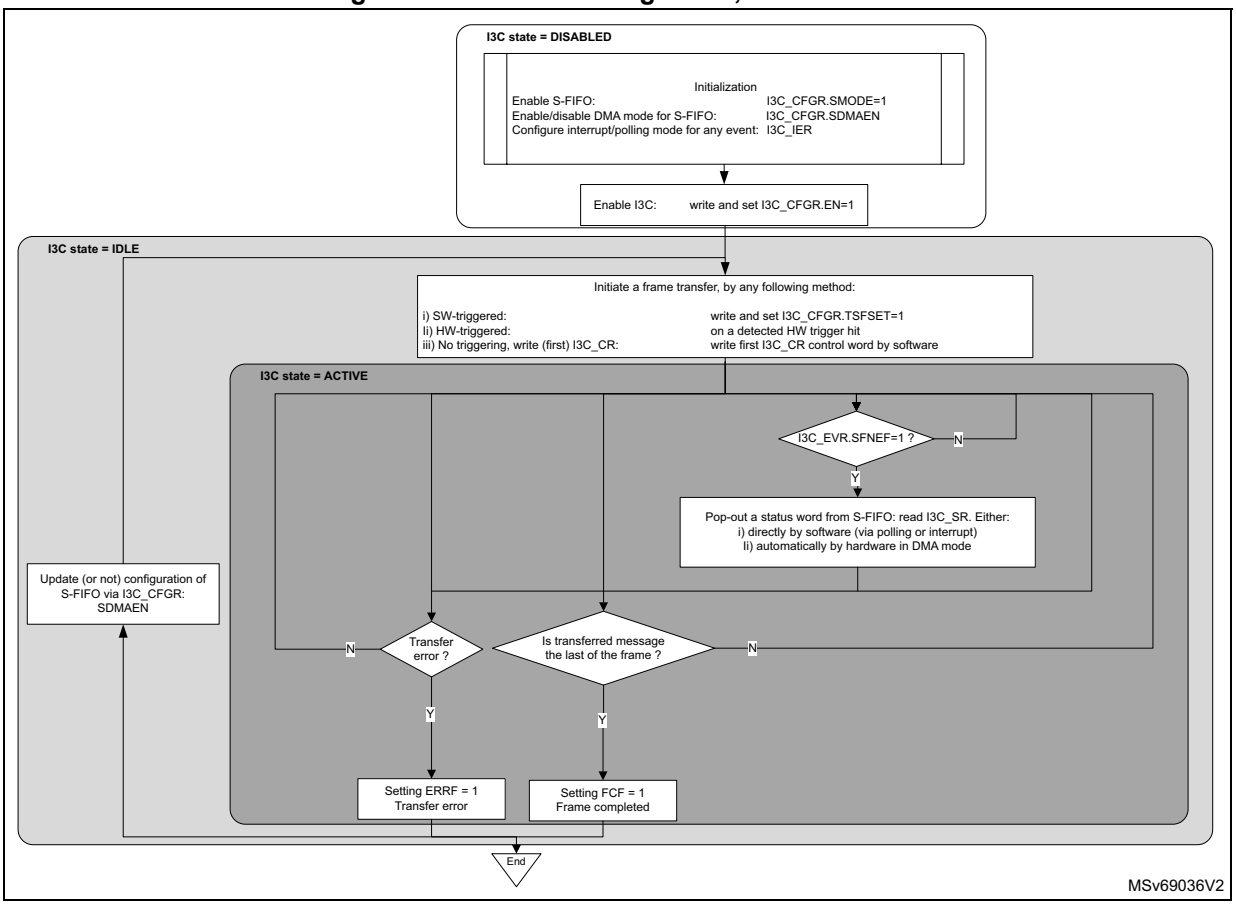
- the software is notified by the flag RXTGTENDF = 1 in the I3C_EVR register and the corresponding interrupt if enabled.
- Then, until that the software has cleared the event flag write and set CRXTGTENDF = 1 in the I3C_CEVR register:
  - no more data byte can be received on the I3C bus and written by the hardware into I3C_RDR/I3C_RDWR registers
  - I3C_SR cannot be updated
  - SCL clock is stalled if needed

Typically, I3C_SR can be read when FCF = 1, or ERRF = 1, or RXTGTENDF = 1 in the I3C_EVR register. XDCNT[15:0] in the I3C_SR register can be read to get the effective number of received data bytes on a private read, after an early termination from the target (refer to *Section 49.10.3*).

Reading status register with enabled S-FIFO

If SMODE = 1 in the I3C_CFGR register, the S-FIFO is enabled. *Figure 670* illustrates the management of the S-FIFO for queuing and popping-out a status word for each executed message on the I3C bus, when the I3C peripheral acts as controller.

Figure 670. S-FIFO management, as controller



First, the software must initialize the S-FIFO management via the SDMAEN field (enable/disable DMA mode for S-FIFO) in the I3C_CFGR register. Then, depending on SDMAEN, the S-FIFO is read either:

- directly by the software (if SDMAEN = 0):
  - via polling mode (SFNEIE = 0 in the I3C_IER register): waiting for a next status word is requested by the hardware (SFNEF = 1 in the I3C_IER register) before an explicit read to the I3C_SR register
  - via enabled interrupt notification (SFNEIE = 1)
- by the allocated DMA channel (if SDMAEN = 1) to the corresponding DMA request from the I3C peripheral (i3c_rs_dma):
  - as configured at DMA block level, the DMA is automatically popping-out/reading status words from the I3C_SR register and writing them into its memory destination buffer, until the frame completion (a stop is emitted on the I3C bus after the last message of the frame), unless a transfer error occurs.

Each message status must be read, else an overrun error is asserted by the hardware (ERRF = 1 in the I3C_EVR register and COVR = 1 in the I3C_SER register) when the S-FIFO is full and a next message status must be written. The corresponding interrupt is raised if enabled by ERRIE = 1 in the I3C_IER register.

The frame completion (FCF = 1 in the I3C_EVR register) is reported only when the S-FIFO is empty.

The configuration for the S-FIFO management can be modified when the I3C peripheral is not in active state.

49.11 I3C FIFOs management, as target

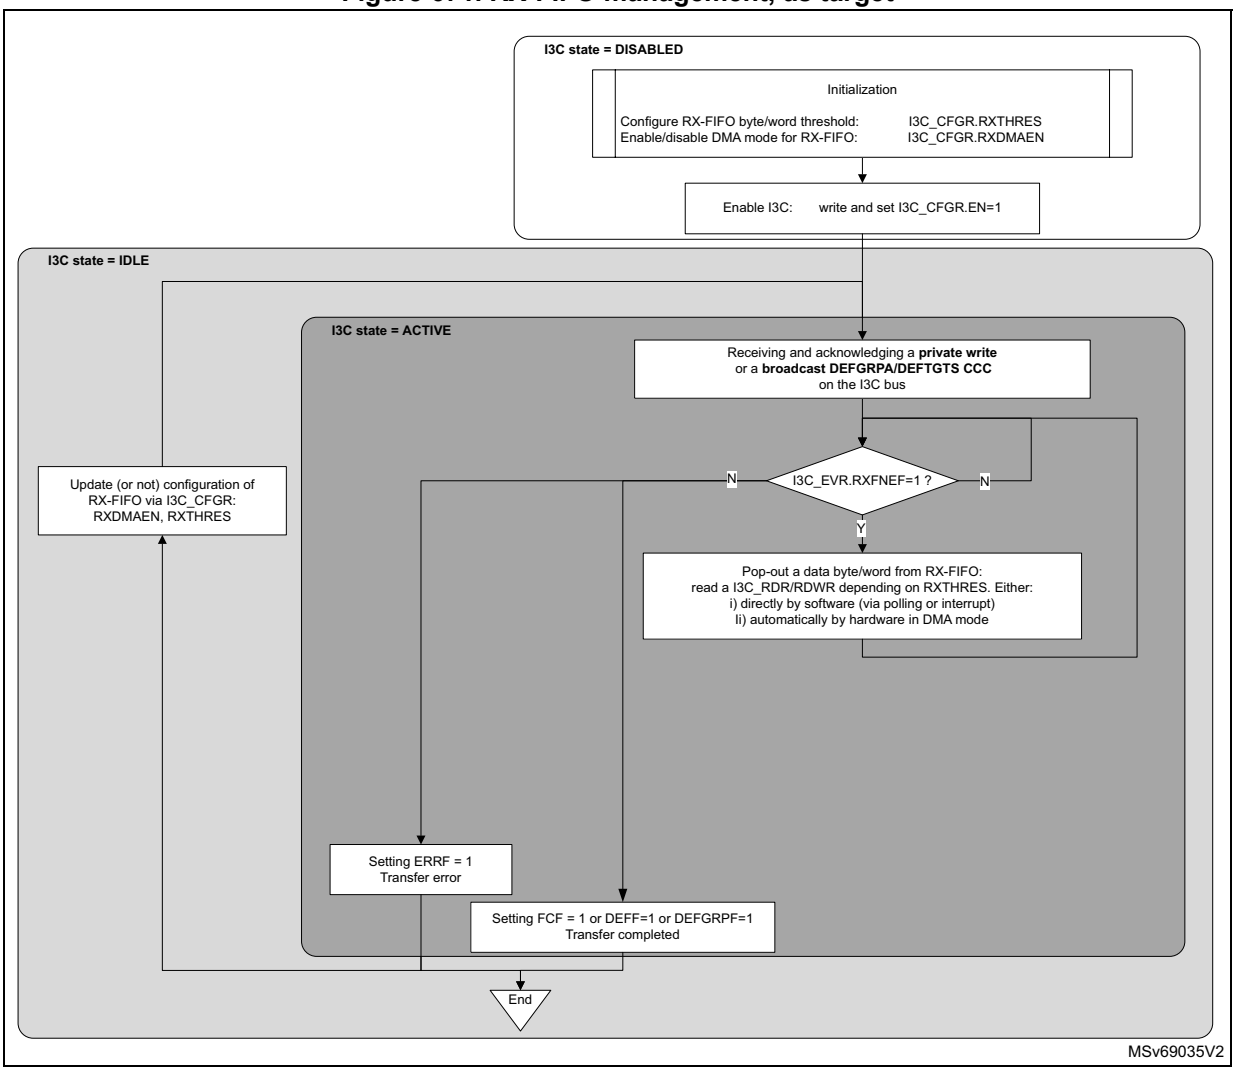
49.11.1 RX-FIFO management, as target

When target, as shown in figures of *Section 49.9*, the RX-FIFO is used during any of the following received and acknowledged transfers:

- broadcast DEFTGTS CCC (*Figure 659*)
- broadcast DEFGRPA CCC (*Figure 660*)
- private write (*Figure 662*)

Figure 671 illustrates the management of the RX-FIFO for queuing and popping-out data bytes or word(s) as received from the I3C bus, when the I3C peripheral acts as target.

Figure 671. RX-FIFO management, as target



First, the software must initialize the RX-FIFO management via the following I3C_CFGR register fields:

- RXDMAEN: enable/disable DMA mode for RX-FIFO
- RXTHRES: pop-out data byte(s) or word(s) from RX-FIFO

Then, depending on RXDMAEN, the RX-FIFO is read either:

- directly by the software (if RXDMAEN = 0) at the byte/word level:
  - via polling mode (RXFNEIE = 0 in the I3C_IER register): waiting for a next data byte/word is requested by the hardware (RXFNEF = 1 in the I3C_IER register) before an explicit read to the I3C_RDR or I3C_RDWR registers, depending upon RXTHRES in the I3C_CGFR register
  - via enabled interrupt notification if RXFNEIE = 1
- by the allocated DMA channel (if RXDMAEN = 1) to the corresponding DMA request from the I3C peripheral (i3c_rx_dma):
  - as configured at DMA block level, the DMA is automatically popping-out/reading data bytes/words from the I3C_RDR or I3C_RDWR register (depending upon RXTHRES) and writing them into its memory destination buffer, until the transfer completion (in the I3C_EVR register, FCF = 1 in case of private write, or GRPF = 1 in case of a DEFGRPA CCC, or DEFF = 1 in case of DEFTGTS CCC), unless a transfer error occurs.

If RX-FIFO is full and a new data byte is received on the I3C bus, a RX-FIFO overrun is reported (ERRF = 1 in the I3C_EVR register and DOVR = 1 in the I3C_SER register) and the corresponding interrupt if enabled.

When the transfer is completed (in the I3C_EVR register, FCF = 1, or GRPF = 1, or DEFF = 1):

- RX-FIFO is empty
- Until software has not processed the RX data buffer corresponding to the completed private write / DEFTGTS / DEFGRPA transfer (meaning until software has not cleared the corresponding flag write and set CFCF / CDEFF / CGRPF to 1 in the I3C_CEVR register), if a next private write / DEFTGTS CCC / DEFGRPA CCC is received and a data byte must be written by the hardware into the RX-FIFO, a transfer error is reported with a RX-FIFO overrun (ERRF = 1 in the I3C_EVR register and DOVR = 1 in the I3C_SER register) and the corresponding interrupt if enabled.

The configuration for the RX-FIFO management can be modified when the I3C peripheral is not in active state.

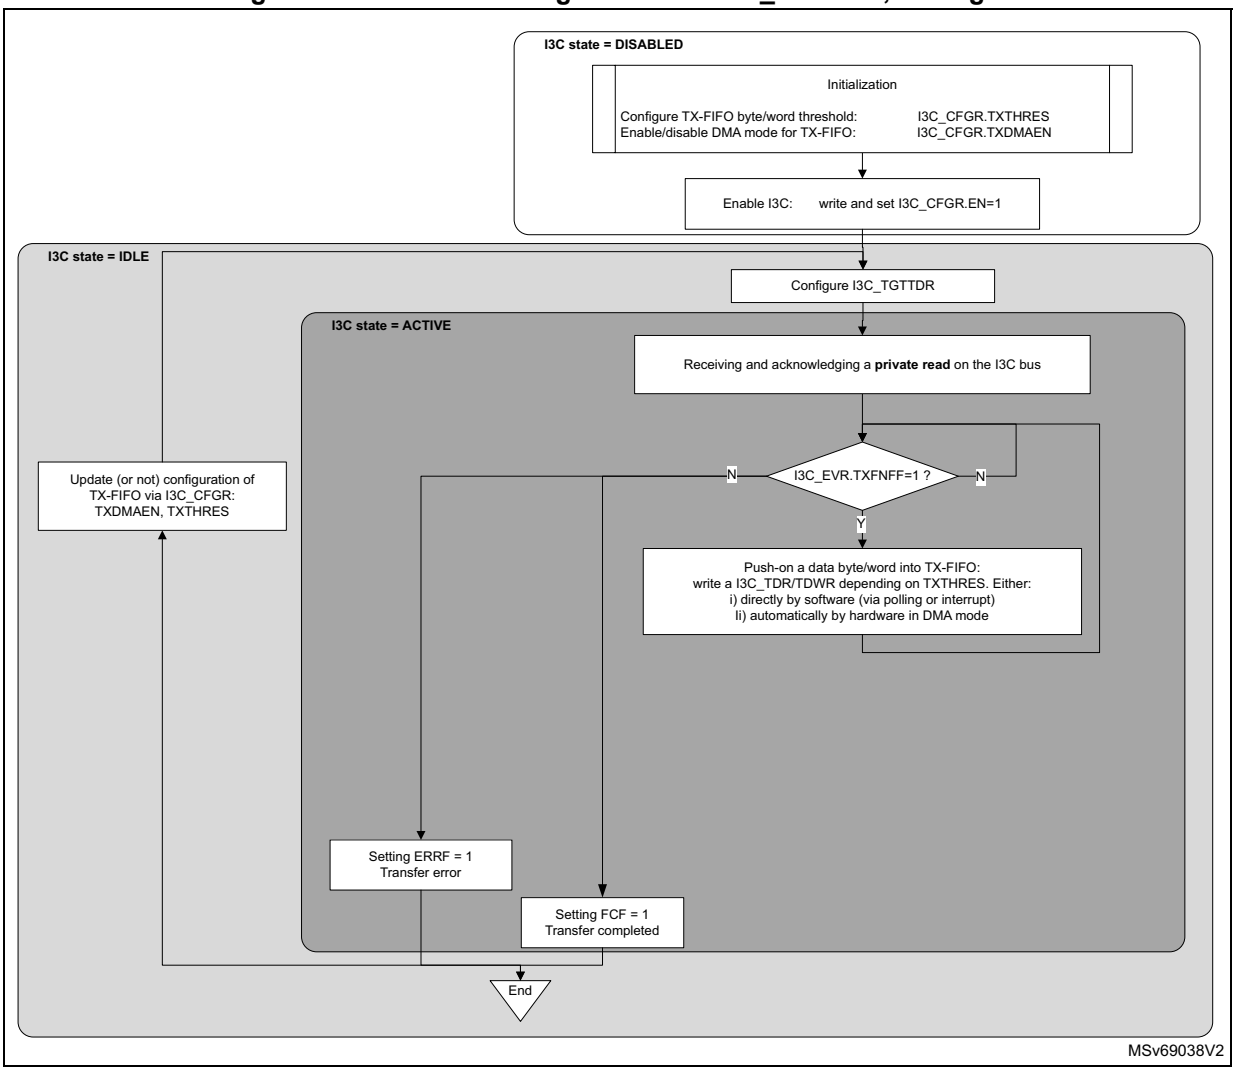
49.11.2 TX-FIFO management, as target

Main scheme

When target, as shown in figures of *Section 49.9*, the TX-FIFO is used only during a private read (*Figure 662*).

Figure 672 illustrates the management of the TX-FIFO for queuing and pushing-on data bytes or word(s) to be transmitted on the I3C bus, when the I3C peripheral acts as target.

Figure 672. TX-FIFO management with I3C_TGTTDR, as target



First, the software must initialize the TX-FIFO management and write I3C_CFGR with

- TXDMAEN: enable/disable DMA mode for TX-FIFO
- TXTHRES: push-on data byte(s) or word(s) to TX-FIFO

Then, before receiving a private read on the I3C bus, the software must configure the *I3C target transmit configuration register (I3C_TGTTDR)* to preload the TX-FIFO with a number of data bytes (write TGTTDCNT[15:0] and PRELOAD = 1 in a single access), so that data bytes from the target are ready to be transmitted on the I3C bus:

- If PRELOAD = 1 and TGTTDCNT[15:0] > TX-FIFO size, TX-FIFO is first preloaded up to the FIFO size.
- If PRELOAD = 1 and TGTTDCNT[15:0] ≤ TX-FIFO size, TX-FIFO is preloaded up to TGTTDCNT[15:0].

Note: TX-FIFO size is 8 bytes (refer to Table 516).

Depending upon TXDMAEN, the TX-FIFO is preloaded either:

- directly by the software (TXDMAEN = 0) at the byte/word level:
  - via polling mode (TXFNFIE = 0 in the I3C_IER register): waiting for a next data byte/word is requested by the hardware (TXFNFF = 1 in the I3C_IER register) before an explicit write to the I3C_TDR or I3C_TDWR register, depending upon TXTHRES in the I3C_CGFR register
  - via enabled interrupt notification if TXFNFIE = 1
- by the allocated DMA channel (TXDMAEN = 1) to the corresponding DMA request from the I3C peripheral (i3c_tx_dma):
  - as configured at DMA block level, the DMA is automatically pushing-on/writing data bytes/words to the I3C_TDR or I3C_TDWR register (depending upon TXTHRES) from its memory source buffer, until the transfer completion (FCF = 1 in the IEC_EVR register), unless a transfer error occurs.

Then, in the same way, either directly by the software or by the allocated DMA channel, if there are remaining TGTTDCNT[15:0] in the I3C_TGTTDR register to be loaded into TX-FIFO for continuing the private read (set PRELOAD = 1 and TGTTDCNT[15:0] > TX-FIFO size), and provided that the private read is not yet completed by the controller:

- If TXTHRES = 0: when a byte is transmitted on the I3C bus, a next byte is preloaded into TX-FIFO
- If TXTHRES = 1: when four bytes are transmitted on the I3C bus, the next word is preloaded into TX-FIFO.

The private read transfer is completed (FCF = 1 in the I3C_EVR register) when either the target or the controller first terminates the data byte transfer.

On transfer completion, the software can:

- read XDCNT[15:0] in the I3C_SR register: the effective number of transmitted data bytes
- read TGTTDCNT[15:0] in the I3C_TGTTDR register: the remaining number of bytes to be loaded and transmitted on the I3C bus
- flush TX-FIFO: write and set (or not) TXFLUSH = 1 in the I3C_CFGR register, continue (or not) for another private read, depending upon the user application

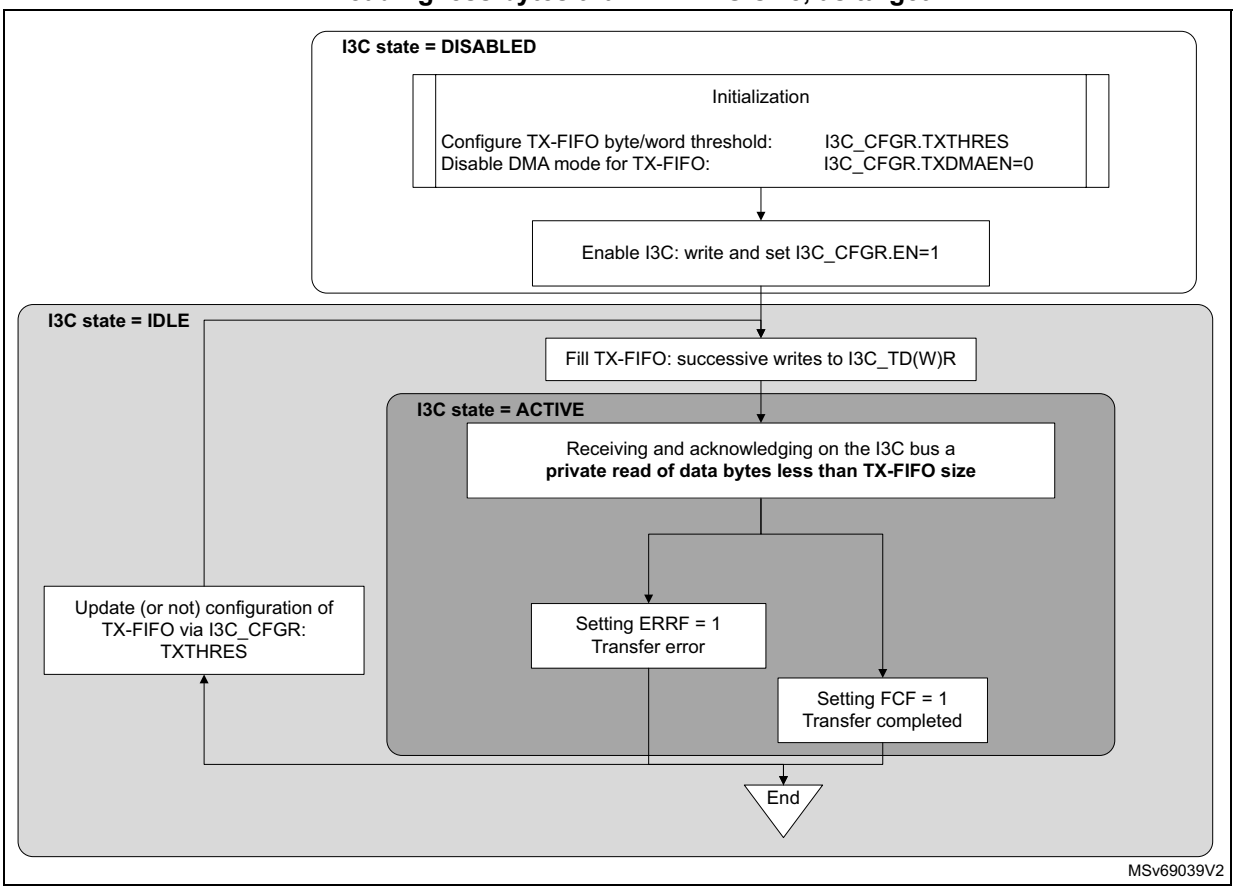
If TX-FIFO is empty and a data byte must be transmitted on the I3C bus, a TX-FIFO underrun is reported (ERRF = 1 in the I3C_EVR register and DOVR = 1 in the I3C_SER register). If enabled by ERRIE = 1 in the I3C_EVR register, an interrupt is generated.

The configuration for the TX-FIFO management can be modified when the I3C peripheral is not in active state.

Alternative without I3C_TGTTDR, if less bytes than the TX-FIFO size

Alternatively to the use of the I3C_TGTTDR register, as shown in the *Figure 673*, when the DMA is not used (TDMAEN = 0), provided that the number of data bytes to be read on the I3C bus is less that the TX-FIFO size, the software can directly prepare and fill the TX-FIFO with the number of bytes to be read directly by the software, by successive writes to the I3C_TDR or I3C_I3C_TDWR, depending upon TXTHRES.

Figure 673. TX-FIFO management by software without I3C_TGTTDR if reading less bytes than TX-FIFO size, as target



49.12 I3C error management

49.12.1 Controller error management

Table 525 enumerates the I3C bus error conditions, and, for each of them, the corresponding detection, action and reporting when the I3C peripheral acts as controller.

Table 525. I3C controller error management

Error type	Description	Error detection	Controller action	Reported error(1)
CE0	Illegally formatted CCC (e.g. less returned data byte(s))	Prematurely ended read data by target on a direct CCC read(2)	Hardware emits a stop.	ERRF = 1 and PERR = 1 and CODERR[3:0] = 0000

Table 525. I3C controller error management (continued)

Error type	Description	Error detection	Controller action	Reported error(1)
CE1	Monitoring error	An incorrect ACK is detected at the end of a legacy I^2C read	Hardware keeps SCL running for nine clock cycles and another byte to be possibly exchanged, then emits again a NACK, followed by a stop.	ERRF = 1 and PERR = 1 and CODERR[3:0] = 0001
		Restart or stop cannot be generated at the end of an I3C SDR read	SCL is kept running. Software can stop SCL by writing a control word with MTYPE[3:0] = 0000 in the I3C_CR register (header message), then must typically wait at least 150 µs before emitting another message.	
		After a CE1 error, a start cannot be generated		
CE2	No response to broadcast address (0b111_1110)	Header (0b111_1110 + RnW = 0) is detected as NACK-ed during a message different from escalation fault or reset pattern message	Hardware emits an HDR exit pattern followed by a stop.	ERRF = 1 and PERR = 1 and CODERR[3:0] = 0010
CE3	Failed controller hand-off	New controller has not driven SCL low after having SDA low (after a start via a test header or a start request from a target) and after the delay time defined by its activity state has elapsed	Hardware emits a start + 0b111_1110 + RnW = 0, followed by ACK/NACK from target(s), then stops.	ERRF = 1 and PERR = 1 and CODERR[3:0] = 0011
-	Incorrect returned 7-bit target address with parity bit on a GETACCCR CCC	Incorrect dynamic address and/or parity bit is detected	Hardware cancels the GETACCCR CCC by emitting a Restart + 0b111_1110 + RnW = 0, followed by ACK/NACK from target(s), then stops.	ERRF = 1 and DERR = 1
-	Addressed target is NACK-ed on a direct CCC read for the first time	NACK is detected	Hardware performs a single-retry by emitting a Restart + 7-bit same target address + RnW = 1.	-
-	Addressed target is NACK-ed on either a direct CCC write, an I3C private read/write, a legacy I^2C, or a direct CCC read for the second time	NACK is detected	Hardware emits a stop.	ERRF = 1 and ANACK= 1

Table 525. I3C controller error management (continued)

Error type	Description	Error detection	Controller action	Reported error(1)
-	Assigned/transmitted dynamic address with parity bit is NACK-ed on a ENTDAA CCC for the first time	NACK is detected	Hardware performs a single-retry assignation loop by emitting a Restart + 0b111_1110 + RnW = 1, followed by an ACK and 8-byte read data from the (most-priority) target, followed by the assigned address + parity bit.	-
-	Assigned/transmitted dynamic address with parity bit is NACK-ed on a ENTDAA CCC for the second time	NACK is detected	Hardware emits a stop.	ERRF = 1 and DNACK= 1
-	Write data is NACK-ed on a legacy I2C write			
-	Control word, status word, transmitted data or read data is not written/read in time vs. I3C bus timings	SCL stall timeout	Hardware emits a stop.	ERRF = 1 and (COVR = 1 or DOVR = 1)

1. ERRF in the I3C_EVR register, PERR, CODERR[3:0], DERR, ANACK, DNACK, COVR, and DOVR in the I3C_SER register.
2. MIPI v1.1: on a GETCAPS CCC, the number of received data bytes can be 2, 3 or 4. However a target compliant with MIPI v1.0 can return only the first byte as per previously named GETHDRCAP CCC. As a result, CE0 is not generated if the number is lower than 4.
On a GETMXDS CCC, the number of received data bytes can be 2 or 5. CE0 is not generated if the number is lower than 5.

49.12.2 Target error management

Table 526 enumerates the I3C bus error conditions, the corresponding detection, action, and reporting when the I3C peripheral acts as target.

Table 526. I3C target error management

Error type	Description	Error detection	Next (when emitted by the controller)	Reported error(1)
TE0	Invalid broadcast address (0b111_1110+RnW = 0) or Invalid 7-bit dynamic address + RnW = 1 after DAA assignment	A forbidden address is detected after a start or a repeated start	Hardware waits for an HDR exit pattern	ERRF = 1 and PERR = 1 and ODERR[3:0] = 1000
TE1	CCC code	A CCC code is detected with a parity error		ERRF = 1 and PERR = 1 and ODERR[3:0] = 1001

Table 526. I3C target error management (continued)

Error type	Description	Error detection	Next (when emitted by the controller)	Reported error(1)
TE2	Write data	A write data byte is detected with a parity error on an I3C private write message	Hardware waits for a stop or a repeated start	ERRF = 1 and PERR = 1 and ODERR[3:0] = 1010
TE3	Assigned address during dynamic address arbitration	Assigned dynamic address is detected with a parity error on a ENTDAA CCC		ERRF = 1 and PERR = 1 and ODERR[3:0] = 1011
TE4	0b111_1110 + RnW = 1 missing after Sr during dynamic address arbitration	Missing {0b111_1110 + RnW = 1} after Sr during dynamic address arbitration is detected		ERRF = 1 and PERR = 1 and ODERR[3:0] = 1100
TE5	Transaction after detecting CCC	Invalid CCC direction is detected vs. direction provided during address phase, on a CCC direct read/write		ERRF = 1 and PERR = 1 and ODERR[3:0] = 1101
TE6	Monitoring error	SDA is detected as driven at unexpected value on an SDR data read (during a CCC direct read or a private read or an IBI)	Hardware releases SDA, then waits for a stop or a repeated start	ERRF = 1 and PERR = 1 and ODERR[3:0] = 1110
-	Monitoring SCL on an SDR data read	SCL is detected as stable for more than 125 µs on an SDR data read (during a CCC direct read or a private read or an IBI)		ERRF = 1 and STALL = 1
-	Data to be transmitted not written/available in time vs. I3C bus timings	Data to be transmitted not written by software or DMA in due time on a private read	Hardware detects a stop or a repeated start	ERRF = 1 and DOVR = 1
-	Received data cannot be registered in time vs. I3C bus timings	Received data is not read by software or DMA in due time on a private write or a DEFTGTS or a DEFGRPA CCC		

1. ERRF in the I3C_EVR register, PERR, ODERR[3:0], STALL, and DOVR in the I3C_SER register.

49.13 I3C wake-up from low-power mode(s)

49.13.1 Wake-up from Stop

The user must first configure the reset and clock controller (RCC) to set up the clock data path down to the I3C peripheral: to select the source oscillator for the I3C kernel clock, the source oscillator for the I3C APB clock, and to set the clocks frequency. At initialization via the RCC, the user must enable the I3C clocks for a given I3C peripheral to be functional, separately for Run/Sleep mode and for Stop mode. For more details about RCC programming, refer to *Section 11: Reset and clock control (RCC)*.

The I3C hardware automatically manages its own clocks gating and generates a separated clock request output signal to the RCC for its kernel clock and its APB clock, whenever the device is in Run, Sleep or Stop mode.

When entering a Stop mode, the V_{CORE} domain is supplied, by default any clock oscillator is disabled, and in any case, neither the system clock nor a peripheral clock is running in the domain.

As controller: wake-up on an IBI without MDB, a hot-join request or a controller-role request

When the peripheral acts as controller, before the product enters a low-power mode, the software must issue an ENTASx CCC, generally with x = 0, 1, 2 or 3, to inform targets that the I3C controller is not expected to exit from idle state neither to communicate on the I3C bus before an interval of, respectively, 1 µs, 100 µs, 2 ms or 50 ms, has elapsed. This delay defines the T_{CAS} delay for the controller to set the SCL bus clock low and running, after a start condition. More specifically for a Stop mode, the CCC must be restricted to an ENTASx with the value x=1, 2, or 3.

The general scheme for the I3C wake-up from Stop is the following:

1. First the I3C peripheral requests its kernel clock to the system:
   - On a detected start condition on the I3C bus (SDA line is detected to be driven low while SCL is high).
   - As controller, as initiated by an external I3C target device for a hot-join/in-band interrupt/controller-role request. Once the kernel clock is provided and running, the I3C hardware uses an internal timer to wait for the corresponding T_{CAS} time to elapse, then drives low SCL and continues toggling SCL to let the target perform its hot-join/in-band interrupt/controller-role request on the I3C bus.
2. The system enables the source oscillator of the I3C kernel clock, and the clock gets ready (after few microseconds from HSI). The user may keep the source oscillator ON in Stop mode to reduce this startup latency, at the expense of power consumption.
   - The I3C peripheral maintains the kernel clock request until the generation of the Stop condition on the I3C bus.
3. After that the kernel clock is running, as controller the I3C peripheral requests its APB clock to the system:
   - On the ACKed address of a received IBI request (*Figure 664*), and it maintains the APB clock request until that IBIF is cleared.

     If the IBI is without MDB: a Stop is normally generated on the I3C bus, even if the APB clock is not yet provided.
   - On the ACKed address of a received controller-role request (*Figure 665*), and it maintains the APB clock request until that CRF is cleared.
   - On the ACKed address of a hot-join request (*Figure 666*), and it maintains the APB clock request until that HJF is cleared.
4. The system is notified of the I3C APB clock request, and the power management unit of the PWR module is awaken.
5. An additional delay may be needed for the regulator, if it must increase the voltage for Run mode.
6. The system enables the system clock that drives the APB clock. There is an additional delay if the selected oscillator source for the system and APB clocks is not the same as the one driving the I3C kernel clock. If so, the system enables the source oscillator of the system clock, which gets ready after a delay.
7. With the APB clock running, the peripheral can log the I3C transfer in its status and data registers. When the bus transfer is completed, the peripheral generates the corresponding flag (IBIF/CRF/HJF), and the enabled interrupt can wake up the CPU.

As target: wake-up on a reset pattern

The target reset pattern is a specific scheme for a controller to wake up and possibly reset a target from a low power mode. It consists both in the RSTACT CCC and in the in-band reset pattern generation.

As target, the sequence for the I3C wake-up from Stop on a reset pattern is the following:

1. When the peripheral detects a reset pattern on the bus (14 SDA transitions while SCL is kept low), it requests its APB clock to the system to set the RSTF flag of the I3C_EVR register
2. The system is notified of the I3C APB clock request, and the power management unit of the PWR module is awaken (after few microseconds).
3. An additional delay may be needed for the regulator, if it must increase the voltage for Run mode.
4. The system enables the source oscillator of the system clock, which gets ready after few microseconds.
5. With the APB clock running, the I3C peripheral can raise the RSTF flag of the I3C_EVR register, and the enabled interrupt can wake up the CPU.

As target: wake-up on a missed start

1. The peripheral requests its kernel clock to the system:
   - On a detected start condition on the I3C bus (SDA line is detected to be driven low while SCL is high)
   - As target, as initiated by an external I3C device, whatever controller or target.
   - If the kernel clock is not provided before that SCL is driven low by the external controller, then the I3C target detects that a I3C bus start is missed and waits for the kernel clock to be provided. It can be noted that an I3C controller message intended to be addressed to it may have been missed (and NAcked). Or may have been missed any I3C CCC or private message from the controller to another addressed target or an IBI/CR/HJF start request from another target.
2. The system enables the source oscillator of the I3C kernel clock, and the clock gets ready (after few microseconds if HSI). The user may keep the source oscillator ON in Stop mode to reduce this startup latency, at the expense of power consumption. Especially if the controller is in an Activity State of x = 0 (with a 1 µs T_{CAS} latency).
3. After that the kernel clock is running, as target, the I3C peripheral requests its APB clock to the system to raise the WKPF flag conditioned by non-user text or:
4. The system is notified of the I3C APB clock request, and the power management unit of the PWR module is awaken (after few microseconds).
5. An additional delay may be needed for the regulator, if it must increase the voltage for Run mode.
6. The system enables the system clock, which drives the APB clock. There is an additional delay if the selected oscillator source for the system and APB clocks is not the same as the one driving the I3C kernel clock. If so, the system enables the source oscillator of the system clock, which gets ready after few microseconds.
7. With the APB clock running:
   - The missed start flag (WKPF of the I3C_EVR register) is raised conditioned by non-user text: if it occurred, and the enabled interrupt can wake up the CPU. It is then known that an I3C bus transaction was missed, but not whether the target was addressed or not. The software should use a timeout in order to return to Stop mode, if it is not addressed by the controller again within this interval.

49.14 I3C in low-power modes

Table 527. Effect of low-power modes

Mode	Description
Sleep	No effect. I3C interrupts cause the device to exit Sleep mode.
Stop(1)	The content of the I3C registers is kept when entering Stop mode. I3C hardware manages automatically its own clocks gating and generates, for its kernel clock and APB clock, a clock request output signal to the RCC. I3C interrupts can cause the device to wake up and exit Stop mode. I3C transfers can occur and can be assisted with an autonomous DMA for data transfers to/from memory, provided that the autonomous DMA can operate in Stop mode. Refer to *Section 49.13* for more details.
Standby	The I3C peripheral is powered down and must be reinitialized after exiting Standby mode.

1. Refer to *Table 515* to know if Stop mode is supported, and which one.

49.15 I3C interrupts

Table 528. I3C interrupt requests

Interrupt acronym		Interrupt event	Used as		Interrupt enable: field in I3C_IER	Event flag: field in I3C_EVR	Event clear method: write 1 to field in I3C_CEVR
			Controller	Target			
I3C	EVT	A control word is requested	X	-	CFNFIE	CFNFF	-
		A status word is available	X	-	SFNEIE	SFNEF	-
		Data to be transmitted are requested	X	X	TXFNFIE	TXFNFF	-
		Received data are available	X	X	RXFNEIE	RXFNEF	-
		Controller: frame transfer is completed Target: private transfer is completed	X	X	FCIE	FCF	CFCF
		A private read transfer is prematurely ended by the target (and SMODE = 0 in the I3C_CFGR register)	X	-	RXTGTENDIE	RXTGTENDF	CRXTGTENDF
		An IBI request is received	X	-	IBIIE	IBIF	CIBIF
		A controller-role request is received	X	-	CRIE	CRF	CCRF
		A hot-join request is received	X	-	HJIE	HJF	CHJF
		IBI request is completed	-	X	IBIENDIE	IBIENDF	CIBIENDF
		I3C bus start is missed	-	X	WKPIE	WKPF	CWKPF
		Direct GETACCR CCC is received	-	X	CRUPDIE	CRUPDF	CCRUPDF
		Direct GETSTATUS CCC is received	-	X	STAIE	STAF	CSTAF
		Any direct GETxxx CCC (except GETSTATUS) is received	-	X	GETIE	GETF	CGETF
		Dynamic address is updated (broadcast ENTDAA or RSTDAA, or direct SETNEWDA is received)	-	X	DAUPDIE	DAUPDF	CDAUPDF
		Direct SETMWL CCC is received	-	X	MWLUPDIE	MWLUPDF	CMWLUPDF
		Direct SETMRL CCC is received	-	X	MRLUPDIE	MRLUPDF	CMRLUPDF
		A reset pattern is detected	-	X	RSTIE	RSTF	CRSTF
		Bus activity state is updated (direct/broadcast ENTASx CCC is received)	-	X	ASUPDIE	ASUPDF	CASUPDF
		Broadcast/direct ENEC/DISEC CCC is received	-	X	INTUPDIE	INTUPDF	CINTUPDF
		Broadcast DEFTGTS CCC is received	-	X	DEFIE	DEFF	CDEFF
		Broadcast DEFGRPA CCC is received	-	X	GRPIE	GRPF	CGRPF
	ERR	An error occurred	X	X	ERRIE	ERRF	CERRF

49.16 I3C registers

The I3C registers must be accessed with a 32-bit word aligned address.

Note: I3C_RDR and I3C_TDR registers must be accessed with a single significant LSB data byte for, respectively, reading RX-FIFO and writing TX-FIFO.

49.16.1 I3C message control register (I3C_CR)

Address offset: 0x000

Reset value: 0x0000 0000

This register must be used to control the message to emit on the I3C bus:

- when I3C acts as controller (bit[30] = MTYPE[3] = 0): if there is no CCC code to be emitted bits[29:27] = MTYPE[2:0] differ from 110; else the alternate register description *Section 49.16.2* must be considered.
- when I3C acts as target (bit[30] = MTYPE[3] = 1).

When I3C acts as controller:

- If the control FIFO (C-FIFO) is not full (CFNFF = 1 in the I3C_EVR register), writing into this register means pushing a new control word into the C-FIFO; either by software, or automatically by DMA, as defined by CDMAEN in the I3C_CFGR register.
- If C-FIFO is empty and a restart must be emitted with a new control word, the I3C hardware asserts the control FIFO error underrun flag (COVR = 1 in the I3C_SER register). If enabled by ERRIE = 1 in the I3C_IER register, an interrupt is generated.
- After the last message of the frame is completed (a message with MEND = 1 in the I3C_CR register), the I3C hardware asserts the frame completed flag (FCF = 1 in the I3C_EVR register) and the corresponding interrupt, if enabled.

When I3C acts as target, this register is used in register mode:

- Software writes into this register to initiate a command (IBI, controller-role or hot-join request) on the I3C bus.
- C-FIFO is disabled, and there is no DMA mode neither for control words.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MEND	MTYPE[3:0]				Res.	Res.	Res.	ADD[6:0]							RNW
w	w	w	w	w				w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DCNT[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bit 31 **MEND**: Message end type/last message of a frame (when the I3C acts as controller)

0: this message from controller is followed by a repeated start (Sr), before another message must be emitted

1: this message from controller ends with a stop (P), being the last message of a frame

Bits 30:27 **MTYPE[3:0]**: Message type (whatever I3C acts as controller/target)

Condition: when I3C acts as I3C controller

0000: **SCL clock is forced to stop** until a next control word is executed

Bits[26:0] are ignored. On a CE1 error detection (ERRF = 1 in the I3C_EVR register and CODERR[3:0] = 0001 in the I3C_SER register) where a start/restart/stop is prevented from being generated, the software must use this message type for SCL “stuck at” recovery. Refer to *Table 525*.

0001: **header message**

Bits[26:0] are ignored. If the addressed target is not responding with an ACK to a private/direct message, as an escalation stage after a failed GETSTATUS tentative, the software must program this with EXITPTRN = 1 in the I3C_CFGR register, so that an HDR exit pattern is emitted on the bus, whatever the header is ACK-ed or NACK-ed (to avoid the target to consider that the I3C bus is in HDR mode). Refer to *Table 525* and MIPI specification about escalation handling.

0010: **private message** (refer to *Figure 661*)

Bits[23:17] (ADD[6:0]) are the emitted 7-bit dynamic address.
Bit[16] (RNW) is the emitted RnW bit.
Bits[15:0] (DCNT[15:0]) are the number of programmed data bytes.
The transferred private message is:

– {S / S + 0b111_1110 + RnW = 0 + Sr/Sr+*} + 7-bit DynAddr + RnW + (8-bit Data + T)* + Sr/P.
– After an S (start), depending upon bit NOARBH in the I3C_CFGR register, the arbitrable header (0b111_1110 + RnW = 0) is inserted or not.
– Sr+*: after an Sr (repeated start), the hardware automatically inserts (0b111_1110 + RnW = 0) if needed, if it follows a previous message without ending by a P (stop).

0011: **direct message (second part of an I3C SDR direct CCC command)** (refer to *Figure 654*)

Bits[23:17] (ADD[6:0]) are the emitted 7-bit dynamic address.
Bit[16] (RNW) is the emitted RnW bit.
Bits[15:0] (DCNT[15:0]) are the number of programmed data bytes.
The transferred direct message is: Sr + 7-bit DynAddr + RnW + (8-bit Data + T)* + Sr/P

0100: **legacy I^2C message** (refer to *Figure 663*)

Bits[23:17] (ADD[6:0]) are the emitted 7-bit static address.
Bit[16] (RNW) is the emitted RnW bit.
Bits[15:0] (DCNT[15:0]) are the number of programmed data bytes.
The transferred legacy I^2C message is:

– {S / S + 0b111_1110 + RnW = 0 + Sr/Sr+*} + 7-bit StaAddr + RnW + (8-bit data + T)* + Sr/P.
– After an S, depending on NOARBH, the arbitrable header (0b111_1110 + RnW = 0) is inserted or not.
– Sr+*: after an Sr (repeated start), the hardware automatically inserts (0b111_1110 + RnW = 0) if needed (if it follows a previous message without ending by a P (stop)).

Others: reserved

Condition: when I3C acts as I3C target

1000: **hot-join request** (W) (refer to *Figure 665*)

The transferred hot-join request is {S +} 0b000_0010 addr + RnW = 0.
Writing the control word initiates the hot-join request if target is allowed to do so (HJEN = 1 in the I3C_DEVR0 register), either actively after a bus idle condition via the hardware issuing a start request (SDA low) and waiting for the controller to activate SCL clock, or passively if the controller initiates a concurrent message.

1001: **controller-role request** (W) (refer to *Figure 666*)

The transferred controller-role request is {S +} DA[6:0] + RnW = 0 (DA in the I3C_DEVR0 register)
Writing the control word initiates the controller-role request if target is allowed to do so (CREN = 1 and DAVAL = 1 in the I3C_DEVR0 register), either actively after a bus idle condition via the hardware issuing a start request (SDA low) and waiting for the controller to activate SCL clock, or passively if the controller initiates a concurrent message.

1010: **IBI (in-band interrupt) request** (R) (refer to *Figure 664*)

Bits[15:0] (DCNT[15:0]) are the number of the IBI data payload (including the first MDB), if any.
The transferred IBI request is {S +} DA[6:0] + RnW = 1 + optional IBI data payload. Writing the control word initiates the IBI request if target is allowed to do so (IBIEN = 1 and DAVAL = 1 in the I3C_DEVR0.register), either actively after a bus idle condition via the hardware issuing a start request (SDA low) and waiting for the controller to activate SCL clock, or passively if the controller initiates a concurrent message.
When acknowledged from controller, the transmitted IBI payload data (optional, depending upon BCR2 in the I3C_BCR register) is defined by DCNT[15:0] in the I3C_CR register and I3C_IBIDR, and must be consistently programmed vs. the IBI payload data size defined by IBIP[2:0] in the I3C_IBIDR register.

Others: reserved

Bits 26:24 Reserved, must be kept at reset value.

Bits 23:17 **ADD[6:0]**: 7-bit I3C dynamic / I^2C static target address (when I3C acts as controller)
When I3C acts as controller, this field is used if MTYPE[3:0] = 0010 (private message), or MTYPE[3:0] = 0011 (direct message), or MTYPE[3:0] = 0100 (legacy I^2C message)

Bit 16 **RNW**: Read / non-write message (when I3C acts as controller)
When I3C acts as controller, this field is used if MTYPE[3:0] = 0010 (private message), or MTYPE[3:0] = 0011 (direct message), or MTYPE[3:0] = 0100 (legacy I^2C message), to emit the RnW bit on the I3C bus.
0: write message
1: read message

Bits 15:0 **DCNT[15:0]**: Count of data to transfer during a read or write message, in bytes (whatever I3C acts as controller/target)
When I3C acts as controller, this field is used if MTYPE[3:0] = 0010 (private message), or MTYPE[3:0] = 0011 (direct message), or MTYPE[3:0] = 0100 (legacy I^2C message), to set the number of exchanged data bytes on the bus. In case of a private or legacy I^2C read/write message, this field must be non-null.
When I3C acts as target, this field is used if MTYPE[3:0] = 1010 (IBI request) and if any IBI data payload (data to be transmitted if BCR2 = 1 in the I3C_BCR register), to set the number of bytes of the IBI data payload (1, 2, 3, or 4).
Linear encoding up to 64 Kbytes - 1
0x0000: no data to transfer
0x0001: 1 byte
0x0002: 2 bytes
...
0xFFFF: 64 Kbytes - 1 byte

49.16.2 I3C message control register [alternate] (I3C_CR)

Address offset: 0x000

Reset value: 0x0000 0000

This write register description must be used to control the message for when the controller has to emit a CCC (whatever is the type of the CCC: for a CCC broadcast, a CCC direct, or a CCC Enter HDR).

This is the alternate description of register I3C_CR, for when MTYPE[3:0] = 0110. Else refer to *Section 49.16.1*.

If the control FIFO (also known as C-FIFO) is not full (CFNFF = 1 in the I3C_EVR register), writing into this register means pushing a new control word into the C-FIFO; either by the software or automatically by DMA, as defined by the CDMAEN bit in the I3C_CFGR register.

When the last message of the frame is completed (a message with MEND = 1 in the I3C_CR register), the I3C hardware asserts the frame completed flag (FCF = 1 in the I3C_EVR register) and the corresponding interrupt, if enabled.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MEND	MTYPE[3:0]				Res.	Res.	Res.	CCC[7:0]							
w	w	w	w	w				w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DCNT[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bit 31 **MEND**: Message end type/last message of a frame (when I3C acts as controller)

0: this message from controller is followed by a repeated start (Sr), before another message must be emitted

1: the message from the controller ends with a stop (P), being the last message of a frame

Bits 30:27 **MTYPE[3:0]**: Message type (when I3C acts as controller)

Condition: when I3C acts as I3C controller

0110: broadcast/direct CCC command (refer to *Table 524*, *Figure 654*, *Figure 655*, *Figure 656*)

Bits[23:16] (CCC[7:0]) are the emitted 8-bit CCC code

Bits[15:0] (DCNT[15:0]) are the number of the CCC defining bytes, or CCC sub-command bytes, or CCC data bytes.

If Bit[23] = CCC[7] = 1: this is the first part of an I3C SDR direct CCC command

The transferred direct CCC command (first part) message is:

– {S / S + 0b111_1110 +RnW = 0 / Sr+*} + (direct CCC + T) + (8-bit Data + T)* + Sr

– After an S (start), depending upon NOARBH in the I3C_CFGR register, the arbitrable header (0b111_1110 + RnW = 0) is inserted or not.

– Sr+*: after an Sr (repeated start), the hardware automatically inserts (0b111_1110 + R/W).

If Bit[23] = CCC[7] = 0: this is an I3C SDR broadcast CCC command (including specific ENTDAA, refer to *Figure 655*)

The transferred broadcast CCC command message is:

– {S / S + 0b111_1110 + RnW = 0 / Sr+*} + (broadcast CCC + T) + (8-bit Data + T)* + Sr/P

– After an S (start), depending on NOARBH, the arbitrable header (0b111_1110 + RnW = 0) is inserted or not.

– Sr+*: after an Sr (repeated start), the hardware automatically inserts (0b111_1110 + R/W).

Others: reserved

Bits 26:24 Reserved, must be kept at reset value.

Bits 23:16 **CCC[7:0]**: 8-bit CCC code (when I3C acts as controller)

If bit[23] = CCC[7] = 1, this is the first part of an I3C SDR direct CCC command.

If bit[23] = CCC[7] = 0, this is an I3C SDR broadcast CCC command (including ENTDAA).

Bits 15:0 **DCNT[15:0]**: Count of related data to the CCC command to transfer as CCC defining bytes, or CCC sub-command bytes, or CCC data bytes, in bytes

Linear encoding up to 64 Kbytes - 1.

0x0000: no data to transfer.

Note: Value mandatory when emitting ENTDAA broadcast CCC (refer to Figure 655).

0x0001: 1 byte

Note: Value mandatory when emitting RSTACT direct/broadcast CCC (refer to Figure 656).

0x0002: 2 bytes

...

0xFFFF: 64 Kbytes - 1 byte

49.16.3 I3C configuration register (I3C_CFGR)

Address offset: 0x004

Reset value: 0x0000 0000

This register is used to configure:

- features that apply when the I3C acts as controller or target: RX-FIFO and TX-FIFO management (RXDMAEN, RXTHRES, RXFLUSH, TXDMAEN, TXTHRES, TXFLUSH), I3C peripheral role (CRINIT)
- dedicated features when the I3C acts as a controller: frame-based control-word triggering (TSFSET), FIFOs management (TMODE, SMODE, SFLUSH, SDMAEN, CDMAEN), and miscellaneous ones (HJACK, HKSDAEN, EXITPTRN, RSTPATRN, NOARBH)

The configuration fields CRINIT, HKSDAEN can be modified only when EN = 0. This condition is respected if they are modified at the same time when EN is set to 1 (it is not necessary to set EN later on, with another write operation).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	TSFSET	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CFLUSH	CDMA EN	TMODE	SMODE	SFLUSH	SDMA EN
	w									w	rw	rw	rw	w	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	TX THRES	TX FLUSH	TX DMAEN	Res.	RX THRES	RX FLUSH	RX DMAEN	HJACK	Res.	HK SDAEN	EXIT PTRN	RST PTRN	NO ARBH	CRINIT	EN
	rw	w	rw		rw	w	rw	rw		rw	rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **TSFSET**: Frame transfer set (software trigger) (when I3C acts as controller)

This bit can only be written. When I3C acts as I3C controller:

0: no action

1: setting this bit initiates a frame transfer by causing the hardware to assert the flag CFNFF in the I3C_EVR register (C-FIFO not full and a control word is needed)

Note: If this bit is not set, the other alternative for the software to initiate a frame transfer is to directly write the first control word register (I3C_CR) while C-FIFO is empty (CFEF = 1 in the I3C_EVR register). Then, if the first written control word is not tagged as a message end (MEND = 0 in the I3C_CR register), it causes the hardware to assert CFNFF.

Bits 29:24 Reserved, must be kept at reset value.

Bit 23 Reserved, must be kept at reset value.

Bit 22 Reserved, must be kept at reset value.

Bit 21 **CFLUSH**: C-FIFO flush (when I3C acts as controller)

This bit can only be written.

0: no action

1: flush C-FIFO

Bit 20 **CDMAEN**: C-FIFO DMA request enable (when I3C acts as controller)

When I3C acts as controller:

0: DMA mode is disabled for C-FIFO

- Software writes and pushes control word(s) into C-FIFO (writes I3C_CR register), as needed for a given frame
- A next control word transfer can be written by software either via polling on the flag CFNFF = 1 in the I3C_EVR register, or via interrupt notification (enabled by CFNFIE = 1 in the I3C_IER register).

1: DMA mode is enabled for C-FIFO

- DMA writes and pushes control word(s) into C-FIFO (writes I3C_CR register), as needed for a given frame.
- A next control word transfer is automatically written by the programmed hardware (via the asserted C-FIFO DMA request from the I3C and the programmed DMA channel).

Bit 19 **TMODE**: Transmit mode (when I3C acts as controller)

When I3C acts as controller, this bit is used for the C-FIFO and TX-FIFO management vs. the emitted frame on the I3C bus.

0: C-FIFO and TX-FIFO are not preloaded before starting to emit a frame transfer.

A frame transfer starts as soon as the first control word is present in C-FIFO.

1: C-FIFO and TX-FIFO are first preloaded (also TX-FIFO if needed, depending on the frame format) before starting to emit a frame transfer. Refer to *Section 49.10.2* for more details.

Bit 18 **SMODE**: S-FIFO enable / status receive mode (when I3C acts as controller)

When I3C acts as controller, this bit is used to enable the FIFO for the status (S-FIFO) of the exchanged message on the I3C bus.

When I3C acts as target, this bit must be cleared.

0: S-FIFO is disabled

- Status register (I3C_SR) is used without FIFO mechanism.
- There is no SCL stalling if a new status register content is not read.
- Status register must be read before being overwritten by the hardware.
- Must have SDMAEN = 0 in the I3C_CFGR register.

1: S-FIFO is enabled.

- Each message status must be read.
- There is SCL stalling when the S-FIFO is full and a next message status must be read.
- S-FIFO overrun error is reported after the maximum SCL clock stalling time.

Bit 17 **SFLUSH**: S-FIFO flush (when I3C acts as controller)

This bit can be written and used only when I3C acts as controller.

0: no action

1: flush S-FIFO

Bit 16 **SDMAEN**: S-FIFO DMA request enable (when I3C acts as controller)

This bit must be cleared if SMODE = 0 in the I3C_CFGR register (S-FIFO is disabled). In other words, DMA mode cannot be used if S-FIFO is disabled. Then the status register I3C_SR can be read or not.

This bit can be set or cleared if SMODE = 1 (S-FIFO is enabled). In other words, status register I3C_SR must be read for each message, either by software, or via an allocated DMA channel.

0: DMA mode is disabled for reading status register I3C_SR

- SMODE = 0: software can read the I3C_SR register after a completed frame (FCF = 1 in the I3C_EVR register) or an error (ERRF = 1 in the I3C_EVR register). Via polling on these register flags or via interrupt notification (enabled by FCIE = 1 and ERRIE = 1 in the I3C_IER register).
- SMODE = 1: software must read and pop a status word from S-FIFO (read I3C_SR register) after each asserted flag SFNEF = 1. Via polling on this register flag or via interrupt notification (enabled by SFNEIE = 1 in the I3C_IER register).

1: DMA mode is enabled for reading status register I3C_SR

- Must have SMODE = 1 in the I3C_CFGR register (S-FIFO enabled)
- DMA reads and pops status word(s) from S-FIFO (it reads I3C_SR register)
- Status word(s) are automatically read by the programmed hardware (via the asserted S-FIFO DMA request from the I3C and the programmed DMA channel).

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TXTHRES**: TX-FIFO threshold (whatever I3C acts as controller/target)

This threshold defines, compared to the TX-FIFO level, when the TXFNFF flag is set in the I3C_EVR register (and consequently if TXDMAEN = 1 when is asserted a DMA TX request).

0: 1-byte threshold

TXFNFF is set when 1 byte must be written in TX-FIFO (in I3C_TDR).

1: 1-word / 4-byte threshold

TXFNFF is set when 1 word / 4 bytes must be written in TX-FIFO (in the I3C_TDWR register). If the a number of the last transmitted data is not a multiple of 4 bytes (XDCNT[1:0] = 00 in the I3C_SR register), only the relevant 1, 2, or 3 valid LSB bytes of the last word are taken into account by the hardware, and sent on the I3C bus.

Bit 13 **TXFLUSH**: TX-FIFO flush (whatever I3C acts as controller/target)

This bit can only be written.

When the I3C acts as target, this bit can be used to flush the TX-FIFO on a private read if the controller has aborted the data read (driven low the T bit), and there is/are remaining data in the TX-FIFO (ABT = 1, and XDCNT[15:0] in the I3C_SR register < TGTTDCNT[15:0] in the I3C_TGTTDR register).

0: no action

1: flush TX-FIFO

Bit 12 **TXDMAEN**: TX-FIFO DMA request enable (whatever I3C acts as controller/target)

0: DMA mode is disabled for TX-FIFO

- Software writes and pushes a data byte/word into TX-FIFO (writes I3C_TDR or I3C_TDWR register), to be transmitted over the I3C bus.
- A next data byte/word must be written by the software either via polling on the flag TXFNFF = 1 or via interrupt notification (enabled by TXFNFIE = 1).

1: DMA mode is enabled for TX-FIFO

- DMA writes and pushes data byte(s)/word(s) into TX-FIFO (writes I3C_TDR or I3C_TDWR register).
- A next data byte/word transfer is automatically pushed by the programmed hardware (via the asserted TX-FIFO DMA request from the I3C and the programmed DMA channel).

Bit 11 Reserved, must be kept at reset value.

Bit 10 **RXTHRES**: RX-FIFO threshold (whatever I3C acts as controller/target)

This threshold defines, compared to the RX-FIFO level, when the RXFNEF flag in the I3C_EVR register is set (and consequently if RXDMAEN = 1 when is asserted a DMA RX request).

0: 1-byte threshold

RXFNEF is set when 1 byte must be read in RX-FIFO (in the I3C_RDR register).

1: 1-word/4-bytes threshold

RXFNEF is set when 1 word / 4 bytes is/are to be read in RX-FIFO (in I3C_RDWR). In the case of a number of last received data being not a multiple of 4 bytes, only the relevant 1, 2 or 3 valid LSB bytes of the last word are to be considered by the software. The number of effective received data bytes is reported by XDCNT[15:0] in the I3C_SR register.

Bit 9 **RXFLUSH**: RX-FIFO flush (whatever I3C acts as controller/target)

This bit can only be written.

0: no action

1: flush RX-FIFO

Bit 8 **RXDMAEN**: RX-FIFO DMA request enable (whatever I3C acts as controller/target)

0: DMA mode is disabled for RX-FIFO

- Software reads and pops a data byte/word from RX-FIFO (it reads I3C_RDR or I3C_RDWR register).
- A next data byte/word must be read by the software either via polling flag RXFNEF = 1 in the I3C_EVR register, or via interrupt notification (enabled by RXFNEIE = 1 in the I3C_IER register).

1: DMA mode is enabled for RX-FIFO

- DMA reads and pops data byte(s)/word(s) from RX-FIFO (reads I3C_RDR or I3C_RDWR register).
- A next data byte/word is automatically read by the programmed hardware (via the asserted RX-FIFO DMA request from the I3C and the programmed DMA channel).

Bit 7 **HJACK**: Hot-join request acknowledge (when I3C acts as a controller)

0: hot-join request is not acknowledged

After the NACK, the controller continues as initially programmed (the hot-joining target is aware of the NACK and must emit another hot-join request later on).

1: hot-join request is acknowledged

After the ACK, the controller continues as initially programmed. The software is notified by the HJ interrupt (flag HJF is set in the I3C_EVR register), and must initiate the ENTDAA sequence later on, potentially preventing other hot-join requests with a disable target events command (DISEC, with DISHJ = 1).

Bit 6 Reserved, must be kept at reset value.

Bit 5 **HKSDAEN:** High-keeper enable on SDA line (when I3C acts as a controller)

0: High-keeper is disabled

1: High-keeper is enabled, and the weak pull-up is effective on the T bit, instead of the open-drain class pull-up.

Note: This bit can be modified only when EN = 0 in the I3C_CFGR register.

Bit 4 **EXITPTRN:** HDR exit pattern enable (when I3C acts as a controller)

This bit can be modified only when there is no on-going frame.

0: HDR exit pattern is not sent after the issued message header (MTYPE[3:0] = 0001 in the I3C_CR register). This is used to send the header, to test ownership of the bus when there is a suspicion of a problem after controller-role hand-off (new controller did not assert its controller-role by accessing the previous one in less than the delay defined by the activity state).

1: HDR exit pattern is sent after the issued message header (MTYPE[3:0] = 0001). This is used on a controller error detection and escalation handling, in case of a not responding target to a private message or a direct read CCC.

The HDR exit pattern is sent whatever the message header {S/Sr + 0x7E addr + W} is ACK-ed or NACK-ed..

Bit 3 **RSTPTRN:** HDR reset pattern enable (when I3C acts as a controller)

This bit can be modified only when there is no on-going frame.

0: standard stop emitted at the end of a frame

1: HDR reset pattern is inserted before the stop of any emitted frame that includes a RSTACT CCC command

Bit 2 **NOARBH**: No arbitrable header after a start (when I3C acts as a controller)

This bit can be modified only when there is no on-going frame.

0: An arbitrable header (0b111_1110 + RnW = 0) is emitted after a start and before a legacy I^2C message or an I3C SDR private read/write message (default).

1: No arbitrable header

- The target address is emitted directly after a start in case of a legacy I^2C message or an I3C SDR private read/write message.

- This is a more performing option (when the emission of the 0x7E arbitrable header is useless), but must be used only when the controller is sure that the addressed target device cannot emit concurrently an IBI or a controller-role request (to insure no misinterpretation and no potential conflict between the address emitted by the controller in open-drain mode and the same address a target device can emit after a start, for IBI or MR).

Bit 1 **CRINIT**: Initial controller/target role

This bit can be modified only when EN = 0 in the I3C_CFGR register.

0: target role

Once enabled by setting EN = 1, the peripheral initially acts as a target. I3C does not drive SCL line and does not enable SDA pull-up, until it eventually acquires the controller role.

1: controller role

Once enabled by setting EN = 1, the peripheral initially acts as a controller. It has the I3C controller role, so drives SCL line and enables SDA pull-up, until it eventually offers the controller role to an I3C secondary controller.

Bit 0 **EN**: I3C enable (whatever I3C acts as controller/target)

0: I3C is disabled

- Except registers, the peripheral is under reset (partial reset).

- Before clearing EN, when I3C acts as a controller, all the possible target requests must be disabled using DISEC CCC.

- When I3C acts as a target, software must not disable the I3C, unless a partial reset is needed.

1: I3C is enabled

In this state, some register fields cannot be modified (like CRINIT, HKSDAEN for the I3C_CFGR)

49.16.4 I3C receive data byte register (I3C_RDR)

Address offset: 0x010

Reset value: 0x0000 0000

This register is used to read received data bytes from the I3C bus if the RX-FIFO is configured with a byte-based read access (RXTHRES = 0 in the I3C_CFGR register). Then:

- On read, I3C_RDR returns a 32-bit data word, with the received data byte in LSB position, and other reserved bits read as 0.
- When RXDMAEN = 1 in the I3C_CFGR register: programmed I3C and DMA automatically manage by hardware the relevant and successive reads.
- When RXDMAEN = 0: before a read, the software must wait to be notified that a next received data byte must be read via the RX-FIFO non empty flag (RXFNEF = 1 in the I3C_EVR register) or via the corresponding interrupt if enabled. Last received byte of a given message to be read is also marked with RXLASTF = 1 in the I3C_EVR register when acting as controller.
- If the RX-FIFO is full, a new byte is received and cannot be pushed into the RX-FIFO without waiting anymore, the software is notified by error flag ERRF = 1 in the I3C_EVR register and by a data overrun flag DOVRF = 1 in the I3C_SER register (and corresponding interrupt if enabled).

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RDB0[7:0]							
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **RDB0[7:0]**: 8-bit received data on I3C bus.

49.16.5 I3C receive data word register (I3C_RDWR)

Address offset: 0x014

Reset value: 0x0000 0000

This register is used to read received data bytes from the I3C bus if the RX-FIFO is configured with a 32-bit word-based read access (RXTHRES = 1 in the I3C_CFGR register). Then:

- When RXDMAEN = 1 in the I3C_CFGR register: programmed I3C and DMA automatically manage by hardware the relevant and successive reads.
- When RXDMAEN = 0: before a read, the software must first wait to be notified that must be read a next received data word via the RX-FIFO non empty flag (RXFNEF = 1 in the I3C_EVR register) or via the corresponding interrupt if enabled. Last received

word/byte(s) of a given message to be read is also marked with RXLASTF = 1 in the I3C_EVR register when acting as controller.

- If the RX-FIFO holds less than four bytes, a read on I3C_RDWR returns a data word padded with null byte(s): the available byte(s) in LSB position(s) is (are) padded with zero byte(s) in MSB position(s).
- If the RX-FIFO is full and a new byte is received and cannot be pushed into the RX-FIFO without waiting anymore, the software is notified by an error flag ERRF = 1 in the I3C_EVR register and a data overrun DOVR = 1 in the I3C_SER register (and corresponding interrupt if enabled).

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:24 **RDB3[7:0]**: 8-bit received data (latest byte on I3C bus).

Bits 23:16 **RDB2[7:0]**: 8-bit received data (next byte after RDB1 on I3C bus).

Bits 15:8 **RDB1[7:0]**: 8-bit received data (next byte after RDB0 on I3C bus).

Bits 7:0 **RDB0[7:0]**: 8-bit received data (earliest byte on I3C bus).

49.16.6 I3C transmit data byte register (I3C_TDR)

Address offset: 0x018

Reset value: 0x0000 0000

This register is used to write data bytes to be transmitted over the I3C bus.

This register implements a byte-based write access to the transmit FIFO (TX-FIFO), and is used when TXTHRES = 0 in the I3C_CFGR register.

When the I3C acts as controller:

- When TXDMAEN = 1 and if TXTHRES = 0 in the I3C_CFGR register: programmed I3C and DMA automatically manage by hardware the relevant and successive writes.
- When TXDMAEN = 0 and if TXTHRES = 0: before a write, the software must wait to be notified that must be written a next data byte via the TX-FIFO non full flag (TXFNFF = 1 in the I3C_EVR register) or via the corresponding interrupt if enabled. Last transmitted byte of a given message to be written is also marked with TXLASTF = 1 in the I3C_EVR register.

When the I3C acts as target:

- When TXDMAEN = 1 and if TXTHRES = 0 and if PRELOAD = 1 in the I3C_TGTTDR register: programmed I3C and DMA automatically manage by hardware the relevant and successive number of writes to I3C_TDR register, according to TGTTDCNT[15:0] in the I3C_TGTDR register.
- When TXDMAEN = 0 and if TXTHRES = 0:
  - when PRELOAD = 1 in the I3C_TGTTDR register: before a write, the software must wait to be notified that must be written a next data byte via the TX-FIFO non

full flag (TXFNFF = 1) or via the corresponding interrupt, if enabled. The last transmitted byte of the initially programmed TGTTDCNT[15:0] is also marked with TXLASTF = 1 in the I3C_EVR register.

– when PRELOAD = 0: before a write, the software must wait to be notified that can be written up to 8 next data bytes (TX-FIFO size) via the TX-FIFO empty flag (TXFEF = 1 in the I3C_EVR register), or via the corresponding interrupt if enabled. If the software needs to write another data byte, it must wait for the TX-FIFO be empty (TXFEF = 1), and then write this data byte to be transmitted before nine SCL clock periods elapse, to avoid a data underrun error flag (ERRF = 1 in the I3C_EVR register and DOVR = 1 in the I3C_SER register).

If the TX-FIFO is empty and the controller cannot wait longer a data byte to be transmitted, the software is notified by an error flag ERRF = 1 in the I3C_EVR register and a data underrun flag DOF = 1 (and corresponding interrupt if enabled) in the I3C_SER register.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TDB0[7:0]							
								w	w	w	w	w	w	w	w

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **TDB0[7:0]**: 8-bit data to transmit on I3C bus.

49.16.7 I3C transmit data word register (I3C_TDWR)

Address offset: 0x01C

Reset value: 0x0000 0000

This register is used to write 32-bit data words to be transmitted over the I3C bus.

This register implements a word-based write access to the transmit FIFO (TX-FIFO), and is used when TXTHRES = 1 in the I3C_CFGR register.

When the I3C acts as controller:

- When TXDMAEN = 1 and if TXTHRES = 1 in the I3C_CFGR register, programmed I3C and DMA automatically manage by hardware the relevant and successive writes.
- When TXDMAEN = 0 and if TXTHRES = 1: before a write, the software must wait to be notified that next data word/byte(s) must be written via the TX-FIFO non full flag (TXFNFF = 1 in the I3C_EVR register), or via the corresponding interrupt if enabled. Last transmitted word/byte(s) of a given message to be written in TX-FIFO is also marked with TXLASTF = 1 in the I3C_EVR register.

When the I3C acts as target:

- When TXDMAEN = 1 and if TXTHRES = 1 and if PRELOAD = 1 in the I3C_TGTTDR register: programmed I3C and DMA automatically manage by hardware the relevant and successive number of writes to the I3C_TDWR register, as per TGTTDCNT[15:0]

in the I3C_TGTDR register.

- When TXDMAEN = 0 and if TXTHRES = 1:
  - when PRELOAD = 1: before a write, the software must wait to be notified that must be written a next data word via the TX-FIFO non full flag (TXFNFF = 1 in the I3C_EVR register) or via the corresponding interrupt, if enabled. Last transmitted word of the initially programmed TGTTDCNT[15:0] in the I3C_TGTTDR register is also marked with TXLASTF = 1 in the I3C_EVR register.
  - when PRELOAD = 0: before a write, the software must wait to be notified that can be written up to two next data words (TX-FIFO size) via the TX-FIFO empty flag (TXFEF = 1 in the I3C_EVR register) or via the corresponding interrupt if enabled. If the software needs to write another data word, it must wait for TX-FIFO to be empty (TXFEF = 1), and then write the next data word to be transmitted before nine SCL clock periods elapse, to avoid a data underrun error flag (ERRF = 1 in the I3C_EVR register and DOVR = 1 in the I3C_SER register).

If the TX-FIFO is empty and the controller/target cannot wait longer a data byte to be transmitted, the software is notified by an error flag ERRF = 1 in the I3C_EVR register and a data underrun flag DOF = 1 in the I3C_SER register (and corresponding interrupt if enabled).

TDB1[7:0]								TDB0[7:0]							
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:24 **TDB3[7:0]**: 8-bit transmit data (latest byte on I3C bus).

Bits 23:16 **TDB2[7:0]**: 8-bit transmit data (next byte after TDB1[7:0] on I3C bus).

Bits 15:8 **TDB1[7:0]**: 8-bit transmit data (next byte after TDB0[7:0] on I3C bus).

Bits 7:0 **TDB0[7:0]**: 8-bit transmit data (earliest byte on I3C bus)

49.16.8 I3C IBI payload data register (I3C_IBIDR)

Address offset: 0x020

Reset value: 0x0000 0000

This register is used for the IBI payload data.

When I3C acts as target:

- if BCR2 = 0 in the I3C_BCR register, this register is useless.
- if BCR2 = 1, this register must be written by software
  - to be emitted on the I3C bus as the IBI payload data, after that the IBI request (MTYPE[3:0] = 1010 in the I3C_CR register) is acknowledged by the controller; with the IBI data payload size defined by DCNT[15:0] in the I3C_CR register.
  - Maximum (static) payload data size is given by IBIP[2:0] in the I3C_MAXRLR register. it can be 1, 2, 3 or 4 bytes.
  - DCNT[15:0] must be set between 1 (for the mandatory data byte MDB[7:0]) and the maximum IBIP[2:0].

When I3C acts as controller: if IBIACK= 1 in the I3C_DEVRx register, once it acknowledges on the I3C bus the IBI request from the target x:

- if IBIDEN = 0 (BCR[2] = 0 received from target x) in the I3C_DEVRx register, this register is useless.
- if IBIDEN = 1 (BCR[2] = 1 received from target x):
  - This register is internally written by hardware from the IBI payload data received on the I3C bus (including the first mandatory data byte MDB[7:0]).
  - When the last byte of the payload is received in I3C_IBIDR (when target drives T-bit = 0), IBIF flag is set (and corresponding interrupt if enabled) in the I3C_EVR register.
  - Then, the software can identify the target x via the received and logged 7-bit address in RADD[6:0] in the I3C_RMR register.
  - The software can read this register and interpret byte(s) according to the number of bytes effectively received and logged in IBIRDCNT[2:0] in the I3C_RMR register.

IBIDB1[7:0]								IBIDB0[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **IBIDB3[7:0]**: 8-bit IBI payload data (latest byte on I3C bus).

Bits 23:16 **IBIDB2[7:0]**: 8-bit IBI payload data (next byte on I3C bus after IBIDB1[7:0]).

Bits 15:8 **IBIDB1[7:0]**: 8-bit IBI payload data (next byte on I3C bus after IBIDB0[7:0]).

Bits 7:0 **IBIDB0[7:0]**: 8-bit IBI payload data (earliest byte on I3C bus, MDB[7:0] mandatory data byte).

49.16.9 I3C target transmit configuration register (I3C_TGTTDR)

Address offset: 0x024

Reset value: 0x0000 0000

When I3C acts as target, this register must be used to preload a number of data bytes in the TX-FIFO, so that they are ready to be transmitted on the I3C bus, when they are accepted/acknowledged by the controller, whatever the DMA mode is used or not (independently from TXDMAEN in the I3C_CFGR register).

When I3C acts as target, alternatively, if the number of data bytes to be transmitted is less than or equal to the TX-FIFO size (8 bytes), the software can directly use and write byte(s) into the I3C_TDR register (or I3C_TDWR register, depending upon TXTHRES in the I3C_CFGR register), via polling on the TX-FIFO empty flag (TXFEF = 1 in the I3C_EVR register), or via the corresponding enabled interrupt.

In any case, since an I3C target is unable to stretch/stall the SCL line, the software can identify a TX-FIFO underrun via DOR = 1 in the I3C_EVR register.

TGTTDCNT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **PRELOAD**: Preload of the TX-FIFO (when I3C is configured as target)

This bit must be written and asserted by software in the same access when is written and defined the number of bytes to preload into the TX-FIFO and to transmit.

This bit is cleared by hardware when all the data bytes to transmit are loaded into the TX-FIFO.

0: no TX-FIFO preload

1: TX-FIFO preload

Bits 15:0 **TGTTDCNT[15:0]**: Transmit data counter, in bytes (when I3C is configured as target)

This bitfield must be written by software in the same access when is asserted PRELOAD, in order to define the number of bytes to preload and to transmit.

This bitfield is updated by hardware and reports, when read, the remaining number of bytes to be loaded into the TX-FIFO.

49.16.10 I3C status register (I3C_SR)

Address offset: 0x030

Reset value: 0x0000 0000

This register is used to read the status about the exchanged message on the I3C bus:

- in FIFO mode: when the I3C acts as controller and if S-FIFO is enabled via SMODE = 1 in the I3C_CFGR register:
  - Software is notified via SFNEF = 1 in the I3C_EVR register if there is a status register to be read (and corresponding interrupt if enabled), when not in DMA mode (SDMAEN = 0)
  - In DMA mode (SDMAEN = 1), programmed I3C and DMA automatically manage by hardware the relevant and successive reads.
  - Software is notified via COVR = 1 in the I3C_SER register on an S-FIFO overflow (and ERRF = 1 in the I3C_EVR register and corresponding interrupt if enabled)
- in register mode: if SMODE = 0 in the I3C_CFGR register
  - Software can use the flags FCF in the I3C_SER register and ERRF = 1 in the I3C_EVR register (and corresponding interrupt if enabled) to read this register
  - This register can be overwritten by hardware on a new message completion, without any notification.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MID[7:0]								Res.	Res.	Res.	Res.	Res.	DIR	ABT	Res.

XDCNT[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:24 **MID[7:0]**: Message identifier/counter of a given frame (when the I3C acts as controller)

When I3C acts as controller, this fbitield identifies the control word message (I3C_CR) to whom the I3C_SR status register refers.

First message of a frame is identified with MID[7:0] = 0.

This bitfield is incremented (by hardware) on the completion of a new message control word (I3C_CR) over I3C bus. This field is reset for every new frame start.

Bits 23:19 Reserved, must be kept at reset value.

Bit 18 **DIR**: Message direction

Whatever the I3C acts as controller or target, this bit indicates the direction of the related message on the I3C bus

0: write

1: read

Note: ENTDAA CCC is considered as a write command.

Bit 17 **ABT**: A private read message is ended prematurely by the target (when the I3C acts as controller)

When the I3C acts as controller, this bit indicates if the private read data transmitted by the target early terminates (the target drives T bit low earlier vs. what the controller expects in terms of programmed number of read data bytes DCNT[15:0] in the I3C_CR register).

0: no early completion from the target

1: early completion from the target

Bit 16 Reserved, must be kept at reset value.

Bits 15:0 **XDCNT[15:0]**: Data counter

Condition: during the dynamic address assignment process (ENTDAA CCC)

- When the I3C acts as controller: number of targets detected on the bus
- When the I3C acts as target: number of transmitted bytes

Condition: for other transfers, during the message

- Whatever the I3C acts as controller or target: number of data bytes read from or transmitted on the I3C bus during the message

49.16.11 I3C status error register (I3C_SER)

Address offset: 0x034

Reset value: 0x0000 0000

This read register is used to get more information about the error when an error is raised by hardware and notified to the software via the error flag ERRF = 1 in the I3C_EVR register (and corresponding interrupt if enabled).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	DERR	DNACK	ANACK	COVR	DOVR	STALL	PERR	CODERR[3:0]			
					r	r	r	r	r	r	r	r	r	r	r

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **DERR**: Data error (when the I3C acts as controller)

0: no detected error

1: controller detected a data error during the controller-role hand-off procedure (GETACCCR CCC, formerly known as GETACCMST) when the received target address or/and the parity bit do no match. Active controller keeps controller-role.

Bit 9 **DNACK**: Data not acknowledged (when the I3C acts as controller)

0: no detected error

1: controller detected that a data byte is not acknowledged by a target, either during:

i) a legacy I2C write transfer

ii) the second trial when sending dynamic address during ENTDAA procedure

Bit 8 **ANACK**: Address not acknowledged (when the I3C is configured as controller)

0: no detected error

1: controller detected that the static/dynamic address was not acknowledged by a target, either during:

i) a legacy I2C read/write transfer

ii) a direct CCC write transfer

iii) the second trial of a direct CCC read transfer

iv) a private read/write transfer

Bit 7 **COVR**: C-FIFO underrun or S-FIFO overrun (when the I3C acts as controller)

0: no detected error

1: controller detected either:

i) a C-FIFO underrun: control FIFO is empty and a restart must be emitted

ii) an S-FIFO overrun: S-FIFO is full and a new message ends

Bit 6 **DOVR**: RX-FIFO overrun or TX-FIFO underrun

0: no detected error

1: whatever controller or target, hardware detected either:

i) a TX-FIFO underrun: TX-FIFO is empty and a write data byte must be transmitted

ii) a RX-FIFO overrun: RX-FIFO is full and a new data byte is received

Bit 5 **STALL**: SCL stall error (when the I3C acts as target)

0: no detected error

1: target detected that SCL was stable for more than 125 µs during an I3C SDR data read (during a direct CCC read, a private read, or an IB)

Bit 4 **PERR**: Protocol error

0: no detected error

1: whatever controller or target, hardware detected a protocol error, as detailed in CODERR[3:0]

Bits 3:0 **CODERR[3:0]**: Protocol error code/type
0000: CE0 error (transaction after sending CCC):
controller detected an illegally formatted CCC
0001: CE1 error (monitoring error):
controller detected that transmitted data on the bus is different from expected
0010: CE2 error (no response to broadcast address):
controller detected a not acknowledged broadcast address (0b111_1110)
0011: CE3 error (failed controller-role hand-off):
controller detected the new controller did not drive bus after controller-role hand-off
1000: TE0 error (invalid broadcast address 0b111_1110 + W):
target detected an invalid broadcast address 0b111_1110 + W
1001: TE1 error (CCC code):
target detected a parity error on a CCC code via a parity check (vs. T bit)
1010: TE2 error (write data):
target detected a parity error on a write data via a parity check (vs. T bit)
1011: TE3 error (assigned address during dynamic address arbitration):
target detected a parity error on the assigned address during dynamic address arbitration via a parity check (vs. PAR bit)
1100: TE4 error (0b111_1110 + R missing after Sr during dynamic address arbitration):
target detected a 0b111_1110 + R missing after Sr during dynamic address arbitration
1101: TE5 error (transaction after detecting CCC):
target detected an illegally formatted CCC
1110: TE6 error (monitoring error):
target detected that transmitted data on the bus is different from expected
others: reserved

49.16.12 I3C received message register (I3C_RMR)

Address offset: 0x040

Reset value: 0x0000 0000

When the I3C acts as controller, this read register is used to log the received target address, and the IBI received payload data size.

When the I3C acts as target, this read register is used to log the received CCC code

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RADD[6:0]							Res.
								r	r	r	r	r	r	r	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RCODE[7:0]								Res.	Res.	Res.	Res.	Res.	IBIRDCNT[2:0]		
r	r	r	r	r	r	r	r						r	r	r

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:17 **RADD[6:0]**: Received target address (when the I3C is configured as controller)
When the I3C is configured as controller, this field logs the received dynamic address from the target during acknowledged IBI or controller-role request.

Bit 16 Reserved, must be kept at reset value.

Bits 15:8 **RCODE[7:0]**: Received CCC code (when the I3C is configured as target)
When the I3C is configured as target, this field logs the received CCC code.

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **IBIRDCNT[2:0]**: IBI received payload data count (when the I3C is configured as controller)
When the I3C is configured as controller, this field logs the number of data bytes effectively received in the I3C_IBIDR register.

49.16.13 I3C event register (I3C_EVR)

Address offset: 0x050

Reset value: 0x0000 0003

This is a read register, used for reporting event flags.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
GRPF	DEFF	INT UPDF	AS UPDF	RSTF	MRL UPDF	MWL UPDF	DA UPDF	STAF	GETF	WKPF	Res.	HJF	CR UPDF	CRF	IBI ENDF
r	r	r	r	r	r	r	r	r	r	r		r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IBIF	Res.	Res.	Res.	ERRF	RXTGT ENDF	FCF	Res.	RX LASTF	TX LASTF	RX FNEF	TX FNFF	SFNEF	CFNFF	TXFEF	CFEF
r				r	r	r		r	r	r	r	r	r	r	r

Bit 31 **GRPF**: Group addressing flag (when the I3C acts as target)
When the I3C acts as target (and is typically controller-capable), this flag is asserted by hardware to indicate that the broadcast DEFGRPA CCC (define list of group addresses) has been received. Then, software can store the received data for when getting controller role.
The flag is cleared when software writes 1 into the corresponding CGRPF bit in the I3C_CR register.

Bit 30 **DEFF**: DEFTGTS flag (when the I3C acts as target)
When the I3C acts as target (and is typically controller capable), this flag is asserted by hardware to indicate that the broadcast DEFTGTS CCC (define list of targets) has been received. Then, software can store the received data for when getting the controller role.
The flag is cleared when software writes 1 into the corresponding CDEFF bit in the I3C_CEVR register.

Bit 29 **INTUPDF**: Interrupt/controller-role/hot-join update flag (when the I3C acts as target)
When the I3C acts as target, this flag is asserted by hardware to indicate that the direct or broadcast ENEC/DISEC CCC (enable/disable target events) has been received, where a target event is either an interrupt/IBI request, a controller-role request, or an hot-join request. Then, software must read respectively IBIEN, CREN, or HJEN in the I3C_DEVR0 register.
The flag is cleared when software writes 1 into the corresponding CINTUPDF bit in the I3C_CEVR register.

Bit 28 **ASUPDF**: Activity state update flag (when the I3C acts as target)
When the I3C acts as target, this flag is asserted by hardware to indicate that the direct or broadcast ENTASx CCC (with x = 0...3) has been received. Then, software must read AS[1:0] in the I3C_DEVR0 register.
The flag is cleared when software writes 1 into the corresponding CASUPDF bit in the I3C_CEVR register.

Bit 27 **RSTF**: Reset pattern flag (when the I3C acts as target)

When I3C acts as target, this flag is asserted by hardware to indicate that a reset pattern has been detected (14 SDA transitions while SCL is low, followed by repeated start, then stop).

Then, when not in Stop mode, software must read RSTACT[1:0] and RSTVAL in the I3C_DEVR0 register, to know the required reset level.

- If RSTVAL = 1: when the RSTF is asserted (and/or the corresponding interrupt if enabled), RSTACT[1:0] in the I3C_DEVR0 register dictates the reset action to be performed by the software, if any.
- If RSTVAL = 0: when the RSTF is asserted (and/or the corresponding interrupt if enabled), the software must issue an I3C reset after a first detected reset pattern, and a system reset on the second one.

When in Stop mode, the corresponding interrupt can be used to wake up the device.

The flag is cleared when software writes 1 into the corresponding CRSTF bit in the I3C_CEVR register.

Bit 26 **MRLUPDF**: Maximum read length update flag (when the I3C acts as target)

When the I3C acts as target, this flag is asserted by hardware to indicate that a direct SETMRL CCC (set max read length) has been received. Then, software must read MRL[15:0] in the I3C_MAXRLR register to get the maximum read length value.

The flag is cleared when software writes 1 into the corresponding CMRLUPDF bit in the I3C_CEVR register.

Bit 25 **MWLUPDF**: Maximum write length update flag (when the I3C acts as target)

When the I3C acts as target, this flag is asserted by hardware to indicate that a direct SETMWL CCC (set max write length) has been received. Then, software must read MWL[15:0] in the I3C_MAXRLR register to get the maximum write length value.

The flag is cleared when software writes 1 into the corresponding CMWLUPDF bit in the I3C_CEVR register.

Bit 24 **DAUPDF**: Dynamic address update flag (when the I3C acts as target)

When the I3C acts as target, this flag is asserted by hardware to indicate that a dynamic address update has been received via any of the broadcast ENTDAA, RSTDAA and direct SETNEWDA CCC. Then, software must read DA[6:0] and DAVAL in the I3C_DEVR0 register to get the dynamic address update.

The flag is cleared when software writes 1 into the corresponding CDAUPDF bit in the I3C_CEVR register.

Bit 23 **STAF**: Get status flag (when the I3C acts as target)

When the I3C acts as target, this flag is asserted by hardware to indicate that a direct GETSTATUS CCC of format 1 (without defining byte or with defining byte TGTSTAT) has been received.

The flag is cleared when software writes 1 into the corresponding CSTAF bit in the I3C_CEVR register.

Bit 22 **GETF**: Get flag (when the I3C acts as target)

When the I3C acts as target, this flag is asserted by hardware to indicate that any direct CCC of get type (GET*** CCC) except the GETSTATUS of format 1 (but including GETSTATUS of format 2) has been received.

The flag is cleared when software writes 1 into the corresponding CGETF bit in the I3C_CEVR register.

Bit 21 **WKPF**: Wake-up/missed start flag (when the I3C acts as target)

When the I3C acts as target, this flag is asserted by hardware to indicate that a start has been detected (an SDA falling edge followed by an SCL falling edge) but on the next SCL falling edge, the I3C kernel clock is (still) gated. Thus an I3C bus transaction may have been lost by the target.

The corresponding interrupt can be used to wake up the device from a low power (Sleep or Stop) mode.

The flag is cleared when software writes 1 into the corresponding CWKPF bit in the I3C_CEVR register.

Bit 20 Reserved, must be kept at reset value.

Bit 19 **HJF**: Hot-join flag (when the I3C acts as controller)

When the I3C acts as controller, this flag is asserted by hardware to indicate that an hot join request has been received.

The flag is cleared when software writes 1 into the corresponding CHJF bit in the I3C_CEVR register.

Bit 18 **CRUPDF**: Controller-role update flag (when the I3C acts as target)

When the I3C acts as target, this flag is asserted by hardware to indicate that it has now gained the controller role after the completed controller-role hand-off procedure.

The flag is cleared when software writes 1 into the corresponding CCRUPDF bit in the I3C_CEVR register.

Bit 17 **CRF**: Controller-role request flag (when the I3C acts as controller)

When the I3C acts as controller, this flag is asserted by hardware to indicate that a controller-role request has been acknowledged and completed (by hardware). The software must then issue a GETACCCR CCC (get accept controller role) for the controller-role hand-off procedure.

The flag is cleared when software writes 1 into the corresponding CCRF bit in the I3C_CEVR register.

Bit 16 **IBIENDF**: IBI end flag (when the I3C acts as target)

When the I3C acts as target, this flag is asserted by hardware to indicate that an IBI transfer has been received and completed (IBI acknowledged and IBI data bytes read by controller if any).

The flag is cleared when software writes 1 into the corresponding CIBIENDF bit in the I3C_CEVR register.

Bit 15 **IBIF**: IBI flag (when the I3C acts as controller)

When the I3C acts as controller, this flag is asserted by hardware to indicate that an IBI request has been received.

The flag is cleared when software writes 1 into the corresponding CIBIF bit in the I3C_CEVR register.

Bits 14:12 Reserved, must be kept at reset value.

Bit 11 **ERRF**: Flag (whatever the I3C acts as controller/target)

This flag is asserted by hardware to indicate that an error occurred.Then, software must read I3C_SER to get the error type.

The flag is cleared when software writes 1 into the corresponding CERRF bit in the I3C_CEVR register.

Bit 10 **RXTGTENDF**: Target-initiated read end flag (when the I3C acts as controller)

When the I3C acts as controller, and only if the S-FIFO is disabled (SMODE = 0 in the I3C_CFGR register), this flag is asserted by hardware to indicate that the target has prematurely ended a read transfer. Then, software must read the status register I3C_SR to check information related to the last message and get the number of received data bytes on the prematurely read transfer (XDCNT in the I3C_SR register).

The flag is cleared when software writes 1 into the corresponding CRXTGTENDF bit in the I3C_CEVR register.

Bit 9 **FCF**: Frame complete flag (whatever the I3C acts as controller/target)

When the I3C acts as controller, this flag is asserted by hardware to indicate that a frame has been (normally) completed on the I3C bus, for example, when a stop is issued.

When the I3C acts as target, this flag is asserted by hardware to indicate that a message addressed to/by this target has been (normally) completed on the I3C bus, for example, when a next stop or repeated start is then issued by the controller.

The flag is cleared when software writes 1 into the corresponding CFCF bit in the I3C_CEVR register.

Bit 8 Reserved, must be kept at reset value.

Bit 7 **RXLASTF**: Last read data byte/word flag (when the I3C acts as controller)

When the I3C acts as controller, this flag is asserted by hardware to indicate that the last data byte/word (depending upon RXTHRES in the I3C_CFGR register) of a message must be read from the RX-FIFO. The flag is de-asserted by hardware when the last data byte/word of a message is read.

Bit 6 **TXLASTF**: Last written data byte/word flag (whatever the I3C acts as controller/target)

This flag is asserted by hardware to indicate that the last data byte/word (depending upon TXTHRES in the I3C_CFGR register) of a message must be written to the TX-FIFO. The flag is de-asserted by hardware when the last data byte/word of a message is written.

Bit 5 **RXFNEF**: RX-FIFO not empty flag (whatever the I3C acts as controller/target)

This flag is asserted/de-asserted by hardware to indicate that a data byte must/must not be read from the RX-FIFO.

Note: The software must wait for RXFNEF = 1 (by polling or via the enabled interrupt) before reading from RX-FIFO (reading from I3C_RDR or I3C_RDWR, depending upon RXTHRES).

Bit 4 **TXFNFF**: TX-FIFO not full flag (whatever the I3C acts as controller/target)

This flag is asserted/de-asserted by hardware to indicate that a data byte/word must/must not be written to the TX-FIFO.

Note: The software must wait for TXFNFF = 1 (by polling or via the enabled interrupt) before writing to TX-FIFO (writing to I3C_TDR or I3C_TDWR, depending upon TXTHRES).

Note: When the I3C acts as target, if the software intends to use the TXFNFF flag for writing into I3C_TDR/I3C_TDWR, it must have configured and set the TX-FIFO preload (write PRELOAD in the I3C_TGTTDR register).

Bit 3 **SFNEF**: S-FIFO not empty flag (when the I3C acts as controller)

When the I3C acts as controller, if the S-FIFO is enabled (SMODE = 1 in the I3C_CFGR register), this flag is asserted by hardware to indicate that a status word must be read from the S-FIFO. The flag is de-asserted by hardware to indicate that a status word is not to be read from the S-FIFO.

Bit 2 **CFNFF**: C-FIFO not full flag (when the I3C acts as controller)

When the I3C acts as controller, this flag is asserted by hardware to indicate that a control word must be written to the C-FIFO. The flag is de-asserted by hardware to indicate that a control word is not to be written to the C-FIFO.

Note: The software must wait for CFNFF = 1 (by polling or via the enabled interrupt) before writing to C-FIFO (writing to I3C_CR).

Bit 1 **TXFEF**: TX-FIFO empty flag (whatever the I3C acts as controller/target)

This flag is asserted by hardware to indicate that the TX-FIFO is empty.

This flag is de-asserted by hardware to indicate that the TX-FIFO is not empty.

Bit 0 **CFEF**: C-FIFO empty flag (whatever the I3C acts as controller)

This flag is asserted by hardware to indicate that the C-FIFO is empty when controller, and that the I3C_CR register contains no control word (none IBI/CR/HJ request) when target.

This flag is de-asserted by hardware to indicate that the C-FIFO is not empty when controller, and that the I3C_CR register contains one control word (a pending IBI/CR/HJ request) when target.

Note: When the I3C acts as controller, if the C-FIFO and TX-FIFO preload is configured (TMODE = 1 in the I3C_CFGR register), the software must wait for TXFEF = 1 and CFEF = 1 before starting a new frame transfer.

49.16.14 I3C interrupt enable register (I3C_IER)

Address offset: 0x054

Reset value: 0x0000 0000

This register is used to enable/disable, at bit level, an interrupt, for each of the following event/flag.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r				r	r	r				r	r	r	r		

Bit 31 **GRPIE**: DEFGRPA CCC interrupt enable (when the I3C acts as target)

0: interrupt disabled

1: interrupt enabled

Bit 30 **DEFIE**: DEFTGTS CCC interrupt enable (when the I3C acts as target)

0: interrupt disabled

1: interrupt enabled

Bit 29 **INTUPDIE**: ENEC/DISEC CCC interrupt enable (when the I3C acts as target)

0: interrupt disabled

1: interrupt enabled

Bit 28 **ASUPDIE**: ENTASx CCC interrupt enable (when the I3C acts as target)
0: interrupt disabled
1: interrupt enabled

Bit 27 **RSTIE**: reset pattern interrupt enable (when the I3C acts as target)
0: interrupt disabled
1: interrupt enabled

Bit 26 **MRLUPDIE**: SETMRL CCC interrupt enable (when the I3C acts as target)
0: interrupt disabled
1: interrupt enabled

Bit 25 **MWLUPDIE**: SETMWL CCC interrupt enable (when the I3C acts as target)
0: interrupt disabled
1: interrupt enabled

Bit 24 **DAUPDIE**: ENTDAA/RSTDAA/SETNEWDA CCC interrupt enable (when the I3C acts as target)
0: interrupt disabled
1: interrupt enabled

Bit 23 **STAIE**: format 1 GETSTATUS CCC interrupt enable (when the I3C acts as target)
0: interrupt disabled
1: interrupt enabled

Bit 22 **GETIE**: GETxxx CCC interrupt enable (except GETSTATUS of format 1) (when the I3C acts as target)
0: interrupt disabled
1: interrupt enabled

Bit 21 **WKPIE**: Wake-up interrupt enable (when the I3C acts as target)
0: interrupt disabled
1: interrupt enabled

Bit 20 Reserved, must be kept at reset value.

Bit 19 **HJIE**: Hot-join interrupt enable (when the I3C acts as controller)
0: interrupt disabled
1: interrupt enabled

Bit 18 **CRUPDIE**: Controller-role update interrupt enable (when the I3C acts as target)
0: interrupt disabled
1: interrupt enabled

Bit 17 **CRIE**: Controller-role request interrupt enable (when the I3C acts as controller)
0: interrupt disabled
1: interrupt enabled

Bit 16 **IBIENDIE**: IBI end interrupt enable (when the I3C acts as target)
0: interrupt disabled
1: interrupt enabled

Bit 15 **IBIIE**: IBI request interrupt enable (when the I3C acts as controller)
0: interrupt disabled
1: interrupt enabled

Bits 14:12 Reserved, must be kept at reset value.

Bit 11 **ERRIE**: error interrupt enable (whatever the I3C acts as controller/target)
0: interrupt disabled
1: interrupt enabled

Bit 10 **RXTGTENDIE**: target-initiated read end interrupt enable (when the I3C acts as controller)
0: interrupt disabled
1: interrupt enabled

Bit 9 **FCIE**: frame complete interrupt enable (whatever the I3C acts as controller/target)
0: interrupt disabled
1: interrupt enabled

Bits 8:6 Reserved, must be kept at reset value.

Bit 5 **RXFNEIE**: RX-FIFO not empty interrupt enable (whatever the I3C acts as controller/target)
0: interrupt disabled
1: interrupt enabled

Bit 4 **TXFNFIE**: TX-FIFO not full interrupt enable (whatever the I3C acts as controller/target)
0: interrupt disabled
1: interrupt enabled

Bit 3 **SFNEIE**: S-FIFO not empty interrupt enable when the I3C acts as controller
0: interrupt disabled
1: interrupt enabled

Bit 2 **CFNFIE**: C-FIFO not full interrupt enable when the I3C acts as controller
0: interrupt disabled
1: interrupt enabled

Bits 1:0 Reserved, must be kept at reset value.

49.16.15 I3C clear event register (I3C_CEVR)

Address offset: 0x058

Reset value: 0x0000 0000

This write register is used to clear individually, at bit level, the corresponding event flag of the I3C_EVR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0: no effect
1: clear ERRF

Bit 10 **CRXTGTENDF**: Clear target-initiated read end flag (when the I3C acts as controller)
0: no effect
1: clear RXTGTENDF

Bit 9 **CFCF**: Clear frame complete flag (whatever the I3C acts as controller/target)
0: no effect
1: clear FCF

Bits 8:0 Reserved, must be kept at reset value.

49.16.16 I3C own device characteristics register (I3C_DEVR0)

Address offset: 0x060

Reset value: 0x0000 0000

When the I3C peripheral acts as target, this register is used to write or read its own device characteristics.

When the I3C peripheral acts as controller, the field DA[6:0] is used to write and store its own dynamic address.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	RSTVAL	RSTACT[1:0]		AS[1:0]		HJEN	Res.	CREN	IBIEN
							r	r	r	r	r	rw		rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DA[6:0]							DAVAL
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **RSTVAL**: Reset action is valid (when the I3C acts as target)
This bit is asserted by hardware to indicate that the RSTACT[1:0] field has been updated on the reception of a broadcast or direct write RSTACT CCC (target reset action) and is valid.
This bit is cleared by hardware when the target receives a frame start.
When the device is not in Stop mode:
– If RSTVAL = 1: when RSTF in the I3C_EVR register is asserted (and/or the corresponding interrupt if enabled), RSTACT[1:0] in the I3C_DEVR0 register dictates the reset action to be performed by the software, if any.
– If RSTVAL = 0: when RSTF is asserted (and/or the corresponding interrupt if enabled), the software must issue an I3C reset after a first detected reset pattern, and a system reset on the second one.
When in Stop mode, the corresponding interrupt can be used to wake up the device.

Bits 23:22 **RSTACT[1:0]**: Reset action/level on received reset pattern (when the I3C acts as target)

This read field is used by hardware on the reception of a direct read RSTACT CCC in order to return the corresponding data byte on the I3C bus.

This read field is updated by hardware on the reception of a broadcast or direct write RSTACT CCC (target reset action).

Only the defining bytes 0x00, 0x01 and 0x02 are mapped, and RSTACT[1:0] = Defining Byte[1:0].

00: no reset action

01: first level of reset: the application software must either:

a) partially reset the peripheral, by a write and clear of the enable bit of the I3C configuration register (write EN = 0). This resets the I3C bus interface and the I3C kernel sub-parts, without modifying the content of the I3C APB registers (except the EN bit).

b) fully reset the peripheral, including all its registers, via a write and set of the I3C reset control bit of the RCC (reset and clock controller) register.

10: second level of reset: the application software must issue a warm reset, also known as a system reset. This (see *Section 11: Reset and clock control (RCC)*) has the same impact as a pin reset (NRST = 0):

– the software writes and sets the SYSRESETREQ control bit of the AITR register, when the device is controlled by a Cortex®-M.

– the software writes and sets SYSRST = 1 in the RCC_GRSTCSETR register, when the device is controlled by a Cortex®-A.

11: no reset action

Bits 21:20 **AS[1:0]**: Activity state (when the I3C acts as target)

This read field is updated by hardware on the reception of a ENTASx CCC (enter activity state, with x = 0-3):

00: activity state 0

01: activity state 1

10: activity state 2

11: activity state 3

Bit 19 **HJEN**: Hot-join request enable (when the I3C acts as target)

This bit is initially written by software when EN = 0, and is updated by hardware on the reception of DISEC CCC with DISHJ= 1 (cleared) and the reception of ENEC CCC with ENHJ= 1 (set). This bit can only be written by software when EN = 0 in the I3C_CFGR register.

0: hot-join request disabled

1: hot-join request enabled

Bit 18 Reserved, must be kept at reset value.

Bit 17 **CREN**: Controller-role request enable (when the I3C acts as target)

This bit is initially written by software when EN = 0, and is updated by hardware on the reception of DISEC CCC with DISCR = 1 (cleared) and the reception of ENEC CCC with ENCR = 1 (set). This bit can only be written by software when EN = 0 in the I3C_CFGR register.

0: controller-role request disabled

1: controller-role request enabled

Bit 16 **IBIEN**: IBI request enable (when the I3C acts as target)

This bit is initially written by software when EN = 0, and is updated by hardware on the reception of DISEC CCC with DISINT = 1 (cleared) and the reception of ENEC CCC with ENINT = 1 (set). This bit can only be written by software when EN = 0 in the I3C_CFGR register.

0: IBI request disabled

1: IBI request enabled

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:1 **DA[6:0]**: 7-bit dynamic address

When the I3C acts as controller, this field can be written by software, for defining its own dynamic address.

When the I3C acts as target, this field is updated by hardware on the reception of either the broadcast ENTDAA CCC or the direct SETNEWDA CCC.

Bit 0 **DAVAL**: Dynamic address is valid (when the I3C acts as target)

When the I3C acts as controller, this bit can be written by software, for validating its own dynamic address, for example before a controller-role hand-off.

When the I3C acts as target, this bit is asserted by hardware on the acknowledge of the broadcast ENTDAA CCC or the direct SETNEWDA CCC, and this field is cleared by hardware on the acknowledge of the broadcast RSTDAA CCC.

49.16.17 I3C device x characteristics register (I3C_DEVRx)

Address offset: 0x060 + 0x4 * x, (x = 1 to 4)

Reset value: 0x0000 0000

When the I3C peripheral acts as controller, this register is used to define and store some characteristics of a device target x with their related management from the controller, to communicate accordingly with any of this target x over the I3C bus. Then, the hardware can autonomously identify and acknowledge an allowed IBI or/and controller-role request from a target x, receive the expected IBI payload data if any, and notify the software via the corresponding flag IBIF/CRF (and the corresponding interrupt if enabled) in the I3C_EVR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DIS	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SUSP	IBIDEN	CRACK	IBIACK
r												rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DA[6:0]							Res.
								rw	rw	rw	rw	rw	rw	rw	

Bit 31 **DIS**: DA[6:0] write disabled (when the I3C acts as controller)

When the I3C acts as controller, once the software sets IBIACK= 1 or CRACK= 1, this read bit is set by hardware (DIS = 1) to lock the configured DA[6:0] and IBIDEN values.

Then, to be able to modify DA[6:0], IBIDEN or SUSP, the software must wait for DIS to be de-asserted by hardware (polling on DIS = 0) before modifying these three assigned values to the target x. Indeed, the target can request an IBI or a controller-role while the controller intends to modify DA[6:0], IBIDEN or SUSP.

0: write to DA[7:0] and to IBIDEN in the I3C_DEVRx register is allowed

1: write to DA[7:0] and to IBIDEN is disabled/locked

Bits 30:20 Reserved, must be kept at reset value.

Bit 19 **SUSP**: Suspend/stop I3C transfer on received IBI (when the I3C acts as controller)

When the I3C acts as controller, this bit can be used to receive an IBI from target x with pending read notification feature (received MDB[7:5] = 3'b101).

If this bit is set, when an IBI is received and completed (IBIF = 1 in the I3C_EVR register), a stop is emitted on the I3C bus and both C-FIFO and TX-FIFO are automatically flushed by hardware. The controller execution flow is stopped, even if a next control message is programmed. When the IBI is completed, the controller software can issue a new control word, such as a private read, to the target device that initiated the IBI request.

0: C-FIFO and TX-FIFO are not flushed after an IBI request from target x is acknowledged and completed, and depending on the presence or absence of a next control word, a repeated start or a stop is emitted

1: I3C transfer is stopped and both C-FIFO and TX-FIFO are flushed after receiving an IBI request from target x

Bit 18 **IBIDEN**: IBI data enable (when the I3C acts as controller)

When the I3C acts as controller, this bit must be written by software to store the BCR[2] bit as received from the target x during broadcast ENTDAA or direct GETBCR CCC via the received I3C_RDR.

Writing to this field has no impact when the DIS = 1 in the I3C_DEVRx register.

0: no data byte follows the acknowledged IBI from target x

1: the mandatory data byte MDB[7:0] follows the acknowledged IBI from target x

Bit 17 **CRACK**: Controller-role request acknowledge (when the I3C acts as controller)

When the I3C acts as controller, this bit is written by software to define the acknowledge policy to be applied on the I3C bus on the reception of a controller-role request from target x:

0: a controller-role request from target x must be NACK-ed

After the NACK, the message continues as initially programmed (the target is aware of the NACK and can emit another controller-role request later on)

1: a controller-role request (with 7-bit dynamic address DA[6:0]) from target x must be ACKed

- The field DIS is asserted by hardware to protect DA[6:0] from being modified by software meanwhile the hardware can store internally the current DA[6:0] into the kernel clock domain.

- After the ACK, the message continues as initially programmed. The software is notified by the controller-role request flag (CRF = 1 in the I3C_EVR register) and/or the corresponding interrupt if enabled; For effectively granting the controller-role to the requesting secondary controller, software must issue a GETACCCR (formerly known as GETACCMST), followed by a stop.

- Independently of CRACK configuration for this or other devices, further controller-role request(s) are NACK-ed until controller-role request flag (CRF) and IBI flag (IBIF) in the I3C_EVR register are both cleared.

Bit 16 **IBIACK**: IBI request acknowledge (when the I3C acts as controller)

When the I3C acts as controller, this bit is written by software to define the acknowledge policy to be applied on the I3C bus on the reception of an IBI request from target x:

0: an IBI request from target x must be NACK-ed

- After the NACK, the message continues as initially programmed (the target is aware of the NACK and can emit another IBI request later on)

1: an IBI request (with 7-bit dynamic address DA[6:0]) from target x must be ACKed

- The field DIS is asserted by hardware to protect DA[6:0] from being modified by software meanwhile the hardware can store internally the current DA[6:0] into the kernel clock domain.

- After the ACK, the controller logs the IBI payload data, if any, depending on I3C_DEVRx.IBIDEN.

- The software is notified by the IBI flag (IBIF = 1) and/or the corresponding interrupt if enabled;

- Independently from IBIACK configuration for this or other devices, further IBI request(s) are NACK-ed until IBI request flag (IBIF) and controller-role request flag (CRF) are both cleared.

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:1 **DA[6:0]**: Assigned I3C dynamic address to target x (when the I3C acts as controller)

When the I3C acts as controller, this field must be written by software to store the 7-bit dynamic address that the controller sends via a broadcast ENTDAA or a direct SETNEWDA CCC acknowledged by the target x.

Writing to this field has no impact when the read field DIS = 1 in the I3C_DEVRx register.

Bit 0 Reserved, must be kept at reset value.

49.16.18 I3C maximum read length register (I3C_MAXRLR)

Address offset: 0x090

Reset value: 0x0000 0000

When the I3C acts as target, this register is used to set or get the maximum read length value exchanged with the controller during respectively GETMRL or SETMRL CCC. This register is also used to set the IBI data payload size.

This register can be written by the software when EN = 0 in the I3C_CFGR register.

When receiving a private read message, the target ends the data transmission (by driving T-bit = 0) when the count of transmitted data reaches MRL[15:0] in the I3C_MAXRLR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IBIP[2:0]

MRL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **IBIP[2:0]**: IBI payload data maximum size, in bytes (when I3C acts as target)
This field is initially written by software when EN = 0 to set the maximum number of data bytes to be sent to the controller after an IBI request has been acknowledged.This field can be updated by hardware on the reception of SETMRL command (which potentially also updated IBIP[2:0]).
Software is notified of an MRL update by MRLUPF in the I3C_EVR register and the corresponding interrupt, if enabled.
000: null payload data size (only allowed when BCR2 = 0 in the IC3_BCR register)
001: 1 byte (mandatory data byte MDB[7:0]
010: 2 bytes (including first MDB[7:0])
011: 3 bytes (including first MDB[7:0])
100: 4 bytes (including first MDB[7:0])
others: same as 100

Bits 15:0 **MRL[15:0]**: Maximum data read length (when I3C acts as target)
This field is initially written by software when EN = 0 and updated by hardware on the reception of SETMRL command (with potentially also updated IBIP[2:0]).
Software is notified of an MRL update by MRLUPF and the corresponding interrupt, if enabled.
This field is used by hardware to return the value on the I3C bus when the target receives a GETMRL CCC.

49.16.19 I3C maximum write length register (I3C_MAXWLR)

Address offset: 0x094

Reset value: 0x0000 0000

When the I3C acts as target, this register is used to set or get the maximum write length value exchanged with the controller during respectively GETMWL or SETMWL CCC.

This register can be written by the software when EN = 0 in the I3C_CFGR register.

On receiving a private write message, the target stops the data reception (extra received data are not written into RX-FIFO) when the count of received data reaches MWL[15:0] in the I3C_MAXWLR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

MWL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **MWL[15:0]**: Maximum data write length (when I3C acts as target)
This field is initially written by software when EN = 0 and updated by hardware on the reception of SETMWL command.
Software is notified of an MWL update by MWLUPF in the I3C_EVR register and the corresponding interrupt, if enabled.
This field is used by hardware to return the value on the I3C bus when the target receives a GETMWL CCC.

49.16.20 I3C timing register 0 (I3C_TIMINGR0)

Address offset: 0x0A0

Reset value: 0x0000 0000

When the I3C acts as controller, this register is used to configure the SCL clock signal waveform.

This register can be written by the software when EN = 0 in the I3C_CFGR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SCLH_I2C[7:0]								SCLL_OD[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SCLH_I3C[7:0]								SCLL_PP[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **SCLH_I2C[7:0]**: SCL high duration, used for legacy I^2C messages, in number of kernel clocks cycles:

$t_{SCLH\_I2C} = (SCLH\_I2C + 1) \times t_{I3CCLK}$

Note: SCLH_I2C is used to generate t_{DIG_H} (I^2C) timing when communicating with I^2C devices.

Note: With I^2C fm+ device t_{DIG_Hmin} = 260 ns, with I^2C fm device t_{DIG_Hmin} = 600 ns.

Bits 23:16 **SCLL_OD[7:0]**: SCL low duration in open-drain phases, used for legacy I^2C messages and for I3C open-drain phases (address phase following a start, ACK phase during controller-initiated messages, and T bit phase during direct/private/IBI payload), in number of kernel clocks cycles:

$t_{SCLL\_OD} = (SCLL\_OD + 1) \times t_{I3CCLK}$

Note: SCLL_OD is used to generate both t_{DIG_L} (I^2C) and $t_{DIG\_OD\_L}$(I3C) timings.

Note: With I^2C fm+ device t_{DIG_Lmin} = 500 ns, with I^2C fm device t_{DIG_Lmin} = 1320 ns.

Note: I3C messages: $t_{DIG\_OD\_Lmin}$ = 200 ns.

Note: If a single I3C frame is gathering I^2C and I3C messages, the SCL low duration during I3C open-drain phases is increased to fit I^2C timings.

Bits 15:8 **SCLH_I3C[7:0]**: SCL high duration, used for I3C messages (both in push-pull and open-drain phases), in number of kernel clocks cycles:

$t_{SCLH\_I3C} = (SCLH\_I3C + 1) \times t_{I3CCLK}$

Note: SCLH_I3C is used to generate both t_{DIG_H} (I3C) and $t_{DIG\_H\_MIXED}$ timings.

Note: For mixed bus (with at least one I^2C target): $t_{DIG\_H\_MIXEDmin}$ = 32 ns and $t_{DIG\_H\_MIXEDmax}$ = 45 ns (due to I^2C 50 ns spike filter).

Note: For pure I3C bus (with no I^2C targets): t_{DIG_Hmin} = 32 ns.

Bits 7:0 **SCLL_PP[7:0]**: SCL low duration in I3C push-pull phases, in number of kernel clocks cycles:

$t_{SCLL\_PP} = (SCLL\_PP + 1) \times t_{I3CCLK}$

Note: SCLL_PP is used to generate t_{DIG_L} (I3C in PP) timing.

Note: t_{DIG_Lmin} = 32 ns (max 40/60 duty cycle at 12.5 MHz).

49.16.21 I3C timing register 1 (I3C_TIMINGR1)

Address offset: 0x0A4

Reset value: 0x0000 0000

When the I3C acts as controller, this register is used to configure some I3C timing settings.

When the I3C acts as target and is controller-capable, this register is used to configure a timing for the controller-role hand-off procedure.

This register can be written by the software when EN = 0 in the I3C_CFGR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	SDA_HD	Res.	Res.	Res.	Res.	Res.	FREE[6:0]						
			rw						rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	ASNCR[1:0]		AVAL[7:0]							
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **SDA_HD**: SDA hold time (when the I3C acts as controller), in number of kernel clocks cycles (refer to MIPI timing SDA hold time in push-pull t_{HD_PP}):

SDA hold time = (SDA_HD + 0.5) x t_{I3CCLK}

Note: when controller: t_{HD_PPmiN} = min (t_{CR} , t_{CF}) + 3 ns.

Bits 27:23 Reserved, must be kept at reset value.

Bits 22:16 **FREE[6:0]**: Number of kernel clocks cycles that is used to set some MIPI timings like bus free condition time (when the I3C acts as controller)

When the I3C acts as controller:

1. for I3C start timing: it must wait for (bus free condition) time to be elapsed after a stop and before a start, refer to MIPI timings (I3C) t_{CAS} and (I^2C) t_{BUF}. These timings are defined by: t_{BUF} = t_{CAS} = [(FREE[6:0] + 1) x 2 - (0.5 + SDA_HD)] x t_{I3CCLK}

Note: For pure I3C bus: t_{CASmin} = 38.4 ns, and t_{CASmax} = 1 µs, 100 µs, 2 ms, 50 ms for, respectively, ENTAS0, 1, 2, and 3.

Note: For mixed bus with I^2C fm+ device t_{BUFmin} = 0.5 µs, for mixed bus with I^2C fm device t_{BUFmin} = 1.3 µs.

2. for I3C repeated start timing: must wait for time to be elapsed after a repeated start (SDA is de-asserted) and before driving SCL low, refer to. MIPI timing t_{CASr}. This timing is defined by: t_{CASr} = [(FREE[6:0] + 1) x 2 - (0.5 + SDA_HD)] x t_{I3CCLK}.

Note: $t_{CASr,\ miN}$ = 19.2 ns.

3. for I3C stop timing: must wait for time to be elapsed after that the SCL clock is driven high, and before the stop condition (SDA is asserted). This timing is defined by: t_{CBP} = (FREE[6:0] + 1) x t_{I3CCLK}.

Note: t_{CBPmiN} = 19.2 ns.

4. for I3C repeated start timing (T-bit when controller ends read with repeated start followed by stop): must wait for time to be elapsed after that the SCL clock is driven high, and before the repeated start condition (SDA is de-asserted). This timing is defined by: t_{CBSr} = (FREE[6:0] + 1) x t_{I3CCLK}.

Note: $t_{CBSr,\ miN}$ = 19.2 ns.

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:8 **ASNCR[1:0]**: Activity state of the new controller (when I3C acts as active controller)

This field indicates the time to wait before being accessed as new target, refer AVAL[7:0].

This field can be modified only when the I3C acts as controller.

Bits 7:0 **AVAL[7:0]**: Number of kernel clock cycles to set a time unit of 1 µs, whatever I3C acts as controller or target.

This time unit is then used by the hardware to build some internal timers, corresponding to the following MIPI I3C timings:

When the I3C acts as target:

1. for bus available condition time: it must wait for (bus available condition) time to be elapsed after a stop and before issuing a start request for an IBI or a controller-role request (bus free condition is sustained for at least t_{AVAL}). Refer to MIPI timing t_{AVAL} = 1 µs. This timing is defined by: t_{AVAL} = (AVAL[7:0] + 2) x t_{I3CCLK}
2. for bus idle condition time: it must wait for (bus idle condition) time to be elapsed after that both SDA and SCL are continuously high and stable before issuing a hot-join event. Refer to MIPI v1.1 timing t_{IDLE} = 200 µs . This timing is defined by: t_{IDLE} = (AVAL[7:0] + 2) x 200 x t_{I3CCLK}

When the I3C acts as controller, it cannot stall the clock beyond a maximum stall time (stall the SCL clock low), as follows:

1. on first bit of assigned address during dynamic address assignment: it cannot stall the clock beyond the MIPI timing $t_{STALLDAA}$ = 15 ms. This timing is defined by: $t_{STALLDAAmax}$ = (AVAL[7:0] + 1) x 15000 x t_{I3CCLK}
2. on ACK/NACK phase of I3C/I^2C transfer, on parity bit of write data transfer, on transition bit of I3C read transfer: it cannot stall the clock beyond the MIPI timing t_{STALL} = 100 µs. This timing is defined by: $t_{STALLmax}$ = (AVAL[7:0] + 1) x 100 x t_{I3CCLK}

Whatever the I3C acts as controller or as (controller-capable) target, during a controller-role hand-off procedure:

1. The new controller must wait for $t_{NEWCRLock}$ before pulling SDA low (issuing a start) after a completed GETACCR CCC. Then the new controller, within t_{CAS}, can pull SCL low to activate SCL clock. The active controller must wait for the same $t_{NEWCRLock}$ time, or at least 100 µs, before testing if the new controller has gained control of the bus by pulling SDA low. The time to wait depends upon the value of ANSCR[1:0] in the I3C_TIMINGR1 register:
   - ASNCR[1:0] = 00: $t_{NEWCRLock}$ = (AVAL[7:0] + 1) x t_{I3CCLK}
   - ASNCR[1:0] = 01: $t_{NEWCRLock}$ = (AVAL[7:0] + 1) x 100 x t_{I3CCLK}
   - ASNCR[1:0] = 10: $t_{NEWCRLock}$ = (AVAL[7:0] + 1) x 2000 x t_{I3CCLK}
   - ASNCR[1:0] = 11: $t_{NEWCRLock}$ = (AVAL[7:0] + 1) x 50000 x t_{I3CCLK}

49.16.22 I3C timing register 2 (I3C_TIMINGR2)

Address offset: 0x0A8

Reset value: 0x0000 0000

When the I3C acts as controller, this register is used to configure and enable SCL clock stalling, to enable SCL clock low stalling, if needed by the addressed I3C or legacy I^2C target(s).

This register can be written only when the I3C acts as controller.

STALL[7:0]								Res.	Res.	Res.	Res.	STALLA	STALLC	STALLD	STALLT
rw	rw	rw	rw	rw	rw	rw	rw					rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **STALL[7:0]**: Controller clock stall time, in number of kernel clock cycles

t_{SCLL_STALL} = STALL x t_{I3CCLK}

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **STALLA:** Controller clock stall enable on ACK phase

The SCL is stalled (during t_{SCLL_STALL}as defined by STALL) in the address ACK/NACK phase (before the ninth bit). This allows the target to prepare data. The ACK driven by the controller itself on a target-initiated request (IBI/HJ/CR) is not impacted by this control bit.

0: no stall

1: stall enabled

Bit 2 **STALLC:** Controller clock stall enable on PAR phase of CCC

The SCL is stalled during STALL x t_{SCLL_PP} in the T-bit phase of common command code (before the ninth bit). This allows the target to decode the command.

0: no stall

1: stall enabled

Note: t_{SCLL_PP} = (I3C_TIMINGR0.SCLL_PP[7:0] + 1) x t_{I3CCLK}

Bit 1 **STALLD:** Controller clock stall enable on PAR phase of Data

The SCL is stalled during STALL x t_{SCLL_PP} in the T-bit phase (before the ninth bit). This allows the target to read received data.

0: no stall

1: stall enabled

Note: t_{SCLL_PP} = (I3C_TIMINGR0.SCLL_PP[7:0] + 1) x t_{I3CCLK}

Bit 0 **STALLT:** Controller clock stall enable on T-bit phase of data (and on the ACK/NACK phase of data byte of a legacy I^2C read)

The SCL is stalled during STALL x t_{SCLL_PP} in the T-bit phase (before the ninth bit). This allows the target to prepare the data to be sent.

0: no stall

1: stall enabled

Note: t_{SCLL_PP} = (I3C_TIMINGR0.SCLL_PP[7:0] + 1) x t_{I3CCLK}

49.16.23 I3C bus characteristics register (I3C_BCR)

Address offset: 0x0C0

Reset value: 0x0000 0000

When the I3C acts as target, this register is used to configure three bits used by hardware to return the data byte BCR[7:0] on reception of GETBCR or ENTDAA CCC. The returned byte BCR[7:0] on the I3C bus is then as follows:

- BCR[7] = 0 (reserved)
- BCR[6] = I3C_BCR6 (controller capable)
- BCR[5] = 1 (advanced capabilities, use GETCAPS CCC to determine which ones)
- BCR[4] = 0 (not a virtual target)
- BCR[3] = 1 (offline capable)
- BCR[2] = I3C_BCR2 (IBI payload)
- BCR[1] = 1 (IBI request capable)
- BCR[0] = I3C_BCR0 (max data speed limitation)

This register can be written by software only when EN = 0 in the I3C_CFGR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BCR6	Res.	Res.	Res.	BCR2	Res.	BCR0
									rw				rw		rw

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **BCR6**: Controller capable
0: I3C target (no controller capable)
1: I3C controller capable

Bits 5:3 Reserved, must be kept at reset value.

Bit 2 **BCR2**: in-band interrupt (IBI) payload
0: no data byte follows the accepted IBI
1: at least one mandatory data byte follows the accepted IBI (and at most 4 data bytes)

Bit 1 Reserved, must be kept at reset value.

Bit 0 **BCR0**: max data speed limitation
0: no limitation
1: limitation, as described by I3C_GETMXDSR.

49.16.24 I3C device characteristics register (I3C_DCR)

Address offset: 0x0C4

Reset value: 0x0000 0000

When the I3C acts as target, this register is used to configure the device characteristics ID, which is used by hardware to return the data byte DCR[7:0] on reception of GETDCR, ENTDAA, or DEFTGTS CCC.

This register can be written by software only when EN = 0 in the I3C_CFGR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DCR[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **DCR[7:0]**: device characteristics ID
0x00: generic device (for v1.0 devices)
others: ID to describe the type of the I3C sensor/device

Note: The latest MIPI DCR ID assignments are available on https://www.mipi.org.

49.16.25 I3C get capability register (I3C_GETCAPR)

Address offset: 0x0C8

Reset value: 0x0000 0000

When the I3C acts as target, this register is used to set the IBI MDB support for pending read notification support, and is used by hardware to return the GETCAP3 byte on reception of GETCAPS CCC, format 1.

The returned byte GETCAP1[7:0] on the I3C bus is then as follows:

- GETCAP1[7:0] = 0 (no HDR)

The returned byte GETCAP2[7:0] on the I3C bus is then as follows:

- GETCAP2[7:6] = 00 (no HDR)
- GETCAP2[5:4] = 00 (no group addressing)
- GETCAP2[3:0] = 0001 (compliant with MIPI specification v1.1)

The returned byte GETCAP3[7:0] on the I3C bus is then as follows:

- GETCAP3[7] = 0 (reserved)
- GETCAP3[6] = CAPPEND in the I3C_GETCAPR register (IBI MDB support for pending read notification)
- GETCAP3[5] = 0 (no HDR)
- GETCAP3[4] = 1 (defining byte support in GETSTATUS)
- GETCAP3[3] = 1 (defining byte support in GETCAPS)
- GETCAP3[2] = 0 (no device-to-device transfer)
- GETCAP3[1] = 0 (no device-to-device transfer)
- GETCAP3[0] = 0 (no multi-lane data transfer)

This register can be written by software only when EN = 0 in the I3C_CFGR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	CAPPEND	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
	rw														

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **CAPPEND**: IBI MDB support for pending read notification

This bit is written by software during bus initialization (EN = 0), and indicates the support (or not) of the pending read notification via the IBI MDB[7:0] value.

This bit is used to return the GETCAP3 byte in response to the GETCAPS CCC format 1.

0: this I3C when acting as target sends an IBI request without a mandatory data byte value indicating a pending read notification

1: this I3C when acting as target sends an IBI request with a mandatory data byte value (MDB[7:5] = 101), indicating a pending read notification

Bits 13:0 Reserved, must be kept at reset value.

49.16.26 I3C controller-role capability register (I3C_CRCAPR)

Address offset: 0x0CC

Reset value: 0x0000 0000

When the I3C acts as target, this register is used to set features the I3C supports as a secondary controller after controller-role hand-off, and is used by hardware to return the CRCAP1 byte and the CRCAP2 byte on reception of GETCAPS CCC, format 2 with the defining byte CRCAPS (0x91).

The returned CRCAP1[7:0] on the I3C bus is then as follows:

- CRCAP1[7:3] = 00000 (reserved)
- CRCAP1[2] = 0 (no multi-lane)
- CRCAP1[1] = CAPGRP in the I3C_CRCAPR register (group management)
- CRCAP1[0] = 1 (hot-join)

The returned CRLCAP2[7:0] on the I3C bus is then as follows:

- CRCAP2[7:4] = 0000 (reserved)
- CRCAP2[3] = CAPDHOFF in the I3C_CRCAPR register (delayed controller-role handoff)
- CRCAP2[2] = 1 (deep sleep capable)
- CRCAP2[1] = 0 (no automatic controller-role pass-back)
- CRCAP2[0] = 1 (IBI ack capable)

This register can be written by software only when EN = 0 in the I3C_CFGR register.

Res.	Res.	Res.	Res.	Res.	Res.	CAP GRP	Res.	Res.	Res.	Res.	Res.	CAP DHOFF	Res.	Res.	Res.
						rw						rw			

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **CAPGRP**: group management support (when acting as controller)

This bit is written by software during bus initialization (EN = 0), and indicates if the I3C is able to support group management when it acts as a controller (after controller-role hand-off) via emitted DEFGRPA, RSTGRPA, and SETGRPA CCC.

This bit is used to return the CRCAP1 byte in response to the GETCAPS CCC format 2.

0: this I3C does not support group address capabilities

1: this I3C supports group address capabilities (when becoming controller)

Bits 8:4 Reserved, must be kept at reset value.

Bit 3 **CAPDHOFF**: delayed controller-role hand-off

This bit is written by software during bus initialization (EN = 0), and indicates if this target I3C needs additional time to process a controller-role hand-off requested by the current controller.

This bit is used to return the CRCAP2 byte in response to the GETCAPS CCC format 2.

0: this I3C does not needs additional time to process a controller-role hand-off

1: this I3C needs additional time to process a controller-role hand-off

Bits 2:0 Reserved, must be kept at reset value.

49.16.27 I3C get max data speed register (I3C_GETMXDSR)

Address offset: 0x0D0

Reset value: 0x0000 0000

When the I3C acts as target, this register is used to set its capabilities and limitations if any. This register is used by hardware to return data byte(s) on reception of GETMXDS CCC, with format 1 (2 bytes, without maxRdTurn), format 2 (5 bytes, with MaxRdTurn), or format 3 (with defining byte WRRDTURN = 0x00: same 5 bytes as format 2, or with defining byte CRHDLY = 0x91: single byte CRHDLY1).

The returned byte MaxWr[7:0] on the I3C bus is then as follows:

- MaxWr[7:4] = 0000 (reserved)
- MaxWr[3] = 1 (defining byte WRRDTURN and CRHDLY support)
- MaxWr[2:0] = 000 (max sustained data rate for non-CCC messages sent by the controller to the target is designed to operate at 12.5 MHz)

The returned byte MaxRd[7:0] on the I3C bus is then as follows:

- MaxRd[7] = 0 (reserved)
- MaxRd[6] = 1 (stop is allowed between write and read)
- MaxRd[5:3] = 100 if TSCO = 0 (clock to data turnaround time t_{SCO} ≤ 12 ns) in the I3C_GETMXDSR register, else 111 (t_{SCO} > 12 ns, refer to the datasheet for more details)
- MaxRd[2:0] = 000 (max sustained data rate for non-CCC messages sent by the target to the controller is designed to operate at 12.5 MHz)

The returned 3-byte MaxRdTurn[23:0], if FMT[1:0] = 00 in the I3C_GETMXDSR register, on the I3C bus is then as follows:

- MaxRdTurn[23:0], with either the MSB (between 65 ms and 16 s), the middle byte (between 256 µs and 65 ms), or the LSB (less than 256 µs) from RDTURN[7:0] in the I3C_GETMXDSR register (others bits are 0), and depending upon FMT[1:0] in the same register.

The returned byte CRHDLY1[7:0] on the I3C bus is then as follows:

- CRHDLY1[7:3] = 00000 (reserved)
- CRHDLY1[2] = 0 if HOFFAS[1:0] = 00 in the I3C_GETMXDSR register, else 1 (set bus activity state)
- CRHDLY1[1:0] = HOFFAS[1:0] (controller-role hand-off activity state)

This register can be written by software only when EN = 0 in the I3C_CFGR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	TSCO	RDTURN[7:0]

Res.	Res.	Res.	Res.	Res.	Res.	FMT[1:0]		Res.	Res.	Res.	Res.	Res.	Res.	HOFFAS[1:0]	
						rw	rw							rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **TSCO**: clock-to-data turnaround time (t_{SCO})

This bit is written by software during bus initialization (EN = 0 in the I3C_CFGR register) and is used to specify the clock-to-data turnaround time t_{SCO} (vs. the value of 12 ns). This bit is used by the hardware in response to the GETMXDS CCC to return the encoded clock-to-data turnaround time via the returned MaxRd[5:3] bits.

0: $t_{SCO} \leq 12$ ns

1: $t_{SCO} > 12$ ns (refer to the datasheet for more details)

Bits 23:16 **RDTURN[7:0]**: programmed byte of the 3-byte MaxRdTurn (maximum read turnaround byte)

This bit is written by software during bus initialization (EN = 0) and writes the value of the selected byte (via the FMT[1:0] field) of the 3-byte MaxRdTurn, which is returned in response to the GETMXDS CCC format 2 to encode the maximum read turnaround time.

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:8 **FMT[1:0]**: GETMXDS CCC format

This field is written by software during bus initialization (EN = 0) and indicates how is returned the GETMXDS format 1 (without MaxRdTurn) and format 2 (with MaxRdTurn).

This field is used to return the 2-byte format 1 (MaxWr, MaxRd) or 5-byte format 2 (MaxWr, MaxRd, 3-byte MaxRdTurn) byte in response to the GETCAPS CCC.

00: format 1 (2 bytes with MaxWr with no defining byte, MaxRd)

01: format 2: (5 bytes w.ith MaxWr with no defining byte, MaxRd, MaxRdTurn)

- 3-byte MaxRdTurn is returned with MSB = 0, middle byte = 0 and LSB = RDTURN[7:0].
- Max read turnaround time is less than 256 µs.

10: format 2 (5 bytes with MaxWr with no defining byte, MaxRd, and middle byte of MaxRdTurn)

- 3-byte MaxRdTurn is returned with MSB = 0, middle byte = RDTURN[7:0] and LSB = 0.
- Max read turnaround time is between 256 and 65535 µs

11: format 2 (5 bytes with MaxWr with no defining byte, MaxRd, MSB of MaxRdTurn)

- 3-byte MaxRdTurn is returned with MSB = RDTURN[7:0], middle byte = 0 and LSB = 0.
- Max read turnaround time is between 65535 µs and 16 s.

Bits 7:2 Reserved, must be kept at reset value.

Bits 1:0 **HOFFAS[1:0]**: Controller hand-off activity state

This field is written by software during bus initialization (EN = 0), and indicates in which initial activity state the (other) current controller must expect the I3C bus after a controller-role hand-off to this controller-capable I3C, when returning the defining byte CRHDLY (0x91) to a GETMXDS CCC.

This 2-bit field is used to return the CRHDLY1 byte in response to the GETCAPS CCC format 3, to state the activity state of this I3C when becoming controller after a controller-role hand-off, and consequently the time the former controller must wait before testing this I3C to be confirmed its ownership.

00: activity state 0 is the initial activity state of this I3C before and when becoming controller

01: activity state 1 is the initial activity state of this I3C when becoming controller

10: activity state 2 is the initial activity state of this I3C when becoming controller

11: activity state 3 is the initial activity state of this I3C when becoming controller

49.16.28 I3C extended provisioned ID register (I3C_EPIDR)

Address offset: 0xD4

Reset value: 0x0208 0000

When the I3C acts as target, this register is used to set the 4-bit MIPI instance ID by software, and some other constant bits used for the 48-bit provisioned ID. It is also used by hardware to return the six bytes for the 48-bit provisioned ID on reception of GETPID and ENTDAA CCC.

This register can be written by software only when EN = 0 in the I3C_CFGR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

MIPIID[3:0]				Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw												

Bits 31:17 **MIPIMID[14:0]**: 15-bit MIPI manufacturer ID
This read field is the 15-bit STMicroelectronics MIPI ID (0x0104).
This field represents bits[47:33] of the 48-bit provisioned ID.

Bit 16 **IDTSEL**: provisioned ID type selector
This field is set as 0 (vendor fixed value).
This field represents bit[32] of the 48-bit provisioned ID.
Note: Bits[31:16] of the provisioned ID can be 0.

Bits 15:12 **MIPIID[3:0]**: 4-bit MIPI Instance ID
This field is written by software to set and identify individually each instance of this I3C IP with a specific number on a single I3C bus.
This field represents bits[15:12] of the 48-bit provisioned ID.
Note: Bits[11:0] of the provisioned ID can be 0.

Bits 11:0 Reserved, must be kept at reset value.

50 Universal synchronous/asynchronous receiver transmitter (USART/UART)

This section describes the universal synchronous asynchronous receiver transmitter (USART/UART).

50.1 Introduction

The USART offers a flexible means to perform Full-duplex data exchange with external equipments requiring an industry standard NRZ asynchronous serial data format. A very wide range of baud rates can be achieved through a fractional baud rate generator.

The USART supports both synchronous one-way and Half-duplex Single-wire communications, as well as LIN (local interconnection network), Smartcard protocol, IrDA (infrared data association) SIR ENDEC specifications, and Modem operations (CTS/RTS). Multiprocessor communications are also supported.

High-speed data communications are possible by using the DMA (direct memory access) for multibuffer configuration.

50.2 USART main features

- Full-duplex asynchronous communication
- NRZ standard format (mark/space)
- Configurable oversampling method by 16 or 8 to achieve the best compromise between speed and clock tolerance
- Baud rate generator systems
- Two internal FIFOs for transmit and receive data

  Each FIFO can be enabled/disabled by software and come with a status flag.
- A common programmable transmit and receive baud rate
- Dual clock domain with dedicated kernel clock for peripherals independent from PCLK
- Auto baud rate detection
- Programmable data word length (7, 8 or 9 bits)
- Programmable data order with MSB-first or LSB-first shifting
- Configurable stop bits (1 or 2 stop bits)
- Synchronous Master/Slave mode and clock output/input for synchronous communications
- SPI slave transmission underrun error flag
- Single-wire Half-duplex communications
- Continuous communications using DMA
- Received/transmitted bytes are buffered in reserved SRAM using centralized DMA.
- Separate enable bits for transmitter and receiver
- Separate signal polarity control for transmission and reception
- Swappable Tx/Rx pin configuration
- Hardware flow control for modem and RS-485 transceiver

- Communication control/error detection flags
- Parity control:
  - Transmits parity bit
  - Checks parity of received data byte
- Interrupt sources with flags
- Multiprocessor communications: wake-up from Mute mode by idle line detection or address mark detection
- Wake-up from Stop mode

50.3 USART extended features

- LIN master synchronous break send capability and LIN slave break detection capability
  - 13-bit break generation and 10/11 bit break detection when USART is hardware configured for LIN
- IrDA SIR encoder decoder supporting 3/16 bit duration for Normal mode
- Smartcard mode
  - Supports the T=0 and T=1 asynchronous protocols for smartcards as defined in the ISO/IEC 7816-3 standard
  - 0.5 and 1.5 stop bits for Smartcard operation
- Support for Modbus communication
  - Timeout feature
  - CR/LF character recognition

50.4 USART implementation

The table below describe USART implementation. It also includes LPUART for comparison.

Table 530. STM32H563/H573 and STM32H562 features

USART modes/features	STM32H563/H573
USART1	Full
USART2	Full
USART3	Full
USART6	Full
USART10	Full
USART11	Full
UART4	Basic
UART5	Basic
UART7	Basic
UART8	Basic
UART12	Basic
LPUART1	Low-power

Table 531. USART/LPUART features

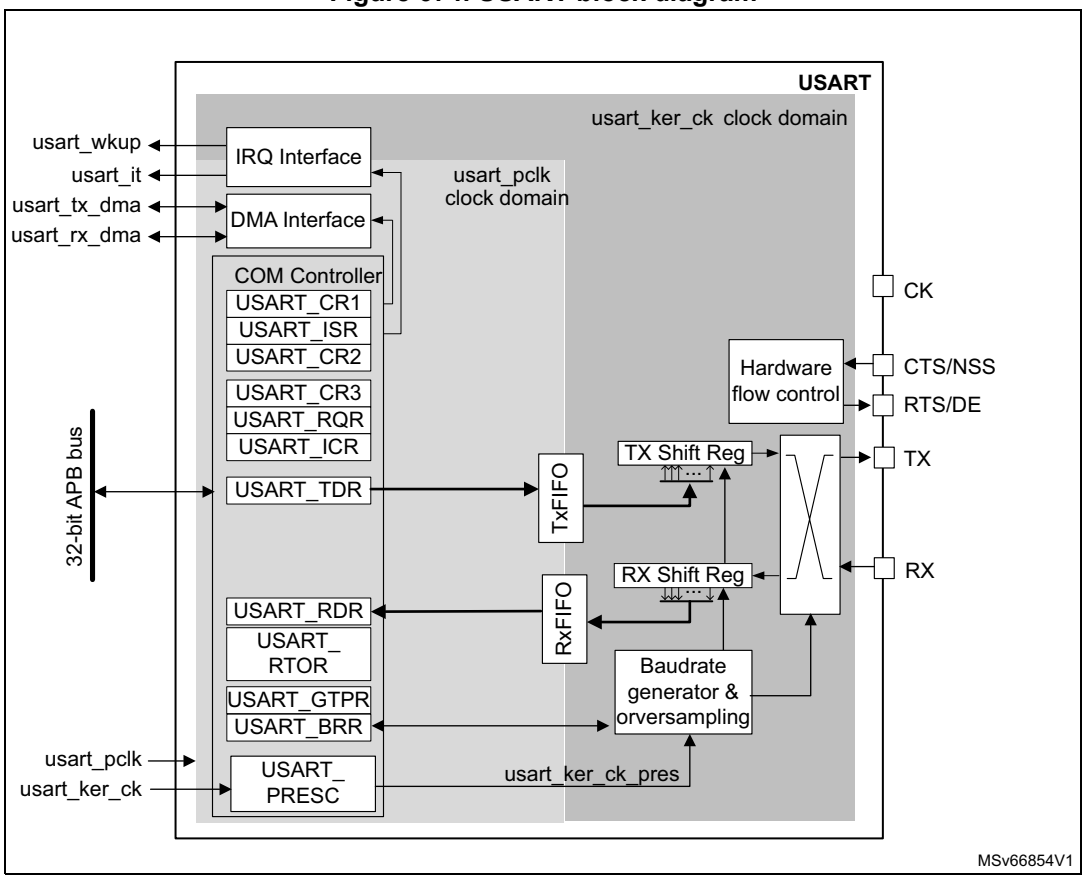
USART modes/features(1)	Full feature set	Basic feature set	Low-power feature set
Hardware flow control for modem	X	X	X
Continuous communication using DMA	X	X	X
Multiprocessor communication	X	X	X
Synchronous mode (Master/Slave)	X	-	-
Smartcard mode	X	-	-
Single-wire Half-duplex communication	X	X	X
IrDA SIR ENDEC block	X	X	-
LIN mode	X	X	-
Dual clock domain	X	X	X
Receiver timeout interrupt	X	X	-
Modbus communication	X	X	-
Auto baud rate detection	X	X	-
Driver Enable	X	X	X
USART data length	7, 8 and 9 bits		
Tx/Rx FIFO	X	X	X
Tx/Rx FIFO size	8		
Wake-up from low-power mode	X(2)	X(2)	X(2)

1. X = supported.
2. Wake-up supported from Stop mode.

50.5 USART functional description

50.5.1 USART block diagram

Figure 674. USART block diagram



50.5.2 USART pins and internal signals

Description USART input/output pins

- USART bidirectional communications

  USART bidirectional communications require a minimum of two pins: Receive Data In (RX) and Transmit Data Out (TX):

  – **RX** (Receive Data Input)

    RX is the serial data input. Oversampling techniques are used for data recovery. They discriminate between valid incoming data and noise.

  – **TX** (Transmit Data Output)

    When the transmitter is disabled, the output pin returns to its I/O port configuration. When the transmitter is enabled and no data needs to be transmitted, the TX pin is High. In Single-wire and Smartcard modes, this I/O is used to transmit and receive data.

- RS232 Hardware flow control mode

  The following pins are required in RS232 Hardware flow control mode:

  – **CTS** (Clear To Send)

    When driven high, this signal blocks the data transmission at the end of the current transfer.

  – **RTS** (Request To Send)

    When it is low, this signal indicates that the USART is ready to receive data.

- RS485 Hardware control mode

  The **DE** (Driver Enable) pin is required in RS485 Hardware control mode. This signal activates the Transmission mode of the external transceiver.

- Synchronous Master/Slave mode and Smartcard mode

  The following pins are required in synchronous Master/Slave mode and Smartcard mode:

  – CK

    This pin acts as Clock output in Synchronous master and Smartcard modes.

    It acts as Clock input is Synchronous slave mode.

    In Synchronous master mode, this pin outputs the transmitter data clock for synchronous transmission corresponding to SPI master mode (no clock pulses on start bit and stop bit, and a software option to send a clock pulse on the last data bit). In parallel, data can be received synchronously on RX pin. This mechanism can be used to control peripherals featuring shift registers (for example LCD drivers). The clock phase and polarity are software programmable.

    In Smartcard mode, CK output provides the clock to the smartcard.

  – NSS

    This pin acts as Slave Select input in Synchronous slave mode.

Refer to *Table 532* and *Table 533* for the list of USART input/output pins and internal signals.

Table 532. USART input/output pins

Pin name	Signal type	Description
USART_RX	Input	Serial data receive input.
USART_TX	Output	Transmit data output.
USART_CTS	Input	Clear to send
USART_RTS	Output	Request to send
USART_DE(1)	Output	Driver enable
USART_CK	Output	Clock output in Synchronous master and Smartcard modes.
USART_NSS(2)	Input	Slave select input in Synchronous slave mode.

1. USART_DE and USART_RTS share the same pin.
2. USART_NSS and USART_CTS share the same pin.

Description of USART input/output signals

Table 533. USART internal input/output signals

Pin name	Signal type	Description
usart_pclk	Input	APB clock
usart_ker_ck	Input	USART kernel clock
usart_wkup	Output	USART provides a wake-up interrupt
usart_it	Output	USART global interrupt
usart_tx_dma	Input/output	USART transmit DMA request
usart_rx_dma	Input/output	USART receive DMA request

50.5.3 USART clocks

The simplified block diagram given in *Figure 674* shows two fully-independent clock domains:

- The **usart_pclk** clock domain

  The **usart_pclk** clock signal feeds the peripheral bus interface. It must be active when accesses to the USART registers are required.
- The **usart_ker_ck** kernel clock domain.

  The **usart_ker_ck** is the USART clock source. It is independent from **usart_pclk** and delivered by the RCC. The USART registers can consequently be written/read even when the **usart_ker_ck** clock is stopped.

  When the dual clock domain feature is not supported, the **usart_ker_ck** clock is the same as the **usart_pclk** clock.

There is no constraint between **usart_pclk** and **usart_ker_ck**: **usart_ker_ck** can be faster or slower than **usart_pclk**. The only limitation is the software ability to manage the communication fast enough.

When the USART operates in SPI slave mode, it handles data flow using the serial interface clock derived from the external CK signal provided by the external master SPI device. The **usart_ker_ck** clock must be at least 3 times faster than the clock on the CK input.

50.5.4 USART character description

The word length can be set to 7, 8 or 9 bits, by programming the M bits (M0: bit 12 and M1: bit 28) in the USART_CR1 register (see *Figure 675*):

- 7-bit character length: M[1:0] = 10
- 8-bit character length: M[1:0] = 00
- 9-bit character length: M[1:0] = 01

Note: In 7-bit data length mode, the Smartcard mode, LIN master mode and Auto baud rate (0x7F and 0x55 frames detection) are not supported.

By default, the signal (TX or RX) is in low state during the start bit. It is in high state during the stop bit.

These values can be inverted, separately for each signal, through polarity configuration control.

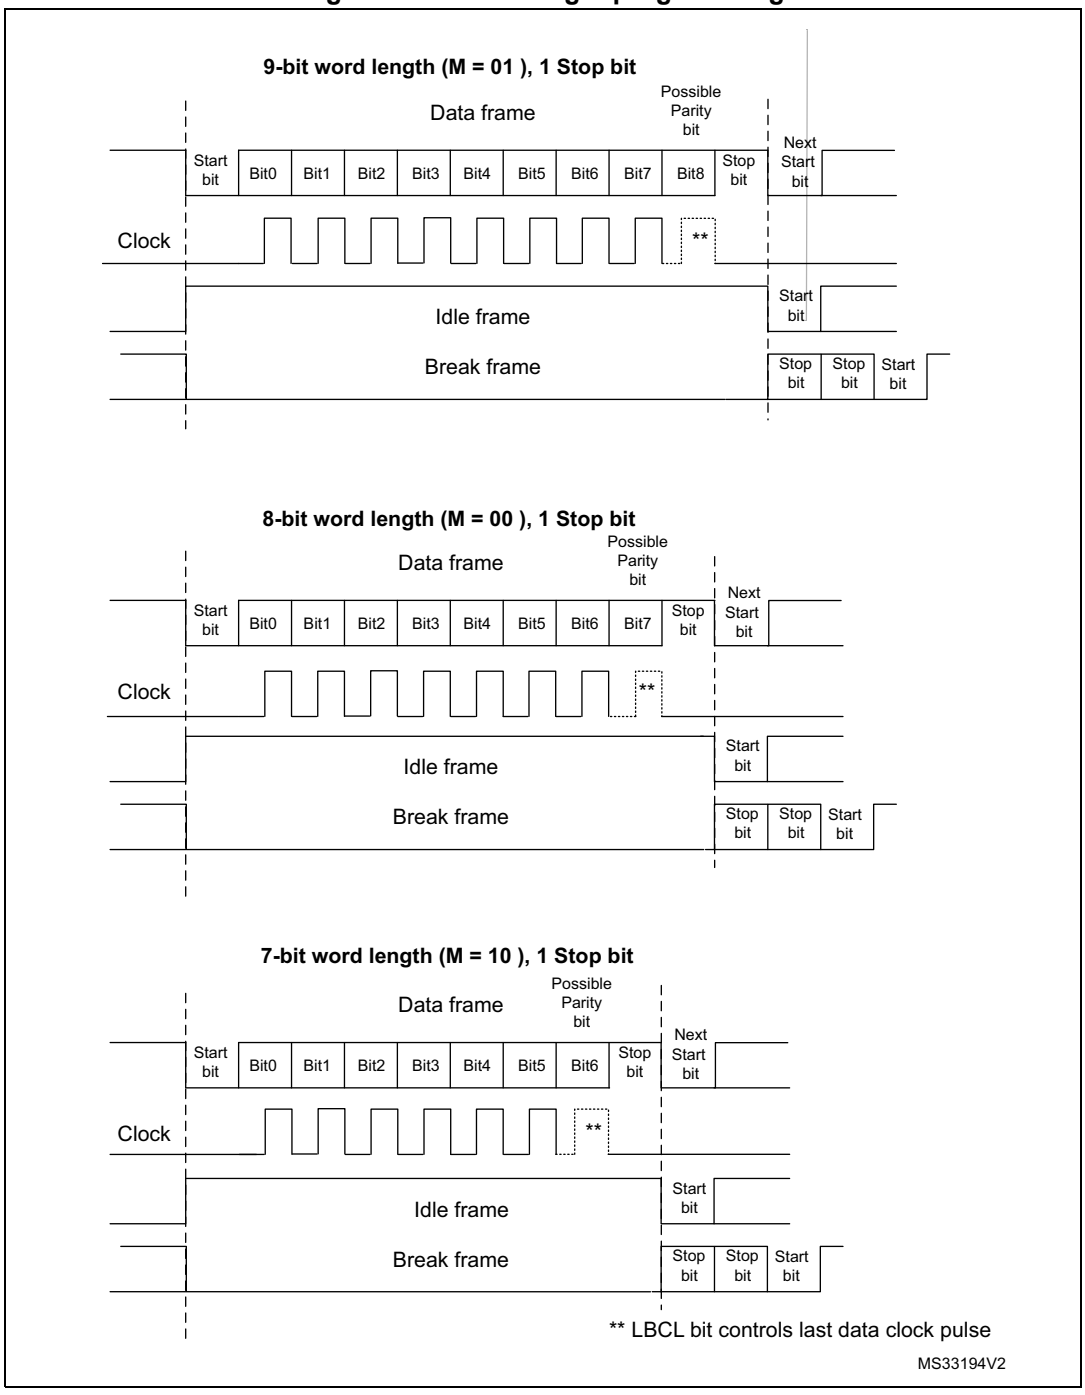
An ***Idle character*** is interpreted as an entire frame of “1”s (the number of “1”s includes the number of stop bits).

A ***Break character*** is interpreted on receiving “0”s for a frame period. At the end of the break frame, the transmitter inserts 2 stop bits.

Transmission and reception are driven by a common baud rate generator. The transmission and reception clock are generated when the enable bit is set for the transmitter and receiver, respectively.

A detailed description of each block is given below.

Figure 675. Word length programming



50.5.5 USART FIFOs and thresholds

The USART can operate in FIFO mode.

The USART comes with a Transmit FIFO (TXFIFO) and a Receive FIFO (RXFIFO). The FIFO mode is enabled by setting FIFOEN in USART_CR1 register (bit 29). This mode is supported only in UART, SPI and Smartcard modes.

Since the maximum data word length is 9 bits, the TXFIFO is 9-bit wide. However the RXFIFO default width is 12 bits. This is due to the fact that the receiver does not only store the data in the FIFO, but also the error flags associated to each character (Parity error, Noise error and Framing error flags).

Note: The received data is stored in the RXFIFO together with the corresponding flags. However, only the data are read when reading the RDR.

The status flags are available in the USART_ISR register.

It is possible to configure the TXFIFO and RXFIFO levels at which the Tx and RX interrupts are triggered. These thresholds are programmed through RXFTCFG and TXFTCFG bitfields in USART_CR3 control register.

In this case:

- The Rx interrupt is generated when the number of received data in the RXFIFO reaches the threshold programmed in the RXFTCFG bits fields.

  In this case, the RXFT flag is set in the USART_ISR register. This means that RXFTCFG data have been received: 1 data in USART_RDR and (RXFTCFG - 1) data in the RXFIFO. As an example, when the RXFTCFG is programmed to 101, the RXFT flag is set when a number of data corresponding to the FIFO size has been received (FIFO size -1 data in the RXFIFO and 1 data in the USART_RDR). As a result, the next received data does not set the overrun flag.
- The Tx interrupt is generated when the number of empty locations in the TXFIFO reaches the threshold programmed in the TXFTCFG bits fields.

50.5.6 USART transmitter

The transmitter can send data words of either 7 or 8 or 9 bits, depending on the M bit status. The Transmit Enable bit (TE) must be set in order to activate the transmitter function. The data in the transmit shift register is output on the TX pin while the corresponding clock pulses are output on the CK pin.

Character transmission

During an USART transmission, data shifts out the least significant bit first (default configuration) on the TX pin. In this mode, the USART_TDR register consists of a buffer (TDR) between the internal bus and the transmit shift register.

When FIFO mode is enabled, the data written to the transmit data register (USART_TDR) are queued in the TXFIFO.

Every character is preceded by a start bit which corresponds to a low logic level for one bit period. The character is terminated by a configurable number of stop bits.

The number of stop bits can be configured to 0.5, 1, 1.5 or 2.

Note: The TE bit must be set before writing the data to be transmitted to the USART_TDR.

The TE bit must not be reset during data transmission. Resetting the TE bit during the transmission corrupts the data on the TX pin as the baud rate counters get frozen. The current data being transmitted are then lost.

An idle frame is sent when the TE bit is enabled.

Configurable stop bits

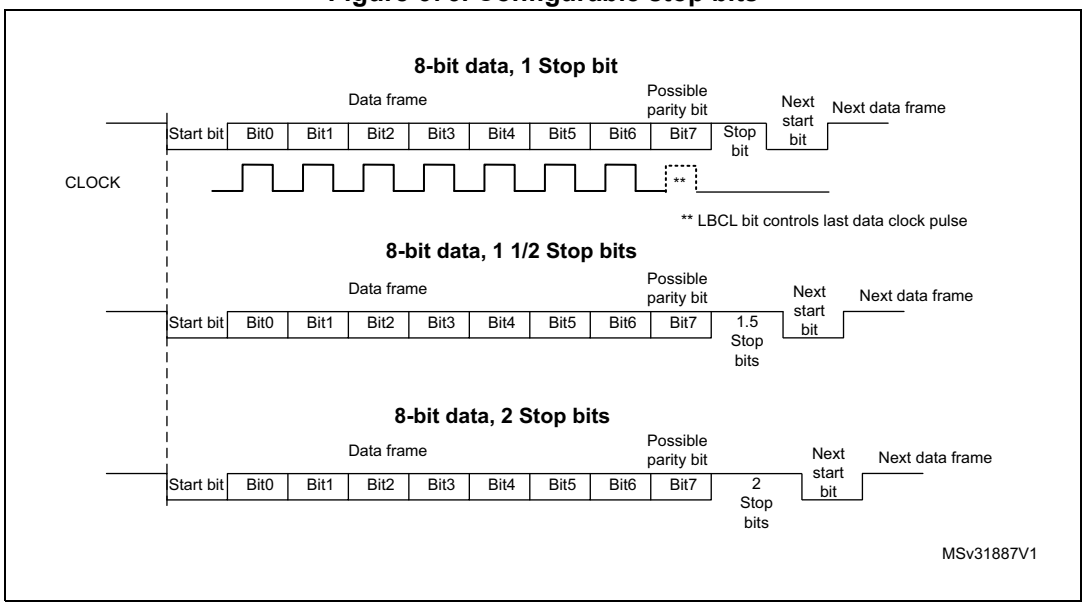
The number of stop bits to be transmitted with every character can be programmed in USART_CR2, bits 13,12.

- ***1 stop bit***: This is the default value of number of stop bits.
- ***2 stop bits***: This is supported by normal USART, Single-wire and Modem modes.
- ***1.5 stop bits***: To be used in Smartcard mode.

An idle frame transmission includes the stop bits.

A break transmission is 10 low bits (when M[1:0] = 00) or 11 low bits (when M[1:0] = 01) or 9 low bits (when M[1:0] = 10) followed by 2 stop bits (see *Figure 676*). It is not possible to transmit long breaks (break of length greater than 9/10/11 low bits).

Figure 676. Configurable stop bits



Character transmission procedure

To transmit a character, follow the sequence below:

1. Program the M bits in USART_CR1 to define the word length.
2. Select the desired baud rate using the USART_BRR register.
3. Program the number of stop bits in USART_CR2.
4. Enable the USART by writing the UE bit in USART_CR1 register to 1.
5. Select DMA enable (DMAT) in USART_CR3 if multibuffer communication must take place. Configure the DMA register as explained in *Section 50.5.20: Continuous communication using USART and DMA*.
6. Set the TE bit in USART_CR1 to send an idle frame as first transmission.

7. Write the data to send in the USART_TDR register. Repeat this for each data to be transmitted in case of single buffer.
   – When FIFO mode is disabled, writing a data to the USART_TDR clears the TXE flag.
   – When FIFO mode is enabled, writing a data to the USART_TDR adds one data to the TXFIFO. Write operations to the USART_TDR are performed when TXFNF flag is set. This flag remains set until the TXFIFO is full.
8. When the last data is written to the USART_TDR register, wait until TC=1.
   – When FIFO mode is disabled, this indicates that the transmission of the last frame is complete.
   – When FIFO mode is enabled, this indicates that both TXFIFO and shift register are empty.

   This check is required to avoid corrupting the last transmission when the USART is disabled or enters Halt mode.

Single byte communication

- When FIFO mode is disabled

  Writing to the transmit data register always clears the TXE bit. The TXE flag is set by hardware. It indicates that:
  – the data have been moved from the USART_TDR register to the shift register and the data transmission has started;
  – the USART_TDR register is empty;
  – the next data can be written to the USART_TDR register without overwriting the previous data.

  This flag generates an interrupt if the TXEIE bit is set.

  When a transmission is ongoing, a write instruction to the USART_TDR register stores the data in the TDR buffer. It is then copied in the shift register at the end of the current transmission.

  When no transmission is ongoing, a write instruction to the USART_TDR register places the data in the shift register, the data transmission starts, and the TXE bit is set.
- When FIFO mode is enabled, the TXFNF (TXFIFO not full) flag is set by hardware to indicate that:
  – the TXFIFO is not full;
  – the USART_TDR register is empty;
  – the next data can be written to the USART_TDR register without overwriting the previous data. When a transmission is ongoing, a write operation to the USART_TDR register stores the data in the TXFIFO. Data are copied from the TXFIFO to the shift register at the end of the current transmission.

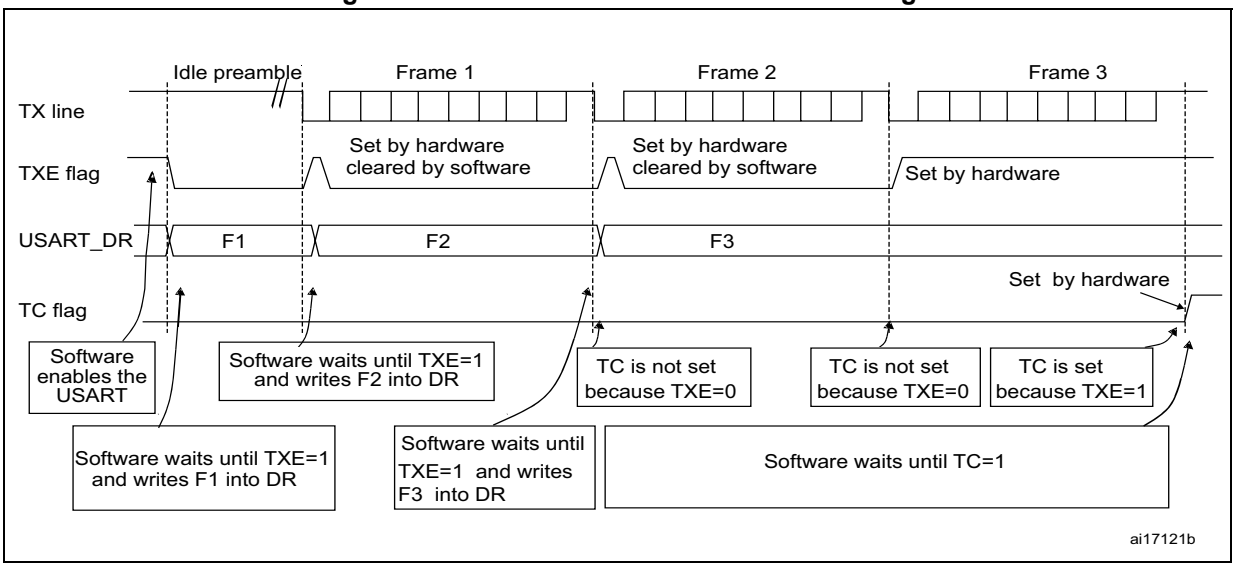
  When the TXFIFO is not full, the TXFNF flag stays at 1 even after a write operation to USART_TDR register. It is cleared when the TXFIFO is full. This flag generates an interrupt if the TXFNFIE bit is set.

  Alternatively, interrupts can be generated and data can be written to the FIFO when the TXFIFO threshold is reached. In this case, the CPU can write a block of data defined by the programmed trigger level.

  If a frame is transmitted (after the stop bit) and the TXE flag (TXFE in case of FIFO mode) is set, the TC flag goes high. An interrupt is generated if the TCIE bit is set in the USART_CR1 register.

After writing the last data to the USART_TDR register, it is mandatory to wait until TC is set before disabling the USART or causing the microcontroller to enter the low-power mode (see *Figure 677: TC/TXE behavior when transmitting*).

Figure 677. TC/TXE behavior when transmitting



Note: When FIFO management is enabled, the TXFNF flag is used for data transmission.

Break characters

Setting the SBKRQ bit transmits a break character. The break frame length depends on the M bit (see *Figure 675*).

If a 1 is written to the SBKRQ bit, a break character is sent on the TX line after completing the current character transmission. The SBKF bit is set by the write operation and it is reset by hardware when the break character is completed (during the stop bits after the break character). The USART inserts a logic 1 signal (stop) for the duration of 2 bits at the end of the break frame to guarantee the recognition of the start bit of the next frame.

When the SBKRQ bit is set, the break character is sent at the end of the current transmission.

When FIFO mode is enabled, sending the break character has priority on sending data even if the TXFIFO is full.

Idle characters

Setting the TE bit drives the USART to send an idle frame before the first data frame.

50.5.7 USART receiver

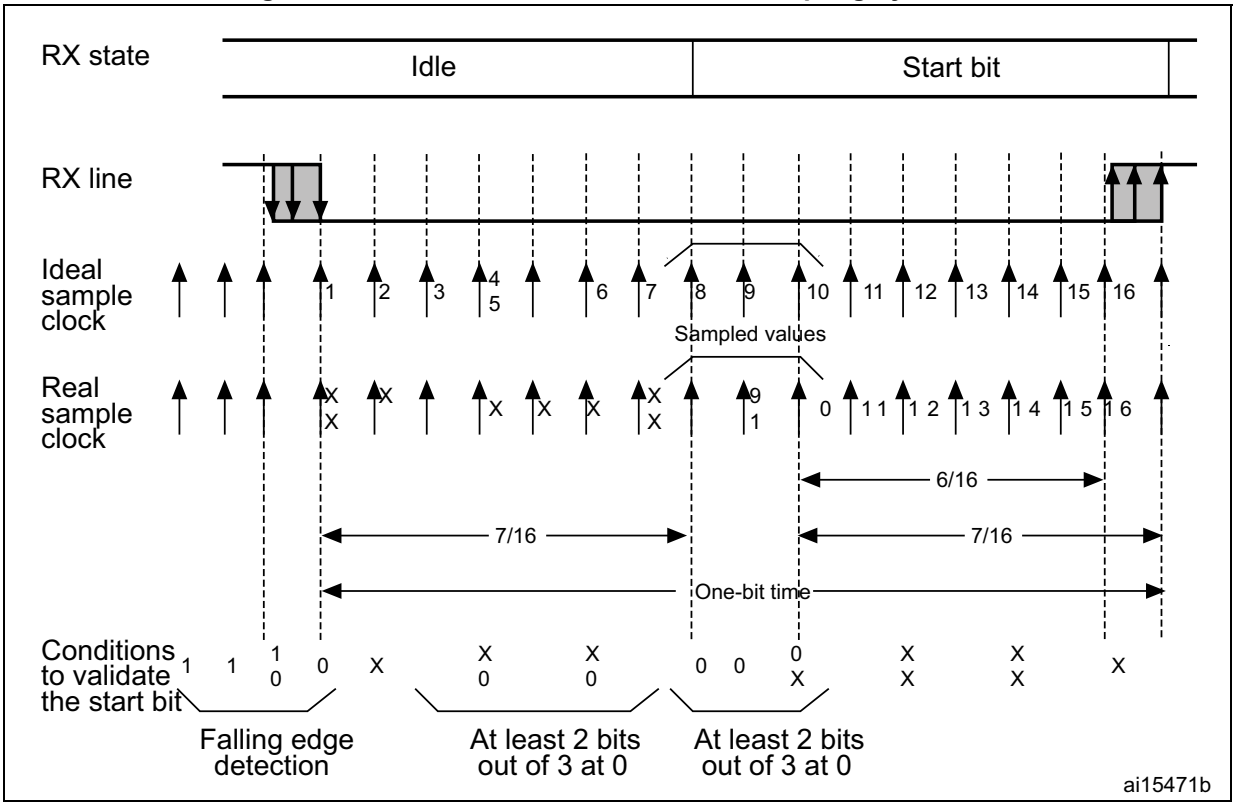
The USART can receive data words of either 7 or 8 or 9 bits depending on the M bits in the USART_CR1 register.

Start bit detection

The start bit detection sequence is the same when oversampling by 16 or by 8.

In the USART, the start bit is detected when a specific sequence of samples is recognized. This sequence is: 1 1 1 0 X 0 X 0X 0X 0 X 0X 0.

Figure 678. Start bit detection when oversampling by 16 or 8



Note: If the sequence is not complete, the start bit detection aborts and the receiver returns to the idle state (no flag is set), where it waits for a falling edge.

The start bit is confirmed (RXNE flag set and interrupt generated if RXNEIE=1, or RXFNE flag set and interrupt generated if RXFNEIE=1 if FIFO mode enabled) if the 3 sampled bits are at 0 (first sampling on the 3rd, 5th and 7th bits finds the 3 bits at 0 and second sampling on the 8th, 9th and 10th bits also finds the 3 bits at 0).

The start bit is validated but the NE noise flag is set if,

a) for both samplings, 2 out of the 3 sampled bits are at 0 (sampling on the 3rd, 5th and 7th bits and sampling on the 8th, 9th and 10th bits)

or

b) for one of the samplings (sampling on the 3rd, 5th and 7th bits or sampling on the 8th, 9th and 10th bits), 2 out of the 3 bits are found at 0.

If neither of the above conditions are met, the start detection aborts and the receiver returns to the idle state (no flag is set).

Character reception

During an USART reception, data are shifted out least significant bit first (default configuration) through the RX pin.

Character reception procedure

To receive a character, follow the sequence below:

1. Program the M bits in USART_CR1 to define the word length.
2. Select the desired baud rate using the baud rate register USART_BRR
3. Program the number of stop bits in USART_CR2.
4. Enable the USART by writing the UE bit in USART_CR1 register to 1.
5. Select DMA enable (DMAR) in USART_CR3 if multibuffer communication is to take place. Configure the DMA register as explained in *Section 50.5.20: Continuous communication using USART and DMA*.
6. Set the RE bit USART_CR1. This enables the receiver which begins searching for a start bit.

When a character is received:

- When FIFO mode is disabled, the RXNE bit is set to indicate that the content of the shift register is transferred to the RDR. In other words, data have been received and can be read (as well as their associated error flags).
- When FIFO mode is enabled, the RXFNE bit is set to indicate that the RXFIFO is not empty. Reading the USART_RDR returns the oldest data entered in the RXFIFO. When a data is received, it is stored in the RXFIFO together with the corresponding error bits.
- An interrupt is generated if the RXNEIE (RXFNEIE when FIFO mode is enabled) bit is set.
- The error flags can be set if a frame error, noise, parity or an overrun error was detected during reception.
- In Multibuffer communication mode:
  - When FIFO mode is disabled, the RXNE flag is set after every byte reception. It is cleared when the DMA reads the Receive data Register.
  - When FIFO mode is enabled, the RXFNE flag is set when the RXFIFO is not empty. After every DMA request, a data is retrieved from the RXFIFO. A DMA request is triggered when the RXFIFO is not empty i.e. when there are data to be read from the RXFIFO.
- In Single-buffer mode:
  - When FIFO mode is disabled, clearing the RXNE flag is done by performing a software read from the USART_RDR register. The RXNE flag can also be cleared by programming RXFRQ bit to 1 in the USART_RQR register. The RXNE flag must be cleared before the end of the reception of the next character to avoid an overrun error.
  - When FIFO mode is enabled, the RXFNE is set when the RXFIFO is not empty. After every read operation from USART_RDR, a data is retrieved from the RXFIFO. When the RXFIFO is empty, the RXFNE flag is cleared. The RXFNE flag can also be cleared by programming RXFRQ bit to 1 in USART_RQR. When the RXFIFO is full, the first entry in the RXFIFO must be read before the end of the reception of the next character, to avoid an overrun error. The RXFNE flag generates an interrupt if the RXFNEIE bit is set. Alternatively, interrupts can be

generated and data can be read from RXFIFO when the RXFIFO threshold is reached. In this case, the CPU can read a block of data defined by the programmed threshold.

Break character

When a break character is received, the USART handles it as a framing error.

Idle character

When an idle frame is detected, it is handled in the same way as a data character reception except that an interrupt is generated if the IDLEIE bit is set.

Overrun error

- FIFO mode disabled

  An overrun error occurs if a character is received and RXNE has not been reset.

  Data can not be transferred from the shift register to the RDR register until the RXNE bit is cleared. The RXN E flag is set after every byte reception.

  An overrun error occurs if RXNE flag is set when the next data is received or the previous DMA request has not been serviced. When an overrun error occurs:

  – the ORE bit is set;
  – the RDR content is not lost. The previous data is available by reading the USART_RDR register.
  – the shift register is overwritten. After that, any data received during overrun is lost.
  – an interrupt is generated if either the RXNEIE or the EIE bit is set.

- FIFO mode enabled

  An overrun error occurs when the shift register is ready to be transferred and the receive FIFO is full.

  Data can not be transferred from the shift register to the USART_RDR register until there is one free location in the RXFIFO. The RXFNE flag is set when the RXFIFO is not empty.

  An overrun error occurs if the RXFIFO is full and the shift register is ready to be transferred. When an overrun error occurs:

  – The ORE bit is set.
  – The first entry in the RXFIFO is not lost. It is available by reading the USART_RDR register.
  – The shift register is overwritten. After that point, any data received during overrun is lost.
  – An interrupt is generated if either the RXFNEIE or EIE bit is set.

The ORE bit is reset by setting the ORECF bit in the USART_ICR register.

Note: The ORE bit, when set, indicates that at least 1 data has been lost.

When the FIFO mode is disabled, there are two possibilities

- *if RXNE=1, then the last valid data is stored in the receive register (RDR) and can be read,*
- *if RXNE=0, the last valid data has already been read and there is nothing left to be read in the RDR register. This case can occur when the last valid data is read in the RDR register at the same time as the new (and lost) data is received.*

Selecting the clock source and the appropriate oversampling method

The choice of the clock source is done through the Clock Control system (see *Section : Reset and Clock Control (RCC)*). The clock source must be selected through the UE bit before enabling the USART.

The clock source must be selected according to two criteria:

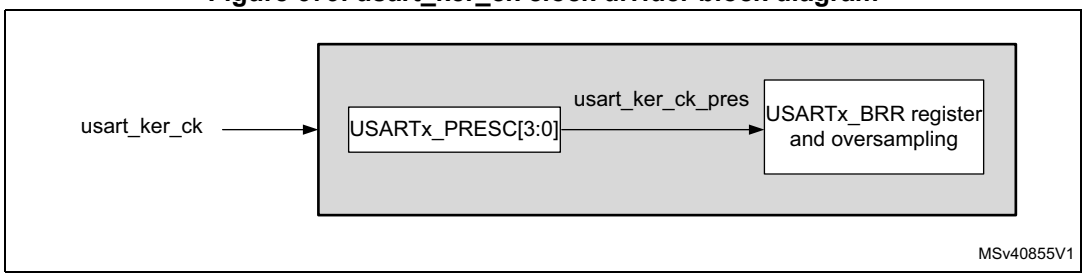
- Possible use of the USART in low-power mode
- Communication speed.

The clock source frequency is usart_ker_ck.

When the dual clock domain and the wake-up from low-power mode features are supported, the usart_ker_ck clock source can be configurable in the RCC (see *Section : Reset and Clock Control (RCC)*). Otherwise the usart_ker_ck clock is the same as usart_pclk.

The usart_ker_ck clock can be divided by a programmable factor, defined in the USART_PRESC register.

Figure 679. usart_ker_ck clock divider block diagram



Some usart_ker_ck sources enable the USART to receive data while the MCU is in low-power mode. Depending on the received data and wake-up mode selected, the USART wakes up the MCU, when needed, in order to transfer the received data, by performing a software read to the USART_RDR register or by DMA.

For the other clock sources, the system must be active to enable USART communications.

The communication speed range (specially the maximum communication speed) is also determined by the clock source.

The receiver implements different user-configurable oversampling techniques (except in Synchronous mode) for data recovery by discriminating between valid incoming data and noise. This enables obtaining the best a trade-off between the maximum communication speed and noise/clock inaccuracy immunity.

The oversampling method can be selected by programming the OVER8 bit in the USART_CR1 register either to 16 or 8 times the baud rate clock (see *Figure 680* and *Figure 681*).

Depending on the application:

- select oversampling by 8 (OVER8=1) to achieve higher speed (up to usart_ker_ck_pres/8). In this case the maximum receiver tolerance to clock deviation is reduced (refer to *Section 50.5.9: Tolerance of the USART receiver to clock deviation on page 2248*)
- select oversampling by 16 (OVER8=0) to increase the tolerance of the receiver to clock deviations. In this case, the maximum speed is limited to maximum

usart_ker_ck_pres/16 (where usart_ker_ck_pres is the USART input clock divided by a prescaler).

Programming the ONEBIT bit in the USART_CR3 register selects the method used to evaluate the logic level. Two options are available:

- The majority vote of the three samples in the center of the received bit. In this case, when the 3 samples used for the majority vote are not equal, the NE bit is set.
- A single sample in the center of the received bit

  Depending on the application:

  – select the three sample majority vote method (ONEBIT=0) when operating in a noisy environment and reject the data when a noise is detected (refer to *Table 534*) because this indicates that a glitch occurred during the sampling.

  – select the single sample method (ONEBIT=1) when the line is noise-free to increase the receiver tolerance to clock deviations (see *Section 50.5.9: Tolerance of the USART receiver to clock deviation on page 2248*). In this case the NE bit is never set.

When noise is detected in a frame:

- The NE bit is set at the rising edge of the RXNE bit (RXFNE in case of FIFO mode enabled).
- The invalid data is transferred from the Shift register to the USART_RDR register.
- No interrupt is generated in case of single byte communication. However this bit rises at the same time as the RXNE bit (RXFNE in case of FIFO mode enabled) which itself generates an interrupt. In case of multibuffer communication an interrupt is issued if the EIE bit is set in the USART_CR3 register.

The NE bit is reset by setting NFCF bit in ICR register.

Note: Noise error is not supported in SPI mode.

Oversampling by 8 is not available in the Smartcard, IrDA and LIN modes. In those modes, the OVER8 bit is forced to 0 by hardware.

Figure 680. Data sampling when oversampling by 16

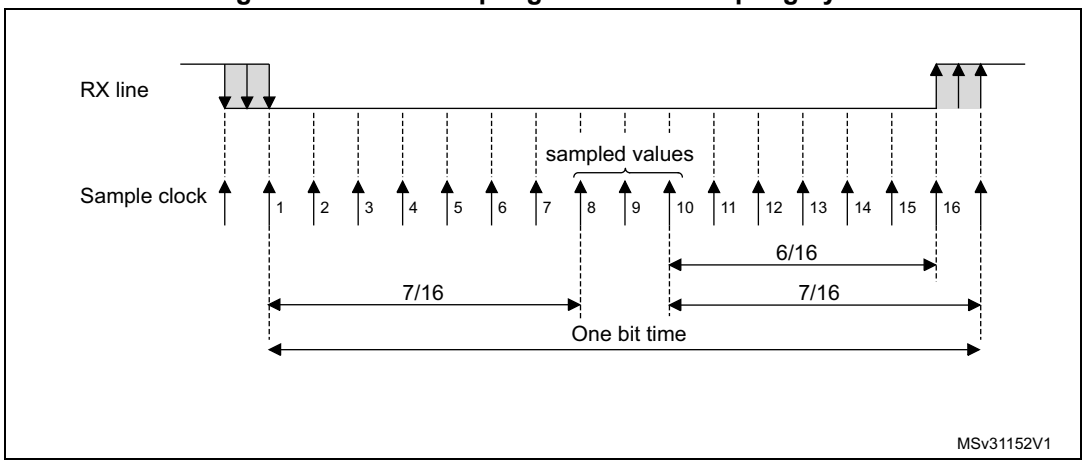


Figure 681. Data sampling when oversampling by 8

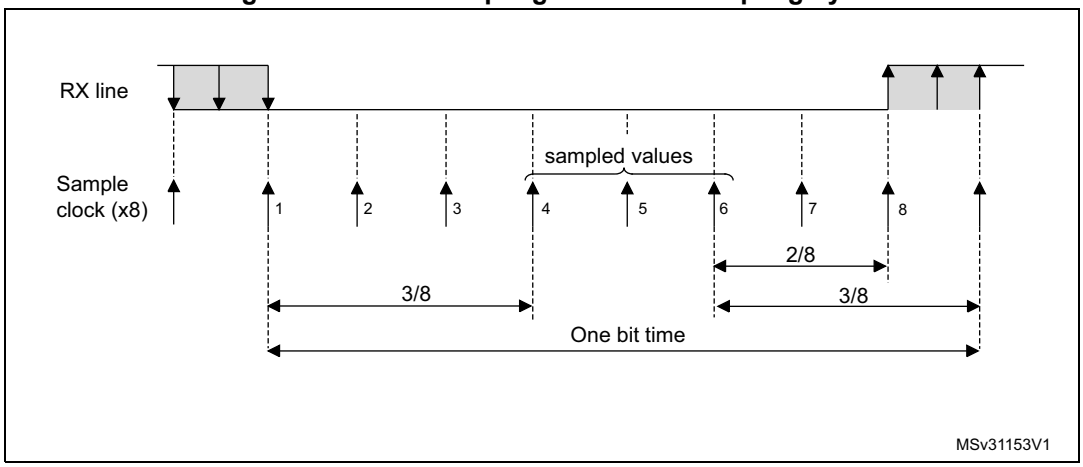

Table 534. Noise detection from sampled data

Sampled value	NE status	Received bit value
000	0	0
001	1	0
010	1	0
011	1	1
100	1	0
101	1	1
110	1	1
111	0	1

Framing error

A framing error is detected when the stop bit is not recognized on reception at the expected time, following either a de-synchronization or excessive noise.

When the framing error is detected:

- the FE bit is set by hardware;
- the invalid data is transferred from the Shift register to the USART_RDR register (RXFIFO in case FIFO mode is enabled).
- no interrupt is generated in case of single byte communication. However this bit rises at the same time as the RXNE bit (RXFNE in case FIFO mode is enabled) which itself generates an interrupt. In case of multibuffer communication an interrupt is issued if the EIE bit is set in the USART_CR3 register.

The FE bit is reset by writing 1 to the FECF in the USART_ICR register.

Note: Framing error is not supported in SPI mode.

Configurable stop bits during reception

The number of stop bits to be received can be configured through the control bits of USART_CR: it can be either 1 or 2 in Normal mode and 0.5 or 1.5 in Smartcard mode.

- **0.5 stop bit (reception in Smartcard mode)**: no sampling is done for 0.5 stop bit. As a consequence, no framing error and no break frame can be detected when 0.5 stop bit is selected.
- **1 stop bit**: sampling for 1 stop bit is done on the 8th, 9th and 10th samples.
- 1.5 stop bits (Smartcard mode)

  When transmitting in Smartcard mode, the device must check that the data are correctly sent. The receiver block must consequently be enabled (RE =1 in USART_CR1) and the stop bit is checked to test if the Smartcard has detected a parity error.

  In the event of a parity error, the Smartcard forces the data signal low during the sampling (NACK signal), which is flagged as a framing error. The FE flag is then set through RXNE flag (RXFNE if the FIFO mode is enabled) at the end of the 1.5 stop bit. Sampling for 1.5 stop bits is done on the 16th, 17th and 18th samples (1 baud clock period after the beginning of the stop bit). The 1.5 stop bit can be broken into 2 parts: one 0.5 baud clock period during which nothing happens, followed by 1 normal stop bit period during which sampling occurs halfway through (refer to *Section 50.5.17: USART receiver timeout on page 2261* for more details).
- 2 stop bits

  Sampling for 2 stop bits is done on the 8th, 9th and 10th samples of the first stop bit.

  The framing error flag is set if a framing error is detected during the first stop bit.

  The second stop bit is not checked for framing error. The RXNE flag (RXFNE if the FIFO mode is enabled) is set at the end of the first stop bit.

50.5.8 USART baud rate generation

The baud rate for the receiver and transmitter (Rx and Tx) are both set to the value programmed in the USART_BRR register.

Equation 1: baud rate for standard USART (SPI mode included) (OVER8 = 0 or 1)

In case of oversampling by 16, the baud rate is given by the following formula:

$$\text{Tx/Rx baud} = \frac{\text{usart\_ker\_ck\_pres}}{\text{USARTDIV}}$$

In case of oversampling by 8, the baud rate is given by the following formula:

$$\text{Tx/Rx baud} = \frac{2 \times \text{usart\_ker\_ck\_pres}}{\text{USARTDIV}}$$

Equation 2: baud rate in Smartcard, LIN and IrDA modes (OVER8 = 0)

The baud rate is given by the following formula:

$$\text{Tx/Rx baud} = \frac{\text{usart\_ker\_ck\_pres}}{\text{USARTDIV}}$$

USARTDIV is an unsigned fixed point number that is coded on the USART_BRR register.

- When OVER8 = 0, BRR = USARTDIV.
- When OVER8 = 1
  - BRR[2:0] = USARTDIV[3:0] shifted 1 bit to the right.
  - BRR[3] must be kept cleared.
  - BRR[15:4] = USARTDIV[15:4]

Note: The baud counters are updated to the new value in the baud registers after a write operation to USART_BRR. Hence the baud rate register value must not be changed during communication.

In case of oversampling by 16 and 8, USARTDIV must be greater than or equal to 16.

How to derive USARTDIV from USART_BRR register values

Example 1

To obtain 9600 bauds with usart_ker_ck_pres= 8 MHz:

- In case of oversampling by 16:
  USARTDIV = 8 000 000/9600
  BRR = USARTDIV = 0d833 = 0x0341
- In case of oversampling by 8:
  USARTDIV = 2 * 8 000 000/9600
  USARTDIV = 1666,66 (0d1667 = 0x683)
  BRR[3:0] = 0x3 >>1 = 0x1
  BRR = 0x681

Example 2

To obtain 921.6 kbauds with usart_ker_ck_pres = 48 MHz:

- In case of oversampling by 16:
  USARTDIV = 48 000 000/921 600
  BRR = USARTDIV = 0x52 = 0x34
- In case of oversampling by 8:
  USARTDIV = 2 * 48 000 000/921 600
  USARTDIV = 104 (0d104 = 0x68)
  BRR[3:0] = USARTDIV[3:0] >> 1 = 0x8 >> 1 = 0x4
  BRR = 0x64

50.5.9 Tolerance of the USART receiver to clock deviation

The USART asynchronous receiver operates correctly only if the total clock system deviation is less than the tolerance of the USART receiver.

The causes which contribute to the total deviation are:

- DTRA: deviation due to the transmitter error (which also includes the deviation of the transmitter's local oscillator)
- DQUANT: error due to the baud rate quantization of the receiver
- DREC: deviation of the receiver local oscillator
- DTCL: deviation due to the transmission line (generally due to the transceivers which can introduce an asymmetry between the low-to-high transition timing and the high-to-low transition timing)

$$DTRA + DQUANT + DREC + DTCL + DWU < USART\ receiver\ tolerance$$

where

DWU is the error due to sampling point deviation when the wake-up from low-power mode is used.

when M[1:0] = 01:

$$DWU = \frac{t_{WUUSART}}{11 \times Tbit}$$

when M[1:0] = 00:

$$DWU = \frac{t_{WUUSART}}{10 \times Tbit}$$

when M[1:0] = 10:

$$DWU = \frac{t_{WUUSART}}{9 \times Tbit}$$

$t_{WUUSART}$ is the time between the detection of the start bit falling edge and the instant when the clock (requested by the peripheral) is ready and reaching the peripheral, and the regulator is ready.

The USART receiver can receive data correctly at up to the maximum tolerated deviation specified in *Table 535*, *Table 536*, depending on the following settings:

- 9-, 10- or 11-bit character length defined by the M bits in the USART_CR1 register
- Oversampling by 8 or 16 defined by the OVER8 bit in the USART_CR1 register
- Bits BRR[3:0] of USART_BRR register are equal to or different from 0000.
- Use of 1 bit or 3 bits to sample the data, depending on the value of the ONEBIT bit in the USART_CR3 register.

Table 535. Tolerance of the USART receiver when BRR [3:0] = 0000

M bits	OVER8 bit = 0		OVER8 bit = 1	
	ONEBIT=0	ONEBIT=1	ONEBIT=0	ONEBIT=1
00	3.75%	4.375%	2.50%	3.75%
01	3.41%	3.97%	2.27%	3.41%
10	4.16%	4.86%	2.77%	4.16%

Table 536. Tolerance of the USART receiver when BRR[3:0] is different from 0000

M bits	OVER8 bit = 0		OVER8 bit = 1	
	ONEBIT=0	ONEBIT=1	ONEBIT=0	ONEBIT=1
00	3.33%	3.88%	2%	3%
01	3.03%	3.53%	1.82%	2.73%
10	3.7%	4.31%	2.22%	3.33%

Note: The data specified in Table 535 and Table 536 may slightly differ in the special case when the received frames contain some Idle frames of exactly 10-bit times when M bits = 00 (11-bit times when M= 01 or 9- bit times when M = 10).

50.5.10 USART auto baud rate detection

The USART can detect and automatically set the USART_BRR register value based on the reception of one character. Automatic baud rate detection is useful under two circumstances:

- The communication speed of the system is not known in advance.
- The system is using a relatively low accuracy clock source and this mechanism enables the correct baud rate to be obtained without measuring the clock deviation.

The clock source frequency must be compatible with the expected communication speed.

- When oversampling by 16, the baud rate ranges from usart_ker_ck_pres/65535 and usart_ker_ck_pres/16.
- When oversampling by 8, the baud rate ranges from usart_ker_ck_pres/65535 and usart_ker_ck_pres/8.

Before activating the auto baud rate detection, the auto baud rate detection mode must be selected through the ABRMOD[1:0] field in the USART_CR2 register. There are four modes based on different character patterns. In these auto baud rate modes, the baud rate is measured several times during the synchronization data reception and each measurement is compared to the previous one.

These modes are the following:

- **Mode 0**: Any character starting with a bit at 1.

  In this case the USART measures the duration of the start bit (falling edge to rising edge).
- **Mode 1:** Any character starting with a 10xx bit pattern.

  In this case, the USART measures the duration of the Start and of the 1st data bit. The measurement is done falling edge to falling edge, to ensure a better accuracy in the case of slow signal slopes.
- **Mode 2**: A 0x7F character frame (it may be a 0x7F character in LSB first mode or a 0xFE in MSB first mode).

  In this case, the baud rate is updated first at the end of the start bit (BRs), then at the end of bit 6 (based on the measurement done from falling edge to falling edge: BR6). Bit0 to bit6 are sampled at BRs while further bits of the character are sampled at BR6.
- **Mode 3**: A 0x55 character frame.

  In this case, the baud rate is updated first at the end of the start bit (BRs), then at the end of bit0 (based on the measurement done from falling edge to falling edge: BR0), and finally at the end of bit6 (BR6). Bit 0 is sampled at BRs, bit 1 to bit 6 are sampled at BR0, and further bits of the character are sampled at BR6. In parallel, another check is performed for each intermediate RX line transition. An error is generated if the transitions on RX are not sufficiently synchronized with the receiver (the receiver being based on the baud rate calculated on bit 0).

Prior to activating the auto baud rate detection, the USART_BRR register must be initialized by writing a non-zero baud rate value.

The automatic baud rate detection is activated by setting the ABREN bit in the USART_CR2 register. The USART then waits for the first character on the RX line. The auto baud rate operation completion is indicated by the setting of the ABRF flag in the USART_ISR register. If the line is noisy, the correct baud rate detection cannot be guaranteed. In this case the BRR value may be corrupted and the ABRE error flag is set. This also happens if the communication speed is not compatible with the automatic baud rate detection range (bit duration not between 16 and 65536 clock periods (oversampling by 16) and not between 8 and 65536 clock periods (oversampling by 8)).

The auto baud rate detection can be re-launched later by resetting the ABRF flag (by writing a 0).

When FIFO management is disabled and an auto baud rate error occurs, the ABRE flag is set through RXNE and FE bits.

When FIFO management is enabled and an auto baud rate error occurs, the ABRE flag is set through RXFNE and FE bits.

If the FIFO mode is enabled, the auto baud rate detection must be made using the data on the first RXFIFO location. So, prior to launching the auto baud rate detection, make sure that the RXFIFO is empty by checking the RXFNE flag in USART_ISR register.

Note: The BRR value might be corrupted if the USART is disabled (UE=0) during an auto baud rate operation.

50.5.11 USART multiprocessor communication

It is possible to perform USART multiprocessor communications (with several USARTs connected in a network). For instance one of the USARTs can be the master with its TX output connected to the RX inputs of the other USARTs, while the others are slaves with their respective TX outputs logically ANDed together and connected to the RX input of the master.

In multiprocessor configurations, it is often desirable that only the intended message recipient actively receives the full message contents, thus reducing redundant USART service overhead for all non addressed receivers.

The non-addressed devices can be placed in Mute mode by means of the muting function. To use the Mute mode feature, the MME bit must be set in the USART_CR1 register.

Note: When FIFO management is enabled and MME is already set, MME bit must not be cleared and then set again quickly (within two usart_ker_ck cycles), otherwise Mute mode might remain active.

When the Mute mode is enabled:

- none of the reception status bits can be set;
- all the receive interrupts are inhibited;
- the RWU bit in USART_ISR register is set to 1. RWU can be controlled automatically by hardware or by software, through the MMRQ bit in the USART_RQR register, under certain conditions.

The USART can enter or exit from Mute mode using one of two methods, depending on the WAKE bit in the USART_CR1 register:

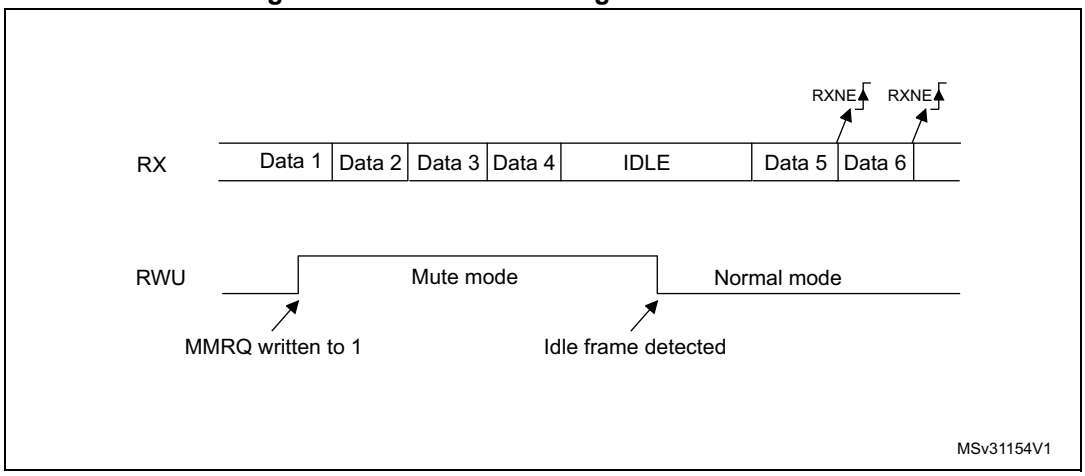
- Idle Line detection if the WAKE bit is reset,
- Address Mark detection if the WAKE bit is set.

Idle line detection (WAKE=0)

The USART enters Mute mode when the MMRQ bit is written to 1 and the RWU is automatically set.

The USART wakes up when an Idle frame is detected. The RWU bit is then cleared by hardware but the IDLE bit is not set in the USART_ISR register. An example of Mute mode behavior using Idle line detection is given in *Figure 682*.

Figure 682. Mute mode using Idle line detection



Note: If the MMRQ is set while the IDLE character has already elapsed, Mute mode is not entered (RWU is not set).

If the USART is activated while the line is IDLE, the idle state is detected after the duration of one IDLE frame (not only after the reception of one character frame).

4-bit/7-bit address mark detection (WAKE=1)

In this mode, bytes are recognized as addresses if their MSB is a 1, otherwise they are considered as data. In an address byte, the address of the targeted receiver is put in the 4 or 7 LSBs. The choice of 7 or 4 bit address detection is done using the ADDM7 bit. This 4-bit/7-bit word is compared by the receiver with its own address which is programmed in the ADD bits in the USART_CR2 register.

Note: In 7-bit and 9-bit data modes, address detection is done on 6-bit and 8-bit addresses (ADD[5:0] and ADD[7:0]) respectively.

The USART enters Mute mode when an address character is received which does not match its programmed address. In this case, the RWU bit is set by hardware. The RXNE flag is not set for this address byte and no interrupt or DMA request is issued when the USART enters Mute mode. When FIFO management is enabled, the software must ensure that there is at least one empty location in the RXFIFO before entering Mute mode.

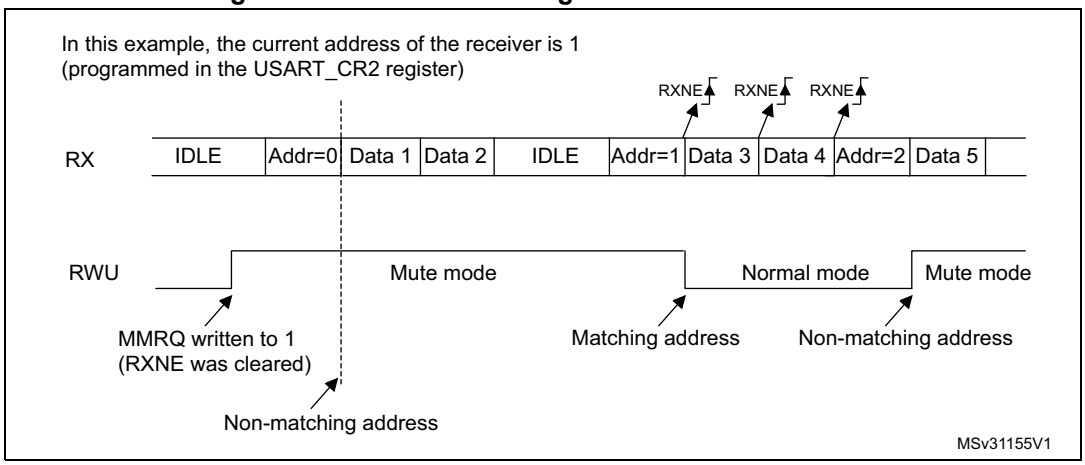
The USART also enters Mute mode when the MMRQ bit is written to 1. The RWU bit is also automatically set in this case.

The USART exits from Mute mode when an address character is received which matches the programmed address. Then the RWU bit is cleared and subsequent bytes are received normally. The RXNE/RXFNE bit is set for the address character since the RWU bit has been cleared.

Note: When FIFO management is enabled, when MMRQ is set while the receiver is sampling last bit of a data, this data may be received before effectively entering in Mute mode

An example of Mute mode behavior using address mark detection is given in *Figure 683*.

Figure 683. Mute mode using address mark detection



50.5.12 USART Modbus communication

The USART offers basic support for the implementation of Modbus/RTU and Modbus/ASCII protocols. Modbus/RTU is a Half-duplex, block-transfer protocol. The control part of the protocol (address recognition, block integrity control and command interpretation) must be implemented in software.

The USART offers basic support for the end of the block detection, without software overhead or other resources.

Modbus/RTU

In this mode, the end of one block is recognized by a “silence” (idle line) for more than 2 character times. This function is implemented through the programmable timeout function.

The timeout function and interrupt must be activated, through the RTOEN bit in the USART_CR2 register and the RTOIE in the USART_CR1 register. The value corresponding to a timeout of 2 character times (for example 22 x bit time) must be programmed in the RTO register. When the receive line is idle for this duration, after the last stop bit is received, an interrupt is generated, informing the software that the current block reception is completed.

Modbus/ASCII

In this mode, the end of a block is recognized by a specific (CR/LF) character sequence. The USART manages this mechanism using the character match function.

By programming the LF ASCII code in the ADD[7:0] field and by activating the character match interrupt (CMIE = 1), the software is informed when a LF has been received and can check the CR/LF in the DMA buffer.

50.5.13 USART parity control

Parity control (generation of parity bit in transmission and parity checking in reception) can be enabled by setting the PCE bit in the USART_CR1 register. Depending on the frame length defined by the M bits, the possible USART frame formats are as listed in *Table 537*.

Table 537. USART frame formats

M bits	PCE bit	USART frame(1)
00	0	| SB | 8 bit data | STB |
00	1	| SB | 7-bit data | PB | STB |
01	0	| SB | 9-bit data | STB |
01	1	| SB | 8-bit data PB | STB |
10	0	| SB | 7bit data | STB |
10	1	| SB | 6-bit data | PB | STB |

1. Legends: SB: start bit, STB: stop bit, PB: parity bit. In the data register, the PB is always taking the MSB position (8th or 7th, depending on the M bit value).

Even parity

The parity bit is calculated to obtain an even number of “1s” inside the frame of the 6, 7 or 8 LSB bits (depending on M bit values) and the parity bit.

As an example, if data=00110101, and 4 bits are set, then the parity bit is equal to 0 if even parity is selected (PS bit in USART_CR1 = 0).

Odd parity

The parity bit is calculated to obtain an odd number of “1s” inside the frame made of the 6, 7 or 8 LSB bits (depending on M bit values) and the parity bit.

As an example, if data=00110101 and 4 bits set, then the parity bit is equal to 1 if odd parity is selected (PS bit in USART_CR1 = 1).

Parity checking in reception

If the parity check fails, the PE flag is set in the USART_ISR register and an interrupt is generated if PEIE is set in the USART_CR1 register. The PE flag is cleared by software writing 1 to the PECF in the USART_ICR register.

Parity generation in transmission

If the PCE bit is set in USART_CR1, then the MSB bit of the data written in the data register is transmitted but is changed by the parity bit (even number of “1s” if even parity is selected (PS=0) or an odd number of “1s” if odd parity is selected (PS=1)).

50.5.14 USART LIN (local interconnection network) mode

This section is relevant only when LIN mode is supported. Refer to *Section 50.4: USART implementation on page 2229*.

The LIN mode is selected by setting the LINEN bit in the USART_CR2 register. In LIN mode, the following bits must be kept cleared:

- CLKEN in the USART_CR2 register,
- STOP[1:0], SCEN, HDSEL and IREN in the USART_CR3 register.

LIN transmission

The procedure described in *Section 50.5.5* has to be applied for LIN Master transmission. It must be the same as for normal USART transmission with the following differences:

- Clear the M bit to configure 8-bit word length.
- Set the LINEN bit to enter LIN mode. In this case, setting the SBKRQ bit sends 13 zero bits as a break character. Then 2 bits of value ‘1 are sent to enable the next start detection.

LIN reception

When LIN mode is enabled, the break detection circuit is activated. The detection is totally independent from the normal USART receiver. A break can be detected whenever it occurs, during Idle state or during a frame.

When the receiver is enabled (RE=1 in USART_CR1), the circuit looks at the RX input for a start signal. The method for detecting start bits is the same when searching break characters or data. After a start bit has been detected, the circuit samples the next bits exactly like for the data (on the 8th, 9th and 10th samples). If 10 (when the LBDL = 0 in USART_CR2) or 11 (when LBDL=1 in USART_CR2) consecutive bits are detected as 0, and are followed by a delimiter character, the LBDF flag is set in USART_ISR. If the LBDIE bit=1, an interrupt is generated. Before validating the break, the delimiter is checked for as it signifies that the RX line has returned to a high level.

If a ‘1 is sampled before the 10 or 11 have occurred, the break detection circuit cancels the current detection and searches for a start bit again.

If the LIN mode is disabled (LINEN=0), the receiver continues working as normal USART, without taking into account the break detection.

If the LIN mode is enabled (LINEN=1), as soon as a framing error occurs (i.e. stop bit detected at 0, which is the case for any break frame), the receiver stops until the break detection circuit receives either a ‘1, if the break word was not complete, or a delimiter character if a break has been detected.

The behavior of the break detector state machine and the break flag is shown on the *Figure 684: Break detection in LIN mode (11-bit break length - LBDL bit is set) on page 2256*.

Examples of break frames are given on *Figure 685: Break detection in LIN mode vs. Framing error detection on page 2257*.

Figure 684. Break detection in LIN mode (11-bit break length - LBDL bit is set)

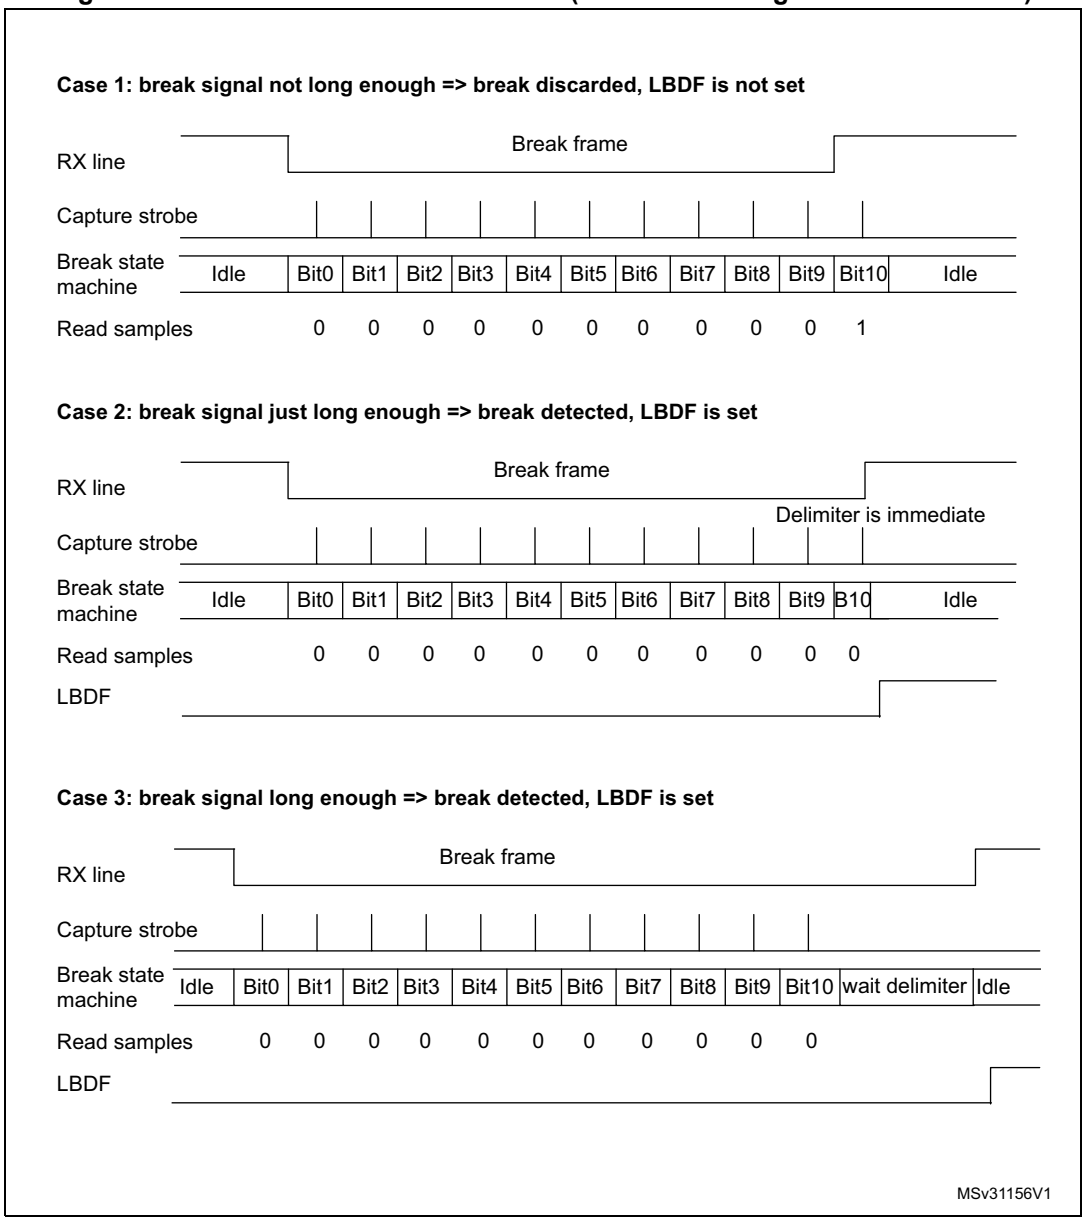


Figure 685. Break detection in LIN mode vs. Framing error detection

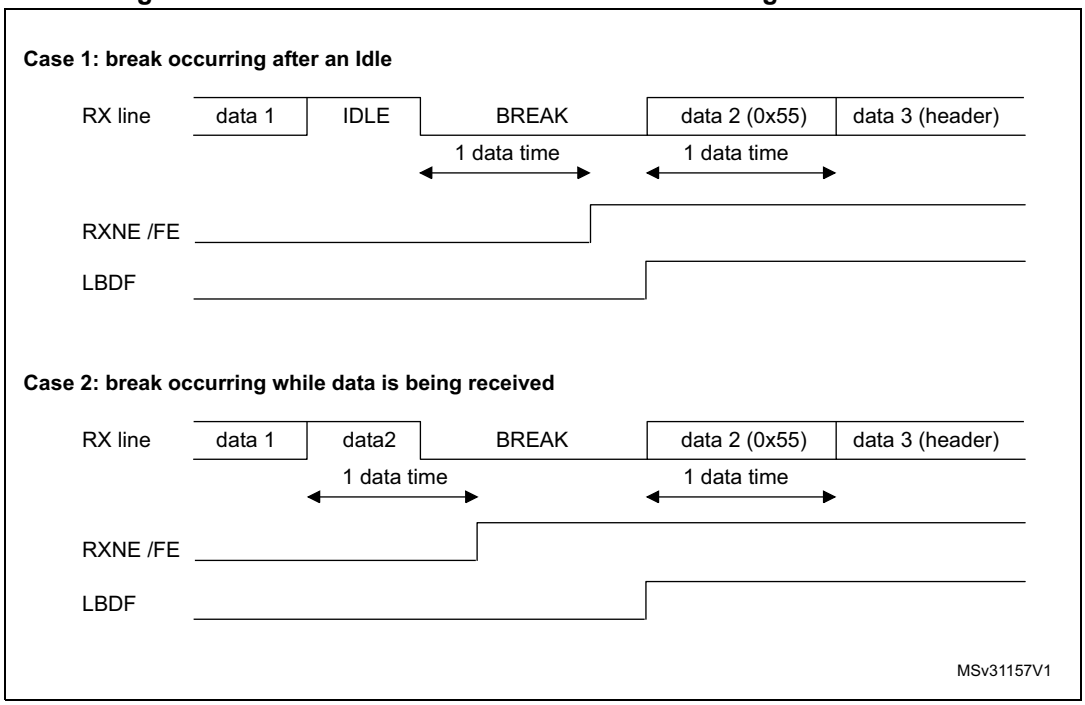

50.5.15 USART synchronous mode

Master mode

The Synchronous master mode is selected by programming the CLKEN bit in the USART_CR2 register to 1. In Synchronous mode, the following bits must be kept cleared:

- LINEN bit in the USART_CR2 register,
- SCEN, HDSEL and IREN bits in the USART_CR3 register.

In this mode, the USART can be used to control bidirectional synchronous serial communications in Master mode. The CK pin is the output of the USART transmitter clock. No clock pulses are sent to the CK pin during start bit and stop bit. Depending on the state of the LBCL bit in the USART_CR2 register, clock pulses are, or are not, generated during the last valid data bit (address mark). The CPOL bit in the USART_CR2 register is used to select the clock polarity, and the CPHA bit in the USART_CR2 register is used to select the phase of the external clock (see *Figure 686*, *Figure 687* and *Figure 688*).

During the Idle state, preamble and send break, the external CK clock is not activated.

In Synchronous master mode, the USART transmitter operates exactly like in Asynchronous mode. However, since CK is synchronized with TX (according to CPOL and CPHA), the data on TX is synchronous.

In Synchronous master mode, the USART receiver operates in a different way compared to Asynchronous mode. If RE is set to 1, the data are sampled on CK (rising or falling edge, depending on CPOL and CPHA), without any oversampling. A given setup and a hold time must be respected (which depends on the baud rate: 1/16 bit time).

Note: In Master mode, the CK pin operates in conjunction with the TX pin. Thus, the clock is provided only if the transmitter is enabled (TE=1) and data are being transmitted (USART_TDR data register written). This means that it is not possible to receive synchronous data without transmitting data.

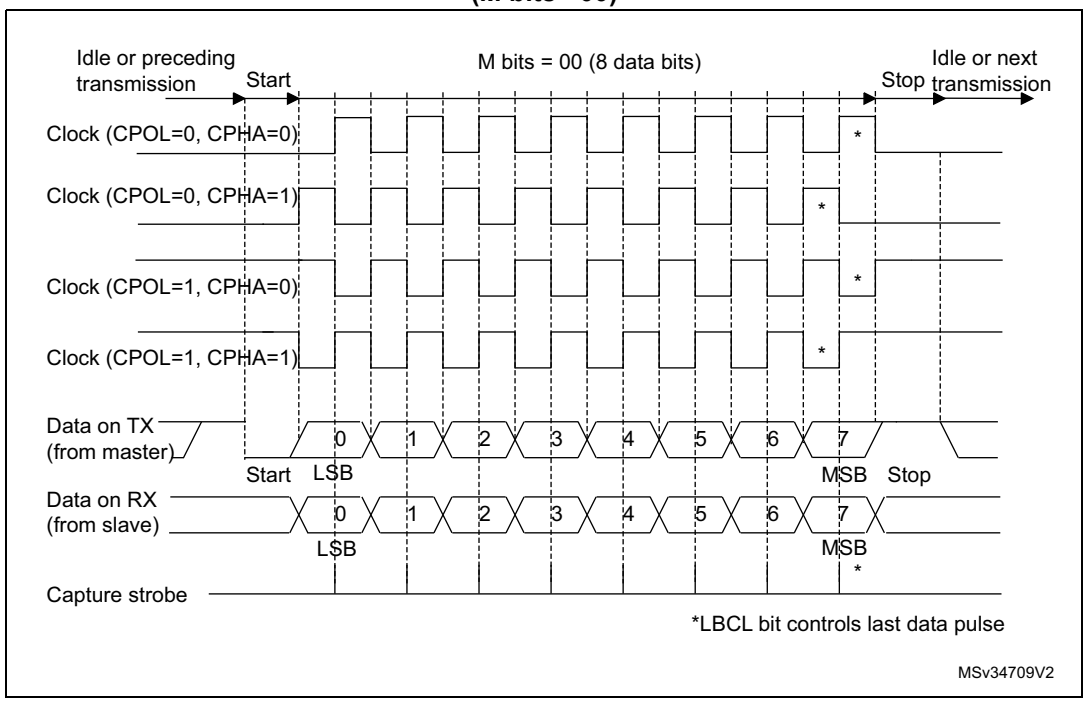

Figure 688. USART data clock timing diagram in Synchronous master mode (M bits = 01)

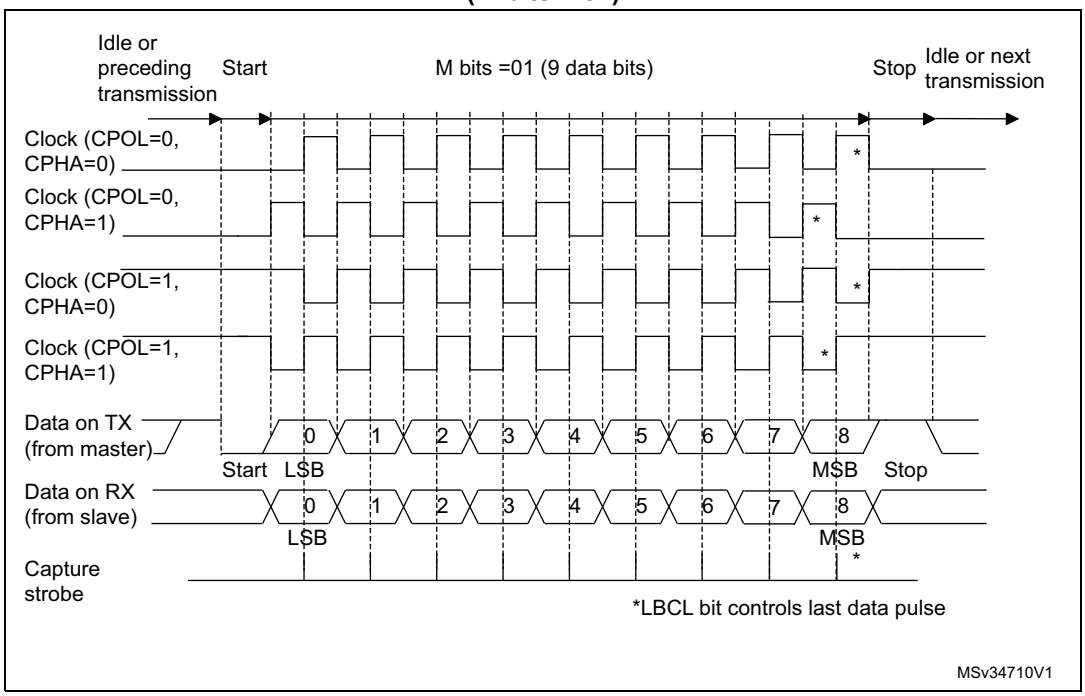


Slave mode

The Synchronous slave mode is selected by programming the SLVEN bit in the USART_CR2 register to 1. In Synchronous slave mode, the following bits must be kept cleared:

- LINEN and CLKEN bits in the USART_CR2 register,
- SCEN, HDSEL and IREN bits in the USART_CR3 register.

In this mode, the USART can be used to control bidirectional synchronous serial communications in Slave mode. The CK pin is the input of the USART in Slave mode.

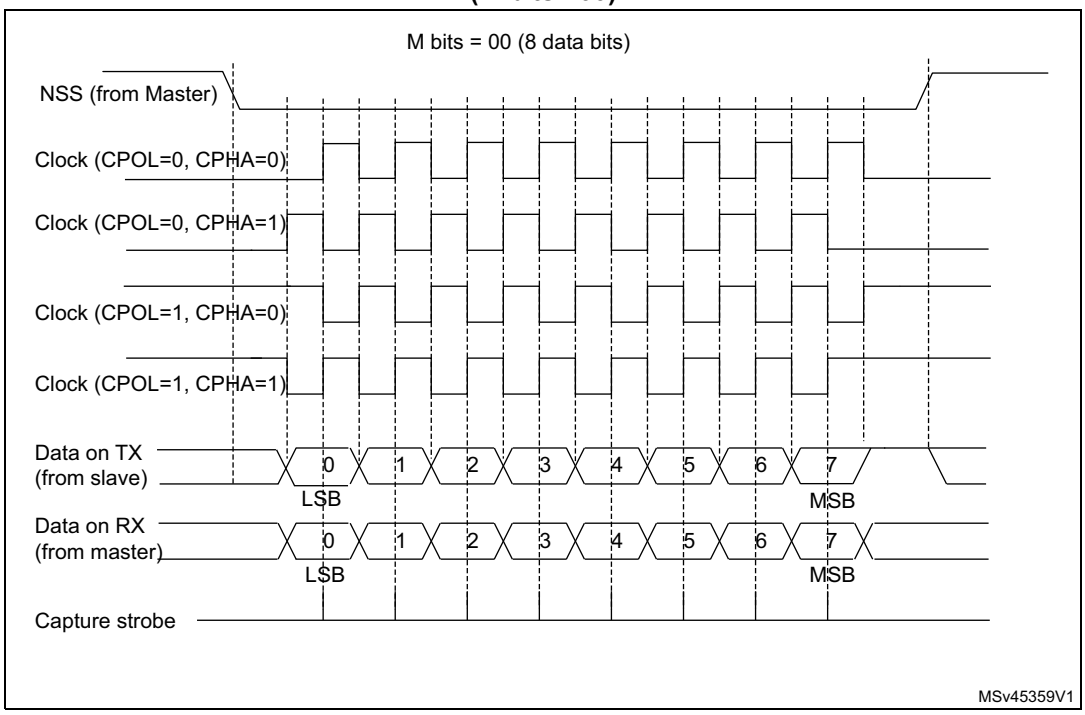
*Note: When the peripheral is used in SPI slave mode, the frequency of peripheral clock source (*usart_ker_ck_pres*) must be greater than 3 times the CK input frequency.*

The CPOL bit and the CPHA bit in the USART_CR2 register are used to select the clock polarity and the phase of the external clock, respectively (see *Figure 689*).

An underrun error flag is available in Slave transmission mode. This flag is set when the first clock pulse for data transmission appears while the software has not yet loaded any value to USART_TDR.

The slave supports the hardware and software NSS management.

Figure 689. USART data clock timing diagram in Synchronous slave mode (M bits =00)



Slave Select (NSS) pin management

The hardware or software slave select management can be set through the DIS_NSS bit in the USART_CR2 register:

- Software NSS management (DIS_NSS = 1)

  SPI slave is always selected and NSS input pin is ignored.

  The external NSS pin remains free for other application uses.
- Hardware NSS management (DIS_NSS = 0)

  The SPI slave selection depends on NSS input pin. The slave is selected when NSS is low and deselected when NSS is high.

Note: The LBCL (used only on SPI master mode), CPOL and CPHA bits have to be selected when the USART is disabled (UE=0) to ensure that the clock pulses function correctly.

In SPI slave mode, the USART must be enabled before starting the master communications (or between frames while the clock is stable). Otherwise, if the USART slave is enabled while the master is in the middle of a frame, it becomes desynchronized with the master. The data register of the slave needs to be ready before the first edge of the communication clock or before the end of the ongoing communication, otherwise the SPI slave transmits zeros.

SPI Slave underrun error

When an underrun error occurs, the UDR flag is set in the USART_ISR register, and the SPI slave goes on sending the last data until the underrrun error flag is cleared by software.

The underrun flag is set at the beginning of the frame. An underrun error interrupt is triggered if EIE bit is set in the USART_CR3 register.

The underrun error flag is cleared by setting bit UDRCF in the USART_ICR register.

In case of underrun error, it is still possible to write to the TDR register. Clearing the underrun error enables sending new data.

If an underrun error occurred and there is no new data written in TDR, then the TC flag is set at the end of the frame.

Note: An underrun error may occur if the moment the data is written to the USART_TDR is too close to the first CK transmission edge. To avoid this underrun error, the USART_TDR must be written 3 usart_ker_ck *cycles before the first CK edge.*

50.5.16 USART single-wire Half-duplex communication

Single-wire Half-duplex mode is selected by setting the HDSEL bit in the USART_CR3 register. In this mode, the following bits must be kept cleared:

- LINEN and CLKEN bits in the USART_CR2 register,
- SCEN and IREN bits in the USART_CR3 register.

The USART can be configured to follow a Single-wire Half-duplex protocol where the TX and RX lines are internally connected. The selection between half- and Full-duplex communication is made with a control bit HDSEL in USART_CR3.

As soon as HDSEL is written to 1:

- The TX and RX lines are internally connected.
- The RX pin is no longer used.
- The TX pin is always released when no data is transmitted. Thus, it acts as a standard I/O in idle or in reception. It means that the I/O must be configured so that TX is configured as alternate function open-drain with an external pull-up.

Apart from this, the communication protocol is similar to normal USART mode. Any conflict on the line must be managed by software (for instance by using a centralized arbiter). In particular, the transmission is never blocked by hardware and continues as soon as data are written in the data register while the TE bit is set.

50.5.17 USART receiver timeout

The receiver timeout feature is enabled by setting the RTOEN bit in the USART_CR2 control register.

The timeout duration is programmed using the RTO bitfields in the USART_RTOR register.

The receiver timeout counter starts counting:

- from the end of the stop bit if STOP = 00 or STOP = 11
- from the end of the second stop bit if STOP = 10.
- from the beginning of the stop bit if STOP = 01.

When the timeout duration has elapsed, the RTOF flag in the USART_ISR register is set. A timeout is generated if RTOIE bit in USART_CR1 register is set.

50.5.18 USART Smartcard mode

This section is relevant only when Smartcard mode is supported. Refer to *Section 50.4: USART implementation on page 2229*.

Smartcard mode is selected by setting the SCEN bit in the USART_CR3 register. In Smartcard mode, the following bits must be kept cleared:

- LINEN bit in the USART_CR2 register,
- HDSEL and IREN bits in the USART_CR3 register.

The CLKEN bit can also be set to provide a clock to the Smartcard.

The Smartcard interface is designed to support asynchronous Smartcard protocol as defined in the ISO 7816-3 standard. Both T=0 (character mode) and T=1 (block mode) are supported.

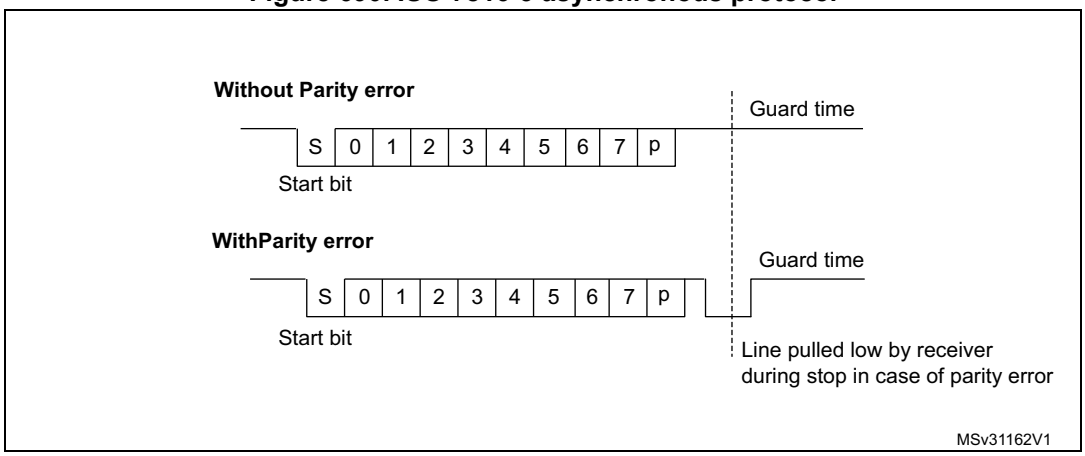
The USART must be configured as:

- 8 bits plus parity: M=1 and PCE=1 in the USART_CR1 register
- 1.5 stop bits when transmitting and receiving data: STOP=11 in the USART_CR2 register. It is also possible to choose 0.5 stop bit for reception.

In T=0 (character) mode, the parity error is indicated at the end of each character during the guard time period.

Figure 690 shows examples of what can be seen on the data line with and without parity error.

Figure 690. ISO 7816-3 asynchronous protocol



When connected to a Smartcard, the TX output of the USART drives a bidirectional line that is also driven by the Smartcard. The TX pin must be configured as open drain.

Smartcard mode implements a single wire half duplex communication protocol.

- Transmission of data from the transmit shift register is guaranteed to be delayed by a minimum of 1/2 baud clock. In normal operation a full transmit shift register starts shifting on the next baud clock edge. In Smartcard mode this transmission is further delayed by a guaranteed 1/2 baud clock.
- In transmission, if the Smartcard detects a parity error, it signals this condition to the USART by driving the line low (NACK). This NACK signal (pulling transmit line low for 1 baud clock) causes a framing error on the transmitter side (configured with 1.5 stop bits). The USART can handle automatic re-sending of data according to the protocol.

The number of retries is programmed in the SCARCNT bitfield. If the USART continues receiving the NACK after the programmed number of retries, it stops transmitting and signals the error as a framing error. The TXE bit (TXFNF bit in case FIFO mode is enabled) may be set using the TXFRQ bit in the USART_RQR register.

- Smartcard auto-retry in transmission: A delay of 2.5 baud periods is inserted between the NACK detection by the USART and the start bit of the repeated character. The TC bit is set immediately at the end of reception of the last repeated character (no guardtime). If the software wants to repeat it again, it must insure the minimum 2 baud periods required by the standard.
