Reference manual

STM32H563/H573 and STM32H562 Arm®-based 32-bit MCUs

Introduction

This document is addressed to application developers. It provides complete information on how to use the STM32H562xx, STM32H563xx, and STM32H573xx microcontrollers memory and peripherals.

For ordering information, mechanical and electrical device characteristics, refer to the corresponding datasheets.

For information on the Arm® Cortex®-M33 core, refer to the corresponding Arm® Technical Reference Manuals available on http://infocenter.arm.com.

1.1 General information

The STM32H563/H573 and STM32H562 devices have an Arm®[a] Cortex-M33 core.

1.2 List of abbreviations for registers

The following abbreviations[b] are used in register descriptions:

read/write (rw)	Software can read and write to this bit.
read-only (r)	Software can only read this bit.
write-only (w)	Software can only write to this bit. Reading this bit returns the reset value.
read/clear write0 (rc_w0)	Software can read as well as clear this bit by writing 0. Writing 1 has no effect on the bit value.
read/clear write1 (rc_w1)	Software can read as well as clear this bit by writing 1. Writing 0 has no effect on the bit value.
read/clear write (rc_w)	Software can read as well as clear this bit by writing to the register. The value written to this bit is not important.
read/clear by read (rc_r)	Software can read this bit. Reading this bit automatically clears it to 0. Writing this bit has no effect on the bit value.
read/set by read (rs_r)	Software can read this bit. Reading this bit automatically sets it to 1. Writing this bit has no effect on the bit value.
read/set (rs)	Software can read as well as set this bit. Writing 0 has no effect on the bit value.
read/write once (rwo)	Software can only write once to this bit and can also read it at any time. Only a reset can return the bit to its reset value.
toggle (t)	The software can toggle this bit by writing 1. Writing 0 has no effect.
read-only write trigger (rt_w1)	Software can read this bit. Writing 1 triggers an event but has no effect on the bit value.
Reserved (Res.)	Reserved bit, must be kept at reset value.

a. Arm is a registered trademark of Arm Limited (or its subsidiaries) in the US and/or elsewhere.

b. This is an exhaustive list of all abbreviations applicable to STMicroelectronics microcontrollers, some of them may not be used in the current document.

1.3 Glossary

This section gives a brief definition of acronyms and abbreviations used in this document:

- **Word**: data of 32-bit length.
- **Half-word**: data of 16-bit length.
- **Byte**: data of 8-bit length.
- **AHB**: advanced high-performance bus.

2 Memory and bus architecture

2.1 System architecture

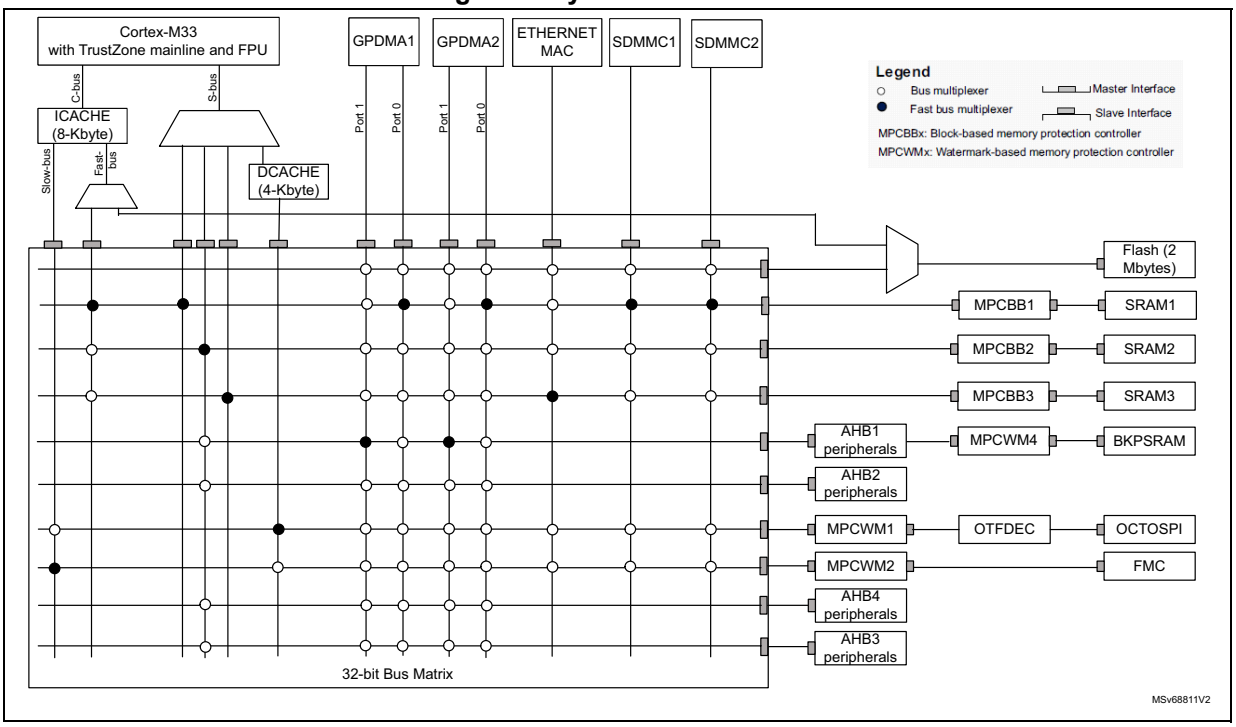
The STM32H563/H573 and STM32H562 architecture relies on a Arm Cortex-M33 core optimized for execution thanks to an instruction cache having a direct access to the embedded Flash memory.

This architecture also features a 32-bit multilayer AHB bus matrix that interconnects:

- up to 13 masters:
  - Fast C-bus, connecting Cortex-M33 with TrustZone® mainline and FPU core C-bus to the internal SRAMs through the instruction cache
  - Slow C-bus, connecting Cortex-M33 with TrustZone mainline and FPU core C-bus to the external memories through the instruction cache
  - Cortex-M33 with TrustZone mainline and FPU core S-bus (three masters connected to three internal SRAMs without latency)
  - Cortex-M33 with TrustZone mainline and FPU core S-bus connected to the external memories through the data cache
  - GPDMA1 (general purpose DMA featuring two master ports)
  - GPDMA2 (general purpose DMA featuring two master ports)
  - SDMMC1
  - SDMMC2
  - Ethernet MAC
- up to 10 slaves:
  - internal Flash memory (2 Mbytes)
  - internal SRAM1 (256 Kbytes)
  - internal SRAM2 (64 Kbytes)
  - internal SRAM3 (320 Kbytes)
  - AHB1 peripherals and backup RAM (4-Kbyte BKPSRAM) including AHB to APB bridges and APB peripherals (connected to APB1 and APB2)
  - AHB2 peripherals
  - FMC (flexible memory controller)
  - OCTOSPI
  - AHB3 peripherals, including AHB to APB bridge and APB peripherals (connected to APB3)
  - AHB4 peripherals

The bus matrix provides access from a master to a slave, enabling concurrent access and efficient operation even when several high-speed peripherals work simultaneously. This architecture is shown in the figure below.

Figure 1. System architecture



2.1.1 Fast C-bus

This bus connects the C-bus of the Cortex-M33 core to the internal Flash memory and to the BusMatrix via the instruction cache. This bus is used for instruction fetch and data access to the internal memories mapped in code region. This bus targets the internal Flash memory and the internal SRAMs (SRAM1, SRAM2 and SRAM3).

SRAM1, SRAM2 and SRAM3 are accessible on this bus with a continuous mapping.

2.1.2 Slow C-bus

This bus connects the C-bus of the Cortex-M33 core to the BusMatrix via the instruction cache. This bus is used for instruction fetch and data access to the external memories mapped in code region. This bus targets the external memories (FMC and OCTOSPI).

2.1.3 S-bus

This bus connects the system bus of the Cortex-M33 core to the BusMatrix. This bus is used by the core to access data located in a peripheral or SRAM area. This bus targets the internal SRAMs (SRAM1, SRAM2, SRAM3, and BKPSRAM), the AHB1 peripherals including the APB1, APB2, AHB2, AHB3 and AHB4 peripherals.

SRAM1, SRAM2 and SRAM3 are accessible on this bus with a continuous mapping.

Note: The Bus Matrix has a zero latency when accessing SRAM1, SRAM2 and SRAM3.

2.1.4 DCache S-bus

This bus connects the system bus of the Cortex-M33 core to the BusMatrix via the data cache. This bus is used for instruction fetch and data access to the external memories mapped in data region. This bus targets the external memories (FMC and OCTOSPI).

Note: Fetching instructions through this bus is less efficient than fetching instructions through the slow C-bus.

2.1.5 GPDMA1 and GPDMA2 buses

These buses connect the four AHB master interfaces of the GPDMA1 and GPDMA2 to the BusMatrix. These buses target the internal Flash memory, the internal SRAMs (SRAM1, SRAM2, SRAM3, and BKPSRAM), the AHB1 peripherals including the APB1 and APB2 peripherals, the AHB2 peripherals, the AHB3 peripherals, AHB4 peripherals and the external memories through FMC or OCTOSPI.

2.1.6 SDMMC1 and SDMMC2 controllers DMA buses

These buses connect the SDMMC1 and SDMMC2 DMA master interfaces to the BusMatrix. These buses are used only by the SDMMC1 and SDMMC2 DMA to load/store data from/to the memory. These buses target the data memories: internal Flash memory, internal SRAMs (SRAM1, SRAM2 and SRAM3) and external memories through FMC or OCTOSPI.

2.1.7 BusMatrix

The BusMatrix manages the access arbitration between masters. The arbitration uses a Round-Robin algorithm. This BusMatrix features a fast bus multiplexer used to connect each master to a given slave without latency (see *Figure 1*). For the same master, other slaves undergo a latency of at least one cycle at each new access.

2.1.8 AHB/APB bridges

The three AHB/APB bridges provide full synchronous connections between the AHB and the APB buses, allowing flexible selection of the peripheral frequency.

Refer to *Section 2.3.2: Memory map and register boundary addresses* for the address mapping of the peripherals connected to these bridges.

After each device reset, all peripheral clocks are disabled (except for the internal SRAMs and Flash memory interfaces). Before using a peripheral, its clock must be enabled in the RCC_AHBxENR and RCC_APBxENR registers.

Note: When a 8- or 16-bit access is performed on an APB register, the access is transformed into a 32-bit access: the bridge duplicates the 8- or 16-bit data to feed the 32-bit vector.

2.1.9 Ethernet MAC

The Ethernet MAC uses a 32-bit bus, connected to the AHB bus matrix. Through the system bus matrices, it can access the internal Flash memory, the internal memories, and the external memories through the OCTOSPI and the FMC.

2.2 TrustZone security architecture

The security architecture is based on Arm TrustZone with the Armv8-M mainline extension.

The TrustZone security is activated by the TZEN option bit in the FLASH_OPTR register.

When the TrustZone is enabled, the SAU (security-attribution unit) and IDAU (implementation-defined-attribution unit) defines the access permissions based on secure and non-secure states.

- SAU: Up to eight SAU configurable regions are available for security attribution.
- IDAU: provides a first memory partition as non-secure or non-secure callable attributes. The IDAU memory map partition is not configurable and fixed by hardware implementation (refer to *Figure 2: Memory map based on IDAU mapping*). It is then combined with the results from the SAU security attribution and the higher security state is selected.

Based on IDAU security attribution, the Flash memory, system SRAMs and peripherals memory space are aliased twice for secure and non-secure states. However, the external memories space is not aliased.

2.2.1 Default TrustZone security state

When the TrustZone security is activated by the TZEN option bit in the FLASH_OPTR, the default system security state is detailed below:

- CPU:
  - Cortex-M33 is in secure state after reset. The boot address must be at a secure address.
- Memory map:
  - SAU is fully secure after reset. Consequently, all memory map is fully secure. Up to height SAU configurable regions are available for security attribution.
- Flash memory:
  - The Flash memory security area is defined by watermark user options.
  - Flash block-based security attributions are non-secure after reset.
- SRAMs:
  - All SRAMs are secure after reset. MPCBBx (block-based memory protection controller) are secure.
- External memories:
  - FMC and OCTOSPI banks are secure after reset. MPCWMx (watermark-based memory protection controller) are secure.
- Peripherals (see *Table 1 and Table 2 for a list of securable and TrustZone-aware peripherals)*
  - Securable peripherals are non-secure after reset.
  - TrustZone-aware peripherals are non-secure after reset. Their secure configuration registers are secure.
- All GPIO are secure after reset.

- Interrupts:
  - NVIC: All interrupts are secure after reset. NVIC is banked for secure and non-secure state.
  - TZIC: All illegal access interrupts are disabled after reset (see *GTZC TrustZone system architecture*).

2.2.2 TrustZone peripheral classification

When the TrustZone security is active, a peripheral can be either securable or TrustZone-aware type as follows:

- Securable: peripheral protected by an AHB/APB firewall gate that is controlled from TZSC controller to define security properties
- TrustZone-aware: peripheral connected directly to AHB or APB bus and implementing a specific TrustZone behavior such as a subset of registers being secure.

Refer to *GTZC TrustZone system architecture* for more details.

The tables below list the securable and TrustZone-aware peripherals within the system.

Table 1. Securable peripherals by TZSC

Bus	Peripheral

2.3 Memory organization

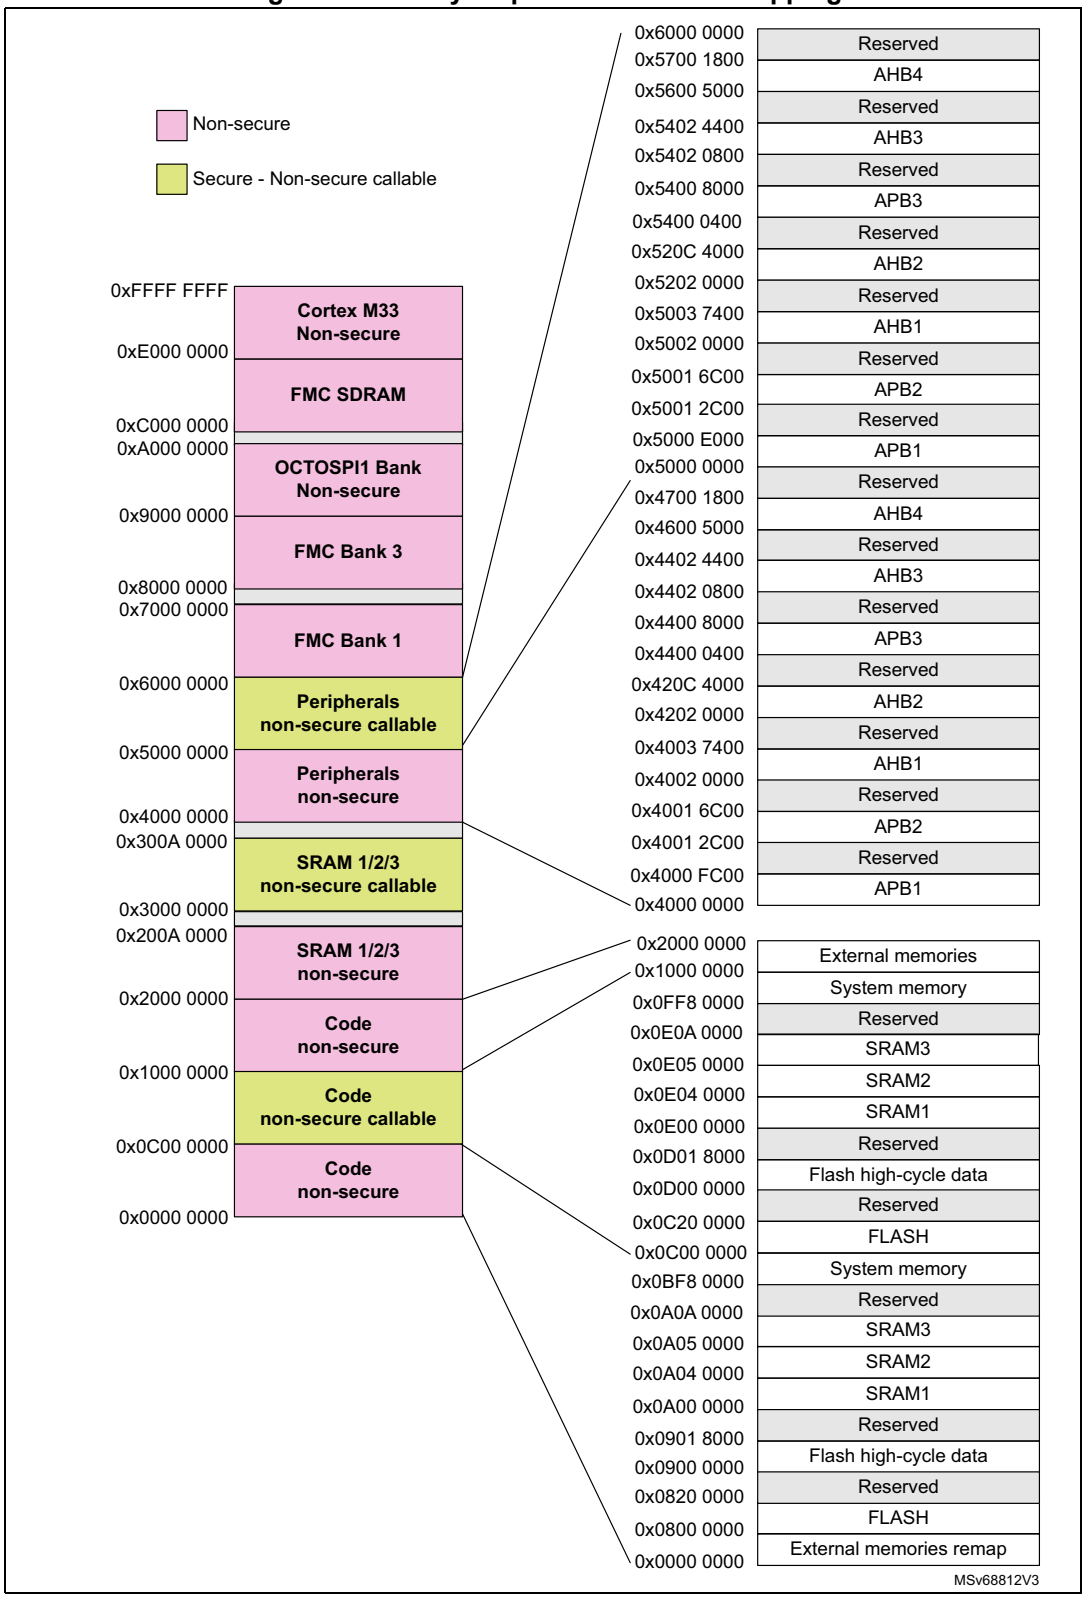
2.3.1 Introduction

Program memory, data memory, registers and I/O ports are organized within the same linear 4-Gbyte address space.

The bytes are coded in memory in Little Endian format. The lowest numbered byte in a word is considered the word's least significant byte and the highest numbered byte the most significant.

2.3.2 Memory map and register boundary addresses

Figure 2. Memory map based on IDAU mapping



All the memory map areas that are not allocated to on-chip memories and peripherals are considered “Reserved”. The following table gives the boundary addresses of the peripherals available in the devices.

Table 3. Memory map and peripheral register boundary addresses

Bus	Secure boundary address	Non-secure boundary address	Peripheral	Peripheral register map
AHB4	0x5700 1800 - 0x57FF FFFF	0x4700 1800 - 0x47FF FFFF	Reserved	-
	0x5700 1400 - 0x5700 17FF	0x4700 1400 - 0x4700 17FF	OCTOSPI1	OCTOSPI register map
	0x5700 0800 - 0x5700 13FF	0x4700 0800 - 0x4700 13FF	Reserved	-

2.3.3 Embedded SRAM

The devices feature up to 644-Kbyte SRAMs:

- 256-Kbyte SRAM1
- 64-Kbyte SRAM2
- 320-Kbyte SRAM3
- 4-Kbyte BKPSRAM

These SRAMs can be accessed as bytes, half-words (16 bits) or full words (32 bits). These memories can be addressed both by CPU and DMAs.

The CPU can access the SRAM1, SRAM2 and SRAM3 through the system bus or through the C-bus depending on the selected address. The CPU can access the BKPSRAM through the system bus only.

When the TrustZone security is enabled, all SRAMs are secure after reset. The SRAM can be programmed as non-secure with a block granularity. For more details, refer to *Section 5: Global TrustZone® controller (GTZC)*.

SRAM features are detailed in *Section 6.3.1: Internal SRAMs features*.

2.3.4 Flash memory overview

The Flash memory is composed of two distinct physical areas:

- The main Flash memory block, that contains the application program and user data.
- The information block, that is composed of the following parts:
  - option bytes for hardware and memory protection user configuration
  - system memory that contains ST proprietary code
  - OTP (one-time programmable) area

The Flash interface implements instruction access and data access based on the AHB protocol. It also implements the logic necessary to carry out the Flash memory operations (program/erase) controlled through the Flash registers plus security access control features. Refer to *Section 7: Embedded flash memory (FLASH)* for more details.

2.3.5 Boot modes

At startup, the core jumps to the boot address configured through the BOOT0 pin, the BOOT_ADDR option bytes, the TZEN option bit, debug request and the product state.

If BOOT_ADDR is not yet configured, dedicated libraries (programmed during ST production), can be used for secure boot. They are located in system Flash memory:

- ST libraries in system Flash memory assist the application software boot with special features such as secure boot and secure firmware install (SFI-RSS).
- ST iROT (immutable root of trust) secure software in user Flash memory are used for secure firmware update and provisioning (SFU).

If a debugger is attached to the product, the entry point is a debug authentication policy, which is used to unlock the device when attached to debugger. Digital signature must be provided to perform a regression to product state, where debug is allowed.

Embedded bootloader

The embedded bootloader is located in the system memory, programmed by ST during production. Refer to the application note *STM32 microcontroller system memory boot mode* (AN2606).

3 System security

The STM32H563/H573 and STM32H562 are designed with a comprehensive set of security features, some of them based on the standard Arm TrustZone® technology.

These security features simplify the process of evaluating IoT devices against security standards. They also significantly reduce the cost and complexity of software development for OEM and third-party developers, by facilitating the reuse, improving the interoperability, and minimizing the API fragmentation.

This section explains the different security features available on the STM32H563/H573 and STM32H562 devices.

3.1 Key security features

- Resource isolation using privilege mode and Armv8-M mainline security extension of Cortex-M33, extended to securable I/Os, memories, and peripherals
- Secure firmware installation (SFI) with device unique cryptographic key pair
  - leveraging the on-chip immutable bootloader that supports the image download through USART, USB, I^2C, I^3C, SPI, FDCAN, and JTAG
- Boot entry: the platform makes it possible to select between native immutable root of trust or proprietary boot entry (in user flash memory).
- Security services (in system flash): the platform comes with native security services, embedded in the system memory to manage the root of trust services. Native root of trust services takes care of: platform security, including secure boot, secure updates of next boot level (uROT: updatable root of trust), secure debug control (debug reopening, regression control). The services can be personalized for each OEM, using the provisioning tools.
- Temporal isolation: boot levels are isolated thanks to HDPL (hide protect level) monotonic counter.
- Secure storage, featuring:
  - Five non volatile areas dedicated to secure storage, protected with HDPL and TrustZone.
  - Battery-powered volatile secure storage, automatically erased in case of tamper
  - Write-only key registers in the AES engines
  - Device 96-bit unique ID and JTAG 32-bit device-specific ID
  - Secure storage can rely upon SAES engine to encrypt the stored data, to benefit of DHUK properties. All data encrypted with the DHUK benefit of temporal and runtime isolation (HDPL and TrustZone), RHUK, EPOCH (version counter) properties.

  a) Data are isolated: all data encrypted/decrypted relying upon SAES+DHUK benefit of the variation of the DHUK for each different isolated area (HDPL0, HDPL1, HDPL2, HDPL3S, HDPL3NS).

  b) RHUK: hardware secret non volatile, unique per device keys (copy protection).

  c) EPOCH: counter incremented each time a regression is done (antirollback).
- General purpose cryptographic acceleration
  - AES 256-bit engine, supporting ECB, CBC, CTR, GCM, and CCM chaining modes

  - Secure AES 256-bit security coprocessor, supporting ECB, CBC, CTR, GCM, and CCM chaining modes with side-channel counter-measures and mitigations
  - HASH processor, supporting SHA-1 checksums and SHA-2 secure hash (SHA2, SHA2-384, SHA2-512)
  - Public key accelerator (PKA) for RSA/DH (up to 4096 bits) and ECC (up to 640 bits), implementing side-channel counter measures. and mitigations when manipulating secrets
  - True random number generator (RNG), NIST SP800-90B precertified
- On-the-fly decryption of encrypted image stored on external flash memory connected through the OCTOSPI
  - Almost-zero latency with standard NOR flash memories
  - Can be used to encrypt the image using device-unique secret keys.
  - Automatic key-erase in case of tamper
- New flexible life-cycle scheme
  - Allows product maintenance in-the-field (debug reopening or regressions)
  - Allows protected firmware distribution in up to three steps: immutable root of trust, secure and non-secure application
- Active tamper and protection against temperature, voltage, and frequency attacks
  - Up to eight active inputs, eight active outputs tamper pins, available in different power modes (refer to TAMP low-power modes)

3.2 Secure install

The secure firmware install (SFI) is an immutable secure service embedded by STMicroelectronics in the devices. The SFI allows secure and counted installation of OEM firmware in an untrusted production environment (such as OEM contract manufacturer).

The confidentiality of the installed images written either in the internal flash memory or encrypted in an external flash memory, is also protected, using the AES.

The SFI native service leverages the following hardware security features:

- secure boot (see *Section 3.3*)
- resource isolation using TrustZone (see *Section 3.6*)
- temporal isolation using hide protection (see *Section 3.7.1*)
- secure execution (see *Section 3.8*)
- secure storage, with associated cryptographic engines (see *Section 3.9* and *Section 3.10*) and flash memory dedicated areas

Further information can be found in AN4992 “*Overview secure firmware install (SFI)”.*

3.3 Secure boot

Secure boot is an immutable code that is always executed after a system reset. As a root of trust, this code checks the device static protections and activates available device runtime protections, reducing the risk of invalid or malicious code running on the platform. As root of trust, the secure boot also checks the integrity and authenticity of the next level firmware before executing it.

The STM32H573 offer two options (using BOOT_UBE) to execute the immutable code after a reset:

- Security services when ST-iROT (code natively present in the system memory) is selected managing the secure boot of the next boot level. ST-iROT takes care of the next level integrity, authenticity using configuration done by OEMs. The next stage can be an ST updatable service (ST-uROT) or a proprietary one (uROT)
- Proprietary boot entry when the OEM manages the full chain (OEM-iROT). To be installed in user flash memory with proper security activation.

The actual functions of the secure boot depend on the availability of TrustZone features, and on the firmware stored in the device. The secure boot typically initializes the secure storage, and installs on-the-fly decryption keys in the OTFDEC, to be able to use encrypted firmware stored in an external flash memory.

TrustZone application, supported by the STM32 ecosystem, provides a root of trust solution, including secure boot functions.

In the devices, the secure boot takes benefit of hardware security features such as:

- resource isolation using TrustZone (see *Section 3.6*)
- temporal isolation using hide protection levels (HDPL) (see *Section 3.7.1*)
- secure execution (see *Section 3.8*)
- secure install and update (see *Section 3.2* and *Section 3.4*)
- per domain secure storage, with associated cryptographic engines if available (see *Section 3.9* and *Section 3.10*)

This section describes the features specifically designed for secure boot.

3.3.1 Unique boot entry

Thanks to unique boot entry (BOOT_UBE) it is possible to select the boot entry point between security services in system flash (ST-iROT) and proprietary boot entry (OEM-iROT). This selection is possible only for products embedding cryptographic acceleration (STM32H573), when TrustZone is enabled (TZEN=0xB4).

When TrustZone is enabled (TZEN = 0xB4) and SECBOOT_LOCK secure option bit is cleared, the application selects a boot entry point located either in the system flash memory (see the next section), or in the secure user flash memory, at the address defined by SECBOOTADD option bytes.

When TrustZone is enabled (TZEN = 0xB4) and SECBOOT_LOCK secure option bit is set, the device unique boot entry is the unmodifiable secure address defined by SECBOOTADD option bytes. The application cannot modify these option bytes when SECBOOT_LOCK is set.

When TrustZone is disabled (TZEN = 0xC3) and NSBOOT_LOCK option bit is cleared, the application selects a boot entry point located in the non-secure user flash memory, at the address defined by NSBOOTADD option bytes.

When TrustZone is disabled (TZEN = 0xC3) and NSBOOT_LOCK option bit is set, the device unique boot entry is the unmodifiable non-secure address defined by NSBOOTADD option bytes. The application cannot modify these option bytes when NSBOOT_LOCK is set.

Note: SECBOOT_LOCK and NSBOOT_LOCK can be changed only when PRODUCT_STATE = Open, Provisioning, or Regression.

For more information on the boot mechanisms, refer to *Section 4: Boot modes*.

3.3.2 Immutable root of trust in system flash memory

The immutable root-of-trust code stored in the system flash memory is first used to perform SFI, allowing secure and counted installation of OEM firmware in untrusted production environments (such as OEM contract manufacturer).

The STMicroelectronics immutable code also includes secure runtime services that can be called at runtime, when a secure application sets the SBS_RSSCMDR register to a non-null value, before triggering a system reset. This runtime feature is deactivated when the BOOT_LOCK secure option bit is set or when the PRODUCT_STATE is different from “Open”.

The STM32H563/H573 products offer security services:

- ST-DA (debug authentication), to manage the debug authentication control feature, allowing to control the debug reopening and regressions of the product for after sales (field return) of the product.

The STM32H573xx products offer security services:

- ST-iROT (immutable root of trust), to handle the secure provisioning, secure boot, secure updates of the first updatable level of the platform.

3.4 Secure update

The secure firmware update is a secure service that runs after a secure boot. Its actual functions depend on the availability of the TrustZone features, and on the firmware stored in the device.

Cortex-M based application processors is commonly used to run trusted boot and a trusted OS to create a Trusted Execution Environment (TEE). The trusted boot and TEE application, supported by the STM32 ecosystem, allow the update of the microcontroller built-in program with new firmware versions, adding new features and correcting potential issues. The update process is performed in a secure way, to prevent unauthorized updates and access to confidential on-device data.

A firmware update can be done either on a single firmware image including both secure and non-secure parts, or on the secure (respectively non-secure) part of the firmware image, independently.

In the devices, the secure update application leverages the same hardware security as the firmware install described in *Section 3.2*.

3.5 Resource isolation using hide protect levels

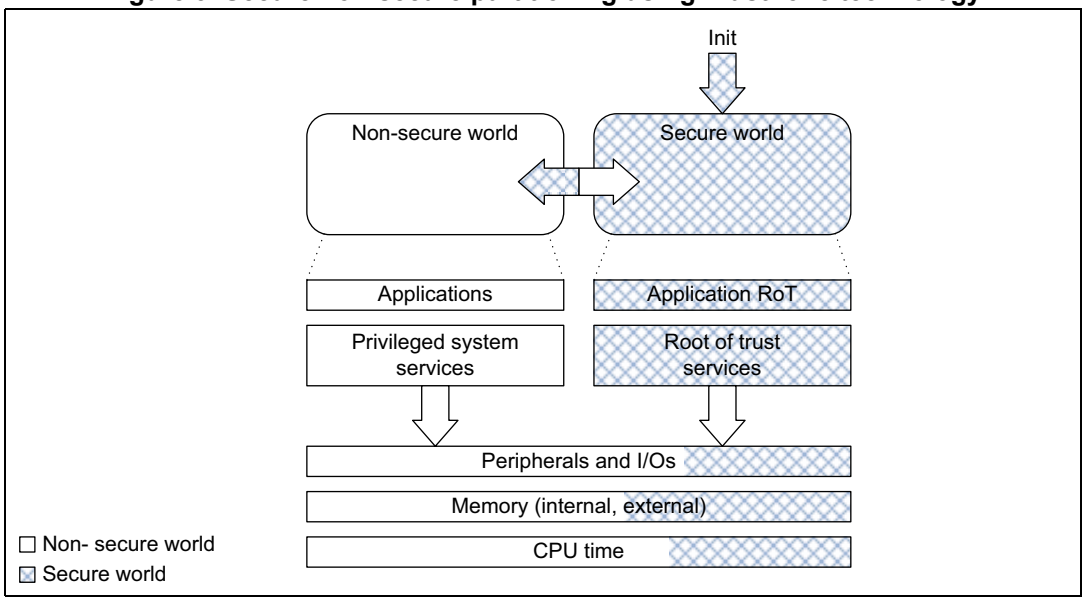
In the STM32H563/H573 and STM32H562 devices, the hardware and software resources used to boot can be isolated. This is called temporal isolation.

It is based on a monotonic counter taking care of only incrementing the levels. When the counter is incremented, the resources of the previous levels become hidden (code and data).

3.6 Resource isolation using TrustZone

In the STM32H563/H573 and STM32H562 devices, the hardware and software resources can be partitioned so that they exist either in the secure world or in the non-secure world, as shown in *Figure 3*.

Figure 3. Secure/non-secure partitioning using TrustZone technology



Note: The initial partitioning of the platform is under the responsibility of the secure firmware executed after device reset.

Thanks to this resource isolation technology, the secure world can be used to protect critical code against intentional or unintentional tampering from the more exposed code running in the non-secure world.

Note: The secure code is typically small and rarely modified, while non-secure code is more exposed, and prone to firmware updates.

3.6.1 TrustZone security architecture

The Armv8-M TrustZone technology is a comprehensive hardware architecture that proposes to developers a comprehensive, holistic protection across the entire processor and system. The device TrustZone hardware features include:

- the Armv8-M mainline security extension of Cortex-M33, enabling a new processor secure state, with its associated secure interrupts
- the dynamic allocation of memory and peripherals to TrustZone using eight security attribution unit (SAU) regions of Cortex-M33
- a global TrustZone framework (GTZC), extending the TrustZone protection against transactions coming from masters in the system different from Cortex-M33
- TrustZone-aware embedded flash memory and peripherals

Note: The TZEN option bit in the FLASH_OPTSR2_PRG register activates TrustZone security.

3.6.2 Armv8-M security extension of Cortex-M33

The Arm security extension of the Cortex-M33 is an evolution, not a revolution. It uses the programmer model from earlier Cortex-M subfamilies like Cortex-M4. Indeed, Armv8-M is architecturally similar to Armv7-M, using the same 32-bit architecture, the same memory mapped resources protected with an MPU. Armv8-M also uses the nested vectored interrupt controller (NVIC).

The Armv8-M TrustZone implementation in STM32H563/H573 and STM32H562 devices is composed of the following features:

- a new processor state, with almost no additional code/cycle overhead (as opposed to Armv8-A TrustZone) that uses a dedicated exception routine to trigger a secure/non-secure world change
- two memory map views of a shared 4-Gbyte address space
- a low interrupt latency for both secure and non-secure domains, and a new interrupt configuration for security grouping and priority setting
- separated exception vector tables for the secure and non-secure exceptions
- micro-coded context preservation
- banking of specific registers across secure/non-secure states, including stack pointers with stack-limit checkers
- banking of following Cortex-M33 programmable components (two separate units for secure and non-secure):
  - SysTick timer
  - MPU configuration registers (12 MPU regions in secure, eight in non-secure)
  - some of the system control block (SCB) registers
- new system exception (SecureFault) for handling of security violations
- configurable debug support, as defined in *Section 3.12*

For more information, refer to Cortex-M33 programming manual (PM0264).

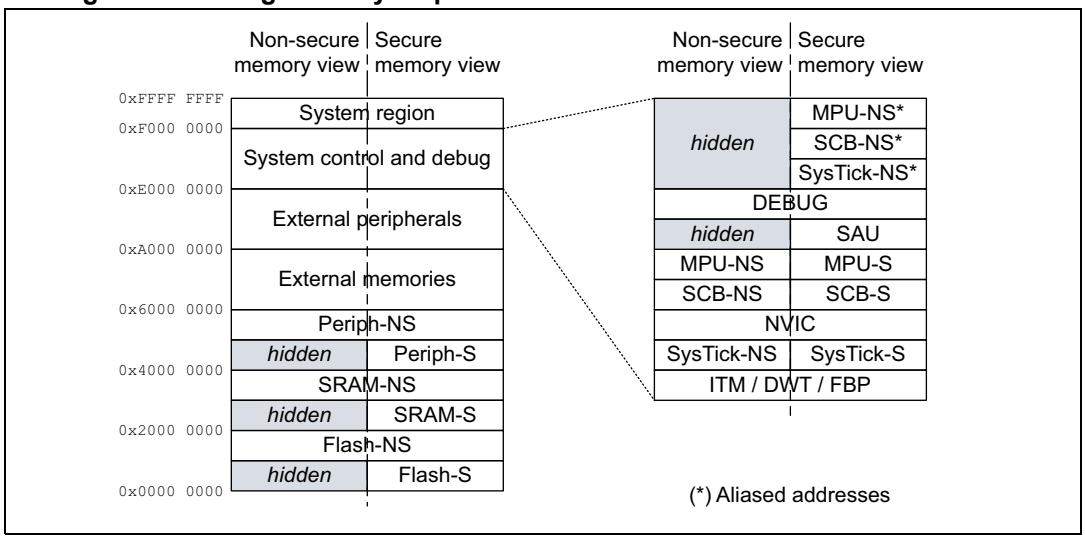
3.6.3 Memory and peripheral allocation using IDAU/SAU

Security attributes

As illustrated on *Figure 4*, the Armv8-M non-secure memory view is similar to Armv7-M (found in Cortex-M4), with the difference that the secure memory is hidden. The secure memory view shows the flash memory, SRAM and peripherals that are only accessible while the Cortex processor executes in Secure state.

Note: Figure 4 shows the 32-bit address space viewed after SAU configuration by the secure code.

Figure 4. Sharing memory map between CPU in secure and non-secure state

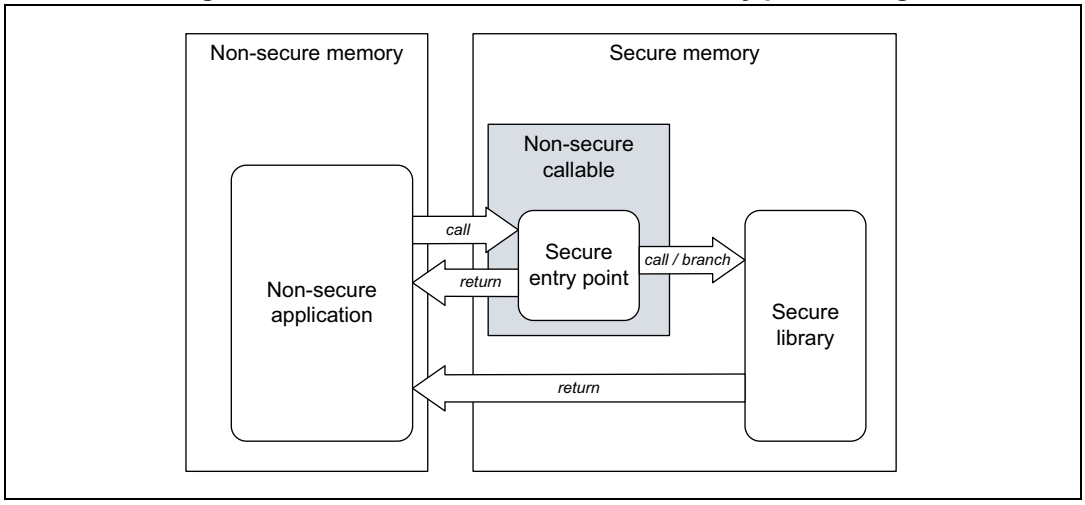


The Cortex processor state (and the associated rights) depends upon the security attribute assigned to the memory region where it is executed:

- A processor in a non-secure/secure state executes only from non-secure (NS)/secure (S) program memory.
- When running in secure state, the processor can access data from both S and NS memories. When running in non-secure state, the CPU is limited to non-secure memories.

To manage transitions to the secure world, developers must create non-secure callable (NSC) regions containing valid entry points to the secure libraries. The first instruction in these entry points must be the new secure gate (SG) instruction, used by the non-secure code to call a secure function (see *Figure 5*).

Figure 5. Secure world transition and memory partitioning



Programming security attributes

In Cortex-M33, the static implementation defined attribution unit (IDAU) works in conjunction with the programmable security attribution unit (SAU) to assign a specific security attribute (S, NS, or NSC) to a specific address, as shown in *Table 4*.

Table 4. Configuring security attributes with IDAU and SAU

IDAU security attribution	SAU security attribution(1)	Final security attribution
Non-secure	Secure	Secure
	Secure-NSC	Secure-NSC
	Non-secure	Non-secure
Secure-NSC	Secure	Secure
	Non-secure	Secure-NSC

1. Defined regions are aligned to 32-byte boundaries.

The the Cortex-M33 can configure the SAU only in the secure-privilege state. When the TrustZone is enabled, the SAU defaults all addresses as secure (S). A secure boot application can then program the SAU to create NSC or NS regions, as shown in *Table 4*.

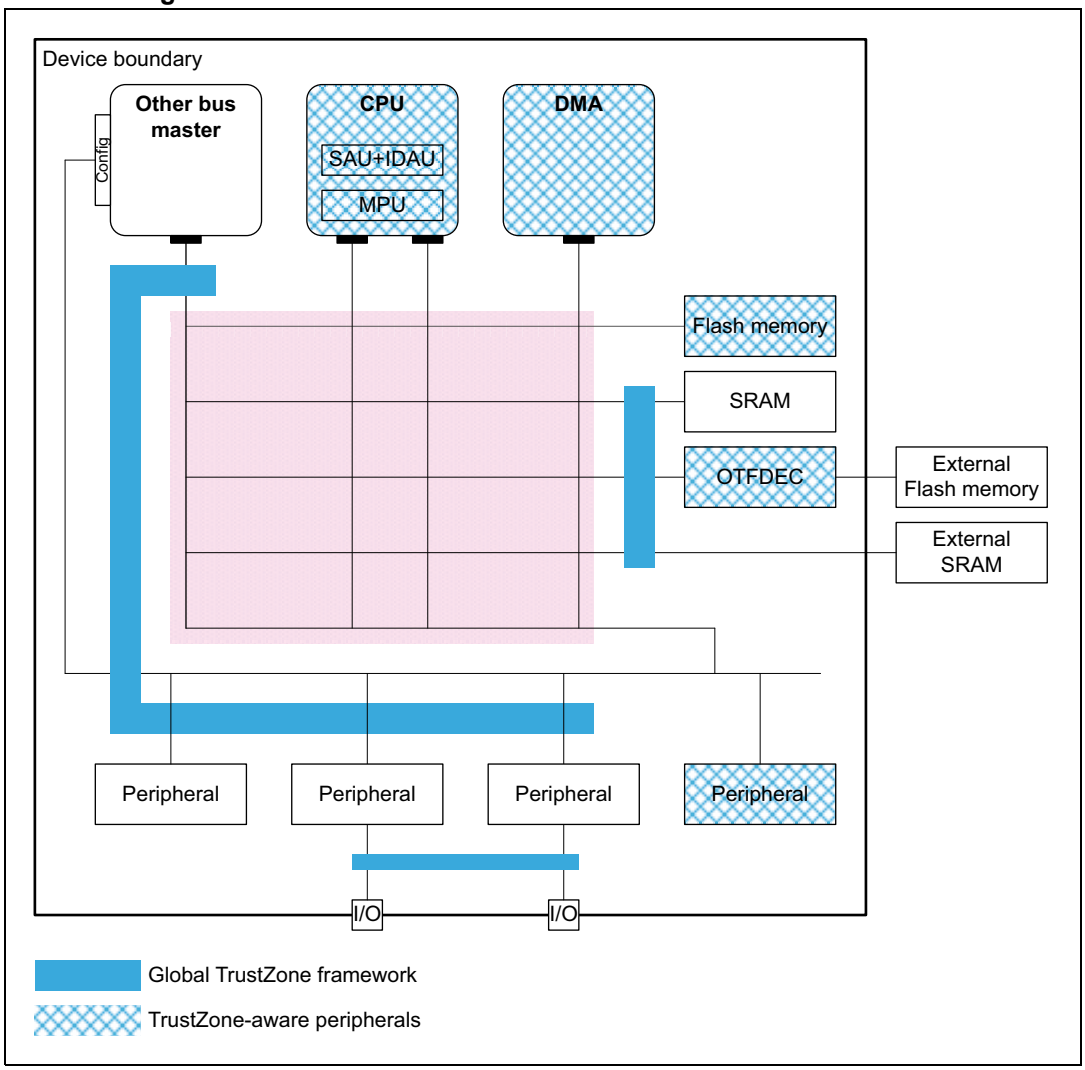
Note: The SAU/IDAU settings are applicable only to the Cortex-M33*. The other masters, like DMA, are not affected by these policies.*

3.6.4 Memory and peripheral allocation using GTZC

Global TrustZone framework architecture

On top of the Armv8-M TrustZone security extension in Cortex-M33, the devices embed complementary security features that reinforce, in a flexible way, the isolation between secure and non-secure worlds. Unlike the SAU/IDAU, the GTZC can protect legacy memories and peripherals against non-secure transactions coming from other masters than the Cortex-M33.

Figure 6. Global TrustZone framework and TrustZone awareness



Securing peripherals with TZSC

When the TrustZone security is active, a peripheral is either securable through the GTZC, or is natively TrustZone-aware, as shown in the previous figure:

- A securable peripheral or memory is protected by an AHB/APB firewall gate, controlled by the TrustZone security controller (TZSC).
- A TrustZone-aware peripheral or memory is connected directly to AHB or APB interconnect, implementing a specific TrustZone behavior, such as a subset of secure registers or a secure memory area.

When a securable peripheral is made secure-only with the GTZC, if this peripheral is master on the interconnect, it automatically issues secure transactions. The SDMMC is an example of securable master. TrustZone-aware AHB masters like Cortex-M33 or DMAs, drive a secure signal in the AHB interconnect, according to their security mode, independently to the GTZC.

Note: Like with TrustZone, a peripheral can be made privileged-only with TZSC (see Section 3.7.2). In this case, if this peripheral is master on the interconnect, it automatically issues privileged transactions.

Securing memories with TZSC and MPCBB

The TZSC block in GTZC provides the capability to manage the security and privilege for all securable external memories, programming the MPCWM resources as defined in *Table 5*.

Table 5. MPCWMx resources

Memory	MPC resource	Type of filtering	Number of regions	Default security	On-the-fly decryption(1)
OCTOSPI1	MPCWM1	Non-secure privileged or unprivileged region (watermarks)	2	Secure privileged(2)	Yes
FMC_NOR bank	MPCWM2		2		No
FMC_NAND / FMC_SDRAM bank	MPCWM3		1		
Backup SRAM (BKPSRAM)/FMC_SDRAM	MPCWM4		1		

1. Using the OTFDEC.
2. Assuming TrustZone is activated on the device, non-secure unprivileged otherwise.

The MPCBB resources in GTZC provide the capability to configure the security and privilege of embedded SRAM blocks, as defined in *Table 6*.

Table 6. MPCBBx resources

Memory	MPC resource	Type of filtering	Memory size	Block size	Number of super-blocks	Default security
SRAM1	GTZC1_MPCBB1	Block based, managing security and privilege	256 KB	512(1) bytes	16	Secure privileged(2)
SRAM2	GTZC1_MPCBB2		64 KB		4	
SRAM3	GTZC1_MPCBB3		320 KB		20	

1. Blocks are grouped in super-blocks of 32 consecutive blocks, to manage the configuration locking.
2. Assuming TrustZone is activated on the device, non-secure unprivileged otherwise.

Applying GTZC configurations

The TZSC and MPCBB blocks can be used in one of the following ways:

- statically programmed during the secure boot, locked and not changed afterwards
- dynamically re-programmed using a specific application code or real-time kernel

When the dynamic option is selected and the configuration is not locked:

- MPCBB secure blocks or MPCWM non-secure region size can be changed by a secure software. This software must be privileged for MPCWM, can be unprivileged if the particular block is not privileged-only.
- The secure (respectively privilege) state of each peripheral can be changed writing to GTZC_TZSC_SECCFRGx (respectively GTZC_TZSC_PRIVCFGRx) registers.

Securing peripherals with TZSC

The TZSC block in GTZC provides the capability to manage the security and the privilege for all securable peripherals. The list of these peripherals can be found in *Section 5: Global TrustZone controller (GTZC)*.

Note: When the TrustZone is deactivated, the resource isolation hardware GTZC can still be used to isolate peripherals to privileged code only (see Section 3.7.2).

When the TrustZone is activated, peripherals are set as non-secure and unprivileged after reset.

TrustZone-aware peripherals

The devices include the following TrustZone-aware peripherals:

- GPIOA to GPIOI
- GTZCx_MPCBB, GTZCx_TZIC and GTZCx_TZSC (GTZC blocks)
- OTFDEC1, writable only in secure if TZEN = 1
- EXTI
- Flash memory
- RCC and PWR
- GPDMA1 and GPDMA2
- SBS registers
- RTC and TAMP
- MCU debug unit DBGMCU

The way illegal accesses to those peripherals are monitored through the TZIC registers is described in *Section 5: Global TrustZone controller (GTZC)*.

For more details, refer to *Section 3.6.5*.

TrustZone illegal access controller (TZIC)

The TZIC block in GTZC gathers all illegal access events originated from sources either protected by GTZC or TrustZone-aware, generating one global secure interrupt towards the NVIC.

TZIC is available only when the system is TrustZone enabled (TZEN = 0xB4). All accesses to TZIC registers must be secured.

For each illegal event source, a status flag and a clear bit exist. Each illegal event can be masked, not generating an interrupt toward the NVIC.

Note: By default, all events are masked.

3.6.5 Managing security in TrustZone-aware peripherals

This section gives more details on how the security is implemented in the TrustZone-aware peripherals listed in the previous section.

Embedded flash memory

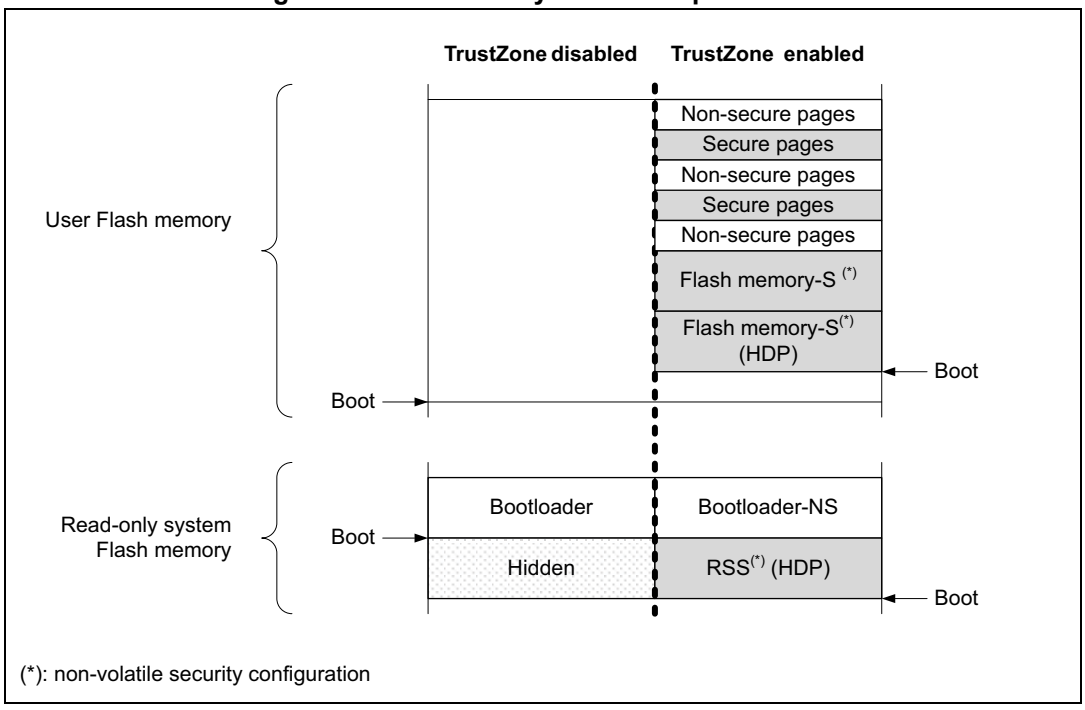
When the TrustZone security is enabled through option bytes (TZEN = 0xB4), the whole memory is secure after reset. The following protections, shown in *Figure 7*, are available to the application:

- nonvolatile user secure areas, defined with nonvolatile secure user option bytes
  - watermark-based secure only area (x2)
  - secure hide protection (HDP) area, stickily hidden after boot (x2)
- volatile user secure pages, defined with volatile secure registers (lost after reset)
  - Any page set as non-secure (example: outside watermark-based secure only area), can be set as secure on-the-fly using the block-based configuration registers.

Note: All areas are aligned on the page granularity of the flash memory, which can be configured as secure while it is tagged as non-secure in Cortex-M33 IDAU/SAU. In this case, non-secure accesses by the CPU to the flash memory are denied.

Erase or program operations can be available to secure/non-secure code only for secure/ non-secure pages or memory. A flash memory is considered secure if at least one page is secure.

Figure 7. Flash memory TrustZone protections



As shown above, when TrustZone is enabled (TZEN = 0xB4), the application code can use the HDP area that is part of the flash memory watermark-based secure area. Indeed, when

the application sets the HDPx_ACCDIS bit, data read, write, and instruction fetch on this HDP area is denied until the next system reset.

For example, the software code in the secure flash memory HDP area can be executed only once, with any further access to this area denied until the next system reset. Additionally, any flash memory page belonging to an active HDP area cannot be erased anymore.

When the TrustZone is disabled (TZEN = 0xC3), the volatile/non-volatile secure area features are deactivated and all secure registers are RAZ/WI.

See *Section 7: Embedded flash memory (FLASH)* for more details.

On-the-fly encryption/decryption (OTFDEC)

When the TrustZone security is enabled (TZEN = 0xB4), the OTFDEC can be initialized only by secure applications. Each of the four encrypted regions, once the configuration is confirmed, can be write-locked until the next power-on-reset.

Note: Any application (secure or non-secure) can verify the initialization context of each OTFDEC region (including CRC of the keys), by reading the peripheral registers.

Key registers in each OTFDEC are write-only.

See *Section 3.10.3* for more details on this cryptographic engine.

Direct memory access controllers (GPDMAx)

When a DMA channel x is defined as secure (SECx = 1 in GPDMA_SECCFGR), the source and destination transfers can be independently set as secure or non-secure by a secure application using SSEC and DSEC bits in GPDMA_CxTR1. *Table 7* summarizes these security options available in each DMA channel.

Table 7. DMA channel use (security)(1)

Destination type	Secure DMA channel x (SECx = 1)		Non-secure DMA channel y (SECy = 0)	
	Secure source	Non-secure source	Secure source	Non-secure source
Secure destination	OK	OK(2)	Transfer blocked	
Non-secure destination	OK(3)	OK(4)	Transfer blocked	OK

1. When a transfer is blocked, the transfer completes but the corresponding writes are ignored, and reads return 0s. An illegal access event to TZIC is automatically triggered by the memory/peripheral used as source or destination.
2. If the source is a memory, the transfer is possible only if SSEC = 0, otherwise the transfer is blocked.
3. If the destination is a memory, the transfer is possible only if DSEC = 0, otherwise the transfer is blocked.
4. If the transfer is memory-to-memory, it is possible only if SSEC = 0 and DSEC = 0, otherwise it is blocked.

When a channel is configured as secure:

- Registers allocated to this channel (excluding GPDMA_SECCFGR, GPDMA_PRIVCFGR and GPDMA_RCFGLOCKR) are read as 0. Writes are ignored for non-secure accesses. A secure illegal access event may also be triggered towards the TZIC peripheral.
  - Writes to GPDMA_SECCFGR and GPDMA_RCFGLOCKR must be secure. For each bit in GPDMA_PRIVCFGR, write must be secure if the corresponding bit in GPDMA_SECCFGR is set.

- In linked-list mode, the loading of the next linked-list data structure from memory is performed with secure transfers.
- When switching to a non-secure state, the secure application must abort the channel or wait until the secure channel is completed before doing the switch.

Note: DMA secure channels are not available when TrustZone is deactivated. When a channel is configured as non-secure, in linked-list mode, the loading of the next linked-list data structure from memory is performed with non-secure transfers.

See *Section 16: General purpose direct memory access controller (GPDMA)* for more details.

Power control (PWR)

When the TrustZone security is enabled (TZEN = 0xB4), the selected PWR registers can be secured through PWR_SECCFGR, protecting the following PWR features:

- low power mode setup
- wake-up (WKUP) pins definition
- voltage detection and monitoring
- backup domain control

Other PWR configuration bits become secure:

- when the system clock selection is secure in the RCC: the voltage scaling (VOS) becomes secure.
- when a GPIO is configured as secure: its corresponding bit for pull-up/pull-down configuration in Standby mode becomes secure.
- when the USB Type-C/USB power delivery interface (UCPD) is configured as secure in TZSC: PWR_UCPDR register becomes secure.

See *Section 10: Power control (PWR)* for details.

Secure clock and reset (RCC)

When the TrustZone security is enabled (TZEN = 0xB4) and security is enabled in the RCC, the bits controlling the peripheral clocks and resets become TrustZone-aware:

- If the peripheral is securable and programmed as secure in the TZSC, the peripheral clock and reset bits become secure.
- If the peripheral is TrustZone-aware, the peripheral clock and reset bits become secure when at least one function is configured as secure inside the peripheral.

Note: Refer to Section 3.6.4 for the list of securable and TrustZone-aware peripherals.

Additionally, the following configurations can be made secure-only using RCC_SECCFGR:

- external clock (such as HSE or LSE), internal oscillator (such as HSI, CSI, or LSI)
- main PLL and AHB prescaler
- system clock source selection
- MCO clock output
- reset flag
- automatic internal oscillator waking up configuration

See *Section 11: Reset and clock control (RCC)* for details.

Real time clock (RTC)

Like all TrustZone-aware peripherals, a non-secure read/write access to a secured RTC register is RAZ/WI. It also generates an illegal access event that triggers a secure illegal access interrupt if the RTC illegal access event is enabled in the TZIC.

After a backup domain power-on reset, all RTC registers can be read or written in both secure and non-secure modes. The secure boot code can then change the security setup, making registers Alarm A, Alarm B, wakeup timer, and timestamp secure or not, using RTC_SECCFGR.

When the SEC bit is set in secure-only RTC_SECCFGR:

- Writing the RTC registers is possible only in secure mode.
- Reading RTC_SECCFGR, RTC_PRIVCFGR, RTC_MISR, RTC_TR, RTC_DR, RTC_SSR, RTC_PRER, and RTC_CALR is always possible in secure and non-secure modes. All the other RTC registers can be read only in secure mode.

When SEC is cleared in secure-only RTC_SECCFGR, it is still possible to restrict access in secure mode to some RTC registers by setting dedicated control bits: INITSEC, CALSEC, TSSEC, WUTSEC, ALRASEC, and ALRBSEC.

Note: The RTC security configuration is not affected by a system reset.

See *Section 46: Real-time clock (RTC)* for more details.

Tamper and backup registers (TAMP)

Like all TrustZone-aware peripherals, a non-secure read/write access to a secured TAMP register is RAZ/WI. It also generates an illegal access event that triggers a secure illegal access interrupt if the TAMP illegal access event is enabled in the TZIC.

After a backup domain power-on reset, all TAMP registers can be read or written in both secure and non-secure modes. The secure boot code can change this security setup, making some registers secure or not as needed, using TAMP_SECCFGR register.

When TAMPSEC is set in TAMP_SECCFGR:

- Writing the TAMP registers is possible only in secure mode. Backup registers have their own write protection (see below).
- Reading the TAMP registers (exception TAMP_SECCFGR, TAMP_PRIVCFGR, and TAMP_MISR) returns 0 if the access is non-secure. Backup registers have their own read protection (see below).

The application can also:

- make TAMP_COUNTR register read and write secure-only by setting the CNT1SEC bit in TAMP_SECCFGR secure register
- increase security in backup registers for two of the three protection zones configured using BKPRWSEC[7:0] and BKPWSEC[7:0] bitfields in TAMP_SECCFGR:
  - protection zone 1 is read non-secure, write non-secure
  - protection zone 2 is read non-secure, write secure
  - protection zone 3 is read secure, write secure

Note: The TAMP security configuration is not affected by a system reset.

See *Section 47: Tamper and backup registers (TAMP)* for more details.

General-purpose I/Os (GPIO)

When the TrustZone security is enabled (TZEN = 0xB4), each I/O pin of the GPIO ports can be individually configured as secure through the GPIOx_SECCFGR registers. Only a secure application can write to GPIOx_SECCFGR registers. After boot, each I/O pin is set as secure.

When an I/O pin is configured as secure, its corresponding configuration bits for alternate function (AF), mode selection (MODE), and I/O data are RAZ/WI in case of non-secure access.

When a digital alternate function is used (input/output mode) to protect data transiting from/to the I/O managed by a secure peripheral, the devices add a secure alternate function gate on the path between the peripheral and its allocated I/Os:

- if the peripheral is secure, the I/O pin must also be secure to allow input/output of data
- if the peripheral is not secure, the connection is allowed regardless of the I/O pin state.

The TrustZone-aware logic around GPIO ports, used as alternate function, is summarized in *Table 8*.

Table 8. Secure alternate function between peripherals and allocated I/Os

Security configuration		Alternate function logic		Comment
Peripheral	Allocated I/O pin	Input	Output	
Secure	Secure	I/O data	Peripheral data	-
Non-secure				Out of reset configuration
Secure	Non-secure	0	0	-
Non-secure		I/O data	Peripheral data	

When an analog function with an analog switch is used, the connection to the peripherals listed in *Table 9* is blocked by hardware when the peripheral is non-secure and the I/O is secure.

Table 9. Non-secure peripheral functions that cannot be connected to secure I/Os

Peripheral	Analog function(1)	Input	Output
ADC12	ADC12_INy (y = 1 to 17)	X	-

1. Used to find the I/O corresponding to the signal/function on the package (refer to the product datasheet).

Finally, regarding GPIO and security, *Table 10* summarizes the list of I/Os without any hardware protection linked to TrustZone. The listed signals (input and/or outputs) are not blocked when the I/O is set as secure, and the associated peripheral is non secure.

For example, when a secure application sets PA4 as secure to be used as LPTIM2_CH1, if the DAC is non-secure, it can be programmed to output data to PA4, potentially causing malfunction to the secure application.

Similarly, when a secure application sets PA0 as secure to be used as UART4_TX, if TAMP is non-secure, it can be programmed to capture the USART input traffic through the TAMP_IN signal.

It is important that, for each case described in *Table 10*, the secure application decides if a potential effect on data integrity or confidentiality is critical or not. For example, if the USART situation described above is not acceptable (data transiting on secure USART is confidential), then the secure application must configure the TAMP as secure even if not used by the secure application.

Table 10. Non-secure peripheral functions that can be connected to secure I/Os

Peripheral	Signal(1)	Input	Output	How to set the peripheral or function as secure
DAC	DAC1_OUTx (x = 1, 2)	-	X	Set DAC1SEC in GTZC1_TZSC_SECCFGR1.
UCPD	UCPD1_CCx (x = 1, 2)	X	X	Set UCPD1SEC in GTZC1_TZSC_ SECCFGR1.
	UCPD1_DBx (x = 1, 2)	X	-	
TAMP	TAMP_INx (x = 1 to 8)	X	-	Set TAMPSEC in TAMP_SECCFGR
	TAMP_OUTx (x = 1 to 8)	-	X	
RTC	RTC_OUTx (x = 1, 2)	-	X	Set SEC in RTC_SECCFGR.
	RTC_TS	X	-	Set TSSEC in RTC_SECCFGR.
PWR	WKUPx (x = 1 to 8)	X	-	Set WUPxSEC in PWR_SECCFGR.
RCC	LSCO	-	X	Set LSESEC in RCC_SECCFGR.
EXTI	EXTIx (x= 0 to 58)	X	-	Set SECx bit in EXTI_SECCFGR.

1. To find the I/O corresponding to the signal/function on the package, refer to the product datasheet.

Refer to *Section 13: General-purpose I/Os (GPIO)* for more details.

Extended interrupts and event controller (EXTI)

When the TrustZone security is enabled (TZEN = 0xB4), the EXTI is able to protect event register bits from being modified by non-secure accesses. The protection can individually be activated per input event via the register bits in EXTI_SECCFGRx. When an input event is configured as secure, only a secure application can change the configuration (including security), change the masking or clear the status of this input event.

The security configuration in EXTI_SECCFGR1 and EXTI_SECCFGR2 can be globally locked after reset in EXTI_LOCKR.

See *Section 23: Extended interrupts and event controller (EXTI)* for more details.

System configuration, boot and security (SBS)

Like all TrustZone-aware peripherals, when the TrustZone security is enabled (TZEN = 0xB4), a non-secure read/write access to a secured SBS register is RAZ/WI. Such access also generates an illegal access event that triggers a secure illegal access interrupt if the SBS illegal access event is not masked in the TZIC.

See *Section 14: System configuration, boot, and security (SBS)* for more details.

Microcontroller debug unit (DBGMCU)

The MCU debug component (DBGMCU) helps the debugger, providing support for:

- low-power modes behavior during debug
- peripheral freeze during debug, applicable to I2Cs, IWDG, WWDG, timers, low-power timers, and GPDMA channels

The DBGCMU is a TrustZone-aware peripheral, managing accesses to its control registers as described in *Table 11*.

Table 11. TrustZone-aware DBGMCU non-secure accesses management

Debug profile	Peripheral status(1)	DBG_xx_STOP control bits	
		Write access	Read access
Non-secure invasive (SPIDEN = 0)	NS	Yes (S(2) or NS)	Yes (S or NS)
	S	None (S or NS)	
Secure invasive (SPIDEN =1)	NS	Yes (S or NS)	
	S	Yes (S only)	

1. As reported by the GTZC, the TrustZone-aware peripheral or the DMA channel.
2. Secure access from debugger is converted to non-secure access in the device.

Refer to *Section 75.12: Microcontroller debug unit (DBGMCU)* for more details.

3.6.6 Activating TrustZone security

The TrustZone is deactivated by default in all STM32H563/H573 and STM32H562 devices. It can be activated by setting the TZEN option bit in FLASH_OPTSR2_PRG when PRODUCT_STATE is Open. Once TZEN has changed from disabled to enabled (0xC3 to 0xB4), the default security state, after reset, is always the following:

- CPU subsystem
  - Cortex-M33 exits reset in secure state, hence the boot address must point toward a secure memory area.
  - All interrupt sources are secure (in NVIC).
  - The memory mapped viewed by the CPU through IDAU/SAU is fully secure.
- Embedded flash memory
  - Flash memory nonvolatile secure areas (with their HDP zone), are defined with nonvolatile registers FLASH_SECWMxR (x = 1, 2). Default secure option bytes setup is all user flash secure, without HDP area defined.
  - Volatile block-based security attributions of the flash memory are non-secure.
- Embedded SRAMs
  - All SRAMs are secure, as defined in GTZC/MPCBB (see *Section 3.6.4*). The secure boot code can change this security setup, making blocks secure or not.
- External memories
  - All memory devices connected to the FMC and OCTOSPI are secure, as defined in GTZC/MPCWM (see *Section 3.6.4*). The secure-boot code can change this security setup, making components secure or not.
- All GPIOs are secure.

- All GPDMA channels are non-secure.
- Backup registers are non-secure.
- Peripherals and GTZC:
  - Securable peripherals are non-secure and unprivileged.
  - TrustZone-aware peripherals are non-secure, with their secure configuration registers being secure.
  - All illegal access interrupts in GTZC/TZIC are disabled.

Note: Refer to Section 3.6.4 for the list of securable and TrustZone-aware peripherals.

3.6.7 Deactivating TrustZone security

Once TrustZone is activated, it can only be deactivated during a PRODUCT_STATE regression to Open.

Note: Such PRODUCT_STATE regression triggers the erasing of embedded memories (SRAM2, flash), and the reset of all peripherals, including the OTFDEC and all crypto engines.

After the TrustZone deactivation, most features mentioned in *Section 3.6* are no longer available:

- The nonvolatile secure area of the embedded flash memory is deactivated, including the HDP area.
- Only the NVIC manages non-secure interrupts.
- All secure registers in TrustZone-aware peripherals are RAZ/WI.

Note: When the TrustZone is deactivated, the resource isolation using privilege stays available (see Section 3.7.2 for details).

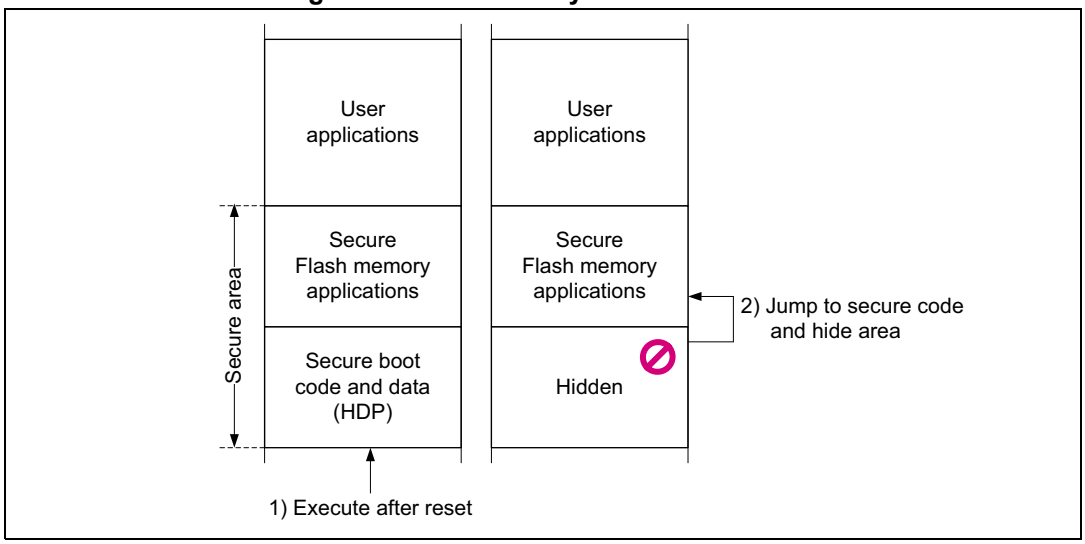
3.7 Other resource isolation

These are hardware mechanisms offering an additional level of isolation on top of the TrustZone technology.

3.7.1 Temporal isolation using secure hide protection (HDP)

When the TrustZone security is enabled (TZEN = 0xB4), the embedded flash memory allows to define an HDP area per watermarked-secure area of each bank (8-Kbyte page granularity). The code executed in this HDP area, with its related data and keys, can be hidden after boot, until the next system reset. The hide protection principle is shown in *Figure 8*.

Figure 8. Flash memory secure HDP area



Activation of HDP area in user flash memory is related to HDPL1: as soon as HDPL ≥ 2, data read, write, and instruction fetch (on the area defined by HDPx_PSTRT and HDPx_PEND in FLASH_HDPxR_PRG option bytes), are denied until the next device reset.

The END of the HDPx areas can be extended (dynamically by the application) thanks to FLASH_HDPEXTR flash memory register.

Note: Bank erase aborts when it contains a write-protected area (WRP or HDP area).

3.7.2 Resource isolation using Cortex privileged mode

In parallel to the TrustZone isolation described in *Section 3.6*, the hardware and software resources can be partitioned so that they are restricted to software running in Cortex privileged mode.

Thanks to this hardware isolation technology, available even if TrustZone is disabled (TZEN = 0XC3), critical code or data can be protected against intentional or unintentional tampering from the more exposed unprivileged code.

Memory and peripheral privileged allocation using MPU

The Cortex-M33 MPU divides the unified memory into eight regions in non-secure and twelve in TrustZone, each aligned to a multiple of 32 bytes. Each memory region can be programmed to generate faults when accessed inappropriately by unprivileged software.

Memory and peripheral privileged allocation using GTZC

For the Cortex-M33 master, to complement the coarse isolation provided by the MPU, the GTZC reinforces, in a flexible way, the isolation between privileged and unprivileged tasks, for peripherals and selected memories.

For masters other than the Cortex-M33, the GTZC can assign them as unprivileged initiators, automatically protecting resources defined as privileged against this master.

- Securing peripherals with TZSC (privileged-only)

  In the devices, a peripheral is either securable privileged-only through GTZC, or is natively privileged-aware:

  – A securable privileged-only peripheral or memory is protected by an AHB/APB firewall gate controlled by the TZSC.

  – A privileged-aware peripheral or memory is connected directly to AHB or APB interconnect, implementing a specific behavior (for example, a subset of registers or a memory area is privilege-only).

    When such peripheral is made privileged-only with GTZC, if it is master on the interconnect (SDMMC), it automatically issues privileged transactions. Privilege-aware masters like GPDMA1 and GPDMA2, drive privileged signal in the AHB interconnect according to their internal privileged mode, independently to the GTZC.

    The list of securable peripherals can be found in *Section 5: Global TrustZone controller (GTZC)*.

- Securing memories with TZSC and MPCBB (privileged-only)

  The TZSC logic in GTZC provides the capability to manage the privilege level for all securable external memories, programming the MPCWM resources defined in *Section 3.6.4*.

  Similarly, the TZSC logic in GTZC provides the capability to configure the privilege level of embedded SRAM blocks, programming the MPCBB resources defined in *Section 3.6.4*.

- Error management (privileged-only)

  – Any unprivileged transaction trying to access a privileged resource is considered as illegal. There is no illegal access event generated for illegal unprivileged read and write accesses.

  – The addressed resource follows a silent-fail behavior, returning all-0 data for read and ignoring any write.

  – When an illegal unprivileged access occurs, no bus error is generated, except when this is an instruction fetch, accessing a privileged memory or a peripheral register.

Managing security in privileged-aware peripherals

TrustZone-aware peripherals also implement privileged-only access mode. The privileged protection is valid even if TrustZone is disabled (TZEN = 0xC3):

- *Embedded flash memory*

  By default, all registers can be read or programmed in both privileged and unprivileged modes.

  When secure privileged bit SPRIV is set in FLASH_PRIVCFGR, reading and writing the secure registers is possible only in privileged mode. Write access to this bit is ignored if TrustZone is disabled (TZEN = 0xC3).

  When non-secure privileged bit NSPRIV is set in FLASH_PRIVCFGR, reading and writing the flash memory non-secure registers is possible only in privileged mode.

  Regarding privileged protection, the devices offer the following features:

  – The system flash memory can be accessed both in privileged and unprivileged modes.

  – Each watermark-based secure area, including its secure HDP area, is accessible in secure-privileged and secure-unprivileged mode, if applicable.

  – Each 8-Kbyte page of the embedded flash memory can be programmed on-the-fly as privileged only, using the block-based privileged configuration registers FLASH_PRIV1BBRx and FLASH_PRIV2BBRx. An unprivileged page is accessible by privileged or unprivileged access.

Note: Switching a page from privileged to unprivileged does not erase its content.

When applicable, an erase or program operation is always available to privileged code, and is available to unprivileged code only for unprivileged pages or unprivileged memory.

- *On-the-fly encryption/decryption (OTFDEC)*

  When privileged bit PRIV is set in OTFDEC_PRIVCFGR, only a privileged application can initialize the OTFDEC.

Note: OTFDEC_PRIVCFGR can be read by both privileged and unprivileged code.

- *Direct memory access controllers (GPDMAx)*

  When a DMA channel x is defined as privileged (PRIVx = 1 in GPDMA_PRIVCFGR), special rules (see *Table 12*) apply when accessing privileged/unprivileged source or destination.

Table 12. DMA channel use (privilege)

Destination	Privileged DMA channel x (PRIVx = 1)		Unprivileged DMA channel y (PRIVy = 0)	
	Privileged source	Unprivileged source	Privileged source	Unprivileged source
Privileged	OK		Transfer blocked(1)	
Unprivileged			Transfer blocked	OK

1. When a transfer is blocked, the transfer completes but the corresponding writes are ignored, and reads return 0s.

- *Power control (PWR)*

  By default, after a power-on or a system reset, all PWR registers except PWR_PRIVCFGR, can be read or written in both privileged and unprivileged modes.

  When secure privileged bit SPRIV is set in PWR_PRIVCFGR, reading and writing the PWR securable registers are possible only in privileged mode. Write access to this bit is ignored if TrustZone is disabled (TZEN = 0xC3).

  When non-secure privileged bit NSPRIV is set in PWR_PRIVCFGR, reading and writing the PWR non-secure registers are possible only in privileged mode.

  See *Section 10: Power control (PWR)* for details.

- *Secure clock and reset (RCC)*

  By default, after a power-on or a system reset, all RCC registers except RCC_PRIVCFGR can be read or written in both privileged and unprivileged modes.

  When secure privileged bit SPRIV is set in RCC_PRIVCFGR, reading and writing the RCC securable bits are possible only in privileged mode. Write access to this bit is ignored if TrustZone is disabled (TZEN = 0xC3).

  When non-secure privileged bit NSPRIV is set in RCC_PRIVCFGR, reading and writing the RCC non-secure bits are possible only in privileged mode.

  See *Section 11: Reset and clock control (RCC)* for details.

- *Real time clock (RTC)*

  By default after any backup domain reset, all RTC registers except RTC_PRIVCFGR, can be read or written in both privileged and unprivileged modes.

  When PRIV bit is set in privileged-only RTC_PRIVCFGR:

  – Writing the RTC registers is possible only in privileged mode.
  – Reading the RTC_SECCFGR, RTC_PRIVCFGR, RTC_TR, RTC_DR, RTC_SSR, RTC_PRER and RTC_CALR is always possible in privileged and unprivileged modes.

  All the other RTC registers can be read only in privileged mode.

  When PRIV bit is cleared in privileged-only RTC_PRIVCFGR register, it is still possible to restrict access to privileged mode to some RTC registers by setting dedicated control bits: INITPRIV, CALPRIV, TSPRIV, WUTPRIV, ALRAPRV, or ALRBPRIV.

  See *Section 46: Real-time clock (RTC)* chapter for details.

- *Tamper and backup registers (TAMP)*

  By default after any backup domain reset, all TAMP registers except TAMP_PRIVCFGR can be read or written in both privileged and unprivileged modes.

  When PRIV bit is set in privileged-only TAMP_PRIVCFGR:

  – Writing the TAMP registers is possible only in privileged mode, except for the backup registers and the monotonic counters that have their own protection setting.
  – Reading the TAMP_SECCFGR or TAMP_PRIVCFGR is always possible in privilege and unprivilege modes. All the other TAMP registers can be read only in privilege mode, except for the backup registers and the monotonic counters that have their own protection setting.

The application can also:

– make TAMP_COUNT1R register read and write privileged-only by setting the CNTPRIV bit in TAMP_PRIVCFGR

– increase security for two of the three protection zones in backup registers, using BKPRWPRIV and BKPWPRIV bits in TAMP_PRIVCFGR:

– Make protection zone 1 read privileged, write privileged.

– Make protection zone 2 read privileged or unprivileged, write privileged.

– Protection zone 3 is always read and write privileged or unprivileged.

- *General-purpose I/Os (GPIO)*

  All GPIO registers can be read and written by privileged and unprivileged accesses, whatever the security state (secure or non-secure).

- *Extended interrupts and event controller (EXTI)*

  The EXTI peripheral is able to protect event register bits from being modified by unprivileged accesses. The protection is individually activated per input event via the register bits in the privileged-only EXTI_PRIVCFGRx registers. When an input event is configured as privileged, only a privileged application can change the configuration (including security if applicable), change the masking or clear the status of this input event.

  The security configuration in EXTI_PRIVCFGR1 and EXTI_PRIVCFGR2 can be globally locked after reset in EXTI_LOCKR.

  See *Section 23: Extended interrupts and event controller (EXTI)* for more details.

- *System configuration boot and security (SBS)*

  All SBS registers can be read and written in both privileged and unprivileged modes, except:

  – FPUSEC bit in SBS_SECCFGR registers (privileged only)

  – SBS registers for CPU configuration: SBS _CSLOCKR, SBS _FPUIMR, and SBS _CNSLCKR

  See *Section 14: System configuration, boot, and security (SBS)* for more details.

3.8 Secure execution

Through a mix of special software and hardware features, the devices ensure the correct operation of their functions against abnormal situations caused by programmer errors, software attacks through network access or local attempt for tampering code execution.

This section describes the hardware features specifically designed for secure execution.

3.8.1 Memory protection unit (MPU)

The Cortex-M33 includes a memory protection unit (MPU) that can restrict the read and write accesses to Each memory region (including those mapped to peripherals), based on one or more of the following parameters

- Cortex-M33 operating mode (privileged, unprivileged)
- data/instruction fetch

The memory map and the programming of the non-secure and secure MPUs split memory into regions (up to eight for the non-secure, and up to twelve for the TrustZone). Secure MPU is only available when TrustZone is activated.

3.8.2 Embedded flash memory write protection

The embedded flash memory write protection (WRP) prevents illegal or unwanted write/erase to special sections of the embedded flash memory user area (system area is permanently write protected).

Write protected area is defined through the option bytes, writing the start and end addresses: two write-protected areas can be defined in each bank, with the granularity of a 32-Kbyte page.

WRP areas can be modified through option byte changes unless corresponding FLASH_WRPSGNxR has its UNLOCK option bit cleared (meaning ROM emulation). UNLOCK can be set only when regressing to PRODUCT_STATE=Open.

Note: Bank erase aborts when it contains a write-protected area (WRP or HDP area).

3.8.3 Tamper detection and response

Principle

The devices include active protection of critical security assets against temperature, voltage and frequency attacks, with the following features:

- erasure of device secrets upon tamper detection
- improved guarantee of safe execution for the CPU and its associated security peripherals, including:
  - out-of-range voltage (example: V_{BAT}, V_{DDA}), temperature and clocking (LSE) detection
  - security watchdog IWDG clocked by the internal oscillator LSI
  - possible selection of internal oscillator HSI as system clock
- power supply protection
  - RTC/TAMP domain powered automatically with V_{DD} or V_{BAT}

See *Section 47: Tamper and backup registers (TAMP)* for more details.

Tamper detection sources

The devices support eight active input/output pins, allowing four independent active-tamper meshes, or up to seven meshes if the same output pin is shared by several input pins (for a total of eight active-tamper I/Os). The active-tamper balls are mapped in the center of packages that can be used in POS market (such as WLCSP80).

The active pins are clocked by the LSE, and are functional in different system operating modes (Run, Sleep, Stop, or Standby), and in VBAT mode. Refer to TAMP pins functionality over modes for list of tamper pins and their availability across power modes

Detection time is programmable, and a digital filtering is available (tamper triggered after two false comparisons in four consecutive comparison samples).

Note: Timestamps are automatically generated when a tamper event occurs.

The internal tamper sources are listed in *Table 13*.

Table 13. Internal tampers in TAMP

Tamper input	NOER bit number in TAMP_CR3	Tamper source
itamp1	0	Backup domain voltage continuous monitoring, functional in VBAT mode
itamp2	1	Temperature monitoring, functional in VBAT mode
itamp3	2	LSE monitoring(1), functional in VBAT mode
itamp4	3	HSE monitoring
itamp5	4	RTC calendar overflow (rtc_calovf)
itamp6	5	JTAG/SWD access
itamp7, 12, 13	6, 11, 12	Voltage monitoring (V_{CORE}, V_{REF+}), through ADC analog watchdog
itamp8	7	Monotonic counter overflow (generated internally)
itamp9	8	Fault generation for cryptographic peripherals (SAES, PKA, AES, RNG)
itamp11	10	IWDG timeout and potential tamper (IWDG reset when at least one enabled tamper flag is set)
itamp15	14	System fault detection

1. LSE missing or over frequency detection (> 2 MHz), Glitch filter (> 2 MHz).

Response to tampers

Each source of tamper in the device can be configured to trigger the following events:

- Generate an interrupt, capable of waking up the device from Stop and Standby modes (see TAMPxMSK bits in TAMP_CR2 register).
- Generate a hardware trigger for the low-power timers.
- Erase device secrets if the corresponding TAMPxNOER bit is cleared in TAMP_CR2 (for tamper pins) or TAMP_CR3 (for internal tamper). These erasable secrets are:
  - symmetric keys stored in backup registers (x32), in AES, HASH and OTFDEC (encrypted flash memory regions are read as 0)
  - asymmetric keys stored in PKA SRAM, erased when V_{DD} is present
  - other secrets stored in SRAM2 and CPU instruction cache memory (SRAM2 erased when V_{DD} is present)
  - nonvolatile information used to derive the DHUK in SAES is 0-ed until complete SRAM2 erase
  - 4-Kbyte backup SRAM (depending on configuration bit), erased when V_{DD} is present

Read/write accesses by software to all these secrets can be blocked, by setting the BKBLOCK bit in TAMP_CR2. The device secrets access is possible only when BKBLOCK is cleared, and no tamper flag is set for any enabled tamper source.

If V_{DD} is not present, the secrets that are erased when V_{DD} is present, are only erased at the next V_{DD} power on.

Note: Device secret erase is also triggered by setting the BKERASE bit in TAMP_CR2, or by performing a PRODUCT_STATE regression as defined in Section 3.11.2.

Device secrets are not reset by system reset or when the device wakes up from Standby mode.

Software filtering mechanism

Each tamper source can be configured not to launch an immediate erase, by setting the corresponding TAMPxNOER bit in TAMP_CR2 (for external tamper pin) or TAMP_CR3 (for internal tamper).

In such situation, when the tamper flag is raised, access to below secrets is blocked until all tamper flags are cleared:

- DHUK in SAES: fixed to a dummy value
- Backup registers, backup SRAM, SRAM2: read as 0, write-ignored
- AES, SAES and HASH peripherals: automatically reset by RCC
- PKA peripheral: reset, with memory use blocked (meaning PKA not usable)

Once the application, notified by the tamper event, analyzes the situation, there are two possible cases:

- The application launches secrets erase with a software command (confirmed tamper).
- The application just clears the flags to release secrets blocking (false tamper).

Note: If the tamper software fails to react to such a tamper flag, an IWDG reset triggers an automatic erasing of secrets.

Tamper detection and low-power modes

The effect of low-power modes on a tamper detection are summarized in *Table 14*.

Table 14. Effect of low-power modes on TAMP

Mode	Description
Sleep	No effect on tamper detection features. TAMP interrupts cause the device to exit the Sleep mode.
Stop	No effect on tamper detection features, except for level detection with filtering and active tamper modes that remain active only when the clock source is LSE or LSI. Tamper events cause the device to exit the Stop mode.
Standby	No effect on tamper detection features, except for level detection with filtering and active tamper modes which remain active only when the clock source is LSE or LSI. Tamper events cause the device to exit the Standby mode.

3.9 Secure storage

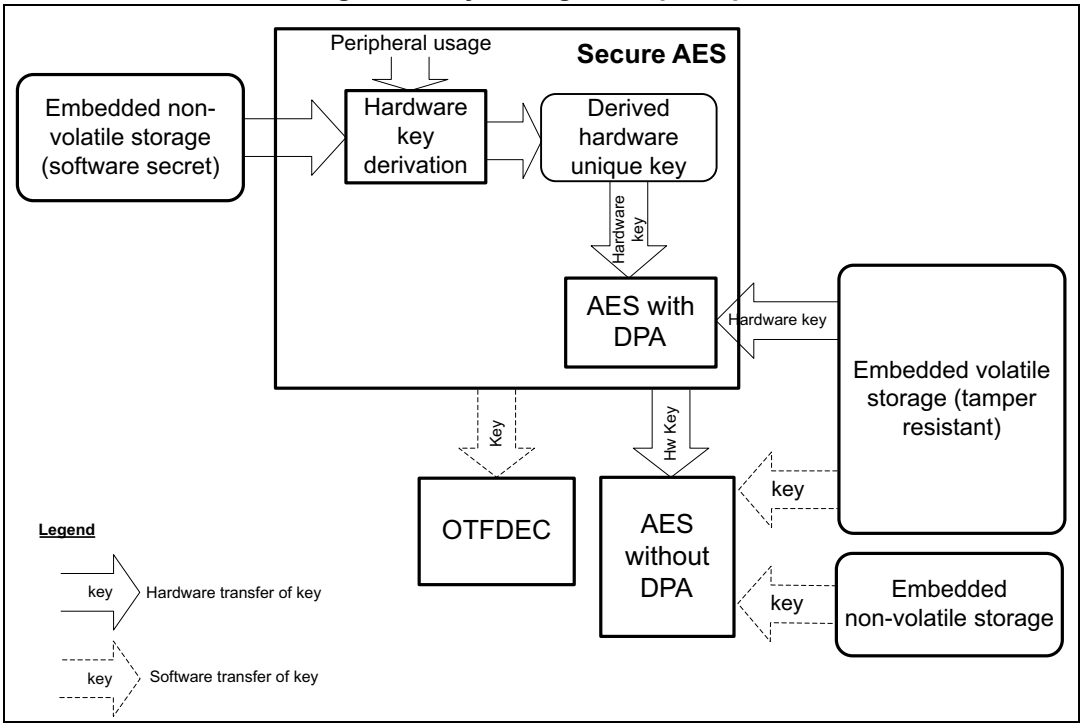
A critical feature of security systems is how long term keys are stored, protected, and provisioned. Such keys are typically used for loading a boot image, or handling of critical user data.

Figure 9 shows how key management service application can use the AES engine for example to compute external image decryption keys. Non-volatile keys are stored in the flash memory in a dedicated area including access control (see *Section 3.7.1*), while volatile

key storage consists in the battery-powered, tamper-protected SRAM or registers in TrustZone-aware TAMP.

Figure 9 also shows keys that are manipulated by software (like OTFDEC keys), or keys that are managed only by hardware (like DHUK). More information on those hardware keys can be found in *Section 3.9.1*.

Figure 9. Key management principle



Details on tamper protection is found in *Section 3.8.3*, while TAMP TrustZone features are briefly described in *Section 3.6.5*.

3.9.1 Hardware secret key management

As shown in the previous figure, the devices propose a better protection for application keys, using hardware secret keys. These AES keys can be made usable to the application, without exposing them in clear-text (unencrypted). Such keys also become immediately unusable in case of tamper.

There are three different sources of hardware secret keys:

- DHUK: derived keys based on 256-bit nonvolatile device unique secret in flash memory. The flash memory provides value provisioned during product manufacturing (called RHUK). The generation of DHUK key takes into account the TrustZone state, the OBK-HDPLx (temporal isolation counter), the EPOCH (regression counter allowing anti-replay protection) and key use state (KMOD).
- BHK: 256-bit application key stored in tamper-resistant volatile storage in TAMP

  This key is written at boot time, then read/write locked to application until next reset.
- XORK: result of a XOR of BHK and DHUK

Those keys can be used in the following modes:

- as a normal key, loading in write-only key registers (software key mode)
- as an encryption/decryption key for another key, to be used in the DPA-resistant SAES (wrapped key mode)
- as an encryption/decryption key for another key, to be used in a faster AES engine (shared key mode)

3.9.2 Unique ID

The devices store a 96-bit ID that is unique to each device (see *Section 76.1: Unique device ID register (96 bits)*).

Application services can use this unique identity key to identify the product in the cloud network, or make it difficult for counterfeit devices or clones to inject untrusted data into the network.

Alternatively, the 256-bit device unique key (DHUK) can be used (see *Section 3.9.1*).

3.10 Crypto engines

The devices implement state-of-the-art cryptographic algorithms featuring key sizes and computing protection as recommended by national security agencies such as NIST for the U.S.A, BSI for Germany or ANSSI for France. Those algorithms are used to support privacy, authentication, integrity, entropy and identity attestation.

The embedded crypto engines reduce weaknesses on the implementation of critical cryptographic functions, preventing, for example, the use of weak cryptographic algorithms and key sizes. They also enable lower processing times and lower power consumption when performing cryptographic operations, offloading those computations from Cortex-M33. This is especially true for asymmetric cryptography.

For product certification purpose, ST can provides certified device information on how these security functions are implemented and validated.

For more information on crypto engine processing times, refer to their respective sections in the reference manual.

3.10.1 Crypto engines features

Table 15 lists the accelerated cryptographic operations available in the devices. Two AES accelerators are available (both can be reserved to secure application only).

Note: Additional operations can be added using firmware. The PKA can accelerate asymmetric crypto operations (like key pair generation, ECC scalar multiplication, point on curve check). See Section 36: Public key accelerator (PKA) for more details.

Table 15. Accelerated cryptographic operations

Operations	Algorithm	Specification	Length of keys (in bit)	Modes
Get entropy	RNG	NIST SP800-90B(1)	N/A	Software and hardware(2) modes running in parallel
Encryption, decryption	AES	FIPS PUB 197 NIST SP800-38A	128, 256	ECB, CBC, CTR(3)
Authenticated encryption or decryption		NIST SP800-38C NIST SP800-38D	128, 256	GCM, CCM
Cipher-based message authentication code		NIST SP800-38D	128, 256	GMAC
Checksum	SHA-1	FIPS PUB 180-4	N/A	Digest 160-bit
Cryptographic hash	SHA-2		-	SHA-224, SHA-256 SHA2-384, SHA2-512
Keyed-hashing for message authentication	HMAC	FIPS PUB 198-1 IETF RFC 2104	Short, long (>64 bytes)	-
Encryption/decryption key-pair generation(4)	RSA	IETF RFC 8017 NIST SP800-56B	Up to 4160	RSAES-OAEP
Signature(4) with hashing	RSA	IETF RFC 8017 FIPS PUB 186-4	Up to 4160	PKCS1-v1_5, PSS
Signature verification	ECDSA	ANSI X9.62 IETF RFC 7027 FIPS PUB 186-4	Up to 640	Refer to table 'Family of supported curves for ECC operations' in PKA section for details
Key agreement	ECDH	ANSI X9.42		

1. Certifiable using STMicroelectronics reviewed documents.
2. Random numbers distribution to SAES and PKA using a dedicated hardware bus.
3. ECB and CBC chaining modes protected against side-channel and timing attacks in SAES (see *Section 3.10.2*).
4. Private key cryptography protected against side-channel and timing attacks.

Note: Binary curves, Edwards curves and Curve25519 are not supported by the PKA.

3.10.2 Secure AES co-processor (SAES)

The devices provide an additional on-chip hardware AES encryption and decryption engine, that implements counter-measures and mitigations against power and electromagnetic side-channel attacks.

Clocked by the system clock the SAES results in very good performance for a dpa resistant hardware accelerator. The SAES engine supports 128-bit or 256-bit key in electronic code book (ECB), cipher block chaining (CBC), (CTR), (GCM), (CCM), (GMAC) modes.

As shown in *Section 3.9*, the SAES can be used for extra-secure on-chip storage for sensitive information. It can also be made secure-only.

For more information, refer to *Section 34: Secure AES coprocessor (SAES)*.

3.10.3 On-the-fly decryption engine (OTFDEC)

The OTFDEC TrustZone-aware peripheral proposes on-the-fly decryption of encrypted images stored on external flash memory, connected through the OCTOSPI. This decryption process introduces almost no additional cycle overhead when the standard NOR flash memory is used. The OTFDEC can also be used to encrypt flash memory images on the device (for example to encrypt with a device unique secret key).

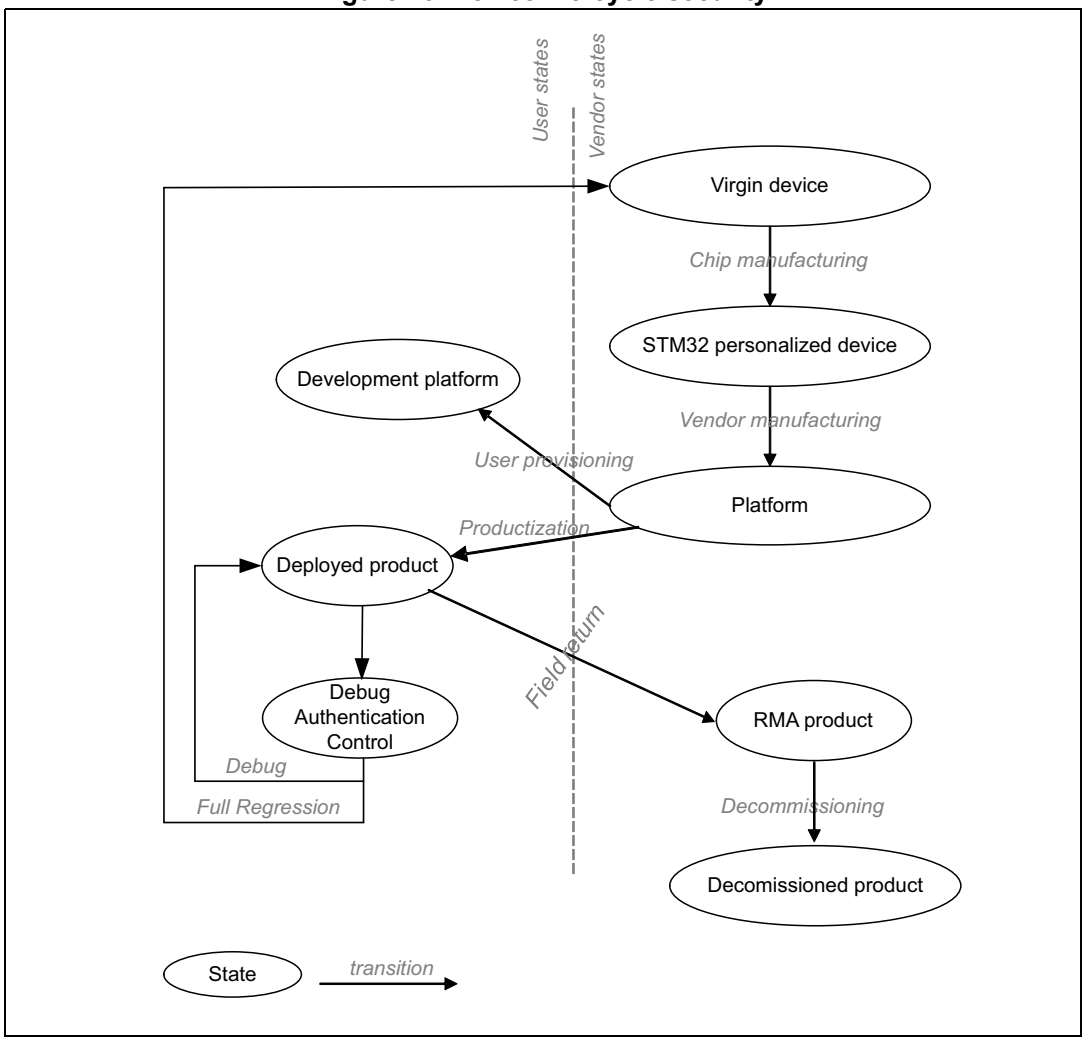
When a tamper event is confirmed in TAMP, all OTFDEC keys are erased and encrypted regions are read as 0 until the OTFDEC is properly initialized again.

An OTFDEC typical use is detailed in *Section 3.12.2*. For more details on the peripheral programming, refer to *Section 37: On-the-fly decryption engine (OTFDEC)*.

3.11 Product life-cycle

A typical IoT device life-cycle is summarized in *Figure 10*. For each step, the devices propose secure life-cycle management mechanisms embedded in the hardware.

Figure 10. Device life-cycle security



Additional details on the various phases and associated transitions, found either at the vendor or end-user premises, are summarized in *Table 16*.

Table 16. Main product life-cycle transitions

Transitions	Description
Device manufacturing	ST creates new STM32 devices, always checking for manufacturing defects. During this process, the device is provisioned with ROM firmware, secure firmware install (SFI) unique key pair, and a public ID.
Vendor manufacturing	One (or more) vendor is responsible for the platform assembly, initialization, and provisioning before delivery to the end user. This end user can use the final product (“productization” transition) or he/she can use the platform for software development (“user provisioning” transition).
Productization	The end user gets a product ready for use. All security functions of the platform are enabled, the debugging/testing features are restricted/disabled, and unique boot entry to immutable code is enforced.
User provisioning	Platform vendor prepares an individual platform for development, not to be connected to a production cloud network.
Field return	The product is returned for analysis to field return centers. Analysis is possible by opening it partially, or by launching a partial or a full regression. Such accesses require provisioning, including certificates provided by the vendor.

The features described hereafter contribute to secure the device life-cycle.

3.11.1 Product configurations and security services

The product is provisioned with ST security services in system flash, but can be configured to let the full control of the boot chain to OEMs. This is done thanks to the unique boot entry (FLASH_OPTSR: BOOT_UBE) option byte, allowing to select between the security services (ST-iROT: ST immutable root of trust), or OEM boot implementation (OEM-iROT: OEM immutable root of trust) to be installed in the user part of the flash memory.

Security services are provisioned by ST in system flash (immutable). They provides the root of trust of the platform managing the verification and the update of the first updatable code (uROT).

3.11.2 Life-cycle management

The product life-cycle allows to control access to different assets (code and data) of the product, including during development, manufacturing, and after sales.

It allows to provision the product with different distribution models taking care on the code and data provisioned.

Table 17. Typical product life-cycle phases

PRODUCT_STATE + DebugState		Debug (default configuration)	Comments
Open	Device open	Secure(1) and non-secure	Allows to develop the product, as it provides the debug of the code. Boot address must target a secure area when TrustZone is enabled. Using the boot pin allows to launch the bootloader. Using boot pin and BOOT_UBE allows to launch user flash code through ST-iROT.
Provisioning	Debug partially opened (only non-secure)	HDPL3 + Non-secure only	Allows to manage the provisioning of the product (partial or full). It allows to launch secure firmware Install, or bootloader to provision the product. Boot address must target a secure area when TrustZone is enabled. Boot on SRAM is not permitted.
iROT-Provisioned	Debug partially opened (only non-secure)	HDPL3 + Non-secure only	Assumes that immutable root of trust is installed, including its configuration (code, option bytes, secure storage). Boot address must target a secure area when TrustZone is enabled. Boot on SRAM is not permitted.
TZ-Closed	Debug partially opened (only non-secure)	HDPL3 + Non-secure only	Assumes that the Secure OS is installed in TrustZone (this state exist only if TZEN = 0xB4). Debug is opened for non-secure applications
Closed	Debug closed	NoDebug + debug authentication control	Assumes the product configuration as finalized. It allows to support debug authentication for in-the-field repair (read the dedicated application note).
Locked	Debug locked	None	Assumes the product configuration as finalized. The debug authentication is not permitted. The product is definitively in this state.
NS-Regression	Debug closed	NoDebug	This is a temporal (but nonvolatile) state to manage the partial regression to the TZ-Closed, removing all non-secure code and data including in secure storage.
Regression	Debug closed	NoDebug	This is a temporal state (but nonvolatile) to manage the full regression to Open state, removing all user flash code and data including in secure storage (HDPL1 to HDPL3).
Debug Constrained	Debug opened following debug authentication permissions	Depends upon permissions	This is a temporal state (until power-on-reset) to manage debug based on the permissions acquired by the debug authentication protocol.

1. Debug is not available when executing RSS code.

The supported transitions, summarized in *Figure 11*, can be requested (when available) through the debug interface or via the system bootloader.

Figure 11. PRODUCT_STATEs (simplified TrustZone activated view)

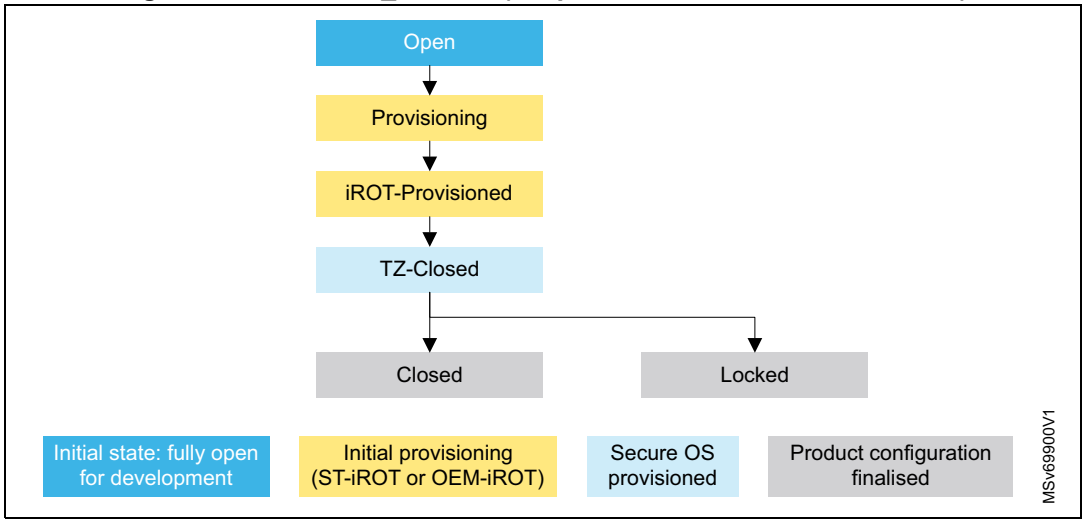


Figure 12. PRODUCT_STATEs (full TrustZone activated view)

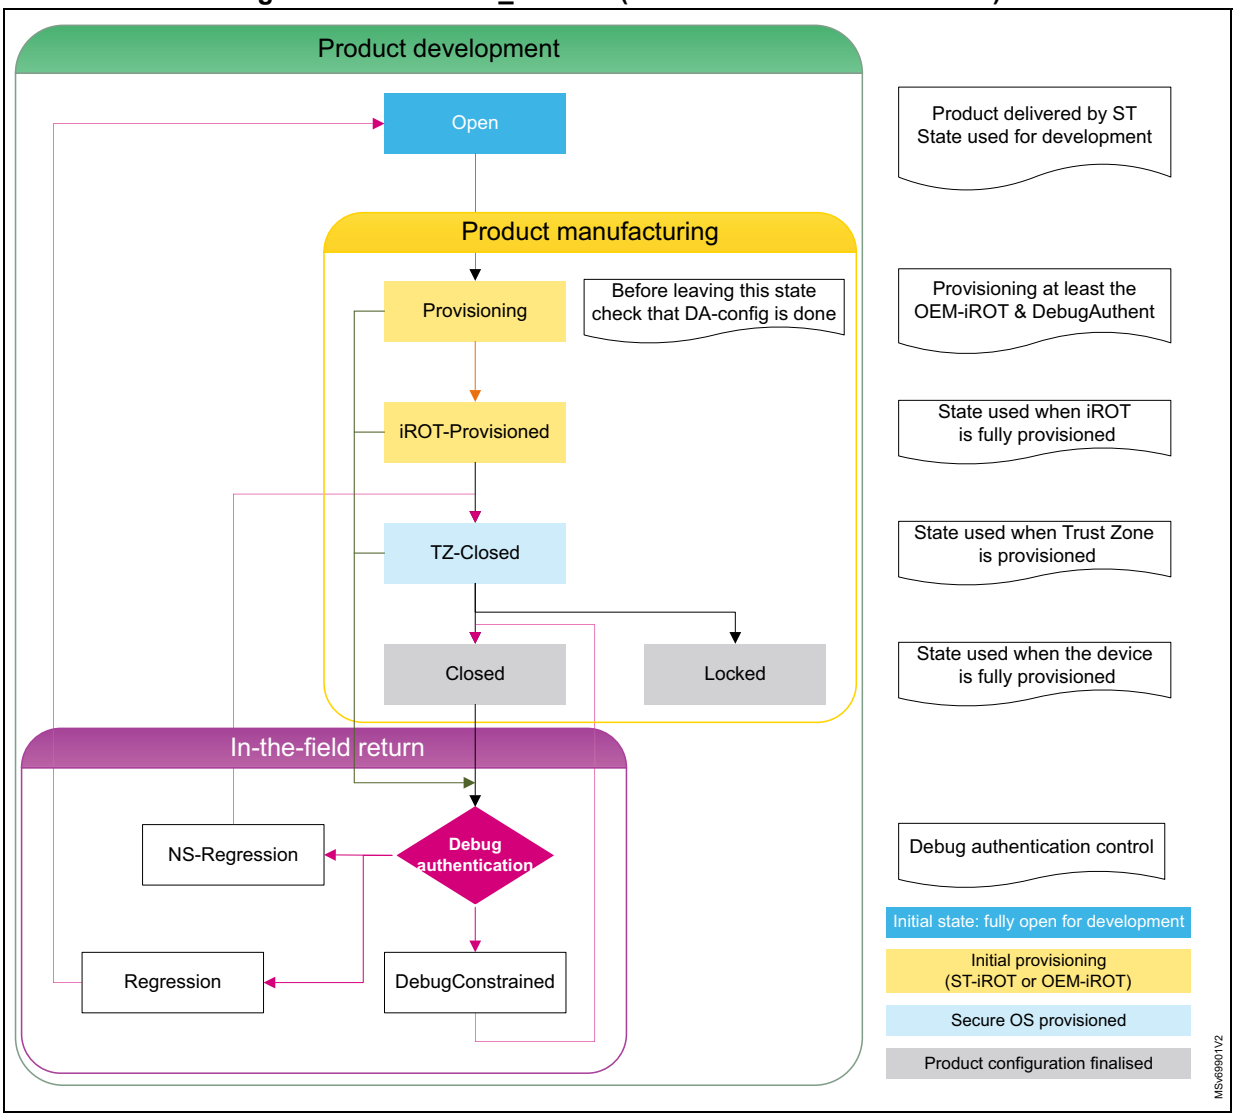


The full view of the life cycle includes the debug authentication part, to help product maintenance to manage field returns (in-the-field centers). The debug authentication control is ensured thanks to a protocol based on Arm PSA ADAC specification. It allows controlling that the host has a trusted certificate with permissions. Permissions definition allow a lot of flexibility, in our default model we consider: Full or Partial regression, or to open the debug for non-secure.

When TrustZone is disabled (TZEN = 0xC3), the state TZ-Closed does not exist, and the debug authentication is based on a password authentication method. For details on the debug authentication feature, refer to the corresponding application note.

The procotol includes a “DISCOVER” command allowing to get basic informations of the target: manufacturer, product name, device identifier, protocol version supported and crypto scheme for authentication (this help selecting between certificates and password).

3.11.3 Recommended product settings

To ease the product maintenance (in-the-field), we recommend to take benefit of the feature called debug authentication control. This enables the maintenance of product activating the debug and makes possible to manage regressions while considering the security of the sensible information.

This implies the following actions:

- set the PRODUCT_STATE in Closed state when the product has been configured
- When debug authentication control is based on certificates (when TrustZone enabled (TZEN = 0xB4)), then **provision the OEM-PublicKey and the SOC-Mask**. Setting the SOC-Mask to only propose the non-secure-debug and partial and full regression guaranty to be compliant with the Arm PSA security model.
- When debug authentication control is based on password (when TrustZone disabled (TZEN = 0xC3)), then only the HASH of the password has to be provisioned.

A dedicated application note is available to help configuring the platform, the host tools and to generate certificates.

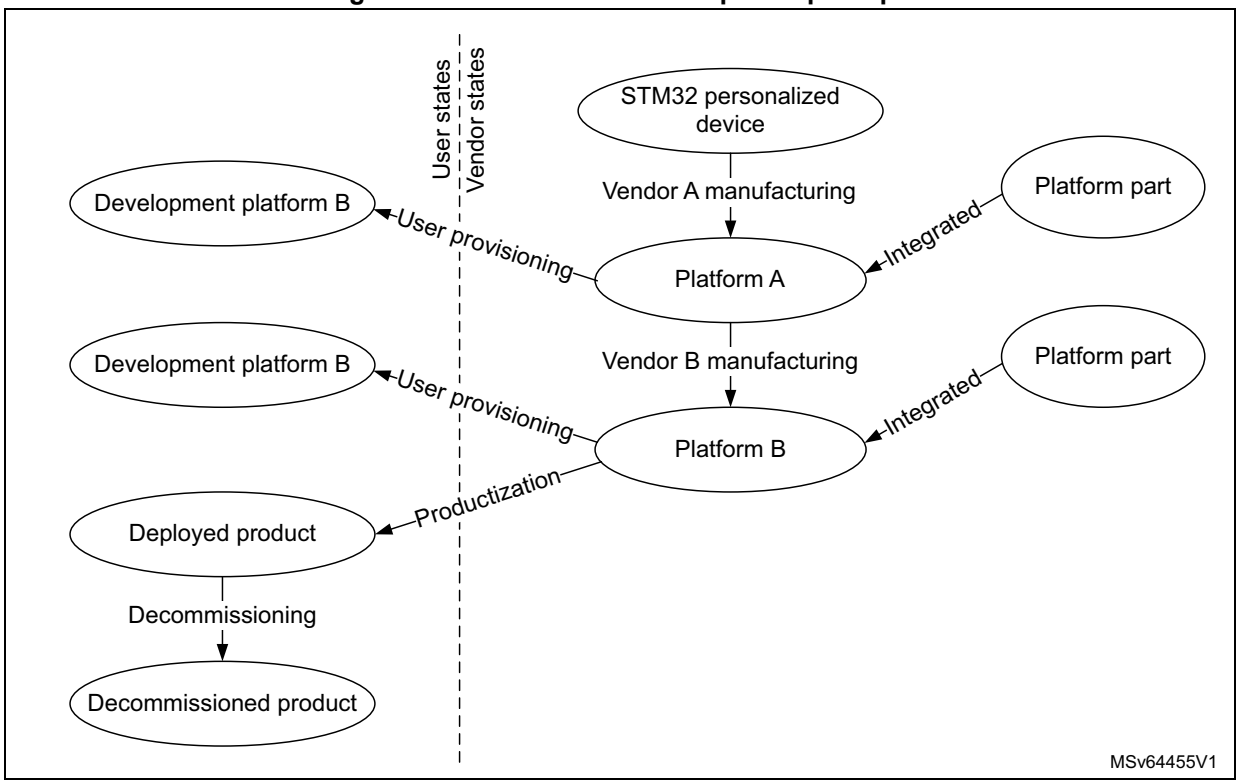
3.12 Software intellectual property protection and collaborative development

Thanks to software intellectual property protection and collaborative model, the devices allow the design of solutions integrating innovative third-party libraries.

Collaborative development is summarized in *Figure 13*. Starting from a personalized device sold by STMicroelectronics, a vendor A can integrate a portion of hardware and software on a platform A, that can then be used by a vendor B, who does the same before deploying a final product to the end users.

Note: Each platform vendor can provision individual platforms for development not to be connected to a production cloud network (“Development Platform X”).

Figure 13. Collaborative development principle



The features described hereafter contribute to securing the software intellectual property within such a collaborative development.

3.12.1 Software intellectual property protection

As described in *Section 3.11.2,* the hardware PRODUCT_STATE mechanism automatically controls the accesses to secrets provisioned in the device. The protection of these secrets are defined in *Table 18*.

Table 18. Software intellectual property protection with PRODUCT_STAT

PRODUCT_STATE protection level		Secrets protection
Open	Device open	No special protections.
Provisioning	Debug partially opened (only non-secure)	All areas protected with HDPL1 cannot be dumped, debugged or traced. The iROT can setup a higher level of protection.
iROT-Provisioned	Debug partially opened (only non-secure)	All areas protected with HDPL1 cannot be dumped, debugged or traced. The iROT can setup a higher level of protection.
TZ-Closed	Debug partially opened (only non-secure)	All peripherals and memories mapped as secure during secure boot cannot be dumped, debugged or traced
Closed	No debug	No debug possible except through debug authentication.
Locked	No debug	All data and code stored in the device or encrypted in external flash memory cannot be dumped clear-text, debugged or traced.

3.12.2 Software intellectual property protection with OTFDEC

As described in *Section 3.10.3,* the OTFDEC associated with the OCTOSPI is able to decrypt on the fly, the encrypted images stored in external SPI flash memories.

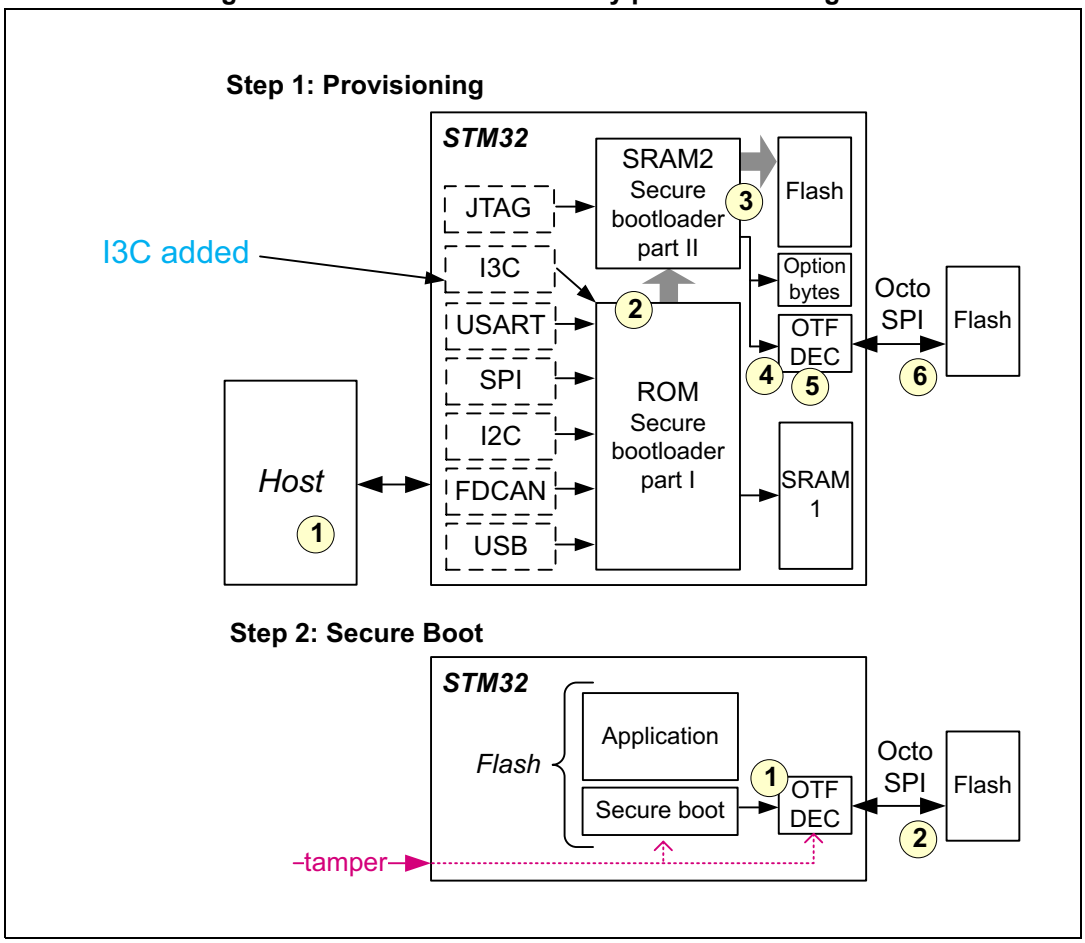
Thanks to this feature, the devices allow the installation of intellectual properties, in one of the following ways:

- over the air, with the image already encrypted with a key provisioned in the device
- through a provisioning host located in a trusted or a non-trusted environment/facility

Figure 14 illustrates this last case, with the provisioning, in a non-trusted environment, of software intellectual properties both in the embedded flash memory and in an external SPI flash memory (encrypted).

Note: Since the OTFDEC uses the AES in counter mode (CTR) to achieve the lowest possible latency, each time the content of one encrypted region is changed, the corresponding cryptographic context (key or initialization vector) must be changed. This constraint makes OTFDEC suitable to decrypt read-only data or code, stored in external NOR flash memory.

Figure 14. External Flash memory protection using SFI



Provisioning

Assuming the device is virgin, the first step is to provision both flash memories, as detailed below:

1. The user creates a SFI image, composed of:
   - encrypted internal firmware and data (including external flash memory drivers)
   - encrypted external firmware and data AES key (up to 4)
   - encrypted external firmware and data image
2. The secure bootloader stored in the system memory, loads the second part of the secure bootloader in SRAM2, through the supported communication ports (USART, SPI, I2C, FDCAN, USB, I3C and JTAG). This second part runs in the secure SRAM2 and is responsible for executing the SFI process, applying the SFI protocol thanks to the commands received through the above mentioned supported communication ports.
3. The internal flash memory is programmed with decrypted option bytes, internal firmware and data, and external firmware and data AES keys. Alternatively, device unique external firmware AES keys can be used instead of such global keys.
4. The OTFDEC is properly initialized with encrypted region information, including the corresponding external firmware and data AES key.
5. Running the SFI process, chunks of encrypted external firmware and data image are decrypted in the device, then re-encrypted in the OTFDEC.

6. After a chunk OTFDEC re-encryption, the user external flash memory programmer is responsible for programming the last encrypted chunks to the external SPI flash memories through the OCTOSPI.

Secure boot

After provisioning, each time the device initializes on a trusted firmware, the following actions are required:

1. Secure-boot firmware executes, programming the external firmware and data AES keys to the OTFDEC write-only key registers, along with the other needed information.
2. The application reads or executes the encrypted external firmware and data through the OCTOSPI in memory mapped mode, unless a tamper event is detected. In this case, all OTFDEC keys are erased and encrypted regions are read as 0 until the OTFDEC is properly initialized.

For more information on SFI solutions for the devices, refer to the AN4993 “*Overview secure firmware install (SFI)”.*

3.12.3 Other software intellectual property protections

The device additional protections to software intellectual property are:

- Invasive attacks such as physical tampering or perturbation are countered by detection then decommissioning of the device before the detected attack succeeds.
- Noninvasive attacks, such as side channel attacks, are countered by not leaking secret information via side channels (such as timing, power, and EM emissions).

4 Boot modes

At startup, a BOOT0 pin and NSBOOTADD[31:8]/SECBOOTADD[31:8] option bytes are used to select the boot memory address that includes:

- Boot from any address in user flash memory
- Boot from system memory
  - Bootloader
  - ST immutable root of trust (ST-iROT)
  - Root security service (RSS)
  - Debug authentication library (RSS-DA)

Embedded bootloader

The embedded bootloader is located in the system memory, programmed by ST during production. It is used to reprogram the flash memory by using USART, I2C, I3C, SPI, FDCAN, or USB_FS in device mode through the DFU (device firmware upgrade).

Refer to AN2606 "*STM32 microcontroller system memory boot mode*".

Embedded root security services (RSS)

The embedded RSS are located in the secure information block, programmed by ST during production.

Refer to AN4992 "*Overview secure firmware install (SFI)*".

Embedded immutable root of trust (ST-iROT)

The embedded ST-iROT in the system memory, programmed by ST during production. ST-iROT is the immutable root of trust managing the secure boot and secure install of the first updatable level to execute in a boot sequence.

Embedded debug authentication (ST-DA)

The embedded ST-DA in the system memory, programmed by ST during production. ST-DA is the library that manages the debug authentication protocol by allowing to securely reopen the debug or to launch regressions on secured products in the field.

4.1 STM32H562/H563 boot modes

Table 19 provides the detail of the boot mode when the TrustZone is disabled (TZEN = 0xC3), for the STM32H562/H563 devices.

Table 19. STM32H562/H563 Boot mode when TrustZone is disabled (TZEN = 0xC3)

PRODUCT_STATE	BOOT0 pin	Boot address option-byte selection	Boot area	ST programmed default value
Open	0	NSBOOTADD[31:8]	Boot address defined by user option byte NSBOOTADD[31:8]	Flash: 0x0800 0000
-	1	NA	Bootloader	Bootloader
Provisioning	x	NA	RSS	RSS
Provisioned, Closed, Locked	x	NSBOOTADD[31:8]	Boot address defined by user option byte NSBOOTADD[31:8]	Flash: 0x0800 0000

Note: The BOOT_UBE is only available on STM32H573x devices. Refer to Section 4.2.

Table 20 provides the detail of the boot mode when the TrustZone is enabled (TZEN=0xB4), for the STM32H562/H563 devices.

Table 20. STM32H562/H563 Boot mode when TrustZone is enabled (TZEN = 0xB4)

PRODUCT_STATE	BOOT0 pin	Boot address option-byte selection	Boot area	ST programmed default value
Open	0	SECBOOTADD[31:8]	Boot address defined by user option byte SECBOOTADD[31:8]	Flash: 0x0C00 0000
-	1	NA	Bootloader	Bootloader
Provisioning	x	NA	RSS	RSS
Provisioned, TZ_Closed, Closed, Locked	x	SECBOOTADD[31:8]	Boot address defined by user option byte SECBOOTADD[31:8]	Flash: 0x0C00 0000

Note: The BOOT_UBE is only available on STM32H573x devices. Refer to Section 4.2.

When TrustZone is enabled (TZEN=0xB4), the boot space must be in secure area. The SECBOOTADD0[24:0] option bytes are used to select the boot secure memory address. A unique boot entry option can be selected by setting the SECBOOT_LOCK option bit.

4.2 STM32H573x boot modes

Table 21 provides the detail of the boot mode when the TrustZone is disabled (TZEN = 0xC3), for the STM32H573x products.

Table 21. STM32H573x Boot mode when TrustZone is disabled (TZEN = 0xC3)

PRODUCT_STATE	BOOT0 pin	BOOT_UBE FLASH_OPTSR [29:22]	Boot address option-byte selection	Boot area	ST programmed default value

		0xB4	SECBOOTADD [31:8]	Boot address defined by user option byte SECBOOTADD[31:8]	Flash: 0x0C00 0000

When TrustZone is enabled (TZEN=0xB4), the boot space must be in secure area. The SECBOOTADD0[24:0] option bytes are used to select the boot secure memory address. A unique boot entry option can be selected by setting the SECBOOT_LOCK option bit.

5 Global TrustZone® controller (GTZC)

5.1 Introduction

This section describes the global TrustZone controller (GTZC) block that contains the following sub-blocks:

- **TZSC**: TrustZone security controller

  This sub-block defines the secure/privileged state of slave peripherals. It also controls the subregion area size and properties for the watermark memory peripheral controller (MPCWM). The TZSC informs some peripherals (such as RCC or GPIOs) about the secure status of each securable peripheral, by sharing with RCC and I/O logic.
- **MPCBB**: memory protection controller - block based

  This sub-block configures the internal RAM in a TrustZone-system product having segmented SRAM (pages of 512 bytes) with programmable-security and privileged attributes.
- **TZIC**: TrustZone illegal access controller

  This sub-block gathers all illegal access events in the system and generates a secure interrupt towards NVIC.

These sub-blocks are used to configure TrustZone system security in a product having bus agents with programmable-security and privileged attributes such as:

- on-chip RAM with programmable secure and/or privileged blocks (pages)
- AHB and APB peripherals with programmable security and/or privileged access
- off-chip memories with secure and/or privileged areas

5.2 GTZC main features

The GTZC main features are listed below:

- 3 independent 32-bit AHB interface for TZSC, TZIC and MPCBB
- TZIC accessible only with secure transactions
- Secure and non-secure access supported for privileged and unprivileged parts of TZSC and MPCBB
- Set of registers to define product security settings:
  - Secure/privileged blocks for internal SRAMs
  - Secure/privileged regions for external memories and internal backup SRAM
  - Secure/privileged access mode for securable peripherals
  - Secure/privileged access mode for securable masters

GTZC TrustZone system architecture

The Armv8-M supports security per TrustZone-M model with isolation between:

- a secure world, where usually security sensitive applications are run and critical resources are located
- a non-secure or public world (such as the usual non secure operating system and user space)

The TrustZone architecture is extended beyond AHB and Armv8-M with:

- AHB/APB bridge used as secure gate to block or propagate secure/non-secure and privileged/unprivileged transaction towards APB agents
- PPC (peripheral protection controller) used as secure gate to block or propagate secure/non-secure and privileged/unprivileged transaction towards AHB agents
- TrustZone block-based MPC firewalls used as secure gate to filter secure/non secure, privileged/unprivileged access towards internal SRAMs
- TrustZone watermark MPC firewalls used as secure gate to filter secure/non secure, privileged/unprivileged access towards external memories

AHB and APB peripherals can be categorized as:

- **privileged**: peripherals protected by AHB/APB firewall stub that is controlled from TZSC to define privilege properties
- **secure**: peripherals always protected by an AHB/APB firewall stub. These peripherals are always secure (such as TZIC)
- **securable**: peripherals protected by an AHB/APB firewall stub that is controlled from TZSC to define security properties (optional)
- **non-secure and unprivileged:** peripherals connected directly to AHB/APB interconnect without any secure gate
- **TrustZone-aware**: peripherals connected directly to the AHB or APB bus and implementing a specific TrustZone behavior (such as a subset of registers being secure). TrustZone-aware AHB masters always drive HNONSEC signal according to their security mode (such as Armv8-M core or DMA)

AHB securable masters can be configured in the TZSC to be secure/non-secure and/or privileged/unprivileged.

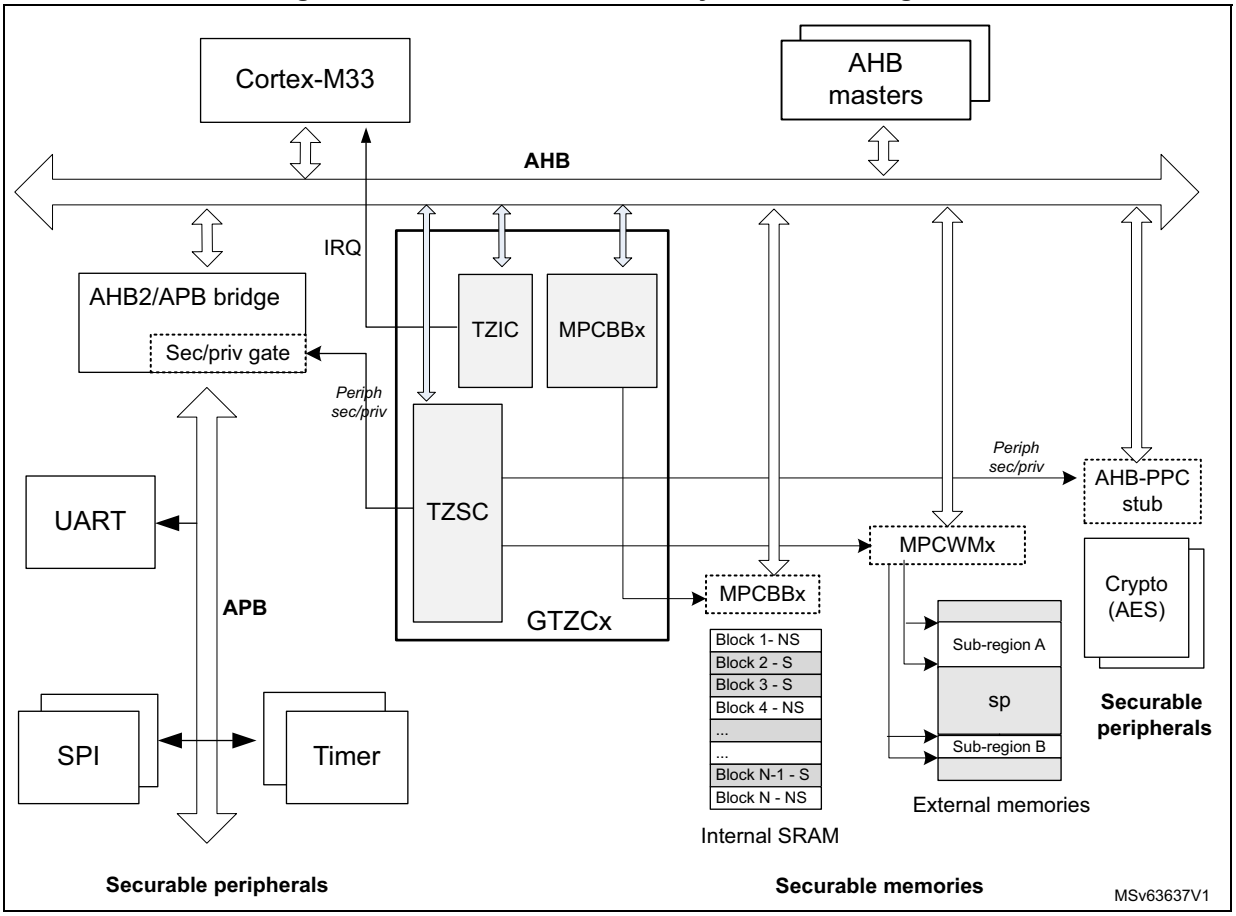
Application information

The TZSC, MPCBB, and TZIC can be used in one of the following ways:

- programmed during secure boot only, locked and not changed afterwards
- dynamically re-programmed when using specific application code or secure kernel (microvisor). When not locked, MPC secure blocks or region size can be changed by secure software executing from the secure FLASH region or secure SRAM. Same remark applies to the GTZC1_TZSC_SECCFGRx/PRIVCFGRx registers that define secure/privileged state of each peripheral.

The Armv8-M security architecture with secure, securable, and TrustZone-aware peripherals is shown in *Figure 15*.

Figure 15. GTZC in Armv8-M subsystem block diagram



5.3 GTZC implementation

The STM32H563/H573 and STM32H562 devices embed one instance of GTZC.

Table 23. GTZC features

GTZC sub-blocks	GTZC1
TZSC	X
TZIC	X
MPCBB sub-block (number of MPCBB)	X (3)

Table 24 shows the address offset of GTZC sub-blocks versus GTZC base address (refer to *Section 2.3* for GTZC1 base address).

Table 24. GTZC1 sub-block address offset

GTZC1 sub-block	Address offset
GTZC1_TZSC	0x0
GTZC1_TZIC	0x400
GTZC1_MPCBB1	0x800
GTZC1_MPCBB2	0xC00
GTZC1_MPCBB3	0x1000

Table 25 describes the characteristics of the available MPCWM.

Table 25. MPCWM resource assignment

GTZC	MPC	Target memory interface	Number of sec/non-sec and priv/unpriv regions	Watermark granularity (bytes)
GTZC1	MPCWM1	OCTOSPI1	2	128 K
	MPCWM2	FMC_NOR bank	2	128 K
	MPCWM3	FMC_NAND bank	1	128 K
		FMC_SDRAM bank 1	1	128 K
	MPCWM4	BKPSRAM	1	32
		FMC_SDRAM_bank 2	1	128 K

Table 26 describes the characteristics of the available MPCBB.

Table 26. MPCBB resource assignment

GTZC	MPC	Resource	Memory size (Kbytes)	Block size (bytes)	Number of blocks	Number of super-blocks
GTZC1	MPCBB1	SRAM1	256	512	512	16
	MPCBB2	SRAM2	64		128	4
	MPCBB3	SRAM3	320		640	20

5.4 GTZC functional description

5.4.1 GTZC block diagram

Figure 16 describes the combined feature of TZSC, MPCBB, and TZIC. Each sub-block is controlled by its own AHB configuration port.

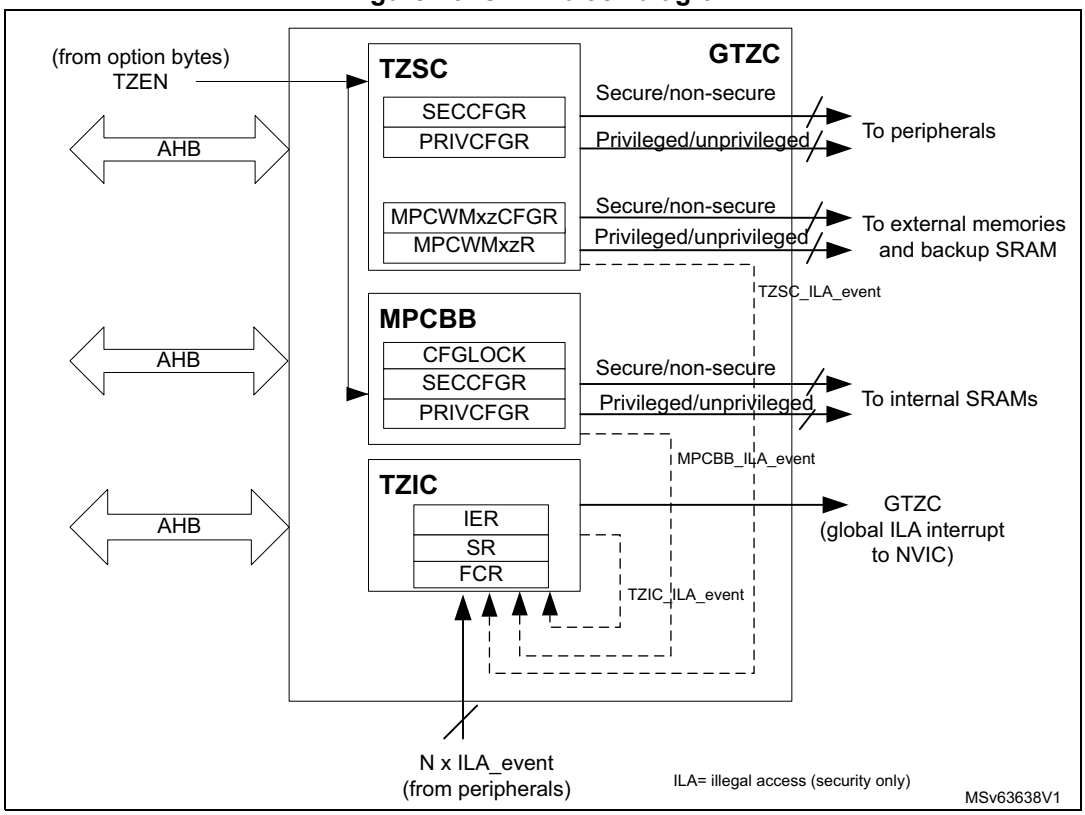
The TZSC defines which peripheral is secure and/or privileged. The privileged configuration bit of a peripheral can be modified by a secure privileged transaction when the peripheral is configured as secure. Otherwise, a privileged transaction (non-secure) is sufficient.

On the opposite, the secure configuration bit of a peripheral can be modified only with a secure privileged transaction if the peripheral is configured as privileged. Otherwise, a secure transaction (unprivileged) is sufficient.

The secure configuration bit of a given ram block can be modified only with a secure privileged transaction if the same RAM block is configured as privileged. Otherwise, a secure transaction (unprivileged) is sufficient.

The TZIC gathers illegal events generated within the system when an illegal access is detected. TZIC can then generate a secure interrupt towards the CPU if needed.

Figure 16. GTZC block diagram



5.4.2 Illegal access definition

Three different types of illegal access exist:

- Illegal non-secure access

  Any non-secure transaction trying to write a secure resource is considered as illegal, hence the addressed resource generates an illegal access interrupt for illegal write access and a bus error for illegal fetch access. There are some exceptions on secure and privileged configuration registers: these latter ones authorize non secure read access to secure registers (see GTZC1_TZSC_SECCFGRx and GTZC1_TZSC_PRIVCFGRx).

- Illegal secure access

  Any secure transaction trying to access non-secure block in internal block-based SRAM or watermarked memory is considered as illegal.

  A correct TZIC setting allows the capture of the associated event and then generates the GTZC_IRQn interrupt to the NVIC. This applies for read, write, and execute access.

  Concerning the MPCBB controller, there is an option to ignore secure data read/write access on non-secure SRAM blocks, by setting the SRWILADIS bit in the GTZC1_MPCBBz_CR register. Secure read and write data transactions are then allowed on non-secure SRAM blocks, while secure execution access remains not allowed.

  Any secure execute transaction trying to access a non-secure peripheral register is considered as illegal and generate a bus error.

- Illegal unprivileged access

  Any unprivileged transaction trying to access a privileged resource is considered as illegal. There is no illegal access event generated for illegal read and write access. The addressed resource follows a silent-fail behavior, returning all zero data for read and ignoring any write. No bus error is generated. A bus error is generated when any unprivileged execute transaction tries to access a privileged memory.

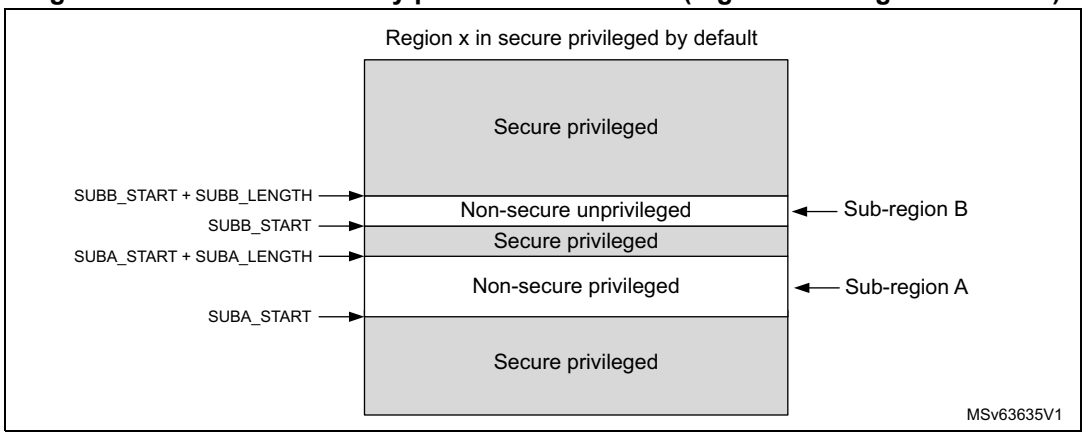
5.4.3 TrustZone security controller (TZSC)

The TZSC is composed of a configurable set of registers, providing the following features:

- Control of secure and privileged state for all peripherals, done through:
  - GTZC1_TZSC_SECCFGRx registers to control AHB/APB firewall stubs for the securable peripherals
  - GTZC1_TZSC_PRIVCFGRx registers to control AHB/APB firewall stubs for the privileged peripherals
- For watermark memory protection controller (external memories and backup SRAM), two independent regions can be defined and the following fields are used to program:
  - the start of the first protected subregion on the external memory/backup SRAM: SUBA_START[10:0]
  - the length of the first protected subregion on the external memory/backup SRAM: SUBA_LENGTH[11:0]
  - the start of the second protected subregion on the external memory/backup SRAM: SUBB_START[10:0]
  - the length of the second protected subregion on the external memory/backup SRAM: SUBB_LENGTH[11:0]

A control register for each subregion can be used to enable/disable the watermark memory protection controller as well as defining the right attributes of each subregion.

Figure 17. Watermark memory protection controller (region x/subregions A and B)



In *Figure 17*, region x represents the external memory or backup SRAM region (such as FMC bank, OCTOSPI1, or BKPSRAM). Secure and privileged attributes of subregions A and B are independently configurable. When no subregions are defined or enabled on the region x, then the default attribute of the region x is set as secure-privileged.

The following tables describe the secure/privileged properties of the common area of subregion A and B, when an overlap exists.

Table 27. Secure properties of subregions A and B

subregion A	subregion B	Properties of overlapped region A and B
Non-secure	Non-secure	Non-secure
Non-secure	Secure	Non-secure
Secure	Non-secure	Non-secure
Secure	Secure	Secure

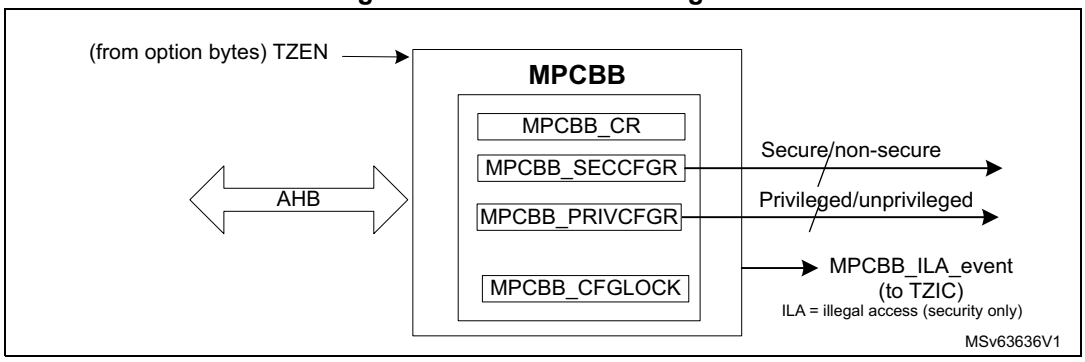
Table 28. Privileged properties of subregions A and B

subregion A	subregion B	Properties of overlapped region A and B
Unprivileged	Unprivileged	Unprivileged
Unprivileged	Privileged	Unprivileged
Privileged	Unprivileged	Unprivileged
Privileged	Privileged	Privileged

5.4.4 Memory protection controller - block based (MPCBB)

The MPCBB is composed of a configurable set of registers allowing to define security and privileged policy for internal SRAM memories. The security and privileged policy can be individually configured per each 512-byte block of SRAM.

Figure 18. MPCBB block diagram



To set up the MPCBB, the following actions are needed (for example at boot time):

- Secure firmware must define which memory blocks are secure by setting the correct bits in GTZC1_MPCBBz_SECCFGRx.
- Privileged firmware must define which memory blocks are privileged by setting the correct bits in GTZC1_MPCBBz_PRIVCFGRx.

A MPCBB super-block is made of 32 consecutive blocks. For each super-block, secure application can lock all related security/privileged bits using the correct bits in GTZC1_MPCBBz_CFGLOCK. This lock remains active until the next system reset.

*Note: The block size is 512 bytes. The super-block size is 512 * 32 = 16 Kbytes.*

5.4.5 TrustZone illegal access controller (TZIC)

The TZIC concentrates all illegal access source events. It is used only when the system is TrustZone enabled (TZEN = 0xB4).

TZIC allows to trace (flag) the event that triggered the secure illegal access interrupt. Register masks (GTZC1_TZIC_IERx) are available to filter unwanted event. On unmasked illegal event, TZIC generates the GTZC_IRQn interrupt to the NVIC.

For each illegal event source, a status flag and a clear bit exist (respectively within GTZC1_TZIC_SRx and GTZC1_TZIC_FCRx). The reset value of mask registers (GTZC1_TZIC_IERx) is such that all events are masked.

5.4.6 Power-on/reset state

The power-on and reset state of the TZSC clear to 0 all bits of GTZC1_TZSC_SECCFGRx and GTZC1_TZSC_PRIVCFGRx, meaning that all securable peripherals are respectively set to non-secure and unprivileged.

For internal SRAMx (x = 1 to 3), all GTZC1_MPCBBz_SECCFGRx and GTZC1_MPCBBz_PRIVCFGRx are set:

- to 0xFFFF FFFF, making these internal memories block secure and privileged by default when TrustZone security is enabled at system level (TZEN = 0xB4).
- to 0x0000 0000, making these internal memories block non-secure and unprivileged by default when TrustZone security is disabled at system level (TZEN = 0xC3)

For external memories and backup SRAM, all GTZC1_TZSC_MPCWMxzR registers are set:

- to 0x0000 0000, making these memories secure and privileged by default when TrustZone security is enabled a system level (TZEN = 0xB4).
- to 0x0800 0000, making these memories non-secure and non-privilege by default when TrustZone security is disabled at system level (TZEN = 0xC3)

Secure boot code can then program the security settings, making components secure or not as needed.

5.5 GTZC interrupts

TZIC is a secure peripheral, thus it systematically generates an illegal access event when accessed by a non-secure access. The MPCBB and TZSC are TrustZone-aware peripherals, meaning that secure and non-secure registers coexist within the peripheral.

Table 29. GTZC interrupt request

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit Sleep mode	Exit Stop mode	Exit Standby mode
GTZC	Illegal access	All flags in GTZC1_TZIC_SRx	All bits in GTZC1_TZIC_IERx	Write 1 in the bit GTZC1_TZIC_FCRx	Yes	Yes	No

5.6 GTZC1 TZSC registers

All registers are accessed only by words (32-bit).

5.6.1 GTZC1 TZSC control register (GTZC1_TZSC_CR)

Address offset: 0x000

Reset value: 0x0000 0000

Secure privileged access only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LCK
															rs

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **LCK**: lock the configuration of GTZC1_TZSC_SECCFGRx and GTZC1_TZSC_PRIVCFGRx until next reset

This bit is cleared by default and once set, it can not be reset until system reset.

0: configuration of all GTZC1_TZSC_SECCFGRx and GTZC1_TZSC_PRIVCFGRx not locked

1: configuration of all GTZC1_TZSC_SECCFGRx and GTZC1_TZSC_PRIVCFGRx locked

5.6.2 GTZC1 TZSC secure configuration register 1 (GTZC1_TZSC_SECCFGR1)

Address offset: 0x010

Reset value: 0x0000 0000

Write-secure access only.

This register can be written only by secure privileged transaction when the corresponding GTZC1_TZSC_PRIVCFGR signal is set to 1. If a given PRIV bit is not set, the equivalent SEC bit can be written by secure unprivileged transaction.

Read accesses are authorized for any type of transactions, secure or not, privileged or not.

5.6.4 GTZC1 TZSC secure configuration register 3 (GTZC1_TZSC_SECCFGR3)

Address offset: 0x018

Reset value: 0x0000 0000

Write-secure access only.

This register can be written only by secure privileged transaction when the corresponding GTZC1_TZSC_PRIVCFGR is set to 1. If a given PRIV is not set, the equivalent SEC bit can be written by secure unprivileged transaction.

Read accesses are authorized for any type of transactions, secure or not, privileged or not.

5.6.5 GTZC1 TZSC privilege configuration register 1 (GTZC1_TZSC_PRIVCFGR1)

Address offset: 0x020

Reset value: 0x0000 0000

Write-privileged access only.

This register can be read or written only by secure privileged transaction when the corresponding GTZC1_TZSC_SECCFGR signal is set to1. If a given SEC bit is not set, the equivalent PRIV bit can be read/written by non-secure privileged transaction.

Read accesses are authorized for any type of transactions, secure or not, privileged or not.

5.6.8 GTZC1 TZSC memory x subregion z watermark configuration register (GTZC1_TZSC_MPCWMxzCFGR) (z = A to B)

Address offset: Block A: 0x40 + 0x10 *(x - 1) (x = 1 to 4)

Address offset: Block B: 0x48 + 0x10 *(x - 1) (x = 1 to 4)

Reset value: 0x0000 0000

Secure privilege access only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	PRIV	SEC	Res.	Res.	Res.	Res.	Res.	Res.	SRLOCK	SREN
						rw	rw							rs	rw

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **PRIV**: Privileged subregion z of base region x

This bit is taken into account only if SREN is set.

0: Privileged and unprivileged accesses are granted in subregion z.

1: Only privileged accesses are granted in subregion z of region x.

Bit 8 **SEC**: Secure subregion z of base region x

This bit is taken into account only if SREN is set.

0: Only non-secure data accesses are granted to subregion z of region x.

1: Only secure data accesses are granted to subregion z of region x.

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **SRLOCK**: subregion z lock

This bit, once set, can be cleared only by a system reset.

0: GTZC1_TZSC_MPCWMxCFGR, GTZC1_TZSC_MPCWMxAR and GTZC1_TZSC_MPCWMxBR can be written.

1: Writes to GTZC1_TZSC_MPCWMxCFGR, GTZC1_TZSC_MPCWMxAR and GTZC1_TZSC_MPCWMxBR are ignored.

Bit 0 **SREN**: subregion z enable

0: subregion z is disabled. Access control of base region x applies to any access between this subregion start- and end-addresses.

1: subregion z of region x is enabled. Access control defined in GTZC1_TZSC_MPCWMx_CFGR applies to any access between this subregion start- and end-addresses, both defined in GTZC1_TZSC_MPCWMxAR and GTZC1_TZSC_MPCWMxBR.

Note: External memories that are watermark controlled start fully non-secure/unprivileged at reset when TZEN = 0xC3. When TZEN = 0xB4, external memories start fully secure/fully privileged (inverted reset-value).

5.6.9 GTZC1 TZSC memory x subregion A watermark register (GTZC1_TZSC_MPCWMxAR)

Address offset: 0x44 + 0x10 *(x - 1) (x = 1 to 4)

Reset value: 0x0000 0000

The given reset value is valid when TZEN = 0xB4. The reset value is 0x0800 0000 when TZEN = 0xC3.

Secure privilege access only.

When SUBA_START + SUBA_LENGTH is higher than the maximum size allowed for the memory, a saturation of SUBA_LENGTH is applied automatically.

When an overlap of subregion A and B exists, secure/privileged attributes of both subregions apply on the common section (see *Section 5.4.3*)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	SUBA_LENGTH[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Res.	Res.	Res.	Res.	Res.	SUBA_START[10:0]										
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **SUBA_LENGTH[11:0]**: Length of subregion A in region x

This field defines the length of the subregion A, to be multiplied by the granularity defined in *Table 25*.

When SUBA_START + SUBA_LENGTH is higher than the maximum size allowed for the memory, a saturation of SUBA_LENGTH is applied automatically.

If SUBA_LENGTH = 0, the subregion A is disabled.(SREN bit in GTZC1_TZSC_MPCMWxACFGR is cleared).

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 **SUBA_START[10:0]**: Start of subregion A in region x

This field defines the address offset of the subregion A, to be multiplied by the granularity defined in *Table 25*, versus the start of the region x.

External memories that are watermark controlled, start fully non-secure at reset when TZEN = 0xC3. When TZEN = 0xB4, external memories start fully secure (inverted reset value).

5.6.10 GTZC1 TZSC memory x subregion B watermark register (GTZC1_TZSC_MPCWMxBR)

Address offset: 0x4C + 0x10 *(x - 1) (x = 1 to 4)

Reset value: 0x0000 0000

The given reset value is valid when TZEN = 0xB4. The reset value is 0x0800 0000 when TZEN = 0xC3.

Secure privilege access only.

When SUBB_START + SUBB_LENGTH is higher than the maximum size allowed for the memory, a saturation of SUBB_LENGTH is applied automatically.

When an overlap of subregion A and B exists, secure/privileged attributes of both subregions apply on the common section (see *Section 5.4.3*)

Res.	Res.	Res.	Res.	Res.	SUBB_START[10:0]										
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **SUBB_LENGTH[11:0]**: Length of subregion B in region x

This field defines the length of the subregion B, to be multiplied by the granularity defined in *Table 25*.

When SUBB_START + SUBB_LENGTH is higher than the maximum size allowed for the memory, a saturation of SUBB_LENGTH is applied automatically.

If SUBB_LENGTH = 0, the subregion B is disabled.(SREN bit in GTZC1_TZSC_MPCMWxBCFGR is cleared).

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 **SUBB_START[10:0]**: Start of subregion B in region x

This field defines the address offset of the subregion B, to be multiplied by the granularity defined in *Table 25*, versus the start of the region x.

External memories that are watermark controlled, start fully non-secure at reset when TZEN = 0xC3. When TZEN = 0xB4, external memories start fully secure (inverted reset value).

Refer to *Table 24: GTZC1 sub-block address offset*.

5.7 GTZC1 TZIC registers

All registers are accessed only by words (32-bit).

5.7.1 GTZC1 TZIC interrupt enable register 1 (GTZC1_TZIC_IER1)

Address offset: 0x000

Reset value: 0x0000 0000

Secure privileged access only.

This register is used to enable interrupt of illegal access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **LPTIM2IE**: illegal access interrupt enable for LPTIM2
0: interrupt disabled
1: interrupt enabled

Bit 30 **DTSIE**: illegal access interrupt enable for DTS
0: interrupt disabled
1: interrupt enabled

Bit 29 **UART12IE**: illegal access interrupt enable for UART12
0: interrupt disabled
1: interrupt enabled

Bit 28 **UART9IE**: illegal access interrupt enable for UART9
0: interrupt disabled
1: interrupt enabled

Bit 27 **UART8IE**: illegal access interrupt enable for UART8
0: interrupt disabled
1: interrupt enabled

Bit 26 **UART7IE**: illegal access interrupt enable for UART7
0: interrupt disabled
1: interrupt enabled

Bit 25 **DAC1IE**: illegal access interrupt enable for DAC1
0: interrupt disabled
1: interrupt enabled

Bit 24 **HDMICECIE**: illegal access interrupt enable for HDMICEC
0: interrupt disabled
1: interrupt enabled

Bit 23 **USART11IE**: illegal access interrupt enable for USART11
0: interrupt disabled
1: interrupt enabled

Bit 22 **USART10IE**: illegal access interrupt enable for USART10
0: interrupt disabled
1: interrupt enabled

Bit 21 **USART6IE**: illegal access interrupt enable for USART6
0: interrupt disabled
1: interrupt enabled

Bit 20 **CRSIE**: illegal access interrupt enable for CRS
0: interrupt disabled
1: interrupt enabled

Bit 19 **I3C1IE**: illegal access interrupt enable for I3C1
0: interrupt disabled
1: interrupt enabled

Bit 18 **I2C2IE**: illegal access interrupt enable for I2C2
0: interrupt disabled
1: interrupt enabled

Bit 17 **I2C1IE**: illegal access interrupt enable for I2C1
0: interrupt disabled
1: interrupt enabled

Bit 16 **UART5IE**: illegal access interrupt enable for UART5
0: interrupt disabled
1: interrupt enabled

Bit 15 **UART4IE**: illegal access interrupt enable for UART4
0: interrupt disabled
1: interrupt enabled

Bit 14 **USART3IE**: illegal access interrupt enable for USART3
0: interrupt disabled
1: interrupt enabled

Bit 13 **USART2IE**: illegal access interrupt enable for USART2
0: interrupt disabled
1: interrupt enabled

Bit 12 **SPI3IE**: illegal access interrupt enable for SPI3
0: interrupt disabled
1: interrupt enabled

Bit 11 **SPI2IE**: illegal access interrupt enable for SPI2
0: interrupt disabled
1: interrupt enabled

Bit 10 **IWDGIE**: illegal access interrupt enable for IWDG
0: interrupt disabled
1: interrupt enabled

Bit 9 **WWDGIE**: illegal access interrupt enable for WWDG
0: interrupt disabled
1: interrupt enabled

Bit 8 **TIM14IE**: illegal access interrupt enable for TIM14
0: interrupt disabled
1: interrupt enabled

Bit 7 **TIM13IE**: illegal access interrupt enable for TIM13
0: interrupt disabled
1: interrupt enabled

Bit 6 **TIM12IE**: illegal access interrupt enable for TIM12
0: interrupt disabled
1: interrupt enabled

Bit 5 **TIM7IE**: illegal access interrupt enable for TIM7
0: interrupt disabled
1: interrupt enabled

Bit 4 **TIM6IE**: illegal access interrupt enable for TIM6
0: interrupt disabled
1: interrupt enabled

Bit 3 **TIM5IE**: illegal access interrupt enable for TIM5
0: interrupt disabled
1: interrupt enabled

Bit 2 **TIM4IE**: illegal access interrupt enable for TIM4
0: interrupt disabled
1: interrupt enabled

Bit 1 **TIM3IE**: illegal access interrupt enable for TIM3
0: interrupt disabled
1: interrupt enabled

Bit 0 **TIM2IE**: illegal access interrupt enable for TIM2
0: interrupt disabled
1: interrupt enabled

5.7.2 GTZC1 TZIC interrupt enable register 2 (GTZC1_TZIC_IER2)

Address offset: 0x004

Reset value: 0x0000 0000

Secure privileged access only.

This register is used to enable interrupt of illegal access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31 **LPTIM5IE**: illegal access interrupt enable for LPTIM5
0: interrupt disabled
1: interrupt enabled

Bit 30 **LPTIM4IE**: illegal access interrupt enable for LPTIM4
0: interrupt disabled
1: interrupt enabled

Bit 29 **LPTIM3IE**: illegal access interrupt enable for LPTIM3
0: interrupt disabled
1: interrupt enabled

Bit 28 **LPTIM1IE**: illegal access interrupt enable for LPTIM1
0: interrupt disabled
1: interrupt enabled

Bit 27 **I2C4IE**: illegal access interrupt enable for I2C4
0: interrupt disabled
1: interrupt enabled

Bit 26 **I2C3IE**: illegal access interrupt enable for I2C3
0: interrupt disabled
1: interrupt enabled

Bit 25 **LPUART1IE**: illegal access interrupt enable for LPUART
0: interrupt disabled
1: interrupt enabled

Bit 24 **SPI5IE**: illegal access interrupt enable for SPI5
0: interrupt disabled
1: interrupt enabled

Bits 23:20 Reserved, must be kept at reset value.

Bit 19 **USBIE**: illegal access interrupt enable for USB
0: interrupt disabled
1: interrupt enabled

Bit 18 **SAI2IE**: illegal access interrupt enable for SAI2
0: interrupt disabled
1: interrupt enabled

Bit 17 **SAI1IE**: illegal access interrupt enable for SAI1
0: interrupt disabled
1: interrupt enabled

Bit 16 **SPI6IE**: illegal access interrupt enable for SPI6
0: interrupt disabled
1: interrupt enabled

Bit 15 **SPI4IE**: illegal access interrupt enable for SPI4
0: interrupt disabled
1: interrupt enabled

Bit 14 **TIM17IE**: illegal access interrupt enable for TIM17
0: interrupt disabled
1: interrupt enabled

Bit 13 **TIM16IE**: illegal access interrupt enable for TIM16
0: interrupt disabled
1: interrupt enabled

Bit 12 **TIM15IE**: illegal access interrupt enable for TIM15
0: interrupt disabled
1: interrupt enabled

Bit 11 **USART1IE**: illegal access interrupt enable for USART1
0: interrupt disabled
1: interrupt enabled

Bit 10 **TIM8IE**: illegal access interrupt enable for TIM8
0: interrupt disabled
1: interrupt enabled

Bit 9 **SPI1IE**: illegal access interrupt enable for SPI1
0: interrupt disabled
1: interrupt enabled

Bit 8 **TIM1IE**: illegal access interrupt enable for TIM1
0: interrupt disabled
1: interrupt enabled

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **UCPDIE**: illegal access interrupt enable for UCPD
0: interrupt disabled
1: interrupt enabled

Bit 1 **FDCAN2IE**: illegal access interrupt enable for FDCAN2
0: interrupt disabled
1: interrupt enabled

Bit 0 **FDCAN1IE**: illegal access interrupt enable for FDCAN1
0: interrupt disabled
1: interrupt enabled

5.7.3 GTZC1 TZIC interrupt enable register 3 (GTZC1_TZIC_IER3)

Address offset: 0x008

Reset value: 0x0000 0000

Secure privileged access only.

This register is used to enable interrupt of illegal access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

1: interrupt enabled

Bit 18 **RNGIE**: illegal access interrupt enable for RNG
0: interrupt disabled
1: interrupt enabled

Bit 17 **HASHIE**: illegal access interrupt enable for HASH
0: interrupt disabled
1: interrupt enabled

Bit 16 **AESIE**: illegal access interrupt enable for AES
0: interrupt disabled
1: interrupt enabled

Bit 15 **DCMIIE**: illegal access interrupt enable for DCMI
0: interrupt disabled
1: interrupt enabled

Bit 14 **ADC12IE**: illegal access interrupt enable for ADC1 and ADC2
0: interrupt disabled
1: interrupt enabled

Bit 13 **DCACHEIE**: illegal access interrupt enable for DCACHE
0: interrupt disabled
1: interrupt enabled

Bit 12 **ICACHEIE**: illegal access interrupt enable for ICACHE
0: interrupt disabled
1: interrupt enabled

Bit 11 **ETHIE**: illegal access interrupt enable for register of ETH
0: interrupt disabled
1: interrupt enabled

Bit 10 **FMACIE**: illegal access interrupt enable for FMAC
0: interrupt disabled
1: interrupt enabled

Bit 9 **CORDICIE**: illegal access interrupt enable for CORDIC
0: interrupt disabled
1: interrupt enabled

Bit 8 **CRCIE**: illegal access interrupt enable for CRC
0: interrupt disabled
1: interrupt enabled

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **VREFBUFIE**: illegal access interrupt enable for VREFBUF
0: interrupt disabled
1: interrupt enabled

Bit 0 **LPTIM6IE**: illegal access interrupt enable for LPTIM6
0: interrupt disabled
1: interrupt enabled

5.7.4 GTZC1 TZIC interrupt enable register 4 (GTZC1_TZIC_IER4)

Address offset: 0x00C

Reset value: 0x0000 0000

Secure privileged access only.

This register is used to enable interrupt of illegal access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 25 **MPCBB1_REGIE**: illegal access interrupt enable for MPCBB1 registers
0: interrupt disabled
1: interrupt enabled

Bit 24 **SRAM1IE**: illegal access interrupt enable for SRAM1
0: interrupt disabled
1: interrupt enabled

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **BKPSRAMIE**: illegal access interrupt enable for MPCWM4 (BKPSRAM) memory bank
0: interrupt disabled
1: interrupt enabled

Bit 19 **FMC_MEMIE**: illegal access interrupt enable for MPCWM2 (FMC_NOR bank), MPCWM3 (FMC_NAND bank and FMC_SDRAM bank 1), and MPCWM4 (FMC_SDRAM bank 2)
0: interrupt disabled
1: interrupt enabled

Bit 18 **OCTOSPI1_MEMIE**: illegal access interrupt enable for MPCWM1 (OCTOSPI1) memory bank
0: interrupt disabled
1: interrupt enabled

Bit 17 **TZIC1IE**: illegal access interrupt enable for GTZC1 TZIC registers
0: interrupt disabled
1: interrupt enabled

Bit 16 **TZSC1IE**: illegal access interrupt enable for GTZC1 TZSC registers
0: interrupt disabled
1: interrupt enabled

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **EXTIIE**: illegal access interrupt enable for EXTI
0: interrupt disabled
1: interrupt enabled

Bit 10 **RCCIE**: illegal access interrupt enable for RCC
0: interrupt disabled
1: interrupt enabled

Bit 9 **PWRIE**: illegal access interrupt enable for PWR
0: interrupt disabled
1: interrupt enabled

Bit 8 **TAMPIE**: illegal access interrupt enable for TAMP
0: interrupt disabled
1: interrupt enabled

Bit 7 **RTCIE**: illegal access interrupt enable for RTC
0: interrupt disabled
1: interrupt enabled

Bit 6 **SBSIE**: illegal access interrupt enable for SBS
0: interrupt disabled
1: interrupt enabled

Bit 5 Reserved, must be kept at reset value.

Bit 4 **OTFDEC1IE**: illegal access interrupt enable for OTFDEC1
0: interrupt disabled
1: interrupt enabled

Bit 3 **FLASHIE**: illegal access interrupt enable for FLASH memory
0: interrupt disabled
1: interrupt enabled

Bit 2 **FLASH_REGIE**: illegal access interrupt enable for FLASH registers
0: interrupt disabled
1: interrupt enabled

Bit 1 **GPDMA2IE**: illegal access interrupt enable for GPDMA2
0: interrupt disabled
1: interrupt enabled

Bit 0 **GPDMA1IE**: illegal access interrupt enable for GPDMA1
0: interrupt disabled
1: interrupt enabled

5.7.5 GTZC1 TZIC status register 1 (GTZC1_TZIC_SR1)

Address offset: 0x010

Reset value: 0x0000 0000

Secure privileged access only.

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **CMPCBB3_REGF**: clear the illegal access flag for MPCBB3 registers
0: no action
1: status flag cleared

Bit 28 **CSRAM3F**: clear the illegal access flag for SRAM3
0: no action
1: status flag cleared

Bit 27 **CMPCBB2_REGF**: clear the illegal access flag for MPCBB2 registers
0: no action
1: status flag cleared

Bit 26 **CSRAM2F**: clear the illegal access flag for SRAM2
0: no action
1: status flag cleared

Bit 25 **CMPCBB1_REGF**: clear the illegal access flag for MPCBB1 registers
0: no action
1: status flag cleared

Bit 24 **CSRAM1F**: clear the illegal access flag for SRAM1
0: no action
1: status flag cleared

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **CBKPSRAMF**: clear the illegal access flag for MPCWM4 (BKPSRAM) memory bank
0: no action
1: status flag cleared

Bit 19 **CFMC_MEMF**: clear the illegal access flag for MPCWM2 (FMC_NOR bank), MPCWM3 (FMC_NAND bank and FMC_SDRAM bank 1), and MPCWM4 (FMC_SDRAM bank 2)
0: no action
1: status flag cleared

Bit 18 **COCTOSPI1_MEMF**: clear the illegal access flag for MPCWM1 (OCTOSPI1) memory bank
0: no action
1: status flag cleared

Bit 17 **CTZIC1F**: clear the illegal access flag for GTZC1 TZIC registers
0: no action
1: status flag cleared

Bit 16 **CTZSC1F**: clear the illegal access flag for GTZC1 TZSC registers
0: no action
1: status flag cleared

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **CEXTIF**: clear the illegal access flag for EXTI
0: no action
1: status flag cleared

Bit 10 **CRCCF**: clear the illegal access flag for RCC
0: no action
1: status flag cleared

Bit 9 **CPWRF**: clear the illegal access flag for PWR

Refer to *Table 24: GTZC1 sub-block address offset*.

5.8 GTZC1 MPCBBz registers (z = 1 to 3)

All registers are accessed only by words (32-bit).

5.8.1 GTZC1 SRAMz MPCBB control register (GTZC1_MPCBBz_CR) (z = 1 to 3)

Address offset: 0x000

Reset value: 0x0000 0000

Secure privileged access only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31 **SRWILADIS**: secure read/write illegal access disable

This bit disables the detection of an illegal access when a secure read/write transaction access a non-secure blocks of the block-based SRAM (secure fetch on non-secure block is always considered illegal).

0: enabled, secure read/write access not allowed on non-secure SRAM block

1: disabled, secure read/write access allowed on non-secure SRAM block

Bit 30 **INVSECSTATE**: SRAMx clocks security state

This bit is used to define the internal SRAMs clocks control in RCC as secure or not.

0: SRAMs clocks are secure if a secure area exists in the MPCBB. It is non secure if there is no secure area.

1: SRAMs clocks are non-secure even if a secure area exists in the MPCBB, and secure even if no secure block is set in the MPCBB.

Bits 29:1 Reserved, must be kept at reset value.

Bit 0 **GLOCK**: lock the control register of the MPCBB until next reset

This bit is cleared by default and once set, it can not be reset until system reset.

0: control register not locked

1: control register locked

5.8.2 GTZC1 SRAMz MPCBB configuration lock register 1 (GTZC1_MPCBBz_CFGLOCK1) (z = 1 to 3)

Address offset: 0x010

Reset value: 0x0000 0000

Secure privileged access only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:0 **SPLCKy**: Security/privilege configuration lock for super-block (y = 31 to 0)
This bit is set by software and can be cleared only by system reset.
0: GTZC1_MPCBBz_SECCFGRy and GTZC1_MPCBBz_PRIVCFGRy can be written.
1: Writes to GTZC1_MPCBBz_SECCFGRy and GTZC1_MPCBBz_PRIVCFGRy are ignored

5.8.3 GTZC1 SRAMz MPCBB security configuration for super-block x register (GTZC1_MPCBBz_SECCFGRx) (z = 1 to 3)

Address offset: 0x100 + 0x4 * x, (x = 0 to 31)

Reset value: 0xFFFF FFFF

The given reset value is valid when TZEN = 0xB4. The reset value is 0x0000 0000 when TZEN = 0xC3.

Write access to this register is secure only. Any read is allowed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SECy**: Security configuration for block y (y = 31 to 0)
0: Non-secure access only to block y, belonging to super-block x. Secure access is also allowed if the SRWILADIS bit is set in GTZC1_MPCBBz_CR.
1: Secure access only to block y, belonging to super-block x.
Unprivileged write to this bit is ignored if PRIVy bit is set in GTZC1_MPCBBz_PRIVCFGRx.
Writes are ignored if SPLCKx bit is set in GTZC1_MPCBBz_CFGLOCK.

5.8.4 GTZC1 SRAMz MPCBB privileged configuration for super-block x register (GTZC1_MPCBBz_PRIVCFGRx) (z = 1 to 3)

Address offset: 0x200 + 0x * x, (x = 0 to 31)

Reset value: 0xFFFF FFFF

The given reset value is valid when TZEN = 0xB4. The reset value is 0x0000 0000 when TZEN = 0xC3. Write access to this register is privileged only. Any read is allowed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **PRIVy**: Privileged configuration for block y, belonging to super-block x (y = 31 to 0).
0: Privileged and unprivileged access to block y, belonging to super-block x
1: Only privileged access to block y, belonging to super-block x
Non-secure write to this bit is ignored if SECy bit is set in GTZC1_MPCBBz_SECCFGRx.
Writes are ignored if SPLCKx bit is set in GTZC1_MPCBBz_CFGLOCK.

5.8.5 GTZC1 MPCBBz register map (z = 1 to 3)

Refer to *Table 24: GTZC1 sub-block address offset*.

6 RAMs configuration controller (RAMCFG)

6.1 Introduction

The RAMCFG configures the features of the internal SRAMs (SRAM1, SRAM2, SRAM3, and BKPSRAM).

6.2 RAMCFG main features

The internal SRAM supports some of the features listed hereafter, configured in RAMCFG:

- Error code correction (ECC):
  - Single error detection and correction with interrupt generation
  - Double error detection with interrupt or NMI generation
  - Status with failing address
- Write protection (1-Kbyte granularity)
- SRAM software erase

6.3 RAMCFG functional description

6.3.1 Internal SRAMs features

Five SRAMs are embedded in the devices, each with specific features:

- SRAM1, SRAM2, SRAM3 are the main SRAMs.

  These SRAMs are made of several blocks that can be powered down in Stop mode to reduce consumption:
  - SRAM1: four 64-Kbyte blocks (total 256 Kbytes)
  - SRAM2: 16-Kbyte + 48-Kbyte blocks (total 64 Kbytes)
  - SRAM3: five 64-Kbyte blocks (total 320 Kbytes)

  The backup SRAM (BKPSRAM) can be retained in all low-power modes and when V_{DD} is off in VBAT mode.

  Refer to *Section 10: Power control (PWR)* for more details.
- SRAM2 is erased when a system reset occurs if the SRAM2_RST option bit is selected in the Flash memory user option bytes. SRAM1 and SRAM3 are erased when a system reset occurs if the SRAM13_RST option bit is selected in the Flash memory user option bytes. Refer to *Section 7: Embedded flash memory (FLASH)* for more details.
- SRAM2 and optionally backup SRAM are protected by the tamper detection circuit, and are erased by hardware in case of tamper detection. Refer to *Section 76: Tamper and backup registers (TAMP) (TBD)* for more details.
- The RAMCFG embeds the registers related to the internal SRAMs ECC, write protection and software erase.

The table below summarizes the features supported by each internal SRAM

Table 33. Internal SRAMs features

SRAM feature	SRAM1 (256 Kbytes)	SRAM2 (64 Kbytes)	SRAM3 (320 Kbytes)	BKPSRAM (4 Kbytes)
Optional retention in Standby mode	-	-	-	X
Optional retention in VBAT mode	-	-	-	X
Erased with tamper detection and Backup domain reset	-	X	-	X(1)
Optionally erased with system reset	X	X	X	-
Software erase	X	X	X	X
ECC	-	X	X	X
Write protection	-	X	-	-

1. Optional: BKPSRAM can be configured to be erased or not on tamper detection.

6.3.2 Error code correction (SRAM2, SRAM3, BKPSRAM)

The ECC is supported by SRAM2, SRAM3 and BKPSRAM when enabled with the SRAM2_ECC, SRAM3_ECC and BKPRAM_ECC user option bits. Refer to *Section 7: Embedded flash memory (FLASH)* for more details.

Seven ECC bits are added per 32 bits of SRAM, allowing two bits error detection and one bit error correction on memory read access.

As the ECC is calculated and checked for a 32-bit word, the byte and half-word write accesses are managed by the SRAM interface by first reading the whole word, then write the word again with the new byte/half-word value. ECC double errors are also detected during these byte or half-word AHB write accesses (read/modify/write done by interface). The byte or half-word write access latency is 2 AHB clock cycles .

Caution: In case of a byte or half-word write on SRAM with ECC, the read/modify/write operation is done in a buffer. The buffer content is written into the SRAM two AHB clock cycles after the SRAM AHB is released (when SRAM is no more accessed).

Single and double ECC errors

When a single error is detected, it is automatically corrected and the SEDC/CSEDC bits are set in the *RAMCFG memory interrupt status register (RAMCFG_MxISR)* and *RAMCFG memory x interrupt clear register x (RAMCFG_MxICR)* respectively. An interrupt is generated if enabled by the SEIE bit in the *RAMCFG memory x interrupt enable register (RAMCFG_MxIER)*. The failing address is stored in the *RAMCFG memory x ECC single error address register (RAMCFG_MxSEAR)* if the ALE bit is set in the *RAMCFG memory x control register (RAMCFG_MxCR)*.

Caution: Single errors cannot be detected when the SEDC bit is set.

When a double error is detected, the DED and CDED bits are set in the *RAMCFG memory interrupt status register (RAMCFG_MxISR)* and *RAMCFG memory x interrupt clear register x (RAMCFG_MxICR)* respectively. An interrupt or NMI is generated if enabled by the DEIE or ECCNMI bit in the *RAMCFG memory x interrupt enable register (RAMCFG_MxIER)*. The failing address is stored in the *RAMCFG memory x ECC double error address register*

(RAMCFG_MxDEAR) if the ALE bit is set in the *RAMCFG memory x control register (RAMCFG_MxCR)*.

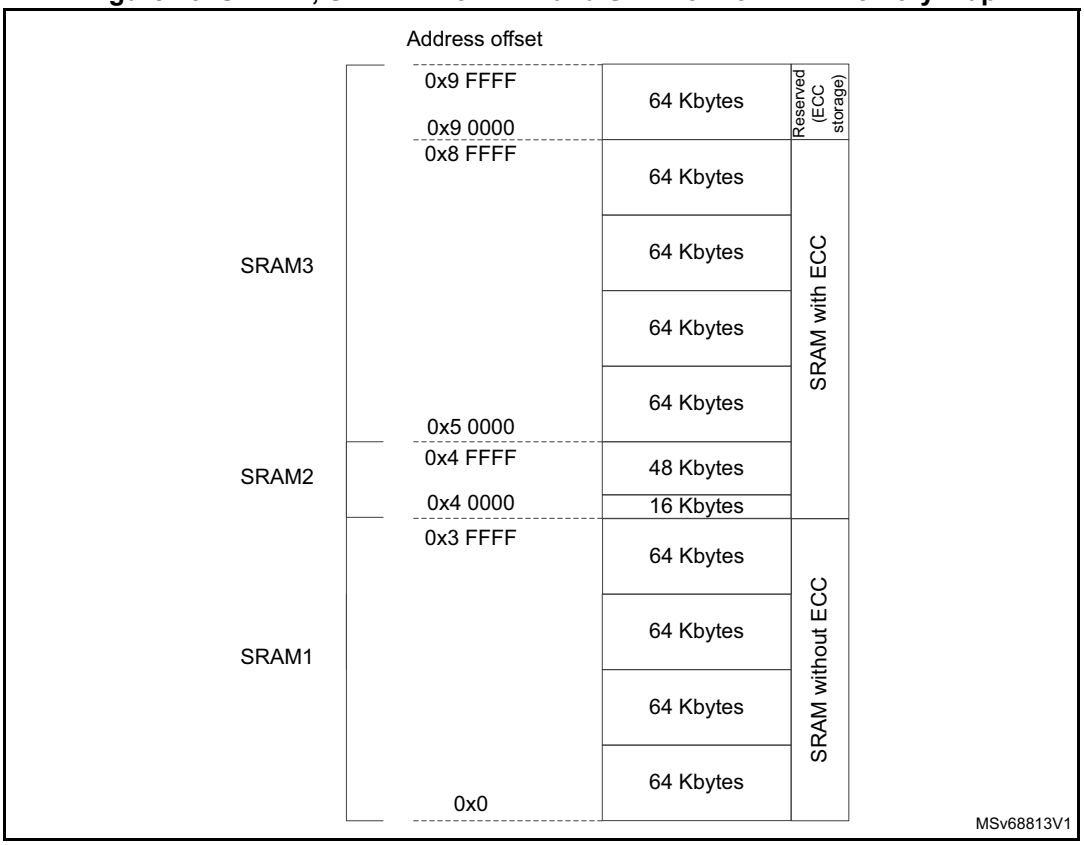
Caution: Double errors cannot be detected when the DED bit is set.

SRAM3 ECC specific management

When the ECC is enabled for SRAM3, only the first 256 Kbytes of SRAM3 are with ECC. The next 64 Kbytes are without ECC, and the last block is used to store the ECC, so cannot be used for application.

The figure below shows the SRAM areas, when SRAM2 and SRAM3 ECC are enabled.

Figure 19. SRAM1, SRAM2 with ECC and SRAM3 with ECC memory map



When ECC is enabled by user option bits, the ECCE bit is automatically set after system reset in the related *RAMCFG memory x control register (RAMCFG_MxCR)*.

The ECC can be deactivated by executing the following software sequence:

1. Write 0xAE in the *RAMCFG memory x ECC key register (RAMCFG_MxECCKEYR)*.
2. Write 0x75 in the *RAMCFG memory x ECC key register (RAMCFG_MxECCKEYR)*.
3. Write 0 in the ECCE bit of the *RAMCFG memory x control register (RAMCFG_MxCR)*.

When ECC is deactivated (ECCE = 0), the SRAM3 ECC storage area can be read and written for ECC user test purpose. When the ECC is activated (ECCE = 1), this area is reserved for ECC storage purpose and cannot be read nor written.

6.3.3 Write protection (SRAM2)

The SRAM2 is made of 64 1-Kbyte pages. Each 1-Kbyte page can be write-protected by setting its corresponding PxWP (x = 0 to 63) bit in the *RAMCFG memory 2 write protection register 1 (RAMCFG_M2WPR1)* and *RAMCFG memory 2 write protection register 2 (RAMCFG_M2WPR2)*.

6.3.4 Software erase

SRAM erase can be requested by executing this software sequence:

1. Write 0xCA in the *RAMCFG memory x erase key register (RAMCFG_MxERKEYR)*.
2. Write 0x53 in the *RAMCFG memory x erase key register (RAMCFG_MxERKEYR)*.
3. Write 1 in the SRAMER bit of the *RAMCFG memory x control register (RAMCFG_MxCR)*.

SRAMBUSY flag is set in the related SRAM interrupt status register as long as the erase is on going.

The total duration of each SRAM erase is N AHB clock cycles, where N is the size of the SRAM in 32-bit words.

If the SRAM is read or written while an erase is on going, wait states are inserted on the AHB bus until the end of the erase operation.

6.4 RAMCFG low-power modes

Table 34. Effect of low-power modes on RAMCFG

Mode	Description
Sleep	No effect. RAMCFG interrupts cause the device to exit the Sleep mode.
Stop	The content of RAMCFG registers is kept.
Standby	The RAMCFG peripheral is powered down and must be reinitialized after exiting Standby.

6.5 RAMCFG interrupts

The table below gives the list of RAMCFG interrupt requests.

Table 35. RAMCFG interrupt requests

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit the Sleep mode	Exit the Stop mode	Exit the Standby modes
RAMCFG	ECC single error detection and correction	SEDC	SEIE	Write 1 in CSEDC	Yes	No	No
	ECC double error detection	DED	DEIE = 1 and ECCNMI = 0	Write 1 in CDED	Yes	No	No
NMI	ECC double error detection	DED	ECCNMI	Write 1 in CDED	Yes	No	No

6.6 RAMCFG registers

In the registers described below, x refers to:

- SRAM1/2/3 when x = 1/2/3 respectively
- BKPSRAM when x = 5

6.6.1 RAMCFG memory x control register (RAMCFG_MxCR)

Address offset: 0x040 * (x - 1), (x = 1, 2, 3, and 5)

Reset value: 0x0000 000X

ECCE reset value depends on ECC enable user option bit.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	SRAMER	Res.	Res.	Res.	ALE	Res.	Res.	Res.	ECCE
							rs				rw				rw

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **SRAMER**: SRAM erase

This bit can be set by software only after writing the unlock sequence in the ERASEKEY field of the RAMCFG_MxERKEYR register. Setting this bit starts the SRAM erase. This bit is automatically cleared by hardware at the end of the erase operation.

0: No erase operation on going

1: Erase operation on going

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **ALE**: Address latch enable

0: Failing address not stored in the SRAMx ECC single/double error address registers

1: Failing address stored in the SRAMx ECC single/double error address registers

Note: This bit is reserved and must be kept at reset value in SRAM1 control register.

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **ECCE**: ECC enable.

This bit reset value is defined by the user option bit configuration. When set, it can be cleared by software only after writing the unlock sequence in the RAMCFG_MxECCKEYR register.

0: ECC disabled

1: ECC enabled

Note: This bit is reserved and must be kept at reset value in SRAM1 control register.

6.6.2 RAMCFG memory x interrupt enable register (RAMCFG_MxIER)

Address offset: 0x004 + 0x040 * (x - 1), (x = 2, 3, 5)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ECCNMI	Res.	DEIE	SEIE
												rs		rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **ECCNMI**: Double error NMI

This bit is set by software and cleared only by a global RAMCFG reset.

0: NMI not generated in case of ECC double error

1: NMI generated in case of ECC double error

Note: if ECCNMI is set, the RAMCFG maskable interrupt is not generated whatever DEIE bit value.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **DEIE**: ECC double error interrupt enable

0: Double error interrupt disabled

1: Double error interrupt enabled

Bit 0 **SEIE**: ECC single error interrupt enable

0: Single error interrupt disabled

1: Single error interrupt enabled

6.6.3 RAMCFG memory interrupt status register (RAMCFG_MxISR)

Address offset: 0x008 + 0x040 * (x - 1), (x = 1, 2, 3 and 5)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	SRAM BUSY	Res.	Res.	Res.	Res.	Res.	Res.	DED	SEDC
							r							r	r

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **SRAMBUSY**: SRAM busy with erase operation

0: No erase operation on going

1: Erase operation on going

Note: Depending on the SRAM, the erase operation can be performed due to software request, system reset if the option bit is enabled, tamper detection or readout protection regression. Refer to Table 33: Internal SRAMs features.

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **DED**: ECC double error detected
0: No double error
1: Double error detected
Note: This bit is reserved and must be kept at reset value in SRAM1 interrupt status register.

Bit 0 **SEDC**: ECC single error detected and corrected
0: No single error
1: Single error detected and corrected
Note: This bit is reserved and must be kept at reset value in SRAM1 interrupt status register.

6.6.4 RAMCFG memory x ECC single error address register (RAMCFG_MxSEAR)

Address offset: 0x00C + 0x040 * (x - 1), (x = 2, 3, 5)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ESEA[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ESEA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **ESEA[31:0]**: ECC single error address
When the ALE bit is set in the RAMCFG_MxCR register, this field is updated with the address corresponding to the ECC single error.

6.6.5 RAMCFG memory x ECC double error address register (RAMCFG_MxDEAR)

Address offset: 0x010 + 0x040 * (x - 1), (x = 2, 3, 5)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
EDEA[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EDEA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **EDEA[31:0]**: ECC double error address
When the ALE bit is set in the RAMCFG_MxCR register, this field is updated with the address corresponding to the ECC double error.

6.6.6 RAMCFG memory x interrupt clear register x (RAMCFG_MxICR)

Address offset: 0x014 + 0x040 * (x - 1), (x = 2, 3, 5)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CDED	CSEDC
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **CDED**: Clear ECC double error detected

Writing 1 to this flag clears the DED bit in the RAMCFG_MxISR register. Reading this flag returns the DED value.

Bit 0 **CSEDC**: Clear ECC single error detected and corrected

Writing 1 to this flag clears the SEDC bit in the RAMCFG_MxISR register. Reading this flag returns the SEDC value.

6.6.7 RAMCFG memory 2 write protection register 1 (RAMCFG_M2WPR1)

Address offset: 0x058

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:0 **PyWP**: SRAM2 1-Kbyte page y write protection (y = 31 to 0)

These bits are set by software and cleared only by a global RAMCFG reset.

0: Write protection of SRAM2 1-Kbyte page y is disabled.

1: Write protection of SRAM2 1-Kbyte page y is enabled.

6.6.8 RAMCFG memory 2 write protection register 2 (RAMCFG_M2WPR2)

Address offset: 0x05C

Reset value: 0x0000 0000

Bits 31:0 **PyWP**: SRAM2 1-Kbyte page y write protection (y = 63 to 32)
These bits are set by software and cleared only by a global RAMCFG reset.
0: Write protection of SRAM2 1-Kbyte page y is disabled.
1: Write protection of SRAM2 1-Kbyte page y is enabled.

6.6.9 RAMCFG memory x ECC key register (RAMCFG_MxECCKEYR)

Address offset: 0x024 + 0x040 * (x - 1), (x = 2, 3, 5)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ECCKEY[7:0]							
								w	w	w	w	w	w	w	w

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **ECCKEY[7:0]**: ECC write protection key
The following steps are required to unlock the write protection of the ECCE bit in the RAMCFG_MxCR register.
1) Write 0xAE into ECCKEY[7:0].
2) Write 0x75 into ECCKEY[7:0].

Note: Writing a wrong key reactivates the write protection.

6.6.10 RAMCFG memory x erase key register (RAMCFG_MxERKEYR)

Address offset: 0x028 + 0x040 * (x - 1), (x = 1 to 5)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ERASEKEY[7:0]							
								w	w	w	w	w	w	w	w

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **ERASEKEY[7:0]**: Erase write protection key

The following steps are required to unlock the write protection of the SRAMER bit in the RAMCFG_MxCR register.

1) Write 0xCA into ERASEKEY[7:0].

2) Write 0x53 into ERASEKEY[7:0].

Note: Writing a wrong key reactivates the write protection.

6.6.11 RAMCFG register map

Table 36. RAMCFG register map and reset values

7 Embedded flash memory (FLASH)

7.1 Introduction

The embedded flash memory (FLASH) manages the accesses of any master to the 2 Mbytes of embedded nonvolatile memory. It implements the read, program and erase operations, error corrections, as well as various integrity and confidentiality protection mechanisms.

FLASH manages the automatic loading of nonvolatile user option bytes at power-on reset, and implements the dynamic update of these options. It also features a high-cycle data area, a one-time-programmable (OTP) area, a secure key storage area (OBKeys), and a read-only area configured by STMicroelectronics during manufacturing.

7.2 FLASH main features

- Up to 2 Mbytes of nonvolatile memory, divided into two 1 Mbyte banks
- Flash memory read operations supporting multiple lengths: 128 bits, 64 bits, 32 bits, 16 bits, or one byte
- Flash memory programming by 128 (user area, OBKeys) and by 16 bits (OTP and flash high-cycle data area)
- 8-Kbyte sector erase, bank erase and dual-bank mass erase
- Dual-bank organization supporting:
  - Simultaneous operations: read-while-write (program and erase) is supported, including flash high-cycle data area. The two banks share the same interface, hence write and erase cannot be performed in parallel (write-while-write is not supported).
  - Bank swapping: the address mapping of the user memory of each bank can be swapped, along with the corresponding registers. Security flags remain valid for the physical bank, so the data are not reveled by swapping to a bank with lower security configuration.
- Error code correction (ECC): one error detection/correction, or two errors detection per 128-bit flash word using nine ECC bits, on 16-bit words with six bits within configurable flash high-cycle data area.
- User configurable nonvolatile option bytes
- Flash memory enhanced protections, activated by option bytes
  - different product states for protecting memory content from debug access
  - sector group write-protection (WRPSG), protecting up to 32 groups of four sectors (32 Kbytes) per bank
  - two secure-only areas (one per user flash bank): when enabled, these areas are accessible only if the microcontroller operates in Secure access mode
  - HDP protection, providing temporal isolation for startup code
- 2-Kbyte one-time programmable (OTP) area
- Read-only area configured by STMicroelectronics
- Prefetch reads the next sequential instruction from flash memory

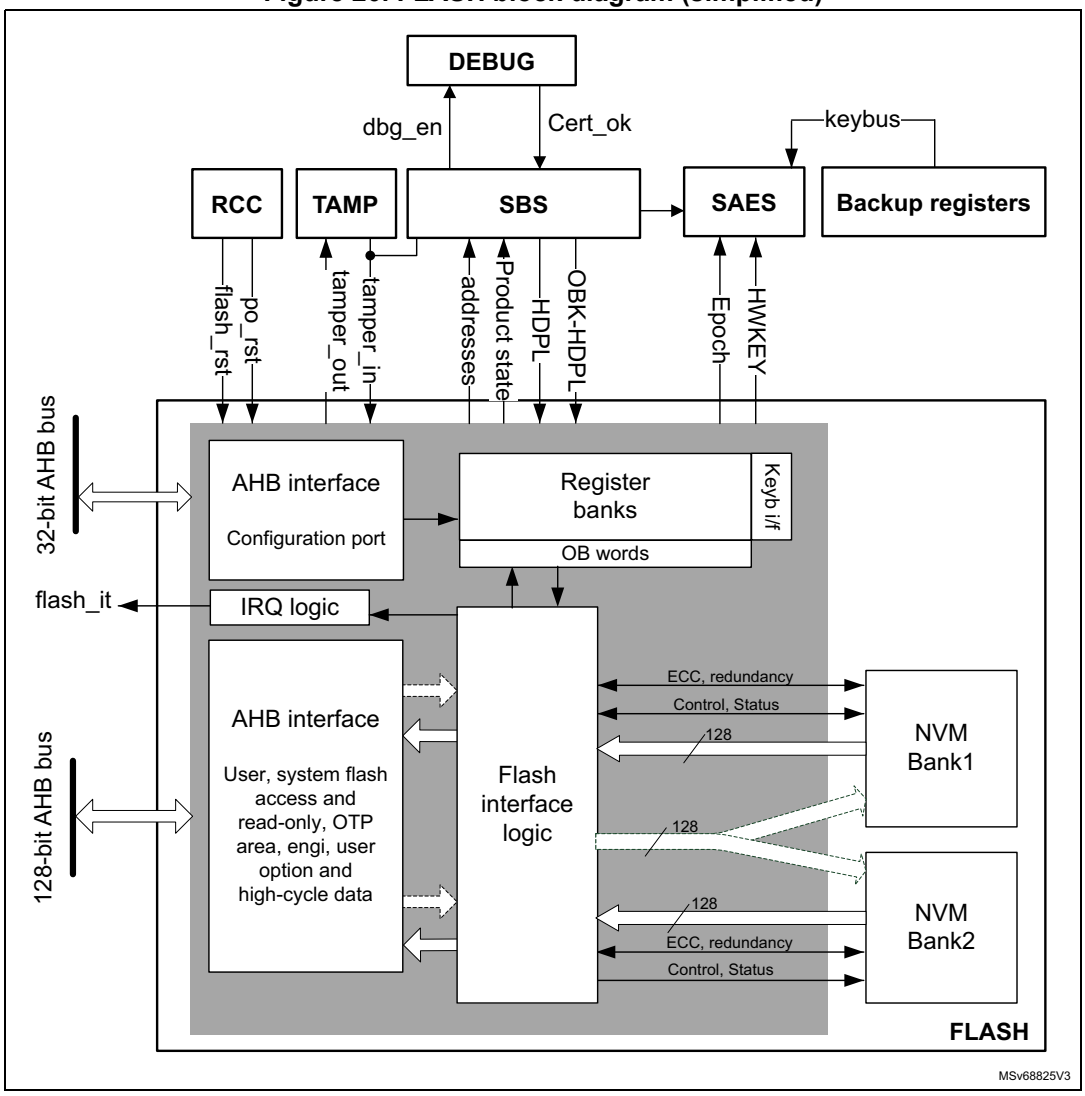
- Up to 48 Kbytes per bank supporting high-cycling capability (100 kcycles), to be used for data (EEPROM emulation)

7.3 FLASH functional description

7.3.1 FLASH block diagram

Figure 20 shows the embedded flash memory block diagram.

Figure 20. FLASH block diagram (simplified)



7.3.2 FLASH signals

The flash memory has two AHB connections, namely the flash AHB register interface and the main AHB interface.

Flash AHB register interface

- Data size is 32 bits
- Except for some registers (FLASH_NS/SECKEYR, FLASH_NS/SECOBKKEYR and FLASH_OPTKEYR, used to insert unlock sequences for control, and option registers that can be written by 32 bits), it is possible to read and write all registers by 8, 16 and 32 bits.
- When unlock sequence for control and option registers is wrong, a bus error is raised, otherwise no read or write errors are generated on the bus.

Main AHB interface

The AHB data bus size is 128 bits. This interface is used to handle three different targets:

- Code placed in user and system memory. It is protected by 9 bits of ECC.
- Secure keys placed in OBKey sectors, and protected by 9 bits of ECC.
- OTP, read-only and flash memory high-cycle data area protected by 6 bits of ECC.

The main AHB interface is implemented as follows:

- User and system memory, OBKeys storage:
  - Supports multiple length: 128-, 64-, 32-, 16- and 8-bit data width.
  - There is a read buffer of 128 bits for each bank where the last data read is stored. If data are available in the read buffer, no read access is given to the flash memory. Buffer is flushed when write access, OTP access, OBK swap, OBK alternate sector erase, high-cycle data area access, user option change request or erase operation occur.
  - There is a prefetch of the same size as the read buffer.
  - A 9-bit ECC is associated to each 128-bit data flash memory word.
- OTP, read-only and flash high-cycle data
  - Two dedicated data buffer of 137 bits are used to manage 16-bit data with 6-bit ECC
  - Reading two times the same address triggers two flash read accesses.
  - During a read access, two wait states are added in addition to the memory wait states. These wait states are necessary to parse the data buffer.
  - Each write access triggers a write in the flash memory.
  - 6-bit ECC is associated to each 16-bit data.

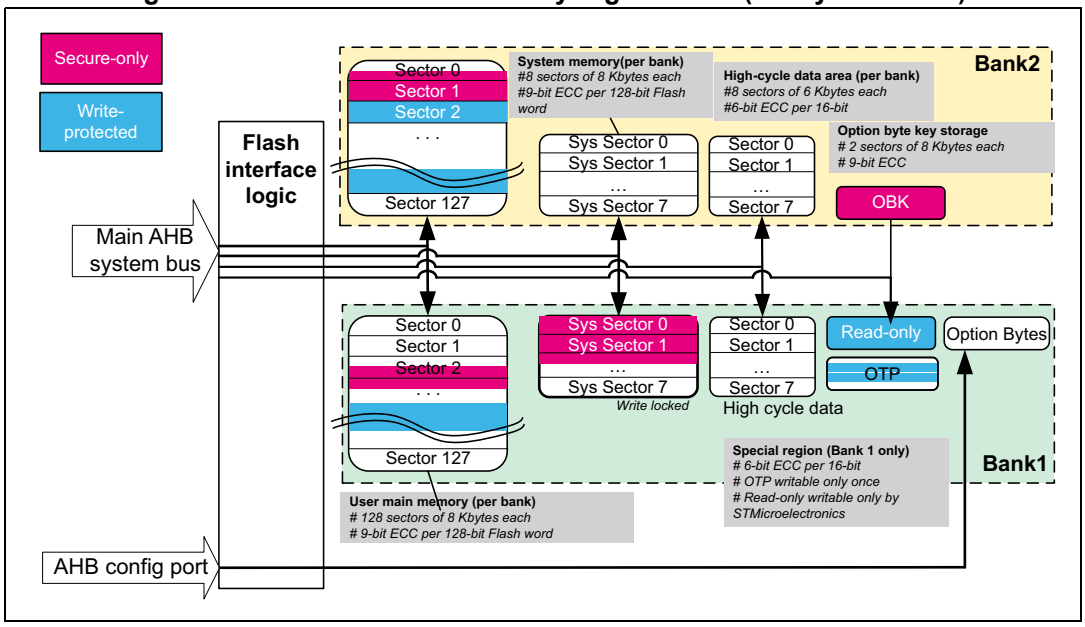
By default, all the AHB memory range is cacheable. For regions where caching is not practical (OTP, RO, data area), MPU must be used to disable local cacheability.

7.3.3 Flash memory architecture and usage

Flash memory architecture

Figure 21 shows the organization supported by the embedded flash memory.

Figure 21. Embedded flash memory organization (2-Mbyte devices)



The embedded flash nonvolatile memory is composed of:

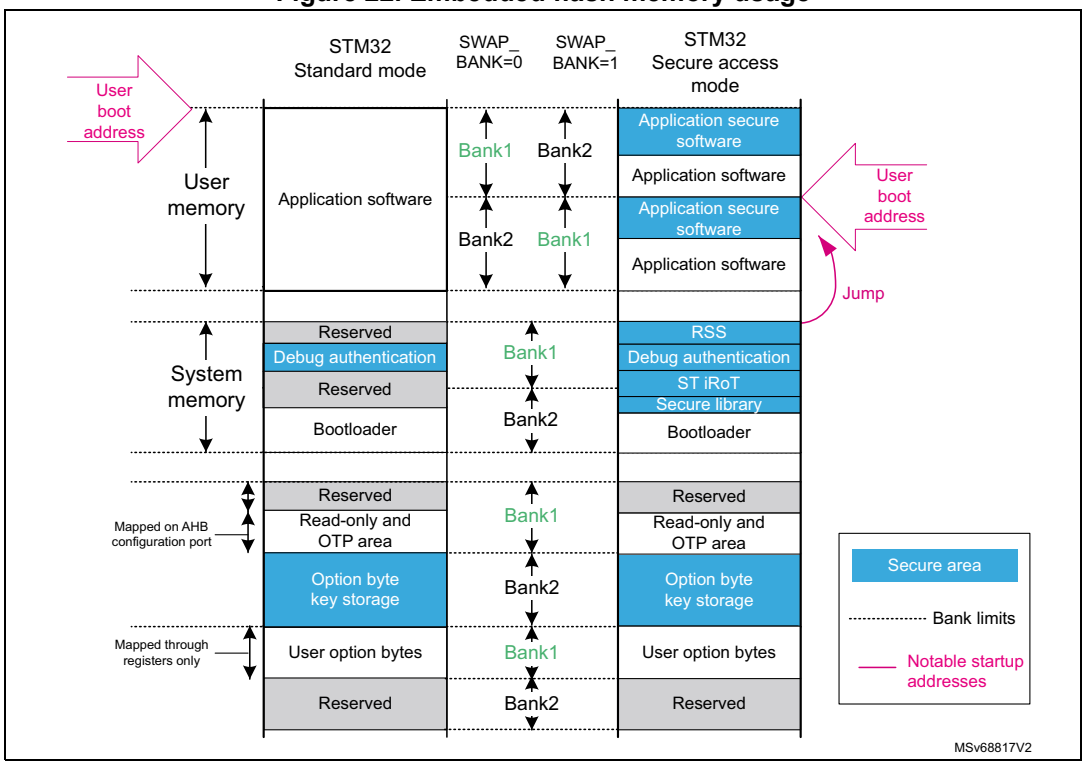
- A 2-Mbyte main memory block, organized in two banks, 1 Mbyte each. Each bank is divided in 128 sectors of 8 Kbytes each, and features flash-word rows of 128 bits + 9 bits of ECC per word.
- A system memory block of 128 Kbytes, divided into two 64-Kbyte banks. Each bank is divided in eight 8-Kbyte sectors. The system flash memory is ECC protected (9-bit ECC per 128-bit word).
- A set of nonvolatile option bytes loaded at reset by the embedded flash memory and accessible by the application software only through the AHB configuration register interface.
- A 2-Kbyte one-time-programmable (OTP) area that can be written only once by the application software.
- A 2-Kbyte read-only area. It contains a unique device ID and product information.
- Two memory sectors (2 x 8 Kbytes) of secure key storage, OBKeys.
- Up to 16 sectors of user flash memory with high cycling capability (100 K cycles) for data, 8 sectors per bank.

The overall flash memory architecture and its corresponding access interface is summarized in *Table 40*.

Partition usage

Figure 22 shows how the embedded flash memory is used by STMicroelectronics and by the application software.

Figure 22. Embedded flash memory usage



User and system memories are used differently, according to product state and other option bytes settings:

- The user memory contains the application code and data, while the system memory is used with root secure services (RSS), the debug authentication code, and the STM32 bootloader. When a reset occurs, the core jumps to the boot address configured through the BOOT pin, the (SEC/NS)BOOTADD option bytes and the product state.
- The unique boot entry (BOOT_UBE) is set to either ST iRoT located in the system flash memory, or iRoT in the user flash memory. This feature is available only on cryptography enabled devices.
- Secure service library in system flash memory is available in secure mode.
- If the debugger is attached to the product, the entry point is the debug authentication policy, used to unlock the device via the SBS when attached to debugger. A digital signature must be provided to perform a regression to product state, where debug is allowed.
- If (SEC/NS)BOOTADD is not yet configured, dedicated libraries can be used for secure boot. They are located in the system flash memory:
  - ST libraries in system flash memory assist the application software boot with special features, such as secure boot and secure firmware install (SFI-RSS)
  - ST iROT (immutable root of trust) secure software in user flash memory is used for secure firmware update and provisioning (SFU)

Note: For more information on option byte setup for boot, refer to Section 7.4.6.

7.3.4 FLASH read operations

Read operation overview

Read access to main and system flash memory operates as follows:

- There is a 128 bit read data buffer associated to each bank, which stores the last data read. If several consecutive read accesses request data belonging to the same flash data word (128 bits), data are read directly from the current data read buffer, without triggering additional flash read operations. This mechanism occurs each time a read access is granted. When a read access is rejected for security reasons, the corresponding read error response is issued by the embedded flash memory and no read operation to flash memory is triggered.
- The read data buffer is disabled when write access or OTP access, user option change request, OBK swap, OBK erase or other erase operation occur.

Read access to OTP, RO and flash high-cycle data operates as follows:

1. Flash data word of 137 bits is read and stored in a temporary buffer.
2. The interface parses the 137 bits data word, and selects the 16- or 32-bit data requested.
3. While parsing the 137-bit data word, (two) wait states are added, and the AHB bus is stalled.
4. If the application reads an OTP data or flash high-cycle data not previously written, **a double ECC error** is reported and **only a word full of set bits is returned** (see *Section 7.3.9* for details). The read data (in 16 bits) is stored in FLASH_ECCDR register, so that the user can identify if the double ECC error is due to a virgin data or a real ECC error.
5. Reading two times the same address triggers two reads in the flash memory.
6. For 8-bit accesses, an AHB bus error is generated.

Note: The embedded flash memory can perform single-error correction and double-error detection while read operations are being executed (see Section 7.3.8).

Instruction prefetch

The Cortex-M33 fetches instructions and literal pools (constants/data) over the C-Bus and through the instruction cache, if it is enabled. The prefetch block aims at increasing the efficiency of C-Bus accesses when the instruction cache is enabled, by reducing the cache refill latency.

Prefetch is efficient in case of sequential code; prefetch in the flash memory allows the next sequential instruction line to be read from the memory, while the current instruction line is being filled in instruction cache and executed by the CPU.

Prefetch is enabled by setting the PRFTEN bit in the FLASH access control register (FLASH_ACR). PRFTEN must be set only if at least one wait state is needed to access the flash memory.

Adjusting read timing constraints

The embedded clock must be enabled and running before reading data from a nonvolatile memory.

To correctly read data from the memory, the number of wait states (LATENCY) must be correctly programmed in the access control register (FLASH_ACR), according to the main AHB interface clock frequency, and the internal voltage range of the device (V_{core}).

Table 37 shows the correspondence between the number of wait states (LATENCY), the programming delay parameter (WRHIGHFREQ), the embedded flash memory clock frequency, and the supply voltage range.

Table 37. FLASH recommended number of wait states and programming delay

Number of wait states (LATENCY)	Programming delay (WRHIGHFREQ)	Interface clock frequency vs. V_{CORE} range(1)			
		VOS3 range 0.95 to 1.05 V	VOS2 range 1.05 to 1.15 V	VOS1 range 1.15 to 1.26 V	VOS0 range 1.30 to 1.40 V
0 WS (1 FLASH clock cycle)	00	0 to 20 MHz	0 to 30 MHz	0 to 34 MHz	0 to 42 MHz
1 WS (2 FLASH clock cycles)		20 to 40 MHz	30 to 60 MHz	34 to 68 MHz	42 to 84 MHz
2 WS (3 FLASH clock cycles)	01	40 to 60 MHz	60 to 90 MHz	68 to 102 MHz	84 to 126 MHz
3 WS (4 FLASH clock cycles)		60 to 80 MHz	90 to 120 MHz	102 to 136 MHz	126 to 168 MHz
4 WS (5 FLASH clock cycles)	10	80 to 100 MHz	120 to 150 MHz	136 to 170 MHz	168 to 210 MHz
5 WS (6 FLASH clock cycles)		N/A	N/A	170 to 200 MHz	210 to 250 MHz

1. Voltage range from 1.26 to 1.30 V is not supported.

Adjusting system frequency

After power-on, the embedded flash memory is clocked by the 64 MHz high-speed internal oscillator (HSI), with a voltage range set at a scaled value of VOS3: a conservative 3 wait-state latency is specified in FLASH_ACR register (see *Table 37*).

When changing the bus frequency, the application software must follow the sequence described below, to tune the number of wait states required to access the memory.

To increase the CPU frequency:

1. If necessary, program the LATENCY and WRHIGHFREQ bits to the right value in the FLASH_ACR register, as described in *Table 37.*
2. Check that the new number of wait states is taken into account by reading back the FLASH_ACR register.
3. Modify the embedded flash memory clock source and/or the clock prescaler in the RCC_CFGR register of the reset and clock controller (RCC).
4. Check that the new embedded flash memory clock source and/or the new AHB clock prescaler value are taken in account by reading back the embedded flash memory clock source status and/or the prescaler value in the RCC_CFGR register of the reset and clock controller (RCC).

To decrease the CPU frequency:

1. Modify the embedded flash memory clock source and/or the clock prescaler in the RCC_CFGR register of reset and clock controller (RCC).
2. Check that the embedded flash memory new clock source and/or the new clock prescaler value are taken into account by reading back the embedded flash memory clock source status and/or the AHB interface prescaler value in the RCC_CFGR register of reset and clock controller (RCC).
3. If necessary, program the LATENCY and WRHIGHFREQ bits to the right value in FLASH_ACR register, as described in *Table 37.*
4. Check that the new number of wait states has been taken into account by reading back the FLASH_ACR register.

Error code correction (ECC)

The memory embeds an error correction mechanism. Single-error correction and double-error detection are performed for each read operation. For more details, refer to *Section 7.3.8*.

Read errors

When the ECC mechanism is unable to correct the read operation, the memory reports read errors, as described in *Section 7.9.10*.

Read interrupts

See *Section 7.10* for details.

7.3.5 FLASH program operations

Program operation overview

Program operation consists in issuing write commands. The memory supports the execution of only one write-command at a time. Write-while-write is not supported. Nothing prevents overwriting a non-virgin flash word, but this is not recommended. The result may lead to invalid data and inconsistent ECC code.

User flash, OBK storage and system flash memories sectors

For the user and system flash memories, 9-bit ECC is associated to each 128-bit data flash word. In this case, the embedded flash memory must always perform write operations to nonvolatile memory with a 128-bit word granularity. Once the write buffer is full (128 bits), the Busy flag is set, and a programming operation is triggered.

There is a write buffer common to Bank1 and 2, which supports multiple write-access types (128, 64, 32, 16 or 8 bits). The application can decide to write from 8 bits to 128 words. In this case, a force-write mechanism to the 128 bits + ECC is used (see FW bit of FLASH_NS/SECCR register).

When the write request is issued to the memory, any new write request stalls the main AHB bus. Moreover, while a write operation is ongoing, any new read request to the same bank stalls the main AHB bus.

OTP, RO, flash high-cycle data

When the target memory is OTP, RO and flash high-cycle data sectors, 6-bits ECC code is associated to each 16-bit data flash word. The embedded flash memory supports 16- or 32-bit write operations (8-bit write operations are not supported).For 8-bit accesses, write accesses are ignored. There is no write data buffer. Each write access triggers a write in the flash memory.

Note: The OTP area is typically write-protected on the final product, as described in Section 7.3.9.

The write protection check is performed at the reception of the write request (during address phase).Write protection is not checked anymore at the output of the write buffer. If a write protection violation is detected, the write operation is canceled, and write protection error (WRPERR) is raised in FLASH_NS/SECSR register.

Note: For write protections of main flash, ICP, and OTP see Section 7.6.

Monitoring ongoing write operations

The application software can use a status flag located in FLASH_NS/SECSR to monitor ongoing write operations. Since only one operation is possible at a time, this flag indicates if any operation (write, erase, option change) is ongoing, whatever the bank.

- **BSY**: indicates that an effective write, erase, option byte change, OBK swap, OBK alt sector erase is ongoing in the nonvolatile memory. This flag is not dedicated to a specific bank. It is set when an operation is starting on the memory, whatever the bank. An operation is triggered by:
  - An erase (FLASH_NS/SECCR.STRT)
  - A write (FLASH_NS/SECCR.PG + AHB write)
  - An option modification (FLASH_OPTCR.OPTSTRT)
  - OBKeys sector swap and OBKeys sector erase (FLASH_NS/SECOBKCFGR.SWAP_SECT_REQ and FLASH_NS/SECOBKCFGR.ALT_SECT_ERASE)

They are cleared when the current operation ends, or in case of error.

- **WBNE**: this bit indicates that the embedded flash memory is waiting for new data to complete the 128-bit write buffer. In this state the write buffer is not empty. It is reset as soon as the application software fills the write buffer, or forces the writes by using FW bit in FLASH_NS/SECCR, or an error is detected. When WBNE is high, it is not possible to launch an erase, an option modification, an OBK swap or OBK alternate sector erase operation on flash memory.
- **DBNE**: this bit indicates that the data buffer for parsing 16-bits data is not empty:
  - 16-bit data write access is received, and the data buffer is being filled. It is set at the receipt of the a valid write access, and reset as soon as the write request preparation has been processed.

Note: If the memory is busy at the receipt of the AHB write request, the CPU execution is stalled.

Enabling write operations

Before programming the user flash memory in Bank1 or in Bank2, the application software must ensure that the PG bit is set to 1 in FLASH_NS/SECCR. If not, an unlock sequence must be used (see *Section 7.6.7*), and the PG bit must be set.

When the option bytes or option bytes key must be modified, or a mass erase must be started, the application software must ensure that FLASH_OPTCR is unlocked. If this is not the case, an unlock sequence must be used (see *Section 7.6.7*).

A separate mechanism with similar use exists for FLASH_NS/SECOBKCFGR. The control register must be unlocked prior to a start of any OBKeys storage modification. Writing correct sequence to the FLASH_NSOBKKEYR unlocks FLASH_NSOBKCFGR. FLASH_SECOBKKEYR is linked to FLASH_SECOBKCFGR, as described in the *Section 7.6.7*.

Note: The application software must not unlock an already unlocked register, otherwise this register remains locked until the next system reset.

If needed, the application software can update the programming delay, as described in *Adjusting programming timing constraints*.

Writing to the FLASH control register FLASH_NS/SECCR and FLASH_OPTCR

The FLASH_NS/SECCR, FLASH_OPTCR and FLASH_NS/SECOBKCFGR registers are not accessible in write mode when the BSY bit is set. Any attempt to write these registers while the BSY bits is set causes the AHB bus to stall until SEC/NSBSY bit is cleared.

Single-write sequence

The recommended single-write sequence is the following:

1. Make sure protection mechanism does not prevent programming
2. Check that no flash memory operation is ongoing by checking the BSY bit in the FLASH_NS/SECSR register and CDBNE bits in the FLASH_NS/SECSR register. Check that the write buffer is empty by checking the WBNE bit in the FLASH_NS/SECSR register
3. Check and clear all the error flags due to previous programming/erase operation
4. Unlock the FLASH_NS/SECCR register, as described in *Section 7.6.7* (only if this register is not already unlocked)
5. Enable write operations by setting PG bit in the FLASH_NS/SECCR register
6. Write one flash-word at aligned address

Note: NS/SECWBNE flag indicates if the 128-bit write buffer is waiting for new data.

Note: No erase request, options change request, OBK operation is allowed between the first write and the completion of the write operation.

7. Wait for the BSY bit to be cleared in the corresponding FLASH_NS/SECSR register
8. Clear PG bit in FLASH_NS/SECCR register if there are not any more programming requests

If step *6* is executed incrementally (for example byte per byte), the write buffer can become partially filled. In this case the application software can decide to force-write what is stored in the write buffer by using FW bit in FLASH_NS/SECCR register. In this particular case, the unwritten bits are automatically set to 1. If no bit in the write buffer is cleared to 0, the FW bit has no effect.

Note: The usage of a force-write operation prevents the application from updating, in a later stage, the missing bits with a value different from 1. This can lead to unexpected or inconsistent data, or ECC.

Adjusting programming timing constraints

Program operation timing constraints depend of the memory clock frequency, which directly impacts the performance. If timing constraints are too tight, the nonvolatile memory does not operate correctly, if they are too lax, the programming speed is not optimal.

The user must therefore trim the optimal programming delay through the WRHIGHFREQ parameter in the FLASH_ACR register. Refer to *Table 37* for the recommended programming delay, depending upon the memory clock frequency.

FLASH_ACR configuration register is common to both banks.

The application software must check that no program/erase operation is ongoing before modifying WRHIGHFREQ.

Caution: Modifying WRHIGHFREQ while programming/erasing the memory can corrupt its content.

Programming errors

When a program operation fails, an error is reported, as described in *Section 7.9*.

Programming interrupts

See *Section 7.10: FLASH interrupts* for details.

7.3.6 FLASH erase operations

Erase operation overview

The memory can perform erase operations on 8-Kbyte user sectors, on one user flash memory bank, or on two user flash memory banks (for example mass erase). For more details in user flash memory, ICP, user options and OTP erase protection, see *Section 7.6*.

Erase commands are issued through the AHB configuration interface. The memory supports one operation at a time, if it receives simultaneously a write and an erase request an error flag is raised, and both operations are canceled. See *Section 7.9* for details.

Erase and WRP

If the application software attempts to erase a write-protected user sector, the sector erase operation is aborted, and the WRPERR flag is raised in the FLASH_NS/SECSR register, as described in *Section 7.9.2*.

Flash busy

Busy signals is described in *Monitoring ongoing write operations*.

Writing to the FLASH control register FLASH_NS/SECCR and FLASH_OPTCR

Refer to *Writing to the FLASH control register FLASH_NS/SECCR and FLASH_OPTCR*.

Enabling erase operations

Before erasing a sector, the application software must make sure that FLASH_NS/SECCR is unlocked. If this is not the case, an unlock sequence must be used (see *Section 7.6.7*).

Note: The application software must not unlock a register that is already unlocked, otherwise this register remains locked until next system reset. This can be used to deliberately lock-out a register from further accesses.

Similar constraints apply to bank erase requests.

Standard flash sector erase sequence

To erase an 8- or 6-Kbyte data user sector without security protections, proceed as follows:

1. Make sure protection mechanism does not prevent sector erase (WRP, secure flag, HDP).
2. Check that no FLASH memory operation is ongoing by checking the BSY and DBNE bits in the FLASH_NSSR register, and that the write buffer is empty by checking the WBNE bit in the FLASH_NSSR register.
3. Check and clear all the non-secure error flags due to previous programming/erase operation. Refer to *Section 7.9* for details.
4. Unlock the FLASH_NSCR register, as described in *Section 7.6.7* (only if this register is not already unlocked).
5. Set the BKSEL bit, the SER bit and SNB bitfield in the FLASH_NSCR register. BKSEL indicates in which physical bank sector must be erased, then SER indicates a sector erase operation, while SNB contains the target sector number. In case of data sector, use the number of the corresponding regular sector.
6. Set the STRT bit in the FLASH_NSCR register.
7. Wait for the BSY bit to be cleared in the FLASH_NSSR register.
8. STRT bit is automatically cleared at the end of the sector erase, or in case of error.
9. Clear SER in FLASH_NSCR register if there are not anymore sector erase request to be issued.

Note: If another erase flag is requested simultaneously to the sector erase, a PGSERR error is generated.

Secure flash memory sector erase sequence

To erase an 8- or 6-Kbyte data secure configured user sector, proceed as follows:

1. Make sure write protection or HDP mechanism does not prevent sector erase.
2. Ensure that no flash memory operation is ongoing (by checking the BSY and DBNE bits in the FLASH_SECSR register), and that the write buffer is empty (by checking the WBNE bit in the FLASH_SECSR register).
3. Check and clear all the secure error flags due to previous programming/erase operations. Refer to *Section 7.9* for details.
4. Unlock the FLASH_SECCR register, as described in *Section 7.6.7* (only if this register is not already unlocked).
5. Set the BKSEL bit, the SER bit and SNB bitfield in the FLASH_SECCR register. BKSEL indicates in which physical bank sector must be erased, then SER indicates a sector erase operation, while SNB contains the target secure sector number. In case of data sector, use the number of the corresponding regular sector.

6. Set the STRT bit in the FLASH_SECCR register.
7. Wait for the BSY bit to be cleared in the FLASH_SECSR register.
8. STRT bit is automatically cleared at the end of the sector erase or in case of error.
9. Clear SER in FLASH_SECCR register if there are not any secure sector erase request to be issued.

Note: If another erase flag is requested simultaneously to the sector erase, a PGSERR error is generated.

Standard flash memory bank erase sequence

To erase bank where no sector is configured as secure:

1. Make sure protection mechanism does not prevent sector erase.
2. Check that no flash memory operation is ongoing by checking the BSY and DBNE bits in the FLASH_NSSR register and that the write buffer is empty by checking the WBNE bit in the same register.
3. Check and clear all the non-secure error flags due to previous programming/erase operation. Refer to *Section 7.9* for details.
4. Unlock the FLASH_NSCR register, as described in *Section 7.6.7* (only if this register is not already unlocked).
5. Set the BKSEL bit and the BER bit in the FLASH_NSCR register to the targeted physical bank (swap setting is ignored).
6. Set the STRT bit in the FLASH_NSCR register to start the bank erase operation. Then wait until the BSY bit is cleared in the FLASH_NSSR register.
7. STRT bit is automatically cleared at the end of erase sequence or in case of error.
8. Clear BER in FLASH_NSCR register if there is not other bank erase request to be issued.

Secure flash memory bank erase sequence

To erase bank where all sectors are configured with secure flag:

1. Make sure protection mechanism does not prevent sector erase (Note that for mass erase the HDP is also considered, it cannot be fully executed from HDPL=2,3 if HDP is defined).
2. Check that no flash memory operation is ongoing by checking the BSY and DBNE bits in the FLASH_SECSR register and that the write buffer is empty by checking the WBNE bit in the same register.
3. Check and clear all the secure error flags due to previous programming/erase operation. Refer to *Section 7.9* for details.
4. Unlock the FLASH_SECCR register, as described in *Section 7.6.7* (only if this register is not already unlocked).
5. Set the BKSEL bit and the BER bit in the FLASH_SECCR register to the targeted physical bank (swap setting is ignored).
6. Set the STRT bit in the FLASH_SECCR register to start the bank erase operation. Then wait until the BSY bit is cleared in the FLASH_SECSR register.
7. STRT bit is automatically cleared at the end of erase sequence or in case of error.
8. Clear BER in FLASH_SECCR register if there is not other bank erase request to be issued.

Flash mass erase sequence

To erase all sectors of both banks, using non-secure access, all sectors must be configured as non-secure. The application software can set the MER bit to 1 in FLASH_NSCR register, as described below:

1. Make sure protection mechanisms do not prevent mass erase (*Section 7.6*).
2. Check that no flash memory operation is ongoing by checking the BSY and DBNE bits in the FLASH_NSSR register and that the write buffer is empty by checking the WBNE bit in the FLASH_NSSR register.
3. Check and clear all the non-secure error flags due to previous programming/erase operation. Refer to *Section 7.9* for details.
4. Unlock the FLASH_NSCR register as described in *Section 7.6.7* (only if the registers are not already unlocked).
5. Set the MER bit to 1 in FLASH_NSCR register.
6. Set the STRT bit in the FLASH_NSCR register. Then wait until BSY bit is cleared in the FLASH_NSSR register.
7. STRT bit is cleared automatically at the end of the erase sequence, or in case of error.
8. Clear MER in FLASH_NSCR register.

Secure flash memory mass erase sequence

To erase all sectors of both banks simultaneously, using secure access, all sectors must be configured as secure. The application software can set the MER bit to 1 in FLASH_SECCR register, as described below:

1. Make sure protection mechanisms do not prevent mass erase (*Section 7.6*).
2. Check that no flash memory operation is ongoing by checking the BSY and DBNE bits in the FLASH_SECSR register and that the write buffer is empty by checking the WBNE bit in the FLASH_SECSR register.
3. Check and clear all the secure error flags due to previous programming/erase operation. Refer to *Section 7.9* for details.
4. Unlock the FLASH_SECCR register as described in *Section 7.6.7* (only if the registers are not already unlocked).
5. Set the MER bit to 1 in FLASH_SECCR register.
6. Set the STRT bit in the FLASH_SECCR register. Then wait until BSY bit is cleared in the FLASH_SECSR register.
7. STRT bit is cleared automatically at the end of the erase sequence, or in case of error.
8. Clear MER in FLASH_SECCR register.

Note: Mass and bank erase also erase high-cycle data sectors aliased from the erased bank.

7.3.7 FLASH parallel operations

As the nonvolatile memory is divided into two independent banks encapsulated in the same macro, the embedded flash memory interface supports a read in one bank while a write (RWW. read while write) or an erase is executed in the other bank. It does not support write-while-write, nor read-while-read. Same is valid for the high-cycle data area, system flash libraries, or the OBK (located on Bank 2).

In all cases, the sequences described in *Section 7.3.4*, *Section 7.3.5* and *Section 7.3.6* apply.

7.3.8 FLASH error protections

Error correction codes (ECC)

The embedded flash memory supports an error correction code (ECC) mechanism, based on the SECDED algorithm, to correct single errors and detect double errors.

This mechanism uses nine ECC bits per 128-bit flash word, and applies to user and system memory.For read-only, OTP, flash high-cycle data, a stronger six ECC bits per 16-bit word is used. A double ECC error is generated for an OTP or flash high-cycle data virgin word (for example a word with 22 bits at 1). When this OTP or flash high-cycle data word is no more virgin, the ECC error disappears.

More specifically, during each read operation from a 128-bit flash word, the embedded flash memory retrieves the 9-bit ECC information, computes the ECC of the flash word, and compares the result with the reference value. If they do not match, the corresponding ECC error is raised, as described in *Section 7.9.10*.

During each program operation, a 9-bit ECC code is associated to each 128-bit data flash word, and the resulting 137-bit flash word information is written in nonvolatile memory.

A similar mechanism applies to read-only and OTP areas, but with 6-bit ECC for 16-bit data.

7.3.9 OTP and RO memory access

OTP and RO memory are accessed through main AHB interface. The OTP is accessible at addresses 0x08FF_F000 to 0x08FF F7FF, and the read-only section is accessible from 0x08FF F800 to 0x08FF_FFFF.

FLASH one-time programmable area

The embedded flash memory offers a 2048-byte memory area dedicated to application non-confidential, one-time programmable data (OTP). This area is composed by 1024 words of 16 bits (plus 6 bits of ECC). It cannot be erased, and can be written only once. The OTP area can be accessed through the main AHB interface from address 0x08FF F000 to 0x08FF F7FE.

OTP data can be programmed by the application software by 16-bit chunks. Overwriting an already programmed16-bit half-word can lead to data and ECC errors, and is therefore not supported.

Note: The OTP area is virgin when the device is delivered by STMicroelectronics.

When reading OTP data with a single error corrected or a double error detected, the embedded flash memory reports read errors, as described in *Section 7.9.10*.

When reading OTP data not written by the application software (such as virgin OTP), the ECC correction reports a double-error detection (ECCD), and the data are to be found in the FLASH_ECCDR register. ECCD implies an NMI raised.

OTP write protection

OTP data are organized as 32 blocks of 32 OTP words, as shown in *Table 38*. An entire OTP block can be protected (locked) from write accesses by setting the LOCKBLi bit (i = 0 to 31) corresponding to each OTP block in the FLASH_OTPBLR option byte register. A block can be write-protected, if it has been programmed (even partially) or not.

The OTP block locking operation is irreversible, and independent from the product life state.

Note: The OTP area can be accessed only in read mode.

Table 38. Flash memory OTP organization

OTP block	AHB address	AHB word		Lock bit
		[31:16]	[15:0]	
Block 0	0x08FF F000	OTP001	OTP000	LOCKBL0
	0x08FF F004	OTP003	OTP002	
	...			
	0x08FF F03C	OTP031	OTP030	
Block 1	0x08FF F040	OTP033	OTP032	LOCKBL1
	0x08FF F044	OTP035	OTP034	
	...			
	0x08FF F07C	OTP063	OTP062	
Block 2	0x08FF F080	OTP065	OTP064	LOCKBL2
	0x08FF F084	OTP067	OTP066	
	...			
	0x08FF F0BC	OTP95	OTP94	
...				
Block 31	0x08FF F7C0	OTP993	OTP992	LOCKBL31
	0x08FF F7C4	OTP995	OTP994	
	...			
	0x08FF F7FC	OTP1023	OTP1022	

OTP write sequence

Follow the sequence below to write an OTP word:

1. Check that no flash memory operation is ongoing by checking the BSY bit in the FLASH_NSSR register and that the data buffer is empty by checking the DBNE bit in the FLASH_NSSR register.
2. Check and clear all the error flags due to previous programming/erase operation.
3. Set PG bit in the FLASH_NSCR register.
4. Check the protection status of the target OTP word (see *Table 38*). The corresponding LOCKBLi bit must not be set to 1.
5. Write two OTP words (32 bits) corresponding to the 4-byte aligned address shown in *Table 38*. Alternatively, the application software can program separately the 16-bit MSB or 16-bit LSB. In this case the first 16-bit write operation starts immediately without waiting for the second one.
6. Wait for the BSY bit to be cleared in the FLASH_NSSR register.
7. Clear PG bit in FLASH_NSCR register if there is not any programming request anymore in the bank.
8. Optionally, lock the OTP block using LOCKBLi to prevent further data changes.

Note: Do not write twice an OTP 16-bit word, otherwise an ECC error is generated.

Writing OTP data at byte level is not supported, and generates a bus error.

To avoid data corruption, it is important to complete the OTP write process (for example by reading back the OTP value), before starting an option change.

Flash read-only area

The embedded flash memory offers a 2-Kbyte area to store read-only data. This area can be accessed through the AHB main port, and is protected by a robust ECC scheme, as detailed in *Section 7.3.8*.

The read-only information (programmed by STMicroelectronics) that can be used by the application software is detailed in *Table 39*.

Table 39. Read-only public data organization

Read-only data name	Address	Comment
Unique device ID	0x08FF F800	U_ID[31:0]
	0x08FF F804	U_ID[63:32]
	0x08FF F808	U_ID[96:64]
Flash memory size/ package	0x08FF F80C	Flash memory size[15:0] / Package code[15:0]
Reserved	0x08FF F810 to 0x08FF FFFF	Reserved information

7.3.10 Flash high-cycle data

The embedded flash memory offers up to 96 Kbytes (maximum) memory area with high-cycling capability (100 kcycles) to store data and emulate EEPROM. It can be accessed through the AHB system port from address 0x0900_0000 to 0x0901_7FFF (see *Figure 23*). It is mapped in the 8 (or 4) last sectors of Bank1 and 2. This area is protected by a robust 6-bit ECC, which allows a read and write granularity of 16 bits at the expense of having sector size shrunk to 6 Kbytes.

A threshold per bank (EDATA(1/2)_STRT) is programmable in user option bytes to determine the beginning of the data flash area. By default, all flash is used for code.

For example, if 48 Kbytes of data are needed in Bank1, set EDATA1_EN to 1, and EDATA1_STRT to 7. If no data are needed in Bank 2, set EDATA2_EN to 0. In this case the data are accessible from address 0x0900_0000 to 0x0900_BFFF for Bank1.

For greater efficiency, it is always recommended to use sector on the other bank for flash high-cycle data, so that the application benefits from RWW capability of the dual-bank arrangement.

When SWAP_BANK feature is enabled, the banks are swapped: the flash high-cycle data in Bank 2 are accessible from 0x0900_000 to 0x0900_BFFF and the data in Bank 1 are accessible from 0x0900_C000 to 0x0901_7FFF.

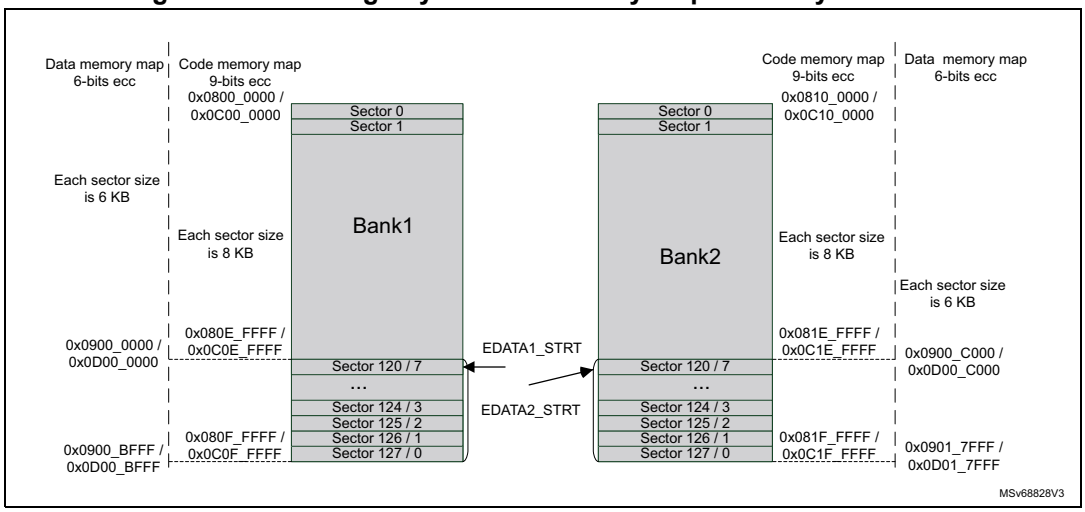
A bus error is generated on:

- Attempt to access an address between 0x0900_0000 to 0x0901_7FFF and this address is not valid (EDATA(1/2)_EN not enabled or EDATA(1/2)_STRT not correct).
- Attempt to fetch instructions from flash high-cycle data area.

Erasing the data area sector is possible by normal erase request for corresponding user flash sector (120-127).

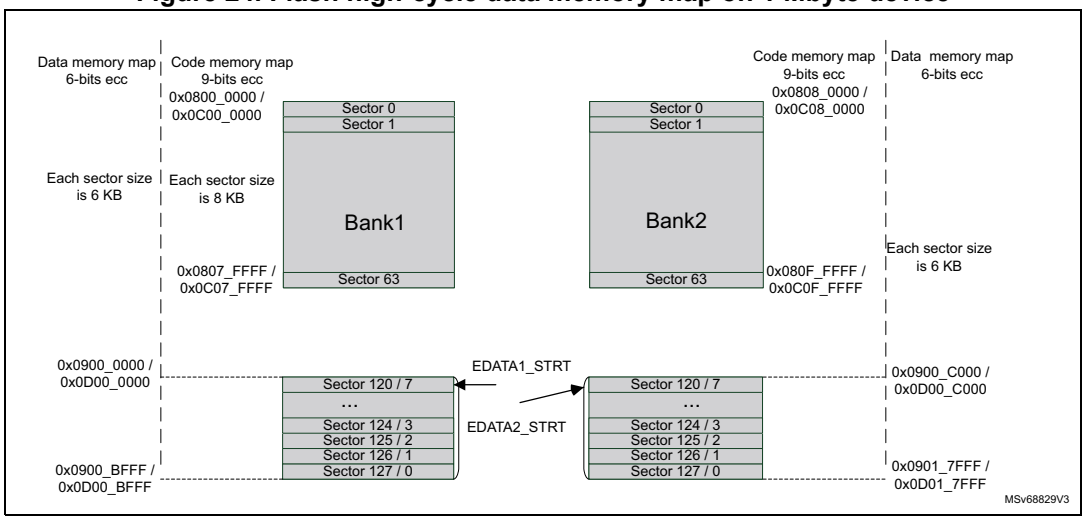
Protections and security of high-cycle area are detailed in *Section 7.6.9*.

Figure 23. Flash high-cycle data memory map on 2 Mbytes device



Note: When flash high-cycle data area on Bank1 is enabled, the code memory map is not continuous from Bank1 to Bank2 on a 2 Mbytes device.

Figure 24. Flash high-cycle data memory map on 1 Mbyte device



7.3.11 Flash bank swapping

Bank1 and Bank2 can be swapped for the user flash. This feature can be used after a firmware upgrade to restart the device on the new firmware. Bank swapping is an user option byte flag controlled by the SWAP_BANK bit of the FLASH_OPTCR register.

Bank specific settings for data area and security attributes follow the original bank and its contents. Control bit BKSEL always refers to physical bank, not the SWAP_BANK setting.

Table 40 shows the accessible memory, depending upon the SWAP_BANK bit value.

Table 40. Memory map and swapping option

Flash memory area	Flash memory corresponding bank		Start address	End address	Size (bytes)	Region name
	SWAP_BANK = 0	SWAP_BANK = 1				
User main memory	Bank1	Bank2	0x0800 0000	0x0800 1FFF	8 K	Sector 0
			0x0800 2000	0x0800 3FFF	8 K	Sector 1
			...	...	...	...
			0x080F E000	0x080F FFFF	8 K	Sector 127
	Bank2	Bank1	0x0810 0000	0x0810 1FFF	8 K	Sector 0
			0x0810 2000	0x0810 3FFF	8 K	Sector 1
			...	...	...	...
			0x081F E000	0x081F FFFF	8 K	Sector 127
System memory	Bank1		0x0BF8 0000	0x0BF8 1FFF	8 K	System 1 Sector 0
			0x0BF8 2000	0x0BF8 3FFF	8 K	System 1 Sector 1
			...	...	...	...
			0x0BF8 E000	0x0BF8 FFFF	8 K	System 1 Sector 7
	Bank2		0x0BF9 0000	0x0BF9 1FFF	8 K	System 2 Sector 0
			0x0BF9 0000	0x0BF9 3FFF	8 K	System 2 Sector 1
			...	...	...	...
			0x0BF9 E000	0x0BF9 FFFF	8 K	System 2 Sector 7

The SWAP_BANK bit in FLASH_OPTCR register is loaded from the SWAP_BANK option bit only after system reset or POR.

To change the SWAP_BANK bit (for example to apply a new firmware update), follow the sequence below:

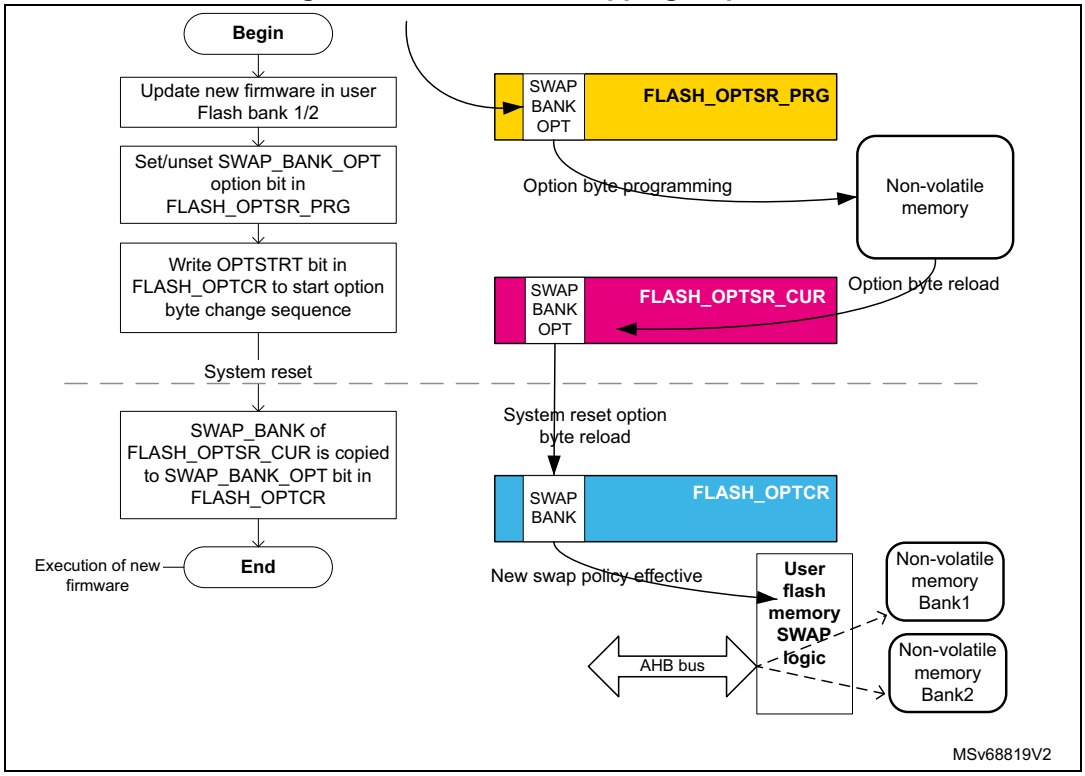
1. Check that no flash memory operation is ongoing by checking the BSY and DBNE bits in the FLASH_NS/SECSR register and that the write buffer is empty by checking the WBNE bit in the FLASH_NS/SECSR register.
2. Clear all error flags due to a previous operation.
3. Unlock OPTLOCK bit, if not already unlocked.
4. Set the new desired SWAP_BANK value in the FLASH_OPTSR_PRG register.
5. Start the option byte change sequence by setting the OPTSTRT bit in the FLASH_OPTCR register.
6. Once the option byte change has completed, FLASH_OPTSR_CUR contains the expected SWAP_BANK value, but SWAP_BANK bit in FLASH_OPTCR has not yet been modified and the bank swapping is not yet effective.
7. Force a system reset or a POR. When the reset rises up, the bank swapping is effective (SWAP_BANK value updated in FLASH_OPTCR) and the new firmware shall be executed.

Note: The SWAP_BANK bit in FLASH_OPTCR is read-only, and cannot be modified by the application software.

The SWAP_BANK option bit in FLASH_OPTSR_PRG can be modified whatever the product state. Instead of being locked by PRODUCT_STATE, it is locked by (NS/SEC)BOOT_LOCK User OB.

Figure 25 gives an overview of the bank swapping sequence.

Figure 25. Flash bank swapping sequence



7.3.12 FLASH reset and clocks

Reset management

The embedded flash memory can be reset by a core domain reset, driven by the reset and clock control (RCC). The main effects of this reset are the following:

- All registers, except for option byte registers, are cleared, including read and write latencies. If the bank swapping option is changed, it is applied.
- Most control registers are automatically protected against write operations. To unprotect them, new unlock sequences must be used as described in *Section 7.6.7*.

The memory can be reset by a power-on core domain reset, driven by the reset and clock control (RCC). When the reset falls, all option byte registers are reset. When the reset rises up, the option bytes are loaded, potentially applying new features. During this loading sequence, the device remains under reset, and the memory is not accessible.

The reset signal can have a critical impact on the memory: the content is not guaranteed if a device reset occurs during a write or erase operation.

Reset occurring during flash operation

If a reset occurs during a flash operation (programing, erase or option change), the content of the memory is not guaranteed. It is mandatory for integrity to restart the operation. The status register FLASH_OPSR gives information about operations interrupted by a reset.

FLASH_OPSR.CODE_OP gives opcode of operation. *Table 41* indicates how to use FLASH_OPSR, and which operation is required.

Table 41. Recommended reactions to FLASH_OPSR contents

CODE_OP	Operation interrupted	OTP_OP	SYSF_OP	BK_OP	DATA_OP	Flash area	ADDR_OP min	ADDR_OP max	Recommended action
0x000	No operation ongoing while reset	0	0	0	0	-(1)	-	-	No extra action
0x001	Write operation	0	0	0/1	0	User flash	0x0000	0xFFFF	Erase sector and rewrite
		0	1	0/1	0	System flash	0x0000	0x0FFF	
		1	0	0	0	OTP	0x0600	0x07FF	
		1	0	1	0	OBKeys(2)	0x0000	0x03FF	
		0	0	0/1	1	Data area(3)	0xF000	0xFFFF	
0x010	OBK alternate sector erase	0	0	1	0	OBKeys	0	0	Relaunch the alternate sector erase
0x011	Sector erase(4)	0	0	0/1	0	User flash	0x0000	0xFFFF	Relaunch sector erase
		0	1	0/1	0	System flash	0x0000	0x0FFF	
0x100	Bank erase	0	0	0/1	0	User flash	-	-	Relaunch bank erase
0x101	Mass erase	0	0	0	0		-	-	Relaunch mass erase
0x110	Option change	0	0	0	0	User configuration	-	-	New attempt on option change
0x111	OBK swap sector	0	0	1	0	OBKeys	-	-	Erase alternate sector, reprogram new OBKeys and relaunch swap

1. Dash represents “does not matter”.
2. Depends on current OBK sector.
3. Depends on EDATA setting in the OB.
4. Addresses indicated are aligned to sector start, data area sectors are erased by erase request to corresponding user flash memory sector.

Clock management

The memory uses the microcontroller system clock (sys_ck), here the AHB interface clock.

7.4 FLASH option bytes

7.4.1 About option bytes

The memory includes a set of nonvolatile option bytes. They are loaded at power-on reset and can be read and modified only through configuration registers.This section documents:

- when option bytes are loaded
- how application software can modify them
- the detailed list of option bytes, together with their initial values (before the first option byte change, user default configuration).

7.4.2 Option-byte loading

There are multiple ways of loading the option bytes into embedded flash memory:

- **Power-on wakeup**

  When the device is first powered, the embedded flash memory automatically loads all the option bytes. During the option byte loading sequence, the device remains under reset and the embedded flash memory cannot be accessed.
- **Wakeup from system Standby**

  When the core power domain, which contains the embedded flash memory, is switched from Standby mode to Run mode, the embedded flash memory behaves as during a power-on sequence. **During loading time the device is not under reset, unlike power-on sequence.**
- **Dedicated option byte reloading by the application**

  When the user application successfully modifies the option byte content through the memory registers, the nonvolatile option bytes are programmed and the memory automatically reloads all option bytes to update the option registers.

Note: The option-byte read sequence is protected by error correction code.In case of error, the option bytes are loaded with default values (see Section 7.4.3), different from the initial values (user default configuration), and more restrictive.

7.4.3 Option-byte modification

Changing user option bytes

A user option-byte change operation can be used to modify the configuration and the protection settings saved in the nonvolatile option byte area.

There are several rules enforced when attempting to change a user option byte, they are summarized in *Section 7.4.7*. Failing to stick to those rules usually results in errors, described in *Section 7.9.12*.

The embedded flash memory features two sets of option byte registers:

- The first register set contains the current values of the option bytes. Their names have the _CUR extension. All “_CUR” registers are read-only. Their values are automatically loaded from the nonvolatile memory after power-on reset, wakeup from system standby or after an option byte change operation.
- The second register set allows the modification of the option bytes. Their names contain the _PRG extension. All “_PRG” registers can be accessed in read/write mode.

When the OPTLOCK bit in FLASH_OPTCR register is set, modifying the FLASH_XXX_PRG registers is not possible.

When OPTSTRT bit is set to 1, the memory checks the programming sequence (PGSERR) and the conditions described in *Section 7.4.7* (OPTCHANGEERR). If no error has been detected (PGSERR/OPTCHANGEERR), the embedded flash memory launches the option byte modification in its nonvolatile memory and updates the option byte registers with _CUR extension.

If one of the condition described in *Section 7.4.7*, *Section 7.9.12* or *Section 7.9.5*, alternatively *Section 7.9.4* is not respected, the memory aborts the option byte change operation. In this case, the FLASH_XXX_PRG registers are not overwritten by current option value. The user application can check what was wrong in their configuration.

Unlocking the option-byte modification

After reset, the OPTLOCK bit is set to 1 and the FLASH_OPTCR is locked. As a result, the application software must unlock the option configuration register before attempting to change the option bytes. The FLASH_OPTCR unlock sequence is described in *Section 7.6.7*.

Option-byte modification sequence

To modify user option bytes, follow the sequence below:

1. Check that no FLASH memory operation is ongoing by checking the BSY bit in the FLASH_NS/SECSR register and that the write buffer is empty by checking the WBNE bit in the FLASH_NS/SECSR register.
2. Check the data buffer is empty (DBNE = 0) in FLASH_NS/SECSR register.
3. Clear all error flags due to a previous operation.
4. Unlock FLASH_OPTCR register as described in *Section 7.6.7*, unless the register is already unlocked.
5. Write the desired new option byte values in the corresponding option registers (FLASH_XXX_PRG).
6. Set the option byte start change OPTSTRT bit to 1 in the FLASH_OPTCR register.
7. Wait until BSY bit is cleared in FLASH_NS/SECSR register.
8. OPTSTRT bit is cleared automatically at the end of the sequence (or in case of error).
9. Reset the device. This step is always recommended, becomes mandatory when one of the following option bytes is impacted:
   a) SECBOOTADDR
   b) NSBOOTADDR
   c) TZEN
   d) BOOT_UBE

Note: If a reset or a power-down occurs while the option byte modification is ongoing, the original option byte value is kept. A new option byte modification sequence is required to program it.

Option-byte overview

Table 42 lists all the user option bytes managed through the memory registers, as well as initial values before the first option byte change (user default configuration).

Table 42. Option-byte organization

7.4.4 Description of user and system option bytes

The general-purpose option bytes that can be used by the application are listed below:

- Watchdog management
  - IWDG_STOP: independent watchdog IWDG (also known as WDGLS_CD) counter active in Stop mode if 1 (stop counting or freeze if 0)
  - IWDG_STDBY: independent watchdog IWDG (also known as WDGLS_CD) counter active in Standby mode if 1 (stop counting or freeze if 0)
  - IWDG_SW: hardware (0) or software (1) IWDG (also known as WDGLS_CD) watchdog control selection

Note: If the hardware watchdog "control selection" feature is enabled (set to 0), the watchdog is automatically enabled at power-on, thus generating a reset unless the watchdog key register is written to or the down-counter is reloaded before the end-of-count is reached.

Depending on the configuration of IWDG_STOP and IWDG_STDBY options, the IWDG can continue counting (1) or not (0) when the device is in Stop or Standby mode, respectively.

When the IWDG is kept running during Stop or Standby mode, it can wake up the device from these modes.

- Reset management
  - BOR_LEV: Brownout level option, indicating the supply level threshold that activates/releases the reset
  - BORH_EN: enabling a high BOR level
  - NRST_STDBY: generates a reset when entering Standby mode if cleared to 0
  - NRST_STOP: generates a reset when entering Stop mode if cleared to 0.

Note: Whenever a Standby (Stop) mode entry sequence is successfully executed, the device is reset instead of entering Standby (Stop) mode if NRST_STDBY (NRST_STOP) is cleared to 0.

- Device options
  - IO_VDDIO2_HSLV: enables the configuration of pads below 2.7 V for VDDIO2 power rail if set to 1
  - IO_VDD_HSLV: enables the configuration of pads below 2.7 V for VDD power rail if set to 1
  - USBPD_DIS: bit to disable USB PD

At device deliver, the values programmed in the general-purpose option bytes are the following:

- Watchdog management
  - IWDG (also known as WDGLS_CD) active in Standby and Stop modes: 0x1
  - IWDG (also known as WDGLS_CD) not automatically enabled at power-on: 0x1
- Reset management
  - BOR: brownout level option (reset level = 2.1 V): 0x0. A reset is not generated when the device enters Standby, Stop low-power mode (value = 0x1)
- Device working in the full voltage range with I/O speed optimization at low-voltage disabled (IO_VDDIO2_HSLV = 0 and IO_VDD_HSLV = 0)

Refer to *Section 7.11* for details.

7.4.5 Description of data protection option bytes

The option bytes that can be used to enhance data protection are listed below:

- PRODUCT_STATE[7:0]: A product life cycle state (see *Section 7.6.11* for details).
- WRPSGn1/2: write protection option of the corresponding group of four consecutive sectors in Bank1 (respectively Bank2). It is active low. Refer to *Section 7.6.8* for details.
  - Bit N: Group embedding sectors 4 x N to 4 x N + 3
- SECWMx: TrustZone® secure only watermark area definition (refer to *Section 7.6.1* for details).
  - SECWM1_STRT (respectively SECWM1_END) contains the first (respectively last) sector of the secure access only zone in Bank1
  - SECWM2_STRT (respectively SECWM1_END) contains the first (respectively last) sector of the secure access only zone in Bank 2.
- TZEN: this nonvolatile option can be used by the application to activate the secure access mode, as described in *Section 7.6*. For security reasons the TZEN is stored with redundancy on 8 bits. While the TZEN OB value is set immediately after

programming, to actually use TZ features, reset is required to set the TZ_STATE in SBS.

When TZEN is activated, secure watermark settings and secure boot address may be reset to default to prevent a deadlock in case the previous values were not correct.

- HDPx: Secure hide protection - HDPL exclusive area control in the user flash memory.

When factory programmed values of the data protection option bytes are the following:

- Product state depends on sales type
- Flash bank erase operations do not impact watermarked secure data areas
- Secure watermark areas protections disabled (start addresses higher than end addresses)
- Write protection disabled (all option byte bits set to 1)
- TrustZone Secure access mode disabled (TZEN option byte value = 0xC3)

Refer to *Section 7.11* for details.

7.4.6 Description of boot address option bytes

Below the list of option bytes that can be used to configure the appropriate boot address for an application:

- PRODUCT_STATE
- BOOT_UBE: Available only on cryptography enabled devices.
  Selects either ST-iRoT or User flash as default boot address. Also used by RSS(SFI) to choose either Bootloader or ST-iRoT as next stage.
- NSBOOTADD: Selects default boot address when TZ is disabled.
- SECBOOTADD: Selects default boot address when TZ is enabled.
- (NS/SEC)BOOT_LOCK: Protects the boot configuration from further modification attempts.
- SWAP_BANK: bank swapping option, set to 1 to swap user flash banks after boot (see *Section 7.3.11*). If BOOT_LOCK corresponding to TZEN state (SEC/NS) is active, the value in SWAP_BANK is fixed, read-only.

When STMicroelectronics delivers the device, the PRODUCT_STATE is Open, BOOT_LOCK is not set (0xC3) and the BOOT_UBE is set to user flash (0xB4). Addresses are SECBOOTADD = 0x0C00 0000, NSBOOTADD = 0x0800 0000.

Refer to *Section 7.11* for details.

7.4.7 Specific rules for modifying option bytes

On top of OPTLOCK bit and register access rules, there are also other protection means for selected security-sensitive option byte fields.

More option bytes can be modified simultaneously, but if they rely on each other for protection, both states are checked. For example, when trying to modify PRODUCT_STATE and TZEN simultaneously, resulting state must be coherent with the rules. With few exceptions, listed in this section, failing to uphold the rules results in raising OPTCHANGEERR flag (*Section 7.9.12* for additional details).

Table 43. Specific OB modifying rules

Option byte	HDPL	TZ secure	Value	Product state
PRODUCT_STATE	0,1(1)	Some values only when TZ is enabled	Set of possible transitions	Set of possible transitions (*Table 37*)
HDP	0,1(2)	(3)	-	Refer to *Table 44*
TZEN	-	-	-	Regression, Open or Provisioning
EPOCH	0	-	PRG > CUR	Regression
EPOCH_NS	0(2)	-	PRG > CUR	NS-Regression, Regression
SECWM	-	Secure mode only(2)	-	Refer to *Table 44*
BOOT_UBE	-	-	-	Open or Provisioning, SECBOOT_LOCK disabled
SECBOOTADD	-	Secure mode only(2)	-	
NSBOOTADD	-	-	-	Open or Provisioning, NSBOOT_LOCK disabled
LOCKBL	-	-	One way switch(2)	-
SWAP_BANK	-	Fixed if BOOT_LOCK corresponding to TZEN is set	-	-
SECBOOT_LOCK	-	Secure mode only(2)	-	Open, Regression or Provisioning to unlock
NSBOOT_LOCK	-	-	-	

1. Most transitions are possible regardless of HDPL, only a few require specific HDPL, see text below.
2. No OPTCHANGEERR raised in violation of this.
3. Dash means there is no limitation from this side.

Even in the closed PRODUCT_STATE progression, some OB can still be modified, if all the other constraints are satisfied. An overview is presented in *Table 44*.

Table 44. OB modifiable in closed product

PRODUCT_STATE	OBs that may be modified
TZ-Closed	SWAP_BANK, LOCKBL, PRODUCT_STATE, SECWM, HDP
Closed	SWAP_BANK, LOCKBL, PRODUCT_STATE
Locked	SWAP_BANK, LOCKBL

Specific rules must be respected to update the following OB:

- **PRODUCT_STATE**

  PRODUCT_STATE transitions follow a state machine with two types of transition. Locking down the product is allowed without restriction. Opening the product is possible only using a debug interface and following a digital signature verification. The regression to a less secure state results in the erasing of the protected content. More details are given in *Section 7.6.11*.

  Summary: Selected changes are only possible in HDPL1, regression in HDPL0. Some states are accessible only when TZEN is enabled.

- **HDP**

  Can only be modified in HDPL0 and HDPL1. Must not be set to overlap with flash high-cycle data area.
- **TrustZone access mode (TZEN)**

  Can only be changed in Open, Regression and Provisioning.
- **SEC_EPOCH and NS_EPOCH**

  The value programmed must be greater than current value.The increment is done in specific product states: Regression and NS-Regression.
- **Secure watermark area (SECWM1/2_STRT and SECWM1/2_END)**

  Can be changed only in secure mode (TZ_state = 0xB4). Automatically reset to default value when TZEN is enabled. Must not be set to overlap with flash high-cycle data area.
- **BOOT_UBE**

  Available only on cryptography enabled devices.
  Can only be changed in product states open for debug like Open and also in Provisioning. SECBOOT_LOCK must be disabled to change.
- **SECBOOTADD**

  Can only be changed in Open and Provisioning. Locked by SECBOOT_LOCK. Automatically reset to default value when TZEN is enabled.
- **NSBOOTADD**

  Can only be changed in Open and Provisioning. Locked by NSBOOT_LOCK.
- **LOCKBL**

  Can only be changed freely in one direction. A permanent irreversible switch.
- **SWAP_BANK**

  Not modifiable when both TZEN and SECBOOT_LOCK are 0xB4 (set) or when TZEN = 0xC3 (disabled) and NSBOOT_LOCK is active (0xB4).
- **SECBOOT_LOCK**

  Can only be changed freely in locking direction. Unlock is possible in Open, Provisioning and Regression.
- **NSBOOT_LOCK**

  Can only be changed freely in locking direction. Unlock is possible in Open, Provisioning and Regression.

Note: For all user option bytes above: default values are loaded and Tamper is signaled when a double ECC error occurs during OBL.

7.5 Option-byte key management

This section describes the key storage tied with SAES and OBK-HDPL value set by the SBS (refer to *Section 14.3.7: SBS hardware secure storage control*). The OBKs are stored in 128 bits and protected by 9-bit ECC (SEC/DED). They are written alternatively in two sectors.

7.5.1 OBK loading

OBKs are memory mapped, and accessible through the main AHB bus (C-Bus), starting from address 0x0FFD 0000. A 9-bit ECC is associated to each 128-bit data flash word.

Note: Read access is allowed in the current and alternate sector, except for the last address of the current and alternate sector. In case of read access, no error is reported but the read data is always 0x0 (see Section 7.6.12).

7.5.2 OBK access per HDPL level

Table 45 describes the option-byte key areas. The key storage is not dedicated to a particular key, and the usage is defined by the application.

An option-byte key can be accessed only if the OBK-HDPL (set in SBS) matches the HDPL associated to the storage offset (as indicated below) (refer to *Section 14.3.7: SBS hardware secure storage control*). If it is not the case, an OBKERR error is raised.

Table 45. Option-byte key area

OBK-HDPL	Address offset start	Address offset end	Comment
0	0x0000	0x00FF	Reserved for HDPL0 key storage
1	0x0100	0x08FF	OEM iRoT keys
2	0x0900	0x0BFF	uRoT, OS or secure application
3	0x0C00	0x17FF	HDPL 3 secure keys
3	0x1800	0x1FEF	HDPL 3 non-secure keys

7.5.3 OBK programming sequence

The sequence to write OBK is the same as a write to main flash except that the “alternate sector” (ALT_SECT) bit must be set to write in the alternate OBK sector. The ALT_SECT bit is checked each time a write access is received. If it does not match the one stored in the write buffer, an error is raised.

Note: Before writing in the alternate OBK sector the user must ensure that the whole key space (128, 256, or 512 bits) is free, by reading the alternate OBK sector.

If the alternate sector is not free, the user must erase the sector using the dedicated erase command ALT_SECT_ERASE.

Secure programming method

Using the secure register if TrustZone is active (TZ_STATE = 0xB4):

1. Program the ALT_SECT bit.
2. Make sure protection mechanism does not prevent programming (TZ, PRIV and OBK-HDPL).
3. Check that no FLASH memory operation is ongoing by checking the BSY and DBNE bits in the FLASH_SECSR register and that the write buffer is empty by checking the WBNE bit in the FLASH_SECSR register.
4. Check and clear all the secure error flags due to previous operation.
5. Unlock the FLASH_SECCR register only if this register is not already unlocked, as described in *Section 7.6.7*.
6. Enable write operations by setting the SECPG bit in the FLASH_SECCR register.
7. Write one flash-word corresponding to 16-byte data starting at 16-byte aligned address.

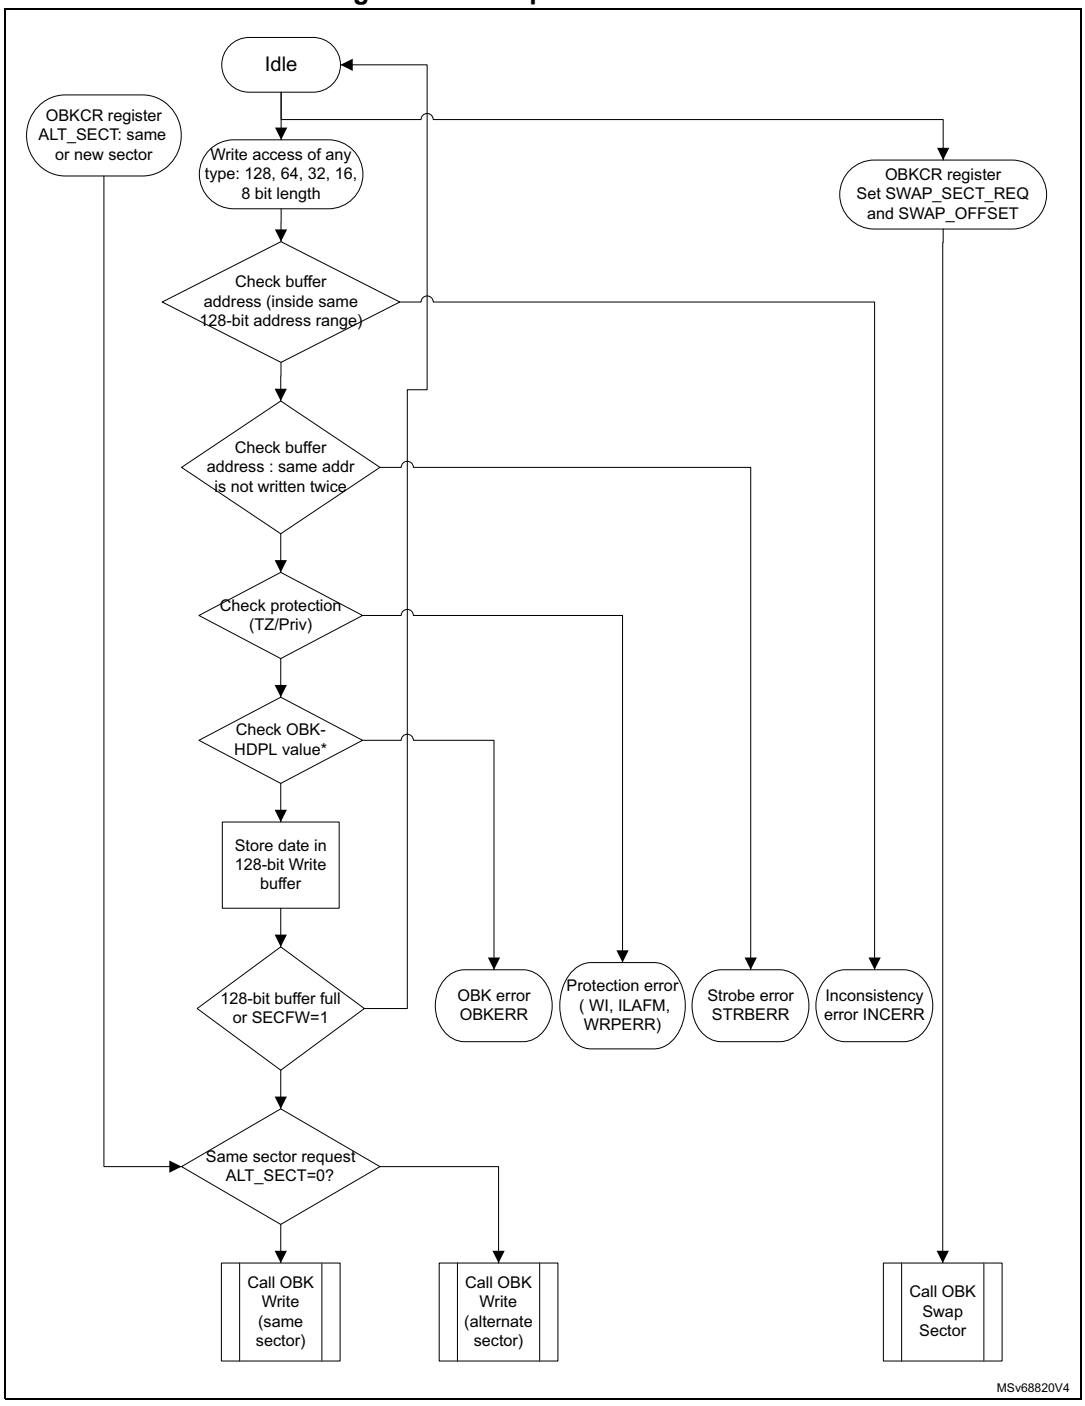
Note: WBNE flag indicates if the 128-bit write buffer is waiting for new data.

Note: No erase request, options change request, OBK swap sector or OBK alternate sector erase is allowed between first write and the completion of flash write operation.

8. Wait for the BSY bit to be cleared in the corresponding FLASH_SECSR register.
9. Clear PG bit in FLASH_SECCR register if there is not any programming request anymore in the bank.

If step 7 is executed incrementally (byte per byte), the write buffer can become partially filled. In this case the application software can decide to force-write what is stored in the write buffer by using FW bit in FLASH_SECCR register. In this particular case, the unwritten bits are automatically set to 1. If no bit in the write buffer is cleared to 0, the FW bit has no effect.

Figure 26. OBK protection checks

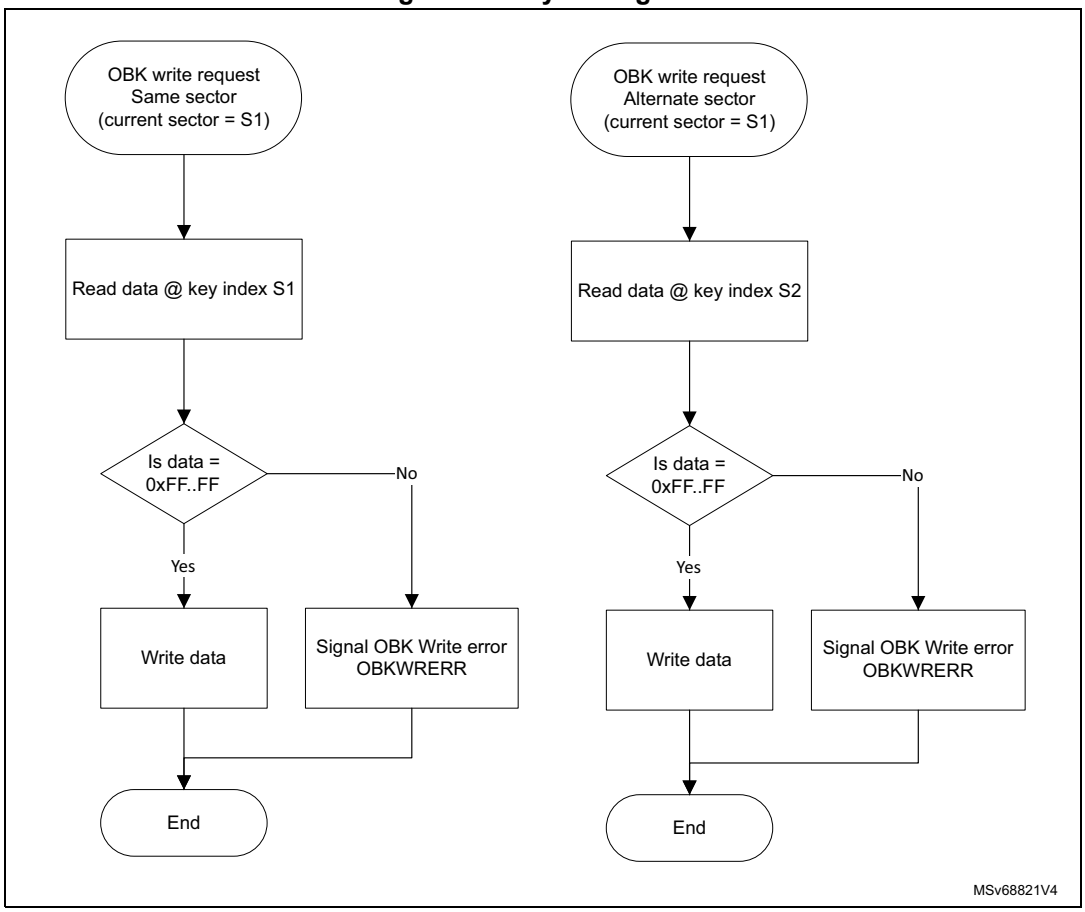


7.5.4 OBK programming finite state machine

When the OBK write buffer is filled, the OBK programing is launched automatically either in the current OBK sector or in the alternate OBK sector depending on the ALT_SECT bit.

If the address is not virgin, the OBKWRERR is raised.

Figure 27. Key writing flow



7.5.5 OBK swap sector

The user can request a swap of the Option Byte Keys by setting the bit SWAP_SECT_REQ in the NS/SECOBKCFGR register. The number of keys swapped are defined by the SWAP_OFFSET in NS/SECOBKCFGR register.

Swap is limited by OBK-HDPL value, following SWAP_OFFSET values are permitted:

OBK_HDPL0_OFFSET = 16

OBK_HDPL1_OFFSET = 144

OBK_HDPL2_OFFSET = 192

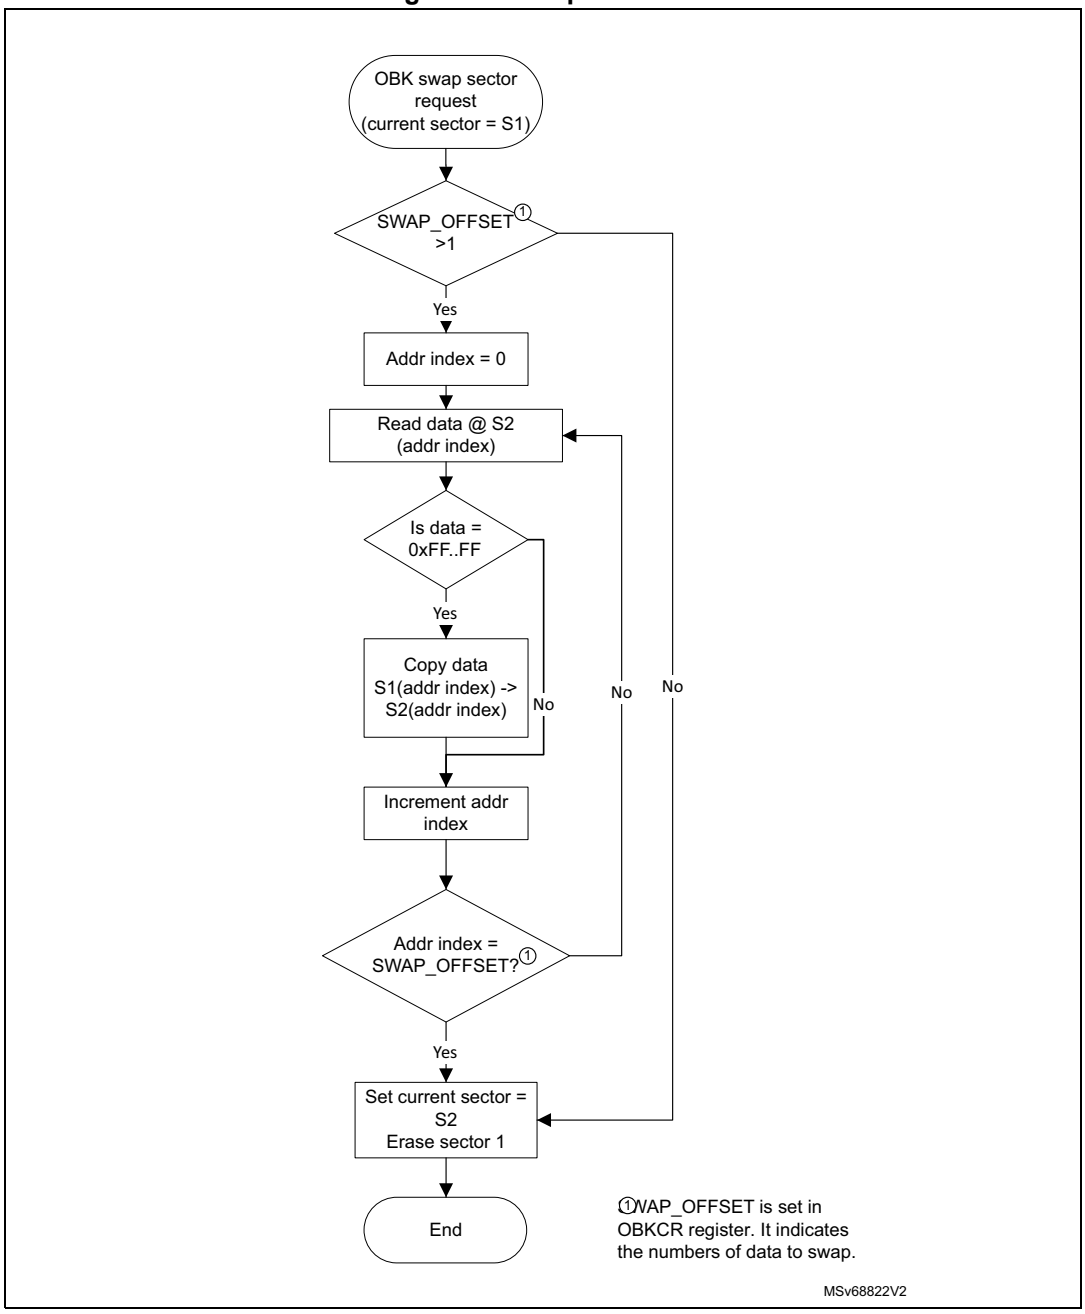
OBK_HDPL3SEC_OFFSET = 384

OBK_HDPL3NS_OFFSET = 511

The programming sequence is the following:

1. Check that no FLASH memory operation is ongoing by checking the BSY and DBNE bit in the FLASH_SEC/NSSR register and that the write buffer is empty by checking the WBNE bit in the FLASH_SEC/NSSR register.
2. Check and clear all the secure/non-secure error flags due to previous operation.
3. Unlock NS/SECOBKCFGR register if not unlocked already thanks to FLASH_NS/SECOBKKEYR.
4. Define the numbers of keys to be swapped thanks to SWAP_OFFSET field in NS/SECOBKCFGR. SWAP_OFFSET must be equal to or greater than OBK_HDPL<N-1>_OFFSET.
5. Set bit SWAP_SECT_REQ in NS/SECOBKCFGR.
6. Wait for BSY bit to be cleared. In case of error OBKERR flag is set.
7. SWAP_SECT_REQ is cleared automatically at the end of the operation or in case of error.

Figure 28. Swap workflow



While the OBK SWAP operation is ongoing, the BSY flag is set and no other operation (write, erase, user opt change) can be launched in parallel.

7.5.6 OBK alternate sector erase

The user can request the erase of the alternate OBK sector by setting the bit ALT_SECT_ERASE in the FLASH_NS/SECOBKCFGR register.

The programming sequence must be:

1. Check that no FLASH memory operation is ongoing by checking the BSY and DBNE bits in the FLASH_SEC/NSSR register and that the write buffer is empty by checking the WBNE bit in the FLASH_SEC/NSSR register.
2. Check and clear all the secure/non-secure error flags due to previous operation.
3. Set bit ALT_SECT_ERASE in NS/SECOBKCFGR.
4. Wait for BSY bit to be cleared.
5. ALT_SECT_ERASE is cleared automatically at the end of the operation or in case of error.

7.6 FLASH security and protections

Since sensitive information are stored in the flash memory, it is important to protect it against unwanted operations such as reading confidential areas, illegal programming of immutable sectors, or malicious flash memory erasing.

For that purpose FLASH implements the following protection mechanisms:

- TrustZone backed watermark and block security protection
- Temporal isolation protection (HDP)
- Configuration protection
- User flash write protection
- Device nonvolatile security life cycle and application boot state management
- OTP locking

The microcontroller can have TrustZone active (TZ_STATE = 0xB4) or not (TZ_STATE = 0xC3).

While TrustZone is active the flash memory can be accessed in four basic modes:

- non-secure and unprivilege
- non-secure and privilege
- secure and privilege
- secure and unprivilege

While TrustZone is disabled, only two modes are possible:

- non-secure and unprivilege
- non-secure and privilege

The flash interface evaluates the access restrictions in the following order:

1. TrustZone security
2. Write protection (for write access)
3. HDP
4. Privilege

7.6.1 TrustZone security protection

The global TrustZone system security is activated by setting the TZEN option in the FLASH_OPTSR2_PRG register. The actual state of TZ is however determined by the SBS and the setting of TZ_STATE (refer to *Section 14.3.5: SBS boot control*).

When TrustZone is active (TZ_STATE = 0xB4), the following additional security features are available:

- Secure watermark-based user options bytes defining secure areas
- Secure or non-secure block-based areas can be configured on-the-fly after reset. This is a volatile secure area
- Additional product states associated with **closed_secure** provide protection of secure domain against external access (debug or bootloader)
- Erase or program operation can be performed in secure or non-secure mode with associated configuration bit. When the TrustZone is disabled (TZ_STATE = 0xC3), the above features are deactivated and all secure registers are RAZ/WI.

Activating TrustZone security

When the TrustZone is activated (TZ_STATE = 0xB4), the SECBOOTADD and the secure watermark areas are set to a secure default value. Default settings are also used in case of corrupted configuration. In this default state, user flash memory is secure as shown in the table below.

Table 46. Default secure watermark

Secure watermark in case of configuration error	Security attribute
SECWMx_STRT = 0 SECWMx_END = 0x7F	All flash memory is secure

Illegal access generation

A non-secure access to a secure flash memory area is RAZ/WI and generates an illegal access event. An illegal access interrupt is generated if the FLASHIE illegal access interrupt is enabled in the TZIC_IER2 register.

A non-secure access to a secure flash register generates an illegal access event. An illegal access interrupt is generated if the FLASH_REGIE illegal access interrupt is enabled in the TZIC_IER2 register.

Table 47. Flash memory TZ protection summary

TZ protection (TZ_STATE = 0xB4)		Main flash	
		Non-secure sector	Secure sector
Secure	Fetch	BUS ERROR	OK
	Read	RAZ, ILAFM	
	Write	WI, WRPERR, ILAFM	If not WRP: OK else: WI, WRPERR
	Erase		

Table 47. Flash memory TZ protection summary (continued)

TZ protection (TZ_STATE = 0xB4)		Main flash	
		Non-secure sector	Secure sector
Non-secure	Fetch	OK	BUS ERROR
	Read		RAZ, ILAFM
	Write	If not WRP: OK else: WI, WRPERR	WI, WRPERR, ILAFM
	Erase		

Table 48. TZ protection and bank or mass erase summary

TZ protection (TZ_STATE = 0xB4)	Main flash		
	Non-secure flash	Secure flash	Mix of secure and non-secure
MES	WI, WRPERR, ILAFM	OK	WI, WRPERR, ILAFM
MENS	OK	WI, WRPERR, ILAFM	WI, WRPERR, ILAFM

Deactivate TrustZone security

Reversing of the TZ setting in OB (TZEN) is possible when the product state is ST-RoT-Ready or Provisioning. Deactivating TZEN from other states requires full regression (Regression state).

When the TrustZone is deactivated (TZ_STATE = 0xC3) after option bytes loading, the following security features are deactivated:

- Watermark-based secure area (refer to *Watermark-based secure flash area protection*)
- block-based secure area (refer to *Section 7.6.3*)
- Secure interrupts (refer to *Section 7.9.11*)
- All secure registers are RAZ/WI.

Watermark-based secure flash area protection

When TrustZone security is active (TZ_STATE = 0xB4), a part of the flash memory can be protected against non-secure read and write accesses. Up to two different nonvolatile secure areas can be defined by option bytes and can be read or written by a secure access only: one area per bank can be selected with a sector granularity.

The secure areas are defined by a start sector offset and end sector offset using the SECWMx_STRT and SECWMx_END option bytes. These offsets are defined in the secure watermark registers address registers *FLASH security watermark for Bank 1 (FLASH_SECWM1R_CUR)*, *FLASH security watermark for Bank 2 (FLASH_SECWM2R_CUR)* and modified by corresponding FLASH_XXX_PRG registers.

The SECWMx_STRT and SECWMx_END option bytes can only be modified by secure firmware.

Table 49. Secure watermark-based area

Secure watermark option bytes values (x = 1,2)	Secure watermark protection area
SECWMx_STRT > SECWMx_END	No secure area
SECWMx_STRT = SECWMx_END	One sector defined by SECWMx_STRT is secure watermark-based protected
SECWMx_STRT < SECWMx_END	The area between SECWMx_STRT and SECWMx_END is secure watermark-based protected

Caution: Switching a memory area from secure to no-secure does not erase its content. The user secure software must perform the needed operation to erase the secure area before switching an area to non-secure attribute whenever is needed. It is also recommended to flush the instruction cache.

7.6.2 Hide protection (HDP)

The HDP area is independent of the flash watermark-based secure area. One nonvolatile secure hide protection (HDP) area per bank can be defined with a sector granularity. Access to the hide protection area can be denied by progressing the HDPL level in the SBS.

When the HDPL = 1, no user flash is protected by the HDP. With HDPL ≥ 2 the user OB defined HDP area in each bank is closed. No read, write, fetch or erase is allowed in the HDP area.

The HDP area can be extended, the extension setting is only a register value, not stored in OB. With HDPL = 3 the HDP area remains activated and the extension is added. If extension is added while the base user OB defined area is not active, the extension covers one more sector, because HDPx_END sector is also protected.

The HDPL level can be only cleared by a system reset, there is no means to deactivate the HDP area.

The protected HDP area is defined by setting its size using start and end sectors in a similar way as the secure watermark.

The size of the inaccessible area can be extended using register FLASH_HDPEXTR values HDPx_EXT. The value HDPx_EXT is a number of sectors added to the HDP area (past the HDPx_END sector). The volatile HDPx_EXT value in the register can be increased, but cannot decrement.

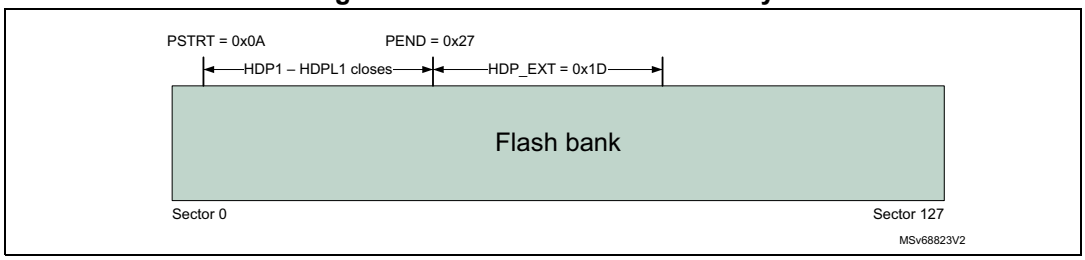
In case of HDPx_STRT > HDPx_END the extension will cover (HDPx_EXT + 1) size area between sectors marked by HDPx_END and HDPx_END + HDPx_EXT.

By default both the HDPx_END is set to zero and HDPx_STRT is set to one. This means that the HDP area in user flash is zero size and extends from the flash start address (first sector).

For example, to protect area by HDP from the address 0x0801 4000 (included) to the address 0x0804 FFFF (included):

- For physical Bank1, the option-byte registers must be programmed with:
  - HDP1_STRT = 0x0A
  - HDP1_END = 0x27

Figure 29. HDP in user flash memory



- Once the HDPL is incremented to 2, the marked area becomes inaccessible.
  The HDPL = 2 code then sets the extension size to 29. Once the HDPL is incremented to 3, the extension area becomes also inaccessible.
- Alternatively, if:

  HDP1_END = 0
  HDP1_START = 1
  HDPx_EXT = 1
  Sector 0 and Sector 1 are HDP protected.
  Or a rather unusual example:
  HDP1_END = 2
  HDP1_START = 7
  HDPx_EXT = 3

  Sectors 2 to 5 are HDP protected.
  Here the user should know that if his application needs sectors 2 to 4 only as HDP area, he should program HDPx_EXT at 2 instead of 3.
- If the two banks are swapped, the protection defined to physical Bank1 remains on the physical Bank1, unaffected by swapping. Separate protection applies to physical Bank2 and the option bytes registers must also be programmed with:
  - HDP2_STRT = 0x0A
  - HDP2_END = 0x27

Note: For more details on the bank swapping mechanism, refer to Section 7.6.6.

Table 50. Secure hide protection

HDPx watermark option-byte values (x = 1, 2)		Hide protection area
HDPL ≤ 1	-	No inaccessible HDP area in user flash memory
HDPL = 2	HDPx_END < HDPx_STRT	No inaccessible HDP area in user flash memory
	HDPx_END = HDPx_STRT	Exactly one sector is protected by HDP.
	HDPx_END > HDPx_STRT	The area between HDPx_STRT and HDPx_END is HDP protected.

Table 50. Secure hide protection (continued)

HDPx watermark option-byte values (x = 1, 2)		Hide protection area
HDPL = 3	HDPx_END < HDPx_STRT and HDPx_EXT = 0	No inaccessible HDP area in user flash memory
	HDPx_END ≥ HDPx_STRT or HDPx_EXT > 0	The area between min (HDPx_STRT, HDPx_END) and (HDPx_END + HDPx_EXT) is HDP protected.

Table 51. HDP protections summary

HDP protection	User flash			
	Access to OB HDP area		Access to EXT HDP area	
	HDPL 2 or 3	HDPL0 or HDPL1	HDPL3	HDPL0, HDPL1, or HDPL 2
Fetch	BUS ERROR	OK	BUS ERROR	OK
Read	RAZ		RAZ	
Write	WI, WRPERR	If not WRP: OK else: WI, WRPERR	WI, WRPERR	If not WRP: OK else: WI, WRPERR
Erase (mass erase)				

7.6.3 Block-based secure flash memory area protection

Any sector can be programmed on-the-fly as secure or non-secure using the block-based configuration registers. FLASH_SECBB1x (respectively FLASH_SECBB2x) registers are used to configure the security attribute for sectors in Bank1 (respectively Bank2).

When the sector security attribute bit SECBByx[i] is set, the security attribute is the same as the secure watermark-based area. The secure sector is only accessible by a secure access.

If the SECBBy[i] bit is set or reset for a sector already included in a secure watermark-based area, the sector keeps the watermark-based protection security attributes.

To modify a block-based sector security attribute, it is recommended to:

- Check that no flash operation is ongoing on the related sector.
- Add an ISB instruction after modifying the sector security attribute SECBByx[i].

Caution: Switching a sector from secure to non-secure does not erase the content of the associated sector. User secure software must perform the needed operations before switching to non-secure attribute:

- Erase sector content.
- Invalidate the instruction cache.

Note: For SECBByx[i] access control, refer to Table 52.

Execute protection for S-Bus (AHB register bus) is done in AHB decoder, not in flash memory interface itself.

Table 52. Secure configuration block-based registers access conditions

Access			Corresponding sector privilege status	Sector setting in SECBBxy
Fetch	Secure/ non-secure	Privilege/ unprivilege	-	BUS ERROR
Read			-	OK
Write	Secure	Privilege	-	OK
		Unprivilege	0	OK
			1	WI
	Non-secure	Privilege/ unprivilege	-	WI, ILAP

7.6.4 Block-based privileged flash memory area protection

Any sector can be programmed on-the-fly as privileged or unprivileged using the block-based configuration registers. FLASH_PRIVBB1x (respectively FLASH_PRIVBB2x) registers are used to configure the privilege attribute for sectors in Bank1 (respectively Bank2).

When the sector privilege attribute PRIVBByx[i] bit is set, the sector is only accessible by a privileged access. An unprivileged sector is accessible by a privileged or unprivileged access.

To modify a block-based privilege attribution, it is recommended to:

- Check that no flash operation is ongoing on the related sector.
- Add an ISB instruction after modifying the sector security attribute PRIVBByx[i].

Caution: Switching a sector from privileged to unprivileged does not erase the content of the associated sector.

Table 53. Privilege protection summary

Access (TZ not relevant)		Main flash	
		Unprivileged sector	Privileged sector
Privilege	Fetch	OK	
	Read		
	Write		
	Erase		
Unprivilege	Fetch	OK	RAZ
	Read		
	Write		WI, WRPERR
	Erase		

Table 54. Privilege and mass or bank erase

Access (TZ state not relevant)	Main flash		
	Unprivileged FLASH	Privileged FLASH	Mix unprivileged and privileged FLASH
MEP	OK		
MENP	OK	WI, WRPERR	

Note: For PRIVBByx[i] access control, refer to Table 55 and Table 56.

Table 55. Privilege configuration register access conditions (TZ enabled)

Access			Corresponding sector secure status(1)	Sector setting access in PRIVBBxy
Fetch	Privileged/ unprivileged	Secure/ non-secure	-	BUS ERROR
Read			-	OK (all sectors)
Write	Privileged	Secure	-	OK (all sectors)
		Non-secure	NS	OK (only the sector corresponding to the bit)
			S	WI (only the sector corresponding to the bit)
	Unprivileged	Secure/ non-secure	-	WI

1. Either watermark or block-based.

Table 56. Privilege configuration register access conditions (TZ disabled)

Access		Sector setting access in PRIVBBRxy
Fetch	Privileged/ unprivileged	BUS ERROR
Read		OK
Write	Privileged	OK
	Unprivileged	WI

7.6.5 Flash memory register privileged and unprivileged modes

The flash registers can be read and written by privileged and unprivileged accesses depending on the SPRIV and NSPRIV bits in *FLASH privilege configuration register (FLASH_PRIVCFGR)*:

- When the SPRIV (respectively NSPRIV) bit is reset, all secure (respectively non-secure) flash registers can be read and written by both privileged or unprivileged access.
- When the SPRIV (respectively NSPRIV) bit is set, all secure (respectively non-secure) flash registers can be read and written by privileged access only. Unprivileged access to a privileged registers is RAZ/WI.

The registers related to key storage (FLASH_NSOBKCFGR, FLASH_SECOBKCFGR, FLASH_NSOBKKEYR, FLASH_SECOBKEYR) are exceptions to this rule and can be only accessed in privilege, regardless of other settings.

The next table summarizes flash registers access control.

Table 57. Flash register accesses(1)

Access			Non-secure register		Secure register	
			NSPRIV = 1	NSPRIV = 0	SPRIV = 1	SPRIV = 0
X	Secure/ non-secure	Privileged/ unprivileged	Bus error			
R/W	Secure	Privileged	OK			
R/W		Unprivileged	RAZ, WI	OK	RAZ, WI	OK
R/W	Non-secure	Privileged	OK		RAZ, WI, ILAP	
R/W		Unprivileged	RAZ, WI	OK		

1. Some registers are privilege only, not configurable.

7.6.6 Flash memory banks attributes in case of bank swap

The SWAP_BANK option bit modifies the address of each bank in the memory map. When SWAP_BANK is reset, flash Bank1 is mapped at the lower address range. When SWAP_BANK is set, flash Bank1 is mapped at the higher address range. flash bank attributes follow their bank contents so there is no need to modify their setting registers when swapping banks:

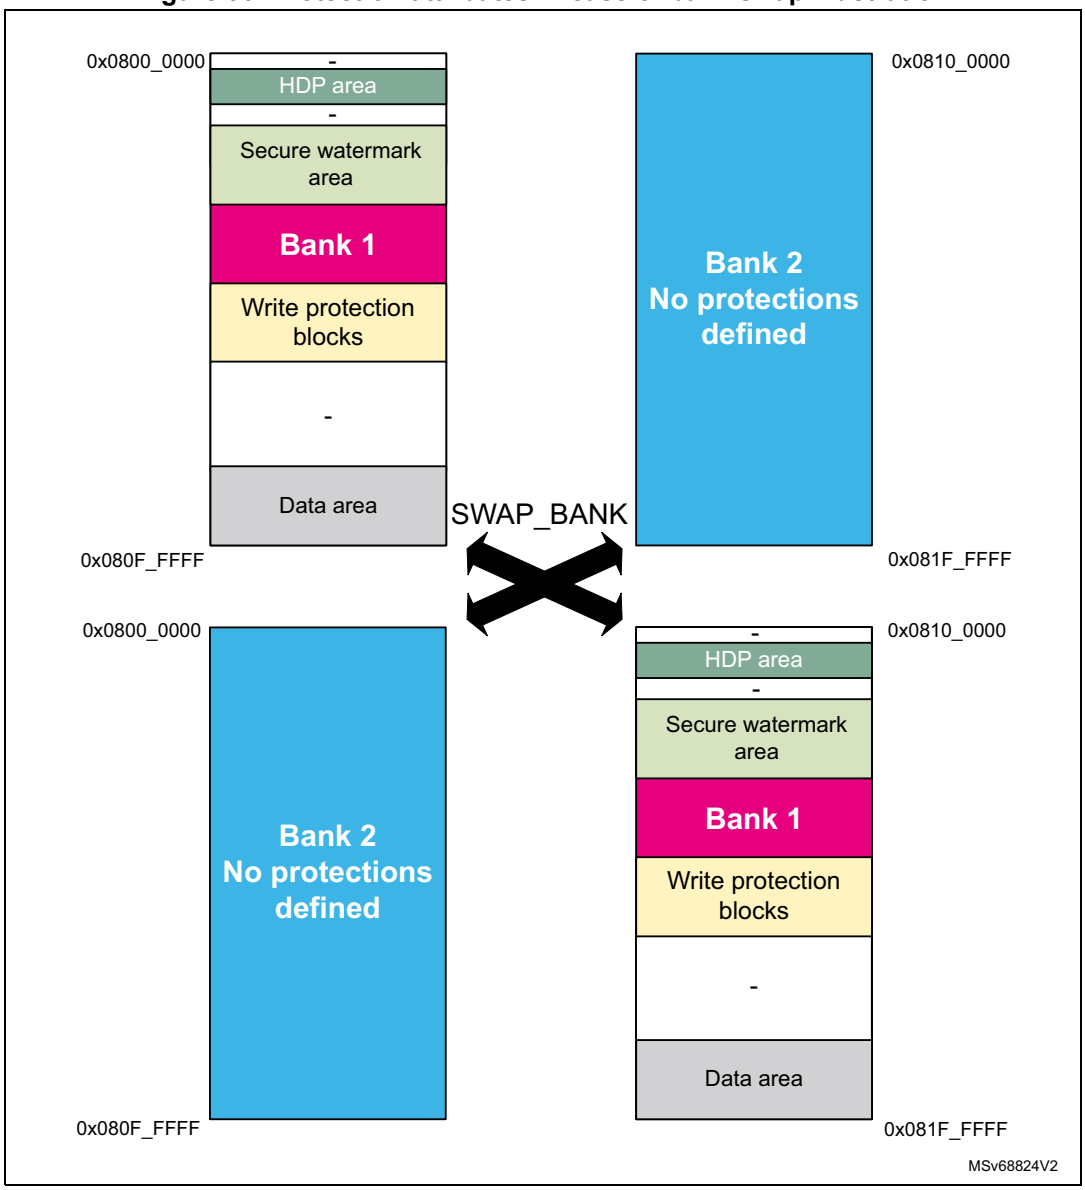
- Flash secure watermark x FLASH_SECWMx
- Flash write protection sector group FLASH_WRPSG (refer to *Section 7.6.8*)
- Hide protection in FLASH_HDPx registers
- Flash secure block based bank x register y FLASH_SECBBxy
- Flash privilege block based bank x register y FLASH_PRIVBBxy
- The data area configuration FLASH_EDATA

The SWAP_BANK is rendered immutable by setting BOOT_LOCK in the user OB. If TZEN is enabled, then SECBOOT_LOCK locks the option. If TZEN is disabled, then NSBOOT_LOCK locks the SWAP_BANK option.

Note: The BK_ECC bit in the FLASH ECC detection register (FLASH_ECCDETR) and FLASH ECC correction register (FLASH_ECCCORR), BKSEL bit in FLASH non-secure control register (FLASH_NSCR) and BKSEL bit in FLASH secure control register (FLASH_SECCR) always refers to Bank1 (respectively Bank2) when it is low (respectively high), regardless of the SWAP_BANK value.

Figure 30 shows how security attributes and protections behave in case of bank swap.

Figure 30. Protection attributes in case of bank swap illustration



7.6.7 Flash memory configuration protection

The memory uses hardware mechanisms to protect the following assets against unwanted or spurious modifications (such as software bugs):

- Option bytes change
- Write operations
- Erase commands
- Interrupt masking

The memory configuration registers protection is summarized in *Table 58*. Registers not present in this table are not protected by a key.

Table 58. Flash interface register protection summary

Register name	Unlocking register	Protected asset
FLASH_NSCR	FLASH_NSKEYR	Write/erase control
FLASH_SECCR	FLASH_SECKEYR	Secure write/erase control
FLASH_OPTCR + all _PRG registers	FLASH_OPTKEYR	Flash bank option byte words change
FLASH_NSOBKCFGR	FLASH_NSOBKKEYR	Flash OBKey storage manipulation
FLASH_SECOBKCFGR	FLASH_SECOBKKEYR	

7.6.8 Write protection

The purpose of the write protection is to prevent unwanted modifications to code and/or data.

Any flash group of four consecutive 8-Kbyte sectors can be independently write-protected or unprotected by clearing/setting the corresponding WRPSGn1/2 bit in the FLASH_WRPSG1/2 register (see *FLASH write sector group protection for Bank 1 (FLASH_WRP1R_CUR)* and *FLASH write sector group protection for Bank 2 (FLASH_WRP2R_CUR)*).

A write-protected group of sectors cannot be erased nor programmed. As a result, a bank erase cannot be performed if one group of sectors is write-protected, unless a NVSTATE transition to OPEN is triggered (erasing the whole user flash memory).

Note: Write protection errors are documented in Section 7.9.

7.6.9 Flash high-cycle data protections

The embedded flash memory can be configured to have 96-Kbyte memory area with high-cycling capability (100 kcycles) to store data and emulate EEPROM, see *Section 7.3.10*.

Option-byte controlled security features for user flash memory prevent sectors from being used as high-cycle data area. No OPTCHANGEERR is raised in case of setting conflict, it only makes the sectors unusable. Details are listed in *Table 59*.

Volatile settings using FLASH_SECBBxx and FLASH_PRIVBBxx can be applied. In this case the security setting of user flash sector 127 applies to flash high-cycle data sector 0 and so on, as indicated in *Figure 23*, *Figure 24* and *Figure 25*.

Volatile setting of HDP extension that protrudes into sectors of data area also effectively causes the data area to be inaccessible.

Table 59. High-cycle area protection summary: access to data area address range

<table>
<tr><th colspan="2" rowspan="3">TZ protection (when TZ_STATE = 0xB4)(1)</th><th colspan="6">Data sector enabled</th><th rowspan="3">Data sector not enabled</th></tr>

</table>

7.6.10 Life cycle management

Non-volatile states, or debug states, are determined by the product state set by user option bytes. Debug possibility and possibility to change selected security settings are related to this state. While the state is stored in the OB, it is the SBS that controls the debug policy.

OBK storage access conditions are unaffected by the PRODUCT_STATE, but keys may be evicted in regression transitions.

HDP works equally regardless of the debug state. Even in debug the HDP area is hidden when HDPL increments.

The following states are defined:

Table 62. Product states, debug states and debug policy

PRODUCT_STATE	Code in OB	Description
Open	0xED	User flash open (TZ secure and non-secure open). External access (debug) N and NS enabled (~RDP0).
Provisioning	0x17	Provisioning - immutable root of trust is being installed. Open if TZEN = 0xC3.
iROT-Provisioned	0x2E	The immutable root of trust is installed (~RDP 0.5).
TZ-Closed	0xC6	State for debugging the NS application. Debug is restrained to non-secure areas.
Closed	0x72	State for running a secure application. Debug disabled, regression is possible.
Locked	0x5C	Transition to other state, policy change or debug not permitted(1).
Regression	0x9A	The temporary state initiated by the debug authentication system in transition to Open.
NS-Regression	0xA3	The temporary state initiated by the debug authentication system in transition to TZ-Closed.

1. The same situation is Closed state with incorrect or not defined debug certificates.

1. No debug protection

Read, program and erase operations into the flash main memory area are possible. Least restriction on the option bytes.

2. Non-secure debug only

All read and write operations (if no write protection is set) from/to the non-secure flash memory are possible. The debug access to secure area is prohibited. Debug access to non-secure area remains possible.

The following rules are enforced:

- User mode: code executing in user mode (boot flash) can access flash main memory and option bytes with all operations (read, erase, program).
- Non-secure debug mode: The secure flash memory areas are inaccessible; the non-secure flash memory areas remain accessible for debug purpose.
- Boot RAM mode: boot from SRAM is not possible.
- Transition to Open state is possible with the consequence of flash mass erase and key slots revocation. Depends on debug unlock policy (see below).

3. Full product protection

All debug features are disabled and following rules enforced:

- User mode: code executing in user mode (boot flash) can access flash main memory and selected option bytes with all operations (read, erase, program).
- Boot RAM mode: boot from SRAM is not possible.
- Transition to TZ-Closed or Open state is possible with the consequence of flash mass erase and key slots revocation. Depends on debug unlock policy (see below).

7.6.11 Product state transitions

Progressing to more closed state is the normal product life cycle, that does not require security measures. Transition in direction to open state is a regression, controlled by the debug authentication control. If debug unlock policy is set to “locked”, no regression is accepted. Locked state may be reinforced by invalidating the debug authentication certificates.

All transitions not listed in this chapter are invalid.

There is no restriction on reading the current product state.

Transitions in progress direction

Transition from Open to any of the closed states is matter of correct product configuration and provisioning. The transitions must be done in correct order.

The normal progression is:

- Open, Provisioning or iROT-Provisioned
- Provisioning to iROT-Provisioned
- iROT-Provisioned to Closed, Locked or Closed
- Closed to Locked or Closed

Transition is managed either by a software running on the device, or directly, using a debug interface. Transitions from Closed are only possible by software running on the device. By software it is assumed that transitions are triggered by bootloader, or root-of-trust services, but generally any software running on the device can do a progress transition.

Transition to Open state

This transition is a full regression. The starting state is any except Open and Locked. The debug tools are used to authenticate debug regression access rights with the debug authentication library, running on the device in HDPL1 (refer to *Section 14.3.6: SBS debug control*). After verifying the credentials, it puts the device into intermediate state Regression. From this state the device regresses securely in HDPL0 to Open.

The transition has the following consequence:

- Epoch secure counter is incremented
- Key slots revocation
- Product state updated
- User options updated (security settings reset, TZEN reset)
- Flash memory mass erase
- Backup RAM erase is requested

Transition from closed to closed-secure debug state

This transition opens the device to authorize the debug of the non-secure application software without compromising the security of the ROT functions.

The starting state is Closed. The debug tools are used to authenticate debug regression access rights with the debug authentication library, running on the device in the HDPL1 (refer to *Section 14.3.6: SBS debug control*). After verifying the credentials, it puts the device into intermediate state NS-Regression. From this state, the device regresses securely in HDPL0 to Closed.

The transition has the following consequence:

- Epoch non-secure counter is incremented
- Non-secure slots revocation
- Product state updated
- Flash memory sectors that are not covered by the secure watermark are erased
- Backup RAM erase is requested

Table 63. PRODUCT_STATE transitions

From	To(1)							
	Open	Provisioning	iROT-Provisioned	TZ-Closed(2)	Closed	Locked	Regression	NS-Regression(2)
Open	-	OK	OK	X	X	X	X	X
Provisioning	X	-	OK	OK	OK	OK	OK (HDPL1)	X
iROT-Provisioned	X	X	-	OK	OK	OK	OK (HDPL1)	X
TZ-Closed	X	X	X	-	OK	OK	OK (HDPL1)	X
Closed	X	X	X	X	-	X	OK (HDPL1)	OK (HDPL1)
Locked	X	X	X	X	X	-	X	X

Table 63. PRODUCT_STATE transitions (continued)

From	To[1]							
	Open	Provisioning	iROT-Provisioned	TZ-Closed[2]	Closed	Locked	Regression	NS-Regression[2]
Regression	OK (HDPL0)	X	X	X	X	X	-	X
NS-Regression	X	X	X	OK (HDPL0)	X	X	X	-

1. X = transitions not permitted (OPTCHANGEERR raised), - = no change, OK = valid transitions.
2. To transition into this state, both current and programmed value of TZEN must be enabled (TZEN = 0xB4), otherwise the change is ignored with OPTCHANGEERR.

In *Table 63*, X indicates transitions that are not permitted, dash indicates no change, OK indicates valid transitions. Some transitions are possible only in correct HDPL provided in parenthesis. Attempts to do an illegal transition result in OPTCHANGEERR.

Incorrect PRODUCT_STATE (no OBL) is interpreted as Locked.

7.6.12 OBK protection

At the receipt of an OBK access (read/write/execute), secure and privilege attributes are first checked, followed by OBK-HDPL. The OBK-HDPL value must exactly match the HDPL assigned to the key location, otherwise OBKERROR flag is raised. Flash interface response is described in *Table 64*.

Table 64. TZ OBK protection summary

TZ protection (when TZ_STATE = 0xB4)	OBK access		
	No tamper		Tamper
	HDPL0/1/2/3	OBK selector	
XS	BUS ERROR	BUS ERROR	RAZ, WI
RS	OK if privilege, otherwise RAZ	RAZ	
WS	OK if privilege, otherwise WI, WRPERR	WI, if not privilege also WRPERR	
XNS	BUS ERROR	BUS ERROR	
RNS	RAZ, ILAFM	RAZ, ILAFM	
WNS	WI, WRPERR, ILAFM	WI, WRPERR, ILAFM	
Erase	NA	NA	NA

Table 65. OBK protection summary with TZ disabled

TZ protection (when TZ_STATE = 0xC3)	OBK access		
	No tamper		Tamper
	HDPL0/1/2/3	OBK selector	
XNS	BUS ERROR	BUS ERROR	RAZ, WI
RNS	OK if privilege, otherwise RAZ	RAZ	
WNS	OK if privilege, otherwise WI, WRPERR	WI if privilege, otherwise WI, WRPERR	
Erase	NA	NA	NA

Note: Cacheable access is managed at system level and not in the flitf. The MPU needs to be configured to disable cache where it is not desirable.

In case of tamper, all keys are read as 0x00s.

There are also rules for accessing the OBKFGCR and OBKKEYR registers.

Table 66. Access conditions to secure control register

-	S/NS	P/NP	TZ state	SECOBKCFGR and SECOBKKEYR access
X	-	-	-	Bus error
R/W	S	P	Active	OK
R/W	S	NP	Active	RAZ, WI
R/W	NS	P	Active	RAZ, WI, ILAP
R/W	NS	NP	Active	RAZ, WI, ILAP
R/W	-	-	Deactivated	RAZ, WI

Table 67. Access conditions to non-secure control register

	S/NS	P/NP	TZ state	NSOBKCFGR and NSOBKKEYR access
X	-	-	-	Bus error
R/W	-	-	Active	RAZ, WI
R/W	-	P	Deactivated	OK
R/W	-	NP	Deactivated	RAZ, WI

7.6.13 One-time-programmable and read-only memory protections

Sections of OTP/RO in the flash memory are described in details in *Section 7.3.9*. There is no protection provided by the flash memory interface other than the dedicated write protection.

No write is possible to the RO area, once it was established in manufacturing. The *OTP write protection* describes a method of locking out the OTP area.

The access conditions are summarized in *Table 68*.

Table 68. OTP/RO access constraints

-	8 Kbytes sector dedicated to RO/OTP			
	0x08FF_E000 - E7FF	**0x08FF_E800 - EFFF Reserved**	**0x08FF_F000 - F7FF OTP**	**0x08FF_F800 - FFFF RO**
XS	BUS ERROR	BUS ERROR		
RS		RAZ, ILAC		
WS		WI, WRPERR, ILAFM		
XNS	BUS ERROR	BUS ERROR		
RNS		If correct size(1) RAZ, else BUS ERROR	If correct size OK, else BUS ERROR	
WNS		If correct size WI, else BUS ERROR	BUS ERROR if incorrect size. WRPERR if block is protected by LOCKBL, else OK.	If correct size WI, else BUS ERROR
Erase	WI			

1. Word size is 16 bits. 32-bit access is possible. Other access attempt leads to bus error.

7.7 System memory

7.7.1 Introduction

System memory stores RSS (root secure services) firmware programmed by ST during production. The RSS provides runtime services to user firmware.

When TrustZone is enabled (user sets TZEN bitfield to 0xB4) then RSS provides secure services to secure user firmware only; when TrustZone is disabled (user sets TZEN bitfield to 0xC3), RSS provides services to user firmware.

7.7.2 RSS user functions

The RSS provides runtime services thanks to RSS library, whose functions are exposed to user within the CMSIS device header file provided by the STM32CubeH5 firmware package (see UM3065 "*Getting started with STM32CubeH5 for STM32H5 Series*" for more details).

RSS provides services through two different libraries, RSSLIB and NSSLIB, dedicated to secure user firmware when system is configured, respectively, with TrustZone enabled (TZEN bitfield set to 0xB4) and TrustZone disabled (TZEN bitfield set to 0xC3).

Table 69. Macros for RSS services

TrustZone	C defined macro	Location in flash memory
Enabled	RSSLIB_PFUNC	0xBF9FB78
Disabled	NSSLIB_PFUNC	0xBF9FB6C

RSSLIB

The secure user firmware calls RSSLIB functions using RSSLIB_PFUNC C defined macro, which points to a location within non-secure system memory.Before calling RSSLIB functions, the secure user firmware must define a non-secure region above this location within SAU of the Cortex®-M33, starting from RSSLIB_SYS_FLASH_NS_PFUNC_START (0xBF9FB78), up to RSSLIB_SYS_FLASH_NS_PFUNC_END (0xBF9FB84). These last addresses are provided within the CMSIS device header file.

The user can set this non-secure region either by using the CMSIS system partition header file, or by implementing its own code for SAU setup. The CMSIS system partition header file is part of the STM32CubeH5 firmware package.

Table 70. RSS lib interface functions

Library	Function	Attributes
RSSLIB_PFUNC	JumpHDPLvl2	Secure callable function
	JumpHDPLvl3	
	JumpHDPLvl3NS	
	RSSLIB_DataProvisioning	Non-secure callable function

RSSLIB_DataProvisioning

Secure attribute: Non-secure callable function.

Prototype:

```
uint32_t RSSLIB_DataProvisioning_(RSSLIB_DataProvisioningConf_t *pConfig)
```

Arguments:

pConfig: input parameter. **RSSLIB_DataProvisioningConf_t**

C structure definition is described below:

```
typedef struct
{
  uint32_t *pSource;
  uint32_t *pDestination;
  uint32_t Size;
  uint32_t DoEncryption;
  uint32_t Crc;
} RSSLIB_DataProvisioningConf_t;
```

Structure elements

pSource Provides the address of data to be provisioned. Must be within SRAM3 address range (non-secure aliases).

pDestination Provides the address where to store data to be provisioned. Must be within OBKeys address range. To be aligned on 16 bytes.

Size Provides the size of data to be provisioned (the number of bytes, must be a multiple of 16).

DoEncryption Notifies RSSLIB_DataProvisioning function if it must encrypt or not data within OBKeys.

DoEncrypt can be either 0xF5F5A0AAU or 0xCACA0AA0U (the only one allowed on STM32H563xx devices)

– 0xF5F5A0AAU: notifies RSSLIB_DataProvisioning to encrypt data with relevant DHUK before programming it within OBKeys. DHUK is selected according to **pDestination** value.

– 0xCACA0AA0U: notifies RSSLIB_DataProvisioning to program in clear data within OBKeys.

Crc CRC over full source data buffer, **pConfig->pDestination** value, **pConfig->Size** value and finally **pConfig->DoEncryption** value.

CRC computation uses CRC-32 (Ethernet):

– CRC polynomial: 0x04C11DB7U

– Initial value: 0xFFFFFFFFU

Returned values

0xEAEAEAEAU	Success
0xF5F5E0E0U	Error: – **pConfig** or **pSource** are not in SRAM3 – **pDestination** is not aligned on 16 bytes – **pDestination + Size** does not fit within an OBKey section
0xF5F50E0EU	Error: **Size** is not a multiple of 16
0xF5F58080U	Error: computed CRC is not the expected one provided within **pConfig->CRC**
0xF5F58008U	Error: cannot program data within OBKeys destination section
0xF5F5E00EU	Error: wrong **DoEncryption** parameter value
0xF5F50880U	Error: encryption requested, butw platform does not support it
0xF5F50EE0U	Error: encryption error
0xF5F50808U.	Error: OBKeys programming error

RSSLIB_DataProvisioning receives in input a data buffer and programs it within OBKeys. A CRC prevents any data and parameters tampering issue.

The destination address (**pDestination**) added to the size (**Size**) of the data to be provisioned must not cross the OBKeys section boundaries, listed below.

OBKeys Level1	Start address: 0x0FFD0100UL
	End address: 0x0FFD08FFUL
OBKeys Level2	Start address: 0x0FFD0900UL
	End address: 0x0FFD0BFFUL
OBKeys Level3 secure	Start address: 0x0FFD0C00UL
	End address: 0x0FFD17FFUL
OBKeys Level3 non-secure	Start address: 0x0FFD1800UL
	End address: 0x0FFD1FEFUL

When requested through **pConfig->DoEncryption** parameter, RSSLIB_DataProvisioning encrypts data before programming them within OBKeys.

RSSLIB_DataProvisioning uses AES CBC 128 bits with:

- IV: defined as (using C definition format)

  uint32_t IV = {0x8001D1CEU, 0xD1CED1CEU, 0xD1CE8001U, 0xCED1CED1U};
- Key: DHUK corresponding to the targeted OBKeys section defined by **pConfig->pDestination** parameter.

Note: Data encryption within OBkeys is supported only by STM32H573xx devices.

JumpHDPLvl2

Secure attribute: Secure callable function.

Prototype:

```
uint32_t JumpHDPLvl2(uint32_t VectorTableAddr, uint32_t MPUIndex)
```

User code function call example:

```
RSSLIB_PFUNC->S.JumpHDPLvl2((uint32_t)NextVectorTableAddr, 1U );
```

Arguments:

- VectorTableAddr:
  - Input parameter, address of the next vector table to apply.
  - The vector table format is the one used by the Cortex-M33 core.
- MPUIndex:
  - Input parameter, MPU region index. Caller function must define (but keep disabled) the corresponding MPU region before calling JumpHDPLvl2. The function enables the MPU region before jumping to the reset handler of the vector table. The vector table reset handler function belongs to the MPU region.

User calls JumpHDPLvl2 to close user Flash HDPL1 area by incrementing HDPL to 2, then jump to the reset handler embedded within the vector table, whose address is passed as input parameter.

After closing HDPL1, JumpHDPLvl2 enables the MPU region provided as input parameter. Once the MPU is enabled, the function sets the SP to the address provided by the passed vector table, and jumps to the reset handler function supported by it. JumpHDPLvl2 does not set the new vector table.

On successful execution, the function does not return and does not push LR onto the stack.

In case of failure (bad input parameter value), RSSLIB_Sec_JumpHDPLvl2 returns 0xF5F5F5F5.

JumpHDPLvl3

Secure attribute: Secure callable function.

Prototype:

```
uint32_t JumpHDPLvl3(uint32_t VectorTableAddr, uint32_t MPUIndex)
```

User code function call example:

```
RSSLIB_PFUNC->S.JumpHDPLvl3((uint32_t)NextVectorTableAddr, 1U );
```

Arguments:

- VectorTableAddr:
  - Input parameter, address of the next vector table to apply.
  - The vector table format is the one used by the Cortex-M33 core.
- MPUIndex:
  - Input parameter, MPU region index. Caller function must define but keep disabled the corresponding MPU region before calling JumpHDPLvl3. The function enables the MPU region before jumping to the reset handler of the vector table, whose function belongs to the MPU region.

User calls JumpHDPLvl3 to close user Flash HDPL1 and HDPL2 areas by incrementing HDPL up to 3, then jump to the reset handler embedded within the vector table, whose address is passed as input parameter.

After closing HDPL1/2, JumpHDPLvl3 enables the MPU region provided as input parameter. Once the MPU is enabled, the function sets the SP to the address provided by the passed vector table, and jumps to the reset handler function supported by the vector table. JumpHDPLvl3 does not set the new vector table.

On successful execution, the function does not return and does not push LR onto the stack.

In case of failure (bad input parameter value), JumpHDPLvl3 returns 0xF5F5F5F5.

JumpHDPLvl3NS

Secure attribute: Secure callable function.

Prototype:

```
uint32_t JumpHDPLvl3NS(uint32_t VectorTableAddr)
```

User code function call example:

```
RSSLIB_PFUNC->S.JumpHDPLvl3NS((uint32_t)NextVectorTableAddr, 1U );
```

Arguments:

- VectorTableAddr:
  - Input parameter, address of the next vector table to apply.
  - The vector table format is the one used by the Cortex-M33 core.

User calls JumpHDPLvl3NS to close user flash HDPL1 and HDPL2 areas by incrementing HDPL up to 3, to move from secure to non-secure domain, then jump to the non-secure

reset handler embedded within the vector table, whose address is passed as input parameter.

After closing HDPL1/2, JumpHDPLvl3 jumps to the non-secure reset handler function supported by the vector table. JumpHDPLvl3NS does not set the new vector table.

On successful execution, the function does not return and does not push LR onto the stack.

In case of failure (bad input parameter value), JumpHDPLvl3NS returns 0xF5F5F5F5.

NSSLIB

The user firmware calls only the NSSLIB function when TrustZone is disabled (TZEN bitfield is set to 0xC3).

The user firmware calls NSSLIB functions using NSSLIB_PFUNC C defined macro, which points to a location within system memory.

Table 71. NSS lib interface functions

Library	Function	Attributes
NSSLIB_PFUNC	JumpHDPLvl2	Non-secure function
	JumpHDPLvl3	

JumpHDPLvl2

Prototype:

```
uint32_t JumpHDPLvl2(uint32_t VectorTableAddr, uint32_t MPUIndex)
```

User code function call example:

```
NSSLIB_PFUNC->JumpHDPLvl2((uint32_t)NextVectorTableAddr, 1U );
```

Arguments:

- VectorTableAddr:
  - Input parameter, address of the next vector table to apply.
  - The vector table format is the one used by the Cortex-M33 core.
- MPUIndex:
  - Input parameter, MPU region index. Caller function shall define but keep disable the corresponding MPU region before calling JumpHDPLvl2. The function enables the MPU region before jumping to the reset handler of the vector table. The vector table reset handler function belongs to the MPU region.

User calls JumpHDPLvl2 to close user Flash HDPL1 area by incrementing HDPL to 2, and to jump to the reset handler embedded within the vector table which address is passed as input parameter

After closing HDPL1, JumpHDPLvl2 enables the MPU region provided as input parameter. Once the MPU is enabled, the function sets the SP to the address provided by the passed vector table and jumps to the reset handler function supported by the vector table too. JumpHDPLvl2 does not set the new vector table.

On successful execution, the function does not return and does not push LR onto the stack.

In case of failure (bad input parameter value), RSSLIB_Sec_JumpHDPLvl2 returns 0xF5F5F5F5.

JumpHDPLvl3

Prototype:

```
uint32_t JumpHDPLvl3(uint32_t VectorTableAddr, uint32_t MPUIndex)
```

User code function call example:

```
NSSLIB_PFUNC->JumpHDPLvl3((uint32_t)NextVectorTableAddr, 1U );
```

Arguments:

- VectorTableAddr:
  - Input parameter, address of the next vector table to apply.
  - The vector table format is the one used by the Cortex-M33 core.
- MPUIndex:
  - Input parameter, MPU region index. Caller function shall define but keep disable the corresponding MPU region before calling JumpHDPLvl3. The function enables the MPU region before jumping to the reset handler of the vector table. The vector table reset handler function belongs to the MPU region.

User calls JumpHDPLvl3 to close user Flash HDPL1 and HDPL2 areas by incrementing HDPL up to 3, and then jump to the reset handler embedded within the vector table, whose address is passed as input parameter

After closing HDPL1/2, JumpHDPLvl3 enables the MPU region provided as input parameter. Once the MPU is enabled, the function sets the SP to the address provided by the passed vector table, and jumps to the reset handler function supported by it. JumpHDPLvl3 does not set the new vector table.

On successful execution, the function does not return and does not push LR onto the stack.

In case of failure (bad input parameter value), JumpHDPLvl3 returns 0xF5F5F5F5.

7.8 FLASH low-power modes

Table 72 summarizes the memory behavior in STM32 low-power modes. Embedded flash memory belongs to the core domain.

Table 72. Effect of low-power modes on the embedded flash memory

Power mode	Core domain voltage range	Allowed if FLASH busy	FLASH power mode
Run	VOS0/1/2/3	Yes	Run
Stop1 (clock stopped)	SVOS3/4/5	No	Clock gated or stopped in case of SVOS5
Standby	Off	No	Off

When the system state changes or within a given system state, the memory can operate with a different voltage supply range (VOS), according to the application. The procedure to switch the memory into power modes (run, clock gated, stopped, off) is described hereafter.

Note: For more information on the microcontroller power states, refer to Section 10: Power control (PWR).

Managing the FLASH domain switching to Stop or Standby

As explained in *Table 72*, if the memory informs the reset and clock controller (RCC) that it is busy (BSY, DBNE, WBNE is set), the microcontroller cannot switch the core domain to Stop or Standby mode.

There are two ways to release the memory:

- Reset the WBNE busy flag in FLASH_NS/SECSR register by any of the following actions:
  - Complete the write buffer with missing data.
  - Force the write operation without filling the missing data by activating the FW bit in FLASH_NS/SECCR register. This forces all missing data “high”.
- Poll BSY busy bits in FLASH_NS/SECSR register until they are cleared. This indicates that all recorded write, erase and option change operations are complete.

The microcontroller can then switch the domain to Stop or Standby mode.

7.9 FLASH error management

7.9.1 Introduction

The memory automatically reports when an error occurs during a read, program or erase operation. A wide range of errors are reported:

- *Non-secure write protection error (WRPERR)*
- *Secure write protection error (WRPERR)*
- *Non secure programming sequence error (PGSERR)*
- *Secure programming sequence error (PGSERR)*
- *Secure strobe error (STRBERR)*
- *Error correction code error (ECCC, ECCD)*
- *Illegal access (ILAFM/ILAP)*
- *Option-byte change error (OPTCHANGEERR)*
- OBK non-secure general error (OBKERR)
- OBK secure general error (OBKERR)
- OBK non-secure write error (OBKWERR)
- OBK secure write error (OBKWERR)

The application software can individually enable the interrupt for each error, as detailed in *Section 7.10*.

The flash memory interface uses different interrupt lines to trigger the event. There are two direct lines to NVIC, one for secure interrupts, other for non secure. Third line leads to TZIC, for the ILAFM interrupt.

Note: For all errors, the application software must clear the error flag before attempting a new modify operation.

Since there is just one write buffer and only one operation is allowed at a time, the write control bits and status bits are shared by both banks:

- Write control bits (PG, FW, EOPIE, WRPERRIE, PGSERRIE, STRBERRIE, INCERRIE, CLR_EOP, CLR_WRPERR, CLR_STRBERR, CLR_INCERR, CLR_PGSERR) controls bank1 and 2 at the same time.
- Write status flag reports (WBNE, DBNE, EOP, WRPERR, PGSERR, STRBERR, INCERR, BSY) error for Bank1 and 2 at the same time.

7.9.2 Non-secure write protection error (WRPERR)

When an illegal non-secure erase/program operation is attempted to the nonvolatile memory, the flash interface sets the write protection error flag WRPERR in FLASH_NSSR register.

An erase operation is rejected and flagged as illegal if it targets one of the following memory areas:

- A sector write-protected with WRPSGn
- An HDP area while the HDPL has made it inaccessible
- Secure (TZ) state not matching the erased memory attribute
- Attempt to erase privilege sector within unprivileged mode

A program operation is ignored and flagged as illegal if it targets one of the following memory areas:

- System flash memory
- A user sector write-protected with WRPSGn
- An OTP block, locked with LOCKBL
- A read-only section
- A reserved area
- Secure area
- Privileged area from within unprivileged mode
- OBK access conditions check error

When WRPERR flag is raised, the operation is rejected and nothing is changed in the corresponding bank. If this error is detected, the write buffer is invalidated.

Note: WRPERR flag must be cleared before any erase/program operation.

WRPERR flag is cleared by setting CLR_WRPERR bit to 1 in FLASH_NSCCR register.

If WRPERRIE bit in FLASH_NSCR register is set to 1, an interrupt is generated when WRPERR flag is raised (see *Section 7.10* for details).

7.9.3 Secure write protection error (WRPERR)

When an illegal secure erase/program operation is attempted to the nonvolatile memory, the flash interface sets the write protection error flag WRPERR in FLASH_SECSR register.

An erase operation is rejected and flagged as illegal if it targets one of the following memory areas:

- A sector write-protected with WRPSGn
- An HDP area while the HDPL has made it inaccessible
- Secure (TZ) state not matching the erased memory attribute
- Attempt to erase privilege sector within unprivileged mode

A program operation is ignored and flagged as illegal if it targets one of the following memory areas:

- System flash memory
- A user sector write-protected with WRPSGn
- An OTP block, locked with LOCKBL
- A read-only section
- A reserved area
- Non-secure area
- Privileged area from within unprivileged mode
- OBK access condition check error

When WRPERR flag is raised, the operation is rejected and nothing is changed in the corresponding bank.

If this error is detected the write buffer is invalidated.

Note: WRPERR flag must be cleared before any erase/program operation.

WRPERR flag is cleared by setting CLR_WRPERR bit to 1 in FLASH_SECCCR register.

If WRPERRIE bit in FLASH_SECCR register is set to 1, an interrupt is generated when WRPERR flag is raised (see *Section 7.10* for details).

7.9.4 Non secure programming sequence error (PGSERR)

When the non-secure programming sequence is incorrect, the flash interface sets the programming sequence error flag PGSERR in FLASH_NSSR register.

More specifically, PGSERR flag is set when one of below conditions is met:

- An error like INCERR, WRPERR, PGSERR, STRBERR, OPTCHANGEERR, OBKERR or OBKWERR have not been cleared before requesting a new write or erase operation, OBK operation or options change.
- For erase, PGSERR is set if:
  - missing erase operation (FLASH_NSCR): STRT = 1 with (MER = 0, SER = 0 and BER = 0)
  - sector and bank erase requested at the same time (NSSTRT and more than one of MER, SER and BER)
  - PG set during erase operation (it ensures that no erase req and write req happen at the same time): (STRT = 1) with (PG = 1)
  - Erase operation is started while write buffer is waiting for next data: (STRT = 1) with WBNE = 1.
  - STRT = 1 set by secure access.
  - Erase operation is started while DBNE = 1.

- For programming, PGSERR is set if:
  - missing write flag: A write operation is requested but the program enable bit PG has not been set in FLASH_NSCR register prior to the request.
  - write operation to flash high-cycle data is requested but PG = 0.
  - AHB write request is received and (SER = 1, BER = 1 or MER = 1)
  - 16 bit data access requested while WBNE = 1
- For options change, PGSERR is set if:
  - option change is started while write buffer is waiting for next data: OPTSTRT = 1 with WBNE = 1
  - OPTSTRT set with non-secure DBNE = 1.
- For options byte key storage access, PGSERR is set if:
  - error flags from previous operation not cleared
  - ALT_SECT_ERASE and SWAP_SECT_REQ in FLASH_NSOBKCFGR are set at the same time
  - SWAP_OFFSET value is wrong: when SWAP_SECT_REQ is set to 1, the SWAP_OFFSET should be equal or greater than OBK_HDPL< N - 1 > _SWAP_OFFSET
  - ALT_SECT_ERASE or OBK_SWAP set while DBNE = 1
  - OBK-HDPL is incorrect and non-secure OBK_SWAP is requested
  - If OBKSWAP or OBK alternate erase is started while write buffer is waiting for new data (WBNE = 1).

When PGSERR flag is raised as consequence of failed write attempt (flash programming), the current program operation is aborted and nothing is changed in the corresponding bank. The write data buffer is also invalidated.

Note: When PGSERR flag is raised, there is a risk that the last write operation performed by the application has been lost because of the above protection mechanism. It is recommended to generate interrupts on PGSERR and verify in the interrupt handler if the last write operation has been successful, by reading back the value in the flash memory.

The PGSERR flag also blocks any new program operation. This means that PGSERR must be cleared before starting a new program operation.

PGSERR flag is cleared by setting CLR_PGSERR bit to 1 in FLASH_NSCCR register.

If PGSERRIE bit in FLASH_NSCR register is set to 1, an interrupt is generated when PGSERR flag is raised. See *Section 7.10* for details.

7.9.5 Secure programming sequence error (PGSERR)

When the secure programming sequence is incorrect, the flash interface sets the programming sequence error flag PGSERR in FLASH_SECSR register.

More specifically, PGSERR flag is set when one of below conditions is met:

- An error like INCERR, WRPERR, PGSERR, STRBERR, OBKERR, or OBKWERR has not been cleared before requesting a new write or erase operation, OBK operation or options change.
- For erase, PGSERR is set if:
  - missing erase operation (FLASH_SECCR): STRT = 1 with (SER = 0 and BER = 0, MER = 0)
  - sector and bank erase requested at the same time (SECSTRT and more than one of MER, SER, and BER)
  - PG set during erase operation (it ensures that no erase request and write request happen at the same time): (STRT = 1) with (PG = 1)
  - erase operation is started while write buffer is waiting for next data: (STRT = 1) with WBNE = 1.
  - operation started while secure DBNE = 1.
- For programming, PGSERR is set if:
  - missing write flag: a write operation is requested but the program enable bit PG has not been set in FLASH_SECCR register prior to the request
  - write operation to flash high-cycle data is requested but PG = 0
  - AHB write request is received and (SER = 1, SBER = 1, or MER = 1)
  - 16 bit data access requested while WBNE = 1
- For options change, PGSERR is set if:
  - Option change is started while write buffer is waiting for next data: OPTSTRT = 1 with WBNE = 1
  - OPTSTRT set with secure DBNE = 1
- For options byte key storage access, SECPGSERR is set if:
  - error flags from previous operation not cleared
  - ALT_SECT_ERASE and SWAP_SECT_REQ are set at the same time
  - SWAP_OFFSET value is wrong: when SWAP_SECT_REQ = 1, SWAP_OFFSET must be equal or greater than OBK_HDPL<N-1>_SWAP_OFFSET.
  - SWAP_SECT_REQ or OBK_SWAP set while DBNE = 1
  - OBK-HDPL is incorrect and secure OBK_SWAP is requested
  - If OBKSWAP or OBK alternate erase is started while write buffer is waiting for new data (WBNE = 1)

When PGSERR flag is raised as consequence of failed write attempt (flash programming), the current program operation is aborted and nothing is changed in the corresponding bank. The write data buffer is also invalidated.

Note: When PGSERR flag is raised, there is a risk that the last write operation performed by the application has been lost because of the above protection mechanism. It is recommended to generate interrupts on PGSERR and verify in the interrupt handler if the last write operation has been successful by reading back the value in the flash memory.

The PGSERR flag also blocks any new program operation. This means that PGSERR must be cleared before starting a new program operation.

PGSERR flag is cleared by setting CLR_SECPGSERR bit to 1 in FLASH_SECCCR register.

If PGSERRIE bit in FLASH_SECCR register is set to 1, an interrupt is generated when PGSERR flag is raised. See *Section 7.10* for details.

7.9.6 Non-secure strobe error (STRBERR)

When the non-secure application software writes several times to the same byte in the write buffer, the flash interface sets the strobe error flag STRBERR (FLASH_NSSR) whatever the target bank of the write access.

When STRBERR flag is raised, the current program operation is aborted and the write buffer is invalidated.

STRBERR flag is cleared by setting CLR_STRBERR bit to 1 in FLASH_NSCCR register.

If STRBERRIE bit in FLASH_NSCR register is set to 1, an interrupt is generated when STRBERR flag is raised. See *Section 7.10* for details.

7.9.7 Secure strobe error (STRBERR)

When the secure application software writes several times to the same byte in the write buffer, the memory sets the strobe error flag STRBERR (FLASH_SECSR) whatever the target bank of the write access.

When STRBERR flag is raised, the current program operation is aborted and the write buffer is invalidated.

STRBERR flag is cleared by setting CLR_STRBERR bit to 1 in FLASH_SECCCR register.

If STRBERRIE bit in FLASH_SECCR register is set to 1, an interrupt is generated when STRBERR flag is raised. See *Section 7.10* for details.

7.9.8 Non-secure inconsistency error (INCERR)

When a programming inconsistency in non-secure access is detected, the flash interface sets the inconsistency error flag INCERR in register FLASH_NSSR.

More specifically, INCERR flag is set when one of the following conditions is met:

- A write operation is attempted before completion of the previous write operation, for example:
  - The application software starts a write operation to fill the 128-bit write buffer, but sends a new write burst request to a different flash memory address before the buffer is full.
  - One master starts a write operation, but before the buffer is full, another master starts a new write operation to the same address or to a different address.
  - ALT_SECT in FLASH_NSOBKCFGR changed while filling the write buffer.

Note: INCERR flag must be cleared before starting a new write operation, otherwise a sequence error (PGSERR) is raised.

It is recommended to follow the following sequence to avoid losing data when an inconsistency error occurs:

1. Execute a handler routine when INCERR flag is raised.
2. Stop all write requests to the memory.
3. Clear INCERR bit.
4. Restart the write operations from where they have been interrupted.

INCERR flag is cleared by setting CLR_INCERR bit to 1 in FLASH_NSCCR register.

If INCERRIE bit in FLASH_NSCR register is set to 1, an interrupt is generated when INCERR flag is raised (see *Section 7.10* for details).

7.9.9 Secure inconsistency error (INCERR)

When a programming inconsistency is detected, the flash interface sets the inconsistency error flag INCERR in register FLASH_SECSR.

More specifically, INCERR flag is set when one of the following conditions is met:

- A write operation is attempted before completion of the previous write operation, for example:
  - The application software starts a write operation to fill the 128-bit write buffer, but sends a new write burst request to a different flash memory address before the buffer is full.
  - One master starts a write operation, but before the buffer is full, another master starts a new write operation to the same address or to a different address.

Note: INCERR flag must be cleared before starting a new write operation, otherwise a sequence error (PGSERR) is raised.

It is recommended to follow the sequence below to avoid losing data when an inconsistency error occurs:

1. Execute a handler routine when INCERR flag is raised.
2. Stop all write requests to the flash memory.
3. Clear INCERR bit.
4. Restart the write operations from where they have been interrupted.

INCERR flag is cleared by setting CLR_INCERR bit to 1 in FLASH_SECCCR register.

If INCERRIE bit in FLASH_SECCR register is set to 1, an interrupt is generated when INCERR flag is raised (see *Section 7.10* for details).

7.9.10 Error correction code error (ECCC, ECCD)

When a single-error correction is detected during a read, the flash interface sets the single-error correction flag ECCC in FLASH_ECCCORR register.

When two ECC errors are detected during a read, the flash interface sets the double error detection flag ECCD in FLASH_ECCDETR register.

When the ECCC flag is raised, the corrected read data are returned. The application can ignore the error, and request new read operations. When the ECCD the flag is raised, an NMI is generated, it can be masked in SBS registers (*SBS flift ECC NMI mask register (SBS_ECCNMIR)*) for data access (OTP, data area, RO data). Software must invalidate the instruction cache (CACHEINV = 1) in the NMI interrupt service routine when the ECCD flag is set.

When ECCC or ECCD flag is raised, the address of the flash word that generated the error is saved in the FLASH_ECCCORR (FLASH_ECCDETR) register. If the address corresponds to a read-only area or to an OTP area or flash high-cycle data, the OTP_ECC bit is also set to 1 in the FLASH_ECCCORRR (FLASH_ECCDETR) register. This register is automatically cleared when the associated flag that generated the error is reset.

A BK_ECC flag indicates in which flash bank the error occurred.

A SYSF_ECC flag indicates an error detected in the system flash area.

Table 73. Locating ECC failure

OTP_ECC	SYSF_ECC	BK_ECC	EDATA_ECC	OBK_ECC	Flash area	ADDR_ECC min	ADDR_ECC max
0	0	0/1	0	0	User flash	0x0000	0xFFFF
0	1	0/1	0	0	System flash	0x0000	0x0FFF
1	0	0	0	0	OTP	0x0600	0x07FF
0	0	1	0	1	OBKeys	0x0000	0x03FF
0	0	0/1	1	0	Data area sector 7	0xF000	0xF1FF
0	0	0/1	1	0	Data area sector 6	0xF200	0xF3FF
0	0	0/1	1	0	Data area sector 5	0xF400	0xF5FF
0	0	0/1	1	0	Data area sector 4	0xF600	0xF7FF
0	0	0/1	1	0	Data area sector 3	0xF800	0xF9FF
0	0	0/1	1	0	Data area sector 2	0xFA00	0xFBFF
0	0	0/1	1	0	Data area sector 1	0xFC00	0xFDFF
0	0	0/1	1	0	Data area sector 0	0xFE00	0xFFFF

Note: In case of successive single correction or double detection errors, only the address corresponding to the first error is stored in FLASH_ECCCORR (FLASH_ECCDETR) *register.*

It is mandatory to clear ECCC or ECCD flags before starting a new read operation.

As the ECC interface is shared by the two banks, if the same error is registered simultaneously, a physical Bank1 error is registered. Both errors are registered if one bank reports ECCD and the other bank ECCC.

ECCC (respectively ECCD) flag is cleared by setting to 1 ECCC bit (respectively ECCD bit) in FLASH_ECCCORR (FLASH_ECCDETR) register.

If ECCC bit in FLASH_ECCCORR register is set to 1, an interrupt is generated when ECCC flag is raised. Only NMI is generated for the ECCD. See *Section 7.10* for details.

7.9.11 Illegal access (ILAFM/ILAP)

Illegal access is a signal to the TZIC, triggering a secure interrupt in there. It is complementary to the other interrupts and only generated when the TZ is enabled (TZ_STATE = 0xB4).

It can be masked only on GTZC level.

ILAFM is generated when rules on secure flash memory access are violated:

- Attempt to access secure memory location in non-secure mode.
- Attempt to access non-secure memory location in secure mode.

ILAP is generated on:

- Attempt to access secure register in non-secure mode.

If ILAFM is detected during write, the write buffer is invalidated.

Note: ILAFM *and ILAP has no flag within the flash memory controller to clear to resume operation. It is dealt within the TZIC.*

7.9.12 Option-byte change error (OPTCHANGEERR)

When the flash interface finds an error during an option change operation, it aborts the operation and sets the option byte change error flag OPTCHANGEERR in FLASH_NSSR register.

The error is raised after OPTSTRT bit set if:

- TZEN is not set and transition to TZ-Closed or NS-Regression state is requested. Also any other forbidden PRODUCT_STATE transition (*Table 63*).
- SWAP_BANK is locked out by combination of TZEN and BOOT_LOCK.
- OB modification is attempted in wrong HDPL (selected PRODUCT_STATE transitions)
- Attempt to modify OB with invalid value
  - New EPOCH value not greater than current
  - Value not recognized by the specification (enumerated magic numbers only)
- Attempt to modify OB in product state where it is not allowed (usually a state open for debug is required for change).

Note: Exceptions and details provided in the OB description (see Section 7.4.7 and Table 43).

OPTCHANGEERR flag is cleared by setting CLR_OPTCHANGEERR bit to 1 in FLASH_NSCCR register.

If OPTCHANGEERRIE bit in FLASH_NSCR register is set to 1, an interrupt is generated when OPTCHANGEERR flag is raised (see *Section 7.10* for details).

It is mandatory to clean the OPTCHANGEERR flag before starting a new operation (option change, erase or write).

7.9.13 Miscellaneous HardFault errors

The following events generate a bus error on the corresponding bus interface:

- On main AHB system bus for access targeting code and data with 9 bits ECC.
  - Fetching from secure user flash memory in non-secure mode.
  - Fetching from non-secure user flash memory in secure mode.
  - Access to invalid address (including data addresses forbidden for code use).
  - Fetching from HDP area with incorrect HDPL value.
  - Fetching from privilege area in unprivilege mode.
- On AHB configuration or system bus for accesses targeting OTP/RO (all addresses using 6bits ECC):
  - wrong key input to FLASH_NS/SECKEYR or FLASH_OPTKEYR.
  - 8-bit accesses to system AHB interface.
  - Wrong unlock sequence on a register.

7.9.14 OBK error cases (OBKERR, OBKWERR)

Four error types can be detected while filling the OBK write buffer: STRBERR, INCERR, WRPERR or OBKERR. The OBKERR is specific to the OBK access and cannot be raised by access to any other flash memory asset.

Note: For STRBERR, INCERR and WRPERR, non-secure or secure flags are used depending on the AHB access type (sec or non-secure). If a non-secure access is received, the non-secure error flags are used. If a secure access is received, the secure error flags are used.

For OBKERR and OBKWERR, non-secure or secure flags are used depending on the value of the secure state. If the SOC is in secure state (TZ_STATE active), the secure error flags (OBKERR and OBKWERR) are used. Otherwise the non-secure error flags (OBKERR and OBKWERR) are used.

OBKERR is raised when:

- the OBK-HDPL (input signal from SBS) does not match the HDPL associated to the key during a read or write access, and the TZ and PRIV attributes are correct (See *Section 7.5.2* for more details).

If OBKERR is raised during write access, the write buffer is flushed. If the OBKERR is raised on read access, the write buffer is intact. In both cases the flag must be cleared to enable write/erase access to flash memory.

OBKWERR is detected after filling the write buffer and raised if:

- the address is not virgin during a write access.
- OBK selector in the alternate sector is not virgin during a SWAP operation.

If OBKWERR is raised, the write buffer is flushed. The flag must be cleared to enable write/erase access to flash memory.

7.10 FLASH interrupts

The flash interface can generate a maskable interrupt to signal the following events on a given bank:

- Read and write errors (see *Section 7.9*)
  - Single ECC error correction during read operation
  - Write inconsistency error
  - Bad programming sequence
  - Strobe error during write operations
  - option change operation error
- Security errors (see *Section 7.9*)
  - Write protection error
  - Illegal access error - signal to TZIC
- Miscellaneous events (described below)
  - End of programming

A NMI is raised on double ECC error detection during read operation.

Two interrupt lines gather all the error sources, one for errors in non-secure access and second for errors that happen in secure access.

The user can individually enable or disable flash interface interrupt sources by changing the mask bits in the FLASH_NS/SECCR, FLASH_ECCCORR and FLASH_ECCDETR register. Setting the appropriate mask bit to 1 enables the interrupt.

Note: Prior to writing, FLASH_NS/SECCR register must be unlocked as explained in Section 7.6.7.

Table 74 gives a summary of the available flash interface interrupt features. As mentioned in the table below, some flags need to be cleared before a new operation is triggered.

Table 74. Flash interrupt request

Interrupt event Event flag	Error flag label in register	Enable control bit	Clear flag to resume operation
End of operation event	EOP	EOPIE	N/A
Write protection error	WRPERR	WRPERRIE	Yes
Programming sequence error	PGSERR	PGSERRIE	Yes
Strobe error	STRBERR	STRBERRIE	Yes
OBK write error	OBKWERR	OBKWERRIE	Yes
OBK general error	OBKERR	OBKERRIE	Yes
Inconsistency error	INCERR	INCERRIE	Yes
Illegal access error	ILAFM	TZEN	No
Option byte error	OPTCHANGEERR	-	Yes
ECC single error correction event	ECCC	ECCCIE	No
ECC double error detection event(1)	ECCD	Disabled	No

1. NMI.

The status of the individual maskable interrupt sources described in *Table 74* (except for option byte error and ECC) can be read from the FLASH_NS/SECSR register. They can be cleared by setting to 1 the adequate bit in FLASH_NS/SECCCR register.

Note: No unlocking mechanism is required to clear an interrupt.

End of operation event

Setting the end of operation interrupt enable bit (EOPIE) in the FLASH_NS/SECCR register enables the generation of an interrupt at the end of an erase operation, a program operation, or an option byte change.

When managing the OBKey storage area, the EOP is associated also with the OBK swap operation and the alternate area erase operation. EOP bit in the FLASH_NS/SECSR register is also set when one of these events occurs.

Setting CLR_EOP bit to 1 in FLASH_NS/SECCCR register clears EOP flag.

7.11 FLASH registers

Each register is assigned a offset address and a reset value. In case of registers representing option byte value, the reset value is determined by the OBL process. In case of success the reset value is loaded from OB. In case of OBL failure, a highly restrictive default value is set.

7.11.1 FLASH access control register (FLASH_ACR)

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

For more details, refer to *Section 7.3.4* and *Section 7.3.5*.

Address offset: 0x000

Reset value: 0x0000 0013

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRFTEN	Res.	Res.	WRHIGHFREQ[1:0]		LATENCY[3:0]			
							rw			rw	rw	rw	rw	rw	rw

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **PRFTEN**: Prefetch enable. When bit value is modified, user must read back ACR register to be sure PRFTEN has been taken into account.
Bits used to control the prefetch.
0: prefetch disabled.
1: prefetch enabled when latency is at least one wait state.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **WRHIGHFREQ[1:0]**: Flash signal delay
These bits are used to control the delay between nonvolatile memory signals during programming operations. Application software has to program them to the correct value depending on the memory interface frequency. Please refer to *Table 37* for details.
Note: No check is performed to verify that the configuration is correct.
Two WRHIGHFREQ values can be selected for some frequencies.

Bits 3:0 **LATENCY[3:0]**: Read latency
These bits are used to control the number of wait states used during read operations on both nonvolatile memory banks. The application software has to program them to the correct value depending on the memory interface frequency and voltage conditions.
0000: zero wait states used to read a word from nonvolatile memory
0001: one wait state used to read a word from nonvolatile memory
0010: two wait states used to read a word from nonvolatile memory
...
0111: seven wait states used to read a word from nonvolatile memory
1111: 15 wait states used to read a word from nonvolatile memory
Note: No check is performed by hardware to verify that the configuration is correct.

7.11.2 FLASH non-secure key register (FLASH_NSKEYR)

This register is non-secure. It can written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

FLASH_NSKEYR is a write-only register. The following values must be programmed consecutively to unlock FLASH_NSCR register and allow programming/erasing it. A wrong sequence locks the FLASH_NSCR register until next system reset.

First key = 0x4567 0123

Second key = 0xCDEF 89AB

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

NSKEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **NSKEY[31:0]**: Non-volatile memory non-secure configuration access unlock key

7.11.3 FLASH secure key register (FLASH_SECKEYR)

This register is secure. It can be written only by secure access. A non-secure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register.

FLASH_SECKEYR is a write-only register. The following values must be programmed consecutively to unlock FLASH_SECCR register and allow programming/erasing it. A wrong sequence locks the FLASH_SECCR register until next system reset.

First key = 0x4567 0123

Second key = 0xCDEF 89AB

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

SECKEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **SECKEY[31:0]**: Non-volatile memory secure configuration access unlock key

7.11.4 FLASH option key register (FLASH_OPTKEYR)

This register is non-secure. It can be written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

FLASH_OPTKEYR is a write-only register. The following values must be programmed consecutively to unlock FLASH_OPTCR register. A wrong sequence locks FLASH_OPTCR register until next system reset.

First key = 0x0819 2A3B

Second key = 0x4C5D 6E7F

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OPTKEY[31:16]

OPTKEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **OPTKEY[31:0]**: FLASH option bytes control access unlock key

7.11.5 FLASH non-secure OBK key register (FLASH_NSOBKKEYR)

FLASH_NSOBKKEYR is a write-only register. The following values must be programmed consecutively to unlock FLASH_NSOBKCFGR register. A wrong sequence locks FLASH_NSOBKCFGR register until next system reset.

This register is non-secure. This register can be written only by privileged access.

First key = 0x192A 083B

Second key = 0x6E7F 4C5D

Address offset: 0x0010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

NSOBKKEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **NSOBKKEY[31:0]**: FLASH non-secure option bytes keys control access unlock key

7.11.6 FLASH secure OBK key register (FLASH_SECOBKKEYR)

FLASH_SECOBKKEYR is a write-only register. The following values must be programmed consecutively to unlock FLASH_SECOBKCFGR register. A wrong sequence locks FLASH_SECOBKCFGR register until next system reset.

First key = 0x192A 083B

Second key = 0x6E7F 4C5D

This register is secure. This register can only be written by privileged access.

Address offset: 0x0014

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

SECOBKKEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **SECOBKKEY[31:0]**: FLASH secure option bytes keys control access unlock key

7.11.7 FLASH operation status register (FLASH_OPSR)

This register is non-secure. This register can be read by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x0018

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CODE_OP[2:0]			Res.	Res.	Res.	Res.	OTP_OP	SYSF_OP	BK_OP	DATA_OP	Res.	ADDR_OP[19:16]

ADDR_OP[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:29 **CODE_OP[2:0]**: Flash memory operation code
000: No flash operation on going during previous reset
001: Single write operation interrupted
010: OBK alternate sector erase
011: Sector erase operation interrupted
100: Bank erase operation interrupted
101: Mass erase operation interrupted
110: Option change operation interrupted
111: OBK swap sector request

Bits 28:25 Reserved, must be kept at reset value.

Bit 24 **OTP_OP**: OTP operation interrupted
Indicates that reset interrupted an ongoing operation in OTP area (or OBKeys area).

Bit 23 **SYSF_OP**: Operation in system flash memory interrupted
Indicates that reset interrupted an ongoing operation in system flash.

Bit 22 **BK_OP**: Interrupted operation bank
It indicates which bank was concerned by operation.

Bit 21 **DATA_OP**: Flash high-cycle data area operation interrupted
It indicates if flash high-cycle data area is concerned by operation.

Bit 20 Reserved, must be kept at reset value.

Bits 19:0 **ADDR_OP[19:0]**: Interrupted operation address

7.11.8 FLASH option control register (FLASH_OPTCR)

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Access: No wait state when no FLASH memory operation is ongoing. The FLASH_OPTCR register is not accessible in write mode when the BSY bit is set. Any attempt to write to it while the BSY bit set causes the AHB bus to stall until the BSY bit is cleared.

Address offset: 0x01C

Reset value: 0xX000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWAP_BANK	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OPT STRT	OPT LOCK
														rw	rs

Bit 31 **SWAP_BANK**: Bank swapping option configuration bit
SWAP_BANK controls whether Bank1 and Bank2 are swapped or not. This bit is loaded with the SWAP_BANK bit of FLASH_OPTSR_CUR register only after reset or POR.
0: Bank1 and Bank2 not swapped
1: Bank1 and Bank2 swapped

Bits 30:2 Reserved, must be kept at reset value.

Bit 1 **OPTSTRT**: Option byte start change option configuration bit

OPTSTRT triggers an option byte change operation. The user can set OPTSTRT only when the OPTLOCK bit is cleared to 0. It is set only by Software and cleared when the option byte change is completed or an error occurs (PGSERR or OPTCHANGEERR). It is reseted at the same time as BSY bit.

The user application cannot modify any FLASH_XXX_PRG flash interface register until the option change operation has been completed.

Before setting this bit, the user has to write the required values in the FLASH_XXX_PRG registers. The FLASH_XXX_PRG registers are locked until the option byte change operation has been executed in nonvolatile memory.

Bit 0 **OPTLOCK**: FLASH_OPTCR lock option configuration bit

The OPTLOCK bit locks the FLASH_OPTCR register as well as all _PRG registers. The correct write sequence to FLASH_OPTKEYR register unlocks this bit. If a wrong sequence is executed, or the unlock sequence to FLASH_OPTKEYR is performed twice, this bit remains locked until next system reset.

It is possible to set OPTLOCK by programming it to 1. When set to 1, a new unlock sequence is mandatory to unlock it. When OPTLOCK changes from 0 to 1, the others bits of FLASH_OPTCR register do not change.

0: FLASH_OPTCR register unlocked

1: FLASH_OPTCR register locked.

7.11.9 FLASH non-secure status register (FLASH_NSSR)

This register is non-secure. It can be read by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x020

Reset value: 0x0000 000X

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DBNE	Res.	WBNE	BSY
												r		r	r

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **OPTCHANGEERR**: Option byte change error flag

OPTCHANGEERR flag indicates that an error occurred during an option byte change operation. When OPTCHANGEERR is set to 1, the option byte change operation did not successfully complete. An interrupt is generated when this flag is raised if the OPTCHANGEERRIE bit of FLASH_NSCR register is set to 1.

Writing 1 to CLR_OPTCHANGEERR of register FLASH_NSCCR clears OPTCHANGEERR.

0: no option byte change errors occurred

1: one or more errors occurred during an option byte change operation.

Note: The OPTSTRT bit in FLASH_OPTCR cannot be set while OPTCHANGEERR is set.

Bit 22 **OBKWERR**: OBK write error flag

OBKWERR flag is raised when the address is not virgin on a write access to the OBK storage. Alternatively also when the OBK selector in the alternate sector is not virgin during a swap operation.

0: no OBK write error occurred
1: an OBK write error occurred

Bit 21 **OBKERR**: OBK general error flag

OBKERR flag is raised when the OBK-HDPL signal from the SBS does not match the HDPL value associated with the key slot during access to the key location. Alternatively also when the ALT_SECT is unexpectedly changed while the write buffer is being filled.

0: no OBK general error occurred
1: an OBK general error occurred

Bit 20 **INCERR:** inconsistency error flag

NSINCERR flag is raised when a inconsistency error occurs. An interrupt is generated if INCERRIE is set to 1. Writing 1 to CLR_INCERR bit in the FLASH_NSCCR register clears NSINCERR.

0: no inconsistency error occurs
1: a inconsistency error occurs

Bit 19 **STRBERR:** strobe error flag

STRBERR flag is raised when a strobe error occurs (when the master attempts to write several times the same byte in the write buffer). An interrupt is generated if the STRBERRIE bit is set to 1. Writing 1 to CLR_STRBERR bit in FLASH_NSCCR register clears STRBERR.

0: no strobe error occurred
1: a strobe error occurred

Bit 18 **PGSERR:** programming sequence error flag

PGSERR flag is raised when a sequence error occurs. An interrupt is generated if the PGSERRIE bit is set to 1. Writing 1 to CLR_PGSERR bit in FLASH_NSCCR register clears PGSERR.

0: no sequence error occurred
1: a sequence error occurred

Bit 17 **WRPERR**: write protection error flag

WRPERR flag is raised when a protection error occurs during a program operation. An interrupt is also generated if the WRPERRIE is set to 1. Writing 1 to CLR_WRPERR bit in FLASH_NSCCR register clears WRPERR.

0: no write protection error occurred
1: a write protection error occurred

Bit 16 **EOP**: end of operation flag

EOP flag is set when a operation (program/erase) completes. An interrupt is generated if the EOPIE is set to 1. It is not necessary to reset EOP before starting a new operation. EOP bit is cleared by writing 1 to CLR_EOP bit in FLASH_NSCCR register.

0: no operation completed
1: a operation completed

Bits 15:4 Reserved, must be kept at reset value.

Bit 3 **DBNE**: data buffer not empty flag

DBNE flag is set when the flash interface is processing 6-bits ECC data in dedicated buffer. This bit cannot be set to 0 by software. The hardware resets it once the buffer is free.

0: data buffer not used
1: data buffer used, wait

Bit 2 Reserved, must be kept at reset value.

Bit 1 **WBNE**: write buffer not empty flag

WBNE flag is set when the flash interface is waiting for new data to complete the write buffer. In this state, the write buffer is not empty. WBNE is reset by hardware each time the write buffer is complete or the write buffer is emptied following one of the event below:

– the application software forces the write operation using FW bit in FLASH_NSCR

– the memory detects an error that involves data loss

This bit cannot be reset by software writing 0 directly. To reset it, clear the write buffer by performing any of the above listed actions, or send the missing data.

0: write buffer empty or full

1: write buffer waiting data to complete

Bit 0 **BSY**: busy flag

BSY flag indicates that a flash memory is busy by an operation (write, erase, option byte change, OBK operation). It is set at the beginning of a flash memory operation and cleared when the operation finishes, or an error occurs.

0: no programming, erase or option byte change operation being executed

1: programming, erase or option byte change operation being executed

7.11.10 FLASH secure status register (FLASH_SECSR)

This register is secure. It can be read only by secure access. A non-secure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x024

Reset value: 0x0000 000X

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

												r		r	r

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **OBKWERR**: OBK write error flag

OBKWERR flag is raised when the address is not virgin on a write access to the OBK storage. Alternatively also when the OBK selector in the alternate sector is not virgin during a swap operation.

0: no OBK write error occurred

1: an OBK write error occurred

Bit 21 **OBKERR**: OBK general error flag

OBKERR flag is raised when the OBK-HDPL signal from the SBS does not match the HDPL value associated with the key slot during access to the key location. Alternatively also when the ALT_SECT is unexpectedly changed while the write buffer is being filled.

0: no OBK general error occurred

1: an OBK general error occurred

Bit 20 **INCERR:** inconsistency error flag

INCERR flag is raised when a inconsistency error occurs. An interrupt is generated if INCERRIE is set to 1. Writing 1 to CLR_INCERR bit in the FLASH_SECCCR register clears INCERR.

0: no inconsistency error occurred

1: a inconsistency error occurred

Bit 19 **STRBERR:** strobe error flag

STRBERR flag is raised when a strobe error occurs (when the master attempts to write several times the same byte in the write buffer). An interrupt is generated if the STRBERRIE bit is set to 1. Writing 1 to CLR_STRBERR bit in FLASH_SECCCR register clears STRBERR.

0: no strobe error occurred

1: a strobe error occurred

Bit 18 **PGSERR:** programming sequence error flag

PGSERR flag is raised when a sequence error occurs. An interrupt is generated if the PGSERRIE bit is set to 1. Writing 1 to CLR_PGSERR bit in FLASH_SECCCR register clears PGSERR.

0: no sequence error occurred

1: a sequence error occurred

Bit 17 **WRPERR**: write protection error flag

WRPERR flag is raised when a protection error occurs during a program operation. An interrupt is also generated if the WRPERRIE is set to 1. Writing 1 to CLR_WRPERR bit in FLASH_SECCCR register clears WRPERR.

0: no write protection error occurred

1: a write protection error occurred

Bit 16 **EOP**: end of operation flag

EOP flag is set when a operation (program/erase) completes. An interrupt is generated if the EOPIE is set to. It is not necessary to reset EOP before starting a new operation. EOP bit is cleared by writing 1 to CLR_EOP bit in FLASH_SECCCR register.

0: no operation completed

1: a operation completed

Bits 15:4 Reserved, must be kept at reset value.

Bit 3 **DBNE**: data buffer not empty flag

DBNE flag is set when the memory interface is processing 6-bits ECC data in dedicated buffer. This bit cannot be set to 0 by software. The hardware resets it once the buffer is free.

0: data buffer not used

1: data buffer used, wait

Bit 2 Reserved, must be kept at reset value.

Bit 1 **WBNE**: write buffer not empty flag

WBNE flag is set when the flash interface is waiting for new data to complete the write buffer. In this state, the write buffer is not empty. WBNE is reset by hardware each time the write buffer is complete or the write buffer is emptied following one of the event below:

- the application software forces the write operation using FW bit in FLASH_SECCR
- the flash interface detects an error that involves data loss

This bit cannot be reset by writing 0 directly by software. To reset it, clear the write buffer by performing any of the above listed actions, or send the missing data.

0: write buffer empty or full

1: write buffer waiting data to complete

Bit 0 **BSY**: busy flag

BSY flag indicates that a FLASH memory is busy (write, erase, option byte change, OBK operations). It is set at the beginning of a flash memory operation and cleared when the operation finishes or an error occurs.

0: no programming, erase or option byte change operation being executed

1: programming, erase or option byte change operation being executed

7.11.11 FLASH non-secure control register (FLASH_NSCR)

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Access: No wait state when no FLASH memory operation is ongoing. The FLASH_NSCR register is not accessible in write mode when the BSY bit is set. Any attempt to write to it with the BSY bit set causes the AHB bus to stall until the BSY bit is cleared.

Address offset: 0x028

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw			rw	rw	rw	rw	rw	rw	rw	rs	rw	rw	rw	rw	rs

Bit 31 **BKSEL**: Bank selector bit

BKSEL can only be programmed when LOCK is cleared to 0. The bit selects physical bank, SWAP_BANK setting is ignored.

0: Bank1 is selected for Bank erase / sector erase / interrupt enable

1: Bank2 is selected for BER / SER

Bits 30:24 Reserved, must be kept at reset value.

Bit 23 **OPTCHANGEERRIE**: Option byte change error interrupt enable bit

This bit controls if an interrupt must be generated when an error occurs during an option byte change. It can be programmed only when LOCK bit is cleared to 0.

0: no interrupt is generated when an error occurs during an option byte change

1: an interrupt is generated when and error occurs during an option byte change.

Bit 22 **OBKWERRIE**: OBK write error interrupt enable bit

OBKWERRIE enables generation of interrupt in case of OBK specific write error. This bit can be programmed only when LOCK bit is cleared to 0.

0: no interrupt is generated on OBK write error

1: an interrupt is generated on OBK write error

Bit 21 **OBKERRIE**: OBK general error interrupt enable bit

OBKERRIE enables generating an interrupt in case of OBK specific access error. This bit can be programmed only when LOCK bit is cleared to 0.

0: no interrupt is generated on OBK general access error

1: an interrupt is generated on OBK general access error

Bit 20 **INCERRIE**: inconsistency error interrupt enable bit

When INCERRIE bit is set to 1, an interrupt is generated when an inconsistency error occurs during a write operation. INCERRIE can be programmed only when LOCK is cleared to 0.

0: no interrupt generated when a inconsistency error occurs

1: interrupt generated when a inconsistency error occurs.

Bit 19 **STRBERRIE**: strobe error interrupt enable bit

When STRBERRIE bit is set to 1, an interrupt is generated when a strobe error occurs (the master programs several times the same byte in the write buffer) during a write operation. STRBERRIE can be programmed only when LOCK is cleared to 0.

0: no interrupt generated when a strobe error occurs

1: interrupt generated when strobe error occurs.

Bit 18 **PGSERRIE**: programming sequence error interrupt enable bit

When this bit is set to 1, an interrupt is generated when a sequence error occurs during a program operation. PGSERRIE can be programmed only when LOCK is cleared to 0.

0: no interrupt generated when a sequence error occurs

1: interrupt generated when sequence error occurs

Bit 17 **WRPERRIE**: write protection error interrupt enable bit

When this bit is set to 1, an interrupt is generated when a protection error occurs during a program operation. WRPERRIE can be programmed only when LOCK is cleared to 0.

0: no interrupt generated when a protection error occurs

1: interrupt generated when a protection error occurs

Bit 16 **EOPIE**: end of operation interrupt control bit

Setting EOPIE bit to 1 enables the generation of an interrupt at the end of a program or erase operation. EOPIE can be programmed only when LOCK is cleared to 0.

0: no interrupt generated at the end of operation.

1: interrupt enabled when at the end of operation

Bit 15 **MER**: Mass erase request

Setting MER bit to 1 requests a mass erase operation (user flash memory only). MER can be programmed only when LOCK is cleared to 0.

If BER or SER are both set, a PGSERR is raised.

0: mass erase not requested

1: mass erase requested

Error is triggered when a mass erase is required and some sectors are protected.

Bits 14:13 Reserved, must be kept at reset value.

Bits 12:6 **SNB[6:0]**: sector erase selection number

These bits are used to select the target sector for an erase operation (they are unused otherwise). SNB can be programmed only when LOCK is cleared to 0.

0x00: Sector 0 selected

0x01: Sector 1 selected

..

0x7F: Sector 127 selected

Bit 5 **STRT**: erase start control bit

STRT bit is used to start a sector erase or a bank erase operation. STRT can be programmed only when LOCK is cleared to 0.

STRT is reset at the end of the operation or when an error occurs. It cannot be reseted by software.

Bit 4 **FW:** write forcing control bit

FW forces a write operation even if the write buffer is not full. In this case all bits not written are set to 1 by hardware. FW can be programmed only when LOCK is cleared to 0.

The memory resets FW when the corresponding operation has been acknowledged.

Note: Using a force-write operation prevents the application from updating later the missing bits with something else than 1, because it is likely that it leads to permanent ECC error.

Write forcing is effective only if the write buffer is not empty and was filled by non-secure access (in particular, FW does not start several write operations when the force-write operations are performed consecutively).

Since there is just one write buffer, FW can force a write in bank1 or bank2.

Bit 3 **BER**: erase request

Setting BER bit to 1 requests a bank erase operation (user flash memory only). BER can be programmed only when LOCK is cleared to 0.

If MER and SER are also set, a PGSERR is raised.

0: bank erase not requested

1: bank erase requested

Note: Write protection error is triggered when a bank erase is required and some sectors are protected.

Bit 2 **SER**: sector erase request

Setting SER bit to 1 requests a sector erase. SER can be programmed only when LOCK is cleared to 0.

If MER and SER are also set, a PGSERR is raised.

0: sector erase not requested

1: sector erase requested

Bit 1 **PG**: programming control bit

PG can be programmed only when LOCK is cleared to 0.

PG allows programming in Bank1 and Bank2.

0: programming disabled

1: programming enabled

Bit 0 **LOCK**: configuration lock bit

This bit locks the FLASH_NSCR register. The correct write sequence to FLASH_NSKEYR register unlocks this bit. If a wrong sequence is executed, or if the unlock sequence to FLASH_NSKEYR is performed twice, this bit remains locked until the next system reset.

LOCK can be set by programming it to 1. When set to 1, a new unlock sequence is mandatory to unlock it. When LOCK changes from 0 to 1, the other bits of FLASH_NSCR register do not change.

0: FLASH_NSCR register unlocked

1: FLASH_NSCR register locked

7.11.12 FLASH secure control register (FLASH_SECCR)

This register is secure. It can be read and written only by secure access. A non-secure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register.

Access: No wait state when no FLASH memory operation is ongoing. The FLASH_SECCR register is not accessible in write mode when the BSY bit is set. Any attempt to write to it with the BSY bit set causes the AHB bus to stall until the BSY bit is cleared.

Address offset: 0x02C

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw			rw	rw	rw	rw	rw	rw	rw	rs	rw	rw	rw	rw	rs

Bit 31 **BKSEL**: bank selector bit

BKSEL can only be programmed when LOCK is cleared to 0. The bit selects physical bank, SWAP_BANK setting is ignored.

0: Bank1 is selected for Bank erase / sector erase / interrupt enable

1: Bank2 is selected for BER / SER

Bit 30 Reserved, must be kept at reset value.

Bit 29 **INV**: Flash memory security state invert.

This bit inverts the flash memory security state.

Bits 28:23 Reserved, must be kept at reset value.

Bit 22 **OBKWERRIE**: OBK write error interrupt enable bit

OBKWERRIE enables generation of interrupt in case of OBK specific write error. OBKWERRIE can be programmed only when LOCK is cleared to 0.

0: no interrupt is generated on OBK write error

1: an interrupt is generated on OBK write error

Bit 21 **OBKERRIE**: OBK general error interrupt enable bit

OBKERRIE enables generating an interrupt in case of OBK specific access error. OBKERRIE can be programmed only when LOCK is cleared to 0.

0: no interrupt is generated on OBK general access error

1: an interrupt is generated on OBK general access error

Bit 20 **INCERRIE**: inconsistency error interrupt enable bit

When INCERRIE bit is set to 1, an interrupt is generated when an inconsistency error occurs during a write operation. INCERRIE can be programmed only when LOCK is cleared to 0.

0: no interrupt generated when a inconsistency error occurs

1: interrupt generated when a inconsistency error occurs.

Bit 19 **STRBERRIE**: strobe error interrupt enable bit

When STRBERRIE bit is set to 1, an interrupt is generated when a strobe error occurs (the master programs several times the same byte in the write buffer) during a write operation. STRBERRIE can be programmed only when LOCK is cleared to 0.

0: no interrupt generated when a strobe error occurs

1: interrupt generated when strobe error occurs.

Bit 18 **PGSERRIE**: programming sequence error interrupt enable bit

When PGSERRIE bit is set to 1, an interrupt is generated when a sequence error occurs during a program operation. PGSERRIE can be programmed only when LOCK is cleared to 0.

0: no interrupt generated when a sequence error occurs

1: interrupt generated when sequence error occurs

Bit 17 **WRPERRIE**: write protection error interrupt enable bit

When WRPERRIE bit is set to 1, an interrupt is generated when a protection error occurs during a program operation. WRPERRIE can be programmed only when LOCK is cleared to 0.

0: no interrupt generated when a protection error occurs

1: interrupt generated when a protection error occurs

Bit 16 **EOPIE**: end of operation interrupt control bit

Setting EOPIE bit to 1 enables the generation of an interrupt at the end of a program/erase operation. EOPIE can be programmed only when LOCK is cleared to 0.

0: no interrupt generated at the end of operation.

1: interrupt enabled when at the end of operation

Bit 15 **MER**: mass erase request

Setting MER bit to 1 requests a mass erase operation (user flash memory only). MER can be programmed only when LOCK is cleared to 0.

If BER or SER are also set, a PGSERR is raised.

0: mass erase not requested

1: mass erase requested

Error is triggered when a mass erase is required and some sectors are protected.

Bits 14:13 Reserved, must be kept at reset value.

Bits 12:6 **SNB[6:0]**: sector erase selection number

These bits are used to select the target sector for an erase operation (they are unused otherwise). SNB can be programmed only when LOCK is cleared to 0.

0x00: Sector 0 selected

0x01: Sector 1 selected

..

0x7F: Sector 127 selected

Bit 5 **STRT**: erase start control bit

STRT bit is used to start a sector erase or a bank erase operation. STRT can be programmed only when LOCK is cleared to 0.

STRT is reseted at the end of the operation or when an error occurs. It cannot be reset by software.

Bit 4 **FW:** write forcing control bit

FW forces a write operation even if the write buffer is not full. In this case all bits not written are set to 1 by hardware. FW can be programmed only when LOCK is cleared to 0.

The memory resets FW when the corresponding operation has been acknowledged.

Note: Using a force-write operation prevents the application from updating later the missing bits with something else than 1, because it is likely that it leads to permanent ECC error.

Write forcing is effective only if the write buffer is not empty and was filled by secure access (in particular, FW does not start several write operations when the force-write operations are performed consecutively).

Since there is just one write buffer, FW can force a write in bank1 or bank2.

Bit 3 **BER**: erase request

Setting BER bit to 1 requests a bank erase operation (user flash memory only). BER can be programmed only when LOCK is cleared to 0.

If MER and SER are also set, a PGSERR is raised.

0: bank erase not requested

1: bank erase requested

Note: Write protection error is triggered when a bank erase is required and some sectors are protected.

Bit 2 **SER**: sector erase request

Setting SER bit to 1 requests a sector erase. SER can be programmed only when LOCK is cleared to 0.

If BER and MER are also set, a PGSERR is raised.

0: sector erase not requested

1: sector erase requested

Bit 1 **PG**: programming control bit

PG can be programmed only when LOCK is cleared to 0.

PG allows programming in Bank1 and Bank2.

0: programming disabled

1: programming enabled

Bit 0 **LOCK**: configuration lock bit

This bit locks the FLASH_SECCR register. The correct write sequence to FLASH_SECKEYR register unlocks this bit. If a wrong sequence is executed, or if the unlock sequence to FLASH_NSKEYR is performed twice, this bit remains locked until the next system reset.

LOCK can be set by programming it to 1. When set to 1, a new unlock sequence is mandatory to unlock it. When LOCK changes from 0 to 1, the other bits of FLASH_SECCR register do not change.

0: FLASH_SECCR register unlocked

1: FLASH_SECCR register locked

7.11.13 FLASH non-secure clear control register (FLASH_NSCCR)

This register is non-secure. It can be written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x030

Reset value: 0x0000 0000

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **CLR_OPTCHANGEERR:** Clear the flag corresponding flag in FLASH_NSSR by writing this bit.

Bit 22 **CLR_OBKWERR**: OBKWERR flag clear bit.
Setting this bit to 1 resets to 0 OBKWERR flag in FLASH_NSSR register.

Bit 21 **CLR_OBKERR**: OBKERR flag clear bit.
Setting this bit to 1 resets to 0 OBKERR flag in FLASH_NSSR register.

Bit 20 **CLR_INCERR**: INCERR flag clear bit
Setting this bit to 1 resets to 0 INCERR flag in FLASH_NSSR register.

Bit 19 **CLR_STRBERR**: STRBERR flag clear bit
Setting this bit to 1 resets to 0 STRBERR flag in FLASH_NSSR register.

Bit 18 **CLR_PGSERR**: PGSERR flag clear bit
Setting this bit to 1 resets to 0 PGSERR flag in FLASH_NSSR register.

Bit 17 **CLR_WRPERR**: WRPERR flag clear bit
Setting this bit to 1 resets to 0 WRPERR flag in FLASH_NSSR register.

Bit 16 **CLR_EOP**: EOP flag clear bit
Setting this bit to 1 resets to 0 EOP flag in FLASH_NSSR register.

Bits 15:0 Reserved, must be kept at reset value.

7.11.14 FLASH secure clear control register (FLASH_SECCCR)

This register is secure. It can be written only by secure access. A non-secure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x034

Reset value: 0x0000 0000

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **CLR_OBKWERR**: OBKWERR flag clear bit
Setting this bit to 1 resets to 0 OBKWERR flag in FLASH_SECSR register.

Bit 21 **CLR_OBKERR**: OBKWERR flag clear bit
Setting this bit to 1 resets to 0 OBKWERR flag in FLASH_SECSR register.

Bit 20 **CLR_INCERR**: INCERR flag clear bit
Setting this bit to 1 resets to 0 INCERR flag in FLASH_SECSR register.

Bit 19 **CLR_STRBERR**: STRBERR flag clear bit
Setting this bit to 1 resets to 0 STRBERR flag in FLASH_SECSR register.

Bit 18 **CLR_PGSERR**: PGSERR flag clear bit
Setting this bit to 1 resets to 0 PGSERR flag in FLASH_SECSR register.

Bit 17 **CLR_WRPERR**: WRPERR flag clear bit
Setting this bit to 1 resets to 0 WRPERR flag in FLASH_SECSR register.

Bit 16 **CLR_EOP**: EOP flag clear bit
Setting this bit to 1 resets to 0 EOP flag in FLASH_SECSR register.

Bits 15:0 Reserved, must be kept at reset value.

7.11.15 FLASH privilege configuration register (FLASH_PRIVCFGR)

Address offset: 0x03C

Reset value: 0x0000 0000

This register can be read by both privileged and unprivileged access. NSPRIV is a non-secure bit. SPRIV is a secure bit. It can only be written by privilege mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	NSPRIV	SPRIV
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **NSPRIV**: privilege attribute for non secure registers
0: access to non secure registers is always granted
1: access to non secure registers is denied in case of unprivileged access.

Bit 0 **SPRIV**: privilege attribute for secure registers
0: access to secure registers is always granted
1: access to secure registers is denied in case of unprivileged access.

7.11.16 FLASH non-secure OBK configuration register (FLASH_NSOBKCFGR)

Register is only available when TZ_STATE = 0xC3. This register is non-secure. It can be read and written by both secure and non-secure access. This register can only be accessed by privilege code.

The FLASH_NSOBKCFGR register is not accessible in write mode when the BSY bit is set. Any attempt to write to it with the BSY bit set causes the AHB bus to stall until the BSY bit is cleared.

Address offset: 0x040

Reset value: 0x01FF 0000

												rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:16 **SWAP_OFFSET[8:0]**: Key index (offset /16 bits) pointing for next swap.
0x00: means that no OBK is copied from current to alternate OBK sector during SWAP operation.
0x01 means that only the first OBK data (128 bits) is copied from current to alternate OBK sector
0x02 means that the two first OBK data is copied …
…
0x1FF: means that all OBK data (511) is copied

Bits 15:4 Reserved, must be kept at reset value.

Bit 3 **ALT_SECT_ERASE**: alternate sector erase bit
0: do not touch OBK sector
1: erase the alternate OBK sector
When ALT_SECT bit is set, use this bit to generate an erase command for the OBK alternate sector. It is set only by Software and cleared when the OBK swap operation is completed or an error occurs (PGSERR). It is reseted at the same time as BUSY bit.

Bit 2 **ALT_SECT**: alternate sector bit
0: current OBK sector is mapped to OBK address range for access
1: alternate OBK sector is mapped to OBK address range for access
This bit must not change while filling the write buffer, otherwise an error (OBKERR) is generated

Bit 1 **SWAP_SECT_REQ**: OBK swap sector request bit
0: no swap requested
1: launch the sector swap
When set, all the OBKs which have not been updated in the alternate sector is copied from current sector to alternate one.
The SWAP_OFFSET value must be a certain minimum value in order for the swap to be launched in OBK-HDPL ≠ 0. Minimum value is 16 for OBK-HDPL = 1, 144 for OBK-HDPL = 2 and 192 for OBK-HDPL = 3.

Bit 0 **LOCK**: OBKCFGR lock option configuration bit
This bit locks the FLASH_NSOBKCFGR register. The correct write sequence to FLASH_NSOBKKEYR register unlocks this bit. If a wrong sequence is executed, or if the unlock sequence to FLASH_NSOBKKEYR is performed twice, this bit remains locked until the next system reset. LOCK can be set by programming it to 1. When set to 1, a new unlock sequence is mandatory to unlock it. When LOCK changes from 0 to 1, the other bits of FLASH_NSCR register do not change.
0: FLASH_NSOBKCFGR register unlocked
1: FLASH_NSOBKCFGR register locked

7.11.17 FLASH secure OBK configuration register (FLASH_SECOBKCFGR)

This register can be accessed only in secure privilege mode. The FLASH_SECOBKCFGR register is not accessible in write mode when the BSY bit is set. Any attempt to write to it with the BSY bit set causes the AHB bus to stall until the BSY bit is cleared.

Address offset: 0x044

Reset value: 0x01FF 0000

												rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:16 **SWAP_OFFSET[8:0]**: key index (offset /16 bits) pointing for next swap.
0x0: no OBK is copied from current to alternate OBK sector during SWAP operation.
0x1: only the first OBK data (128 bits) is copied from current to alternate OBK sector
0x2: the two first OBK data are copied …
…
0x1FF: that the 511 first OBK data are copied

Bits 15:4 Reserved, must be kept at reset value.

Bit 3 **ALT_SECT_ERASE**: alternate sector erase bit
0: do not touch OBK sector
1: erase the alternate OBK sector
When ALT_SECT bit is set, use this bit to generate an erase command for the OBK alternate sector. It is set only by Software and cleared when the OBK swap operation is completed or an error occurs (PGSERR). It is reseted at the same time as the BUSY bit.

Bit 2 **ALT_SECT**: alternate sector bit
0: current OBK sector is mapped to OBK address range for access
1: alternate OBK sector is mapped to OBK address range for access
This bit must not change while filling the write buffer, otherwise an error is generated

Bit 1 **SWAP_SECT_REQ**: OBK swap sector request bit
0: no swap requested
1: launch the sector swap
When set, all the OBKs which have not been updated in the alternate sector is copied from current sector to alternate one.
The SWAP_OFFSET value must be a certain minimum value in order for the swap to be launched in OBK-HDPL ≠ 0. Minimum value is 16 for OBK-HDPL = 1, 144 for OBK-HDPL = 2 and 192 for OBK-HDPL = 3.

Bit 0 **LOCK**: OBKCFGR lock option configuration bit

This bit locks the FLASH_OBKCFGR register. The correct write sequence to FLASH_SECOBKKEYR register unlocks this bit. If a wrong sequence is executed, or if the unlock sequence to FLASH_SECOBKKEYR is performed twice, this bit remains locked until the next system reset. LOCK can be set by programming it to 1. When set to 1, a new unlock sequence is mandatory to unlock it. When LOCK changes from 0 to 1, the other bits of FLASH_NSCR register do not change.

0: FLASH_OBKCFGR register unlocked

1: FLASH_OBKCFGR register locked

7.11.18 FLASH HDP extension register (FLASH_HDPEXTR)

All bits in this register are non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

The register can only be modified in HDPL<=2.

The values in this register cannot be decremented. Attempt to write a lower value that current is ignored.

Address offset: 0x048

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HDP1_EXT[6:0]						
									rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:16 **HDP2_EXT[6:0]**: HDP area extension in 8 Kbytes sectors in bank 2. Extension is added after the HDP2_END sector (included).

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:0 **HDP1_EXT[6:0]**: HDP area extension in 8 Kbytes sectors in Bank1. Extension is added after the HDP1_END sector (included).

7.11.19 FLASH option status register (FLASH_OPTSR_CUR)

This register is non-secure. It can be read by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Default value: 0x0030 5CD8 (value in case of double ECC issue during OBL).

This read-only register reflects the current values of corresponding option bits.

Address offset: 0x050

Reset value: 0xXXXX XXXX

(Register bits 0 to 31 are loaded with values from the flash memory at OBL)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r	r	r	r	r	r	r	r	r	r		r	r	r	r	r

Bit 31 **SWAP_BANK**: Bank swapping option status bit
SWAP_BANK reflects whether Bank1 and Bank2 are swapped or not.
SWAP_BANK is loaded to SWAP_BANK of FLASH_OPTCR after a reset.
0: Bank1 and Bank2 not swapped
1: Bank1 and Bank2 swapped

Bit 30 Reserved, must be kept at reset value.

Bits 29:22 **BOOT_UBE[7:0]:** Available only on cryptography enabled devices.
Unique boot entry control, selects either ST or OEM iRoT for secure boot.
0xC3: ST-iRoT (system flash) selected
0xB4: OEM-iRoT (user flash) selected. In Open PRODUCT_STATE this value selects bootloader. Defaut value.

Bit 21 **IWDG_STDBY**: IWDG Standby mode freeze option status bit
When set the independent watchdog IWDG is frozen in system Standby mode.
0: Independent watchdog frozen in Standby mode
1: Independent watchdog keep running in Standby mode.

Bit 20 **IWDG_STOP**: IWDG Stop mode freeze option status bit
When set the independent watchdog IWDG is in system Stop mode.
0: Independent watchdog frozen in system Stop mode
1: Independent watchdog keep running in system Stop mode.

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **IO_VDDIO2_HSLV**: High-speed IO at low V_{DDIO2} voltage configuration bit.
This bit can be set only with V_{DDIO2} below 2.7 V.
0: High-speed IO at low V_{DDIO2} voltage feature disabled (V_{DDIO2} can exceed 2.7 V)
1: High-speed IO at low V_{DDIO2} voltage feature enabled (V_{DDIO2} remains below 2.7 V)

Bit 16 **IO_VDD_HSLV**: High-speed IO at low V_{DD} voltage configuration bit.
This bit can be set only with V_{DD} below 2.7 V.
0: High-speed IO at low V_{DD} voltage feature disabled (V_{DD} can exceed 2.7 V)
1: High-speed IO at low V_{DD} voltage feature enabled (V_{DD} remains below 2.7 V)

Bits 15:8 **PRODUCT_STATE[7:0]**: Life state code (based on Hamming 8,4). More information in *Section 7.6.11: Product state transitions*.

Bit 7 **NRST_STDBY**: Core domain Standby entry reset option status bit
0: a reset is generated when entering Standby mode on core domain
1: no reset generated when entering Standby mode on core domain.

Bit 6 **NRST_STOP**: Core domain Stop entry reset option status bit
0: a reset is generated when entering Stop mode on core domain
1: no reset generated when entering Stop mode on core domain.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **WWDG_SW**: WWDG control mode option status bit
0: WWDG watchdog is controlled by hardware
1: WWDG watchdog is controlled by software

Bit 3 **IWDG_SW**: IWDG control mode option status bit
0: IWDG watchdog is controlled by hardware
1: IWDG watchdog is controlled by software

Bit 2 **BORH_EN**: Brownout high enable
0: disable
1: enable

Bits 1:0 **BOR_LEV[1:0]**: Brownout level option status bit
These bits reflects the power level that generates a system reset.
00 or 11: BOR Level 1, the threshold level is low (around 2.1 V)
01: BOR Level 2, the threshold level is medium (around 2.4 V)
10: BOR Level 3, the threshold level is high (around 2.7 V)

7.11.20 FLASH option status register (FLASH_OPTSR_PRG)

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

This register is used to program values in corresponding option bits. Values after reset reflects the current values of the corresponding option bits.

Address offset: 0x054

Reset value: 0xXXXX XXXX

(Register bits 0 to 31 are loaded with values from the flash memory at OBL)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWAP_BANK	Res.	BOOT_UBE[7:0]								IWDG_STDBY	IWDG_STOP	Res.	Res.	IO_VDDIO2_HSLV	IO_VDD_HSLV

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

Bit 31 **SWAP_BANK**: Bank swapping option configuration bit
SWAP_BANK option bit is used to configure whether the Bank1 and Bank2 are swapped or not. This bit is loaded with the SWAP_BANK bit of FLASH_OPTSR_CUR register after a reset.
0: Bank1 and Bank2 not swapped
1: Bank1 and Bank2 swapped

Bit 30 Reserved, must be kept at reset value.

Bits 29:22 **BOOT_UBE[7:0]:** Available only on cryptography enabled devices.
Unique boot entry control, selects either ST or OEM iRoT for secure boot.
0xC3: ST-iRoT (system flash) selected
0xB4: OEM-iRoT (user flash) selected.
In Open PRODUCT_STATE this value selects bootloader. Defaut value.

Bit 21 **IWDG_STDBY**: IWDG Standby mode freeze option status bit
When set the independent watchdog IWDG is frozen in system Standby mode.
0: Independent watchdog frozen in Standby mode
1: Independent watchdog keep running in Standby mode.

Bit 20 **IWDG_STOP**: IWDG Stop mode freeze option status bit
When set the independent watchdog IWDG is in system Stop mode.
0: Independent watchdog frozen in system Stop mode
1: Independent watchdog keep running in system Stop mode.

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **IO_VDDIO2_HSLV**: High-speed IO at low VDDIO2 voltage configuration bit.
This bit can be set only with VDDIO2 below 2.7 V.
0: High-speed IO at low VDDIO2 voltage feature disabled (VDDIO2 can exceed 2.7 V)
1: High-speed IO at low VDDIO2 voltage feature enabled (VDDIO2 remains below 2.7 V)

Bit 16 **IO_VDD_HSLV**: High-speed IO at low VDD voltage configuration bit.
This bit can be set only with VDD below 2.7 V.
0: High-speed IO at low VDD voltage feature disabled (VDD can exceed 2.7 V)
1: High-speed IO at low VDD voltage feature enabled (VDD remains below 2.7 V)

Bits 15:8 **PRODUCT_STATE[7:0]**: Life state code (based on Hamming 8,4). More information in *Section 7.6.11: Product state transitions*.

Bit 7 **NRST_STDBY**: Core domain Standby entry reset option configuration bit
0: a reset is generated when entering Standby mode on core domain
1: no reset generated when entering Standby mode on core domain.

Bit 6 **NRST_STOP**: Core domain Stop entry reset option configuration bit
0: a reset is generated when entering Stop mode on core domain
1: no reset generated when entering Stop mode on core domain.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **WWDG_SW**: WWDG control mode option configuration bit
0: WWDG watchdog is controlled by hardware
1: WWDG watchdog is controlled by software

Bit 3 **IWDG_SW**: IWDG control mode option configuration bit
0: IWDG watchdog is controlled by hardware
1: IWDG watchdog is controlled by software

Bit 2 **BORH_EN**: Brownout high enable configuration bit
0: disable
1: enable

Bits 1:0 **BOR_LEV[1:0]**: Brownout level option configuration bit
These bits reflects the power level that generates a system reset.
00 or 11: BOR Level 1, the threshold level is low (around 2.1 V)
01: BOR Level 2, the threshold level is medium (around 2.4 V)
10: BOR Level 3, the threshold level is high (around 2.7 V)

7.11.21 FLASH non-secure EPOCH register (FLASH_NSEPOCHR_CUR)

This register is non-secure. It can be read by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

This read-only register reflects the current values of corresponding option bits.

Address offset: 0x060

Reset value: 0xXXXX XXXX

(Register bits 0 to 31 are loaded with values from the flash memory at OBL)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 **NS_EPOCH[23:0]:** Non-volatile non-secure EPOCH counter

7.11.22 FLASH secure EPOCH register (FLASH_SECEPOCHR_CUR)

This register is non-secure. It can be read by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

This read-only register reflects the current values of corresponding option bits.

Address offset: 0x068

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 **SEC_EPOCH[23:0]:** Non-volatile secure EPOCH counter

7.11.23 FLASH option status register 2 (FLASH_OPTSR2_CUR)

This register is non-secure. It can be read by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Default value: 0xB400 0170

This read-only register reflects the current values of corresponding option bits.

Address offset: 0x070

Reset value: 0xXXXX XXXX

(Register bits 0 to 31 are loaded with values from the flash memory at OBL)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TZEN[7:0]								Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

							r		r	r	r	r	r		

Bits 31:24 **TZEN[7:0]**: TrustZone enable configuration bits
This bit enables the device is in TrustZone mode during an option byte change.
0xC3: TrustZone disabled
0xB4: TrustZone enabled.

Bits 23:15 Reserved, must be kept at reset value.

Bits 14:9 Reserved, must be kept at reset value.

Bit 8 **USBPD_DIS**: USB power delivery configuration option bit
0: Enabled
1: Disabled

Bit 7 Reserved, must be kept at reset value.

Bit 6 **SRAM2_ECC**: SRAM2 ECC detection and correction disable
0: SRAM2 ECC check enabled
1: SRAM2 ECC check disabled

Bit 5 **SRAM3_ECC**: SRAM3 ECC detection and correction disable
0: SRAM3 ECC check enabled
1: SRAM3 ECC check disabled

Bit 4 **BKPRAM_ECC**: Backup RAM ECC detection and correction disable
0: BKPRAM ECC check enabled
1: BKPRAM ECC check disabled

Bit 3 **SRAM2_RST**: SRAM2 erase when system reset
0: SRAM2 erased when a system reset occurs
1: SRAM2 not erased when a system reset occurs.

Bit 2 **SRAM13_RST**: SRAM1 and SRAM3 erase upon system reset
0: SRAM1 and SRAM3 erased when a system reset occurs
1: SRAM1 and SRAM3 not erased when a system reset occurs

Bits 1:0 Reserved, must be kept at reset value.

7.11.24 FLASH option status register 2 (FLASH_OPTSR2_PRG)

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

This register is used to program values in corresponding option bits. Values after reset reflects the current values of the corresponding option bits.

Address offset: 0x074

Reset value: 0xXXXX XXXX

(Register bits 0 to 31 are loaded with values from the flash memory at OBL)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TZEN[7:0]								Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

							rw		rw	rw	rw	rw	rw		

Bits 31:24 **TZEN[7:0]**: TrustZone enable configuration bits
This bit enables the device is in TrustZone mode during an option byte change.
0xC3: TrustZone disabled
0xB4: TrustZone enabled

Bits 23:15 Reserved, must be kept at reset value.

Bits 14:9 Reserved, must be kept at reset value.

Bit 8 **USBPD_DIS**: USB power delivery configuration option bit
0: Enabled
1: Disabled

Bit 7 Reserved, must be kept at reset value.

Bit 6 **SRAM2_ECC**: SRAM2 ECC detection and correction disable
0: SRAM2 ECC check enabled
1: SRAM2 ECC check disabled

Bit 5 **SRAM3_ECC**: SRAM3 ECC detection and correction disable
0: SRAM3 ECC check enabled
1: SRAM3 ECC check disabled

Bit 4 **BKPRAM_ECC**: Backup RAM ECC detection and correction disable
0: BKPRAM ECC check enabled
1: BKPRAM ECC check disabled

Bit 3 **SRAM2_RST**: SRAM2 erase when system reset
0: SRAM2 erased when a system reset occurs
1: SRAM2 not erased when a system reset occurs.
Note: SRAM erase is triggered by option byte change operation, when enabling this feature.

Bit 2 **SRAM1_3_RST**: SRAM1 and SRAM3 erase upon system reset
0: SRAM1 and SRAM3 erased when a system reset occurs
1: SRAM1 and SRAM3 not erased when a system reset occurs
Note: SRAM erase is triggered by option byte change operation, when enabling this feature.

Bits 1:0 Reserved, must be kept at reset value.

7.11.25 FLASH non-secure boot register (FLASH_NSBOOTR_CUR)

This register is non-secure. It can be read by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

This register reflects the current values of corresponding option bits.

Address offset: 0x080

Reset value: 0xXXXX XXXX

(Register bits 0 to 31 are loaded with values from the flash memory at OBL)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
NSBOOTADD[23:8]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NSBOOTADD[7:0]								NSBOOT_LOCK[7:0]							
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:8 **NSBOOTADD[23:0]**: Non secure unique boot entry address
These bits reflect the Non secure UBE address

Bits 7:0 **NSBOOT_LOCK[7:0]:** A field locking the values of SWAP_BANK, and NSBOOTADD settings.
0xC3: The SWAP_BANK and NSBOOTADD can still be modified following their individual rules.
0xB4: The NSBOOTADD is frozen. SWAP_ BANK can only be modified with TZEN set to 0xB4 (enabled).

7.11.26 FLASH non-secure boot register (FLASH_NSBOOTR_PRG)

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

This register is used to program values in corresponding option bits.

Address offset: 0x084

Reset value: 0xXXXX XXXX

(Register bits 0 to 31 are loaded with values from the flash memory at OBL)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NSBOOTADD[7:0]								NSBOOT_LOCK[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 **NSBOOTADD[23:0]**: Non secure unique boot entry address
These bits allow configuring the Non secure BOOT address

Bits 7:0 **NSBOOT_LOCK[7:0]:** A field locking the values of SWAP_ BANK, and NSBOOTADD settings.
0xC3: The SWAP_ BANK and NSBOOTADD can still be modified following their individual rules.
0xB4: The NSBOOTADD is frozen. SWAP_ BANK can only be modified with TZEN set to 0xB4 (enabled).

7.11.27 FLASH secure boot register (FLASH_SECBOOTR_CUR)

This register is secure. It can be read only by secure access. A non-secure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register.

This register reflects the current values of corresponding option bits.

Address offset: 0x088

Reset value: 0xXXXX XXXX

(Register bits 0 to 31 are loaded with values from the flash memory at OBL)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SECBOOTADD[23:8]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SECBOOTADD[7:0]								SECBOOT_LOCK[7:0]							
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:8 **SECBOOTADD[23:0]**: Unique boot entry secure address
These bits reflect the Secure UBE address

Bits 7:0 **SECBOOT_LOCK[7:0]:** A field locking the values of UBE, SWAP_BANK, and SECBOOTADD settings.
0xC3: The BOOT_UBE, SWAP_BANK and SECBOOTADD can still be modified following their individual rules.
0xB4: The BOOT_UBE and SECBOOTADD are frozen. SWAP_ BANK can only be modified with TZEN set to 0xC3 (disabled).

7.11.28 FLASH secure boot register (FLASH_BOOTR_PRG)

This register is secure. It can be read and written only by secure access. A non-secure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register.

This register is used to program values in corresponding option bits.

Address offset: 0x08C

Reset value: 0xXXXX XXXX

(Register bits 0 to 31 are loaded with values from the flash memory at OBL)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SECBOOTADD[23:8]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SECBOOTADD[7:0]								SECBOOT_LOCK[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 **SECBOOTADD[23:0]**: Secure unique boot entry address.
These bits allow configuring the secure UBE address.

Bits 7:0 **SECBOOT_LOCK[7:0]:** A field locking the values of UBE, SWAP_ BANK, and SECBOOTADD setting.
0xC3: The BOOT_UBE, SWAP_ BANK and SECBOOTADD can still be modified following their individual rules.
0xB4: The BOOT_UBE and SECBOOTADD are frozen. SWAP_BANK can only be modified with TZEN set to 0xC3 (disabled).

7.11.29 FLASH non-secure OTP block lock (FLASH_OTPBLR_CUR)

This register is non-secure. It can be read by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

This register reflects the current values of corresponding option bits.

Address offset: 0x090

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LOCKBL[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LOCKBL[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **LOCKBL[31:0]**: OTP block lock

Block *n* corresponds to OTP 16-bit word 32 x *n* to 32 x *n* + 31.
LOCKBL[n] = 1 indicates that all OTP 16-bit words in OTP Block *n* are locked and attempt to program them results in WRPERR.
LOCKBL[n] = 0 indicates that all OTP 16-bit words in OTP Block *n* are not locked.
When one block is locked, it's not possible to remove the write protection.
Also if not locked, it is not possible to erase OTP words.

7.11.30 FLASH non-secure OTP block lock (FLASH_OTPBLR_PRG)

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

This register is used to program values in corresponding option bits.

Address offset: 0x094

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LOCKBL[31:16]															
rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LOCKBL[15:0]															
rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:0 **LOCKBL[31:0]**: OTP block lock

Block *n* corresponds to OTP 16-bit word 32 x *n* to 32 x *n* + 31.
LOCKBL[n] = 1 indicates that all OTP 16-bit words in OTP Block *n* are locked and attempt to program them results in WRPERR.
LOCKBL[n] = 0 indicates that all OTP 16-bit words in OTP Block *n* are not locked.
When one block is locked, it is not possible to remove the write protection.
LOCKBL bits can be set if the corresponding bit in FLASH_OTPBLR_CUR is cleared.

7.11.31 FLASH secure block based register for Bank 1 (FLASH_SECBB1Rx)

This register is secure. It can be read and written only by secure access. A non-secure read/write access is RAZ/WI.

Address offset: 0x0A0 + 0x004 * (x-1), (x = 1 to 4)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SECBB1[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SECBB1[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SECBB1[31:0]**: Secure/non-secure 8 Kbytes flash Bank 1 sector attributes (y= 0 to 31)
0: sector (32 * (x-1) + y) in bank 1 is non secure.
1: sector (32 * (x-1) + y) in bank 1 is secure.

7.11.32 FLASH privilege block based register for Bank 1 (FLASH_PRIVBB1Rx)

This register is privileged. It can be read written only by a privileged access. This register can be protected against non-secure write access.

Address offset: 0x0C0 + 0x004 * (x-1), (x = 1 to 4)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PRIVBB1[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PRIVBB1[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **PRIVBB1[31:0]**: Privileged/unprivileged 8-Kbyte flash Bank 1 sector attribute (y = 0 to 31)
0: sectors (32 * (x-1) + y) in bank 1 is unprivileged.
1: sector (32 * (x-1) + y) in bank 1 is privileged.

7.11.33 FLASH security watermark for Bank 1 (FLASH_SECWM1R_CUR)

This register is non-secure. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

This read-only register reflects the current values of corresponding option bits.

Address offset: 0x0E0

Reset value: 0x00XX 00XX

(Register bits 0 to 31 are loaded with values from the flash memory at OBL)

ADDR_ECC[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 Reserved, must be kept at reset value.

Bit 30 **ECCC:** ECC correction set by hardware when single ECC error has been detected and corrected.

Cleared by writing 1.

Bits 29:26 Reserved, must be kept at reset value.

Bit 25 **ECCCIE**: ECC single correction error interrupt enable bit

When ECCCIE bit is set to 1, an interrupt is generated when an ECC single correction error occurs during a read operation.

0: no interrupt generated when an ECC single correction error occurs

1: non-secure interrupt generated when an ECC single correction error occurs

Bit 24 **OTP_ECC**: OTP ECC error bit

This bit is set to 1 when one single ECC correction occurred during the last successful read operation from the read-only/ OTP area. The address of the ECC error is available in ADDR_ECC bitfield.

Bit 23 **SYSF_ECC**: ECC fail for corrected ECC error in system flash memory

It indicates if system flash memory is concerned by ECC error.

Bit 22 **BK_ECC**: ECC fail bank for corrected ECC error

It indicates which bank is concerned by ECC error

Bit 21 **EDATA_ECC**: ECC fail for corrected ECC error in flash high-cycle data area
It indicates if flash high-cycle data area is concerned by ECC error.

Bit 20 **OBK_ECC**: Single ECC error corrected in flash OB Keys storage area. It indicates the OBK storage concerned by ECC error.

Bits 19:16 Reserved, must be kept at reset value.

Bits 15:0 **ADDR_ECC[15:0]**: ECC error address
When an ECC error occurs (for single correction) during a read operation, the ADDR_ECC contains the address that generated the error.
ADDR_ECC is reset when the flag error is reset.
The flash interface programs the address in this register only when no ECC error flags are set. This means that only the first address that generated an ECC error is saved.
The address in ADDR_ECC is relative to the flash memory area where the error occurred (user flash memory, system flash memory, data area, read-only/OTP area).

7.11.42 FLASH ECC detection register (FLASH_ECCDETR)

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x104

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ADDR_ECC[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 **ECCD:** ECC detection
Set by hardware when two ECC error has been detected.
When this bit is set, a NMI is generated.
Cleared by writing 1. Needs to be cleared in order to detect subsequent double ECC errors.

Bits 30:25 Reserved, must be kept at reset value.

Bit 24 **OTP_ECC**: OTP ECC error bit
This bit is set to 1 when double ECC detection occurred during the last read operation from the read-only/ OTP area. The address of the ECC error is available in ADDR_ECC bitfield.

Bit 23 **SYSF_ECC**: ECC fail for double ECC error in system flash memory
It indicates if system flash memory is concerned by ECC error.

Bit 22 **BK_ECC**: ECC fail bank for double ECC error
It indicates which bank is concerned by ECC error

Bit 21 **EDATA_ECC**: ECC fail double ECC error in flash high-cycle data area
It indicates if flash high-cycle data area is concerned by ECC error.

Bit 20 **OBK_ECC**: ECC fail double ECC error in flash OB Keys storage area. It indicates the OBK storage concerned by ECC error.

Bits 19:16 Reserved, must be kept at reset value.

Bits 15:0 **ADDR_ECC[15:0]**: ECC error address

When an ECC error occurs (double detection) during a read operation, the ADDR_ECC contains the address that generated the error.

ADDR_ECC is reset when the flag error is reset.

The flash interface programs the address in this register only when no ECC error flags are set. This means that only the first address that generated an double ECC error is saved.

The address in ADDR_ECC is relative to the flash memory area where the error occurred (user flash memory, system flash memory, data area, read-only/OTP area).

7.11.43 FLASH ECC data (FLASH_ECCDR)

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x108

Reset value: 0x0000 0000

DATA_ECC[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **DATA_ECC[15:0]**: ECC error data

When an double detection ECC error occurs on special areas with 6-bit ECC on 16-bit data (data area, read-only/OTP area), the failing data is read to this register.

By checking if it is possible to determine whether the failure was on a real data, or due to access to uninitialized memory.

7.11.44 FLASH secure block-based register for Bank 2 (FLASH_SECBB2Rx)

This register is secure. It can be read and written only by secure access. A non-secure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x1A0 + 0x004 * (x-1), (x = 1 to 4)

Reset value: 0x0000 0000

r													r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **EDATA2_EN:** Bank2 flash high-cycle data enable
0: No flash high-cycle data area
1: Flash high-cycle data is used

Bits 14:3 Reserved, must be kept at reset value.

Bits 2:0 **EDATA2_STRT[2:0]:**
EDATA2_STRT contains the start sectors of the flash high-cycle data area in Bank 2 There is no hardware effect to those bits. They shall be managed by ST tools in Flasher.
000: The last sector of the bank 2is reserved for flash high-cycle data
001: The two last sectors of the Bank 2 are reserved for flash high-cycle data
010: The three last sectors of the Bank 2 are reserved for flash high-cycle data
...
Note: 111: The eight last sectors of the Bank 2 are reserved for flash high-cycle data

7.11.51 FLASH data sector configuration Bank 2 (FLASH_EDATA2R_PRG)

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

This register is used to program values in corresponding options bits.

Address offset: 0x1F4

Reset value: 0xXXXX XXXX

Refer to *Section 2.3* for the register boundary addresses.

8 Instruction cache (ICACHE)

8.1 ICACHE introduction

The instruction cache (ICACHE) is introduced on C-AHB code bus of Cortex-M33 processor to improve performance when fetching instruction and data from internal and external memories.

Some specific features like dual master ports, hit-under-miss and critical-word-first refill policy, allow close to zero-wait-state performance in most use cases.

8.2 ICACHE main features

The main features of ICACHE are described below:

- Bus interface
  - one 32-bit AHB slave port, the execution port (input from Cortex-M33 C-AHB code interface)
  - two AHB master ports: master1 and master2 ports (outputs to Fast and Slow buses of main AHB bus matrix, respectively)
  - one 32-bit AHB slave port for control (input from AHB peripherals interconnect, for ICACHE registers access)
- Cache access
  - 0 wait-state on hits
  - Hit-under-miss capability: ability to serve processor requests (access to cached data) during an ongoing line refill due to a previous cache miss
  - Dual master access: feature used to decouple the traffic according to targeted memory. For example, the ICACHE assigns fast traffic (addressing flash and SRAM memories) to the AHB master1 port, and slow traffic (addressing external memories) to AHB master2 port, thus preventing processor stalls on lines refills from external memories. This allows ISR (interrupt service routine) fetching on internal flash memory to take place in parallel with a cache line refill from external memories.
  - Minimal impact on interrupt latency, thanks to dual master
  - Optimal cache line refill thanks to WRAPw bursts of the size of the cache line (32-bit word size, w, aligned on cache line size)
  - n-way set-associative default configuration with possibility to configure as 1-way, means direct mapped cache, for applications needing very-low-power consumption profile
- Memory address remap
  - Possibility to remap input address falling into up to four memory regions (used to remap aliased code in external memories to the Code region, for execution from C-AHB code interface)
- Replacement and refill
  - pLRU-t replacement policy (pseudo-least-recently-used, based on binary tree), algorithm with best complexity/performance balance
  - Critical-word-first refill policy, minimizing processor stalls

  - Possibility to configure burst type of AHB memory transaction for remapped regions: INCRw or WRAPw (size w aligned on cache line size)
- Performance counters

  The ICACHE implements two performance counters:
  - Hit monitor counter (32-bit)
  - Miss monitor counter (16-bit)
- Error management
  - Possibility to detect an unexpected cacheable write access, to flag an error and optionally to raise an interrupt
- TrustZone security support
- Maintenance operation
  - Cache invalidate: full cache invalidation, fast command, non interruptible

8.3 ICACHE implementation

Table 76. ICACHE features

Feature	ICACHE
Number of ways	2
Cache size	8 Kbytes
Cache line width	16 bytes
Range granularity of memory regions to be remapped	2 Mbytes
Number of regions to remap	4
Data size of AHB slave interface	32 bits
Data size of AHB fast master1 interface	128 bits
Data size of AHB slow master2 interface	32 bits

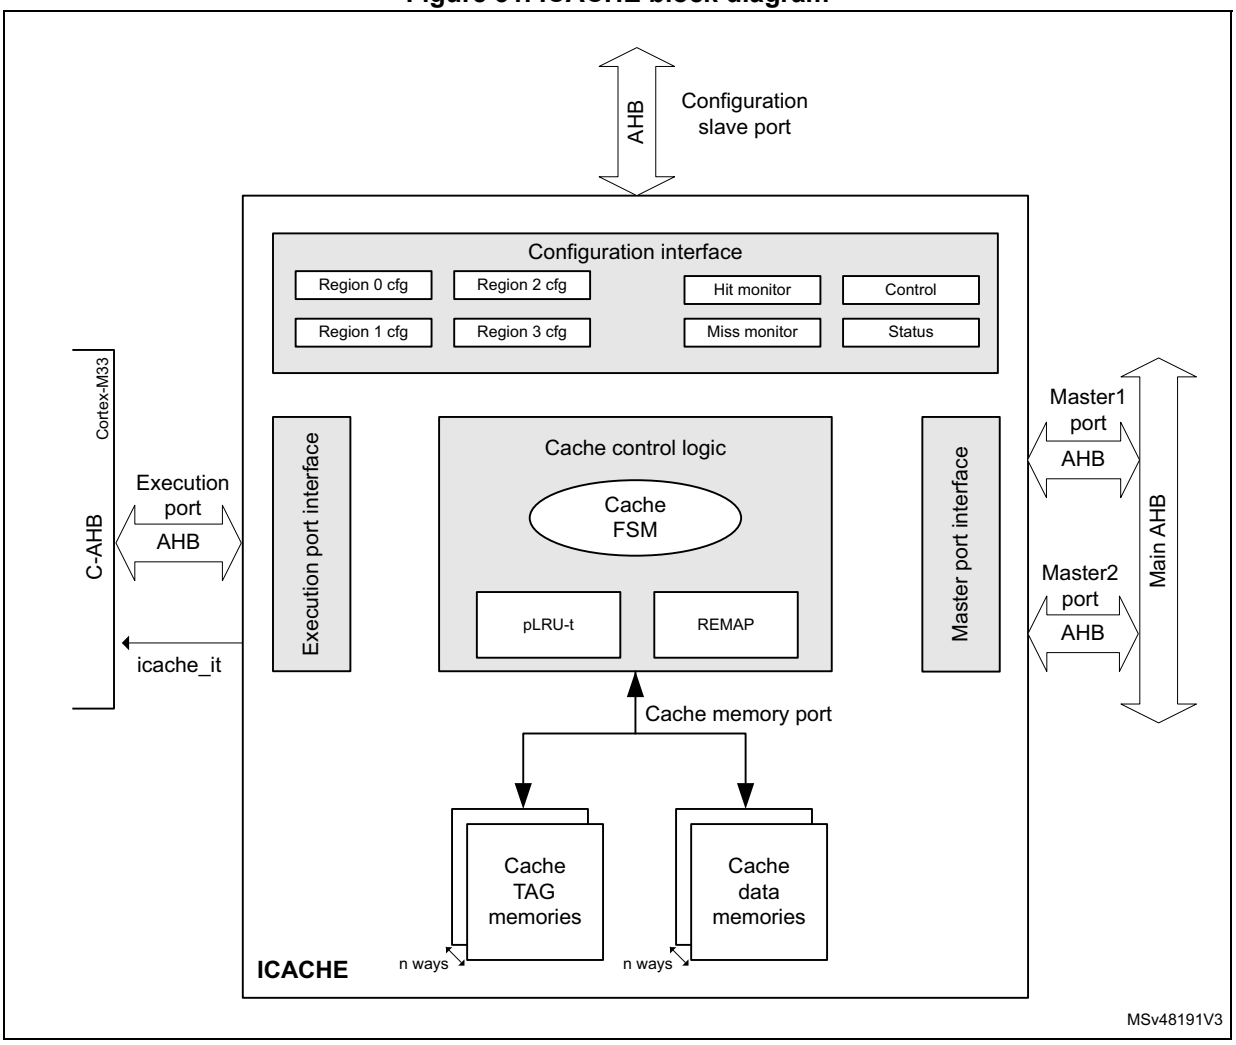
8.4 ICACHE functional description

The purpose of the instruction cache is to cache instruction fetches or instruction memories loads, coming from the processor. As such, the ICACHE only manages read transactions and does not manage write transactions.

For error management purpose, in case a write cacheable transaction is presented (this only happens in case of bad software programming), the ICACHE sets an error flag and, if enabled, raises an interrupt to the processor.

8.4.1 ICACHE block diagram

Figure 31. ICACHE block diagram



8.4.2 ICACHE reset and clocks

The ICACHE is clocked on Cortex-M33 C-AHB bus clock.

When the ICACHE reset signal is released, a cache invalidate procedure is automatically launched, making the ICACHE busy (ICACHE_SR = 0x0000 0001).

When this procedure is finished:

- the ICACHE is invalidated: “cold cache”, with all cache line valid bits = 0 (ICACHE must be filled up)
- ICACHE_SR = 0x0000 0002 (reflecting the cache is no more busy)
- the ICACHE is disabled: the EN bit in ICACHE_CR holds its reset state (=0).

Note: When disabled, the ICACHE is bypassed, except the remapping mechanism that is still functional: slave input requests (remapped or not) are just forwarded to the master port(s).

8.4.3 ICACHE TAG memory

The ICACHE TAG memory contains:

- address tags, that indicate which data are contained in the cache data memories
- validity bits

There is one valid bit per cache line (per way).

The valid bit is set when a cache line is refilled (after a miss).

Valid bits are reset in any of the below cases:

- after the ICACHE reset is released
- when the cache is disabled, by setting EN = 0 in ICACHE_CR (by software)
- when executing an ICACHE invalidate command, by setting CACHEINV = 1 in ICACHE_CR (by software)

When a cacheable transaction is received at the execution input port, its AHB address (HADDR_in) is split into the following fields (see *Table 77* for B and W definitions):

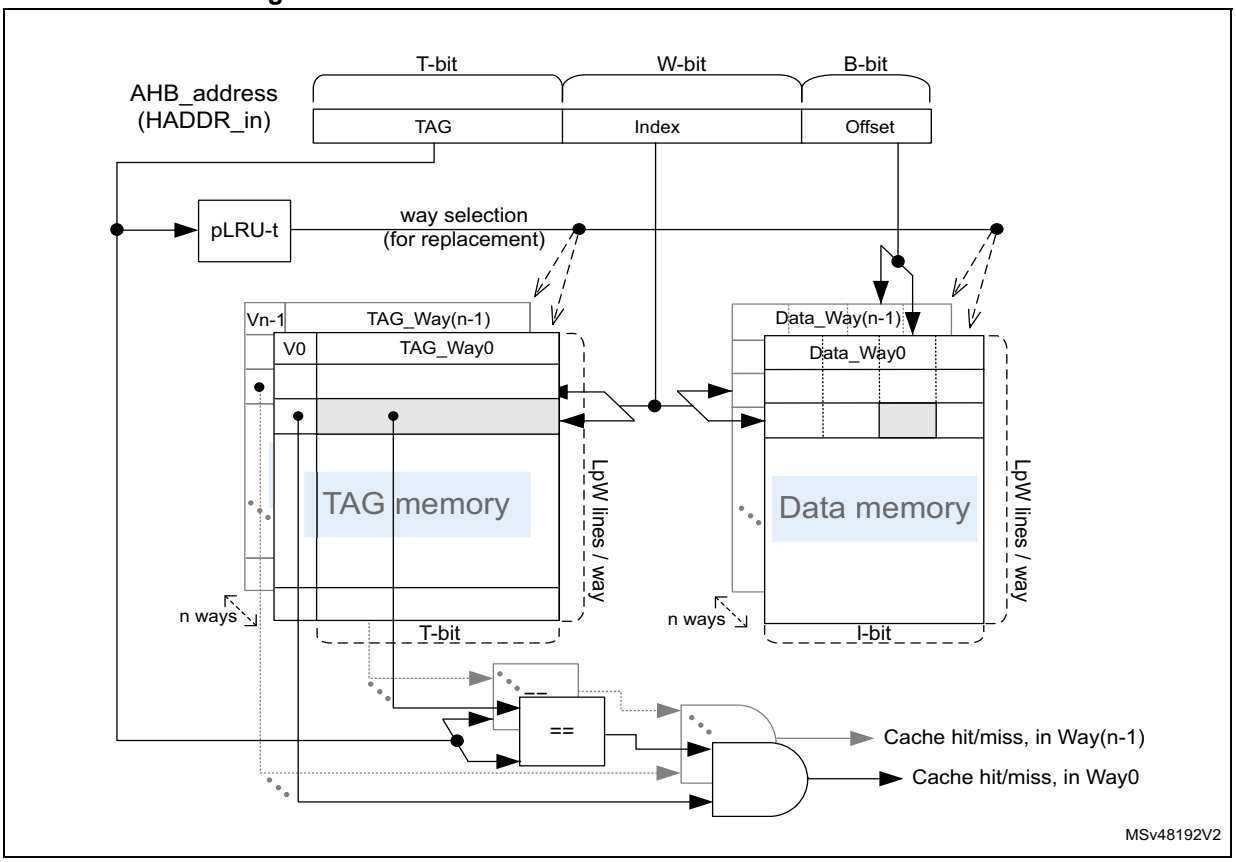
- HADDR_in[B-1:0]: address byte offset, indicates which byte to select inside a cache line.
- HADDR_in[B+W-1:B]: address way index, indicates which cache line to select inside each way.
- HADDR_in[31:B+W]: tag address, to be compared to the TAG memory address to check if the requested data is already available (meaning valid) inside the ICACHE.

The table below gives a summary of ICACHE main parameters for TAG memory dimensioning. *Figure 32* shows the functional view of TAG and data memories, for an n-way set associative ICACHE.

Table 77. TAG memory dimensioning parameters for n-way set associative operating mode (default)

Parameter	Value	Example
Cache size	S Kbytes = s bytes (s = 1024 x S)	8 Kbytes = 8192 bytes
Cache number of ways	n	2
Cache line size	L-byte = l-bit (l = 8 x L)	16-byte = 128-bit
Number of cache lines (per way)	LpW = s / (n x L) lines / way	256 lines / way
Address byte offset size	B = log2(L) bit	4-bit
Address way index size	W = log2(LpW) bit	8-bit
TAG address size	T = (32 - W - B) bit	20-bit

Figure 32. ICACHE TAG and data memories functional view



8.4.4 Direct-mapped ICACHE (1-way cache)

The default configuration (at reset) is an n-way set associative cache (WAYSEL = 1 in ICACHE_CR), but the user can configure the ICACHE as direct mapped by writing WAYSEL = 0 (only possible when the cache is disabled, EN = 0 in ICACHE_CR).

The table below gives a summary of ICACHE main parameters for TAG memory when the direct-mapped cache operating mode is selected.

Table 78. TAG memory dimensioning parameters for direct-mapped cache mode

Parameter	Value	Example
Cache size	S Kbytes = s bytes (s = 1024 x S)	8 Kbytes = 8192 bytes
Cache number of ways	1	1
Cache line size	L-byte = l-bit (l = 8 x L)	16-byte = 128-bit
Number of cache lines	LpW = s / L lines	512 lines
Address byte offset size	B = log2(L) bit	4-bit
Address way index size	W = log2(LpW) bit	9-bit
TAG address size	T = (32 - W - B) bit	19-bit

All cache operations (such as read, refill, remapping, invalidation) remain the same in direct-mapped configuration. The only difference is the absence of a replacement algorithm in case of line eviction (as explained in *Section 8.4.8*): only one way (the unique one) is possible for any data refill.

8.4.5 ICACHE enable

To activate the ICACHE, the EN bit must be set to 1 in ICACHE_CR.

When the ICACHE is disabled, it is bypassed and all transactions are copied from the slave port to the master ports in the same clock cycle.

It is recommended to initialize or modify the main memory content (region to be later cached) with the ICACHE disabled, and to enable the ICACHE only when this region remains unchanged (an enabled ICACHE detects cacheable write transactions as errors).

In order to insure performance determinism, it is recommended to wait for the end of a potential cache invalidate procedure before enabling the ICACHE. This invalidate procedure occurs when the hardware reset signal is released, when CACHEINV is set, or when EN is cleared in ICACHE_CR. During the procedure, BUSYF is set in ICACHE_SR, and once finished, BUSYF is cleared and BSYENDF is set in the same register (raising the ICACHE interrupt if enabled on such a busy end condition).

The software must test BUSYF and/or BSYENDF values before enabling the ICACHE. Else, if the ICACHE is enabled before the end of an invalidate procedure, any cache access (while BUSYF = 1) is treated as non cacheable, and its performance depends on the main memory access time.

The address remapping is performed, whether the ICACHE is enabled or not, if the input transaction address falls into memory regions defined and enabled in ICACHE_CRRx (see *Figure 33*).

The ICACHE is by default disabled at boot.

8.4.6 Cacheable and non-cacheable traffic

The ICACHE is developed for Cortex-M33 core. It is placed on C-AHB bus, and thus caches the code memory region, ranging from address 0x0000 0000 to 0x1FFF FFFF of the memory map.

In order to make some other memory regions cacheable, the ICACHE supports a memory-region-remapping feature. It is used to define up to four external memory regions, which addresses have an alias in the code region. Addressing these external memory regions through their code alias address allows the memory request to be routed to the C-AHB bus, and to be managed by the ICACHE.

Any external memory space physically mapped at an address in range [0x6000 0000:0xAFFF FFFF] can be aliased with an address in range [0x0000 0000:0x07FF FFFF] or [0x1000 0000:0x1FFF FFFF].

For a given memory request in the code region, the ICACHE implements the address remapping functionality first. If aliased, it is the remapped address which is then cached, and, if needed, provided to the master port to address the main AHB bus matrix. The destination physical address does not need further manipulation on the AHB bus.

The remapping functionality is available also for non-cacheable traffic, and when the cache is disabled.

Further details on address remapping are provided in *Section 8.4.7*.

An incoming memory request to the ICACHE is defined as cacheable according to its AHB transaction memory lookup attribute, as shown in *Table 79*. This AHB attribute depends on the MPU (memory protection unit) programming for the addressed region.

Table 79. ICACHE cacheability for AHB transaction

AHB lookup attribute	Cacheability
1	Cacheable
0	Non cacheable

In case of a non-cacheable access, the ICACHE is bypassed, meaning that the AHB transaction is propagated unchanged to the master output port, except the transaction address which may be modified due to the address remapping feature (see *Section 8.4.7*).

The bypass, and eventual remap logic, does not increase the latency of the access to the targeted memory.

In case of a cacheable access, the ICACHE behaves as explained in *Section 8.4.8*.

Cacheable memory regions are defined and programmed by the user in the MPU, that is responsible for the generation of the AHB attribute signals for any transaction addressing a given region.

The table below summarizes programmable configurations of various memories.

Table 80. Memory configurations

Memory	Cacheable (MPU programming)	Remapped in the ICACHE (ICACHE_CRRx programming)
Flash memory	Yes or No	Not required
SRAM	Not recommended	Not required
External memories	Yes	Required
	No	Required if the user wants code in external memories fetched on C-AHB bus (else on S-AHB bus)

8.4.7 Address remapping

The ICACHE allows an alias address to be defined in the code region for up to four external memory regions.

The address remapping is applied on the code alias address, transforming it into the destination external physical address.

The remapping operation is fully software configurable by programming ICACHE_CRRx (x = 0 to 3, number of remapped regions). This programming can be done only when the ICACHE is disabled.

Each region x can be individually enabled with REN in ICACHE_CRRx. Once enabled, the remap operation occurs even if the ICACHE is disabled, or if the transaction is not cacheable.

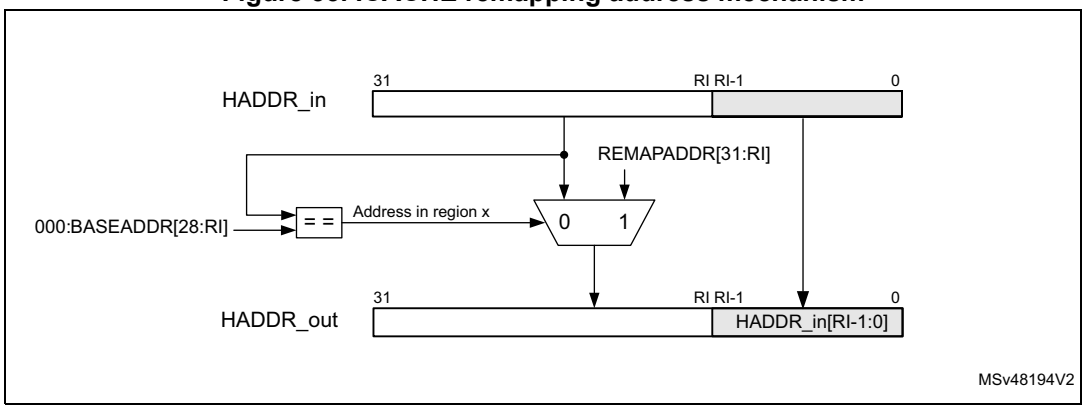
Remap regions can have different size: each region size can be programmed in RSIZE of its ICACHE_CRRx. The size of each region is a power of two multiple of range granularity (2 Mbytes), with a minimum region size of 2 Mbytes, and a maximum region size of 128 Mbytes.

The address remapping mechanism is based on the matching of an incoming AHB address (HADDR_in) with a given code subregion base-address, and the modification of this address into its (remapped) external physical address, as follows:

- HADDR_in belongs to region x if HADDR_in[31:RI] = 000:BASEADDR[28:RI], where:
  - 000:BASEADDR is the code subregion base-address programmed in BASEADDR of ICACHE_CRRx.
  - RI defines the number of significant bits to consider. RI = log2(region size) with a minimum value of 21 (for a 2-Mbyte region) and a maximum value of 27 (for a 128-Mbyte region).
- If the region x is enabled, the master port output AHB address (HADDR_out) is composed by concatenating the two below parts:
  - REMAPADDR[31:RI] field of ICACHE_CRRx as MSBs
  - HADDR_in[RI-1:0] as LSBs.

The figure below describes the matching and the output address generation.

Figure 33. ICACHE remapping address mechanism



The table below summarizes all possible configurations of BASEADDR and REMAPADDR sizes (number of significant MSBs) in ICACHE_CRRx, depending on RSIZE.

Table 81. ICACHE remap region size, base address and remap address

Region size (Mbytes)	Base address size (MSBs)	Remap address (MSBs)
2	8	11
4	7	10
8	6	9
16	5	8
32	4	7
64	3	6
128	2	5

Care must be taken while programming BASEADDR and REMAPADDR in ICACHE_CRRx: if the programmed value is bigger than expected (number of MSBs, see *Table 81*), the unnecessary extra LSBs are ignored.

Typical remapping example: a 128-Mbyte FMC region (NOR/SRAM) physically located in the external address range [0x6800 0000:0x6FFF FFFF], remapped in the code section range [0x1000 0000:0x17FF FFFF]:

- REMAPADDR[31:21] = 0x340
- BASEADDR[28:21] = 0x80
- HADDR_in[31:27] is compared to 000:BASEADDR[28:27], and HADDR_in/BASEADDR[26:21] are ignored for the comparison.

If the comparison matches:

- HADDR_out[31:27] gets REMAPADDR[31:27] (in place of HADDR_in[31:27])
- HADDR_out[26:0] gets HADDR_in[26:0]

The software can program the kind of AHB burst that is generated by the ICACHE master ports on the bus matrix (for cache line refill), by setting HBURST in ICACHE_CRRx with:

- WRAP for remapped external memories accessed through interfaces that can support WRAP burst mode, providing the benefit of the critical-word-first feature performance:
  - WRAP burst size = cache line size
  - WRAP burst start address = word address of the first data requested by the core
- INCR: INCR burst mode for external memories accessed through the interfaces that do not support WRAP burst mode (losing the benefit of critical-word-first feature):
  - INCR burst size = cache line size
  - INCR burst start address = address aligned on the boundary of the cache line containing the requested word.

Note: Coherency is needed when programming the SAU (secure attribution unit) and the MPU (memory protection unit) attributes for both the external *regions and their aliased code subregions.*

8.4.8 Cacheable accesses

When the ICACHE receives a cacheable transaction from the Cortex-M33, the ICACHE checks if the address requested is present in its TAG memory, and if the corresponding cache line is valid.

There are then three alternatives:

- The address is present inside the TAG memory, the cache line is valid: **cache hit**, the data is read from the cache and provided to the processor in the same cycle.
- The address is not present in the TAG memory: **cache miss**, the data is read from the main memory and provided to the processor, and a cache line refill is performed.

  The critical-word-first policy insures minimum wait cycles for the processor, since read data can be provided while the cache still performs a cache line refill (associated latency is the latency of fetching one word from the main memory).

  The burst generated on the ICACHE master bus is WRAPw (w being the cache line width, in words) in case no address remap occurs. If an address remap occurs, the kind of burst depends on HBURST programmed in corresponding ICACHE_CRRx.

  The AHB transaction attributes are also propagated to the main AHB bus matrix on the master port selected for the line refill.

- The address is not present in TAG memory, but belongs to the refill burst from the main memory that is currently ongoing: **cache hit** (hit-under-miss feature).

  This happens during cache-line refill. The ICACHE can provide the requested data as soon as the data is available at its master interface, thus avoiding a miss (fetching data from the main memory).

In case of cache refill (due to cache miss), the ICACHE selects which cache line is written with the refill data:

- In direct map (1-way) mode, only one line can be used to store the refill data: the line pointed by the index of the input address.
- In n-way set associative mode, one line among n can be used (the line pointed by the address index, in each of the n ways). The way selection is based on a pLRU-t replacement algorithm, that points, for each index, on the way candidate for the next refill.

If ever the cache line where the refill data must be written is already valid, the targeted cache line must be invalidated first. This is true whatever the direct map or n-way set associative cache mode.

8.4.9 Dual-master cache

The ICACHE can implement a dual-port AHB master on the main AHB bus matrix: master1 and master2 ports. This is used to split the traffic going to different destination memories.

The non-remapped traffic goes systematically to master1 port. The re-mapped traffic to external memories must be routed on master2 port by programming MSTSEL in ICACHE_CRRx (on a region basis).

The code can typically be fetched as follows:

- internal flash memory and internal SRAM on master1 port (Fast bus)
- external flash memory/RAM on master2 port (Slow bus)

For systems not implementing external memories, the traffic to the internal flash memory can be decoupled from the traffic to the internal SRAM (when remapped by the ICACHE). This feature is used to prevent further processor stalls on misses.

Alongside with hit-under-miss, this dual-master feature allows the processor to have an alternative path in case of fetching from different memories.

8.4.10 ICACHE security

The ICACHE implements an Armv8-M TrustZone.

ICACHE configuration registers are protected at system level.

8.4.11 ICACHE maintenance

The software can invalidate the whole content of the ICACHE by programming CACHEINV in ICACHE_CR register.

When CACHEINV = 1, the ICACHE control logic sets BUSYF flag in ICACHE_SR and launches the invalidate cache operation, reseting each TAG valid bit to 0 (one valid bit per cache line). CACHEINV is automatically cleared.

Once the invalidate operation is finished, the ICACHE automatically clears BUSYF, and sets BSYENDF in ICACHE_SR register.

If enabled on this flag condition (BSYENDIE = 1 in ICACHE_IER), the ICACHE interrupt is raised. Then, the (empty) cache is available again.

8.4.12 ICACHE performance monitoring

The ICACHE provides the following monitors for performance analysis:

- The 32-bit hit monitor counts the cacheable AHB-transactions on the slave cache port that hits the ICACHE content.

  It also takes into account all accesses whose address is present in the TAG memory or in the refill buffer (due to a previous miss, and whose data is coming, or is soon to come, from cache master port) (see *Section 8.4.8*).
- The 16-bit miss monitor counts the cacheable AHB-transactions on the slave cache port that misses the ICACHE content.

  It also takes into account all accesses whose address is not present neither in the TAG memory nor in the refill buffer.

Upon reaching their maximum values, these monitors do not wrap over.

Hit and miss monitors can be enabled and reset by software allowing the analysis of specific pieces of code.

The software can perform the following tasks:

- Enable/stop the hit monitor through HITMEN in ICACHE_CR.
- Reset the hit monitor by setting HITMRST in ICACHE_CR.
- Enable/stop the miss monitor through MISSMEN in ICACHE_CR.
- Reset the miss monitor by setting MISSMRST in ICACHE_CR.

To reduce power consumption, these monitors are disabled (stopped) by default.

8.4.13 ICACHE boot

The ICACHE is disabled (EN = 0 in ICACHE_CR) at boot.

The code remapping at boot is not needed for Cortex-M33 since it implements the VTOR (vector tables) that allows a boot start address definition different than 0x0.

Once the boot is finished, the ICACHE can be enabled (software setting EN = 1 in CACHE_CR).

8.5 ICACHE low-power modes

At device level, using the ICACHE reduces the power consumption by fetching instructions from the internal ICACHE most of the time, rather than from the bigger and then more-power-consuming main memories. This reduction is even higher if the cached main memories are external.

Applications with a lower-performance profile (in terms of hit ratio) and stringent low-power consumption constraints may benefit from the lower power consumption of an ICACHE configured as direct mapped. This single-way cache configuration is obtained by programming WAYSEL = 0 in ICACHE_CR (see *Figure 32*). The power consumption is then reduced by accessing, for each request, only the necessary cut of TAG and data memories. Meanwhile, the cache effect still improves fetch performance. Even if for most code execution, it is a little less efficient than with an n-way set associative cache mode.

8.6 ICACHE error management and interrupts

In case an unsupported cacheable write request is detected (functional error), the ICACHE generates an error by setting the ERRF flag in ICACHE_SR. An interrupt is then generated if the corresponding interrupt enable bit is set (ERRIE = 1 in ICACHE_IER).

The other possible interrupt generation is at the end of a cache invalidation operation. When the cache-busy state is finished, the ICACHE sets BSYENDF flag in ICACHE_SR. An interrupt is then generated if the corresponding interrupt enable bit is set (BSYENDIE = 1 in ICACHE_IER).

All ICACHE interrupt sources raise the same and unique interrupt signal, icache_it, and then use the same interrupt vector.

Table 82. ICACHE interrupts

Interrupt vector	Interrupt event	Event flag	Enable control bit	Interrupt clear method
ICACHE	Functional error	ERRF in ICACHE_SR	ERRIE in ICACHE_IER	Set CERRF to 1 in ICACHE_FCR
	End of busy state (invalidate finished)	BSYENDF in ICACHE_SR	BSYENDIE in ICACHE_IER	Set CBSYENDF to 1 in ICACHE_FCR

The ICACHE also propagates all AHB bus errors (such as security issues, address decoding issues) from master1 or master2 port back to the execution port.

8.7 ICACHE registers

8.7.1 ICACHE control register (ICACHE_CR)

Address offset: 0x000

Reset value: 0x0000 0004

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MISSMRST	HITMRST	MISSMEN	HITMEN
												rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WAYSEL	CACHEINV	EN
													rw	w	rw

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **MISSMRST**: miss monitor reset
0: no effect
1: reset cache miss monitor

Bit 18 **HITMRST**: hit monitor reset
0: no effect
1: reset cache hit monitor

Bit 17 **MISSMEN**: miss monitor enable
0: cache miss monitor switched off. Stopping the monitor does not reset it.
1: cache miss monitor enabled

Bit 16 **HITMEN**: hit monitor enable
0: cache hit monitor switched off. Stopping the monitor does not reset it.
1: cache hit monitor enabled

Bits 15:3 Reserved, must be kept at reset value.

Bit 2 **WAYSEL**: cache associativity mode selection
This bit allows user to choose ICACHE set-associativity. It can be written by software only when cache is disabled (EN = 0).
0: direct mapped cache (1-way cache)
1: n-way set associative cache (reset value)

Bit 1 **CACHEINV**: cache invalidation
Set by software and cleared by hardware when the BUSYF flag is set (during cache maintenance operation). Writing 0 has no effect.
0: no effect
1: invalidate entire cache (all cache lines valid bit = 0)

Bit 0 **EN**: enable
0: cache disabled
1: cache enabled

8.7.2 ICACHE status register (ICACHE_SR)

Address offset: 0x004

Reset value: 0x0000 0001

													r	r	r

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **ERRF**: cache error flag
0: no error
1: an error occurred during the operation (cacheable write)

Bit 1 **BSYENDF**: busy end flag
0: cache busy
1: full invalidate CACHEINV operation finished

Bit 0 **BUSYF**: busy flag
0: cache not busy on a CACHEINV operation
1: cache executing a full invalidate CACHEINV operation

8.7.3 ICACHE interrupt enable register (ICACHE_IER)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

													rw	rw	

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **ERRIE**: interrupt enable on cache error

Set by software to enable an interrupt generation in case of cache functional error (cacheable write access)

0: interrupt disabled on error

1: interrupt enabled on error

Bit 1 **BSYENDIE**: interrupt enable on busy end

Set by software to enable an interrupt generation at the end of a cache invalidate operation.

0: interrupt disabled on busy end

1: interrupt enabled on busy end

Bit 0 Reserved, must be kept at reset value.

8.7.4 ICACHE flag clear register (ICACHE_FCR)

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CERRF	CBSYENDF	Res.
													w	w	

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **CERRF**: clear cache error flag

Set by software.

0: no effect

1: clears ERRF flag in ICACHE_SR

Bit 1 **CBSYENDF**: clear busy end flag

Set by software.

0: no effect

1: clears BSYENDF flag in ICACHE_SR.

Bit 0 Reserved, must be kept at reset value.

8.7.5 ICACHE hit monitor register (ICACHE_HMONR)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **MISSMON[15:0]**: cache miss monitor counter

8.7.7 ICACHE region x configuration register (ICACHE_CRRx)

Address offset: 0x020 + 0x4 * x, (x = 0 to 3)

Reset value: 0x0000 0200

Define an alias address in Code region for other regions, making them cacheable.

BASEDADDR and REMAPADDR fields are write locked (read only) when EN = 1 in ICACHE_CR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
HBURST	Res.	Res.	MSTSEL	Res.	REMAPADDR[31:21]

REN	Res.	Res.	Res.	RSIZE[2:0]			Res.	BASEADDR[28:21]							
rw				rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **HBURST**: output burst type for region x
0: WRAP
1: INCR

Bits 30:29 Reserved, must be kept at reset value.

Bit 28 **MSTSEL**: AHB cache master selection for region x
0: no action (master1 selected by default)
1: master2 selected

Bit 27 Reserved, must be kept at reset value.

Bits 26:16 **REMAPADDR[31:21]**: remapped address for region x
This field replaces the alias address defined by BASEADDR field.
The only useful bits are [31:RI], where 21 ≤ RI ≤ 27 is the number of bits of RSIZE (see *Section 8.4.7*). If the programmed value has more LSBs, the useless bits are ignored.

Bit 15 **REN**: enable for region x
0: disabled
1: enabled

Bits 14:12 Reserved, must be kept at reset value.

Bits 11:9 **RSIZE[2:0]**: size for region x
000: reserved
001: 2 Mbytes
010: 4 Mbytes
011: 8 Mbytes
100: 16 Mbytes
101: 32 Mbytes
110: 64 Mbytes
111: 128 Mbytes

Bit 8 Reserved, must be kept at reset value.

Bits 7:0 **BASEADDR[28:21]**: base address for region x
This alias address is replaced by REMAPADDR field.
The only useful bits are [28:RI], where 21 ≤ RI ≤ 27 is the number of bits of RSIZE (see *Section 8.4.7*). If the programmed value has more LSBs, the useless bits are ignored.

Refer to *Section 2.3* for the register boundary addresses.

9 Data cache (DCACHE)

9.1 DCACHE introduction

The data cache (DCACHE) is introduced on S-AHB system bus of Cortex-M33 processor to improve the performance of data traffic to/from external memories.

Some specific features like hit-under-miss and critical-word-first refill policy allow optimum performance on external memories data accesses.

9.2 DCACHE main features

The main features of DCACHE are described below:

- Bus interface
  - one 32-bit AHB slave port, the system port (input from Cortex-M33 S-AHB system interface)
  - one 32-bit AHB master port (output to main AHB bus matrix)
  - one 32-bit AHB slave port for control (input from AHB peripherals interconnect, for access to DCACHE registers)
- Cache access
  - 0 wait-state on hits
  - Hit-under-miss capability: ability to serve processor requests (access to cached data) during an ongoing line refill due to a previous cache miss
  - Optimized cache line refill thanks to WRAP bursts of the size of the cache line (such as WRAP4 for 128-bit cache line)
  - 2-ways set-associative
  - Supports both write-back and write-through policies (selectable with AHB bufferable attribute)
  - Read and write-back always allocate
  - Write-through always non-allocate (write-around)
  - Supports byte, half-word and word writes
- Replacement and refill
  - pLRU-t replacement policy (pseudo-least-recently-used, based on binary tree), algorithm with best complexity/performance balance
  - Critical-word-first refill policy for read transactions, minimizing processor stalls
  - Possibility to configure burst type of all AHB memory transactions: INCRw or WRAPw (size w aligned on cache line size)
- Performance counters

  The DCACHE implements four performance counters:
  - Two hit-monitor counters (32-bit): number of read hits, number of write hits
  - Two miss-monitor counters (16-bit): number of read misses, number of write misses

- Error management
  - Possibility to detect error for master port request initiated by DCACHE itself (a cache line written back into main memory, because of an eviction or a clean operation), to flag this error, and optionally to raise an interrupt
- TrustZone security support
- Maintenance operations
  - Cache invalidate: full cache invalidation, fast command, non interruptible
  - Cache invalidate range: invalidates cache lines (reset valid bit = 0) whose address belongs to defined range, background task, interruptible
  - Cache clean range: cleans cache lines (if dirty bit = 1, write back line, then clear dirty bit) whose address belongs to defined range, background task, interruptible
  - Cache clean and invalidate range: cleans and invalidates cache lines (if dirty bit = 1, write back line, then clear valid bit) whose address belongs to defined range, background task, interruptible

9.3 DCACHE implementation

The DCACHE1 is placed on Cortex-M33 S-AHB bus and caches only the external RAM memory region (OCTOSPI and FMC), in address range [0x6000 0000:0x9FFF FFFF] of the memory map.

Indeed, by placing a bus matrix demultiplexing node in front of the DCACHE1, S-AHB bus memory requests addressing SRAM region or peripherals region (respectively in ranges [0x2000 0000:0x3FFF FFFF] and [0x4000 0000:0x5FFF FFFF]) are routed directly to the main AHB bus matrix, and the DCACHE1 is bypassed.

Table 84. DCACHE features

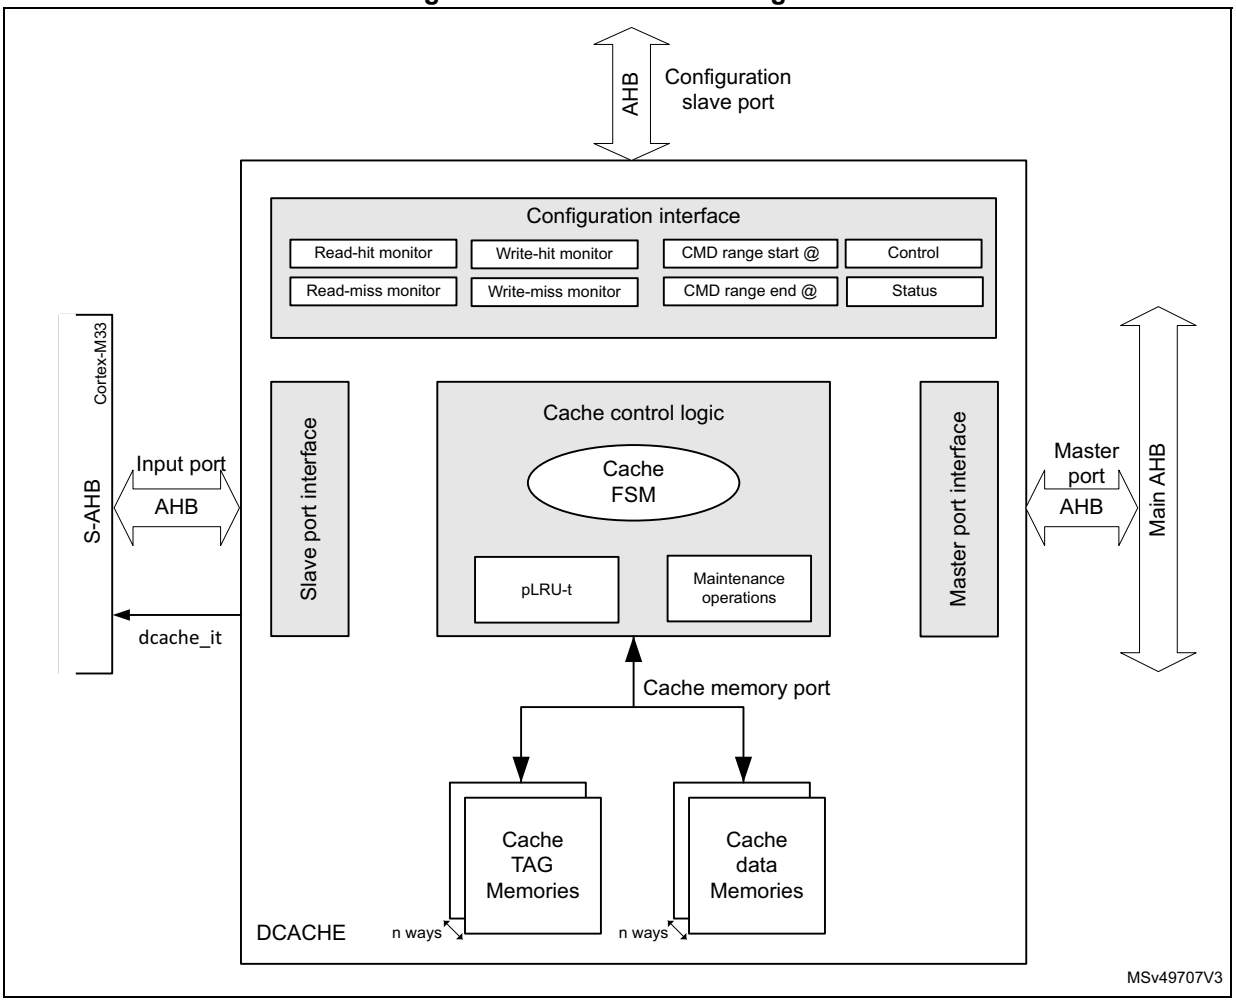
Features	DCACHE1
Number of ways	2
Cache size	4 Kbytes
Cache line width	16 bytes
Data size of AHB Master interface	32 bits

9.4 DCACHE functional description

The purpose of the data cache is to cache external memory data loads and stores, coming from the processor. These accesses include the instruction fetches that may occur at an external memory address. The DCACHE manages both read and write transactions.

9.4.1 DCACHE block diagram

Figure 34. DCACHE block diagram



9.4.2 DCACHE reset and clocks

The DCACHE is clocked on the Cortex-M33 S-AHB bus clock.

When the DCACHE reset signal is released, a cache invalidate procedure is automatically launched, making the DCACHE busy (DCACHE_SR = 0x0000 0001).

When this procedure is finished:

- The DCACHE is invalidated: “cold cache”, with all cache line valid, dirty and privilege bits = 0 (DCACHE must be filled up)
- DCACHE_SR = 0x0000 0002 (reflecting the cache is no more busy)
- The DCACHE is disabled: the EN bit in DCACHE_CR holds its reset state (= 0).

Note: When disabled, the DCACHE is bypassed: slave input requests are just forwarded to the master port.

9.4.3 DCACHE TAG memory

The DCACHE TAG memory contains:

- address tags, that indicate which data are contained in the cache data memories
- validity bits
- dirty bits
- privilege bits

There is one valid bit, one dirty bit, and one privilege bit per cache line (per way).

The valid bit enables/disables access to the data cache line: if the line is not valid, the data access (read or write) is performed in the main memory.

The valid bit is set when the cache line is written (refilled by either a read miss or a write-back miss).

Valid bits are reset in any of the below cases:

- after the DCACHE reset is released
- when the cache is disabled, by setting EN = 0 in DCACHE_CR (by software)
- when executing one of the DCACHE invalidate commands, setting by software CACHEINV = 0, or CACHECMD = 0b010 or 0b011 in DCACHE_CR (see *Section 9.4.8*).

The dirty bit indicates that the cache line has up-to-date values with respect to the main memory content (the cache has last right value, the main memory is not up to date).

The dirty bit is set when the cache line is written by a slave port write transaction (only in case of an access with write-back attribute).

Dirty bits are reset in any of the below cases:

- after the DCACHE reset is released
- when a line refill is performed on a read miss (on a write-back miss, the refilled cache line is modified by the written data, and dirty bit = 1)
- when the cache invalidation is performed
- when executing one of the DCACHE clean operations (cache line written back to the main memory), setting by software CACHECMD = 0b001 or 0b011 in DCACHE_CR (see *Section 9.4.8*).

The privilege bit indicates if the data is managed by a privileged entity. It is assigned according to the value of AHB privileged attribute at input slave port, for the first access to this line (it is written only during the line refill, on read miss or write-back miss).

The privilege bit holds same polarity as the privileged attribute: 1 for privileged access, 0 for unprivileged access.

Privilege bits are reset when the cache is invalidated, and after the DCACHE reset is released.

When a cacheable transaction is received at input slave port, its AHB address (HADDR_in) is split into the following fields (see the table below for B and W values):

- HADDR_in[B-1:0]: address byte offset, indicates which byte to select inside a cache line.
- HADDR_in[B+W-1:B]: address way index, indicates which cache line to select inside each way.
- HADDR_in[31:B+W]: tag address, to be compared to TAG memory address to check if the requested data is already available (meaning valid) inside the DCACHE

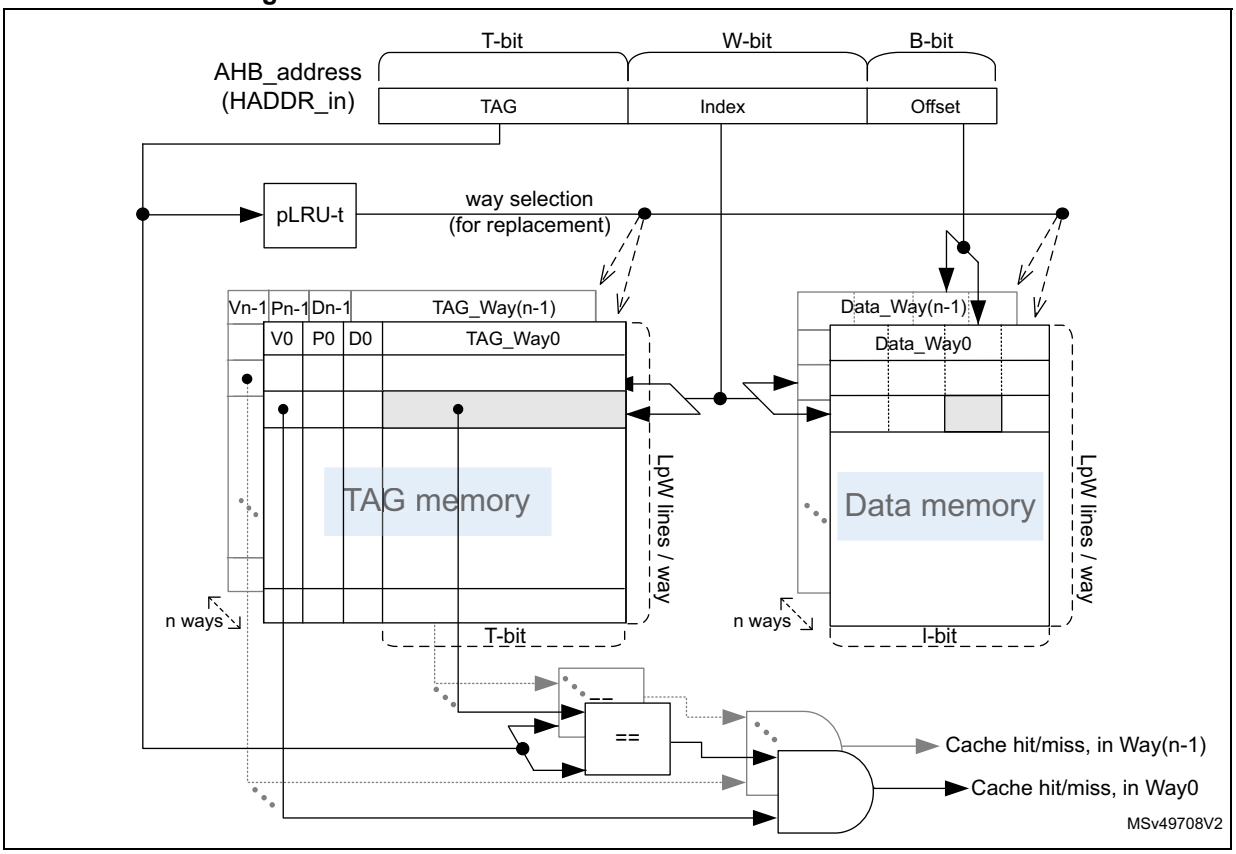
The table below gives DCACHE main parameters for TAG memory dimensioning.

Figure 35. shows the functional view of TAG and data memories, for an n-way set associative DCACHE.

Table 85. TAG memory dimensioning parameters

Parameter	Value	Example
Cache size	S Kbytes = s bytes (s = 1024 x S)	4 Kbytes = 4096 bytes
Cache number of ways	n	2
Cache line size	L-byte = l-bit (l = 8 x L)	16-byte = 128-bit
Number of cache lines (per way)	LpW = s / (n x L) lines/way	128 lines/way
Address byte offset size	B = log2(L) bit	4-bit
Address way index size	W = log2(LpW) bit	7-bit
TAG address size	T = (32 - W - B) bit	21-bit

Figure 35. DCACHE TAG and data memories functional view



9.4.4 DCACHE enable

In order to activate the DCACHE functioning, the EN bit must be set in DCACHE_CR control register.

When DCACHE is disabled, it is bypassed and all transactions are copied from slave port to master port in the same clock cycle, and no comparison is performed with TAG address.

DCACHE is by default disabled at boot.

9.4.5 Cacheable and non-cacheable traffic

DCACHE is developed for Cortex-M33 core and caches the memory regions addressed by the AHB bus connected to it.

In addition, the AHB bus traffic to the memory regions can be cacheable or non-cacheable. An incoming memory request to DCACHE is defined as cacheable according to its AHB transaction memory lookup attribute.

In case of write transaction, the DCACHE write policy is defined as write-through or write-back according to its AHB transaction memory bufferable attribute (see the table below).

These AHB attributes depend on the memory protection unit (MPU) programming for the addressed region.

Table 86. DCACHE cacheability for AHB transaction

AHB lookup attribute	AHB bufferable attribute	Cacheability
0	x	Read and write: non cacheable
1	0	Read: cacheable Write: (cacheable) write-through
1	1	Read: cacheable Write: (cacheable) write-back

In case of non cacheable access, the DCACHE is bypassed, meaning that the AHB transaction is propagated unchanged to the master output port.

The bypass does not increase the latency of the access to the targeted memory.

In case of cacheable access, the DCACHE behaves as explained in *Section 9.4.6*.

Cacheable memory regions are defined and programmed by the user in the MPU, responsible for the generation of the AHB attribute signals for any transaction addressing a given region.

9.4.6 Cacheable accesses

When the DCACHE receives a cacheable transaction from Cortex-M33 , on its slave port, the DCACHE checks if the address requested is present in its TAG memory and if the corresponding cache line is valid.

For **read** transaction, there are three alternatives:

- The address is present inside the TAG memory, cache line is valid: **cache read hit**, the data is read from cache and provided to the processor in the same cycle.
- The address is not present in the TAG memory: **cache read miss**, the data is read from the main memory and provided to the processor, and a cache line refill is performed.

  The critical-word-first refill policy insures minimum wait cycles for the processor, since read data can be provided while cache is still performing cache line refill (associated latency is the latency of fetching one word from main memory).

  The kind of burst generated on the DCACHE master bus depends on HBURST bit in DCACHE_CR: either INCRw or WRAPw (w being the cache line width, in words).

  The AHB transaction attributes are also propagated from the slave input (missing) request to the master output refill request.
- The address is not present in the TAG memory but belongs to the refill burst from main memory that is currently ongoing: **cache read hit** as well (hit-under-miss feature).

  Whatever the line refill is due to a read or write (missing) transaction, the DCACHE can provide the requested read data as soon as the data is available at its master interface, thus avoiding a miss (with data fetch from main memory).

For **write-back** transaction (write transaction, with write-back bufferable attribute), there are three alternatives as well:

- The address is present inside the TAG memory, cache line is valid: **cache write-back hit**, the data is written in cache.
- The address is not present in the TAG memory (or cache line is not valid): **cache write-back miss**.

  First, a line allocation is performed by reading the entire cache line data from main memory. The kind of burst generated on the DCACHE master bus for this line refill depends on HBURST bit in DCACHE_CR: either INCRw or WRAPw (w being the cache line width, in words), and the AHB transaction attributes are propagated from the slave port initial request.

  Once the refilled line is written in the DCACHE, the initial data provided on slave port is written in this DCACHE line (it overwrites the data part of the cache line that was refilled just before).
- The address is not present in the TAG memory but belongs to the refill burst from main memory that is currently ongoing: **cache write-back hit** as well (hit-under-miss feature).

  Whatever the line refill is due to a read or write (missing) transaction, the DCACHE can write incoming data directly inside the refilled line, thus avoiding a miss (with refill from main memory).

For **write-through** transaction (write transaction, with write-through bufferable attribute), only two alternatives exist:

- The address is present inside the TAG memory, cache line is valid: **cache write-through hit**, the data is written both in cache and in main memory (through master port).
- The address is not present in the TAG memory (or cache line is not valid): **cache write-through miss**, the data incoming at slave port is written only in main memory (unlike the write-back miss, there is no line allocation and data written in cache).

In case of cache refill (due to cache miss), the DCACHE selects which cache line is written with the refill data: as a 2-way set associative cache, one line among two can be used (line pointed by the address index, in each of the two ways). The way selection is based on a pLRU-t replacement algorithm, that points, for each index, on the way candidate for the next refill.

If the cache line where the refill data must be written is already valid, the targeted cache line must be evicted first:

- If the dirty tag of this line equals 0 (clean data), the line is simply invalidated.
- If it equals 1 (dirty data), the line must be written back in the main memory.

  The DCACHE generates a burst write transaction on its master port, with burst type set to INCRw (w being the cache line width, in words), and with AHB memory transaction attribute signals set as below:
  - data (not instruction)
  - privileged = TAG privilege bit
  - write-back (even if it does not care)
  - normal memory
  - cacheable
  - allocate (even if it does not care)

– non shareable

These AHB attributes cannot be propagated from the slave port (as it is the case for all other transactions emitted by the DCACHE) because the evicting transaction has no relation with the initial missing transaction. Setting of the AHB attributes is fixed, except for the privileged bit that is copied from the TAG privilege bit of the evicted line.

9.4.7 DCACHE security

The DCACHE implements an Armv8-M TrustZone.

DCACHE configuration registers are protected at system level.

9.4.8 DCACHE maintenance

The DCACHE features several maintenance operations that the software can programmed in DCACHE_CR control register:

- **Full invalidate**: invalidates the whole cache, non interruptible task.

  The software can invalidate the whole DCACHE content by programming CACHEINV in DCACHE_CR.

  When CACHEINV = 1, the DCACHE control logic sets BUSYF flag in DCACHE_SR status register, and performs the operation of cache invalidation, reseting each TAG valid bit to 0 (one valid bit per cache line). Each dirty and privilege bits are also reset during cache invalidation to prevent unknown values at next cache line validation. CACHEINV is automatically cleared.

  Once the full invalidate operation is finished, the DCACHE automatically clears BUSYF flag, and sets BSYENDF in DCACHE_SR.

  If enabled on this flag condition (BSYENDIE = 1 in DCACHE_IER), the DCACHE interrupt is raised. Then, the (empty) cache is available again.

  This full invalidate operation is not interruptible, meaning that the cache does not treat any cacheable request while BUSYF = 1. However, non-cacheable traffic is treated (since the request address is not compared to TAG ones), the DCACHE being bypassed in the same clock cycle (same behavior as when the DCACHE is disabled).

- **Invalidate range**: invalidates a certain range of addresses in the cache, background task (interruptible).

  The software can invalidate a given data region in the DCACHE by programming STARTCMD = 1 and CACHECMD = 0b010 in DCACHE_CR, after the address range was programmed into DCACHE_CMDRSADDRR (range start address) and DCACHE_CMDREADDRR (range end address).

  The DCACHE control logic then parses the whole TAG memory. If the read line address (TAG address + line index) falls in the programmed address range (DCACHE_CMDRSADDRR ≤ Line Addr ≤ DCACHE_CMDREADDRR), the

corresponding cache line is invalidated (line TAG bits cleared, valid bit = dirty bit = privilege bit = 0).

When STARTCMD is set, the DCACHE control logic sets BUSYCMDF in DCACHE_SR and launches the invalidate range operation. STARTCMD is also automatically cleared.

Once the operation is finished (all TAG memory parsed), the DCACHE automatically clears BUSYCMDF and sets CMDENDF in DCACHE_SR.

If enabled on this flag condition (CMDENDIE = 1 in DCACHE_IER), the DCACHE interrupt is raised.

During this invalidate range operation, the DCACHE is interruptible, meaning it can accept new incoming requests that take higher priority than the invalidation process. The TAG memory is accessed for invalidate range operation only if not already accessed by an external cache request. This implies that invalidate range execution is usually not performed in one go, but can be interrupted.

- **Clean range**: cleans a certain range of addresses in the cache, background task (interruptible).

  Cleaning a cache line means making sure that the main memory content is up-to-date with the data which may have been modified in the cache. The clean operation consists in performing the write-back in the main memory of the cache lines that are tagged as “dirty” (the ones with TAG dirty bit set).

  The software can clean a given data region in DCACHE by programming STARTCMD = 1, and CACHECMD = 0b001 in DCACHE_CR, after the address range was programmed into DCACHE_CMDRSADDRR (range start address) and DCACHE_CMDREADDRR (range end address).

  The DCACHE control logic then parses the whole TAG memory. If the read line address (TAG address + line index) falls in the programmed address range (DCACHE_CMDRSADDRR ≤ Line Addr ≤ DCACHE_CMDREADDRR), and the corresponding line is dirty, this line is cleaned, meaning the whole cache line is written-back in the memory through the DCACHE master port, and its TAG dirty bit is cleared.

  When STARTCMD is set, the DCACHE control logic sets BUSYCMDF in DCACHE_SR and launches the clean range operation. STARTCMD is also automatically cleared.

  Once the operation is finished (all TAG memory parsed), the DCACHE automatically clears BUSYCMDF and sets CMDENDF in DCACHE_SR.

  If enabled on this flag condition (CMDENDIE = 1 in DCACHE_IER), the DCACHE interrupt is raised.

  During this clean range operation, the DCACHE is interruptible, meaning it can accept new incoming requests that take higher priority than the cleaning process. The TAG memory is accessed for clean range operation only if not already accessed by an external cache request. This implies that clean range execution is usually not performed in one go, but can be interrupted.

  It is under the software responsibility that no bus initiator attempts to change the content of the region being cleaned until clean range is completed. For that, the software can take advantage of BUSYCMDF flag in DCACHE_SR, and can poll this flag to prevent any spurious access to the area being cleaned.

Alternatively it can also rely on the command end flag (CMDENDF) or on the DCACHE interrupt to detect the end of the clean range execution.

- **Clean and invalidate range**: cleans and invalidates a certain range of addresses in the cache, background task (interruptible).

  This operation cleans the “dirty” cache lines that belong to the operation address range (the same as clean range operation), and also invalidates all the (valid) cache lines that belong to this address range (whether they are dirty or not).

  The software can launch this clean and invalidate range operation, by programming STARTCMD = 1, and CACHECMD = 0b011 in DCACHE_CR, after the address range was programmed into DCACHE_CMDRSADDRR (range start address) and DCACHE_CMDREADDRR (range end address).

  This sets and clears the same flags, and potentially the same interrupt as invalidate range or clean range operations.

9.4.9 DCACHE performance monitoring

The DCACHE provides the following monitors for performance analysis:

- The two 32-bit read-hit and write-hit monitors count the AHB transactions at the DCACHE input (slave port) that do not generate a transaction on the DCACHE output (master port).

  These monitors also take into account all accesses whose address is present in the TAG memory, or in the refill buffer (due to a previous miss, and whose data is coming, or is soon to come, from cache master port) (see *Section 9.4.6*).
- The two 16-bit read-miss and write-miss monitors count the AHB transactions at the DCACHE input (slave port) that generate a transaction on the DCACHE output (master port).

  These monitors also take into account all accesses whose address is not present neither in the TAG memory, nor in the refill buffer.

Upon reaching their maximum values, the monitors do not wrap over.

The software can perform the following tasks:

- Enable/stop the read (write) hit monitor, through R(W)HITMEN in DCACHE_CR.
- Reset the read (write) hit monitor, by setting R(W)HITMRST in DCACHE_CR.
- Enable/stop the read (write) miss monitor, through R(W)MISSMEN in DCACHE_CR.
- Reset the read (write) miss monitor, by setting R(W)MISSMRST in DCACHE_CR.

To reduce power consumption, these monitors are disabled (stopped) by default.

9.4.10 DCACHE boot

The DCACHE is disabled (EN = 0 in DCACHE_CR) at boot.

Once the boot is finished, the DCACHE can be enabled (software setting EN = 1 in DCACHE_CR).

9.5 DCACHE low-power modes

At product level, using the DCACHE reduces the power consumption by loading/storing data from/to the internal DCACHE most of the time, rather than from the bigger and then

more power consuming main memories. This reduction is even much higher, since the cached main memories are external.

9.6 DCACHE error management and interrupts

A transaction initiated on the DCACHE master port may return an error (a write attempt into a read-only memory, for instance). If the master port request was propagated from a slave port request, the error is propagated back to the slave port. If ever the master port request is initiated by the DCACHE itself (a cache line is written back into the main memory because of an eviction or a clean operation), the DCACHE receives this functional error and flags it internally by setting the ERRF flag in DCACHE_SR.

In such a case, an interrupt is generated if the corresponding interrupt enable bit is set (ERRIE = 1 in DCACHE_IER).

Another case of potential interrupt generation is at the end of a full invalidate operation: when the cache busy state is finished, the DCACHE sets BSYENDF flag in DCACHE_SR.

An interrupt is then generated if the corresponding interrupt enable bit is set (BSYENDIE = 1 in DCACHE_IER).

Last case is at the end of invalidate and/or clean range operations: when the command busy state is finished, the DCACHE sets CMDENDF flag in DCACHE_SR.

An interrupt is also generated if the corresponding interrupt enable bit is set (CMDENDIE = 1 in DCACHE_IER).

All DCACHE interrupt sources raise the same and unique interrupt signal, dcache_it, and then use the same interrupt vector.

Table 87. DCACHE interrupts

Interrupt vector	Interrupt event	Event flag	Enable control bit	Interrupt clear method
DCACHE	Functional error	ERRF in DCACHE_SR	ERRIE in DCACHE_IER	Set CERRF to 1 in DCACHE_FCR
	End of busy state (full invalidate finished)	BSYENDF in DCACHE_SR	BSYENDIE in DCACHE_IER	Set CBSYENDF to 1 in DCACHE_FCR
	End of cache operations (address range based)	CMDENDF in DCACHE_SR	CMDENDIE in DCACHE_IER	Set CCMDENDF to 1 in DCACHE_FCR

The DCACHE also propagates all AHB bus errors (such as security issues, address decoding issues) from master port back to the S-AHB slave port.

9.7 DCACHE registers

9.7.1 DCACHE control register (DCACHE_CR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
HBURST	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WMISSMRST	WHITMRST	WMISSMEN	WHITMEN	RMISSMRST	RHITMRST	RMISSMEN	RHITMEN
rw								rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	STARTCMD	CACHECMD[2:0]			Res.	Res.	Res.	Res.	Res.	Res.	CACHEINV	EN
				w	rw	rw	rw							w	rw

Bit 31 **HBURST:** output burst type for cache master port read accesses
Can be set by software, only when EN = 0.
Master port write accesses are always done in INCR burst type.
0: WRAP
1: INCR

Bits 30:24 Reserved, must be kept at reset value.

Bit 23 **WMISSMRST:** write-miss monitor reset
0: no effect
1: reset cache write-miss monitor

Bit 22 **WHITMRST:** write-hit monitor reset
0: no effect
1: reset cache write-hit monitor

Bit 21 **WMISSMEN:** write-miss monitor enable
0: cache write-miss monitor switched off. Stopping the monitor does not reset it.
1: cache write-miss monitor enabled

Bit 20 **WHITMEN:** write-hit monitor enable
0: cache write-hit monitor switched off. Stopping the monitor does not reset it.
1: cache write-hit monitor enabled

Bit 19 **RMISSMRST:** read-miss monitor reset
0: no effect
1: reset cache read-miss monitor

Bit 18 **RHITMRST:** read-hit monitor reset
0: no effect
1: reset cache read-hit monitor

Bit 17 **RMISSMEN:** read-miss monitor enable
0: cache read-miss monitor switched off. Stopping the monitor does not reset it.
1: cache read-miss monitor enabled

Bit 16 **RHITMEN:** read-hit monitor enable
0: cache read-hit monitor switched off. Stopping the monitor does not reset it.
1: cache read-hit monitor enabled

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **STARTCMD:** starts maintenance command (maintenance operation defined in CACHECMD).
Can be set by software, only when EN = 1, BUSYCMDF = 0, BUSYF = 0 and CACHECMD = 0b001, 0b010 or 0b011.
Cleared by hardware when the BUSYCMDF flag is set (during cache maintenance operation). Writing 0 has no effect.
0: command operation (cache maintenance) finished
1: start maintenance command (cache maintenance)

Bits 10:8 **CACHECMD[2:0]:** cache command maintenance operation (cleans and/or invalidates an address range)
Can be set and cleared by software, only when no maintenance command is ongoing (BUSYCMDF = 0).
000: no operation
001: clean range
010: invalidate range
011: clean and invalidate range
others: reserved

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **CACHEINV:** full cache invalidation
Can be set by software, only when EN = 1.
Cleared by hardware when the BUSYF flag is set (during full cache invalidation operation). Writing 0 has no effect.
0: no effect
1: invalidate entire cache (all cache lines valid bit = 0)

Bit 0 **EN:** enable
0: cache disabled
1: cache enabled

9.7.2 DCACHE status register (DCACHE_SR)

Address offset: 0x004

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CMDENDF	BUSYCMDF	ERRF	BSYENDF	BUSYF
											r	r	r	r	r

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **CMDENDF:** command end flag
Cleared by writing DCACHE_FCR.CCMDENDF = 1.
0: cache busy or in idle
1: CACHECMD command finished

Bit 3 **BUSYCMDF:** command busy flag
0: cache not busy on a CACHECMD command
1: cache busy on a CACHECMD command (clean and/or invalidate an address range)

Bit 2 **ERRF:** cache error flag
Cleared by writing DCACHE_FCR.CERRF = 1.
0: no error
1: an error occurred during the operation (eviction or clean operation write-back error).

Bit 1 **BSYENDF:** full invalidate busy end flag
Cleared by writing DCACHE_FCR.CBSYENDF = 1.
0: cache busy or in idle
1: full invalidate CACHEINV operation finished

Bit 0 **BUSYF:** full invalidate busy flag
0: cache not busy on a CACHEINV operation
1: cache executing a full invalidate CACHEINV operation

9.7.3 DCACHE interrupt enable register (DCACHE_IER)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CMDENDIE	Res.	ERRIE	BSYENDIE	Res.
											rw		rw	rw	

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **CMDENDIE**: interrupt enable on command end
Set by software to enable an interrupt generation at the end of a cache command (clean and/or invalidate an address range)
0: interrupt disabled on command end
1: interrupt enabled on command end

Bit 3 Reserved, must be kept at reset value.

Bit 2 **ERRIE:** interrupt enable on cache error
Set by software to enable an interrupt generation in case of cache functional error (eviction or clean operation write-back error)
0: interrupt disabled on error
1: interrupt enabled on error

Bit 1 **BSYENDIE:** interrupt enable on busy end
Set by SW to enable an interrupt generation at the end of a cache full invalidate operation.
0: Interrupt disabled on busy end
1: Interrupt enabled on busy end

Bit 0 Reserved, must be kept at reset value.

9.7.4 DCACHE flag clear register (DCACHE_FCR)

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CCMDENDF	Res.	CERRF	CBSYENDF	Res.
											w		w	w	

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **CCMDENDF:** clear command end flag
Set by software.
0: no effect
1: clears CMDENDF flag in DCACHE_SR

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CERRF:** clear cache error flag
Set by software.
0: no effect
1: clears ERRF flag in DCACHE_SR

Bit 1 **CBSYENDF:** clear full invalidate busy end flag
Set by software.
0: no effect
1: clears BSYENDF flag in DCACHE_SR

Bit 0 Reserved, must be kept at reset value.

9.7.5 DCACHE read-hit monitor register (DCACHE_RHMONR)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Refer to *Section 2.3* for the register boundary addresses.

10 Power control (PWR)

10.1 Introduction

The power controller manages the device power supplies and power modes transitions.

10.2 PWR main features

The power controller (PWR) main features are:

- Power supplies and supply domains
  - Core domain (V_{CORE})
  - V_{DD} domain
  - Backup domain (V_{SW})
  - Analog domain (V_{DDA})
  - Supply for the SMPS power stage (available on SMPS packages)
  - V_{DDIO2} supply for ten I/Os (PD6, PD7, PG9:14, PB8, PB9)
  - V_{DDUSB} for USB transceiver
- System supply voltage regulation
  - SMPS step-down converter
  - Linear voltage regulator (LDO)
- Power supply supervision
  - POR/PDR monitor
  - BOR monitor
  - PVD monitor
  - AVD monitor
  - Out of functional range temperature monitor
  - Out of functional range Backup domain voltage monitor
- Power management
  - Operating modes
  - Voltage scaling control
  - Low-power modes
- V_{BAT} battery charging
- TrustZone security and privileged protection

10.3 PWR pins and internal signals

Table 89. PWR input/output pins

Pin name	Signal type	Description
VDD	Supply	Main supply
GND	Supply	Main ground
VDDA	Supply	Analog peripherals supply
VSSA	Supply	Analog peripherals ground
VDDIO2	Supply	Independent I/O supply
VDDUSB	Supply	USB supply
VCAP	Supply	Logic supply (V_{CORE})
VBAT	Supply	Backup domain supply
VDDSMPS	Supply	SMPS supply
VSSSMPS	Supply	SMPS ground
VLXSMPS	Supply	SMPS output
VREF+	Supply	ADC/DAC high reference voltage
VREF-	Supply	ADC/DAC low reference voltage
WKUPx (x = 1 to 8)	Input	Wake-up pins
CSLEEP	Output	MCU in Sleep mode
CDSTOP	Output	CPU in Stop modes

Table 90. PWR internal input/output signals

Internal signal name	Signal type	Description
WKUPx (x = 1 to 8)	Input	Wake-up event source

10.4 PWR power supplies and supply domains

Figure 36. Power supply with SMPS

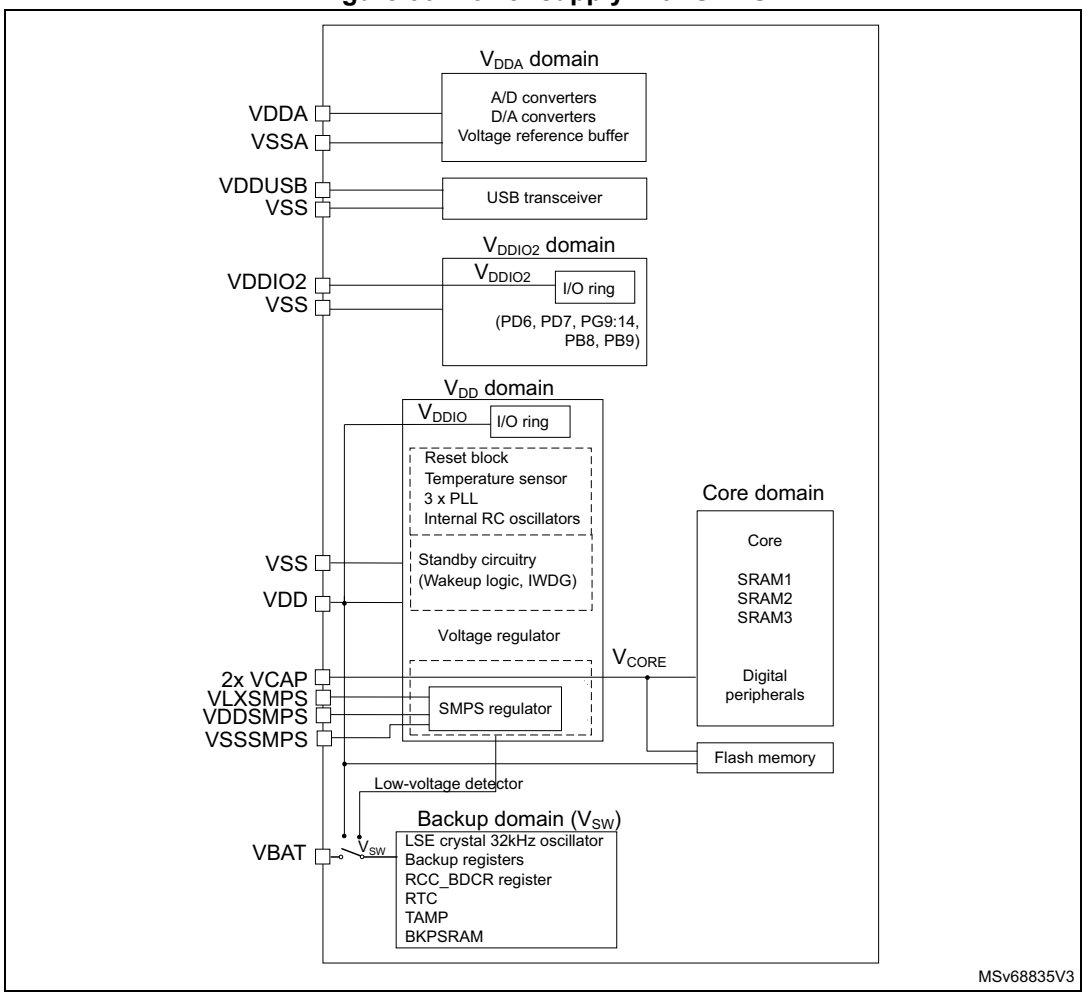

Figure 37. Power supply with LDO

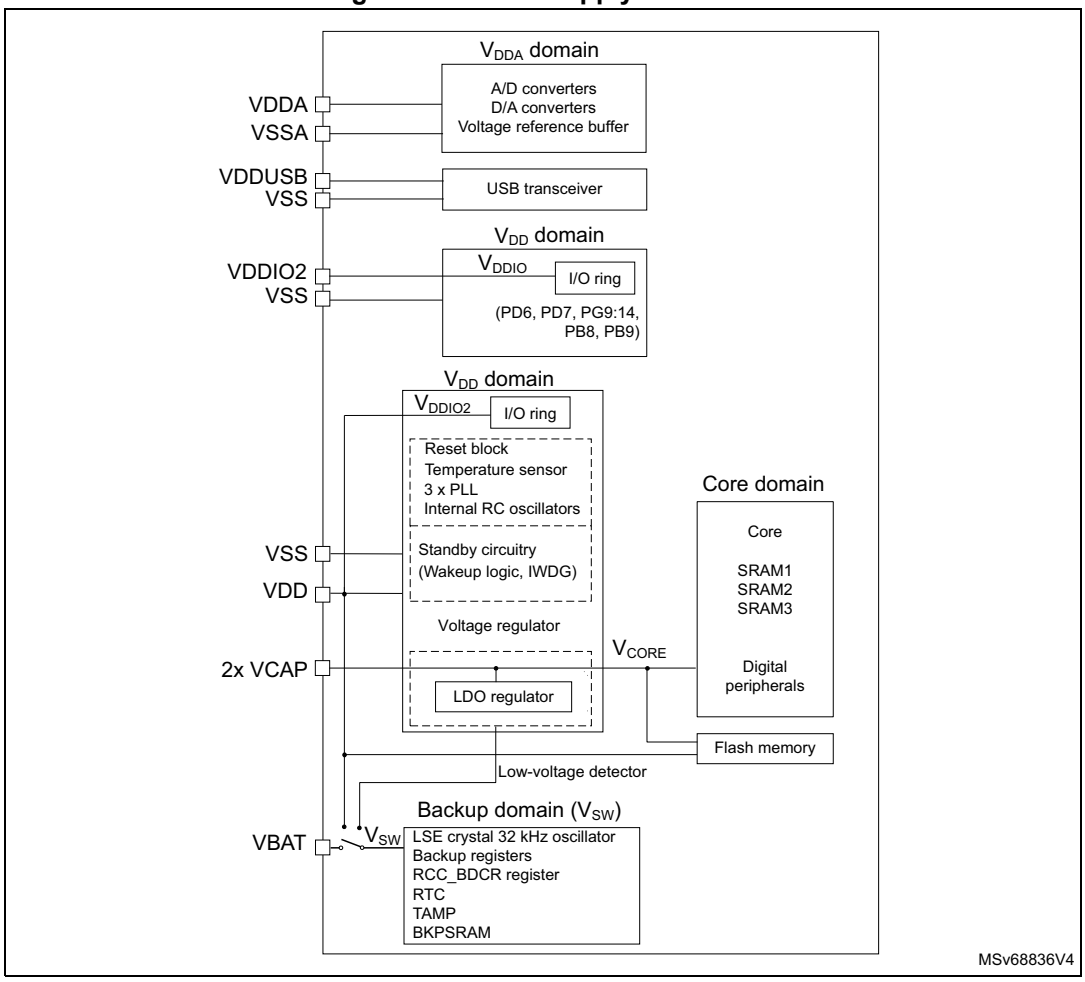


10.4.1 External power supplies

The devices require a 1.71 to 3.6 V V_{DD} operating voltage supply. Several independent supplies can be provided for specific peripherals, but must not be provided without a valid operating supply on the VDD pin:

- V_{DD} = 1.71 to 3.6 V

  V_{DD} is the external power supply for the I/Os, the internal regulator, and the system analog (such as reset, power management, and internal clocks). It is provided externally through the VDD pins.

- V_{DDA} = 1.62 V (ADCs, DACs) / 2.1 (VREFBUF) to 3.6 V

  V_{DDA} is the external analog power supply for A/D converters, D/A converters, and voltage reference buffer. The V_{DDA} voltage level is independent from the V_{DD} voltage, and must preferably be connected to V_{DD} when these peripherals are not used.

- V_{DDSMPS} = 1.71 to 3.6 V

  V_{DDSMPS} is the external power supply for the SMPS step-down converter. It is provided externally through the VDDSMPS supply pin, and must be connected to the same supply as the VDD pin.

- V_{LXSMPS} is the switched SMPS step-down converter output.

Note: The SMPS power supply pins are available only on specific packages, with SMPS step-down converter option.

- V_{DDUSB} = 3.0 to 3.6 V

  V_{DDUSB} is the external independent power supply for USB transceivers. The V_{DDUSB} voltage level is independent from the V_{DD} voltage and must preferably be connected to V_{DD} when the USB is not used.
- V_{DDIO2} = 1.08 to 3.6 V

  V_{DDIO2} is the external power supply for 10 I/Os (PD6, PD7, PG9:14, PB8, PB9). The V_{DDIO2} voltage level is independent from the V_{DD} voltage and must preferably be connected to V_{DD} when those pins are not used.
- V_{CAP} = 1.0V to 1.35V: digital core domain supply

  This power supply is independent from all the other power supplies:
  - When the voltage regulator is enabled, V_{CORE} is delivered by the internal voltage regulator.
  - When the voltage regulator is disabled, V_{CORE} is delivered by an external power supply through VCAP pin, or by the SMPS
- V_{BAT} = 1.62 to 3.6 V

  V_{BAT} is the power supply when V_{DD} is not present (through power switch) for RTC, external clock 32 kHz oscillator, backup registers, and, optionally, backup SRAM.
- V_{REF-}, V_{REF+}

  V_{REF+} is the input reference voltage for ADCs and DACs. It is also the output of the internal voltage reference buffer when enabled.

  V_{REF+} can be grounded when ADC and DAC are not active.

  The internal voltage reference buffer supports four output voltages, configured with VRS bit in the VREFBUF_CSR register:
  - V_{REF+} ~ 1.8 V. (requires V_{DDA} ≥ 2.1 V)
  - V_{REF+} ~ 2.048 V (requires V_{DDA} ≥ 2.4 V)
  - V_{REF+} ~ 2.5 V (requires V_{DDA} ≥ 2.8 V)

  VREF- and VREF+ pins are not available on all packages. When not available, they are bonded to VSSA and VDDA, respectively.

  When the VREF+ is double-bonded with VDDA in a package, the internal voltage reference buffer is not available and must be kept disabled.

  V_{REF-} must always be equal to V_{SSA}.

10.4.2 Internal regulators

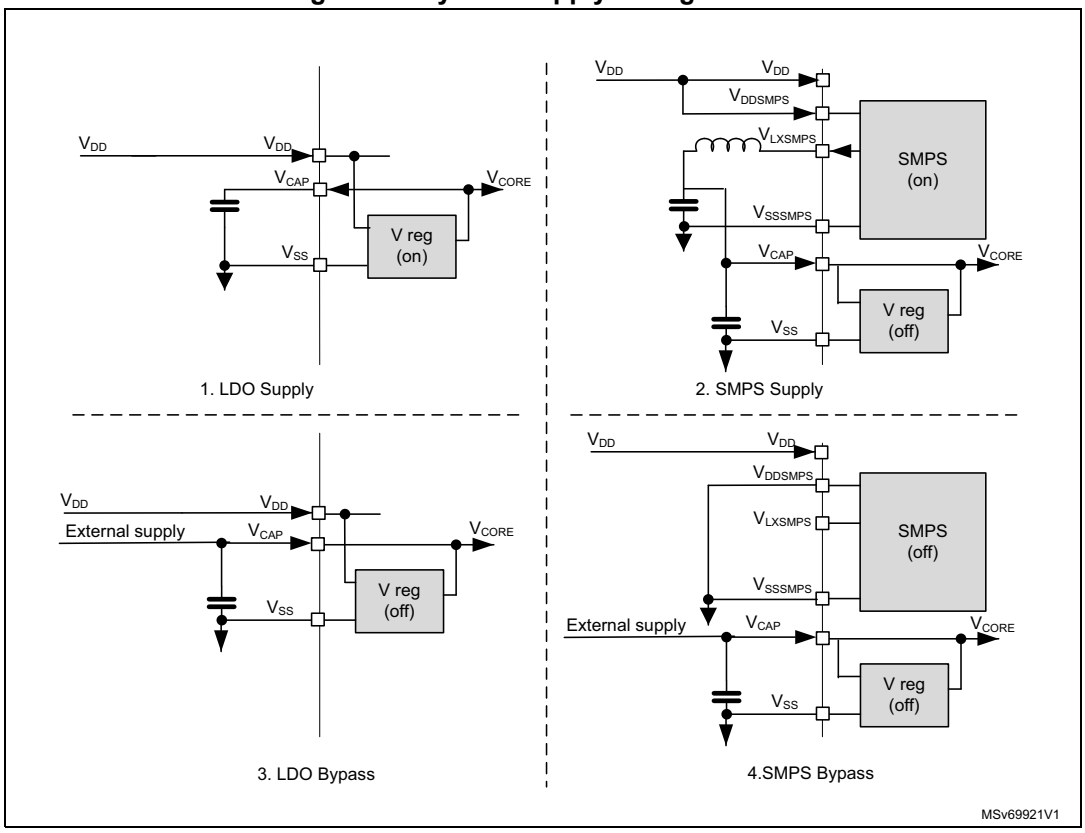
The devices embed two regulators: one LDO or one SMPS to provide the V_{CORE} supply for digital peripherals, SRAMs (except BKPSRAM), and embedded flash memory. The SMPS generates this voltage on VCAP (two pins), with a total external capacitor of 10 µF (typical) and requires an external coil of 2.2 µH (typical).

The LDO generates this voltage on VCAP, with a total external capacitance of 4.7 µF (typical).

Both regulators can provide four different voltages (voltage scaling), and can operate in Stop modes.

Depending on the package configuration (SMPS or LDO), the regulator is selected by hardware. SMPS and LDO regulator are exclusively selected. The supply configurations shown in *Figure 38* are supported for the V_{CORE} domain supply.

Figure 38. System supply configurations



Startup with V_{CORE} provided from an external supply (Bypass)

When supplied in Bypass mode, V_{CORE} must first settle at a default level (≥ 1.1 V), before V_{DD} reaches POR threshold level.

Due to the LDO default state after power-up (enabled by default), the external V_{CORE} voltage must remain higher than 1.1 V until the LDO is disabled by software. When the LDO is disabled, the external V_{CORE} voltage can be adjusted according to the user application needs (refer to section *General operating conditions* of the datasheet for details on V_{CORE} level versus the maximum operating frequency).

When operating in Bypass mode, the application must adjust VOS, using bits VOS[1:0] in PWR_VOSCR register. VOS[1:0] must be set according to the external provided core voltage level and related performance.

To adjust the VOS level, the software must select sequentially the intermediate levels.

- When increasing the performance:
  - First, voltage scaling must be incremented (for example when changing from VOS3 to VOS0, lower levels must be selected in the VOS[1:0] bits: VOS2, VOS1, and then VOS0).
  - The external voltage can be increased
  - The system frequency can be increased
- When decreasing the performance:
  - The system frequency must be decreased
  - The external voltage must be decreased
  - The voltage scaling can be decremented (for example when changing from VOS1 to VOS3, lower levels must be selected in the VOS[1:0] bits: VOS2, and then VOS3)

10.4.3 Power-up and power-down power sequences

During power-up and power-down phases, the following power sequence requirements must be respected:

- When V_{DD} is below 1 V, other power supplies (V_{DDA}, V_{DDIO2}, V_{DDUSB}) must remain below V_{DD} + 300 mV.
- When V_{DD} is above 1 V, all power supplies are independent.

During the power-down phase, V_{DD} can temporarily become lower than other supplies only if the energy provided to the MCU remains below 1 mJ. This allows external decoupling capacitors to be discharged with different time constants during the power-down transient phase.

10.4.4 Independent analog peripherals supply

To improve ADC and DAC conversion accuracy and to extend the supply flexibility, the analog peripherals have an independent power supply that can be separately filtered and shielded from noise on the PCB:

- The voltage supply input of the analog peripherals is available on a separate VDDA pin.
- An isolated supply ground connection is provided on the VSSA pin.

The V_{DDA} supply voltage can be different from V_{DD}. The presence of V_{DDA} must be checked before enabling any of the analog peripherals supplied by V_{DDA} (A/D converter, D/A converter, voltage reference buffer).

Power supply level monitoring is available on VDDA via AVDO bit in PWR_VMSR register.

When a single supply is used, V_{DDA} can be externally connected to V_{DD} through the external filtering circuit to ensure a noise-free V_{DDA} reference voltage.

ADC and DAC reference voltage

To ensure a better accuracy on low-voltage inputs and outputs, the user can connect to VREF+, a separate reference voltage lower than V_{DDA}. V_{REF+} is the highest voltage, represented by the full scale value, for an analog input (ADC) or output (DAC) signal.

V_{REF+} can be provided either by an external reference of by an internal buffered voltage reference (VREFBUF). The internal voltage reference can output a configurable voltage,

namely 1.8, 2.048 or 2.4 V. The internal voltage reference can also provide the voltage to external components through VREF+ pin. Refer to the device datasheet and to *Section 29: Voltage reference buffer (VREFBUF)* for further information.

Note: The VREF+ and VREF- pins are not available on all packages (internally connected, respectively, to VDDA and VSSA). Do not enable the internal voltage reference buffer when an external power supply is applied to the VREF+ pin.

10.4.5 Independent I/O supply rail

Some I/Os (PD6, PD7, PG9:14, PB8, PB9) are supplied from a separate supply rail. The power supply for this rail can range from 1.08 to 3.6 V, and is provided externally through the VDDIO2 pin. The V_{DDIO2} voltage level is completely independent from V_{DD} or V_{DDA}. The VDDIO2 pin is available only for some packages. Refer to the pinout diagrams or tables in the related device datasheet(s) for the I/O list(s).

Power supply level monitoring is available on VDDIO2 via VDDIO2RDY bit in PWR_VMSR register.

10.4.6 Independent USB transceivers supply

The USB transceivers are supplied from a separate VDDUSB power supply pin. V_{DDUSB} range is from 3.0 to 3.6 V and is completely independent from V_{DD} or V_{DDA}.

Power supply level monitoring is available on VDDUSB via the USB33RDY bit in PWR_VMSR register.

Before setting USB33SV bit in PWR USB supply control register (PWR_USBSCR), check that V_{DDUSB} is available by monitoring USB33RDY bit in PWR voltage monitor status register (PWR_VMSR). The $V_{DD33USB}$ supply level detector must be enabled through USB33DEN bit in PWR USB supply control register (PWR_USBSCR).

Setting USB33SV bit is mandatory to use the USBFS peripheral. It is used to validate the V_{DDUSB} supply for electrical and logical isolation purposes.

10.4.7 Backup domain

To retain the content of the backup registers and to supply the RTC function when V_{DD} is turned off, the VBAT pin can be connected to an optional backup voltage supplied by a battery or by another source.

The VBAT pin powers the RTC unit, the LSE oscillator, the PI8 and PC13 to PC15 I/Os, allowing the RTC to operate even when the main power supply is turned off. The backup SRAM is optionally powered by VBAT pin when the BREN bit is set in the *PWR Backup domain control register (PWR_BDCR)*. The switch to the V_{BAT} supply is controlled by the power-down reset embedded in the Reset block.

Warning: During $t_{RSTTEMPO}$ (temporization at V_{DD} startup) or after a PDR has been detected, the power switch between V_{BAT} and V_{DD} remains connected to V_{BAT}.
During the startup phase, if V_{DD} is established in less than $t_{RSTTEMPO}$ (refer to the datasheet for the value of $t_{RSTTEMPO}$) and $V_{DD} > V_{BAT} + 0.6$ V, a current may be injected into V_{BAT} through an internal diode connected between V_{DD} and the

power switch (V_{BAT}).
If the power supply/battery connected to the VBAT pin cannot support this current injection, it is strongly recommended to connect an external low-drop diode between this power supply and the VBAT pin.

If no external battery is used in the application, it is recommended to connect V_{BAT} externally to V_{DD} with a 100 nF external ceramic decoupling capacitor.

When the Backup domain is supplied by V_{BAT} (analog switch connected to V_{BAT}), the following pins are available:

- PC13, PI8, PC14 and PC15, which can be configured by RTC or LSE (refer to *Section 30.3: RTC functional description*)
- PC13, PI8, PA0, PA1, and PA2 when they are configured by TAMP peripheral as tamper pins.

Note: As the analog switch can transfer only a limited amount of current, the use of GPIOs PC13 to PC15 and PI8 in output mode is restricted: the speed must be limited to 2 MHz with a maximum load of 30 pF, and these I/Os must not be used as a current source (for example to drive a LED).

Backup domain access

After a system reset, the Backup domain (RCC Backup domain control register RCC_BDCR, RTC registers, TAMP registers, backup registers, and backup SRAM) is protected against possible unwanted write accesses. To enable access to the Backup domain, set the DBP bit in the *PWR Backup domain control register (PWR_BDCR)* to enable access to the Backup domain.

Backup RAM

The Backup domain includes 4 Kbytes of backup RAM accessible in 32-, 16-, or 8-bit data mode. The backup RAM is supplied from the backup regulator in the Backup domain. When the backup regulator is enabled through BREN bit in the PWR_BDCR, the backup RAM content is retained in Standby and/or VBAT mode (it can be considered as an internal EEPROM if VBAT is always present).

The backup regulator can be ON or OFF depending whether the application needs the backup RAM function in Standby or VBAT modes.

The backup RAM is read protected and mass erased when a tamper event occurs, this is to prevent confidential data (such as a cryptographic private key) from being accessed.

The backup RAM can be erased in the following ways:

- through the flash interface after a full product state regression
- after a tamper event
- after a Backup domain reset

V_{BAT} battery charging

When V_{DD} is present, it is possible to charge the external battery on VBAT through an internal resistance.

The V_{BAT} charging is done either through a 5 kΩ or a 1.5 kΩ resistor, depending upon the VBRS bit value in the PWR_BDCR register.

The battery charging is enabled by setting VBE bit in the PWR_BDCR register. It is automatically disabled in V_{BAT} mode.

10.5 PWR system supply voltage regulation

10.5.1 SMPS and LDO embedded regulators

The devices embed two internal regulators, exclusively enabled by hardware, depending upon package configuration. The regulator is enabled on power-on reset. To supply the V_{CORE} from external source, it is possible to disable the regulator by setting BYPASS bit in the PWR_SCCR register.

The BYPASS bit is written once after power-on reset. Written-once mechanism locks the register and any further write access is ignored. The system must be power cycled before writing a new value.

When V_{CORE} is supplied from an external source the externally applied voltage level must be reflected in the VOSx bits in the PWR_VOSCR register.

Both regulators can provide four different voltages (voltage scaling) and can operate in Stop modes.

10.5.2 V_{CORE} supply versus reset, voltage scaling, and low-power modes

After reset, the V_{CORE} is in VOS3.

When exiting the Stop or Standby mode, the voltage range is the VOS3.

10.5.3 Embedded voltage regulator operating modes

There are three different power modes: Run, Stop, and Standby modes.

Run mode

The voltage regulator (LDO or SMPS) provides full power to the V_{CORE} domain (core, memories, and digital peripherals). The regulator output voltage (LDO or SMPS) can be scaled by software to different voltage levels (VOS0, VOS1, VOS2, and VOS3) that are configured through the VOS bits in the PWR voltage scaling control register (PWR_VOSCR).

The VOS voltage scaling allows optimization of the power consumption when the system is clocked below the maximum frequency. By default, VOS3 is selected after system reset.

VOSx bits can be changed on-the-fly to adapt to the required system performance.

Stop mode

The voltage regulator (LDO or SMPS) supplies the V_{CORE} domain to retain the content of registers and internal memories. The regulator mode is selected through the SVOS bits in the PWR power mode control register (PWR_PMCR).

Stop mode power consumption can be further reduced using SVO4 (lower voltage level than VOS3) and even further with SVOS5.

Standby mode

The regulator (LDO or SMPS) is OFF and the V_{CORE} domains are powered down. The content of the registers and memories is lost except for the Standby circuitry and the Backup domain.

10.6 PWR power supply and temperature supervision

Power supply level monitoring is available on the following supplies:

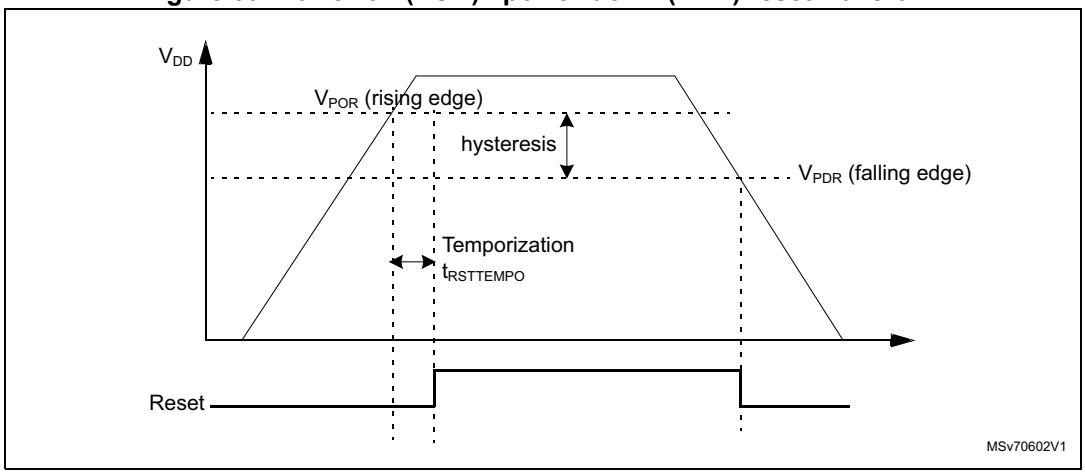
- V_{DD} via POR/PDR (see *Section 10.6.1*), BOR (see *Section 10.6.2*), and PVD monitor (see *Section 10.6.3*)
- V_{DDA} via AVD monitor see (*Section 10.6.4*)
- V_{BAT} via V_{BAT} threshold (see *Section 10.6.6*)
- V_{DDIO2} via VDDIO2RDY bit (see *Section 10.11.10*)
- Temperature monitoring (see *Section 10.6.7*)

10.6.1 Power-on reset (POR)/power-down reset (PDR)

The system has an integrated POR/PDR circuitry that ensures proper startup operation.

The system remains in reset mode when V_{DD} is below a specified VPOR threshold, without the need for an external reset circuit. Once the supply level is above the VPOR threshold, the system is taken out of reset (see *Figure 39*). For more details concerning the reset thresholds refer to the electrical characteristics section of the datasheets.

Figure 39. Power-on (POR) / power-down (PDR) reset waveform



1. For thresholds and hysteresis values refer to the datasheets.

10.6.2 Brownout reset (BOR)

During power-on, the brownout reset (BOR) keeps the system under reset until the V_{DD} supply voltage reaches the specified V_{BOR} threshold.

The V_{BOR} threshold is configured through system option bytes:

- BOR OFF (BORH_EN = 0)
- BOR level 1 (V_{BOR1})
- BOR level 2 (V_{BOR2})
- BOR level 3 (V_{BOR3})

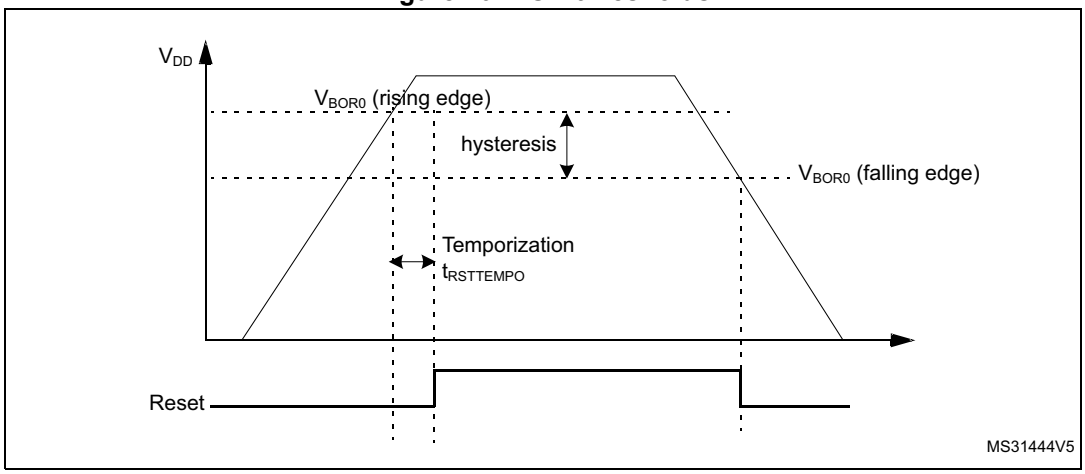
By default, BOR is OFF, it can be enabled by setting BORH_EN option bit.

For more details on the brownout reset thresholds, refer to the section "*Electrical characteristics*" of the product datasheets.

A system reset is generated when the BOR is enabled and V_{DD} supply voltage drops below the selected V_{BOR} threshold.

BOR can be disabled by programming the BORH_EN option bit to 0. To disable the BOR function, V_{DD} must have been higher than the POR threshold to start the system option byte programming sequence. Once BOR is disabled, the power-down is monitored by the PDR.

Figure 40. BOR thresholds



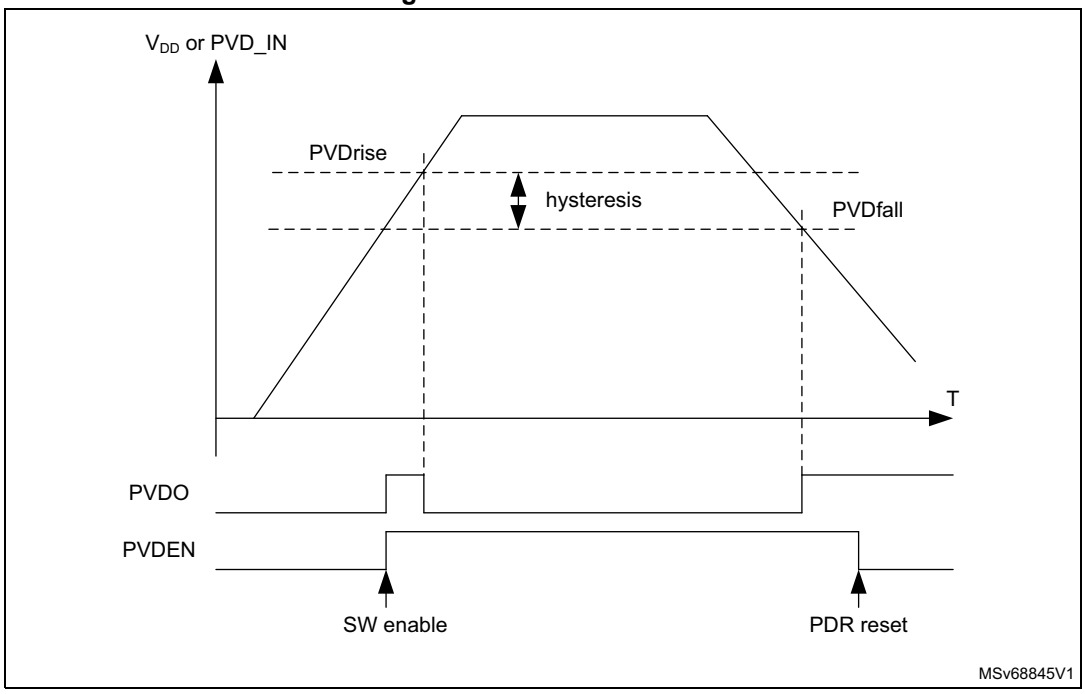
10.6.3 Programmable voltage detector (PVD)

The PVD can be used to monitor the V_{DD} power supply by comparing it to a threshold selected by the PLS[2:0] bits in the *PWR voltage monitor control register (PWR_VMCR)*. The PVD can also be used to monitor a voltage level on the PVD_IN pin. In this case PVD_IN voltage is compared to the internal VREFINT level.

The PVD is enabled by setting the PVDE bit in *PWR voltage monitor control register (PWR_VMCR)*.

A PVDO flag is available in the *PWR voltage monitor status register (PWR_VMSR)* to indicate if V_{DD} or PVD_IN voltage is higher or lower than the PVD threshold. This event is internally connected to the EXTI and can generate an interrupt, provided it has been enabled through the EXTI registers. The rising/falling edge sensitivity of the EXTI line must be configured according to PVD output behavior. As an example, if the EXTI line is configured to rising edge sensitivity, the interrupt is generated when V_{DD} or PVD_IN voltage drops below the PVD threshold. The service routine can then start an emergency shutdown.

Figure 41. PVD thresholds



1. For thresholds and hysteresis values, refer to the datasheets.

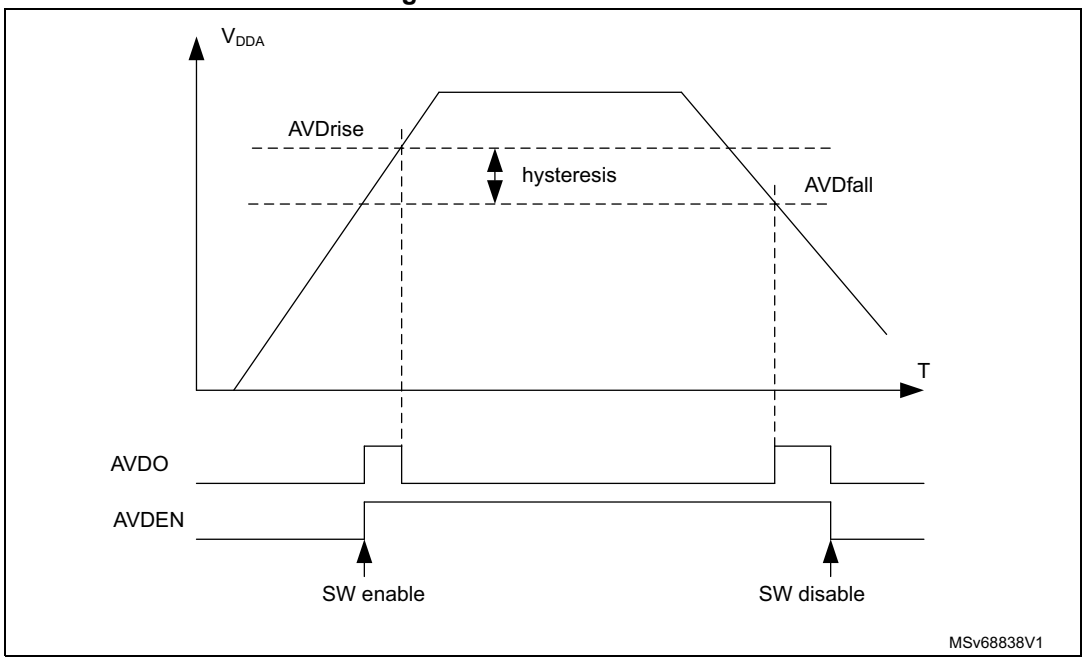
10.6.4 Analog voltage detector (AVD)

The AVD can be used to monitor the V_{DDA} supply by comparing it to a threshold selected by the ALS[1:0] bits in the *PWR voltage monitor control register (PWR_VMCR)*.

The AVD is enabled by setting the AVDEN bit in *PWR voltage monitor control register (PWR_VMCR)*.

An AVDO flag is available in the *PWR voltage monitor status register (PWR_VMSR)* to indicate whether V_{DDA} is higher or lower than the AVD threshold. This event is internally connected to the EXTI and can generate an interrupt if enabled through the EXTI registers. The AVDO interrupt can be generated when V_{DDA} drops below the AVD threshold and/or when V_{DDA} rises above the AVD threshold, depending on EXTI rising/falling edge configuration. As an example, the service routine can indicate when the V_{DDA} supply drops below a minimum level.

Figure 42. AVD thresholds



1. For thresholds and hysteresis values, refer to the datasheets.

10.6.5 V_{DDIO2} voltage monitor (IO2VM)

The IO2VM monitors the independent supply voltage V_{DDIO2} to ensure that the peripheral is in its functional supply range. The VDDIO2RDY flag (see *PWR voltage monitor control register (PWR_VMCR)*) indicates whether a valid supply is present or not.

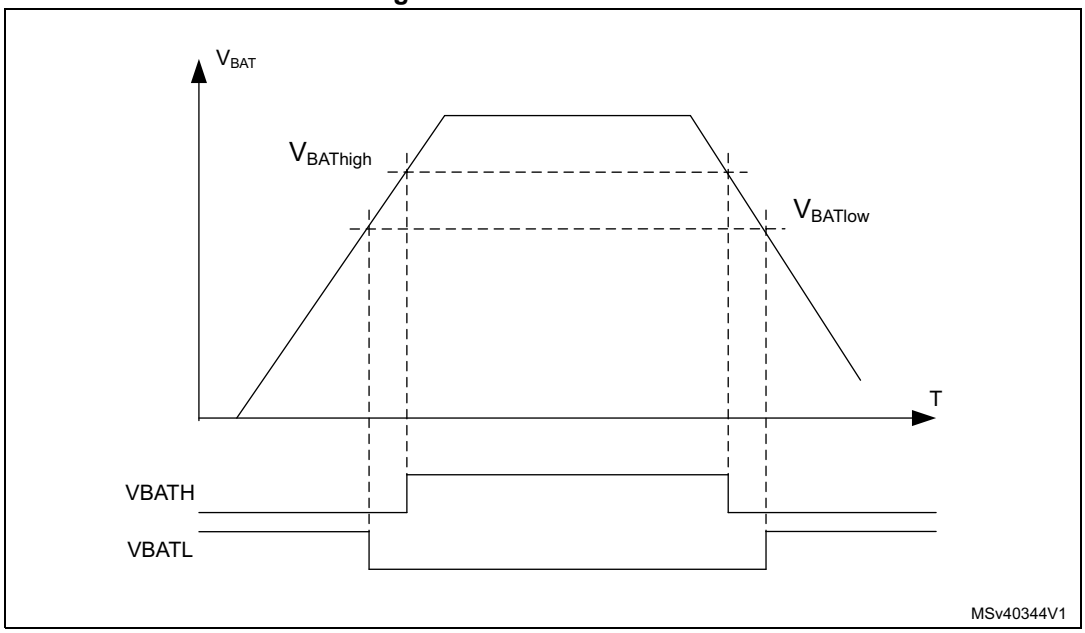
10.6.6 Backup domain voltage monitoring

In VBAT mode, the battery voltage supply (backup domain) can be monitored by comparing it with two threshold levels: $V_{BAThigh}$ and V_{BATlow}. The VBAT supply monitoring can be enabled/disabled via MONEN bit in *PWR Backup domain control register (PWR_BDCR)*. When it is enabled, the battery voltage thresholds increase power consumption.

If the Backup domain voltage monitoring internal tamper is enabled in the TAMP peripheral (ITAMP1E = 1 in the TAMP_CR1 register), a tamper event is generated when the battery voltage is above the functional range.

Note: The Backup domain voltage is V_{DD} when present, V_{BAT} otherwise.

Figure 43. VBAT thresholds



1. For thresholds and hysteresis values, refer to the datasheets.

10.6.7 Temperature monitoring

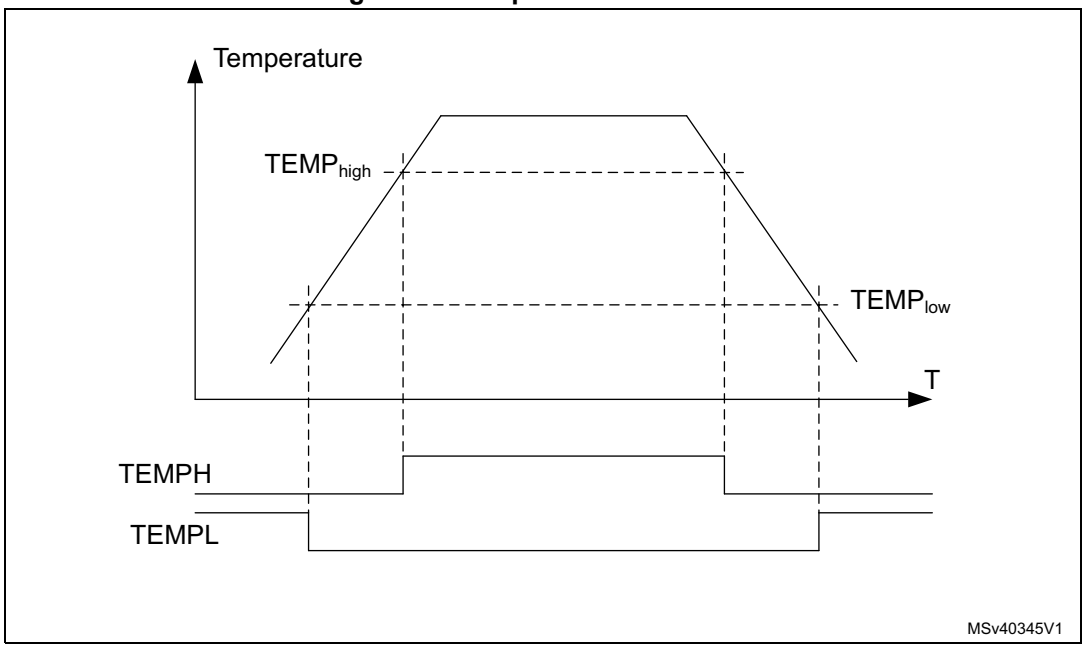
A dedicated temperature sensor cell is embedded in the power control. The junction temperature can be monitored by comparing it with two threshold levels, TEMPhigh and TEMPlow. TEMPH and TEMPL flags in the *PWR Backup domain status register (PWR_BDSR)*, which indicates whether the device temperature is higher or lower than the threshold. The temperature monitoring can be enabled/disabled via MONEN bit in *PWR Backup domain control register (PWR_BDCR)*.

When enabled, the temperature thresholds increase power consumption. As an example the levels may be used to trigger a routine to perform temperature control tasks.

If the temperature monitoring internal tamper is enabled in the TAMP peripheral (ITAMP2E = 1 in the TAMP_CR1 register), a tamper event is generated when the temperature is above or below the functional range.

TEMPH and TEMPL wake-up interrupts are available on the RTC tamper signals (see *Section 47: Tamper and backup registers (TAMP)*).

Figure 44. Temperature thresholds



1. For thresholds and hysteresis values, refer to the datasheets.

10.7 PWR management

10.7.1 Voltage scaling

The voltage regulator supporting voltage scaling with the following features:

- Run mode voltage scaling
  - VOS0: scale 0
  - VOS1: scale 1
  - VOS2: scale 2
  - VOS3: scale 3
- Stop mode voltage scaling
  - SVOS3: scale 3
  - SVOS4: scale 4
  - SVOS5: scale 5

For more details on voltage scaling values, refer to the product datasheets.

After reset, the system starts on the lowest Run mode voltage scaling (VOS3). The voltage scaling can then be changed on-the-fly by software by programming VOS bits in PWR_VOSCR register according to the required system performance. When exiting from the Stop mode or Standby mode, the Run mode voltage scaling is reset to the default VOS3 value.

Before entering Stop mode, the software should preselect the SVOS level in *PWR power mode control register (PWR_PMCR)*. The Stop mode voltage scaling for SVOS4 and SVOS5 also sets the voltage regulator in Low-power mode, to further reduce power consumption.

10.7.2 Power management examples

Example of V_{CORE} voltage scaling behavior in Run mode.

Figure 45. Dynamic voltage scaling in Run mode

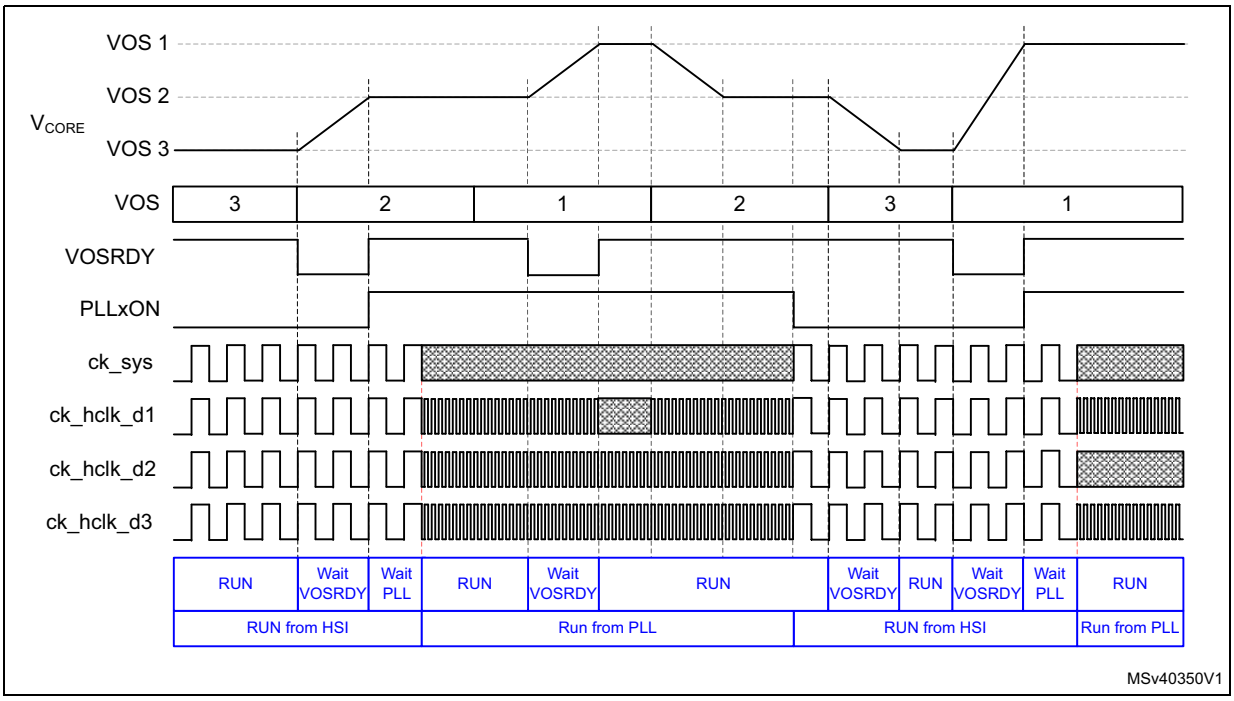


Figure 45 illustrates the following system operation sequence example:

1. After reset, the system starts from HSI with VOS3.
2. The system performance is first increased to a medium-speed clock from the PLL with voltage scaling VOS2. To do this:
   a) Program the voltage scaling to VOS2.
   b) Once the V_{CORE} supply has reached the required level indicated by VOSRDY, increase the clock frequency by enabling the PLL.
   c) Once the PLL is locked, switch the system clock.
3. The system performance is then increased to high-speed clock from the PLL with voltage scaling VOS1. To do this:
   a) Program the voltage scaling to VOS1.
   b) Once the VCORE supply has reached the required level indicated by VOSRDY, increase the clock frequency.
4. The system performance is then reduced to a medium-speed clock with voltage scaling VOS2. To do this:
   a) First decrease the system frequency.
   b) Then decrease the voltage scaling to VOS2.

5. The next step is to reduce the system performance to the HSI clock with voltage scaling VOS3. To do this:
   a) Switch the clock to HSI.
   b) Disable the PLL.
   c) Decrease the voltage scaling to VOS3.
6. The system performance can then be increased to high-speed clock from the PLL. To do this:
   a) Program the voltage scaling to VOS1.
   b) Once the V_{CORE} supply has reached the required level indicated by VOSRDY, increase the clock frequency by enabling the PLL.
   c) Once the PLL is locked, switch the system clock.

When the system performance (clock frequency) is changed, VOS must be set accordingly, otherwise the system can be unreliable.

10.8 Power modes

By default, the microcontroller is in Run mode after a system or a power reset. Several low-power modes are available to save power when there is no need to keep the CPU running, for example when waiting for an external event. The user can select the mode that gives the best compromise between low-power consumption, short startup time, and wake-up sources.

The device features the following low-power modes:

- Sleep mode

  CPU clock off, all peripherals including Cortex-M33 core such as NVIC and SysTick can run and wake-up the CPU when an interrupt or an event occurs. Refer to *Section 10.8.4: Sleep mode*.

- Stop mode

  Stop mode achieves the lowest power consumption, while retaining the content of SRAM and registers. All clocks in the core domain are stopped. The PLL, the HSE crystal oscillators, HSI (except if HSIKERON is set), HSI48 and CSI RC (except if CSIKERON is set) are disabled. The LSE or LSI is still running.

  The RTC can remain active (Stop mode with RTC, Stop mode without RTC).

  The system clock when exiting from Stop mode can be either HSI up to 64 MHz or CSI, depending on software configuration.

  Refer to *Section 10.8.5: Stop mode*.

- Standby mode

  This mode achieves the lowest power consumption with BOR. The internal regulator is switched off so that the core domain is powered off. The PLL, the HSI RC, HSI48, the CSI RC, and the HSE crystal oscillators are also switched off.

  The RTC can remain active (Standby mode with RTC, Standby mode without RTC).

  The brownout reset (BOR) always remains active in Standby mode.

  The state of the I/O (except I/Os used by standby mode) during Standby mode can be retained.

  After entering Standby mode, SRAMs and register contents are lost except for registers

and backup SRAM in the Backup domain and Standby circuitry.

The device exits Standby mode when an external reset (NRST pin), an IWDG reset, WKUP pin event (configurable rising or falling edge), an RTC event occurs (alarm, periodic wake-up, timestamp), or a tamper detection. The tamper detection can be raised either due to external pins or due to an internal failure detection.

The system clock after wake-up is HSI at 32 MHz.

Refer to *Section 10.8.6: Standby mode*.

Table 91 shows the power modes overview.

Table 91. Low-power mode summary

Mode name	Entry	Wake-up source(1)	Wake-up system clock	Effect on clocks	Voltage regulators
Sleep (Sleep-now or Sleep-on-exit)	WFI or Return from ISR	Any interrupt	Same as before entering Sleep mode	– CPU clock OFF – No effect on other clocks or analog clock sources	VOS3, VOS2, VOS1, or VOS0
	WFE	Wake-up event			
Stop	LPMS = 0 + SLEEPDEEP bit + WFI or Return from ISR or WFE	– Any EXTI line (configured in the EXTI registers) – Specific peripherals events(2)	– CSI when STOPWUCK = 1 in RCC_CFGR – HSI with the frequency before entering Stop mode, up to 64 MHz, when STOPWUCK = 0	– All clocks OFF except LSI and LSE – HSI or CSI can be enabled temporarily when requested by software	SVOS3, SVOS4, or SVOS5
Standby	LPMS = 1 + SLEEPDEEP bit + WFI or Return from ISR or WFE	WKUP pin edge, RTC event, IWDG reset, external reset in NRST pin	HSI clock at 64 MHz	All clocks OFF except LSI and LSE	OFF

1. Refer to *Table 92*.
2. Peripherals able to wake-up the system from Stop mode (this is only possible when SVOS3 is selected before entering Stop mode).

Table 92. Functionalities depending on the working mode(1)

1. Y = yes (enabled). O = optional (disabled by default, can be enabled by software). - = not available.
   HSI or CSI are available as kernel clock for peripherals only in SVOS3.
2. The memory can be configured in Low-power mode. By default, it is not in Low-power mode during Stop (SVOS3, SVOS4).
3. The SRAM clock can be gated on or off independently. By default clock is enabled in Run and Sleep mode.
4. The SRAMs can be powered on or off independently. By default, they are not in Power-off mode during Stop.
5. Wake-up with internal tamper.
6. GPIOs state can be retained during Standby mode. By default GPIOs states are not retained.
7. 8-pin capable of wake-up from Standby mode PA0, PA2, PB7, PC1, PC13, PD2, PD3 and PI8.

In addition, the power consumption in Run mode can be reduced by slowing down the system clocks, configuring voltage scaling to lower-power ranges, and by gating the clocks to the APB and AHB peripherals when they are not used.

Debug mode

By default, the debug connection is lost if the application puts the MCU in Stop or Standby mode while the debug features are used. This is due to the fact that the Cortex-M33 core is no longer clocked.

However, by setting some configuration bits in the DBGMCU control registers, the software can be debugged even when using the low-power modes extensively. For more details, refer to *Section 75.2.5: Debug and low-power modes*.

10.8.1 Slowing down system clocks

In Run mode, the speed of the system clocks (SYSCLK, HCLK, PCLK) can be reduced by programming the prescaler registers. These prescalers can also be used to slow down the peripherals before entering the Sleep mode.

For more details, refer to *Section 11: Reset and clock control (RCC)*.

10.8.2 Peripheral clock gating

In Run mode, the HCLK and PCLK for individual peripherals and memories can be stopped at any time to reduce the power consumption.

To further reduce the power consumption in Sleep mode, the peripheral clocks can be disabled before executing the WFI or WFE instructions.

The peripheral clock gating is controlled by the RCC_AHBxENR and RCC_APBxENR registers.

Disabling the peripherals clocks in Sleep mode can be performed automatically by resetting the corresponding bit in the RCC_AHBxLPENR and RCC_APBxLPENR registers.

10.8.3 Low-power modes

Entering into a low-power mode

The MCU enters in low-power modes by executing the WFI (wait for interrupt), or WFE (wait for event) instructions, or when the SLEEPONEXIT bit in the Cortex-M33 system control register is set on *Return fom ISR*.

Entering into a low-power mode through WFI or WFE is executed only if no interrupt is pending or no event is pending.

Exiting a low-power mode

The MCU exits the Sleep or Stop mode according to how the low-power mode was entered:

- If the WFI instruction or Return from ISR was used to enter the low-power mode, any peripheral interrupt acknowledged by the NVIC can wake up the device.
- If the WFE instruction is used to enter the low-power mode, the MCU exits the low-power mode as soon as an event occurs. The wake-up event can be generated either by:
  - an NVIC IRQ interrupt:
    - When SEVONPEND = 0 in the Cortex-M33 system control register
      By enabling an interrupt in the peripheral control register and in the NVIC.
      When the MCU resumes from WFE, the peripheral interrupt pending bit and.

the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) must be cleared. Only NVIC interrupts with high enough priority can wake up and interrupt the MCU.

> When SEVONPEND = 1 in the Cortex-M33 system control register
By enabling an interrupt in the peripheral control register and optionally in the NVIC. When the MCU resumes from WFE, the peripheral interrupt pending bit and when enabled the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) must be cleared. All NVIC interrupts wake up the MCU, even the disabled ones. Only enabled NVIC interrupts with high enough priority can wake up and interrupt the MCU.

– an event:

> Configuring an EXTI line in event mode. When the CPU resumes from WFE, it is not necessary to clear the EXTI peripheral interrupt pending bit or the NVIC IRQ channel pending bit, as the pending bits corresponding to the event line are not set. It may be necessary to clear the interrupt flag in the peripheral.

The MCU exits Standby mode through an external reset (NRST pin), an IWDG reset, a rising edge on one of the enabled WKUPx pins or a RTC/TAMP event (see *Figure 617: RTC block diagram*).

After waking up from Standby mode, the program execution restarts in the same way as after a reset (boot pin sampling, option bytes loading, reset vector is fetched).

Caution: When the device is in Stop mode, a peripheral interrupt powers on an internal oscillator. The corresponding NVIC interrupt channel must be enabled to allow the interrupt to exit the device from Stop mode. It is not allowed to disable a peripheral interrupt by disabling only the NVIC channel while keeping the peripheral interrupt enable, as the device could remain in Stop mode with clock ON.

10.8.4 Sleep mode

I/O states in Sleep mode

In Sleep mode, all I/O pins keep the same state as in Run mode.

Entering the Sleep mode

The MCU enters the Sleep mode as described in *Entering into a low-power mode*, when the SLEEPDEEP bit in the Cortex-M33 system control register is clear (see the table below for details on how to enter the Sleep mode).

Exiting the Sleep mode

The MCU exits the Sleep mode as described in *Exiting a low-power mode* (see the table below for details on how to exit the Sleep mode).

Table 93. Sleep mode

Sleep mode	Description
Mode entry	WFI (wait for interrupt) or WFE (wait for event) while: – SLEEPDEEP = 0 – No interrupt (for WFI) or event (for WFE) pending Refer to the Cortex-M33 system control register.
	On return from ISR while: – SLEEPDEEP = 0 and – SLEEPONEXIT = 1 – No interrupt pending Refer to the Cortex-M33 system control register.
Mode exit	If WFI or Return from ISR was used for entry Interrupt (see *Table 135: STM32H563/H573 and STM32H562 vector table*) If WFE was used for entry and SEVONPEND = 0: Wake-up event (see *Section 18.3: EXTI functional description*) If WFE was used for entry and SEVONPEND = 1: Interrupt even when disabled in NVIC (see *Table 135: STM32H563/H573 and STM32H562 vector table*) or wake-up event (see *Section 18.3: EXTI functional description*)
Wake-up latency	None

10.8.5 Stop mode

The Stop mode is based on the Cortex-M33 Deepsleep mode combined with the peripheral clock gating. The voltage regulator is configured by SVOSx bits (the selected SVOS4 and SVOS5 levels add an additional startup delay when exiting from system Stop mode). In Stop mode, all clocks in the core domain are stopped. The PLL, HSI, HSI48, CSI and HSE oscillators are disabled.

It is possible to keep the HSI or CSI clock enabled during Stop mode, to be quickly available as kernel clock for peripherals.

All SRAMs and register contents are preserved, but the SRAMs can be totally or partially switched off to further reduced consumption. The user can select which memory is discarded during Stop mode by means of xxSO bits in *PWR power mode control register (PWR_PMCR)*.

Table 94. Memory shut-off block selection

Selection bit	Shut-off block in Stop mode
SRAM1SO	AHB SRAM1
SRAM2_48SO	AHB SRAM2 48-Kbyte
SRAM2_16SO	AHB SRAM2 16-Kbyte
SRAM3SO	AHB SRAM3
ETHERNETSO	ETHERNET RAM

The BOR is always available in Stop mode.

I/O states in Stop mode

In the Stop mode, all I/O pins keep the same state as in the Run mode.

Entering the Stop mode

The MCU enters the Stop mode as described in *Entering into a low-power mode*, when the SLEEPDEEP bit in the Cortex-M33 system control register is set (see *Table 95* for details on how to enter the Stop mode).

If the flash memory programming is ongoing, the Stop mode entry is delayed until the memory access is finished.

If an access to the APB domain is ongoing, the Stop mode entry is delayed until the APB access is finished.

In Stop mode, the following features can be selected by programming the individual control bits:

- The independent watchdog (IWDG) is started by writing to its key register or by hardware option. Once started, it can be stopped only by a reset (see *Section 44: Independent watchdog (IWDG)*).
- The real-time clock (RTC) is configured by the RTCEN bit in the *RCC backup domain control register (RCC_BDCR)*.
- The internal RC oscillator LSI clock is configured by the LSION bit in RCC_BCDR.
- The external 32.768 kHz oscillator (LSE) is configured by the LSEON bit in RCC_BCDR.

The AVD and the PVD can be used in Stop mode. If they are not needed, they must be disabled by software to save their power consumptions.

The ADCx (x = 1, 2), the DAC1 (two channels), the temperature sensor, and the VREFBUF can consume power during the Stop mode, unless they are disabled before entering this mode.

Exiting the Stop mode

The MCU exits Stop mode by enabling an EXTI interrupt or event depending on how the low-power mode was entered. Some peripherals are able to wake up the system (refer to *Table 138: EXTI line connections*) from Stop mode, this is only possible when SVOS3 is selected before entering Stop mode.

Note: When wake-up from Stop with peripherals is needed, SVOS3 must be selected.

When exiting Stop mode by issuing an interrupt or a wake-up event, CSI is selected as system clock if bit STOPWUCK is set in RCC clock configuration register 1 (RCC_CFGR). The HSI oscillator is selected as system clock if STOPWUCK is cleared. The wake-up time is shorter when CSI is selected as wake-up system clock. The HSI selection allows a wake-up at higher frequency (up to 64 MHz).

The MCU exits Stop mode by enabling an EXTI interrupt or event depending on how the low-power mode was entered.

When exiting the Stop mode, the MCU is in Run mode, VOS3.

Table 95. Stop mode

Stop mode	Description
Mode entry	WFI (wait for interrupt) or WFE (wait for event) while: – SLEEPDEEP bit is set in Cortex-M33 system control register – No interrupt (for WFI) or event (for WFE) pending – LPMS = 000 in PWR_CR1
	On Return from ISR while: – SLEEPDEEP bit is set in Cortex-M33 system control register – SLEEPONEXIT = 1 – No interrupt pending – LPMS = 0 in PWR_PMCR
	Note: To enter Stop mode, all EXTI line pending bits (in the EXTI rising edge pending register 2 (EXTI_RPR2)), and the peripheral flags generating wake-up interrupts must be cleared. Otherwise, the Stop mode entry procedure is ignored and the program execution continues.
Mode exit	If WFI or Return from ISR was used for entry: - any EXTI line configured in interrupt mode (the corresponding EXTI interrupt vector must be enabled in the NVIC). The interrupt source can be external interrupts or peripherals with wake-up capability (see *Table 135: STM32H563/H573 and STM32H562 vector table*). - any peripheral interrupt occurring when the AHB/APB clocks are present due to an autonomous peripheral clock request (the peripheral vector must be enabled in the NVIC) If WFE was used for entry and SEVONPEND = 0: - any EXTI line configured in event mode (see *Section 18.3: EXTI functional description*). If WFE was used for entry and SEVONPEND = 1: - any EXTI line configured in interrupt mode (even if the corresponding EXTI interrupt vector is disabled in the NVIC). The interrupt source can be external interrupts or peripherals with wake-up capability (see *Table 135: STM32H563/H573 and STM32H562 vector table*). - any EXTI line is configured in event mode (see *Section 18.3: EXTI functional description*)
	Note: All peripheral clocks must be enabled to allow this peripheral to generate a wake-up from Stop interrupt ([PERIPH]EN and [PERIPH]LPEN bits must be set in the RCC, and a functional independent clock must be selected).
Wake-up latency	Longest wake-up time between: HSI or CSI wake-up time and flash memory wake-up time from Stop mode.

10.8.6 Standby mode

The lowest power mode in which the BOR is active is the Standby mode. It is based on the Cortex-M33 Deepsleep mode, with the voltage regulators disabled. The PLL, HSI, HSI48, CSI, and HSE oscillators are also switched off.

The SRAMs and register contents are lost except for registers in the Backup domain and Standby circuitry (see *Figure 36: Power supply with SMPS*).

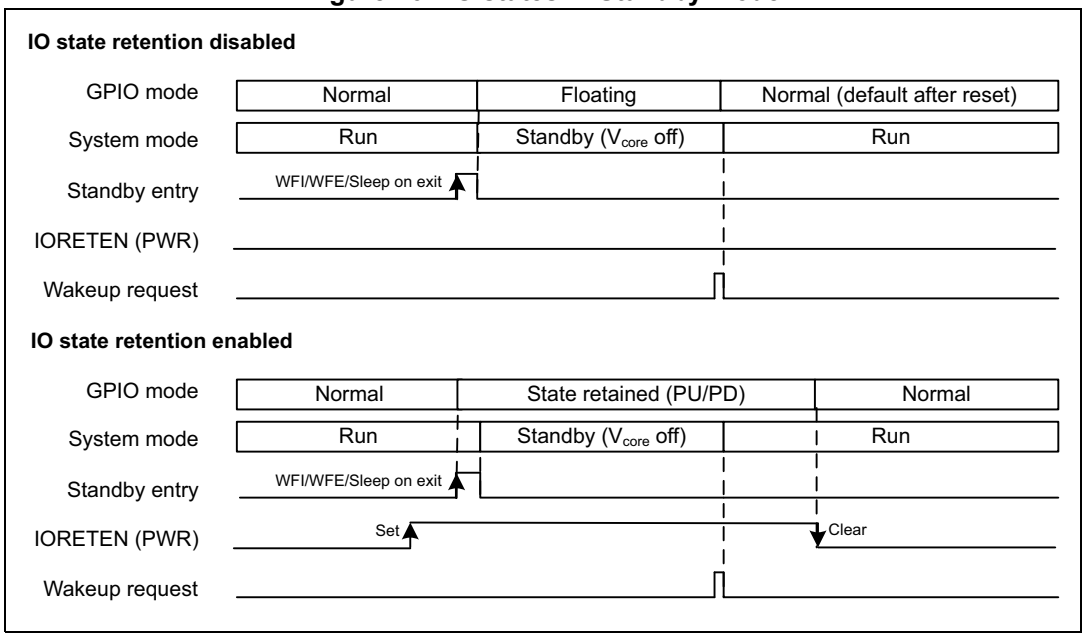
The BOR is always available in Standby mode.

I/O states in Standby mode

In the Standby mode, the I/Os are by default in floating state. If the IORETEN bit in the PWR_IORETR register is set, the I/Os output state is retained. I/O retention mode is enabled for all I/Os except those supporting the standby functionality and JTAG IOs (PA13, PA14, PA15 and PB4). When entering into Standby mode, the state of the output is sampled, and pull-up or pull-down resistor are set to maintain the I/O output during Standby mode.

If the JTAGIORETEN bit in the PWR_IORETR register is set, the I/Os output state is retained. I/O retention mode is enabled for PA13, PA14, PA15 and PB4 (default JTAG pull-up/pull-down after wake-up is not enabled).

Figure 46. I/O states in Standby mode



After wakeup from Standby mode, as long as IORETEN (or JTAGIORETEN for JTAG IOs) is set, the retained stated (pull-up/pull-down) remains applied.

The GPIO pin state before standby can be identified with GPIO_IDR register (when both GPIO port clock and input buffer are enabled).

The application can release the IO state (clear the retained Pull-up/Pull-down) by clearing the IORETEN (or JTAGIORETEN for JTAG IOs) bit, this can be done before or after reconfiguring the GPIOs and related peripherals. This lets the application configure the GPIO to a known state before releasing the retained state.

The RTC outputs on PC13 and PI8 are functional in Standby mode. PC14 and PC15 used for LSE are also functional. The 8 wake-up pins (WKUPx, x = 1 to 8) and four RTC tampers pins are available.

Entering Standby mode

The MCU enters the Standby mode as described in *Entering into a low-power mode*, when the SLEEPDEEP bit in the Cortex-M33 system control register is set (see *Table 96* for details on how to enter Standby mode).

In Standby mode, the following features can be selected by programming individual control bits:

- The independent watchdog (IWDG) is started by writing to its Key register or by hardware option. Once started it can be stopped only by a reset (see *Section 44.4: IWDG functional description*).
- The real-time clock (RTC) is configured by the RTCEN bit in *RCC backup domain control register (RCC_BDCR)*.
- The internal RC oscillator LSI clock, is configured by the LSION bit in RCC_BDCR.
- The external 32.768 kHz oscillator (LSE) is configured by the LSEON bit in RCC_BDCR.
- The IOs retention is configured by the IORETEN bit in the PWR_IORETR register.

Exiting Standby mode

The MCU exits the Standby mode as described in *Exiting a low-power mode*. The SBF status flag in the *PWR status register (PWR_PMSR)* indicates that the MCU was in Standby mode. All registers are reset after wake-up from Standby except for *PWR Backup domain control register (PWR_BDCR)* and *PWR I/O retention register (PWR_IORETR)* (see *Table 96* for more details on how to exit Standby mode).

When exiting Standby mode, I/Os output state that were retained during Standby through IORETEN bit, keep this configuration upon exiting Standby mode until the IORETEN bit in PWR_IORETR register is cleared. Once IORETEN is cleared, the I/Os are either configured to their reset values or to the pull-up/pull-down state according to the GPIOx_PUPDR registers.

For I/Os, with a pull-up or pull-down predefined after reset (some JTAG/SWD I/Os), in case those pull-up or pull-down are different from the retained values during Standby, both a pull-down and pull-up are applied until IORETEN is cleared, releasing the retained value.

Also in case the GPIOx_PUPDR values programed after exiting from Standby are different from the retained values during Standby, both a pull-down and pull-up are applied until IORETEN is cleared, releasing the retained value.

Table 96. Standby mode

Standby mode	Description
Mode entry	WFI (wait for interrupt) or WFE (wait for event) while: – SLEEPDEEP bit is set in Cortex-M33 system control register – No interrupt (for WFI) or event (for WFE) pending – LPMS = 1 in PWR_PMCR – WUFx bits cleared in PWR_WUSR
	On Return from ISR while: – SLEEPDEEP bit is set in Cortex-M33 system control register – SLEEPONEXIT = 1 – No interrupt pending – LPMS = 1 in PWR_PMCR – WUFx bits cleared in PWR_WUSR – RTC/TAMP flags corresponding to the chosen wake-up source, cleared

Table 96. Standby mode

Standby mode	Description
Mode exit	WKUPx pin edge, RTC event, external Reset in NRST pin, IWDG Reset, BOR reset
Wake-up latency	Reset phase

10.8.7 Power modes output pins

In order to help the debug, three signals are available as device pins alternate functions:

- **CSLEEP**

  When set, CSLEEP indicates that the system is in Sleep mode: WFI or WFE has been executed.

  When cleared, CSLEEP indicates that the system is in Run mode.

- **CDSTOP**

  When set, CDSTOP indicates that the system is in CStop mode, meaning that the following conditions are fulfilled:

  – WFI or WFE has been executed with CPU SLEEPDEEP = 1.

  – No AHB/APB clock is running.

  When cleared, CDSTOP indicates that the system is not in CStop mode: AHB/APB clocks are running.

The table below explains the MCU power mode depending on these signals states.

Table 97. Power modes output states versus MCU power modes

CSLEEP	CSTOP	MCU power modes(1)
0	0	Run mode
1	0	Sleep mode or Stop mode, with AHB/APB clocks running
1	1	Stop mode

1. CSLEEP and CDSTOP are generated in core domain, consequently they are not driven in Standby mode.

10.9 PWR security and privileged protection

10.9.1 PWR security protection

When the TrustZone security is activated by the TZEN option byte in the flash memory option byte configuration register, some PWR register fields can be secured against non-secure access.

The PWR TrustZone security allows the following features to be secured through the PWR_SECCFGR register:

- Low-power mode
- Wake-up (WKUP) pins
- Voltage detection and monitoring
- VBAT mode
- I/Os retention configuration

Other PWR configuration bits are secure when:

- The system clock selection is secure in RCC: the voltage scaling (VOS) configuration is secure.
- The UCPD1 is secure in the GTZC: the PWR_UCPDR register is secure.

Table 98 gives a summary of the PWR secured bits following the security configuration bit in PWR_SECCFGR.

A non-secure access to a secure-protected register bit is denied:

- The secured bits are not written (WI) with a non-secure write access.
- The secured bits are read as 0 (RAZ) with a non-secure read access.

A non-secure write access to PWR_SECCFGR is WI and generates an illegal access event and an interrupt if enabled in the GTZC. It can be read with a non-secure read access.

When the TrustZone security is disabled (TZEN = 0xC3), PWR_SECCFGR is RAZ/WI and all other registers are non-secure.

Table 98. PWR security configuration summary

Secure configuration register	Security configuration bit	Register name	Secured bits	Non-secure access on secure bits
PWR_SECCFGR	Not applicable(1)	PWR_SECCFGR	All bits	Read OK. WI and illegal access event
PWR_SECCFGR	At least one bit is set	PWR_PRIVCFGR	SPRIV	Read OK. WI
PWR_SECCFGR	LPMSEC	PWR_PMCR	All bits	WI
PWR_SECCFGR	VUSBSEC	PWR_USBSCR	All bits	WI
PWR_SECCFGR	VBSEC	PWR_BDCR	All bits	WI
		PWR_DBPCR	All bits	WI
PWR_SECCFGR	RETSEC	PWR_IORETR	All bits	WI
PWR_SECCFGR	WUPxSEC (x = 1 to 8)	PWR_WUCR	WUPENx	RAZ/WI
			WUPPx	RAZ/WI
			WUPPUPD	RAZ/WI
		PWR_WUSCR	CWUFx	WI
GTZC_TZSC_ SECCFGR	UCPD1SEC	PWR_UCPDR	All bits	RAZ/WI

Table 98. PWR security configuration summary (continued)

Secure configuration register	Security configuration bit	Register name	Secured bits	Non-secure access on secure bits
RCC_SECCFGR	SYSCLKSEC	PWR_VOSCR	VOS[1:0]	RAZ/WI
RCC_SECCFGR	SCMSEC	PWR_SCCR	All bits	WI
RCC_SECCFGR	SCMSEC	PWR_VMCR	All bits	WI

1. PWR_SECCFGR is always secure.

10.9.2 PWR privileged protection

By default, after a reset, all registers can be read or written with both privileged and unprivileged accesses, except PWR_PRIVCFGR, which can be written only with privileged access. PWR_PRIVCFGR can be read by secure and non secure, privileged and unprivileged accesses.
The SPRIV bit in PWR_PRIVCFGR can be written only with secure privileged access. This bit configures the privileged access of all PWR secure functions (defined by PWR_SECCFGR, GTZC, RCC, or GPIO, as shown in *Table 98*).
When the SPRIV bit is set in PWR_PRIVCFGR:

- The PWR secure bits can be written only with privileged access, including PWR_SECCFGR.
- The PWR secure bits can be read only with privileged access except PWR_SECCFGR and PWR_PRIVCFGR that can be read by privileged or unprivileged access.
- An unprivileged access to a privileged PWR bit or register is discarded: the bits are read as 0 and the write to these bits is ignored (RAZ/WI).

The NSPRIV bit of PWR_PRIVCFGR can be written only with privileged access, secure or non-secure. It configures the privileged access of all PWR securable functions configured as non-secure (defined by PWR_SECCFGR, GTZC, RCC, or GPIO, see *Table 98*).
When the NSPRIV bit is set in PWR_PRIVCFGR:

- The PWR securable bits configured as non-secure, can be written only with privileged access.
- The PWR securable bits configured as non-secure, can be read only with privileged access except PWR_PRIVCFGR, which can be read by privileged or unprivileged accesses.
- The VOSRDY and BOOSTRDY bits in PWR_VOSR, PWR_SR, PWR_SVMSR, PWR_BDSR and PWR_WUSR, can be read with privileged or unprivileged accesses.
- An unprivileged access to a privileged PWR bit or register is discarded: the bits are read as 0, and the write to these bits is ignored (RAZ/WI).

10.10 PWR interrupts

Table 99 gives a summary of the interrupt sources and the way to control them.

Table 99. PWR interrupt requests

Interrupt vector	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit Sleep, Stop modes	Exit Standby modes
PVD/AVD output	Programmable voltage detector through EXTI line 16	PVDO/AVDO	EXTI line 16 enabled	Write EXTI PIF16 = 1	Yes	No

10.11 PWR registers

The PWR registers can be accessed in word, half-word and byte format, unless otherwise specified.

10.11.1 PWR power mode control register (PWR_PMCR)

This register is protected against non-secure access when LPMSEC = 1 in the PWR_SECCFGR register.

This register is protected against unprivileged access when LPMSEC = 1 and SPRIV = 1 in the PWR_PRIVCFGR register, or when LPMSEC = 0 and NSPRIV = 1.

Address offset: 0x000

Reset value: 0x0000 000C

		rw	rw			rw		rw				rw	rw		rw

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **SRAM1SO**: AHB SRAM1 shut-off in Stop mode
0: AHB RAM1 content is kept in Stop mode.
1: AHB RAM1 content is lost in Stop mode.

Bit 25 **SRAM2_48SO**: AHB SRAM2 48-Kbyte shut-off in Stop mode.
0: AHB RAM2 48-Kbyte content is kept in Stop mode.
1: AHB RAM2 48-Kbyte content is lost in Stop mode.

Bit 24 **SRAM2_16SO**: AHB SRAM2 16-Kbyte shut-off in Stop mode.
0: AHB RAM2 16-Kbyte content is kept in Stop mode.
1: AHB RAM2 16-Kbyte content is lost in Stop mode.

Bit 23 **SRAM3SO**: AHB SRAM3 shut-off in Stop mode.
0: AHB RAM3 content is kept in Stop mode.
1: AHB RAM3 content is lost in Stop mode.

Bits 22:17 Reserved, must be kept at reset value.

Bit 16 **ETHERNETSO**: ETHERNET RAM shut-off in Stop mode.
0: ETHERNET RAM content is kept in Stop mode.
1: ETHERNET RAM content is lost in Stop mode.

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **AVD_READY**: analog voltage ready

This bit is used only when the analog switch boost needs to be enabled (see BOOSTE bit). It must be set by software when the expected V_{DDA} analog supply level is available. The correct analog supply level is indicated by the AVDO bit (PWR_VMSR register) after setting the AVDEN bit (PWR_VMCR register) and selecting the supply level to be monitored (ALS bits).

0: peripheral analog voltage V_{DDA} not ready (default)

1: peripheral analog voltage V_{DDA} ready.

Bit 12 **BOOSTE**: analog switch V_{BOOST} control

This bit enables the booster to guarantee the analog switch AC performance when the V_{DD} supply voltage is below 2.7 V (reduction of the total harmonic distortion to have the same switch performance over the full supply voltage range) The V_{DD} supply voltage can be monitored through the PVD and the PLS bits.

0: booster disabled (default)

1: booster enabled if analog voltage ready (AVD_READY = 1)

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **FLPS**: flash memory low-power mode in Stop mode

This bit is used to obtain the best trade-off between low-power consumption and restart time when exiting from Stop mode.

When it is set, the flash memory enters low-power mode when the system is in Stop mode.

0: flash memory remains in normal mode when the system enters Stop mode (quick restart time).

1: flash memory enters low-power mode when the system enters Stop mode (low-power consumption).

Note: When system enters Stop mode with SVOS5 enabled, flash memory is automatically forced in low-power mode.

Bit 8 Reserved, must be kept at reset value.

Bit 7 **CSSF**: clear Standby and Stop flags (always read as 0)

This bit is cleared to 0 by hardware.

0: no effect

1: STOPF and SBF flags cleared

Bits 6:4 Reserved, must be kept at reset value.

Bits 3:2 **SVOS[1:0]**: system Stop mode voltage scaling selection

These bits control the V_{CORE} voltage level in system Stop mode, to obtain the best trade-off between power consumption and performance.

00: reserved

01: SVOS5 scale 5

10: SVOS4 scale 4

11: SVOS3 scale 3 (default)

Bit 1 Reserved, must be kept at reset value.

Bit 0 **LPMS**: low-power mode selection

This bit defines the Deepsleep mode.

0: Keeps Stop mode when entering DeepSleep.

1: Allows Standby mode when entering DeepSleep.

10.11.2 PWR status register (PWR_PMSR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SBF	STOPF	Res.	Res.	Res.	Res.	Res.
									r	r					

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **SBF**: System standby flag

This bit is set by hardware and cleared only by a POR or by setting the CSSF bit.

0: system has not been in Standby mode.

1: system has been in Standby mode.

Bit 5 **STOPF**: Stop flag

This bit is set by hardware and cleared only by any reset or by setting the CSSF bit.

0: system has not been in Stop mode.

1: system has been in Stop mode.

Bits 4:0 Reserved, must be kept at reset value.

10.11.3 PWR voltage scaling control register (PWR_VOSCR)

Some register fields are protected against non-secure access depending on RCC_SECCFGR register.

These fields can be protected against unprivileged access depending on PWR_PRIVCFGR register configuration.

Address offset: 0x0010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VOS[1:0]		Res.	Res.	Res.	Res.
										rw	rw				

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:4 **VOS[1:0]**: voltage scaling selection according to performance

These bits control the V_{CORE} voltage level and allow to obtain the best trade-off between power consumption and performance:

- In bypass mode, these bits must also be set according to the external provided core voltage level and related performance.
- When increasing the performance, the voltage scaling must be changed before increasing the system frequency.
- When decreasing performance, the system frequency must first be decreased before changing the voltage scaling.

00: scale 3 (default)

01: scale 2

10: scale 1

11: scale 0

Bits 3:0 Reserved, must be kept at reset value.

10.11.4 PWR voltage scaling status register (PWR_VOSSR)

Address offset: 0x0014

Reset value: 0x0000 2008

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ACTVOS[1:0]		ACTVOS RDY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VOS RDY	Res.	Res.	Res.
r	r	r										r			

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:14 **ACTVOS[1:0]**: voltage output scaling currently applied to V_{CORE}

This field provides the last VOS value.

00: VOS3 (lowest power)

01: VOS2

10: VOS1

11: VOS0 (highest frequency)

Bit 13 **ACTVOSRDY**: Voltage level ready for currently used VOS

0: V_{CORE} is above or below the current voltage scaling provided by ACTVOS[1:0]

1: V_{CORE} is equal to the current voltage scaling provided by ACTVOS[1:0]

Bits 12:4 Reserved, must be kept at reset value.

Bit 3 **VOSRDY**: Ready bit for V_{CORE} voltage scaling output selection.

0: Not ready, voltage level below VOS selected level

1: Ready, voltage level at or above VOS selected level

The VOSRDY flag must be used only when switching from low to high-voltage scale (like switching from VOS3 to VOS0).

Bits 2:0 Reserved, must be kept at reset value.

10.11.5 PWR Backup domain control register (PWR_BDCR)

This register is protected against non-secure access when VBSEC = 1 in the PWR_SECCFGR register.

This register is protected against unprivileged access when VBSEC = 1 and SPRIV = 1 in the PWR_PRIVCFGR register, or when VBSEC = 0 and NSPRIV = 1.

This register is not reset by wake-up from Standby mode, RESET signal and VDD POR. It is only reset by VSW POR and VSWRST reset. This register must not be accessed when VSWRST bit in RCC_BDCR register resets the VSW domain.

MONEN and BREN bits must not be accessed when VSWRST bit in RCC_BDCR register resets the VSW domain. After reset, MONEN and BREN of this register are write-protected. Prior to modifying their content, the DBP bit in PWR_DBPCR register must be set to disable the write protection.

Address offset:0x20

Power-on reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	VBRS	VBE	Res.	Res.	Res.	Res.	Res.	Res.	MONEN	BREN
						rw	rw							rw	rw

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **VBRS**: V_{BAT} charging resistor selection
0: Charge V_{BAT} through a 5 kΩ resistor.
1: Charge V_{BAT} through a 1.5 kΩ resistor.

Bit 8 **VBE**: V_{BAT} charging enable
0: V_{BAT} battery charging disabled.
1: V_{BAT} battery charging enabled.
Note: Reset only by POR.

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **MONEN**: Backup domain voltage and temperature monitoring enable
0: Backup domain voltage and temperature monitoring disabled
1: Backup domain voltage and temperature monitoring enabled

Bit 0 **BREN**: Backup RAM retention in Standby and V_{BAT} modes
When this bit set, the backup regulator (used to maintain the backup RAM content in Standby and V_{BAT} modes) is enabled.
If BREN is cleared, the backup regulator is switched off. The backup RAM can still be used in Run and Stop modes. However its content is lost in Standby and V_{BAT} modes.
If BREN is set, the application must wait till the backup regulator ready flag (BRRDY) is set to indicate that the data written into the SRAM is maintained in Standby and V_{BAT} modes.
0: Backup RAM content lost in Standby and V_{BAT} modes.
1: Backup RAM content preserved in Standby and V_{BAT} modes

10.11.6 PWR Backup domain control register (PWR_DBPCR)

This register is protected against non-secure access when VBSEC = 1 in the PWR_SECCFGR register.

This register is protected against unprivileged access when VBSEC = 1 and SPRIV = 1 in the PWR_PRIVCFGR register, or when VBSEC = 0 and NSPRIV = 1.

Address offset: 0x24

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DBP
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **DBP**: Disable Backup domain write protection

In reset state, all registers and SRAM in Backup domain are protected against parasitic write access. This bit must be set to enable write access to these registers.

0: Write access to Backup domain disabled

1: Write access to Backup domain enabled

10.11.7 PWR Backup domain status register (PWR_BDSR)

This register is not reset by wake-up from Standby mode, RESET signal and VDD POR. It is only reset by VSW POR and VSWRST reset.

Address offset: 0x028

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TEMPH	TEMPL	VBATH	VBATL	Res.	Res.	Res.	BRRDY

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **TEMPH**: temperature level monitoring versus high threshold

0: temperature below high threshold level

1: temperature equal or above high threshold level

Bit 22 **TEMPL**: temperature level monitoring versus low threshold

0: temperature above low threshold level

1: temperature equal or below low threshold level

Bit 21 **VBATH**: V_{BAT} level monitoring versus high threshold
0: V_{BAT} level below high threshold level
1: V_{BAT} level equal or above high threshold level

Bit 20 **VBATL**: V_{BAT} level monitoring versus low threshold
0: V_{BAT} level above low threshold level
1: V_{BAT} level equal or below low threshold level

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **BRRDY**: backup regulator ready
This bit is set by hardware to indicate that the backup regulator is ready.
0: backup regulator not ready
1: backup regulator ready

Bits 15:0 Reserved, must be kept at reset value.

10.11.8 PWR USB Type-C power delivery register (PWR_UCPDR)

This register is protected against non-secure access when UCPD1SEC = 1 in the TZSC_SECCFGR register.

This register is protected against unprivileged access when UCPD1SEC = 1 and SPRIV = 1 in the PWR_PRIVCFGR register, or when UCPD1SEC = 0 and NSPRIV = 1.

Address offset: 0x02C

Reset value: 0x0000 0000

Not affected by exit Standby mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	UCPD_STBY	UCPD_DBDIS
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **UCPD_STBY**: USB Type-c and Power delivery Standby mode
When set, this bit is used to memorize the UCPD configuration in Standby mode. This bit must be written to 1 just before entering Standby mode when using UCPD, and it must be written to 0 after exiting the standby mode and before writing any UCPD register.

Bit 0 **UCPD_DBDIS**: USB Type-C and power delivery dead battery disable
After exiting reset, the USB Type-C “dead battery” behavior is enabled, which may have a pull-down effect on CC1 and CC2 pins. It is recommended to disable it in all case, either to stop this pull-down or to hand over control to the UCPD (which should therefore be initialized before doing the disable).
0: Enable USB Type-C dead battery pull-down behavior on UCPDx_CC1 and UCPDx_CC2 pins.
1: Disable USB Type-C dead battery pull-down behavior on UCPDx_CC1 and UCPDx_CC2 pins.

10.11.9 PWR supply configuration control register (PWR_SCCR)

This register is protected against non-secure access when SCMSEC = 1 in the PWR_SECCFGR register.

This register is protected against unprivileged access when SCMSEC = 1 and SPRIV = 1 in the PWR_PRIVCFGR register, or when SCMSEC = 0 and NSPRIV = 1.

Address offset: 0x030

Reset value: 0x0000 0X00

The reset value of register change according to the package. The bits 9 and 8 indicate the power configuration. Their values are exclusive.

Reset by POR only, not reset by wake-up from Standby mode and RESET pad. The BYPASS bit of this register is written once after POR. Written-once mechanism locks the register and any further write access is ignored. The system must be power cycled before writing a new value.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	SMPSEN	LDOEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BYPASS
						r	r								rwo

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **SMPSEN**: SMPS enable
The value is set by hardware when the package uses the SMPS regulator.

Bit 8 **LDOEN**: LDO enable
The value is set by hardware when the package uses the LDO regulator.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **BYPASS**: power management unit bypass
0: Power management unit normal operation. Use the internal regulator.
1: Power management unit bypassed. Use the external power (voltage monitoring still active)

10.11.10 PWR voltage monitor control register (PWR_VMCR)

This register is protected against non-secure access when SCMSEC = 1 in the PWR_SECCFGR register.

This register is protected against unprivileged access when SCMSEC = 1 and SPRIV = 1 in the PWR_PRIVCFGR register, or when SCMSEC = 0 and NSPRIV = 1.

The PVDE and PLS bits are protected by lock mechanism. The lock control is in the SBS module controlled by PVDL bit in SBS_CFGR2 register. By default, the PVDE and PLS are unlocked.

Address offset: 0x034

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

					rw	rw	rw					rw	rw	rw	rw

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:9 **ALS[1:0]**: analog voltage detector (AVD) level selection
These bits select the analog voltage detector (AVD) thresholds.
00: AVD level0 (V_{AVD0} ~ 1.7 V)
01: AVD level1 (V_{AVD1} ~ 2.1 V)
10: AVD level2 (V_{AVD2} ~ 2.5 V)
11: AVD level3 (V_{AVD3} ~ 2.8 V)

Bit 8 **AVDEN**: peripheral voltage monitor on V_{DDA} enable
0: peripheral voltage monitor on V_{DDA} disabled
1: peripheral voltage monitor on V_{DDA} enabled

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:1 **PLS[2:0]**: programmable voltage detector (PVD) level selection
These bits select the programmable voltage detector (PVD) thresholds.
000: PVD level0 (VPVD0 ~ 1.95 V)
001: PVD level1 (VPVD1 ~ 2.10 V)
010: PVD level2 (VPVD2 ~ 2.25 V)
011: PVD level3 (VPVD3 ~ 2.40 V)
100: PVD level4 (VPVD4 ~ 2.55 V)
101: PVD level5 (VPVD5 ~ 2.70 V)
110: PVD level6 (VPVD6 ~ 2.85 V)
111: PVD_IN pin

Bit 0 **PVDE**: PVD enable
0: PVD disabled
1: PVD enabled

10.11.11 PWR USB supply control register (PWR_USBSCR)

This register is protected against non-secure access when VUSBSEC = 1 in the PWR_SECCFGR register.

This register is protected against unprivileged access when VUSBSEC = 1 and SPRIV = 1 in the PWR_PRIVCFGR register, or when VUSBSEC = 0 and NSPRIV = 1.

Address offset: 0x038

Reset value: 0x0000 0000

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **USB33SV:** independent USB supply valid

This bit is used to validate the V_{DDUSB} supply for electrical and logical isolation purpose. Setting this bit is mandatory to use the USBFS peripheral. If V_{DDUSB} is not always present in the application, the V_{DDUSB} voltage monitor can be used to determine whether this supply is ready or not.

0: V_{DDUSB} is not present. Logical and electrical isolation is applied to ignore this supply.

1: V_{DDUSB} is valid.

Bit 24 **USB33DEN**: V_{DDUSB} voltage level detector enable

0: V_{DDUSB} voltage level detector disabled

1: V_{DDUSB} voltage level detector enabled

Bits 23:0 Reserved, must be kept at reset value.

10.11.12 PWR voltage monitor status register (PWR_VMSR)

Address offset: 0x03C

Reset value: 0x00X0 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **USB33RDY**: V_{DDUSB} ready

0: V_{DDUSB} is below the threshold of the V_{DDUSB} voltage monitor.

1: V_{DDUSB} is equal or above the threshold of the V_{DDUSB} voltage monitor.

Bit 23 Reserved, must be kept at reset value.

Bit 22 **PVDO**: programmable voltage detect output

This bit is set and cleared by hardware. It is valid only if the PVD has been enabled by the PVDE bit.

0: V_{DD} is equal or higher than the PVD threshold selected through the PLS[2:0] bits.

1: V_{DD} is lower than the PVD threshold selected through the PLS[2:0] bits.

Note: Since the PVD is disabled in Standby mode, this bit is equal to 0 after Standby or reset until the PVDE bit is set.

Bit 21 Reserved, must be kept at reset value.

Bit 20 **VDDIO2RDY**: voltage detector output on V_{DDIO2}
This bit is set and cleared by hardware.
0: V_{DDIO2} is below 1.2 V.
1: V_{DDIO2} is above or equal to 1.2 V.

Bit 19 **AVDO**: analog voltage detector output on V_{DDA}
This bit is set and cleared by hardware. It is valid only if AVD on VDDA is enabled by the AVDEN bit.
0: V_{DDA} is equal or higher than the AVD threshold selected with the ALS[2:0] bits.
1: V_{DDA} is lower than the AVD threshold selected with the ALS[2:0] bits.
Note: Since the AVD is disabled in Standby mode, this bit is equal to 0 after standby or reset until the AVDEN bit is set.

Bits 18:0 Reserved, must be kept at reset value.

10.11.13 PWR wake-up status clear register (PWR_WUSCR)

Each register bit CWUFx (x = 1 to 8) is protected against non-secure access when WUPxSEC = 1 in the PWR_SECCFGR register.

Each bit CWUFx is protected against unprivileged access when WUPxSEC = 1 in PWR_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when WUPxSEC 0 and NSPRIV = 1.

Address offset: 0x040

Reset value: 0x0000 0000

								w	w	w	w	w	w	w	w

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **CWUFx**: clear wake-up pin flag for WUFx (x = 8 to 1)
These bits are always read as 0.
0: no effect
1: writing 1 clears the WUFx wake-up pin flag (bit is cleared to 0 by hardware).

10.11.14 PWR wake-up status register (PWR_WUSR)

Address offset: 0x044

Reset value: 0x0000 0000

								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **WUFx**: wake-up pin WUFx flag (x = 8 to 1)

This bit is set by hardware and cleared only by a RESET pin or by setting the CWUFx bit in PWR_WUSCR register.

0: no wake-up event occurred.

1: a wake-up event received from WUFx pin.

10.11.15 PWR wake-up configuration register (PWR_WUCR)

Each register bit WUPPUPDx (x = 1 to 8) and WUPPx (x = 1 to 8) and WUPENx (x = 1 to 8) is protected against non-secure access when WUPxSEC = 1 (x = 1 to 8) in the PWR_SECCFGR register.

Each bit WUPENx is protected against unprivileged access when WUPxSEC = 1 in PWR_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when WUPxSEC = 0 and NSPRIV=1.

Address offset: 0x048

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **WUPPUPDx[1:0]**: wake-up pin pull configuration for WKUPx (x = 8 to 1)

These bits define the I/O pad pull configuration used when WUPENx = 1. The associated GPIO port pull configuration must be set to the same value or to 00. The wake-up pin pull configuration is kept in Standby mode.

00: no pull-up

01: pull-up

10: pull-down

11: reserved

Bits 15:8 **WUPPx**: wake-up pin polarity bit for WUPx (x = 8 to 1)

These bits define the polarity used for event detection on WUPx external wake-up pin.

0: detection on high level (rising edge)

1: detection on low level (falling edge)

Bits 7:0 **WUPENx**: enable wake-up pin WUPx (x = 8 to 1)

These bits are set and cleared by software.

0: an event on WUPx pin does not wake-up the system from Standby mode.

1: a rising or falling edge on WUPx pin wakes up the system from Standby mode.

Note: An additional wake-up event is detected if WUPx pin is enabled (by setting the WUPENx bit) when WUPx pin level is already high when WUPPx selects rising edge, or low when WUPPx selects falling edge.

10.11.16 PWR I/O retention register (PWR_IORETR)

This register is protected against non-secure access when RETSEC=1 in the PWR_SECCFGR register.

This register is protected against unprivileged access when RETBSEC=1 and SPRIV=1 in the PWR_PRIVCFGR register, or when RETSEC=0 and NSPRIV=1.

Address offset: 0x050

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

															rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **JTAGIORETEN**: IO retention enable for JTAG IOs

0: IO Retention mode is disable.

1: IO Retention mode is enabling for PA13, PA14, PA15 and PB4.

when entering into standby mode, the output is sampled, and apply to the output IO during the standby power mode

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **IORETEN**: IO retention enable:

0: IO Retention mode is disabled.

1: IO Retention mode is enabling for all IO except the IO support the standby functionality and PA13, PA14, PA15 and PB4.

When entering into standby mode, the output is sampled, and apply to the output IO during the standby power mode.

Note: The IO state is not retained if the DBG_STANDBY bit is set in DBGMCU_CR register.

10.11.17 PWR security configuration register (PWR_SECCFGR)

This register can be written only when the access is secure. It can be read by secure or non-secure access.

This register is write-protected against unprivileged write access when SPRIV=1 in the PWR_PRIVCFGR.

Address offset: 0x100

Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **VUSBSEC**: voltage USB secure protection
0: PWR_USBSCR can be read and written with secure or non-secure access.
1: PWR_USBSCR can be read and written only with secure access..

Bit 14 **VBSEC**: Backup domain secure protection
0: PWR_BDCR, PWR_DBPCR can be read and written with secure or non-secure access.
1: PWR_BDCR, PWR_DBPCR can be read and written only with secure access.

Bit 13 **SCMSEC**: supply configuration and monitoring secure protection.
0: PWR_SCCR and PWR_VMCR can be read and written with secure or non-secure access.
1: PWR_SCCR and PWR_VMCR can be read and written only with secure access.

Bit 12 **LPMSEC**: low-power modes secure protection
0: PWR_PMCR can be read and written with secure or non-secure access.
1: PWR_PMCR can be read and written only with secure access.

Bit 11 **RETSEC**: retention secure protection
0: PWR_IORETR can be read and written with secure or non-secure access.
1: PWR_IORETR can be read and written only with secure access.

Bits 10:8 Reserved, must be kept at reset value.

Bits 7:0 **WUPxSEC**: WUPx secure protection (x = 8 to 1)
0: The bits related to the WKUPx wake-up pin in PWR_WUSCR and PWR_WUCR can be read and written with secure or non-secure access.
1: The bits related to the WKUPx wake-up pin in PWR_WUSCR and PWR_WUCR can be read and written only with secure access.

10.11.18 PWR privilege configuration register (PWR_PRIVCFGR)

This register can be written only when the access is privileged. It can be read by privileged or unprivileged access.

Address offset: 0x104

Reset value: 0x0000 0000

11 Reset and clock control (RCC)

11.1 Introduction

The reset and clock control (RCC) manages the different resets, and generates the clocks for the bus and peripherals.

11.2 RCC pins and internal signals

The table below lists the RCC inputs and output signals connected to package pins or balls.

Table 101. RCC input/output signals connected to package pins or balls

Signal name	Signal type	Description
NRST	I/O	System reset, can be used to provide reset to external devices
OSC32_IN	I	32 kHz oscillator input
OSC32_OUT	O	32 kHz oscillator output
OSC_IN	I	System oscillator input
OSC_OUT	O	System oscillator output
MCO	O	Output clock for external devices
LSCO	O	Low-speed output clock for external devices
AUDIOCLK	I	External kernel clock input for SAI1, SAI2, I2S1, I2S2, and I2S3

11.3 RCC reset functional description

There are three types of reset:

- a system reset
- a power reset
- a Backup domain reset

11.3.1 Power reset

A power reset is generated when one of the following events occurs:

- a brownout reset (BOR)
- when exiting Standby mode

A brownout reset, including power-on or power-down reset (POR/PDR), sets all registers to their reset values except the ones in the Backup domain.

When exiting Standby mode, all registers in the core domain are set to their reset value. Registers outside the core domain (RTC, WKUP, IWDG, and GPIO pullup/pulldown configuration during Standby and Standby mode exit) are not impacted.

11.3.2 System reset

A system reset sets all registers to their reset values except the reset flags in *RCC reset status register (RCC_RSR)* and the registers in the Backup domain.

A system reset is generated when one of the following events occurs:

- a low level on the NRST pin (external reset)
- a window watchdog event (WWDG reset)
- an independent watchdog event (IWDG reset)
- a software reset (SW reset) (see *Software reset*)
- a low-power mode security reset (see *Low-power mode security reset*)
- a brownout reset

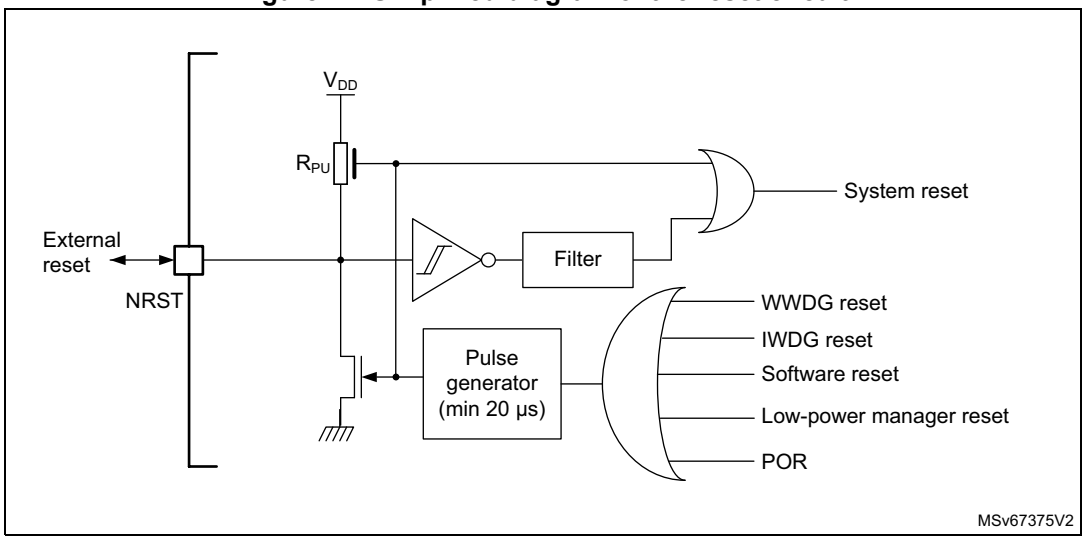
The reset source can be identified by checking the reset flags in *RCC reset status register (RCC_RSR)*.

These sources act on the NRST pin and this pin is always kept low during the delay phase. The reset service routine vector is selected depending on product state, on Boot option bytes or on both.

The system reset signal provided to the device is output on the NRST pin. The pulse generator guarantees a minimum reset pulse duration of 20 µs for each internal reset source. In case of an external reset, the reset pulse is generated while the NRST pin is asserted low.

In case on an internal reset, the internal pull-up R_{PU} is deactivated to save the power consumption through the pull-up resistor.

Figure 47. Simplified diagram of the reset circuit



Software reset

The SYSRESETREQ bit in Cortex-M33 application interrupt and reset control register must be set to force a software reset on the device.

Low-power mode security reset

To avoid that critical applications mistakenly enter a low-power mode, the following low-power mode security resets are available. If enabled in option bytes, the resets are generated in any of the following conditions:

- Entering Standby mode: this type of reset is enabled by resetting nRST_STDBY bit in user option bytes. In this case, whenever a Standby mode entry sequence is successfully executed, the device is reset instead of entering Standby mode.
- Entering Stop mode: this type of reset is enabled by resetting nRST_STOP bit in user option bytes. In this case, whenever a Stop mode entry sequence is successfully executed, the device is reset instead of entering Stop mode.

For further information on the user option bytes, refer to *Section 7.4.1: Option bytes description*.

11.3.3 Backup domain reset

The Backup domain has two specific resets, generated when one of the following events occurs:

- a software reset, triggered by setting the VSWRST bit in the *RCC Backup domain control register (RCC_BDCR)*. Write access to this domain must be enabled before setting VSWRST bit to perform the reset.
- a V_{DD} or V_{BAT} power on, if both supplies have previously been powered off

A Backup domain reset affects the LSE oscillator, the RTC, the backup registers, the backup SRAM, and the RCC_BDCR register.

11.3.4 Reset source identification

The application can identify the reset source by checking the reset flags in the RCC_RSR register.

The software can reset the flags by setting RMVF bit.

Table 102 shows how the status bits of the RCC_RSR register behave according to the situation that generated the reset. For example, when an IWDG timeout occurs, if the CPU is reading the RCC_RSR register during the boot phase, both PINRSTF and IWDGRSTF bits are set, indicating that the IWDG also generated a pin reset.

Table 102. Reset source identification (RCC_RSR)(1)

Reset		LPWRRSTF	WWDGRSTF	IWDGRSTF	SFTRSTF	BORRSTF	PINRSTF
1	Power-on reset	0	0	0	0	1	1
2	Pin/pad reset	0	0	0	0	0	1
3	Brownout (low or high) reset	0	0	0	0	1	1
4	System reset generated by CPU	0	0	0	1	0	1
5	WWDG reset	0	1	0	0	0	1

Table 102. Reset source identification (RCC_RSR)(1) (continued)

Reset		LPWRRSTF	WWDGRSTF	IWDGRSTF	SFTRSTF	BORRSTF	PINRSTF
6	IWDG reset	0	0	1	0	0	1
7	Illegal stop entry reset	1	0	0	0	0	1

1. Gray cells highlight the register bits that are set.

11.4 RCC clocks functional description

Four different clock sources can be used to drive the system clock (SYSCLK):

- HSI: high-speed internal up to 64 MHz RC oscillator clock
- CSI: low power internal RC oscillator clock
- HSE: high-speed external crystal or clock, from 4 to 50 MHz
- PLL1 clock

The HSI is used as system clock source after startup from reset, configured at 32 MHz.

The device has the following additional clock sources:

- LSI: 32 kHz low-speed internal RC that drives the independent watchdog and optionally the RTC used for auto-wakeup from Stop and Standby modes
- LSE: 32.768 kHz low-speed external crystal or clock that optionally drives the real-time clock (rtc_ck)
- HSI48: internal 48 MHz RC that potentially drives the USB FS and the RNG
- PLL2 and PLL3 clocks

Each clock source can be switched on or off independently when it is not used, to optimize power consumption.

Several prescalers can be used to configure the AHB frequency, the APB1 and APB2 domains. The maximum frequency of the AHB and APB domains is 250 MHz.

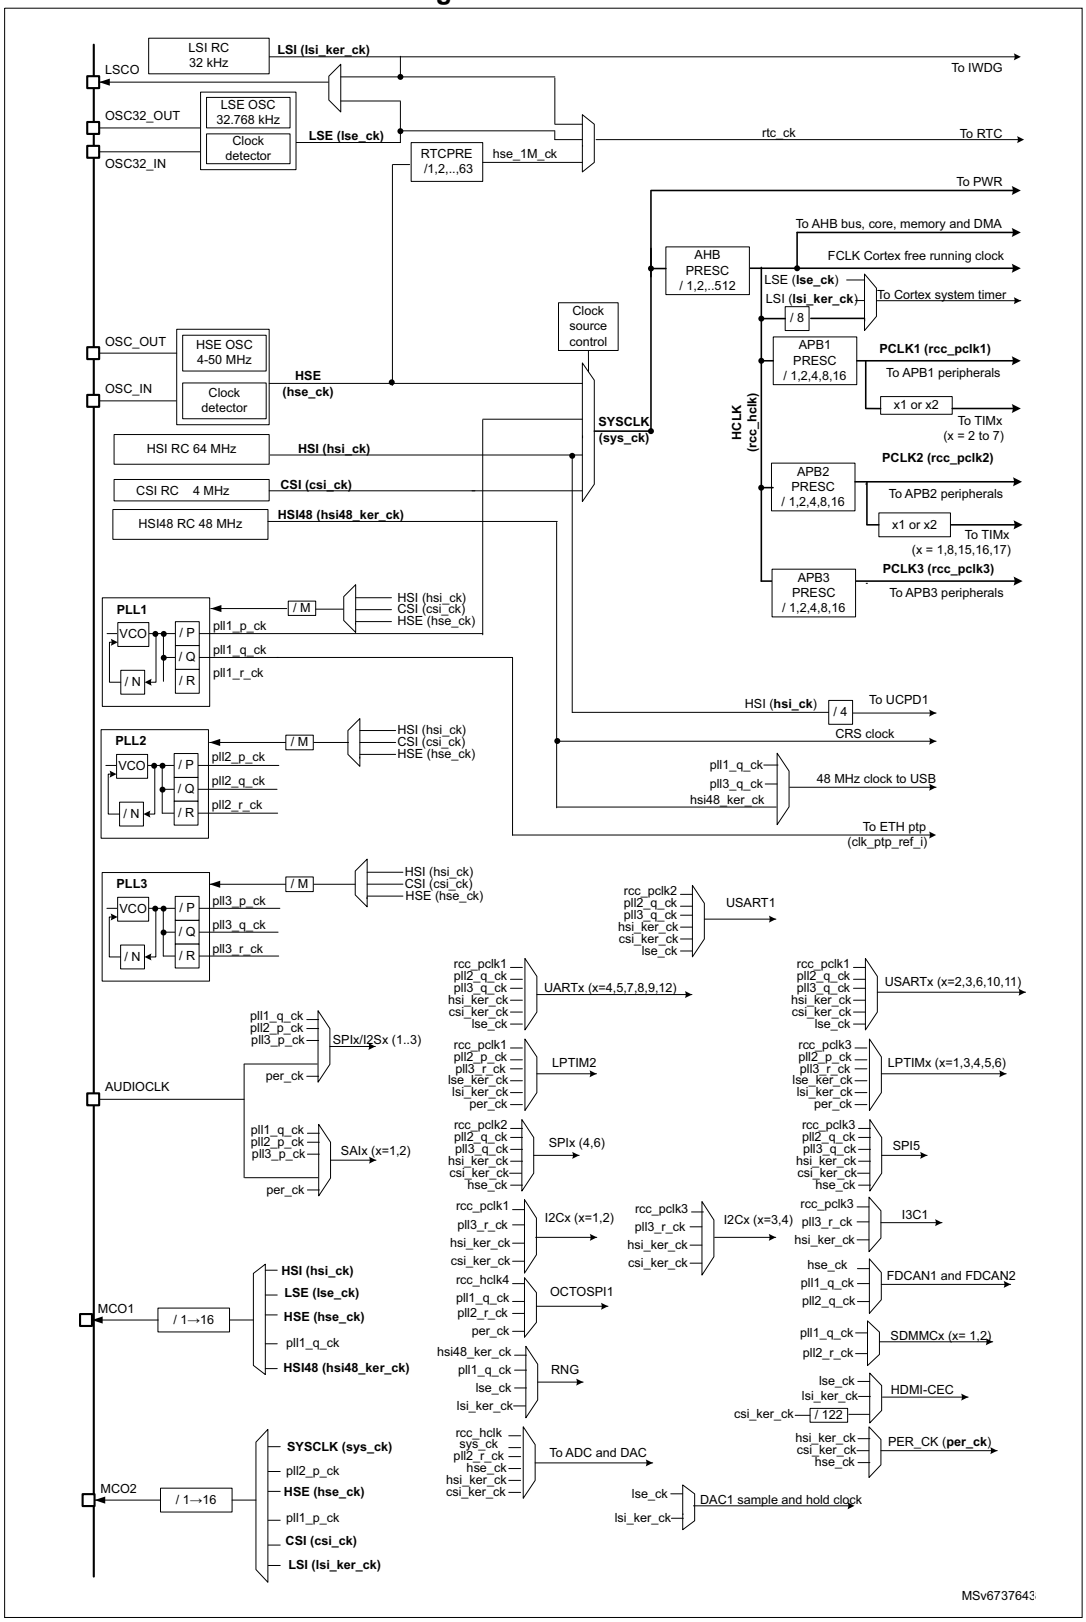
All the peripheral clocks are derived from their bus clock (HCLK, PCLK1, PCLK2 or PCLK3) except the following ones that receive an independent kernel clock. This kernel clock can be selected by software between several sources thanks to RCC_CCIPRx registers (x = 1,2,3, 4,5).

In addition, the RTC kernel clock is selected by software in RCC_BDCR. The IWDG clock is always the LSI 32 kHz clock.

The RCC feeds the Cortex system timer (SysTick) external clock with the AHB clock (HCLK) divided by eight, or LSE or LSI. The SysTick can work either with this clock or directly with the Cortex clock (HCLK), configurable in the SysTick control and status register.

FCLK acts as Cortex-M33 free-running clock.

Figure 48. Clock tree



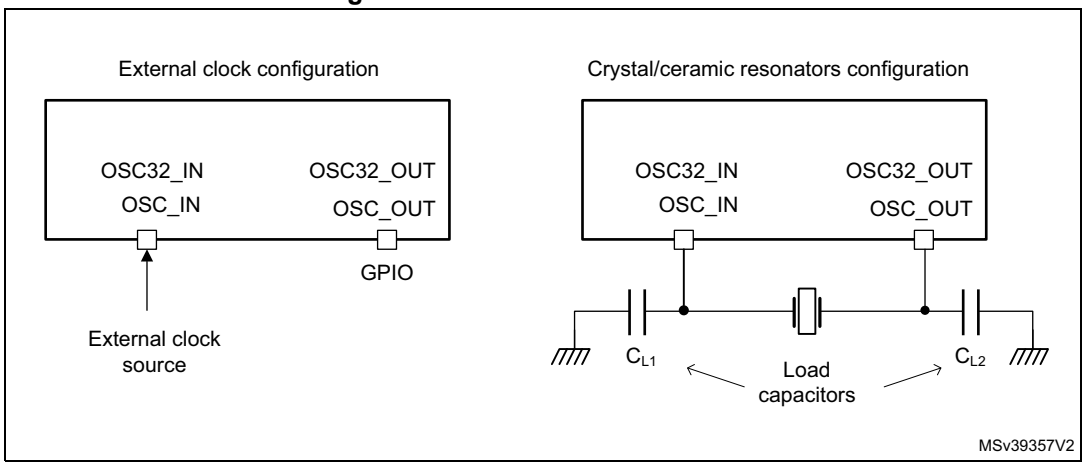
1. For details on the internal/external clock source, refer to the Electrical characteristics in the datasheet.

11.4.1 HSE clock

The HSE block can generate a clock from two possible sources:

- an external crystal/ceramic resonator
- an external clock source

Figure 49. HSE/ LSE clock sources



External clock source (HSE bypass)

In this mode, an external clock source must be provided to OSC_IN pin. The external clock can be low swing (analog) or digital. If this clock is directly used by a peripheral, the duty cycle requirement is defined by the peripheral and the application (refer to datasheet for more details).

In case of an analog clock (low swing) the HSEBYP and HSEON bits must be set to 1 in the *RCC clock control register (RCC_CR)*.

In case of a digital clock, the HSEBYP and the HSEEXT bits must be set to 1 followed by setting the HSEON bit to 1 in the *RCC clock control register (RCC_CR)*.

External crystal/ceramic resonator

The oscillator is enabled by setting the HSEBYP bit to 0 and HSEON bit to 1.

The HSE can be used when the product requires a very accurate high-speed clock.

The associated hardware configuration is shown in *Figure 49*: the resonator and the load capacitors must be placed as close as possible to the oscillator pins to minimize output distortion and startup stabilization time. The loading capacitance values must be adjusted according to the selected crystal or ceramic resonator. Refer to the electrical characteristics section of the datasheet for more details.

The HSERDY flag of the *RCC clock control register (RCC_CR)* indicates whether the HSE oscillator is stable or not. At startup, the **hse_ck** clock is not released until this bit is set by hardware. An interrupt can be generated if enabled in the *RCC clock source interrupt enable register (RCC_CIER)*.

The HSE can be switched ON and OFF through the HSEON bit. Note that the HSE cannot be switched OFF if one of the following two conditions is met:

- the HSE is used directly (via software mux) as system clock
- the HSE is selected as reference clock for PLL1, with PLL1 enabled and selected to provide the system clock (via software mux).

In that case the hardware does not allow programming the HSEON bit to 0.

The HSE is automatically disabled by hardware, when the system enters Stop or Standby mode.

In addition, the HSE clock can be driven to the MCO1 and MCO2 outputs and used as clock source for other application components.

11.4.2 HSI clock

The HSI block provides the default clock to the product.

The HSI is a high-speed internal RC oscillator that can be used directly as system clock, peripheral clock, or as PLL input. A predivider allows the application to select an HSI output frequency of 8, 16, 32 or 64 MHz. This predivider is controlled by the HSIDIV.

The HSI advantages are the following:

- low-cost clock source, as no external crystal is required
- faster startup time than HSE (a few microseconds)

The HSI frequency, even with frequency calibration, is less accurate than an external crystal oscillator or ceramic resonator.

The HSI can be switched ON and OFF using the HSION bit. Note that the HSI cannot be switched OFF if one of the two conditions is met:

- the HSI is used directly (via software mux) as system clock
- the HSI is selected as reference clock for PLL1, with PLL1 enabled and selected to provide the system clock (via software mux).

In that case the hardware does not allow programming the HSION bit to 0. Note that the HSIDIV cannot be changed if the HSI is selected as reference clock for at least one enabled PLL (PLLxON bit set to 1). In that case the hardware does not update the HSIDIV with the new value. However it is possible to change the HSIDIV if the HSI is used directly as system clock.

The HSIRDY flag indicates if the HSI is stable or not. At startup, the HSI output clock is not released until this bit is set by hardware.

The HSI clock can also be used as a backup source (auxiliary clock) if the HSE fails (refer to *Section 11.4.10: Clock security system (CSS)*). The HSI can be disabled or not when the system enters Stop mode.

In addition, the HSI clock can be driven to the MCO1 output and used as clock source for other application components.

Care must be taken when the HSI is used as kernel clock for communication peripherals, the application must take into account the following parameters:

- the time interval between the moment where the peripheral generates a kernel clock request and the moment where the clock is really available
- the frequency accuracy.

Note: The HSI can remain enabled when the system is in Stop mode.

HSI calibration

RC oscillator frequencies can vary from one chip to another due to manufacturing process variations. That is why each device is factory calibrated by STMicroelectronics to achieve an accuracy of ACCHSI (refer to the product datasheet for more information).

After a power-on reset, the factory calibration value is loaded in the HSICAL[11:0] bits. If the application is subject to voltage or temperature variations, this may affect the RC oscillator frequency. The user application can trim the HSI frequency using the HSITRIM[6:0] bits.

Note: HSICAL[11:0] and HSITRIM[6:0] bits are located in the RCC CSI calibration register (RCC_CSICFGR).

11.4.3 CSI oscillator

The CSI is a low-power RC oscillator that can be used directly as system clock, peripheral clock, or PLL input.

The CSI advantages are the following:

- low-cost clock source since no external crystal is required
- faster startup time than HSE (a few microseconds)
- very low-power consumption,

The CSI provides a clock frequency of about 4 MHz, while the HSI is able to provide a clock up to 64 MHz.

CSI frequency, even with frequency calibration, is less accurate than an external crystal oscillator or ceramic resonator.

The CSI can be switched ON and OFF through the CSION bit. The CSIRDY flag indicates whether the CSI is stable or not. At startup, the CSI output clock is not released until this bit is set by hardware.

The CSI cannot be switched OFF if one of the two conditions is met:

- The CSI is used directly (via software mux) as system clock.
- The CSI is selected as reference clock for PLL1, with PLL1 enabled and selected to provide the system clock (via software mux).

In that case the hardware does not allow programming the CSION bit to 0.

The CSI can be disabled or not when the system enters Stop mode.

In addition, the CSI clock can be driven to the MCO2 output and used as clock source for other application components.

Even if the CSI settling time is faster than the HSI, care must be taken when the CSI is used as kernel clock for communication peripherals: the application must take into account the following parameters:

- the time interval between the moment where the peripheral generates a kernel clock request and the moment where the clock is really available,
- the frequency precision.

Note: CSION and CSIRDY bits are located in the RCC clock control register (RCC_CR).

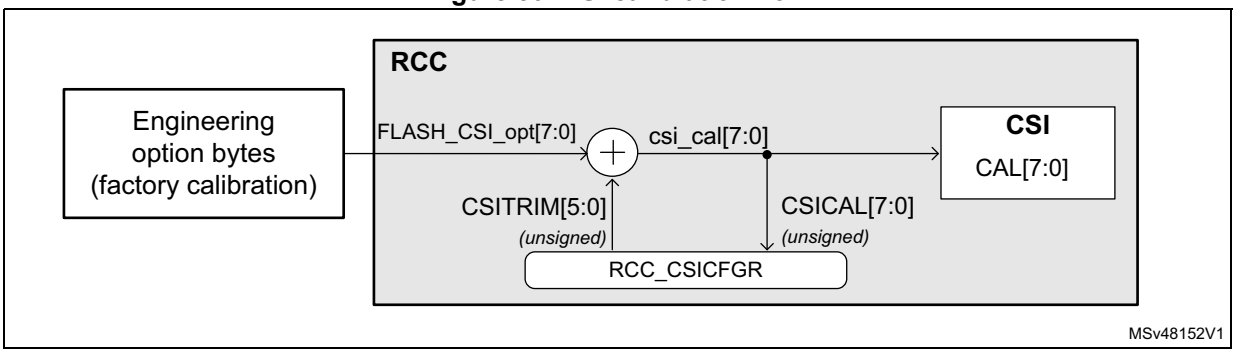
CSI calibration

RC oscillator frequencies can vary from one chip to another due to manufacturing process variations, this is why each device is factory calibrated to achieve ACC_{CSI} accuracy (refer to the product datasheet for more information). After reset, the factory calibration value is loaded in the CSICAL[7:0] bits.

Voltage and/or temperature variations affect the RC oscillator frequency. The user application can trim the CSI frequency using the CSITRIM[5:0] bits.

Note: Bits CSICAL[7:0] and CSITRIM[5:0] are located into the RCC CSI calibration register (RCC_CSICFGR).

Figure 50. CSI calibration flow



11.4.4 HSI48 clock

The HSI48 clock signal is generated from an internal 48 MHz RC oscillator, and can be used directly for USB and for random number generator (RNG).

The internal 48 MHz RC oscillator is mainly dedicated to provide a high-precision clock to the USB peripheral by means of a special clock recovery system (CRS) circuitry. The CRS can use the USB SOF signal, the LSE, or an external signal to automatically and quickly adjust the oscillator frequency on-the-fly. It is disabled as soon as the system enters Stop or Standby mode. When the CRS is not used, the HSI48 RC oscillator runs on its default frequency, subject to manufacturing process variations.

For more details on how to configure and use the CRS peripheral, refer to *Section 12: Clock recovery system (CRS)*.

The HSI48RDY flag in the RCC_CR register indicates whether the HSI48 RC oscillator is stable or not. At startup, the HSI48 RC oscillator output clock is not released until this bit is set by hardware.

The HSI48 can be switched on and off using the HSI48ON bit in the RCC_CR register.

11.4.5 PLL description

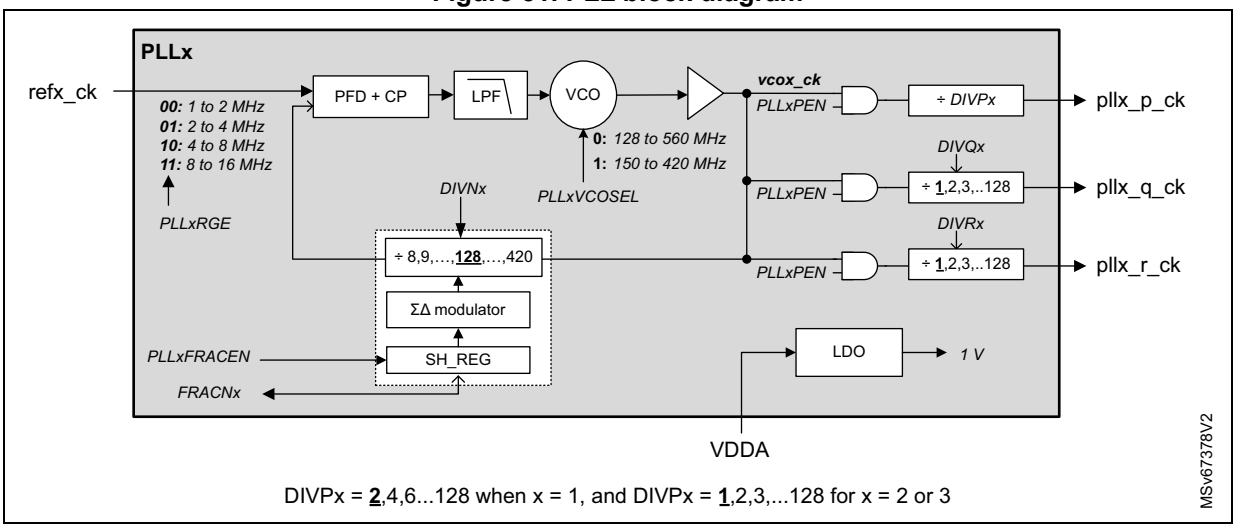
The RCC features three PLLs:

- a main PLL (PLL1), generally used to provide clocks to the CPU and some peripherals
- two dedicated PLLs (PLL2 and PLL3), used to generate the kernel clock for peripherals

The PLLs integrated into the RCC are completely independent. They offer the following features:

- A VCO supporting two modes:
  - a wide-range
  - a low-range used, for instance, in audio applications
- Input frequency range:
  - 2 to 16 MHz for the VCO in wide-range mode
  - 1 to 2 MHz for the VCO in low-range mode
- Capability to work either in integer or fractional mode
- 13-bit sigma-delta modulator, allowing to fine-tune the VCO frequency by steps of 11 to 0.3 ppm
- The sigma-delta modulator can be updated on-the-fly without generating frequency overshoots on PLLs outputs
- Each PLL offers three outputs with post-dividers

Figure 51. PLL block diagram



The PLLs are controlled via RCC_PLLxDIVR, RCC_PLLxFRACR, RCC_PLLCFGR, and RCC_CR registers.

The frequency of the reference clock provided to the PLLs (**refx_ck**) must range from 1 to 16 MHz. The PLLxM dividers of the RCC PLLx clock source selection register (RCC_PLLxCFGR) must be properly programmed to match this condition. In addition, the PLLxRGE[1:0] field of the RCC PLLx clock source selection register (RCC_PLLxCFGR) must be set according to the reference input frequency to optimize performance.

The user application can then configure the VCO. The smaller range (150 to 420 MHz) must be chosen when the reference clock frequency is lower than 2 MHz.

To reduce the power consumption, it is recommended to configure the VCO output to the smaller range.

DIVNx loop divider must be programmed to achieve the expected frequency at VCO output. In addition, the VCO output range must be respected.

The PLLs operate in integer mode when the value of SH_REG bit of the FRACNx shadow register is set to 0. The SH_REG bit is updated with the FRACNx value when PLLxFRACEN

bit goes from 0 to 1. The sigma-delta modulator is designed to minimize the jitter impact, while allowing very small frequency steps.

The PLLs can be enabled by setting PLLxON to 1. The PLLxRDY bits indicate that the PLL is ready (locked).

*Note: Before enabling the PLLs, make sure that the reference frequency (**refx_ck**) provided to it is stable, so the hardware does not allow changing PLLxM when the PLLx is ON, and it is also not possible to change PLLSRC when one of the PLLs is ON.*

The hardware prevents writing PLL1ON to 0 if the PLL1 is currently used to deliver the system clock. There are other hardware protections on the clock generators (refer to HSE clock, HSI clock, and CSI oscillator).

The following PLL parameters cannot be changed once the PLL is enabled: DIVNx, PLLxRGE, PLLxVCOSEL, PLLxP (DIVP), PLLxQ (DIVQ), and PLLxR (DIVR).

For optimal behavior of the PLL when one of the post-divider (DIVP, DIVQ or DIVR) is not used, the application must set the enable bit (DIVyEN) as well as the corresponding post-divider bits (DIVP, DIVQ or DIVR) to 0.

If the above rules are not respected, the PLL output frequency is not guaranteed.

Output frequency computation

When the PLL is configured in integer mode (SH_REG = 0), the VCO frequency (F_{VCO}) is given by the following expression:

$$F_{VCO} = F_{REF\_CK} \times DIVN$$

$$F_{PLL\_y\_CK} = (F_{VCO} / (DIVy + 1)) \text{ with y = P, Q or R}$$

When the PLL is configured in fractional mode (SH_REG different from 0), the DIVN divider must be initialized before enabling the PLLs. However, it is possible to change the value of FRACNx on-the-fly without disturbing the PLL output.

This feature can be used either to generate a specific frequency from any crystal value with a good accuracy, or to fine-tune the frequency on-the-fly.

For each PLL, the VCO frequency is given by the following formula:

$$F_{VCO} = F_{ref\_ck} \times \left(DIVN + \frac{FRACN}{2^{(13)}} \right)$$

Note: For PLL1, DIVP can only take odd values.

The PLLs are disabled by hardware when:

- the system enters Stop or Standby mode
- an HSE failure occurs when HSE or PLL (clocked by HSE) are used as system clock

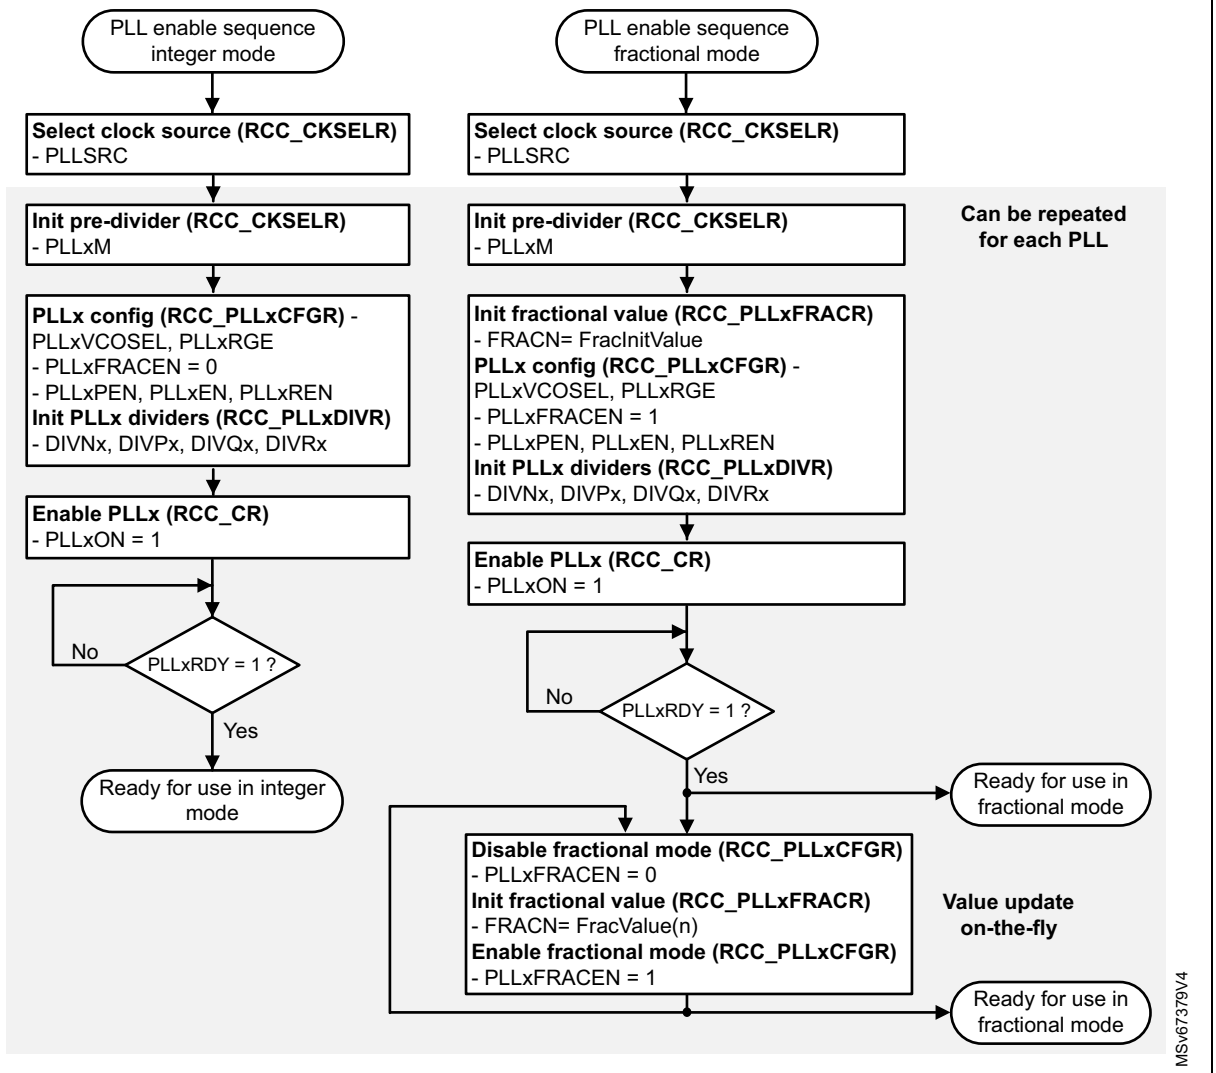
PLL initialization phase

Figure 52 shows the recommended PLL initialization sequence in integer and fractional mode. The PLLx are supposed to be disabled at the start of the initialization sequence:

1. Initialize the PLLs registers according to the required frequency.
   – Set PLLxFRACEN of RCC PLLx clock source selection register (RCC_PLLxCFGR) to 0 for integer mode.
   – For fractional mode, set FRACN to the required initial value (FracInitValue) and then set PLLxFRACEN to 1.
2. Once the PLLxON bit is set to 1, the user application must wait until PLLxRDY bit is set to 1. If the PLLx is in fractional mode, the PLLxFRACEN bit must not be set back to 0 as long as PLLxRDY = 0.
3. Once the PLLxRDY bit is set to 1, the PLLx is ready to be used.
4. If the application intends to tune the PLLx frequency on-the-fly (possible only in fractional mode), then:
   a) PLLxFRACEN must be set to 0. When PLLxFRACEN = 0, the sigma-delta modulator is still operating with the value latched into SH_REG. The application must wait for three clock periods of refx_ck (PLLxFRACEN bit propagation delay).
   b) A new value must be uploaded into PLLxFRACR (FracValue(n)).
   c) PLLxFRACEN must be set to 1, to latch the content of PLLxFRACR into its shadow register.The new value is considered after three clock periods of refx_ck (PLLxFRACEN bit propagation delay).

Note: When the PLLxRDY goes to 1 the difference between the PLLx output frequency and the target value is lower than ±2%.

Figure 52. PLLs initialization flow



11.4.6 LSE clock

The LSE block can generate a clock from two possible sources:

- an external crystal/ceramic resonator
- an external user clock

External clock source (LSE bypass)

In this mode, an external clock source must be provided to OSC32_IN pin. The input clock can have a frequency up to 1 MHz, and be low swing (analog) or digital. A duty cycle close to 50% is recommend]ed.

This external clock is provided to the OSC32_IN pin while the OSC32_OUT pin must be left Hi-Z (see *Figure 48*).

In case of an analog clock (low swing), the LSEBYP and LSEON bits must be set to 1 (*RCC Backup domain control register (RCC_BDCR)*).

In case of a digital clock, the LSEBYP and the LSEEXT bits must be set to 1 followed by setting the LSEON bit to 1 (*RCC Backup domain control register (RCC_BDCR)*). If the RTC is used, the LSE bypass must not be configured in digital mode, but in low swing analog mode (default value after reset).

External crystal/ceramic resonator (LSE crystal)

The LSE clock is generated from a 32.768 kHz crystal or ceramic resonator. It has the advantage to provide a low-power, highly accurate clock source to the real-time clock (RTC) for clock/calendar or other timing functions.

The LSERDY flag of the *RCC Backup domain control register (RCC_BDCR)*) indicates whether the LSE crystal is stable or not. At startup, the LSE crystal output clock signal is not released until this bit is set by hardware. An interrupt can be generated if enabled in the *RCC clock source interrupt enable register (RCC_CIER)*.

The LSE oscillator is switched ON and OFF using the LSEON bit. The LSE remains enabled when the system enters Stop or Standby mode.

In addition, the LSE clock can be driven to the MCO1 output and used as clock source for other application components.

The LSE also offers a programmable driving capability (LSEDRV[1:0]), which can be used to modulate the amplifier driving capability. This driving capability is chosen according to the external crystal/ceramic component requirement to ensure a stable oscillation.

The driving capability must be set before enabling the LSE oscillator.

11.4.7 LSI clock

The LSI acts as a low-power clock source that can be kept running when the system is in Stop or Standby mode for the independent watchdog (IWDG) and auto-wakeup unit (AWU).

The clock frequency is around 32 kHz. For more details, refer to the electrical characteristics section of the datasheet.

The LSI can be switched ON and OFF using the LSION bit. The LSIRDY flag indicates whether the LSI oscillator is stable or not. If an independent watchdog is started either by hardware or software, the LSI is forced ON and cannot be disabled.

The LSI remains enabled when the system enters Stop or Standby mode.

At LSI startup, the clock is not provided until the hardware sets the LSIRDY bit. An interrupt can be generated if enabled in the *RCC clock source interrupt enable register (RCC_CIER)*.

In addition, the LSI clock can be driven to the MCO2 output and used as a clock source for other application components.

Note: Bits LSION and LSIRDY are located in the RCC Backup domain control register (RCC_BDCR).

11.4.8 System clock (SYSCLK) selection

Four different clock sources can be used to drive the system clock (SYSCLK):

- HSI oscillator
- CSI oscillator
- HSE oscillator
- PLL

The system clock maximum frequency is 250 MHz. After a system reset (or after leaving Standby mode), the HSI oscillator, at 32 MHz, is selected as system clock. When a clock source is used directly or through the PLL as a system clock, it is not possible to stop it.

A switch from one clock source to another occurs only if the target clock source is ready (clock stable after startup delay or PLL locked). If a clock source not yet ready is selected, the switch occurs when the clock source becomes ready. Status bits in the *RCC clock control register (RCC_CR)* indicate which clocks are ready ,and which clock is currently used as a system clock.

11.4.9 Handling clock generators in stop and standby modes

When the whole system enters Stop mode, all the clocks (system and kernel clocks) are stopped, as well as the following clock sources:

- CSI, HSI (depending on HSIKERON and CSIKERON bits)
- HSE
- PLL1 and PLL2
- HSI48

The content of the RCC registers is not altered except for PLL1ON, PLL2ON, HSEON, and HSI48ON, set to 0.

Exiting Stop mode

When the system exits this mode via a wake-up event, the application can select which oscillator (HSI and/or CSI) is used to restart. The STOPWUCK bit selects the oscillator used as system clock. The STOPKERWUCK bit selects the oscillator used as kernel clock for peripherals. The STOPKERWUCK bit is useful if after a system Stop, a peripheral needs a kernel clock generated by an oscillator different from the one used for the system clock.

These bits belong to the *RCC clock configuration register1 (RCC_CFGR1)*

Table 103. STOPWUCK and STOPKERWUCK description

STOPWUCK	STOPKERWUCK	Activated oscillator when the system exits Stop mode	Distributed clocks when the system exits Stop mode	
			System clock	Kernel clock
0	0	HSI	HSI	HSI
	1	HSI and CSI		HSI and/or CSI
1	0		CSI	
	1	CSI		CSI

During Stop mode

There are two specific cases where the HSI or CSI can be enabled during this mode.

- When a dedicated peripheral requests the kernel clock the peripheral receives the HSI or CSI according to the kernel clock source selected for this peripheral (via CKPERSEL[1:0]).
- When the HSIKERON or CSIKERON bits of the *RCC clock control register (RCC_CR)* are set, the HSI and CSI are kept running, but the outputs are gated. The clock is then available immediately when the system exits Stop mode, or when a peripheral requests the kernel clock (see *Table 101* for details).

Table 104. HSIKERON and CSIKERON behavior

HSIKERON (CSIKERON)	HSI (CSI) state during Stop mode	HSI (CSI) state setting time
0	OFF	$t_{su(HSI)}$ $t_{su(CSI)}$ (1)
1	Running and gated	Immediate

1. $t_{su(HSI)}$ and $t_{su(CSI)}$ are the startup times of, respectively, the HSI and CSI oscillators (refer to the product datasheet for the values of these parameters).

When the microcontroller exists system standby mode, the HSI is selected as system and kernel clock. The RCC registers are reset to their initial values except for the RCC_RSR and RCC_BDCR registers.

Note: The HSI and CSI outputs provide two clock paths:

- one path for the system clock (hsi_ck or csi_ck)
- one path for the peripheral kernel clock (hsi_ker_ck or csi_ker_ck).

When a peripheral requests the kernel clock in system stop mode, only the path providing the hsi_ker_ck or csi_ker_ck is activated.

11.4.10 Clock security system (CSS)

Clock security system on HSE

The clock security system can be enabled by software via the HSECSSON bit, which can be enabled even when the HSEON is set to 0.

The CSS on HSE is enabled by the hardware when the HSE is enabled and ready, and HSECSSON set to 1.

The CSS on HSE is disabled when the HSE is disabled. As a result, this function does not work when the system is in Stop mode.

It is not possible to clear directly the HSECSSON bit by software.

The HSECSSON bit is cleared by hardware when a system reset occurs or when the system enters Standby mode.

If a failure is detected on the HSE clock, the system automatically switches to the HSI or CSI, depending on STOPWUCK bit configuration in *RCC clock configuration register1 (RCC_CFGR1)*, to provide a safe clock. The HSE is then automatically disabled, a clock failure event is sent to the break inputs of advanced-control timer (TIM1), and an NMI is automatically generated to inform the application about the failure, allowing the MCU to

perform rescue operations. If the HSE output was used as clock source for PLLs when the failure occurred, the PLLs are also disabled.

If an HSE clock failure occurs when the CSS is enabled, the CSS generates an interrupt that causes the automatic generation of an NMI. The HSECSSF flag in *RCC clock source interrupt flag register (RCC_CIFR)* is set to 1 to allow the application to identify the failure source. The NMI routine is executed indefinitely until the HSECSSF bit is cleared. As a consequence, the application must clear the HSECSSF flag in the NMI ISR by setting the HSECSSC bit in the *RCC clock source interrupt clear register (RCC_CICR)*.

Clock security system on LSE

A clock security system on LSE can be activated by software writing the LSECSSON bit in the *RCC Backup domain control register (RCC_BDCR)*. This bit can be disabled only by a hardware reset or RTC software reset, or after a failure detection on LSE. LSECSSON must be written after LSE is enabled (LSEON enabled) and ready (LSERDY set by hardware), and after the RTC clock has been selected by RTCSEL.

The CSS on LSE is working in all modes including VBAT. It works also under system reset (excluding power-on reset).

The clock security system on LSE detects when the LSE disappears or in case of over frequency. In addition, the glitches on LSE can be filtered by setting LSEGFON. LSEGFON must be written when the LSE is disabled (LSEON = 0 and LSERDY = 0).

If a failure is detected on the external 32 kHz oscillator, the LSE clock is no longer supplied to the RTC, but no hardware action is made to the registers.

The CSS on LSE detection event is connected to the internal tamper 3 of the TAMP peripheral. The internal tamper 3 must be enabled (ITAMP3E = 1 in TAMP_CR1 register) and the associated interrupt enabled (ITAMP3IE in TAMP_IER) to wake up from the low-power modes. This erases also the TAMP backup registers and backup SRAM unless the ITAMP3NOER = 1 in the TAMP_CR3 (see *Section 47: Tamper and backup registers (TAMP)* for more details).

In case of CSS on LSE detection event (LSECSSD = 1 in the RCC_BDCR), the software must disable the LSECSSON bit, stop the defective 32 kHz oscillator (disabling LSEON), and change the RTC clock source (no clock or LSI or HSE, with RTCSEL), or take actions to secure the application.

Refer to datasheet for CSS on LSE electrical characteristics.

11.4.11 Clock output generation (MCO1/MCO2)

Two microcontroller clock output pins (MCO1 and MCO2) are available. A clock source can be selected for each output.The selected clock can be divided thanks to configurable prescaler (refer to *Figure 48* for additional information on signal selection).

MCO1 and MCO2 outputs are controlled via MCO1PRE[3:0], MCO1[2:0], MCO2PRE[3:0], and MCO2[2:0], located in the *RCC clock configuration register1 (RCC_CFGR1)*.

The GPIO port corresponding to each MCO pin must be programmed in alternate function mode.

The clock provided to the MCOs outputs must not exceed the maximum pin speed (refer to the product datasheet for information on the supported speed).

Another output (LSCO) allows one of the low-speed clocks (LSI, LSE) to be output onto the external LSCO pin. This output is available in Stop mode, not available in Standby and VBAT modes. The selection is controlled by the LSCOSEL bit, and enabled by the LSCOEN bit in the *RCC Backup domain control register (RCC_BDCR)*.

The MCO clock output requires the corresponding alternate function selected on the MCO pin. The LSCO pin must be left in default POR state.

11.4.12 Kernel clock selection

Some peripherals are designed to work with two different clock domains that operate asynchronously:

- a clock domain synchronous with the register and bus interface (**ckg_bus_perx** clock)
- a clock domain generally synchronous with the peripheral (kernel clock)

The benefit of having peripherals supporting these two clock domains is that the user application has more freedom to choose optimized clock frequency for the CPU, bus matrix and for the kernel part of the peripheral. The user application can thus change the bus frequency without reprogramming the peripherals. As an example, an ongoing transfer with UART is not disturbed if its APB clock is changed on-the-fly.

Table 105 shows the kernel clock that the RCC can deliver to the peripherals. Each row represents a multiplexer and the peripherals connected to its output.

Table 105. Kernel clock distribution overview

Peripherals	Clock multiplexer control bits	pll1_q_ck	pll2_p_ck	pll2_q_ck	pll2_r_ck	pll3_p_ck	pll3_q_ck	pll3_r_ck	sys_ck	bus clocks(1)	hse_ck	hsi_ker_ck	csi_ker_ck	hsi48_ck	lse_ck	lsi_ck	per_ck(2)	AUDIOCLK	Disabled

1. The bus (AP or AHB) clocks are the bus interface clocks to whom the peripherals are connected.
2. The per_ck clock can be hse_ck, hsi_ker_ck, or csi_ker_ck, according to CKPERSEL selection.
3. With a duty cycle close to 50%, meaning that DIV[P/Q/R]x, values must be even. For SDMMCx, the duty cycle must be 50% when supporting DDR.
4. Clock CSI divided by 122.
5. With a duty cycle close to 50%, meaning that DIV[P/Q/R]x, values must be even. For ADC, the duty cycle must be 50% when supporting DDR.
6. Clock HSI divided by 4.
7. Clock HSE divided by RTCPRE.

To reduce the number of switches, some peripherals share the same kernel clock source. Nevertheless, all peripherals have their dedicated enable signal.

Peripherals dedicated to audio applications

The audio peripherals generally need specific accurate frequencies, the kernel clock of the SAIs or SPI(I2S)s can be generated by:

- PLL1 when the amount of active PLLs must be reduced (for SAIs and SPI/I2S1 to 3)
- APB2 peripheral clock (for SPI/I2S4 and 5)
- APB3 peripheral clock (for SPI/I2S6)
- PLL2 or 3 for optimal flexibility in frequency generation
- HSE, HSI or CSI for use-cases where the current consumption is critical
- AUDIOCLK when an external clock reference needs to be used

Peripherals dedicated to control and data transfer

Peripherals such as SPIs, I2Cs, UARTs do not need a specific kernel clock frequency but a clock fast enough to generate the correct baud rate, or the required bit clock on the serial interface. For that purpose the source can be selected among the following ones:

- PLL1 when the amount of active PLLs must be reduced
- PLL2 or PLL3 if better flexibility is required. As an example, this solution allows changing the frequency bus via PLL1 without affecting the speed of some serial interfaces.
- HSI or CSI for low-power use-cases or when the peripheral must quickly wake up from Stop mode (such as UART or I2C)

Note: UARTs also need the LSE clock when high baud rates are not required.

The OCTOSPI and SDMMC1/2 can also use a clock different from the bus interface one for more flexibility.

RTC/AWU clock

The **rtc_ck** clock source can be one of the following:

- the **hse_1M_ck** (**hse_ck** divided by a programmable prescaler)
- the **lse_ck**
- the **lsi_ck** clock

The source clock is selected by programming the RTCSEL[1:0] bits in the *RCC Backup domain control register (RCC_BDCR)* and the RTCPRE[5:0] bits in the *RCC clock configuration register1 (RCC_CFGR1)*.

This selection cannot be modified without resetting the Backup domain.

If the LSE is selected as RTC clock, the RTC works normally even if the backup or the V_{DD} supply disappears.

The LSE clock is in the Backup domain, whereas the other oscillators are not. As a consequence:

- If LSE is selected as RTC clock, the RTC continues working even if the V_{DD} supply is switched OFF, provided the V_{BAT} supply is maintained.
- If LSI is selected as the RTC clock, the AWU state is not guaranteed if the V_{DD} supply is powered off.
- If the HSE clock is used as RTC clock, the RTC state is not guaranteed if the V_{DD} supply is powered off or if the V_{CORE} supply is powered off.

The **rtc_ck** clock is enabled through RTCEN bit located in the *RCC Backup domain control register (RCC_BDCR)*.

The RTC bus interface clock (APB clock) is enabled through RTCAPBEN and RTCAPBLPEN bits located in RCC_APB3ENR/LPENR registers.

Note: To read the RTC calendar register when the APB clock frequency is less than seven times the RTC clock frequency ($F_{APB} < 7 \times F_{RTCLCK}$), the software must read the calendar time and date registers twice. The data are correct if the second read access to RTC_TR gives the same result than the first one. Otherwise a third read access must be performed.

Watchdog clocks

The RCC provides the clock for the two watchdog blocks available on the circuit. The independent watchdog (IWDG) is connected to the LSI. The window watchdog (WWDG) is connected to the APB clock.

If an independent watchdog is started by either hardware option or software access, the LSI is forced ON and cannot be disabled. After the LSI oscillator setup delay, the clock is provided to the IWDG.

Clock frequency measurement using TIMx

Most of the clock source generator frequencies can be measured by means of the input capture of TIMx.

- Calibrating the HSI or CSI with the LSE:

  The primary purpose of having the LSE connected to a TIMx input capture is to be able to accurately measure the HSI or CSI. This requires to use the HSI or CSI as system clock source either directly or via PLL1. The number of system clock counts between consecutive edges of the LSE signal gives a measurement of the internal clock period. Taking advantage of the high precision of LSE crystals (typically a few tens of ppm) we can determine the internal clock frequency with the same resolution, and trim the source to compensate for manufacturing-process and/or temperature- and voltage-related frequency deviations.

  The basic concept consists in providing a relative measurement (e.g. HSI/LSE ratio). The precision is therefore tightly linked to the ratio between the two clock sources. The greater the ratio is, the more accurate the measurement is.

  The HSI and CSI oscillators have dedicated user-accessible calibration bits for this purpose (see *RCC CSI calibration register (RCC_CSICFGR)*). When HSI or CSI is used via the PLLx, the system clock can also be fine-tuned by using the fractional divider of the PLLs.

- Calibrating the LSI with the HSI:

  The LSI frequency can also be measured: this is useful for applications that do not have a crystal. The ultra-low-power LSI oscillator has a large manufacturing process deviation. The LSI clock frequency can be measured using the more precise HSI clock source. Using this measurement, a more accurate RTC time base timeouts (when LSI is used as the RTC clock source) and/or an IWDG timeout with an acceptable accuracy can be obtained.

11.4.13 RTC and TAMP clock

The RTCCLK clock source is used by RTC and TAMP, and can be either the HSE / 32, LSE or LSI clock. It is selected by programming the RTCSEL[1:0] bits in the *RCC Backup domain*

control register (RCC_BDCR). This selection cannot be modified without resetting the Backup domain. The system must always be configured so as to get a PCLK frequency greater than or equal to the RTCCLK frequency for a proper operation of the RTC. The TAMP does not require any kernel clock if only the backup registers are used, with tampers in edge detection mode. All other tamper detection modes require a kernel clock (refer to *Section 47: Tamper and backup registers (TAMP)* for more details).

The LSE is in the Backup domain, whereas the HSE and LSI clocks are not. Consequently:

- If LSE is selected as RTC and TAMP clock, these peripherals continue to work even if the V_{DD} supply is switched off, provided the V_{BAT} supply is maintained.
- If the HSE clock divided by a prescaler is used as the RTC or TAMP clock, the RTC state is not guaranteed if the V_{DD} supply is powered off or if the internal voltage regulator is powered off (removing power from the core domain). Depending on the TAMP configuration, this one can remain functional if used in a mode that does not need any kernel clock.
- If the LSI is used as the RTC or TAMP clock, the RTC state is not guaranteed if the V_{DD} supply is powered off. Depending on the TAMP configuration, this one can remain functional if used in a mode that does not need any kernel clock.

When the RTC and TAMP clock is LSE or LSI, the RTC remains clocked and functional under system reset.

11.4.14 Timer clock

The timer clock frequencies are automatically defined by hardware.

There are two cases:

- If the APB prescaler equals 1, the timer clock frequencies are set to the APB domain frequency.
- Otherwise, they are set to twice (×2) the APB domain frequency.

11.4.15 Watchdog clock

If the independent watchdog (IWDG) is started by either hardware option or software access, the LSI oscillator is forced on and cannot be disabled. After the LSI oscillator temporization, the LSI 32 kHz clock is provided to the IWDG.

11.4.16 Peripherals clock gating and autonomous mode

Peripherals clock gating in Run mode

Each peripheral clock can be enabled by the corresponding EN bit in the RCC_AHBxENR and RCC_APBxENR registers.

When the peripheral clock is not active, read or write accesses to the peripheral registers are not supported.

The enable bit has a synchronization mechanism to create a glitch-free clock for the peripheral. After the enable bit is set, there the clock is active after 2 cycles of the peripheral bus clock.

Caution: Just after enabling the clock for a peripheral, the software must wait for these 2 clock cycles before accessing the peripheral registers.

Peripherals clock gating in Sleep mode

When a peripheral is enabled, its clock can be automatically gated off when the device is in Sleep mode, by clearing the peripheral LPEN bit in the RCC_AHBxLPENR and RCC_APBxLPENR registers. Both EN and LPEN bit of the peripheral must be set to keep the clock on in Sleep mode.

11.5 RCC security and privilege functional description

11.5.1 RCC TrustZone security protection modes

When the TrustZone security is activated by the TZEN option byte in the Flash option byte configuration register, the RCC is able to secure RCC configuration and status bits from being modified by non-secure accesses.

This is configured through the *RCC secure configuration register (RCC_SECCFGR)* to prevent non-secure access to read or modify the following features:

- HSE, HSE-CSS, HSI, CSI, LSI, LSE, LSE-CSS, LSCO, HSI48 configuration and status bits
- PLL1, PLL2, PLL3, AHB and APB prescalers configuration and status bits
- system clock (SYSCLK) and ICLK source clock selection and status bits
- MCO clock output configuration and STOPWUCK and STOPKERWUCK bit
- Remove reset flag RMVF configuration

If SPRIV is set in the *RCC privilege configuration register (RCC_PRIVCFGR)*, the RCC_SECCFGR register can be written only by secure and privileged access. If SPRIV is cleared in RCC_PRIVCFGR, RCC_SECCFGR can be written only by secure access, privileged or unprivileged.

RCC_SECCFGR can be read by secure, non-secure, privileged and unprivileged access.

When a peripheral is configured as secure, its related clock, reset, clock source selection and clock enable during low-power modes control bits, are also secure in the RCC_AHBxENR, RCC_APBxENR, RCC_CCIPRx and RCC_BDCR registers.

A peripheral is secure when:

- For securable peripherals by TZSC (see *Section 5.4.3: TrustZone security controller (TZSC)*), the SEC security bit corresponding to this peripheral is set in the GTZC TZSC secure configuration registers.
- For TrustZone®-aware peripherals, a security feature of this peripheral is enabled through its dedicated bits.

Table 106 summarizes the RCC secured bits following the security configuration bit in the RCC_SECCFGR register.

When one security configuration bit is set, some configuration and status bits are secured. The RCC registers may contain secure and non-secure bits:

- Secured bits: read and write operations are only allowed by a secure access. Non-secure read returns 0 and write accesses are ignored. No illegal access event is generated.
- Non-secure bits: no restriction. Read and write operations are allowed by both secure and non-secure accesses.
- A non-secure write access to RCC_SECCFGR is ignored and generates an illegal access event. An illegal access interrupt is generated if the RCC illegal access interrupt is enabled in the GTZC TZIC registers. RCC_SECCFGR can be read by secure or non-secure access.

When the TrustZone security is disabled (TZEN = 0xC3), all registers are non-secure. RCC_SECCFGR write accesses are ignored.

Table 106. RCC security configuration summary

Table 106. RCC security configuration summary (continued)

Configuration bit in RCC_SECCFGR	Secured bits	Corresponding register
IPKERSECCFG	CKERPSEL[1:0]	RCC_CCIPR5
RMVFSEC	RMVF	RCC_CSR

1. TRIM field of the HSI48 is located in CRS peripheral. Be sure to secure it using CRSSEC bit in GTZC1 TZSC secure configuration register 1.

11.5.2 RCC privilege protection modes

By default, after reset, all RCC registers can be read or written with both privileged and unprivileged access except *RCC privilege configuration register (RCC_PRIVCFGR)* that can be written with privileged access only. RCC_PRIVCFGR can be read by secure and non secure, privileged and unprivileged access.

The SPRIV bit in RCC_PRIVCFGR can be written with secure privileged access only. This bit configures the privileged access of all RCC secure functions (as defined by *RCC secure configuration register (RCC_SECCFGR)* or by the GTZC for securable peripherals, or by the peripheral itself in case of TrustZone-aware peripherals).

When the SPRIV bit is set in RCC_PRIVCFGR:

- Writing the RCC secure bits is possible only with privileged access, including RCC_SECCFGR.
- The RCC secure bits can be read only with privileged access except RCC_SECCFGR and RCC_PRIVCFGR that can be read by privileged or unprivileged access.
- An unprivileged access to a privileged RCC bit or register is discarded: the bits are read as zero and the write to these bits is ignored (RAZ/WI).

The NSPRIV bit in RCC_PRIVCFGR can be written with privileged access only, secure or non-secure. This bit configures the privileged access of all RCC non-secure functions (as defined by RCC_SECCFGR, or by the GTZC for securable peripherals, or by the peripheral itself in case of TrustZone-aware peripherals).

When the NSPRIV bit is set in RCC_PRIVCFGR:

- Writing the RCC non-secure bits is possible only with privileged access.
- The RCC non-secure bits can be read only with privileged access except RCC_PRIVCFGR that can be read by privileged or unprivileged access.
- An unprivileged access to a privileged RCC bit or register is discarded: the bits are read as zero and the write to these bits is ignored (RAZ/WI).

11.6 RCC low-power modes

- AHB and APB peripheral clocks, including DMA clock, can be disabled by software.
- Sleep mode stops the CPU clock. The memory interface clocks (flash memory, caches and all SRAM interfaces) can be stopped by software during Sleep mode. The AHB to

APB bridge clocks are disabled by hardware during Sleep mode when all the clocks of the peripherals connected to them are disabled.

- Stop mode stops all the clocks in the core domain and disable the PLLs, HSI, HSI48, CSI and HSE oscillators. However, HSI or CSI can be switched ON to generate a wakeup interrupt. LSI and LSE remain active in Stop mode.
- Standby mode stops all the clocks in the core domain and disable the PLLs, HSI, HSI48, CSI and HSE oscillators.

The CPU DeepSleep mode can be overridden for debugging by setting the DBG_STOP or DBG_STANDBY bit in the DBGMCU_CR register.

When exiting Stop mode, the system clock is either HSI or CSI, depending on the software configuration of STOPWUCK in the *RCC CPU domain clock configuration register 2 (RCC_CFGR2)*. The frequency (range and user trim) of the HSI is the one configured before entering Stop mode.

The other internal oscillator can be automatically woken up in addition to the one used by the system clock, to avoid waiting for the other oscillator wakeup time when the device is back in Run mode. This is done thanks to STOPKERWUCK in RCC_CFGR1.

When leaving the Standby mode, the system clock is HSI (32 MHz). The user trim is lost.

If a flash memory programming operation is ongoing, Stop or Standby mode entry is delayed until the flash memory interface access is finished. If an access to the APB domain is ongoing, Stop or Standby mode entry is delayed until the APB access is finished.

11.7 RCC interrupts

Table 107 summarizes the interrupt sources and the way to control them.

Table 107. Interrupt sources and control

Interrupt vector	Interrupt event flag	Description	Enable control bits	Interrupt clear method	Exit from Sleep mode	Exit from Stop, Standby modes
RCC	LSIRDYF	LSI ready	LSIRDYIE and LSISEC = 0	Set LSIRDYC to 1	Yes	No
	LSERDYF	LSE ready	LSERDYIE and LSESEC = 0	Set LSERDYC to 1	Yes	No
	HSIDRYF	HSI ready	HSIDRYIE and HSISEC = 0	Set HSIRDYC to 1	Yes	No
	HSERDYF	HSE ready	HSERDYIE and HSESEC = 0	Set HSERDYC to 1	Yes	No
	CSISRDYF	CSIS ready	CSISRDYIE and CSISEC = 0	Set CSISRDYC to 1	Yes	No
	HSI48RDYF	HSI48 ready	HSI48RDYIE and HSI48SEC = 0	Set HSI48RDYC to 1	Yes	No
	PLL1RDYF	PLL1 ready	PLL1RDYIE and PLL1SEC = 0	Set PLL1RDYC to 1	Yes	No
	PLL2RDYF	PLL2 ready	PLL2RDYIE and PLL2SEC = 0	Set PLL2RDYC to 1	Yes	No
	PLL3RDYF	PLL3 ready	PLL3RDYIE and PLL3SEC = 0	Set PLL3DYC to 1	Yes	No
RCC_S (1)	LSIRDYF	LSI ready	LSIRDYIE and LSISEC = 1	Set LSIRDYC to 1	Yes	No
	LSERDYF	LSE ready	LSERDYIE and LSESEC = 1	Set LSERDYC to 1	Yes	No
	HSIDRYF	HSI ready	HSIDRYIE and HSISEC = 1	Set HSIRDYC to 1	Yes	No
	HSERDYF	HSE ready	HSERDYIE and HSESEC = 1	Set HSERDYC to 1	Yes	No
	CSISRDYF	CSIS ready	CSISRDYIE and CSISEC = 1	Set CSISRDYC to 1	Yes	No
	HSI48RDYF	HSI48 ready	HSI48RDYIE and HSI48SEC = 1	Set HSI48RDYC to 1	Yes	No
	PLL1RDYF	PLL1 ready	PLL1RDYIE and PLL1SEC = 1	Set PLL1RDYC to 1	Yes	No
	PLL2RDYF	PLL2 ready	PLL2RDYIE and PLL2SEC = 1	Set PLL2RDYC to 1	Yes	No
	PLL3RDYF	PLL3 ready	PLL3RDYIE and PLL3SEC = 1	Set PLL3RDYC to 1	Yes	No

Table 107. Interrupt sources and control (continued)

Interrupt vector	Interrupt event flag	Description	Enable control bits	Interrupt clear method	Exit from Sleep mode	Exit from Stop, Standby modes
TAMP	ITAMP3F(2)	LSE CSS failure	LSECSSON and ITAMP3E(2) and ITAMP3IE(2)	Set CITAMP3F(2) to 1	Yes	Yes
NMI	HSECSSF	HSE CSS failure	(3)	Set HSECSSC to 1	Yes	No

1. The RCC secure interrupt vector is used only when TrustZone is enabled.
2. The LSE CSS failure event (LSECSSD) is connected to TAMP internal tamper 3. to get the interrupt associated to this event, the internal tamper 3 must be enabled, and the internal tamper 3 interrupt must be enabled. The ITAMP3F, ITAMP3E, ITAMP3IE, and CITAMP3F bits are in the TAMP peripheral.
3. It is not possible to mask this interrupt when the security system feature is enabled (HSECSSON = 1).

11.8 RCC registers

11.8.1 RCC clock control register (RCC_CR)

Address offset: 0x000

Reset value: 0x0000 002B

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	PLL3 RDY	PLL3 ON	PLL2 RDY	PLL2 ON	PLL1 RDY	PLL1 ON	Res.	Res.	Res.	HSE EXT	HSE CSSON	HSE BYP	HSE RDY	HSE ON
		r	rw	r	rw	r	rw				rw	rs	rw	r	rw

		r	rw		rw	r	rw			r	rw	rw	rw	r	rw

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **PLL3RDY:** PLL3 clock ready flag
Set by hardware to indicate that the PLL3 is locked.
0: PLL3 unlocked (default after reset)
1: PLL3 locked

Bit 28 **PLL3ON**: PLL3 enable
Set and cleared by software to enable PLL3.
Cleared by hardware when entering Stop or Standby mode.
0: PLL3 OFF (default after reset)
1: PLL3 ON

Bit 27 **PLL2RDY**: PLL2 clock ready flag
Set by hardware to indicate that the PLL is locked.
0: PLL2 unlocked
1: PLL2 locked

Bit 26 **PLL2ON**: PLL2 enable
Set and cleared by software to enable PLL2.
Cleared by hardware when entering Stop or Standby mode.
0: PLL2 OFF (default after reset)
1: PLL2 ON

Bit 25 **PLL1RDY**: PLL1 clock ready flag
Set by hardware to indicate that the PLL1 is locked.
0: PLL1 unlocked (default after reset)
1: PLL1 locked

Bit 24 **PLL1ON**: PLL1 enable
Set and cleared by software to enable PLL1.
Cleared by hardware when entering Stop or Standby mode. Note that the hardware prevents writing this bit to 0, if the PLL1 output is used as the system clock.
0: PLL1 OFF (default after reset)
1: PLL1 ON

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **HSEEXT**: external high speed clock type in Bypass mode

Set and reset by software to select the external clock type (analog or digital).
The external clock must be enabled with the HSEON bit to be used by the device. The HSEEXT bit can be written only if the HSE oscillator is disabled.
0: HSE in analog mode (default after reset)
1: HSE in digital mode

Bit 19 **HSECSSON**: HSE clock security system enable

Set by software to enable clock security system on HSE.
This bit is “set only” (disabled by a system reset or when the system enters in Standby mode). When HSECSSON is set, the clock detector is enabled by hardware when the HSE is ready and disabled by hardware if an oscillator failure is detected.
0: CSS on HSE OFF (clock detector OFF) (default after reset)
1: CSS on HSE ON (clock detector ON if the HSE oscillator is stable, OFF if not).

Bit 18 **HSEBYP**: HSE clock bypass

Set and cleared by software to bypass the oscillator with an external clock. The external clock must be enabled with the HSEON bit to be used by the device.
The HSEBYP bit can be written only if the HSE oscillator is disabled.
0: HSE oscillator not bypassed (default after reset)
1: HSE oscillator bypassed with an external clock

Bit 17 **HSERDY**: HSE clock ready flag

Set by hardware to indicate that the HSE oscillator is stable.
0: HSE clock is not ready (default after reset)
1: HSE clock is ready

Bit 16 **HSEON**: HSE clock enable

Set and cleared by software.
Cleared by hardware to stop the HSE when entering Stop or Standby mode.
This bit cannot be cleared if the HSE is used directly (via SW mux) as system clock, or if the HSE is selected as reference clock for PLL1 with PLL1 enabled (PLL1ON bit set to 1).
0: HSE is OFF (default after reset)
1: HSE is ON

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **HSI48RDY**: HSI48 clock ready flag

Set by hardware to indicate that the HSI48 oscillator is stable.
0: HSI48 clock is not ready (default after reset)
1: HSI48 clock is ready

Bit 12 **HSI48ON**: HSI48 clock enable

Set by software and cleared by software or by the hardware when the system enters to Stop or Standby mode.
0: HSI48 is OFF (default after reset)
1: HSI48 is ON

Bit 11 Reserved, must be kept at reset value.

Bit 10 **CSIKERON**: CSI clock enable in Stop mode

Set and reset by software to force the CSI to ON, even in Stop mode, to be quickly available as kernel clock for some peripherals. This bit has no effect on the value of CSION.
0: no effect on CSI (default after reset)
1: CSI is forced to ON even in Stop mode

Bit 9 **CSIRDY**: CSI clock ready flag

Set by hardware to indicate that the CSI oscillator is stable. This bit is activated only if the RC is enabled by CSION (it is not activated if the CSI is enabled by CSIKERON or by a peripheral request).

0: CSI clock is not ready (default after reset)

1: CSI clock is ready

Bit 8 **CSION**: CSI clock enable

Set and reset by software to enable/disable CSI clock for system and/or peripheral.

Set by hardware to force the CSI to ON when the system leaves Stop mode, if STOPWUCK = 1 or STOPKERWUCK = 1.

This bit cannot be cleared if the CSI is used directly (via SW mux) as system clock, or if the CSI is selected as reference clock for PLL1 with PLL1 enabled (PLL1ON bit set to 1).

0: CSI is OFF (default after reset)

1: CSI is ON

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **HSIDIVF**: HSI divider flag

Set and reset by hardware.

As a write operation to HSIDIV has not an immediate effect on the frequency, this flag indicates the

current status of the HSI divider. HSIDIVF goes immediately to 0 when HSIDIV value is changed, and is set back to 1 when the output frequency matches the value programmed into HSIDIV.

0: new division ratio not yet propagated to hsi_ck , hsi_ker_ck (default after reset)

1: hsi_ck , hsi_ker_ck clock frequency reflects the new HSIDIV value (default register value when the clock setting is completed).

Bits 4:3 **HSIDIV[1:0]**: HSI clock divider

Set and reset by software.

These bits allow selecting a division ratio to configure the wanted HSI clock frequency. The HSIDIV cannot be changed if the HSI is selected as reference clock for at least one enabled PLL (PLLxON bit set to 1). In that case, the new HSIDIV value is ignored..

00: division by 1, hsi_ck, hsi_ker_ck = 64 MHz

01: division by 2, hsi_ck, hsi_ker_ck = 32 MHz (default after reset)

10: division by 4, hsi_ck, hsi_ker_ck = 16 MHz

11: division by 8, hsi_ck, hsi_ker_ck = 8 MHz

Bit 2 **HSIKERON**: HSI clock enable in Stop mode

Set and reset by software to force the HSI to ON, even in Stop mode, to be quickly available as kernel clock for peripherals. This bit has no effect on the value of HSION.

0: no effect on HSI (default after reset)

1: HSI is forced to ON even in Stop mode

Bit 1 **HSIRDY**: HSI clock ready flag

Set by hardware to indicate that the HSI oscillator is stable.

0: HSI clock is not ready (default after reset)

1: HSI clock is ready

Bit 0 **HSION**: HSI clock enable

Set and cleared by software.

Set by hardware to force the HSI to ON when the product leaves Stop mode, if STOPWUCK = 1 or STOPKERWUCK = 1.

Set by hardware to force the HSI to ON when the product leaves Standby mode or in case of a failure of the HSE which is used as the system clock source.

This bit cannot be cleared if the HSI is used directly (via SW mux) as system clock, or if the HSI is selected as reference clock for PLL1 with PLL1 enabled (PLL1ON bit set to 1).

0: HSI is OFF

1: HSI is ON (default after reset)

11.8.2 RCC HSI calibration register (RCC_HSICFGR)

Address offset: 0x010

Reset value: 0x0040 0XXX

Reset value depends on the flash memory option bytes setting.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HSITRIM[6:0]

Res.	Res.	Res.	Res.	HSICAL[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:16 **HSITRIM[6:0]**: HSI clock trimming

Set by software to adjust calibration.

HSITRIM field is added to the engineering option bytes loaded during reset phase (FLASH_HSI_OPT) to form the calibration trimming value.

HSICAL = HSITRIM + FLASH_HSI_OPT.

After a change of HSITRIM it takes one system clock cycle before the new HSITRIM value is updated

Note: The reset value of the field is 0x40.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **HSICAL[11:0]**: HSI clock calibration

Set by hardware by option byte loading during system reset nreset. Adjusted by software through trimming bits HSITRIM.

This field represents the sum of engineering option byte calibration and HSITRIM bits values.

11.8.3 RCC clock recovery RC register (RCC_CRRCR)

Address offset: 0x014

Reset value: 0x0000 0XXX

Reset value depends on the flash option bytes setting

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	HSI48CAL[9:0]									
						r	r	r	r	r	r	r	r	r	r

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **HSI48CAL[9:0]**: Internal RC 48 MHz clock calibration

Set by hardware by option-byte loading during system reset NRESET. Read-only.

11.8.4 RCC CSI calibration register (RCC_CSICFGR)

Address offset: 0x018

Reset value: 0x0020 0XXX

Reset value depends on the flash option bytes setting

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CSITRIM[5:0]					
										rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CSICAL[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:16 **CSITRIM[5:0]**: CSI clock trimming

Set by software to adjust calibration.

CSITRIM field is added to the engineering option bytes loaded during reset phase (FLASH_CSI_OPT) to form the calibration trimming value.

CSICAL = CSITRIM + FLASH_CSI_OPT.

Note: The reset value of the field is 0x20.

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **CSICAL[7:0]**: CSI clock calibration

Set by hardware by option byte loading during system reset NRESET. Adjusted by software through trimming bits CSITRIM.

This field represents the sum of engineering option byte calibration value and CSITRIM bits value.

11.8.5 RCC clock configuration register1 (RCC_CFGR1)

Address offset: 0x01C

Reset value: 0x0000 0000

Access: 0 ≤ wait state ≤ 2; word, half-word and byte access

One or two wait states are inserted only if the access occurs during clock source switch.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MCO2SEL[2:0]			MCO2PRE[3:0]				MCO1SEL[2:0]			MCO1PRE[3:0]				Res.	Res.

rw		rw	rw	rw	rw	rw	rw	rw	rw		r	r		rw	rw

Bits 31:29 **MCO2SEL[2:0]**: microcontroller clock output 2

Set and cleared by software. Clock source selection may generate glitches on MCO2.
It is highly recommended to configure these bits only after reset, before enabling the external oscillators and the PLLs.
000: system clock selected (**sys_ck**) (default after reset)
001: PLL2 oscillator clock selected (**pll2_p_ck**)
010: HSE clock selected (**hse_ck**)
011: PLL1 clock selected (**pll1_p_ck**)
100: CSI clock selected (**csi_ck**)
101: LSI clock selected (**lsi_ck**)
others: reserved

Bits 28:25 **MCO2PRE[3:0]**: MCO2 prescaler

Set and cleared by software to configure the prescaler of the MCO2. Modification of this prescaler may generate glitches on MCO2. It is highly recommended to change this prescaler only after reset, before enabling the external oscillators and the PLLs.
0000: prescaler disabled (default after reset)
0001: division by 1 (bypass)
0010: division by 2
0011: division by 3
0100: division by 4
...
1111: division by 15

Bits 24:22 **MCO1SEL[2:0]**: Microcontroller clock output 1

Set and cleared by software. Clock source selection may generate glitches on MCO1.
It is highly recommended to configure these bits only after reset, before enabling the external oscillators and the PLLs.
000: HSI clock selected (**hsi_ck**) (default after reset)
001: LSE oscillator clock selected (**lse_ck**)
010: HSE clock selected (**hse_ck**)
011: PLL1 clock selected (**pll1_q_ck**)
100: HSI48 clock selected (**hsi48_ck**)
others: reserved

Bits 21:18 **MCO1PRE[3:0]**: MCO1 prescaler

Set and cleared by software to configure the prescaler of the MCO1. Modification of this prescaler may generate glitches on MCO1. It is highly recommended to change this prescaler only after reset, before enabling the external oscillators and the PLLs.
0000: prescaler disabled (default after reset)
0001: division by 1 (bypass)
0010: division by 2
0011: division by 3
0100: division by 4
...
1111: division by 15

Bits 17:16 Reserved, must be kept at reset value.

Bit 15 **TIMPRE**: timers clocks prescaler selection

This bit is set and reset by software to control the clock frequency of all the timers connected to APB1 and APB2 domains.
0: The timers kernel clock is equal to **rcc_hclk1** if PPRE1 or PPRE2 corresponds to a division by 1 or 2, else it is equal to 2 x F_{rcc_pclk1} or 2 x F_{rcc_pclk2} (default after reset)
1: The timers kernel clock is equal to 2 x F_{rcc_pclk1} or 2 x F_{rcc_pclk2} if PPRE1 or PPRE2 corresponds to a division by 1, 2 or 4, else it is equal to 4 x F_{rcc_pclk1} or 4 x F_{rcc_pclk2}

Bit 14 Reserved, must be kept at reset value.

Bits 13:8 **RTCPRE[5:0]**: HSE division factor for RTC clock

Set and cleared by software to divide the HSE to generate a clock for RTC.
Caution: The software must set these bits correctly to ensure that the clock supplied to the RTC is lower than 1 MHz. These bits must be configured if needed before selecting the RTC clock source.
000000: no clock (default after reset)
000001: no clock
000010: HSE/2
000011: HSE/3
000100: HSE/4
...
111110: HSE/62
111111: HSE/63

Bit 7 **STOPKERWUCK**: kernel clock selection after a wakeup from system Stop

Set and reset by software to select the kernel wakeup clock from system Stop.
0: HSI selected as wakeup clock from system Stop (default after reset)
1: CSI selected as wakeup clock from system Stop

Bit 6 **STOPWUCK**: system clock selection after a wakeup from system Stop

Set and reset by software to select the system wakeup clock from system Stop.
The selected clock is also used as emergency clock for the clock security system (CSS) on HSE. 0: HSI selected as wakeup clock from system Stop (default after reset)
1: CSI selected as wakeup clock from system Stop

Caution: STOPWUCK must not be modified when CSS is enabled (by HSECSSON bit) and the system clock is HSE (SWS = 10) or a switch on HSE is requested (SW =10).

Bit 5 Reserved, must be kept at reset value.

Bits 4:3 **SWS[1:0]**: system clock switch status
Set and reset by hardware to indicate which clock source is used as system clock. 000: HSI used as system clock (**hsi_ck**) (default after reset).
01: CSI used as system clock (**csi_ck**)
10: HSE used as system clock (**hse_ck**)
11: PLL1 used as system clock (**pll1_p_ck**)
others: reserved

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **SW[1:0]**: system clock and trace clock switch
Set and reset by software to select system clock and trace clock sources (**sys_ck**).
Set by hardware to:
-force the selection of the HSI or CSI (depending on STOPWUCK selection) when leaving a system Stop mode
-force the selection of the HSI in case of failure of the HSE when used directly or indirectly as system clock
00: HSI selected as system clock (**hsi_ck**) (default after reset)
01: CSI selected as system clock (**csi_ck**)
10: HSE selected as system clock (**hse_ck**)
11: PLL1 selected as system clock (**pll1_p_ck** for **sys_ck**)
others: reserved

11.8.6 RCC CPU domain clock configuration register 2 (RCC_CFGR2)

Address offset: 0x020

Reset value: 0x0000 0000

1 or 2 wait states are inserted only if the access occurs during clock source switch.

From 0 to 15 wait states are inserted if the access occurs when the APB or AHB prescalers values update is ongoing.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	APB3 DIS	APB2 DIS	APB1 DIS	AHB4 DIS	Res.	AHB2 DIS	AHB1 DIS

	rw	rw	rw		rw	rw	rw		rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **APB3DIS**: APB3 clock disable value.Set and cleared by software
This bit can be set to further reduce power consumption, when none of the APB3 peripherals are used and when their clocks are disabled in RCC_APB3ENR. When this bit is set, all the APB3 peripherals clocks are off.
0: APB3 clock enabled, distributed to peripherals according to their dedicated clock enable control bits
1: APB3 clock disabled

Bit 21 **APB2DIS**: APB2 clock disable value

This bit can be set to further reduce power consumption, when none of the APB2 peripherals are used and when their clocks are disabled in RCC_APB2ENR. When this bit is set, all the APB2 peripherals clocks are off.

0: APB2 clock enabled, distributed to peripherals according to their dedicated clock enable control bits

1: APB2 clock disabled

Bit 20 **APB1DIS**: APB1 clock disable value

This bit can be set to further reduce power consumption, when none of the APB1 peripherals (except IWDG) are used and when their clocks are disabled in RCC_APB1ENR. When this bit is set, all the APB1 peripherals clocks are off, except for IWDG.

0: APB1 clock enabled, distributed to peripherals according to their dedicated clock enable control bits

1: APB1 clock disabled

Bit 19 **AHB4DIS**: AHB4 clock disable

This bit can be set to further reduce power consumption, when none of the AHB4 peripherals from RCC_AHB4ENR are used and when their clocks are disabled in RCC_AHB4ENR. When this bit is set, all the AHB4 peripherals clocks from RCC_AHB4ENR are off.

0: AHB4 clock enabled, distributed to peripherals according to their dedicated clock enable control bits

1: AHB4 clock disabled

Bit 18 Reserved, must be kept at reset value.

Bit 17 **AHB2DIS**: AHB2 clock disable

This bit can be set to further reduce power consumption, when none of the AHB2 peripherals from RCC_AHB2ENR are used and when their clocks are disabled in RCC_AHB2ENR. When this bit is set, all the AHB2 peripherals clocks are off, except for SRAM2 and SRAM3.

0: AHB2 clock enabled, distributed to peripherals according to their dedicated clock enable control bits

1: AHB2 clock disabled

Bit 16 **AHB1DIS**: AHB1 clock disable

This bit can be set to further reduce power consumption, when none of the AHB1 peripherals from RCC_AHB1ENR are used and when their clocks are disabled in RCC_AHB1ENR. When this bit is set, all the AHB1 peripherals clocks are off, except for FLASH, BKPSRAM, ICACHE, DCACHE1 and SRAM1.

0: AHB1 clock enabled, distributed to peripherals according to their dedicated clock enable control bits

1: AHB1 clock disabled

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **PPRE3[2:0]**: APB low-speed prescaler (APB3)

Set and reset by software to control APB low-speed clocks division factor.

The clocks are divided with the new prescaler factor from 1 to 16 APB cycles after PPRE3 write.

0xx: rcc_pclk3 = rcc_hclk1

100: rcc_pclk3 = rcc_hclk1 / 2

101: rcc_pclk3 = rcc_hclk1 / 4

110: rcc_pclk3 = rcc_hclk1 / 8

111: rcc_pclk3 = rcc_hclk1 / 16

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **PPRE2[2:0]**: APB high-speed prescaler (APB2)

Set and reset by software to control APB high-speed clocks division factor.
The clocks are divided with the new prescaler factor from 1 to 16 APB cycles after PPRE2 write.
0xx: rcc_pclk2 = rcc_hclk1
100: rcc_pclk2 = rcc_hclk1 / 2
101: rcc_pclk2 = rcc_hclk1 / 4
110: rcc_pclk2 = rcc_hclk1 / 8
111: rcc_pclk2 = rcc_hclk1 / 16

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **PPRE1[2:0]**: APB low-speed prescaler (APB1)

Set and reset by software to control the division factor of rcc_pclk1.
The clock is divided by the new prescaler factor from 1 to 16 cycles of rcc_hclk after PPRE write.
0xx: rcc_pclk1 = rcc_hclk1 (default after reset)
100: rcc_pclk1 = rcc_hclk1 / 2
101: rcc_pclk1 = rcc_hclk1 / 4
110: rcc_pclk1 = rcc_hclk1 / 8
111: rcc_pclk1 = rcc_hclk1 / 16

Bits 3:0 **HPRE[3:0]**: AHB prescaler

Set and reset by software to control the division factor of rcc_hclk. Changing this division ratio has an impact on the frequency of all bus matrix clocks
0xxx: rcc_hclk = sys_ck (default after reset)
1000: rcc_hclk = sys_ck / 2
1001: rcc_hclk = sys_ck / 4
1010: rcc_hclk = sys_ck / 8
1011: rcc_hclk = sys_ck / 16
1100: rcc_hclk = sys_ck / 64
1101: rcc_hclk = sys_ck / 128
1110: rcc_hclk = sys_ck / 256
1111: rcc_hclk = sys_ck / 512

Caution: Be careful when using the voltage scaling. Due to the propagation delay of the new division factor, after a prescaler factor change, and before lowering the V_{CORE} voltage, this register must be read to check that the new prescaler value has been taken into account.
Depending upon the clock source frequency and the voltage range, the software application must program a correct value in HPRE to make sure that the system frequency does not exceed the maximum frequency.

11.8.7 RCC PLL clock source selection register (RCC_PLL1CFGR)

Address offset: 0x028

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PLL1REN	PLL1QEN	PLL1PEN

		rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bits 31:19 Reserved, must be kept at reset value.

Bit 18 **PLL1REN**: PLL1 DIVR divider output enable

Set and reset by software to enable the pll1_r_ck output of the PLL1.

To save power, DIVR1EN and DIVR1 bits must be set to 0 when the pll1_r_ck is not used.

This bit can be written only when the PLL1 is disabled (PLL1ON = 0 and PLL1RDY = 0).

0: pll1_r_ck output disabled (default after reset)

1: pll1_r_ck output enabled

Bit 17 **PLL1QEN**: PLL1 DIVQ divider output enable

Set and reset by software to enable the pll1_q_ck output of the PLL1.

To save power, when the pll1_q_ck output of the PLL1 is not used, the pll1_q_ck must be disabled.

This bit can be written only when the PLL1 is disabled (PLL1ON = 0 and PLL1RDY = 0).

0: pll1_q_ck output disabled (default after reset)

1: pll1_q_ck output enabled

Bit 16 **PLL1PEN**: PLL1 DIVP divider output enable

Set and reset by software to enable the pll1_p_ck output of the PLL1.

This bit can be written only when the PLL1 is disabled (PLL1ON = 0 and PLL1RDY = 0).

To save power, when the pll1_p_ck output of the PLL1 is not used, the pll1_p_ck must be disabled.

0: pll1_p_ck output disabled (default after reset)

1: pll1_p_ck output enabled

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **PLL1M[5:0]**: prescaler for PLL1

Set and cleared by software to configure the prescaler of the PLL1.
The hardware does not allow any modification of this prescaler when PLL1 is enabled (PLL1ON = 1 or PLL1RDY = 1).
To save power when PLL1 is not used, the value of PLL1M must be set to 0.
000000: prescaler disabled (default after reset)
000001: division by 1 (bypass)
000010: division by 2
000011: division by 3
...
100000: division by 32
...
111111: division by 63

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **PLL1VCOSEL**: PLL1 VCO selection

Set and reset by software to select the proper VCO frequency range used for PLL1. This bit must be written before enabling the PLL1.
0: wide VCO range: 192 to 836 MHz (default after reset)
1: medium VCO range: 150 to 420 MHz

Bit 4 **PLL1FRACEN**: PLL1 fractional latch enable

Set and reset by software to latch the content of FRACN1 into the sigma-delta modulator.
To latch the FRACN1 value into the sigma-delta modulator, PLL1FRACEN must be set to 0, then set to 1. The transition 0 to 1 transfers the content of FRACN1 into the modulator.

Bits 3:2 **PLL1RGE[1:0]**: PLL1 input frequency range

Set and reset by software to select the proper reference frequency range used for PLL1. This bit must be written before enabling the PLL1.
00: PLL1 input (ref1_ck) clock range frequency between 1 and 2 MHz (default after reset)
01: PLL1 input (ref1_ck) clock range frequency between 2 and 4 MHz
10: PLL1 input (ref1_ck) clock range frequency between 4 and 8 MHz
11: PLL1 input (ref1_ck) clock range frequency between 8 and 16 MHz

Bits 1:0 **PLL1SRC[1:0]**: PLL1M and PLLs clock source selection

Set and reset by software to select the PLL clock source. These bits can be written only when all PLLs are disabled.
To save power, when no PLL is used, the value of PLL1SRC must be set to '00'.
00: no clock send to PLL1M divider and PLLs (default after reset).
01: HSI selected as PLL clock (hsi_ck)
10: CSI selected as PLL clock (csi_ck)
11: HSE selected as PLL clock (hse_ck)

11.8.8 RCC PLL clock source selection register (RCC_PLL2CFGR)

Address offset: 0x02C

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

		rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bits 31:19 Reserved, must be kept at reset value.

Bit 18 **PLL2REN**: PLL2 DIVR divider output enable

Set and reset by software to enable the pll2_r_ck output of the PLL2.

To save power, DIVR2EN and DIVR2 bits must be set to 0 when the pll2_r_ck is not used.

0: pll2_r_ck output disabled (default after reset)

1: pll2_r_ck output enabled

Bit 17 **PLL2QEN**: PLL2 DIVQ divider output enable

Set and reset by software to enable the pll2_q_ck output of the PLL2.

To save power, when the pll2_q_ck output of the PLL2 is not used, the pll2_q_ck must be disabled.

0: pll2_q_ck output disabled (default after reset)

1: pll2_q_ck output enabled

Bit 16 **PLL2PEN**: PLL2 DIVP divider output enable

Set and reset by software to enable the pll2_p_ck output of the PLL2.

To save power, when the pll2_p_ck output of the PLL2 is not used, the pll2_p_ck must be disabled.

0: pll2_p_ck output disabled (default after reset)

1: pll2_p_ck output enabled

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **PLL2M[5:0]**: prescaler for PLL2

Set and cleared by software to configure the prescaler of the PLL2.

The hardware does not allow any modification of this prescaler when PLL2 is enabled (PLL2ON = 1 or PLL2RDY = 1).

To save power when PLL2 is not used, the value of PLL2M must be set to 0.

000000: prescaler disabled (default after reset)

000001: division by 1 (bypass)

000010: division by 2

000011: division by 3

...

100000: division by 32

...

111111: division by 63

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **PLL2VCOSEL**: PLL2 VCO selection
Set and reset by software to select the proper VCO frequency range used for PLL2.
This bit must be written before enabling the PLL2.
0: wide VCO range 192 to 836 MHz (default after reset)
1: medium VCO range 150 to 420 MHz

Bit 4 **PLL2FRACEN**: PLL2 fractional latch enable
Set and reset by software to enable the pll2_p_ck output of the PLL2.
To save power, when the pll2_p_ck output of the PLL2 is not used, the pll2_p_ck must be disabled.
0: pll2_p_ck output disabled (default after reset)
1: pll2_p_ck output enabled

Bits 3:2 **PLL2RGE[1:0]**: PLL2 input frequency range
Set and reset by software to select the proper reference frequency range used for PLL2.
These bits must be written before enabling the PLL2.
00: PLL2 input (ref2_ck) clock range frequency between 1 and 2 MHz (default after reset)
01: PLL2 input (ref2_ck) clock range frequency between 2 and 4 MHz
10: PLL2 input (ref2_ck) clock range frequency between 4 and 8 MHz
11: PLL2 input (ref2_ck) clock range frequency between 8 and 16 MHz

Bits 1:0 **PLL2SRC[1:0]**: PLL2M and PLLs clock source selection
Set and reset by software to select the PLL clock source.
These bits can be written only when all PLLs are disabled.
To save power, when no PLL is used, the value of PLL2SRC must be set to '00'.
00: no clock send to PLL2M divider and PLLs (default after reset)
01: HSI selected as PLL clock (hsi_ck)
10: CSI selected as PLL clock (csi_ck)
11: HSE selected as PLL clock (hse_ck)

11.8.9 RCC PLL clock source selection register (RCC_PLL3CFGR)

Address offset: 0x030

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

		rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bits 31:19 Reserved, must be kept at reset value.

Bit 18 **PLL3REN**: PLL3 DIVR divider output enable
Set and reset by software to enable the pll3_r_ck output of the PLL3.
To save power, DIVR2EN and DIVR2 bits must be set to 0 when the pll3_r_ck is not used.
0: pll3_r_ck output disabled (default after reset)
1: pll3_r_ck output enabled

Bit 17 **PLL3QEN**: PLL3 DIVQ divider output enable
Set and reset by software to enable the pll3_q_ck output of the PLL3.
To save power, when the pll3_q_ck output of the PLL3 is not used, the pll3_q_ck must be disabled.
0: pll3_q_ck output disabled (default after reset)
1: pll3_q_ck output enabled

Bit 16 **PLL3PEN**: PLL3 DIVP divider output enable
Set and reset by software to enable the pll3_p_ck output of the PLL3.
To save power, when the pll3_p_ck output of the PLL3 is not used, the pll3_p_ck must be disabled.
0: pll3_p_ck output disabled (default after reset)
1: pll3_p_ck output enabled

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **PLL3M[5:0]**: prescaler for PLL3
Set and cleared by software to configure the prescaler of the PLL3.
The hardware does not allow any modification of this prescaler when PLL3 is enabled (PLL3ON = 1 or PLL3RDY = 1).
To save power when PLL3 is not used, the value of PLL3M must be set to 0.
000000: prescaler disabled (default after reset)
000001: division by 1 (bypass)
000010: division by 2
000011: division by 3
...
100000: division by 32
...
111111: division by 63

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **PLL3VCOSEL**: PLL3 VCO selection
Set and reset by software to select the proper VCO frequency range used for PLL3.
This bit must be written before enabling the PLL3.
0: wide VCO range 192 to 836 MHz (default after reset)
1: medium VCO range 150 to 420 MHz

Bit 4 **PLL3FRACEN**: PLL3 fractional latch enable
Set and reset by software to latch the content of FRACN3 into the sigma-delta modulator.
To latch the FRACN3 value into the sigma-delta modulator, PLL3FRACEN must be set to 0, then set to 1. The transition 0 to 1 transfers the content of FRACN3 into the modulator.

Bits 3:2 **PLL3RGE[1:0]**: PLL3 input frequency range
Set and reset by software to select the proper reference frequency range used for PLL3.
This bit must be written before enabling the PLL3.
00: PLL3 input (ref3_ck) clock range frequency between 1 and 2 MHz (default after reset)
01: PLL3 input (ref3_ck) clock range frequency between 2 and 4 MHz
10: PLL3 input (ref3_ck) clock range frequency between 4 and 8 MHz
11: PLL3 input (ref3_ck) clock range frequency between 8 and 16 MHz

Bits 1:0 **PLL3SRC[1:0]**: PLL3M and PLLs clock source selection

Set and reset by software to select the PLL clock source. These bits can be written only when all PLLs are disabled.
To save power, when no PLL is used, the value of PLL3SRC must be set to '00'.
00: no clock send to PLL3M divider and PLLs (default after reset)
01: HSI selected as PLL clock (hsi_ck)
10: CSI selected as PLL clock (csi_ck)
11: HSE selected as PLL clock (hse_ck)

11.8.10 RCC PLL1 dividers register (RCC_PLL1DIVR)

Address offset: 0x034

Reset value: 0x0101 0280

Access: no wait state, word, half-word and byte access

Bit 31 Reserved, must be kept at reset value.

Bits 30:24 **PLL1R[6:0]**: PLL1 DIVR division factor

Set and reset by software to control the frequency of the pll1_r_ck clock.
These bits can be written only when the PLL1 is disabled (PLL1ON = 0 and PLL1RDY = 0).
0000000: pll1_r_ck = vco1_ck / 1
0000001: pll1_r_ck = vco1_ck / 2 (default after reset)
0000010: pll1_r_ck = vco1_ck / 3
0000011: pll1_r_ck = vco1_ck / 4
...
1111111: pll1_r_ck = vco1_ck / 128

Bit 23 Reserved, must be kept at reset value.

Bits 22:16 **PLL1Q[6:0]**: PLL1 DIVQ division factor

Set and reset by software to control the frequency of the pll1_q_ck clock.
These bits can be written only when the PLL1 is disabled (PLL1ON = 0 and PLL1RDY = 0).
0000000: pll1_q_ck = vco1_ck
0000001: pll1_q_ck = vco1_ck / 2 (default after reset)
0000010: pll1_q_ck = vco1_ck / 3
0000011: pll1_q_ck = vco1_ck / 4
...
1111111: pll1_q_ck = vco1_ck / 128

Bits 15:9 **PLL1P[6:0]**: PLL1 DIVP division factor

Set and reset by software to control the frequency of the pll1_p_ck clock.
These bits can be written only when the PLL1 is disabled (PLL1ON = 0 and PLL1RDY = 0).
Note that odd division factors are not allowed.
0000000: Not allowed
0000001: pll1_p_ck = vco1_ck / 2 (default after reset)
0000010: Not allowed
0000011: pll1_p_ck = vco1_ck / 4
...
1111111: pll1_p_ck = vco1_ck / 128

Bits 8:0 **PLL1N[8:0]**: Multiplication factor for PLL1VCO

Set and reset by software to control the multiplication factor of the VCO.
These bits can be written only when the PLL is disabled (PLL1ON = 0 and PLL1RDY = 0).
0x003: PLL1N = 4
0x004: PLL1N = 5
0x005: PLL1N = 6
...
0x080: PLL1N = 129 (default after reset)
...
0x1FF: PLL1N = 512
Others: reserved

11.8.11 RCC PLL1 fractional divider register (RCC_PLL1FRACR)

Address offset: 0x038

Reset value: 0x0000 0000

Access: no wait state; word and half-word access

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw			

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:3 **PLL1FRACN[12:0]**: fractional part of the multiplication factor for PLL1 VCO

Set and reset by software to control the fractional part of the multiplication factor of the VCO. These bits can be written at any time, allowing dynamic fine-tuning of the PLL1 VCO.

Caution: The software must set correctly these bits to insure that the VCO output frequency is in the valid frequency range, that is:
* 128 to 560 MHz if PLL1VCOSEL = 0
* 150 to 420 MHz if PLL1VCOSEL = 1
VCO output frequency = F_{ref1_ck} x (PLL1N + (PLL1FRACN / 2^{13})), with
* PLL1N between 8 and 420
* PLL1FRACN between 0 and 2^{13} - 1
* The input frequency F_{ref1_ck} must be between 1 and 16 MHz.
To change the PLL1FRACN value on-the-fly even if the PLL is enabled, the application must proceed as follows:
* Set the bit PLL1FRACEN to 0
* Write the new fractional value into PLL1FRACN
* Set the bit PLL1FRACEN to 1

Bits 2:0 Reserved, must be kept at reset value.

11.8.12 RCC PLL1 dividers register (RCC_PLL2DIVR)

Address offset: 0x03C

Reset value: 0x0101 0280

Access: no wait state, word, half-word and byte access

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **PLL3RDYIE**: PLL3 ready interrupt enable

Set and reset by software to enable/disable interrupt caused by PLL3 lock.
0: PLL3 lock interrupt disabled (default after reset)
1: PLL3 lock interrupt enabled

Bit 7 **PLL2RDYIE**: PLL2 ready interrupt enable

Set and reset by software to enable/disable interrupt caused by PLL2 lock.
0: PLL2 lock interrupt disabled (default after reset)
1: PLL2 lock interrupt enabled

Bit 6 **PLL1RDYIE**: PLL1 ready interrupt enable

Set and reset by software to enable/disable interrupt caused by PLL1 lock.
0: PLL1 lock interrupt disabled (default after reset)
1: PLL1 lock interrupt enabled

Bit 5 **HSI48RDYIE: HSI48 ready interrupt enable**

Set and reset by software to enable/disable interrupt caused by the HSI48 oscillator stabilization.
0: HSI48 ready interrupt disabled (default after reset)
1: HSI48 ready interrupt enabled

Bit 4 **HSERDYIE**: HSE ready interrupt enable
Set and reset by software to enable/disable interrupt caused by the HSE oscillator stabilization.
0: HSE ready interrupt disabled (default after reset)
1: HSE ready interrupt enabled

Bit 3 **HSIRDYIE**: HSI ready interrupt enable
Set and reset by software to enable/disable interrupt caused by the HSI oscillator stabilization.
0: HSI ready interrupt disabled (default after reset)
1: HSI ready interrupt enabled

Bit 2 **CSIRDYIE**: CSI ready interrupt enable
Set and reset by software to enable/disable interrupt caused by the CSI oscillator stabilization.
0: CSI ready interrupt disabled (default after reset)
1: CSI ready interrupt enabled

Bit 1 **LSERDYIE**: LSE ready interrupt enable
Set and reset by software to enable/disable interrupt caused by the LSE oscillator stabilization.
0: LSE ready interrupt disabled (default after reset)
1: LSE ready interrupt enabled

Bit 0 **LSIRDYIE**: LSI ready interrupt enable
Set and reset by software to enable/disable interrupt caused by the LSI oscillator stabilization.
0: LSI ready interrupt disabled (default after reset)
1: LSI ready interrupt enabled

11.8.17 RCC clock source interrupt flag register (RCC_CIFR)

Address offset: 0x054

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **HSECSSF**: HSE clock security system interrupt flag
Reset by software by writing HSECSSC bit.
Set by hardware in case of HSE clock failure.
0: no clock security interrupt caused by HSE clock failure (default after reset)
1: clock security interrupt caused by HSE clock failure

Bit 9 Reserved, must be kept at reset value.

Bit 8 **PLL3RDYF**: PLL3 ready interrupt flag
Reset by software by writing PLL3RDYC bit.
Set by hardware when the PLL3 locks and PLL3RDYIE is set.
0: no clock ready interrupt caused by PLL3 lock (default after reset)
1: clock ready interrupt caused by PLL3 lock

Bit 7 **PLL2RDYF**: PLL2 ready interrupt flag
Reset by software by writing PLL2RDYC bit.
Set by hardware when the PLL2 locks and PLL2RDYIE is set.
0: no clock ready interrupt caused by PLL2 lock (default after reset)
1: clock ready interrupt caused by PLL2 lock

Bit 6 **PLL1RDYF**: PLL1 ready interrupt flag
Reset by software by writing PLL1RDYC bit.
Set by hardware when the PLL1 locks and PLL1RDYIE is set.
0: no clock ready interrupt caused by PLL1 lock (default after reset)
1: clock ready interrupt caused by PLL1 lock

Bit 5 **HSI48RDYF**: HSI48 ready interrupt flag
Reset by software by writing HSI48RDYC bit.
Set by hardware when the HSI48 clock becomes stable and HSI48RDYIE is set.
0: no clock ready interrupt caused by the HSI48 oscillator (default after reset)
1: clock ready interrupt caused by the HSI48 oscillator

Bit 4 **HSERDYF**: HSE ready interrupt flag
Reset by software by writing HSERDYC bit.
Set by hardware when the HSE clock becomes stable and HSERDYIE is set.
0: no clock ready interrupt caused by the HSE (default after reset)
1: clock ready interrupt caused by the HSE

Bit 3 **HSIRDYF**: HSI ready interrupt flag
Reset by software by writing HSIRDYC bit.
Set by hardware when the HSI clock becomes stable and HSIRDYIE is set.
0: no clock ready interrupt caused by the HSI (default after reset)
1: clock ready interrupt caused by the HSI

Bit 2 **CSIRDYF**: CSI ready interrupt flag
Reset by software by writing CSIRDYC bit.
Set by hardware when the CSI clock becomes stable and CSIRDYIE is set.
0: no clock ready interrupt caused by the CSI (default after reset)
1: clock ready interrupt caused by the CSI

Bit 1 **LSERDYF**: LSE ready interrupt flag
Reset by software by writing LSERDYC bit.
Set by hardware when the LSE clock becomes stable and LSERDYIE is set.
0: no clock ready interrupt caused by the LSE (default after reset)
1: clock ready interrupt caused by the LSE

Bit 0 **LSIRDYF**: LSI ready interrupt flag
Reset by software by writing LSIRDYC bit.
Set by hardware when the LSI clock becomes stable and LSIRDYIE is set.
0: no clock ready interrupt caused by the LSI (default after reset)
1: clock ready interrupt caused by the LSI

11.8.18 RCC clock source interrupt clear register (RCC_CICR)

Address offset: 0x058

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	HSECSSC	Res.	PLL3RDYC	PLL2RDYC	PLL1RDYC	HSI48RDYC	HSERDYC	HSIRDYC	CSIRDYC	LSERDYC	LSIRDYC
					rc_w1		rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **HSECSSC**: HSE clock security system interrupt clear
Set by software to clear HSECSSF.
Reset by hardware when clear done.
0: HSECSSF no effect (default after reset)
1: HSECSSF cleared

Bit 9 Reserved, must be kept at reset value.

Bit 8 **PLL3RDYC**: PLL3 ready interrupt clear
Set by software to clear PLL3RDYF.
Reset by hardware when clear done.
0: PLL3RDYF no effect (default after reset)
1: PLL3RDYF cleared

Bit 7 **PLL2RDYC**: PLL2 ready interrupt clear
Set by software to clear PLL2RDYF.
Reset by hardware when clear done.
0: PLL2RDYF no effect (default after reset)
1: PLL2RDYF cleared

Bit 6 **PLL1RDYC**: PLL1 ready interrupt clear
Set by software to clear PLL1RDYF.
Reset by hardware when clear done.
0: PLL1RDYF no effect (default after reset)
1: PLL1RDYF cleared

Bit 5 **HSI48RDYC**: HSI48 ready interrupt clear
Set by software to clear HSI48RDYF.
Reset by hardware when clear done.
0: HSI48RDYF no effect (default after reset)
1: HSI48RDYF cleared

Bit 4 **HSERDYC**: HSE ready interrupt clear
Set by software to clear HSERDYF.
Reset by hardware when clear done.
0: HSERDYF no effect (default after reset)
1: HSERDYF cleared

Bit 3 **HSIRDYC**: HSI ready interrupt clear
Set by software to clear HSIRDYF.
Reset by hardware when clear done.
0: HSIRDYF no effect (default after reset)
1: HSIRDYF cleared

Bit 2 **CSIRDYC**: HSI ready interrupt clear
Set by software to clear CSIRDYF.
Reset by hardware when clear done.
0: CSIRDYF no effect (default after reset)
1: CSIRDYF cleared

Bit 1 **LSERDYC**: LSE ready interrupt clear
Set by software to clear LSERDYF.
Reset by hardware when clear done.
0: LSERDYF no effect (default after reset)
1: LSERDYF cleared

Bit 0 **LSIRDYC**: LSI ready interrupt clear
Set by software to clear LSIRDYF.
Reset by hardware when clear done.
0: LSIRDYF no effect (default after reset)
1: LSIRDYF cleared

11.8.19 RCC AHB1 reset register (RCC_AHB1RSTR)

Address offset: 0x060

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ETH RST	Res.	RAMCFG RST	Res.
												rw		rw	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

rw	rw		rw											rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **ETHRST**: ETHRST block reset
Set and reset by software
0: does not reset ETHRST block (default after reset)
1: resets the ETHRST block

Bit 18 Reserved, must be kept at reset value.

Bit 17 **RAMCFGRST**: RAMCFG block reset
Set and reset by software.
0: does not reset RAMCFG block (default after reset)
1: resets RAMCFG block

Bit 16 Reserved, must be kept at reset value.

Bit 15 **FMACRST**: FMAC block reset
Set and reset by software.
0: does not reset FMAC block (default after reset)
1: resets FMAC block

Bit 14 **CORDICRST**: CORDIC block reset
Set and reset by software.
0: does not reset CORDIC block (default after reset)
1: resets CORDIC block

Bit 13 Reserved, must be kept at reset value.

Bit 12 **CRCRST**: CRC block reset Set and reset by software.
0: does not reset CRC block (default after reset)
1: resets CRC block

Bits 11:2 Reserved, must be kept at reset value.

Bit 1 **GPDMA2RST**: GPDMA2 block reset
Set and reset by software.
0: does not reset GPDMA2 block (default after reset)
1: resets GPDMA2 block

Bit 0 **GPDMA1RST**: GPDMA1 block reset
Set and reset by software.
0: does not reset GPDMA1 block (default after reset)
1: resets GPDMA1 block

11.8.20 RCC AHB2 peripheral reset register (RCC_AHB2RSTR)

Address offset: 0x064

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

			rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **SAESRST**: SAES block reset
Set and reset by software.
0: does not reset SAES block (default after reset)
1: resets SAES block

Bit 19 **PKARST**: PKA block reset
Set and reset by software.
0: does not reset PKA block (default after reset)
1: resets PKA block

Bit 18 **RNGRST**: RNG block reset
Set and reset by software.
0: does not reset RNG block (default after reset)
1: resets RNG block

Bit 17 **HASHRST**: HASH block reset
Set and reset by software.
0: does not reset HASH block (default after reset)
1: resets HASH block

Bit 16 **AESRST**: AES block reset
Set and reset by software.
0: does not reset AES block (default after reset)
1: resets AES block

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **DCMI_PSSIRST**: digital camera interface block reset (DCMI or PSSI depending which interface is active)
Set and reset by software.
0: does not reset the DCMI/PSSI block (default after reset)
1: resets the DCMI/PSSI block

Bit 11 **DAC1RST**: DAC block reset
Set and reset by software.
0: does not reset DAC block (default after reset)
1: resets DAC block

Bit 10 **ADCRST**: ADC1 and 2 blocks reset
Set and reset by software.
0: does not reset ADC1 and 2 blocks (default after reset)
1: resets ADC1 and 2 blocks

Bit 9 Reserved, must be kept at reset value.

Bit 8 **GPIOIRST**: GPIOI block reset
Set and reset by software.
0: does not reset the GPIOI block (default after reset)
1: resets the GPIOI block

Bit 7 **GPIOHRST**: GPIOH block reset
Set and reset by software.
0: does not reset the GPIOH block (default after reset)
1: resets the GPIOH block

Bit 6 **GPIOGRST**: GPIOG block reset
Set and reset by software.
0: does not reset the GPIOG block (default after reset)
1: resets the GPIOG block

Bit 5 **GPIOFRST**: GPIOF block reset
Set and reset by software.
0: does not reset the GPIOF block (default after reset)
1: resets the GPIOF block

Bit 4 **GPIOERST**: GPIOE block reset
Set and reset by software.
0: does not reset the GPIOE block (default after reset)
1: resets the GPIOE block

Bit 3 **GPIODRST**: GPIOD block reset
Set and reset by software.
0: does not reset the GPIOD block (default after reset)
1: resets the GPIOD block

Bit 2 **GPIOCRST**: GPIOC block reset
Set and reset by software.
0: does not reset the GPIOC block (default after reset)
1: resets the GPIOC block

Bit 1 **GPIOBRST**: GPIOB block reset
Set and reset by software.
0: does not reset the GPIOB block (default after reset)
1: resets the GPIOB block

Bit 0 **GPIOARST**: GPIOA block reset
Set and reset by software.
0: does not reset the GPIOA block (default after reset)
1: resets the GPIOA block

11.8.21 RCC AHB4 peripheral reset register (RCC_AHB4RSTR)

Address offset: 0x06C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OCTOSPI1 RST	Res.	Res.	Res.	FMC RST
											rw				rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	SDMMC2 RST	SDMMC1 RST	Res.	Res.	Res.	OTFDEC1 RST	Res.	Res.	Res.	Res.	Res.	Res.	Res.
			rw	rw				rw							

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **OCTOSPI1RST**: OCTOSPI1 block reset
Set and reset by software.
0: does not reset OCTOSPI1 block (default after reset)
1: resets OCTOSPI1 block

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **FMCRST**: FMC block reset
Set and reset by software.
0: does not reset FMC block (default after reset)
1: resets FMC block

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **SDMMC2RST**: SDMMC2 and SDMMC2 delay blocks reset
Set and reset by software.
0: does not reset SDMMC2 and SDMMC2 delay blocks (default after reset)
1: resets SDMMC2 and SDMMC2 delay blocks

Bit 11 **SDMMC1RST**: SDMMC1 and SDMMC1 delay blocks reset
Set and reset by software.
0: does not reset SDMMC1 and SDMMC1 delay blocks (default after reset)
1: resets SDMMC1 and SDMMC1 delay blocks

Bits 10:8 Reserved, must be kept at reset value.

Bit 7 **OTFDEC1RST**: OTFDEC1 block reset
Set and reset by software.
0: does not reset OTFDEC1 block (default after reset)
1: resets OTFDEC1 block

Bits 6:0 Reserved, must be kept at reset value.

11.8.22 RCC APB1 peripheral low reset register (RCC_APB1LRSTR)

Address offset: 0x074

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw						rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **UART8RST**: UART8 block reset
Set and reset by software.
0: does not reset the UART8 block (default after reset)
1: resets the UART8 block

Bit 30 **UART7RST**: UART7 block reset
Set and reset by software.
0: does not reset the UART7 block (default after reset)
1: resets the UART7 block

Bit 29 Reserved, must be kept at reset value.

Bit 28 **CECRST**: HDMI-CEC block reset
Set and reset by software.
0: does not reset the HDMI-CEC block (default after reset)
1: resets the HDMI-CEC block

Bit 27 **USART11RST**: USART11 block reset
Set and reset by software.
0: does not reset the USART11 block (default after reset)
1: resets the USART11 block

Bit 26 **USART10RST**: USART10 block reset
Set and reset by software.
0: does not reset the USART10 block (default after reset)
1: resets the USART10 block

Bit 25 **USART6RST**: USART6 block reset
Set and reset by software.
0: does not reset the USART6 block (default after reset)
1: resets the USART6 block

Bit 24 **CRSRST**: CRS block reset
Set and reset by software.
0: does not reset the CRS block (default after reset)
1: resets the CRS block

Bit 23 **I3C1RST**: I3C1 block reset
Set and reset by software.
0: does not reset the I3C1 block (default after reset)
1: resets the I3C1 block

Bit 22 **I2C2RST**: I2C2 block reset
Set and reset by software.
0: does not reset the I2C2 block (default after reset)
1: resets the I2C2 block

Bit 21 **I2C1RST**: I2C1 block reset
Set and reset by software.
0: does not reset the I2C1 block (default after reset)
1: resets the I2C1 block

Bit 20 **UART5RST**: UART5 block reset
Set and reset by software.
0: does not reset the UART5 block (default after reset)
1: resets the UART5 block

Bit 19 **UART4RST**: UART4 block reset
Set and reset by software.
0: does not reset the UART4 block (default after reset)
1: resets the UART4 block

Bit 18 **USART3RST**: USART3 block reset
Set and reset by software.
0: does not reset the USART3 block (default after reset)
1: resets the USART3 block

Bit 17 **USART2RST**: USART2 block reset
Set and reset by software.
0: does not reset the USART2 block (default after reset)
1: resets the USART2 block

Bit 16 Reserved, must be kept at reset value.

Bit 15 **SPI3RST**: SPI3 block reset
Set and reset by software.
0: does not reset the SPI3 block (default after reset)
1: resets the SPI3 block

Bit 14 **SPI2RST**: SPI2 block reset
Set and reset by software.
0: does not reset the SPI2 block (default after reset)
1: resets the SPI2 block

Bits 13:9 Reserved, must be kept at reset value.

Bit 8 **TIM14RST**: TIM14 block reset
Set and reset by software.
0: does not reset the TIM14 block (default after reset)
1: resets the TIM14 block

Bit 7 **TIM13RST**: TIM13 block reset t
Set and reset by software.
0: does not reset the TIM13 block (default after reset)
1: resets the TIM13 block

Bit 6 **TIM12RST**: TIM12 block reset
Set and reset by software.
0: does not reset the TIM12 block (default after reset)
1: resets the TIM12 block

Bit 5 **TIM7RST**: TIM7 block reset
Set and reset by software.
0: does not reset the TIM7 block (default after reset)
1: resets the TIM7 block

Bit 4 **TIM6RST**: TIM6 block reset
Set and reset by software.
0: does not reset the TIM6 block (default after reset)
1: resets the TIM6 block

Bit 3 **TIM5RST**: TIM5 block reset
Set and reset by software.
0: does not reset the TIM5 block (default after reset)
1: resets the TIM5 block

Bit 2 **TIM4RST**: TIM4 block reset
Set and reset by software.
0: does not reset the TIM4 block (default after reset)
1: resets the TIM4 block

Bit 1 **TIM3RST**: TIM3 block reset
Set and reset by software.
0: does not reset the TIM3 block (default after reset)
1: resets the TIM3 block

Bit 0 **TIM2RST**: TIM2 block reset
Set and reset by software.
0: does not reset the TIM2 block (default after reset)
1: resets the TIM2 block

11.8.23 RCC APB1 peripheral high reset register (RCC_APB1HRSTR)

Address offset: 0x078

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	UCPD1RST	Res.	Res.	Res.	Res.	Res.	Res.	Res.

						rw				rw		rw		rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **UCPD1RST**: UCPD1 block reset
Set and reset by software.
0: does not reset the UCPD block (default after reset)
1: resets the UCPD block

Bits 22:10 Reserved, must be kept at reset value.

Bit 9 **FDCANRST**: FDCAN1 and FDCAN2 blocks reset
Set and reset by software.
0: does not reset the FDCAN1 and FDCAN2 blocks (default after reset)
1: resets the FDCAN1 and FDCAN2 blocks

Bits 8:6 Reserved, must be kept at reset value.

Bit 5 **LPTIM2RST**: LPTIM2 block reset
Set and reset by software.
0: does not reset the LPTIM2 block (default after reset)
1: resets the LPTIM2 block

Bit 4 Reserved, must be kept at reset value.

Bit 3 **DTSRST**: DTS block reset
Set and reset by software.
0: does not reset the DTS block (default after reset)
1: resets the DTS block

Bit 2 Reserved, must be kept at reset value.

Bit 1 **UART12RST**: UART12 block reset
Set and reset by software.
0: does not reset the UART12 block (default after reset)
1: resets the UART12 block

Bit 0 **UART9RST**: UART9 block reset
Set and reset by software.
0: does not reset UART9 block (default after reset)
1: resets UART9 block

11.8.24 RCC APB2 peripheral reset register (RCC_APB2RSTR)

Address offset: 0x07C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	rw	rw	rw	rw											

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **USBRST**: USB block reset
Set and reset by software.
0: does not reset the USB block (default after reset)
1: resets the USB block

Bit 23 Reserved, must be kept at reset value.

Bit 22 **SAI2RST**: SAI2 block reset
Set and reset by software.
0: does not reset the SAI2 block (default after reset)
1: resets the SAI2 block

Bit 21 **SAI1RST**: SAI1 block reset
Set and reset by software.
0: does not reset the SAI1 (default after reset)
1: resets the SAI1

Bit 20 **SPI6RST**: SPI6 block reset
Set and reset by software.
0: does not reset the SPI6 block (default after reset)
1: resets the SPI6 block

Bit 19 **SPI4RST**: SPI4 block reset
Set and reset by software.
0: does not reset the SPI4 block (default after reset)
1: resets the SPI4 block

Bit 18 **TIM17RST**: TIM17 block reset
Set and reset by software.
0: does not reset the TIM17 block (default after reset)
1: resets the TIM17 block

Bit 17 **TIM16RST**: TIM16 block reset
Set and reset by software.
0: does not reset the TIM16 block (default after reset)
1: resets the TIM16 block

Bit 16 **TIM15RST**: TIM15 block reset
Set and reset by software.
0: does not reset the TIM15 block (default after reset)
1: resets the TIM15 block

Bit 15 Reserved, must be kept at reset value.

Bit 14 **USART1RST**: USART1 block reset
Set and reset by software.
0: does not reset the USART1 block (default after reset)
1: resets the USART1 block

Bit 13 **TIM8RST**: TIM8 block reset
Set and reset by software.
0: does not reset the TIM8 block (default after reset)
1: resets the TIM8 block

Bit 12 **SPI1RST**: SPI1 block reset
Set and reset by software.
0: does not reset the SPI1 block (default after reset)
1: resets the SPI1 block

Bit 11 **TIM1RST**: TIM1 block reset
Set and reset by software.
0: does not reset the TIM1 block (default after reset)
1: resets the TIM1 block

Bits 10:0 Reserved, must be kept at reset value.

11.8.25 RCC APB3 peripheral reset register (RCC_APB3RSTR)

Address offset: 0x080

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VREF RST	Res.	Res.	Res.	Res.
											rw

rw	rw	rw	rw	rw			rw	rw	rw	rw					

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **VREFRST**: VREFBUF block reset
Set and reset by software.
0: does not reset the VREFBUF block (default after reset)
1: resets the VREFBUF block

Bits 19:16 Reserved, must be kept at reset value.

Bit 15 **LPTIM6RST**: LPTIM6 block reset
Set and reset by software.
0: does not reset the LPTIM6 block (default after reset)
1: resets the LPTIM6 block

Bit 14 **LPTIM5RST**: LPTIM5 block reset
Set and reset by software.
0: does not reset the LPTIM5 block (default after reset)
1: resets the LPTIM5 block

Bit 13 **LPTIM4RST**: LPTIM4 block reset
Set and reset by software.
0: does not reset the LPTIM4 block (default after reset)
1: resets the LPTIM4 block

Bit 12 **LPTIM3RST**: LPTIM3 block reset
Set and reset by software.
0: does not reset the LPTIM3 block (default after reset)
1: resets the LPTIM3 block

Bit 11 **LPTIM1RST**: LPTIM1 block reset
Set and reset by software.
0: does not reset the LPTIM1 block (default after reset)
1: resets the LPTIM1 block

Bits 10:9 Reserved, must be kept at reset value.

Bit 8 **I2C4RST**: I2C4 block reset
Set and reset by software.
0: does not reset the I2C4 block (default after reset)
1: resets the I2C4 block

Bit 7 **I2C3RST**: I2C3 block reset
Set and reset by software.
0: does not reset the I2C3 block (default after reset)
1: resets the I2C3 block

Bit 6 **LPUART1RST**: LPUART1 block reset
Set and reset by software.
0: does not reset the LPUART1 block (default after reset)
1: resets the LPUART1 block

Bit 5 **SPI5RST**: SPI5 block reset
Set and reset by software.
0: does not reset the SPI5 block (default after reset)
1: resets the SPI5 block

Bits 4:0 Reserved, must be kept at reset value.

11.8.26 RCC AHB1 peripherals clock register (RCC_AHB1ENR)

Address offset: 0x088

Reset value: 0xD000 0100

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31 **SRAM1EN**:SRAM1 clock enable
Set and reset by software.
0: SRAM1 clock disabled
1: SRAM1 clock enabled (default after reset)

Bit 30 **DCACHEEN**: DCACHE clock enable
Set and reset by software
0: DCACHE peripheral clock disabled (default after reset)
1: DCACHE peripheral clock enabled

Bit 29 Reserved, must be kept at reset value.

Bit 28 **BKPRAMEN**: BKPRAM clock enable
Set and reset by software
0: BKPRAM peripheral clock disabled (default after reset)
1: BKPRAM peripheral clock enabled

Bits 27:25 Reserved, must be kept at reset value.

Bit 24 **TZSC1EN**: TZSC1 clock enable
Set and reset by software
0: TZSC1 peripheral clock disabled (default after reset)
1: TZSC1 peripheral clock enabled

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **ETHRXEN**: ETHRX clock enable
Set and reset by software
0: ETHRX clock disabled (default after reset)
1: ETHRX clock enabled

Bit 20 **ETHTXEN**: ETHTX clock enable
Set and reset by software
0: ETHTX clock disabled (default after reset)
1: ETHTX clock enabled

Bit 19 **ETHEN**: ETH clock enable
Set and reset by software
0: ETH peripheral clock disabled (default after reset)
1: ETH peripheral clock enabled

Bit 18 Reserved, must be kept at reset value.

Bit 17 **RAMCFGEN**: RAMCFG clock enable
Set and reset by software.
0: RAMCFG peripheral clock disabled (default after reset)
1: RAMCFG peripheral clock enabled

Bit 16 Reserved, must be kept at reset value.

Bit 15 **FMACEN**: FMAC clock enable
Set and reset by software.
0: FMAC peripheral clock disabled (default after reset)
1: FMAC peripheral clock enabled

Bit 14 **CORDICEN**: CORDIC clock enable
Set and reset by software.
0: CORDIC peripheral clock disabled (default after reset)
1: CORDIC peripheral clock enabled

Bit 13 Reserved, must be kept at reset value.

Bit 12 **CRCEN**: CRC clock enable
Set and reset by software.
0: CRC peripheral clock disabled (default after reset)
1: CRC peripheral clock enabled

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **FLITFEN**: Flash interface clock enable
Set and reset by software.
0: FLASH interface clock disabled
1: FLASH interface clock enabled (default after reset)

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **GPDMA2EN**: GPDMA2 clock enable
Set and reset by software.
0: GPDMA2 peripheral clock disabled (default after reset)
1: GPDMA2 peripheral clock enabled

Bit 0 **GPDMA1EN**: GPDMA1 clock enable
Set and reset by software.
0: GPDMA1 peripheral clock disabled (default after reset)
1: GPDMA1 peripheral clock enabled

11.8.27 RCC AHB2 peripheral clock register (RCC_AHB2ENR)

Address offset: 0x08C

Reset value: 0xC000 0000

Bit 31 **SRAM3EN**: SRAM3 clock enable
Set and reset by software.
0: SRAM3 clock disabled
1: SRAM3 clock enabled (default after reset)

Bit 30 **SRAM2EN**: SRAM2 clock enable
Set and reset by software.
0: SRAM2 clock disabled
1: SRAM2 clock enabled (default after reset)

Bits 29:21 Reserved, must be kept at reset value.

Bit 20 **SAESEN**: SAES clock enable
Set and reset by software.
0: SAES peripheral clock disabled (default after reset)
1: SAES peripheral clock enabled

Bit 19 **PKAEN**: PKA clock enable
Set and reset by software.
0: PKA peripheral clock disabled (default after reset)
1: PKA peripheral clock enabled

Bit 18 **RNGEN**: RNG clock enable
Set and reset by software.
0: RNG peripheral clock disabled (default after reset)
1: RNG peripheral clock enabled

Bit 17 **HASHEN**: HASH clock enable
Set and reset by software.
0: HASH peripheral clock disabled (default after reset)
1: HASH peripheral clock enabled

Bit 16 **AESEN**: AES clock enable
Set and reset by software.
0: AES peripheral clock disabled (default after reset)
1: AES peripheral clock enabled

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **DCMI_PSSIEN**: digital camera interface clock enable (DCMI or PSSI depending which interface is active)
Set and reset by software.
0: DCMI/PSSI peripheral clock disabled (default after reset)
1: DCMI/PSSI peripheral clock enabled

Bit 11 **DAC1EN**: DAC clock enable
Set and reset by software.
0: DAC peripheral clock disabled (default after reset)
1: DAC peripheral clock enabled

Bit 10 **ADCEN**: ADC1 and 2 peripherals clock enabled
Set and reset by software.
0: ADC1 and 2 peripherals clock disabled (default after reset)
1: ADC1 and 2 peripherals clock enabled

Bit 9 Reserved, must be kept at reset value.

Bit 8 **GPIOIEN**: GPIOI clock enable
Set and reset by software.
0: GPIOI peripheral clock disabled (default after reset)
1: GPIOI peripheral clock enabled

Bit 7 **GPIOHEN**: GPIOH clock enable
Set and reset by software.
0: GPIOH peripheral clock disabled (default after reset)
1: GPIOH peripheral clock enabled

Bit 6 **GPIOGEN**: GPIOG clock enable
Set and reset by software.
0: GPIOG peripheral clock disabled (default after reset)
1: GPIOG peripheral clock enabled

Bit 5 **GPIOFEN**: GPIOF clock enable
Set and reset by software.
0: GPIOF peripheral clock disabled (default after reset)
1: GPIOF peripheral clock enabled

Bit 4 **GPIOEEN**: GPIOE clock enable
Set and reset by software.
0: GPIOE peripheral clock disabled (default after reset)
1: GPIOE peripheral clock enabled

Bit 3 **GPIODEN**: GPIOD clock enable
Set and reset by software.
0: GPIOD peripheral clock disabled (default after reset)
1: GPIOD peripheral clock enabled

Bit 2 **GPIOCEN**: GPIOC clock enable
Set and reset by software.
0: GPIOC peripheral clock disabled (default after reset)
1: GPIOC peripheral clock enabled

Bit 1 **GPIOBEN**: GPIOB clock enable
Set and reset by software.
0: GPIOB peripheral clock disabled (default after reset)
1: GPIOB peripheral clock enabled

Bit 0 **GPIOAEN**: GPIOA clock enable
Set and reset by software.
0: GPIOA peripheral clock disabled (default after reset)
1: GPIOA peripheral clock enabled

11.8.28 RCC AHB4 peripheral clock register (RCC_AHB4ENR)

Address offset: 0x094

Reset value: 0x0000 0000

			rw	rw				rw							

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **OCTOSPI1EN**: OCTOSPI1 clock enable
Set and reset by software.
0: OCTOSPI1 peripheral clock disabled (default after reset)
1: OCTOSPI1 peripheral clock enabled

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **FMCEN**: FMC clock enable
Set and reset by software.
0: FMC peripheral clock disabled (default after reset)
1: FMC peripheral clock enabled

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **SDMMC2EN**: SDMMC2 and SDMMC2 delay peripheral clock enabled
Set and reset by software.
0: SDMMC2 and SDMMC2 delay peripherals clock disabled (default after reset)
1: SDMMC2 and SDMMC2 delay peripherals clock enabled

Bit 11 **SDMMC1EN**: SDMMC1 and SDMMC1 delay peripheral clock enable reset
0: SDMMC1 and SDMMC1 delay peripherals clock disabled (default after reset)
1: SDMMC1 and SDMMC1 delay peripherals clock enabled

Bits 10:8 Reserved, must be kept at reset value.

Bit 7 **OTFDEC1EN**: OTFDEC1 clock enable
Set and reset by software.
0: OTFDEC1 peripheral clock disabled (default after reset)
1: OTFDEC1 peripheral clock enabled

Bits 6:0 Reserved, must be kept at reset value.

11.8.29 RCC APB1 peripheral clock register (RCC_APB1LENR)

Address offset: 0x09C

Reset value: 0x0000 0000

Bit 31 **UART8EN**: UART8 clock enable
Set and reset by software.
0: UART8 peripheral clock disabled (default after reset)
1: UART8 peripheral clock enabled

Bit 30 **UART7EN**: UART7 clock enable
Set and reset by software.
0: UART7 peripheral clock disabled (default after reset)
1: UART7 peripheral clock enabled

Bit 29 Reserved, must be kept at reset value.

Bit 28 **CECEN**: HDMI-CEC clock enable
Set and reset by software.
0: HDMI-CEC peripheral clock disabled (default after reset)
1: HDMI-CEC peripheral clock enabled

Bit 27 **USART11EN**: USART11 clock enable
0: USART11 peripheral clock disabled (default after reset)
1: USART11 peripheral clock enabled

Bit 26 **USART10EN**: USART10 clock enable
Set and reset by software.
0: USART10 peripheral clock disabled (default after reset)
1: USART10 peripheral clock enabled

Bit 25 **USART6EN**: USART6 clock enable
Set and reset by software.
0: USART6 peripheral clock disabled (default after reset)
1: USART6 peripheral clock enabled

Bit 24 **CRSEN**: CRS clock enable
Set and reset by software.
0: CRS peripheral clock disabled (default after reset)
1: CRS peripheral clock enabled

Bit 23 **I3C1EN**: I3C1 clock enable
Set and reset by software.
0: I3C1 peripheral clock disabled (default after reset)
1: I3C1 peripheral clock enabled

Bit 22 **I2C2EN**: I2C2 clock enable
Set and reset by software.
0: I2C2 peripheral clock disabled (default after reset)
1: I2C2 peripheral clock enabled

Bit 21 **I2C1EN**: I2C1 clock enable
Set and reset by software.
0: I2C1 peripheral clock disabled (default after reset)
1: I2C1 peripheral clock enabled

Bit 20 **UART5EN**: UART5 clock enable
Set and reset by software.
0: UART5 peripheral clock disabled (default after reset)
1: UART5 peripheral clock enabled

Bit 19 **UART4EN**: UART4 clock enable
Set and reset by software.
0: UART4 peripheral clock disabled (default after reset)
1: UART4 peripheral clock enabled

Bit 18 **USART3EN**: USART3 clock enable
Set and reset by software.
0: USART3 peripheral clock disabled (default after reset)
1: USART3 peripheral clock enabled

Bit 17 **USART2EN**: USART2 clock enable
Set and reset by software.
0: USART2 peripheral clock disabled (default after reset)
1: USART2 peripheral clock enabled

Bit 16 Reserved, must be kept at reset value.

Bit 15 **SPI3EN**: SPI3 clock enable
Set and reset by software.
0: SPI3 peripheral clock disabled (default after reset)
1: SPI3 peripheral clock enabled

Bit 14 **SPI2EN**: SPI2 clock enable
Set and reset by software.
0: SPI2 peripheral clock disabled (default after reset)
1: SPI2 peripheral clock enabled

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **WWDGEN**: WWDG clock enable
Set and reset by software.
0: WWDG peripheral clock disabled (default after reset)
1: WWDG peripheral clock enabled

Bits 10:9 Reserved, must be kept at reset value.

Bit 8 **TIM14EN**: TIM14 clock enable
Set and reset by software.
0: TIM14 peripheral clock disabled (default after reset)
1: TIM14 peripheral clock enabled

Bit 7 **TIM13EN**: TIM13 clock enable
Set and reset by software.
0: TIM13 peripheral clock disabled (default after reset)
1: TIM13 peripheral clock enabled

Bit 6 **TIM12EN**: TIM12 clock enable
Set and reset by software.
0: TIM12 peripheral clock disabled (default after reset)
1: TIM12 peripheral clock enabled

Bit 5 **TIM7EN**: TIM7 clock enable
Set and reset by software.
0: TIM7 peripheral clock disabled (default after reset)
1: TIM7 peripheral clock enabled

Bit 4 **TIM6EN**: TIM6 clock enable
Set and reset by software.
0: TIM6 peripheral clock disabled (default after reset)
1: TIM6 peripheral clock enabled

Bit 3 **TIM5EN**: TIM5 clock enable
Set and reset by software.
0: TIM5 peripheral clock disabled (default after reset)
1: TIM5 peripheral clock enabled

Bit 2 **TIM4EN**: TIM4 clock enable
Set and reset by software.
0: TIM4 peripheral clock disabled (default after reset)
1: TIM4 peripheral clock enabled

Bit 1 **TIM3EN**: TIM3 clock enable
Set and reset by software.
0: TIM3 peripheral clock disabled (default after reset)
1: TIM3 peripheral clock enabled

Bit 0 **TIM2EN**: TIM2 clock enable
Set and reset by software.
0: TIM2 peripheral clock disabled (default after reset)
1: TIM2 peripheral clock enabled

11.8.30 RCC APB1 peripheral clock register (RCC_APB1HENR)

Address offset: 0x0A0

Reset value: 0x0000 0000

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **UCPD1EN**: UCPD1 clock enable
Set and reset by software.
0: UCPD peripheral clock disabled (default after reset)
1: UCPD peripheral clock enabled

Bits 22:10 Reserved, must be kept at reset value.

Bit 9 **FDCANEN**: FDCAN1 and FDCAN2 peripheral clock enable
Set and reset by software.
0: FDCAN1 and FDCAN2 peripheral clock disabled (default after reset)
1: FDCAN1 and FDCAN2 peripheral clock enabled

Bits 8:6 Reserved, must be kept at reset value.

Bit 5 **LPTIM2EN**: LPTIM2 clock enable
Set and reset by software.
0: LPTIM2 peripheral clock disabled (default after reset)
1: LPTIM2 peripheral clock enabled

Bit 4 Reserved, must be kept at reset value.

Bit 3 **DTSEN**: DTS clock enable
Set and reset by software.
0: DTS peripheral clock disabled (default after reset)
1: DTS peripheral clock enabled

Bit 2 Reserved, must be kept at reset value.

Bit 1 **UART12EN**: UART12 clock enable
Set and reset by software.
0: UART12 peripheral clock disabled (default after reset)
1: UART12 peripheral clock enabled

Bit 0 **UART9EN**: UART9 clock enable
Set and reset by software.
0: UART9 peripheral clock disabled (default after reset)
1: resets UART9 peripheral clock enabled

11.8.31 RCC APB2 peripheral clock register (RCC_APB2ENR)

Address offset: 0x0A4

Reset value: 0x0000 0000

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **USBEN**: USB clock enable
Set and reset by software.
0: USB peripheral clock disabled (default after reset)
1: USB peripheral clock enabled

Bit 23 Reserved, must be kept at reset value.

Bit 22 **SAI2EN**: SAI2 clock enable
Set and cleared by software.
0: SAI2 clock disabled
1: SAI2 clock enabled

Bit 21 **SAI1EN**: SAI1 clock enable
Set and reset by software.
0: SAI1 peripheral clock disabled (default after reset)
1: SAI1 peripheral clock enabled

Bit 20 **SPI6EN**: SPI6 clock enable
Set and reset by software.
0: SPI6 peripheral clock disabled (default after reset)
1: SPI6 peripheral clock enabled

Bit 19 **SPI4EN**: SPI4 clock enable
Set and reset by software.
0: SPI4 peripheral clock disabled (default after reset)
1: SPI4 peripheral clock enabled

Bit 18 **TIM17EN**: TIM17 clock enable
Set and reset by software.
0: TIM17 peripheral clock disabled (default after reset)
1: TIM17 peripheral clock enabled

Bit 17 **TIM16EN**: TIM16 clock enable
Set and reset by software.
0: TIM16 peripheral clock disabled (default after reset)
1: TIM16 peripheral clock enabled

Bit 16 **TIM15EN**: TIM15 clock enable
Set and reset by software.
0: TIM15 peripheral clock disabled (default after reset)
1: TIM15 peripheral clock enabled

Bit 15 Reserved, must be kept at reset value.

Bit 14 **USART1EN**: USART1 clock enable
Set and reset by software.
0: USART1 peripheral clock disabled (default after reset)
1: USART1 peripheral clock enabled

Bit 13 **TIM8EN**: TIM8 clock enable
Set and reset by software.
0: TIM8 peripheral clock disabled (default after reset)
1: TIM8 peripheral clock enabled

Bit 12 **SPI1EN**: SPI1 clock enable
Set and reset by software.
0: SPI1 peripheral clock disabled (default after reset)
1: SPI1 peripheral clock enabled

Bit 11 **TIM1EN**: TIM1 clock enable
Set and reset by software.
0: TIM1 peripheral clock disabled (default after reset)
1: TIM1 peripheral clock enabled

Bits 10:0 Reserved, must be kept at reset value.

11.8.32 RCC APB3 peripheral clock register (RCC_APB3ENR)

Address offset: 0x0A8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **RTCAPBEN**: RTC APB interface clock enable
Set and reset by software.
0: RTC APB interface clock disabled (default after reset)
1: RTC APB interface clock enabled

Bit 20 **VREFBUFEN**: VREFBUF clock enable
Set and reset by software.
0: VREFBUF peripheral clock disabled (default after reset)
1: VREFBUF peripheral clock enabled

Bits 19:16 Reserved, must be kept at reset value.

Bit 15 **LPTIM6EN**: LPTIM6 clock enable
Set and reset by software.
0: LPTIM6 peripheral clock disabled (default after reset)
1: LPTIM6 peripheral clock enabled

Bit 14 **LPTIM5EN**: LPTIM5 clock enable
Set and reset by software.
0: LPTIM5 peripheral clock disabled (default after reset)
1: LPTIM5 peripheral clock enabled

Bit 13 **LPTIM4EN**: LPTIM4 clock enable
Set and reset by software.
0: LPTIM4 peripheral clock disabled (default after reset)
1: LPTIM4 peripheral clock enabled

Bit 12 **LPTIM3EN**: LPTIM3 clock enable
Set and reset by software.
0: LPTIM3 peripheral clock disabled (default after reset)
1: LPTIM3 peripheral clock enabled

Bit 11 **LPTIM1EN**: LPTIM1 clock enable
Set and reset by software.
0: LPTIM1 peripheral clock disabled (default after reset)
1: LPTIM1 peripheral clock enabled

Bits 10:9 Reserved, must be kept at reset value.

Bit 8 **I2C4EN**: I2C4 clock enable
Set and reset by software.
0: I2C4 peripheral clock disabled (default after reset)
1: I2C4 peripheral clock enabled

Bit 7 **I2C3EN**: I2C3 clock enable
Set and reset by software.
0: I2C3 peripheral clock disabled (default after reset)
1: I2C3 peripheral clock enabled

Bit 6 **LPUART1EN**: LPUART1 clock enable
Set and reset by software.
0: LPUART1 peripheral clock disabled (default after reset)
1: LPUART1 peripheral clock enabled

Bit 5 **SPI5EN**: SPI5 clock enable
Set and reset by software.
0: SPI5 peripheral clock disabled (default after reset)
1: SPI5 peripheral clock enabled

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **SBSEN**: SBS clock enable
Set and reset by software.
0: SBS peripheral clock disabled (default after reset)
1: SBS peripheral clock enabled

Bit 0 Reserved, must be kept at reset value.

11.8.33 RCC AHB1 sleep clock register (RCC_AHB1LPENR)

Address offset: 0x0B0

Reset value: 0xF13A D103

Set and reset by software
0: SRAM1 peripheral clock disabled during Sleep mode
1: SRAM1 peripheral clock enabled during Sleep mode (default after reset)

Bit 30 **DCACHELPEN**: DCACHE clock enable during Sleep mode
Set and reset by software
0: DCACHE peripheral clock disabled during Sleep mode
1: DCACHE peripheral clock enabled during Sleep mode (default after reset)

Bit 29 **ICACHELPEN**: ICACHE clock enable during Sleep mode
Set and reset by software
0: ICACHE peripheral clock disabled during Sleep mode
1: ICACHE peripheral clock enabled during Sleep mode (default after reset)

Bit 28 **BKPRAMLPEN**: BKPRAM clock enable during Sleep mode
Set and reset by software
0: BKPRAM peripheral clock disabled during Sleep mode
1: BKPRAM peripheral clock enabled during Sleep mode (default after reset)

Bits 27:25 Reserved, must be kept at reset value.

Bit 24 **TZSC1LPEN**: TZSC1 clock enable during Sleep mode
Set and reset by software
0: TZSC1 peripheral clock disabled during Sleep mode
1: TZSC1 peripheral clock enabled during Sleep mode (default after reset)

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **ETHRXLPEN**: ETHRX clock enable during Sleep mode
Set and reset by software
0: ETHRX clock disabled during Sleep mode
1: ETHRX clock enabled during Sleep mode (default after reset)

Bit 20 **ETHTXLPEN**: ETHTX clock enable during Sleep mode
Set and reset by software
0: ETHTX clock disabled during Sleep mode
1: ETHTX clock enabled during Sleep mode (default after reset)

Bit 19 **ETHLPEN**: ETH clock enable during Sleep mode
Set and reset by software
0: ETH peripheral clock disabled during Sleep mode
1: ETH peripheral clock enabled during Sleep mode (default after reset)

Bit 18 Reserved, must be kept at reset value.

Bit 17 **RAMCFGLPEN**: RAMCFG clock enable during Sleep mode
Set and reset by software.
0: RAMCFG peripheral clock disabled during Sleep mode
1: RAMCFG peripheral clock enabled during Sleep mode (default after reset)

Bit 16 Reserved, must be kept at reset value.

Bit 15 **FMACLPEN**: FMAC clock enable during Sleep mode
Set and reset by software.
0: FMAC peripheral clock disabled during Sleep mode
1: FMAC peripheral clock enabled during Sleep mode (default after reset)

Bit 14 **CORDICLPEN**: CORDIC clock enable during Sleep mode
Set and reset by software.
0: CORDIC peripheral clock disabled during Sleep mode
1: CORDIC peripheral clock enabled during Sleep mode (default after reset)

Bit 13 Reserved, must be kept at reset value.

Bit 12 **CRCLPEN**: CRC clock enable during Sleep mode
Set and reset by software.
0: CRC peripheral clock disabled during Sleep mode
1: CRC peripheral clock enabled during Sleep mode (default after reset)

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **FLITFLPEN**: Flash interface (FLITF) clock enable during Sleep mode
Set and reset by software.
0: FLITF peripheral clock disabled during Sleep mode
1: FLITF peripheral clock enabled during Sleep mode (default after reset)

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **GPDMA2LPEN**: GPDMA2 clock enable during Sleep mode
Set and reset by software.
0: GPDMA2 peripheral clock disabled during Sleep mode
1: GPDMA2 peripheral clock enabled during Sleep mode (default after reset)

Bit 0 **GPDMA1LPEN**: GPDMA1 clock enable during Sleep mode
Set and reset by software.
0: GPDMA1 peripheral clock disabled during Sleep mode
1: GPDMA1 peripheral clock enabled during Sleep mode (default after reset)

11.8.34 RCC AHB2 sleep clock register (RCC_AHB2LPENR)

Address offset: 0x0B4

Reset value: 0xC01F 1DFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

			rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **SRAM3LPEN**: SRAM3 clock enable during Sleep mode
Set and reset by software.
0: SRAM3 peripheral clock disabled during Sleep mode
1: SRAM3 peripheral clock enabled during Sleep mode (default after reset)

Bit 30 **SRAM2LPEN**: SRAM2 clock enable during Sleep mode
Set and reset by software.
0: SRAM2 peripheral clock disabled during Sleep mode
1: SRAM2 peripheral clock enabled during Sleep mode (default after reset)

Bits 29:21 Reserved, must be kept at reset value.

Bit 20 **SAESLPEN**: SAES clock enable during Sleep mode
Set and reset by software.
0: SAES peripheral clock disabled during Sleep mode
1: SAES peripheral clock enabled during Sleep mode (default after reset)

Bit 19 **PKALPEN**: PKA clock enable during Sleep mode
Set and reset by software.
0: PKA peripheral clock disabled during Sleep mode
1: PKA peripheral clock enabled during Sleep mode (default after reset)

Bit 18 **RNGLPEN**: RNG clock enable during Sleep mode
Set and reset by software.
0: RNG peripheral clock disabled during Sleep mode
1: RNG peripheral clock enabled during Sleep mode (default after reset)

Bit 17 **HASHLPEN**: HASH clock enable during Sleep mode
Set and reset by software.
0: HASH peripheral clock disabled during Sleep mode
1: HASH peripheral clock enabled during Sleep mode (default after reset)

Bit 16 **AESLPEN**: AES clock enable during Sleep mode
Set and reset by software.
0: AES peripheral clock disabled during Sleep mode
1: AES peripheral clock enabled during Sleep mode (default after reset)

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **DCMI_PSSILPEN**: digital camera interface clock enable during Sleep mode (DCMI or PSSI depending which interface is active)
Set and reset by software.
0: DCMI/PSSI peripheral clock disabled during Sleep mode
1: DCMI/PSSI peripheral clock enabled during Sleep mode (default after reset)

Bit 11 **DAC1LPEN**: DAC clock enable during Sleep mode
Set and reset by software.
0: DAC peripheral clock disabled during Sleep mode
1: DAC peripheral clock enabled during Sleep mode (default after reset)

Bit 10 **ADCLPEN**: ADC1 and 2 peripherals clock enable during Sleep mode
Set and reset by software.
0: ADC1 and 2 peripherals clock disabled during Sleep mode
1: ADC1 and 2 peripherals clock enabled during Sleep mode (default after reset)

Bit 9 Reserved, must be kept at reset value.

Bit 8 **GPIOILPEN**: GPIOI clock enable during Sleep mode
Set and reset by software.
0: GPIOI peripheral clock disabled during Sleep mode
1: GPIOI peripheral clock enabled during Sleep mode (default after reset)

Bit 7 **GPIOHLPEN**: GPIOH clock enable during Sleep mode
Set and reset by software.
0: GPIOH peripheral clock disabled during Sleep mode
1: GPIOH peripheral clock enabled during Sleep mode (default after reset)

Bit 6 **GPIOGLPEN**: GPIOG clock enable during Sleep mode
Set and reset by software.
0: GPIOG peripheral clock disabled during Sleep mode
1: GPIOG peripheral clock enabled during Sleep mode (default after reset)

Bit 5 **GPIOFLPEN**: GPIOF clock enable during Sleep mode
Set and reset by software.
0: GPIOF peripheral clock disabled during Sleep mode
1: GPIOF peripheral clock enabled during Sleep mode (default after reset)

Bit 4 **GPIOELPEN**: GPIOE clock enable during Sleep mode
Set and reset by software.
0: GPIOE peripheral clock disabled during Sleep mode
1: GPIOE peripheral clock enabled during Sleep mode (default after reset)

Bit 3 **GPIODLPEN**: GPIOD clock enable during Sleep mode
Set and reset by software.
0: GPIOD peripheral clock disabled during Sleep mode
1: GPIOD peripheral clock enabled during Sleep mode (default after reset)

Bit 2 **GPIOCLPEN**: GPIOC clock enable during Sleep mode
Set and reset by software.
0: GPIOC peripheral clock disabled during Sleep mode
1: GPIOC peripheral clock enabled during Sleep mode (default after reset)

Bit 1 **GPIOBLPEN**: GPIOB clock enable during Sleep mode
Set and reset by software.
0: GPIOB peripheral clock disabled during Sleep mode
1: GPIOB peripheral clock enabled during Sleep mode (default after reset)

Bit 0 **GPIOALPEN**: GPIOA clock enable during Sleep mode
Set and reset by software.
0: GPIOA peripheral clock disabled during Sleep mode
1: GPIOA peripheral clock enabled during Sleep mode (default after reset)

11.8.35 RCC AHB4 sleep clock register (RCC_AHB4LPENR)

Address offset: 0x0BC

Reset value: 0x0011 1880

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

			rw	rw				rw							

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **OCTOSPI1LPEN**: OCTOSPI1 clock enable during Sleep mode
Set and reset by software.
0: OCTOSPI1 peripheral clock disabled during Sleep mode
1: OCTOSPI1 peripheral clock enabled during Sleep mode (default after reset)

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **FMCLPEN**: FMC clock enable during Sleep mode
Set and reset by software.
0: FMC peripheral clock disabled during Sleep mode
1: FMC peripheral clock enabled during Sleep mode (default after reset)

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **SDMMC2LPEN**: SDMMC2 and SDMMC2 delay peripheral clock enable during Sleep mode
Set and reset by software.
0: SDMMC2 and SDMMC2 delay peripherals clock disabled during Sleep mode
1: SDMMC2 and SDMMC2 delay peripherals clock enabled during Sleep mode (default after reset)

Bit 11 **SDMMC1LPEN**: SDMMC1 and SDMMC1 delay peripheral clock enable during Sleep mode
Set and reset by software
0: SDMMC1 and SDMMC1 delay peripherals clock disabled during Sleep mode
1: SDMMC1 and SDMMC1 delay peripherals clock enabled during Sleep mode (default after reset)

Bits 10:8 Reserved, must be kept at reset value.

Bit 7 **OTFDEC1LPEN**: OTFDEC1 clock enable during Sleep mode
Set and reset by software.
0: OTFDEC1 peripheral clock disabled during Sleep mode
1: OTFDEC1 peripheral clock enabled during Sleep mode (default after reset)

Bits 6:0 Reserved, must be kept at reset value.

11.8.36 RCC APB1 sleep clock register (RCC_APB1LLPENR)

Address offset: 0x0C4

Reset value: 0xDFFE C9FF

Bit 31 **UART8LPEN**: UART8 clock enable during Sleep mode
Set and reset by software.
0: UART8 peripheral clock disabled during Sleep mode
1: UART8 peripheral clock enabled during Sleep mode (default after reset)

Bit 30 **UART7LPEN**: UART7 clock enable during Sleep mode
Set and reset by software.
0: UART7 peripheral clock disabled during Sleep mode
1: UART7 peripheral clock enabled during Sleep mode (default after reset)

Bit 29 Reserved, must be kept at reset value.

Bit 28 **CECLPEN**: HDMI-CEC clock enable during Sleep mode
Set and reset by software.
0: HDMI-CEC peripheral clock disabled during Sleep mode
1: HDMI-CEC peripheral clock enabled during Sleep mode (default after reset)

Bit 27 **USART11LPEN**: USART11 clock enable during Sleep mode
Set and reset by software.
0: USART11 peripheral clock disabled during Sleep mode
1: USART11 peripheral clock enabled during Sleep mode (default after reset)

Bit 26 **USART10LPEN**: USART10 clock enable during Sleep mode
Set and reset by software.
0: USART10 peripheral clock disabled during Sleep mode
1: USART10 peripheral clock enabled during Sleep mode (default after reset)

Bit 25 **USART6LPEN**: USART6 clock enable during Sleep mode
Set and reset by software.
0: USART6 peripheral clock disabled during Sleep mode
1: USART6 peripheral clock enabled during Sleep mode (default after reset)

Bit 24 **CRSLPEN**: CRS clock enable during Sleep mode
Set and reset by software.
0: CRS peripheral clock disabled during Sleep mode
1: CRS peripheral clock enabled during Sleep mode (default after reset)

Bit 23 **I3C1LPEN**: I3C1 clock enable during Sleep mode
Set and reset by software.
0: I3C1 peripheral clock disabled during Sleep mode
1: I3C1 peripheral clock enabled during Sleep mode (default after reset)

Bit 22 **I2C2LPEN**: I2C2 clock enable during Sleep mode
Set and reset by software.
0: I2C2 peripheral clock disabled during Sleep mode
1: I2C2 peripheral clock enabled during Sleep mode (default after reset)

Bit 21 **I2C1LPEN**: I2C1 clock enable during Sleep mode
Set and reset by software.
0: I2C1 peripheral clock disabled during Sleep mode
1: I2C1 peripheral clock enabled during Sleep mode (default after reset)

Bit 20 **UART5LPEN**: UART5 clock enable during Sleep mode
Set and reset by software.
0: UART5 peripheral clock disabled during Sleep mode
1: UART5 peripheral clock enabled during Sleep mode (default after reset)

Bit 19 **UART4LPEN**: UART4 clock enable during Sleep mode
Set and reset by software.
0: UART4 peripheral clock disabled during Sleep mode
1: UART4 peripheral clock enabled during Sleep mode (default after reset)

Bit 18 **USART3LPEN**: USART3 clock enable during Sleep mode
Set and reset by software.
0: USART3 peripheral clock disabled during Sleep mode
1: USART3 peripheral clock enabled during Sleep mode (default after reset)

Bit 17 **USART2LPEN**: USART2 clock enable during Sleep mode
Set and reset by software.
0: USART2 peripheral clock disabled during Sleep mode
1: USART2 peripheral clock enabled during Sleep mode (default after reset)

Bit 16 Reserved, must be kept at reset value.

Bit 15 **SPI3LPEN**: SPI3 clock enable during Sleep mode
Set and reset by software.
0: SPI3 peripheral clock disabled during Sleep mode
1: SPI3 peripheral clock enabled during Sleep mode (default after reset)

Bit 14 **SPI2LPEN**: SPI2 clock enable during Sleep mode
Set and reset by software.
0: SPI2 peripheral clock disabled during Sleep mode
1: SPI2 peripheral clock enabled during Sleep mode (default after reset)

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **WWDGLPEN**: WWDG clock enable during Sleep mode
Set and reset by software.
0: WWDG peripheral clock disabled during Sleep mode
1: WWDG peripheral clock enabled during Sleep mode (default after reset)

Bits 10:9 Reserved, must be kept at reset value.

Bit 8 **TIM14LPEN**: TIM14 clock enable during Sleep mode
Set and reset by software.
0: TIM14 peripheral clock disabled during Sleep mode
1: TIM14 peripheral clock enabled during Sleep mode (default after reset)

Bit 7 **TIM13LPEN**: TIM13 clock enable during Sleep mode
Set and reset by software.
0: TIM13 peripheral clock disabled during Sleep mode
1: TIM13 peripheral clock enabled during Sleep mode (default after reset)

Bit 6 **TIM12LPEN**: TIM12 clock enable during Sleep mode
Set and reset by software.
0: TIM12 peripheral clock disabled during Sleep mode
1: TIM12 peripheral clock enabled during Sleep mode (default after reset)

Bit 5 **TIM7LPEN**: TIM7 clock enable during Sleep mode
Set and reset by software.
0: TIM7 peripheral clock disabled during Sleep mode
1: TIM7 peripheral clock enabled during Sleep mode (default after reset)

Bit 4 **TIM6LPEN**: TIM6 clock enable during Sleep mode
Set and reset by software.
0: TIM6 peripheral clock disabled during Sleep mode
1: TIM6 peripheral clock enabled during Sleep mode (default after reset)

Bit 3 **TIM5LPEN**: TIM5 clock enable during Sleep mode
Set and reset by software.
0: TIM5 peripheral clock disabled during Sleep mode
1: TIM5 peripheral clock enabled during Sleep mode (default after reset)

Bit 2 **TIM4LPEN**: TIM4 clock enable during Sleep mode
Set and reset by software.
0: TIM4 peripheral clock disabled during Sleep mode
1: TIM4 peripheral clock enabled during Sleep mode (default after reset)

Bit 1 **TIM3LPEN**: TIM3 clock enable during Sleep mode
Set and reset by software.
0: TIM3 peripheral clock disabled during Sleep mode
1: TIM3 peripheral clock enabled during Sleep mode (default after reset)

Bit 0 **TIM2LPEN**: TIM2 clock enable during Sleep mode
Set and reset by software.
0: TIM2 peripheral clock disabled during Sleep mode
1: TIM2 peripheral clock enabled during Sleep mode (default after reset)

11.8.37 RCC APB1 sleep clock register (RCC_APB1HLPENR)

Address offset: 0x0C8

Reset value: 0x4080 022B

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **UCPD1LPEN**: UCPD1 clock enable during Sleep mode
Set and reset by software.
0: UCPD peripheral clock disabled during Sleep mode
1: UCPD peripheral clock enabled during Sleep mode (default after reset)

Bits 22:10 Reserved, must be kept at reset value.

Bit 9 **FDCANLPEN**: FDCAN1 and FDCAN2 peripheral clock enable during Sleep mode
Set and reset by software.
0: FDCAN1 and FDCAN2 peripheral clock disabled during Sleep mode
1: FDCAN1 and FDCAN2 peripheral clock enabled during Sleep mode (default after reset)

Bits 8:6 Reserved, must be kept at reset value.

Bit 5 **LPTIM2LPEN**: LPTIM2 clock enable during Sleep mode
Set and reset by software.
0: LPTIM2 peripheral clock disabled during Sleep mode
1: LPTIM2 peripheral clock enabled during Sleep mode (default after reset)

Bit 4 Reserved, must be kept at reset value.

Bit 3 **DTSLPEN**: DTS clock enable during Sleep mode
Set and reset by software.
0: DTS peripheral clock disabled during Sleep mode
1: DTS peripheral clock enabled during Sleep mode (default after reset)

Bit 2 Reserved, must be kept at reset value.

Bit 1 **UART12LPEN**: UART12 clock enable during Sleep mode
Set and reset by software.
0: UART12 peripheral clock disabled during Sleep mode
1: UART12 peripheral clock enabled during Sleep mode (default after reset)

Bit 0 **UART9LPEN**: UART9 clock enable during Sleep mode
Set and reset by software.
0: UART9 peripheral clock disabled during Sleep mode
1: resets UART9 peripheral clock enabled during Sleep mode (default after reset)

11.8.38 RCC APB2 sleep clock register (RCC_APB2LPENR)

Address offset: 0x0CC

Reset value: 0x017F 7800

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **USBLPEN**: USB clock enable during Sleep mode
Set and reset by software.
0: USB peripheral clock disabled during Sleep mode
1: USB peripheral clock enabled during Sleep mode (default after reset)

Bit 23 Reserved, must be kept at reset value.

Bit 22 **SAI2LPEN**: SAI2 clock enable during Sleep mode
Set and reset by software.
0: SAI2 peripheral clock disabled during Sleep mode
1: SAI2 peripheral clock enabled during Sleep mode (default after reset)

Bit 21 **SAI1LPEN**: SAI1 clock enable during Sleep mode
Set and reset by software.
0: SAI1 peripheral clock disabled during Sleep mode
1: SAI1 peripheral clock enabled during Sleep mode (default after reset)

Bit 20 **SPI6LPEN**: SPI6 clock enable during Sleep mode
Set and reset by software.
0: SPI6 peripheral clock disabled during Sleep mode
1: SPI6 peripheral clock enabled during Sleep mode (default after reset)

Bit 19 **SPI4LPEN**: SPI4 clock enable during Sleep mode
Set and reset by software.
0: SPI4 peripheral clock disabled during Sleep mode
1: SPI4 peripheral clock enabled during Sleep mode (default after reset)

Bit 18 **TIM17LPEN**: TIM17 clock enable during Sleep mode
Set and reset by software.
0: TIM17 peripheral clock disabled during Sleep mode
1: TIM17 peripheral clock enabled during Sleep mode (default after reset)

Bit 17 **TIM16LPEN**: TIM16 clock enable during Sleep mode
Set and reset by software.
0: TIM16 peripheral clock disabled during Sleep mode
1: TIM16 peripheral clock enabled during Sleep mode (default after reset)

Bit 16 **TIM15LPEN**: TIM15 clock enable during Sleep mode
Set and reset by software.
0: TIM15 peripheral clock disabled during Sleep mode
1: TIM15 peripheral clock enabled during Sleep mode (default after reset)

Bit 15 Reserved, must be kept at reset value.

Bit 14 **USART1LPEN**: USART1 clock enable during Sleep mode
Set and reset by software.
0: USART1 peripheral clock disabled during Sleep mode
1: USART1 peripheral clock enabled during Sleep mode (default after reset)

Bit 13 **TIM8LPEN**: TIM8 clock enable during Sleep mode
Set and reset by software.
0: TIM8 peripheral clock disabled during Sleep mode
1: TIM8 peripheral clock enabled during Sleep mode (default after reset)

Bit 12 **SPI1LPEN**: SPI1 clock enable during Sleep mode
Set and reset by software.
0: SPI1 peripheral clock disabled during Sleep mode
1: SPI1 peripheral clock enabled during Sleep mode (default after reset)

Bit 11 **TIM1LPEN**: TIM1 clock enable during Sleep mode
Set and reset by software.
0: TIM1 peripheral clock disabled during Sleep mode
1: TIM1 peripheral clock enabled during Sleep mode (default after reset)

Bits 10:0 Reserved, must be kept at reset value.

11.8.39 RCC APB3 sleep clock register (RCC_APB3LPENR)

Address offset: 0x0D0

Reset value: 0x0030 F9E2

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **RTCAPBLPEN**: RTC APB interface clock enable during Sleep mode
Set and reset by software.
0: RTC APB interface clock disabled during Sleep mode
1: RTC APB interface clock enabled during Sleep mode (default after reset)

Bit 20 **VREFLPEN**: VREFBUF clock enable during Sleep mode
Set and reset by software.
0: VREFBUF peripheral clock disabled during Sleep mode
1: VREFBUF peripheral clock enabled during Sleep mode (default after reset)

Bits 19:16 Reserved, must be kept at reset value.

Bit 15 **LPTIM6LPEN**: LPTIM6 clock enable during Sleep mode
Set and reset by software.
0: LPTIM6 peripheral clock disabled during Sleep mode
1: LPTIM6 peripheral clock enabled during Sleep mode (default after reset)

Bit 14 **LPTIM5LPEN**: LPTIM5 clock enable during Sleep mode
Set and reset by software.
0: LPTIM5 peripheral clock disabled during Sleep mode
1: LPTIM5 peripheral clock enabled during Sleep mode (default after reset)

Bit 13 **LPTIM4LPEN**: LPTIM4 clock enable during Sleep mode
Set and reset by software.
0: LPTIM4 peripheral clock disabled during Sleep mode
1: LPTIM4 peripheral clock enabled during Sleep mode (default after reset)

Bit 12 **LPTIM3LPEN**: LPTIM3 clock enable during Sleep mode
Set and reset by software.
0: LPTIM3 peripheral clock disabled during Sleep mode
1: LPTIM3 peripheral clock enabled during Sleep mode (default after reset)

Bit 11 **LPTIM1LPEN**: LPTIM1 clock enable during Sleep mode
Set and reset by software.
0: LPTIM1 peripheral clock disabled during Sleep mode
1: LPTIM1 peripheral clock enabled during Sleep mode (default after reset)

Bits 10:9 Reserved, must be kept at reset value.

Bit 8 **I2C4LPEN**: I2C4 clock enable during Sleep mode
Set and reset by software.
0: I2C4 peripheral clock disabled during Sleep mode
1: I2C4 peripheral clock enabled during Sleep mode (default after reset)

Bit 7 **I2C3LPEN**: I2C3 clock enable during Sleep mode
Set and reset by software.
0: I2C3 peripheral clock disabled during Sleep mode
1: I2C3 peripheral clock enabled during Sleep mode (default after reset)

Bit 6 **LPUART1LPEN**: LPUART1 clock enable during Sleep mode
Set and reset by software.
0: LPUART1 peripheral clock disabled during Sleep mode
1: LPUART1 peripheral clock enabled during Sleep mode (default after reset)

Bit 5 **SPI5LPEN**: SPI5 clock enable during Slsleepeep mode
Set and reset by software.
0: SPI5 peripheral clock disabled during Sleep mode
1: SPI5 peripheral clock enabled during Slesleepep mode (default after reset)

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **SBSLPEN**: SBS clock enable during Sleep mode
Set and reset by software.
0: SBS peripheral clock disabled during Sleep mode
1: SBS peripheral clock enabled during Sleep mode (default after reset)

Bit 0 Reserved, must be kept at reset value.

11.8.40 RCC kernel clock configuration register (RCC_CCIPR1)

Address offset: 0x0D8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31 **TIMICSEL**: TIM12, TIM15 and LPTIM2 input capture source selection
Set and reset by software.
0: No internal clock available for timers input capture (default after reset)
1: hsi_ker_ck/1024, hsi_ker_ck/8 and csi_ker_ck/128 selected for timers input capture

Bit 30 Reserved, must be kept at reset value.

Bits 29:27 **USART10SEL[2:0]**: USART10 kernel clock source selection
000: rcc_pclk1 selected as kernel clock (default after reset)
001: pll2_q_ck selected as kernel clock
010: pll3_q_ck selected as kernel clock
011: hsi_ker_ck selected as kernel clock
100: csi_ker_ck selected as kernel clock
101: lse_ck selected as kernel clock
others: reserved, the kernel clock is disabled

Bits 26:24 **UART9SEL[2:0]**: UART9 kernel clock source selection
000: rcc_pclk1 selected as kernel clock (default after reset)
001: pll2_q_ck selected as kernel clock
010: pll3_q_ck selected as kernel clock
011: hsi_ker_ck selected as kernel clock
100: csi_ker_ck selected as kernel clock
101: lse_ck selected as kernel clock
others: reserved, the kernel clock is disabled

Bits 23:21 **UART8SEL[2:0]**: UART8 kernel clock source selection
000: rcc_pclk1 selected as kernel clock (default after reset)
001: pll2_q_ck selected as kernel clock
010: pll3_q_ck selected as kernel clock
011: hsi_ker_ck selected as kernel clock
100: csi_ker_ck selected as kernel clock
101: lse_ck selected as kernel clock
others: reserved, the kernel clock is disabled

Bits 20:18 **UART7SEL[2:0]**: UART7 kernel clock source selection
000: rcc_pclk1 selected as kernel clock (default after reset)
001: pll2_q_ck selected as kernel clock
010: pll3_q_ck selected as kernel clock
011: hsi_ker_ck selected as kernel clock
100: csi_ker_ck selected as kernel clock
101: lse_ck selected as kernel clock
others: reserved, the kernel clock is disabled

Bits 17:15 **USART6SEL[2:0]**: USART6 kernel clock source selection
000: rcc_pclk1 selected as kernel clock (default after reset)
001: pll2_q_ck selected as kernel clock
010: pll3_q_ck selected as kernel clock
011: hsi_ker_ck selected as kernel clock
100: csi_ker_ck selected as kernel clock
101: lse_ck selected as kernel clock
others: reserved, the kernel clock is disabled

Bits 14:12 **UART5SEL[2:0]**: UART5 kernel clock source selection
000: rcc_pclk1 selected as kernel clock (default after reset)
001: pll2_q_ck selected as kernel clock
010: pll3_q_ck selected as kernel clock
011: hsi_ker_ck selected as kernel clock
100: csi_ker_ck selected as kernel clock
101: lse_ck selected as kernel clock
others: reserved, the kernel clock is disabled

Bits 11:9 **UART4SEL[2:0]**: UART4 kernel clock source selection
000: rcc_pclk1 selected as kernel clock (default after reset)
001: pll2_q_ck selected as kernel clock
010: pll3_q_ck selected as kernel clock
011: hsi_ker_ck selected as kernel clock
100: csi_ker_ck selected as kernel clock
101: lse_ck selected as kernel clock
others: reserved, the kernel clock is disabled

Bits 8:6 **USART3SEL[2:0]**: USART3 kernel clock source selection
Set and reset by software.
000: rcc_pclk1 selected as kernel clock (default after reset)
001: pll2_q_ck selected as kernel clock
010: pll3_q_ck selected as kernel clock
011: hsi_ker_ck selected as kernel clock
100: csi_ker_ck selected as kernel clock
101: lse_ck selected as kernel clock
others: reserved, the kernel clock is disabled

Bits 5:3 **USART2SEL[2:0]**: USART2 kernel clock source selection
Set and reset by software.
000: rcc_pclk1 selected as kernel clock (default after reset)
001: pll2_q_ck selected as kernel clock
010: pll3_q_ck selected as kernel clock
011: hsi_ker_ck selected as kernel clock
100: csi_ker_ck selected as kernel clock
101: lse_ck selected as kernel clock
others: reserved, the kernel clock is disabled

Bits 2:0 **USART1SEL[2:0]**: USART1 kernel clock source selection
Set and reset by software.
000: rcc_pclk2 selected as kernel clock (default after reset)
001: pll2_q_ck selected as kernel clock
010: pll3_q_ck selected as kernel clock
011: hsi_ker_ck selected as kernel clock
100: csi_ker_ck selected as kernel clock
101: lse_ck selected as kernel clock
others: reserved, the kernel clock is disabled

000: pll1_q_ck selected as kernel clock (default after reset)
001: pll2_p_ck selected as kernel clock
010: pll3_p_ck selected as kernel clock
011: AUDIOCLK selected as kernel clock
100: per_ck selected as kernel clock
others: reserved, the kernel clock is disabled

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:8 **FDCANSEL[1:0]**: FDCAN1 and FDCAN2 kernel clock source selection
00: hse_ck selected as kernel clock (default after reset)
01: pll1_q_ck selected as kernel clock
10: pll2_q_ck selected as kernel clock
11: reserved, the kernel clock is disabled

Bits 7:6 **CECSEL[1:0]**: HSMI-CEC kernel clock source selection
00: lse_ck selected as kernel clock (default after reset)
01: lsi_ker_ck selected as kernel clock
10: csi_ker_ck/122 selected as kernel clock
11: reserved, the kernel clock is disabled

Bits 5:4 **RNGSEL[1:0]**: RNG kernel clock source selection
00: hsi48_ker_ck selected as kernel clock (default after reset)
01: pll1_q_ck selected as kernel clock
10: lse_ck selected as kernel clock
11: lsi_ker_ck selected as kernel clock

Bit 3 **DACSEL**: DAC sample and hold clock
0: dac_hold_ck selected as kernel clock (default after reset)
1: dac_hold_ck selected as kernel clock

Bits 2:0 **ADCDACSEL[2:0]**: ADC and DAC kernel clock source selection
000: rcc_hclk selected as kernel clock (default after reset)
001: sys_ck selected as kernel clock
010: pll2_r_ck selected as kernel clock
011: hse_ck selected as kernel clock
100: hsi_ker_ck selected as kernel clock
101: csi_ker_ck selected as kernel clock
others: reserved, the kernel clock is disabled

11.8.45 RCC Backup domain control register (RCC_BDCR)

Address offset: 0x0F0

Reset value: 0x0000 0000

Reset by Backup domain reset.

Access: 0 ≤ wait state ≤ 3, word, half-word and byte access.

Wait states are inserted in case of successive accesses to this register.

Note: After a system reset, the RCC_BDCR register is write-protected (except bits 27:24 and bit 16). To modify the backup domain bits, the DBP bit in the PWR backup domain control register 1 (PWR_BDCR1) must be set to 1. RCC_BDCR bits (except bits 27:24 and bit 16)

are reset only after a Backup domain reset (see Section 11.3.3: Backup domain reset). Any other reset does not have any effect on these bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	LSI RDY	LSI ON	LSCO SEL	LSCO EN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VSW RST

rw						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **LSIRDY**: LSI oscillator ready
Set and cleared by hardware to indicate when the LSI oscillator is stable. After the LSION bit is cleared, LSIRDY goes low after three internal low-speed oscillator clock cycles.
This bit is set when the LSI is used by IWDG or RTC, even if LSION = 0.
0: LSI oscillator not ready
1: LSI oscillator ready

Bit 26 **LSION**: LSI oscillator enable
Set and cleared by software.
0: LSI oscillator off
1: LSI oscillator on

Bit 25 **LSCOSEL**: Low-speed clock output selection
Set and cleared by software.
0: LSI clock selected
1: LSE clock selected

Bit 24 **LSCOEN**: Low-speed clock output (LSCO) enable
Set and cleared by software.
0: LSCO output disabled
1: LSCO output enabled

Bits 23:17 Reserved, must be kept at reset value.

Bit 16 **VSWRST**: VSwitch domain software reset
Set and reset by software.
0: reset not activated (default after Backup domain reset)
1: resets the entire VSW domain

Bit 15 **RTCEN**: RTC clock enable
Set and reset by software.
0: rtc_ck disabled (default after Backup domain reset)
1: rtc_ck enabled

Bits 14:10 Reserved, must be kept at reset value.

Bits 9:8 **RTCSEL[1:0]**:RTC clock source selection

Set by software to select the clock source for the RTC.
These bits can be written only one time (except in case of failure detection on LSE).
These bits must be written before LSECSSON is enabled.
The VSWRST bit can be used to reset them, then it can be written one time again.
If HSE is selected as RTC clock, this clock is lost when the system is in Stop mode or in case of a pin reset (NRST).
00: no clock (default after Backup domain reset)
01: LSE selected as RTC clock
10: LSI selected as RTC clock
11: HSE divided by RTCPRE value selected as RTC clock

Bit 7 **LSEEXT**: low-speed external clock type in bypass mode

Set and reset by software to select the external clock type (analog or digital).
The external clock must be enabled with the LSEON bit, to be used by the device.
The LSEEXT bit can be written only if the LSE oscillator is disabled.
0: LSE in analog mode (default after Backup domain reset)
1: LSE in digital mode (do not use if RTC is active).

Bit 6 **LSECSSD**: LSE clock security system failure detection

Set by hardware to indicate when a failure has been detected by the clock security system on the external 32 kHz oscillator.
0: no failure detected on 32 kHz oscillator (default after Backup domain reset)
1: failure detected on 32 kHz oscillator

Bit 5 **LSECSSON**: LSE clock security system enable

Set by software to enable the clock security system on 32 kHz oscillator.
LSECSSON must be enabled after LSE is enabled (LSEON enabled) and ready (LSERDY set by hardware) and after RTCSEL is selected.
Once enabled, this bit cannot be disabled, except after a LSE failure detection (LSECSSD = 1). In that case the software must disable LSECSSON.
0: CSS on 32 kHz oscillator OFF (default after Backup domain reset)
1: CSS on 32 kHz oscillator ON

Bits 4:3 **LSEDRV[1:0]**: LSE oscillator driving capability

Set by software to select the driving capability of the LSE oscillator.
These bit can be written only if LSE oscillator is disabled (LSEON = 0 and LSERDY = 0).
00: lowest drive (default after Backup domain reset)
01: medium-low drive
10: medium-high drive
11: highest drive

Bit 2 **LSEBYP**: LSE oscillator bypass

Set and reset by software to bypass oscillator in debug mode. This bit must not be written when the LSE is enabled (by LSEON) or ready (LSERDY = 1)
0: LSE oscillator not bypassed (default after Backup domain reset)
1: LSE oscillator bypassed

Bit 1 **LSERDY**: LSE oscillator ready

Set and reset by hardware to indicate when the LSE is stable.
This bit needs 6 cycles of lse_ck clock to fall down after LSEON has been set to 0.
0: LSE oscillator not ready (default after Backup domain reset)
1: LSE oscillator ready

Bit 0 **LSEON**: LSE oscillator enabled
Set and reset by software.
0: LSE oscillator OFF (default after Backup domain reset)
1: LSE oscillator ON

11.8.46 RCC reset status register (RCC_RSR)

Address offset: 0x0F4

Reset value: 0x0C00 0000

Reset by power-on reset only.

Access: 0 ≤ wait state ≤ 3, word, half-word and byte access.

Wait states are inserted in case of successive accesses to this register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LPWR RSTF	WWDG RSTF	IWDG RSTF	SFT RSTF	BOR RSTF	PIN RSTF	Res.	Res.	RMVF	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bit 31 **LPWRRSTF**: Low-power reset flag
Set by hardware when a reset occurs due to Stop or Standby mode entry, whereas the corresponding nRST_STOP, nRST_STBY option bit is cleared.
Cleared by writing to the RMVF bit.
0: No illegal low-power mode reset occurred
1: Illegal low-power mode reset occurred

Bit 30 **WWDGRSTF**: window watchdog reset flag
Reset by software by writing the RMVF bit.
Set by hardware when a window watchdog reset occurs.
0: no window watchdog reset occurred from WWDG (default after power-on reset)
1: window watchdog reset occurred from WWDG

Bit 29 **IWDGRSTF**: independent watchdog reset flag
Reset by software by writing the RMVF bit.
Set by hardware when an independent watchdog reset occurs.
0: no independent watchdog reset occurred (default after power-on reset)
1: independent watchdog reset occurred

Bit 28 **SFTRSTF**: system reset from CPU reset flag
Reset by software by writing the RMVF bit.
Set by hardware when the system reset is due to CPU.The CPU can generate a system reset by writing SYSRESETREQ bit of AIRCR register of the core M33.
0: no CPU software reset occurred (default after power-on reset)
1: a system reset has been generated by the CPU

Bit 27 **BORRSTF**: BOR reset flag
Reset by software by writing the RMVF bit.
Set by hardware when a BOR reset occurs (pwr_bor_rst).
0: no BOR reset occurred
1: BOR reset occurred (default after power-on reset)

Bit 26 **PINRSTF**: pin reset flag (NRST)
Reset by software by writing the RMVF bit.
Set by hardware when a reset from pin occurs.
0: no reset from pin occurred
1: reset from pin occurred (default after power-on reset)

Bits 25:24 Reserved, must be kept at reset value.

Bit 23 **RMVF**: remove reset flag
Set and reset by software to reset the value of the reset flags.
0: reset of the reset flags not activated (default after power-on reset)
1: resets the value of the reset flags

Bits 22:0 Reserved, must be kept at reset value.

11.8.47 RCC secure configuration register (RCC_SECCFGR)

Address offset: 0x110

Reset value: 0x0000 0000

Access: no wait state; word, half-word and byte access

When the system is secure (TZEN = 0xB4), this register can be written only by a secure privileged access if SPRIV = 1, and by a secure privileged or unprivileged access if SPRIV = 0. A non-secure write access generates an illegal access event and data is not written. This register can be read by secure or non-secure, privilege or unprivileged access. When the system is not secure (TZEN = 0xC3), this register is read as 0 and the register write is ignored.

		rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **CKPERSELSEC**: per_ck selection security
Set and reset by software.
0: non secure
1: secure

Bit 12 **RMVFSEC**: Remove reset flag security
Set and reset by software.
0: non secure
1: secure

Bit 11 **HSI48SEC**: HSI48 clock configuration and status bits security
Set and reset by software.
0: non secure
1: secure

Bit 10 Reserved, must be kept at reset value.

Bit 9 **PLL3SEC**: PLL3 clock configuration and status bits security
Set and reset by software.
0: non secure
1: secure

Bit 8 **PLL2SEC**: PLL2 clock configuration and status bits security
Set and reset by software.
0: non secure
1: secure

Bit 7 **PLL1SEC**: PLL1 clock configuration and status bits security
Set and reset by software.
0: non secure
1: secure

Bit 6 **PRESCSEC**: AHBx/APBx prescaler configuration bits security
Set and reset by software.
0: non secure
1: secure

Bit 5 **SYSCLKSEC**: SYSCLK clock selection, STOPWUCK bit, clock output on MCO configuration security
Set and reset by software.
0: non secure
1: secure

Bit 4 **LSESEC**: LSE clock configuration and status bits security
Set and reset by software.
0: non secure
1: secure

Bit 3 **LSISEC**: LSI clock configuration and status bits security
Set and reset by software.
0: non secure
1: secure

Bit 2 **CSISEC**: CSI clock configuration and status bits security
Set and reset by software.
0: non secure
1: secure

Bit 1 **HSESEC**: HSE clock configuration bits, status bits and HSE_CSS security
Set and reset by software.
0: non secure
1: secure

Bit 0 **HSISEC**: HSI clock configuration and status bits security
Set and reset by software.
0: non secure
1: secure

11.8.48 RCC privilege configuration register (RCC_PRIVCFGR)

Address offset: 0x114

Reset value: 0x0000 0000

Access: no wait state; word, half-word and byte access

This register can be written only by a privileged access. It can be read by privileged or unprivileged access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	NSPRIV	SPRIV
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **NSPRIV**: RCC non-secure functions privilege configuration

Set and reset by software. This bit can be written only by privileged access, secure or non-secure.

0: Read and write to RCC non-secure functions can be done by privileged or unprivileged access.

1: Read and write to RCC non-secure functions can be done by privileged access only

Bit 0 **SPRIV**: RCC secure functions privilege configuration

Set and reset by software. This bit can be written only by a secure privileged access.

0: Read and write to RCC secure functions can be done by privileged or unprivileged access.

1: Read and write to RCC secure functions can be done by privileged access only

12 Clock recovery system (CRS)

12.1 Introduction

The clock recovery system (CRS) is an advanced digital controller acting on the internal fine-granularity trimmable RC oscillator HSI48. The CRS provides powerful means to evaluate the oscillator output frequency, based on comparison with a selectable synchronization signal. The CRS is capable of automatic trimming adjustments based on the measured frequency error value, while keeping the possibility of a manual trimming.

The CRS is ideally suited to provide a precise clock to the USB peripheral. In this case, the synchronization signal can be derived from the start-of-frame (SOF) packet signalization on the USB bus, sent by a USB host at 1 ms intervals.

The synchronization signal can also be derived from the LSE oscillator output, or generated by user software.

12.2 CRS main features

- Selectable synchronization source with programmable prescaler and polarity:
  - LSE oscillator output
  - USB SOF packet reception
- Possibility to generate synchronization pulses by software
- Automatic oscillator trimming capability with no need of CPU action
- Manual control option for faster startup convergence
- 16-bit frequency error counter with automatic error value capture and reload
- Programmable limit for automatic frequency error value evaluation and status reporting
- Maskable interrupts/events:
  - Expected synchronization (ESYNC)
  - Synchronization OK (SYNCOK)
  - Synchronization warning (SYNCWARN)
  - Synchronization or trimming error (ERR)

12.3 CRS implementation

Table 109. CRS features

Feature	CRS1
TRIM width	6 bits

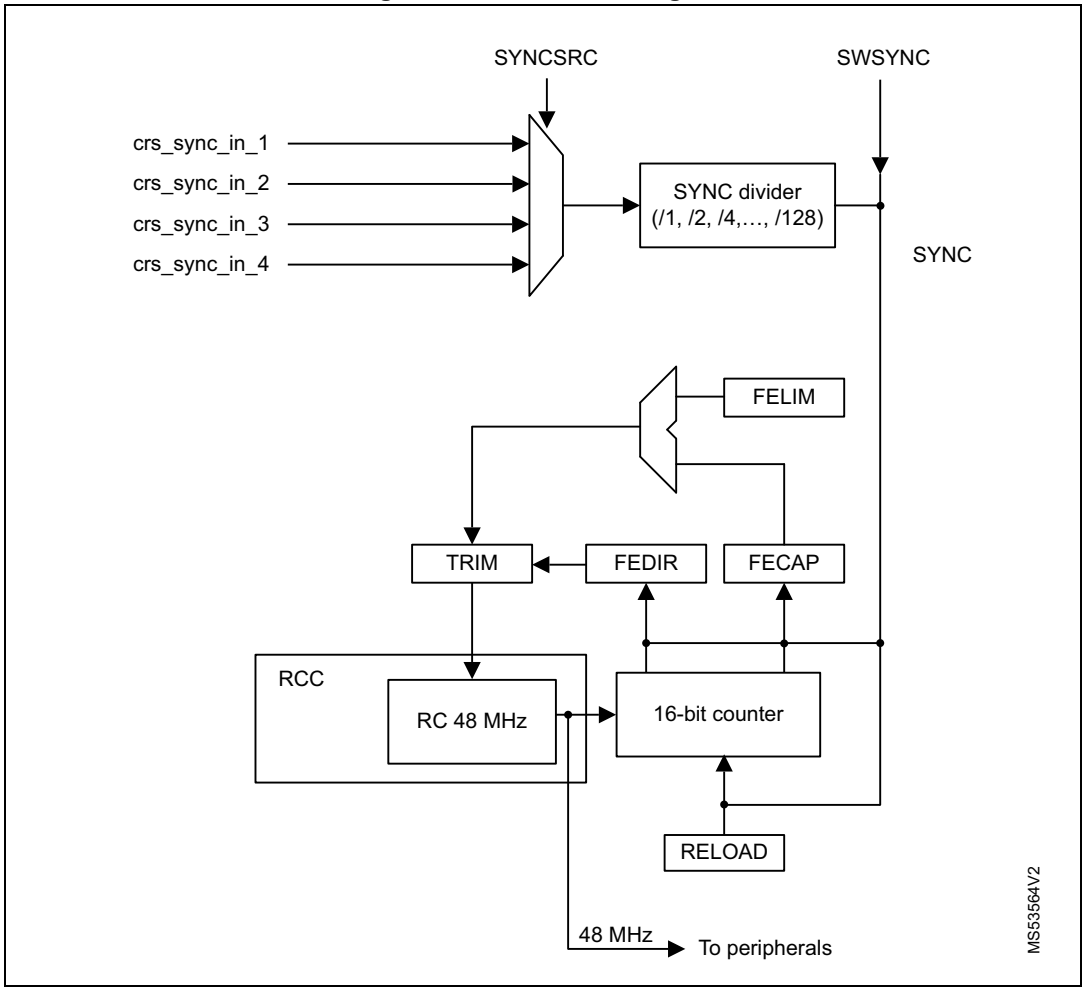
Table 110. CRS internal input/output signals

Internal signal name	Signal type	Description
crs_sync_in_1	Input	00: GPIO AF selected as SYNC signal source
crs_sync_in_2	Input	01: LSE selected as SYNC signal source
crs_sync_in_3	Input	10: USB SOF selected as SYNC signal source (default)
crs_sync_in_4	Input	11: Reserved

12.4 CRS functional description

12.4.1 CRS block diagram

Figure 53. CRS block diagram



12.4.2 Synchronization input

The CRS synchronization (SYNC) source, selectable through the CRS_CFGR register, can be the signal from the LSE clock or the USB SOF signal. For better robustness of the SYNC

input, a simple digital filter (2 out of 3 majority votes, sampled by the HSI48 clock) is implemented to filter out glitches. This source signal has a configurable polarity, and can be divided by a programmable binary prescaler, to obtain a synchronization signal in a suitable frequency range (usually around 1 kHz).

For more information on the CRS synchronization source configuration, refer to *Section 12.7.2*.

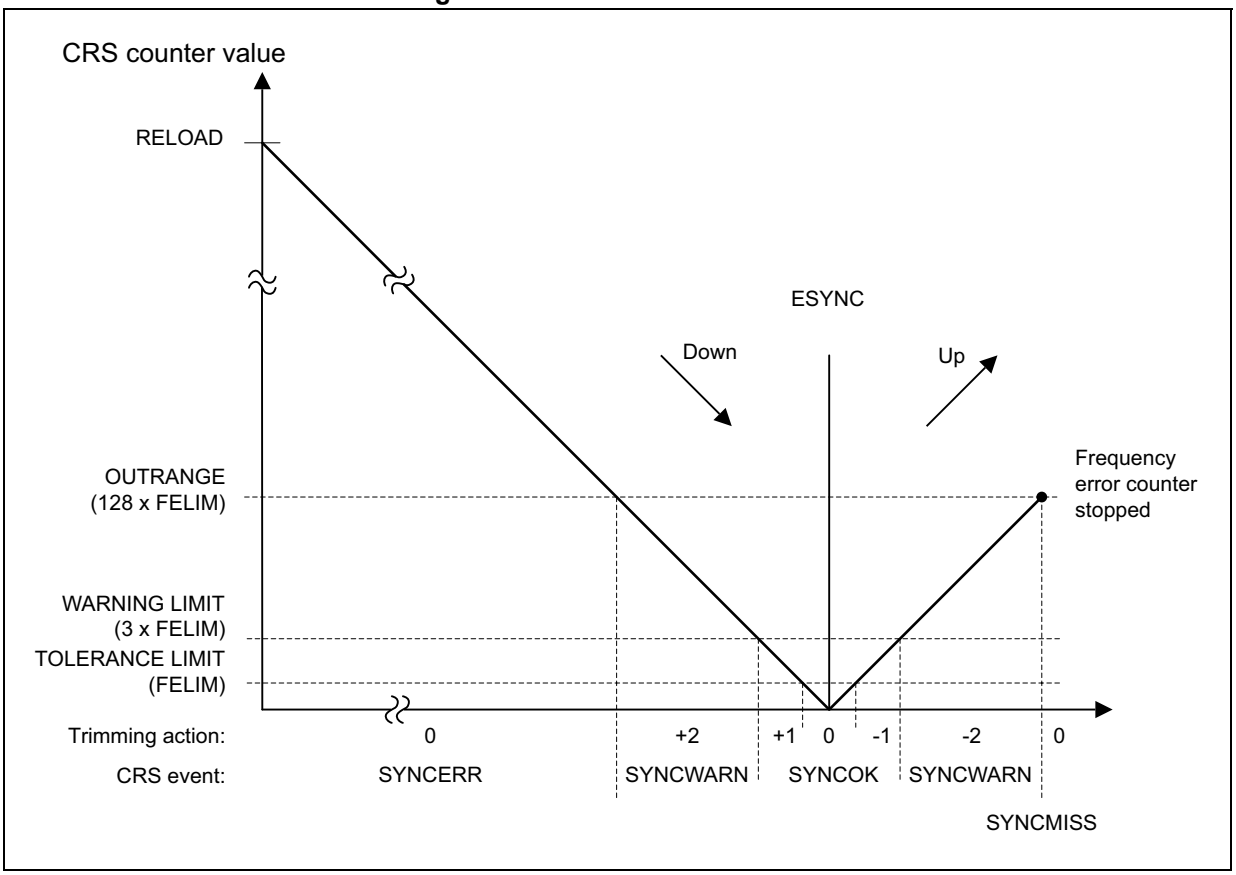
It is also possible to generate a synchronization event by software, by setting the SWSYNC bit in the CRS_CR register.

12.4.3 Frequency error measurement

The frequency error counter is a 16-bit down/up counter, reloaded with the RELOAD value on each SYNC event. It starts counting down until it reaches the 0 value, where the ESYNC (expected synchronization) event is generated. Then it starts counting up to the OUTRANGE limit, where it eventually stops (if no SYNC event is received), and generates a SYNCMISS event. The OUTRANGE limit is defined as the frequency error limit (FELIM field of the CRS_CFGR register) multiplied by 128.

When the SYNC event is detected, the actual value of the frequency error counter and its counting direction are stored in the FECAP (frequency error capture) field and in the FEDIR (frequency error direction) bit of the CRS_ISR register. When the SYNC event is detected during the down-counting phase (before reaching the 0 value), it means that the actual frequency is lower than the target (the TRIM value must be incremented). When it is detected during the up-counting phase, it means that the actual frequency is higher (the TRIM value must be decremented).

Figure 54. CRS counter behavior



12.4.4 Frequency error evaluation and automatic trimming

The measured frequency error is evaluated by comparing its value with a set of limits:

- TOLERANCE LIMIT, given directly in the FELIM field of the CRS_CFGR register
- WARNING LIMIT, defined as 3 × FELIM value
- OUTRANGE (error limit), defined as 128 × FELIM value

The result of this comparison is used to generate the status indication and also to control the automatic trimming which is enabled by setting the AUTOTRIMEN bit in the CRS_CR register:

- When the frequency error is below the tolerance limit, it means that the actual trimming value in the TRIM field is the optimal one, hence no trimming action is needed.
  - SYNCOK status indicated
  - TRIM value not changed in AUTOTRIM mode
- When the frequency error is below the warning limit but above or equal to the tolerance limit, it means that some trimming action is necessary but that adjustment by one trimming step is enough to reach the optimal TRIM value.
  - SYNCOK status indicated
  - TRIM value adjusted by one trimming step in AUTOTRIM mode

- When the frequency error is above or equal to the warning limit but below the error limit, a stronger trimming action is necessary, and there is a risk that the optimal TRIM value is not reached for the next period.
  - SYNCWARN status indicated
  - TRIM value adjusted by two trimming steps in AUTOTRIM mode
- When the frequency error is above or equal to the error limit, the frequency is out of the trimming range. This can also happen when the SYNC input is not clean, or when some SYNC pulse is missing (for example when one USB SOF is corrupted).
  - SYNCERR or SYNCMISS status indicated
  - TRIM value not changed in AUTOTRIM mode

Note: If the actual value of the TRIM field is close to its limits and the automatic trimming can force it to overflow or underflow, the TRIM value is set to the limit, and the TRIMOVF status is indicated.

In AUTOTRIM mode (AUTOTRIMEN bit set in the CRS_CR register) the TRIM field of CRS_CR is adjusted by hardware and is read-only.

12.4.5 CRS initialization and configuration

RELOAD value

The RELOAD value must be selected according to the ratio between the target frequency and the frequency of the synchronization source after prescaling. This value is decreased by 1, to reach the expected synchronization on the 0 value. The formula is the following:

$$RELOAD = (f_{TARGET} / f_{SYNC}) - 1$$

The reset value of the RELOAD field corresponds to a target frequency of 48 MHz and a synchronization signal frequency of 1 kHz (SOF signal from USB).

FELIM value

The selection of the FELIM value is closely coupled with the HSI48 oscillator characteristics and its typical trimming step size. The optimal value corresponds to half of the trimming step size, expressed as a number of oscillator clock ticks. The following formula can be used:

$$FELIM = (f_{TARGET} / f_{SYNC}) * STEP[\%] / 100\% / 2$$

The result must be always rounded up to the nearest integer value to obtain the best trimming response. If frequent trimming actions are not needed in the application, the hysteresis can be increased by slightly increasing the FELIM value.

The reset value of the FELIM field corresponds to $(f_{TARGET} / f_{SYNC}) = 48000$, and to a typical trimming step size of 0.14%.

Note: The trimming step size depends upon the product, check the datasheet for accurate setting.

Caution: There is no hardware protection from a wrong configuration of the RELOAD and FELIM fields, this can lead to an erratic trimming response. The expected operational mode requires proper setup of the RELOAD value (according to the synchronization source frequency), which is also greater than 128 * FELIM value (OUTRANGE limit).

12.5 CRS low-power modes

Table 111. Effect of low-power modes on CRS

Mode	Description
Sleep	No effect. CRS interrupts cause the device to exit the Sleep mode.
Stop	CRS registers are frozen. The CRS stops operating until the Stop mode is exited and the HSI48 oscillator is restarted.
Standby	The CRS peripheral is powered down and must be reinitialized after exiting Standby mode.

12.6 CRS interrupts

Table 112. Interrupt control bits

Interrupt event	Event flag	Enable control bit	Clear flag bit
Expected synchronization	ESYNCF	ESYNCIE	ESYNCC
Synchronization OK	SYNCOKF	SYNCOKIE	SYNCOKC
Synchronization warning	SYNCWARNF	SYNCWARNIE	SYNCWARNC
Synchronization or trimming error (TRIMOVF, SYNCMISS, SYNCERR)	ERRF	ERRIE	ERRC

12.7 CRS registers

Refer to *Section 1.2 on page 101* for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed only by words (32-bit).

12.7.1 CRS control register (CRS_CR)

Address offset: 0x00

Reset value: 0x0000 2000

Reset value: 0x0000 4000 (products supporting 7-bit TRIM width)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	TRIM[5:0]						SW SYNC	AUTO TRIMEN	CEN	Res.	ESYNCIE	ERRIE	SYNC WARNIE	SYNC OKIE
		rw	rw	rw	rw	rw	rw	rt_w1	rw	rw		rw	rw	rw	rw

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:8 **TRIM[5:0]**: HSI48 oscillator smooth trimming

These bits provide a user-programmable trimming value to the HSI48 oscillator. They can be programmed to adjust to variations in voltage and temperature that influence the oscillator frequency.

The default value is 32, corresponding to the middle of the trimming interval. The trimming step is specified in the product datasheet. A higher TRIM value corresponds to a higher output frequency.

When the AUTOTRIMEN bit is set, this field is controlled by hardware and is read-only.

Bit 7 **SWSYNC**: Generate software SYNC event

This bit is set by software in order to generate a software SYNC event. It is automatically cleared by hardware.

0: No action

1: A software SYNC event is generated.

Bit 6 **AUTOTRIMEN**: Automatic trimming enable

This bit enables the automatic hardware adjustment of TRIM bits according to the measured frequency error between two SYNC events. If this bit is set, the TRIM bits are read-only. The TRIM value can be adjusted by hardware by one or two steps at a time, depending on the measured frequency error value. Refer to *Section 12.4.4* for more details.

0: Automatic trimming disabled, TRIM bits can be adjusted by the user.

1: Automatic trimming enabled, TRIM bits are read-only and under hardware control.

Bit 5 **CEN**: Frequency error counter enable

This bit enables the oscillator clock for the frequency error counter.

0: Frequency error counter disabled

1: Frequency error counter enabled

When this bit is set, the CRS_CFGR register is write-protected and cannot be modified.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **ESYNCIE**: Expected SYNC interrupt enable
0: Expected SYNC (ESYNCF) interrupt disabled
1: Expected SYNC (ESYNCF) interrupt enabled

Bit 2 **ERRIE**: Synchronization or trimming error interrupt enable
0: Synchronization or trimming error (ERRF) interrupt disabled
1: Synchronization or trimming error (ERRF) interrupt enabled

Bit 1 **SYNCWARNIE**: SYNC warning interrupt enable
0: SYNC warning (SYNCWARNF) interrupt disabled
1: SYNC warning (SYNCWARNF) interrupt enabled

Bit 0 **SYNCOKIE**: SYNC event OK interrupt enable
0: SYNC event OK (SYNCOKF) interrupt disabled
1: SYNC event OK (SYNCOKF) interrupt enabled

12.7.2 CRS configuration register (CRS_CFGR)

This register can be written only when the frequency error counter is disabled (CEN bit is cleared in CRS_CR). When the counter is enabled, this register is write-protected.

Address offset: 0x04

Reset value: 0x2022 BB7F

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SYNCPOL	Res.	SYNCSRC[1:0]		Res.	SYNCDIV[2:0]			FELIM[7:0]							
rw		rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RELOAD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **SYNCPOL**: SYNC polarity selection
This bit is set and cleared by software to select the input polarity for the SYNC signal source.
0: SYNC active on rising edge (default)
1: SYNC active on falling edge

Bit 30 Reserved, must be kept at reset value.

Bits 29:28 **SYNCSRC[1:0]**: SYNC signal source selection
These bits are set and cleared by software to select the SYNC signal source (see *Table 110*):
00: crs_sync_in_1 selected as SYNC signal source
01: crs_sync_in_2 selected as SYNC signal source
10: crs_sync_in_3 selected as SYNC signal source
11: crs_sync_in_4 selected as SYNC signal source

Note: When using USB LPM (Link Power Management) and the device is in Sleep mode, the periodic USB SOF is not generated by the host. No SYNC signal is therefore provided to the CRS to calibrate the HSI48 oscillator on the run. To guarantee the required clock precision after waking up from Sleep mode, the LSE or reference clock on the GPIOs must be used as SYNC signal.

Bit 27 Reserved, must be kept at reset value.

Bits 26:24 **SYNCDIV[2:0]**: SYNC divider

These bits are set and cleared by software to control the division factor of the SYNC signal.
000: SYNC not divided (default)
001: SYNC divided by 2
010: SYNC divided by 4
011: SYNC divided by 8
100: SYNC divided by 16
101: SYNC divided by 32
110: SYNC divided by 64
111: SYNC divided by 128

Bits 23:16 **FELIM[7:0]**: Frequency error limit

FELIM contains the value to be used to evaluate the captured frequency error value latched in the FECAP[15:0] bits of the CRS_ISR register. Refer to *Section 12.4.4* for more details about FECAP evaluation.

Bits 15:0 **RELOAD[15:0]**: Counter reload value

RELOAD is the value to be loaded in the frequency error counter with each SYNC event. Refer to *Section 12.4.3* for more details about counter behavior.

12.7.3 CRS interrupt and status register (CRS_ISR)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FECAP[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FEDIR	Res.	Res.	Res.	Res.	TRIM OVF	SYNC MISS	SYNC ERR	Res.	Res.	Res.	Res.	ESYNCF	ERRF	SYNC WARNF	SYNC OKF
r					r	r	r					r	r	r	r

Bits 31:16 **FECAP[15:0]**: Frequency error capture

FECAP is the frequency error counter value latched in the time of the last SYNC event. Refer to *Section 12.4.4* for more details about FECAP usage.

Bit 15 **FEDIR**: Frequency error direction

FEDIR is the counting direction of the frequency error counter latched in the time of the last SYNC event. It shows whether the actual frequency is below or above the target.
0: Up-counting direction, the actual frequency is above the target
1: Down-counting direction, the actual frequency is below the target

Bits 14:11 Reserved, must be kept at reset value.

Bit 10 **TRIMOVF**: Trimming overflow or underflow

This flag is set by hardware when the automatic trimming tries to over- or under-flow the TRIM value. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.
0: No trimming error signaled
1: Trimming error signaled

Bit 9 **SYNCMISS**: SYNC missed

This flag is set by hardware when the frequency error counter reaches value FELIM * 128 and no SYNC is detected, meaning either that a SYNC pulse was missed, or the frequency error is too big (internal frequency too high) to be compensated by adjusting the TRIM value, hence some other action must be taken. At this point, the frequency error counter is stopped (waiting for a next SYNC), and an interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No SYNC missed error signaled

1: SYNC missed error signaled

Bit 8 **SYNCERR**: SYNC error

This flag is set by hardware when the SYNC pulse arrives before the ESYNC event and the measured frequency error is greater than or equal to FELIM * 128. This means that the frequency error is too big (internal frequency too low) to be compensated by adjusting the TRIM value, and that some other action has to be taken. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No SYNC error signaled

1: SYNC error signaled

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **ESYNCF**: Expected SYNC flag

This flag is set by hardware when the frequency error counter reached a zero value. An interrupt is generated if the ESYNCIE bit is set in the CRS_CR register. It is cleared by software by setting the ESYNCC bit in the CRS_ICR register.

0: No expected SYNC signaled

1: Expected SYNC signaled

Bit 2 **ERRF**: Error flag

This flag is set by hardware in case of any synchronization or trimming error. It is the logical OR of the TRIMOVF, SYNCMISS and SYNCERR bits. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software in reaction to setting the ERRC bit in the CRS_ICR register, which clears the TRIMOVF, SYNCMISS and SYNCERR bits.

0: No synchronization or trimming error signaled

1: Synchronization or trimming error signaled

Bit 1 **SYNCWARNF**: SYNC warning flag

This flag is set by hardware when the measured frequency error is greater than or equal to FELIM * 3, but smaller than FELIM * 128. This means that to compensate the frequency error, the TRIM value must be adjusted by two steps or more. An interrupt is generated if the SYNCWARNIE bit is set in the CRS_CR register. It is cleared by software by setting the SYNCWARNC bit in the CRS_ICR register.

0: No SYNC warning signaled

1: SYNC warning signaled

Bit 0 **SYNCOKF**: SYNC event OK flag

This flag is set by hardware when the measured frequency error is smaller than FELIM * 3. This means that either no adjustment of the TRIM value is needed or that an adjustment by one trimming step is enough to compensate the frequency error. An interrupt is generated if the SYNCOKIE bit is set in the CRS_CR register. It is cleared by software by setting the SYNCOKC bit in the CRS_ICR register.

0: No SYNC event OK signaled

1: SYNC event OK signaled

12.7.4 CRS interrupt flag clear register (CRS_ICR)

Address offset: 0x0C

Reset value: 0x0000 0000

												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **ESYNCC**: Expected SYNC clear flag
Writing 1 to this bit clears the ESYNCF flag in the CRS_ISR register.

Bit 2 **ERRC**: Error clear flag
Writing 1 to this bit clears TRIMOVF, SYNCMISS and SYNCERR bits and consequently also the ERRF flag in the CRS_ISR register.

Bit 1 **SYNCWARNC**: SYNC warning clear flag
Writing 1 to this bit clears the SYNCWARNF flag in the CRS_ISR register.

Bit 0 **SYNCOKC**: SYNC event OK clear flag
Writing 1 to this bit clears the SYNCOKF flag in the CRS_ISR register.

12.7.5 CRS register map

Table 113. CRS register map and reset values

13 General-purpose I/Os (GPIO)

13.1 Introduction

Each general-purpose I/O port has four 32-bit configuration registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR and GPIOx_PUPDR), two 32-bit data registers (GPIOx_IDR and GPIOx_ODR), a 16 bits reset register (GPIOx_BRR) and a 32-bit set/reset register (GPIOx_BSRR).

In addition, all GPIOs have a 32-bit locking register (GPIOx_LCKR), two 32-bit alternate function selection registers (GPIOx_AFRH and GPIOx_AFRL), a secure configuration register (GPIOx_SECCFGR) and a high-speed low-voltage register (GPIOx_HSLVR).

13.2 GPIO main features

- Output states: push-pull or open drain + pull-up/down
- Output data from output data register (GPIOx_ODR) or peripheral (alternate function output)
- Speed selection for each I/O
- Input states: floating, pull-up/down, analog
- Input data to input data register (GPIOx_IDR) or peripheral (alternate function input)
- Bit set and reset register (GPIOx_ BSRR) for bitwise write access to GPIOx_ODR
- Lock mechanism (GPIOx_LCKR) provided to freeze the I/O port configurations
- Analog function
- Alternate function selection registers
- Fast toggle capable of changing every two clock cycles
- Highly flexible pin multiplexing allows the use of I/O pins as GPIOs or as one of several peripheral functions
- TrustZone security support
- I/Os state retention during Standby mode

13.3 GPIO functional description

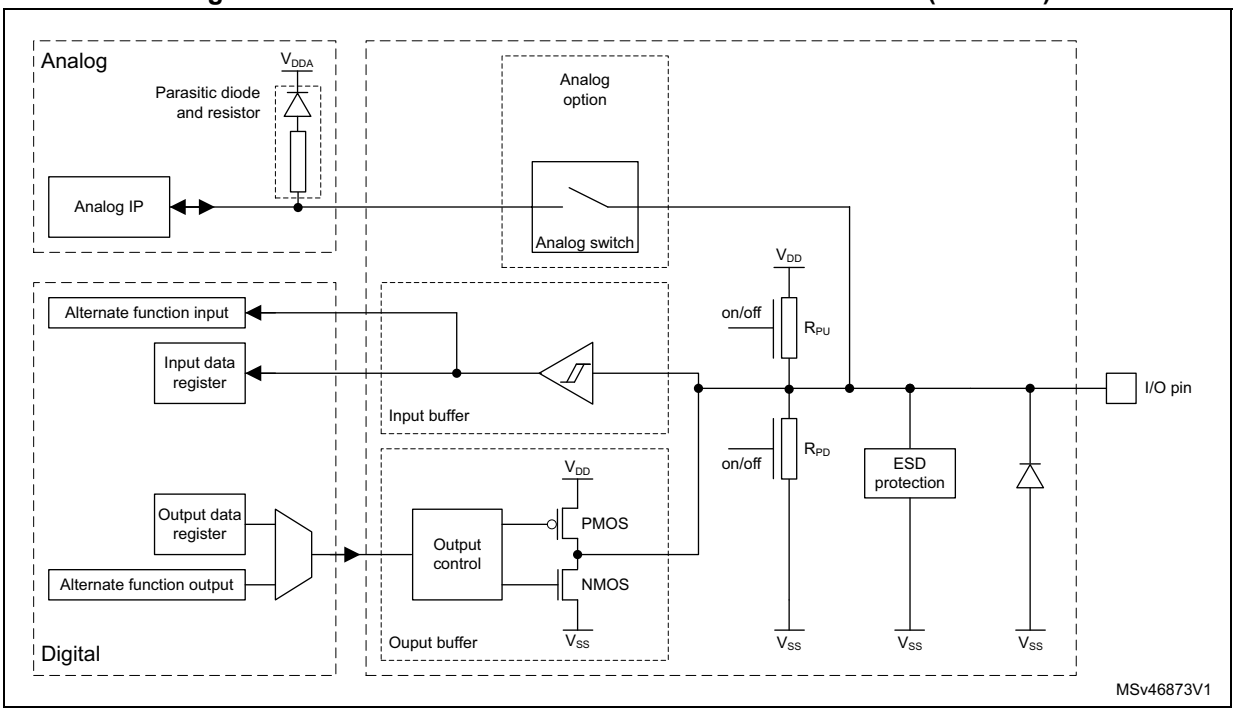
Subject to the specific hardware characteristics of each I/O port listed in the datasheet, each port bit of the general-purpose I/O (GPIO) ports can be individually configured by software in several modes:

- Input floating
- Input pull-up
- Input-pull-down
- Analog
- Output open-drain with pull-up or pull-down capability
- Output push-pull with pull-up or pull-down capability
- Alternate function push-pull with pull-up or pull-down capability
- Alternate function open-drain with pull-up or pull-down capability

Each I/O port bit is freely programmable, however the I/O port registers must be accessed as 32-bit words, half-words or bytes. The GPIOx_BSRR and GPIOx_BRR registers allow atomic read/modify accesses to any of the GPIOx_ODR registers. In this way, there is no risk of an IRQ occurring between the read and the modify access.

The figure below shows the basic structure of a three-volt or five-volt tolerant GPIO (TT or FT). The *Table 114* gives the possible port bit configurations.

Figure 55. Structure of three-volt or five-volt tolerant GPIO (TT or FT)



Note: On a TT GPIO, the analog switch is not present and replaced by a direct connection. The analog bloc parasitic circuitry does not allow five-volt tolerance.

Table 114. Port bit configuration(1)

MODE(i) [1:0]	OTYPE(i)	OSPEED(i) [1:0]	PUPD(i) [1:0]		I/O configuration	
01	0	SPEED [1:0]	0	0	GP output	PP
	0		0	1	GP output	PP + PU
	0		1	0	GP output	PP + PD
	0		1	1	Reserved	
	1		0	0	GP output	OD
	1		0	1	GP output	OD + PU
	1		1	0	GP output	OD + PD
	1		1	1	Reserved (GP output OD)	

Table 114. Port bit configuration[1] (continued)

MODE(i) [1:0]	OTYPE(i)	OSPEED(i) [1:0]		PUPD(i) [1:0]		I/O configuration	
10	0	SPEED [1:0]		0	0	AF	PP
	0			0	1	AF	PP + PU
	0			1	0	AF	PP + PD
	0			1	1	Reserved	
	1			0	0	AF	OD
	1			0	1	AF	OD + PU
	1			1	0	AF	OD + PD
	1			1	1	Reserved	
00	x	x	x	0	0	Input	Floating
	x	x	x	0	1	Input	PU
	x	x	x	1	0	Input	PD
	x	x	x	1	1	Reserved (input floating)	
11	x	x	x	0	0	Input/output	Analog
	x	x	x	0	1	Reserved	
	x	x	x	1	0		
	x	x	x	1	1		

1. GP = general-purpose, PP = push-pull, PU = pull-up, PD = pull-down, OD = open-drain, AF = alternate function.

13.3.1 General-purpose I/O (GPIO)

During and just after reset, the alternate functions are not active and most of the I/O ports are configured in analog mode.

The debug pins are in AF pull-up/pull-down after reset:

- PA15: JTDI in pull-up
- PA14: JTCK/SWCLK in pull-down
- PA13: JTMS/SWDIO in pull-up
- PB4: NJTRST in pull-up
- PB3: JTDO/TRACESWO in floating state no pull-up/pull-down

BOOT0 is in input mode during the reset until at least the end of the option byte loading phase (see *Section 13.3.15: I/Os state retention during standby mode*).

When the pin is configured as output, the value written to the output data register (GPIOx_ODR) is output on the I/O pin. It is possible to use the output driver in push-pull mode or open-drain mode (only the low level is driven, high level is HI-Z).

The input data register (GPIOx_IDR) captures the data present on the I/O pin at every AHB clock cycle.

All GPIO pins have weak internal pull-up and pull-down resistors, that can be activated or not depending on the value in the GPIOx_PUPDR register.

13.3.2 I/O pin alternate function multiplexer and mapping

The device I/O pins are connected to on-board peripherals/modules through a multiplexer that allows only one peripheral alternate function (AF) connected to an I/O pin at a time. In this way, there is no conflict between peripherals available on the same I/O pin.

Each I/O pin has a multiplexer with up to 16 alternate function inputs (AF0 to AF15) that can be configured through the GPIOx_AFRL (for pin 0 to 7) and GPIOx_AFRH (for pin 8 to 15) registers:

- After reset, the multiplexer selection is alternate function 0 (AF0). The I/Os are configured in alternate function mode through GPIOx_MODER register.
- The specific alternate function assignments for each pin are detailed in the device datasheet.

In addition to this flexible I/O multiplexing architecture, each peripheral has alternate functions mapped onto different I/O pins to optimize the number of peripherals available in smaller packages.

To use an I/O in a given configuration, the user must proceed as follows:

- **Debug function**: after each device reset these pins are assigned as alternate function pins immediately usable by the debugger host.
- **GPIO**: configure the desired I/O as output, input or analog in the GPIOx_MODER register.
- **Peripheral alternate function**:
  - Connect the I/O to the desired AFx in one of the GPIOx_AFRL or GPIOx_AFRH register.
  - Select the type, pull-up/pull-down and output speed via the GPIOx_OTYPER, GPIOx_PUPDR and GPIOx_OSPEEDR registers respectively.
  - Configure the desired I/O as an alternate function in the GPIOx_MODER register.
- **Additional functions:**
  - For the ADC and DAC configure the desired I/O in analog mode in the GPIOx_MODER register and configure the required function in the ADC and DAC registers.
  - For the additional functions like RTC, WKUPx and oscillators, configure the required function in the related RTC, PWR and RCC registers. These functions have priority over the configuration in the standard GPIO registers.

Refer to the “Alternate function mapping” table in the device datasheet for the detailed mapping of the alternate function I/O pins.

13.3.3 I/O port control registers

Each of the GPIO ports has four 32-bit memory-mapped control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR) to configure up to 16 I/Os. The GPIOx_MODER register is used to select the I/O mode (input, output, AF, analog). The GPIOx_OTYPER and GPIOx_OSPEEDR registers are used to select the output type (push-pull or open-drain) and speed. The GPIOx_PUPDR register is used to select the pull-up/pull-down whatever the I/O direction.

13.3.4 I/O port data registers

Each GPIO has two 16-bit memory-mapped data registers: input and output data registers (*GPIO port input data register (GPIOx_IDR) (x = A to I)* and *GPIO port output data register (GPIOx_ODR) (x = A to I)*).

GPIOx_ODR stores the data to be output, it is read/write accessible. The data input through the I/O are stored into the input data register (GPIOx_IDR), a read-only register.

13.3.5 I/O data bitwise handling

The bit set reset register (GPIOx_BSRR) is a 32-bit register that allows the application to set and reset each individual bit in the output data register (GPIOx_ODR). The bit set reset register has twice the size of GPIOx_ODR.

To each bit in GPIOx_ODR, correspond two control bits in GPIOx_BSRR: BS(i) and BR(i). When written to 1, BS(i) sets the corresponding ODR(i) bit. When written to 1, BR(i) resets the ODR(i) corresponding bit.

Writing any bit to 0 in GPIOx_BSRR does not have any effect on the corresponding bit in GPIOx_ODR. If there is an attempt to both set and reset a bit in GPIOx_BSRR, the set action takes priority.

Using the GPIOx_BSRR register to change the values of individual bits in GPIOx_ODR is a “one-shot” effect that does not lock the GPIOx_ODR bits. The GPIOx_ODR bits can always be accessed directly. The GPIOx_BSRR register provides a way of performing atomic bitwise handling.

There is no need for the software to disable interrupts when programming the GPIOx_ODR at bit level: one or more bits can be modified in a single atomic AHB write access.

13.3.6 GPIO locking mechanism

The GPIO control registers can be frozen by applying a specific write sequence to the GPIOx_LCKR register. The frozen registers are GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL, GPIOx_AFRH and GPIOx_HSLVR.

To write the GPIOx_LCKR register, a specific write/read sequence must be applied. When the right LOCK sequence is applied to the bit 16 in this register, the value of LCKR[15:0] is used to lock the configuration of the I/Os (during the write sequence the LCKR[15:0] value must be the same). When the LOCK sequence is applied to a port bit, the value of the port bit can no longer be modified until the next MCU reset or peripheral reset. Each GPIOx_LCKR bit freezes the corresponding bit in the control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL and GPIOx_AFRH.

The LOCK sequence can only be performed using a word (32-bit long) access to the GPIOx_LCKR register due to the fact that GPIOx_LCKR bit 16 must be set at the same time as the [15:0] bits.

13.3.7 I/O alternate function input/output

Two registers are provided to select one of the alternate function inputs/outputs available for each I/O. With these registers, the user can connect an alternate function to some other pin as required by the application.

This means that a number of possible peripheral functions are multiplexed on each GPIO using the GPIOx_AFRL and GPIOx_AFRH alternate function registers. The application can

thus select any one of the possible functions for each I/O. The AF selection signal being common to the alternate function input and alternate function output, a single channel is selected for the alternate function input/output of a given I/O.

To know which functions are multiplexed on each GPIO pin, refer to the device datasheet.

13.3.8 External interrupt/wakeup lines

All ports have external interrupt capability. To use external interrupt lines, the port can be configured in input, output or alternate function mode (the port must not be configured in analog mode). Refer to *Section 23: Extended interrupts and event controller (EXTI)*.

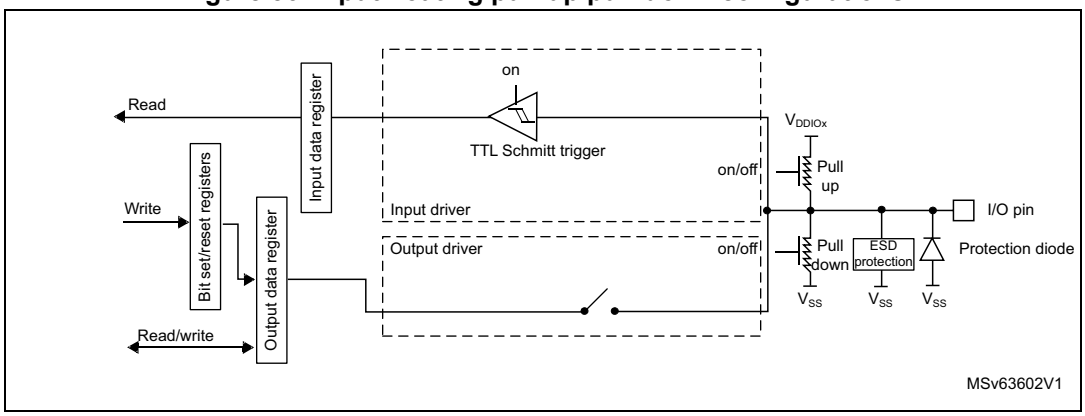
13.3.9 Input configuration

When the I/O port is programmed as input:

- The output buffer is disabled.
- The Schmitt trigger input is activated.
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register.
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register provides the I/O state.

The figure below shows the input configuration of the I/O port bit.

Figure 56. Input floating/pull-up/pull-down configurations



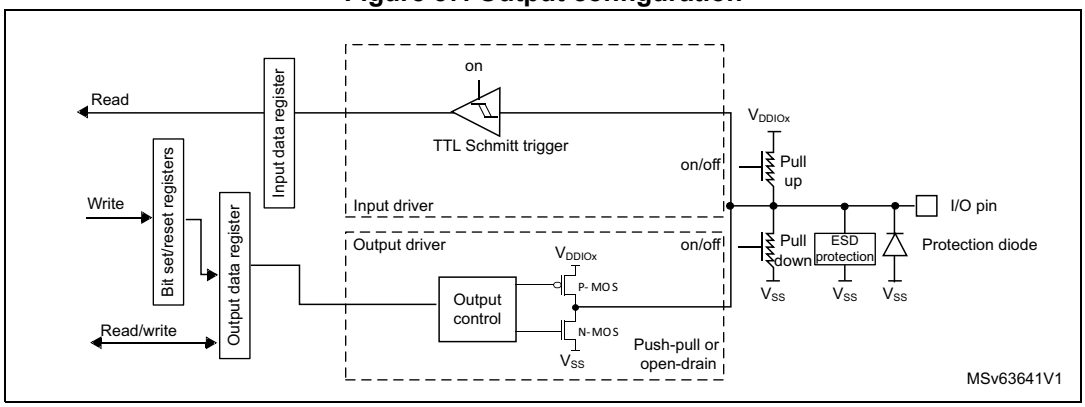
13.3.10 Output configuration

When the I/O port is programmed as output:

- The output buffer is enabled:
  - Open-drain mode: a 0 in the output register activates the N-MOS whereas a 1 in the output register leaves the port in Hi-Z (the P-MOS is never activated).
  - Push-pull mode: a 0 in the output register activates the N-MOS whereas a 1 in the output register activates the P-MOS.
- The Schmitt trigger input is activated.
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register.
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register gets the I/O state.
- A read access to the output data register gets the last written value.

The figure below shows the output configuration of the I/O port bit.

Figure 57. Output configuration



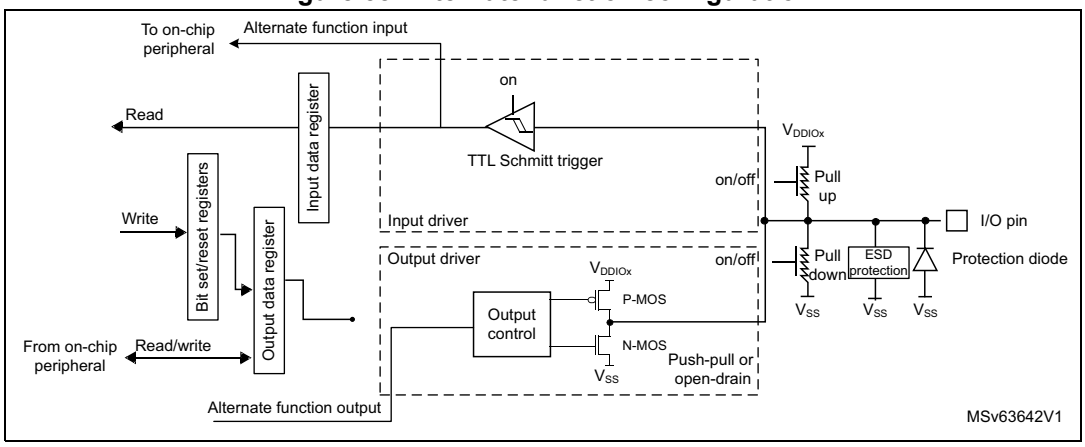
13.3.11 Alternate function configuration

When the I/O port is programmed as alternate function:

- The output buffer can be configured in open-drain or push-pull mode.
- The output buffer is driven by the signals coming from the peripheral (transmitter enable and data).
- The Schmitt trigger input is activated.
- The weak pull-up and pull-down resistors are activated or not depending on the value in the GPIOx_PUPDR register.
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register gets the I/O state.

The figure below shows the alternate function configuration of the I/O port bit.

Figure 58. Alternate function configuration



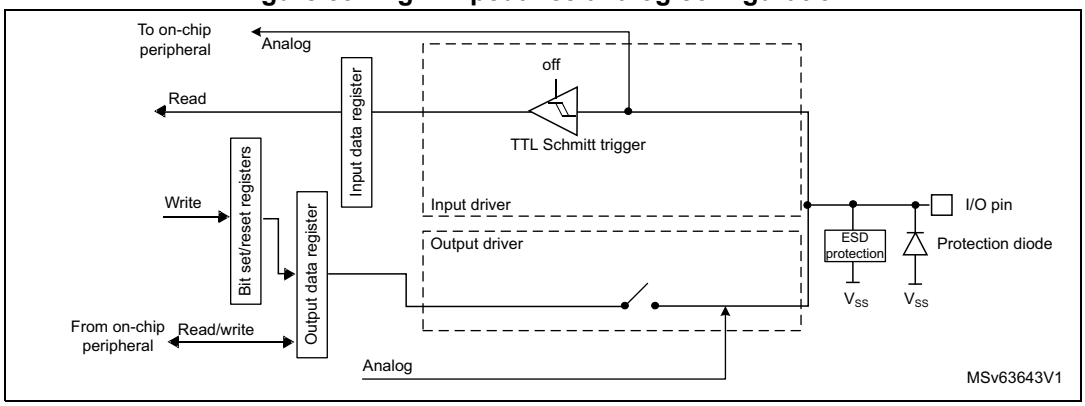
13.3.12 Analog configuration

When the I/O port is programmed as analog configuration:

- The output buffer is disabled.
- The Schmitt trigger input is deactivated, providing zero consumption for every analog value of the I/O pin. The output of the Schmitt trigger is forced to a constant value (0).
- The weak pull-up and pull-down resistors are disabled by hardware.
- Read access to the input data register gets the value 0.

The figure below shows the high-impedance, analog-input configuration of the I/O port bits.

Figure 59. High-impedance analog configuration



13.3.13 Using the HSE or LSE oscillator pins as GPIOs

When the HSE or LSE oscillator is switched off (default state after reset), the related oscillator pins can be used as normal GPIOs.

When the HSE or LSE oscillator is switched on (by setting the HSEON or LSEON bit in the RCC_CSR register), the oscillator takes control of its associated pins and the GPIO configuration of these pins has no effect.

When the oscillator is configured in a user external clock mode, only the pin is reserved for clock input, and the OSC_OUT or OSC32_OUT pin can still be used as normal GPIO.

13.3.14 Using the GPIO pins in the RTC supply domain

The PC13/PC14/PC15/PI8 GPIO functionality is lost when the core supply domain is powered off (when the device enters Standby mode). In this case, if their GPIO configuration is not bypassed by the RTC configuration, these pins are set in an analog input mode.

For details about I/O control by the RTC, refer to *Section 46.3: RTC functional description*

13.3.15 I/Os state retention during standby mode

In the Standby mode, the I/Os are by default in floating state.

If the IORETEN bit in the PWR_IORETR register is set, the I/Os state is sampled during standby entry. The state of I/Os is applied to the pin via pull-up and pull-down resistors. The pull-up and pull-down resistors remains applied after Standby wakeup until the IORETEN bit in the PWR_IORETR register is cleared by software.

13.3.16 TrustZone security

The TrustZone security is activated by the TZEN option byte in the Flash Option Byte register. When the TrustZone is active (TZEN = 0xB4), each I/O pin of GPIO port can be individually configured as secure through the GPIOx_SECCFGR register.

When the selected I/O pin is configured as secure, its corresponding configuration bits for alternate function, mode selection, I/O data are secure against a non-secure access. In case of non-secure access, these bits are RAZ/WI.

The I/Os with peripherals functions are also conditioned by the peripheral security configuration (see *Section 5: Global TrustZone controller (GTZC)* for more details):

- For peripherals for which the I/O pin selection is done through alternate functions registers: if the peripheral is configured as secure, it cannot be connected to a non-secure I/O pin. If this is not respected, the input data to the secure peripheral is forced to 0 (I/O input pin value is ignored) and the output pin value is forced to 0, thus avoiding any secure information leak through non-secure I/Os.
- For I/Os with analog switches, directly controlled by peripherals (such as ADC for instance): If the I/O is secure, the I/O analog switch cannot be controlled by a non-secure peripheral. If this is not respected, the switch remains open. This prevent the redirection of secure data to a non-secure peripheral or I/O through analog path. Refer to *Section 3: System security* for more details.
- Some of the paths between I/Os “additional functions” and peripherals are not blocked if the I/O is secure and the peripheral is non-secure. Therefore it is recommended to configure those peripherals as secure even when not used by the application. Refer to *Section 3: System security* for the list of concerned peripherals. When the path has a security control, it follows the same rule as I/O selection through alternate functions.

Refer to the device pins definition table in datasheet for more information about peripherals alternate functions and additional functions mapping.

After reset, all GPIO ports are secure.

The table below gives a summary of the I/O port secured bits following the security configuration bit in the GPIO_SECCFGR register. When the I/O bit port is configured as secure:

- Secured bits: read and write operations are only allowed by a secure access. Non secure-read or write accesses on secured bits are RAZ/WI. There is no illegal access event generated.
- Non-secure bits: no restriction. Read and write operations are allowed by both secure and non-secure accesses.

When the TrustZone security is disabled (TZEN = 0xC3 in FLASH_OPTSR2 register), all registers bits are non-secure. The GPIOx_SECCFGR register is RAZ/WI.

Table 115. GPIO secured bits

Secure configuration bit	Secured bit	Register name	Non-secure access on secure bits
SECy = 1 in GPIOx_SECCFGR(1)	MODEy[1:0]	GPIOx_MODER	RAZ/WI
	OTy	GPIOx_OTYPER	
	OSPEEDy[1:0]	GPIOx_OSPEEDR	
	PUPDy[1:0]	GPIOx_PUPDR	
	IDy	GPIOx_IDR	
	ODy	GPIOx_ODR	
	BSy and BRy	GPIOx_BSRR	
	LCKy	GPIOx_LCKR	
	BRy	GPIOx_BRR	
	AFSELy[3:0]	GPIOx_AFRH	
		GPIOx_AFRL	
	HSLVy	GPIOx_HSLVR	

1. GPIOx, x = A to I. For x = A to H, y = 0 to 15. For x = I, y = 0 to 11.

13.3.17 Privileged and unprivileged modes

All GPIO registers can be read and written by privileged and unprivileged accesses, whatever the security state (secure or non-secure).

13.3.18 High-speed low-voltage mode (HSLV)

Some I/Os have the capability to increase their maximum speed at low voltage by configuring them in HSLV mode. The I/O HSLV bit controls whether the I/O output speed is optimized to operate at 3.3 V (default setting) or at 1.8 V (HSLV = 1).

Caution: The I/O HSLV configuration bit must not be set if the I/O supply (V_{DD} or V_{DDIO2}) is above 2.7 V. Setting it while the voltage is higher than 2.7 V can damage the device. The I/O HSLV bit can be set only when the corresponding option bit is activated (IO_VDD_HSLV or IO_VDDIO2_HSLV depending on the I/O supply, refer to *Section 7.4: FLASH option bytes*). There is no hardware protection associated to this feature so it is recommended to use it only as a static configuration for fixed I/O supply.

13.3.19 I/O compensation cell

The I/O commutation slew rate (tfall / trise) can be adapted by software depending on process, voltage and temperatures conditions, in order to reduce the I/O noise on power supply. Refer to *Section 14: System configuration, boot, and security (SBS)* for more details.

13.4 GPIO registers

This section gives a detailed description of the GPIO registers.

The peripheral registers can be written in word, half word or byte mode.

13.4.1 GPIO port mode register (GPIOx_MODER) (x = A to I)

Address offset:0x00

Reset value: 0xABFF FFFF (for port A)

Reset value: 0xFFFF FEBF (for port B)

Reset value: 0xFFFF FFFF (for ports C..H)

Reset value: 0x00FF FFFF (for port I)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MODE15[1:0]		MODE14[1:0]		MODE13[1:0]		MODE12[1:0]		MODE11[1:0]		MODE10[1:0]		MODE9[1:0]		MODE8[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MODE7[1:0]		MODE6[1:0]		MODE5[1:0]		MODE4[1:0]		MODE3[1:0]		MODE2[1:0]		MODE1[1:0]		MODE0[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MODEy[1:0]:** Port x configuration I/O pin y (y = 15 to 0)
These bits are written by software to configure the I/O mode.
00: Input mode
01: General purpose output mode
10: Alternate function mode
11: Analog mode (reset state)

Note: The bitfield is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

13.4.2 GPIO port output type register (GPIOx_OTYPER) (x = A to I)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OT15	OT14	OT13	OT12	OT11	OT10	OT9	OT8	OT7	OT6	OT5	OT4	OT3	OT2	OT1	OT0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **OTy:** Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O output type.

0: Output push-pull (reset state)

1: Output open-drain

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

13.4.3 GPIO port output speed register (GPIOx_OSPEEDR) (x = A to I)

Address offset: 0x08

Reset value: 0x0C00 0000 (for port A)

Reset value: 0x0000 00C0 (for port B)

Reset value: 0x0000 0000 (for the other ports)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OSPEED15[1:0]		OSPEED14[1:0]		OSPEED13[1:0]		OSPEED12[1:0]		OSPEED11[1:0]		OSPEED10[1:0]		OSPEED9[1:0]		OSPEED8[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OSPEED7[1:0]		OSPEED6[1:0]		OSPEED5[1:0]		OSPEED4[1:0]		OSPEED3[1:0]		OSPEED2[1:0]		OSPEED1[1:0]		OSPEED0[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **OSPEEDy[1:0]**: Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O output speed.

00: Low speed

01: Medium speed

10: High speed

11: Very-high speed

Note: Refer to the device datasheet for the frequency specifications and the power supply and load conditions for each speed.

The bitfield is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

13.4.4 GPIO port pull-up/pull-down register (GPIOx_PUPDR) (x = A to I)

Address offset: 0x0C

Reset value: 0x6400 0000 (for port A)

Reset value: 0x0000 0100 (for port B)

Reset value: 0x0000 0000 (for the other ports)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PUPD15[1:0]		PUPD14[1:0]		PUPD13[1:0]		PUPD12[1:0]		PUPD11[1:0]		PUPD10[1:0]		PUPD9[1:0]		PUPD8[1:0]

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **PUPDy[1:0]:** Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O pull-up or pull-down

00: No pull-up, pull-down

01: Pull-up

10: Pull-down

11: Reserved

Note: The bitfield is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

13.4.5 GPIO port input data register (GPIOx_IDR) (x = A to I)

Address offset: 0x10

Reset value: 0x0000 XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **IDy:** Port x input data I/O pin y (y = 15 to 0)

These bits are read-only. They contain the input value of the corresponding I/O port.

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

13.4.6 GPIO port output data register (GPIOx_ODR) (x = A to I)

Address offset: 0x14

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

OD15	OD14	OD13	OD12	OD11	OD10	OD9	OD8	OD7	OD6	OD5	OD4	OD3	OD2	OD1	OD0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **ODy:** Port output data I/O pin y (y = 15 to 0)

These bits can be read and written by software.

Note: For atomic bit set/reset, the OD bits can be individually set and/or reset by writing to the GPIOx_BSRR or GPIOx_BRR registers (x = A to I).

The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

13.4.7 GPIO port bit set/reset register (GPIOx_BSRR) (x = A to I)

Address offset: 0x18

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BR15	BR14	BR13	BR12	BR11	BR10	BR9	BR8	BR7	BR6	BR5	BR4	BR3	BR2	BR1	BR0
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BS15	BS14	BS13	BS12	BS11	BS10	BS9	BS8	BS7	BS6	BS5	BS4	BS3	BS2	BS1	BS0
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:16 **BRy:** Port x reset I/O pin y (y = 15 to 0)

These bits are write-only. A read to these bits returns the value 0x0000.

0: No action on the corresponding ODy bit

1: Resets the corresponding ODy bit

Note: If both BSy and BRy are set, BSy has priority.

The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

Bits 15:0 **BSy:** Port x set I/O pin y (y = 15 to 0)

These bits are write-only. A read to these bits returns the value 0x0000.

0: No action on the corresponding ODy bit

1: Sets the corresponding ODy bit

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

13.4.8 GPIO port configuration lock register (GPIOx_LCKR) (x = A to I)

This register is used to lock the configuration of the port bits when a correct write sequence is applied to bit 16 (LCKK). The value of bits [15:0] is used to lock the configuration of the GPIO. During the write sequence, the value of LCKR[15:0] must not change. When the LOCK sequence has been applied on a port bit, the value of this port bit can no longer be modified until the next MCU reset or peripheral reset.

Note: A specific write sequence is used to write to the GPIOx_LCKR register. Only word access (32-bit long) is allowed during this locking sequence.

Each lock bit freezes a specific configuration register (control and alternate function registers).

Address offset: 0x1C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LCKK
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LCK15	LCK14	LCK13	LCK12	LCK11	LCK10	LCK9	LCK8	LCK7	LCK6	LCK5	LCK4	LCK3	LCK2	LCK1	LCK0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **LCKK:** Lock key

This bit can be read any time. It can only be modified using the lock key write sequence.

0: Port configuration lock key not active

1: Port configuration lock key active. The GPIOx_LCKR register is locked until the next MCU reset or peripheral reset.

- LOCK key write sequence:

WR LCKR[16] = 1 + LCKR[15:0]

WR LCKR[16] = 0 + LCKR[15:0]

WR LCKR[16] = 1 + LCKR[15:0]

- LOCK key read

RD LCKR[16] = 1 (this read operation is optional but it confirms that the lock is active)

Note: During the LOCK key write sequence, the value of LCK[15:0] must not change.

Any error in the lock sequence aborts the LOCK.

After the first LOCK sequence on any bit of the port, any read access on the LCKK bit returns 1 until the next MCU reset or peripheral reset.

Bits 15:0 **LCKy:** Port x lock I/O pin y (y = 15 to 0)

These bits are read/write but can only be written when the LCKK bit is 0

0: Port configuration not locked

1: Port configuration locked

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

13.4.9 GPIO alternate function low register (GPIOx_AFRL) (x = A to I)

Address offset: 0x20

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **BRy:** Port x reset IO pin y (y = 15 to 0)
These bits are write-only. A read to these bits returns the value 0x0000.
0: No action on the corresponding ODy bit
1: Reset the corresponding ODy bit

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

13.4.12 GPIO high-speed low-voltage register (GPIOx_HSLVR) (x = A to I)

Address offset: 0x2C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **HSLVy:** Port x high-speed low-voltage configuration (y = 15 to 0)

These bits are written by software to optimize the I/O speed when the I/O supply is low. Each bit is active only if the corresponding IO_VDD_HSLV/IO_VDDIO2_HSLV user option bit is set. It must be used only if the I/O supply voltage is below 2.7 V.

Setting these bits when the I/O supply (VDD or VDDIO2) is higher than 2.7 V may be destructive.

0: I/O speed optimization disabled

1: I/O speed optimization enabled

Note: Not all I/Os support the HSLV mode. Refer to the I/O structure in the corresponding datasheet for the list of I/Os supporting this feature. Other I/Os HSLV configuration must be kept at reset value.

The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

13.4.13 GPIO secure configuration register (GPIOx_SECCFGR) (x = A to I)

When the system is secure (TZEN = 0xB4), this register provides write access security and can be written only by a secure access. It is used to configure a selected I/O as secure. A non-secure write access to this register is discarded.

When the system is not secure (TZEN = 0xC3), this register is RAZ/WI.

Address offset: 0x30

Reset value: 0x0000 FFFF (for ports A to H)

Reset value: 0x0000 0FFF (for port I)

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **SECy**: I/O pin of Port x secure bit enable y (y = 15 to 0)

These bits are written by software to enable or disable the I/O port pin security.

0: The I/O pin is non-secure

1: The I/O pin is secure. Refer to *Table 115* for all corresponding secured bits.

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

13.4.14 GPIO register map

Table 116. GPIO register map and reset values

Refer to *Section 2.3* for the register boundary addresses.

14 System configuration, boot, and security (SBS)

14.1 SBS introduction

The STM32H563/H573 and STM32H562 devices feature a set of configuration registers located in the SBS. On top of various device configurations, this SBS peripheral controls key boot and security features, including debug control and secure storage control.

14.2 SBS main features

- System configuration
  - Manage safety feature
  - Enable/disable the FMP (Fast-mode Plus) high-drive capability of some I/Os and voltage booster for I/O analog switches
  - Manage the I/O compensation cell
  - Configure register security access
- Boot control
  - Upon system reset, configure the Cortex-M33 boot address and the temporal isolation level depending on the current configuration such as PRODUCT_STATE (sbs_product_state), BOOT_UBE (sbs_irot_select), or TZEN (sbs_tzen).
  - Manage the temporal isolation feature implemented thanks to the hide protect level (HDPL) monotonic counter
- Debug control
  - Control the opening of the device debug interface, ensuring the sequencing of events that guarantee the device security
- Hardware secure storage control
  - Control the secure storage selections: OBK-HDPL selection (selects the area of secure storage of the flash memory and selects the corresponding DHUK in SAES), EPOCH selection

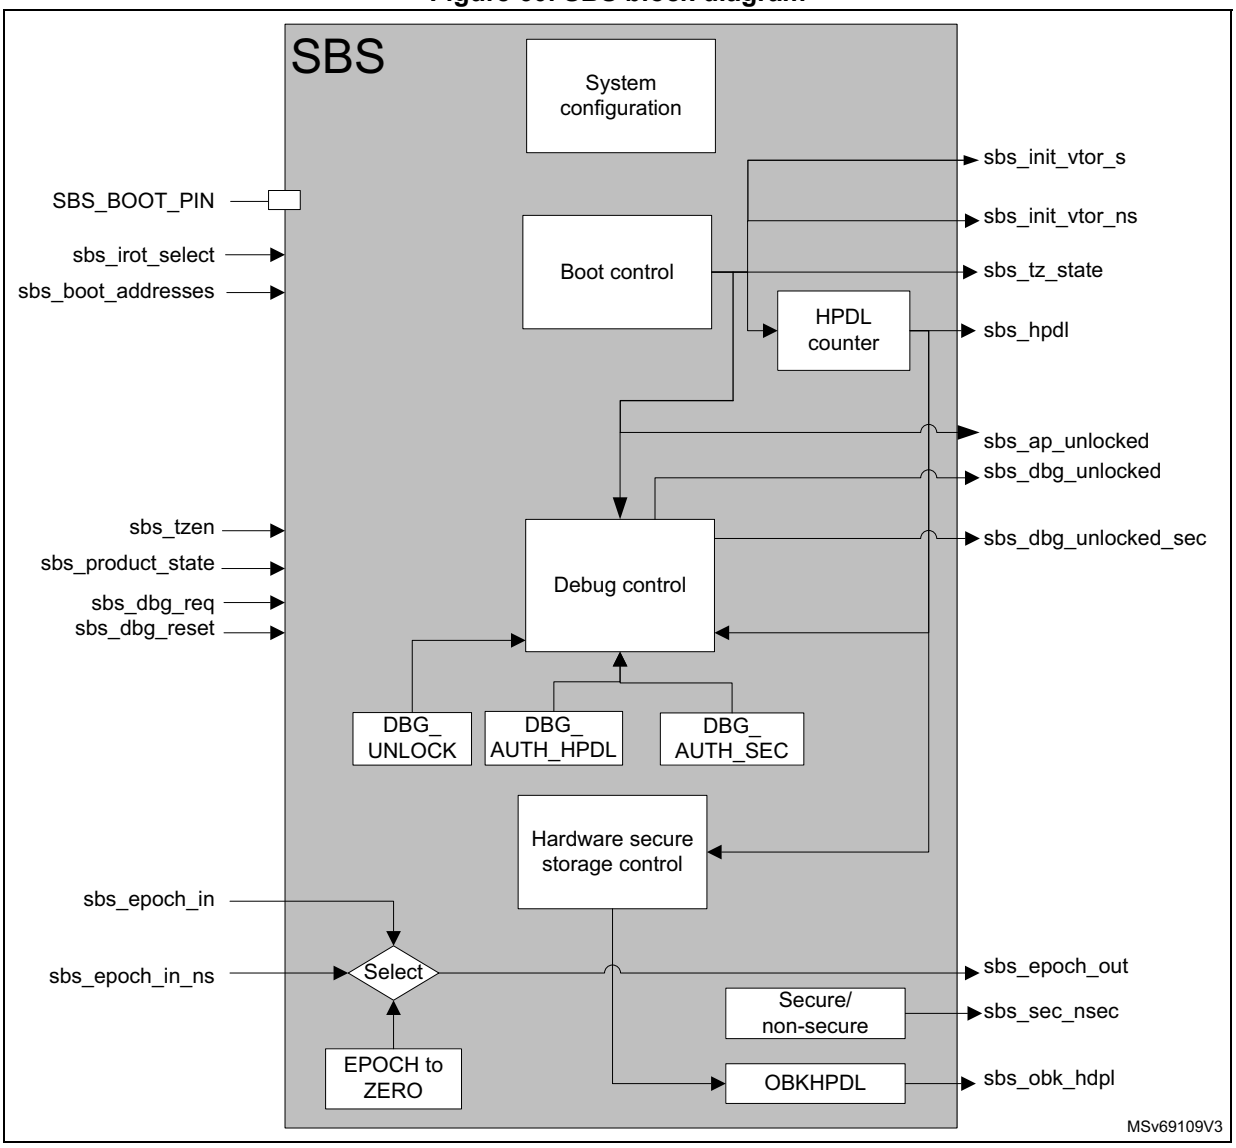
14.3 SBS functional description

14.3.1 SBS block diagram

The figure below shows the SBS block diagram, including the four main functions:

- System configuration
- Boot control
- Debug control
- Hardware secure storage control

Figure 60. SBS block diagram



14.3.2 SBS signals

The table below details the user relevant internal signals that interface the SBS.

Table 117. SBS internal input/output signals

Signal name	Type	Description
BOOT0	Input	Select booting on user flash memory or Bootloader when TrustZone is disabled (TZEN = 0xC3), or on RSS when TrustZone is enabled (TZEN = 0xB4).
sbs_irot_select		Signal based on BOOT_UBE option byte to select the iROT between ST-iROT and user flash memory (OEM-iROT)
sbs_tzen		Signal based on TZEN option byte to activate/deactivate the TrustZone
sbs_boot_addresses		List of addresses defined by the flash memory: – NSBOOTADD: non-secure boot address – SECBOOTADD: secure boot address
sbs_product_state		Signal based on PRODUCT_STATE option byte to activate the different security mechanisms depending on the product use. Expected values are described in *Section 7: Embedded flash memory (FLASH)*.
sbs_dbg_req		Launch the debug authentication protocol when booting.
sbs_init_vtor_s	Output	Vector address for Cortex-M33 secure entry point
sbs_init_vtor_ns		Vector address for Cortex-M33 non-secure entry point
sbs_tz_state		Inform the Cortex-M33 on the secure state of the core.
sbs_hdpl		HDPL (temporal isolation level, ID of the boot level, used to isolate boot levels) This signal reflects a monotonic counter that can be incremented from 0 to 3, and that is reset to zero only on software reset or POR.
sbs_ap_unlocked		Control the Cortex-M33 access port.
sbs_dbg_unlocked		Unlock the debug (when set to 1) for the Cortex-M33 non-secure part.
sbs_dbg_unlocked_sec		Unlock the debug (when set to 1) for the Cortex-M33 secure part.
sbs_dbg_reset	Input	This signal is used to control the reset of the debug authentication configuration to be done with a system reset or a power-on reset. The configuration is done through the DBGMCU using the DCRT bitfield of DBGMCU_CR register.
sbs_obk_hdpl	Output	Select secure storage domain (OBK-HDPL) for current HDPL, or greater ones (to allow provisioning).
sbs_epoch_out		EPOCH counters (NS_EPOCH and SEC_EPOCH, inputs from flash memory) are used to manage the REPLAY protection.
sbs_sec_nsec		Reflect secure/non-secure selection for the secure storage.

14.3.3 SBS reset and clocks

The SBS configuration port is clocked by the AHB bus clock. There is a general reset and a debug configuration reset controlled in DBGMCU.

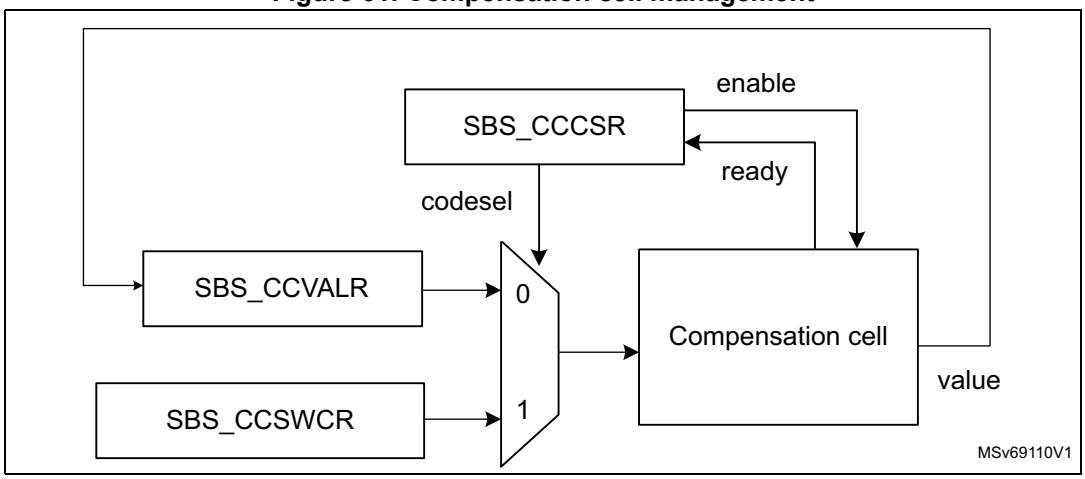
14.3.4 SBS system configuration

SBS I/O compensation cell management

The I/O compensation cell generates an 8-bit value for the I/O buffer (4 bits for N-MOS and 4 bits for P-MOS), that depends on PVT operating conditions (process, voltage, temperature). These bits are used to control the output impedance in the I/O buffer, and the slew rate of the I/O commutation (the t_{fall} and t_{rise} time), in order to reduce the I/O noise on power supply.

As shown in the figure below, the compensation cell is split in two blocks: one block to provide an optimal code for the current PVT, and one block to drive the block controlled by the software.

Figure 61. Compensation cell management



The compensation cell value can be read when the READY flag is set in SBS_CCCSR. With CODESEL in SBS_CCCSR, the application can select the value to apply between two options: the code from the cell or the code from SBS_CCSWCR.

Two compensation cells are embedded in STM32H563/H573 and STM32H562 devices:

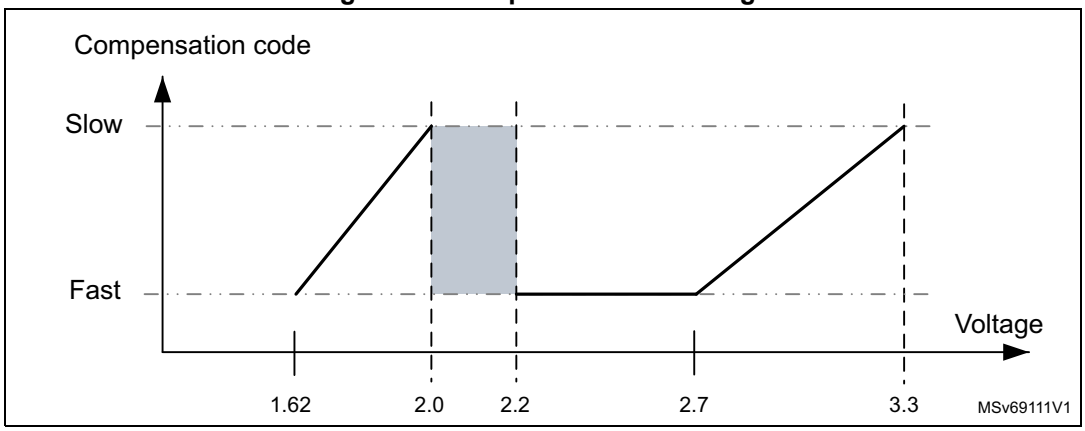
- one for the I/Os supplied by V_{DDIO} power rail
- one for the I/Os supplied by V_{DDIO2} power rail

By default, the compensation cells are disabled, and a fixed code is applied to all the I/Os.

Note: The compensation cell can be used only when 2.7 V ≤ V_{DDIOx} ≤ 3.6 V or 1.62 V ≤ V_{DDIOx} ≤ 2 V (see Figure 62).

Note: The compensation cell can be used only when the CSI oscillator is enabled, see Section 11: Reset and clock control (RCC) for more details on CSI oscillator.

Figure 62. Compensation cell usage



SBS TrustZone security and privilege

- SBS TrustZone security

  When the TrustZone security is activated, the SBS is able to protect secure registers from being modified by non-secure accesses.

  The TrustZone security is activated by the TZEN option byte in FLASH_OPTSR2_PRG.

  A non-secure read/write access to a secured register is RAZ/WI and generates an illegal access event. An illegal access interrupt is generated if the SBS illegal access event is enabled in the GTZC.

- Privileged/unprivileged mode

  The SBS registers can be read and written by privileged and unprivileged accesses except the SBS registers for CPU configuration:

  – SBS_CSLCKR, SBS_FPUIMR and SBS_CNSLCKR

  – FPUSEC in SBS_SECCFGR

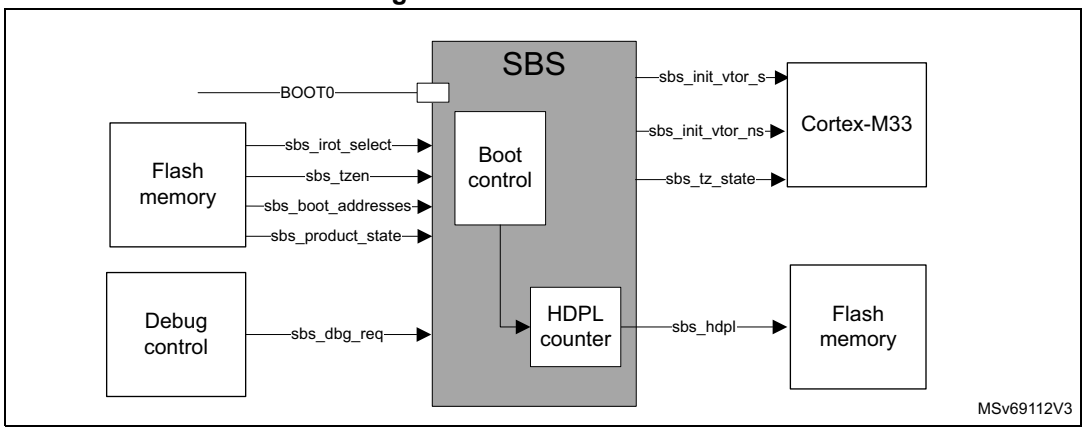
  An unprivileged access to a privileged register is RAZ/WI.

14.3.5 SBS boot control

The SBS can be used to control the boot entry points considering the product settings. The main boot control actions are listed below:

- Run product with or without TrustZone enabled.
- Select between ST-iROT or OEM-iROT.
- Boot when launching a debug authentication sequence.
- Select boot between the Bootloader or the user flash memory boot.
- Initialize the HDPL boot value.

Figure 63. SBS boot control



The boot configurations are selected considering the product settings:

- BOOT0: to select booting on user flash memory or RSS (root secure services)
- BOOT_UBE option byte to select the iROT between ST-iROT and OEM-iROT
- TZEN option byte to activate/deactivate the Trust Zone
- sbs_boot_addresses: list of addresses defined by the flash memory:
  - NSBOOTADD: non-secure boot address
  - SECBOOTADD: secure boot address
- PRODUCT_STATE: option byte to activate the different security mechanisms depending on the product use. Expected values are described in *Section 7: Embedded flash memory (FLASH)*.
- sbs_dbg_req: used to launch the debug authentication protocol when booting

The boot control logic sets the following data:

- sbs_init_vtor_s: vector address for Cortex-M33 secure entry point
- sbs_init_vtor_ns: vector address for Cortex-M33 non-secure entry point
- sbs_tz_state (secure/non-secure): informs the Cortex-M33 on the secure state of the core.
- HDPL (see the description below)

SBS HDPL (temporal isolation level) management

The HDPL is a monotonic counter incremented during the boot stages. The HDPL is reset to its default value only after a power-on or a system reset. This default value (0 or 1) depends on the device life cycle, as defined in boot logic.

The STM32H563/H573 and STM32H562 devices use HDPL information to automatically isolate code and its associated secrets (like keys) during the boot process. Incrementing HPDL ensures that private code and data for one boot stage cannot be directly accessible from later boot stages.

The HDPL is used by the user flash memory, see *Section 7: Embedded flash memory (FLASH)* for more details. The HDPL can take values from 0 to 3. When reaching the value 3, HDPL keeps this value until reset. The current HDPL value is readable in HDPL bitfield in SBS_HDPLSR.

To increment the HDPL by one, the application must write 0x6A to INCR_HDPL in SBS_HDPLCR. After such increment, and before doing any subsequent action, the user must check that the HDPL has effectively been incremented reading SBS_HDPLSR.

Table 118. HDPL encoded values

HDPL	Code
0	0xB4
1	0x51
2	0x8A
3	0x6F

14.3.6 SBS debug control

The SBS debug control is used to manage debug opening, taking care on the product context (PRODUCT_STATE, TZEN, HDPL) on register settings, or through a debug authentication control.

When the debug is forbidden, the mailbox access port, Cortex-M33 access port and CPU debug interface are locked. In this situation, the debugger cannot access the CPU and no effective debug can be done. Refer to the *Section 58: Debug support (DBG)* for more details.

Authenticated debug sequence

1. The external host requests to launch the debug authentication protocol, via the DBGMCU access port mailbox. The rest of the device is kept under reset.
2. SBS selects the STMicroelectronics RSS-DA (debug authentication library) boot address, and requests the CPU to be released from reset.

3. The CPU running RSS-DA library executes the debug authentication protocol in the system flash memory. If the device is closed, the access port mailbox is closed until RSS-DA acknowledges the authentication sequence start request.
4. The authentication method depends on TrustZone activation:
   – When TrustZone is activated (TZEN = 0xB4), the authentication method is based on certificates. As soon as a debug certificate chain is fully verified by the device, if the certificate concerns a debug permission, the RSS-DA programs the debug opening of the Cortex-M33. Alternatively, the certificate can authorize partial or full regression, allowing debug on a regressed part.
   – When TrustZone is disabled (TZEN = 0xC3), the authentication method is based on password. This method only allows the full regression of the product to be controlled.
5. Above reopenings are effective only when HDPL in SBS_HDPLSR has a value equal or superior to the value programmed in DBG_AUTH_HDPL in SBS_DBGCR. In case of authentication failure, the user is informed through the host interface.

*Note: The debug authentication library in system flash memory is available only when HDPL = 0 or 1 in SBS_*HDPL*SR. Only this library can perform the steps 3 and 4 described above.*

Debug reset

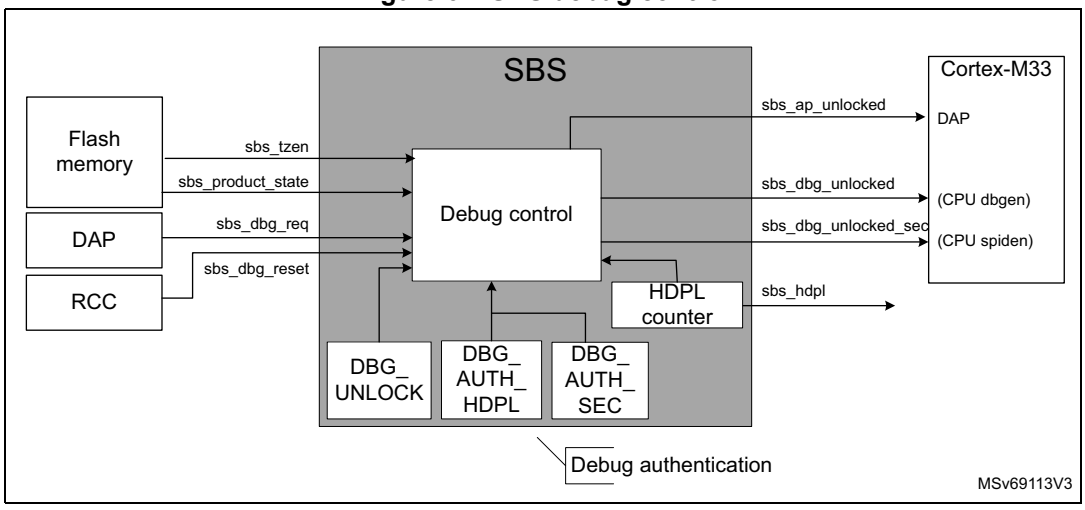
The debug opening can have the configuration to be reset by system or power-on reset, depending on a DBGMCU register field.

Debug locking

The debug configuration can be locked thanks to DBGCFG_LOCK in SBS_DBGLOCKR. SBS_DBGCR is then no longer writable.

When DBGCFG_LOCK is set to 1, it can be reset only by system or power-on reset. The configuration is done through the DBGMCU using the DCRT field of DBGMCU_CR.

Figure 64. SBS debug control



Inputs used to control the debug opening:

- sbs_dbg_req: input signal that a host requests to launch the debug authentication protocol. When this signal is set, the boot address is set to launch the debug authentication library.
- sbs_tzen: inform on the selected platform configuration related to TrustZone activation. When TZEN value is set to zero (0xC3), the platform does not support TrustZone and the simplified life cycle is proposed. See *Section 7: Embedded flash memory (FLASH)* for more details.
- sbs_product_state: provide the current PRODUCT_STATE (from flash memory). See *Section 7: Embedded flash memory (FLASH)* for more details.
- sbs_dbg_reset: reset information coming from the RCC, and reset SBS_DBGCR if this register is configured to be reset.

Configuration

- DBG_UNLOCK in SBS_DBGCR: debug unlock when DBG_AUTH_HDPL is reached
- AP_UNLOCK in SBS_DBGCR: access port unlock
- DBG_AUTH_HDPL in SBS_DBGCR: authenticated debug temporal isolation level. Define the HDPL value from which the debug can be opened. Value can only be from 1 to 3.
- DBG_AUTH_SEC in SBS_DBGCR: specify if the debug reopening is for non-secure only or for both (secure and non-secure).
- DBGC_LOCK in SBS_DBGLOCKR: lock the current debug configuration (released only by a reset).

Outputs

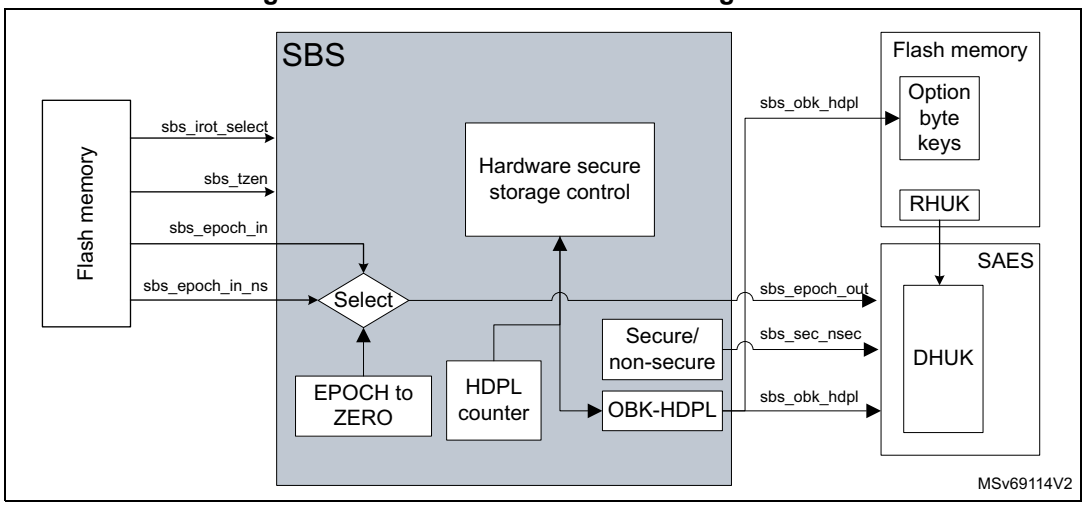
- sbs_ap_unlocked: signal controlling the Cortex-M33 access port
  - 1: 0xB4
  - 0: all other codes
- sbs_dbg_unlocked: unlock the debug (when set to 1) for the Cortex-M33 non-secure.
  - 1: 0xB4
  - 0: all other codes
- sbs_dbg_unlocked_sec: unlock the debug (when set to 1) for the Cortex-M33 secure.
  - 1: 0xB4
  - 0: all other codes

14.3.7 SBS hardware secure storage control

This feature ensures the isolation of keys and data related to ROT (root-of-trust) when re-opening the debug (when product in the field).

This includes a dedicated area called OB-Keys in the flash memory (see *Section 7: Embedded flash memory (FLASH)* for more details), and the key derivation (DHUK) mechanism protecting data using a hardware key different for the identified domains.

Figure 65. SBS hardware secure storage control



- sbs_obk_hdpl: select secure storage context for current HDPL, or greater ones (to allow provisioning). This signal is set thanks to the SBS_NEXTHDPLCR register. This information is used by the flash memory to select the right area, and by the SAES when processing the derived key to generate a key derived related to HDPL context.
- sbs_epoch_out: EPOCH counters are used to manage the REPLAY protection. These counters are incremented when regressions are done. Injecting the EPOCH in the DHUK (in the SAES) ensures that all information encrypted with the DHUK cannot be replayed after a regression.
- sbs_sec_nsec: apply a different protection DHUK for secure and non-secure assets.

All keys encrypted using the SAES/DHUK inherit of the RHUK property: unique per device.

All data encrypted thanks to the SAES using the DHUK are specific to a combination of [sbs_obk_hdpl + sbs_epoch_out + sbs_sec_nsec].

Inputs used to control the hardware secure storage control

sbs_epoch_in and sbs_epoch_in_ns: 24-bit values coming from the flash memory and representing regression counters respectively for secure and non-secure.

Configuration

- NEXTHDPL in SBS_NEXTHDPLCR: access to next HDPL secure storage areas.
- EPOCH_SEL in SBS_EPOCHSELCR: select the EPOCH source related to the secure storage under control (SEC_EPOCH, NS_EPOCH, or FORCED_To_Zero).

Table 120. OBK-HDPL logic

HDPL[7:0] in SBS_HDPLSR	NEXTHDPL[1:0]			
	0x0	0x1	0x2	0x3
0 (0xB4)	0xB4	0x51	0x8A	0x6F

3 (0x6F)	0x6F			
Other				

14.4 SBS interrupts

SBS does not support interrupts.

14.5 SBS registers

14.5.1 SBS temporal isolation control register (SBS_HDPLCR)

Address offset: 0x010

Reset value: 0x0000 00B4

Reset: system reset

Register security: no restriction

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	INCR_HDPL[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **INCR_HDPL[7:0]**: increment HDPL value
0xB4: no increment
0x6A: recommended value to increment HDPL level by one
Other: all other values allow a HDPL level increment.

14.5.2 SBS temporal isolation status register (SBS_HDPLSR)

Address offset: 0x014

Reset value: 0xXXXX XXXX

The reset value depends on boot case: booting with HDPL0 for ST code, or HDPL1 for all other cases. See *Table 119* for more details.

Reset: system reset

Register security: no restriction

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HDPL[7:0]							
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **HDPL[7:0]**: temporal isolation level

This bitfield returns the current temporal isolation level.
0xB4: HDPL0, RSS
0x51: HDPL1, iRoT
0x8A: HDPL2, uRoT
0x6F: HDPL3, application (secure/non-secure)

14.5.3 SBS next HDPL control register (SBS_NEXTHDPLCR)

Address offset: 0x018

Reset value: 0x0000 0000

Reset: system reset

Register security: no restriction

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	NEXTHDPL[1:0]	
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bits 1:0 **NEXTHDPL[1:0]**: index to point to a higher HDPL than the current one

Index to add to the current HDPL to point (through OBK-HDPL) to the next secure storage areas (OBK-HDPL = HDPL + NEXTHDPL). See *Table 120: OBK-HDPL logic* for more details.

14.5.4 SBS debug control register (SBS_DBGCR)

Address offset: 0x020

Reset value: 0x0000 0000

Reset: debug reset (system reset or power-on reset)

Register security: HDPL0/1, RAZ/WI otherwise

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DBG_AUTH_SEC[7:0]								DBG_AUTH_HDPL[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DBG_UNLOCK[7:0]								AP_UNLOCK[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **DBG_AUTH_SEC[7:0]**: control debug opening secure/non-secure
Write 0xB4 to this bitfield to open debug for secure and non-secure.
Writing any other values only open non-secure.

Bits 23:16 **DBG_AUTH_HDPL[7:0]**: authenticated debug temporal isolation level
Writing to this bitfield defines at which HDPL the authenticated debug opens.
0x51: HDPL1
0x8A: HDPL2
0x6F: HDPL3

Note: Writing any other values is ignored. Reading any other value means the debug never opens.

Bits 15:8 **DBG_UNLOCK[7:0]**: debug unlock when DBG_AUTH_HDPL is reached
Write 0xB4 to this bitfield to open the debug when HDPL in SBS_HDPLSR equals to DBG_AUTH_HDPL in this register.

Bits 7:0 **AP_UNLOCK[7:0]**: access port unlock
Write 0xB4 to this bitfield to open the device access port.

14.5.5 SBS debug lock register (SBS_DBGLOCKR)

Address offset: 0x024

Reset value: 0x0000 00B4

Reset: debug reset (system reset or power-on reset)

Register security: HDPL0/1, RAZ/WI otherwise

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DBGCFG_LOCK[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **DBGCFG_LOCK[7:0]**: debug configuration lock
Reading this bitfield returns 0x6A if the bitfield value is different from 0xB4.
0xC3 is the recommended value to lock the debug configuration using this bitfield.
0xB4: Writes to SBS_DBGCR allowed (default)
Other: Writes to SBS_DBGCR ignored

14.5.6 SBS RSS command register (SBS_RSSCMDR)

Address offset: 0x034

Reset value: 0x0000 0000

Reset: power-on reset

Register security: always secure (RAZ/WI if non-secure)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSSCMD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **RSSCMD[15:0]**: RSS command
The application can use this bitfield to pass on a command to the RSS, executed at the next reset.
When RSSCMD ≠ 0 and PRODUCT_STATE is in Open, then the system always boots on RSS whatever is the boot pin value.

14.5.7 SBS EPOCH selection control register (SBS_EPOCHSELCR)

Address offset: 0x0A0

Reset value: 0x0000 0000

Reset: system reset

Register security: Secure when TZ_STATE = 1 (RAZ, WI in non-secure access).
Non-secure protection when TZ_STATE = 0. This register is protected by privileged whatever is TZ_STATE, RAZ/WI if non privileged access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	EPOCH_SEL [1:0]	
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bits 1:0 **EPOCH_SEL[1:0]**: select EPOCH value to be sent to the SAES
00: NS_EPOCH (non-secure) counter input selected
01: SEC_EPOCH counter input selected
1x: EPOCH forced to zero (value used to retrieve PUF reference value at boot time)

14.5.8 SBS security mode configuration control register (SBS_SECCFGR)

Address offset: 0x0C0

Reset value: 0x0000 0000

Reset: system reset

Register security: always secure. RAZ/WI if non-secure transaction and TZ_STATE = 1. RAZ/WI if TZ_STATE = 0.

This register is programmed by secure software if the user wants functions configurable through system registers to be secure or not.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FPUSEC	Res.	CLASSBSEC	SBSSEC
												rw		rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **FPUSEC**: FPU security enable
0: SBS_FPUIMP register accessible through secure or non-secure transaction
1: SBS_FPUIMP register accessible only through secure transaction
Note: This bit can be written only through privilege transaction.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CLASSBSEC**: ClassB security enable
0: SBS_CFGR2 register accessible through secure or non-secure transaction
1: SBS_CFGR2 register accessible only through secure transaction

Bit 0 **SBSSEC**: SBS clock control, memory-erase status register and compensation cell register security enable
0: SBS_MESR, SBS_CCCSR, SBS_CCVALR, SBS_CCSWCR registers accessible through secure or non-secure transaction
1: SBS_MESR, SBS_CCCSR, SBS_CCVALR, SBS_CCSWCR registers accessible only through secure transaction

14.5.9 SBS product mode and configuration register (SBS_PMCR)

Address offset: 0x100

Reset value: 0x0000 0000

Reset: system reset

Register security:

- When TrustZone is activated (TZEN = 0xB4):
  - depending on ADC1_2_SEC_EN secure input for ANASWVDD and IO_ANA_BOOST_EN configuration bits
  - depending on I/O PBx_SEC_EN secure input for PBx_FMP configuration bits
  - depending on Ethernet ETH_SEC_EN secure input for ETH_SEL_PHY configuration bits
  - depending on SDCE_SEC_EN in SBS_SECCFGR for SMPS_DIV_CLOCK_EN
- When TrustZone is disabled (TZEN = 0xC3), there is no access restriction.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:21 **ETH_SEL_PHY[2:0]**: Ethernet PHY interface selection
000: GMII or MII
001: reserved (RGMII)
100: RMII
Other: reserved

Bit 20 Reserved, must be kept at reset value.

Bit 19 **PB9_FMP**: Fast-mode Plus driving capability activation on PB9
This bit can be read and written only with secure access if PB9 is secure in GPIOB. This bit enables the Fm+ driving mode for PB9 when PB9 is not used by I2C peripheral. This can be used to drive a LED for instance.
0: PB9 pin operates in standard mode.
1: Fm+ mode is enabled on PB9 pin and the speed control is bypassed.

Bit 18 **PB8_FMP**: Fast-mode Plus driving capability activation on PB8
This bit can be read and written only with secure access if PB8 is secure in GPIOB. This bit enables the Fm+ driving mode for PB8 when PB8 is not used by I2C peripheral. This can be used to drive a LED for instance.
0: PB8 pin operates in standard mode.
1: Fm+ mode is enabled on PB8 pin and the speed control is bypassed.

Bit 17 **PB7_FMP**: Fast-mode Plus driving capability activation on PB7
This bit can be read and written only with secure access if PB7 is secure in GPIOB. This bit enables the Fm+ driving mode for PB7 when PB7 is not used by I2C peripheral. This can be used to drive a LED for instance.
0: PB7 pin operates in standard mode.
1: Fm+ mode is enabled on PB7 pin and the speed control is bypassed.

Bit 16 **PB6_FMP**: Fast-mode Plus driving capability activation on PB6
This bit can be read and written only with secure access if PB6 is secure in GPIOB. This bit enables the Fm+ driving mode for PB6 when PB6 is not used by I2C peripheral. This can be used to drive a LED for instance.
0: PB6 pin operates in standard mode.
1: Fm+ mode is enabled on PB6 pin and the speed control is bypassed.

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 Reserved, must be kept at reset value.

14.5.10 SBS FPU interrupt mask register (SBS_FPUIMR)

Address offset: 0x104

Reset value: 0x0000 001F

Reset: system reset

Register security: depends on FPUSEC in SBS_SECCFGR

This register is accessible only through privilege transaction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FPU_IE[5:0]					
										rw	rw	rw	rw	rw	rw

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **FPU_IE[5:0]**: FPU interrupt enable
Set and cleared by software to enable the Cortex-M33 FPU interrupts
FPU_IE[5]: inexact interrupt enable (interrupt disabled at reset)
FPU_IE[4]: input abnormal interrupt enable
FPU_IE[3]: overflow interrupt enable
FPU_IE[2]: underflow interrupt enable
FPU_IE[1]: divide-by-zero interrupt enable
FPU_IE[0]: invalid operation interrupt enable

14.5.11 SBS memory erase status register (SBS_MESR)

Address offset: 0x108

Reset value: 0x0000 000X (bit 0 is not affected by system reset)

Register security: depends on SBSSEC in SBS_SECCFGR

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IPMEE
															rc_w1

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MCLR
															rc_w1

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **IPMEE**: ICACHE erase status

This bit is set by hardware when ICACHE and PKA RAMs erase is completed after potential tamper detection or a product state regression (refer to *Section 47: Tamper and backup registers (TAMP)* for more details).

This bit is cleared by software by writing 1 to it.

0: ICACHE and PKA RAM erase on going

1: ICACHE and PKA SRAM erase done

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **MCLR**: device memories erase status

This bit is set by hardware when SRAM2, BKPSRAM, ICACHE, DCACHE and PKA RAMs erase is completed after power-on reset or tamper detection or product state regression (refer to *Section 47: Tamper and backup registers (TAMP)*).

This bit is not reset by system reset and is cleared by software by writing 1 to it.

0: memory erase on going if not yet cleared by software

1: Memory erase done

14.5.12 SBS compensation cell for I/Os control and status register (SBS_CCCSR)

Address offset: 0x110

Reset value: 0x0000 0000

Reset: system reset

Register security: depends on SBSSEC in SBS_SECCFGR

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	RDY2	RDY1	Res.	Res.	Res.	Res.	CS2	EN2	CS1	EN1
						r	r					rw	rw	rw	rw

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **RDY2**: VDDIO2 compensation cell ready flag
This bit provides the status of the VDDIO2 compensation cell.
0: VDDIO2 compensation cell not ready
1: VDDIO2 compensation cell ready (code value provided by the cell can be used)

Bit 8 **RDY1**: VDDIO compensation cell ready flag
This bit provides the status of the compensation cell.
0: VDDIO compensation cell not ready
1: VDDIO compensation cell ready (code value provided by the cell can be used)

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **CS2**: code selection for VDDIO2 power rail (reset value set to 1)
This bit selects the code to be applied for the I/O compensation cell.
0: Code from the cell (available in SBS_CCVR)
1: Code from SBS_CCCR

Bit 2 **EN2**: enable compensation cell for VDDIO2 power rail
This bit enables the I/O compensation cell.
0: I/O compensation cell disabled
1: I/O compensation cell enabled

Bit 1 **CS1**: code selection for VDDIO power rail (reset value set to 1)
This bit selects the code to be applied for the I/O compensation cell.
0: Code from the cell (available in the SBS_CCVR)
1: Code from SBS_CCCR

Bit 0 **EN**1: enable compensation cell for VDDIO power rail
This bit enables the I/O compensation cell.
0: I/O compensation cell disabled
1: I/O compensation cell enabled

14.5.13 SBS compensation cell for I/Os value register (SBS_CCVALR)

Address offset: 0x114

Reset value: 0x0000 0088

Reset: system reset

Register security: depends on SBSSEC in SBS_SECCFGR

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **APSRC2[3:0]**: compensation value for the PMOS transistor
This value is provided by the cell and must be interpreted by the processor to compensate the slew rate in the functional range.

Bits 11:8 **ANSRC2[3:0]**: Compensation value for the NMOS transistor
This value is provided by the cell and must be interpreted by the processor to compensate the slew rate in the functional range.

Bits 7:4 **APSRC1[3:0]**: compensation value for the PMOS transistor
This value is provided by the cell and must be interpreted by the processor to compensate the slew rate in the functional range.

Bits 3:0 **ANSRC1[3:0]**: compensation value for the NMOS transistor
This value is provided by the cell and must be interpreted by the processor to compensate the slew rate in the functional range.

14.5.14 SBS compensation cell for I/Os software code register (SBS_CCSWCR)

Address offset: 0x118

Reset value: 0x0000 7878

Reset: system reset

Register security: depends on SBSSEC in SBS_SECCFGR

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **SW_APSRC2[3:0]**: PMOS compensation code for the V_{DDIO} power rails
This bitfield is written by software to define an I/O compensation cell code for PMOS transistors of the VDDIO power rail. This code is applied to the I/O when CS2 is set in SBS_CCSR.

Bits 11:8 **SW_ANSRC2[3:0]**: NMOS compensation code for VDDIO power rails
This bitfield is written by software to define an I/O compensation cell code for NMOS transistors of the VDD power rail. This code is applied to the I/O when CS2 is set in SBS_CCSR.

Bits 7:4 **SW_APSRC1[3:0]**: PMOS compensation code for the VDD power rails
This bitfield is written by software to define an I/O compensation cell code for PMOS transistors of the VDDIO power rail. This code is applied to the I/O when CS1 is set in SBS_CCSR.

Bits 3:0 **SW_ANSRC1[3:0]**: NMOS compensation code for VDD power rails
This bitfield is written by software to define an I/O compensation cell code for NMOS transistors of the VDD power rail. This code is applied to the I/O when CS1 is set in SBS_CCSR.

14.5.15 SBS Class B register (SBS_CFGR2)

Address offset: 0x120

Reset value: 0x0000 0000

Reset: system reset

Register security: depends on CLASSBSEC in SBS_SECCFGR

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ECCL	PVDL	SEL	CLL
												rs	rs	rs	rs

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **ECCL**: ECC lock

This bit is set and cleared by software. It can be used to enable and lock the flash memory double ECC error with break input of TIM1/8/15/6/17.

0: double ECC error flag disconnected to timer break inputs

1: double ECC error flag connected to timer break inputs

Bit 2 **PVDL**: PVD lock

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the PVD connection with TIM1/8/15/16/17 break inputs.

0: PVD interrupt disconnected from timer break inputs. PVD_EN and PVD_SEL[2:0] in the PWR registers are read/write.

1: PVD interrupt is connected to timer break inputs. PVD_EN and PVD_SEL[2:0] in the PWR registers are read only

Bit 1 **SEL**: SRAM ECC error lock

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the SRAM double ECC error signal with break input of TIM1/8/15/16/17.

0: SRAM double ECC error flag disconnected from timer break inputs

1: SRAM double ECC error flag connected to timer break inputs

Bit 0 **CLL**: core lockup lock

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the lockup (HardFault) output of Cortex-M33 with TIM1/8/15/16/17 break inputs.

0: lockup output disconnected from timer break inputs

1: lockup output connected to timer break inputs

14.5.16 SBS CPU non-secure lock register (SBS_CNSLCKR)

Address offset: 0x144

Reset value: 0x0000 0000

Reset: system reset

Register security: This register can be read and written by privileged access only. Unprivileged access is RAZ/WI.

This register is used to lock the configuration of non-secure MPU and VTOR_NS registers of the Cortex-M33.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LOCKNSMPU	LOCKNSVTOR
														rs	rs

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **LOCKNSMPU**: non-secure MPU register lock

This bit is set by software and cleared only by a system reset. When set, this bit disables write access to non-secure MPU_CTRL_NS, MPU_RNR_NS and MPU_RBAR_NS registers.

0: non-secure MPU registers write enabled

1: non-secure MPU registers write disabled

Bit 0 **LOCKNSVTOR**: VTOR_NS register lock

This bit is set by software and cleared only by a system reset.

0: VTOR_NS register write enabled

1: VTOR_NS register write disabled

14.5.17 SBS CPU secure lock register (SBS_CSLCKR)

Address offset: 0x148

Reset value: 0x0000 0000

Reset: system reset

Register security: This register can be written only when the access is secure/privilege.

A non-secure read/write access is RAZ/WI and generates an illegal access event. When the system is not secure (TZ_STATE = 0), this register is RAZ/WI.

This register is used to lock the configuration of PRIS and BFHFNMINS in the AIRCR, SAU, secure MPU and VTOR_S registers of the Cortex-M33.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LOCKSAU	LOCKSMPU	LOCKSVTAIRCR
													rs	rs	rs

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **LOCKSAU**: SAU registers lock

This bit is set by software and cleared only by a system reset. When set, this bit disables write access to SAU_CTRL, SAU_RNR, SAU_RBAR and SAU_RLAR registers.

0: SAU registers write enabled

1: SAU registers write disabled

Bit 1 **LOCKSMPU**: secure MPU registers lock

This bit is set by software and cleared only by a system reset. When set, this bit disables write access to secure MPU_CTRL, MPU_RNR and MPU_RBAR registers.

0: Secure MPU registers writes enabled

1: Secure MPU registers writes disabled

Bit 0 **LOCKSVTAIRCR**: VTOR_S and AIRCR register lock

This bit is set by software and cleared only by a system reset. When set, this bit disables write access to VTOR_S register, PRIS and BFHFNMINS bits in the AIRCR register.

0: VTOR_S register PRIS and BFHFNMINS bits in the AIRCR register write enabled

1: VTOR_S register PRIS and BFHFNMINS bits in the AIRCR register write disabled

14.5.18 SBS flift ECC NMI mask register (SBS_ECCNMIR)

Address offset: 0x14C

Reset value: 0x0000 0000

Reset: system reset

Register security: secure access only when TZ_STATE = 1 (RAZ/WI in non-secure access). No security protection if TZ_STATE = 0.

This register is accessible only through privilege transaction.

This register sets up the expected behavior on NMI regarding double ECC errors from the flash memory.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **ECCNMI_MASK_EN**: NMI behavior setup when a double ECC error occurs on flitf data part
0: NMI generated if a double ECC error in the flitf data part
1: NMI not generated if a double ECC error in the flitf data part

14.5.19 SBS register map

15 Peripherals interconnect matrix

15.1 Interconnect matrix introduction

Several peripherals have direct connections between them, enabling autonomous communication and/or synchronization: this approach saves CPU resources, and power supply consumption. In addition, these hardware connections remove software latency and help the design of predictable system.

Depending on peripherals, these interconnections can operate in Run, Sleep, and Stop modes.

15.2 Connection summary

Table 122. Peripherals interconnect matrix(1) (2)

1. Numbers in this table are links to corresponding subsections of *Section 15.3*.
2. "-" means no interconnect.

15.3 Interconnection details

15.3.1 Master to slave interconnection for timers

From timer (TIM1/2/3/4/5/8/12/13/14/15/16/17) to timer (TIM1/2/3/4/5/8/12/15).

Purpose

Some timers are linked together internally for synchronization or chaining.

When one timer is configured in master mode, it can reset, start, stop, or clock the counter of another timer configured in slave mode.

A description of the feature is provided in *Section 39.4.23: Timer synchronization*.

The synchronization modes are detailed in:

- *Section 38.3.30* for advanced-control timers TIM1/8
- *Section 39.4.22* for general-purpose timers TIM2/3/4/5
- *Section 41* for the general-purpose timers TIM12/13/14
- *Section 42.4.23* for the general-purpose timer TIM15

Triggering signals

The output (from master) is on signal TIMx_TRGO (and TIMx_TRGO2 for TIM1/8) following a configurable timer event. It can be also from signals tim16_oc1 and tim17_oc1 in case of TIM16/17. The input (to slave) is on signals TIMx_ITR0/1/2/3.

The possible master/slave connections are given in:

- *Table 381* for advanced-control timers TIM1/8
- *Table 404* for general-purpose timers TIM2/3/4/5
- *Table 425* for the general-purpose timers TIM12/13/14
- *Table 437* for the general-purpose timer TIM15

Active power mode

Timers are optionally active in Run and Sleep modes. The effects of low-power modes on TIMx are given in:

- *Table 393: Effect of low-power modes on TIM1/TIM8*
- *Table 411: Effect of low-power modes on TIM2/TIM3/TIM4/TIM5*
- *Table 427: Effect of low-power modes on TIM12/TIM13/TIM14*
- *Table 443: Effect of low-power modes on TIM15/TIM16/TIM17*

15.3.2 Triggers to ADCs

From EXTI, timers (TIM1/2/3/4/6/8/15) and LP timers (LPTIM1/2) to ADC1/ADC2.

Purpose

A conversion (or a sequence of conversions) can be triggered either by software or by an external event (such as timer capture or input pins). For ADC12, if the EXTEN[1:0] (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from 0b00, external events can trigger a conversion with the selected polarity.

More details in:

- *Section 26.4.18: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN,JEXTSEL, JEXTEN)*
- EXTEN[1:0] defined in *ADC configuration register (ADC_CFGR)*
- JEXTEN[1:0] defined in *ADC injected sequence register (ADC_JSQR)*

General-purpose timers (TIM2/3/4), basic timer (TIM6), advanced-control timers (TIM1/8), and general-purpose timer (TIM15) can be used to generate the ADC triggering event through the timer outputs tim_oc and tim_trgo.

Low-power timers (LPTIM1/2) can be used to generate the ADC triggering event through the LPTIM channels, in addition to the EXTI on channels 11 and 15.

Triggering signals

For ADC1/ADC2, the input triggering signals and the description of the interconnection between ADC1/ADC2 and timers are given in:

- adc_ext_trg: *Table 242: ADC interconnection*
- adc_jext_trg: *Table 242: ADC interconnection*
- *Section 26.4.18: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN,JEXTSEL, JEXTEN)*
- *Section 26.4.25: Timing diagrams example (single/continuous modes, hardware/software triggers)*

Active power mode

This interconnection is active in Run and Sleep modes for all ADCs. The timers are active only in Run and Sleep modes. The effects of low-power modes are given in:

- *Table 393: Effect of low-power modes on TIM1/TIM8*
- *Table 411: Effect of low-power modes on TIM2/TIM3/TIM4/TIM5*
- *Table 443: Effect of low-power modes on TIM15/TIM16/TIM17*
- *Table 449: STM32H563/H573 and STM32H562 LPTIM features*
- *Table 464: Effect of low-power modes on the LPTIM*

15.3.3 ADC analog watchdogs as triggers to timers

From ADC1/ADC2 to TIM1/8.

Purpose

The internal analog watchdog output signals coming from ADC1/ADC2 are connected to on-chip timers. ADC1/ADC2 can provide trigger events through analog watchdog signals to advanced-control timers (TIM1/8) to reset, start, stop, or clock the counter.

Settings description of the ADC analog watchdog and timer trigger, are provided in:

- *Section 38.3.6: External trigger input* for TIM1/8
- *Table 382* for the internal ADC1/ADC2 sources connected to TIM1/8 (tim_etr) input multiplexer
- *Section 26.4.28* for the ADC1/ADC2/ADC_AWDy_OUT signal output generation

Triggering signals

The output (from ADC) is on signals ADCn_AWDx_OUT, with n being the ADC instance and x = 1, 2, 3 (three watchdogs per ADC). The input (to timer) is on signal TIMx_ETR (external trigger).

Active power mode

ADC1/ADC2 are active in Run and Sleep modes.

15.3.4 Triggers to DAC

From timer (TIM1/2/4/5/6/7/8/15), low-power timers (LPTIM1/2), and EXTI to DAC.

Purpose

General-purpose timers (TIM2/4/5/15), basic timers (TIM6/7), advanced-control timers (TIM1/8), LP timers (LPTIM1/2) outputs channels (lptim1_ch1 and lptim2_ch1), and EXTI can be used as triggering event to start a DAC conversion.

Triggering signals

The output (from timer) on the TIMx_TRGO signal and from LP timers are directly connected to corresponding DAC inputs.

The selection of input triggers on DAC is provided in:

- *Table 266: DAC interconnection*
- *Section 28.4.8: DAC trigger selection*

Active power mode

This interconnect is active in Run, Sleep, and Stop modes.

15.3.5 Clock sources to timers

From HSE, LSE, LSI, HSI, and MCO to timers (TIM2/12/15/16/17) and LP timers (LPTIM1/2).

Purpose

A timer input or counter can receive different clock sources, and can be used, for example, to calibrate the internal oscillator on a reference clock.

External clocks (HSE, LSE), internal clocks (LSI, CSI, HSI), and microcontroller output clock (MCO) can be used as input to timers:

- LSE, HSI, and CSI are assigned to general purpose timer TIM2 as external inputs signals. LSE can be selected as counter clock provided by an external clock source in mode1 (tim_ti1_in) and mode2 (external trigger input tim_etr_in). Inputs assignment and clock selection description are detailed in:
  - *Section 39.4.5: Clock selection* for TIM2
  - External clock mode1: *Table 423: Interconnect to the tim_ti1 input multiplexer* for TIM12, tim_ti1_in4 (HSI), and tim_ti1_in5 (CSI)
  - External clock mode2: *Table 405: Interconnect to the tim_etr input multiplexer* for tim_etr3 (LSE)

- LSE, LSI, CSI, and HSE are assigned to general purpose timers TIM15/16/17 as external inputs signals. LSE/LSI/CSI/HSE can be selected as counter clock provided by an external clock source in mode1 (tim_ti1 or tim_ti2 signals). Inputs assignment and clock selection description are detailed in:
  - *Section 42.4.6: Clock selection* for TIM15/16/17. External clock mode1: external input pin (tim_ti1 or tim_ti2, if available)
  - *Table 423: Interconnect to the tim_ti1 input multiplexer*, tim_ti1_in1 (LSI-TIM16), tim_ti1_in2 (LSE-TIM16/HSE-TIM17), tim_ti1_in4 (LSE- TIM15), and tim_ti1_in5 (CSI-TIM15)
- Microcontroller output clock (MCO): MCO1 is connected as external input to general-purpose timer TIM17, MCO2 is connected as external input to general-purpose timer TIM15.
  - *Table 435: Interconnect to the tim_ti1 input multiplexer* for TIM15/TIM16/TIM17
- LSI and LSE can be selected as input capture 2 to LPTIM1 as described in *Table 458: LPTIM1 input capture 2 connection*.
- HSI/1024, CSI/128, and HSI/8 can be selected as input capture 2 to LPTIM2 as described in *Table 459: LPTIM2 input capture 2 connection*.

Triggering signals

lptim_ic2_mux1 LPTIM input capture selection can be set in the LPTIM configuration register 2 (LPTIM_CFGR2). For timers, the internal clock signal can be selected as counter clock provided by an external clock source in mode1 (tim_ti1_in) and mode2 (external trigger input tim_etr_in).

Active power mode

This feature is available under Run and Sleep modes.

15.3.6 Triggers to low-power timers

From EXTI, TAMP, and RTC alarm to LP timers (LPTIM1/2/3/4/5/6).

Purpose

LPTIM1/2/3/4/5/6 counters can be started either by software, or after the detection of an active edge on one of the eight trigger inputs (see *Section 43.4.7: Trigger multiplexer*).

GPIO can also be selected as LPTIM input capture selection or LPTIM input selection, according to the LPTIM configuration register 2 (LPTIM_CFGR2).

Triggering signals

This trigger feature is described in *Section 43.4.7: Trigger multiplexer* and the following sections. The input selection is described in *Table 454: LPTIM1/2/3/4/5/6 external trigger connection*.

Active power mode

This interconnection is active in Run, Sleep, and Stop modes.

15.3.7 RTC wake-up as inputs to timers

From RTC to timer (TIM16).

Purpose

RTC wake-up interrupt can be used as input to general-purpose timer (TIM16) channel 1.

Triggering signals

RTC wake-up signal is connected to tim_ti1_in3 signal as described in *Table 435: Interconnect to the tim_ti1 input multiplexer* for TIM16.

Active power mode

This interconnection is active down to Stop mode. Timers are not active but the count is performed at wake-up.

15.3.8 System errors as break signals to timers

From system errors to timers (TIM1/8/15/16/17).

Purpose

CSS, CPU lockup, SRAM2/3 ECC double errors, SRAM1 parity errors, FLASH ECC double-error detection, and PVD can generate system errors in the form of timer break toward timers (TIM1/8/15/16/17).

The purpose of the break function is to protect power switches driven by PWM signals generated by the timers.

Triggering signals

The possible sources of break are described in:

- *Section 38.3.18: Using the break function* for TIM1/8
- *Section 42.4.15: Using the break function* for TIM15/16/17
- *Table 385: System break interconnect* for TIM1/8
- *Table 439: System break interconnect* for TIM15/16/17

Active power mode

Timers are optionally active in Run and Sleep modes. The effects of low-power modes on TIMx are given in:

- *Table 393: Effect of low-power modes on TIM1/TIM8*
- *Table 411: Effect of low-power modes on TIM2/TIM3/TIM4/TIM5*
- *Table 443: Effect of low-power modes on TIM15/TIM16/TIM17*

15.3.9 Triggers for communication peripherals

From Ethernet to timers (TIM2/TIM3).

Purpose

To synchronize system clock with network, internal connections are available between timers and PTP to check for clock drifts.

Triggering signals

- The outputs (from timer) are directly connected to Ethernet PTP triggers inputs. More details are given in the sections below:
- *Section 57.3: Ethernet pins and internal signals*
- *Table 400: Interconnect to the tim_ti1 input multiplexer*
- *Table 405: Interconnect to the tim_etr input multiplexer*

Active power mode

These interconnections remain active in Run and Sleep modes.

15.3.10 Triggers to GPDMA1/2

From EXTI, RTC (alarm/wake-up), TAMP, timers (TIM2/12/15), LP timers (LPTIM1/2/3/4/5/6), GPDMA1 transfer complete (gpdma1_chx_tc, gpdma2_chx_tcf) to GPDMA1/2.

Purpose

A GPDMA trigger can be assigned to GPDMA channel x. A programmed GPDMA transfer can be triggered by a rising/falling edge of a selected input trigger event. The trigger mode can also be programmed to condition the LLI link transfer. More details are given in the sections below:

- *Section 16.3.7: GPDMA triggers*
- *Section 16.4.12: GPDMA triggered transfer*
- *GPDMA channel x transfer register 2 (GPDMA_CxTR2)* for more details on:
  - Trigger selection TRIGSEL[5:0] field
  - Trigger mode (LLI) defined by TRIGM[1:0]
  - Trigger polarity as defined by TRIGPOL[1:0]

Triggering signals

GPDMA trigger mapping is specified in *Table 129: Programmed GPDMA1/2 trigger*, according to GPDMA_CxTR2.TRIGSEL[5:0].

Active power mode

This interconnection remains functional in Sleep mode.

Refer to:

- *Section 16.6: GPDMA in low-power modes*

15.3.11 Internal analog signals to analog peripherals

From internal analog source to ADC (ADC1/2).

Purpose

The internal reference voltage (V_{REFINT}), the internal temperature sensor (V_{SENSE}), the internal digital core voltage (V_{DDCORE}), and the V_{BAT} monitoring channel are connected to ADC (ADC1/2) input channels.

This is according to:

- *Section 26.2: ADC main features*
- *Section 26.4.11: Channel selection (SQRx, JSQRx)*

15.3.12 Clock source for the DAC sample and hold mode

From LSI/LSE to DAC1.

Purpose

DAC1 can run in Stop mode. The sample and hold block and its associated registers use the LSI or LSE clock source (dac_hold_ck) in Stop mode.

Table 265: DAC internal input/output signals: dac_hold_ck, Input, DAC low-power clock used in sample and hold mode

Active power mode

This feature remains available in Run, Sleep and Stop modes.

15.3.13 Internal tamper sources

From internal peripherals, clocks, or monitoring, to tamper.

Purpose

To detect any abnormal activity or tentative to corrupt the device, embedded tampers alert the system of undesired events. Different actions can be taken as consequence.

The list of tamper sources can be found in *Table 489: TAMP interconnection*.

Active power mode

This interconnection is active in all power modes if the tamper source is activated.

15.3.14 Output from tamper to RTC

From TAMP to RTC.

Purpose

The RTC can timestamp a tamper event to retrieve history of the detection. The RTC can also control GPIOs, and set a signal based on tamp or alarm status outside the MCU.

Refer to section *Section 46.3.3: GPIOs controlled by the RTC and TAMP* for more details.

Active power mode

This interconnection remains active in all power modes.

15.3.15 Encryption keys to AES/SAES

From TAMP backup registers, system flash memory to and in between SAES and AES.

Purpose

The encryption mechanism requires an hardware key that must be stored in a protected non-volatile memory. Different approaches are implemented to load them in a non-readable way. Tamper backup registers or system flash memory can be used to store respectively BHK or RHUK, and to implement a dedicated bus to pass it to the SAES.

Refer to *Section 34.4.14: SAES operation with wrapped keys* for more details.

The AES encryption mechanism (faster than the SAES) can benefit from the sharing key of the SAES. Refer to *Section 34.4.15: SAES operation with shared keys* for more details.

Active power mode

AES and SAES are operating under Run and Sleep modes.

16 General purpose direct memory access controller (GPDMA)

16.1 GPDMA introduction

The general purpose direct memory access (GPDMA) controller is a bus master and system peripheral.

The GPDMA is used to perform programmable data transfers between memory-mapped peripherals and/or memories via linked-lists, upon the control of an off-loaded CPU.

16.2 GPDMA main features

- Dual bidirectional AHB master
- Memory-mapped data transfers from a source to a destination:
  - Peripheral-to-memory
  - Memory-to-peripheral
  - Memory-to-memory
  - Peripheral-to-peripheral
- Autonomous data transfers during low-power modes (see *Section 16.3.3*)

  Transfer arbitration based on a 4-grade programmed priority at channel level:
  - One high-priority traffic class, for time-sensitive channels (queue 3)
  - Three low-priority traffic classes, with a weighted round-robin allocation for non time-sensitive channels (queues 0, 1, 2)
- Per channel event generation, on any of the following events: transfer complete, half transfer complete, data transfer error, user setting error, link transfer error, completed suspension, and trigger overrun
- Per channel interrupt generation, with separately programmed interrupt enable per event
- 8 concurrent GPDMA channels:
  - Per channel FIFO for queuing source and destination transfers (see *Section 16.3.2*)
  - Intra-channel GPDMA transfers chaining via programmable linked-list into memory, supporting two execution modes: run-to-completion and link step mode
  - Intra-channel and inter-channel GPDMA transfers chaining via programmable GPDMA input triggers connection to GPDMA task completion events
- Per linked-list item within a channel:
  - Separately programmed source and destination transfers
  - Programmable data handling between source and destination: byte-based reordering, packing or unpacking, padding or truncation, sign extension and left/right realignment
  - Programmable number of data bytes to be transferred from the source, defining the block level

  - Linear source and destination addressing: either fixed or contiguously incremented addressing, programmed at a block level, between successive burst transfers
  - 2D source and destination addressing: programmable signed address offsets between successive burst transfers (non-contiguous addressing within a block, combined with programmable signed address offsets between successive blocks, at a second 2D/repeated block level, for a reduced set of channels (see *Section 16.3.2*)
  - Support for scatter-gather (multi-buffer transfers), data interleaving and deinterleaving via 2D addressing
  - Programmable GPDMA request and trigger selection
  - Programmable GPDMA half transfer and transfer complete events generation
  - Pointer to the next linked-list item and its data structure in memory, with automatic update of the GPDMA linked-list control registers
- Debug:
  - Channel suspend and resume support
  - Channel status reporting, including FIFO level, and event flags
- TrustZone support:
  - Support for secure and nonsecure GPDMA transfers, independently at a first channel level, and independently at a source/destination and link sublevels
  - Secure and nonsecure interrupts reporting, resulting from any of the respectively secure and nonsecure channels
  - TrustZone-aware AHB slave port, protecting any GPDMA secure resource (register, register field) from a nonsecure access
- Privileged/unprivileged support:
  - Support for privileged and unprivileged GPDMA transfers, independently at a channel level
  - Privileged-aware AHB slave port

16.3 GPDMA implementation

16.3.1 GPDMA instances

There are two instances of the GPDMA in the devices, named as GPDMA1 and GPDMA2.

Each GPDMA instance has the same channel-based implementation and is connected to the same requests and triggers, as detailed in the following sub-sections.

16.3.2 GPDMA channels

A given GPDMA channel x is implemented with the following features and intended usage. To make the best use of the GPDMA performances, the table below lists some general recommendations, allowing the user to select and allocate a channel, given its implemented FIFO size and the requested GPDMA transfer.

Table 123. GPDMA1/2 channel implementation

Channel x	Hardware parameters		Features
	dma_fifo_size[x]	dma_addressing[x]	
x = 0 to 3	2	0	Channel x (x = 0 to 3) is implemented with: – a FIFO of 8 bytes, 2 words – fixed/contiguously incremented addressing These channels must be typically allocated for GPDMA transfers between an APB or AHB peripheral, and SRAM.
x = 4, 5	4	0	Channel x (x = 4, 5) is implemented with: – a FIFO of 32 bytes, 8 words – fixed/contiguously incremented addressing These channels may be used for GPDMA transfers between a demanding AHB peripheral and SRAM, or for transfers from/to external memories.
x = 6, 7	4	1	Channel x (x = 6, 7) is implemented with: – a FIFO of 32 bytes, 8 words – 2D addressing These channels may be used for GPDMA transfers between a demanding AHB peripheral and SRAM, or for transfers from/to external memories.

16.3.3 GPDMA autonomous mode in low-power modes

The GPDMA autonomous mode and wake-up feature are implemented in the device low-power modes as per the table below.

Table 124. GPDMA1/2 autonomous mode and wakeup in low-power modes

Feature	Low-power modes
Autonomous mode and wake-up	GPDMA1/2 in Sleep mode

16.3.4 GPDMA requests

A GPDMA request from a peripheral can be assigned to a GPDMA channel x, via REQSEL[7:0] in GPDMA_CxTR2, provided that SWREQ = 0.

The GPDMA requests mapping is specified in the table below.

135	lptim6_ue_dma

1. Depends on which exclusive function is used.

16.3.5 GPDMA block requests

Some GPDMA requests must be programmed as a block request, and not as a burst request. Then BREQ in GPDMA_CxTR2 must be set for a correct GPDMA execution of the requested peripheral transfer at the hardware level.

Table 126. Programmed GPDMA1/2 request as a block request

lptim6_ue_dma

16.3.6 GPDMA channels with peripheral early termination

A GPDMA channel, if implemented with this feature, can support the early termination of the data transfer from the peripheral which does also support this feature.

Table 127. GPDMA1/2 channel with peripheral early termination

GPDMA channel x with peripheral early termination
x = 0 and x = 7

This GPDMA support is activated when the channel x is programmed with GPDMA_CxTR2.PFREQ = 1. Then, the peripheral itself can initiate and request a data transfer completion, before that the GPDMA has transferred the whole block (see *Section 16.4.14* for more details).

Table 128. Programmed GPDMA1/2 request with peripheral early termination

i3c1_rx_dma

16.3.7 GPDMA triggers

A GPDMA trigger can be assigned to a GPDMA channel x, via TRIGSEL[5:0] in GPDMA_CxTR2, provided that TRIGPOL[1:0] defines a rising or a falling edge of the selected trigger (TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).

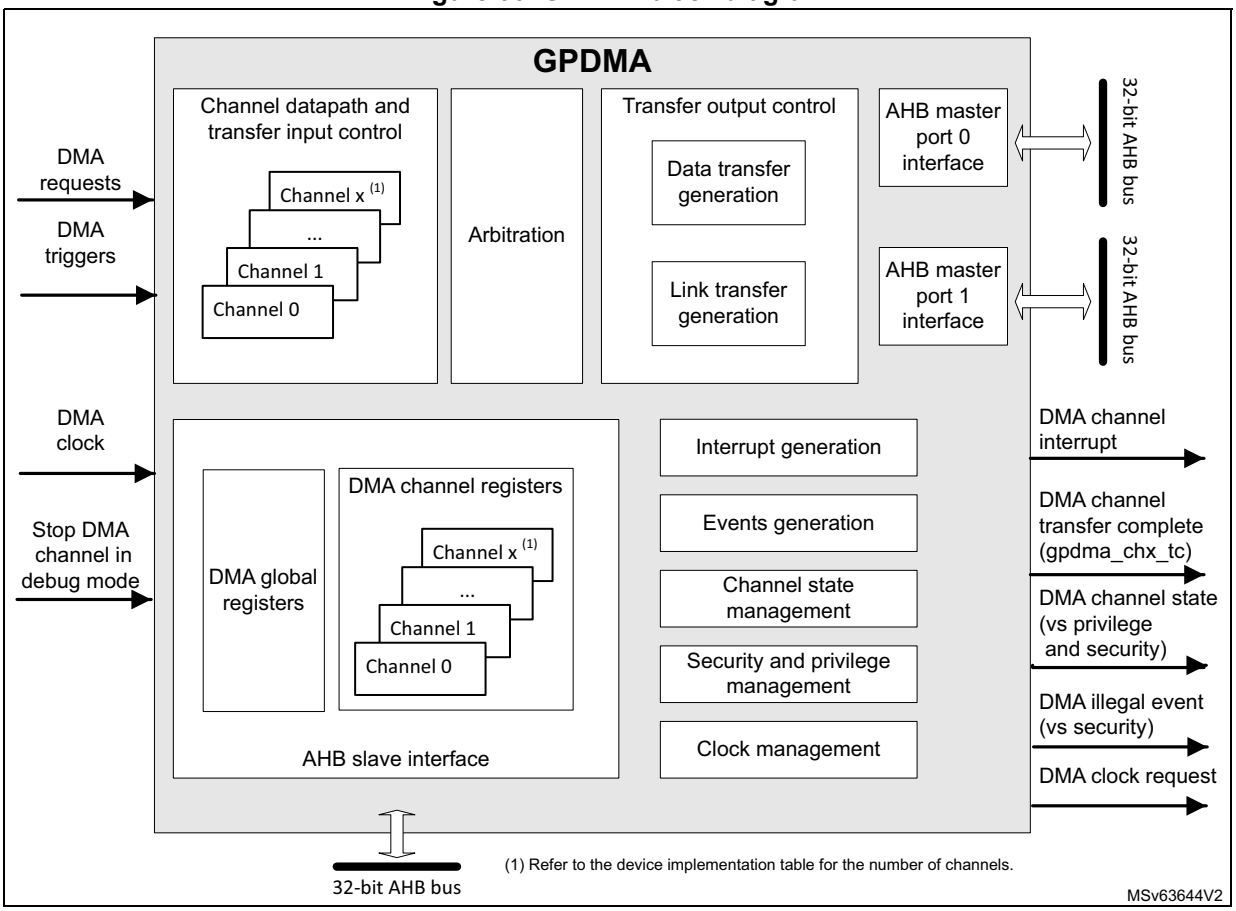
16.4 GPDMA functional description

16.4.1 GPDMA block diagram

Figure 66. GPDMA block diagram



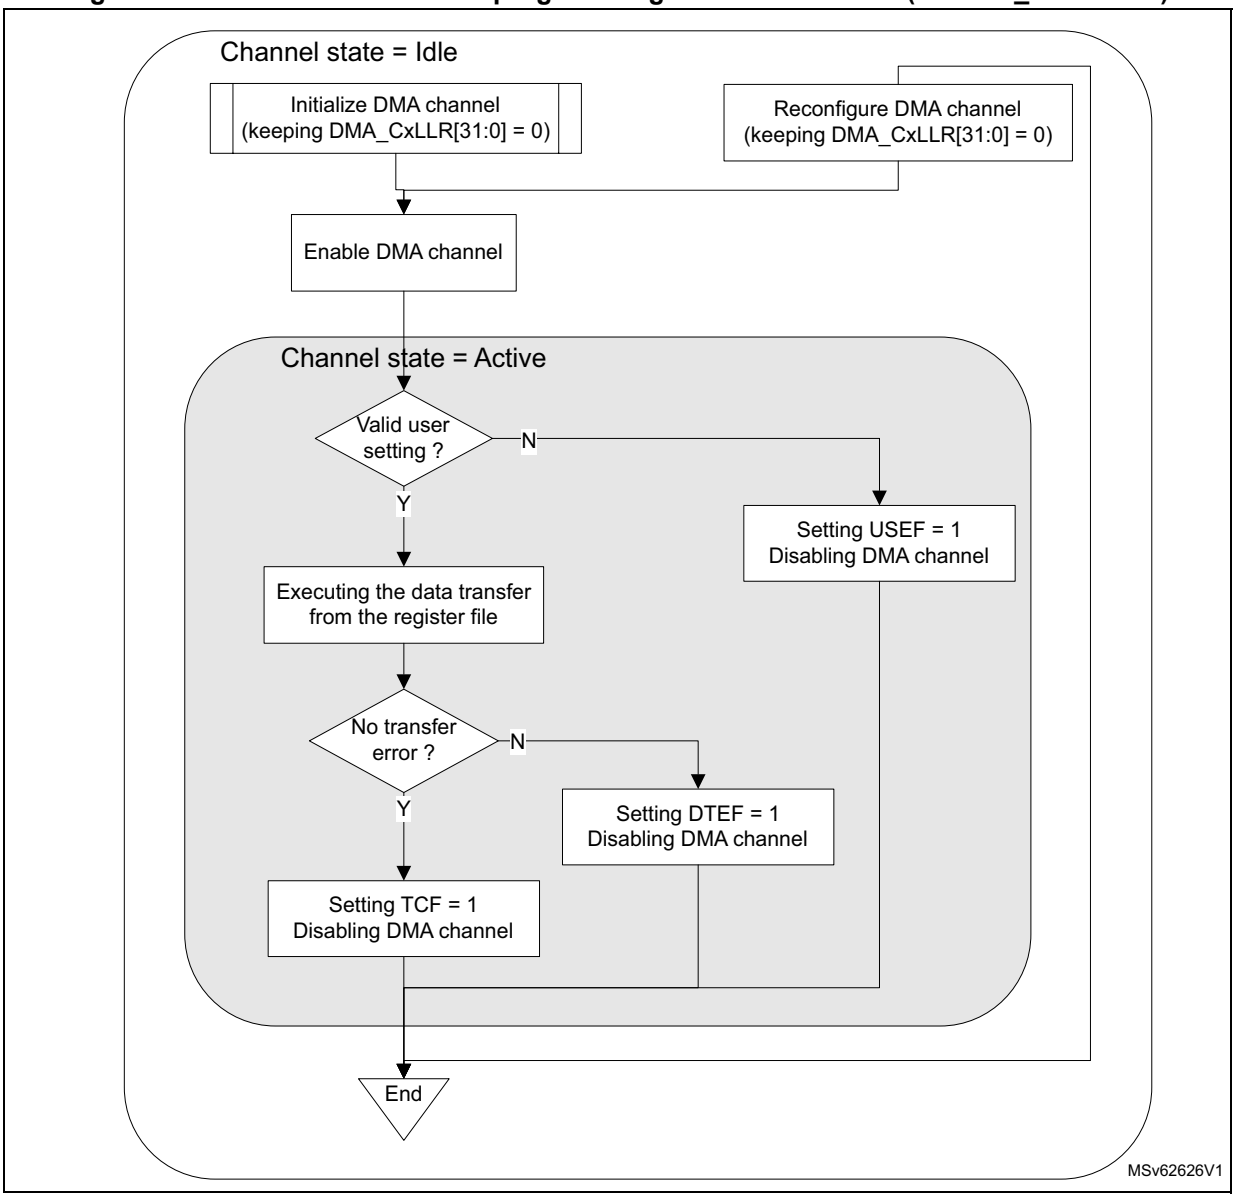
16.4.2 GPDMA channel state and direct programming without any linked-list

After a GPDMA reset, a GPDMA channel x is in idle state. When the software writes 1 in GPDMA_CxCR.EN, the channel takes into account the value of the different channel configuration registers (GPDMA_CxXXX), switches to the active/non-idle state and starts to execute the corresponding requested data transfers.

After enabling/starting a GPDMA channel transfer by writing 1 in GPDMA_CxCR.EN, a GPDMA channel interrupt on a complete transfer notifies the software that the GPDMA channel is back in idle state (EN is then deasserted by hardware) and that the channel is ready to be reconfigured then enabled again.

The figure below illustrates this GPDMA direct programming without any linked-list (GPDMA_CxLLR = 0).

Figure 67. GPDMA channel direct programming without linked-list (GPDMA_CxLLR = 0)



16.4.3 GPDMA channel suspend and resume

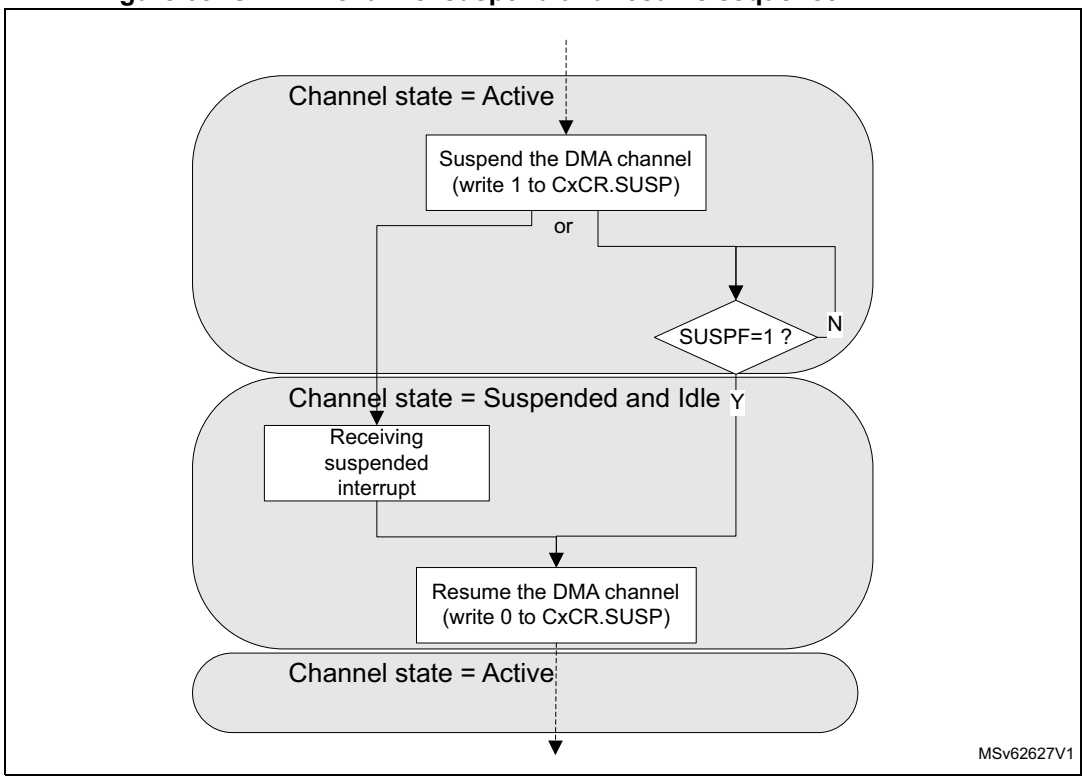
The software can suspend on its own a channel still active, with the following sequence:

1. The software writes 1 into the GPDMA_CxCR.SUSP bit.

2. The software polls the suspended flag GPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to GPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing GPDMA transfer over its master ports. Then the software can observe, in a steady state, any read register or register field that is hardware modifiable.

   Note that an ongoing GPDMA transfer can be a data transfer (a source/destination burst transfer) or a link transfer for the internal update of the linked-list register file from the next linked-list item.
3. The software safely resumes the suspended channel by writing 0 to GPDMA_CxCR.SUSP.

Figure 68. GPDMA channel suspend and resume sequence



Note: A suspend and resume sequence does not impact the GPDMA_CxCR.EN bit. Suspending a channel (transfer) does not suspend a started trigger detection.

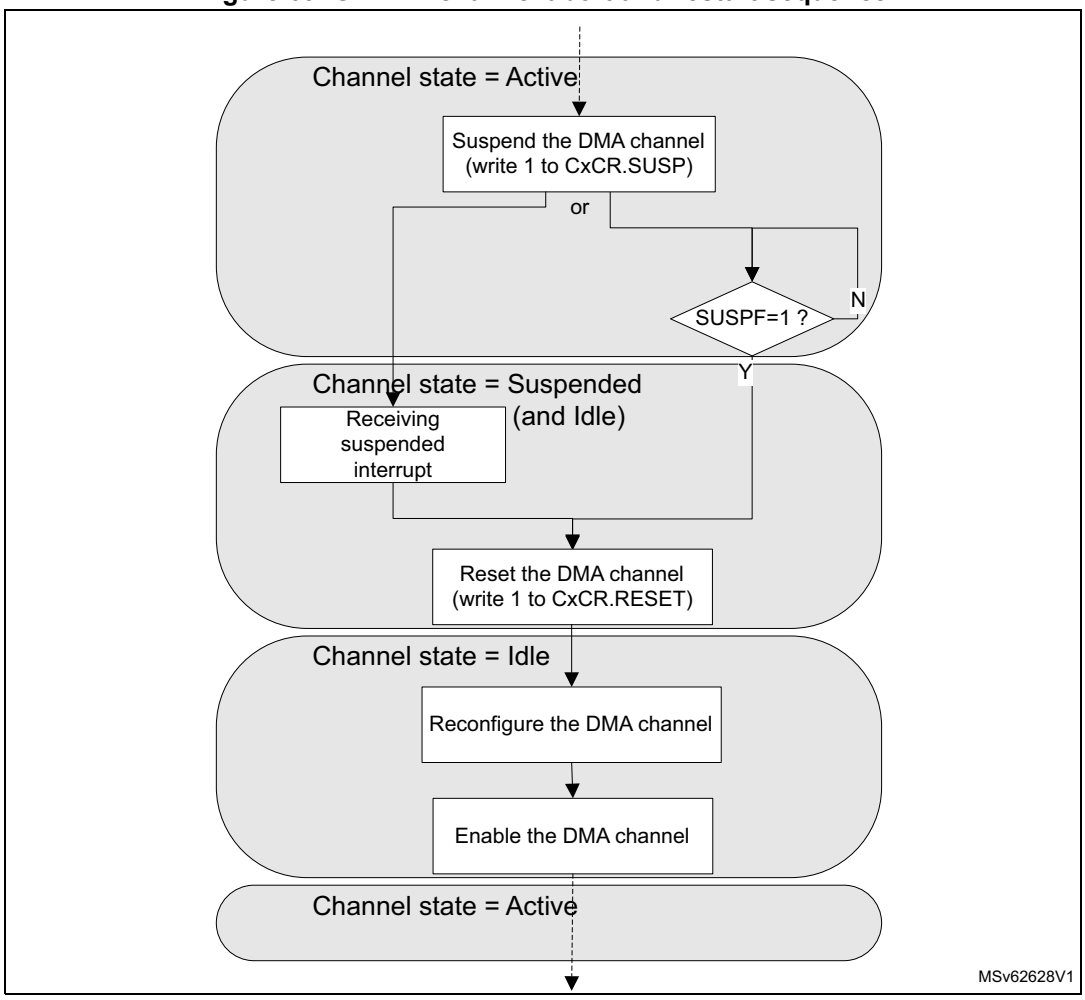
16.4.4 GPDMA channel abort and restart

Alternatively, like for aborting a continuous GPDMA transfer with a circular buffering or a double buffering, the software can abort, on its own, a still active channel with the following sequence:

1. The software writes 1 into the GPDMA_CxCR.SUSP bit.
2. The software polls suspended flag GPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to GPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing GPDMA transfer over its master port.

3. The software resets the channel by writing 1 to GPDMA_CxCR.RESET. This causes the reset of the FIFO, the reset of the channel internal state, the reset of the GPDMA_CxCR.EN bit, and the reset of the GPDMA_CxCR.SUSP bit.
4. The software safely reconfigures the channel. The software must reprogram the hardware-modified GPDMA_CxBR1, GPDMA_CxSAR, and GPDMA_CxDAR registers.
5. In order to restart the aborted then reprogrammed channel, the software enables it again by writing 1 to the GPDMA_CxCR.EN bit.

Figure 69. GPDMA channel abort and restart sequence



16.4.5 GPDMA linked-list data structure

Alternatively to the direct programming mode, a channel can be programmed by a list of transfers, known as a list of linked-list items (LLI). Each LLI is defined by its data structure.

The base address in memory of the data structure of a next LLI_{n+1} of a channel x is the sum of the following:

- the link base address of the channel x (in GPDMA_CxLBAR)
- the link address offset (LA[15:2] field in GPDMA_CxLLR). The linked-list register GPDMA_CxLLR is the updated result from the data structure of the previous LLIn of the channel x.

The data structure for each LLI may be specific.

A linked-list data structure is addressed following the value of the UT1, UT2, UB1, USA, UDA and ULL bits, plus UB2 and UT3, in GPDMA_CxLLR.

In linked-list mode, each GPDMA linked-list register (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR or GPDMA_CxLLR, plus GPDMA_CxTR3 or GPDMA_CxBR2) is conditionally and automatically updated from the next linked-list data structure in the memory, following the current value of the GPDMA_CxLLR register that was conditionally updated from the linked-list data structure of the previous LLI.

Static linked-list data structure

For example, when the update bits (UT1, UT2, UB1, USA, UDA and ULL, plus UB2 and UT3) in GPDMA_CxLLR are all asserted, the linked-list data structure in the memory is maximal with:

- channel x (x = 0 to 5) contiguous 32-bit locations, including GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR and GPDMA_CxLLR (see *Figure 70*) and including the first linked-list register file (LLI_0) and the next LLIs (such as LLI_1, LLI_2) in the memory
- channel x(x = 6 to 7), contiguous 32-bit locations, including GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, and GPDMA_CxLLR, plus GPDMA_CxTR3 and GPDMA_CxBR2 (see *Figure 71*), and including the first linked-list register file (LLI_0) and the next LLIs (such as LLI_1, LLI_2) in the memory

Figure 70. Static linked-list data structure (all Uxx = 1) of a linear addressing channel x

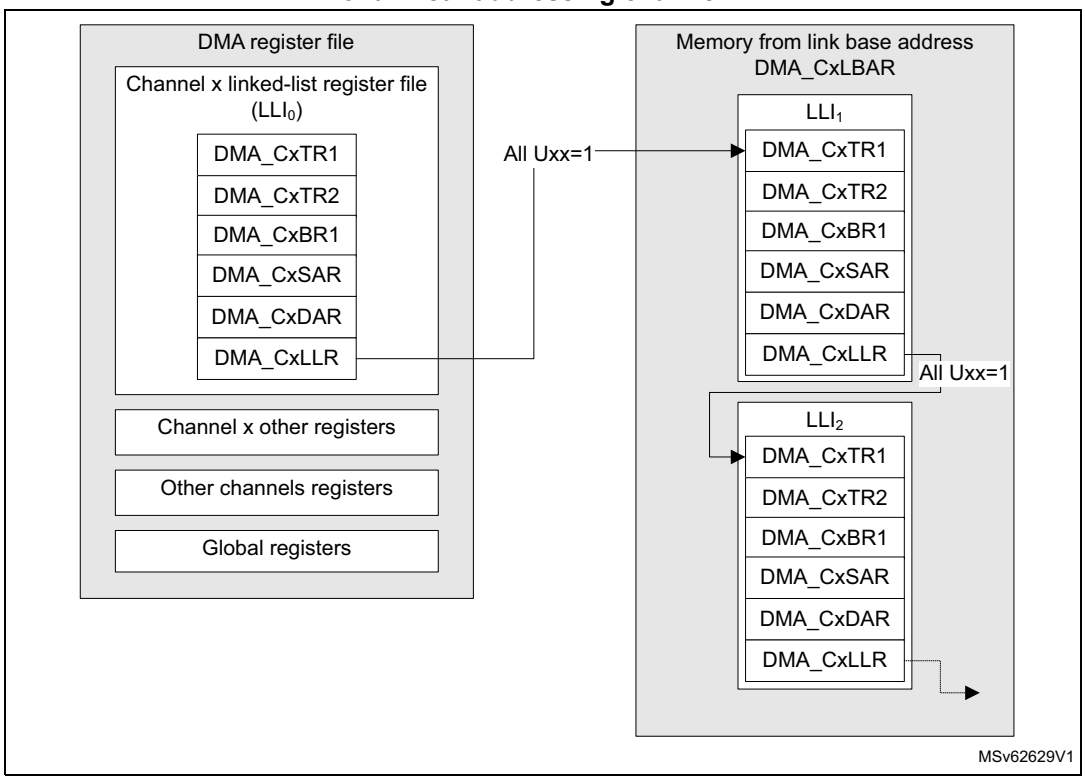


Figure 71. Static linked-list data structure (all Uxx = 1) of a 2D addressing channel x

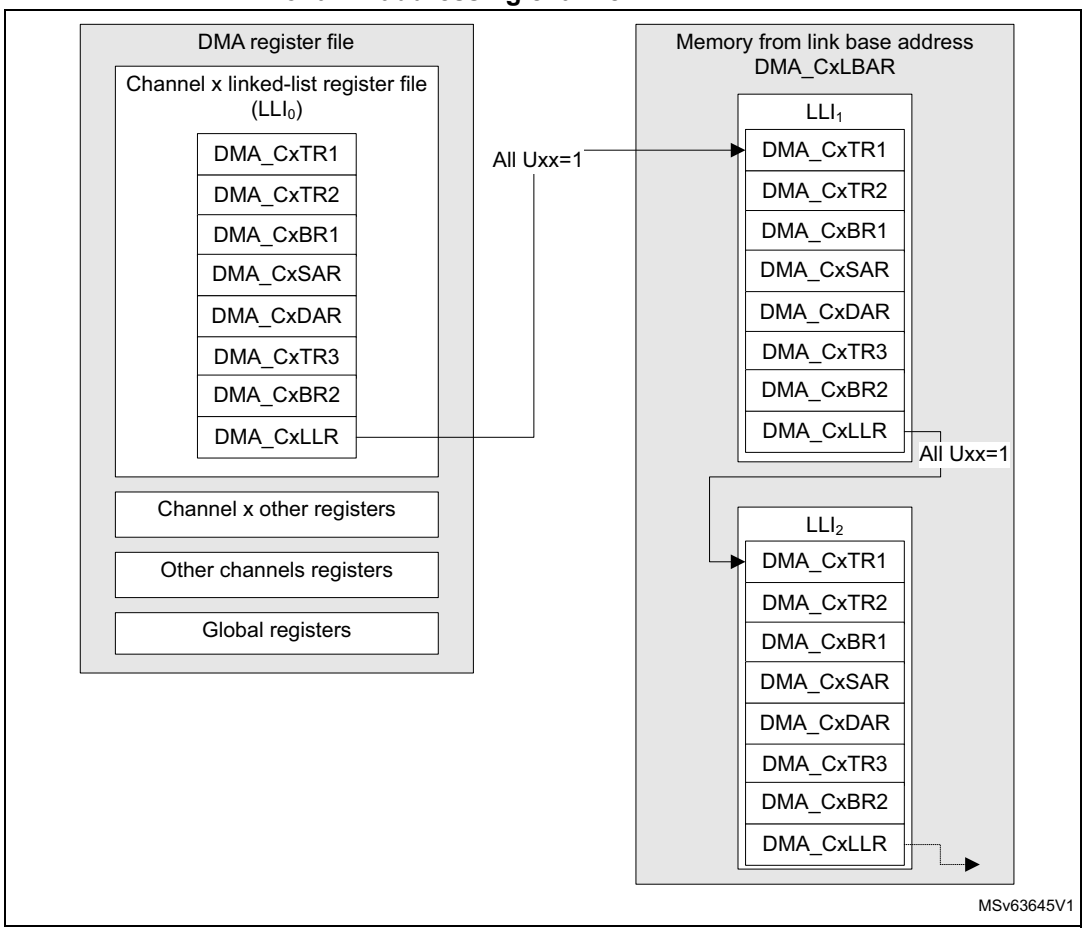

Dynamic linked-list data structure

Alternatively, the memory organization for the full list of LLIs can be compacted with specific data structure for each LLI.

If UT1 = 0 and UT2 = 1, the link address offset of the register GPDMA_CxLLR is pointing to the updated value of the GPDMA_CxTR2 instead of the GPDMA_CxTR1 which is not to be modified (see *Figure 72*).

Example: if UT1 = UB1 = USA = 0 and if UT3 = UB2 = 0, when channel x is with 2D addressing, and if UT2 = UDA = ULL = 1, the next LLI does not contain an (updated) value for GPDMA_CxTR1, nor GPDMA_CxBR1, nor GPDMA_CxSAR, nor GPDMA_CxTR3, nor GPDMA_CxBR2 when channel x is with 2D addressing. The next LLI contains an updated value for GPDMA_CxTR2, GPDMA_CxDAR, and GPDMA_CxLLR, as shown in *Figure 73*.

Figure 72. GPDMA dynamic linked-list data structure of a linear addressing channel x

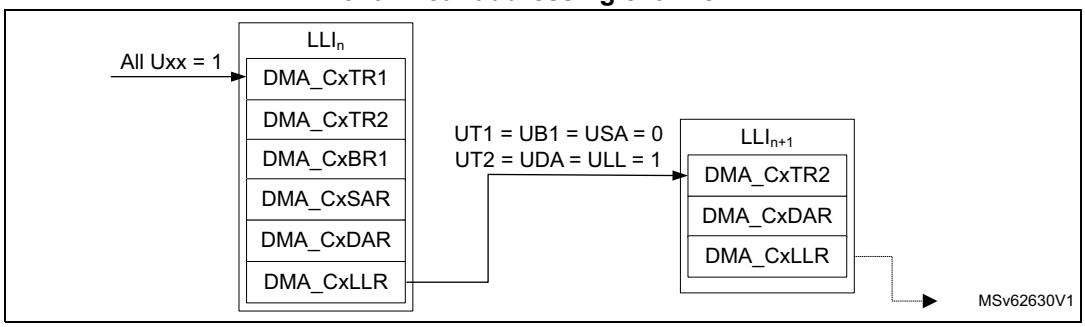

Figure 73. GPDMA dynamic linked-list data structure of a 2D addressing channel x

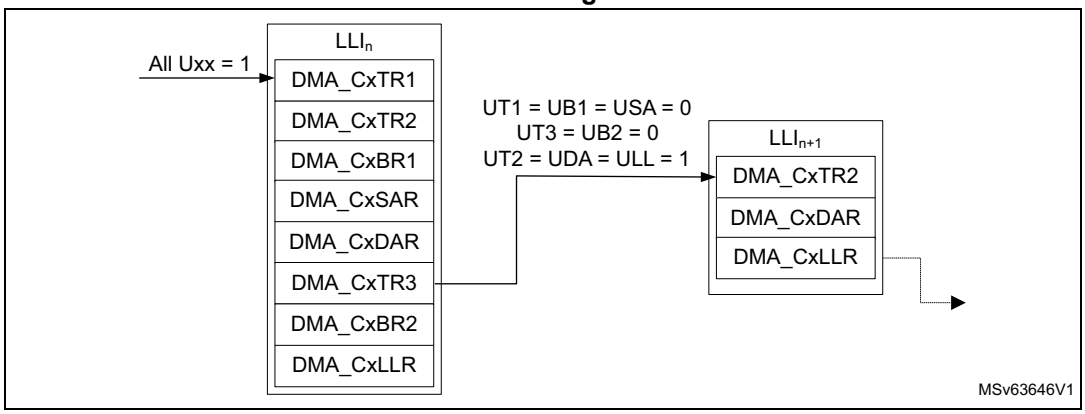


The user must program GPDMA_CxLLR for each LLI_n to be 32-bit aligned and not to exceed the 64-Kbyte addressable space pointed by GPDMA_CxLBAR.

16.4.6 Linked-list item transfer execution

A LLI_n transfer is the sequence of:

1. a data transfer: GPDMA executes the data transfer as described by the GPDMA internal register file (this data transfer can be void/null for LLI_0)
2. a conditional link transfer: GPDMA automatically and conditionally updates its internal register file by the data structure of the next LLI_{n+1}, as defined by the GPDMA_CxLLR value of the LLI_n.

Note: The initial data transfer as defined by the internal register file (LLI_0) can be null (GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxTR2.PFREQ = 0) provided that the conditional update bit UB1 in GPDMA_CxLLR is set (meaning there is a non-null data transfer described by the next LLI_1 in the memory to be executed).

Depending on the intended GPDMA usage, a GPDMA channel x can be executed as described by the full linked-list (run-to-completion mode, GPDMA_CxCR.LSM = 0) or a GPDMA channel x can be programmed for a single execution of a LLI (link step mode, GPDMA_CxCR.LSM = 1), as described in the next sections.

16.4.7 GPDMA channel state and linked-list programming in run-to-completion mode

When GPDMA_CxCR.LSM = 0 (in full list execution mode, execution of the full sequence of LLIs, named run-to-completion mode), a GPDMA channel x is initially programmed, started by writing 1 to GPDMA_CxCR.EN, and after completed at channel level. The channel transfer is:

- configured with at least the following:
  - the first LLI_0, internal linked-list register file: GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, and GPDMA_CxLLR, plus GPDMA_CxTR3 and GPDMA_CxBR2
  - the last LLI_N, described by the linked-list data structure in memory, as defined by the GPDMA_CxLLR reflecting the before last LLI_{N-1}
- completed when GPDMA_CxLLR[31:0] = 0, GPDMA_CxBR1.BRC[10:0] = 0, and GPDMA_CxBR1.BNDT[15:0] = 0, at the end of the last LLI_{N-1} transfer

GPDMA_CxLLR[31:0] = 0 is the condition of a linked-list based channel completion and means the following:

- The 16 low significant bits GPDMA_CxLLR.LA[15:0] of the next link address are null.
- All the update bits GPDMA_CxLLR.Uxx are null (UT1, UT2, UB1, USA, UDA and ULL, plus UB2 and UT3).

The channel may never be completed when GPDMA_CxLLR.LSM = 0:

- If the last LLI_N is recursive, pointing to itself as a next LLI:
  - either GPDMA_CxLLR.ULL = 1 and GPDMA_CxLLR.LA[15:2] is updated by the same value
  - or GPDMA_CxLLR.ULL = 0
- If LLI_N is pointing to a previous LLI

In the regular data transfer completion at a block level, GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0 (if present). Alternatively, a block transfer may be early completed by a peripheral (such as an I3C in Rx mode), and then BNDT[15:0] is not null (see *Section 16.4.14* for more details).

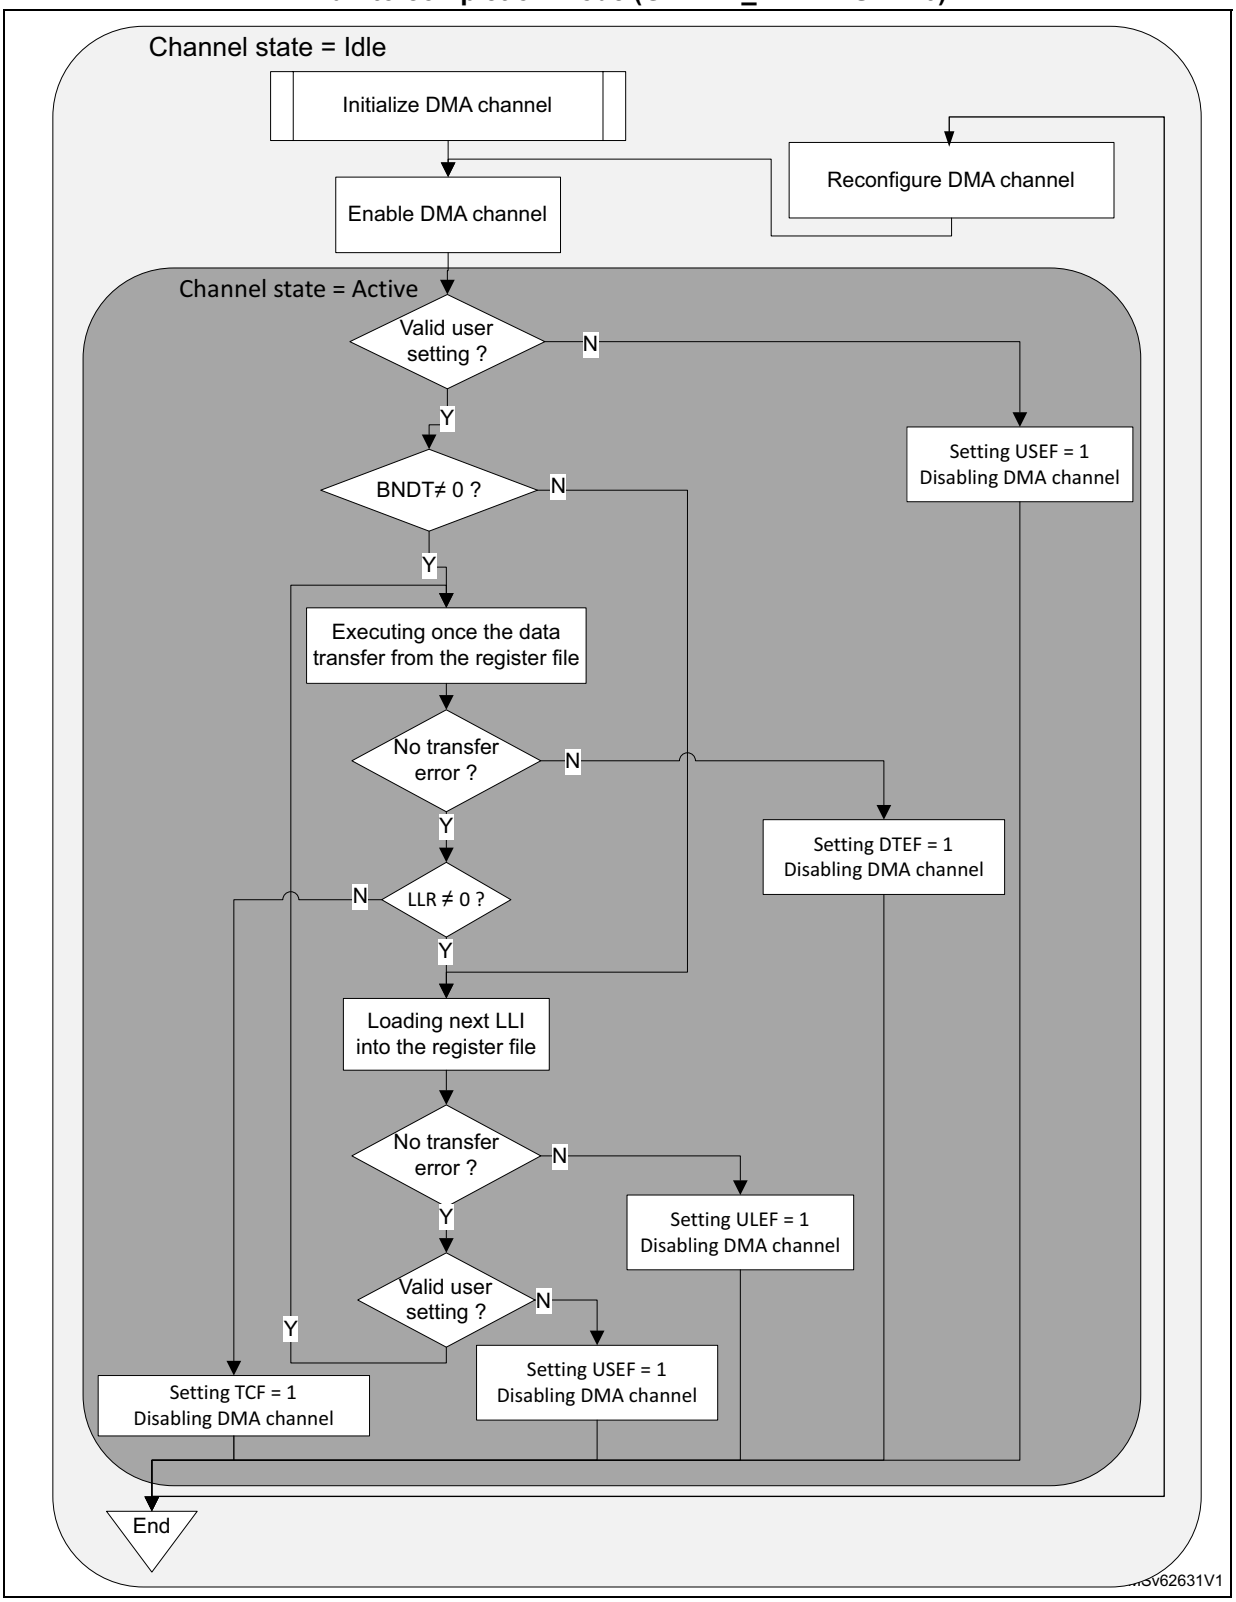
In the typical run-to-completion mode, the allocation of a GPDMA channel, including its fine programming, is done once during the GPDMA initialization. In order to have a reserved data communication link and GPDMA service during run-time, for continuously repeated transfers (from/to a peripheral respectively to/from memory or for memory-to-memory transfers). This reserved data communication link can consist of a channel, or the channel can be shared and a repeated transfer consists of a sequence of LLIs.

Figure 74 depicts the GPDMA channel execution and its registers programming in run-to-completion mode.

Note: Figure 74 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in GPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at channel completion. In run-to-completion mode, whatever is the value of TCEM[1:0], at the channel completion, the hardware always set TCEF = 1 and disables the channel.

In Figure 74, BNDT ≠ 0 is the typical condition for starting the first data transfer in this figure. This condition becomes (BNDT ≠ 0 and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 16.3.6).

Figure 74. GPDMA channel execution and linked-list programming in run-to-completion mode (GPDMA_CxCR.LSM = 0)



Run-time inserting a LLI_n via an auxiliary channel, in run-to-completion mode

The start of the link transfer of the LLI_{n-1} (start of the LLI_n loading) can be conditioned by the occurrence of a trigger, when programming the following fields of the GPDMA_CxTR2 in the data structure of the LLI_{n-1}:

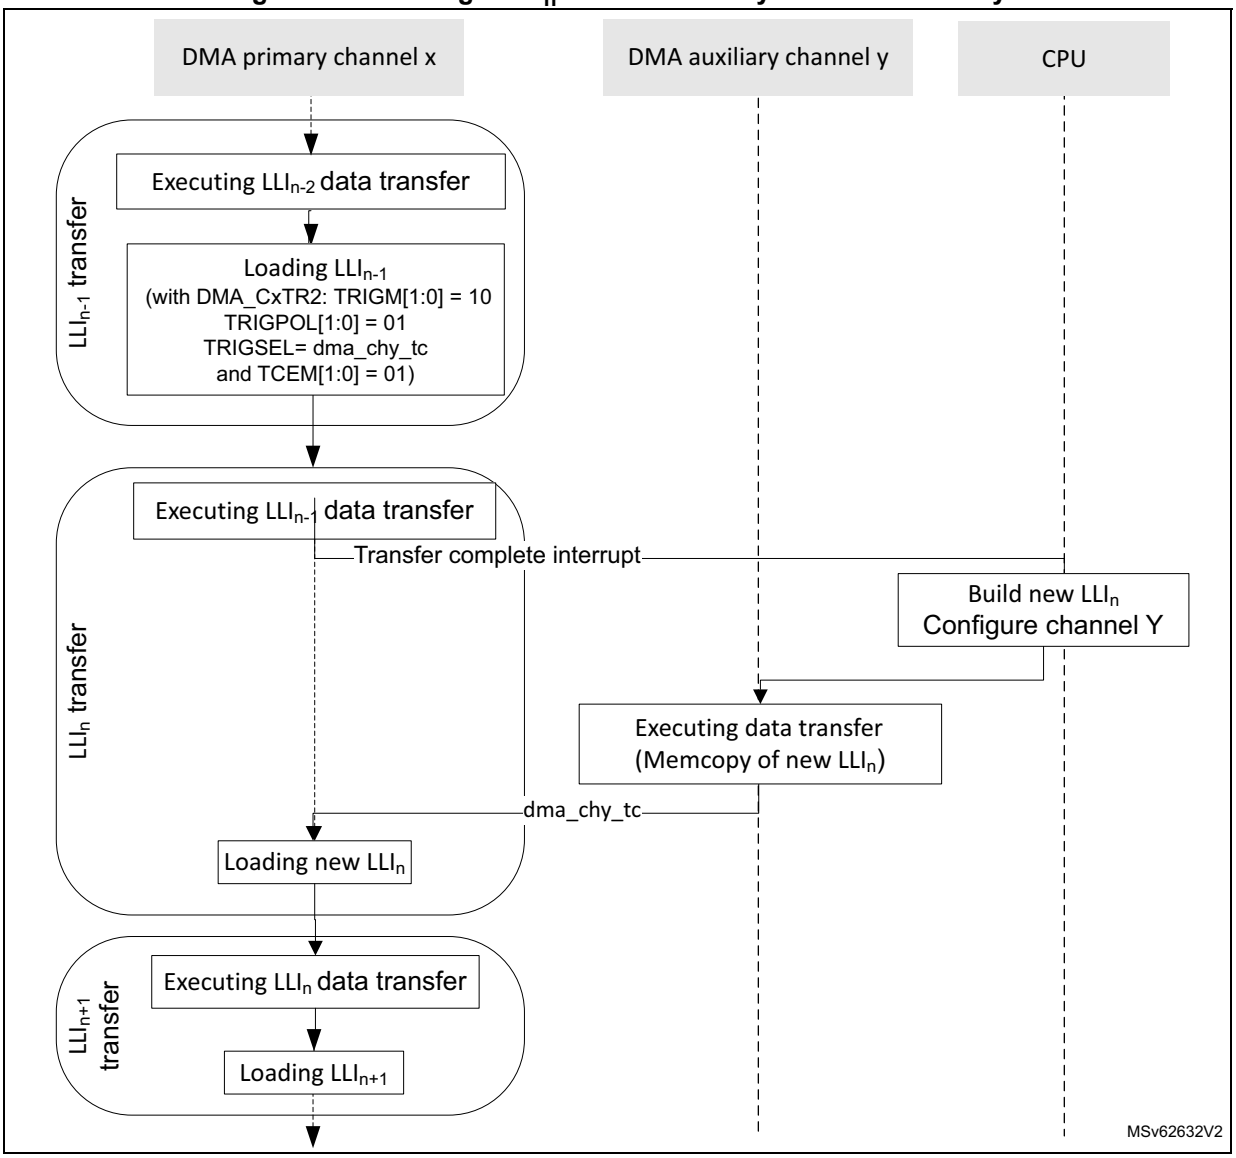
- TRIGM[1:0] = 10 (link transfer triggering mode)
- TRIGPOL[1:0] = 01 or 10 (rising or falling edge)
- TRIGSEL[5:0] (see *Section 16.3.7* for the trigger selection details)

Another auxiliary channel y can be used to store the channel x LLI_n in the memory and to generate a transfer complete event gpdma_chy_tc. By selecting this event as the input trigger of the link transfer of the LLI_{n-1} of the channel x, the software can pause the primary channel x after its LLI_{n-1} data transfer, until it is indeed written the LLI_n.

The figure below depicts such a dynamic elaboration of a linked-list of a primary channel x, via another auxiliary channel y.

Caution: This use case is restricted to an application with a LLI_{n-1} data transfer that does not need a trigger. The triggering mode of this LLI_{n-1} is used to load the next LLI_n.

Figure 75. Inserting a LLI_n with an auxiliary GPDMA channel y



16.4.8 GPDMA channel state and linked-list programming in link step mode

When GPDMA_CxCR.LSM = 1 (in link step execution mode, single execution of one LLI), a channel transfer is executed and completed after each single execution of a LLI, including its (conditional) data transfer and its (conditional) link transfer.

A GPDMA channel transfer can be programmed at LLI level, started by writing 1 into GPDMA_CxCR.EN, and after completed at LLI level:

- The current LLI_n transfer is described with:
  - GPDMA_CxTR1 defines the source/destination elementary single/burst transfers.
  - GPDMA_CxBR1 defines the number of bytes at a block level (BNDT[15:0]) and, for channel x (x = 6 to 7), the number of blocks at a 2D/repeated block level (BRC[10:0]+1) and the incrementing/decrementing mode for address offsets.

  - GPDMA_CxTR2 defines the input control (request, trigger) and the output control (transfer complete event) of the transfer.
  - GPDMA_CxSAR/GPDMA_CxDAR define the source/destination transfer start address.
  - GPDMA_CxTR3 for channel x (x = 6 to 7) defines the source/destination additional address offset between burst transfers.
  - GPDMA_CxBR2 for channel x (x = 6 to 7) defines the source/destination additional address offset between blocks at a 2D/repeated block level.
  - GPDMA_CxLLR defines the data structure and the address offset of the next LLI_{n+1} in the memory.
- The current LLI_n transfer is completed after the single execution of the current LLI_n:
  - after the (conditional) data transfer completion (when GPDMA_CxBR1.BRC[10:0] = 0, and GPDMA_CxBR1.BNDT[15:0] = 0
  - after the (conditional) update of the GPDMA link register file from the data structure of the next LLI_{n+1} in memory

Note: If a LLI is recursive (pointing to itself as a next LLI, either GPDMA_CxLLR.ULL = 1 and GPDMA_CxLLR.LA[15:2] is updated by the same value, or GPDMA_CxLLR.ULL = 0), a channel in link step mode is completed after each repeated single execution of this LLI.

In the regular data transfer completion at a block level, GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0. Alternatively, a block transfer may be early completed by a peripheral (such as an I3C in Rx mode), and then BNDT[15:0] is not null (see *Section 16.4.14* for more details).

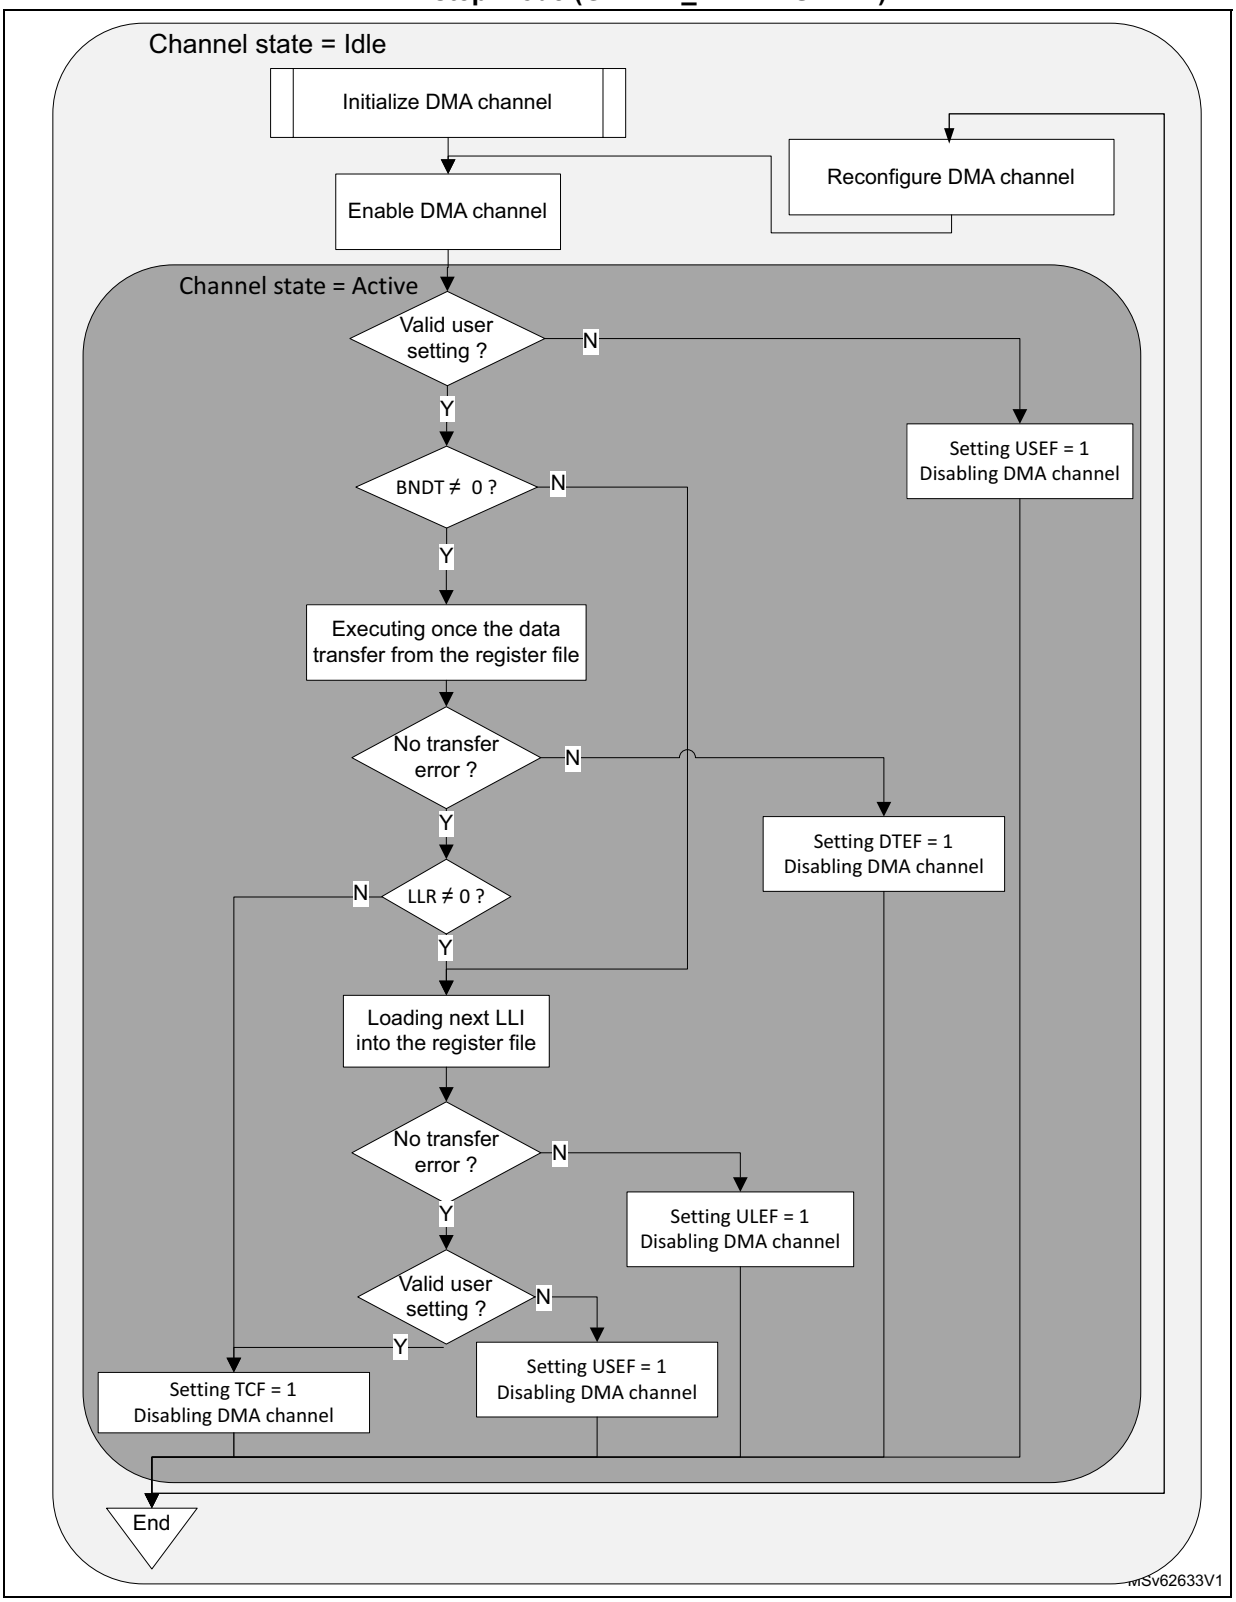
The link step mode can be used to elaborate dynamically LLIs in memory during run-time. The software can be facilitated by using a static data structure for any LLI_n (all update bits of GPDMA_CxLLR have a static value, LLI_n.LLR.LA = LLI_{n-1}.LLR.LA + constant).

Figure 76 depicts the GPDMA channel execution mode, and its programming in link step mode.

Note: Figure 76 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in GPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at the last LLI data transfer completion. In link step mode, the channel is disabled after each single execution of a LLI, and depending on the value of TCEM[1:0] a TCEF is raised or not.

In Figure 76, BNDT ≠ 0 is the typical condition for starting the first data transfer. This condition becomes (BNDT ≠ 0 and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 16.3.6).

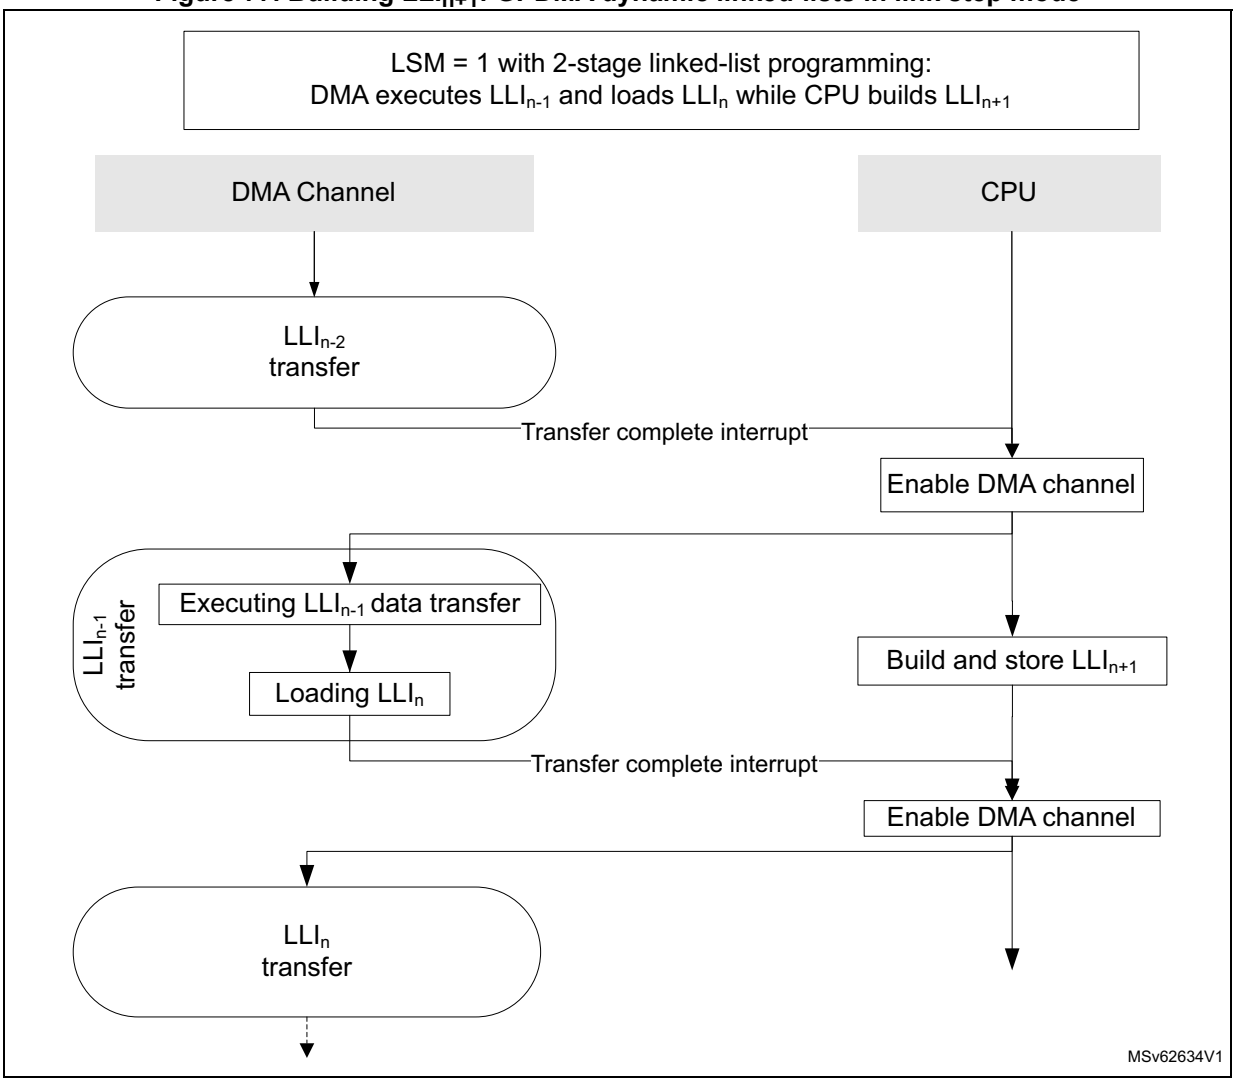
Figure 76. GPDMA channel execution and linked-list programming in link step mode (GPDMA_CxCR.LSM = 1)



Run-time adding a LLI_{n+1} in link step mode

During run-time, the software can defer the elaboration of the LLI_{n+1} (and next LLIs), until/after GPDMA executed the transfer from the LLI_{n-1} and loaded the LLI_n from the memory, as shown in the figure below.

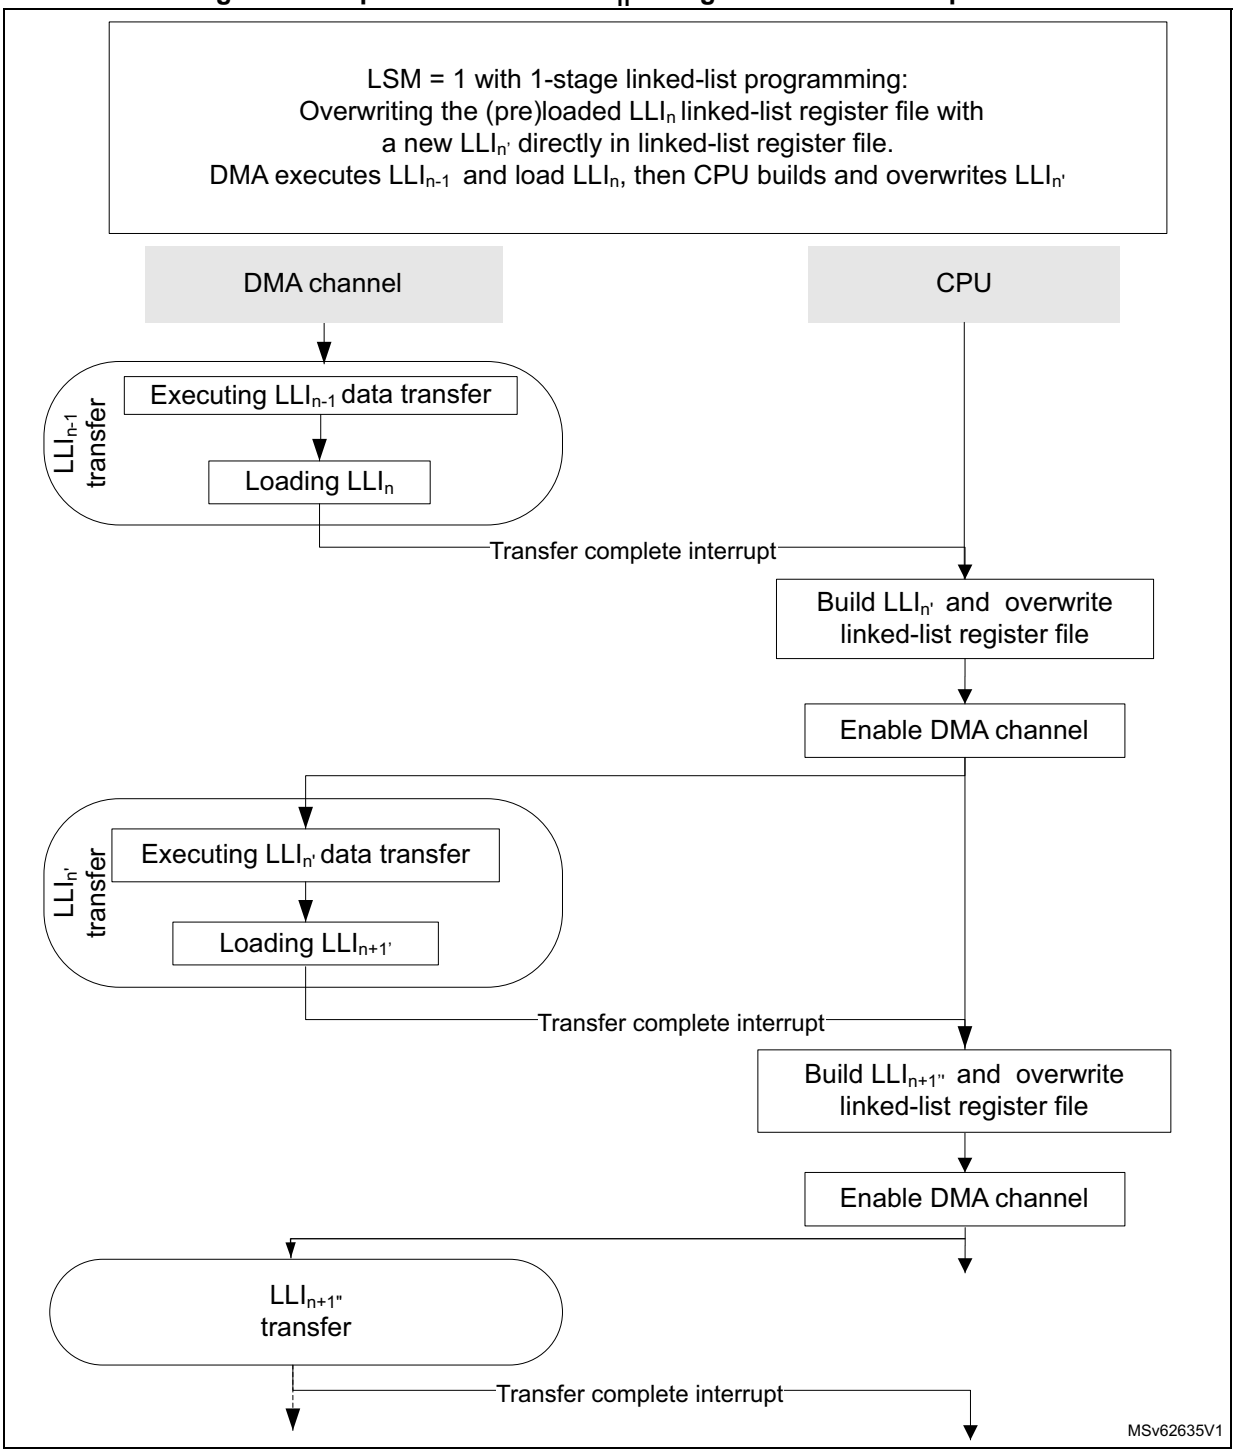
Figure 77. Building LLI_{n+1}: GPDMA dynamic linked-lists in link step mode



Run-time replacing a LLI_n with a new LLI_n', in link step mode (in linked-list register file)

In this link step mode, during run-time, the software can build and insert a new LLI_n', after GPDMA executed the transfer from the LLI_{n-1} and loaded a formerly elaborated LLI_n from the memory by overwriting directly the linked-list register file with the new LLI_n', as shown in the figure below.

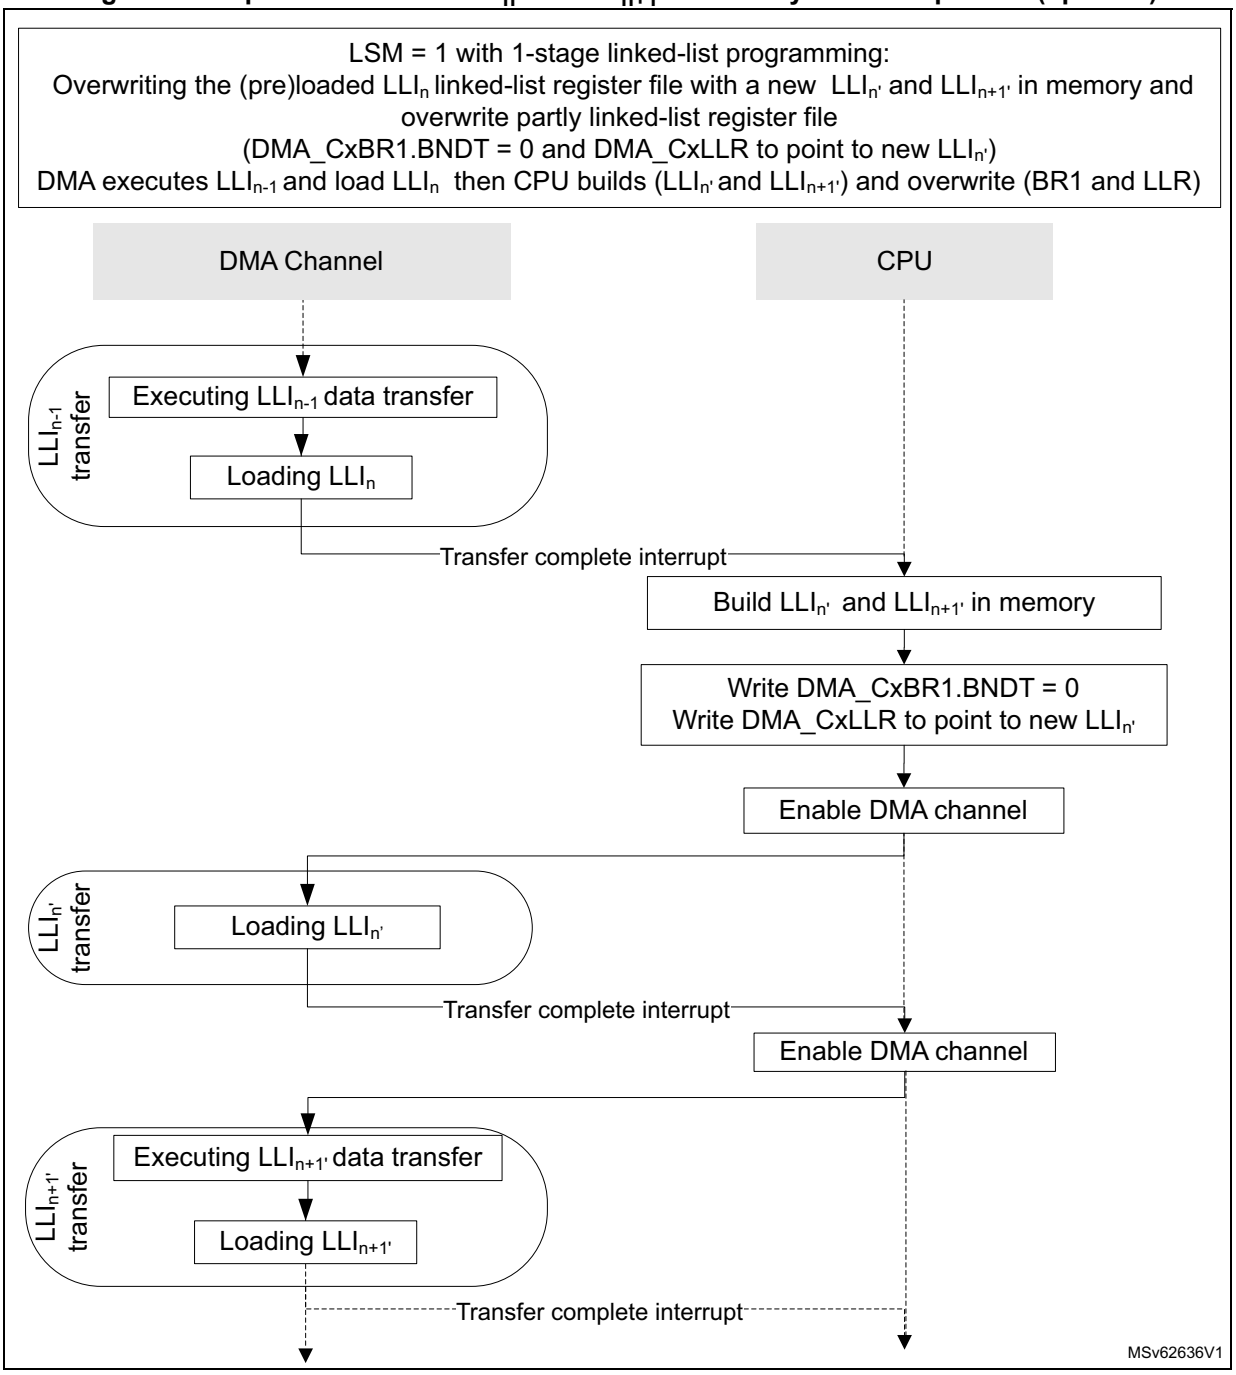
Figure 78. Replace with a new $LLI_{n'}$ in register file in link step mode



Run-time replacing a LLI_n with a new $LLI_{n'}$ in link step mode (in the memory)

The software can build and insert a new $LLI_{n'}$ and $LLI_{n+1'}$ in the memory, after GPDMA executed the transfer from the LLI_{n-1} and loaded a formerly elaborated LLI_n from the memory, by overwriting partly the linked-list register file (GPDMA_CxBR1.BNDT[15:0] to be null and GPDMA_CxLLR to point to new $LLI_{n')}$ as shown in the figure below.

Figure 79. Replace with a new $LLI_{n'}$ and $LLI_{n+1'}$ in memory in link step mode (option 1)



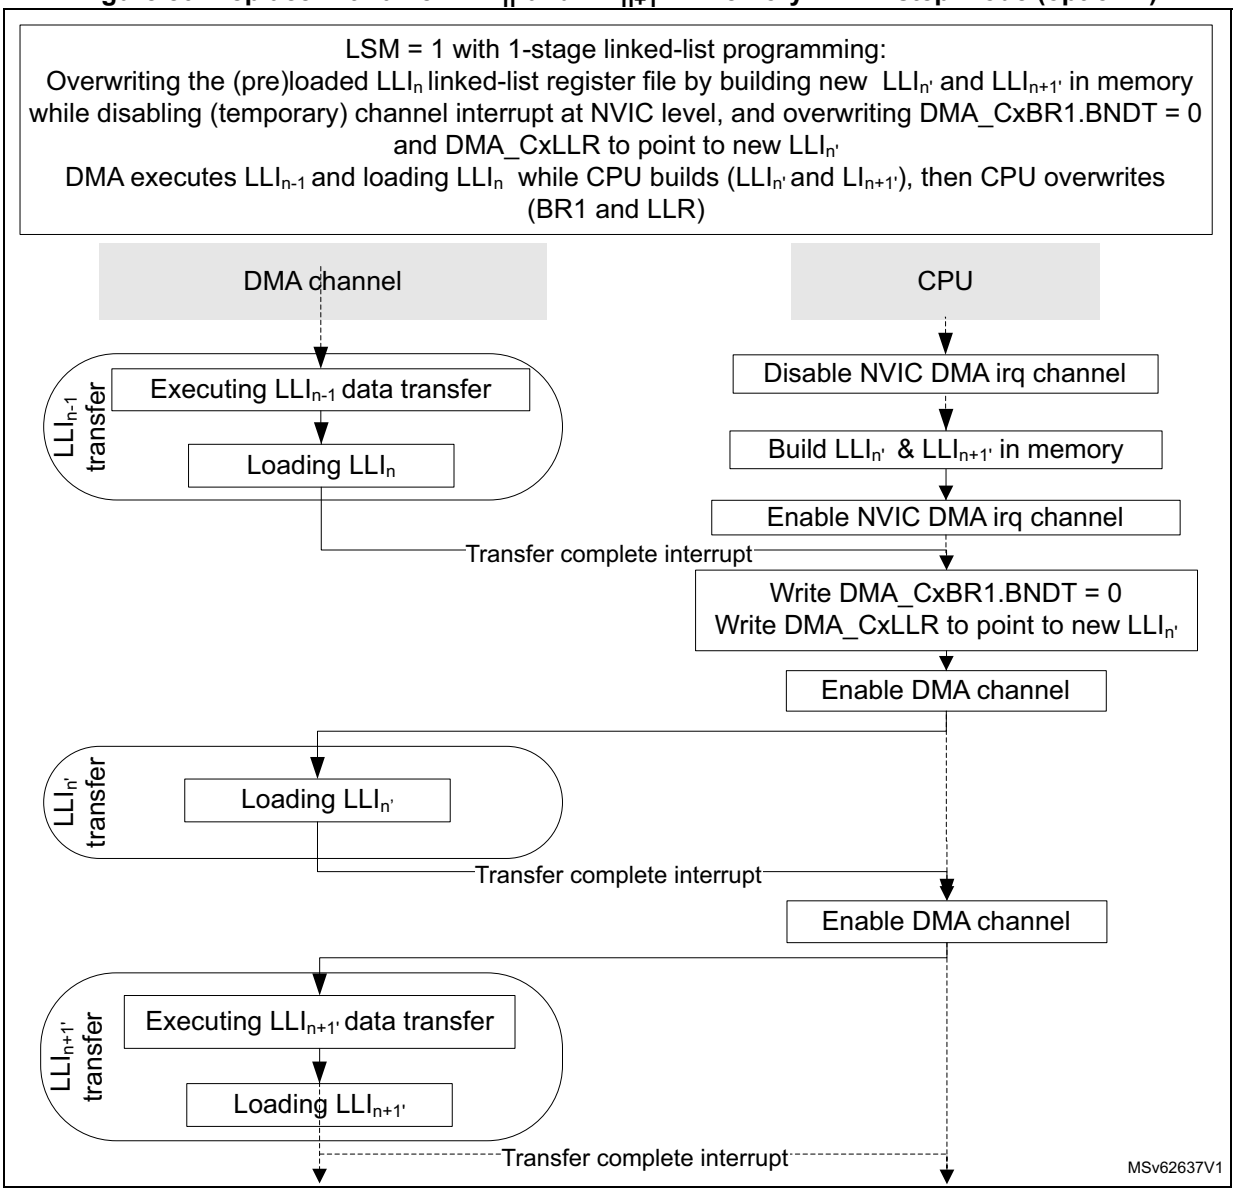
Run-time replacing a LLI_n with a new $LLI_{n'}$ in link step mode

Other software implementations exist. Meanwhile GPDMA executes the transfer from the LLI_{n-1} and loads a formerly elaborated LLI_n from the memory (or even earlier), the software can do the following:

1. Disable the NVIC for not being interrupted by the interrupt handling.
2. Build a new $LLI_{n'}$ and a new $LLI_{n+1'}$.
3. Enable again the NVIC for the channel interrupt (transfer complete) notification.

The software in the interrupt handler for LLI_{n-1} is then restricted to overwrite GPDMA_CxBR1.BNDT[15:0] to be null and GPDMA_CxLLR to point to new $LLI_{n'}$, as shown in the figure below.

Figure 80. Replace with a new $LLI_{n'}$ and $LLI_{n+1'}$ in memory in link step mode (option 2)



16.4.9 GPDMA channel state and linked-list programming

The software can reconfigure a channel when the channel is disabled (GPDMA_CxCR.EN = 0) and update the execution mode (GPDMA_CxCR.LSM) to change from/to run-to-completion mode to/from link step mode.

In any execution mode, the software can:

- reprogram LLI_{n+1} in the memory to finally complete the channel by this LLI_{n+1} (clear the GPDMA_CxLLR of this LLI_{n+1}), before that this LLI_{n+1} is loaded/used by the GPDMA channel
- abort and reconfigure the channel with a LSM update (see *Section 16.4.4*.)

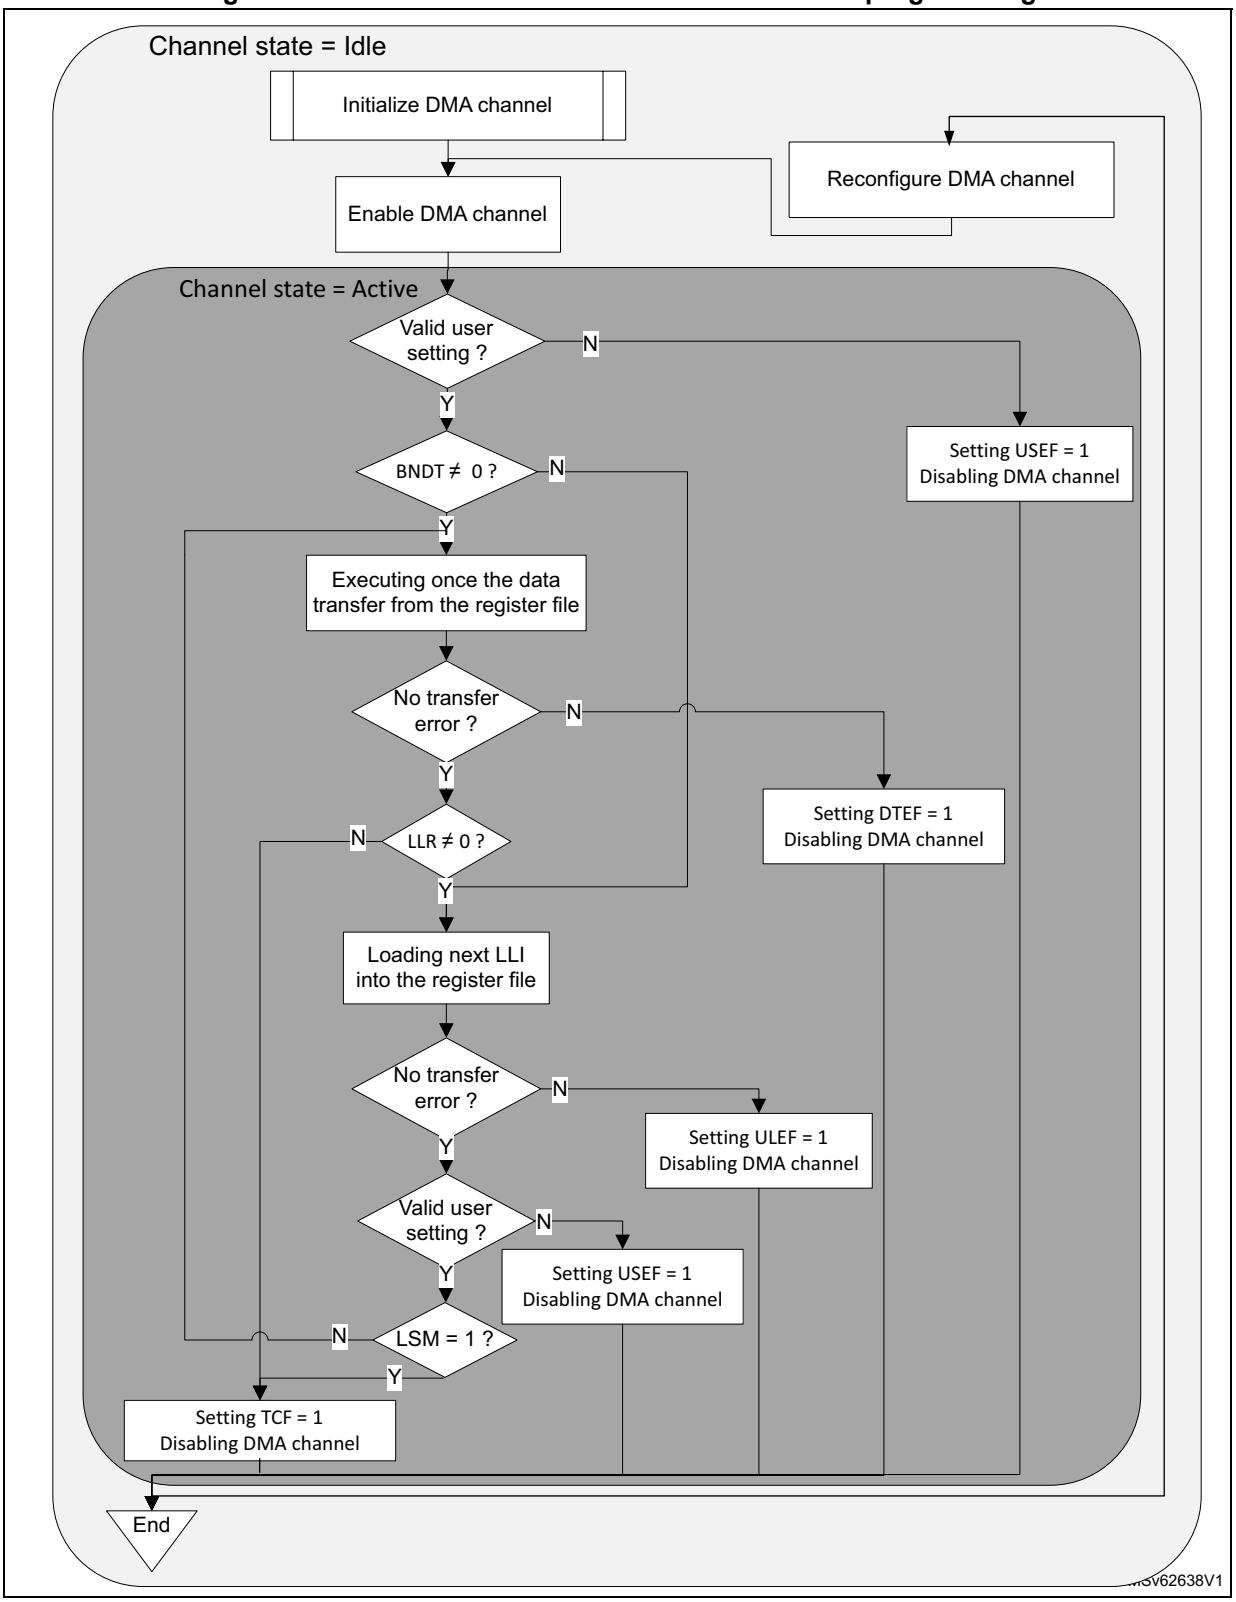
In link step mode, the software can clear LSM after each a single execution of any LLI, during LLI_{n-1}.

Figure 81 shows the overall and unified GPDMA linked-list programming, whatever is the execution mode.

Note: Figure 81 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in GPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at the last LLI data transfer completion. In run-to-completion mode, whatever is the value of TCEM[1:0], at the channel completion the hardware always set TCEF = 1 and disables the channel. In link step mode, the channel is disabled after each single execution of a LLI, and depending on the value of TCEM[1:0] a TCEF is raised or not.

In Figure 81, BNDT ≠ 0 is the typical condition for starting the first data transfer. This condition becomes (BNDT ≠ 0 and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 16.3.6).

Figure 81. GPDMA channel execution and linked-list programming



16.4.10 GPDMA FIFO-based transfers

There is a single transfer operation mode: the FIFO mode. There are FIFO-based transfers. Any channel x is implemented with a dedicated FIFO whose size is defined by dma_fifo_size[x] (see *Section 16.3.2* for more details).

GPDMA burst

A programmed transfer at the lowest level is a GPDMA burst.

A GPDMA burst is a burst of data received from the source, or a burst of data sent to the destination. A source (and destination) burst is programmed with a burst length by the field SBL_1[5:0] (respectively DBL_1[5:0]), and with a data width defined by the field SDW_LOG2[1:0] (respectively DDW_LOG2[1:0]) in the GPDMA_CxTR1 register.

The addressing mode after each data (named beat) of a GPDMA burst is defined by SINC and DINC in GPDMA_CxTR1, for source and destination respectively: either a fixed addressing or an incremented addressing with contiguous data.

The start and next addresses of a GPDMA source/destination burst (defined by GPDMA_CxSAR and GPDMA_CxDAR) must be aligned with the respective data width.

The table below lists the main characteristics of a GPDMA burst.

Table 130. Programmed GPDMA source/destination burst

SDW_LOG2[1:0] DDW_LOG2[1:0]	Data width (bytes)	SINC/DINC	SBL_1[5:0] DBL_1[5:0]	Burst length (data/beats)	Next data/ beat address	Next burst address	Burst address alignment
00	1	0 (fixed)	n = 0 to 63(1)	n+1	+ 0	+ 0	1
01	2						2
10	4						4
00	1	1 (contiguously incremented)			+ 1	+ (n + 1)	1
01	2				+ 2	+ 2 * (n + 1)	2
10	4				+ 4	+ 4 * (n + 1)	4
11	forbidden user setting, causing USEF generation and none burst to be issued.						

1. When S/DBL_1[5:0] = 0, burst is of length 1. Then burst can be also named as single.

The next burst address in the above table is the next source/destination default address pointed by GPDMA_CxSAR or GPDMA_CxDAR, once the programmed source/destination burst is completed. This default value refers to the fixed/contiguously incremented address.

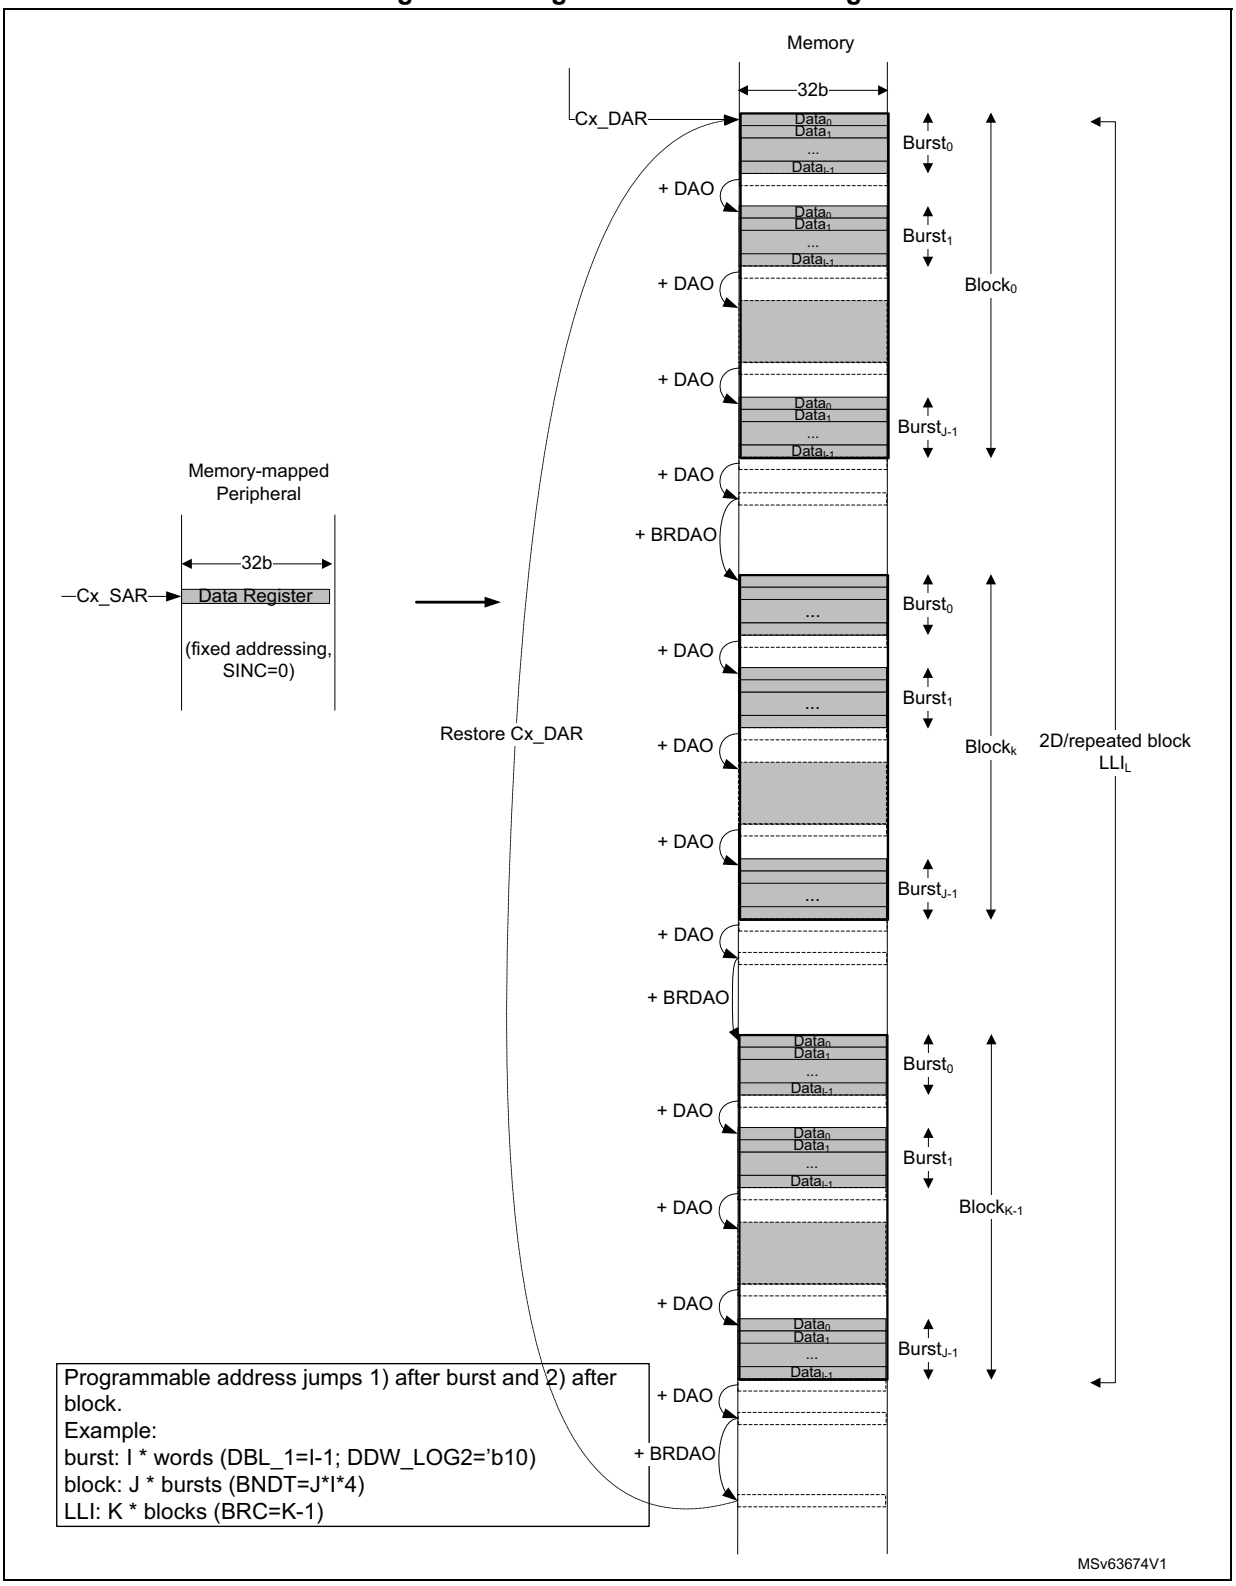
GPDMA burst with 2D addressing (channel x = 6, 7)

When the channel has additional 2D addressing feature, this default value refers to the value without taking into account the two programmed incremented or decremented offsets. These two additional offsets (with a null default value) are applied:

- after each completed source/destination burst, as defined respectively by GPDMA_CxTR2.SAO[12:0]/DAO[12:0] and GPDMA_CxBR1.SDEC/DDEC
- after each completed block, as defined respectively by GPDMA_CxBR2.BRSAO[15:0]/BRDAO[15:0] and GPDMA_CxBR1.BRSDEC/BRDDEC)

Then, a 2D/repeated block can be addressed with a first programmed address jump after each completed burst, and with a second programmed address jump after each block, as depicted by the figure below with a 2D destination buffer.

Figure 82. Programmed 2D addressing



GPDMA FIFO-based burst

In FIFO-mode, a transfer generally consists of two pipelined and separated burst transfers:

- one burst from the source to the FIFO over the allocated source master port, as defined by GPDMA_CxTR1.SAP
- one burst from the FIFO to the destination over the allocated destination master port, as defined by GPDMA_CxTR1.DAP

GPDMA source burst

The requested source burst transfer to the FIFO can be scheduled as early as possible over the allocated port, depending on the current FIFO level versus the programmed burst size (when the FIFO is ready to get one new burst from the source):

when FIFO level ≤ $2^{dma\_fifo\_size[x]}$ - (SBL_1[5:0]+1) * $2^{SDW\_LOG2[1:0]}$

where:

- FIFO level is the current filling level of the FIFO, in bytes.
- $2^{dma\_fifo\_size[x]}$ is the half of the FIFO size of the channel x, in bytes (see *Section 16.3.2* for the implementation details and dma_fifo_size[x] value).
- (SBL_1[5:0]+1) * $2^{SDW\_LOG2[1:0]}$ is the size of the programmed source burst transfer, in bytes.

Based on the channel priority (GPDMA_CxCR.PRIO[1:0]), this ready FIFO-based source transfer is internally arbitrated versus the other requested and active channels.

GPDMA destination burst

The requested destination burst transfer from the FIFO can be scheduled as early as possible over the allocated port, depending on the current FIFO level versus the programmed burst size (when the FIFO is ready to push one new burst to the destination):

when FIFO level ≥ (DBL_1[5:0]+1) * $2^{DDW\_LOG2[1:0]}$

where:

- FIFO level is the current filling level of the FIFO, in bytes.
- (DBL_1[5:0]+1) * $2^{DDW\_LOG2[1:0]}$ is the size of the programmed destination burst transfer, in bytes.

Based on the channel priority, this ready FIFO-based destination transfer is internally arbitrated versus the other requested and active channels.

GPDMA burst vs source block size, 1-Kbyte address boundary and FIFO size

The programmed source/destination GPDMA burst is implemented with an AHB burst as is, unless one of the following conditions is met:

- When half of the FIFO size of the channel x is lower than the programmed source/destination burst size, the programmed source/destination GPDMA burst is implemented with a series of singles or bursts of a lower size, each transfer being of a size that is lower or equal than half of the FIFO size, without any user constraint.
- if the source block size (GPDMA_CxBR1.BNDT[15:0]) is not a multiple of the source burst size but is a multiple of the data width of the source burst (GPDMA_CxTR1.SDW_LOG2[1:0]), the GPDMA modifies and shortens bursts into singles or bursts of lower length, in order to transfer exactly the source block size, without any user constraint.

- if the source/destination burst transfer have crossed the 1-Kbyte address boundary on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol, without any user constraint.
- If the source/destination burst length exceeds 16 on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol, without any user constraint.

In any case, the GPDMA keeps ensuring source/destination data (and address) integrity without any user constraint. The current FIFO level (software readable in GPDMA_CxSR) is compared to and updated with the effective transfer size, and the GPDMA re-arbitrates between each AHB single or burst transfer, possibly modified.

Based on the channel priority, each single or burst of a lower burst size versus the programmed burst, is internally arbitrated versus the other requested and active channels.

Note: In linked-list mode, the GPDMA read transfers related to the update of the linked-list parameters from the memory to the internal GPDMA registers, are scheduled over the link allocated port, as programmed by GPDMA_CxCR.LAP.

GPDMA data handling: byte-based reordering, packing/unpacking, padding/truncation, sign extension and left/right alignment

The data handling is controlled by GPDMA_CxTR1. The source/destination data width of the programmed burst is byte, half-word or word, as per the SDW_LOG2[21:0] and DDW_LOG2[1:0] fields (see *Table 131*).

The user can configure the data handling between transferred data from the source and transfer to the destination. More specifically, programmed data handling is orderly performed with:

1. Byte-based source reordering
   - If SBX = 1 and if source data width is a word, the two bytes of the unaligned half-word at the middle of each source data word are exchanged.
2. Data width conversion by packing, unpacking, padding or truncation, if destination data width is different than the source data width, depending on PAM[1:0]:
   - If destination data width > source data width, the post SBX source data is either right-aligned and padded with 0 s, or sign extended up to the destination data width, or is FIFO queued and packed up to the destination data width.
   - If destination data width < source data width, the post SBX data is either right-aligned and left-truncated down to the destination data width, or is FIFO queued and unpacked and streamed down to the destination data width.
3. Byte-based destination re-ordering:
   - If DBX = 1 and if the destination data width is not a byte, the two bytes are exchanged within the aligned post PAM[1:0] half-words.
   - If DHX = 1 and if the destination data width is neither a byte nor a half-word, the two aligned half-words are exchanged within the aligned post PAM[1:0] words.

Note: Left-alignment with 0s-padding can be achieved by programming both a right-alignment with a 0s-padding and a destination byte-based re-ordering.

The table below lists the possible data handling from the source to the destination.

Table 131. Programmed data handling

SDW_LOG2 [1:0]	Source data	Source data stream(1)	SBX	DDW_LOG2 [1:0]	Destination data	PAM[1:0](2)	DBX	DHX	Destination data stream(1)

1. Data stream is timely ordered starting from the byte with the lowest index (B_0).
2. RA= right aligned, LA = left aligned, RT = right truncated, LT = left truncated, 0P = zero bit padding up to the destination data width, SE = sign bit extended up to the destination data width.

16.4.11 GPDMA transfer request and arbitration

GPDMA transfer request

As defined by GPDMA_CxTR2, a programmed GPDMA data transfer is requested with one of the following:

- a software request if the control bit SWREQ = 1: This is used typically by the CPU for a data transfer from a memory-mapped address to another memory mapped address (memory-to-memory, GPIO to/from memory)
- an input hardware request coming from a peripheral if SWREQ = 0: The selection of the GPDMA hardware peripheral request is driven by the REQSEL[7:0] field (see *Section 16.3.4*). The selected hardware request can be one of the following:
  - an hardware request from a peripheral configured in GPDMA mode (for a transfer from/to the peripheral data register respectively to/from the memory)
  - an hardware request from a peripheral for its control registers update from the memory
  - an hardware request from a peripheral for a read of its status registers transferred to the memory

Caution: The user must not assign a same input hardware peripheral GPDMA request via GPDMA_CxTR.REQSEL[7:0] to two different channels, if at a given time this request is asserted by the peripheral and each channel is ready to execute this requested data transfer. There is no user setting error reporting.

GPDMA transfer request for arbitration

A ready FIFO-based GPDMA source single/burst transfer (from the source address to the FIFO) to be scheduled over the allocated master port (GPDMA_CxTR1.SAP) is arbitrated based on the channel priority (GPDMA_CxCR.PRIO[1:0]) versus the other simultaneous requested GPDMA transfers to the same master port.

A ready FIFO-based GPDMA destination single/burst transfer (from the FIFO to the destination address) to be scheduled over the allocated master port (GPDMA_CxTR1.DAP) is arbitrated based on the channel priority (GPDMA_CxCR.PRIO[1:0]) versus the other simultaneous requested GPDMA transfers to the same master port.

An arbitrated GPDMA requested link transfer consists of one 32-bit read from the linked-list data structure in memory to one of the linked-list registers (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR or GPDMA_CxLLR, plus GPDMA_CxTR3, GPDMA_CxBR2). Each 32-bit read from memory is arbitrated with the same channel priority as for data transfers, in order to be scheduled over the allocated master port (GPDMA_CxCR.LAP).

Whatever the requested data transfer is programmed with a software request for a memory-to- memory transfer (GPDMA_CxTR2.SWREQ = 1), or with a hardware request (GPDMA_CxTR2.SWREQ = 0) for a memory-to-peripheral transfer or a peripheral-to-memory transfer and whatever is the hardware request type, re-arbitration occurs after each granted single/burst transfer.

When an hardware request is programmed from a destination peripheral (GPDMA_CxTR2.SWREQ = 0 and GPDMA_CxTR2.DREQ = 1), the first memory read of a (possibly 2D/repeated) block (the first ready FIFO-based source burst request), is gated by the occurrence of the corresponding and selected hardware request. This first read request to memory is not taken into account earlier by the arbiter (not as soon as the block transfer is enabled and executable).

GPDMA arbitration

The GPDMA arbitration is directed from the 4-grade assigned channel priority (GPDMA_CxCR.PRIO[1:0]). The arbitration policy, as illustrated in *Figure 83*, is defined by:

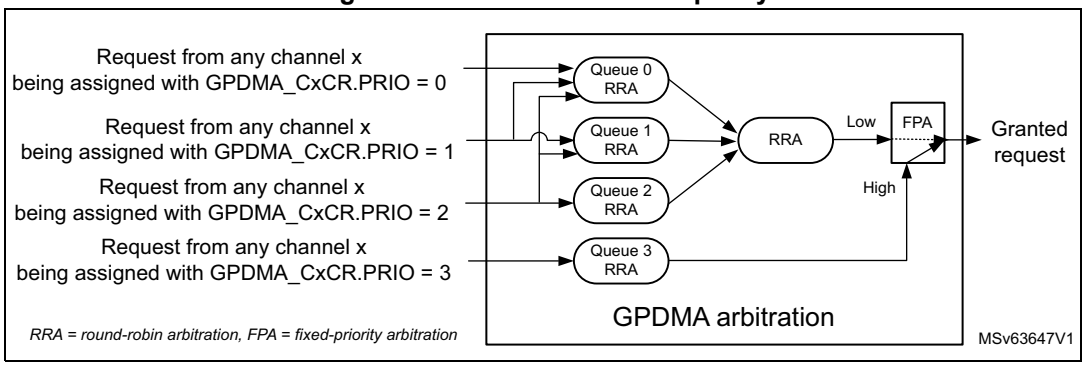
- one high-priority traffic class (queue 3), dedicated to the assigned channels with priority 3, for time-sensitive channels

  This traffic class is granted via a fixed-priority arbitration against any other low-priority traffic class. Within this class, requested single/burst transfers are round-robin arbitrated.
- three low-priority traffic classes (queues 0, 1 or 2) for non time-sensitive channels with priority 0, 1 or 2

  Each requested single/burst transfer within this class is round-robin arbitrated, with a weight that is monotonically driven from the programmed priority:
  - Requests with priority 0 are allocated to the queue 0.
  - Requests with priority 1 are allocated and replicated to the queue 0 and queue 1.

– Requests with priority 2 are allocated and replicated to the queue 0, queue 1, and queue 2.
– Any queue 0, 1 or 2 equally grants any of its active input requests in a round-robin manner, provided there are simultaneous requests.
– Additionally, there is a second stage for the low-traffic with a round-robin arbiter that fairly alternates between simultaneous selected requests from queue 0, queue 1 and queue 2.

Figure 83. GPDMA arbitration policy



GPDMA arbitration and bandwidth

With this arbitration policy, the following is guaranteed:

- Equal maximum bandwidth between requests with same priority
- Reserved bandwidth (noted as B_{Q3}) to the time-sensitive requests (with priority 3)
- Residual weighted bandwidth between different low-priority requests (priority 0 versus priority 1 versus priority 2).

The two following examples highlight that the weighted round-robin arbitration is driven by the programmed priorities:

- **Example 1**: basic application with two non time-sensitive GPDMA requests: req0 and req1. There are the following programming possibilities:
  – If they are assigned with same priority, the allocated bandwidth by the arbiter to req0 (B_{req0}) is **equal** to the allocated bandwidth to req1(B_{req1}).
  $B_{req0} = B_{req1} = 1/2 * (1 - B_{Q3})$
  – If req0 is assigned to priority 0 and req1 to priority 1, the allocated bandwidth to req0 (B_{P0}) is **3 times less** than the allocated bandwidth to req1 (B_{P1}).
  $B_{req0} = B_{P0} = 1/2 * 1/2 * (1 - B_{Q3}) = 1/4 * (1 - B_{Q3})$
  $B_{req1} = B_{P1} = (1/2 + 1) * 1/3 * (1 - B_{Q3}) = 3/4 * (1 - B_{Q3})$
  – If req0 is assigned to priority 0 and req1 to priority 2, the allocated bandwidth to req0 (B_{P0}) is **5 times less** than the allocated bandwidth to req1 (B_{P2}).
  $B_{req0} = B_{P0} = 1/2 * 1/3 * (1 - B_{Q3}) = 1/6 * (1 - B_{Q3})$
  $B_{req1} = B_{P2} = (1/2 + 1 + 1) * 1/3 * (1 - B_{Q3}) = 5/6 * (1 - B_{Q3})$
  The above computed bandwidth calculation is based on a theoretical input request, always active for any GPDMA clock cycle. This computed bandwidth from the arbiter must be weighted by the frequency of the request given by the application, that cannot be always active and may be quite much variable from one GPDMA client (example I2C at 400 kHz) to another one (PWM at 1 kHz) than the above x3 and x5 ratios.

- **Example 2**: application where the user distributes a same non-null N number of GPDMA requests to every non time-sensitive priority 0, 1 and 2. The bandwidth calculation is then the following:
  - The allocated bandwidth to the set of requests of priority 0 (B_{P0}) is
    $B_{P0} = 1/3 * 1/3 * (1 - B_{Q3}) = 1/9 * (1 - B_{Q3})$
  - The allocated bandwidth to the set of requests of priority 1(B_{P1}) is
    $B_{P1} = (1/3 + 1/2) * 1/3 * (1 - B_{Q3}) = 5/18 * (1 - B_{Q3})$
  - The allocated bandwidth to the set of requests of priority 2(B_{P2}) is
    $B_{P2} = (1/3 + 1/2 + 1) * 1/3 * (1 - B_{Q3}) = 11/18 * (1 - B_{Q3})$
  - The allocated bandwidth to any request n ($B_{n)}$ among the N requests of that priority Pi (i = 0 to 2) is $B_n = 1/N * B_{Pi}$
  - The allocated bandwidth to any request n of priority 0i ($B_{n, Pi}$) is
    $B_{n, P0} = 1/N *1/9 * (1 - B_{Q3})$
    $B_{n, P1} = 1/N *5/18 * (1 - B_{Q3})$
    $B_{n, P2} = 1/N *11/18 * (1 - B_{Q3})$

  In this example, when the master port bus bandwidth is not totally consumed by the time-sensitive queue 3, the residual bandwidth is such that 2.5 times less bandwidth is allocated to any request of priority 0 versus priority 1, and 5.5 times less bandwidth is allocated to any request of priority 0 versus priority 2.

More generally, assume that the following requests are present:

- I requests (I ≥ 0) assigned to priority 0
  If I > 0, these requests are noted from i = 0 to I-1.
- J requests (J ≥ 0) assigned to priority 1
  If J > 0, these requests are noted from j = 0 to J-1.
- K requests (K > 0) assigned to priority 2
  These requests are noted from k = 0 to K-1
- L requests (L ≥ 0) assigned to priority 3
  If L > 0, these requests are noted from l = 0 to L-1.

As B_{Q3} is the reserved bandwidth to time-sensitive requests, the bandwidth for each request L with priority 3 is:

- $B_l = B_{Q3} / L$ for L > 0 (else: $B_l = 0$)

The bandwidth for each non-time sensitive queue is:

- $B_{Q0} = 1/3 * (1 - B_{Q3})$
- $B_{Q1} = 1/3 * (1 - B_{Q3})$
- $B_{Q2} = 1/3 * (1 - B_{Q3})$

The bandwidth for the set of requests with priority 0 is:

- $B_{P0} = I / (I + J + K) * B_{Q0}$

The bandwidth for each request i with priority 0 is:

- $B_i = B_{P0} / I$ for L > 0 (else $B_{P0} = 0$)

The bandwidth for the set of requests with priority 1 and routed to queue 0 is:

- $B_{P1,Q0} = J / (I + J + K) * B_{Q0}$

The bandwidth for the set of requests with priority 1 and routed to queue 1 is:

- $B_{P1,Q1} = J / (J + K) * B_{Q1}$

The total bandwidth for the set of requests with priority 1 is:

- $B_{P1} = B_{P1,Q0} + B_{P1,Q1}$

The bandwidth for each request j with priority 1 is:

- $B_j = B_{P1} / J$ for $J > 0$ (else $B_j = 0$)

The bandwidth for the set of requests with priority 2 and routed to queue 0 is:

- $B_{P2,Q0} = K / (I + J + K) * B_{Q0}$

The bandwidth for the set of requests with priority 2 and routed to queue 1 is:

- $B_{P2,Q1} = K / (J + K) * B_{Q1}$

The bandwidth for the set of requests with priority 2 and routed to queue 2 is:

- $B_{P2,Q2} = B_{Q2}$

The total bandwidth for the set of requests with priority 2 is:

- $B_{P2} = B_{P2,Q0} + B_{P2,Q1} + B_{P2,Q2}$

The bandwidth for each request k with priority 2 is:

- $B_k = B_{P2} / K$ ($K>0$ in the general case)

Thus finally the maximum allocated residual bandwidths for any i, j, k non-time sensitive request are:

- in the general case (when there is at least one request k with a priority 2 ($K > 0$)):
  - $B_i = 1/I * 1/3 * I/(I + J + K) * (1 - B_{Q3})$
  - $B_j = 1/J * 1/3 *[J/(I + J + K) + J/(J + K)] * (1 - B_{Q3})$
  - $B_k = 1/K * 1/3 *[K/(I + J + K) + K/(J + K) + 1] * (1 - B_{Q3})$
- in the specific case (when there is no request k with a priority 2 ($K = 0$)):
  - $B_i = 1/I * 1/2 * I/(I + J) * (1 - B_{Q3})$
  - $B_j = 1/J * 1/2 *[J/(I + J) + 1] * (1 - B_{Q3})$

Consequently, the GPDMA arbiter can be used as a programmable weighted bandwidth limiter, for each queue and more generally for each request/channel. The different weights are monotonically resulting from the programmed channel priorities.

16.4.12 GPDMA triggered transfer

A programmed GPDMA transfer can be triggered by a rising/falling edge of a selected input trigger event, as defined by GPDMA_CxTR2.TRIGPOL[1:0] and GPDMA_CxTR2.TRIGSEL[5:0] (see *Section 16.3.7* for the trigger selection).

The triggered transfer, as defined by the trigger mode in GPDMA_CxTR2.TRIGM[1:0], can be at LLI data transfer level, to condition the first burst read of a block, the first burst read of a 2D/repeated block for channel x (x = 6 to 7), or each programmed single read. The trigger mode can also be programmed to condition the LLI link transfer (see TRIGM[1:0] in GPDMA_CxTR2 for more details).

Trigger hit memorization and trigger overrun flag generation

The GPDMA monitoring of a trigger for a channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (respectively TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).

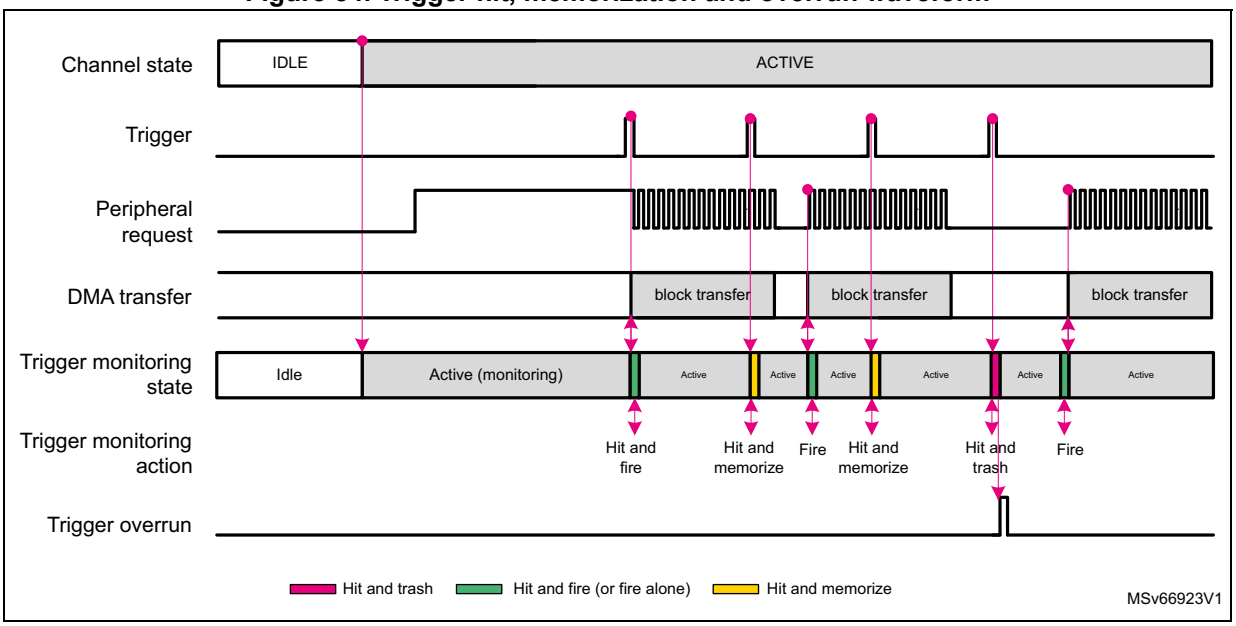
The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer. If a new trigger is detected, this hit is internally memorized to grant the next transfer, as long as the defined rising/falling edge and TRIGSEL[5:0] are not modified, and the channel is enabled.

Transferring a next $LLI_{n+1,}$ that updates the GPDMA_CxTR2 with a new value for any of TRIGSEL[5:0] or TRIGPOL[1:0], resets the monitoring, trashing the possible memorized hit of the formerly defined LLI_n trigger.

Caution: After a first new trigger hit_{n+1} is memorized, if another trigger hit_{n+2} is detected and if the hit_n triggered transfer is still not completed, hit_{n+2} is lost and not memorized. A trigger overrun flag is reported (GPDMA_CxSR.TOF = 1) and an interrupt is generated if enabled (if GPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

The figure below illustrates the trigger hit, memorization and overrun in the configuration example with a block-level trigger mode and a rising edge trigger polarity.

Figure 84. Trigger hit, memorization and overrun waveform



Note: The user can assign the same input trigger event to different channels. This can be used to trigger different channels on a broadcast trigger event.

16.4.13 GPDMA circular buffering with linked-list programming

GPDMA circular buffering for memory-to-peripheral and peripheral-to-memory transfers, with a linear addressing channel

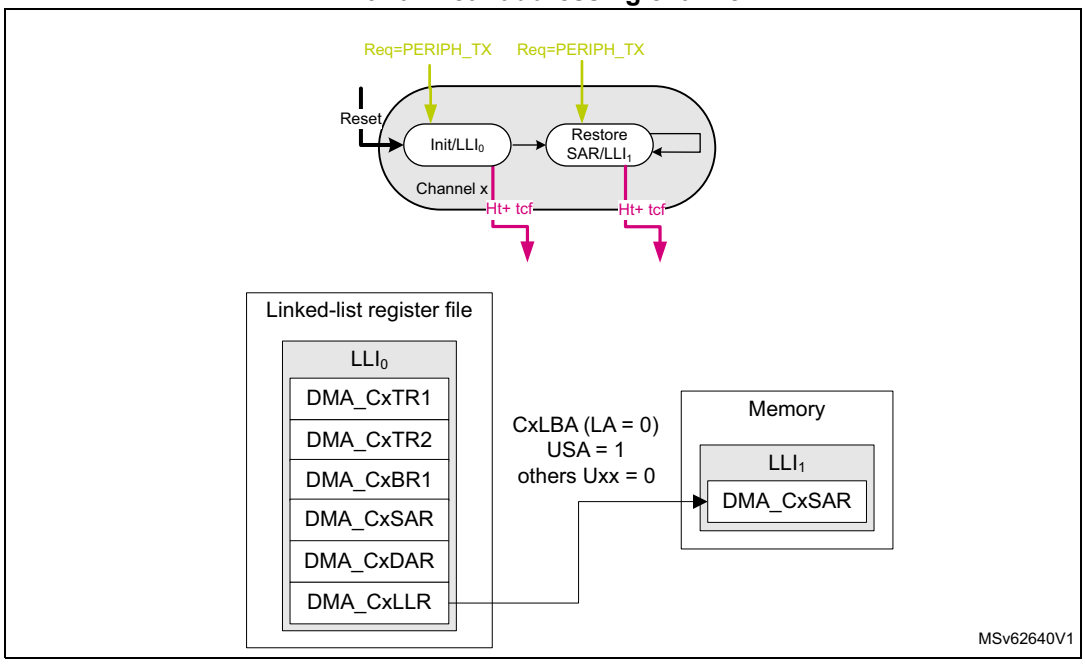
For a circular buffering, with a continuous memory-to-peripheral (or peripheral-to-memory) transfer, the software must set up a channel with half transfer and complete transfer

events/interrupts generation (GPDMA_CxCR.HTIE = 1 and GPDMA_CxCR.TCIE = 1), in order to enable a concurrent buffer software processing.

LLI_0 is configured for the first block transfer with the linear addressing channel. A continuously-executed LLI_1 is needed to restore the memory source (or destination) start address, for the memory-to-peripheral transfer (respectively the peripheral-to-memory transfer). GPDMA automatically reloads the initially programmed GPDMA_CxBR1.BNDT[15:0] when a block transfer is completed, and there is no need to restore GPDMA_CxBR1.

The figure below illustrates this programming with a linear addressing GPDMA channel and a source circular buffer.

Figure 85. GPDMA circular buffer programming: update of the memory start address with a linear addressing channel

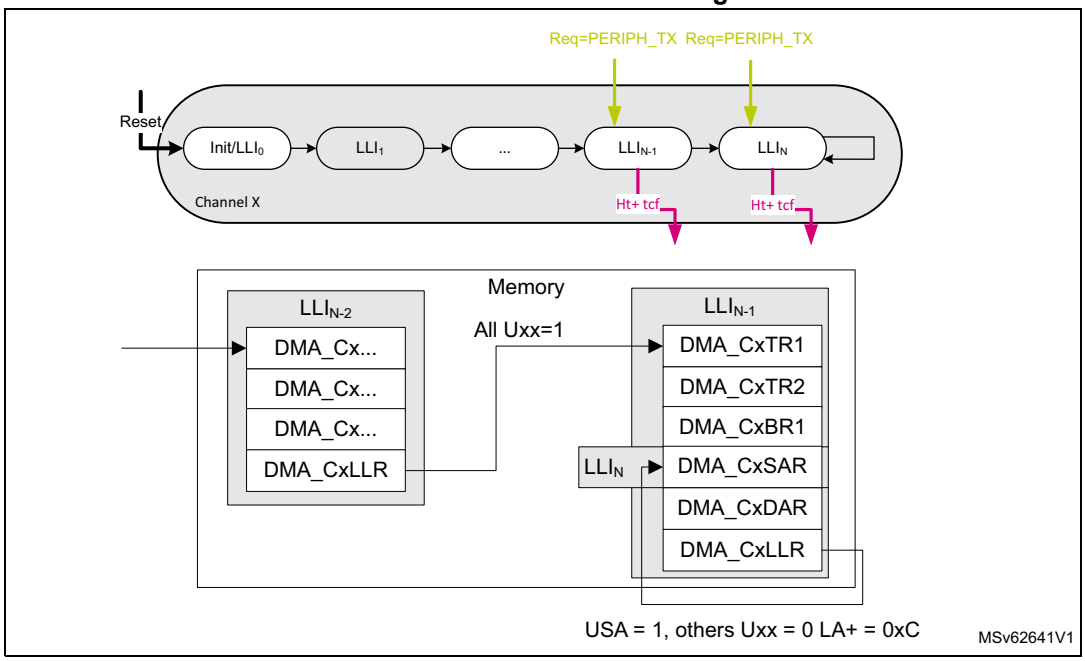


Note: With a 2D addressing channel, the user may use a single LLI with GPDMA_CxBR1.BRC[10:0] = 1, and program a negative memory block address offset with GDMA_CxBR2 and GDMA_CxBR1, in order to jump back to the memory source or the destination start address.

If circular buffering must be executed after some other transfers over the shared GPDMA channel x, the before-last LLI_{N-1} in memory is needed to configure the first block transfer. And the last LLI_N restores the memory source (or destination) start address in memory-to-peripheral transfer (respectively in peripheral-to-memory transfer).

The figure below illustrates this programming with a linear addressing shared GPDMA channel, and a source circular buffer.

Figure 86. Shared GPDMA channel with circular buffering: update of the memory start address with a linear addressing channel



16.4.14 GPDMA transfer in peripheral flow-control mode

A peripheral with the peripheral flow-control mode feature can decide to early terminate a GPDMA block transfer, provided that the allocated channel is implemented with this feature (see *Section 16.3.6*).

If the related GPDMA channel x is also programmed in peripheral flow-control mode (GPDMA_CxTR2.PFREQ = 1):

- The GPDMA block transfer starts as follows:
  - If GPDMA_CxBR1.BNDT[15:0] ≠ 0, the programmed value is internally taken into account by the GPDMA hardware.
  - If GPDMA_CxBR1.BNDT[15:0] = 0, the GPDMA hardware internally considers a 64-Kbyte value for the maximum source block size to be transferred.
- The GPDMA block transfer is completed as soon as the first occurrence of one of the following condition occurs:
  - when GPDMA_CxBR1.BNDT[15:0] = 0
  - when the peripheral early terminates the block. The complete transfer event is generated if programmed, depending on GPDMA_CxTR2 (see *GPDMA channel x transfer register 2 (GPDMA_CxTR2)*). Then the software can read the current number of transferred bytes from the source (GPDMA_CxBR1.BNDT[15:0]), and/or read the current source or destination address of the buffer in memory (GPDMA_CxSAR[31:0] or GPDMA_CxDAR[31:0]).

In peripheral flow-control mode:

- a destination peripheral with a hardware requested transfer is not supported: memory-to-peripheral transfer is not supported.
- Data packing from a source peripheral is not supported.
- 2D/repeated block is not supported.
- GPDMA_CxBR1.BNDT[15:0] must be programmed as a multiple of the source (peripheral) burst size.

16.4.15 GPDMA secure/nonsecure channel

The GPDMA controller is compliant with the TrustZone hardware architecture at channel level, partitioning all its resources so that they exist in one of the secure and nonsecure worlds at any given time.

Any channel x is a secure or a nonsecure hardware resource, as configured by GPDMA_SECCFGR.SECx.

When a channel x is configured in secure state by a secure and privileged agent, the following access control rules are applied:

- A nonsecure read access to a register field of this channel is forced to return 0, except for GPDMA_SECCFGR, GPDMA_PRIVCFGR and GPDMA_RCFGLOCKR that are readable by a nonsecure agent.
- A nonsecure write access to a register field of this channel has no impact.

When a channel x is configured in secure state, a secure agent can configure separately as secure or nonsecure the GPDMA data transfer from the source (GPDMA_CxTR1.SSEC) and the GPDMA data transfer to the destination (GPDMA_CxTR1.DSEC).

When a channel x is configured in secure state and in linked-list mode, the loading of the next linked-list data structure from the GPDMA memory into its register file, is automatically performed with secure transfers via the GPDMA_CxCR.LAP allocated master port.

The GPDMA generates a secure bus that reflects GPDMA_SECCFGR, to keep the other peripherals informed of the secure/nonsecure state of each GPDMA channel x.

The GPDMA also generates a security illegal access pulse signal on an illegal nonsecure access to a secure GPDMA register. This signal is routed to the TrustZone interrupt controller.

When the secure software must switch a channel from a secure state to a nonsecure state, the secure software must abort the channel or wait until the secure channel is completed before switching. This is needed to dynamically re-allocate a channel to a next nonsecure transfer as a nonsecure software is not allowed to do so and must have GPDMA_CxCR.EN = 0 before the nonsecure software can reprogram the GPDMA_CxCR for a next transfer. The secure software may reset not only the channel x (GPDMA_CxCR.RESET = 1) but also the full channel x register file to its reset value.

16.4.16 GPDMA privileged/unprivileged channel

Any channel x is a privileged or unprivileged hardware resource, as configured by a privileged agent via GPDMA_PRIVCFGR.PRIVx.

When a channel x is configured in a privileged state by a privileged agent, the following access control rules are applied:

- An unprivileged read access to a register field of this channel is forced to return 0, except for GPDMA_PRIVCFGR, GPDMA_SECCFGR and GPDMA_RCFGLOCKR that are readable by an unprivileged agent.
- An unprivileged write access to a register field of this channel has no impact.

When a channel is configured in a privileged (or unprivileged) state, the source and destination data transfers are privileged (respectively unprivileged) transfers over the AHB master port.

When a channel is configured in a privileged (or unprivileged) state and in linked-list mode, the loading of the next linked-list data structure from the GPDMA memory into its register file, is automatically performed with privileged (respectively unprivileged) transfers, via the GPDMA_CxCR.LAP allocated master port.

The GPDMA generates a privileged bus that reflects GPDMA_PRIVCFGR, to keep the other peripherals informed of the privileged/unprivileged state of each GPDMA channel x.

When the privileged software must switch a channel from a privileged state to an unprivileged state, the privileged software must abort the channel or wait until that the privileged channel is completed before switching. This is needed to dynamically re-allocate a channel to a next unprivileged transfer as an unprivileged software is not allowed to do so, and must have GPDMA_CxCR.EN = 0 before the unprivileged software can reprogram the GPDMA_CxCR for a next transfer. The privileged software may reset not only the channel x (GPDMA_CxCR.RESET = 1) but also the full channel x register file to its reset value.

16.4.17 GPDMA error management

The GPDMA is able to manage and report to the user a transfer error, as follows, depending on the root cause.

Data transfer error

on a bus access (as a AHB single or a burst) to the source or the destination

- The source or destination target reports an AHB error.
- The programmed channel transfer is stopped (GPDMA_CxCR.EN cleared by the GPDMA hardware). The channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and the data error (GPDMA_CxSR.DTEF = 1).
- After a GPDMA data transfer error, the user must perform a debug session, taking care of the product-defined memory mapping of the source and destination, including the protection attributes.
- After a GPDMA data transfer error, the user must issue a channel reset (set GPDMA_CxCR.RESET) to reset the hardware GPDMA channel data path and the content of the FIFO, before the user enables again the same channel for a next transfer.

Link transfer error

on a tentative update of a GPDMA channel register from the programmed LLI in the memory

- The linked-list memory reports an AHB error.
- The programmed channel transfer is stopped (GPDMA_CxCR.EN cleared by the GPDMA hardware), the channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and the link error (GPDMA_CxSR.ULEF = 1).
- After a GPDMA link error, the user must perform a debug session, taking care of the product-defined memory mapping of the linked-list data structure (GPDMA_CxLBAR and GPDMA_CxLLR), including the protection attributes.
- After a GPDMA link error, the user must explicitly write the linked-list register file (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR and GPDMA_CxLLR, plus GPDMA_CxTR3 and GPDMA_CxBR2), before the user enables again the same channel for a next transfer.

User setting error

on a tentative execution of a GPDMA transfer with an unauthorized user setting:

- The programmed channel transfer is disabled (GPDMA_CxCR.EN forced and cleared by the GPDMA hardware) preventing the next unauthorized programmed data transfer from being executed. The channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and a user setting error (GPDMA_CxSR.USEF = 1).
- After a GPDMA user setting error, the user must perform a debug session, taking care of the GPDMA channel programming. A user setting error can be caused by one of the following:
  - a programmed null source block size without a programmed update of this value from the next LLI_1 (GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxLLR.UB1 = 0)
  - a programmed non-null source block size being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxBR1.BNDT[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
  - when in packing/unpacking mode (if PAM[1] = 1), a programmed non-null source block size being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxBR1.BNDT[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
  - a programmed unaligned source start address, being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxSAR[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
  - for channel x (x = 6 to 7): a programmed unaligned source address offset being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxTR3.SAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
  - for channel x (x = 6 to 7): a programmed unaligned block repeated source address offset being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxBR2.BRSAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
  - a programmed unaligned destination start address, being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxDAR[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
  - for channel x (x = 6 to 7): a programmed unaligned destination address offset being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxTR3.DAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])

- for channel x (x = 6 to 7): a programmed unaligned block repeated destination address offset being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxBR2.BRDAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
- a programmed double-word source data width (GPDMA_CxTR1.SDW_LOG2[1:0] = 11)
- a programmed double-word destination data width (GPDMA_CxTR1.DDW_LOG2[1:0] = 11)
- a programmed linked-list item LLI_{n+1} with a null data transfer (GPDMA_CxLLR.UB1 = 1 and GPDMA_CxBR1. BNDT = 0)

16.4.18 GPDMA autonomous mode

To save dynamic power consumption while the GPDMA executes the programmed linked-list transfers, the GPDMA hardware automatically manages its own clock gating and generates a clock request output signal to the RCC, whenever the device is in Run or low-power modes, provided that the RCC is programmed with the corresponding GPDMA enable control bits.

For more details about the RCC programming, refer to the RCC section of the reference manual.

For mode details about the availability of the GPDMA autonomous feature vs the device low-power modes, refer to *Section 16.3.3*.

The user can program and schedule the execution of a given GPDMA transfer at a LLI_n level of a GPDMA channel x, with GPDMA_CxTR2 as follows:

- The software controls and conditions the input of a transfer with TRIGM[1:0], TRIGPOL[1:0], TRIGSEL[5:0], SWREQ and REQSEL[7:0] for the input trigger and request.
- The software controls and signals the output of a transfer with TCEM[1:0] for generating or not a transfer complete event, and generating or not an associated half data transfer event).

See *GPDMA channel x transfer register 2 (GPDMA_CxTR2)* for more details.

When used in low-power modes, this functionality enables a CPU wake-up on a specific transfer completion by the enabled GPDMA transfer complete interrupt (GPDMA_CxCR.TCIE = 1) or/and enables to continue with the autonomous GPDMA for operating another LLI_{n+1} transfer over the same channel.

The output channel x transfer complete event, gpdma_chx_tc, can be programmed as a selected input trigger for a channel if this event is looped-back and connected at the GPDMA level (see *Section 16.3.7*), allowing autonomous and fine GPDMA inter-channel transfer scheduling, without needing a cleared transfer complete flag (TCF).

A given GPDMA channel x asserts its clock request in one of the following conditions:

- if the next transfer to be executed is programmed as conditioned by a trigger (GPDMA_CxTR2.TRIGPOL[1:0] and GPDMA_CxTR2.TRIGM[1:0]), only when the trigger hit occurs.
- if the next transfer to be executed is not conditioned by a trigger:
  - if GPDMA_CxTR2.SWREQ = 0, only when the hardware request is asserted by the selected peripheral

– if GPDMA_CxTR2.SWREQ = 1 (memory-to-memory, GPIO to/from memory), as soon as the GPDMA is enabled

The GPDMA channel x releases its clock request as soon as all the following conditions are met:

- The transfer to be executed is completed.
- The GPDMA channel x is not immediately ready and requested to execute the next transfer.
- If a channel x interrupt was raised, all the flags of the status register that can cause this interrupt, are cleared by a software agent.

When one channel asserts its clock request, the GPDMA asserts its clock request to the RCC. When none channel asserts its clock request, the GPDMA releases its clock request to the RCC.

16.5 GPDMA in debug mode

When the microcontroller enters debug mode (core halted), any channel x can be individually either continued (default) or suspended, depending on the programmable control bit in the DBGMCU module.

Note: In debug mode, GPDMA_CxSR.SUSPF is not altered by a suspension from the programmable control bit in the DBGMCU module. In this case, GPDMA_CxSR.IDLEF can be checked to know the completion status of the channel suspension.

16.6 GPDMA in low-power modes

Table 132. Effect of low-power modes on GPDMA

Mode	Description
Sleep	No effect. GPDMA interrupts cause the device to exit Sleep mode.
Stop(1)	The content of the GPDMA registers is kept when entering Stop mode. The content of the GPDMA registers can be autonomously updated by a next linked-list item from memory, to perform autonomous data transfers. GPDMA interrupts can cause the device to exit Stop mode(1).
Standby	The GPDMA is powered down and must be reinitialized after exiting Standby mode.

1. Refer to *Section 16.3.3* to know if any Stop mode is supported.

16.7 GPDMA interrupts

There is one GPDMA interrupt line for each channel, and separately for each CPU (if several ones in the devices).

Table 133. GPDMA interrupt requests

Interrupt acronym	Interrupt event	Interrupt enable	Event flag	Event clear method
GPDMA_CHx	Transfer complete	GPDMA_CxCR.TCIE	GPDMA_CxSR.TCF	Write 1 to GPDMA_CxFCR.TCF
	Half transfer	GPDMA_CxCR.HTIE	GPDMA_CxSR.HTF	Write 1 to GPDMA_CxFCR.HTF
	Data transfer error	GPDMA_CxCR.DTEIE	GPDMA_CxSR.DTEF	Write 1 to GPDMA_CxFCR.DTEF
	Update link error	GPDMA_CxCR.ULEIE	GPDMA_CxSR.ULEF	Write 1 to GPDMA_CxFCR.ULEF
	User setting error	GPDMA_CxCR.USEIE	GPDMA_CxSR.USEF	Write 1 to GPDMA_CxFCR.USEF
	Suspended	GPDMA_CxCR.SUSPIE	GPDMA_CxSR.SUSPF	Write 1 to GPDMA_CxFCR.SUSPF
	Trigger overrun	GPDMA_CxCR.TOFIE	GPDMA_CxSR.TOF	Write 1 to GPDMA_CxFCR.TOF

A GPDMA channel x event may be:

- a transfer complete
- a half-transfer complete
- a transfer error, due to either:
  - a data transfer error
  - an update link error
  - a user setting error completed suspension
- a trigger overrun

Note: When a channel x transfer complete event occurs, the output signal gpdma_chx_tc is generated as a high pulse of one clock cycle.

An interrupt is generated following any xx event, provided that both:

- the corresponding interrupt event xx is enabled (GPDMA_CxCR.xxIE = 1)
- the corresponding event flag is cleared (GPDMA_CxSR.xxF = 0). This means that, after a previous same xx event occurrence, a software agent must have written 1 into the corresponding xx flag clear control bit (write 1 into GPDMA_CxFCR.xxF).

TCF (transfer complete) and HTF (half transfer) events generation is controlled by GPDMA_CxTR2.TCEM[1:0] as follows:

- A transfer complete event is a block transfer complete, a 2D/repeated block transfer complete, or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode GPDMA_CxTR2.TCEM[1:0].

- A half transfer event is an half block transfer or a half 2D/repeated block transfer, depending on the transfer complete event mode GPDMA_CxTR2.TCEM[1:0].

  A half-block transfer occurs when half of the source block size bytes (rounded-up integer of GPDMA_CxBR1.BNDT[15:0] / 2) is transferred to the destination.

  A half 2D/repeated block transfer occurs when half of the repeated blocks (rounded-up integer of (GPDMA_CxBR1.BRC[10:0] + 1) / 2) is transferred to the destination.

See *GPDMA channel x transfer register 2 (GPDMA_CxTR2)* for more details.

A transfer error rises in one of the following situations:

- during a single/burst data transfer from the source or to the destination (DTEF)
- during an update of a GPDMA channel register from the programmed LLI in memory (ULEF)
- during a tentative execution of a GPDMA channel with an unauthorized setting (USEF)

  The user must perform a debug session to correct the GPDMA channel programming versus the USEF root causes list (see *Section 16.4.17*).

A trigger overrun is described in *Trigger hit memorization and trigger overrun flag generation*.

16.8 GPDMA registers

The GPDMA registers must be accessed with an aligned 32-bit word data access.

16.8.1 GPDMA secure configuration register (GPDMA_SECCFGR)

Address offset: 0x00

Reset value: 0x0000 0000

A write access to this register must be secure and privileged. A read access is secure or nonsecure, privileged or unprivileged.

A write access is ignored at bit level if the corresponding channel x is locked (GPDMA_RCFGLOCKR.LOCKx = 1).

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be programmed at a bit level, at the initialization/closure of a GPDMA channel (when GPDMA_CxCR.EN = 0), to securely allocate individually any channel x to the secure or nonsecure world.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **SECx**: secure state of channel x (x = 7 to 0)
0: nonsecure
1: secure

16.8.2 GPDMA privileged configuration register (GPDMA_PRIVCFGR)

Address offset: 0x04

Reset value: 0x0000 0000

A write access to this register must be privileged. A read access can be privileged or unprivileged, secure or nonsecure.

This register can mix secure and nonsecure information. If a channel x is configured as secure (GPDMA_SECCFGR.SECx = 1), the PRIVx bit can be written only by a secure (and privileged) agent.

A write access is ignored at bit level if the corresponding channel x is locked (GPDMA_RCFGLOCKR.LOCKx = 1).

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN =1.

This register must be programmed at a bit level, at the initialization/closure of a GPDMA channel (GPDMA_CxCR.EN = 0), to individually allocate any channel x to the privileged or unprivileged world.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **PRIVx**: privileged state of channel x (x = 7 to 0)
0: unprivileged
1: privileged

16.8.3 GPDMA configuration lock register (GPDMA_RCFGLOCKR)

Address offset: 0x08

Reset value: 0x0000 0000

This register can be written by a software agent with secure privileged attributes in order to individually lock, for example at boot time, the secure privileged attributes of any GPDMA

channel/resource (to lock the setting of GPDMA_CxSECCFGR and GPDMA_CxPRIVCFGR for any channel x, for example at boot time).

A read access may be privileged or unprivileged, secure or nonsecure.

Note: If TZEN = 0, this register cannot be written.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LOCK7	LOCK6	LOCK5	LOCK4	LOCK3	LOCK2	LOCK1	LOCK0
								rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **LOCKx**: lock the configuration of GPDMA_SECCFGR.SECx and GPDMA_PRIVCFGR.PRIVx, until a global GPDMA reset (x = 7 to 0)

This bit is cleared after reset and, once set, it cannot be reset until a global GPDMA reset.

0: secure privilege configuration of the channel x is writable.

1: secure privilege configuration of the channel x is not writable.

16.8.4 GPDMA nonsecure masked interrupt status register (GPDMA_MISR)

Address offset: 0x0C

Reset value: 0x0000 0000

This register is a read register.

This is a nonsecure register, containing the masked interrupt status bit MISx for each nonsecure channel x (channel x configured with GPDMA_SECCFGR.SECx = 0). It is a logical OR of all the flags of GPDMA_CxSR, each source flag being enabled by the corresponding interrupt enable bit of GPDMA_CxCR.

Every bit is deasserted by hardware when writing 1 to the corresponding flag clear bit in GPDMA_CxFCR.

If a channel x is in secure state (GPDMA_SECCFGR.SECx = 1), a read access to the masked interrupt status bit MISx of this channel x returns zero.

This register may mix privileged and unprivileged information, depending on the privileged state of each channel GPDMA_PRIVCFGR.PRIVx. A privileged software can read the full nonsecure interrupt status. An unprivileged software is restricted to read the status of unprivileged (and nonsecure) channels, other privileged bit fields returning zero.

								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **MISx**: masked interrupt status of channel x (x = 7 to 0)
0: no interrupt occurred on channel x
1: an interrupt occurred on channel x

16.8.5 GPDMA secure masked interrupt status register (GPDMA_SMISR)

Address offset: 0x10

Reset value: 0x0000 0000

This is a secure read register, containing the masked interrupt status bit MISx for each secure channel x (GPDMA_SECCFGR.SECx = 1). It is a logical OR of all the GPDMA_CxSR flags, each source flag being enabled by the corresponding GPDMA_CxCR interrupt enable bit.

Every bit is deasserted by hardware when securely writing 1 to the corresponding GPDMA_CxFCR flag clear bit.

This register does not contain any information about a nonsecure channel.

This register can mix privileged and unprivileged information, depending on the privileged state of each channel GPDMA_PRIVCFGR.PRIVx. A privileged software can read the full secure interrupt status. An unprivileged software is restricted to read the status of unprivileged and secure channels, other privileged bit fields returning zero.

								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **MISx**: masked interrupt status of the secure channel x (x = 7 to 0)
0: no interrupt occurred on the secure channel x
1: an interrupt occurred on the secure channel x

16.8.6 GPDMA channel x linked-list base address register (GPDMA_CxLBAR)

Address offset: 0x50 + 0x80 * x (x = 0 to 7)

Reset value: 0x0000 0000

This register must be written by a privileged software. It is either privileged readable or not, depending on the privileged state of the channel x GPDMA_PRIVCFGR.PRIVx.

This register is either secure or nonsecure depending on the secure state of the channel x (GPDMA_SECCFGR.SECx).

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This channel-based register is the linked-list base address of the memory region, for a given channel x, from which the LLIs describing the programmed sequence of the GPDMA transfers, are conditionally and automatically updated.

This 64-Kbyte aligned channel x linked-list base address is offset by the 16-bit GPDMA_CxLLR register that defines the word-aligned address offset for each LLI.

Bits 31:16 **LBA[31:16]**: linked-list base address of GPDMA channel x

Bits 15:0 Reserved, must be kept at reset value.

16.8.7 GPDMA channel x flag clear register (GPDMA_CxFCR)

Address offset: 0x5C+ 0x80 * x (x = 0 to 7)

Reset value: 0x0000 0000

This is a write register, secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx) and privileged or unprivileged, depending on the privileged state of the channel x (GPDMA_PRIVCFGR.PRIVx).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	w	w	w	w	w	w	w								

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **TOF**: trigger overrun flag clear
0: no effect
1: corresponding TOF flag cleared

Bit 13 **SUSPF**: completed suspension flag clear
0: no effect
1: corresponding SUSPF flag cleared

Bit 12 **USEF**: user setting error flag clear
0: no effect
1: corresponding USEF flag cleared

Bit 11 **ULEF**: update link transfer error flag clear
0: no effect
1: corresponding ULEF flag cleared

Bit 10 **DTEF**: data transfer error flag clear
0: no effect
1: corresponding DTEF flag cleared

Bit 9 **HTF**: half transfer flag clear
0: no effect
1: corresponding HTF flag cleared

Bit 8 **TCF**: transfer complete flag clear
0: no effect
1: corresponding TCF flag cleared

Bits 7:0 Reserved, must be kept at reset value.

16.8.8 GPDMA channel x status register (GPDMA_CxSR)

Address offset: 0x60 + 0x80 * x (x = 0 to 7)

Reset value: 0x0000 0001

This is a read register, reporting the channel status.

This register is secure or nonsecure, depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of the channel (GPDMA_PRIVCFGR.PRIVx).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FIFOL[7:0]

	r	r	r	r	r	r	r								r

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **FIFOL[7:0]**: monitored FIFO level

Number of available write beats in the FIFO, in units of the programmed destination data width (see GPDMA_CxTR1.DDW_LOG2[1:0], in units of bytes, half-words, or words).

Note: After having suspended an active transfer, the user may need to read FIFOL[7:0], additionally to GPDMA_CxBR1.BDNT[15:0] and GPDMA_CxBR1.BRC[10:0], to know how many data have been transferred to the destination. Before reading, the user may wait for the transfer to be suspended (GPDMA_CxSR.SUSPF = 1).

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TOF**: trigger overrun flag

0: no trigger overrun event

1: a trigger overrun event occurred

Bit 13 **SUSPF**: completed suspension flag

0: no completed suspension event

1: a completed suspension event occurred

Bit 12 **USEF**: user setting error flag

0: no user setting error event

1: a user setting error event occurred

Bit 11 **ULEF**: update link transfer error flag

0: no update link transfer error event

1: a master bus error event occurred while updating a linked-list register from memory

Bit 10 **DTEF**: data transfer error flag

0: no data transfer error event

1: a master bus error event occurred on a data transfer

Bit 9 **HTF**: half transfer flag

0: no half transfer event

1: a half transfer event occurred

A half transfer event is either a half block transfer or a half 2D/repeated block transfer, depending on the transfer complete event mode (GPDMA_CxTR2.TCEM[1:0]).

A half block transfer occurs when half of the bytes of the source block size (rounded up integer of GPDMA_CxBR1.BNDT[15:0]/2) has been transferred to the destination.

A half 2D/repeated block transfer occurs when half of the repeated blocks (rounded up integer of (GPDMA_CxBR1.BRC[10:0] + 1) / 2)) has been transferred to the destination.

Bit 8 **TCF**: transfer complete flag

0: no transfer complete event

1: a transfer complete event occurred

A transfer complete event is either a block transfer complete, a 2D/repeated block transfer complete, or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode (GPDMA_CxTR2.TCEM[1:0]).

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **IDLEF**: idle flag

0: channel not in idle state

1: channel in idle state

This idle flag is deasserted by hardware when the channel is enabled (GPDMA_CxCR.EN = 1) with a valid channel configuration (no USEF to be immediately reported).

This idle flag is asserted after hard reset or by hardware when the channel is back in idle state (in suspended or disabled state).

16.8.9 GPDMA channel x control register (GPDMA_CxCR)

Address offset: 0x64 + 0x80 * x (x = 0 to 7)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of the channel x (GPDMA_PRIVCFGR.PRIVx).

This register is used to control a channel (activate, suspend, abort or disable it).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRIO[1:0]		Res.	Res.	Res.	Res.	LAP	LSM
								rw	rw					rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	TOIE	SUSPIE	USEIE	ULEIE	DTEIE	HTIE	TCIE	Res.	Res.	Res.	Res.	Res.	SUSP	RESET	EN
	rw	rw	rw	rw	rw	rw	rw						rw	w	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 **PRIO[1:0]:** priority level of the channel x GPDMA transfer versus others
00: low priority, low weight
01: low priority, mid weight
10: low priority, high weight
11: high priority
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bits 21:18 Reserved, must be kept at reset value.

Bit 17 **LAP**: linked-list allocated port
This bit is used to allocate the master port for the update of the GPDMA linked-list registers from the memory.
0: port 0 (AHB) allocated
1: port 1 (AHB) allocated
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 16 **LSM**: Link step mode
0: channel executed for the full linked-list and completed at the end of the last LLI (GPDMA_CxLLR = 0). The 16 low-significant bits of the link address are null (LA[15:0] = 0) and all the update bits are null (UT1 = UB1 = UT2 = USA = UDA = ULL = 0 and UT3 = UB2 = 0). Then GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0.
1: channel executed **once** for the current LLI
First the (possible 1D/repeated) block transfer is executed as defined by the current internal register file until GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0. Secondly the next linked-list data structure is conditionally uploaded from memory as defined by GPDMA_CxLLR. Then channel execution is completed.
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TOIE**: trigger overrun interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 13 **SUSPIE**: completed suspension interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 12 **USEIE**: user setting error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 11 **ULEIE**: update link transfer error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 10 **DTEIE**: data transfer error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 9 **HTIE**: half transfer complete interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 8 **TCIE**: transfer complete interrupt enable
0: interrupt disabled
1: interrupt enabled

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **SUSP:** suspend
Writing 1 into the field RESET (bit 1) causes the hardware to de-assert this bit, whatever is written into this bit 2. Else:
Software must write 1 in order to suspend an active channel (channel with an ongoing GPDMA transfer over its master ports).
The software must write 0 in order to resume a suspended channel, following the programming sequence detailed in *Figure 68*.
0: write: resume channel, read: channel not suspended
1: write: suspend channel, read: channel suspended.

Bit 1 **RESET:** reset
This bit is write only. Writing 0 has no impact. Writing 1 implies the reset of the following: the FIFO, the channel internal state, SUSP and EN bits (whatever is written receptively in bit 2 and bit 0).
The reset is effective when the channel is in steady state, meaning one of the following:
- active channel in suspended state (GPDMA_CxSR.SUSPF = 1 and GPDMA_CxSR.IDLEF = GPDMA_CxCR.EN = 1)
- channel in disabled state (GPDMA_CxSR.IDLEF = 1 and GPDMA_CxCR.EN = 0).
After writing a RESET, to continue using this channel, the user must explicitly reconfigure the channel including the hardware-modified configuration registers (GPDMA_CxBR1, GPDMA_CxSAR, and GPDMA_CxDAR) before enabling again the channel (see the programming sequence in *Figure 69*).
0: no channel reset
1: channel reset

Bit 0 **EN:** enable

Writing 1 into the field RESET (bit 1) causes the hardware to de-assert this bit, whatever is written into this bit 0. Else:

this bit is deasserted by hardware when there is a transfer error (master bus error or user setting error) or when there is a channel transfer complete (channel ready to be configured, for example if LSM = 1 at the end of a single execution of the LLI).

Else, this bit can be asserted by software.

Writing 0 into this EN bit is ignored.

0: write: ignored, read: channel disabled

1: write: enable channel, read: channel enabled

16.8.10 GPDMA channel x transfer register 1 (GPDMA_CxTR1)

Address offset: 0x90 + 0x80 * x (x = 0 to 7)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx) except for secure DSEC and SSEC, privileged or non-privileged, depending on the privileged state of the channel x in GPDMA_PRIVCFGR.PRIVx.

This register controls the transfer of a channel x.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed. Then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory if GPDMA_CxLLR.UT1 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DSEC	DAP	Res.	Res.	DHX	DBX	DBL_1[5:0]						DINC	Res.	DDW_LOG2[1:0]	
rw	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SSEC	SAP	SBX	PAM[1:0]		Res.	SBL_1[5:0]						SINC	Res.	SDW_LOG2[1:0]	
rw	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw		rw	rw

Bit 31 **DSEC**: security attribute of the GPDMA transfer to the destination

If GPDMA_SECCFGR.SECx = 1 and the access is secure:

0: GPDMA transfer nonsecure

1: GPDMA transfer secure

This is a secure register bit. This bit can only be read by a secure software. This bit must be written by a secure software when GPDMA_SECCFGR.SECx = 1. A secure write is ignored when GPDMA_SECCFGR.SECx = 0.

When GPDMA_SECCFGR.SECx is deasserted, this DSEC bit is also deasserted by hardware (on a secure reconfiguration of the channel as nonsecure), and the GPDMA transfer to the destination is nonsecure.

Bit 30 **DAP**: destination allocated port

This bit is used to allocate the master port for the destination transfer

0: port 0 (AHB) allocated

1: port 1 (AHB) allocated

Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bits 29:28 Reserved, must be kept at reset value.

Bit 27 **DHX**: destination half-word exchange

If the destination data size is shorter than a word, this bit is ignored.

If the destination data size is a word:

0: no halfword-based exchanged within word

1: the two consecutive (post PAM) half-words are exchanged in each destination word.

Bit 26 **DBX**: destination byte exchange

If the destination data size is a byte, this bit is ignored.

If the destination data size is not a byte:

0:no byte-based exchange within half-word

1: the two consecutive (post PAM) bytes are exchanged in each destination half-word.

Bits 25:20 **DBL_1[5:0]**: destination burst length minus 1, between 0 and 63

The burst length unit is one data named beat within a burst. If DBL_1[5:0] = 0, the burst can be named as single. Each data/beat has a width defined by the destination data width DDW_LOG2[1:0].

Note: If a burst transfer crossed a 1-Kbyte address boundary on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol.

If a burst transfer is of length greater than the FIFO size of the channel x, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the FIFO size. Transfer performance is lower, with GPDMA re-arbitration between effective and lower singles/bursts, but the data integrity is guaranteed.

Bit 19 **DINC**: destination incrementing burst

0: fixed burst

1: contiguously incremented burst

The destination address, pointed by GPDMA_CxDAR, is kept constant after a burst beat/single transfer, or is incremented by the offset value corresponding to a contiguous data after a burst beat/single transfer.

Bit 18 Reserved, must be kept at reset value.

Bits 17:16 **DDW_LOG2[1:0]**: binary logarithm of the destination data width of a burst, in bytes

00: byte

01: half-word (2 bytes)

10: word (4 bytes)

11: user setting error reported and no transfer issued

Note: Setting a 8-byte data width causes a user setting error to be reported and none transfer is issued.

A destination burst transfer must have an aligned address with its data width (start address GPDMA_CxDAR[2:0] and address offset GPDMA_CxTR3.DAO[2:0], versus DDW_LOG2[1:0]). Otherwise a user setting error is reported and no transfer is issued.

Bit 15 **SSEC**: security attribute of the GPDMA transfer from the source

If GPDMA_SECCFGR.SECx = 1 and the access is secure:

0: GPDMA transfer nonsecure

1: GPDMA transfer secure

This is a secure register bit. This bit can only be read by a secure software. This bit must be written by a secure software when GPDMA_SECCFGR.SECx = 1. A secure write is ignored when GPDMA_SECCFGR.SECx = 0.

When GPDMA_SECCFGR.SECx is deasserted, this SSEC bit is also deasserted by hardware (on a secure reconfiguration of the channel as nonsecure), and the GPDMA transfer from the source is nonsecure.

Bit 14 **SAP**: source allocated port

This bit is used to allocate the master port for the source transfer

0: port 0 (AHB) allocated

1: port 1 (AHB) allocated

Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 13 **SBX**: source byte exchange within the unaligned half-word of each source word

If the source data width is shorter than a word, this bit is ignored.

If the source data width is a word:

0:no byte-based exchange within the unaligned half-word of each source word

1: the two consecutive bytes within the unaligned half-word of each source word are exchanged.

Bits 12:11 **PAM[1:0]**: padding/alignment mode

If DDW_LOG2[1:0] = SDW_LOG2[1:0]: if the data width of a burst destination transfer is equal to the data width of a burst source transfer, these bits are ignored.

Else, in the following enumerated values, the condition PAM_1 is when destination data width is higher than source data width, and the condition PAM_2 is when source data width is higher than destination data width.

Condition: PAM_1

00: source data is transferred as right aligned, padded with 0s up to the destination data width

01: source data is transferred as right aligned, sign extended up to the destination data width

10-11: successive source data are FIFO queued and packed at the destination data width, in a left (LSB) to right (MSB) order (named little endian), before a destination transfer

Condition: PAM_2

00: source data is transferred as right aligned, left-truncated down to the destination data width

01: source data is transferred as left-aligned, right-truncated down to the destination data width

10-11: source data is FIFO queued and unpacked at the destination data width, to be transferred in a left (LSB) to right (MSB) order (named little endian) to the destination

Note: If the transfer from the source peripheral is configured with peripheral flow-control mode (SWREQ = 0 and PFREQ = 1 and DREQ = 0), and if the destination data width > the source data width, packing is not supported.

Bit 10 Reserved, must be kept at reset value.

Bits 9:4 **SBL_1[5:0]**: source burst length minus 1, between 0 and 63

The burst length unit is one data named beat within a burst. If SBL_1[5:0] = 0, the burst can be named as single. Each data/beat has a width defined by the destination data width SDW_LOG2[1:0].

Note: If a burst transfer crossed a 1-Kbyte address boundary on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol.

If a burst transfer is of length greater than the FIFO size of the channel x, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the FIFO size. Transfer performance is lower, with GPDMA re-arbitration between effective and lower singles/bursts, but the data integrity is guaranteed.

Bit 3 **SINC**: source incrementing burst

0: fixed burst

1: contiguously incremented burst

The source address, pointed by GPDMA_CxSAR, is kept constant after a burst beat/single transfer or is incremented by the offset value corresponding to a contiguous data after a burst beat/single transfer.

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **SDW_LOG2[1:0]**: binary logarithm of the source data width of a burst in bytes

00: byte

01: half-word (2 bytes)

10: word (4 bytes)

11: user setting error reported and no transfer issued

Note: Setting a 8-byte data width causes a user setting error to be reported and no transfer is issued.

A source block size must be a multiple of the source data width (GPDMA_CxBR1.BNDT[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and no transfer is issued.

A source burst transfer must have an aligned address with its data width (start address GPDMA_CxSAR[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and none transfer is issued.

16.8.11 GPDMA channel x transfer register 2 (GPDMA_CxTR2)

Address offset: 0x94 + 0x80 * x (x = 0 to 7)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (the hardware deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory, if GPDMA_CxLLR.UT2 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TCEM[1:0]		Res.	Res.	Res.	Res.	TRIGPOL[1:0]		Res.	Res.	TRIGSEL[5:0]					
rw	rw					rw	rw			rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TRIGM[1:0]		Res.	PFREQ	BREQ	DREQ	SWREQ	Res.	REQSEL[7:0]							
rw	rw		rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 **TCEM[1:0]**: transfer complete event mode

These bits define the transfer granularity for the transfer complete and half transfer complete events generation.

00: at block level (when GPDMA_CxBR1.BNDT[15:0] = 0): the complete (and the half) transfer event is generated at the (respectively half of the) end of a block.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half transfer event is generated.

01: channel x (x = 0 to 5), same as 00, channel x (x = 6 to 7), at 2D/repeated block level (when GPDMA_CxBR1.BRC[10:0] = 0 and GPDMA_CxBR1.BNDT[15:0] = 0). The complete (and the half) transfer event is generated at the end (respectively half of the end) of the 2D/repeated block.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half transfer event is generated.

10: at LLI level: the complete transfer event is generated at the end of the LLI transfer, including the update of the LLI if any. The half transfer event is generated at the half of the LLI data transfer The LLI data transfer is a block transfer or a 2D/repeated block transfer for channel x (x = 6 to 7), if any data transfer.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then the half transfer event is not generated, and the transfer complete event is generated when is completed the loading of the LLI_1.

11: at channel level: the complete transfer event is generated at the end of the last LLI transfer. The half transfer event is generated at the half of the data transfer of the last LLI. The last LLI updates the link address GPDMA_CxLLR.LA[15:2] to zero and clears all the GPDMA_CxLLR update bits (UT1, UT2, UB1, USA, UDA and ULL, plus UT3 and UB2). If the channel transfer is continuous/infinite, no event is generated.

Bits 29:26 Reserved, must be kept at reset value.

Bits 25:24 **TRIGPOL[1:0]**: trigger event polarity

These bits define the polarity of the selected trigger event input defined by TRIGSEL[5:0].

00: no trigger (masked trigger event)

01: trigger on the rising edge

10: trigger on the falling edge

11: same as 00

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:16 **TRIGSEL[5:0]**: trigger event input selection

These bits select the trigger event input of the GPDMA transfer (as per *Section 16.3.7*), with an active trigger event if TRIGPOL[1:0] ≠ 00.

Bits 15:14 **TRIGM[1:0]**: trigger mode

These bits define the transfer granularity for its conditioning by the trigger.

If the channel x is enabled (GPDMA_CxCR.EN asserted) with TRIGPOL[1:0] = 00 or 11, these TRIGM[1:0] bits are ignored.

Else, a GPDMA transfer is conditioned by at least one trigger hit:

00: at block level: the first burst read of each block transfer is conditioned by one hit trigger (channel x = 12 to 15, for each block if a 2D/repeated block is configured with GPDMA_CxBR1.BRC[10:0] ≠ 0).

01: channel x (x = 0 to 5), same as 00; channel x (x = 6 to 7), at 2D/repeated block level. The first burst read of a 2D/repeated block transfer is conditioned by one hit trigger.

10: at link level: a LLI link transfer is conditioned by one hit trigger. The LLI data transfer (if any) is not conditioned.

11: at programmed burst level: If SWREQ = 1, each programmed burst read is conditioned by one hit trigger. If SWREQ = 0, each programmed burst that is requested by the selected peripheral, is conditioned by one hit trigger.

– If the peripheral is programmed as a source (DREQ = 0) of the LLI data transfer, each programmed burst read is conditioned.

– If the peripheral is programmed as a destination (DREQ = 1) of the LLI data transfer, each programmed burst write is conditioned. The first memory burst read of a (possibly 2D/repeated) block, also named as the first ready FIFO-based source burst, is gated by the occurrence of both the hardware request and the first trigger hit.

The GPDMA monitoring of a trigger for channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (TRIGPOL[1:0] = 01 or respectively TRIGPOL[1:0] = 10).

The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer; and if a new trigger is detected then, this hit is internally memorized to grant the next transfer, as long as the defined rising or falling edge is not modified, and the TRIGSEL[5:0] is not modified, and the channel is enabled.

Transferring a next LLI_{n+1} that updates the GPDMA_CxTR2 with a new value for any of TRIGSEL[5:0] or TRIGPOL[1:0], resets the monitoring, trashing the memorized hit of the formerly defined LLI_n trigger.

After a first new trigger hit_{n+1} is memorized, if another second trigger hit_{n+2} is detected and if the hit_n triggered transfer is still not completed, hit_{n+2} is lost and not memorized.memorized. A trigger overrun flag is reported (GPDMA_CxSR.TOF = 1), and an interrupt is generated if enabled (GPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

Note: When the source block size is not a multiple of the source burst size and is a multiple of the source data width, then the last programmed source burst is not completed and is internally shorten to match the block size. In this case, if TRIGM[1:0] = 11 and (SWREQ = 1 or (SWREQ = 0 and DREQ = 0)), the shortened burst transfer (by singles or/and by bursts of lower length) is conditioned once by the trigger.

When the programmed destination burst is internally shortened by singles or/and by bursts of lower length (versus FIFO size, versus block size, 1-Kbyte boundary address crossing): if the trigger is conditioning the programmed destination burst (if TRIGM[1:0] = 11 and SWREQ = 0 and DREQ = 1), this shortened destination burst transfer is conditioned once by the trigger.

Bit 13 Reserved, must be kept at reset value.

Bit 12 **PFREQ**: Hardware request in peripheral flow control mode

Important: If a given channel x is not implemented with this feature, this bit is reserved and PFREQ is not present (see Section 16.3.2 for the list of the implemented channels with this feature).

If the channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:

0: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol in GPDMA control mode. The GPDMA is programmed with GPDMA_CxTR1.BNDT[15:0] and this is internally used by the hardware for the block transfer completion.

1: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol in peripheral control mode. The GPDMA block transfer can be early completed by the peripheral itself (see *Section 16.3.6* for more details).

Note: In peripheral flow control mode, there are the following restrictions:

- no 2D/repeated block support (GPDMA_CxBR1.BRC[10:0] must be set to 0)

- the peripheral must be set as the source of the transfer (DREQ = 0).

- data packing to a wider destination width is not supported (if destination width > source data width, GPDMA_CxTR1.PAM[1] must be set to 0).

- GPDMA_CxBR1.BNDT[15:0] must be programmed as a multiple of the source (peripheral) burst size.

Bit 11 **BREQ**: Block hardware request

If the channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:

0: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a burst level.

1: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a block level (see *Section 16.3.4*).

Bit 10 **DREQ**: destination hardware request

This bit is ignored if channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer). Else:

0: selected hardware request driven by a source peripheral (request signal taken into account by the GPDMA transfer scheduler over the source/read port)

1: selected hardware request driven by a destination peripheral (request signal taken into account by the GPDMA transfer scheduler over the destination/write port)

Note: If the channel x is activated (GPDMA_CxCR.EN is asserted) with SWREQ = 0 and PFREQ = 1 (peripheral hardware request with peripheral flow-control mode), any software assertion to this DREQ bit is ignored: in peripheral flow-control mode, only a peripheral-to-memory transfer is supported.

Bit 9 **SWREQ**: software request

This bit is internally taken into account when GPDMA_CxCR.EN is asserted.

0: no software request. The selected hardware request REQSEL[7:0] is taken into account.

1: software request for a memory-to-memory transfer. The default selected hardware request as per REQSEL[7:0] is ignored.

Bit 8 Reserved, must be kept at reset value.

Bits 7:0 **REQSEL[7:0]**: GPDMA hardware request selection

These bits are ignored if channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1(software request for a memory-to-memory transfer). Else, the selected hardware request is internally taken into account as per *Section 16.3.4*.

Caution: The user must not assign a same input hardware request (same REQSEL[7:0] value) to different active GPDMA channels (GPDMA_CxCR.EN = 1 and GPDMA_CxTR2.SWREQ = 0 for these channels). GPDMA is not intended to hardware support the case of simultaneous enabled channels incorrectly configured with a same hardware peripheral request signal, and there is no user setting error reporting.

16.8.12 GPDMA channel x block register 1 (GPDMA_CxBR1)

Address offset: 0x98 + 0x80 * x (x = 0 to 5)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, or LLI or full linked-list.

In linked-list mode, during the link transfer:

- if GPDMA_CxLLR.UB1 = 1, this register is automatically updated by the GPDMA from the next LLI in memory.
- If GPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed value for the field BNDT[15:0].
- If all the update bits GPDMA_CxLLR.Uxx are null and if GPDMA_CxLLR.LA[15:0] ≠ 0, the current LLI is the last one and is continuously executed: this register is automatically and internally restored with the programmed value for BNDT[15:0] after each execution of this final LLI
- If GPDMA_CxLLR = 0, this register and BNDT[15:0] are kept as null, channel x is completed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BNDT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **BNDT[15:0]**: block number of data bytes to transfer from the source

Block size transferred from the source. When the channel is enabled, this field becomes read-only and is decremented, indicating the remaining number of data items in the current source block to be transferred. BNDT[15:0] is programmed in number of bytes, maximum source block size is 64 Kbytes -1.

Once the last data transfer is completed (BNDT[15:0] = 0):

- if GPDMA_CxLLR.UB1 = 1, this field is updated by the LLI in the memory.
- if GPDMA_CxLLR.UB1 = 0 and if there is at least one non null Uxx update bit, this field is internally restored to the programmed value.
- if all GPDMA_CxLLR.Uxx = 0 and if GPDMA_CxLLR.LA[15:0] = 0, this field is internally restored to the programmed value (infinite/continuous last LLI).
- if GPDMA_CxLLR = 0, this field is kept as zero following the last LLI data transfer.

Note: A non-null source block size must be a multiple of the source data width (BNDT[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

When configured in packing mode (GPDMA_CxTR1.PAM[1] = 1 and destination data width different from source data width), a non-null source block size must be a multiple of the destination data width (BNDT[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

16.8.13 GPDMA channel x alternate block register 1 (GPDMA_CxBR1)

Address offset: 0x98 + 0x80 * x (x = 6 to 7)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, or LLI or full linked-list.

In linked-list mode, during the link transfer:

- if GPDMA_CxLLR.UB1 = 1, this register is automatically updated by the GPDMA from the next LLI in memory.
- If GPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed value for the fields BNDT[15:0] and BRC[10:0].
- If all the update bits GPDMA_CxLLR.Uxx are null and if GPDMA_CxLLR.LA[15:0] ≠ 0, the current LLI is the last one and is continuously executed: this register is

automatically and internally restored with the programmed value for the fields BNDT[15:0] and BRC[10:0] after each execution of this final LLI

- If GPDMA_CxLLR = 0, BNDT[15:0] and BRC[10:0] are kept as null, channel x is completed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BRDDEC	BRSDEC	DDEC	SDEC	Res.	BRC[10:0]										
rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BNDT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **BRDDEC**: Block repeat destination address decrement

0: at the end of a block transfer, the GPDMA_CxDAR register is updated by adding the programmed offset GPDMA_CxBR2.BRDAO to the current GPDMA_CxDAR value (current destination address)

1: at the end of a block transfer, the GPDMA_CxDAR register is updated by subtracting the programmed offset GPDMA_CxBR2.BRDAO from the current GPDMA_CxDAR value (current destination address)

Note: On top of this increment/decrement (depending on BRDDEC), GPDMA_CxDAR is in the same time also updated by the increment/decrement (depending on DDEC) of the GPDMA_CxTR3.DAO value, as it is usually done at the end of each programmed burst transfer.

Bit 30 **BRSDEC**: Block repeat source address decrement

0: at the end of a block transfer, the GPDMA_CxSAR register is updated by adding the programmed offset GPDMA_CxBR2.BRSAO to the current GPDMA_CxSAR value (current source address)

1: at the end of a block transfer, the GPDMA_CxSAR register is updated by subtracting the programmed offset GPDMA_CxBR2.BRSAO from the current GPDMA_CxSAR value (current source address)

Note: On top of this increment/decrement (depending on BRSDEC), GPDMA_CxSAR is in the same time also updated by the increment/decrement (depending on SDEC) of the GPDMA_CxTR3.SAO value, as it is done after any programmed burst transfer.

Bit 29 **DDEC**: destination address decrement

0: At the end of a programmed burst transfer to the destination, the GPDMA_CxDAR register is updated by adding the programmed offset GPDMA_CxTR3.DAO to the current GPDMA_CxDAR value (current destination address)

1: At the end of a programmed burst transfer to the destination, the GPDMA_CxDAR register is updated by subtracting the programmed offset GPDMA_CxTR3.DAO to the current GPDMA_CxDAR value (current destination address)

Bit 28 **SDEC**: source address decrement

0: At the end of a programmed burst transfer from the source, the GPDMA_CxSAR register is updated by adding the programmed offset GPDMA_CxTR3.SAO to the current GPDMA_CxSAR value (current source address)

1: At the end of a programmed burst transfer from the source, the GPDMA_CxSAR register is updated by subtracting the programmed offset GPDMA_CxTR3.SAO to the current GPDMA_CxSAR value (current source address)

Bit 27 Reserved, must be kept at reset value.

Bits 26:16 **BRC[10:0]**: Block repeat counter

This field contains the number of repetitions of the current block (0 to 2047).

When the channel is enabled, this field becomes read-only. After decrements, this field indicates the remaining number of blocks, excluding the current one. This counter is hardware decremented for each completed block transfer.

Once the last block transfer is completed (BRC[10:0] = BNDT[15:0] = 0):

– If GPDMA_CxLLR.UB1 = 1, all GPDMA_CxBR1 fields are updated by the next LLI in the memory.

– If GPDMA_CxLLR.UB1 = 0 and if there is at least one not null Uxx update bit, this field is internally restored to the programmed value.

– if all GPDMA_CxLLR.Uxx = 0 and if GPDMA_CxLLR.LA[15:0] ≠ 0, this field is internally restored to the programmed value (infinite/continuous last LLI).

– if GPDMA_CxLLR = 0, this field is kept as zero following the last LLI and data transfer.

Bits 15:0 **BNDT[15:0]**: block number of data bytes to transfer from the source

Block size transferred from the source. When the channel is enabled, this field becomes read-only and is decremented, indicating the remaining number of data items in the current source block to be transferred. BNDT[15:0] is programmed in number of bytes, maximum source block size is 64 Kbytes -1.

Once the last data transfer is completed (BNDT[15:0] = 0):

- if GPDMA_CxLLR.UB1 = 1, this field is updated by the LLI in the memory.

- if GPDMA_CxLLR.UB1 = 0 and if there is at least one not null Uxx update bit, this field is internally restored to the programmed value.

- if all GPDMA_CxLLR.Uxx = 0 and if GPDMA_CxLLR.LA[15:0] ≠ 0, this field is internally restored to the programmed value (infinite/continuous last LLI).

- if GPDMA_CxLLR = 0, this field is kept as zero following the last LLI data transfer.

Note: A non-null source block size must be a multiple of the source data width (BNDT[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

When configured in packing mode (GPDMA_CxTR1.PAM[1] = 1 and destination data width different from source data width), a non-null source block size must be a multiple of the destination data width (BNDT[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

16.8.14 GPDMA channel x source address register (GPDMA_CxSAR)

Address offset: 0x9C + 0x80 * x (x = 0 to 7)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the source start address of a transfer.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next burst transfer from the source.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.USA = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SA[31:0]**: source address

This field is the pointer to the address from which the next data is read.

During the channel activity, depending on the source addressing mode (GPDMA_CxTR1.SINC), this field is kept fixed or incremented by the data width (GPDMA_CxTR1.SDW_LOG2[1:0]) after each burst source data, reflecting the next address from which data is read.

During the channel activity, this address is updated after each completed source burst, consequently to:

– the programmed source burst; either in fixed addressing mode or in contiguous-data incremented mode. If contiguously incremented (GPDMA_CxTR1.SINC = 1), then the additional address offset value is the programmed burst size, as defined by GPDMA_CxTR1.SBL_1[5:0] and GPDMA_CxTR1.SDW_LOG2[21:0]

– the additional source incremented/decremented offset value as programmed by GPDMA_CxBR1.SDEC and GPDMA_CxTR3.SAO[12:0].

– once/if completed source block transfer, for a channel x with 2D addressing capability (x = 6 to 7). additional block repeat source incremented/decremented offset value as programmed by GPDMA_CxBR1.BRSDEC and GPDMA_CxBR2.BRSAO[15:0]

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by GPDMA from the memory, provided the LLI is set with GPDMA_CxLLR.USA = 1.

Note: A source address must be aligned with the programmed data width of a source burst (SA[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

When the source block size is not a multiple of the source burst size and is a multiple of the source data width, the last programmed source burst is not completed and is internally shorten to match the block size. In this case, the additional GPDMA_CxTR3.SAO[12:0] is not applied.

16.8.15 GPDMA channel x destination address register (GPDMA_CxDAR)

Address offset: 0xA0 + 0x80 * x (x = 0 to 7)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the destination start address of a transfer.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next burst transfer to the destination.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory if GPDMA_CxLLR.UDA = 1.

DA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DA[31:0]**: destination address

This field is the pointer to the address from which the next data is written.

During the channel activity, depending on the destination addressing mode (GPDMA_CxTR1.DINC), this field is kept fixed or incremented by the data width (GPDMA_CxTR1.DDW_LOG2[21:0]) after each burst destination data, reflecting the next address from which data is written.

During the channel activity, this address is updated after each completed destination burst, consequently to:

– the programmed destination burst; either in fixed addressing mode or in contiguous-data incremented mode. If contiguously incremented (GPDMA_CxTR1.DINC = 1), then the additional address offset value is the programmed burst size, as defined by GPDMA_CxTR1.DBL_1[5:0] and GPDMA_CxTR1.DDW_LOG2[1:0]

– the additional destination incremented/decremented offset value as programmed by GPDMA_CxBR1.DDEC and GPDMA_CxTR3.DAO[12:0].

– once/if completed destination block transfer, for a channel x with 2D addressing capability (x = 6 to 7), the additional block repeat destination incremented/decremented offset value as programmed by GPDMA_CxBR1.BRDDEC and GPDMA_CxBR2.BRDAO[15:0]

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by the GPDMA from the memory, provided the LLI is set with GPDMA_CxLLR.UDA = 1.

Note: A destination address must be aligned with the programmed data width of a destination burst (DA[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

16.8.16 GPDMA channel x transfer register 3 (GPDMA_CxTR3)

Address offset: 0xA4 + 0x80 * x (x = 6 to 7)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.UT3 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	DAO[12:0]												
			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	SAO[12:0]												
			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:16 **DAO[12:0]**: destination address offset increment

The destination address, pointed by GPDMA_CxDAR, is incremented or decremented (depending on GPDMA_CxBR1.DDEC) by this offset DAO[12:0] for each programmed destination burst. This offset is not including and is added to the programmed burst size when the completed burst is addressed in incremented mode (GPDMA_CxTR1.DINC = 1).

Note: A destination address offset must be aligned with the programmed data width of a destination burst (DAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:0 **SAO[12:0]**: source address offset increment

The source address, pointed by GPDMA_CxSAR, is incremented or decremented (depending on GPDMA_CxBR1.SDEC) by this offset SAO[12:0] for each programmed source burst. This offset is not including and is added to the programmed burst size when the completed burst is addressed in incremented mode (GPDMA_CxTR1.SINC = 1).

Note: A source address offset must be aligned with the programmed data width of a source burst (SAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and none transfer is issued.

When the source block size is not a multiple of the destination burst size, and is a multiple of the source data width, then the last programmed source burst is not completed and is internally shorten to match the block size. In this case, the additional GPDMA_CxTR3.SAO[12:0] is not applied.

16.8.17 GPDMA channel x block register 2 (GPDMA_CxBR2)

Address offset: 0xA8 + 0x80 * x (x = 6 to 7)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a 2D/repeated block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.UB2 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

BRSAO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **BRDAO[15:0]**: Block repeated destination address offset

For a channel with 2D addressing capability, this field is used to update (by addition or subtraction depending on GPDMA_CxBR1.BRDDEC) the current destination address (GPDMA_CxDAR) at the end of a block transfer.

Note: A block repeated destination address offset must be aligned with the programmed data width of a destination burst (BRDAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued. BRDAO[15:0] must be set to 0 in peripheral flow-control mode (if GPDMA_CxTR2.PFREQ = 1).

Bits 15:0 **BRSAO[15:0]**: Block repeated source address offset

For a channel with 2D addressing capability, this field is used to update (by addition or subtraction depending on GPDMA_CxBR1.BRSDEC) the current source address (GPDMA_CxSAR) at the end of a block transfer.

Note: A block repeated source address offset must be aligned with the programmed data width of a source burst (BRSAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued. BRSAO[15:0] must be set to 0 in peripheral flow-control mode (if GPDMA_CxTR2.PFREQ = 1).

16.8.18 GPDMA channel x linked-list address register (GPDMA_CxLLR)

Address offset: 0xCC + 0x80 * x (x = 0 to 5)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.ULL = 1.

LA[15:2]														Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		

Bit 31 **UT1**: Update GPDMA_CxTR1 from memory

This bit controls the update of GPDMA_CxTR1 from the memory during the link transfer.
0: no GPDMA_CxTR1 update
1: GPDMA_CxTR1 update

Bit 30 **UT2**: Update GPDMA_CxTR2 from memory

This bit controls the update of GPDMA_CxTR2 from the memory during the link transfer.
0: no GPDMA_CxTR2 update
1: GPDMA_CxTR2 update

Bit 29 **UB1**: Update GPDMA_CxBR1 from memory

This bit controls the update of GPDMA_CxBR1 from the memory during the link transfer.
If UB1 = 0 and if GPDMA_CxLLR ≠ 0, the linked-list is not completed.
GPDMA_CxBR1.BNDT[15:0] is then restored to the programmed value after data transfer is completed and before the link transfer.
0: no GPDMA_CxBR1 update from memory (GPDMA_CxBR1.BNDT[15:0] restored if any link transfer)
1: GPDMA_CxBR1 update

Bit 28 **USA**: update GPDMA_CxSAR from memory

This bit controls the update of GPDMA_CxSAR from the memory during the link transfer.
0: no GPDMA_CxSAR update
1: GPDMA_CxSAR update

Bit 27 **UDA**: Update GPDMA_CxDAR register from memory
This bit is used to control the update of GPDMA_CxDAR from the memory during the link transfer.
0: no GPDMA_CxDAR update
1: GPDMA_CxDAR update

Bits 26:17 Reserved, must be kept at reset value.

Bit 16 **ULL**: Update GPDMA_CxLLR register from memory
This bit is used to control the update of GPDMA_CxLLR from the memory during the link transfer.
0: no GPDMA_CxLLR update
1: GPDMA_CxLLR update

Bits 15:2 **LA[15:2]**: pointer (16-bit low-significant address) to the next linked-list data structure
If UT1 = UT2 = UB1 = USA = UDA = ULL = 0 and if LA[15:20] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list GPDMA register file.
Else, this field is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list GPDMA internal register file (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, and GPDMA_CxLLR).

Note: The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.

Bits 1:0 Reserved, must be kept at reset value.

16.8.19 GPDMA channel x alternate linked-list address register (GPDMA_CxLLR)

Address offset: 0xCC + 0x80 * x (x = 6 to 7)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.ULL = 1.

Bit 31 **UT1**: Update GPDMA_CxTR1 from memory

This bit controls the update of GPDMA_CxTR1 from the memory during the link transfer.

0: no GPDMA_CxTR1 update

1: GPDMA_CxTR1 update

Bit 30 **UT2**: Update GPDMA_CxTR2 from memory

This bit controls the update of GPDMA_CxTR2 from the memory during the link transfer.

0: no GPDMA_CxTR2 update

1: GPDMA_CxTR2 update

Bit 29 **UB1**: Update GPDMA_CxBR1 from memory

This bit controls the update of GPDMA_CxBR1 from the memory during the link transfer.
If UB1 = 0 and if GPDMA_CxLLR ≠ 0, the linked-list is not completed.
GPDMA_CxBR1.BNDT[15:0] is then restored to the programmed value after data transfer is completed and before the link transfer.

0: no GPDMA_CxBR1 update from memory (GPDMA_CxBR1.BNDT[15:0] restored if any link transfer)

1: GPDMA_CxBR1 update

Bit 28 **USA**: update GPDMA_CxSAR from memory

This bit controls the update of GPDMA_CxSAR from the memory during the link transfer.

0: no GPDMA_CxSAR update

1: GPDMA_CxSAR update

Bit 27 **UDA**: Update GPDMA_CxDAR register from memory
This bit is used to control the update of GPDMA_CxDAR from the memory during the link transfer.
0:no GPDMA_CxDAR update
1: GPDMA_CxDAR update

Bit 26 **UT3**: Update GPDMA_CxTR3 from memory
This bit controls the update of GPDMA_CxTR3 from the memory during the link transfer.
0: no GPDMA_CxTR3 update
1: GPDMA_CxTR3 update

Bit 25 **UB2**: Update GPDMA_CxBR2 from memory
This bit controls the update of GPDMA_CxBR2 from the memory during the link transfer.
0: no GPDMA_CxBR2 update
1: GPDMA_CxBR2 update

Bits 24:17 Reserved, must be kept at reset value.

Bit 16 **ULL**: Update GPDMA_CxLLR register from memory
This bit is used to control the update of GPDMA_CxLLR from the memory during the link transfer.
0: no GPDMA_CxLLR update
1: GPDMA_CxLLR update

Bits 15:2 **LA[15:2]**: pointer (16-bit low-significant address) to the next linked-list data structure
If UT1 = UT2 = UB1 = USA = UDA = ULL = 0 and if LA[15:20] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list GPDMA register file.
Else, this field is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list GPDMA internal register file (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, and GPDMA_CxLLR).
Note: The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.

Bits 1:0 Reserved, must be kept at reset value.

Refer to *Section 2.3* for the register boundary addresses.

17 Nested vectored interrupt controller (NVIC)

17.1 NVIC main features

- 131 maskable interrupt channels (not including the 16 Cortex-M33 with FPU interrupt lines)
- 16 programmable priority levels (4 bits of interrupt priority used)
- Low-latency exception and interrupt handling
- Power management control
- Implementation of system control registers

The NVIC and the processor core interface are closely coupled, enabling low-latency interrupt processing and efficient processing of late arriving interrupts.

The NVIC registers are banked across secure and non-secure states.

All interrupts including the core exceptions are managed by the NVIC.

17.2 SysTick calibration value register

The Cortex-M33 with TrustZone mainline security extension embeds two SysTick timers.

When TrustZone is activated, the following SysTick timers are available:

- SysTick, secure instance
- SysTick, non-secure instance

When TrustZone is disabled, only one SysTick timer is available.

The SysTick timer calibration value (STCALIB) is 0x3E8. It gives a reference time base of 1 ms based on a SysTick clock frequency of 1 MHz. In order to match the 1 ms time base for an application running at a given frequency, the SysTick reload value must be programmed as follows in the SYST_RVR register:

- When SysTick clock source is CPU clock HCLK
  reload value = (HCLK x STCALIB) - 1
- When SysTick clock source is external clock (HCLK/8)
  reload value = ((HCLK/8) x STCALIB) - 1

The HCLK refers to the AHB frequency value in MHz.

Example: SysTick clock source is CPU clock HCLK of 100 MHz, to match a time base of 1 ms:

SysTick reload value = (100 x STCALIB) - 1 = 0x1869F

17.3 Interrupt and exception vectors

The grey rows in the following table describe the vectors without specific position.

Table 135. STM32H563/H573 and STM32H562 vector table

18 Extended interrupts and event controller (EXTI)

The extended interrupts and event controller (EXTI) manages the individual CPU and system wakeup through configurable and direct event inputs. It provides wakeup requests to the power control and generates an interrupt request to the CPU NVIC and events to the CPU event input. For the CPU, an additional event generation block (EVG) is needed to generate the CPU event signal.

The EXTI wakeup requests allow the system to be woken up from Stop modes.

The interrupt request and event request generation can be used also in Run modes.

The EXTI also includes the EXTI mux IO port selection.

18.1 EXTI main features

The EXTI main features are the following:

- 58 input events supported
- All event inputs allow the possibility to wake up the system.
- Events that do not have an associated wakeup flag in the peripheral, have a flag in the EXTI and generate an interrupt to the CPU from the EXTI.
- Events can be used to generate a CPU wakeup event.

The asynchronous event inputs are classified in two groups:

- Configurable events (signals from I/Os or peripherals able to generate a pulse), with the following features
  - Selectable active trigger edge
  - Interrupt pending status register bits independent for the rising and falling edge
  - Individual interrupt and event generation mask, used for conditioning the CPU wakeup, interrupt and event generation
  - Software trigger possibility
  - Secure events: The access to control and configuration bits of secure input events can be made secure and or privilege.
  - EXTI IO port selection
- Direct events (interrupt and wake-up sources from peripherals having an associated flag which requires to be cleared in the peripheral), with the following features:
  - Fixed rising edge active trigger
  - No interrupt pending status register bit in the EXTI (the interrupt pending status flag is provided by the peripheral generating the event)
  - Individual interrupt and event generation mask, used to condition the CPU wake-up and event generation
  - No software trigger possibility

18.2 EXTI block diagram

The EXTI consists of a register block accessed via an AHB interface, the event input trigger block, the masking block and EXTI mux as shown in *Figure 87*.

The register block contains all the EXTI registers.

The event input trigger block provides event input edge trigger logic.

The masking block provides the event input distribution to the different wakeup, interrupt and event outputs, and their masking.

The EXTI mux provides the IO port selection on to the EXTI event signal.

Figure 87. EXTI block diagram

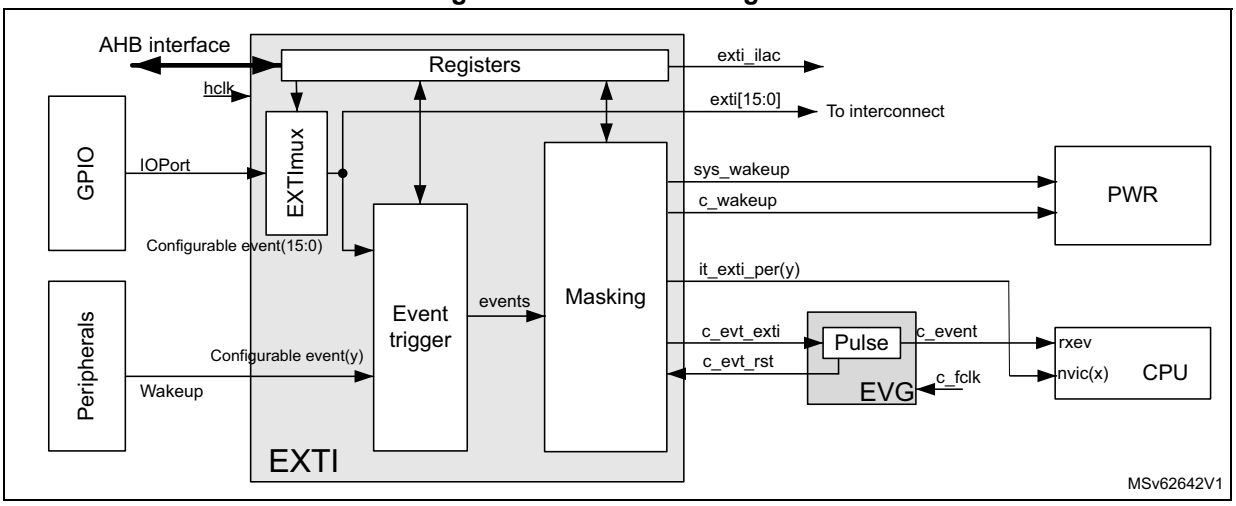

Table 136. EXTI signals

Pin name	I/O	Description
AHB interface	I/O	EXTI register bus interface. When one event is configured to enable security, the AHB interface supports secure accesses.
hclk	I	AHB bus clock and EXTI system clock
Configurable event(y)	I	Asynchronous wake-up events from peripherals without an associated interrupt and flag
Direct event(x)	I	Synchronous and asynchronous wake-up events from peripherals with an associated interrupt and flag
exti_ilac	O	Illegal access event
IOPort(n)	I	GPIOs block IO ports[15:0]
exti[15:0]	O	EXTI GPIO output port to trigger other peripherals
it_exti_per (y)	O	Interrupts to the CPU associated with configurable event (y)
c_evt_exti	O	High-level sensitive event output for CPU, synchronous to hclk
c_evt_rst	I	Asynchronous reset input to clear c_evt_exti
sys_wakeup	O	Asynchronous system wakeup request to PWR for ck_sys and hclk
c_wakeup	O	Wakeup request to PWR for CPU, synchronous to hclk

Table 137. EVG signals

Pin name	I/O	Description
c_fclk	I	CPU free running clock
c_evt_in	I	High-level sensitive events input from EXTI, asynchronous to CPU clock
c_event	O	Event pulse, synchronous to CPU clock
c_evt_rst	O	Event reset signal, synchronous to CPU clock

18.2.1 EXTI connections between peripherals and CPU

Some peripherals able to generate wake-up or interrupt events when the system is in Stop mode, are connected to the EXTI.

- Peripheral wakeup signals that generate a pulse or do not have an interrupt status bits in the peripheral, are connected to an EXTI configurable event input. For these events, the EXTI provides a status pending bit to be cleared. It is the EXTI interrupt, associated with the status bit, that interrupts the CPU.
- Peripheral interrupt and wake-up signals with a status bit in the peripheral to be cleared are connected to an EXTI direct event input. There is no status pending bit within the EXTI. The interrupt or wake-up is cleared by the CPU in the peripheral. It is the peripheral interrupt that interrupts the CPU directly.

All GPIO ports input to the EXTI multiplexer allow the selection of a port pin to wake up the system via a configurable event.

The EXTI configurable event interrupts are connected to the NVIC.

The dedicated EXTI/EVG CPU event is connected to the CPU rxev input.

The EXTI CPU wakeup signals are connected to the PWR and are used to wake up the system and the CPU sub-system bus clocks.

18.2.2 EXTI interrupt/event mapping

The EXTI lines are connected as shown in the table below.

Table 138. EXTI line connections

EXTI Line	Line source	Line type

18.3 EXTI functional description

The events features are controlled from register bits as follows:

- Active trigger edge enable
  - by rising edge selection in the *EXTI rising trigger selection register (EXTI_RTSR1)* and *EXTI rising trigger selection register 2 (EXTI_RTSR2)*
  - by falling edge selection in the *EXTI falling trigger selection register (EXTI_FTSR1)* and *EXTI falling trigger selection register 2 (EXTI_FTSR2)*
- Software trigger in the *EXTI software interrupt event register (EXTI_SWIER1)* and *EXTI software interrupt event register 2 (EXTI_SWIER2)*
- Interrupt pending flag in the

  EXTI rising edge pending register (EXTI_RPR1) and *EXTI rising edge pending register 2 (EXTI_RPR2)*

  EXTI falling edge pending register (EXTI_FPR1) and *EXTI falling edge pending register 2 (EXTI_FPR2)*
- CPU wakeup and interrupt enable in the

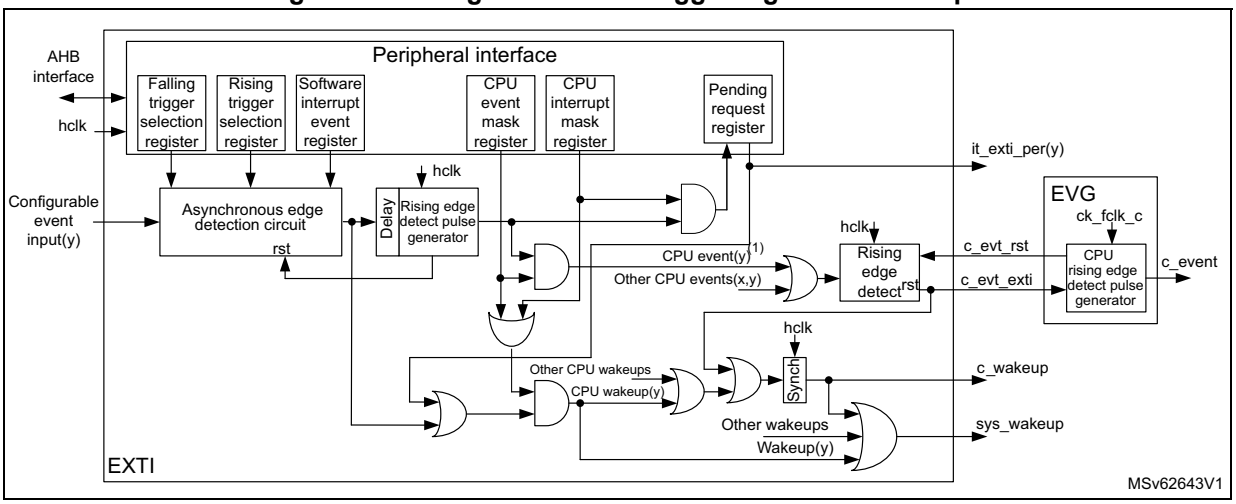
  EXTI CPU wakeup with interrupt mask register (EXTI_IMR1) and *EXTI CPU wakeup with interrupt mask register 2 (EXTI_IMR2)*
- CPU wakeup and event enable

  EXTI CPU wakeup with event mask register (EXTI_EMR1) and *EXTI CPU wakeup with event mask register 2 (EXTI_EMR2)*

18.3.1 EXTI configurable event input wakeup

The figure below is a detailed representation of the logic associated with configurable event inputs that wake up the CPU sub-system bus clocks and generate an EXTI pending flag and interrupt to the CPU, and/or a CPU wakeup event.

Figure 88. Configurable event trigger logic CPU wakeup



1. Only for the input events that support CPU rxev generation c_event.

The software interrupt event register allows configurable events to be triggered by software, writing the corresponding register bit, whatever the edge selection setting.

The configurable event active trigger edge (or both edges) is selected and enabled in the rising/falling edge selection registers.

The CPU has its dedicated wakeup (interrupt) mask register and a dedicated event mask registers. When the event is enabled, it is generated to the CPU. All events for the CPU are ORed together into a single CPU event signal. The event pending registers (EXTI_RPR and EXTI_FPR) are not set for an unmasked CPU event.

The configurable events have unique interrupt pending request registers. The pending register is only set for an unmasked interrupt. Each configurable event provides a common interrupt to the CPU. The configurable event interrupts must be acknowledged by software in the EXTI_RPR and/or EXTI_FPR registers.

When a CPU wakeup (interrupt) or CPU event is enabled, the asynchronous edge detection circuit is reset by the clocked delay and rising edge detect pulse generator. This guarantees that the EXTI hclk clock is woken up before the asynchronous edge detection circuit is reset.

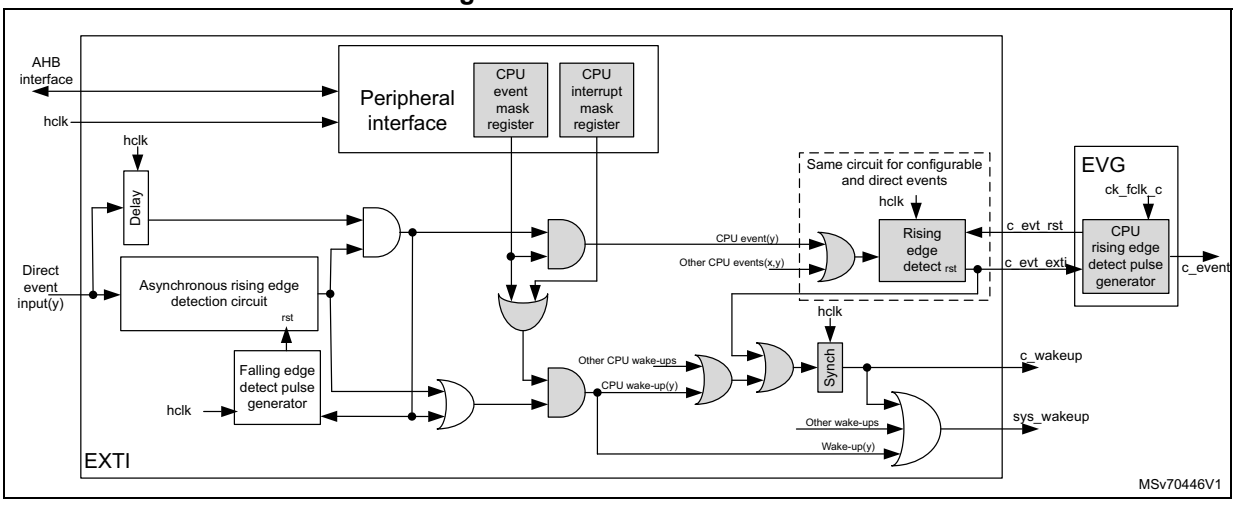
Note: A detected configurable event interrupt pending request can be cleared by the CPU with the correct access permission. The system is not able to enter into low-power modes as long as an interrupt pending request is active.

18.3.2 EXTI direct event input wake-up

The direct events do not have an associated EXTI interrupt. The EXTI only wakes up the system and CPU subsystem clocks, and can generate a CPU wake-up event. The peripheral synchronous interrupt, associated with the direct wake-up event, wakes up the CPU.

The EXTI direct event is able to generate a CPU event that wakes up the CPU. The CPU event may occur before the associated peripheral interrupt flag is set.

Figure 89. EXTI direct events

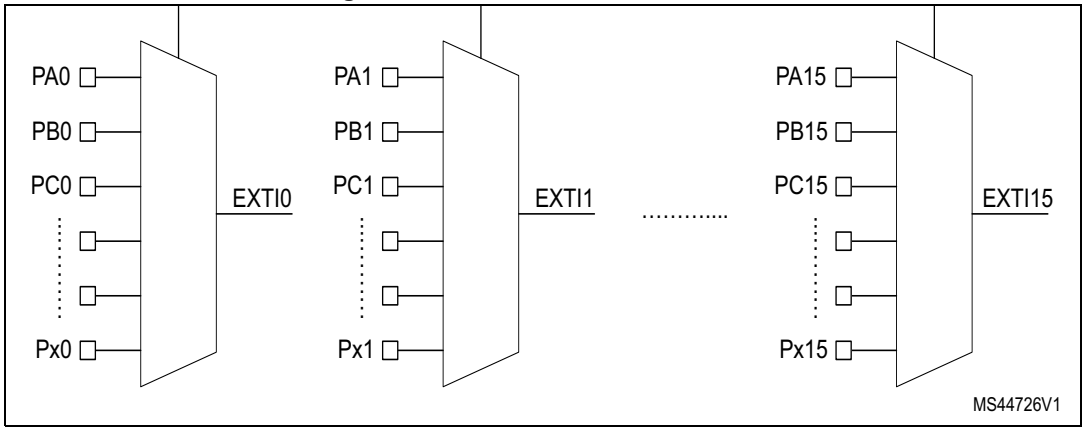


18.3.3 EXTI mux selection

The EXTI mux allows the selection of GPIOs as interrupts and wakeup. GPIOs are connected via 16 EXTI mux lines to the first 16 EXTI events as configurable event. The

selection of GPIO port as EXTI mux output is controlled in the *EXTI external interrupt selection register (EXTI_EXTICR1)*.

Figure 90. EXTI mux GPIO selection



The EXTI mux outputs are available as output signals from the EXTI to trigger other peripherals, whatever the masking in EXTI_IMR and EXTI_EMR registers.

18.4 EXTI functional behavior

The configurable events are enabled by enabling at least one of the trigger edges.

Once an event input is enabled, the CPU wakeup generation is conditioned by the CPU interrupt mask and CPU event mask.

Table 139. Masking functionality

CPU interrupt enable (in EXTI_IMR.IMn)	CPU event enable (in EXTI_EMR.EMn)	Configurable event inputs (in EXTI_RPR.RPIFn and EXTI_FPR.FPIFn)	Exti(n) interrupt(1)	CPU event	CPU wakeup
0	0	No	Masked	Masked	Masked
	1	No	Masked	Yes	Yes
1	0	Status latched	Yes	Masked	Yes(2)
	1	Status latched	Yes	Yes	Yes

1. The single exti(n) interrupt goes to the CPU. If no interrupt is required for CPU(m), the exti(n) interrupt must be masked in the CPU NVIC.
2. Only if CPU interrupt is enabled in EXTI_IMR.IMn.

For configurable event inputs, when the enabled edges occur on the event input, an event request is generated. When the associated CPU interrupt is unmasked, the corresponding pending bits EXTI_RPR.RPIFn and/or EXTI_FPR.FPIFn is/are set: the CPU sub-system is woken up and the CPU interrupt signal is activated. The EXTI_RPR.RPIFn and/or EXTI_FPR.FPIFn pending bits must be cleared by software writing it to 1. This action clears the CPU interrupt.

For the configurable event inputs, an event request can be generated by software when writing a 1 in the software interrupt/event register EXTI_SWIER, allowing the generation of a

rising edge on the event. The rising edge event pending bit is set in EXTI_RPR, whatever the setting in EXTI_RTSR.

18.5 EXTI event protection

The EXTI is able to protect event register bits from being modified by non-secure and unprivileged accesses. The protection is individually activated per input event via the register bits in EXTI_SECCFGR and EXTI_PRIVCFGR. At EXTI level, the protection consists in preventing the following unauthorized write access:

- Change the settings of the secure and/or privileged configurable events.
- Change the masking of the secure and/or privileged input events.
- Clear pending status of the secure and/or privileged input events.

Table 140. Register protection overview

Register name	Access type	Protection(1)(2)
EXTI_RTSR	RW	Security and privilege can be bit-wise enabled in EXTI_SECCFGR and EXTI_PRIVCFGR.
EXTI_FTSR	RW	
EXTI_SWIER	RW	
EXTI_RPR	RW	
EXTI_FPR	RW	
EXTI_SECCFGR	RW	Always secure. Privilege can be bit-wise enabled in EXTI_PRIVCFGR.
EXTI_PRIVCFGR	RW	Always privilege. Security can be bit-wise enabled in EXTI_SECCFGR.
EXTI_EXTICRn	RW	Security and privilege can be bit-wise enabled in EXTI_SECCFGR and EXTI_PRIVCFGR.
EXTI_LOCKR	RW	Always secure
EXTI_IM	RW	Security and privilege can be bit-wise enabled in EXTI_SECCFGR and EXTI_PRIVCFGR.
EXTI_EMR	RW	

1. Security is enabled with the individual input event (EXTI_SECCFGR register).
2. Privilege is enabled with the individual Input event (EXTI_PRIVCFGR register).

18.5.1 EXTI security protection

When security is enabled for an input event, the associated input event configuration and control bits can only be modified and read by a secure access. A non-secure write access is discarded and a read returns 0.

When input events are non-secure, the security is disabled. The associated input event configuration and control bits can be modified and read by a secure access and non-secure access.

The security configuration in registers EXTI_SECCFGR can be globally locked after reset by EXTI_LOCKR.LOCK.

18.5.2 EXTI privilege protection

When privilege is enabled for an input event, the associated input event configuration and control bits can only be modified and read by a privileged access. An unprivileged write access is discarded and a read returns 0.

When input events are unprivileged, the privilege is disabled. The associated input event configuration and control bits can be modified and read by a privileged access and unprivileged access.

The privileged configuration in registers EXTI_PRIVCFGR can be globally locked after reset by EXTI_LOCKR.LOCK.

18.6 EXTI registers

The EXTI register map is divided in the following sections:

Table 141. EXTI register map sections

Address offset	Description
0x000 - 0x01C	General configurable event [31:0] configuration
0x020 - 0x03C	General configurable event [57:32] configuration
0x060 - 0x06C	EXTI IO port mux selection
0x070	EXTI protection lock configuration
0x080 - 0x0BC	CPU input event configuration

All the registers can be accessed with word (32-bit), half-word (16-bit) and byte (8-bit) access.

18.6.1 EXTI rising trigger selection register (EXTI_RTSR1)

Address offset: 0x000

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RT16
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RT15	RT14	RT13	RT12	RT11	RT10	RT9	RT8	RT7	RT6	RT5	RT4	RT3	RT2	RT1	RT0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bits 16:0 **RTx:** Rising trigger event configuration bit of configurable event input x[(1)] (x = 16 to 0)

When EXTI_SECCFGR.SECx is disabled, RTx can be accessed with non-secure and secure access.

When EXTI_SECCFGR.SECx is enabled, RTx can only be accessed with secure access. Non-secure write to this bit x is discarded and non-secure read returns 0.

When EXTI_PRIVCFGR.PRIVx is disabled, RTx can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIVx is enabled, RTx can only be accessed with privileged access. Unprivileged write to this bit x is discarded, unprivileged read returns 0.

0: Rising trigger disabled (for event and interrupt) for input line

1: Rising trigger enabled (for event and interrupt) for input line

1. The configurable event inputs are edge triggered, no glitch must be generated on these inputs.
If a rising edge on the configurable event input occurs during writing of the register, the associated pending bit is not set.
Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

18.6.2 EXTI falling trigger selection register (EXTI_FTSR1)

Address offset: 0x004

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FT16
															rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FT15	FT14	FT13	FT12	FT11	FT10	FT9	FT8	FT7	FT6	FT5	FT4	FT3	FT2	FT1	FT0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bits 16:0 **FTx:** Falling trigger event configuration bit of configurable event input x [(1)] (x = 16 to 0)

When EXTI_SECCFGR.SECx is disabled, FTx can be accessed with non-secure and secure access.

When EXTI_SECCFGR.SECx is enabled, FTx can only be accessed with secure access. Non-secure write to this FTx is discarded, non-secure read returns 0.

When EXTI_PRIVCFGR.PRIVx is disabled, FTx can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIVx is enabled, FTx can only be accessed with privileged access. Unprivileged write to this FTx is discarded, unprivileged read returns 0.

0: Falling trigger disabled (for event and Interrupt) for input line

1: Falling trigger enabled (for event and Interrupt) for input line.

1. The configurable event inputs are edge triggered, no glitch must be generated on these inputs.
If a falling edge on the configurable event input occurs during writing of the register, the associated pending bit is not set.
Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

18.6.3 EXTI software interrupt event register (EXTI_SWIER1)

Address offset: 0x008

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWI16
															rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWI15	SWI14	SWI13	SWI12	SWI11	SWI10	SWI9	SWI8	SWI7	SWI6	SWI5	SWI4	SWI3	SWI2	SWI1	SWI0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bits 16:0 **SWIx:** Software interrupt on event x (x = 16 to 0)

When EXTI_SECCFGR.SECx is disabled, SWIx can be accessed with non-secure and secure access.

When EXTI_SECCFGR.SECx is enabled, SWIx can only be accessed with secure access. Non-secure write to this SWI x is discarded, non-secure read returns 0.

When EXTI_PRIVCFGR.PRIVx is disabled, SWIx can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIVx is enabled, SWIx can only be accessed with privileged access. Unprivileged write to this SWIx is discarded, unprivileged read returns 0.

A software interrupt is generated independent from the setting in EXTI_RTSR and EXTI_FTSR. It always returns 0 when read.

0: Writing 0 has no effect.

1: Writing 1 triggers a rising edge event on event x. This bit is auto cleared by hardware.

18.6.4 EXTI rising edge pending register (EXTI_RPR1)

Address offset: 0x00C

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RPIF16
															rw

RPIF15	RPIF14	RPIF13	RPIF12	RPIF11	RPIF10	RPIF9	RPIF8	RPIF7	RPIF6	RPIF5	RPIF4	RPIF3	RPIF2	RPIF1	RPIF0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bits 16:0 **RPIFx:** configurable event inputs x rising edge pending bit (x = 16 to 0)

When EXTI_SECCFGR.SECx is disabled, RPIFx can be accessed with non-secure and secure access.

When EXTI_SECCFGR.SECx is enabled, RPIFx can only be accessed with secure access. Non-secure write to this RPIFx is discarded, non-secure read returns 0.

When EXTI_PRIVCFGR.PRIVx is disabled, RPIFx can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIVx is enabled, RPIFx can only be accessed with privileged access. Unprivileged write to this RPIFx is discarded, unprivileged read returns 0.

0: No rising edge trigger request occurred

1: Rising edge trigger request occurred

This bit is set when the rising edge event or an EXTI_SWIER software trigger arrives on the configurable event line. This bit is cleared by writing 1 to it.

18.6.5 EXTI falling edge pending register (EXTI_FPR1)

Address offset: 0x010

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FPIF16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bits 16:0 **FPIFx:** configurable event inputs x falling edge pending bit (x = 16 to 0)

When EXTI_SECCFGR.SECx is disabled, FPIFx can be accessed with non-secure and secure access.
When EXTI_SECCFGR.SECx is enabled, FPIFx can only be accessed with secure access. Non-secure write to this FPIFx is discarded, non-secure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, FPIFx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, FPIFx can only be accessed with privileged access. Unprivileged write to this FPIFx is discarded, unprivileged read returns 0.
0: No falling edge trigger request occurred
1: Falling edge trigger request occurred
This bit is set when the falling edge event arrives on the configurable event line. This bit is cleared by writing 1 to it.

18.6.6 EXTI security configuration register (EXTI_SECCFGR1)

Address offset: 0x014

Reset value: 0x0000 0000

This register provides write access security, a non-secure write access is ignored and causes the generation of an illegal access event. A non-secure read returns the register data.

Contains only register bits for security capable input events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SEC31	SEC30	SEC29	SEC28	SEC27	SEC26	SEC25	SEC24	SEC23	SEC22	SEC21	SEC20	SEC19	SEC18	SEC17	SEC16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SECx:** Security enable on event input x (x = 31 to 0)
When EXTI_PRIVCFGR.PRIVx is disabled, SECx can be accessed with privileged and unprivileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, SECx can only be written with privileged access. Unprivileged write to this SECx is discarded.
0: Event security disabled (non-secure)
1: Event security enabled (secure)

18.6.7 EXTI privilege configuration register (EXTI_PRIVCFGR1)

Address offset: 0x018

Reset value: 0x0000 0000

This register provides privileged write access protection. An unprivileged read returns the register data.

Contains only register bits for privilege capable input events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PRIV31	PRIV30	PRIV29	PRIV28	PRIV27	PRIV26	PRIV25	PRIV24	PRIV23	PRIV22	PRIV21	PRIV20	PRIV19	PRIV18	PRIV17	PRIV16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **PRIVx:** Security enable on event input x (x = 31 to 0)
When EXTI_SECCFGR.SECx is disabled, PRIVx can be accessed with secure and non-secure access.
When EXTI_SECCFGR.SECx is enabled, PRIVx can only be written with secure access. Non-secure write to this PRIVx is discarded.
0: Event privilege disabled (unprivileged)
1: Event privilege enabled (privileged)

18.6.8 EXTI rising trigger selection register 2 (EXTI_RTSR2)

Address offset: 0x020

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RT53	Res.	Res.	RT50	Res.	Res.

Res.	RT46	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
	rw														

Bits 31:22, 20:19, 17:15, 13:0 Reserved, must be kept at reset value.

Bit 21 **RT53:** Rising trigger event configuration bit of configurable event input x[1]

When EXTI_SECCFGR.SECx is disabled, RTx can be accessed with non-secure and secure access.
When EXTI_SECCFGR.SECx is enabled, RTx can only be accessed with secure access. Non-secure write to this bit x is discarded and non-secure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, RTx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, RTx can only be accessed with privileged access. Unprivileged write to this bit x is discarded, unprivileged read returns 0.
0: Rising trigger disabled (for event and interrupt) for input line
1: Rising trigger enabled (for event and interrupt) for input line

Bit 18 **RT50:** Rising trigger event configuration bit of configurable event input x[1]

When EXTI_SECCFGR.SECx is disabled, RTx can be accessed with non-secure and secure access.
When EXTI_SECCFGR.SECx is enabled, RTx can only be accessed with secure access. Non-secure write to this bit x is discarded and non-secure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, RTx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, RTx can only be accessed with privileged access. Unprivileged write to this bit x is discarded, unprivileged read returns 0.
0: Rising trigger disabled (for event and interrupt) for input line
1: Rising trigger enabled (for event and interrupt) for input line

Bit 14 **RT46:** Rising trigger event configuration bit of configurable event input x[1]

When EXTI_SECCFGR.SECx is disabled, RTx can be accessed with non-secure and secure access.
When EXTI_SECCFGR.SECx is enabled, RTx can only be accessed with secure access. Non-secure write to this bit x is discarded and non-secure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, RTx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, RTx can only be accessed with privileged access. Unprivileged write to this bit x is discarded, unprivileged read returns 0.
0: Rising trigger disabled (for event and interrupt) for input line
1: Rising trigger enabled (for event and interrupt) for input line

1. The configurable event inputs are edge triggered, no glitch must be generated on these inputs.
If a rising edge on the configurable event input occurs during writing of the register, the associated pending bit is not set.
Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

18.6.9 EXTI falling trigger selection register 2 (EXTI_FTSR2)

Address offset: 0x024

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FT53	Res.	Res.	FT50	Res.	Res.
										rw			rw		
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	FT46	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
	rw														

Bits 31:22, 20:19, 17:15, 13:0 Reserved, must be kept at reset value.

Bit 21 **FT53:** Falling trigger event configuration bit of configurable event input x [1]

When EXTI_SECCFGR.SECx is disabled, FTx can be accessed with non-secure and secure access.
When EXTI_SECCFGR.SECx is enabled, FTx can only be accessed with secure access. Non-secure write to this FTx is discarded, non-secure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, FTx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, FTx can only be accessed with privileged access. Unprivileged write to this FTx is discarded, unprivileged read returns 0.
0: Falling trigger disabled (for event and Interrupt) for input line
1: Falling trigger enabled (for event and Interrupt) for input line.

Bit 18 **FT50:** Falling trigger event configuration bit of configurable event input x [1]

When EXTI_SECCFGR.SECx is disabled, FTx can be accessed with non-secure and secure access.
When EXTI_SECCFGR.SECx is enabled, FTx can only be accessed with secure access. Non-secure write to this FTx is discarded, non-secure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, FTx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, FTx can only be accessed with privileged access. Unprivileged write to this FTx is discarded, unprivileged read returns 0.
0: Falling trigger disabled (for event and Interrupt) for input line
1: Falling trigger enabled (for event and Interrupt) for input line.

Bit 14 **FT46:** Falling trigger event configuration bit of configurable event input x [1]

When EXTI_SECCFGR.SECx is disabled, FTx can be accessed with non-secure and secure access.
When EXTI_SECCFGR.SECx is enabled, FTx can only be accessed with secure access. Non-secure write to this FTx is discarded, non-secure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, FTx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, FTx can only be accessed with privileged access. Unprivileged write to this FTx is discarded, unprivileged read returns 0.
0: Falling trigger disabled (for event and Interrupt) for input line
1: Falling trigger enabled (for event and Interrupt) for input line.

1. The configurable event inputs are edge triggered, no glitch must be generated on these inputs.
If a falling edge on the configurable event input occurs during writing of the register, the associated pending bit is not set.
Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

18.6.10 EXTI software interrupt event register 2 (EXTI_SWIER2)

Address offset: 0x028

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWI53	Res.	Res.	SWI50	Res.	Res.
										rw			rw		
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	SWI46	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
	rw														

Bits 31:22, 20:19, 17:15, 13:0 Reserved, must be kept at reset value.

Bit 21 **SWI53:** Software interrupt on event x

When EXTI_SECCFGR.SECx is disabled, SWIx can be accessed with non-secure and secure access.

When EXTI_SECCFGR.SECx is enabled, SWIx can only be accessed with secure access. Non-secure write to this SWI x is discarded, non-secure read returns 0.

When EXTI_PRIVCFGR.PRIVx is disabled, SWIx can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIVx is enabled, SWIx can only be accessed with privileged access. Unprivileged write to this SWIx is discarded, unprivileged read returns 0.

A software interrupt is generated independent from the setting in EXTI_RTSR and EXTI_FTSR. It always returns 0 when read.

0: Writing 0 has no effect.

1: Writing 1 triggers a rising edge event on event x. This bit is auto cleared by hardware.

Bit 18 **SWI50:** Software interrupt on event x

When EXTI_SECCFGR.SECx is disabled, SWIx can be accessed with non-secure and secure access.

When EXTI_SECCFGR.SECx is enabled, SWIx can only be accessed with secure access. Non-secure write to this SWI x is discarded, non-secure read returns 0.

When EXTI_PRIVCFGR.PRIVx is disabled, SWIx can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIVx is enabled, SWIx can only be accessed with privileged access. Unprivileged write to this SWIx is discarded, unprivileged read returns 0.

A software interrupt is generated independent from the setting in EXTI_RTSR and EXTI_FTSR. It always returns 0 when read.

0: Writing 0 has no effect.

1: Writing 1 triggers a rising edge event on event x. This bit is auto cleared by hardware.

Bit 14 **SWI46:** Software interrupt on event x

When EXTI_SECCFGR.SECx is disabled, SWIx can be accessed with non-secure and secure access.

When EXTI_SECCFGR.SECx is enabled, SWIx can only be accessed with secure access. Non-secure write to this SWI x is discarded, non-secure read returns 0.

When EXTI_PRIVCFGR.PRIVx is disabled, SWIx can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIVx is enabled, SWIx can only be accessed with privileged access. Unprivileged write to this SWIx is discarded, unprivileged read returns 0.

A software interrupt is generated independent from the setting in EXTI_RTSR and EXTI_FTSR. It always returns 0 when read.

0: Writing 0 has no effect.

1: Writing 1 triggers a rising edge event on event x. This bit is auto cleared by hardware.

18.6.11 EXTI rising edge pending register 2 (EXTI_RPR2)

Address offset: 0x02C

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RPIF53	Res.	Res.	RPIF50	Res.	Res.
										rw			rw		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	RPIF46	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
	rw														

Bits 31:22, 20:19, 17:15, 13:0 Reserved, must be kept at reset value.

Bit 21 **RPIF53:** configurable event inputs x rising edge pending bit

When EXTI_SECCFGR.SECx is disabled, RPIFx can be accessed with non-secure and secure access.

When EXTI_SECCFGR.SECx is enabled, RPIFx can only be accessed with secure access. Non-secure write to this RPIFx is discarded, non-secure read returns 0.

When EXTI_PRIVCFGR.PRIVx is disabled, RPIFx can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIVx is enabled, RPIFx can only be accessed with privileged access. Unprivileged write to this RPIFx is discarded, unprivileged read returns 0.

0: No rising edge trigger request occurred

1: Rising edge trigger request occurred

This bit is set when the rising edge event or an EXTI_SWIER software trigger arrives on the configurable event line. This bit is cleared by writing 1 to it.

Bit 18 **RPIF50:** configurable event inputs x rising edge pending bit

When EXTI_SECCFGR.SECx is disabled, RPIFx can be accessed with non-secure and secure access.
When EXTI_SECCFGR.SECx is enabled, RPIFx can only be accessed with secure access. Non-secure write to this RPIFx is discarded, non-secure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, RPIFx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, RPIFx can only be accessed with privileged access. Unprivileged write to this RPIFx is discarded, unprivileged read returns 0.
0: No rising edge trigger request occurred
1: Rising edge trigger request occurred
This bit is set when the rising edge event or an EXTI_SWIER software trigger arrives on the configurable event line. This bit is cleared by writing 1 to it.

Bit 14 **RPIF46:** configurable event inputs x rising edge pending bit

When EXTI_SECCFGR.SECx is disabled, RPIFx can be accessed with non-secure and secure access.
When EXTI_SECCFGR.SECx is enabled, RPIFx can only be accessed with secure access. Non-secure write to this RPIFx is discarded, non-secure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, RPIFx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, RPIFx can only be accessed with privileged access. Unprivileged write to this RPIFx is discarded, unprivileged read returns 0.
0: No rising edge trigger request occurred
1: Rising edge trigger request occurred
This bit is set when the rising edge event or an EXTI_SWIER software trigger arrives on the configurable event line. This bit is cleared by writing 1 to it.

18.6.12 EXTI falling edge pending register 2 (EXTI_FPR2)

Address offset: 0x030

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FPIF53	Res.	Res.	FPIF50	Res.	Res.
										rw			rw

Res.	FPIF46	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
	rw														

Bits 31:22, 20:19, 17:15, 13:0 Reserved, must be kept at reset value.

Bit 21 **FPIF53:** configurable event inputs x falling edge pending bit

When EXTI_SECCFGR.SECx is disabled, FPIFx can be accessed with non-secure and secure access.
When EXTI_SECCFGR.SECx is enabled, FPIFx can only be accessed with secure access. Non-secure write to this FPIFx is discarded, non-secure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, FPIFx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, FPIFx can only be accessed with privileged access. Unprivileged write to this FPIFx is discarded, unprivileged read returns 0.
0: No falling edge trigger request occurred
1: Falling edge trigger request occurred
This bit is set when the falling edge event arrives on the configurable event line. This bit is cleared by writing 1 to it.

Bit 18 **FPIF50:** configurable event inputs x falling edge pending bit

When EXTI_SECCFGR.SECx is disabled, FPIFx can be accessed with non-secure and secure access.
When EXTI_SECCFGR.SECx is enabled, FPIFx can only be accessed with secure access. Non-secure write to this FPIFx is discarded, non-secure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, FPIFx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, FPIFx can only be accessed with privileged access. Unprivileged write to this FPIFx is discarded, unprivileged read returns 0.
0: No falling edge trigger request occurred
1: Falling edge trigger request occurred
This bit is set when the falling edge event arrives on the configurable event line. This bit is cleared by writing 1 to it.

Bit 14 **FPIF46:** configurable event inputs x falling edge pending bit

When EXTI_SECCFGR.SECx is disabled, FPIFx can be accessed with non-secure and secure access.
When EXTI_SECCFGR.SECx is enabled, FPIFx can only be accessed with secure access. Non-secure write to this FPIFx is discarded, non-secure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, FPIFx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, FPIFx can only be accessed with privileged access. Unprivileged write to this FPIFx is discarded, unprivileged read returns 0.
0: No falling edge trigger request occurred
1: Falling edge trigger request occurred
This bit is set when the falling edge event arrives on the configurable event line. This bit is cleared by writing 1 to it.

18.6.13 EXTI security configuration register 2 (EXTI_SECCFGR2)

Address offset: 0x034

Reset value: 0x0000 0000

This register provides write access security, a non-secure write access is ignored and causes the generation of an illegal access event. A non-secure read returns the register data.

Contains only register bits for privilege capable input events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	SEC57	SEC56	SEC55	SEC54	SEC53	SEC52	SEC51	SEC50	SEC49	SEC48
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 **SECx:** Security enable on event input x (x = 57 to 32)

When EXTI_PRIVCFGR.PRIVx is disabled, SECx can be accessed with privileged and unprivileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, SECx can only be written with privileged access. Unprivileged write to this SECx is discarded.
0: Event security disabled (non-secure)
1: Event security enabled (secure)

18.6.14 EXTI privilege configuration register 2 (EXTI_PRIVCFGR2)

Address offset: 0x038

Reset value: 0x0000 0000

This register provides privileged write access protection. An unprivileged read returns the register data.

Contains only register bits for security capable input events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	PRIV57	PRIV56	PRIV55	PRIV54	PRIV53	PRIV52	PRIV51	PRIV50	PRIV49	PRIV48

18.6.19 EXTI lock register (EXTI_LOCKR)

Address offset: 0x070

Reset value: 0x0000 0000

This register provides write access security: a non-secure write access is ignored and a read access returns zero data, and both generates an illegal access event.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LOCK
															rs

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **LOCK**: Global security and privilege configuration registers (EXTI_SECCFGR and EXTI_PRIVCFGR) lock

This bit is written once after reset.

0: Security and privilege configuration open, can be modified.

1: Security and privilege configuration locked, can no longer be modified.

18.6.20 EXTI CPU wakeup with interrupt mask register (EXTI_IMR1)

Address offset: 0x080

Reset value: 0xFFFE 0000

Contains register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IM31	IM30	IM29	IM28	IM27	IM26	IM25	IM24	IM23	IM22	IM21	IM20	IM19	IM18	IM17	IM16
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IM15	IM14	IM13	IM12	IM11	IM10	IM9	IM8	IM7	IM6	IM5	IM4	IM3	IM2	IM1	IM0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **IMx:** CPU wakeup with interrupt mask on event input x [(1)] (x = 31 to 0)

When EXTI_SECCFGR.SECx is disabled, IMx can be accessed with non-secure and secure access.

When EXTI_SECCFGR.SECx is enabled, IMx can only be accessed with secure access. Non-secure write to this bit is discarded and non-secure read returns 0.

When EXTI_PRIVCFGR.PRIVx is disabled, IMx can be accessed with privileged and unprivileged access.

When EXTI_PRIVCFGR.PRIVx is enabled, IMx can only be accessed with privileged access. Unprivileged write to this bit is discarded.

0: Wakeup with interrupt request from input event x is masked.

1: Wakeup with interrupt request from input event x is unmasked.

1. The reset value for configurable event inputs is set to 0 in order to disable the interrupt by default.

18.6.21 EXTI CPU wakeup with event mask register (EXTI_EMR1)

Address offset: 0x084

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
EM31	EM30	EM29	EM28	EM27	EM26	EM25	EM24	EM23	EM22	EM21	EM20	EM19	EM18	EM17	EM16
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **EMx:** CPU wakeup with event generation mask on event input x (x = 31 to 0)

When EXTI_SECCFGR.SECx is disabled, EMx can be accessed with non-secure and secure access.

When EXTI_SECCFGR.SECx is enabled, EMx can only be accessed with secure access. Non-secure write to this bit x is discarded and non-secure read returns 0.

When EXTI_PRIVCFGR.PRIVx is disabled, EMx can be accessed with privileged and unprivileged access.

When EXTI_PRIVCFGR.PRIVx is enabled, EMx can only be accessed with privileged access. Unprivileged write to this bit is discarded.

0: Wakeup with event generation from Line x is masked.

1: Wakeup with event generation from Line x is unmasked.

18.6.22 EXTI CPU wakeup with interrupt mask register 2 (EXTI_IMR2)

Address offset: 0x090

Reset value: 0x03DB BFFF

Contains register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	IM57	IM56	IM55	IM54	IM53	IM52	IM51	IM50	IM49	IM48

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 **IMx:** CPU wakeup with interrupt mask on event input x [(1)] (x = 57 to 0)

When EXTI_SECCFGR.SECx is disabled, IMx can be accessed with non-secure and secure access.

When EXTI_SECCFGR.SECx is enabled, IMx can only be accessed with secure access. Non-secure write to this bit is discarded and non-secure read returns 0.

When EXTI_PRIVCFGR.PRIVx is disabled, IMx can be accessed with privileged and unprivileged access.

When EXTI_PRIVCFGR.PRIVx is enabled, IMx can only be accessed with privileged access. Unprivileged write to this bit is discarded.

0: Wakeup with interrupt request from input event x is masked.

1: Wakeup with interrupt request from input event x is unmasked.

1. The reset value for configurable event inputs is set to 0 in order to disable the interrupt by default.

18.6.23 EXTI CPU wakeup with event mask register 2 (EXTI_EMR2)

Address offset: 0x094

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 **EMx:** CPU wakeup with event generation mask on event input x (x = 57 to 32)

When EXTI_SECCFGR.SECx is disabled, EMx can be accessed with non-secure and secure access.

When EXTI_SECCFGR.SECx is enabled, EMx can only be accessed with secure access. Non-secure write to this bit x is discarded and non-secure read returns 0.

When EXTI_PRIVCFGR.PRIVx is disabled, EMx can be accessed with privileged and unprivileged access.

When EXTI_PRIVCFGR.PRIVx is enabled, EMx can only be accessed with privileged access. Unprivileged write to this bit is discarded.

0: Wakeup with event generation from Line x is masked.

1: Wakeup with event generation from Line x is unmasked.

19 Cyclic redundancy check calculation unit (CRC)

19.1 Introduction

The CRC (cyclic redundancy check) calculation unit is used to get a CRC code from 8-, 16- or 32-bit data word and a generator polynomial.

Among other applications, CRC-based techniques are used to verify data transmission or storage integrity. In the scope of the functional safety standards, they offer a means of verifying the flash memory integrity. The CRC calculation unit helps compute a signature of the software during runtime, to be compared with a reference signature generated at link time and stored at a given memory location.

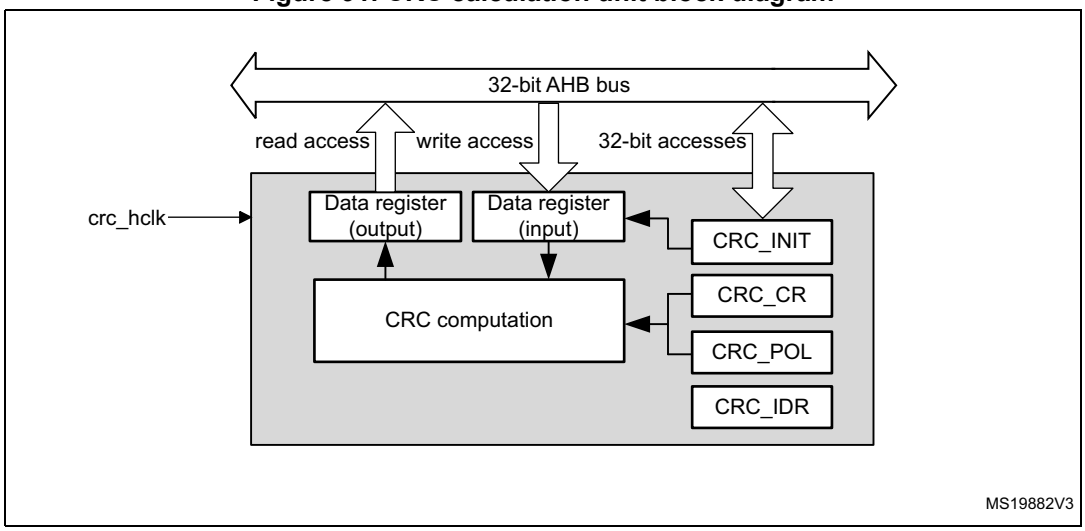
19.2 CRC main features

- Uses CRC-32 (Ethernet) polynomial: 0x4C11DB7
  $X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$
- Alternatively, uses fully programmable polynomial with programmable size (7, 8, 16, 32 bits)
- Handles 8-,16-, 32-bit data size
- Programmable CRC initial value
- Single input/output 32-bit data register
- Input buffer to avoid bus stall during calculation
- CRC computation done in 4 AHB clock cycles (HCLK) for the 32-bit data size
- General-purpose 8-bit register (can be used for temporary storage)
- Reversibility option on I/O data
- Accessed through AHB slave peripheral by 32-bit words only, with the exception of CRC_DR register that can be accessed by words, right-aligned half-words and right-aligned bytes

19.3 CRC functional description

19.3.1 CRC block diagram

Figure 91. CRC calculation unit block diagram



19.3.2 CRC internal signals

Table 143. CRC internal input/output signals

Signal name	Signal type	Description
crc_hclk	Digital input	AHB clock

19.3.3 CRC operation

The CRC calculation unit has a single 32-bit read/write data register (CRC_DR). It is used to input new data (write access), and holds the result of the previous CRC calculation (read access).

Each write operation to the data register creates a combination of the previous CRC value (stored in CRC_DR) and the new one. CRC computation is done on the whole 32-bit data word or byte by byte depending on the format of the data being written.

The CRC_DR register can be accessed by word, right-aligned half-word and right-aligned byte. For the other registers only 32-bit accesses are allowed.

The duration of the computation depends on data width:

- 4 AHB clock cycles for 32 bits
- 2 AHB clock cycles for 16 bits
- 1 AHB clock cycles for 8 bits

An input buffer allows a second data to be immediately written without waiting for any wait states due to the previous CRC calculation.

The data size can be dynamically adjusted to minimize the number of write accesses for a given number of bytes. For instance, a CRC for 5 bytes can be computed with a word write followed by a byte write.

The input data can be reversed to manage the various endianness schemes. The reversing operation can be performed on 8 bits, 16 bits and 32 bits depending on the REV_IN[1:0] bits in the CRC_CR register.

For example, 0x1A2B3C4D input data are used for CRC calculation as:

- 0x58D43CB2 with bit-reversal done by byte
- 0xD458B23C with bit-reversal done by half-word
- 0xB23CD458 with bit-reversal done on the full word

The output data can also be reversed by setting the REV_OUT bit in the CRC_CR register.

The operation is done at bit level. For example, 0x11223344 output data are converted to 0x22CC4488.

The CRC calculator can be initialized to a programmable value using the RESET control bit in the CRC_CR register (the default value is 0xFFFFFFFF).

The initial CRC value can be programmed with the CRC_INIT register. The CRC_DR register is automatically initialized upon CRC_INIT register write access.

The CRC_IDR register can be used to hold a temporary value related to CRC calculation. It is not affected by the RESET bit in the CRC_CR register.

Polynomial programmability

The polynomial coefficients are fully programmable through the CRC_POL register, and the polynomial size can be configured to be 7, 8, 16 or 32 bits by programming the POLYSIZE[1:0] bits in the CRC_CR register. Even polynomials are not supported.

Note: The type of an even polynomial is $X+X^2+..+X^n$, while the type of an odd polynomial is $1+X+X^2+..+X^n$.

If the CRC data is less than 32-bit, its value can be read from the least significant bits of the CRC_DR register.

To obtain a reliable CRC calculation, the change on-fly of the polynomial value or size can not be performed during a CRC calculation. As a result, if a CRC calculation is ongoing, the application must either reset it or perform a CRC_DR read before changing the polynomial.

The default polynomial value is the CRC-32 (Ethernet) polynomial: 0x4C11DB7.

19.4 CRC registers

The CRC_DR register can be accessed by words, right-aligned half-words and right-aligned bytes. For the other registers only 32-bit accesses are allowed.

19.4.1 CRC data register (CRC_DR)

Address offset: 0x00

Reset value: 0xFFFF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DR[31:0]:** Data register bits

This register is used to write new data to the CRC calculator.

It holds the previous CRC calculation result when it is read.

If the data size is less than 32 bits, the least significant bits are used to write/read the correct value.

19.4.2 CRC independent data register (CRC_IDR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IDR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **IDR[31:0]**: General-purpose 32-bit data register bits

These bits can be used as a temporary storage location for four bytes.

This register is not affected by CRC resets generated by the RESET bit in the CRC_CR register

19.4.3 CRC control register (CRC_CR)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	REV_OUT	REV_IN[1:0]		POLYSIZE[1:0]		Res.	Res.	RESET
								rw	rw	rw	rw	rw			rs

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **REV_OUT**: Reverse output data

This bit controls the reversal of the bit order of the output data.
0: Bit order not affected
1: Bit-reversed output format

Bits 6:5 **REV_IN[1:0]**: Reverse input data

This bitfield controls the reversal of the bit order of the input data
00: Bit order not affected
01: Bit reversal done by byte
10: Bit reversal done by half-word
11: Bit reversal done by word

Bits 4:3 **POLYSIZE[1:0]**: Polynomial size

These bits control the size of the polynomial.
00: 32 bit polynomial
01: 16 bit polynomial
10: 8 bit polynomial
11: 7 bit polynomial

Bits 2:1 Reserved, must be kept at reset value.

Bit 0 **RESET**: RESET bit

This bit is set by software to reset the CRC calculation unit and set the data register to the value stored in the CRC_INIT register. This bit can only be set, it is automatically cleared by hardware

19.4.4 CRC initial value (CRC_INIT)

Address offset: 0x10

Reset value: 0xFFFF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CRC_INIT[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CRC_INIT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **CRC_INIT[31:0]**: Programmable initial CRC value
This register is used to write the CRC initial value.

19.4.5 CRC polynomial (CRC_POL)

Address offset: 0x14

Reset value: 0x04C1 1DB7

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
POL[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
POL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **POL[31:0]**: Programmable polynomial
This register is used to write the coefficients of the polynomial to be used for CRC calculation.
If the polynomial size is less than 32 bits, the least significant bits have to be used to program the correct value.

19.4.6 CRC register map

Table 144. CRC register map and reset values

Refer to *Section 2.3 on page 111* for the register boundary addresses.

20 CORDIC co-processor (CORDIC)

20.1 CORDIC introduction

The CORDIC co-processor provides hardware acceleration of mathematical functions (mainly trigonometric ones) commonly used in motor control, metering, signal processing and many other applications.

It speeds up the calculation of these functions compared to a software implementation, making it possible the use of a lower operating frequency, or freeing up processor cycles in order to perform other tasks.

20.2 CORDIC main features

- 24-bit CORDIC rotation engine
- Circular and Hyperbolic modes
- Rotation and Vectoring modes
- Functions: sine, cosine, sinh, cosh, atan, atan2, atanh, modulus, square root, natural logarithm
- Programmable precision
- Low latency AHB slave interface
- Results can be read as soon as ready, without polling or interrupt
- DMA read and write channels
- Multiple register read/write by DMA

20.3 CORDIC functional description

20.3.1 General description

The CORDIC is a cost-efficient successive approximation algorithm for evaluating trigonometric and hyperbolic functions.

In trigonometric (circular) mode, the sine and cosine of an angle θ are determined by rotating the unit vector [1, 0] through decreasing angles until the cumulative sum of the rotation angles equals the input angle θ. The x and y cartesian components of the rotated vector then correspond, respectively, to the cosine and sine of θ. Inversely, the angle of a vector [x, y] corresponding to arctangent (y / x), is determined by rotating [x, y] through successively decreasing angles to obtain the unit vector [1, 0]. The cumulative sum of the rotation angles gives the angle of the original vector.

The CORDIC algorithm can also be used for calculating hyperbolic functions (sinh, cosh, atanh), by replacing the successive circular rotations by steps along a hyperbole.

Other functions can be derived from the basic functions described above.

20.3.2 CORDIC functions

The first step when using the co-processor is to select the required function, by programming the FUNC field of the CORDIC_CR register accordingly.

Table 145 lists the functions supported by the CORDIC co-processor.

Table 145. CORDIC functions

Function	Primary argument (ARG1)	Secondary argument (ARG2)	Primary result (RES1)	Secondary result (RES2)
Cosine	angle θ	modulus m	$m \cdot \cos\theta$	$m \cdot \sin\theta$
Sine	angle θ	modulus m	$m \cdot \sin\theta$	$m \cdot \cos\theta$
Phase	x	y	atan2(y,x)	$\sqrt{x^2+y^2}$
Modulus	x	y	$\sqrt{x^2+y^2}$	atan2(y,x)
Arctangent	x	none	$\tan^{-1} x$	none
Hyperbolic cosine	x	none	cosh x	sinh x
Hyperbolic sine	x	none	sinh x	cosh x
Hyperbolic arctangent	x	none	$\tanh^{-1} x$	none
Natural logarithm	x	none	ln x	none
Square root	x	none	$\sqrt{x}$	none

Several functions take two input arguments (ARG1 and ARG2) and some generate two results (RES1 and RES2) simultaneously. This is a side-effect of the algorithm and means that only one operation is needed to obtain two values. This is the case, for example, when performing polar-to-rectangular conversion: sin θ also generates cos θ, cos θ also generates sin θ. Similarly for rectangular-to-polar conversion (phase(x,y), modulus(x,y)) and for hyperbolic functions (cosh θ, sinh θ).

Note: The exponential function, exp x, can be obtained as the sum of sinh x and cosh x. Furthermore, base N logarithms, $\log_N x$, can be derived by multiplying ln x by a constant K, where K = 1/ln N.

For certain functions (atan, log, sqrt) a scaling factor (see *Section 20.3.4*) can be applied to extend the range of the function beyond the maximum [-1, 1] supported by the q1.31 fixed point format. The scaling factor must be set to 0 for all other circular functions, and to 1 for hyperbolic functions.

Cosine

Table 146. Cosine parameters

Parameter	Description	Range
ARG1	Angle θ in radians, divided by π	[-1, 1]
ARG2	Modulus m	[0, 1]
RES1	m · cos θ	[-1, 1]

Table 146. Cosine parameters (continued)

Parameter	Description	Range
RES2	m · sin θ	[-1, 1]
SCALE	Not applicable	0

This function calculates the cosine of an angle in the range -π to π. It can also be used to perform polar to rectangular conversion.

The primary argument is the angle θ in radians. It must be divided by π before programming ARG1.

The secondary argument is the modulus m. If m is greater than 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the cosine of the angle, multiplied by the modulus.

The secondary result, RES2, is the sine of the angle, multiplied by the modulus.

Sine

Table 147. Sine parameters

Parameter	Description	Range
ARG1	Angle θ in radians, divided by π	[-1, 1]
ARG2	Modulus m	[0, 1]
RES1	m · sin θ	[-1, 1]
RES2	m · cos θ	[-1, 1]
SCALE	Not applicable	0

This function calculates the sine of an angle in the range -π to π. It can also be used to perform polar to rectangular conversion.

The primary argument is the angle θ in radians. It must be divided by π before programming ARG1.

The secondary argument is the modulus m. If m is greater than 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the sine of the angle, multiplied by the modulus.

The secondary result, RES2, is the cosine of the angle, multiplied by the modulus.

Phase

Table 148. Phase parameters

Parameter	Description	Range
ARG1	x coordinate	[-1, 1]
ARG2	y coordinate	[-1, 1]
RES1	Phase angle θ in radians, divided by π	[-1, 1]

Table 148. Phase parameters (continued)

Parameter	Description	Range
RES2	Modulus m	[0, 1]
SCALE	Not applicable	0

This function calculates the phase angle in the range -π to π of a vector **v** = [x y] (also known as atan2(y,x). It can also be used to perform rectangular to polar conversion.

The primary argument is the x coordinate, that is, the magnitude of the vector in the direction of the x axis. If |x| > 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG1.

The secondary argument is the y coordinate, that is, the magnitude of the vector in the direction of the y axis. If |y| > 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the phase angle θ of the vector **v**. RES1 must be multiplied by π to obtain the angle in radians. Note that values close to π may sometimes wrap to -π due to the circular nature of the phase angle.

The secondary result, RES2, is the modulus, given by: $|v| = \sqrt{x^2 + y^2}$. If |**v**| > 1 the result in RES2 is saturated to 1.

Modulus

Table 149. Modulus parameters

Parameter	Description	Range
ARG1	x coordinate	[-1, 1]
ARG2	y coordinate	[-1, 1]
RES1	Modulus m	[0, 1]
RES2	Phase angle θ	[-1, 1]
SCALE	Not applicable	0

This function calculates the magnitude, or modulus, of a vector **v** = [x y]. It can also be used to perform rectangular to polar conversion.

The primary argument is the x coordinate, that is, the magnitude of the vector in the direction of the x axis. If |x| > 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG1.

The secondary argument is the y coordinate, that is, the magnitude of the vector in the direction of the y axis. If |y| > 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the modulus, given by: $|v| = \sqrt{x^2 + y^2}$. If |**v**| > 1 the result in RES1 is saturated to 1.

The secondary result, RES2, is the phase angle θ of the vector **v**. RES2 must be multiplied by π to obtain the angle in radians. Note that values close to π may sometimes wrap to -π due to the circular nature of the phase angle.

Arctangent

Table 150. Arctangent parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[-1, 1]
ARG2	Not applicable	-
RES1	$2^{-n} \cdot \tan^{-1} x$, in radians, divided by p	[-1, 1]
RES2	Not applicable	-
SCALE	n	[0 7]

This function calculates the arctangent, or inverse tangent, of the input argument x.

The primary argument, ARG1, is the input value, $x = \tan \theta$. If $|x| > 1$, a scaling factor of 2^{-n} must be applied in software such that $-1 < x \cdot 2^{-n} < 1$. The scaled value $x \cdot 2^{-n}$ is programmed in ARG1 and the scale factor n must be programmed in the SCALE parameter.

Note that the maximum input value allowed is $\tan \theta = 128$, which corresponds to an angle $\theta = 89.55$ degrees. For $|x| > 128$, a software method must be used to find $\tan^{-1} x$.

The secondary argument, ARG2, is unused.

The primary result, RES1, is the angle $\theta = \tan^{-1} x$. RES1 must be multiplied by $2^n \cdot \pi$ to obtain the angle in radians.

The secondary result, RES2, is unused.

Hyperbolic cosine

Table 151. Hyperbolic cosine parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[-0.559 0.559]
ARG2	Not applicable	-
RES1	$2^{-n} \cdot \cosh x$	[0.5 0.846]
RES2	$2^{-n} \cdot \sinh x$	[-0.683 0.683]
SCALE	n	1

This function calculates the hyperbolic cosine of a hyperbolic angle x. It can also be used to calculate the exponential functions $e^x = \cosh x + \sinh x$, and $e^{-x} = \cosh x - \sinh x$.

The primary argument is the hyperbolic angle x. Only values of x in the range -1.118 to +1.118 are supported. Since the minimum value of cosh x is 1, which is beyond the range of the q1.31 format, a scaling factor of 2^{-n} must be applied in software. The factor n = 1 must be programmed in the SCALE parameter.

The secondary argument is not used.

The primary result, RES1, is the hyperbolic cosine, cosh x. RES1 must be multiplied by 2 to obtain the correct result.

The secondary result, RES2, is the hyperbolic sine, sinh x. RES2 must be multiplied by 2 to obtain the correct result.

Hyperbolic sine

Table 152. Hyperbolic sine parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[-0.559, 0.559]
ARG2	Not applicable	-
RES1	$2^{-n} \cdot \sinh x$	[-0.683, 0.683]
RES2	$2^{-n} \cdot \cosh x$	[0.5, 0.846]
SCALE	n	1

This function calculates the hyperbolic sine of a hyperbolic angle x. It can also be used to calculate the exponential functions $e^x = \cosh x + \sinh x$, and $e^{-x} = \cosh x - \sinh x$.

The primary argument is the hyperbolic angle x. Only values of x in the range -1.118 to +1.118 are supported. For all input values, a scaling factor of 2^{-n} must be applied in software, where n = 1. The scaled value $x \cdot 0.5$ is programmed in ARG1 and the factor n = 1 must be programmed in the SCALE parameter.

The secondary argument is not used.

The primary result, RES1, is the hyperbolic sine, sinh x. RES1 must be multiplied by 2 to obtain the correct result.

The secondary result, RES2, is the hyperbolic cosine, cosh x. RES2 must be multiplied by 2 to obtain the correct result.

Hyperbolic arctangent

Table 153. Hyperbolic arctangent parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[-0.403 0.403]
ARG2	Not applicable	-
RES1	$2^{-n} \cdot \text{atanh } x$	[-0.559 0.559]
RES2	Not applicable	-
SCALE	n	1

This function calculates the hyperbolic arctangent of the input argument x.

The primary argument is the input value x. Only values of x in the -0.806 to +0.806 range are supported. The value x must be scaled by a factor 2^{-n}, where n = 1. The scaled value

$x \cdot 0.5$ is programmed in ARG1 and the factor n = 1 must be programmed in the SCALE parameter.

The secondary argument is not used.

The primary result is the hyperbolic arctangent, atanh x. RES1 must be multiplied by 2 to obtain the correct value.

The secondary result is not used.

Natural logarithm

Table 154. Natural logarithm parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[0.054 0.875]
ARG2	Not applicable	-
RES1	$2^{-(n+1)}.\ln x$	[-0.279 0.137]
RES2	Not applicable	-
SCALE	n	[1 4]

This function calculates the natural logarithm of the input argument x.

The primary argument is the input value x. Only values of x in the range 0.107 to 9.35 are supported. The value x must be scaled by a factor 2^{-n}, such that $x \cdot 2^{-n} < 1-2^{-n}$. The scaled value $x \cdot 2^{-n}$ is programmed in ARG1 and the factor n must be programmed in the SCALE parameter.

Table 155 lists the valid scaling factors, n, and the corresponding ranges of x and ARG1.

Table 155. Natural log scaling factors and corresponding ranges

n	x range	ARG1 range
1	$0.107 \le x < 1$	$0.0535 \le ARG1 < 0.5$
2	$1 \le x < 3$	$0.25 \le ARG1 < 0.75$
3	$3 \le x < 7$	$0.375 \le ARG1 < 0.875$
4	$7 \le x \le 9.35$	$0.4375 \le ARG1 < 0.584$

The secondary argument is not used.

The primary result is the natural logarithm, ln x. RES1 must be multiplied by $2^{(n+1)}$ to obtain the correct value.

The secondary result is not used.

Square root

Table 156. Square root parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[0.027 0.875]
ARG2	Not applicable	-
RES1	$2^{-n}\sqrt{x}$	[0.04 1]
RES2	Not applicable	-
SCALE	n	[0 2]

This function calculates the square root of the input argument x.

The primary argument is the input value x. Only values of x in the range 0.027 to 2.34 are supported. The value x must be scaled by a factor 2^{-n}, such that $x \cdot 2^{-n} < (1 - 2^{(-n-2)})$.

The scaled value $x \cdot 2^{-n}$ is programmed in ARG1 and the factor n must be programmed in the SCALE parameter.

Table 157 lists the valid scaling factors, n, and the corresponding ranges of x and ARG1.

Table 157. Square root scaling factors and corresponding ranges

n	x range	ARG1 range
0	$0.027 \leq x < 0.75$	$0.027 \leq ARG1 < 0.75$
1	$0.75 \leq x < 1.75$	$0.375 \leq ARG1 < 0.875$
2	$1.75 \leq x \leq 2.341$	$0.4375 \leq ARG1 \leq 0.585$

The secondary argument is not used.

The primary result is the square root of x. RES1 must be multiplied by 2^n to obtain the correct value.

The secondary result is not used.

20.3.3 Fixed point representation

The CORDIC operates in fixed point signed integer format. Input and output values can be either q1.31 or q1.15.

In q1.31 format, numbers are represented by one sign bit and 31 fractional bits (binary decimal places). The numeric range is therefore -1 (0x80000000) to $1 - 2^{-31}$ (0x7FFFFFFF).

In q1.15 format, the numeric range is 1 (0x8000) to $1 - 2^{-15}$ (0x7FFF). This format has the advantage that two input arguments can be packed into a single 32-bit write, and two results can be fetched in one 32-bit read.

20.3.4 Scaling factor

Several of the functions listed in *Section 20.3.2* specify a scaling factor, SCALE. This allows the function input range to be extended to cover the full range of values supported by the CORDIC, without saturating the input, output or internal registers. If the scaling factor is

required, it has to be calculated in software and programmed into the SCALE field of the CORDIC_CSR register. The input arguments must be scaled accordingly before programming the scaled values in the CORDIC_WDATA register. The scaling must also be undone on the results read from the CORDIC_RDATA register.

Note: The scaling factor entails a loss of precision due to truncation of the scaled value.

20.3.5 Precision

The precision of the result is dependent on the number of CORDIC iterations. The algorithm converges at a constant rate of one binary digit per iteration for trigonometric functions (sine, cosine, phase, modulus), see *Figure 92*.

For hyperbolic functions (hyperbolic sine, hyperbolic cosine, natural logarithm), the convergence rate is less constant due to the peculiarities of the CORDIC algorithm (see *Figure 93*). The square root function converges at roughly twice the speed of the hyperbolic functions (see *Figure 94*).

Figure 92. CORDIC convergence for trigonometric functions

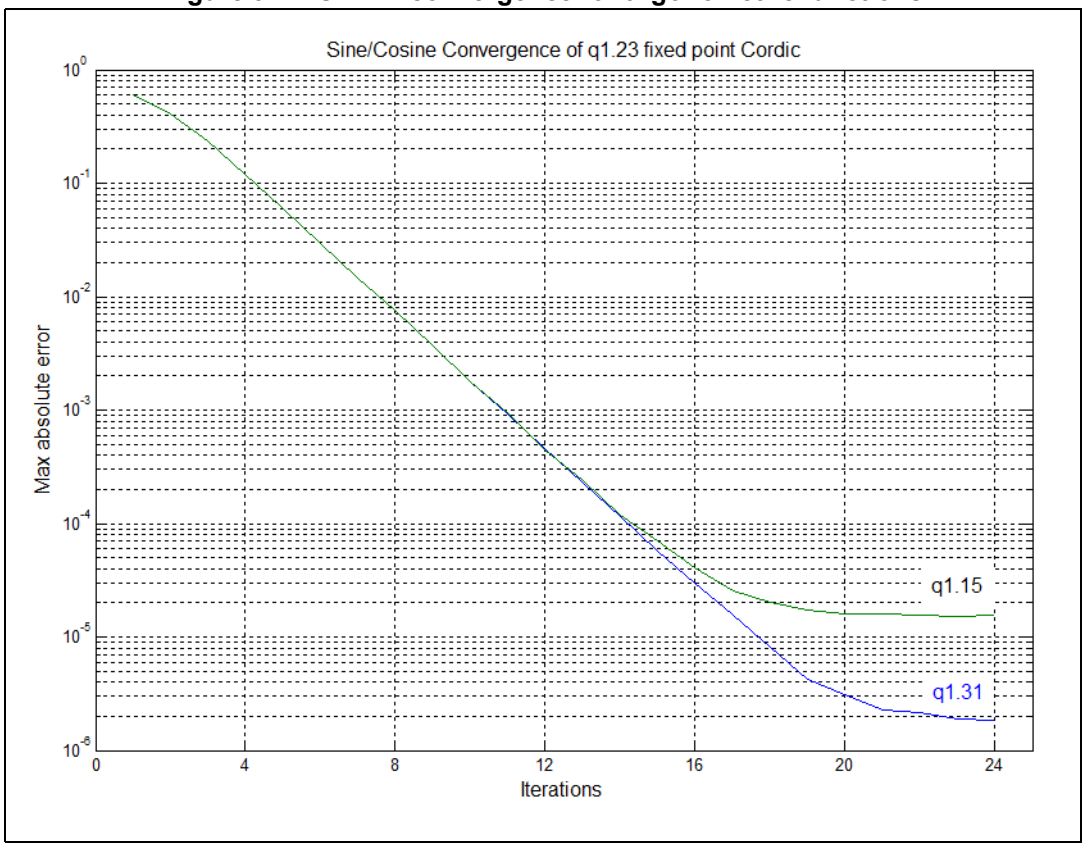

Figure 93. CORDIC convergence for hyperbolic functions

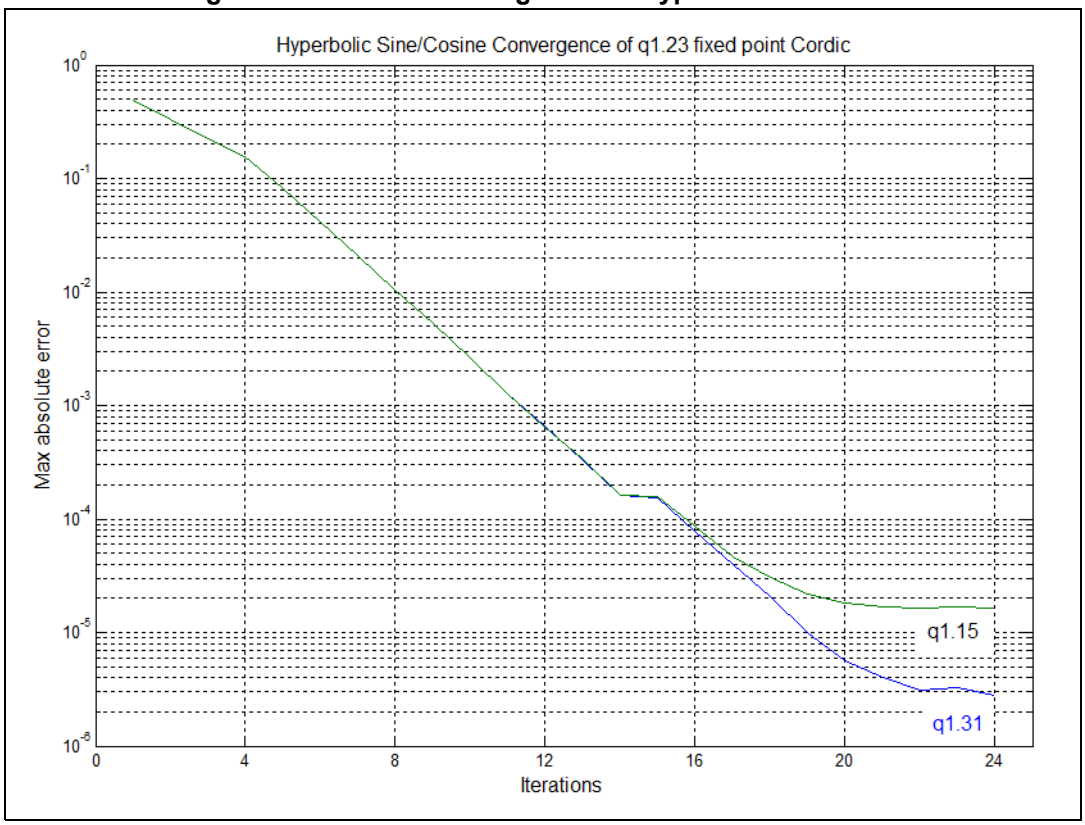

Figure 94. CORDIC convergence for square root

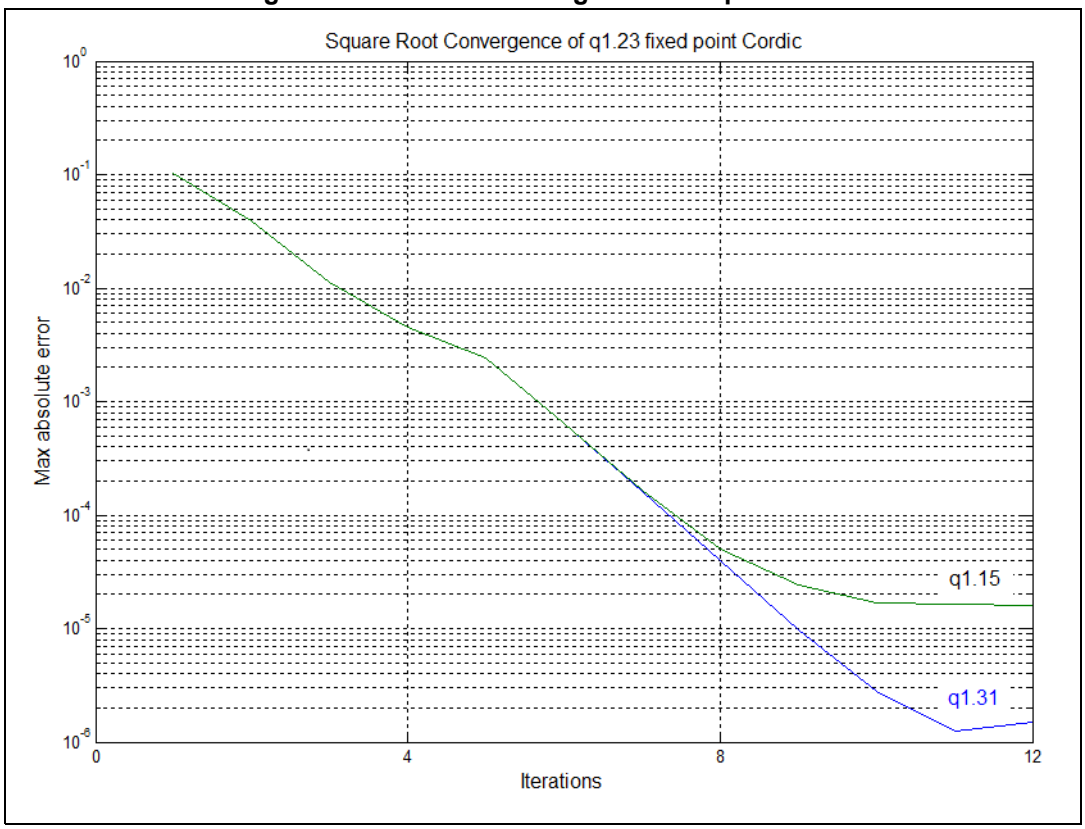

Note: The convergence rate decreases as the quantization error starts to become significant.

The CORDIC can perform four iterations per clock cycle. For each function, the maximum error remaining after every four iterations is shown in *Table 158*, together with the number of clock cycles required to reach that precision. From this table, the desired number of cycles can be determined and programmed in the PRECISION field of the CORDIC_CR register. The co-processor stops as soon as the programmed number of iterations has completed, and the result can be read immediately.

Table 158. Precision vs. number of iterations

Function	Number of iterations	Number of cycles	Max residual error(1)	
			q1.31 format	q1.15 format
Sin, Cos, Phase(2), Mod, Atan(4)	4	1	2^{-3}	2^{-3}
	8	2	2^{-7}	2^{-7}
	12	3	2^{-11}	2^{-11}
	16	4	2^{-15}	2^{-15}
	20	5	2^{-18}	2^{-16}
	24	6	2^{-19}	2^{-16}

Table 158. Precision vs. number of iterations (continued)

Function	Number of iterations	Number of cycles	Max residual error(1)	
			q1.31 format	q1.15 format
Sinh, Cosh, Atanh, Ln(3)	4	1	2^{-2}	2^{-2}
	8	2	2^{-6}	2^{-6}
	12	3	2^{-10}	2^{-10}
	16	4	2^{-13}	2^{-13}
	20	5	2^{-17}	2^{-15}
	24	6	2^{-18}	2^{-15}
Sqrt(4)	4	1	2^{-7}	2^{-7}
	8	2	2^{-14}	2^{-14}
	12	3	2^{-19}	2^{-15}

1. Max residual error is the maximum error remaining after the given number of iterations, compared to the identical calculation performed in double precision floating point. An additional rounding error may be incurred, of up to 2^{-16} for q15 format or 2^{-20} for q31 format.
2. For modulus > 0.5. The achievable precision reduces proportionally to the magnitude of the modulus, as quantization error becomes significant.
3. SCALE = 1. If a higher scaling factor is used, the achievable precision is reduced proportionally.
4. SCALE = 0. If a higher scaling factor is used, the achievable precision is reduced proportionally.

20.3.6 Zero-overhead mode

The fastest way to use the co-processor is to pre-program the CORDIC_CSR register with the function to be performed (FUNC), the desired number of clock cycles (PRECISION), the size of the input and output values (ARGSIZE, RESSIZE), the number of input arguments (NARGS) and/or results (NRES), and the scaling factor (SCALE), if applicable.

Subsequently, a calculation is triggered by writing the input arguments to the CORDIC_WDATA register. As soon as the correct number of input arguments has been written (and any ongoing calculation has finished) a new calculation is launched using these input arguments and the current CORDIC_CSR settings. There is no need to re-program the CORDIC_CSR register if there is no change.

If a dual 32-bit input argument is needed (ARGSIZE = 0, NARGS = 1), the primary input argument, ARG1, must be written first, followed by the secondary argument, ARG2. If the secondary argument remains unchanged for a series of calculations, the second write can be avoided, by reprogramming the number of arguments to one (NARGS = 0), once the first calculation has started. The secondary argument retains its programmed value as long as the function is not changed.

Note: ARG2 is set to +1 (0x7FFFFFFF) after a reset.

If two 16-bit arguments are used (ARGSIZE = 1) they must be packed into a 32-bit word, with ARG1 in the least significant half-word and ARG2 in the most significant half-word. The packed 32-bit word is then written to the CORDIC_WDATA register. Only one write is needed in this case (NARGS = 0).

For functions taking only one input argument, ARG1, it is recommended to set NARGS = 0. If NARGS = 1, a second write to CORDIC_WDATA must be performed to trigger the calculation. The ARG2 data in this case is not used.

Once the calculation starts, any attempt to read the CORDIC_RDATA register inserts bus wait states until the calculation is completed, before returning the result. Hence it is possible for the software to write the input and immediately read the result without polling to see if it is valid. Alternatively, the processor can wait for the appropriate number of clock cycles before reading the result. This time can be used to program the CORDIC_CSR register for the next calculation and prepare the next input data, if needed. The CORDIC_CSR register can be re-programmed while a calculation is in progress, without affecting the result of the ongoing calculation. In the same way, the CORDIC_WDATA register can be updated with the next argument(s) once the previous arguments have been taken into account. The next arguments and settings remain pending until the previous calculation has completed.

When a calculation is finished, the result(s) can be read from the CORDIC_RDATA register. If two 32-bit results are expected (NRES = 1, RESSIZE = 0), the primary result (RES1) is read out first, followed by the secondary result (RES2). If only one 32-bit result is expected (NRES = 0, RESSIZE = 0), then RES1 is output on the first read.

If 16-bit results are expected (RESSIZE = 1), a single read to CORDIC_RDATA fetches both results packed into a 32-bit word. RES1 is in the lower half-word, and RES2 in the upper half-word. In this case, it is recommended to program NRES = 0. IF NRES = 1, a second read of CORDIC_RDATA must be performed in order to free up the CORDIC for the next operation. The data from this second read must be discarded.

The next calculation starts when the expected number of results has been read, provided the expected number of arguments has been written. This means that at any time, there can be one calculation in progress, or waiting for the results to be read, and one operation pending. Any further access to CORDIC_WDATA while an operation is pending, cancels the pending operation and overwrite the data.

The following sequence summarizes the use of the CORDIC_IP in zero-overhead mode:

1. Program the CORDIC_CSR register with the appropriate settings
2. Program the argument(s) for the first calculation in the CORDIC_WDATA register. This launches the first calculation.
3. If needed, update the CORDIC_CSR register settings for the next calculation.
4. Program the argument(s) for the next calculation in the CORDIC_WDATA register.
5. Read the result(s) from the CORDIC_RDATA register. This triggers the next calculation.
6. Go to step *3*.

20.3.7 Polling mode

When a new result is available in the CORDIC_RDATA register, the RRDY flag is set in the CORDIC_CSR register. The flag can be polled by reading the register. It is reset by reading the CORDIC_RDATA register (once or twice depending on the NRES field of the CORDIC_CSR register).

Polling the RRDY flag takes slightly longer than reading the CORDIC_RDATA register directly, since the result is not read as soon as it is available. However the processor and bus interface are not stalled while reading the CORDIC_CSR register, so this mode may be of interest if stalling the processor is not acceptable (e.g. if low latency interrupts must be serviced).

20.3.8 Interrupt mode

By setting the interrupt enable (IE) bit in the CORDIC_CSR register, an interrupt is generated whenever the RRDY flag is set. The interrupt is cleared when the flag is reset.

This mode allows the result of the calculation to be read under interrupt service routine, and hence given a priority relative to other tasks. However it is slower than directly reading the result, or polling the flag, due to the interrupt handling delays.

20.3.9 DMA mode

If the DMA write enable (DMAWEN) bit is set in the CORDIC_CSR register, and no operation is pending, a DMA write channel request is generated. The DMA controller can transfer a primary input argument (ARG1) from memory into the CORDIC_WDATA register. Writing into the register deasserts the DMA request. If NARGS = 1 in the CORDIC_CSR register, a second DMA write channel request is generated to transfer the secondary input argument (ARG2) into the CORDIC_WDATA register. When all input arguments have been written, and any ongoing calculation has been completed (by reading the results), a new calculation is started and another DMA write channel request is generated.

If the DMA read enable (DMAREN) bit is set in the CORDIC_CSR register, the RRDY flag going active generates a DMA read channel request. The DMA controller can then transfer the primary result (RES1) from the CORDIC_RDATA register to memory. Reading the register deasserts the DMA request. If NRES = 1 in the CORDIC_CSR register, a second DMA request is generated to read out the secondary result (RES2). When all results have been read, the RRDY flag is deasserted.

The DMA read and write channels can be enabled separately. If both channels are enabled, the CORDIC can autonomously perform repeated calculations on a buffer of data without processor intervention.This allows the processor to perform other tasks. The DMA controller is operating in memory-to-peripheral mode for the write channel, and peripheral-to-memory mode for the read channel. Note that the sequence is started by the processor setting the DMAWEN flag. Thereafter the DMA read and write requests are generated as fast as the CORDIC can process the data.

In some cases, the input data may be stored in memory, and the output is transferred at regular intervals to another peripheral, such as a digital-to-analog converter. In this case, the destination peripheral generates a DMA request each time it needs a new data. The DMA controller can directly fetch the next sample from the CORDIC_RDATA register (in this case the DMA controller is operating in memory-to-peripheral mode, even though the source is a peripheral register). The act of reading the result allows the CORDIC to start a new calculation, which in turn generates a DMA write channel request, and the DMA controller transfers the next input value to the CORDIC_WDATA register. The DMA write channel is enabled (DMAWEN = 1), but the read channel must not be enabled.

In a similar way, data coming from another peripheral, such as an ADC, can be transferred directly to the CORDIC_WDATA register (in peripheral-to-memory mode). The DMA write channel must not be enabled. The CORDIC processes the input data and generate a DMA read request when complete, if DMAREN = 1. The DMA controller then transfers the result from CORDIC_RDATA register to memory (peripheral-to-memory mode).

Note: No DMA request is generated to program the CORDIC_CSR register. DMA mode is therefore only useful when repeatedly performing the same function with the same settings. The scale factor cannot be changed during a series of DMA transfers.

Note: Each DMA request must be acknowledged, as a result of the DMA performing an access to the CORDIC_WDATA or CORDIC_RDATA register. If an extraneous access to the relevant register occurs before this, the acknowledge is asserted prematurely, and may block the DMA channel. Therefore, when the DMA read channel is enabled, CPU access to the CORDIC_RDATA register must be avoided. Similarly, the processor must avoid accessing the CORDIC_WDATA register when the DMA write channel is enabled.

20.4 CORDIC registers

The CORDIC registers can only be accessed in 32-bit word format

20.4.1 CORDIC control/status register (CORDIC_CSR)

Address offset: 0x00

Reset value: 0x0000 0050

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RRDY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ARG SIZE	RES SIZE	NARG S	NRES	DMA WEN	DMA REN	IEN
r									rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	SCALE[2:0]			PRECISION[3:0]				FUNC[3:0]			
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **RRDY**: Result ready flag

0: No new data in output register

1: CORDIC_RDATA register contains new data.

This bit is set by hardware when a CORDIC operation completes. It is reset by hardware when the CORDIC_RDATA register is read (NRES+1) times.

When this bit is set, if the IEN bit is also set, the CORDIC interrupt is asserted. If the DMAREN bit is set, a DMA read channel request is generated. While this bit is set, no new calculation is started.

Bits 30:23 Reserved, must be kept at reset value.

Bit 22 **ARGSIZE**: Width of input data

0: 32-bit

1: 16-bit

ARGSIZE selects the number of bits used to represent input data.

If 32-bit data is selected, the CORDIC_WDATA register expects arguments in q1.31 format.

If 16-bit data is selected, the CORDIC_WDATA register expects arguments in q1.15 format. The primary argument (ARG1) is written to the least significant half-word, and the secondary argument (ARG2) to the most significant half-word.

Bit 21 **RESSIZE**: Width of output data

0: 32-bit

1: 16-bit

RESSIZE selects the number of bits used to represent output data.

If 32-bit data is selected, the CORDIC_RDATA register contains results in q1.31 format.

If 16-bit data is selected, the least significant half-word of CORDIC_RDATA contains the primary result (RES1) in q1.15 format, and the most significant half-word contains the secondary result (RES2), also in q1.15 format.

Bit 20 **NARGS**: Number of arguments expected by the CORDIC_WDATA register

0: Only one 32-bit write (or two 16-bit values if ARGSIZE = 1) is needed for the next calculation.

1: Two 32-bit values must be written to the CORDIC_WDATA register to trigger the next calculation.

Reads return the current state of the bit.

Bit 19 **NRES**: Number of results in the CORDIC_RDATA register

0: Only one 32-bit value (or two 16-bit values if RESSIZE = 1) is transferred to the CORDIC_RDATA register on completion of the next calculation. One read from CORDIC_RDATA resets the RRDY flag.

1: Two 32-bit values are transferred to the CORDIC_RDATA register on completion of the next calculation. Two reads from CORDIC_RDATA are necessary to reset the RRDY flag.

Reads return the current state of the bit.

Bit 18 **DMAWEN**: Enable DMA write channel

0: Disabled. No DMA write requests are generated.

1: Enabled. Requests are generated on the DMA write channel whenever no operation is pending

This bit is set and cleared by software. A read returns the current state of the bit.

Bit 17 **DMAREN**: Enable DMA read channel

0: Disabled. No DMA read requests are generated.

1: Enabled. Requests are generated on the DMA read channel whenever the RRDY flag is set.

This bit is set and cleared by software. A read returns the current state of the bit.

Bit 16 **IEN**: Enable interrupt.

0: Disabled. No interrupt requests are generated.

1: Enabled. An interrupt request is generated whenever the RRDY flag is set.

This bit is set and cleared by software. A read returns the current state of the bit.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:8 **SCALE[2:0]**: Scaling factor

The value of this field indicates the scaling factor applied to the arguments and/or results. A value n implies that the arguments have been multiplied by a factor 2^{-n}, and/or the results need to be multiplied by 2^{n}. Refer to *Section 20.3.2* for the applicability of the scaling factor for each function and the appropriate range.

Bits 7:4 **PRECISION[3:0]**: Precision required (number of iterations)

0: reserved

1 to 15: (Number of iterations)/4

To determine the number of iterations needed for a given accuracy refer to *Table 158*.

Note that for most functions, the recommended range for this field is 3 to 6.

Bits 3:0 **FUNC[3:0]**: Function

0: Cosine
1: Sine
2: Phase
3: Modulus
4: Arctangent
5: Hyperbolic cosine
6: Hyperbolic sine
7: Arctanh
8: Natural logarithm
9: Square Root
10 to 15: reserved

20.4.2 CORDIC argument register (CORDIC_WDATA)

Address offset: 0x04

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ARG[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ARG[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **ARG[31:0]**: Function input arguments

This register is programmed with the input arguments for the function selected in the CORDIC_CSR register FUNC field.

If 32-bit format is selected (CORDIC_CSR.ARGSIZE = 0) and two input arguments are required (CORDIC_CSR.NARGS = 1), two successive writes are required to this register. The first writes the primary argument (ARG1), the second writes the secondary argument (ARG2).

If 32-bit format is selected and only one input argument is required (NARGS = 0), only one write is required to this register, containing the primary argument (ARG1).

If 16-bit format is selected (CORDIC_CSR.ARGSIZE = 1), one write to this register contains both arguments. The primary argument (ARG1) is in the lower half, ARG[15:0], and the secondary argument (ARG2) is in the upper half, ARG[31:16]. In this case, NARGS must be set to 0.

Refer to *Section 20.3.2* for the arguments required by each function, and their permitted range.

When the required number of arguments has been written, the CORDIC evaluates the function designated by CORDIC_CSR.FUNC using the supplied input arguments, provided any previous calculation has completed. If a calculation is ongoing, the ARG1 and ARG 2 values are held pending until the calculation is completed and the results read. During this time, a write to the register cancels the pending operation and overwrite the argument data.

20.4.3 CORDIC result register (CORDIC_RDATA)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RES[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RES[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **RES[31:0]**: Function result

If 32-bit format is selected (CORDIC_CSR.RESSIZE = 0) and two output values are expected (CORDIC_CSR.NRES = 1), this register must be read twice when the RRDY flag is set. The first read fetches the primary result (RES1). The second read fetches the secondary result (RES2) and resets RRDY.

If 32-bit format is selected and only one output value is expected (NRES = 0), only one read of this register is required to fetch the primary result (RES1) and reset the RRDY flag.

If 16-bit format is selected (CORDIC_CSR.RESSIZE = 1), this register contains the primary result (RES1) in the lower half, RES[15:0], and the secondary result (RES2) in the upper half, RES[31:16]. In this case, NRES must be set to 0, and only one read performed.

A read from this register resets the RRDY flag in the CORDIC_CSR register.

20.4.4 CORDIC register map

Table 159. CORDIC register map and reset value

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3* for the register boundary addresses.

21 Filter math accelerator (FMAC)

21.1 FMAC introduction

The filter math accelerator unit performs arithmetic operations on vectors. It comprises a multiplier/accumulator (MAC) unit, together with address generation logic which allows it to index vector elements held in local memory.

The unit includes support for circular buffers on input and output, which allows digital filters to be implemented. Both finite and infinite impulse response filters can be realized.

The unit allows frequent or lengthy filtering operations to be offloaded from the CPU, freeing up the processor for other tasks. In many cases it can accelerate such calculations compared to a software implementation, resulting in a speed-up of time critical tasks.

21.2 FMAC main features

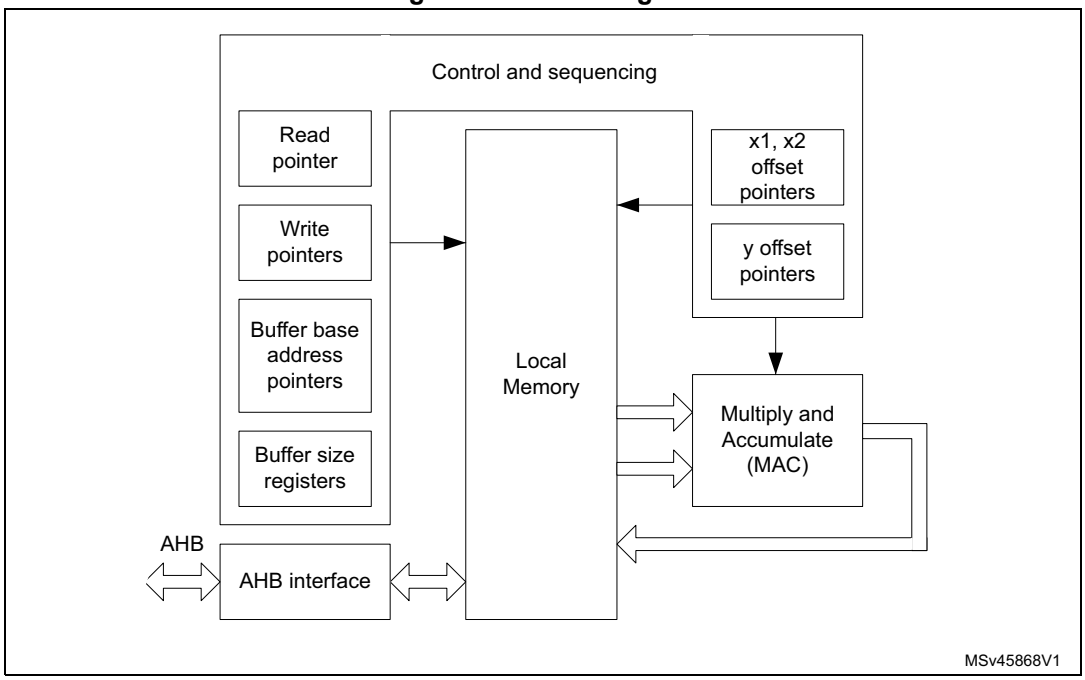
- 16 x 16-bit multiplier
- 24 + 2-bit accumulator with addition and subtraction
- 16-bit input and output data
- 256 x 16-bit local memory
- Up to three areas can be defined in memory for data buffers (two input, one output), defined by programmable base address pointers and associated size registers
- Input and output buffers can be circular
- Filter functions: FIR, IIR (direct form 1)
- Vector functions: Dot product, convolution, correlation
- AHB slave interface
- DMA read and write data channels

21.3 FMAC functional description

21.3.1 General description

The FMAC is shown in *Figure 95*.

Figure 95. Block diagram



The unit is built around a fixed point multiplier and accumulator (MAC). The MAC can take two 16-bit input signed values from memory, multiply them together and add them to the contents of the accumulator. The address of the input values in memory is determined using a set of pointers. These pointers can be loaded, incremented, decremented or reset by the internal hardware. The pointer and MAC operations are controlled by a built-in sequencer in order to execute the requested operation.

To calculate a dot product, the two input vectors are loaded into the local memory by the processor or DMA controller, and the requested operation is selected and started. Each pair of input vector elements is fetched from memory, multiplied together and accumulated. When all the vector elements have been processed, the contents of the accumulator are stored in the local memory, from where they can be read out by the processor or DMA.

The finite impulse response (FIR) filter operation (also known as convolution) consists in repeatedly calculating the dot product of the coefficient vector and a vector of input samples, the latter being shifted by one sample delay, with the least recent sample being discarded and a new sample added, at each repetition.

The infinite impulse response (IIR) filter operation is the convolution of the feedback coefficients with the previous output samples, added to the result of the FIR convolution.

A more detailed description of the filter operations is given in *Section 21.3.6: Filter functions*.

21.3.2 Local memory and buffers

The unit contains a 256 x 16-bit read/write memory which is used for local storage:

- Input values (the elements of the input vectors) are stored in two buffers, X1 and X2.
- Output values (the results of the operations) are stored in another buffer, Y.
- The locations and sizes of the buffers are designated as follows:
  - x1_base: the base address of the X1 buffer
  - x2_base: the base address of the X2 buffer
  - y_base: the base address of the Y buffer
  - x1_buf_size: the number of 16-bit addresses allocated to the X1 buffer
  - x2_buf_size: the number of 16-bit addresses allocated to the X2 buffer
  - y_buf_size: the number of 16-bit addresses allocated to the Y buffer.

These parameters are programmed in the corresponding registers when configuring the unit.

The CPU (or DMA controller) can initialize the contents of each buffer using the Initialization functions (*Section 21.3.5: Initialization functions*) and writing to the write data register. The data is transferred to the location within the target buffer indicated by a write pointer. After each new write, the write pointer is incremented. When the write pointer reaches the end of the allocated buffer space, it wraps back to the base address. This feature is used to load the elements of a vector prior to an operation, or to initialize a filter and load filter coefficients.

Buffer configuration

The buffer sizes and base address offsets must be configured in the X1, X2 and Y buffer configuration registers. For each function, the required buffer size is specified in the function description in *Section 21.3.6: Filter functions*. The base addresses can be chosen anywhere in internal memory, provided that all buffers fit within the internal memory address range (0x00 to 0xFF), that is, base address + buffer size must be less than 256.

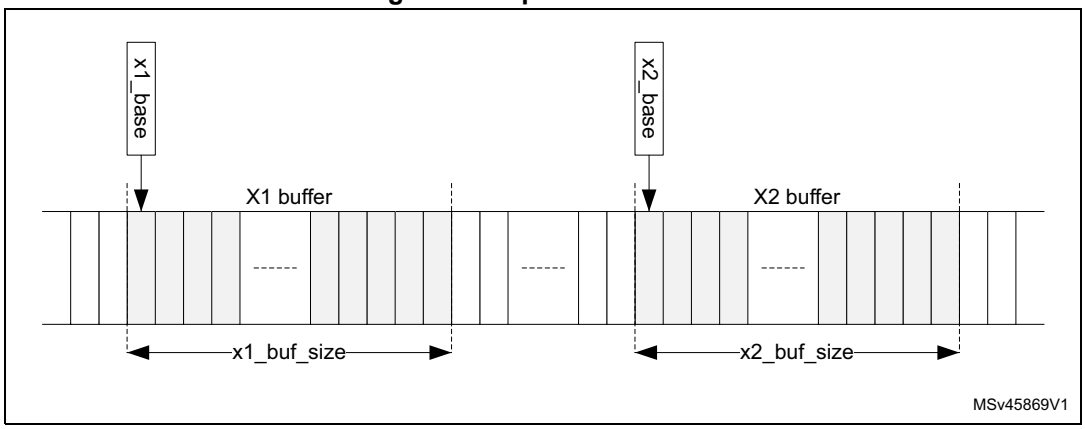
There is no constraint on the size and location of the buffers (they can overlap or even coincide exactly). For filter functions it is recommended not to overlap buffers as this can lead to erroneous behavior.

When circular buffer operation is required, an optional “headroom”, d, can be added to the buffer size. Furthermore, a watermark level can be set, to regulate the CPU or DMA activity. The value of d and the watermark level must be chosen according to the application performance requirements. For maximum throughput, the input buffer must never go empty, so d must be somewhat greater than the watermark level, allowing for any interrupt or DMA latency. On the other hand, if the input data can not be provided as fast as the unit can process them, the buffer can be allowed to empty waiting for the next data to be written, so d can be equal to the watermark level (to ensure that no overflow occurs on the input).

21.3.3 Input buffers

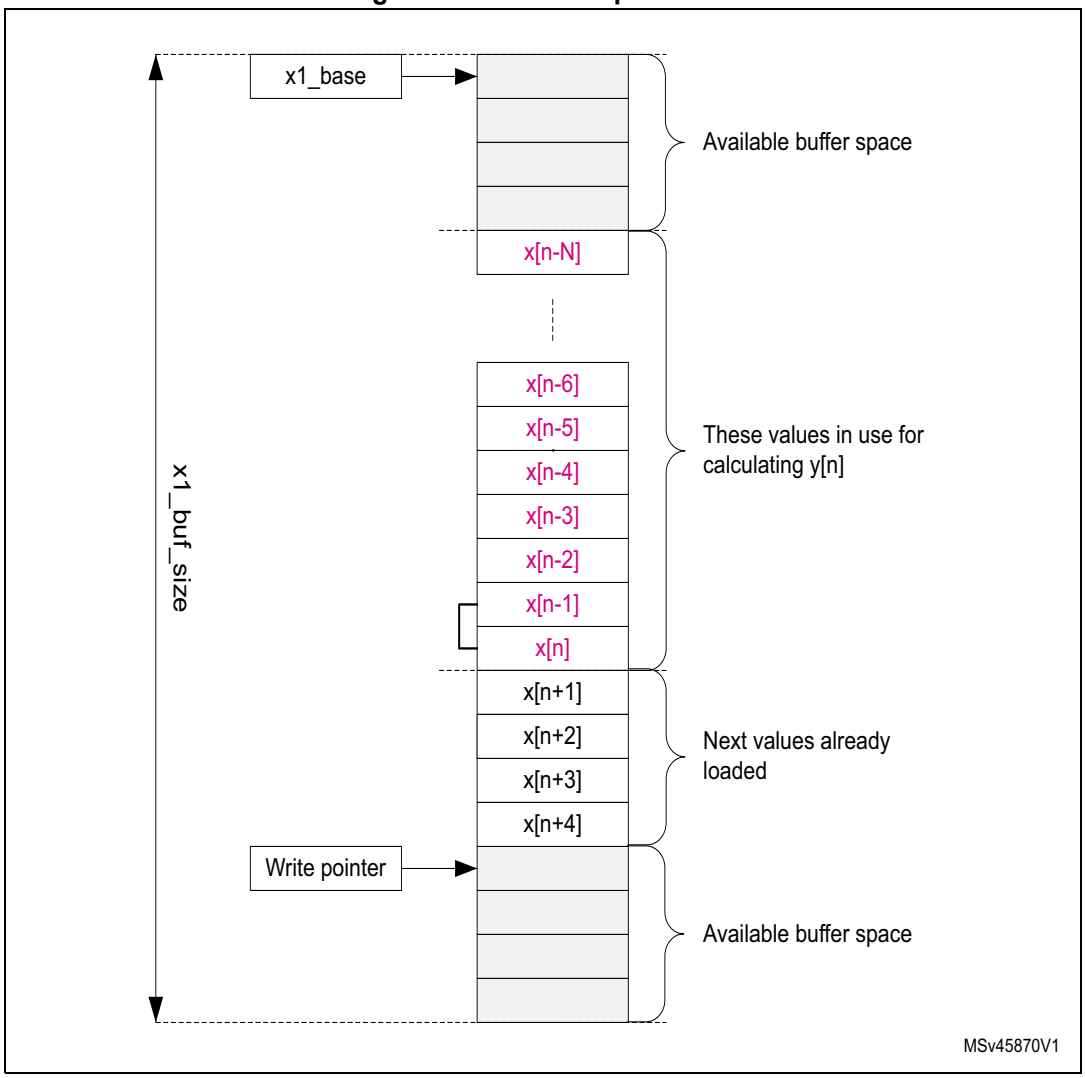
The X1 and X2 buffers are used to store data for input to the MAC. Each multiplication takes a value from the X1 buffer and a value from the X2 buffer and multiplies them together. A pointer in the control unit generates the read address offset (relative to the buffer base address) for each value. The pointers are managed by hardware according to the current function.

Figure 96. Input buffer areas



The X1 buffer can be used as a circular buffer, in which case new data are continually transferred into the input buffer whenever space is available. Pre-loading this buffer is optional for digital filters, since if no input samples have been written in the buffer when the operation is started, it is flagged as empty, which triggers the CPU or DMA to load new samples until there are enough to begin operation. Pre-loading is nevertheless useful in the case of a vector operation, that is, the input data is already available in system memory and circular operation is not required.

Figure 97. Circular input buffer



The X2 buffer can only be used in vector mode (that is not circular), and needs to be pre-loaded, except if the contents of the buffer do not change from one operation to the next. For filter functions, the X2 buffer is used to store the filter coefficients.

When operating as a circular buffer, the space allocated to the buffer (x1_buf_size) must generally be bigger than the number of elements in use for the current calculation, so that there are always new values available in the buffer. *Figure 97* illustrates the layout of the buffer for a filter operation. While calculating an output sample y[n], the unit uses a set of N+1 input samples, x[n-N] to x[n]. When this is finished, the unit starts the calculation of y[n+1], using the set of input samples x[n-N+1] to x[n+1]. The least-recent input sample, x[n-N], drops out of the input set, and a new sample, x[n+1], is added to it.

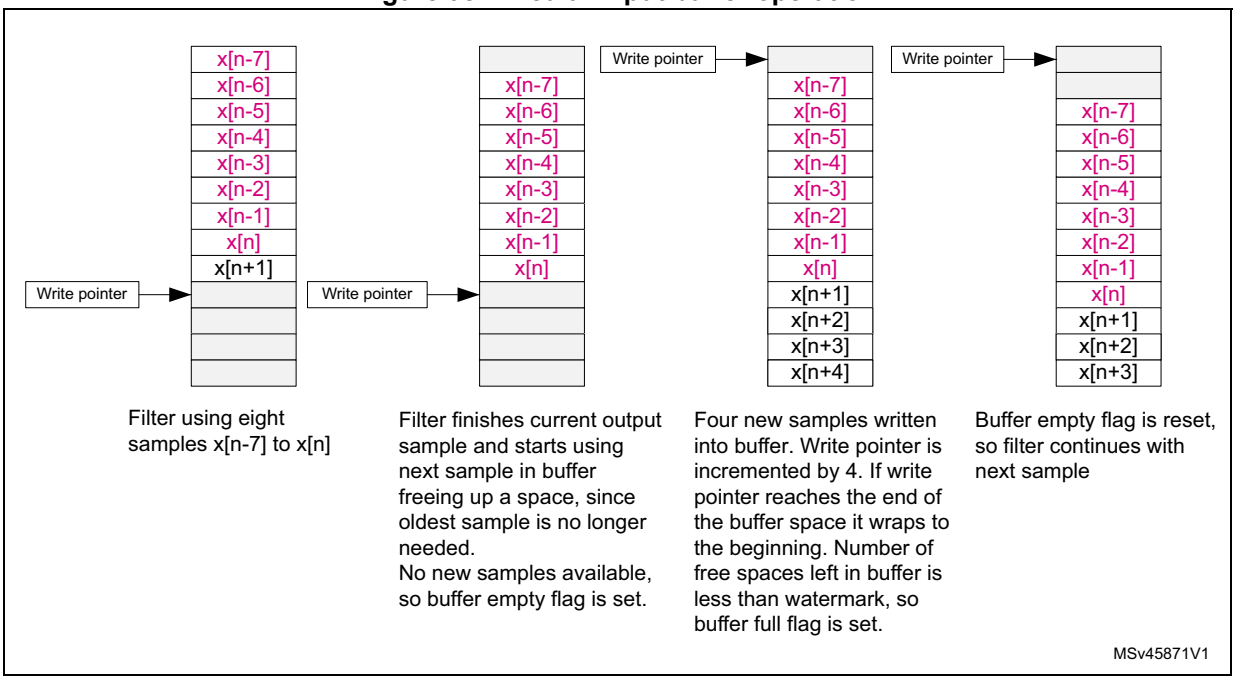
The processor, or DMA controller, must ensure that the new sample x[n+1] is available in the buffer space when required. If not, the buffer is flagged as empty, which stalls the execution of the unit until a new sample is added. No underflow condition is signaled on the X1 buffer.

Note: If the flow of samples is controlled by a timer or other peripheral such as an ADC, the buffer regularly goes empty, since the filter processes each new sample faster than the source can provide it. This is an essential feature of filter operation.

If the number of free spaces in the buffer is less than the watermark threshold programmed in the FULL_WM bitfield of the FMAC_X1BUFCFG register, the buffer is flagged as full. As long as the full flag is not set, interrupts are generated, if enabled, to request more data for the buffer. The watermark allows several data to be transferred under one interrupt, without danger of overflow. Nevertheless, if an overflow does occur, the OVFL error flag is set and the write data is ignored. The write pointer is not incremented in the event of an overflow.

The operation of the X1 buffer during a filtering operation is illustrated in *Figure 98*. This example shows an 8-tap FIR filter with a watermark set to four.

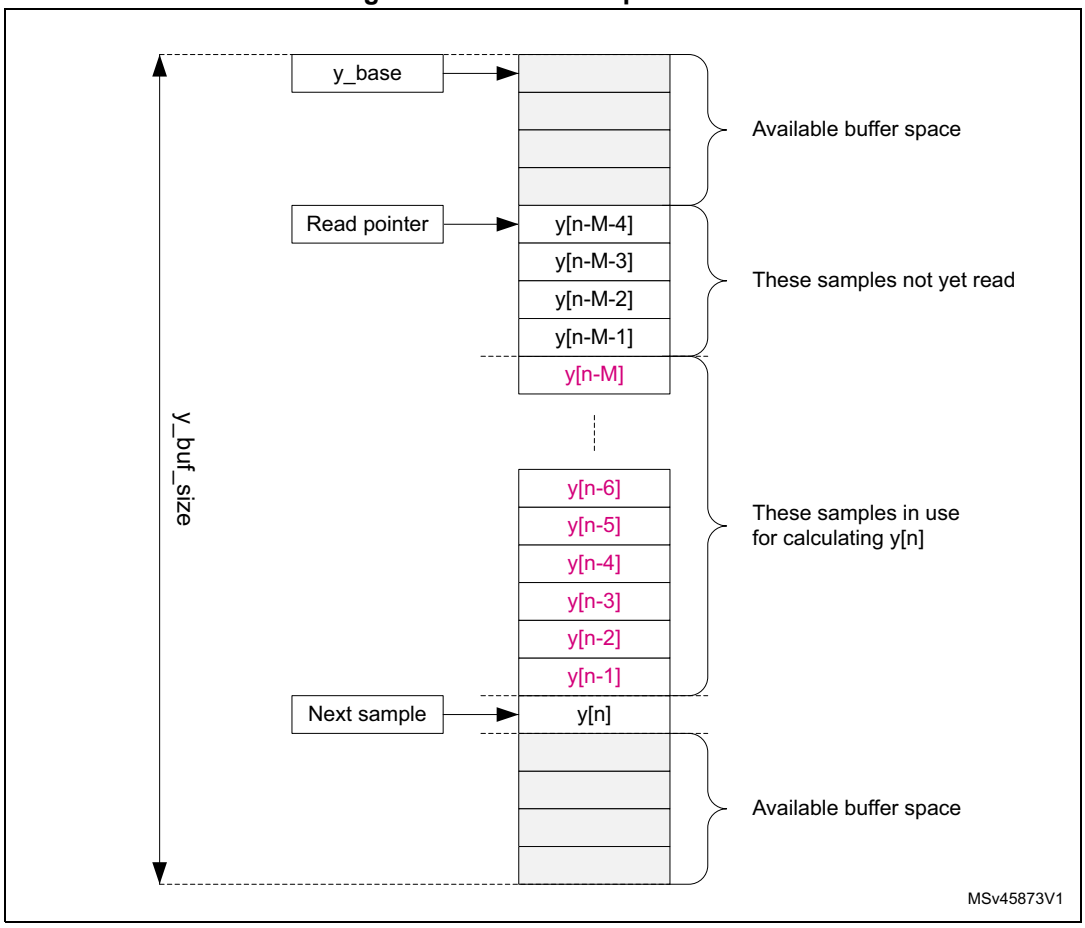
Figure 98. Circular input buffer operation



21.3.4 Output buffer

The Y (output) buffer is used to store the output of an accumulation. Each new output value is stored in the buffer until it is read by the processor or DMA controller. Each time a read access is made to the read data register, the read data is fetched from the address indicated by the read pointer. This pointer is incremented after each read, and wraps back to the base address when it reaches the end of the allocated Y buffer space.

Figure 99. Circular output buffer



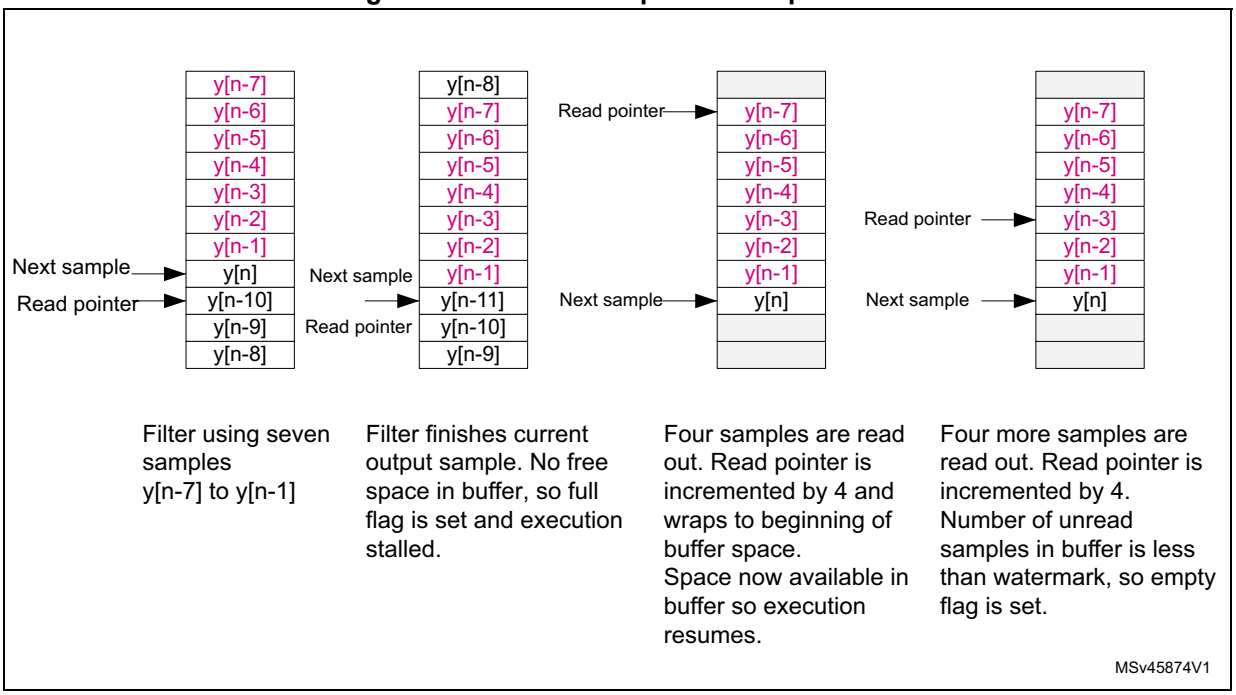
The Y buffer can also operate as a circular buffer. If the address for the next output value is the same as that indicated by the read pointer (an unread sample), then the buffer is flagged as full and execution stalled until the sample is read.

In the case of IIR filters, the Y buffer is used to store the set of M previous output samples, y[n-M] to y[n-1], used for calculating the next output sample y[n]. Each time a new sample is added to the set, the least recent sample y[n-M] drops out.

If the number of unread data in the buffer is less than the watermark threshold programmed in the EMPTY_WM bitfield of the FMAC_YBUFCFG register, the buffer is flagged as empty. As long as the empty flag is not set, interrupts or DMA requests are generated, if enabled, to request reads from the buffer. The watermark allows several data to be transferred under one interrupt, without danger of underflow. Nevertheless, if an underflow does occur, the UNFL error flag is set. In this case, the read pointer is not incremented and the read operation returns the content of the memory at the read pointer address.

The operation of the Y buffer in circular mode is illustrated in *Figure 100*. This example shows a 7-tap IIR filter with a watermark set to four.

Figure 100. Circular output buffer operation



21.3.5 Initialization functions

The following functions initialize the FMAC unit. They are triggered by writing the appropriate value in the FUNC bitfield of the FMAC_PARAM register, with the START bit set. The P and Q bitfields must also contain the appropriate parameter values for each function as detailed below. The R bitfield is not used. When the function completes, the START bit is automatically reset by hardware.

During initialization, it is recommended that the DMA requests and interrupts be disabled. The transfer of data into the FMAC memory can be done by software or by memory-to-memory DMA transfers, since no flow control is required.

Load X1 buffer

This function pre-loads the X1 buffer with N values, starting from the address in X1_BASE. Successive writes to the FMAC_WDATA register load the write data into the X1 buffer and increment the write address. The write pointer points to the address X1_BASE + N when the function completes.

The function can be used to pre-load the buffer with the elements of a vector, or to initialize the input storage elements of a filter.

Parameters

- The parameter P contains the number of values, N, to be loaded into the X1 buffer.
- The parameters Q and R are not used.

The function completes when N writes have been performed to the FMAC_WDATA register.

Load X2 buffer

This function pre-loads the X2 buffer with N + M values, starting from the address in X2_BASE. Successive writes to the FMAC_WDATA register load the write data into the X2 buffer and increment the write address.

The function can be used to pre-load the buffer with the elements of a vector, or the coefficients of a filter. In the case of an IIR, the N feed-forward and M feed-back coefficients are concatenated and loaded together into the X2 buffer. The total number of coefficients is equal to N + M. For an FIR, there are no feedback coefficients, so M = 0.

Parameters

- The parameter P contains the number of values, N, to be loaded into the X2 buffer starting from address X2_BASE.
- The parameter Q contains the number of values, M, to be loaded into the X2 buffer starting from address X2_BASE + N.
- The parameter R is not used.

The function completes when N + M writes have been performed to the FMAC_WDATA register.

Load Y buffer

This function pre-loads the Y buffer with N values, starting from the address in Y_BASE. Successive writes to the FMAC_WDATA register load the write data into the Y buffer and increment the write address. The read pointer points to the address Y_BASE + N when the function completes.

The function can be used to pre-load the feedback storage elements of an IIR filter.

Parameters

- The parameter P contains the number of values to be loaded into the Y buffer.
- The parameters Q and R are not used.

The function completes when N writes have been performed to the FMAC_WDATA register.

21.3.6 Filter functions

The following filter functions are supported by the FMAC unit. These functions are triggered by writing the corresponding value in the FUNC bitfield of the FMAC_PARAM register with the START bit set. The P, Q and R bitfields must also contain the appropriate parameter values for each function as detailed below. The filter functions continue to run until the START bit is reset by software.

Convolution (FIR filter)

Y = **B***__X__

$$y_n = 2^R \cdot \sum_{k=0}^{N} b_k x_{n-k}$$

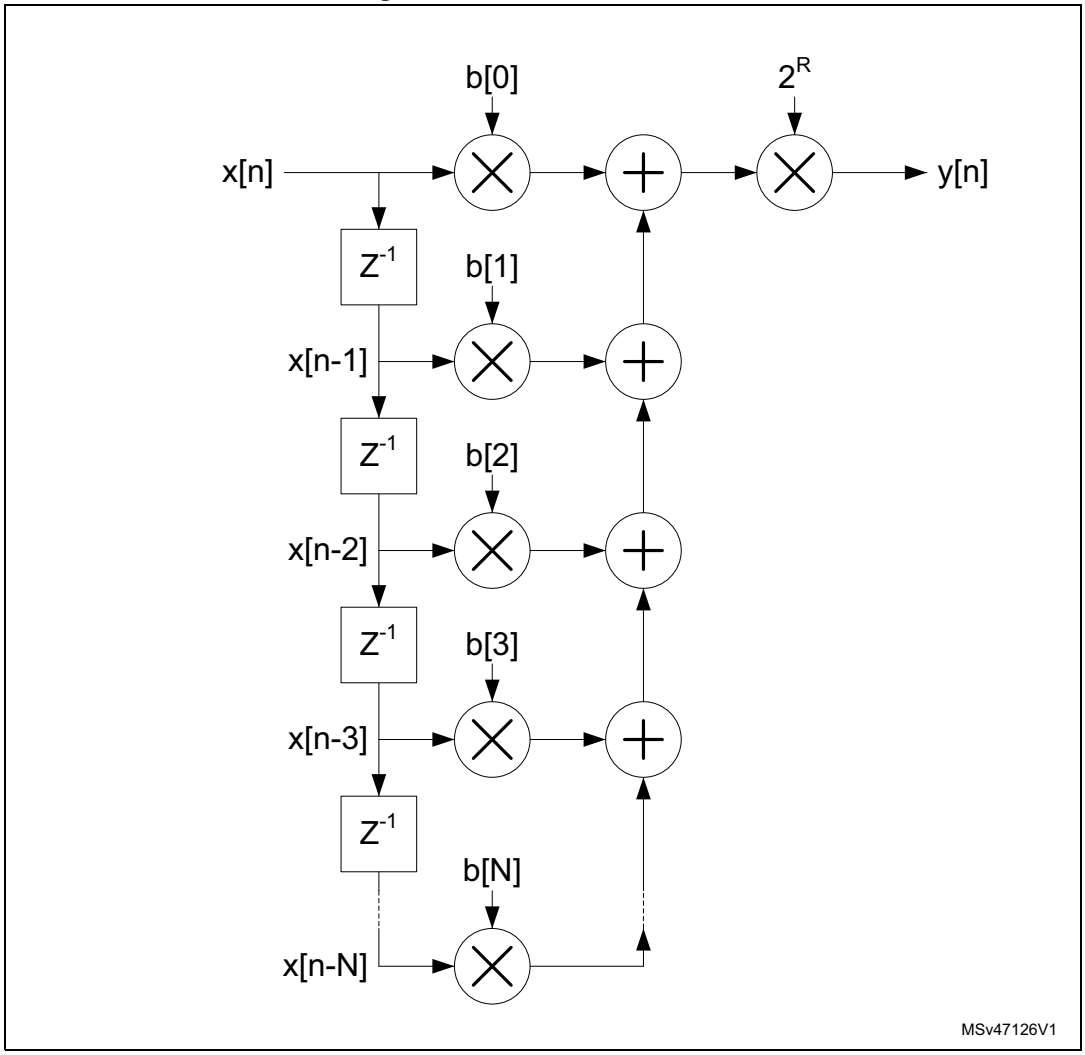
This function performs a convolution of a vector **B** of length N+1 and a vector **X** of indefinite length. The elements of **Y** for incrementing values of n are calculated as the dot product,

$y_n = \underline{\mathbf{B}}.\underline{\mathbf{X}}_{\mathbf{n}}$, where $\underline{\mathbf{X}}_{\mathbf{n}} = [x_{n-N},...,x_n]$ is composed of the N+1 elements of **X** at indexes n - N to n.

This function corresponds to a finite impulse response (FIR) filter, where vector **B** contains the filter coefficients and vector **X** the sampled data.

The structure of the filter (direct form) is shown in *Figure 101*.

Figure 101. FIR filter structure



Note that the cross correlation vector can be calculated by reversing the order of the coefficient vector **B**.

Input:

- X1 buffer contains the elements of vector **X**. It is a circular buffer of length N + 1 + d.
- X2 buffer contains the elements of vector **B**. It is a fixed buffer of length N + 1.

Output:

- Y buffer contains the output values, y_n. It is a circular buffer of length d.

Parameters:

- The parameter P contains the length, N+1, of the coefficient vector **B** in the range [2:127].
- The parameter R contains the gain to be applied to the accumulator output. The value output to the Y buffer is multiplied by 2^R, where R is in the range [0:7]
- The parameter Q is not used.

The function completes when the START bit in the FMAC_PARAM register is reset by software.

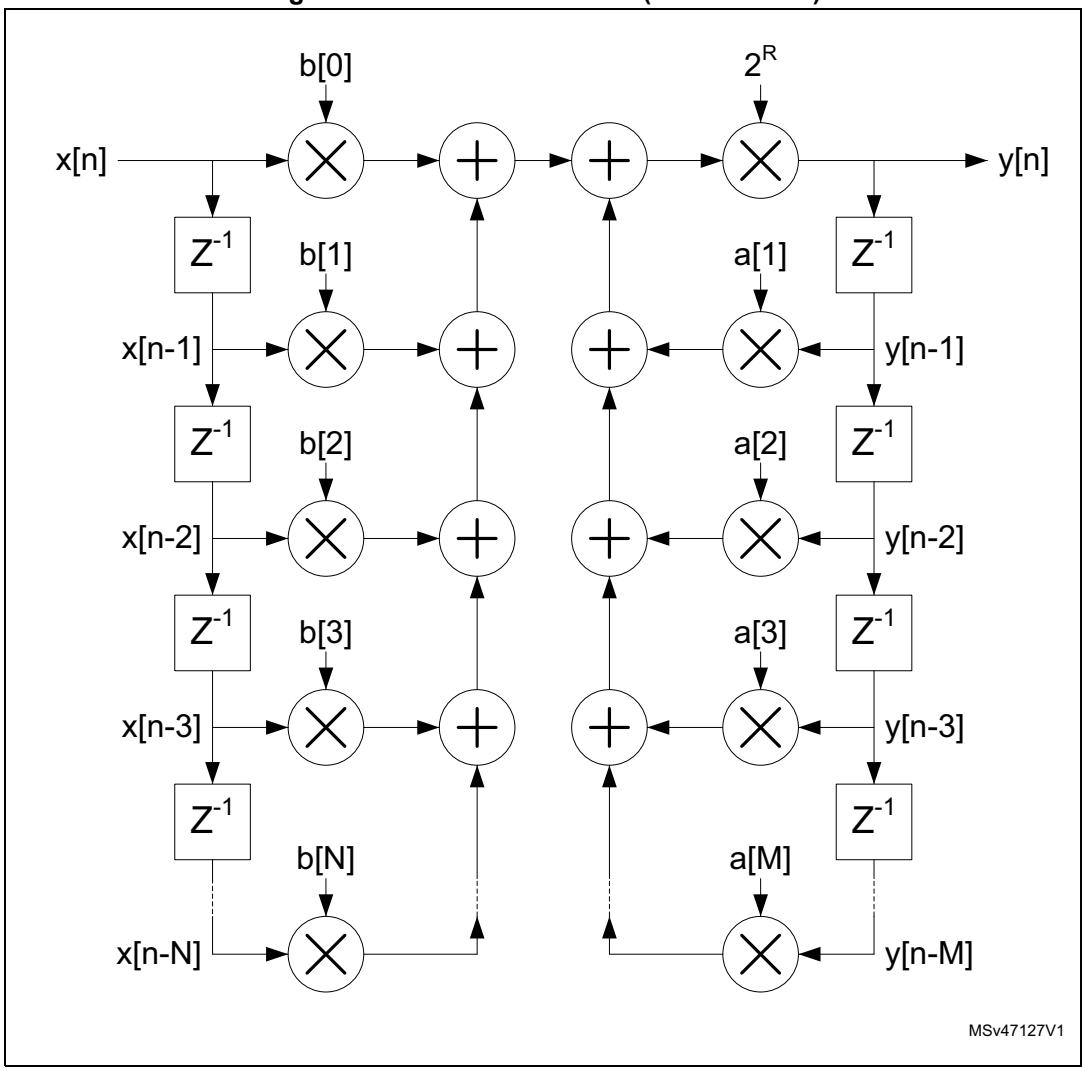
IIR filter

Y = B*X+A*Y'

$$y_n = 2^R \cdot \left(\sum_{k=0}^{N} b_k x_{n-k} + \sum_{k=1}^{M} a_k y_{n-k} \right)$$

This function implements an infinite impulse response (IIR) filter. The filter output vector **Y** is the convolution of a coefficient vector **B** of length N+1 and a vector **X** of indefinite length, plus the convolution of the delayed output vector **Y'** with a second coefficient vector **A**, of length M. The elements of **Y** for incrementing values of n are calculated as y_n = **B**.$\mathbf{X_n}$ + **A**.$\mathbf{Y_{n-1}}$, where $\mathbf{X_n}$ = $[x_{n-N},...,x_n]$ comprises the N+1 elements of **X** at indexes n - N to n, while $\mathbf{Y_{n-1}}$ = $[y_{n-M},...,y_{n-1}]$ comprises the M elements of **Y** at indexes n - M to n - 1. The structure of the filter (direct form 1) is shown in *Figure 102*.

Figure 102. IIR filter structure (direct form 1)



Input:

- X1 buffer contains the elements of vector **X**. It is a circular buffer of length N + 1+ d.
- X2 buffer contains the elements of coefficient vectors **B** and **A** concatenated (b_0, b_1, b_2..., b_N, a_1, a_2, ..., a_M). It is a fixed buffer of length M+N+1.

Output:

- Y buffer contains the output values, y_n. It is a circular buffer of length M + d.

Parameters

- The parameter P contains the length, N + 1, of the coefficient vector **B** in the range [2:64].
- The parameter Q contains the length, M, of the coefficient vector **A** in the range [1:63].
- The parameter R contains the gain to be applied to the accumulator output. The value output to the Y buffer is multiplied by 2^R, where R is in the range [0:7].

The function completes when the START bit in the FMAC_PARAM register is reset by software.

21.3.7 Fixed point representation

The FMAC operates in fixed point signed integer format. Input and output values are q1.15.

In q1.15 format, numbers are represented by one sign bit and 15 fractional bits (binary decimal places). The numeric range is therefore -1 (0x8000) to 1 - 2^{-15} (0x7FFF).

The accumulator has 26 bits, of which 22 are fractional and 4 are integer/sign (q4.22). This allows it to support partial accumulation sums in the range -8 (0x2000000) to +7.99999976 (0x1FFFFFF). A programmable gain from 0dB to 42dB in steps of 6dB can be applied at the output of the accumulator.

Note that the content of the accumulator is not saturated if the numeric range is exceeded. Partial sums whose value is greater than +7.99999976 or less than -8, wrap but this is harmless provided subsequent accumulations undo the wrapping. Nevertheless, the SAT flag in the FMAC_SR register is set if wrapping occurs, and generates an interrupt if the SATIEN bit is set in the FMAC_CR register. This helps in debugging the filter.

The data output by the accumulator can optionally be saturated, after application of the programmable gain, by setting the CLIPEN bit in the FMAC_CR register. If this bit is set, then any value which exceeds the numeric range of the q1.15 output, is set to 1 - 2^{-15} or -1, according to the sign. If clipping is not enabled, the unused accumulator bits after applying the gain is simply truncated.

21.3.8 Implementing FIR filters with the FMAC

The FMAC supports FIR filters of length N, where N is the number of taps or coefficients. The minimum local memory requirement for a FIR filter of length N is 2N + 1:

- N coefficients
- N input samples
- 1 output sample

Since the local memory size is 256, the maximum value for N is 127.

If maximum throughput is required, it may be necessary to allocate a small amount of extra space, d1 and d2, to the input and output sample buffers respectively, to ensure that the filter never stalls waiting for a new input sample, or waiting for the output sample to be read. In this case, the local memory requirement is 2N + d1 + d2.

The buffers must be configured as follows:

- X1_BUF_SIZE = N + d1;
- X2_BUF_SIZE = N;
- Y_BUF_SIZE = d2 (or 1 if no extra space is required)

The buffer base addresses can be allocated anywhere, but the X2 buffer must not overlap with the others, or else the coefficients are overwritten. An example configuration is:

- X2_BASE = 0;
- X1_BASE = N;
- Y_BASE = 2N + d1

However, if the memory space is limited, the X1 and Y buffer areas can be overlapped, such that each output sample takes the place of the oldest input sample, which is no longer required:

- X2_BASE = 0;
- X1_BASE = N;
- Y_BASE = N

In this case, Y_BUF_SIZE = X1_BUF_SIZE = N + d1, so that the buffers remain in sync.

Note: The FULL_WM bitfield of X1 buffer configuration register must be programmed with a value less than or equal to $log_2(d1)$, otherwise the buffer is flagged full before N input samples have been written, and no more samples are requested. Similarly, the EMPTY_WM bitfield of the Y buffer configuration register must be less than or equal to $log_2(d2)$.

The filter coefficients **must** be pre-loaded into the X2 buffer, using the Load X2 Buffer function. The X1 buffer can optionally be pre-loaded with any number of samples up to a maximum of N. There is no point in pre-loading the Y buffer, since for the FIR filter there is no feedback path.

After configuring and initializing the buffers, the FMAC_CR register must be programmed according to the method used for writing and reading data to and from the FMAC memory.

Three methods are supported:

- Polling: No DMA request or Interrupt request is generated. Software must check that the X1_FULL flag is low before writing to WDATA, or that the Y_EMPTY flag is low before reading from RDATA.
- Interrupt: The interrupt request is asserted while the X1_FULL flag is low, for writes, or when the Y_EMPTY flag is low, for reads.
- DMA: DMA requests are asserted on the DMA write channel while the X1_FULL flag is low, and on the read channel while the Y_EMPTY flag is low.

Different methods can be used for read and for write. However it is not recommended to use both interrupts and DMA requests for the same operation[(a)]. The valid combinations are listed in *Table 160*.

Table 160. Valid combinations for read and write methods

WIEN	RIEN	DMAWEN	DMAREN	Write	Read
0	0	0	0	Polling	Polling
0	1	0	0	Polling	Interrupt
1	0	0	0	Interrupt	Polling
1	1	0	0	Interrupt	Interrupt
0	0	0	1	Polling	DMA
0	0	1	0	DMA	Polling
0	0	1	1	DMA	DMA
0	1	1	0	DMA	Interrupt
1	0	0	1	Interrupt	DMA

a. If both interrupts and DMA requests are enabled then only DMA must perform the transfer.

The filter is started by writing to the FMAC_PARAM register with the following bitfield values:

- FUNC = 8 (FIR filter);
- P = N (number of coefficients);
- Q = “Don’t care”;
- R = Gain;
- START = 1;

If less than N + d - 2^{FULL_WM} values have been pre-loaded in the X1 buffer, the X1FULL flag remains low. If the WIEN bit is set in the FMAC_CR register, then the interrupt request is asserted immediately to request the processor to write 2^{FULL_WM} additional samples into the buffer, via the FMAC_WDATA register. It remains asserted until the X1FULL flag goes high in the FMAC_SR register. The interrupt service routine must check the X1FULL flag after every 2^{FULL_WM} writes to the FMAC_WDATA register, and repeat the transfer until the flag goes high. Similarly, if the DMAWEN bit is set in the FMAC_CR register, DMA write channel requests are generated until the X1FULL flag goes high.

The filter calculates the first output sample when at least N samples have been written into the X1 buffer (including any pre-loaded samples).

When 2^{EMPTY_WM} output samples have been written into the Y buffer, the YEMPTY flag in the FMAC_SR register goes low. If the RIEN bit is set in the FMAC_CR register, the interrupt request is asserted to request the processor to read 2^{EMPTY_WM} samples from the buffer, via the FMAC_RDATA register. It remains asserted until the YEMPTY flag goes high. The interrupt service routine must check the YEMPTY flag after every 2^{EMPTY_WM} reads from the FMAC_RDATA register, and repeat the transfer until the flag goes high. If the DMAREN bit is set in the FMAC_CR, DMA read channel requests are generated until the YEMPTY flag goes high.

The filter continues to operate in this fashion until it is stopped by the software resetting the START bit.

21.3.9 Implementing IIR filters with the FMAC

The FMAC supports IIR filters of length N, where N is the number of feed-forward taps or coefficients. The number of feedback coefficients, M, can be any value from 1 to N-1. Only direct form 1 implementations can be realized, so filters designed for other forms need to be converted.

The minimum memory requirement for an IIR filter with N feed-forward coefficients and M feed-back coefficients is 2N + 2M:

- N + M coefficients
- N input samples
- M output samples

If M = N-1, then the maximum filter length that can be implemented is N = 64.

As for the FIR, for maximum throughput, a small amount of additional space, d1 and d2, is allowed in the input and output buffer size respectively, making the total memory requirement 2M + 2N + d1 + d2.

The buffers must be configured as follows:

- X1_BUF_SIZE = N + d1;
- X2_BUF_SIZE = N + M;
- Y_BUF_SIZE = M + d2;

The buffer base addresses can be allocated anywhere, but must not overlap. An example configuration is given below:

- X2_BASE = 0;
- X1_BASE = N + M;
- Y_BASE = 2N + M + d1;

Note: The FULL_WM bitfield of X1 buffer configuration register must be programmed with a value less than or equal to $log_2(d1)$, otherwise the buffer is flagged full before N input samples have been written, and no more samples are requested. Similarly, the EMPTY_WM bitfield of the Y buffer configuration register must be less than or equal to $log_2(d2)$.

The filter coefficients (N feed-forward followed by M feedback) **must** be pre-loaded into the X2 buffer, using the Load X2 Buffer function. The X1 buffer can optionally be pre-loaded with any number of samples up to a maximum of N. The Y buffer can optionally be pre-loaded with any number of values up to a maximum of M. This has the effect of initializing the feedback delay line.

After configuring the buffers, the FMAC_CR register must be programmed in the same way as for the FIR filter (see *Section 21.3.8: Implementing FIR filters with the FMAC*).

The filter is started by writing to the FMAC_PARAM register with the following bitfield values:

- FUNC = 9 (IIR filter);
- P = N (number of feed-forward coefficients);
- Q = M (number of feed-back coefficients);
- R = Gain;
- START = 1;

If less than N + d - 2^{FULL_WM} values have been pre-loaded in the X1 buffer, the X1FULL flag remains low. If the WIEN bit is set in the FMAC_CR register, then the interrupt request is asserted immediately to request the processor to write 2^{FULL_WM} additional samples into the buffer, via the FMAC_WDATA register. It remains asserted until the X1FULL flag goes high in the FMAC_SR register. The interrupt service routine must check the X1FULL flag after every 2^{FULL_WM} writes to the FMAC_WDATA register, and repeat the transfer until the flag goes high. Similarly, if the DMAWEN bit is set in the FMAC_CR register, DMA write channel requests are generated until the X1FULL flag goes high.

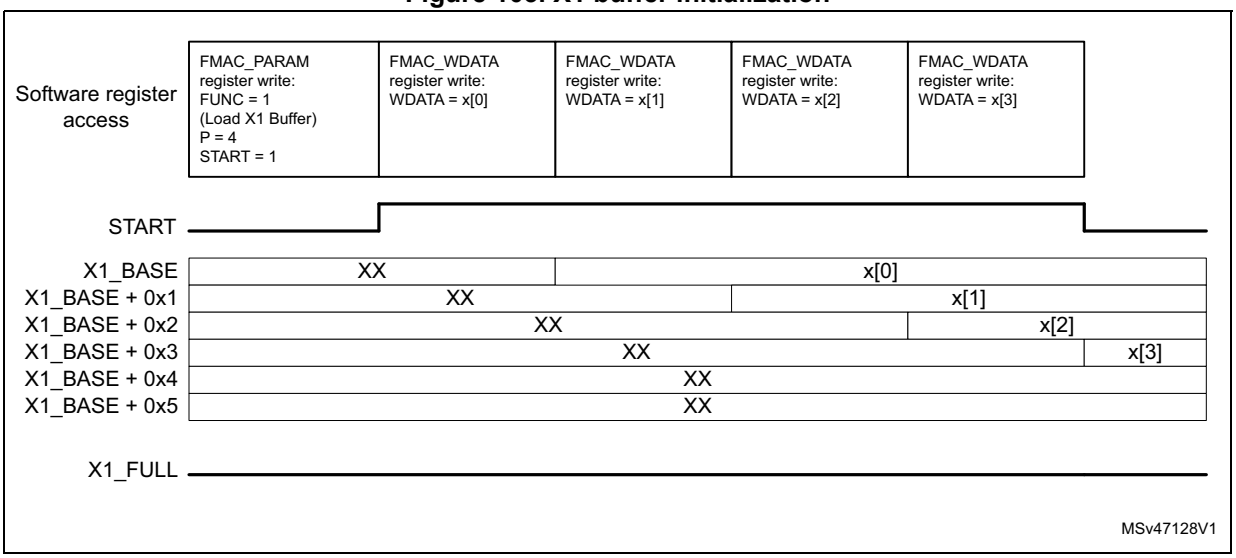
The filter calculates the first output sample when at least N samples have been written into the X1 buffer (including any pre-loaded samples). The first sample is calculated using the first N samples in the X1 buffer, and the first M samples in the Y buffer (whether or not they are preloaded. The first output sample is written into the Y buffer at Y_BASE + M.

When 2^{EMPTY_WM} new output samples have been written into the Y buffer, the YEMPTY flag in the FMAC_SR register goes low. If the RIEN bit is set in the FMAC_CR register, the interrupt request is asserted to request the processor to read 2^{EMPTY_WM} samples from the buffer, via the FMAC_RDATA register. It remains asserted until the YEMPTY flag goes high. The interrupt service routine must check the YEMPTY flag after every 2^{EMPTY_WM} reads from the FMAC_RDATA register, and repeat the transfer until the flag goes high. If the DMAREN bit is set in the FMAC_CR, DMA read channel requests are generated until the YEMPTY flag goes high

The filter continues to operate in this fashion until it is stopped by the software resetting the START bit.

21.3.10 Examples of filter initialization

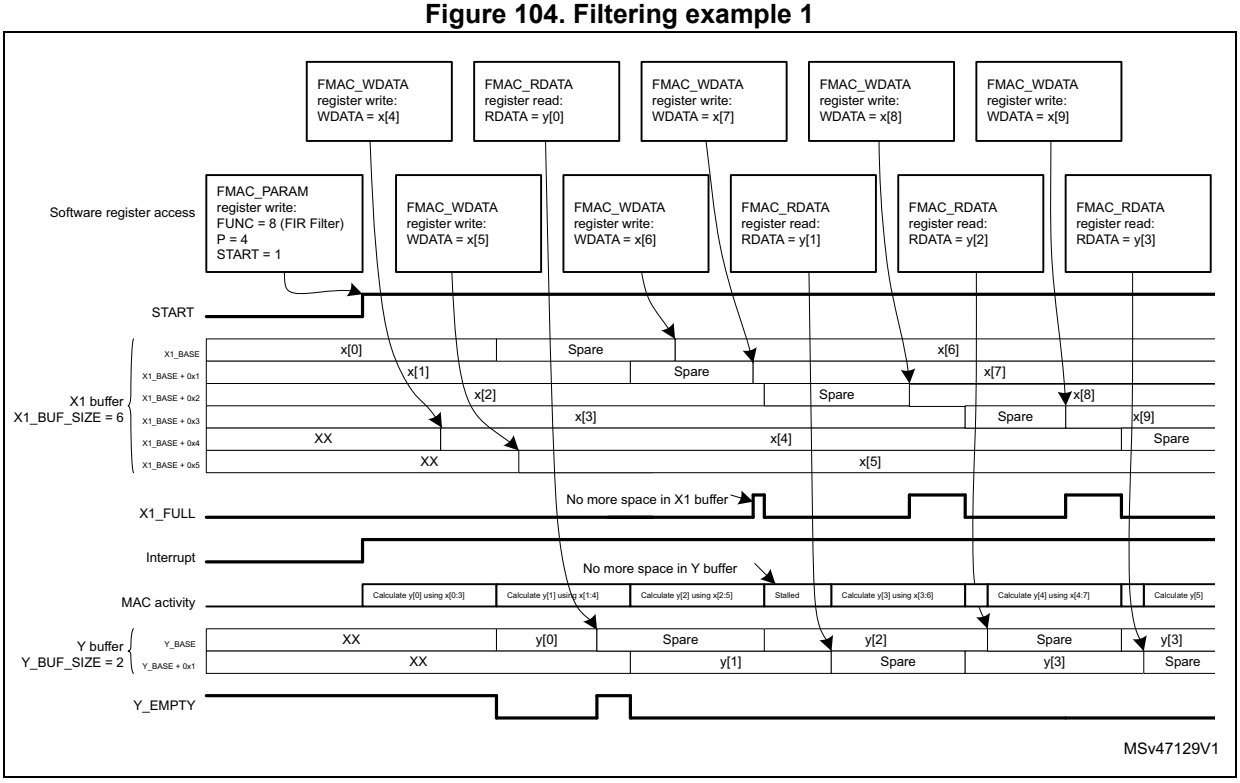
Figure 103. X1 buffer initialization



The example in *Figure 103* illustrates an X1 buffer pre-load with four samples (P = 4). The buffer size is six (X1_BUF_SIZE = 6). The initialization is launched by programming the FMAC_PARAM register with the START bit set. The four samples are then written to FMAC_WDATA, and transferred into local memory from X1_BASE onwards. The START bit resets after the fourth sample has been written. At this point, the X1 buffer contains the four samples, in order of writing, and the write pointer (next empty space) is at X1_BASE + 0x4.

21.3.11 Examples of filter operation

Figure 104. Filtering example 1



The example in *Figure 104* illustrates the beginning of a filter operation. The filter has four taps (P=4). The X1 buffer size is six and the Y buffer size is two. The FULL_WM and EMPTY_WM bitfields are both set to 0. Prior to starting the filter, the X1 buffer has been pre-loaded with four samples, x[0:3] as in *Figure 103*. So the filter starts calculating the first output sample, y[0], immediately after the START bit is set. Since the X1FULL flag is not set (due to two uninitialized spaces in the X1 buffer), the interrupt is asserted straight away, to request new data. The processor writes two new samples, x[4] and x[5], to the FMAC_WDATA register, which are transferred to the empty locations in the X1 buffer.

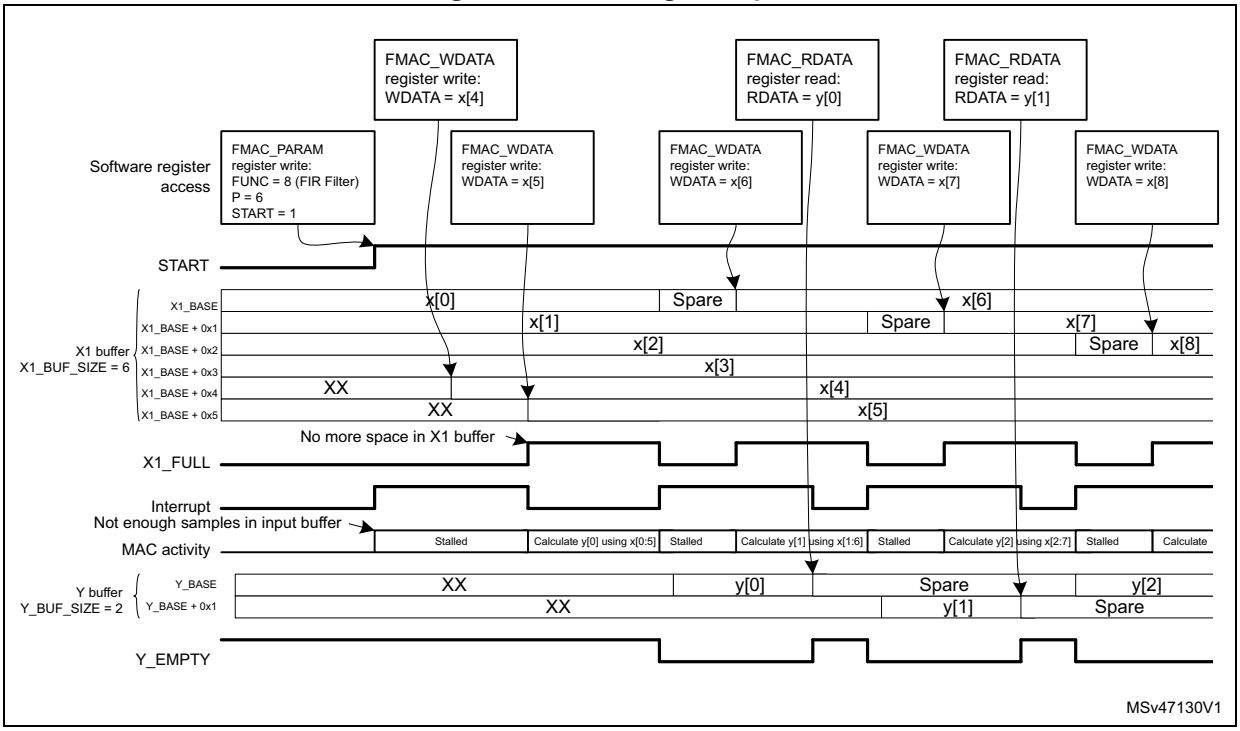
In the mean time, the FMAC finishes calculating the first output sample, y[0], and writes it into the Y buffer, causing the Y_EMPTY flag to go low. At the same time, the x[0] sample is discarded, as it is no longer required, freeing up its location in memory (at X1_BASE). The FMAC can immediately start work on the second output sample, y[1], since all the required input samples x[1:5] are present in the X1 buffer.

Since the Y_EMPTY flag is low, the interrupt remains active after the processor finishes writing x[5]. The processor reads y[0] from the FMAC_RDATA register, freeing up its location in the Y buffer. There are now no samples in the output buffer since y[1] is still being calculated, so the Y_EMPTY flag goes high. Nevertheless, the interrupt remains active, because there is still free space in the X1 buffer, which the processor next fills with x[6], and so on.

Note: In this example, the processor can fill the input buffer more quickly than the FMAC can process them, so the X1_full flag regularly goes active. However, it struggles to read the Y buffer fast enough, so the FMAC stalls regularly waiting for space to be freed up in the Y buffer. This means the filter is not executing at maximum throughput. The reason is that the

filter length is small and the processor relatively slow, in this example. So increasing the Y buffer size would not help.

Figure 105. Filtering example 2



The example in *Figure 105* illustrates the beginning of the same filter operation, but this time the filter has six taps (P=6). The X1 buffer size is six and the Y buffer size is two. The FULL_WM and EMPTY_WM bitfields are both set to 0. Prior to starting the filter, the X1 buffer has been pre-loaded with four samples, x[0:3] as in *Figure 103*. Because there are not enough samples in the input buffer, the X1FULL flag is not set, so the interrupt is asserted straight away, to request new data. The FMAC is stalled.

The processor writes two new samples, x[4] and x[5], to the FMAC_WDATA register, which are transferred to the empty locations in the X1 buffer. As soon as there are six unused samples in the X1 buffer, the X1_FULL flag goes active (since the buffer size is six), causing the interrupt to go inactive. The FMAC starts calculating the first output sample, y[0]. Since this requires all six input samples, there are no free spaces in the X1 buffer and so the X1_FULL flag remains active. Only when the FMAC finishes calculating y[0] and writes it into the Y buffer, can x[0] be discarded, freeing up a space in the X1 buffer, and deasserting X1_FULL. At the same time, the Y_EMPTY flag goes inactive. Both these flag states cause the interrupt to be asserted, requesting the processor to write a new input sample, first of all, and then read the output sample just calculated. The FMAC remains stalled until a new input sample is written.

In this example, the processor has to wait for the FMAC to finish calculating the current output sample, before it can write a new input sample, and therefore the X1 buffer regularly goes empty, stalling the FMAC. This can be avoided by allowing some extra space in the input buffer.

21.3.12 Filter design tips

The FMAC architecture imposes some constraints detailed below, on the design of digital filters.

1. Implementation of direct form 2, or transposed forms, is not efficient. Filters which have been designed for such forms must be converted to direct form 1.
2. Cascaded filters must either be combined into a single stage, or implemented as separate filters. In the latter case, multiple sets of filter coefficients can be pre-loaded into the memory, one set per stage, and only the X2_BASE address changed to select which set is used. The most efficient method of implementing a multi-stage filter is to pre-load a large X1 buffer with input samples, run the IIR filter function on it using the first stage coefficients, and store the output samples back in memory. Then change the X2_BASE pointer to point to the 2nd stage coefficients, and reload the input buffer with the output of the first stage (with a gain if required), before running the IIR function again. The procedure is repeated for all stages. Once the final stage samples have been transferred back into system memory, the input buffer can be loaded with the next set of input samples, and a new round of calculations started. Note that the N sample input buffer of each stage must be pre-loaded first of all with the N-1 last inputs from the previous round, plus one new sample, in order to keep continuity between each round. Similarly, the output buffer of each stage must be loaded with the last M samples from the previous round, for the same reason.
3. The use of direct form 1 for IIR designs can lead to large positive or negative partial sums in the accumulator, if for example a large step occurs on the input, or some of the filter coefficients' absolute values are >1. Since the accumulator is limited to 26 bits, the biggest value that it can handle without wrapping (changing sign) is 0x1FFFFFF positive or 0x2000000 negative. This corresponds to 3.99999988 and -4 respectively in q3.23 fixed point format. Wrapping does not represent a problem provided the wrapping is "undone" before the end of the accumulation. However this is not always the case when a filter is starting up and can lead to unexpected results. Consider pre-loading the output buffer with suitable values to avoid this.
4. The IIR filter has feed-forward (numerator) coefficients $[b_0, b_1, ..., b_{N-1}]$, and feed-back (denominator) coefficients $[1, a_1, ..., a_M]$. Many IIR filters require some of the denominator coefficients to have an absolute value greater than 1 to achieve a steep roll-off in the frequency response. Given that the coefficients are coded in fixed point q1.15 format, this is not possible. Nevertheless, by scaling the denominator coefficients by a factor 2^{-R}, such that $2^{-R}.[1, a_1, ..., a_M]$ are all less than 1, such filters can be implemented. However an inverse gain of 2^R must be applied at the output of the accumulator to compensate the scaling. This has an adverse effect on the signal-to-noise ratio.

21.4 FMAC registers

21.4.1 FMAC X1 buffer configuration register (FMAC_X1BUFCFG)

Address offset: 0x00

Reset value: 0x0000 0000

Access: word access

This register can only be modified if START = 0 in the FMAC_PARAM register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	FULL_WM[1:0]		Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
						rw	rw								

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
X1_BUF_SIZE[7:0]								X1_BASE[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:24 **FULL_WM[1:0]**: Watermark for buffer full flag

Defines the threshold for setting the X1 buffer full flag when operating in circular mode. The flag is set if the number of free spaces in the buffer is less than 2^{FULL_WM}.

0: Threshold = 1

1: Threshold = 2

2: Threshold = 4

3: Threshold = 8

Setting a threshold greater than 1 allows several data to be transferred into the buffer under one interrupt.

Threshold must be set to 1 if DMA write requests are enabled (DMAWEN = 1 in FMAC_CR register).

Bits 23:16 Reserved, must be kept at reset value.

Bits 15:8 **X1_BUF_SIZE[7:0]**: Allocated size of X1 buffer in 16-bit words

The minimum buffer size is the number of feed-forward taps in the filter (+ the watermark threshold - 1).

Bits 7:0 **X1_BASE[7:0]**: Base address of X1 buffer

21.4.2 FMAC X2 buffer configuration register (FMAC_X2BUFCFG)

Address offset: 0x04

Reset value: 0x0000 0000

Access: word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
X2_BUF_SIZE[7:0]								X2_BASE[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **X2_BUF_SIZE[7:0]**: Size of X2 buffer in 16-bit words
This bitfield can not be modified when a function is ongoing (START = 1).

Bits 7:0 **X2_BASE[7:0]**: Base address of X2 buffer
The X2 buffer base address can be modified while START=1, for example to change coefficient values. The filter must be stalled when doing this, since changing the coefficients while a calculation is ongoing affects the result.

21.4.3 FMAC Y buffer configuration register (FMAC_YBUFCFG)

Address offset: 0x08

Reset value: 0x0000 0000

Access: word access

This register can only be modified if START = 0 in the FMAC_PARAM register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	EMPTY_WM[1:0]		Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
						rw	rw								
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Y_BUF_SIZE[7:0]								Y_BASE[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:24 **EMPTY_WM[1:0]**: Watermark for buffer empty flag
Defines the threshold for setting the Y buffer empty flag when operating in circular mode. The flag is set if the number of unread values in the buffer is less than 2^{EMPTY_WM}.
0: Threshold = 1
1: Threshold = 2
2: Threshold = 4
3: Threshold = 8
Setting a threshold greater than 1 allows several data to be transferred from the buffer under one interrupt.
Threshold must be set to 1 if DMA read requests are enabled (DMAREN = 1 in FMAC_CR register).

Bits 23:16 Reserved, must be kept at reset value.

Bits 15:8 **Y_BUF_SIZE[7:0]**: Size of Y buffer in 16-bit words
For FIR filters, the minimum buffer size is 1 (+ the watermark threshold). For IIR filters the minimum buffer size is the number of feedback taps (+ the watermark threshold).

Bits 7:0 **Y_BASE[7:0]**: Base address of Y buffer

21.4.4 FMAC parameter register (FMAC_PARAM)

Address offset: 0x0C

Reset value: 0x0000 0000

Access: word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
START	FUNC[6:0]							R[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Q[7:0]								P[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **START**: Enable execution
0: Stop execution
1: Start execution
Setting this bit triggers the execution of the function selected in the FUNC bitfield. Resetting it by software stops any ongoing function. For initialization functions, this bit is reset by hardware.

Bits 30:24 **FUNC[6:0]**: Function
0: Reserved
1: Load X1 buffer
2: Load X2 buffer
3: Load Y buffer
4 to 7: Reserved
8: Convolution (FIR filter)
9: IIR filter (direct form 1)
10 to 127: Reserved
This bitfield can not be modified when a function is ongoing (START = 1)

Bits 23:16 **R[7:0]**: Input parameter R.
The value of this parameter is dependent on the function.
This bitfield can not be modified when a function is ongoing (START = 1)

Bits 15:8 **Q[7:0]**: Input parameter Q.
The value of this parameter is dependent on the function.
This bitfield can not be modified when a function is ongoing (START = 1)

Bits 7:0 **P[7:0]**: Input parameter P.
The value of this parameter is dependent on the function
This bitfield can not be modified when a function is ongoing (START = 1)

21.4.5 FMAC control register (FMAC_CR)

Address offset: 0x10

Reset value: 0x0000 0000

Access: word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RESET
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CLIP EN	Res.	Res.	Res.	Res.	Res.	DMA WEN	DMA REN	Res.	Res.	Res.	SAT IEN	UNFL IEN	OVFL IEN	WIEN	RIEN
rw						rw	rw				rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **RESET**: Reset FMAC unit

This resets the write and read pointers, the internal control logic, the FMAC_SR register and the FMAC_PARAM register, including the START bit if active. Other register settings are not affected. This bit is reset by hardware.

0: Reset inactive

1: Reset active

Bit 15 **CLIPEN**: Enable clipping

0: Clipping disabled. Values at the output of the accumulator which exceed the q1.15 range, wrap.

1: Clipping enabled. Values at the output of the accumulator which exceed the q1.15 range are saturated to the maximum positive or negative value (+1 or -1) according to the sign.

Bits 14:10 Reserved, must be kept at reset value.

Bit 9 **DMAWEN**: Enable DMA write channel requests

0: Disable. No DMA requests are generated

1: Enable. DMA requests are generated while the X1 buffer is not full.

This bit can only be modified when START= 0 in the FMAC_PARAM register. A read returns the current state of the bit.

Bit 8 **DMAREN**: Enable DMA read channel requests

0: Disable. No DMA requests are generated

1: Enable. DMA requests are generated while the Y buffer is not empty.

This bit can only be modified when START= 0 in the FMAC_PARAM register. A read returns the current state of the bit.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **SATIEN**: Enable saturation error interrupts

0: Disabled. No interrupts are generated upon saturation detection.

1: Enabled. An interrupt request is generated if the SAT flag is set

This bit is set and cleared by software. A read returns the current state of the bit.

Bit 3 **UNFLIEN**: Enable underflow error interrupts

0: Disabled. No interrupts are generated upon underflow detection.

1: Enabled. An interrupt request is generated if the UNFL flag is set

This bit is set and cleared by software. A read returns the current state of the bit.

Bit 2 **OVFLIEN**: Enable overflow error interrupts
0: Disabled. No interrupts are generated upon overflow detection.
1: Enabled. An interrupt request is generated if the OVFL flag is set
This bit is set and cleared by software. A read returns the current state of the bit.

Bit 1 **WIEN**: Enable write interrupt
0: Disabled. No write interrupt requests are generated.
1: Enabled. An interrupt request is generated while the X1 buffer FULL flag is not set.
This bit is set and cleared by software. A read returns the current state of the bit.

Bit 0 **RIEN**: Enable read interrupt
0: Disabled. No read interrupt requests are generated.
1: Enabled. An interrupt request is generated while the Y buffer EMPTY flag is not set.
This bit is set and cleared by software. A read returns the current state of the bit.

21.4.6 FMAC status register (FMAC_SR)

Address offset: 0x14

Reset value: 0x0000 0001

Access: word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	SAT	UNFL	OVFL	Res.	Res.	Res.	Res.	Res.	Res.	X1 FULL	Y EMPTY
					r	r	r							r	r

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **SAT**: Saturation error flag
Saturation occurs when the result of an accumulation exceeds the numeric range of the accumulator.
0: No saturation detected
1: Saturation detected. If the SATIEN bit is set, an interrupt is generated.
This flag is cleared by a reset of the unit.

Bit 9 **UNFL**: Underflow error flag
An underflow occurs when a read is made from FMAC_RDATA when no valid data is available in the Y buffer.
0: No underflow detected
1: Underflow detected. If the UNFLIEN bit is set, an interrupt is generated.
This flag is cleared by a reset of the unit.

Bit 8 **OVFL**: Overflow error flag
An overflow occurs when a write is made to FMAC_WDATA when no free space is available in the X1 buffer.
0: No overflow detected
1: Overflow detected. If the OVFLIEN bit is set, an interrupt is generated.
This flag is cleared by a reset of the unit.

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **X1FULL**: X1 buffer full flag

The buffer is flagged as full if the number of available spaces is less than the FULL_WM threshold. The number of available spaces is the difference between the write pointer and the least recent sample currently in use.

0: X1 buffer not full. If the WIEN bit is set, the interrupt request is asserted until the flag is set. If DMAWEN is set, DMA write channel requests are generated until the flag is set.

1: X1 buffer full.

This flag is set and cleared by hardware, or by a reset.

Note: after the last available space in the X1 buffer is filled there is a delay of 3 clock cycles before the X1FULL flag goes high. To avoid any risk of overflow it is recommended to insert a software delay after writing to the X1 buffer before reading the FMAC_SR. Alternatively, a FULL_WM threshold of 2 can be used.

Bit 0 **YEMPTY**: Y buffer empty flag

The buffer is flagged as empty if the number of unread data is less than the EMPTY_WM threshold. The number of unread data is the difference between the read pointer and the current output destination address.

0: Y buffer not empty. If the RIEN bit is set, the interrupt request is asserted until the flag is set. If DMAREN is set, DMA read channel requests are generated until the flag is set.

1: Y buffer empty.

This flag is set and cleared by hardware, or by a reset.

Note: after the last sample is read from the Y buffer there is a delay of 3 clock cycles before the YEMPTY flag goes high. To avoid any risk of underflow it is recommended to insert a software delay after reading from the Y buffer before reading the FMAC_SR. Alternatively, an EMPTY_WM threshold of 2 can be used.

21.4.7 FMAC write data register (FMAC_WDATA)

Address offset: 0x18

Reset value: 0x0000 0000

Access: word and half-word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WDATA[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **WDATA[15:0]**: Write data

When a write access to this register occurs, the write data are transferred to the address offset indicated by the write pointer. The pointer address is automatically incremented after each write access.

21.4.8 FMAC read data register (FMAC_RDATA)

Address offset: 0x1C

Reset value: 0x0000 0000

Access: word and half-word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RDATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **RDATA[15:0]**: Read data

When a read access to this register occurs, the read data are the contents of the Y output buffer at the address offset indicated by the READ pointer. The pointer address is automatically incremented after each read access.

21.4.9 FMAC register map

Table 161.FMAC register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3* for the register boundary addresses.

22 Flexible static memory controller (FSMC)

22.1 Introduction

The flexible static memory controller (FSMC) includes three memory controllers:

- The NOR/PSRAM memory controller
- The NAND memory controller
- The Synchronous DRAM (SDRAM/Mobile LPSDR SDRAM) controller

This memory controller is also named flexible memory controller (FMC).

22.2 FMC main features

The FMC functional block makes the interface with: synchronous and asynchronous static memories, SDRAM memories, and NAND flash memory. Its main purposes are:

- to translate AHB transactions into the appropriate external device protocol
- to meet the access time requirements of the external memory devices

All external memories share the addresses, data and control signals with the controller. Each external device is accessed by means of a unique chip select. The FMC performs only one access at a time to an external device.

The main features of the FMC controller are the following:

- Interface with static-memory mapped devices including:
  - Static random access memory (SRAM)
  - NOR flash memory/OneNAND flash memory
  - PSRAM (4 memory banks)
  - Ferroelectric RAM (FRAM)
  - NAND flash memory with ECC hardware to check up to 8 Kbytes of data
- Interface with synchronous DRAM (SDRAM/Mobile LPSDR SDRAM) memories
- Interface with parallel LCD modules, supporting Intel 8080 and Motorola 6800 modes.
- Burst mode support for faster access to synchronous devices such as NOR flash memory, PSRAM and SDRAM)
- Programmable continuous clock output for asynchronous and synchronous accesses
- 8-,16-bit wide data bus
- Independent chip select control for each memory bank
- Independent configuration for each memory bank
- Write enable and byte lane select outputs for use with PSRAM, SRAM and SDRAM devices
- External asynchronous wait control
- Write FIFO with 16 x32-bit depth
- Cacheable Read FIFO with 6 x32-bit depth (6 x14-bit address tag) for SDRAM controller.

The Write FIFO is common to all memory controllers and consists of:

- a Write Data FIFO which stores the AHB data to be written to the memory (up to 32 bits) plus one bit for the AHB transfer (burst or not sequential mode)
- a Write Address FIFO which stores the AHB address (up to 28 bits) plus the AHB data size (up to 2 bits). When operating in burst mode, only the start address is stored except when crossing a page boundary (for PSRAM and SDRAM). In this case, the AHB burst is broken into two FIFO entries.

At startup the FMC pins must be configured by the user application. The FMC I/O pins which are not used by the application can be used for other purposes.

The FMC registers that define the external device type and associated characteristics are usually set at boot time and do not change until the next reset or power-up.

However, only a few bits can be changed on-the-fly:

- MBKEN, FMCEN, WEN bits in FMC_BCRx register
- ECCEN and PBKEN bits in the FMC_PCR register
- IFS, IRS and ILS bits in the FMC_SR register

Follow the below sequence to modify parameters while the FMC is enabled:

1. First disable the FMC controller to prevent further accesses to any memory controller while the register is modified.
2. Update all required configurations.
3. Enable the FMC controller again.

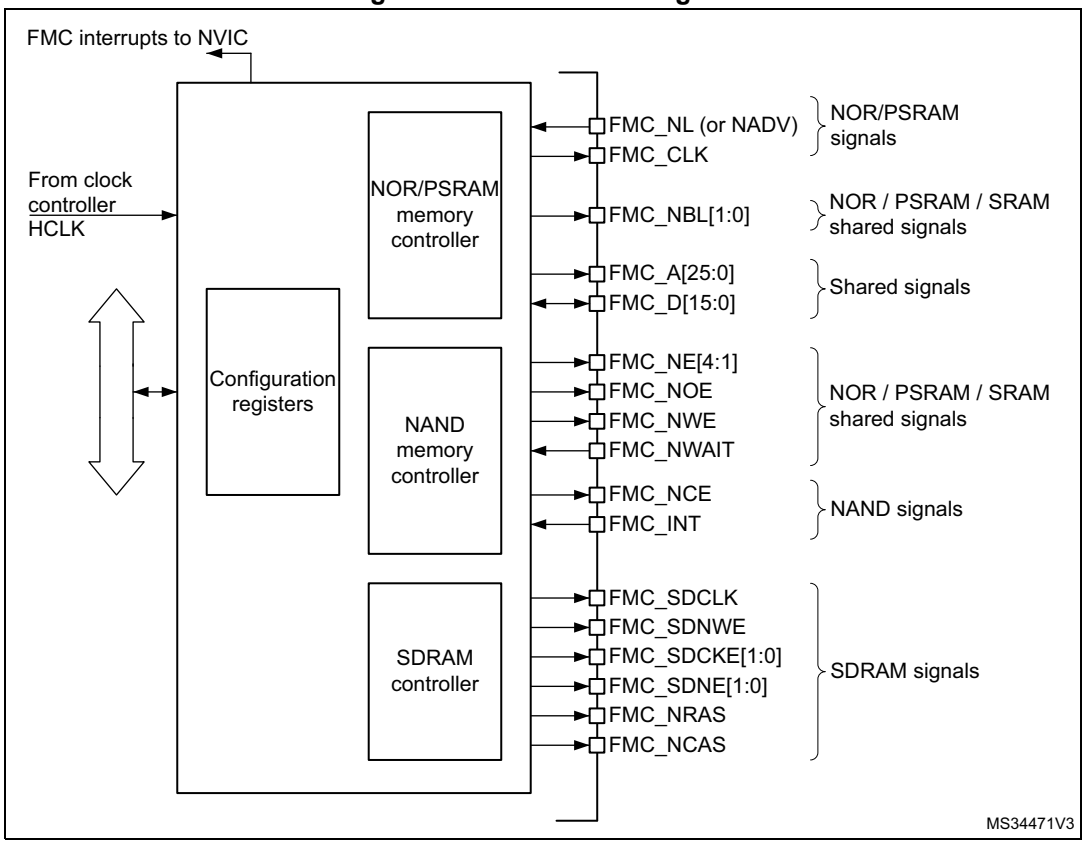
22.3 FMC block diagram

The FMC consists of the following main blocks:

- The AHB interface (including the FMC configuration registers)
- The NOR flash/PSRAM/SRAM controller
- The SDRAM controller

The block diagram is shown in the figure below.

Figure 106. FMC block diagram



22.4 AHB interface

The AHB slave interface allows internal CPUs and other bus master peripherals to access the external memories.

AHB transactions are translated into the external device protocol. In particular, if the selected external memory is 16- or 8-bit wide, 32-bit wide transactions on the AHB are split into consecutive 16- or 8-bit accesses. The FMC chip select (FMC_NEx) does not toggle between the consecutive accesses except in case of Access mode D when the Extended mode is enabled.

The FMC generates an AHB error in the following conditions:

- When reading or writing to a FMC bank (Bank 1 to 4) which is not enabled.
- When reading or writing to the NOR flash bank while the FACCEN bit is reset in the FMC_BCRx register.
- When writing to a write protected SDRAM bank (WP bit set in the SDRAM_SDCRx register).
- When the SDRAM address range is violated (access to reserved address range)

The effect of an AHB error depends on the AHB master which has attempted the R/W access:

- If the access has been attempted by the Cortex-M33 CPU, a hard fault interrupt is generated.
- If the access has been performed by a DMA controller, a DMA transfer error is generated and the corresponding DMA channel is automatically disabled.

The AHB clock (HCLK) is the reference clock for the FMC.

22.4.1 Supported memories and transactions

General transaction rules

The requested AHB transaction data size can be 8-, 16- or 32-bit wide whereas the accessed external device has a fixed data width. This may lead to inconsistent transfers.

Therefore, some simple transaction rules must be followed:

- AHB transaction size and memory data size are equal

  There is no issue in this case.
- AHB transaction size is greater than the memory size:

  In this case, the FMC splits the AHB transaction into smaller consecutive memory accesses to meet the external data width. The FMC chip select (FMC_NEx) does not toggle between the consecutive accesses. If the bus turnaround timings is configured to any other value than 0, the FMC chip select (FMC_NEx) toggles between the consecutive accesses. This feature is required when interfacing with FRAM memory.
- AHB transaction size is smaller than the memory size:

  The transfer may or not be consistent depending on the type of external device:
  - Accesses to devices that have the byte select feature (SRAM, ROM, PSRAM, SDRAM)

    In this case, the FMC allows read/write transactions and accesses to the right data through its byte lanes NBL[1:0].

    Bytes to be written are addressed by NBL[1:0].

    All memory bytes are read (NBL[1:0] are driven low during read transaction) and the useless ones are discarded.
  - Accesses to devices that do not have the byte select feature (NOR and NAND flash memories)

    This situation occurs when a byte access is requested to a 16-bit wide flash memory. Since the device cannot be accessed in Byte mode (only 16-bit words can be read/written from/to the flash memory), Write transactions and Read transactions are allowed (the controller reads the entire 16-bit memory word and uses only the required byte).

Wrap support for NOR flash/PSRAM and SDRAM

Wrap burst mode for synchronous memories is not supported. The memories must be configured in Linear burst mode of undefined length.

Configuration registers

The FMC can be configured through a set of registers. Refer to *Section 22.6.6*, for a detailed description of the NOR flash/PSRAM controller registers. Refer to *Section 22.7.7*,

for a detailed description of the NAND flash registers and to *Section 22.8.5* for a detailed description of the SDRAM controller registers.

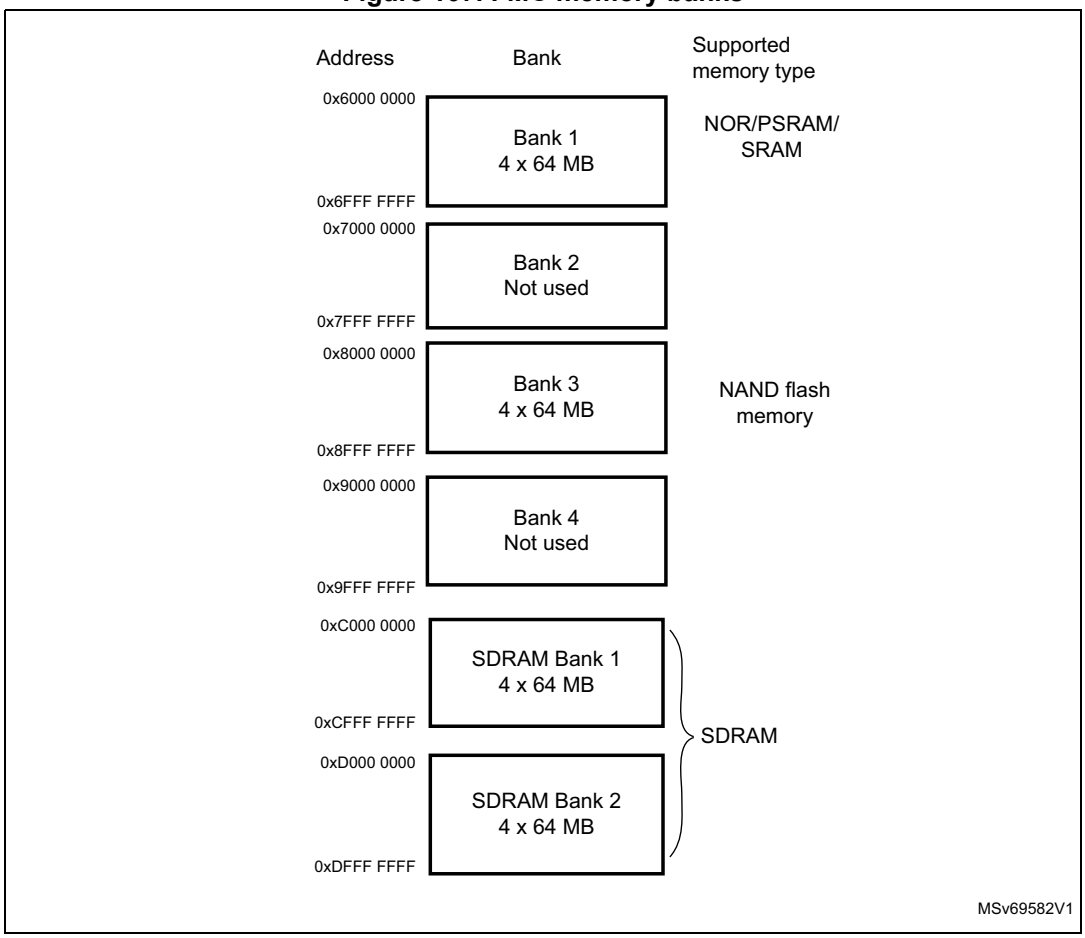
22.5 External device address mapping

From the FMC point of view, the external memory is divided into fixed-size banks of 256 Mbytes each (see *Figure 107*):

- Bank 1 used to address up to 4 NOR flash memory or PSRAM devices. This bank is split into 4 NOR/PSRAM subbanks with 4 dedicated chip selects, as follows:
  - Bank 1 - NOR/PSRAM 1
  - Bank 1 - NOR/PSRAM 2
  - Bank 1 - NOR/PSRAM 3
  - Bank 1 - NOR/PSRAM 4
- Bank 3 used to address NAND flash memory devices.The MPU memory attribute for this space must be reconfigured by software to Device.
- Bank 4 and 5 used to address SDRAM devices (1 device per bank).

For each bank the type of memory to be used can be configured by the user application through the Configuration register.

Figure 107. FMC memory banks



22.5.1 NOR/PSRAM address mapping

HADDR[27:26] bits are used to select one of the four memory banks as shown in *Table 162*.

Table 162. NOR/PSRAM bank selection

HADDR[27:26](1)	Selected bank
00	Bank 1 - NOR/PSRAM 1
01	Bank 1 - NOR/PSRAM 2
10	Bank 1 - NOR/PSRAM 3
11	Bank 1 - NOR/PSRAM 4

1. HADDR are internal AHB address lines that are translated to external memory.

The HADDR[25:0] bits contain the external memory address. Since HADDR is a byte address whereas the memory is addressed at word level, the address actually issued to the memory varies according to the memory data width, as shown in the following table.

Table 163. NOR/PSRAM External memory address

Memory width(1)	Data address issued to the memory	Maximum memory capacity (bits)
8-bit	HADDR[25:0]	64 Mbytes x 8 = 512 Mbits
16-bit	HADDR[25:1] >> 1	64 Mbytes/2 x 16 = 512 Mbits

1. In case of a 16-bit external memory width, the FMC internally uses HADDR[25:1] to generate the address for external memory FMC_A[24:0].
Whatever the external memory width, FMC_A[0] must be connected to external memory address A[0].

22.5.2 NAND flash memory address mapping

The NAND bank is divided into memory areas as indicated in *Table 164*.

Table 164. NAND memory mapping and timing registers

Start address	End address	FMC bank	Memory space	Timing register
0x8800 0000	0x8BFF FFFF	Bank 3 - NAND flash	Attribute	FMC_PATT (0x8C)
0x8000 0000	0x83FF FFFF		Common	FMC_PMEM (0x88)

For NAND flash memory, the common and attribute memory spaces are subdivided into three sections (see in *Table 165* below) located in the lower 256 Kbytes:

- Data section (first 64 Kbytes in the common/attribute memory space)
- Command section (second 64 Kbytes in the common / attribute memory space)
- Address section (next 128 Kbytes in the common / attribute memory space)

Table 165. NAND bank selection

Section name	HADDR[17:16]	Address range
Address section	1X	0x020000-0x03FFFF
Command section	01	0x010000-0x01FFFF
Data section	00	0x000000-0x0FFFF

The application software uses the 3 sections to access the NAND flash memory:

- **To sending a command to NAND flash memory**, the software must write the command value to any memory location in the command section.
- **To specify the NAND flash address that must be read or written**, the software must write the address value to any memory location in the address section. Since an address can be 4 or 5 bytes long (depending on the actual memory size), several consecutive write operations to the address section are required to specify the full address.
- **To read or write data,** the software reads or writes the data from/to any memory location in the data section.

Since the NAND flash memory automatically increments addresses, there is no need to increment the address of the data section to access consecutive memory locations.

22.5.3 SDRAM address mapping

The HADDR[28] bit (internal AHB address line 28) is used to select one of the two memory banks as indicated in *Table 166*.

Table 166. SDRAM bank selection

HADDR[28]	Selected bank	Control register	Timing register
0	SDRAM Bank1	FMC_SDCR1	FMC_SDTR1
1	SDRAM Bank2	FMC_SDCR2	FMC_SDTR2

The following table shows SDRAM mapping for a 13-bit row, a 11-bit column and a 4 internal bank configuration.

Table 167. SDRAM address mapping

Memory width(1)	Internal bank	Row address	Column address(2)	Maximum memory capacity (Mbytes)
8-bit	HADDR[25:24]	HADDR[23:11]	HADDR[10:0]	64 Mbytes: 4 x 8K x 2K
16-bit	HADDR[26:25]	HADDR[24:12]	HADDR[11:1]	128 Mbytes: 4 x 8K x 2K x 2

1. When interfacing with a 16-bit memory, the FMC internally uses the HADDR[11:1] internal AHB address lines to generate the external address. Whatever the memory width, FMC_A[0] has to be connected to the external memory address A[0].
2. The AutoPrecharge is not supported. FMC_A[10] must be connected to the external memory address A[10] but it will be always driven ‘low’.

The HADDR[27:0] bits are translated to external SDRAM address depending on the SDRAM controller configuration:

- Data size:8 or 16 bits
- Row size:11, 12 or 13 bits
- Column size: 8, 9, 10 or 11 bits
- Number of internal banks: two or four internal banks

The following tables show the SDRAM address mapping versus the SDRAM controller configuration.

Table 168. SDRAM address mapping with 8-bit data bus width(1)(2)

<table>
<tr><th rowspan="2">Row size configuration</th><th colspan="28">HADDR(AHB Internal Address Lines)</th></tr>
<tr><th>27</th><th>26</th><th>25</th><th>24</th><th>23</th><th>22</th><th>21</th><th>20</th><th>19</th><th>18</th><th>17</th><th>16</th><th>15</th><th>14</th><th>13</th><th>12</th><th>11</th><th>10</th><th>9</th><th>8</th><th>7</th><th>6</th><th>5</th><th>4</th><th>3</th><th>2</th><th>1</th><th>0</th></tr>

<tr><td colspan="2">Res.</td><td colspan="2">Bank [1:0]</td><td colspan="10">Row[12:0]</td><td colspan="8">Column[10:0]</td></tr>
</table>

1. BANK[1:0] are the Bank Address BA[1:0]. When only 2 internal banks are used, BA1 must always be set to ‘0’.
2. Access to Reserved (Res.) address range generates an AHB error.

Table 169. SDRAM address mapping with 16-bit data bus width(1)(2)

Row size Configuration	HADDR(AHB address Lines)																										
	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
11-bit row size configuration	Res.						Bank [1:0]		Row[10:0]											Column[7:0]								BM0(3)
	Res.						Bank [1:0]		Row[10:0]											Column[8:0]								BM0
	Res.						Bank [1:0]		Row[10:0]											Column[9:0]								BM0
	Res.						Bank [1:0]		Row[10:0]											Column[10:0]								BM0
12-bit row size configuration	Res.						Bank [1:0]		Row[11:0]											Column[7:0]								BM0
	Res.						Bank [1:0]		Row[11:0]											Column[8:0]								BM0
	Res.						Bank [1:0]		Row[11:0]											Column[9:0]								BM0
	Res.						Bank [1:0]		Row[11:0]											Column[10:0]								BM0
13-bit row size configuration	Res.						Bank [1:0]		Row[12:0]											Column[7:0]								BM0
	Res.						Bank [1:0]		Row[12:0]											Column[8:0]								BM0
	Res.						Bank [1:0]		Row[12:0]											Column[9:0]								BM0
	Res.						Bank [1:0]		Row[12:0]											Column[10:0]								BM0

1. BANK[1:0] are the Bank Address BA[1:0]. When only 2 internal banks are used, BA1 must always be set to ‘0’.
2. Access to Reserved space (Res.) generates an AHB error.
3. BM0: is the byte mask for 16-bit access.

22.6 NOR flash/PSRAM controller

The FMC generates the appropriate signal timings to drive the following types of memories:

- Asynchronous SRAM, FRAM and ROM
  - 8 bits
  - 16 bits
- PSRAM (CellularRAM™)
  - Asynchronous mode
  - Burst mode for synchronous accesses
  - Multiplexed or non-multiplexed
- NOR flash memory
  - Asynchronous mode
  - Burst mode for synchronous accesses
  - Multiplexed or non-multiplexed

The FMC outputs a unique chip select signal, NE[4:1], per bank. All the other signals (addresses, data and control) are shared.

The FMC supports a wide range of devices through a programmable timings among which:

- Programmable wait states (up to 15)
- Programmable bus turnaround cycles (up to 15)
- Programmable output enable and write enable delays (up to 15)
- Independent read and write timings and protocol to support the widest variety of memories and timings
- Programmable continuous clock (FMC_CLK) output.

The FMC Clock (FMC_CLK) is a submultiple of the HCLK clock. It can be delivered to the selected external device either during synchronous accesses only or during asynchronous and synchronous accesses depending on the CCKEN bit configuration in the FMC_BCR1 register:

- If the CCLKEN bit is reset, the FMC generates the clock (CLK) only during synchronous accesses (Read/write transactions).
- If the CCLKEN bit is set, the FMC generates a continuous clock during asynchronous and synchronous accesses. To generate the FMC_CLK continuous clock, Bank 1 must be configured in Synchronous mode (see *Section 22.6.6: NOR/PSRAM controller registers*). Since the same clock is used for all synchronous memories, when a continuous output clock is generated and synchronous accesses are performed, the AHB data size has to be the same as the memory data width (MWID) otherwise the FMC_CLK frequency is changed depending on AHB data transaction (refer to *Section 22.6.5: Synchronous transactions* for FMC_CLK divider ratio formula).

The size of each bank is fixed and equal to 64 Mbytes. Each bank is configured through dedicated registers (see *Section 22.6.6: NOR/PSRAM controller registers*).

The programmable memory parameters include access times (see *Table 170*) and support for wait management (for PSRAM and NOR flash accessed in Burst mode).

Table 170. Programmable NOR/PSRAM access parameters

Parameter	Function	Access mode	Unit	Min.	Max.
Address setup	Duration of the address setup phase	Asynchronous	AHB clock cycle (HCLK)	0	15
Address hold	Duration of the address hold phase	Asynchronous, muxed I/Os	AHB clock cycle (HCLK)	1	15
NBL setup	Duration of the byte lanes setup phase	Asynchronous	AHB clock cycle (HCLK)	0	3
Data setup	Duration of the data setup phase	Asynchronous	AHB clock cycle (HCLK)	1	256
Data hold	Duration of the data hold phase	Asynchronous	AHB clock cycle (HCLK)	0	3
Bust turn	Duration of the bus turnaround phase	Asynchronous and synchronous read / write	AHB clock cycle (HCLK)	0	15

Table 170. Programmable NOR/PSRAM access parameters (continued)

Parameter	Function	Access mode	Unit	Min.	Max.
Clock divide ratio	Number of AHB clock cycles (HCLK) to build one memory clock cycle (CLK)	Synchronous	AHB clock cycle (HCLK)	2	16
Data latency	Number of clock cycles to issue to the memory before the first data of the burst	Synchronous	Memory clock cycle (CLK)	2	17

22.6.1 External memory interface signals

Table 171, *Table 172* and *Table 173* list the signals that are typically used to interface with NOR flash memory, SRAM and PSRAM.

Note: The prefix "N" identifies the signals that are active low.

NOR flash memory, non-multiplexed I/Os

Table 171. Non-multiplexed I/O NOR flash memory

FMC signal name	I/O	Function
CLK	O	Clock (for synchronous access)
A[25:0]	O	Address bus
D[15:0]	I/O	Bidirectional data bus
NE[x]	O	Chip select, x = 1..4
NOE	O	Output enable
NWE	O	Write enable
NL(=NADV)	O	Latch enable (this signal is called address valid, NADV, by some NOR flash devices)
NWAIT	I	NOR flash wait input signal to the FMC

The maximum capacity is 512 Mbits (26 address lines).

NOR flash memory, 16-bit multiplexed I/Os

Table 172. 16-bit multiplexed I/O NOR flash memory

FMC signal name	I/O	Function
CLK	O	Clock (for synchronous access)
A[25:16]	O	Address bus
AD[15:0]	I/O	16-bit multiplexed, bidirectional address/data bus (the 16-bit address A[15:0] and data D[15:0] are multiplexed on the databus)
NE[x]	O	Chip select, x = 1..4
NOE	O	Output enable
NWE	O	Write enable

Table 172. 16-bit multiplexed I/O NOR flash memory (continued)

FMC signal name	I/O	Function
NL(=NADV)	O	Latch enable (this signal is called address valid, NADV, by some NOR flash devices)
NWAIT	I	NOR flash wait input signal to the FMC

The maximum capacity is 512 Mbits.

PSRAM/FRAM/SRAM, non-multiplexed I/Os

Table 173. Non-multiplexed I/Os PSRAM/SRAM

FMC signal name	I/O	Function
CLK	O	Clock (only for PSRAM synchronous access)
A[25:0]	O	Address bus
D[15:0]	I/O	Data bidirectional bus
NE[x]	O	Chip select, x = 1..4 (called NCE by PSRAM (CellularRAM™ i.e. CRAM))
NOE	O	Output enable
NWE	O	Write enable
NL(= NADV)	O	Address valid only for PSRAM input (memory signal name: NADV)
NWAIT	I	PSRAM wait input signal to the FMC
NBL[1:0]	O	Byte lane output. Byte 0 and Byte 1 control (upper and lower byte enable)

The maximum capacity is 512 Mbits.

PSRAM, 16-bit multiplexed I/Os

Table 174. 16-Bit multiplexed I/O PSRAM

FMC signal name	I/O	Function
CLK	O	Clock (for synchronous access)
A[25:16]	O	Address bus
AD[15:0]	I/O	16-bit multiplexed, bidirectional address/data bus (the 16-bit address A[15:0] and data D[15:0] are multiplexed on the databus)
NE[x]	O	Chip select, x = 1..4 (called NCE by PSRAM (CellularRAM™ i.e. CRAM))
NOE	O	Output enable
NWE	O	Write enable
NL(= NADV)	O	Address valid PSRAM input (memory signal name: NADV)
NWAIT	I	PSRAM wait input signal to the FMC
NBL[1:0]	O	Byte lane output. Byte 0 and Byte 1 control (upper and lower byte enable)

The maximum capacity is 512 Mbits (26 address lines).

22.6.2 Supported memories and transactions

Table 175 below shows an example of the supported devices, access modes and transactions when the memory data bus is 16-bit wide for NOR flash memory, PSRAM and SRAM. The transactions not allowed (or not supported) by the FMC are shown in gray in this example.

Table 175. NOR flash/PSRAM: example of supported memories and transactions

Device	Mode	R/W	AHB data size	Memory data size	Allowed/ not allowed	Comments
NOR flash (muxed I/Os and nonmuxed I/Os)	Asynchronous	R	8	16	Y	-
	Asynchronous	W	8	16	N	-
	Asynchronous	R	16	16	Y	-
	Asynchronous	W	16	16	Y	-
	Asynchronous	R	32	16	Y	Split into 2 FMC accesses
	Asynchronous	W	32	16	Y	Split into 2 FMC accesses
	Asynchronous page	R	-	16	N	Mode is not supported
	Synchronous	R	8	16	N	-
	Synchronous	R	16	16	Y	-
	Synchronous	R	32	16	Y	-
PSRAM (multiplexed I/Os and non-multiplexed I/Os)	Asynchronous	R	8	16	Y	-
	Asynchronous	W	8	16	Y	Use of byte lanes NBL[1:0]
	Asynchronous	R	16	16	Y	-
	Asynchronous	W	16	16	Y	-
	Asynchronous	R	32	16	Y	Split into 2 FMC accesses
	Asynchronous	W	32	16	Y	Split into 2 FMC accesses
	Asynchronous page	R	-	16	N	Mode is not supported
	Synchronous	R	8	16	N	-
	Synchronous	R	16	16	Y	-
	Synchronous	R	32	16	Y	-
	Synchronous	W	8	16	Y	Use of byte lanes NBL[1:0]
	Synchronous	W	16/32	16	Y	-
SRAM and ROM	Asynchronous	R	8 / 16	16	Y	-
	Asynchronous	W	8 / 16	16	Y	Use of byte lanes NBL[1:0]
	Asynchronous	R	32	16	Y	Split into 2 FMC accesses
	Asynchronous	W	32	16	Y	Split into 2 FMC accesses Use of byte lanes NBL[1:0]

22.6.3 General timing rules

Signals synchronization

- All controller output signals change on the rising edge of the internal clock (HCLK)
- In Synchronous mode (read or write), all output signals change on the rising edge of HCLK. Whatever the CLKDIV value, all outputs change as follows:
  - NOEL/NWEL/ NEL/NADVL/ NADVH /NBLL/ Address valid outputs change on the falling edge of FMC_CLK clock.
  - NOEH/ NWEH / NEH/ NOEH/NBLH/ Address invalid outputs change on the rising edge of FMC_CLK clock.

22.6.4 NOR flash/PSRAM controller asynchronous transactions

Asynchronous static memories (NOR flash, PSRAM, SRAM, FRAM)

- Signals are synchronized by the internal clock HCLK. This clock is not issued to the memory
- The FMC always samples the data before de-asserting the NOE signal. This guarantees that the memory data hold timing constraint is met (minimum Chip Enable high to data transition is usually 0 ns)
- If the Extended mode is enabled (EXTMOD bit is set in the FMC_BCRx register), up to four extended modes (A, B, C and D) are available. It is possible to mix A, B, C and D modes for read and write operations. For example, read operation can be performed in mode A and write in mode B.
- If the Extended mode is disabled (EXTMOD bit is reset in the FMC_BCRx register), the FMC can operate in mode 1 or mode 2 as follows:
  - Mode 1 is the default mode when SRAM/PSRAM memory type is selected (MTYP = 0x0 or 0x01 in the FMC_BCRx register)
  - Mode 2 is the default mode when NOR memory type is selected (MTYP = 0x10 in the FMC_BCRx register).

Mode 1 - SRAM/FRAM/PSRAM (CRAM)

The next figures show the read and write transactions for the supported modes followed by the required configuration of FMC_BCRx, and FMC_BTRx/FMC_BWTRx registers.

Figure 108. Mode 1 read access waveforms

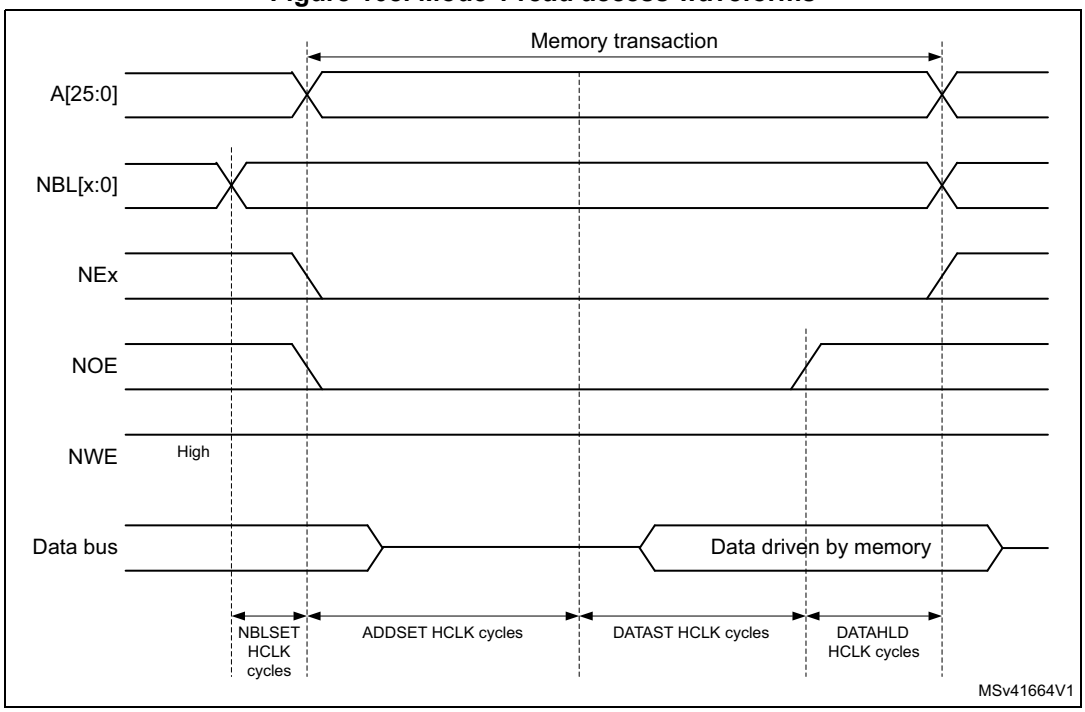

Figure 109. Mode 1 write access waveforms

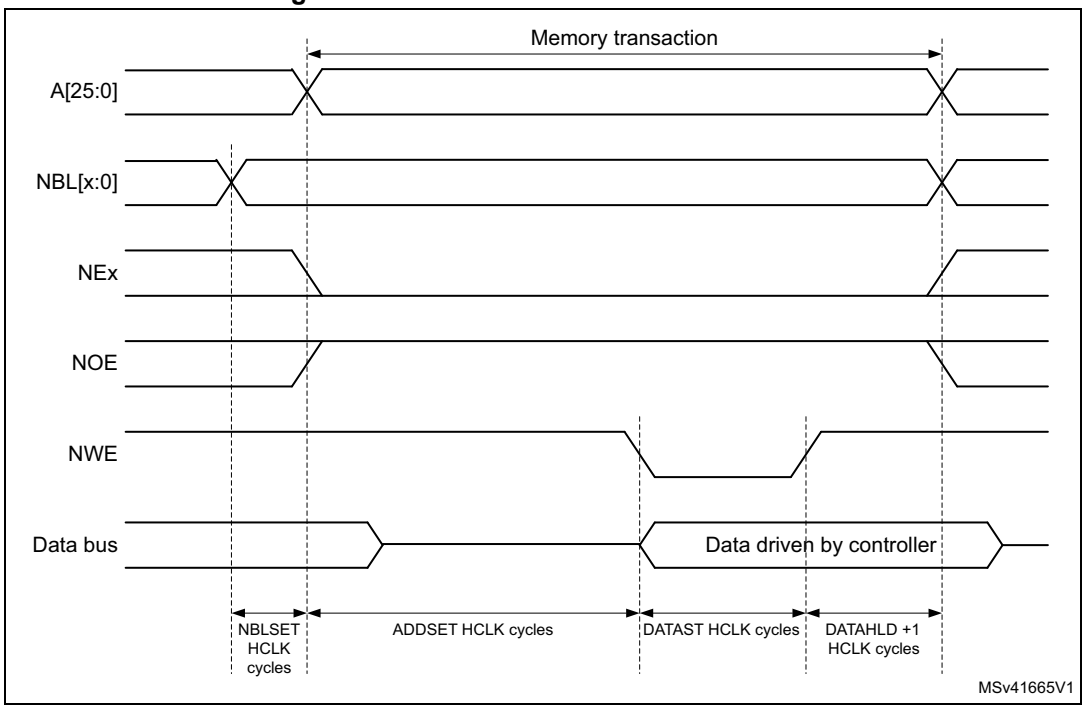

The DATAHLD time at the end of the read and write transactions guarantee the address and data hold time after the NOE/NWE rising edge. The DATAST value must be greater than zero (DATAST > 0).

Table 176. FMC_BCRx bitfields (mode 1)

Bit number	Bit name	Value to set
31	FMCEN	0x1
30:24	Reserved	0x000
23:22	NBLSET[1:0]	As needed
20	CCLKEN	As needed
19	CBURSTRW	0x0 (no effect in Asynchronous mode)
18:16	CPSIZE	0x0 (no effect in Asynchronous mode)
15	ASYNCWAIT	Set to 1 if the memory supports this feature. Otherwise keep at 0.
14	EXTMOD	0x0
13	WAITEN	0x0 (no effect in Asynchronous mode)
12	WREN	As needed
10	Reserved	0x0
9	WAITPOL	Meaningful only if bit 15 is 1
8	BURSTEN	0x0
7	Reserved	0x1
6	FACCEN	Don’t care
5:4	MWID	As needed
3:2	MTYP	As needed, exclude 0x2 (NOR flash memory)
1	MUXE	0x0
0	MBKEN	0x1

Table 177. FMC_BTRx bitfields (mode 1)

Bit number	Bit name	Value to set
31:30	DATAHLD	Duration of the data hold phase (DATAHLD HCLK cycles for read accesses, DATAHLD+1 HCLK cycles for write accesses).
29:28	ACCMOD	Don’t care
27:24	DATLAT	Don’t care
23:20	CLKDIV	Don’t care

3:0	ADDSET	Duration of the first access phase (ADDSET HCLK cycles). Minimum value for ADDSET is 1.

WAIT management in asynchronous accesses

If the asynchronous memory asserts the WAIT signal to indicate that it is not yet ready to accept or to provide data, the ASYNCWAIT bit has to be set in FMC_BCRx register.

If the WAIT signal is active (high or low depending on the WAITPOL bit), the second access phase (Data setup phase), programmed by the DATAST bits, is extended until WAIT becomes inactive. Unlike the data setup phase, the first access phases (Address setup and Address hold phases), programmed by the ADDSET and ADDHLD bits, are not WAIT sensitive and so they are not prolonged.

The data setup phase must be programmed so that WAIT can be detected 4 HCLK cycles before the end of the memory transaction. The following cases must be considered:

1. The memory asserts the WAIT signal aligned to NOE/NWE which toggles:

$$DATAST \geq (4 \times HCLK) + max\_wait\_assertion\_time$$

2. The memory asserts the WAIT signal aligned to NEx (or NOE/NWE not toggling):
   if

$$max\_wait\_assertion\_time > address\_phase + hold\_phase$$

   then:

$$DATAST \geq (4 \times HCLK) + (max\_wait\_assertion\_time - address\_phase - hold\_phase)$$

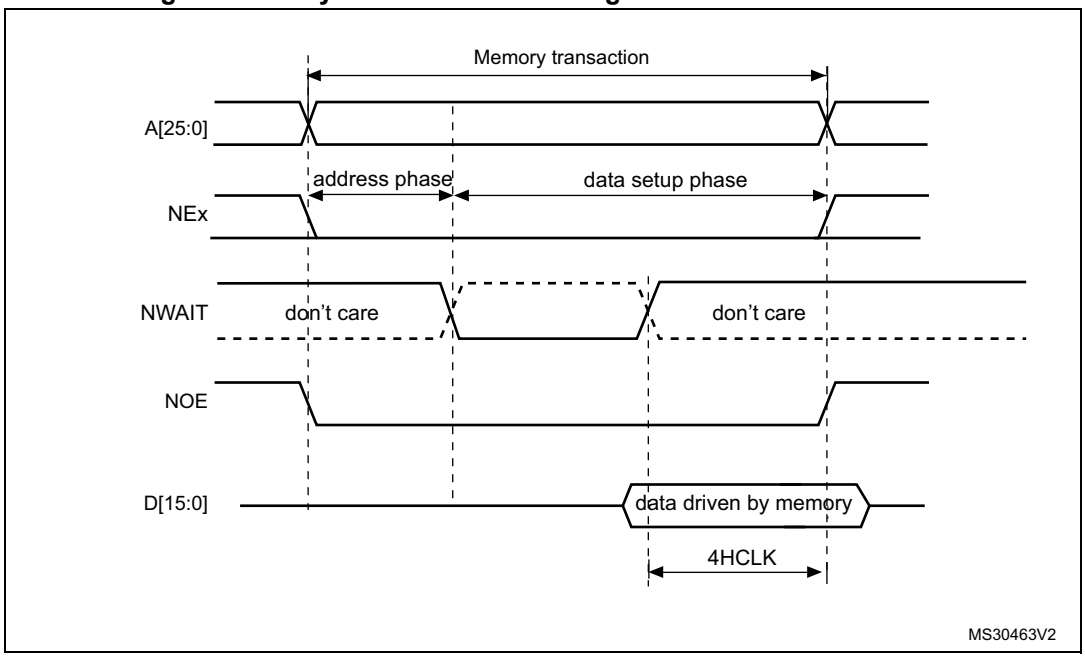
   otherwise

$$DATAST \geq 4 \times HCLK$$

   where max_wait_assertion_time is the maximum time taken by the memory to assert the WAIT signal once NEx/NOE/NWE is low.

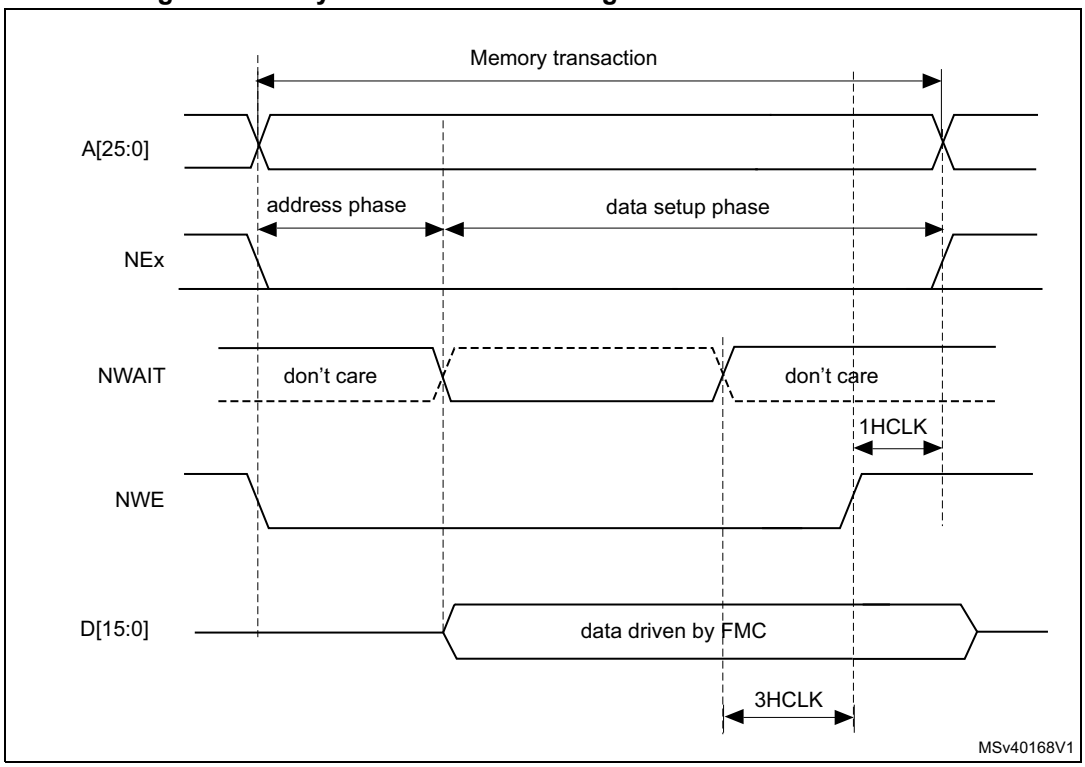
Figure 121 and *Figure 122* show the number of HCLK clock cycles that are added to the memory access phase after WAIT is released by the asynchronous memory (independently of the above cases).

Figure 121. Asynchronous wait during a read access waveforms



1. NWAIT polarity depends on WAITPOL bit setting in FMC_BCRx register.

Figure 122. Asynchronous wait during a write access waveforms



1. NWAIT polarity depends on WAITPOL bit setting in FMC_BCRx register.

CellularRAM™ (PSRAM) refresh management

The CellularRAM™ does not enable maintaining the chip select signal (NE) low for longer than the t_{CEM} timing specified for the memory device. This timing can be programmed in the FMC_PCSCNTR register. It defines the maximum duration of the NE low pulse in HCLK cycles for asynchronous accesses and FMC_CLK cycles for synchronous accesses

22.6.5 Synchronous transactions

The memory clock, FMC_CLK, is a submultiple of HCLK. It depends on the value of CLKDIV and the MWID/ AHB data size, following the formula given below:

Whatever MWID size: 16 or 8-bit, the FMC_CLK divider ratio is always defined by the programmed CLKDIV value.

Example:

- If CLKDIV=1, MWID = 16 bits, AHB data size=8 bits, FMC_CLK=HCLK/2.

NOR flash memories specify a minimum time from NADV assertion to CLK high. To meet this constraint, the FMC does not issue the clock to the memory during the first internal clock cycle of the synchronous access (before NADV assertion). This guarantees that the rising edge of the memory clock occurs in the middle of the NADV low pulse.

Data latency versus NOR memory latency

The data latency is the number of cycles to wait before sampling the data. The DATLAT value must be consistent with the latency value specified in the NOR flash configuration

register. The FMC does not include the clock cycle when NADV is low in the data latency count.

Caution: Some NOR flash memories include the NADV Low cycle in the data latency count, so that the exact relation between the NOR flash latency and the FMC DATLAT parameter can be either:

- NOR flash latency = (DATLAT + 2) CLK clock cycles
- or NOR flash latency = (DATLAT + 3) CLK clock cycles

Some recent memories assert NWAIT during the latency phase. In such cases DATLAT can be set to its minimum value. As a result, the FMC samples the data and waits long enough to evaluate if the data are valid. Thus the FMC detects when the memory exits latency and real data are processed.

Other memories do not assert NWAIT during latency. In this case the latency must be set correctly for both the FMC and the memory, otherwise invalid data are mistaken for good data, or valid data are lost in the initial phase of the memory access.

Single-burst transfer

When the selected bank is configured in Burst mode for synchronous accesses, if for example an AHB single-burst transaction is requested on 16-bit memories, the FMC performs a burst transaction of length 1 (if the AHB transfer is 16 bits), or length 2 (if the AHB transfer is 32 bits) and de-assert the chip select signal when the last data is strobed.

Such transfers are not the most efficient in terms of cycles compared to asynchronous read operations. Nevertheless, a random asynchronous access would first require to re-program the memory access mode, which would altogether last longer.

Cross boundary page for CellularRAM™ 1.5

CellularRAM™ 1.5 does not allow burst access to cross the page boundary. The FMC controller is used to split automatically the burst access when the memory page size is reached by configuring the CPSIZE bits in the FMC_BCR1 register following the memory page size.

Wait management

For synchronous NOR flash memories, NWAIT is evaluated after the programmed latency period, which corresponds to (DATLAT+2) CLK clock cycles.

If NWAIT is active (low level when WAITPOL = 0, high level when WAITPOL = 1), wait states are inserted until NWAIT is inactive (high level when WAITPOL = 0, low level when WAITPOL = 1).

When NWAIT is inactive, the data is considered valid either immediately (bit WAITCFG = 1) or on the next clock edge (bit WAITCFG = 0).

During wait-state insertion via the NWAIT signal, the controller continues to send clock pulses to the memory, keeping the chip select and output enable signals valid. It does not consider the data as valid.

In Burst mode, there are two timing configurations for the NOR flash NWAIT signal:

- The flash memory asserts the NWAIT signal one data cycle before the wait state (default after reset).
- The flash memory asserts the NWAIT signal during the wait state

The FMC supports both NOR flash wait state configurations, for each chip select, thanks to the WAITCFG bit in the FMC_BCRx registers (x = 0..3).

Figure 123. Wait configuration waveforms

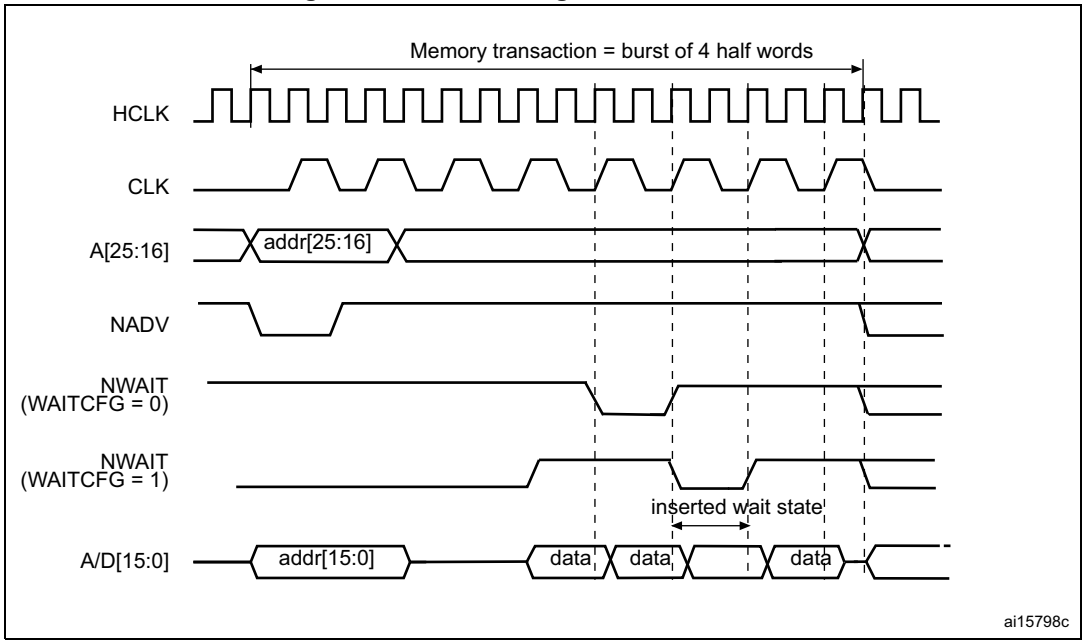


Figure 124. Synchronous multiplexed read mode waveforms - NOR, PSRAM (CRAM)

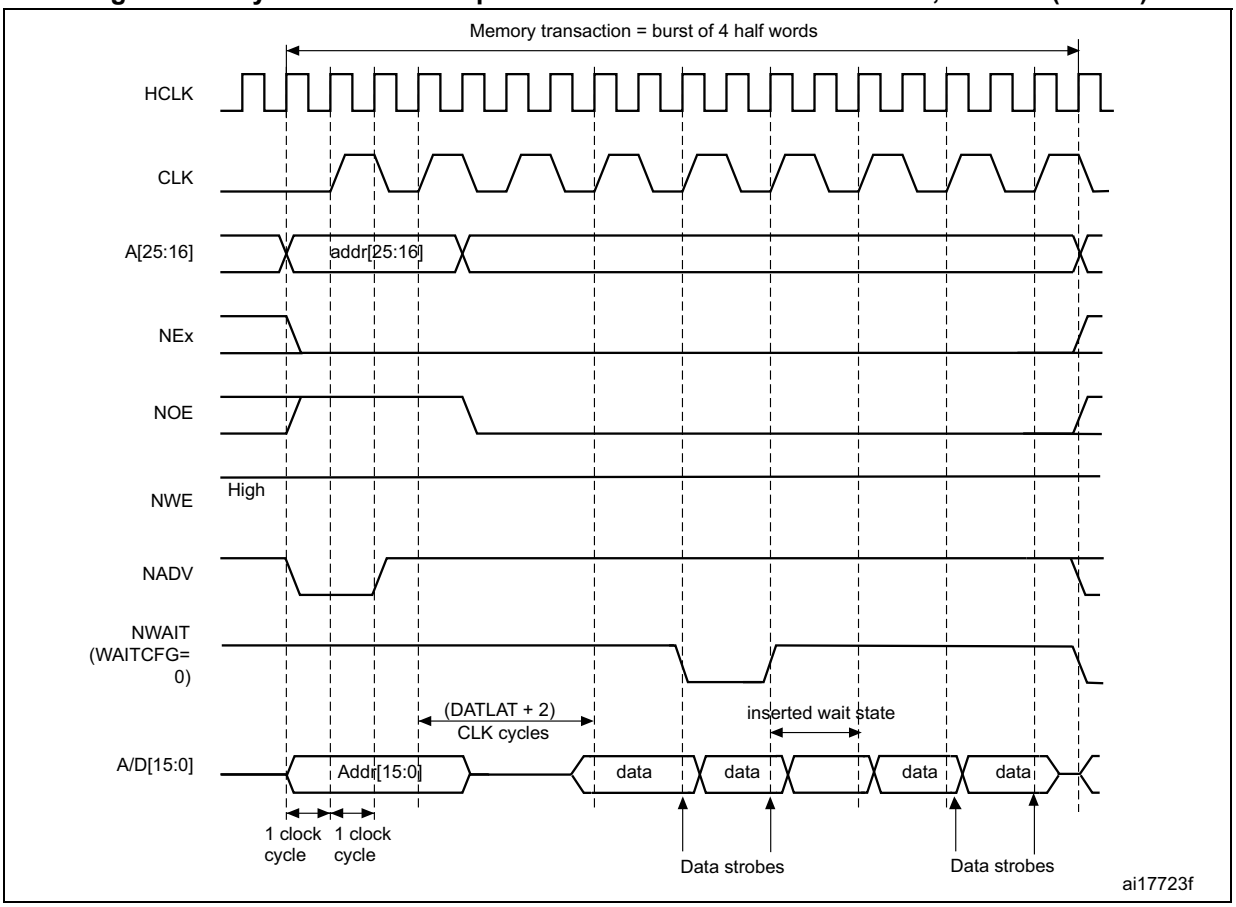

1. Byte lane outputs (NBL are not shown; for NOR access, they are held high, and, for PSRAM (CRAM) access, they are held low.

Table 192. FMC_BCRx bitfields (Synchronous multiplexed read mode)

22.6.6 NOR/PSRAM controller registers

SRAM/NOR-flash chip-select control register for bank x (FMC_BCRx) (x = 1 to 4)

Address offset: 0x00 + 0x8 * (x - 1), (x = 1 to 4)

Reset value: 0x0000 30DB, 0x0000 30D2, 0x0000 30D2, 0x0000 30D2

This register contains the control information of each memory bank, used for SRAMs, PSRAM, FRAM and NOR flash memories.

Bit 31 **FMCEN**: FMC controller enable

This bit enables or disables the FMC controller.

0: Disable the FMC controller

1: Enable the FMC controller

Note: The FMCEN bit of the FMC_BCR2..4 registers is don't care. It is only enabled through the FMC_BCR1 register.

Bits 30:24 Reserved, must be kept at reset value.

Bits 23:22 **NBLSET[1:0]:** Byte lane (NBL) setup

These bits configure the NBL setup timing from NBLx low to chip select NEx low.

00: NBL setup time is 0 AHB clock cycle

01: NBL setup time is 1 AHB clock cycle

10: NBL setup time is 2 AHB clock cycles

11: NBL setup time is 3 AHB clock cycles

Bit 21 **WFDIS:** Write FIFO disable

This bit disables the Write FIFO used by the FMC controller.

0: Write FIFO enabled (Default after reset)

1: Write FIFO disabled

Note: The WFDIS bit of the FMC_BCR2..4 registers is don't care. It is only enabled through the FMC_BCR1 register.

Bit 20 **CCLKEN:** Continuous clock enable

This bit enables the FMC_CLK clock output to external memory devices.

0: The FMC_CLK is only generated during the synchronous memory access (read/write transaction). The FMC_CLK clock ratio is specified by the programmed CLKDIV value in the FMC_BCRx register (default after reset).

1: The FMC_CLK is generated continuously during asynchronous and synchronous access. The FMC_CLK clock is activated when the CCLKEN is set.

Note: The CCLKEN bit of the FMC_BCR2..4 registers is don't care. It is only enabled through the FMC_BCR1 register. Bank 1 must be configured in Synchronous mode to generate the FMC_CLK continuous clock.

Note: If CCLKEN bit is set, the FMC_CLK clock ratio is specified by CLKDIV value in the FMC_BTR1 register. CLKDIV in FMC_BWTR1 is don't care.

Note: If the Synchronous mode is used and CCLKEN bit is set, the synchronous memories connected to other banks than Bank 1 are clocked by the same clock (the CLKDIV value in the FMC_BTR2..4 and FMC_BWTR2..4 registers for other banks has no effect.)

Bit 19 **CBURSTRW:** Write burst enable

For PSRAM (CRAM) operating in Burst mode, the bit enables synchronous accesses during write operations. The enable bit for synchronous read accesses is the BURSTEN bit in the FMC_BCRx register.

0: Write operations are always performed in Asynchronous mode.

1: Write operations are performed in Synchronous mode.

Bits 18:16 **CPSIZE[2:0]**: CRAM page size

These are used for CellularRAM™ 1.5 which does not allow burst access to cross the address boundaries between pages. When these bits are configured, the FMC controller splits automatically the burst access when the memory page size is reached (refer to memory datasheet for page size).

000: No burst split when crossing page boundary (default after reset)

001: 128 bytes

010: 256 bytes

011: 512 bytes

100: 1024 bytes

Others: reserved

Bit 15 **ASYNCWAIT**: Wait signal during asynchronous transfers

This bit enables/disables the FMC to use the wait signal even during an asynchronous protocol.

0: NWAIT signal is not taken in to account when running an asynchronous protocol (default after reset).

1: NWAIT signal is taken in to account when running an asynchronous protocol.

Bit 14 **EXTMOD:** Extended mode enable

This bit enables the FMC to program the write timings for non multiplexed asynchronous accesses inside the FMC_BWTR register, thus resulting in different timings for read and write operations.

0: values inside FMC_BWTR register are not taken into account (default after reset)

1: values inside FMC_BWTR register are taken into account

Note: When the Extended mode is disabled, the FMC can operate in mode 1 or mode 2 as follows:

- *Mode 1 is the default mode when the SRAM/PSRAM memory type is selected (MTYP = 0x0 or 0x01)*
- *Mode 2 is the default mode when the NOR memory type is selected (MTYP = 0x10).*

Bit 13 **WAITEN:** Wait enable bit

This bit enables/disables wait-state insertion via the NWAIT signal when accessing the memory in Synchronous mode.

0: NWAIT signal is disabled (its level not taken into account, no wait state inserted after the programmed flash latency period).

1: NWAIT signal is enabled (its level is taken into account after the programmed latency period to insert wait states if asserted) (default after reset).

Bit 12 **WREN:** Write enable bit

This bit indicates whether write operations are enabled/disabled in the bank by the FMC.

0: Write operations are disabled in the bank by the FMC, an AHB error is reported.

1: Write operations are enabled for the bank by the FMC (default after reset).

Bit 11 **WAITCFG:** Wait timing configuration

The NWAIT signal indicates whether the data from the memory are valid or if a wait state must be inserted when accessing the memory in Synchronous mode. This configuration bit determines if NWAIT is asserted by the memory one clock cycle before the wait state or during the wait state:

0: NWAIT signal is active one data cycle before wait state (default after reset).

1: NWAIT signal is active during wait state (not used for PSRAM).

Bit 10 Reserved, must be kept at reset value.

Bit 9 **WAITPOL:** Wait signal polarity bit

Defines the polarity of the wait signal from memory used for either in Synchronous or Asynchronous mode.

0: NWAIT active low (default after reset)

1: NWAIT active high

Bit 8 **BURSTEN:** Burst enable bit

This bit enables/disables synchronous accesses during read operations. It is valid only for synchronous memories operating in Burst mode.

0: Burst mode disabled (default after reset). Read accesses are performed in Asynchronous mode.

1: Burst mode enable. Read accesses are performed in Synchronous mode.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **FACCEN:** Flash access enable

Enables NOR flash memory access operations.

0: Corresponding NOR flash memory access is disabled.

1: Corresponding NOR flash memory access is enabled (default after reset).

Bits 5:4 **MWID[1:0]:** Memory data bus width

Defines the external memory device width, valid for all type of memories.

00: 8 bits

01: 16 bits (default after reset)

10: reserved

11: reserved

Bits 3:2 **MTYP[1:0]:** Memory type

Defines the type of external memory attached to the corresponding memory bank.

00: SRAM/FRAM (default after reset for Bank 2...4)

01: PSRAM (CRAM) / FRAM

10: NOR flash/OneNAND flash (default after reset for Bank 1)

11: reserved

Bit 1 **MUXEN:** Address/data multiplexing enable bit

When this bit is set, the address and data values are multiplexed on the data bus, valid only with NOR and PSRAM memories:

0: Address/data non multiplexed

1: Address/data multiplexed on databus (default after reset)

Bit 0 **MBKEN:** Memory bank enable bit

Enables the memory bank. After reset Bank1 is enabled, all others are disabled. Accessing a disabled bank causes an ERROR on AHB bus.

0: Corresponding memory bank is disabled.

1: Corresponding memory bank is enabled.

SRAM/NOR-flash chip-select timing register for bank x (FMC_BTRx)

Address offset: 0x04 + 0x8 * (x - 1), (x = 1 to 4)

Reset value: 0x0FFF FFFF

This register contains the control information of each memory bank, used for SRAMs, PSRAM and NOR flash memories.If the EXTMOD bit is set in the FMC_BCRx register, then this register is partitioned for write and read access, that is, 2 registers are available: one to configure read accesses (this register) and one to configure write accesses (FMC_BWTRx registers).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DATAHLD[1:0]		ACCMOD[1:0]		DATLAT[3:0]				CLKDIV[3:0]				BUSTURN[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATAST[7:0]								ADDHLD[3:0]				ADDSET[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 **DATAHLD[1:0]:** Data hold phase duration

These bits are written by software to define the duration of the data hold phase in HCLK cycles (refer to *Figure 108* to *Figure 120*), used in asynchronous accesses:

For read accesses

00: DATAHLD phase duration = 0 × HCLK clock cycle (default)

01: DATAHLD phase duration = 1 × HCLK clock cycle

10: DATAHLD phase duration = 2 × HCLK clock cycle

11: DATAHLD phase duration = 3 × HCLK clock cycle

For write accesses

00: DATAHLD phase duration = 1 × HCLK clock cycle (default)

01: DATAHLD phase duration = 2 × HCLK clock cycle

10: DATAHLD phase duration = 3 × HCLK clock cycle

11: DATAHLD phase duration = 4 × HCLK clock cycle

Bits 29:28 **ACCMOD[1:0]:** Access mode

Specifies the asynchronous access modes as shown in the timing diagrams. These bits are taken into account only when the EXTMOD bit in the FMC_BCRx register is 1.

00: Access mode A

01: Access mode B

10: Access mode C

11: Access mode D

Bits 27:24 **DATLAT[3:0]:** (see note below bit descriptions): Data latency for synchronous memory
For synchronous access with read/write Burst mode enabled (BURSTEN / CBURSTRW bits set), defines the number of memory clock cycles (+2) to issue to the memory before reading/writing the first data:
This timing parameter is not expressed in HCLK periods, but in FMC_CLK periods.
For asynchronous access, this value is don't care.
0000: Data latency of 2 CLK clock cycles for first burst access
1111: Data latency of 17 CLK clock cycles for first burst access (default value after reset)

Bits 23:20 **CLKDIV[3:0]:** Clock divide ratio (for FMC_CLK signal)
Defines the period of FMC_CLK clock output signal, expressed in number of HCLK cycles:
0000: FMC_CLK period= 1x HCLK period
0001: FMC_CLK period = 2 × HCLK periods
0010: FMC_CLK period = 3 × HCLK periods
1111: FMC_CLK period = 16 × HCLK periods (default value after reset)
In asynchronous NOR flash, SRAM or PSRAM accesses, this value is don't care.
Note: Refer to Section 22.6.5: Synchronous transactions for FMC_CLK divider ratio formula)

Bits 19:16 **BUSTURN[3:0]:** Bus turnaround phase duration
These bits are written by software to add a delay at the end of current read or write transaction to next transaction on the same bank.
This delay is used to match the minimum time between consecutive transactions (t_{EHEL} from NEx high to NEx low) and the maximum time needed by the memory to free the data bus after a read access (t_{EHQZ}, chip enable high to output Hi-Z). This delay is recommended for mode D and muxed mode. For non-muxed memory, the bus turnaround delay can be set to minimum value.
(BUSTURN + 1)HCLK period ≥ max(t_{EHEL} min, t_{EHQZ} max)
For FRAM memories, the bus turnaround delay must be configured to match the minimum tPC (precharge time) timings. The bus turnaround delay is inserted between any consecutive transactions on the same bank (read/read, write/write, read/write and write/read) to match the tPC memory timing. The chip select is toggling between any consecutive accesses.
(BUSTURN + 1)HCLK period ≥ t_{PC} min

0000: BUSTURN phase duration = 1 HCLK clock cycle added
...
1111: BUSTURN phase duration = 16 x HCLK clock cycles added (default value after reset)

Bits 15:8 **DATAST[7:0]:** Data-phase duration
These bits are written by software to define the duration of the data phase (refer to *Figure 108* to *Figure 120*), used in asynchronous accesses:
0000 0000: Reserved
0000 0001: DATAST phase duration = 1 × HCLK clock cycles
0000 0010: DATAST phase duration = 2 × HCLK clock cycles
...
1111 1111: DATAST phase duration = 255 × HCLK clock cycles (default value after reset)
For each memory type and access mode data-phase duration, refer to the respective figure (*Figure 108* to *Figure 120*).
Example: Mode 1, write access, DATAST=1: Data-phase duration= DATAST+1 = 2 HCLK clock cycles.
Note: In synchronous accesses, this value is don't care.

Bits 7:4 **ADDHLD[3:0]:** Address-hold phase duration

These bits are written by software to define the duration of the *address hold* phase (refer to *Figure 108* to *Figure 120*), used in mode D or multiplexed accesses:
0000: Reserved
0001: ADDHLD phase duration =1 × HCLK clock cycle
0010: ADDHLD phase duration = 2 × HCLK clock cycle
...
1111: ADDHLD phase duration = 15 × HCLK clock cycles (default value after reset)
For each access mode address-hold phase duration, refer to the respective figure (*Figure 108* to *Figure 120*).

Note: In synchronous accesses, this value is not used, the address hold phase is always 1 memory clock period duration.

Bits 3:0 **ADDSET[3:0]:** Address setup phase duration

These bits are written by software to define the duration of the *address setup* phase (refer to *Figure 108* to *Figure 120*), used in SRAMs, ROMs, asynchronous NOR flash and PSRAM:
0000: ADDSET phase duration = 0 × HCLK clock cycle
...
1111: ADDSET phase duration = 15 × HCLK clock cycles (default value after reset)
For each access mode address setup phase duration, refer to the respective figure (*Figure 108* to *Figure 120*).

Note: In synchronous accesses, this value is don't care.
In Muxed mode or mode D, the minimum value for ADDSET is 1.
In mode 1 and PSRAM memory, the minimum value for ADDSET is 1.

Note: PSRAMs (CRAMs) have a variable latency due to internal refresh. Therefore these memories issue the NWAIT signal during the whole latency phase to prolong the latency as needed.
With PSRAMs (CRAMs) the filled DATLAT must be set to 0, so that the FMC exits its latency phase soon and starts sampling NWAIT from memory, then starts to read or write when the memory is ready.
This method can be used also with the latest generation of synchronous flash memories that issue the NWAIT signal, unlike older flash memories (check the datasheet of the specific flash memory being used).

SRAM/NOR-flash write timing registers x (FMC_BWTRx)

Address offset: 0x104 + 0x8 * (x - 1), (x = 1 to 4)

Reset value: 0x0FFF FFFF

This register contains the control information of each memory bank. It is used for SRAMs, PSRAMs and NOR flash memories. When the EXTMOD bit is set in the FMC_BCRx register, then this register is active for write access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 **DATAHLD[1:0]:** Data hold phase duration

These bits are written by software to define the duration of the data hold phase in HCLK cycles (refer to *Figure 108* to *Figure 120*), used in asynchronous write accesses:
00: DATAHLD phase duration = 1 × HCLK clock cycle (default)
01: DATAHLD phase duration = 2 × HCLK clock cycle
10: DATAHLD phase duration = 3 × HCLK clock cycle
11: DATAHLD phase duration = 4 × HCLK clock cycle

Bits 29:28 **ACCMOD[1:0]:** Access mode.

Specifies the asynchronous access modes as shown in the next timing diagrams.These bits are taken into account only when the EXTMOD bit in the FMC_BCRx register is 1.
00: Access mode A
01: Access mode B
10: Access mode C
11: Access mode D

Bits 27:20 Reserved, must be kept at reset value.

Bits 19:16 **BUSTURN[3:0]**: Bus turnaround phase duration

These bits are written by software to add a delay at the end of current write transaction to next transaction on the same bank.
For FRAM memories, the bus turnaround delay must be configured to match the minimum t_{PC} (precharge time) timings. The bus turnaround delay is inserted between any consecutive transactions on the same bank (read/read, write/write, read/write and write/read). The chip select is toggling between any consecutive accesses.
(BUSTURN + 1)HCLK period ≥ tPC min

0000: BUSTURN phase duration = 1 HCLK clock cycle added
...
1111: BUSTURN phase duration = 16 x HCLK clock cycles added (default value after reset)

Bits 15:8 **DATAST[7:0]:** Data-phase duration.

These bits are written by software to define the duration of the data phase (refer to *Figure 108* to *Figure 120*), used in asynchronous SRAM, PSRAM and NOR flash memory accesses:
0000 0000: Reserved
0000 0001: DATAST phase duration = 1 × HCLK clock cycles
0000 0010: DATAST phase duration = 2 × HCLK clock cycles
...
1111 1111: DATAST phase duration = 255 × HCLK clock cycles (default value after reset)

Bits 7:4 **ADDHLD[3:0]:** Address-hold phase duration.

These bits are written by software to define the duration of the *address hold* phase (refer to *Figure 117* to *Figure 120*), used in asynchronous multiplexed accesses:
0000: Reserved
0001: ADDHLD phase duration = 1 × HCLK clock cycle
0010: ADDHLD phase duration = 2 × HCLK clock cycle
...
1111: ADDHLD phase duration = 15 × HCLK clock cycles (default value after reset)

Note: In synchronous NOR flash accesses, this value is not used, the address hold phase is always 1 flash clock period duration.

Bits 3:0 **ADDSET[3:0]:** Address setup phase duration.

These bits are written by software to define the duration of the *address setup* phase in HCLK cycles (refer to *Figure 108* to *Figure 120*), used in asynchronous accesses:

0000: ADDSET phase duration = 0 × HCLK clock cycle

...

1111: ADDSET phase duration = 15 × HCLK clock cycles (default value after reset)

Note: In synchronous accesses, this value is not used, the address setup phase is always 1 flash clock period duration. In muxed mode, the minimum ADDSET value is 1.

PSRAM chip select counter register (FMC_PCSCNTR)

Address offset: 0x20

Reset value: 0x0000 0000

This register contains the PSRAM chip select counter value for Synchronous and Asynchronous modes. The chip select counter is common to all banks and can be enabled separately on each bank. During PSRAM read or write accesses, this value is loaded into a timer which is decremented while the NE signal is held low. When the timer reaches 0, the PSRAM controller splits the current access, toggles NE to allow PSRAM device refresh, and restarts a new access. The programmed counter value guarantees a maximum NE pulse width (t_{CEM}) as specified for PSRAM devices. The counter is reloaded and starts decrementing each time a new access is started by a transition of NE from high to low.

CSCOUNT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **CNTB4EN:** Counter Bank 4 enable

This bit enables the chip select counter for PSRAM/NOR Bank 4.

0: Counter disabled for Bank 4

1: Counter enabled for Bank 4

Bit 18 **CNTB3EN:** Counter Bank 3 enable

This bit enables the chip select counter for PSRAM/NOR Bank 3.

0: Counter disabled for Bank 3.

1: Counter enabled for Bank 3

Bit 17 **CNTB2EN:** Counter Bank 2 enable

This bit enables the chip select counter for PSRAM/NOR Bank 2.

0: Counter disabled for Bank 2

1: Counter enabled for Bank 2

Bit 16 **CNTB1EN:** Counter Bank 1 enable

This bit enables the chip select counter for PSRAM/NOR Bank 1.

0: Counter disabled for Bank 1

1: Counter enabled for Bank 1

Bits 15:0 **CSCOUNT[15:0]:** Chip select counter.

This bitfield is used to define the maximum duration of the chip select low, which is obtained by the formula:

CSCOUNT[15:0] * T_{AHB}, where T_{AHB} is the AHB clock period.

For refresh considerations, the PSRAM chip select must not stay low for more than t_{CEM} = ~4 µs.

CSCOUNT[15:0] applies both to asynchronous and synchronous modes.

When CSCOUNT[15:0] = 0x0000, the feature is disabled.

22.7 NAND flash controller

The FMC generates the appropriate signal timings to drive the following types of device:

- 8- and 16-bit NAND flash memories

The NAND bank is configured through dedicated registers (*Section 22.7.7*). The programmable memory parameters include access timings (shown in *Table 196*) and ECC configuration.

Table 196. Programmable NAND flash access parameters

Parameter	Function	Access mode	Unit	Min.	Max.
Memory setup time	Number of clock cycles (HCLK) required to set up the address before the command assertion	Read/Write	AHB clock cycle (HCLK)	1	255
Memory wait	Minimum duration (in HCLK clock cycles) of the command assertion	Read/Write	AHB clock cycle (HCLK)	2	255
Memory hold	Number of clock cycles (HCLK) during which the address must be held (as well as the data if a write access is performed) after the command de-assertion	Read/Write	AHB clock cycle (HCLK)	1	254
Memory databus high-Z	Number of clock cycles (HCLK) during which the data bus is kept in high-Z state after a write access has started	Write	AHB clock cycle (HCLK)	1	255

22.7.1 External memory interface signals

The following tables list the signals that are typically used to interface NAND flash memory.

Note: The prefix “N” identifies the signals which are active low.

8-bit NAND flash memory

Table 197. 8-bit NAND flash

FMC signal name	I/O	Function
A[17]	O	NAND flash address latch enable (ALE) signal
A[16]	O	NAND flash command latch enable (CLE) signal
D[7:0]	I/O	8-bit multiplexed, bidirectional address/data bus

Table 197. 8-bit NAND flash (continued)

FMC signal name	I/O	Function
NCE	O	Chip select
NOE(= NRE)	O	Output enable (memory signal name: read enable, NRE)
NWE	O	Write enable
NWAIT/INT	I	NAND flash ready/busy input signal to the FMC

Theoretically, there is no capacity limitation as the FMC can manage as many address cycles as needed.

16-bit NAND flash memory

Table 198. 16-bit NAND flash

FMC signal name	I/O	Function
A[17]	O	NAND flash address latch enable (ALE) signal
A[16]	O	NAND flash command latch enable (CLE) signal
D[15:0]	I/O	16-bit multiplexed, bidirectional address/data bus
NCE	O	Chip select
NOE(= NRE)	O	Output enable (memory signal name: read enable, NRE)
NWE	O	Write enable
NWAIT/INT	I	NAND flash ready/busy input signal to the FMC

Theoretically, there is no capacity limitation as the FMC can manage as many address cycles as needed.

22.7.2 NAND flash supported memories and transactions

Table 199 shows the supported devices, access modes and transactions. Transactions not allowed (or not supported) by the NAND flash controller are shown in gray.

Table 199. Supported memories and transactions

Device	Mode	R/W	AHB data size	Memory data size	Allowed/ not allowed	Comments
NAND 8-bit	Asynchronous	R	8	8	Y	-
	Asynchronous	W	8	8	Y	-
	Asynchronous	R	16	8	Y	Split into 2 FMC accesses
	Asynchronous	W	16	8	Y	Split into 2 FMC accesses
	Asynchronous	R	32	8	Y	Split into 4 FMC accesses
	Asynchronous	W	32	8	Y	Split into 4 FMC accesses

Table 199. Supported memories and transactions (continued)

Device	Mode	R/W	AHB data size	Memory data size	Allowed/ not allowed	Comments
NAND 16-bit	Asynchronous	R	8	16	Y	-
	Asynchronous	W	8	16	N	-
	Asynchronous	R	16	16	Y	-
	Asynchronous	W	16	16	Y	-
	Asynchronous	R	32	16	Y	Split into 2 FMC accesses
	Asynchronous	W	32	16	Y	Split into 2 FMC accesses

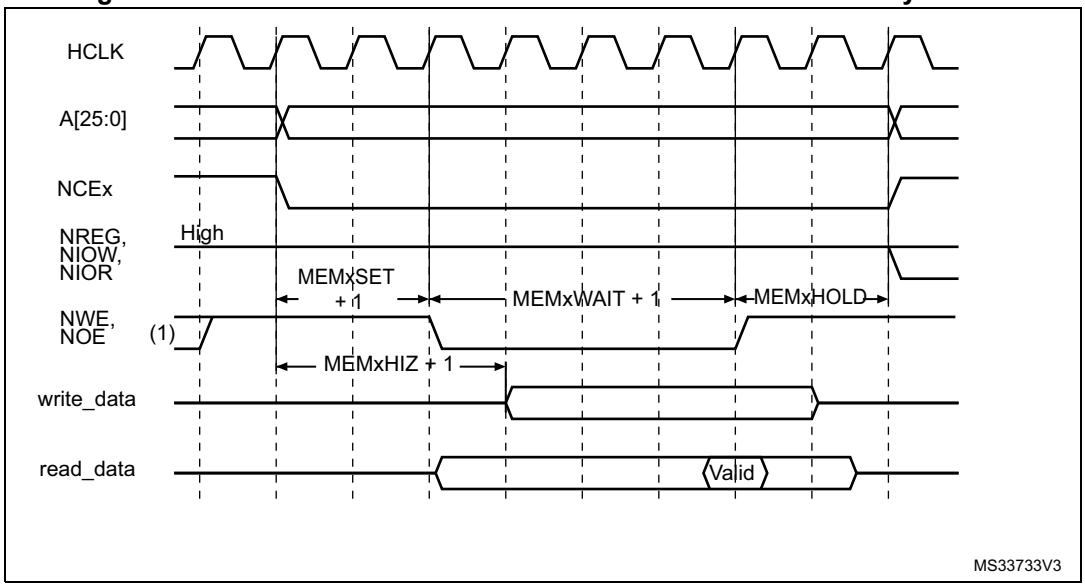
22.7.3 Timing diagrams for NAND flash memory

The NAND flash memory bank is managed through a set of registers:

- Control register: FMC_PCR
- Interrupt status register: FMC_SR
- ECC register: FMC_ECCR
- Timing register for Common memory space: FMC_PMEM
- Timing register for Attribute memory space: FMC_PATT

Each timing configuration register contains three parameters used to define number of HCLK cycles for the three phases of any NAND flash access, plus one parameter that defines the timing for starting driving the data bus when a write access is performed. *Figure 126* shows the timing parameter definitions for common memory accesses, knowing that Attribute memory space access timings are similar.

Figure 126. NAND flash controller waveforms for common memory access



1. NOE remains high (inactive) during write accesses. NWE remains high (inactive) during read accesses.
2. For write access, the hold phase delay is (MEMHOLD) HCLK cycles and for read access is (MEMHOLD + 2) HCLK cycles.

22.7.4 NAND flash operations

The command latch enable (CLE) and address latch enable (ALE) signals of the NAND flash memory device are driven by address signals from the FMC controller. This means that to send a command or an address to the NAND flash memory, the CPU has to perform a write to a specific address in its memory space.

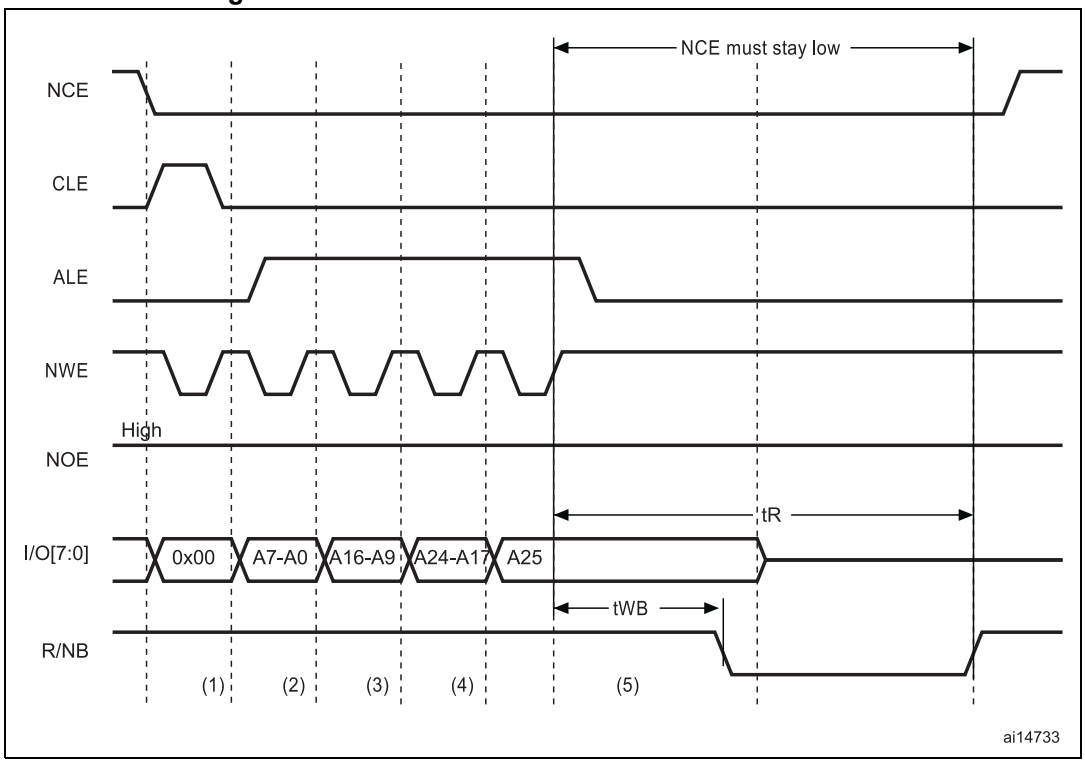
A typical page read operation from the NAND flash device requires the following steps:

1. Program and enable the corresponding memory bank by configuring the FMC_PCR and FMC_PMEM (and for some devices, FMC_PATT, see *Section 22.7.5: NAND flash prewait functionality*) registers according to the characteristics of the NAND flash memory (PWID bits for the data bus width of the NAND flash, PTYP = 1, PWAITEN = 0 or 1 as needed, see *Section 22.5.2: NAND flash memory address mapping* for timing configuration).
2. The CPU performs a byte write to the common memory space, with data byte equal to one flash command byte (for example 0x00 for Samsung NAND flash devices). The LE input of the NAND flash memory is active during the write strobe (low pulse on NWE), thus the written byte is interpreted as a command by the NAND flash memory. Once the command is latched by the memory device, it does not need to be written again for the following page read operations.
3. The CPU can send the start address (STARTAD) for a read operation by writing four bytes (or three for smaller capacity devices), STARTAD[7:0], STARTAD[16:9], STARTAD[24:17] and finally STARTAD[25] (for 64 Mb x 8 bit NAND flash memories) in the common memory or attribute space. The ALE input of the NAND flash device is active during the write strobe (low pulse on NWE), thus the written bytes are interpreted as the start address for read operations. Using the attribute memory space makes it possible to use a different timing configuration of the FMC, which can be used to implement the prewait functionality needed by some NAND flash memories (see details in *Section 22.7.5: NAND flash prewait functionality*).
4. The controller waits for the NAND flash memory to be ready (R/NB signal high), before starting a new access to the same or another memory bank. While waiting, the controller holds the NCE signal active (low).
5. The CPU can then perform byte read operations from the common memory space to read the NAND flash page (data field + Spare field) byte by byte.
6. The next NAND flash page can be read without any CPU command or address write operation. This can be done in three different ways:
   - by simply performing the operation described in step 5
   - a new random address can be accessed by restarting the operation at step 3
   - a new command can be sent to the NAND flash device by restarting at step 2

22.7.5 NAND flash prewait functionality

Some NAND flash devices require that, after writing the last part of the address, the controller waits for the R/NB signal to go low. (see *Figure 127*).

Figure 127. Access to non 'CE don't care' NAND-flash



1. CPU wrote byte 0x00 at address 0x7001 0000.
2. CPU wrote byte A7~A0 at address 0x7002 0000.
3. CPU wrote byte A16~A9 at address 0x7002 0000.
4. CPU wrote byte A24~A17 at address 0x7002 0000.
5. CPU wrote byte A25 at address 0x7802 0000: FMC performs a write access using FMC_PATT timing definition, where ATTHOLD ≥ 7 (providing that (7+1) × HCLK = 112 ns > t_{WB} max). This guarantees that NCE remains low until R/NB goes low and high again (only requested for NAND flash memories where NCE is not don't care).

When this functionality is required, it can be ensured by programming the MEMHOLD value to meet the t_{WB} timing. However any CPU read access to the NAND flash memory has a hold delay of (MEMHOLD + 2) HCLK cycles and CPU write access has a hold delay of (MEMHOLD) HCLK cycles inserted between the rising edge of the NWE signal and the next access.

To cope with this timing constraint, the attribute memory space can be used by programming its timing register with an ATTHOLD value that meets the t_{WB} timing, and by keeping the MEMHOLD value at its minimum value. The CPU must then use the common memory space for all NAND flash read and write accesses, except when writing the last address byte to the NAND flash device, where the CPU must write to the attribute memory space.

22.7.6 Computation of the error correction code (ECC) in NAND flash memory

The FMC NAND Card controller includes two error correction code computation hardware blocks, one per memory bank. They reduce the host CPU workload when processing the ECC by software.

These two ECC blocks are identical and associated with Bank 2 and Bank 3. As a consequence, no hardware ECC computation is available for memories connected to Bank 4.

The ECC algorithm implemented in the FMC can perform 1-bit error correction and 2-bit error detection per 256, 512, 1 024, 2 048, 4 096 or 8 192 bytes read or written from/to the NAND flash memory. It is based on the Hamming coding algorithm and consists in calculating the row and column parity.

The ECC modules monitor the NAND flash data bus and read/write signals (NCE and NWE) each time the NAND flash memory bank is active.

The ECC operates as follows:

- When accessing NAND flash memory bank 2 or bank 3, the data present on the D[15:0] bus is latched and used for ECC computation.
- When accessing any other address in NAND flash memory, the ECC logic is idle, and does not perform any operation. As a result, write operations to define commands or addresses to the NAND flash memory are not taken into account for ECC computation.

Once the desired number of bytes has been read/written from/to the NAND flash memory by the host CPU, the FMC_ECCR registers must be read to retrieve the computed value. Once read, they must be cleared by resetting the ECCEN bit to ‘0’. To compute a new data block, the ECCEN bit must be set to one in the FMC_PCR registers.

To perform an ECC computation:

1. Enable the ECCEN bit in the FMC_PCR register.
2. Write data to the NAND flash memory page. While the NAND page is written, the ECC block computes the ECC value.
3. Read the ECC value available in the FMC_ECCR register and store it in a variable.
4. Clear the ECCEN bit and then enable it in the FMC_PCR register before reading back the written data from the NAND page. While the NAND page is read, the ECC block computes the ECC value.
5. Read the new ECC value available in the FMC_ECCR register.
6. If the two ECC values are the same, no correction is required, otherwise there is an ECC error and the software correction routine returns information on whether the error can be corrected or not.

22.7.7 NAND flash controller registers

NAND flash control registers (FMC_PCR)

Address offset: 0x80

Reset value: 0x0000 0018

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw	

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:17 **ECCPS[2:0]:** ECC page size
Defines the page size for the extended ECC:
000: 256 bytes
001: 512 bytes
010: 1024 bytes
011: 2048 bytes
100: 4096 bytes
101: 8192 bytes

Bits 16:13 **TAR[3:0]:** ALE to RE delay
Sets time from ALE low to RE low in number of AHB clock cycles (HCLK).
Time is: t_ar = (TAR + SET + 2) × THCLK where THCLK is the HCLK clock period
0000: 1 HCLK cycle (default)
1111: 16 HCLK cycles
Note: SET is MEMSET or ATTSET according to the addressed space.

Bits 12:9 **TCLR[3:0]:** CLE to RE delay
Sets time from CLE low to RE low in number of AHB clock cycles (HCLK).
Time is t_clr = (TCLR + SET + 2) × THCLK where THCLK is the HCLK clock period
0000: 1 HCLK cycle (default)
1111: 16 HCLK cycles
Note: SET is MEMSET or ATTSET according to the addressed space.

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **ECCEN:** ECC computation logic enable bit
0: ECC logic is disabled and reset (default after reset),
1: ECC logic is enabled.

Bits 5:4 **PWID[1:0]:** Data bus width
Defines the external memory device width.
00: 8 bits
01: 16 bits (default after reset).
10: reserved.
11: reserved.

Bit 3 **PTYP:** Memory type
Defines the type of device attached to the corresponding memory bank:
0: Reserved, must be kept at reset value
1: NAND flash (default after reset)

Bit 2 **PBKEN:** NAND flash memory bank enable bit
Enables the memory bank. Accessing a disabled memory bank causes an ERROR on AHB bus
0: Corresponding memory bank is disabled (default after reset)
1: Corresponding memory bank is enabled

Bit 1 **PWAITEN:** Wait feature enable bit
Enables the Wait feature for the NAND flash memory bank:
0: disabled
1: enabled

Bit 0 Reserved, must be kept at reset value.

FIFO status and interrupt register (FMC_SR)

Address offset: 0x84

Reset value: 0x0000 0040

This register contains information about the FIFO status and interrupt. The FMC features a FIFO that is used when writing to memories to transfer up to 16 words of data from the AHB.

This is used to quickly write to the FIFO and free the AHB for transactions to peripherals other than the FMC, while the FMC is draining its FIFO into the memory. One of these register bits indicates the status of the FIFO, for ECC purposes.

The ECC is calculated while the data are written to the memory. To read the correct ECC, the software must consequently wait until the FIFO is empty.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

									r	rw	rw	rw	rw	rw	rw

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **FEMPT:** FIFO empty
Read-only bit that provides the status of the FIFO
0: FIFO not empty
1: FIFO empty

Bit 5 **IFEN:** Interrupt falling edge detection enable bit
0: Interrupt falling edge detection request disabled
1: Interrupt falling edge detection request enabled

Bit 4 **ILEN:** Interrupt high-level detection enable bit
0: Interrupt high-level detection request disabled
1: Interrupt high-level detection request enabled

Bit 3 **IREN:** Interrupt rising edge detection enable bit
0: Interrupt rising edge detection request disabled
1: Interrupt rising edge detection request enabled

Bit 2 **IFS:** Interrupt falling edge status
The flag is set by hardware and reset by software.
0: No interrupt falling edge occurred
1: Interrupt falling edge occurred
Note: If this bit is written by software to 1 it is set.

Bit 1 **ILS:** Interrupt high-level status
The flag is set by hardware and reset by software.
0: No Interrupt high-level occurred
1: Interrupt high-level occurred

Bit 0 **IRS:** Interrupt rising edge status

The flag is set by hardware and reset by software.

0: No interrupt rising edge occurred

1: Interrupt rising edge occurred

Note: If this bit is written by software to 1 it is set.

Common memory space timing register (FMC_PMEM)

Address offset: Address: 0x88

Reset value: 0xFCFC FCFC

The FMC_PMEM read/write register contains the timing information for NAND flash memory bank. This information is used to access either the common memory space of the NAND flash for command, address write access and data read/write access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MEMHIZ[7:0]								MEMHOLD[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MEMWAIT[7:0]								MEMSET[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **MEMHIZ[7:0]:** Common memory x data bus Hi-Z time

Defines the number of HCLK clock cycles during which the data bus is kept Hi-Z after the start of a NAND flash write access to common memory space on socket. This is only valid for write transactions:

0000 0000: 1 HCLK cycle

1111 1110: 255 HCLK cycles

1111 1111: reserved.

Bits 23:16 **MEMHOLD[7:0]:** Common memory hold time

Defines the number of HCLK clock cycles for write access and HCLK (+2) clock cycles for read access during which the address is held (and data for write accesses) after the command is deasserted (NWE, NOE), for NAND flash read or write access to common memory space on socket x:

0000 0000: reserved.

0000 0001: 1 HCLK cycle for write access / 3 HCLK cycles for read access

1111 1110: 254 HCLK cycles for write access / 256 HCLK cycles for read access

1111 1111: reserved.

Bits 15:8 **MEMWAIT[7:0]:** Common memory wait time

Defines the minimum number of HCLK (+1) clock cycles to assert the command (NWE, NOE), for NAND flash read or write access to common memory space on socket. The duration of command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of HCLK:

0000 0000: reserved

0000 0001: 2HCLK cycles (+ wait cycle introduced by deasserting NWAIT)

1111 1110: 255 HCLK cycles (+ wait cycle introduced by deasserting NWAIT)

1111 1111: reserved.

Bits 7:0 **MEMSET[7:0]:** Common memory x setup time

Defines the number of HCLK (+1) clock cycles to set up the address before the command assertion (NWE, NOE), for NAND flash read or write access to common memory space on socket x:

0000 0000: 1 HCLK cycle

1111 1110: 255 HCLK cycles

1111 1111: reserved

Attribute memory space timing register (FMC_PATT)

Address offset: 0x8C

Reset value: 0xFCFC FCFC

The FMC_PATT read/write register contains the timing information for NAND flash memory bank. It is used for 8-bit accesses to the attribute memory space of the NAND flash for the last address write access if the timing must differ from that of previous accesses (for Ready/Busy management, refer to *Section 22.7.5: NAND flash prewait functionality*).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ATTHIZ[7:0]								ATTHOLD[7:0]

ATTWAIT[7:0]								ATTSET[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **ATTHIZ[7:0]:** Attribute memory data bus Hi-Z time

Defines the number of HCLK clock cycles during which the data bus is kept in Hi-Z after the start of a NAND flash write access to attribute memory space on socket. Only valid for writ transaction:

0000 0000: 0 HCLK cycle

1111 1110: 255 HCLK cycles

1111 1111: reserved.

Bits 23:16 **ATTHOLD[7:0]:** Attribute memory hold time

Defines the number of HCLK clock cycles for write access and HCLK (+2) clock cycles for read access during which the address is held (and data for write access) after the command deassertion (NWE, NOE), for NAND flash read or write access to attribute memory space on socket:

0000 0000: reserved

0000 0001: 1 HCLK cycle for write access / 3 HCLK cycles for read access

1111 1110: 254 HCLK cycles for write access / 256 HCLK cycles for read access

1111 1111: reserved.

Bits 15:8 **ATTWAIT[7:0]:** Attribute memory wait time

Defines the minimum number of HCLK (+1) clock cycles to assert the command (NWE, NOE), for NAND flash read or write access to attribute memory space on socket x. The duration for command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of HCLK:

0000 0000: reserved

0000 0001: 2 HCLK cycles (+ wait cycle introduced by deassertion of NWAIT)

1111 1110: 255 HCLK cycles (+ wait cycle introduced by deasserting NWAIT)

1111 1111: reserved.

Bits 7:0 **ATTSET[7:0]:** Attribute memory setup time

Defines the number of HCLK (+1) clock cycles to set up address before the command assertion (NWE, NOE), for NAND flash read or write access to attribute memory space on socket:
0000 0000: 1 HCLK cycle
1111 1110: 255 HCLK cycles
1111 1111: reserved.

ECC result registers (FMC_ECCR)

Address offset: 0x94

Reset value: 0x0000 0000

This register contain the current error correction code value computed by the ECC computation modules of the FMC NAND controller. When the CPU reads the data from a NAND flash memory page at the correct address (refer to *Section 22.7.6: Computation of the error correction code (ECC) in NAND flash memory*), the data read/written from/to the NAND flash memory are processed automatically by the ECC computation module. When X bytes have been read (according to the ECCPS field in the FMC_PCR registers), the CPU must read the computed ECC value from the FMC_ECC registers. It then verifies if these computed parity data are the same as the parity value recorded in the spare area, to determine whether a page is valid, and, to correct it otherwise. The FMC_ECCR register must be cleared after being read by setting the ECCEN bit to 0. To compute a new data block, the ECCEN bit must be set to 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

100	4096	ECC[29:0]
101	8192	ECC[31:0]

22.8 SDRAM controller

22.8.1 SDRAM controller main features

The main features of the SDRAM controller are the following:

- Two SDRAM banks with independent configuration
- 8-bit, 16-bit data bus width
- 13-bits Address Row, 11-bits Address Column, 4 internal banks: 4x16Mx16bit (128 MB), 4x16Mx8bit (64 MB)
- Word, half-word, byte access
- Automatic row and bank boundary management
- Multibank ping-pong access
- Programmable timing parameters
- Automatic Refresh operation with programmable Refresh rate
- Self-refresh mode
- Power-down mode
- SDRAM power-up initialization by software
- CAS latency of 1,2,3
- Cacheable Read FIFO with depth of 6 lines x32-bit (6 x14-bit address tag)

22.8.2 SDRAM External memory interface signals

At startup, the SDRAM I/O pins used to interface the FMC SDRAM controller with the external SDRAM devices must configured by the user application. The SDRAM controller I/O pins which are not used by the application, can be used for other purposes.

Table 201. SDRAM signals

SDRAM signal	I/O type	Description	Alternate function
SDCLK	O	SDRAM clock	-
SDCKE[1:0]	O	SDCKE0: SDRAM Bank 1 Clock Enable SDCKE1: SDRAM Bank 2 Clock Enable	-
SDNE[1:0]	O	SDNE0: SDRAM Bank 1 Chip Enable SDNE1: SDRAM Bank 2 Chip Enable	-
A[12:0]	O	Address	FMC_A[12:0]
D[15:0]	I/O	Bidirectional data bus	FMC_D[15:0]
BA[1:0]	O	Bank Address	FMC_A[15:14]
NRAS	O	Row Address Strobe	-
NCAS	O	Column Address Strobe	-
SDNWE	O	Write Enable	-
NBL[1:0]	O	Output Byte Mask for write accesses (memory signal name: DQM[1:0]	FMC_NBL[1:0]

22.8.3 SDRAM controller functional description

All SDRAM controller outputs (signals, address and data) change on the falling edge of the memory clock (FMC_SDCLK).

SDRAM initialization

The initialization sequence is managed by software. If the two banks are used, the initialization sequence must be generated simultaneously to Bank 1and Bank 2 by setting the Target Bank bits CTB1 and CTB2 in the FMC_SDCMR register:

1. Program the memory device features into the FMC_SDCRx register. The SDRAM clock frequency, RBURST and RPIPE must be programmed in the FMC_SDCR1 register.
2. Program the memory device timing into the FMC_SDTRx register. The TRP and TRC timings must be programmed in the FMC_SDTR1 register.
3. Set MODE bits to ‘001’ and configure the Target Bank bits (CTB1 and/or CTB2) in the FMC_SDCMR register to start delivering the clock to the memory (SDCKE is driven high).
4. Wait during the prescribed delay period. Typical delay is around 100 µs (refer to the SDRAM datasheet for the required delay after power-up).
5. Set MODE bits to ‘010’ and configure the Target Bank bits (CTB1 and/or CTB2) in the FMC_SDCMR register to issue a “Precharge All” command.
6. Set MODE bits to ‘011’, and configure the Target Bank bits (CTB1 and/or CTB2) as well as the number of consecutive Auto-refresh commands (NRFS) in the FMC_SDCMR register. Refer to the SDRAM datasheet for the number of Auto-refresh commands that should be issued. Typical number is 8.
7. Configure the MRD field according to the SDRAM device, set the MODE bits to '100', and configure the Target Bank bits (CTB1 and/or CTB2) in the FMC_SDCMR register to issue a "Load Mode Register" command in order to program the SDRAM device. In particular:
   a) the CAS latency must be selected following configured value in FMC_SDCR1/2 registers
   b) the Burst Length (BL) of 1 must be selected by configuring the M[2:0] bits to 000 in the mode register. Refer to SDRAM device datasheet.

   If the Mode Register is not the same for both SDRAM banks, this step has to be repeated twice, once for each bank, and the Target Bank bits set accordingly.
8. Program the refresh rate in the FMC_SDRTR register

   The refresh rate corresponds to the delay between refresh cycles. Its value must be adapted to SDRAM devices.
9. For mobile SDRAM devices, to program the extended mode register it should be done once the SDRAM device is initialized: First, a dummy read access should be performed while BA1=1 and BA=0 (refer to SDRAM address mapping section for BA[1:0] address mapping) in order to select the extended mode register instead of the load mode register and then program the needed value.

At this stage the SDRAM device is ready to accept commands. If a system reset occurs during an ongoing SDRAM access, the data bus might still be driven by the SDRAM device. Therefor the SDRAM device must be first reinitialized after reset before issuing any new access by the NOR flash/PSRAM/SRAM or NAND flash controller.

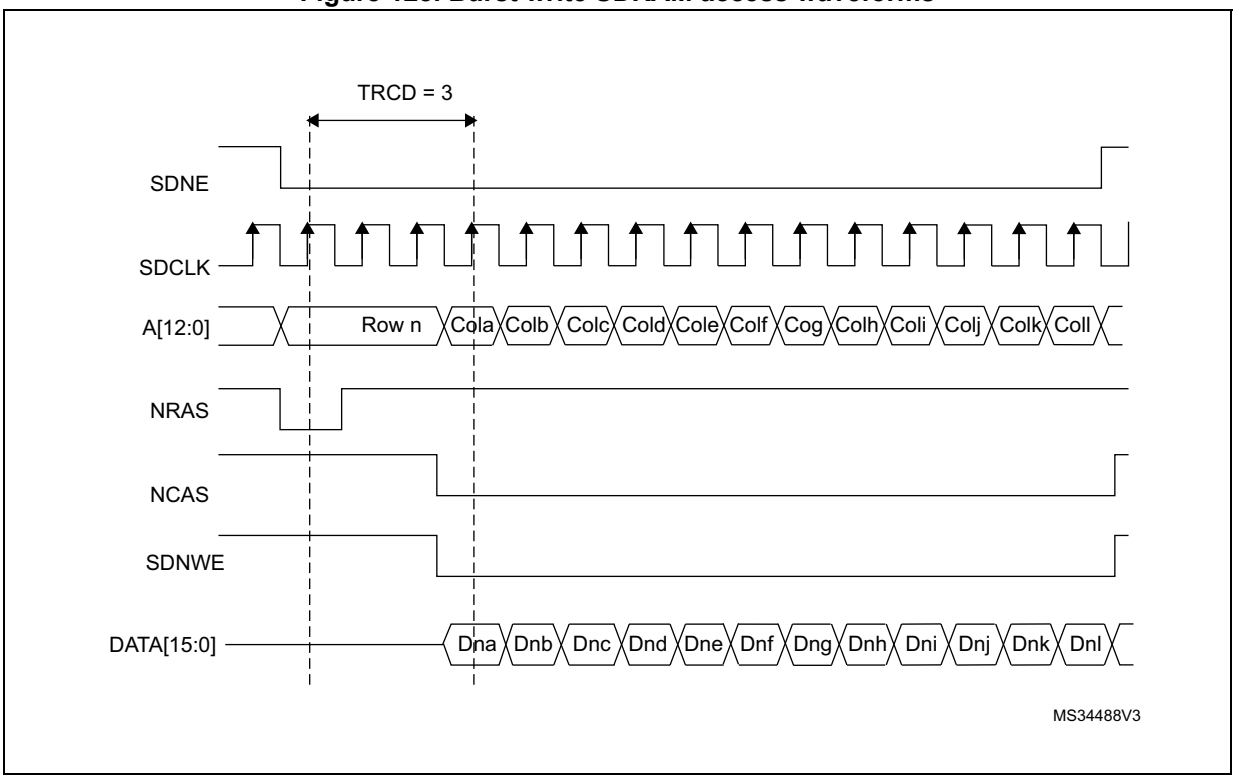
Note: If two SDRAM devices are connected to the FMC, all the accesses performed at the same time to both devices by the Command Mode register (Load Mode Register command) are issued using the timing parameters configured for SDRAM Bank 1 (TMRD andTRAS timings) in the FMC_SDTR1 register.

SDRAM controller write cycle

The SDRAM controller accepts single and burst write requests and translates them into single memory accesses. In both cases, the SDRAM controller keeps track of the active row for each bank to be able to perform consecutive write accesses to different banks (Multibank ping-pong access).

Before performing any write access, the SDRAM bank write protection must be disabled by clearing the WP bit in the FMC_SDCRx register.

Figure 128. Burst write SDRAM access waveforms



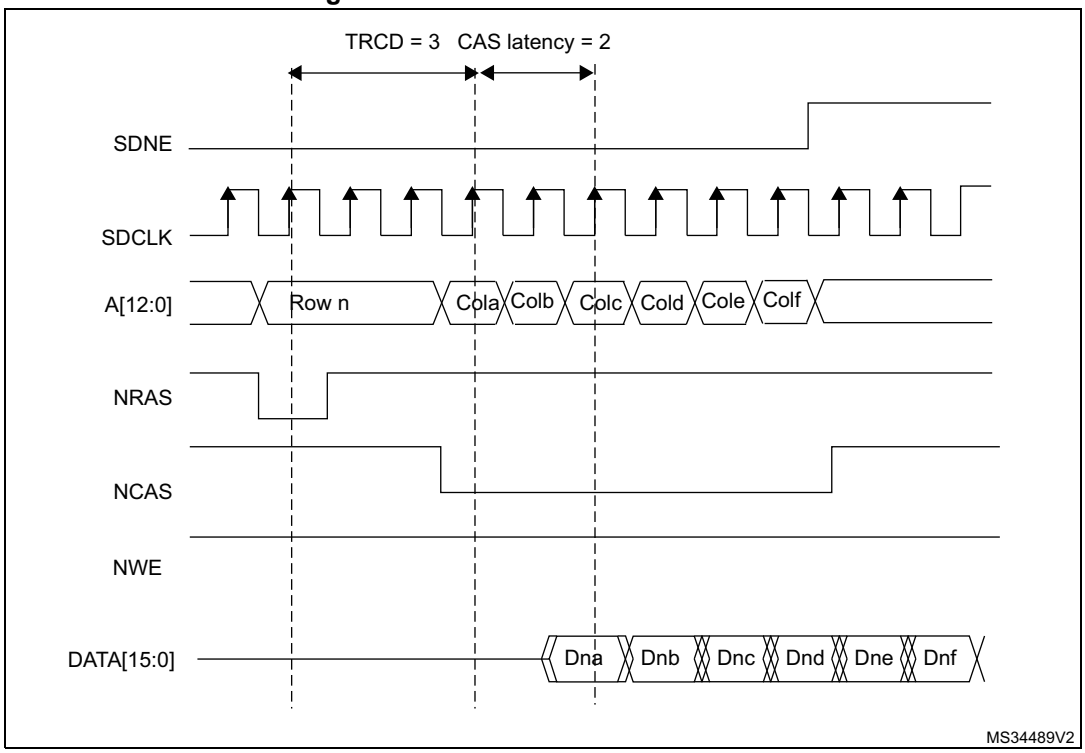
The SDRAM controller always checks the next access.

- If the next access is in the same row or in another active row, the write operation is carried out,
- if the next access targets another row (not active), the SDRAM controller generates a precharge command, activates the new row and initiates a write command.

SDRAM controller read cycle

The SDRAM controller accepts single and burst read requests and translates them into single memory accesses. In both cases, the SDRAM controller keeps track of the active row in each bank to be able to perform consecutive read accesses in different banks (Multibank ping-pong access).

Figure 129. Burst read SDRAM access



The FMC SDRAM controller features a Cacheable read FIFO (6 lines x 32 bits). It is used to store data read in advance during the CAS latency period and the RPIPE delay following the below formula. The RBURST bit must be set in the FMC_SDCR1 register to anticipate the next read access.

Number for anticipated data = CAS latency + 1 + (RPIPE delay)/2

Examples:

- CAS latency = 3, RPIPE delay = 0: Four data (not committed) are stored in the FIFO.
- CAS latency = 3, RPIPE delay = 2: Five data (not committed) are stored in the FIFO.

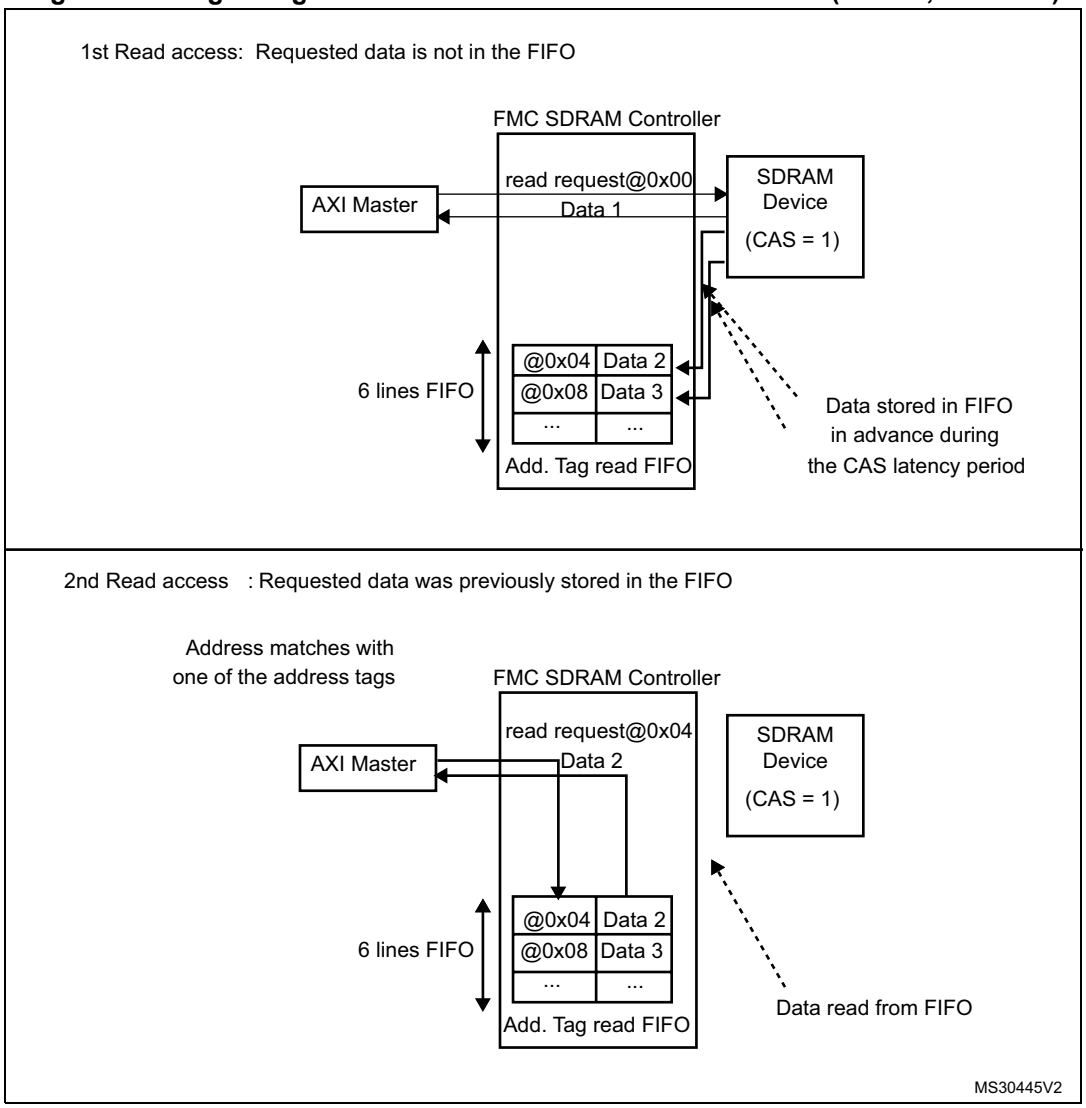
The read FIFO features a 14-bit address tag to each line to identify its content: 11 bits for the column address, 2 bits to select the internal bank and the active row, and 1 bit to select the SDRAM device

When the end of the row is reached in advance during an AHB burst read, the data read in advance (not committed) are not stored in the read FIFO. For single read access, data are correctly stored in the FIFO.

Each time a read request occurs, the SDRAM controller checks:

- If the address matches one of the address tags, data are directly read from the FIFO and the corresponding address tag/ line content is cleared and the remaining data in the FIFO are compacted to avoid empty lines.
- Otherwise, a new read command is issued to the memory and the FIFO is updated with new data. If the FIFO is full, the older data are lost.

Figure 130. Logic diagram of Read access with RBURST bit set (CAS=1, RPIPE=0)



During a write access or a Precharge command, the read FIFO is flushed and ready to be filled with new data.

After the first read request, if the current access was not performed to a row boundary, the SDRAM controller anticipates the next read access during the CAS latency period and the RPIPE delay (if configured). This is done by incrementing the memory address. The following condition must be met:

- RBURST control bit should be set to ‘1’ in the FMC_SDCR1 register.

The address management depends on the next AHB request:

- Next AHB request is sequential (AHB Burst)

  In this case, the SDRAM controller increments the address.
- Next AHB request is not sequential
  - If the new read request targets the same row or another active row, the new address is passed to the memory and the master is stalled for the CAS latency period, waiting for the new data from memory.
  - If the new read request does not target an active row, the SDRAM controller generates a Precharge command, activates the new row, and initiates a read command.

If the RURST is reset, the read FIFO is not used.

Row and bank boundary management

When a read or write access crosses a row boundary, if the next read or write access is sequential and the current access was performed to a row boundary, the SDRAM controller executes the following operations:

1. Precharge of the active row,
2. Activation of the new row
3. Start of a read/write command.

At a row boundary, the automatic activation of the next row is supported for all columns and data bus width configurations.

If necessary, the SDRAM controller inserts additional clock cycles between the following commands:

- Between Precharge and Active commands to match TRP parameter (only if the next access is in a different row in the same bank),
- Between Active and Read commands to match the TRCD parameter.

These parameters are defined into the FMC_SDTRx register.

Refer to *Figure 128* and *Figure 129* for read and burst write access crossing a row boundary.

Figure 131. Read access crossing row boundary

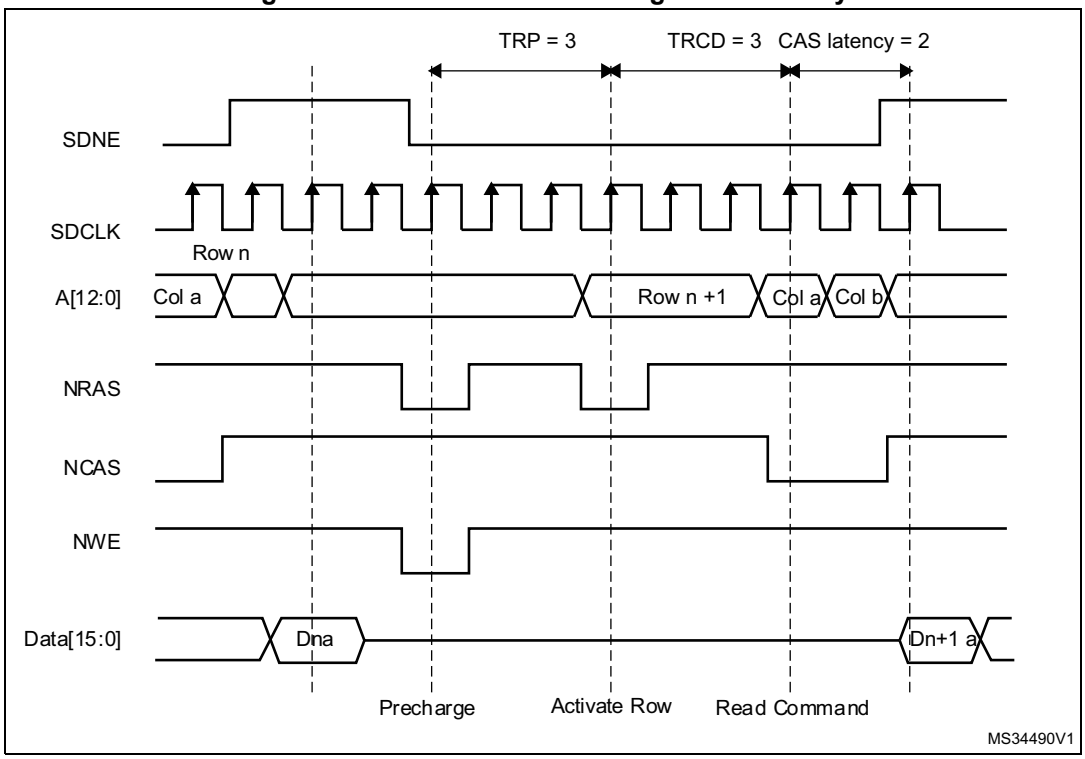


Figure 132. Write access crossing row boundary

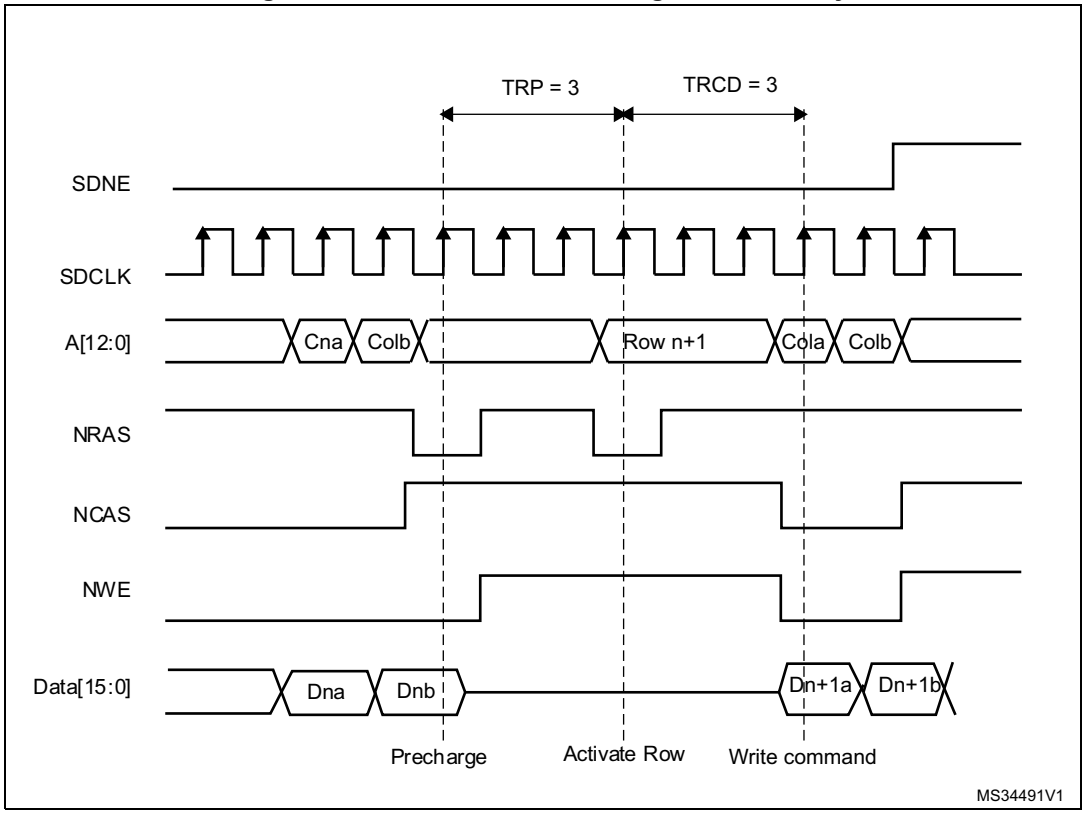


If the next access is sequential and the current access crosses a bank boundary, the SDRAM controller activates the first row in the next bank and initiates a new read/write command. Two cases are possible:

- If the current bank is not the last one, the active row in the new bank must be precharged.At a bank boundary, the automatic activation of the next row is supported for all rows/columns and data bus width configuration.
- If the current bank is the last one and the selected SDRAM device is connected to Bank 1, the automatic activation of the next row in device connected to SDRAM Bank2 is not supported. A PALL software command must be issused on Bank1 before any any access on Bank2.

SDRAM controller refresh cycle

The Auto-refresh command is used to refresh the SDRAM device content. The SDRAM controller periodically issues auto-refresh commands. An internal counter is loaded with the COUNT value in the register FMC_SDRTR. This value defines the number of memory clock cycles between the refresh cycles (refresh rate). When this counter reaches zero, an internal pulse is generated.

If a memory access is ongoing, the auto-refresh request is delayed. However, if the memory access and the auto-refresh requests are generated simultaneously, the auto-refresh request takes precedence.

If the memory access occurs during an auto-refresh operation, the request is buffered and processed when the auto-refresh is complete.

If a new auto-refresh request occurs while the previous one was not served, the RE (Refresh Error) bit is set in the Status register. An Interrupt is generated if it has been enabled (REIE = ‘1’).

If SDRAM lines are not in idle state (not all row are closed), the SDRAM controller generates a PALL (Precharge ALL) command before the auto-refresh.

If the Auto-refresh command is generated by the FMC_SDCMR Command Mode register (Mode bits = ‘011’), a PALL command (Mode bits =’ 010’) must be issued first.

22.8.4 Low-power modes

Two low-power modes are available:

- Self-refresh mode

  The auto-refresh cycles are performed by the SDRAM device itself to retain data without external clocking.
- Power-down mode

  The auto-refresh cycles are performed by the SDRAM controller.

Self-refresh mode

This mode is selected by setting the MODE bits to ‘101’ and by configuring the Target Bank bits (CTB1 and/or CTB2) in the FMC_SDCMR register.

The SDRAM clock stops running after a TRAS delay and the internal refresh timer stops counting only if one of the following conditions is met:

- A Self-refresh command is issued to both devices
- One of the devices is not activated (SDRAM bank is not initialized).

Before entering Self-Refresh mode, the SDRAM controller automatically issues a PALL command.

If the Write data FIFO is not empty, all data are sent to the memory before activating the Self-refresh mode and the BUSY status flag remains set.

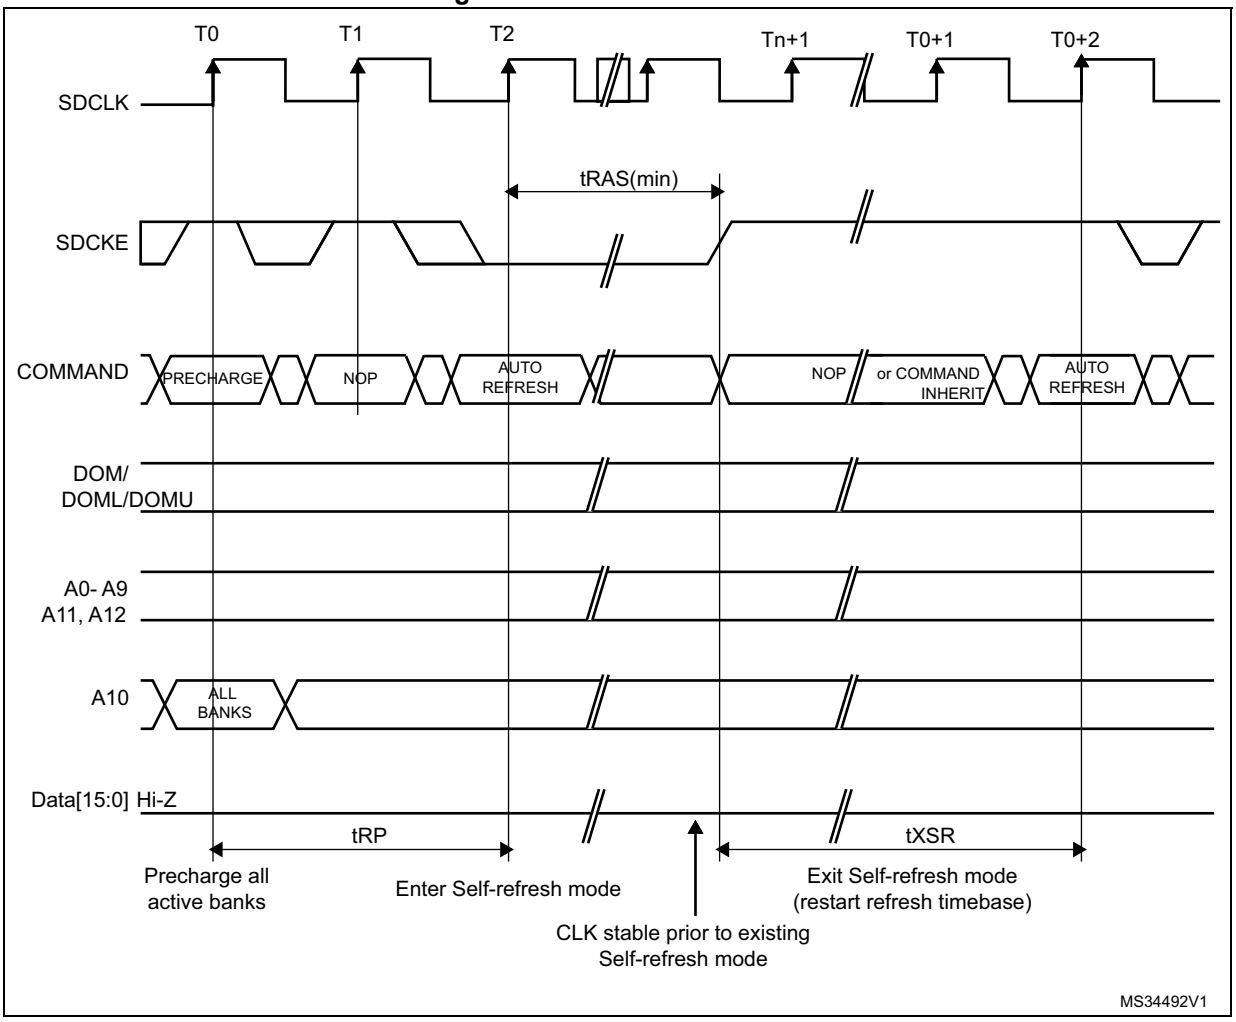
In Self-refresh mode, all SDRAM device inputs become don't care except for SDCKE which remains low.

The SDRAM device must remain in Self-refresh mode for a minimum period of time of TRAS and can remain in Self-refresh mode for an indefinite period beyond that. To guarantee this minimum period, the BUSY status flag remains high after the Self-refresh activation during a TRAS delay.

As soon as an SDRAM device is selected, the SDRAM controller generates a sequence of commands to exit from Self-refresh mode. After the memory access, the selected device remains in Normal mode.

To exit from Self-refresh, the MODE bits must be set to '000' (Normal mode) and the Target Bank bits (CTB1 and/or CTB2) must be configured in the FMC_SDCMR register.

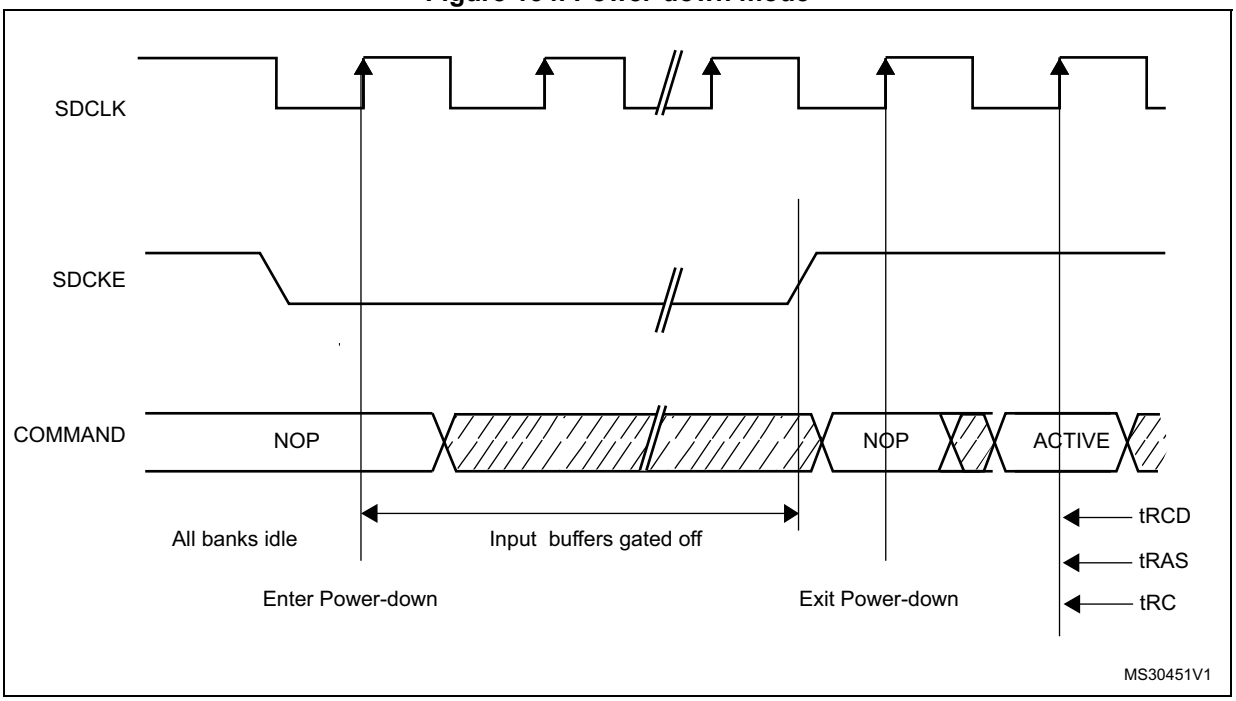
Figure 133. Self-refresh mode



Power-down mode

This mode is selected by setting the MODE bits to ‘110’ and by configuring the Target Bank bits (CTB1 and/or CTB2) in the FMC_SDCMR register.

Figure 134. Power-down mode



If the Write data FIFO is not empty, all data are sent to the memory before activating the Power-down mode.

As soon as an SDRAM device is selected, the SDRAM controller exits from the Power-down mode. After the memory access, the selected SDRAM device remains in Normal mode.

During Power-down mode, all SDRAM device input and output buffers are deactivated except for the SDCKE which remains low.

The SDRAM device cannot remain in Power-down mode longer than the refresh period and cannot perform the Auto-refresh cycles by itself. Therefore, the SDRAM controller carries out the refresh operation by executing the operations below:

1. Exit from Power-down mode and drive the SDCKE high
2. Generate the PALL command only if a row was active during Power-down mode
3. Generate the auto-refresh command
4. Drive SDCKE low again to return to Power-down mode.

To exit from Power-down mode, the MODE bits must be set to ‘000’ (Normal mode) and the Target Bank bits (CTB1 and/or CTB2) must be configured in the FMC_SDCMR register.

22.8.5 SDRAM controller registers

SDRAM control registers 1,2 (FMC_SDCR1,2)

Address offset: 0x140+ 0x4* (x -1), (x = 1,2)

Reset value: 0x0000 02D0

This register contains the control parameters for each SDRAM memory bank

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	RPIPE[1:0]		RBURST	SDCLK[1:0]		WP	CAS[1:0]		NB	MWID[1:0]		NR[1:0]		NC[1:0]	
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:13 **RPIPE[1:0]:** Read pipe

These bits define the delay, in clock cycles, for reading data after CAS latency.

00: No clock cycle delay

01: One clock cycle delay

10: Two clock cycle delay

11: reserved.

Note: The corresponding bits in the FMC_SDCR2 register is read only.

Bit 12 **RBURST:** Burst read

This bit enables Burst read mode. The SDRAM controller anticipates the next read commands during the CAS latency and stores data in the Read FIFO.

0: single read requests are not managed as bursts

1: single read requests are always managed as bursts

Note: The corresponding bit in the FMC_SDCR2 register is don't care.

Bits 11:10 **SDCLK[1:0]:** SDRAM clock configuration

These bits define the SDRAM clock period for both SDRAM banks and allow disabling the clock before changing the frequency. In this case the SDRAM must be re-initialized.

00: SDCLK clock disabled

10: SDCLK period = 2 x HCLK periods

11: SDCLK period = 3 x HCLK periods

Note: The corresponding bits in the FMC_SDCR2 register are don't care.

Bit 9 **WP:** Write protection

This bit enables write mode access to the SDRAM bank.

0: Write accesses allowed

1: Write accesses ignored

Bits 8:7 **CAS[1:0]:** CAS Latency

This bits sets the SDRAM CAS latency in number of memory clock cycles

00: reserved.

01: 1 cycle

10: 2 cycles

11: 3 cycles

Bit 6 **NB:** Number of internal banks
This bit sets the number of internal banks.
0: Two internal Banks
1: Four internal Banks

Bits 5:4 **MWID[1:0]:** Memory data bus width.
These bits define the memory device width.
00: 8 bits
01: 16 bits
10: reserved
11: reserved.

Bits 3:2 **NR[1:0]:** Number of row address bits
These bits define the number of bits of a row address.
00: 11 bit
01: 12 bits
10: 13 bits
11: reserved.

Bits 1:0 **NC[1:0]:** Number of column address bits
These bits define the number of bits of a column address.
00: 8 bits
01: 9 bits
10: 10 bits
11: 11 bits.

Note: Before modifying the RBURST or RPIPE settings or disabling the SDCLK clock, the user must first send a PALL command to make sure ongoing operations are complete.

SDRAM timing registers 1,2 (FMC_SDTR1,2)

Address offset: 0x148 + 0x4 * (x - 1), (x = 1,2)

Reset value: 0x0FFF FFFF

This register contains the timing parameters of each SDRAM bank

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	TRCD[3:0]				TRP[3:0]				TWR[3:0]			
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TRC[3:0]				TRAS[3:0]				TXSR[3:0]				TMRD[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 **TRCD[3:0]:** Row to column delay
These bits define the delay between the Activate command and a Read/Write command in number of memory clock cycles.
0000: 1 cycle.
0001: 2 cycles
....
1111: 16 cycles

Bits 23:20 **TRP[3:0]:** Row precharge delay

These bits define the delay between a Precharge command and another command in number of memory clock cycles. The TRP timing is only configured in the FMC_SDTR1 register. If two SDRAM devices are used, the TRP must be programmed with the timing of the slowest device.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

Note: The corresponding bits in the FMC_SDTR2 register are don't care.

Bits 19:16 **TWR[3:0]:** Recovery delay

These bits define the delay between a Write and a Precharge command in number of memory clock cycles.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

Note: TWR must be programmed to match the write recovery time (t_{WR}) defined in the SDRAM datasheet, and to guarantee that:

TWR ≥ TRAS - TRCD and TWR ≥TRC - TRCD - TRP

Example: TRAS= 4 cycles, TRCD= 2 cycles. So, TWR >= 2 cycles. TWR must be programmed to 0x1.

If two SDRAM devices are used, the FMC_SDTR1 and FMC_SDTR2 must be programmed with the same TWR timing corresponding to the slowest SDRAM device.

If only one SDRAM device is used, the TWR timing must be kept at reset value (0xF) for the not used bank.

Bits 15:12 **TRC[3:0]:** Row cycle delay

These bits define the delay between the Refresh command and the Activate command, as well as the delay between two consecutive Refresh commands. It is expressed in number of memory clock cycles. The TRC timing is only configured in the FMC_SDTR1 register. If two SDRAM devices are used, the TRC must be programmed with the timings of the slowest device.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

Note: TRC must match the TRC and TRFC (Auto Refresh period) timings defined in the SDRAM device datasheet.

Note: The corresponding bits in the FMC_SDTR2 register are don't care.

Bits 11:8 **TRAS[3:0]:** Self refresh time

These bits define the minimum Self-refresh period in number of memory clock cycles.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

Bits 7:4 **TXSR[3:0]:** Exit Self-refresh delay

These bits define the delay from releasing the Self-refresh command to issuing the Activate command in number of memory clock cycles.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

Note: If two SDRAM devices are used, the FMC_SDTR1 and FMC_SDTR2 must be programmed with the same TXSR timing corresponding to the slowest SDRAM device.

Bits 3:0 **TMRD[3:0]:** Load Mode Register to Active

These bits define the delay between a Load Mode Register command and an Active or Refresh command in number of memory clock cycles.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

Note: If two SDRAM devices are connected, all the accesses performed simultaneously to both devices by the Command Mode register (Load Mode Register command) are issued using the timing parameters configured for Bank 1 (TMRD and TRAS timings) in the FMC_SDTR1 register.

The TRP and TRC timings are only configured in the FMC_SDTR1 register. If two SDRAM devices are used, the TRP and TRC timings must be programmed with the timings of the slowest device.

SDRAM Command Mode register (FMC_SDCMR)

Address offset: 0x150

Reset value: 0x0000 0000

This register contains the command issued when the SDRAM device is accessed. This register is used to initialize the SDRAM device, and to activate the Self-refresh and the Power-down modes. As soon as the MODE field is written, the command will be issued only to one or to both SDRAM banks according to CTB1 and CTB2 command bits. This register is the same for both SDRAM banks.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MRD[12:7]					
										rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MRD[6:0]							NRFS[3:0]				CTB1	CTB2	MODE[2:0]		
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:9 **MRD[12:0]:** Mode Register definition

This 13-bit field defines the SDRAM Mode Register content. The Mode Register is programmed using the Load Mode Register command.

Bits 8:5 **NRFS[3:0]:** Number of Auto-refresh
These bits define the number of consecutive Auto-refresh commands issued when MODE = '011'.
0000: 1 Auto-refresh cycle
0001: 2 Auto-refresh cycles
....
1110: 15 Auto-refresh cycles
1111: 16 Auto-refresh cycles

Bit 4 **CTB1:** Command Target Bank 1
This bit indicates whether the command will be issued to SDRAM Bank 1 or not.
0: Command not issued to SDRAM Bank 1
1: Command issued to SDRAM Bank 1

Bit 3 **CTB2:** Command Target Bank 2
This bit indicates whether the command will be issued to SDRAM Bank 2 or not.
0: Command not issued to SDRAM Bank 2
1: Command issued to SDRAM Bank 2

Bits 2:0 **MODE[2:0]:** Command mode
These bits define the command issued to the SDRAM device.
000: Normal Mode
001: Clock Configuration Enable
010: PALL ("All Bank Precharge") command
011: Auto-refresh command
100: Load Mode Register
101: Self-refresh command
110: Power-down command
111: Reserved

Note: When a command is issued, at least one Command Target Bank bit (CTB1 or CTB2) must be set otherwise the command will be ignored.

Note: If two SDRAM banks are used, the Auto-refresh and PALL command must be issued simultaneously to the two devices with CTB1 and CTB2 bits set otherwise the command will be ignored.

Note: If only one SDRAM bank is used and a command is issued with it's associated CTB bit set, the other CTB bit of the the unused bank must be kept to 0.

SDRAM refresh timer register (FMC_SDRTR)

Address offset:0x154

Reset value: 0x0000 0000

This register sets the refresh rate in number of SDCLK clock cycles between the refresh cycles by configuring the Refresh Timer Count value.

$$\text{Refresh rate} = (\text{COUNT} + 1) \times \text{SDRAM clock frequency}$$

$$\text{COUNT} = (\text{SDRAM refresh period} / \text{Number of rows}) - 20$$

Example

$$\text{Refresh rate} = 64\ \text{ms} / (8196\text{rows}) = 7.81\mu\text{s}$$

where 64 ms is the SDRAM refresh period.

$$7.81\mu s \times 60MHz = 468.6$$

The refresh rate must be increased by 20 SDRAM clock cycles (as in the above example) to obtain a safe margin if an internal refresh request occurs when a read request has been accepted. It corresponds to a COUNT value of ‘0000111000000’ (448).

This 13-bit field is loaded into a timer which is decremented using the SDRAM clock. This timer generates a refresh pulse when zero is reached. The COUNT value must be set at least to 41 SDRAM clock cycles.

As soon as the FMC_SDRTR register is programmed, the timer starts counting. If the value programmed in the register is ’0’, no refresh is carried out. This register must not be reprogrammed after the initialization procedure to avoid modifying the refresh rate.

Each time a refresh pulse is generated, this 13-bit COUNT field is reloaded into the counter.

If a memory access is in progress, the Auto-refresh request is delayed. However, if the memory access and Auto-refresh requests are generated simultaneously, the Auto-refresh takes precedence. If the memory access occurs during a refresh operation, the request is buffered to be processed when the refresh is complete.

This register is common to SDRAM bank 1 and bank 2.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	REIE	COUNT[12:0]													CRE
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	w

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **REIE:** RES Interrupt Enable
0: Interrupt is disabled
1: An Interrupt is generated if RE = 1

Bits 13:1 **COUNT[12:0]:** Refresh Timer Count
This 13-bit field defines the refresh rate of the SDRAM device. It is expressed in number of memory clock cycles. It must be set at least to 41 SDRAM clock cycles (0x29).
Refresh rate = (COUNT + 1) x SDRAM frequency clock
COUNT = (SDRAM refresh period / Number of rows) - 20

Bit 0 **CRE:** Clear Refresh error flag
This bit is used to clear the Refresh Error Flag (RE) in the Status Register.
0: no effect
1: Refresh Error flag is cleared

Note: The programmed COUNT value must not be equal to the sum of the following timings: TWR+TRP+TRC+TRCD+4 memory clock cycles.

SDRAM status register (FMC_SDSR)

Address offset: 0x158

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BUSY	MODES2[1:0]		MODES1[1:0]		RE
										r	r	r	r	r	r

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **BUSY:** Busy status

This bit defines the status of the SDRAM controller after a Command Mode request

0: SDRAM Controller is ready to accept a new request

1; SDRAM Controller is not ready to accept a new request

Bits 4:3 **MODES2[1:0]:** Status Mode for Bank 2

This bit defines the Status Mode of SDRAM Bank 2.

00: Normal Mode

01: Self-refresh mode

10: Power-down mode

Bits 2:1 **MODES1[1:0]:** Status Mode for Bank 1

This bit defines the Status Mode of SDRAM Bank 1.

00: Normal Mode

01: Self-refresh mode

10: Power-down mode

Bit 0 **RE:** Refresh error flag

0: No refresh error has been detected

1: A refresh error has been detected

An interrupt is generated if REIE = 1 and RE = 1

23 Octo-SPI interface (OCTOSPI)

23.1 Introduction

The OCTOSPI supports most external serial memories such as serial PSRAMs, serial NAND and serial NOR flash memories, HyperRAM™ and HyperFlash™ memories, with the following functional modes:

- indirect mode: all the operations are performed using the OCTOSPI registers to preset commands, addresses, data, and transfer parameters.
- automatic status-polling mode: the external memory status register is periodically read and an interrupt can be generated in case of flag setting. This feature is only available in regular-command protocol.
- memory-mapped mode: the external memory is memory mapped and it is seen by the system as if it was an internal memory, supporting both read and write operations.

The OCTOSPI supports the following protocols with associated frame formats:

- the regular-command frame format with the command, address, alternate byte, dummy cycles, and data phase
- the HyperBus™ frame format

23.2 OCTOSPI main features

- Functional modes: indirect, automatic status-polling, and memory-mapped
- Read and write support in memory-mapped mode
- External (P)SRAM memory support
- Support for single, dual, quad, and octal communication
- Dual memory configuration, where eight bits can be sent/received simultaneously by accessing two quad memories in parallel
- SDR (single-data rate) and DTR (double-transfer rate) support
- Data strobe support
- Fully programmable opcode
- Fully programmable frame format
- Support wrapped-type access to memory in read direction
- HyperBus support
- Integrated FIFO for reception and transmission
- Asynchronous bus clock versus kernel clock support
- 8-, 16-, and 32-bit data accesses allowed
- DMA protocol support
- DMA channel for indirect mode operations
- Interrupt generation on FIFO threshold, timeout, operation complete, and access error
- AHB interface with transaction acceptance limited to one: the interface accepts the next transfer on AHB bus only once the previous is completed on memory side.

23.3 OCTOSPI implementation

Table 203. OCTOSPI implementation

OCTOSPI feature	OCTOSPI1/2
HyperBus standard compliant	X
Xcella standard compliant	X

23.4 OCTOSPI functional description

23.4.1 OCTOSPI block diagram

Figure 135. OCTOSPI block diagram in octal configuration

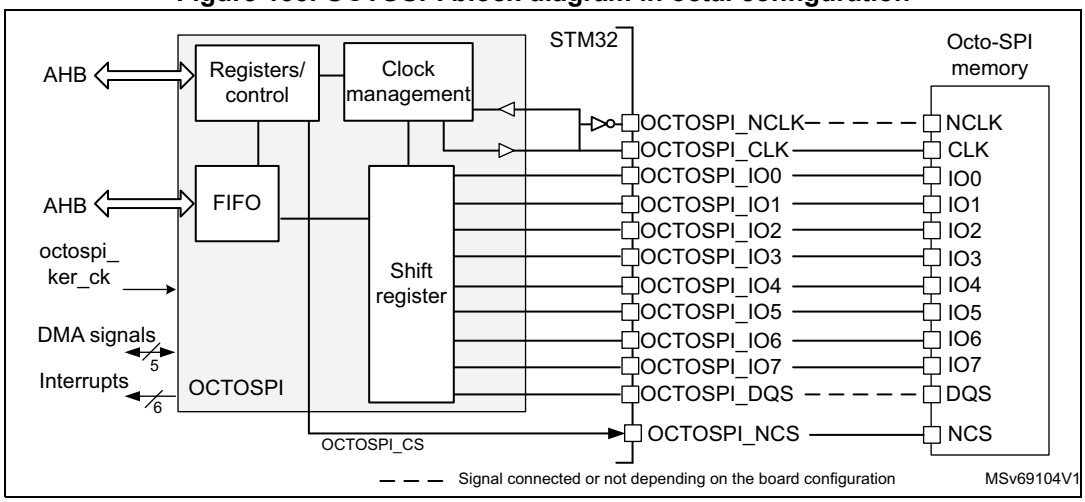

Figure 136. OCTOSPI block diagram in quad configuration

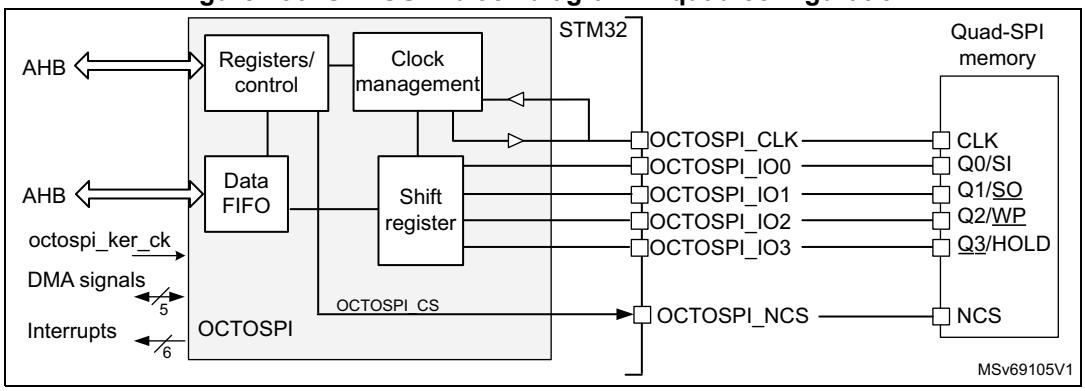

Figure 137. OCTOSPI block diagram in dual-quad configuration

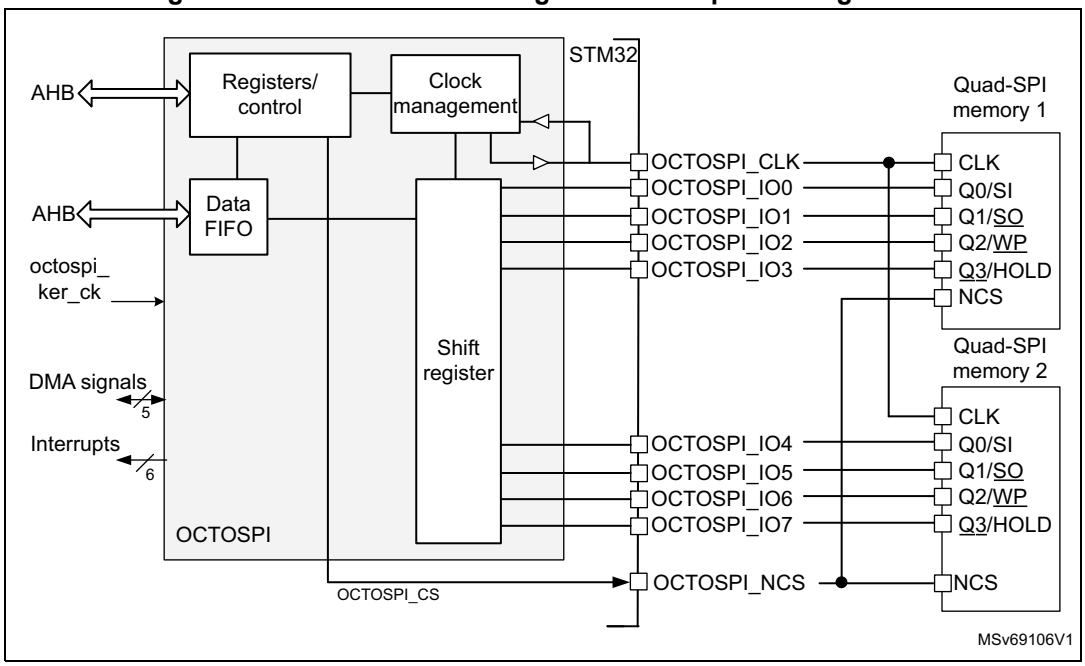


23.4.2 OCTOSPI pins and internal signals

Table 204. OCTOSPI input/output pins

Pin name	Type	Description
OCTOSPI_NCLK	Output	OCTOSPI inverted clock to support 1.8 V HyperBus protocol
OCTOSPI_CLK		OCTOSPI clock
OCTOSPI_IOn (n = 0 to 7)	Input/output	OCTOSPI data pins
OCTOSPI_NCS	Output	Chip select for the memory
OCTOSPI_DQS	Input/output	Data strobe/write mask signal from/to the memory

Caution: Use the same configuration (output speed, HSLV) for all OCTOSPI input/output pins to avoid any data corruption.

Table 205. OCTOSPI internal signals

Signal name	Type	Description
octospi_hclk	Input	OCTOSPI AHB clock
octospi_ker_ck	Input	OCTOSPI kernel clock
octospi_dma	N/A	DMA request signal
octospi_it	Output	Global interrupt line (see *Table 208* for the multiple sources of interrupt)

23.4.3 OCTOSPI interface to memory modes

The OCTOSPI supports the following protocols:

- regular-command protocol
- HyperBus protocol

The OCTOSPI uses from 6 to 12 signals to interface with a memory, depending on the functional mode:

- NCS: chip-select
- CLK: communication clock
- NCLK: inverted clock used only in the 1.8 V HyperBus protocol
- DQS: data strobe used only in regular-command protocol as input only
- IO[3:0]: data bus LSB
- IO[7:4]:
  - data bus MSB used in dual-quad and octal configurations
  - data bus can be used as possible remap for quad-SPI mode

23.4.4 OCTOSPI regular-command protocol

When in regular-command protocol, the OCTOSPI communicates with the external device using commands. Each command can include the following phases:

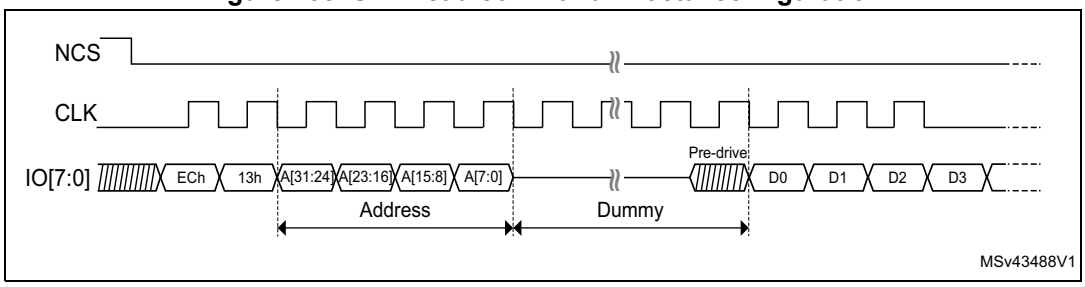
- Instruction phase
- Address phase
- Alternate-byte phase
- Dummy-cycle phase
- Data phase

Any of these phases can be configured to be skipped but, in case of single-phase command, the only use case supported is instruction-phase-only.

The NCS falls before the start of each command and rises again after each command finishes.

In memory-mapped mode, both read and write operations are supported: as a consequence, some of the configuration registers are duplicated to specify write operations (read operations are configured using regular registers).

Figure 138. SDR read command in octal configuration



The specific regular-command protocol features are configured through the registers in the 0x0100-0x01FC offset range.

Instruction phase

During this phase, a 1- to 4-byte instruction is sent to the external device specifying the type of operation to be performed. The size of the instruction to be sent is configured by ISIZE[1:0] in OCTOSPI_CCR and the instruction is programmed in INSTRUCTION[31:0] of OCTOSPI_IR.

The instruction phase can optionally send:

- 1 bit at a time (over IO0, SO single in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode).

This can be configured using IMODE[2:0] of OCTOSPI_CCR.

The instruction can be sent in DTR mode on each rising and falling edge of the clock, by setting IDTR in OCTOSPI_CCR.

When IMODE[2:0] = 000 in OCTOSPI_CCR, the instruction phase is skipped, and the command sequence starts with the address phase, if present.

In memory-mapped mode, the instruction used for the write operation is specified in OCTOSPI_WIR, and the instruction format is specified in OCTOSPI_WCCR. The instruction used for the read operation and the instruction format are specified in OCTOSPI_IR and OCTOSPI_CCR.

Address phase

In the address phase, 1 to 4 bytes are sent to the external device, to indicate the address of the operation. The number of address bytes to be sent is configured by ADSIZE[1:0] in OCTOSPI_CCR.

In indirect and automatic status-polling modes, the address bytes to be sent are specified by ADDRESS[31:0] in OCTOSPI_AR. In memory-mapped mode, the address is given directly via the AHB (from any master in the system).

The address phase can send:

- 1 bit at a time (over IO0, SO single in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using ADMODE[2:0] in OCTOSPI_CCR.

The address can be sent in DTR mode (on each rising and falling edge of the clock) setting ADDTR in OCTOSPI_CCR.

When ADMODE[2:0] = 000, the address phase is skipped and the command sequence proceeds directly to the next phase, if any.

In memory-mapped mode, the address format for the write operation is specified in OCTOSPI_WCCR. The address format for the read operation is specified in OCTOSPI_CCR.

Alternate-byte phase

In the alternate-byte phase, 1 to 4 bytes are sent to the external device, generally to control the mode of operation. The number of alternate bytes to be sent is configured by ABSIZE[1:0] in OCTOSPI_CCR. The bytes to be sent are specified in OCTOSPI_ABR.

The alternate-byte phase can send:

- 1 bit at a time (over IO0, SO single in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using ABMODE[2:0] in OCTOSPI_CCR.

The alternate bytes can be sent in DTR mode (on each rising and falling edge of the clock) setting ABDTR in OCTOSPI_CCR.

When ABMODE[2:0] = 000, the alternate-byte phase is skipped and the command sequence proceeds directly to the next phase, if any.

There may be times when only a single nibble needs to be sent during the alternate-byte phase rather than a full byte, such as when the dual-SPI mode is used and only two cycles are used for the alternate bytes.

In this case, the firmware can use the quad-SPI mode (ABMODE[2:0] = 011) and send a byte with bits 7 and 3 of ALTERNATE[31:0] set to 1 (keeping the IO3 line high), and bits 6 and 2 set to 0 (keeping the IO2 line low), in OCTOSPI_IR.

The upper two bits of the nibble to be sent are then placed in bits 5:4 of ALTERNATE[31:0] while the lower two bits are placed in bits 1:0. For example, if the nibble 2 (0010) is to be sent over IO0/IO1, then ALTERNATE[31:0] must be set to 0x8A (1000_1010).

In memory-mapped mode, the alternate bytes used for the write operation are specified in OCTOSPI_WABR, and the alternate byte format is specified in OCTOSPI_WCCR. The alternate bytes used for read operation and the alternate byte format are specified in OCTOSPI_ABR and OCTOSPI_CCR.

Dummy-cycle phase (memory latency)

In the dummy-cycle phase, 1 to 31 cycles are given without any data being sent or received, in order to give the external device, the time to prepare for the data phase when the higher clock frequencies are used. The number of cycles given during this phase is specified by DCYC[4:0] in OCTOSPI_TCR. In both SDR and DTR modes, the duration is specified as a number of full CLK cycles.

When DCYC[4:0] = 00000, the dummy-cycle phase is skipped, and the command sequence proceeds directly to the data phase, if present.

In order to assure enough “turn-around” time for changing the data signals from the output mode to the input mode, there must be at least one dummy cycle when using the dual-SPI, the quad-SPI, or the octal-SPI mode, to receive data from the external device.

In memory-mapped mode, the dummy cycles for the write operations are specified in OCTOSPI_WTCR. The dummy cycles for the read operation are specified in OCTOSPI_TCR.

Data phase

During the data phase, any number of bytes can be sent to or received from the external device.

In indirect mode, the number of bytes to be sent/received is specified in OCTOSPI_DLR. In this mode, the data to be sent to the external device must be written to OCTOSPI_DR, while in indirect-read mode the data received from the external device is obtained by reading OCTOSPI_DR.

In automatic status-polling mode, the number of bytes to be received is specified in OCTOSPI_DLR, and the data received from the external device can be obtained by reading OCTOSPI_DR.

In memory-mapped mode, the data read or written, is sent or received directly over the AHB to the Cortex core or to a DMA.

The data phase can send/receive:

- 1 bit at a time (over IO0/IO1 (SO/SI respectively) in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using DMODE[2:0] in OCTOSPI_CCR.

The data can be sent or received in DTR mode (on each rising and falling edge of the clock) setting DDTR in OCTOSPI_CCR.

When DMODE[2:0] = 000, the data phase is skipped, and the command sequence finishes immediately by raising the NCS. This configuration must be used only in indirect-write mode.

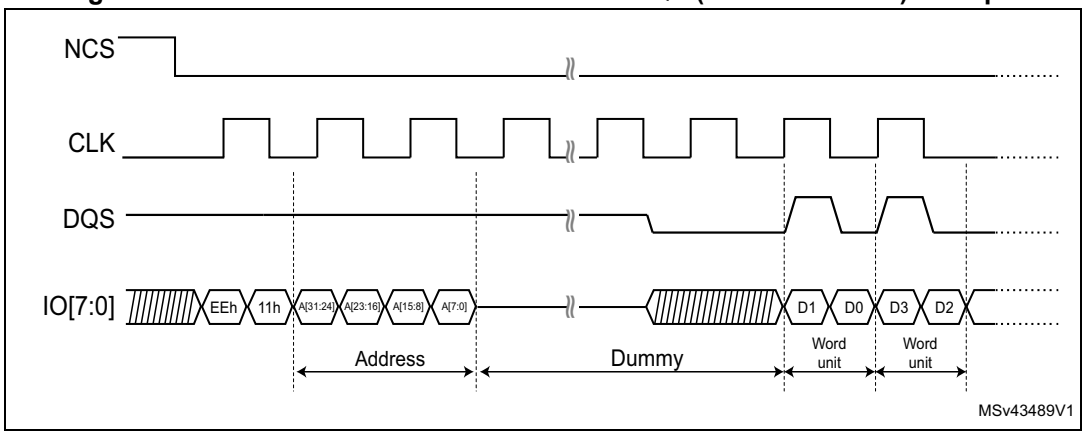
In memory-mapped mode, the data format for the write operation is specified in OCTOSPI_WCCR. The data format for the read operation is specified in OCTOSPI_CCR.

DQS use

The DQS signal can be used for data strobing during the read transactions when the device toggles the DQS aligned with the data.

The DQS management can be enabled by setting DQSE in OCTOSPI_CCR.

Figure 139. DTR read in octal-SPI mode with DQS (Macronix mode) example



23.4.5 OCTOSPI regular-command protocol signal interface

Single-SPI mode

The legacy SPI mode allows just a single bit to be sent/received serially. In this mode, the data is sent to the external device over the SO signal (whose I/Os are shared with IO0). The data received from the external device arrives via SI (whose I/Os are shared with IO1).

The different phases can each be configured separately to use this single-SPI mode by setting to 001 the IMODE, ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase configured in single-SPI mode:

- IO0 (SO) is in output mode.
- IO1 (SI) is in input mode (high impedance).
- IO2 is in output mode and forced to 0 (to deactivate the “write protect” function).
- IO3 is in output mode and forced to 1 (to deactivate the “hold” function).
- IO4 to IO7 are in output mode and forced to 0.

This is the case even for the dummy phase if DMODE[2:0] = 001.

Dual-SPI mode

In dual-SPI mode, two bits are sent/received simultaneously over the IO0/IO1 signals.

The different phases can each be configured separately to use dual-SPI mode by setting to 010 the IMODE, ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase configured in dual-SPI mode:

- IO0/IO1 are at high-impedance (input) during the data phase for the read operations, and outputs in all other cases.
- IO2 is in output mode and forced to 0.
- IO3 is in output mode and forced to 1.
- IO4 to IO7 are in output mode and forced to 0.

In the dummy phase when DMODE[2:0] = 010, IO0/IO1 are always high-impedance.

Quad-SPI mode

In quad-SPI mode, four bits are sent/received simultaneously over the IO0/IO1/IO2/IO3 signals.

The different phases can each be configured separately to use the quad-SPI mode by setting to 011 the IMODE, ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase configured in quad-SPI mode:

- IO0 to IO3 are all at high-impedance (inputs) during the data phase for the read operations, and outputs in all other cases.
- IO4 to IO7 are in output mode and forced to 0.

In the dummy phase when DMODE[2:0] = 011, IO0 to IO3 are all high-impedance.

Octal-SPI mode

In regular octal-SPI mode, the eight bits are sent/received simultaneously over the IO[0:7] signals.

The different phases can each be configured separately to use the octal-SPI mode by setting to 100 the IMODE, ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase that is configured in octal-SPI mode, IO[0:7] are all at high-impedance (input) during the data phase for read operations, and outputs in all other cases.

In the dummy phase when DMODE[2:0] = 100, IO[0:7] are all high-impedance.

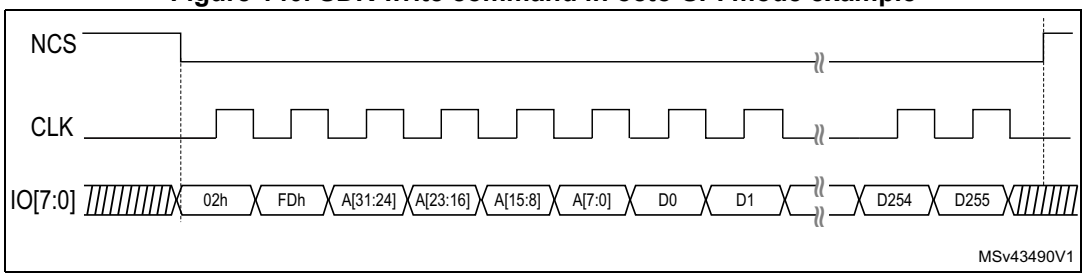
Single-data rate (SDR) mode

By default, all the phases operate in SDR mode.

In this mode, when the OCTOSPI drives the IO0/SO, IO1 to IO7 signals, these signals transition only with the falling edge of CLK.

When receiving data in SDR mode, the OCTOSPI assumes that the external devices also send the data using CLK falling edge. By default (when SSHIFT = 0 in OCTOSPI_TCR), the signals are sampled using the following (rising) edge of CLK.

Figure 140. SDR write command in octo-SPI mode example



Note: Due to internal synchronization, up to six extra dummy clock cycles may be generated by the Octo-SPI interface after the last data is read.

Double-transfer rate (DTR) mode

Each of the instruction, address, alternate-byte, and data phases can be configured to operate in DTR mode setting IDTR, ADDTR, ABDTR, and DDTR in OCTOSPI_CCR.

In memory-mapped mode, the DTR mode for each phase of the write operations is specified in OCTOSPI_WCCR. The DTR mode for each phase of the read operations is specified in OCTOSPI_CCR.

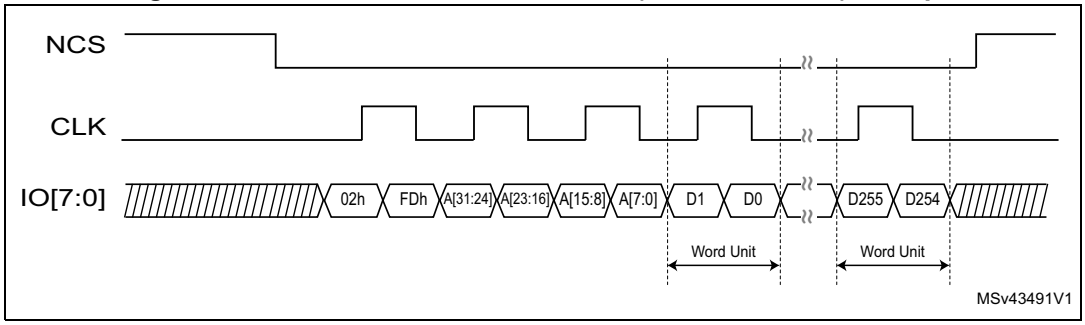
In DTR mode, when the OCTOSPI drives the IO0/SO and IO1to IO7 signals in the instruction, address, and alternate-byte phases, a bit is sent or received on each of the falling and rising edges of CLK.

When receiving data in DTR mode, the OCTOSPI assumes that the external devices also send the data using both CLK rising and falling edges. When DDTR = 1 in OCTOSPI_CCR, the software must clear SSHIFT in OCTOSPI_TCR. Thus, the signals are sampled one half of a CLK cycle later (on the following, opposite edge).

In DTR mode, it is recommended to set DHQC of OCTOSPI_TCR, to shift the outputs by a quarter of cycle and avoid holding issues on the memory side.

Note: DHQC must not be set when the prescaler value is 0, as this action leads to unpredictable behavior.

Figure 141. DTR write in octal-SPI mode (Macronix mode) example



Note: Due to internal synchronization, up to six extra dummy clock cycles may be generated by the Octo-SPI interface after the last data is read.

Dual-quad configuration

When DMM = 1 in OCTOSPI_CR, the OCTOSPI is in dual-memory configuration: if DMODE = 011, two external Quad-SPI devices (device A and device B) are used in order to send/receive eight bits (or 16 bits in DTR mode) every cycle, effectively doubling the throughput.

Each device (A or B) uses the same CLK and NCS signals, but each has separate IO0 to IO3 signals.

The dual-quad configuration can be used in conjunction with the single-SPI, dual-SPI, and quad-SPI modes, as well as with either the SDR or DTR mode.

The device size, as specified by DEVSIZE[4:0] in OCTOSPI_DCR1, must reflect the total external device capacity that is the double of the size of one individual component.

If address X is even, then the byte that the OCTOSPI gives for address X is the byte at the address X/2 of device A, and the byte that the OCTOSPI gives for address X + 1 is the byte at the address X/2 of device B. In other words, the bytes at even addresses are all stored in device A and the bytes at odd addresses are all stored in device B.

When reading the status registers of the devices in dual-quad configuration, twice as many bytes must be read compared to the same read in regular-command protocol: if each device gives eight valid bits after the instruction for fetching the status register, then the OCTOSPI must be configured with a data length of 2 bytes (16 bits), and the OCTOSPI receives one byte from each device.

If each device gives a status of 16 bits, then the OCTOSPI must be configured to read 4 bytes to get all the status bits of both devices in dual-quad configuration. The least-significant byte of the result (in the data register) is the least-significant byte of device A status register. The next byte is the least-significant byte of device B status register. Then, the third byte of the data register is the device A second byte. The fourth byte is the device B second byte (if devices have 16-bit status registers).

An even number of bytes must always be accessed in dual-quad configuration. For this reason, bit 0 of DL[31:0] in OCTOSPI_DLR is stuck at 1 when DMM = 1.

In dual-quad configuration, the behavior of device A interface signals is basically the same as in normal mode. Device B interface signals have exactly the same waveforms as

device A ones during the instruction, address, alternate-byte, and dummy-cycle phases. In other words, each device always receives the same instruction and the same address.

Then, during the data phase, the AIOx and the BIOx buses both transfer data in parallel, but the data that is sent to (or received from) device A is distinct than the one from device B.

23.4.6 HyperBus protocol

The OCTOSPI can communicate with the external device using the HyperBus protocol.

The HyperBus uses 11 to 12 pins depending on the operating voltage:

- IO[7:0] as bidirectional data bus
- RWDS for read and write data strobe and latency insertion (mapped on DQS pin)
- NCS
- CLK
- NCLK for 1.8 V operations (to support this mode, the device must be powered with 1.8 V)

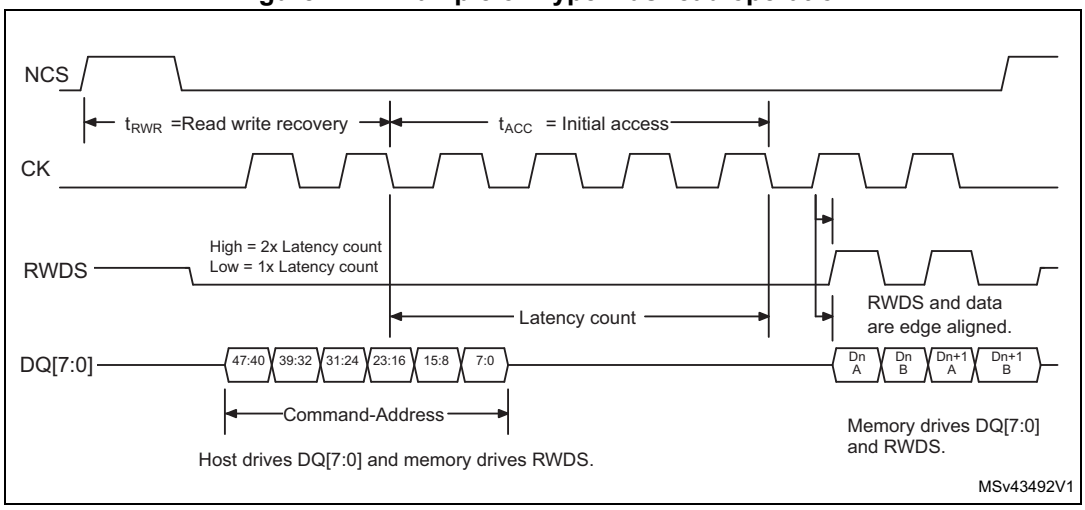
The HyperBus does not require any command specification nor any alternate bytes. As a consequence, a separate register set is used to define the timing of the transaction.

The HyperBus frame is composed of the following phases:

- Command/address phase
- Data phase

The NCS falls before the start of a transaction and rises again after each transaction finishes.

Figure 142. Example of HyperBus read operation



Note: Due to internal synchronization, up to six extra dummy clock cycles may be generated by the Octo-SPI interface after the last data is read.

The specific HyperBus features are configured through the registers in the 0x0200-0x02FC offset range.

Command/address phase

During this initial phase, the OCTOSPI sends 48 bits over IO[7:0] to specify the operations to be performed with the external device.

Table 206. Command/address phase description

CA bit	Bit name	Description
47	R/W#	Identifies the transaction as a read or a write.
46	Address space	Indicates if the transaction accesses the memory or the register space.
45	Burst type	Indicates if the burst is linear or wrapped.
44-16	Row and upper column address	Selects the row and the upper column addresses.
15-3	Reserved	-
2-0	Lower column address	Selects the starting 16-bit word within the half page.

The address space is configured through the memory type MTYP[2:0] in OCTOSPI_DCR1.

The total size of the device is configured in DEVSIZE[4:0] of OCTOSPI_DCR1. In case of multi-chip product (MCP), the device size is the sum of all the sizes of all the MCP dies.

Read/write operation with initial latency

The HyperBus read and write operations need to respect two timings:

- t_{RWR}: minimal read/write recovery time for the device (defined by TRWR[7:0] in OCTOSPI_HLCR)
- t_{ACC}: access time for the device (defined by TACC[7:0] in OCTOSPI_HLCR) according to the memory latency

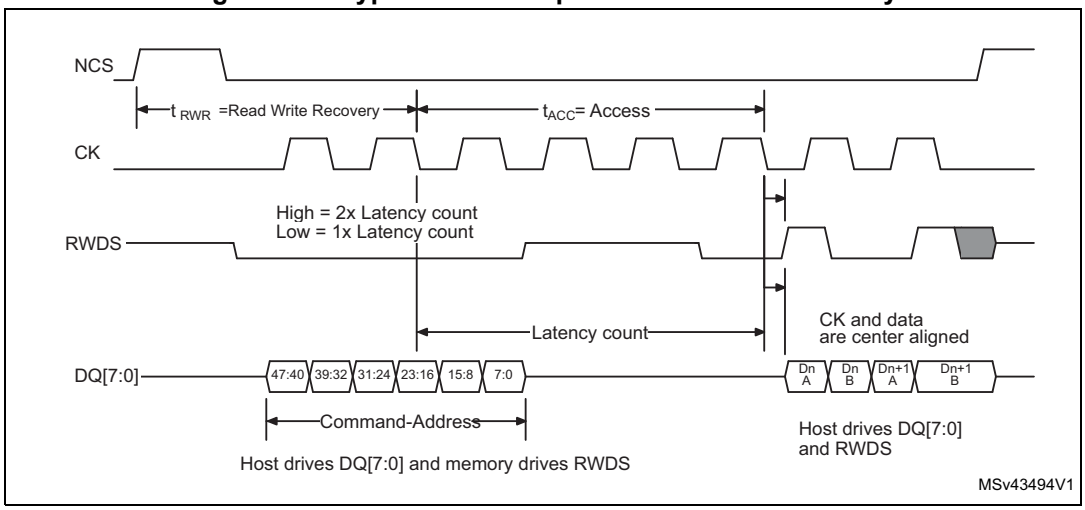
During the read operation, the RWDS is used by the device, in two ways (see *Figure 142*):

- during the command/address phase, to request an additional latency
- during the data phase, for data strobing

During the write operation, the RWDS is used:

- by the device, during the command/address phase, to request an additional latency.
- by the OCTOSPI, during the data phase, for write data masking.

Figure 143. HyperBus write operation with initial latency



Read/write operation with additional latency

If the device needs an additional latency (during refresh period of an SDRAM for example), RWDS must be tied to one during one of the RWDS signals, during the command/address phase.

An additional t_{ACC} duration is added by the OCTOSPI to meet the device request.

Figure 144. HyperBus read operation with additional latency

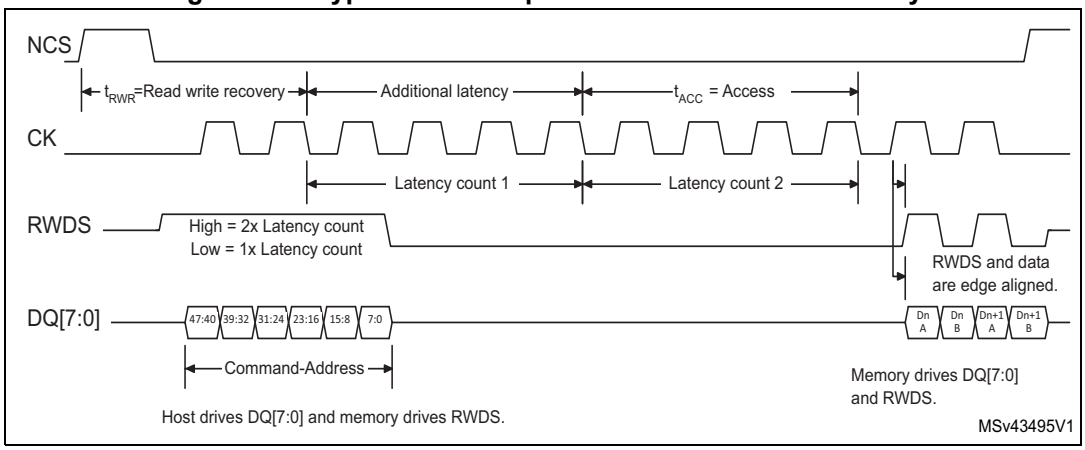


Figure 145. HyperBus write operation with additional latency

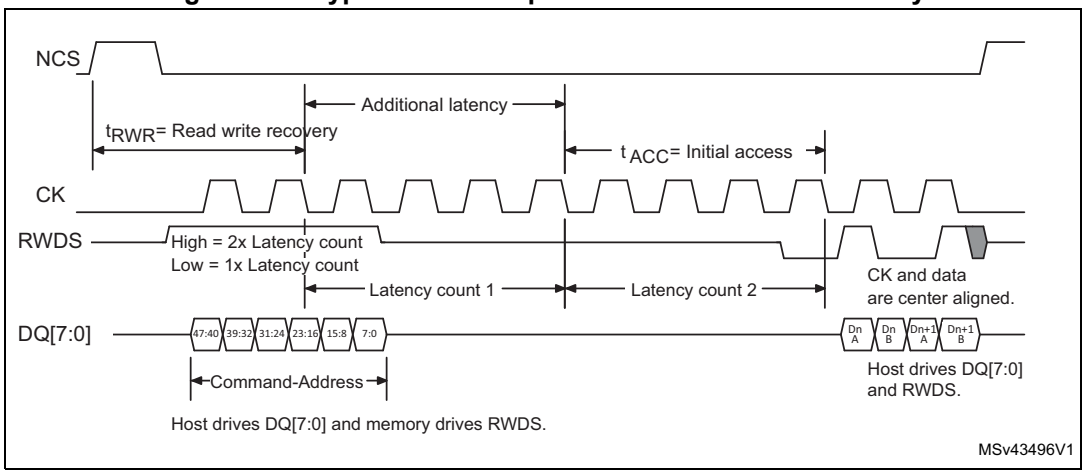


Fixed-latency mode

Some devices or some applications may not want to operate with a variable latency time as described above.

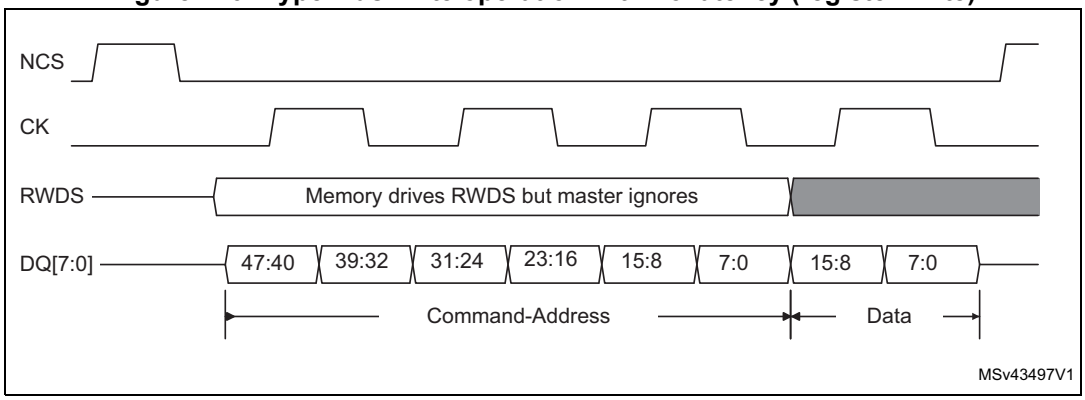
The latency can be forced to 2 x t_{ACC} by setting LM in OCTOSPI_HLCR.

In this OCTOSPI latency mode, the state of the RWDS signal is not taken into account by the OCTOSPI, and an additional latency is always added, leading to a fixed 2 x t_{ACC} latency time.

Write operation with no latency

Some devices can also require a zero latency for the write operations. This write-zero latency can be forced by setting WZL in OCTOSPI_HLCR.

Figure 146. HyperBus write operation with no latency (register write)

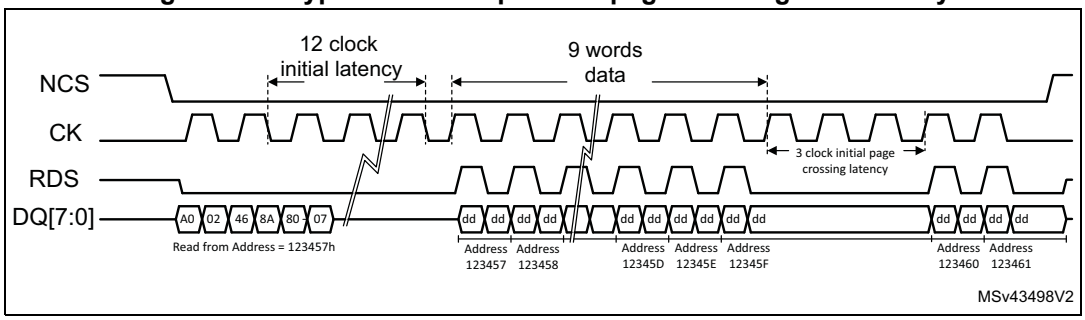


Latency on page-crossing during the read operations

An additional latency can be needed by some devices for the read operation when crossing pages.

The initial latency must be respected for any page access, as a consequence, when the first access is close to the page boundary, a latency is automatically added at the page crossing to respect the t_{ACC} time.

Figure 147. HyperBus read operation page crossing with latency



23.4.7 Specific features

The OCTOSPI supports some specific features, such as:

- Wrap support
- NCS boundary and refresh

Wrap support

The OCTOSPI supports a hybrid wrap as defined by the HyperBus protocol. A hybrid wrap is also supported in the regular-command protocol.

In hybrid wrap, the transaction can continue after the initial wrap with an incremental access.

The wrap size supported by the target memory is configured by WRAPSIZE in OCTOSPI_DCR2.

Wrap is supported only in memory-read direction and only for data size = 4 bytes. Wrapped reads are supported for both HyperBus and regular-command protocols. To enable wrapped-read accesses, the dedicated OCTOSPI_WPxxx registers must be programmed according to the wrapped-read access characteristics. These registers apply for both HyperBus and regular-command protocols.

If the target memory is not supporting the hybrid wrap, WRAPSIZE must be set to 0.

Note: The wrap operation cannot be interrupted by a refresh. The refresh event is only considered after the wrap completion.

NCS boundary and refresh

Two processes can be activated to regulate the OCTOSPI transactions:

- NCS boundary
- Refresh

The NCS boundary feature limits a transaction to a boundary of aligned addresses. The size of the address to be aligned with, is configured by CSBOUND[4:0] in OCTOSPI_DCR3: it is equal to $2^{CSBOUND}$.

As an example, if CSBOUND(4:0] = 0x4, the boundary is set to 2^4 = 16 bytes. The NCS is then released each time the LSB address is equal to 0xF, and each time a new transaction is issued to address the next data.

If CSBOUND[4:0] = 0, the feature is disabled. A minimum value of three is recommended.

The NCS boundary feature cannot be used for flash memory devices in write mode since a command is necessary to program another page of the flash memory.

The refresh feature limits the duration of the transactions to the value programmed by REFRESH[31:0] in OCTOSPI_DCR4. The duration is expressed in number of cycles. This allows an external RAM to perform its internal refresh operation regularly.

The refresh value must be greater than the minimal transaction size in terms of number of cycles including the command/address/alternate/dummy phases.

If NCS boundary and refresh are enabled at the same time, the NCS is released on the first condition met.

Restarting after an interrupted transfer

When a read or write operation is interrupted by a timeout or communication regulation feature, the Octo-SPI interface, as soon as possible after getting back the port ownership, reissues the initial command sequence together with the address following the last address actually accessed before interruption. The transfer initially set goes on and ends seamlessly.

23.4.8 OCTOSPI operating mode introduction

The OCTOSPI has the following operating modes regardless of the low-level protocol used (either regular-command or HyperBus):

- indirect mode (read or write)
- automatic status-polling mode (only in regular-command protocol)
- memory-mapped mode

23.4.9 OCTOSPI indirect mode

In indirect mode, the commands are started by writing to the OCTOSPI registers, and data are transferred by writing or reading the data register, in a similar way to other communication peripherals.

When FMODE[1:0] = 00 in OCTOSPI_CR, the OCTOSPI is in indirect-write mode: bytes are sent to the external device during the data phase. Data are provided by writing to OCTOSPI_DR.

When FMODE[1:0] = 01, the OCTOSPI is in indirect-read mode: bytes are received from the external device during the data phase. Data are recovered by reading OCTOSPI_DR.

In indirect mode, when the OCTOSPI is configured in DTR mode over eight lanes with DQS disabled, the given starting address and the data length must be even.

Note: The OCTOSPI_AR register must be updated even if the start address is the same as the start address of the previous indirect access.

The number of bytes to be read/written is specified in OCTOSPI_DLR:

- If DL[31:0] = 0xFFFF FFFF, the data length is considered undefined and the OCTOSPI simply continues to transfer data until it reaches the end of the external device (as defined by DEVSIZE). If no bytes are to be transferred, DMODE[2:0] must be set to 0 in OCTOSPI_CCR.
- If DL[31:0] = 0xFFFF FFFFF and DEVSIZE[4:0] = 0x1F (its maximum value indicating at 4-Gbyte device), the transfers continue indefinitely, stopping only after an abort

request or after the OCTOSPI is disabled. After the last memory address is read (at address 0xFFFF FFFF), reading continues with address = 0x0000 0000.

When the programmed number of bytes to be transmitted or received is reached, the TCF bit is set in OCTOSPI_SR, and an interrupt is generated if TCIE = 1 in OCTOSPI_CR. In the case of an undefined number of data, TCF is set when the limit of the external SPI memory is reached, according to the device size defined in OCTOSPI_DCR1.

Triggering the start of a transfer in regular-command protocol

Depending on the OCTOSPI configuration, there are three different ways to trigger the start of a transfer in indirect mode when using the regular-command protocol. In general, the start of transfer is triggered as soon as the software gives the last information that is necessary for the command. More specifically in indirect mode, a transfer starts when one of the following sequence of events occurs:

- if no address is necessary (ADMODE[2:0] = 000) and if no data need to be provided by the software (FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to INSTRUCTION[31:0] in OCTOSPI_IR
- if an address is necessary (when ADMODE[2:0] ≠ 000) and if no data need to be provided by the software (when FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to ADDRESS[31:0] in OCTOSPI_AR
- if data need to be provided by the software (when FMODE[1:0] = 00 and DMODE[2:0] ≠ 000), and at the moment when a write is performed to DATA[31:0] in OCTOSPI_DR

A write to OCTOSPI_ABR never triggers the communication start. If alternate bytes are required, they must have been programmed before.

As soon as a command is started, the BUSY bit is automatically set in OCTOSPI_SR.

Triggering the start of a transfer in HyperBus protocol

Depending on the OCTOSPI configuration, there are different ways to trigger the start of a command in indirect mode. In general, it is triggered as soon as the firmware gives the last information that is necessary for the transfer to start, and more specifically, a communication in indirect mode is triggered by one of the following register settings, when it is the last one to be executed:

- when a write is performed to ADDRESS[31:0] (OCTOSPI_AR) with ADMODE[2:0] ≠ 000 in indirect read mode (FMODE[1:0] = 01).
- when a write is performed to DATA[31:0] (OCTOSPI_DR) in indirect-write mode (when FMODE = 00).
- when a (dummy) write is performed to INSTRUCTION[31:0] (OCTOSPI_IR) for indirect read mode (with ADMODE[2:0] = 000 and FMODE = 01).

As soon as a transfer is started, the BUSY bit (OCTOSPI_SR[5]) is automatically set.

FIFO and data management

Data in indirect mode passes through a 32-byte FIFO that is internal to the OCTOSPI. FLEVEL in OCTOSPI_SR indicates how many bytes are currently being held in the FIFO.

AHB burst transactions are supported. Data of the burst are successively written in OCTOSPI_DR, and immediately transferred in the internal FIFO.

In indirect-write mode (FMODE[1:0] = 00), the software adds data to the FIFO when it writes in OCTOSPI_DR. A word write adds 4 bytes to the FIFO, a half-word write adds 2 bytes, and a byte write adds only 1 byte. If the software adds too many bytes to the FIFO (more than indicated in DL[31:0]), the extra bytes are flushed from the FIFO at the end of the write operation (when TCF is set).

The byte/half-word accesses to OCTOSPI_DR must be done only to the least significant byte/halfword of the 32-bit register.

FTHRES is used to define a FIFO threshold after which point the FIFO threshold flag, FTF, gets set. In indirect-read mode, FTF is set when the number of valid bytes to be read from the FIFO is above the threshold. FTF is also set if there is any data left in the FIFO after the last byte is read from the external device, regardless of FTHRES setting. In indirect-write mode, the FTF is set when the number of empty bytes in the FIFO is above the threshold.

If FTIE = 1, there is an interrupt when the FTF is set. If DMAEN = 1, a DMA transfer is initiated when the FTF is set. The FTF is cleared by hardware as soon as the threshold condition is no longer true (after enough data has been transferred by the CPU or DMA).

The last data read in RX FIFO remains valid as long as there is no request for the next line. This means that, when the application reads several times in a row at the same location, the data is provided from the RX FIFO and not read again from the distant memory.

23.4.10 OCTOSPI automatic status-polling mode

In automatic status-polling mode, the OCTOSPI periodically starts a command to read a defined number of status bytes (up to four). The received bytes can be masked to isolate some status bits and an interrupt can be generated when the selected bits have a defined value. The automatic status-polling mode must be used only in regular-command protocol. For HyperBus protocol, it is not exploitable since the read status register into the HyperFlash memory must be performed in two steps (a write operation followed by a read operation).

The access to the device begins in the same manner as in indirect-read mode. BUSY in OCTOSPI_SR goes high at this point and stays high even between the periodic accesses.

The content of MASK[31:0] in OCTOSPI_PSMAR is used to mask the data from the external device in automatic status-polling mode:

- If the MASK[n] = 0, then bit n of the result is masked and not considered.
- If MASK[n] = 1, and the content of bit[n] is the same as MATCH[n] in OCTOSPI_PSMAR, then there is a match for bit n.

If PMM = 0 in OCTOSPI_CR, the AND-match mode is activated: SMF is set in OCTOSPI_SR only when there is a match on all of the unmasked bits.

If PMM = 1 in OCTOSPI_CR, the OR-match mode is activated: SMF gets set if there is a match on any of the unmasked bits.

An interrupt is called when SMF = 1 if SMIE = 1.

If APMS is set in OCTOSPI_CR, the operation stops and BUSY goes to 0 as soon as a match is detected. Otherwise, BUSY stays at 1 and the periodic accesses continue until there is an abort or until the OCTOSPI is disabled (EN = 0).

OCTOSPI_DR contains the latest received status bytes (FIFO deactivated). The content of this register is not affected by the masking used in the matching logic. FTF in OCTOSPI_SR

is set as soon as a new reading of the status is complete. FTF is cleared as soon as the data is read.

In automatic status-polling mode, variable latency is not supported. The memory must then be configured in fixed latency.

23.4.11 OCTOSPI memory-mapped mode

When configured in memory-mapped mode, the external SPI device is seen as an internal memory.

Note: No more than 256 Mbytes can be addressed even if the external device capacity is larger.

If an access is made to an address outside of the range defined by DEVSIZE[4:0] but still within the 256 Mbytes range, then an AHB error is given. The effect of this error depends on the AHB master that attempted the access:

- If it is the Cortex CPU, a hard-fault interrupt is generated.
- If it is a DMA, a DMA transfer error is generated, and the corresponding DMA channel is automatically disabled.

Byte, half-word, and word access types are all supported.

A support for execute in place (XIP) operation is implemented, where the OCTOSPI continues to load the bytes to the addresses following the most recent access. If subsequent accesses are continuous to the bytes that follow, then these operations end up quickly since their results were prefetched.

By default, the OCTOSPI never stops its prefetch operation. It either keeps the previous read operation active with the NCS maintained low or it relaunches a new transfer, even if no access to the external device occurs for a long time.

Since external devices tend to consume more when the NCS is held low, the application may want to activate the timeout counter (TCEN = 1 in OCTOSPI_CR): the NCS is released after a period defined by TIMEOUT[15:0] in OCTOSPI_LPTR, when x cycles have elapsed without access since the clock is inactive.

BUSY goes high as soon as the first memory-mapped access occurs. Because of the prefetch operations, BUSY does not fall until there is an abort, or the peripheral is disabled.

It is not recommended to program the flash memory using the memory-mapped writes: the indirect-write mode fulfills this operation.

23.4.12 OCTOSPI configuration introduction

The OCTOSPI configuration is done in three steps:

1. OCTOSPI system configuration
2. OCTOSPI device configuration
3. OCTOSPI mode configuration

23.4.13 OCTOSPI system configuration

The OCTOSPI is configured using OCTOSPI_CR. The user must program:

- the functional mode with FMODE[1:0]
- the automatic status-polling mode behavior if needed with PMM and APMS
- the FIFO level with FTHRES

- the DMA use with DMAEN
- the timeout counter use with TCEN
- the dual-memory configuration, if needed, with DMM

In case of an interrupt use, the respective enable bit can also be set during this phase.

If the timeout counter is used, the timeout value is programmed in OCTOSPI_LPTR.

The DMA channel must not be enabled during the OCTOSPI configuration: it must be enabled only when the operation is fully configured, to avoid any unexpected request generation.

The DMA and OCTOSPI must be configured in a coherent manner regarding data length: FTHRES value must reflect the DMA burst size.

23.4.14 OCTOSPI device configuration

The parameters related to the external device targeted are configured through OCTOSPI_DCR1 and OCTOSPI_DCR2.The user must program:

- the device size with DEVSIZE[4:0]
- the chip-select minimum high time with CSHT[5:0]
- the clock mode with FRCK and CKMODE
- the device frequency with PRESCALER[7:0]

MTYP[2:0] defines the memory type to be used for 8-line modes:

- Micron mode with D0/D1 ordering in 8-data-bit mode (DMODE[2:0] = 100)
- Macronix mode with D1/D0 ordering in 8-data-bit mode (DMODE[2:0] = 100). MTYP[2:0] = 001 targets Octaflash memory whereas MTYP[2:0] = 011 addresses OctaRAM™ memory having specific address phase (address is built with row and column to fit with Macronix requirements).
- HyperBus memory mode: the protocol follows the HyperBus specification.
- HyperBus register mode, addressing register space: the memory-mapped accesses in this mode must be noncacheable, or the indirect-read/write modes must be used.

DEVSIZE[4:0] defines the size of external memory using the following formula:

$$\text{Number of bytes in the device} = 2^{\text{DEVSIZE+1}}$$

where DEVSIZE+1 is the number of address bits required to address the external device. The external device capacity can go up to 4 Gbytes (addressed using 32 bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256 Mbytes.

If DMM = 1, DEVSIZE[4:0] indicates the total capacity of the two devices together.

When the OCTOSPI executes two commands, one immediately after the other, it raises the chip-select signal (NCS) high between the two commands for only one CLK cycle by default.

If the external device requires more time between commands, the chip-select high time CSHT[5:0] can be used to specify the minimum number of CLK cycles for which the NCS must remain high.

CKMODE indicates the level that the CLK takes between commands (when NCS = 1).

In HyperBus protocol, the device timing (t_{ACC} and t_{RWR}) and the latency mode must be configured in OCTOSPI_HLCR.

23.4.15 OCTOSPI regular-command mode configuration

Indirect mode configuration

When FMODE[1:0] = 00, the indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the indirect-read mode is selected, and data can be read from the external device.

When the OCTOSPI is used in indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in OCTOSPI_DLR.
2. Specify the frame timing in OCTOSPI_TCR.
3. Specify the frame format in OCTOSPI_CCR.
4. Specify the instruction in OCTOSPI_IR.
5. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_ABR.
6. Specify the targeted address in OCTOSPI_AR.
7. Enable the DMA channel if needed.
8. Read/write the data from/to the FIFO through OCTOSPI_DR (if no DMA usage).

If neither the address register (OCTOSPI_AR) nor the data register (OCTOSPI_DR) need to be updated for a particular command, then the command sequence starts as soon as OCTOSPI_IR is written. This is the case when both ADMODE[2:0] and DMODE[2:0] equal 000, or if just ADMODE[2:0] = 000 when in indirect-read mode (FMODE[1:0] = 01).

When an address is required (ADMODE[2:0] ≠ 000) and the data register does not need to be written (FMODE[1:0] = 01 or DMODE[2:0] = 000), the command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.

In case of data transmission (FMODE[1:0] = 00 and DMODE[2:0] ≠ 000), the communication start is triggered by a write in the FIFO through OCTOSPI_DR.

Automatic status-polling mode configuration

The automatic status-polling mode is enabled by setting FMODE[1:0] = 10. In this mode, the programmed frame is sent and data are retrieved periodically.

The maximum amount of data read in each frame is 4 bytes. If more data is requested in OCTOSPI_DLR, it is ignored, and only 4 bytes are read. The periodicity is specified in OCTOSPI_PIR.

Once the status data has been retrieved, the following can be processed:

- Set SMF (an interrupt is generated if enabled).
- Stop automatically the periodic retrieving of the status bytes.

The received value can be masked with the value stored in OCTOSPI_PSMKR, and can be ORed or ANDed with the value stored in OCTOSPI_PSMAR.

In case of a match, SMF is set and an interrupt is generated if enabled. The OCTOSPI can be automatically stopped if AMPS is set. In any case, the latest retrieved value is available in OCTOSPI_DR.

When the OCTOSPI is used in automatic status-polling mode, the frames are constructed in the following way:

1. Specify the input mask in OCTOSPI_PSMKR.

2. Specify the comparison value in OCTOSPI_PSMAR.
3. Specify the read period in OCTOSPI_PIR.
4. Specify a number of data bytes to read in OCTOSPI_DLR.
5. Specify the frame timing in OCTOSPI_TCR.
6. Specify the frame format in OCTOSPI_CCR.
7. Specify the instruction in OCTOSPI_IR.
8. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_ABR.
9. Specify the optional targeted address in OCTOSPI_AR.

If the address register (OCTOSPI_AR) does not need to be updated for a particular command, then the command sequence starts as soon as OCTOSPI_CCR is written. This is the case when ADMODE[2:0] = 000.

When an address is required (ADMODE[2:0] ≠ 000), the command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.

Memory-mapped mode configuration

In memory-mapped mode, the external device is seen as an internal memory but with some latency during accesses. Read and write operations are allowed to the external device in this mode.

It is not recommended to program the flash memory using memory-mapped writes, as the internal flags for erase or programming status have to be polled. The indirect-write mode fulfills this operation, possibly in conjunction with the automatic status-polling mode.

The memory-mapped mode is entered by setting FMODE[1:0] = 11 in OCTOSPI_CR.

The programmed instruction and frame are sent when an AHB master accesses the memory-mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to OCTOSPI_DR in this mode returns zero.

The data length register (OCTOSPI_DLR) has no meaning in memory-mapped mode.

When the OCTOSPI is used in memory-mapped mode, the frames are constructed in the following way:

1. Specify the frame timing in OCTOSPI_TCR for read operation.
2. Specify the frame format in OCTOSPI_CCR for read operation.
3. Specify the instruction in OCTOSPI_IR.
4. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_ABR for read operation.
5. Specify the frame timing in OCTOSPI_WTCR for write operation.
6. Specify the frame format in OCTOSPI_WCCR for write operation.
7. Specify the instruction in OCTOSPI_WIR.
8. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_WABR for write operation.

All configuration operations must be completed (ensured by checking BUSY = 0) before the first access to the memory area: any register write operation when BUSY = 1 has no effect and is not signaled with an error response. On the first access, the OCTOSPI becomes

busy, and no further configuration is allowed. Then, the only way to get BUSY low is to clear the ENABLE bit or to abort by setting the ABORT bit.

OCTOSPI delayed data sampling when no DQS is used

By default, when no DQS is used, the OCTOSPI samples the data driven by the external device one half of a CLK cycle after the external device drives the signal.

In case of any external signal delays, it may be useful to sample the data later. Using SSHIFT in OCTOSPI_TCR, the sampling of the data can be shifted by half of a CLK cycle.

The firmware must clear SSHIFT when the data phase is configured in DTR mode (DDTR = 1).

OCTOSPI delayed data sampling when DQS is used

When external DQS is used as a sampling clock, it can be shifted in time to compensate the data propagation delay. This shift is performed by an external delay block located outside the OCTOSPI. The control of this feature depends on the device implementation (see the product reference manual for more details).

In configurations where delay does not need to be compensated, the external delay block can be bypassed by setting DLYBYP in OCTOSPI_DCR1.

23.4.16 OCTOSPI HyperBus protocol configuration

Indirect mode configuration (HyperBus)

When FMODE[1:0] = 00, the indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the indirect-read mode is selected where data can be read from the external device. ADMODE must be configured with a value different from 000 (for instance ADMODE = 100).

When the OCTOSPI is used in indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in OCTOSPI_DLR.
2. Specify the targeted address in OCTOSPI_AR.
3. Enable the DMA channel if needed.
4. Read/write the data from/to the FIFO through OCTOSPI_DR (if no DMA usage).

In indirect-read mode, the command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.

In indirect-write mode, the communication start is triggered by a write in the FIFO through OCTOSPI_DR.

Memory-mapped mode configuration (HyperBus)

In memory-mapped mode, the external device is seen as an internal memory but with some latency during the accesses. Read and write operations are allowed to the external device in this mode.

It is not recommended to program the flash memory using the memory-mapped writes: the indirect-write mode fulfills this operation.

The memory-mapped mode is entered by setting FMODE[1:0] = 11. The programmed instruction and frame is sent when an AHB master accesses the memory-mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to OCTOSPI_DR in this mode returns zero.

The data length register (OCTOSPI_DLR) has no meaning in memory-mapped mode.

All the configuration operation must be completed before the first access to the memory area. On the first access, the OCTOSPI becomes busy, and no configuration is allowed. Then, the only way to get BUSY low is to clear the ENABLE bit, or to abort by setting the ABORT bit.

23.4.17 OCTOSPI error management

An error can be generated in the following cases:

- in indirect or automatic status-polling mode, when a wrong address has been programmed in OCTOSPI_AR (according to the device size defined by DEVSIZE[4:0]): this sets TEF and an interrupt is generated if enabled.
- in indirect mode, if the address plus the data length exceed the device size: TEF is set as soon as the access is triggered.
- in memory-mapped mode when an out-of-range access is done by an AHB master: this generates an AHB error as a response to the faulty AHB request.
- when the memory-mapped mode is disabled: an access to the memory-mapped area generates an AHB error as a response to the faulty AHB request.

The OCTOSPI generates an AHB slave error in the following situations:

- The memory-mapped mode is disabled and an AHB read request occurs.
- A read or write address exceeds the size of the external memory.
- An abort is received while a read or write burst is ongoing.
- The OCTOSPI is disabled while a read or write burst is ongoing.
- A write wrap burst is received.
- A write request is received while DQSE = 0 in OCTOSPI_WCCR in octal DTR mode or in dual-memory configuration.
- Write request is received while DMODE[2:0] = 000 (no data phase), except when MTYP[2:0] is HyperBus.
- Illegal access size when wrap read burst. This means that the HSIZE is different from 4 bytes (only for memory-mapped mode).
- Illegal wrap size when receiving read wrap burst with size different from 4 bytes (only for memory-mapped mode).

23.4.18 OCTOSPI BUSY and ABORT

Once the OCTOSPI starts an operation with the external device, BUSY is automatically set in OCTOSPI_SR.

In indirect mode, BUSY is reset once the OCTOSPI has completed the requested command sequence and the FIFO is empty.

In automatic status-polling mode, BUSY goes low only after the last periodic access is complete, due to a match when APMS = 1 or due to an abort.

After the first access in memory-mapped mode, BUSY goes low only on an abort.

Any operation can be aborted by setting ABORT in OCTOSPI_CR. Once the abort is completed, BUSY and ABORT are automatically reset, and the FIFO is flushed.

Before setting ABORT, the software must ensure that all the current transactions are finished using the synchronization barriers. When DMA is enabled to handle the data read or write operations in OCTOSPI_DR, it is recommended to disable the DMA channel before aborting the OCTOSPI.

Note: Some devices may misbehave if a write operation to a status register is aborted.

23.4.19 OCTOSPI reconfiguration or deactivation

Before any OCTOSPI reconfiguration, the software must ensure that all the transactions are completed:

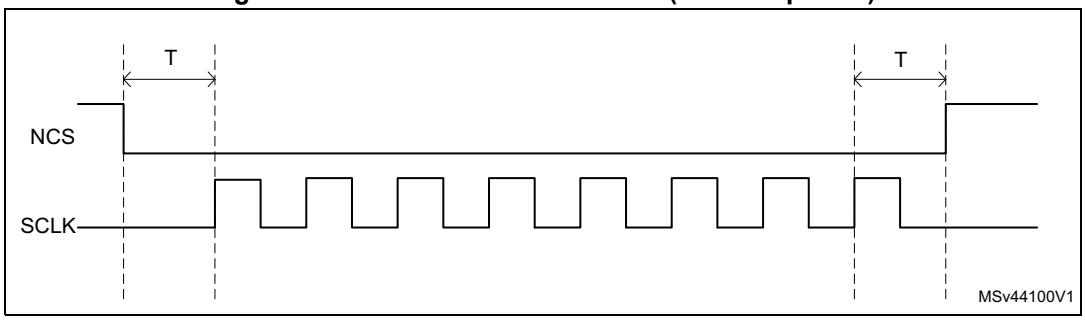
- After a memory-mapped write, the software must perform a dummy read followed by a synchronization barrier, then an abort.
- After a memory-mapped read, the software must perform a synchronization barrier than an abort.

23.4.20 NCS behavior

By default, NCS is high, deselecting the external device. NCS falls before an operation begins and rises as soon as it finishes.

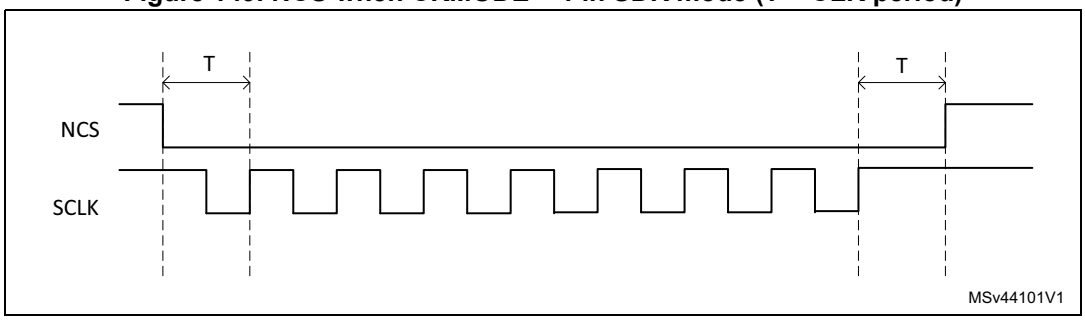
When CKMODE = 0 (clock mode 0: CLK stays low when no operation is in progress), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge (see the figure below).

Figure 148. NCS when CKMODE = 0 (T = CLK period)



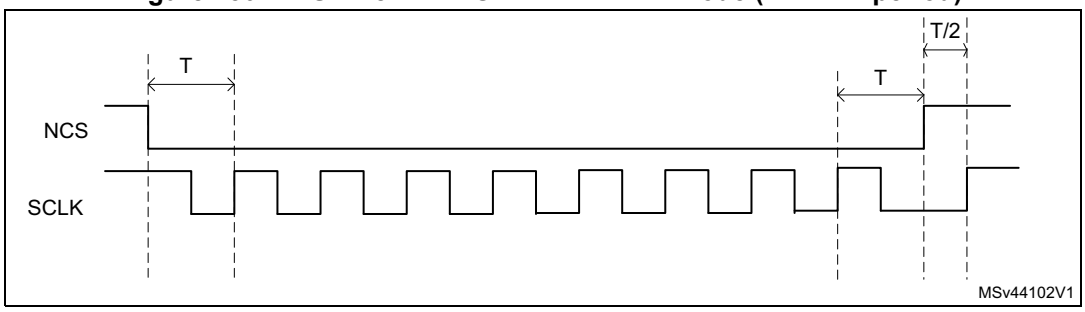
When CKMODE = 1 (clock mode 3: CLK goes high when no operation is in progress) and when in SDR mode, NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge (see the figure below).

Figure 149. NCS when CKMODE = 1 in SDR mode (T = CLK period)



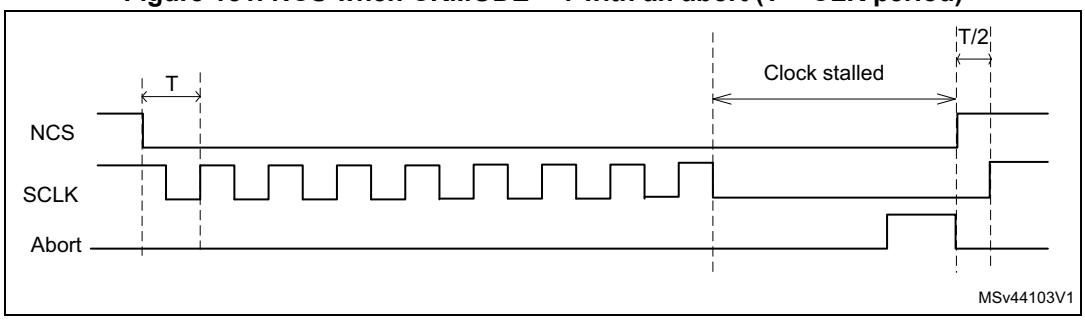
When the CKMODE = 1 (clock mode 3) and DDTR = 1 (data DTR mode), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final active rising CLK edge (see the figure below). Because the DTR operations must finish with a falling edge, CLK is low when NCS rises, and CLK rises back up one half of a CLK cycle afterwards.

Figure 150. NCS when CKMODE = 1 in DTR mode (T = CLK period)



When the FIFO stays full during a read operation, or if the FIFO stays empty during a write operation, the operation stalls and CLK stays low until the software services the FIFO. If an abort occurs when an operation is stalled, NCS rises just after the abort is requested and then CLK rises one half of a CLK cycle later (see the figure below).

Figure 151. NCS when CKMODE = 1 with an abort (T = CLK period)



23.5 Address alignment and data number

The table below summarizes the effect of the address alignment and programmed data number depending on the use case.

Table 207. Address alignment cases

Memory type	Transaction type	Constraint on address(1)	Impact if constraint on address not respected	Constraint on number of bytes(1)	Impact if constraint on bytes not respected
Single, dual, quad flash or SRAM (DMM = 0)	IND(2) read	None	None	None	None
	MM(3) read				
	IND write				
	MM write				

Table 207. Address alignment cases (continued)

Memory type	Transaction type	Constraint on address(1)	Impact if constraint on address not respected	Constraint on number of bytes(1)	Impact if constraint on bytes not respected
Single, dual, quad flash or SRAM (DMM = 1)	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM write	Even	Slave error	Even	Last byte is lost.
Octal flash in SDR mode	IND read	None	None	None	None
	MM read				
	IND write				
	MM write				
Octal memory in DTR mode without WDM(6)	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM write	Even	Slave error	Even	Last byte is lost.
Octal flash or RAM in DTR mode with WDM	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write				
	MM write				
HyperBus	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write				
	MM write				

1. To be respected by the software.
2. IND = indirect mode.
3. MM = memory-mapped mode
4. Extra data at transfer start.
5. Extra data at transfer end.
6. WDM = write data mask.

23.6 OCTOSPI interrupts

An interrupt can be produced on the following events:

- Timeout
- Status match
- FIFO threshold
- Transfer complete
- Transfer error

Separate interrupt enable bits are available to provide more flexibility.

Table 208. OCTOSPI interrupt requests

Interrupt event	Event flag	Enable control bit
Timeout	TOF	TOIE
Status match	SMF	SMIE
FIFO threshold	FTF	FTIE
Transfer complete	TCF	TCIE
Transfer error	TEF	TEIE

23.7 OCTOSPI registers

23.7.1 OCTOSPI control register (OCTOSPI_CR)

Address offset: 0x0000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	FMODE[1:0]		Res.	Res.	Res.	Res.	PMM	APMS	Res.	TOIE	SMIE	FTIE	TCIE	TEIE
		rw	rw					rw	rw		rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	FTHRES[4:0]					MSEL	DMM	Res.	Res.	TCEN	DMAEN	ABORT	EN
			rw	rw	rw	rw	rw	rw	rw			rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **FMODE[1:0]**: Functional mode

This bitfield defines the OCTOSPI functional mode of operation.

00: Indirect-write mode

01: Indirect-read mode

10: Automatic status-polling mode (relevant in regular-command protocol only)

11: Memory-mapped mode

If DMAEN = 1 already, then the DMA controller for the corresponding channel must be disabled before changing the FMODE[1:0] value. If FMODE[1:0] and FTHRES[4:0] are wrongly updated while DMAEN = 1, the DMA request signal automatically goes to inactive state.

Note: This bitfield can be modified only when BUSY = 0.

Bits 27:24 Reserved, must be kept at reset value.

Bit 23 **PMM**: Polling match mode

This bit indicates which method must be used to determine a match during the automatic status-polling mode.

0: AND-match mode, SMF is set if all the unmasked bits received from the device match the corresponding bits in the match register.

1: OR-match mode, SMF is set if any of the unmasked bits received from the device matches its corresponding bit in the match register.

Note: This bit can be modified only when BUSY = 0.

Bit 22 **APMS**: Automatic status-polling mode stop
This bit determines if the automatic status-polling mode is stopped after a match.
0: Automatic status-polling mode is stopped only by abort or by disabling the OCTOSPI.
1: Automatic status-polling mode stops as soon as there is a match.
Note: This bit can be modified only when BUSY = 0.

Bit 21 Reserved, must be kept at reset value.

Bit 20 **TOIE**: Timeout interrupt enable
This bit enables the timeout interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 19 **SMIE**: Status-match interrupt enable
This bit enables the status-match interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 18 **FTIE**: FIFO threshold interrupt enable
This bit enables the FIFO threshold interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 17 **TCIE**: Transfer complete interrupt enable
This bit enables the transfer complete interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 16 **TEIE**: Transfer error interrupt enable
This bit enables the transfer error interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **FTHRES[4:0]**: FIFO threshold level
This bitfield defines, in indirect mode, the threshold number of bytes in the FIFO that causes the FIFO threshold flag FTF in OCTOSPI_SR, to be set.
00000: FTF is set if there are one or more free bytes available to be written to in the FIFO in indirect-write mode, or if there are one or more valid bytes can be read from the FIFO in indirect-read mode.
00001: FTF is set if there are two or more free bytes available to be written to in the FIFO in indirect-write mode, or if there are two or more valid bytes can be read from the FIFO in indirect-read mode.
...
11111: FTF is set if there are 32 free bytes available to be written to in the FIFO in indirect-write mode, or if there are 32 valid bytes can be read from the FIFO in indirect-read mode.
Note: If DMAEN = 1, the DMA controller for the corresponding channel must be disabled before changing the FTHRES[4:0] value.

Bit 7 **MSEL**: External memory select
This bit selects the external memory to be addressed in single-, dual-, quad-SPI mode in single-memory configuration (when DMM = 0).
0: External memory 1 selected (data exchanged over IO[3:0])
1: External memory 2 selected (data exchanged over IO[7:4])
This bit is ignored when DMM = 1 or when octal-SPI mode is selected.

Bit 6 **DMM**: Dual-memory configuration

This bit activates the dual-memory configuration, where two external devices are used simultaneously to double the throughput and the capacity

0: Dual-memory configuration disabled

1: Dual-memory configuration enabled

Note: This bit can be modified only when BUSY = 0.

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **TCEN**: Timeout counter enable

This bit is valid only when the memory-mapped mode (FMODE[1:0] = 11) is selected. This bit enables the timeout counter.

0: The timeout counter is disabled, and thus the chip-select (NCS) remains active indefinitely after an access in memory-mapped mode.

1: The timeout counter is enabled, and thus the chip-select is released in the memory-mapped mode after TIMEOUT[15:0] cycles of external device inactivity.

Note: This bit can be modified only when BUSY = 0.

Bit 2 **DMAEN**: DMA enable

In indirect mode, the DMA can be used to input or output data via OCTOSPI_DR. DMA transfers are initiated when FTF is set.

0: DMA disabled for indirect mode

1: DMA enabled for indirect mode

Note: Resetting the DMAEN bit while a DMA transfer is ongoing, breaks the handshake with the DMA. Do not write this bit during DMA operation.

Bit 1 **ABORT**: Abort request

This bit aborts the ongoing command sequence. It is automatically reset once the abort is completed. This bit stops the current transfer.

0: No abort requested

1: Abort requested

Note: This bit is always read as 0.

Bit 0 **EN**: Enable

This bit enables the OCTOSPI.

0: OCTOSPI disabled

1: OCTOSPI enabled

Note: The DMA request can be aborted without having received the ACK in case this EN bit is cleared during the operation.
In case this bit is set to 0 during a DMA transfer, the REQ signal to DMA returns to inactive state without waiting for the ACK signal from DMA to be active.

23.7.2 OCTOSPI device configuration register 1 (OCTOSPI_DCR1)

Address offset: 0x0008

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	MTYP[2:0]			Res.	Res.	Res.	DEVSIZE[4:0]				
					rw	rw	rw				rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	CSHT[5:0]						Res.	Res.	Res.	Res.	DLY BYP	Res.	FRCK	CKMODE
		rw	rw	rw	rw	rw	rw					rw		rw	rw

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:24 **MTYP[2:0]**: Memory type

This bitfield indicates the type of memory to be supported.

000: Micron mode, D0/D1 ordering in DTR 8-data-bit mode. regular-command protocol in single-, dual-, quad- and octal-SPI modes.

Note: In this mode, DQS signal polarity is inverted with respect to the memory clock signal. This is the default value and care must be taken to change MTYP[2:0] for memories different from Micron.

001: Macronix mode, D1/D0 ordering in DTR 8-data-bit mode. regular-command protocol in single-, dual-, quad- and octal-SPI modes.

010: Standard mode

011: Macronix RAM mode, D1/D0 ordering in DTR 8-data-bit mode. regular-command protocol in single-, dual-, quad- and octal-SPI modes with dedicated address mapping.

100: HyperBus memory mode, the protocol follows the HyperBus specification.

101: HyperBus register mode, addressing register space. The memory-mapped accesses in this mode must be non-cacheable, or indirect-read/write modes must be used.

Others: Reserved

Bits 23:21 Reserved, must be kept at reset value.

Bits 20:16 **DEVSIZE[4:0]**: Device size

This bitfield defines the size of the external device using the following formula:
Number of bytes in device = $2^{[DEVSIZE+1]}$.

DEVSIZE + 1 is effectively the number of address bits required to address the external device. The device capacity can be up to 4 Gbytes (addressed using 32-bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256 Mbytes.

In regular-command protocol, if DMM = 1, DEVSIZE[4:0] indicates the capacity of one of the two external devices.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **CSHT[5:0]**: Chip-select high time

CSHT + 1 defines the minimum number of CLK cycles where the chip-select (NCS) must remain high between commands issued to the external device.

0x0: NCS stays high for at least 1 cycle between external device commands.

0x1: NCS stays high for at least 2 cycles between external device commands.

...

0x3F: NCS stays high for at least 64 cycles between external device commands.

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **DLYBYP**: Delay block bypass

0: The internal sampling clock (called feedback clock) or the DQS data strobe external signal is delayed by the delay block (for more details on this block, refer to the dedicated section of the reference manual as it is not part of the OCTOSPI peripheral).

1: The delay block is bypassed, so the internal sampling clock or the DQS data strobe external signal is not affected by the delay block. The delay is shorter than when the delay block is not bypassed, even with the delay value set to minimum value in delay block.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **FRCK**: Free running clock

This bit configures the free running clock.

0: CLK is not free running.

1: CLK is free running (always provided).

Note: Free running clock mode is intended for delay calibration only. No memory or other device access is possible when FRCK is set.

Bit 0 **CKMODE**: Clock mode 0/mode 3

This bit indicates the level taken by the CLK between commands (when NCS = 1).

0: CLK must stay low while NCS is high (chip-select released). This is referred to as clock mode 0.

1: CLK must stay high while NCS is high (chip-select released). This is referred to as clock mode 3.

23.7.3 OCTOSPI device configuration register 2 (OCTOSPI_DCR2)

Address offset: 0x000C

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRAPSIZE[2:0]		
													rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRESCALER[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **WRAPSIZE[2:0]**: Wrap size

This bitfield indicates the wrap size to which the memory is configured. For memories which have a separate command for wrapped instructions, this bitfield indicates the wrap-size associated with the command held in the OCTOSPI1_WPIR register.

000: Wrapped reads are not supported by the memory.

010: External memory supports wrap size of 16 bytes.

011: External memory supports wrap size of 32 bytes.

100: External memory supports wrap size of 64 bytes.

101: External memory supports wrap size of 128 bytes.

Others: Reserved

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **PRESCALER[7:0]**: Clock prescaler

This bitfield defines the scaler factor for generating the CLK based on the kernel clock (value + 1).

0: $F_{CLK} = F_{KERNEL}$, kernel clock used directly as OCTOSPI CLK (prescaler bypassed). In this case, if the DTR mode is used, it is mandatory to provide to the OCTOSPI a kernel clock that has 50% duty-cycle.

1: $F_{CLK} = F_{KERNEL}/2$

2: $F_{CLK} = F_{KERNEL}/3$

...

255: $F_{CLK} = F_{KERNEL}/256$

For odd clock division factors, the CLK duty cycle is not 50 %. The clock signal remains low one cycle longer than it stays high.

23.7.4 OCTOSPI device configuration register 3 (OCTOSPI_DCR3)

Address offset: 0x0010

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CSBOUND[4:0]				
											rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **CSBOUND[4:0]**: NCS boundary

This bitfield enables the transaction boundary feature. When active, a minimum value of 3 is recommended. The NCS is released on each boundary of $2^{CSBOUND}$ bytes.

0: NCS boundary disabled

Others: NCS boundary set to $2^{CSBOUND}$ bytes

Bits 15:0 Reserved, must be kept at reset value.

23.7.5 OCTOSPI device configuration register 4 (OCTOSPI_DCR4)

Address offset: 0x0014

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
REFRESH[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REFRESH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **REFRESH[31:0]**: Refresh rate

This bitfield enables the refresh rate feature. The NCS is released every REFRESH + 1 clock cycles for writes, and REFRESH + 4 clock cycles for reads. These two values can be extended with few clock cycles when refresh occurs during a byte transmission in single-, dual- or quad-SPI mode, because the byte transmission must be completed.

0: Refresh disabled

Others: Maximum communication length is set to REFRESH + 1 clock cycles.

Note: REFRESH count is based on the divided clock period: if OCTOSPI_DCR2 PRESCALER bitfield is changed, the REFRESH field must be updated accordingly.

23.7.6 OCTOSPI status register (OCTOSPI_SR)

Address offset: 0x0020

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	FLEVEL[5:0]						Res.	Res.	BUSY	TOF	SMF	FTF	TCF	TEF
		r	r	r	r	r	r			r	r	r	r	r	r

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:8 **FLEVEL[5:0]**: FIFO level

This bitfield gives the number of valid bytes that are being held in the FIFO. FLEVEL = 0 when the FIFO is empty, and 32 when it is full.

In automatic status-polling mode, FLEVEL is zero.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **BUSY**: Busy

This bit is set when an operation is ongoing. It is cleared automatically when the operation with the external device is finished and the FIFO is empty.

Bit 4 **TOF**: Timeout flag

This bit is set when timeout occurs. It is cleared by writing 1 to CTOF.

Bit 3 **SMF**: Status match flag

This bit is set in automatic status-polling mode when the unmasked received data matches the corresponding bits in the match register (OCTOSPI_PSMAR).

It is cleared by writing 1 to CSMF.

Bit 2 **FTF**: FIFO threshold flag

In indirect mode, this bit is set when the FIFO threshold has been reached, or if there is any data left in the FIFO after the reads from the external device are complete.

It is cleared automatically as soon as the threshold condition is no longer true.

In automatic status-polling mode, this bit is set every time the status register is read, and the bit is cleared when the data register is read.

Bit 1 **TCF**: Transfer complete flag

This bit is set in indirect mode when the programmed number of data has been transferred or in any mode when the transfer has been aborted.It is cleared by writing 1 to CTCF.

Bit 0 **TEF**: Transfer error flag
This bit is set in indirect mode when an invalid address is being accessed in indirect mode.
It is cleared by writing 1 to CTEF.

23.7.7 OCTOSPI flag clear register (OCTOSPI_FCR)

Address offset: 0x0024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CTOF	CSMF	Res.	CTCF	CTEF
											w	w		w	w

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **CTOF**: Clear timeout flag
Writing 1 clears the TOF flag in the OCTOSPI_SR register.

Bit 3 **CSMF**: Clear status match flag
Writing 1 clears the SMF flag in the OCTOSPI_SR register.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CTCF**: Clear transfer complete flag
Writing 1 clears the TCF flag in the OCTOSPI_SR register.

Bit 0 **CTEF**: Clear transfer error flag
Writing 1 clears the TEF flag in the OCTOSPI_SR register.

23.7.8 OCTOSPI data length register (OCTOSPI_DLR)

Address offset: 0x0040

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DL[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DL[31:0]**: Data length

Number of data to be retrieved (value+1) in indirect and automatic status-polling modes. A value not greater than three (indicating 4 bytes) must be used for automatic status-polling mode.

All 1's in indirect mode means undefined length, where OCTOSPI continues until the end of the memory, as defined by DEVSIZE.

0x0000_0000: 1 byte is to be transferred.

0x0000_0001: 2 bytes are to be transferred.

0x0000_0002: 3 bytes are to be transferred.

0x0000_0003: 4 bytes are to be transferred.

...

0xFFFF_FFFD: 4,294,967,294 (4G-2) bytes are to be transferred.

0xFFFF_FFFE: 4,294,967,295 (4G-1) bytes are to be transferred.

0xFFFF_FFFF: undefined length; all bytes, until the end of the external device, (as defined by DEVSIZE) are to be transferred. Continue reading indefinitely if DEVSIZE = 0x1F.

DL[0] is stuck at 1 in dual-memory configuration (DMM = 1) even when 0 is written to this bit, thus assuring that each access transfers an even number of bytes.

This bitfield has no effect in memory-mapped mode.

23.7.9 OCTOSPI address register (OCTOSPI_AR)

Address offset: 0x0048

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0 and FMODE ≠ 11.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADDRESS[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDRESS[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ADDRESS[31:0]**: Address

Address to be sent to the external device. In HyperBus protocol, this field must be even as this protocol is 16-bit word oriented. In dual-memory configuration, AR[0] is forced to 0.

23.7.10 OCTOSPI data register (OCTOSPI_DR)

Address offset: 0x0050

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DATA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DATA[31:0]**: Data

Data to be sent/received to/from the external SPI device

In indirect-write mode, data written to this register is stored on the FIFO before it is sent to the external device during the data phase. If the FIFO is too full, a write operation is stalled until the FIFO has enough space to accept the amount of data being written.

In indirect-read mode, reading this register gives (via the FIFO) the data that was received from the external device. If the FIFO does not have as many bytes as requested by the read operation and if BUSY = 1, the read operation is stalled until enough data is present or until the transfer is complete, whichever happens first.

In automatic status-polling mode, this register contains the last data read from the external device (without masking).

Word, half-word, and byte accesses to this register are supported. In indirect-write mode, a byte write adds 1 byte to the FIFO, a half-word write 2 bytes, and a word write 4 bytes.

Similarly, in indirect-read mode, a byte read removes 1 byte from the FIFO, a halfword read 2 bytes, and a word read 4 bytes. Accesses in indirect mode must be aligned to the bottom of this register: A byte read must read DATA[7:0] and a half-word read must read DATA[15:0].

23.7.11 OCTOSPI polling status mask register (OCTOSPI_PSMKR)

Address offset: 0x0080

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MASK[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MASK[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MASK[31:0]**: Status mask

Mask to be applied to the status bytes received in automatic status-polling mode

For bit n:

0: Bit n of the data received in automatic status-polling mode is masked and its value is not considered in the matching logic.

1: Bit n of the data received in automatic status-polling mode is unmasked and its value is considered in the matching logic.

23.7.12 OCTOSPI polling status match register (OCTOSPI_PSMAR)

Address offset: 0x0088

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MATCH[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MATCH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MATCH[31:0]**: Status match
Value to be compared with the masked status register to get a match

23.7.13 OCTOSPI polling interval register (OCTOSPI_PIR)

Address offset: 0x0090

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

INTERVAL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **INTERVAL[15:0]**: Polling interval
Number of CLK cycles between a read during the automatic status-polling phases

23.7.14 OCTOSPI communication configuration register (OCTOSPI_CCR)

Address offset: 0x0100

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	DQSE	Res.	DDTR	DMODE[2:0]			Res.	Res.	ABSIZE[1:0]		ABDTR	ABMODE[2:0]

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **DQSE**: DQS enable
This bit enables the data strobe management.
0: DQS disabled
1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **DDTR**: Data double transfer rate
This bit sets the DTR mode for the data phase.
0: DTR mode disabled for data phase
1: DTR mode enabled for data phase

Bits 26:24 **DMODE[2:0]**: Data mode
This bitfield defines the data phase mode of operation.
000: No data
001: Data on a single line
010: Data on two lines
011: Data on four lines
100: Data on eight lines
Others: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate-byte size
This bitfield defines the alternate-byte size.
00: 8-bit alternate bytes
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes

Bit 19 **ABDTR**: Alternate- byte double transfer rate
This bit sets the DTR mode for the alternate-byte phase.
0: DTR mode disabled for the alternate-byte phase
1: DTR mode enabled for the alternate-byte phase

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This bitfield defines the alternate-byte phase mode of operation.
000: No alternate bytes
001: Alternate bytes on a single line
010: Alternate bytes on two lines
011: Alternate bytes on four lines
100: Alternate bytes on eight lines
Others: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This bitfield defines the address size.
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
0: DTR mode disabled for the address phase
1: DTR mode enabled for the address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This bitfield defines the address phase mode of operation.
000: No address
001: Address on a single line
010: Address on two lines
011: Address on four lines
100: Address on eight lines
Others: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size
This bitfield defines instruction size.
00: 8-bit instruction
01: 16-bit instruction
10: 24-bit instruction
11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate
This bit sets the DTR mode for the instruction phase.
0: DTR mode disabled for the instruction phase
1: DTR mode enabled for the instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode
This bitfield defines the instruction phase mode of operation.
000: No instruction
001: Instruction on a single line
010: Instruction on two lines
011: Instruction on four lines
100: Instruction on eight lines
Others: Reserved

23.7.15 OCTOSPI timing configuration register (OCTOSPI_TCR)

Address offset: 0x0108

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	SSHIFT	Res.	DHQC	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
	rw		rw

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DCYC[4:0]				
											rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **SSHIFT**: Sample shift
By default, the OCTOSPI samples data 1/2 of a CLK cycle after the data is driven by the external device.
This bit allows the data to be sampled later in order to consider the external signal delays.
0: No shift
1: 1/2 cycle shift
The software must ensure that SSHIFT = 0 when the data phase is configured in DTR mode (when DDTR = 1.)

Bit 29 Reserved, must be kept at reset value.

Bit 28 **DHQC**: Delay hold quarter cycle
0: No delay hold
1: 1/4 cycle hold

Bits 27:5 Reserved, must be kept at reset value.

Bits 4:0 **DCYC[4:0]**: Number of dummy cycles
This bitfield defines the duration of the dummy phase according to the memory latency.
In both SDR and DTR modes, it specifies a number of CLK cycles (0-31).

23.7.16 OCTOSPI instruction register (OCTOSPI_IR)

Address offset: 0x0110

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

INSTRUCTION[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **INSTRUCTION[31:0]**: Instruction
Instruction to be sent to the external SPI device

23.7.17 OCTOSPI alternate bytes register (OCTOSPI_ABR)

Address offset: 0x0120

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ALTERNATE[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

ALTERNATE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ALTERNATE[31:0]**: Alternate bytes

Optional data to be sent to the external SPI device right after the address.

23.7.18 OCTOSPI low-power timeout register (OCTOSPI_LPTR)

Address offset: 0x00130

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

TIMEOUT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **TIMEOUT[15:0]**: Timeout period

After each access in memory-mapped mode, the OCTOSPI prefetches the subsequent bytes and hold them in the FIFO.

This bitfield indicates how many CLK cycles the OCTOSPI waits after the clock becomes inactive and until it raises the NCS, putting the external device in a lower-consumption state.

23.7.19 OCTOSPI wrap communication configuration register (OCTOSPI_WPCCR)

Address offset: 0x0140

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

		rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **DQSE**: DQS enable

This bit enables the data strobe management.

0: DQS disabled

1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **DDTR**: Data double transfer rate
This bit sets the DTR mode for the data phase.
0: DTR mode disabled for the data phase
1: DTR mode enabled for the data phase

Bits 26:24 **DMODE[2:0]**: Data mode
This bitfield defines the data phase mode of operation.
000: No data
001: Data on a single line
010: Data on two lines
011: Data on four lines
100: Data on eight lines
Others: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate-byte size
This bitfield defines the alternate-byte size.
00: 8-bit alternate bytes
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes

Bit 19 **ABDTR**: Alternate-byte double transfer rate
This bit sets the DTR mode for the alternate-byte phase.
0: DTR mode disabled for the alternate-byte phase
1: DTR mode enabled for the alternate-byte phase

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This bitfield defines the alternate-byte phase mode of operation.
000: no alternate bytes
001: alternate bytes on a single line
010: alternate bytes on two lines
011: alternate bytes on four lines
100: alternate bytes on eight lines
Others: reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This bitfield defines the address size.
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
0: DTR mode disabled for address phase
1: DTR mode enabled for address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This bitfield defines the address phase mode of operation.
000: No address
001: Address on a single line
010: Address on two lines
011: Address on four lines
100: Address on eight lines
Others: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size
This bitfield defines the instruction size.
00: 8-bit instruction
01: 16-bit instruction
10: 24-bit instruction
11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate
This bit sets the DTR mode for the instruction phase.
0: DTR mode disabled for the instruction phase
1: DTR mode enabled for the instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode
This bitfield defines the instruction phase mode of operation.
000: No instruction
001: Instruction on a single line
010: Instruction on two lines
011: Instruction on four lines
100: Instruction on eight lines
Others: Reserved

23.7.20 OCTOSPI wrap timing configuration register (OCTOSPI_WPTCR)

Address offset: 0x0148

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	SSHIFT	Res.	DHQC	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DCYC[4:0]				
											rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **SSHIFT**: Sample shift
By default, the OCTOSPI samples data 1/2 of a CLK cycle after the data is driven by the external device.
This bit allows the data to be sampled later in order to consider the external signal delays.
0: No shift
1: 1/2 cycle shift
The firmware must assure that SSHIFT=0 when the data phase is configured in DTR mode (when DDTR = 1).

Bit 29 Reserved, must be kept at reset value.

Bit 28 **DHQC**: Delay hold quarter cycle
Add a quarter cycle delay on the outputs in DTR communication to match hold requirement.
0: No quarter cycle delay
1: 1/4 cycle delay inserted

Bits 27:5 Reserved, must be kept at reset value.

Bits 4:0 **DCYC[4:0]**: Number of dummy cycles
This bitfield defines the duration of the dummy phase according to the memory latency.
In both SDR and DTR modes, it specifies a number of CLK cycles (0-31).

23.7.21 OCTOSPI wrap instruction register (OCTOSPI_WPIR)

Address offset: 0x0150

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
INSTRUCTION[31:16]

ALTERNATE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ALTERNATE[31:0]**: Alternate bytes
Optional data to be sent to the external SPI device right after the address

23.7.23 OCTOSPI write communication configuration register (OCTOSPI_WCCR)

Address offset: 0x0180

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0. Its content has a meaning only when requesting write operations in memory-mapped mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **DQSE**: DQS enable
This bit enables the data strobe management.
0: DQS disabled
1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **DDTR**: data double transfer rate
This bit sets the DTR mode for the data phase.
0: DTR mode disabled for the data phase
1: DTR mode enabled for the data phase

Bits 26:24 **DMODE[2:0]**: Data mode
This bitfield defines the data phase mode of operation.
000: No data
001: Data on a single line
010: Data on two lines
011: Data on four lines
100: Data on eight lines
Others: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate-byte size
This bitfield defines the alternate-byte size.
00: 8-bit alternate bytes
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes

Bit 19 **ABDTR**: Alternate bytes double transfer rate
This bit sets the DTR mode for the alternate-bytes phase.
0: DTR mode disabled for alternate-bytes phase
1: DTR mode enabled for alternate-bytes phase

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This bitfield defines the alternate-byte phase mode of operation.
000: No alternate bytes
001: Alternate bytes on a single line
010: Alternate bytes on two lines
011: Alternate bytes on four lines
100: Alternate bytes on eight lines
Others: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This bitfield defines the address size.
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
0: DTR mode disabled for the address phase
1: DTR mode enabled for the address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This bitfield defines the address phase mode of operation.
000: No address
001: Address on a single line
010: Address on two lines
011: Address on four lines
100: Address on eight lines
Others: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size
This bitfield defines the instruction size.
00: 8-bit instruction
01: 16-bit instruction
10: 24-bit instruction
11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate
This bit sets the DTR mode for the instruction phase.
0: DTR mode disabled for instruction phase
1: DTR mode enabled for instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode
This bitfield defines the instruction phase mode of operation.
000: No instruction
001: Instruction on a single line
010: Instruction on two lines
011: Instruction on four lines
100: Instruction on eight lines
Others: Reserved

23.7.24 OCTOSPI write timing configuration register (OCTOSPI_WTCR)

Address offset: 0x0188

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0. Its content has a meaning only when requesting write operations in memory-mapped mode.

											rw	rw	rw	rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bits 4:0 **DCYC[4:0]**: Number of dummy cycles
This bitfield defines the duration of the dummy phase according to the memory latency.
In both SDR and DTR modes, it specifies a number of CLK cycles (0-31).

23.7.25 OCTOSPI write instruction register (OCTOSPI_WIR)

Address offset: 0x0190

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0. Its content has a meaning only when requesting write operations in memory-mapped mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw							rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **TRWR[7:0]:** Read-write minimum recovery time

Device read-to-write/write-to-read minimum recovery time expressed in number of communication clock cycles

Bits 15:8 **TACC[7:0]**: Access time

Device access time according to the memory latency, expressed in number of communication clock cycles

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **WZL:** Write zero latency

This bit enables zero latency on write operations.

0: Latency on write accesses

1: No latency on write accesses

Bit 0 **LM:** Latency mode
This bit selects the latency mode.
0: Variable initial latency
1: Fixed latency

Refer to *Section 2.3* for the register boundary addresses.

24 Secure digital input/output MultiMediaCard interface (SDMMC)

24.1 SDMMC main features

The SD/SDIO, embedded MultiMediaCard (*e*•MMC) host interface (SDMMC) provides an interface between the AHB bus and SD memory cards, SDIO cards and *e*•MMC devices.

The MultiMediaCard system specifications are available through the MultiMediaCard Association website at www.jedec.org, published by the MMCA technical committee.

SD memory card and SD I/O card system specifications are available through the SD card Association website at www.sdcard.org.

The SDMMC features include the following:

- Compliance with *Embedded MultiMediaCard System Specification Version 5.1*.
  Card support for three different databus modes: 1-bit (default), 4-bit and 8-bit.
  (HS200 SDMMC_CK speed limited to maximum allowed I/O speed)(HS400 is not supported).
- Full compatibility with previous versions of MultiMediaCards (backward compatibility).
- Full compliance with *SD memory card specifications version 6.0*.
  (SDR104 SDMMC_CK speed limited to maximum allowed I/O speed, SPI mode and UHS-II mode not supported).
- Full compliance with *SDIO card specification version 4.0.*
  Card support for two different databus modes: 1-bit (default) and 4-bit.
  (SDR104 SDMMC_CK speed limited to maximum allowed I/O speed, SPI mode and UHS-II mode not supported).
- Data transfer up to 208 Mbyte/s for the 8-bit mode.
  (depending maximum allowed I/O speed).
- Data and command output enable signals to control external bidirectional drivers.
- IDMA linked list support

The MultiMediaCard/SD bus connects cards to the host.

The current version of the SDMMC supports only one SD/SDIO/*e*•MMC card at any one time and a stack of *e*•MMC.

24.2 SDMMC implementation

Table 210. SDMMC features

SDMMC modes/features(1)	SDMMC1	SDMMC2
Variable delay (SRD104, HS200)	X	X
SDMMC_CKIN	X	X
SDMMC_CDIR, SDMMC_D0DIR	X	-
SDMMC_D123DIR	X	-

1. X = supported.

24.3 SDMMC bus topology

Communication over the bus is based on command/response and data transfers.

The basic transaction on the SD/SDIO/*e*•MMC bus is the command/response transaction. These types of bus transaction transfer their information directly within the command or response structure. In addition, some operations have a data token.

Data transfers are done in the following ways:

- Block mode: data block(s) with block size 2^N bytes with N in the range 0-14.
- SDIO multibyte mode: single data block with block size range 1-512 bytes
- *e*•MMC Stream mode: continuous data stream

Data transfers to/from *e*•MMC cards are done in data blocks or streams.

Figure 152. SDMMC "no response" and "no data" operations

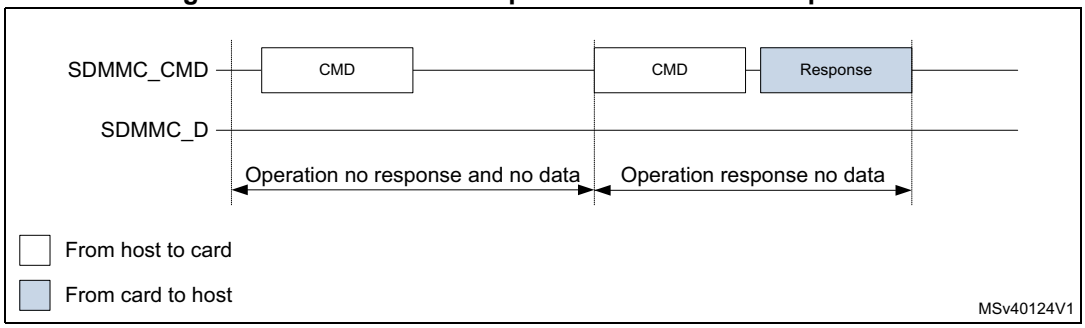

Figure 153. SDMMC (multiple) block read operation

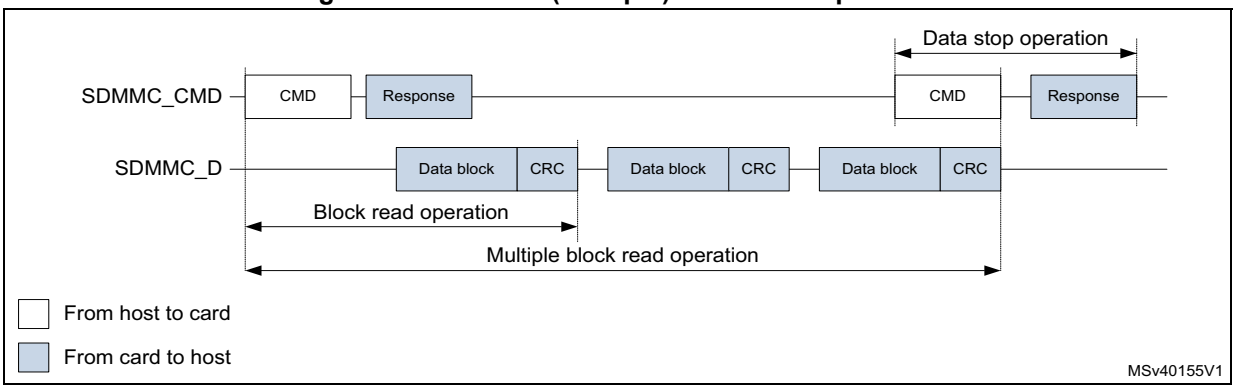
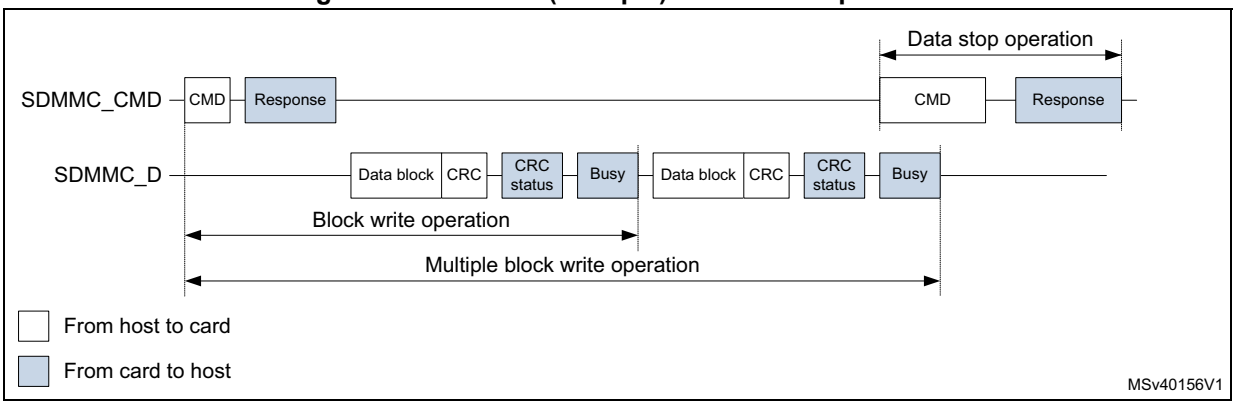


Note: The Stop Transmission command is not required at the end of a e•MMC multiple block read with predefined block count.

Figure 154. SDMMC (multiple) block write operation



Note: The Stop Transmission command is not required at the end of an e•MMC multiple block write with predefined block count.

Note: The SDMMC does not send any data as long as the Busy signal is asserted (SDMMC_D0 pulled low).

Figure 155. SDMMC (sequential) stream read operation

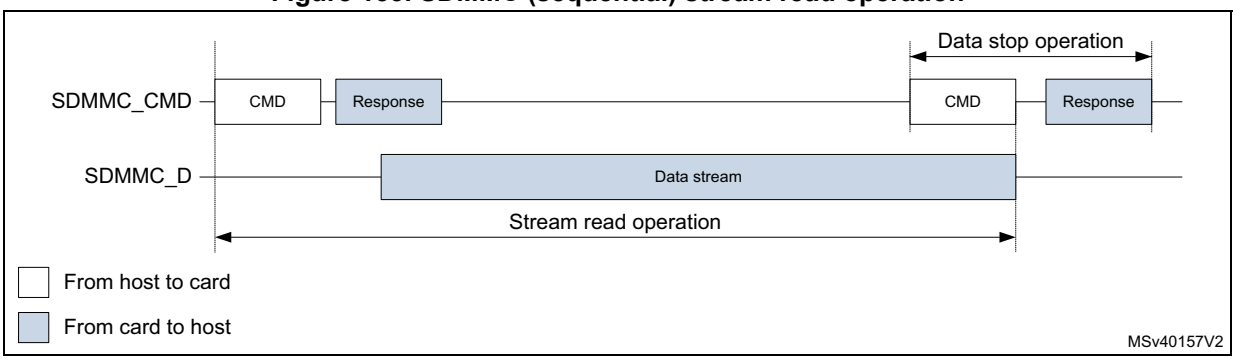


Figure 156. SDMMC (sequential) stream write operation

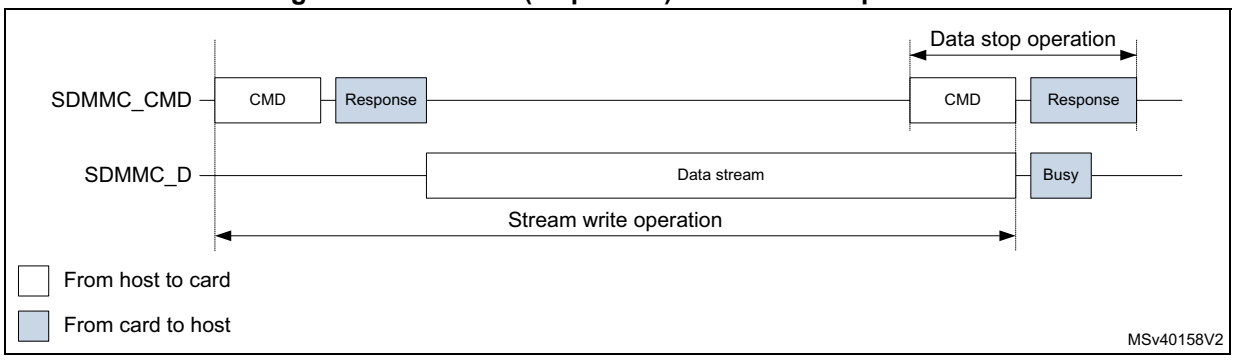


Stream data transfer operates only in a 1-bit wide bit bus configuration on SDMMC_D0 in single data rate modes (DS, HS, and SDR).

24.4 SDMMC operation modes

Table 211. SDMMC operation modes SD and SDIO

SDIO Bus Speed modes(1)(2)	Max Bus Speed (3) [Mbyte/s]	Max Clock frequency [MHz](4)	Signal Voltage [V]
DS (Default Speed)	12.5	25	3.3
HS (High Speed)	25	50	3.3
SDR12	12.5	25	1.8
SDR25	25	50	1.8
DDR50	50	50	1.8
SDR50	50	100	1.8
SDR104	104	208	1.8

1. SDR single data rate signaling.
2. DDR double data rate signaling. (data is sampled on both SDMMC_CK clock edges).
3. SDIO bus speed with 4bit bus width.
4. Maximum frequency depending on maximum allowed IO speed.

SDR104 mode requires variable delay support using sampling point tuning. The use of variable delay is optional for SDR50 mode.

Table 212. SDMMC operation modes *e*•MMC

e•MMC bus speed modes (1)(2)	Max bus speed (3) [Mbyte/s]	Max clock frequency [MHz](4)	Signal voltage [V](5)
Legacy compatible	26	26	3/1.8/1.2V
High speed SDR	52	52	3/1.8/1.2V
High speed DDR	104	52	3/1.8/1.2V
High speed HS200	200	200	1.8/1.2V

1. SDR single data rate signaling.
2. DDR double data rate signaling. (data is sampled on both SDMMC_CK clock edges).
3. *e*•MMC bus speed with 8bit bus width.
4. Maximum frequency depending on maximum allowed I/O speed.
5. Supported signal voltage level depends on I/O port characteristics, refer to device datasheet.

HS200 mode requires variable delay support using sampling point tuning.

24.5 SDMMC functional description

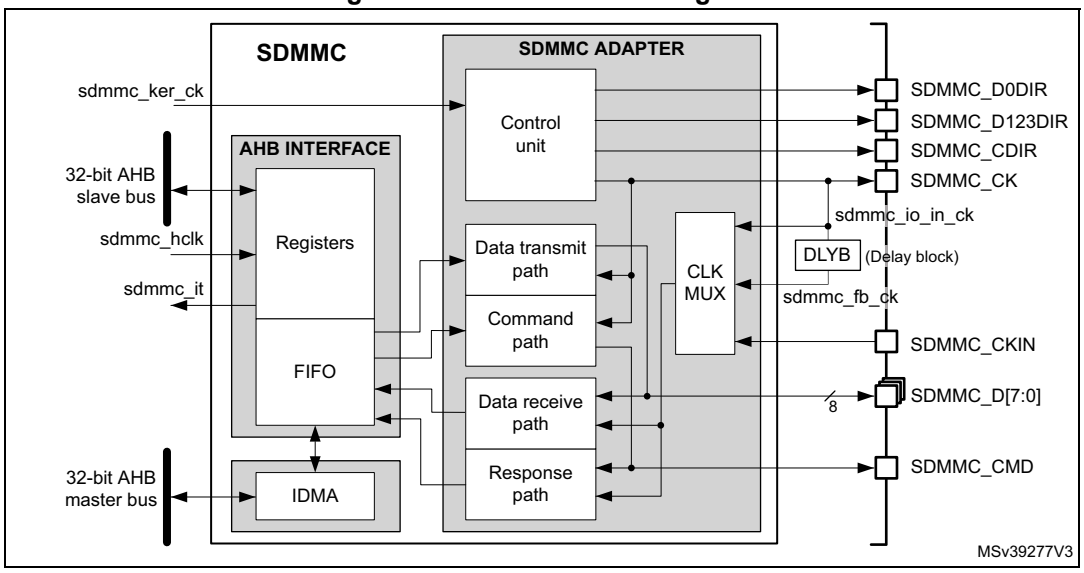
The SDMMC consists of four parts:

- The AHB slave interface accesses the SDMMC adapter registers, and generates interrupt signals and IDMA control signals.
- The SDMMC adapter block provides all functions specific to the *e*•MMC/SD/SD I/O card such as the clock generation unit, command and data transfer.
- The internal DMA (IDMA) block with its AHB master interface.
- A delay block (DLYB) taking care of the receive data sample clock alignment. The delay block is NOT part of the SDMMC. A delay block is mandatory when supporting SDR104 or HS200.

24.5.1 SDMMC block diagram

Figure 157 shows the SDMMC block diagram.

Figure 157. SDMMC block diagram



24.5.2 SDMMC pins and internal signals

Table 213 lists the SDMMC internal input/output signals, *Table 214* the SDMMC pins (alternate functions).

Table 213. SDMMC internal input/output signals

Signal name	Signal type	Description
sdmmc_ker_ck	Digital input	SDMMC kernel clock
sdmmc_hclk	Digital input	AHB clock
sdmmc_it	Digital output	SDMMC global interrupt

Table 213. SDMMC internal input/output signals (continued)

Signal name	Signal type	Description
sdmmc_io_in_ck	Digital input	SD/SDIO/*e*•MMC card feedback clock. This signal is internally connected to the SDMMC_CK pin (for DS and HS modes).
sdmmc_fb_ck	Digital input	SD/SDIO/*e*•MMC card tuned feedback clock after DLYB delay block (for SDR50, DDR50, SDR104, HS200)

Table 214. SDMMC pins

Signal name	Signal type	Description
SDMMC_CK	Digital output	Clock to SD/SDIO/*e*•MMC card
SDMMC_CKIN	Digital input	Clock feedback from an external driver for SD/SDIO/*e*•MMC card. (for SDR12, SDR25, SDR50, DDR50)
SDMMC_CMD	Digital input/output	SD/SDIO/*e*•MMC card bidirectional command/response signal.
SDMMC_CDIR	Digital output	SD/SDIO/*e*•MMC card I/O direction indication for the SDMMC_CMD signal.
SDMMC_D[7:0]	Digital input/output	SD/SDIO/*e*•MMC card bidirectional data lines.
SDMMC_D0DIR	Digital output	SD/SDIO/*e*•MMC card I/O direction indication for the SDMMC_D0 data line.
SDMMC_D123DIR	Digital output	SD/SDIO/*e*•MMC card I/O direction indication for the data lines SDMMC_D[3:1].

24.5.3 General description

The **SDMMC_D[7:0]** lines have different operating modes:

- By default, SDMMC_D0 line is used for data transfer. After initialization, the host can change the databus width.
- For an *e*•MMC, 1-bit (SDMMC_D0), 4-bit (SDMMC_D[3:0]) or 8-bit (SDMMC_D[7:0]) data bus widths can be used.
- For an SD or an SDIO card, 1-bit (SDMMC_D0) or 4-bit (SDMMC_D[3:0]) can be used. All data lines operate in push-pull mode.

To allow the connection of an external driver (a voltage switch transceiver), the direction of data flow on the data lines is indicated with I/O direction signals. The **SDMMC_D0DIR** signal indicates the I/O direction for the SDMMC_D0 data line, the **SDMMC_D123DIR** for the SDMMC_D[3:1] data lines.

SDMMC_CMD only operates in push-pull mode:

To allow the connection of an external driver (a voltage switch transceiver), the direction of data flow on the SDMMC_CMD line is indicated with the I/O direction signal **SDMMC_CDIR**.

SDMMC_CK clock to the card originates from **sdmmc_ker_ck**:

- When the sdmmc_ker_ck clock has 50 % duty cycle, it can be used even in bypass mode (CLKDIV = 0).
- When the sdmmc_ker_ck duty cycle is not 50 %, the CLKDIV must be used to divide it by 2 or more (CLKDIV > 0).
- The phase relation between the SDMMC_CMD / SDMMC_D[7:0] outputs and the SDMMC_CK can be selected through the NEGEDGE bit. The phase relation depends on the CLKDIV, NEGEDGE, and DDR settings. See *Figure 158*.

Figure 158. SDMMC Command and data phase relation

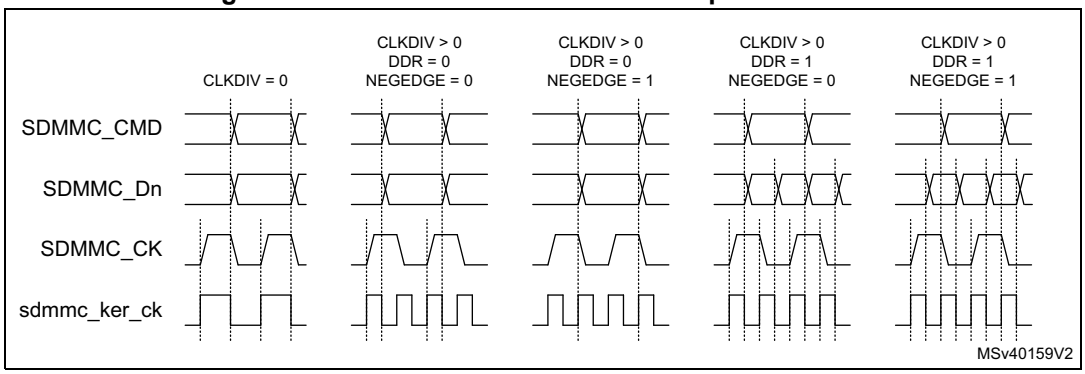


Table 215. SDMMC Command and data phase selection

CLKDIV	DDR	NEGEDGE	SDMMC_CK	Command out	Data out
0	x	x	= sdmmc_ker_ck	generated on sdmmc_ker_ck falling edge	
>0	0	0	generated on sdmmc_ker_ck rising edge	generated on sdmmc_ker_ck falling edge succeeding the SDMMC_CK rising edge.	
		1		generated on the same sdmmc_ker_ck rising edge that generates the SDMMC_CK falling edge.	
	1	0		generated on sdmmc_ker_ck falling edge succeeding the SDMMC_CK rising edge.	generated on sdmmc_ker_ck falling edge succeeding a SDMMC_CK edge.
		1		generated on the same sdmmc_ker_ck rising edge that generates the SDMMC_CK falling edge.	

By default, the **sdmmc_io_in_ck** feedback clock input is selected for sampling incoming data in the SDMMC receive path. It is derived from the SDMMC_CK pin.

For tuning the phase of the sampling clock to accommodate the receive data timing, the DLYB delay block available on the device can be connected between **sdmmc_io_in_ck** signal (DLYB input dlyb_in_ck) and **sdmmc_fb_ck** clock input of SDMMC (DLYB output dlyb_out_ck). Selecting the **sdmmc_fb_ck** clock input in the receive path then enables using the phase-tuned sampling clock for the incoming data. This is required for SDMMC to support the SDR104 and HS200 operating mode and optional for SDR50 and DDR50 modes.

When using an external driver (a voltage switch transceiver), the SDMMC_CKIN feedback clock input can be selected to sample the receive data.

For an SD/SDIO/*e*•MMC card, the clock frequency can vary between 0 and 208 MHz (limited by maximum I/O speed).

Depending on the selected bus mode (SDR or DDR), one bit or two bits are transferred on SDMMC_D[7:0] lines with each clock cycle. The SDMMC_CMD line transfers only one bit per clock cycle.

24.5.4 SDMMC adapter

The SDMMC adapter (see *Figure 157: SDMMC block diagram*) is a multimedia/secure digital memory card bus master that provides an interface to a MultiMediaCard stack or to a secure digital memory card. It consists of the following subunits:

- Control unit
- Data transmit path
- Command path
- Data receive path
- Response path
- Receive data path clock multiplexer
- Delay block (DLYB), external to the SDMMC
- Adapter register block
- Data FIFO
- Internal DMA (IDMA)

Note: The adapter registers and FIFO use the AHB clock domain (sdmmc_hclk). The control unit, command path and data transmit path use the SDMMC adapter clock domain (sdmmc_ker_ck). The response path and data receive path use the SDMMC adapter feedback clock domain from the sdmmc_io_in_ck, or SDMMC_CKIN, or from the sdmmc_fb_ck generated by DLYB.

The DLYB delay block on the device can be used in conjunction with the SDMMC adapter, to tune the phase of the sampling clock for incoming data in SDMMC receive mode. It is required for the SDMMC to support the SDR104 and HS200 operating mode and optional for SDR50 and DDR50 modes.

Adapter register block

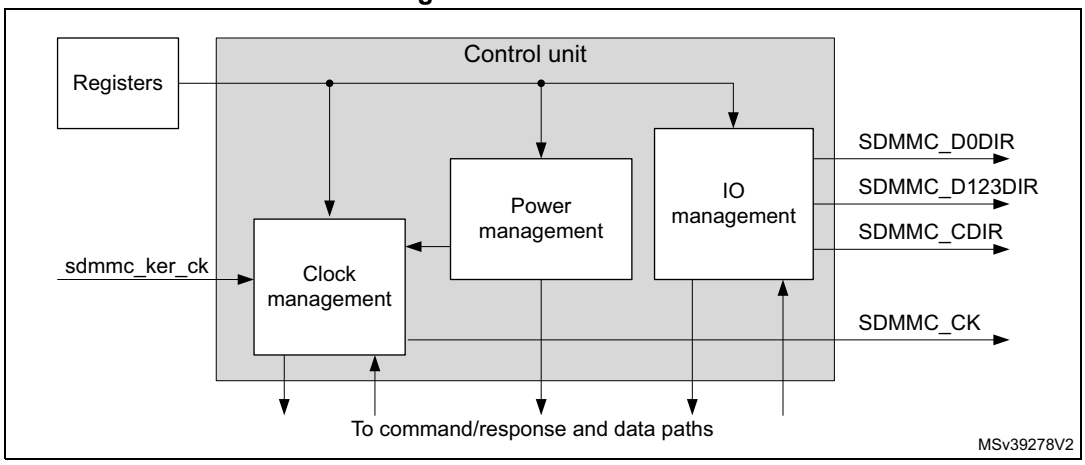
The adapter register block contains all system control registers, the SDMMC command and response registers and the data FIFO.

This block also generates the signals from the corresponding bit location in the SDMMC Clear register that clear the static flags in the SDMMC adapter.

Control unit

The control unit illustrated in *Figure 159*, contains the power management functions, the SDMMC_CK clock management with divider, and the I/O direction management.

Figure 159. Control unit



The power management subunit disables the card bus output signals during the power-off and power-up phases.

There are three power phases:

- power-off
- power-up
- power-on

The clock management subunit uses the sdmmc_ker_ck to generate the SDMMC_CK and provides the division control. It also takes care of stopping the SDMMC_CK for i.e. flow control.

The clock outputs are inactive:

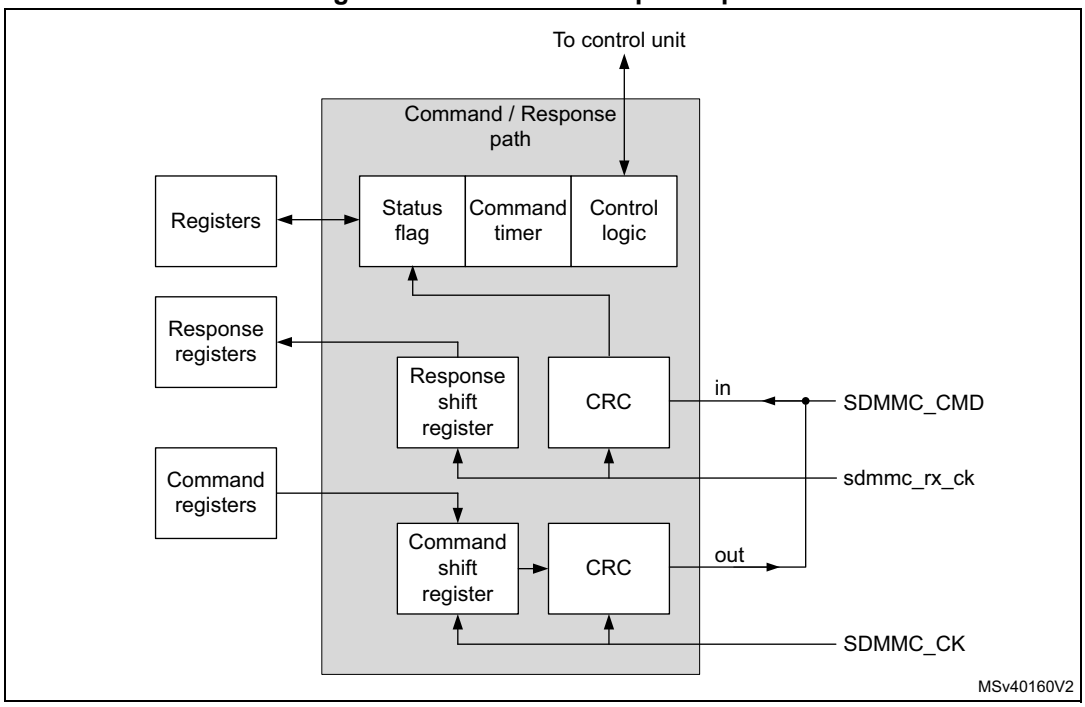
- after reset
- during the power-off or power-up phases
- if the power saving mode (register bit PWRSAV) is enabled and the card bus is in the Idle state for eight clock periods. The clock is stopped eight cycles after both the command/response CPSM and data path DPSM subunits have enter the Idle phase. The clock is restarted when the command/response CPSM or data path DPSM is activated (enabled).

The I/O management subunit takes care of the SDMMC_Dn and SDMMC_CMD I/O direction signals, which controls the external voltage transceiver.

Command/response path

The command/response path subunit transfers commands and responses on the SDMMC_CMD line. The command path is clocked on the SDMMC_CK and sends commands to the card,. The response path is clocked on the sdmmc_rx_ck and receives responses from the card.

Figure 160. Command/response path

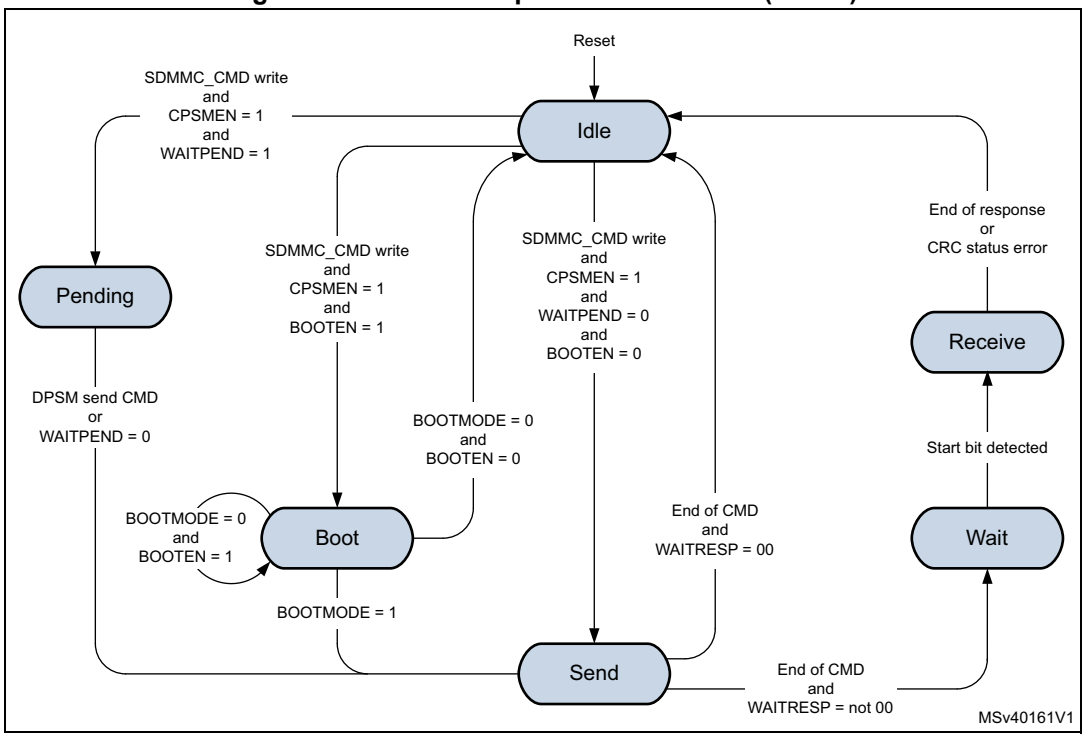


Command/response path state machine (CPSM)

- When the command register is written to and the enable bit is set, command transfer starts. When the command has been sent the CRC is appended and the command path state machine (CPSM) sets the status flags and:
  - if a response is not required enters the Idle state.
  - If a response is required, it waits for the response.
- When the response is received,
  - for a response with CRC, the received CRC code and the internally generated code are compared, and the appropriate status flag is set according the result.
  - for a response without CRC, no CRC is checked, and the appropriate status flag is not set.

When ever the CPSM is active, i.e. not in the Idle state, the CPSMACT bit is set.

Figure 161. Command path state machine (CPSM)



- **Idle**: The command path is inactive. When the command control register is written and the enable bit (CPSMEN) is set, the CPSM activates the SDMMC_CK clock (when stopped due to power save PWRSAV bit) and moves
  - to the Send state when WAITPEND = 0 and BOOTEN = 0.
  - to the Pending state when WAITPEND = 1.
  - to the Boot state when BOOTEN = 1.
- **Send**: The command is sent and the CRC is appended.
  - When CMDTRANS bit is set or when BOOTEN bit is set and BOOTMODE is alternative boot, and the DTDIR = receive, the CPSM DataEnable signal is issued to the DPSM at the end of the command.
  - When the CMDTRANS bit is set and the CMDSUSPEND bit is 0 the interrupt period is terminated at the end of the command.
  - When CMDSTOP bit is set the CPSM Abort signal is issued to the DPSM at the end of the command.
  - If no response is expected (WAITRESP = 00) the CPSM moves to the Idle state and the CMDSENT flag is set. When BOOTMODE = 1 and BOOTEN = 0 the CMDSENT flag is delayed 56 cycles after the command end bit, otherwise the

CMDSENT flag is generated immediately after the command end bit.
The RESPCMDR and RESPxR registers are not modified.

– If a command response is expected (WAITRESP = not 00) the CPSM moves to the Wait state and start the response timeout.

- **Wait**: The command path waits for a response.
  – When WAITINT bit is 0 the command timer starts running and the CPSM waits for a start bit.
  a) If a start bit is detected before the timeout the CPSM moves to the Receive state.
  b) If the timeout is reached before the CPSM detect a response start bit, the timeout flag (CTIMEOUT) is set and the CPSM moves to the Idle state.
  The RESPCMDR and RESPxR registers are not modified.
  – When WAITINT bit is 1, the timer is disabled and the CPSM waits for an interrupt request (response start bit) from one of the cards.
  a) When a start bit is detected the CPSM moves to the Receive state.
  b) When writing WAITINT to 0 (interrupt mode abort), the host sends a response by its self and on detecting the start bit the CPSM move to the Receive state.
- **Receive**: The command response is received. Depending the response mode bits WAITRESP in the command control register, the response can be either short or long, with CRC or without CRC. The received CRC code when present is verified against the internally generated CRC code.
  – When the CMDSUSPEND bit is set and the SDIO Response bit BS = 0 (response bit [39]), the interrupt period is started after the response.
  When the CMDSUSPEND bit is cleared, or the CMDSUSPEND bit is 1 and the SDIO Response bit BS = 1 (response bit [39]), there is no interrupt period started.
  – When the CMDTRANS bit is set and the CMDSUSPEND bit is set and the SDIO Response bit DF= 1 (response bit [32]) the interrupt period is terminated after the response.
  – When the CRC status passes or no CRC is present the CMDREND flag is set, the CPSM moves to the Idle state.
  The RESPCMDR and RESPxR registers are updated with received response.
  - When BOOTMODE = 1 and BOOTEN = 0 the CMDREND flag is delayed 56 cycles after the response end bit, otherwise the CMDREND flag is generated immediately after the response end bit.
  - When CMDTRANS bit is set and the DTDIR = transmit, the CPSM DataEnable signal is issued to the DPSM at the end of the command response.
  – When the CRC status fails the CCRCFAIL flag is set and the CPSM moves to the Idle state.
  The RESPCMDR and RESPxR registers are updated with received response.
- **Pending**: According the pending WAITPEND bit in the command register, the CPSM enters the pending state.
  – When DATALENGTH =< 5 bytes the CPSM moves to the Sent state and generates the DataEnable signal to start the data transfer aligned with the CMD12 Stop Transmission command.
  – When DATALENGTH > 5 bytes, the CPSM DataEnable signal is issued to the DPSM to start the data transfer. The CPSM waits for a send CMD signal from the

DPSM before moving to the Send state. This enables i.e. the CMD12 Stop Transmission command to be sent aligned with the data.

– When writing WAITPEND to 0, the CPSM moves to the Send state.

- **Boot**: If the BOOTEN bit is set in the command register, the CPSM enters the Boot state, and when:
  – BOOTMODE = 0 the SDMMC_CMD line is driven low and when CMDTRANS bit is set and the DTDIR = receive, the CPSM DataEnable signal is issued to the DPSM. This enables normal boot operation. This state is left at the end of the boot procedure by clearing the register bit BOOTEN, which cause the SDMMC_CMD line to be driven high and the CPSM Abort signal is issued to the DPSM, before moving to the Idle state. The CMDSENT flag is generated 56 cycles after SDMMC_CMD line is high.
  – BOOTMODE = 1, move to the Send state. This enables sending of the CMD0 (boot). Clearing BOOTEN has no effect.

Note: The CPSM remains in the Idle state for at least eight SDMMC_CK periods to meet the N_{CC} and N_{RC} timing constraints. N_{CC} is the minimum delay between two host commands, and N_{RC} is the minimum delay between the host command and the card response.

Note: The response timeout has a fixed value of 64 SDMMC_CK clock periods.

A command is a token that starts an operation. Commands are sent from the host to either a single card (addressed command) or all connected cards (broadcast command are available for *e*•MMC V3.31 or previous). Commands are transferred serially on the SDMMC_CMD line. All commands have a fixed length of 48 bits. The general format for a command token for SD-Memory cards, SDIO cards, and *e*•MMC cards is shown in *Table 216.*

The command token data is taken from 2 registers, one containing a 32-bits argument and the other containing the 6-bits command index (six bits sent to a card).

Table 216. Command token format

Bit position	Width	Value	Description
47	1	0	Start bit
46	1	1	Transmission bit
[45:40]	6	x	Command index
[39:8]	32	x	Argument
[7:1]	7	x	CRC7
0	1	1	End bit

Next to the command data there are command type (WAITRESP) bits controlling the command path state machine (CPSM). These bits also determine whether the command requires a response, and whether the response is short (48 bit) or long (136 bits) long, and if a CRC is present or not.

A response is a token that is sent from an addressed card or synchronously from all connected cards to the host as an answer to a previous received command. All responses are sent via the command line SDMMC_CMD. The response transmission always starts with the left bit of the bit string corresponding to the response code word. The code length depends on the response type. Response tokens R1, R2, R3, R4, R5, and R6 have various

coding schemes, depending on their content. The general formats for the response tokens for SD-Memory cards, SDIO cards, and *e*•MMC cards are shown in *Table 217*, *Table 218* and *Table 219*.

A response always starts with a start bit (always 0), followed by the bit indicating the direction of transmission (card = 0). A value denoted by x in the tables below indicates a variable entry. Most responses, except some, are protected by a CRC. Every command code word is terminated by the end bit (always 1).

The response token data is stored in 5 registers, four containing the 32-bits card status, OCR register, argument or 127-bits CID or CSD register including internal CRC, and one register containing the 6-bits command index.

Table 217. Short response with CRC token format

Bit position	Width	Value	Description
47	1	0	Start bit
46	1	0	Transmission bit
[45:40]	6	x	Command index (or reserved 111111)
[39:8]	32	x	Argument
[7:1]	7	x	CRC7
0	1	1	End bit

Table 218. Short response without CRC token format

Bit position	Width	Value	Description
47	1	0	Start bit
46	1	0	Transmission bit
[45:40]	6	x	Command index (or reserved 111111)
[39:8]	32	x	Argument
[7:1]	7	1111111	(reserved 1111111)
0	1	1	End bit

Table 219. Long response with CRC token format

Bit position	Width	Value	Description
135	1	0	Start bit
134	1	0	Transmission bit
[133:128]	6	111111	Reserved
[127:1]	127:8	x	CID or CSD slices
	7:1	x	CRC7 (included in CID or CSD)
0	1	1	End bit

The command/response path operates in a half-duplex mode, so that either commands can be sent or responses can be received. If the CPSM is not in the Send state, the

SDMMC_CMD output is in the Hi-Z state. Data sent on SDMMC_CMD are synchronous with the SDMMC_CK according the NEGEDGE register bit see *Figure 158*.

The command and short response with CRC, the CRC generator calculates the CRC checksum for all 40 bits before the CRC code. This includes the start bit, transmission bit, command index, and command argument (or card status).

For the long response the CRC checksum is calculated only over the 120 bits of R2 CID or CSD. Note that the start bit, transmission bit and the six reserved bits are not used in the CRC calculation.

The CRC checksum is a 7-bit value:

CRC[6:0] = remainder [(M(x) * x^7) / G(x)]

G(x) = $x^7 + x^3 + 1$

M(x) = (first bit) * x^n + (second bit) * x^{n-1}+... + (last bit before CRC) * x^0

Where n = 39 or 119.

The CPSM can send a number of specific commands to handle various operating modes when CPSMEN is set, see *Table 220*.

Table 220. Specific Commands overview

VSWITCH	BOOTEN	BOOTMOD	CMDTRAN	WAITPEND	CMDSTOP	WAITINT	Description
1	x	x	x	x	x	x	Start Voltage Switch Sequence
0	1	x	x	x	x	x	Start normal boot
0	1	1	x	x	x	x	Start alternative boot
0	0	1	x	x	x	x	Stop alternative boot.
0	0	0	1	x	x	x	Send command with associated data transfer.
0	0	0	0	1	1	x	*e*•MMC stream data transfer, command (STOP_TRANSMISSION) pending until end of data transfer.
0	0	0	0	1	0	x	*e*•MMC stream data transfer, command different from (STOP_TRANSMISSION) pending until end of data transfer.
0	0	0	0	0	1	x	Send command (STOP_TRANSMISSION), stopping any ongoing data transmission.
0	0	0	0	0	0	1	Enter *e*•MMC wait interrupt (Wait-IRQ) mode.
0	0	0	0	0	0	0	Any other none specific command

The command/response path implements the status flags and associated clear bits shown in *Table 221*:

Table 221. Command path status flags

Flag	Description
CMDSENT	Set at the end of the command without response. (CPSM moves from Send to Idle)
CMDREND	Set at the end of the command response when the CRC is OK. (CPSM moves from Receive to Idle)
CCRCFAIL	Set at the end of the command response when the CRC is FAIL. (CPSM moves from Receive to Idle)
CTIMEOUT	Set after the command when no response start bit received before the timeout. (CPSM moves from Wait to Idle)
CKSTOP	Set after the voltage switch (VSWITCHEN = 1) command response when the CRC is OK and the SDMMC_CK is stopped. (no impact on CPSM)
VSWEND	Set after the voltage switch (VSWITCH = 1) timeout of 5 ms + 1 ms. (no impact on CPSM)
CPSMACT	Command transfer in progress. (CPSM not in Idle state)

The command path error handling is shown in *Table 222*:

Table 222. Command path error handling

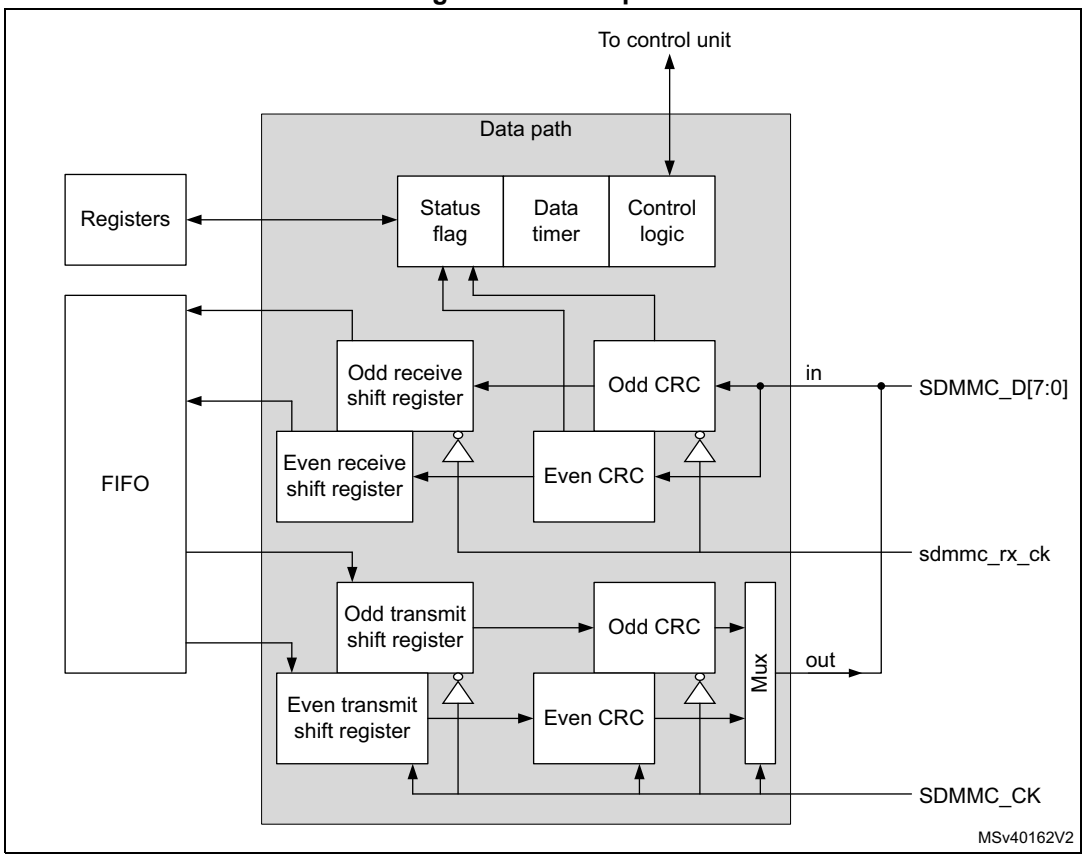
Error	CPSM state	Cause	Card action	Host action	CPSM action
Timeout	Wait	No start bit in time	Unknown	Reset or cycle power card(1)	Move to Idle
CRC status	Receive	Negative status	Command ignored	Resend command(1)	Move to Idle
		Transmission error	Command accepted	Resend command(1)	

1. When CMDTRANS is set, also a stop_transmission command must be send to move the DPSM to Idle.

Data path

The data path subunit transfers data on the SDMMC_D[7:0] lines to and from cards. The data transmit path is clocked on the SDMMC_CK and sends data to the card. The data receive path is clocked on the sdmmc_rx_ck and receives data from the card. *Figure 162* shows the data path block diagram.

Figure 162. Data path



The card data bus width can be programmed in the clock control register bits WIDBUS. The supported data bus width modes are:

- If the wide bus mode is not enabled, only one bit is transferred over SDMMC_D0.
- If the 4-bit wide bus mode is enabled, data is transferred at four bits over SDMMC_D[3:0].
- If the 8-bit wide bus mode is enabled, data is transferred at eight bits over SDMMC_D[7:0].

Next to the data bus width the data sampling mode can be programmed in the clock control register bit DDR. The supported data sampling modes are:

- Single data rate signaling (SDR), data is clocked on the rising edge of the clock.
- Double data rate signaling (DDR), data is clocked on the both edges of the clock. DDR mode is only supported in wide bus mode (4-bit wide and 8-bit wide).

Note: The data sampling mode only applies to the SDMMC_D[7:0] lines. (not applicable to the SDMMC_CMD line.)

In DDR mode, data is sampled on both edges of the SDMMC_CK according the following rules, see also *Figure 163* and *Figure 164*:

- On the rising edge of the clock odd bytes are sampled.
- On the falling edge of the clock even bytes are sampled.
- Data payload size is always a multiple of 2 Bytes.
- Two CRC16 are computed per data line
  - Odd bits CRC16 clocked on the falling edge of the clock.
  - Even bits CRC16 clocked on the rising edge of the clock.
- Start, end bits and idle conditions are full cycle.
- CRC status / boot acknowledgment and busy signaling are full cycle and are only sampled on the rising edge of the clock.

In DDR mode the SDMMC_CK clock division must be >= 2.

Figure 163. DDR mode data packet clocking

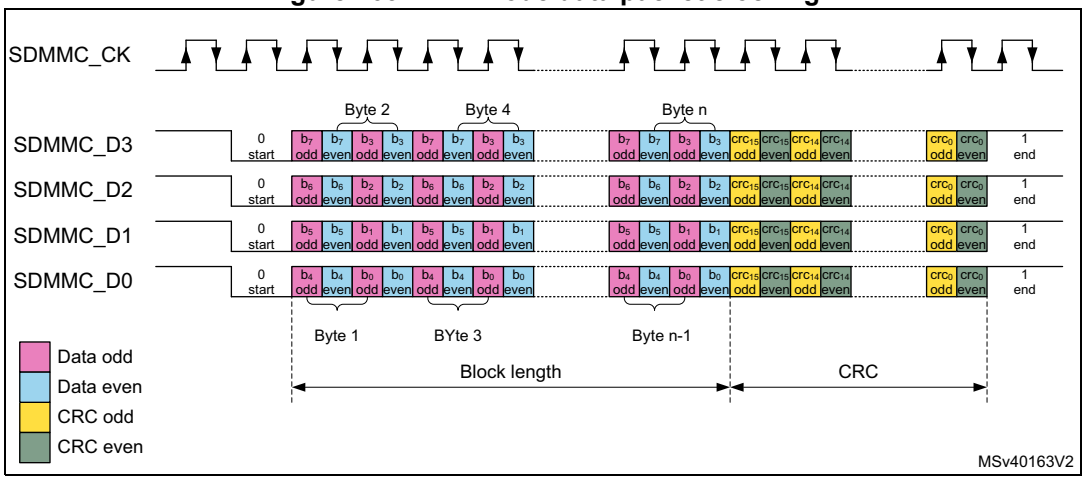


Figure 164. DDR mode CRC status / boot acknowledgment clocking

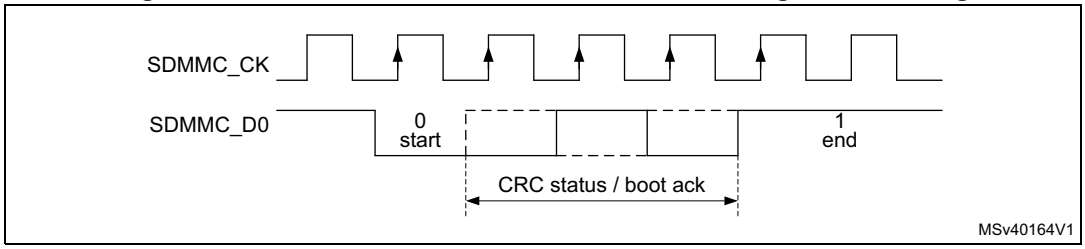


Data path state machine (DPSM)

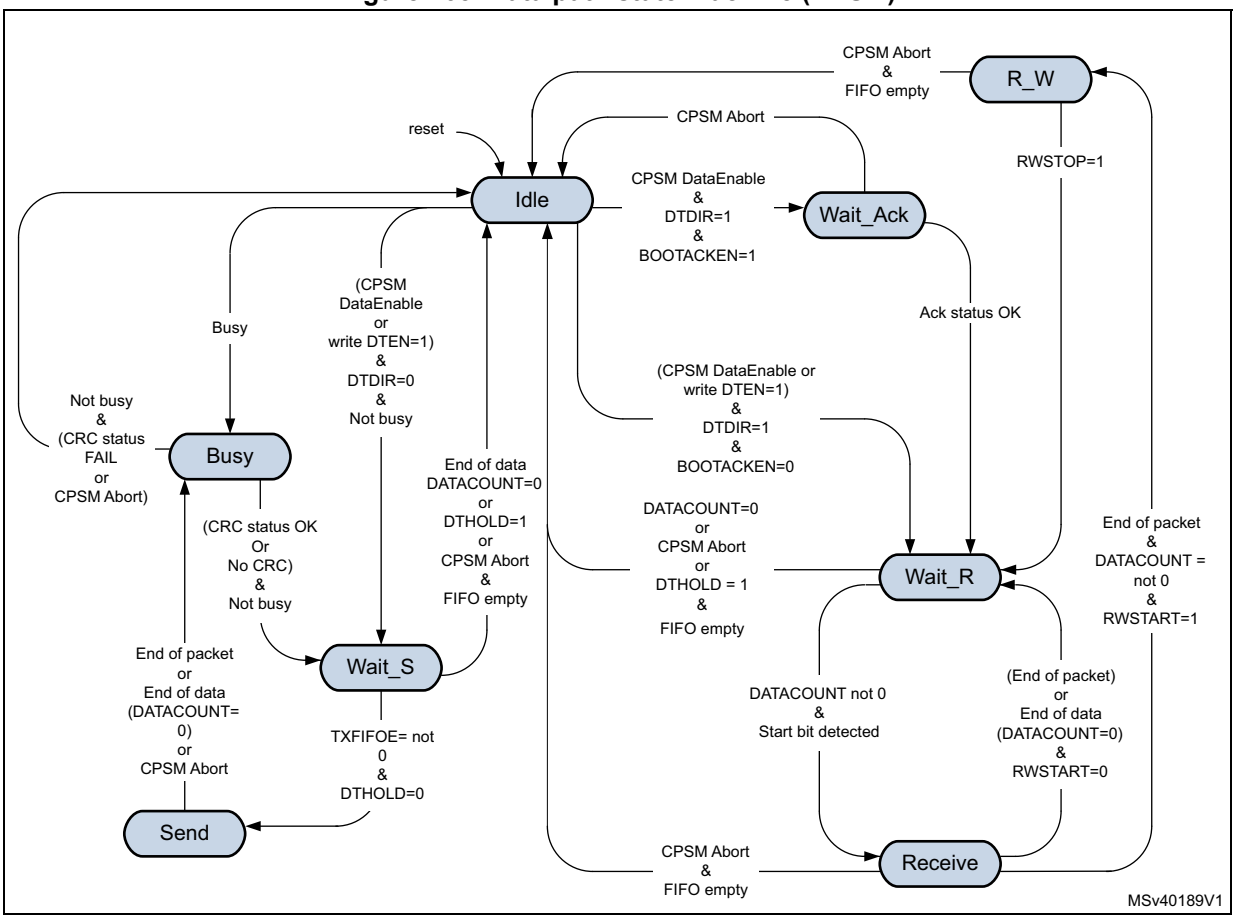
Depending on the transfer direction (send or receive), the data path state machine (DPSM) moves to the Wait_S or Wait_R state when it is enabled:

- Send: the DPSM moves to the Wait_S state. If there is data in the transmit FIFO, the DPSM moves to the Send state, and the data path subunit starts sending data to a card.
- Receive: the DPSM moves to the Wait_R state and waits for a start bit. When it receives a start bit, the DPSM moves to the Receive state, and the data path subunit starts receiving data from a card.

For boot operation with acknowledgment the DPSM moves to the Wait_Ack state and waits for the boot acknowledgment before moving to the Wait_R state.

The DPSM operates at SDMMC_CK. The DPSM has the following states, as shown in *Figure 165*. When ever the DPSM is active, i.e. not in the Idle state, the DPSMACT bit is set.

Figure 165. Data path state machine (DPSM)



- **Idle** state: the data path is inactive, and the SDMMC_D[7:0] outputs are according the PWRCTRL setting. The DPSM is activated either by sending a command with CMDTRANS bit set or by setting the DTEN bit, or by detecting Busy on SDMMC_D0 (that is, after a command with R1b response).

  When not busy, the DPSM activates the SDMMC_CK clock (when stopped due to power save PWRSAV bit), loads the data counter with a new (DATALENGTH) value and:

  – When the data direction bit (DTDIR) indicates send, moves to the Wait_S.

  – When the data direction bit (DTDIR) indicates receive, moves to the
  - Wait_R when BOOTACKEN register bit is clear.
  - Wait_Ack when BOOTACKEN register bit is set and start the acknowledgment timeout.

  When busy the DPSM keeps the SDMMC_CK clock active and move to the Busy state.

Note: DTEN must not be used to start data transfer with SD, SDIO and e•MMC cards.

- **Wait_Ack** state: the data path waits for the boot acknowledgment token.
  - The DPSM moves to the Wait_R state if it receives an error free acknowledgment before a timeout.
  - When a pattern different from the acknowledgment is received an acknowledgment status error is generated, and the ack fail status flag (ACKFAIL) is set. The DPSM stays in Wait_Ack.
  - If it reaches a timeout (ACKTIME) before it detects a start bit, it sets the timeout status flag (ACKTIMEOUT). The DPSM stays in Wait_Ack.
  - When the CPSM Abort signal is set it moves to the Idle state and sets the DABORT flag.
- **Wait_R** state: the data path, if the data counter is not zero and data is not hold, waits for a start bit on SDMMC_D[n:0]. If the data counter is zero or data is hold, wait for the FIFO to be empty.
  - In block mode, if a start bit is received before a timeout the DPSM moves to the Receive state and loads the data block counter with DBLOCKSIZE.
  - In SDIO multibyte mode, if a start bit is received before a timeout the DPSM moves to the Receive state and loads the data block counter with DATALENGTH.
  - In stream mode, if a start bit is received before a timeout the DPSM moves to the Receive state and loads the data counter with DATALENGTH.
  - if the data counter (DATACOUNT) equals zero (end of data) the DPSM moves to the Idle state when the receive FIFO is empty and the DATAEND flag is set.
  - If it reaches a timeout (DATATIME) before it detects a start bit, it sets the timeout status flag (DTIMEOUT) and the DPSM stays in the Wait_R state.
  - If the CPSM Abort signal is set:
    If DATACOUNT > 0, the DPSM moves to the Idle state when the FIFO is empty and when IDMAEN = 0 reset with FIFORST, and sets the DABORT flag.
    If DATACOUNT is zero normal operation is continued, there is no DABORT flag since the transfer has completed normally.
  - if the DTHOLD bit is set:
    - When DATACOUNT > 0, the DPSM moves to the Idle state when the receive FIFO is empty and when IDMAEN = 0 reset with FIFORST, and issues the DHOLD flag. When holding the timeout is disabled. When an CPSM Abort signal is received during holding, the transfer is aborted.

- When DATACOUNT = 0, the transfer is completed normally and there is no DHOLD flag.

– When DPSM has been started with DTEN, after an error (DTIMEOUT) the DPSM moves to the Idle state when the FIFO is empty and when IDMAEN = 0 reset with FIFORST.

- **R_W** state: the data path Read Wait the bus.
  – The DPSM moves to the Wait_R state when the Read Wait stop bit (RWSTOP) is set, and start the receive timeout.
  – If the CPSM Abort signal is set, wait for the FIFO to be empty and when IDMAEN = 0 reset with FIFORST, then moves to the Idle state and sets the DABORT flag.
- **Receive** state: the data path receives serial data from a card. Pack the data in bytes and written it to the data FIFO. Depending on the transfer mode selected in the data control register (DTMODE), the data transfer mode can be either block or stream:
  – In block mode, when the data block size (DBLOCKSIZE) number of data bytes are received, the DPSM waits until it receives the CRC code.
  – In SDIO multibyte mode, when the data block size (DATALENGTH) number of data bytes are received, the DPSM waits until it receives the CRC code.
  a) If the received CRC code matches the internally generated CRC code, the DPSM moves to the
  - R_W state when RWSTART = 1 and DATACOUNT > zero, the DBCKEND flag is set.
  - Wait_R state otherwise.
  b) If the received CRC code fails the internally generated CRC code any further data reception is prevented.
  - When not all data has been received (DATACOUNT > 0), the CRC fail status flag (DCRCFAIL) is set and the DPSM stays in the Receive state.
  - When all data has been received (DATACOUNT = 0), wait for the FIFO to be empty after which the CRC fail status flag (DCRCFAIL) is set and the DPSM moves to the Idle state.
  – In stream mode, the DPSM receives data while the data counter DATACOUNT > 0. When the counter is zero, the remaining data in the shift register is written to the data FIFO, and the DPSM moves to the Wait_R state.
  – When a FIFO overrun error occurs, the DPSM sets the FIFO overrun error flag (RXOVERR) and any further data reception is prevented. The DPSM stays in the Receive state.
  – When an CPSM Abort signal is received:
  - If the CPSM Abort signal is received before the 2 last bits of the data with DATACOUNT = 0, the transfer is aborted. The remaining data in the shift register is written to the data FIFO, wait for the FIFO to be empty and when IDMAEN = 0 reset with FIFORST, then the DPSM moves to the Idle state and the DABORT flag is set.
  - If the CPSM Abort signal is received during or after the 2 last bits of the transfer with DATACOUNT=0, the transfer is completed normally. The DPSM stays in the Receive state no DABORT flag is generated.
  – When DPSM has been started with DTEN, after an error (DCRCFAIL when DATACOUNT > 0, or RXOVERR) the DPSM moves to the Idle state when the FIFO is empty and when IDMAEN = 0 reset with FIFORST.

- **Wait_S** state: the data path waits for data to be available from the FIFO.
  - If the data counter DATACOUNT > 0, waits until the data FIFO empty flag (TXFIFOE) is de-asserted and DTHOLD is not set, and moves to the Send state.
  - If the data counter (DATACOUNT) = 0 the DPSM moves to the Idle state.
    - When DTHOLD is disabled, the DATAEND flag is set.
    - When DTHOLD is enabled, the DHOLD flag is set.
  - When DTHOLD is set and the DATACOUNT > 0
    - When IDMA is enabled, the DBCKEND flag is set and subsequently the FIFO is flushed, furthermore the DPSM moves to the Idle state and the DHOLD flag is set.
    - When IDMA is disabled the DBCKEND flag is set. Wait for the FIFO to be reset by software with FIFORST, then DPSM moves to the Idle state and issues the DHOLD flag.
  - When DTHOLD is set and DATACOUNT = 0 the transfer is completed normally.
  - When receiving the CPSM Abort signal
    - If the CPSM Abort signal is received before the 2 last bits of the data with DATACOUNT = 0, the transfer is aborted, wait for the FIFO to be empty and when IDMAEN = 0 reset with FIFORST, then the DPSM moves to the Idle state and sets the DABORT flag.
    - If the CPSM Abort signal is received during or after the 2 last bits of the transfer with DATACOUNT=0, normal operation is continued, there is no DABORT flag since the transfer has completed normally.

Note: The DPSM remains in the Wait_S state for at least two clock periods to meet the N_{WR} timing requirements, where N_{WR} is the number of clock cycles between the reception of the card response and the start of the data transfer from the host.

- **Send** state: the DPSM starts sending data to a card. Depending on the transfer mode bit in the data control register, the data transfer mode can be either block, SDIO multibyte or stream:
  - In block mode, when the data block size (DBLOCKSIZE) number of data bytes are send, the DPSM sends an internally generated CRC code and end bit, and moves to the Busy state and start the transmit timeout.
  - In SDIO multibyte mode, when the data block size (DATALENGTH) number of data bytes are send, the DPSM sends an internally generated CRC code and end bit, and moves to the Busy state and start the transmit timeout.
  - In stream mode, the DPSM sends data to a card while the data counter DATACOUNT > 0. When the data counter reaches zero moves to the Busy state and start the transmit timeout.
    Before sending the last stream Byte according to DATACOUNT, the DPSM issues a trigger on the send CMD signal. This signal is used by the CPSM to sent any pending command. (i.e. CMD12 Stop Transmission command)
  - If a FIFO underrun error occurs, the DPSM sets the FIFO underrun error flag (TXUNDERR). The DPSM stays in the Send state.
  - When receiving the CPSM Abort signal
    - If the CPSM Abort signal is received before the 2 last bits of the transfer with DATACOUNT=0, the transfer is aborted. The DPSM sends a last data bit followed by an end bit. The FIFO is disabled/flushed, and the DPSM moves to the Busy state to wait for not busy before setting the DABORT flag.
    - If the CPSM Abort signal is received during or after the 2 last bits of the transfer

with DATACOUNT=0, the transfer is completed normally, there is no DABORT flag.

- **Busy** state: the DPSM waits for the CRC status token when expected, and wait for a not busy signal:
  - If a CRC status token is expected and indicate “non-erroneous transmission” or when there is no CRC expected:
    - it moves to the Wait_S state when SDMMC_D0 is not low (the card is not busy).
    - When the card is busy SDMMC_D0 is low it remains in the Busy state.
  - If a CRC status token is expected and indicates “erroneous transmission”.
    - When not all data has been send (DATACOUNT > 0). The DPSM waits for not busy after which the CRC fail status flag (DCRCFAIL) is set. The FIFO is disabled/flushed and the DPSM stays in the Busy state.
    - When all data has been send (DATACOUNT = 0). The DPSM waits for not busy after which the CRC fail status flag (DCRCFAIL) is set and the DPSM moves to the Idle state.
  - If a CRC status (Ncrc) timeout occurs while the DPSM is in the Busy state, it sets the data timeout flag (DTIMEOUT) and stays in the Busy state.
  - If a busy timeout occurs while the DPSM is in the Busy state, it sets the data timeout flag (DTIMEOUT) and stays in the Busy state.
  - When receiving the CPSM Abort signal in the Busy state:
    - If the CPSM Abort signal is received before the 2 last bits of the CRC response with DATACOUNT > 0, the data transfer is aborted. The DPSM waits for not busy and the FIFO to be disabled/flushed before moving to the Idle state and the DABORT flag is set.
    - If the CPSM Abort signal is received during or after the 2 last bits of the CRC response when DATACOUNT=0 or when no CRC is expected and DATACOUNT = 0 and there has been no DTIMEOUT error, the DPSM stays in the Busy state no DABORT flag is generated, since the transfer may completed normally.
    - If the CPSM Abort signal is received when a DTIMEOUT error has occurred the DPSM waits for not busy and the FIFO to be disabled/flushed before moving to the Idle state and the DABORT flag is set.
  - When entering the Busy state due to an abort in the Send state, the DPSM waits for not busy before moving to the Idle state and the DABORT flag is set.
  - When DPSM has been started with DTEN, after an error (DCRCFAIL when DATACOUNT > 0, or DTIMEOUT) the DPSM moves to the Idle state when the FIFO is reset.
  - When the DPSM has been started due to Busy on SDMMC_D0, waits for not busy after which the Busy end status flag (BUSYD0END) is set and the DPSM moves to the Idle state.

The data timer (DATATIME) is enabled when the DPSM is in the Wait_R or Busy state 2 cycles after the data block end bit, or data read command end bit, or R1b response, and generates the data timeout error (DTIMEOUT):

- When transmitting data, the timeout occurs
  - when a CRC status is expected and no start bit is received withing 8 SDMMC_CK cycles, the DTIMEOUT flag is set.
  - when the Busy state takes longer than the programmed timeout period., the DTIMEOUT flag is set.
- When receiving data, the timeout occurs
  - when there is still data to be received DATACOUNT > 0 and no start bit is received before the programmed timeout period, the DTIMEOUT flag is set.
- After a R1b response, the timeout occurs
  - when the Busy state takes longer than the programmed timeout period., the DTIMEOUT flag is set.

When DATATIME = 0,

- In receive the start bit must be present 2 cycles after the data block end bit or data read command end bit.
- In transmit busy is timed out 2 cycles after the CRC token end bit or stream data end bit.
- After a R1b response busy is timed out 2 cycles after the response end bit.

Data can be transferred from the card to the host (transmit, send) or vice versa (receive). Data are transferred via the SDMMC_Dn data lines, they are stored in a FIFO.

Table 223. Data token format

Description	Start bit	Data(1)	CRC16	End bit	DTMODE
Block data	0	(DBLOCKSIZE, DATALENGTH)	yes	1	00
SDIO multibyte	0	(DATALENGTH)	yes	1	01
e•MMC stream	0	(DATALENGTH)	no	1	10

1. The total amount of data to transfer is given by DATALENGTH. Where for Block data the amount of data in each block is given by DBLOCKSIZE.

The data token format is selected with register bits DTMODE according.

The data path implements the status flags and associated clear bits shown in *Table 224*:

Table 224. Data path status flags and clear bits

Flag		Description
DATAEND	TX	Set at the end of the complete data transfer when the CRC is OK and busy has finished and both DTHOLD = 0 and DATACOUNT = 0. (DPSM moves from Wait_S to Idle)
	RX	Set at the end of the complete data transfer when the CRC is OK and all data has been read, (DATACOUNT = 0 and FIFO is empty). (DPSM moves from Wait_R to Idle)
	Boot	

Table 224. Data path status flags and clear bits (continued)

Flag		Description
DCRCFAIL	TX	Set at the end of the CRC when FAIL and busy has finished. (DPSM stay in Busy when there is still data to send and wait for CPSM Abort) (DPSM moves from Busy to Idle when all data has been sent) or DPSM has been started with DTEN
	RX	Set at the end of the CRC when FAIL and FIFO is empty. (DPSM stays in Receive when there is still data to be received and wait for CPSM Abort) (DPSM moves from Receive to Idle when all data has been received or DPSM has been started with DTEN)
	Boot	
ACKFAIL	Boot	Set at the end of the boot acknowledgment when fail. (DPSM stays in Wait_Ack and wait for CPSM Abort)
DTIMEOUT	CMD R1b	Set after the command response no end of busy received before the timeout. (DPSM stays in Busy and wait for CPSM Abort)
	TX	Set when no CRC token start bit received within Ncrc, or no end of busy received before the timeout. (DPSM stays in Busy and wait for CPSM Abort) (When DPSM has been started with DTEN move to Idle) Note: The DCRCFAIL flag may also be set when CRC failed before the busy timeout.
	RX	Set when no start bit received before the timeout. (DPSM stays in Wait_R and wait for CPSM Abort) (When DPSM has been started with DTEN move to Idle)
	Boot	
ACKTIMEOUT	Boot	Set when no start bit received before the timeout. (DPSM stays in Wait_Ack and wait for CPSM Abort)
DBCKEND	TX	When DTHOLD = 1 and IDMAEN = 0: Set at the end of data block transfer when the CRC is OK and busy has finished, when data transfer is not complete (DATACOUNT >0). (DPSM moves from Busy to Wait_S)
	RX	When RWSTART = 1: Set at the end of data block transfer when the CRC is OK, when data transfer is not complete (DATACOUNT > 0). (DPSM moves from Receive to R_W)
	Boot	
DHOLD	TX	When DTHOLD = 1: Set at the end of data block transfer when the CRC is OK and busy has finished. (DPSM moves from Wait_S to Idle)
	RX	When DTHOLD = 1: Set at the end of data block transfer when the CRC is OK and all data has been read (FIFO is empty), when data transfer is not complete (DATACOUNT >0). (DPSM moves from Wait_R to Idle)
DABORT	CMD R1b	When CPSM Abort event has been sent by the CPSM and busy has finished. (DPSM moves from Busy to Idle)
	TX	When CPSM Abort event has been sent by the CPSM before the 2 last bits of the transfer. (DPSM moves from any state to Idle)
	RX	
	Boot	
BUSYD0END	CMD R1b	Set after the command response when end of busy before the timeout. (DPSM moves from Busy to Idle)
DPSMACT		Data transfer in progress. (DPSM not in Idle state)

The data path error handling is shown in *Table 225*:

Table 225. Data path error handling

Error	DPSM state	Cause	Card action	Host action	DPSM action
Timeout	Wait_Ack	No Ack in time	unknown	Card cycle power	Stay in Wait_Ack (reset the SDMMC with the RCC.SDMMCxRST register bit)
	Wait_R	No start bit in time	unknown	Stop data reception Send stop transmission command	On CPSM Abort move to Idle
			unknown	Stop boot procedure	
	Busy	Busy too long (due to data transfer)	unknown	Stop data reception Send stop transmission command	
		Busy too long (due to R1b)	unknown	Send reset command	
CRC	Receive	transmission error	Send further data	Stop data reception Send stop transmission command	On CPSM Abort move to Idle
CRC status	Busy	Negative status	Ignore further data	Stop data transmission Send stop transmission command	On CPSM Abort move to Idle
		transmission error	wait for further data		
Ack status	Wait_Ack	transmission error	Send boot data	Stop boot procedure	On CPSM Abort move to Idle
Overrun	Receive	FIFO full	Send further data	Stop data reception Send stop transmission command	On CPSM Abort move to Idle
Underrun	Send	FIFO empty	Receive further data	Stop data transmission Send stop transmission command	On CPSM Abort move to Idle

Data FIFO

The data FIFO (first-in-first-out) subunit contains the transmit and receive data buffer. A single FIFO is used for either transmit or receive as selected by the DTDIR bit. The FIFO contain a 32-bit wide, 16-word deep data buffer and control logic. Because the data FIFO operates in the AHB clock domain (sdmmc_hclk), all signals from the subunits in the SDMMC clock domain (SDMMC_CK/sdmmc_rx_ck) are resynchronized.

The FIFO can be in one of the following states:

- The transmit FIFO refers to the transmit logic and data buffer when sending data out to the card. (DTDIR = 0)
- The receive FIFO refers to the receive logic and data buffer when receiving data in from the card. (DTDIR = 1)

The end of a correctly completed SDMMC data transfer from the FIFO is indicated by the DATAEND flags driven by the data path subunit. Any incorrect (aborted) SDMMC data transfer from the FIFO is indicated by one of the error flags (DCRCFAIL, DTIMEOUT, DABORT) driven by the data path subunit, or one of the FIFO error flags (TXUNDERR, RXOVERR) driven by the FIFO control.

The data FIFO can be accessed in the following ways, see *Table 226*.

Table 226. Data FIFO access

Data FIFO access	IDMAEN
From firmware via AHB slave interface	0
From IDMA via AHB master interface	1

Transmit FIFO:

Data can be written to the transmit FIFO when the DPSM has been activated (DPSMACT = 1).

When IDMAEN = 1 the FIFO is fully handled by the IDMA.

When IDMAEN = 0 the FIFO is controlled by firmware via the AHB slave interface. The transmit FIFO is accessible via sequential addresses. The transmit FIFO contains a data output register that holds the data word pointed to by the read pointer. When the data path subunit has loaded its shift register, it increments the read pointer and drives new data out. The transmit FIFO is handled in the following way:

1. Write the data length into DATALENGTH and the block length in DBLOCKSIZE.
   - For block data transfer (DTMODE = 0), DATALENGTH must be an integer multiple of DBLOCKSIZE.
2. Set the SDMMC in transmit mode (DTDIR = 0).
   - Configures the FIFO in transmit mode.
3. Enable the data transfer
   - either by sending a command from the CPSM with the CMDTRANS bit set
   - or by setting DTEN bit
4. When (DPSMACT = 1) write data to the FIFO.
   - The DPSM stays in the Wait_S state until FIFO is full (TXFIFOF = 1), or the number indicated by DATALENGTH.

- The SDMMC keeps sending data as long as FIFO is not empty, hardware flow control during data transfer is used to prevent FIFO underrun.

5. Write data to the FIFO.
   – When the FIFO is handled by software, wait until the FIFO is half empty (TXFIFOHE flag), write data to the FIFO until FIFO is full (TXFIFOF = 1), or last data has been written.
   – When the FIFO is handled by the IDMA, the IDMA transfers the FIFO date.
6. When last data has been written wait for end of data (DATAEND flag)
   – SDMMC has completely sent all data and the DPSM is disabled (DPSMACT = 0).

In case of a data transfer error or transfer hold when IDMAEN = 0, firmware must stop writing to the FIFO and flush and reset the FIFO with the FIFORST register bit.

The transmit FIFO status flags are listed in *Table 227*.

Table 227. Transmit FIFO status flags

Flag	Description
TXFIFOF	Set to high when all transmit FIFO words contain valid data.
TXFIFOE	Set to high when the transmit FIFO does not contain valid data.
TXFIFOHE	Set to high when half or more transmit FIFO words are empty.
TXUNDERR	Set to high when an underrun error occurs. This flag is cleared by writing to the SDMMC Clear register.

Receive FIFO:

Data can be read from the receive FIFO when the DPSM is activated (DPSMACT = 1).

When IDMAEN = 1 the FIFO is fully handled by the IDMA.

When IDMAEN = 0 the FIFO is controlled by firmware via the AHB slave interface.When the data path subunit receives a word of data, it drives the data on the write databus. The write pointer is incremented after the write operation completes. On the read side, the contents of the FIFO word pointed to by the current value of the read pointer is driven onto the read databus. The receive FIFO is accessible via sequential addresses.

The receive FIFO is handled in the following way:

1. Write the data length into DATALENGTH and the block length in DBLOCKSIZE.
   – For block data transfer (DTMODE = 0), DATALENGTH must be an integer multiple of DBLOCKSIZE.
2. Set the SDMMC in receive mode (DTDIR = 1).
   – Configures the FIFO in receive mode.
3. Enable the DPSM transfer
   – either by sending a command from the CPSM with the CMDTRANS bit set
   – or by setting DTEN bit.
4. When (DPSMACT = 1) the FIFO is ready to receive data.
   – The DPSM writes the received data to the FIFO.
   - The SDMMC keeps receiving data as long as FIFO is not full, hardware flow control during the data transfer is used to prevent FIFO overrun.
5. Read data from the FIFO.
   – When the FIFO is handled by software, wait until the FIFO is half full (RXFIFOHF flag), read data from the FIFO until FIFO is empty (RXFIFOE = 1).
   - When last data has been received, read data from the FIFO until FIFO is empty (DATAEND = 1).
   – When the FIFO is handled by the IDMA, the IDMA transfers the FIFO date.
6. SDMMC has completely received all data and the DPSM is disabled (DPSMACT = 0).

In case of a data transfer hold when IDMAEN = 0, the firmware must read the remaining data until the FIFO is empty and reset the FIFO with the FIFORST register bit. This causes the DPSM to go to the Idle state (DPSMACT = 0).

In case of a data transfer error when IDMAEN = 0, the firmware must stop reading the FIFO and flush and reset the FIFO with the FIFORST register bit. This causes the DPSM to go to the Idle state (DPSMACT = 0).

The receive FIFO status flags are listed in *Table 228*.

Table 228. Receive FIFO status flags

Flag	Description
RXFIFOF	Set to high when all receive FIFO words contain valid data
RXFIFOE	Set to high when the receive FIFO does not contain valid data.
RXFIFOHF	Set to high when half or more receive FIFO words contain valid data.
RXOVERR	Set to high when an overrun error occurs. This flag is cleared by writing to the SDMMC Clear register.

CLKMUX unit

The CLKMUX selects the source for clock sdmmc_rx_ck to be used with the received data and command response. The receive data clock source can be selected by the clock control register bit SELCLKRX, between:

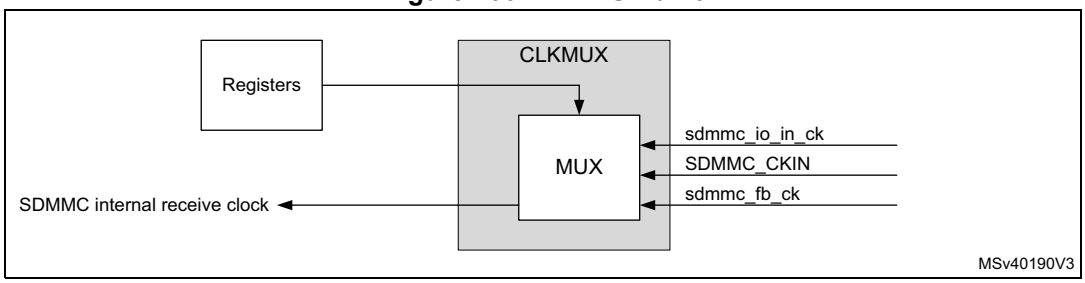
- sdmmc_io_in_ck bus master main feedback clock.
- SDMMC_CKIN external bus feedback clock.
- sdmmc_fb_ck bus tuned feedback clock.

The sdmmc_io_in_ck is selected when there is no external driver, with DS and HS.

The SDMMC_CKIN is selected when there is an external driver with SDR12, SDR25, SDR50 and DDR50.

The sdmmc_fb_ck clock input must be selected when the DLYB block on the device is used with SDR104, HS200 and optionally with SDR50 and DDR50 modes.

Figure 166. CLKMUX unit



The sdmmc_rx_ck source must be changed when the CPSM and DPSM are in the Idle state.

24.5.5 SDMMC AHB slave interface

The AHB slave interface generates the interrupt requests, and accesses the SDMMC adapter registers and the data FIFO. It consists of a data path, register decoder, and interrupt logic.

SDMMC FIFO

The FIFO access is restricted to word access only:

- In transmit FIFO mode
  - Data are written to the FIFO in words (32-bits) until all data according DATALENGTH has been transfered. When the DATALENGTH is not an integer multiple of 4, the last remaining data (1, 2 or 3 bytes) are written with a word transfer.
- In receive FIFO mode
  - Data are read from the FIFO in words (32-bits) until all data according DATALENGTH has been transfered. When the DATALENGTH is not an integer multiple of 4, the last remaining data (1, 2 or 3 bytes) are read with a word transfer padded with 0 value bytes.

When accessing the FIFO with half word or byte accesses an AHB bus fault is generated.

SDMMC interrupts

The interrupt logic generates an interrupt request signal that is asserted when at least one of the unmasked status flags is active. A mask register is provided to allow selection of the conditions that generate an interrupt. A status flag generates the interrupt request if a corresponding mask flag is set. Some status flags require an implicit clear in the clear register.

24.5.6 SDMMC AHB master interface

The AHB master interface is used to transfer the data between a memory and the FIFO using the SDMMC IDMA.

SDMMC IDMA

Direct memory access (DMA) is used to provide high-speed transfer between the SDMMC FIFO and the memory. The AHB master optimizes the bandwidth of the system bus. The SDMMC internal DMA (IDMA) provides one channel to be used either for transmit or receive.

The IDMA is enabled by the IDMAEN bit and supports burst transfers of 8 beats.

- In transmit burst transfer mode:
  - Data are fetched in burst from memory whenever the FIFO is empty for the number of burst transfers, until all data according DATALENGTH has been transfered. When the DATALENGTH is not an integer multiple of the burst size the remaining, smaller then burst size data is transfered using single transfer mode. When the DATALENGTH is not an integer multiple of 4, the last remaining data (1, 2 or 3 bytes) are fetched with a word transfer.
- In receive burst transfer mode:
  - Data are stored in burst in to memory whenever the FIFO contains the number of burst transfers, until all data according DATALENGTH has been transfered. When the DATALENGTH is not an integer multiple of the burst transfer the remaining, smaller then burst size data, is transfered using single transfer mode. When the DATALENGTH is not an integer multiple of 4, the last remaining data (1, 2 or 3 bytes) are stored with halfword and or byte transfers.

In addition the IDMA provides the following channel configurations selected by bit IDMABMODE:

- single buffered channel
- linked list channel

Single buffered channel

In single buffer configuration the data at the memory side is accessed in a linear matter starting from the base address IDMABASE. When the IDMA has finished transferring all data the and the DPSM has completed the transfer the DATAEND flag is set.

Linked list channel

In linked list configuration, IDMAMODE = 1, the data at the memory side is subsequently accessed from linked buffers, located at base address IDMABASE. The size of the memory buffers is defined by IDMABSIZE. The buffer size must be an integer multiple of the burst size. The bit ULA is used to indicate if a new linked list buffer configuration has to be loaded from the linked list table. A new linked list configuration is loaded when the ULA bit for the current linked list item is set.

The first linked list item configuration is programmed by firmware directly in the SDMMC registers.

When the IDMA has finished transferring all the data of one linked list buffer, according IDMABSIZE, and when the linked list item ULA bit is set, the IDMA loads the new linked list item from the linked list table, and continues transferring data from the next linked list buffer. When the IDMA has finished transferring all data, according IDMABSIZE and ULA, and the DPSM has completed the transfer, according DATALENGHT, the DATAEND flag is set.

In the following cases, the linked list provides more buffer space than the data to transfer which means the current linked list buffer data has not completely be transfered:

- the ULA bit is set, and all SDMMC data according DATALENGTH has been transfered (DATAEND flag)
- a transfer error (DCRCFAIL when DATACOUNT > 0, RXOVERR, TXUNDERR) occurs
- a transfer is hold (DTHOLD)

In all above cases, the IDMA linked list is stopped and the FIFO is flushed/reset. Before starting or restarting a new SDMMC transfer, the software must initialize a new linked list with correct IDMABASE and IDMABSIZE.

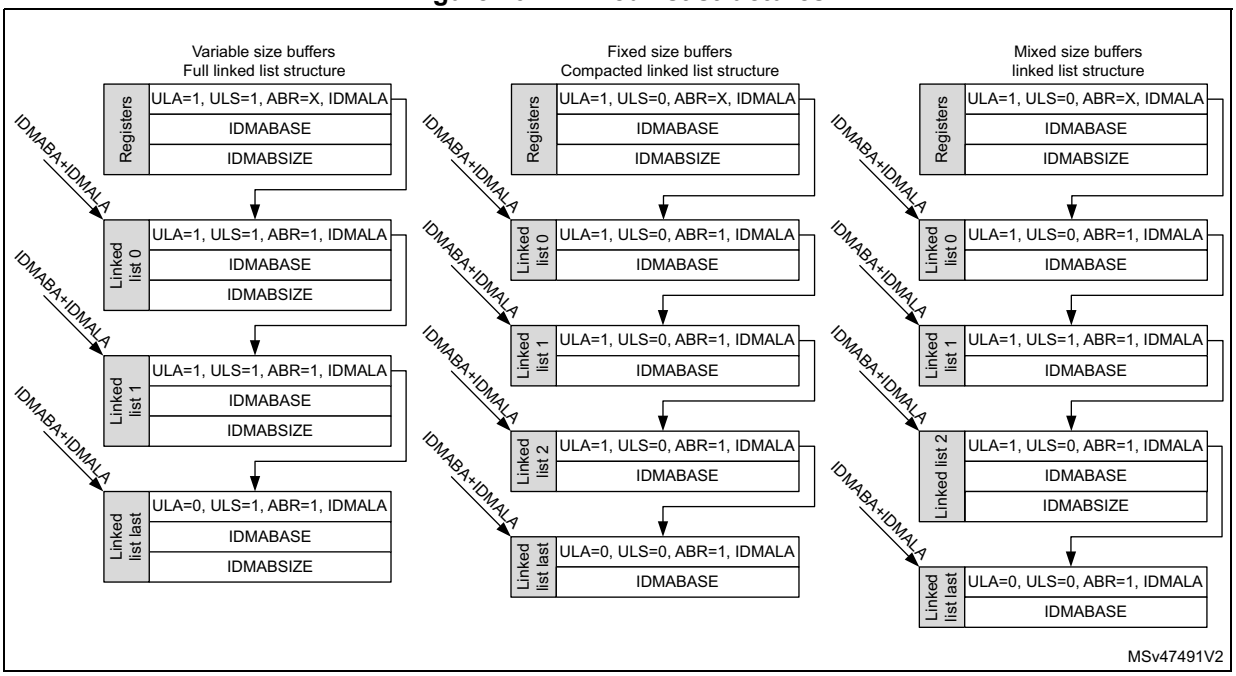
When a IDMA transfer error occurs (see *Section : IDMA transfer error management*) or when the linked list does not provide sufficient buffer space:

- the linked list ends with ULA = 0 and all last linked list buffer data has been transfered, and not all SDMMC data according DATALENGTH has been transfered. The SDMMC transfer is stopped and an IDMA transfer error is generated (see *Section : IDMA transfer error management*).

For a given linked list item, the base address is given by the linked list base IDMABA register value plus the linked list offset IDMALA register value.

The content of each linked list item can be specified by the ULS bit, which makes possible to optionally load the IDMABSIZE, resulting in a 3-word linked list structure. When the IDMABSIZE is not to be loaded (i.e. fixed size buffers) a compacted reduced 2-word linked list structure can be used containing only the IDMABASER and the IDMALAR values.

Figure 167. Linked list structures



There is no restriction on mixing both linked list item structures in a single list, this enables the IDMABSIZE to be updated only when needed.

Whenever a linked list buffer has been transfered and the current buffer ULA = 1, an end-of-linked-list-buffer-transfer-complete interrupt (IDMABTC) may be generated (if interrupt is enabled).

Linked list acknowledgment

In the case where software dynamically updates the linked list, during the SDMMC transfer, the availability of a new linked list buffer can be acknowledged by the acknowledge buffer ready (ABR) bit.

When ABR acknowledges that the new linked list buffer is ready, the IDMA continues transferring data from the new linked list buffer.

When ABR indicates that the new linked list buffer is not ready, an IDMA transfer error is generated (see *Section : IDMA transfer error management*). Depending when the IDMA transfer error occurs, it normally causes the generation of an TXUNDERR or RXOVERR error. When a linked list buffer is not acknowledged in time the SDMMC transfer is stopped.

The ABR information is “don't care” when starting the linked list from software programmed register information. The first linked list buffer must be ready to be used before starting the SDMMC transfer.

IDMA transfer error management

An IDMA transfer error can occur:

- When reading or writing a reserved address space (for data or linked list information).
- When there is no more linked list buffer space to store received SDMMC data.
- When all linked list buffer data has been transfered and still more SDMMC data needs to be sent.
- When the availability of a linked list buffer is not acknowledged.

On a IDMA transfer error subsequent IDMA transfers are disabled and an IDMATE flag is set and hardware flow control is disabled. Depending when the IDMA transfer error occurs, it normally causes the generation of a TXUNDERR or RXOVERR error.

The behavior of the IDMATE flag depend on when the IDMA transfer error occurs during the SDMMC transfer:

- An IDMA transfer error is detected before any SDMMC transfer error (TXUNDERR, RXOVERR, DCRCFAIL, or DTIMEOUT):
  - The IDMATE flag is set at the same time as the SDMMC transfer error flag.
  - The TXUNDERR, RXOVERR, DCRCFAIL, or DTIMEOUT interrupt is generated.
- An IDMA transfer error is detected during a STOP_TRANSNMISSION command:
  - The IDMATE flag is set at the same time as the DABORT flag.
  - The DABORT interrupt is generated.
- An IDMA transfer error is detected at the end of the SDMMC transfer (DHOLD, or DATAEND).
  - The IDMATE flag is set at the end of the SDMMC transfer.
  - A SDMMC transfer end interrupt is generated and a DHOLD or DATAEND flag is set.

The IDMATE is generated on an other SDMMC transfer interrupt (TXUNDERR. RXOVERR, DCRCFAIL, DTIMEOUT, DABORT, DHOLD, or DATAEND).

24.5.7 AHB and SDMMC_CK clock relation

The AHB must at least have 3x more bandwidth than the SDMMC bus bandwidth i.e. for SDR50 4-bit mode (50 Mbyte/s) the minimum sdmmc_hclk frequency is 37.5 MHz (150 Mbyte/s).

Table 229. AHB and SDMMC_CK clock frequency relation

SDMMC bus mode	SDMMC bus width	Maximum SDMMC_CK [MHz]	Minimum AHB clock [MHz]
e•MMC DS	8	26	19.5
e•MMC HS	8	52	39
e•MMC DDR52	8	52	78
e•MMC HS200	8	200	150
SD DS / SDR12	4	25	9.4
SD HS / SDR25	4	50	18.8
SD DDR50	4	50	37.5
SD SDR50	4	100	37.5
SD SDR104	4	208	78

24.6 Card functional description

24.6.1 SD I/O mode

The following features are SDMMC specific operations:

- SDIO interrupts
- SDIO suspend/resume operation (write and read suspend)
- SDIO Read Wait operation by stopping the clock
- SDIO Read Wait operation by SDMMC_D2 signaling

Table 230. SDIO special operation control

Operation mode	SDIOEN	RWMOD	RWSTOP	RWSTART	DTDIR
Interrupt detection	1	X	X	X	X
Suspend/Resume operation	X	X	X	X	X
Read Wait SDMMC_CK clock stop (START)	X	1	0	1	1
Read Wait SDMMC_CK clock stop (STOP)	X	1	1	1	1
Read Wait SDMMC_D2 signaling (START)	X	0	0	1	1
Read Wait SDMMC_D2 signaling (STOP)	X	0	1	1	1

SD I/O interrupts

To allow the SD I/O card to interrupt the host, an interrupt function is available on pin 8 (shared with SDMMC_D1 in 4-bit mode) on the SD interface. The use of the interrupt is optional for each card or function within a card. The SD I/O interrupt is level-sensitive, which means that the interrupt line must be held active (low) until it is either recognized and acted upon by the host or deasserted due to the end of the interrupt period. After the host has serviced the interrupt, the interrupt status bit is cleared via an I/O write to the appropriate bit in the SD I/O card internal registers. The interrupt output of all SD I/O cards is active low and the application must provide external pull-up resistors on all data lines (SDMMC_D[3:0]).

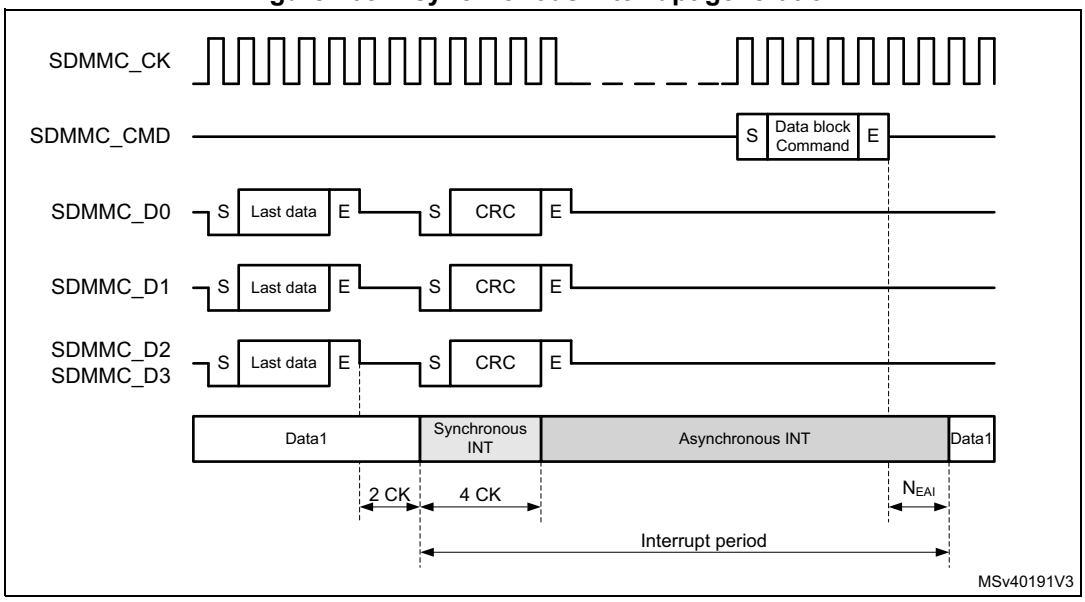
In SD 1-bit mode pin 8 is dedicated to the interrupt function (IRQ), and there are no timing constraints on interrupts.

In SD 4-bit mode the host samples the level of pin 8 (SDMMC_D1/IRQ) into the interrupt detector only during the interrupt period. At all other times, the host interrupt ignores this value. The interrupt period begins when interrupts are enabled at the card and SDIOEN bit is set see register settings in *Table 230*.

In 4-bit mode the card can generate a synchronous or asynchronous interrupt as indicated by the card CCCR register SAI and EAI bits.

- Synchronous interrupt, require the SDMMC_CK to be active.
- Asynchronous interrupt, can be generated when the SDMMC_CK is stopped, 4 cycles after the start of the card interrupt period following the last data block.

Figure 168. Asynchronous interrupt generation



The timing of the interrupt period is depended on the bus speed mode:

In DS, HS, SDR12, and SDR25 mode, selected by register bit BUSSPEED, the interrupt period is synchronous to the SD clock.

- The interrupt period ends at the next clock from the end bit of a command that transfers data block(s) (Command sent with the CMDTRANS bit is set), or when the DTEN bit is set.
- The interrupt period resumes 2 SDMMC_CK after the completion of the data block.
- At the data block gap the interrupt period is limited to 2 SDMMC_CK cycles.

Note: DTEN must not be used to start data transfer with SD and e•MMC cards.

Figure 169. Synchronous interrupt period data read

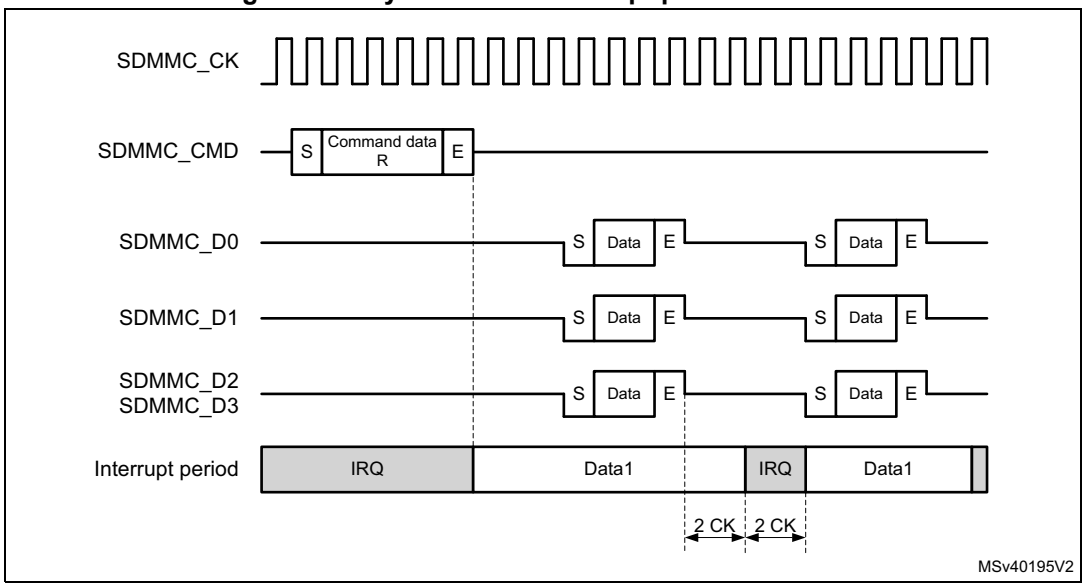


Figure 170. Synchronous interrupt period data write

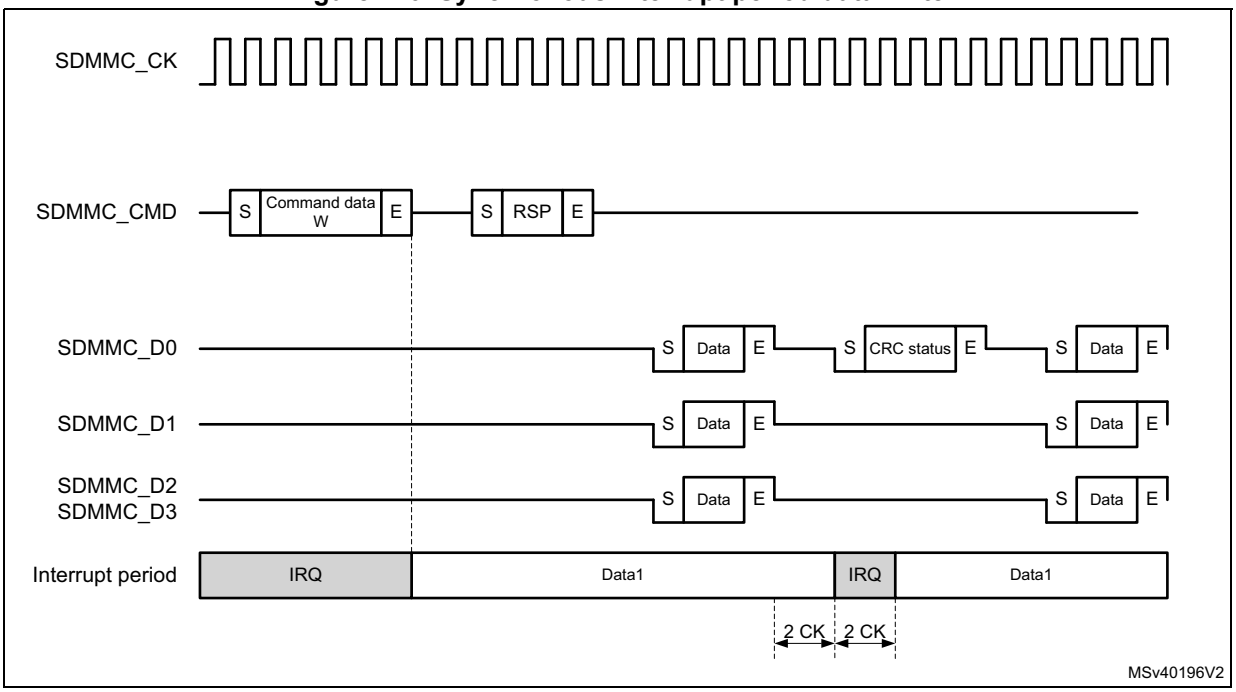

In SDR50, SDR104, and DDR50, selected by register bit BUSSPEED, due to propagation delay from the card to host, the interrupt period is asynchronous.

- The card interrupt period ends after 0 to 2 SDMMC_CK cycles after the end bit of a command that transfers data block(s) (Command sent with the CMDTRANS bit is set), or when the DTEN bit is set. At the host the interrupt period ends after the end bit of a command that transfers data block(s). A card interrupt issued in the 1 to 2 cycles after the command end bit are not detected by the host during this interrupt period.
- The card interrupt period resumes 2 to 4 SDMMC_CK after the completion of the last data block. The host resumes the interrupt period always 2 cycles after the last data block.
- There is NO interrupt period at the data block gap.

Note: DTEN must not be used to start data transfer with SD and e•MMC cards.

Figure 171. Asynchronous interrupt period data read

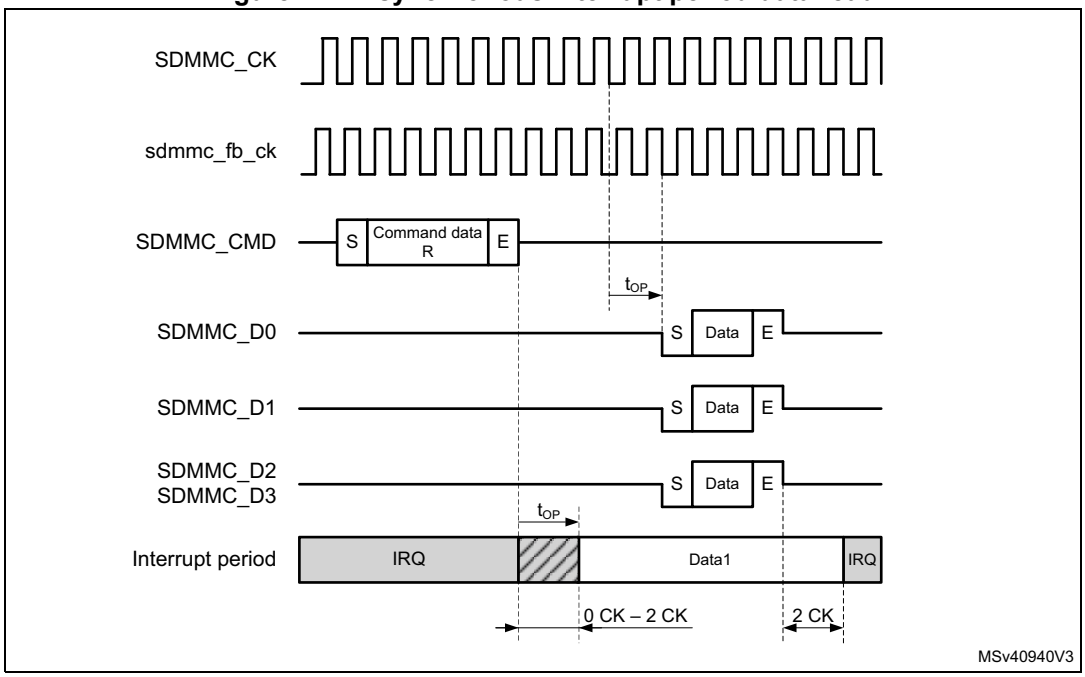

Figure 172. Asynchronous interrupt period data write

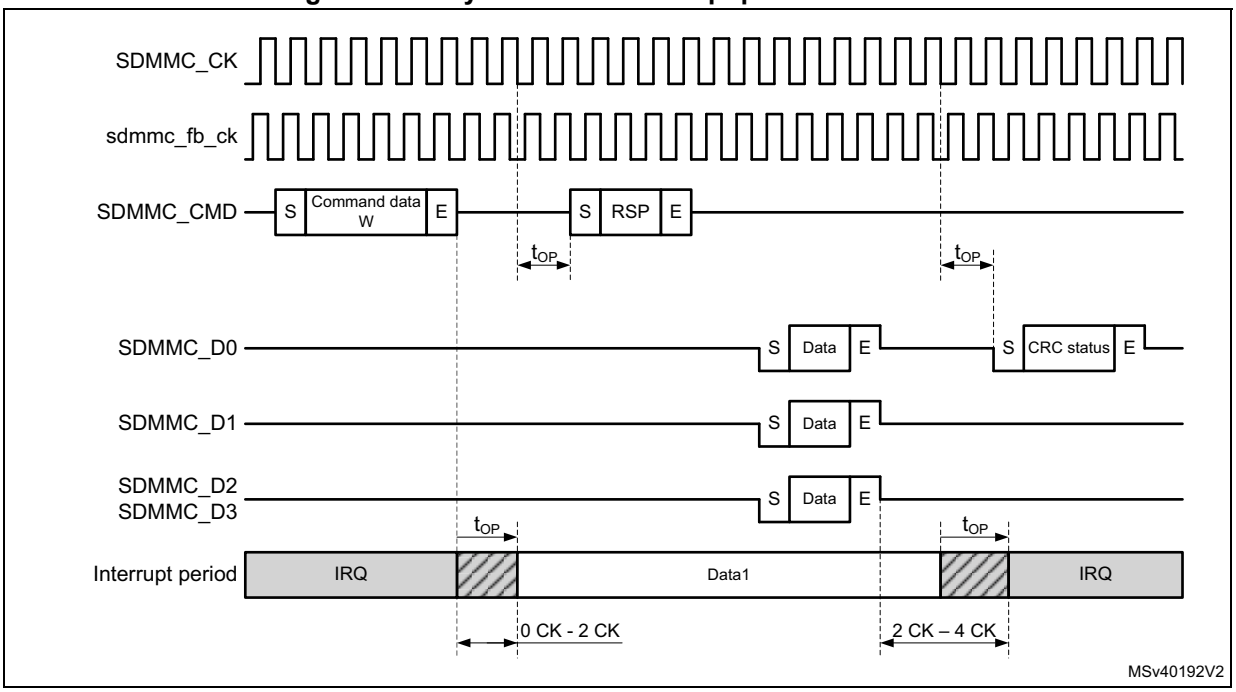


When transferring Open-ended multiple block data and using DTMODE “block data transfer ending with STOP_TRANSMISSION command”, the SDMMC masks the interrupt period after the last data block until the end of the CMD12 STOP_TRANSMISSION command.

The interrupt period is applicable for both memory and I/O operations.

In 4-bit mode interrupts can be differentiated from other signaling according *Table 231*.

Table 231. 4-bit mode Start, interrupt, and CRC-status Signaling detection

SDMMC data line	Start	Interrupt	CRC-status
SDMMC_D0	0	1 or CRC-status	0
SDMMC_D1	0	0	X
SDMMC_D2	0	1 or Read Wait	X
SDMMC_D3	0	1	X

SD I/O suspend and resume

This function is NOT supported in SDIO version 4.00 or later.

Within a multifunction SD I/O or a card with both I/O and memory functions, there are multiple devices (I/O and memory) that share access to the *e*•MMC/SD bus. To share access to the host among multiple devices, SD I/O and combo cards optionally implement the concept of suspend/resume. When a card supports suspend/resume, the host can temporarily halt (suspend) a data transfer operation to one function or memory to free the bus for a higher-priority transfer to a different function or memory. After this higher-priority transfer is complete, the original transfer is restarted (resume) where it left off.

To perform the suspend/resume operation on the bus, the host performs the following steps:

1. Determines the function currently using the SDMMC_D[3:0] line(s)
2. Requests the lower-priority or slower transaction to suspend
3. Waits for the transaction suspension to complete
4. Begins the higher-priority transaction
5. Waits for the completion of the higher priority transaction
6. Restores the suspended transaction

The card receiving a suspend command responds with its current bus status. Only when the bus has been suspended by the card the bus status indicates suspension completed.

There are different suspend cases conditions:

- Suspend request accepted prior to the start of data transfer.
- Suspend request not accepted, (due to data being transfered at the same time), the host keeps checking the request until it is accepted. (data transfer has suspended)
- Suspend request during write busy.
- Suspend request with write multiple.
- Suspend request during Read Wait.

For the host to know if the bus has been released it must check the status of the suspend request, suspension completed.

When the bus status of the suspend request response indicates suspension completed, the card has released the bus. At this time the state of the suspended operation must be saved where after an other operation can start.

The suspend command must be sent with the CMDSUSPEND bit set. This makes possible to start the interrupt period after the suspend command response when the bus is suspended (response bit BS = 0).

The hardware does not save the number of remaining data to be transfered when resuming the suspended operation. It is up to firmware to determine the data that has been transferred and resume with the correct remaining number of data bytes.

While receiving data from the card, the SDMMC can suspend the read operation after the read data block end (DPSM in Wait_R). After receiving the suspend acknowledgment response from the card the following steps must be taken by firmware:

1. The normal receive process must be stopped by setting DTHOLD bit.
   a) The remaining number of data bytes in the FIFO must be read until the receive FIFO is empty (RXFIFOE flag is set), and when IDMAEN = 0 the FIFO must be reset with FIFORST.
2. The confirmation that all data has been read from the FIFO, and that the suspend is completed is indicated by the DHOLD flag.
   a) The remaining number of data bytes (multiple of data blocks) still to be read when resuming the operation must be determined from the remaining number of bytes indicated by the DATACOUNT.

Note: When a DTIMEOUT flag occurs during the suspend procedure, this must be ignored.

To resume receiving data from the card, the following steps must be taken by firmware:

1. The remaining number of data bytes (multiple of data blocks) must be programmed in DATALENGTH.
2. The DPSM must be configured to receive data in the DTDIR bit.
3. The resume command must be sent from the CPSM, with the CMDTRANS bit set and the CMDSUSPEND bit set, which ends the interrupt period when data transfer is resumed (response bit DF = 1) and enabled the DPSM, after which the card resumes sending data.

While sending data to the card, the SDMMC can suspend the write operation after the write data block CRC status end (DPSM in Busy). Before sending the suspend command to the card the following steps must be taken by firmware:

1. Enable DHOLD flag (and DBCKEND flag when IDMAEN = 0)
2. The DPSM must be prevented from start sending a new data block by setting DTHOLD.
3. When IDMAEN = 0: When receiving the DBCKEND flag the data transfer is stopped. Firmware can stop filling the FIFO, after which the FIFO must be reset with FIFORST. Any bytes still in the FIFO need to be rewritten when resuming the operation.
4. When receiving the DHOLD flag the data transfer is stopped. The remaining number of data bytes still to be written when resuming must be determined from the remaining number of bytes indicated by the DATACOUNT.
5. To suspend the card the suspend command must be sent by the CPSM with the CMDSUSPEND bit set. This makes possible to start the interrupt period after the suspend command response when the bus is suspended (response bit BS = 0).

To resume sending data to the card, the following steps must be taken by firmware:

1. The remaining number of data bytes must be programmed in DATALENGTH.
2. The DPSM must be configured for transmission with DTDIR set and enabled by having the CPSM send the resume command with the CMDTRANS bit set and the CMDSUSPEND bit set. This ends the interrupt period and start the data transfer. The DPSM either goes to the Wait_S state when SDMMC_D0 does not signal busy, or goes to the Busy state when busy is signaled.
3. When IDMAEN = 1: The IDMA needs to be reprogrammed for the remaining bytes to be transfered.
4. When IDMAEN = 0: Firmware must start filling the FIFO with the remaining data.

SD I/O Read Wait

There are 2 methods to pause the data transfer during the Block gap:

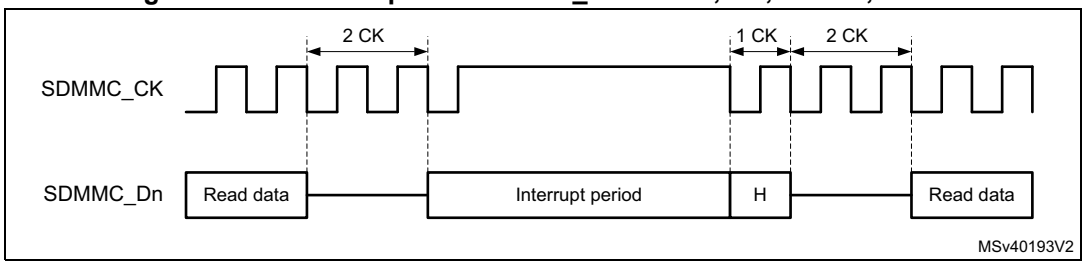
1. Stopping the SDMMC_CK.
2. Using Read Wait signaling on SDMMC_D2.

The SDMMC can perform a Read Wait with register settings according *Table 230*.

Depending the SDMMC operation mode (DS, HS, SDR12, SDR25) or (SDR50, SDR104, DDR) each method has a different characteristic.

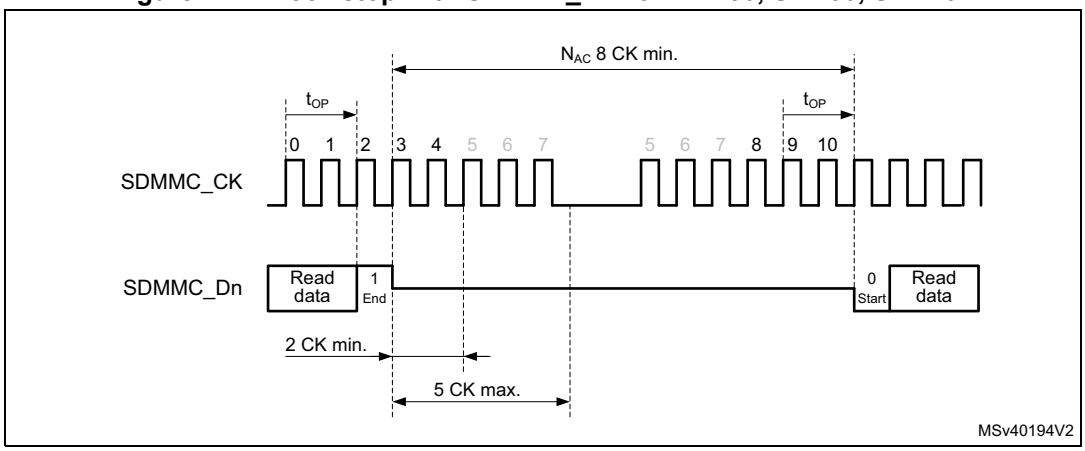
The timing for pause read operation by stopping the SDMMC_CK for DS, HS, SDR12, and SDR25, the SDMMC_CK may be stopped 2 SDMMC_CK cycles after the end bit. When ready the host resumes by restarting clock, see *Figure 173*.

Figure 173. Clock stop with SDMMC_CK for DS, HS, SDR12, SDR25



The timing for pause read operation by stopping the SDMMC_CK for SDR50, SDR104, and DDR50, the SDMMC_CK may be stopped minimum 2 SDMMC_CK cycles and maximum 5 SDMMC_CK cycles, after the end bit. When ready the host resumes by restarting clock, see *Figure 174*. (In DDR50 mode the SDMMC_CK must only be stopped after the falling edge, when the clock line is low.)

Figure 174. Clock stop with SDMMC_CK for DDR50, SDR50, SDR104



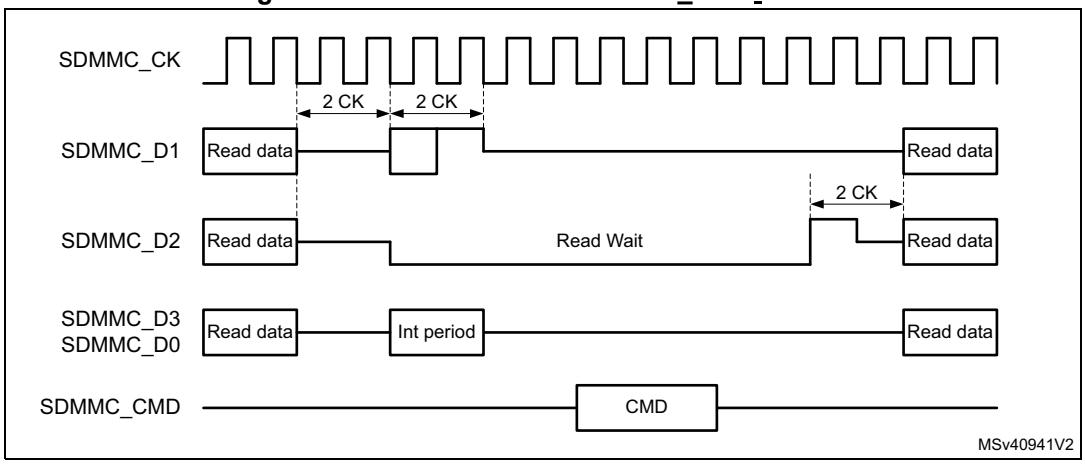
In Read Wait SDMMC_CK clock stopping, when RWSTART is set, the DSPM stops the clock after the end bit of the current received data block CRC. The clock start again after writing 1 to the RWSTOP bit, where after the DPSM waits for a start bit from the card.

As SDMMC_CK is stopped, no command can be issued to the card. During a Read Wait interval, the SDMMC can still detect SDIO interrupts on SDMMC_D1.

The optional Read Wait signaling on SDMMC_D2 (RW) operation is defined only for the SD 1-bit and 4-bit modes. The Read Wait operation enables the host to signal a card that is reading multiple registers (IO_RW_EXTENDED, CMD53) to temporarily stall the data transfer while allowing the host to send commands to any function within the SD I/O device. To determine when a card supports the Read Wait protocol, the host must test capability bits in the internal card registers.

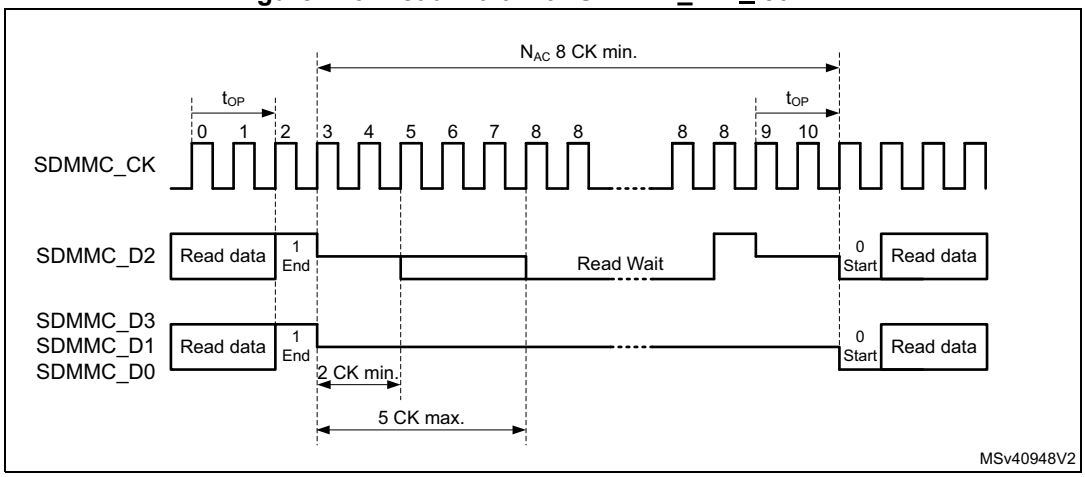
The timing for Read Wait with a SDMMC_CK less then 50MHz (DS, HS, SDR12, SDR25) is based on the interrupt period generated by the card on SDMMC_D1. The host by asserting SDMMC_D2 low during the interrupt period requests the card to enter Read Wait. To exit Read Wait the host must raise SDMMC_D2 high during one SDMMC_CK cycles before making it Hi-Z, see *Figure 175*.

Figure 175. Read Wait with SDMMC_CK < 50 MHz



For SDR50, SDR104 with a SDMMC_CK more than 50MHz, and DDR50, the card treats the Read Wait request on SDMMC_D2 as an asynchronous event. The host by asserting SDMMC_D2 low after minimum 2 SDMMC_CK cycles and maximum 5 SDMMC_CK cycles, request the card to enter Read Wait. To exit Read Wait the host must raise SDMMC_D2 high during one SDMMC_CK cycles before making it Hi-Z. The host must raise SDMMC_D2 on the SDMMC_CK clock (see *Figure 176*).

Figure 176. Read Wait with SDMMC_CK ≥ 50 MHz



In Read Wait SDMMC_D2 signaling, when RWSTART is set, the DPSM drives SDMMC_D2 after the end bit of the current received data block CRC. The Read Wait signaling on SDMMC_D2 is removed when writing 1 to the RWSTOP bit. The DPSM remains in R_W state for two more SDMMC_CK clock cycles to drive SDMMC_D2 to 1 for one clock cycle (in accordance with SDIO specification), where after the DPSM waits for a start bit from the card.

During the Read Wait signaling on SDMMC_D2 commands can be issued to the card. During the Read Wait interval, the SDMMC can detect SDIO interrupts on SDMMC_D1.

24.6.2 CMD12 send timing

CMD12 is used to stop/abort the data transfer, the card data transmission is terminated two clock cycles after the end bit of the Stop Transmission command.

Table 232. CMD12 use cases

Data operation	Stop Transmission command CMD12 Description
SDMMC stream write	The data transfer is stopped/aborted by sending the Stop Transmission command.
SDMMC open ended multiple block write	The data transfer is stopped/aborted by sending the Stop Transmission command. If the card detects an error, the host must abort the operation by sending the Stop Transmission command.
SDMMC block write with predefined block count	The Stop Transmission command is not required at the end of this type of multiple block write. (sending the Stop Transmission command after the card has received the last block is regarded as an illegal command.) If the card detects an error, the host must abort the operation by sending the Stop Transmission command.
SDMMC stream read	The data transfer is stopped/aborted by sending the Stop Transmission command.
SDMMC open ended multiple block read	The data transfer is stopped/aborted by sending the Stop Transmission command. If the card detects an error, the host must abort the operation by sending the Stop Transmission command.
SDMMC block read with predefined block count	The Stop Transmission command is not required at the end of this type of multiple block read. (sending the Stop Transmission command after the card has transmitted the last block is regarded as an illegal command.) Transaction can be aborted by sending the Stop Transmission command. If the card detects an error, the host must abort the operation by sending the Stop Transmission command.

All data write and read commands can be aborted any time by a Stop Transmission command CMD12. The following data abort procedure applies during an ongoing data transfer:

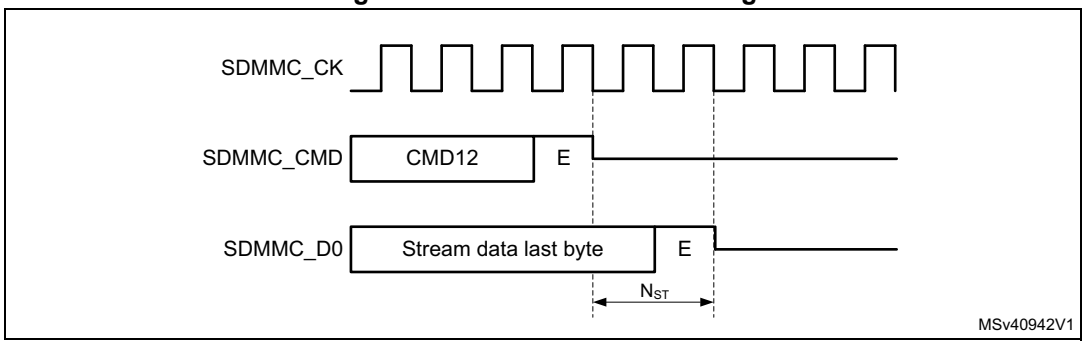
1. Load CMD12 Stop Transmission command in registers and set the CMDSTOP bit.
   a) This causes the CPSM Abort signal to be generated when the command is sent to the DPSM.
2. Configure the CPSM to send a command immediately (clear WAITPEND bit).
   a) The card, when sending data, stops data transfer 2 cycles after the Stop Transmission command end bit.
   The card when no data is being sent, does not start sending any new data.
   b) The host, when sending data, sends one last data bit followed by an end bit after the Stop Transmission command end bit.
   The host when not sending data, does not start sending any new data.
3. When IDMAEN = 0, the FIFO need to be reset with FIFORST.
   a) When writing data to the card. On the CMDREND flag, firmware must stop writing data to the FIFO. Subsequently the FIFO must be reset with FIFORST, this flushes the FIFO.
   b) When reading data from the card. On the CMDREND flag, firmware must read the remaining data from the FIFO. Subsequently the FIFO must be reset with FIFORST.
4. When IDMAEN = 1, hardware takes care of the FIFO.
   a) When writing data to the card. On the CPSM Abort signal, hardware stops the IDMA and subsequently the FIFO is flushed.
   b) When reading data from the card. On the CPSM Abort signal, hardware instructs the IDMA to transfer the remaining data from the FIFO to RAM.
5. When the FIFO is empty/reset the DABORT flag is generated.

Stream operation and CMD12

To stop the stream transfer after the last byte to be transfered, the CMD12 end bit timing must be sent aligned with the data stream end of last byte. The following write stream data procedure applies:

1. Initialize the stream data in the DPSM, DTMODE = MCC stream data transfer.
2. Send the WRITE_DATA_STREAM command from the CPSM with CMDTRANS = 1.
3. Preload CMD12 in command registers, with the CMDSTOP bit set.
4. Configure the CPSM to send a command only after a wait pending (WAITPEND = 1) end of last data (according DATALENGTH).
5. Enabling the CPSM to send the STOP_TRANSMISSION command, the stream data end bit and command end bit are aligned.
   a) When DATALENGTH > 5 bytes, Command CMD12 is waited in the CPSM to be aligned with the data transfer end bit.
   b) When DATALENGHT < 5 bytes, Command CMD12 is started before and the DPSM remains in the Wait_S state to align the data transfer end with the CMD12 end bit.
6. The write stream data can be aborted any time by clearing the WAITPEND bit. This causes the Preloaded CMD12 to be sent immediately and stop the write data stream.

Figure 177. CMD12 stream timing



To stop the read stream transfer after the last byte, the CMD12 end bit timing must occur after the last data stream byte. The following read stream data procedure applies:

1. Wait for all data to be received by the DPSM and read from the FIFO (DATAEND flag).
   a) The DPSM does not receive more data than indicated by DATALENGTH, even if the card is sending more data.
2. Send CMD12 by the CPSM.
   a) CMD12 stops the card sending data.

Note: The SDMMC does not receive any more data from the card when DATACOUNT = 0, even when the card continues sending data.

Block operation and CMD12

To stop block transfer at the end of the data, the CMD12 end bit must be sent after the last block end bit.

When writing data to the card the CMD12 end bit must be sent after the write data block CRC token end bit. This requires the CMD12 sending to be tied to the data block transmission timing. To stop an Open-ended Multiple block write, the following procedure applies:

1. Before starting the data transfer, set DTMODE to “block data transfer ending with STOP_TRANSMISSION command”.
2. Wait for all data to be sent by the DPSM and the CRC token to be received, (DATAEND flag).
   a) The DPSM does not send more data than indicated by DATALENGTH.
3. Send CMD12 by the CPSM.
   a) CMD12 sets the card to Idle mode.

When reading data from the card the CMD12 end bit must be sent earliest at the same time as the card read data block last data bit. This requires the CMD12 sending to be tied to the data block reception timing. The following stop Open-ended Multiple block read data block procedure applies:

1. Before starting the data transfer, set DTMODE to “block data transfer ending with STOP_TRANSMISSION command”.
2. Wait for all data to be received by the DPSM and read from the FIFO (DATAEND flag).
   a) The DPSM does not receive more data than indicated by DATALENGTH, even if the card is sending more data.
3. Send CMD12 with CMDSTOP bit set by the CPSM.
   a) CMD12 stops the Card sending more data and set the card to Idle mode. Any ongoing block transfer is aborted by the Card.

Note: The SDMMC does not receive any more data from the card when DATACOUNT = 0, even when the card continues sending data.

24.6.3 Sleep (CMD5)

The *e*•MMC card may be switched between a Sleep state and a Standby state by CMD5. In the Sleep state the power consumption of the card is minimized and the Vcc power supply may be switched off.

The CMD5 (SLEEP) is used to initiate the state transition from Standby state to Sleep state. The card indicates Busy, pulling down SDMMC_D0, during the transition phase. The Sleep state is reached when the card stops pulling down the SDMMC_DO line.

To set the card into Sleep state the following procedure applies:

1. Enable interrupt on BUSYD0END.
2. Send CMD5 (SLEEP).
3. On BUSYD0END interrupt, card is in Sleep state
4. Vcc power supply can be switched off

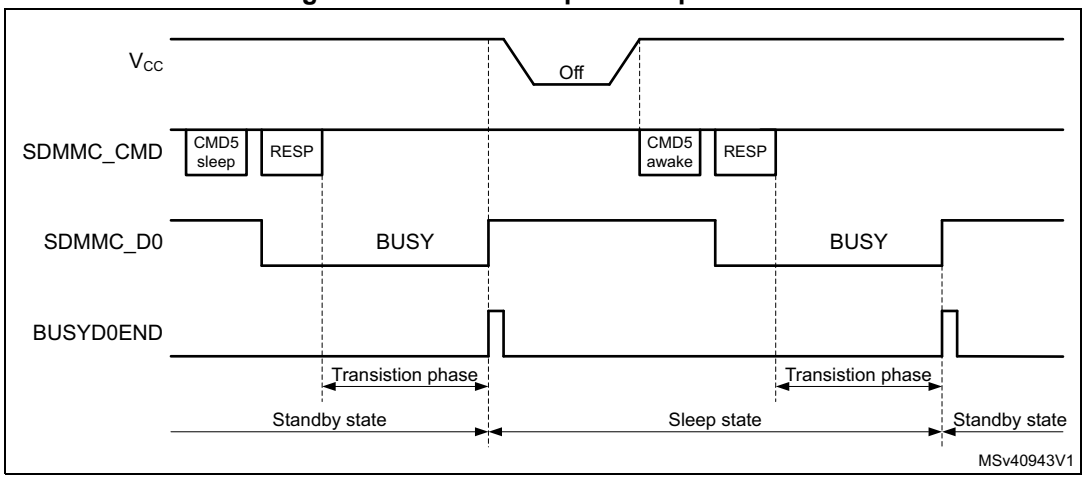
The CMD5 (AWAKE) is used to initiate the state transition from Sleep state to Standby state. The card indicates Busy, pulling down SDMMC_D0, during the transition phase. The Standby state is reached when the card stops pulling down the SDMMC_DO line.

To set the card into Sleep state the following procedure applies:

1. Switch on Vcc power supply and wait unit minimum operating level is reached.
2. Enable interrupt on BUSYD0END.
3. Send CMD5 (AWAKE).
4. On BUSYD0END interrupt card is in Standby state.

The Vcc power supply can be switched off only after the Sleep state has been reached. The Vcc supply must be reinstalled before CMD5 (AWAKE) is sent.

Figure 178. CMD5 Sleep Awake procedure



24.6.4 Interrupt mode (Wait-IRQ)

The host and card enter and exit interrupt mode (Wait-IRQ) simultaneously. In interrupt mode there is no data transfer. The only message allowed is an interrupt service request response from the card or the host. For the interrupt mode to work correctly the SDMMC_CK frequency must be set in accordance with the achievable SDMMC_CMD data rate in Open Drain mode, which depend on the capacitive load and pull-up resistor. The CLKDIV must be set >1, and the SETCLKRX must select either the sdmmc_io_in_ck or SDMMC_CLKin source.

The host must ensure that the card is in Standby state before issuing the CMD40 (GO_IRQ_STATE). While waiting for an interrupt response the SDMMC_CK clock signal must be kept active.

A card in interrupt mode (IRQ state):

- is waiting for an internal card interrupt event. Once the event occurs, the card starts to send the interrupt service request response. The response is sent in open-drain mode.
- while waiting for the internal card interrupt event, the card also monitors the SDMMC_CMD line for a start bit. Upon detection of a start bit the card aborts the interrupt mode and switch to Standby state.

The host in interrupt mode (CPSM Wait state waiting for interrupt):

- is waiting for a card interrupt service request response (start bit).
- while waiting for a card interrupt service request response the host may abort the interrupt mode (by clearing the WAITINT register bit), which causes the host to send a interrupt service request response R5 with RCA = 0x0000 in open-drain mode.

When sending the interrupt service request response, the sender bit-wise monitors the SDMMC_CMD bit stream. The sender whose interrupt service request response bit does not correspond to the bit on the SDMMC_CMD line stops sending. In the case of multiple senders only one successfully sends its full interrupt service request response. If the host sends simultaneously, it loses sending after the transmission bit.

To handle the interrupt mode, the following procedure applies:

1. Set the SDMMC_CK frequency in accordance with the achievable SDMMC_CMD data rate in Open-drain mode, CLKDIV must be set >1, and SETCLKRX must select the sdmmc_io_in_ck.
2. Load CMD40 (GO_IRQ_STATE) in the command registers.
3. Enable wait for interrupt by setting WAITINT register bit.
4. Configure the CPSM to send a command immediately.
   a) This causes the CMD40 to be sent and the CPSM to be halted in the Wait state, waiting for a interrupt service request response.
5. To exit the wait for interrupt state (CPSM Wait state):
   a) Upon the detection of an interrupt service request response start bit the CPSM moves to the Receive state where the response is received. The complete reception of the response is indicated by the CMDREND or the command CRC error flags.
   b) To abort the interrupt mode the host clears the WAITINT register bit, which causes the host to send an interrupt service request response by itself. This moves the CPSM to the Receive state. The complete reception of the response is indicated by the CMDREND or the command CRC error flags.

Note: On a simultaneous send interrupt service request response start bit collision the host loses the bus access after the transmission bit.

24.6.5 Boot operation

In boot operation mode the host can read boot data from the card by either one of the 2 boot operation functions:

1. Normal boot. (keeping CMD line low)
2. Alternative boot (sending CMD0 with argument 0xFFFFFFFA)

The boot data can be read according the following configuration options, depending on card register settings:

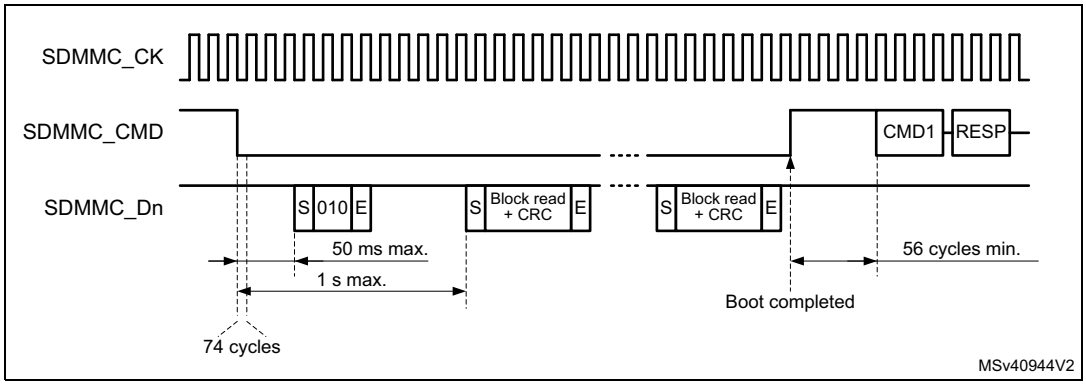
- The partition from which boot data is read (EXT_CSD Byte[179])
- The boot data size (EXT_CSD Byte[226])
- The bus configuration during boot (EXT_CSD Byte[177])
- Receiving boot acknowledgment from the card. (EXT_CSD Byte[179])

If boot acknowledgment is enabled the card send pattern 010 on SDMMC_D0 within 50ms after boot mode has been requested by either CMD line going low or after CMD0 with argument 0xFFFFFFFA. A boot acknowledgment timeout (ACKTIMEOUT) and acknowledgment status (ACKFAIL) is provided.

Normal boot operation

If the SDMMC_CMD line is held low for at least 74 clock cycles after card power-up or reset, before the first command is issued, the card recognizes that boot mode is being initiated. Within 1 second after the CMD line goes low, the card starts to sent the first boot code data on the SDMMC_Dn line(s). The host must keep the SDMMC_CMD line low until after all boot data has been read. The host can terminate boot mode by pulling the SDMMC_CMD line high.

Figure 179. Normal boot mode operation



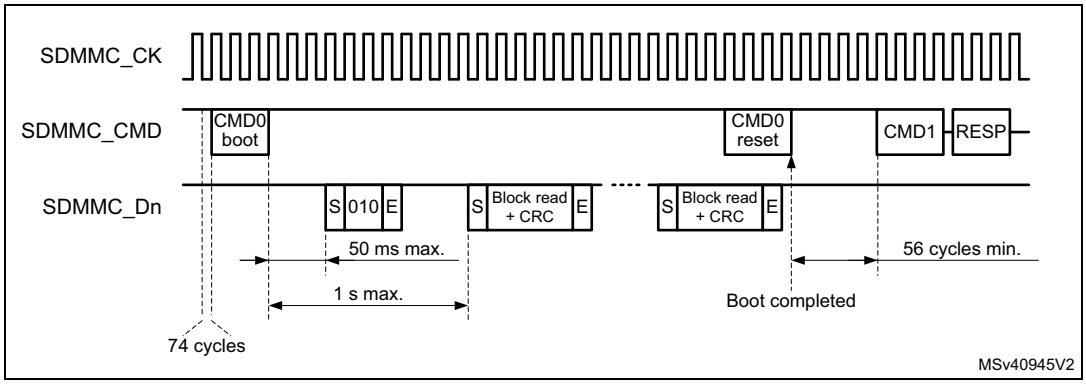
To perform the normal boot procedure the following steps needed:

1. Reset the card.
2. if a boot acknowledgment is requested enable the BOOTACKEN and set the ACKTIME and enable the ACKFAIL and ACKTIMEOUT interrupt.
3. enable the data reception by setting the DPSM in receive mode (DTDIR) and the number of data bytes to be received in DATALENGTH.
4. Enable the DTIMEOUT, DATAEND, and CMDSENT interrupts for end of boot command confirmation.
5. Select the normal boot operation mode in BOOTMODE, and enable boot in BOOTEN. The boot procedure is started by enabling the CPSM with CPSMEN.This causes:
   – the SDMMC_CMD to be driven low. (BOOTMODE = normal boot).
   – the ACK timeout to start.
   – DPSM to be enabled.
6. The incorrect reception of the boot acknowledgment can be detected with ACKFAIL flag or ACKTIMEOUT flag when enabled.
   – when an incorrect boot acknowledgment is received the ACKFAIL flag occurs.
   – when the boot acknowledgment is not received in time the ACKTIMEOUT flag occurs.
7. when all boot data has been received the DATAEND flag occurs.
   – when data CRC fails the DCRCFAIL flag is also generated.
   – when the data timeout occurs the DTIMEOUT flag is also generated.
8. When last data has been received, read data from the FIFO until FIFO is empty after which end of data DATAEND flag is generated.
   – SDMMC has completely received all data and the DPSM is disabled.
9. The boot procedure is terminated by firmware clearing BOOTEN, which causes the SDMMC_CMD line to go high. The CMDSENT flag is generated 56 cycles later to indicate that a new command can be sent.
   a) If the boot procedure is aborted by firmware before all data has been received the CPSM Abort signal stops data reception and disables the DPSM which triggers an DABORT flag when enabled.
10. The CMDSENT flag signals the end of the boot procedure and the card is ready to receive a new command.

Alternative boot operation

After card power-up or reset, if the host send CMD0 with the argument 0xFFFFFFFA after 74 clock cycles before CMD0 is issued, the card recognizes that boot mode is being initiated. Within 1 second after the CMD0 with argument 0xFFFFFFFA has been sent, the card starts to send the first boot code data on the SDMMC_Dn line(s). The master terminates boot operation by sending CMD0 (Reset).

Figure 180. Alternative boot mode operation



To perform the alternative boot procedure the following steps needed:

1. Move the SDMMC to power-off state, and reset the card
2. Move the SDMMC to power-on state. This guarantees the 74 SCDMMC_CK cycles to be clocked before any command.
3. if a boot acknowledgment is requested enable the BOOTACKEN and set the ACKTIME and enable the ACKTIMEOUT flag.
4. enable the data reception by setting the DPSM in receive mode (DTDIR) and the number of data to be received in DATALENGTH. Enable the DTIMEOUT and DATAEND flags.
5. Select the alternative boot operation mode in BOOTMODE, load the CMD0 with the 0xFFFFFFFA argument in the command registers. Enable CMDSENT flag for end of

boot command confirmation, and enable boot in BOOTEN. The boot procedure is started by enabling the CPSM with CPSMEN. This causes:

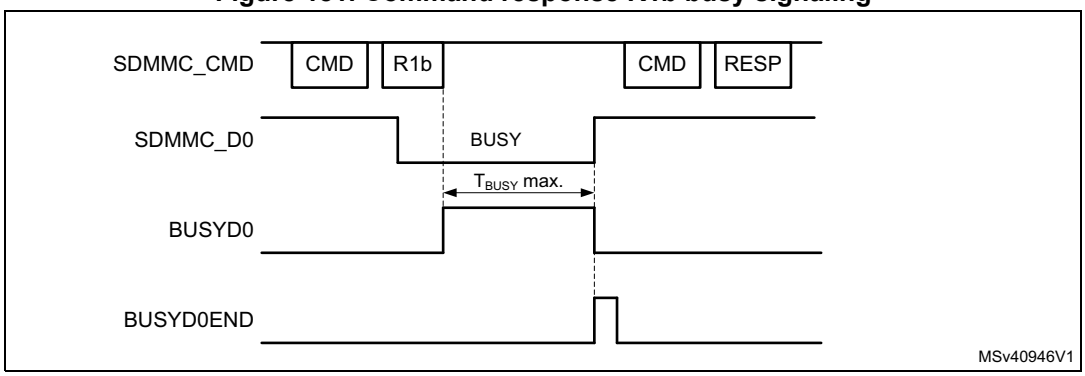
- the loaded command and argument to be sent out. (BOOTMODE = alternative boot).
- the ACK timeout to start.
- DPSM to be enabled.

6. When the command has been sent the CMDSENT flag is generated, at which time the BOOTEN bit must be cleared.
7. the reception of the boot acknowledgment can be detected with ACKFAIL flag when enabled.
   - when the boot acknowledgment is not received in time the ACKTIMEOUT flag occurs.
8. when all boot data has been received the DATAEND flag occurs.
   - when data CRC fails the DCRCFAIL flag is also generated.
   - when the data timeout occurs the DTIMEOUT flag is also generated.
9. When last data has been received, read data from the FIFO until FIFO is empty after which end of data DATAEND flag is generated.
   - SDMMC has completely received all data and the DPSM is disabled.
10. The BOOTEN bit must be cleared, before terminating the boot procedure by sending CMD0 (Reset) with BOOTMODE = alternative boot. This causes the CMDSENT flag to occur 56 cycles after the Command.
    - if the boot procedure is aborted by firmware before all data has been received the CPSM Abort signal stops the data transfer and disable the DPSM which triggers an DABORT flag when enabled.
11. The CMDSENT flag signals the end of the boot procedure and the card is ready to receive a new command. When the RESET command has been sent successfully, the BOOTMODE control bit has to be cleared to terminate the boot operation.

24.6.6 Response R1b handling

When sending commands which have a R1b response the busy signaling is reflected in the BUSYD0 register bit and the release of busy with the BUSYD0END flag. The SDMMC_D0 line is sampled at the end of the R1b response and signaled in the BUSYD0 register bit. The BUSYD0 register bit is reset to not busy when the SDMMC_D0 line release busy, at the same time the BUSYD0END flag is generated.

Figure 181. Command response R1b busy signaling



The expected maximum busy time must be set in the DATATIME register before sending the command. When enabled, the DTIMEOUT flag is set when after the R1b response busy stays active longer then the programmed time.

To detect the SDMMC_D0 busy signaling when sending a Command with R1b response the following procedure applies:

- Enable CMDREND flag
- Send Command through CPSM.
- On the CMDREND flag check the BUSYD0 register bit.
  - If BUSYD0 signals not busy, signal busy release to the Firmware
  - If BUSYD0 signals busy, wait for BUSYD0END flag
- On BUSYD0END flag signal busy released to the firmware.
- On DTIMEOUT flag busy is active longer then programmed time.

24.6.7 Reset and card cycle power

Reset

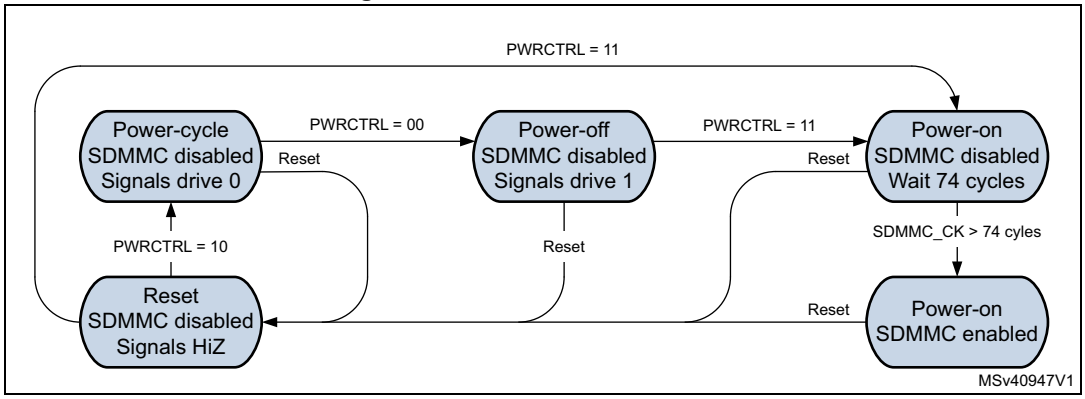
Following reset the SDMMC is in the reset state. In this state the SDMMC is disabled and no command nor data can be transfered. The SDMMC_D[7:0], and SDMMC_CMD are in HiZ and the SDMMC_CK is driven low.

Before moving to the power-on state the SDMMC must be configured.

In the power-on state the SDMMC_CK clock is running. First 74 SDMMC_CK cycles are clocked after which the SDMMC is enabled and command and data can be transfered.

The SDMMC states are controlled by Firmware with the PWRCTL register bits according *Figure 182.*.

Figure 182. SDMMC state control

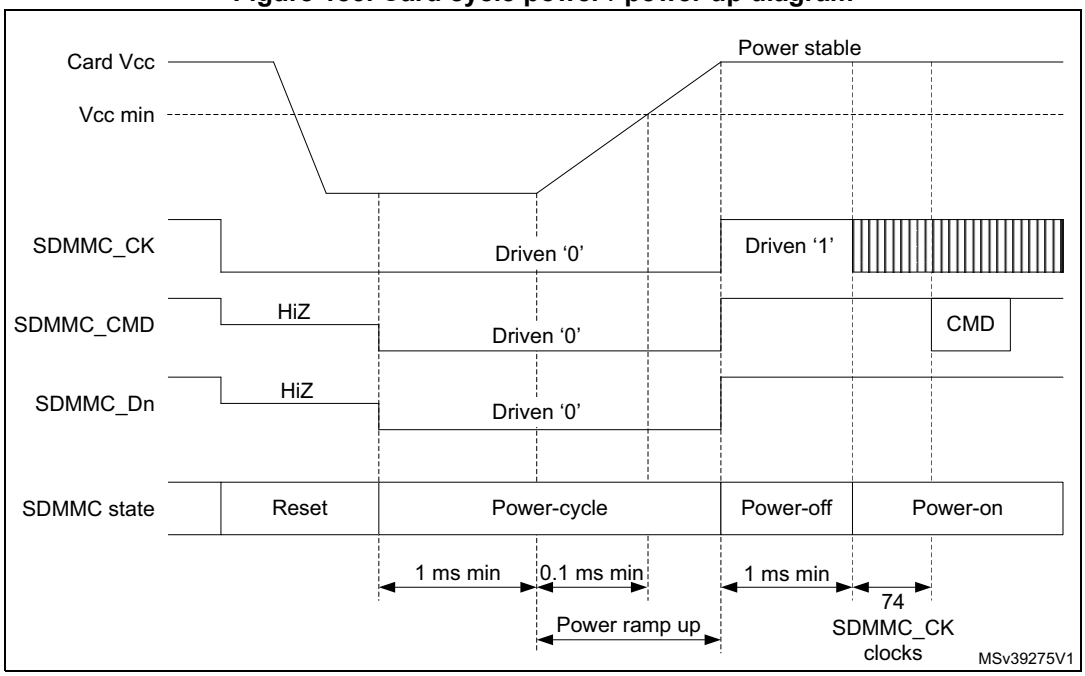


Card cycle power

To perform a card cycle power the following procedure applies:

1. Reset the SDMMC with the RCC.SDMMCxRST register bit. This resets the SDMMC to the reset state and the CPSM and DPSM to the Idle state.
2. Disable the Vcc power to the card.
3. Set the SDMMC in power-cycle state. This makes that the SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are driven low, to prevent the card from being supplied through the signal lines.
4. After minimum 1 ms enable the Vcc power to the card.
5. After the power ramp period set the SDMMC to the power-off state for minimum 1 ms. The SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are set to drive “1”.
6. After the 1 ms delay set the SDMMC to power-on state in which the SDMMC_CK clock is enabled.
7. After 74 SDMMC_CK cycles the first command can be sent to the card.

Figure 183. Card cycle power / power up diagram



24.7 Hardware flow control

The hardware flow control during data transfer functionality is used to avoid FIFO underrun (TX mode) and overrun (RX mode) errors.

The behavior is to stop SDMMC_CK during data transfer and freeze the SDMMC state machines. The data transfer is stalled when the FIFO is unable to transmit or receive data. The data transfer remains stalled until the transmit FIFO is half full or all data according DATALENGHT has been stored, or until the receive FIFO is half empty. Only state machines clocked by SDMMC_CK are frozen, the AHB interfaces are still alive. The FIFO can thus be filled or emptied even if flow control is activated.

On an IDMA linked list transfer error, the hardware flow control is disabled. As a consequence, depending on when the IDMA linked list transfer error occurs, an underrun or overrun error may also occur (see *Section : IDMA transfer error management*).

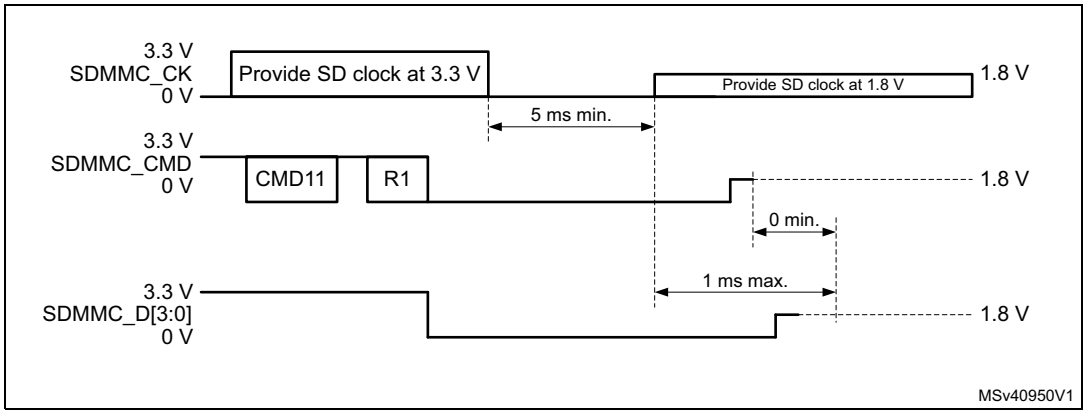
To enable hardware flow control during data transfer, the HWFC_EN register bit must be set to 1. After reset hardware flow control is disabled.

Hardware flow control must only be used when the SDMMC_Dn data is cycle-aligned with the SDMMC_CK. Whenever the sdmmc_fb_ck from the DLYB delay block is used, i.e in the case of SDR104 mode with a t_{OP} and Dt_{OP} delay > 1 cycle, hardware flow control can not be used.

24.8 Ultra-high-speed phase I (UHS-I) voltage switch

UHS-I mode (SDR12, SDR25, SDR50, SDR104, and DDR50) requires the support for 1.8V signaling. After power up the card starts in 3.3V mode. CMD11 invokes the voltage switch sequence to the 1.8V mode. When the voltage sequence is completed successfully the card enters UHS-I mode with default SDR12 and card input and output timings are changed.

Figure 184. CMD11 signal voltage switch sequence



To perform the signal voltage switch sequence the following steps are needed:

1. Before starting the Voltage Switch procedure, the SDMMC_CK frequency must be set in the range 100 kHz - 400 kHz.
2. The host starts the Voltage Switch procedure by setting the VSWITCHEN bit before sending the CMD11.
3. The card returns an R1 response.
   - if the response CRC is pass, the Voltage Switch procedure continues the host does no longer drive the CMD and SDMMC_D[3:0] signals until completion of the voltage switch sequence. Some cycles after the response the SDMMC_CK is stopped and the CKSTOP flag is set.
   - if the response CRC is fail (CCRCFAIL flag) or no response is received before the timeout (CTIMEOUT flag), the Voltage Switch procedure is stopped.
4. The card drives CMD and SDMMC_D[3:0] to low at the next clock after the R1 response.
5. The host, after having received the R1 response, may monitor the SDMMC_D0 line using the BUSYD0 register bit. The SDMMC_D0 line is sampled two SDMMC_CK clock cycles after the Response. The Firmware may read the BUSYD0 register bit following the CKSTOP flag.
   - When the BUSYD0 is detected low the host firmware switches the Voltage regulator to 1.8V, after which it instructs the SDMMC to start the timing critical

section of the Voltage Switch sequence by setting register bit VSWITCH. The hardware continues to stop the SDMMC_CK by holding it low for at least 5 ms.

– When the BUSYD0 is detected high the host aborts the Voltage Switch sequence and cycle power the card.

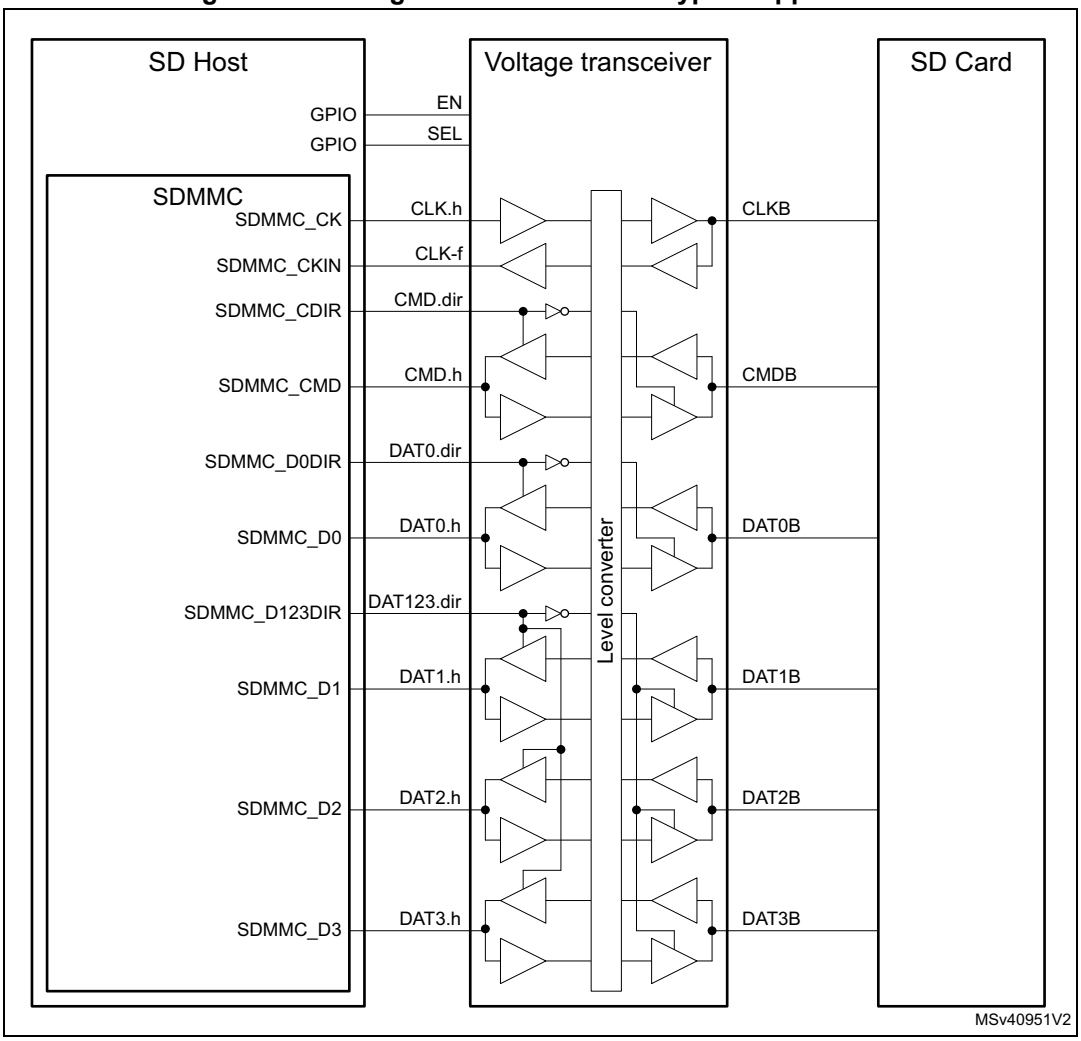
6. The card after detecting SDMMC_CK low begins switching signaling voltage to 1.8 V.
7. The host SDMMC hardware after at least 5 ms restarts the SDMMC_CK.
8. The card within 1 ms from detecting SDMMC_CK transition drives CMD and DAT[3:0] high for at least 1 SDMMC_CK cycle and then stop driving CMD and DAT[3:0].
9. The host SDMMC hardware, 1 ms after the SDMMC_CK has been restarted, the SDMMC_D0 is sampled into BUSYD0 and the VSWEND flag is set.
10. The host, on the VSWEND flag, checks SDMMC_D0 line using the BUSYD0 register bit, to confirm completion of voltage switch sequence:
    – When BUSYD0 is detected high, Voltage Switch has been completed successfully.
    – When BUSYD0 is detected low, Voltage Switch has failed, the host cycles the card power.

The minimum 5 ms time to stop the SDMMC_CK is derived from the internal un-gated SDMMC_CK clock, which has a maximum frequency of 25 MHz (SD mode), as set by the clock divider CLKDIV. The >5 ms time is counted by 2^{12} cycles (10.24 ms @ 400 kHz). If a lower SDMMC_CK frequency is selected by the clock divider CLKDIV the time for the SDMMC_CK clock to be stopped is longer.

The maximum 1 ms time for the card to drive the SDMMC_Dn and SDMMC_CMD lines high is derived from the internal ungated SDMMC_CK which has a maximum frequency of 25 MHz (SD mode), as set by the clock divider CLKDIV. The SDMMC checks the lines after >1 ms time which is counted by 2^9 cycles (1.28 ms @ 25 MHz). If a lower SDMMC_CK frequency is selected by the clock divider CLKDIV the time to check the lines is longer.

The signal voltage level is supported through an external voltage translation transceiver like STMicroelectronics ST6G3244ME.

Figure 185. Voltage switch transceiver typical application



To interface with an external driver (a voltage switch transceiver), next to the standard signals the SDMMC uses the following signals:

SDMMC_CKIN feedback input clock

SDMMC_CDIR I/O direction control for the CMD signal.

SDMMC_D0DIR I/O direction control for the SDMMC_D0 signal.

SDMMC_D123DIR I/O direction control for the SDMMC_D1, SDMMC_D2 and SDMMC_D3 signals.

The voltage transceiver signals **EN** and **SEL** are to be handled through general-purpose I/O.

The polarity of the SDMMC_CDIR, SDMMC_D0DIR and SDMMC_D123DIR signals can be selected through SDMMC_POWER.DIRPOL control bit.

24.9 SDMMC interrupts

Table 233. SDMMC interrupts

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit from Sleep mode
SDMMC	Command response CRC fail	CCRCFAIL	CCRCFAILIE	CCRCFAILC	Yes
SDMMC	Data block CRC fail	DCRCFAIL	DCRCFAILIE	DCRCFAILC	Yes

24.10 SDMMC registers

The device communicates to the system via 32-bit control registers accessible via AHB slave interface.

The peripheral registers have to be accessed by words (32-bit). Byte (8-bit) and halfword (16-bit) accesses trigger an AHB bus error.

24.10.1 SDMMC power control register (SDMMC_POWER)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DIR POL	VSWI TCHEN	VSWI TCH	PWRCTRL[1:0]	
											rw	rw	rw	rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **DIRPOL**: Data and command direction signals polarity selection

This bit can only be written when the SDMMC is in the power-off state (PWRCTRL = 00).

0: Voltage transceiver IOs driven as output when direction signal is low.

1: Voltage transceiver IOs driven as output when direction signal is high.

Bit 3 **VSWITCHEN**: Voltage switch procedure enable

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).

This bit is used to stop the SDMMC_CK after the voltage switch command response:

0: SDMMC_CK clock kept unchanged after successfully received command response.

1: SDMMC_CK clock stopped after successfully received command response.

Bit 2 **VSWITCH**: Voltage switch sequence start

This bit is used to start the timing critical section of the voltage switch sequence:

0: Voltage switch sequence not started and not active.

1: Voltage switch sequence started or active.

Bits 1:0 **PWRCTRL[1:0]**: SDMMC state control bits

These bits can only be written when the SDMMC is not in the power-on state (PWRCTRL ≠ 11).

These bits are used to define the functional state of the SDMMC signals:

00: After reset, Reset: the SDMMC is disabled and the clock to the Card is stopped, SDMMC_D[7:0], and SDMMC_CMD are HiZ and SDMMC_CK is driven low. When written 00, power-off: the SDMMC is disabled and the clock to the card is stopped, SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are driven high.

01: Reserved. (When written 01, PWRCTRL value does not change)

10: Power-cycle, the SDMMC is disabled and the clock to the card is stopped, SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are driven low.

11: Power-on: the card is clocked, The first 74 SDMMC_CK cycles the SDMMC is still disabled. After the 74 cycles the SDMMC is enabled and the SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are controlled according the SDMMC operation.

Any further write is ignored, PWRCTRL value keeps 11.

24.10.2 SDMMC clock control register (SDMMC_CLKCR)

Address offset: 0x004

Reset value: 0x0000 0000

The SDMMC_CLKCR register controls the SDMMC_CK output clock, the sdmmc_rx_ck receive clock, and the bus width.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SELCLKRX[1:0]		BUS SPEED	DDR	HWFC_EN	NEG EDGE
										rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WID BUS[1:0]		Res.	PWR SAV	Res.	Res.	CLKDIV[9:0]									
rw	rw		rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:20 **SELCLKRX[1:0]**: Receive clock selection

These bits can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)

00: sdmmc_io_in_ck selected as receive clock

01: SDMMC_CKIN feedback clock selected as receive clock

10: sdmmc_fb_ck tuned feedback clock selected as receive clock.

11: Reserved (select sdmmc_io_in_ck)

Bit 19 **BUSSPEED**: Bus speed for selection of SDMMC operating modes

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)

0: DS, HS, SDR12, SDR25, Legacy compatible, High speed SDR, High speed DDR bus speed mode selected

1: SDR50, DDR50, SDR104, HS200 bus speed mode selected.

Bit 18 **DDR**: Data rate signaling selection

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)

DDR rate must only be selected with 4-bit or 8-bit wide bus mode. (WIDBUS > 00). DDR = 1 has no effect when WIDBUS = 00 (1-bit wide bus).

DDR rate must only be selected with clock division >1. (CLKDIV > 0)

0: SDR Single data rate signaling

1: DDR double data rate signaling

Bit 17 **HWFC_EN**: Hardware flow control enable

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)

0: Hardware flow control is disabled

1: Hardware flow control is enabled

When Hardware flow control is enabled, the meaning of the TXFIFOE and RXFIFOF flags change, see SDMMC status register definition in *Section 24.10.11*.

Bit 16 **NEGEDGE**: SDMMC_CK dephasing selection bit for data and command

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0).

When clock division = 1 (CLKDIV = 0), this bit has no effect. Data and Command change on SDMMC_CK falling edge.

0: When clock division >1 (CLKDIV > 0) and DDR = 0:

- Command and data changed on the sdmmc_ker_ck falling edge succeeding the rising edge of SDMMC_CK.
- SDMMC_CK edge occurs on sdmmc_ker_ck rising edge.

When clock division >1 (CLKDIV > 0) and DDR = 1:

- Command changed on the sdmmc_ker_ck falling edge succeeding the rising edge of SDMMC_CK.
- Data changed on the sdmmc_ker_ck falling edge succeeding a SDMMC_CK edge.
- SDMMC_CK edge occurs on sdmmc_ker_ck rising edge.

1: When clock division >1 (CLKDIV > 0) and DDR = 0:

- Command and data changed on the same sdmmc_ker_ck rising edge generating the SDMMC_CK falling edge.

When clock division >1 (CLKDIV > 0) and DDR = 1:

- Command changed on the same sdmmc_ker_ck rising edge generating the SDMMC_CK falling edge.
- Data changed on the SDMMC_CK falling edge succeeding a SDMMC_CK edge.
- SDMMC_CK edge occurs on sdmmc_ker_ck rising edge.

Bits 15:14 **WIDBUS[1:0]**: Wide bus mode enable bit

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)

00: Default 1-bit wide bus mode: SDMMC_D0 used (Does not support DDR)

01: 4-bit wide bus mode: SDMMC_D[3:0] used

10: 8-bit wide bus mode: SDMMC_D[7:0] used

Bit 13 Reserved, must be kept at reset value.

Bit 12 **PWRSAV**: Power saving configuration bit

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)

For power saving, the SDMMC_CK clock output can be disabled when the bus is idle by setting PWRSAV:

0: SDMMC_CK clock is always enabled

1: SDMMC_CK is only enabled when the bus is active

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:0 **CLKDIV[9:0]**: Clock divide factor

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0).

This field defines the divide factor between the input clock (sdmmc_ker_ck) and the output clock (SDMMC_CK): SDMMC_CK frequency = sdmmc_ker_ck / [2 * CLKDIV].

0x000: SDMMC_CK frequency = sdmmc_ker_ck / 1 (Does not support DDR)

0x001: SDMMC_CK frequency = sdmmc_ker_ck / 2

0x002: SDMMC_CK frequency = sdmmc_ker_ck / 4

0x0XX: etc..

0x080: SDMMC_CK frequency = sdmmc_ker_ck / 256

0xXXX: etc..

0x3FF: SDMMC_CK frequency = sdmmc_ker_ck / 2046

Note: 1 While the SD/SDIO card or e•MMC is in identification mode, the SDMMC_CK frequency must be less than 400 kHz.

2 The clock frequency can be changed to the maximum card bus frequency when relative card addresses are assigned to all cards.

3 At least seven sdmmc_hclk clock periods are needed between two write accesses to this register. SDMMC_CK can also be stopped during the Read Wait interval for SD I/O cards: in this case the SDMMC_CLKCR register does not control SDMMC_CK.

24.10.3 SDMMC argument register (SDMMC_ARGR)

Address offset: 0x008

Reset value: 0x0000 0000

The SDMMC_ARGR register contains a 32-bit command argument, which is sent to a card as part of a command message.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CMDARG[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CMDARG[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **CMDARG[31:0]**: Command argument

These bits can only be written by firmware when CPSM is disabled (CPSMEN = 0). Command argument sent to a card as part of a command message. If a command contains an argument, it must be loaded into this register before writing a command to the command register.

24.10.4 SDMMC command register (SDMMC_CMDR)

Address offset: 0x00C

Reset value: 0x0000 0000

The SDMMC_CMDR register contains the command index and command type bits. The command index is sent to a card as part of a command message. The command type bits control the command path state machine (CPSM).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CMD SUS PEND
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BOOT EN	BOOT MODE	DT HOLD	CPSM EN	WAITP END	WAIT INT	WAITRESP[1:0]		CMD STOP	CMD TRANS	CMDINDEX[5:0]					
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **CMDSUSPEND**: The CPSM treats the command as a Suspend or Resume command and signals interrupt period start/end

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).
CMDSUSPEND = 1 and CMDTRANS = 0 Suspend command, start interrupt period when response bit BS=0.
CMDSUSPEND = 1 and CMDTRANS = 1 Resume command with data, end interrupt period when response bit DF=1.

Bit 15 **BOOTEN**: Enable boot mode procedure

0: Boot mode procedure disabled
1: Boot mode procedure enabled

Bit 14 **BOOTMODE**: Select the boot mode procedure to be used

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0)
0: Normal boot mode procedure selected
1: Alternative boot mode procedure selected.

Bit 13 **DTHOLD**: Hold new data block transmission and reception in the DPSM

If this bit is set, the DPSM does not move from the Wait_S state to the Send state or from the Wait_R state to the Receive state.

Bit 12 **CPSMEN**: Command path state machine (CPSM) enable bit

This bit is written 1 by firmware, and cleared by hardware when the CPSM enters the Idle state.
If this bit is set, the CPSM is enabled.
When DTEN = 1, no command is transfered nor boot procedure is started. CPSMEN is cleared to 0.
During Read Wait with SDMMC_CK stopped no command is sent and CPSMEN is kept 0.

Bit 11 **WAITPEND**: CPSM waits for end of data transfer (CmdPend internal signal) from DPSM

This bit when set, the CPSM waits for the end of data transfer trigger before it starts sending a command.
WAITPEND is only taken into account when DTMODE = *e*•MMC stream data transfer, WIDBUS = 1-bit wide bus mode, DPSMACT = 1 and DTDIR = from host to card.

Bit 10 **WAITINT**: CPSM waits for interrupt request

If this bit is set, the CPSM disables command timeout and waits for an card interrupt request (Response).
If this bit is cleared in the CPSM Wait state, it causes the abort of the interrupt mode.

Bits 9:8 **WAITRESP[1:0]**: Wait for response bits

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).
They are used to configure whether the CPSM is to wait for a response, and if yes, which kind of response.
00: No response, expect CMDSENT flag
01: Short response, expect CMDREND or CCRCFAIL flag
10: Short response, expect CMDREND flag (No CRC)
11: Long response, expect CMDREND or CCRCFAIL flag

Bit 7 **CMDSTOP**: The CPSM treats the command as a Stop Transmission command and signals abort to the DPSM

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).

If this bit is set, the CPSM issues the abort signal to the DPSM when the command is sent.

Bit 6 **CMDTRANS**: The CPSM treats the command as a data transfer command, stops the interrupt period, and signals DataEnable to the DPSM

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).

If this bit is set, the CPSM issues an end of interrupt period and issues DataEnable signal to the DPSM when the command is sent.

Bits 5:0 **CMDINDEX[5:0]**: Command index

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).

The command index is sent to the card as part of a command message.

Note: 1 At least seven sdmmc_hclk clock periods are needed between two write accesses to this register.

2 MultiMediaCard can send two kinds of response: short responses, 48 bits, or long responses,136 bits. SD card and SD I/O card can send only short responses, the argument can vary according to the type of response: the software distinguishes the type of response according to the send command.

24.10.5 SDMMC command response register (SDMMC_RESPCMDR)

Address offset: 0x010

Reset value: 0x0000 0000

The SDMMC_RESPCMDR register contains the command index field of the last command response received. If the command response transmission does not contain the command index field (long or OCR response), the RESPCMD field is unknown, although it must contain 111111b (the value of the reserved field from the response).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RESPCMD[5:0]					
										r	r	r	r	r	r

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **RESPCMD[5:0]**: Response command index

Read-only bit field. Contains the command index of the last command response received.

24.10.6 SDMMC response x register (SDMMC_RESPxR)

Address offset: 0x010 + 0x004 * x, (x = 1 to 4)

Reset value: 0x0000 0000

The SDMMC_RESP1/2/3/4R registers contain the status of a card, which is part of the received response.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CARDSTATUS[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

CARDSTATUS[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **CARDSTATUS[31:0]**: Card status according table below
See *Table 234*.

The card status size is 32 or 128 bits, depending on the response type.

Table 234. Response type and SDMMC_RESPxR registers

Register(1)	Short response	Long response
SDMMC_RESP1R	Card status[31:0]	Card status [127:96]
SDMMC_RESP2R	all 0	Card status [95:64]
SDMMC_RESP3R	all 0	Card status [63:32]
SDMMC_RESP4R	all 0	Card status [31:0](2)

1. The most significant bit of the card status is received first.
2. The SDMMC_RESP4R register LSB is always 0.

24.10.7 SDMMC data timer register (SDMMC_DTIMER)

Address offset: 0x024

Reset value: 0x0000 0000

The SDMMC_DTIMER register contains the data timeout period, in card bus clock periods.

A counter loads the value from the SDMMC_DTIMER register, and starts decrementing when the data path state machine (DPSM) enters the Wait_R or Busy state. If the timer reaches 0 while the DPSM is in either of these states, the timeout status flag is set.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DATATIME[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATATIME[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DATATIME[31:0]**: Data and R1b busy timeout period

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0).

Data and R1b busy timeout period expressed in card bus clock periods.

Note: A data transfer must be written to the data timer register and the data length register before being written to the data control register.

24.10.8 SDMMC data length register (SDMMC_DLENR)

Address offset: 0x028

Reset value: 0x0000 0000

The SDMMC_DLENR register contains the number of data bytes to be transferred. The value is loaded into the data counter when data transfer starts.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	DATALENGTH[24:16]								
							rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATALENGTH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:0 **DATALENGTH[24:0]**: Data length value

This register can only be written by firmware when DPSM is inactive (DPSMACT = 0).

Number of data bytes to be transferred.

When DDR = 1 DATALENGTH is truncated to a multiple of 2. (The last odd byte is not transfered)

When DATALENGTH = 0 no data are transfered, when requested by a CPSMEN and CMDTRANS = 1 also no command is transfered. DTEN and CPSMEN are cleared to 0.

Note: For a block data transfer, the value in the data length register must be a multiple of the block size (see SDMMC_DCTRL). A data transfer must be written to the data timer register and the data length register before being written to the data control register.

For an SDMMC multibyte transfer the value in the data length register must be between 1 and 512.

24.10.9 SDMMC data control register (SDMMC_DCTRL)

Address offset: 0x02C

Reset value: 0x0000 0000

The SDMMC_DCTRL register control the data path state machine (DPSM).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	FIFO RST	BOOT ACK EN	SDIO EN	RW MOD	RW STOP	RW START	DBLOCKSIZE[3:0]				DTMODE[1:0]		DTDIR	DTEN
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **FIFORST**: FIFO reset, flushes any remaining data

This bit can only be written by firmware when IDMAEN= 0 and DPSM is active (DPSMACT = 1). This bit only takes effect when a transfer error or transfer hold occurs.

0: FIFO not affected.

1: Flush any remaining data and reset the FIFO pointers. This bit is automatically cleared to 0 by hardware when DPSM gets inactive (DPSMACT = 0).

Bit 12 **BOOTACKEN**: Enable the reception of the boot acknowledgment

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

0: Boot acknowledgment disabled, not expected to be received

1: Boot acknowledgment enabled, expected to be received

Bit 11 **SDIOEN**: SD I/O interrupt enable functions

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

If this bit is set, the DPSM enables the SD I/O card specific interrupt operation.

Bit 10 **RWMOD**: Read Wait mode

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

0: Read Wait control using SDMMC_D2

1: Read Wait control stopping SDMMC_CK

Bit 9 **RWSTOP**: Read Wait stop

This bit is written by firmware and auto cleared by hardware when the DPSM moves from the R_W state to the Wait_R or Idle state.

0: No Read Wait stop.

1: Enable for Read Wait stop when DPSM is in the R_W state.

Bit 8 **RWSTART**: Read Wait start

If this bit is set, Read Wait operation starts.

Bits 7:4 **DBLOCKSIZE[3:0]**: Data block size

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).
Define the data block length when the block data transfer mode is selected:
0000: Block length = 2^0 = 1 byte
0001: Block length = 2^1 = 2 bytes
0010: Block length = 2^2 = 4 bytes
0011: Block length = 2^3 = 8 bytes
0100: Block length = 2^4 = 16 bytes
0101: Block length = 2^5 = 32 bytes
0110: Block length = 2^6 = 64 bytes
0111: Block length = 2^7 = 128 bytes
1000: Block length = 2^8 = 256 bytes
1001: Block length = 2^9 = 512 bytes
1010: Block length = 2^{10} = 1024 bytes
1011: Block length = 2^{11} = 2048 bytes
1100: Block length = 2^{12} = 4096 bytes
1101: Block length = 2^{13} = 8192 bytes
1110: Block length = 2^{14} = 16384 bytes
1111: Reserved
When DATALENGTH is not a multiple of DBLOCKSIZE, the transfered data is truncated at a multiple of DBLOCKSIZE. (None of the remaining data are transfered.)
When DDR = 1, DBLOCKSIZE = 0000 must not be used. (No data are transfered)

Bits 3:2 **DTMODE[1:0]**: Data transfer mode selection

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).
00: Block data transfer ending on block count.
01: SDIO multibyte data transfer.
10: *e*•MMC Stream data transfer. (WIDBUS must select 1-bit wide bus mode)
11: Block data transfer ending with STOP_TRANSMISSION command (not to be used with DTEN initiated data transfers).

Bit 1 **DTDIR**: Data transfer direction selection

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).
0: From host to card.
1: From card to host.

Bit 0 **DTEN**: Data transfer enable bit

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0). This bit is cleared by Hardware when data transfer completes.
This bit must only be used to transfer data when no associated data transfer command is used, i.e. must not be used with SD or *e*•MMC cards.
0: Do not start data transfer without CPSM data transfer command.
1: Start data transfer without CPSM data transfer command.

24.10.10 SDMMC data counter register (SDMMC_DCNTR)

Address offset: 0x030

Reset value: 0x0000 0000

The SDMMC_DCNTR register loads the value from the data length register (see SDMMC_DLENR) when the DPSM moves from the Idle state to the Wait_R or Wait_S state. As data is transferred, the counter decrements the value until it reaches 0. The DPSM then

moves to the Idle state and when there has been no error, and no transmit data transfer hold, the data status end flag (DATAEND) is set.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	DATACOUNT[24:16]

DATACOUNT[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:0 **DATACOUNT[24:0]**: Data count value

When read, the number of remaining data bytes to be transferred is returned. Write has no effect.

Note: This register must be read only after the data transfer is complete, or hold. When reading after an error event the read data count value may be different from the real number of data bytes transfered.

24.10.11 SDMMC status register (SDMMC_STAR)

Address offset: 0x034

Reset value: 0x0000 0000

The SDMMC_STAR register is a read-only register. It contains two types of flag:

- Static flags (bits [28, 21, 11:0]): these bits remain asserted until they are cleared by writing to the SDMMC interrupt Clear register (see SDMMC_ICR)
- Dynamic flags (bits [20:12]): these bits change state depending on the state of the underlying logic (for example, FIFO full and empty flags are asserted and deasserted as data while written to the FIFO)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **IDMABTC**: IDMA buffer transfer complete

The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 27 **IDMATE**: IDMA transfer error

The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 26 **CKSTOP**: SDMMC_CK stopped in Voltage switch procedure

The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 25 **VSWEND**: Voltage switch critical timing section completion
The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 24 **ACKTIMEOUT**: Boot acknowledgment timeout
The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 23 **ACKFAIL**: Boot acknowledgment received (boot acknowledgment check fail)
The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 22 **SDIOIT**: SDIO interrupt received
The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 21 **BUSYD0END**: end of SDMMC_D0 Busy following a CMD response detected
This indicates only end of busy following a CMD response. This bit does not signal busy due to data transfer. Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.
0: card SDMMC_D0 signal does NOT signal change from busy to not busy.
1: card SDMMC_D0 signal changed from busy to NOT busy.

Bit 20 **BUSYD0**: Inverted value of SDMMC_D0 line (Busy), sampled at the end of a CMD response and a second time 2 SDMMC_CK cycles after the CMD response
This bit is reset to not busy when the SDMMCD0 line changes from busy to not busy. This bit does not signal busy due to data transfer. This is a hardware status flag only, it does not generate an interrupt.
0: card signals not busy on SDMMC_D0.
1: card signals busy on SDMMC_D0.

Bit 19 **RXFIFOE**: Receive FIFO empty
This is a hardware status flag only, does not generate an interrupt. This bit is cleared when one FIFO location becomes full.

Bit 18 **TXFIFOE**: Transmit FIFO empty
This bit is cleared when one FIFO location becomes full.

Bit 17 **RXFIFOF**: Receive FIFO full
This bit is cleared when one FIFO location becomes empty.

Bit 16 **TXFIFOF**: Transmit FIFO full
This is a hardware status flag only, does not generate an interrupt. This bit is cleared when one FIFO location becomes empty.

Bit 15 **RXFIFOHF**: Receive FIFO half full
There are at least half the number of words in the FIFO. This bit is cleared when the FIFO becomes half+1 empty.

Bit 14 **TXFIFOHE**: Transmit FIFO half empty
At least half the number of words can be written into the FIFO. This bit is cleared when the FIFO becomes half+1 full.

Bit 13 **CPSMACT**: Command path state machine active, i.e. not in Idle state
This is a hardware status flag only, does not generate an interrupt.

Bit 12 **DPSMACT**: Data path state machine active, i.e. not in Idle state
This is a hardware status flag only, does not generate an interrupt.

Bit 11 **DABORT**: Data transfer aborted by CMD12
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 10 **DBCKEND**: Data block sent/received
DBCKEND is set when:
- CRC check passed and DPSM moves to the R_W state
or
- IDMAEN = 0 and transmit data transfer hold and DATACOUNT >0 and DPSM moves to Wait_S.
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 9 **DHOLD**: Data transfer Hold
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 8 **DATAEND**: Data transfer ended correctly
DATAEND is set if data counter DATACOUNT is zero and no errors occur, and no transmit data transfer hold.
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 7 **CMDSENT**: Command sent (no response required)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 6 **CMDREND**: Command response received (CRC check passed, or no CRC)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 5 **RXOVERR**: Received FIFO overrun error (masked by hardware when IDMA is enabled)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 4 **TXUNDERR**: Transmit FIFO underrun error (masked by hardware when IDMA is enabled)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 3 **DTIMEOUT**: Data timeout
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 2 **CTIMEOUT**: Command response timeout
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.
The Command Timeout period has a fixed value of 64 SDMMC_CK clock periods.

Bit 1 **DCRCFAIL**: Data block sent/received (CRC check failed)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 0 **CCRCFAIL**: Command response received (CRC check failed)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Note: FIFO interrupt flags must be masked in SDMMC_MASKR when using IDMA mode.

24.10.12 SDMMC interrupt clear register (SDMMC_ICR)

Address offset: 0x038

Reset value: 0x0000 0000

The SDMMC_ICR register is a write-only register. Writing a bit with 1 clears the corresponding bit in the SDMMC_STAR status register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **IDMABTCC**: IDMA buffer transfer complete clear bit
Set by software to clear the IDMABTC flag.
0: IDMABTC not cleared
1: IDMABTC cleared

Bit 27 **IDMATEC**: IDMA transfer error clear bit
Set by software to clear the IDMATE flag.
0: IDMATE not cleared
1: IDMATE cleared

Bit 26 **CKSTOPC**: CKSTOP flag clear bit
Set by software to clear the CKSTOP flag.
0: CKSTOP not cleared
1: CKSTOP cleared

Bit 25 **VSWENDC**: VSWEND flag clear bit
Set by software to clear the VSWEND flag.
0: VSWEND not cleared
1: VSWEND cleared

Bit 24 **ACKTIMEOUTC**: ACKTIMEOUT flag clear bit
Set by software to clear the ACKTIMEOUT flag.
0: ACKTIMEOUT not cleared
1: ACKTIMEOUT cleared

Bit 23 **ACKFAILC**: ACKFAIL flag clear bit
Set by software to clear the ACKFAIL flag.
0: ACKFAIL not cleared
1: ACKFAIL cleared

Bit 22 **SDIOITC**: SDIOIT flag clear bit
Set by software to clear the SDIOIT flag.
0: SDIOIT not cleared
1: SDIOIT cleared

Bit 21 **BUSYD0ENDC**: BUSYD0END flag clear bit
Set by software to clear the BUSYD0END flag.
0: BUSYD0END not cleared
1: BUSYD0END cleared

Bits 20:12 Reserved, must be kept at reset value.

Bit 11 **DABORTC**: DABORT flag clear bit
Set by software to clear the DABORT flag.
0: DABORT not cleared
1: DABORT cleared

Bit 10 **DBCKENDC**: DBCKEND flag clear bit
Set by software to clear the DBCKEND flag.
0: DBCKEND not cleared
1: DBCKEND cleared

Bit 9 **DHOLDC**: DHOLD flag clear bit
Set by software to clear the DHOLD flag.
0: DHOLD not cleared
1: DHOLD cleared

Bit 8 **DATAENDC**: DATAEND flag clear bit
Set by software to clear the DATAEND flag.
0: DATAEND not cleared
1: DATAEND cleared

Bit 7 **CMDSENTC**: CMDSENT flag clear bit
Set by software to clear the CMDSENT flag.
0: CMDSENT not cleared
1: CMDSENT cleared

Bit 6 **CMDRENDC**: CMDREND flag clear bit
Set by software to clear the CMDREND flag.
0: CMDREND not cleared
1: CMDREND cleared

Bit 5 **RXOVERRC**: RXOVERR flag clear bit
Set by software to clear the RXOVERR flag.
0: RXOVERR not cleared
1: RXOVERR cleared

Bit 4 **TXUNDERRC**: TXUNDERR flag clear bit
Set by software to clear TXUNDERR flag.
0: TXUNDERR not cleared
1: TXUNDERR cleared

Bit 3 **DTIMEOUTC**: DTIMEOUT flag clear bit
Set by software to clear the DTIMEOUT flag.
0: DTIMEOUT not cleared
1: DTIMEOUT cleared

Bit 2 **CTIMEOUTC**: CTIMEOUT flag clear bit
Set by software to clear the CTIMEOUT flag.
0: CTIMEOUT not cleared
1: CTIMEOUT cleared

Bit 1 **DCRCFAILC**: DCRCFAIL flag clear bit
Set by software to clear the DCRCFAIL flag.
0: DCRCFAIL not cleared
1: DCRCFAIL cleared

Bit 0 **CCRCFAILC**: CCRCFAIL flag clear bit
Set by software to clear the CCRCFAIL flag.
0: CCRCFAIL not cleared
1: CCRCFAIL cleared

24.10.13 SDMMC mask register (SDMMC_MASKR)

Address offset: 0x03C

Reset value: 0x0000 0000

The interrupt mask register determines which status flags generate an interrupt request by setting the corresponding bit to 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **IDMABTCIE**: IDMA buffer transfer complete interrupt enable
Set and cleared by software to enable/disable the interrupt generated when the IDMA has transferred all data belonging to a memory buffer.
0: IDMA buffer transfer complete interrupt disabled
1: IDMA buffer transfer complete interrupt enabled

Bit 27 Reserved, must be kept at reset value.

Bit 26 **CKSTOPIE**: Voltage Switch clock stopped interrupt enable
Set and cleared by software to enable/disable interrupt caused by Voltage Switch clock stopped.
0: Voltage Switch clock stopped interrupt disabled
1: Voltage Switch clock stopped interrupt enabled

Bit 25 **VSWENDIE**: Voltage switch critical timing section completion interrupt enable
Set and cleared by software to enable/disable the interrupt generated when voltage switch critical timing section completion.
0: Voltage switch critical timing section completion interrupt disabled
1: Voltage switch critical timing section completion interrupt enabled

Bit 24 **ACKTIMEOUTIE**: Acknowledgment timeout interrupt enable
Set and cleared by software to enable/disable interrupt caused by acknowledgment timeout.
0: Acknowledgment timeout interrupt disabled
1: Acknowledgment timeout interrupt enabled

Bit 23 **ACKFAILIE**: Acknowledgment Fail interrupt enable
Set and cleared by software to enable/disable interrupt caused by acknowledgment Fail.
0: Acknowledgment Fail interrupt disabled
1: Acknowledgment Fail interrupt enabled

Bit 22 **SDIOITIE**: SDIO mode interrupt received interrupt enable
Set and cleared by software to enable/disable the interrupt generated when receiving the SDIO mode interrupt.
0: SDIO Mode interrupt received interrupt disabled
1: SDIO Mode interrupt received interrupt enabled

Bit 21 **BUSYD0ENDIE**: BUSYD0END interrupt enable
Set and cleared by software to enable/disable the interrupt generated when SDMMC_D0 signal changes from busy to NOT busy following a CMD response.
0: BUSYD0END interrupt disabled
1: BUSYD0END interrupt enabled

Bits 20:19 Reserved, must be kept at reset value.

Bit 18 **TXFIFOEIE**: Tx FIFO empty interrupt enable
Set and cleared by software to enable/disable interrupt caused by Tx FIFO empty.
0: Tx FIFO empty interrupt disabled
1: Tx FIFO empty interrupt enabled

Bit 17 **RXFIFOFIE**: Rx FIFO full interrupt enable
Set and cleared by software to enable/disable interrupt caused by Rx FIFO full.
0: Rx FIFO full interrupt disabled
1: Rx FIFO full interrupt enabled

Bit 16 Reserved, must be kept at reset value.

Bit 15 **RXFIFOHFIE**: Rx FIFO half full interrupt enable
Set and cleared by software to enable/disable interrupt caused by Rx FIFO half full.
0: Rx FIFO half full interrupt disabled
1: Rx FIFO half full interrupt enabled

Bit 14 **TXFIFOHEIE**: Tx FIFO half empty interrupt enable
Set and cleared by software to enable/disable interrupt caused by Tx FIFO half empty.
0: Tx FIFO half empty interrupt disabled
1: Tx FIFO half empty interrupt enabled

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **DABORTIE**: Data transfer aborted interrupt enable
Set and cleared by software to enable/disable interrupt caused by a data transfer being aborted.
0: Data transfer abort interrupt disabled
1: Data transfer abort interrupt enabled

Bit 10 **DBCKENDIE**: Data block end interrupt enable
Set and cleared by software to enable/disable interrupt caused by data block end.
0: Data block end interrupt disabled
1: Data block end interrupt enabled

Bit 9 **DHOLDIE**: Data hold interrupt enable
Set and cleared by software to enable/disable the interrupt generated when sending new data is hold in the DPSM Wait_S state.
0: Data hold interrupt disabled
1: Data hold interrupt enabled

Bit 8 **DATAENDIE**: Data end interrupt enable
Set and cleared by software to enable/disable interrupt caused by data end.
0: Data end interrupt disabled
1: Data end interrupt enabled

Bit 7 **CMDSENTIE**: Command sent interrupt enable
Set and cleared by software to enable/disable interrupt caused by sending command.
0: Command sent interrupt disabled
1: Command sent interrupt enabled

Bit 6 **CMDRENDIE**: Command response received interrupt enable
Set and cleared by software to enable/disable interrupt caused by receiving command response.
0: Command response received interrupt disabled
1: command Response received interrupt enabled

Bit 5 **RXOVERRIE**: Rx FIFO overrun error interrupt enable
Set and cleared by software to enable/disable interrupt caused by Rx FIFO overrun error.
0: Rx FIFO overrun error interrupt disabled
1: Rx FIFO overrun error interrupt enabled

Bit 4 **TXUNDERRIE**: Tx FIFO underrun error interrupt enable
Set and cleared by software to enable/disable interrupt caused by Tx FIFO underrun error.
0: Tx FIFO underrun error interrupt disabled
1: Tx FIFO underrun error interrupt enabled

Bit 3 **DTIMEOUTIE**: Data timeout interrupt enable
Set and cleared by software to enable/disable interrupt caused by data timeout.
0: Data timeout interrupt disabled
1: Data timeout interrupt enabled

Bit 2 **CTIMEOUTIE**: Command timeout interrupt enable
Set and cleared by software to enable/disable interrupt caused by command timeout.
0: Command timeout interrupt disabled
1: Command timeout interrupt enabled

Bit 1 **DCRCFAILIE**: Data CRC fail interrupt enable
Set and cleared by software to enable/disable interrupt caused by data CRC failure.
0: Data CRC fail interrupt disabled
1: Data CRC fail interrupt enabled

Bit 0 **CCRCFAILIE**: Command CRC fail interrupt enable
Set and cleared by software to enable/disable interrupt caused by command CRC failure.
0: Command CRC fail interrupt disabled
1: Command CRC fail interrupt enabled

24.10.14 SDMMC acknowledgment timer register (SDMMC_ACKTIMER)

Address offset: 0x040

Reset value: 0x0000 0000

The SDMMC_ACKTIMER register contains the acknowledgment timeout period, in SDMMC_CK bus clock periods.

A counter loads the value from the SDMMC_ACKTIMER register, and starts decrementing when the data path state machine (DPSM) enters the Wait_Ack state. If the timer reaches 0 while the DPSM is in this states, the acknowledgment timeout status flag is set.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	ACKTIME[24:16]								
							rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ACKTIME[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:0 **ACKTIME[24:0]**: Boot acknowledgment timeout period
This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).
Boot acknowledgment timeout period expressed in card bus clock periods.

Note: The data transfer must be written to the acknowledgment timer register before being written to the data control register.

24.10.15 SDMMC data FIFO registers x (SDMMC_FIFORx)

Address offset: 0x080 + 0x004 * x, (x =0 to 15)

Reset value: 0x0000 0000

The receive and transmit FIFOs can be only read or written as word (32-bit) wide registers. The FIFOs contain 16 entries on sequential addresses. This enables the CPU to use its load and store multiple operands to read from/write to the FIFO. The FIFO register interface takes care of correct data alignment inside the FIFO, the FIFO register address used by the CPU does matter.

When accessing SDMMC_FIFOR with half word or byte access an AHB bus fault is generated.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FIFODATA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FIFODATA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **FIFODATA[31:0]**: Receive and transmit FIFO data

This register can only be read or written by firmware when the DPSM is active (DPSMACT = 1).

The FIFO data occupies 16 entries of 32-bit words.

24.10.16 SDMMC DMA control register (SDMMC_IDMACTRLR)

Address offset: 0x050

Reset value: 0x0000 0000

The receive and transmit FIFOs can be read or written as 32-bit wide registers. The FIFOs contain 32 entries on 32 sequential addresses. This enables the CPU to use its load and store multiple operands to read from/write to the FIFO.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IDMABMODE	IDMAEN
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **IDMABMODE**: Buffer mode selection

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

0: Single buffer mode.

1: Linked list mode.

Bit 0 **IDMAEN**: IDMA enable

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

0: IDMA disabled

1: IDMA enabled

24.10.17 SDMMC IDMA buffer size register (SDMMC_IDMABSIZER)

Address offset: 0x054

Reset value: 0x0000 0000

The SDMMC_IDMABSIZER register contains the buffer size when in linked list configuration.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IDMABNDT[11]
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDMABNDT[10:0]											Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw					

Bits 31:17 Reserved, must be kept at reset value.

Bits 16:5 **IDMABNDT[11:0]**: Number of bytes per buffer

This 12-bit value must be multiplied by 8 to get the size of the buffer in 32-bit words and by 32 to get the size of the buffer in bytes.
Example: IDMABNDT = 0x001: buffer size = 8 words = 32 bytes.
Example: IDMABNDT = 0x800: buffer size = 16384 words = 64 Kbyte.
These bits can only be written by firmware when DPSM is inactive (DPSMACT = 0).

Bits 4:0 Reserved, must be kept at reset value.

24.10.18 SDMMC IDMA buffer base address register (SDMMC_IDMABASER)

Address offset: 0x058

Reset value: 0x0000 0000

The SDMMC_IDMABASER register contains the memory buffer base address in single buffer configuration and linked list configuration.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IDMABASE[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDMABASE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	r	r

Bits 31:0 **IDMABASE[31:0]**: Buffer memory base address bits [31:2], must be word aligned (bit [1:0] are always 0 and read only)

This register can be written by firmware when DPSM is inactive (DPSMACT = 0), and can dynamically be written by firmware when DPSM active (DPSMACT = 1).

24.10.19 SDMMC IDMA linked list address register (SDMMC_IDMALAR)

Address offset: 0x064

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ULA	ULS	ABR	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw													
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDMALA[13:0]														Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		

Bit 31 **ULA**: Update SDMMC_IDMALAR from linked list when in linked list mode (SDMMC_IDMACTRLR.IDMABMODE select linked list mode)
This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).
0: SDMMC_IDMALAR is not to be updated, last linked list item.
1: SDMMC_IDMALAR is to be updated from linked list table.

Bit 30 **ULS**: Update SDMMC_IDMABSIZE from the next linked list when in linked list mode (SDMMC_IDMACTRLR.IDMABMODE select linked list mode and ULA = 1)
This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).
0: SDMMC_IDMABSIZER is not to be updated from next linked list table.
1: SDMMC_IDMABSIZER is to be updated from next linked list table.

Bit 29 **ABR**: Acknowledge linked list buffer ready
This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).
This bit is not taken into account when starting the first linked list buffer from the software programmed register information. ABR is only taken into account on subsequent loaded linked list items.
0: Loaded linked list buffer is not ready (this causes a linked list IDMA transfer error to be generated).
1: Loaded linked list buffer ready acknowledge. Linked list buffer data are transfered by IDMA.

Bits 28:16 Reserved, must be kept at reset value.

Bits 15:2 **IDMALA[13:0]**: Word aligned linked list item address offset
Linked list item offset pointer to the base of the next linked list item structure.
Linked list item base address is IDMABA + IDMALA.
These bits can only be written by firmware when DPSM is inactive (DPSMACT = 0).

Bits 1:0 Reserved, must be kept at reset value.

24.10.20 SDMMC IDMA linked list memory base register (SDMMC_IDMABAR)

Address offset: 0x068

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IDMABA[29:14]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDMABA[13:0]														Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		

Bits 31:2 **IDMABA[29:0]**: Word aligned Linked list memory base address
Linked list memory base pointer.
These bits can only be written by firmware when DPSM is inactive (DPSMACT = 0).

Bits 1:0 Reserved, must be kept at reset value.

Refer to *Section 2.3 on page 111* for the register boundary addresses.

25 Delay block (DLYB)

25.1 Introduction

The delay block (DLYB) is used to generate an output clock that is dephased from the input clock. The phase of the output clock must be programmed by the user application. The output clock is then used to clock the data received by another peripheral such as an SDMMC or Octo-SPI interface.

The delay is voltage- and temperature-dependent, that may require the application to re-configure and recenter the output clock phase with the receive data.

25.2 DLYB main features

The delay block has the following features:

- Input clock frequency ranging from 25 MHz to the maximum frequency supported by the communication interface (see datasheet)
- Up to 12 oversampling phases.

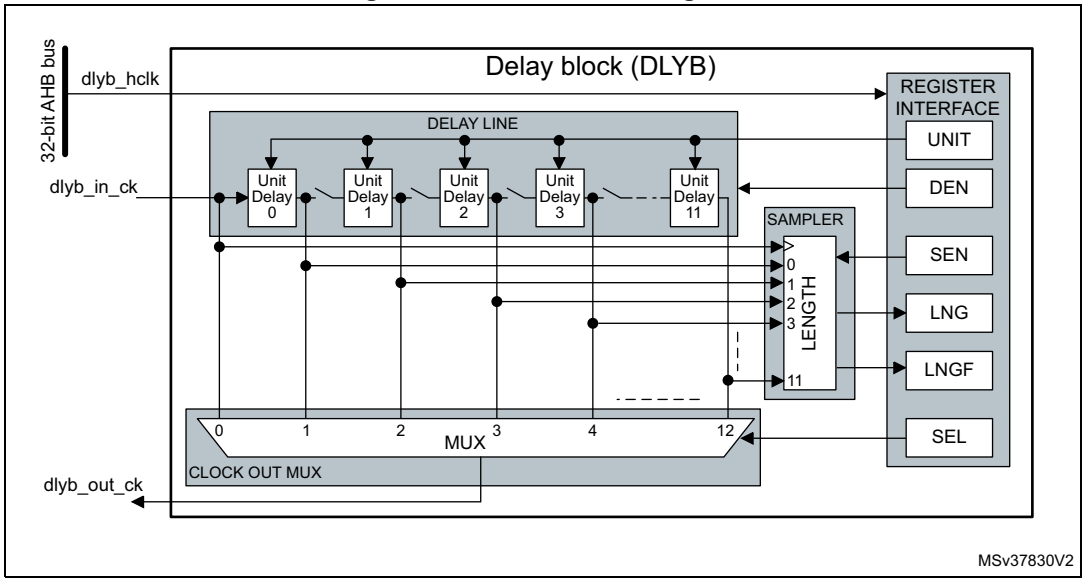
25.3 DLYB functional description

25.3.1 DLYB diagram

The delay block includes the following sub-blocks (shown in the figure below):

- register interface block providing AHB access to the DLYB registers
- delay line supporting the unit delays
- delay line length sampling
- output clock selection multiplexer

Figure 186. DLYB block diagram



25.3.2 DLYB pins and internal signals

Table 236 lists the DLYB internal signals.

Table 236. DLYB internal input/output signals

Signal name	Signal type	Description
dlyb_hclk	Digital input	Delay block register interface clock
dlyb_in_ck	Digital input	Delay block input clock
dlyb_out_ck	Digital output	Delay block output clock

25.3.3 General description

The delay block is enabled by setting the DEN bit in the DLYB control register (DLYB_CR). The length sampler is enabled through the SEN bit in DLYB_CR register.

When the delay block is enabled, the delay added by a unit delay is defined by the UNIT[6:0] field in the DLYB configuration register (DLYB_CFGR).

Note: UNIT[6:0] can be programmed only when the output clock is disabled (SEN = 1).

When the delay block is enabled, the output clock phase is selected through the SEL[3:0] field in DLYB_CFGR register.

Note: SEL can be programmed only when the output clock is disabled (SEN = 1).

The output clock can be de-phased over one input clock period by configuring the delay line length to span one period. The delay line length can be configured by enabling the length sampler through the SEN bit, that gives access to the delay line length (LNG[11:0]) and length valid flag (LNGF) in DLYB_CFGR.

If an output clock delay smaller than one input clock period is needed the delay line length can be reduced. This allows a smaller unit delay providing higher resolution.

Once the delay line length is configured, a dephased output clock can be selected by the output clock multiplexer. This is done through SEL[3:0]. The output clock is only available on the selected phase when SEN is set to 0.

The table below gives a summary of the delay block control.

Table 237. Delay block control

DEN	SEN	UNIT	SEL	LNG	LNGF	Output clock
0	0	Don’t care	Don’t care	Don’t care	Don’t care	Enabled (= Input clock)
x	1	Unit delay	Output clock phase	Length	Length flag	Disabled
1	0	Unit delay(1)	Output clock phase(2)	Don’t care	Don’t care	Enabled (= selected phase)

1. The unit delay can only be changed when SEN = 1.
2. The output clock phase can only be changed when SEN = 1.

25.3.4 Delay line length configuration procedure

LNG[11:0] is used to determine the delay line length with respect to the input clock period. The length must be configured so that one full input clock period is covered by the delay line length.

Note that despite the delay line has 12 unit delay elements, the following procedure description returns a length between 0 and 10, as the upper delay output value is used to ensure that the delay is calibrated over one full input clock cycle. Depending on the clock frequency and UNIT value, unit delay element 10 may also be truncated from the clock cycle length.

A clock input (free running clock) must be present during the whole tuning procedure.

To configure the delay line length to one period of the Input clock, follow the sequence below:

1. Enable the delay block by setting DEN bit to 1.
2. Enable the length sampling by setting SEN bit to 1.
3. Enable all delay cells by setting SEL[3:0] to 12.
4. For UNIT[6:0] = 0 to 127 (this step must be repeated until the delay line length is configured):
   a) Update the UNIT[6:0] value and wait till the length flag LNGF is set to 1.
   b) Read LNG[11:0].

   If (LNG[10:0] > 0) and (LNG[11] or LNG[10] = 0), the delay line length is configured to one input clock period.
5. Determine how many unit delays (N) span one input clock period: for N = 0 to 10, if LNG[N] = 1, the number of unit delays spanning the input clock period = N.
6. Disable the length sampling by clearing SEN to 0.

If an output clock delay smaller than one input clock period is needed the delay line length can be reduced smaller than one input clock period. This allows a smaller unit delay, providing a higher resolution spanning a shorter time interval.

25.3.5 Output clock phase configuration procedure

When the delay line length is configured to one input clock period, the output clock phase can be selected between the unit delays spanning one Input clock period.

Follow the steps below to select the output clock phase:

1. Disable the output clock and enable the access to the phase selection SEL[3:0] bits by setting SEN bit to 1.
2. Program SEL[3:0] with the desired output clock phase value.
3. Enable the output clock on the selected phase by clearing SEN to 0.

Octo-SPI use case:

The delay block is used in conjunction with Octo-SPI interface to allow shifting the input data sampling signal. This sampling signal can be the feedback clock or the data strobe (DQS) signal, which is delivered by certain type of devices. Note that in case DQS is used, the calibration procedure must be performed beforehand with a free running clock, as DQS is a discontinuous signal.

In case of SDR (single data rate) mode the user must typically shift the sampling signal by half period, so that the sampling edges are positioned in the middle of the valid data phase.

In case of DDR (dual data rate) mode, for which data are transitioning at start and middle of period, typical value must be close to N/4, once the calibration is completed.

In case of high frequencies and tight timing constraints, the delay setting granularity (10) might be too coarse. Since in most cases it is not necessary to have a possible delay value covering the whole sampling clock period, the "Unit" value can be overridden by application in order to improve the accuracy of the sampling edge position (example: providing a twice as small "Unit" gives twice better timing accuracy. The counterpart being that the maximum possible delay is divided by 2).

SDMMC use case:

The delay block is used in conjunction with SDMMC interface variable delay. For correct sampling point tuning the delay value must cover a whole SDMMC_CK clock period. After having tuned the delay line length the individual delays are used in the sampling point tuning to find the optimal sampling point.

25.4 DLYB registers

All registers can be accessed in word, half-word and byte access.

25.4.1 DLYB control register (DLYB_CR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SEN	DEN
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **SEN:** Sampler length enable bit

0: Sampler length and register access to UNIT[6:0] and SEL[3:0] disabled, output clock enabled.

1: Sampler length and register access to UNIT[6:0] and SEL[3:0] enabled, output clock disabled.

Bit 0 **DEN:** Delay block enable bit

0: DLYB disabled.

1: DLYB enabled.

25.4.2 DLYB configuration register (DLYB_CFGR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LNGF	Res.	Res.	Res.	LNG[11:0]											
r				r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	UNIT[6:0]							Res.	Res.	Res.	Res.	SEL[3:0]			
	rw	rw	rw	rw	rw	rw	rw					rw	rw	rw	rw

Bit 31 **LNGF:** Length valid flag

This flag indicates when the delay line length value contained in LNG[11:0] is valid after UNIT[6:0] bits changed.

0: Length value in LNG is not valid.

1: Length value in LNG is valid.

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 **LNG[11:0]:** Delay line length value

These bits reflect the 12 unit delay values sampled at the rising edge of the input clock. The value is only valid when LNGF = 1.

Bit 15 Reserved, must be kept at reset value.

Bits 14:8 **UNIT[6:0]:** Delay of a unit delay cell.

These bits can only be written when SEN = 1.

Unit delay = initial delay + UNIT[6:0] x delay step

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **SEL[3:0]:** Phase for the output clock.

These bits can only be written when SEN = 1.

Output clock phase = input clock + SEL[3:0] x unit delay

25.4.3 DLYB register map

Table 238. DLYB register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

26 Analog-to-digital converters (ADC1/2)

26.1 Introduction

This section describes the implementation of up to 2 ADCs:

- ADC1 and ADC2 are tightly coupled and can operate in dual mode (ADC1 is master).

Each ADC consists of a 12-bit successive approximation analog-to-digital converter.

Each ADC has up to 20 multiplexed channels. A/D conversion of the various channels can be performed in single, continuous, scan or discontinuous mode. The result of the ADC is stored in a left-aligned or right-aligned 16-bit data register.

The ADCs are mapped on the AHB bus to allow fast data handling.

The analog watchdog features allow the application to detect if the input voltage goes outside the user-defined high or low thresholds.

A built-in hardware oversampler allows improving analog performances while off-loading the related computational burden from the CPU.

An efficient low-power mode is implemented to allow very low consumption at low frequency.

26.2 ADC main features

- High-performance features
  - Up to 2 ADCs which can operate in dual mode:
    ADC1 is connected to 18 external channels and to 2 internal channels
    ADC2 is connected to 18 external channels and to 2 internal channels
  - 12, 10, 8 or 6-bit configurable resolution
  - ADC conversion time independent from the AHB bus clock frequency
  - Faster conversion time by lowering resolution
  - Manage single-ended or differential inputs
  - AHB slave bus interface to allow fast data handling
  - Self-calibration
  - Channel-wise programmable sampling time
  - Flexible sampling time control
  - Up to 4 injected channels (analog inputs assignment to regular or injected channels is fully configurable)
  - Hardware assistant to prepare the context of the injected channels to allow fast context switching
  - Data alignment with in-built data coherency
  - Data can be managed by DMA for regular channel conversions
  - Four dedicated data registers for the injected channels
- Low-power features
  - Speed adaptive low-power mode to reduce ADC consumption when operating at low frequency

  - Allows slow bus frequency application while keeping optimum ADC performance
  - Provides automatic control to avoid ADC overrun in low AHB bus clock frequency application (auto-delayed mode)
- Oversampler
  - 16-bit data register
  - Oversampling ratio adjustable from 2 to 256x
  - Programmable data shift up to 8 bits
- Data preconditioning
  - Offset compensation
- Analog input channels
  - External analog inputs (per ADC):

    Up to 6 fast channels from GPIO pads

    Up to 12 slow channels from GPIO pads
  - 1 channel for the internal temperature sensor (V_{SENSE})
  - 1 channel for the internal reference voltage (V_{REFINT})
  - 1 channel for monitoring the external VBAT power supply pin
  - 1 channel for monitoring the internal V_{DDCORE} supply
- Start-of-conversion can be initiated:
  - By software for both regular and injected conversions
  - By hardware triggers with configurable polarity (internal timers events or GPIO input events) for both regular and injected conversions
- Conversion modes
  - Each ADC can convert a single channel or can scan a sequence of channels
  - Single mode converts selected inputs once per trigger
  - Continuous mode converts selected inputs continuously
  - Discontinuous mode
- Interrupt generation at ADC ready, the end of sampling, the end of conversion (regular or injected), end of sequence conversion (regular or injected), analog watchdog 1, 2 or 3 or overrun events
- 3 analog watchdogs per ADC
  - Watchdog can perform filtering to ignore out-of-range data
- ADC input range: $V_{SSA} \leq V_{IN} \leq V_{REF+}$

Figure 187 shows the block diagram of one ADC.

26.3 ADC implementation

Table 239. ADC features

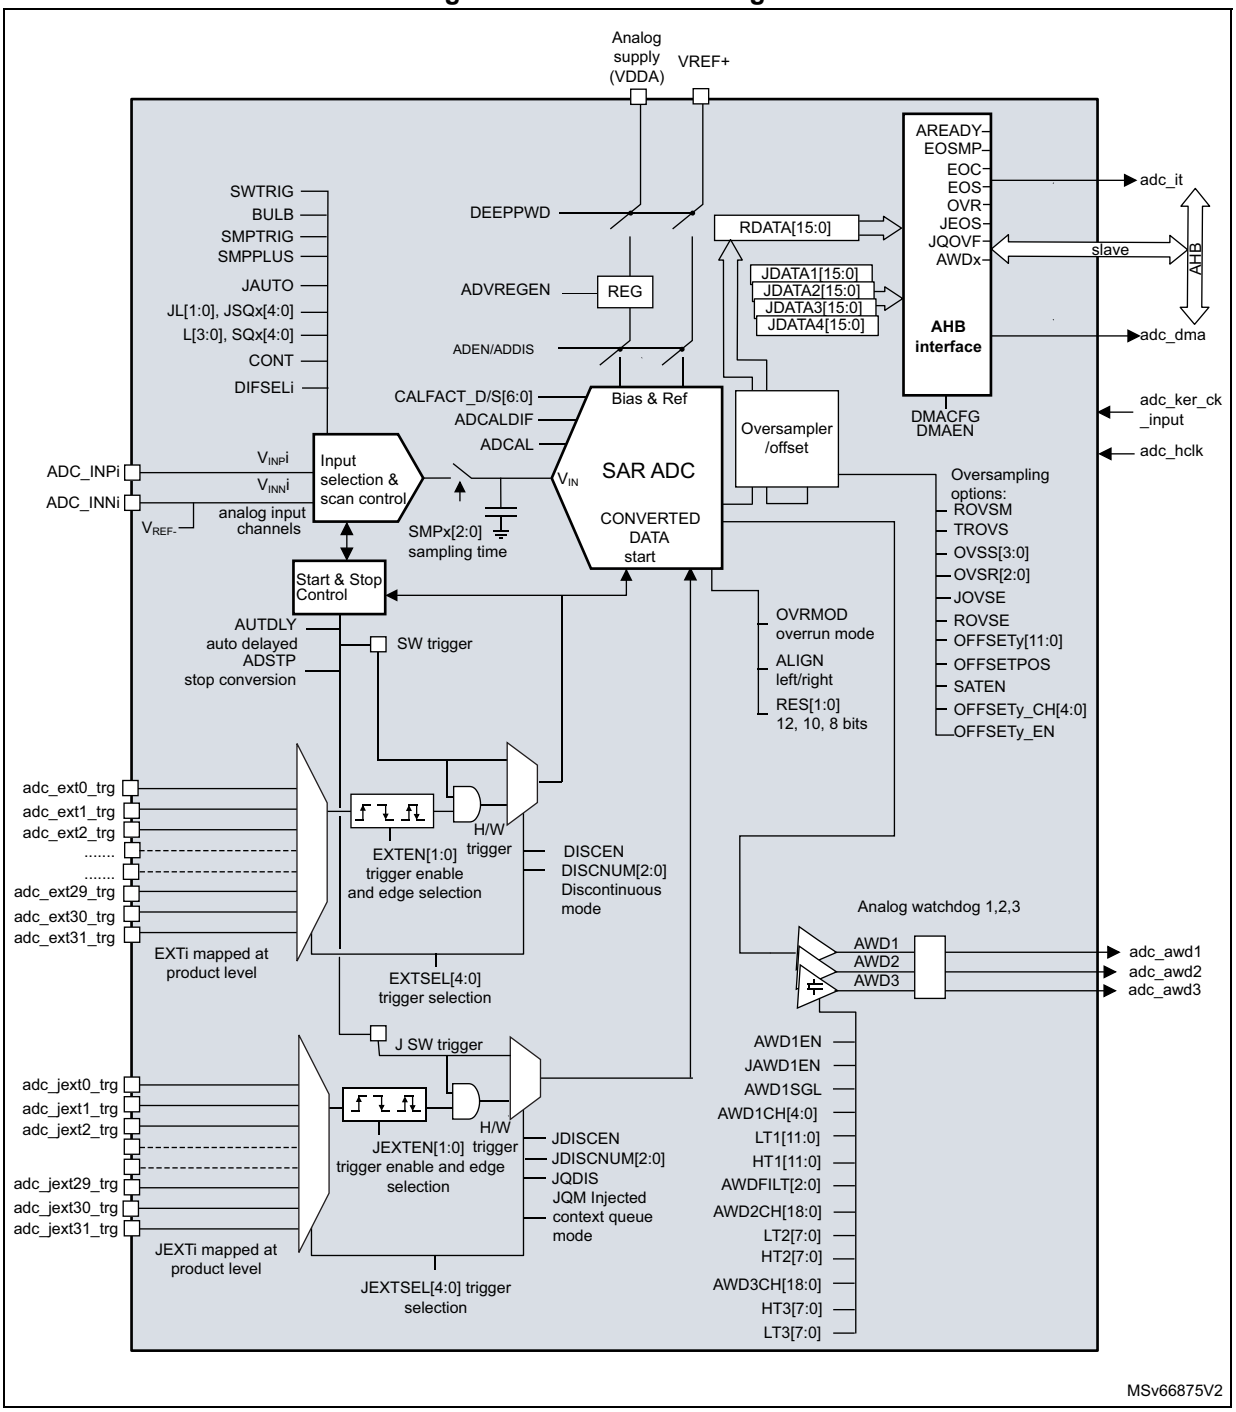
26.4 ADC functional description

26.4.1 ADC block diagram

Figure 187 shows the ADC block diagram and *Table 240* gives the ADC pin description.

Figure 187. ADC block diagram



26.4.2 ADC pins and internal signals

Table 240. ADC input/output pins

Pin name	Signal type	Description
VDDA	Input, analog supply	Analog power supply and positive reference voltage for the ADC
VSSA	Input, analog supply ground	Ground for analog power supply, equal to V_{SS}.
VREF+	Input, analog reference positive	The higher/positive reference voltage for the ADC.
VREF−	Input, analog reference negative	The lower/negative reference voltage for the ADC. V_{REF-} is internally connected to V_{SSA}
ADC1/2_INNi/INPi	Negative/positive external analog input signals	20 negative/positive external analog input channels (refer to *Section 26.4.4: ADC connectivity* for details)

Table 241. ADC internal input/output signals

Internal signal name	Signal type	Description
$V_{INP}i$	Positive analog input channels	Positive internal analog input channels connected either to ADC1/2_INP*i* external channels or to internal channels.
$V_{INN}i$	Negative analog input channels	Negative internal analog input channels connected either to ADC1/2_INN*i* external channels or to internal channels
adc_ext_trgi	Inputs	ADC external trigger inputs for regular conversions.These inputs are shared between the ADC master and the ADC slave.
adc_jext_trgi	Inputs	ADC external trigger inputs for the injected conversions. These inputs are shared between the ADC master and the ADC slave.
adc_awdx	Output	Internal analog watchdog output signal connected to on-chip timers. (x = Analog watchdog number 1,2,3)
adc_ker_ck_input	Output	ADC kernel clock
adc_hclk	Input	ADC peripheral clock
adc_it	Output	ADC interrupt
adc_dma	Output	ADC DMA request

Table 242. ADC interconnection

Signal name	Source/destination

26.4.3 ADC clocks

Dual clock domain architecture

The dual clock-domain architecture means that the ADC clock is independent from the AHB bus clock.

The ADC input clock can be selected between two different clock sources (see *Figure 188: ADC clock scheme*):

1. The ADC clock can be a specific clock source (adc_ker_ck_input), independent and asynchronous with the AHB clock.

   Refer to section *Reset and clock control (RCC)* for more information on how to generate the ADC dedicated clock. To select this scheme, CKMODE[1:0] bits of ADC_CCR register must be set to 00.

2. The ADC clock can be derived from the AHB clock interface divided by a programmable factor of 1, 2 or 4. To select this scheme, CKMODE[1:0] bits of ADC_CCR must be different from 00. The programmable divider factor can be configured through to CKMODE[1:0] bits of ADC_CCR.

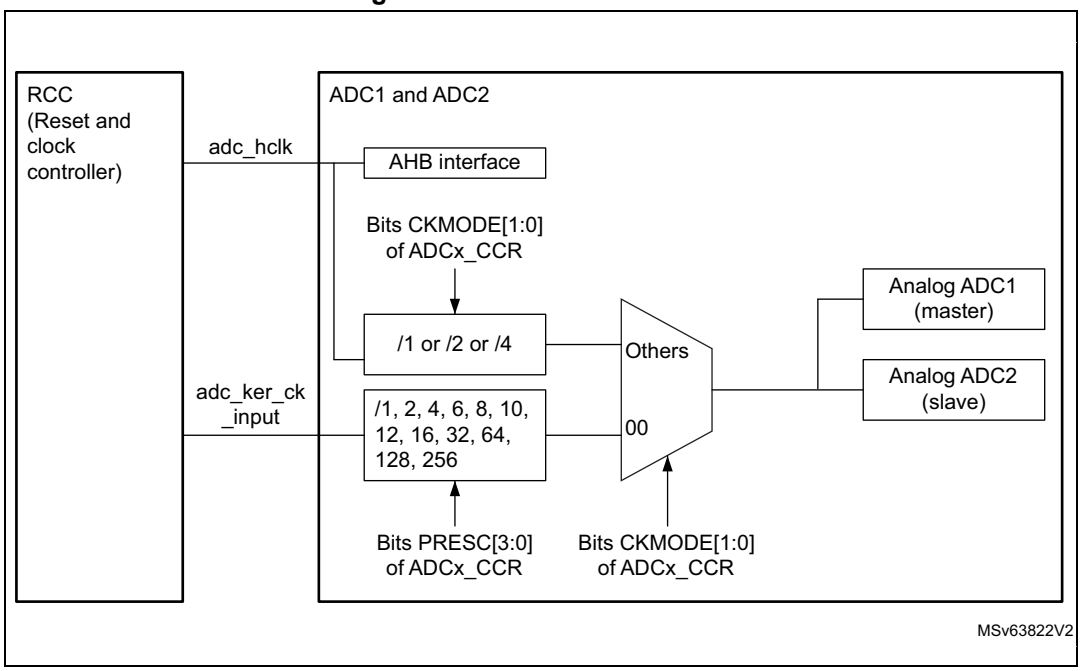
   The prescaling factor of 1 (CKMODE[1:0] = 01) can be used only if the AHB prescaler is set to 1 (HPRE[3:0] = 0xxx in the RCC_CFGR register).

Option **1** has the advantage of achieving the maximum ADC clock frequency whatever the AHB clock scheme selected. The ADC clock can eventually be divided by the following ratio: 1, 2, 4, 6, 8, 12, 16, 32, 64, 128, 256, using the prescaler configured with bits PRESC[3:0] in the ADC_CCR register.

Option **2** has the advantage of bypassing the clock domain resynchronizations. This can be useful when the ADC is triggered by a timer and if the application requires that the ADC is precisely triggered without any uncertainty (otherwise, an uncertainty of the trigger instant is added by the resynchronizations between the two clock domains).

The clock is configured through CKMODE[1:0] bits must be compliant with the operating frequency specified in the device datasheet.

Figure 188. ADC clock scheme



Clock ratio constraint between ADC clock and AHB clock

There are generally no constraints to be respected for the ratio between the ADC clock and the AHB clock except if some injected channels are programmed. In this case, it is mandatory to respect the following ratio:

- $F_{adc\_hclk} \geq F_{ADC} / 4$ if the resolution of all channels are 12-bit or 10-bit
- $F_{adc\_hclk} \geq F_{ADC} / 3$ if there are some channels with resolutions equal to 8-bit (and none with lower resolutions)
- $F_{adc\_hclk} \geq F_{ADC} / 2$ if there are some channels with resolutions equal to 6-bit

Constraints between ADC clocks

When several ADC interfaces are used simultaneously, it is mandatory to use the same clock source from the RCC block without prescaler ratio for all ADC interfaces.

26.4.4 ADC connectivity

ADC inputs are connected to the external channels as well as internal sources as described below.

Figure 189. ADC1 connectivity

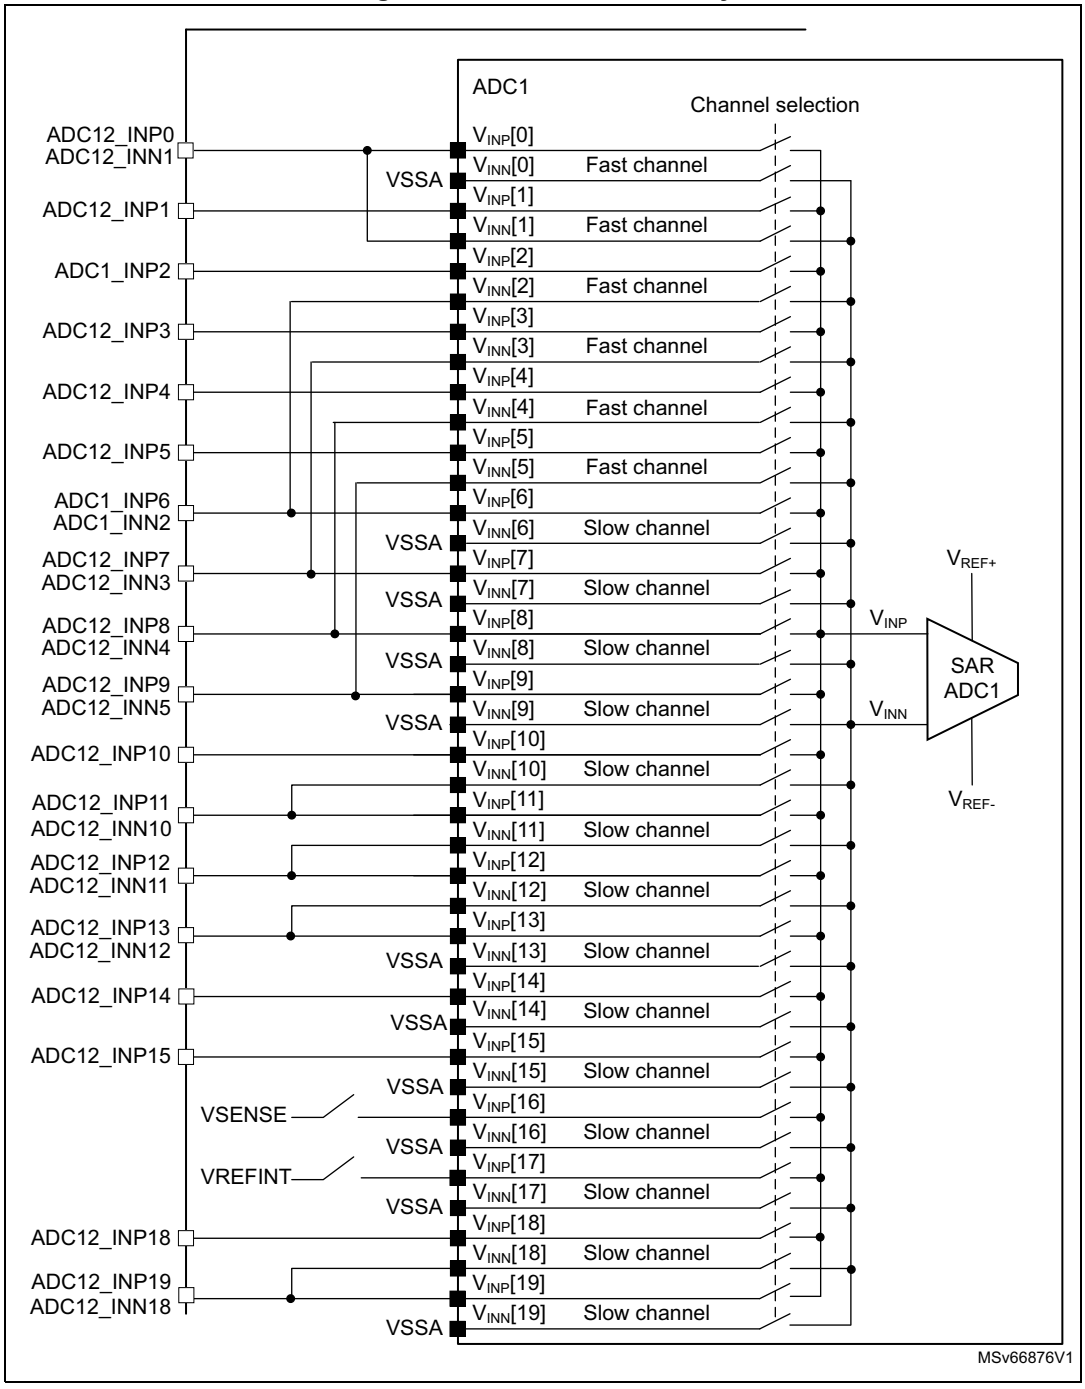


Figure 190. ADC2 connectivity

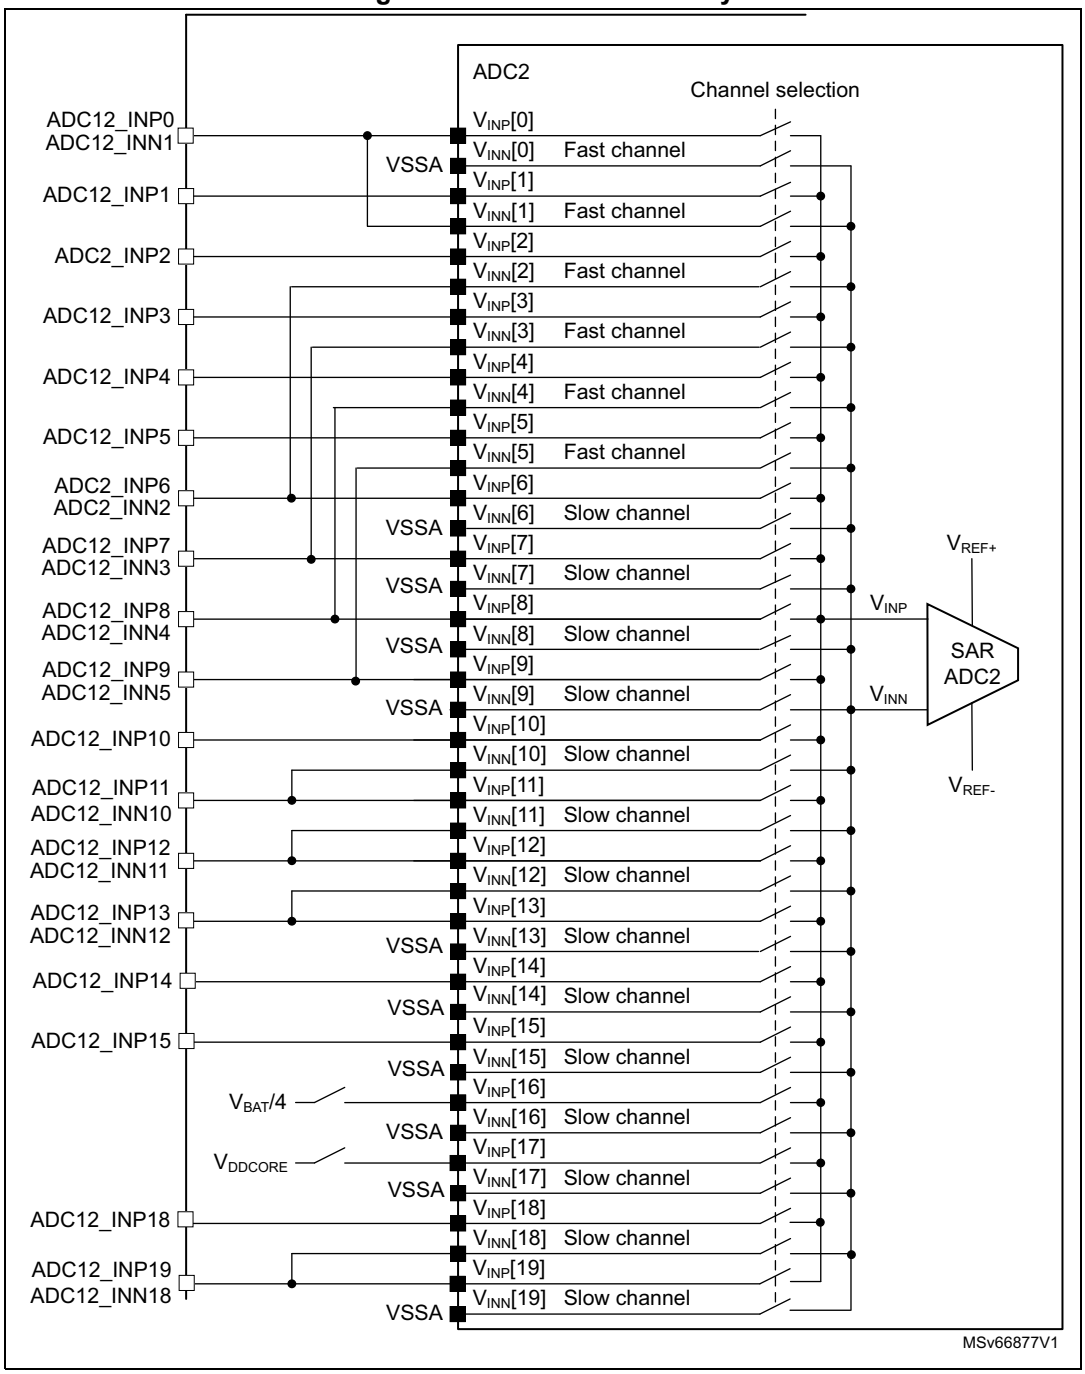


26.4.5 Slave AHB interface

The ADCs implement an AHB slave port for control/status register and data access. The features of the AHB interface are listed below:

- Word (32-bit) accesses
- Single cycle response
- Response to all read/write accesses to the registers with zero wait states.

The AHB slave interface does not support split/retry requests, and never generates AHB errors.

26.4.6 ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)

By default, the ADC is in Deep-power-down mode where its supply is internally switched off to reduce the leakage currents (the reset state of bit DEEPPWD is 1 in the ADC_CR register).

To start ADC operations, it is first needed to exit Deep-power-down mode by setting bit DEEPPWD = 0.

Then, it is mandatory to enable the ADC internal voltage regulator by setting the bit ADVREGEN = 1 into ADC_CR register. The software must wait for the startup time of the ADC voltage regulator ($T_{ADCVREG\_STUP}$) before launching a calibration or enabling the ADC. This delay must be implemented by software.

For the startup time of the ADC voltage regulator, refer to device datasheet for $T_{ADCVREG\_STUP}$ parameter.

When ADC operations are complete, the ADC can be disabled (ADEN = 0). It is possible to save power by also disabling the ADC voltage regulator. This is done by writing bit ADVREGEN = 0.

Then, to save more power by reducing the leakage currents, it is also possible to re-enter in ADC Deep-power-down mode by setting bit DEEPPWD = 1 into ADC_CR register. This is particularly interesting before entering Stop mode.

Note: Writing DEEPPWD = 1 automatically disables the ADC voltage regulator and bit ADVREGEN is automatically cleared.

When the internal voltage regulator is disabled (ADVREGEN = 0), the internal analog calibration is kept.

In ADC Deep-power-down mode (DEEPPWD = 1), the internal analog calibration is lost and it is necessary to either relaunch a calibration or re-apply the calibration factor which was previously saved (refer to *Section 26.4.8: Calibration (ADCAL, ADCALDIF, ADC_CALFACT)*).

26.4.7 Single-ended and differential input channels

Channels can be configured to be either single-ended input or differential input by programming DIFSEL[i] bits in the ADC_DIFSEL register. This configuration must be written while the ADC is disabled (ADEN = 0). Note that the DIFSEL[i] bits corresponding to single-ended channels are always programmed at 0.

In single-ended input mode, the analog voltage to be converted for channel “i” is the difference between the external voltage $V_{INP[i]}$ (positive input) and V_{REF-} (negative input).

In differential input mode, the analog voltage to be converted for channel “i” is the difference between the external voltage $V_{INP[i]}$ (positive input) and $V_{INN[i]}$ (negative input).

The output data for the differential mode is an unsigned data. When $V_{INP[i]}$ equals V_{REF-}, $V_{INN[i]}$ equals V_{REF+} and the output data is 0x000 (12-bit resolution mode). When $V_{INP[i]}$ equals V_{REF+}, $V_{INN[i]}$ equals V_{REF-} and the output data is 0xFFF.

$$\text{Converted value} = \frac{\text{ADC\_Full\_Scale}}{2} \times \left[1 + \frac{V_{INP} - V_{INN}}{V_{REF+}}\right]$$

When ADC is configured as differential mode, both inputs should be biased at (V_{REF+}) /2 voltage.

The input signals are supposed to be differential (common mode voltage should be fixed).

Internal channels (such as V_{REFINT} and V_{SENSE}) are used in single-ended mode only.

For a complete description of how the input channels are connected for each ADC, refer to *Section 26.4.4: ADC connectivity*.

Caution: When configuring the channel “i” in differential input mode, its negative input voltage $V_{INN[i]}$ is connected to another channel. As a consequence, this channel is no longer usable in single-ended mode or in differential mode and must never be configured to be converted. Some channels are shared between ADC1/ADC2: this can make the channel on the other ADC unusable. Only exception is interleaved mode for ADC master and the slave.

26.4.8 Calibration (ADCAL, ADCALDIF, ADC_CALFACT)

Each ADC provides an automatic calibration procedure which drives all the calibration sequence including the power-on/off sequence of the ADC. During the procedure, the ADC calculates a calibration factor which is 7-bit wide and which is applied internally to the ADC until the next ADC power-off. During the calibration procedure, the application must not use the ADC and must wait until calibration is complete.

Calibration is preliminary to any ADC operation. It removes the offset error which may vary from chip to chip due to process or bandgap variation.

The calibration factor to be applied for single-ended input conversions is different from the factor to be applied for differential input conversions:

- Write ADCALDIF = 0 before launching a calibration which will be applied for single-ended input conversions.
- Write ADCALDIF = 1 before launching a calibration which will be applied for differential input conversions.

The calibration is then initiated by software by setting bit ADCAL = 1. Calibration can only be initiated when the ADC is disabled (when ADEN = 0). ADCAL bit stays at 1 during all the

calibration sequence. It is then cleared by hardware as soon the calibration completes. At this time, the associated calibration factor is stored internally in the analog ADC and also in the bits CALFACT_S[6:0] or CALFACT_D[6:0] of ADC_CALFACT register (depending on single-ended or differential input calibration)

The internal analog calibration is kept if the ADC is disabled (ADEN = 0). However, if the ADC is disabled for extended periods, then it is recommended that a new calibration cycle is run before re-enabling the ADC.

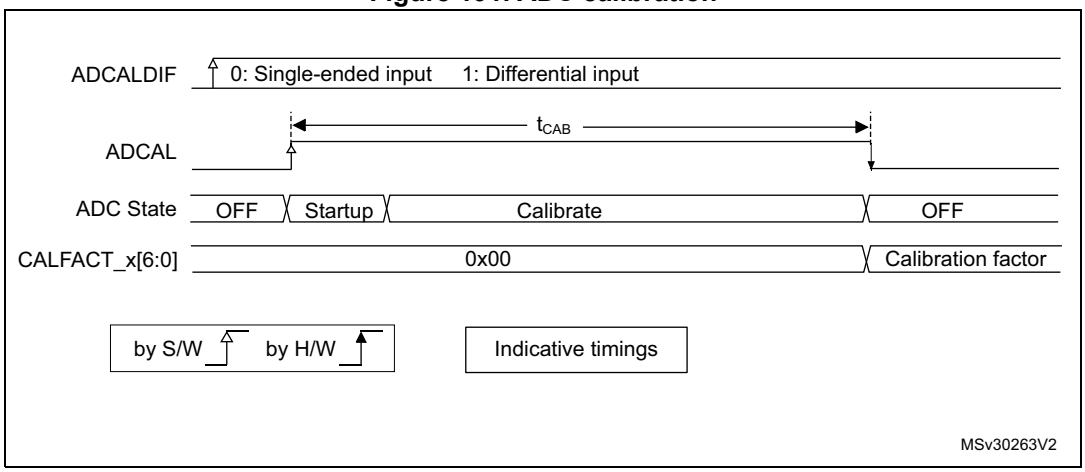
The internal analog calibration is lost each time the power of the ADC is removed (example, when the product enters in Standby or VBAT mode). In this case, to avoid spending time recalibrating the ADC, it is possible to re-write the calibration factor into the ADC_CALFACT register without recalibrating, supposing that the software has previously saved the calibration factor delivered during the previous calibration.

The calibration factor can be written if the ADC is enabled but not converting (ADEN = 1 and ADSTART = 0 and JADSTART = 0). Then, at the next start of conversion, the calibration factor is automatically injected into the analog ADC. This loading is transparent and does not add any cycle latency to the start of the conversion. It is recommended to recalibrate when V_{REF+} voltage changed more than 10%.

Software procedure to calibrate the ADC

1. Ensure DEEPPWD = 0, ADVREGEN = 1 and that ADC voltage regulator startup time has elapsed.
2. Ensure that ADEN = 0.
3. Select the input mode for this calibration by setting ADCALDIF = 0 (single-ended input) or ADCALDIF = 1 (differential input).
4. Set ADCAL = 1.
5. Wait until ADCAL = 0.
6. The calibration factor can be read from ADC_CALFACT register.

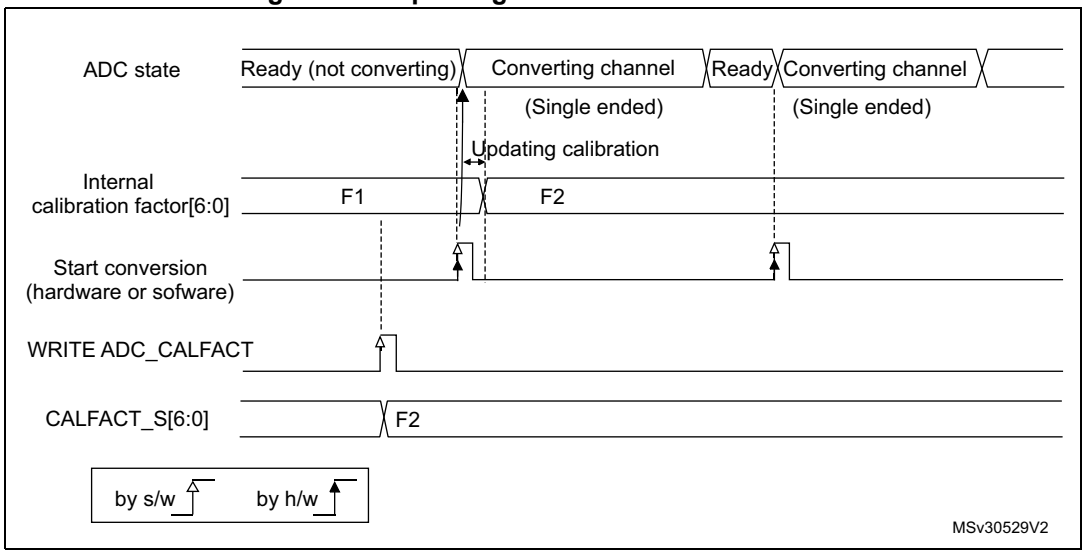
Figure 191. ADC calibration



Software procedure to reinject a calibration factor into the ADC

1. Ensure ADEN = 1 and ADSTART = 0 and JADSTART = 0 (ADC enabled and no conversion is ongoing).
2. Write CALFACT_S and CALFACT_D with the new calibration factors.
3. When a conversion is launched, the calibration factor is injected into the analog ADC only if the internal analog calibration factor differs from the one stored in bits CALFACT_S for single-ended input channel or bits CALFACT_D for differential input channel.

Figure 192. Updating the ADC calibration factor

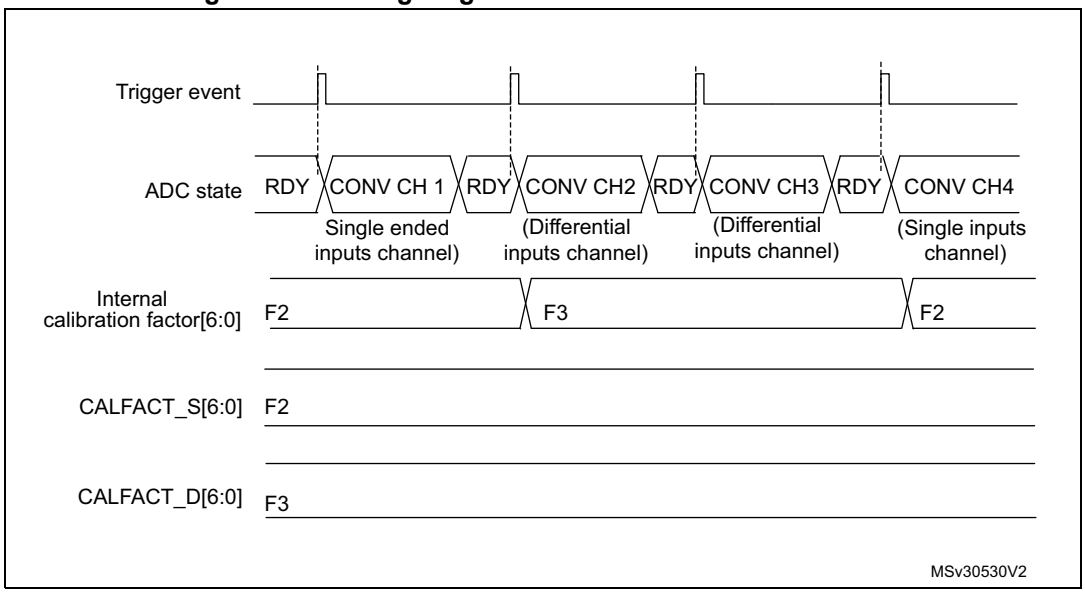


Converting single-ended and differential analog inputs with a single ADC

If the ADC is supposed to convert both differential and single-ended inputs, two calibrations must be performed, one with ADCALDIF = 0 and one with ADCALDIF = 1. The procedure is the following:

1. Disable the ADC.
2. Calibrate the ADC in single-ended input mode (with ADCALDIF = 0). This updates the register CALFACT_S[6:0].
3. Calibrate the ADC in differential input modes (with ADCALDIF = 1). This updates the register CALFACT_D[6:0].
4. Enable the ADC, configure the channels and launch the conversions. Each time there is a switch from a single-ended to a differential inputs channel (and vice-versa), the calibration is automatically injected into the analog ADC.

Figure 193. Mixing single-ended and differential channels



26.4.9 ADC on-off control (ADEN, ADDIS, ADRDY)

First of all, follow the procedure explained in *Section 26.4.6: ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)*).

Once DEEPPWD = 0 and ADVREGEN = 1, the ADC can be enabled and the ADC needs a stabilization time of t_{STAB} before it starts converting accurately, as shown in *Figure 194*. Two control bits enable or disable the ADC:

- ADEN = 1 enables the ADC. The flag ADRDY is set once the ADC is ready for operation.
- ADDIS = 1 disables the ADC. ADEN and ADDIS are then automatically cleared by hardware as soon as the analog ADC is effectively disabled.

Regular conversion can then start either by setting ADSTART = 1 (refer to *Section 26.4.18: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN,JEXTSEL, JEXTEN)*) or when an external trigger event occurs, if triggers are enabled.

Injected conversions start by setting JADSTART = 1 or when an external injected trigger event occurs, if injected triggers are enabled.

Software procedure to enable the ADC

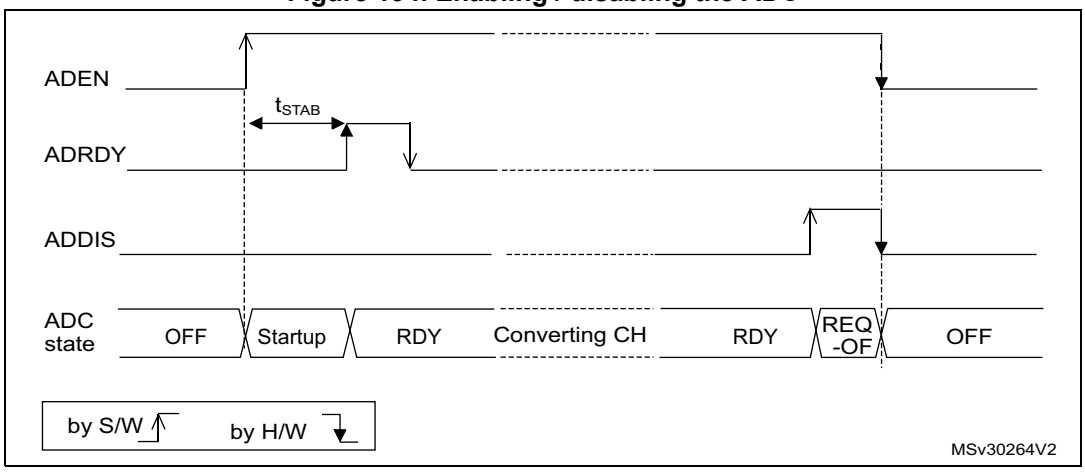
1. Clear the ADRDY bit in the ADC_ISR register by writing ‘1’.
2. Set ADEN = 1.
3. Wait until ADRDY = 1 (ADRDY is set after the ADC startup time). This can be done using the associated interrupt (setting ADRDYIE = 1).
4. Clear the ADRDY bit in the ADC_ISR register by writing ‘1’ (optional).

Caution: ADEN bit cannot be set when ADCAL is set and during four ADC clock cycles after the ADCAL bit is cleared by hardware (end of the calibration).

Software procedure to disable the ADC

1. Check that both ADSTART = 0 and JADSTART = 0 to ensure that no conversion is ongoing. If required, stop any regular and injected conversion ongoing by setting ADSTP = 1 and JADSTP = 1 and then wait until ADSTP = 0 and JADSTP = 0.
2. Set ADDIS = 1.
3. If required by the application, wait until ADEN = 0, until the analog ADC is effectively disabled (ADDIS is automatically reset once ADEN = 0).

Figure 194. Enabling / disabling the ADC



26.4.10 Constraints when writing the ADC control bits

The software is allowed to write the RCC control bits to configure and enable the ADC clock (refer to RCC Section), the DIFSEL[i] control bits in the ADC_DIFSEL register and the control bits ADCAL and ADEN in the ADC_CR register, only if the ADC is disabled (ADEN must be equal to 0).

The software is then allowed to write the control bits ADSTART, JADSTART and ADDIS of the ADC_CR register only if the ADC is enabled and there is no pending request to disable the ADC (ADEN must be equal to 1 and ADDIS to 0).

For all the other control bits of the ADC_CFGR, ADC_SMPRx, ADC_TRy, ADC_SQRy, ADC_JDRy, ADC_OFRy, ADC_OFCHRy and ADC_IER registers:

- For control bits related to configuration of regular conversions, the software is allowed to write them only if the ADC is enabled (ADEN = 1) and if there is no regular conversion ongoing (ADSTART must be equal to 0).
- For control bits related to configuration of injected conversions, the software is allowed to write them only if the ADC is enabled (ADEN = 1) and if there is no injected conversion ongoing (JADSTART must be equal to 0).
- ADC_TRy registers can be modified when an analog-to-digital conversion is ongoing (refer to *Section 26.4.28: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)* for details).

The software is allowed to write the ADSTP or JADSTP control bits of the ADC_CR register only if the ADC is enabled, possibly converting, and if there is no pending request to disable the ADC (ADSTART or JADSTART must be equal to 1 and ADDIS to 0).

The software can write the register ADC_JSQR at any time, when the ADC is enabled (ADEN = 1). Refer to *Section 26.6.16: ADC injected sequence register (ADC_JSQR)* for additional details.

Note: There is no hardware protection to prevent these forbidden write accesses and ADC behavior may become in an unknown state. To recover from this situation, the ADC must be disabled (clear ADEN = 0 as well as all the bits of ADC_CR register).

26.4.11 Channel selection (SQRx, JSQRx)

The ADC features up to 20 multiplexed channels per ADC, out of which:

- Up to 18 analog inputs coming from GPIO pads (ADC_INP/INN[i]) depending on the products, not all of them are available on GPIO pads.
- ADC is connected to 4 internal analog inputs:
  - the internal temperature sensor (V_{SENSE})
  - the internal reference voltage (V_{REFINT})
  - the V_{BAT} monitoring channel ($V_{BAT}/4$)
  - the internal digital core voltage (V_{DDCORE})

  To convert one of the internal analog channels, the corresponding analog sources must first be enabled by programming bits VREFEN, VBATEN or TSEN in the ADC_CCR registers.

Refer to *Table ADC interconnection* in *Section 26.4.2: ADC pins and internal signals* for the connection of the above internal analog inputs to external ADC pins or internal signals.

The conversions can be organized in two groups: regular and injected. A group consists of a sequence of conversions that can be done on any channel and in any order. For instance, it is possible to implement the conversion sequence in the following order: ADC1/2_INP/INN3, ADC1/2_INP/INN8, ADC1/2_INP/INN2, ADC1/2_INN/INP2, ADC1/2_INP/INN0, ADC1/2_INP/INN2, ADC1/2_INP/INN2, ADC1/2_INP/INN15.

- A **regular group** is composed of up to 16 conversions. The regular channels and their order in the conversion sequence must be selected in the ADC_SQRy registers. The total number of conversions in the regular group must be written in the L[3:0] bits in the ADC_SQR1 register.
- An **injected group** is composed of up to 4 conversions. The injected channels and their order in the conversion sequence must be selected in the ADC_JSQR register. The total number of conversions in the injected group must be written in the L[1:0] bits in the ADC_JSQR register.

ADC_SQRy registers must not be modified while regular conversions can occur. For this, the ADC regular conversions must be first stopped by writing ADSTP = 1 (refer to *Section 26.4.17: Stopping an ongoing conversion (ADSTP, JADSTP)*).

The software is allowed to modify on-the-fly the ADC_JSQR register when JADSTART is set to 1 (injected conversions ongoing) only when the context queue is enabled (JQDIS = 0 in ADC_CFGR register). Refer to *Section 26.4.21: Queue of context for injected conversions*

26.4.12 Channel-wise programmable sampling time (SMPR1, SMPR2)

Before starting a conversion, the ADC must establish a direct connection between the voltage source under measurement and the embedded sampling capacitor of the ADC. This sampling time must be enough for the input voltage source to charge the embedded capacitor to the input voltage level.

Each channel can be sampled with a different sampling time which is programmable using the SMP[2:0] bits in the ADC_SMPR1 and ADC registers. It is therefore possible to select among the following sampling time values:

- SMP = 000: 2.5 ADC clock cycles
- SMP = 001: 6.5 ADC clock cycles
- SMP = 010: 12.5 ADC clock cycles
- SMP = 011: 24.5 ADC clock cycles
- SMP = 100: 47.5 ADC clock cycles
- SMP = 101: 92.5 ADC clock cycles
- SMP = 110: 247.5 ADC clock cycles
- SMP = 111: 640.5 ADC clock cycles

The total conversion time is calculated as follows:

T_{CONV} = Sampling time + 12.5 ADC clock cycles

Example:

With $F_{adc\_ker\_ck}$ = 30 MHz and a sampling time of 2.5 ADC clock cycles:

T_{CONV} = (2.5 + 12.5) ADC clock cycles = 15 ADC clock cycles = 500 ns

The ADC notifies the end of the sampling phase by setting the status bit EOSMP (only for regular conversion).

Note: Depending on the ADC conversion mode, the real sampling time can vary compared to the SMP value programmed above, while the equivalent total conversion time (T_{CONV}) does not change:

- *For the first conversion in scan or continuous mode and all the conversions in discontinuous mode, the real sampling time is 0.5 clock cycle less compared to the value configured above.*
- *For the second and subsequent conversions in scan or continuous mode, 0.5 cycle is added to the configured sampling time. This additional 0.5 clock cycle overlaps with the previous conversion cycle.*

Constraints on the sampling time

For each channel, SMP[2:0] bits must be programmed to respect a minimum sampling time as specified in the ADC characteristics section of the datasheets.

Bulb sampling mode

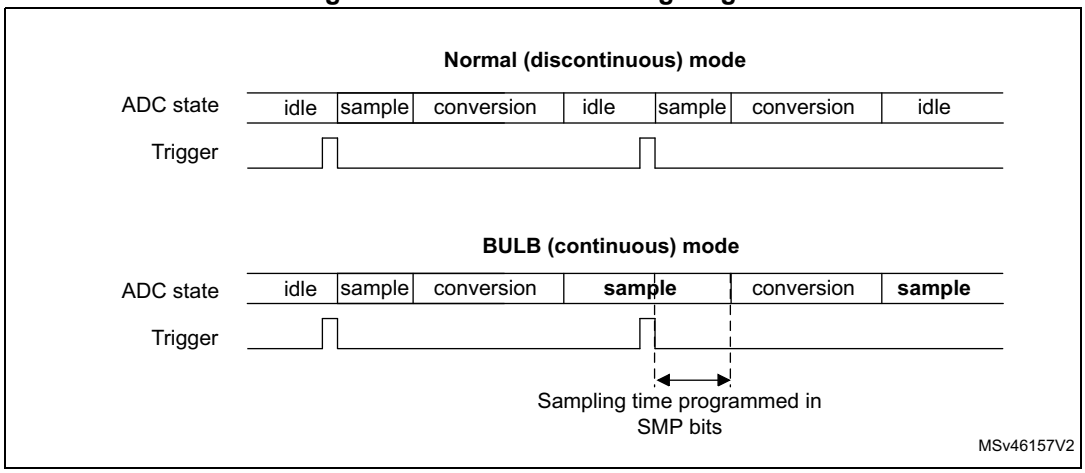
When the BULB bit is set in ADC register, the sampling period starts immediately after the last ADC conversion. A hardware or software trigger starts the conversion after the sampling time has been programmed in ADC_SMPR1 register. The very first ADC conversion, after the ADC is enabled, is performed with the sampling time programmed in SMP bits. The bulb mode is effective starting from the second conversion.

The maximum sampling time is limited (refer to the ADC characteristics section of the datasheet).

The bulb mode is neither compatible with the continuous conversion mode nor with the injected channel conversion.

When the BULB bit is set, it is not allowed to set SMPTRIG bit in ADC_CFGR2.

Figure 195. Bulb mode timing diagram



Sampling time control trigger mode

When the SMPTRIG bit is set, the sampling time programmed though SMPx bits is not applicable. The sampling time is controlled by the trigger signal edge.

When a hardware trigger is selected, each rising edge of the trigger signal starts the sampling period. A falling edge ends the sampling period and starts the conversion.

When a software trigger is selected, the software trigger is not the ADSTART bit in ADC_CR but the SWTRIG bit. SWTRIG bit has to be set to start the sampling period, and the SWTRIG bit has to be cleared to end the sampling period and start the conversion.

The maximum sampling time is limited (refer to the ADC characteristics section of the datasheet).

This mode is neither compatible with the continuous conversion mode, nor with the injected channel conversion.

When SMPTRIG bit is set, it is not allowed to set BULB bit.

I/O analog switch voltage booster

The resistance of the I/O analog switches increases when the V_{DDA} voltage is too low. The sampling time must consequently be adapted accordingly (refer to the device datasheet for the corresponding electrical characteristics). This resistance can be minimized at low V_{DDA}

by enabling an internal voltage booster through BOOSTE bit or by selecting a V_{DD} booster voltage (if V_{DD} > 2.7 V) through the ADV_READY bit of the PWR_PMCR register.

SMPPLUS control bit

The SMPPLUS bit can be used to change the sampling time from 2.5 ADC clock cycles to 3.5 ADC clock cycles.

26.4.13 Single conversion mode (CONT = 0)

In single conversion mode, the ADC performs once all the conversions of the channels. This mode is started with the CONT bit at 0 by either:

- Setting the ADSTART bit in the ADC_CR register (for a regular channel)
- Setting the JADSTART bit in the ADC_CR register (for an injected channel)
- External hardware trigger event (for a regular or injected channel)

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the 16-bit ADC_DR register
- The EOC (end of regular conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

Inside the injected sequence, after each conversion is complete:

- The converted data are stored into one of the four 16-bit ADC_JDRy registers
- The JEOC (end of injected conversion) flag is set
- An interrupt is generated if the JEOCIE bit is set

After the regular sequence is complete:

- The EOS (end of regular sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

After the injected sequence is complete:

- The JEOS (end of injected sequence) flag is set
- An interrupt is generated if the JEOSIE bit is set

Then the ADC stops until a new external regular or injected trigger occurs or until bit ADSTART or JADSTART is set again.

Note: To convert a single channel, program a sequence with a length of 1.

26.4.14 Continuous conversion mode (CONT = 1)

This mode applies to regular channels only.

In continuous conversion mode, when a software or hardware regular trigger event occurs, the ADC performs once all the regular conversions of the channels and then automatically restarts and continuously converts each conversions of the sequence. This mode is started with the CONT bit at 1 either by external trigger or by setting the ADSTART bit in the ADC_CR register.

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the 16-bit ADC_DR register
- The EOC (end of conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

After the sequence of conversions is complete:

- The EOS (end of sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

Then, a new sequence restarts immediately and the ADC continuously repeats the conversion sequence.

Note: To convert a single channel, program a sequence with a length of 1.

It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN = 1 and CONT = 1.

Injected channels cannot be converted continuously. The only exception is when an injected channel is configured to be converted automatically after regular channels in continuous mode (using JAUTO bit), refer to Auto-injection mode section).

26.4.15 Starting conversions (ADSTART, JADSTART)

Software starts ADC regular conversions by setting ADSTART = 1.

When ADSTART is set, the conversion starts:

- Immediately: if EXTEN = 0x0 (software trigger)
- At the next active edge of the selected regular hardware trigger: if EXTEN is not equal to 0x0

Software starts ADC injected conversions by setting JADSTART = 1.

When JADSTART is set, the conversion starts:

- Immediately, if JEXTEN = 0x0 (software trigger)
- At the next active edge of the selected injected hardware trigger: if JEXTEN is not equal to 0x0

Note: In auto-injection mode (JAUTO = 1), use ADSTART bit to start the regular conversions followed by the auto-injected conversions (JADSTART must be kept cleared).

ADSTART and JADSTART also provide information on whether any ADC operation is currently ongoing. It is possible to re-configure the ADC while ADSTART = 0 and JADSTART = 0 are both true, indicating that the ADC is idle.

ADSTART is cleared by hardware:

- In single mode with software regular trigger (CONT = 0, EXTSEL = 0x0)
  - At any end of regular conversion sequence (EOS assertion) or at any end of subgroup processing if DISCEN = 1
- In all cases (CONT = x, EXTSEL = x)
  - After execution of the ADSTP procedure asserted by the software.

Note: In continuous mode (CONT = 1), ADSTART is not cleared by hardware with the assertion of EOS because the sequence is automatically relaunched.

When a hardware trigger is selected in single mode (CONT = 0 and EXTSEL # 0x00), ADSTART is not cleared by hardware with the assertion of EOS to help the software which does not need to reset ADSTART again for the next hardware trigger event. This ensures that no further hardware triggers are missed.

JADSTART is cleared by hardware:

- In single mode with software injected trigger (JEXTSEL = 0x0)
  - At any end of injected conversion sequence (JEOS assertion) or at any end of subgroup processing if JDISCEN = 1
- in all cases (JEXTSEL = x)
  - After execution of the JADSTP procedure asserted by the software.

Note: When the software trigger is selected, ADSTART bit should not be set if the EOC flag is still high.

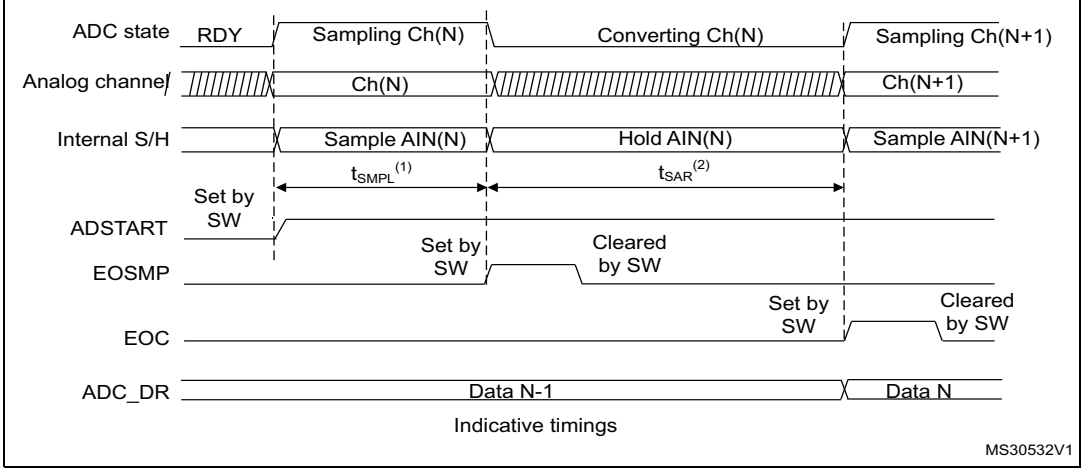
26.4.16 ADC timing

The elapsed time between the start of a conversion and the end of conversion is the sum of the configured sampling time plus the successive approximation time depending on data resolution:

$$T_{CONV} = T_{SMPL} + T_{SAR} = [2.5\ _{|min} + 12.5\ _{|12bit}] \times T_{ADC\_CLK}$$

$$T_{CONV} = T_{SMPL} + T_{SAR} = 83.33\ ns\ _{|min} + 416.67\ ns\ _{|12bit} = 500.0\ ns\ (for\ F_{ADC\_CLK} = 30\ MHz)$$

Figure 196. Analog to digital conversion time



1. T_{SMPL} depends on SMP[2:0].
2. T_{SAR} depends on RES[2:0].

26.4.17 Stopping an ongoing conversion (ADSTP, JADSTP)

The software can decide to stop regular conversions ongoing by setting ADSTP = 1 and injected conversions ongoing by setting JADSTP = 1.

Stopping conversions resets the ongoing ADC operation. Then the ADC can be reconfigured (ex: changing the channel selection or the trigger) ready for a new operation.

Note that it is possible to stop injected conversions while regular conversions are still operating and vice-versa. This allows, for instance, re-configuration of the injected conversion sequence and triggers while regular conversions are still operating (and vice-versa).

When the ADSTP bit is set by software, any ongoing regular conversion is aborted with partial result discarded (ADC_DR register is not updated with the current conversion).

When the JADSTP bit is set by software, any ongoing injected conversion is aborted with partial result discarded (ADC_JDRy register is not updated with the current conversion). The scan sequence is also aborted and reset (meaning that relaunching the ADC would restart a new sequence).

Once this procedure is complete, bits ADSTP/ADSTART (in case of regular conversion), or JADSTP/JADSTART (in case of injected conversion) are cleared by hardware and the software must poll ADSTART (or JADSTART) until the bit is reset before assuming the ADC is completely stopped.

Note: In auto-injection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (JADSTP must not be used).

Figure 197. Stopping ongoing regular conversions

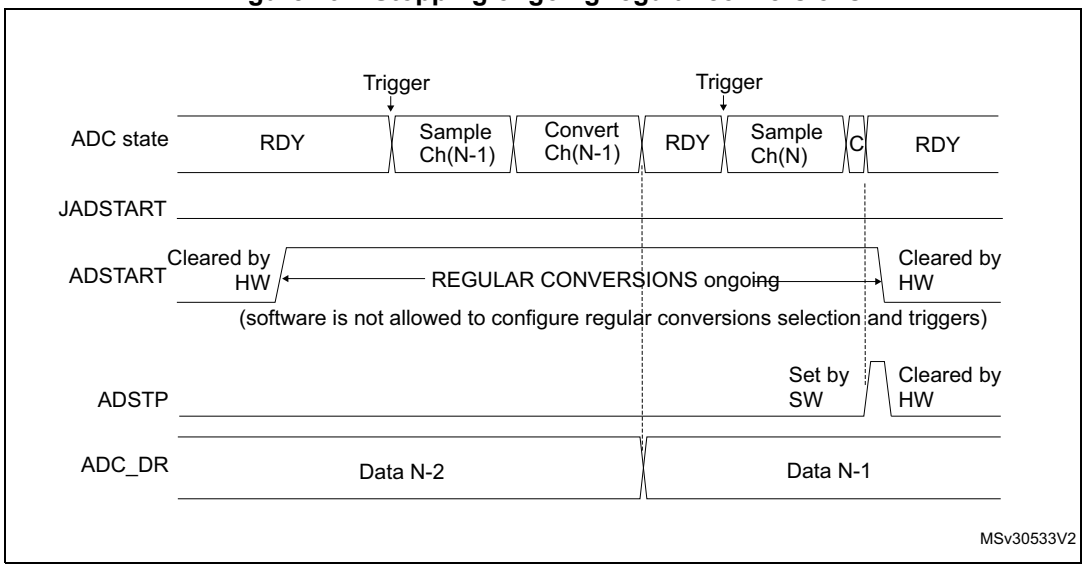


Figure 198. Stopping ongoing regular and injected conversions

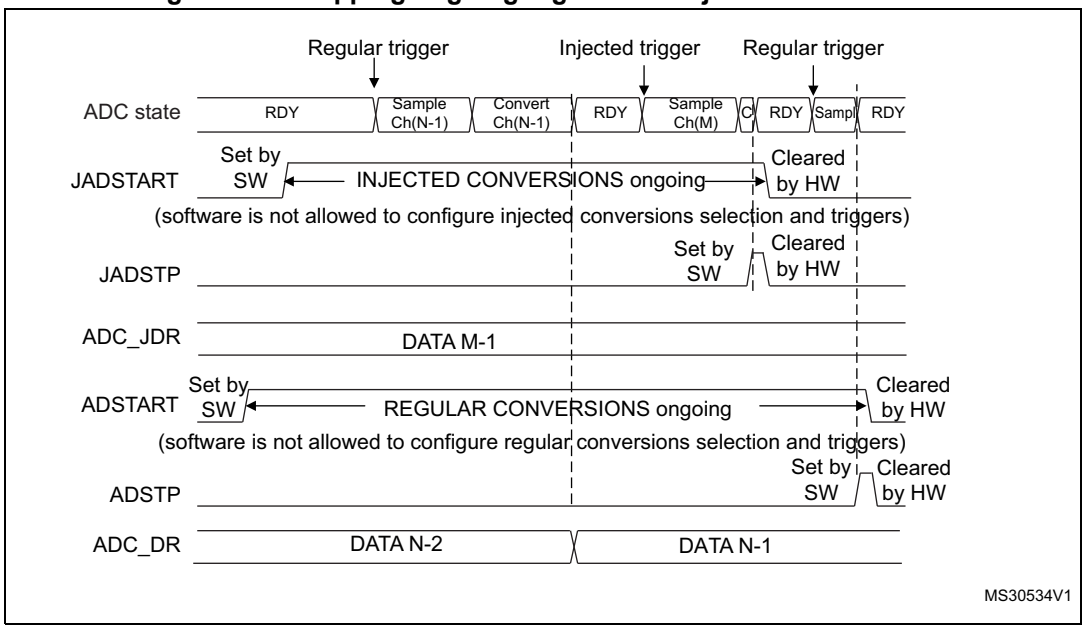


26.4.18 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN,JEXTSEL, JEXTEN)

A conversion or a sequence of conversions can be triggered either by software or by an external event (such as timer capture, input pins). If the EXTEN[1:0] control bits (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from 0b00, then external events are able to trigger a conversion with the selected polarity.

When the Injected Queue is enabled (bit JQDIS = 0), injected software triggers are not possible.

The regular trigger selection is effective once software has set bit ADSTART = 1 and the injected trigger selection is effective once software has set bit JADSTART = 1.

Any hardware triggers which occur while a conversion is ongoing are ignored.

- If bit ADSTART = 0, any regular hardware triggers which occur are ignored.
- If bit JADSTART = 0, any injected hardware triggers which occur are ignored.

Table 243 provides the correspondence between the EXTEN[1:0] and JEXTEN[1:0] values and the trigger polarity.

Table 243. Configuring the trigger polarity for regular external triggers

EXTEN[1:0]	Source
00	Hardware Trigger detection disabled, software trigger detection enabled
01	Hardware Trigger with detection on the rising edge
10	Hardware Trigger with detection on the falling edge
11	Hardware Trigger with detection on both the rising and falling edges

Note: The polarity of the regular trigger cannot be changed on-the-fly.

Table 244. Configuring the trigger polarity for injected external triggers

JEXTEN[1:0]	Source
00	– If JQDIS = 1 (Queue disabled): Hardware trigger detection disabled, software trigger detection enabled – If JQDIS = 0 (Queue enabled), Hardware and software trigger detection disabled
01	Hardware Trigger with detection on the rising edge
10	Hardware Trigger with detection on the falling edge
11	Hardware Trigger with detection on both the rising and falling edges

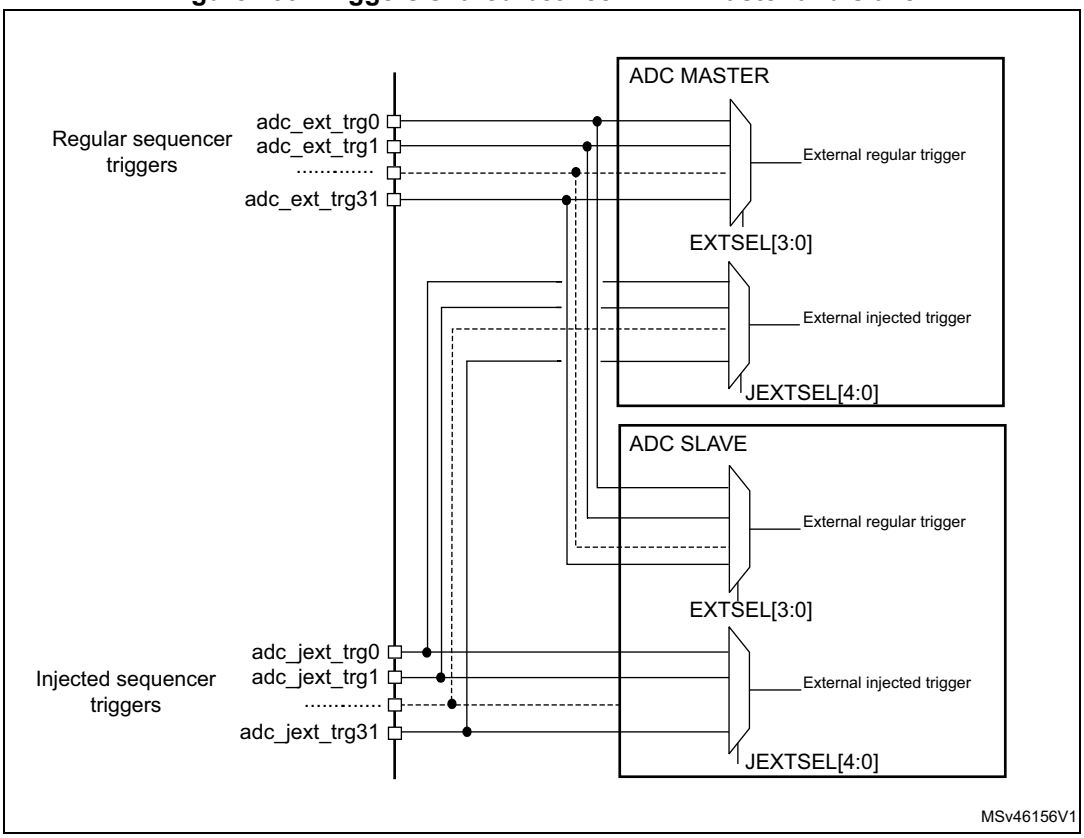
Note: The polarity of the injected trigger can be anticipated and changed on-the-fly when the queue is enabled (JQDIS = 0). Refer to Section 26.4.21: Queue of context for injected conversions.

The EXTSEL and JEXTSEL control bits select which out of 32 possible events can trigger conversion for the regular and injected groups.

A regular group conversion can be interrupted by an injected trigger.

Note: The regular trigger selection cannot be changed on-the-fly. The injected trigger selection can be anticipated and changed on-the-fly. Refer to Section 26.4.21: Queue of context for injected conversions on page 1041.

Figure 199. Triggers shared between ADC master and slave



Refer to Table ADC interconnection in *Section 26.4.2: ADC pins and internal signals* for the list of all the external triggers that can be used for regular conversion.

26.4.19 Injected channel management

Triggered injection mode

To use triggered injection, the JAUTO bit in the ADC_CFGR register must be cleared.

1. Start the conversion of a group of regular channels either by an external trigger or by setting the ADSTART bit in the ADC_CR register.
2. If an external injected trigger occurs, or if the JADSTART bit in the ADC_CR register is set during the conversion of a regular group of channels, the current conversion is reset and the injected channel sequence switches are launched (all the injected channels are converted once).
3. Then, the regular conversion of the regular group of channels is resumed from the last interrupted regular conversion.
4. If a regular event occurs during an injected conversion, the injected conversion is not interrupted but the regular sequence is executed at the end of the injected sequence. *Figure 200* shows the corresponding timing diagram.

Note: When using triggered injection, one must ensure that the interval between trigger events is longer than the injection sequence. For instance, if the sequence length is 30 ADC clock cycles (that is two conversions with a sampling time of 2.5 clock periods), the minimum interval between triggers must be 31 ADC clock cycles.

Auto-injection mode

If the JAUTO bit in the ADC_CFGR register is set, then the channels in the injected group are automatically converted after the regular group of channels. This can be used to convert a sequence of up to 20 conversions programmed in the ADC_SQRy and ADC_JSQR registers.

In this mode, the ADSTART bit in the ADC_CR register must be set to start regular conversions, followed by injected conversions (JADSTART must be kept cleared). Setting the ADSTP bit aborts both regular and injected conversions (JADSTP bit must not be used).

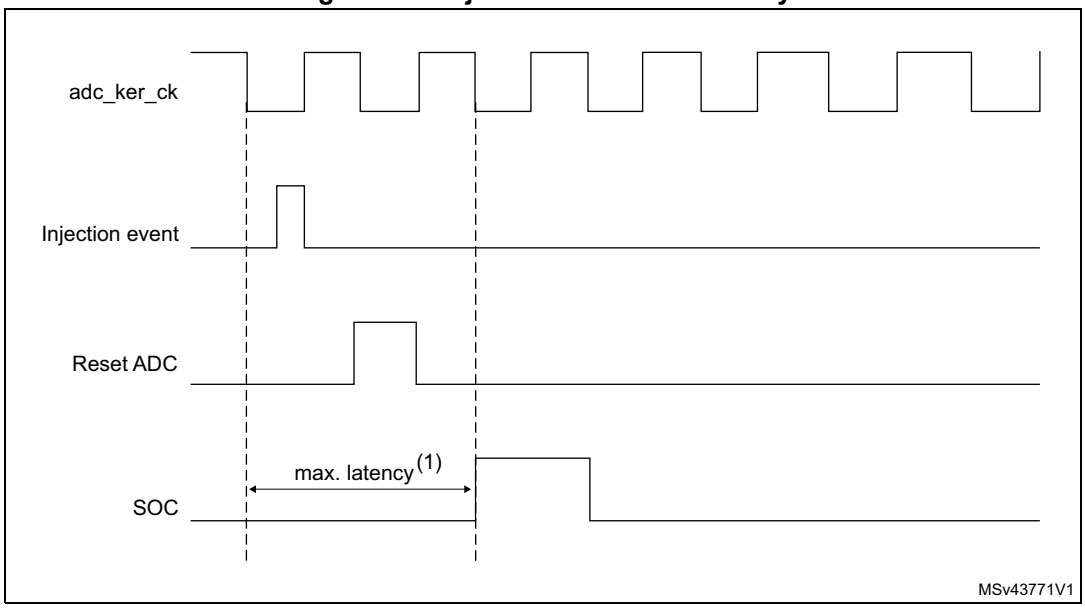
In this mode, external trigger on injected channels must be disabled.

If the CONT bit is also set in addition to the JAUTO bit, regular channels followed by injected channels are continuously converted.

Note: It is not possible to use both the auto-injected and discontinuous modes simultaneously.

When the DMA is used for exporting regular sequencer's data in JAUTO mode, it is necessary to program it in circular mode (CIRC bit set in DMA_CCRx register). If the CIRC bit is reset (single-shot mode), the JAUTO sequence is stopped upon DMA Transfer Complete event.

Figure 200. Injected conversion latency



1. The maximum latency value can be found in the electrical characteristics of the device datasheet.

26.4.20 Discontinuous mode (DISCEN, DISCNUM, JDISCEN)

Regular group mode

This mode is enabled by setting the DISCEN bit in the ADC_CFGR register.

It is used to convert a short sequence (subgroup) of n conversions (n ≤ 8) that is part of the sequence of conversions selected in the ADC_SQRy registers. The value of n is specified by writing to the DISCNUM[2:0] bits in the ADC_CFGR register.

When an external trigger occurs, it starts the next n conversions selected in the ADC_SQRy registers until all the conversions in the sequence are done. The total sequence length is defined by the L[3:0] bits in the ADC_SQR1 register.

Example:

- DISCEN = 1, n = 3, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11
  - 1st trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
  - 2nd trigger: channels converted are 6, 7, 8 (an EOC event is generated at each conversion).
  - 3rd trigger: channels converted are 9, 10, 11 (an EOC event is generated at each conversion) and an EOS event is generated after the conversion of channel 11.
  - 4th trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
  - ...
- DISCEN = 0, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10,11
  - 1st trigger: the complete sequence is converted: channel 1, then 2, 3, 6, 7, 8, 9, 10 and 11. Each conversion generates an EOC event and the last one also generates an EOS event.
  - All the next trigger events relaunch the complete sequence.

Note: The channel numbers referred to in the above example might not be available on all microcontrollers.

When a regular group is converted in discontinuous mode, no rollover occurs (the last subgroup of the sequence can have less than n conversions).

When all subgroups are converted, the next trigger starts the conversion of the first subgroup. In the example above, the 4th trigger reconverts the channels 1, 2 and 3 in the 1st subgroup.

It is not possible to have both discontinuous mode and continuous mode enabled. In this case (if DISCEN = 1, CONT = 1), the ADC behaves as if continuous mode was disabled.

Injected group mode

This mode is enabled by setting the JDISCEN bit in the ADC_CFGR register. It converts the sequence selected in the ADC_JSQR register, channel by channel, after an external injected trigger event. This is equivalent to discontinuous mode for regular channels where ‘n’ is fixed to 1.

When an external trigger occurs, it starts the next channel conversions selected in the ADC_JSQR registers until all the conversions in the sequence are done. The total sequence length is defined by the JL[1:0] bits in the ADC_JSQR register.

Example:

- JDISCEN = 1, channels to be converted = 1, 2, 3
  - 1st trigger: channel 1 converted (a JEOC event is generated)
  - 2nd trigger: channel 2 converted (a JEOC event is generated)
  - 3rd trigger: channel 3 converted and a JEOC event + a JEOS event are generated
  - ...

Note: The channel numbers referred to in the above example might not be available on all microcontrollers.

When all injected channels have been converted, the next trigger starts the conversion of the first injected channel. In the example above, the 4th trigger reconverts the 1st injected channel 1.

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

26.4.21 Queue of context for injected conversions

A queue of context is implemented to anticipate up to 2 contexts for the next injected sequence of conversions. JQDIS bit of ADC_CFGR register must be reset to enable this feature. Only hardware-triggered conversions are possible when the context queue is enabled.

This context consists of:

- Configuration of the injected triggers (bits JEXTEN[1:0] and JEXTSEL bits in ADC_JSQR register)
- Definition of the injected sequence (bits JSQx[4:0] and JL[1:0] in ADC_JSQR register)

All the parameters of the context are defined into a single register ADC_JSQR and this register implements a queue of 2 buffers, allowing the bufferization of up to 2 sets of parameters:

- The JSQR register can be written at any moment even when injected conversions are ongoing.
- Each data written into the JSQR register is stored into the Queue of context.
- At the beginning, the Queue is empty and the first write access into the JSQR register immediately changes the context and the ADC is ready to receive injected triggers.
- Once an injected sequence is complete, the Queue is consumed and the context changes according to the next JSQR parameters stored in the Queue. This new context is applied for the next injected sequence of conversions.
- A Queue overflow occurs when writing into register JSQR while the Queue is full. This overflow is signaled by the assertion of the flag JQOVF. When an overflow occurs, the write access of JSQR register which has created the overflow is ignored and the queue of context is unchanged. An interrupt can be generated if bit JQOVFIE is set.
- Two possible behaviors are possible when the Queue becomes empty, depending on the value of the control bit JQM of register ADC_CFGR:
  - If JQM = 0, the Queue is empty just after enabling the ADC, but then it can never be empty during run operations: the Queue always maintains the last active context and any further valid start of injected sequence is served according to the last active context.
  - If JQM = 1, the Queue can be empty after the end of an injected sequence or if the Queue is flushed. When this occurs, there is no more context in the queue and hardware triggers are disabled. Therefore, any further hardware injected triggers are ignored until the software re-writes a new injected context into JSQR register.
- Reading JSQR register returns the current JSQR context which is active at that moment. When the JSQR context is empty, JSQR is read as 0x0000.
- The Queue is flushed when stopping injected conversions by setting JADSTP = 1 or when disabling the ADC by setting ADDIS = 1:
  - If JQM = 0, the Queue is maintained with the last active context.
  - If JQM = 1, the Queue becomes empty and triggers are ignored.

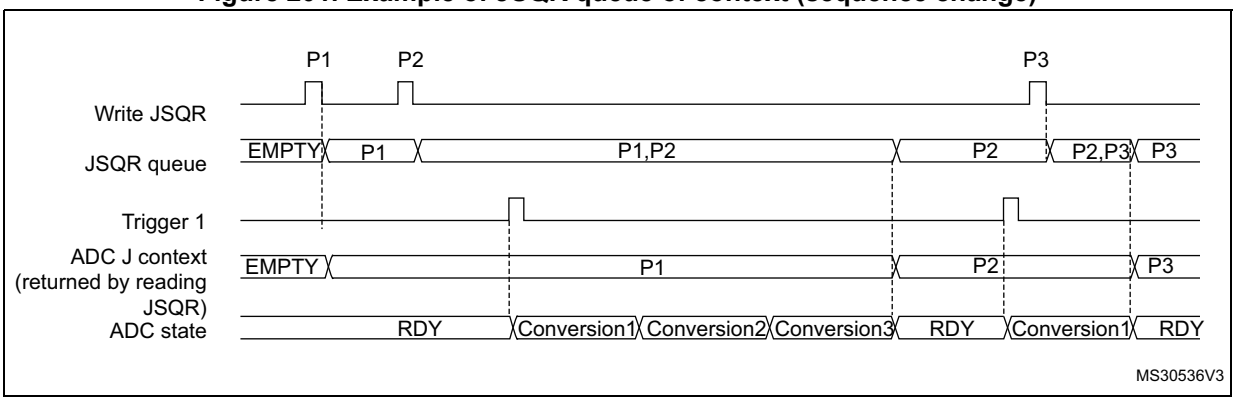
Note: When configured in discontinuous mode (bit JDISCEN = 1), only the last trigger of the injected sequence changes the context and consumes the Queue.The 1st trigger only consumes the queue but others are still valid triggers as shown by the discontinuous mode example below (length = 3 for both contexts):

- *1st trigger, discontinuous. Sequence 1: context 1 consumed, 1st conversion carried out*
- *2nd trigger, disc. Sequence 1: 2nd conversion.*
- *3rd trigger, discontinuous. Sequence 1: 3rd conversion.*
- *4th trigger, discontinuous. Sequence 2: context 2 consumed, 1st conversion carried out.*
- *5th trigger, discontinuous. Sequence 2: 2nd conversion.*
- *6th trigger, discontinuous. Sequence 2: 3rd conversion.*

Behavior when changing the trigger or sequence context

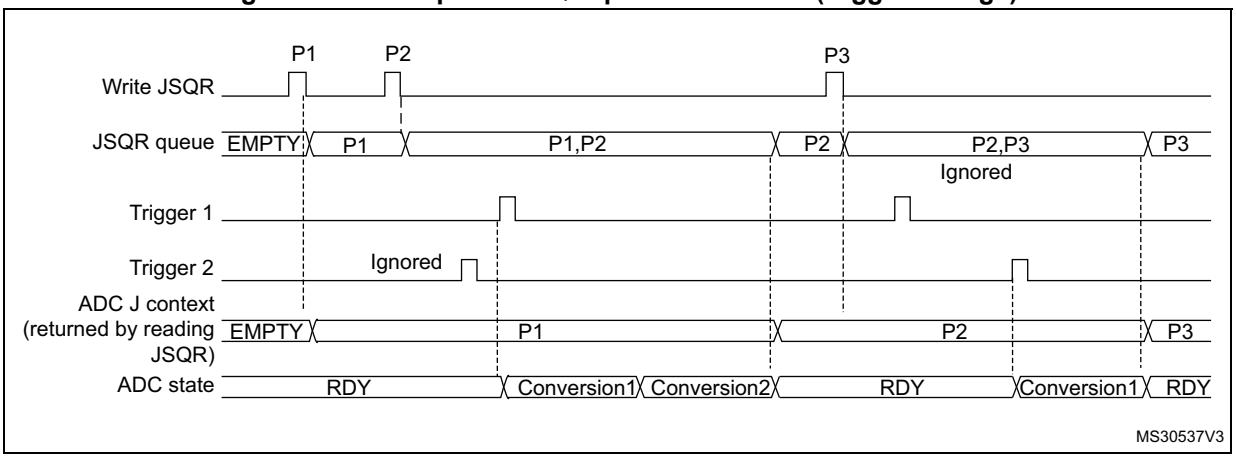
Figure 201 and *Figure 202* show the behavior of the context Queue when changing the sequence or the triggers.

Figure 201. Example of JSQR queue of context (sequence change)



1. Parameters:
   P1: sequence of 3 conversions, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 4 conversions, hardware trigger 1

Figure 202. Example of JSQR queue of context (trigger change)

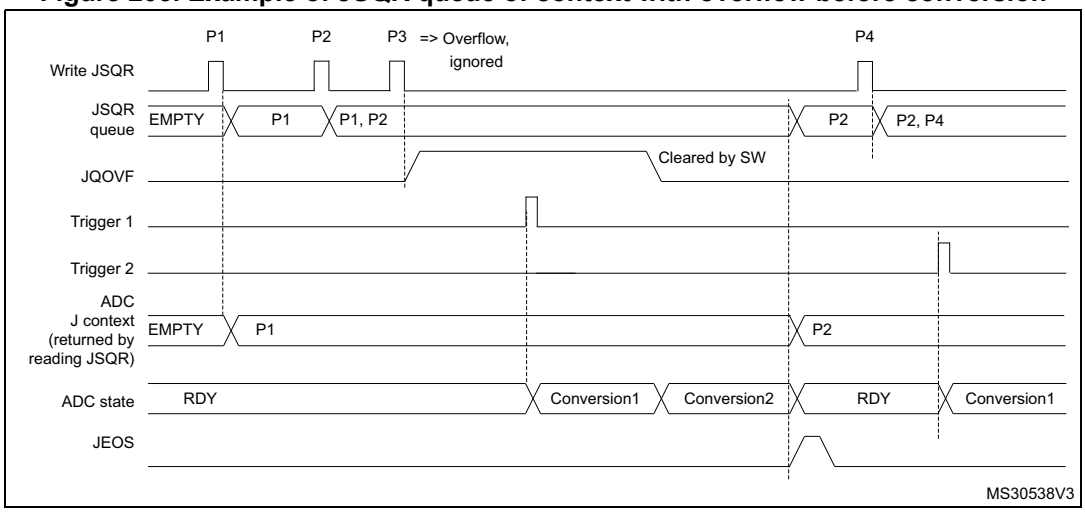


1. Parameters:
   P1: sequence of 2 conversions, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 2
   P3: sequence of 4 conversions, hardware trigger 1

Queue of context: Behavior when a queue overflow occurs

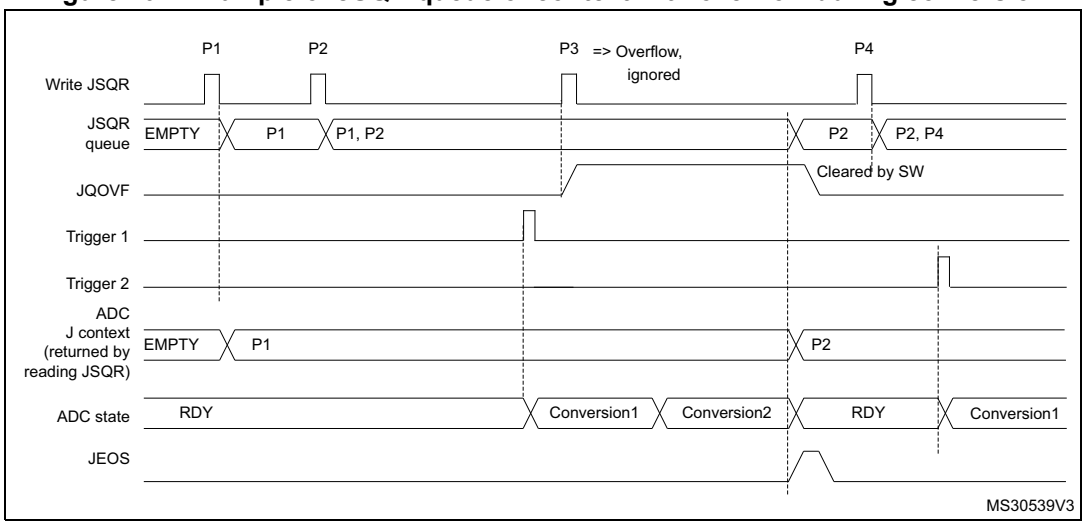
The *Figure 203* and *Figure 204* show the behavior of the context Queue if an overflow occurs before or during a conversion.

Figure 203. Example of JSQR queue of context with overflow before conversion



1. Parameters:
   P1: sequence of 2 conversions, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 2
   P3: sequence of 3 conversions, hardware trigger 1
   P4: sequence of 4 conversions, hardware trigger 1

Figure 204. Example of JSQR queue of context with overflow during conversion



1. Parameters:
   P1: sequence of 2 conversions, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 2
   P3: sequence of 3 conversions, hardware trigger 1
   P4: sequence of 4 conversions, hardware trigger 1

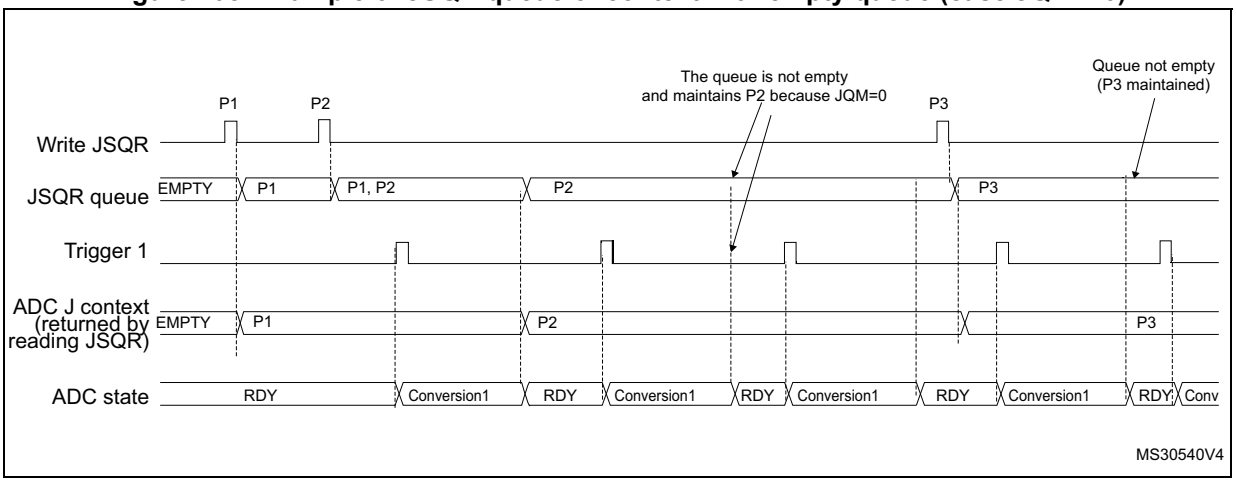
It is recommended to manage the queue overflows as described below:

- After each P context write into JSQR register, flag JQOVF shows if the write has been ignored or not (an interrupt can be generated).
- Avoid Queue overflows by writing the third context (P3) only once the flag JEOS of the previous context P2 has been set. This ensures that the previous context has been consumed and that the queue is not full.

Queue of context: Behavior when the queue becomes empty

Figure 205 and *Figure 206* show the behavior of the context Queue when the Queue becomes empty in both cases JQM = 0 or 1.

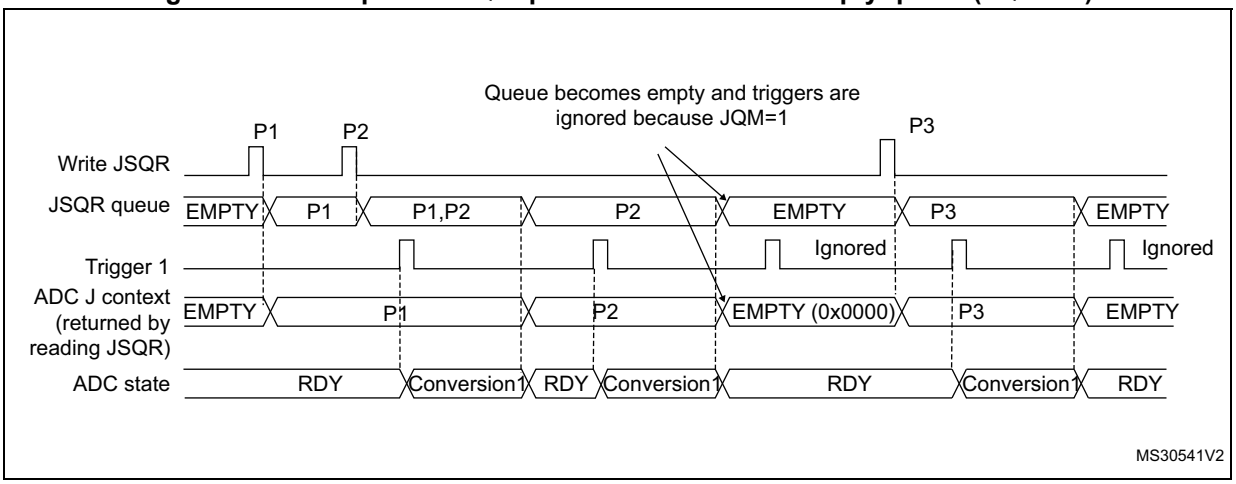
Figure 205. Example of JSQR queue of context with empty queue (case JQM = 0)



1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Note: When writing P3, the context changes immediately. However, because of internal resynchronization, there is a latency and if a trigger occurs just after or before writing P3, it can happen that the conversion is launched considering the context P2. To avoid this situation, the user must ensure that there is no ADC trigger happening when writing a new context that applies immediately.

Figure 206. Example of JSQR queue of context with empty queue (JQM = 1)

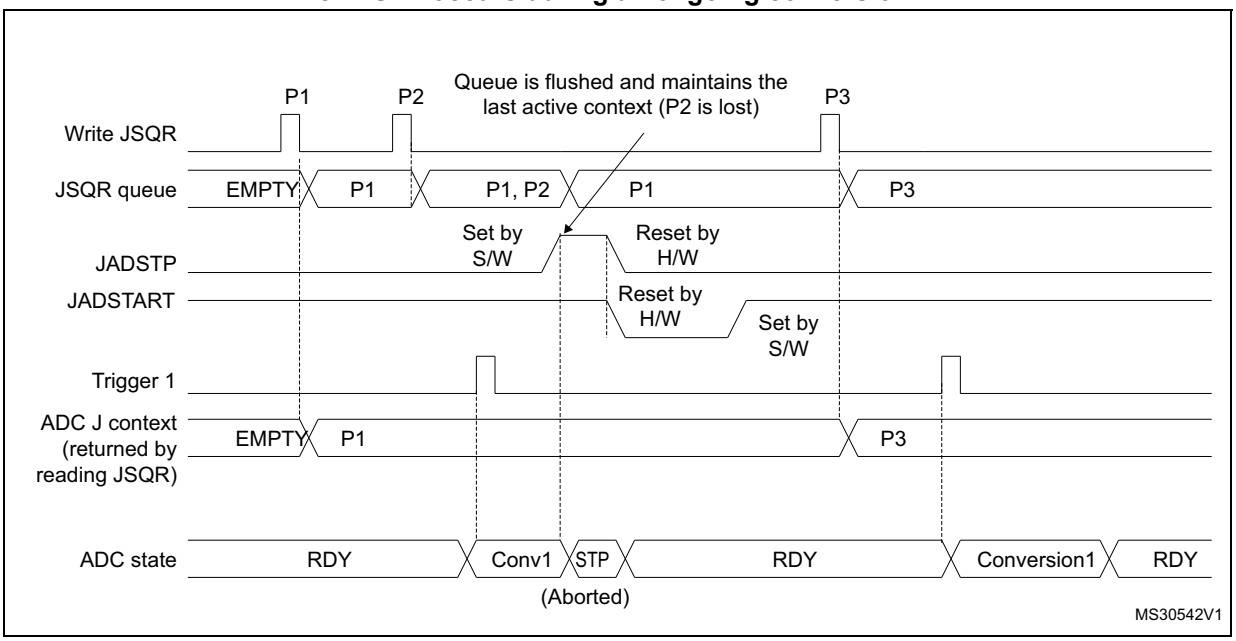


1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Flushing the queue of context

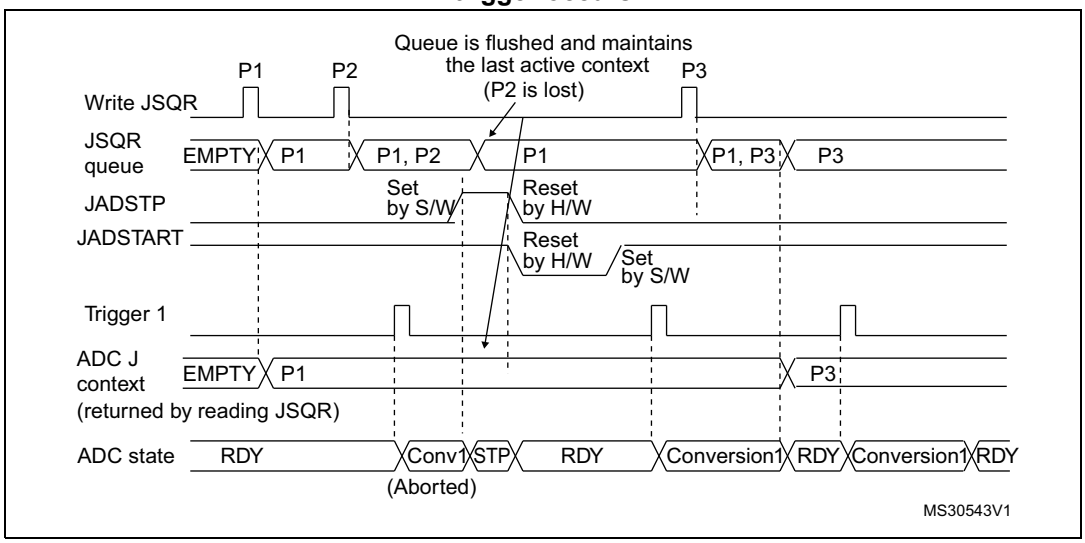
The figures below show the behavior of the context Queue in various situations when the queue is flushed.

Figure 207. Flushing JSQR queue of context by setting JADSTP = 1 (JQM = 0) - JADSTP occurs during an ongoing conversion.



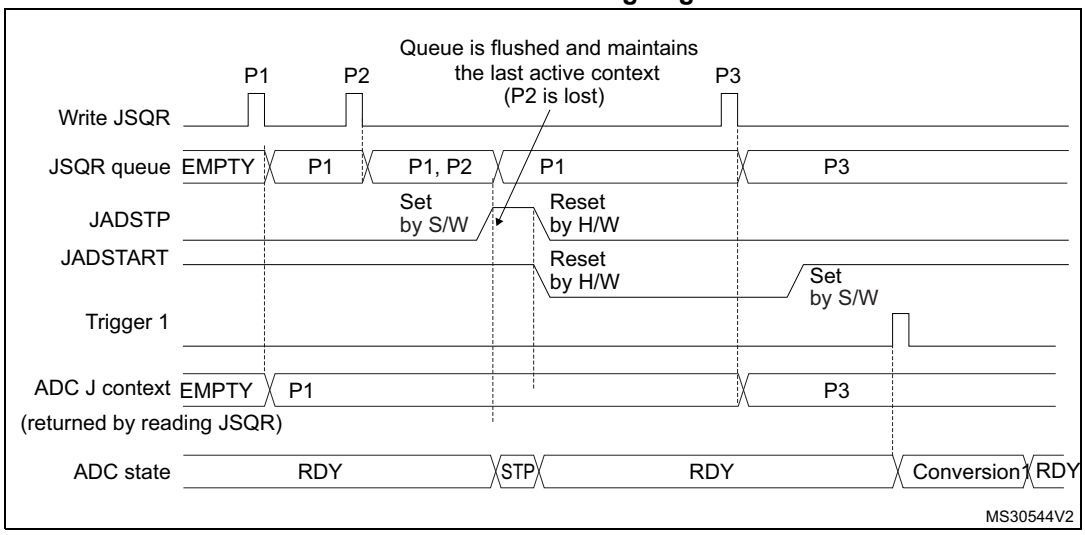
1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Figure 208. Flushing JSQR queue of context by setting JADSTP = 1 (JQM = 0) - JADSTP occurs during an ongoing conversion and a new trigger occurs



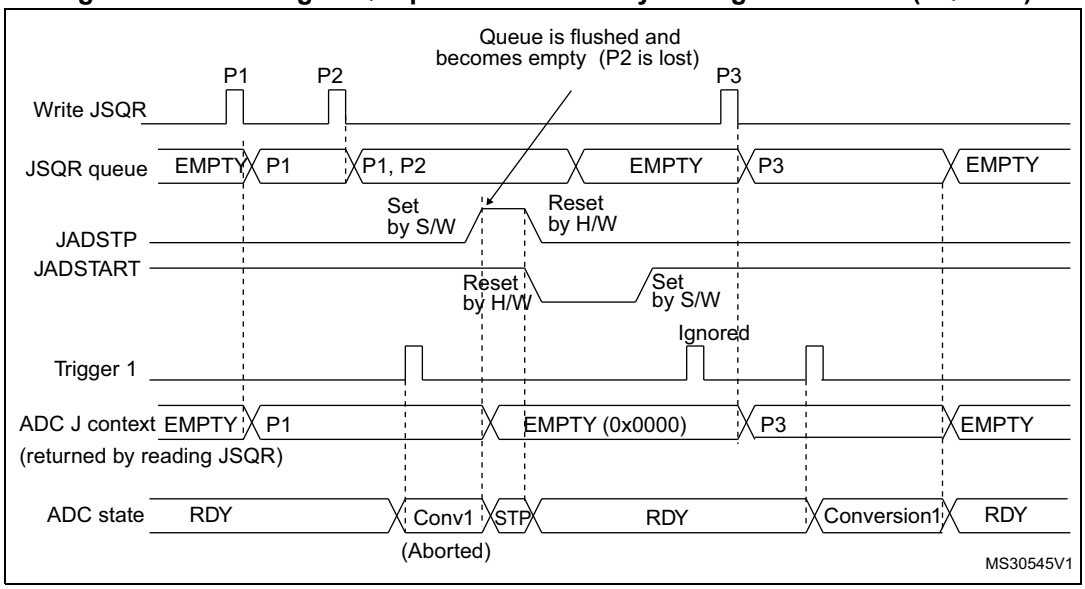
1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Figure 209. Flushing JSQR queue of context by setting JADSTP = 1 (JQM = 0) - JADSTP occurs outside an ongoing conversion



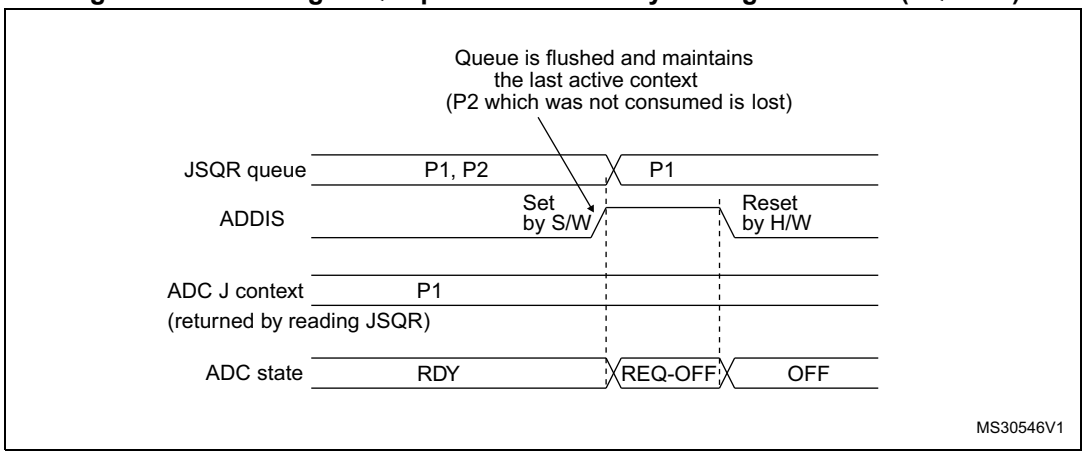
1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Figure 210. Flushing JSQR queue of context by setting JADSTP = 1 (JQM = 1)



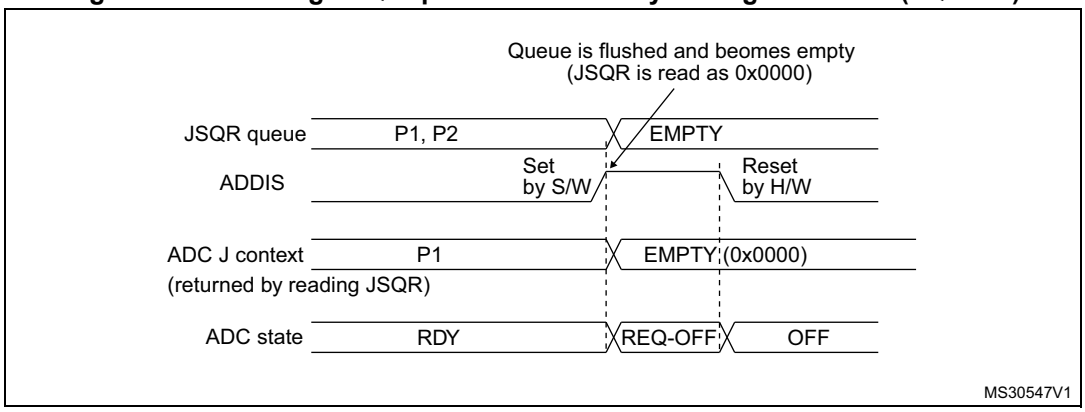
1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Figure 211. Flushing JSQR queue of context by setting ADDIS = 1 (JQM = 0)



1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Figure 212. Flushing JSQR queue of context by setting ADDIS = 1 (JQM = 1)



1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Queue of context: Starting the ADC with an empty queue

The following procedure must be followed to start ADC operation with an empty queue, in case the first context is not known at the time the ADC is initialized. This procedure is only applicable when JQM bit is reset:

5. Write a dummy JSQR with JEXTEN not equal to 0 (otherwise triggering a software conversion)
6. Set JADSTART
7. Set JADSTP
8. Wait until JADSTART is reset
9. Set JADSTART.

Disabling the queue

It is possible to disable the queue by setting bit JQDIS = 1 into the ADC_CFGR register.

26.4.22 Programmable resolution (RES) - fast conversion mode

It is possible to perform faster conversion by reducing the ADC resolution.

The resolution can be configured to be either 12, 10, 8, or 6 bits by programming the control bits RES[1:0]. *Figure 217*, *Figure 218*, *Figure 219* and *Figure 220* show the conversion result format with respect to the resolution as well as to the data alignment.

Lower resolution allows faster conversion time for applications where high-data precision is not required. It reduces the conversion time spent by the successive approximation steps according to *Table 245*.

Table 245. T_{SAR} timings depending on resolution

RES (bits)	T_{SAR} (ADC clock cycles)	T_{SAR} (ns) at F_{ADC} = 30 MHz	T_{CONV} (ADC clock cycles) (with Sampling Time = 2.5 ADC clock cycles)	T_{CONV} (ns) at F_{ADC} = 30 MHz
12	12.5 ADC clock cycles	416.67 ns	15 ADC clock cycles	500.0 ns
10	10.5 ADC clock cycles	350.0 ns	13 ADC clock cycles	433.33 ns
8	8.5 ADC clock cycles	203.33 ns	11 ADC clock cycles	366.67 ns
6	6.5 ADC clock cycles	216.67 ns	9 ADC clock cycles	300.0 ns

26.4.23 End of conversion, end of sampling phase (EOC, JEOC, EOSMP)

The ADC notifies the application for each end of regular conversion (EOC) event and each injected conversion (JEOC) event.

The ADC sets the EOC flag as soon as a new regular conversion data is available in the ADC_DR register. An interrupt can be generated if bit EOCIE is set. EOC flag is cleared by the software either by writing 1 to it or by reading ADC_DR.

The ADC sets the JEOC flag as soon as a new injected conversion data is available in one of the ADC_JDRy register. An interrupt can be generated if bit JEOCIE is set. JEOC flag is cleared by the software either by writing 1 to it or by reading the corresponding ADC_JDRy register.

The ADC also notifies the end of Sampling phase by setting the status bit EOSMP (for regular conversions only). EOSMP flag is cleared by software by writing 1 to it. An interrupt can be generated if bit EOSMPIE is set.

26.4.24 End of conversion sequence (EOS, JEOS)

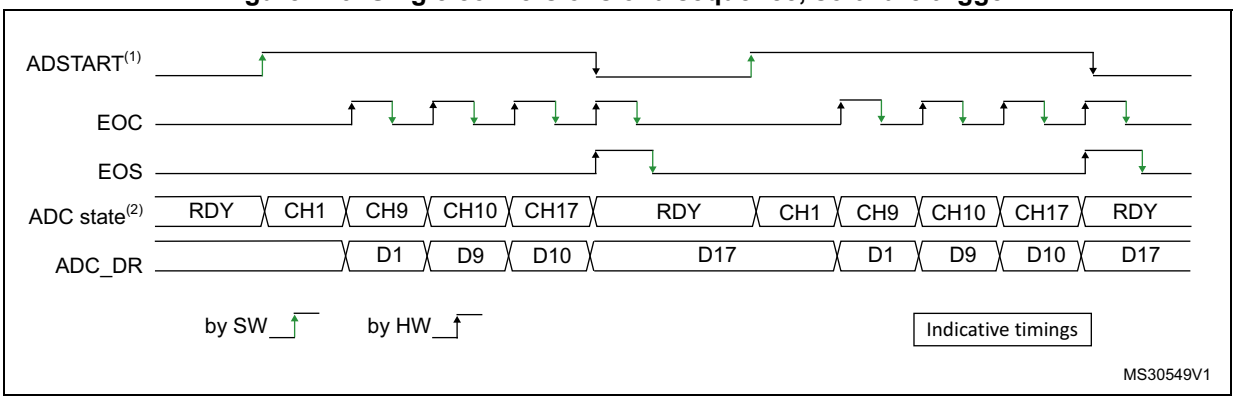
The ADC notifies the application for each end of regular sequence (EOS) and for each end of injected sequence (JEOS) event.

The ADC sets the EOS flag as soon as the last data of the regular conversion sequence is available in the ADC_DR register. An interrupt can be generated if bit EOSIE is set. EOS flag is cleared by the software either by writing 1 to it.

The ADC sets the JEOS flag as soon as the last data of the injected conversion sequence is complete. An interrupt can be generated if bit JEOSIE is set. JEOS flag is cleared by the software either by writing 1 to it.

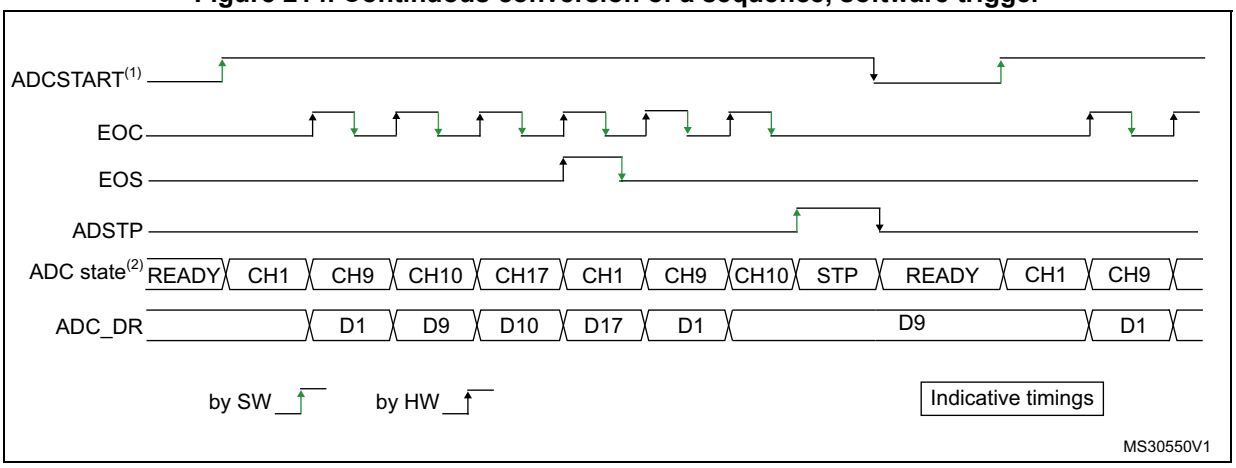
26.4.25 Timing diagrams example (single/continuous modes, hardware/software triggers)

Figure 213. Single conversions of a sequence, software trigger



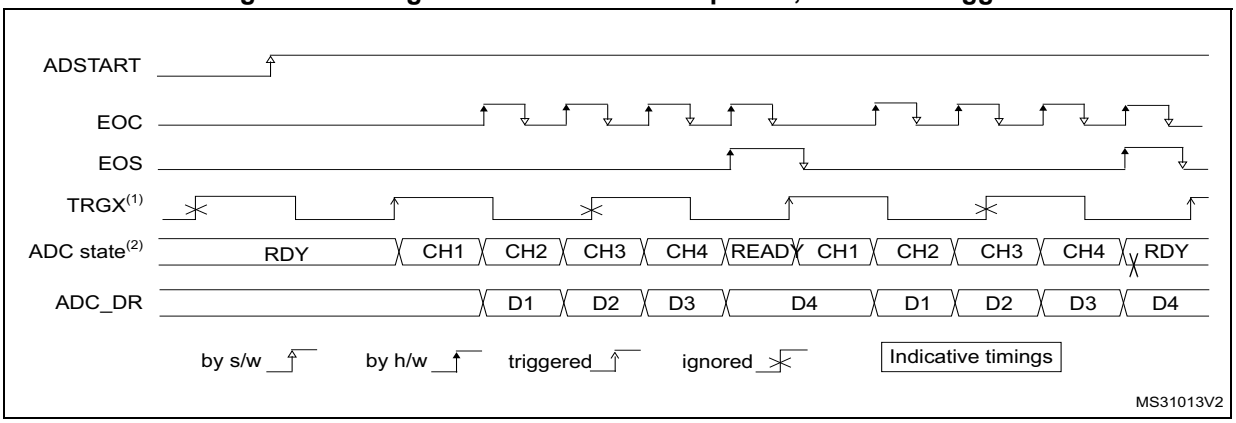
1. EXTEN = 0x0, CONT = 0
2. Channels selected = 1,9, 10, 17; AUTDLY = 0.

Figure 214. Continuous conversion of a sequence, software trigger



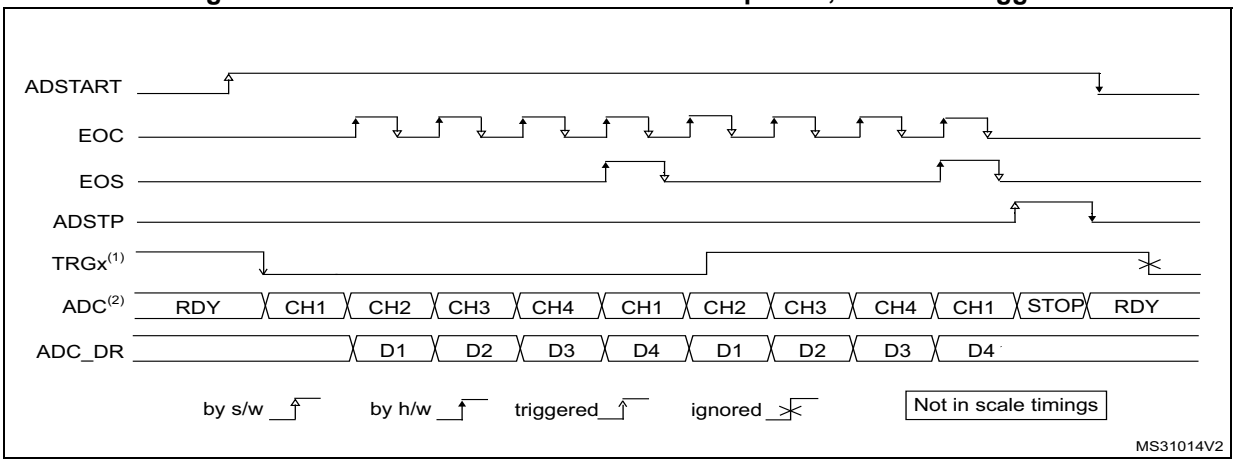
1. EXTEN = 0x0, CONT = 1
2. Channels selected = 1,9, 10, 17; AUTDLY = 0.

Figure 215. Single conversions of a sequence, hardware trigger



1. TRGx (over-frequency) is selected as trigger source, EXTEN = 01, CONT = 0
2. Channels selected = 1, 2, 3, 4; AUTDLY = 0.

Figure 216. Continuous conversions of a sequence, hardware trigger



1. TRGx is selected as trigger source, EXTEN = 10, CONT = 1
2. Channels selected = 1, 2, 3, 4; AUTDLY = 0.

26.4.26 Data management

Data register, data alignment and offset (ADC_DR, OFFSET, OFFSET_CH, ALIGN)

Data and alignment

At the end of each regular conversion channel (when EOC event occurs), the result of the converted data is stored into the ADC_DR data register which is 16 bits wide.

At the end of each injected conversion channel (when JEOC event occurs), the result of the converted data is stored into the corresponding ADC_JDRy data register which is 16 bits wide.

The ALIGN bit in the ADC_CFGR register selects the alignment of the data stored after conversion. Data can be right- or left-aligned as shown in *Figure 217*, *Figure 218*, *Figure 219* and *Figure 220*.

Special case: when left-aligned, the data are aligned on a half-word basis except when the resolution is set to 6-bit. In that case, the data are aligned on a byte basis as shown in *Figure 219* and *Figure 220*.

Note: Left-alignment is not supported in oversampling mode. When ROVSE and/or JOVSE bit is set, the ALIGN bit value is ignored and the ADC only provides right-aligned data.

Offset

An offset y (y = 1,2,3,4) can be applied to a channel by setting the bit OFFSET_EN = 1 into ADC_OFRy register. The channel to which the offset will be applied is programmed into the bits OFFSET_CH[4:0] of ADC_OFRy register. In this case, the converted value is decreased by the user-defined offset written in the bits OFFSET[11:0]. The result may be a negative value so the read data is signed and the SEXT bit represents the extended sign value.

Note: Offset correction is not supported in oversampling mode. When ROVSE and/or JOVSE bit is set, the value of the OFFSET_EN bit in ADC_OFRy register is ignored (considered as reset).

Table 248 describes how the comparison is performed for all the possible resolutions for analog watchdog 1.

Table 246. Offset computation versus data resolution

Resolution (bits RES[1:0])	Subtraction between raw converted data and offset		Result	Comments
	Raw converted Data, left aligned	Offset		
00: 12-bit	DATA[11:0]	OFFSET[11:0]	Signed 12-bit data	-
01: 10-bit	DATA[11:2],00	OFFSET[11:0]	Signed 10-bit data	The user must configure OFFSET[1:0] to “00”

Table 246. Offset computation versus data resolution (continued)

Resolution (bits RES[1:0])	Subtraction between raw converted data and offset		Result	Comments
	Raw converted Data, left aligned	Offset		
10: 8-bit	DATA[11:4],0000	OFFSET[11:0]	Signed 8-bit data	The user must configure OFFSET[3:0] to “0000”
11: 6-bit	DATA[11:6],000000	OFFSET[11:0]	Signed 6-bit data	The user must configure OFFSET[5:0] to “000000”

When reading data from ADC_DR (regular channel) or from ADC_JDRy (injected channel, y = 1,2,3,4) corresponding to the channel “i”:

- If one of the offsets is enabled (bit OFFSET_EN = 1) for the corresponding channel, the read data is signed.
- If none of the four offsets is enabled for this channel, the read data is not signed.

Figure 217, *Figure 218*, *Figure 219* and *Figure 220* show alignments for signed and unsigned data.

Figure 217. Right alignment (offset disabled, unsigned value)

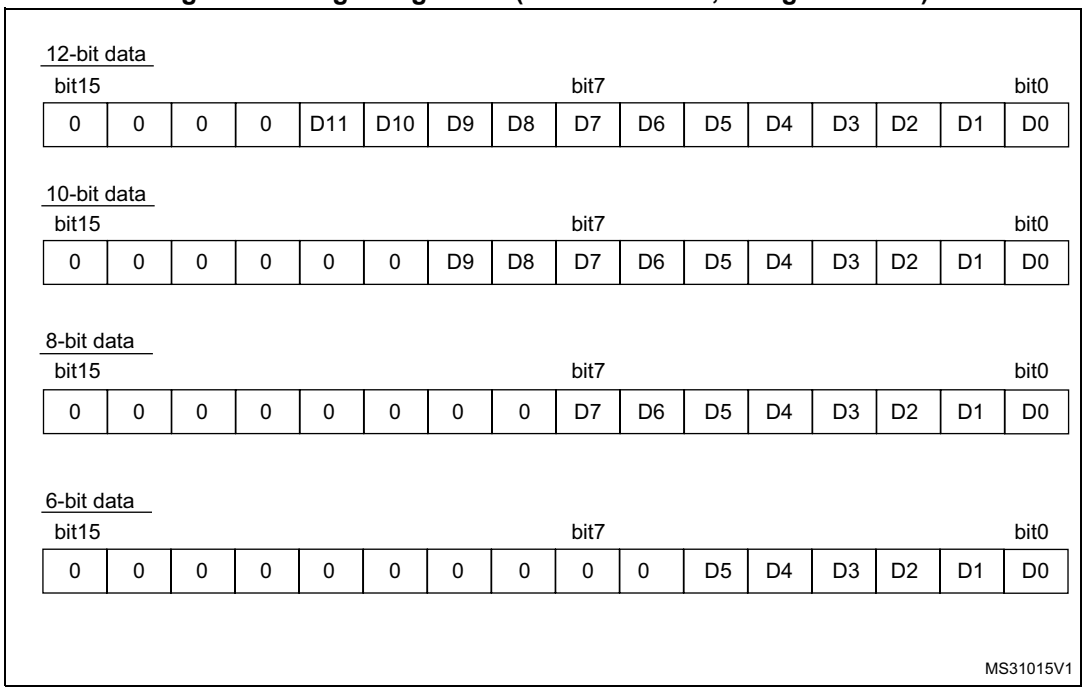


Figure 218. Right alignment (offset enabled, signed value)

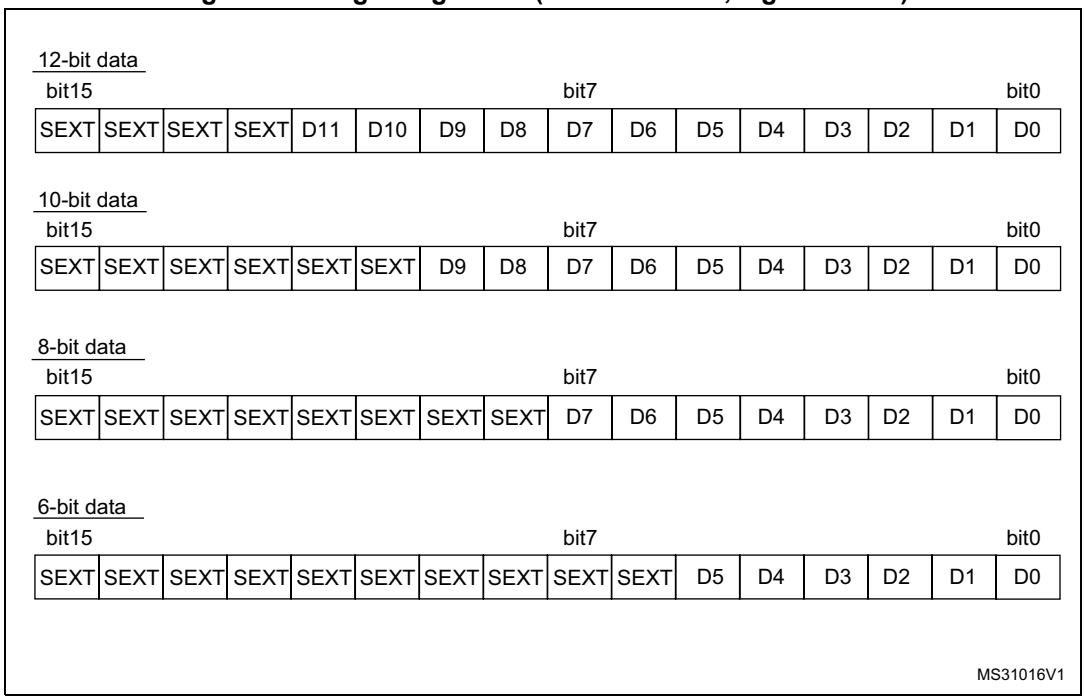

Figure 219. Left alignment (offset disabled, unsigned value)

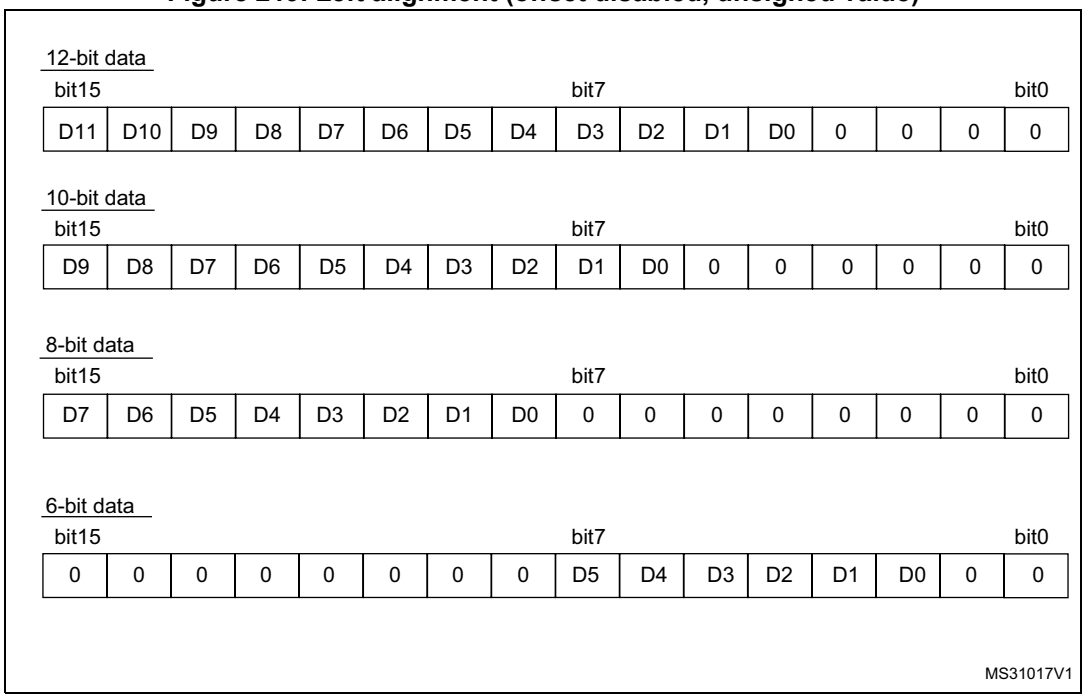

Figure 220. Left alignment (offset enabled, signed value)

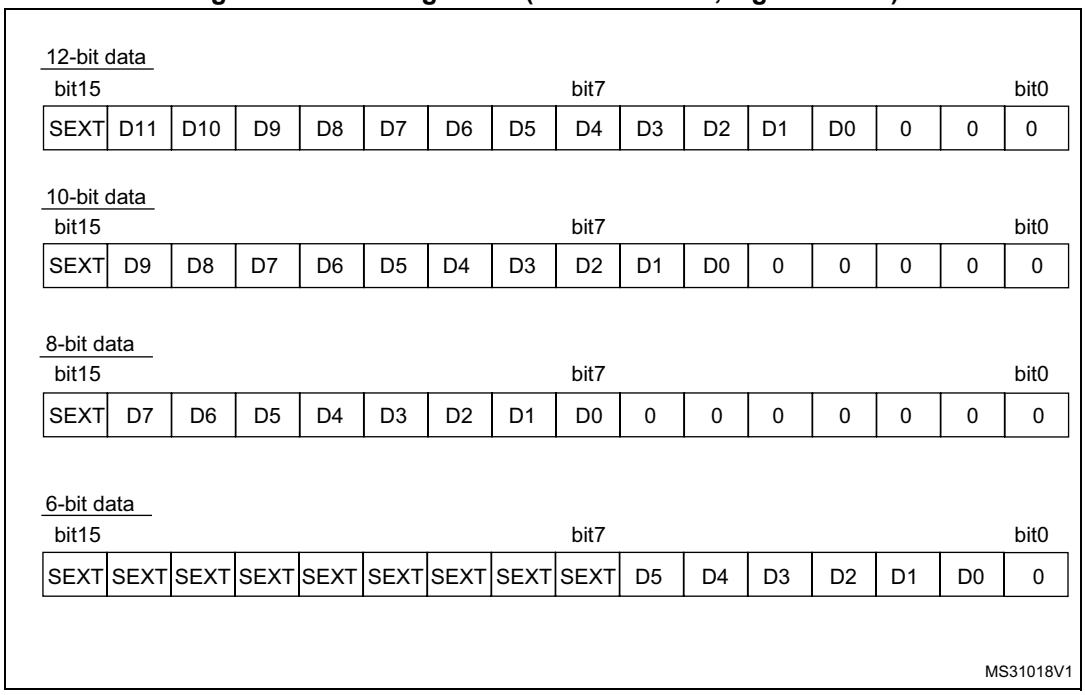

Offset compensation

When SATEN bit is set in ADC_OFRy register during offset operation, data are unsigned. All the offset data saturate at 0x000 (in 12-bit mode). When OFFSETPOS bit is set, the offset direction is positive and the data saturate at 0xFFF (in 12-bit mode). In 8-bit mode, data saturate at 0x00 and 0xFF, respectively.

The analog watchdog comparison is performed before the offset compensation.

ADC overrun (OVR, OVRMOD)

The overrun flag (OVR) notifies when the regular converted data has not been read (by the CPU or the DMA) before ADC_DR FIFO (three stages) is overflowed.

The OVR flag is set when a new conversion completes while ADC_CR register FIFO was full. An interrupt is generated if OVRIE bit is set to 1.

When an overrun condition occurs, the ADC is still operating and can continue converting unless the software decides to stop and reset the sequence by setting ADSTP to 1. Since ADC_DR FIFO features three stages, up to three data are stored in the FIFO.

OVR flag is cleared by software by writing 1 to it.

It is possible to configure if data is preserved or overwritten when an overrun event occurs by programming the control bit OVRMOD:

- OVRMOD = 0: The overrun event preserves the data register from being overwritten: the old data is maintained up to ADC_DR FIFO depth (three stages) and the new conversion is discarded and lost. In this mode, ADC_DR FIFO is disabled. If the FIFO is full, any further conversion is performed but the resulting data is also discarded. EOC

is cleared by reading ADC_DR register. However, the FIFO can still contain previously converted data.

- OVRMOD = 1: The data register is overwritten with the last conversion result and the previous unread data is lost. In this mode, ADC_DR FIFO is disabled. If OVR remains at 1, any further conversions is performed normally and the ADC_DR register always contains the latest converted data.

Figure 221. Example of overrun (OVRMOD = 0)

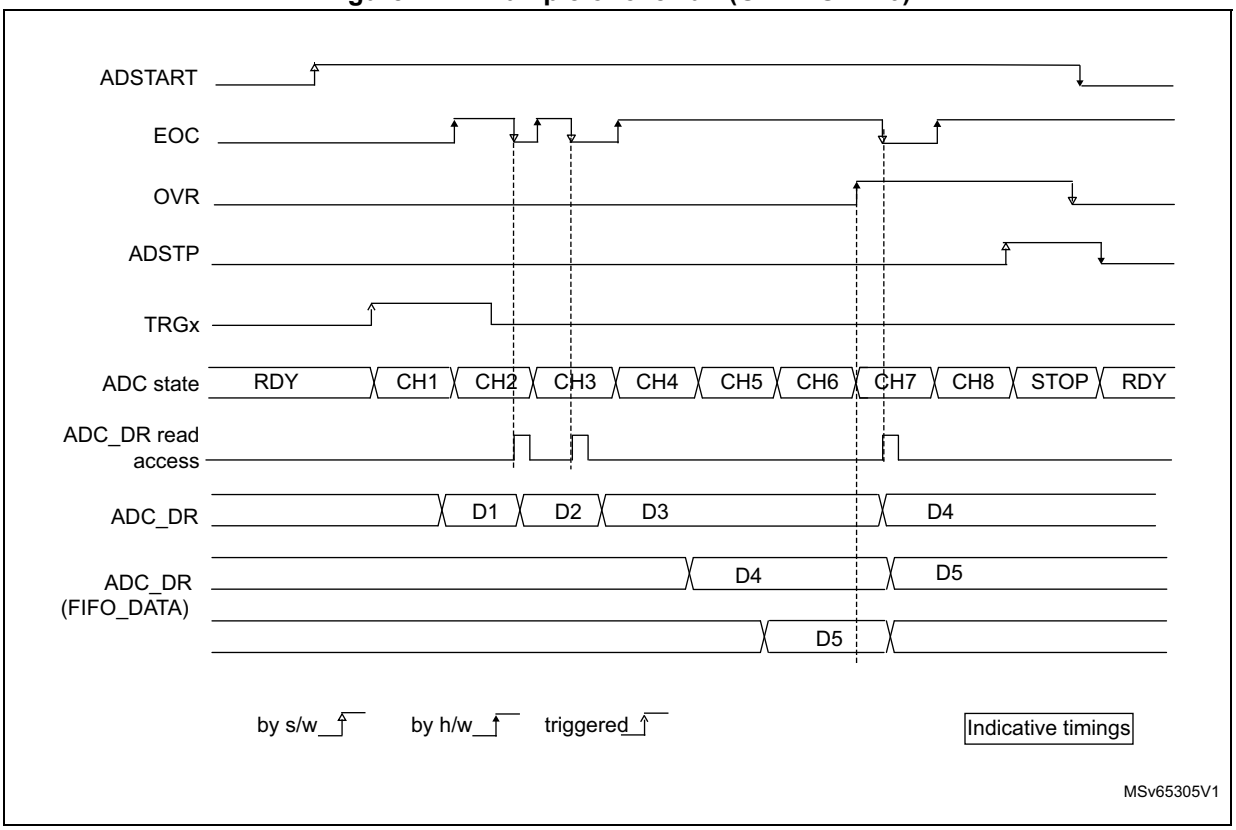

Figure 222. Example of overrun (OVRMOD = 1)

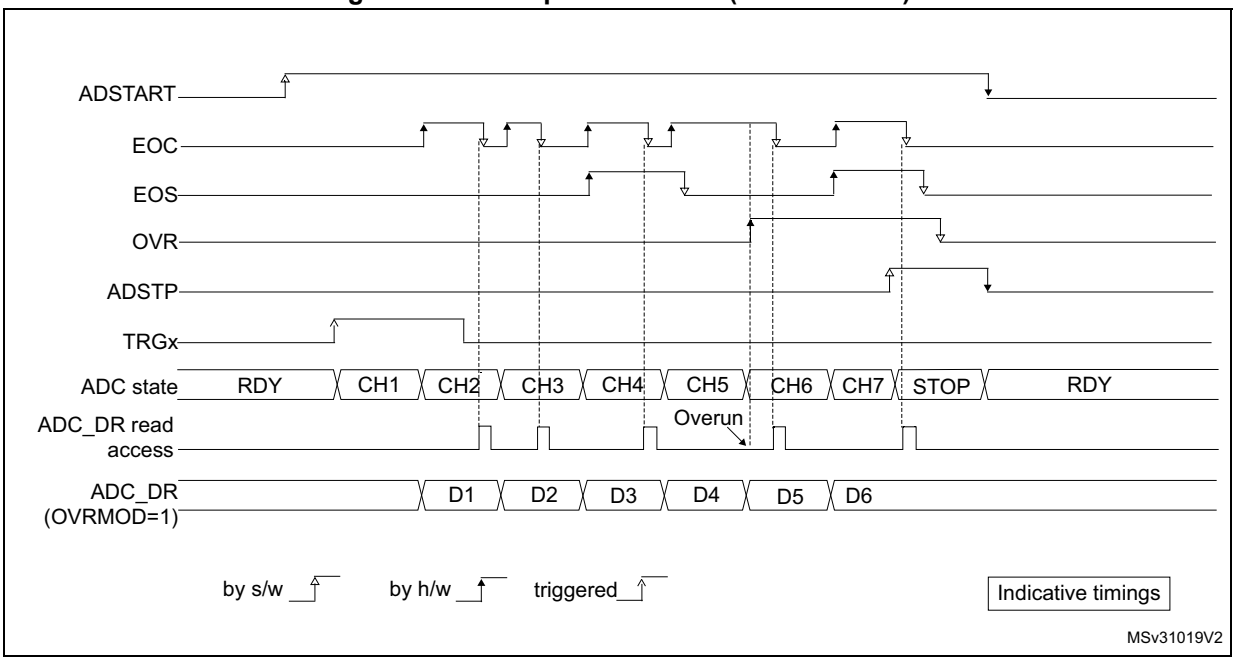

Note: There is no overrun detection on the injected channels since there is a dedicated data register for each of the four injected channels.

Managing a sequence of conversions without using the DMA

If the conversions are slow enough, the conversion sequence can be handled by the software. In this case the software must use the EOC flag and its associated interrupt to handle each data. Each time a conversion is complete, EOC is set and the ADC_DR register can be read. OVRMOD must be configured to 0 to manage overrun events or FIFO overflow as an error.

Managing conversions without using the DMA and without overrun

It may be useful to let the ADC convert one or more channels without reading the data each time (if there is an analog watchdog for instance). In this case, the OVRMOD bit must be configured to 1 and OVR flag should be ignored by the software. An overrun event does not prevent the ADC from continuing to convert and the ADC_DR register always contains the latest conversion.

Managing conversions using the DMA

Since converted channel values are stored into a unique data register, it is useful to use DMA for conversion of more than one channel. This avoids the loss of the data already stored in the ADC_DR register.

When the DMA mode is enabled (DMAEN bit set to 1 in the ADC_CFGR register in single ADC mode or MDMA different from 0b00 in dual ADC mode), a DMA request is generated after each conversion of a channel. This allows the transfer of the converted data from the ADC_DR register to the destination location selected by the software.

Despite this, if an overrun occurs (OVR = 1) because the DMA could not serve the DMA transfer request in time, the ADC stops generating DMA requests and the data corresponding to the new conversion is not transferred by the DMA. Which means that all the data transferred to the RAM can be considered as valid.

Depending on the configuration of OVRMOD bit, the data is either preserved or overwritten (refer to *Section : ADC overrun (OVR, OVRMOD)*).

The DMA transfer requests are blocked until the software clears the OVR bit.

Two different DMA modes are proposed depending on the application use and are configured with bit DMACFG of the ADC_CFGR register in single ADC mode, or with bit DMACFG of the ADC_CCR register in dual ADC mode:

- DMA one shot mode (DMACFG = 0).
  This mode is suitable when the DMA is programmed to transfer a fixed number of data.
- DMA circular mode (DMACFG = 1)
  This mode is suitable when programming the DMA in circular mode.

DMA one shot mode (DMACFG = 0)

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available and stops generating DMA requests once the DMA has reached the last DMA transfer (when a transfer complete interrupt occurs - refer to DMA section) even if a conversion has been started again.

When the DMA transfer is complete (all the transfers configured in the DMA controller have been done):

- The content of the ADC data register is frozen.
- Any ongoing conversion is aborted with partial result discarded.
- No new DMA request is issued to the DMA controller. This avoids generating an overrun error if there are still conversions which are started.
- Scan sequence is stopped and reset.
- The DMA is stopped.

DMA circular mode (DMACFG = 1)

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available in the data register, even if the DMA has reached the last DMA transfer. This allows configuring the DMA in circular mode to handle a continuous analog input data stream.

26.4.27 Dynamic low-power features

Auto-delayed conversion mode (AUTDLY)

The ADC implements an auto-delayed conversion mode controlled by the AUTDLY configuration bit. Auto-delayed conversions are useful to simplify the software as well as to optimize performance of an application clocked at low frequency where there would be risk of encountering an ADC overrun.

When AUTDLY = 1, a new conversion can start only if all the previous data of the same group has been treated:

- For a regular conversion: once the ADC_DR register has been read or if the EOC bit has been cleared (see *Figure 223*).
- For an injected conversion: when the JEOS bit has been cleared (see *Figure 224*).

This is a way to automatically adapt the speed of the ADC to the speed of the system which reads the data.

The delay is inserted after each regular conversion (whatever DISCEN = 0 or 1) and after each sequence of injected conversions (whatever JDISCEN = 0 or 1).

Note: There is no delay inserted between each conversions of the injected sequence, except after the last one.

During a conversion, a hardware trigger event (for the same group of conversions) occurring during this delay is ignored.

Note: This is not true for software triggers where it remains possible during this delay to set the bits ADSTART or JADSTART to restart a conversion: it is up to the software to read the data before launching a new conversion.

No delay is inserted between conversions of different groups (a regular conversion followed by an injected conversion or conversely):

- If an injected trigger occurs during the automatic delay of a regular conversion, the injected conversion starts immediately (see *Figure 224*).
- Once the injected sequence is complete, the ADC waits for the delay (if not ended) of the previous regular conversion before launching a new regular conversion (see *Figure 226*).

The behavior is slightly different in auto-injected mode (JAUTO = 1) where a new regular conversion can start only when the automatic delay of the previous injected sequence of conversion has ended (when JEOS has been cleared). This is to ensure that the software can read all the data of a given sequence before starting a new sequence (see *Figure 227*).

To stop a conversion in continuous auto-injection mode combined with autodelay mode (JAUTO = 1, CONT = 1 and AUTDLY = 1), follow the following procedure:

1. Wait until JEOS = 1 (no more conversions are restarted)
2. Clear JEOS,
3. Set ADSTP = 1
4. Read the regular data.

If this procedure is not respected, a new regular sequence can restart if JEOS is cleared after ADSTP has been set.

In AUTDLY mode, a hardware regular trigger event is ignored if it occurs during an already ongoing regular sequence or during the delay that follows the last regular conversion of the sequence. It is however considered pending if it occurs after this delay, even if it occurs during an injected sequence of the delay that follows it. The conversion then starts at the end of the delay of the injected sequence.

In AUTDLY mode, a hardware injected trigger event is ignored if it occurs during an already ongoing injected sequence or during the delay that follows the last injected conversion of the sequence.

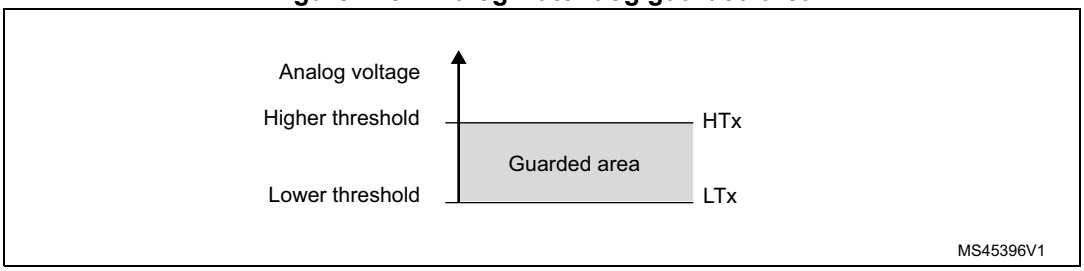
3. Injected configuration: JAUTO = 1, CHANNELS = 5,6

26.4.28 Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)

The three AWD analog watchdogs monitor whether some channels remain within a configured voltage range (window).

Figure 228. Analog watchdog guarded area



AWDx flag and interrupt

An interrupt can be enabled for each of the 3 analog watchdogs by setting AWDxIE in the ADC_IER register (x = 1,2,3).

AWDx (x = 1,2,3) flag is cleared by software by writing 1 to it.

The ADC conversion result is compared to the lower and higher thresholds before alignment.

Description of analog watchdog 1

The AWD analog watchdog 1 is enabled by setting the AWD1EN bit in the ADC_CFGR register. This watchdog monitors whether either one selected channel or all enabled channels(1) remain within a configured voltage range (window).

Table 247 shows how the ADC_CFGR registers should be configured to enable the analog watchdog on one or more channels.

Table 247. Analog watchdog channel selection

Channels guarded by the analog watchdog	AWD1SGL bit	AWD1EN bit	JAWD1EN bit
None	x	0	0
All injected channels	0	0	1
All regular channels	0	1	0
All regular and injected channels	0	1	1
Single(1) injected channel	1	0	1
Single(1) regular channel	1	1	0
Single(1) regular or injected channel	1	1	1

1. Selected by the AWD1CH[4:0] bits. The channels must also be programmed to be converted in the appropriate regular or injected sequence.

The AWD1 analog watchdog status bit is set if the analog voltage converted by the ADC is below a lower threshold or above a higher threshold.

These thresholds are programmed in bits HT1[11:0] and LT1[11:0] of the ADC_TR1 register for the analog watchdog 1. When converting data with a resolution of less than 12 bits (according to bits RES[1:0]), the LSB of the programmed thresholds must be kept cleared because the internal comparison is always performed on the full 12-bit raw converted data (left aligned) before the offset compensation stage.

Table 248 describes how the comparison is performed for all the possible resolutions for analog watchdog 1.

Table 248. Analog watchdog 1 comparison

Resolution(bit RES[1:0])	Analog watchdog comparison between:		Comments
	Raw converted data, left aligned	Thresholds	
00: 12-bit	DATA[11:0]	LT1[11:0] and HT1[11:0]	-
01: 10-bit	DATA[11:2],00	LT1[11:0] and HT1[11:0]	User must configure LT1[1:0] and HT1[1:0] to 00
10: 8-bit	DATA[11:4],0000	LT1[11:0] and HT1[11:0]	User must configure LT1[3:0] and HT1[3:0] to 0000
11: 6-bit	DATA[11:6],000000	LT1[11:0] and HT1[11:0]	User must configure LT1[5:0] and HT1[5:0] to 000000

Analog watchdog filter for watchdog 1

When an ADC is configured with only one input channel (selecting several channels in scan mode not allowed), a valid ADC conversion data interval can be configured through the ADC_TR1 register:

- When converted data belong to the interval defined in ADC_TR1, a DMA request is generated.
- Otherwise, no DMA request is issued. RDATA register is updated at each conversion. If data are out-of-range a number of times higher than the value specified in AWDFILT bit of ADC_TR1, the AWDx flag is set an the corresponding interrupt is issued.

Description of analog watchdog 2 and 3

The second and third analog watchdogs are more flexible and can guard several selected channels by programming the corresponding bits in AWDxCH[19:0] (x = 2,3).

The corresponding watchdog is enabled when any bit of AWDxCH[19:0] (x = 2,3) is set.

They are limited to a resolution of 8 bits and only the 8 MSBs of the thresholds can be programmed into HTx[7:0] and LTx[7:0]. *Table 249* describes how the comparison is performed for all the possible resolutions.

Table 249. Analog watchdog 2 and 3 comparison

Resolution (bits RES[1:0])	Analog watchdog comparison between:		Comments
	Raw converted data, left aligned	Thresholds	
00: 12-bit	DATA[11:4]	LTx[7:0] and HTx[7:0]	DATA[3:0] are not relevant for the comparison
01: 10-bit	DATA[11:4]	LTx[7:0] and HTx[7:0]	DATA[3:2] are not relevant for the comparison
10: 8-bit	DATA[11:4]	LTx[7:0] and HTx[7:0]	-
11: 6-bit	DATA[11:6],00	LTx[7:0] and HTx[7:0]	User must configure LTx[1:0] and HTx[1:0] to 00

ADCy_AWDx_OUT signal output generation

Each analog watchdog is associated to an internal hardware signal ADCy_AWDx_OUT (y = ADC number, x = watchdog number) which is directly connected to the ETR input (external trigger) of some on-chip timers. Refer to the on-chip timers section to understand how to select the ADCy_AWDx_OUT signal as ETR.

ADCy_AWDx_OUT is activated when the associated analog watchdog is enabled:

- ADCy_AWDx_OUT is set when a guarded conversion is outside the programmed thresholds.
- ADCy_AWDx_OUT is reset after the end of the next guarded conversion which is inside the programmed thresholds (It remains at 1 if the next guarded conversions are still outside the programmed thresholds).
- ADCy_AWDx_OUT is also reset when disabling the ADC (when setting ADDIS = 1). Note that stopping regular or injected conversions (setting ADSTP = 1 or JADSTP = 1) has no influence on the generation of ADCy_AWDx_OUT.

Note: AWDx flag is set by hardware and reset by software: AWDx flag has no influence on the generation of ADCy_AWDx_OUT (ex: ADCy_AWDx_OUT can toggle while AWDx flag remains at 1 if the software did not clear the flag).

Figure 229. ADCy_AWDx_OUT signal generation (on all regular channels)

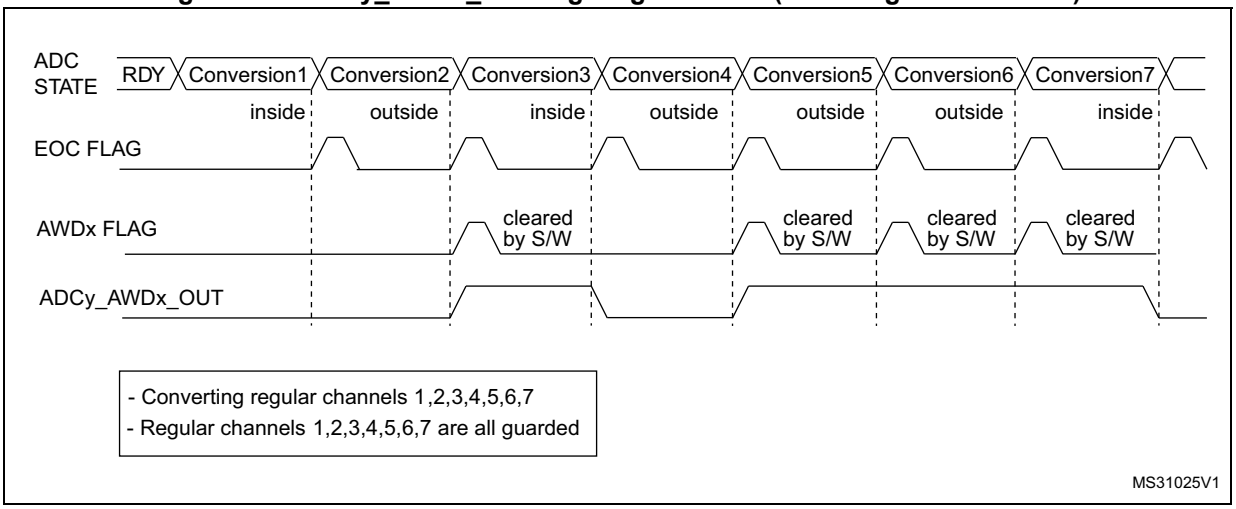


Figure 230. ADCy_AWDx_OUT signal generation (AWDx flag not cleared by software)

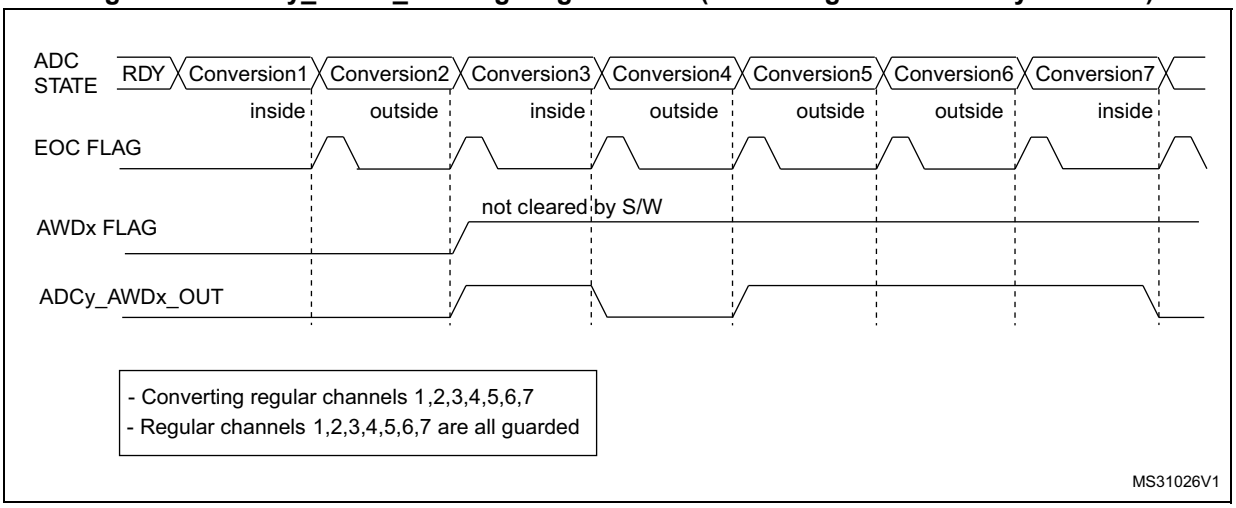

Figure 231. ADCy_AWDx_OUT signal generation (on a single regular channel)

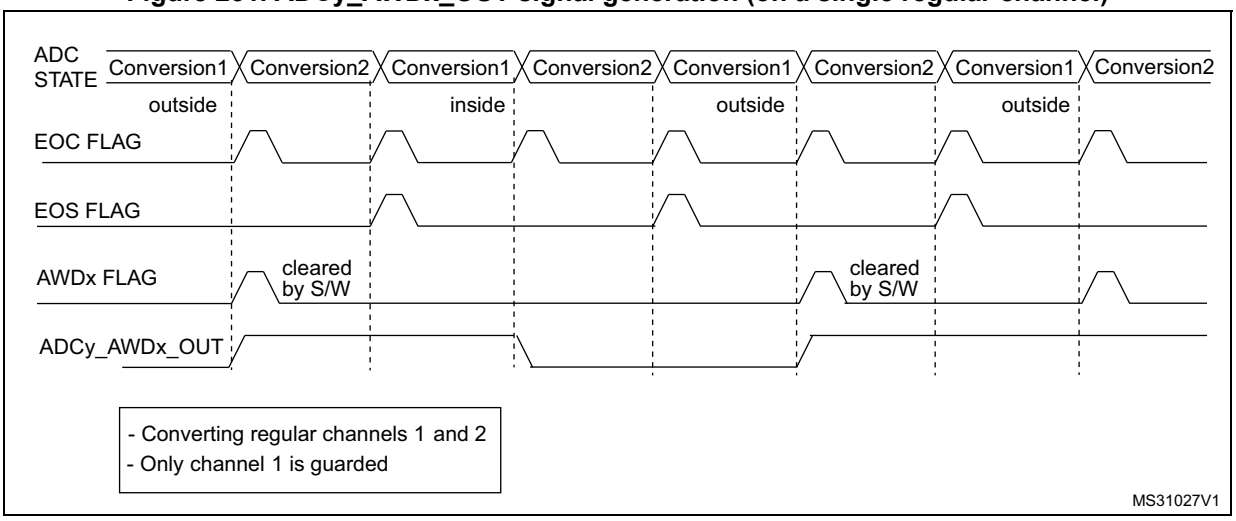

Figure 232. ADCy_AWDx_OUT signal generation (on all injected channels)

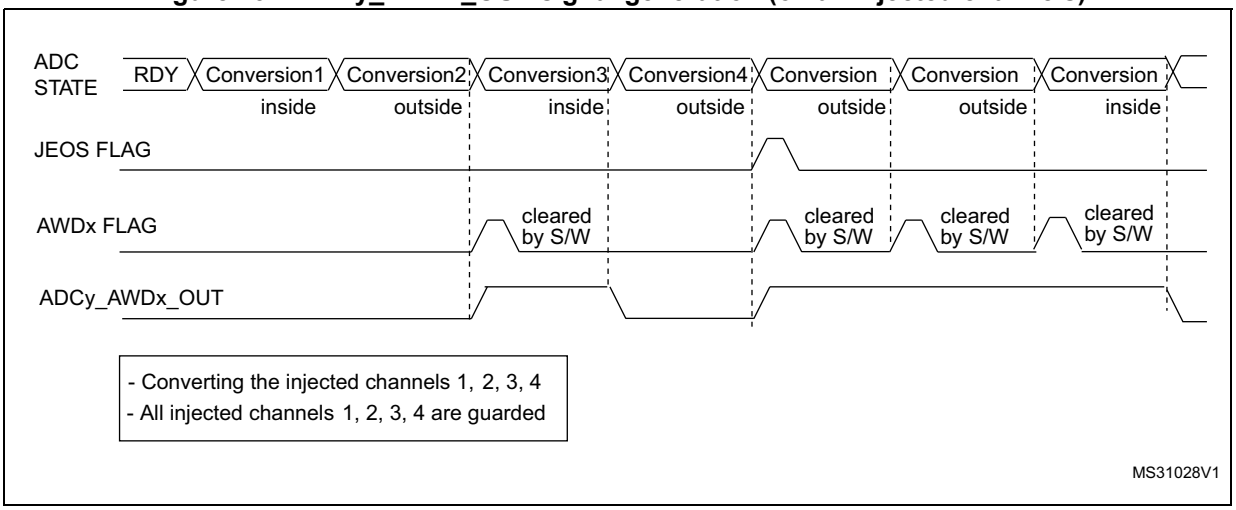

Analog watchdog threshold control

LTx[11:0] and HTx[11:0] can be changed when an analog-to-digital conversion is ongoing (that is between the start of conversion and the end of conversion of the ADC internal state). If LTx[11:0] and HTx[11:0] are updated during the ADC conversion of the ADC guarded channel, the watchdog function is masked for this conversion. This masking is removed at the next start of conversion, resulting in a analog watchdog thresholds to be applied from the next ADC conversion. The analog watchdog comparison is performed at each end of conversion. If the current ADC data is out of the new interval, no interrupt and AWDx_OUT signal are issued. The Interrupt and the AWD generation only happen at the end of the conversion which started after the threshold update. If AWD_xOUT is already asserted, programming the new thresholds does not deassert the AWDx_OUT signal.

Analog watchdog with offset compensation

When the offset compensation is enabled, the analog watchdog compares the threshold before the data compensation.

26.4.29 Oversampler

The oversampling unit performs data pre-processing to offload the CPU. It is able to handle multiple conversions and average them into a single data with increased data width, up to 16-bit.

It provides a result with the following form, where N and M can be adjusted:

$$\text{Result} = \frac{1}{M} \times \sum_{n=0}^{n=N-1} \text{Conversion}(t_n)$$

It allows to perform by hardware the following functions: averaging, data rate reduction, SNR improvement, basic filtering.

The oversampling ratio N is defined using the OVFS[2:0] bits in the ADC_CFGR2 register, and can range from 2x to 256x. The division coefficient M consists of a right bit shift up to 8 bits, and is defined using the OVSS[3:0] bits in the ADC_CFGR2 register.

The summation unit can yield a result up to 20 bits (256x 12-bit results), which is first shifted right. It is then truncated to the 16 least significant bits, rounded to the nearest value using the least significant bits left apart by the shifting, before being finally transferred into the ADC_DR data register.

Note: If the intermediary result after the shifting exceeds 16-bit, the result is truncated as is, without saturation.

Figure 233. 20-bit to 16-bit result truncation

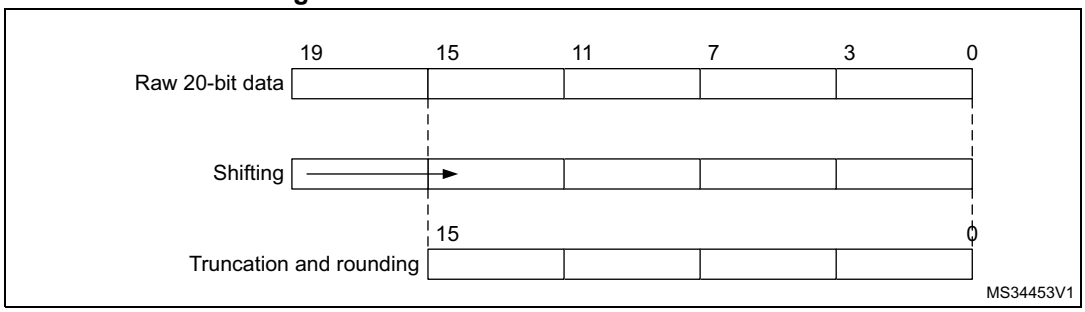

Figure 234 gives a numerical example of the processing, from a raw 20-bit accumulated data to the final 16-bit result.

Figure 234. Numerical example with 5-bit shift and rounding

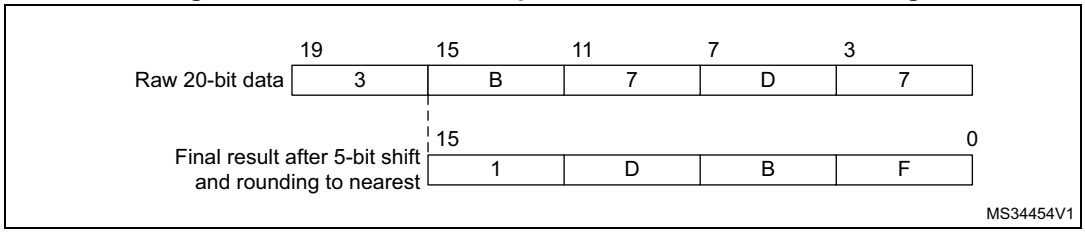

Table 250 gives the data format for the various N and M combinations, for a raw conversion data equal to 0xFFF.

Table 250. Maximum output results versus N and M (gray cells indicate truncation)

Over sampling ratio	Max Raw data	No-shift OVSS = 0000	1-bit shift OVSS = 0001	2-bit shift OVSS = 0010	3-bit shift OVSS = 0011	4-bit shift OVSS = 0100	5-bit shift OVSS = 0101	6-bit shift OVSS = 0110	7-bit shift OVSS = 0111	8-bit shift OVSS = 1000

256x	0xFFF00	0xFF00	0xFF80	0xFFC0	0xFFE0	0xFFF0	0x7FF8	0x3FFC	0x1FFE	0x0FFF

There are no changes for conversion timings in oversampled mode: the sample time is maintained equal during the whole oversampling sequence. A new data is provided every N

conversions, with an equivalent delay equal to N x T_{CONV} = N x (t_{SMPL} + t_{SAR}). The flags are set as follow:

- The end of the sampling phase (EOSMP) is set after each sampling phase
- The end of conversion (EOC) occurs once every N conversions, when the oversampled result is available
- The end of sequence (EOS) occurs once the sequence of oversampled data is completed (that is after N x sequence length conversions total)

ADC operating modes supported when oversampling (single ADC mode)

In oversampling mode, most of the ADC operating modes are maintained:

- Single or continuous conversion modes
- ADC conversions start either by software or with triggers
- ADC stop during a conversion (abort)
- Data read via CPU or DMA with overrun detection
- Low-power modes (AUTDLY)
- Programmable resolution: in this case, the reduced conversion values (as per RES[1:0] bits in ADC_CFGR register) are accumulated, truncated, rounded and shifted in the same way as 12-bit conversions are

Note: The alignment mode is not available when working with oversampled data. The ALIGN bit in ADC_CFGR is ignored and the data are always provided right-aligned.

Offset correction is not supported in oversampling mode. When ROVSE and/or JOVSE bit is set, the value of the OFFSET_EN bit in ADC_OFRy register is ignored (considered as reset).

Analog watchdog

The analog watchdog functionality is maintained, with the following difference:

- The RES[1:0] bits are ignored, the comparison is always done by using the full 12-bit values HT1[11:0] and LT1[11:0] for AWD1, and the 8-MSB value of HT2/HT3[7:0] and LT2/LT3[7:0] for AWD2 and AWD3.
- The comparison is done on the most significant 12-bit of the 16-bit oversampled results ADC_DR[15:4] for AWD1, and ADC_DR[15:8] for AWD2 and ADW3

Note: Care must be taken when using high shifting values, this reduces the comparison range. For instance, if the oversampled result is shifted by 4 bits, thus yielding a 12-bit data right-aligned, the effective analog watchdog comparison can only be performed on 8 bits. The comparison is done between ADC_DR[11:4] and HTx[7:0] / LTx[7:0] (AWD1/2/3), with HT1[11:8] and LT1[11:8] kept reset (AWD1 only).

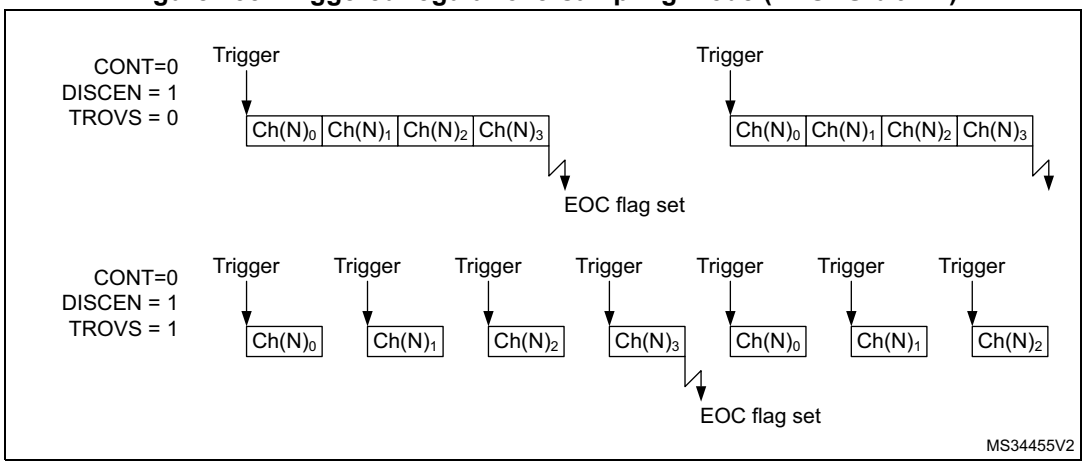
Triggered mode

The averager can also be used for basic filtering purpose. Although not a very powerful filter (slow roll-off and limited stop band attenuation), it can be used as a notch filter to reject constant parasitic frequencies (typically coming from the mains or from a switched mode power supply). For this purpose, a specific discontinuous mode can be enabled with TROVS bit in ADC_CFGR2, to be able to have an oversampling frequency defined by a user and independent from the conversion time itself.

The *Figure 235* below shows how conversions are started in response to triggers during discontinuous mode.

If the TROVS bit is set, the content of the DISCEN bit is ignored and considered as 1.

Figure 235. Triggered regular oversampling mode (TROVS bit = 1)



Injected and regular sequencer management when oversampling

In oversampling mode, it is possible to have differentiated behavior for injected and regular sequencers. The oversampling can be enabled for both sequencers with some limitations if they have to be used simultaneously (this is related to a unique accumulation unit).

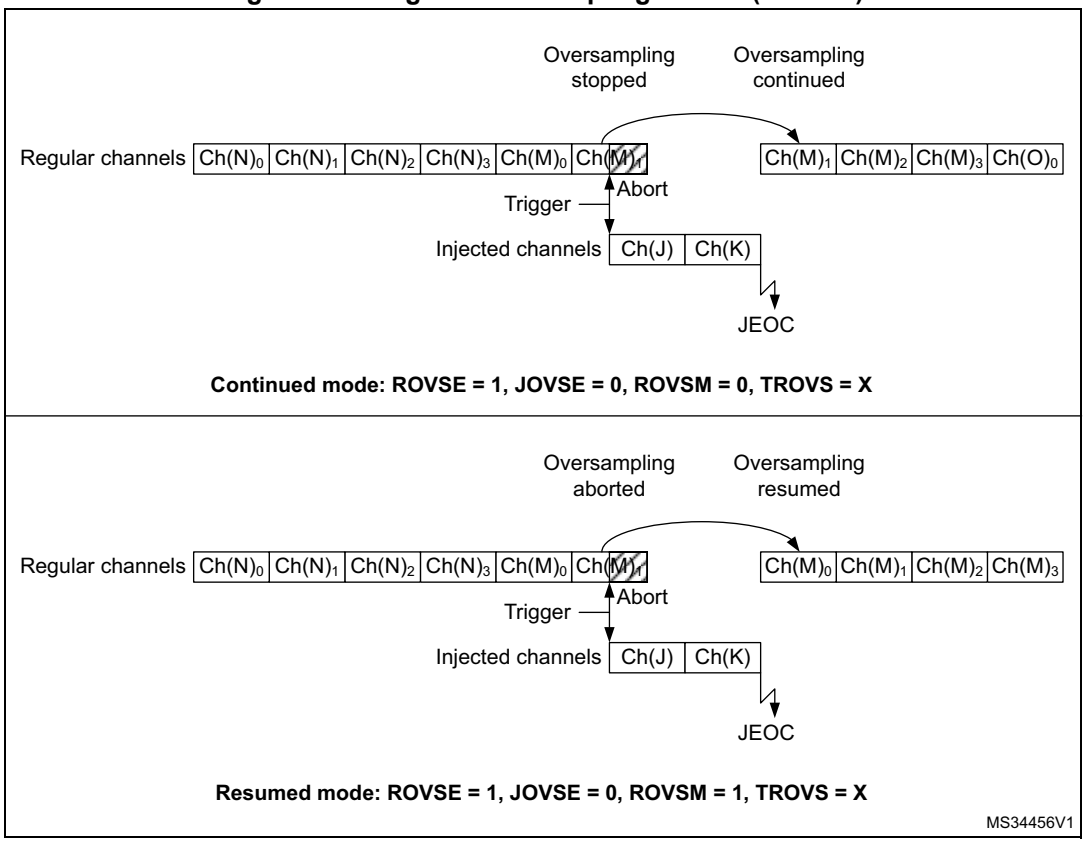
Oversampling regular channels only

The regular oversampling mode bit ROVSM defines how the regular oversampling sequence is resumed if it is interrupted by injected conversion:

- In continued mode, the accumulation restarts from the last valid data (prior to the conversion abort request due to the injected trigger). This ensures that oversampling is complete whatever the injection frequency (providing at least one regular conversion can be completed between triggers);
- In resumed mode, the accumulation restarts from 0 (previous conversions results are ignored). This mode allows to guarantee that all data used for oversampling were converted back-to-back within a single timeslot. Care must be taken to have a injection trigger period above the oversampling period length. If this condition is not respected, the oversampling cannot be completed and the regular sequencer is blocked.

The *Figure 236* gives examples for a 4x oversampling ratio.

Figure 236. Regular oversampling modes (4x ratio)



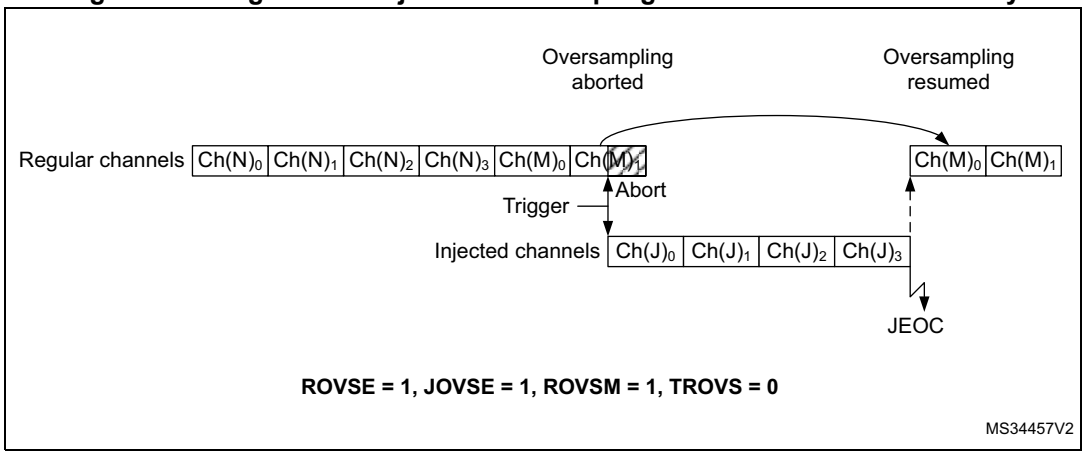
Oversampling Injected channels only

The Injected oversampling mode bit JOVSE enables oversampling solely for conversions in the injected sequencer.

Oversampling regular and Injected channels

It is possible to have both ROVSE and JOVSE bits set. In this case, the regular oversampling mode is forced to resumed mode (ROVSM bit ignored), as represented on *Figure 237* below.

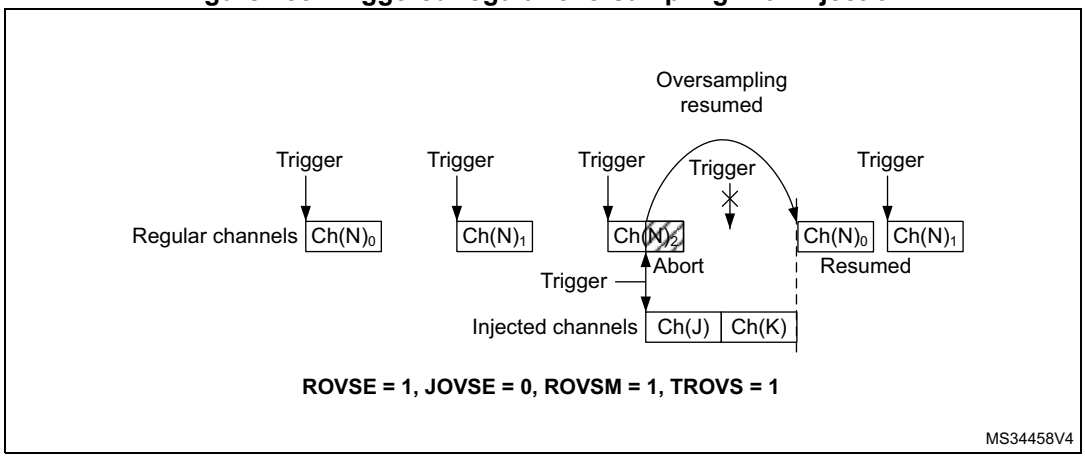
Figure 237. Regular and injected oversampling modes used simultaneously



Triggered regular oversampling with injected conversions

It is possible to have triggered regular mode with injected conversions. In this case, the injected mode oversampling mode must be disabled, and the ROVSM bit is ignored (resumed mode is forced). The JOVSE bit must be reset. The behavior is represented on *Figure 238* below.

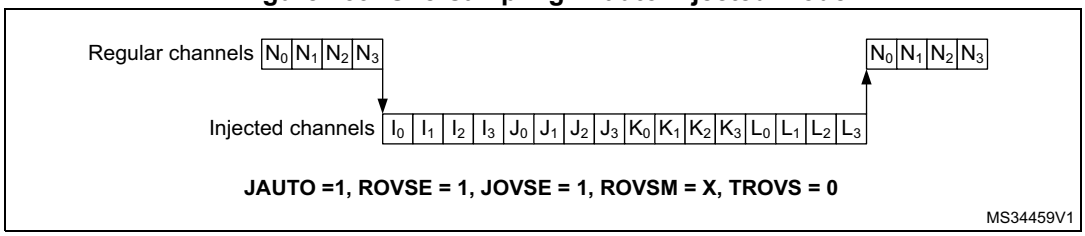
Figure 238. Triggered regular oversampling with injection



Auto-injected mode

It is possible to oversample auto-injected sequences and have all conversions results stored in registers to save a DMA resource. This mode is available only with both regular and injected oversampling active: JAUTO = 1, ROVSE = 1 and JOVSE = 1, other combinations are not supported. The ROVSM bit is ignored in auto-injected mode. The *Figure 239* below shows how the conversions are sequenced.

Figure 239. Oversampling in auto-injected mode



It is possible to have also the triggered mode enabled, using the TROVS bit. In this case, the ADC must be configured as following: JAUTO = 1, DISCEN = 0, JDISCEN = 0, ROVSE = 1, JOVSE = 1 and TROVSE = 1.

Dual ADC modes supported when oversampling

It is possible to have oversampling enabled when working in dual ADC configuration, for the injected simultaneous mode and regular simultaneous mode. In this case, the two ADCs must be programmed with the very same settings (including oversampling).

All other dual ADC modes are not supported when either regular or injected oversampling is enabled (ROVSE = 1 or JOVSE = 1).

Combined modes summary

The *Table 251* below summarizes all combinations, including modes not supported.

Table 251. Oversampler operating modes summary

Regular Oversampling ROVSE	Injected Oversampling JOVSE	Oversampler mode ROVSM 0 = continued 1 = resumed	Triggered Regular mode TROVS	Comment
1	0	0	0	Regular continued mode
1	0	0	1	Not supported
1	0	1	0	Regular resumed mode
1	0	1	1	Triggered regular resumed mode
1	1	0	X	Not supported
1	1	1	0	Injected and regular resumed mode
1	1	1	1	Not supported
0	1	X	X	Injected oversampling

26.4.30 Dual ADC modes

Dual ADC modes can be used in devices with two ADCs or more (see *Figure 240*).

In dual ADC mode the start of conversion is triggered alternately or simultaneously by the ADCx master to the ADC slave, depending on the mode selected by the bits DUAL[4:0] in the ADC_CCR register.

Four possible modes are implemented:

- Injected simultaneous mode
- Regular simultaneous mode
- Interleaved mode
- Alternate trigger mode

It is also possible to use these modes combined in the following ways:

- Injected simultaneous mode + regular simultaneous mode
- Regular simultaneous mode + alternate trigger mode
- Injected simultaneous mode + interleaved mode

In dual ADC mode (when bits DUAL[4:0] in ADC_CCR register are not equal to zero), the bits CONT, AUTDLY, DISCEN, DISCNUM[2:0], JDISCEN, JQM, JAUTO of the ADC_CFGR register are shared between the master and slave ADC: the bits in the slave ADC are always equal to the corresponding bits of the master ADC.

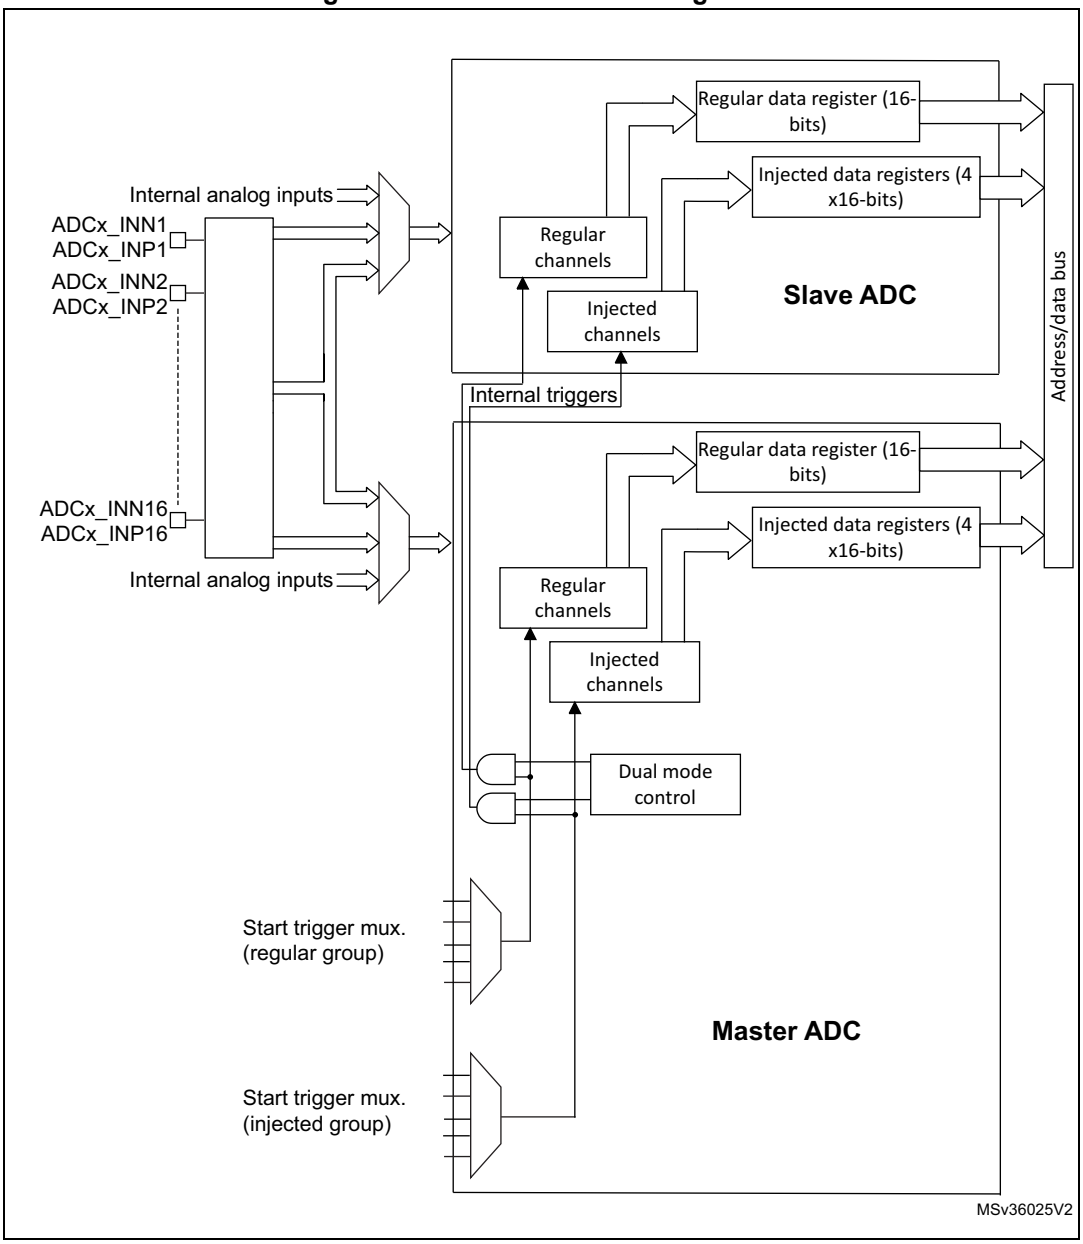
To start a conversion in dual mode, the user must program the bits EXTEN, EXTSEL, JEXTEN, JEXTSEL of the master ADC only, to configure a software or hardware trigger, and a regular or injected trigger. (the bits EXTEN[1:0] and JEXTEN[1:0] of the slave ADC are don’t care).

In regular simultaneous or interleaved modes: once the user sets bit ADSTART or bit ADSTP of the master ADC, the corresponding bit of the slave ADC is also automatically set. However, bit ADSTART or bit ADSTP of the slave ADC is not necessary cleared at the same time as the master ADC bit.

In injected simultaneous or alternate trigger modes: once the user sets bit JADSTART or bit JADSTP of the master ADC, the corresponding bit of the slave ADC is also automatically set. However, bit JADSTART or bit JADSTP of the slave ADC is not necessary cleared at the same time as the master ADC bit.

In dual ADC mode, the converted data of the master and slave ADC can be read in parallel, by reading the ADC common data register (ADC_CDR). The status bits can be also read in parallel by reading the dual-mode status register (ADC_CSR).

Figure 240. Dual ADC block diagram(1)



1. External triggers also exist on slave ADC but are not shown for the purposes of this diagram.
2. The ADC common data register (ADC_CDR) contains both the master and slave ADC regular converted data.

Injected simultaneous mode

This mode is selected by programming bits DUAL[4:0] = 00101

This mode converts an injected group of channels. The external trigger source comes from the injected group multiplexer of the master ADC (selected by the JEXTSEL bits in the ADC_JSQR register).

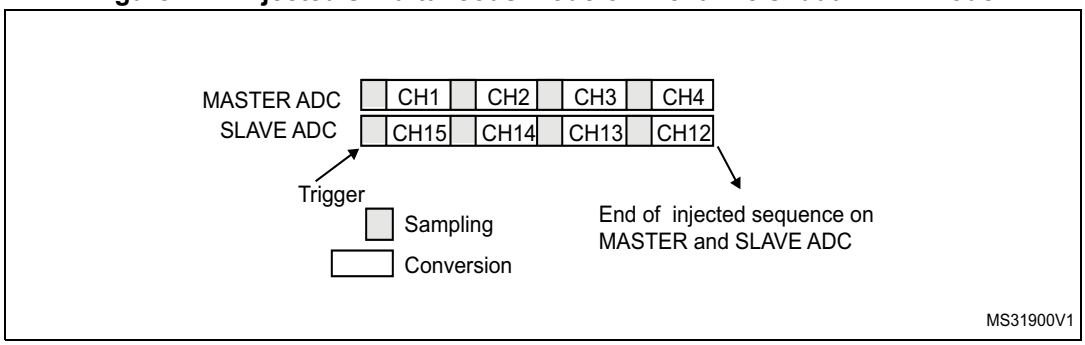
Note: Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

In simultaneous mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the longer of the 2 sequences. Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

Regular conversions can be performed on one or all ADCs. In that case, they are independent of each other and are interrupted when an injected event occurs. They are resumed at the end of the injected conversion group.

- At the end of injected sequence of conversion event (JEOS) on the master ADC, the converted data is stored into the master ADC_JDRy registers and a JEOS interrupt is generated (if enabled)
- At the end of injected sequence of conversion event (JEOS) on the slave ADC, the converted data is stored into the slave ADC_JDRy registers and a JEOS interrupt is generated (if enabled)
- If the duration of the master injected sequence is equal to the duration of the slave injected one (like in *Figure 241*), it is possible for the software to enable only one of the two JEOS interrupt (ex: master JEOS) and read both converted data (from master ADC_JDRy and slave ADC_JDRy registers).

Figure 241. Injected simultaneous mode on 4 channels: dual ADC mode



If JDISCEN = 1, each simultaneous conversion of the injected sequence requires an injected trigger event to occur.

This mode can be combined with AUTDLY mode:

- Once a simultaneous injected sequence of conversions has ended, a new injected trigger event is accepted only if both JEOS bits of the master and the slave ADC have been cleared (delay phase). Any new injected trigger events occurring during the ongoing injected sequence and the associated delay phase are ignored.
- Once a regular sequence of conversions of the master ADC has ended, a new regular trigger event of the master ADC is accepted only if the master data register (ADC_DR) has been read. Any new regular trigger events occurring for the master ADC during the

ongoing regular sequence and the associated delay phases are ignored.
There is the same behavior for regular sequences occurring on the slave ADC.

Regular simultaneous mode with independent injected

This mode is selected by programming bits DUAL[4:0] = 00110.

This mode is performed on a regular group of channels. The external trigger source comes from the regular group multiplexer of the master ADC (selected by the EXTSEL bits in the ADC_CFGR register). A simultaneous trigger is provided to the slave ADC.

In this mode, independent injected conversions are supported. An injection request (either on master or on the slave) aborts the current simultaneous conversions, which are restarted once the injected conversion is completed.

Note: Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

In regular simultaneous mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the longer conversion time of the 2 sequences. Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

Software is notified by interrupts when it can read the data:

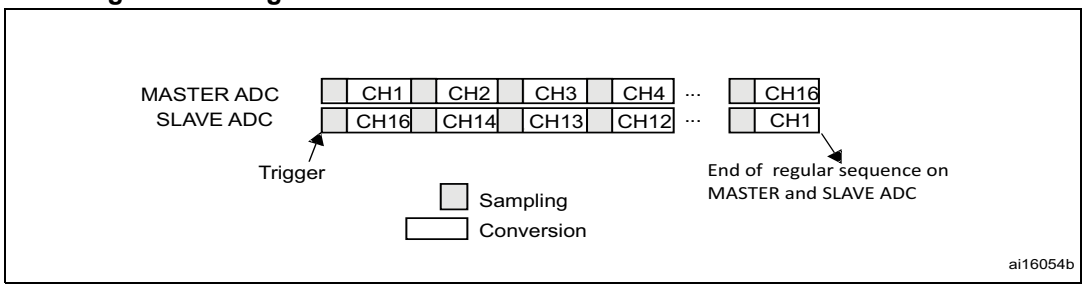
- At the end of each conversion event (EOC) on the master ADC, a master EOC interrupt is generated (if EOCIE is enabled) and software can read the ADC_DR of the master ADC.
- At the end of each conversion event (EOC) on the slave ADC, a slave EOC interrupt is generated (if EOCIE is enabled) and software can read the ADC_DR of the slave ADC.
- If the duration of the master regular sequence is equal to the duration of the slave one (like in *Figure 242*), it is possible for the software to enable only one of the two EOC interrupt (ex: master EOC) and read both converted data from the Common Data register (ADC_CDR).

It is also possible to read the regular data using the DMA. Two methods are possible:

- Using two DMA channels (one for the master and one for the slave). In this case bits MDMA[1:0] must be kept cleared.
  - Configure the DMA master ADC channel to read ADC_DR from the master. DMA requests are generated at each EOC event of the master ADC.
  - Configure the DMA slave ADC channel to read ADC_DR from the slave. DMA requests are generated at each EOC event of the slave ADC.
- Using MDMA mode, which leaves one DMA channel free for other uses:
  - Configure MDMA[1:0] = 0b10 or 0b11 (depending on resolution).
  - A single DMA channel is used (the one of the master). Configure the DMA master ADC channel to read the common ADC register (ADC_CDR)
  - A single DMA request is generated each time both master and slave EOC events have occurred. At that time, the slave ADC converted data is available in the upper half-word of the ADC_CDR 32-bit register and the master ADC converted data is available in the lower half-word of ADC_CDR register.
  - Both EOC flags are cleared when the DMA reads the ADC_CDR register.

Note: In MDMA mode (MDMA[1:0] = 0b10 or 0b11), the user must program the same number of conversions in the master's sequence as in the slave's sequence. Otherwise, the remaining conversions does not generate a DMA request.

Figure 242. Regular simultaneous mode on 16 channels: dual ADC mode



If DISCEN = 1 then each “n” simultaneous conversions of the regular sequence require a regular trigger event to occur (“n” is defined by DISCNUM).

This mode can be combined with AUTDLY mode:

- Once a simultaneous conversion of the sequence has ended, the next conversion in the sequence is started only if the common data register, ADC_CDR (or the regular data register of the master ADC) has been read (delay phase).
- Once a simultaneous regular sequence of conversions has ended, a new regular trigger event is accepted only if the common data register (ADC_CDR) has been read (delay phase). Any new regular trigger events occurring during the ongoing regular sequence and the associated delay phases are ignored.

It is possible to use the DMA to handle data in regular simultaneous mode combined with AUTDLY mode, assuming that multiple-DMA mode is used: bits MDMA must be set to 0b10 or 0b11.

When regular simultaneous mode is combined with AUTDLY mode, it is mandatory for the user to ensure that:

- The number of conversions in the master’s sequence is equal to the number of conversions in the slave’s.
- For each simultaneous conversions of the sequence, the length of the conversion of the slave ADC is inferior to the length of the conversion of the master ADC. Note that the length of the sequence depends on the number of channels to convert and the sampling time and the resolution of each channels.

Note: This combination of regular simultaneous mode and AUTDLY mode is restricted to the use case when only regular channels are programmed: it is forbidden to program injected channels in this combined mode.

Interleaved mode with independent injected

This mode is selected by programming bits DUAL[4:0] = 00111.

This mode can be started only on a regular group (usually one channel). The external trigger source comes from the regular channel multiplexer of the master ADC.

After an external trigger occurs:

- The master ADC starts immediately.
- The slave ADC starts after a delay of several-ADC clock cycles after the sampling phase of the master ADC has complete.

The minimum delay which separates two conversions in interleaved mode is configured in the DELAY bits in the ADC_CCR register. This delay starts counting one half cycle after the end of the sampling phase of the master conversion. This way, an ADC cannot start a

conversion if the complementary ADC is still sampling its input (only one ADC can sample the input signal at a given time).

- The minimum possible DELAY is 1 to ensure that there is at least one cycle time between the opening of the analog switch of the master ADC sampling phase and the closing of the analog switch of the slave ADC sampling phase.
- The maximum DELAY is equal to the number of cycles corresponding to the selected resolution. However the user must properly calculate this delay to ensure that an ADC does not start a conversion while the other ADC is still sampling its input.

If the CONT bit is set on both master and slave ADCs, the selected regular channels of both ADCs are continuously converted.

The software is notified by interrupts when it can read the data at the end of each conversion event (EOC) on the slave ADC. A slave and master EOC interrupts are generated (if EOCIE is enabled) and the software can read the ADC_DR of the slave/master ADC.

Note: It is possible to enable only the EOC interrupt of the slave and read the common data register (ADC_CDR). But in this case, the user must ensure that the duration of the conversions are compatible to ensure that inside the sequence, a master conversion is always followed by a slave conversion before a new master conversion restarts. It is recommended to use the MDMA mode.

It is also possible to have the regular data transferred by DMA. In this case, individual DMA requests on each ADC cannot be used and it is mandatory to use the MDMA mode, as following:

- Configure MDMA[1:0] = 0b10 or 0b11 (depending on resolution).
- A single DMA channel is used (the one of the master). Configure the DMA master ADC channel to read the common ADC register (ADC_CDR).
- A single DMA request is generated each time both master and slave EOC events have occurred. At that time, the slave ADC converted data is available in the upper half-word of the ADC_CDR 32-bit register and the master ADC converted data is available in the lower half-word of ADC_CCR register.
- Both EOC flags are cleared when the DMA reads the ADC_CCR register.

Figure 243. Interleaved mode on one channel in continuous conversion mode: dual ADC mode

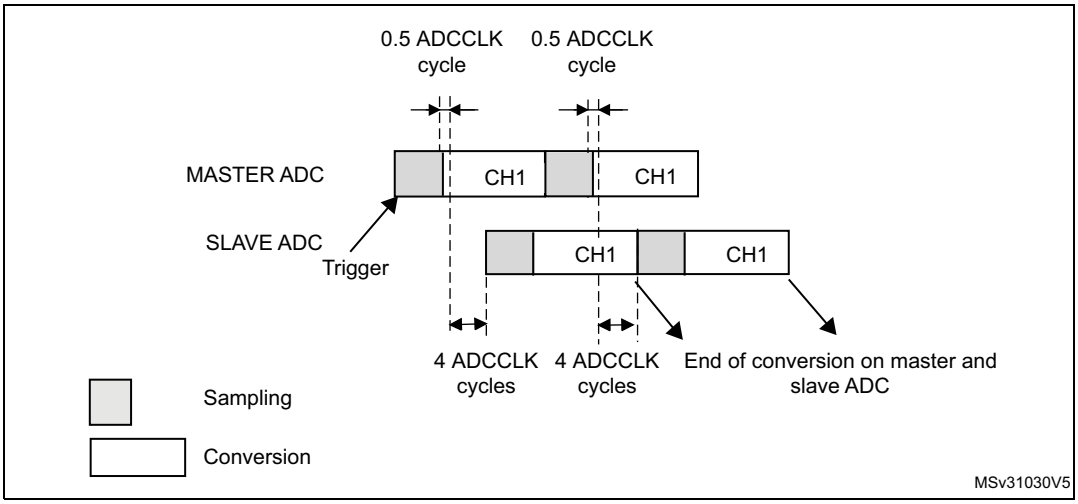


Figure 244. Interleaved mode on 1 channel in single conversion mode: dual ADC mode

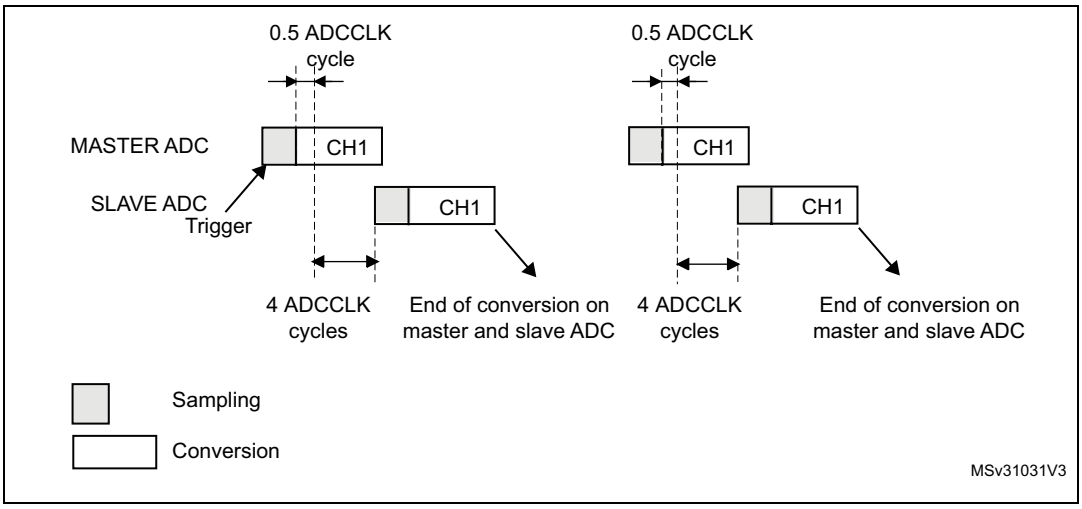
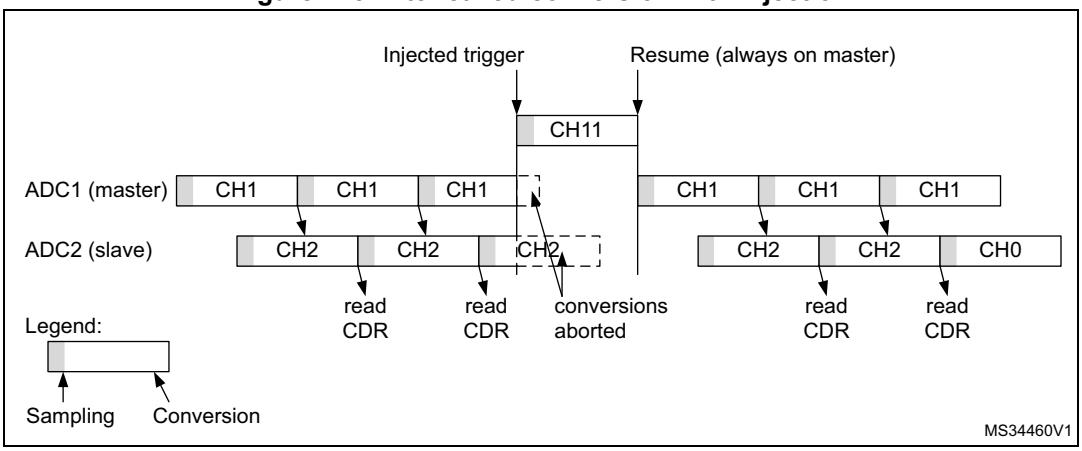


If DISCEN = 1, each “n” simultaneous conversions (“n” is defined by DISCNUM) of the regular sequence require a regular trigger event to occur.

In this mode, injected conversions are supported. When injection is done (either on master or on slave), both the master and the slave regular conversions are aborted and the sequence is restarted from the master (see *Figure 245* below).

Figure 245. Interleaved conversion with injection



Alternate trigger mode

This mode is selected by programming bits DUAL[4:0] = 01001.

This mode can be started only on an injected group. The source of external trigger comes from the injected group multiplexer of the master ADC.

This mode is only possible when selecting hardware triggers: JEXTEN must not be 0x0.

Injected discontinuous mode disabled (JDISCEN = 0 for both ADC)

1. When the 1st trigger occurs, all injected master ADC channels in the group are converted.
2. When the 2nd trigger occurs, all injected slave ADC channels in the group are converted.
3. And so on.

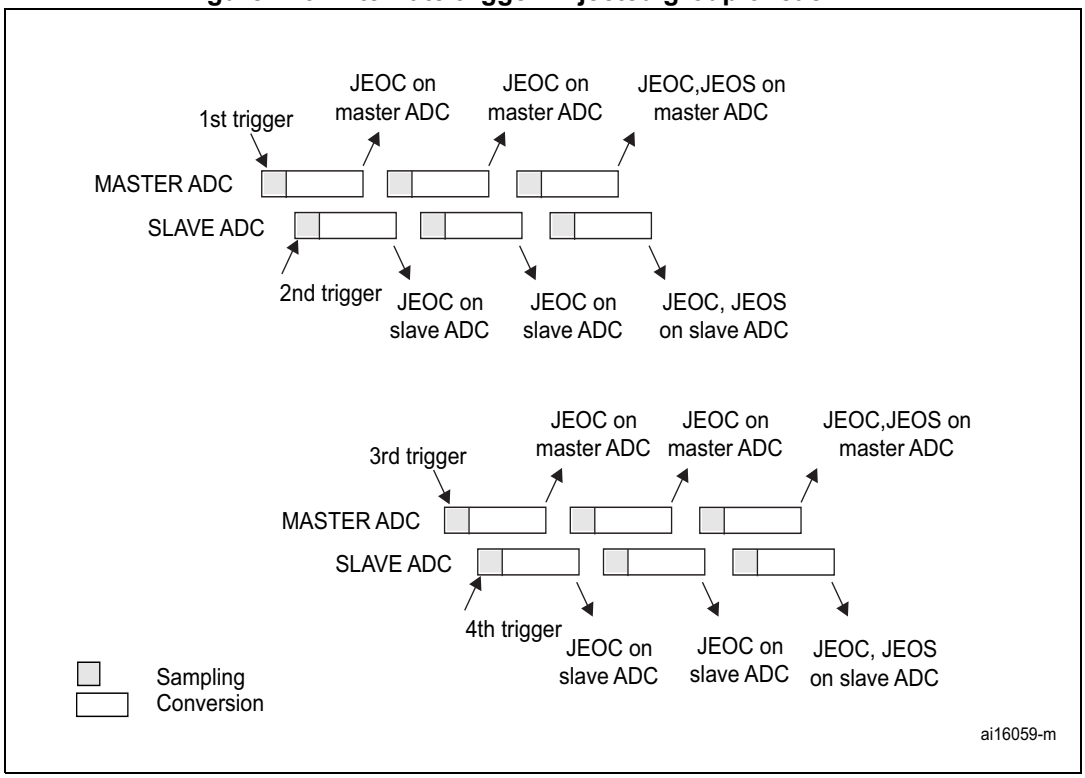
A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversion.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts by converting the injected channels of the master ADC in the group.

Figure 246. Alternate trigger: injected group of each ADC



Note: Regular conversions can be enabled on one or all ADCs. In this case the regular conversions are independent of each other. A regular conversion is interrupted when the ADC has to perform an injected conversion. It is resumed when the injected conversion is finished.

The time interval between 2 trigger events must be greater than or equal to 1 ADC clock period. The minimum time interval between 2 trigger events that start conversions on the same ADC is the same as in the single ADC mode.

Injected discontinuous mode enabled (JDISCEN = 1 for both ADC)

If the injected discontinuous mode is enabled for both master and slave ADCs:

- When the 1st trigger occurs, the first injected channel of the master ADC is converted.
- When the 2nd trigger occurs, the first injected channel of the slave ADC is converted.
- And so on.

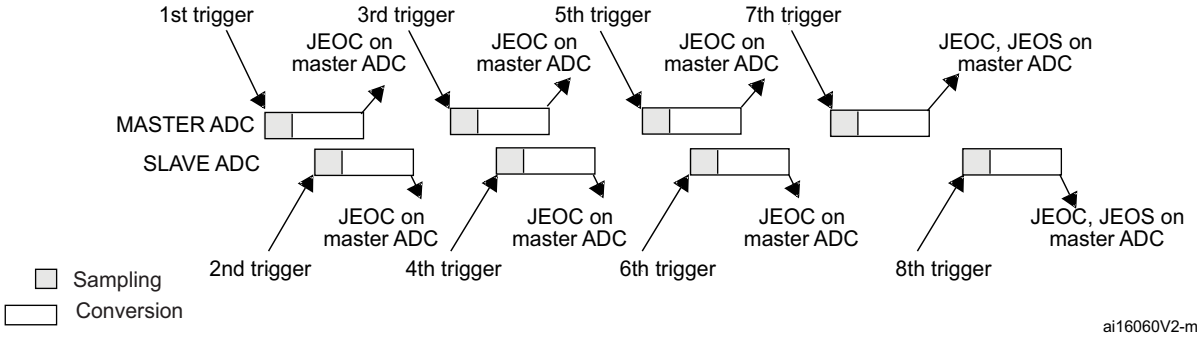
A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversions.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts.

Figure 247. Alternate trigger: 4 injected channels (each ADC) in discontinuous mode



Combined regular/injected simultaneous mode

This mode is selected by programming bits DUAL[4:0] = 00001.

It is possible to interrupt the simultaneous conversion of a regular group to start the simultaneous conversion of an injected group.

Note: In combined regular/injected simultaneous mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the long conversion time of the 2 sequences. Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

Combined regular simultaneous + alternate trigger mode

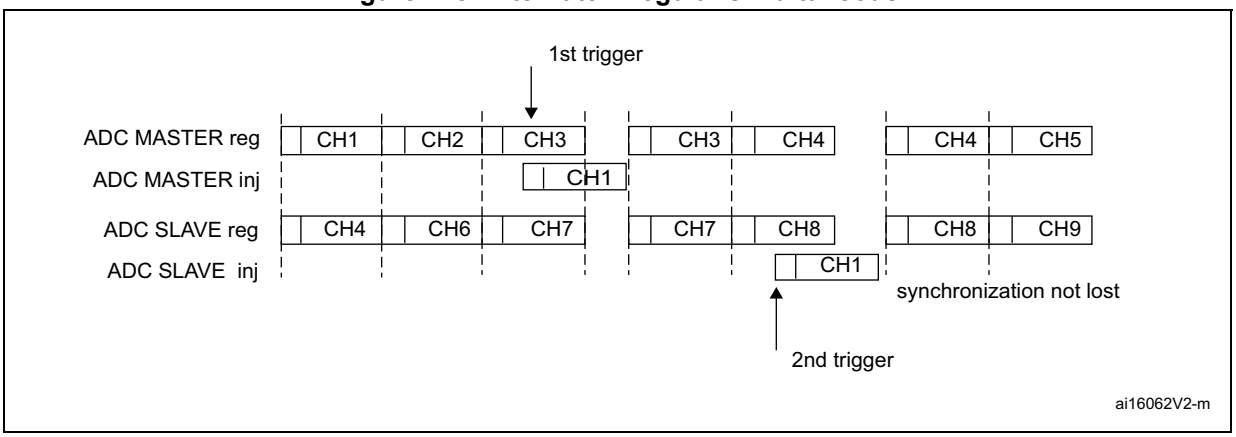
This mode is selected by programming bits DUAL[4:0] = 00010.

It is possible to interrupt the simultaneous conversion of a regular group to start the alternate trigger conversion of an injected group. *Figure 248* shows the behavior of an alternate trigger interrupting a simultaneous regular conversion.

The injected alternate conversion is immediately started after the injected event. If a regular conversion is already running, in order to ensure synchronization after the injected conversion, the regular conversion of all (master/slave) ADCs is stopped and resumed synchronously at the end of the injected conversion.

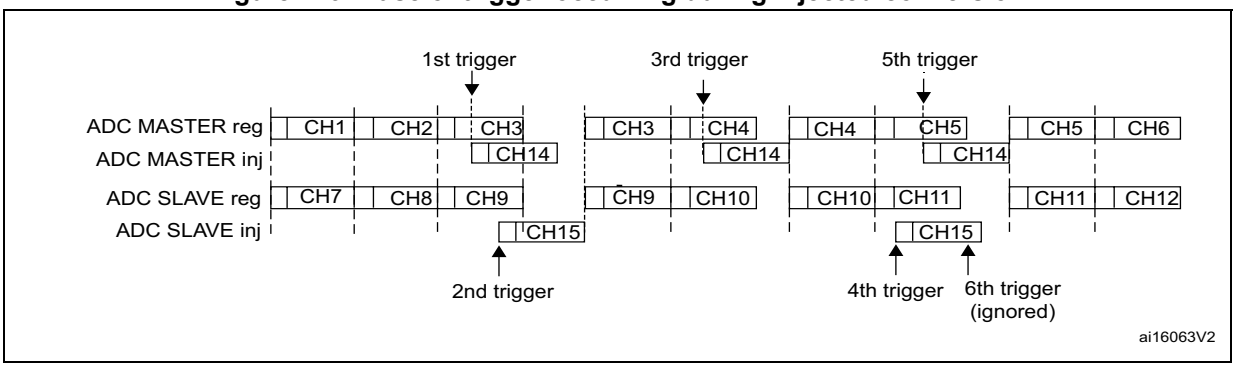
Note: In combined regular simultaneous + alternate trigger mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the long conversion time of the 2 sequences. Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

Figure 248. Alternate + regular simultaneous



If a trigger occurs during an injected conversion that has interrupted a regular conversion, the alternate trigger is served. *Figure 249* shows the behavior in this case (note that the 6th trigger is ignored because the associated alternate conversion is not complete).

Figure 249. Case of trigger occurring during injected conversion



Combined injected simultaneous plus interleaved

This mode is selected by programming bits DUAL[4:0] = 00011

It is possible to interrupt an interleaved conversion with a simultaneous injected event.

In this case the interleaved conversion is interrupted immediately and the simultaneous injected conversion starts. At the end of the injected sequence the interleaved conversion is resumed. When the interleaved regular conversion resumes, the first regular conversion which is performed is alway the master's one. *Figure 250*, *Figure 251* and *Figure 252* show the behavior using an example.

Caution: In this mode, it is mandatory to use the Common Data Register to read the regular data with a single read access. On the contrary, master-slave data coherency is not guaranteed.

Figure 250. Interleaved single channel CH0 with injected sequence CH11, CH12

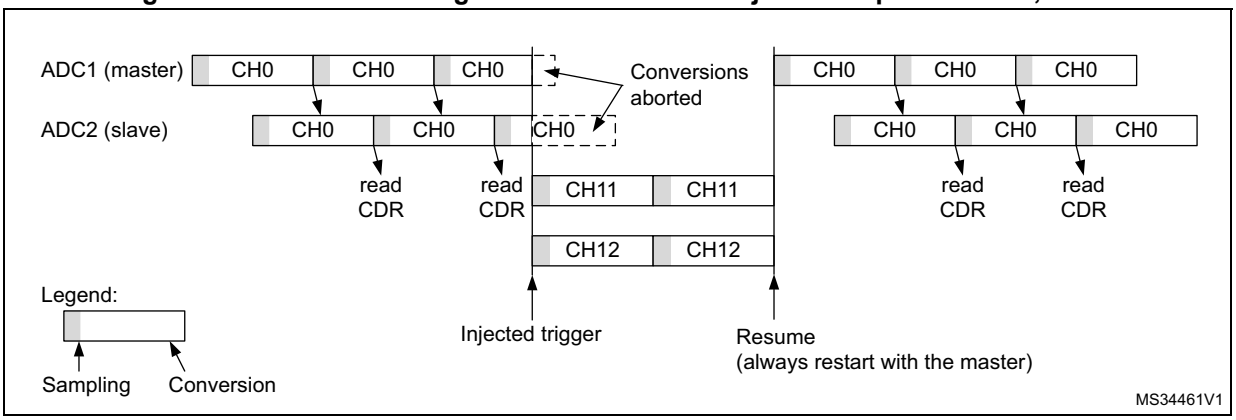


Figure 251. Two Interleaved channels (CH1, CH2) with injected sequence CH11, CH12 - case 1: Master interrupted first

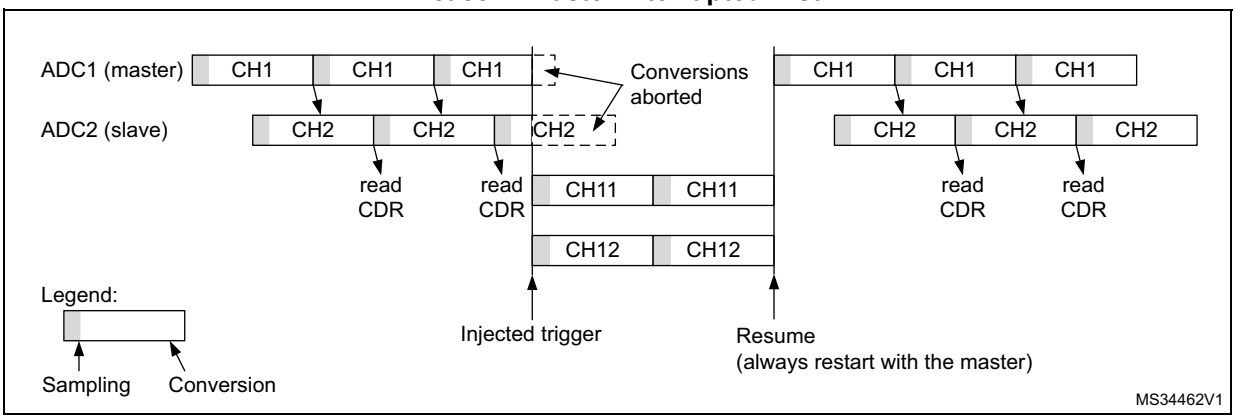

Figure 252. Two Interleaved channels (CH1, CH2) with injected sequence CH11, CH12 - case 2: Slave interrupted first

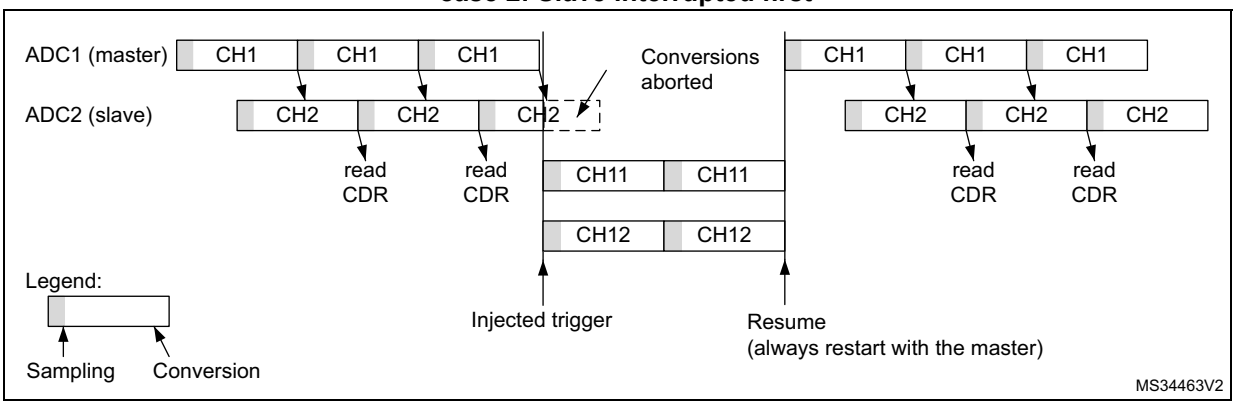
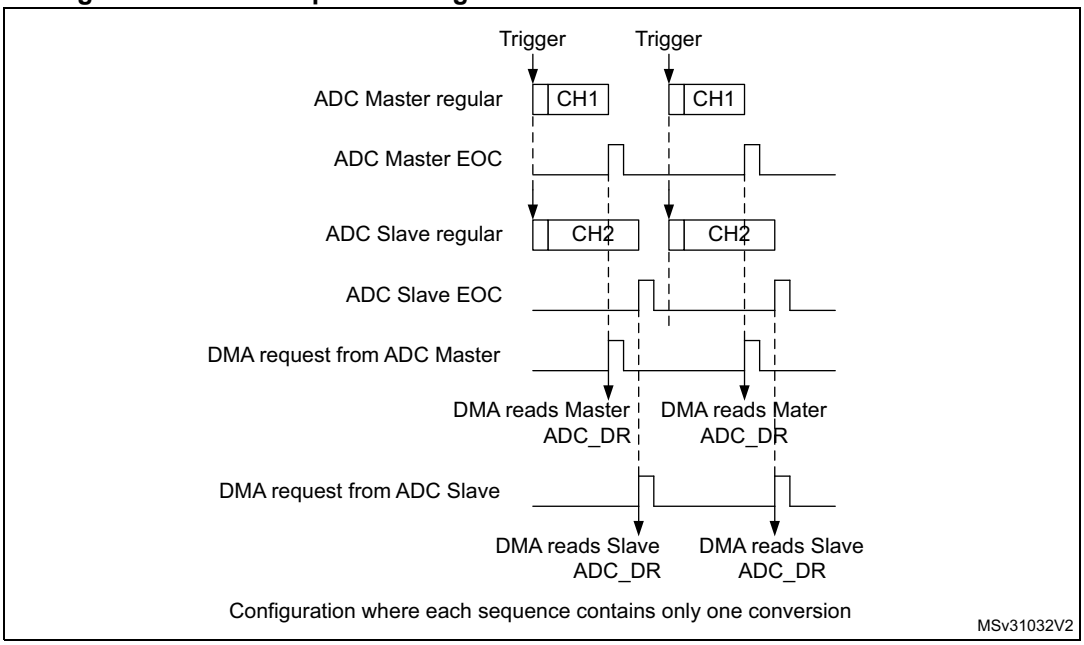


DMA requests in dual ADC mode

In all dual ADC modes, it is possible to use two DMA channels (one for the master, one for the slave) to transfer the data, like in single mode (refer to *Figure 253: DMA Requests in regular simultaneous mode when MDMA = 0b00*).

Figure 253. DMA Requests in regular simultaneous mode when MDMA = 0b00



In simultaneous regular and interleaved modes, it is also possible to save one DMA channel and transfer both data using a single DMA channel. For this MDMA bits must be configured in the ADC_CCR register:

- **MDMA = 0b10**: A single DMA request is generated each time both master and slave EOC events have occurred. At that time, two data items are available and the 32-bit register ADC_CDR contains the two half-words representing two ADC-converted data items. The slave ADC data take the upper half-word and the master ADC data take the lower half-word.
  This mode is used in interleaved mode and in regular simultaneous mode when resolution is 10-bit or 12-bit.

  Example:

  Interleaved dual mode: a DMA request is generated each time 2 data items are available:

  1st DMA request: ADC_CDR[31:0] = SLV_ADC_DR[15:0] | MST_ADC_DR[15:0]

  2nd DMA request: ADC_CDR[31:0] = SLV_ADC_DR[15:0] | MST_ADC_DR[15:0]

Figure 254. DMA requests in regular simultaneous mode when MDMA = 0b10

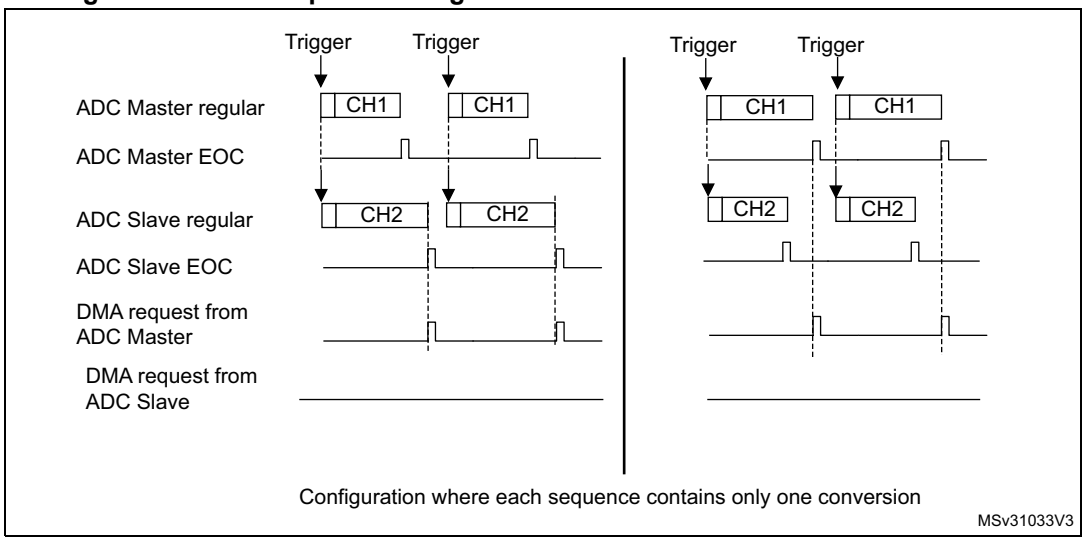


Figure 255. DMA requests in interleaved mode when MDMA = 0b10

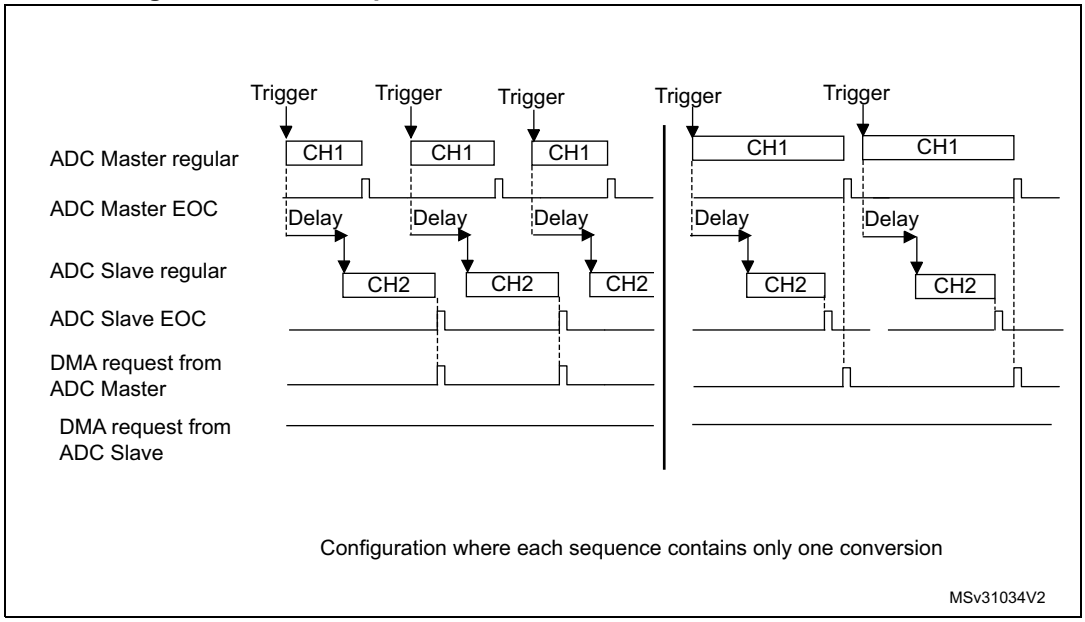


Note: When using MDMA mode, the user must take care to configure properly the duration of the master and slave conversions so that a DMA request is generated and served for reading both data (master + slave) before a new conversion is available.

- **MDMA = 0b11**: This mode is similar to the MDMA = 0b10. The only differences are that on each DMA request (two data items are available), two bytes representing two ADC converted data items are transferred as a half-word.

  This mode is used in interleaved and regular simultaneous mode when resolution is 6-bit or when resolution is 8-bit and data is not signed (offsets must be disabled for all the involved channels).

  Example:

  Interleaved dual mode: a DMA request is generated each time 2 data items are available:

  1st DMA request: ADC_CDR[15:0] = SLV_ADC_DR[7:0] | MST_ADC_DR[7:0]

  2nd DMA request: ADC_CDR[15:0] = SLV_ADC_DR[7:0] | MST_ADC_DR[7:0]

Overrun detection

In dual ADC mode (when DUAL[4:0] is not equal to b00000), if an overrun is detected on one of the ADCs, the DMA requests are no longer issued to ensure that all the data transferred to the RAM are valid (this behavior occurs whatever the MDMA configuration). It may happen that the EOC bit corresponding to one ADC remains set because the data register of this ADC contains valid data.

DMA one shot mode/ DMA circular mode when MDMA mode is selected

When MDMA mode is selected (0b10 or 0b11), bit DMACFG of the ADC_CCR register must also be configured to select between DMA one shot mode and circular mode, as explained in section *Section : Managing conversions using the DMA* (bits DMACFG of master and slave ADC_CFGR are not relevant).

Stopping the conversions in dual ADC modes

The user must set the control bits ADSTP/JADSTP of the master ADC to stop the conversions of both ADC in dual ADC mode. The other ADSTP control bit of the slave ADC has no effect in dual ADC mode.

Once both ADC are effectively stopped, the bits ADSTART/JADSTART of the master and slave ADCs are both cleared by hardware.

26.4.31 Temperature sensor

The temperature sensor can be used to measure the junction temperature (Tj) of the device.

The temperature sensor is internally connected to the ADC input channels which are used to convert the sensor output voltage to a digital value (see *Table: ADC interconnection* in *Section 26.4.2: ADC pins and internal signals* for more details). When not in use, the sensor can be put in power down mode. It support the temperature range –40 to 125 °C.

Figure 256 shows the block diagram of connections between the temperature sensor and the ADC.

The temperature sensor output voltage changes linearly with temperature. The offset of this line varies from chip to chip due to process variation (up to 45 °C from one chip to another).

The uncalibrated internal temperature sensor is more suited for applications that detect temperature variations instead of absolute temperatures. To improve the accuracy of the temperature sensor measurement, calibration values are stored in system memory for each device by ST during production.

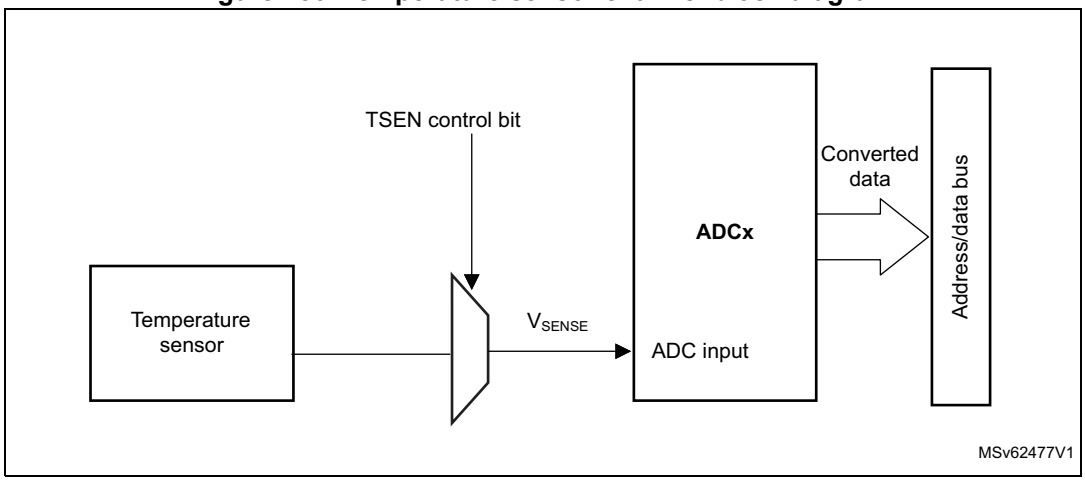
During the manufacturing process, the calibration data of the temperature sensor and the internal voltage reference are stored in the system memory area. The user application can then read them and use them to improve the accuracy of the temperature sensor or the internal reference (refer to the datasheet for additional information).

The temperature sensor is internally connected to the ADC input channel which is used to convert the sensor's output voltage to a digital value. Refer to the electrical characteristics section of the device datasheet for the sampling time value to be applied when converting the internal temperature sensor.

When not in use, the sensor can be put in power-down mode.

Figure 256 shows the block diagram of the temperature sensor.

Figure 256. Temperature sensor channel block diagram



Reading the temperature

To use the sensor:

1. Select the ADC input channels that is connected to V_{SENSE}.
2. Program with the appropriate sampling time (refer to electrical characteristics section of the device datasheet).
3. Set the bit in the ADC_CCR register to wake up the temperature sensor from power-down mode.
4. Start the ADC conversion.
5. Read the resulting V_{SENSE} data in the ADC data register.
6. Calculate the actual temperature using the following formula:

$$\text{Temperature (in °C)} = \frac{\text{TS\_CAL2\_TEMP} - \text{TS\_CAL1\_TEMP}}{\text{TS\_CAL2} - \text{TS\_CAL1}} \times (\text{TS\_DATA} - \text{TS\_CAL1}) + \text{TS\_CAL1\_TEMP}$$

where:

- TS_CAL2 is the temperature sensor calibration value acquired at TS_CAL2_TEMP.
- TS_CAL1 is the temperature sensor calibration value acquired at TS_CAL1_TEMP.
- TS_DATA is the actual temperature sensor output value converted by ADC.

  Refer to the device datasheet for more information about TS_CAL1 and TS_CAL2 calibration points.

Note: The sensor has a startup time after waking from power-down mode before it can output V_{SENSE} at the correct level. The ADC also has a startup time after power-on, so to minimize the delay, the ADEN and bits should be set at the same time.

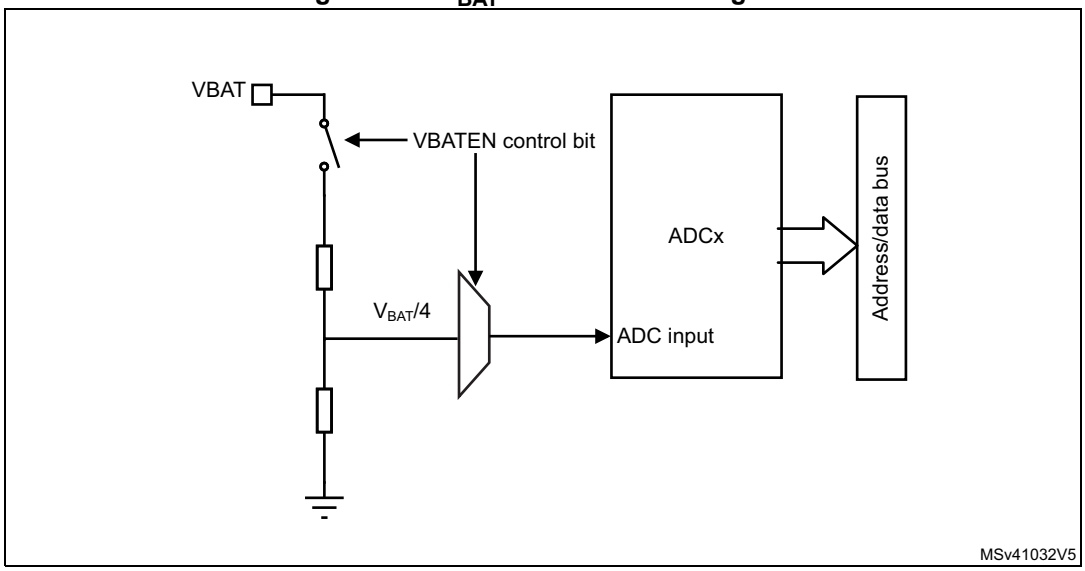
26.4.32 V_{BAT} supply monitoring

The VBATEN bit in the ADC_CCR register is used to switch to the battery voltage. As the V_{BAT} voltage could be higher than V_{DDA}, to ensure the correct operation of the ADC, the V_{BAT} pin is internally connected to a bridge divider by 4. This bridge is automatically enabled when VBATEN is set, to connect $V_{BAT}/4$ to the ADC input channels (see *Table: ADC interconnection* in *Section 26.4.2: ADC pins and internal signals* for more details). As a consequence, the converted digital value is one third of the V_{BAT} voltage. To prevent any unwanted consumption on the battery, it is recommended to enable the bridge divider only when needed, for ADC conversion.

Refer to the electrical characteristics of the device datasheet for the sampling time value to be applied when converting the $V_{BAT}/4$ voltage.

Figure 257 shows the block diagram of the V_{BAT} sensing feature.

Figure 257. V_{BAT} channel block diagram



1. The VBATEN bit must be set to enable the conversion of internal channel for $V_{BAT}/4$.

26.4.33 Monitoring the internal voltage reference

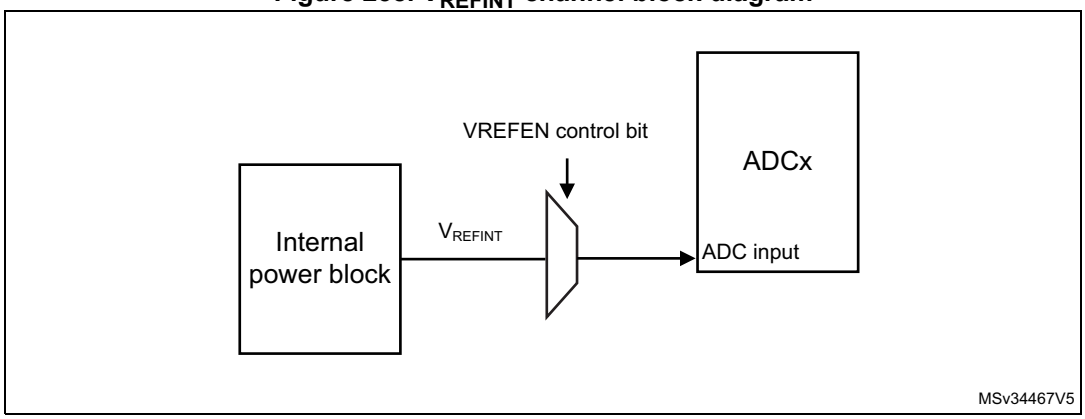
It is possible to monitor the internal voltage reference (V_{REFINT}) to have a reference point for evaluating the ADC V_{REF+} voltage level.

Refer to *Table: ADC interconnection* in *Section 26.4.2: ADC pins and internal signals* for details on the ADC input channels to which the internal voltage reference is internally connected.

Refer to the electrical characteristics section of the product datasheet for the sampling time value to be applied when converting the internal voltage reference voltage.

Figure 258 shows the block diagram of the V_{REFINT} sensing feature.

Figure 258. V_{REFINT} channel block diagram



1. The VREFEN bit into ADC_CCR register must be set to enable the conversion of internal channels (V_{REFINT}).

Calculating the actual V_{REF+} voltage using the internal reference voltage

V_{REF+} voltage may be subject to variations or not precisely known. The embedded internal reference voltage V_{REFINT} and its calibration data acquired by the ADC during the manufacturing process at V_{REF+_charac} can be used to evaluate the actual V_{REF+} voltage level.

The following formula gives the actual V_{REF+} voltage supplying the device:

$$V_{REF+} = V_{REF+\_Charac} \times VREFINT\_CAL / VREFINT\_DATA$$

Where:

- V_{REF+_Charac} is the value of V_{REF+} voltage characterized at V_{REFINT} during the manufacturing process. It is specified in the device datasheet.
- VREFINT_CAL is the VREFINVREFINT_CAL is the VREFINT calibration value
- VREFINT_DATA is the actual VREFINT output value converted by ADC

Converting a supply-relative ADC measurement to an absolute voltage value

The ADC is designed to deliver a digital value corresponding to the ratio between V_{REF+} and the voltage applied on the converted channel.

For applications where V_{REF+} value is unknown and ADC converted values are right-aligned. In this case, it is necessary to convert this ratio into a voltage independent from V_{REF+}:

$$V_{CHANNELx} = \frac{V_{REF+}}{FULL\_SCALE} \times ADC\_DATA$$

By replacing V_{REF+} by the formula provided above, the absolute voltage value is given by the following formula

$$V_{CHANNELx} = \frac{V_{REF+\_Charac} \times VREFINT\_CAL \times ADC\_DATA}{VREFINT\_DATA \times FULL\_SCALE}$$

Where:

- V_{REF+_Charac} is the value of V_{REF+} voltage characterized at V_{REFINT} during the manufacturing process.
- VREFINT_CAL is the VREFINT calibration value
- ADC_DATA is the value measured by the ADC on channel x (right-aligned)
- VREFINT_DATA is the actual VREFINT output value converted by the ADC
- FULL_SCALE is the maximum digital value of the ADC output. For example with 12-bit resolution, it is 2^{12} - 1 = 4095 or with 8-bit resolution, 2^8 - 1 = 255.

Note: If ADC measurements are done using an output format other than 12-bit right-aligned, all the parameters must first be converted to a compatible format before the calculation is done.

26.4.34 Monitoring the supply voltage

ADC2 is connected to the internal supply voltage. To use the ADC to measure this voltage, enable the connection through ADC option register.

26.5 ADC interrupts

For each ADC, an interrupt can be generated:

- After ADC power-up, when the ADC is ready (flag ADRDY)
- On the end of any conversion for regular groups (flag EOC)
- On the end of a sequence of conversion for regular groups (flag EOS)
- On the end of any conversion for injected groups (flag JEOC)
- On the end of a sequence of conversion for injected groups (flag JEOS)
- When an analog watchdog detection occurs (flag AWD1, AWD2 and AWD3)
- When the end of sampling phase occurs (flag EOSMP)
- When the data overrun occurs (flag OVR)
- When the injected sequence context queue overflows (flag JQOVF)

Separate interrupt enable bits are available for flexibility.

Table 252. ADC interrupts

Interrupt vector	Interrupt event	Event flag	Enable Control bit	Interrupt clear method	Exit from Sleep mode	Exit from Stop, Standby mode
ADC	ADC ready	ADRDY	ADRDYIE	Set by hardware and cleared by software	Yes	No
	End of conversion of a regular group	EOC	EOCIE			
	End of conversion sequence of a regular group	EOS	EOSIE			
	End of conversion of an injected group	JEOC	JEOCIE			
	End of conversion sequence of an injected group	JEOS	JEOSIE			
	Analog watchdog 1 status bit is set	AWD1	AWD1IE			
	Analog watchdog 2 status bit is set	AWD2	AWD2IE			
	Analog watchdog 3 status bit is set	AWD3	AWD3IE			
	End of sampling phase	EOSMP	EOSMPIE			
	Overrun	OVR	OVRIE			
	Injected context queue overflows	JQOVF	JQOVFIE			

26.6 ADC registers (for each ADC)

Refer to *Section 1.2 on page 101* for a list of abbreviations used in register descriptions.

26.6.1 ADC interrupt and status register (ADC_ISR)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	JQOVF	AWD3	AWD2	AWD1	JEOS	JEOC	OVR	EOS	EOC	EOSMP	ADRDY
					rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **JQOVF**: Injected context queue overflow

This bit is set by hardware when an Overflow of the Injected Queue of Context occurs. It is cleared by software writing 1 to it. Refer to *Section 26.4.21: Queue of context for injected conversions* for more information.

0: No injected context queue overflow occurred (or the flag event was already acknowledged and cleared by software)

1: Injected context queue overflow has occurred

Bit 9 **AWD3**: Analog watchdog 3 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT3[7:0] and HT3[7:0] of ADC_TR3 register. It is cleared by software writing 1 to it.

0: No analog watchdog 3 event occurred (or the flag event was already acknowledged and cleared by software)

1: Analog watchdog 3 event occurred

Bit 8 **AWD2**: Analog watchdog 2 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT2[7:0] and HT2[7:0] of ADC_TR2 register. It is cleared by software writing 1 to it.

0: No analog watchdog 2 event occurred (or the flag event was already acknowledged and cleared by software)

1: Analog watchdog 2 event occurred

Bit 7 **AWD1**: Analog watchdog 1 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT1[11:0] and HT1[11:0] of ADC_TR1 register. It is cleared by software. writing 1 to it.

0: No analog watchdog 1 event occurred (or the flag event was already acknowledged and cleared by software)

1: Analog watchdog 1 event occurred

Bit 6 **JEOS:** Injected channel end of sequence flag

This bit is set by hardware at the end of the conversions of all injected channels in the group. It is cleared by software writing 1 to it.

0: Injected conversion sequence not complete (or the flag event was already acknowledged and cleared by software)

1: Injected conversions complete

Bit 5 **JEOC:** Injected channel end of conversion flag

This bit is set by hardware at the end of each injected conversion of a channel when a new data is available in the corresponding ADC_JDRy register. It is cleared by software writing 1 to it or by reading the corresponding ADC_JDRy register

0: Injected channel conversion not complete (or the flag event was already acknowledged and cleared by software)

1: Injected channel conversion complete

Bit 4 **OVR**: ADC overrun

This bit is set by hardware when an overrun occurs on a regular channel, meaning that a new conversion has completed while the EOC flag was already set. It is cleared by software writing 1 to it.

0: No overrun occurred (or the flag event was already acknowledged and cleared by software)

1: Overrun has occurred

Bit 3 **EOS**: End of regular sequence flag

This bit is set by hardware at the end of the conversions of a regular sequence of channels. It is cleared by software writing 1 to it.

0: Regular Conversions sequence not complete (or the flag event was already acknowledged and cleared by software)

1: Regular Conversions sequence complete

Bit 2 **EOC**: End of conversion flag

This bit is set by hardware at the end of each regular conversion of a channel when a new data is available in the ADC_DR register. It is cleared by software writing 1 to it or by reading the ADC_DR register

0: Regular channel conversion not complete (or the flag event was already acknowledged and cleared by software)

1: Regular channel conversion complete

Bit 1 **EOSMP**: End of sampling flag

This bit is set by hardware during the conversion of any channel (only for regular channels), at the end of the sampling phase.

0: not at the end of the sampling phase (or the flag event was already acknowledged and cleared by software)

1: End of sampling phase reached

Bit 0 **ADRDY**: ADC ready

This bit is set by hardware after the ADC has been enabled (ADEN = 1) and when the ADC reaches a state where it is ready to accept conversion requests.

It is cleared by software writing 1 to it.

0: ADC not yet ready to start conversion (or the flag event was already acknowledged and cleared by software)

1: ADC is ready to start conversion

26.6.2 ADC interrupt enable register (ADC_IER)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	JQOVFIE	AWD3IE	AWD2IE	AWD1IE	JEOSIE	JEOCIE	OVRIE	EOSIE	EOCIE	EOSMPIE	ADRDYIE
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **JQOVFIE**: Injected context queue overflow interrupt enable

This bit is set and cleared by software to enable/disable the Injected Context Queue Overflow interrupt.

0: Injected Context Queue Overflow interrupt disabled

1: Injected Context Queue Overflow interrupt enabled. An interrupt is generated when the JQOVF bit is set.

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 9 **AWD3IE**: Analog watchdog 3 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog 2 interrupt.

0: Analog watchdog 3 interrupt disabled

1: Analog watchdog 3 interrupt enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 8 **AWD2IE**: Analog watchdog 2 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog 2 interrupt.

0: Analog watchdog 2 interrupt disabled

1: Analog watchdog 2 interrupt enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 7 **AWD1IE**: Analog watchdog 1 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog 1 interrupt.

0: Analog watchdog 1 interrupt disabled

1: Analog watchdog 1 interrupt enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 6 **JEOSIE**: End of injected sequence of conversions interrupt enable

This bit is set and cleared by software to enable/disable the end of injected sequence of conversions interrupt.

0: JEOS interrupt disabled

1: JEOS interrupt enabled. An interrupt is generated when the JEOS bit is set.

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 5 **JEOCIE**: End of injected conversion interrupt enable

This bit is set and cleared by software to enable/disable the end of an injected conversion interrupt.

0: JEOC interrupt disabled.

1: JEOC interrupt enabled. An interrupt is generated when the JEOC bit is set.

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 4 **OVRIE**: Overrun interrupt enable

This bit is set and cleared by software to enable/disable the Overrun interrupt of a regular conversion.

0: Overrun interrupt disabled

1: Overrun interrupt enabled. An interrupt is generated when the OVR bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 3 **EOSIE**: End of regular sequence of conversions interrupt enable

This bit is set and cleared by software to enable/disable the end of regular sequence of conversions interrupt.

0: EOS interrupt disabled

1: EOS interrupt enabled. An interrupt is generated when the EOS bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 2 **EOCIE**: End of regular conversion interrupt enable

This bit is set and cleared by software to enable/disable the end of a regular conversion interrupt.

0: EOC interrupt disabled.

1: EOC interrupt enabled. An interrupt is generated when the EOC bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 1 **EOSMPIE**: End of sampling flag interrupt enable for regular conversions

This bit is set and cleared by software to enable/disable the end of the sampling phase interrupt for regular conversions.

0: EOSMP interrupt disabled.

1: EOSMP interrupt enabled. An interrupt is generated when the EOSMP bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 0 **ADRDYIE**: ADC ready interrupt enable

This bit is set and cleared by software to enable/disable the ADC Ready interrupt.

0: ADRDY interrupt disabled

1: ADRDY interrupt enabled. An interrupt is generated when the ADRDY bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

26.6.3 ADC control register (ADC_CR)

Address offset: 0x08

Reset value: 0x2000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADCAL	ADCALDIF	DEEPPWD	ADVREGEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rs	rw	rw	rw												
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	JADSTP	ADSTP	JADSTART	ADSTART	ADDIS	ADEN
										rs	rs	rs	rs	rs	rs

Bit 31 **ADCAL**: ADC calibration

This bit is set by software to start the calibration of the ADC. Program first the bit ADCALDIF to determine if this calibration applies for single-ended or Differential inputs mode.

It is cleared by hardware after calibration is complete.

0: Calibration complete

1: Write 1 to calibrate the ADC. Read at 1 means that a calibration in progress.

Note: The software is allowed to launch a calibration by setting ADCAL only when ADEN = 0.

The software is allowed to update the calibration factor by writing ADC_CALFACT only when ADEN = 1 and ADSTART = 0 and JADSTART = 0 (ADC enabled and no conversion is ongoing)

Bit 30 **ADCALDIF**: Differential mode for calibration

This bit is set and cleared by software to configure the single-ended or Differential inputs mode for the calibration.

0: Writing ADCAL launches a calibration in single-ended inputs mode.

1: Writing ADCAL launches a calibration in Differential inputs mode.

Note: The software is allowed to write this bit only when the ADC is disabled and is not calibrating (ADCAL = 0, JADSTART = 0, JADSTP = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bit 29 **DEEPPWD**: Deep-power-down enable

This bit is set and cleared by software to put the ADC in Deep-power-down mode.

0: ADC not in Deep-power down

1: ADC in Deep-power-down (default reset state)

Note: The software is allowed to write this bit only when the ADC is disabled (ADCAL = 0, JADSTART = 0, JADSTP = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bit 28 **ADVREGEN**: ADC voltage regulator enable

This bits is set by software to enable the ADC voltage regulator.

Before performing any operation such as launching a calibration or enabling the ADC, the ADC voltage regulator must first be enabled and the software must wait for the regulator start-up time.

0: ADC Voltage regulator disabled

1: ADC Voltage regulator enabled.

For more details about the ADC voltage regulator enable and disable sequences, refer to *Section 26.4.6: ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)*.

The software can program this bit field only when the ADC is disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bits 27:6 Reserved, must be kept at reset value.

Bit 5 **JADSTP**: ADC stop of injected conversion command

This bit is set by software to stop and discard an ongoing injected conversion (JADSTP Command).

It is cleared by hardware when the conversion is effectively discarded and the ADC injected sequence and triggers can be re-configured. The ADC is then ready to accept a new start of injected conversions (JADSTART command).

0: No ADC stop injected conversion command ongoing

1: Write 1 to stop injected conversions ongoing. Read 1 means that an ADSTP command is in progress.

Note: The software is allowed to set JADSTP only when JADSTART = 1 and ADDIS = 0 (ADC is enabled and eventually converting an injected conversion and there is no pending request to disable the ADC)

In auto-injection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP)

Bit 4 **ADSTP**: ADC stop of regular conversion command

This bit is set by software to stop and discard an ongoing regular conversion (ADSTP Command).

It is cleared by hardware when the conversion is effectively discarded and the ADC regular sequence and triggers can be re-configured. The ADC is then ready to accept a new start of regular conversions (ADSTART command).

0: No ADC stop regular conversion command ongoing

1: Write 1 to stop regular conversions ongoing. Read 1 means that an ADSTP command is in progress.

Note: The software is allowed to set ADSTP only when ADSTART = 1 and ADDIS = 0 (ADC is enabled and eventually converting a regular conversion and there is no pending request to disable the ADC).

In auto-injection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP).

Bit 3 **JADSTART**: ADC start of injected conversion

This bit is set by software to start ADC conversion of injected channels. Depending on the configuration bits JEXTEN, a conversion immediately starts (software trigger configuration) or once an injected hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:

– in single conversion mode when software trigger is selected (JEXTSEL = 0x0): at the assertion of the End of Injected Conversion Sequence (JEOS) flag.

– in all cases: after the execution of the JADSTP command, at the same time that JADSTP is cleared by hardware.

0: No ADC injected conversion is ongoing.

1: Write 1 to start injected conversions. Read 1 means that the ADC is operating and eventually converting an injected channel.

Note: The software is allowed to set JADSTART only when ADEN = 1 and ADDIS = 0 (ADC is enabled and there is no pending request to disable the ADC).

In auto-injection mode (JAUTO = 1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared)

Bit 2 **ADSTART**: ADC start of regular conversion

This bit is set by software to start ADC conversion of regular channels. Depending on the configuration bits EXTEN, a conversion immediately starts (software trigger configuration) or once a regular hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:

– in single conversion mode when software trigger is selected (EXTSEL = 0x0): at the assertion of the End of Regular Conversion Sequence (EOS) flag.

– in all cases: after the execution of the ADSTP command, at the same time that ADSTP is cleared by hardware.

0: No ADC regular conversion is ongoing.

1: Write 1 to start regular conversions. Read 1 means that the ADC is operating and eventually converting a regular channel.

Note: The software is allowed to set ADSTART only when ADEN = 1 and ADDIS = 0 (ADC is enabled and there is no pending request to disable the ADC)

In auto-injection mode (JAUTO = 1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared)

Bit 1 **ADDIS**: ADC disable command

This bit is set by software to disable the ADC (ADDIS command) and put it into power-down state (OFF state).

It is cleared by hardware once the ADC is effectively disabled (ADEN is also cleared by hardware at this time).

0: no ADDIS command ongoing

1: Write 1 to disable the ADC. Read 1 means that an ADDIS command is in progress.

Note: The software is allowed to set ADDIS only when ADEN = 1 and both ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing)

Bit 0 **ADEN**: ADC enable control

This bit is set by software to enable the ADC. The ADC is effectively ready to operate once the flag ADRDY has been set.

It is cleared by hardware when the ADC is disabled, after the execution of the ADDIS command.

0: ADC is disabled (OFF state)

1: Write 1 to enable the ADC.

Note: The software is allowed to set ADEN only when all bits of ADC_CR registers are 0 (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0) except for bit ADVREGEN which must be 1 (and the software must have wait for the startup time of the voltage regulator)

26.6.4 ADC configuration register (ADC_CFGR)

Address offset: 0x0C

Reset value: 0x8000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
JQDIS	AWD1CH[4:0]					JAUTO	JAWD1EN	AWD1EN	AWD1SGL	JQM	JDISCEN	DISCNUM[2:0]			DISCEN
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw

Bit 31 **JQDIS**: Injected queue disable

This bit is set and cleared by software to disable the injected queue mechanism:

0: Injected queue enabled

1: Injected queue disabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no regular nor injected conversion is ongoing).

A set or reset of JQDIS bit causes the injected queue to be flushed and the JSQR register is cleared.

Bits 30:26 **AWD1CH[4:0]**: Analog watchdog 1 channel selection

These bits are set and cleared by software. They select the input channel to be guarded by the analog watchdog.

00000: ADC analog input channel 0 monitored by AWD1 (available on ADC1 only)

00001: ADC analog input channel 1 monitored by AWD1

.....

10011: ADC analog input channel 19 monitored by AWD1

others: reserved, must not be used

Note: Some channels are not connected physically. Keep the corresponding AWD1CH[4:0] setting to the reset value.

The channel selected by AWD1CH must be also selected into the SQRi or JSQRi registers.

The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 25 **JAUTO:** Automatic injected group conversion

This bit is set and cleared by software to enable/disable automatic injected group conversion after regular group conversion.

0: Automatic injected group conversion disabled

1: Automatic injected group conversion enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no regular nor injected conversion is ongoing).

When dual mode is enabled (DUAL bits in ADC_CCR register are not equal to zero), the bit JAUTO of the slave ADC is no more writable and its content is equal to the bit JAUTO of the master ADC.

Bit 24 **JAWD1EN**: Analog watchdog 1 enable on injected channels

This bit is set and cleared by software

0: Analog watchdog 1 disabled on injected channels

1: Analog watchdog 1 enabled on injected channels

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 23 **AWD1EN**: Analog watchdog 1 enable on regular channels

This bit is set and cleared by software

0: Analog watchdog 1 disabled on regular channels

1: Analog watchdog 1 enabled on regular channels

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 22 **AWD1SGL**: Enable the watchdog 1 on a single channel or on all channels

This bit is set and cleared by software to enable the analog watchdog on the channel identified by the AWD1CH[4:0] bits or on all the channels

0: Analog watchdog 1 enabled on all channels

1: Analog watchdog 1 enabled on a single channel

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 21 **JQM**: JSQR queue mode

This bit is set and cleared by software.

It defines how an empty Queue is managed.

0: JSQR mode 0: The Queue is never empty and maintains the last written configuration into JSQR.

1: JSQR mode 1: The Queue can be empty and when this occurs, the software and hardware triggers of the injected sequence are both internally disabled just after the completion of the last valid injected sequence.

Refer to *Section 26.4.21: Queue of context for injected conversions* for more information.

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

When dual mode is enabled (DUAL bits in ADC_CCR register are not equal to zero), the bit JQM of the slave ADC is no more writable and its content is equal to the bit JQM of the master ADC.

Bit 20 **JDISCEN:** Discontinuous mode on injected channels

This bit is set and cleared by software to enable/disable discontinuous mode on the injected channels of a group.

0: Discontinuous mode on injected channels disabled

1: Discontinuous mode on injected channels enabled

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

When dual mode is enabled (bits DUAL of ADC_CCR register are not equal to zero), the bit JDISCEN of the slave ADC is no more writable and its content is equal to the bit JDISCEN of the master ADC.

Bits 19:17 **DISCNUM[2:0]:** Discontinuous mode channel count

These bits are written by software to define the number of regular channels to be converted in discontinuous mode, after receiving an external trigger.

000: 1 channel
001: 2 channels
...
111: 8 channels

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

When dual mode is enabled (DUAL bits in ADC_CCR register are not equal to zero), the bits DISCNUM[2:0] of the slave ADC are no more writable and their content is equal to the bits DISCNUM[2:0] of the master ADC.

Bit 16 **DISCEN**: Discontinuous mode for regular channels

This bit is set and cleared by software to enable/disable discontinuous mode for regular channels.

0: Discontinuous mode for regular channels disabled
1: Discontinuous mode for regular channels enabled

Note: It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN = 1 and CONT = 1.

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

When dual mode is enabled (DUAL bits in ADC_CCR register are not equal to zero), the bit DISCEN of the slave ADC is no more writable and its content is equal to the bit DISCEN of the master ADC.

Bit 15 **ALIGN**: Data alignment

This bit is set and cleared by software to select right or left alignment. Refer to *Section : Data register, data alignment and offset (ADC_DR, OFFSET, OFFSET_CH, ALIGN)*.

0: Right alignment
1: Left alignment

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 14 **AUTDLY**: Delayed conversion mode

This bit is set and cleared by software to enable/disable the Auto Delayed Conversion mode.

0: Auto-delayed conversion mode off
1: Auto-delayed conversion mode on

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

When dual mode is enabled (DUAL bits in ADC_CCR register are not equal to zero), the bit AUTDLY of the slave ADC is no more writable and its content is equal to the bit AUTDLY of the master ADC.

Bit 13 **CONT**: Single / continuous conversion mode for regular conversions

This bit is set and cleared by software. If it is set, regular conversion takes place continuously until it is cleared.

0: Single conversion mode

1: Continuous conversion mode

Note: It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN = 1 and CONT = 1.

The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

When dual mode is enabled (DUAL bits in ADC_CCR register are not equal to zero), the bit CONT of the slave ADC is no more writable and its content is equal to the bit CONT of the master ADC.

Bit 12 **OVRMOD**: Overrun mode

This bit is set and cleared by software and configure the way data overrun is managed.

0: ADC_DR register is preserved with the old data when an overrun is detected.

1: ADC_DR register is overwritten with the last conversion result when an overrun is detected.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 11:10 **EXTEN[1:0]**: External trigger enable and polarity selection for regular channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of a regular group.

00: Hardware trigger detection disabled (conversions can be launched by software)

01: Hardware trigger detection on the rising edge

10: Hardware trigger detection on the falling edge

11: Hardware trigger detection on both the rising and falling edges

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 9:5 **EXTSEL[4:0]**: External trigger selection for regular group

These bits select the external event used to trigger the start of conversion of a regular group:

00000: adc_ext_trg0

00001: adc_ext_trg1

00010: adc_ext_trg2

00011: adc_ext_trg3

00100: adc_ext_trg4

00101: adc_ext_trg5

00110: adc_ext_trg6

00111: adc_ext_trg7

...

11111: adc_ext_trg31

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 4:3 **RES[1:0]**: Data resolution

These bits are written by software to select the resolution of the conversion.

00: 12-bit

01: 10-bit

10: 8-bit

11: 6-bit

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 2 Reserved, must be kept at reset value.

Bit 1 **DMACFG**: Direct memory access configuration

This bit is set and cleared by software to select between two DMA modes of operation and is effective only when DMAEN = 1.

0: DMA One Shot mode selected

1: DMA Circular mode selected

For more details, refer to *Section : Managing conversions using the DMA*

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

In dual-ADC modes, this bit is not relevant and replaced by control bit DMACFG of the ADC_CCR register.

Bit 0 **DMAEN**: Direct memory access enable

This bit is set and cleared by software to enable the generation of DMA requests. This allows to use the DMA to manage automatically the converted data. For more details, refer to *Section : Managing conversions using the DMA*.

0: DMA disabled

1: DMA enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

In dual-ADC modes, this bit is not relevant and replaced by control bits MDMA[1:0] of the ADC_CCR register.

26.6.5 ADC configuration register 2 (ADC_CFGR2)

Address offset: 0x10

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	SMPTRIG	BULB	SWTRIG	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
				rw	rw	rw

Res.	Res.	Res.	Res.	Res.	ROVSM	TROVS	OVSS[3:0]				OVSR[2:0]			JOVSE	ROVSE
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **SMPTRIG**: Sampling time control trigger mode

This bit is set and cleared by software to enable the sampling time control trigger mode.

0: Sampling time control trigger mode disabled

1: Sampling time control trigger mode enabled

The sampling time starts on the trigger rising edge, and the conversion on the trigger falling edge.

EXTEN bit should be set to 01. BULB bit must not be set when the SMPTRIG bit is set.

When EXTEN bit is set to 00, set SWTRIG to start the sampling and clear SWTRIG bit to start the conversion.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bit 26 **BULB**: Bulb sampling mode

This bit is set and cleared by software to enable the bulb sampling mode.

0: Bulb sampling mode disabled

1: Bulb sampling mode enabled. The sampling period starts just after the previous end of conversion.

SAMPTRIG bit must not be set when the BULB bit is set.

The very first ADC conversion is performed with the sampling time specified in SMPx bits.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bit 25 **SWTRIG**: Software trigger bit for sampling time control trigger mode

This bit is set and cleared by software to enable the bulb sampling mode.

0: Software trigger starts the conversion for sampling time control trigger mode

1: Software trigger starts the sampling for sampling time control trigger mode

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bits 24:17 Reserved, must be kept at reset value.

Bits 16:11 Reserved, must be kept at reset value.

Bit 10 **ROVSM**: Regular oversampling mode

This bit is set and cleared by software to select the regular oversampling mode.

0: Continued mode: When injected conversions are triggered, the oversampling is temporary stopped and continued after the injection sequence (oversampling buffer is maintained during injected sequence)

1: Resumed mode: When injected conversions are triggered, the current oversampling is aborted and resumed from start after the injection sequence (oversampling buffer is zeroed by injected sequence start)

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bit 9 **TROVS**: Triggered Regular oversampling

This bit is set and cleared by software to enable triggered oversampling

0: All oversampled conversions for a channel are done consecutively following a trigger

1: Each oversampled conversion for a channel needs a new trigger

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bits 8:5 **OVSS[3:0]**: Oversampling shift

This bitfield is set and cleared by software to define the right shifting applied to the raw oversampling result.

0000: No shift
0001: Shift 1-bit
0010: Shift 2-bits
0011: Shift 3-bits
0100: Shift 4-bits
0101: Shift 5-bits
0110: Shift 6-bits
0111: Shift 7-bits
1000: Shift 8-bits
Other codes reserved

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bits 4:2 **OVSR[2:0]**: Oversampling ratio

This bitfield is set and cleared by software to define the oversampling ratio.

000: 2x
001: 4x
010: 8x
011: 16x
100: 32x
101: 64x
110: 128x
111: 256x

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bit 1 **JOVSE**: Injected oversampling Enable

This bit is set and cleared by software to enable injected oversampling.

0: Injected oversampling disabled
1: Injected oversampling enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing)

Bit 0 **ROVSE**: Regular oversampling Enable

This bit is set and cleared by software to enable regular oversampling.

0: Regular oversampling disabled
1: Regular oversampling enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing)

26.6.6 ADC sample time register 1 (ADC_SMPR1)

Address offset: 0x14

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SMPPLUS	Res.	SMP9[2:0]			SMP8[2:0]			SMP7[2:0]			SMP6[2:0]			SMP5[2:1]	
rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SMP5[0]	SMP4[2:0]			SMP3[2:0]			SMP2[2:0]			SMP1[2:0]			SMP0[2:0]		
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **SMPPLUS:** Addition of one clock cycle to the sampling time.

1: 2.5 ADC clock cycle sampling time becomes 3.5 ADC clock cycles for the ADC_SMPR1 and ADC_SMPR2 registers.

0: The sampling time remains set to 2.5 ADC clock cycles remains

To make sure no conversion is ongoing, the software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0.

Bit 30 Reserved, must be kept at reset value.

Bits 29:0 **SMPx[2:0]:** Channel x sampling time selection (x = 9 to 0)

These bits are written by software to select the sampling time individually for each channel. During sample cycles, the channel selection bits must remain unchanged.

000: 2.5 ADC clock cycles

001: 6.5 ADC clock cycles

010: 12.5 ADC clock cycles

011: 24.5 ADC clock cycles

100: 47.5 ADC clock cycles

101: 92.5 ADC clock cycles

110: 247.5 ADC clock cycles

111: 640.5 ADC clock cycles

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Some channels are not connected physically. Keep the corresponding SMPx[2:0] setting to the reset value.

26.6.7 ADC sample time register 2 (ADC_SMPR2)

Address offset: 0x18

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:0 **SMPx[2:0]:** Channel x sampling time selection (x = 19 to 10)

These bits are written by software to select the sampling time individually for each channel. During sampling cycles, the channel selection bits must remain unchanged.

000: 2.5 ADC clock cycles
001: 6.5 ADC clock cycles
010: 12.5 ADC clock cycles
011: 24.5 ADC clock cycles
100: 47.5 ADC clock cycles
101: 92.5 ADC clock cycles
110: 247.5 ADC clock cycles
111: 640.5 ADC clock cycles

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Some channels are not connected physically. Keep the corresponding SMPx[2:0] setting to the reset value.

26.6.8 ADC watchdog threshold register 1 (ADC_TR1)

Address offset: 0x20

Reset value: 0x0FFF 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	HT1[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Res.	AWDFILT[2:0]			LT1[11:0]											
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **HT1[11:0]**: Analog watchdog 1 higher threshold

These bits are written by software to define the higher threshold for the analog watchdog 1.

Refer to *Section 26.4.28: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)*

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **AWDFILT[2:0]**: Analog watchdog filtering parameter

This bit is set and cleared by software.

000: No filtering

001: two consecutive detection generates an AWDx flag or an interrupt

...

111: Eight consecutive detection generates an AWDx flag or an interrupt

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bits 11:0 **LT1[11:0]**: Analog watchdog 1 lower threshold

These bits are written by software to define the lower threshold for the analog watchdog 1.

Refer to *Section 26.4.28: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)*

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

26.6.9 ADC watchdog threshold register 2 (ADC_TR2)

Address offset: 0x24

Reset value: 0x00FF 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LT2[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **HT2[7:0]**: Analog watchdog 2 higher threshold

These bits are written by software to define the higher threshold for the analog watchdog 2.

Refer to *Section 26.4.28: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)*

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **LT2[7:0]**: Analog watchdog 2 lower threshold

These bits are written by software to define the lower threshold for the analog watchdog 2.

Refer to *Section 26.4.28: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)*

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

26.6.10 ADC watchdog threshold register 3 (ADC_TR3)

Address offset: 0x28

Reset value: 0x00FF 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HT3[7:0]

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LT3[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **HT3[7:0]**: Analog watchdog 3 higher threshold

These bits are written by software to define the higher threshold for the analog watchdog 3.

Refer to *Section 26.4.28: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)*

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **LT3[7:0]**: Analog watchdog 3 lower threshold

These bits are written by software to define the lower threshold for the analog watchdog 3.

This watchdog compares the 8-bit of LT3 with the 8 MSB of the converted data.

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

26.6.11 ADC regular sequence register 1 (ADC_SQR1)

Address offset: 0x30

Reset value: 0x0000 0000

rw	rw	rw	rw		rw	rw	rw	rw	rw			rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ4[4:0]:** 4th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 4th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ3[4:0]:** 3rd conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 3rd in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ2[4:0]:** 2nd conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 2nd in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ1[4:0]:** 1st conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 1st in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 5:4 Reserved, must be kept at reset value.

Bits 3:0 **L[3:0]:** Regular channel sequence length

These bits are written by software to define the total number of conversions in the regular channel conversion sequence.

0000: 1 conversion
0001: 2 conversions
...
1111: 16 conversions

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

26.6.12 ADC regular sequence register 2 (ADC_SQR2)

Address offset: 0x34

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	SQ9[4:0]					Res.	SQ8[4:0]					Res.	SQ7[4]
			rw	rw	rw	rw	rw		rw	rw	rw	rw	rw		rw

SQ7[3:0]				Res.	SQ6[4:0]					Res.	SQ5[4:0]				
rw	rw	rw	rw		rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ9[4:0]:** 9th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 9th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ8[4:0]:** 8th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 8th in the regular conversion sequence

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ7[4:0]:** 7th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 7th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ6[4:0]:** 6th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 6th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ5[4:0]:** 5th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 5th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

26.6.13 ADC regular sequence register 3 (ADC_SQR3)

Address offset: 0x38

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	SQ14[4:0]					Res.	SQ13[4:0]					Res.	SQ12[4]

SQ12[3:0]				Res.	SQ11[4:0]					Res.	SQ10[4:0]				
rw	rw	rw	rw		rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ14[4:0]:** 14th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 14th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ13[4:0]:** 13th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 13th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ12[4:0]:** 12th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 12th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ11[4:0]:** 11th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 11th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ10[4:0]:** 10th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 10th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

26.6.14 ADC regular sequence register 4 (ADC_SQR4)

Address offset: 0x3C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	SQ16[4:0]					Res.	SQ15[4:0]				
					rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:6 **SQ16[4:0]:** 16th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 16th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ15[4:0]:** 15th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 15th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

26.6.15 ADC regular data register (ADC_DR)

Address offset: 0x40

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RDATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **RDATA[15:0]**: Regular data converted

These bits are read-only. They contain the conversion result from the last converted regular channel. The data are left- or right-aligned as described in *Section 26.4.26: Data management*.

26.6.16 ADC injected sequence register (ADC_JSQR)

Address offset: 0x4C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
JSQ4[4:0]					Res.	JSQ3[4:0]					Res.	JSQ2[4:1]			
rw	rw	rw	rw	rw		rw	rw	rw	rw	rw		rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
JSQ2[0]	Res.	JSQ1[4:0]					JEXTEN[1:0]		JEXTSEL[4:0]					JL[1:0]	
rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:27 **JSQ4[4:0]:** 4th conversion in the injected sequence

These bits are written by software with the channel number (0 to 19) assigned as the 4th in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 26 Reserved, must be kept at reset value.

Bits 25:21 **JSQ3[4:0]:** 3rd conversion in the injected sequence

These bits are written by software with the channel number (0 to 19) assigned as the 3rd in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 20 Reserved, must be kept at reset value.

Bits 19:15 **JSQ2[4:0]:** 2nd conversion in the injected sequence

These bits are written by software with the channel number (0 to 19) assigned as the 2nd in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 14 Reserved, must be kept at reset value.

Bits 13:9 **JSQ1[4:0]:** 1st conversion in the injected sequence

These bits are written by software with the channel number (0 to 19) assigned as the 1st in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bits 8:7 **JEXTEN[1:0]**: External trigger enable and polarity selection for injected channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of an injected group.

00: If JQDIS = 0 (queue enabled), hardware and software trigger detection disabled. Otherwise, the queue is disabled as well as hardware trigger detection (conversions can be launched by software)

01: Hardware trigger detection on the rising edge

10: Hardware trigger detection on the falling edge

11: Hardware trigger detection on both the rising and falling edges

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

If JQM = 1 and if the Queue of Context becomes empty, the software and hardware triggers of the injected sequence are both internally disabled (refer to Section 26.4.21: Queue of context for injected conversions)

Bits 6:2 **JEXTSEL[4:0]**: External Trigger Selection for injected group

These bits select the external event used to trigger the start of conversion of an injected group:

00000: adc_jext_trg0

00001: adc_jext_trg1

00010: adc_jext_trg2

00011: adc_jext_trg3

00100: adc_jext_trg4

00101: adc_jext_trg5

00110: adc_jext_trg6

00111: adc_jext_trg7

...

11111: adc_jext_trg31

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bits 1:0 **JL[1:0]:** Injected channel sequence length

These bits are written by software to define the total number of conversions in the injected channel conversion sequence.

00: 1 conversion

01: 2 conversions

10: 3 conversions

11: 4 conversions

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

26.6.17 ADC offset y register (ADC_OFRy)

Address offset: 0x60 + 0x04 * (y -1), (y = 1 to 4)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OFFSET_EN	OFFSET_CH[4:0]					SATEN	OFFSETPOS	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw								
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	OFFSET[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **OFFSET_EN:** Offset y enable

This bit is written by software to enable or disable the offset programmed into bits OFFSET[11:0].

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 30:26 **OFFSET_CH[4:0]:** Channel selection for the data offset y

These bits are written by software to define the channel to which the offset programmed into bits OFFSET[11:0] applies.

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Some channels are not connected physically and must not be selected for the data offset y.

If OFFSET_EN is set, it is not allowed to select the same channel for different ADC_OFRy registers.

Bit 25 **SATEN**: Saturation enable

This bit is set and cleared by software to enable the saturation at 0x000 and 0xFFF for the offset function.

0: No saturation control, offset result can be signed

1: Saturation enabled, offset result unsigned and saturated at 0x000 and 0xFFF

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 24 **OFFSETPOS**: Positive offset

This bit is set and cleared by software to enable the positive offset.

0: Negative offset

1: Positive offset

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 23:12 Reserved, must be kept at reset value.

Bits 11:0 **OFFSET[11:0]:** Data offset y for the channel programmed into bits OFFSET_CH[4:0]

These bits are written by software to define the offset to be subtracted from the raw converted data when converting a channel (can be regular or injected). The channel to which applies the data offset must be programmed in the bits OFFSET_CH[4:0]. The conversion result can be read from in the ADC_DR (regular conversion) or from in the ADC_JDRyi registers (injected conversion).

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

If several offset (OFFSET) point to the same channel, only the offset with the lowest x value is considered for the subtraction.
Ex: if OFFSET1_CH[4:0] = 4 and OFFSET2_CH[4:0] = 4, this is OFFSET1[11:0] which is subtracted when converting channel 4.

26.6.18 ADC injected channel y data register (ADC_JDRy)

Address offset: 0x80 + 0x04 * (y - 1), (y = 1 to 4)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

JDATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **JDATA[15:0]:** Injected data

These bits are read-only. They contain the conversion result from injected channel y. The data are left -or right-aligned as described in *Section 26.4.26: Data management*.

26.6.19 ADC analog watchdog 2 configuration register (ADC_AWD2CR)

Address offset: 0xA0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

AWD2CH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **AWD2CH[19:0]**: Analog watchdog 2 channel selection

These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 2.

AWD2CH[i] = 0: ADC analog input channel i is not monitored by AWD2

AWD2CH[i] = 1: ADC analog input channel i is monitored by AWD2

When AWD2CH[19:0] = 000..0, the analog Watchdog 2 is disabled

Note: The channels selected by AWD2CH must be also selected into the SQRi or JSQRi registers.

The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Some channels are not connected physically and must not be selected for the analog watchdog.

26.6.20 ADC analog watchdog 3 configuration register (ADC_AWD3CR)

Address offset: 0xA4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	AWD3CH[19:16]			
												rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
AWD3CH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **AWD3CH[19:0]**: Analog watchdog 3 channel selection

These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 3.

AWD3CH[i] = 0: ADC analog input channel i is not monitored by AWD3

AWD3CH[i] = 1: ADC analog input channel i is monitored by AWD3

When AWD3CH[19:0] = 000..0, the analog Watchdog 3 is disabled

Note: The channels selected by AWD3CH must be also selected into the SQRi or JSQRi registers.

The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Some channels are not connected physically and must not be selected for the analog watchdog.

26.6.21 ADC Differential mode selection register (ADC_DIFSEL)

Address offset: 0xB0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DIFSEL[19:16]			
												rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DIFSEL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	r

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **DIFSEL[19:0]:** Differential mode for channels 19 to 0.

These bits are set and cleared by software. They allow to select if a channel is configured as single-ended or Differential mode.

DIFSEL[i] = 0: ADC analog input channel is configured in single-ended mode

DIFSEL[i] = 1: ADC analog input channel i is configured in Differential mode

Note: The DIFSEL bits corresponding to channels that are either connected to a single-ended I/O port or to an internal channel must be kept their reset value (single-ended input mode).

The software is allowed to write these bits only when the ADC is disabled (ADCAL = 0, JADSTART = 0, JADSTP = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

26.6.22 ADC calibration factors (ADC_CALFACT)

Address offset: 0xB4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CALFACT_D[6:0]						
									rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CALFACT_S[6:0]						
									rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:16 **CALFACT_D[6:0]**: Calibration Factors in differential mode

These bits are written by hardware or by software.

Once a differential inputs calibration is complete, they are updated by hardware with the calibration factors.

Software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored into the analog ADC, it is then applied once a new differential calibration is launched.

Note: The software is allowed to write these bits only when ADEN = 1, ADSTART = 0 and JADSTART = 0 (ADC is enabled and no calibration is ongoing and no conversion is ongoing).

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:0 **CALFACT_S[6:0]**: Calibration Factors In single-ended mode

These bits are written by hardware or by software.

Once a single-ended inputs calibration is complete, they are updated by hardware with the calibration factors.

Software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored into the analog ADC, it is then applied once a new single-ended calibration is launched.

Note: The software is allowed to write these bits only when ADEN = 1, ADSTART = 0 and JADSTART = 0 (ADC is enabled and no calibration is ongoing and no conversion is ongoing).

26.6.23 ADC option register (ADC_OR)

Address offset: 0xC8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OP0
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **OP0**: Option bit 0
For ADC1:
0: INP0/INN1 GPIO switch control disabled
1: INP0/INN1 GPIO switch control enabled
Note: This option bit must be set to 1 when ADCx_INP0 or ADCx_INN1 channel is selected.
For ADC2:
0: V_{DDCORE} channel disabled
1: V_{DDCORE} channel enabled

Note: ADC_OR register might be reserved on some ADC instances. Refer to Section 26.3: ADC implementation.

26.7 ADC common registers

These registers define the control and status registers common to master and slave ADCs:

26.7.1 ADC common status register (ADC_CSR)

Address offset: 0x300

Reset value: 0x0000 0000

This register provides an image of the status bits of the different ADC. Nevertheless it is read-only and does not allow to clear the different status bits. Instead each status bit must be cleared by writing 0 to it in the corresponding ADC_ISR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

					r	r	r	r	r	r	r	r	r	r	r

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **JQOVF_SLV:** Injected Context Queue Overflow flag of the slave ADC
This bit is a copy of the JQOVF bit in the corresponding ADC_ISR register.

Bit 25 **AWD3_SLV:** Analog watchdog 3 flag of the slave ADC
This bit is a copy of the AWD3 bit in the corresponding ADC_ISR register.

Bit 24 **AWD2_SLV:** Analog watchdog 2 flag of the slave ADC
This bit is a copy of the AWD2 bit in the corresponding ADC_ISR register.

Bit 23 **AWD1_SLV:** Analog watchdog 1 flag of the slave ADC
This bit is a copy of the AWD1 bit in the corresponding ADC_ISR register.

Bit 22 **JEOS_SLV:** End of injected sequence flag of the slave ADC
This bit is a copy of the JEOS bit in the corresponding ADC_ISR register.

Bit 21 **JEOC_SLV:** End of injected conversion flag of the slave ADC
This bit is a copy of the JEOC bit in the corresponding ADC_ISR register.

Bit 20 **OVR_SLV:** Overrun flag of the slave ADC
This bit is a copy of the OVR bit in the corresponding ADC_ISR register.

Bit 19 **EOS_SLV:** End of regular sequence flag of the slave ADC. This bit is a copy of the EOS bit in the corresponding ADC_ISR register.

Bit 18 **EOC_SLV:** End of regular conversion of the slave ADC
This bit is a copy of the EOC bit in the corresponding ADC_ISR register.

Bit 17 **EOSMP_SLV:** End of Sampling phase flag of the slave ADC
This bit is a copy of the EOSMP2 bit in the corresponding ADC_ISR register.

Bit 16 **ADRDY_SLV:** Slave ADC ready
This bit is a copy of the ADRDY bit in the corresponding ADC_ISR register.

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **JQOVF_MST:** Injected Context Queue Overflow flag of the master ADC
This bit is a copy of the JQOVF bit in the corresponding ADC_ISR register.

Bit 9 **AWD3_MST:** Analog watchdog 3 flag of the master ADC
This bit is a copy of the AWD3 bit in the corresponding ADC_ISR register.

Bit 8 **AWD2_MST:** Analog watchdog 2 flag of the master ADC
This bit is a copy of the AWD2 bit in the corresponding ADC_ISR register.

Bit 7 **AWD1_MST:** Analog watchdog 1 flag of the master ADC
This bit is a copy of the AWD1 bit in the corresponding ADC_ISR register.

Bit 6 **JEOS_MST:** End of injected sequence flag of the master ADC
This bit is a copy of the JEOS bit in the corresponding ADC_ISR register.

Bit 5 **JEOC_MST:** End of injected conversion flag of the master ADC
This bit is a copy of the JEOC bit in the corresponding ADC_ISR register.

Bit 4 **OVR_MST:** Overrun flag of the master ADC
This bit is a copy of the OVR bit in the corresponding ADC_ISR register.

Bit 3 **EOS_MST:** End of regular sequence flag of the master ADC
This bit is a copy of the EOS bit in the corresponding ADC_ISR register.

Bit 2 **EOC_MST:** End of regular conversion of the master ADC
This bit is a copy of the EOC bit in the corresponding ADC_ISR register.

Bit 1 **EOSMP_MST:** End of Sampling phase flag of the master ADC
This bit is a copy of the EOSMP bit in the corresponding ADC_ISR register.

Bit 0 **ADRDY_MST:** Master ADC ready
This bit is a copy of the ADRDY bit in the corresponding ADC_ISR register.

26.7.2 ADC common control register (ADC_CCR)

Address offset: 0x308

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	VBATEN	TSEN	VREFEN	PRESC[3:0]				CKMODE[1:0]	
							rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MDMA[1:0]		DMACFG	Res.	DELAY[3:0]				Res.	Res.	Res.	DUAL[4:0]				
rw	rw	rw		rw	rw	rw	rw				rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **VBATEN**: VBAT enable

This bit is set and cleared by software to control.

0: V_{BAT} channel disabled

1: V_{BAT} channel enabled

Bit 23 **TSEN**: V_{SENSE} enable

This bit is set and cleared by software to control V_{SENSE}.

0: Temperature sensor channel disabled

1: Temperature sensor channel enabled

Bit 22 **VREFEN**: V_{REFINT} enable

This bit is set and cleared by software to enable/disable the V_{REFINT} channel.

0: V_{REFINT} channel disabled

1: V_{REFINT} channel enabled

Bits 21:18 **PRESC[3:0]**: ADC prescaler

These bits are set and cleared by software to select the frequency of the clock to the ADC. The clock is common for all the ADCs.

0000: input ADC clock not divided

0001: input ADC clock divided by 2

0010: input ADC clock divided by 4

0011: input ADC clock divided by 6

0100: input ADC clock divided by 8

0101: input ADC clock divided by 10

0110: input ADC clock divided by 12

0111: input ADC clock divided by 16

1000: input ADC clock divided by 32

1001: input ADC clock divided by 64

1010: input ADC clock divided by 128

1011: input ADC clock divided by 256

other: reserved

Note: The software is allowed to write these bits only when the ADC is disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0). The ADC prescaler value is applied only when CKMODE[1:0] = 0b00.

Bits 17:16 **CKMODE[1:0]:** ADC clock mode

These bits are set and cleared by software to define the ADC clock scheme (which is common to both master and slave ADCs):

00: adc_ker_ck (x = 1/2) (Asynchronous clock mode), generated at product level (refer to *Section 6: Reset and clock control (RCC)*)

01: adc_hclk/1 (Synchronous clock mode). This configuration must be enabled only if the AHB clock prescaler is set to 1 (HPRE[3:0] = 0XXX in RCC_CFGR register) and if the system clock has a 50% duty cycle.

10: adc_hclk/2 (Synchronous clock mode)

11: adc_hclk/4 (Synchronous clock mode)

In all synchronous clock modes, there is no jitter in the delay from a timer trigger to the start of a conversion.

Note: The software is allowed to write these bits only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bits 15:14 **MDMA[1:0]:** Direct memory access mode for dual ADC mode

This bitfield is set and cleared by software. Refer to the DMA controller section for more details.

00: MDMA mode disabled

01: Reserved

10: MDMA mode enabled for 12 and 10-bit resolution

11: MDMA mode enabled for 8 and 6-bit resolution

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 13 **DMACFG**: DMA configuration (for dual ADC mode)

This bit is set and cleared by software to select between two DMA modes of operation and is effective only when DMAEN = 1.

0: DMA One Shot mode selected

1: DMA Circular mode selected

For more details, refer to *Section : Managing conversions using the DMA*

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 12 Reserved, must be kept at reset value.

Bits 11:8 **DELAY[3:0]:** Delay between 2 sampling phases

These bits are set and cleared by software. These bits are used in dual interleaved modes. Refer to *Table 253* for the value of ADC resolution versus DELAY bits values.

Note: The software is allowed to write these bits only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DUAL[4:0]:** Dual ADC mode selection

These bits are written by software to select the operating mode. 00000 corresponds to Independent mode. Values 00001 to 01001 correspond to dual mode, master and slave ADCs working together.

00000: Independent mode
00001: Combined regular simultaneous + injected simultaneous mode
00010: Combined regular simultaneous + alternate trigger mode
00011: Combined interleaved mode + injected simultaneous mode
00100: Reserved
00101: Injected simultaneous mode only
00110: Regular simultaneous mode only
00111: Interleaved mode only
01001: Alternate trigger mode only
Others: Reserved, must not be used

Note: The software is allowed to write these bits only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Table 253. DELAY bits versus ADC resolution

DELAY bits	12-bit resolution	10-bit resolution	8-bit resolution	6-bit resolution
0000	1 * $T_{adc\_ker\_ck}$	1 * $T_{adc\_ker\_ck}$	1 * $T_{adc\_ker\_ck}$	1 * $T_{adc\_ker\_ck}$
0001	2 * $T_{adc\_ker\_ck}$	2 * $T_{adc\_ker\_ck}$	2 * $T_{adc\_ker\_ck}$	2 * $T_{adc\_ker\_ck}$

0111	8 * $T_{adc\_ker\_ck}$	8 * $T_{adc\_ker\_ck}$	8 * $T_{adc\_ker\_ck}$	6 * $T_{adc\_ker\_ck}$
1000	9 * $T_{adc\_ker\_ck}$	9 * $T_{adc\_ker\_ck}$	8 * $T_{adc\_ker\_ck}$	6 * $T_{adc\_ker\_ck}$
1001	10 * $T_{adc\_ker\_ck}$	10 * $T_{adc\_ker\_ck}$	8 * $T_{adc\_ker\_ck}$	6 * $T_{adc\_ker\_ck}$
1010	11 * $T_{adc\_ker\_ck}$	10 * $T_{adc\_ker\_ck}$	8 * $T_{adc\_ker\_ck}$	6 * $T_{adc\_ker\_ck}$
1011	12 * $T_{adc\_ker\_ck}$	10 * $T_{adc\_ker\_ck}$	8 * $T_{adc\_ker\_ck}$	6 * $T_{adc\_ker\_ck}$
others	12 * $T_{adc\_ker\_ck}$	10 * $T_{adc\_ker\_ck}$	8 * $T_{adc\_ker\_ck}$	6 * $T_{adc\_ker\_ck}$

26.7.3 ADC common regular data register for dual mode (ADC_CDR)

Address offset: 0x30C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RDATA_SLV[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RDATA_MST[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 **RDATA_SLV[15:0]:** Regular data of the slave ADC

In dual mode, these bits contain the regular data of the slave ADC. Refer to *Section 26.4.30: Dual ADC modes*.

The data alignment is applied as described in *Section : Data register, data alignment and offset (ADC_DR, OFFSET, OFFSET_CH, ALIGN)*)

Bits 15:0 **RDATA_MST[15:0]**: Regular data of the master ADC.

In dual mode, these bits contain the regular data of the master ADC. Refer to *Section 26.4.30: Dual ADC modes*.

The data alignment is applied as described in *Section : Data register, data alignment and offset (ADC_DR, OFFSET, OFFSET_CH, ALIGN)*)

In MDMA = 0b11 mode, bits 15:8 contains SLV_ADC_DR[7:0], bits 7:0 contains MST_ADC_DR[7:0].

26.7.4 ADC hardware configuration register (ADC_HWCFGR0)

Address offset: 0x3F0

Reset value: 0x0000 1212

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

IDLEVALUE[3:0]				OPBITS[3:0]				MULPIPE[3:0]				ADCNUM[3:0]			
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **IDLEVALUE[3:0]**: Idle value for non-selected channels

0000: Dummy channel selection is 0x13

0001: Dummy channel selection is 0x1F

Bits 11:8 **OPBITS[3:0]**: Number of option bits
0000: No option register implemented
0001: 1 option bit implemented in the ADC option register (ADC_OR) at address offset 0xC8

Bits 7:4 **MULPIPE[3:0]**: Number of pipeline stages
0001: One-stage pipeline

Bits 3:0 **ADCNUM[3:0]**: Number of ADCs implemented
0001: One ADC instance implemented
0010: Two ADC instances implemented
0011: Three ADCs instances implemented

26.7.5 ADC version register (ADC_VERR)

Address offset: 0x3F4

Reset value: 0x0000 0012

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MAJREV[3:0]				MINREV[3:0]			
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **MAJREV[3:0]**: Major revision
These bits returns the ADC IP major revision
0001: Major revision = 1.X

Bits 3:0 **MINREV[3:0]**: Minor revision
These bits returns the ADC IP minor revision
0001: Minor revision = X.1
0002: Minor revision = X.2
0003: Minor revision = X.3

26.7.6 ADC identification register (ADC_IPDR)

Address offset: 0x3F8

Reset value: 0x0011 0006

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ID[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ID[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **ID[31:0]**: Peripheral identifier
These bits returns the ADC identifier.
ID[31:0] = 0x0011 0006: c7amba_aditf5_90_v1

26.7.7 ADC size identification register (ADC_SIDR)

Address offset: 0x3FC

Reset value: 0xA3C5 DD01

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SID[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SID[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **SID[31:0]**: Size Identification
SID[31:8]: fixed code that characterizes the ADC_SIDR register. This field is always read at 0xA3C5DD.
SID[7:0]: read-only numeric field that returns the address offset (in Kbytes) of the identification registers from the IP base address:
0x01: 1 Kbytes address offset
0x02: 2 Kbytes address offset
0x04: 4 Kbytes address offset
0x08: 8 Kbytes address offset

26.8 ADC register map

The following table summarizes the ADC registers.

Table 254. ADC global register map

Offset	Register
0x000 - 0x0B4	Master ADC1
0x0B8 - 0x0FC	Reserved
0x100 - 0x1B4	Slave ADC2
0x1B8 - 0x2FC	Reserved
0x300 - 0x30C	Master and slave ADCs common registers

Table 255. ADC register map and reset values for each ADC (offset = 0x000 for master ADC, 0x100 for slave ADC)

Refer to *Section 2.3 on page 111* for the register boundary addresses.

27 Digital temperature sensor (DTS)

27.1 Introduction

The device embeds a sensor that converts the temperature into a square wave which frequency is proportional to the temperature. The frequency is measured either with the PCLK or the LSE clock.

27.2 DTS main features

The temperature sensor block main features are the following:

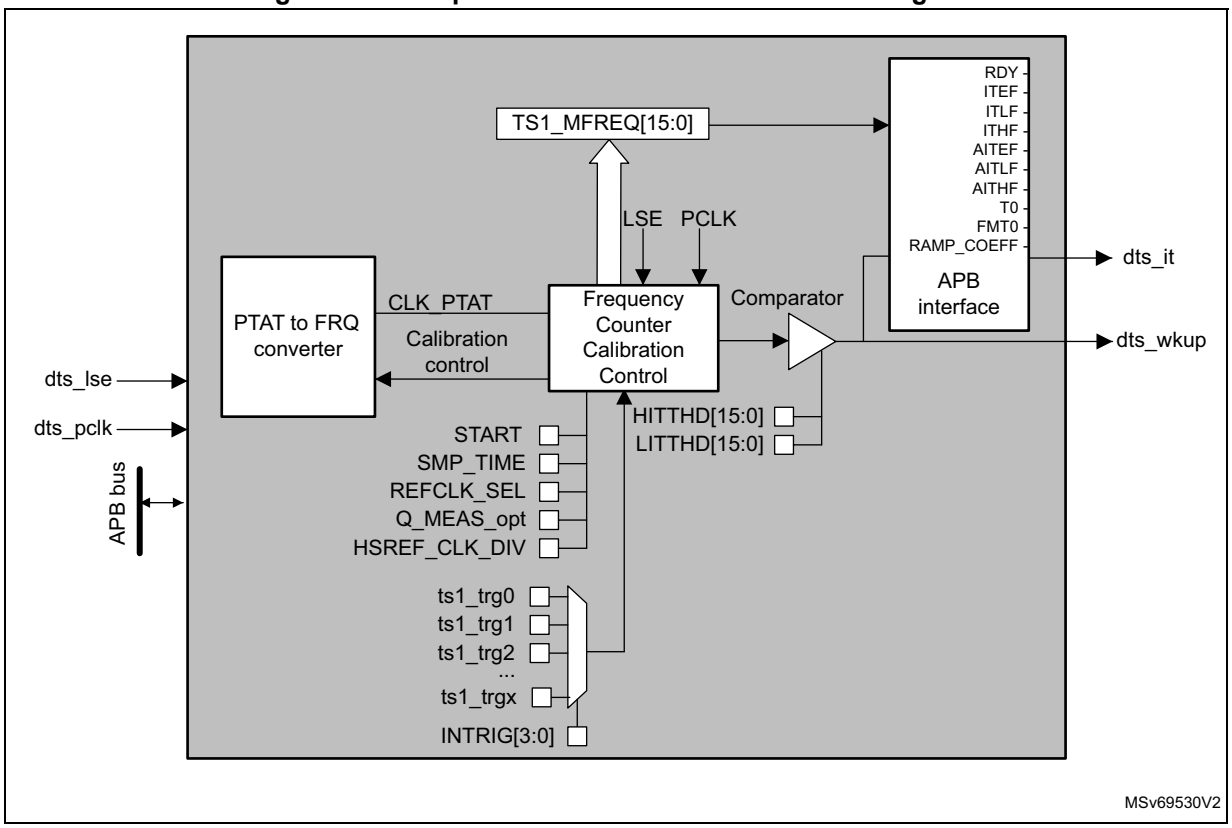
- Start of measurement triggered by software or 4 hardware sources
- Programmable sampling time to increase temperature measurement precision
- Counter synchronized on LSE or PCLK clock
- Temperature watchdog on low and high threshold
- Interrupt generation when the temperature is lower or higher than predefined thresholds and at the end of measurement.
- Asynchronous wakeup signal generation when the temperature is higher/lower than a predefined threshold (LSE mode only)
- Quick measurement using LSE clock

27.3 DTS functional description

27.3.1 DTS block diagram

The temperature sensor block diagram is shown in *Figure 259*.

Figure 259. Temperature sensor functional block diagram



27.3.2 DTS internal signals

Table 257. DTS internal input/output signals

Signal name	Signal type	Description
dts_lse	Digital input	LSE clock
dts_pclk	Digital input	APB clock
dts_it	Digital output	Temperature sensor interrupt
dts_wkup	Digital output	Temperature sensor wakeup

27.3.3 DTS block operation

The analog part of the temperature sensor outputs a frequency that is proportional to the absolute temperature (CLK_PTAT). The frequency measurement is based on the PCLK or the LSE clock.

Before each measurement, the temperature sensor performs a calibration of the frequency generation blocks.

27.3.4 Operating modes

Several operating modes can be selected by setting the REFCLK_SEL bit in *Temperature sensor configuration register 1 (DTS_CFGR1)*:

- PCLK only (REFCLK_SEL = 0)

  The temperature sensor registers can be accessed. The interface can consequently be reconfigured and the measurement sequence is performed using PCLK clock
- PCLK and LSE (REFCLK_SEL = 1)

  The temperature sensor registers can be accessed. The interface can consequently be reconfigured and the measurement sequence is performed using the LSE clock.
- LSE only (REFCLK_SEL = 1) and PCLK OFF

  The registers cannot be accessed. The measurement can be performed using the LSE clock. This mode is used to exit from Sleep mode by using hardware triggers and the asynchronous interrupt line.

27.3.5 Calibration

The temperature sensor must run the calibration prior to any frequency measurement. The calibration is performed automatically when the temperature measurement is triggered except for quick measurement mode (Q_MEAS_OPT set to 1 in DTS_CFGR1).

27.3.6 Prescaler

When a calibration is ongoing, the counter clock must be slower than 1 MHz. This is achieved by the PCLK clock prescaler embedded in the temperature sensor.

During the temperature measurement period, the prescaler is bypassed.

- When PCLK is used as reference clock (REFCLK_SEL set to 0 in DTS_CFGR1), a prescaler is used. Its division ratio must be configured up to 127 (refer to the HSREF_CLK_DIV[6:0] register definition for the divider setting).
- When LSE is used as reference clock (REFCLK_SEL set to 1 in DTS_CFGR1), the timebase is equal to 2 LSE periods. In this case, no prescaler is used.

27.3.7 Temperature measurement principles

The analog part of temperature sensor outputs a signal (CLK_PTAT) which FM(T) frequency is temperature-dependent.

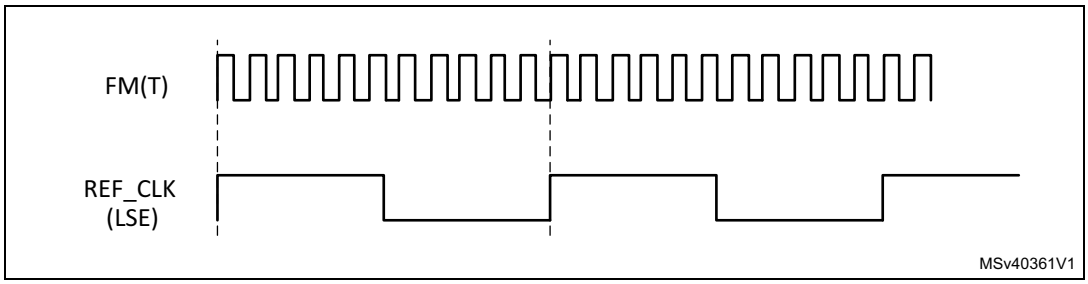
Either PCLK or LSE can be selected as reference clock (REF_CLK) through the REFCLK_SEL bit in DTS_CFGR1.

The counting method depends on the REF_CLK frequency. This is due to the fact that two counters are implemented in the temperature sensor block:

- For low REF_CLK frequencies, a counting of FM(T) cycles is performed during one or several REF_CLK cycles.
- For high REF_CLK frequencies, a counting of REF_CLK cycles is performed during one or several FM(T) cycles.

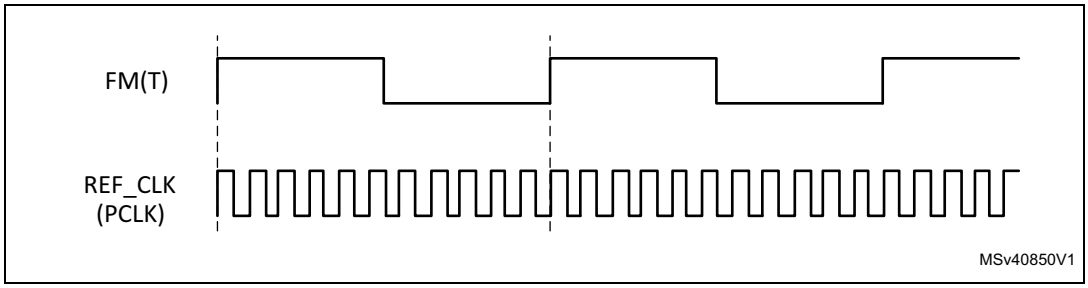
This counter behavior is shown in *Figure 260* and *Figure 261*.

Figure 260. Method for low REF_CLK frequencies



1. To increase the precision, FM(T) measurement can be done on several LSE periods.

Figure 261. Method for high REF_CLK frequencies



1. To increase the precision, PCLK measurement can be done on several FM(T) periods.

The counting result is stored in the DTS_DR register (see *Temperature sensor data register (DTS_DR)*.

Once the FM(T) frequency has been obtained, the corresponding temperature can be calculated by software using the following formula:

- When PCLK is used:

$$T = T_0 + ((F_{PCLK} / TS1\_MFREQ) \times TS1\_SMP\_TIME - 100 \times TS1\_FMT0) / TS1\_RAMP\_COEFF$$

where

T0 (factory calibration temperature) is equal to 30 °C.

TS1_FMT0 is measured and stored in the DTS_T0VALR1 register. It is expressed in hundreds of Hertz.

TS1_RAMP_COEFF is measured during tests in factory and stored in DTS_RAMPVALR register. This value is expressed in Hz/°C.

- When the LSE clock is used

$$T = T_0 + ((F_{LSE} \times TS1\_MFREQ / TS1\_SMP\_TIME) - (100 \times TS1\_FMT0)) / TS1\_RAMP\_COEFF$$

27.3.8 Sampling time

The sampling period can be increased to improve measurement accuracy. This is useful when the reference frequency (REF_CLK) is close to the FM(T) frequency. The default value is one REF_CLK cycle in LSE mode, and one FM(T) cycle in PCLK mode.

The sampling time is configured through TS1_SMP_TIME bits in DTS_CFGR1 register (see *Table 258*).

Table 258. Sampling time configuration

TS1_SMP_TIME[3:0]	LSE or FM(T) clock cycle(s)
0000	1
0001	1
0010	2
0011	3
0100	4
0101	5
0110	6
0111	7
1000	8
1001	9
1010	10
1011	11
1100	12
1101	13
1110	14
1111	15

27.3.9 Quick measurement mode

If a high precision is not required, the calibration step included in each measurement sequence can be skipped by setting Q_MEAS_OPT to 1 in the DTS_CFGR1 register. This method must used only when the LSE clock is selected as reference clock (LSREF_CLK set to 1). This mode can reduce the measurement time.

27.3.10 Trigger input

The temperature measurement can be triggered either by software or by an external event. The trigger source can be selected through TS1_INTRIG[3:0] bits in DTS_CFGR1.

Table 259. Trigger configuration

Name	TS1_INTRIG[3:0]				Comment
N.A	0	0	0	0	No hardware trigger
ts1_trg0	0	0	0	1	lptim1_ch1
ts1_trg1	0	0	1	0	lptim2_ch1
ts1_trg2	0	0	1	1	lptim3_ch1
ts1_trg3	0	1	0	0	exti13
ts1_trg4	0	1	0	1	Reserved
ts1_trg5	0	1	1	0	
ts1_trg6	0	1	1	1	
ts1_trg7	1	0	0	0	
ts1_trg8	1	0	0	1	
ts1_trg9	1	0	1	0	
ts1_trg10	1	0	1	1	
ts1_trg11	1	1	0	0	
ts1_trg12	1	1	0	1	
ts1_trg13	1	1	1	0	
ts1_trg14	1	1	1	1	

Note: Hardware triggers are active only on the rising edge.

The temperature sensor can only capture a hardware trigger rising edge when TS1_RDY bit is set (see Section 27.3.11: On-off control and ready flag, otherwise the trigger is ignored.

If a trigger source changes on-the-fly, the new trigger source signal should be low. If the new source signal is high, the temperature sensor detects a rising edge and start the measurement sequence.

27.3.11 On-off control and ready flag

The DTS block can be enabled by setting TS1_EN bit in DTS_CFGR1 register. The TS1_RDY flag in the *Temperature sensor status register (DTS_SR)* indicate that the DTS block is ready for temperature measurement: when TS1_RDY bit is set to 1, the measurement can be started. Once a measurement has started, TS1_RDY bit is reset. New measurement requests are then ignored. Once the measurement is finished, TS1_RDY bit is set again to indicate the sensor is ready to start a new measurement.

27.3.12 Temperature measurement sequence

Start of measurement can be triggered by software or hardware.

Software trigger

The software trigger is selected when TS1_INTRIG_SEL[3:0] is set to ‘0000’ in DTS_CFGR1.

If TS1_RDY is set to 1, writing TS1_START bit to 1 in DTS_CFGR1 starts the measurement.

If TS1_RDY equals 0, the software trigger does not start until TS1_RDY is set.

If TS1_START bit is kept at 1 once the measurement is finished, then the TS1_RDY flag become 1 and the measurement restarts.

Hardware trigger

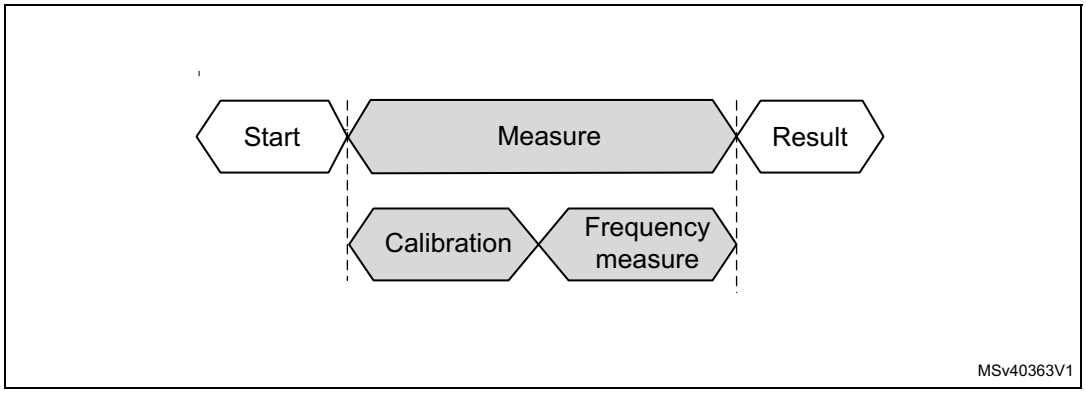
TS1_INTRIG_SEL[3:0] bits allow selecting one hardware trigger out of 4. If TS1_RDY is set to 1, a rising edge on the trigger signal starts the measurement. When TS1_RDY is 0, the rising edge is ignored.

Temperature measurement sequence

One measurement contains two steps: the calibration of the analog blocks and the measurement. The calibration automatically starts when the measurement is triggered (see *Section 27.3.5: Calibration*). The measurement period depends on the following DTS_CFGR1 bits:

- the reference clock selected through REFCLK_SEL bit
- the divider ratio configured by HSREF_CLK_DIV bits
- the sampling time defined by TS1_SMP_TIME bits.

Figure 262. Temperature sensor sequence



27.4 DTS low-power modes

Table 260. Temperature sensor behavior in low-power modes

Mode	Description
Sleep	Only works in LSE mode. DTS interrupt causes the device to exit from Sleep mode.
Stop	Only works in LSE mode. DTS interrupt cause the device to exit from Stop mode.

27.5 DTS interrupts

There are two ways to use the DTS block as an interrupt source.The DTS interrupt line can be connected to the EXTI controller (see *Section 27.5.3: Asynchronous wakeup*) or to the CPU NVIC (see *Section 27.5.2: Synchronous interrupt*).

27.5.1 Temperature window comparator

The DTS_ITR1 register allows defining the high and low threshold that are used for temperature comparison. If the temperature data is equal or higher than TS1_HITTHD, or equal or lower than TS1_LITTHD bit, an interrupt is generated and the corresponding flag, TS1_ ITLF, TS1_ITHF, TS1_AITLF and TS1_AITHF, is set in the DTS_SR register (see *Section 27.6.6*).

27.5.2 Synchronous interrupt

A global interrupt output line is available on the DTS block. The interrupt can be generated at the end of measurement and/or when the measurement result is equal/higher or equal/lower than a predefined threshold (see *Section 27.5.1: Temperature window comparator*).

Three interrupt events can be select via 3 bits in DTS_ITENR register (see *Section 27.6.7*). All combinations of interrupts are allowed.

The TS1_ITEF, TS1_ITLF and TS1_ITHF flags in the DTS_SR register reflect the interrupt event. They can be reset with the correspond bits of the DTS_ICIFR register (see *Section 27.6.8*).

27.5.3 Asynchronous wakeup

The DTS block also provides an asynchronous interrupt line. It is used only when the LSE is selected as reference clock (REFCLK_SEL=1).

This line can generate a signal that wakes up the system from Sleep mode at the end of measurement and/or when the measurement result is equal/higher or equal/lower than a predefined threshold (see *Section 27.5.1: Temperature window comparator*).

Three asynchronous wakeup events can be selected via 3 bits in DTS_ITENR register. All combination of interrupts are allowed.

The TS1_AITEF, TS1_AITLF and TS1_AITHF flags in the DTS_SR register reflect the interrupt status. They can be reset with the correspond bits of the DTS_ICIFR register.

The following table shows the interrupt bits an the their description.

Table 261. Interrupt control bits

Interrupt event	Interrupt flag	Enable control bit	Interrupt clear bit	Exit from Sleep mode	Synchronous/ Asynchronous
At the end of measurement	TS1_ITEF in DTS_SR	TS1_ITEEN in DTS_ITENR	TS1_CITEF in DTS_ICIFR	NO	Synchronous on PCLK
When the measure is equal or exceeds the low threshold	TS1_ITLF in DTS_SR	TS1_ITLEN in DTS_ITENR	TS1_CITLF in DTS_ICIFR	NO	
When the measure is equal or exceeds the high threshold	TS1_ITHF in DTS_SR	TS1_ITHEN in DTS_ITENR	TS1_CITHF in DTS_ICIFR	NO	
At the end of measurement	TS1_AITEF in DTS_SR	TS1_AITEEN in DTS_ITENR	TS1_CAITEF in DTS_ICIFR	YES	Asynchronous
When the measure is equal or exceeds the low threshold	TS1_AITLF in DTS_SR	TS1_AITLEN in DTS_ITENR	TS1_CAITLF in DTS_ICIFR	YES	
When the measure is equal or exceeds the high threshold	TS1_AITHF in DTS_SR	TS1_AITHEN in DTS_ITENR	TS1_CAITHF in DTS_ICIFR	YES	

27.6 DTS registers

The registers of this peripheral can only be accessed by-word (32-bit).

27.6.1 Temperature sensor configuration register 1 (DTS_CFGR1)

DTS_CFGR1 is the configuration register for temperature sensor 1.

Address offset: 0x00

Reset value: 0x0000 0000

				rw	rw	rw	rw				rw				rw

Bit 31 Reserved, must be kept at reset value.

Bits 30:24 **HSREF_CLK_DIV[6:0]**: High speed clock division ratio

These bits are set and cleared by software. They can be used to define the division ratio for the main clock in order to obtain the internal frequency lower than 1 MHz required for the calibration. They are applicable only for calibration when PCLK is selected as reference clock (REFCLK_SEL=0).

0000000: No divider

0000001: No divider

0000010: 1/2 division ratio

...

1111111: 1/127 division ratio

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **Q_MEAS_OPT**: Quick measurement option bit

This bit is set and cleared by software. It is used to increase the measurement speed by suppressing the calibration step. It is effective only when the LSE clock is used as reference clock (REFCLK_SEL=1).

0: Measurement with calibration

1: Measurement without calibration

Bit 20 **REFCLK_SEL**: Reference clock selection bit

This bit is set and cleared by software. It indicates whether the reference clock is the high speed clock (PCLK) or the low speed clock (LSE).

0: High speed reference clock (PCLK)

1: Low speed reference clock (LSE)

Bits 19:16 **TS1_SMP_TIME[3:0]**: Sampling time for temperature sensor 1

These bits allow increasing the sampling time to improve measurement precision.

When the PCLK clock is selected as reference clock (REFCLK_SEL = 0), the measurement is performed at TS1_SMP_TIME period of CLK_PTAT.

When the LSE is selected as reference clock (REFCLK_SEL = 1), the measurement is performed at TS1_SMP_TIME period of LSE.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **TS1_INTRIG_SEL[3:0]**: Input trigger selection bit for temperature sensor 1

These bits are set and cleared by software. They select which input triggers a temperature measurement. Refer to *Section 27.3.10: Trigger input*.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **TS1_START:** Start frequency measurement on temperature sensor 1

This bit is set and cleared by software.

0: No software trigger.

1: Software trigger for a frequency measurement. (only if TS1 is ready).

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **TS1_EN:** Temperature sensor 1 enable bit

This bit is set and cleared by software.

0: Temperature sensor 1 disabled

1: Temperature sensor 1 enabled

Note: Once enabled, the temperature sensor is active after a specific delay time. The TS1_RDY flag is set when the sensor is ready.

27.6.2 Temperature sensor T0 value register 1 (DTS_T0VALR1)

DTS_T0VALR1 contains the value of the factory calibration temperature (T0) for temperature sensor 1. The reset value is factory trimmed.

Address offset: 0x08

Reset value: 0x000X XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TS1_T0[1:0]	
														r	r

TS1_FMT0[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:18 Reserved, must be kept at reset value.

Bits 17:16 **TS1_T0[1:0]**: Engineering value of the T0 temperature for temperature sensor 1.
00: 30 °C
01: 130 °C
Others: Reserved, must not be used.

Bits 15:0 **TS1_FMT0[15:0]**: Engineering value of the frequency measured at T0 for temperature sensor 1
This value is expressed in 0.1 kHz.

27.6.3 Temperature sensor ramp value register (DTS_RAMPVALR)

The DTS_RAMPVALR is the ramp coefficient for the temperature sensor. The reset value is factory trimmed.

Address offset: 0x10

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

TS1_RAMP_COEFF[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **TS1_RAMP_COEFF[15:0]**: Engineering value of the ramp coefficient for the temperature sensor 1.
This value is expressed in Hz/°C.

27.6.4 Temperature sensor interrupt threshold register 1 (DTS_ITR1)

DTS_ITR1 contains the threshold values for sensor 1.

Address offset: 0x14

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

TS1_LITTHD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **TS1_HITTHD[15:0]:** High interrupt threshold for temperature sensor 1
These bits are set and cleared by software. They indicate the highest value than can be reached before raising an interrupt signal.

Bits 15:0 **TS1_LITTHD[15:0]:** Low interrupt threshold for temperature sensor 1
These bits are set and cleared by software. They indicate the lowest value than can be reached before raising an interrupt signal.

27.6.5 Temperature sensor data register (DTS_DR)

The DTS_DR contains the number of REF_CLK cycles used to compute the FM(T) frequency.

Address offset: 0x1C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r									r	r	r		r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **TS1_RDY:** Temperature sensor 1 ready flag
This bit is set and reset by hardware.
It indicates that a measurement is ongoing.
0: Temperature sensor 1 busy
1: Temperature sensor 1 ready

Bits 14:7 Reserved, must be kept at reset value.

Bit 6 **TS1_AITHF:** Asynchronous interrupt flag for high threshold on temperature sensor 1
This bit is set by hardware when the high threshold is reached.
It is cleared by software by writing 1 to the TS1_CAITHF bit in the DTS_ICIFR register.
0: High threshold not reached on temperature sensor 1
1: High threshold reached on temperature sensor 1
Note: This bit is active only when the TS1_AITHFEN bit is set

Bit 5 **TS1_AITLF:** Asynchronous interrupt flag for low threshold on temperature sensor 1
This bit is set by hardware when the low threshold is reached.
It is cleared by software by writing 1 to the TS1_CAITLF bit in the DTS_ICIFR register.
0: Low threshold not reached on temperature sensor 1
1: Low threshold reached on temperature sensor 1
Note: This bit is active only when the TS1_AITLFEN bit is set

Bit 4 **TS1_AITEF:** Asynchronous interrupt flag for end of measure on temperature sensor 1
This bit is set by hardware when a temperature measure is done.
It is cleared by software by writing 1 to the TS1_CAITEF bit in the DTS_ICIFR register.
0: End of measure not detected on temperature sensor 1
1: End of measure detected on temperature sensor 1
Note: This bit is active only when the TS1_AITEFEN bit is set

Bit 3 Reserved, must be kept at reset value.

Bit 2 **TS1_ITHF:** Interrupt flag for high threshold on temperature sensor 1, synchronized on PCLK
This bit is set by hardware when the high threshold is set and reached.
It is cleared by software by writing 1 to the TS1_CITHF bit in the DTS_ICIFR register.
0: High threshold not reached on temperature sensor 1
1: High threshold reached on temperature sensor 1
Note: This bit is active only when the TS1_ITHFEN bit is set

Bit 1 **TS1_ITLF:** Interrupt flag for low threshold on temperature sensor 1, synchronized on PCLK.
This bit is set by hardware when the low threshold is set and reached.
It is cleared by software by writing 1 to the TS1_CITLF bit in the DTS_ICIFR register.
0: Low threshold not reached on temperature sensor 1
1: Low threshold reached on temperature sensor 1
Note: This bit is active only when the TS1_ITLFEN bit is set

Bit 0 **TS1_ITEF:** Interrupt flag for end of measurement on temperature sensor 1, synchronized on PCLK.
This bit is set by hardware when a temperature measure is done.
It is cleared by software by writing 1 to the TS2_CITEF bit in the DTS_ICIFR register.
0: No end of measurement detected on temperature sensor 1
1: End of measure detected on temperature sensor 1
Note: This bit is active only when the TS1_ITEFEN bit is set

27.6.7 Temperature sensor interrupt enable register (DTS_ITENR)

Address offset: 0x24

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

									rw	rw	rw		rw	rw	rw

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **TS1_AITHEN:** Asynchronous interrupt enable flag on high threshold for temperature sensor 1.
This bit are set and cleared by software.
It enables the asynchronous interrupt when the temperature is above the high threshold (only when REFCLK_SEL= 1")
0: Asynchronous interrupt on high threshold disabled for temperature sensor 1
1: Asynchronous interrupt on high threshold enabled for temperature sensor 1

Bit 5 **TS1_AITLEN:** Asynchronous interrupt enable flag for low threshold on temperature sensor 1.
This bit are set and cleared by software.
It enables the asynchronous interrupt when the temperature is below the low threshold (only when REFCLK_SEL= 1)
0: Asynchronous interrupt on low threshold disabled for temperature sensor 1
1: Asynchronous interrupt on low threshold enabled for temperature sensor 1

Bit 4 **TS1_AITEEN:** Asynchronous interrupt enable flag for end of measurement on temperature sensor 1

This bit are set and cleared by software.
It enables the asynchronous interrupt for end of measurement (only when REFCLK_SEL = 1).
0: Asynchronous interrupt for end of measurement disabled on temperature sensor 1
1: Asynchronous interrupt for end of measurement enabled on temperature sensor 1

Bit 3 Reserved, must be kept at reset value.

Bit 2 **TS1_ITHEN:** Interrupt enable flag for high threshold on temperature sensor 1, synchronized on PCLK.

This bit are set and cleared by software.
It enables the interrupt when the measure reaches or is above the high threshold.
0: Synchronous interrupt for high threshold disabled on temperature sensor 1
1: Synchronous interrupt for high threshold enabled on temperature sensor 1

Bit 1 **TS1_ITLEN:** Interrupt enable flag for low threshold on temperature sensor 1, synchronized on PCLK.

This bit are set and cleared by software.
It enables the synchronous interrupt when the measure reaches or is below the low threshold.
0: Synchronous interrupt for low threshold disabled on temperature sensor 1
1: Synchronous interrupt for low threshold enabled on temperature sensor 1

Bit 0 **TS1_ITEEN:** Interrupt enable flag for end of measurement on temperature sensor 1, synchronized on PCLK.

This bit are set and cleared by software.
It enables the synchronous interrupt for end of measurement.
0: Synchronous interrupt for end of measurement disabled on temperature sensor 1
1: Synchronous interrupt for end of measurement enabled on temperature sensor 1

27.6.8 Temperature sensor clear interrupt flag register (DTS_ICIFR)

DTS_ICIFR is the control register for the interrupt flags.

Address offset: 0x28

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

									rc_w1	rc_w1	rc_w1		rc_w1	rc_w1	rc_w1

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **TS1_CAITHF:** Asynchronous interrupt clear flag for high threshold on temperature sensor 1
Writing 1 to this bit clears the TS1_AITHF flag in the DTS_SR register.

Bit 5 **TS1_CAITLF:** Asynchronous interrupt clear flag for low threshold on temperature sensor 1
Writing 1 to this bit clears the TS1_AITLF flag in the DTS_SR register.

Bit 4 **TS1_CAITEF:** Write once bit. Clear the asynchronous IT flag for End Of Measure for thermal sensor 1.
Writing 1 clears the TS1_AITEF flag of the DTS_SR register.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **TS1_CITHF:** Interrupt clear flag for high threshold on temperature sensor 1
Writing this bit to 1 clears the TS1_ITHF flag in the DTS_SR register.

Bit 1 **TS1_CITLF:** Interrupt clear flag for low threshold on temperature sensor 1
Writing 1 to this bit clears the TS1_ITLF flag in the DTS_SR register.

Bit 0 **TS1_CITEF:** Interrupt clear flag for end of measurement on temperature sensor 1
Writing 1 to this bit clears the TS1_ITEF flag in the DTS_SR register.

27.6.9 Temperature sensor option register (DTS_OR)

The DTS_OR contains general-purpose option bits.

Address offset: 0x2C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Refer to *Section 2.3 on page 111* for the register boundary addresses.

28 Digital-to-analog converter (DAC)

28.1 Introduction

The DAC module is a 12-bit, voltage output digital-to-analog converter. The DAC can be configured in 8- or 12-bit mode and may be used in conjunction with the DMA controller. In 12-bit mode, the data can be left- or right-aligned. The DAC features two output channels, each with its own converter. In dual DAC channel mode, conversions can be done independently or simultaneously when both channels are grouped together for synchronous update operations. An input reference pin, V_{REF+} (shared with others analog peripherals) is available for better resolution. An internal reference can also be set on the same input. Refer to *voltage reference buffer (VREFBUF)* section.

The DAC output buffer can be optionally enabled to obtain a high drive output current. An individual calibration can be applied on each DAC output channel. The DAC output channels support a low power mode, the Sample and hold mode.

28.2 DAC main features

The DAC main features are the following (see *Figure 263: Dual-channel DAC block diagram*)

- One DAC interface, maximum two output channels
- Left or right data alignment in 12-bit mode
- Synchronized update capability
- Noise-wave and Triangular-wave generation
- Dual DAC channel for independent or simultaneous conversions
- DMA capability for each channel including DMA underrun error detection
- Double data DMA capability to reduce the bus activity
- External triggers for conversion
- DAC output channel buffered/unbuffered modes
- Buffer offset calibration
- Sample and hold mode for low power operation in Stop mode
- Input voltage reference from V_{REF+} pin or internal VREFBUF reference

Figure 263 shows the block diagram of a DAC channel and *Table 264* gives the pin description.

28.3 DAC implementation

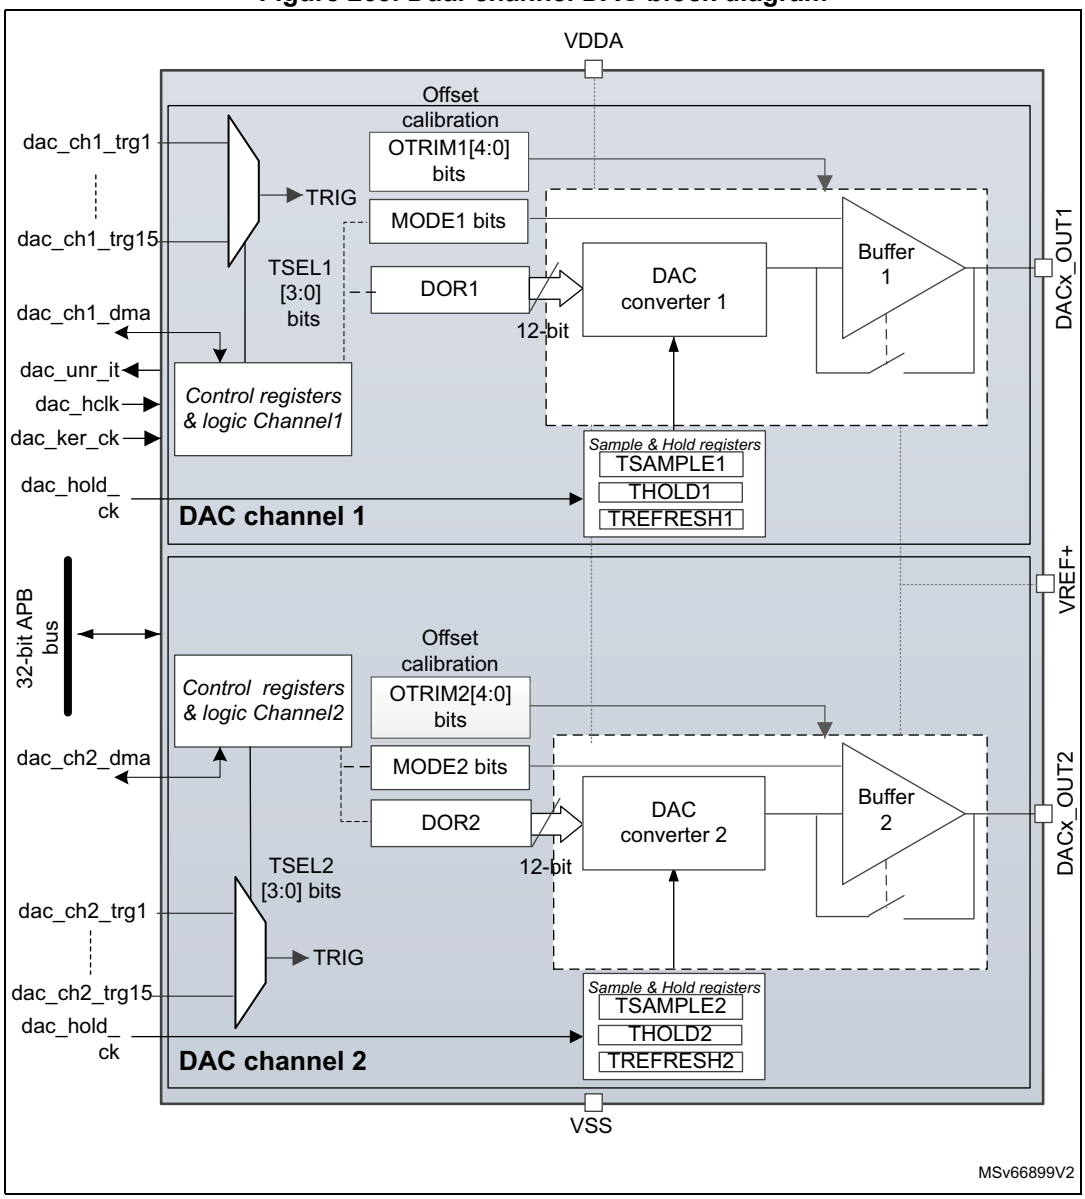
Table 263. DAC features

DAC features	DAC1
Dual channel	X
Output buffer	X
I/O connection	DAC1_OUT1 on PA4, DAC1_OUT2 on PA5
Maximum sampling time	1 Msps
Autonomous mode	-
VREF+ pin	X

28.4 DAC functional description

28.4.1 DAC block diagram

Figure 263. Dual-channel DAC block diagram



1. MODEx bits in the DAC_MCR control the output mode and allow switching between the Normal mode in buffer/unbuffered configuration and the Sample and hold mode.
2. Refer to *Section 28.3: DAC implementation* for channel2 availability.

28.4.2 DAC pins and internal signals

The DAC includes:

- Up to two output channels
- DAC output channel buffered or non buffered
- Sample and hold block and registers operational in Stop mode, using the LSI/LSE clock source (dac_hold_ck) for static conversion.

The DAC includes up to two separate output channels. Each output channel can be connected to on-chip peripherals such as comparator, operational amplifier and ADC (if available). In this case, the DAC output channel can be disconnected from the DACx_OUTy output pin and the corresponding GPIO can be used for another purpose.

The DAC output can be buffered or not. The Sample and hold block and its associated registers can run in Stop mode using the LSI/LSE clock source (dac_hold_ck).

Table 264. DAC input/output pins

Pin name	Signal type	Remarks
VREF+	Input, analog reference positive	The higher/positive reference voltage for the DAC, $V_{REF+} \leq V_{DDAmax}$ (refer to datasheet)
VDDA	Input, analog supply	Analog power supply
VSSA	Input, analog supply ground	Ground for analog power supply
DACx_OUTy	Analog output signal	DACx channely analog output

Table 265. DAC internal input/output signals

Internal signal name	Signal type	Description
dac_ch1_dma	Bidirectional	DAC channel1 DMA request/acknowledge
dac_ch2_dma	Bidirectional	DAC channel2 DMA request/acknowledge
dac_ch1_trgx (x = 1 to 15)	Inputs	DAC channel1 trigger inputs
dac_ch2_trgx (x = 1 to 15)	Inputs	DAC channel2 trigger inputs
dac_unr_it	Output	DAC underrun interrupt
dac_hclk	Input	DAC peripheral clock
dac_ker_ck	Input	DAC kernel clock
dac_hold_ck	Input	DAC low-power clock used in Sample and hold mode

Table 266. DAC interconnection

Signal name	Source	Source type
dac_hold_ck	ck_lsi or ck_lse	LSI or LSE clock selected in the RCC
dac_chx_trg1 (x = 1, 2)	tim1_trgo	Internal signal from on-chip timers
dac_chx_trg2 (x = 1, 2)	tim2_trgo	Internal signal from on-chip timers
dac_chx_trg3 (x = 1, 2)	tim4_trgo	Internal signal from on-chip timers
dac_chx_trg4 (x = 1, 2)	tim5_trgo	Internal signal from on-chip timers
dac_chx_trg5 (x = 1, 2)	tim6_trgo	Internal signal from on-chip timers

Table 266. DAC interconnection (continued)

Signal name	Source	Source type
dac_chx_trg6 (x = 1, 2)	tim7_trgo	Internal signal from on-chip timers
dac_chx_trg7 (x = 1, 2)	tim8_trgo	Internal signal from on-chip timers
dac_chx_trg8 (x = 1, 2)	tim15_trgo	Internal signal from on-chip timers
dac_chx_trg11 (x = 1, 2)	lptim1_ch1	Internal signal from on-chip timers
dac_chx_trg12 (x = 1, 2)	lptim2_ch1	Internal signal from on-chip timers
dac_chx_trg13 (x = 1, 2)	exti9	External pin

28.4.3 DAC clocks

Two clock sources can be used to update the DAC:

- dac_hclk: DAC peripheral clock (AHB clock)
- dac_ker_ck: DAC kernel clock: this clock can be used to synchronize DAC and ADC.
- dac_hold_ck: low-power clock used in Sample and hold mode

The DAC clock is selected in the RCC.

28.4.4 DAC channel enable

Each DAC channel can be powered on by setting its corresponding ENx bit in the DAC_CR register. The DAC channel is then enabled after a t_{WAKEUP} startup time.

DACxRDY bit is set in the DAC_SR register when the DAC interface is ready to accept data. Writing new data or asserting the trigger is not allowed when ENx bit is set while DACxRDY signal is reset.

Note: The ENx bit enables the analog DAC channelx only. The DAC channelx digital interface is enabled even if the ENx bit is reset.

28.4.5 DAC data format

Depending on the selected configuration mode, the data have to be written into the specified register as described below:

- Single DAC channel

  There are three possibilities:

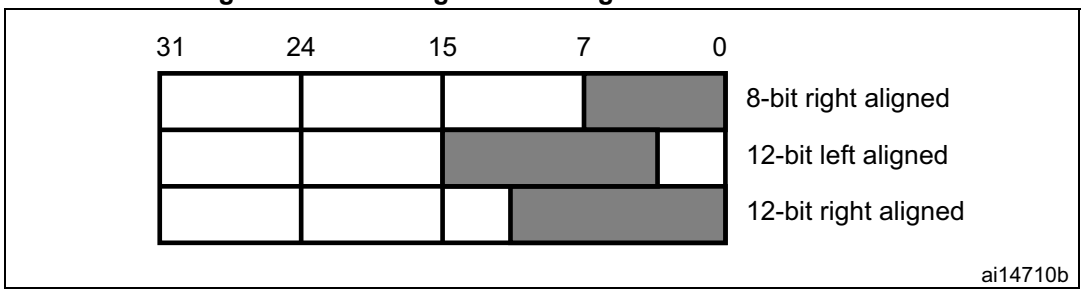
  – 8-bit right alignment: the software has to load data into the DAC_DHR8Rx[7:0] bits (stored into the DHRx[11:4] bits)

  – 12-bit left alignment: the software has to load data into the DAC_DHR12Lx [15:4] bits (stored into the DHRx[11:0] bits)

  – 12-bit right alignment: the software has to load data into the DAC_DHR12Rx [11:0] bits (stored into the DHRx[11:0] bits)

Depending on the loaded DAC_DHRyyyx register, the data written by the user is shifted and stored into the corresponding DHRx (data holding registerx, which are internal non-memory-mapped registers). The DHRx register is then loaded into the DORx register either automatically, by software trigger or by an external event trigger.

Figure 264. Data registers in single DAC channel mode



- Dual DAC channels (when available)

  There are three possibilities:

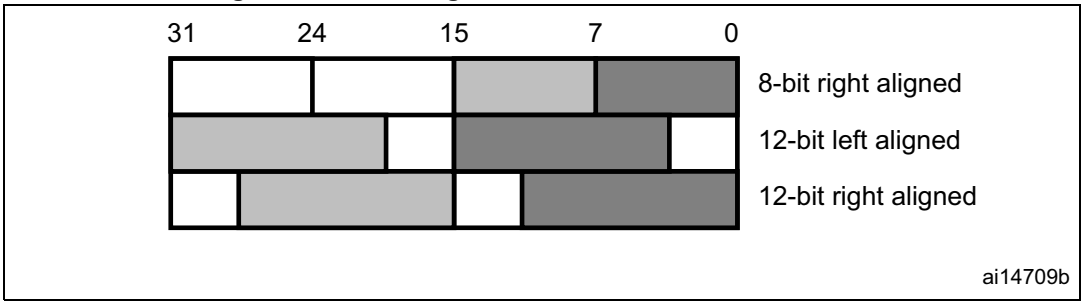
  – 8-bit right alignment: data for DAC channel1 to be loaded into the DAC_DHR8RD [7:0] bits (stored into the DHR1[11:4] bits) and data for DAC channel2 to be loaded into the DAC_DHR8RD [15:8] bits (stored into the DHR2[11:4] bits)

  – 12-bit left alignment: data for DAC channel1 to be loaded into the DAC_DHR12LD [15:4] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC_DHR12LD [31:20] bits (stored into the DHR2[11:0] bits)

  – 12-bit right alignment: data for DAC channel1 to be loaded into the DAC_DHR12RD [11:0] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC_DHR12RD [27:16] bits (stored into the DHR2[11:0] bits)

Depending on the loaded DAC_DHRyyyD register, the data written by the user is shifted and stored into DHR1 and DHR2 (data holding registers, which are internal non-memory-mapped registers). The DHR1 and DHR2 registers are then loaded into the DAC_DOR1 and DOR2 registers, respectively, either automatically, by software trigger or by an external event trigger.

Figure 265. Data registers in dual DAC channel mode



Signed/unsigned data

DAC input data are unsigned: 0x000 corresponds to the minimum value and 0xFFF to the maximum value for 12-bit mode.

The DAC can also handle signed input data in 2’s complement format. This is done by setting SINFORMATx bit in the DAC_MCR register.

When SINFORMATx bit is set, the MSB bit of the data written to DHRx registers is inverted when it is copied to the DAC_DORx register, and the DAC interface can accept signed data (Q1.15, Q1.11 or Q1.7 format). DAC_DHR12Lx register can be used to store 16-bit signed data in the data holding registers. The 12 MSBs of 16-bit data are used for the DAC output data and the MSB bit is inverted. The four LSBs are simply ignored.

Table 267. Data format (case of 12-bit data)

SINFORMATx bit	DATA written to DHRx register	DATA transfered to DORx register
0	0x000	0x000
0	0xFFF	0xFFF
1	0x7FF	0xFFF
1	0x000	0x800
1	0xFFF	0x7FF
1	0x800	0x000

28.4.6 DAC conversion

The DAC_DORx cannot be written directly and any data transfer to the DAC channelx must be performed by loading the DAC_DHRx register (write operation to DAC_DHR8Rx, DAC_DHR12Lx, DAC_DHR12Rx, DAC_DHR8RD, DAC_DHR12RD or DAC_DHR12LD).

Data stored in the DAC_DHRx register are automatically transferred to the DAC_DORx register after one dac_hclk clock cycle, if no hardware trigger is selected (TENx bit in DAC_CR register is reset). However, when a hardware trigger is selected (TENx bit in DAC_CR register is set) and a trigger occurs, the transfer is performed three dac_hclk clock cycles after the trigger signal.

When DAC_DORx is loaded with the DAC_DHRx contents, the analog output voltage becomes available after a time $t_{SETTLING}$ that depends on the power supply voltage and the analog output load.

To synchronize DAC and ADC, the same clock source can be used for both peripherals. This is done by selecting the dac_ker_ck clock instead of the dac_hclk clock (AHB clock) in the RCC.

HFSEL bits of DAC_MCR must be set when dac_hclk or dac_ker_ck clock speed is faster than 80 MHz. It adds an extra delay to the transfer from DAC_DHRx register to DAC_DORx register.

Refer to Table *HFSEL description* below for the limitation of the DAC_DORx update rate depending on HFSEL bits and dac_hclk clock frequency.

If the data is updated or a software/hardware trigger event occurs during the non-allowed period, the peripheral behavior is unpredictable.

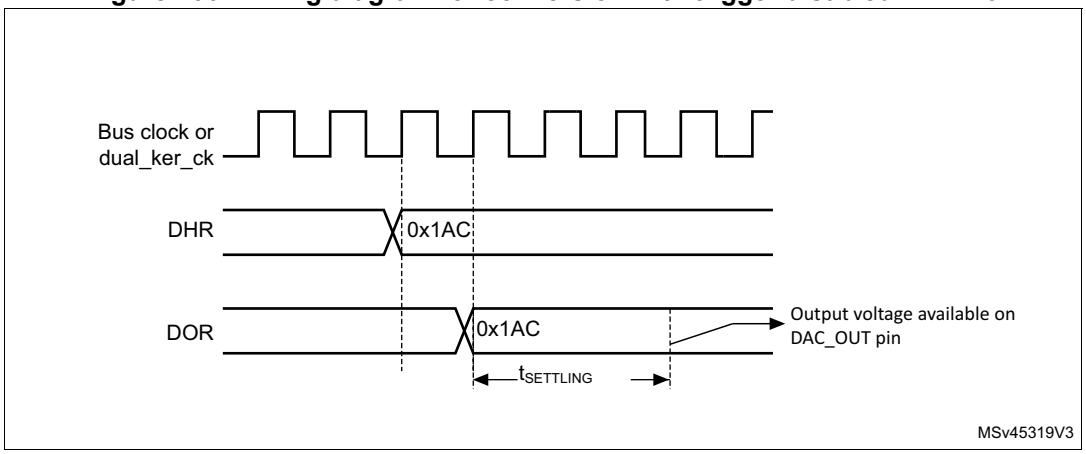
The above timing is only related to the limitation of the DAC interface. Refer also to the $t_{SETTLING}$ parameter value in the product datasheet.

Table 268. HFSEL description

HFSEL [1:0]	AHB frequency	Latency using AHB clock (dac_hclk)	Latency using dac_ker_ck clock	Function
00	< 80 MHz	3	4	DAC_DOR update rate up to 3 AHB clock cycles or 4 dac_ker_ck cycles.
01	≥ 80 MHz(1)	5	5	DAC_DOR update rate up to 5 AHB clock or dac_ker_ck cycles.
10	≥ 160 MHz	7	6	DAC_DOR update rate up to 7 AHB clock cycles or 6 dac_ker_ck cycles.
11	Reserved	-	-	-

1. Refer to the device datasheet for the value of the maximum AHB frequency.

Figure 266. Timing diagram for conversion with trigger disabled TEN = 0



28.4.7 DAC output voltage

Digital inputs are converted to output voltages on a linear conversion between 0 and V_{REF+}.

The analog output voltages on each DAC channel pin are determined by the following equation:

$$\text{DACoutput} = V_{REF} \times \frac{DOR}{4096}$$

28.4.8 DAC trigger selection

If the TENx control bit is set, the conversion can then be triggered by an external event (timer counter, external interrupt line). The TSELx[3:0] control bits determine which out of 16 possible events triggers the conversion as shown in TSELx[3:0] bits of the DAC_CR register. These events can be either the software trigger or hardware triggers. Refer to the interconnection table in *Section 28.4.2: DAC pins and internal signals*.

Each time a DAC interface detects a rising edge on the selected trigger source (refer to the table below), the last data stored into the DAC_DHRx register are transferred into the

DAC_DORx register. The DAC_DORx register is updated three dac_hclk cycles after the trigger occurs.

If the software trigger is selected, the conversion starts once the SWTRIG bit is set. SWTRIG is reset by hardware once the DAC_DORx register has been loaded with the DAC_DHRx register contents.

Note: TSELx[3:0] bit cannot be changed when the ENx bit is set.

When software trigger is selected, the transfer from the DAC_DHRx register to the DAC_DORx register takes only one dac_hclk clock cycle.

28.4.9 DMA requests

Each DAC channel has a DMA capability. Two DMA channels are used to service DAC channel DMA requests.

When an external trigger (but not a software trigger) occurs while the DMAENx bit is set, the value of the DAC_DHRx register is transferred into the DAC_DORx register when the transfer is complete, and a DMA request is generated.

In dual mode, if both DMAENx bits are set, two DMA requests are generated. If only one DMA request is needed, only the corresponding DMAENx bit must be set. In this way, the application can manage both DAC channels in dual mode by using one DMA request and a unique DMA channel.

As DAC_DHRx to DAC_DORx data transfer occurred before the DMA request, the very first data has to be written to the DAC_DHRx before the first trigger event occurs.

DMA underrun

The DAC DMA request is not queued so that if a second external trigger arrives before the acknowledgment for the first external trigger is received (first request), then no new request is issued and the DMA channelx underrun flag DMAUDRx in the DAC_SR register is set, reporting the error condition. The DAC channelx continues to convert old data.

The software must clear the DMAUDRx flag by writing 1, clear the DMAEN bit of the used DMA stream and re-initialize both DMA and DAC channelx to restart the transfer correctly. The software must modify the DAC trigger conversion frequency or lighten the DMA workload to avoid a new DMA underrun. Finally, the DAC conversion can be resumed by enabling both DMA data transfer and conversion trigger.

For each DAC channelx, an interrupt is also generated if its corresponding DMAUDRIEx bit in the DAC_CR register is enabled.

DMA Double data mode

When the DMA controller is used in Normal mode, only 12-bit (or 8-bit) data are transferred by a DMA request. As the AHB width is 32 bits, two 12-bit data may be transferred simultaneously. To use this mode, set the DMADOUBLEx bit of DAC_MCR register.

A DAC DMA request is generated every two external triggers (except for software triggers) when the DMAENx bit is set:

1. When the first trigger is detected, the value of the DAC_DHRx and DAC_DHRBx registers are transferred into the DAC_DORx and DAC_DORBx registers. The actual

DAC data is loaded into the DAC_DORx register. A DMA request is then generated. The DMA writes the new data to the DAC_DHRx and DAC_DHRBx data registers.

2. When the next trigger is detected, the actual DAC data is loaded into the DAC_DHRBx register. This second trigger does not generate any DMA request. The DORSTATx bit indicates which DOR data is actually loaded into the analog DAC input.

DMA underrun function is also supported in DMA Double data mode.

In DMA Double mode, DMA requests can only handle one DAC channel. To use two channel outputs in DMA Double mode, each DMA channel has to be configured separately.

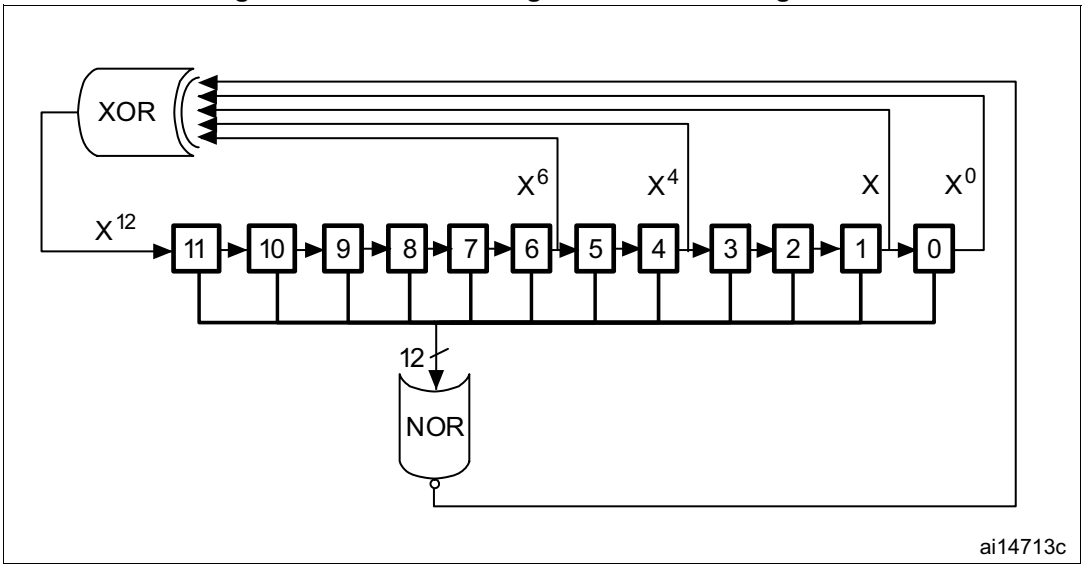
The following conditions must be met to change from Double data to single data mode or vice versa:

- The DAC must be disabled.
- DMAEN bit must be cleared (ENx = 0 and DMAEN = 0).

28.4.10 Noise generation

In order to generate a variable-amplitude pseudonoise, an LFSR (linear feedback shift register) is available. DAC noise generation is selected by setting WAVEx[1:0] to 01. The preloaded value in LFSR is 0xAAA. This register is updated three dac_hclk clock cycles after each trigger event, following a specific calculation algorithm.

Figure 267. DAC LFSR register calculation algorithm

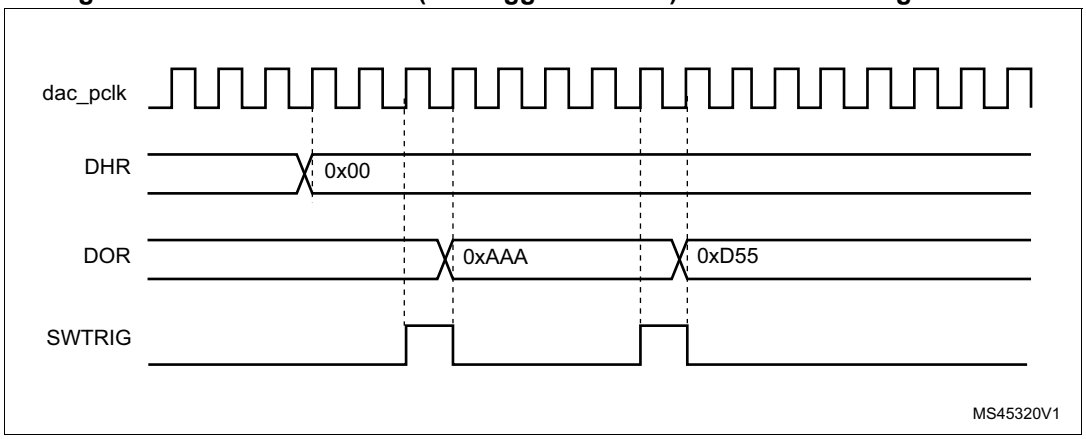


The LFSR value, that may be masked partially or totally by means of the MAMPx[3:0] bits in the DAC_CR register, is added up to the DAC_DHRx contents without overflow and this value is then transferred into the DAC_DORx register.

If LFSR is 0x0000, a ‘1 is injected into it (antilock-up mechanism).

It is possible to reset LFSR wave generation by resetting the WAVEx[1:0] bits.

Figure 268. DAC conversion (SW trigger enabled) with LFSR wave generation



Note: The DAC trigger must be enabled for noise generation by setting the TENx bit in the DAC_CR register.

28.4.11 Triangle-wave generation

It is possible to add a small-amplitude triangular waveform on a DC or slowly varying signal. DAC triangle-wave generation is selected by setting WAVEx[1:0] to 10”. The amplitude is configured through the MAMPx[3:0] bits in the DAC_CR register. An internal triangle counter is incremented three dac_hclk clock cycles after each trigger event. The value of this counter is then added to the DAC_DHRx register without overflow and the sum is transferred into the DAC_DORx register. The triangle counter is incremented as long as it is less than the maximum amplitude defined by the MAMPx[3:0] bits. Once the configured amplitude is reached, the counter is decremented down to 0, then incremented again and so on.

It is possible to reset triangle wave generation by resetting the WAVEx[1:0] bits.

Figure 269. DAC triangle wave generation

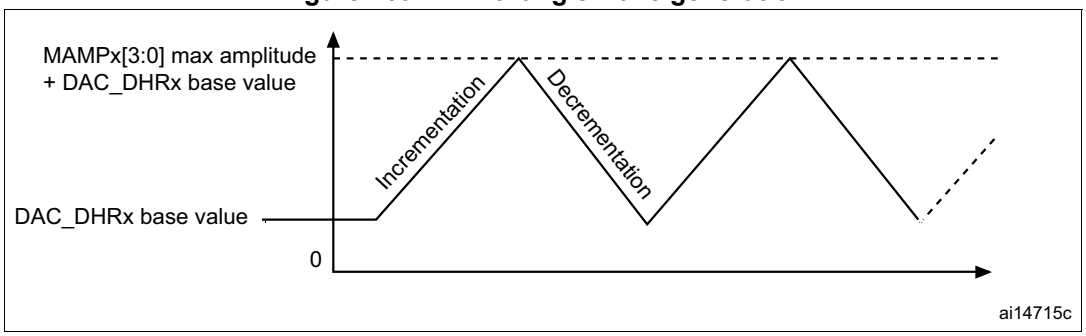


Figure 270. DAC conversion (SW trigger enabled) with triangle wave generation

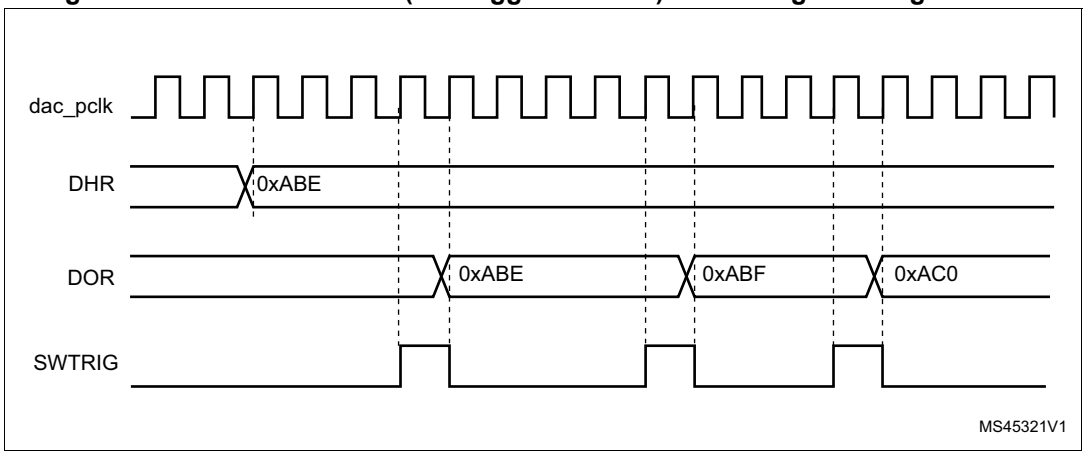


Note: The DAC trigger must be enabled for triangle wave generation by setting the TENx bit in the DAC_CR register.

The MAMPx[3:0] bits must be configured before enabling the DAC, otherwise they cannot be changed.

28.4.12 DAC channel modes

Each DAC channel can be configured in Normal mode or Sample and hold mode. The output buffer can be enabled to obtain a high drive capability. Before enabling output buffer, the voltage offset needs to be calibrated. This calibration is performed at the factory (loaded after reset) and can be adjusted by software during application operation.

Normal mode

In Normal mode, there are four combinations, by changing the buffer state and by changing the DACx_OUTy pin interconnections.

To enable the output buffer, the MODEx[2:0] bits in DAC_MCR register must be:

- 000: DAC is connected to the external pin

To disable the output buffer, the MODEx[2:0] bits in DAC_MCR register must be:

- 010: DAC is connected to the external pin

Sample and hold mode

In Sample and hold mode, the DAC core converts data on a triggered conversion, and then holds the converted voltage on a capacitor. When not converting, the DAC cores and buffer are completely turned off between samples and the DAC output is tri-stated, therefore reducing the overall power consumption. A stabilization period, which value depends on the buffer state, is required before each new conversion.

In this mode, the DAC core and all corresponding logic and registers are driven by the LSI/LSE low-speed clock (dac_hold_ck) in addition to the dac_hclk clock, allowing using the DAC channels in deep low power modes such as Stop mode.

The LSI/LSE low-speed clock (dac_hold_ck) must not be stopped when the Sample and hold mode is enabled.

The sample/hold mode operations can be divided into 3 phases:

1. Sample phase: the sample/hold element is charged to the desired voltage. The charging time depends on capacitor value (internal or external, selected by the user). The sampling time is configured with the TSAMPLEx[9:0] bits in DAC_SHSRx register. During the write of the TSAMPLEx[9:0] bits, the BWSTx bit in DAC_SR register is set to 1 to synchronize between both clocks domains (AHB and low speed clock) and allowing the software to change the value of sample phase during the DAC channel operation
2. Hold phase: the DAC output channel is tri-stated, the DAC core and the buffer are turned off, to reduce the current consumption. The hold time is configured with the THOLDx[9:0] bits in DAC_SHHR register
3. Refresh phase: the refresh time is configured with the TREFRESHx[7:0] bits in DAC_SHRR register

The timings for the three phases above are in units of LSI/LSE clock periods. As an example, to configure a sample time of 350 µs, a hold time of 2 ms and a refresh time of 100 µs assuming LSI/LSE ~32 KHz is selected:

12 cycles are required for sample phase: TSAMPLEx[9:0] = 11,

62 cycles are required for hold phase: THOLDx[9:0] = 62,

and 4 cycles are required for refresh period: TREFRESHx[7:0] = 4.

In this example, the power consumption is reduced by almost a factor of 15 versus Normal modes.

The formulas to compute the right sample and refresh timings are described in the table below, the Hold time depends on the leakage current.

Table 269. Sample and refresh timings

Buffer State	t_{SAMP} (1)(2)	$t_{REFRESH}$ (2)(3)
Enable	7 µs + (10*R_{BON}*C_{SH})	7 µs + (R_{BON}*C_{SH})*ln(2*N_{LSB})
Disable	3 µs + (10*R_{BOFF}*C_{SH})	3 µs + (R_{BOFF}*C_{SH})*ln(2*N_{LSB})

1. In the above formula the settling to the desired code value with ½ LSB or accuracy requires 10 constant time for 12 bits resolution. For 8 bits resolution, the settling time is 7 constant time.
2. C_{SH} is the capacitor in Sample and hold mode.
3. The tolerated voltage drop during the hold phase “Vd” is represented by the number of LSBs after the capacitor discharging with the output leakage current. The settling back to the desired value with ½ LSB error accuracy requires ln(2*Nlsb) constant time of the DAC.

Example of the sample and refresh time calculation with output buffer on

The values used in the example below are provided as indication only. Refer to the product datasheet for product data.

C_{SH} = 100 nF

V_{REF+} = 3.0 V

Sampling phase:

t_{SAMP} = 7 µs + (10 * 2000 * 100 * 10^{-9}) = 2.007 ms

(where R_{BON} = 2 kΩ)

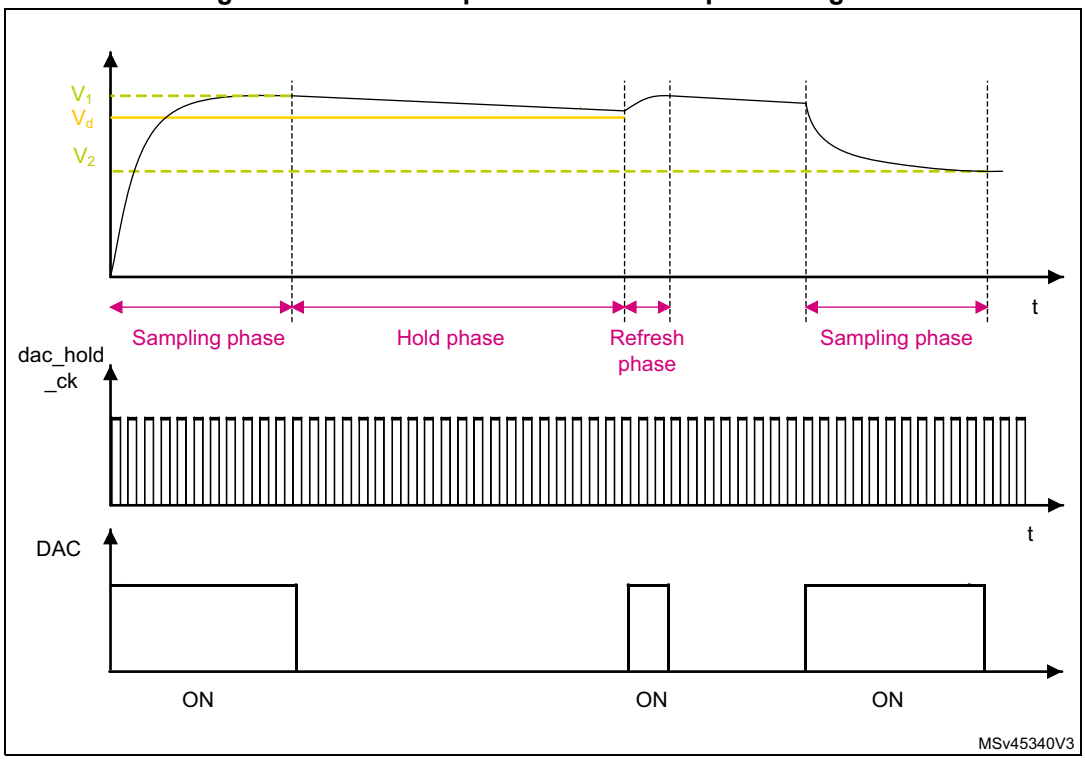
Refresh phase:

$t_{REFRESH}$ = 7 µs + (2000 * 100 * 10^{-9}) * ln(2*10) = 606.1 µs
(where N_{LSB} = 10 (10 LSB drop during the hold phase)

Hold phase:

$D_V = i_{leak} * t_{hold} / C_{SH}$ = 0.0073 V (10 LSB of 12bit at 3 V)
i_{leak} = 150 nA (worst case on the IO leakage on all the temperature range)
t_{hold} = 0.0073 * 100 * 10^{-9} / (150 * 10^{-9}) = 4.867 ms

Figure 271. DAC Sample and hold mode phase diagram



Like in Normal mode, the Sample and hold mode has different configurations.

To enable the output buffer, MODEx[2:0] bits in DAC_MCR register must be set to:

- 100: DAC is connected to the external pin

To disabled the output buffer, MODEx[2:0] bits in DAC_MCR register must be set to:

- 110: DAC is connected to external pin

  When MODEx[2:0] bits are equal to 111, an internal capacitor, C_{Lint}, holds the voltage output of the DAC core and then drive it to on-chip peripherals.

All Sample and hold phases are interruptible, and any change in DAC_DHRx immediately triggers a new sample phase.

Table 270. Channel output modes summary

MODEx[2:0]			Mode	Buffer	Output connections
0	0	0	Normal mode	Enabled	Connected to external pin
0	1	0		Disabled	Connected to external pin
1	0	0	Sample and hold mode	Enabled	Connected to external pin
1	1	0		Disabled	Connected to external pin and to on chip peripherals (such as comparators)

28.4.13 DAC channel buffer calibration

The transfer function for an N-bit digital-to-analog converter (DAC) is:

$$V_{out} = ((D / 2^N) \times G \times V_{ref}) + V_{OS}$$

Where V_{OUT} is the analog output, D is the digital input, G is the gain, V_{ref} is the nominal full-scale voltage, and V_{os} is the offset voltage. For an ideal DAC channel, G = 1 and V_{os} = 0.

Due to output buffer characteristics, the voltage offset may differ from part-to-part and introduce an absolute offset error on the analog output. To compensate the V_{os}, a calibration is required by a trimming technique.

The calibration is only valid when the DAC channelx is operating with buffer enabled (MODEx[2:0] = 0b000 or 0b001 or 0b100 or 0b101). if applied in other modes when the buffer is off, it has no effect. During the calibration:

- The buffer output is disconnected from the pin internal/external connections and put in tristate mode (HiZ).
- The buffer acts as a comparator to sense the middle-code value 0x800 and compare it to VREF+/2 signal through an internal bridge, then toggle its output signal to 0 or 1 depending on the comparison result (CAL_FLAGx bit).

Two calibration techniques are provided:

- Factory trimming (default setting)

  The DAC buffer offset is factory trimmed. The default value of OTRIMx[4:0] bits in DAC_CCR register is the factory trimming value and it is loaded once DAC digital interface is reset.
- User trimming

  The user trimming can be done when the operating conditions differs from nominal factory trimming conditions and in particular when V_{DDA} voltage, temperature, VREF+ values change and can be done at any point during application by software.

Note: Refer to the datasheet for more details of the Nominal factory trimming conditions

In addition, when V_{DD} is removed (example the device enters in STANDBY or VBAT modes) the calibration is required.

The steps to perform a user trimming calibration are as below:

1. If the DAC channel is active, write 0 to ENx bit in DAC_CR to disable the channel.
2. Select a mode where the buffer is enabled, by writing to DAC_MCR register, MODEx[2:0] = 0b000 or 0b001 or 0b100 or 0b101.
3. Start the DAC channelx calibration, by setting the CENx bit in DAC_CR register to 1.
4. Apply a trimming algorithm:
   a) Write a code into OTRIMx[4:0] bits, starting by 0b00000.
   b) Wait for t_{TRIM} delay.
   c) Check if CAL_FLAGx bit in DAC_SR is set to 1.
   d) If CAL_FLAGx is set to 1, the OTRIMx[4:0] trimming code is found and can be used during *device* operation to compensate the output value, else increment OTRIMx[4:0] and repeat sub-steps from (a) to (d) again.

The software algorithm may use either a successive approximation or dichotomy techniques to compute and set the content of OTRIMx[4:0] bits in a faster way.

The commutation/toggle of CAL_FLAGx bit indicates that the offset is correctly compensated and the corresponding trim code must be kept in the OTRIMx[4:0] bits in DAC_CCR register.
